# SOCIETY FOR NEUROSCIENCE POLICIES ON THE USE OF ANIMALS AND HUMANS IN NEUROSCIENCE RESEARCH

Recently Council approved a revised version of the Society's Policy on the Use of Animals in Neuroscience Research and adopted a new policy on the use of human subjects in neuroscience research. The revised version of the animal policy, drafted by the Committee on Animals in Research, in conjunction with the editor-in-chief of *The Journal of Neuroscience* and the chair of the Publications Committee, is printed below. The amendment is contained in the "Recommended References" section. The Policy on the Use of Human Subjects in Neuroscience Research is printed after the animal policy.

## POLICY ON THE USE OF ANIMALS IN NEUROSCIENCE RESEARCH

The Policy on the Use of Animals in Neuroscience Research affects a number of the Society's functions that involve making decisions about animal research conducted by individual members. These include the scheduling of scientific presentations at the Annual Meeting, the review and publication of original research papers in *The Journal of Neuroscience*, and the defense of members whose ethical use of animals in research is questioned by antivivisectionists. The responsibility for implementing the policy in each of these areas will rest with the relevant administrative body (Program Committee, Publications Committee, Editorial Board, and Committee on Animals in Research, respectively), in consultation with Council.

### Introduction

The Society for Neuroscience, as a professional society for basic and clinical researchers in neuroscience, endorses and supports the appropriate and responsible use of animals as experimental subjects. Knowledge generated by neuroscience research on animals has led to important advances in the understanding of diseases and disorders that affect the nervous system and in the development of better treatments that reduce suffering in humans and animals. This knowledge also makes a critical contribution to our understanding of ourselves, the complexities of our brains, and what makes us human. Continued progress in understanding how the brain works and further advances in treating and curing disorders of the nervous system require investigation of complex functions at all levels in the living nervous system. Because no adequate alternatives exist, much of this research must be done on animal subjects. The Society takes the position that neuroscientists have an obligation to contribute to this progress through responsible and humane research on animals.

Several functions of the Society are related to the use of animals in research. A number of these involve decisions about research conducted by individual members of the Society, including the scheduling of scientific presentations at the Annual Meeting, the review and publication of original research papers in *The Journal of Neuroscience*, and the defense of members whose ethical use of animals in research is questioned by antivivisectionists. Each of these functions, by establishing explicit support of the Society for the research of individual members, defines a relationship between the Society and its members. The purpose of this document is to outline the policy that guides that relationship. Compliance with the following policy will be an important

factor in determining the suitability of research for presentation at the Annual Meeting or for publication in *The Journal of Neuroscience*, and in situations where the Society is asked to provide public and active support for a member whose use of animals in research has been questioned.

### General Policy

Neuroscience research uses complicated, often invasive methods, each of which is associated with different problems, risks, and specific technical considerations. An experimental method that would be deemed inappropriate for one kind of research may be the method of choice for another kind of research. It is therefore impossible for the Society to define specific policies and procedures for the care and use of all research animals and for the design and conduct of every neuroscience experiment.

The U.S. *Public Health Service Policy on Humane Care and Use of Laboratory Animals* (PHS Policy) and the National Institutes of Health *Guide for the Care and Use of Laboratory Animals* (NIH Guide) describe a set of general policies and procedures designed to ensure the humane and appropriate use of live vertebrate animals in all forms of biomedical research. The Society finds the policies and procedures set forth in the PHS Policy and the NIH Guide to be both necessary and sufficient to ensure a high standard of animal care and use and adopts them as its official Policy on the Use of Animals in Neuroscience Research (Society Policy). All Society members are expected to conduct their animal research in compliance with the Society Policy and are required to verify that they have done so when submitting abstracts for presentation at the Annual Meeting or manuscripts for publication in *The Journal of Neuroscience*. Adherence to the Society Policy is also an important step toward receiving help from the Society in responding to questions about a member's use of animals in research. A complete description of the Society's policy and procedures for defending members whose research comes under attack is given in the Society's *Handbook for the Use of Animals in Neuroscience Research*.

### Local Committee Review

An important element of the Society Policy is the establishment of a local committee that is charged with reviewing and approving all proposed animal care and use procedures. In addition to scientists experienced in research involving animals and a veterinarian, the membership of this local committee should include an individual who is not affiliated with the member's institution in any other way. In reviewing a proposed use of animals, the committee should evaluate the adequacy of institutional policies, animal husbandry, veterinary care, and the physical plant. Specific attention should be paid to proposed procedures for animal procurement, quarantine and stabilization, separation by species, disease diagnosis and treatment, anesthesia and analgesia, surgery and postsurgical care, and euthanasia. The review committee also should ensure that procedures involving live vertebrate animals are designed and performed with due consideration of their relevance to human or animal health, the advancement of knowledge, or the good of society. This review and approval of a member's use of live vertebrate animals in research by a local committee is an essential

component of the Society Policy. Assistance in developing appropriate animal care and use procedures and establishing a local review committee can be obtained from the documents listed below and from the Society.

### Other Laws, Regulations, and Policies

In addition to complying with the policy described above, Regular Members (i.e., North American residents) of the Society must also adhere to all relevant national, state, or local laws and/or regulations that govern their use of animals in neuroscience research. Thus, U.S. members must observe the U.S. Animal Welfare Act (as amended in 1985) and its implementing regulations from the U.S. Department of Agriculture. Canadian members must abide by the *Guide to the Care and Use of Experimental Animals*, and members in Mexico must comply with the *Reglamento de la Ley General de Salud en Materia de Investigacion para la Salud of the Secretaria de Salud* (published on Jan. 6, 1987). Similarly, in addition to complying with the laws and regulations of their home countries, Foreign Members of the Society should adhere to the official Society Policy outlined here.

The following principles, based largely on the PHS *Policy on Humane Care and Use of Laboratory Animals*, can be a useful guide in the design

and implementation of experimental procedures involving laboratory animals.

Animals selected for a procedure should be of an appropriate species and quality and the minimum number required to obtain valid results.

Proper use of animals, including the avoidance or minimization of discomfort, distress, and pain, when consistent with sound scientific practices, is imperative.

Procedures with animals that may cause more than momentary or slight pain or distress should be performed with appropriate sedation, analgesia, or anesthesia. Surgical or other painful procedures should not be performed on unanesthetized animals paralyzed by chemical agents.

Postoperative care of animals shall be such as to minimize discomfort and pain and, in any case, shall be equivalent to accepted practices in schools of veterinary medicine.

Animals that would otherwise suffer severe or chronic pain or distress that cannot be relieved should be painlessly killed at the end of the procedure or, if appropriate, during the procedure. If the study requires the death of the animal, the animal must be killed in a humane manner.

Living conditions should be appropriate for the species and contribute to the animals' health and comfort. Normally, the housing, feeding, and care of all animals used for biomedical purposes must be directed by a veterinarian or other scientist trained and experienced in the proper care, handling, and use of the species being maintained or studied. In any case, appropriate veterinary care shall be provided.

Exceptions to these principles require careful consideration and should only be made by an appropriate review group such as an institutional animal care and use committee.

## POLICY ON THE USE OF HUMAN SUBJECTS IN NEUROSCIENCE RESEARCH

Experimental procedures involving human subjects must have been conducted in conformance with the policies and principles contained in the Federal Policy for the Protection of Human Subjects (United States Office of Science and Technology Policy) and in the Declaration of Helsinki. When publishing a paper in *The Journal of Neuroscience* or submitting an abstract for presentation at the Annual Meeting, authors must sign a statement of compliance with this policy.

# POLICY ON ETHICS

It is expected that authors submitting papers or abstracts will have conducted their work in strict accordance with the following statement on ethics approved by the Society for Neuroscience in November 1989 and amended in November 1993.

The Society for Neuroscience believes that progress in understanding the nervous system materially benefits human welfare. It recognizes that such progress depends on the honest pursuit of scientific research and the truthful representation of findings. While recognizing that both scientific error and differences of interpretation are a natural part of the creative process, the Society affirms that misconduct, in the form of fabrication, falsification, or plagiarism, jeopardizes the success of the entire scientific endeavor. Members of the Society assume an obligation to maintain the highest level of integrity in all scientific activities.

The primary responsibility for considering and resolving allegations of scientific misconduct lies within the individual academic communities and institutions where scientific work is carried out. The Society for Neuroscience therefore supports the principle that academic institutions should develop and have in place procedures to deal with allegations of scientific misconduct. However, the Society has a special responsibility and interest surrounding those scientific activities for which it is directly responsible, e.g., publication of *The Journal of Neuroscience* and the presentations at the Annual Meeting.

Every author of articles or abstracts submitted for publication in *The Journal of Neuroscience* or the neuroscience *Abstracts* agrees to assume full responsibility, within the limits of his or her professional competence, for the accuracy of the report. In the case of multiple-authored papers, each author should have made a significant intellectual or practical contribution to the scientific work; “honorary authorship,” i.e., the granting of authorship to persons who have made no substantive contribution to a scientific report, is not appropriate.

Scientists must have access to their original research results. The retention of accurately recorded and retrievable results is essential for the progress of scientific inquiry. Moreover, errors may be mistaken for misconduct when primary results are unavailable. Primary data should remain in the laboratory and should be preserved as long as there may be a reasonable need to refer to them.

Authors submitting articles or abstracts do so with the understanding that reports have not been submitted elsewhere. An abstract is a proper forum for rapid communication of work that will subsequently appear as a full-length article. However, submission of abstracts reporting already published work or publication of multiple similar manuscripts or abstracts, i.e., duplicate publication, is improper. When previously published data are presented as part of a new manuscript or abstract, as in a gradually developing longitudinal data set, or if a subject group or condition is included again for comparison purposes, citations to the previously published work should appear explicitly in the new report.

Scientific publication is an important part of the process by which priority is established for experimental work and ideas. Duplicating without citation of text previously published by others or expropriating the experimental findings of others without attribution, i.e., plagiarism, is unethical. When authors of articles or abstracts have prepublication access to related work of others, as in a review process, care must be taken to avoid the appearance that priority is being claimed for work already done by others.

It is the responsibility of the authors, therefore, and not of the Society or the Editorial Board of *The Journal of Neuroscience*, to ensure that relevant prior discoveries are appropriately acknowledged in manuscripts that are submitted to the *Journal* for publication.

Questions raised about the conduct of experiments or their presentation will be evaluated preliminarily by the Editor of *The Journal of Neuroscience* (in the case of an article in the *Journal*) or by the Chair of the Program Committee (in the case of an abstract), in consultation with the Chair of the Publications Committee and the Secretary of the Society. If possible, the matter may be resolved informally at this level. However, if deemed appropriate, the matter will be referred to the institution where the scientific work in question was done. There, it would be expected that the matter would be reviewed in accordance with institutional procedures for handling allegations of misconduct. At all stages, every effort should be made to ensure that the process is fair and just, both for those who are accused of misconduct and for those who have raised the issue of scientific misconduct.

Based on their own findings or those of the institution, the *Journal* Editor or the Chair of the Program Committee, in consultation with the Chair of the Publications Committee and the Secretary of the Society, may recommend action to the Publications Committee. The Publications Committee will then decide on appropriate action, including, for example, retracting a published report. The Council of the Society and the relevant institution will be informed of any action that is taken. Council retains the right to consider additional action. In accordance with the Bylaws, this action could include, for example, expulsion from the Society. If it is found that allegations were not made in good faith, or were maliciously motivated, action may be recommended for those responsible.

In the event that a published article or abstract is to be retracted, a statement of retraction will be published in *The Journal of Neuroscience* or in the *Abstracts* for the next Annual Meeting.

# CHRONOLOGICAL LIST OF SESSIONS

(See page xix for Thematic List of Sessions)

Session Number & Title	Page
---------------------------	------

## SATURDAY, NOV. 11

### Panel—3:00 p.m.

1. Panel on Responsible Conduct in Science . . . . .No Abstract

### Decade of the Brain Lecture—8:00 p.m.

2. Illusions of Body Image in Neurological Disease: What They  
Reveal about Human Nature  
*Chaired by:* V.S. RAMACHANDRAN . . . . .No Abstract

## SUNDAY, NOV. 12

### Symposia—8:00 a.m.

3. Molecular Biological Studies of the Newly Cloned Opioid  
Receptors  
*Chaired by:* H. AKIL . . . . .1
4. Cellular and Molecular Mechanisms of Integration  
in Mammalian Retina  
*Chaired by:* G.L. FAIN . . . . .1

### Special Lecture—10:00 a.m.

5. The Basal Ganglia and Parkinson's Disease: Lessons from the  
Laboratory and the Operating Room  
M.R. DELONG . . . . .No Abstract

### Warner-Lambert Lecture—11:15 a.m.

6. Embryonic Chimeras to Study the Development of the Nervous  
System  
N.N.M. LE DOUARIN . . . . .No Abstract

### Slides Sessions—8:00 a.m.

7. Neuronal death I . . . . .1
8. Neuroglia and myelin I . . . . .3
9. Beta-amyloid: ApoE I . . . . .5
10. Ingestive behavior—peptides . . . . .7
11. Acetylcholine receptor: nicotinic I . . . . .9
12. Subcortical visual pathways I . . . . .11
13. Process outgrowth, growth cones, and sprouting I . . . . .13
14. Cardiovascular regulation: central modulation . . . . .15
15. Visual cortex: extrastriate—ventral stream I . . . . .18
16. Genetic models of human neuropsychiatric  
disorders I . . . . .20
17. Visual cortex: striate I . . . . .21
18. Presynaptic mechanisms I . . . . .23
19. GABA receptors: regulation and recombinant  
expression . . . . .25
20. Neural plasticity . . . . .27

### Poster Sessions—8:00 a.m.

21. Cell differentiation and migration I . . . . .29
22. Neurotrophic factors: expression and regulation I . . . . .32
23. Neurotrophic factors: expression and regulation II . . . . .35

Session Number & Title	Page

141. Calcium channels: modulation by non-peptide neurotransmitters . . . . .	340
142. Acetylcholine receptor: nicotinic—biophysics . . . . .	343
143. Acetylcholine receptor: nicotinic—acetylcholine- regulation, distribution, and physiology . . . . .	344
144. Excitatory amino acids: anatomy and physiology— regional localization . . . . .	346
145. Excitatory amino acids: pharmacology—drugs . . . . .	349
146. GABA receptors I . . . . .	354
147. Neuropeptide localization: endocrine peptides . . . . .	357

Session Number & Title	Page
148. Opioids: anatomy, physiology and behavior I . . . . .	360
149. Catecholamine receptors: antisense and knock outs . . . . .	363
150. Catecholamine receptors: distribution . . . . .	365
151. Other neurotransmitters: adenosine . . . . .	366
152. Interactions between neurotransmitters I . . . . .	368
153. Interactions between neurotransmitters II . . . . .	371
154. Uptake and transporters: catecholamines I . . . . .	373
155. Sensory systems: spinal cord I . . . . .	377
156. Sensory systems: spinal cord II . . . . .	379
157. Sensory systems: spinal cord III . . . . .	381
158. Pain modulation: anatomy and physiology— spinal cord I . . . . .	383
159. Pain modulation: anatomy and physiology— periaqueductal gray . . . . .	386
160. Pain modulation: anatomy and physiology— behavior . . . . .	387
161. Retinal subcellular mechanisms I . . . . .	389
162. Visual cortex: striate II . . . . .	392
163. Visual cortex: striate III . . . . .	394
164. Auditory, vestibular, and lateral line: periphery . . . . .	395
165. Auditory systems: central physiology II . . . . .	399
166. Auditory systems: central anatomy I . . . . .	402
167. Invertebrate sensory systems I . . . . .	405
168. Invertebrate sensory systems II . . . . .	407
169. Motor cortex: anatomy . . . . .	409
170. Basal ganglia: neuron activity during behavior . . . . .	411
171. Spinal cord and brainstem: spinal reflexes . . . . .	413
172. Control of posture and movement: injury and disease . . . . .	415
173. Control of posture and movement: locomotion . . . . .	418
174. Control of posture and movement: reaching I . . . . .	422
175. Invertebrate motor functions . . . . .	424
176. Limbic system and hypothalamus: chemical anatomy . . . . .	428
177. Comparative neuroanatomy: forebrain II . . . . .	431
178. Brain metabolism and blood flow: nitric oxide . . . . .	433
179. Cognition II . . . . .	436
180. Cognition III . . . . .	438
181. Neural plasticity: LTP . . . . .	440
182. Neural plasticity: structural correlates . . . . .	444
183. Motivation and emotion: animal models . . . . .	446
184. Biological rhythms and sleep: neurotransmitters and hormones II . . . . .	449
185. Biological rhythms and sleep: neurotransmitters and hormones III . . . . .	452
186. Neuroethology: other taxa . . . . .	454
187. Neuroethology: invertebrates . . . . .	457
188. Ingestive behavior I . . . . .	459
189. Stress: neurotransmitter systems . . . . .	461
190. Hormonal control of reproductive behavior: parenting and sex differences . . . . .	464
191. Psychotherapeutic drugs: antipsychotics I . . . . .	467
192. Aging: cell biology . . . . .	470
193. Beta-amyloid: neurotoxicity and aggregation . . . . .	474
194. Beta-amyloid: neuromodulation . . . . .	477
195. Degenerative disease: Alzheimer's—cognitive function . . . . .	480
196. Degenerative disease: other—genetics and mechanisms . . . . .	483

Session Number & Title	Page
197. Degenerative disease: other—metabolic and inflammatory . . . . .	485
198. Degenerative disease: other—Huntington's . . . . .	488
199. Degenerative disease: other—ALS and dementias . . . . .	491
200. Trauma models and cell biology . . . . .	494
<b>100. History of neuroscience . . . . .</b>	<b>244</b>
<b>101. Teaching of neuroscience: curriculum development . . . . .</b>	<b>247</b>
<b>102. Teaching of neuroscience: computer programs and internet . . . . .</b>	<b>251</b>
<b>103. Teaching of neuroscience: laboratory courses and exercises . . . . .</b>	<b>253</b>

#### Animals in Research Panel—5:30 p.m.

201. Everything You Ever Wanted to Know About the Revised *Guide* and Its Interpretation by Regulatory Agencies . . . . . No Abstract

#### Presidential Symposium—8:00 p.m.

202. **The Making of the Brain: The Siring, Wiring, and Firing of Neurons**  
Pattern Formation in the Avian Hindbrain  
A.G.S. LUMSDEN . . . . . No Abstract  
Molecules and Mechanisms That Control Growth Cone Guidance and Target Recognition  
C.S. GOODMAN . . . . . No Abstract  
Making Sparks Fly: Constructing Neuronal Assemblies in Cortex  
L.C. KATZ . . . . . No Abstract

## MONDAY, NOV. 13

#### Symposia—8:00 a.m.

203. Neural Progenitor Cells and CNS Lineage Development  
*Chaired by:* M.F. MEHLER . . . . . 498  
204. The Neurobiology of Early Trauma: Implications for the Pathophysiology of Mood and Anxiety Disorders  
*Chaired by:* N.H. KALIN . . . . . 498

#### Special Lecture—11:15 a.m.

205. Comparative Studies of the Organization of Neocortex Help Us Understand the Human Brain  
J.H. KAAS . . . . . No Abstract

#### Slide Sessions—8:00 a.m.

206. Drugs of abuse: alcohol I . . . . . 498  
207. Stress: HPA axis . . . . . 500  
208. Beta-amyloid: secretion I . . . . . 502  
209. Potassium channel physiology, pharmacology and modulation I . . . . . 504  
210. Peptides: physiology and anatomy . . . . . 506  
211. Retina I . . . . . 508  
212. Visual psychophysics and behavior II . . . . . 510  
213. Ischemia: ischemic tolerance . . . . . 512  
214. Calcium channels: physiology, pharmacology and modulation I . . . . . 514  
215. Motor systems: cortex . . . . . 516

Session Number & Title	Page
216. Oculomotor system: smooth pursuit and vestibuloocular reflex . . . . .	518
217. Excitatory amino acids: excitotoxicity III . . . . .	520
218. Hypothalamic-pituitary-adrenal regulation . . . . .	522
219. Opioid receptors I . . . . .	525
<b>Poster Sessions—8:00 a.m.</b>	
220. Cell lineage and determination I . . . . .	527
221. Process outgrowth, growth cones, and sprouting II . . . . .	530
222. Axon guidance mechanisms and pathways III . . . . .	532
223. Neurotransmitter systems and channels I . . . . .	535
224. Neurotrophic factors: biologic effects II . . . . .	537
225. Neurotrophic factors: biologic effects III . . . . .	541
226. Neurotrophic factors: biologic effects IV . . . . .	545
227. Neurotrophic factors: biologic effects V . . . . .	548
228. Other factors and trophic agents I . . . . .	552
229. Other factors and trophic agents II . . . . .	556
230. Neuronal death III . . . . .	559
231. Glia and other non-neuronal cells III . . . . .	562
232. Sensory systems: central and peripheral responses to nerve injury . . . . .	565
233. Sensory systems: activity-dependent mechanisms of OP development . . . . .	567
234. Sensory systems: somatosensory development . . . . .	569
235. Sensory systems: olfactory, gustatory, and acoustico-vestibular development . . . . .	571
236. Aging processes: calcium . . . . .	573
237. Aging processes: physiology . . . . .	574
238. Staining, tracing, and imaging techniques I . . . . .	577
239. Neuroglia and myelin IV . . . . .	580
240. Postsynaptic mechanisms I . . . . .	584
241. Postsynaptic mechanisms II . . . . .	587
242. Postsynaptic mechanisms III . . . . .	590
243. Postsynaptic mechanisms IV . . . . .	592
244. Postsynaptic mechanisms V . . . . .	595
245. Long-term potentiation: physiology I . . . . .	598
246. Long-term potentiation: physiology II . . . . .	601
247. Acetylcholine receptor: nicotinic—acetylcholine-pharmacology and behavior . . . . .	605
248. Excitatory amino acids: excitotoxicity IV . . . . .	607
249. Excitatory amino acids: anatomy and physiology I . . . . .	610
250. Excitatory amino acids: anatomy and physiology II . . . . .	612
251. Excitatory amino acids: pharmacology—mGluRs . . . . .	614
252. Catecholamine receptors: D <sub>2</sub> , D <sub>3</sub> , D <sub>4</sub> pharmacology . . . . .	617
253. Catecholamine receptors: structure and function . . . . .	621
254. Other neurotransmitters: nitric oxide . . . . .	624
255. Transmitters in invertebrates: neuropeptides . . . . .	626
256. Transmitters in invertebrates: NO, amines, etc. . . . .	630
257. Catecholamines: noradrenergic systems . . . . .	633
258. Cardiovascular regulation: supramedullary mechanisms . . . . .	636
259. Cardiovascular regulation: vagal organization . . . . .	640
260. Pain pathways: peripheral nerves and spinal cord . . . . .	643
261. Pain modulation: anatomy and physiology—higher centers . . . . .	646

Session Number & Title	Page
262. Pain modulation: anatomy and physiology—receptor and nerve . . . . .	647
263. Pain modulation: pharmacology—amino acids, adenosine, cannabinoids . . . . .	650
264. Subcortical visual pathways II . . . . .	652
265. Subcortical visual pathways III . . . . .	654
266. Subcortical visual pathways IV . . . . .	657
267. Visual cortex: extrastriate—ventral stream II . . . . .	659
268. Visual cortex: extrastriate—dorsal stream II . . . . .	662
269. Auditory systems: central physiology III . . . . .	666
270. Auditory systems: central physiology IV . . . . .	670
271. Auditory systems: central anatomy II . . . . .	673
272. Basal ganglia: primate anatomy . . . . .	676
273. Reflex function: human studies . . . . .	679
274. Control of posture and movement: modelling . . . . .	681
275. Control of posture and movement: posture I . . . . .	683
276. Control of posture and movement: motor control II . . . . .	685
277. Circuitry and pattern generation: spinal cord . . . . .	687
278. Comparative neuroanatomy: non-forebrain . . . . .	690
279. Cognition IV . . . . .	693
280. Ingestive behavior II . . . . .	696
281. Stress: behavior . . . . .	698
282. Hormonal control of reproductive behavior: functional anatomy . . . . .	701
283. Drugs of abuse: cocaine—development I . . . . .	704
284. Drugs of abuse: cocaine—development II . . . . .	707
285. Drugs of abuse: cocaine I . . . . .	710
286. Drugs of abuse: cocaine II . . . . .	712
287. Drugs of abuse: cocaine III . . . . .	715
288. Drugs of abuse: cocaine IV . . . . .	718
289. Drugs of abuse: opioids and others I . . . . .	722
290. Drugs of abuse: opioids and others—heroin and cannabinoids . . . . .	725
291. Drugs of abuse: opioids and others—morphine . . . . .	728
292. Drugs of abuse: opioids and others II . . . . .	731
293. Developmental disorders I . . . . .	733
294. Beta-amyloid: processing I . . . . .	736
295. Alzheimer's disease: chemical neuroanatomy . . . . .	738
296. Alzheimer's disease: tau and neurofibrillary degeneration . . . . .	741
297. Mental illness—schizophrenia II . . . . .	744
298. Neurotoxins II . . . . .	749
<b>100. History of neuroscience . . . . .</b>	<b>244</b>
<b>101. Teaching of neuroscience: curriculum development . . . . .</b>	<b>247</b>
<b>102. Teaching of neuroscience: computer programs and internet . . . . .</b>	<b>251</b>
<b>103. Teaching of neuroscience: laboratory courses and exercises . . . . .</b>	<b>253</b>
<b>Symposia—1:00 p.m.</b>	
299. Gap Junctions in the Normal and Pathologic Nervous System <i>Chaired by:</i> D.C. SPRAY . . . . .	753
300. New Vistas in the Control of Arm Movement Trajectories <i>Chaired by:</i> J.R. LACKNER . . . . .	753

Session Number & Title	Page
---------------------------	------

**Special Lecture—1:00 p.m.**

- |  |             |
|--|-------------|
| 301. Sexual Differentiation: Hormonal Control of Developing Neuron and Muscle Targets<br>D.B. KELLEY | No Abstract |
|--|-------------|

**Social Issues Roundtable—3:30 p.m.**

- |  |             |
|--|-------------|
| 495. What's the Biology of Violent Behavior?<br><i>Sponsored by:</i> Social Issues Committee of the Society for Neuroscience<br>S.F. WITELSON, Chairperson | No Abstract |
|--|-------------|

**Presidential Special Lecture—4:15 p.m.**

- |   |             |
|---|-------------|
| 302. Plasticity of Neocortical Synaptic Connections<br>B. SAKMANN | No Abstract |
|---|-------------|

**Slide Sessions—1:00 p.m.**

- |  |     |
|--|-----|
| 303. Learning and memory: systems and functions II     | 753 |
| 304. Neuropeptides and behavior I                      | 755 |
| 305. Behavioral pharmacology: psychostimulants         | 757 |
| 306. Neurotransmitter characterization and degradation | 760 |
| 307. Trauma  | 762 |
| 308. Excitatory amino acid receptors IV                | 764 |
| 309. Psychotherapeutic drugs                           | 766 |
| 310. Beta-amyloid: processing II                       | 768 |
| 311. Visual cortex: striate IV                         | 770 |
| 312. Serotonin receptors II                            | 772 |
| 313. Second messengers I                               | 775 |
| 314. Epilepsy: basic mechanisms I                      | 777 |
| 315. Cell lineage and determination II                 | 779 |
| 316. Uptake and transporters: monoamines               | 781 |

**Poster Sessions—1:00 p.m.**

- |   |     |
|---|-----|
| 317. Genesis of neurons and glia II   | 783 |
| 318. Cell differentiation and migration II                                  | 786 |
| 319. Cell differentiation and migration III                                 | 788 |
| 320. Pattern formation, compartments and boundaries II                      | 790 |
| 321. Process outgrowth, growth cones, and sprouting III                     | 794 |
| 322. Axon guidance mechanisms and pathways IV                               | 796 |
| 323. Formation and specificity of synapses:<br>molecules of synapses        | 799 |
| 324. Formation and specificity of synapses:<br>cell-cell interactions       | 802 |
| 325. Neurotrophic factors: receptors and cellular<br>mechanisms I           | 805 |
| 326. Neuronal death IV  | 809 |
| 327. Glia and other non-neuronal cells IV                                   | 812 |
| 328. Development of tectum and optic nerve                                  | 816 |
| 329. Transplant-assisted axonal regeneration                                | 819 |
| 330. Transplantation I  | 820 |
| 331. Blood-brain barrier: function  | 824 |
| 332. Gene structure and function II   | 827 |
| 333. Pharmacology of synaptic transmission I                                | 830 |
| 334. Acetylcholine receptor: nicotinic—acetylcholine-genetics:<br>molecular | 832 |
| 335. Excitatory amino acid receptors V                                      | 834 |
| 336. Excitatory amino acid receptors VI                                     | 837 |

Session Number & Title	Page
---------------------------	------

- |   |     |
|---|-----|
| 337. Excitatory amino acid receptors VII                              | 840 |
| 338. Excitatory amino acid receptors VIII                             | 843 |
| 339. GABA receptors II  | 847 |
| 340. Catecholamine receptors: in vivo drug effects I                  | 852 |
| 341. Catecholamine receptors: in vivo drug effects II                 | 855 |
| 342. Serotonin: regulation  | 858 |
| 343. Serotonin: development   | 862 |
| 344. Uptake and transporters: serotonin                               | 864 |
| 345. Second messengers II   | 868 |
| 346. Second messengers III  | 870 |
| 347. Hypothalamic-pituitary-adrenal regulation:<br>glucocorticoids    | 872 |
| 348. Osmoregulation: magnocellular endocrine neurons                  | 875 |
| 349. Osmoregulation: mechanisms                                       | 877 |
| 350. Thermoregulation and fever                                       | 879 |
| 351. Neuroendocrine regulation: thyroid and<br>gonadal axes           | 880 |
| 352. Neural-immune interactions: cytokines II                         | 883 |
| 353. Cardiovascular regulation: vagal pharmacology<br>and physiology  | 886 |
| 354. Cardiovascular regulation: medullary reticular<br>formation      | 889 |
| 355. Pain pathways: gene expression                                   | 892 |
| 356. Pain modulation: anatomy and physiology—neuropathic<br>pain      | 894 |
| 357. Pain modulation: pharmacology—inflammation and<br>prostaglandins | 897 |
| 358. Retinal subcellular mechanisms II                                | 900 |
| 359. Visual cortex: extrastriate—functional<br>organization I         | 903 |
| 360. Visual cortex: extrastriate—functional<br>organization II        | 905 |
| 361. Auditory systems: central anatomy III                            | 908 |
| 362. Basal ganglia: physiology  | 911 |
| 363. Cerebellum: behavior, development, models                        | 914 |
| 364. Cerebellum: clinical studies                                     | 916 |
| 365. Vestibular system: nerve and nuclei                              | 918 |
| 366. Oculomotor system: saccades—behavior and<br>imaging              | 920 |
| 367. Oculomotor system: clinical studies                              | 922 |
| 368. Spinal cord and brainstem: pharmacology and<br>transmitters      | 924 |
| 369. Spinal cord and brainstem: anatomy                               | 926 |
| 370. Limbic system and hypothalamus: anatomy                          | 929 |
| 371. Association cortex and thalamocortical relations:<br>anatomy     | 931 |
| 372. Association cortex and thalamocortical relations:<br>physiology  | 933 |
| 373. Cognition V  | 935 |
| 374. Cognition VI   | 936 |
| 375. Learning and memory: physiology I                                | 940 |
| 376. Learning and memory: physiology II                               | 943 |
| 377. Learning and memory: pharmacology IV                             | 947 |
| 378. Motivation and emotion: primates<br>including humans             | 951 |
| 379. Biological rhythms and sleep: physiology I                       | 952 |

Session Number & Title	Page
380. Biological rhythms and sleep: physiology II	955
381. Neuroethology: songbirds I	958
382. Neuroethology: songbirds II	961
383. Ingestive behavior III	965
384. Drugs of abuse: amphetamines and other stimulants I	968
385. Drugs of abuse: amphetamines and other stimulants II	971
386. Psychotherapeutic drugs: antidepressants	975
387. Genetic models of human neuropsychiatric disorders III	978
388. Epilepsy: basic mechanisms II	981
389. Epilepsy: basic mechanisms III	984
390. Beta-amyloid: secretion II	988
391. Ischemia: apoptosis and gene expression	991
392. Ischemia: glutamate	994
393. Ischemia: nitric oxide and other transmitters	997
394. Ischemia: oxidative injury	1000
395. Trauma: white matter	1003
396. Neuromuscular diseases: motoneurons	1004
<b>100. History of neuroscience</b>	<b>244</b>
<b>101. Teaching of neuroscience: curriculum development</b>	<b>247</b>
<b>102. Teaching of neuroscience: computer programs and internet</b>	<b>251</b>
<b>103. Teaching of neuroscience: laboratory courses and exercises</b>	<b>253</b>

#### The Grass Foundation Lecture—8:00 p.m.

397. Hemispheric Specialization, Memory, and the Human  
Brain: Old and New Perspectives  
B.A. MILNER . . . . .No Abstract

## TUESDAY, NOV. 14

#### Silver Anniversary Symposium—8:00 a.m.

398. **Neuroscience: 25 Years of Progress**  
Communication in the Brain  
C.F. STEVENS . . . . .No Abstract  
Messengers in Molecular Neuroscience  
S.H. SNYDER . . . . .No Abstract  
Cerebral Cortex: Progress Over Four Decades  
D.H. HUBEL . . . . .No Abstract  
Psychology, Neurology, and the Emergence of  
Modern Neuroscience  
L.R. SQUIRE . . . . .No Abstract

#### Special Lecture—11:15 a.m.

399. Mechanisms and Molecules Controlling the  
Development of Neural Maps  
D.D.M. O'LEARY . . . . .No Abstract

#### Slide Sessions—8:00 a.m.

400. Alzheimer's disease: ApoE and genetics . . . . .1007  
401. Beta-amyloid: neurotoxicity . . . . .1009  
402. Peptide receptor structure and function I . . . . .1011  
403. Cardiovascular regulation: spinalmedullary  
mechanisms . . . . .1014

Session Number & Title	Page
404. Somatosensory cortex and thalamocortical relationships IV	1017
405. Hypothalamic-pituitary-gonadal regulation III	1018
406. Axon guidance mechanisms and pathways V	1020
407. Invertebrate learning and behavior I	1023
408. GABA receptors: neuromodulators	1025
409. Excitatory amino acids: excitotoxicity V	1027
410. Ingestive behavior IV	1028
411. Ischemia: neuroprotection and trophic factors	1030
412. Potassium channel structure, function and expression II	1032
413. Retina II	1034

#### Poster Sessions—8:00 a.m.

414. Cell differentiation and migration IV . . . . .1036  
415. Cell differentiation and migration V . . . . .1039  
416. Pattern formation, compartments and  
boundaries III . . . . .1041  
417. Neurotrophic factors: expression and regulation V . . . . .1045  
418. Neurotrophic factors: biologic effects VI . . . . .1048  
419. Neurotrophic factors: biologic effects VII . . . . .1050  
420. Neurotrophic factors: biologic effects VIII . . . . .1054  
421. Neurotrophic factors: biologic effects IX . . . . .1056  
422. Neurotrophic factors: receptors and cellular  
mechanisms II . . . . .1059  
423. Hormones and development II . . . . .1063  
424. Neuronal death V . . . . .1066  
425. Glia and other non-neuronal cells V . . . . .1070  
426. Molecular changes after lesions . . . . .1073  
427. Staining, tracing, and imaging techniques II . . . . .1077  
428. Neuroglia and myelin V . . . . .1080  
429. Blood-brain barrier: pathology and disease . . . . .1083  
430. Presynaptic mechanisms VI . . . . .1086  
431. Presynaptic mechanisms VII . . . . .1090  
432. Presynaptic mechanisms VIII . . . . .1093  
433. Long-term potentiation: physiology III . . . . .1096  
434. Long-term potentiation: physiology IV . . . . .1100  
435. Excitatory amino acids: pharmacology—  
secondary messenger . . . . .1103  
436. Excitatory amino acids: pharmacology—NMDA . . . . .1105  
437. Excitatory amino acid receptors IX . . . . .1108  
438. Excitatory amino acid receptors X . . . . .1110  
439. Excitatory amino acid receptors XI . . . . .1113  
440. Neuropeptide localization: sensory peptides . . . . .1115  
441. Catecholamine receptors: D<sub>1</sub> and D<sub>5</sub> pharmacology . . . . .1118  
442. Serotonin receptors: structure and structure/function . . . . .1121  
443. Serotonin receptors: 5-HT<sub>2</sub> . . . . .1123  
444. Second messengers: calcium . . . . .1127  
445. Behavioral pharmacology: serotonin and dopamine . . . . .1130  
446. Catecholamines: biosynthetic enzymes . . . . .1133  
447. Catecholamines: microdialysis/voltammetric studies . . . . .1137  
448. Catecholamines: electrophysiological studies . . . . .1140  
449. Receptor modulation, up- and down-regulation II . . . . .1143  
450. Neuroendocrine regulation: vasopressin and  
oxytocin . . . . .1146  
451. Neural-immune interactions: pathology . . . . .1149

Session Number & Title	Page
452. Neural-immune interactions: inflammation . . . . .	1152
453. Somatic and visceral afferents: visceral afferents . . . . .	1155
454. Somatic and visceral afferents: nociceptors . . . . .	1159
455. Somatic and visceral afferents: mechanoreceptors . . . . .	1162
456. Pain pathways: supraspinal centers . . . . .	1164
457. Pain modulation: pharmacology—opioids I . . . . .	1166
458. Pain modulation: pharmacology—opioids II . . . . .	1169
459. Pain modulation: pharmacology—allodynia . . . . .	1171
460. Photoreceptors and RPE . . . . .	1173
461. Auditory systems: central physiology V . . . . .	1175
462. Auditory systems: central physiology VI . . . . .	1178
463. Olfactory senses: accessory olfactory system . . . . .	1181
464. Olfactory senses: olfactory bulb . . . . .	1182
465. Olfactory senses: olfactory cortex . . . . .	1185
466. Basal ganglia: thalamus . . . . .	1187
467. Cerebellum: anatomy and pharmacology . . . . .	1190
468. Oculomotor system: saccades—superior colliculus . . . . .	1193
469. Oculomotor system: saccades—cortex . . . . .	1195
470. Oculomotor system: head movements and Listing's Law . . . . .	1197
471. Spinal cord and brainstem: functional neurophysiology . . . . .	1199
472. Control of posture and movement: posture II . . . . .	1202
473. Limbic system and hypothalamus: function I . . . . .	1204
474. Brain metabolism and blood flow: methods . . . . .	1208
475. Cognition VII . . . . .	1210
476. Cognition VIII . . . . .	1212
477. Learning and memory: systems and functions III . . . . .	1214
478. Learning and memory: systems and functions IV . . . . .	1217
479. Learning and memory: systems and functions V . . . . .	1221
480. Learning and memory: systems and functions VI . . . . .	1225
481. Learning and memory: pharmacology V . . . . .	1228
482. Learning and memory: pharmacology VI . . . . .	1232
483. Biological rhythms and sleep: aging . . . . .	1234
484. Biological rhythms and sleep: disorders and clinical studies . . . . .	1235
485. Drugs of abuse: alcohol II . . . . .	1238
486. Drugs of abuse: alcohol III . . . . .	1241
487. Degenerative disease: Parkinson's—other models . . . . .	1244
488. Degenerative disease: Parkinson's—clinical . . . . .	1247
489. Degenerative disease: Parkinson's—mechanisms . . . . .	1250
490. Degenerative disease: Parkinson's—pharmacology . . . . .	1253
491. Degenerative disease: Parkinson's—MPTP models . . . . .	1256
<b>100. History of neuroscience . . . . .</b>	<b>244</b>
<b>101. Teaching of neuroscience: curriculum development . . . . .</b>	<b>247</b>
<b>102. Teaching of neuroscience: computer programs and internet . . . . .</b>	<b>251</b>
<b>103. Teaching of neuroscience: laboratory courses and exercises . . . . .</b>	<b>253</b>
 <b>Symposia—1:00 p.m.</b>	
492. Sensory Circumventricular Organs (CVOs): Body-Brain Coupling and Mechanisms of Afferent Signaling <i>Chaired by:</i> A.K. JOHNSON . . . . .	1259
493. GDNF: A New Neurotrophic Factor with Multiple Roles <i>Chaired by:</i> L. OLSON . . . . .	1259

Session Number & Title	Page
 <b>History of Neuroscience Lecture—1:00 p.m.</b>	
494. Cortical Cell Types: Their Once and Future History F.H.C. CRICK . . . . .	No Abstract
 <b>Presidential Special Lecture—4:15 p.m.</b>	
496. Brain and Language: Linguistic Experience Forms the Brain's Perceptual Maps for Speech P.K. KUHL . . . . .	No Abstract
 <b>Slide Session—1:00 p.m.</b>	
497. Gene structure and function III . . . . .	1260
498. Ligand-gated ion channels II . . . . .	1262
499. Excitatory amino acids: pharmacology—NMDA/AMPA receptors . . . . .	1263
500. Invertebrate learning and behavior II . . . . .	1266
501. Ischemia: molecular mechanisms . . . . .	1268
502. Oculomotor system: saccades . . . . .	1270
503. Degenerative disease: Parkinson's . . . . .	1272
504. Visual cortex: extrastriate—functional organization III . . . . .	1274
505. Invertebrate sensory and motor . . . . .	1276
506. Axonal regeneration I . . . . .	1278
507. Beta-amyloid: aggregation . . . . .	1280
508. Calcium channel structure, function and expression I . . . . .	1282
509. Development of visual system I . . . . .	1284
 <b>Poster Sessions—1:00 p.m.</b>	
510. Genesis of neurons and glia III . . . . .	1285
511. Cell lineage and determination III . . . . .	1288
512. Process outgrowth, growth cones, and sprouting IV . . . . .	1290
513. Axon guidance mechanisms and pathways VI . . . . .	1293
514. Neurotransmitter systems and channels II . . . . .	1296
515. Neurotrophic factors: receptors and cellular mechanisms III . . . . .	1299
516. Neuronal death VI . . . . .	1302
517. Development of visual thalamus . . . . .	1306
518. Transplantation: evidence of function . . . . .	1308
519. Membrane composition and cell-surface macromolecules I . . . . .	1310
520. Membrane composition and cell-surface macromolecules II . . . . .	1314
521. Gene structure and function IV . . . . .	1316
522. Long-term potentiation: pharmacology II . . . . .	1319
523. Long-term potentiation: pharmacology III . . . . .	1321
524. Potassium channel structure, function and expression III . . . . .	1323
525. Potassium channel structure, function and expression IV . . . . .	1327
526. Acetylcholine receptor: nicotinic—acetylcholine-effects of nicotine on specific brain regions . . . . .	1330
527. Acetylcholine receptor: nicotinic expression and treatment effects . . . . .	1332
528. Acetylcholine receptor: nicotinic expression . . . . .	1335
529. Excitatory amino acids: excitotoxicity VI . . . . .	1339
530. Excitatory amino acids: excitotoxicity VII . . . . .	1342
531. GABA receptors III . . . . .	1344
532. Peptide receptor structure and function II . . . . .	1348

Session Number & Title	Page
533. Opioid receptors: cell biology and physiology . . . . .	1352
534. Opioid receptors: development and regulation . . . . .	1355
535. Opioid receptors: localization . . . . .	1358
536. Opioids: anatomy, physiology and behavior II . . . . .	1361
537. Serotonin receptors: effectors . . . . .	1364
538. Serotonin receptors: behavior . . . . .	1366
539. Serotonin receptors: autoreceptors . . . . .	1368
540. Serotonin: uptake, function . . . . .	1369
541. Interactions between neurotransmitters III . . . . .	1372
542. Interactions between neurotransmitters IV . . . . .	1376
543. Uptake and transporters: catecholamines II . . . . .	1379
544. Behavioral pharmacology I . . . . .	1383
545. Hypothalamic-pituitary-adrenal regulation: other I . . . . .	1386
546. Hypothalamic-pituitary-adrenal regulation: CRF . . . . .	1389
547. Neuroendocrine regulation: hypothalamic peptides . . . . .	1392
548. Neural-immune interactions: depression and stress . . . . .	1395
549. Cardiovascular regulation: determinants of sympathetic nerve response . . . . .	1398
550. Cardiovascular regulation: organization and pathology . . . . .	1402
551. Cardiovascular regulation: pharmacology . . . . .	1404
552. Pain modulation: anatomy and physiology— spinal cord II . . . . .	1407
553. Pain modulation: pharmacology—anesthetics . . . . .	1411
554. Pain modulation: pharmacology—neuropeptides . . . . .	1412
555. Pain modulation: pharmacology—serotonin, histamine, catecholamines . . . . .	1415
556. Retina III . . . . .	1417
557. Motor cortex: human studies I . . . . .	1418
558. Motor cortex: human studies II . . . . .	1421
559. Basal ganglia: striatal anatomy . . . . .	1424
560. Basal ganglia: movement disorders and experimental models . . . . .	1427
561. Reflex function: animal studies . . . . .	1429
562. Control of posture and movement: motor units and reflexes . . . . .	1432
563. Muscle: biomechanics . . . . .	1434
564. Limbic system and hypothalamus: function II . . . . .	1437
565. Learning and memory: systems and functions VII . . . . .	1440
566. Learning and memory: systems and functions VIII . . . . .	1444
567. Learning and memory: systems and functions IX . . . . .	1448
568. Neuroethology: fish . . . . .	1451
569. Invertebrate learning and behavior III . . . . .	1453
570. Invertebrate learning and behavior IV . . . . .	1456
571. Ingestive behavior V . . . . .	1459
572. Hormonal control of reproductive behavior: behavioral measures . . . . .	1462
573. Drugs of abuse: amphetamines and other stimulants III . . . . .	1465
574. Drugs of abuse: amphetamines and other stimulants IV . . . . .	1468
575. Epilepsy: animal models I . . . . .	1472
576. Epilepsy: basic mechanisms IV . . . . .	1474
577. Beta-amyloid: neuropathology I . . . . .	1477
578. Beta-amyloid: localization . . . . .	1481
579. Beta-amyloid: animal models II . . . . .	1482

Session Number & Title	Page
580. Alzheimer's disease: ApoE . . . . .	1483
581. Alzheimer's disease: genetics and clinical studies . . . . .	1487
582. Neuromuscular diseases . . . . .	1489
<b>100. History of neuroscience . . . . .</b>	<b>241</b>
<b>101. Teaching of neuroscience: curriculum development . . . . .</b>	<b>244</b>

<b>103. Teaching of neuroscience: laboratory courses and exercises . . . . .</b>	<b>253</b>

## WEDNESDAY, NOV. 15

### Symposia—8:00 a.m.

583. What Is the Specific Role of the Cerebellum in Cognition? <i>Chaired by:</i> W.T. THACH, JR. . . . .	1492
584. Ligand-Gated Ion Channel Superfamily Feud <i>Chaired by:</i> R.J. LUKAS . . . . .	1492

### Presidential Special Lecture—11:15 a.m.

585. Genes Controlling the Development of the CNS in the Zebrafish <i>Danio Rerio</i> C. NUSSLEIN-VOLHARD . . . . .	No Abstract
---	-------------

### Slide Sessions—8:00 a.m.

586. Learning and memory: systems and functions X . . . . .	1493
587. Biological rhythms and sleep . . . . .	1495
588. Cognition IX . . . . .	1497
589. Beta-amyloid: neuropathology II . . . . .	1499
590. Neural-immune interactions: other . . . . .	1501
591. Development of visual system II . . . . .	1503
592. Visual cortex: striate V . . . . .	1505
593. Cerebral cortex and limbic system III . . . . .	1507
594. Axon guidance mechanisms and pathways VII . . . . .	1509
595. Genesis of neurons and glia IV . . . . .	1512
596. Catecholamines . . . . .	1514
597. Epilepsy: animal models II . . . . .	1516
598. Neurotoxicity I . . . . .	1518
599. Presynaptic mechanisms IX . . . . .	1520

### Poster Sessions—8:00 a.m.

600. Genesis of neurons and glia V . . . . .	1522
601. Cell differentiation and migration VI . . . . .	1524
602. Cell differentiation and migration VII . . . . .	1526
603. Pattern formation, compartments and boundaries IV . . . . .	1529
604. Neurotrophic factors: expression and regulation VI . . . . .	1532
605. Neurotrophic factors: biologic effects X . . . . .	1534
606. Neurotrophic factors: biologic effects XI . . . . .	1539
607. Neurotrophic factors: biologic effects XII . . . . .	1542
608. Neurotrophic factors: biologic effects XIII . . . . .	1546
609. Neurotrophic factors: receptors and cellular mechanisms IV . . . . .	1550
610. Neuronal death VII . . . . .	1553
611. Retinal development . . . . .	1556
612. Axonal regeneration II . . . . .	1559
613. Transplantation: growth factors . . . . .	1561

Session Number & Title	Page	Session Number & Title	Page
614. Aging processes: anatomy . . . . .	1563	657. Motivation and emotion: biochemistry and pharmacology . . . . .	1671
615. Pharmacology of synaptic transmission II . . . . .	1565	658. Biological rhythms and sleep: molecular and cellular biology . . . . .	1675
616. Pharmacology of synaptic transmission III . . . . .	1568	659. Invertebrate learning and behavior V . . . . .	1679
617. Calcium channel structure, function and expression II . . . . .	1571	660. Ingestive behavior VI . . . . .	1682
618. Calcium channel structure, function and expression III . . . . .	1573	661. Stress: preclinical and clinical studies . . . . .	1685
619. Calcium channels: modulation by peptides and hormones . . . . .	1575	662. Monoamines and behavior: dopamine I . . . . .	1687
620. Calcium channels: characterization and electrophysiology . . . . .	1577	663. Monoamines and behavior: serotonin . . . . .	1691
621. Acetylcholine receptor: nicotinic II . . . . .	1580	664. Neuropeptides and behavior II . . . . .	1695
622. Excitatory amino acids: excitotoxicity VIII . . . . .	1584	665. Drugs of abuse: alcohol IV . . . . .	1698
623. Excitatory amino acid receptors XII . . . . .	1587	666. Drugs of abuse: alcohol V . . . . .	1701
624. GABA receptors IV . . . . .	1589	667. Psychotherapeutic drugs: antipsychotics II . . . . .	1705
625. Peptide receptor structure and function III . . . . .	1593	668. Aging: primates including humans . . . . .	1708
626. Neurotransmitter release . . . . .	1596	669. Developmental disorders II . . . . .	1711
627. Peptides: physiological effects II . . . . .	1599	670. Beta-amyloid: ApoE II . . . . .	1713
628. Peptides: physiological effects III . . . . .	1601	671. Beta-amyloid: cellular effects I . . . . .	1716
629. Opioid receptors: molecular biology . . . . .	1603	672. Beta-amyloid: cellular effects II . . . . .	1719
630. Opioid receptors: pharmacology . . . . .	1606	673. Alzheimer's disease: mechanisms of degeneration I . . . . .	1722
631. Opioid receptors: sigma receptors . . . . .	1608	674. Alzheimer's disease: neuronal injury and death . . . . .	1725
632. Catecholamine receptors: alpha adrenergic . . . . .	1611	675. Ischemia: ischemic tolerance and stress proteins . . . . .	1727
633. Catecholamine receptors: beta adrenergic . . . . .	1614	676. Trauma: miscellaneous . . . . .	1731
634. Other neurotransmitters: GABA, glycine, purine . . . . .	1616	677. Mental illness II . . . . .	1732
635. Regional localization of receptors and transmitters I . . . . .	1617	678. Mental illness—depression . . . . .	1734
636. Regional localization of receptors and transmitters II . . . . .	1620	679. Neurotoxins III . . . . .	1737
637. Behavioral pharmacology II . . . . .	1623	<b>100. History of neuroscience . . . . .</b>	<b>241</b>
638. Hypothalamic-pituitary-adrenal regulation: other II . . . . .	1626	<b>101. Teaching of neuroscience: curriculum development . . . . .</b>	<b>244</b>
639. Neuroendocrine regulation: other I . . . . .	1629	<b>102. Teaching of neuroscience: computer programs and internet . . . . .</b>	<b>251</b>
640. Gastrointestinal regulation: gastroesophageal control . . . . .	1632	<b>103. Teaching of neuroscience: laboratory courses and exercises . . . . .</b>	<b>253</b>
641. Gastrointestinal regulation: intestinal hepatic and pancreatic control . . . . .	1634	<b>Symposia—1:00 p.m.</b>	
642. Pain pathways: human studies . . . . .	1636	680. Molecular Organization of the Postsynaptic Membrane <i>Chaired by: M.B. KENNEDY . . . . .</i>	1741
643. Pain modulation: anatomy and physiology— human studies . . . . .	1637	681. Developmental Determinants of Retinal Ganglion Cells <i>Chaired by: L.M. CHALUPA . . . . .</i>	1741
644. Pain modulation: anatomy and physiology— brainstem . . . . .	1638	<b>Special Lecture—1:00 p.m.</b>	
645. Pain modulation: pharmacology—NMDA and NO . . . . .	1640	682. Schizophrenia C.A. TAMMINGA . . . . .	No Abstract
646. Retinal function . . . . .	1643	<b>Special Lecture—4:15 p.m.</b>	
647. Damaged retinas . . . . .	1646	683. Cell-cell Interactions Required for Synapse Formation and the Molecules That Mediate Them S.C. LANDIS . . . . .	No Abstract
648. Visual cortex: striate VI . . . . .	1647	<b>Slide Sessions—1:00 p.m.</b>	
649. Visual cortex: striate VII . . . . .	1650	684. Postsynaptic mechanisms VI . . . . .	1742
650. Visual cortex: striate VIII . . . . .	1653	685. Degenerative disease: other . . . . .	1744
651. Gustatory senses . . . . .	1656	686. Chemical senses . . . . .	1746
652. Basal ganglia: ventral striatal/ventral pallidal systems . . . . .	1659	687. Formation and specificity of synapses I . . . . .	1747
653. Basal ganglia: nigra and related systems . . . . .	1660	688. Blood-brain barrier: other . . . . .	1750
654. Muscle: cellular and molecular physiology . . . . .	1662	689. Visual cortex: striate IX . . . . .	1751
655. Limbic system and hypothalamus: amygdala and hypothalamus . . . . .	1664		
656. Brain metabolism and blood flow: physiology and biochemistry . . . . .	1668		

Session Number & Title	Page
690. Calcium channels: physiology, pharmacology and modulation II	1753
691. Transplantation II	1755
692. Somatosensory cortex and thalamocortical relationships V	1757
693. Visual cortex: extrastriate—attention	1759
694. Pain: pathways and modulation	1761
695. Cognition X	1763
696. Circuitry and pattern generation	1764
<b>Poster Sessions—1:00 p.m.</b>	
697. Cell lineage and determination IV	1766
698. Process outgrowth, growth cones, and sprouting V	1769
699. Process outgrowth, growth cones, and sprouting VI	1772
700. Formation and specificity of synapses: agrin	1775
701. Formation and specificity of synapses II	1777
702. Neurotransmitter systems and channels III	1780
703. Neurotrophic factors: receptors and cellular mechanisms—miscellaneous	1783
704. Neuronal death VIII	1786
705. Motor systems	1790
706. Visual cortical development I	1793
707. Axonal regeneration III	1796
708. Staining, tracing, and imaging techniques III	1799
709. Staining, tracing, and imaging techniques IV	1802
710. Gene structure and function V	1803
711. Long-term potentiation: physiology V	1807
712. Long-term potentiation: physiology VI	1810
713. Ligand-gated ion channels III	1813
714. Sodium channels I	1815
715. Sodium channels II	1817
716. Sodium channels III	1819
717. Sodium channels IV	1822
718. Potassium channel physiology, pharmacology and modulation II	1824
719. Potassium channel physiology, pharmacology and modulation III	1827
720. Potassium channel physiology, pharmacology and modulation IV	1830
721. Acetylcholine receptor: nicotinic—pharmacology	1833
722. Excitatory amino acid receptors: receptor localization	1835
723. GABA receptors V	1838
724. Peptide receptor structure and function IV	1842
725. Neurotransmitter processing	1845
726. Opioids: anatomy, physiology and behavior III	1848
727. Serotonin receptors: 5-HT <sub>1</sub>	1851
728. Serotonin receptors: 5-HT <sub>1A</sub> , 5-HT <sub>1B</sub> , 5-HT <sub>2</sub> , 5-HT <sub>2A</sub>	1856
729. Other neurotransmitters: histamine	1857
730. Uptake and transporters: glutamate	1859
731. Second messengers: G-proteins	1863
732. Second messengers IV	1865
733. Neuroendocrine regulation: other II	1869
734. Urogenital regulation: bladder and micturition	1872
735. Urogenital regulation: sexual function	1874
736. Respiratory regulation: amino acid transmitters	1876

Session Number & Title	Page
737. Respiratory regulation: brainstem and spinal cord	1878
738. Respiratory regulation: central chemoreception	1881
739. Respiratory regulation: signal transduction in the carotid body	1883
740. Respiratory regulation: developmental mechanisms	1884
741. Respiratory regulation: reflex mechanisms and pathways	1886
742. Hypothalamic-pituitary-gonadal regulation IV	1888
743. Hypothalamic-pituitary-gonadal regulation V	1891
744. Hypothalamic-pituitary-gonadal regulation VI	1894
745. Hypothalamic-pituitary-gonadal regulation VII	1897
746. Motor cortex: functional organization and plasticity I	1899
747. Motor cortex: functional organization and plasticity II	1901
748. Basal ganglia: striatal systems	1903
749. Basal ganglia: drugs of abuse	1905
750. Basal ganglia: anatomy	1906
751. Cerebellum: physiology	1909
752. Vestibular system: vestibular nuclei	1911
753. Oculomotor system: brainstem and pretectum	1914
754. Oculomotor system: near response, blink, and muscle	1917
755. Control of posture and movement: prehension	1919
756. Control of posture and movement: reaching II	1921
757. Cognition XI	1923
758. Learning and memory: physiology III	1927
759. Learning and memory: physiology IV	1930
760. Learning and memory: systems and functions XI	1934
761. Learning and memory: systems and functions XII	1937
762. Learning and memory: systems and functions XIII	1941
763. Learning and memory: systems and functions XIV	1944
764. Stress: neurochemistry	1948
765. Drugs of abuse: cocaine V	1950
766. Drugs of abuse: cocaine VI	1953
767. Drugs of abuse: cocaine VII	1956
768. Epilepsy: animal models III	1959
769. Epilepsy: primate studies	1962
770. Epilepsy: genetic models	1965
771. Epilepsy: basic mechanisms V	1968
772. Epilepsy: basic mechanisms VI	1970
773. Alzheimer's disease: cholinergic neuropharmacology	1974
774. Alzheimer's disease: neuropharmacology	1977
775. Degenerative disease: Parkinson's—transplantation, pallidotomy and imaging	1980
776. Neurotoxicity: heavy metals	1983
<b>100. History of neuroscience</b>	<b>241</b>
<b>101. Teaching of neuroscience: curriculum development</b>	<b>244</b>
<b>102. Teaching of neuroscience: computer programs and internet</b>	<b>251</b>
<b>103. Teaching of neuroscience: laboratory courses and exercises</b>	<b>253</b>

Session Number & Title	Page
---------------------------	------

## THURSDAY, NOV. 16

### Symposia—8:00 a.m.

777. Opioidergic Modulation of Long-term Potentiation in the Hippocampus: Insights Into Peptidergic Regulation of Synaptic Plasticity <i>Chaired by: C.R. BRAMHAM</i> . . . . .	1987
778. Neural Control of Breathing <i>Chaired by: J.E. REMMERS</i> . . . . .	1987

### Slide Sessions—8:00 a.m.

779. Cognition XII . . . . .	1987
780. Neurotrophic factors: receptors and cellular mechanisms V . . . . .	1989
781. Excitatory amino acid receptors XIII . . . . .	1991
782. Neuroendocrine regulation: other III . . . . .	1993
783. Ion channels: cell function III . . . . .	1995
784. Opioid receptors II . . . . .	1997
785. Cell differentiation and migration VIII . . . . .	1999
786. Neurotoxicity II . . . . .	2001
787. Alzheimer's disease: mechanisms of degeneration II . . . . .	2003
788. Long-term potentiation: physiology VII . . . . .	2005

### Poster Sessions—8:00 a.m.

789. Process outgrowth, growth cones, and sprouting VII . . . . .	2007
790. Neurotrophic factors: expression and regulation VII . . . . .	2009
791. Hormones and development III . . . . .	2013
792. Nutritional and prenatal factors . . . . .	2015
793. Neuronal death IX . . . . .	2018
794. Cerebral cortex and limbic system IV . . . . .	2021
795. Visual cortical development II . . . . .	2023
796. Transplantation: dissociated cells . . . . .	2026
797. Aging processes: molecular characteristics . . . . .	2029
798. Chloride and other channels . . . . .	2032
799. Calcium channels: miscellaneous blockers . . . . .	2034
800. Acetylcholine receptor muscarinic: muscarinic receptors—molecular biology and electrophysiology . . . . .	2036
801. Acetylcholine receptor muscarinic: agonist/antagonist for receptors . . . . .	2039
802. Acetylcholine receptor muscarinic: receptors—expression . . . . .	2041
803. Excitatory amino acids: excitotoxicity IX . . . . .	2044
804. GABA receptors VI . . . . .	2046
805. Neuropeptide localization: CNS regulation . . . . .	2048

Session Number & Title	Page
---------------------------	------

806. Peptides: physiological effects IV . . . . .	2051
807. Catecholamine receptors: genetics . . . . .	2053
808. Serotonin receptors: 5-HT <sub>3</sub> . . . . .	2054
809. Serotonin . . . . .	2056
810. Other neurotransmitters: miscellaneous . . . . .	2059
811. Uptake and transporters: miscellaneous . . . . .	2061
812. Second messengers: kinases . . . . .	2065
813. Second messengers V . . . . .	2068
814. Neural-immune interactions: neurotransmitters and neuromodulators . . . . .	2071
815. Motor cortex: behavioral physiology, models I . . . . .	2074
816. Motor cortex: behavioral physiology, models II . . . . .	2076
817. Basal ganglia: behavior . . . . .	2078
818. Cerebellum: genetic models . . . . .	2081
819. Control of posture and movement: human locomotion . . . . .	2082
820. Cognition XIII . . . . .	2085
821. Monoamines and behavior: dopamine II . . . . .	2087
822. Monoamines and behavior: norepinephrine . . . . .	2091
823. Neuropeptides and behavior III . . . . .	2093
824. Drugs of abuse: alcohol and benzodiazepines . . . . .	2096
825. Drugs of abuse: alcohol VI . . . . .	2099
826. Drugs of abuse: amphetamines and other stimulants V . . . . .	2102
827. Psychotherapeutic drugs: other . . . . .	2106
828. Genetic models of human neuropsychiatric disorders IV . . . . .	2109
829. Developmental disorders III . . . . .	2111
830. Epilepsy: kindling . . . . .	2113
831. Epilepsy: anticonvulsant drugs II . . . . .	2116
832. Trauma: treatment I . . . . .	2117
833. Trauma: treatment II . . . . .	2121
834. Infectious diseases: other . . . . .	2122
835. Mental illness—schizophrenia III . . . . .	2125
836. Neurotoxins IV . . . . .	2129
837. Neuro-oncology: tumor biology . . . . .	2133
838. Neuro-oncology: treatment . . . . .	2134
839. Acetylcholine: modulators . . . . .	2137
<b>100. History of neuroscience . . . . .</b>	<b>241</b>
<b>101. Teaching of neuroscience: curriculum development . . . . .</b>	<b>244</b>
<b>102. Teaching of neuroscience: computer programs and internet . . . . .</b>	<b>251</b>
<b>103. Teaching of neuroscience: laboratory courses and exercises . . . . .</b>	<b>253</b>

# THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions and symposia only.)

Session Number	Session Title	Type	Sun.	Day and Time Mon.	Tue.	Wed.	Thu.
<b>THEME A: DEVELOPMENT AND REGENERATION</b>							
614.	Aging processes: anatomy	Poster				Wed AM	
236.	Aging processes: calcium	Poster		Mon AM			
797.	Aging processes: molecular characteristics	Poster					Thu AM
237.	Aging processes: physiology	Poster		Mon AM			
132.	Assisted axonal regeneration	Poster	Sun PM				
123.	Axon guidance mechanisms and pathways I	Poster	Sun PM				
124.	Axon guidance mechanisms and pathways II	Poster	Sun PM				
222.	Axon guidance mechanisms and pathways III	Poster		Mon AM			
322.	Axon guidance mechanisms and pathways IV	Poster		Mon PM			
406.	Axon guidance mechanisms and pathways V	Slide			Tue AM		
513.	Axon guidance mechanisms and pathways VI	Poster			Tue PM		
594.	Axon guidance mechanisms and pathways VII	Slide				Wed AM	
506.	Axonal regeneration I	Slide			Tue PM		
612.	Axonal regeneration II	Poster				Wed AM	
707.	Axonal regeneration III	Poster				Wed PM	
21.	Cell differentiation and migration I	Poster	Sun AM				
318.	Cell differentiation and migration II	Poster		Mon PM			
319.	Cell differentiation and migration III	Poster		Mon PM			
414.	Cell differentiation and migration IV	Poster			Tue AM		
415.	Cell differentiation and migration V	Poster			Tue AM		
601.	Cell differentiation and migration VI	Poster				Wed AM	
602.	Cell differentiation and migration VII	Poster				Wed AM	
785.	Cell differentiation and migration VIII	Slide					Thu AM
220.	Cell lineage and determination I	Poster		Mon AM			
315.	Cell lineage and determination II	Slide		Mon PM			
511.	Cell lineage and determination III	Poster			Tue PM		
697.	Cell lineage and determination IV	Poster				Wed PM	
26.	Cerebral cortex and limbic system I	Poster	Sun AM				
129.	Cerebral cortex and limbic system II	Poster	Sun PM				
593.	Cerebral cortex and limbic system III	Slide				Wed AM	
794.	Cerebral cortex and limbic system IV	Poster					Thu AM
328.	Development of tectum and optic nerve	Poster		Mon PM			
509.	Development of visual system I	Slide			Tue PM		
591.	Development of visual system II	Slide				Wed AM	
517.	Development of visual thalamus	Poster			Tue PM		
681.	<b>Developmental Determinants of Retinal Ganglion Cells</b>	SYMP				Wed PM	
687.	Formation and specificity of synapses I	Slide				Wed PM	
701.	Formation and specificity of synapses II	Poster				Wed PM	
700.	Formation and specificity of synapses: agrin	Poster				Wed PM	
324.	Formation and specificity of synapses: cell-cell interactions	Poster		Mon PM			
323.	Formation and specificity of synapses: molecules of synapses	Poster		Mon PM			
493.	<b>GDNF: A New Neurotrophic Factor with Multiple Roles</b>	SYMP			Tue PM		
122.	Genesis of neurons and glia I	Poster	Sun PM				
317.	Genesis of neurons and glia II	Poster		Mon PM			
510.	Genesis of neurons and glia III	Poster			Tue PM		
595.	Genesis of neurons and glia IV	Slide				Wed AM	
600.	Genesis of neurons and glia V	Poster				Wed AM	

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
25.	Glia and other non-neuronal cells I . . . . .	Poster	Sun AM				
128.	Glia and other non-neuronal cells II . . . . .	Poster	Sun PM				
231.	Glia and other non-neuronal cells III . . . . .	Poster		Mon AM			
327.	Glia and other non-neuronal cells IV . . . . .	Poster		Mon PM			
425.	Glia and other non-neuronal cells V . . . . .	Poster			Tue AM		
24.	Hormones and development I . . . . .	Poster	Sun AM				
423.	Hormones and development II . . . . .	Poster			Tue AM		
791.	Hormones and development III . . . . .	Poster					Thu AM
426.	Molecular changes after lesions . . . . .	Poster			Tue AM		
705.	Motor systems . . . . .	Poster				Wed PM	
<b>203.</b>	<b>Neural Progenitor Cells and CNS Lineage</b>						
	<b>Development . . . . .</b>	<b>SYMP</b>		<b>Mon AM</b>			
7.	Neuronal death I . . . . .	Slide	Sun AM				
127.	Neuronal death II . . . . .	Poster	Sun PM				
230.	Neuronal death III . . . . .	Poster		Mon AM			
326.	Neuronal death IV . . . . .	Poster		Mon PM			
424.	Neuronal death V . . . . .	Poster			Tue AM		
516.	Neuronal death VI . . . . .	Poster			Tue PM		
610.	Neuronal death VII . . . . .	Poster				Wed AM	
704.	Neuronal death VIII . . . . .	Poster				Wed PM	
793.	Neuronal death IX . . . . .	Poster					Thu AM
223.	Neurotransmitter systems and channels I . . . . .	Poster		Mon AM			
514.	Neurotransmitter systems and channels II . . . . .	Poster			Tue PM		
702.	Neurotransmitter systems and channels III . . . . .	Poster				Wed PM	
119.	Neurotrophic factors: biologic effects I . . . . .	Slide	Sun PM				
224.	Neurotrophic factors: biologic effects II . . . . .	Poster		Mon AM			
225.	Neurotrophic factors: biologic effects III . . . . .	Poster		Mon AM			
226.	Neurotrophic factors: biologic effects IV . . . . .	Poster		Mon AM			
227.	Neurotrophic factors: biologic effects V . . . . .	Poster		Mon AM			
418.	Neurotrophic factors: biologic effects VI . . . . .	Poster			Tue AM		
419.	Neurotrophic factors: biologic effects VII . . . . .	Poster			Tue AM		
420.	Neurotrophic factors: biologic effects VIII . . . . .	Poster			Tue AM		
421.	Neurotrophic factors: biologic effects IX . . . . .	Poster			Tue AM		
605.	Neurotrophic factors: biologic effects X . . . . .	Poster				Wed AM	
606.	Neurotrophic factors: biologic effects XI . . . . .	Poster				Wed AM	
607.	Neurotrophic factors: biologic effects XII . . . . .	Poster				Wed AM	
608.	Neurotrophic factors: biologic effects XIII . . . . .	Poster				Wed AM	
22.	Neurotrophic factors: expression and regulation I . . . . .	Poster	Sun AM				
23.	Neurotrophic factors: expression and regulation II . . . . .	Poster	Sun AM				
125.	Neurotrophic factors: expression and regulation III . . . . .	Poster	Sun PM				
126.	Neurotrophic factors: expression and regulation IV . . . . .	Poster	Sun PM				
417.	Neurotrophic factors: expression and regulation V . . . . .	Poster			Tue AM		
604.	Neurotrophic factors: expression and regulation VI . . . . .	Poster				Wed AM	
790.	Neurotrophic factors: expression and regulation VII . . . . .	Poster					Thu AM
325.	Neurotrophic factors: receptors and cellular mechanisms I . . . . .	Poster		Mon PM			
422.	Neurotrophic factors: receptors and cellular mechanisms II . . . . .	Poster			Tue AM		
515.	Neurotrophic factors: receptors and cellular mechanisms III . . . . .	Poster			Tue PM		
609.	Neurotrophic factors: receptors and cellular mechanisms IV . . . . .	Poster				Wed AM	
780.	Neurotrophic factors: receptors and cellular mechanisms V . . . . .	Slide					Thu AM
703.	Neurotrophic factors: receptors and cellular mechanisms—miscellaneous . . . . .	Poster				Wed PM	
792.	Nutritional and prenatal factors . . . . .	Poster					Thu AM
130.	Optic nerve regeneration . . . . .	Poster	Sun PM				
228.	Other factors and trophic agents I . . . . .	Poster		Mon AM			

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
229.	Other factors and trophic agents II	Poster		Mon AM			
118.	Pattern formation, compartments and boundaries I	Slide	Sun PM				
416.	Pattern formation, compartments and boundaries III	Poster			Tue AM		
603.	Pattern formation, compartments and boundaries IV	Poster				Wed AM	
13.	Process outgrowth, growth cones, and sprouting I	Slide	Sun AM				
221.	Process outgrowth, growth cones, and sprouting II	Poster		Mon AM			
321.	Process outgrowth, growth cones, and sprouting III	Poster		Mon PM			
512.	Process outgrowth, growth cones, and sprouting IV	Poster			Tue PM		
698.	Process outgrowth, growth cones, and sprouting V	Poster				Wed PM	
699.	Process outgrowth, growth cones, and sprouting VI	Poster				Wed PM	
789.	Process outgrowth, growth cones, and sprouting VII	Poster					Thu AM
131.	Regeneration of nervous systems	Poster	Sun PM				
611.	Retinal development	Poster				Wed AM	
233.	Sensory systems: activity-dependent mechanisms of development	Poster		Mon AM			
232.	Sensory systems: central and peripheral responses to nerve injury	Poster		Mon AM			
235.	Sensory systems: olfactory, gustatory, and acoustico-vestibular development	Poster		Mon AM			
234.	Sensory systems: somatosensory development	Poster		Mon AM			
329.	Transplant-assisted axonal regeneration	Poster		Mon PM			
330.	Transplantation I	Poster		Mon PM			
691.	Transplantation II	Slide				Wed PM	
796.	Transplantation: dissociated cells	Poster					Thu AM
518.	Transplantation: evidence of function	Poster			Tue PM		
613.	Transplantation: growth factors	Poster				Wed AM	
133.	Transplantation: Parkinson's disease—related	Poster	Sun PM			Wed PM	
706.	Visual cortical development I	Poster				Wed PM	
795.	Visual cortical development II	Poster					Thu AM
<b>THEME B: CELL BIOLOGY</b>							
331.	Blood-brain barrier: function	Poster		Mon PM			
688.	Blood-brain barrier: other	Slide				Wed PM	
429.	Blood-brain barrier: pathology and disease	Poster			Tue AM		
27.	Cytoskeleton transport and membrane targeting: cytoskeletal proteins	Poster	Sun AM				
28.	Cytoskeleton transport and membrane targeting: organelles and proteins	Poster	Sun AM				
29.	Gene structure and function I	Poster	Sun AM				
332.	Gene structure and function II	Poster		Mon PM			
497.	Gene structure and function III	Slide			Tue PM		
521.	Gene structure and function IV	Poster			Tue PM		
710.	Gene structure and function V	Poster				Wed PM	
519.	Membrane composition and cell-surface macromolecules I	Poster			Tue PM		
520.	Membrane composition and cell-surface macromolecules II	Poster			Tue PM		
8.	Neuroglia and myelin I	Slide	Sun AM				
134.	Neuroglia and myelin II	Poster	Sun PM				
135.	Neuroglia and myelin III	Poster	Sun PM				
239.	Neuroglia and myelin IV	Poster		Mon AM			
428.	Neuroglia and myelin V	Poster			Tue AM		
238.	Staining, tracing, and imaging techniques I	Poster		Mon AM			
427.	Staining, tracing, and imaging techniques II	Poster			Tue AM		
708.	Staining, tracing, and imaging techniques III	Poster				Wed PM	

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
709.	Staining, tracing, and imaging techniques IV	Poster				Wed PM	
<b>THEME C: EXCITABLE MEMBRANES AND SYNAPTIC TRANSMISSION</b>							
508.	Calcium channel structure, function and expression I	Slide			Tue PM		
617.	Calcium channel structure, function and expression II	Poster				Wed AM	
618.	Calcium channel structure, function and expression III	Poster				Wed AM	
620.	Calcium channels: characterization and electrophysiology	Poster				Wed AM	
799.	Calcium channels: miscellaneous blockers	Poster					Thu AM
31.	Calcium channels: modulation by intracellular messengers	Poster	Sun AM				
141.	Calcium channels: modulation by non-peptide neurotransmitters	Poster	Sun PM				
140.	Calcium channels: modulation by peptide toxins	Poster	Sun PM				
619.	Calcium channels: modulation by peptides and hormones	Poster				Wed AM	
214.	Calcium channels: physiology, pharmacology and modulation I	Slide		Mon AM			
690.	Calcium channels: physiology, pharmacology and modulation II	Slide				Wed PM	
798.	Chloride and other channels	Poster					Thu AM
32.	Ion channels: cell function I	Poster	Sun AM				
33.	Ion channels: cell function II	Poster	Sun AM				
783.	Ion channels: cell function III	Slide					Thu AM
30.	Ligand-gated ion channels I	Poster	Sun AM				
498.	Ligand-gated ion channels II	Slide			Tue PM		
713.	Ligand-gated ion channels III	Poster				Wed PM	
111.	Long-term potentiation: pharmacology I	Slide	Sun PM				
522.	Long-term potentiation: pharmacology II	Poster			Tue PM		
523.	Long-term potentiation: pharmacology III	Poster			Tue PM		
245.	Long-term potentiation: physiology I	Poster		Mon AM			
246.	Long-term potentiation: physiology II	Poster		Mon AM			
433.	Long-term potentiation: physiology III	Poster			Tue AM		
434.	Long-term potentiation: physiology IV	Poster			Tue AM		
711.	Long-term potentiation: physiology V	Poster				Wed PM	
712.	Long-term potentiation: physiology VI	Poster				Wed PM	
788.	Long-term potentiation: physiology VII	Slide					Thu AM
680.	Molecular Organization of the Postsynaptic Membrane	SYMP				Wed PM	
777.	Opioidergic Modulation of Long-term Potentiation in the Hippocampus: Insights Peptidergic Regulation of Synaptic Plasticity	SYMP					Thu AM
333.	Pharmacology of synaptic transmission I	Poster		Mon PM			
615.	Pharmacology of synaptic transmission II	Poster				Wed AM	
616.	Pharmacology of synaptic transmission III	Poster				Wed AM	
240.	Postsynaptic mechanisms I	Poster		Mon AM			
241.	Postsynaptic mechanisms II	Poster		Mon AM			
242.	Postsynaptic mechanisms III	Poster		Mon AM			
243.	Postsynaptic mechanisms IV	Poster		Mon AM			
244.	Postsynaptic mechanisms V	Poster		Mon AM			
684.	Postsynaptic mechanisms VI	Slide				Wed PM	
209.	Potassium channel physiology, pharmacology and modulation I	Slide		Mon AM			
718.	Potassium channel physiology, pharmacology and modulation II	Poster				Wed PM	
719.	Potassium channel physiology, pharmacology and modulation III	Poster				Wed PM	

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
720.	Potassium channel physiology, pharmacology and modulation IV . . . . .	Poster	Sun PM				Wed PM
121.	Potassium channel structure, function and expression I . . . . .	Slide					
412.	Potassium channel structure, function and expression II . . . . .	Slide			Tue AM		
524.	Potassium channel structure, function and expression III . . . . .	Poster			Tue PM		
525.	Potassium channel structure, function and expression IV . . . . .	Poster			Tue PM		
18.	Presynaptic mechanisms I . . . . .	Slide	Sun AM				
136.	Presynaptic mechanisms II . . . . .	Poster	Sun PM				
137.	Presynaptic mechanisms III . . . . .	Poster	Sun PM				
138.	Presynaptic mechanisms IV . . . . .	Poster	Sun PM				
139.	Presynaptic mechanisms V . . . . .	Poster	Sun PM				
430.	Presynaptic mechanisms VI . . . . .	Poster			Tue AM		
431.	Presynaptic mechanisms VII . . . . .	Poster			Tue AM		
432.	Presynaptic mechanisms VIII . . . . .	Poster			Tue AM		
599.	Presynaptic mechanisms IX . . . . .	Slide				Wed AM	
714.	Sodium channels I . . . . .	Poster				Wed PM	
715.	Sodium channels II . . . . .	Poster				Wed PM	
716.	Sodium channels III . . . . .	Poster				Wed PM	
717.	Sodium channels IV . . . . .	Poster				Wed PM	
<b>THEME D: NEUROTRANSMITTERS, MODULATORS, TRANSPORTERS, AND RECEPTORS</b>							
34.	Acetylcholine . . . . .	Poster	Sun AM				
801.	Acetylcholine receptor muscarinic: agonist/antagonist for receptors . . . . .	Poster					Thu AM
800.	Acetylcholine receptor muscarinic: muscarinic receptors—molecular biology and electrophysiology . . . . .	Poster					Thu AM
802.	Acetylcholine receptor muscarinic: receptors—expression . . . . .	Poster					Thu AM
11.	Acetylcholine receptor: nicotinic I . . . . .	Slide	Sun AM				
621.	Acetylcholine receptor: nicotinic II . . . . .	Poster				Wed AM	
528.	Acetylcholine receptor: nicotinic expression . . . . .	Poster			Tue PM		
527.	Acetylcholine receptor: nicotinic expression and treatment effects . . . . .	Poster			Tue PM		
526.	Acetylcholine receptor: nicotinic—acetylcholine-effects of nicotine on specific brain regions . . . . .	Poster			Tue PM		
334.	Acetylcholine receptor: nicotinic—acetylcholine-genetics: molecular . . . . .	Poster		Mon PM			
247.	Acetylcholine receptor: nicotinic—acetylcholine-pharmacology and behavior . . . . .	Poster		Mon AM			
143.	Acetylcholine receptor: nicotinic—acetylcholine-regulation, distribution, and physiology . . . . .	Poster	Sun PM				
142.	Acetylcholine receptor: nicotinic—biophysics . . . . .	Poster	Sun PM				
721.	Acetylcholine receptor: nicotinic—pharmacology . . . . .	Poster				Wed PM	
36.	Acetylcholine receptor: nicotinic—structure/function . . . . .	Poster	Sun AM				
35.	Acetylcholine: distribution . . . . .	Poster	Sun AM				
839.	Acetylcholine: modulators . . . . .	Poster					Thu AM
544.	Behavioral pharmacology I . . . . .	Poster			Tue PM		
637.	Behavioral pharmacology II . . . . .	Poster				Wed AM	
305.	Behavioral pharmacology: psychostimulants . . . . .	Slide		Mon PM			
445.	Behavioral pharmacology: serotonin and dopamine . . . . .	Poster			Tue AM		
632.	Catecholamine receptors: alpha adrenergic . . . . .	Poster				Wed AM	
149.	Catecholamine receptors: antisense and knock outs . . . . .	Poster	Sun PM				
633.	Catecholamine receptors: beta adrenergic . . . . .	Poster				Wed AM	
441.	Catecholamine receptors: D <sub>1</sub> and D <sub>3</sub> pharmacology . . . . .	Poster			Tue AM		
252.	Catecholamine receptors: D <sub>2</sub> , D <sub>3</sub> , D <sub>4</sub> pharmacology . . . . .	Poster		Mon AM			

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
150.	Catecholamine receptors: distribution	Poster	Sun PM				
807.	Catecholamine receptors: genetics	Poster					Thu AM
340.	Catecholamine receptors: in vivo drug effects I	Poster		Mon PM			
341.	Catecholamine receptors: in vivo drug effects II	Poster		Mon PM			
253.	Catecholamine receptors: structure and function	Poster		Mon AM			
596.	Catecholamines	Slide				Wed AM	
446.	Catecholamines: biosynthetic enzymes	Poster			Tue AM		
448.	Catecholamines: electrophysiological studies	Poster			Tue AM		
43.	Catecholamines: gene structure and regulation	Poster	Sun AM				
447.	Catecholamines: microdialysis/voltammetric studies	Poster			Tue AM		
257.	Catecholamines: noradrenergic systems	Poster		Mon AM			
39.	Excitatory amino acid receptors I	Poster	Sun AM				
40.	Excitatory amino acid receptors II	Poster	Sun AM				
41.	Excitatory amino acid receptors III	Poster	Sun AM				
308.	Excitatory amino acid receptors IV	Slide		Mon PM			
335.	Excitatory amino acid receptors V	Poster		Mon PM			
336.	Excitatory amino acid receptors VI	Poster		Mon PM			
337.	Excitatory amino acid receptors VII	Poster		Mon PM			
338.	Excitatory amino acid receptors VIII	Poster		Mon PM			
437.	Excitatory amino acid receptors IX	Poster			Tue AM		
438.	Excitatory amino acid receptors X	Poster			Tue AM		
439.	Excitatory amino acid receptors XI	Poster			Tue AM		
623.	Excitatory amino acid receptors XII	Poster				Wed AM	
781.	Excitatory amino acid receptors XIII	Slide					Thu AM
722.	Excitatory amino acid receptors: receptor localization	Poster				Wed PM	
249.	Excitatory amino acids: anatomy and physiology I	Poster		Mon AM			
250.	Excitatory amino acids: anatomy and physiology II	Poster		Mon AM			
144.	Excitatory amino acids: anatomy and physiology—regional localization	Poster	Sun PM				
37.	Excitatory amino acids: excitotoxicity I	Poster	Sun AM				
38.	Excitatory amino acids: excitotoxicity II	Poster	Sun AM				
217.	Excitatory amino acids: excitotoxicity III	Slide		Mon AM			
248.	Excitatory amino acids: excitotoxicity IV	Poster		Mon AM			
409.	Excitatory amino acids: excitotoxicity V	Slide			Tue AM		
529.	Excitatory amino acids: excitotoxicity VI	Poster			Tue PM		
530.	Excitatory amino acids: excitotoxicity VII	Poster			Tue PM		
622.	Excitatory amino acids: excitotoxicity VIII	Poster				Wed AM	
803.	Excitatory amino acids: excitotoxicity IX	Poster					Thu AM
145.	Excitatory amino acids: pharmacology—drugs	Poster	Sun PM				
251.	Excitatory amino acids: pharmacology—mGluRs	Poster		Mon AM			
436.	Excitatory amino acids: pharmacology—NMDA	Poster			Tue AM		
499.	Excitatory amino acids: pharmacology—NMDA/AMPA receptors	Slide			Tue PM		
435.	Excitatory amino acids: pharmacology—secondary messenger	Poster			Tue AM		
146.	GABA receptors I	Poster	Sun PM				
339.	GABA receptors II	Poster		Mon PM			
531.	GABA receptors III	Poster			Tue PM		
624.	GABA receptors IV	Poster				Wed AM	
723.	GABA receptors V	Poster				Wed PM	
804.	GABA receptors VI	Poster					Thu AM
408.	GABA receptors: neuromodulators	Slide			Tue AM		
19.	GABA receptors: regulation and recombinant expression	Slide	Sun AM				
299.	Gap Junctions in the Normal and Pathologic Nervous System	SYMP		Mon PM			

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
152.	Interactions between neurotransmitters I	Poster	Sun PM				
153.	Interactions between neurotransmitters II	Poster	Sun PM				
541.	Interactions between neurotransmitters III	Poster			Tue PM		
542.	Interactions between neurotransmitters IV	Poster			Tue PM		
584.	<b>Ligand-Gated Ion Channel Superfamily Feud</b>	SYMP				Wed AM	
3.	<b>Molecular Biological Studies of the Newly Cloned Opioid Receptors</b>	SYMP	Sun AM				
805.	Neuropeptide localization: CNS regulation	Poster					Thu AM
147.	Neuropeptide localization: endocrine peptides	Poster	Sun PM				
440.	Neuropeptide localization: sensory peptides	Poster			Tue AM		
306.	Neurotransmitter characterization and degradation	Slide		Mon PM			
725.	Neurotransmitter processing	Poster				Wed PM	
626.	Neurotransmitter release	Poster				Wed AM	
219.	Opioid receptors I	Slide		Mon AM			
784.	Opioid receptors II	Slide					Thu AM
533.	Opioid receptors: cell biology and physiology	Poster			Tue PM		
534.	Opioid receptors: development and regulation	Poster			Tue PM		
535.	Opioid receptors: localization	Poster			Tue PM		
629.	Opioid receptors: molecular biology	Poster				Wed AM	
630.	Opioid receptors: pharmacology	Poster				Wed AM	
631.	Opioid receptors: sigma receptors	Poster				Wed AM	
148.	Opioids: anatomy, physiology and behavior I	Poster	Sun PM				
536.	Opioids: anatomy, physiology and behavior II	Poster			Tue PM		
726.	Opioids: anatomy, physiology and behavior III	Poster				Wed PM	
151.	Other neurotransmitters: adenosine	Poster	Sun PM				
634.	Other neurotransmitters: GABA, glycine, purine	Poster				Wed AM	
729.	Other neurotransmitters: histamine	Poster				Wed PM	
810.	Other neurotransmitters: miscellaneous	Poster					Thu AM
254.	Other neurotransmitters: nitric oxide	Poster		Mon AM			
402.	Peptide receptor structure and function I	Slide			Tue AM		
532.	Peptide receptor structure and function II	Poster			Tue PM		
625.	Peptide receptor structure and function III	Poster				Wed AM	
724.	Peptide receptor structure and function IV	Poster				Wed PM	
42.	Peptides: physiological effects I	Poster	Sun AM				
627.	Peptides: physiological effects II	Poster				Wed AM	
628.	Peptides: physiological effects III	Poster				Wed AM	
806.	Peptides: physiological effects IV	Poster					Thu AM
210.	Peptides: physiology and anatomy	Slide		Mon AM			
44.	Receptor modulation, up- and down-regulation I	Poster	Sun AM				
449.	Receptor modulation, up- and down-regulation II	Poster			Tue AM		
635.	Regional localization of receptors and transmitters I	Poster				Wed AM	
636.	Regional localization of receptors and transmitters II	Poster				Wed AM	
313.	Second messengers I	Slide		Mon PM			
345.	Second messengers II	Poster		Mon PM			
346.	Second messengers III	Poster		Mon PM			
732.	Second messengers IV	Poster				Wed PM	
813.	Second messengers V	Poster					Thu AM
444.	Second messengers: calcium	Poster			Tue AM		
731.	Second messengers: G-proteins	Poster				Wed PM	
812.	Second messengers: kinases	Poster					Thu AM
809.	Serotonin	Poster					Thu AM
113.	Serotonin receptors I	Slide	Sun PM				
312.	Serotonin receptors II	Slide		Mon PM			
727.	Serotonin receptors: 5-HT <sub>1</sub>	Poster				Wed PM	
443.	Serotonin receptors: 5-HT <sub>2</sub>	Poster			Tue AM		
808.	Serotonin receptors: 5-HT <sub>3</sub>	Poster					Thu AM

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
728.	Serotonin receptors: 5-HT <sub>4</sub> , 5-HT <sub>7</sub> , 5-HT <sub>6</sub> , 5-HT <sub>2</sub> , . . . . .	Poster	Sun PM	Mon PM Mon PM Mon AM Mon AM Mon PM Mon PM	Tue PM Tue PM Tue PM Tue AM Tue PM Tue PM Tue PM Tue AM Tue PM Tue PM Tue PM Tue AM Tue		

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
733.	Neuroendocrine regulation: other II . . . . .	Poster				Wed PM	
782.	Neuroendocrine regulation: other III . . . . .	Slide					Thu AM
351.	Neuroendocrine regulation: thyroid and gonadal axes . . . . .	Poster		Mon PM			
450.	Neuroendocrine regulation: vasopressin and oxytocin . . . . .	Poster			Tue AM		
348.	Osmoregulation: magnocellular endocrine neurons . . . . .	Poster		Mon PM			
349.	Osmoregulation: mechanisms . . . . .	Poster		Mon PM			
736.	Respiratory regulation: amino acid transmitters . . . . .	Poster				Wed PM	
737.	Respiratory regulation: brainstem and spinal cord . . . . .	Poster				Wed PM	
738.	Respiratory regulation: central chemoreception . . . . .	Poster				Wed PM	
740.	Respiratory regulation: developmental mechanisms . . . . .	Poster				Wed PM	
741.	Respiratory regulation: reflex mechanisms and pathways . . . . .	Poster				Wed PM	
739.	Respiratory regulation: signal transduction in the carotid body . . . . .	Poster				Wed PM	
492.	<b>Sensory Circumventricular Organs (CVOs): Body-Brain Coupling and Mechanisms of Afferent Signaling . . . . .</b>	SYMP			Tue PM		
350.	Thermoregulation and fever . . . . .	Poster		Mon PM			
734.	Urogenital regulation: bladder and micturition . . . . .	Poster				Wed PM	
735.	Urogenital regulation: sexual function . . . . .	Poster				Wed PM	
<b>THEME F: SENSORY SYSTEMS</b>							
166.	Auditory systems: central anatomy I . . . . .	Poster	Sun PM				
271.	Auditory systems: central anatomy II . . . . .	Poster		Mon AM			
361.	Auditory systems: central anatomy III . . . . .	Poster		Mon PM			
56.	Auditory systems: central physiology I . . . . .	Poster	Sun AM				
165.	Auditory systems: central physiology II . . . . .	Poster	Sun PM				
269.	Auditory systems: central physiology III . . . . .	Poster		Mon AM			
270.	Auditory systems: central physiology IV . . . . .	Poster		Mon AM			
461.	Auditory systems: central physiology V . . . . .	Poster			Tue AM		
462.	Auditory systems: central physiology VI . . . . .	Poster			Tue AM		
164.	Auditory, vestibular, and lateral line: periphery . . . . .	Poster	Sun PM				
4.	<b>Cellular and Molecular Mechanisms of Integration in Mammalian Retina . . . . .</b>	SYMP	Sun AM				
686.	Chemical senses . . . . .	Slide				Wed PM	
647.	Damaged retinas . . . . .	Poster				Wed AM	
651.	Gustatory senses . . . . .	Poster				Wed AM	
505.	Invertebrate sensory and motor . . . . .	Slide			Tue PM		
167.	Invertebrate sensory systems I . . . . .	Poster	Sun PM				
168.	Invertebrate sensory systems II . . . . .	Poster	Sun PM				
463.	Olfactory senses: accessory olfactory system . . . . .	Poster			Tue AM		
58.	Olfactory senses: invertebrates . . . . .	Poster	Sun AM				
464.	Olfactory senses: olfactory bulb . . . . .	Poster			Tue AM		
465.	Olfactory senses: olfactory cortex . . . . .	Poster			Tue AM		
57.	Olfactory senses: olfactory receptor cells . . . . .	Poster	Sun AM				
160.	Pain modulation: anatomy and physiology—behavior . . . . .	Poster	Sun PM				
644.	Pain modulation: anatomy and physiology—brainstem . . . . .	Poster				Wed AM	
261.	Pain modulation: anatomy and physiology—higher centers . . . . .	Poster		Mon AM			
643.	Pain modulation: anatomy and physiology—human studies . . . . .	Poster				Wed AM	
356.	Pain modulation: anatomy and physiology—neuropathic pain . . . . .	Poster		Mon PM			
159.	Pain modulation: anatomy and physiology—periaqueductal gray . . . . .	Poster	Sun PM				
262.	Pain modulation: anatomy and physiology—receptor and nerve . . . . .	Poster		Mon AM			

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
158.	Pain modulation: anatomy and physiology—spinal cord I . . . . .	Poster	Sun PM				
552.	Pain modulation: anatomy and physiology—spinal cord II . . . . .	Poster			Tue PM		
459.	Pain modulation: pharmacology—allodynia . . . . .	Poster			Tue AM		
263.	Pain modulation: pharmacology—amino acids, adenosine, cannabinoids . . . . .	Poster		Mon AM			
553.	Pain modulation: pharmacology—anesthetics . . . . .	Poster			Tue PM		
357.	Pain modulation: pharmacology—inflammation and prostaglandins . . . . .	Poster		Mon PM			
554.	Pain modulation: pharmacology—neuropeptides . . . . .	Poster			Tue PM		
645.	Pain modulation: pharmacology—NMDA and NO . . . . .	Poster				Wed AM	
457.	Pain modulation: pharmacology—opioids I . . . . .	Poster			Tue AM		
458.	Pain modulation: pharmacology—opioids II . . . . .	Poster			Tue AM		
555.	Pain modulation: pharmacology—serotonin, histamine, catecholamines . . . . .	Poster			Tue PM		
355.	Pain pathways: gene expression . . . . .	Poster		Mon PM			
642.	Pain pathways: human studies . . . . .	Poster				Wed AM	
260.	Pain pathways: peripheral nerves and spinal cord . . . . .	Poster		Mon AM			
456.	Pain pathways: supraspinal centers . . . . .	Poster			Tue AM		
694.	Pain: pathways and modulation . . . . .	Slide				Wed PM	
<b>104.</b>	<b>Patterns of Activity Shaped by Local Circuitry in Mammalian Visual Cortex . . . . .</b>	<b>SYMP</b>	<b>Sun PM</b>				
460.	Photoreceptors and RPE . . . . .	Poster			Tue AM		
211.	Retina I . . . . .	Slide		Mon AM			
413.	Retina II . . . . .	Slide			Tue AM		
556.	Retina III . . . . .	Poster			Tue PM		
646.	Retinal function . . . . .	Poster				Wed AM	
161.	Retinal subcellular mechanisms I . . . . .	Poster	Sun PM				
358.	Retinal subcellular mechanisms II . . . . .	Poster		Mon PM			
155.	Sensory systems: spinal cord I . . . . .	Poster	Sun PM				
156.	Sensory systems: spinal cord II . . . . .	Poster	Sun PM				
157.	Sensory systems: spinal cord III . . . . .	Poster	Sun PM				
455.	Somatic and visceral afferents: mechanoreceptors . . . . .	Poster			Tue AM		
454.	Somatic and visceral afferents: nociceptors . . . . .	Poster			Tue AM		
453.	Somatic and visceral afferents: visceral afferents . . . . .	Poster			Tue AM		
50.	Somatosensory cortex and thalamocortical relationships I . . . . .	Poster	Sun AM				
51.	Somatosensory cortex and thalamocortical relationships II . . . . .	Poster	Sun AM				
52.	Somatosensory cortex and thalamocortical relationships III . . . . .	Poster	Sun AM				
404.	Somatosensory cortex and thalamocortical relationships IV . . . . .	Slide			Tue AM		
692.	Somatosensory cortex and thalamocortical relationships V . . . . .	Slide				Wed PM	
53.	Somatosensory cortex and thalamocortical relationships: barrels I . . . . .	Poster	Sun AM				
54.	Somatosensory cortex and thalamocortical relationships: barrels II . . . . .	Poster	Sun AM				
47.	Subcortical somatosensory pathways I . . . . .	Poster	Sun AM				
48.	Subcortical somatosensory pathways II . . . . .	Poster	Sun AM				
49.	Subcortical somatosensory pathways III . . . . .	Poster	Sun AM				
12.	Subcortical visual pathways I . . . . .	Slide	Sun AM				
264.	Subcortical visual pathways II . . . . .	Poster		Mon AM			
265.	Subcortical visual pathways III . . . . .	Poster		Mon AM			
266.	Subcortical visual pathways IV . . . . .	Poster		Mon AM			
693.	Visual cortex: extrastriate—attention . . . . .	Slide				Wed PM	
120.	Visual cortex: extrastriate—dorsal stream I . . . . .	Slide	Sun PM				
268.	Visual cortex: extrastriate—dorsal stream II . . . . .	Poster		Mon AM			

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
359.	Visual cortex: extrastriate—functional organization I . . . . .	Poster		Mon PM			
360.	Visual cortex: extrastriate—functional organization II . . . . .	Poster		Mon PM			
504.	Visual cortex: extrastriate—functional organization III . . . . .	Slide			Tue PM		
15.	Visual cortex: extrastriate—ventral stream I . . . . .	Slide	Sun AM				
267.	Visual cortex: extrastriate—ventral stream II . . . . .	Poster		Mon AM			
17.	Visual cortex: striate I . . . . .	Slide	Sun AM				
162.	Visual cortex: striate II . . . . .	Poster	Sun PM				
163.	Visual cortex: striate III . . . . .	Poster	Sun PM				
311.	Visual cortex: striate IV . . . . .	Slide		Mon PM			
592.	Visual cortex: striate V . . . . .	Slide				Wed AM	
648.	Visual cortex: striate VI . . . . .	Poster				Wed AM	
649.	Visual cortex: striate VII . . . . .	Poster				Wed AM	
650.	Visual cortex: striate VIII . . . . .	Poster				Wed AM	
689.	Visual cortex: striate IX . . . . .	Slide				Wed PM	
55.	Visual psychophysics and behavior I . . . . .	Poster	Sun AM				
212.	Visual psychophysics and behavior II . . . . .	Slide		Mon AM			
<b>THEME G: MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION</b>							
750.	Basal ganglia: anatomy . . . . .	Poster				Wed PM	
817.	Basal ganglia: behavior . . . . .	Poster					Thu AM
749.	Basal ganglia: drugs of abuse . . . . .	Poster				Wed PM	
560.	Basal ganglia: movement disorders and experimental models . . . . .	Poster			Tue PM		
170.	Basal ganglia: neuron activity during behavior . . . . .	Poster	Sun PM				
653.	Basal ganglia: nigra and related systems . . . . .	Poster				Wed AM	
362.	Basal ganglia: physiology . . . . .	Poster		Mon PM			
272.	Basal ganglia: primate anatomy . . . . .	Poster		Mon AM			
559.	Basal ganglia: striatal anatomy . . . . .	Poster			Tue PM		
748.	Basal ganglia: striatal systems . . . . .	Poster				Wed PM	
466.	Basal ganglia: thalamus . . . . .	Poster			Tue AM		
652.	Basal ganglia: ventral striatal/ventral pallidal systems . . . . .	Poster				Wed AM	
115.	Cerebellum . . . . .	Slide	Sun PM				
467.	Cerebellum: anatomy and pharmacology . . . . .	Poster			Tue AM		
363.	Cerebellum: behavior, development, models . . . . .	Poster		Mon PM			
364.	Cerebellum: clinical studies . . . . .	Poster		Mon PM			
818.	Cerebellum: genetic models . . . . .	Poster					Thu AM
751.	Cerebellum: physiology . . . . .	Poster				Wed PM	
696.	Circuitry and pattern generation . . . . .	Slide				Wed PM	
64.	Circuitry and pattern generation: models and methods . . . . .	Poster	Sun AM				
66.	Circuitry and pattern generation: modulation of CPG . . . . .	Poster	Sun AM				
65.	Circuitry and pattern generation: simple systems . . . . .	Poster	Sun AM				
277.	Circuitry and pattern generation: spinal cord . . . . .	Poster		Mon AM			
819.	Control of posture and movement: human locomotion . . . . .	Poster					Thu AM
172.	Control of posture and movement: injury and disease . . . . .	Poster	Sun PM				
173.	Control of posture and movement: locomotion . . . . .	Poster	Sun PM				
274.	Control of posture and movement: modelling . . . . .	Poster		Mon AM			
114.	Control of posture and movement: motor control I . . . . .	Slide	Sun PM				
276.	Control of posture and movement: motor control II . . . . .	Poster		Mon AM			
562.	Control of posture and movement: motor units and reflexes . . . . .	Poster			Tue PM		
275.	Control of posture and movement: posture I . . . . .	Poster		Mon AM			
472.	Control of posture and movement: posture II . . . . .	Poster			Tue AM		
755.	Control of posture and movement: prehension . . . . .	Poster				Wed PM	
174.	Control of posture and movement: reaching I . . . . .	Poster	Sun PM				

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
756.	Control of posture and movement: reaching II . . . . .	Poster	Sun PM Sun PM	Mon AM	Tue PM Tue PM	Wed PM	Thu AM Thu AM
175.	Invertebrate motor functions . . . . .	Poster					
169.	Motor cortex: anatomy . . . . .	Poster					
815.	Motor cortex: behavioral physiology, models I . . . . .	Poster					
816.	Motor cortex: behavioral physiology, models II . . . . .	Poster					
746.	Motor cortex: functional organization and plasticity I . . . . .	Poster				Wed PM	
747.	Motor cortex: functional organization and plasticity II . . . . .	Poster				Wed PM	
557.	Motor cortex: human studies I . . . . .	Poster					
558.	Motor cortex: human studies II . . . . .	Poster					
215.	Motor systems: cortex . . . . .	Slide					
563.	Muscle: biomechanics . . . . .	Poster	Sun AM	Mon PM	Tue AM Tue AM	Wed AM	
654.	Muscle: cellular and molecular physiology . . . . .	Poster					
300.	<b>New Vistas in the Control of Arm Movement</b>						
	<b>Trajectories . . . . .</b>	SYMP					
753.	Oculomotor system: brainstem and pretectum . . . . .	Poster				Wed PM	
367.	Oculomotor system: clinical studies . . . . .	Poster					
470.	Oculomotor system: head movements and Listing's Law . . . . .	Poster					
754.	Oculomotor system: near response, blink, and muscle . . . . .	Poster				Wed PM	
502.	Oculomotor system: saccades . . . . .	Slide					
366.	Oculomotor system: saccades—behavior and imaging . . . . .	Poster					
469.	Oculomotor system: saccades—cortex . . . . .	Poster	Sun AM	Mon AM Mon PM	Tue PM	Wed PM	
468.	Oculomotor system: saccades—superior colliculus . . . . .	Poster					
61.	Oculomotor system: smooth movements . . . . .	Poster					
216.	Oculomotor system: smooth pursuit and vestibuloocular reflex . . . . .	Slide					
561.	Reflex function: animal studies . . . . .	Poster					
273.	Reflex function: human studies . . . . .	Poster					
369.	Spinal cord and brainstem: anatomy . . . . .	Poster

## 327.3

A STUDY OF OPTIMAL CONDITIONS FOR HUMAN SCHWANN CELL HARVEST AND GROWTH IN VITRO. G.T.B. Casella, N. Kleitman\*, R.P. Bunge and P.M. Wood. The Miami Project to Cure Paralysis, University of Miami School of Medicine, Miami, FL 33136.

The construction of cellular prostheses containing Schwann cells (SC) has been proposed as a future therapeutic approach in the repair of injury to neural tissue. To establish optimal conditions for SC harvest and growth, human SC were isolated from explanted adult (20-26 years old) peripheral nerve fragments after various time *in vitro*. The growth of SC in the presence of double (forskolin and heregulin) or triple (forskolin, cholera toxin and heregulin) mitogens in serum containing medium was compared at different concentrations of heregulin, and on different substrates (plastic, polylysine, collagen, fibronectin and laminin). Maximal cell yield was obtained by dissociating explants after a 2 week period *in vitro* ( $12.05 \pm 2.43 \times 10^4$  cells/mg fresh weight of nerve, 2 donors). Maximal growth was observed on collagen substrata in double mitogen ( $2 \mu\text{M}$  forskolin and  $10.0 \text{ nM}$  heregulin). These conditions maintained the purity of the SC at  $95.3 \pm 3.2\%$ . These results differ from previously reported results which described maximum cell proliferation with the triple mitogen mixture and indicate that cholera toxin is not required for maximal SC proliferation. Initially labelling indices following a 24 hour exposure to tritiated thymidine were  $44.5 \pm 2.1\%$ . This high rate of SC proliferation was not maintained and SC did not increase in number after 6-8 doublings. A total increase of 50-70 fold was observed. Thus a substantial expansion of adult derived human SC can be obtained for use in promoting repair of neural tissues. (This research is supported by NIH grants NS09923 and NS28059, the Hollfelder Foundation, and The Miami Project to Cure Paralysis. Heregulin was generously provided by Genentech, and the human nerves by the University of Miami transplant team.)

## 327.5

INTRACRANIAL GRAFTS OF GLIOMA CELL LINES EXPRESS THE CNS SPECIFIC HA-BINDING PROTEIN, BEHAB. D.M. Jaworski\*, G.M. Kelly, J.M. Piepmeyer#, and S. Hockfield. Section of Neurobiology and #Department of Neurosurgery, Yale Univ. School of Medicine, New Haven CT 06510.

Glial cells contribute to the microenvironment of the CNS. They express a number of extracellular matrix molecules, including hyaluronan (HA) and the HA receptor CD44. HA can organize water and create hydrated spaces, and thereby foster cell migration. HA levels are highest in the embryo during the period of rapid cell proliferation and migration. Postnatally, HA levels decline. Tumor invasion is accompanied by the synthesis and deposition of a pathologic matrix that contains high levels of HA and resembles the embryonic matrix. The increase in HA in tumorigenesis has led to the suggestion that HA may play a role in tumor invasion.

Previously, we reported that the expression of the CNS specific HA-binding protein, BEHAB, is dramatically increased in glioma compared to normal brain (Soc. Neurosci. 20:475). However, tumor-associated BEHAB expression is not maintained *in vitro*. No BEHAB was detected in seventeen glioma cell lines maintained under standard culture conditions. To determine whether BEHAB expression requires intercellular signals present in the intact brain, but missing in culture, the rat glioma cell lines C6 and 9L were grown as subcutaneous or intracranial grafts. Neither the C6 nor the 9L cell line expresses BEHAB when grown in culture or when grafted subcutaneously. When grafted into the brain parenchyma, the 9L cells do not express BEHAB; however, the intracranial grafts of C6 cells do express BEHAB. This difference in BEHAB expression correlates with differences in tumor growth characteristics: 9L tumors grow as circumscribed masses, while C6 tumors display invasive potential. These results show that the cellular environment can influence the molecular phenotype of a brain tumor cell line. They further suggest that BEHAB may be an important element in tumor invasion. Supported by EYO6511(SH) and EYO6451(DJ).

## 327.7

# TARGETED EXPRESSION OF INTERFERON- $\gamma$ TO THE CNS OF TRANSGENIC MICE

Corbin, J.G.<sup>1\*</sup>, Kelly, D.<sup>2</sup>, Rath, E.M.<sup>1</sup>, Suzuki, K.<sup>1,2,3</sup>, and Popko, B.<sup>1,2</sup> Curriculum in Neurobiology<sup>1</sup> and Brain and Development Research Center<sup>2</sup>, and Department of Pathology<sup>3</sup>, UNC-Chapel Hill, NC, 27599-7250.

Much circumstantial evidence has implicated the immune cytokine interferon-gamma (IFN- $\gamma$ ) as a key mediator in the pathological changes that are observed in many demyelinating disorders, including the most common human demyelinating disease, multiple sclerosis (MS). Previous *in vitro* experiments in our laboratory have shown that application of IFN- $\gamma$  to the MOCH-1 oligodendrocyte cell line results in dramatic molecular and morphological changes that may reflect the *in vivo* response of oligodendrocytes to perturbations that occur in demyelinating disorders. To produce an animal model with which to study the effects of IFN- $\gamma$  on the central nervous system, we have generated transgenic mice in which the expression of IFN- $\gamma$  has been placed under the transcriptional control of the myelin basic protein (MBP) gene. Transgenic mice generated with this construct have a shaking/shivering phenotype that is similar to that observed in known animal models of hypomyelination (e.g. *shiverer*, *jimpy*, *quaking*). Moreover, histological and immunohistochemical analyses have revealed that the CNS of these animals have dramatically less myelin than that which is present in non-transgenic control animals. Reactive gliosis as well as a large induction of MHC class I and class II mRNA in the CNS of MBP/IFN- $\gamma$  transgenic mice was also observed. Additionally, development of the internal granule cell layer of the cerebellum was disrupted. These results strongly support the hypothesis that IFN- $\gamma$  is a key mediator in immune-mediated demyelinating disorders and suggest that the MBP/IFN- $\gamma$  transgenic mice will serve as a good model with which to further explore the effects of this cytokine in CNS disorders.

## 327.4

POSTTRANSCRIPTIONAL REGULATION OF IGFBP-5 BY IGF-I IN CULTURED SCHWANN CELLS. H.-L. Cheng\* and E.L. Feldman. Department of Neurology, University of Michigan, Ann Arbor, MI 48109.

The insulin-like growth factors (IGFs) are trophic factors whose growth-promoting actions are mediated via the IGF-I receptor and modulated, in part, by six structurally related proteins, the IGF binding proteins (IGFBPs).

In the current study, we determined the profile of IGFBP gene and protein expression in transfected MT4H1 rat Schwann cells (SC). These cells resemble untransfected secondary SC in morphology, and the expression of P0 and glial fibrillary acidic protein. We speculated that SC secrete IGFBPs which modulate IGF actions for SC growth. In the current study, IGF-I promoted SC growth and DNA synthesis in a dose-dependent manner. IGF-I treatment of SC increased the intensity of IGFBP-5 expression in SC conditioned media measured by Western immunoblotting. Des(1,3)IGF-I, an IGF-I analog with low affinity for IGFBP-5 but normal affinity for the IGF-I receptor, had no such effect, suggesting direct extracellular interaction between IGF-I and IGFBP-5 is essential for IGF-I regulation of IGFBP-5. Additionally, IGF-I treatment had no effect on IGFBP-5 gene expression as measured by Northern blotting and quantitative autoradiography. These observations suggested that IGF-I could protect IGFBP-5 from protease degradation. To test this concept, recombinant human IGFBP-5 was incubated in SC conditioned media at  $37^\circ\text{C}$  in the presence or absence of IGF-I. In the presence of IGF-I, IGFBP-5 remained intact at 34 kDa; however, in the absence of IGF-I, IGFBP-5 was degraded into 23-kDa fragments. Collectively, these data support a role for IGF-I in SC growth and imply that IGF-I treatment protects secreted IGFBP-5 from proteolytic degradation. This protection, in turn, could allow secreted IGFBP-5 to target IGF-I to SC and enhance IGF-I's biological effects. This work was supported by R29 NS32843.

## 327.6

SEROTONIN RECEPTORS ON SCHWANN CELLS IN RAT SCIATIC NERVE. E. Yoder\*<sup>†</sup>, H. Tamir<sup>‡</sup>, and M. H. Ellisman\*<sup>§</sup>. <sup>†</sup>San Diego Microscopy and Imaging Resource, Department of Neurosciences, UCSD School of Medicine, La Jolla CA 92093 and <sup>‡</sup>Division of Neurosciences, New York State Psychiatric Institute, New York NY 10032.

We previously reported that Schwann cells cultured from rat sciatic nerve express 5-HT<sub>2A</sub> receptors (Yoder *et al.*, *NS Abstract* 299.5, 1994; Yoder *et al.*, *NS Abstract* 460.18, 1993). In order to determine if these observations *in vitro* reflect the characteristics of Schwann cells *in situ*, we examined healthy and injured sciatic nerves using immunohistochemistry with an anti-idiotypic antibody that recognizes 5-HT receptors. Nerves were also labeled with  $\alpha$ -S100 $\beta$ , a Schwann cell marker. Nerves from the operated and contralateral legs of adult rats were removed at 1, 2, 3, and 5 weeks following nerve crush (regenerating nerves) and 2, 3, and 5 weeks following nerve transection (degenerating nerves). Nerves from nonsurgical animals were also examined.

In a preliminary study, S100 $\beta$  labeling was observed in Schwann cells on all nerves examined. 5-HT receptor labeling was also observed on Schwann cells in injured nerves, both degenerating and regenerating. Additionally, weaker 5-HT receptor staining was often seen on Schwann cells in sciatic nerves from unoperated contralateral control legs. However, 5-HT receptor labeling was not observed on Schwann cells in sciatic nerves from nonsurgical animals. Thus, the 5-HT receptors expressed by cultured Schwann cells seem to correlate with Schwann cells *in vivo*, especially those responding to nerve injury. These results suggest that Schwann cells may be a target of 5-HT released from endoneurial mast cells responding to nerve injury. The function of 5-HT receptors on Schwann cells remains to be determined.

# THE PERIPHERAL NERVE AS A TARGET FOR GENE THERAPY

E. D. Rabinovsky\*, C. Papakonstantinou, T. Nichols, M. Katash, and S. Shenaq Div. Plastic Surgery, Baylor College of Medicine, Houston Tx, 77030

Injury to the peripheral nerve elicits a complex interaction of neurotrophic factors, leading to nerve regeneration. If neurotrophic genes responsible for neuronal survival and neurite growth can be transferred to Schwann cells, it may be possible to enhance peripheral nerve regeneration. Adenoviruses can efficiently transfer genes to dividing and non-dividing cells which makes this vector useful to transfer DNA to Schwann cells. In this study we test the ability of adenovirus to infect Schwann cells in normal and injured sciatic nerve using a replicative-defective adenovirus encoding the lacZ gene. Adenovirus ( $10^8$ - $2 \times 10^9$  pfu's) was injected into sciatic nerve of female Sprague-Dawley female rats (N=40). Sciatic nerve was harvested 1-30 days after injection, cyro-sectioned and stained for beta-galactosidase (b-gal) by histochemical staining and immunofluorescence. Adenovirus ( $1 \times 10^8$  pfu's) is able to infect Schwann cells, as shown by double-labelled immunofluorescence using polyclonal antibody to b-gal and monoclonal antibody to S-100. In uncrushed nerve, Schwann cell staining was observed between 2 and 14 days after injection, with the highest levels seen after 7 days. The number of infected cells was increased after nerve injury. Adenovirus ( $1 \times 10^8$  pfu's) was injected 3 days after a sciatic nerve crush. The time of expression increased to 3 weeks, and the number of infected cells increased at each time point, as compared to infected normal nerve. Viral toxicity was evaluated by immunohistochemical analysis for cytotoxic T-cells (CTL), quantifying the number of myelinated axons, and muscle weights. At  $1 \times 10^8$  pfu's no viral toxicity was observed. At  $2 \times 10^9$  pfu's, infiltrating CTL's were observed after 7 days. The size and number of axons and muscle weight was also reduced. These results show that adenovirus transfer genes to Schwann cells of normal and injured nerve. Using this technique, it may be possible to enhance peripheral nerve regeneration by local overexpression of neurotrophic genes.

Transgenic mice expressing HSV-thymidine kinase under the control of the mouse GFAP promoter: for the targeted ablation of astrocytes.

Toby G. Bush<sup>1</sup>, Martin H. Johnson<sup>1</sup>, Lennart Mucke<sup>2</sup> and Michael V. Sofroniew<sup>1\*</sup>.

<sup>1</sup>MRC Cambridge Centre for Brain Repair and Department of Anatomy, University of Cambridge, Forvie Site, Robinson Way, Cambridge CB2 2PY, UK and <sup>2</sup>The Scripps Research Institute, 10666 North Torrey Pines Road, La Jolla, CA 92037.

To investigate the role of astrocytes in a variety of processes it would be useful to have a means of their selective ablation. Towards this end, three lines of transgenic mice have been generated that have the herpes simplex virus thymidine kinase (HSV-TK) under the control of the mouse glial fibrillary acidic protein (GFAP) promoter. HSV-TK is necessary to metabolise the benign substrate ganciclovir (GCV) to a toxic product inducing autonomous cell death.

Preliminary evidence suggests that in response to manipulations that upregulate GFAP expression in vivo, at least one transgenic line shows upregulation of HSV-TK immunoreactivity. The efficacy of astrocyte ablation after addition of GCV is under investigation both in vitro and in vivo.

Supported by the Wellcome Trust and the MRC.

## 327.11

CHANGES IN GAP JUNCTION EXPRESSION AFTER PERIPHERAL NERVE INJURY. K.J. Chandross<sup>1</sup>, R. Dermietzel<sup>2</sup>, E. Simburger<sup>2</sup>, D.C. Spray<sup>1</sup>, J.A. Kessler<sup>1</sup>. <sup>1</sup>Dept. Neuroscience, Albert Einstein Coll. Med., Bronx, NY and <sup>2</sup>Dept. Anatomy, Univ. Regensburg, Regensburg, Germany.

Following peripheral nerve injury the nonneuronal cellular components of the nerve undergo programs of phenotypic and functional changes in the distal region. Schwann cells dedifferentiate and divide within their original endoneurial tubes surrounding the degenerating axons. Macrophages and fibroblasts respond to injury by altering their phenotype and proliferating. We used molecular and immunocytochemical techniques to examine changes in connexin (Cx) expression that occur after peripheral nerve injury. In normal rat nerve, Cx32 was localized to Schwann cell nodes of Ranvier and Schmidt-Lantermann incisures (previously reported by Bergoffen et al., Science, 262:2039, 1993), and Cx43 was localized to perineurial cells. After crush injury, Cx32 mRNA and protein rapidly decreased within 24 hr, at and distal to the injury site, and returned to control levels after 20 d. In contrast, Cx43 expression dramatically increased in endoneurial fibroblasts in the crush and distal region by 3 d, coincident with macrophage infiltration, and decreased to control levels by 12 d. Schwann cells distal to the crush site are coupled as evidenced by intercellular exchange of Lucifer Yellow and calcium. Since the distal Schwann cells do not express either Cx32 or Cx43, this suggests that they express a different Cx after nerve injury. Molecular and immunocytochemical analyses of the injured region suggest that Schwann cells express a Group II Cx, possibly Cx46. Thus, injury responses in peripheral nerve include spatiotemporal patterns of Cx expression in nonneuronal cells that may coordinate degeneration and facilitate recovery of function.

## 327.13

WIDE-SPACED MYELIN FORMATION IN SITU IN THE PRESENCE OF IGM-PRODUCING HYBRIDOMAS. J. Rosenbluth<sup>\*</sup>, W.L. Liang, Z. Liu, D. Guo and R. Schiff. Dep't. of Physiology & Neuroscience and Institute of Rehabilitation Medicine, N.Y.U. School of Medicine, New York, NY 10016.

Implantation of the O1 hybridoma, which produces an IgM antigalactocerebroside, into rat spinal cord before or during myelin formation, results in some myelination but also in the development of abnormal myelin in which most lamellae are separated by wide gaps, resulting in spacings of ~10nm (0 gap), ~19nm (~9nm gap) and ~32nm (~22nm gap). The gaps contain dense structures compatible with IgM molecules in single or multiple rows. The number of lamellae is often smaller than normal in wide-spaced sheaths, and the radial component is absent, as are tight junctions between adjacent paranodal loops, thus opening shunt pathways for nodal action currents that could compromise conduction. The paranodal axoglial junction does form, however. We conclude that abnormal CNS myelin is able to develop in the presence of the O1 antibody, even without direct contact between lamellae. Intercalated, multivalent IgM molecules may serve to anchor lamellae together, substituting for myelin constituents too widely separated to interact. Wide-spaced myelin also occurs after implantation of O4 or A2B5 hybridomas at comparable ages and has been reported in CNS myelin exposed to MS or EAE sera. Supp. by NIH and NMSS.

IMMUNOHISTOCHEMICAL STUDIES OF THE GLIAL RESPONSE TO PYRITHIAMINE-INDUCED THIAMINE DEFICIENCY IN THE RAT USING GFAP AND ED1 ANTIBODIES. D.K. Leong<sup>\*</sup>, L. Oliva, R.E. Butterworth. Neuroscience Research Unit, Hôpital St-Luc, University of Montreal, Montreal, Quebec, Canada, H2X 3J4.

Thiamine deficiency results in the Wernicke-Korsakoff Syndrome (WKS), which is characterized by symmetrical lesions in the diencephalon and brainstem. Experimental WKS can be produced in rats by the combined administration of pyriethamine and a thiamine deficient diet. In a recent study, using quantitative receptor autoradiography (QRA), significant increases in densities of <sup>3</sup>H-PK11195 (a ligand for the "peripheral-type" benzodiazepine receptor; PTBR) binding sites were found in selective brain regions, including the thalamus, of thiamine-deficient rats compared to control rats (Leong et al., *J. Cereb. Blood Flow & Metab.* 14; 100-15, 1994). In the present study immunohistochemistry with antibodies to astrocytes (anti-glial fibrillary protein; GFAP) and macrophages (anti-ED1), was used to examine the cellular localization of PTBRs in the brains of rats at different stages of thiamine deficiency. Histological studies showed evidence of significant neuronal loss and reactive gliosis within the medial thalamus. QRA and immunohistochemical studies of this region revealed significant increases in densities of PTBR binding sites, and markedly increased numbers of GFAP-positive cells. A fewer number of ED1-positive cells were found within the medial thalamus. Thus, increased densities of PTBRs correlated principally with the distribution of reactive astrocytes in the medial thalamus of thiamine deficient animals. Positron Emission Tomography (PET) using <sup>11</sup>C-PK11195 offers a potentially useful tool in WKS in humans. (Funded by MRC Canada).

Cx43/Cx32 GAP JUNCTION CHIMERAS PERMIT CALCIUM SIGNALING. M. L. Cotrina<sup>1</sup>, C. C. G. Naus<sup>2</sup>, S. L. Bond<sup>2</sup>, S. A. Goldman<sup>3</sup> and M. Nedergaard<sup>1\*</sup>. Depts. of <sup>1</sup>Cell Biology, New York Med. Col., Valhalla, NY, 10595, <sup>2</sup>Anatomy, Univ. of Western Ontario, London, ON, Canada N6A 5C1 and <sup>3</sup>Neurology, Cornell Univ. Med. Col., NY, 10021.

Cultured astrocytes can generate long-range calcium waves that travel from cell to cell by means of gap junctions. These calcium waves can modulate neuronal calcium levels, suggesting that astrocytes might play an active role in establishing neuronal firing patterns. However, it is not clear if gap junctions mediate calcium signaling between neurons and astrocytes, because different gap junction proteins are expressed in the two cell types. Neurons express connexin-32 (Cx32), while astrocytes express Cx43. We therefore asked whether chimeric gap junctions composed of Cx43 and Cx32 are competent to carry the intercellular calcium wave. To this end, we used C6 glioma cells, a cell line that expresses low levels of Cx43 and cannot propagate intercellular calcium waves (Charles, *JCB* 118: 195, 1992). C6 cells transfected with Cx43 cDNA were labeled with the membrane dye, DiIC18, then mixed with other C6 transfected with Cx32 cDNA, in a 1:250 or 250:1 ratio. Two days later, mechanically induced calcium waves were followed with the calcium indicator fluo-3. We found that signaling was transmitted bidirectionally between Cx43 and Cx32 transfectants. Although some signaling to non-transfected and nonsense-transfected controls was observed, the rate of communication was 20% higher in the direction from Cx43 to Cx32 than opposite. Our results suggest that 1) Cx32 and Cx43 are capable of forming functional pairs, 2) this coupling allows transmission of calcium signals, and 3) although coupling is bidirectional, transmission of a calcium signal seems facilitated in the direction from Cx43 to Cx32. Our data suggest that the unidirectionality of calcium signaling between astrocytes and neurons in mammalian forebrain cultures might reflect the transmission characteristics of the chimeric Cx32/Cx43 gap junction.

MODULATION OF ASTROGLIOSIS BY BASIC FIBROBLAST GROWTH FACTOR, HEPARAN SULFATE AND  $\beta$ -ADRENERGIC BLOCKADE. J. F. Reilly<sup>\*</sup>, L. Bair, and V. K. Menon. Department of Cell Biology & Human Anatomy, School of Medicine, University of California, Davis, CA 95616.

Traumatic injury to the brain results in astrocyte hypertrophy and the formation of a dense scar at the site of the wound. This scar may present physical and chemical barriers to axonal regrowth and functional recovery. In the present study, we describe experimental modulations that increase and decrease astrocyte hypertrophy following traumatic injury to the adult rat cerebral cortex and hippocampus. IntraleSION injection of 20 ng or 200 ng basic fibroblast growth factor (bFGF) significantly increased the area of GFAP-stained profiles in the vicinity of the wound, as demonstrated by quantitative image analysis. Co-administration of 48  $\mu$ g heparan sulfate (HS) with 200 ng bFGF elicited a broader zone of astrocyte hypertrophy, compared to bFGF alone. This suggests that HS permits more extensive diffusion of bFGF from the site of injection. Systemic administration of DL-propranolol, a non-selective  $\beta$ -adrenergic antagonist, resulted in a significant decrease in the area of GFAP-stained profiles. Administration of a  $\beta$ -adrenergic agonist has been shown to increase bFGF mRNA expression in the non-injured rat brain, and it is possible that propranolol acts to reduce astrogliosis by reducing the synthesis and level of bFGF at the site of injury. These studies demonstrate that the astrocyte response to traumatic injury can be both enhanced and reduced, and provide useful models for future investigations. Supported by NIH AG 06159.

## 327.15

**TUMOR NECROSIS FACTOR INFUSION IN ADULT RAT BRAIN CAUSES INFLAMMATION AND DEMYELINATION** J.P.O. Hobb\*, D. Sadi, T. Hagg

Dept. Anatomy &amp; Neurobiology, Dalhousie Univ., Halifax, B3H 4H7, Canada

TNF (tumor necrosis factor) is a cytokine thought to play a key role in demyelinating diseases such as multiple sclerosis. Here we have infused PBS or PBS containing recombinant human TNF $\alpha$  (1 or 3  $\mu$ g/day; Preprotech) for 14 days into the cortex just above the corpus callosum of adult female Sprague-Dawley rats using Alzet pumps. With control PBS, essentially no tissue damage beyond the infusion-cannula tract was observed and infiltration of leukocytes was minimal and limited to the wall of the tract. In contrast, with 3  $\mu$ g/d TNF, an area of tissue necrosis had developed with an abundant infiltration of leukocytes into a large area (2-3 mm diameter) of the cortex, corpus callosum and underlying striatum. In the same area, immunoreactivity for the MBP and MOBP markers for oligodendrocytes was absent, indicative of demyelination. Antero- and retrogradely labeled (choleratoxin B; List) axons of the corpus callosum were present in the area of demyelination but appeared to have undergone degenerative changes. CNTF (ciliary neurotrophic factor) is known to prevent TNF-induced oligodendrocyte death in vitro (Louis et al., Science 259:689-92). Our preliminary results suggest that recombinant human CNTF (3  $\mu$ g/d; a gift from SCIOS Nova, Inc.) administered at the same time as TNF into the adult rat cortex has a modest protective effect against TNF-induced demyelination. CNTF itself caused the same limited extent of tissue damage and inflammation as control PBS infusion.

Thus, TNF appears to be useful for establishing in vivo adult CNS models for demyelination which can be used to test agents for oligotrophic and remyelination activities.

Supported by a grant to TH from National Multiple Sclerosis Society, USA.

## 327.17

**EFFECTS OF HIGH-DOSE METHYLPREDNISOLONE AND 21-AMINOSTEROID ON REMOTE GLIAL ACTIVATION IN EXPERIMENTAL ACUTE SPINAL CORD INJURY.** M. Mizuno, S. Shimosaka, T. Tanaka\*, S. Waga, T. Kojima and Y. Kubo.

Department of Neurosurgery, Mie University School of Medicine, Tsu, Mie, 514, Japan

It is well known that high-dose methylprednisolone sodium succinate (MPSS) and 21-aminosteroid U-74006F are effective in the treatment of experimental acute spinal cord injury, but effect for the site away from the impact site is not known.

We studied the efficacy of high-dose MPSS and U-74006F on nucleus gracilis in rats with Th8 spinal cord injury. MPSS was administered intravenously in dose of 30mg/kg during a 15-minute period, followed by 45-minute pause and then a 23-hour maintenance infusion of 5.4mg/kg. U-74006F was administered intravenously in dose of 1.5mg/kg and then a 9-hour maintenance infusion of 0.5mg/kg. Control rats were treated with saline. Three days postlesion, the rats were sacrificed and the brain section was stained immunocytochemically with glial fibrillary acidic protein (GFAP) and OX-42. GFAP and OX-42 immunoreactivity of the nucleus gracilis in MPSS group (n=10) and U-74006F group (n=10) were higher than that in the control group (n=10). Astrocytes and microglia have been known as the source of neurotrophic factors and play significant roles in neuroprotective and regenerative responses, so the high density of astrocytes and microglia reaction in the nucleus gracilis in the MPSS and U74006F group may suggest neuroprotective and regenerative effect on the remote site. MPSS and U74006F may be effective on the distal site far away from the impact site.

## 327.19

**STEROIDS MODULATE LEPTOMENINGEAL CELL INFILTRATION INTO CEREBRAL CORTICAL STAB WOUNDS.** M.S. Li\* and S. David.

Centre for Res. Neurosci., Montreal Gen. Hosp. Res. Inst. and McGill University, Montreal, Quebec, Canada, H3G 1A4

We have previously shown that topical applications of glucocorticoids can attenuate the lesion interface after cortical stab wounds in adult rats. In this study we have examined whether this is due to changes in the number of leptomeningeal cells that migrate into the wound. The surface of cortical stab wounds in adult rats were treated with topical applications of either 0.1% Halog or 0.05% Diprolene, and 3 weeks later cryostat sections through the lesion site were labeled with anti-laminin, anti-GFAP and Nuclear yellow. Because of the inavailability of leptomeninges-specific antibodies, leptomeningeal cells were quantified by estimating the number of elongated nuclei within laminin-positive and laminin-negative areas of the wound. Laminin-negative areas of the wound contained fewer elongated nuclei (3/500 $\mu$ m) as compared to laminin-positive areas (13/500 $\mu$ m). These results were further confirmed by EM, which showed limited migration of leptomeningeal cells into the wound after steroid treatments. In vitro studies indicate that treatment of dissociated cultures of adult leptomeninges with these steroids at  $10^{-5}$  M reduces proliferation assessed by  $^3$ H-thymidine uptake. The attachment and spreading of these cells was also found to be better on laminin and fibronectin substrates. These results suggest that local steroid treatments may attenuate the lesion interface after penetrating wounds to the CNS by reducing the proliferation and possibly also the migration of leptomeningeal cells into the wound.

## 327.16

**A NOVEL ACTION FOR ADENOSINE IN THE CENTRAL NERVOUS SYSTEM SUGGESTED BY CELL DEATH IN RAT STRIATUM CULTURES** M.P. Abbracchio<sup>1</sup>, S. Cenuti<sup>1</sup>, G. Burnstock<sup>2</sup>, D. Barbieri<sup>3</sup>, C. Franceschi<sup>3</sup>, W. Malorni<sup>4</sup>, H.O. Kim<sup>5</sup>, D.K.J.F. von Lubitz<sup>5</sup>, E. Cattabeni<sup>1</sup> and K.A. Jacobson<sup>5</sup>, <sup>1</sup>Inst. Pharmacol. Sci., Univ. Milan, Italy; <sup>2</sup>Dept. Anat. Dev. Biol., Uni. Coll. London, UK; <sup>3</sup>1st Gen Pathol., Univ. Modena, Italy; <sup>4</sup>1st Sup. Sanita', Rome, Italy; <sup>5</sup>Mol. Recogn. Sect., Lab. Bioorg. Chem., NIDDK/NIH, Bethesda, MA, USA

We have previously shown that exposure of rat brain primary cultures to the adenosine analogue 2-chloro-adenosine (2-CA,  $10^{-6}$ - $10^{-4}$  M) results in a reduction of astrocytic cell number that was not antagonized by xanthine antagonists at A1 and A2 adenosine receptors. In the present study, we have characterized 2-CA-induced cell death and tested the possible involvement of the recently cloned xanthine-insensitive adenosine A3 receptor by using the two selective A3 agonists, N<sup>6</sup>-(3-iodo-benzyl)adenosine-5'-N-methyluronamide (IB-MECA) and its 2-chloro-derivate (Cl-IB-MECA). All compounds induced a concentration-dependent decrease of astrocytic cell number. However, agonists at the A3 receptor were effective at a much lower concentration range (0.1-10 nM) with respect to 2-CA. Maximal reduction of cell number was approx. 60-70% with 2-CA and 30-40% with the A3 agonists; these effects were also detected if agents were added 24 hours after cell plating, therefore ruling out any influence on cell adhesion. Both flow-cytometric analysis of propidium iodide-stained nuclei and light and electron microscopy demonstrated that 2-CA induced apoptosis. In contrast, no apoptosis was detected with the A3 agonists, but electron microscopy analysis suggested induction of cytoskeletal damage. These results suggest that adenosine may act as a negative regulator of astrocytic cell number in the brain; data with different adenosine analogues suggest that multiple mechanisms might be involved including apoptosis and necrosis.

## 327.18

**EXPRESSION OF POLYPEPTIDE VARIANTS OF RECEPTOR-TYPE PROTEIN TYROSINE PHOSPHATASE (RPTP) $\beta$ : THE SECRETED FORM, PHOSPHACAN, INCREASES DRAMATICALLY DURING EMBRYONIC DEVELOPMENT AND MODULATES GLIAL CELL BEHAVIOR IN VITRO.** T. Sakurai, D. R. Friedlander and M. Grumet\* Dept. of Pharmacology, New York University Medical Center, NY, NY 10016.

Glial cells express three splicing variants of a receptor-type protein tyrosine phosphatase called RPTP $\beta$ . Two are receptor forms that differ in a large extracellular domain that is absent in the deleted variant form dRPTP $\beta$  and the third is a secreted proteoglycan called phosphacan that lacks the cytoplasmic phosphatase domains. We have now identified by immunoblotting proteins corresponding to these three forms of RPTP $\beta$  in rat C6 glioma cells and brain. Although dRPTP $\beta$  is more prevalent than the full length receptor in C6 glioma cells, there is much less difference between them in rat brain. The secreted form, phosphacan, is much more abundant than either of the receptor forms in rat brain and increases progressively during development while the receptor forms show only moderate changes. In contrast to the long form of RPTP $\beta$  and phosphacan that contain a large alternatively spliced domain and were detected as proteoglycans, the dRPTP $\beta$  form did not appear to be a proteoglycan. We recently showed that phosphacan binds to the neuron-glia cell adhesion molecule, Ng-CAM, and we now report that glia expressing RPTP $\beta$  adhered and extended processes on substrates coated with Ng-CAM. After one day in culture, however, the glia retracted their processes and often lifted off the substrate. Glial cells secrete large amounts of phosphacan which was found to inhibit adhesion of glia to Ng-CAM. Conditioned medium from glial cells inhibited glial adhesion, and depletion of phosphacan from the conditioned medium by immunoadsorption reduced the inhibitory activity. The results show that secreted forms of RPTP $\beta$  (phosphacan) increase dramatically during development and indicate that they can modulate glial cell adhesion and behavior.

## 327.20

**OLFACTORY GLIA: ARE SOME MORE EQUAL THAN OTHERS? AN EXAMINATION OF GLIAL SUBPOPULATIONS ALONG THE OLFACTORY PATHWAY.** A.C. Puche\*, K. Tisak and B. Key, Laboratory of Molecular Neurodevelopment, Dept. Anatomy and Cell Biology, Melbourne University, Parkville, Australia 3052.

The mosaic topographical projection of primary neurons in the olfactory system is a key determinant in the processing of olfactory information. The topographical projection formed during development is maintained in adult, despite continual neuronal turnover throughout life in the olfactory neuroepithelium. Growth cones and their axons continually grow along the olfactory nerve and form functionally correct synaptic connections within the bulb. Our laboratory has identified subpopulations of primary sensory olfactory neurons, distinguished by expression of specific cell surface carbohydrates, that self-fasciculate and sort into axon bundles only upon entering the olfactory bulb. We have hypothesized that local environmental cues in the olfactory bulb, generated by unique subpopulations of glia, may be involved in axon growth and/or sorting in the olfactory bulb. We analysed the expression of numerous antigens within the olfactory pathway by immunohistochemistry in order to identify specific markers of glial subpopulations. Three distinct subpopulations of glia were defined with antibodies against the low affinity nerve growth factor receptor (p75) and the cell surface carbohydrate Lewis<sup>x</sup> (Le<sup>x</sup>), a ligand for the selectin receptors, and with a plant lectin from *Burhinia purpurea* (BPA), which exhibits specificity for N-acetyl-galactosamine. Peripheral Schwann cells ensheathing the olfactory nerve express only p75, both in vivo and in vitro. In vitro these glia support extensive olfactory neurite outgrowth. Ensheathing cells within the olfactory bulb, however, appear instead to only express Le<sup>x</sup>. Astrocytes in the glomerular layer and deeper regions of the bulb selectively express N-acetyl-galactosamine. These results demonstrate that the olfactory system contains discrete subpopulations of glia which are spatially segregated to distinct regions of the pathway. These glial populations may be responsible for modulating axon fasciculation within the primary olfactory projection.

## 328.1

SYNCHRONIZED VISUAL ACTIVITY IN BOTH EYES DISRUPTS BINOCULAR MAP DEVELOPMENT IN *XENOPUS* OPTIC TECTUM. S. Grant, S.G. Brickley, E.A. Dawes and M.J. Keating (SPON: Brain Research Association). Dept. of Anatomy, Charing Cross & Westminster Medical School, London W6, and Div. of Neurophysiology, NIMR, London NW7, UK.

Activity-dependent rearrangements of axons and synapses are common processes underlying the refinement and alignment of topographic maps in the developing visual system. Temporal correlations in the activity of appropriately converging inputs - e.g., from neighbouring ganglion cells (GCs) in the retina - are believed to be essential for the success of these processes, by providing sufficient drive to activate voltage-gated, post-synaptic NMDA receptors. We have examined the effects of inducing temporal correlations in the activity of GCs across both retinas during development and after larval eye rotation, on the order and alignment of binocular maps in the optic tectum of the frog, *Xenopus laevis*.

Animals were reared in an environment of continuous 1Hz stroboscopic illumination. In control experiments, exposure to this environment was shown to produce synchronization in the firing of all 3 classes of retinal GC axon in the tectum, so that similar temporal correlations in afferent activity were present in all regions of both tectal lobes. Developmental refinement of the contralateral (retinotectal) map was unaffected by strobe-rearing, but ipsilateral (crossed isthmotectal) maps showed significant disorder and misalignment with the direct visual map from the retina, especially when its orientation had been rotated. These findings support conclusions from previous dark-rearing studies that precise rearrangements of retinotectal axons and synapses in developing *Xenopus* depend little on visually-evoked activity, and suggest that crossed isthmotectal axons are unable to find appropriate sites for synaptic convergence when all available targets are visually-activated in near-synchrony.

## 328.3

DL-2-AMINO-5-PHOSPHONOVALERIC ACID (APV) GREATLY SUPPRESSES SPONTANEOUS ACTIVITY IN GOLDFISH TECTAL NEURONS. Brad J. Kolts\* and R. L. Meyer. Dept. Dev. & Cell Biol. University of California, Irvine, CA 92717

The NMDA antagonist, APV, inhibits activity-dependent synaptic refinement during the formation of connections in the retinotectal projection of goldfish. This has been interpreted to mean that NMDA receptors act as detectors of correlated activity at the primary synapse. However, other synaptic loci and roles for NMDA receptors remain possible. Here, we examine the possibility that NMDA receptors might regulate spontaneous activity, and thereby excitability, in the tectal cells of goldfish. Spontaneous multiunit activity as well as evoked optic field potentials were recorded in the isolated tectum of normal, regenerating, and enucleated adult goldfish. The tecta were removed, together with the optic nerves, and placed in a perfusion chamber into which drugs were infused during recording. Multiunit activity was recorded with extracellular metal electrodes inserted into the SFGS. Field potentials were elicited by optic nerve shock and recorded with pipettes in the SFGS. Exposure to 2.5-25µM APV resulted in a rapid and dramatic decrease in the background multiunit activity which was dose dependent and reversible. At 25µM, activity was reduced by >90%. Comparable effects were found in tecta from normal, enucleated and regenerating fish. In contrast, 25µM APV had relatively little effect on the field potential in both normal and regenerating tecta. No effects were seen on the height and latency to peak of the early component of the evoked potential. However, the width of the peak at half maximum was reduced on average by 32%. These data suggest that NMDA receptors may play an important role in regulating spontaneous background activity in tectal target cells which in turn might determine their overall level of excitability. The data do not strongly support a critical role for these receptors at the primary optic synapse. We suggest APV might prevent refinement by reducing the excitability of tectal neurons and thereby preventing regenerating optic axons from driving their postsynaptic targets. (Supported by EY6746)

EYE IMPLANTS WITH PERIPHERAL NERVE BRIDGES TO THE SUPERIOR COLLICULUS: EFFECTS OF NGF AND DELAYED CONNECTION. B. H. Hallas\*, P. Jacovina, S. Lehman, R. Galler, L. Guerra and M. Wells. Departments of Neuroscience and Anatomy, New York College of Osteopathic Medicine, Old Westbury, New York 11568.

Adult Wistar host rats were blinded in the left eye by the removal of the lens retina and vitreous body. Simultaneously, a 3-4 cm portion of the right sciatic nerve was removed for a bridge segment. Entire eyes from 3 day postnatal rats of the same strain containing an attached 2 mm segment of the optic nerve was removed from donor animals. The donor eye optic nerve was then inserted into the sciatic nerve and held in place with 10-0 sutures. In one set of experiments the eyes attached to bridges were incubated in 1µg/ml NGF or saline for one hour. The eye was then implanted into the empty left orbit of the adult host and the attached nerve held in place with 10-0 suture through the cornea. In other experiments agar containing either NGF or saline was also implanted in the orbit with the donor eye. The attached peripheral nerve bridge was placed in a subcutaneous pocket over the cranium. After two weeks, the bridge was exposed, the distal end trimmed and inserted into the superior colliculus through a hole drilled in the cranium. The peripheral nerve bridge was allowed to remain intact for three weeks at which time HRP was injected intra-orbitally or in the bridge. At the time of HRP injection, the implanted eyes appeared viable and healthy. The resulting tissue was processed histochemically and HRP label was demonstrated in the superior colliculus. Densitometric measurements of sections suggested that eyes and bridges incubated with NGF showed twice the amount of label transported to the superior colliculus compared to those incubated in saline alone.

## 328.2

ON AND OFF EVOKED FIELD POTENTIALS IN THE SUPERIOR COLLICULUS OF NEONATAL RATS. S. Fortin, C. Allal, Y. Xu, S. Molotchnikoff, and S. Itaya\*, Dept. Biology, Univ. de Montreal, Que., Canada, and Dept. Biomed. Sci., Univ. South Alabama, Mobile, AL 36688

In anesthetized young rats we have recorded on and off field potentials which were evoked by light on and off steps, respectively. These responses were analyzed in the dorso-ventral axis of the superior colliculus in order to investigate extracellular current sources. Furthermore, power spectrum analyses were performed on these potentials. Data were collected on animals from postnatal day 11 (first light evoked responses appear at day 12) to postnatal day 18. Adult rats were investigated as controls. The eyelids open at postnatal day 14. Results indicate that: (1) on and off responses appear at the same age; (2) their latencies are long and variable, but more importantly only slow waves are present; (3) on and off potentials are not distributed in the same collicular layers; (4) as the rat grows older, off field potentials exhibit more complex patterns, i.e., they contain oscillatory wavelets which are never seen in on-responses. Power spectral analysis reflects these characteristics. From day 12 to 18 the frequency increases from approximately 6 up to 30 Hz. We are also studying GABA immunohistochemical staining in the developing superior colliculus. GABA positive cells are present at birth, but their density and size appear to change with age. We are investigating the potential contribution of GABA circuitry development to the maturation of responses to light.

## 328.4

RETINAL NMDA-TOXICITY ALTERS RETINO-TECTAL PROJECTIONS IN THE RAT. J. Weise<sup>1</sup>, M.R. Kreutz<sup>1</sup>, T.M. Böckers<sup>2</sup>, M.C. Humphrey<sup>1\*</sup>, B.A. Sabel<sup>1</sup>. Inst. of <sup>1</sup>Med. Psychology, Otto-v-Guericke University, Magdeburg, F.R.G.; <sup>2</sup>Anatomy, Westf. Wilh. University, Münster, F.R.G.

In the past decade various glutamate receptor subtypes have been reported in the retina and evidence was provided that the mammalian retina is highly susceptible to NMDA-toxicity. We have studied the topography of retino-tectal projections after NMDA-induced retinal lesions with intraocular injection of Fluorescein-isothiocyanat (FITC) and HRP. Anterograde tract tracing revealed that 6 weeks post lesion most of the fluorescent fibers were found in the rostro-medial part of the superior colliculus (SC) with a gradient of intensity in the rostro-caudal axis in comparison to control animals. In the lateral part of the SC the fluorescence signal was clearly diminished in NMDA treated animals. Changes in the dorso-lateral geniculate were less specific. Apart from a general but not dramatic loss of signal intensity only minor changes were observed. Axonal reorganization is suggested by the findings that 1 week after NMDA toxicity a general reduction of fluorescent fibers and HRP reaction products occurred in all parts of the SC and that GAP 43 immunoreactivity was increased in the RGC layer after the lesion but not in controls. These data suggest that an axonal reorganization of surviving RGCs might be involved in recovery from visual deficits observed in this model of excitotoxicity.

## 328.6

QUANTITATIVE CYTOARCHITECTURE AND CYTOCHROME OXYDASE ACTIVITY IN THE SUPERIOR COLLICULUS OF THE VERVET MONKEY AFTER NEONATAL HEMISPHERECTOMY. 3A. Pito<sup>1</sup>, 3D. Boire<sup>1,2</sup>, M. Herbin<sup>1</sup>, and 1,2,3M. Pito<sup>1</sup>. <sup>1</sup>Neuropsychol. Unit and <sup>2</sup>CRSN, Université de Montréal and <sup>3</sup>MNI, McGill University, Montreal, CAN.

Quantitative morphometry was used to study the effects of early hemispherectomy on the superior colliculus (SC) in the vervet monkey. The SC contralateral to the lesion does not differ significantly from normals. The ipsilateral SC is significantly reduced in size, the superficial layers (I-III) undergoing a more important reduction than the intermediate layers (IV). The shrinkage of the SC results mainly from a reduction of its surface rather than of the thickness of each layer. The stratum opticum (layer III) is reduced, being less discernible on Nissl and cytochrome oxidase (CO) stained sections. There is a light reduction in neuronal density in the superficial layers of the affected SC and light gliosis is evidenced by an increase in the density of oligodendrocytes. CO histochemistry suggest that the superficial layers of the SC contralateral to the lesion exhibits an oxydative metabolism similar to what is observed in the normal SC. CO staining in the superficial layers is intense and similar to what is seen in the contralateral SC. These results show that the SC on the lesioned side of the brain is affected by the loss of cortical input but remains a functional subcortical endstation for the analysis of visual information. Cellular integrity and metabolism of the SC are much less affected than those of the dLGN in hemispherectomized monkeys and could better subserve the residual vision observed in the blind field of hemispherectomized subjects rather than the heavily degenerated dLGN.

## 328.7

DEVELOPMENT OF NADPH-DIAPHORASE ACTIVITY IN THE SUPERFICIAL LAYERS OF THE RAT SUPERIOR COLLICULUS (SC): EFFECTS OF EYE ENUCLEATION AND OF ACTIVITY. A. Vercelli\*, S. Biasoli and S. Jhaveri (§). Department of Human Anatomy and Physiology, Torino Univ. Sch. Med., Italy; (§) Department of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Nitric oxide (NO) is a gaseous neurotransmitter/neuromodulator possibly involved in the stabilization of active synapses in the developing CNS. NADPH-d is a NO synthase: it may be revealed in neurons and fibers of the superficial layers of the SC by histochemistry. To examine the regulation of NADPH-d levels in the SC by retinal axons, we studied its postnatal expression in normal Wistar rats, in animals with one eye enucleated (P0 or P5) and in rats injected with of tetrodotoxin (TTX, weekly intravitreal injection of  $100 \pm 25$  nl of  $1.6 \times 10^{-5}$  M TTX starting on P0-Galli-Resta et al., J Neurosci. 13:243-250). Animals were perfused at various postnatal ages and brain processed to visualize the NADPH-d in the superficial layers of the SC. The morphology, cell size and dendritic arborization of NADPH-d positive neurons were studied. NADPH-d activity was found in control rats at the end of the first postnatal week. NADPH-d positive neurons are first detected in the superficial layers of the SC on P8; they are abundant by P12. Following P0 enucleation, expression of NADPH-d is delayed in the deafferented SC; in adult rats the overall levels of enzyme are lower on the experimental side, enzyme-positive neurons can no longer be classified according to cell types or dendritic orientation. After P5 eye enucleation, the numbers of neurons of many cell types show a shift in distribution; cell sizes are smaller than normal and dendritic length and orientation are abnormal. TTX-treated rats also exhibit a delayed expression of NADPH-d in the silenced SC. These data suggest that NADPH-d expression in the superficial layers of rat SC is influenced by the presence or absence of retinocollicular fibers and also by the levels of activity in these afferents. ## 328.9

DEVELOPMENT OF PROJECTION NEURONS CONTAINING SOMATOSTATIN (SS) IN THE RAT VISUAL SYSTEM.

G. Fontanesi, S. Thanos and P. Bagnoli\*. \*Dept. of Physiology and Biochemistry, University of Pisa, 56127 Pisa, Italy and \*\*Dept. of Ophthalmology, University of Tübingen, 72076 Tübingen, Germany.

In the mammalian brain, SS immunoreactivity (ir) is generally confined to intrinsic neurons that project locally. To investigate the possibility that SS is expressed in long projection systems within either the visual cortex (VC) or the retina of the rat, retrograde tracing of nerve cell bodies through Fluoro-Gold (2% in PBS 0.1M) injections (1  $\mu$ l) into the superior colliculus (SC) has been combined with SS immunocytochemistry (Mab S8, 1:750 in PBS 0.1M, FITC conjugated) at different postnatal stages. Early postnatal development of VC is characterized by the presence of SSir in immature bipolar neurons of deep cortical layers. Some SS-positive pyramidal cells can also be observed. In particular, at postnatal day (PD) 15, a small percentage of SS-containing pyramidal cells of layer 5 project to SC. Their number drastically increases during the third postnatal week when the adult pattern of SSir distribution in the different cortical layers is also reached. In the retina, early development of SSir is characterized by the presence of numerous labeled cells in the ganglion cell layer. Double labeling experiments show that about 10% of SS-positive cells of the temporal retina project to SC. At PD15, double labeled cells disappear and SSir is mostly confined to amacrine cells of the inner nuclear layer. These observations suggest that SS may play different roles in different visual regions, i.e. it may act as a neuromodulator in mature projections from VC to SC or it may be a factor regulating the establishment of retino-collicular projections in a restricted period of postnatal development.

## 328.11

NITRIC OXIDE SYNTHASE IS EXPRESSED EARLY IN THE PRENATAL DEVELOPMENT OF THE CAT SUPERIOR COLLICULUS. C.A. Scheiner\*, E.T. Benfro, R.D. Arceneaux, K.E. Kratz, and R.R. Mize. Department of Anatomy and the Neuroscience Center, Louisiana State University Medical Center, New Orleans, LA 70112.

Nitric oxide is a neuronal messenger which may play a role in synapse stabilization during development. We have used nicotinamide adenine dinucleotide phosphate diaphorase (NADPH-d) histochemistry and brain NO synthase (bNOS) immunocytochemistry to examine expression of NO in the developing cat superior colliculus (sc). Prenatal, postnatal, and adult animals beginning at gestational day E41 were used. Labeled neuron distributions were mapped using a computerized neuron tracing system.

At E41, NADPH-d labeled cells intensely in the deep gray layer (dgl) of sc and in the upper-lateral aspect of the periaqueductal gray (pag). At E58, a similar pattern was observed excepting the intermediate gray layer (igl), where sparsely distributed but regularly spaced neurons were first observed at 300-350  $\mu$ m intervals. These igl neurons increased in number by P1 and at P3 had formed regularly spaced clusters consisting of 3-5 closely apposed neurons. By P7, these clusters were more apparent, with as many as 5 clusters containing up to ten cells. In addition, fiber labeling was first visible at this age and increased markedly until it appeared adult-like at P57. While fiber labeling remained intense in adult animals, neuronal labeling was markedly reduced. bNOS immunocytochemistry showed a similar pattern of labeling as NADPH-d at P1, P7, P14 and later ages. Both NADPH-d and bNOS labeled cells had relatively mature morphologies in igl at the earliest times at which these substances were expressed.

The transient postnatal expression of NOS in the igl cluster cells suggests that NO is involved in synapse stabilization in these cell groups, in part because the choline acetyltransferase containing patches that overlap these clusters are also first visible during this early postnatal period. OPTIC NERVE-DEPENDENT CHANGES IN ADULT FROG TECTAL CELL PHENOTYPES. E.A. Debski\* and Q. Liu. School of Biol. Sciences, Univ. of Kentucky, Lexington, KY 40506.

Optic nerve activity plays a role in determining the placement of retinal ganglion cell terminals in the optic tectum of the frog (Cline et al., PNAS 84:4342-4345, 1987). We have begun to investigate whether input from the optic nerve might also help shape the neurotransmitter phenotype of cells within this neuronal target. The optic nerves of adult frogs were unilaterally transected and prevented from regenerating for 5 months after which the expression of substance P- and serotonin-like immunoreactivity of tectal cells was assessed.

The percent of substance P-like immunoreactive (SP-ir) cells was significantly higher in the tectal lobe to which direct optic nerve input had been eliminated than in the tectal lobe of the same animals in which optic nerve input had been maintained. Serotonin-like immunoreactive (5-HT-ir) cells were found in significantly greater percents only in medial regions of deafferented tectum. Measurements of the intensity of 5-HT-ir cells using a computer-aided confocal microscope showed that the intensity of cells in the deafferented tectal lobe was 156% of that of the afferented lobe. There were no differences in the intensity of the SP-ir cells. Our data suggest that activity and/or factors supplied by the optic nerve influence the neurotransmitter phenotype of tectal cells. Supported by NSF grant IBN-9209651.

## 328.10

DEVELOPMENTAL CHANGES IN NMDA RECEPTOR INVOLVEMENT IN VISUAL RESPONSES IN SUPERFICIAL SUPERIOR COLLICULUS (SC). K.E. Binns\* & T.E. Salt. Dept Visual Science, Inst. Ophthalmology, Bath St., London, EC1V 9EL, UK.

NMDA receptors may have a role in the maturation of sensory responses. In rat SC NMDA receptor density peaks at P20 [Hofer et al 1994, J Neurochem., 62, p2300]. Over a similar period, the expression of individual NMDA receptor subunits alters considerably in SC [Watanabe et al 1992, Neuroreport, 3, p1138]. Also Hestrin [1992, Nature, 357 p686] noted developmental changes NMDA receptor ion channel kinetics. We investigated the possibility that the changes in receptor number, subunit expression and channel properties may be reflected in the synaptic response to visual stimulation and the role of NMDA receptors in generation of the visual response.

In urethane anaesthetized hooded rats aged P14 to P45, multi-barrel electrodes were used for single neurone extracellular recording and iontophoresis of NMDA, AMPA and AP5. The response to a standard (300ms) LED visual stimulus was challenged with NMDA receptor selective currents of the antagonist AP5. At P14 the visual response was biphasic, consisting of a burst of action potentials followed by sustained discharge for up to 4sec. With time, the duration of the later phase shortened, and began earlier, until at P20 the response was monophasic and lasted 1-1.5sec. By P22 this had reduced to 0.5-1sec and the response resembled that of P45 and adult rats. At P14-P19 AP5 reduced the visual response of 37% of the neurones studied (mean = 23.6 $\pm$ 4). Between P20-P21 71% of neurones had visual responses which were reduced by AP5 (mean = 32 $\pm$ 3). In P22-P45 rats adult values were reached: 60% of neurones had AP5 sensitive visual responses (mean = 45 $\pm$ 8). The data indicate that in rat SC the visual response matures between P14 and P22. The proportion of neurones with AP5 sensitive visual responses peaked at P20-P21. However the involvement of NMDA receptors in the visual responses of AP5 sensitive neurones increased with age from P14 to adult.

\*Values are mean reduction from control level  $\pm$  SEM.

EFFECTS OF NEONATAL AND ADULT ENUCLEATION ON THE SYNAPTIC ORGANIZATION OF THE SEROTONINERGIC PROJECTION TO THE SUPERFICIAL GRAY LAYER OF THE HAMSTER'S SUPERIOR COLLICULUS. E.A. Arce, R.D. Mooney\* and R.W. Rhoades. Dept. of Anatomy and Neurobiology, Medical College of Ohio, Toledo OH 43699

We have previously shown that removal of one eye in either neonatal or adult hamsters results in a marked increase in the density of serotonergic (5-HT) axons in the superficial layers (*stratum griseum superficiale* and *stratum opticum*) of the superior colliculus (SC) ipsilaterally to the remaining eye. However, nothing is known about the synaptic organization of these altered projections. In the present study, immunocytochemistry for 5-HT and electron microscopy was used to compare the synaptic organization of the 5-HT projection to SC in normal animals and hamsters that sustained eye removal at birth or in adulthood. In normal adult hamsters, only 4.0% of 500 5-HT-positive profiles made synaptic contacts. Of these, 30% were axodendritic, 65% were axoaxonic, and 5% were axosomatic. In the animals that sustained eye removal at birth, 22% of 400 profiles made synaptic contacts; 26% were axodendritic, 73% were axoaxonic, and 1% were axosomatic. In the hamsters that sustained adult enucleation, 18% of 400 5-HT-immunoreactive profiles made synapses; 26% were axodendritic, 73% were axoaxonic, and 1% were axosomatic. The present results thus demonstrate that 5-HT axonal sprouting after enucleation in hamsters results in a significant increase in the percentage of 5-HT-positive profiles that make synapses in this nucleus, but that the relative proportions of synaptic types made by these axons remains normal.

## 328.13

AUGMENTATION OF SEROTONIN IN THE DEVELOPING SUPERIOR COLLICULUS ALTERS THE NORMAL DEVELOPMENT OF THE UNCROSSED RETINOTECTAL PROJECTION. Tracy Crnko, R.D. Mooney, C.A. Bennett-Clarke, R.D. Lane, N.L. Chiaia, and R.W. Rhoades\*

A previous study from this laboratory showed that sprouting of serotonergic (5-HT) axons in the hamster's superior colliculus (SC) induced by a single subcutaneous injection of 5,7-dihydroxytryptamine (5,7-DHT) at birth (P-0) resulted in an abnormal terminal distribution of the uncrossed retinotectal projection such that these axons extended throughout the rostrocaudal extent of this nucleus and failed to form distinct clusters in the rostral *stratum opticum* (SO). The present study provided further evidence to support the role of increased SC 5-HT levels in this phenomenon by placing 5-HT-impregnated ELVAX chips over the SC on either P-1 or P-3 and assessing retinotectal projections via anterograde HRP transport when animals reached P>18. Analysis of ELVAX chips indicated that they released 5-HT for at least 14 days. Implantation of 5-HT-, but not vehicle-impregnated, chips resulted in abnormalities in the uncrossed retinotectal projection similar to those observed in the 5,7-DHT-treated animals. The patches that normally develop in the rostral SO were not present and uncrossed axons were distributed densely in this layer and the lower portion of the *stratum griseum superficiale* throughout the SC. These results suggest that the increase in 5-HT levels within the SC associated with the sprouting of the axons containing this amine in hamsters that received neonatal injections of 5,7-DHT is the most likely cause of the abnormalities in the uncrossed retinotectal projection in these animals.

## 328.15

NITRIC OXIDE ENHANCES ACTIVITY IN THE DEVELOPING AMPHIBIAN TECTUM. M.-S. Rioult-Pedotti\*, R.C. Renteria and M. Constantine-Paton. Department of Biology and Interdepartmental Neuroscience Program, Yale University, New Haven CT 06511.

In retinal ganglion cell axons extending from tadpole retinal explants, nitric oxide (NO) produces growth cone collapse in a cGMP-independent manner (Renteria and Constantine-Paton, 1994). To determine if this morphological observation might have a functional correlate in the intact retinal projection, we studied the effect of NO and its underlying mechanism in the developing tadpole tectum at a time when synaptic plasticity is prominent.

Spontaneous activity was recorded from layer VI neurons, the main recipients of retinal input, in slices from larval *Rana* optic tectum. Exogenous application of NO using S-nitrosocysteine (SNOC, 100  $\mu$ M) reversibly increased the frequency and amplitude of spontaneous synaptic currents. Neither frequency nor amplitude were enhanced by exposure to NO-exhausted SNOC. This increase in amplitude was more prominent when the cell was held at depolarized potentials. The NMDA receptor antagonist APV (100  $\mu$ M) did not prevent the NO effect on the frequency of spontaneous currents. Bath application of the membrane-permeable cGMP analogue 8-Br-cGMP (200  $\mu$ M) increased the frequency and amplitude of spontaneous synaptic currents similar to SNOC application. These data suggest that the effect of NO on synaptic function is distinct from the effect of NO on retinal axon growth cone motility. The present data are consistent with the involvement of NO as a retrograde messenger in activity-dependent plasticity in the developing amphibian tectum. (Supported by NIH EY06039. RCR is a Howard Hughes Medical Institute Predoctoral Fellow.)

## 328.17

EFFECTS OF RETINAL LESIONS ON METABOLIC RESPONSES TO PHOTIC STIMULATION IN THE GOLDFISH TECTUM: A DEOXYGLUCOSE STUDY. M. K. Powers\* and P. Melzer. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

We applied the autoradiographic deoxyglucose method to study the effects of unilateral retinal lesions on stimulus-related metabolic activation in the optic tectum of goldfish. Three types of lesions were carried out: 1) enucleation of the right eye, 2) injection of ouabain (1-2  $\mu$ L; 0.4 mM) into the vitreal chamber of the right eye, and 3) surgical removal of a small patch of retina (ca. 5% of the total area) near the vertical meridian in the dorsal half of the right eye. Eight days after the lesion, the fish were injected i.p. with 2-deoxy-D-[1- $^{14}$ C]glucose (DG; 15  $\mu$ Ci/100 g b.w.) and exposed to moving black-and-white gratings. After one hour the fish were euthanized. The brains were frozen and cut transversely. The sections were autoradiographed with X-ray film and stained for Nissl substance or for cytochrome oxidase (CO) activity. In all fish the tectum contralateral to the intact eye showed the most prominent DG uptake. The metabolic activation was greatest in the *stratum fibrosum et griseum superficiale* (sfgs), i.e. the layer in which most retinotectal afferents terminate, and extended into the *stratum opticum*. A separate thinner band of high metabolic activity spanned the *stratum album centrale* (sac). DG uptake in the other strata was low. Sfgs and sac contralateral to the enucleation showed reduced DG uptake, though their metabolic activity remained discernible. Injection of ouabain led to even more drastically reduced DG uptake in the two layers. The partial retinal lesion resulted in a diminished DG uptake in the whole contralateral sfgs and sac. However, DG uptake was reduced even further in the tectal portion corresponding to the site of the lesion. Staining for CO activity did not show any effects of the lesions. The autoradiographic DG method, therefore, is an effective tool to resolve subtle differences in tectal impairment caused by the three types of retinal lesions, and it may demonstrate the potential of the goldfish visual system to recover from the loss of function (support: NIH R01-EY08126 and P30-EY08256).

## 328.14

FACTORS UNDERLYING RESTRICTION OF THE EARLY UNCROSSED RETINOCOLLICULAR PROJECTION. Cara J. Snider & Leo M. Chalupa\*. Neurobiology, Physiology & Behavior, University of California, Davis, CA 95616.

In all mammals the uncrossed retinocollicular pathway is restricted at maturity to the binocular segment in the rostral half of the superior colliculus (SC). Early in development this retinal pathway is widespread, innervating an expanded portion of the rostral-caudal aspect of the fetal SC (Williams and Chalupa, 1982). We have examined the organization of the early uncrossed retinocollicular pathway of developing cats and ferrets using retrograde as well as anterograde tracing methods. Our findings demonstrate two novel observations. First, the ipsilateral projection is topographically organized throughout development. At the time of the widespread retinocollicular projection, cells in temporal retina arborize in the rostral segment of the ipsilateral SC, while those in nasal retina terminate more caudally. Throughout development the contingent of nasal uncrossed cells is much lower in numbers and innervation density than uncrossed cells in temporal retina. Second, the normal restriction of the uncrossed retinocollicular pathway stems from multiple factors: the loss of uncrossed nasal RGCs, an elimination of a small number of widely misprojecting RGCs, as well as a reduction of retinocollicular terminal zones. (Supported by NEI-NIH 03991).

## 328.16

MATURATION GRADIENT OF THE CORTICOCOLLICULAR VISUAL PATHWAY. L. Martínez-Millán\*, G. García del Caño and F. Jiménez Samadío. Department of Neurosciences, Faculty of Medicine, University of the Basque Country, 48940-Lejona, Vizcaya, Spain. nilatera

Corticocollicular fibers of normal (P0-P30) albino rabbits and of visually deafferented rabbits (monocularly deprived at P1-P14) were labelled by extracellular iontophoresis of anterograde biotinylated tracers. Corticocollicular fibers first arrive to the stratum opticum (SO) and lower part of the stratum griseum superficiale (SGS) forming a broad plexus of tangential and oblique fibers. During subsequent days, an increasing number of fibers from this plexus ascend vertically to the stratum zonale (SZ), where they bend and follow a trajectory parallel to the collicular surface. As this projection matures, the volume of the terminal field is reduced and increases in the density of fibers in all visual collicular strata as well as in the number of synaptic boutons and the number of axonal branches in the SGS.

The first visual cortical fibers arriving to the anterolateral part of the superior colliculus (SC) originate in the anterolateral part of the striate cortex and are already present in newborn animals. The posteromedial part of the striate cortex sends the last fibres to the SC and they reach to the posteromedial SO at P3. This maturation lag is also observed at later stages in the development of this projection. At P15, the cortical visual projection to the anterolateral part of the superior colliculus is mature whereas in the posteromedial collicular region the visuocortical terminal field still shows signs of immaturity such as a low density of fibers and long tangential fibers in the SZ.

This anterolateral to posteromedial gradient of maturation is also manifest in the sprouting capacity of this pathway. Unilateral visual deafferentation at P14 does not induce sprouting of corticocollicular fibers originating in anterolateral striate cortex whereas, under the same circumstances, fibers coming from posteromedial striate cortex show a clear amplification of their collicular terminal field. ## 328.18

SEROTONERGIC FIBERS IN THE OPTIC NERVE OF XENOPUS TADPOLES ARE NOT FROM RETINAL GANGLION CELLS BUT TRANSIENT RETINOPETAL AXONS. Sen Huang\* and S.A. Moody. Department of Anatomy and Neuroscience Program, The George Washington University Medical Center, Washington, D.C. 20037

Optic nerve fibers are believed to be retinofugal and the identification of serotonergic fibers in the optic nerve has been taken as evidence for the existence of serotonergic ganglion cells in the retina. Using immunofluorescence and confocal microscopy we studied the serotonergic nerve fibers in the optic nerve of early *Xenopus* tadpoles. Serial frozen sections from stage 26 (1½ days of development) to 48 (15 days) retina were examined. Serotonergic cells were first seen in the ventral hindbrain at stage 28, in the inner nuclear layer of the retina at stage 39 and in the ganglion cell layer at stage 42. Serotonergic axons were first seen in the optic nerve at stage 42 and started to disappear by stage 48. They are not observed in premetamorphic tadpole or adult *Xenopus* retina. In serial sections, the serotonergic nerve fibers could always be traced proximally to the site of the exit in the ventral forebrain, where they entered amongst a mass of labeled fibers in the ventral forebrain. Growth cones were often seen at the distal tip of the serotonergic fibers either in the optic stalk or just proximal to the optic nerve head. Only rarely were serotonergic fibers observed in the optic nerve layer or ganglion cell layer. These did not merge with a serotonergic cell body in the ganglion cell layer. Thus, the serotonergic fibers in the optic nerve are indeed transient retinopetal fibers, although we have yet to discover the identity of the cell body of origin. In the frog retina, serotonergic amacrine and bipolar cells were mostly located in the inner nuclear layer. A few serotonergic cells (<5%) were in the ganglion cell layer. Since there were no retinofugal serotonergic fibers detected, thus this study demonstrates that the serotonergic cells in the ganglion cell layer are displaced amacrine cells. Supported by NIH grant EY10096.

## 329.1

THE REGENERATION OF CNS NEURONS INTO PERIPHERAL NERVE GRAFTS IMPLANTED INTO THE THALAMUS OF ADULT MICE. **G. Campbell, O. Aywenagha and A. R. Lieberman**, Dept. of Anatomy and Developmental Biology, University College London. (SPON: Brain Research Association).

Previous studies have shown that the majority of neurons regenerating into a peripheral nerve graft implanted into the thalamus of adult rats lie in the thalamic reticular nucleus (TRN) with relatively few in dorsal thalamic and other nuclei. We are planning studies of the regeneration of CNS neurons into such grafts in genetically manipulated mice which either overexpress the cell adhesion molecule L1 (which we have recently shown is upregulated in regenerating neurons of the TRN) or in which the gene for the substrate adhesion molecule tenascin (the role of which in CNS regeneration is currently controversial) has been deleted. As a preliminary step to studying the transgenic mice we have assessed whether the normal mouse is a valid model for such studies. Segments of tibial nerve were implanted into the thalamus of 6 deeply anaesthetised normal adult ICR mice. After 1 month the animals were reanaesthetised and the distal end of the graft injected with a mixture of cholera toxin subunit B-HRP and WGA-HRP. 48 hr later the animals were again anaesthetised and perfused with fixative; serial frozen sections of the brain were reacted with TMB.

Between 92 and 374 retrogradely labelled neurons were located in the TRN. 1-113 labelled neurons were present in dorsal thalamic nuclei, in hypothalamic nuclei and in other areas projecting to the thalamus/TRN including the basal ganglia and various nuclei of the caudal brainstem. The distribution of regenerating neurons was very similar to that previously found for the rat. These results show that the response to peripheral nerve grafts in the mouse thalamus is comparable with that in the rat, validating the use of mice in the planned studies. In addition, these results show that some forebrain and caudal brainstem neurons, axotomised in their terminal fields, a long distance from their perikarya, are nevertheless capable of a strong regenerative response in the presence of a nerve graft, and can regenerate an axon over distances far greater than their normal length.

## 329.3

ELECTROPHYSIOLOGICAL IMPROVEMENT AFTER CO-IMPLANTATION OF CARBON FILAMENTS AND FETAL TISSUE IN THE CONTUSED RAT SPINAL CORD. **L. S. Liu\*, T. Khan, S. Sayers, M. Dauzyardis, C. Traush**, Rehabilitation R&D Center, Hines VA Hospital, Hines, IL 60141.

Our previous studies showed that carbon filaments provide directionality and support to growing neurites *in vitro*, and that severed spinal cord axons grew on and between carbon filaments which were implanted into the completely transected rat spinal cord. The aim of the present study was to determine whether the co-implantation of carbon filaments and fetal spinal cord tissue would promote functional recovery following spinal cord injury as determined by somatosensory evoked potentials (SSEPs) and motor evoked potentials (MEPs).

Rats were anesthetized and subjected to a severe contusion injury at the T8 level by dropping a 10g weight from a height of 18cm. The rats were divided into five groups. Group One consisted of normal rats (n=7); Group Two consisted of rats which received carbon filament implants cultured with fetal spinal cord explants after contusion injury (n=5); Group Three consisted of rats which received fetal spinal cord tissue implants after contusion injury (n=4); Group Four consisted of rats which received carbon filament implants after contusion injury (n=4); and Group Five consisted of rats which sustained a contusion injury only (n=4). The SSEPs were recorded at L4, C6 and the cortex after stimulating the left sciatic nerve. The MEPs were recorded from the left and right tibialis anterior muscles after magnetic stimulation of the lumbar and thoracic spinal cord and the cortex. Both SSEPs and MEPs were recorded 8 weeks after injury.

The results showed that the most dramatic recovery of potentials was seen in Group Two. In Groups Four and Five, SSEPs and MEPs were completely abolished in 50% of the rats, and of a very low amplitude and prolonged latency in the remaining 50% of the rats. These results suggest that the co-implantation of carbon filaments and fetal spinal cord tissue play an important role in promoting spinal cord functional recovery after injury. (Supported by funds from the Veterans Administration, Rehabilitation R&D Center.)

## 329.5

TRANSPLANTATION-INDUCED MYELINATION BY SCHWANN CELLS IMPROVES CONDUCTION PROPERTIES IN ADULT RAT DEMYELINATED SPINAL CORD. **Q. Honnou\*, P. A. Felts, S. G. Waxman and J. D. Kocsis**, Dept. of Neurology, Yale Univ. Med. Sch., New Haven, CT. 06510, and Neuroscience Res. Ctr., VAMC, West Haven, CT. 06516.

Transplantation of myelin-forming cells derived from the central and peripheral nervous system into dysmyelinating mutants or the area of demyelination in genetically normal host animals results in varying degrees of anatomically-defined myelination. We transplanted genetically marked (LacZ gene) glial cells from neonatal rats into adult rat spinal cord which had been demyelinated by prior spinal cord X-irradiation and injection of ethidium bromide and assessed the electrophysiological properties of the remyelinated adult dorsal column axons *in vitro*. Histological examination of the dorsal columns in the transplanted group demonstrated extensive myelin formation in over 99% of the region, although the region in the non-transplanted group did not show any remyelination. LacZ marking of Schwann cells indicated that the new myelin was formed by exogenous cells.

Stimulation of the dorsal columns was obtained with bipolar electrodes placed lightly on the dorsal surface of the spinal cord, and action potentials were recorded with glass microelectrodes attached to a high input impedance amplifier and stored on a digital oscilloscope. The conduction velocity in the region of remyelination increased to normal values. Moreover, impulses could propagate into and out of the transplant region. Conduction block which was observed in demyelinated axons was overcome by remyelination. The axons remyelinated by transplanted cells also improved frequency-response properties as compared to the demyelinated axons; the Schwann cell remyelinated axons could follow higher frequency than control myelinated axons. These results demonstrate that central remyelination by exogenously derived Schwann cells can lead to improved and secure conduction in the adult mammalian central nervous system. Supported in part by the VA and the NMSS.

## 329.2

STRUCTURAL AND FUNCTIONAL EVIDENCE OF RECOVERY FOLLOWING COMPLETE TRANSECTION OF THE ADULT RAT SPINAL CORD. **H. Cheng†\*, S. Almström, M. Casserlov and L. Olson**, Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden; †Neurologic Institute, Veterans General Hospital-Taipei and Division of Surgery, National Yang-Ming University, Taiwan.

Methods allow meaningful functional regeneration across a complete spinal cord transection in man do not exist. To ensure absolute spinal cord discontinuity in the present rat experiments, 5 mm-long sections of the spinal cord were removed at the level of T10 in adult rats. The gaps were bridged by multiple, precisely neuroanatomically located peripheral nerve grafts using intercostal homografts and allografts to redirect between proximal white matter and distal grey matter in the stumps. aFGF-containing fibrin glue (2.5 µg/ml) was applied to stabilize the anastomoses in the grafted area. The thoracic spinal columns were rigidly fixed in dorsiflexion by compressive wiring of the posterior spinal processes. Rats subjected only to complete transection at T10 were used as controls. All operated animals were video-recorded monthly and rated on a blind basis for hind limb functional deficits for up to 13 months using standardized APA and CBS scoring. Treated animals improved significantly and progressively on both scores during the first 6 months, while controls did not change. Seemingly voluntary hindlimb movements and partial weight-bearing were noted in the treated group. Retrograde tracing studies with WGA-HRP demonstrated transport from low lumbar levels to neurons at many levels of the neuraxis proximal to the transection, including raphe regions, reticular nuclei, red nuclei, dorsal tegmentum of the midbrain, and remarkably, pyramidal nerve cell bodies in the hindlimb motor areas of cortex cerebri on both sides. The data demonstrate that it is indeed possible to obtain meaningful regeneration across a complete spinal cord transection in an adult mammal. To our knowledge, this is the first structural and functional evidence of recovery following complete transection of the adult mammalian spinal cord.

## 329.4

MACROPHAGE-RELATED EFFECTS ON THE REGENERATION OF SENSORY AXONS INTO THE INJURED SPINAL CORD. **J.D. Houle\* and C.J.M. Kang**, Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205

To test for the possible involvement of macrophages in promotion of the regeneration of dorsal root axons, nitrocellulose strips treated with the macrophage activating factor lipopolysaccharide (LPS) or transforming growth factor beta (TGFβ) or macrophage inhibitory factor (MIF) were co-transplanted with fetal spinal cord tissue into an adult rat spinal cord lesion cavity. Cut dorsal roots were apposed to the nitrocellulose. Thirty days later animals were sacrificed and tissue sections processed for immunocytochemical detection of regenerated sensory axons containing calcitonin gene-related peptide (CGRP-ir) and for characterization of the non-neuronal cell types present at the nitrocellulose-transplant interface.

A graded macrophage response was observed, being most intense with LPS treatment and virtually non-existent with MIF treatment. TGFβ stimulated a macrophage response less intense than that induced by LPS. The extent of regeneration of CGRP-ir axons mirrored the intensity and distribution of the macrophage response, with axonal number and length of growth being greatest with the LPS-treated implant, in contrast to a minimal response with the MIF-treated implants. The non-neuronal cell layer between the nitrocellulose and the fetal tissue was the preferred site for axonal growth in all conditions tested, however, axonal association with a specific cell type was difficult to determine. The thickness of the non-neuronal cell layer was variable, but did not appear to influence the extent of axonal growth. These results implicate activated macrophages in the promotion of axonal regeneration from injured dorsal roots. It appears likely that the interaction of macrophages with non-neuronal cells positively influences these cells to provide an environment capable of support and guidance of axonal regrowth.

## 329.6

SCHWANN CELL SUSPENSION GRAFTS PROMOTE RECONSTRUCTION OF TRANSECTED POSTCOMMISSURAL FORNIX IN ADULT RAT **C.C. Stichel\*, K. Lips, G. Wunderlich and H.W. Müller**, Molecular Neurobiology Lab., Dept. of Neurology, Univ. of Düsseldorf, D-40225 Düsseldorf, Germany

During the past years glial cell transplantation has emerged as a powerful tool for promoting axonal regeneration in adult mammalian CNS. It has been shown that transplanted juvenile astrocytes as well as Schwann cells foster axonal regrowth. In a well defined lesion model, the transected postcommissural fornix, we have shown that astroblasts increase the number of regrowing axons while they are unable to guide the fibers across the lesion site (Wunderlich et al., 1994, Glia 10: 49-58). In order (1) to obtain a beneficial axotrophic effect, (2) to bridge the impermeable lesion site and (3) to avoid extensive host tissue damage we implanted dissociated Schwann cells into the transected postcommissural fornix using a microtransplantation extrusion technique.

Schwann cells (SC) were prepared from sciatic nerves of neonatal rats, depleted of fibroblasts and prelabeled with the fluorochrome Hoechst 33342. Immediately after lesion cells were pressure injected (1.6 µl of a 1x10<sup>6</sup> cells/ml suspension) into the unilaterally transected fornix. Implant characteristics and the spatio-temporal pattern of axonal regeneration were analysed using immunocytochemical and tracing methods.

The prelabeled SC integrated well into host tissue, exhibited extensive migration and proliferated only during the first week after implantation. They did not prevent axonal degeneration but induced extensive regeneration of transected fornix fibers. The regrowing fibers invaded the implant, crossed the lesion site and grew within their former pathway for approximately 1.2 mm up to their target area, the mammillary body. The regenerating axons were found to be myelinated at 4 weeks after implantation. The growth supporting effects were independent of the number of passages of the SC. Supported by the DFG (SFB 194/B5).

THE INFLUENCE OF PREDEGENERATED NERVE GRAFTS ON AXONAL REGENERATION FROM PRE-LESIONED PERIPHERAL NERVES. K.S. Bedi<sup>1</sup>, M.N. A-K E-S Hasan, M.M. Neumann, M.A. DeSouky<sup>2</sup>, and K-F. So<sup>3</sup>. Department of Anatomical Sciences, University of Queensland, St. Lucia, Australia, 4072 and <sup>2</sup>Department of Anatomy, University of Minia, Egypt and <sup>3</sup>Department of Anatomy, University of Hong Kong, Hong Kong.

Previous *in vivo* studies which have investigated whether or not predegenerated nerve segments used as grafts are capable of enhancing axonal regeneration have produced conflicting results. We have reinvestigated this question by using predegenerated nerve grafts in combination with preconditioning lesions of the host nerve to determine the optimal conditions for obtaining regeneration of myelinated axons. The right sciatic nerve of adult Dark Agouti rats was sectioned at mid-thigh level, and the distal portion was allowed to predegenerate for 0, 6 or 12 days *in situ*. These distal nerve segments were then syngeneically grafted onto the central stumps of sciatic nerves which had themselves received a conditioning lesion 0, 6 and 12 days previously, making a total of 9 different donor-host combinations. All surgical procedures were carried out under Ketamine/Xylazine anaesthesia. The grafts were assessed histologically 3 or 8 weeks after grafting. All grafts examined contained regenerating myelinated axons. The rats given a 3-week post-grafting survival period had an average of between 1,400 and 5,300 such axons. The rats given an 8-week post-grafting survival period had between about 13,000 and 25,000 regenerating myelinated axons. Analysis of variance procedures revealed significant main effects of both the donor and host conditions as well as Weeks (i.e. survival period post-grafting). These results indicate that both a conditioning lesion of the host neurons and the degree of predegeneration of peripheral nerve segments to be used as grafts are of importance in influencing the degree of axonal regeneration.

## 329.9

TRANSPLANTED SCHWANN CELLS ENGRAFT IN THE ADULT RAT CEREBELLUM AND PROMOTE REGENERATION OF INJURED OLIVARY AXONS. M. Bravin<sup>1</sup>, T. Savio<sup>2</sup>, F. Rossi<sup>1</sup>, and P. Strata<sup>1</sup>. <sup>1</sup>Dept. of Human Anat. and Physiol., University of Torino, I-10125, Torino, Italy; <sup>2</sup>Inst. of Anatomy, University of Genova, I-16132, Genova, Italy.

Axon regeneration in the adult central nervous system (CNS) is generally hampered by the presence of unfavourable environmental conditions. However, permissive conditions can be created in the CNS by grafting cells endowed with growth promoting properties, such as those from embryonic or peripheral nervous tissues. This study was aimed at assessing the capability of Schwann cells (SC) to promote the regeneration of injured olivocerebellar axons. Inferior olivary axons were transected in the white matter of adult rat cerebellum and SC suspensions, obtained from P1-P2 aged rat pups, were immediately grafted into the lesion site. At different survival times (up to 20 days after lesion/grafting), grafted SC were labelled by anti-P75 antibodies, whereas olivary axons were traced by means of biotinylated dextran amine. In most of the examined cases, the transplanted SC filled the cavity produced by the injury bridging the host cerebellar tissue at the opposite sides of the lesion. In addition, numerous SC were able to migrate inside the recipient white matter and cortical layers where they acquired the typical fusiform shape with a small ovoid cell body and long thin processes. In the absence of the graft, the sectioned olivary axons invariably ended close to the lesion site with small terminal bulbs. By contrast, when the graft was apposed to the lesion site, bundles of labelled olivary axons, which could be followed for several hundred  $\mu$ m, were present inside the graft aligned to SC, indicating that regenerative phenomena have occurred in response to the transplant. These results indicate that grafted dissociated SC are able to bridge the gap produced by the injury, integrate within the host cerebellar parenchyma, and interact with injured olivary axons to promote their regeneration.

CELLULAR TRANSPLANTATION INTO A PARTIAL LESION MODEL TO STUDY AXONAL REGROWTH IN THE ADULT RAT SPINAL CORD. X.M. Xu<sup>1</sup>, V. Guenard<sup>2</sup>, N.H. Kabeer<sup>1</sup>, P. Bates<sup>1</sup>, and M.B. Bunge<sup>1</sup>. <sup>1</sup>Dept. Anat. & Neurobiol., St. Louis Univ. Sch. of Med., St. Louis, MO 63104; <sup>2</sup>ETH-Honggerberg, Neurobiology, Zurich, Switzerland; <sup>3</sup>The Miami Project, Univ. of Miami Sch. of Med., Miami, FL 33136.

Schwann cells (SCs) in guidance channels effectively promote propriospinal axons to regenerate in adult rat spinal cord transected mid-thoracically (J. Comp. Neurol. 351:145-160, 1995). When BDNF and NT-3 were infused, axons recruited from distinct brain regions also grew into these grafts (Soc. Neurosci. Abstr. 20:1111, 1994). As an initial step to explore regrowth of specific descending spinal pathways with neurotrophic factors, we developed a partial lesion-SC transplantation model. SCs were purified in culture from adult rat sciatic nerves, suspended in a 30:70 solution of Matrigel:DMEM (M/D), and placed in semipermeable channels (1.25 x 3 mm, MWCO=50K Da)(120 x 10<sup>6</sup> cells/ml). M/D channels served as controls. Adult Fischer rat spinal cord was hemisectioned at T8 on the right and a 2.5 mm gap created caudally. The SC-channel was placed into the gap with the rostral and caudal cord stumps closely contacting both openings of the channel. One month later, a blood vessel-rich cable bridged rostral and caudal hemisections. Cables through SC-seeded channels contained more myelinated axons at their midpoint when compared to control channels (mean = 1054 vs mean = 240). Electron microscopy revealed that the ratio between myelinated and unmyelinated axons was 1:8. When distally capped SC channels were implanted and animals were sacrificed 3, 6, 9, and 12 days after grafting, neurofilament positive axons were observed entering the graft 0.1 mm from the host-graft interface on day 3. By day 9, leading axons extended to the distal end of the cable, 2.5 mm from the interface. The present study shows the feasibility of using this model to investigate mechanisms underlying the regrowth of specific spinal pathways. (Supported by NS09923, NS28059 and The Miami Project to Bunge Lab. and Daniel Heumann Fund for Spinal Cord Research to XMX).

## 329.10

ACTIVATION OF SEROTONERGIC MECHANISMS ENHANCES LOCOMOTOR PERFORMANCE IN SPINAL + TRANSPLANT RATS. D. Miya<sup>1</sup>, V. Adipudi<sup>1</sup>, E. Mori<sup>1</sup>, A. Tessler<sup>1</sup>, S. Giszter<sup>1</sup>, K.J. Simonsky<sup>2</sup>, S. Croul<sup>3</sup> and M. Murray<sup>1</sup>. <sup>1</sup>Departments of Anatomy/ Neurobiology. <sup>2</sup>Pharmacology, <sup>3</sup>Pathology. Medical College of Pennsylvania & Hahnemann University, Philadelphia, PA 19129.

Intraspinal transplants of fetal spinal cord permit development of useful locomotor function in rats transected as neonates (Miya et al., 1994). Transplants promote connectivity across the lesion, allowing increased weight support and fore-hind limb coordination. Since 5-HT axons originating in the brainstem regenerate through grafts in neonatal recipients, we investigated whether serotonin agonists would further enhance locomotion that develops as a result of the graft. The serotonergic agonists quipazine and DOI were administered to neonatally transected (n=3), transplanted (n=8), and normal (n=3) rats. The rats were trained daily starting at 3 weeks postsurgery on the treadmill, and wide and narrow runways, and were videotaped both before and after drug administration for kinematic and qualitative analyses. A dose response function was developed for quipazine (0.7, 1.0 and 1.4 mg/kg). Quipazine (1.0 mg/kg) increased weight support in transected rats with transplants but also produced pronounced hypermetria and tremors in these animals and in transected animals without transplants. DOI (0.3 mg/kg) improved weight support and other locomotor functions in rats with transplants without the hypermetria and tremors seen with quipazine. Our results indicate that activation of the serotonergic system improves overground locomotion in transected newborn rats with transplants and suggest that 5-HT<sub>2</sub> receptors are specifically implicated in the improved performance. Supported by grants NS 24707 from NIH, SCRF #300 from PVA and ASRI.

## 330.1

A HELPER VIRUS-FREE PACKAGING SYSTEM FOR HSV-1 PLASMID VECTORS THAT SUPPORTS EFFICIENT GENE TRANSFER IN THE RAT BRAIN. Alfred Geller\*, Song Song, Filip Lim, Phung Lang, Linda Yu, Yaming Wang, and Cornel Fraefel. Div. Endocrinology, Children's Hosp., 300 Longwood Avenue, Boston, MA 02115.

Herpes simplex virus type 1 (HSV-1) vectors have potential for delivering genes into cells in the brain to study neuronal physiology and to perform gene therapy of neurological disorders. However, several unresolved problems with HSV-1 plasmid vectors have limited their potential utility. These unresolved problems include: i) acute cytopathic effects due to either gene expression from the helper virus or specific proteins in the HSV-1 particle, ii) potential interactions between the helper virus and endogenous latent viruses, iii) efficiency of long-term gene expression, and iv) reversion to wild type HSV-1 of the deletion mutant helper virus.

To essentially eliminate those problems associated with the helper virus, we have developed a helper virus-free packaging system for HSV-1 plasmid vectors. Crude, unconcentrated vector stocks produced by this procedure contain ~4X10<sup>5</sup> infectious vector particles (ivp) of pHSVlac/ml (the prototype vector which expresses the Lac Z gene), and plaque assays revealed no contaminating helper virus (< 1 pfu/ml). Upon concentration and purification a titer of ~1X10<sup>7</sup> ivp pHSVlac/ml can be achieved.

Infection of cultured cortical cells with helper virus-free pHSVlac resulted in expression of  $\beta$ -galactosidase, and the number of positive cells remained relatively stable over a one week period. In contrast, using pHSVlac packaged using a helper virus, the number of positive cells was maximal at two days following gene transfer and decreased to ~30 % at one week. Following injection into the adult rat brain, pHSVlac packaged using a helper virus caused both significant cell damage and cell infiltration at the injection site. In contrast, injection of helper virus-free pHSVlac caused a level of cell damage that was similar to that observed following injection of saline. In the absence of helper virus, the number of positive cells was higher at both 4 days and 1 month after gene transfer compared to helper virus packaged pHSVlac, suggesting that the decreased cytotoxicity increased the efficiency of gene transfer.

## 330.2

ADENOVIRUS MEDIATED GENE TRANSFER TO ASTROCYTES FROM ADULT AND AGED ANIMALS. A METHOD FOR EX VIVO GENE THERAPY. S. Ausim Azizi\*, Dept. of Neurology, Thomas Jefferson University, 1025 Walnut St., Philadelphia, PA 19107.

Astrocytes, because of their natural properties of migration and integration into the CNS and elaboration of growth factors, as well as their availability may serve as ideal candidates for cell replacement therapy. In the present study, using dispase enzyme and shaking methods, primary cultures of astrocytes (> 90% pure) from adult and aged rats (>6 mos.) were obtained. Beta Galactosidase (Lac-Z) gene transfer was achieved using a replication-defective recombinant adenovirus vector with a CMV promoter. Immunofluorescence and X-gal histochemistry techniques were used to characterize the cells and visualize Lac-Z. The cultured cells uniformly express Vimentin, and depending on the stage of growth, 20 - 40% express GFAP activity. Viable astrocytes and stable gene transfer was achieved using 1 - 5 X 10<sup>5</sup> particles/cell. Two populations of infected cells were identified: adherent and non-adherent. Adherent cells maintain their morphological characteristics, whereas non-adherent cells become rounded and float in the culture medium, though remain viable and express Lac-Z. Infected cells remained viable in culture for at least 8 weeks. These cells were transplanted into the striatum of adult rats. Lac-Z positive cells were found in the brain for at least six weeks after grafting. Currently, we are in the process of cataloguing the patterns of migration, integration and long term survival as well as the host reaction to the grafted transformed astrocytes. It appears that initial reaction to the graft in the brain is marshalled by the glia. We believe that these techniques will provide a convenient method for *ex vivo* gene therapy in treatment of neurodegenerative diseases.

## 330.3

**FUNCTIONAL ASSESSMENT OF ADENOVIRAL VECTOR FOR GENE TRANSFER OF DOPAMINE D<sub>2</sub> RECEPTOR cDNA INTO RAT STRIATUM.** H. Ikari<sup>1</sup>, H. Umegaki<sup>1</sup>, L. Zhang<sup>1</sup>, J.M. Chernak<sup>1</sup>, H. Kuo<sup>1</sup>, A. Mastrangeli<sup>1</sup>, R.G. Crystal<sup>1</sup>, G.S. Roth<sup>1</sup>, D. Ingram<sup>1</sup>, Gerontol. Res. Ctr., NIH, Baltimore, MD 21224 and Div. Pulmonary & Critical Care Med., Cornell U., New York, NY 10021.

Dopamine D<sub>2</sub> receptors (D<sub>2</sub>R) in the striatum (STR) show declines in normal aging and in neurodegenerative disorders, such as Huntington's disease and late-stage Parkinson's disease. To assess the feasibility of gene transfer of D<sub>2</sub>R, we have constructed two vectors: (1) AdCMV.DopD<sub>2</sub>R as an Ad5 E1' E3' replication-deficient recombinant adenovirus vector containing the rat D<sub>2</sub>R cDNA driven by the cytomegalovirus (CMV) immediate early promoter, and (2) AdCMV.null, an identical vector without D<sub>2</sub>R cDNA as a control. By injecting AdCMV.DopD<sub>2</sub>R unilaterally by cannulae into rat STR, we have accomplished *in vivo* gene transfer of D<sub>2</sub>R cDNA into brain. Using receptor autoradiography of tissue-mounted brain sections obtained several days after treatment, we observed markedly increased binding of the D<sub>2</sub>R ligand, [<sup>3</sup>H]spiperone, at the injection site of AdCMV.DopD<sub>2</sub>R but not near contralateral sites receiving the control AdCMV.null. To begin assessing if the AdCMV.DopD<sub>2</sub>R can produce functional receptors, we are using apomorphine (APO)-induced rotational behavior as a model. Behavior was assessed following unilateral injection of AdCMV.DopD<sub>2</sub>R into intact STR or kainate-lesioned STR of rats. In kainate-lesioned rats, APO-induced (1 mg/kg) rotational behavior was not attenuated by injection of AdCMV.DopD<sub>2</sub>R into the lesioned STR when assessed up to 12 wk after vector injection and compared to controls receiving injections of AdCMV.null or vehicle alone. In contrast, beginning about 5 weeks after injection of AdCMV.DopD<sub>2</sub>R into intact STR, we have observed the initiation of APO-induced rotational behavior in a number of rats. These results must be confirmed in additional studies to determine whether the AdCMV.DopD<sub>2</sub>R can produce D<sub>2</sub>R functionally coupled to a behavioral response in this model.

## 330.5

**GROWTH PROPERTIES OF NEURAL CELLS IMMORTALIZED WITH THE TSA58 ALLELE OF SV40 LARGE T ANTIGEN.** O. Dillon-Carter<sup>1</sup>, M.E. Truckenmiller<sup>1</sup>, H. Kulaga<sup>1</sup>, C. Tornatore<sup>1</sup>, W. J. Freed<sup>1</sup>, NIMH Neuroscience Center at St. Elizabeths Hospital, Washington DC, 20032; NINDS, NIH, Bethesda, MD 20892

The temperature-sensitive tsA58 allele of the SV40 large T antigen is frequently used to immortalize cells for transplantation studies. The tsA58 protein is reported to be active at 33°C, thereby permitting cell propagation. At 39.5°C, it is presumed that a conformational change in tsA58 occurs resulting in loss of binding activity and growth arrest. Effects of temperature on growth were studied in three rat cell lines: a striatal cell line (M213-20) and a mesencephalic cell line (J30a) immortalized with tsA58, and the A7 cell line from rat optic nerve immortalized with wild-type SV40 large T. At low density, growth arrest was not observed when the cells were shifted from 33°C to 39.5°C. Moreover, cells maintained at 39°C for more than 100 divisions continued to grow at the same rate as cells maintained continuously at 33°C. When, however, cells were grown to confluency at 33°C and then shifted to 39°C, there was 80-90% rate of cell death as measured by propidium iodide exclusion. BrdU incorporation and cell cycle analysis by FACS did not reveal growth arrest or significant differences in the percent of cells in S-phase at the "non-permissive" temperature. Thus, at the "non-permissive" temperature, cells immortalized with the tsA58 form of SV40 large T continue to be immortal. Growth arrest at the non-permissive temperature in these cells may require additional inhibitory conditions, such as confluency or serum starvation.

## 330.7

**PHARMACOLOGICAL NEUROPROTECTION (NP) AND EARLY VIABILITY OF INTRASPINAL FETAL GRAFTS.** T.E. White, G.W. Schrimsher, D.K. Anderson, D.P. Theele, and P.J. Reier<sup>1</sup>, Univ. Florida, Gainesville, FL 32610.

There is a rapid attrition of intraspinal fetal grafts that is evident by 4d after grafting (pt). Thereafter, surviving cells give rise to expanding grafts that span lesion sites. The early loss of graft tissue may limit the extent of host-graft neuritic interactions. We have thus explored whether pharmacological interventions aimed at limiting possible graft susceptibility to secondary pathology can enhance early transplant viability. Adult S-D rats received E14 SC grafts in hemilesson cavities made at C1-C2. The animals were then divided into three groups: graft-only controls, rats receiving fetal tissue previously exposed to the synthetic glucocorticoid, methylprednisolone (MP), and rats treated with MP after grafting. Donor tissue treatment with MP entailed injecting the mother with MP (30mg/kg, i.v.) 1hr before the fetuses were removed. Subsequent fetal SC tissue preparation was done in Hank's Balanced Salt Solution containing MP (100µM). In the third group, recipients received injections of MP (30mg/kg, i.v.) at 5 min., 2hrs, and 4hrs after grafting. At 4d pt, the SCs were prepared for light microscopy. In controls, the transplants consisted of small islands of cells apposed to either host gray matter or pia, and there was extensive tissue necrosis surrounding these foci of donor tissue. MP-treated grafts in the second group of rats showed similar results except that the clusters of tissue were slightly larger. However, grafts in MP-treated hosts were substantially larger than in either of the other groups. There also was a suggestion of reduced inflammation and less host tissue loss. It thus seems that the addition of pharmacological NP enhances early SC reconstruction with fetal cell grafts, particularly if treatment is directed at the host. These findings also agree with reports of better fetal dopaminergic cell survival after exposure to 21-aminosteroids. Future studies will determine whether connectivity is better as a consequence of NP improved early graft survival. ## 330.4

**LACZ GENE TRANSFER TO RAT RPE CELLS *IN VITRO* USING HERPES AND ADENOVIRAL VECTORS.** B.V. Castillo<sup>1</sup>\*, M. del Cerro<sup>1</sup>, B.L. Davidson<sup>2</sup>, H.J. Federoff<sup>3</sup>, M.D. Geschwind<sup>3</sup>, and M.C. Bohn<sup>1</sup>, (<sup>1</sup>Dept. of Neurobiol. & Anat., U. of Rochester Sch. of Med., Rochester NY; <sup>2</sup>Dept. of Med., U. of Iowa Sch. of Med., Iowa City IA; <sup>3</sup>Dept. of Med. & Neurosci., Albert Einstein Coll. of Med., Bronx NY)

Genetic modification of retinal pigment epithelial (RPE) cells has the potential of providing trophic support to photoreceptor cells. **Objective:** Our goal was to determine and compare the efficacy of virally-mediated gene transfer into rat RPE cells *in vitro* using herpes and adenoviral vectors carrying lacZ. **Methods:** RPE from P7 rat pups were isolated with 2% dispase (Chang et al. '91, Curr. Eye Res. 10:1081) and grown in DMEM low glucose + 10% FBS at 1x10<sup>4</sup> cells/well (48 well plate). After 4 d in culture, cells were infected with different titers of a defective HSV-1 lacZ vector (0.02, 0.2, 2, 20 infectious particle (i.p./cell) or a recombinant adeno lacZ vector (0.1, 1, 10, 100 i.p./cell) for 2h at 37°C. The HSVlac vector is driven by a HSV IE 4/5 promoter whereas the adeno lacZ vector is driven by a RSV promoter and contains a nuclear localizing signal. RPE cells were fixed 2 d post-transfection for X-gal histochemistry. The percentage of blue X-gal reactive cells was determined from 9 pre-determined areas of the well. **Results:** Infection with adenovirus (100 i.p./cell) resulted in lacZ expression in 38.6 ± 7% of the cells. Percentage of blue cells decreased to <1% at lower viral titers. Infection with HSVlac resulted only in 11.1 ± 3% transfection efficiency at the maximal titer used (20 i.p./cell). The percentage of blue cells decreased ten-fold to 1.25 ± 0.6% at 2 i.p./cell and <0.1% for lower HSV titers. No significant difference in cell survival was seen after infection with HSV by comparing the total number of cells in infected and uninfected groups. However, total cell number increased two-fold after adenoviral infection compared to uninfected controls. **Conclusions:** Rat RPE cells can be transformed *in vitro* using high titers of adeno or herpes viral vectors. No cytotoxicity was seen with either viral vector at the maximal titers used.

## 330.6

**TEMPERATURE-SENSITIVITY OF THE P53 AND DNA BINDING FUNCTIONS OF SV40 LARGE T TSA58** C. Conejero\*, C. Tornatore and W. Freed. SPN, NPB, NIMH Neuroscience Center at St. Elizabeths, Washington D.C. 20032, and Laboratory of Molecular Medicine and Neuroscience, NINDS, Bethesda, MD, 20892.

SV40 large T antigen is commonly used to immortalize cells *in vitro*. The immortalization is thought to be due in part to the binding of p53 by T protein. Cells immortalized by the temperature-sensitive tsA58 mutant of SV40 large T express an immortal phenotype at the permissive temperature (33°C). When tsA58-immortalized cells are grown at 39.5°C, the T protein is thought to be inactivated, p53 is released, and the cells lose the immortal phenotype. To study this phenomenon, we used the pG-13 Luc reporter plasmid described by El-Deiry et al. (Cell, 75, 817-835, 1993). This construct has a p53-responsive enhancer element cloned upstream from the luciferase reporter gene. When transfected into cells, this construct can be used to test p53 activity under different growth conditions. This plasmid was transfected into a rat striatal cell line immortalized with tsA58 SV40 large T (M213-20 cells), and luciferase activity was measured at both the permissive and nonpermissive temperature. A peak of p53 activity was observed approximately 24 hr following a shift to the non-permissive temperature. In addition, at the permissive temperature there was a 200-fold increase in luciferase activity over 48 hr from the baseline reading, suggesting that plasmid replication and DNA binding occurred at 33°C. Paradoxically, at the non-permissive temperature a 70-fold increase in luciferase activity was seen over the same period. These data suggest that both the DNA and p53 binding functions of the tsA58 allele of the SV40 large T antigen are temperature sensitive.

## 330.8

**FUNCTIONAL OUTCOME OF RATS SUBJECTED TO SPINAL CORD CONTUSION TREATED WITH METHYLPREDNISOLONE, ISOGENIC TRANSPLANT OF PERIPHERAL NERVE, OR BOTH.** G. Guizar-Sahagun\*, J. Grijalva, H. Salgado-Ceballos, A. Gómez, A. Martínez, A. Ibarra, P. García-López, S. Méndez, A. Feria-Velasco, R. Franco-Bourland and J. Madrazo. Proyecto Camina, A.C., and U. Clin. Res. Neurological Diseases, IMSS, Mexico City, 14050, Mexico.

To compare the effect of several treatments for acute spinal cord (SC) injury, adult female inbred Fisher 344 rats were subjected to SC contusion with the method of Allen at T9 level, with an intensity of 45 g/cm. All rats received the corresponding management immediately after the injury. Five groups of 6 rats each were formed. Rats of a group were treated with methylprednisolone (MP), 3 doses (30 mg/kg IP) followed by 2 doses (60 mg/kg IM) during the first 24 h post-injury; other rats were transplanted in the SC injured area with dissociated cells (in Hanks solution) from sciatic nerve obtained from an inbred adult rat; in other rats a combination of MP and transplant as described before was used. Two groups were used as control: rats injected with Hanks solution in the SC injured area, and rats without any treatment (only contused). Rats were submitted to a battery of functional tests weekly during 8 weeks, then were killed to SC morphologic analysis. Comparing all groups, better functional outcome was observed in rats treated with MP only, even though this situation was reached from the second week to the end of the study. Rats of the control group without any treatment had the poorest functional score. Rats treated with transplantation only showed similar functional outcome compared with non-treated rats. Our hypothesis that the combination of MP and transplant of peripheral nerve will have the best functional outcome could not be sustained. In conclusion, under the paradigms used in this work, the best option to improve the functional outcome is the treatment with MP.

## 330.9

**THE INFLUENCE OF CYCLOSPORIN A TREATMENT AND XENOTRANSPLANT IMMUNOGENICITY ON HOST MHC EXPRESSION IN THE RAT MIDBRAIN** K.A. Czach\*, J.W. Ryan, G.D. Pappas, and J. Sagen, Dept. of Anatomy & Cell Biology, University of Illinois at Chicago, Chicago, IL, 60612.

Previously, it has been shown that a short course of cyclosporin A (CSA) is sufficient to achieve survival long-term survival of bovine adrenal chromaffin cells, BCCs, transplanted in rat brain. If immunosuppression is omitted before graft stabilization during these initial few weeks, the BCCs are rapidly rejected by the host. Since highly immunogenic passenger cells (e.g. endothelial, fibroblast, and smooth muscle cells) represent roughly 5% of the cell population, their role in graft rejection during this critical time needs to be assessed. To address this question, the influence of graft immunogenicity on host MHC I and II expression was determined. Rats were transplanted with either 1) isolated bovine chromaffin cells (approx. 95% pure) or 2) non-chromaffin cell constituents of the bovine adrenal medulla (NCC) or 3) isolated bovine adrenal endothelial cells. Half in each group were immunosuppressed with CSA for the duration of the experiment. Survival and MHC I and II were assessed using immunocytochemical staining at two weeks. Without CSA treatment, there was considerable graft degeneration in groups 2) and 3) that coincided with profound MHC I and II expression. In BCC transplants, graft rejection also occurred together with MHC I and II expression, but was less robust than groups 2) and 3). CSA treatment yielded healthy viable grafts with markedly decreased MHC I and II expression in all groups. In BCC transplants, no significant expression of MHC I and II was detectable in immunosuppressed animals. In summary, BCCs weakly induce host MHC expression as compared to NCC and endothelial cell transplants, and this can be completely eliminated by CSA treatment. Supported by NS25054.

## 330.11

**DIFFERENTIATION OF TRANSPLANTED NEURONAL PRECURSORS IS ALTERED IN THE LESIONED SPINAL CORD.** S.M. Onifer<sup>1,2</sup>, J.T. Pacheco<sup>1</sup>, S.R. Whittemore<sup>1,3</sup>. <sup>1</sup>The Miami Project to Cure Paralysis, Departments of <sup>2</sup>Neurological Surgery & <sup>3</sup>Physiology and Biophysics, University of Miami School of Medicine, Miami, FL 33136.

RN33B is a clonal neuronal cell line that was generated from dissociated, embryonic rat raphe nuclei following infection with a retrovirus encoding the temperature-sensitive allele of SV40 large T-antigen (Whittemore and White, *Brain Res.*, 615, 1993, 27-40). RN33B cells transplanted into the normal adult rat CNS differentiate with a morphology indistinguishable from that of endogenous neurons at the transplantation site (Onifer et al., *Exper. Neurol.*, 122, 1993, 130-142). These results suggest that RN33B cell differentiation in the adult CNS can be variably regulated by local epigenetic signals. The present study examines the differentiation of RN33B cells after transplantation into the adult CNS under different lesion conditions. Adult rats underwent unilateral lesion of interneurons and motor neurons in the cervical spinal cord by injecting 0.5% kainic acid into the grey matter of the C7 and C8 segments. Two weeks later,  $2 \times 10^5$  E. coli lacZ-labeled RN33B cells were transplanted into the grey matter at each segment. At 2 weeks post-transplantation,  $\beta$ -galactosidase immunohistochemistry revealed relatively undifferentiated RN33B cells throughout the grey matter. This observation contrasts with our previous finding that RN33B cells differentiated with a bipolar morphology similar to spinal interneurons 2 weeks after transplantation into the normal adult spinal cord grey matter. It also indicates that either the signal(s) which regulate RN33B cell differentiation is derived from interneurons, motor neurons, non-neural cells, and/or is suppressed by molecules released by the injured CNS tissue. To address this issue, experiments involving transplantation of RN33B cells into the selectively lesioned and chronically injured spinal cord are in progress. Supported by The Miami Project to Cure Paralysis, General Reinsurance, and NS26887.

## 330.13

**PROTEOGLYCAN AND GFAP EXPRESSION FOLLOWING SPINAL CORD INJURY AND INTRASPINAL TRANSPLANTATION.** M.L. Lemons\*, D.R. Howland and D.K. Anderson, VAMC and Dept. of Neuroscience, University of Florida, Gainesville, FL 32610.

Failure of injured axons to regenerate in the central nervous system is not fully understood. In an attempt to better understand the mechanisms that inhibit this neuritic outgrowth, we have examined an extracellular matrix molecule (ECM), chondroitin-sulfate containing proteoglycan (CSPG), which can inhibit neuritic outgrowth and is associated with astrocytes. We have studied the expression of this ECM and glial fibrillary acidic protein (GFAP) in three groups: sham injury (laminectomy only), spinal cord contusion injury and contusion plus a suspension of E14 fetal spinal cord tissue transplanted ten days post-injury. The thoracic spinal cords of adult rats were contused using the New York University impactor device. Immunocytochemical techniques were utilized to identify CSPG and GFAP one week or forty days post-injury. One week post-injury, GFAP positive cells were enlarged and their processes were prominent along motor neuron axons. Their processes also appeared to form a glial boundary by one week. CSPG was generally co-localized with GFAP. At forty days post-injury, GFAP positive cells remained enlarged and radiated from the gray to the white matter. CSPG followed the GFAP radiating pattern in the areas close to the gray-white matter border. Although fetal tissue transplants did not appear to reduce hypertrophy of GFAP positive cells, interruptions in the apparent glial boundary were observed. CSPG staining was reduced in the host but was still seen around the graft. To determine if axonal growth across the host-graft interface is greater in the absence or decreased expression of GFAP and/or CSPG, we are using immunocytochemical labeling of neurofilament protein, serotonin (to identify descending projections) and calcitonin gene related peptide (to identify segmental afferents). Supported by C.M. and K.E. Overstreet Foundation and Department of Veterans Affairs.

## 330.10

**XENOGRAFT REJECTION IN THE BRAIN: THE ROLE OF ASTROCYTIC AND NEURONAL CELLS.** A. Pagenstecher\*, P. Fisch, B. Volk, Dept. of Neuropathology, University of Freiburg, 79106 Freiburg, Germany.

Rejection of xeno- and allografts in the central nervous system is frequently variable and incomplete. The mechanisms of the immune response in the brain are yet not fully understood. To elucidate the role of astroglial and neural cells in graft rejection we transplanted cells from human glioma (U373MG) and human neuroblastoma (SH-SY5Y) cell lines into the rat striate body and into the skin. Furthermore, we determined the expression of surface antigens on the tumor cells by flow cytometry and the stimulation of rat lymphocytes in a proliferation assay.

While the SH-SY5Y cells proliferated in the host brain, the U373MG cells were rejected vigorously. This rejection was likely mediated by lymphocytes. In mixed U373MG/SH-SY5Y grafts, only the SH-SY5Y cells survived. In contrast, both cell types were rejected in the skin. FACS analysis revealed several antigens including MHC I and II on U373MG cells. IFN- $\gamma$  stimulation increased the expression of MHC antigens. Also, SH-SY5Y expressed B7.2 after IFN- $\gamma$  stimulation. Weak proliferative responses of rat lymphocytes to both cell lines were detected in vitro.

Our observations suggest an important role of astrocytes in the rejection of transplanted neural tissue. Expression of MHC I and II antigens by astrocytes is inducible by INF- $\gamma$ , a cytokine which is secreted by microglia in the course of tissue damage. Moreover astrocytes produce several cytokines e.g. IL-1 and IL-6 which stimulate the rat lymphocytes. Thus astrocytes act together with microglial cells as propagators of the immune response.

## 330.12

**DEVELOPMENT OF WHOLE EMBRYONIC RETINAL TRANSPLANTS ON BRUCH'S MEMBRANE IN RABBITS.** T. Grasbon, B. K. Sieglö\*, and B. Ehinger, Dept. of Ophthalmology, University of Lund, S-221 85 Lund, Sweden.

Ganglion cells are the only retinal cells which have not been convincingly demonstrated in embryonic retinal transplants to the eye. Such cells are needed if a transplant is to send axons to the brain. Therefore, trying to find a developmental window for ganglion cells, we examined transplants placed on Bruch's membrane. Such transplants mostly show good but inverted lamination. Several time points were examined.

Adult rabbits received a single 15 embryonic days old (E 15) rabbit neuroretina transplant. The transplantation tube was inserted into the subretinal space in such a way that the host pigment epithelium was scraped off, exposing the transplant directly to Bruch's membrane. Rabbits were enucleated at several transplant ages corresponding to E 26 up to postnatal day 26, and the eyes were fixed overnight in 4% paraformaldehyde. Cryostat section immunocytochemistry for ganglion cells was performed with an antibody against human protein gene product 9.5 (PGP 9.5, Ultraclone®).

Morphologically, the time course of the general transplant development was to a great extent similar to that of the normal retina. An inverted laminar organization was seen in the parts of the transplants facing denuded Bruch's membrane, particularly in the oldest transplants. A ganglion cell layer was apparent in the part of the transplant facing Bruch's membrane. However, there was no PGP immunoreactivity in the cells of the ganglion cell layer. It thus appears that the cells in this layer are mainly other cells than true ganglion cells and that the development of transplant ganglion cells is retarded and/or arrested before E26.

## 330.14

**STUDY OF THE ROLE OF PSA-NCAM IN THE DEVELOPMENT OF INTRASTRIATAL GRAFTS OF EMBRYONIC DOPAMINERGIC NEURONS.**

J.P. Herman\*, H. Becq, A. Enjalbert, <sup>1</sup>H. Cremer and <sup>1</sup>G. Rougon, Laboratoire des Interactions Cellulaires Neuroendocriniennes, CNRS UMR 9941 and <sup>1</sup>Laboratoire de Génétique et Physiologie du Développement, CNRS UMR 9943, Marseille, France

Polysialylated form of the neuronal cell adhesion molecule (PSA-NCAM) has been implicated in various phenomena in the developing nervous system, such as axonal elongation and/or bundling or cellular migration. Similar processes take place during the development of intracerebral neural grafts. The present study aimed at testing the role of PSA-NCAM in the development of such grafts. A cell suspension prepared from embryonic mesencephalon, and containing dopaminergic (DA) neurons, was implanted into the striatum of rat pups, the nigrostriatal DA pathway of which had been destroyed previously using the neurotoxin 6-OHDA. Neonatal hosts were chosen because in such hosts, in contrast with adult host, there is an effective migration of implanted cells into the host parenchyma. For half of the animals, the cell suspension to be implanted was incubated before implantation with a phage-derived endoneuraminidase that specifically cleaves the PSA moieties of PSA-NCAM. The absence of PSA does not seem to influence the development of implanted DA neurons, indicating that the role of PSA in cell migration and development of innervation is not universal. As a second approach to the same aim, we used NCAM knock-out mice as donors and/or hosts as developmental abnormalities observed in such mice have been attributed primarily to the absence of PSA. The development of grafted neurons in these conditions will also be presented.

## 330.15

THE REEXPRESSION OF TENASCIN AND CHONDROITIN SULFATE IN WOUNDS OF THE ADULT MOUSE STRIATUM, AND THEIR EFFECTS ON EMBRYONIC DOPAMINE CELL ATTACHMENT AND NEURITE GROWTH *IN VITRO*. **MA Gates and DA Steindler**, Dept. of Anat. & Neurobiol., The Univ. of Tennessee, Memphis, TN 38163.

Failed regeneration in the injured brain has been attributed to the formation of an impeding glial scar. Extracellular matrix (ECM) molecules, such as tenascin and chondroitin sulfate proteoglycans (CSPGs), which are known to have effects on neuronal adhesion and neurite outgrowth during development, are upregulated in and around adult brain wounds. In the present study, striatal wounds from adult mice were used as *in vitro* substrates (after various survival times *in vivo*) for dissociated dopamine neurons from the embryonic ventral mesencephalon. By removing striatal wounds before or after the upregulation of tenascin and/or CSPG, it was shown that dopamine cell attachment increased (compared to unwounded controls) in relation to the reexpression of these ECM constituents, yet there was a concomitant decrease in neurite growth corresponding to the presence of tenascin. Dopamine cell attachment in this culture paradigm was totally abolished when wounds were exposed to the CS-56 antibody before being used as a substrate. Similar perturbations with a tenascin antibody revealed a decrease in dopamine cell attachment, but a significant increase in dopamine cell neurite outgrowth. These data suggest that CSPG facilitates embryonic dopamine cell adhesion, and that tenascin may augment this process while simultaneously inhibiting neurite growth. This work has implications toward understanding the role of ECM during failed regeneration of the mature brain, as well as the influence that wound-related molecules may have on immature dopamine neurons that are sometimes grafted into the adult striatum. Supported by NIH/NINDS grant NS29225.

## 330.17

HOST NERVE FIBERS THAT REGENERATE AND RESIDE LONG-TERM IN A REJECTED NERVE ALLOGRAFT ARE NOT PROTECTED BY PERMEABILITY BARRIERS. **N. A. Azzam\*, A. A. Zalewski and R. N. Azzam**, Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892-4120.

Host nerve fibers can regenerate through a short length of nerve allograft in a non-immunosuppressed recipient despite the fact that allogeneic Schwann, vascular and perineurial cells are rejected. This regeneration occurs because host axons and Schwann cells utilize the basement membrane tubes of rejected Schwann cells as pathways for growth. We investigated whether permeability barriers develop and protect host nerve fibers in a rejected nerve allograft. In order for barriers to form, host cells have to enter the allograft and differentiate into endothelial and perineurial cells that respectively form the impermeable endoneurial blood- and perineurium-nerve barriers that are present in normal nerve. A 2-cm long graft of peroneal nerve was taken from American Cancer Institute (ACI) or Fischer (FR) rats and transplanted to bridge a 2-cm gap between the cut ends of the peroneal nerve of other FR rats. Six months postoperatively, light and electron microscopic histology revealed that regenerated host nerve fibers in rejected ACI allografts were compartmentalized into numerous minifascicles by perineurial cells and that blood vessels were located outside the perineurial compartments rather than interspersed among the nerve fibers. Administration of the permeability indicator horseradish peroxidase (HRP) to allograft recipients (i.e., intravenously or topically to the graft *in situ*), revealed that HRP entered the endoneurium of microcompartments and spread among and into the nerve fibers. In contrast, no HRP reached nerve fibers in non-immunogenic FR nerve grafts which survived and were histologically normal. We concluded that host nerve fibers that regenerate and reside long-term in a rejected nerve allograft were not protected by permeability barriers.

## 330.19

PLASTICITY OF LOCUS COERULEUS NEURONS DURING AGING: EVIDENCE FROM INTRAOCULAR TRIPLE TRANSPLANTS. **A.C. Granholm<sup>1,2</sup>, G.A. Gerhardt<sup>1</sup>, and N. Srivastava<sup>1</sup>**, Departments of Basic Science<sup>1</sup> and Pharmacology<sup>2</sup>, Univ. Colorado HSC, Denver, CO 80262.

The age-related plasticity of central noradrenergic neurons was investigated, using intraocular transplantation of fetal brain tissue. Tissue pieces of fetal brainstem tissue (E17) and hippocampal CA1 tissue (E18) were placed adjacent to each other in the anterior chamber of the eye of 3 months old Fischer 344 hosts. The double transplants were allowed to mature for 16 months, after which a second fetal hippocampal tissue piece was placed next to the brainstem transplant. The triple transplants were then allowed to grow for an additional 2 months *in oculo*. Immunohistochemical studies of the triple transplants demonstrated that tyrosine hydroxylase (TH)-immunoreactive neurons in the brainstem transplant innervated both the young (2 months old) and the aged (18 months old) hippocampal transplants with a dense network of thin, varicose fibers. Furthermore, the aged double transplants exhibited a denser pattern of astrocytes than the young hippocampal grafts, as evidenced with glial fibrillary acidic protein immunohistochemistry. All three transplants displayed an intact blood-brain barrier, and contained significant densities of synaptic profiles, which were visualized with antibodies directed against synapsin. Electrophysiological and electrochemical properties of the noradrenergic innervation of the young and the aged hippocampal components of the triple grafts are currently under investigation. The present data demonstrate that aged locus coeruleus neurons maintain their ability to innervate appropriate targets, at least at 18 months of age in the rat. Thus, aging does not appear to impair the endogenous plasticity of these neurons. Supported by USPHS grants AG12122 and MH49661.

## 330.16

GRAFTS OF THE CHOROID PLEXUS INTO THE BRAIN PRODUCE A PERMANENT OPENING OF THE BLOOD-BRAIN-BARRIER (BBB).

**J.M. Rosenstein\***, Departments of Anatomy and Neurological Surgery, The George Washington University Medical Center, Washington, D.C. 20037

Our previous studies have shown that when tissue containing permeable vessels such as autonomic ganglia or adrenal medulla is grafted to the brain it produces a permanent and focal opening in the BBB such that large proteins may enter the host parenchyma where normally they would not. Autonomic tissues, however either degenerate or become encapsulated by connective tissue or reactive astroglia. This report describes studies using the choroid plexus (CP) which is comprised of fenestrated vessels and epithelial cells as a viable tissue to produce a permanent opening in the BBB. Small (0.5mm<sup>3</sup>) pieces of rat E18-19 choroid plexus or corgrafts of choroid and neocortex from the same donor fetus were placed in the host cortex or striatum. After survival periods up to 6 months, the host animals were examined immunocytochemically for antibodies to rat serum albumin (SA), the BBB glucose transporter (GLUT1) and GFAP. Some hosts also received a systemic injection of <sup>3</sup>H GABA which does not cross the BBB. By the latest time examined the CP grafts survived almost entirely intact. Immunostaining for SA showed a focal leakage of protein extending 0.5-0.8 mm from the graft into the host and co-graft neuropil at both light and electron microscopic level. GLUT1 staining showed that the graft vessels retained their non-CNS phenotype and there was only minor astroglial (GFAP) reactivity. Radiolabelled GABA was sequestered by some graft neurons. These results would indicate that the fetal choroid could be useful as a biological portal across the BBB and may provide a window for focal ingress of systemically administered bioactive materials. (NS-17468).

## 330.18

DEPLETION OF MAJOR HISTOCOMPATIBILITY COMPLEX (MHC)-BEARING CELLS FROM EMBRYONIC RAT SPINAL CORD. **N.A. Pennell\*, A.G. Rabchevsky, and W.J. Streit**, Dept. Neuroscience, Univ. of Florida, Gainesville, FL 32610

It is common practice among researchers and clinicians to use immunosuppressive agents, such as cyclosporin A and FK 506, to prevent neural allograft rejection. However, immunosuppression causes increased susceptibility to secondary infection and the tissue is still subject to rejection should the agent be removed. While immunosuppression is designed to prevent the amplification of an already existing immune response, efforts would be better aimed at preventing the initiation of the immune response itself.

Major Histocompatibility Complex (MHC) antigens are expressed on the surfaces of three types of cells in the CNS; microglia, perivascular cells or pericytes, and endothelial cells. These cells, when grafted into an allogeneic host, are recognized as foreign and instigate an immune response against the graft. Presumably, if these cells were removed from grafted neural tissue, the remaining cells would not be recognized as foreign and the immune response would be attenuated or absent.

The B<sub>2</sub>-isolectin from *Griffonia simplicifolia* (GSL I) binds microglia and endothelial cells specifically among cells of the rat CNS. In this study, we have created highly viable single cell suspensions of E14 rat spinal cord tissue and tested the feasibility of depleting these suspensions of GSL I-binding cells, thus removing the majority of MHC-expressing cells. The suspensions were incubated with GSL I-conjugated Dynabeads and the bound cells were pulled out utilizing a magnetic particle concentrator. Depleted and control suspensions were analyzed histochemically for GSL I expression. Freshly depleted suspensions showed significant lack of GSL I expression in comparison to non-depleted suspensions. In addition, depleted suspensions showed similar lack of GSL I expression after one week in culture, indicating that the depleted cell populations were not replaced by endothelial or microglial progenitors within the fetal tissue. Future studies will involve transplanting the depleted suspension into an allogeneic rat strain and analyzing the graft for strain-specific MHC expression.

## 330.20

REGULATION OF L-DOPA PRODUCTION BY GENETICALLY MODIFIED PRIMARY FIBROBLASTS WITH RETROVIRAL VECTOR

**A. Ishida<sup>1</sup>, K. Yamashiro, J. Mukawa, M. Hasegawa**, Dept. of Neurosurgery, Faculty of Medicine, Univ. of the Ryukyus, 207 Uehara, Nishihara-cho, Okinawa 903-01, JAPAN. DNABVEC Reserch Inc., 25-11, Kannondai 1-chome, Tsukuba-shi, Ibaraki 305, JAPAN

Intracerebral grafting is a new strategy of the treatment for Parkinson's disease. We focused on primary skin fibroblasts. Rat primary skin fibroblasts were transfected with a retroviral vector containing the cDNA (pLTHSNL) for human tyrosine hydroxylase type I (TH) or cytomegalovirus promoter (pCTHSNL) as a foreign promoter. These cells were measured by immunocytochemistry and high performance liquid chromatography with electrochemical detection (HPLC-ECD) analysis of L-DOPA production and release *in vitro*. When supplemented with bipterin (BH4; (6R)-L-erythro-tetrahydrobiopterin) cofactors required for TH activity, these cells produced and released L-DOPA into the culture medium, especially fibroblasts containing a foreign promoter increased in releasing L-DOPA in time-dependent manner. This suggest that production of L-DOPA from genetically modified fibroblasts can be regulated by foreign promoter and BH4. This character was not affected by the number of cell-passage and freeze. Because retroviral vector including the foreign gene (THcDNA) integrate into chromosomal DNA of the target cells (fibroblasts). Primary skin fibroblasts can be obtained and cultured easily. And these cells did not produce tumors by transfection with a retroviral vector.

In conclusion, genetically modified primary skin fibroblasts transfected with THcDNA using retroviral vector must be a worthy graft for gene therapy in Parkinson's disease.

## 331.1

AN "IN VITRO" DYNAMIC MODEL OF BLOOD-BRAIN BARRIER. D. Janigro and K. A. Stanness, Dept. of Neurosurgery, ZX-18 University of Washington, Seattle, WA 98104

Cell culture models have been widely used for screening of neurotoxins and represent a viable alternative to direct *in vivo* experiments. We have developed a dynamic *in vitro* blood-brain barrier (BBB) model designed to allow for extensive pharmacological and physiological testing. Induction of blood-brain barrier properties in a tri-dimensional hollow fiber culturing apparatus (CellCo Inc.) were investigated by co-culturing a bovine aortic cell line and rat brain endothelial cell with rat brain astrocytes (or C6 rat glioma cells) under pulsatile flow conditions to mimic intraluminal blood flow. Cell growth was monitored over time by measuring glucose consumption and lactate production: these experiments confirmed that the hollow fiber cell culturing systems can maintain viable cells in culture for extended (>1 month) periods of time. Cells were visually inspected after culturing and dissociation from the hollow fiber cartridge and identified as endothelial (by fluorescent DiI-Ac-LDL uptake) or glial (by GFAP immunoreactivity). BBB properties were tested by intraluminal injection of horse-radish peroxidase (HRP, mol. weight 44,000), glucose (m.w. 180) or potassium. Either procedure demonstrated that BAEC co-cultured with astrocytes (or C6 cells) developed a selective barrier with an estimated electrical resistance of  $2,900 \Omega/\text{cm}^2$ . The electrophysiological and morphological properties of BAEC were also affected by the co-culturing process, suggesting that astrocytes induced CNS properties in these cells. These results demonstrate that the hollow fiber cell co-culturing system may be used as a dynamic model of mammalian blood-brain barrier for both pharmacological and neurotoxicological studies. Supported by NS 51614.

## 331.3

EXPRESSION OF BLOOD-BRAIN BARRIER CHARACTERISTICS FOLLOWING NEURONAL LOSS USING A SUICIDE TRANSPORT AGENT. J.M. Krum\*, K. Kenyon, and J.M. Rosenstein, Dept. of Anatomy, George Washington University Medical Center, Washington, D.C. 20037

Recent studies have suggested that astrocytes can induce certain endothelial blood-brain barrier (BBB) characteristics *in vitro*. There is also some evidence that neurons may influence BBB marker expression. The aim of this *in vivo* study is to determine whether the expression of certain BBB markers will change following neuronal loss in a localized area of the cerebrum. To effect neuronal death, adult rats were given intrastriatal injections (1-3  $\mu\text{l}$ ) of the immunotoxin OX7-SAP. OX7-SAP is a conjugate of a Thy-1 antibody and the ribosome inactivating protein saporin. Since Thy-1 antigen is expressed only on adult rat neurons throughout the CNS, OX7-SAP is an effective neurotoxic agent. At the injection site, neuronal degeneration, angiogenesis and gliosis occur in an area proportional to the volume of the injection, with the larger volumes forming a cystic area by two weeks postinjection. The immunocytochemical expression of BBB markers, including the brain endothelial glucose transporter (GLUT-1) and permeability to endogenous protein (rat serum albumin - RSA) were examined together with astroglial, macrophage and neuronal markers from one to six weeks after the injection. Preliminary results indicate that the barrier to endogenous protein had not reformed even after four weeks, despite dense astrocytic reactivity. In contrast, the vasculature maintained expression of GLUT-1 throughout the lesioned area, and most notably in regions of granulation tissue that lacked both astroglia and neurons. These results suggest that astrocytes may not be the sole regulating factor for BBB maintenance *in situ*. (Supported by NS-17468).

## 331.5

PHARMACOKINETICS AND BLOOD-BRAIN BARRIER (BBB) TRANSPORT OF [ $^3\text{H}$ ]-BIOTINYLATED PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDE COUPLED TO A VECTOR-MEDIATED DRUG DELIVERY SYSTEM. D. Wu, R.J. Boado, B. Howard\*, and W.M. Pardridge, Depts. of Medicine and Biological Chemistry, UCLA School of Medicine, Los Angeles, CA 90024.

Phosphorothioate oligodeoxynucleotides (PS-ODN) are potential neuropharmaceuticals, should these highly charged anionic molecules be made transportable through the brain capillary endothelial wall, which makes up the BBB *in vivo*. The present studies examine the extent to which BBB transport of a PS-ODN may be enhanced by coupling to a vector-mediated drug delivery system. The vector is comprised of a conjugate of streptavidin (SA) and the OX26 monoclonal antibody to the rat transferrin receptor. The PS-ODN was an 18-mer complementary to the *gag* gene and nucleotides 5551-5568 of the human immunodeficiency virus (HIV)-1 genome. The PS-ODN was synthesized with a 3'-biotin moiety and 5'-amino group, which allowed for tritiation with [ $^3\text{H}$ ]-N-succinimidyl propionate. In the absence of conjugation to the vector, the BBB transport of the PS-ODN was negligible. Following conjugation of the [ $^3\text{H}$ ]-bio-PS-ODN to the OX26/SA vector, the BBB transport of the ODN was appreciable with a BBB permeability-surface area (PS) product of  $5.2 \mu\text{l}/\text{min}/\text{g}$ , as measured with an internal carotid artery perfusion method. However, following intravenous injection, the BBB PS product of the [ $^3\text{H}$ ]-bio-PS-ODN/OX26-SA was 30-fold lower,  $0.17 \pm 0.01 \mu\text{l}/\text{min}/\text{g}$ . The inhibition of BBB transport of the PS-ODN conjugated to the OX26/SA vector following intravenous injection was attributed to avid plasma protein binding of the PS-ODN. The inclusion of physiologic concentrations of plasma proteins to the internal carotid artery perfusate resulted in a reduction of the BBB transport of the PS-ODN. In summary, the advantages of metabolic stability conferred by the use of PS-ODN is offset by the avid plasma protein binding of PS-ODNs, and this binding retards the BBB transport *in vivo* of PS-ODNs conjugated to vector-mediated delivery systems.

## 331.2

CHEMICAL INDUCTION OF FENESTRAE IN VESSELS OF THE BLOOD-BRAIN BARRIER. M. Kaya, L. Chang, A. Truong, M. Brightman\*, LN, N.I.H., Bethesda, Md. 20892

Some brain microvessels, normally impermeable to circulating solutes, become fenestrated (FV) and permeable when they enter brain tumors. It is shown here for the first time, that retinoic acid (RA) and phorbol myristate acetate (PMA), both known to *re-induce* fenestrae in adrenal gland vessels *in vitro*, induce fenestrae in blood-brain barrier capillaries *in vivo*. When  $100 \mu\text{M}$  RA or  $150 \text{ ng/ml}$  PMA are infused by an osmotic pump for 28 d into cerebral cortex, some brain vessels around the cannula site became FV. In 2 rats given RA, tissue identified as being near the cannula, contained FV. In 4 rats infused with PMA, about 1/3 of the total number of 136 were FV, with a range of 13 to 56. A total of 329 remained continuous, like those of the blood-brain barrier, with a range of 13 to 138. In one rat, there were 56 FV and 58 continuous microvessels. Only those vessels at the interface of brain and cannula, where the concentration of reagent should be highest during delivery, became fenestrated. Fenestra formation was irreversible for at least one month. One month after cannula removal, fenestrae persisted in some vessels and exogenous, circulating peroxidase tracer could exude from vessels.

## 331.4

HISTOLOGICAL CHANGES DURING THE FIRST DAYS FOLLOWING INTRAPERITONEAL ADMINISTRATION OF GOLD THIOGLUCOSE. A. Czurko<sup>1</sup> and F. Gallyas<sup>2</sup>, SPON; European Neuroscience Association, Inst. of Behavioral Sciences<sup>1</sup> and Inst. of Neurosurgery<sup>2</sup>, Pécs Univ. Med. School, H-7643 Pécs, Hungary.

Histopathological changes in the mouse brain during the first days following intraperitoneal administration of gold thioglucose were examined. For the demonstration of blood brain barrier dysfunction anti mouse IgG immunocytochemistry was used. Diffuse neuronal damage was demonstrated by a special silver method selectively staining "dark" (collapsed) neurons.

At the 12th hour after gold thioglucose administration the blood brain barrier opened in two isodimensional hypothalamic areas next to the median eminence. Diffuse neuronal damage was observed only in a  $200 \mu\text{m}$  thick hypothalamic zone bordering them. No morphologically damaged neurons were seen in any hypothalamic areas before the appearance of blood brain barrier disturbance. The size of the foci with opened blood brain barrier considerably increased with time while the "dark" neuronal damage did not "infiltrate" hypothalamic areas far from these foci.

These findings support the idea that gold thioglucose-induced disturbance of feeding behavior is caused by a parenchymal lesion having its origin in the opening of the blood brain barrier rather than by a putative selective vulnerability of certain hypothalamic neurons to gold thioglucose.

## 331.6

KINETICS OF [D-PENICILLAMINE- $^2,5$ ]ENKEPHALIN (DPDPE) ENTRY ACROSS THE BLOOD-BRAIN AND BLOOD-CSF BARRIERS. S. A. Williams, T. J. Abbruscato, V. J. Hruby and T. P. Davis\*, Departments of Pharmacology and Chemistry, University of Arizona, Tucson, AZ 85724.

Previously in our laboratory we have found that intravenously administered DPDPE, a  $\delta$  opioid-receptor selective enkephalin, can enter the CNS and produce analgesia (*J. Pharm. Exp. Ther.* 259, 1109-1117). Its route of CNS entry has also been investigated and has been shown to occur mainly through the blood-brain barrier (BBB), the blood-CSF barrier playing only a minor role. The aim of this present study was to further characterize the kinetics of the uptake of DPDPE into the CNS, by means of a vascular brain perfusion technique. Adult rats were anaesthetized and heparinized, the carotid arteries cannulated and perfusion started with an oxygenated, mammalian Ringer. The jugular veins were sectioned and [ $^3\text{H}$ ]DPDPE, in the presence of unlabelled DPDPE (0-0.1 mM), was infused into the perfusion medium for 20 minutes. A cisterna magna CSF sample was taken and the animal decapitated. Brain, CSF and perfusate samples were then taken for radioactive counting. These experiments revealed a saturable [ $^3\text{H}$ ]DPDPE uptake into brain that followed Michaelis-Menten kinetics with a  $K_m$  of  $1.87 \pm 0.82 \mu\text{M}$  and  $V_{max}$  of  $3.34 \pm 0.31 \text{ pmol} \cdot \text{min}^{-1} \cdot \text{g}^{-1}$  ( $n=39$ , 5 concs;  $\pm \text{S.E.M.}$ ). These values are similar to those achieved with arginine-vasopressin (*Biochim. Biophys. Acta*, 1025, 191-198). However, in the presence of 0.1 mM unlabelled DPDPE, uptake of [ $^3\text{H}$ ]DPDPE into the CSF could not be inhibited. The non-saturable component,  $K_d$ , was significantly different from zero for both brain  $0.88 \pm 0.10$  and CSF  $0.89 \pm 0.07 \mu\text{l} \cdot \text{min}^{-1} \cdot \text{g}^{-1}$ . We conclude that using this brain perfusion technique in the anaesthetized rat, [ $^3\text{H}$ ]DPDPE entry into the CNS can occur by a high affinity saturable transport mechanism, which is likely to be found at the BBB. However, [ $^3\text{H}$ ]DPDPE can also enter into brain and CSF by non-saturable mechanisms. This work supported by NIDA #DA-06284.

## 331.7

BLOOD-BRAIN BARRIER PERMEABILITY AND BIOAVAILABILITY OF A POTENT AND SELECTIVE MU OPIOID RECEPTOR ANTAGONIST, CTAP. T.J. Abbruscato\*, S.A. Williams, V.J. Hruby, T.P. Davis. Departments of Pharmacology and Chemistry, University of Arizona, Tucson, AZ 85724

CTAP (D-Phe-Cys-Tyr-D-Trp-Arg-Thr-Pen-Thr-NH<sub>2</sub>) is a cyclic octapeptide that is structurally related to somatostatin. It displays greater antagonist potency and a greater degree of selectivity for mu opioid receptors than the classical mu-selective antagonist CTOP (D-Phe-Cys-Tyr-D-Trp-Orn-Thr-Pen-Thr-NH<sub>2</sub>). These investigations attempt to characterize the ability of CTAP to cross the blood-brain and the blood-CSF barriers of the rat using a vascular brain perfusion technique. Adult rats were anaesthetized and the carotid arteries cannulated. Perfusion was performed with an oxygenated mammalian Ringer and outflow was through the sectioned jugular veins. Radiolabelled CTAP and sucrose were introduced into the perfusate via a slow-drive syringe. After a set perfusion time, a cisterna magna CSF sample was taken and the animal decapitated. The uptake of radiolabelled CTAP and sucrose into the brain and CSF was expressed as the percentage ratio of tissue to plasma activities (RTissue, mean  $\pm$  S.E.M. ml g<sup>-1</sup>; n=4-6).

Time	<sup>3</sup> H]CTAP		<sup>14</sup> C]sucrose	
	RBrain	RCSF	RBrain	RCSF
2.5min	0.023 $\pm$ 0.003	0.005 $\pm$ 0.001	0.014 $\pm$ 0.003	0.003 $\pm$ 0.011
10min	0.038 $\pm$ 0.002	0.025 $\pm$ 0.035	0.017 $\pm$ 0.002	0.014 $\pm$ 0.004
20min	0.044 $\pm$ 0.003	0.052 $\pm$ 0.012	0.018 $\pm$ 0.001	0.012 $\pm$ 0.002

Results show that the brain and CSF uptake of <sup>3</sup>H]CTAP was significantly greater than that of <sup>14</sup>C]sucrose. (P<0.01; Students t-test). In addition, protein binding studies revealed that <sup>3</sup>H]CTAP bound extensively (45.1%) to the 0.1% bovine serum albumin in the perfusion medium thereby limiting the bioavailability of CTAP. These data suggest that <sup>3</sup>H]CTAP can cross the blood-brain and the blood-CSF barriers of the rat. This work is supported by NIDA #DA-06284.

## 331.9

NITRIC OXIDE SYNTHASE INHIBITION BY BREFELDIN IN CEREBROVASCULAR ENDOTHELIUM IS REVERSIBLE. A. M. Morin\*, A. Stanboli, A. Pham, F. Solamo and L. Te, V.A. Medical Center\*, Sepulveda, CA and Dept. Neurology, UCLA School of Medicine, Los Angeles.

Nitric oxide synthase (NOS) can be visualized in paraformaldehyde-fixed cultured cerebrovascular endothelium (CVE) cells by NADPH diaphorase activity and immunostaining with anti-endothelial NOS antibody. CVE NOS is predominantly membrane-bound and appears to be associated with the Golgi complex (GC) in a unique juxtanuclear position (Morin A. & A. Stanboli, J. Neurosci. Res. 36(1993)272-279). Exposure of the CVE to Brefeldin A (BFA), a mold metabolite which binds to specific ADP-ribosylation factor recognition sites on the Golgi complex, inhibits NOS activity. Decreased production of <sup>3</sup>H-citulline from <sup>3</sup>H-arginine was observed when CVE were pretreated with BFA for 90min ( $\downarrow$  78%) during which time the GC became disrupted and dispersed into the cytoplasm. NADPH diaphorase staining was also dispersed. BFA also inhibited NOS when present only during the 15min assay ( $\downarrow$  44%). BFA inhibition of NOS was reversible after removal of the compound and 4hrs recovery. GC and NADPH diaphorase staining also returned to pre-BFA-exposure state. BFA inhibits the binding of specific ADP-ribosylation factors (ARFs) to the GC in brain (Tsai et al., J. Biol. Chem., 268(1993) 10820-10825). These ARFs bind GTP very tightly and are required for the integrity of the secretory processes of the GC. The role of NOS at the GC remains to be elucidated but appears likely to involve a membrane-mediated stimulation of ADP-ribosylation.

## 331.11

PERMEABILITY AT THE BLOOD-BRAIN AND BLOOD-NERVE BARRIERS OF THE NEUROTROPHIC FACTORS: NGF, CNTF, NT3, BDNF Joseph F. Poduslo\* and Geoffrey L. Curran, Molec. Neurobiol. Lab. Mayo Clinic and Foundation, Rochester, MN 55905

A comparison was made of the permeabilities of different neurotrophic factors at the BBB and BNB in normal adult rats by quantifying the permeability coefficient-surface area (PS) product after correction for the residual plasma volume (V<sub>p</sub>) occupied by the protein in the capillary bed. The I.V. bolus injection technique was used in the cannulated brachial vein and artery using the same protein radiiodinated with a second isotope of iodine (<sup>125</sup>I vs. <sup>131</sup>I) to separately determine the PS and V<sub>p</sub> values. The plasma washout showed a decreasing plasma half-life in the order of BDNF < NT3 < CNTF < NGF. The PS at the BNB for NGF was 1.40  $\pm$  0.15  $\times$  10<sup>-6</sup> ml/g/s ( $\bar{x} \pm$  SEM). The other neurotrophic proteins were all significantly higher than NGF (CNTF: 9.5X; NT3: 20.8X; BDNF: 18.9X). The V<sub>p</sub> for NGF was 1.92  $\pm$  0.12  $\mu$ l/g and was not significantly different from the other proteins except for NGF vs. BDNF (P < 0.05). The PS at the BBB for NGF ranged from 1.5 to 2.7  $\times$  10<sup>-6</sup> ml/g/s for six different brain regions. The PS for CNTF ranged from 6.0 - 8.0 fold higher than NGF; NT3: 10.6 - 15.2 fold higher; and BDNF: 11.3 - 16.4 fold higher. The V<sub>p</sub> values were not significantly different except for CNTF in the hippocampus and cortex (P < 0.05) (ANOVA). SDS-PAGE analyses of all the radiiodinated neurotrophic proteins after 60 min of uptake revealed intact protein in the endoneurium and in the six different brain regions with exposure times of 2-42 days. The quantification of the permeability of these neurotrophic proteins provides baseline values for comparison of different protein modifications that enhance the PS while still preserving the neurotrophic activity (e.g., protein glycation; see Molec. Brain Res. 23, 157, 1994).

## 331.8

EXTENDED MODEL OF THE BINDING SITE OF THE CEREBROVASCULAR LARGE NEUTRAL AMINO ACID TRANSPORTER. Mitsuhiro Hokari and Quentin R. Smith\*. Lab. of Neurosciences, National Institute on Aging, NIH, Bethesda MD 20892.

The structure of the binding pocket of the cerebrovascular large neutral amino acid transporter (System L1) was probed by competitive inhibition of L-[<sup>14</sup>C]leucine uptake into brain using various cyclic aliphatic and aromatic L-amino acid analogs. Solute affinity was estimated as the inverse of the concentration that gave 50% inhibition of cerebrovascular L-[<sup>14</sup>C]leucine transport into brain using the *in situ* rat brain perfusion technique. L-[<sup>14</sup>C]leucine influx was shown to be mediated by a single, BCH-inhibitable mechanism (System L1) that exhibited strong preference for amino acids with hydrophobic side chains. The apparent linear relation between transport affinity and amino acid side chain hydrophobicity, which was first noted in 1987, was extended 2-orders of magnitude in the hydrophobic direction using various long-chain aliphatic and aromatic amino acids with octanol/water partition coefficients ranging from 0.1 to 300. Marked preference was noted for the meta-substituent position of L-phenylalanine, though the para position could be used with appropriate modification. Hydrophobic non-amino acid analogs were also identified that inhibited transport, thus demonstrating that the amino acid functional group was not required for binding activity. The minimum dimensions of the binding pocket cavity were probed with hydrophobic amino acids with fixed ring structures. From these data, a preliminary 3-dimensional model was developed of the L1 system binding site that will be of use in future studies of brain amino acid transport.

## 331.10

CHANGES IN THE EFFLUX OF ACIDIC AMINO ACIDS FROM BRAIN TO BLOOD WITH MATURITY IN RATS. H. Al-Sarraf, J.E. Preston\*, M.B. Segal. Physiology Dept., UMDS, London SE1 7EH, UK. \*ACIOG, King's College, London.

The acidic amino acids, aspartate (Asp) and Glutamate (Glu), are major excitatory neurotransmitters in the CNS. Their brain concentrations exceed plasma concentration by 20-100 fold (Price et al, 1990). In our earlier studies, we have shown a decline in the entry from blood to brain of Asp and Glu with age in the rats (Al-Sarraf et al, 1994). In this investigation using the bilateral *in situ* brain perfusion (Preston et al, 1995), the efflux of these amino acids from brain to blood was studied in adult and 2 week old rats. The brain was perfused with Ringer containing <sup>14</sup>C-Asp or <sup>14</sup>C-Glu for 10 min. The perfusion was then continued with <sup>14</sup>C-free perfusate for a further 20 min and samples of the jugular venous outflow taken at 30 sec intervals. The *ln* dpm in each sample was then plotted against sample time and the half time (t<sub>1/2</sub>) was measured (Preston et al, 1993). The t<sub>1/2</sub> for 2 week old Asp was 16.16  $\pm$  0.76 min, while that for the adult was 10.06  $\pm$  0.46 min (means  $\pm$  sem, n=3-4). Glu t<sub>1/2</sub> was also smaller in the adult which was 50% of the 2 week old value. The above results, in addition to our previous studies, suggest that the systems involved in the influx and efflux of the acidic amino acids into and out of the brain, favour increased brain levels of amino acids in the developing brain.

## 331.12

REGIONAL DIFFERENCES IN BLOOD-BRAIN BARRIER TO ALBUMIN IN NORMAL AND SENESCENCE-ACCELERATED MICE. A.W. Viorbodr\*, D.H. Dobrogowska and M. Ueno. NYS Institute for Basic Research in Develop. Disabilities, Staten Island, NY 10314.

The blood-brain barrier (BBB) to endogenous albumin was studied in the cerebral cortex, hippocampus, pons and bulbus olfactorius of senescence-accelerated prone (SAMP8) and senescence-accelerated resistant (SAMR1) mouse strains in corresponding age groups (4-month-old and 12-month-old). Ultrathin sections of immersion-fixed brain samples embedded in Lowicryl K4M were exposed to anti-albumin antiserum followed by protein A-gold. The density of immunosignals (gold particles per  $\mu$ m<sup>2</sup>) was recorded over four compartments: vascular lumen, endothelium, subendothelial space, and the neuropil. Morphometric and statistical analysis indicated that the barrier function of the capillaries located in the cerebral cortex and pons of SAMP8 mice was not significantly different from that in control (SAMR1) mice, although the percentage of leaking capillaries was higher in SAMP8 in both age groups. In the hippocampus, significantly higher extravasation of albumin in SAMP8 than in SAMR1 mice was observed, even in 4-month-old animal groups. Also, the labeling density of the hippocampal neuropil of both groups of mice was significantly higher than that in the cerebral cortex. These observations suggest that blood-borne albumin has access to the parenchyma of the hippocampus, presumably from the barrier-free areas such as the subfornical organ, and that this phenomenon is more pronounced during aging. Only in the bulbus olfactorius were some capillaries and larger microvessels (presumably venules) leaking in both control and SAMP8 groups, although in the latter group, older animals (12-month-olds) show an increased percentage of leaking vessels up to 35%, as compared to 10% in controls. These data indicate that the BBB in the olfactory bulb is not as tight as it is in other examined brain regions. (Supported by the National Institute on Aging, grant R01-AG 10279-04).

## 331.13

CIS-ELEMENT/CYTOPLASMIC PROTEIN INTERACTIONS BETWEEN THE 3'-UNTRANSLATED REGION OF THE HUMAN GLUT1 GLUCOSE TRANSPORTER mRNA AND CYTOSOLIC PROTEINS IN HUMAN BRAIN TUMORS. H. Tsukamoto, R.J. Boado, C. Markham\*, K.L. Black, and W.M. Pardridge. Depts. of Medicine, Neurology, and Surgery/Neurosurgery. UCLA School of Medicine, Los Angeles, CA 90024.

The principal glucose transporter at the blood-brain barrier is GLUT1, and mechanisms of GLUT1 gene expression may be evaluated in human brain tumors. High grade gliomas express the GLUT1 glucose transporter mRNA but have depressed levels of the immunoreactive protein, suggesting possible post-transcriptional mechanisms of GLUT1 gene expression. The interactions of cytosolic proteins isolated from human glioblastoma multiforme (GBM) with specific sequences within the 3'-untranslated region (UTR) of the GLUT1 mRNA were evaluated with RNase T1 protection assays. Full-length human GLUT1 mRNA was prepared from a transcription plasmid and, following protection by binding with GBM cytosolic proteins, was degraded with RNase T1. The protected RNA fragments were cross-linked to cytosolic proteins using ultraviolet (UV) light and separated by SDS-PAGE. These studies identified complexes of 120, 44, and 41 kDa molecular weight. The formation of the complexes was inhibited by high concentrations of unlabeled competitor GLUT1 mRNA. Cis sequences were mapped with RNase T1 to the region of nucleotides 2173-2224 of the GLUT1 mRNA. Competition studies with specific oligodeoxynucleotides further defined the location of the cis-regulatory region to nucleotides 2186-2203, which specifically bound to the 120 kDa protein. The 44/41 kDa complex was overexpressed in GBM compared to a human hemangioblastoma, a tumor that overexpresses GLUT1 immunoreactive protein. These studies support the hypothesis that GLUT1 gene expression in human brain tumors is subject to post-transcriptional regulation involving cytosolic proteins and specific cis sequences within the 3'-UTR of the GLUT1 mRNA.

## 331.15

THE EFFECT OF AMMONIUM ON POTASSIUM ENTRY INTO THE BRAIN, CHOROID PLEXUS AND CSF OF THE RAT. K.A. Smart and M.B. Segal\*, Physiology Dept., UMDS, London, SE1 7EH, UK.

During acute liver failure, it is well known that plasma  $\text{NH}_4^+$  levels rise to in excess of three times their normal plasma concentration ( $39.9 \pm 3.7 \mu\text{M}$ ). For this reason,  $\text{NH}_4^+$  is believed to be one of the major toxins involved in the clinical symptoms of Hepatic Encephalopathy (Schenker et al, 1974). It has also been proposed that lipid insoluble  $\text{NH}_4^+$  crosses the blood brain barrier (BBB) by competing with  $\text{K}^+$  at channels and carrier molecules of the BBB (Cooper and Plum, 1987). Using the bilateral in situ brain perfusion technique of Preston et al (1995), and dextran density capillary depletion analysis, we have established a unidirectional uptake profile for  $\text{K}^+$  ions using  $^{86}\text{Rb}$  as a marker molecule.  $K_{in}$  values were calculated for brain tissue, choroid plexuses (CP), CSF, and capillary endothelial cells (CE), for  $^{86}\text{Rb}$  alone, and  $^{86}\text{Rb}$  in the presence of  $1\text{mM NH}_4^+$  ions:

	Brain	CP	CSF	CE
$^{86}\text{Rb}$	$4.10 \pm 0.113$	$75.45 \pm 1.3$	$5.75 \pm 0.54$	$0.38 \pm 0.18$
$^{86}\text{Rb} + \text{NH}_4^+$	$3.03 \pm 0.115$	$49.54 \pm 0.9$	$4.70 \pm 0.18$	$0.86 \pm 0.15$

Values are means  $\pm$  sem, in  $\mu\text{L} \cdot \text{min}^{-1} \cdot \text{g}^{-1}$ , (n=6).

The above results may suggest that  $\text{NH}_4^+$  ions inhibit  $\text{K}^+$  uptake at the abluminal face of the BBB, due to the accumulation of  $^{86}\text{Rb}$  in the CE in the presence of  $\text{NH}_4^+$ . Separate experiments using  $^{22}\text{Na}$  as a permeability marker, have shown that the permeability and integrity of the BBB are not altered by  $\text{NH}_4^+$ .

## 331.17

THE PRESENCE OF ARGININE VASOPRESSIN IN THE CHOROID PLEXUS OF THE BRATTLEBORO RAT. A. Chodobska\*, S. Corsetti, J. Szmjdynger-Chodobska, P.R. Monfils, and C.E. Johanson. Program Neurosurg., Dept. Clin. Neurosci. and Central Res. Labs., Brown Univ./R.I. Hospital, Providence, RI 02903.

Arginine vasopressin (AVP) has been shown to be produced in several peripheral tissues in the *diabetes insipidus* Brattleboro rats despite the lack of the central AVP synthesis in these animals. In the present study, we demonstrate by immunohistochemistry the presence of AVP in the choroid plexus of the homozygous (*di/di*) Brattleboro rats. Animals were perfused transcardially with 4% paraformaldehyde. Choroid plexuses were subsequently dissected and postfixed for 2 h at  $4^\circ\text{C}$  in paraformaldehyde solution. Free-floating tissue was incubated with polyclonal rabbit anti-AVP antibodies (Incstar; 1:1000-1:2000) for 68 h at  $4^\circ\text{C}$ . The immunopositive reaction was visualized by using secondary antibody (biotinylated donkey anti-rabbit IgG) and streptavidin-biotin-peroxidase complex. DAB-NiSO<sub>4</sub> was used as a chromogen. A distinct pattern of AVP-immunopositive staining was detected in the choroid epithelium, with the immunoreactive product predominantly localized close to the apical (CSF-facing) membrane of epithelial cells. This AVP-immunopositive staining of choroid tissue was similar to that observed in AVP-competent animals. As expected, no AVP-immunopositive neurons were found in both paraventricular and supraoptic hypothalamic nuclei of Brattleboro rats. The ability of choroid epithelium to produce AVP in Brattleboro rats may be due to the presence of AVP synthetic pathways that are alternate to those operating in hypothalamic neurons. Supported by RIH RD Grant 7512-01-95 and by NIH Grant NS27601.

## 331.14

IN VIVO PHOTOLABELING AND VISUALIZATION OF BLOOD-BRAIN BARRIER GLUT1 GLUCOSE TRANSPORTER. Nathan, M., Appel\*, Mitsuhiro Hokari, Fran Maher, Ian A. Simpson, Quentin B. Smith and Susan J. Vannucci. FDA CDER, Laurel, MD 20708; NIDDK and NIA LNS, Bethesda, MD 20892; Pediatrics, Penn. State U., Hershey, PA 17033.

The 55 kDa form of the GLUT1 glucose transporter protein in cerebral microvessels mediates glucose transport from blood into brain. It appears to be asymmetrically distributed across endothelial cells with the greater proportion on the abluminal membrane. Acute and chronic changes in glucose transport rate into brain may be mediated by a redistribution of GLUT1 transporters. The impermeant photolabel 2-N-4-[<sup>3</sup>H](1-azido-2,2,2-trifluoroethyl) benzoyl - 1,3-bis-(D-mannose-4-yloxy) - 2 - propylamine ([<sup>3</sup>H]ATB-BMPA) binds to exofacial glucose transporters. We used this to develop a method to quantitate and visualize GLUT1 present on luminal membranes of cerebral microvessels. Brains of anesthetized male Sprague-Dawley rats were perfused through a carotid artery with 1 mCi [<sup>3</sup>H]ATB-BMPA in the absence or presence of 0.5 mM cytochalasin B. The brains were collected, cut into slabs and irradiated with high intensity UV light. Microvessels or 15  $\mu\text{m}$  cryostat sections were prepared from the slabs. Binding to GLUT1 was quantitated from solubilized extracts of microvessels and by Western blot analysis. There was significant incorporation of [<sup>3</sup>H]ATB-BMPA into 55 kDa GLUT1 and it was inhibited by cytochalasin B. Autoradiography revealed grains in registration with vascular endothelium. These data demonstrate the feasibility of quantifying GLUT1 glucose transporters on the blood brain barrier luminal surface *in vivo* and of assessing alterations in accessible GLUT1 under experimental and pathological conditions.

## 331.16

IMMUNOHISTOCHEMICAL LOCALIZATION OF ARGININE VASOPRESSIN IN RAT CHOROID PLEXUS. J. Szmjdynger-Chodobska\*, S. Corsetti, N. Limthong, P.R. Monfils, C.E. Johanson, and A. Chodobska. Program Neurosurg., Dept. Clin. Neurosci. and Central Res. Labs., Brown Univ./R.I. Hospital, Providence, RI 02903.

Arginine vasopressin (AVP) has been shown both *in vivo* and *in vitro* to regulate the secretory function of the choroid plexus. In the present study, we demonstrate by immunohistochemistry the presence of AVP in rat choroid tissue. Both polyclonal rabbit anti-AVP (Incstar) and anti-vasopressin-associated neurophysin (NP) (provided by Dr. A.G. Robinson of University of Pittsburgh) antibodies were used. Rats were perfused transcardially with 4% paraformaldehyde. Choroid plexuses were subsequently dissected and postfixed for 2 h at  $4^\circ\text{C}$  in paraformaldehyde solution. Free-floating tissue was incubated with primary antibodies (1:1000-1:2000) for 68 h at  $4^\circ\text{C}$ . The immunopositive reaction was visualized by using secondary antibody (biotinylated donkey anti-rabbit IgG) and streptavidin-biotin-peroxidase complex. DAB-NiSO<sub>4</sub> was used as a chromogen. A distinct pattern of both AVP- and NP-immunopositive staining was detected in the choroid epithelium, with the immunoreactive product predominantly localized close to the apical (CSF-facing) membrane of epithelial cells. The AVP-ergic innervation was not found to be present in the choroid plexus. Similar to choroid epithelium, the AVP-immunoreactive staining was also identified in the tracheal secretory epithelium. Our findings suggest that AVP plays a role in the regulation of epithelial secretory function. Supported by RIH RD Grant 7512-01-95 and by NIH Grants NS27601 and AM16166 (A.G. Robinson).

AGRIN EXPRESSION ON BRAIN CAPILLARIES DEVELOPS SIMULTANEOUSLY WITH THE BLOOD-BRAIN BARRIER. A. Barber\* and E. Lieth. Dept. Neurosci. & Anat., Penn. State Med. Sch., Hershey, PA 17033.

Agrin organizes components of the post-synaptic membrane at the neuromuscular junction (NMJ), but is also found on brain capillaries, where it may function at the blood-brain barrier (BBB). Expression of vascular agrin on capillaries with or without selective barrier properties in various rat and chick tissues was therefore compared by double label immunohistochemistry using monoclonal antibodies to agrin and a specific endothelial cell marker.

In tissues with vascular diffusion barriers (brain, choroid plexus, retina, kidney and testicle) capillaries are agrin immunoreactive (IR) while in other tissues such as heart, skeletal muscle and liver agrin IR is not evident on microvessels. On adult brain microvessels agrin IR forms a continuous layer around the entire surface of both *in situ* and isolated brain capillaries and is indistinguishable from laminin IR, consistent with localization at endothelial cell basal lamina. Over the period of BBB development on rat microvessels weakly stained patches of agrin IR are present before embryonic day 14 and coalesce into bright, continuous tubes by postnatal week 2, while in chick brain vascular agrin IR is first observed at E9 and maximizes just before hatching.

The selective expression of agrin at the developing BBB and capillaries with barrier properties in other tissues suggests that agrin is a component of the BBB and may, by analogy to its function at the NMJ, organize the other components of the BBB.

## 331.19

EXPRESSION OF THROMBOMODULIN mRNA IN BOVINE BRAIN CAPILLARIES. L. Wang<sup>1</sup>, N. D. Tran, J. Goodman, J. G. McComb, M. H. Weiss, S. S. Schreiber and B. V. Zlokovic. Dept. of Neurosurg. and Divn. of Neurosurg. CHLA, USC Sch. Med., Los Angeles, CA 90033.

Thrombomodulin (TM) is normally expressed at the luminal surface of endothelial cells from the systemic circulation. TM serves as a binding site for thrombin and the thrombin-TM complex activates protein C which shifts the hemostatic balance toward anticoagulation. The evidence for the presence of TM in brain microvascular endothelium, i.e., at the blood-brain barrier (BBB), is controversial. In this study we used isolated bovine brain capillaries as a model system to examine the expression of TM at the mRNA level. By using the reverse transcription-polymerase chain reaction (RT-PCR), we were successful in amplifying 707 basepair (bp) fragment of the TM coding sequence (primer pair from nucleotides 228-256 and 908-935) from cortical capillaries. TM mRNA was absent from capillary-depleted brains. Next, we determined whether there are regional differences in TM capillary expression. The amount of TM mRNA from capillaries obtained from the cortex, pons and cerebellum were compared by competitive quantitative PCR. A modified PCR mutagenesis technique was used to synthesize the TM competitor, a TM fragment of equivalent length containing a unique Sal I restriction site. Preliminary analysis revealed that the TM mRNA was most abundant in cortical capillaries, while its level of expression was significantly lower in cerebellar capillaries. Pons capillaries expressed only very little TM mRNA. It is concluded that the BBB may have a role in promoting the protein C anticoagulation pathway within brain microcirculation, and that this function may be region dependent.

## GENE STRUCTURE AND FUNCTION II

## 332.1

AN ALTERNATIVE PROMOTER IN THE MOUSE ACETYLCHOLINESTERASE GENE? E. Atanasova, S. Chiappa and S. Brimijoin<sup>1</sup> Dept. of Pharmacol., Mayo Clinic, Rochester, MN 55905

Despite advances in the molecular neurobiology of acetylcholinesterase (AChE), regulation of the AChE gene in neurons is poorly understood. A minimal promoter has been identified, but alternative promoters may exist. We examined this possibility using RAGE (Rapid Amplification of Genomic Ends), a PCR method to amplify unknown genomic DNA next to known sequences. Mouse genomic DNA and Bluescript II SK(+) plasmid were digested in separate reactions with one of several restriction endonucleases and ligated to each other. Using the ligated samples as templates, two consecutive PCR amplifications were performed with nested pairs of Bluescript-specific primers and AChE primers targeted at the 5' end of the known genomic sequence. With XhoI digests, a 761 bp DNA product was obtained, which extended 5' from the cap site to position -1261. Digoxigenin-labeled RAGE DNA hybridized to the same clones in a mouse genomic library as full length AChE cDNA. Analysis of the RAGE sequence revealed potential binding sites for transcription factors including SP1, ATF/CREB, AP2, clustered Myo D and NFkB. One CCAAT box was found, but no typical TATA box. To test for promoter activity, RAGE-DNA was linked to the open reading frame of a luciferase reporter in a pGL2 vector and transfected into NIE.115 neuroblastoma. Cell lysates were tested for luciferase activity at 48 & 72 h. Compared with a positive control (luciferase gene + SV40 promoter & enhancer) the RAGE construct yielded 15% as much luciferase activity, over 4 times the yield from a promoterless construct. Therefore the RAGE sequence can serve as a weak AChE promoter in neuronal cell culture. Whether it does so *in vivo* remains to be determined.

## 332.3

MOLECULAR MECHANISMS OF INCREASED EXPRESSION OF DOPAMINE  $\beta$ -HYDROXYLASE BY STRESS E.L. Sabban<sup>1</sup>, B. Nankova<sup>1</sup>, R. Kvetnansky<sup>2</sup> and B. Hiremagalur<sup>1</sup>. <sup>1</sup>Dept. Biochem & Mol. Biol., New York Medical Coll., Valhalla, NY 10595; <sup>2</sup>Inst. Exp. Endocrinology, Bratislava, Slovakia.

Dopamine  $\beta$ -hydroxylase (DBH) gene expression is elevated *in vivo* and *in vitro* by a number of physiologically relevant treatments. Cloning of the 5' upstream region of the gene (McMahon & Sabban, 1992, JNC, 52, 2042-2047) revealed several putative promoter elements which may be involved in regulation of DBH including 3 putative glucocorticoid regulatory sites. Another element termed DBH-1, was shown to be involved in induction of DBH expression by cAMP and phorbol esters in cell cultures (Shaskus et al., 1992, JBC, 267, 18821-30). Our previous studies found activation of DBH gene expression with immobilization stress. The aim of this study was to analyze the molecular mechanism of this regulation. Increased binding to adrenomedullary nuclear factors to DBH-1 was observed with repeated IMO by electrophoretic mobility shift analysis. Specific antisera and UV-cross linking indicated that the complex contains fos-related proteins, but not c-fos. Site directed mutation of DBH-1 showed that, the more distal of two adjacent putative cAMP-regulatory sites in DBH-1, is involved in the binding.

To test the possible additional involvement of glucocorticoid regulatory elements, the requirement for an intact adrenocortical axis and for neuronal inputs to the adrenal in the stress elicited changes in DBH gene expression was studied.

## 332.2

YY-1 REGULATES THE TRANSCRIPTIONAL LEVEL OF HUMAN DOPAMINE  $\beta$ -HYDROXYLASE GENE BY TPA STIMULATION.

H. Ishiguro<sup>1</sup>, K. Yamada, T. Nagatsu and K. Fujita. Institute for Comprehensive Medical Science, School of Medicine, Fujita Health University, Toyoake, Aichi 470-11, Japan.

Dopamine  $\beta$ -hydroxylase (DBH) converts dopamine to norepinephrine and is specifically expressed in noradrenergic and adrenergic neurons. Cyclic AMP response element (CRE, TGACGTCC) of human DBH gene is an essential transcriptional element in the promoter region. In downstream of this CRE, there are three important DNA elements such as YY-1 binding sequence (CCAT), E-box (CANNTG), and AP-1 like sequence (TGTGTCA) that may regulate the transcription of many genes.

To identify the DNA binding proteins, 26 bp oligonucleotide (actgatGACGTCCATGTGTCAattag) was used as a probe for the electrophoretic mobility shift assay (EMSA). According to the site-directed mutagenesis, both CRE and YY-1 binding sequence formed complexes with proteins, but E-box and AP-1 like sequences did not. The addition of CRE oligonucleotides for tyrosine hydroxylase (TH) and somatostatin genes as competitors eliminated upper-shifted bands that were formed with CRE and CRE binding protein (CREB or ATF). Furthermore, an excess amount of oligonucleotide that is the YY-1 binding sequence of *c-fos* gene as a competitor, completely eliminated the intermediate-shifted band. In order to assess the function of YY-1 binding to the CCAT motif, transient transfection experiments were performed in the DBH-expressing neuroblastoma cells (SK-N-SH). Site-directed mutagenesis experiments indicated that YY-1, a ubiquitously expressed zinc finger type DNA binding protein, positively regulated the transcriptional level of human DBH gene by the phorbol ester (TPA) stimulation. These data suggest that YY-1 is important in the transcriptional regulation of DBH gene.

## 332.4

ADJACENT CRE-LIKE AND HOMEODOMAIN SITES IN THE PROMOTER OF THE RAT DOPAMINE  $\beta$ -HYDROXYLASE GENE CAN CONTRIBUTE INDIVIDUALLY TO SECOND MESSENGER RESPONSES. D.J. Swanson, E. Zellmer, Z. Zhang, E.J. Lewis<sup>1</sup>. Dept. Biochemistry and Molecular Biology, Oregon Health Sci. Univ., Portland OR, 97201

Dopamine  $\beta$ -hydroxylase (DBH), the enzyme which converts dopamine to norepinephrine, is expressed in a cell-type restricted manner in neuroendocrine tissues which secrete norepinephrine and epinephrine. Studies have suggested that the regulation of DBH gene expression by activators of cAMP/PKA second messenger systems may contribute to the tissue specificity of gene expression. We have previously identified a pair of homeodomain (HD) core recognition sites (ATTA) within the proximal 230 bp of the promoter of the rat DBH gene. Adjacent to the 5' HD domain are two CRE-like domains separated by a single base pair. Through systematic deletion and mutational analyses of a wild-type DBH (-230/+14)-CAT construct we have examined the contribution of these recognition sequences in cAMP/phorbol ester-regulated induction of reporter gene expression.

Mutation or deletion of one of the pair of CREs and/or HDs had no effect on the cAMP/PMA induction of reporter gene expression. There was, however, a marked decrease (5-10 fold) in induction following the deletion or disruption of both CRE domains or both HD core sites separately. This effect was most severe when both CRE and HD sites are deleted. These findings suggest that either domain within the CRE-like pair or HD pair is functional in the 2nd messenger response from this proximal portion of the DBH promoter. Furthermore, it appears that the maintenance of at least one of each CRE and HD site is required for a normal 2nd messenger response.

Preliminary studies have also shown that cotransfection of the wild-type 5' DBH-reporter construct with a DNA binding protein which specifically recognizes either core HD site augments the reporter induction by cAMP. Taken together these findings suggest a possible interaction between these two adjacent promoter proximal regulatory regions of the DBH gene. This interaction may contribute to the tissue specificity of DBH expression.

## 332.5

PROMOTER ELEMENTS AND SECOND MESSENGERS MEDIATING FGF-2 INDUCTION OF TYROSINE HYDROXYLASE TRANSCRIPTION. H. Osaka\*, A. Menezes and E.L. Sabban, Dept. Biochemistry & Molecular Biology, New York Medical College, Valhalla, NY 10595.

Basic fibroblast growth factor (FGF-2) play important roles in neuronal development and survival. Among the effects of FGF-2 in PC12 cells are induction of c-fos and neurite outgrowth. Treatment of PC12 cells with increasing concentrations of FGF-2 elevated tyrosine hydroxylase (TH) mRNA levels in a concentration dependent manner, maximal at 1-8 days of exposure. Promoter elements responsible for induction by FGF-2 were examined by transient transfection of plasmids containing the chloramphenicol acetyl transferase (CAT) reporter gene under control of the TH promoter. Previous studies showed that mutation of the AP1-like site (-205 to -199) of the TH promoter did not prevent the induction of transcription by FGF-2. In this regard, inhibition of protein kinase C by bisindolylmaleimide prevented the rise in CAT activity by TPA, but not by FGF-2. A TH promoter construct spanning -60 to +27 was sufficient for induction of CAT reporter activity by FGF-2. This construct contains the CRE/CarE and part of a putative AP2 site. Mutagenesis and gel-shift analysis were conducted to assess the contribution of these elements in TH mRNA induction by FGF-2.

## 332.7

ANGIOTENSIN II REGULATION OF TYROSINE HYDROXYLASE GENE PROMOTER ACTIVITY IS MEDIATED BY MULTIPLE ELEMENTS. E. Kim, M.K. Stachowiak, Barrow Neurological Institute, Phoenix AZ 85013.

In adrenal chromaffin cells (AMC) angiotensin II stimulates transcription of the TH gene by acting through cAMP- and Ca<sup>2+</sup>/PKC-signaling pathways. The roles of CRE- and TRE-like sequences in regulation of bovine TH gene promoter activity were examined by transfecting TH promoter-luciferase constructs into bovine AMC. Mutation of CRE did not affect basal promoter activity but it reduced stimulation with angiotensin from 2.9- to 1.75-fold. A similar reduction was observed when TRE was mutated. Mutation of TRE resulted in reduction of basal promoter activity (-60%) indicating a dual function of this element. The TRE site overlaps with dyad symmetry element (DSE) suggesting regulation by interacting transcriptional factors. DNA mobility gel shift assays detected protein binding to TRE but not to DSE. DSE was sensitive to digestion with S1 nuclease in supercoiled plasmid DNA. Pattern of S1 digestion is consistent with extrusion of cruciform-like structure in which the right arm of TRE is included in cruciform stem. Mutation that disrupts symmetry of DSE prevented secondary structure and enhanced angiotensin stimulation, from 2.2- to 4.4-fold. This enhancement was abolished by additional mutation of TRE. Together, our observations suggest that: (1) both CRE and TRE mediate angiotensin stimulation, and (2) the function of TRE in bovine TH gene promoter is modulated by an extrusion of secondary structure within overlapping DSE (supported by NIH).

## 332.9

SPECIES DIFFERENCES IN THE 5' FLANKING REGION OF THE RODENT OXYTOCIN RECEPTOR GENE. L. J. Young\* and T. R. Insel, Dept. of Psychiatry and Behavioral Sciences, Emory University, Atlanta GA 30322

Oxytocin and its receptor are involved in the control of complex, species-specific social behaviors such as sexual, maternal and pair bonding behaviors. The neuroanatomical distribution of oxytocin receptors differs greatly among species. These differences in oxytocin receptor distribution are thought to be responsible for species differences in behavior patterns. In order to better understand the molecular basis of the species differences in oxytocin receptor expression in the brain, we have cloned and sequenced the 5' flanking region of the oxytocin receptor gene from two species of microtine voles (*Microtus ochrogaster* and *M. montanus*) which differ extensively in oxytocin receptor distribution in the brain as well as in social behaviors. The two vole species share 99% nucleotide homology in the 1300 bp sequence upstream of the transcription start site. However, two potential cis regulatory elements in this region differ between the species. In contrast, the 5' flanking region of the oxytocin receptor in the rat differs considerably from that of the voles. Although the rat and vole share 90% nucleotide homology in the coding region, the homology drops to 60% in the first 500 bp of the 5' flanking region and is unrecognizable beyond that. As a result, the pattern of potential cis regulatory elements differs greatly between the species. These differences may be responsible for the species differences in oxytocin receptor gene expression in the brain and provide a potential mechanism for the evolution of species-typical social behaviors. We are currently testing this hypothesis using transgenic technology with an oxytocin receptor promoter construct.

## 332.6

An Ets-like Transcription Factor(s) Affects Cell-Type Specific Expression of the Rat Tyrosine Hydroxylase Gene in PC12 Cells. S. C. Wong\*, M. A. Moffat, and K. L. O'Malley, Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Previously we have shown that sequences between -505 and -575 of the rat tyrosine hydroxylase (TH) promoter contribute to cell-type specific expression when introduced into the rat PC12 cell line. Sequence analysis of this 75 bp region revealed the presence of a consensus interferon response factor (IRF-1) binding site (AAGTGG) and two consensus Ets-binding sites (GGAATA). Electrophoresis mobility shift assays (EMSA) using oligonucleotides with mutagenized IRF-1 and Ets-binding sites indicated that neither the IRF-1 site nor the 5' Ets-binding site contributed to the cell-type specific EMSA pattern observed in PC12 versus HepG2 cell lines. Instead the 3' Ets motif was critical for this response. UV crosslinking experiments showed the molecular weight of the putative transcription factor interacting with the 3' Ets-binding site to be approximately 52 kD, which is in the size range of the Ets-like protein family. We used oligonucleotides complementary to Ets proteins, Ets-1 and Ets-2, coupled with RT-PCR and cycle sequencing to show that only Ets-2 is present in PC12 cells. Co-transfection experiments were performed using -575 and -505 TH promoter/Luciferase reporter gene constructs together with Ets-1 sense, Ets-1 anti-sense and Ets-2 sense expression vectors. None of these Ets constructs affected luciferase activity in PC12 cells; however, co-transfection of Ets-2 with the -575 TH promoter construct increased reporter gene activity in HepG2 cells at least 5-fold. These data imply that Ets-2 or an Ets-like factor can regulate TH gene expression in immortalized cell lines. Ets proteins have been shown to play a role in cell growth and differentiation by forming heterodimers with other Ets family members or other non-Ets transcription factors. Conceivably other cell-type specific factors interact with the Ets-like molecule binding the GGAATA motif in the rat TH promoter to generate the observed pattern of expression.

## 332.8

HUMAN VGF PROMOTER: HOMOLOGY TO RAT AND CELL TYPE SPECIFIC EXPRESSION. N. Canu, R. Possenti\*, A.M. Rinaldi, E. Trani, B. Giovannone and A. Levi, Institute of Neurobiology CNR, Via K. Marx 43, 00137 Rome, Italy.

VGF is a neuroendocrine specific gene which is transcriptionally induced by the nerve growth factor NGF in the rat PC12 cell line. To better understand the molecular mechanism involved in transcriptional regulation and tissue specific expression of VGF, we have isolated the human gene and its 5' flanking region by screening a human genomic library with a rat probe. We sequenced a 3 kb region upstream of the ATG and by primer extension analysis we localised the transcription initiation site of the gene 29 nt downstream the TATA box. Comparison with the rat sequence revealed striking homology, especially notable over 400 bp upstream the transcription initiation site. This region, previously shown to be the core promoter of the rat VGF gene, displays a high concentration of transcription factors binding sites including TATA box, CCAAT box and cAMP responsive element as well as AP-2 and Sp1 consensus sequences. Furthermore the overall structure of the gene is conserved since all these elements are localised to comparable distance with respect to the transcription initiation site, both in the human and rat gene. The 3kb genomic DNA fragment (-2300/+718) was fused in front of the CAT reporter gene and tested for transcriptional activity by transient transfection in several cell lines. This sequence was able to drive high expression of the reporter gene when transfected in neuronal cell lines. The region between -175/+718 was both necessary and sufficient for cell specific expression. Deletions which affect the integrity of the cAMP responsive element, dramatically reduced the induction by NGF and cAMP of the recombinant plasmids transfected in PC12 cell line. Supported by PF: ACRO and Intecchiamento by C.N.R.

## 332.10

BOTH UPSTREAM AND INTRAGENIC SEQUENCES OF THE HUMAN NEUROFILAMENT LIGHT GENE DIRECT EXPRESSION OF lacZ IN NEURONS OF TRANSGENIC MOUSE EMBRYOS. L. Leconte, O. Semonin, A. Zvara, S. Boisseau, C. Poujeol, R. Kado\* and M. Simonneau, Laboratoire de Neurobiologie Cellulaire & Moléculaire du CNRS, 91198 Gif sur Yvette & LIRBA, Ecole Normale Supérieure de Cachan, 94235 Cachan Cédex, France. Molecular mechanisms generating post-mitotic neurons from dividing neuroblasts remain largely unknown in mammals. One strategy is to identify DNA sequences which are sufficient to direct neuronal specificity during embryogenesis. During the development of the mouse embryo, initial expression of the neurofilament coincides with the appearance of post-mitotic neurons and axon extensions. To investigate the molecular mechanisms involved in neuron-specific gene expression during embryogenesis, we generated transgenic mice expressing the lacZ reporter gene under the control of various genomic regions of the human neurofilament light gene (hNf-L). We found that 2.3 or 0.3 kb of the hNf-L promoter region directs expression of lacZ specifically in neurons of transgenic embryos. Addition of the 1.8 kb of the hNf-L intragenic sequences (including first and second introns) to hNf-L promoter constructs gave a broader neuronal expression pattern of the transgene. Furthermore, the use of an heterologous promoter such as the mouse heat shock promoter allowed demonstration that the 1.8 kb hNf-L intragenic sequences alone are sufficient to direct neuron-specific expression of lacZ. We conclude that these hNf-L intragenic sequences contain cis-acting DNA regulatory elements that specify neuronal expression (Leconte et al., 1995 J. Molecular Neuroscience, in press). Taken together, these results show that the neurofilament light gene contains separate upstream and intragenic elements, each of which directs lacZ expression in embryonic neurons.

We are presently using these constructs to direct the expression of modified potassium channels in neurons. (Supported in part by FRM & DRET).

## 332.11

SIGNIFICANCE OF THE TRE (AP-1 BINDING SITE) IN THE GLUCOCORTICOID REGULATION OF THE GFAP PROMOTER ACTIVITY IN CULTURED ASTROCYTES. I. Rozovsky\*, B. Teter, K.K. Krohn, T.H. Hogan and C.E. Finch. Andrus Gerontology Center, Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089.

Transcriptional regulation of GFAP by corticosterone (CORT) in primary cultured astrocytes is influenced by the duration of time in culture and by astrocyte-neuron interactions. In short-term cultures (3 weeks) CORT strongly increased GFAP transcription rate, mRNA, and protein. In contrast, in cultures maintained for 12 weeks, the direction of GFAP response by CORT switched to a decrease, the *in vivo* phenotype of response ("the switch"). The 1.9 kb of the 5'-upstream region of the rat GFAP promoter contains sufficient information to mediate the switch in the direction of GFAP response to CORT. Short- and long-term astrocytes *in vitro* were transiently transfected with the rat GFAP promoter nested-deletion constructs with luciferase reporter. Further analysis of the CORT responsiveness of these promoter constructs revealed a potential role for the TRE (AP-1 binding site) at -1501 in mediating the switch. We also showed synergistic effects of two glucocorticoid response elements in the GFAP promoter sequence that are involved in the regulation of GFAP transcription by CORT in short-term astrocyte cultures.

These findings are relevant to analysis of GFAP responses to neurodegeneration in transgenic mice models which use the human GFAP promoter constructs. (Supported by AG-07909 to CEF).

## 332.13

TRANSCRIPTIONAL ENHANCEMENT BY ELEMENT(S) LOCATED IN THE FIRST INTRON OF THE MYELIN PROTEOLIPID PROTEIN GENE. P.A. Wight\* and A. Dobretsova. Dept. of Physiol. & Biophysics, Univ. of Arkansas for Med. Sci., Little Rock, AR 72205.

The myelin proteolipid protein (PLP) gene is expressed primarily in oligodendrocytes, although low levels have been detected in Schwann cells and cardiac myocytes. We have previously demonstrated that transgenic mice expressing a PLP-lacZ fusion gene regulated the transgene in both a spatial and temporal manner, consistent with endogenous PLP expression. Given that: 1) PLP intron A sequences were maintained in the transgene, and 2) the structure of the PLP gene is highly conserved, with the first intron accounting for almost half of the gene, we hypothesized that important transcription regulatory element(s) might reside in PLP intron A. To test this hypothesis, deletion-transfection analysis was performed with PLP-lacZ fusion genes that contained 2.4 kb of PLP 5'-flanking DNA downstream to the Apal site in exon 2 with various deletions of PLP intron A DNA, driving expression of the lacZ reporter gene. The PLP-lacZ fusion genes were used to transiently transfect an immortalized oligodendroglial cell line N20.1 or NIH3T3 cells. Reporter gene expression was lower in both N20.1 and NIH3T3 cells transfected with a construct that contained a PstI deletion in intron A sequences compared to cells transfected with a construct that contained all of intron A DNA, although the degree of diminution was greater in the N20.1 cells. To see if the diminution could be explained by the presence of enhancer elements contained within the deleted portion of PLP intron A DNA, various portions of PLP intron A sequences were tested in an "enhancer-trap" assay using constructs that contained the luciferase reporter gene driven by the basal HSV thymidine kinase (TK) promoter. With this system, we have identified a 541 bp fragment from PLP intron A that enhances the level of luciferase expression by the heterologous TK promoter.

## 332.15

A 5' FLANKING SEGMENT OF MOUSE ZIC GENE MEDIATES NEURAL TISSUE SPECIFIC GENE EXPRESSION IN TRANSGENIC MICE. J. Aruga<sup>1</sup>\*, K. Shimoda<sup>2</sup> and K. Mikoshiba<sup>1,3</sup>. <sup>1</sup>Mol. Neurobiol. Lab. RIKEN, Tsukuba, Ibaraki 305, Japan, <sup>2</sup>Sch. of Med., Keio Univ. <sup>3</sup>Inst. of Med. Sci., Univ. of Tokyo

Zic is a novel zinc finger protein which we identified as a nuclear factor expressed in the cerebellar granule cell lineage in a highly restricted manner. The gene shows a significant homology to the recently cloned *Drosophila* paired-rule gene, *odd-paired*. We found that *zic* is also expressed in dorsal half of neural tube at certain embryonic stage and human medulloblastoma, whose oncogenesis is involved in the cerebellar granule cell lineage. Recent our study indicates that there are several *zic* related gene in mouse genome.

To explore how *zic* expression is restricted, we determined the genomic organization and promoter elements of *zic* gene. We cloned and sequenced 8 kb region of mouse *zic* gene including the 5' flanking region. The mouse *zic* gene is a single gene composed of 3 exons, in which the zinc finger motif is divided into 3 exons. In the 5' flanking region, there are several regulatory elements which have been implicated in neural tissue specific gene expression. In order to define the regulatory region, we first produced transgenic mice bearing  $\beta$ -galactosidase gene linked to a 2.8 kb 5' flanking segment of the mouse *zic* gene. We observed that 2.8 kb of the 5' flanking is capable of restricting the transgene expression in nervous tissue that mimics the spatial and temporal expression of the endogenous gene. Transfection assays in a *zic*-expressing neuroblastoma cell line indicate that strong promoter activity is located in a proximal 246 bp segment while the upstream region contains a negative regulatory elements.

## 332.12

IDENTIFICATION OF A PHORBOL ESTER RESPONSE ELEMENT IN THE RAT GALANIN GENE PROMOTER. J.D. Corness, P.H. Burbach\*, A. Pramanik\*, T. Hökfelt. Dept. of Neuroscience, Karolinska Institute, 17177 Stockholm, Sweden. \*Dept. of Medical Pharmacology, Rudolf Magnus Institute for Neurosciences, Utrecht University, 3584 CG Utrecht, The Netherlands.

Expression of the neuropeptide galanin has been shown to be affected by a diverse range of conditions *in vivo* (e.g. salt loading, axotomy), yet the molecular mechanisms responsible for these changes are largely unknown. We have recently cloned a genomic fragment of the rat galanin gene for the purpose of studying the regulatory elements which confer transcriptional regulation of this gene to its promoter. The study of transcriptional control has been focused on the 5' flanking region of the clone, which totals 6.0Kb in length. Constructs of various lengths have been made from this region, which consist of DNA extending 5' from the transcriptional start site. In addition, PCR-generated mutant promoter constructs have been created with short-sequence deletions. Each of these fragments have then been coupled to a luciferase reporter gene and transfected into the placental cell line JEG-3. Following transfection, reporter gene expression was studied in response to 12-O-tetradecanoyl-phorbol-13 acetate (TPA), a direct activator of protein kinase C and a known stimulator of c-jun/c-fos complex-mediated transcription. As a result of these treatments, we have been able to identify a putative phorbol ester response element located within 100 base pairs of the transcription start site for the galanin gene. Furthermore, gel shift mobility assays demonstrated specific binding of nuclear HeLa-cell extracts containing c-jun/c-fos protein complexes to a 31bp PCR-generated fragment corresponding to a sequence within this region of the promoter. We conclude that a functional phorbol ester response element is present in the 100bp proximal region of the rat galanin gene promoter.

## 332.14

DEFINING CIS-REGULATORY ELEMENTS THAT CONTROL EXPRESSION OF THE RAT SKELETAL MUSCLE TYPE 1 (SKM1) SODIUM CHANNEL GENE. S.D. Kraner\*, R. Kleinfield, M. Rich, & R.L. Barchi. Dept. of Neuroscience, Univ. of Pennsylvania, Philadelphia, PA, 19104-6074.

A rat genomic library was screened with oligonucleotide probes directed against the SkM 1 5'untranslated region. A 3.1 kb clone encoding 222 bp of intronic sequence, the first exon (80-90 bp), and 2800 bp of 5'flanking sequence was selected for further study. Transcriptional start sites were determined by both RNase protection and 5'RACE. A fragment from -2800 to +26 was inserted in front of the reporter gene for chloramphenicol acetyl-transferase (CAT) and the resulting construct, as well as nested 5'deletions thereof, were tested in transient expression assays using rat primary muscle cells and NIH 3T3 cells. The full-length construct and deletions up to -192 consistently exhibited 10-fold greater expression in primary muscle cells. Deletion to -82 resulted in a 12-fold increase in CAT activity in 3T3 cells with only a concomitant 2-fold increase in primary muscle cells. The activity of this repressor could be transferred to a heterologous promoter, although the repressor was more tissue-specific on its native promoter. In addition to this repressor, a positive element located within a 210 bp fragment encoding sequences +27 to +68 of the first exon and 168 bp of the first intron was discovered by similar analysis. This positive element can work in either orientation downstream of the promoter, but does not work in front of the promoter. Together the positive and negative element confer 18-fold higher CAT activity in primary muscle cells than in 3T3 cells. Supported by USPHS grant NS 18013.

## 332.16

MOLECULAR CHARACTERIZATION OF THE PROMOTER REGION OF NEURON-SPECIFIC HEL-N1: EVIDENCE FOR ENHANCED TRANSCRIPTIONAL ACTIVITY IN NEURAL CELLS. P.H. King and J.N. Whitaker\*. Dept. of Neurology, University of Alabama, Birmingham, AL 35294.

Hel-N1 (human *glav*-like neuronal protein) belongs to a family of neural-specific genes that are homologous to the *Drosophila* prototype, *elav* (*embryonic-lethal abnormal visual*). This gene family encodes highly conserved RNA-binding proteins which are expressed at the earliest stages of neuronal differentiation and play a vital role in development. Here I present the initial molecular and functional characterization of the promoter region of Hel-N1.

A 5.4 kbp fragment was isolated from a human genomic library and found to contain the initial exon of Hel-N1. The transcriptional start site was determined by primer extension using RNA from human occipital cortex and several neuroblastoma cell lines (SK-N-SH, NBL-S, and 1691). Analysis of the sequence immediately upstream from this start site revealed several transcription-factor-binding sites including SP1, AP2 and two CCAAT boxes. Using a reporter-gene assay, analysis of various upstream segments in 1691 cells indicated strong transcriptional activity within the initial 530 bp (-1 to -529). When compared to U105 (glial) or HeLa (epitheloid) cells, this activity was significantly greater in 1691 cells. These findings suggest that *cis* elements for neural-specific Hel-N1 transcription reside within this segment.

## 332.17

**TRANSIENT TRANSFECTION AND MUTATIONAL ANALYSIS OF THE DYNCRE3 ELEMENT OF THE PRODYNORPHIN PROMOTER.** D.J. Kim, D.J. Messersmith, J. Gu, R. Dubner and M.J. Iadarola\*. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

Previous studies have shown that the DYNCRE3 sequence located at -1545 from the transcription start site participates in basal and cAMP-dependent expression of the rat prodynorphin gene. This element has a core heptanucleotide sequence (TGCCTCA) that is similar to the CRE (TGACGTCA) and AP-1 (TGAGTCA) consensus sequences and identical to the ENKCRE II sequence. We have compared the transcriptional efficacy of the DYNCRE3 to mutations that (a) convert it to consensus CRE or AP1 sites and (b) modify the core and flanking regions of a 41 bp oligonucleotide centered on the core and fused to a dynorphin minimal promoter (-135 to +65). Two base substitutions within the core reduced CAT activity to levels of the minimal promoter and nearly eliminated forskolin stimulation in transiently transfected PC12 cells. Mutation of the two bases immediately flanking the core produced a minimal effect on activity, whereas mutations further 5' and 3' yielded partial reductions in activity. Comparison between DYNCRE3 and its AP-1 and CRE "analogs" showed that it exhibited properties of both consensus elements. Under forskolin stimulation the DYNCRE3 showed an identical degree of inducibility as the CRE consensus (25-35 fold); the AP-1 element was less active (~7-fold). The three constructs were stimulated to a lesser degree (3 to 5-fold) by phorbol ester. All three were stimulated by co-transfection with a c-Jun expression vector with the CRE consensus being the least active. These data suggest 1) an essential role for the core heptanucleotide, 2) a partially stabilizing role for the flanking regions, and 3) that the DYNCRE3 site can display functional similarity to both AP-1 and CRE sequences depending on cellular context and experimental conditions.

## 332.19

**IDENTIFICATION OF cis-ELEMENTS AND trans-ACTIVATING FACTORS REQUIRED FOR THE GERM CELL-SPECIFIC EXPRESSION OF THE PROENKEPHALIN GENE** Feng Liu, John P. Tokeson, Karl M. Ebert, Stephan P. Persengiev and Daniel L. Kilpatrick\*. Worcester Found. Exp. Biol. Shrewsbury MA 01545, & Tufts Vet. School of Med., Grafton, MA 01536

Rat and mouse spermatogenic cells use an alternate, germ cell-specific proenkephalin promoter. Previous studies have demonstrated that the rat proenkephalin germ-line promoter encompasses a TATA-less 500 sequence which is located downstream of the somatic promoter, within the first intron for the somatic transcript. To identify cis-elements required for expression of the germ line promoter, rat proenkephalin-CAT fusion genes containing different portions of the germ-line promoter were generated and analyzed in transgenic mice, using RNase protection assays. It was found that deletion of the 5' flanking sequence of the germ line promoter almost completely abolished CAT expression in constructs RPKCAT0.4 and RPKCAT0.5-5' del containing respectively, 100bp and 121bp deletions of the 5' end. This suggests that the 5' flanking sequence is important in directing germ line-specific proenkephalin gene expression. To identify functional trans-activating factors, gel retardation assays were performed. Four DNA-nuclear protein complexes were identified using the 150bp 5' flanking sequence and germ cell nuclear extracts. Further competition assays revealed that all the four complexes can be depleted by a cold oligo competitor containing the 45bp sequence immediately upstream of the transcription initiation sites (GCP1), suggesting the exclusive involvement of this region in DNA-protein complex formation. A consensus binding site for TFII-I is present in the GCP1 sequence. Supershift, footprinting, and UV-crossing analysis are underway to further identify trans-activating factors that are required for the germ cell-specific expression of the proenkephalin gene. (Supported by NIH DK36468 and F32 DK09006)

## 332.18

**CELL SPECIFIC BINDING OF PROTEINS TO THE ENKEPHALIN CRE-2 ELEMENT.** L. MacArthur<sup>1</sup>\*, A. Jacangelo<sup>2</sup>, L. Eiden<sup>2</sup>, D. Messersmith<sup>1</sup>. <sup>1</sup>Neurobiology Anesthesiology Branch/NIDR, <sup>2</sup>Laboratory of Cell Biology/NIMH, Bethesda, MD 20892.

Although a number of transcription factors up-regulate the enkephalin gene in recombinant systems, the factors that bind in a homogeneous tissue in which enkephalin is expressed have not been addressed. This study uses gel shift analysis to examine this question.

Chromaffin cells of the adrenal medulla are homologs of sympathetic ganglia neurons which express a variety of neuropeptide genes, including enkephalin, both *in vivo* and in primary culture. Gel shift analysis of three previously described enkephalin enhancers with extracts from chromaffin cells (CC) and PC12 cells, which do not express the enkephalin gene, demonstrate that all of the binding activity is to a single element, ENKCRE-2, a cAMP response-like element. CC and PC12 cells give different gel shift patterns and different competition profiles with oligos to consensus AP-1 and CRE sequences indicating different proteins bind to this site. Antibody supershifts demonstrate the majority of CC and PC12 cell binding can be shifted or competed with antibodies against Fos and Jun family members while only a small amount of binding is shifted by antibodies cross-reactive to CREB family members. Furthermore, distinct proteins are bound i.e. Jun D binds in CC whereas both Jun D and Jun B bind in PC12 cells, although not as heterodimers with each other. These data demonstrate that the ENKCRE-2 element is the major enhancer for enkephalin regulation in primary neuroendocrine cells and is the site where CC and PC12 cells exhibit differences in the ability to bind specific proteins.

## 332.20

**Protein-DNA Interactions in the Promoter of the Cyclooxygenase (COX2) Primary Response Element in NG108-15 cells and in Rat and Human Brain.** W.J. Lukiw\*, V.L. Marcheselli, P.K. Mukherjee and N.G. Bazan. LSU Neuroscience Center, Louisiana State University School of Medicine, New Orleans, LA 70112 USA

The cyclooxygenase-2 (COX2, also TIS10, PGS-2, PTGS2) gene is a primary genetic response element that codes for the inducible form of prostaglandin synthetase. This enzyme, which catalyzes the oxidation of arachidonic acid derived from membrane phospholipids, represents the rate-limiting step in the synthesis of prostaglandins. These, in turn, are potent mediators of cellular damage induced by brain injury.

Using nuclear protein extracts (NPXTs) derived from platelet activating factor (PAF) induced NG108 cells, and the hippocampus of rats subjected to cryogenic injury (CI), electroconvulsive shock (ECS) or kindled seizures induced by kainic acid (KA), i.e. experimental protocols which are known to rapidly activate transcription of the COX2 gene, we have mapped protein-DNA interactions in the COX2 promoter during gene induction. As analyzed by electrophoretic mobility shift assay (EMSA) and automated DNA sequence analysis, transcription factor recognition sites for NFkB, AP2, NFIL6, PAF and several GC islands are present within the -463 to +30 bp region of the COX2 gene. As analyzed by EMSA, magnetic bead based purification of COX2 promoter binding proteins and SDS/PAGE/silver staining of NG108, rat and human brain hippocampal cell NPXTs, some 25 nuclear proteins were found to bind onto the -463 to -259 bp upstream region of the COX2 gene. This GC-rich upstream DNA contains a -371 to -370 bp region necessary for PAF-mediated COX2 gene activation. A ~35 Kd protein binding onto this DNA, present only in the uninduced (inactive) state, disappeared during induction of the COX2 gene. We speculate that one mechanism responsible for COX2 activation may be an alleviation of protein-mediated COX2 gene repression. This may represent one important endpoint in the cellular signal transduction pathway by which events initiated at the brain cell periphery are relayed to the nucleus to give primary genetic responses. Supported by NIH NINDS NS23002.

## PHARMACOLOGY OF SYNAPTIC TRANSMISSION I

## 333.1

**MECHANISMS OF ACTION OF A MUSCLE RELAXANT, CS-722, ON CULTURED HIPPOCAMPAL NEURONS.** W. Marszalec\*, J.-H. Song and T. Narahashi. Dept of Mol. Pharmacol. and Biol. Chem., Northwestern Univ. Med. Sch., Chicago, IL 60611.

A recently synthesized compound, CS-722, reduces experimental muscular rigidity in rats, an effect accompanied by a depression of polysynaptic spinal reflexes (Tanabe et al., Neuropharmacol., 31: 1059, 1992). A further study of the mechanisms of action of CS-722 was undertaken with cultured rat hippocampal neurons using the whole-cell patch clamp technique. Bath perfusions of 100 and 300  $\mu$ M CS-722 reduced the frequency of spontaneously occurring postsynaptic currents which were sensitive to 0.4  $\mu$ M tetrodotoxin. This decrease was observed for both inhibitory and excitatory postsynaptic currents, with the latter being affected more. CS-722 produced no significant change in currents evoked by the direct application of GABA, glycine, or glutamate. Preliminary experiments suggested that CS-722 did not inhibit presynaptic transmitter release. However, CS-722 did significantly reduce voltage-gated sodium currents, suggesting that it may be acting like a local anesthetic on these cells leading to suppression of synaptic transmission.

## 333.2

**CHARACTERIZATION OF GIANT MEPPS INDUCED AT NEUROMUSCULAR JUNCTIONS BY 2,4-DITHIOBIURET.** Y. F. XU\* and W. D. ATCHISON. Dept. Pharmacol. Toxicol., & Neurosci. Progrm., Mich. State Univ., E. Lansing, MI 48824

Rats treated with small daily doses of 2,4-dithiobiuret (DTB) develop a delayed onset neuromuscular weakness after 6 days of treatment. Evoked quantal release of ACh is impaired, and the frequency of giant miniature end-plate potentials (gMEPP) is increased dramatically in DTB-treated preparations. A comparison of the sensitivity of MEPP and gMEPP frequency to various treatments known to alter MEPP frequency was made using extensor digitorum longus preparations of normal and DTB-treated (1 mg/kg/day, 6 days) rats. Increasing extracellular  $Ca^{2+}$  from 2 to 8mM, depolarizing the nerve terminals with 30mM  $K^{+}$  or addition of  $\alpha$ -latrotoxin ( $\alpha$ -LTx), or  $La^{3+}$  markedly increased MEPP frequency in normal muscles. In DTB-treated muscles, these agents were much less effective at increasing MEPP frequency than in controls. Similarly, the gMEPP frequency in normal preparations was increased dramatically by  $\alpha$ -LTx,  $K^{+}$  depolarization and  $La^{3+}$ , while in DTB-treated preparations, there was no significant effect of these treatments. gMEPPs are thought to result from addition of newly-synthesized ACh to quanta, as they are inhibited by treatment with vesamicol, which blocks active uptake of ACh into synaptic vesicles. Although vesamicol inhibited gMEPP frequency in DTB-treated preparations, the time necessary to block gMEPPs by vesamicol was longer than in controls. It is known that botulinum toxin A (BoTx) also induces gMEPPs, characterized by being insensitive to nerve terminal depolarization and to transmembrane  $Ca^{2+}$  fluxes. However,  $\alpha$ -LTx is effective in increasing gMEPP frequency at BoTx-poisoned junctions. Taken collectively, the data indicate that the pharmacological sensitivity of gMEPPs induced by DTB is different from that not only of normal junctions but also that of BoTx-poisoned junctions. Supported by NINDS grant NS20683.

## 333.3

**STRUCTURAL EFFECTS OF 2,4-DITHIOBIURET ON THE RAT MOTOR ENDPLATE RESEMBLE THOSE SEEN IN CHRONIC NEUROMUSCULAR DISORDERS.** M.B. Rheuben\*, D.M. Autio, and W.D. Atchison. Departments of Anatomy, and Pharmacology and Toxicology, Michigan State University, East Lansing, MI 48824.

Rats treated with daily doses of 2,4-dithiobiuret develop hindlimb weakness and a paralysis which is reversible upon cessation of treatment. Previous studies of treated animals have reported tubulovesicular profiles within the nerve terminal and abnormalities in the axonal glial wrappings, with long term treatment producing sprouting. A combination of light, transmission, and scanning electron microscopy was used to monitor the endplate region of the extensor digitorum longus in association with physiological studies (Xu and Atchison, Soc. Neurosci. Abstr. 1995). When paralysis was first evoked, after 5-6 days of treatment, we found a constellation of pre- and postsynaptic changes. The degree of abnormality varied both intratermally and among terminals in the same muscle; one or more individual boutons might be swollen or the entire endplate could be deformed. Terminal Schwann cells responded systemically, with both changes in cytoplasmic organelles and changes in overall shape. The postsynaptic folds swelled and the interfold spacing increased. The synaptic cleft became wider. Some terminal regions appeared relatively normal and capable of release; other were retracted from the folds and many contained tubulovesicular profiles. Similar morphological responses have been found in association with both experimentally-induced and naturally occurring chronic dysfunctional conditions of the neuromuscular junction, and have broad functional implications. Supported by NIH Grant NS20683.

## 333.5

**McN-A-343 (McN) INCREASES RENAL SYMPATHETIC NERVE ACTIVITY (RSNA) BY TWO MECHANISMS.** J.R. Martin\*, Dept. of Pharmacol., Kirksville Col. Osteo. Med., Kirksville, MO 63501

Intravenous injection of the muscarinic M<sub>1</sub> agonist McN into rats evokes an increase in mean arterial pressure (MAP) which correlates with an increase in RSNA. The present study shows that McN increases RSNA by two mechanisms. Male Sprague-Dawley rats (280-320 gm) were anesthetized with urethane (1.6 gm/kg), and implanted with a catheter in the left femoral artery and vein for monitoring MAP and drug administration. An isolated nerve branch arising from the coeliac ganglia and following the renal blood vessels was then placed on a bipolar hook electrode. All rats were pretreated with the nicotinic ganglionic antagonist pentolinium (10 mg/kg) to block baroreflex-mediated bradycardia. Methylatropine (MeATR; 0.25 and 2 mg/kg) and telenzepine (TLZP; .07 and .6 mg/kg) identically inhibited the McN-evoked increases in MAP and RSNA. Doses of McN greater than 0.3 mg/kg evoked increases in RSNA which could not be blocked by MeATR or TLZP but which still correlated with the increase in MAP. This increase in MAP, but not the increase in RSNA, involved catecholamines as it was attenuated by  $\alpha$ -adrenergic receptor blockade. Benextramine (BNXT; 20 mg/kg) blocked the increase in RSNA evoked by the higher doses of McN without affecting the increase evoked by lower doses. Combining BNXT with MeATR (0.25 mg/kg) or TLZP (0.07 mg/kg) completely blocked the McN-evoked increases in RSNA and MAP. These results show that McN-evoked increases in RSNA occurs: (1) at low doses via an action on muscarinic M<sub>1</sub> receptors, and (2) at high doses via a BNXT-sensitive mechanism. (Supported by NIH HL44531.)

## 333.7

**SUBSTANCE P AND VIP POTENTIATE KETAMINE-INDUCED INHIBITION OF CALCIUM-ACTIVATED K-CONDUCTANCE IN GUINEA-PIG SYMPATHETIC NEURONS.** W.H. Stapelfeldt\*, J.M. Oleszewski. Depts. of Anesthesiology & CCM, Univ. of Pittsburgh, Pittsburgh, PA 15261, and VA Medical Center, Pittsburgh, PA 15240.

We recently demonstrated that the general anesthetic agent propofol augments substance P (SP)-mediated postsynaptic inward current responses of guinea-pig inferior mesenteric ganglion (IMG) neurons through synergistic interaction with a SP-invoked signal transduction mechanism to potentiate the inhibition of a  $G_{K(CA)}$ -conductance which normally restrains SP excitatory responses and which also contributes to the afterdepolarization (ASH) of these neurons. Since the general anesthetic agent ketamine has recently been reported to specifically inhibit BK-channels, inhibition of ASH by ketamine was examined with regard to its possible analogous sensitivity to neuromodulation by SP- or VIP-evoked signal transduction mechanisms. Study parameters included baseline ASH amplitudes, neuropeptide-evoked inward current responses, and associated changes in ASH amplitudes of intermittently (0.5 Hz) evoked electrotonic action potentials before and during neuropeptide responses using single-electrode (manual) voltage clamp recordings from isolated perfused IMGs. Exogenous SP or VIP were applied by pressure microinjection from nearby micropipets (Picospritzer). Ketamine (100  $\mu$ M) caused significant ( $p < 0.05$ ) increases in the amplitude of inward current responses to both SP ( $32 \pm 16\%$ ) and VIP ( $38 \pm 15\%$ ) which were both associated and related in amplitude with more pronounced decreases in peak ASH amplitudes of intermittently evoked action potentials when compared to those produced by the neuropeptides alone or by ketamine alone. These findings suggest that the anesthetic sensitivity of the underlying  $G_{K(CA)}$ -conductance to inhibition by ketamine in sympathetic neurons is subject to physiologic neuromodulation by signal transduction steps invoked by synaptic inputs utilizing the neuropeptide transmitters SP and VIP. Supported by UACCMF, VA RAG B, FAER & Syntex Laboratories.

## 333.4

**TWO TYPES OF TRAIN EPP CHANGES IN RAT'S ISOLATED DIAPHRAM AFTER EXPOSURE TO NEOSTIGMINE AND SOMAN**

Chuan-gui Liu, Jun Li and Ming-yao Liu\*. Dept. of Neuropharmacol., Institute of Pharmacol. & Toxicol., Acad. Mil. Med. Sci., P.O. Box 130, Beijing 100850, China. It has been reported that in isolated rat diaphragm the indirect stimulation evoked train EPPs changed in two types after exposure to neostigmine (neo) or soman: the decreased amplitude with definite depolarization of membrane, which repolarized immediately after cessation of stimulation (Type I) and the disappearance of EPPs with sustained depolarization of membrane, which repolarized in definite period independent of stimulation duration (Type II, sustained or regenerative depolarization). In isolated nonuniform stretched muscle preparation of rat's diaphragm we were able to induce either Type I or Type II response (50 Hz, 1s) after exposure to neo or soman depending on different drug concentrations or different time schedule of stimulation. It was demonstrated that neo 0.3, 2.0 mM or soman 0.5, 5.5 mM could induce Type II response in 100% with no Type I, while increasing or decreasing the drug concentration both 'Type I and Type II responses with different percentages were observed. In preparations exposed to neo 2.0 mM or soman 5.5 mM given two successive indirect train stimulations with interval more than 20 sec., second stimulation induced Type II response in 100%, while with interval less than 5 sec. 100% of Type I responses were induced. When this interval was ranging 10-20 sec. the 60% or 80% of train EPPs were Type II response after exposure to neo or soman respectively. If the duration of indirect train stimulation was increased from 1s to 2s the response was transformed from Type II to Type I in the second half of the stimulation period in 100% or 80% preparations exposed to neo or soman respectively. It is suggested that in unrestrained rats the interval between two successive inspiratory contractions of diaphragm is much less than 5 seconds and the above mentioned Type I response rather than Type II response may be the main response of train EPPs after exposure to neostigmine or soman.

## 333.6

**P<sub>2X</sub> PURINOCEPTORS MEDIATE FAST SYNAPTIC TRANSMISSION IN MYENTERIC NEURONS OF THE GUINEA PIG ILEUM** K.J. LePard\* and J.J. Galligan, Dept. of Pharmacology and Toxicology and the Neuroscience Program, Michigan State University, East Lansing, MI 48824.

ATP is a fast excitatory neurotransmitter in numerous biological systems. Recent evidence suggests that purinergic P<sub>2</sub> receptors mediate fast excitatory actions of ATP in enteric neurons. The present studies characterize the P<sub>2</sub> receptor subtype mediating fast excitatory postsynaptic potentials (fEPSPs) recorded using conventional electrophysiological methods. In 23 of 66 neurons (35%), fEPSPs were cholinergic as they were blocked by hexamethonium (C6, 100  $\mu$ M) [amplitude (mV), N=23: control,  $19 \pm 2$ ; C6,  $1 \pm 0.2$ ;  $P < 0.001$ ]. However, in 43 (65%) neurons, fEPSPs were only partially blocked ( $\leq 67\%$ ) by C6. In this subset, 70% of fEPSPs were dose-dependently (1-30  $\mu$ M) inhibited by the P<sub>2X</sub> antagonist pyridoxal-phosphate-6-azophenyl-2',4'-disulphonic acid (PPADS, EC<sub>50</sub> = 3  $\mu$ M). In addition, superfusion of the P<sub>2X</sub> agonist  $\alpha, \beta$ -methylene adenosine 5'-triphosphate ( $\alpha, \beta$ -Me ATP, 1  $\mu$ M) desensitized PPADS-sensitive fEPSPs [amplitude (mV), N=6: control,  $30 \pm 6$ ; C6,  $16 \pm 4$ ; C6 plus PPADS (10  $\mu$ M),  $5 \pm 1$ ; C6 plus  $\alpha, \beta$ -Me ATP,  $4 \pm 1$ ]. PPADS and  $\alpha, \beta$ -Me ATP had no effect on cholinergic fEPSPs or on responses to locally-applied acetylcholine. These experiments indicate that P<sub>2X</sub> receptors mediate some fEPSPs in the guinea pig myenteric plexus. (Supported by DK40210, NS01738.)

## 333.8

**INHIBITORY EFFECTS OF NITRIC OXIDE ON SYNAPTIC TRANSMISSION IN RAT INTRACARDIAC GANGLIA.** S.W. Jeong, J.S. Walter\* and R.D. Wurster. Depts. of Physiology and Neurolog. Surg., Loyola Medical Center, Maywood IL 60153. \*Hines VA Hospital, Rehab. Res. Dev. Ctr, Hines IL 60141

Some evidence has suggested that nitric oxide (NO) acts as a local neuromodulator in the central and peripheral nervous systems. Nitric oxide synthase (NOS) has recently been localized within parasympathetic intracardiac ganglia. However, the role of NO in this system is not well known. In the present study we investigated whether rat intracardiac neurons contain NOS and whether the NO produced modulates ganglionic synaptic transmission. NOS was localized using NADPH-diaphorase histochemistry. A large population of intracardiac neurons revealed NADPH-diaphorase activity. To test the effect of NO on synaptic transmission, intracardiac ganglia with intact preganglionic nerve fibers were isolated and superfused with the oxygenated Krebs solution at 36 °C. The orthodromic nerve potentials were evoked by the electrical stimulation of preganglionic nerve fibers using a concentric bipolar electrode. L-arginine, a substrate for NOS, reversibly decreased the amplitude of synaptic response. This effect was blocked by N<sup>G</sup>-nitro-L-arginine, a competitive NOS inhibitor. To confirm the inhibitory effect of NO on synaptic transmission, the well known NO donors, sodium nitroprusside and 3-morpholinosydnonimine (SIN-1), were used. These NO donors also depressed synaptic transmission similar to the results obtained with L-arginine. The NO scavenger, hemoglobin, prevented the inhibitory effects of NO donors. Methylene blue, a guanylate cyclase (GC) inhibitor, enhanced synaptic transmission and also prevented the NO donor-induced inhibition. In addition, a membrane permeable cGMP analogue, 8-bromo-cGMP mimicked the inhibitory effects of L-arginine and NO donors. We concluded that NO is produced endogenously in rat intracardiac ganglia and inhibits synaptic transmission via the activation of GC and a resultant increase in the cGMP level. Supported by NIH grant 27595.

## 333.9

**NITRIC OXIDE POTENTIATES INHIBITORY POSTSYNAPTIC CURRENTS IN RAT SYMPATHETIC PREGANGLIONIC NEURONS.** S. Y. Wu\* and N. J. Dun. Dept. of Anat & Neurobiol., Medical College of Ohio, Toledo, OH 43614.

Whole-cell patch-clamp recordings were made from sympathetic preganglionic neurons (SPNs), the majority of which contain nitric oxide synthase (NOS)-immunoreactivity, from thoracolumbar spinal cord slices from 8-12 day old rats. Electrical stimulation of lateral funiculus evoked in a population of SPNs an inhibitory postsynaptic current (IPSC) that was sensitive to either strychnine or bicuculline. Superfusing the slices with the NO precursor L-arginine (L-arg, 300  $\mu$ M) and the NO donor nitroprusside (SNP, 100  $\mu$ M) increased the IPSCs. D-Arg was without effect. The potentiating effect was attenuated by bovine hemoglobin (100  $\mu$ M). Pretreating the slices with the NOS inhibitors N<sup>G</sup>-Nitro-L-arginine (30  $\mu$ M) or N<sup>G</sup>-monomethyl-L-arginine (100  $\mu$ M) reduced the IPSCs by an average of 30%. Superfusing the slices with dibutyl cGMP (750  $\mu$ M) in the presence of the phosphodiesterase inhibitor IBMX (750  $\mu$ M) potentiated the IPSCs as well. L-Arg and SNP had no significant effects on outward currents induced by pressure application of glycine. These studies raise the possibility that NO released endogenously from SPNs may be a retrograde messenger that enhances inhibitory transmitter release via a cyclic GMP-dependent mechanism. (Supported by NS18710).

### ACETYLCHOLINE RECEPTOR: NICOTINIC—ACETYLCHOLINE-GENETICS: MOLECULAR

## 334.1

#### IDENTIFICATION OF NICOTINIC ACETYLCHOLINE RECEPTOR

(nAChR) GENES FROM THE PARASITIC NEMATODE *ASCARIS SUUM*. H. L. Brooks<sup>1</sup>, R. C. Foreman<sup>1</sup>, J. F. Burke<sup>2</sup>, L. Holden-Dye\*<sup>1</sup> & R. J. Walker<sup>1</sup>.<sup>1</sup> Department of Physiology and Pharmacology, University of Southampton, SO16 7PX, <sup>2</sup> Department of Biochemistry, University of Sussex, BN1 9QG, UK.

Previous studies on the nematode *Ascaris suum* have pharmacologically characterized the native nicotinic receptors on somatic muscle (Colquhoun *et al.*, *J. exp. Biol.*, 158, 509-530 & *Mol. Neuropharm.*, 3, 11-16, 1993). The native receptor has pharmacological similarities to a mammalian neuronal subtype of nicotinic receptor. Previous studies on the nematode *Caenorhabditis elegans* have implicated a specific type of nicotinic receptor as the site of action for the anthelmintic levamisole. We are interested in isolating and characterizing the nAChR subunit genes from *A. suum* in order to compare the pharmacological properties of the subunits to those of the native receptor. PCR was used on genomic DNA to produce *unc-38* (Fleming *et al.*, unpublished), an alpha-like nicotinic subunit from *C. elegans*. To identify the subunit genes in *A. suum* molecular cloning techniques have been employed to screen both genomic and cDNA libraries. PCR studies using degenerate probes to the conserved regions of other invertebrate AChR genes were performed. Genomic fragments have been isolated with homology to vertebrate and invertebrate neuronal nicotinic ACh receptors. RT-PCR on muscle tissue and the head region of *A. suum* identified cDNA fragments that hybridized to the *unc-38* gene from *C. elegans*. Evolutionary comparisons of the nicotinic receptor and cytoskeletal genes of *A. suum* to the corresponding invertebrate and mammalian sequences have been performed. Further characterization and expression of the *A. suum* nicotinic receptor genes is currently under investigation.

## 334.3

**SCIP IS A SPECIFIC ACTIVATOR OF THE ACETYLCHOLINE RECEPTOR  $\alpha 3$  GENE IN PC12 CELLS BUT ACTIVATION IS NOT INFLUENCED BY POU-DOMAIN BINDING SITES POSITIONED UPSTREAM OF THE GENE** Evan Deneris\*, Dmitry Fyodorov, and Xiangdong Yang. Dept. Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

The POU-domain factor, SCIP/Tst-1/Oct-6, can activate transcription by binding to A+T-rich sequences, such as the octamer motif. In PC12 cells, the nicotinic acetylcholine receptor  $\alpha 3$  gene promoter is activated by SCIP. Each of the A+T-rich SCIP binding sites present in the  $\alpha 3$  upstream region were analyzed for a contribution to activation. We found that elimination of these sites either singly or in combination did not affect the response to SCIP. Even when re-positioned near the  $\alpha 3$  transcription start site region SCIP binding sites did not influence activation. This was paralleled by an inability of SCIP to activate octamer-dependent transcription from a simple octamer/TATA promoter. The  $\alpha 3$  core promoter, which does not contain detectable SCIP binding sites, is strongly responsive to SCIP but not Oct-2. We analyzed the core promoter for sequences that might mediate the response to SCIP and were unable to find a region that was important for activation but not basal activity. SCIP domains important for activation were investigated by analyzing the activity of a set of amino-terminal and carboxy-terminal deletion mutants. We found that the activity of the POU domain alone was 50% of the activity of the full length protein. Restoration of wild type activity required two positively acting regions in the amino-terminal domain and an inhibitory region in the carboxy-terminal domain. Our results reveal distinct POU factor actions in PC12 cells and suggest that SCIP transactivates through specific protein-protein interactions with the basal transcription complex.

## 334.2

#### CELLULAR CONTROL OF NICOTINIC ACETYLCHOLINE RECEPTOR GENE

EXPRESSION R.T. Boyd\*. Department of Pharmacology and The Neuroscience Program, The Ohio State University College of Medicine, Columbus, Ohio, 43210.

The nicotinic acetylcholine receptor (nAChR)  $\beta 4$ ,  $\alpha 3$ , and  $\alpha 5$  subunit genes are tightly clustered in the genomes of several species. The conserved organization of these nAChR genes implies a functional role for this arrangement. We have previously identified promoter elements in the region between the rat  $\beta 4$  and  $\alpha 3$  genes and made luciferase reporter constructs containing DNA segments from this region. In this study we have examined the effects of increased adenyl cyclase activity and decreased protein kinase C activity on transcription of the  $\alpha 3$  nAChR gene in PC12 cells using these constructs. Increased cAMP levels or reduced protein kinase C activity both produced increased levels of  $\alpha 3$  RNA and increased transcriptional activity of the  $\alpha 3$  promoter. These promoter-luciferase constructs were also transfected into non-neuronal cells and the sequences required for neuronal-specific activity were identified. We have also mapped the organization of  $\beta 4$  and  $\alpha 3$  transcripts in the intergenic region and have revealed that some  $\beta 4$  transcripts extend far into the intergenic region and overlap DNA sequences upstream of the  $\alpha 3$  gene which have promoter activity in PC12 cells.

## 334.4

**PURIFICATION OF RECOMBINANT  $\alpha$ -BUNGAROTOXIN AND TWO MUTANTS USING A 7-RESIDUE HISTIDINE TAG.** J.A. Rosenthal, Q.-L. Shi and E. Hawrot\*. Dept. of Molecular Pharmacology and Biotechnology, Division of Biology and Medicine, Brown University, Providence, RI 02912.

We have previously demonstrated the production of biologically active, recombinantly produced  $\alpha$ -Bungarotoxin (Bgtx) which was designed as a fusion protein with a highly soluble T7 coat protein. In an effort to maximize the recovery of recombinantly produced Bgtx, we have inserted a seven amino acid histidine tag N-terminal to the Bgtx sequence and C-terminal to the engineered thrombin protease site. Cleavage of the affinity-purified Histag-fusion protein with thrombin, results in a major ~9 kD protein as determined by SDS-PAGE. A final purification step using cation exchange chromatography separates fully active material from fractions with reduced activity. The fully active material is indistinguishable from native toxin under the solid-phase assay conditions used. We can produce ~600  $\mu$ g of active toxin/L of starting LB culture, a 25% increase in active toxin produced in comparison to the non-Histag protein.

We further report the purification of two mutants of Bgtx, an R36A and a truncation mutant in which the carboxy-terminal 7 residues have been deleted. R36 was a target for mutagenesis as it is conserved in all toxins within the neurotoxin family and was proposed to be a critically important contact site in nicotinic receptor recognition. Substitution of the R36 in Bgtx with Ala results in a toxin with a <20-fold reduction in binding activity, suggesting that although this residue contributes to binding, it is not absolutely essential for toxin activity. We have similarly produced a shortened Bgtx protein to assess what, if any, role the carboxy-terminal tail plays in receptor recognition. We observe an 11-fold reduction in binding affinity. We are beginning to assess the physiological effects that these alterations may have on heterologously expressed mouse nicotinic acetylcholine receptors using two-electrode voltage clamp techniques.

## 334.5

A RAPID AND SIMPLE METHOD FOR SIMULTANEOUSLY LABELING TWO DIFFERENT MESSAGES *IN SITU*. K-P. Chiu, S.A. Berman, T. Sullivan, S. Bursztajn.\* McLean Hospital and Psychiatry Dept., Harvard Medical School, Belmont, MA 02178.

AChRs subunits are expressed heterogeneously among the nuclei of a myotube. Does the nucleus which expresses one AChR subunit also express other AChRs subunits? To answer this question we have further improved our double label *in situ* hybridization procedure. For this purpose we have combined radiolabeled cDNA probes and conventional autoradiography with colorimetric detection methods using 4-chloro-2-methylbenzenediazonium-3-hydroxy-2-naphthoic acid 2,4-dimethylamide phosphate (Fast Red). This substrate is fully compatible with <sup>35</sup>S-labeled probe and generates a higher subcellular resolution and higher contrast than nitro blue tetrazolium chloride (NBT). The digoxigenin labeled probe is identified immunochemically with anti-digoxigenin antibody conjugated to alkaline phosphatase and the colorimetric reaction revealed with Fast Red. Cells are coated with NTB3 emulsion developed for an appropriate time period and the radioactive and colorimetric signals are readily detected and quantitated. The colorimetric signal is quantitated with a computer assisted densitometry program, permitting for the first time simultaneous detection of two different messages in the same muscle cell.

## 334.7

IDENTIFICATION AND MOLECULAR CLONING OF A FAMILY OF NICOTINIC ACETYLCHOLINE RECEPTOR GENES FROM THE LEECH. R. S. Allen\*, M. Hartley and S. F. Heinemann. Molecular Neurobiology Laboratory, The Salk Institute, La Jolla, CA 92037.

Acetylcholine, GABA, glycine and 5HT<sub>3</sub> mediate distinct physiological effects via interaction with multiple functionally diverse but homologous receptor subtypes which share sequence and structural features. Studies in several invertebrate species reveal unusual and complex responses to many neurotransmitters, suggesting that novel receptor subtypes exist. The aim of this project is to clone and functionally characterize cDNAs encoding leech neuronal nicotinic receptor (nAChR) subtypes. This gene family contains at least 7 different members, as determined by an RT-PCR based strategy using degenerate primers to conserved nAChR sequences. Subtypes are designated as neuronal or muscle based upon Northern blot hybridization. DNA sequence analysis reveals 3 neuronal subtypes: 1) alpha-like, 2) beta-like and 3) a novel, intermediate subtype. A random-primed cDNA library has been constructed from leech ventral nerve cords, amplified from ~3x10<sup>6</sup> independent recombinants. The average (avg.) insert size is ~2 Kb. Screening of ~1.5x10<sup>6</sup> phage yielded 73 alpha-like, 29 beta-like and 28 intermediate-positive clones. ~20 of each have been further processed by phagemid excision, plasmid DNA purification and restriction analysis. 18 alpha-like clones have inserts ranging from ~1.1-4.3 Kb, (avg. ~2 Kb), 6x2 Kb. 16 appear to be independent, on the basis of size. 17 beta-like clones have inserts ~0.3-5.3 Kb (avg. ~1.7 Kb), 6x2 Kb, with 7 independent. 22 intermediate clones have inserts ~0.9-4.6 Kb (avg. ~2 Kb), 7x2 Kb, with 12 independent. Identification of full-length clones by sequence analysis will be followed by functional characterization using a *Xenopus* oocyte expression system.

## 334.9

THE RELATIONSHIP BETWEEN  $\alpha 7$  GENOTYPE AND  $\alpha$ -BTX LEVELS IS LIKELY DUE TO VARIATION IN NON-CODING PORTIONS OF  $\alpha 7$ . J.A. Stitzel, D.A. Farnham, and A.C. Collins. University of Colorado, Boulder, CO 80309.

We have shown previously that inbred mouse strains differ in their sensitivity to nicotine-induced seizures and that this sensitivity significantly correlated with levels of hippocampal  $\alpha$ -BTX binding. Classic genetic cross studies confirmed this relationship. However, seizure sensitivity was inherited with a significant dominance component whereas inheritance of  $\alpha$ -BTX binding levels appeared to be additive. Recently, we have found that two strains (C3H and DBA/2) that differ in seizure sensitivity and  $\alpha$ -BTX levels are polymorphic for the nAChR  $\alpha 7$  subunit gene which codes for the  $\alpha$ -BTX binding site in brain. A comparison of  $\alpha 7$  genotype versus  $\alpha$ -BTX levels and seizure sensitivity in a C3H-DBA-derived F2 generation demonstrated that  $\alpha 7$  genotype is significantly correlated with levels of hippocampal  $\alpha$ -BTX binding. Animals homozygous for the C3H variant of  $\alpha 7$  had high levels of  $\alpha$ -BTX binding and those animals homozygous for the DBA variant had low levels. Heterozygous animals exhibited intermediate levels of  $\alpha$ -BTX binding. No significant relationship between  $\alpha 7$  genotype and seizure sensitivity was observed. RNase protection assays were conducted with RNA isolated from these two strains and results indicated that there is a nucleotide difference in the open reading frame of  $\alpha 7$  mRNAs between these strains. Sequence analysis of several PCR-generated clones confirmed this nucleotide difference. However, the mutation was found to be silent; it did not alter the amino acid sequence. Therefore, differences in  $\alpha 7$  genotype affect  $\alpha$ -BTX levels in some fashion independent of the primary amino acid sequence of  $\alpha 7$ . These findings suggest that either differences in RNA stability or rates of transcription of the  $\alpha 7$  strain variants are likely responsible for differences in  $\alpha$ -BTX binding levels. Supported by DA-05131, DA-00197, and AA-07464.

## 334.6

RECONSTITUTION OF A FUNCTIONAL HOMOMERIC NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR FROM C-ELEGANS. D. Bertrand, S. Bertrand and M. Ballivet.\*University of Geneva, 1211 Geneva, Switzerland

Eleven genes encoding neuronal acetylcholine receptor (nAChRs) subunits have been isolated from the vertebrate genome. There is now mounting evidence that the diversity of nAChR genes may be just as high in *D. melanogaster* and in *C. elegans* as it is in vertebrates. To take advantage of the powerful genetic tools available in *C. elegans*, we have cloned the cDNAs and genes of two putative nAChR subunits from this organism. One of these (Ce21) is an alpha-like subunit and shares 49% amino-acid identity with the vertebrate  $\alpha 7$  subunit. Functional homomeric nAChRs are obtained in *Xenopus* oocytes upon nuclear cDNA injection of Ce21 alone. ACh-evoked currents were very robust in these experiments (in the  $\mu$ A range) and displayed physiological and pharmacological profiles typical of nicotinic receptors. Unexpectedly, however, the Ce21 receptor was not activated by the anthelmintic levamisole, a full agonist of the nematode neuromuscular junction. In the 50-100  $\mu$ M, levamisole efficiently antagonized ACh-evoked currents through the Ce21 channels with features compatible with an open channel block. Our data suggest that the Ce21 channel is a neuronal nAChR.

## 334.8

CLONING AN *UNC-29* ACETYLCHOLINE RECEPTOR SUBUNIT FROM THE HUMAN PARASITIC NEMATODE *ONCHOCERCA VOLVULUS*.

J.A. Lewis\*, P. Gamez, A. Mendoza, P. Hernandez, and J. Sorrell. Division of Life Sciences, Univ. of Texas at San Antonio, San Antonio, TX 78249

We are interested in cloning acetylcholine receptor (AChR) subunit genes from the human parasitic nematode *Onchocerca volvulus* and expressing the genes in the laboratory nematode *C. elegans* to facilitate study of potential therapeutic drug targets. *Onchocerca* causes river blindness in tropical regions of Africa and Central and South America. We have screened an *Onchocerca volvulus* cDNA library at reduced stringency with four different *C. elegans* hybridization probes corresponding to highly conserved region of the AChR subunit genes *unc-29*, *unc-38*, *lev-1*, and a new AChR alpha subunit located near *unc-74*. Hybridization probes were made by PCR using nonradioactively labeled digoxigenin dUTP and PCR primers that flanked highly conserved subunit sequences. Two strongly positive *Onchocerca* clones were identified and plaque-purified in screening 470,000 clones (47 plates, 94 filters) from the cDNA library. The two clones are different isolates of an *Onchocerca* homolog to the *C. elegans* *unc-29* nonalpha AChR subunit gene. The longer *Onchocerca* cDNA contains the sequence expected for the amino terminal two thirds of the AChR subunit, including the signal sequence. Over this region, the *Onchocerca* clone is 88% identical to *C. elegans* *unc-29* at the amino acid level and about 75% identical at the nucleic acid level. The sequences of the first three (TM1-3) of the four highly conserved AChR transmembrane domains are virtually identical between *Onchocerca* and *C. elegans*. These results indicate that the function of the *unc-29* nonalpha subunit of the levamisole AChR has been highly conserved in evolution during the separation of free-living from parasitic nematodes. As only the 3' end of our clone is missing, reconstruction of a full-length *Onchocerca* clone should be possible, allowing tests of subunit functionality by substitution of the *Onchocerca* subunit for the *C. elegans* *unc-29* subunit in transgenic nematodes and in frog oocyte expressions assays.

## 335.1

**PRENATAL EXPOSURE TO MORPHINE INDUCES AN ALTERATION IN THE ONTOGENIC EXPRESSION OF NMDA RECEPTOR** G.C. Yeh<sup>1,\*</sup>, C.H. Chen<sup>2</sup>, and P.L. Tiao<sup>3</sup>, Taipei Medical College<sup>1</sup>, National Defense Medical Center<sup>2</sup>, Taipei, Taiwan, ROC

A transient increase of the N-methyl-D-aspartate (NMDA) receptor number during a postnatal period critical for the developmental plasticity of brain has been observed in both of animals and human. Lack of this normal ontogenic change may lead to a permanent sequel in learning, memory or other high cortical function. It has been recognized that child born to morphine-addicting mother have a higher percentage to suffer mild or moderate defect in psychomotor and intellectual activities. To determine whether prenatal exposure to morphine could induce an alteration in the ontogenicity of NMDA receptor, which may contribute to the long-term neuropsychological sequelae, we examined the binding of [<sup>3</sup>H]TCP, a ligand binding to the NMDA receptor-gated ion channel, in membrane preparation of whole brain tissues from different ages (5 day, 14 day and 30 day after birth) of rats born to mother-rats received daily injection of morphine after pregnancy. In naive rats, the [<sup>3</sup>H]TCP binding affinity increase from 24 nM to 9.7 nM from day 5 to day 30. The number of TCP binding showed a transient increase at day 14 by a 31% (day-5:  $0.70 \pm 0.15$  pmol/mg, day-14:  $0.92 \pm 0.02$  pmol/mg, day-30:  $0.5 \pm 0.04$  pmol/mg). However, such transient increase in NMDA receptor binding number did not present in rats born to mother treated with morphine (day-5:  $0.58 \pm 0.06$  pmol/mg, day-14:  $0.65 \pm 0.05$  pmol/mg, day-30:  $0.60 \pm 0.02$  pmol/mg). There is no significant difference in affinity of [<sup>3</sup>H]TCP binding between naive rats and rats born to morphine-treated mother. This finding suggests that prenatal exposure to morphine alters the ontogenic change of NMDA receptor. Further studies in evaluating the long-term effect of this alteration will be required.

## 335.3

**COEXPRESSION OF CaM-KINASE II WITH IONOTROPIC GLUTAMATE RECEPTOR ACCELERATES ITS RECOVERY FROM DESENSITIZATION.** V. Derkach, D. Brickley and T.R. Soderling\*, Vollum Institute, Oregon Health Sciences University, Portland, OR. 97201

Desensitization of ionotropic glutamate receptors (GluRs) and their recovery are important parameters which may modulate synaptic transmission. We studied these parameters using whole cell recording at -80 mV for GluR6 expressed in HEK 293 cells without or with co-transfected CaM-kinase II which is known to phosphorylate and regulate GluR6 (Yakel et al, PNAS 92: 1376-80, 1995). The onset of desensitization with glutamate (0.1-1 mM) and kainate (0.1-0.2 mM) was very fast and was fitted to a single exponential function with time constants of  $17.7 \pm 2.4$  ms (n=9) and  $16.6 \pm 6.0$  ms (n=4), respectively. Recovery from desensitization, determined by application of a second pulse of agonist, was slow with time constants of  $2.64 \pm 0.35$  sec (n=9) and  $18.1 \pm 2.3$  sec (n=5, p<0.001) for glutamate and kainate, respectively. These data suggest the rate of recovery depends on the rate of dissociation of agonist from the receptor. Co-transfection of GluR6 with a mutant of CaM-kinase II (His282Arg; Brickley et al, J. Biol. Chem. 269: 29047-54, 1994) which is 20% constitutively active decreased by 5-fold the time constant of recovery from kainate desensitization to  $3.4 \pm 0.6$  sec (n=5, p<0.001). The time constant for onset of desensitization was not effected. This study indicates that phosphorylation of GluR6 by CaM-kinase II, both of which are co-localized in the postsynaptic density, may be important in determining the involvement of this GluR type in synaptic transmission. Supported by NIH grant NS27037.

## 335.5

**Inhibition of NMDA-activated current by dynorphin (1-13) is subunit-specific and proceeds by a non-opioid mechanism** Ulrike Brauneis\*, Murat Oz, Forrest F. Weight, and Li Zhang, Cellular and Molecular Neurobiology, NIH, Bethesda, MD 20892-8205

Heteromeric mouse N-methyl-D-aspartate (NMDA) receptors were expressed in *Xenopus* oocytes. The  $\kappa$ -opioid receptor agonist dynorphin (1-13) inhibited NMDA-activated currents of all heteromeric NMDA receptors in a subunit-specific manner. The EC<sub>50</sub> for  $\epsilon 1/\zeta 1$  was 17  $\mu$ M, and the respective potencies were: 1 : 0.32 : 0.32 : 0.17 for  $\epsilon 1/\zeta 1$ ,  $\epsilon 2/\zeta 1$ ,  $\epsilon 4/\zeta 1$  and  $\epsilon 3/\zeta 1$ . The threshold for the dynorphin effect was about 0.3  $\mu$ M for  $\epsilon 1/\zeta 1$  and  $\geq 10 \mu$ M for the other subunit combinations. Dynorphin inhibition of NMDA-activated currents was voltage-independent and not competitive with regard to NMDA. NMDA-activated currents were not affected by the synthetic  $\kappa$ -opioid receptor agonist trans-3,4-dichloro-N-methyl-N-[2-(1-pyrrolidinyl)-cyclohexyl]benzene-acetamide (U50488) or the specific  $\kappa$ -opioid receptor antagonist nor-binaltorphimine (NorBNI). Also, NorBNI did not attenuate dynorphin inhibition when coapplied. These observations suggest that the interaction between dynorphin and the NMDA receptor is direct, rather than involving the  $\kappa$ -opioid receptor. There was also an interaction between dynorphin and the NMDA receptor that was dependent on glycine concentration. At low glycine concentrations ( $\leq 100$  nM) dynorphin potentiated NMDA-activated currents for all heteromeric NMDA receptors.

## 335.2

**PHYSICAL AND FUNCTIONAL EVIDENCE FOR ASSOCIATION OF NMDA-R1 WITH PKC AND CAM KINASES IN THE POSTSYNAPTIC DENSITY (PSD) OF ADULT RAT HIPPOCAMPUS.** P.C. Suen<sup>1,2</sup>, K. Wu<sup>1,2</sup>, R.J. Wenthold<sup>3</sup>, S.Y. Lin<sup>1,2</sup>, and J.B. Black<sup>1,2</sup>, <sup>1</sup>Dept. Neurosci. and Cell Biol., Robert Wood Johnson Med. Sch.; <sup>2</sup>Program in Physiol. and Neurobiol., Rutgers-The State Univ. of NJ, Piscataway, NJ 08854; <sup>3</sup>Lab. of Neurochem., NIDCD, NIH, Bethesda, MD 20892.

N-methyl-D-aspartate receptors (NRs) play critical roles in synaptogenesis, neuronal degeneration and synaptic plasticity. The receptors are heteromeric complexes comprised of NR1 and NR2A-D subunits. We previously reported that NR complexes are intrinsic components of PSD and are phosphorylated by endogenous PKC and CaM kinases (CKs) in the density. The identity of specific protein kinases involved in the phosphorylation remains unclear. To begin examining this issue, we focused on PKC $\gamma$  and CKs, enzymes that are intrinsic to the PSD. Immunoprecipitation and Western blot analysis, using anti-PKC $\gamma$  antibodies or anti- $\alpha$ CKII antibodies which also recognize the major PSD protein (mPSDp), revealed that anti-NR1 antibodies immunoprecipitated PKC $\gamma$  and/or CKs from hippocampal PSD solubilized in a buffer containing 50 mM Tris-HCl, 0.1% SDS, 1% CHAPS, 1% Triton X-100 and 0.5% NP-40 (pH 7.4). Antibodies that recognize PKC $\gamma$  ( $\approx 70$  kDa) and CKs ( $\approx 50$  kDa) immunoprecipitated NR1/PKC $\gamma$  and NR1/CKs complexes, respectively. When the PSD was solubilized under more stringent conditions (at 100 °C), none of these associations was detected, suggesting that the NR1 complexes with PKC $\gamma$  and/or CKs through noncovalent interaction. NR1 in the NR1/PKC $\gamma$  and NR1/CKs complexes was phosphorylated upon specific activation of PKC $\gamma$  and CKs. Our findings indicate that NR1 in the PSD is closely associated with PKC $\gamma$  and CKs, which may regulate NMDA receptors through phosphorylation. (Supported by NICH23315.)

## 335.4

**THE ROLE OF NITRIC OXIDE IN THE MODULATION OF THE NMDA RECEPTOR BY INTERLEUKIN-1 $\beta$  AND PREGNENOLONE SULFATE.**

J.M. Fahey\*, D.G. Lindquist and L.G. Miller, Department of Pharmacology and Experimental Therapeutics, Tufts University School of Medicine, Boston, MA 02111.

Previously, this laboratory has demonstrated modulation of the NMDA receptor by both the proinflammatory cytokine interleukin-1 $\beta$  (IL-1 $\beta$ ) and the neuroactive steroid pregnenolone sulfate (PS). NMDA-mediated increases in intracellular calcium are antagonized by IL-1 $\beta$  and potentiated in the presence of PS. The present study examines the role of nitric oxide (NO) in the modulation of the NMDA receptor by IL-1 $\beta$  and PS by examining the intracellular calcium concentration in cultured chick cortical neurons using the fluorescent dye Fura2. N<sup>G</sup>-Monomethyl-L-arginine acetate (L-NMMA), a nitric oxide synthase (NOS) inhibitor, antagonized the decrease in intracellular calcium caused by IL-1 $\beta$  in the presence of both NMDA/glycine and the endogenous polyamine spermine. L-arginine, the precursor of NO, had no effect on intracellular calcium levels in cells treated with IL-1 $\beta$ . L-NMMA also inhibited the increase in intracellular calcium caused by PS in the presence of both NMDA/glycine and spermine. L-arginine, however, only antagonized the increase in intracellular calcium seen in the presence of NMDA/glycine. These data indicate that the mechanism by which IL-1 $\beta$  and PS modulate NMDA-mediated increases in intracellular calcium may involve the NO signal transduction system.

## 335.6

**BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) POTENTIATES NMDA-EVOKED RESPONSES** C.R. Jarvis<sup>1</sup>, J. Plant<sup>1</sup>, D. Churchill<sup>1</sup>, Z. Xiong<sup>2</sup>, J. F. MacDonald<sup>2</sup> and B.A. MacVicar<sup>1</sup>, <sup>1</sup>The University of Calgary, Calgary, Alberta and <sup>2</sup>The University of Toronto, Toronto, Ontario

Neurotrophins have been suggested to be potentially therapeutic in the treatment of neurodegenerative diseases and neurotoxicity because they promote cell survival, growth, and differentiation. BDNF receptors, which are in the hippocampus and striatum, possess intrinsic protein tyrosine kinase activity. Since NMDA receptors are modulated by protein kinases and phosphatases, we hypothesize that BDNF may modulate NMDA currents. Voltage clamp recordings from neurons cultured from the hippocampus or striatum in the presence of low glycine revealed that BDNF (0.1 to 10 ng/ml) reversibly potentiated NMDA currents by up to 600% in a dose dependent manner (n=66). BDNF's potentiation was voltage-independent at -70 mV and +60 mV, had a time course for onset and offset of <1 sec, but was not observed in saturating glycine (>1  $\mu$ M). These results demonstrate that BDNF acutely enhances NMDA receptor-activated currents. Moreover, imaging of [Ca<sup>2+</sup>]<sub>i</sub> in fura-2-loaded cells revealed that BDNF (10 ng/ml) potentiated NMDA-evoked [Ca<sup>2+</sup>]<sub>i</sub> increases by 207% (n=44 cells). Enhancement of NMDA-activated responses may be important in the short-term actions of neurotrophins. Supported by NCE.

## 335.7

**COCAINE MODULATION OF STRIATAL NMDA CURRENTS.** J.R. Plant\*, D. Churchill, C.R. Jarvis and B.A. MacVicar. Neurosci. Research Group, Univ. of Calgary, 3330 Hospital Dr. NW, Calgary, AB. T2N 4N1

Cocaine abuse is a pressing social and medical problem. Although cocaine's reinforcing and stimulant properties are thought to be mediated by inhibition of dopamine (DA) re-uptake, recent reports have linked NMDA receptors to some of cocaine's actions. Perforated patch-clamp recordings, and fura-2,AM imaging of NMDA-evoked increases in intracellular calcium ( $[Ca^{2+}]_i$ ) were used to investigate whether cocaine modulates NMDA receptor-mediated responses in cultured striatal neurons. Cocaine at low concentrations (0.1-100  $\mu$ M) potentiated NMDA-evoked currents and calcium signals in a glycine-dependent manner, while higher concentrations (>100  $\mu$ M) inhibited. Cocaine had no effect on AMPA or kainate-evoked currents. Procaine, a structural analogue of cocaine with similar psychoactive properties, was also tested for its ability to modulate NMDA-evoked responses. Like cocaine, procaine at low concentrations (0.1-20  $\mu$ M) enhanced NMDA-evoked currents and  $[Ca^{2+}]_i$  increases, and inhibited at higher concentrations (>20  $\mu$ M). Since procaine lacks cocaine's ability to inhibit DA re-uptake, our results suggest that their shared psychoactive properties might be mediated by their ability to directly and selectively modulate striatal NMDA transmission.

## 335.9

**THEANINE, A GLUTAMATE ANALOG, STIMULATES NMDA-RECEPTORS BUT SUPPRESSES EXCITATORY EFFECT OF CAFFEINE IN CORTICAL NEURONS** A. Nozawa<sup>1,2</sup>, K. Umezawa<sup>1</sup>, K. Kobayashi<sup>1</sup>, K. Muramoto<sup>1</sup>, M. Kawahara<sup>1</sup>, A. Mizutani<sup>1</sup>, T. Kakuda<sup>2</sup> and Y. Kuroda<sup>1</sup>. <sup>1</sup>Dept. of Molecular and Cellular Neurobiology, Tokyo Metropolitan Institute for Neuroscience, Tokyo 183, Japan, <sup>2</sup>TOEN Central Research Institute, Shizuoka 421-05, Japan.

Green tea leaves contain 1-2%(W/W) theanine (L-glutamate  $\gamma$ -ethylamide) which makes up 60% of the total amino acid content. Since theanine can pass through blood-brain barrier, we have carried out an initial study on its effects on brain function, using cultured cortical neurons. When intracellular  $Ca^{2+}$  was monitored by fura-2 fluorometry (Kuroda et al.; Neurosci. Lett., 135: 255, 1992), the addition of theanine produced a  $Ca^{2+}$  increase in the neurons. This effect was inhibited in the presence of D-APV, suggesting that theanine stimulates NMDA-receptors. Since it has been reported that theanine prevents caffeine-induced convulsions and behavioral activation in mice, we studied whether theanine could inhibit the effect of caffeine on cultured neurons. Cultured neuronal networks with high synaptic convergence fire spontaneously in synchronous oscillations which can be monitored by  $Ca^{2+}$  fluorometry (Robinson et al., J. Neurophysiol., 70: 1606, 1993). Caffeine increased the frequency of the  $Ca^{2+}$  oscillation, but theanine was able to inhibit the effect of caffeine. These results suggest that theanine is an interesting glutamate analog which has a dual function on neuronal activity, stimulatory at low concentration, but sedative at high concentration, suppressing excitation produced by caffeine, which is also a neuro-active constituent of tea leaves.

## 335.11

**REGULATION OF NMDAR1 PROMOTER BY NGF AND GROWTH FACTORS IN PC12 CELLS.** G. Bai\* and J.W. Kusiak. Mol. Neurobiol. Unit, Gerontology Research Center, NIA, NIH, Baltimore, MD 21224.

We previously analyzed the function of a 3 kb promoter of the NMDAR1 subunit gene of the glutamate receptor family (JBC 270:7737, 1995). In its proximal region, it has a GSG binding motif for NGF1 zinc finger protein family of immediate early genes which can be rapidly induced by NGF in PC12 cells. To clarify whether NMDAR1 promoter is regulated by NGF, we transfected NMDAR1 promoter-linked luciferase reporter gene constructs into PC12 cells and measured luciferase activity after adding NGF and other growth factors. Our results showed that NGF treatment increased the luciferase activity in both transient and stable transfectants. This response is time and dose dependent. In stable transfectants, luciferase activity increased one hour after addition of NGF and reached a peak in 4 hours. Some growth factors, e.g., EGF and FGF, showed a similar potency, while phorbol ester had a greater effect than NGF. Either a cAMP analog or forskolin alone had weak effects, but cAMP strongly potentiated the NGF effect. 5' deletion studies indicated that the NGF response elements reside in the proximal 356 bp promoter fragment which we previously showed was sufficient for activity in PC12 cells. Adding 1  $\mu$ g/ml actinomycin D abolished the NGF effect. Single mutations of GSG and two Sp1 sites in the 356 bp fragment slightly reduced the NGF effect, however, a double mutation of the two Sp1 sites greatly decreased the response. The endogenous NMDAR1 mRNA, measured with an RNase protection assay, in PC12 cells treated with NGF did not show any significant change, nor did mRNA turn-over rate change. Our studies suggest that NGF and some growth factors are able to up-regulate the NMDAR1 promoter. This promoter is subject to regulation by other signaling pathways, as well. The interactions of the basal promoter of NMDAR1 with multiple factors may control this up-regulation. In PC12 cells, the effect of NGF on endogenous NMDAR1 gene expression may be countered by strong, as yet unknown, inhibitory factors.

## 335.8

**Mag-1, a novel group of peptide modulators for NMDA receptors.**

Weifeng Yu<sup>1,2</sup>, Chien-Huan Chen<sup>1</sup>, Bill Dower<sup>2</sup> and Min Li<sup>1</sup>. <sup>1</sup>Department of Physiology, The Johns Hopkins University, School of Medicine, 725 N. Wolfe St., Baltimore, MD 21205; <sup>2</sup>Laboratory of Molecular Biology, Affymax Research Institute, 4001 Miranda Ave., Palo Alto, CA 94304.

Several groups of peptides that specifically bind NMDAR1 have been identified from random peptide libraries. The purpose of this study is to characterize physiological function of one group of peptides, Mag-1, on NMDA receptors. The core sequence of Mag-1 peptides is CDGLRHMWFC. Human embryonic kidney (HEK) 293 cell line was used for transient coexpression of NMDAR1 and NMDA2A. At 36-72 hours after transfection, whole-cell recordings were carried out to study the function of the Mag-1 peptides. In the presence of 10  $\mu$ M glycine, 50  $\mu$ M NMDA-induced currents were significantly reduced by coapplication of Mag-1 peptides. The inhibition on NMDA-evoked current is dose-dependent and voltage insensitive. Increase of NMDA concentration, up to 500  $\mu$ M, can not reverse the blockade of Mag-1 peptides, indicating the inhibition is non-competitive. In addition, the peptides were found to bind N-terminal extracellular domain of NMDAR1. The binding is not sensitive to  $Mg^{2+}$ ,  $Zn^{2+}$ , Gly, Glu, MK-801, polyamines and Conantokin-G. These results suggest that the peptides recognize a new site and modulate the receptor activity.

## 335.10

**INSULIN POTENTIATES NMDA RECEPTOR ACTIVITY IN XENOPUS OOCYTES AND RAT HIPPOCAMPUS** L. Liu, J. C. Brown III, W. W. Webster, R. A. Morrisett, and D. T. Monaghan\*. Department of Pharmacology, Univ. Nebr. Med. Center, Omaha NE 68198-6260.

Growth factor signal transduction pathways have recently been shown to affect voltage-gated ion channel activity. In this study we report that insulin can modulate the activity of a ligand-gated ion channel, the N-methyl-D-aspartate (NMDA) receptor. In *Xenopus* oocytes, a 2 min. insulin exposure rapidly potentiated NR1a/NR2A and NR1a/NR2B receptor responses 2-3 fold and weakly potentiated NR1a/NR2C and NR1a/NR2D mediated-responses 20-40% above baseline. Peak enhancement was observed at 10 min. followed by a return to baseline within 30 min. The PKC inhibitor staurosporine more potently inhibited phorbol ester-enhanced NR1a/NR2A receptor responses than insulin potentiated-responses suggesting involvement of kinases other than PKC in insulin action. Insulin modulation of native NMDA receptors is suggested by the observation that insulin potentiated the NMDA receptor-mediated synaptic component in region CA1 of hippocampal slices by 26  $\pm$  6% with peak enhancement observed at 20-30 minutes after initiating insulin exposure. Regulation of NMDA receptor activity by growth factors may account for previous observations of growth factor modulation of CNS excitotoxicity. This work was supported by NIH grant NS 28966.

**ANTAGONISM OF NMDA RECEPTORS BY SIGMA SITE LIGANDS** V. Ilyin, E. R. Whittemore, and R. M. Woodward\*. Acea Pharmaceuticals, a subsidiary of CoCensys Inc., 213 Technology Drive, Irvine, CA 92718.

Haloperidol is a non-competitive subtype-selective antagonist of mammalian NMDA receptors [Ilyin et al. Soc. Neurosci. Abstr. 20:1143 1994]. Like ifenprodil, haloperidol selectively inhibits NR1 / 2B subunit combinations ( $IC_{50}$  ~3  $\mu$ M). NMDA responses in cultured rat cortical neurons (E17, 4-10 days *in vitro*) are inhibited at similar potency. A recent report proposes that modulation of NMDA receptors by haloperidol and other  $\sigma$ -ligands is due to actions at the  $\sigma$ 1-site, mediated indirectly via a second messenger system [Yamamoto et al. J. Neurosci. 15:731 1995]. To investigate this idea we assayed a variety of  $\sigma$ -site ligands for inhibition of cloned NMDA receptors expressed in *Xenopus* oocytes, and also characterized inhibition of neuronal NMDA receptors by haloperidol at the single channel level. Carbetapentane, DTG, 4-IBP, 3-PPP, pentazocine, rimcazole and SK&F10047 inhibited NMDA responses with a wide range of potencies ( $IC_{50}$ 's ~0.1-300  $\mu$ M) but did not have pronounced subtype-selectivity. We found no clear correlation between affinity at  $\sigma$ 1-sites and antagonism of NMDA currents. Inhibition by DTG, pentazocine and SK&F10047 showed use- and voltage-dependence suggesting a PCP-like channel block. Single channel conductance of neuronal NMDA receptors in excised patches was ~50 pS. Mean channel open times were fit by two exponentials;  $\tau_1$  0.4-0.9,  $\tau_2$  2-6 msec. Haloperidol (3-30  $\mu$ M) inhibited single channel currents at the same or greater potency as whole cell currents, arguing against involvement of a second messenger system. Inhibition was mainly due to reduction in mean open probability. Our results suggest that antagonism of NMDA receptors by  $\sigma$ -site ligands is through direct interactions at two types of site on the receptor; allosteric modulatory sites (e.g. haloperidol and ifenprodil), and sites in the channel pore (e.g. DTG, pentazocine and SK&F10047).

## 335.13

EFFECTS OF TRYPSIN AND PAPAIN ON N-METHYL-D-ASPARTATE (NMDA) ACTIVATED WHOLE-CELL CURRENT. D. W. Frederick, J. M. Wright\*. Howard Univ., Washington, D.C. 20059 and Lab. Molecular & Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892.

We studied whether enzymes used to dissociate neuronal cells may affect the function of NMDA receptor-channels. Whole-cell patch-clamp recording was used to investigate the effects of trypsin (0.25%) and papain (14.1 U/ml) on NMDA-activated current in cultured mouse cortical neurons. Acute application of either enzyme generated a large inward current. Preapplication of pertussis toxin blocked the current generated by trypsin suggesting G<sub>i</sub> protein involvement. Current generated by papain reversed near 0 mV and was not blocked by pertussis toxin. Application of trypsin for 150 sec did not cause a reduction of NMDA-activated currents. Application of papain for 40 sec. produced a >50% decrease of NMDA-activated current amplitude. Recovery from papain's effect was not observed over 20 min. Although papain is considered to be the gentler of the two enzymes, the results suggest that trypsin digestion would be better for studying NMDA-activated currents in acute preparations. DWF was supported by NIMH grant #5T32MH19547.

## 335.15

ISOPROTERENOL POTENTIATES SYNAPTIC TRANSMISSION PRIMARILY BY ENHANCING PRESYNAPTIC CALCIUM INFLUX VIA P-TYPE CALCIUM CHANNELS. C.C. Huang, K.S. Hsu and P.W. Gean\*. Dept. of Pharmacol. College of Medicine, National Cheng-Kung University, Tainan City, Taiwan, R.O.C.

The effects of the selective  $\beta$ -adrenergic receptor agonist isoproterenol (Iso) on synaptic transmission was investigated in slices of rat amygdala using intracellular recording techniques. A 10-15 min application of Iso (15  $\mu$ M) produced a long-lasting enhancement of EPSP without altering the resting membrane potential or neuronal input resistance. The sensitivity of postsynaptic neurons to AMPA was unchanged by Iso pretreatment. The Iso-induced potentiation was not affected by pretreatment with APV, or Kynurenic acid+APV. However, substituting Mg<sup>2+</sup> for Ca<sup>2+</sup> in the medium blocked the effect of Iso suggesting that Ca<sup>2+</sup> entry into presynaptic terminals, but not into postsynaptic cell via glutamate receptors, is required for the action of Iso. Amygdala neurons fired rapid action potentials which accommodated in response to a long-duration depolarizing pulse. The end of depolarizing pulse was followed by an afterhyperpolarization (AHP). Superfusion of Iso reversibly blocked the AHP and accommodation resulting in more action potential firing. Intracellular applied PKI, a selective blocker of the catalytic subunit of PKA, blocked the effect of Iso on the AHP, whereas the Iso-induced potentiation was entirely normal in the same neuron. These results indicate that Iso-induced potentiation is not due to blockade of postsynaptic I<sub>AHP</sub>. Iso-induced potentiation was not affected by nifedipine or  $\omega$ -conotoxin-GVIA, but was blocked by  $\omega$ -agatoxin-IVA or  $\omega$ -conotoxin-MV1C, suggesting that the mechanism underlying the potentiating effect of Iso is likely due to an increased Ca<sup>2+</sup> influx through P-type Ca<sup>2+</sup> channels presynaptically.

## 335.17

PURIFICATION OF A 20 kD PROTEIN WHICH ASSOCIATES WITH THE NR1 SUBUNIT OF THE NMDA RECEPTOR.

Michael D. Ehlers, Su Zhang\* and Richard L. Huganir\*. Dept. of Neuroscience, HHMI, Johns Hopkins University, Baltimore, MD 21205.

NMDA receptors play important roles in synaptic plasticity, neural development and excitotoxicity. Molecular cloning studies have shown that NMDA receptors consist of two types of subunits: NR1 and NR2A-D. These subunits contain large COOH-terminal domains which may interact with cellular proteins. To identify proteins which interact with NMDA receptors, NR1 immunoprecipitates were examined for the presence of coprecipitating cellular proteins. A 20 kD protein was observed to specifically associate with the NR1 subunit. Moreover, this protein, termed RAP-20, preferentially associates with the NR1 subunit splice variants containing the C1 exon cassette at the COOH-terminus. We have utilized an NR1 COOH-terminus fusion protein affinity resin to purify this protein. RAP-20 is present in the brain, and coimmunoprecipitates with NMDA receptors from rat cortex. We are currently attempting to determine the identity and the functional implications of this potentially important protein.

## 335.14

PHARMACOLOGICAL CHARACTERIZATION OF THE [3H]SPERMINE BINDING TO THE POLYAMINE-SITE OF NMDA RECEPTOR IN THE RAT BRAIN. T.Yamamoto<sup>1</sup>\* and H.Yamamoto<sup>2</sup>. <sup>1</sup>Lab. of Mol.Recognition, Grad. Sch. Integ. Sci., Yokohama City Univ., Yokohama 236, <sup>2</sup>Dep. of Psychopharmacol., Tokyo Inst. Psychiatry, Tokyo 156, Japan.

We investigated the [3H]spermine binding which recognized the polyamine-site of NMDA receptor in the rat cortical membranes. [3H]Spermine bound apparently to two binding sites, with K<sub>d</sub> of 185 nM (high affinity) and 5.9  $\mu$ M (low affinity). Displacement analysis of [3H]spermine binding shows a pharmacological profile similar to that reported for [3H]ifenprodil binding as a ligand for spermine-site of NMDA receptor. Polyamines displaced [3H]spermine binding with the order of potency spermine > spermidine > diaminodecane > diethylenetriamine > putrescine. The binding of [3H]spermine was also inhibited by arcaine, ifenprodil and neomycine. In addition, MK801, an antagonist of the NMDA receptor, inhibited the [3H]spermine binding (IC<sub>50</sub>=745  $\mu$ M). However, glutamate, glycine and their antagonists, D-AP5, D-AP7 and 7-chlorokynurenic acid, did not affect the binding. These results show that [3H]spermine has a relatively higher affinity than other polyamine ligands, such as spermidine, and is a useful ligand for investigating the polyamine-site of NMDA receptor.

## 335.16

THE NMDA RECEPTOR NR2 SUBUNITS INTERACT WITH THE POSTSYNAPTIC DENSITY PROTEIN PSD-95. H.-C. Kornau<sup>1</sup>, G. Köhr<sup>1</sup>, M.B. Kennedy<sup>2</sup> and P.H. Seeburg<sup>1</sup>. <sup>1</sup>Center for Molecular Biology (ZMBH), University of Heidelberg, 69120 Heidelberg, Germany and <sup>2</sup>Division of Biology 216-76, Caltech, Pasadena, CA 91125.

NMDA receptors mediate the slow component of excitatory postsynaptic currents and activity-dependent plasticity in the mammalian central nervous system (CNS). Different NMDA receptor subtypes have been molecularly characterized and these assemble from a common NMDAR1 subunit and a modulatory NMDAR2 (NR2A-D) subunit. The four NR2 subunits are uniquely equipped with long cytoplasmic C-terminal tails. Screening a rat brain cDNA library with the two-hybrid system we found that these tails interact with PSD-95, a major postsynaptic density protein. PSD-95 is a multidomain protein which consists of three PDZ domains (also termed GLGF or DHR domains), one SH3 domain and a region homologous to yeast guanylate kinase. Molecular and biochemical analyses showed that the interaction results from binding between the C-terminal domain common to all NR2 subunits and a particular PDZ domain in PSD-95. Immunohistochemistry documented subcellular co-localization of NR2B subunits and PSD-95 in cultured hippocampal neurons, and *in situ* hybridization revealed a wide-spread and largely congruent expression pattern of transcripts for PSD-95 and NMDA receptor subunits. Our data suggest that the NR2/PSD-95 interaction is involved in localizing NMDA receptors at postsynaptic sites in the CNS.

## 336.1

## NMDA NR1 SPLICE VARIANTS AND NR2A AND NR2B SUBUNITS: DIFFERENTIAL PROTEIN EXPRESSION IN RAT BRAIN REGIONS.

J. Blahos\* and R. J. Wenthold, Laboratory of Neurochemistry, NIDCD, NIH Bethesda, MD 20892

NMDAR1 splice variants and NMDAR2 subunits show developmental and regional heterogeneity in rat brain resulting in physiological and pharmacological diversity of the NMDA receptor complex. To determine the nature of the association between NR1 splice variants and NR2 subunits, we developed antibodies specific for the alternatively spliced regions of NR1. These are: an antibody AbN1 recognizing N-terminus insert (insertion of 21 a.a. residues located between residues 190 and 191), antibodies AbC1 and AbC2 recognizing variants of the C-terminus (C1-a.a. residues 901 to 938, and alternatively spliced C2 composed of 22 a.a. residues), and an antibody C36 recognizing the sequence known as deletion 1 present in some variants (a.a. residues 864 to 900). Antibodies selective for the NR2 subunits, NR2A and NR2B, were also used.

Rat brains were dissected and regions solubilized under conditions maximally preserving the NMDA receptor complex for co-immunoprecipitation studies, or solubilized with SDS when studying relative amounts of each protein. Antibodies specific for the NR1 alternatively spliced regions were used for immunoprecipitation. These and an antibody recognizing all of the NR1 variants, as well as antibodies to the NR2 subunits, were used for detection on western blots. This allowed us to study relative amounts of some of the NR1 splice variants.

Differences of NR1 splice variant expression were found both during postnatal development and between regions in the adult brain. For example, NR1 protein with C1 was more abundant in the cortex and the hippocampus than in the thalamus or the striatum, whereas the opposite was found for the NR1 variants with C2. NR1 subunits containing N1 were far more abundant in the thalamus, and less expressed in the cortex and the hippocampus. Expression of NR2A and NR2B was also found to vary between these regions; for example, NR2B was found to be expressed at higher levels in the striatum than in the thalamus, whereas the same levels of the NR2A subunit were expressed in both regions.

## 336.3

## GLUR2 RECEPTOR PROTEIN EXPRESSION IS REDUCED IN HIPPOCAMPAL CA1 AFTER GLOBAL ISCHEMIA.

W.A. Pulsinelli\*, L.K. Friedman, T. Nowak, D. Pellegrini, J.M. Morrison, R.S. Zukin. Dept. Neurology, Univ. TN, TN 38163 and Dept. Neurosci. Albert Einstein Coll. Med. Bronx, NY 10461

Transient global ischemia results in delayed, selective cell death of hippocampal CA1 neurons. Reduced mRNA expression of GluR2 (the AMPA receptor subunit that limits  $Ca^{2+}$  permeability) occurs in CA1 neurons after induction of global ischemia and prior to neuronal cell death. The present study was undertaken to examine AMPA and NMDA receptor protein expression in ischemic and control (sham-operated) rats at the level of the hippocampus. Global ischemia was induced by four-vessel occlusion; cerebral circulation was restored after 10 min. At 24 hrs, GluR2 immunolabeling (detected with a monoclonal Ab to GluR2) was decreased in CA1 neurons. Isolated CA1 neurons exhibited somatic staining in the absence of dendritic staining. At 48 hrs, GluR2 immunoreactivity in CA1 was virtually absent in 6 of 7 animals. Histological examination revealed little or no neurodegeneration at this time. In conclusion, changes in GluR2 receptor protein follow changes in GluR2 mRNA in the CA1 subfield prior to neurodegeneration. These findings provide further support that increased formation of  $Ca^{2+}$ -permeable AMPA receptors in CA1 neurons may enhance glutamate pathogenicity in this region.

## 336.5

## ANTISENSE OLIGODEOXYNUCLEOTIDES TARGETED TO GLUR-B mRNA ALTER THE CALCIUM PERMEABILITY OF AMPA RECEPTORS IN RAT CULTURED CORTICAL NEURONS

A.L. Uitz\* and T.A. Verdoorn. Dept. of Pharmacology, Vanderbilt University, Nashville, TN 37232-6600.

We tested the role of GluR-B in controlling the functional properties of neuronal AMPA receptors. In cortical neurons cultured from embryonic day 17 rats, the calcium permeability decreased as the number of days *in vitro* (DIV) increased. Whole cell patch clamp, with 100  $\mu$ M cyclothiazide and 100  $\mu$ M AMPA, was used to obtain current-voltage relationships in external solutions containing either sodium or calcium as the sole external cation. Neurons at 9 DIV and 24 DIV had  $P_{Ca}/P_{Na}$  ratios of  $0.13 \pm 0.088$  (n=7) and  $0.0068 \pm 0.0019$  (n=7), respectively. Additionally, 9 DIV neurons obtained from postnatal day 1 rats exhibited a ratio of  $0.010 \pm 0.0041$  (n=5).

In one experiment, cortical neurons obtained from postnatal day 0 rats were maintained in MEM plus N2 supplement. At days 3 and 5 *in vitro*, antisense and sense phosphodiester oligonucleotides targeted to the GluR-B mRNA translation start site were added to the culture medium at a concentration of 1.0  $\mu$ M. At 7 DIV, the average  $P_{Ca}/P_{Na}$  ratio for 1  $\mu$ M antisense was  $1.29 \pm 1.0$  (n=3) and the ratio for sense treated cells was  $0.018 \pm 0.017$  (n=4). Subsequent experiments have focused on increasing the efficiency and detection of oligonucleotide uptake. For example, liposome-mediated transfection of 0.3  $\mu$ M antisense oligonucleotide increases average calcium permeability, producing a  $P_{Ca}/P_{Na}$  ratio of  $0.54 \pm 0.75$  (n=2).

Treatment of cortical neurons with antisense oligonucleotides may decrease the expression of GluR-B and subsequently prevent the decline in calcium permeability that occurs during *in vitro* cortical neuron maturation.

## 336.2

## FOCAL CEREBRAL ISCHEMIA ALTERS NMDA AND AMPA RECEPTOR AND PREPROENKEPHALIN GENE EXPRESSION IN STRIATUM AND CORTEX

L.K. Friedman\*, M.D. Ginsberg<sup>1</sup>, O.F. Alonso<sup>1</sup>, R.S. Zukin. Dept. Neuroscience, Albert Einstein Coll. Med. Bronx, NY 10461 <sup>1</sup>Dept. Neurology, Univ. Miami, FL 33101

Activation of NMDA receptors by glutamate may play a role in neuronal cell death following middle cerebral arterial occlusion (MCA-O). NMDA and AMPA antagonists reduce the extent of infarction produced by MCA occlusion. *In situ* hybridization was used to measure glutamate and preproenkephalin (PPE), (precursor of enkephalin peptides) expression in the striatum and cortex of adult rats following 1.5 hrs of MCA occlusion and three recirculation (R) periods. At 1.5 hrs R, autoradiography indicated pronounced but differential decreases in NR1, GluR2, GluR3, and PPE expression throughout the ipsilateral striatum. In the cortex more selective changes in expression were observed. NR1 was reduced in most of the ipsilateral cortex relative to control brain and the contralateral side. GluR2 was predominantly reduced in parietal cortex. In contrast, cortical GluR1, GluR3 and PPE mRNAs were unaltered. At 3 hrs R, MCA-O animals showed a regional specificity in glutamate receptor gene expression in ipsilateral striatum; reduced expression was restricted to the dorsomedial striatal subfield. At 24 hrs R, reduced mRNA expression occurred only in animals that exhibited some neuronal damage in ipsilateral striatum and cortex. PPE expression was reduced in the contralateral side of these animals. All mRNA changes were in mRNA content per neuron. Histological evaluation showed pallor in the absence of neurodegeneration in areas that showed marked changes in glutamate and PPE mRNAs at all three recirculation periods. Changes in mRNA expression occur prior to obvious neuronal cell damage or loss but persist in animals that exhibit cell damage. In addition, the region where PPE expression is reduced in the ipsilateral striatum is primarily innervated by the affected ipsilateral cortical region suggesting a relationship between glutamatergic and enkephalin synapses.

## 336.4

EXPRESSION PATTERN OF THE KAINATE RECEPTORS STUDIED BY *IN SITU* HYBRIDIZATION IN THE BASAL GANGLIA AND VENTRAL MESENCEPHALON. S. BISCHOFF\* and S. HEINEMANN. Salk Institute, Mol. Neurobiol. Lab., La Jolla, CA 92037

Molecular cloning led to the identification of five kainate receptor subunits, GluR5-7, KA1 and KA2. To gain knowledge on their possible functions within the CNS, we performed a detailed mapping of the mRNA encoding each of them in the mouse brain basal ganglia. This circuitry plays a pivotal role in the translation of motivation into action and receives multiple glutamatergic inputs. mRNA transcripts were mapped by using *in situ* hybridization histochemistry with <sup>35</sup>S-labeled antisense riboprobes. The kainate receptor subunits were found to be expressed at various degrees in all aspects of the basal ganglia. However, they differ from each other in their relative expression levels as well as in their specific localization. GluR6 is expressed at highest levels in the striatum in the soma of the descending GABAergic pathways, in the nucleus accumbens and olfactory tubercles, and in the subthalamic nucleus. GluR7 is the major subunit in the ascending nigrostriatal and mesolimbic DAergic neurons. GluR5 is only expressed at high levels in the islands of Calleja and the substantia nigra pars compacta. KA2 usually followed the distribution of GluR6, though with a generally much lower level of expression. Finally, KA1 is not expressed at significant levels in any region of this neuronal circuitry. These data suggest that the kainate receptors in general might be involved in the functions associated with the basal ganglia such as the control of the motor programs. Often co-expressed with dopamine receptors, the kainate receptors may regulate the central dopaminergic transmission. Consequently, they might also be implicated in diseases associated with movement disorders, in neurodegenerative processes as well as psychiatric illnesses associated with impairment of the basal ganglia and limbic structures.

## 336.6

## USE OF ANTISENSE OLIGODEOXYNUCLEOTIDES TO DEFINE DEVELOPMENTAL CHANGES IN THE SENSITIVITIES OF NMDA RECEPTORS TO ANTAGONISTS. J. Zhong\*, V. K. Gribkoff and P. B. Molinoff. Dept. of Pharm. Univ. of Penn. Sch. of Med., Phila., PA 19104 and CNS Drug Discovery, Bristol-Myers Squibb, Wallingford, CT 06492.

Antisense oligodeoxynucleotides were used to determine whether alterations in the expression of NMDA receptor subunit mRNAs are responsible for developmental changes in the sensitivities of the receptor to different NMDA receptor antagonists. *Xenopus* oocytes were injected with mRNA prepared from neonatal and adult rat cortex, and the affinities of the receptor for different NMDA receptor antagonists were determined under voltage clamp. NMDA receptors expressed from adult rat cortex mRNAs have higher affinities for glycine site antagonists like 7-chlorokynureneate and for glutamate site antagonists like CGP-39653 than those expressed from 1 day old rat mRNAs. The properties of receptors seen when adult brain mRNA was coinjected with antisense oligonucleotide against the NMDA receptor subunit NR2A were similar to receptors expressed following injection of 1 day old rat cortex mRNA in sensitivity to 7-chlorokynureneate and CGP 39653. We have previously reported the delayed expression of NMDA receptors having a low affinity for ifenprodil during development. Coinjection of antisense oligonucleotide for the NR2A subunit with adult mRNA selectively blocked the expression of receptors with a low affinity for ifenprodil. These data suggest that the sensitivity of NMDA receptors to various antagonists changes during development, and alterations in the expression of different subunits during development can account for those changes.

## 336.7

**CHARACTERIZATION OF NMDA RECEPTOR SUBUNITS IN HIPPOCAMPAL AND CEREBELLAR PRIMARY CULTURES.** M. Didier\*, M. Xu, S.A. Berman, S. Bursztajn. Lab. for Molecular Neuroscience, McLean Hospital and \*Dept of Psychiatry, Harvard Med. Sch. Belmont and Boston, MA, USA.

We characterized the molecular nature and the excitotoxic properties of NMDA receptors expressed in mouse hippocampal and cerebellar granule neurons. RT-PCR revealed that NMDA $\epsilon$ 1 as well as NMDA $\epsilon$ 1-4 subunits were expressed in cerebellar cultures. In contrast, mRNA for NMDA $\epsilon$ 3 was undetectable in cultured hippocampal neurons. In cerebellar cultures, western-blot analysis showed that the amount of membrane-bound NMDA $\epsilon$ 1,  $\epsilon$ 1 and  $\epsilon$ 3 subunits increased throughout the neuronal development *in vitro*. In contrast, the  $\epsilon$ 2 expression was already high after 3 days in culture and remained relatively stable thereafter. At 9 days in culture, a somatic and neuritic immunolocalization for all these NMDA subunits was clearly identified in most granule neurons but not glial cells. In hippocampal cultures, an increase in NMDA $\epsilon$ 1,  $\epsilon$ 1 and  $\epsilon$ 2 proteins was observed during the neuronal development. Most of pyramidal cells were immunoreactive for these NMDA subunits. The NMDA $\epsilon$ 3 subunit was never detected either by western-blot analysis or immunocytochemistry in hippocampal primary cultures. In both cerebellar and hippocampal neurons, an overactivation of NMDA receptor induced a dramatic neuronal cell death. The NMDA receptor subunits involvement in excitotoxicity was assayed using an antisense oligonucleotide (ODN) strategy. The antisense ODN treatment reduced significantly and specifically the amount of the respective NMDA subunits. In cerebellar cultures, antisense, but not sense, ODNs for NMDA $\epsilon$ 1,  $\epsilon$ 1 and 2 rescued granule cells from NMDA excitotoxicity, without protecting them from toxicity mediated by kainate or MPP<sup>+</sup> exposure. In hippocampal cells, antisense ODNs for NMDA $\epsilon$ 1,  $\epsilon$ 1 and 2 reduced NMDA-induced neurotoxicity. In many experiments, co-treatments with several antisense ODNs for NMDA $\epsilon$  subunits did not improve the neuroprotection suggesting that several NMDA $\epsilon$  subunits may be colocalized in the same NMDA receptor. Immunoprecipitation experiments indicated that at least NMDA $\epsilon$ 1,  $\epsilon$ 1 and 2 can be present as heteromer complexes in both cerebellar and hippocampal cultured neurons. Further experiments are in progress to identify other NMDA receptor subunits which may mediate neurotrophic and neurotoxic glutamate properties in cerebellar and hippocampal cells.

## 336.9

**IMMUNOHISTOCHEMICAL LOCALIZATION OF GLUTAMATE RECEPTORS IN THE CAT BRAIN STEM.** R. Ambalavanar, C. Ludlow, Y. Tanaka and R.J. Wenthold\*. NIH, NIDCD, Building 10, Room 5D38, 10, Center Drive MSC 1416, Bethesda, Maryland, MD 20892.

The glottic closure reflex in the larynx plays an important role in protecting the lower airway from invasion of foreign bodies. Excitatory amino acid receptors may play an important role in the laryngeal sensory-motor network. In the present study we investigated the distribution of AMPA-selective glutamate receptor subunits (GluR1-GluR4) and the NMDA receptor subunit NMDAR1 in the cat brain stem. Eight cats of both sexes were deeply anaesthetized with pentobarbital (100 mg/kg, i.p.) and perfused transcardially with 0.1M phosphate buffer (PB, pH 7.4) followed by Zamboni fixative. Transverse sections (30 $\mu$ m thick) of the brain stem were incubated in antibodies to GluR1, GluR2/3, GluR4 and NMDAR1 (1-3mg/ml) and then with avidin-biotin complex (ABC-kit). Controls were carried out by substituting either PBS for primary antibody or preabsorbed antibodies with their corresponding peptide antigens. The controls did not show any evidence of nonspecific labeling. Generally, denser staining of perikarya and neuropil was observed with GluR2/3 and GluR4. GluR4 labeling was particularly clear in the cell bodies including their fine processes. In the nucleus tractus solitarius (NTS), which receives afferent input from the larynx, staining was found with all four antibodies. The solitary tract showed punctate staining. Cell body staining was more common for GluR1 and GluR2/3 than for NMDAR1 or GluR4 in different subnuclei of the NTS. Staining was observed with varying intensity in the reticular core and other sensory and motor nuclei in the brain stem including the nucleus ambiguus where laryngeal efferent neurons are located. The present results suggest that both NMDAR1 and AMPA receptor subtypes are involved in the laryngeal neural circuitry and that there may be an overlap in their distribution.

## 336.11

**IMMUNOCYTOCHEMICAL LOCALIZATION OF GLUTAMATE RECEPTOR SUBUNITS IN PURKINJE CELLS IN DEVELOPING AND ADULT RATS.** R.S. Petralia\*, H.M. Zhao, Y.-X. Wang and R.J. Wenthold. Lab. of Neurochemistry, NIDCD, NIH, Bethesda, MD 20892.

Cerebellar Purkinje cells receive 2 major excitatory inputs: an extrinsic input from climbing fibers originating from inferior olive neurons, and an intrinsic input from parallel fibers originating from granule cells of the cerebellar cortex. Activity in both of these afferents may be necessary for plastic changes (i.e., long-term depression) needed to modulate the inhibitory response of the Purkinje cells. Previous *in situ* hybridization and immunocytochemical studies indicated that a number of glutamate receptor subunits are prevalent in adult Purkinje cells, with the most abundant including GluR2, GluR3, NR1, delta 2, and mGluR1. In this study, we used C-terminus peptide antibodies recognizing GluR1, GluR2/3, delta 1/2, NR1, and mGluR1 $\alpha$  (the latter provided by Drs. C.D. Blackstone and R.L. Huganir) as well as an N-terminus fusion protein antibody to GluR5-7 (provided by Dr. J.H. Morrison). Light microscope studies of Purkinje cell development revealed that staining with GluR2/3, delta 1/2, NR1 and mGluR1 $\alpha$  antibodies was light at 10 days postnatal (P10). By P15, staining was moderate to dense and was similar to adult levels. Since maximum synaptogenesis occurs between P10 and P15, expression of all of these subunits simultaneously may be necessary for function of Purkinje cell circuitry. Ultrastructural examination of adult Purkinje cell parallel and climbing fiber synapses revealed differing patterns of postsynaptic staining with the 6 antibodies, with dense staining in both types of synapses seen most commonly with mGluR1 $\alpha$  antibody. In addition, some presynaptic staining was seen with GluR5-7, and staining in Bergmann glial wrappings of parallel fiber synapses was common with GluR1, as noted previously. Thus, a particular combination of glutamate receptor types at Purkinje cell synapses may be established late in postnatal development and be required for Purkinje cell responses.

## 336.8

**TIME DEPENDENT CHANGES IN EXPRESSION OF NR1, NR2A AND NR2B NMDA RECEPTOR SUBUNITS IN RAT BRAIN AFTER MK801** X.M. Gao\*, T. Hashimoto and C.A. Tamminga. Maryland Psychiatric Research Center, University of Maryland School of Medicine, Baltimore, MD 21228

A single dose of either PCP or MK801 in rat produces a dose-related increase in NMDA-sensitive <sup>3</sup>H-glutamate binding in CA<sub>1</sub> (29%) and DG (22%) of hippocampus 24 hours after a dose (Neurosci. Lett. 1994, J. Neuro. Transm. 1995). We have now examined the time-dependent action of MK801 on the expression pattern of NR1, NR2A, and NR2B NMDA receptor subunits in rat hippocampus across a MK801 dose range. The three mRNAs encoding the NMDA subunits NR1, NR2A and 2B were quantified at 1, 3, 6, 24 and 48 hours after MK801. *In situ* hybridization and quantitative autoradiography using specific oligonucleotide probes for each subunit showed that these 3 subunits were expressed throughout the brain although this analysis focuses on hippocampus. Quantitative analysis of film densities indicated that in hippocampal CA<sub>1</sub>, an increase of 26%, 32% and 35% expression of the mRNA coding for the NR1 NMDA subunit was observed at 3h, 6h and 24h respectively after MK801 (P<0.001). Also, an increase in the expression of NR1 mRNA was found in CA<sub>3</sub> and DG between 3h to 24h (P<0.05). In addition, an increase in expression of NR2A mRNA was observed both in CA<sub>1</sub> (16-23%, P<0.01) and DG (15-21%, P<0.01) between 3h and 24h. No change was found at 1h after MK801 in the expression of NR1 and NR2A in any hippocampal region. By 48 h after drug the expression of NMDA subunits had returned to control levels. This result indicates that time dependent increases in NMDA receptor binding after PCP or MK801 in CA<sub>1</sub> and DG of hippocampus are mediated by increased NMDA receptor subunit gene expression.

## 336.10

**DISTRIBUTION OF NMDA AND NON-NMDA RECEPTORS IN THE FELINE PONS AND MEDULLA.** Y.Y. Lai\*, J.-P. Wu, J.S. Kuo and J.M. Siegel. Dept. Psychiat. Sch Med, UCLA, VAMC, Sepulveda, CA 91343 and Dept Med Res, Taichung Veterans General Hospital, Taiwan.

We have reported that microinjection of nonNMDA agonists produces muscle tone suppression, while NMDA agonists produce motor excitation in both pons and medulla of the cat. We have shown that glutamatergic neurons in brainstem nuclei project to both the pontine inhibitory area and nucleus magnocellularis. The present study identified brainstem neurons containing NMDA and nonNMDA receptors using immunohistochemical techniques. Alternate 50  $\mu$  sections were processed for NMDA receptors with NMDAR1 (PharMingen) and kainate with GluR5/6/7 (PharMingen). In both pons and medulla, the number of neurons labelling for NMDA was higher than the number labelling for kainate. The number of NMDA and kainate receptor immunoreactive neurons was found to be high in pontine gray, dorsal and ventral nuclei of the lateral lemniscus, tegmental reticular nucleus, trapezoid body, cochlear, superior and inferior olivary, hypoglossal, dorsal raphe nuclei, and motor neurons; moderate in laterodorsal tegmental, vestibular, spinal trigeminal, paragigantocellularis, and magnocellularis nuclei; low in gigantocellularis nucleus and pontine reticular formation.

## 336.12

**QUANTITATION OF AMPA RECEPTOR SURFACE EXPRESSION IN CULTURED HIPPOCAMPAL NEURONS.** R.A. Hall\* and T.R. Soderling. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Protein and mRNA levels of the AMPA-type glutamate receptor subunits GluR1-3 are high in many brain regions, but it is not known how much of the GluR protein is expressed on the surface of neurons in the form of functional receptors. To provide insight into this matter, GluR1 and GluR2/3 immunostaining in primary hippocampal cultures was quantified via western blot before and after three different treatments: cleavage of surface receptors by chymotrypsin, cross-linking of surface receptors with the amine-reactive cross-linker BS<sup>3</sup>, and biotinylation of surface receptors with the amine-reactive reagent NHS-ss-biotin. None of these three treatments affected immunostaining for the intracellular proteins actin, tubulin or CaM kinase II; immunostaining for the GluR1-3 subunits, however, was reduced by approximately 75% by all three methods, suggesting that at least three-quarters of the total receptor protein resides in the plasma membrane. The same three methods were also used to quantify [<sup>3</sup>H]AMPA binding to membrane preparations derived from control vs. treated cultures; chymotrypsin reduces binding presumably by cleaving binding sites, while BS<sup>3</sup> and NHS-ss-biotin reduce binding presumably by reacting with lysine residues known to be crucial for agonist binding to AMPA receptors. Estimates of the percentage of surface [<sup>3</sup>H]AMPA binding sites were quite different from the estimates of surface GluR protein, as less than 25% of total [<sup>3</sup>H]AMPA binding could be inactivated by the three treatments; parallel studies with the biotinylated samples demonstrated that, even though only a small fraction of the binding sites were inactivated by the biotinylation, the majority of binding sites could still be immunoprecipitated with streptavidin beads. These data suggest that the majority of AMPA receptors in hippocampal neurons are located in the plasma membrane and are exposed extracellularly, but that the binding sites of most of these receptors are not accessible to the reagents used in the present study (Supported by NIH grant NS27037).

## 336.13

MK-801 DIFFERENTIALLY REGULATES AMPA RECEPTOR SUBUNIT GENE EXPRESSION IN LIMBIC AREAS AND HIPPOCAMPUS. D.J. Healy\*, J. Frederick, H. Hamid, J.H. Meador-Woodruff. Department of Psychiatry and Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

The NMDA receptor is blocked by a magnesium ion at rest. In order to extrude the magnesium ion, the cell membrane must be partially depolarized. Complete depolarization cannot occur unless preceded by this partial depolarization. AMPA and kainate receptors have been shown to be colocalized with NMDA receptors, and may facilitate NMDA function by partially depolarizing the membrane. Therefore, any change in NMDA function may cause a compensatory change in AMPA or kainate receptor subunit expression. We tested this hypothesis by treating rats with 0.3 mg/kg, 1.0 mg/kg, and 3.0 mg/kg of MK-801, an NMDA antagonist, daily for one week. Then we measured AMPA and kainate receptor subunit mRNA levels in cortical, subcortical, and hippocampal structures, using *in situ* hybridization. Preliminary data suggest differential regulation of AMPA subunit gene expression in limbic cortex and hippocampus, indicating that the NMDA receptor may be able to autoregulate its activity via non-NMDA receptors. This may reflect a postsynaptic mechanism by which glutamatergic tone is self-regulated, in parallel with a presynaptic, autoreceptor-mediated mechanism.

## 336.15

DISTRIBUTION OF NMDA AND AMPA RECEPTOR mRNA IN THE RHESUS MACAQUE TEMPORAL CORTEX. Y.T. Garyfallou, S.G. Kohama and H.F. Urbanski\*. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, Oregon, 97006.

To complement and extend data from previous immunocytochemical studies, we have examined the distribution of NMDAR1, GluR1, GluR2 and GluR3 mRNA in the temporal cortex of the rhesus macaque (*Macaca mulatta*). Using [35-S]-labelled cRNA antisense probes transcribed from rat cDNA templates, sections of temporal cortex at the level of the caudal hippocampus and lateral geniculate body were hybridized overnight at 60 C. Following various washes, RNase treatment and a criterion wash at 70 C in 0.1X SSC, the sections were apposed to Hyperfilm (Betamax) for autoradiography. The hybridization patterns for the NMDA and AMPA receptors were similar in both distribution and intensity. High levels of hybridization were seen in the dentate gyrus and CA3, followed by slightly lower signal in the CA1, dentate hilus, entorhinal and surrounding temporal cortex. Despite high levels of NMDAR1 mRNA in the lateral geniculate body there was an apparent lack of GluR1, 2 or 3 mRNA in this region. Also of note was the differential expression of GluR1 mRNA in the temporal cortex. Unlike the other receptors examined, GluR1 expression was lacking in an intermediate layer of the cortex, but still present in apical and basal layers. The apparent colocalization of receptors in many areas is of integrative importance, but the lack of specific receptor subtypes may be equally important for regional function.

## 336.17

TWO DIFFERENT EXPRESSION PATTERNS FOR THE N-METHYL-D-ASPARTATE RECEPTOR CHANNEL IN CEREBELLAR PURKINJE CELLS OF THE *REELER* MUTANT MOUSE. Masahiko Watanabe\*, Shin Nakagawa and Yoshiro Inoue. Dept. of Anatomy, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

The purpose of this investigation is to clarify the molecular-anatomical organization of the N-methyl-D-aspartate (NMDA) receptor channel in the cerebellum of the *reeler* mutant mouse, in which various categories of the Purkinje cells are present as to the cell position and synaptic connectivity. The  $\epsilon 1$  subunit mRNA of the NMDA receptor channel was shown to be expressed in a subset of the adult *reeler* Purkinje cells. In the rostrocaudal extent, the Purkinje cells expressing the  $\epsilon 1$  subunit mRNA were distributed preferentially in the rostral cerebellum, irrespective of the normal and heterotopic positions. In the mediolateral extent, they formed segregated cell clusters, interposed by the  $\epsilon 1$  subunit mRNA-negative cell clusters. Hybridizing signals for the  $\zeta 1$  subunit mRNA were found in all the Purkinje cells, whereas those for the  $\epsilon 2$ ,  $\epsilon 3$ , and  $\epsilon 4$  subunit mRNAs were not detected in the cells. Thus, it is clear that there are two different expression patterns in the *reeler* Purkinje cells, one expressing the  $\zeta 1$  subunit mRNA alone, and the other expressing the  $\epsilon 1$  and  $\zeta 1$  subunit mRNAs. Developmentally, it was found that the *reeler* cerebellum were composed only of the former cells during 1-3 postnatal weeks, and that later and additional expression of the  $\epsilon 1$  subunit mRNA in some of these cells led to appearance of the latter cells. These findings suggest that postnatal maturation of the *reeler* cerebellum has evolved the Purkinje cell heterogeneity, with respect to the gene expression for the NMDA receptor channel.

## 336.14

DISTRIBUTION OF IMMUNOCYTOCHEMICALLY IDENTIFIED NMDA RECEPTOR SUBUNIT NMDAR1 IN THE FROG *RANA PIPIENS*. Z. Li\*, C. L. Bengston and K. V. Fite. Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

NMDA receptors have been suggested to play an essential role in neural development, synaptic plasticity, and compensation following injury. In the present study, immunocytochemistry using a polyclonal antibody that recognizes NMDA receptor subunit NMDAR1 was used to assess the localization of NMDA receptors in the CNS of the adult frog *Rana pipiens*.

Observations revealed NMDAR1 immunoreactivity in the diencephalon, midbrain and brainstem. The densest stained perikarya and dendrites were observed in the anterior preoptic area (POa) and magnocellular preoptic nucleus (Mg) of the central diencephalon. In the pretectum, scattered perikarya in the posterior thalamic neuropil (PTN) were moderately stained. Weak NMDAR1 immunoreactivity was noted in the nucleus of the basal optic root (nBOR). Perikarya in the ocular motor nucleus as well as many reticular and motor nuclei in the caudal midbrain and brainstem were moderately to densely immunostained.

Currently, assessment of how behavioral training and surgical manipulation may affect the distribution of the NMDA receptors in the frog CNS is under investigation. (supported by NSF Grant # IBN 921157 to K.V.F.)

## 336.16

DIFFERENTIAL EXPRESSION OF NMDA RECEPTOR SUBUNITS NR2A AND NR2B IN ADULT AND DEVELOPING RAT CNS REVEALED BY SUBUNIT SPECIFIC ANTIBODIES. DL Price\*, LJ Martin, and C Portera-Cailliau. Neuropathology lab, The Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

N-methyl-D-aspartate (NMDA) receptors participate in physiological and pathological processes in developing and mature CNS and are probably assemblies of NR1 with NR2 subunits. We have generated two affinity-purified polyclonal subunit-specific anti-peptide antibodies that recognize NR2A and NR2B. In Western blots of rat, pig, monkey, or human brain homogenates, each antibody detects a single 172 kD protein corresponding to its homologous subunit. In adult rat CNS, NR2A and NR2B are enriched in cortex and hippocampus, but are present in other forebrain regions. In hindbrain, NR2A is present at low levels but NR2B is barely detectable. By immunocytochemistry, both subunits are enriched in neuropil and in some cell bodies of neurons and astroglia. These subunits are also differentially expressed in postnatal CNS development. In cerebellum and spinal cord, low levels of NR2A are present throughout development, whereas NR2B is only transiently expressed in the first weeks of postnatal life. In cortex and striatum, NR2A is absent at birth but levels progressively increase thereafter, while NR2B is expressed at nearly adult levels throughout cortical development, and its developmental increase in striatum is less than that of NR2A. These results suggest that some NMDA receptors may consist of assemblies of NR1 subunits with either NR2A or NR2B, and that transient changes in NMDA receptor function may occur during maturation of certain neuronal and/or glial populations.

## 336.18

EXPRESSION OF KAINATE-PREFERRING GLUTAMATE RECEPTORS IN PRIMARY NEURAL PROGENITOR CELLS. S. Scherer\* and V. Gallo. Lab. Cell Mol. Neurophysiol., NICHD, NIH, Bethesda, MD 20892.

Primary neural progenitor cells, derived from E10 rat neural tube and neural crest, provide an ideal system for the study of various developmental processes in the mammalian nervous system. These 100% nestin-positive cultures are comprised of approximately 60% GD3-positive neural progenitors and 20% of cells which coexpress antigens characteristic of both neural and smooth muscle progenitors. These cells are capable of differentiation along both neuronal and glial pathways, and stimulation of differentiation by the adenylate cyclase agonist forskolin, increases the size of neuronal and glial cell clusters, and degree of neurite extension and branching. Furthermore, plating the cells on polyamines as opposed to fibronectin has a marked effect on morphology and significantly increases the percentage of GD3-positive cells. Using RT-PCR analysis, we have found transcripts for all of the non-NMDA ionotropic glutamate receptor subunits with the exception of GluR2 and GluR5. Previous data has shown that the kainate-preferring subunits GluR6 and KA2 are capable of forming functional heteromeric channels (Wenthold et al., J. Biol. Chem., 1994, 269:1332, and Patneau et al., Neuron, 1994, 12:357) Indirect immunohistochemistry of our primary progenitor cells, using antibodies directed against these subunits, suggests expression in both mature neurons and immature neuroepithelial precursors.

## 336.19

EXPRESSION OF NON-NMDA GLUTAMATE RECEPTOR (GluR) SUBTYPES IS TIME- AND LAMINAR-DEPENDENT DURING CORTICOGENESIS. A. Furuta, M.E. Blue\*, R.C. Koehler, R.J. Traystman and L.J. Martin. Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

We tested the hypothesis that different molecular subtypes of GluRs have distinct patterns of expression during corticogenesis. Fetal lamb brains at 60, 71, 93, 110, and 136 days gestation (term = 145 days) and adult sheep brain were prepared for immunoblotting and immunocytochemistry to determine the neocortical protein expression of AMPA receptors (GluR1, GluR2/GluR3 [GluR2/3]), kainate (KA) receptors (GluR6/GluR7 [GluR6/7]), and a metabotropic GluR (mGluR5). Synaptophysin expression was used as an index of synaptic maturation. AMPA and KA receptors and mGluR5 are present at E60, at least 10 days before the onset of synaptogenesis. With maturation, AMPA receptor expression increases to reach adult levels near E136, whereas KA receptor and mGluR5 expression decreases. GluR subtypes have distinct localizations in the developing telencephalic vesicle. GluR1 is enriched in superficial cortical plate at E60-E93 and later is expressed in nonpyramidal neurons, whereas GluR2/3 is enriched early in deep cortical plate (layer 5) and later is localized to pyramidal neurons. GluR6/7 is highly expressed in marginal zone, mid-cortical plate, and layer 5 at E60-E71 and then is down-regulated. mGluR5 is highly expressed in marginal zone at E60-E93 and is down-regulated to minimal expression in layer 1 at E136. GluR1, GluR2/3 and GluR6/7 are expressed transiently in germinal matrix. AMPA and KA receptors are expressed in developing white matter. mGluR5 is not expressed in germinal matrix or white matter. We conclude that the expression of ion channel and metabotropic GluR subtypes is dynamic during corticogenesis, with subtype- and subunit-specific regulation. This laminar and temporal segregation of GluRs may be important for cortical pattern formation. (Supported by NS20020)

## 336.21

ALTERED GENE EXPRESSION FOR NMDA RECEPTOR SUBUNITS IN CEREBELLAR NEURONS OF THE *STAGGERER* MUTANT MOUSE. Shin Nakagawa\*, Masahiko Watanabe and Yosiro Inoue. Dept. of Anatomy, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

The *staggerer* is an autosomal recessive mutation, resulting in a selective and almost complete absence of the parallel fiber-Purkinje cell (PC) synapses, where glutamate is the major neurotransmitter. In the present investigation, we have examined the gene expression of the NMDA receptor channel subunits in cerebellar neurons of the *staggerer* mutant mouse, with <sup>35</sup>S-labeled antisense oligonucleotide probes. At postnatal day 21 (P21), a subset of medium-to-large neurons (MLNs) in the cerebellar cortex, which compromise PCs and Golgi cells, showed strong signals for the  $\epsilon 1$  and  $\zeta 1$  subunit mRNAs and weaker signals for the  $\epsilon 4$  subunit mRNA, with regional variations. The MLNs expressing the  $\epsilon 1$ ,  $\epsilon 4$  and  $\zeta 1$  subunit mRNAs were aligned as monolayer in the midline region of the *staggerer* cerebellum, whereas in the lateral (hemisphere) region they were dispersed in various depths of the granular layer or just beneath the layer. The distribution of the MLNs was virtually consistent with that of neurons expressing the calbindin mRNA strongly, suggesting that they are, if not all but mostly, the Purkinje cells. The granule cells displayed marked signals for the  $\epsilon 1$ ,  $\epsilon 2$ ,  $\epsilon 3$  and  $\zeta 1$  subunit mRNA at P14 and P21. When compared to expression patterns in corresponding neurons in the wild-type mouse (Watanabe et al. 1994), it is evident that the *staggerer* PCs expressed the  $\epsilon 1$  and  $\epsilon 4$  subunit mRNAs additionally and anomalously, while down-regulation of the  $\epsilon 2$  subunit expression was retarded in the *staggerer* granule cells. These findings raise a possibility that time-dependent and neuron type-specific expression of the NMDA receptor channel subunits is not only regulated by genetic programs of individual neuron, but could be modified by certain epigenetic factors.

## 336.20

DISTRIBUTION OF AMPA-GLUTAMATE RECEPTOR b mRNA AND PROTEIN IN RAT HIPPOCAMPAL GABAergic NEURONES C. Racca\*, M.V. Catania\*, H. Monyer\*, and B. Sakmann<sup>1</sup>. Max-Planck-Institut für Medizinische Forschung<sup>1</sup> and Zentrum für Molekulare Biologie der Universität Heidelberg<sup>1</sup>, 69120 Heidelberg, Germany

The distribution of GluR-B mRNA and protein in adult rat hippocampal GABAergic neurones was studied by performing a cross-labeling study (GluR-B mRNA *in situ* hybridization with GAD67 immunohistochemistry, and GAD67 mRNA *in situ* hybridization with GluR-B immunolabeling), accompanied by the respective controls (GAD67 or GluR-B mRNA *in situ* hybridization plus GAD67 or GluR-B/C protein immunocytochemistry). Digoxigenin-labeled cRNA probes against GluR-B mRNA subunit, or GAD67 and 65 enzyme mRNAs were used in *in situ* hybridization experiments. In immunocytochemical studies, we used an antibody recognizing an epitope conserved on GluR-B, -C, and 4c subunits and common to both flip and flop variants or a polyclonal antibody for GAD67 enzyme.

GABAergic hippocampal neurones expressed varying levels of GluR-B mRNA. Although the majority were GluR-B mRNA positive, the levels of GluR-B mRNA observed in GABAergic neurones were overall lower than in pyramidal and granule cells, which showed the highest hybridization signal.

The differential GluR-B mRNA expression levels in GABAergic versus principal neurones was also observed at the protein level. There was a paucity of GluR-B/C labeling in the vast majority of somata of GABAergic neurones which contrasted with the strong expression of GluR-B/C proteins in the hippocampal principal neurones. Only a few immunoreactive somata of inhibitory neurones were found in the hilus and stratum lucidum.

Our results illustrate the low expression of the GluR-B subunit mRNA and GluR-B/C proteins in GABAergic hippocampal neurones. Considering the dominant role of this subunit in determining the divalent ion permeability of the receptor, it can be predicted that most GABAergic neurones express calcium-highly permeable AMPA receptor channels.

## 336.22

ANATOMICAL DISTRIBUTION AND POSTNATAL DEVELOPMENT OF ENDOGENOUS FREE D-ASPARTATE AND D-SERINE IN THE RAT BRAIN AND PERIPHERY. A. Hashimoto\*, T. Oka and T. Nishikawa. PRESTO, Research Development Corporation of Japan, Saitama 332 Japan and National Institute of Neuroscience, NCNP, Tokyo 187 Japan.

We have investigated the anatomical distribution and postnatal changes in D-aspartate and D-serine in the rat brain and periphery using HPLC techniques. D-Serine was concentrated predominantly in the brain throughout postnatal life. A substantial quantity of D-serine was seen throughout the brain areas at birth. The cerebral D-serine content increased from birth to postnatal week (PW) 3 and remained constant thereafter, whereas the cerebellar D-serine content peaked at PW 1. In contrast, the transient emergence of D-aspartate was observed in almost all brain and peripheral organs. A substantial quantity of D-aspartate was also seen in all brain areas at birth, whereas the D-aspartate content in the cerebrum and cerebellum decreased dramatically by PW 1 and 7, respectively. Further, the D-aspartate content and the ratio of D- to total aspartate were highest in the adrenal at PW 3 ( $608 \pm 70$  nmol/g, 45.9%) and in the testis at PW 14 ( $221 \pm 7$  nmol/g, 57.8%), respectively. Because D-serine potentiates NMDA receptor-mediated transmission through the strychnine-insensitive glycine site and because D-serine exhibits an NMDA receptor-related distribution and development, D-serine may be a tenable candidate for an intrinsic ligand for the glycine site. In contrast, because the periods of maximal emergence of D-aspartate in the brain and periphery occur during critical periods of morphological and functional maturation of organs, D-aspartate could participate in the regulation of these developmental processes of organs.

## EXCITATORY AMINO ACID RECEPTORS VII

## 337.1

CHARACTERIZATION OF [<sup>3</sup>H]ANIRACETAM BINDING IN BRAIN MEMBRANES. E. Fallarino<sup>1</sup>, A.A. Genazzani<sup>2</sup>, S. Silla<sup>1</sup>, M.R. L'Episcopo<sup>2</sup>, E. Nicoletti<sup>\*1</sup> and M.C. Fioretti<sup>1</sup>. <sup>1</sup>Dept. Exp. Med. Biochem. Sci., University of Perugia, and <sup>2</sup>Institute of Pharmacology, University of Catania, Italy.

[<sup>3</sup>H]Aniracetam bound to specific and saturable recognition sites in membranes prepared from discrete regions of rat brain (specific binding was high in purified synaptosomes or mitochondria, and low in the myelin fraction). In cortical membranes, binding was Na<sup>+</sup>-independent, was still detectable at 4°C, and underwent rapid dissociation. Scatchard analysis revealed a single population of sites with an apparent K<sub>D</sub> value of 70 nM. Specific [<sup>3</sup>H]aniracetam binding was displaced neither by various metabolites of aniracetam, nor by piracetam, oxiracetam, cyclothiazide, or GYKI 52466. Specific binding was abolished when membranes were incubated at 37°C under shaking and then washed (a procedure that reduces the amount of endogenous glutamate), and could be restored after addition of glutamate or AMPA, but not of kainate. The action of AMPA was antagonized by DNQX, which also reduced [<sup>3</sup>H]aniracetam binding in unwashed membranes. It appears therefore that activation of AMPA receptors facilitates the access of [<sup>3</sup>H]aniracetam to its specific binding sites in brain membranes.

## 337.2

SUBTYPE SELECTIVE ACTION OF THE AMPA ANALOG (RS)-2-AMINO-2-[3-CARBOXYMETHOXY]-5-METHYLISOXAZOL-4-YL]PROPANOIC ACID (AMOA) ON RECOMBINANT IONOTROPIC GLUTAMATE RECEPTORS. P. Wahl\*, K.M. Houamed, P. Krogsgaard-Larsen, J.S. Rasmussen, J. Egebjerg. Novo Nordisk A/S, DK-2880 Bagsvaerd, and Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark

The effects of AMOA on kainate- and AMPA-preferring glutamate receptor subtypes, expressed in *Xenopus* oocytes or mammalian cells, were investigated using electrophysiological methods. AMOA at concentrations up to 500  $\mu$ M did not antagonize currents evoked by submaximal concentrations (3 - 5  $\mu$ M) kainate on homomeric GluR6(Q) expressed in mammalian cells. At identical concentrations AMOA reduced the currents evoked by 100  $\mu$ M kainate on homomeric GluR1, expressed in oocytes, by 70 to 80%. The actions of AMOA on GluR currents in oocytes injected with brain mRNA were complex, and agonist dependent. When AMPA was used as an agonist the effects of AMOA were biphasic; at low AMPA concentrations AMOA depressed the currents, while currents evoked by high AMPA concentrations were augmented by AMOA. In contrast, kainate currents were depressed by AMOA at all agonist concentrations tested. The mechanism(s) of AMOA action are currently being investigated. AMOA may turn out to be a useful tool for elucidating structure-function relations of GluRs, as well as being basis for novel therapeutics.

## 337.3

MODULATION OF FAST GLUTAMATERGIC EXCITATORY SYNAPTIC TRANSMISSION BY NBQX AND CYCLOTHIAZIDE IN THE CA1 REGION OF HIPPOCAMPAL SLICES. G. Rammes<sup>1</sup>, C.G. Parsons<sup>2</sup>, D. Swandulla<sup>1</sup>, and G.L. Collingridge<sup>3</sup>. Dept. Molecular Pharmacol., Univ. Erlangen, Germany<sup>1</sup>, Dept. Pharmacol., Merz+Co., Frankfurt, Germany<sup>2</sup>, Dept. Anatomy, The Medical School, Bristol, England<sup>3</sup>.

We have previously shown that the AMPA receptor positive modulator cyclothiazide and the non-competitive AMPA receptor antagonist GYKI-52466 have very strong allosteric interactions when tested on agonist-induced currents in cultured cells and on synaptic transmission in hippocampal slices (Rammes et al., Soc. Neurosci. Abs. (1994) 20: 1535). The purpose of the present study was to test the specificity of this effect by accessing possible interactions of cyclothiazide and the competitive AMPA receptor antagonist NBQX on isolated AMPA receptor-mediated EPSCs (AMPA-EPSCs) recorded in the CA<sub>1</sub> region of hippocampal slices. Cyclothiazide concentration-dependently slowed the decay of AMPA-EPSCs with an EC<sub>50</sub> of 31 μM (control τ=23ms, cyclothiazide 330 μM τ=70ms) and produced a variable increase in the amplitude of AMPA-EPSCs (up to 133% of control). NBQX (1 μM) almost abolished EPSCs (4% of control) but had little discernible effect on time constants. The effects of this concentration of NBQX were reduced (response amplitude 25% of control) in the presence of cyclothiazide (330 μM). Moreover, NBQX (1 μM) was able to partially reverse the effects of cyclothiazide in slowing decay time constants by about 50%. Further experiments are being performed to test the concentration-dependency of these effects. These provisional data indicate that cyclothiazide has allosteric interactions with both competitive and non-competitive AMPA receptor antagonists but do not lend support to the hypothesis that GYKI-52466 and cyclothiazide actually bind to the same site. As our previous data indicate that cyclothiazide increases and GYKI-52466 decreases the affinity of AMPA it may be that these interactions on response kinetics are mediated via such a mechanism. Furthermore, the cyclothiazide-induced changes in AMPA-EPSC response kinetics may be governed by changes in agonist affinity i.e. a slowing of *toff*, rather than by desensitisation.

## 337.5

HETEROMERIC NMDA RECEPTOR CALCIUM RESPONSES MEASURED USING AEQUORIN BIOLUMINESCENCE. E.R. Grant<sup>1</sup>, L. Kricka<sup>2</sup>, D.E. Pleasure<sup>3</sup>, and D.R. Lynch<sup>1</sup>. Dept. of Pharmacology, Neurology, and Pathology, Univ. of Pennsylvania and Children's Hospital of Philadelphia, Philadelphia, PA 19104.

The NMDA receptor mediates increases in intracellular calcium levels. These calcium changes in response to native NMDA receptor activation have been characterized in a variety of neuronal cell types. However, the receptor subunit requirements for eliciting such responses as measured in non-neuronal expression systems have not yet been determined. Thus, we measured the relative calcium changes mediated by heteromeric NMDA receptor subunit combinations transiently expressed in HEK-293 cells cotransfected with the calcium sensitive bioluminescent protein, aequorin. Aequorin emits blue light proportional to binding of calcium (wavelength=464 nm) in the presence of its chromophore cofactor *h*-coelenterazine. Upon addition of NMDA receptor agonists and antagonists, luminescence responses were measured in individual wells of 96-well microtiter plates using a luminometer. Addition of 100 μM glutamate, 100 μM glycine, and 2 mM Ca<sup>++</sup> to the assay buffer elicited robust luminescence responses (10-100 fold over baseline) in cells expressing the NMDA 1a-2A or NMDA 1a-2B subunit combinations. Glutamate and glycine in the absence of extracellular calcium elicited no response, and calcium alone in the absence of agonists elicited no response. MK-801 inhibited NMDA 1a-2A mediated responses to 100 μM glutamate, 100 μM glycine, and 2 mM Ca<sup>++</sup> with an IC<sub>50</sub> of 93±21 nM. NMDA 1a-2A responses to quinolinic acid were dose-responsive. Cells expressing the NMDA 1a-2C combination consistently showed no substantial response to 100 μM glutamate, 100 μM glycine, and 2 mM Ca<sup>++</sup> or to quinolinic acid (at best 1.5-2 fold over baseline), even though this combination's expression levels were similar to that of NMDA 1a-2A based on <sup>3</sup>H-glutamate binding and whole cell current amplitudes. These data suggest that NMDA receptor mediated changes in intracellular calcium are partly dependent on the receptor subunit composition. The source of these calcium changes in non-neuronal cells requires calcium influx through the receptor channel, but other intracellular factors may be involved. (NIH-DA07130)

## 337.7

KAINATE INDUCED DOSE-DEPENDENT Ca<sup>2+</sup> WAVES SIGNALING PATTERNS IN ASTROCYTES. A.H. Cornell-Bell<sup>1</sup>, W. T. Kim<sup>2</sup>, R.M. Villalba, Lion Imaging, Inc. Westbrook CT 06498 and <sup>2</sup>Yale University School of Medicine, New Haven CT 06510.

Time-lapse confocal scanning laser microscopy was used to study Ca<sup>2+</sup> waves in rat hippocampal astrocytes exposed to increasing doses of kainate (KA= 1, 10, 25, 50, 100 μM). There is a progression of wave patterns generated depending upon dose of agonist. When the astrocyte ionotropic glutamate receptor is bound with KA (100 μM) there is a sustained rise in cytoplasmic Ca<sup>2+</sup> levels followed by a regenerative curvilinear intercellular Ca<sup>2+</sup> wave that is driven by the Na<sup>+</sup>/Ca<sup>2+</sup> exchanger (Kim et al., 1994). In this ionotropic response Na<sup>+</sup> and Ca<sup>2+</sup> do not flux through voltage-gated channels: a) TTX (10 μM) which blocks Na<sup>+</sup> channels had no effect on the wave b). Blocking the dihydropyridine-sensitive Ca<sup>2+</sup> channels with Nifedipine (10 μM) or Nimodipine (1 μM) likewise had no effect on this wave. However, inhibiting the Na<sup>+</sup>/Ca<sup>2+</sup> exchanger with Benzamil (100 μM) completely abolishes the Ca<sup>2+</sup> wave. Astrocytes were loaded with the fluorophore Fluo-3AM (4 mM with Pluronic acid). At low KA (1 μM) multiple target waves develop that involve 4-10 cells. These waves spread from a single site and then collapse back upon their point of origin. As KA dose increases the velocity of the spreading target waves increases from 7.5 ± 2.3 μm/sec (1-10 μM KA) to 8.8 ± 9 μm/sec (25 μM KA) to 15 ± 3.3 μm/sec (50 μM KA) to 25.7 ± 6 μm/sec (100 μM KA). Target waves develop into regenerating spiral waves at a dose of 100 μM KA. With increased doses of KA (50-100 μM) there is a significant increase in the number of individual cells involved in a wave. This data suggests that astrocytes near the site of neurotransmitter release will produce a Ca<sup>2+</sup> wave that extends longer and faster than a wave initiated by astrocytes at site of lower neurotransmitter concentration.

## 337.4

INHIBITION OF HIPPOCAMPAL FIELD POTENTIALS *IN VIVO* BY AMPA RECEPTOR-SELECTIVE ANTAGONISTS. J.C.R. Randle<sup>1</sup>, V. Borday<sup>2</sup>, D. Briet<sup>1</sup> and G.A. Böhm<sup>1</sup>. Rhône-Poulenc Rorer Central Research, CNS Pharmaceuticals Research Program, 94400 Vitry-sur-Seine, France.

AMPA receptors are a promising molecular target for the development of neuroprotectant drugs. We have evaluated the blood brain barrier (BBB) penetration of AMPA receptor antagonists by recording their effects on central glutamatergic neurotransmission *in vivo* after intravenous administration. The excitatory post-synaptic potential (EPSP) and population spike (PS) evoked in the hilus of the dentate gyrus following stimulation of the perforant pathway (at 30 sec intervals) were measured (slope of EPSP, amplitude of PS) in urethane-anesthetized male Sprague-Dawley rats (300 g ± 10%). The competitive AMPA antagonist, YM-900 [6-(1*H*-imidazol-1-yl)-7-nitro-(1*H*,4*H*)-quinoxaline-2,3-dione], dose-dependently inhibited the PS (ID<sub>50</sub> = 9 mg/kg) and EPSP (ID<sub>50</sub> = 13 mg/kg), when infused over 32 min at 2-16 mg/kg (0.0625-0.5 mg/kg/min). In contrast, perfusions of NBQX (6-nitro-7-sulfamoylbenzo[*h*]quinoxaline-2,3-dione; 8-64 mg/kg) were virtually inactive unless preceded by an intraperitoneal injection (200 mg/kg) of the organic acid transport inhibitor, probenecid, suggesting rapid elimination upon slow infusion. Accordingly, NBQX (8-64 mg/kg i.v.) inhibited evoked potentials when administered as a bolus (ID<sub>50</sub> = 25 mg/kg on PS, 15 min post-treatment). GYKI 52466, an allosteric AMPA receptor antagonist, partially inhibited hippocampal field potentials when perfused at doses of 8 and 16 mg/kg and, like NBQX, was more effective when administered as a bolus. These results confirm that all three compounds are able to penetrate the BBB to inhibit glutamatergic neurotransmission at doses at which they are anti-convulsant and neuroprotective. However, rapid elimination appears to limit their efficacy, particularly for NBQX and GYKI 52466 compared to YM-900.

## 337.6

DIRECT DEMONSTRATION THAT FUNCTIONAL N-GLYCOSYLATION SITES ENGINEERED INTO GluR1 TO PROBE TOPOLOGY ARE EXTRACELLULAR. M. Hollmann<sup>1</sup> and T. Morth<sup>2</sup>. Glutamate Receptor Lab., Max-Planck-Inst. f. Experim. Medicine, D-37075 Göttingen.

The transmembrane domain (TMD) topology of glutamate receptors (GluRs) is currently hotly debated. Several epitope-tagging studies have concluded that a 3-TMD model featuring a non-membrane-crossing hairpin loop as the pore region best fits the available data (inter alia, Hollmann et al. *Neuron*, 1994, 13: 1331-1343). Analysis of the utilization of native and engineered N-glycosylation sites by gel shift assays has been widely used to evaluate receptor topology. It has been contended, however, that N-glycosylation might occur at intracellular sites, thus invalidating gel shifts as topological evidence.

The goal of this study was to confirm that carbohydrates attached to ectopic sites are indeed located extracellularly in GluR1 expressed in *Xenopus* oocytes. Biotinylated concanavalin A (ConA) was reacted with intact oocytes expressing N-glycosylation mutants of GluR1. ConA-labeled receptors were solubilized, precipitated with streptavidin-sepharose beads, and analyzed on Western blots. It was found that all actively N-glycosylating mutants (which cause gel shifts) can be labeled and precipitated by biotinyl-ConA/streptavidin. Conversely, non-N-glycosylating mutants (which cause no gel shifts) cannot be precipitated. This shows that N-glycosylation in the oocyte expression system is a valid and reliable topological marker for extracellular sites. In addition, these data confirm the 3-TMD topology for GluR1.

NMDA RECEPTOR-MEDIATED REGULATION OF AMPA RECEPTORS IN ORGANOTYPIC HIPPOCAMPAL CULTURES. D. M. Gellerman<sup>1</sup>, X. Bi<sup>2</sup>, and M. Baudry<sup>1</sup>. Neurobiology Program, University of Southern California, Los Angeles, CA 90089.

Several laboratories have shown that activation of calpain, a calcium-dependent protease, is a necessary step in the formation of long-term potentiation (LTP) in the hippocampus. Specifically, it has been proposed that stimulation of NMDA receptors leads to an increase in intracellular calcium concentrations, calpain activation, proteolysis or cytoskeletal elements, and modification of AMPA receptor properties. We recently showed that calpain activation in frozen-thawed rat brain sections produces striking modifications of the immunological properties of the AMPA receptors, suggesting that calpain might produce a partial proteolysis of the AMPA receptors, thereby altering their properties. Organotypic hippocampal slices in culture have been shown to represent a useful tool to investigate mechanisms of synaptic plasticity. In particular, NMDA treatment has been shown to result in rapid calpain activation as evidenced by the accumulation of a specific breakdown product of spectrin (SBDP). In the present study, we evaluated the effect of NMDA treatment of cultured hippocampal slices on the properties of AMPA receptors. Slices were treated with NMDA (100 μM) for 10 minutes and [<sup>3</sup>H]-AMPA binding to membrane fractions was measured. NMDA-treated slices exhibited a significant increase in [<sup>3</sup>H]-AMPA binding. This increase was significantly reduced by incubation of slices with 100 μM calpain inhibitor I. Furthermore, we confirmed that under these conditions, NMDA treatment resulted in SBDP accumulation, an effect completely blocked by calpain inhibitor I. These results indicate that NMDA receptor stimulation activates calpain and produces modifications of AMPA receptor properties. Thus, our results support the hypothesis that changes in AMPA receptor properties underlie changes in synaptic plasticity. (Supported by grants from NIH and Sankyo.)

## 337.9

**SELECTIVE BLOCK OF NATIVE  $\text{Ca}^{2+}$ -PERMEABLE AMPA RECEPTORS BY JORO SPIDER TOXIN IN RAT SPINAL CORD DORSAL HORN NEURONS** J.G. Gu\*, C. Albuquerque, and A.B. MacDermott. Dept. of Physiology and Cellular Biophysics and Center for Neurobiology and Behavior, Columbia Univ., 1106 Black Building, 630 West 168th Street, New York, NY 10032

We have examined the relative distribution of  $\text{Ca}^{2+}$ -permeable AMPA receptors on cultured embryonic rat dorsal horn neurons with perforated patch recordings and  $\text{Ca}^{2+}$  imaging using Joro Spider Toxin (JSTX) (Blaschke et al., 1993). 100  $\mu\text{M}$  kainate evoked sustained inward currents (0 - 400 pA) with apparent reversal potentials (Er) ranging from -35 to -100 mV in extracellular bath containing 10 mM  $\text{Ca}^{2+}$  as the only permeant extracellular cation. Kainate-evoked inward  $\text{Ca}^{2+}$  current was strongly inhibited by 1  $\mu\text{M}$  JSTX. The JSTX block occurred in a use-dependent manner. The block was not reversible at holding potentials (Vh) ranging from -100 to +10 mV, but it could be reversed at +70 mV in the presence of kainate. Three types of dorsal horn neurons were identified according to changes in the I-V relationship and Er after using 1  $\mu\text{M}$  JSTX. In neurons where Er was ~ -40 mV, JSTX decreased the slope of the I-V curve without significantly changing Er, suggesting that these neurons predominantly express  $\text{Ca}^{2+}$ -permeable AMPA receptors. In neurons where Er was ~ -70 mV, a large negative shift in aEr was evident in JSTX and the slope of the I-V curve was decreased, suggesting that both  $\text{Ca}^{2+}$ -permeable and -impermeable AMPA receptors were co-expressed on this type of neuron. The third group of neurons did not show any inward  $\text{Ca}^{2+}$  current indicating that no  $\text{Ca}^{2+}$ -permeable AMPA receptors were present. In these cells, JSTX did not significantly change the I-V relationships.  $\text{Ca}^{2+}$ -permeable AMPA receptors were determined to be predominantly localized on neurites. Taken together, these results suggest that JSTX is highly selective to native  $\text{Ca}^{2+}$ -permeable AMPA receptors and it may be useful for the study of functional role of  $\text{Ca}^{2+}$ -permeable AMPA receptors in synaptic transmission. (supported by NIH Grant NS29797).

## 337.11

**CHARACTERIZATION OF HIGH AND LOW AFFINITY  $[^3\text{H}]$ -KAINIC ACID BINDING SITES IN RODENT FOREBRAIN, CEREBELLUM AND SPINAL CORD** C.B. Nelson, C.J. Spencer and R.D. Schwarz\* Parke-Davis

Pharmaceutical Research, Division of Warner Lambert Co., Ann Arbor, MI 48105

Pharmacologically, ionotropic non-NMDA glutamate receptors have been divided into two groups based on binding preference for either AMPA or kainate (KA), the KA group being further subdivided into high and low affinity populations. Molecular biology has supported this receptor diversity identifying at least five different subunits that in various combinations might contribute to such KA-preferring receptors.

Initial characterization of KA binding sites was carried out in extensively washed rat forebrain synaptosomal membranes in 50mM Tris-HCl buffer with and without 20mM calcium ( $\text{Ca}^{2+}$ ). With  $\text{Ca}^{2+}$ , KA recognized a single binding site with a Kd of 33.2 nM and Bmax of 2.429 fmol/mg protein. KA binding without  $\text{Ca}^{2+}$  revealed a higher affinity site having a Kd of 2.8 nM and a Bmax of 849 fmol/mg. Variation in method of membrane preparation and degree of tissue washing may explain differences in the absolute values of dissociation constants when compared with previously reported numbers. However, the rank order of potency for agonist binding was in agreement with previous findings, with the high affinity assay showing KA > domoate > glutamate >> AMPA, and the low affinity assay having domoate > KA > glutamate >> AMPA. In general agonists had greater relative affinity for the high affinity site, with the exception of domoate which saw both sites equally. Next, in an attempt to ascertain if high and/or low affinity binding sites would show regional variation, binding was compared in membrane preparations from forebrain, cerebellum, and spinal cord. Preliminary results suggest that ligands differ in their ability to displace KA from different regions of the nervous system, suggesting that high and low binding sites are not uniform in all areas. This heterogeneity may be explained by differences in subunit type and stoichiometry contributing to receptors that comprise high and low affinity populations in different brain regions.

**RASMUSSEN'S ENCEPHALITIS PATIENTS' SERA ACTIVATE GLUR3 RECEPTORS EXPRESSED IN X. LAEVIS OOCYTES.**

J. Eichten Gunther\* & R. E. Twyman. Programs in Neuroscience and Human Molecular Biology & Genetics, Depts of Neurology & Pharmacology, Univ. of Utah School of Medicine, Salt Lake City, UT

An autoimmune response to the GluR3 subunit has been associated with Rasmussen's encephalitis, a childhood epilepsy of intractable focal seizures. Whole cell electrophysiological studies of cultured mouse cortical neurons demonstrated that both rabbit antisera to the GluR3 subunit and Rasmussen's encephalitis patient antibodies have agonist properties on a subset of neurons. Application of these samples evoked non-NMDA sodium currents (Twyman, Neuron 14:755, 1995). We further studied the effect of these Rasmussen's encephalitis patients' sera on rat GluR3 homomeric receptors expressed in *Xenopus laevis* oocytes.

TEVC electrophysiology revealed that a sera dilution of 1:16 evoked sodium currents with an average response of 29.7% (S.E.M. = 8.0, n = 5) of the control kainic acid response (500  $\mu\text{M}$ ). Sera-evoked currents were blocked by 30  $\mu\text{M}$  CNQX. Patient sera did not evoke currents in water injected oocytes. Control sera did not evoke sodium currents in GluR3 homomeric expressing oocytes. This study demonstrates that the GluR3 subunit alone is sufficient to bind patient antibody and to evoke a glutamate receptor response. This provides further evidence that antibodies to glutamate receptors may be involved in the pathophysiological mechanism of Rasmussen's encephalitis.

## 337.10

**CALCIUM SIGNALLING BY NON-NMDA GLUTAMATE RECEPTORS EXPRESSED IN HEK293 CELLS.** R.E. Petroski\*, Y. Stern-Bach, S.F. Heinemann. The Salk Institute, La Jolla, CA 92037

In neurons, intracellular calcium ( $[\text{Ca}^{2+}]_i$ ) signals are generated by influx of calcium through voltage-dependent ion channels and neurotransmitter receptors as well as by release of calcium from intracellular stores. In order to examine the ability of non-NMDA glutamate receptors to induce calcium signals in isolation of other calcium-signal-generating channels and/or receptors, non-NMDA receptors were transiently expressed in HEK293 cells and calcium signals were optically detected using Fura-2.

Homomeric kainate receptors of GluR6(Q) or GluR6(R) did not produce calcium signals in response to glutamate or kainate. However, when HEK293 cells expressing GluR6(Q) were treated with ConA to block receptor desensitization, agonists rapidly elevated  $[\text{Ca}^{2+}]_i$  by 50%-400% above resting levels. The calcium signals were abolished in  $\text{Ca}^{2+}$ -free bath and reversed when agonists were washed out. In contrast, ConA treated GluR6(R) failed to elicit a detectable calcium response suggesting that the edited receptor is less calcium permeable than the unedited receptor. Homomeric AMPA receptors of GluR3 flip or GluR3 flop did not produce calcium signals in response to glutamate or kainate. Co-application of agonist with cyclothiazide to block receptor desensitization resulted in elevated  $[\text{Ca}^{2+}]_i$  in GluR3 flip but not GluR3 flop expressing cells. This is consistent with flop splice variants being less sensitive to cyclothiazide than flip variants. In order to examine the structural components required for calcium signalling, receptor chimeras constructed from GluR6(R) and GluR3 flop were tested.

## 337.12

**AUTOANTIBODIES TO GLUR2 FROM A PATIENT WITH CEREBELLAR DEGENERATION ENHANCE GLUTAMATE RECEPTOR CURRENTS.**

R.E. Twyman\*, L.C. Gahring\* and S.W. Rogers\*. Programs in Neuroscience and Human Molecular Biology & Genetics, Depts. of Neurology, \*Medicine and \*Neurobiology & Anatomy, Univ. of Utah School of Medicine and \*VA-GRECC, Salt Lake City, UT 84112

Autoantibodies to glutamate receptor (GluR) subunits modulate glutamate receptors. Anti-GluR3 antibodies found in association with Rasmussen's encephalitis (Twyman et al., Neuron 14:755-762, 1995) activate and anti-GluR5/6 antibodies found in association with some paraneoplastic degenerative syndromes (Gahring et al., Molecular Medicine 1:245-253, 1995) enhance glutamate receptor currents. We recently studied the serum from a 65 year old Asian male with a 4 year history of non-familial progressive olivopontocerebellar degeneration with pseudobulbar palsy. Specific immunostaining to GluR2 was demonstrated on transfected cells and to a fusion protein constructed from an extracellular domain of GluR2. Whole cell recording using cultured mouse cortical neurons indicate that the serum (1:8 dilution) did not activate non-NMDA glutamate receptor currents. The serum rapidly and reversibly enhanced glutamate-evoked (100  $\mu\text{M}$ ) non-desensitizing currents by 200-500% in a subset of neurons. Sera from healthy controls did not alter glutamate-evoked currents. Enhanced currents could be reduced by a GluR2 specific peptide. These results implicate autoantibodies to GluR2 in the pathophysiological processes of this patient's disease and also extend our observations that autoimmunity targeted against GluR epitopes present on some neurons may contribute to specific neurotoxicity in conditions such as epilepsy, paraneoplastic syndromes and neurodegenerative diseases.

## 337.14

**MODULATION OF AMPA/KA-INDUCED  $\text{Ca}^{2+}$  FLUXES IN BRAIN NEURONS.** S. Liljequist\* and G. Cebers. Dept. of Clin.

Neuroscience, Sect. Drug Dependence Res., Karolinska Institute, Stockholm, Sweden.

$\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazole propionic acid (AMPA)-induced  $\text{Ca}^{2+}$  responses, and their modulation by cyclothiazide, were investigated in two functional assays of  $\text{Ca}^{2+}$  channel activity. AMPA produced a marked increase in cytoplasmic free  $\text{Ca}^{2+}$  levels  $[\text{Ca}^{2+}]_i$  in single neocortical neurons, whereas no such effects of AMPA could be observed in intact cerebellar granule neurons. In monolayer cultures of cortical cells, cyclothiazide caused a pronounced enhancement of AMPA-induced stimulation of  $^{45}\text{Ca}^{2+}$  uptake, whereas similar studies in cerebellar granule neurons revealed only a weak potentiation of AMPA-induced  $^{45}\text{Ca}^{2+}$  uptake. Higher concentrations of cyclothiazide alone produced a dose-dependent increase of spontaneous  $[\text{Ca}^{2+}]_i$  oscillations as well as an increase of basal  $^{45}\text{Ca}^{2+}$  uptake in cortical neurons, whereas no such effects were obtained in cerebellar granule neurons. Our data indicate that AMPA receptors located on cortical and cerebellar granule neurons, respectively, may differ in their permeability to  $\text{Ca}^{2+}$  and that this difference is markedly potentiated following the application of cyclothiazide.

(Supported by the Swedish Medical Research Council; grant #7688)

## 337.15

DIFFERENTIAL EFFECT OF PHOSPHATIDYL SERINE ON THE BINDING PROPERTIES OF AMPA RECEPTORS IN BRAIN SECTIONS OF NEONATAL AND ADULT RATS. J. Gagné, C. Giguère, G. Tocco, R. F. Thompson, M. Baudry and G. Massicotte\*, Lab. of Neurobiology, Univ. Québec à Trois-Rivières, Canada G9A 5H7.

The effects of phosphatidylserine (PS) on the binding properties of the AMPA ( $\alpha$ -amino-3-hydroxy-5-methylisoxazolepropionic acid) and NMDA (N-methyl-D-aspartate) subtypes of glutamate receptors were analyzed by using qualitative as well as quantitative autoradiographic analysis of  $^3\text{H}$ -AMPA and  $^3\text{H}$ -6-cyano-7-nitroquinoxaline-2,3-dione (CNQX) and  $^3\text{H}$ -glutamate binding on rat brain tissue sections. Preincubation of brain sections with PS produced an increase in  $^3\text{H}$ -AMPA binding, while the same treatment had no effect on the binding properties of  $^3\text{H}$ -CNQX, an antagonist of AMPA receptors. Furthermore, PS-induced increase in  $^3\text{H}$ -AMPA binding was different among various brain structures, being larger in the molecular layer of the cerebellum and almost absent in the striatum. The effect of PS appeared to be specific for the AMPA subtypes of glutamate receptors as the same treatment did not modify  $^3\text{H}$ -glutamate binding to the NMDA receptors. Finally, the effect of PS on AMPA receptor properties was markedly reduced in rat brain sections prepared from neonatal rats. The present data are consistent with the hypothesis that an alteration in lipid environment of synaptic membranes may be an important mechanism for regulating AMPA receptor properties, which could produce long-lasting changes in synaptic operation.

## 337.17

INTRACELLULAR POLYAMINES MAY DETERMINE RECTIFICATION IN THE AMPA SUBTYPE OF GLUTAMATE RECEPTORS. C. B. McCullum, R. I. Hume, Dept. of Biology, Univ. of Michigan, Ann Arbor MI.

Glutamate receptors transduce most of the excitatory synaptic information in the mammalian central nervous system. We have studied the mechanism of rectification in the GluR1, GluR2 and GluR3 subunits of the AMPA class glutamate receptor expressed in *Xenopus* oocytes. When the GluR1 or GluR3 subunits are expressed alone, the whole cell I-V curves inwardly rectify and the permeability to divalent cations such as calcium is high compared to that of monovalent cations. When the GluR1 or GluR3 subunit is co-expressed with the GluR2 subunit, the whole-cell current-voltage relationship becomes linear and the relative permeability to divalent cations is low. Surprisingly, we found that when outside-out patches were pulled from oocytes expressing homomeric GluR1 or GluR3, the inward rectification was lost within 3-5 minutes following patch excision. This finding led us to hypothesize that a substance within the oocyte induces inward rectification and that this substance diffuses away when outside-out patches are excised. In a search for this putative substance, we decided to test the role of intracellular polyamines. This idea was based on work by Lopatin et al. (Nature 372: 366-369) which demonstrated that intracellular polyamines cause inward rectification in some potassium channels. In outside out patches from oocytes expressing GluR1 or GluR3 receptors, we found that 100  $\mu\text{M}$  spermine can block the change from inward rectification to linear current-voltage relationship. However, 100  $\mu\text{M}$  spermine had no effect on the current-voltage relationship of oocytes co-expressing the GluR3 and GluR2 subunits, suggesting a specific effect. Polyamines may mediate rectification physiologically, because oocytes and many neuronal types contain 100-500  $\mu\text{M}$  polyamines cytoplasmically.

## 337.16

CHARACTERIZATION OF NATIVE AMPA RECEPTORS BY MEASURING RECEPTOR-MEDIATED CALCIUM INFLUX IN CEREBELLAR GRANULE CELLS. E. Li\* and T. A. Verdoorn, Dept. Pharmacology, Vanderbilt Univ. Sch. of Med., Nashville, TN 37232

We have tested the ability of glutamate receptor agonists to cause accumulation of  $^{45}\text{Ca}^{2+}$  in cultured cerebellar granule neurons. Kainate and L-glutamate caused  $^{45}\text{Ca}^{2+}$  accumulation in a time- and concentration dependent manner (average kainate  $\text{EC}_{50}=85.41\pm9.87\ \mu\text{M}$ ,  $n=6$ , glutamate  $\text{EC}_{50}=21.02\pm1.77\ \mu\text{M}$ ,  $n=15$ ). AMPA by itself evoked little excess accumulation, but in the presence of 50  $\mu\text{M}$  cyclothiazide AMPA induced accumulation that was similar in magnitude to that of kainate (AMPA  $\text{EC}_{50}=7.65\pm1.38\ \mu\text{M}$ ,  $n=6$ ).  $^{45}\text{Ca}^{2+}$  accumulation evoked by 30  $\mu\text{M}$  L-glutamate was blocked completely by D(-)-AP-5 ( $\text{IC}_{50}=6.09\pm1.19\ \mu\text{M}$ ,  $n=3$ ) or CNQX ( $\text{IC}_{50}=1.76\pm0.325\ \mu\text{M}$ ,  $n=5$ ). Although CNQX completely blocked the accumulation caused by 100  $\mu\text{M}$  kainate or 30  $\mu\text{M}$  AMPA plus 50  $\mu\text{M}$  cyclothiazide ( $\text{IC}_{50}$ 's in two experiments were 2.197  $\mu\text{M}$  for AMPA and 0.417  $\mu\text{M}$  for kainate), D(-)-AP-5 blocked only 75.7 to 60.8% of the accumulation evoked by these two agonists. High concentrations of potassium (50 to 100 mM) were ineffective at causing  $^{45}\text{Ca}^{2+}$  accumulation in these cells (between 4 to 7 DIV) and the calcium channel antagonists nifedipine and omega-Conotoxin MVIIC did not block agonist-induced accumulation. Electrophysiology experiments showed that the  $\text{Ca}^{2+}$  permeability of the NMDA receptors in these cells was high (average  $\text{PCa}^{2+}/\text{PNa}^{+}$  was  $2.84\pm0.422$ ,  $n=6$ , at 6 DIV) whereas the AMPA receptors had low calcium permeability ( $\text{PCa}^{2+}/\text{PNa}^{+}$  was  $0.053\pm0.0033$ ,  $n=6$ , at 6 DIV). Our results suggest that glutamate evoked calcium accumulation has both NMDA and non-NMDA receptor components.

## 337.18

SINGLE-CHANNEL CONDUCTANCES OF RECOMBINANT CALCIUM-PERMEABLE AND -IMPERMEABLE AMPA RECEPTORS. S. K. Kamboj\*, G. T. Swanson and S. G. Cull-Candy, Department of Pharmacology, University College London, London WC1E 6BT, UK.

The presence of the RNA-edited GluR2 subunit reduces  $\text{Ca}^{2+}$ -permeability of AMPA receptors. To characterize channels of known subunit composition, we have examined the single-channel properties of a  $\text{Ca}^{2+}$ -permeable AMPA receptor (homomeric GluR4) and two  $\text{Ca}^{2+}$ -impermeable receptors (homomeric GluR2 and the heteromer GluR2/4), expressed in HEK 293 cells. Flip subunit isoforms were used.

The single-channel conductance of GluR4 receptors was apparently agonist-dependent. Kainate (300  $\mu\text{M}$ ) elicited a noise increase but no discrete channel openings. The conductance estimated from noise analysis was 2 pS ( $n=6$  outside-out patches). AMPA (10  $\mu\text{M}$ ) gave discrete channel openings which were time-course fitted to levels of 7, 17 and 29 pS ( $n=6$ ). Glutamate also activated multiple conductances from the GluR4 receptor. Homomeric GluR2 gave an estimated conductance of 200 fS (variance analysis of whole-cell currents activated by various agonists;  $n=5$  cells). Heteromeric GluR2/4 receptors had a mean conductance of 2 pS (determined by noise analysis of AMPA and glutamate activated currents;  $n=6$  patches). Time-course fitting of GluR2/4 channel openings (activated by 10  $\mu\text{M}$  AMPA) revealed a main conductance of 4 pS with few larger events (3 patches).

Our data show that in addition to reducing  $\text{Ca}^{2+}$ -permeability, the presence of the GluR2 subunit in the AMPA receptor complex appears to reduce the single-channel conductance. Furthermore, the agonist-dependence of the GluR4 (flip) single-channel conductance is strikingly similar to that of the 'low-conductance' response seen in cerebellar granule cell patches (J. Physiol., 463, 193-226, 1993).

## EXCITATORY AMINO ACID RECEPTORS VIII

## 338.1

$\text{Cd}^{2+}$  IONS "IRREVERSIBLY" INHIBIT EAA-ELICITED INOSITOL PHOSPHATE FORMATION IN RAT TERMINALS M. Récasens\*, M. Vignes, E. Blanc and J. Guiramaud, INSERM U 254 and Université de Montpellier II, Hôpital St Charles, 34295 Montpellier Cedex 5, France

In 8-day-old rat forebrain synaptoneurosomes (Sn),  $\text{Cd}^{2+}$  ions inhibit inositol phosphate (IP) formation stimulated by metabotropic glutamate receptor (mGluR) agonists, but not the IP response elicited by muscarinic agonists. Here, the mechanism of  $\text{Cd}^{2+}$  action was examined. We found that: 1°) Sn pretreatment with 100  $\mu\text{M}$   $\text{Cd}^{2+}$  for 1 to 30 min at 37°C, followed by extensive washing, block GLU- but not carbachol-induced IP formations. 2°) A heavy metal chelator, TPEN (100  $\mu\text{M}$ ), possessing a high affinity for  $\text{Cd}^{2+}$  and added after  $\text{Cd}^{2+}$  pretreatment, does not reverse the inhibitory effect of  $\text{Cd}^{2+}$ . 3°) 100  $\mu\text{M}$  TPEN Sn pretreatment does not prevent the inhibitory effect of later added  $\text{Cd}^{2+}$  on GLU-evoked IP formation. However, TPEN blocks the Fura-2 fluorescence increase induced by  $\text{Cd}^{2+}$  influx, which demonstrates the efficacy of TPEN to form a complex with  $\text{Cd}^{2+}$ . 4°)  $\text{Ca}^{2+}$  ions does not reverse  $\text{Cd}^{2+}$  inhibitory effect. 5°) Only  $\text{Hg}^{2+}$  ions mimic the  $\text{Cd}^{2+}$  action.

Taken together-----r, these data indicate that  $\text{Cd}^{2+}$  selectively and irreversibly inhibit IP formation induced by mGluR activation in terminals.  $\text{Cd}^{2+}$  does not compete with  $\text{Ca}^{2+}$  and acts extracellularly, likely by forming covalent bonds with -SH free groups of the mGluR  $\text{NH}_2$  extracellular domain, which possesses numerous cysteine residues.

## 338.2

L-AP4-SENSITIVE METABOTROPIC GLUTAMATE RECEPTORS ACTIVATE THE G PROTEIN-COUPLED INWARDLY RECTIFYING POTASSIUM CHANNEL IN *XENOPUS* OOCYTES. J.A. Saugstad\*, T.P. Segerson and G.L. Westbrook, Vollum Institute for Advanced Biomedical Research, OHSU, Portland, OR 97201.

L-AP4-sensitive metabotropic glutamate receptors (mGluRs) are involved in the inhibition of synaptic transmission, presumably by acting as presynaptic autoreceptors. Mechanisms of presynaptic inhibition include the inhibition of calcium currents or the activation of potassium currents. mGluRs inhibit calcium currents in central neurons, however, the activation of G protein-coupled inward rectifying potassium channels (GIRK) by glutamate has only been demonstrated in molluscs and *Aplysia*. We examined whether L-AP4-sensitive mGluRs could activate GIRK in *Xenopus* oocytes. The mGluRs effects were compared to oocytes injected with the D2 dopamine receptor which is known to couple to GIRK in neurons. Co-expression of mGluR7 and GIRK cRNA results in the activation of the potassium channel in response to glutamate (2 mM) or L-AP4 (1 mM). The peak amplitude of the mGluR7 response is smaller than that induced by the D2 receptor in response to dopamine (1  $\mu\text{M}$ ). Also, the time to peak amplitude was longer for mGluR7 than the D2 receptor suggesting that a component of mGluR7 coupling to GIRK is rate-limiting. The mGluR7 response and the D2 response both desensitize with repeated agonist application. However, sequential activation of co-expressed D2 and mGluR7 receptors yield maximal GIRK responses and thus demonstrate no cross-desensitization. These results suggest that mGluR7 and D2 receptors activate GIRK in *Xenopus* oocytes via distinct G proteins. However, the coupling efficiency for mGluR7 appears to be lower than for the D2 receptor. Supported by R01DC01783, F32NS09200 and the Klingenstein Foundation.

MODULATION OF  $[^3H]$  GLUTAMATE RELEASE FROM RAT CEREBRO-CORTICAL SYNAPTOSOMES BY METABOTROPIC GLUTAMATE RECEPTOR ACTIVATION. J.S. Bedingfield, P.J. Roberts\*, and J.C. Watkins. Department of Pharmacology, School of Medical Sciences, University of Bristol, Bristol, BS8 1TD, UK.

Of the eight known metabotropic glutamate receptors (mGluRs), subtypes 1 and 5 (group 1) are found to couple to phosphoinositide (PI) hydrolysis, while 2 and 3 (group 2) and 4, 6, 7 and 8 (group 3) all negatively couple to cyclic AMP. All groups of mGluR are found to be present both pre and postsynaptically. Here we report the effects of mGluR agonists on presynaptic receptors.

Synaptosomes were prepared from adult rat cerebral cortices, preloaded with  $[^3H]$  glutamic acid and superfused continuously. Drugs were applied 1 min before and during a 1 min depolarisation by 200  $\mu M$  4-aminopyridine (4AP) (approximate  $EC_{50}$  value). Superfusate was collected in 1 min fractions (2 ml) and counted by liquid scintillation spectrometry.

The non-selective mGluR agonists, (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid, (2S,3S,4S)- $\alpha$ -(carboxycyclopropyl)-glycine and the group 3 selective agonist L-(+)-2-amino-4-phosphonobutyric acid caused a dose-dependent inhibition of 4AP-stimulated  $[^3H]$  glutamate release with  $IC_{50}$  values of 32, 1.2, and 3  $\mu M$  respectively. The group 1 selective agonist (RS)-3,5-dihydroxyphenylglycine produced a dose-dependent potentiation of 4AP-stimulated  $[^3H]$  glutamate release ( $EC_{50} \approx 1.2 \mu M$ ).

From this, it is evident that activation of the different presynaptic mGluRs can differentially modulate the synaptic release of glutamate. This may prove to be an important control mechanism and its modulation by drugs may be useful in the prevention of the known pathological effects of excessive or insufficient release of glutamate.

## 338.5

METABOTROPIC GLUTAMATE RECEPTOR (mGluR)-ACTIVATED INWARD CURRENTS IN BASOLATERAL AMYGDALA NEURONS. N.B. Keele\*, V.L. Arvanov and P. Shinnick-Gallagher. Dept. of Pharmacology, Univ. of Texas Medical Branch, Galveston, TX 77555.

Inward currents evoked by mGluR agonists 1S,3R-ACPD (ACPD) and quisqualate (QUIS) were investigated using standard intracellular and whole-cell recordings in brain slice. In D-APV (50  $\mu M$ ), CNQX (30  $\mu M$ ) and TTX (1  $\mu M$ ), the inward current evoked by ACPD (I<sub>ACPD</sub>, 50–200  $\mu M$ ; 31  $\pm$  9 pA;  $n$  = 21) is associated with a membrane conductance ( $G_m$ ) decrease (control:  $7.1 \pm 0.5$  nS; ACPD:  $6.6 \pm 0.5$  nS;  $p < 0.001$ ;  $n$  = 21) and reverses polarity at  $-95 \pm 7$  mV ( $n$  = 14); whereas the QUIS-evoked current (I<sub>QUIS</sub>, 50–100  $\mu M$ , 73  $\pm$  12 pA;  $n$  = 19) occurs without a reversal or significant change in  $G_m$  between  $-110$  and  $-50$  mV ( $p > 0.05$ ,  $n$  = 19). I<sub>QUIS</sub> and I<sub>ACPD</sub> were similar recorded with K<sup>+</sup>-filled patch or standard sharp electrodes.

mGluR activated current(s) not mediated by a K<sup>+</sup> conductance were further characterized with Cs<sup>+</sup>-filled electrodes in the presence of external Cs<sup>+</sup> (2 mM) and Ba<sup>2+</sup> (0.5 mM). Under these conditions, I<sub>QUIS</sub> (10–50  $\mu M$ ;  $n$  = 10) and I<sub>ACPD</sub> (20–200  $\mu M$ ;  $n$  = 7) produce inward currents (I<sub>QUIS</sub> =  $48 \pm 11$ ; I<sub>ACPD</sub> =  $26 \pm 8$ ), also without significant  $G_m$  changes between  $-110$  and  $-50$  mV. Removal of external Ca<sup>2+</sup> greatly reduced (or blocked) I<sub>QUIS</sub> ( $n$  = 5) and I<sub>ACPD</sub> ( $n$  = 4). In low Ca<sup>2+</sup> (100  $\mu M$ ), Cd<sup>2+</sup>-containing (200  $\mu M$ ) external solution (to eliminate voltage-activated Ca<sup>2+</sup> currents), ACPD and QUIS usually produced currents associated with increased  $G_m$  between  $-110$  and  $+50$  mV. The reversal potential of I<sub>ACPD</sub> was  $0 \pm 3$  mV ( $n$  = 3) whereas I<sub>QUIS</sub> did not reverse between  $-110$  and  $+50$  mV in 4 of 5 neurons tested. I<sub>ACPD</sub> and I<sub>QUIS</sub> persisted in some but not all neurons after reducing external Na<sup>+</sup> by equimolar substitution of Li<sup>+</sup>, suggesting that ACPD and QUIS may activate a nonspecific cation conductance, electrogenic Na<sup>+</sup>/Ca exchange, or perhaps both. [Supported by NS24643].

## 338.7

A FREQUENCY-DEPENDENT SUPPRESSION OF THE SLOW AHP IN RAT HIPPOCAMPAL CA1 PYRAMIDAL NEURONS IS BLOCKED BY THE METABOTROPIC GLUTAMATE RECEPTOR ANTAGONIST MCPG.

G. Woodhall\*, J.E. Chad & H.V. Wheal. Dept. of Physiology and Pharmacology, University of Southampton, Southampton, SO16 7PX, U.K.

A stepped frequency paradigm was designed to generate stimulation of the Schaffer collateral/commissural input to CA1 at frequencies between 0.67 and 100 Hz, representing a frequency progression on a natural log scale. Stimulation was delivered via a bipolar NiCr electrode placed in radiatum and intensity set at three times that required to elicit a spike in neurons recorded from the whole-cell current clamp technique. After a stimulus train lasting for 1 s at the desired frequency, 500 ms positive current injections (0.1–0.7 nA) were used to evoke repetitive spike activity and an AHP. Prior to stimulation, the AHP amplitude measured at peak and 200 ms after cessation of current injection was  $6.88 \pm 0.40$  and  $5.22 \pm 0.33$  mV respectively (mean  $\pm$  sem, 13 cells). The sAHP at 200 ms was depressed significantly following 13.5, 36 and 100 Hz stimulation for 1 s, with a maximum depression after 100 Hz such that the sAHP amplitude was  $25.68 \pm 5.21$  % of control. Recovery was complete within 1–2 minutes.

This suppression of the AHP in response to high frequency stimulation was blocked by prior application of 400  $\mu M$  MCPG which appeared to shift to the left the frequency response curve in the manner of a competitive antagonist. In the presence of MCPG no significant attenuation of the AHP was noted at 13.5 and 36 Hz, and a weak response occurred after 100 Hz stimulation (AHP amplitude at 200 ms =  $75.44 \pm 9.66$  % of control).

The suppression of the AHP after 100 Hz stimulation was also elicited in the presence of 20  $\mu M$  CNQX and 20  $\mu M$  APV, which completely abolished AMPA and NMDA receptor mediated responses to stimulation. Taken together, these data suggest that metabotropic glutamate receptors are activated during high-frequency synaptic activity, as reported by a suppression of the slow AHP.

Supported by the Wellcome Trust.

## 338.4

AGONIST SENSITIVITY OF METABOTROPIC GLUTAMATE RECEPTOR-MEDIATED SUPPRESSION OF CALCIUM CURRENT IN RAT NEOCORTICAL NEURONS IS CONSISTENT WITH RECEPTORS OF THE MGLUR1/5 SUBGROUP. R.I. Sayer\* Dept. of Physiology, University of Otago, Dunedin, New Zealand.

Calcium currents in rat neocortical pyramidal neurons are suppressed by the metabotropic glutamate receptor (mGluR) agonist (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (1S,3R-ACPD). The aim of this study was to gain further information about the mGluR subtype(s) involved, by testing agonists that are putatively selective for subgroups of mGluR. Neurons were acutely isolated from the dorsal frontoparietal neocortex of 10–21 day old rats. Whole-cell recordings of calcium currents were made at 30–34 °C, because responses to 1S,3R-ACPD were found to be larger and more reliably evoked than at room temperature.

The calcium current suppression by 200  $\mu M$  1S,3R-ACPD was mimicked by 200  $\mu M$  (RS)-3,5-dihydroxyphenylglycine (DHPG), a probable selective mGluR1/5 subgroup agonist. (2S,3S,4S)- $\alpha$ -(carboxycyclopropyl)-glycine (L-CCG-I) at 1  $\mu M$ , a concentration active at mGluR2 in other preparations, had no effect. L-(+)-2-amino-4-phosphonobutyric acid (L-AP4) (1 mM), an agonist at mGluR4/6/7, did not inhibit the calcium currents. Responses to 50  $\mu M$  1S,3R-ACPD were partially and reversibly antagonized by 1 mM (+)- $\alpha$ -methyl-4-carboxyphenylglycine (MCPG). The findings are consistent with the rank order of potency quisqualate > glutamate > trans-ACPD found previously for calcium current suppression in these neurons, suggesting involvement of mGluR1 or mGluR5.

## 338.6

FUNCTIONAL ANALYSIS OF CHIMERAS CONSTRUCTED FROM METABOTROPIC GLUTAMATE AND CALCIUM RECEPTORS. L.G. Hammerland, K.J. Krapcho, N. Alasti, R. Simin, J.E. Garrett, E.F. Nemeth\* and E.H. Fuller. NPS Pharmaceuticals, Inc., Salt Lake City, UT 84108.

The calcium receptor (CaR) is a novel type of G-protein coupled receptor which responds to extracellular cations and shares sequence homology (~25% amino acid identity) only with metabotropic glutamate receptors (mGluRs). In addition to sequence similarities, the CaR and mGluRs each contain a large (~600 amino acid) extracellular domain (ECD), which precedes the putative seven transmembrane spanning domains (7TMDs). To determine whether these two receptors share functional as well as structural characteristics, and to identify domains necessary for ligand binding, two chimeric receptors were constructed in which the large ECDs of the CaR and mGluR1 were interchanged and their functional activity was assessed following expression in *Xenopus* oocytes. The CaR is activated *in vitro* by several different cations including gadolinium, neomycin or calcium, but not by the mGluR1 agonists glutamate or quisqualate. The chimera CaR/mGluR1 (ECD of the CaR and 7TMD of the mGluR1) was responsive to the above cations but not to glutamate or quisqualate. mGluR1/CaR (ECD of the mGluR1 and 7TMD of the CaR) responded to glutamate and quisqualate as well as to cations. mGluR1/CaR activation by glutamate was blocked by the competitive mGluR1 antagonist 4C3H-PG, but gadolinium-evoked responses were not affected. Consistent with previous studies using mGluRs, these data show that ligand binding specificity is primarily determined by the ECD of the mGluR. However, cation binding domains of the CaR exist in both the ECD and 7TMD. Furthermore, functional determinants in the CaR and mGluR appear to have been conserved such that they can complement each other with regard to cation responsiveness.

## 338.8

t-ACPD ENHANCEMENT OF NMDA RESPONSES IN FROG MOTONEURONS IS MAGNESIUM DEPENDENT. A.M. Holohean\*, J.C. Hackman and R.A. Davidoff. Neurology Service, VAMC and Neurology Dept., Univ. Miami Sch. Med. Miami, FL 33101.

The metabotropic glutamate receptor agonist, t-ACPD [(±)-1-aminocyclopentane-trans-1,3-dicarboxylic acid] has been reported to enhance ionotropic glutamate responses. We compared the effects of t-ACPD on depolarizations induced by ionotropic glutamate receptor agonists in frog motoneurons bathed in HCO<sub>3</sub><sup>-</sup>-buffered Ringer's solution with and without Mg<sup>2+</sup> ions. We used sucrose gap recording techniques from the ventral roots of the isolated, hemisectioned, frog spinal cord.

ACPD (30  $\mu M$ , 20 min) in the presence of TTX had no significant effect on the depolarizations of motoneurons evoked by 5 sec applications of NMDA (100  $\mu M$ ), AMPA (10  $\mu M$ ) or kainate (30  $\mu M$ ). Addition of a "physiological" concentration of Mg<sup>2+</sup> (1.0 mM) to the Ringer reduced NMDA-induced motoneuron depolarizations by 30 to 90%. These reduced NMDA depolarizations were enhanced 193  $\pm$  47% by t-ACPD (30  $\mu M$ ). The depolarizations evoked by AMPA and kainate remained unchanged in the presence of t-ACPD (100% and 95%, respectively), whether or not Mg<sup>2+</sup> was present in the medium.

Unexpectedly, depolarization of motoneurons by addition of AMPA or K<sup>+</sup> ions had no effect on the release of the Mg<sup>2+</sup> blockade of NMDA. Intracellular mechanisms that may be responsible for the unique effect of t-ACPD are currently being investigated. To date, neither caffeine-induced release of Ca<sup>2+</sup> stores nor phorbol 12-myristate 13-acetate reduces t-ACPD activated enhancement of NMDA depolarizations in the presence of Mg<sup>2+</sup>. (Supported by VAMC MRIS #1769 and 3369 and USPHS #NS17577).

## 338.9

REDUCTION OF GABA-INDUCED DEPOLARIZATIONS OF AFFERENT TERMINALS BY *t*-ACPD IN THE FROG SPINAL CORD IS CAMP-DEPENDENT. J.C. Hackman\*, A.M. Holohean and R.A. Davidoff. Neurology Service, VAMC and Neurology Dept. Univ. of Miami Sch. Med. Miami, FL 33101.

Activation of metabotropic glutamate receptors by the selective agonist *t*-ACPD [(±)-1-aminocyclopentane-*trans*-1,3-dicarboxylic acid] reduces GABA-induced depolarizations of frog primary afferent terminals. We used the isolated, hemisectioned, frog spinal cord superfused with HCO<sub>3</sub><sup>-</sup>-Ringer solution and sucrose gap recording techniques to investigate the interactions between *t*-ACPD and GABA.

In the presence of TTX, *t*-ACPD (30 μM, 15 min) reduced the afferent terminal depolarizations evoked by short applications of GABA (1.0 mM, 10 sec, 29 ± 10%, n = 3) and the GABA<sub>A</sub> agonist muscimol (10 μM, 10 s, 25 ± 4%, n = 5). The phosphodiesterase inhibitor IBMX (1 mM, 25 min) diminished the GABA-induced depolarizations and occluded the effects of *t*-ACPD. The adenylate cyclase activators, 8-bromo-cAMP (0.5 to 1.0 mM) and forskolin (10 to 50 μM) also reduced the GABA-induced depolarizations. In contrast, the calcium uptake blocker, thapsigargin (1 to 2 μM), the calcium releasing agent, ryanodine (5 to 10 μM) and the protein kinase inhibitor, staurosporine (1 to 2 μM) did not affect either the GABA response or the ability of *t*-ACPD to reduce GABA responses.

In sum, the *t*-ACPD-induced reduction of GABA responses in the spinal cord appears to result from enhanced adenylate cyclase activity. (Supported by VAMC MRIS #1769 and 3369 and USPHS #NS17577).

## 338.11

ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS POTENTIATES RESPONSES OF SPINAL DORSAL HORN NEURONS. D. Budai\* and A. A. Larson. Department of Veterinary Pathobiology, University of Minnesota, Saint Paul, MN 55108.

We have investigated the role of metabotropic glutamate receptors (mGluRs) in the transmission of sensory information from the primary afferent fibers to secondary dorsal horn neurons of the rat spinal cord. Our method utilized single neuron recordings from wide dynamic range dorsal horn neurons responding to both innocuous and noxious mechanical stimuli delivered to the cutaneous receptive field.

Activation of mGluRs at these synapses by local iontophoresis of (1S,3R)-1-amino-cyclopentane-1,3-dicarboxylic acid (1S,3R-ACPD) resulted in a long-lasting increased response of dorsal horn neurons to ionotropic glutamate receptor agonists (NMDA and kainic acid) applied by iontophoresis. Application of 1S,3R-ACPD also led to a significant increase in responses to innocuous (brush, pressure) rather than in responses to noxious (pinch, squeeze) mechanical stimulation. The excitatory effects of 1S,3R-ACPD were selectively blocked by the selective mGluR antagonist, (S)-4-carboxy-3-hydroxyphenyl-glycine (S-4C3H-PG), confirming that such effects were due to mGluRs. Wind-up, the progressive potentiation of C-fiber-evoked responses during a train of stimuli, was increased and decreased by (1S,3R-ACPD) and S-4C3H-PG, respectively. The long-lasting effects of 1S,3R-ACPD on wind-up strongly support the view that mGluRs in spinal wide dynamic range neurons may play a role in spinal synaptic plasticity, and therefore, may contribute to the central sensitization during increased pain sensation.

## 338.13

HETEROLOGOUS EXPRESSION OF A RAT METABOTROPIC GLUTAMATE RECEPTOR (mGluR2) IN HEK293 CELLS: FUNCTIONAL COUPLING TO A STABLY EXPRESSED ω-CONOTOXIN-SENSITIVE CALCIUM CHANNEL. B.A. McCool\*, P.E. Brust\*, M.M. Harpold\*, and D.M. Lovinger\*. Dept. Molec. Physiol. & Biophys., Vanderbilt Univ. Med. School, Nashville, TN 37232\*; The Salk Inst. Biotech./Industrial Assoc., Inc., La Jolla, CA 92037#

Metabotropic glutamate receptors (mGluRs) perform a variety of modulatory roles in the central and peripheral nervous systems. The development of receptor subtype-specific agonists has lagged far behind the isolation of receptor cDNAs; and, the coupling of specific receptor subtypes to various neuronal effectors has not been well studied. We have recently demonstrated (Ikeda et al., *Neuron*, in press) that mGluR2, a Group II metabotropic receptor, is capable of coupling to endogenous N-type calcium channels when its cDNA is heterologously expressed in adult rat sympathetic neurons. To better understand the molecular aspects of mGluR2 modulation of voltage-gated calcium channels, we have transiently expressed this receptor in HEK293 cells which stably express the human α<sub>1B</sub>, α<sub>2B</sub>, β<sub>1</sub>, β<sub>3</sub> calcium channel subunits (GIA1 cell line). These mGluR2 receptors reversibly inhibit the ω-conotoxin GVIA-sensitive barium current in GIA1 cells as measured by the whole cell patch clamp technique. Furthermore, this inhibition displays a number of characteristics typical of heterotrimeric G protein-mediated modulation: it is voltage dependent, is partially relieved by strongly depolarizing prepulses, and results in slowing of macroscopic current activation kinetics. These mGluR2 receptors also display the appropriate Group II receptor pharmacology, with L-glutamate (EC<sub>50</sub> 0.5 μM), (+/-)-1-aminocyclopentane-*trans*-1,3-dicarboxylic acid (*t*-ACPD; EC<sub>50</sub> 8.4 μM), (2S,1'S,2'S)-2-(carboxycyclopropyl) glycine (L-CCG-I), and (2S,1'R,2'R,3'R)-2-(2,3-dicarboxycyclopropyl) glycine (DCG-IV) acting as agonists. The Group III mGluR agonists L-2-amino-4-phosphonobutyric acid (L-AP4; 100 μM) and L-serine-O-phosphate (L-SOP; 100 μM) are without effect. These results indicate that mGluR2 is capable of functionally coupling to Ca<sup>++</sup> channels in a recombinant system using an endogenous HEK293 signal transduction pathway. Supported by NS09719 (B.A.M.) and NS30470 (D.M.L.).

## 338.10

FACILITATORY METABOTROPIC GLUTAMATE RECEPTORS REGULATE EXCITATORY AMINO ACID RELEASE IN RAT DORSAL VAGAL COMPLEX. P.M. Beart\*, A.J. Lawrence and N.M. Jones. Dept. Pharmacology, Monash University, Clayton, Vic. 3168, Australia.

Recent *ex vivo* electrophysiological observations have suggested that metabotropic glutamate receptors (mGluRs) modulate the activity of first and second order barosensitive neurones in the rat nucleus of the solitary tract (NTS: Glaum et al., *Neuropharmacol.* 32, 1419, 1993). Here the functional involvement of mGluRs in NTS has been investigated by studying the effects of (±)-1-aminocyclopentane-*trans*-1,3-dicarboxylate (tACPD) on the release of L-glutamate (GLU) and L-aspartate (ASP) by *in vivo* microdialysis. In urethane anaesthetized (1.5g/kg i.p.) male WKY rats, a microdialysis probe was inserted unilaterally into the medial NTS and perfused with artificial cerebrospinal fluid (1 μl/min). After 60 min equilibration, 20 min samples were collected from amino acid analysis (Lawrence & Jarrott, *Neurosci.* 58, 585, 1994). Basal levels of GLU and ASP were 8.6 and 3.3 pmol/20 μl sample, respectively. tACPD (10-100 μM) produced concentration-dependent increases in release; at 30 μM 190 and 500% increases in the release of GLU and ASP, respectively. Two periods of stimulation (S1 & S2) with tACPD (30 μM) yielded S2/S1 ratios of 0.95 ± 0.14 for GLU and 1.06 ± 0.28 (both n=5) for ASP. Other experiments indicated release was tetrodotoxin (0.1 μM)- and Ca<sup>2+</sup>-sensitive. Actions of tACPD (30 μM) were attenuated by α-methyl-4-carboxyphenylglycine (200 μM; S2/S1 ratios 0.19 ± 0.04 (n=4) for GLU and 0.17 ± 0.02 (n=4) for ASP) and by 4-carboxyphenylglycine (500 μM; S2/S1 ratios 0.52 ± 0.07 (n=3) for GLU and 0.51 ± 0.06 (n=3) for ASP) (all P < 0.05). These data establish the existence of functional mGluRs, which seem to be facilitatory homoreceptors, in the NTS.

## 338.12

METABOTROPIC GLUTAMATE RECEPTOR mGluR1 BUT NOT mGluR7 AGONISTS ALTER EXCITABILITY OF CULTURED PURKINJE NEURONS. J.G. Netzeband\*, D.D. Sweeney and D.L. Gruol. Dept. Neuropharmacol., The Scripps Research Institute, La Jolla, CA 92037.

Cerebellar Purkinje neurons express an abundance of metabotropic glutamate receptors (mGluR), particularly mGluR1, but also mGluR7. We have used both electrophysiological and fura-2 microscopic calcium imaging to record the responses of cultured Purkinje neurons (> 16 days in culture) to mGluR agonists. DNQX (50 μM) and bicuculline (30 μM) were present in the bathing media for all experiments. For electrophysiological studies, current clamp recordings were made using the nystatin-patch technique. Rapid microperfusion (1.5 s) of the mGluR1 agonists (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (ACPD, 300 μM) or quisqualate (Quis, 5 μM) caused a membrane depolarization that was accompanied by an increase in both simple and complex spike activity. These responses were blocked by the mGluR1 antagonist (+)-α-methyl-4-carboxyphenylglycine (1 mM). Inclusion of caffeine (20 mM) in the bathing media attenuated the electrophysiological responses to ACPD and Quis, whereas calcium-free media did not, suggesting that release of calcium from intracellular stores is important for these responses. In calcium imaging studies, ACPD elicited rises in intracellular calcium in both somata and dendrites. In contrast to the effects of mGluR1 agonists, the mGluR7 selective agonists L-(+)-2-amino-4-phosphonobutyric acid (L-AP4, 200 μM and 1 mM) and O-phospho-L-serine (L-SOP, 200 μM and 1 mM) did not alter the level of membrane polarization or spike firing, nor did L-AP4 affect intracellular calcium levels. The data suggest that in Purkinje neurons, mGluR-mediated changes in neuronal excitability and increases in calcium levels are mediated primarily through activation of mGluR1. Supported by ARC 6420 and AA 0756.

## 338.14

MODULATION OF SYNAPTIC TRANSMISSION IN LOCUS COERULEUS BY METABOTROPIC GLUTAMATE RECEPTORS. G.R. Dube\* and K.C. Marshall. Dept. of Physiology, Univ. of Ottawa, Ottawa, On, K1H 8M5.

Metabotropic glutamate receptors (mGluR) have been implicated in positive and/or negative modulation of synaptic transmission in many different systems, though the significance of this modulation is not always well understood. Here, we report on the effects of selective activation of mGluR on synaptic transmission to intracellularly recorded locus coeruleus (LC) neurons in superfused rat brain slice preparations. Excitatory postsynaptic potentials (EPSPs) were evoked in the presence of 10 μM bicuculline and 0.8 mM Mg<sup>2+</sup>. These were mediated mainly through activation of postsynaptic non-NMDA receptors, as EPSP amplitude could be blocked by more than 85% by 20 μM 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX), while 3-(R)-2-carboxypiperazin-4-yl-propyl-1-phosphonate (CPP, 20 μM), a specific NMDA antagonist, had little effect. Bath application of the selective mGluR agonists L-(+)-2-amino-4-phosphonobutyric acid (L-AP4) or (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (1S,3R-ACPD) (0.1-50 μM), caused a depression of EPSPs in a dose dependent fashion to about 50% of control at high doses. However, the potency of the two agonists was different. The IC<sub>50</sub> for this effect was 0.9 μM and 7.2 μM for L-AP4 and 1S,3R-ACPD respectively. Focal application of glutamate to cells also caused a depolarization and this was not affected by the activation of mGluR by either agonist, indicating that the modulation of the EPSPs occurs presynaptically. In addition, neither agonist, had any effect on cell input resistance, intrinsic oscillatory activity, or spontaneous firing rate of the LC neurons. Owing to the specificity of L-AP4 and 1S,3R-ACPD for selected mGluR subtypes, we speculate that the receptor is of the mGluR 4, 6, 7 subtypes (highest affinity to L-AP4). LC provides noradrenergic innervation to extensive regions of the brain. Glutamate feedback signalling through presynaptic autoreceptors may, therefore, represent one mechanism by which LC activity, which results in noradrenaline release throughout the CNS, is modulated. Supported by the MRC, Canada and FCAR (Quebec).

## 338.15

EFFECTS OF LORAZEPAM TOLERANCE AND WITHDRAWAL ON METABOTROPIC GLUTAMATE RECEPTOR FUNCTION. Christian Thomsen\*, Peter D. Suzdak and Martin Mortensen, Health Care Discovery, Neuroscience, Novo Nordisk A/S, Novo Nordisk Park, DK-2760 Måløv, Denmark.

Mice were exposed to lorazepam (4 mg/kg) or vehicle by continuous infusion using implanted (s.c.) osmotic minipumps which were removed after seven days. Dose-response curves for stimulation of phosphoinositide (PI)-hydrolysis by the selective metabotropic glutamate receptor (mGluR) agonist, (1S,3R)-ACPD were performed with cortical slices from mice treated with lorazepam or vehicle for 7 days and subject to 0, 1, 2, 3, 4 and 7 days of withdrawal. The efficacy of (1S,3R)-ACPD to stimulate PI-hydrolysis was significantly increased at 2 and 3 days of lorazepam withdrawal when compared to comparable responses in control slices. The effect was blocked by the mGluR antagonist, L-2-amino-3-phosphonopropionate (L-AP3). Enhancement of PI-hydrolysis in cortical slices from mice at 2 days of discontinuation from 7 days exposure to lorazepam was also observed with agonists of  $\alpha(1)$  adrenergic- and of histamine- receptors, but not with agonists of muscarinic- or serotonin- receptors when compared to comparable responses in control slices. I.e.v. infusion of L-AP3 significantly increased pentylenetetrazol-seizure threshold in mice withdrawn for 2 days from 7 days of lorazepam-exposure, but showed no effect in comparable vehicle-exposed mice. These data suggest that PI-coupled mGluRs may be implicated in regulation of GABAergic functionality as observed following withdrawal from prolonged exposure to lorazepam.

## 338.17

DISTRIBUTION OF METABOTROPIC GLUTAMATE RECEPTOR 7 mRNA IN ADULT AND DEVELOPING RAT BRAIN. J.M. Kinzie, M.L. Baccei, J.A. Saugstad, E.A. Zimmerman\*, G.L. Westbrook and T.P. Segerson, Vollum Institute and Dept. of Neurology, Oregon Health Sciences University, Portland, Oregon, 97201.

The pattern of mRNA expression of metabotropic glutamate receptor subtypes in brain can give clues to subtype-specific functions. mGluR7 is a metabotropic glutamate receptor that is sensitive to the agonist L-2-amino-4-phosphonobutyric acid (L-AP4), a presynaptic inhibitor of neurotransmitter release. To determine the anatomical distribution of mGluR7 mRNA, we performed *in situ* hybridization on rat brain slices using an antisense mGluR7 RNA probe. We found that mGluR7 mRNA is widely distributed in both adult and developing rat brain with expression in neocortex, hippocampus, olfactory bulb, olfactory cortex, thalamus, hypothalamus, spinal cord and superior and inferior colliculi. mGluR7 mRNA is also expressed in most neuronal groups known to respond to L-AP4 including mitral cells of the olfactory bulb, granule cells of the dentate gyrus and neurons of the entorhinal cortex and dorsal root ganglion. The expression of mGluR7 mRNA in neurons sensitive to presynaptic effects of L-AP4 implies that mGluR7 is a candidate for the presynaptic L-AP4 receptor in these neurons. In addition, mGluR7 mRNA is highly expressed in areas involving sensory processing. Most strikingly, neurons at all levels of olfactory circuitry including mitral cells, neurons of the anterior olfactory nucleus and pyramidal neurons of the olfactory tubercle and primary olfactory cortex express high levels of mGluR7 mRNA, suggesting that mGluR7 activation may participate in olfactory information processing. ## 338.19

DEVELOPMENTAL SWITCH IN THE EXPRESSION OF mGluR5 AND mGluR1a RECEPTORS IN CULTURED CEREBELLAR NEURONS. A. Copani<sup>1</sup>, G. Casabona<sup>1</sup>, Y. Bruvo<sup>1</sup>, T. Kuopfel<sup>2</sup>, R. Kuhn<sup>2</sup>, and E. Nicoletti<sup>3</sup>. <sup>1</sup>Institute of Pharmacology, University of Catania, and <sup>2</sup>Dept. Exp. Med. Biochem Sci. University of Perugia, Italy; <sup>3</sup>CIBA-GEIGY, Basel, Switzerland.

In cultured cerebellar granule cells, stimulation of polyphosphoinositide (PI) hydrolysis by metabotropic glutamate receptor (mGluR) agonists is developmentally regulated and exhibits a transient peak after 4 days *in vitro* (DIV), which is observed when cultures are grown in either 25 or 10 mM K<sup>+</sup> (the latter condition leading to apoptotic death). We have characterized the expression of the various mGluR subtypes coupled to PI hydrolysis using polyclonal antibodies raised against non-conserved regions of the carboxy-terminal domains. Cells were stained with mGluR5 antibodies since the earlier stages of maturation, and, at 4 DIV virtually all viable cells were immunopositive. At 8 DIV, the percentage of mGluR5-positive cells was reduced. Immunostaining was more intense in cultures grown in 10 mM K<sup>+</sup> throughout the cultivation time. In contrast, immunostaining with mGluR1a antibodies increased with age and was maximal at 8 DIV. Interestingly, quisqualate-stimulated PI hydrolysis at 4 DIV (when mGluR5 was prevalent) was insensitive to inhibition by either pertussis toxin or phorbol esters, which instead substantially reduced the action of quisqualate at 8 DIV (when mGluR1a was prevalent). This is in agreement with results obtained in cells transfected with mGluR5 and mGluR1a, respectively.

## 338.16

NOVEL GLIAL-NEURONAL COMMUNICATION MEDIATED BY COACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS AND  $\beta$ -ADRENERGIC RECEPTORS. D.G. Winder\*, R.W. Gereau, P.S. Ritch and P.J. Conn, Dept. of Pharmacology and Prog. in Neuroscience, Emory Univ. Sch. of Med., Atlanta, GA 30322.

We have previously reported that activation of group II-like mGluRs in hippocampus results in potentiation of cAMP responses. Activation of this mGluR effector system in conjunction with stimulation of  $\beta$ -adrenergic receptors ( $\beta$ ARs) in area CA1 results in depression of synaptic transmission. *In situ* hybridization studies suggest that group II mGluRs are not present in neurons in area CA1. Thus, we tested the hypothesis that this mGluR effector system is present in glia in area CA1. If mGluRs that potentiate cAMP responses were present on CA1 pyramidal cells, it would be predicted that activation of this effector system would enhance cAMP-mediated events in these cells. However, we were unable to see such enhancement. Further, preincubation with either of the selective glial toxins fluorocitrate or L- $\alpha$ -aminoadipic acid completely blocked the cAMP responses elicited by activation of mGluRs and  $\beta$ ARs, while having no effect on membrane properties or receptor-mediated increases in cAMP in the CA1 pyramidal cells. Finally, preincubation of hippocampal slices with kainate resulted in complete disruption of neuronal transmission, but had no effect on the cAMP response elicited by activation of mGluRs and  $\beta$ ARs. In total, these data suggest that mGluRs coupled to potentiation of cAMP responses may be present on glia rather than neurons in area CA1 of hippocampus.

## 338.18

DIFFERENTIAL GENE EXPRESSION OF METABOTROPIC GLUTAMATE RECEPTOR SUBTYPES (mGluRs) AFTER KAINIC ACID INDUCED STATUS EPILEPTICUS IN RAT PUPS AND MATURE RATS.

Eleonora Aronica\*, Jan A. Gorter, Hong Shen, Linda K. Friedman, Marie C. Paupard, Michael V.L. Bennett, R. Suzanne Zukin, Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY10461.

It has been well documented that kainic acid induced seizures lead to cell loss in several brain regions including the hippocampal CA3 region in the adult rat but not in the rat pup. We examined the expression of the metabotropic glutamate receptors (mGluRs) after status epilepticus induced by subcutaneous kainate injection in pups at postnatal day 10 (P10) (2 mg/kg) and adult rats (P40; 10 mg/kg). At 24 hrs mGluR1, mGluR3 and mGluR5 mRNAs were not affected after status epilepticus. mGluR2 mRNA expression however, was strongly downregulated in pups as well as in the adult rats in all brain regions examined (dentate gyrus, neocortex). Since mGluR2 is involved in the activation of potassium channels, decreasing excitability, a downregulation of this receptor could contribute to the enhanced excitability. mGluR4 mRNA was significantly upregulated in the CA3 region of the hippocampus in the rat pup but not in the adult rat. Since mGluR4 receptors are putative presynaptic receptors (inhibiting glutamate release), upregulation of mGluR4 in the CA3 region in the rat pup might protect these neurons against excessive glutamate release from CA3 recurrent collaterals. Failure of such mGluR4 upregulation however, could lead to CA3 cell loss as is observed in adult rats.

DIFFERENTIAL PRESYNAPTIC LOCALIZATION OF METABOTROPIC GLUTAMATE RECEPTOR SUBTYPES, mGluR2/3 and mGluR7, IN THE RAT HIPPOCAMPUS. R. Shigemoto<sup>1,2</sup>, E. Wada<sup>1</sup>, H. Ohishi<sup>1</sup>, M. Takada<sup>1</sup>, N. Mizuno<sup>1</sup>, J. D. B. Roberts<sup>4</sup>, and P. Somogyi<sup>2</sup>.

<sup>1</sup>Dept. Morph. Brain Science, Kyoto Univ., Japan, <sup>2</sup>Medical Res. Council, Anatomical Neuropharm. Unit, Oxford Univ., Mansfield Rd. Oxford, U.K.

The release of glutamate from nerve terminals is depressed by agonists for metabotropic glutamate receptors (mGluRs). At least 8 mGluR subtypes have been cloned and they are classified into 3 subgroups based on their pharmacology and transduction mechanisms. Subtypes in the first subgroup (mGluR1 and mGluR5) are largely localized in postsynaptic elements (Baudé et al., Neuron 1993, 11, 771; Shigemoto et al. Neuroscience Lett., 1993, 163, 53). In the present study, antibodies specific to mGluR2/3 in the second subgroup and mGluR7 in the third subgroup were used for immunocytochemical analysis in the rat hippocampus.

mGluR2/3 immunoreactivity (IR) was prominent in terminal zones of mossy and perforant path fibers, while mGluR7 IR was dense in all dendritic layers. By generating lesions in the entorhinal cortex, granule cell layer, or CA3 pyramidal cell layer, it was revealed that axons constituting the perforant path and mossy fibers have mGluR2/3 and mGluR7 IR, while axons from CA3 pyramidal cells have only mGluR7 IR. Electron microscopic immunogold localisation revealed an exclusively presynaptic distribution of mGluR7 IR in axon terminals that formed type I (asymmetrical) synapses. mGluR7 immunoparticles were restricted to the presynaptic membrane specialisation at the synaptic junctions. On the contrary, mGluR2/3 immunoparticles were found on membranes of the preterminal rather than terminal portions of axons, and never at the presynaptic membrane specialisation.

In conclusion, the results demonstrate that there is differential compartmentalised distribution of mGluRs in the plasma membrane of glutamatergic afferents; mGluR7 IR is restricted to the presynaptic grid where the receptor may interact with the vesicle fusion apparatus and/or with calcium channels to participate in dynamic changes in the release of glutamate. The location of mGluR2/3 away from the release site suggest a different effector mechanism for the regulation of glutamate release.

## 338.21

**THROMBIN DOWN-REGULATES mGluR5 LEVELS AND TRANS-ACPD STIMULATION OF PHOSPHOINOSITIDE HYDROLYSIS IN CORTICAL ASTROCYTES.** S. Miller<sup>1</sup>\*, N. Sehati<sup>1</sup>, C. Romano<sup>2</sup>, and C.W. Cotman<sup>1</sup>.  
<sup>1</sup>Brain Aging and Dementia Institute, University of California, Irvine, CA 92717. <sup>2</sup>Departments of Ophthalmology and Neurobiology, Washington University Medical School, St. Louis, MO 63110.

Disruptions of glutamate homeostasis have been implicated in several pathological conditions in the CNS. We have thus investigated the effects of regulatory molecules involved in CNS pathology on the expression of metabotropic glutamate receptors. We have recently demonstrated that treatment of cultured astrocytes with EGF, TGF- $\alpha$ , or basic FGF produces a robust increase in the expression of mGluR5 and in the ability of metabotropic glutamate receptor agonists to stimulate phosphoinositide (PI) hydrolysis (*J. Neurosci.*, in press). Treatment with these growth factors also alters astrocyte morphology, producing a stellate shape with numerous branching processes. Thrombin is one of the first regulatory molecules present at sites of CNS trauma or injury, and it has diverse biological actions both through its extracellular proteolytic activity and through direct activation of cell-surface receptors. Since thrombin has been shown to reverse the morphological differentiation of astrocytes, we investigated its effects on mGluR5 levels and agonist-stimulated PI hydrolysis. Treatment of astrocytes with concentrations of thrombin as low as 100 pM inhibited the ability of TGF- $\alpha$  to up-regulate trans-ACPD stimulation of PI hydrolysis. Interestingly, thrombin treatment did not affect the stimulation of PI hydrolysis by norepinephrine or carbachol. Western immunoblotting demonstrated that the thrombin treatment also produced a reduction of mGluR5 expression which corresponded with the reduction in PI hydrolysis.

## 338.23

**NAAG ACTS THROUGH METABOTROPIC GLUTAMATE RECEPTORS IN CULTURED GLIAL CELLS.** M.R. Santi, B. Wroblewska and J.H. Neale\*. Department of Biology, Georgetown University, Washington D.C. 20057.

Recent findings suggest that glial cells can actively participate in neurotransmission. The presence of several voltage- and receptor-operated ion channels in glial cell membranes has been shown by both electrophysiological methods and molecular cloning. Glia also express several receptors which are positively linked to adenylate cyclase and  $\text{PI/Ca}^{2+}$  signal transduction. Our goal was to investigate glial cell responses to glutamate and N-acetylaspartylglutamate (NAAG) through the metabotropic glutamate receptors (mGluRs). Cerebellar glial cell cultures were obtained from 8 days old rats by trypsin digestion. Cells were grown in medium containing D-Valine to reduce fibroblast contamination; at confluence, cultures contained about 80 % astrocytes type I, and 10-15 % astrocytes type II (as characterized by GFAP and A2B5 staining), and no oligodendrocyte progenitor cells. Qualitative RT-PCR assays with specific primers for mGluR subtypes 1a, 2, 3, 4, 5, 6, and 7 subtypes indicates that in cultured glial cells only mRNA for mGluR2 is absent. Treatment of cultured glial cells with forskolin causes a dose-dependent increase in cAMP accumulation. This increase was inhibited, dose-dependently, by mGluR agonists: glutamate, trans-ACPD, NAAG, and AP4. The most potent agonists to inhibit forskolin-stimulated cAMP formation in glial cells were glutamate, and NAAG. The effects of NAAG were not mimicked by  $\beta$ -NAAG. Our results suggest that in cultured glial cells, mGluR3 is a predominant subtype within the family of glutamate metabotropic receptors, and may respond physiologically to NAAG.

## 338.22

**NAAG ACTIVATES CLONED mGluR3 RECEPTOR.** B. Wroblewska\*, M.R. Santi, J.H. Neale. Dept. Biology, Georgetown Univ., Washington D.C. 20057.

We have shown previously that in cultured cerebellar granule cells N-acetylaspartylglutamate (NAAG) decreases forskolin-stimulated cAMP formation, indicating the activation of metabotropic glutamate receptor(s). The effects of NAAG are as potent as glutamate and trans-ACPD. Inhibition of forskolin-stimulated cAMP formation is pertussis toxin-sensitive, and not due to the stimulation of phosphodiesterase activity. In cerebellar granule cells inhibition of forskolin-stimulated cAMP by NAAG was additive to the inhibition caused by AP4, but not trans-ACPD. These pharmacological data suggested that in cultured cerebellar granule cells NAAG interacts with mGluR2 and/or mGluR3 type of metabotropic glutamate receptor. To evaluate this hypothesis we prepared cell lines stably transfected with mGluR2, mGluR3 or mGluR4 gene. The clones of metabotropic glutamate receptors mGluR2, mGluR3, and mGluR4 (kindly provided by Dr. S. Nakanishi) were excised from pmGR2, pmGR3, and pmGR4, respectively and inserted into the R1 site of pcDNA 1/Amp vector. Stably transfected cell lines were developed in Chinese hamster ovary cells using the calcium phosphate technique, and selection by G-418 sulfate. Selected positive clones were analyzed for cAMP formation in the presence of forskolin, and glutamate, trans-ACPD, AP4, and NAAG. Forskolin-stimulated cAMP responses in the cells transfected with mGluR3 were inhibited by glutamate, trans-ACPD, and NAAG to about 40-50% of maximal stimulation with forskolin alone. Selective agonist of the mGluR4 receptor, AP4, had no inhibitory effect in these cells. In the cells permanently expressing mGluR2 receptor, forskolin-stimulated cAMP formation was inhibited by trans-ACPD, and glutamate (by about 80 %), while NAAG and AP4 had no effect. These results indicate that NAAG selectively activates mGluR3 receptor.

## GABA RECEPTORS II

## 339.1

**LOCALIZATION OF THE HUMAN GABA<sub>A</sub> RECEPTOR  $\alpha_4$  SUBUNIT GENE TO CHROMOSOME 4 DEFINES AN  $\alpha_2$ - $\alpha_4$ - $\beta_1$ - $\gamma_1$  GENE CLUSTER.** P.J. McLean\*, D.H. Farb and S.J. Russek. Laboratory of Molecular Neurobiology, Department of Pharmacology, Boston University School of Medicine, Boston, MA 02118.

Many of the genes encoding GABA<sub>A</sub> receptor subunits have been localized to human chromosomes and these mapping experiments have revealed a clustering of loci. We demonstrated previously that the genes encoding subunits of the most abundant isoform of the GABA<sub>A</sub> receptor are located in an  $\alpha_1$ - $\beta_2$ - $\gamma_2$  cluster on human chromosome 5 (Russek and Farb, (1994), *Genomics*, 23:528-533) and that an ancestral  $\alpha$ - $\beta$ - $\gamma$  gene cluster probably spawned clusters on chromosomes 4, 5 and 15. We now report the localization of the  $\alpha_4$  subunit gene to human chromosome 4 using PCR to identify sequences unique to the human  $\alpha_4$  intron-1 in a panel of human-hamster somatic cell hybrid DNAs. Our results demonstrate that the  $\alpha_4$  gene is located on chromosome 4p14-q12, a region that also contains the  $\alpha_2$ ,  $\beta_1$  and  $\gamma_1$  genes. The mapping of the  $\alpha_4$  gene to an  $\alpha_2$ - $\alpha_4$ - $\beta_1$ - $\gamma_1$  gene cluster on human chromosome 4, and the fact that human chromosome 5 contains a cluster of  $\alpha_1$ ,  $\alpha_6$ ,  $\beta_2$  and  $\gamma_2$  genes, suggests that duplication of an ancestral  $\alpha$  subunit gene occurred prior to duplication of an ancestral gene cluster. Furthermore, these results suggest that there may be a heretofore undiscovered subtype of  $\alpha$  subunit on chromosome 15, since this chromosome also contains an  $\alpha$ - $\beta$ - $\gamma$  gene cluster. The fact that GABA<sub>A</sub> receptor subunit genes have remained in clusters indicates that this chromosomal organization is crucial to the coordinate regulation of GABA<sub>A</sub> receptor gene expression in the nervous system.

## 339.2

**IDENTIFICATION OF PUTATIVE GABA-A RECEPTOR  $\beta_2$  SPLICE VARIANT IN SINGLE CULTURED MOUSE CEREBELLAR GRANULE CELLS.** S.N. Sudweeks<sup>1</sup>\* and R.E. Twyman<sup>1,2</sup>. Dept. of Pharmacology and Toxicology<sup>1,2</sup>, Program in Human Molecular Biology and Genetics<sup>1,2</sup>, and Dept. of Neurology<sup>2</sup>, University of Utah, SLC, Utah, 84112.

A large number of GABA-A receptor subunits have been cloned and examined experimentally. Subunit heterogeneity in GABA-A receptor content has been shown to cause functional diversity. Additional functional diversity and modulatory potential is supplied by splice variants of certain subunits that contain phosphorylation sites. The  $\gamma_2$  subunit short and long forms are the best characterized examples. Single cell reverse transcription-polymerase chain reaction (RT-PCR) analysis of chronically depolarized (high KCl) mouse cerebellar granule cell neurons in culture for GABA-A receptor subunits revealed the existence of an apparent  $\beta_2$  subunit splice variant (approximately 50 b.p. in length) in the intracellular loop between putative transmembrane regions three and four. This is possibly analogous to the  $\beta_2$  long variant isolated in chick brain by Harvey *et al.* reported in *J. Neurochem.* 62:10-16 that contains a consensus sequence for both protein kinase C and casein kinase I, both of which could be important in the physiological modulation of the receptor. Enzyme restriction digest of the amplified DNA yields bands of the expected sizes for the  $\beta_2$  subunit with the inclusion of the inserted sequence. RT-PCR analysis of RNA obtained from whole culture dishes and adult mouse cerebellum did not yield any bands of the larger size, indicating that the splice variant may be rare and difficult to detect at a level higher than individual neurons. This may be why Harvey *et al.* report not finding the splice variant in either rat or bovine RNA. Such a rare splice variant could be an example of localized or transient control of GABA responsiveness.

## 339.3

**THE RECEPTOR CHANNEL SYSTEM RESPONSE: RAPID "FINGERPRINTING" OF NATIVE AND EXPRESSED GABA-A RECEPTORS.** A.M. LAVOIE\* & R.E. TWYMAN. Programs in Neuroscience, Human Molecular Biology & Genetics, Departments of Neurology & Pharmacology, Univ. of Utah, Salt Lake City, UT

Exposure of a multichannel patch to a sufficiently brief pulse of agonist produces a characteristic current response ("fingerprint") with receptor specific kinetic rates, which we have termed the receptor channel system response. GABA-A receptor system responses were obtained using ultrafast ligand exchange techniques (100 $\mu$ s exchange time) to apply brief pulses (800 $\mu$ s) of GABA (10 $\mu$ M-10mM) to native (fetal mouse cortex) and expressed (acute transfection of  $\alpha$ 1 $\beta$ 1 $\gamma$ 2 &  $\alpha$ 2 $\beta$ 1 $\gamma$ 2 in HEK293 cells) receptor populations. Outside-out patches contained >10 channels and were voltage clamped at -75mV in symmetrical chloride solutions.

Receptor channel system response kinetics were consistent within a defined ( $\alpha$ 1 $\beta$ 1 $\gamma$ 2 or  $\alpha$ 2 $\beta$ 1 $\gamma$ 2) receptor set, but varied across undefined (native) receptor populations. There were kinetic similarities within subgroups of native system responses, suggesting some subunit homology. However, none of the native system responses resembled those of expressed receptors. Modeling programs demonstrated that native system responses could not be replicated by receptor populations containing only various proportions of  $\alpha$ 1 $\beta$ 1 $\gamma$ 2 &  $\alpha$ 2 $\beta$ 1 $\gamma$ 2 containing receptors. These results suggest that native populations of GABA-A receptors are not comprised of either homogeneous or heterogeneous populations of  $\alpha$ 1 $\beta$ 1 $\gamma$ 2 or  $\alpha$ 2 $\beta$ 1 $\gamma$ 2 containing receptors, but may consistently contain other preferred subunit combinations.

## 339.5

**THE EFFECT OF UNSATURATED FFA ON THE GABA<sub>A</sub>/BENZODIAZEPINE RECEPTOR IS SUBUNIT SPECIFIC.** M.R. Witt, S.E. West-Hansen and M. Nielsen\*. Dept. of Biochemistry, Research Institute of Biological Psychiatry, St. Hans Hospital, DK-4000 Roskilde, Denmark.

Unsaturated free fatty acids (FFA) strongly enhance the binding of agonist benzodiazepine receptor ligands in the CNS *in-vitro*. To determine the selectivity and specificity of these interactions, recombinant human GABA<sub>A</sub>/benzodiazepine receptor complexes assembled by different subunit compositions ( $\alpha$ 1 $\beta$ 2 $\gamma$ 2,  $\alpha$ 2 $\beta$ 2 $\gamma$ 2,  $\alpha$ 3 $\beta$ 2 $\gamma$ 2,  $\alpha$ 4 $\beta$ 2 $\gamma$ 2) were expressed using the baculovirus-transfected Sf9 insect cell system. At 10<sup>-6</sup>M, unsaturated FFA, in particular, arachidonic (20:4) and docosahexaenoic (22:6) strongly stimulated (>200% of control) the binding of <sup>3</sup>H-flunitrazepam to the  $\alpha$ 3 $\beta$ 2 $\gamma$ 2 receptor combination in whole cell preparations. No effect of unsaturated FFA on <sup>3</sup>H-flunitrazepam binding to  $\alpha$ 1 $\beta$ 2 $\gamma$ 2 and  $\alpha$ 2 $\beta$ 2 $\gamma$ 2 receptor combinations was observed, and only weak effects (30% of control) were observed using the  $\alpha$ 3 $\beta$ 2 $\gamma$ 2 receptor combination. The saturated FFAs stearic and palmitic acid were without effect. The hydroxylated unsaturated FFAs ricinoleic and ricinelaidic acid were shown to decrease the binding of <sup>3</sup>H-flunitrazepam only if an  $\alpha$ 1 $\beta$ 2 $\gamma$ 2 receptor combination was used, while being inactive in all other receptor combinations. The binding of the benzodiazepine antagonist Ro15-1788 was not influenced or weakly enhanced by unsaturated FFA in any receptor combination. Scatchard plot analysis of the stimulation of <sup>3</sup>H-flunitrazepam binding to an  $\alpha$ 3 $\beta$ 2 $\gamma$ 2 combination shows that the enhancement is due to an increase in binding affinity (decrease of the dissociation constant K<sub>D</sub>). Our data indicate the effect of FFA on agonist benzodiazepine receptor ligands is dependent on the receptor subunit combination used and that the  $\alpha$  subunit is essential to mediate these effects. Given the heterogeneity of the GABA<sub>A</sub>/benzodiazepine receptor subunit distribution in the CNS, the overall effect of FFA on the benzodiazepine receptor can be assumed to vary at both cellular and regional level.

## 339.7

**PROPOFOL AND FLURAZEPAM ACT SYNERGISTICALLY TO POTENTIATE GABA<sub>A</sub> RECEPTOR ACTIVATION IN HUMAN RECOMBINANT RECEPTORS.** J.N. Reynolds\* and R. Maitra. Faculty of Medicine, Memorial University of Newfoundland, St. John's, Nfld., Canada, A1B 3V6.

Propofol (2,6-di-isopropylphenol) is an increasingly popular intravenous general anesthetic which is frequently combined with a benzodiazepine, either to enhance anesthesia or to alleviate anxiety. We have investigated the interaction between propofol and flurazepam on human recombinant GABA<sub>A</sub> receptors expressed in *Xenopus* oocytes. Combinations of cRNAs encoding the  $\alpha$ 1 $\beta$ 2 $\gamma$ 2L or the  $\alpha$ 2 $\beta$ 2 $\gamma$ 2L subunits of the GABA<sub>A</sub> receptor were injected into *Xenopus* oocytes, and the effects of GABA and modulation of GABA-evoked currents by propofol and benzodiazepines were measured using standard two-electrode voltage-clamp recordings 2-10 days after cRNA injection. Propofol (0.5-20  $\mu$ M) produced a concentration-dependent increase in membrane currents activated by GABA. When flurazepam (0.5  $\mu$ M) was combined with propofol, the resulting current in the presence of 3  $\mu$ M GABA was significantly greater than that predicted from an additive effect. This synergism between propofol and flurazepam was evident over the whole range of concentrations (0.5-20  $\mu$ M) of propofol examined. There was a strong concentration dependence to this effect; higher concentrations of GABA or flurazepam failed to produce this synergism. In contrast, the cyclopyrrolone derivative, zopiclone, which is classified as a full agonist at the benzodiazepine site of the GABA<sub>A</sub> receptor, failed to act either synergistically or additively with propofol. Our studies suggest that the synergism observed between benzodiazepines and propofol *in vivo* can be accounted for by an interaction between these two drugs at the GABA<sub>A</sub> receptor. It is also suggested that zopiclone acts at a site which is distinct from the site of binding of classical benzodiazepine agonists, since the combination of zopiclone with propofol results in a negative allosteric interaction.

## 339.4

**HYDRODYNAMIC PROPERTIES OF  $\alpha$ 1 $\beta$ 1 AND  $\alpha$ 1 $\beta$ 1 $\gamma$ 2 RECOMBINANT GABA<sub>A</sub> RECEPTORS EXPRESSED IN Sf9 CELLS.** A.R. Knight\*, M. Brown, C. Kostas, C. Hartnett, D. Gallager, J. Tallman, T.V. Ramabhadran. Neurogen Corporation, Branford, CT. 06405.

Expression of GABA<sub>A</sub> receptor subunits in Sf9 insect cells using recombinant baculoviruses is a valuable method for investigating the assembly of individual GABA<sub>A</sub> receptor subunits into functional ion channels. It has been shown previously that such receptors show the appropriate pharmacological and electrophysiological properties. In the present study, the physical characteristics of GABA<sub>A</sub> receptors obtained from Sf9 cells expressing  $\alpha$ 1 and  $\beta$ 1 subunits and cells expressing  $\alpha$ 1,  $\beta$ 1, and  $\gamma$ 2 subunits were compared. Receptors were solubilized in 1% Triton X100. In sucrose density gradients,  $\alpha$ 1 $\beta$ 1 and  $\alpha$ 1 $\beta$ 1 $\gamma$ 2 constructs both sedimented as sharp peaks suggesting constrained assembly into specific oligomeric complexes. The sedimentation coefficients and partial specific volumes for  $\alpha$ 1 $\beta$ 1 and  $\alpha$ 1 $\beta$ 1 $\gamma$ 2 GABA<sub>A</sub> receptors were calculated by comparison of sedimentation rates through sucrose density gradients prepared in H<sub>2</sub>O and D<sub>2</sub>O. GABA receptors from  $\alpha$ 1 $\beta$ 1 expressing cells (3H-muscimol binding) sedimented more slowly (S<sub>20,w</sub> = 7.3 S) than GABA receptors from  $\alpha$ 1 $\beta$ 1 $\gamma$ 2 expressing cells (3H-Ro 151788 binding) (S<sub>20,w</sub> = 8.2 S). Gel filtration chromatography through a Sephacryl S-300 column was also used to determine the Stokes radii of the receptors. An estimate of the molecular weights of the two constructs is consistent with a 4 ( $\alpha$ 1 $\beta$ 1) and a 5 ( $\alpha$ 1 $\beta$ 1 $\gamma$ 2) subunit construct.

## 339.6

**MODULATION OF RECOMBINANT GABA<sub>A</sub> RECEPTORS BY THE GENERAL ANAESTHETIC ETOMIDATE IS SUBUNIT DEPENDENT.** C. Hill-Venning\*, D. Belelli, A.G. Hope, J.A. Peters and J.J. Lambert. Department of Pharmacology, Ninewells Hospital and Medical School, The University, Dundee DD1 9SY, U.K.

The GABA enhancing and direct 'agonist' effects of the general anaesthetic etomidate have been determined on *Xenopus laevis* oocytes expressing human recombinant GABA<sub>A</sub> receptors of different subunit composition. cRNAs coding for human  $\alpha$  (1.2,3 or 6)  $\beta$  (1 or 2)  $\gamma$ 21 receptor subunits were injected into *Xenopus* oocytes and responses to GABA and etomidate were determined using a two-point voltage-clamp. In all combinations tested, etomidate concentration-dependently enhanced the current response to GABA (EC<sub>50</sub>), but preferentially augmented currents mediated by receptors containing  $\beta$ 2 rather than  $\beta$ 1 subunits. For example, etomidate EC<sub>50</sub> values for  $\alpha$ 1 $\beta$ 2 $\gamma$ 21 and  $\alpha$ 1 $\beta$ 1 $\gamma$ 21 are 1.2 $\pm$ 0.1  $\mu$ M (n=4) and 10.8 $\pm$ 1.1  $\mu$ M (n=4) respectively and the E<sub>max</sub> values (expressed as percent of the maximal GABA response) are 127 $\pm$ 12% (n=4) (30  $\mu$ M) and 79 $\pm$ 2% (n=4) (100  $\mu$ M) respectively. Additionally, the maximal direct currents induced by etomidate were substantially larger for receptors containing a  $\beta$ 2 subunit, e.g. 19 $\pm$ 2% (300  $\mu$ M) and 4 $\pm$ 0.5% (1mM) in  $\alpha$ 1 $\beta$ 2 $\gamma$ 21 and  $\alpha$ 1 $\beta$ 1 $\gamma$ 21 respectively. The type of  $\alpha$  subunit expressed also influenced the modulatory effect of etomidate; the ratio of potency for the  $\alpha$ 1 $\beta$ 2 $\gamma$ 21 versus  $\alpha$ 1 $\beta$ 1 $\gamma$ 21 constructs was 13.3, 6.9, 8.8, 8.0, where x was  $\alpha$ 6,  $\alpha$ 2,  $\alpha$ 1,  $\alpha$ 3 respectively. By contrast, the anaesthetics propofol and 5 $\alpha$ -pregnan-3 $\alpha$ -ol-20-one displayed similar potencies in  $\beta$ 1 versus  $\beta$ 2 containing receptors both as modulators and agonists. These findings suggest that comparison of the  $\beta$ 1 and  $\beta$ 2 amino acid sequences will be instructive in identifying the molecular determinants of the action of this anaesthetic.

Work supported in part by Organon Teknika and the MRC.

## 339.8

**MODULATION OF  $\beta$ 3 AND  $\alpha$ 1 $\beta$ 3 GABA<sub>A</sub> RECEPTORS BY PROPOFOL.**

P.A. Davies, T.G. Hales and E.F. Kirkness\*. Dept. Anaesthesiology, UCLA, LA, CA 90025 and Inst. for Genomic Research, 932 Clopper Rd. Gaithersburg, MD 20878.

The general anesthetic propofol modulates neuronal receptors for the inhibitory transmitter  $\gamma$ -aminobutyric acid (GABA). Low concentrations of propofol potentiate responses to GABA and at higher concentrations propofol directly activates GABA<sub>A</sub> receptors in the absence of GABA. There are 16 different GABA<sub>A</sub> receptor subunits which may combine to form pentameric receptors with different pharmacological properties. Using radioligand binding and patch-clamp techniques we are investigating which subunit(s) are involved in the modulation of the GABA<sub>A</sub> receptors by propofol.

Human embryonic kidney (HEK) cells were transfected with rat  $\alpha$ 1 and  $\beta$ 3 cDNAs, alone, or in combination. Both GABA and propofol displaced [<sup>35</sup>S]TBPS binding from membranes of HEK cells expressing  $\alpha$ 1 $\beta$ 3 GABA<sub>A</sub> receptors. Both GABA (100  $\mu$ M) and propofol (100  $\mu$ M) directly activated whole cell currents recorded from 42% of HEK cells tested expressing  $\alpha$ 1 $\beta$ 3 receptors. Propofol (10  $\mu$ M) also potentiated GABA (100  $\mu$ M)-activated currents in these cells. Cells transfected with  $\alpha$ 1 subunits alone did not bind [<sup>35</sup>S]TBPS. Likewise, neither GABA nor propofol activated currents when applied to cells expressing only  $\alpha$ 1 subunits. By contrast, propofol but not GABA displaced [<sup>35</sup>S]TBPS from the membranes of cells expressing  $\beta$ 3 homomers. Propofol evoked currents in 63% of cells transfected with  $\beta$ 3 cDNA, but GABA was ineffective as an agonist in the same cells.

Therefore  $\alpha$ 1 and  $\beta$ 3 subunits together form functional GABA<sub>A</sub> receptors. GABA-evoked currents mediated by  $\alpha$ 1 $\beta$ 3 receptors are potentiated by propofol and propofol directly activates this combination. When expressed alone  $\alpha$ 1 subunits did not form functional GABA<sub>A</sub> receptors. By contrast,  $\beta$ 3 homomers formed receptors which were activated by propofol, but were insensitive to GABA.

## 339.9

SUBUNIT SELECTIVITY FOR ANESTHETIC MODULATION OF GABA<sub>A</sub> RECEPTORS EXPRESSED IN Sf9 CELLS USING BACULOVIRUS. **B.X. Carlson\*, S. Srinivasan, R.W. Olsen**, Dept. of Pharmacology, UCLA School of Medicine, Los Angeles, CA 90095.

Anesthetic interactions with various subunit combinations of recombinant GABA<sub>A</sub> receptors (GABAR) were compared in the baculovirus Sf9 cell expression system. GABA<sub>A</sub> chloride ionophores have potentially a diverse composition of polypeptides, and except for the  $\rho$  subunit, all GABAR subunit combinations tested have demonstrated sensitivity to most anesthetic agents. Using receptor autoradiography, however, it has been shown that anesthetics like alphaxalone and pentobarbital modulate GABAR ligand binding differentially throughout the brain (Carlson et al., 1992; Sapp et al., 1992; Bureau and Olsen, 1993; Nguyen et al., 1995). The greatest increases in barbiturate enhancement of benzodiazepine binding occurred in brainstem nuclei. In the presence of intravenous and volatile anesthetics, glucose metabolism and acetylcholine release are also enhanced in similar brainstem nuclei (Herkenham, 1981; Taguchi et al., 1991). What is the subunit composition of GABAR in these brainstem nuclei? *In situ* hybridization and immunohistochemistry have demonstrated that the subunits,  $\alpha 5$ ,  $\beta 3$ , and  $\gamma 1$  appear to colocalize in the brainstem. Using the baculovirus expression system,  $\alpha 5$ ,  $\beta 3$ , and  $\gamma 1$  subunits were subcloned and expressed into Sf9 insect cells in order to test the hypothesis that GABAR comprised of  $\alpha 5\beta 3\gamma 1$  are more sensitive to anesthetic agents than the generic composition of  $\alpha 1\beta 2\gamma 2$ . Subunit selectivity for intravenous and volatile anesthetics was studied using radioligand binding and electrophysiological assays. Supported by NIH grant NS28772.

## 339.11

A NOVEL GABA<sub>A</sub> RECEPTOR SUBUNIT THAT IS EXPRESSED IN REPRODUCTIVE TISSUES AFFECTS SENSITIVITY TO STEROIDS. **E.F. Kirkness, E. Hedblom and C.M. Fraser\*** The Institute for Genomic Research, 932 Clopper Road, Gaithersburg, MD 20878.

The cloning of a novel member of the GABA<sub>A</sub> receptor subunit family has revealed a new subunit class, termed  $\pi$ . The human  $\pi$  subunit mRNA is expressed at low levels within specific brain regions but is relatively abundant in those tissues of the reproductive system that have been reported to express GABA<sub>A</sub> receptors.

The human  $\pi$  gene is 30 kb in length and exhibits an intron/exon structure that is identical to known GABA<sub>A</sub> receptor subunit genes within its protein-coding sequence. Unusually, the  $\pi$  gene also contains a 5'-untranslated exon. The  $\pi$  gene has been localized to chromosome 5q33-34 by FISH mapping. The GABA<sub>A</sub> receptor  $\alpha 1$ ,  $\alpha 6$ ,  $\beta 2$  and  $\gamma 2$  subunit genes have also been mapped to this region. However, the  $\pi$  gene is not contained within the YAC clone yGABR $\gamma 2$ , and its physical proximity to the other 4 subunits is unknown at present.

When expressed alone in HeLa or 293 cells,  $\pi$  subunits do not form homomeric binding sites for known GABA<sub>A</sub> receptor ligands. In contrast,  $\beta 3$  subunits will form homomeric TBPS-binding sites that are sensitive to barbiturates, propofol and pregnanolone. Co-transfection of  $\beta 3$  and  $\pi$  subunits results in expression of TBPS-binding sites that are distinct from either  $\pi$  or  $\beta 3$  homomers. In particular, the  $\pi/\beta 3$  receptor is much less sensitive to the steroid pregnanolone. It is therefore likely that the  $\pi$  subunit plays a role in the steroid-sensitivity of GABA<sub>A</sub> receptors within the reproductive system.

## 339.13

PENTOBARBITAL INDUCES TERNARY EFFECTS ON RECOMBINANT GABA<sub>A</sub> RECEPTORS. **K.J. Gingrich, W.A. Roberts\*, P.M. Burkat, R. Wissler**, Departments of Anesthesiology and Physiology, University of Rochester, School of Medicine, Rochester, N.Y. 14642.

Pentobarbital (PB) directly activates GABA<sub>A</sub> receptors (GABAR) but paradoxically enhances current magnitude during washout (Akaie, 1985). To elucidate the gating mechanisms underlying this complex function, we studied Cl<sup>-</sup> currents during the rapid application (I<sub>BARB</sub>) and termination (I<sub>TAIL</sub>) of PB pulses (50-5000  $\mu$ M, 0.10-30s) in single HEK-293 cells expressing rat brain  $\alpha 1\beta 2\gamma 2$  S-GABAR subunits. The peak I<sub>BARB</sub> concentration response relationship was bell-shaped (peak=500  $\mu$ M). Increasing PB concentrations enhanced I<sub>BARB</sub> desensitization. The termination of high concentration PB (>750  $\mu$ M) pulses triggered a rapid increase in current causing enhancement of peak I<sub>TAIL</sub> before decay. I<sub>TAIL</sub> enhancement showed a sigmoidal relationship with PB concentration (Hill coefficient=2, EC50=740  $\mu$ M). I<sub>TAIL</sub> relaxation kinetics manifested a complex dependence on PB concentration (10s pulses, mean $\pm$ SEM): fast monoexponential decay (time constant ( $\tau$ )=224 $\pm$ 18ms, 100  $\mu$ M PB) at low PB concentrations (<250  $\mu$ M), biexponential decay ( $\tau_{FAST}$  = 96 $\pm$ 11ms,  $\tau_{SLOW}$  = 570 $\pm$ 39ms, percentage fast component = 49 $\pm$ 5.5, 750  $\mu$ M PB) at higher concentrations (250-750  $\mu$ M), and a near-plateau period (duration-T<sub>p</sub>) followed by slow monoexponential decay (T<sub>p</sub>=646 $\pm$ 20ms,  $\tau$ =828 $\pm$ 77ms, 1.25mM PB) at high PB concentrations (>750  $\mu$ M). T<sub>p</sub> also increased monoexponentially with pulse duration ( $\tau$ =4.4s, plateau=560ms, 3mM). The results demonstrate that PB modulates the enhancement and relaxation kinetics of I<sub>TAIL</sub>, as well as induces receptor activation. These findings are consistent with PB inhibition accomplished by binding to low affinity sites that result in rapid and slow transitions to non-conducting states.

## 339.10

PHARMACOLOGY OF  $\alpha 5\beta 2$  and  $\alpha 5\beta 2\gamma 2$  GABA<sub>A</sub> RECEPTORS IN Sf9 CELLS. **S. Srinivasan\*<sup>1</sup>, G.M. Lawless<sup>2</sup>, A.J. Tobin<sup>2-5</sup> and R.W. Olsen<sup>1,4,5</sup>**. Department of <sup>1</sup>Pharmacology, <sup>2</sup>Physiological Sciences, <sup>3</sup>Neurology, <sup>4</sup>Brain Research Institute and <sup>5</sup>Molecular Biology Institute, University of California, Los Angeles, CA 90095.

We have used a "bacmid" expression system, based on baculovirus, to express large amounts of GABA<sub>A</sub> receptors of known subunit compositions. Our initial experiments have compared the pharmacology of GABA<sub>A</sub> receptors that contain the  $\alpha 5$  and  $\beta 2$  subunits with those containing the  $\alpha 5$ ,  $\beta 2$ , and  $\gamma 2$  subunits. Membranes from these cells were tested for their ability to bind [<sup>3</sup>H]muscimol and [<sup>3</sup>H]flunitrazepam, and for the relative affinities of the receptors for other benzodiazepines, including diazepam, flurazepam, clonazepam and zolpidem. We have also compared ligand binding of receptors containing  $\alpha 5\beta 2$  and  $\alpha 5\beta 2\gamma 2$  with that of receptors containing  $\alpha 1\beta 2$  and  $\alpha 1\beta 2\gamma 2$  respectively.

(Supported by and NINDS grants NS 28772 and NS22256.)

## 339.12

A NOVEL GABA RECEPTOR IS EXPRESSED BY LOBSTER OLFACTORY INTERNEURONS. **M. Wachowiak\*, A. Boettcher, A.B. Zhainazarov, S. Flenes, and B.W. Ache**. Whitney Lab and Dept. of Neuroscience, Univ. of Florida, St. Augustine, FL 32086.

GABA is an important central neurotransmitter in many animals, yet GABA receptors in crustaceans remain poorly characterized. In the spiny lobster *Panulirus argus*, GABA applied to the somata of olfactory interneurons elicits a current which reverses at E<sub>Cl</sub>, has a half-maximal GABA response at approximately 30  $\mu$ M, and an agonist profile of muscimol > GABA > CACA (a GABA<sub>C</sub> agonist), with no response to baclofen. The receptor is potently blocked by picrotoxin, but not by the noncompetitive antagonist TBPS or the GABA<sub>A</sub> antagonists bicuculline and hydrastine. The receptor is also insensitive to the GABA<sub>C</sub> antagonists I-4AA, 3-APA and THIP, with I-4AA and 3-APA actually acting as weak agonists. The receptor is also insensitive to strychnine, a glycine receptor antagonist, and cimetidine, which blocks a histamine-activated chloride current in these neurons. In outside-out patch recordings from these neurons in culture, GABA directly gates a 44 pS channel with a current reversal at E<sub>Cl</sub>, consistent with the pharmacological evidence that the receptor is an ionotropic chloride channel. This receptor is similar if not identical to one reported by Jackel et al. (J. Exp. Biol. 191:167-193) on cultured CNS neurons from the clawed lobster *Homarus gammarus*. Our data extend their findings to show that the lobster receptor is pharmacologically distinct from vertebrate GABA<sub>C</sub> receptors as well as from other known GABA receptors. Its presence in two functionally diverse systems in different crustacean species underscores the importance of this novel receptor type in mediating the effects of GABA in the crustacean CNS.

Supported by a Univ. Fla. Presidential Fellowship to MW, NSF IBN-9222765 and NIH DC01655.

## 339.14

STABLE HIGH EXPRESSION OF HUMAN GAMMA-AMINOBUTYRIC ACID<sub>A</sub> RECEPTORS COMPOSED OF ALPHA AND BETA SUBUNITS. **J.-S. Chen, J.A. Drewes, A.A. Reyes # and N.C. Lan\***. CoCensys Inc., 213 Technology Drive, Irvine, CA 92718.

# Current address: Bio-Rad Laboratories, Inc., Life Science Group, Hercules, CA

Multiple classes of pharmacological agents including benzodiazepines, "cage convulsants" like *t*-butylbicyclopenthyrathionate (TBPS), barbiturates and neuroactive steroids allosterically modulate the  $\gamma$ -aminobutyric acid<sub>A</sub> receptor-chloride ionophore complex (GRC). The function of benzodiazepines requires a GRC comprised of  $\alpha$ ,  $\beta$  and  $\gamma$  subunits, while TBPS, barbiturates and neuroactive steroids will allosterically modulate GRCs comprised of  $\alpha$  and  $\beta$  subunits. Binary  $\alpha\beta$  complexes are still hypothesized to be expressed in the mammalian brain particularly during development and could contribute to the pharmacological action of neuroactive steroids and barbiturates. In order to examine binary  $\alpha\beta$  complexes we report here the establishment of stable cell lines that express high levels of human GABA<sub>A</sub> receptors comprised of  $\alpha 1\beta 1$ ,  $\alpha 2\beta 1$  and  $\alpha 3\beta 1$  subunit combinations. The apparent potencies for allosteric modulation of [<sup>3</sup>S]TBPS for most naturally occurring neuroactive steroids for the binary subunit combinations was similar to that of the  $\gamma$ -containing subunit combinations. Also discussed is the usefulness of these cell lines for the biophysical analysis of the GABA<sub>A</sub> receptor stoichiometry.

## 339.15

CLONING AND CHARACTERIZATION OF THE HUMAN GABA<sub>A</sub> RECEPTOR  $\alpha 4$  SUBUNIT: IDENTIFICATION OF A UNIQUE DIAZEPAM-INSENSITIVE BINDING SITE. W. Yang\*, J.A. Drewe and N.C. Lan, CoCensys Inc., 213 Technology Drive, Irvine, CA 92718

The heterogeneity of diazepam-insensitive (DI) benzodiazepine binding sites are found, spatially distributed between cerebral cortical and cerebellar regions. Coexpression of  $\alpha 6$  with  $\beta 2$  and  $\gamma 2L$  subunits creates a pharmacologically similar benzodiazepine receptor to the DI site observed in cerebellum, however, there is no evidence regarding the possible subunit combination forming the DI site in cerebral tissues. Here we report the cloning of the human  $\alpha 4$  cDNA and the pharmacology derived from coexpression of this  $\alpha 4$  subunit with  $\beta 2$  and  $\gamma 2L$  subunits. This recombinant receptor complex showed a high affinity for the previously described benzodiazepine partial agonist bretazenil, the pyrazoloquinoline compounds CGS-9895 and CGS-9896, as well as the inverse agonists DMCM and Ro15-4513 as determined by [<sup>3</sup>H]Ro15-4513 binding. However, it is insensitive to the benzodiazepine type I selective compounds CL 218,872 and zolpidem as well as the benzodiazepine full agonists diazepam, halazepam and midazolam. In addition, the benzodiazepine receptor ligands DMCM,  $\beta$ -CCE,  $\beta$ -CCM, FG-7142, CGS-9895 and CGS-9896 showed 7 to 10 times higher affinity for  $\alpha 4\beta 2\gamma 2L$  than for  $\alpha 6\beta 2\gamma 2L$ . The pharmacology of the  $\alpha 4\beta 2\gamma 2L$  receptor complex appears to resemble those of the DI site found in the cerebral cortex. Our study thus suggests that this subpopulation of DI GABA<sub>A</sub> receptors may be composed of  $\alpha 4\beta 2\gamma 2L$  subunits.

## 339.17

NOVEL PHARMACOLOGY OF THE GABA<sub>A</sub> RECEPTOR  $\alpha 5$  SUBUNIT EXPRESSED IN XENOPUS OOCYTES STUDIED WITH THE TWO ELECTRODE VOLTAGE-CLAMP TECHNIQUE. D.A. Gurley\*, V. Stirling and G. White, Neurogen Corporation, Branford, CT 06405.

The pharmacology of zolpidem at GABA<sub>A</sub> receptors (GABA<sub>A</sub>Rs) expressed in HEK cells and Xenopus oocytes is consistent for GABA<sub>A</sub>Rs containing  $\alpha 1$ ,  $\alpha 2$  and  $\alpha 3$  subunits. While zolpidem does not bind to GABA<sub>A</sub>Rs containing the  $\alpha 5$  subunit in HEK cells, we report that zolpidem potentiates GABA current by 194±24% (EC<sub>50</sub>=227±38nM, Hill slope=0.9±0.1, n=7) in oocytes injected with cRNA coding for  $\alpha 5\beta 1\gamma 2$  subunits. We also observed 10-30% potentiation to zolpidem (500nM-1000nM) in most cells injected with  $\alpha 5\beta 2\gamma 2$  and  $\alpha 5\beta 3\gamma 2$ . Zolpidem potentiation was blocked by flumazenil in all subunit combinations.

Zolpidem also potentiated GABA current in oocytes expressing  $\beta 1\gamma 2$  by 211±24% (EC<sub>50</sub>=247±47nM, Hill slope=1.0±0.1, n=10), thus a positive control was required to demonstrate that the  $\alpha 5$  subunit was incorporated into the GABA<sub>A</sub>Rs that were potentiated by zolpidem in oocytes injected with cRNA coding for  $\alpha 5$ ,  $\beta 1$ , and  $\gamma 2$  subunits. The  $\alpha 5$  subunit was mutated within the M2 region to abolish sensitivity to picrotoxin (PTX) as described previously (Gurley et al., 1995). Expression of  $\alpha 5(T295F/T301A)\beta 1\gamma 2$  GABA<sub>A</sub>Rs yielded GABA-gated current that was not blocked by 100 $\mu$ M PTX. Wild-type  $\beta 1\gamma 2$  GABA<sub>A</sub>Rs were blocked 99±1% by 100 $\mu$ M PTX. Zolpidem sensitivity of  $\alpha 5(T295F/T301A)\beta 1\gamma 2$  was determined in the presence of 100 $\mu$ M PTX to block any existing  $\beta 1\gamma 2$  GABA<sub>A</sub>Rs in the receptor population. This  $\alpha 5(T295F/T301A)\beta 1\gamma 2$  PTX-resistant current was potentiated by zolpidem 276±30% (EC<sub>50</sub>=146±14nM, Hill slope=1.1, n=6). Potentiation of  $\alpha 5(T295F/T301A)\beta 2\gamma 2$  and  $\alpha 5(T295F/T301A)\beta 3\gamma 2$  to zolpidem in the presence of 100 $\mu$ M PTX was not different from the potentiation observed for the wild-type GABA<sub>A</sub>Rs.

These results indicate that some pharmacological properties of  $\alpha 5$ -containing GABA<sub>A</sub>Rs differ between expression systems in vitro. Similarly,  $\alpha 5$ -containing GABA<sub>A</sub>Rs with identical subunit composition may differ pharmacologically between cell types in vivo.

## 339.19

PRIMATE DERIVED GABA<sub>A</sub>  $\alpha 1$ ,  $\alpha 2$ ,  $\alpha 3$ , or  $\alpha 5$ , SUBUNITS IN COMBINATION WITH EITHER  $\beta 1\gamma 2L$ ,  $\beta 2\gamma 2L$ , OR  $\beta 3\gamma 2L$  SUBUNITS FORM TWELVE PHARMACOLOGICALLY DISTINCT RECEPTOR SUBTYPES IN XENOPUS OOCYTES. G. White\* and D. A. Gurley, Neurogen Corp. 35 NE Industrial Rd, Branford, CT 06405.

$\alpha$  subunits of the GABA<sub>A</sub> receptor complex (GABA<sub>A</sub>Rs) are known to influence GABA<sub>A</sub>R pharmacology. Little information exists on the influence of  $\beta$  subunits and on the interaction between  $\alpha$  and  $\beta$  subunits for influencing pharmacological properties of the GABA<sub>A</sub>R. Using the two electrode voltage-clamp technique, the effects of  $\alpha$  and  $\beta$  subunits on pharmacological properties of the GABA<sub>A</sub>R were evaluated in Xenopus oocytes injected with cRNA coding for the  $\gamma 2L$  subunit plus one  $\alpha$  and one  $\beta$  subunit subtype of the GABA<sub>A</sub>R. For each subunit combination, we evaluated a concentration response curve to GABA. For GABA evoked current at each subunit combination, we evaluated a concentration effect curve for Zn and a number of benzodiazepine receptor ligands. A two-way ANOVA was carried out on EC<sub>50</sub>s of GABA. A two-way ANOVA was carried out on inhibition by Zn and a separate two-way ANOVA was carried out on the effects of each benzodiazepine site ligand. In every ANOVA, the interaction effect between  $\alpha$  and  $\beta$  subunits was significant ( $p < 0.03$ ). In addition, no pair of subunit combinations shared the same pharmacological profile across the different drug treatment groups. Thus, each subunit combination exhibited a unique and identifiable pharmacological profile. For some benzodiazepine site ligands, effects at  $\alpha 1$ - and  $\alpha 3$ -containing GABA<sub>A</sub>Rs were not significantly different, whereas effects at  $\alpha 1$ - and  $\alpha 3$ -containing GABA<sub>A</sub>Rs were different from effects at  $\alpha 2$  containing GABA<sub>A</sub>Rs. In other comparisons,  $\alpha 1$ - and  $\alpha 2$ -containing GABA<sub>A</sub>Rs were not significantly different, whereas effects at  $\alpha 1$ - and  $\alpha 2$ -containing GABA<sub>A</sub>Rs were different from  $\alpha 3$  containing GABA<sub>A</sub>Rs. These findings indicate that Type I and II terminology may no longer be appropriate for benzodiazepine receptors. More importantly, the finding that each subunit combination has a unique pharmacological profile suggests that each subunit combination may be selectively targeted by therapeutic agents and investigational tools.

## 339.16

FUNCTIONAL AND PHARMACOLOGICAL CHARACTERIZATION OF THE HUMAN GABA<sub>A</sub> RECEPTOR  $\alpha 4$  SUBUNIT EXPRESSED IN XENOPUS OOCYTES. E. R. Whittemore\*, W. Yang, J.A. Drewe, and R. M. Woodward, CoCensys, Inc., 213 Technology Drive, Irvine, California 92718.

The human GABA<sub>A</sub> receptor  $\alpha 4$  subunit has recently been cloned and characterized pharmacologically using binding techniques [Yang et al. see adjacent abstract]. These studies suggest that the  $\alpha 4$  subunit forms a novel diazepam-insensitive benzodiazepine binding site. To further investigate the functional pharmacology of the  $\alpha 4$  subunit we expressed  $\alpha 4\beta 2\gamma 2L$  subunit combinations in Xenopus oocytes, comparing the properties of these receptors with  $\alpha 1\beta 2\gamma 2L$  and with various binary subunit combinations (e.g.  $\alpha 4\beta 2$ ,  $\alpha 4\gamma 2L$ , and  $\beta 2\gamma 2L$ ). Maximal GABA responses were generally smaller for  $\alpha 4\beta 2\gamma 2L$ , as compared to  $\alpha 1\beta 2\gamma 2L$ , while apparent GABA affinity was higher for  $\alpha 4\beta 2\gamma 2L$ . Modulatory effects of benzodiazepine site ligands and other GABA<sub>A</sub> receptor modulators were assayed on currents that were ~10% of the maximal GABA response. In agreement with the binding studies, diazepam (0.01-1  $\mu$ M), normally classed as a full agonist at benzodiazepine sites, had no effect on  $\alpha 4\beta 2\gamma 2L$ , whereas it increased  $\alpha 1\beta 2\gamma 2L$  responses up to ~100%. Ro15-4513 (1  $\mu$ M), a benzodiazepine partial inverse agonist, potentiated  $\alpha 4\beta 2\gamma 2L$  by ~60%, but inhibited  $\alpha 1\beta 2\gamma 2L$  by ~10%. Flumazenil (1  $\mu$ M), a benzodiazepine antagonist, potentiated  $\alpha 4\beta 2\gamma 2L$  by ~40% and did not modulate  $\alpha 1\beta 2\gamma 2L$ . The benzodiazepine ligands bretazenil, CGS-9895, and DMCM had qualitatively similar effects at both subtypes of receptor. Pentobarbital, loreclezole, mefenamic acid and 3 $\alpha$ -hydroxy-5 $\alpha$ -pregnan-20-one all induced potentiation of  $\alpha 4\beta 2\gamma 2L$  responses, similar to that seen with  $\alpha 1\beta 2\gamma 2L$ . Our results suggest that the  $\alpha 4$  subunit selectively confers novel benzodiazepine site pharmacology on GABA<sub>A</sub> receptors.

## 339.18

CHARACTERIZATION OF THE MURINE GABA<sub>A</sub> RECEPTOR  $\alpha 6$ -SUBUNIT GENE. T.A. Glencorse\*, D. Livingston, H.H. Xue and R.W. Davies, Robertson Laboratory of Biotechnology, Institute of Biomedical and Life Sciences, University of Glasgow, Glasgow G11 6NU, Scotland, U.K.

$\gamma$ -Aminobutyric acid (GABA), the major inhibitory neurotransmitter in the vertebrate central nervous system, primarily mediates its actions via the pentameric GABA<sub>A</sub> receptor. To date, 15 genes encoding GABA<sub>A</sub> receptor subunits have been identified, each of which exhibit distinct developmental-, regional- and cell-specific expression patterns. Further, chronic treatment with therapeutic agents such as the benzodiazepines (e.g., diazepam and lorazepam which are used in the treatment of anxiety) and with ethanol, modulates the expression and function of GABA<sub>A</sub> receptors. The molecular mechanisms by which GABA<sub>A</sub> receptor expression is regulated in normal and pathological states are not known. We are currently investigating the transcriptional regulation of the GABA<sub>A</sub> receptor  $\alpha 6$ -subunit gene since the expression of this gene is tightly regulated. It is expressed solely in cerebellar granule cells, is developmentally regulated and is altered in response to chronic benzodiazepine treatment. Using a PCR probe from the 5' end of the published  $\alpha 6$ -subunit cDNA sequence we have isolated several genomic clones from mouse 129 genomic library ( $\lambda$ 2001). Three of these clones, which were found to overlap in the region of the translational start site, were further characterized by restriction mapping, DNA sequence analysis and localization of the transcriptional start site(s). A series of GABA<sub>A</sub> receptor  $\alpha 6$ -subunit gene promoter deletion constructs are presently under investigation in cultured primary cerebellar granule cells.

## 339.20

GAMMA SUBUNIT INFLUENCES THE MECHANISM OF ZINC INHIBITION IN RECOMBINANT GABA<sub>A</sub> RECEPTORS. P.M. Burkat, W.A. Roberts, K.J. Gingrich\*, Departments of Anesthesiology and Physiology, University of Rochester, School of Medicine, Rochester, N.Y. 14642.

The inclusion of the  $\gamma$  subunit class in recombinant GABA<sub>A</sub> receptors (GABAR) changes the apparent mechanism of Zn<sup>2+</sup> inhibition from a non-competitive (Draguhn et al, 1990) to a competitive mechanism (Chang et al, 1995). Yet, the details of Zn<sup>2+</sup> interaction with  $\alpha\beta(\gamma)$  GABARs remain unclear. To investigate the nature of Zn<sup>2+</sup> inhibition and its dependence on the  $\gamma$  subunit, we performed whole-cell patch clamp on single HEK-293 cells transfected with cDNAs encoding rat brain  $\alpha 1\beta 2$  or  $\alpha 1\beta 2\gamma 2S$  GABA receptor subunits. Cl<sup>-</sup> currents (I<sub>GABA</sub>) triggered by rapidly applied GABA pulses (1-5000 $\mu$ M, 2-10s) were examined in the presence of Zn<sup>2+</sup> (0.5-5000 $\mu$ M). Zn<sup>2+</sup> inhibited I<sub>GABA</sub> (5 $\mu$ M GABA) of both receptors in sigmoidal fashion ( $\alpha 1\beta 2$ : Hill coefficient-0.6, EC<sub>50</sub>-1.4 $\mu$ M;  $\alpha 1\beta 2\gamma 2S$ : Hill coefficient-1.01, EC<sub>50</sub>-177 $\mu$ M) consistent with previous reports. Zn<sup>2+</sup> (10 $\mu$ M) suppressed peak I<sub>GABA</sub>s of  $\alpha 1\beta 2$  independent of GABA concentration and without appreciable changes in time-course. However, Zn<sup>2+</sup> (200 $\mu$ M) reduced peak I<sub>GABA</sub>s of  $\alpha 1\beta 2\gamma 2S$  that was relieved by increasing GABA concentration and nearly abolished at high concentrations (>1000 $\mu$ M), as reported for Xenopus. Furthermore, Zn<sup>2+</sup> (200 $\mu$ M) accelerated markedly  $\alpha 1\beta 2\gamma 2S$  I<sub>GABA</sub> (1mM) desensitization kinetics (biexponential function fits (mean±SEM): fast time constant - 281±64ms to 95±24ms, slow time constant - 2480±634ms to 1340±149ms, and percentage fast component - 33±5 to 47±7). These results suggest that the nature of the Zn<sup>2+</sup> inhibition of GABARs is influenced by the presence of the  $\gamma$  subunit class. When present ( $\alpha 1\beta 2\gamma 2S$ ), Zn<sup>2+</sup> suppresses GABARs through dual mechanisms of competitive inhibition of GABA at activating sites and accelerated desensitization.

## 339.21

STUDY OF THE BENZODIAZEPINE SITE ON THE  $\alpha 6\beta 2\gamma 2$  GABA<sub>A</sub> RECEPTOR SUBTYPE VIA SITE-DIRECTED MUTAGENESIS. J.F.Pregenzer, G.L.Alberts, W.B.Im\* and J.A.Binder. CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

The  $\alpha 6\beta 2\gamma 2$  subtype of cloned GABA<sub>A</sub> receptors is unique among similar subtypes made of different  $\alpha$  isoforms in its inability to interact with classical benzodiazepines, its agonistic response to Ro 15-1788, and its low half-maximal concentration ( $EC_{50}$ ) for GABA to induce Cl currents. A point mutation of arginine 100 of  $\alpha 6$  to histidine (the corresponding residue in  $\alpha 1$ ) enables the subtype to interact with diazepam (Wieland *et al.*, J. Biol. Chem. 267:1426, 1992). Here we generated  $\alpha 6$  mutants where several nonconservatively substituted amino acid residues near R100 were mutated to the corresponding  $\alpha 1$  residues (H121, N122, V142, N143, and the segment from P161 to L187). Studies with the mutants indicate that the agonistic activity of Ro 15-1788 disappeared only with mutation of all the residues cited above, and that the  $EC_{50}$  for GABA to induce Cl currents was variable among the mutants, ranging from 0.1 to 1.2  $\mu$ M (although far from that for the  $\alpha 1\beta 2\gamma 2$ , about 10  $\mu$ M). It appears that the N-terminal region of the  $\alpha$  subunit includes functional and binding pharmacophores for the benzodiazepine site and influences low affinity GABA sites, allosterically.

## 339.23

ACTIONS OF ALLOSTERIC MODULATORS ON EXPRESSED HOMO-OLIGOMERIC *DROSOPHILA* GABA RECEPTORS: INSIGHTS INTO STRUCTURE OF NATIVE RECEPTORS. A. M. Hosie and D. B. Sattelle.\* Babraham Institute Laboratory of Molecular Signalling, Department of Zoology, University of Cambridge, Downing St., Cambridge CB2 3EJ, U. K.

The activity of insect GABA receptors, like that of vertebrate GABA<sub>A</sub> receptors, is subject to allosteric modulation. Under two-electrode voltage clamp, we have tested a range of candidate modulators on homo-oligomeric GABA-gated chloride-channels formed by the expression, in *Xenopus* oocytes, of cRNA encoding the *Drosophila* GABA receptor subunit, RDL. The potency and effects of allosteric modulators on RDL homo-oligomers and native insect GABA receptors were strikingly similar for those compounds that do not show subunit specificity in vertebrate GABA<sub>A</sub> receptors (i.e. barbiturates, pregnane steroids and picrotoxin binding site ligands). In contrast to *in situ* insect receptors, 1000-fold higher concentrations of 4'-chloro-diazepam (Ro5-4864) were required to enhance the GABA response of RDL homo-oligomers whereas flunitrazepam was without effect. In vertebrates, the co-expression of specific subunits is a prerequisite for native benzodiazepine pharmacology. Thus, the differences between the pharmacology of RDL homo-oligomers and *in situ* insect receptors may reflect the hetero-oligomeric nature of native insect GABA receptors.

## 339.25

Assembly and cell surface expression of functional  $\gamma$ -aminobutyric acid type A receptors. C.N.Connolly\*<sup>2</sup>, B.J.Krishek<sup>1</sup>, B.J.McDonald<sup>2</sup>, T.G.Smart<sup>1</sup>, and S.J.Moss<sup>2</sup>. 1. Department of Pharmacology, The School of Pharmacy, London WC1N 1AX. 2. MRC LMCB, U.C.L., London WC1E 6BT.

The ability of differing subunit combinations of GABA<sub>A</sub> receptors, produced from  $\alpha 1$ ,  $\beta 2$  and  $\gamma 2L$  subunits, to form functional cell surface receptors was analysed in both A293 cells and *Xenopus* oocytes. Receptor assembly occurred within the endoplasmic reticulum (ER) where the chaperone molecules Heavy chain binding protein (BiP) and calnexin participated. Assembly was unaffected by glycosylation inhibitors and could occur rapidly between immature subunits. Despite all three subunits possessing the ability to oligomerise with each other, only  $\alpha 1\beta 2$  and  $\alpha 1\beta 2\gamma 2L$  subunit combinations could produce functional surface expression. Single subunits and the  $\alpha 1\gamma 2L$  and  $\beta 2\gamma 2L$  combinations were retained within the ER. These results suggest that receptor assembly occurs by defined pathways, which may serve to limit the diversity of GABA<sub>A</sub> receptors that are expressed on the surface of neurones.

## 339.22

MAPPING THE Picrotoxin BINDING SITE IN THE GABA-A RECEPTOR CHANNEL USING CYSTEINE MUTAGENESIS.

Myles H. Akabas\* and Ming Xu. Center for Molecular Recognition, Columbia University, New York, NY 10032.

We identified the residues from the entire M2 membrane spanning segment of the rat GABA<sub>A</sub> receptor  $\alpha 1$  subunit which line the ion channel using the scanning cysteine accessibility method (JBC 268:21505-21508). The cysteine-substitution mutant  $\alpha 1$  subunits were expressed with wild type  $\beta 1$  &  $\gamma 2$  subunits in *Xenopus* oocytes. Irreversible alteration of GABA-induced currents following reaction with water soluble, charged sulfhydryl-specific reagents indicates that the residues N275, S272, I271, T268, T265, L264, T262, T261 and V257 are exposed in the channel. Picrotoxin and cyclodiene insecticides are non-competitive inhibitors of GABA-induced currents. When picrotoxin is coapplied with the sulfhydryl reagents in the presence of GABA it protects V257C from modification. Although picrotoxin blocks conduction in the T261C mutant, it does not protect T261C from modification. In an  $\alpha$  helix, T261 would be 6 Å closer to the extracellular end of the channel than V257. This suggests that picrotoxin binds in the channel lumen at the level of V257. Supported by NIH NS30808, AHA Grant-in-Aid, NYHA Estab. Sci. Award, Klingenstein Award in Neuroscience.

## 339.24

CO-ASSEMBLY OF TWO DIVERGENT INSECT GABA RECEPTOR SUBUNITS

Hai-Guang Zhang<sup>#</sup>, Kate Aronstein<sup>\*</sup>, Thomas Rocheleau<sup>\*</sup>, Richard H. French-Constant<sup>+</sup> & Meyer B. Jackson<sup>#</sup>. <sup>#</sup>Department of Physiology, <sup>+</sup>Departments of Neuroscience and Entomology, University of Wisconsin-Madison, Madison, Wisconsin 53706

In comparison with the large number and variety of vertebrate GABA<sub>A</sub> receptors, few insect GABA receptors or 'GABA receptor like' subunits have been cloned to date. We have investigated the coexpression of two *Drosophila* GABA receptor subunits, *Resistance to dieldrin* or *Rdl* and a homolog of the vertebrate GABA<sub>A</sub> receptor  $\beta$  subunit. Unlike vertebrate GABA<sub>A</sub> receptors *Rdl* forms highly functional picrotoxin (PTX) sensitive but bicuculline (BIC) insensitive homomeric channels, and cannot be readily classified within any of the known GABA<sub>A</sub> receptor subtypes. In contrast to *Rdl*, successful functional expression of the *Drosophila*  $\beta$  subunit homolog has not been reported. Here we report that co-infection of cells with recombinant baculoviruses containing both subunits induces expression of GABA receptors having distinct pharmacological and kinetic properties. Whole cell patch clamp recordings reveal two separate populations, one highly sensitive to PTX but BIC insensitive (*Rdl* homomultimers) and the other PTX insensitive and BIC sensitive (*Rdl*+ $\beta$  heteromultimers). Putative *Rdl*+ $\beta$  channels also show very different channel properties with slow activation, rapid bursting, prolonged open time and a shorter closed time. These studies not only localize sensitivity to PTX and BIC to two distinct GABA receptor subunits but also demonstrate an unprecedented assembly of two highly divergent GABA receptors subunits. Further, the difference in channel conductance between *in vivo* and recombinant channels predicts the existence of a novel uncharacterized GABA receptor subunit in *Drosophila*.

## 340.1

**CHARACTERIZATION OF PD 152255, A NOVEL DIMERIC BENZIMIDAZOLE DOPAMINE D<sub>1</sub> ANTAGONIST.** A.E. Corbin\*, T.A. Pugsley, H.C. Akunne, S.Z. Whetzel, R.G. MacKenzie, L.M. Georgic, J.L. Wright, L.D. Wise, T.G. Heffner. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105.

PD 152255 (*E*-1,1'-(2-butene-1,4-diyl)bis[2-[4-[3-(1-piperidinyl)propoxy]phenyl]-1H-benzimidazole]) is a novel agent with high affinity for dopamine (DA) D<sub>1</sub> receptors. PD 152255 displaced the DA antagonist [<sup>3</sup>H]-spiperone with a K<sub>i</sub> value of 10 nM from human DA D<sub>1</sub> receptors expressed in CHO K1 cells. PD 152255 had low affinity for human DA D<sub>2</sub> receptors expressed in CHO K1 cells, whether labelled with [<sup>3</sup>H]-spiperone (K<sub>i</sub>: 516 nM) or [<sup>3</sup>H]-N-0437 (K<sub>i</sub>: 271 nM) and lacked affinity for DA D<sub>3</sub> and DA D<sub>4</sub> receptors (K<sub>i</sub> > 3 μM). PD 152255 exhibited effects consistent with DA D<sub>3</sub> receptor antagonist activity in vitro: it did not cause DA agonist-like stimulation of mitogenesis in D<sub>3</sub>-transfected CHO p-5 cells and it antagonized the stimulation of mitogenesis produced by the DA agonist quinpirole in this assay (IC<sub>50</sub>: 19 nM), in line with its D<sub>3</sub> receptor binding affinity. PD 152255 produced dose-related inhibition of spontaneous locomotor activity in mice (ED<sub>50</sub>: 7 mg/kg IP; maximal effect: 70%). Unlike classical DA antagonists, PD 152255 produced minimal effects on brain DA synthesis and spontaneous or amphetamine-stimulated locomotor activity in rats. However, PD 152255 increased locomotion in rats showing low basal activity after a period of habituation to the test chambers, a profile also seen with other D<sub>3</sub> antagonist-like compounds, including U-99194, (+)-AJ-76 and (+)-UH-232. These results suggest that PD 152255 is a DA D<sub>3</sub> antagonist that does not produce behavioral effects characteristic of classical DA antagonists.

## 340.3

**DIFFERENTIAL SENSITIVITY OF [<sup>3</sup>H]7-OH-DPAT-LABELED BINDING SITES IN RAT BRAIN TO INACTIVATION BY EEDQ.** Beth Levant\*. Department of Pharmacology, University of Kansas Medical Center, Kansas City, KS 66160-7417.

The alkylating agent EEDQ irreversibly inactivates a variety of neuroreceptors including the classical dopamine receptor subtypes, D<sub>1</sub> and D<sub>2</sub>. [<sup>3</sup>H]7-OH-DPAT is a selective ligand for the novel D<sub>3</sub> dopamine receptor (K<sub>i</sub> = 1.4 nM). The effects of EEDQ on [<sup>3</sup>H]7-OH-DPAT labeled receptors were assessed in ventral striatal (n. accumbens and olf. tubercle) membranes of adult, male Sprague-Dawley rats according to the methods of Lévesque et al. (PNAS, 89:8155, 1992). [<sup>3</sup>H]Spiperone binding in striatal membranes was also determined as a positive control. *In vitro*, EEDQ inactivated both [<sup>3</sup>H]7-OH-DPAT- and [<sup>3</sup>H]Spiperone-labeled receptors with IC<sub>50</sub> values of 13 μM and 19 μM, respectively. *In vivo*, [<sup>3</sup>H]Spiperone binding was rapidly inhibited in a dose-dependent manner. In contrast, [<sup>3</sup>H]7-OH-DPAT binding was not significantly altered by EEDQ at any dose (3 - 10 mg/kg, sc), or at any time point (2 - 24 h) examined. Depletion of endogenous catecholamines with α-methyltyrosine (300 mg/kg, ip) and reserpine (5 mg/kg, ip), revealed a second, higher affinity [<sup>3</sup>H]7-OH-DPAT binding site (K<sub>i</sub> = 0.15 nM). EEDQ treatment in catecholamine depleted animals decreased [<sup>3</sup>H]7-OH-DPAT binding by 33% relative to controls and yielded a single population of sites (K<sub>i</sub> = 1.3 nM). This suggests that [<sup>3</sup>H]7-OH-DPAT labels two populations of binding sites in rat brain which differ in their susceptibility to modification by EEDQ. These sites may represent high and low affinity states of the D<sub>3</sub> receptor. Supported by the Pharmaceutical Research and Manufacturers Association and NIMH MH 52839.

## 340.5

**S-(-)-HA-966, A γ-HYDROXYBUTYRATE-LIKE AGONIST, BLOCKS BEHAVIORAL AND MESOACCUMBAL, IN ADDITION TO MESOCORTICAL, DOPAMINERGIC STRESS ACTIVATION.** B.A. Morrow\*, E.J.K. Lee, J.D. Elsworth, H.E. Nye and R.H. Roth. Depts. of Pharmacology and Psychiatry, Yale Univ. School of Med., New Haven, CT 06520

Recently, we demonstrated that R-(+)-HA-966, a glycine/NMDA antagonist, selectively attenuated stress-induced increases in dopamine (DA) metabolism in the medial prefrontal cortex (mPFC), but not the nucleus accumbens (NAS). S-(-)-HA-966, however, has been noted to have actions similar to γ-hydroxybutyrate (Singh et al. *Proc. Natl. Acad. Sci.* 87:347-3451, 1989). We tested the effect of S-(-)-HA-966 on restraint and conditioned fear stressor-induced monoamine metabolism and fear-associated behaviors-immobilization and defecation. S-(-)-HA-966, 5 mg/kg i.p., prevented the stress-induced increase in mesocortical DA, but not serotonin, metabolism, similar to the R-(+) enantiomer, but at 1/3 the dose. Additionally, S-(-)-HA-966 blunted condition fear-induced immobility and increased defecation. In contrast to these similar effects of both enantiomers, S-(-)-HA-966 had unique actions on mesoaccumbal DA activity. Interestingly, conditioned fear elevated DA metabolism in both the core and shell subdivisions of the NAS. The S-(-) enantiomer blocked the stress-induced increase in DA metabolism in the whole NAS and in both the core and shell subdivisions, by restraint and conditioned stressors, respectively. These studies indicate differences with regards to the stress-activation of the mesoaccumbal DA projections between the R-(+) and S-(-) enantiomers. The mechanism of the action of S-(-)-HA-966 is not clear, however a GABA-B linked mechanism has been proposed. Initial studies, however, do not indicate that S-(-)-HA-966 displaces [<sup>3</sup>H]-baclofen binding. Additional studies will further examine the possibility of a GABAergic mechanism for S-(-)-HA-966, as well as the effects of both enantiomers on post-synaptic activity utilizing the immediate-early gene, fos, as a marker. Supported in part by MH-14092.

## 340.2

**PD 156586, A NOVEL DOPAMINE (DA) D<sub>3</sub> PREFERRED PARTIAL AGONIST: BIOCHEMICAL AND LOCOMOTOR EFFECTS IN RODENTS.** T.A. Pugsley\*, H.C. Akunne, S.Z. Whetzel, A.E. Corbin, L.M. Georgic, Y.H. Shih, R.G. MacKenzie, J.L. Wright, L.D. Wise, T.G. Heffner. Departments of Therapeutics and Chemistry, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105.

The present study examines some aspects of the *in vitro* and *in vivo* pharmacology of PD 156586 (3-[4-(1H-benzimidazol-2-yl)-phenoxy]-propyl-(2-thiophen-2-yl-ethyl)amine). In transfected Chinese hamster ovary cells (CHO K1) using [<sup>3</sup>H]spiperone as the ligand, PD 156586 had K<sub>i</sub> values of 8 nM, 118 nM, and 584 nM for human D<sub>3</sub>, D<sub>2</sub>L and D<sub>4</sub>2, respectively. PD 156586 stimulated [<sup>3</sup>H]thymidine uptake in CHO p-5 cells transfected with either D<sub>3</sub> (EC<sub>50</sub> = 1.1 nM) or D<sub>2</sub> receptors (EC<sub>50</sub> = 138 nM) with intrinsic activities suggestive of partial agonist action at both sites. PD 156586 (3-30 mg/kg, s.c.) produced a mild behavioral stimulation in habituated rats, without an effect on locomotor activity in nonhabituated rats or mice, effects like those of (+)-AJ76 and (+)-UH23. PD 156586 partially antagonized apomorphine-stimulated locomotor activity in rats. Like classical DA antagonists, PD 156586 (5-30 mg/kg, i.p.) increased rat brain DA synthesis. PD 156586 (5 mg/kg, i.p.) reversed the decrease in rat striatal DA synthesis induced by the D<sub>3</sub> preferring agonist PD 128907. By itself PD 156586 had no effect on DA synthesis in gamma-butyrolactone pretreated rats indicating a lack of DA autoreceptor agonist action. These results suggest that PD 156586 is acting as an antagonist at DA synthesis-regulating autoreceptors. It is tempting to suggest that the *in vivo* actions of PD 156586 are due in part to a D<sub>3</sub> receptor interaction. However, the influence of the DA D<sub>3</sub> receptor preference of such compounds on their pharmacological profile is still not fully understood. Compounds such as PD 156586 may help to further our understanding of the function of D<sub>3</sub> receptors.

## 340.4

**NEUROCHEMICAL INVESTIGATIONS OF THE ROLE OF DOPAMINE D-3 RECEPTORS IN COCAINE SELF-ADMINISTRATION.** E. Weiss\*, L.H. Parsons, S.B. Caine, J.C. Schwartz, P. Sokoloff, and G.F. Koob. Department of Neuropsychopharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The present study was designed to test the hypothesis that the D-3 receptor modulates cocaine self-administration via a post-synaptic mechanism. The selective D-3 agonist quinlorane attenuated cocaine self-administration at a 16-fold lower dose than 7-OH-DPAT. The addition of quinlorane (0.25 μg/injection) to the self-administered cocaine solution (0.25 mg/inf) reduced cocaine intake by 50% (from 2.4±0.1 to 1.2±0.1 infusions per ten minutes), while also decreasing nucleus accumbens (NAC) dialysate DA levels from 366±63% of baseline during cocaine self-administration to a stable level of 187±25% of baseline. When the drug solution was switched to quinlorane alone (0.25 μg/inf) the number of self-administered infusions increased to an average of 5.3±0.2 infusions per ten minutes. During this time dialysate DA levels decreased to a stable level of 71±8% of baseline. Combined with the 7-OH-DPAT findings referred to above, these results suggest that D-3 receptor agonists modify cocaine reinforcement via a post-synaptic mechanism. To test the regional specificity of 7-OH-DPAT, this agonist was locally applied to the NAC and ipsilateral striatum of the same animal (n = 5) via reverse dialysis. DA efflux in the NAC was dose-dependently decreased by 7-OH-DPAT (30, 100 nM) while there was no effect of this agonist on DA efflux in the striatum. These results suggest that this agonist selectively modifies mesolimbic DA neurotransmission, and at low concentrations may selectively activate D-3 receptors. Finally, the D-3 receptor antagonist nafadotride dose-dependently (0.1 - 0.3 mg/kg s.c.) increased both locomotor activity and NAC dialysate DA (133±13% and 160±22% of baseline, per dose). These findings suggest that at low doses D-3 antagonists induce locomotor activity via an increase in DA efflux produced by a presynaptic action. These results suggest that the D-3 receptor has both a presynaptic and postsynaptic functional action similar to dopamine D-2 receptors except that they appear restricted to the mesolimbic system.

## 340.6

**D-2 AND D-3 RECEPTORS MODULATE LEARNING AND MEMORY PROCESSES IN THE RAT.** S. Sigala\*, C. Missale, M. Frassine, P.F. Spano. Div. Pharmacol., Dept. Biomed. Sci. & Biotech., Brescia Univ. Med. Sch., 25123 Brescia, Italy.

Molecular cloning techniques revealed the existence of different dopamine (DA) receptors. Currently, six receptors have been cloned and grouped into two original families, D-1 and D-2. However, the paucity of highly selective ligands for each of these receptor subtypes makes functional studies difficult. Recently, a new D-3 antagonist compound called nafadotride has been developed.

It is well known that there is a DAergic control of septohippocampal cholinergic system involved in learning and memory; in particular DA has a permissive role on hippocampal acetylcholine release, mediated by receptors belonging to the D-2 DA family.

In the present study, using the model of transient memory disruption induced by scopolamine in the passive avoidance behavioural test, pharmacological characterization confirm that the DAergic modulation of septohippocampal system is due to D-2 DA receptor family; in particular, two members of this family are involved, namely D-2 and D-3 receptors. Interestingly, they shown an opposite effect on antagonizing scopolamine-induced memory impairment; in fact the amnesic effect elicited by scopolamine is blocked by the D-2 DA receptor stimulation and this effect is potentiated by the contemporary block of D-3 DA receptor activity.

Our data firstly demonstrated a functional role of D-3 receptors located in limbic areas; this could have important pharmacological and therapeutic implications and it could give input for the development of new selective drugs, which would help to well define the localization and the role of the various receptor subtypes.

This work was supported by the European Commission, contract Biomed I BMH1-CT92-1086.

## 340.7

U-95666A, A DOPAMINE D<sub>2</sub> AGONIST: BEHAVIORAL STUDIES IN RATS. P.J.K.D. Schreur\* and N.F. Nichols. CNS Research, The Upjohn Company, Kalamazoo, MI 49001

U-95666A is a dopamine (DA) agonist which binds to D<sub>2</sub> receptors but not D<sub>1</sub>, D<sub>3</sub>, or D<sub>4</sub> (M.W. Smith *et al.*, this meeting). We examined the activity of U-95666A in turning and locomotor assays using Omnitech Roto-Scan and Digiscan equipment. In rats with unilateral substantia nigra (SN) lesions, 1-3 mg/kg s.c. U-95666A caused contralateral turning in the manner of direct-acting postsynaptic dopamine agonists, but with a delayed time to maximum turning. The response was long-lasting, with a plateau of 2-2.5 hrs, and ending at about 5 hrs. Haloperidol, which had no effect on rotation by itself, completely antagonized the turning induced by U-95666A. When given daily for 2 weeks, U-95666A-induced turning showed a profound sensitization which remained high for weeks or months afterward. These withdrawn, sensitized rats respond with cross-sensitivity to the D<sub>1</sub> agonist SKF 38393 (which did not cause sensitization by itself), but without cross-sensitivity to the D<sub>2</sub>/D<sub>3</sub>/D<sub>4</sub> agonist quinpirole (which did cause sensitization by itself).

In intact, habituated rats, U-95666A stimulated locomotor activity at 3 mg/kg s.c. at 50-120 mins after injection (1 mg/kg was not active). Given U-95666A 1 mg/kg daily for 2 weeks, rats did not have increased activity in either their baseline activity or their response to an acute dose of 1 mg/kg s.c. Hence, no sensitization was seen here, in contrast to that seen in rats with SN lesions.

## 340.9

PRESYNAPTIC AND POSTSYNAPTIC PHARMACOLOGY OF U-95666A, A DOPAMINE AGONIST SELECTIVE FOR THE D<sub>2</sub> RECEPTOR SUBTYPE: INCREASE IN POSTSYNAPTIC RESPONSE IN PARKINSON'S DISEASE (PD) MODEL. M. Camacho-Ochoa\*, W.E. Hoffmann, M.W. Moon, L.M. Figur, A.H. Tang, C.S. Himes, N.F. Nichols, and M.F. Piercey. The Upjohn Company, Kalamazoo, MI 49001

In receptor binding assays using cloned receptors in CHO cells, U-95666A bound with high affinity to dopamine (DA) D<sub>2</sub> receptors; it also bound with moderate affinity to 5-HT<sub>1A</sub> and 5-HT<sub>1D</sub> receptors (Smith *et al.*, this meeting). Large differences in affinity for the high and low affinity forms of the D<sub>2</sub> receptor are consistent with functional data demonstrating high intrinsic activity for U-95666A (Smith *et al.*, this meeting). U-95666A depressed locomotor activity in rats with low doses and stimulated it with a high (10 mg/kg) dose; stereotypy was minimal with all doses but was prominent when U-95666A was combined with SKF 38393. In electrophysiology tests, U-95666A depressed firing rates of DA neurons in substantia nigra pars compacta (SNPC) by a haloperidol-sensitive mechanism, but it did not alter firing rates of 5-HT neurons in dorsal raphe. In normal rats, U-95666A did not alter neuronal firing rates in substantia nigra pars reticulata (SNPR), an area sensitive to striatal control. However, in animals where SNPC DA neurons were destroyed by 6-OHDA lesions, U-95666A depressed SNPR neuron firing rates with potencies similar to those depressing SNPC neuron firing. It is concluded that, in normal animals, presynaptic D<sub>2</sub> receptors are more responsive than postsynaptic D<sub>2</sub> receptors; however, in denervated animals, postsynaptic D<sub>2</sub> sensitivity is equal to that observed for presynaptic D<sub>2</sub> receptors in normal animals. These data suggest a potential utility for a selective D<sub>2</sub> agonist such as U-95666A in treatment of PD.

## 340.11

ANTI-AGGRESSION EFFECT OF THE D<sub>2</sub> AGONIST U-95667E: AN ANALOG OF U-95666A. N.F. Nichols\*, P.J.K.D. Schreur. CNS Research, The Upjohn Co., Kalamazoo, MI 49001

The shock-induced aggression test in mice picks up activity of both benzodiazepine- and serotonin-related anxiolytic compounds. U-95667E, a compound with both dopamine (DA) and serotonin (5-HT) agonist activity, is highly efficacious in this test. Stress increases the synthesis and release of DA, and increases DA metabolites in the prefrontal cortex of rats, and this can be modulated by benzodiazepine (BZD) receptors. There is also a close link between this BZD modulation and stress-induced behavior. However, it is unclear to what extent DA "drives" stress-induced behaviors. Pretreatment with  $\alpha$ -methyl-para-tyrosine ( $\alpha$ -MPT) alone gave only weak activity at best, but facilitated anti-aggression effects of 8-OH-DPAT (DPAT), diazepam (DIAZ) and U-95667E. Neither apomorphine (APO) nor haloperidol (HALO) alone altered latency to fighting in this assay, but APO antagonized and HALO potentiated all of the following: DPAT, DIAZ and U-95667E. Flumazenil attenuated DIAZ latencies, but had no effect on DPAT or U-95667E latencies. In conclusion, this testing shows U-95667E anti-aggression activity to be independent of BZD. This leaves the DA agonist property of U-95667E linked to the anti-aggression effect. Since APO alone was inactive, and in fact antagonized the anti-aggression effects of DPAT, DIAZ and U-95667E, it would seem paradoxical for the DA agonist activity of U-95667E to be responsible for increasing latency to fighting. Peripheral effects, regional specificity or effects on other transmitters may be involved.

## 340.8

MONOAMINERGIC RECEPTOR PROFILES OF IMIDAZOQUINOLINONES: AGONISTS POTENTIALLY USEFUL FOR THE TREATMENT OF PARKINSON'S DISEASE. M.W. Smith, M.J. Bienkowski, W.H. Darlington, D.M. Dinh, D.W. Harris, R.M. Huff, M.E. Laiiness, C.F. Lawson, R.B. McCall\*, J.C. McGuire, M.W. Moon, and S.K. Schlachter. Upjohn Laboratories, The Upjohn Company, Kalamazoo, MI 49001

Parkinson's Disease (PD) results from the progressive degeneration of a small population of dopamine producing brain cells. Although the traditional symptomatic treatment for the disease has been with the dopamine precursor L-DOPA, direct-acting dopamine agonists have been increasingly used to supplement or replace L-DOPA therapy. The imidazoquinolines and imidazoquinolinones are a series of mixed serotonergic/dopaminergic agonists under development at The Upjohn Company. Members of this series have a variety of interesting effects in biochemical, neurochemical and behavioral assays. We have evaluated the *in vitro* binding and functional intrinsic activities of selected members of this series for mammalian monoaminergic receptors expressed in cultured cell lines. Members of the series were found to have generally low affinity for D<sub>1</sub>, D<sub>3</sub>- and D<sub>4</sub>-dopamine, 5-HT<sub>2</sub> and 5-HT<sub>1D</sub> sites. Some had high to moderate affinity for and were found to activate D<sub>2</sub>-dopamine, 5-HT<sub>1A</sub> and/or 5-HT<sub>1D</sub> receptors. The imidazoquinolinone U-95666A, in particular, had potent *in vitro* D<sub>2</sub>-dopamine activity, exceptionally good selectivity within the dopamine receptor subtypes, and modest affinity for 5-HT<sub>1A</sub> and 5-HT<sub>1D</sub> sites. The structure-activity relationships within this series will be discussed and compared with the binding properties of a variety of standard agonist compounds either currently used or under development for the treatment of PD.

## 340.10

EFFECTS OF THE PUTATIVE ANTI-PARKINSON COMPOUND U-95666A ON BRAIN DOPAMINE ON SEROTONIN NEUROCHEMISTRY. K.A. Svensson\*, M.P. Stone, J.E. Myers, S. Koch, and N.F. Nichols. The Upjohn Company, Kalamazoo, MI 49001

The dopamine D<sub>2</sub> receptor agonist U-95666A is an imidazoquinolinone analog that induces locomotor stimulation and stereotypies in habituated and reserpine pretreated rats, and strong turning behavior in the 6-OHDA lesioned rat. No signs of the 5-HT behavioral syndrome were noted. U-95666A binds to D<sub>2</sub> receptors with high affinity, and with moderate affinity to 5-HT<sub>1D</sub> and 5-HT<sub>1A</sub> receptors (cf. Smith *et al.* and Schreur *et al.*, this meeting). In neurochemical studies in the rat, U-95666 (1-10 mg/kg s.c.) reduced limbic and striatal DOPA and 5-HTP accumulation with a similar potency and a high degree of intrinsic efficacy. Also, the steady-state levels of dopamine and 5-HT were increased, while the metabolites DOPAC, HVA and 5-HIAA were reduced, thus indicating reduced dopamine and serotonin turnover. These data suggest that U-95666 acts as an agonist at both dopamine and serotonin synthesis/release regulating autoreceptors. The inhibitory effects on striatal dopamine release were confirmed in a microdialysis study in freely moving rats. The inhibition of DA turnover may add "neuroprotective properties" that may impact the progression of Parkinson's disease.

## 340.12

UP-REGULATION OF RAT D<sub>3</sub> DOPAMINE RECEPTOR mRNA BY NEUROLEPTICS. W. Wang, K.-H. Hahn, J. F. Bishop, D.-Q. Gao, P. A. Jose\*, M. M. Mouradian. Genetic Pharmacology Unit, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD, 20892 and Department of Pediatrics, Georgetown University Medical Center, Washington, D.C. 20007.

The predominant localization of the D<sub>3</sub> dopamine receptor in the limbic part of the striatum complex, including the olfactory tubercle-island of Calleja complex, the bed nucleus of stria terminalis and nucleus accumbens suggests that this receptor could be an important mediator of the antipsychotic action of neuroleptics. In this study, the effects of four neuroleptics on the expression of D<sub>3</sub> dopamine receptor gene after 14 days treatment were investigated in different regions of the rat brain using a sensitive quantitative polymerase chain reaction (Q-PCR) assay. The levels of D<sub>3</sub> dopamine receptor mRNA increased in olfactory tubercle following 0.5mg/kg/day haloperidol (40%), 0.25mg/kg/day pimozide (56%) and 40mg/kg/day sulpiride (63%) administration (ANOVA p<0.002). In nucleus accumbens, D<sub>3</sub> mRNA levels increased after haloperidol (50%) and sulpiride (50%) (ANOVA p<0.05). D<sub>3</sub> message levels in the motor striatum did not change with any antagonist tested. The atypical neuroleptic clozapine (20mg/kg/day) did not affect D<sub>3</sub> expression in any brain region examined. These findings suggest that the extrapyramidal side effects of chronic antipsychotic therapy are not due to D<sub>3</sub> receptor up-regulation in the motor striatum and thus neuroleptics with selective D<sub>3</sub> antagonism may be free of these complications.

## 340.13

D2 DOPAMINE RECEPTOR ACTIVATION INDUCES FOS IN THE RAT STRIATUM. A.E. Pollack\* and J.S. Fink, Molecular Neurobiology Laboratory, Massachusetts General Hospital and Department of Neurology, Harvard Medical School, Boston, MA 02114.

Stimulation of D1 dopamine (DA), but not D2 DA receptors is associated with c-Fos activation in the striatum. In this study we tested whether repeated treatment of 6-hydroxydopamine (6-OHDA) lesioned rats with the mixed D1-D2 DA agonist apomorphine (APO) could alter the responsiveness of striatal neurons upon challenge with the D2 DA agonist quinpirole (QUIN). Three weeks following unilateral injections of the 6-OHDA in the medial forebrain bundle rats were treated with APO 3x over 10 days. One week later when these 3xAPO rats were treated with QUIN (0.25mg/kg) there was a significant increase in contralateral rotation ( $554 \pm 70$ ) and ipsilateral Fos-like immunoreactivity (Fos-LI) ( $835 \pm 69$ ) in the dorsal striatum after 2 hours as compared to 3xAPO control rats ( $H_2O$ -injected) (rotation:  $5 \pm 2$ ; Fos-LI:  $91 \pm 7$ ). The effect of QUIN on contralateral rotation and ipsilateral striatal Fos-LI was dose-dependent and could be blocked by the D2 DA antagonist eticlopride (0.5mg/kg), but not by the D1 DA antagonist SCH 23390 (2 or 0.5 mg/kg). Fos immunohistochemistry combined with colloidal gold retrograde tract-tracing showed that 78  $\pm$  1% of cells expressing Fos-LI following administration of QUIN were gold-labeled striatonigrostriatal neurons. Lastly, 6-OHDA lesioned rats pretreated with  $H_2O$  (No APO) showed little contralateral rotation ( $20 \pm 8$ ) or ipsilateral striatal Fos-LI ( $223 \pm 40$ ) following administration of QUIN (0.25mg/kg), while 1xAPO rats treated with QUIN had an intermediate amount of rotation ( $314 \pm 52$ ) and striatal Fos-LI ( $489 \pm 98$ ) compared to 3xAPO rats treated with QUIN. These data suggest that pretreatment of 6-OHDA lesioned rats with APO alters the responsiveness of striatal neurons to a D2 DA agonist.

## 340.15

D1 AND D2 DOPAMINERGIC AGONISTS INCREASE FOS IMMUNOREACTIVITY IN THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS AND CENTRAL NUCLEUS OF THE AMYGDALA IN RAT. M.J. Eaton\*, K.E. Moore and K.J. Lookingland, Dept. of Pharmacology and Toxicology, Michigan State University, East Lansing, MI 48824.

Populations of corticotropin-releasing hormone (CRH)-containing neurons which play an important role during stress are found in the paraventricular nucleus of the hypothalamus (PVN) and the central nucleus of the amygdala (cAMY). Dopaminergic (DA) fibers terminate in close association with CRH-containing neurons in both PVN and cAMY suggesting that CRH-synthesizing neurons could be regulated by DA receptors. The purpose of the present study was to determine the effects of selective D1 and D2 DA agonists on FOS immunoreactivity in neurons of PVN and cAMY (some of which contain CRH). Transverse sections through the middle of PVN or cAMY were chosen macroscopically and FOS-positive cells within each nucleus were counted. Ninety min after systemic injection of either the D1 agonist SKF 38393 (20 mg/kg; i.p.) or its 0.1% ascorbic acid vehicle (5 ml/kg; i.p.), the number of FOS-positive cells increased from  $69.6 \pm 12.7$  to  $145.4 \pm 29.3$  in PVN and from  $18.8 \pm 3.7$  to  $146.2 \pm 14.9$  in cAMY. Similarly, 90 min after systemic injection of either the D2 agonist quinlorane (100  $\mu$ g/kg; i.p.) or its 0.9% saline vehicle (1 ml/kg; i.p.), the number of FOS-immunoreactive cells increased from  $52.2 \pm 7.5$  to  $141.4 \pm 11.0$  in PVN and from  $30.6 \pm 4.1$  to  $123.8 \pm 29.3$  in cAMY. The results of this study reveal that activation of either D1 or D2 receptors stimulates neurons in both PVN and cAMY. (Supported by NS 15911)

## 340.17

ACUTE AND PROLONGED ANTIPSYCHOTIC TREATMENTS LEAD TO DIFFERENT PATTERNS OF IEG EXPRESSION IN THE CNS. P. Rogue\*, T. Leveillard, A. N. Malviya, UPR416-CNRS, Centre Neurochem., 5 rue Blaise Pascal, Strasbourg 67084 France.

Using gel-shift assays, we studied the effect of antipsychotics on AP-1 binding activity in the CNS. A single injection of haloperidol (2 mg/kg i.p.), which induces *c-fos* and *jun B* mRNA in the rat striatum, similarly produces a transient increase in AP-1 binding activity in both the dorsal and the ventral striatum. After prolonged haloperidol administration (2 mg/kg for 15 days), both *c-fos* and *jun B* induction were significantly desensitized, though not completely abolished. However, despite this down-regulation, AP-1 binding activity remained elevated at levels comparable to those seen after acute haloperidol administration. This increase persisted for at least 4 days following the last administration of haloperidol. Similar results were found in the dorsal and in the ventral striatum. Thus the composition of the AP-1 transcription factor complex appears modified upon prolonged neuroleptic administration. The effect of clozapine will be presented. Supershift assays were also conducted using various antibodies.

## 340.14

*c-fos* AND NEUROTENSIN mRNA INDUCTION IN THE RAT MEDIAL PREFRONTAL CORTEX AND NUCLEUS ACCUMBENS BY ATYPICAL ANTIPSYCHOTICS: ROLE OF D3 DOPAMINE RECEPTORS. L.M.Figur\*, D.L.Evans and K.M.Merchant, CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001

Previous studies have shown that administration of some atypical antipsychotic agents (but not typical ones) increases *c-fos* gene expression in the rat medial prefrontal cortex. Characterization of the effects of a dopamine receptor antagonist, U-99194A, with 20-fold preference for D3 versus D2 receptors, has aided in investigating the role of D3 receptors in this phenomenon. Acute administration of U-99194A at 25, 50 or 100  $\mu$ mol/kg (i.p.) produced large increases in *c-fos* mRNA levels in the medial prefrontal cortical regions. Unlike the effects of clozapine, the response to U-99194A was not restricted largely to the deep cortical layers. The greatest response was observed in the anterior dorsal cingulate cortex, followed by the pre-limbic, infralimbic (IL), and the lateral orbital (Orb) cortices. Interestingly, the highest dose of 100  $\mu$ mol/kg produced lower responses in the IL and Orb cortices as compared to those induced by 50  $\mu$ mol/kg. These data raise the question whether blockade of D2 receptors may prevent *c-fos* gene induction in the IL and Orb cortex. In the nucleus accumbens-shell where several clinically efficacious antipsychotics (typical and atypical) induce neurotensin (NT) gene expression, U-99194A did not produce statistically significant alterations at any dose tested. However, at the two higher doses, it induced NT mRNA in the accumbal shell and dorsolateral striatum in 2 out of 5 animals. It is likely that the effects of the higher doses are mediated by D2 receptors. These data show that D3 receptors may regulate the activity of prefrontal cortical neurons, but not accumbal systems.

## 340.16

ACUTE ADMINISTRATION OF A D<sub>2</sub> DOPAMINERGIC RECEPTOR AGONIST DECREASES FOS IMMUNOREACTIVITY IN THE PERIVENTRICULAR NUCLEUS, MEDIAL PREOPTIC AREA AND HORIZONTAL LIMB OF THE DIAGONAL BAND OF BROCA IN MALE RATS. S. Cheung\*, M.J. Eaton, K.E. Moore and K.J. Lookingland, Dept. of Pharmacology/Toxicology, Michigan State University, East Lansing, MI 48824.

Dopaminergic (DA) agonists increase gonadotropin-releasing hormone (GnRH) mRNA levels in the brain of male rats. In the rat brain, GnRH containing cells are diffusely distributed within several nuclear groups, including periventricular nucleus (PeVN), medial preoptic area (MPOA), and the horizontal limb of the diagonal band of Broca (HDB). The purpose of the present study was to determine the effects of selective D<sub>1</sub> and D<sub>2</sub> agonists on FOS immunoreactivity in GnRH neurons in these regions. Transverse sections through the middle of the PeVN, MPOA and HDB were chosen macroscopically and FOS-positive cells within each nucleus were counted bilaterally. GnRH positive neurons were identified by immunohistochemistry, but no FOS-positive GnRH neurons were found in any of these brain regions. Ninety min after systemic injection of either the D<sub>1</sub> agonist SKF 38393 (20 mg/kg; i.p.) or its 0.1% ascorbic acid vehicle (5 ml/kg; i.p.), there was no difference in the number of FOS-positive cells between control and treatment groups. However, 90 min after systemic injection of either the D<sub>2</sub> agonist quinlorane (100  $\mu$ g/kg; i.p.) or its 0.9% saline vehicle (1 ml/kg; i.p.), the number of FOS-immunoreactive cells decreased from  $25.4 \pm 0.98$  to  $14.4 \pm 2.23$  in the PeVN, from  $193 \pm 11.91$  to  $119.2 \pm 20.3$  in the MPOA and from  $39.4 \pm 5.12$  to  $11.2 \pm 2.96$  in the HDB. The results of this study reveal that activation of D<sub>2</sub> receptors inhibits FOS expression in unidentified, non-GnRH neurons in the PeVN, MPOA and HDB. (Supported by NS15911)

## 340.18

DECREASE IN TYROSINE HYDROXYLASE mRNA EXPRESSION IN THE CAROTID BODY DURING DEVELOPMENT: POSSIBLE REGULATION BY D2-DOPAMINE AUTORECEPTORS. E.B. Gauda<sup>1</sup>, C.R. Gerfen<sup>2\*</sup>, <sup>1</sup>Johns Hopkins Medical Institutions, Baltimore, MD 21287 and <sup>2</sup>Laboratory of Systems Neuroscience, NIMH, Bethesda, MD 20892.

Type 1 cells in the carotid body synthesize dopamine and express D2-dopamine receptors. Binding of dopamine to D2 receptors decreases cAMP which has been shown to alter gene transcription of tyrosine hydroxylase (TH), the rate limiting enzyme for dopamine synthesis. Furthermore, D2 receptor antagonists increase TH mRNA expression in nigrostriatal neurons in the brain. We have shown that in the newborn rat, TH mRNA expression in the carotid body at birth is significantly greater than it is at postnatal days 2 and 14. In this study, we examined the relationship between TH and D2 mRNA expression in the carotid body in animals at postnatal days 0 and 14. Quantitative, double-label *in situ* hybridization using <sup>35</sup>S-UTP and digoxigenin labeled ribonucleotide probes enabled the comparison of TH and D2 mRNAs in the same cells in the carotid body of both age groups. At postnatal day 0, TH mRNA expression was greater ( $P < 0.002$ ) while D2 mRNA was less ( $P < 0.001$ ) than TH and D2 mRNA expression, respectively, in animals at postnatal day 14. Thus, TH mRNA expression is inversely correlated with D2 mRNA expression in the carotid body at two time points during development. Experiments to determine the mechanism of this correlation are being performed. <sup>1</sup>Supported by RWJ Foundation.

**CHRONIC NEUROLEPTICS DO NOT ALTER G PROTEIN EXPRESSION IN RAT BRAIN.** E. Meller, K. Bohmker and A.J. Friedhoff. Dept. of Psychiatry, NYU Medical Center, New York, NY 10016.

Chronic treatment with a number of psychotropic drugs (morphine, cocaine, lithium, antidepressants) alters expression of various G proteins in discrete regions of rat brain. The present study assessed the effects of chronic treatment with several dopamine receptor antagonists on expression of G proteins. Groups of rats were treated for 3 weeks with vehicle, haloperidol (0.5 mg/kg), SCH 23390 (0.2 mg/kg) and clozapine (20 mg/kg). Animals were sacrificed 3 hr after the final treatment and micropunches of tissue were obtained from 6 brain regions (striatum, nucleus accumbens, frontal cortex, hippocampus, substantia nigra and ventral tegmental area). Membrane fractions were denatured by standard techniques and G proteins were separated by SDS-PAGE on 28 cm long gels, followed by Western blotting and detection of G protein  $\alpha$  subunits with specific antibodies using the enhanced chemiluminescence technique. This method allowed the clear separation and effortless densitometric analysis of the 3 main pertussis toxin-sensitive G proteins present in rat brain ( $G_{i1}$ ,  $G_{i2}$  and  $G_{o1}$ ) in a single lane using an appropriately diluted mixture of two antibodies ( $\alpha_{i1}/\alpha_{i2}$ , Calbiochem;  $\alpha_{o1}$ , Upstate Biotechnology, Inc.).

Despite reports that other psychotropic drugs alter expression of specific G proteins in discrete brain regions, none of the D1 or D2 receptor antagonists modified the expression of these G protein  $\alpha$  subunits in the 6 brain regions examined. Supported in part by PHS grants NS 23618 and MH 08618.

## 340.20

**G-PROTEIN EXPRESSION IN 6-HYDROXYDOPAMINE LESIONED RATS AND 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE TREATED MICE.** E.R. Marcotte, A. Chugh, C. Barlas, and R.K. Mishra. Depts. of Psychiatry and Biomedical Sciences, McMaster University, Hamilton, Ontario, L8N 3Z5, Canada.

Parkinson's disease (PD) is a progressive neurodegenerative condition characterized by the loss of dopaminergic neurons in the substantia nigra, with the subsequent depletion of striatal dopamine levels. In the 6-hydroxydopamine (6-OHDA) lesioned rat model of PD, striatal dopamine receptors exhibit behavioural and pharmacological supersensitivity to both D<sub>1</sub> and D<sub>2</sub> receptor agonists, despite significant upregulation of only D<sub>2</sub> receptors. Here we report the persistent elevation of striatal stimulatory G-proteins Gs and Golf, but not Gi or Go, as measured by immunoblotting. These results suggest that D<sub>1</sub> receptor supersensitivity may be maintained by stimulatory G-proteins in the absence of D<sub>1</sub> receptor upregulation. To examine the relative contributions of Gs and Golf in post-synaptic supersensitivity, antisense oligonucleotides have been prepared for in vivo administration in 6-OHDA lesioned rats. G-protein levels have also been examined in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) treated C57 BL/6 mice (30mg/kg/day for 10 days). Although these animals show >90% striatal dopamine depletion, dopamine receptor upregulation has only rarely been reported. We have found no significant change in Gs, Gi, or Go levels 10 days post-lesion. However, preliminary data suggests that Golf levels may be reduced by MPTP treatment, in contrast to 6-OHDA lesions. In any case, these results clearly indicate that G-proteins are primarily involved in the expression of post-synaptic dopamine receptor supersensitivity (supported by PFD Canada).

## CATECHOLAMINE RECEPTORS: IN VIVO DRUG EFFECTS II

## 341.1

**EFFECTS OF HALOPERIDOL TREATMENT ON DOPAMINE D2 AND D3 RECEPTOR DENSITIES IN RAT BRAIN.** M.-P. Kung\*, D. Frederick, J. Vessotskie and H. F. Kung. Departments of Radiology and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Up-regulation of dopamine D2-like receptors following neuroleptic treatment (i.e., haloperidol) has been reported previously, and may produce extrapyramidal side effects. Lack of selective ligands, however, has hampered the study of differential changes of various D2-like subtypes. Recently, a novel radioiodinated 5-OH-DPAT analog, S(-)-5-OH-PIPAT, displaying high affinities for dopamine D3 and the high affinity state of D2 (D2H) receptors, was reported (Chumpradit et al., J. Med. Chem. 37:4245-4250, 1994). Regional changes of dopamine D2 (high and low affinity states) and D3 receptor densities in rat brain after chronic treatment with haloperidol (1.5 mg/kg/day, i.p., for 18 days) were re-examined using homogenate binding and quantitative receptor autoradiography. The binding affinities ( $K_d$ ) with both [I-125]S(-)-5-OH-PIPAT (measuring D2 and D2H) and [I-125]NCQ298 (measuring total D2 and D3 binding sites) were similar between control and treated rats. A prominent increase of specific binding of [I-125]S(-)-5-OH-PIPAT (40-80%) in regions of striatum, nucleus accumbens and olfactory tubercle was observed for haloperidol-treated rats as opposed to a moderate increase shown in [I-125]NCQ298 binding (10-30%). Autoradiographic analysis of brain sections revealed that there was no significant difference in the densities in cerebellar lobules 9 and 10 (pure D3) than labeled with either [I-125]NCQ298 or [I-125]S(-)-5-OH-PIPAT. These data suggested that dopamine D2 and D3 receptors may be regulated differently by the neuroleptic treatment. It appeared that the high affinity state (agonist binding) of D2 receptors was up-regulated, while D3 receptors remained relatively constant. (supported by MH-51880)

## 341.2

**CHARACTERIZATION OF DOPAMINE D3 RECEPTORS IN A NATIVE STATE USING QUANTITATIVE AUTORADIOGRAPHY.** J. Vessotskie\*, M.-P. Kung, S. Chumpradit and H. F. Kung. Departments of Pharmacology and Radiology, University of Pennsylvania, Philadelphia, PA 19104.

Recently, a radioiodinated analog of R(+)-7-OH-PIPAT, S(-)-5-OH-PIPAT (5-hydroxy-2-(N-n-propyl-N-3'-iodo-2'-propenyl)aminotetralin), was shown to bind with similar high affinities ( $K_d = 0.2-0.4$  nM) to dopamine (DA) D2-like receptors expressed in cell lines (Vessotskie, Neurosci. Abs. 524, 1994). The presence of MgCl<sub>2</sub> (2 mM) is necessary for binding of [I-125]S(-)-5-OH-PIPAT to high affinity states of DA D2 and D4 receptors expressed in HEK293 and CHO cells, but 100 mM Gpp(NH)p greatly reduces binding by converting the receptors to low affinity states. However, increasing concentrations of Gpp(NH)p or MgCl<sub>2</sub> did not influence binding of [I-125]S(-)-5-OH-PIPAT to DA D3 receptors expressed in HEK293 cells. The results of experiments performed to compare D3 receptor density (expressed in HEK293 and Sf9 cells) revealed that putative agonist [I-125]S(-)-5-OH-PIPAT labeled 27% and 39% less D3 sites, respectively, than antagonist [I-125]NCQ298. To further investigate the effects of MgCl<sub>2</sub> and Gpp(NH)p on the D3 receptor binding of these iodinated ligands and the difference in the binding sites labeled with the two ligands, experiments were carried out in the native state. Molecular layers 9 and 10 of the rat cerebellum, containing high D3 densities with minimal contamination of D2 or D4 receptors (based on mRNA expression; Bouthenet et al., Brain Res. 564:203, 1991; Van Tol et al., Nature 350:610, 1991), were chosen for the studies. Preliminary results using quantitative autoradiography are consistent with cell line findings. [I-125]S(-)-5-OH-PIPAT appears to label fewer sites in molecular layers 9 and 10 than [I-125]NCQ298, and the presence of MgCl<sub>2</sub> or Gpp(NH)p does not influence this binding. These results suggest that DA D3 receptors in native tissue bind to agonist and antagonists differently and also that binding to D3 receptors is GTP insensitive. (supported by MH-51880)

## 341.3

**EFFECT OF 6-OHDA LESION ON THE DENSITIES OF D1, D2, D3, AND D4 DOPAMINE RECEPTORS.** G.D. Stanwood\*, I. Lucki, and P. McGonigle. Institute of Neurological Sciences and Department of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Adult male Sprague-Dawley rats received a unilateral infusion of the neurotoxin 6-hydroxydopamine (6-OHDA) in the medial forebrain bundle to produce a selective lesion of the ascending dopaminergic pathways and were sacrificed 7 or 28 days after lesion (n=6/group). The extent of the lesion was determined by measurement of DA uptake sites using <sup>3</sup>H-WIN 35,428 (mean loss = 95.3±1.2%). Consistent with previous reports, D1 receptors labeled with <sup>3</sup>H-SCH 23390 were unchanged both at 7 and 28 days post-lesion in the striatum, nucleus accumbens (NA), and substantia nigra (SN). Additionally, a 20% increase was observed in the binding of <sup>3</sup>H-spiperone (which has high affinity for D2, D3, and D4 receptors) in the striatum of animals sacrificed 28 days after lesion. However, no corresponding change was observed in the binding of [<sup>125</sup>I]-NCQ 298 under conditions which limited its binding only to D2 receptors. As there was no detectable labeling of D3 receptors with [<sup>125</sup>I]-7-OH-PIPAT in this region, the increase in striatal <sup>3</sup>H-spiperone binding appears to represent an upregulation of D4 receptors. This upregulation may mediate the electrophysiological and behavioral supersensitivity which has been observed following 6-OHDA lesion. D3 receptors, labeled with [<sup>125</sup>I]-7-OH-PIPAT, were significantly reduced in the NA and SN both at 7 days (-35% and -45%, respectively) and 28 days (-50% and -52%, respectively) following 6-OHDA lesion. These data, in conjunction with a previous report from this laboratory (Chen, et al., Neurosci Abs 555.2, 1994) support a dual pre- and post-synaptic localization of the D3 receptor in the NA and SN. (Supported by NS-18591, GM-34781 and MH-51880.)

## 341.4

**STREPTOZOTOCIN-INDUCED DIABETIC RAT IS RESISTANT TO CHRONIC EFFECTS OF HALOPERIDOL ON DOPAMINE-D2 RECEPTORS.** T. Sumiyoshi\*, J. Ichikawa, H.A. Johnston and H.Y. Meltzer. Department of Psychiatry, Case Western Reserve University, Cleveland, OH 44106.

The incidence of neuroleptic-induced tardive dyskinesia in patients with schizophrenia is increased in patients who are co-morbid for diabetes mellitus (DM). The present study was performed to determine the effect of chronic haloperidol (HPD) treatment on dopamine-D2 receptor number and vacuuous chewing movements (VCMs) in the streptozotocin (STZ)-induced DM rat. Nine weeks after STZ (65 mg/kg i.v.) treatment, male Sprague-Dawley rats with DM showed an increase in the number of VCMs (mean ± S.E.M.) counted for 90 min following an injection of (-)-apomorphine (250 µg/kg s.c.), as compared to controls (55.1 ± 8.4 vs 13.5 ± 3.9). There was no significant change in the density of [<sup>3</sup>H]spiperone binding sites in the striatum, representing D<sub>2</sub> (and partially, D<sub>3</sub>+D<sub>4</sub>) receptors, in DM rats (26.3 ± 1.3 vs 28.2 ± 1.1 pmol/g tissue in controls). Four weeks of depot HPD treatment (4 mg/kg/wk, i.m.) followed by a one-week withdrawal period did not affect either the density of D<sub>2</sub> receptors (28.4 ± 1.6 pmol/g tissue) or VCMs (47.0 ± 5.8) in DM rats. In non-DM rats, HPD treatment caused D<sub>2</sub> receptor up-regulation (37.0 ± 2.3 pmol/g tissue) and an increase in VCMs (105.1 ± 6.0). These results indicate increased abnormal oral movements and the lack of effect of HPD on post-synaptic D<sub>2</sub> receptors in the STZ-induced DM rat.

## 341.5

CRITICAL EVALUATION OF [<sup>3</sup>H]SPIPERONE, [<sup>3</sup>H]RACLOPRIDE, [<sup>3</sup>H]YM-09151-2 AND [<sup>125</sup>I]NCQ-298 BINDING TO DOPAMINE D<sub>2</sub> RECEPTORS. A. Malmberg<sup>a,c</sup>, E. Jerning<sup>a</sup>, D.M. Jackson<sup>b,\*</sup> and N. Mohell<sup>a</sup>. Departments of Molecular Pharmacology<sup>a</sup> and Behavioural and Biochemical Pharmacology<sup>b</sup>, Preclinical R & D, Astra Arcus AB, S-151 85 Södertälje and Department of Organic Pharmaceutical Chemistry<sup>c</sup>, Uppsala Biomedical Center, Uppsala University, S-751 23 Uppsala, Sweden

Neuroleptics from several chemical classes have been used as radioligands to selectively label dopamine D<sub>2</sub> receptors in various parts of the brain. There are, however, several inconsistencies in the literature as regards the characteristics of benzamide and butyrophenone binding to D<sub>2</sub>-like receptors. We have previously suggested that the discrepancies in B<sub>max</sub> as well as K<sub>d</sub> and K<sub>i</sub> values may be related to methodological difficulties associated with the use of very high-affinity radioligands (e.g. ligand depletion and failure to achieve equilibrium). The present study was designed to reinvestigate the characteristics of [<sup>3</sup>H]spiperone, [<sup>3</sup>H]YM-09151-2, [<sup>125</sup>I]NCQ-298 and [<sup>3</sup>H]raclopride binding to cloned human D<sub>2A</sub> and rat striatal D<sub>2</sub> receptors using optimized experimental assay conditions. We found that the K<sub>d</sub> values of [<sup>3</sup>H]spiperone, [<sup>125</sup>I]NCQ-298 and [<sup>3</sup>H]YM-09151-2 were about 20 pM and that of [<sup>3</sup>H]raclopride about 1 nM. There were no significant differences between the B<sub>max</sub> values determined with the various radioligands. The cross-competition studies showed that the K<sub>i</sub> values of spiperone and NCQ-298 for D<sub>2</sub> receptors labeled with [<sup>3</sup>H]spiperone or [<sup>125</sup>I]NCQ-298 were in good agreement with the corresponding K<sub>d</sub> values. Furthermore, the binding of both radioligands was fully displaceable by spiperone and NCQ-298. We conclude that, when studied under correct experimental conditions, all four radioligands label an identical receptor population.

## 341.7

EFFECTS OF THE SELECTIVE DOPAMINE D<sub>1</sub> AGONIST U91356A ON REGIONAL CEREBRAL BLOOD FLOW. M. Gado, K. J. Black, J. S. Perlmutter, M.E. Raichle,\* Departments of Radiology, Psychiatry and Neurology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Based on known basal ganglia anatomy, and the results of our previous work with the dopamine D<sub>2</sub>-like agonist quinpirole, we hypothesized that blood flow in the globus pallidus (GP) would fall after administration of the more specific D<sub>2</sub> agonist U91356A. We measured quantitative regional cerebral blood flow using H<sub>2</sub><sup>18</sup>O and positron emission tomography in 6 baboons before and after intravenous administration of U91356A. We then performed automated registration of the PET blood flow images with anatomic magnetic resonance images of the same animal using the method of Woods et al. (*J Comput Assist Tomogr* 17:536-546, 1993). In this manner, we could precisely localize blood flow responses to predefined anatomic areas. At high doses of U91356A (0.2 mg/kg), global blood flow declined. However, at intermediate doses (0.02-0.1 mg/kg), there was a significant regional decline in GP blood flow (mean ΔrCBF = -4.79%, *p* = 0.05) when averaged across all 6 animals. The response was bilateral in normals and was present in five of six animals. The decline in pallidus flow was completely blocked by prior intravenous administration of the dopamine D<sub>2</sub> antagonist eticlopride, but was unaffected by prior intravenous administration of the D<sub>1</sub> antagonist SCH 23390. Two animals with unilateral MPTP lesions had the usual decline in globus pallidus blood flow in the normal hemisphere but not in the lesioned hemisphere. These preliminary results strongly suggest that this technique is an effective *in vivo* test of the function of dopamine D<sub>2</sub>-receptor-bearing neurons. This "pharmacological activation" technique complements receptor binding studies, and may prove to be a more sensitive probe for investigation of neuropsychiatric diseases in which a functional abnormality of dopamine D<sub>2</sub> neuronal circuits is suspected. (We thank the Upjohn Company for supply of U91356A).

## 341.9

PHARMACOLOGICAL CHARACTERIZATION OF MAO INHIBITOR INTERACTIONS WITH [<sup>3</sup>H]QUINPIROLE BINDING IN RAT BRAIN. K.A. Morgan\*, J.D. Mochlenkamp, N.L. Leonard, C.C. Cheng, and B. Levant. Department of Pharmacology, University of Kansas Medical Center, Kansas City, KS 66160

[<sup>3</sup>H]Quinpirole is an ergoline dopamine agonist with 1.2 nM affinity for the D<sub>2</sub> and D<sub>3</sub> dopamine receptor subtypes. MAO inhibitors (MAOI) inhibit the binding of [<sup>3</sup>H]quinpirole, but not [<sup>3</sup>H]spiperone or [<sup>3</sup>H]propylorapomorphine, in rat striatal membranes by a competitive mechanism that does not appear to involve the enzymatic activity of MAO. To further characterize this observation, studies were undertaken to determine the activity profile of MAOI-displaceable [<sup>3</sup>H]quinpirole binding. Binding assays were performed in striatal membranes from adult, male Sprague-Dawley rats. Clorgyline, Ro 41-1049, pargyline, and phenelzine exhibited high affinity in competition for [<sup>3</sup>H]quinpirole binding (K<sub>i</sub> = 21, 33, 85 and 100 nM, respectively) and greater than 1,000-fold selectivity between [<sup>3</sup>H]quinpirole and [<sup>3</sup>H]spiperone binding. Other MAOI's inhibited [<sup>3</sup>H]quinpirole binding with the following rank order of potency: (-)deprenyl ≥ tranylcypromine > (+)deprenyl > isocarboxazid > Ro 16-6493 ≥ nialamide > iproniazid ≥ moclobemide > semicarbazid. The affinities of additional, structurally-related compounds were also evaluated. In contrast, classical dopaminergic compounds, such as haloperidol and (+)butaclamol, exhibited high affinity in competition with both ligands. These studies should aid in the elucidation of the specific mechanism by which these compounds inhibit [<sup>3</sup>H]quinpirole binding. Supported by NARSAD.

## 341.6

ENDOGENOUSLY RELEASED DOPAMINE INHIBITS THE BINDING OF DOPAMINERGIC PET AND SPECT RADIOLIGANDS IN SUPERFUSED RAT STRIATAL SLICES. Andrew N. Gifford\*, S. John Gatley and Charles R. Ashby, Jr. Medical Department, Brookhaven National Laboratory, NY 11973.

Pharmacologically induced changes in synaptic cleft levels of dopamine (DA) have been found, in some cases, to affect the *in vivo* binding of dopaminergic radioligands. In the present study we used a superfused brain slice preparation to examine the effect of synaptically released dopamine on the binding of some commonly used PET and SPECT radioligands under more controlled conditions than those present *in vivo*. The release of DA was evoked by electrical stimulation of the slices and the sensitivity of binding of the D<sub>1</sub> receptor ligand, [<sup>3</sup>H]SCH 23390, the D<sub>2</sub> receptor ligands [<sup>3</sup>H]raclopride and [<sup>125</sup>I]epidepride, and the DA uptake transporter ligands, [<sup>3</sup>H]WIN 35,428 and [<sup>125</sup>I]RTI-55, to the frequency of stimulation examined. Most affected by stimulation was the specific binding of [<sup>3</sup>H]SCH 23390, which was fully inhibited at 2.5 Hz. This was followed by [<sup>3</sup>H]raclopride and [<sup>125</sup>I]epidepride, respectively, the binding of the latter showing only a 50% reduction at the highest frequency of 10 Hz. [<sup>3</sup>H]WIN 35,428 and [<sup>125</sup>I]RTI-55 binding was unaffected by stimulation. Examination of the effects of dopamine depletion on the inhibition of [<sup>3</sup>H]raclopride binding by electrical stimulation revealed that the effects of stimulation could be prevented by reserpine treatment of the rat, when combined with inclusion of the dopamine synthesis inhibitor, α-methyl-p-tyrosine, in the superfusion medium. We conclude that, at least in brain slices, the binding of D<sub>1</sub> and D<sub>2</sub> receptor ligands, but not that of DA uptake transporter ligands, is readily inhibited by DA released into the synaptic cleft.

## 341.8

BIPHASIC EFFECT OF DOPAMINE ON HYPOTHALAMIC ANF-PRODUCING NEURONS: INTERACTION OF D<sub>1</sub> AND D<sub>2</sub> RECEPTORS. D. Lee, D.L. Copolov and A.T. Lim\*. Cell Biology Unit, Mental Health Research Institute of Victoria, Royal Park Hospital, Parkville 3052, Australia

Previously we have reported that ANF neurons of rat hypothalamus are dopamine sensitive and shown that the catecholamine exerts a direct stimulatory or inhibitory effect on the neurons acting on D<sub>1</sub> or D<sub>2</sub> receptors respectively, through the modulation of cAMP dependent pathway. Employing well characterised radioimmunoassay and colorimetric Northern blot analysis with synthetic oligonucleotide probes complementary to pro-ANF mRNA, we report here the effect of dopamine (DA), a physiological ligand for both D<sub>1</sub> and D<sub>2</sub> receptors, on ANF neurons in long term primary cultures of neonatal rat hypothalamic cells. At low concentrations (10<sup>-8</sup> to 10<sup>-7</sup> M), DA was found to suppress pro-ANF mRNA expression as well as immunoreactive (ir) ANF release, whereas at high doses (10<sup>-6</sup> to 10<sup>-5</sup> M), the amine acts by stimulating both the production and the secretion of irANF. The inhibitory effect of DA was abolished by sulpiride, a D<sub>2</sub> antagonist and the stimulatory effect was suppressed by SCH-23390, a D<sub>1</sub> antagonist. Furthermore, the augmenting effect of DA was mimicked by quinpirole, a D<sub>2</sub> receptor agonist, coincubated with 10<sup>-5</sup> M of SKF-38393, a D<sub>1</sub> receptor antagonist. This synergistic effect of SKF-38393 and quinpirole was reproduced by concurrent treatment of quinpirole with forskolin or cholera toxin, but not with cAMP. The stimulatory effects of SKF-38393 and quinpirole as well as that of DA alone were suppressed in cultures incubated with antisense oligonucleotide probes complementary to type 2 adenylyl cyclase (ACII) mRNA. We thus conclude that in rat hypothalamic cultures, DA produces a biphasic effect on the function of ANF neurons. The inhibition of DA is mediated through D<sub>2</sub> receptors whereas the stimulatory effect involves a complex interaction between D<sub>1</sub> and D<sub>2</sub> receptors, partly through modulating the biological activity of the adenylyl cyclase-cAMP system.

## 341.10

MONAMINE OXIDASE INHIBITOR INTERACTIONS WITH [<sup>3</sup>H]QUINPIROLE BINDING IN RAT BRAIN AND PERIPHERAL ORGANS. J.D. Mochlenkamp\* and B. Levant. Dept. of Pharmacology, University of Kansas Medical Center, Kansas City, KS 66160

Quinpirole, a dopamine receptor agonist, has high affinity for the D<sub>2</sub> and D<sub>3</sub> receptor subtypes. We have shown that monoamine oxidase inhibitors (MAOI) competitively inhibit [<sup>3</sup>H]quinpirole binding in rat striatal membranes by a mechanism that does not appear to involve the enzymatic activity of MAO. Ro 41-1049 is a MAOI that inhibits [<sup>3</sup>H]quinpirole binding with a K<sub>i</sub> of 34 ± 6 nM, but has low potency in competition with other D<sub>2</sub> ligands, such as [<sup>3</sup>H]spiperone or [<sup>3</sup>H]NPA. Additional studies were performed to further characterize the interaction of Ro 41-1049 at [<sup>3</sup>H]quinpirole labeled sites. Assays were performed using Sprague-Dawley rats as described by Levant, et al (*EJP* 246:171, 1993). In striatal membranes, Ro41-1049 inhibited [<sup>3</sup>H]quinpirole binding at a variety of incubation temperatures, (4°, 23°, 30°, 37°C), assay tissue concentrations, (5, 10, 20 mg/ml) and time points (2-240 min). Ro41-1049 displaceable [<sup>3</sup>H]quinpirole binding was observed in hippocampus, hypothalamus, cerebellum, cortex, substantia nigra, nucleus accumbens, amygdala in addition to the striatum. In the periphery, Ro 41-1049 displaceable [<sup>3</sup>H]quinpirole binding was observed in the liver. These data suggest that MAOI may interact by a novel binding site which is labeled by [<sup>3</sup>H]quinpirole or which modulates [<sup>3</sup>H]quinpirole binding to D<sub>2</sub>-like receptors. Supported by NARSAD.

## 341.11

DOPAMINE AND SEROTONIN RECEPTOR OCCUPANCY BY NOVEL ANTIPSYCHOTIC DRUG, SM-9018 AND ITS METABOLITE, *IN VIVO*.

Y. Takahashi\*, I. Kusumi, T. Ishikane and T. Koyama, Dept. of Psychiatry, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan

*In vivo* occupancy of dopamine D<sub>1</sub>, D<sub>2</sub> and serotonin (5-HT)<sub>2</sub> receptors by novel antipsychotic drug, SM-9018 and its metabolite (M-1) was measured using N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ), an irreversible antagonist at these receptor sites. EEDQ was administered i.p. an hour after pretreatment with SM-9018 or M-1. Twenty-four hours later, male Wistar rats (130-160g) were decapitated and the brains were removed. Receptor occupancy was estimated by measuring the receptor number that had escaped EEDQ-induced reduction.

SM-9018 (1mg/kg i.p.) was nearly equipotent in occupying D<sub>2</sub> (76.7%) and 5-HT<sub>2</sub> receptors (95.5%), whereas it had no effect on D<sub>1</sub> receptor. The metabolite of SM-9018, M-1 (1mg/kg i.p.), however, was more potent in occupying 5-HT<sub>2</sub> (70.7%) than D<sub>2</sub> receptor (21.2%). We previously reported atypical antipsychotic drugs such as clozapine were characterized by high occupancy of 5-HT<sub>2</sub> receptors with low or minimum occupancy of D<sub>2</sub> receptors *in vivo*. The present study suggests that clozapine-like atypical properties of SM-9018 may be, at least in part, due to the pharmacological actions of M-1.

## 341.13

## NEUROCHEMICAL EFFECTS OF INTRA-STRIATAL ADMINISTRATION OF ADTN. D.J. McGRATH\*, J.M. ARNOLD, A.L. DRUMHELLER, &amp; F.B. JOLICOEUR. Dept of Psychiatry, University of Sherbrooke, Sherbrooke, Qc., J1H 5N4 and Dept of Psychology, Bishops University, Lennoxville, Qc, Canada, J1M 1Z7.

We have shown previously that an injection of ADTN, a potent and long acting mixed dopamine agonist, results, 2 hours later, in a prominent motor hyperactivity which is accompanied by enduring changes in dopamine, serotonin, and their metabolites in several brain regions (Neuropsychopharmacology 9:147, 1993). In order to examine the specificity of these effects to the nucleus accumbens, the neurochemical effects of intra-striatal administration of ADTN were examined. The effects of bilateral administration of ADTN (12.5ug) on concentrations of dopamine (DA), its metabolites DOPAC and HVA, serotonin (5-HT), and its metabolite 5-HIAA were examined in several regions, including substantia nigra (SN), ventral tegmentum (VTA), prefrontal cortex (PFC), nucleus accumbens (NA), septum (SEP), globus pallidus (GP), amygdala (AM), and the striatum (ST) itself. Neurochemical changes were assessed at 120 minutes following ADTN injections. Concentrations of DA were significantly increased in the ST, NA, and SEP and significantly decreased in the PFC, GP, and AM. DOPAC concentrations were significantly increased in the SEP and significantly decreased in the GP. Except for the SEP, ADTN induced prominent and significant increases in HVA concentrations in all regions. For example, concentrations of HVA in the PFC were 240 times higher than control levels. 5-HT was significantly decreased in both the SEP and AM and concentrations of its metabolite 5-HIAA also showed significant decreases in the ST, SEP, and GP.

These results indicate that, similarly to what was observed in the NA, a strong DA stimulation in the ST induces pervasive and enduring neurochemical changes. However, the nature of the changes were different between the two regions. These differences may underlie the different behavioral effects induced by DA stimulation in each of these regions. Supported by the MRCC.

## 341.15

U-99194A, A D<sub>3</sub> RECEPTOR ANTAGONIST, SELECTIVELY ABOLISHES AMPHETAMINE'S NON-STRIATAL INCREASES IN BRAIN ENERGY METABOLISM: IMPLICATIONS FOR ANTIPSYCHOTIC THERAPY. E.L. Walker, M.W. Smith, P.J.K.D. Schreur, C.S. Fitch and M.F. Pierce\*, The Upjohn Company, Kalamazoo, MI 49001

The dopamine (DA) D<sub>3</sub> receptor is a member of the D2 receptor subfamily that, based on mRNA distribution, is speculated to be preferentially distributed in limbic rather than striatal pathways (Bouthenet *et al.*, Br Res 564:203, 1991). We now describe the regional distribution of the functional effects of U-99194A, a D<sub>3</sub> receptor antagonist. Receptor binding experiments demonstrated a K<sub>d</sub> of 46 nM for displacing [<sup>3</sup>H]spiperone from cloned D<sub>3</sub> receptors and a K<sub>d</sub> of 1393 nM for displacing [<sup>3</sup>H]U-86170E from cloned D<sub>2</sub> receptors. In 2-deoxyglucose (2-DG) autoradiography studies (Sokoloff *et al.*, J Neurochem 28:897, 1977), amphetamine (AMP, 1.0 mg/kg i.v.) increased brain energy metabolism in 21 of 65 brain regions, including several regions of cerebral cortex (anterior cingulate, sensorimotor, parietal, auditory) and basal ganglia (caudate, globus pallidus). Alone, U-99194A (10 mg/kg i.p.) had no effect on regional brain energy metabolism. However, U-99194A antagonized AMP's stimulant effects in 10 regions, including all cortical areas where AMP induced significant effects. However, AMP effects in basal ganglia areas were not significantly altered. It is concluded that D<sub>3</sub> antagonist activity could lead to selective antagonism of mesocortico-limbic as opposed to nigrostriatal DA function. Such actions hold promise for treatment of schizophrenia without production of extrapyramidal symptoms (EPS). Consistent with this prediction, U-99194A was not active in producing catalepsy in rats, an assay predictive of EPS.

## 341.12

## A TRIFLATE SUBSTITUTED ISO-CLOZAPINE ANALOGUE: A NEW, POTENT, ATYPICAL NEUROLEPTIC. H. Wikström\*, Y. Liao, D. Dijkstra and P. de Boer, Department of Med. Chem., Univ. Center of Pharmacy, Univ. of Groningen, A. Deusinglaan 2, NL-9713 AW, Groningen, The Netherlands. E. Meier, K. Fredriksen and J. Hyttel, Lundbeck A/S, Ottiliavej 9, DK-2500, Copenhagen-Valby, Denmark.

Clozapine is the most effective neuroleptic today, and it has inspired the search for other, equally efficient antipsychotic drugs with even lower propensity of side-effects. One approach is to change the substitution pattern on the 5H-dibenzo[b,e][1,4]diazepine skeleton. In this study, we report on the pharmacological effects of 8- and 2-trifluorosulfonyloxy analogues 1 and 2 of clozapine and iso-clozapine, respectively. The compounds were tested for their effects on dopamine release *in vivo* in dorsal and ventral striatum; their propensity to induce catalepsy; their effects on locomotion in a novel environment and inhibition of locomotion after administration of 1 mg/kg apomorphine. Both clozapine and 2 were characterized as atypical neuroleptics in this test system. Compound 2, however, proved to be acting on dopamine output at doses that were 100 times lower than for clozapine (0.1 µmol/kg vs. 10 µmol/kg). This difference cannot be explained from the binding profiles of clozapine and 2. Consequently, compound 2 may have an efficacy advantage over clozapine, potentially leading to a lower clinical dose necessary, which may prove to be important for avoiding side-effects, including blood dyscrasias.

## 341.14

UNUSUAL PROFILE OF <sup>3</sup>H-CLOZAPINE BINDING IN CALF BRAIN.

H. Fang, M. Li, D.M. Helmeste and S.W. Tang\* Departments of Psychiatry and Pharmacology, University of California, Irvine. Irvine, California 92717

Clozapine has become an important alternate drug of choice in the treatment of schizophrenia. We have previously questioned its apparent lack of regulation on the dopamine D<sub>2</sub> receptors and demonstrated its potent action in reducing serotonin S<sub>2</sub> receptor numbers (Lee and Tang, Psychiatry Res. 12(4):277 1984). Loxapine and amoxapine also showed these same effects as clozapine. To evaluate further the mechanism of action of clozapine, we examined the binding of <sup>3</sup>H-clozapine to calf frontal cortex and striatal tissues. In view of the recent report showing that <sup>3</sup>H-clozapine is not suitable for dopamine D<sub>2</sub> labeling, we also examined the effect of assay conditions on the binding profile. A variety of drugs was used to compete against <sup>3</sup>H-clozapine in binding to calf frontal or striatal membranes in either Hepes (Flamez *et al.*, Neuroscience Letters 175:17 1994) or D<sub>2</sub> (Van Tol *et al.*, Nature 358:149, 1992) buffer. The profile of <sup>3</sup>H-clozapine binding under the two different buffer/assay conditions was very similar. Essentially, under our conditions, there was no nanomolar displacement of <sup>3</sup>H-clozapine binding by dopamine, sulpiride, or spiperone. Atropine, however, potentially displaced <sup>3</sup>H-clozapine and clearly showed a biphasic competition curve. At micromolar concentrations, spiperone, mianserin, loxapine and clozapine showed the ability to displace <sup>3</sup>H-clozapine from a low affinity site. Changing the assay conditions did not affect the binding profile to a significant degree. The *in vitro* binding profile of <sup>3</sup>H-clozapine again raises questions about its clinical sites of action.

## 341.16

Differential regional potencies of D<sub>3</sub>-preferring agonists at synthesis modulating dopamine autoreceptors *in vitro*: Cheryl Wiley Aretha\* and Matthew P. Galloway, Cell & Clin Neurobiology, Dept Psych & Behav Neurosci., Wayne State Univ Sch Med, Detroit MI 48202

We have recently reported that 7-OH DPAT, a dopamine (DA) D<sub>3</sub>-preferring ligand was more potent in the olfactory tubercles (OT) vs. either the striatum (STR) or n. accumbens (NAC) using the GBL model *in vivo* (Aretha *et al.*, JPET, 1995). To further examine the role of D<sub>3</sub> receptors in the autoregulation of DA synthesis, the potencies of D<sub>3</sub>-preferring agonists were determined *in vitro*. K<sup>+</sup> (25 mM) increased DOPA accumulation by approximately 50% in STR slices and 110% in OT slices, an effect that was inhibited by the D<sub>3</sub>-preferring agonists PD128907 and 7-OH DPAT. 7-OH DPAT completely blocked the K<sup>+</sup>-induced increase in both regions with ED-50's of 144 ± 2 and 400 ± 1 nM in OT and STR slices, respectively. PD128907 also significantly inhibited the K<sup>+</sup>-stimulated increase in the two regions although with less efficacy and greater potency than 7-OH DPAT (ED-50 = 35 ± 2 and 162 ± 2 nM in OT and STR slices, respectively). The greater potency of 7-OH DPAT and PD128907 observed in the OT may be related to the greater density of D<sub>3</sub> receptors in the OT. The adenylyl cyclase activator, forskolin (10 µM), increased DOPA accumulation by 210% in OT slices, and 140% in STR slices. While PD128907 (10 µM) significantly inhibited forskolin-stimulated DA synthesis in STR slices, PD128907 did not affect forskolin-stimulated synthesis in OT slices, consistent with the lack of coupling of D<sub>3</sub> receptors to adenylyl cyclase activity. Together, these data support the probable role of D<sub>3</sub> receptors as DA autoreceptors. Support: NIDA 04120 and Joe Young Sr. Research Fund.

## 341.17

**PHARMACOLOGY OF DOPAMINE D<sub>3</sub> RECEPTORS IN THE RAT CAUDATE-PUTAMEN.** M. Hillefors-Berglund\* and G. von Euler, Dept. of Neuroscience, Karolinska Institutet, S-17177 Stockholm, Sweden.

We have analyzed the binding properties of [<sup>3</sup>H]R(+)-7-OH-DPAT binding in freshly prepared membrane preparations from the caudate-putamen of the male rat. Both the association rate and the dissociation rate could be resolved into two components. Also, saturation curves of specific [<sup>3</sup>H]R(+)-7-OH-DPAT binding could be resolved into two binding sites. The B<sub>max</sub>(H) + B<sub>max</sub>(L) value of [<sup>3</sup>H]R(+)-7-OH-DPAT binding of about 600 fmol/mg protein was similar to the B<sub>max</sub> value of [<sup>3</sup>H]N-propylnorapomorphine, and 3-4 times higher than [<sup>3</sup>H]R(+)-7-OH-DPAT binding in the subcortical limbic area. The K<sub>D</sub>(H) value of 0.7 nM in the caudate-putamen were slightly higher than that in the subcortical limbic area, whereas the K<sub>D</sub>(L) value of 9.6 nM was similar. Coincubation with GTP (100 μM) reduced the total B<sub>max</sub> value by about 40 % in the caudate-putamen, and by 20 % in the subcortical limbic region. The binding of [<sup>3</sup>H]R(+)-7-OH-DPAT could be resolved into four specific binding sites (R<sub>1</sub>-R<sub>4</sub>) and one nonspecific binding site. The major component was made up by R<sub>1</sub> and R<sub>2</sub>. The rank order of potencies for various agonists and antagonists were R(-)-NPA > dopamine > PD 128907 ~ quinpirole > bromocriptine and haloperidol > raclopride > remoxipride > clozapine, respectively, at R<sub>1</sub>, and PD 128907 > R(-)-NPA > dopamine > quinpirole > bromocriptine and haloperidol > raclopride ~ clozapine > remoxipride, respectively, at R<sub>2</sub>. These results indicate that D<sub>3</sub> receptors are present at high concentrations in the caudate-putamen, and are coupled to endogenous G proteins.

## 341.19

**3H-EMONAPRIDE BINDS WITH HIGH AFFINITY TO SIGMA SITES IN THE GUINEA PIG BRAIN.** T.F. Seeger\*, C.G. Johnson and S. Zorn, Department of Neuroscience, Pfizer Inc., Central Research Division, Groton, CT 06340.

[3H]-emonapride (YM09151-2), binds with high affinity to D<sub>2</sub>, D<sub>3</sub>, and D<sub>4</sub> dopamine receptors, while [3H]-raclopride binds with high affinity to D<sub>2</sub> and D<sub>3</sub>, and with low affinity to D<sub>4</sub> receptors. Recent studies in human postmortem brain tissue have subtracted 3H-raclopride binding from that found with 3H-emonapride, and assumed that the difference reflected D<sub>4</sub> receptor density. These results suggested an increase in D<sub>4</sub> receptor density in schizophrenic vs. normal brain. These conclusions presume minimal interaction with other receptor types. We found that emonapride appears to bind to the guinea pig sigma binding site with nM affinity, while raclopride binds with μM affinity. Autoradiographic distribution of 3H-emonapride binding in guinea pig cerebellum and frontal cortex matches that found with the selective sigma ligand, 3H-DTG, and is displaced by (+)-pentazocine, a high affinity sigma ligand. Saturation analysis with 3H-emonapride in guinea pig cerebellum and frontal cortex homogenates fits a one site model with K<sub>d</sub>'s between 0.65-0.9 nM and B<sub>max</sub> between 350-600 fmol/mg protein. DTG, 3PPP, (+)pentazocine, and (-)butaclamol potentially displace 3H-emonapride binding, although these compounds have low affinity for both D<sub>2</sub> and D<sub>4</sub> dopamine receptors (IC<sub>50</sub>'s > 2 μM). 3H-emonapride binding is displaced more potently by (-)butaclamol than by (+)butaclamol while the reverse is true for all D<sub>2</sub>-like receptors. Since human brain has moderate levels of sigma binding, if 3H-emonapride is used as a D<sub>4</sub> label then an appropriate sigma masking compound should be included in the assay.

## 341.18

**ARE THE PUTATIVE D<sub>3</sub> ANTAGONISTS (+)AJ 76 AND U99194A AGONISTS AT A DOPAMINE RECEPTOR SUBTYPE?** A. Ekman, S.R. Haadsma-Svensson, I.A. Engel\*, and E. Eriksson, Department of Physiology and Pharmacology, Division of Pharmacology, Göteborg University, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

(+)AJ 76 has been characterized as a dopamine (DA) antagonist preferentially blocking DA D<sub>3</sub> receptors and DA D<sub>2</sub> autoreceptors. The present study shows that (+)AJ 76 displaces [<sup>3</sup>H]spiperone *in vitro* in the limbic region of male rat brain in a biphasic manner with one binding site - comprising about 15% of the total amount of receptors - showing an unexpectedly high affinity (K<sub>H</sub> 1.4±0.4 nM, K<sub>L</sub> 319±39 nM). In the presence of guanosine triphosphate (GTP), the high affinity site was shifted to the right whereas the low affinity site was unaffected; thus, the displacement curve became monophasic. The data indicate that (+)AJ 76 acts as an agonist at the high affinity site and as an antagonist at the low affinity site. The putative preferential D<sub>3</sub> receptor antagonist U99194A also displaced [<sup>3</sup>H]spiperone in limbic regions of rat brain in a similar biphasic manner (K<sub>H</sub> 55±21 nM, K<sub>L</sub> 2511±209 nM); again the high affinity site comprised 15% of the receptor population and was shifted to the right in the presence of GTP. For both substances, it was more difficult to detect a high affinity site in striatal tissue than in limbic regions. The possibility that some of the behavioral effects observed after administration of (+)AJ 76 and U99194A to rodents are due to the activation of a subtype of DA receptors (D<sub>3</sub>?) should be taken into consideration.

## 341.20

**MODULATION OF DOPAMINE RECEPTOR SENSITIVITY BY L-PROLYL-L-LEUCYL-GLYCINAMIDE (PLG) ANALOGUES: NEUROCHEMICAL AND BEHAVIOURAL STUDIES.** P.W. Bauer<sup>1</sup>, R.L. Johnson<sup>1</sup>, A. Chugh<sup>2</sup>, E. Marcotte<sup>2</sup>, C. Barlas<sup>2</sup>, and E.W. Werstliuk<sup>2</sup>, <sup>1</sup>Dept. of Medicinal Chem., Univ. of Minnesota, Minneapolis, MN, USA <sup>2</sup>Dept. of Biomed. Sci., McMaster Univ., Hamilton, Ont., Canada.

In order to establish the mechanism of action of the endogenous peptide, PLG, a series of analogues were designed, the most potent being 2-oxo-3-(R)-[(2(S)-pyrrolidinylcarbonyl)amino]-1-pyrrolidineacetamide. The modulatory effect of several of these compounds was studied in three models of dopamine receptor sensitivity: (a) in mice treated with MPTP, which induces a depletion of dopamine, (b) in radioligand binding assays, to determine the prevention of GTP-induced conversion of dopamine D<sub>2</sub> receptors from the high-affinity to the low-affinity state, and (c) in 6-hydroxydopamine-lesioned rats, to observe the potentiation of rotational behaviour, induced by apomorphine. In all of these paradigms, PLG, as well as the potent analogues, displayed a modulatory effect on dopamine receptor sensitivity. These compounds were able to prevent the MPTP-induced depletion of dopamine, at concentrations as low as 1-10 μg/kg and were also effective at extremely low concentrations in the other two paradigms. Furthermore, these analogues were 100-1000 times more potent than PLG itself. These results suggest, that these analogues also interact at the same site as PLG and indicate their potential therapeutic use in the management of drug-induced tardive dyskinesia and Parkinsonism. (Supported by NIH-USA, OMHF).

## SEROTONIN: REGULATION

## 342.1

**THE 5-HT<sub>1A</sub> AGONIST 8-OH-DPAT MODULATES EXTRACELLULAR DOPAMINE AND SEROTONIN IN THE MPOA.** D. S. Lorrain, L. Matuszewich, R. Trullillo and E. M. Hull\*, Dept. Psychology, State Univ. of New York at Buffalo, Buffalo, NY 14260 USA

Serotonin (5-HT) in the medial preoptic area (MPOA) inhibits, while MPOA dopamine (DA) facilitates, male rat sexual behavior (Verma et al., 1988; Hull, et al., 1986). In spite of the generally inhibitory effects of 5-HT, stimulation of the 5-HT<sub>1A</sub> receptor subtype enhances copulation (Ahlenius & Larsson, 1991; Fernandez-Guasti et al., 1992). The present experiments investigated effects of intracranial and systemic 5-HT<sub>1A</sub> agonists on extracellular levels of DA and 5-HT.

Five male rats received 8-OH-DPAT (250, 500, and 1000 μM) via a microdialysis probe in the MPOA for 18 min (flow rate, 4 μL/min). Two 6-min samples were collected during drug infusion and assayed for 5-HT and DA by HPLC-EC. The 5-HT<sub>1A</sub> agonist significantly increased extracellular levels of both DA and 5-HT. In different animals (n=7), a systemic injection of 8-OH-DPAT (4 mg/kg i.p.) significantly increased DA metabolites DOPAC and HVA. Both the 4 mg/kg and a lower dose (2 mg/kg, i.p., n=5) significantly decreased 5-HT levels. Thus, both central and systemic injections of 8-OH-DPAT modulate MPOA DA and 5-HT activity.

The decrease in 5-HT following systemic 8-OH-DPAT may be due to stimulation of autoreceptors in the raphe nuclei and may contribute to the enhancement of male sexual behavior. The facilitation of MPOA DA activity by both central and systemic administration of 8-OH-DPAT may also enhance the copulatory ability of the males. However, the mechanism of this interaction remains unknown. The increase of 5-HT in the MPOA during MPOA administration of 8-OH-DPAT is more difficult to explain. Supported by NIH grant MH-40826 to EMH.

## 342.2

**FUNCTIONAL EVALUATION OF SEROTONINERGIC PLASTICITY AFTER NEONATAL DOPAMINERGIC DENERVATION.** M.A. Alonso-Vanegas\*, A.F. Sadikot, A. Jevric-Causevic, A. Olivier, M. Diksic, Cone Laboratory for Neurosurgical Research, Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada, H3A 2B4.

Under normal circumstances, serotonin (5-HT) neurons innervate both the substantia nigra (SN) and the neostriatum, though the density of striatal 5-HT innervation is lower than that of dopamine (DA). Previous studies have shown that DA denervation results in a marked increase in the density of 5-HT immunoreactive fibers and synapses throughout the neostriatum. We examine the functional response of the striatal 5-HT system using [<sup>14</sup>C]-labeled alpha-methyl-L-tryptophan, a synthetic analogue of L-tryptophan, to study 5-HT synthesis. Neonatal rat pups (P3) underwent catecholamine denervation using 6-hydroxydopamine injected bilaterally into the striatum. Control rats received similar injections of vehicle only. At 30 days after denervation rats were processed for [<sup>14</sup>C]-labeled α-methyl-L-tryptophan (α-MTrp) radioautography as previously described (Diksic et al., 1990). Our data suggests that the rate of 5-HT synthesis increases by 50% in the striatum in lesioned animals as compared to vehicle-injected controls. These results suggest that 30 days after DA denervation, 5-HT sprouting correlates with an increase in 5-HT synthesis rate. (Supported by MRC, FRQS, AANS, NIH)

## 342.3

DOPAMINERGIC FACILITATION OF SEROTONIN RELEASE FROM THE RAT HIPPOCAMPUS: *IN VIVO* MICRODIALYSIS STUDY.

M. Matsumoto, M. Yoshioka\*, H. Togashi and H. Saito. First Department of Pharmacology, Hokkaido University School of Medicine, Sapporo 060, Japan.

The present study was undertaken to elucidate the functional regulation of dopaminergic receptors on serotonin (5-HT) release from the rat hippocampus as measured by *in vivo* microdialysis coupled with HPLC-ECD. Dialysate 5-HT concentrations were reduced by co-perfusion of TTX (10  $\mu$ M) and were increased by both local (10  $\mu$ M) and systemic (10 and 20 mg/kg, i.p.) administration of fluoxetine. These results indicate that the spontaneous 5-HT levels can be used as indices of neuronal origin from the serotonergic nerve terminals. Non selective dopamine (DA) receptor agonist, apomorphine (1, 10 and 100  $\mu$ M) co-perfused during 40 min produced increases in the 5-HT release in a concentration-dependent manner. Apomorphine-induced (100  $\mu$ M) increases in 5-HT release were abolished by pretreatment with D2 receptor antagonist, S(-)-Sulpiride (1 and 10  $\mu$ M), but not by pretreatment with D1 receptor antagonist, R(+)-SCH-23390 (1  $\mu$ M). S(-)-Sulpiride by itself did not alter the 5-HT levels. The 5-HT release was also elevated by co-perfused D2 receptor agonist, (+)-PPHT (1, 10 and 100  $\mu$ M) in a concentration-dependent manner. (+)-PPHT-induced (100  $\mu$ M) increases in 5-HT release were inhibited by 10  $\mu$ M of S(-)-Sulpiride. The inhibitory effect of S(-)-Sulpiride was augmented by pretreatment with  $\alpha$ 2-adrenoceptor antagonist, idazoxan (5mg/kg, i.p.). In 6-OHDA (200  $\mu$ g/rat, i.c.v.) treated rats, (+)-PPHT (100  $\mu$ M) failed to increase 5-HT release. These findings suggest the possibility that the functional regulation of 5-HT release via D2 receptors exists in the rat hippocampus, which may be indirectly mediated by noradrenergic neurons.

## 342.5

COMPARATIVE *IN VIVO* AND *IN VITRO* STUDIES OF STRIATAL C-FOS EXPRESSION AFTER STIMULATION OF 5-HT<sub>1A</sub> AND 5-HT<sub>2A/2C</sub> RECEPTORS. J. Gervais<sup>1</sup> and C. Rouillard<sup>1,2</sup>. <sup>1</sup>Lab. of Neurobiology, <sup>2</sup>Dept. of Pharmacology, Laval University, Québec, Canada G1J 1Z4.

We have previously demonstrated that *in vivo* concomitant stimulation of 5-HT<sub>1A</sub> and 5-HT<sub>2A/2C</sub> has a powerful synergistic effects on striatal (STR) and accumbal *c-fos* expression. Expression of Fos-like immunoreactivity (Fos-LI) was restricted to dorsomedial and ventromedial parts of the STR. No Fos-LI was found in the lateral part of the STR. This topographical expression could be the result of intrinsic striatal factors or the result of a differential modulation by afferences. To investigate this latter possibility, we chose to compare *c-fos* expression induced by 5-HT agonists *in vivo* and in a brain slice preparation which correspond to a deafferented system. For *in vivo* studies, rats were injected with 5-HT agonists and sacrificed 2 hrs later. Groups were: a) 8-OHDPAT (2.5 mg/kg i.p.), b) DOI (2.5 mg/kg i.p.), and c) 8-OHDPAT + DOI. For *in vitro* studies, coronal striatal slices (400  $\mu$ m) were prepared from rats weighing 150-175 g. Slices were transferred into a chamber and perfused with oxygenated Ringer solution (95% O<sub>2</sub>-5% CO<sub>2</sub>) at room temperature for 1 hour. After, the chamber was heated slowly from room temperature to 34°C. Slices were then perfused with Ringer containing 5-HT drugs for an additional 2 hrs. Groups were: a) 8-OH-DPAT (10  $\mu$ M), b) DOI (10  $\mu$ M) and c) 8-OH-DPAT+DOI. After removal from the chamber, slices were fixed in 2% paraformaldehyde and equilibrated in 30% sucrose. Sections were cut at 40  $\mu$ m on a cryostat and processed for Fos-LI. *In vivo*, only the combination of 8-OHDPAT + DOI induced strong expression of Fos-LI and the expression was restricted to the medial part of the STR. *In vitro*, Fos expression was induced by each drug treatment and was uniformly distributed over the entire extent of the STR. These results strongly suggest that striatal afferences play an important role on Fos expression induced *in vivo* by 5-HT agonists. (Supported by NSERC and FRSQ)

## 342.7

POTENTIATION OF THE FLUOXETINE-DEPENDENT ELEVATION OF EXTRACELLULAR 5-HT LEVELS IN HYPOTHALAMUS BY PINDOLOL, AN ANTAGONIST AT SOMATODENDRITIC 5-HT<sub>1A</sub> AUTORECEPTORS, IN CONSCIOUS RATS. L. J. Dreshfield\*, E. A. Engleman, K. W. Perry, and D. T. Wong. CNS Division, Eli Lilly and Company, Indianapolis, IN 46285.

Antagonists at the somatodendritic 5-HT<sub>1A</sub> autoreceptor have been shown to facilitate elevation of extracellular 5-HT levels upon cocomitant inhibition of 5-HT uptake *in vivo* (Hjorth, S., 1993; Artigas, F., et al., 1994). In the present study, we elaborate on the ability of (-)-pindolol to enhance the increase of 5-HT after fluoxetine administration (Wong, D. T., et al., 1994). Rats were implanted with microdialysis probes under chloral hydrate/pentobarbital anesthesia. After a 48-hour recovery period, artificial CSF was perfused through the probe. The output dialysate was passed on to an analytical column for HPLC electrochemical detection of monoamines and their metabolites. Fluoxetine alone (10 mg/kg i.p.) caused 5-HT levels to increase 200% over basal levels. This increase was stable and long lasting. Administration of (-)-pindolol (1, 3, and 5 mg/kg s.c.) following fluoxetine led to significant increases in 5-HT levels. Coadministration of fluoxetine (10 mg/kg i.p.) and (-)-pindolol (5 mg/kg s.c.) led to an increase similar to that shown by sequential administration (270% over basal). An additional dose of (-)-pindolol (5 mg/kg s.c.) caused a further increase in 5-HT levels of 400% over basal levels. These results suggest that coadministration of (-)-pindolol with fluoxetine can potentiate fluoxetine-dependent elevations in rat hypothalamic 5-HT.

## 342.4

DECREASED SYNAPTIC DENSITY IN DENTATE MOLECULAR LAYER AFTER 5-HT DEPLETION OR 5-HT<sub>1A</sub> ANTAGONIST TREATMENT IN ADULT RATS. C.C. Wilson, N.J. Bamber, N.A. Connors\* and J.H. Haring. Dept. of Anatomy and Neurobiology, St. Louis Univ. Sch. Med., St. Louis, MO 63104.

Evidence for synapse stabilization by 5-HT in adult rats has appeared in reports of synapse loss in neocortex (J. Neurobiol. 24:687, 1993) and a decrease in synaptophysin staining in area dentata (Soc. Neurosci. Abstr. 20:290, 1994) after 5-HT depletion. The present EM study evaluated changes in synaptic density in the molecular layer of area dentata of adult rats (180-200g) after 5-HT depletion (PCA, 15mg/kg, 2 injections 24h apart), NE depletion (DSP-4, 50mg/kg) and treatment with NAN-190 (3.5mg/kg daily for 7d). Rats were studied 7 days after the start of treatment. Controls received vehicle injections. Synaptic densities were counted in electron photomicrographs of a strip of molecular layer related to the middle of the suprapyramidal blade extending from the hippocampal fissure to the granule cell layer. PCA and NAN-190 rats had significant reductions in molecular layer synaptic densities. Synapses were within normal range in DSP-4 rats. These data indicate that 5-HT may stabilize synapses via 5-HT<sub>1A</sub> stimulation.

## 342.6

## mCPP INDUCED INCREASE OF SEROTONIN AND DOPAMINE RELEASE: ANALYSIS OF THE MECHANISM OF ACTION. H. Nissbrandt\* and E. Eriksson. Department of Pharmacology, Göteborg University, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

m-Chloro-phenylpiperazine (mCPP) has recently gained marked attention as a putative probe of serotonergic function in clinical psychiatric research. The administration of mCPP has been shown to elicit, and/or aggravate, anxiety attacks in patients with panic disorder, obsessions in patient with obsessive compulsive disorder, elation in alcoholics and cocaine addicts, and positive symptoms in schizophrenic patients. The effects of mCPP have generally been attributed to direct interactions with various subtypes of serotonin receptors although recent findings suggest that mCPP also releases serotonin.

In order to further elucidate the mechanism of action of mCPP, the effects of the drug on serotonin release in the hippocampus and on dopamine release in the striatum and nucleus accumbens were investigated by *in vivo* microdialysis in awake rats.

Intravenous administration of mCPP (0.25 or 2.5 mg/kg) induced a marked and dose-dependent increase in extracellular concentrations of serotonin. The highest dose of mCPP increased the serotonin levels by more than 1000%. The effects of the drug on extracellular dopamine concentrations were less pronounced; mCPP (2.5 mg/kg) increased the dopamine concentrations by 50% in the nucleus accumbens and only slightly in the striatum. The increase of serotonin concentration was antagonised by pretreatment with the serotonin reuptake inhibitor citalopram (10 mg/kg) but was unaffected by local administration of the sodium blocker tetrodotoxin (TTX), whereas the increase in dopamine levels were completely abolished by TTX.

The findings give support to the notion that mCPP releases serotonin by reversing the serotonin transporter. The effects of mCPP on dopamine release can, however, not be explained by a reversal of the dopamine transporter, but can tentatively be a secondary effect due to the release of serotonin. The possibility that the clinical effects of mCPP, at least partly, are due to the release of endogenous serotonin and dopamine should be taken into consideration.

## 342.8

## DIFFERENTIAL EFFECTS OF GLUTAMATE RECEPTOR AGONISTS ON SEROTONIN IN RAT MIDBRAIN RAPHE AND FOREBRAIN SITES. R. Tao\*, Z. Ma, S.B. Auerbach. Nelson Biol. Lab., Rutgers Univ., Piscataway, NJ 08855.

To investigate the regulation of serotonin (5-HT) release by excitatory amino acids, the effects of NMDA, kainic acid and AMPA in rat midbrain raphe and forebrain sites were examined by microdialysis. In dorsal raphe nucleus (DRN), all three compounds induced significant increases in extracellular 5-HT in a dose-dependent manner. Relative potency was kainate > NMDA > AMPA. NMDA (300  $\mu$ M) produced a four fold increase in DRN 5-HT. Competitive (AP-5 and CPP) and non competitive (MK-801 and PCP) NMDA antagonists blocked the effect of NMDA. Significant enhancement of 5-HT was also seen in median raphe nucleus (MRN), but the efficacy of NMDA was lower as compared to DRN. In the MRN, NMDA (1000  $\mu$ M) produced less than a two fold increase in 5-HT.

Infusion of NMDA into the DRN and MRN elicited an increase in 5-HT in the n. accumbens and hippocampus, respectively. In contrast, extracellular 5-HT was slightly decreased in forebrain sites when NMDA was locally applied in the n. accumbens and hippocampus. These data suggest that NMDA, kainate and AMPA act on excitatory amino acid receptors in the midbrain raphe to enhance 5-HT neurotransmission in the forebrain. Supported by NIMH grant #51080

## 342.9

**DIFFERENTIAL INHIBITORY INFLUENCE OF GABA<sub>A</sub> AND GABA<sub>B</sub> RECEPTORS ON SEROTONIN IN THE RAPHE AND N. ACCUMBENS OF RATS.** S.B. Auerbach\*, Z. Ma, R. Tao, Nelson Biol. Lab., Rutgers Univ., Piscataway, NJ 08855.

Microdialysis was used to assess the contribution of GABA receptors to regulation of serotonin (5-HT) release in the dorsal raphe nucleus (DRN) and a forebrain project site, nucleus accumbens (NAC). DRN 5-HT was dose-dependently decreased during infusion of the GABA<sub>A</sub> receptor agonist muscimol into the DRN. Extracellular 5-HT in the NAC was dose-dependently decreased by the GABA<sub>B</sub> receptor agonist baclofen, but not by muscimol, infusion into the NAC.

Infusion of the GABA<sub>A</sub> receptor antagonists bicuculline and picrotoxin into the DRN produced dose-dependent increases in extracellular 5-HT in DRN and NAC. In contrast, infusion of the GABA<sub>A</sub> receptor antagonists into the NAC had no effect on 5-HT. Infusion of the GABA<sub>B</sub> receptor antagonists phaclofen and 2-hydroxysaclofen into the DRN had no effect on 5-HT in the DRN and NAC. These results suggest that GABA<sub>A</sub> receptors play a selective role in the DRN to tonically inhibit 5-HT neuronal activity under our experimental conditions. In contrast stimulation of GABA<sub>B</sub> receptors may selectively inhibit 5-HT release in forebrain projection sites of the DRN. Supported by NIMH grant #51080

## 342.11

**SEROTONIN FUNCTION DURING WITHDRAWAL FROM A SENSITIZING REGIMEN OF COCAINE.** R.L. Wirth\*, N. Parekh, B.J. Chadwick and K.A. Cunningham, Dept. Pharmacol., Univ. Texas Med. Branch, Galveston, TX 77555.

Rats sensitive to the behavioral effects of cocaine (COC) with repeated exposure. The mechanisms of this behavioral sensitization may be relevant to psychoses and affective disturbances associated with repeated cocaine use and withdrawal in humans. This laboratory has previously reported enhanced sensitivity of dorsal raphe (DR) serotonin (5-HT) neurons to COC, 8-OH-DPAT (DPAT) and fluoxetine 24 hrs following COC sensitization, as well as decreased numbers and firing rates of DR 5-HT cells (Cunningham *et al.*, Synapse 11: 112, 1992). The present studies investigate changes in 5-HT neuron and 5-HT<sub>1A</sub> receptor function 72 hrs following a sensitizing COC regimen. Male Sprague-Dawley rats (225-350 g) were injected with COC (15 mg/kg, ip, bid) or saline (SAL) for 7 days to induce sensitization. Using single unit extracellular recording techniques, a significant decrease in the number of DR 5-HT cells electrode pass was observed (sal: 11.8±1.3, coc: 7.8±1.3; n=26), although cell firing rates were not altered (sal: 12.5±1.3, coc: 11.1±0.9; n=26). In contrast to data at 24 hrs, sensitivity of DR 5-HT cells to COC at 72 hrs withdrawal was significantly decreased in COC-treated compared to SAL-treated rats. In each of the 1st 3 min following injection of 0.5 mg/kg COC (iv), firing was reduced to 27±6, 9±6 and 1±10% of basal rate in SAL-treated rats (n=4), and 50±10, 32±12 and 48±13% of basal rate in COC-treated rats (n=6). As cocaine inhibits DR 5-HT neurons at least partially via indirect 5-HT<sub>1A</sub> receptor stimulation, 5-HT<sub>1A</sub> receptor sensitivity was compared in COC- and SAL-treated rats. No differences in the hypothermia (sal: -1.7±0.2, coc: -1.3±0.1; n=12) induced by 0.12 mg/kg DPAT (s.c.) or the behavioral syndrome (flat body posture, forepaw treading, lower lip retraction and forward locomotion) induced by systemic or intra-raphe DPAT (0.12 mg/kg, s.c. n=12 and 7.5 µg 0.5 µL, n=20) were observed in SAL- and COC-treated rats. With results from the 24 hrs withdrawal time point, these data indicate that the activity and sensitivity of DR 5-HT neurons in sensitized rats are in rapid flux during withdrawal from cocaine. Supported by DA 06511.

## 342.13

**MODIFICATION OF 5-HT RESPONSES IN RAT DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS BY ACUTE AND CHRONIC COCAINE.** D. Simms\* and J.P. Gallagher, Dept. of Pharm. and Tox., Univ. of Texas Med. Br., Galveston, TX 77555.

This lab has previously demonstrated that DLSN neurons can be hyperpolarized by 5-HT via activation of a postsynaptic 5-HT<sub>1A</sub> receptor (Joëls *et al.*, 1987) that is PTX sensitive. Superfusion with a high concentration of 5-HT can, in addition to a brief hyperpolarization, induce a long-lasting depolarization which is antagonized by ketanserin (Van den Hooff & Galvan, 1992), and unmasked by PTX pretreatment. We used standard intracellular electrophysiological recording techniques to determine whether chronic cocaine administration would: 1) alter the sensitivity of the septal brain slice to exogenous 5-HT application and 2) modify the interaction of 5-HT with cocaine *in vitro*.

Standard intracellular current-clamp recordings were made from neurons in rat brain slices which contained the DLSN obtained from drug naive (DN) rats or rats administered cocaine (15 mg/kg, IP, 2x daily) for periods of 7 (CC7) or 14 (CC14) days. In addition, some of these rats also received intraventricular PTX injections 2-3 days prior to experimentation. In comparison to DN and CC7, CC14 slices showed an increased sensitivity to 5-HT as revealed by a 1 to 2-fold leftward shift in 5-HT EC<sub>50</sub> values. Most notable was the shift at the base of the CC14 5-HT dose-response curve. In addition, in PTX-CC14 slices, 5-HT could hyperpolarize the cell membrane while 8-OHDPAT and baclofen failed to do so. We also observed that cocaine (3 µM) in CC14 slices could not significantly potentiate and prolong 5-HT hyperpolarizations. We conclude that in the CC14 septal slice: 1) a 5-HT transporter is downregulated 2) a 5-HT<sub>1A</sub> receptor is upregulated 3) a 5-HT<sub>2</sub> receptor is downregulated and 4) a 5-HT receptor not coupled to a PTX sensitive G-protein is expressed. Supported by DA-07190.

## 342.10

**CITALOPRAM TREATMENT AND HYPOTHALAMIC 5-HT LEVELS AS MEASURED BY IN VIVO MICRODIALYSIS.** C. Moret\* and M. Briley, Centre de Recherche Pierre Fabre, 17 Ave. J. Moulin, 81100 Castres, France.

Chronic administration with the selective serotonin reuptake inhibitor, citalopram, has been reported to down-regulate serotonergic terminal autoreceptors as measured *in vitro* (Moret & Briley, 1990 *Eur. J. Pharmacol.* 180, 351-356). The present study compared the effects of acute and chronic administration of citalopram on extracellular levels of 5-HT and their terminal autoreceptor modulation in the hypothalamus of freely moving rats by *in vivo* microdialysis. Rats were administered citalopram as in the previous study (50 mg/kg in the diet for 2 days or 21 days). On the last day of treatment or 24 h after change to a non-drug containing diet (washout), extracellular levels of 5-HT were measured before and after the addition (in the perfusion medium) of the non-selective serotonergic autoreceptor antagonists, methiothepin (100 µM) or 1-(1-naphthyl)piperazine (NP) (10 µM). When studied without washout, extracellular levels of 5-HT were increased by both acute and chronic citalopram. In rats treated chronically, however, extracellular 5-HT levels were 43% greater than in those treated acutely. Extracellular levels of 5-HT did not differ between control and citalopram-treated rats when measured after 24 h washout. The enhancing effect of methiothepin or NP, administered through the microdialysis probe, after 24 h washout was similar in both control and chronically treated groups. These results suggest that chronic administration of citalopram does not lead to desensitization of the terminal autoreceptor as measured *in vivo* in contrast to that shown previously *in vitro*. The higher levels of extracellular 5-HT following chronic rather than acute administration with citalopram under conditions where the drug is still present (no washout) suggest, however, that certain adaptive changes do take place in the regulation of serotonergic neurotransmission, presumably at sites other than the terminal autoreceptor.

## 342.12

**SEROTONERGIC REGULATION OF RAT AMYGDALA ELECTROPHYSIOLOGY: EFFECT OF CHRONIC FENFLURAMINE ON SPONTANEOUS FIRING RATES AND RESPONSE TO COCAINE.** E.J. Mah\* and K.A. Cunningham, Dept. of Pharmacology, University of Texas Medical Branch, Galveston, TX 77555-1031.

Investigating the role of serotonin (5-HT) as a neurotransmitter in the amygdala could shed light on the etiology of several psychiatric disorders. The present study employs single-unit extracellular recording techniques to test the effect of chronic fenfluramine (FEN), a 5-HT releaser and neurotoxin, on spontaneous firing rates of amygdala (AMY) neurons and their response to bolus doses of intravenous (i.v.) cocaine (COC). Male Sprague Dawley rats (220-300g) were treated subcutaneously with either FEN (12 mg/kg) or saline (SAL; 1 ml/kg) BID for 4 days. Rats were prepared for recording either 36 hr or 2 wks after the final injection. Withdrawal time did not affect spontaneous firing rates within treatment groups, thus both time points were pooled for all analyses. Cells from FEN-treated animals exhibited higher mean firing rates as compared to cells from SAL-treated animals (4.39 ± 0.70/10 sec vs. 1.39 ± 0.14/10 sec, respectively; Student's *t*-test, *p* < 0.05). FEN treatment also altered the response of AMY neurons to COC. In FEN-treated rats, firing rates were either increased (4/10 cells) or decreased (6/10) following COC (1 mg/kg) whereas in the SAL group, firing rates were either inhibited (7/11) or unaffected (4/11; Fisher's Exact test, *p* < 0.05). After a 4 mg/kg dose of COC, the primary neuronal response was inhibitory, but the time course of the inhibition was of shorter duration in FEN animals (ANOVA, *F*<sub>(3,42)</sub> = 4.03, *p* < 0.05). The increased firing rates and shift in responsiveness to COC in FEN-treated animals may reflect disinhibition of AMY cells due to removal of 5-HT input. These data suggest a tonic inhibitory role for 5-HT in regulation of AMY neuronal firing and 5-HT involvement in the observed effects of COC on AMY neurons.

Supported by DA 05708 and DA 06511.

## 342.14

**MORPHINE ACTIVATES THE SEROTONERGIC NEURONS OF THE DORSAL BUT NOT THE MEDIAN RAPHE NUCLEUS OF THE RAT.** K.C. Corley\*, T.H. Phan and M.C. Boadle-Biber, Physiology Dept, Medical College of Virginia, Virginia Commonwealth Univ., Richmond, VA 23298.

Morphine activates the ascending 5-HT neurons that arise from the midbrain as shown by the increase in the *ex vivo* activity of the rate-limiting enzyme in serotonin (5-HT) synthesis, tryptophan hydroxylase, as well as by the increase in the level of the 5-HT metabolite, 5-hydroxyindoleacetic acid (*Eur. J. Pharmacol.* 139 (1987) 193). In this study, we examined whether morphine activates 5-HT neurons in the median (MRN) and dorsal raphe nuclei (DRN), or both nuclei, by measuring 5-hydroxytryptophan (5-HTP) accumulation after inhibition of aromatic amino acid decarboxylase (AADC), as an index of *in vivo* tryptophan hydroxylase activity. Male Sprague Dawley rats were injected with morphine (10mg/kg s.c.) or saline, followed 10 min later by the AADC inhibitor, NSD 1015 (m-hydroxybenzylhydrazine, 100 mg/kg i.p.). Thirty min later, rats were killed by decapitation, the DRN and MRN removed by 2 mm punches of a 3 mm coronal section of midbrain (*J. Neurochem.* 64 (1995) S35A) and stored at -70°C until analysed by HPLC-EC for 5-HTP content. Mean levels of 5-HTP, in ng/mg protein ± S.E.M., increased 85 % in the DRN from 8.4 ± 0.2 to 15.5 ± 0.8 (N=5, *P* < 0.001) in response to morphine, but were unchanged in the MRN. These results contrast with those obtained with sound stress in which 5-HTP levels increase in MRN but not DRN (*J. Neurochem.* 64 (1995) S35A). This differential responsiveness of DRN and MRN 5-HT neurons suggests the presence of distinct subpopulations of 5-HT neurons, within these nuclei, that can also be differentiated from 5-HT neurons that discharge in patterns related to the alertness state of the animal. Supported by grant NS14090 to MCB.

## 342.15

DETECTION OF MDMA NEUROTOXICITY IN VIVO. PET STUDIES IN THE LIVING BABOON BRAIN. U. Scheffel\*, Z. Szabo, W. B. Mathews, P. A. Finley, R. F. Dannals, H. T. Ravert, K. Szabo, G. A. Ricaurte. The Johns Hopkins Medical Institutions, Baltimore, Maryland 21205.

In vivo detection of damage to serotonergic (5-HT) neurons with imaging techniques has not been possible so far because of the lack of a suitable imaging ligand. Recently we have developed [<sup>11</sup>C]labeled McN 5652 ([<sup>11</sup>C]McN) for in vivo visualization of 5-HT reuptake sites using positron emission tomography (PET). In the present study we evaluated [<sup>11</sup>C]McN /PET imaging as a method to quantify 5-HT neurotoxicity in the baboon brain.

A 32.7 kg male baboon was anesthetized and received PET scans 3x before and 3x after treatment with MDMA (8 doses of 5mg/kg, injected s.c. twice a day for 4 days). In each study, 25-32 mCi each of [<sup>11</sup>C](-)-McN 5652 (the inactive enantiomer), [<sup>11</sup>C](+)-McN 5652 (the active enantiomer known to bind to 5-HT transporters) and [<sup>11</sup>C]RTI-55, a cocaine analog which binds to both 5-HT and DA transporters were injected, followed by dynamic PET acquisition over 115 min. Time activity curves were calculated for 13 brain regions.

Comparing the mean radioactivity concentrations (nCi/cc/mCi I.D. between 75-115 min p.i.) before and after MDMA treatment, significant decreases were observed with [<sup>11</sup>C](+), but not with (-) McN or [<sup>11</sup>C]RTI-55. Mean reductions in specific [<sup>11</sup>C](+)-McN binding (difference in regional [<sup>11</sup>C](+) and (-)McN radioactivity) ranged from 44% in pons, 51% in hypothalamus, 70% in striatum to 74-89% in frontal- and occipital cortex. The results indicate that [<sup>11</sup>C](+)-McN 5652 and PET can be used for in vivo measurement of 5-HT neuronal damage by repeated doses of MDMA.

## 342.17

ACUTE DEXFENFLURAMINE AND CORTICAL GLUTAMATE AND ASPARTATE CONCENTRATIONS: IN VIVO MICRODIALYSIS COUPLED WITH CAPILLARY ELECTROPHORESIS AND LASER-INDUCED FLUORESCENCE DETECTION (LIFD). C. Rocher<sup>1</sup>, L. Ben<sup>2</sup>, E. Robert<sup>2</sup>, J.-H. Trouvin<sup>1</sup>, B. Renaud<sup>2</sup>, C. Jacquot<sup>1</sup> and A.M. Gardier<sup>1</sup>. <sup>1</sup>Dept. Neuropharmacol. JE 92-372, Fac. Pharmacie, Univ. Paris-Sud, F92296-Chatenay-Malabry. <sup>2</sup>Lab. Neuropharmacol., Univ. Claude Bernard, CNRS UMR 105, 69373 Lyon 08, France.

The indirect serotonergic agonist dexfenfluramine (d-fen) releases serotonin (5-HT) and blocks its reuptake. The reason high d-fen doses induce a persistent reduction of brain 5-HT remains unclear. Since 5-HT has been shown to play a modulatory role on glutamate receptor subtypes (Mennini and Miar, *Life Sci.*, (1991) 49: 283), we investigated the effects of an acute d-fen injection on extracellular concentrations of 5-HT, 5-HIAA, Excitatory (glutamate GLU, aspartate ASP) and Inhibitory (glycine GLY,  $\gamma$ -aminobutyric acid GABA, taurine TAU) Amino Acids as measured by *in vivo* microdialysis in the frontal cortex (FC) of awake, freely-moving rats. Forty  $\mu$ l samples collected for a 190 min period after a single d-fen injection (0.5, 1.3, 5 et 10 mg/kg i.p.) were used as follows 1) 20  $\mu$ l for HPLC with amperometric detection (BAS) for 5-HT and 5-HIAA measurements, 2) 10  $\mu$ l for capillary electrophoresis with laser-induced fluorescence detection (LIFD, IRIS 2000, Europhor Inst.) for GLU and ASP measurements according to a modification by Robert et al. (*Anal. Chem.*, in press) of a previously described method, 3) 10  $\mu$ l for HPLC with coulometric detection (ESA) for glutamine GLN, TAU, GLY and GABA measurements. Dialysate 5-HT increased in a dose-dependent manner in FC (max. increase, % of baseline: SEM: 127 $\pm$ 17, 219 $\pm$ 18, 410 $\pm$ 126 and 1082 $\pm$ 265 for 0.5, 1.3, 5 et 10 mg/kg, respectively). By contrast, no change in extracellular levels of any Amino Acid was found after acute injection of any d-fen dose, except significant increases in ASP and GABA at 5 mg/kg (309 $\pm$ 64% and 290 $\pm$ 78%, respectively). Indeed, only a very high d-fen dose (2.4 mM locally applied through the probe in FC), increasing dialysate 5-HT by 1804 $\pm$ 336%, was able to increase extracellular GLU (218 $\pm$ 34%, P<0.01). Thus, no major changes in extracellular transmitters' levels, except those found for 5-HT, occur after acute peripheral injection of a wide range of d-fen doses.

## 342.19

Anorectic and Neurotoxic Effects of Fenfluramine:

Distinct and Separable Phenomena U.D. McCann\*, J. Yuan, and G.A. Ricaurte. Dept. of Neurology, Johns Hopkins Bayview Medical Center, Baltimore, MD 21224

Fenfluramine, an amphetamine analog and clinically prescribed anorectic drug, is a serotonin (5-HT) neurotoxin in experimental animals. Fluoxetine, a selective 5-HT reuptake inhibitor, has been shown to prevent fenfluramine-induced 5-HT neurotoxicity, as well as that induced by MDMA, a related toxic amphetamine derivative. Reports from humans who have taken MDMA in combination with fluoxetine indicate that fluoxetine does not significantly interfere with MDMA's unique psychoactive effects. The present studies sought to determine whether fluoxetine, given at doses that prevent fenfluramine-induced 5-HT neurotoxicity, interferes with fenfluramine's anorectic properties. Thirty four SD rats were randomized to one of four treatments: 1) Fenfluramine 5 mg/kg po BID X 6 days; 2) Fluoxetine 5 mg/kg po BID X 6 days; 3) Fenfluramine plus fluoxetine, both at 5 mg/kg po BID X 6 days; or 4) Vehicle po BID X 6 days. Treatment effects on food intake and body weight were evaluated, along with effects on regional brain concentrations of 5-HT, 5-HIAA, paroxetine-labelled 5-HT reuptake sites, and 5-HT immunoreactive (5-HT-IR) axons. Fenfluramine alone or fenfluramine plus fluoxetine led to similar, significant decreases in food intake and body weight that were not seen in animals in the other treatment groups. Fenfluramine alone led to significant decreases in regional brain 5-HT, 5-HIAA, paroxetine-labelled 5-HT reuptake sites and 5-HT-IR axon density two weeks after drug treatment, while animals treated with fluoxetine plus fenfluramine did not exhibit changes in any serotonergic measure. These data indicate that the anorectic and neurotoxic effects of fenfluramine are distinct and separable.

## 342.16

AGE DEPENDENT SENSITIVITY OF RATS TO THE LONG-TERM EFFECTS OF THE SEROTONERGIC NEUROTOXICANT (+)3,4-METHYLENEDIOXY-METHAMPHETAMINE (MDMA) CORRELATES WITH THE MAGNITUDE OF MDMA-INDUCED HYPERTHERMIA. H.W. Broening\*, J.F. Bowyer, and W. Slikker, Jr. Interdisciplinary Toxicology Program, Univ. of Ark. for Med. Sci., Little Rock, AR, and Division of Neurotoxicology, FDA, Nat'l. Center for Tox. Research, Jefferson, AR.

The effects of developmental age on MDMA-induced reductions in 5-hydroxytryptamine (5-HT) content and 5-HT reuptake sites were investigated in conjunction with the effects of developmental age on MDMA-induced thermoregulatory responses. MDMA was administered to rats at postnatal days (PND) 10, 40 and 70 in a range of ambient temperature environments (10°C, 25°C and 33°C). Animals were monitored for alterations in body temperature and sacrificed 1 week after MDMA administration. MDMA administration at PND 10 did not result in persistent reductions in 5-HT content or 5-HT reuptake sites in frontal cortex, nor could a hyperthermic response be elicited. In contrast, MDMA administration at PND 40 and PND 70 resulted in a hyperthermic response in cold environments (10°C) and a hyperthermic response in warm environments ( $\geq$  25°C). Increases in developmental age enhanced the hyperthermic response to MDMA. When hypothermia was observed after MDMA (10°C environment), long-term reductions in 5-HT content and 5-HT reuptake sites were significantly attenuated or abolished. Conversely, when a hyperthermic response was observed (25°C and 33°C environments), long-term MDMA-induced reductions in 5-HT content and 5-HT reuptake sites were significantly enhanced. Thus, hyperthermia was predictive, in part, of the degree to which 5-HT content and 5-HT reuptake sites were diminished after MDMA administration. These experiments demonstrate a role for hyperthermia in the expression of serotonergic neurotoxicity after MDMA administration.

## 342.18

EFFECTS OF N-METHYLATION ON THE NEUROTOXIC AND BEHAVIORAL EFFECTS OF SELECTED RING-SUBSTITUTED AMPHETAMINES. J. A. Wlos, J. Yuan, G. Hatzidimitriou, N. Castagnoli, J. L. Katz, and G. A. Ricaurte. Dept. of Neurology, Johns Hopkins Sch. Med. and NIDA, DIR., Baltimore, MD 21224.

N-methylation of the amphetamine derivative methamphetamine (MA) to dimethylamphetamine (DMA) eliminates its neurotoxicity toward brain serotonin (5-HT) neurons, but also diminishes its behavioral potency tenfold. The present study sought to determine: 1) Whether rats given DMA at behaviorally equipotent doses to those of MA show evidence of 5-HT neurotoxicity; and, if not, 2) Whether N-methylation can be used as a strategy to prevent 5-HT neurotoxicity induced by (+)3,4-methylenedioxymethamphetamine (MDMA) or fenfluramine (FEN). Rats were treated with MA, MDMA, FEN, or their respective N-methylated analogues, DMA, MDMA, and N-Me-FEN. MA (10 mg/kg) and DMA (100 mg/kg) were administered s.c. every 6 hrs X 5, a regimen that permitted use of behaviorally equipotent doses. Other drugs were given s.c. twice daily for 4 days, at doses ranging from 0.1 mg/kg to 40 mg/kg, depending on the drug and paradigm. Behavioral (n=6) and anorectic (n=6) effects were assessed using a drug discrimination paradigm and by measuring daily food intake and body weight. Neurotoxic (n=6) effects were assessed by measuring regional brain 5-HT and 5-HIAA two weeks after the last drug dose. DMA, given at behaviorally equipotent doses to MA, did not lead to a long-term depletion of serotonergic markers. N-methylation of both MDMA and FEN diminished their behavioral effects without preventing dose-related loss of 5-HT and 5-HIAA. These findings indicate that while effective in dissociating behavioral and neurotoxic effects of MA, N-methylation is not an effective strategy for selectively attenuating 5-HT neurotoxicity secondary to MDMA or FEN.

## 343.1

MATURATION OF CEREBRAL CORTICAL NEURONS *IN VITRO* IS MODULATED BY SEROTONIN RECEPTOR SUBTYPES. E. Köster and J.P. Hornung\*. Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.

The mammalian cerebral cortex is innervated by serotonergic axons early during fetal development, while cortical neurons are still undifferentiated and migrating from germinal zone. Serotonin transmission in cerebral cortex could affect pre- or postsynaptic neuronal and glial cells via distinct receptor subtypes. Several lines of evidence suggest a morphogenetic function for the early serotonergic transmission. We have studied this issue in an organotypic culture system. Slices of neonatal rat cortex were maintained two weeks on a millipore filter at the air-medium interface, using medium completed with normal horse serum (NHS) or dialyzed - serotonin-free - serum (DHS). The morphology of selected populations of cortical neurons was assessed by immunocytochemistry. In presence of NHS, calcitonin-immunoreactive (CR-IR) interneurons developed a complex dendritic arborization. Cultivated with DHS, CR-IR cells reduced drastically their dendritic branches, without change in their population size. On the other hand, slices treated with DHS medium with 5 or 10  $\mu$ M serotonin (5-HT) showed matured CR-IR neurons with a complex dendritic morphology. In DHS, the 5-HT<sub>1A</sub> agonist (8-OHDPAT) was ineffective, while 5-HT<sub>2</sub> agonist ( $\alpha$ -methyl-5-HT) mimicked the effect of 5-HT on the dendritic morphology of CR-IR neurons. Likewise, with 5 $\mu$ M 5-HT in DHS, 5-HT<sub>1A</sub> antagonist (NAN-190) allowed the differentiation of CR-IR interneurons, whereas 5-HT<sub>2</sub> antagonist (ritanserin) prevented it. The overall dendritic labeling for the microtubule-associated protein MAP2 was insensitive to these treatments. The present results suggest a morphogenetic effect of serotonin on cortical neurons mediated by one class of postsynaptic serotonergic receptor. Support: SNF 31-30-852.94

## 343.3

POSTNATAL DEFICIENCY OF DOPAMINE BUT NOT SEROTONIN AFFECTS THE DEVELOPMENT OF STRIATAL ENKEPHALIN AND TACHYKININ SYSTEMS. S.P. Sivam\*. Dept. Pharmacol. & Toxicol., Northwest Center for Medical Education, Indiana University School of Medicine, 3400 Broadway, Gary IN 46408

Previous studies have shown that neonatal dopaminergic lesion augments striatal enkephalin and decreases tachykinin biosynthesis. The present study examined whether a lack of dopamine (DA) and/or 5-hydroxytryptamine (5HT) during early postnatal period will modify the development of enkephalin and tachykinin neurons. The neurotoxins 6-Hydroxydopamine (6OHDA) and 5,7-dihydroxytryptamine (DHT) were used to lesion dopaminergic and serotonergic neurons on the third and fifth day after birth, respectively. Four groups of rats were used for study: control, 6OHDA-lesioned, DHT-lesioned and 6OHDA/DHT-lesioned. The animals were sacrificed at sixty days of age and the striatal tissues were used for neurochemical determinations. The levels of amines (DA and 5HT) and acid metabolites (DOPAC and 5HIAA) were determined by HPLC. The levels of peptides (Met<sup>5</sup>-enkephalin, ME; substance P, SP and neurokinin A, NKA) and precursor mRNAs [preproenkephalin, PPE; preprotachykinin, PPT] were determined by radioimmunoassays and Northern blot analyses, respectively. The neonatal 6OHDA lesion depleted DA, DOPAC and increased 5HT, 5HIAA; increased ME and PPE levels; decreased SP, NKA and PPT levels. The neonatal DHT lesion depleted 5HT and 5HIAA and did not affect any other parameter studied. The combined 6OHDA/DHT lesions produced only the changes associated with the 6OHDA or DHT lesion alone. The results suggest that the availability of DA but not 5HT during early postnatal period is essential for the normal development of striatal enkephalin and tachykinin neurons. (Supported by USPHS grant NS 26063).

## 343.5

5-HT<sub>1A</sub> RECEPTORS MEDIATE THE EFFECTS OF 5-HT ON DEVELOPING DENTATE GRANULE CELLS. J.H. Haring\*, W. Yan and C.C. Wilson. Dept. of Anatomy and Neurobiology, St. Louis Univ. Sch. Med., St. Louis, MO 63104.

High 5-HT<sub>1A</sub> receptor densities are present in the neonatal area dentata and neonatal 5-HT depletion results in decreased numbers of dendritic spines on dentate granule cells. 5-HT<sub>1A</sub> control of spine numbers was tested by treating neonatal rats with PCA (15mg/kg, SC) on PND3 and 4 followed by daily buspirone (agonist) treatment (1mg/kg) to PND14. A second group received daily NAN-190 (antagonist) injections (3.5mg/kg) from PND3 to PND14. Slices were prepared from male rats on PND14, 21 and 60. Granule cells were filled and analyzed. In contrast to the reduced spine densities observed after neonatal PCA treatment, buspirone-treated rats had normal numbers of dendritic spines at all ages studied. NAN-190 treatment resulted in dendritic spine densities similar to those observed after 5-HT depletion by neonatal PCA treatment. The development of normal granule cell spine densities in 5-HT-depleted rats receiving 5-HT<sub>1A</sub> agonist injections and the replication of 5-HT depletion effects by 5-HT<sub>1A</sub> antagonist treatment of normal rats indicate a role for 5-HT<sub>1A</sub> receptors in granule cell development.

## 343.2

NEONATAL 5-HT DEPLETION REDUCES DENTATE GRANULE CELL SPINE DENSITY. W. Yan, C.C. Wilson, W.M. Panneton\* and J.H. Haring. Dept. of Anatomy and Neurobiology, St. Louis Univ. Sch. Med., St. Louis, MO 63104.

We have been studying the role of 5-HT in dentate granule cell development. Pups were treated on PND 3 with either PCA (15mg/kg, 2 injections SC 24h apart) or 5,7-DHT (50 $\mu$ g in 5 $\mu$ l saline, IC) to produce a transient (Dev. Br. Res. 83:142, 1994) or permanent (Br. Res. 310:67, 1984) depletion of CNS 5-HT, respectively. Controls received vehicle injections. On PND14, 21, 60 and 120, hippocampal slices were prepared from male rats and granule cells were filled with neurobiotin. Filled cells were analyzed for changes in total dendritic length, segment number, segment length and spine density. Dendritic length, segment number and segment length showed some effects of treatment but these were rarely significant. Only spine density was significantly altered by 5-HT depletion. PCA treatment produced around 28% reduction in spines at all ages. 5,7-DHT resulted in a 40% spine decrease by P14 that reached 46% by P21. These results suggest that 5-HT can affect spine density development in a concentration dependent way since 5-HT depletion by IC 5,7-DHT is greater than by PCA.

## 343.4

PUTATIVE ROLE OF SEROTONIN IN THE MATURATION OF AMPHIBIAN OOCYTES.

L.A. Nikitina<sup>1</sup>, G.A. Buznikov<sup>2</sup> and J.M. Lauder<sup>3</sup>. <sup>1</sup>Group of Gametogenesis, <sup>2</sup>Lab. of Embryophysiology, N.K. Koltzov Inst. of Developmental Biology, Moscow 117808, Russia, <sup>3</sup>Dept. of Cell Biology and Anatomy, Lab. for Cell Biology, Univ. of N. Carolina Sch. of Med., Chapel Hill, NC 27599-7090.

Serotonin (5-HT) added to the medium or injected intracellularly inhibits or prevents the maturation of intact and denuded full-grown oocytes of *Rana temporaria*, *Bufo bufo*, *B. viridis* and *Xenopus laevis*. Some 5-HT antagonists reinitiate the meiosis, i.e. have a progesterone-like effect. 5-HT (both the neuronal and synthesized in follicles) probably maintains the meiosis block in the oocytes up to start of breeding season and modulates the progesterone action during maturation.

## 343.6

PRENATAL EXPOSURE TO THE ANTIDEPRESSANT FLUOXETINE (PROZAC<sup>TM</sup>) PRODUCES SITE-SPECIFIC ALTERATIONS IN BRAIN SEROTONIN (5-HT) RECEPTORS: AUTORADIOGRAPHIC STUDIES IN RAT OFFSPRING. T.M. Cabrera\*, F. Garcia, L.D. Van de Kar, W. Pinto and G. Battaglia. Department of Pharmacology, Loyola University of Chicago, Stritch School of Medicine, Maywood, IL 60153.

We have observed altered neuroendocrine responses to the 5-HT<sub>1A</sub> agonist 8-OH-DPAT and to the 5-HT<sub>2A/2C</sub> agonist DOI (JPET 269(2):637-645, 1994) in male progeny following prenatal exposure to fluoxetine. The current studies determined the consequences of prenatal fluoxetine exposure on the regional density of central 5-HT<sub>1A</sub> and 5-HT<sub>2A</sub> receptors in prepubescent and adult male progeny. Pregnant rats were administered saline or fluoxetine (10 mg/kg, sc) daily from gestational day 13 through 20. Alterations in serotonin receptor density were determined in 5-HT cell body regions as well as in brain regions receiving serotonergic innervation. The density of 5-HT<sub>1A</sub> receptors was not altered in 5-HT cell body regions (dorsal and median raphe) in either prepubescent or adult offspring. In contrast, regional changes in 5-HT<sub>1A</sub> receptors were observed in 5-HT target areas. In some of these regions, 5-HT<sub>1A</sub> receptors were significantly elevated (e.g. entorhinal cortex), whereas in other brain regions, 5-HT<sub>1A</sub> receptors were significantly reduced (e.g. ventromedial hypothalamus). The nature of the changes were dependent on the age of the offspring. Autoradiographic analysis of 5-HT<sub>2A</sub> receptors is currently in progress and the results will be presented at the meeting. In conclusion, prenatal exposure to fluoxetine alters the density of 5-HT receptor subtypes in discrete brain regions in both prepubescent and adult progeny. (Supported in part by NSF GER-9253875, and DA 07741; Fluoxetine was a generous gift from Eli Lilly and Co.).

## 343.7

AGE-RELATED LOSS OF HIPPOCAMPAL SEROTONERGIC TRANSPORTER FUNCTION: CELLULAR ELECTROPHYSIOLOGICAL STUDIES WITH DULOXETINE. J.E. Smith\* and J.M. Lakoski. Departments of Pharmacology and Anesthesia, Pennsylvania State University College of Medicine, Hershey, PA 17033.

Alterations in serotonergic neuronal system function have been documented with aging. To further understand synaptic responses which change with age, electrophysiologic techniques were used to study the sensitivity of hippocampal neurons to serotonin (5-HT) and antidepressants selective for the serotonin transporter (5-HTT). Duloxetine, a selective serotonin reuptake inhibitor, was utilized to determine age-related changes in neuronal responses mediated at the serotonergic transporter.

Female Fischer 344 rats divided into four age groups (young, middle, old, senescent; 3-8, 11-18, 20-24, >24 mo, respectively) were studied using an *in vivo* chloral hydrate anesthetized preparation. Drug solutions of 5-HT (0.01-0.04 M, pH 5.0-6.0), the 5-HT<sub>1A</sub> agonist 8-OH-DPAT, duloxetine, and desipramine were applied microiontophoretically (5-60 nA, 1-5 min duration) to hippocampal neurons recorded extracellularly in pyramidal subfields CA1 and CA3; data collected were analyzed to compare the differences in the neuronal sensitivity between age groups. A decrease in the  $IT_{50}$  values was seen with aging, demonstrating an increase in sensitivity to 5-HT. Across all ages, microiontophoretic application of duloxetine potentiated the inhibitory effect of co-applied 5-HT and/or 8-OH-DPAT ( $n=40$  cells). Presynaptic function was analyzed by calculation of  $RT_{50}$  values with a decrease found in the old and senescent groups. At 20-22 mo, the recovery time decreased with prolonged duloxetine co-application; this decrease was significant ( $p<0.05$ ) in the 27 mo group. With aging, the potentiation of 5-HT by duloxetine is rapidly lost and results in a functional desensitization. In summary, these studies have identified a significant age-related change in the physiological function of the hippocampal presynaptic serotonergic transporter.

## 343.9

### ENHANCED SYNAPTOPHYSIN IMMUNOREACTIVITY IN RAT HIPPOCAMPAL CULTURE BY 5-HT<sub>1A</sub> AGONIST, S100 $\beta$ AND CORTICOSTEROID RECEPTOR AGONIST.

M. Nishi<sup>1</sup>, P.M. Whitaker-Azmitia<sup>2</sup> and E.C. Azmitia<sup>1</sup>. 1. Dept. of Biology, New York Univ., New York, NY 10003. 2. Dept. of Psychiatry, SUNY, Stony Brook, NY 11794.

Serotonin (5-HT) has been shown to modulate brain maturation during development and adult plasticity. This effect may be due to activation of 5-HT<sub>1A</sub> receptors and a corresponding increase in S100 $\beta$  and corticosterone. Synaptophysin, an integral protein of the synaptic vesicle membrane that correlates with synaptic density and neurotransmitter release, is reduced by depletion of 5-HT in the cortex and hippocampus of the adult rat. Injections of a 5-HT<sub>1A</sub> agonist or dexamethasone can reverse the loss of synaptophysin immunoreactivity (IR).

In this study, we used morphometric analysis of synaptophysin-IR to evaluate the effects of the 5-HT<sub>1A</sub> agonist, ipsapirone and the neuronal extension factor, S100 $\beta$  on hippocampal neurons grown in a serum and steroid free media. Both compounds increased the synaptophysin-IR. Ipsapirone (10<sup>-6</sup> M) was more effective on neuronal cell bodies staining and S100 $\beta$  (10 ng/ml) was more effective in increasing the number of synaptophysin-IR varicosities on neuronal processes. In addition both types of corticosteroid receptor agonists, RU28362 (10<sup>-6</sup> M) and aldosterone (10<sup>-6</sup> M) produced smaller increases compared to control groups in both the cell body staining and the number of varicosities.

The effect of these differentiating factors on the expression of synaptophysin-IR suggests multiple regulation sites for producing and maintaining presynaptic elements in the brain. This work has been supported by funds from NIA program project #1 P01 AG10208.

## 343.11

### EFFECTS OF SHORT-TERM ADRENALECTOMY IN THE RAT HIPPOCAMPUS: CHANGES IN MAP-2, S-100 $\beta$ AND 5-HT 1A RECEPTOR. Prashanth AK<sup>1,2</sup>, Jose C. Poblete<sup>1</sup>, Baolang Liao<sup>1</sup>, Edgar E. Coons<sup>2</sup> & E.C. Azmitia<sup>1,2</sup>. 1-Center for Neural Science, NYU 2-Dept. Psychology, NYU 3-Lab. of Mol. Neuroplasticity, Dept. Biol. NYU and NY 10003.

Previous studies have indicated that long-term (LT) adrenalectomy (ADX) results in loss of mature glia and granule cells in the dentate gyrus with little effect on CA neurons. The LT-ADX effects were reversed by 72 hr. of dexamethasone. Recently, we observed that para-chloro-amphetamine (PCA) decreased 5-HT levels as well as S-100, MAP-2 and synaptophysin immunoreactivity (IR) and these markers could be restored with a 5-HT<sub>1A</sub> agonist or dexamethasone. In this study, adult female rats (125g-175g) were ADX and kept on saline (0.9%) for 10 days and given 5-HT<sub>1A</sub> agonist ipsapirone (1 mg/kg IP) twice daily for two days before perfusion. All animals were perfused transcardially with 4% paraformaldehyde, 0.1% MgCl<sub>2</sub> in 0.1M phosphate buffered saline. The brains were sectioned on a vibratome, and stained 5-HT<sub>1A</sub> receptor, S-100 $\beta$  and MAP-2. The sections were counter-stained with methyl green.

The ADX animals showed an increase in staining for the 5-HT<sub>1A</sub> receptor. They also showed decreased staining for MAP-2 and for S-100 $\beta$  protein. The results are consistent with previous studies of short- and long-term adrenalectomy. Preliminary observations indicate that ipsapirone treatment may not have a major effect in reversing the ADX-induced changes. Supported NIA Grant # P01 AG 10208

## 343.8

CELL- AND SITE-SPECIFIC EFFECTS OF SEROTONIN ON THE MORPHOLOGICAL DEVELOPMENT *IN VITRO* OF ANTENNAL LOBE INTERNEURONS OF THE SPHINX MOTH *MANDUCA SEXTA*. A.R. Mercer<sup>1,2</sup>, B.S. Kirchhof<sup>2</sup>, and J.G. Hildebrand<sup>1\*</sup>. <sup>1</sup>Dept. of Zool., Univ. Otago, Dunedin, NZ; <sup>2</sup>ARL Div. of Neurobiol., Univ. Arizona, Tucson, AZ 85721.

Serotonergic neurons in the primary olfactory centers (antennal lobes) of the brain of the sphinx moth *Manduca sexta* express their chemical phenotype early in development (Kent et al., *J. Neurobiol.* 19:451, 1987) and are well placed to influence events that occur during metamorphic adult development of the antennal-lobe neuropil. These neurons do not affect formation of the glomerular arrangement of the antennal lobes (Oland et al., *Soc. Neurosci. Abstr.* 19:443, 1993), but may regulate the structural or functional development of antennal-lobe interneurons. To begin to address this possibility, we have examined the effects of serotonin (5-hydroxytryptamine, 5HT) on the morphological development of *M. sexta* antennal-lobe interneurons *in vitro*. Cells were taken from pupae at stages 5 and 12 of the 18 stages of metamorphic adult development. 5HT (50  $\mu$ M) added daily to the culture medium increased significantly the total neurite length of two groups of cells identified elsewhere as local interneurons. In contrast, the total neurite length of a group of neurons thought to be projection (output) neurons was not affected by 5HT, although the growth of branches arising from the primary neurites of these neurons was significantly enhanced by exposure to this amine. These results indicate that responses to 5HT are not only cell-specific but also site-specific in some neurons. Furthermore, responses of cells from stage-5 pupae were not identical to those of cells from pupae at stage 12. While supporting the hypothesis that 5HT influences the morphological development of antennal-lobe interneurons of the moth, the data suggest that the modulatory actions of this amine may change during the course of metamorphic adult development.

## 343.10

### DEPLETION OF SEROTONIN DURING PEAK SYNAPTOGENESIS IN IMMATURE RATS LEADS TO LOSS OF A DENDRITIC MARKER (MAP-2) AND LEARNING DISABILITIES AS ADULTS. P.M. Whitaker-Azmitia<sup>1</sup>, A. Borella and J. Muneyvici. Dept. Psychiatry, SUNY, Stony Brook, NY 11794.

As a brain trophic factor, serotonin increases synaptogenesis in target regions. In the present study, we determined the longterm consequences of removing serotonin at the critical period for synapse formation. Rat pups were injected with PCPA, 100 mg/kg, from PND 10 to 20. On days 30 and 62, the animals were stained immunochemically for MAP-2 and staining density determined. At PND 62, animals were also tested for changes in reference and working memories in a maze with olfactory cues.

The cortex showed a significant dendritic loss at PND 30 (ROD's .299 vs .184,  $p<.0001$ ) but not at PND 62. The hippocampus showed dendritic loss at both PND 30 (.436 vs .344  $p<.01$ ) and PND 62 (.431 vs .376  $p<.003$ ). Treated animals learned the maze as rapidly as controls (reference memory, sec. to goal 47 vs. 54), but failed to re-learn the maze, when the cues were changed (working memory, 54 vs. 97 sec.  $p<.001$ ).

These results show that depletion of serotonin during a critical time for synaptogenesis leaves a permanent change in dendritic number and in a working memory task.

## 343.12

### CORTICOSTEROIDS MODULATE NEUROTRANSMITTER RESPONSIVENESS OF RAT CA1 PYRAMIDAL NEURONS THROUGH STEROID RECEPTOR ACTIVATION.

W.S. Hesen and M. Joëls\*. Dept. of Exp. Zoology, University of Amsterdam, Kruislaan 320, 1098 SM Amsterdam, the Netherlands.

The adrenal hormone corticosterone can bind to two different corticosteroid receptor types in the CNS: the high affinity mineralocorticoid receptor (MR,  $K_d=0.2$  nM) and the lower affinity glucocorticoid receptor (GR,  $K_d=3-5$  nM) which are both present in CA1 pyramidal neurons. With intracellular recordings in hippocampal slices, CA1 neurons were tested for their responsiveness to serotonin (5HT, 10  $\mu$ M) and carbachol (CCh, 3  $\mu$ M), which evoked hyperpolarizing and depolarizing responses respectively. Modulatory effects of MR and/or GR activation on these responses were studied using different protocols for steroid receptor activation. Male Wistar rats (120-200g) were adrenalectomized (ADX, 2-7d); subsequently steroid receptors were occupied i) *in vitro* by application of aldosterone (3 nM, MR-occupation) or corticosterone (30 nM, MR and GR occupation) to ADX-slices or ii) by *in vivo* application of a single doses of corticosterone (sc., 10-100  $\mu$ g/100g body weight: mainly MR occupation and 1 mg/100g: MR and GR activated). It appeared that 5HT as well as CCh responses were relatively large under conditions where either no (ADX) or both MR and GR were activated. However these transmitter responses were suppressed when predominantly MRs were activated. Interestingly, large 5HT responses were observed in adrenalectomized rats with high levels of corticosterone induced by a short stress stimulus; pretreatment of rats with RU38486 (sc., 1 mg/100g) prevented the stress-induced increased 5HT-responsiveness. Similarly, low levels of corticosterone circulating in the morning were associated with smaller 5HT-hyperpolarizations. These data show that physiological variations in corticosteroid levels, and therefore MR/GR occupation, modulate neurotransmitter responsiveness in the rat hippocampus.

## 343.13

REPEATED INJECTIONS OF FLUOXETINE PRODUCE DELAYED AND GRADUAL REDUCTIONS IN THE ACTH AND OXYTOCIN RESPONSES TO THE 5-HT<sub>1A</sub> AGONIST 8-OH-DPAT. Q. Li\*, G. Battaglia, T. M. Cabrera, W. Pinto, A. Vicentic, C. B. Chambers and L. D. Van de Kar. Dept. Pharmacol. Sch. Med., Loyola Univ. Chicago, Maywood, IL 60153.

Our previous studies indicate that long-term exposure to the 5-HT uptake blocker and antidepressant fluoxetine (PROZAC) reduces the ACTH, corticosterone and oxytocin responses to 5-HT<sub>1A</sub> agonists. A single injection of fluoxetine did not produce this effect. In the present study, we examined the onset of the fluoxetine-induced reduction in the hormone responses to 8-OH-DPAT. Male rats were injected daily with fluoxetine (10 mg/kg, ip) for 3, 7, 14 or 22 days or with saline for 22 days. The rats were challenged with the 5-HT<sub>1A</sub> agonist 8-OH-DPAT (0, 50, 200 or 500 µg/kg, sc) 18 hr after the last injection of fluoxetine. The rats were decapitated 15 min later and plasma was collected for hormone assays. 8-OH-DPAT dose-dependently increased the hormone levels. Repeated injections of fluoxetine decreased the ACTH and corticosterone responses to the 50 µg/kg dose of 8-OH-DPAT, but not to higher 8-OH-DPAT doses. The increases in plasma oxytocin after challenge with all three doses of 8-OH-DPAT were blunted by fluoxetine. A partial reduction of the hormone responses to 8-OH-DPAT appeared within 3 days and reached a maximum reduction after 14 days of injections of fluoxetine. The hormone responses to 8-OH-DPAT are mediated by postsynaptic 5-HT<sub>1A</sub> receptors in the hypothalamus. Therefore, our results suggest that repeated injections of fluoxetine produce a delayed onset, gradual reduction in the function of 5-HT<sub>1A</sub> receptors in the hypothalamus, which appear at 3 days and are maximal after 14 days (Supported by USPHS MH 45812 to LVDK).

BIOCHEMICAL AND FUNCTIONAL IMPAIRMENT OF BRAIN 5-HT SYSTEMS FOLLOWING VARIOUS FENFLURAMINE DOSE-REGIMENS W. Pinto\*, F. Garcia, T.M. Cabrera, Q. Li, L.D. Van de Kar and G. Battaglia Neuroscience Grad. Prog. and Dept. of Pharmacology, Loyola University of Chicago, Stritch School of Medicine, Maywood, IL 60153.

This study investigates the correspondence between the magnitude of biochemical and functional alterations following impairment of central serotonergic systems. 5-HT neurons which innervate most forebrain structures, also send collaterals to the hypothalamus (HYPO) where they can elevate several plasma hormones including ACTH, corticosterone (CORT), oxytocin and prolactin. Therefore, alterations in neuroendocrine responses to 5-HT releasers can provide a sensitive marker of the functional integrity of presynaptic 5-HT terminals. Adult, male Sprague-Dawley rats were treated with either saline or increasing doses of d,l-fenfluramine (2.5, 5.0 and 8.0 mg/kg, s.c. b.i.d. 4 days). 14 days post-treatment, the rats were challenged with a single dose of the 5-HT releaser p-chloroamphetamine (PCA) (8.0 mg/kg, i.p.). Low-dose fenfluramine treatment produced no reductions in 5-HT levels or in the density of 5-HT uptake sites in hypothalamic homogenates. However, a significant functional attenuation was observed in the PCA-mediated elevation of plasma ACTH (-21%) and oxytocin (-37%). In contrast, higher doses of fenfluramine reduced hypothalamic 5-HT levels (-40%), as well as 5-HT uptake sites (-56%) suggesting lesion of hypothalamic 5-HT terminals. Consequently, somewhat greater functional deficits were observed in the PCA-induced elevation of plasma ACTH (-30%) and oxytocin (-44%). These data suggest that low dose fenfluramine can produce a functional impairment of 5-HT systems in the absence of biochemical evidence for 5-HT axotomy. However, higher doses of fenfluramine can produce both biochemical and functional deficits which may be attributed to 5-HT axotomy and/or an impairment of remaining 5-HT terminals. (Supported by USPHS DA07741).

## 343.14

EVIDENCE THAT THE PROLACTIN RESPONSE TO THE 5-HT<sub>1A</sub> AGONIST 8-OH-DPAT IS MEDIATED BY G<sub>i</sub> PROTEINS. L.D. Van de Kar\*, Q. Li, A. Vicentic, G. Battaglia, Loyola U. Sch. Med., Dept. Pharmacol. 2160 S. First Av, Maywood, IL 60153.

5-HT<sub>1A</sub> receptors are coupled to G<sub>i</sub> proteins which inhibit adenylyl cyclase and reduce the intracellular levels of cAMP. To examine the hypothesis that the 5-HT<sub>1A</sub> receptor-mediated increase in prolactin secretion is mediated by G<sub>i</sub> proteins, the G<sub>10</sub> toxin pertussis toxin, or vehicle were injected into the lateral cerebral ventricle (ICV) of male rats, 48 hr before they were challenged with saline or with a single dose of 8-OH-DPAT (50 µg/kg sc, 15 min before sacrifice). The prolactin response to 8-OH-DPAT was significantly inhibited by pertussis toxin although the density of 5-HT<sub>1A</sub> receptors in the hypothalamus was not altered. To examine the hypothesis that a reduction in intracellular cAMP is involved in prolactin release, rats received an ICV injection of 8-OH-DPAT (0, 0.1, 1 or 10 µg/kg ICV, 15 min before sacrifice) and two injections of saline or forskolin (10 nmol/kg ICV, 7 and 15 min before sacrifice). Since forskolin can directly activate adenylyl cyclase, elevating cAMP would counteract the effect of G<sub>i</sub> protein activation, which would reduce the intracellular concentrations of cAMP. The ICV injection of 8-OH-DPAT dose-dependently increased plasma prolactin. Forskolin produced a shift to the right in the dose-response curve and reduced the maximal response. Combined, the data suggest that 8-OH-DPAT acts centrally to increase prolactin release by activation of 5-HT<sub>1A</sub> receptors that are coupled through G<sub>i</sub> proteins to adenylyl cyclase (supported in part by USPHS MH45812 to LVDK).

## 343.16

NEUROTENSIN BLOCKS ACTIVATION BY SOUND STRESS AND CORTI-COTROPIN RELEASING FACTOR OF MEDIAN RAPHE SEROTONERGIC NEURONS M. C. Boadle-Biber\*, K. C. Corley and T. H. Phan. Physiology Dept, Med. Coll. Virginia, VCU, Richmond, VA 23298

Sound stress (SS) activates serotonergic (5-HT) neurons within the median (MRN) but not dorsal raphe nucleus (DRN) of the rat as shown by the enhanced 30 min accumulation of 5-hydroxytryptophan (5-HTP) after inhibition of aromatic amino acid decarboxylase with NSD 1015 (m-hydroxybenzylhydrazine, 100 mg/kg i.p.) (J. Neurochem. 64 (1995) S53A). In the present study, we show that neurotensin (NT) blocks activation of MRN 5-HT neurons by SS as well as corticotropin releasing factor (CRF), a peptide that mimics many of the actions of SS on 5-HT neurons (Brain Res., 628 (1993) 105-114). Male Sprague Dawley rats, with indwelling bilateral ventricular cannulae, were divided into two groups; one received ICV NT (0.15 nmol in 3 µl per side), the other saline. For the SS exposure, NSD 1015 was given 5 min after NT and both groups exposed to a 30 min SS (30 randomly presented, 100 msec, 2.9 kHz, 110 dB sound pulses) or no SS (sham SS controls). For CRF treatment, CRF (0.3 nmol in 3 µl per side, or vehicle) was infused ICV, 10 min after NT; NSD 1015 was injected 30 min after CRF. Rats were killed by decapitation after accumulation of 5-HTP for 30 min, the MRN and DRN removed with 2 mm punches from a 3 mm coronal section of midbrain (J. Neurochem. 64 (1995) S35A) and stored at -70°C until analysed by HPLC-EC for 5-HTP content. Mean levels of 5-HTP, in ng/mg protein, increased 112 and 85% in MRN with SS and CRF respectively (from 9.3 to 19.7 ± 0.7 with SS and from 9.5 ± 0.4 to 17.6 ± 1.0 with CRF (P < 0.01) but were unchanged in DRN. NT had no significant effect on 5-HTP levels given alone, but blocked the increase in 5-HTP levels in MRN after SS or CRF infusion. Supported by NIH NINDS grant NS14090 to MCB.

# UPTAKE AND TRANSPORTERS: SEROTONIN

## 344.1

CLONING AND CHARACTERIZATION OF THE PROMOTER REGION OF THE MOUSE SEROTONIN TRANSPORTER GENE. N. Sakai\*, O. Morikawa, N. Ikegaki, S. Kobayashi, M. Fujimoto and N. Saito Lab. of Mol. Pharmacol., Biosignal Research Center, Kobe University, Kobe 657, Japan

The serotonin transporter has been known to be the main target of the antidepressants and involved in the pathogenesis of the affective disorder. To study the transcriptional regulation of the serotonin transporter, we screened a mouse genomic library using a cDNA probe encoding the 5'-region of the rat serotonin transporter cDNA. We obtained an approximately 3 kbp fragment which contained the 5'-flanking region and exon 1 of the serotonin transporter. We sequenced the 0.9 kbp region upstream from the ATG and identified the translation-initiation site, 302 bp upstream from the ATG, by primer extension analysis. This promoter had a TATA box 84 bp upstream from the translation-initiation site and contained many transcription factor binding sites such as AP-2, α-INF, γ-IRE, NF-IL6, NF-κB and SPI. The transient chloramphenicol acetyltransferase (CAT) expression assay demonstrated that it functioned as a promoter in COS-7 cells. We examined the effects of phorbol ester and interferon on the promoter activity of the serotonin transporter using a CAT assay.

## 344.2

RANDOM MUTAGENESIS OF A LOOP REGION IN THE RAT BRAIN SEROTONIN TRANSPORTER. M. M. Stephan\* and G. Rudnick. Pharmacology Dept., Yale School of Med., New Haven, CT.

The rat brain serotonin transporter is responsible for the re-uptake of serotonin from the synaptic cleft following neurotransmission. This transporter is predicted to contain twelve hydrophobic transmembrane α-helices, linked together by hydrophilic loops. Oligonucleotide-directed random mutagenesis was performed on a region of the transporter cDNA encoding 16 amino acid residues predicted to lie near the C-terminal end of the 7th transmembrane span (6 membrane-bound and 10 in the following extracellular loop). Random base changes were introduced into the mutagenic oligonucleotide by "dirty bottle" synthesis, in which low levels (1-2%) of the other three nucleotides were included in each of the A, T, C and G synthesizer bottles. Analysis of the transport abilities of these mutants has revealed at least one position which may be important for activity: F380, at which the relatively conservative substitution of V results in complete loss of activity. By contrast, several other positions were revealed as relatively unimportant for transport activity. D393 accepts nonconservative substitutions of G and H with no detectable loss of activity. I379 accepts the substitution of T with 95% activity remaining. Other nonconservative substitutions which do affect activity somewhat but are still well-tolerated (40-50% activity remaining) are R390M and E392G. Application of this method will allow relatively rapid identification of residues important for the transport mechanism as well as for other activities such as the binding of antidepressants and cocaine analogs.

## 344.3

## SEROTONIN TRANSPORTER mRNA LOCALIZATION IN THE

DEVELOPING RAT EMBRYO. Stefan R. Hansson, E. Mezey<sup>1</sup> and B.J.Hoffman<sup>2</sup>. Lab of Cell Biology, NIMH and <sup>2</sup>Clinical Neurosciences Branch, NINDS, Bethesda, MD 20892

A role for serotonin (5HT) has been implicated in the developing rodent. For instance, blockade of the 5HT transporter (5HTT) leads to craniofacial and heart malformations of mouse embryos in culture. This suggests that the 5HTT may play a critical role in regulating the effects of 5HT in the embryo. We have used *in situ* hybridization histochemistry with RNA probes to delineate 5HTT gene expression during rat embryonic development. In the central nervous system (CNS), 5HTT mRNA was present in cells of the neural tube at embryonic day 11 (E11). By E15, mRNA was localized to midbrain and cingulate cortex. In addition, labeling was detected in retina and sympathetic ganglia. While the intensity of labeling in individual cells of raphe nuclei increased from E15 to E21, positive cells were also identified in the medulla, thalamus, caudate, hippocampus, subependyma and dura mater of E21 embryos. In addition to the CNS, 5HTT mRNA was detected in heart, bone, intestine, spleen, lung, aorta and adrenal medulla. In general, throughout embryonic development, those areas which expressed 5HTT mRNA continued to show labeling, either increasing in intensity or remaining the same. Expression of 5HTT suggests the importance of maintaining 5HT homeostasis even in tissues which may not synthesize 5HT. Further, presence of 5HTT mRNA in numerous sites throughout the embryo suggests a previously unappreciated role for 5HT in diverse physiologic systems during embryonic development. Whether 5HT provides important developmental cues, through which receptors these cues are relayed and whether 5HTT plays a critical role remains to be determined.

## 344.5

## TOWARDS EXPRESSION OF THE HUMAN AND RAT BRAIN SEROTONIN

TRANSPORTER (SERT) IN BACTERIA AND YEAST. <sup>1</sup>E. Titgemeyer, <sup>1</sup>S. Hilberer-Ehret, <sup>2</sup>K.N. Faber, <sup>2</sup>M. Veenhuis, <sup>3</sup>C. Tate, <sup>4</sup>P. Schloss, <sup>4</sup>H. Betz, <sup>5</sup>S. Boyce, <sup>5</sup>C. Williams, <sup>2</sup>S. de Boer\* and <sup>1</sup>G.T. Robillard. <sup>1</sup>Dept. of Biochem., Nijenborgh 4, 9747AG Groningen; <sup>2</sup>Biology, Kerklaan 30, 9751NN Haren, Netherlands; <sup>3</sup>MRC Lab., Hills Road, Cambridge CB2 2QH, United Kingdom; <sup>4</sup>MPI Brain Res., Deutschordenstr. 46, 60528 Frankfurt, Germany; <sup>5</sup>Dept. of Biochem., Trinity College, Univ. Dublin, Dublin 2, Ireland.

SERT terminates the action of the neurotransmitter serotonin by reuptake into the presynapse. SERT is believed to be involved in mental diseases, i.e. depression. Antidepressants such as imipramine, fluoxetine and citalopram and the drugs cocaine and MDMA (ecstasy) are acting directly on SERT. Therefore, it is of medical interest to elucidate the structure and function of SERT at the molecular level. Basis for structural analysis will be purification of mg quantities of protein. We have addressed this by studying overexpression in bacteria and yeast. We have expressed SERT in *Escherichia coli* taking advantage of the T7 phage expression system. *In vivo* labelled SERT protein migrates on SDS-PAGE at 55 kDa. Binding to [<sup>3</sup>H]imipramine was detectable only when SERT was expressed as a fusion protein. The N-terminal 85aa protein domain (NSERT) was overexpressed of >10% of total protein. Purification to obtain protein quantities sufficient for structural work could be demonstrated. Using the methylotropic yeast *Hansenula polymorpha*, we have studied homologous (PER9) and heterologous (SERT) expression of membrane proteins. Morphological changes of *H. polymorpha* integrants were observed under conditions when membrane protein was expressed.

## 344.7

## PHOSPHORYLATION OF SEROTONIN TRANSPORTER DOMAINS AND THE ROLE OF PHOSPHORYLATION IN ACUTE TRANSPORTER

REGULATION. Y. Qian<sup>1</sup>, H.E. Melikian<sup>1</sup>, K.R. Moore<sup>2</sup>, B.J. Duke<sup>3</sup> and R.D. Blakely<sup>3</sup>. <sup>1</sup>Grad. Prog. Neuroscience, <sup>2</sup>Dept. Anatomy & Cell Biol., Emory Univ., Atlanta, GA 30322 and <sup>3</sup>Dept. Pharmacol., Vanderbilt Univ., Nashville, TN 37232-6600.

Serotonin (5HT) transporters (SERTs) are responsible for efficient clearance of the amine from extracellular spaces. Although multiple reports demonstrate a capacity of SERTs to be acutely regulated by second messenger-linked systems, direct mechanisms have yet to be established. We examined the potential for SERT phosphorylation as a mechanism for acute regulation in two ways. We used PKC activators in HEK-293 cells stably transfected with human SERT cDNA. PMA treatment of these cells caused a rapid and dose-dependent inhibition of 5HT uptake. Similar results were obtained with the PKC activator PDBu. The inactive  $\alpha$  forms of these agents were ineffective. Kinetic analysis show that reductions induced by PMA are principally mediated by a decrease in  $V_{max}$  (46% of control) with little or no change in 5HT  $K_m$ . SERT antibodies that can blot and immunoprecipitate posttranslationally modified SERT proteins are being used to assess the contribution of direct protein phosphorylation to PKC-mediated reductions. Human and rodent SERT proteins contain multiple, conserved sites for Ser/Thr-based protein phosphorylation, with most of these sites found in the presumed cytoplasmic NH2 and COOH termini. *In vitro* phosphorylation experiments were performed using glutathione-S-transferase (GST) fusion proteins containing either the NH2 or COOH termini of rat SERT. Purified protein kinase C and protein kinase A phosphorylated both NH2 and COOH fusion proteins with little or no phosphorylation of the GST backbone. Interestingly, neither fusion protein is phosphorylated by purified cGMP dependent protein kinase *in vitro*. Additional studies seek to reveal residues phosphorylated under *in vitro* conditions and relate these changes to *in vivo* regulation of 5HT uptake activity. Support by NIDA DA07390 to R.D.B.

## 344.4

5-HT<sub>2</sub> RECEPTORS INCREASE 5-HT TRANSPORT VIA NITRIC OXIDE AND

cGMP. Keith J. Miller\* and Beth J. Hoffman. Lab of Cell Biology, NIMH; Bethesda, MD.

We have previously determined that the maximal rate of 5-HT transport can be regulated by nitric oxide and cGMP in an RBL 2H3 cell line and in brain synaptosomes. 5-HT receptors of the 5-HT<sub>2</sub> sub-family are coupled to elevations in calcium via IP3 and thus could be coupled to nitric oxide production. The 5HT<sub>2C</sub> receptor has been demonstrated to be coupled to cGMP in the choroid plexus. Therefore we determined whether 5HT<sub>2</sub> receptor activation could result in the regulation of 5-HT uptake by nitric oxide and cGMP. Brain slices were incubated with the 5-HT<sub>2</sub> receptor agonist DOI for 15 min. Nitrites and cGMP were measured or synaptosomes were prepared following treatment of the slices. DOI produced a dose-dependent increase in nitric oxide levels, cGMP levels, and <sup>3</sup>H-5HT uptake. <sup>3</sup>H-5HT uptake was increased from 1700±96 to 4400±120 cpm/mg protein in hippocampal synaptosomes with an EC<sub>50</sub> of 6nM which was blocked by the antagonist mianserin. cGMP levels increased from 157 to 340 fmol/mg protein and nitrite levels rose from 22 to 31 µg/ml/mg protein. In the cortex the dose-response curve for <sup>3</sup>H-5HT uptake, cGMP and nitrite, was bell-shaped with maximal stimulation in uptake occurring at 0.1µM (from 10900±300 to 13400±150), with an EC<sub>50</sub> of 40nM. Nitrite levels rose from 8.6 to 9.9 µg/ml/mg protein and cGMP levels were elevated from 49 to 100 fmol/mg protein. Inhibition of uptake occurred at 10µM DOI and was enhanced by 10µM mianserin. These results suggest that 5HT<sub>2</sub> receptors are coupled to nitric oxide and cGMP in the rat brain and that the activation of pre and/or postsynaptic 5-HT<sub>2</sub> receptors results in increased levels of 5-HT uptake. Further pharmacological characterization is necessary to identify which 5HT<sub>2</sub> subtype is involved. Alteration of the ability of the 5-HT transporter to remove 5-HT from the synapse may change the concentration of neurotransmitter in the synapse and thus may significantly alter serotonergic neurotransmission.

## 344.6

## SUBTYPES OF 5-HT AXONS DIFFER IN THEIR EXPRESSION OF

SEROTONIN TRANSPORTER. K.J. Axt<sup>1</sup>, M.E. Molliver<sup>1</sup>, Y. Qian<sup>1</sup> and R.D. Blakely<sup>2</sup>. The Johns Hopkins Univ. Sch. Med., Baltimore, MD, 21205; Vanderbilt Univ., Nashville, TN, 37232.

p-Chloroamphetamine (pCA) and d-fenfluramine (FEN) are neurotoxic drugs since they ablate *fine* 5-HT axons, demonstrated by 5-HT and TPH immunocytochemistry (ICC). A subtype of 5-HT axons, *beaded* axons, is resistant to the neurotoxic effects of pCA and FEN. The 5-HT uptake inhibitor fluoxetine prevents the toxicity, indicating that the serotonin transporter (SERT) is critical for the neurotoxic effects of pCA and related drugs. It has been postulated that the differential vulnerability of *fine* and *beaded* axons might be explained by differences in the number or affinity of 5-HT uptake carrier sites. To test this hypothesis, we analyzed axon morphology using antisera to 5-HT or to SERT (CT-2). Control rats were compared to pCA- or FEN-treated rats, where *fine* 5-HT axons are ablated. In certain brain regions at 7-10 days after pCA or FEN, the 5-HT and SERT-IR axons are similar in morphology and density: in the glomerular layer of the olfactory bulb (MOB), layer III of lateral entorhinal cortex, and ventricular plexus, spared 5-HT axons are intensely reactive for both 5-HT and SERT. Since many spared 5-HT axons express high levels of SERT, neurotoxic resistance cannot be attributed solely to lack of the 5-HT transporter. However, in dentate gyrus (DG) and parietal cortex, where many 5-HT-IR axons survive, relatively few spared axons are SERT-IR, suggesting that some 5-HT axons may not express the transporter. Of the spared SERT-IR axons, many stain weakly and their varicosities are either not reactive or appear smaller than varicosities stained by 5-HT or TPH ICC, which may reflect a difference in distribution or density of the transporter. Compared with spared 5-HT-IR axons in DG and parietal cortex, the smaller number of surviving SERT-IR axons and the reduced staining of varicosities suggests the existence of multiple subtypes of drug-resistant 5-HT axons. [Support: DA04431, NS15199, DA07390]

## 344.8

TRANSCRIPTIONAL REGULATION AND MESSAGE HETEROGENEITY OF THE HUMAN SEROTONIN TRANSPORTER GENE. C.C. Bradley<sup>1</sup> and R.D. Blakely<sup>2</sup>.<sup>1</sup>Graduate Program in Neuroscience, Emory University School of Medicine, Atlanta, GA 30322 and <sup>2</sup>Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN 37235.

The human antidepressant sensitive serotonin transporter (SERT) terminates serotonergic transmission. Compromised SERT expression may contribute to neuropsychiatric disorders. We have used the human placental JAR cell line (Cool et al. JBC 266:15750-7, 1991) as an *in vitro* model of chronic SERT regulation mediated by second messenger systems. Three SERT mRNAs can be detected in Northern blots of JAR and human brainstem mRNA. SERT-associated binding and uptake levels in JAR cells are markedly increased following chronic cholera toxin (CTX) or forskolin treatment, coincident with an increase in steady-state SERT mRNA levels (Ramamoorthy et al. JBC 268:21626-31, 1993). We have employed a competitive RT-PCR strategy to quantitate SERT mRNA levels and applied it to CTX-treated JAR cells to assess changes in mRNA half-life. In this method, a single PCR product is amplified from JAR cDNA, consistent with multiple mRNAs derived from noncoding variants. RT-PCR of control JAR RNA revealed basal expression levels reflecting ~0.1pg of SERT RNA/µg total RNA whereas JAR cells treated with 100 ng/ml CTX for 16 hours showed mRNA levels of ~1.0pg/µg total RNA. Quantitation performed at different time points after actinomycin-D treatment indicate a SERT mRNA half-life of ~18 hours. CTX treatment caused little or no change in SERT mRNA half-life, consistent with increased nuclear initiation underlying elevations of SERT mRNA. Human SERT genomic fragments are presently being used to clarify the contribution of noncoding elements to SERT mRNA heterogeneity and CTX-induced transcriptional activation.

## 344.9

EMBRYONIC EXPRESSION OF MOUSE SEROTONIN TRANSPORTERS REVEALED BY [<sup>125</sup>I]RTI-55 AUTORADIOGRAPHY, IN SITU HYBRIDIZATION, AND IMMUNOCYTOCHEMISTRY. S. Schroeter\* and R.D. Blakely. Dept. of Pharmacology, Vanderbilt University, Nashville, TN.

In addition to their role as neurotransmitters, biogenic amines such as serotonin (5-HT) have been implicated in morphogenetic signaling events in the early embryo. Embryos have been shown to accumulate neurotransmitters in a number of tissues during morphogenesis. For instance, chick and mouse embryos accumulate serotonin in the neural tube and at other morphogenetically active sites. 5-HT transport antagonists block this accumulation and lead to developmental defects. Due to difficulties inherent with *in vivo* and *in vitro* embryo preparations, a direct link to specific proteins involved in 5-HT accumulation has not been achieved. As part of our ongoing effort to characterize the role of transport proteins in early development, we determined 5-HT transporter (SERT) mRNA distribution with *in situ* hybridization and compared this with two functional measures of SERT protein expression: [<sup>125</sup>I]RTI-55 autoradiography and SERT immunocytochemistry. SERT's contribution to [<sup>125</sup>I]RTI-55 binding was assessed by parallel incubations with 10nM paroxetine or 100nM citalopram whereas the contribution of norepinephrine and dopamine transporters was assessed with 100nM nomifensine. As early as embryonic day 9, mouse embryos demonstrate SERT expression in the neural tube and in several peripheral tissues, consistent with a role of 5-HT in early developmental events. However, these sites appear to only partially overlap with sites of 5-HT accumulation previously defined *in vitro* and may indicate the involvement of additional processes or transporters in embryonic 5-HT accumulation. Supported by a Pharmaceutical Manufacturers Association Foundation fellowship to S.S. and by NIDA award DA-07390 to R.D.B.

## 344.11

IN VIVO INHIBITION OF THE SEROTONIN TRANSPORTER BY THE ANTIDEPRESSANT NEFAZODONE IN THE RAT. D.L. Knight\*, M.J. Owens, K.J. Winders, J. Ieni and C.B. Nemeroff. Dept. Psychiatry & Behavioral Sciences, Emory Univ. Sch. of Med., Atlanta, GA 30322.

Nefazodone HCl (Serzone®) is a new antidepressant with a chemical structure unrelated to SSRIs, tricyclics, tetracyclics, or MAO inhibitors. Nefazodone is active in a number of preclinical tests for antidepressant activity and shows clinical efficacy in the treatment of depression with a more favorable side-effect profile than the structurally similar antidepressant trazodone. Previous studies have shown that nefazodone is a potent antagonist of 5-HT<sub>2A</sub> receptors and binds to the serotonin transporter *in vitro* and *in vivo*. To further investigate the ability of nefazodone to modify serotonergic transmission, the ability of systemically administered nefazodone to inhibit the serotonin transporter was assessed by measuring [<sup>3</sup>H]-5-HT uptake *ex vivo* and by preventing parachloroamphetamine (PCA) induced depletions of cortical 5-HT concentrations. In addition, the ability of *in vivo* nefazodone administration to inhibit 5-HT uptake following sub-chronic dosing was assessed.

Acute administration of nefazodone (100 and 150 mg/kg, sc) significantly increased the K<sub>m</sub> for [<sup>3</sup>H]-5-HT uptake in rat cortical synaptosomes from 60 nM/L in controls to 230 and 242 nM/L in nefazodone-treated rats, respectively. Acute nefazodone administration (30, 100, and 150 mg/kg) antagonized PCA-induced depletion of cortical 5-HT concentrations in a dose-dependent manner as measured by HPLC at 1, 2, and 3 hours post treatment. In fact, 100 and 150 mg/kg nefazodone was equipotent with fluoxetine (10 mg/kg) over the course of the experiment. Sub-chronic administration of nefazodone (100 and 150 mg/kg, sc, b.i.d. X 11 days) reduced [<sup>3</sup>H]-5-HT uptake by 24% and 29%. Sub-chronic dosing with fluoxetine (5 mg/kg, sc, b.i.d. X 11 days) reduced [<sup>3</sup>H]-5-HT uptake by approximately 65%. These experiments confirm and extend previous reports concerning the ability of nefazodone to inhibit the 5-HT transporter *in vivo*. Supported by a grant from Bristol Myers-Squibb.

## 344.13

IN VIVO STUDIES OF THE SEROTONIN TRANSPORTER WITH 5-iodo-6-nitroquipazine. A. Biegon\*, J.L. Eberling, S.E. Taylor, H.F. Van Brocklin, S. Jordan, S.M. Hanrahan, J.A. Roberts, K.M. Brennan, C.A. Mathis, W.J. Jagust. Center for Functional Imaging, Lawrence Berkeley Laboratory, Berkeley, CA 94720.

*In vivo* imaging of serotonergic function is potentially useful in understanding several diseases of the nervous system. Promising preliminary results with the tracer 5-iodo-6-nitroquipazine (INQUIP) have prompted us to perform further studies designed to validate the use of the tracer as an *in vivo* ligand for the serotonin transporter. We studied 6 adult macaca mulatta in 8 experiments which involved single photon emission computed tomographic (SPECT) imaging at 17 to 24 hours post tracer injection, including 3 experiments with co-injection of the [<sup>123</sup>I] and [<sup>125</sup>I] radiolabeled tracer for direct comparison of SPECT and autoradiography, and 3 experiments in which animals were lesioned with the serotonergic neurotoxin (±)3,4-methylenedioxymethamphetamine (MDMA). In addition, we evaluated the metabolism of the tracer in the brain and periphery.

SPECT images obtained at 17 and 24 hours reflected both the known pattern of distribution of serotonin transporters and also showed close correspondence to the autoradiograms. The sites of greatest binding in both were brainstem (the raphe nuclei and colliculi) and thalamus (particularly central nucleus), followed by the basal ganglia, cerebral cortex, and cerebellum. SPECT ratios of binding in the brainstem to cerebellum were close to 3 at 17 h, and ratios for most regions changed little by 24 h. Autoradiograms from an MDMA treated animal showed 30 to 70% reductions of binding, which was also detectable in the SPECT data. At 17 h, virtually all of the tracer in the brainstem was in the form of unmetabolized parent compound. Plasma showed rapid peripheral metabolism of the tracer shortly after injection.

These results demonstrate that INQUIP SPECT images reflect binding to the serotonin transporter *in vivo*, with good target to background ratios and little brain metabolism. In addition, the tracer is sensitive enough to detect serotonergic lesions in the primate brain. These data suggest that further development of the tracer as a method for the *in vivo* study of serotonergic neurons in humans is warranted.

## 344.10

SEROTONIN TRANSPORT KINETICS IN RATS GENETICALLY RESISTANT AND PRONE TO TASTE AVERSION CONDITIONING R. L. Elkins\*, T. E. Orr, J. Li, J. Hunter, J. Hutcheson, P. A. Walters, J. L. Rausch. Veterans Administration Medical Center, Augusta, GA 30904, and The Medical College of Georgia, Augusta, GA 30910.

Synaptosomal serotonin (5-HT) transport kinetics were examined in two selectively bred lines of taste aversion prone (TAP) and taste aversion resistant (TAR) rats. Strain selection methodology paired a saccharin flavored conditional stimulus (CS) with the aversive unconditional stimulus (US) consequences of a cyclophosphamide injection. The selectively bred line differences in taste aversion (TA) conditionability are maintained with other injected US conditioning agents including ethanol. A range of ethanol doses produced dose dependent differences in TA acquisition in TAP rats without inducing TA in TAR rats (Elkins, et al., *Alcohol Clin Exp Res*, 16, 928-934, 1992). In a related study of naive free-choice ethanol acceptance, TAR rats consumed significantly more ethanol (presented as a 1% to 20% ethanol/water solution with plain water also freely available) than TAP rats (Elkins, et al., *Alcohol Clin Exp Res*, 17, 445, 1993). TAR rats also have been found to have lower levels of whole brain 5-HT than TAP rats (Orr, et al., *Physiol Behav*, 53, 495-500, 1992). In the present between lines comparisons of 5-HT transport kinetics, whole brain synaptosomal samples were examined in 12 TAP and 12 TAR adult rats. The TAR group was found to have a significantly ( $p < .01$ ) lower affinity for synaptosomal 5-HT transport ( $K_m = 1.42$  mM,  $SD = 0.31$ ) in comparison to the TAP group ( $K_m = 1.11$  mM,  $SD = 0.16$ ). No significant difference was found in  $V_{max}$  values between the groups. These results are consistent with observations that low 5-HT activity could constitute a vulnerability factor for alcohol drinking. They also point to the potential relevance of a mediating serotonergic link between taste aversion conditionability and the propensity to drink alcohol.

## 344.12

EFFECTS OF ACUTE PAROXETINE AND FLUOXETINE ON EXTRACELLULAR SEROTONIN IN THE RAPHE: AN IN VIVO MICRODIALYSIS STUDY. I. Malagré\*, C. Jacquot and A.M. Gardier. Lab. Pharmacol. JE92-372, Fac. Pharm Univ. Paris-Sud, 92290 Chateau-Malabry, France.

Activation of 5-HT<sub>1A</sub> receptors located in median+dorsal raphe nuclei (RN) may be involved in the long delay of action of selective serotonin (5-HT) reuptake inhibitors (SSRI) in rodents and humans. High densities of these autoreceptors and of 5-HT transporter in RN may explain preferential effects of peripheral fluvoxamine in the raphe compared to those in serotonergic terminal areas like the frontal cortex (FC) (Bel and Artigas, *Eur. J. Pharmacol.* (1992) 229:101). To know if this property is shared by other SSRIs and concerns other terminal areas, *in vivo* microdialysis was simultaneously performed in FC, ventral hippocampus (vHi) and RN after acute injection of fluoxetine (Flx, 1, 10 and 20 mg/kg i.p.) or paroxetine (Prx, 15 mg/kg s.c.) in anaesthetized rats. Basal extracellular 5-HT levels in vHi ( $m \pm S.E.M.$  in fmol/20µl: 10.8±1.9, F2,59=5.17  $P<0.01$ ) were lower than in FC (23.7±2.4) and in RN (21.2±4.5). In the 3 brain area studied, extracellular 5-HT concentrations were increased following the 2 SSRI administrations. Prx induced a 7 fold increase in raphe 5-HT (+726%,  $P<0.001$ ) compared to FC (+363%,  $P<0.001$ ) and vHi (+446%,  $P<0.001$ ). Flx (10 mg/kg) increased 5-HT preferentially in RN (+268%,  $P<0.001$ ) compared to FC (+164%,  $P<0.001$ ) and vHi (+205%,  $P<0.001$ ). The regional specificity of Flx effects disappeared at higher dosage (20 mg/kg): similar increases were observed in the 3 structures, +252%, +267% and +236% in FC, vHi and RN, respectively, likely suggesting uptake site saturation. Thus, only a 10 mg/kg Flx dose qualitatively mimics those of Prx at 15 mg/kg inducing a preferential increase in raphe 5-HT: Flx and Prx presumably stimulated somatodendritic 5-HT<sub>1A</sub> receptors, thus decreasing the firing rate and leading to small increases in FC and vHi extracellular 5-HT. However, quantitative differences in the effects of the 2 SSRIs may occur as the maximal 5-HT augmentation (% of baseline) in the RN induced by the 3 doses of Flx is limited to one-third of that induced by Prx. Distinct pharmacokinetic profiles of these SSRIs (a long elimination half-life for Flx, a short one for Prx; an active metabolite for Flx, an inactive one for Prx) may account for these differences.

## 344.14

RELEASE OF [<sup>3</sup>H]MPP<sup>+</sup> FROM C6 GLIOMA CELLS EXPRESSING THE HUMAN DOPAMINE OR SEROTONIN TRANSPORTERS. R.A. Johnson\*, A.J. Eshleman, T.T. Meyers, A.K. Evenson, K.A. Neve, and A. Janowsky. Dept. Pharmacology, Oregon Health Sciences Univ. and VAMC, Portland, OR 97201.

C6 rat glioma cells, stably expressing the human dopamine transporter (C6-hDAT) or serotonin transporter (C6-hSERT), were used to examine the modulation of [<sup>3</sup>H]MPP<sup>+</sup> release by an array of drugs via the transporters. Preliminary experiments revealed that both cell lines take up [<sup>3</sup>H]MPP<sup>+</sup> in a time- and dose-dependent manner, with maximal uptake occurring after 120 minutes. For release experiments, cells were preloaded with [<sup>3</sup>H]MPP<sup>+</sup>, rinsed, and release buffer was added. After a 10 minute equilibration period, drugs were added to a final volume of 500 µl. For concentration-response experiments, the contents of the well were aspirated at 30 or 45 min for C6-hDAT or C6-hSERT, respectively. Spontaneous release in the absence of drugs was <10% for C6-hDAT and 10-20% for C6-hSERT after 45 min at 37°C. Preliminary results for the effects of an array of substrates and non-substrates are shown below:

Compound	C6-hDAT EC <sub>50</sub> (nM)	C6-hDAT % release	C6-hSERT EC <sub>50</sub> (nM)	C6-hSERT % release
RTI-55	45	40	10	50
Mazindol	100	40	240	57
CFT	156	40	750	55
Amphetamine	250	93	630	87
Cocaine	185	55	750	56
Dopamine	1200	86	8500	90
Fenfluramine	10,000	60	21800	80
Serotonin	100,000	60	78300	60

(Supported by NIDA Drug Development Contract; hSERT cDNA was kindly provided by Dr. Randy Blakely, Dept. Pharmacol., Vanderbilt Univ.)

## 344.15

**HETEROGENEITY OF ANTIDEPRESSANT BINDING SITES ON THE RECOMBINANT RAT SEROTONIN TRANSPORTER SERT1.** P. Schloss, S. Sur, S. Löwel\* and H. Betz. Max-Planck-Institut für Hirnforschung, Deutschordenstrasse 46, 60528 Frankfurt, Germany

Antidepressants block the uptake of serotonin into serotonergic nerve terminals and blood platelets. Binding of the tricyclic antidepressant [ $^3$ H]imipramine to the recombinant rat serotonin transporter SERT1 expressed in HEK293 cells was found to be non-homogeneous. Scatchard analysis and competition experiments revealed the existence of two distinct antidepressant binding sites. At site 1, [ $^3$ H]imipramine binding was strictly sodium-dependent with an apparent  $K_D$  of about 10 nM. In contrast, [ $^3$ H]imipramine binding to site 2 occurred also in the absence of sodium and exhibited a lower affinity. Binding of the non-tricyclic antidepressant [ $^3$ H]citalopram was observed only at site 2. Serotonin competitively inhibited antidepressant binding at both sites.

## 344.17

**MODULATION OF SEROTONIN TRANSPORTER ACTIVITY BY INTERFERON- $\alpha$ .** N. Saito\*, K. Seno, N. Sakai, N. Murakami and S. Honda. Laboratory of Molecular Pharmacology, Biosignal Research Center, Kobe University, Kobe 657, Japan

Molecular cloning revealed that various neurotransmitter transporters have similar structure with 12 putative transmembrane domains. Serotonin transporter (SET), a member of the neurotransmitter transporter family, is known to be a site of action for antidepressants. Functional experiment using mammalian cells expressing SET revealed that various antidepressants inhibit SET activity. To elucidate the molecular mechanism of depression, it is necessary to examine the modulation of SET activity in depression. Interferon(IFN)- $\alpha$  is commonly used as an antiviral drug in case of hepatitis, but the occurrence of depression after the treatment with IFN- $\alpha$  has been clinically attentioned. In the present study, we have examined the effect of IFN- $\alpha$  on the serotonin uptake through SET. The cDNA for SET (kindly provided from R.D. Blakely) was subcloned into pRC/CMV plasmids, and transfected by electroporation into COS-7 cells. Eadie-Hofstee analysis revealed that IFN- $\alpha$  inhibited the serotonin uptake by reducing the  $V_{max}$  without affecting  $K_m$ . This suggests that at least IFN- $\alpha$  does not cause depression by the direct modulation of SET. The molecular mechanism of inhibitory effect of IFN- $\alpha$  on SET was further examined.

## 344.19

**SUBCELLULAR DISTRIBUTION OF A PUTATIVE TRANSPORTER FOR THE TRANSMITTER HISTAMINE IN AN ARTHROPOD PHOTORECEPTOR.** J.R. Morgan and A.E. Stuart\*. Dept. of Physiology, Univ. of North Carolina, Chapel Hill, NC 27599-7545.

Substantial evidence indicates that histamine (HA) is the neurotransmitter at many arthropod photoreceptor (PR) synapses. In barnacle, [ $^3$ H]HA is taken up into PR presynaptic terminals by a presumed transporter specific for HA over 5-hydroxytryptamine (5HT) (Neurosci. Res. Suppl., 1991, 15:S13-S23). We asked whether the PR axons and/or somata also take up [ $^3$ H]HA using light microscopic autoradiography as our assay. Incubations in [ $^3$ H]HA were for 15min in flashing light. Whole cells incubated in [ $^3$ H]HA took it up along their length, although their presynaptic terminals and axons labeled much more densely than their somata. To confine the [ $^3$ H]HA to particular cellular domains, preparations were placed in chambers in which the PR somata, axons or terminals could be separately exposed to [ $^3$ H]HA (20 $\mu$ M). When axons, but not the somata or terminals, were bathed in [ $^3$ H]HA, heavy label was found along the axon length. PR somata incubated in [ $^3$ H]HA labeled only moderately. Addition of 1mM unlabelled HA to the incubation saline blocked uptake in all regions. [ $^3$ H]5HT was not taken up into any cellular domain. [ $^3$ H]HA was not taken up into axons when Na was replaced by choline, indicating that uptake is Na-dependent. We conclude that a HA uptake mechanism, presumably a plasma membrane protein related to the Na-dependent aminergic transporters, exists on the barnacle PR's axons and somata membrane as well as at its presynaptic terminals. Experiments are in progress to determine the basis of quantitative differences in label along the length of the cell. Supported by NIH grant EY03347 to AES.

## 344.16

**SHORT-TERM REGULATION OF GLIAL AND NEURONAL SEROTONIN UPTAKE.** G. M. Anderson\*, F. M. Vaccarino, and L. M. Hall. Child Study Center, Yale Univ. Sch. of Medicine, New Haven, CT 06510.

In previous studies we have demonstrated that 5-20 minute treatment with activators of protein kinase C (PKC) decreases the rate ( $V_{max}$ ) of serotonin (5HT) uptake in human platelets (Anderson and Horne, BBA, 1992). A similar effect has been reported for a rat basophilic cell line, and for human lung endothelium (Miller and Hoffman, JBC, 1994; Myers et al., AJP, 1989). Due to the potential importance of short-term regulation of brain 5HT re-uptake we have examined the short-term (10-12 min) effects of PKC activators on 5HT uptake by primary cultures of rat embryonic neurons and of rat neonatal glia.

Glial cultures were obtained from the brainstem of neonatal (P1-P2) rats and cultured in 10 % fetal calf serum. Neuronal cultures were from the brainstem of embryonic (E13.5) rats. Preliminary experiments have indicated that glial uptake of 5HT is not affected by treatment with phorbol ester (B-TPA, 0.01-1.0  $\mu$ M) or mezerein (0.01-1.0  $\mu$ M). However, it appears that 5HT uptake in cultured rat embryonic neurons may be regulated in a complex fashion by phorbol ester. Low doses of B-TPA (0.01  $\mu$ M) increased 5HT uptake, while high doses (1.0  $\mu$ M) appeared to down-regulate uptake. The dose-response characteristics of the PKC activators with respect to 5HT uptake, as well as the effects of specific serotonergic agents, will be presented and the implications of possible short-term regulation of central 5HT uptake discussed.

## 344.18

**INCREASED SEROTONIN TRANSPORTER GENE EXPRESSION IN RAPHE NEURONS OF THE AGED RAT.** B. Meister\*, H. Johnson and B. Ulfhake. Department of Neuroscience, Karolinska Institute, 171 77 Stockholm, Sweden

The action of serotonin (5-hydroxytryptamine; 5HT) in the nervous system is terminated by rapid Na $^+$ /Cl $^-$ -dependent reaccumulation of the neurotransmitter into the presynaptic nerve terminal via a plasma membrane-bound transporter protein. The serotonin transporter is the major site of action for some antidepressants and drugs of abuse such as cocaine and amphetamine. Recently, cDNAs encoding serotonin transporter protein were cloned. Several studies suggest that the brain serotonergic system undergoes changes with increasing age. Whereas the levels of 5HT in the spinal cord appear unchanged, the levels of 5HIAA, the major metabolite of 5HT, are increased in aged rodents. Serotonergic nerve fibers show morphological signs of degeneration and a decrease in numbers. In the present study we have used *in situ* hybridization to study expression of serotonin transporter mRNA in the descending bulbospinal 5HT-system of adult (2-3 months) and aged (30 months) rats. In adult rats, serotonin transporter mRNA labelled neurons were detected in the nucleus raphe obscurus, pallidus and magnus. In all aged rats, the optical density of the serotonin transporter mRNA labelling of individual cell profiles was increased by 20-30% ( $p < 0.001$ ) when compared with adult rats. Five of the six aged rats studied had various degrees of hindlimb motor dysfunctions. In rats with the most pronounced signs of hindlimb motor dysfunction the number of labelled neurons was increased by 25-75% ( $p < 0.01$ ) when compared with young adult rats. It is concluded that an increased serotonin transporter gene expression is present in the bulbospinal 5HT system of aged animals.

## 345.1

LOCALIZATION OF AN INS 1,3,4,5-P<sub>4</sub> RECEPTOR IN THE RAT CENTRAL NERVOUS SYSTEM BY IN-SITU HYBRIDIZATION.

G. Reiser<sup>1</sup>\*, T.M. Böckers<sup>3</sup>, B.A. Sabel<sup>2</sup>, E. Hülser<sup>1</sup>, M.R. Kreutz<sup>2</sup>, U. of Magdeburg. Inst. of Neurobiochemistry, <sup>2</sup>Medical Psychology, Magdeburg, <sup>3</sup>Inst. of Anatomy, U. of Münster, Münster, F.R.G.

The recently identified 42-kDa high-affinity-InsP<sub>4</sub> receptor is thought to play a crucial role in intracellular Ca<sup>2+</sup> homeostasis [1]. Sequencing peptides of the receptor protein and PCR yielded partial sequence information [2]. Two antisense oligonucleotides (AO) were synthesized based on different sequences of the InsP<sub>4</sub> receptor protein to analyze the cellular expression of the protein in the central nervous system. Northern blot analysis of rat total poly A<sup>+</sup> RNA using these AO revealed a band of approximately 1.3 kb. In-situ hybridization with both AO of rat brain cryostat sections showed a rather ubiquitous distribution of InsP<sub>4</sub>-receptor RNA. A very dense accumulation of silver grains was observed in the hippocampus, septum, cerebellum, cortex and the dorso-lateral geniculate (>80% of all cells positive). In the cerebellum the signal was most prominent in the granular cell layer. Also some cells in the molecular layer were found to be positive. The superior colliculus, most nuclei of the brain stem, the nucleus accumbens and the olfactory bulb exhibited a moderate signal intensity whereas the caudate nucleus, putamen and hypothalamus were weakly labelled. In rat retinal cryostat sections, silver grains were mainly associated with the inner nuclear and the ganglion cell layer. Thus, evidence is presented that prominent InsP<sub>4</sub> receptor gene expression is found in cell types known to be especially vulnerable to excitotoxicity and Ca<sup>2+</sup> overload. ## 345.3

NITRIC OXIDE EVOKES THE RELEASE OF ADENOSINE FROM RAT HIPPOCAMPAL SLICES. R.M. Broad<sup>1</sup> and B.B. Fredholm<sup>2</sup> Dept. of Physiology and Pharmacology, Karolinska Institutet, Stockholm, SWEDEN, 171 77.

Nitric Oxide (NO) has previously been shown to act as a neuromediator in the central nervous system, modulating the release of several classical and excitatory amino acid neurotransmitters. Adenosine is an endogenous inhibitory neuromodulator that has been shown to attenuate the release of many neurotransmitters in the CNS, and therefore may be responsible for the actions of NO. Using an electrically-stimulated, perfused rat hippocampal slice preparation, we have investigated the influence of NO on the release of adenosine. Following preincubation with [<sup>3</sup>H]adenine, electrically-stimulated release of [<sup>3</sup>H] (consisting of ATP and ATP breakdown products) was dramatically enhanced in the presence of the NO donor S-nitroso-N-acetylpenicillamine (SNAP). This effect was concentration dependent, becoming evident at 100 μM SNAP and significant at 1 mM SNAP. At this higher concentration, adenosine release in the presence of the NO donor was increased 80-fold above control. HPLC analysis revealed that the increase in [<sup>3</sup>H] was accompanied by an increase in both [<sup>3</sup>H]adenosine and endogenous adenosine as well as tritiated and endogenous inosine. SNAP also significantly enhanced the release of basal [<sup>3</sup>H]purines and adenosine, although not to the same extent as that of electrically stimulated release. N-acetyl penicillamine (N-AP: 1 mM), the breakdown product of SNAP, did not alter adenosine release. Sodium nitroprusside was considerably less potent than SNAP, evoking only a modest increase in release at the highest concentration used (1 mM). These data directly demonstrate the ability of nitric oxide to evoke the release of adenosine. We propose that NO-mediated adenosine release may be responsible for some of the neuromodulatory effects of NO.

## 345.5

DIFFERENTIAL REGULATION OF TETRAHYDROBIOTERIN SYNTHESIS IN MONOAMINE AND NITRIC OXIDE-PRODUCING NEURONS. M. Hahn<sup>1</sup>, M. Khalil<sup>2</sup>, K. Hirayama<sup>2</sup> and G. Kapatos<sup>2</sup>. Cellular and Clinical Neurobiology Program, Department of Psychiatry and Behavioral Neurosciences, Wayne State University, School of Medicine, Detroit, MI 48201.

Tetrahydrobiopterin (BH<sub>4</sub>) is the essential cofactor for the synthesis of monoamines (MA) and nitric oxide (NO). Although BH<sub>4</sub> synthesis has been localized to MA neurons, no direct evidence exists for BH<sub>4</sub> synthesis by NO-producing neurons. Cultures of postmitotic cerebellar granule neurons offer a model system to study BH<sub>4</sub> synthesis within a homogeneous population of NO-producing neurons. Cerebellar granule neurons maintained in culture were harvested after 1-21 days *in vitro* (DIV) and then assayed for BH<sub>4</sub> content. BH<sub>4</sub> levels increased 10-fold by 7 DIV and then declined slightly after 9 DIV. Following inhibition of its synthesis, BH<sub>4</sub> declined with a *t*<sub>1/2</sub> of approximately 5 hours. Previous work, using primary cultures of the mesencephalon and hypothalamus, has shown that in these MA neurons the *t*<sub>1/2</sub> of BH<sub>4</sub> is 4-5 hours, and that BH<sub>4</sub> synthesis is stimulated by a cAMP-dependent mechanism that is sensitive to inhibitors of transcription or translation. Thus, the developmental profile and the rapid rate of turnover in cerebellar granule neurons prompted us to examine the regulation of BH<sub>4</sub> synthesis. A 24-hour incubation with 8-Bromo-cAMP or IBMX elevated BH<sub>4</sub> levels in cerebellar granule neurons by 30-50%. Unexpectedly, treatment with forskolin decreased BH<sub>4</sub> levels by 25%. In addition, the ability of 8-Bromo-cAMP to stimulate BH<sub>4</sub> levels was not prevented by actinomycin D or cycloheximide, and actinomycin D actually augmented BH<sub>4</sub> levels. In conclusion, the rapid developmental increase in BH<sub>4</sub> content and the turnover rate of BH<sub>4</sub> in cultured cerebellar granule neurons suggest a high degree of regulation of BH<sub>4</sub> synthesis in these postmitotic neurons. In addition, these findings argue that different modes of regulating BH<sub>4</sub> synthesis are found associated with MA and NO neurotransmitter phenotypes. (supported by NIH NS26081)

## 345.2

ACIDIFICATION OF 5-HT-CONTAINING VESICLES INDUCED BY A G-PROTEIN-COUPLED PLASMALEMMAL CALCIUM RECEPTOR. H. Tamir<sup>\*</sup>, K.P. Liu, M. Adlersberg, S.H. Hsiung, & M.D. Gershon, NYS Psych. Inst. & Dept. Anat. & Cell Biol. Columbia Univ. P&S NY, NY.

The neural crest-derived paratollicular (PF) cell secretes 5-HT and calcitonin in response to increased extracellular Ca<sup>2+</sup> ([Ca<sup>2+</sup>]<sub>e</sub>). PF secretory vesicles acidify in response to [Ca<sup>2+</sup>]<sub>e</sub>. This acidification, which drives vesicular uptake of 5-HT, results from the stimulus-induced opening of vesicular Cl<sup>-</sup> channels, which permits Cl<sup>-</sup> to serve as a counterion for H<sup>+</sup> influx. PF cells express a plasmalemmal G protein-coupled receptor (CaR) that binds Ca<sup>2+</sup> and Gd<sup>3+</sup>. We tested the hypothesis that [Ca<sup>2+</sup>]<sub>e</sub> and Gd<sup>3+</sup> activate the CaR, which mediates vesicle acidification. Radioactive Gi and Gq were specifically immunoprecipitated from PF membranes incubated with [Ca<sup>2+</sup>]<sub>e</sub> or Gd<sup>3+</sup> in the presence of <sup>35</sup>S-GTPγS. Gd<sup>3+</sup>-induced both vesicle acidification and [Ca<sup>2+</sup>]<sub>i</sub>; both effects were antagonized by thapsigargin, but only vesicle acidification was blocked by calmodulin inhibitors. PF cells displayed NO synthase (NOS) immunoreactivity. NO donors acidified vesicles, and NOS inhibitors blocked Gd<sup>3+</sup> induced vesicle acidification (but not [Ca<sup>2+</sup>]<sub>i</sub>). Vesicles were acidified by dibutyryl-cGMP and LY83583, a guanylate cyclase inhibitor, antagonized Gd<sup>3+</sup>-induced vesicle acidification. Our observations suggest the following signal transduction pathway: [Ca<sup>2+</sup>]<sub>e</sub> stimulates the CaR → activates Gi and/or Gq → activates PI-PLC → releases Ca<sup>2+</sup> from the ER → [Ca<sup>2+</sup>]<sub>i</sub> complexes with calmodulin to stimulate NOS → NO activates guanylate cyclase → ↑ cGMP → opens the vesicular Cl<sup>-</sup> channel. Supported by grants DK19743 and NS12969.

## 345.4

IMMUNOCYTOCHEMICAL STUDY OF THE DEVELOPMENTAL PROFILE OF NO-RESPONSIVE AND ANF-RESPONSIVE cGMP PRODUCTION IN THE FRONTAL CORTEX OF THE RAT. L.de Vente, M. Markerink-van Ittersum and H.W.M. Steinbusch<sup>\*</sup>. European Graduate School for Neuroscience 'Brain and Behavior', Dept. of Psychiatry and Neuropsychology, University of Limburg, Maastricht, The Netherlands.

We have previously described that ANF stimulated cGMP accumulation in the cerebellum of the rat during maturation was partly inhibited by the NOS-inhibitor L-NAME, suggesting that an NO-activated guanylate cyclase (GNC) participated in the cGMP response (De Vente et al. Eur.J.Neurosci 2:845-862 (1990)). In this study we investigated the localization of cGMP during development in slices of the frontal cortex of the rat, using nitroprusside (SNP) or ANF to stimulate sGNC or pGNC.

In unstimulated slices at day P4 we found cGMP-IR cell somata with extensive ramifications in layer 2 and 3 of the cortex. The number of these cells decreased sharply from day P8 till day P24. cGMP-IR was absent in slices incubated in the presence of L-NAME.

SNP stimulated cGMP production strongly in cell somata and fibers throughout the cortex. The number of cGMP-IR reactive cells decreased whereas the number of varicose fibers increased from day P8 till day P24.

The number of ANF-responsive cells increased from day P4 till day P8, thereafter a decline in the number of cGMP-IR cell somata was observed. At day P24 ANF-responsive, cGMP-producing cells were still present. L-NAME partly inhibited cGMP accumulation.

These results indicate differences in development for (NO responsive) sGNC and (ANF-responsive) pGNC. The data suggest that part of the cGMP-response to ANF stimulation is secondary to the stimulation of NOS. Both forms of the GNC may be present in the same cell.

## 345.6

CIRCADIAN CYCLING OF NITRIC OXIDE SYNTHASE (NOS) ACTIVITY AND CYTOSOLIC PROTEIN CONTENT IN RAT BRAIN. N. A. Ayers, L. Kapas, and J. M. Krueger<sup>\*</sup>. Department of Physiology and Biophysics, University of Tennessee, Memphis, TN 38163.

Nitric oxide (NO) is implicated in sleep maintenance (1) and circadian rhythm regulation (2). To further elucidate the role of NO in sleep regulation and its association with circadian rhythms, we examined the circadian variation of NOS activity in the cerebellum, brain stem, hypothalamus, hippocampus, and "rest of brain" from male Sprague Dawley rats habituated to a 12:12 light dark cycle (lights on at 0900h). Six rats were decapitated at each of the following times: 1500h, 2100h, 0300h, 0900h. NOS activity was measured by the conversion of [<sup>3</sup>H]-arginine to [<sup>3</sup>H]-citrulline (3). Cytosolic protein concentrations were measured by standard bicinchoninic acid method (Pierce, Rockford, IL). There were significant differences of NOS activity among brain regions and in all five brain regions NOS exhibited significant changes with time (p<0.0001). For example at 2100h hypothalamus contained 51.0 ± 6.1 unit NOS activity/g wet tissue whereas the brain stem contained 20.5 ± 2.3 unit/g. Significant differences were also demonstrated between any two time points except between 0300h and 0900h. Basically NOS activity was higher during the dark phase and lower during the light period, e.g., for hypothalamus values at 1500h were 35.4 ± 4.2 compared to 77.9 ± 7.1 unit/g at 0300h. Protein concentrations also demonstrated circadian variation. Overall there was a significant increase in protein content in all brain regions, except "rest of the brain", during the dark period (ANOVA across 4 time points and 5 brain regions; time effect: F(3,96)=17.69, p<0.0001). These results augment the present evidence of NO as a key player in the physiological maintenance of biological rhythms and sleep.

## 345.7

**PROTEIN TYROSINE NITRATION IN THE NERVOUS SYSTEM: A MARKER OF BRAIN NITRIC OXIDE PRODUCTION.** R.R. Trifiletti, A.N. Bandele and E.A. Bolan. Departments of Neurology/Neuroscience and Pediatrics, New York Hospital-Cornell Medical Center, New York, NY 10021

Nitric oxide (NO) appears to be a key mediator of a variety of physiologic and toxic mechanisms in the brain. Based on *in vitro* studies with model proteins, we hypothesized that tyrosine nitration may be an important reaction of NO (or NO-derived peroxynitrite) with protein.

We utilized antibodies directed toward tetranitromethane-treated keyhole limpet hemocyanin to explore whether tyrosine-nitrated proteins (nitroproteins) exist in the rat central nervous system. We demonstrate at least 80 electrophoretically distinct nitroproteins in brain detected by 2-dimensional SDS/PAGE immunoblots. Nitroprotein immunostaining can be abolished by treatment of blots with sodium hydrosulfite, co-incubation with *in vitro* nitrated bovine serum albumin (BSA), 3-nitro-, or 3,5-dinitrotyrosine, but not by co-incubation with native BSA, tyrosine or 4-O-phosphotyrosine. Nitroprotein staining does not simply parallel total protein staining.

Nitroprotein composition of various rat brain regions appear to be similar, with some minor regional and developmental differences noted; staining was also noted in a number of other tissues including liver and kidney.

Newborn rat pups were treated with 25 mg/kg  $N^G$ -nitroarginine, i.p. daily for 10 days, resulting in a marked diminution in nitroprotein immunostaining. Thus, pharmacologic blockade of *de novo* NO synthesis markedly depletes the brain and other tissues of nitroproteins, supporting the hypothesis that nitroproteins are produced by reaction of nitric oxide, or nitric oxide-derived free radicals (such as peroxynitrite) with proteins.

Nitroproteins may represent a useful "integrated" marker of NO production in the brain, and nitroproteins are potential targets for NO action or toxicity

## 345.9

**ACUTE LIVER FAILURE AND HYPERAMMONEMIA INCREASE NITRIC OXIDE SYNTHASE IN MOUSE BRAIN.**

M.D. Norenberg\* and Y. Itzhak. Departments of Pathology and Biochemistry & Molecular Biology, University of Miami School of Medicine and VA Medical Center, Miami, FL 33101.

Hyperammonemia and treatment of animals with thioacetamide (TAA) which causes acute liver failure, both reproduce many of the clinical and morphological features of hepatic encephalopathy (HE). There is evidence that the extracellular concentration of glutamate is elevated in HE and that ammonia impairs the function of the astrocytic glutamate transporter. Since stimulation of glutamate receptors activates the constitutive isoform of nitric oxide synthase (cNOS), we sought to investigate whether cNOS activity was affected in the brain of animals exposed to TAA and ammonium acetate. Mice were administered with either saline, TAA (100 mg/kg; i.p.) or ammonium acetate (5 mmole/kg; i.p.) once a day for 3 days. Mice were sacrificed 24 h after the last injection and the cerebellum was studied. Kinetics of cNOS activity was determined in the 10,000 g supernatant fraction by the conversion of L-[ $^3H$ ]arginine to L-[ $^3H$ ]citrulline. Lineweaver-Burke plots showed a 30-40% increase in  $V_{max}$  and a 40-50% decrease in  $K_m$  values after TAA and ammonium acetate administration. Since the acute addition of ammonium acetate (up to 10 mM) to homogenates of normal cerebellum did not affect cNOS activity *in vitro*, it appears that ammonia acutely has no direct effect on cNOS activity. We suggest that the increase of cNOS in hyperammonemia and TAA-induced acute liver failure may contribute to the pathogenesis of HE. (Supported by NIH grants DK38153 and NS30291, VA and GRECC)

## 345.11

**ROLE OF  $[Ca^{2+}]_i$  IN THE NEURONAL EXPRESSION OF CALCITONIN GENE-RELATED PEPTIDE.** M.D. Christensen\*, S.C. Supowit, B.N. Christensen, D.J. DiPette. The University of Texas Medical Branch at Galveston, Texas 77555

Preliminary whole animal data suggests that an increase in  $Ca^{2+}$  intake results in an increase in CGRP mRNA in dorsal root ganglia (DRG). The effect of  $Ca^{2+}$  supplementation on CGRP message could be the result of changes in  $[Ca^{2+}]_i$ , subsequent to an increase in extracellular  $Ca^{2+}$ . We tested the effect of altering  $Ca^{2+}$  (0.05 to 1.6 mM) on the expression of CGRP in primary cultures of adult rat DRG neurons. In the range of 0.05 to 1 mM  $Ca^{2+}$  there was a large attenuation of basal mRNA. At 1.0 and 2.0 mM, there was a 1.4 and 1.6 times increase in CGRP message respectively. To determine if the effect of  $Ca^{2+}$  on expression of CGRP message was mediated via changes in  $[Ca^{2+}]_i$ , we assessed the effect of (a) increased release from intracellular stores induced by thapsigargin (TH) and (b) increased influx of  $Ca^{2+}$  induced by Bay K 8644. In 1 mM extracellular  $Ca^{2+}$ , neither TH nor Bay K 8644 altered CGRP mRNA although both increased free  $[Ca^{2+}]_i$  (determined by fura). We tested the hypothesis that  $Ca^{2+}$  is an important co-factor for a PKC-dependent second messenger pathway involved in CGRP expression. Activation of PKC by phorbol ester during a TH-induced increase in  $[Ca^{2+}]_i$  enhanced CGRP mRNA by 1.7 times versus PMA alone ( $n=3, p<0.01$ ). The PKC inhibitor bisindolylmaleimide significantly reduced the PMA induced response versus PMA alone ( $n=4, p<0.05$ ). These results support the hypothesis that increased dietary  $Ca^{2+}$  enhances CGRP production through an extracellular  $Ca^{2+}$  dependent increase in mRNA production that involves a PKC-dependent pathway. This pathway could serve as a target for promoting CGRP mRNA production which may be useful for therapeutic intervention by increasing CGRP mRNA and protein production.

## 345.8

**CEREBELLAR NITRIC OXIDE SYNTHASE (NOS) IS EXPRESSED WITHIN GRANULE CELL PATCHES INNERVATED BY SPECIFIC MOSSY FIBER TERMINALS: A DEVELOPMENTAL PROFILE.** J. Li\*, S. Chen\*, R.C.S. Lin\* and S.S. Smith\*. \*Dept of Anatomy and Neurobiology, \*Mental Health Sci., MCP-Hahnemann Univ., Broad and Vine St., Phila. PA 19102

The nicotinamide adenine dinucleotide phosphate diaphorase (NADPH-d) staining technique was utilized as a marker of nitric oxide synthase (NOS) to map NOS expression in developmental and adult rat cerebellum. Schilling et al. (1991) have recently demonstrated that NADPH-d positive granule cells in adult cerebellum were identified within irregular patches. In order to investigate the anatomical significance of this pattern of distribution, we have examined the relationship between NADPH-d stained patches and mossy fiber innervations. Mossy fiber projections were traced using cholera toxin B subunit (CTb) injected into the lateral reticular nuclei (LRN). Then double labelling techniques were implemented to determine a possible co-localization of NADPH-d patches within the granule cell layer innervated by specific mossy fiber terminals. During development, NOS expression in both molecular and granule cell layers increased from post-natal day 5 to peak levels at PND 30, which were maintained in the adult. By PND 19 and in the adult, NADPH-d stained granule cells were visualized as "patches" throughout the cerebellum. Injection of CTb into the ventro-rostral LRN resulted in clustered mossy fiber terminals matched (74-82%) with NADPH-d stained patches. In contrast, CTb injections into other areas of the LRN were not as well overlapped with NADPH-d stained areas. These data suggest that patch-like localizations of NOS are innervated by mossy fiber projections from distinct areas of brainstem in adult cerebellum. It is possible that NOS patches may thus serve as defining specific functional or anatomical zones in adult cerebellum. (Supp. by USAF grant #93-1-0156 to S.S. Smith)

**THE NO-CGMP PATHWAY IN RAT LOCUS COERULEUS: ELECTROPHYSIOLOGICAL AND IMMUNOHISTOCHEMICAL STUDIES.** Z.-Q. Xu, O. Johansson\*, H.W.M. Steinbusch\*, S. Grillner and T. Hökfelt. Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden. \*Dept. of Psychiatry & Neuropsychology, Univ. of Limburg, Maastricht, The Netherlands.

We have previously shown that application of nitric oxide synthase (NOS) inhibitors enhance the excitatory postsynaptic potential in locus coeruleus (LC) neurons, suggesting a functional role for nitric oxide in LC. Now we analyse the activation of guanylate cyclase (GC) by NO in the LC neurons *in vitro* using electrophysiology and immunohistochemistry. Local application of the NO-generating drug SIN-1 resulted in hyperpolarization of 25 out of 52 neurons. In 8 neurons, the action potential threshold was decreased and the firing rate was increased, while the membrane potential was not changed or slightly hyperpolarized. In 3 neurons, SIN-1 induced an increase in firing rate and/or a depolarization, but did not change the action potential threshold. In the remaining 16 neurons, no change in the membrane potential, firing rate or action potential threshold was observed. The SIN-1 derivative molsidomin did not exert any measurable effect in LC neurons ( $n=10$ ). Another NO-generating substance, DEA/NO, mimicked the effects of SIN-1. Prior application of hemoglobin prevented or largely reduced the action of SIN-1. Under voltage-clamp conditions SIN-1 caused an outward current in SIN-1-inhibited cells ( $n=6$ ), while it reduced the amplitude of the evoked excitatory postsynaptic currents. Local application of 8-bromo-cGMP mimicked the action of SIN-1 in SIN-1-inhibited neurons ( $n=6$ ). It caused an increase in firing rate in 3 neurons, in which SIN-1 application increased the firing rate. 8-Bromo-cGMP had no effect on neurons which did not respond to SIN-1. Using immunohistochemical methods, the cGMP levels were measured in the slices with or without SIN-1 stimulation. Exposure to SIN-1 resulted in increased cGMP staining in 40% of the LC neurons. Almost all of these neurons were TH-positive, e.g. noradrenergic neurons. These results suggest that the NO donors are acting through the NO-cGMP pathway to hyperpolarize the membrane potential, by stimulating GC and increasing endogenous levels of cGMP.

## 345.12

**POSSIBLE REGULATION OF PLATELET SEROTONIN UPTAKE BY TYROSINE KINASES.** D.M. Helmeste\* and S.W. Tang. Department of Psychiatry, University of California, Irvine. Irvine, California 92717

Abnormalities in serotonin uptake and calcium mobilization in the platelets of affective disorder patients have fostered speculation regarding underlying mechanisms, but very little is known regarding biochemical pathways that regulate these functions. As phosphorylation is an important step in regulation of protein functions, we investigated the role of tyrosine kinases in the regulation of the serotonin uptake process. Our investigations demonstrate that platelet serotonin uptake appears to be closely regulated by tyrosine kinase activity, since three structurally distinct inhibitors of tyrosine kinase (genistein, herbimycin A and methyl 2,5-dihydroxycinnamate) cause rapid and dramatic reductions in tritiated serotonin uptake. Inhibition of uptake did not correlate with IC50's for inhibition of tritiated imipramine binding, suggesting that uptake inhibition was not due to direct binding of these drugs to the transporter. Investigation of drugs that cause release of intracellular calcium (thapsigargin, thrombin and agents that stimulate protein kinase C) were found by us to also inhibit platelet serotonin uptake. Since tyrosine kinase inhibition is also known to affect calcium fluxes in platelets, we wanted to determine whether changes in mobilizable calcium mediated the effects of genistein on serotonin uptake. Pretreatment of platelets with BAPTA-AM (10 micromolar, 37° C, 30 min.), a chelator of intracellular calcium, did not prevent genistein from inhibiting serotonin uptake. Additionally, measurement of changes in intracellular calcium (fura-2 method) after BAPTA-AM, genistein or methyl 2,5-dihydroxycinnamate administration did not show a clear correlation between reductions in intracellular calcium and effects on serotonin uptake. A more direct mechanism of tyrosine kinase-induced modulation of serotonin uptake (i.e., phosphorylation) is consistent with these results.

## 346.1

**APLYSIA MAP KINASE IS ACTIVATED BY SEROTONIN AND PHOSPHORYLATES TRANSCRIPTION MODULATORS FOR LONG-TERM FACILITATION.** D. Michael<sup>1</sup>\*, D. Bartsch<sup>1</sup>, M. M. Ning<sup>1</sup>, R. Bastón<sup>1</sup>, and R. Seger<sup>2</sup>. <sup>1</sup>HIMI, Ctr. Neurobiol. & Behav., Columbia Univ., NY, NY 10032; <sup>2</sup>Membrane Research & Biophys., Weizmann Inst. Sci., Rehovot, Israel.

Long-term facilitation of the sensory-motor synapse in *Aplysia*, which is induced by serotonin (5-HT), involves the growth of new synaptic connections by sensory cells and the activation of transcription. Two key transcription regulators of long-term facilitation have consensus sequences for phosphorylation by MAP kinase (MAPK): *Aplysia* C/EBP and *Aplysia* CREB-2. This has led us to clone the *Aplysia* gene for MAPK (ApMAPK) and to characterize its activity. The enzyme, which is 85% identical to the mammalian MAPK, was activated by 5-HT (20  $\mu$ M, 30 minutes) in isolated ganglia. Both C/EBP and CREB-2 were phosphorylated effectively by partially purified fractions enriched for ApMAPK. Using "in-gel" kinase assays with C/EBP and CREB-2 as substrates, and using fully purified mammalian MAPK, we found that both proteins were phosphorylated by MAPK. However, MAPK targeted C/EBP more efficiently than CREB-2. Therefore, an additional kinase may be targeting CREB-2. To study the possible link between PKA and MAPK, we applied forskolin to isolated ganglia and found that it enhanced MAPK activity. Thus, PKA and MAPK might coordinately mediate the transcriptional changes responsible for the transition to long-term facilitation. Interestingly, the mammalian C/EBP is phosphorylated in vivo by the MAPK pathway, and this event may lead to its activation (Nakajima et al., PNAS 90:2207, 1993; Kowenz-Leutz, Gen. Dev. 8:2781, 1994). It is therefore possible that ApMAPK directly mediates transcriptional activation in *Aplysia*.

## 346.3

**THE TRANSCRIPTION FACTORS C/EBP $\beta$  AND C/EBP $\delta$  ARE INDUCED BY VIP, PACAP AND NORADRENALINE IN MOUSE CORTICAL ASTROCYTES: A ROLE IN ENERGY METABOLISM REGULATION.** J.-R. Cardinaux\* and P.J. Magistretti. Institut de Physiologie, Université de Lausanne, Lausanne, Switzerland.

We have previously described a transcription-dependent induction of glycogen resynthesis by VIP or noradrenaline (NA) in astrocytes, which is mediated by cAMP (Sorg and Magistretti, 1992, J. Neurosci. 12:4923). Since it has been postulated that the regulation of energy balance in hepatocytes and adipocytes may be channeled at least in part through the CCAAT/enhancer binding protein (C/EBP) family of transcription factors, we tested the hypothesis that C/EBP isoforms could be expressed in astrocytes and their level of expression regulated by VIP, the VIP-related peptide PACAP, or by NA. By Northern and Western blot analysis, we observed that C/EBP $\beta$  and C/EBP $\delta$  mRNA and protein are induced by VIP 10 nM as well as PACAP 1 nM or by NA 100 nM in astrocytes prepared from mouse cerebral cortex. A pharmacological analysis indicated that the induction of C/EBP $\beta$  and - $\delta$  by NA is mediated by  $\beta$ -subtype adrenergic receptors. VIP, PACAP and NA therefore probably increase C/EBP $\beta$  and - $\delta$  expression via the cAMP second-messenger pathway. This is further confirmed by the induction of both proteins by 8-(4Br)-cAMP or forskolin. Induction of C/EBP $\beta$  and - $\delta$  mRNA by VIP occurs in the presence of a protein synthesis inhibitor. Thus, *c/ebp $\beta$*  and *c/ebp $\delta$*  can be considered as cAMP-inducible immediate-early genes in mouse astrocytes. Overexpression of C/EBP $\delta$  by transient transfection of astrocytes with an expression vector containing its cDNA sequence results in a marked increase of glycogen over basal levels ( $227 \pm 3$  vs  $104 \pm 7$  nmol of glycogen/mg of protein). These results suggest that C/EBP $\delta$  may regulate gene expression of energy metabolism-related enzymes in astrocytes.

## 346.5

**EXPRESSION OF A CORTEX SPECIFIC PKA ISOFORM CONFERS ON CEREBELLAR GRANULE CELLS HIGH SENSITIVITY TO THE cAMP-INDUCED GENE TRANSCRIPTION.** M. Paolillo\*, C. Ventura, G. Schettini and V.E. Avvedimento. Dipartimento di Neuroscienze, Dipartimento di Biologia e Patologia Cellulare e Molecolare, II Facoltà di Medicina, 80131 Napoli, Casa di Cura "Villa Chiarugi", 84014 Nocera Inf. ITALY.

The subunits composition of PKA varies greatly in the CNS. The expression of the regulatory subunit RII $\beta$  and of the relative anchor protein AKAP is almost undetectable in the brainstem and cerebellum while is maximal in the cortex. Cortical neurons show a poor dissociation of PKA cytoplasmic holoenzyme following a cAMP pulse and an efficient accumulation of catalytic subunit in the nucleus. On the other hand, cerebellar granule cells show a marked holoenzyme dissociation after cAMP stimulation while nuclear translocation is almost undetectable. The functional correlate of the catalytic subunit nuclear translocation is the phosphorylation of CREB (cAMP responsive element binding protein) which is strong in cortical neurons and undetectable in cerebellar granule cells. To verify whether the different nuclear responses to cAMP in these areas could be due to the expression of different PKA isoforms, we reconstituted the cortical PKA in cerebellar granule cells by microinjecting the cells with the expression vectors carrying RII $\beta$ , AKAP, PKA catalytic subunit and a reporter gene (lac-Z) under the control of a cAMP responsive element (CRE). The injection of RII $\beta$  and AKAP genes efficiently stimulated the cAMP-induced expression of lac-Z gene. RII $\beta$  alone was able to slightly stimulate lac-Z transcription, AKAP and catalytic subunit alone or in combination were ineffective. These data indicate that the expression of the PKA regulatory subunit RII $\beta$  and of the anchor protein AKAP can amplify cAMP signals to the nucleus and dictate different responses to cAMP in the brain.

## 346.2

**REGULATION BY VIP AND NORADRENALINE (NA) OF GLYCOGEN SYNTHASE mRNA EXPRESSION.**

G. Pellegrini, J.-L. Martin\* and P.J. Magistretti. Institut de Physiologie, Université de Lausanne, Lausanne, Switzerland.

Glycogen is the single largest energy reserve of the brain. Brain glycogen is predominantly localized in astrocytes and its metabolism is under the control of two principal enzymes: glycogen synthase (GlyS) and glycogen phosphorylase (GlyP). VIP and NA promote two opposed cAMP-dependent and temporally regulated actions on glycogen levels in primary cultures of cortical astrocytes: glycogenolysis within a few minutes (Sorg and Magistretti, (1991) Brain Res. 563:227-233), and a subsequent resynthesis of glycogen, resulting within 8-10 hours in a 6-10 fold increase in glycogen content (Sorg and Magistretti (1992) J. Neurosci. 12: 4923-4931). The long-term action of VIP and NA is sensitive to protein synthesis inhibitors, suggesting that the synthesis of one or more enzymes involved in glycogen metabolism are modulated by VIP and NA. Two potential candidates for this regulation are GlyS and GlyP. We have cloned and characterized the astrocyte GlyS isozyme. The 3.5 kb clone isolated contains an open reading frame of 2214 bp encoding a protein of 737 amino acids. The cellular distribution of the GlyS mRNA, studied by Northern blot, shows the presence of a single transcript of 4 kb in cultures of astrocytes and, to a lesser degree, of neurons. As revealed by Northern blot analysis, VIP 1  $\mu$ M and NA 100  $\mu$ M increase the level of GlyS mRNA within 8-10 hours, while GlyP mRNA levels were not affected by VIP or NA. The same treatment in the cortical neuron cultures did not modulate the levels of GlyS mRNA. This study indicates that VIP and NA, by increasing cAMP levels, simultaneously trigger a short-term effect (glycogenolysis), as well as a delayed one that is transcriptionally regulated (glycogen resynthesis). This long-term effect ensures that sufficient substrate is available for the continued expression of the short-term action.

## 346.4

**MOLECULAR MECHANISMS OF cAMP RESPONSE ELEMENT BINDING PROTEIN (CREB) REGULATION IN A LOCUS COERULEUS-LIKE (CATH.a) CELL LINE.** K.L. Widnell\*, P.A. Iredale, R.S. Duman, and E.J. Nestler. Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Studies of the regulation of gene expression by the cAMP intracellular signaling pathway have focused on CREB and related proteins. It is generally believed that the CREB gene is constitutively expressed and not subject to regulation. However, in the course of investigating effects of chronic morphine on cAMP pathway proteins in the locus coeruleus (LC), a brain region important for physical aspects of opiate addiction, we observed that levels of CREB immunoreactivity and CRE binding are increased by chronic morphine administration (Widnell et al. (1994) PNAS 91:10947). CREB expression is also subject to dynamic regulation by the cAMP pathway in an LC-like (CATH.a) cell line. We are currently investigating the molecular mechanisms underlying cAMP regulation of CREB expression in the LC-like cell line using forskolin, an activator of adenylyl cyclase. These studies demonstrate that the forskolin-induced decrease in CREB message depends upon protein synthesis. Furthermore, a decrease in the rate of CREB gene transcription, as assessed by nuclear run-on assays, could account for the forskolin-induced decrease in CREB message. Interestingly, while forskolin results in a long-term down-regulation of CREB protein, there is a transient increase in CREB immunoreactivity that occurs in the absence of any observed increase in CREB mRNA levels. The observed up-regulation of CREB protein is not dependent upon protein synthesis, and may represent a phosphorylation-induced stabilization of CREB protein. These studies, which will delineate the mechanisms controlling CREB expression, should contribute to our understanding of the precise molecular steps by which morphine produces addiction via actions on specific target brain regions.

## 346.6

**Differential display PCR of mRNA expression after sustained expression of FOS in neurons.** McPhie, D.L.\*1, Lim, F.L. 2, Geller, A.I. 2, and Neve R.L.1 (1. Laboratory of Molecular Neurogenetics, McLean Hospital, Belmont, MA 02178 and 2. Laboratory of Endocrinology Childrens Hospital, Boston MA. 02115) Numerous models of neuronal plasticity feature alterations in expression of the immediate early gene c-fos. However, the significance of these fos expression changes is not known. Sustained increases in FOS protein levels in neurons and resultant increases in neurotransmitter release, can be achieved by infecting primary rat cortical neurons in culture with a Herpes Simplex Virus One (HSV-1) vector expressing recombinant Fos (Lim et al., this meeting). To study the downstream genetic changes accompanying the experimentally-induced long-term increases in neuronal Fos expression, we used differential-display reverse transcription PCR (DDRT-PCR) to examine the mRNA populations in neurons infected with HSV1 or with HSV expressing a non-functional Fos protein. Total RNA was prepared and a subset of the expressed mRNA's were reverse transcribed using an anchored T<sub>12</sub>VN (V=A, G, or C; N= A, G, T, or C). CDNAs were then amplified by PCR using random 10mers after which the PCR products were examined on 5% denaturing polyacrylamide gels. At least 9 PCR fragments were differentially expressed. The bands were isolated, reamplified and cloned into vectors. These probes will be used to screen RNA blots to confirm differential expression after which they will be sequenced and characterized functionally. Supported by NIH Grant HD24236.

## 346.7

ENHANCED DNA BINDING ACTIVITY OF AP-1 BY THE ANTICONVULSIVE AND ANTIMANIC AGENT VALPROIC ACID IN VITRO. G. Chen\*, W. Z. Potter, D. B. Hawver and H. K. Manji. Dept. of Psychiatry and Behavioral Neurosciences, Wayne State University School of Medicine, Detroit, MI 48201, and Sec. Clin. Pharmacol. NIMH, NIH, Bethesda, MD 20892.

Despite extensive research, the mechanisms by which lithium, carbamazepine and valproic acid (VPA) produce their clinical antimanic actions are still unclear. Recently, we found that chronic, but not acute, VPA treatment has marked effects on the cAMP second messenger generating system, protein kinase C (PKC) isozymes, and PKC's substrate MARCKS in vitro. These effects of VPA are similar to the effects of lithium which we and other investigators have observed both in vitro and in vivo. Since both VPA's biochemical effects and clinical antimanic action require chronic administration, we investigated the possible role of VPA in the modulation of gene expression. DNA binding activities of activator protein 1 (AP-1) and cAMP responsive element binding protein (CREB), which are regulated by PKC and PKA catalyzed phosphorylations, were studied in acute (hours) and chronic (days) VPA treated rat C6 glioma cells. VPA did not affect CREB DNA binding activity, but concentration- and time-dependently increased AP-1 DNA binding activity. The activity was raised at 2 hours (the shortest time examined) and remained high after 6 days (the longest time used) of continuing VPA treatment. VPA also enhanced AP-1 DNA binding activity in human neuroblastoma SH-SY5Y cells. Addition of VPA to the binding mixture had no effect on the activity. Co-treatment of cells with either bisindolymaleimide or chelerythrine, the PKC inhibitors, did not block the increasing effects of VPA. VPA had no effects on protein phosphatase (PP) 1 or PP2A activity in vitro. The mechanism underlying VPA's effect on AP-1 DNA binding activity is unclear, but currently under investigation. The present study provides evidence for the modulation of gene expression by antimanic agents, which may be one of the reasons for late onset of clinical antimanic action.

## 346.9

REPEATED AMPHETAMINE ADMINISTRATION INDUCES A PROLONGED AUGMENTATION OF PHOSPHORYLATED-CREB AND FOS-RELATED ANTIGEN IMMUNOREACTIVITY IN RAT STRIATUM. J.N. Simpson<sup>1</sup>, J.Q. Wang and J.F. McGinty. Dept. Anatomy and Cell Biology, School of Medicine, East Carolina University, Greenville, NC 27858-4354.

Semi-quantitative immunocytochemistry was used to investigate the levels of CREB-, phosphorylated-CREB (P-CREB)-, Fos-, and Fos-related antigen (FRA)-immunoreactivity (IR) in the striatum of rats after acute or repeated amphetamine (AMPH) administration. Rats were perfused 20 min (P-CREB) or 2 h (CREB, P-CREB, Fos, FRA) after a single injection (5 mg/kg, i.p.) or 5 daily injections of AMPH. The latency to onset of stereotypical behaviors was significantly reduced in rats exposed to repeated amphetamine as compared to acute AMPH, indicating development of behavioral sensitization. CREB-IR was not altered in the dorsal or ventral striatum following acute or repeated AMPH. P-CREB-IR was significantly induced 20 min, but not 2 h, following acute AMPH whereas a significant induction of P-CREB-IR was found 20 min and 2 h after repeated AMPH in the dorsal striatum only. Fos-IR was significantly induced in the dorsal striatum following acute and repeated AMPH. Fos-IR in the core of the nucleus accumbens (NAC) was significantly increased following repeated AMPH only. Acute AMPH induced, and repeated AMPH further augmented, FRA-IR in the dorsal striatum while not affecting FRA-IR in the NAC. These data demonstrate that repeated AMPH administration results in a prolonged induction of P-CREB- and FRA-IR in the dorsal striatum, indicating that alterations in striatal gene expression associated with the development of behavioral sensitization may be mediated, in part, by these transcription factors. Supported by DA 05470 (JNS) and DA 03982 (JFM).

## 346.11

NEURONAL LOCALIZATION OF THE *dbl* GENE PRODUCT (*Dbf*)

Joseph A. Haney\*, Robert A. Forbes, Shiva Srivastava\*\*, and Ajay Verma. Depts. of Neurology, Surgery\*\* and Anesthesiology, Uniformed Services Univ. of the Health Sciences, Bethesda, Maryland 20814

The *dbl* oncogene was initially identified from a human diffuse B-cell lymphoma DNA in NIH3T3 transfection assay. Its normal cellular homologue codes for a 115 kD protein which is known to have GDP/GTP exchange protein activity towards the *rho* family small GTP-binding protein members including *RhoA* and *Cdc42HS*. Several proteins with *dbl* homology regions have been identified and some of these are enriched in brain. We have used a polyclonal rabbit antibody generated against a peptide sequence (residues 818-831) found uniquely in mouse *Dbf* and outside of the *dbl* homology region to map the immunohistochemical distribution of *Dbf* in rat brain. This antibody specifically recognized *Dbf* in transformed NIH3T3 fibroblasts stably overexpressing this protein. Rat brain *Dbf* immunoreactivity was confined to neurons with high level of expression in hippocampus, cortex and brainstem. Cerebellar neurons, however, showed minimal immunoreactivity. Neuronal *Dbf* staining was eliminated by competition with the *Dbf* specific peptide (818-831). Western blots of hippocampal extracts identified a 115 kD band which was eliminated by *Dbf* peptide competition. Whole body sections of neonatal rat pups also showed prominent neuronal immunoreactivity. The high level of expression and regional heterogeneity of *Dbf* immunoreactivity in rat brain suggests a role for this protein in neuronal signalling pathways.

## 346.8

CONVULSANT AGENTS INDUCE c-FOS EXPRESSION IN PRIMARY CORTICAL NEURONS THROUGH DIFFERENT PATHWAYS. J.M. Tusell<sup>1</sup>, S. Barrón\* and J. Serratos\*. Depts. Neurochem<sup>1</sup> and Pharmacol. & Toxicol. CID-CSIC. Barcelona. Spain.

In neurons, an increase in calcium levels after an external signal represents the initial step in many signalling pathways. The goal of this work has been to determine the possible role of L-type calcium voltage sensitive channels (VSCC) of the calcium binding protein, calmodulin (CaM), in the induction of c-fos expression following administration of different convulsant drugs. These drugs act at the level of L-type VSCC (BAY K 8644 (BK)) and  $\gamma$ -hexachlorocyclohexane ( $\gamma$ -HCH). NMDA and non NMDA receptors (NMDA and kainic acid) and at the level of the GABAergic system (picrotoxinin (PTX) and pentylenetetrazole (PTZ)). The inhibition of c-fos induction elicited by these drugs was studied using the L-Type VSCC antagonist, nifedipine, and the CaM antagonist W-7. We also determined the inhibitory effect of the nervous system depressor  $\delta$ -hexachlorocyclohexane ( $\delta$ -HCH). Primary cortical neurons were obtained from rat embryos (E17). c-fos protein and mRNA were detected by means of immunocytochemistry and Northern Blot. Approximately 30% of the neurons displayed c-fos nuclear immunoreactivity under basal condition. This value was increased to about 55% after treatment with any convulsant used. Nifedipine and  $\delta$ -HCH acted in a similar way reducing c-fos induction due to BK,  $\gamma$ -HCH and PTZ to basal or below levels. However, they were not able to inhibit the proto-oncogene induction elicited by PTX. W-7 abolished c-fos induction elicited by BK,  $\gamma$ -HCH, PTZ and kainic acid. The CaM antagonist did not affect NMDA or PTX-mediated increases in c-fos expression in neurons. The results obtained with  $\delta$ -HCH, nifedipine and W-7 suggest that PTX and NMDA activate c-fos expression through calcium-dependent intracellular mechanisms, that are different from those activated by the other convulsant, which at least in part, act via L-type VSCC and CaM.

## 346.10

A NEW GTPase-ACTIVATING PROTEIN GENE FAMILY IN BRAIN. H. Baba<sup>1</sup>, B. Fuss<sup>2</sup>, P. Puollet<sup>3</sup>, J. Urano<sup>3</sup>, F. Tamanoi<sup>3</sup> and W.B. Macklin<sup>2\*</sup>.

<sup>1</sup>Natl. Inst. Physiol. Sci., Okazaki, Japan. <sup>2</sup>Ment. Retard. Res. Ctr. and

<sup>3</sup>Dept. Microbiol. Moll. Genet., UCLA, Los Angeles, CA 90024

GAPIII is a newly identified GTPase-activating protein (GAP), which is a class of proteins that acts as negative regulators of p21ras. Amino acid sequence studies suggest that GAPIII and another known mammalian GAP, Gap1<sup>m</sup>, are members of a new gene family, which may be the mammalian homologs of Drosophila Gap1. This protein family has several functional protein domains such as the Ca<sup>2+</sup>-dependent phospholipid-binding domain (C2), the Pleckstrin homology domain (PH), Bruton's tyrosine kinase domain (btk) and the GAP-related domain (GRD). The protein structures of GAPIII and Gap1<sup>m</sup> are unique from other mammalian GAPs, such as p120GAP and neurofibromin, which suggests that there may be unique mechanisms by which these proteins interact with cell surface receptors and p21ras. To investigate the functional elements of GAPIII, constructs containing different segments of GAPIII were transformed into *ira1* mutant yeast. In such yeast cells, which lack their own GAP, IRA1 protein, GAPIII was tested for complementation of the missing GAP activity. Constructs containing either the GRD domain alone or the GRD domain with the full PH/btk domain complement the *ira* mutation and induce down-regulation of ras proteins, whereas constructs containing the GRD domain and the PH/btk domain with no btk domain have only a weak ability to complement this mutant. These data suggest that the btk domain may have some influence on the ability of the GRD domain of GAPIII to activate ras GTPase in yeast. Since GAPIII is expressed mainly in the adult brain, especially in neurons, it may play a significant role for ras-mediated signal transduction in mature neurons. (Supported by the Natl. Mult. Scler. Soc.)

ORAL CONTRACEPTIVE USERS SHOW BLUNTED FREE CORTISOL RESPONSES TO PSYCHOLOGICAL AND PHYSICAL STRESS. C. Kirschbaum, K.-M. Pirke and D.H. Hellhammer\*, Center for Psychobiology and Psychosomatic Research, University of Trier, D-54286 Trier, Germany.

In three studies the effect of oral contraceptives on free cortisol responsiveness was investigated. In the first two studies, saliva cortisol responses to the psychological stress of public speaking and mental arithmetic were investigated in women using oral contraceptives (OC; n=28) and in control women (n=29). While no significant differences in baseline levels were observed, altered adrenocortical responses were found in OC users. These women showed significantly attenuated cortisol responses to the experimental stressor in both studies, with peak cortisol levels only slightly elevated above baseline levels. These differences could not be attributed to affective responses as indicated in ratings on visual analogue scales assessing subjective stress responses (Study 2). A comparison between control women and men (n=19) again revealed the previously reported result of larger cortisol responses to psychological stress in males. In a third study, free cortisol, heart rate and affective responses were studied in 31 women using oral contraceptives (OC) and 22 control women performing bicycle ergometry until exhaustion. While OC users and control women showed significant increases in both free cortisol and heart rate, OC users had significantly attenuated cortisol responses. Individual work load, peak heart rates and affective responses were similar in both groups. Menstrual or pill cycle phase did not affect any of the parameters studied. It is concluded that the use of OC may interfere with the adrenocortical response to psychological and physical stress and should therefore be viewed as an important intervening variable. While it appears that differences at a supra-adrenal site is responsible for the observed cortisol hyporesponsiveness in OC users, the physiological mechanisms remain to be elucidated.

## 347.3

GLUCOCORTICOIDS REGULATE SYNTHESIS OF HEAT-INDUCIBLE PROTEINS IN RAT BRAIN. C.S. Barr\* and L.A. Dokas, Departments of Neurology and Biochemistry/Molecular Biology, Medical College of Ohio, Toledo, OH 43699-0008.

Age-related increases in the secretion of glucocorticoids are thought to be involved in the reduction in cognition which is associated with aging, dementia, and other neuropathologies involving damage to the limbic system. It is thought that corticosteroids place neurons in "endangerment", thus rendering them susceptible to various metabolic insults, with a progressive reduction in the number in hippocampal neurons concomitant with aging. Using heat shock of rat brain slices as a model for cellular insult, we have found the synthesis of several proteins to be altered 4 hr following a single corticosterone injection: a 25 kDa protein is down-regulated in the synaptosomal-mitochondrial fraction of the hippocampus; a 47 kDa protein is down-regulated in the hippocampus, cortex and cerebellum; and a 28kDa, cytosolic protein is up-regulated in the cerebellum. Since these effects are mimicked by the administration of RU-23862, a specific GR or Type II receptor agonist, it is likely that the regulation of these proteins occurs predominantly in the presence of elevated titers of circulating glucocorticoids. It is, therefore, possible that these corticosteroid-sensitive proteins are molecular markers for the endangered state which is thought to occur in the senescent brain as a result of increases in the cumulative exposure to glucocorticoids.

## 347.5

CHRONIC GABAERGIC DYSFUNCTION IN THE DORSOMEDIAL HYPOTHALAMUS DISRUPTS THE NORMAL DIURNAL RHYTHM OF CORTICOSTERONE SECRETION IN THE RAT. S.R. Keim\* and A. Shekhar, Dept. of Psychiatry, Indiana University Medical Center, Indianapolis, Indiana 46202.

Previous studies have demonstrated that acute GABA<sub>A</sub> receptor blockade in the dorsomedial hypothalamus (DMH) of rats elicits a panic-like response and significant increases in plasma ACTH and corticosterone (CS) levels. It has been suggested that the suprachiasmatic nucleus may regulate the circadian rhythm of corticotrophin-releasing hormone secretion by the paraventricular nucleus via a pathway that has an intermediate synapse within the DMH (Buijs et al., *J. Comp. Neurol.* 335:42-54, 1993). Therefore, the present study was conducted to test if chronic dysfunction of GABA inhibition within the DMH would disrupt the normal circadian rhythm of CS secretion. At baseline, plasma samples for CS measurement were taken at 8.00 A.M., 12.00 Noon, and 4.00 PM in a group of rats fitted with femoral arterial catheters. These rats were then implanted with stereotactically placed chronic Alzet mini-pumps filled with the GABA synthesis inhibitor, L-Allylglycine (L-AG) into the DMH. After 4 days of chronic L-AG infusion into the DMH, plasma CS samples were once again obtained at above time intervals. The levels of plasma CS were significantly increased at times 8.00 A.M. and 4.00 P.M. compared to baseline, showing a clear disruption of CS diurnal rhythm. (Supported by MH 45362)

## 347.2

NON-GENOMIC MECHANISM OF GLUCOCORTICOID INHIBITION ON ADRENOCORTICOTROPHIN EXPRESSION: POSSIBLE INVOLVEMENT OF PERTUSSIS TOXIN-SENSITIVE GTP-BINDING PROTEIN.

Y. Iwasaki, Y. Oiso, Y. Aoki, H. Nagasaki, A. Oka\* and H. Saito, First Department of Internal Medicine, Nagoya University School of Medicine, Nagoya 466; Department of Pediatrics, University of Tokyo, Tokyo 113, Japan.

We investigated the cellular, especially non-genomic mechanism of glucocorticoid negative feedback on corticotroph cells using the AtT-20 mouse corticotroph tumor cell line. Dexamethasone (DEX; 100 nM) potently suppressed forskolin-induced cAMP increase / ACTH release, and proopiomelanocortin gene expression. When *de novo* protein synthesis was blocked by cycloheximide (CHX; 100 µM), DEX still suppressed cAMP increase and ACTH secretion, although less potently than without CHX. The inhibition may be at the level of adenylate cyclase and distal to cAMP generation. Interestingly, pre-treatment of the cells with pertussis toxin (PTX; 50 ng/ml) abolished the cAMP decrease and partially eliminated ACTH inhibition by DEX, and combined treatment with CHX and PTX completely abolished the DEX suppression of ACTH secretion. These results suggest that non-genomic as well as genomic mechanisms are involved in the glucocorticoid negative regulation of adrenocorticotropin expression, and PTX-sensitive GTP-binding protein (G-protein) might, at least partly, participate in the non-genomic effect. This may be the first report showing the functional involvement of G-protein in some of the biological effects of glucocorticoid hormone.

## 347.4

ANDROGENS DECREASE GLUCOCORTICOID RECEPTOR mRNA IN THE CA1 REGION OF THE RAT HIPPOCAMPUS. J.E. Kerr\*, G. Hejna, S.G. Beck, R.J. Handa, Depts. of Pharmacol. and Cell Biol., Neurobiol., and Anat. Loyola Univ. Chicago, Stritch School of Medicine, Maywood, IL 60153.

Androgen, mineralocorticoid and glucocorticoid receptors (AR, MR and GR) are ligand-activated transcription factors that influence gene expression in CNS neurons. High levels of expression of AR, MR and GR mRNA have been found in the CA1 region of the rat hippocampus and suggest that cross-talk between these receptors could occur at some level of transcription. To begin to investigate this hypothesis, we examined the regulation MR, GR and AR mRNA expression in the rat hippocampus by both androgens and glucocorticoids. Three month old male Sprague-Dawley rats were either castrated for three weeks, castrated and immediately implanted with two Silastic capsules filled with dihydrotestosterone propionate (DHT), or left gonadally intact. Four days prior to sacrifice, these animals were either adrenalectomized (ADX'd), or sham operated. GR, MR and AR mRNA levels were measured in the CA1, CA3 and dentate gyrus (DG) cell regions using *in situ* hybridization. In the CA1 region, DHT treatment decreased GR mRNA levels to 69 percent of levels found in gonadally intact rats ( $p < 0.01$ ) and prevented the ADX-induced increases in GR mRNA observed in the gonadally intact and castrated animals ( $p < 0.01$ ). No changes in were observed in the DG, where AR expression is low. ADX also increased MR mRNA expression in the CA1 region, and there was no effect of DHT on MR mRNA levels. AR mRNA levels in the CA1 region were unchanged across all treatment groups. *In vitro* binding studies revealed almost complete nuclear occupancy of hippocampal AR in DHT-treated castrates and no appreciable binding of DHT to hippocampal GRs ( $K_d > 1000$  nM) which suggest that androgen regulation of GR mRNA is occurring through AR binding. These data demonstrate an interaction between AR and GR which may prove critical in hippocampal development, memory and cell survival.

## 347.6

FEEDBACK INHIBITION OF cAMP-INDUCED POMC GENE TRANSCRIPTION BY GLUCOCORTICOID: VARIATION IN cFOS PHOSPHORYLATION

A.-L. Routillier\* and J.L. Roberts, Fishberg Research Center for Neurobiology, Mount Sinai Medical Center, NY, NY 10029.

In the anterior pituitary, the POMC gene is transcriptionally activated by Corticotropin Releasing Hormone (CRH), whose receptors are positively coupled to adenylate cyclase, and down-regulated by glucocorticoids. Using a corticotroph-derived cell line, the AtT20 cells, we have previously shown that CRH induces cFos, thus leading to the activation of POMC gene transcription through an AP1 site within the first exon. Several regulatory interactions between the AP1 and the glucocorticoid receptor (GR) have been reported and we addressed these interactions in AtT20 cells.

Our results show that overexpression of cFos counteracts the inhibitory effect of dexamethasone on CRH-induced POMC gene transcription. This inhibition is mediated at least in part through GR's ability to block AP1 function at the exonic site. Moreover, co-treatment of AtT20 cells by CRH and dexamethasone strongly reduces the AP1 binding activity. In an attempt to decipher the molecular mechanisms by which this interaction occurs, we investigated whether it is dependent on the phosphorylation status of the cFos protein. We show that cFos is rapidly phosphorylated in response to CRH. Interestingly, co-treatment of the cells with CRH and dexamethasone significantly reduced the phosphorylation of cFos. 2D tryptic map analysis of phosphorylated cFos revealed a different pattern when dexamethasone is co-applied with CRH.

We propose that the interaction of the GR with cFos masks a functional phosphorylation site, resulting in the inactivation of AP1 activity. cFos mutation analyses are currently under investigation in order to localize these phosphorylation sites.

## 347.7

**DIAZEPAM'S INHIBITORY EFFECT ON STRESS-INDUCED CORTICOSTERONE LEVELS IS INFLUENCED BY PRIOR EXPOSURE TO REPEATED RESTRAINT AND DIAZEPAM.** B.A. Kalman\*, M. A. Cole, P.J. Kim, R.L. Spencer. Behavioral Neuroscience Div., Dept. of Psychology, University of Colo., Boulder, CO 80309.

Prior research has shown diazepam acts as a potent anxiolytic in stressful contexts and, paradoxically, as a stimulator of HPA axis activity. We have examined the effects of diazepam on plasma corticosterone (CORT) levels in the rat utilizing a repeated restraint paradigm. Consistent with most literature, it was revealed that diazepam administered IP (1.5, 3.0, or 6.0 mg/kg) 1 hr prior to restraint increased non-stress, baseline plasma CORT levels in a dose-dependent fashion. CORT levels of diazepam-injected rats did not differ from the stress levels of controls during the 1 hr restraint-stress procedure. However, diazepam was able to dramatically attenuate the stress-induced increase in CORT when preceded by 4 days of repeated diazepam injections combined with daily restraint. This decrease was greater than that produced by 4 days of prior restraint stress alone (i.e., habituation to a repeated stressor) and was apparent even when we failed to observe significant habituation in repeatedly restrained controls. Furthermore, diazepam by itself given once a day for 4 consecutive days prior to administering diazepam in conjunction with restraint was not sufficient to decrease stress-induced levels of CORT. These results indicate that the inhibitory effect of diazepam on the HPA axis stress response is not observed initially but is apparent following exposure to repeated restraint and diazepam. Supported by the UROP, JFDA and GIA programs of the Univ. of Colorado.

## 347.9

**Glucocorticoids block the compensatory release of inhibitory neurotransmitters following an excitotoxic insult to the hippocampus.** B. Dash, H. Maecker, A. Smith, F. Weiss, A. Ngai, B. Winn, B. Sapolsky. Dept. Biol. Sciences, Stanford Univ., Stanford, CA 94305-5020; Dept. Neuropharm., The Scripps Research Institute, La Jolla, CA 92037; Dept. Neurol. Surgery, Univ. Washington School of Medicine, Seattle, WA. 98195

Glucocorticoids (GCs), the adrenal steroid hormones released during stress, can endanger hippocampal neurons, impairing their capacity to survive excitotoxic insults. Recent data suggest a mechanism for this endangerment. GCs inhibit glucose uptake into hippocampal neurons and, consequently, such cells are less capable of carrying out the costly tasks of controlling concentrations of synaptic glutamate and of free cytosolic calcium during excitotoxic insults; the result is a greater likelihood of the neuron dying. We now report an additional way in which GCs might compromise hippocampal neurons during an insult. A number of events have been characterized in neurons that can be viewed as protective, compensatory responses to excitotoxic insults. Among them are the release of inhibitory neurotransmitters such as GABA, adenosine and taurine. We observe that GCs block this protective response. Rats were adrenalectomized and maintained either GC-free or exposed to constant GC concentrations in the upper physiological range. Three days later, microdialysis of the hippocampal CA3 cell field was carried out. Excitotoxic seizures were induced with kainic acid in the perfusate; extracellular accumulation of GABA, adenosine and taurine was measured by HPLC. Seizures triggered a significant accumulation of all three neurotransmitters in adrenalectomized rats; GCs blocked the GABA and adenosine responses. Thus, GCs may exacerbate excitotoxic insults by preventing the protective release of these inhibitory neurotransmitters.

## 347.11

**FOOD RESTRICTION ALTERS CIRCADIAN VARIATION OF HIPPOCAMPAL CORTICOSTEROID RECEPTOR BUT NOT 5-HT<sub>2C</sub> RECEPTOR mRNA EXPRESSION.** M.C. Holmes\*, K.L. French and J.R. Seckl. Dept. of Medicine, University of Edinburgh, Western General Hospital, Edinburgh EH4 2XU, Scotland, UK.

Animals housed in pairs, in a light controlled room (lights on 07.00-19.00h) and given food and water *ad libitum* exhibited a monophasic rhythm in plasma corticosterone levels, glucocorticoid receptor (GR) and 5-HT<sub>2C</sub> receptor mRNA expression in the hippocampus. To determine factors involved in the circadian regulation of these receptor transcripts, a set of animals were only allowed access to food for 2h (10.00-12.00h). The rats were entrained to food restriction for 3 weeks and showed a biphasic rhythm in plasma corticosterone levels (peaking at 08.00 and 20.00h). The restriction of food to the daylight hours produced a shift in normal feeding and behaviour, both thought to be mediated by 5-HT<sub>2C</sub> receptors. However, the diurnal variation of 5-HT<sub>2C</sub> mRNA expression in the ventral hippocampus (vCA1 and subiculum) was not altered by food restriction, suggesting that 5-HT<sub>2C</sub> receptor mRNA is regulated by light-dark cues rather than feeding behaviour. GR mRNA expression was altered in the food-restricted animals to give a biphasic rhythm similar to the rhythm in plasma corticosterone but displaced by 4h. In animals with no diurnal variation of plasma corticosterone (adrenalectomized + corticosterone pellet s.c.) the rhythm in both GR and 5-HT<sub>2C</sub> receptor mRNA expression was abolished. Hence, we suggest that while circadian variations of hippocampal GR mRNA expression are closely regulated by plasma glucocorticoid levels, 5-HT<sub>2C</sub> receptor mRNA expression is regulated by glucocorticoid levels in conjunction with other factors associated with light-dark cues.

## 347.8

**OSMOLALITY-DEPENDENT STEROID FEEDBACK REGULATION OF VASOPRESSIN GENE EXPRESSION.** L.T. Knapp, K.A. Berghorn, W.-W. Le\*, G.E. Hoffman, and T.G. Sherman. Depts of Neuroscience and Neurobiology, University of Pittsburgh, Pittsburgh PA 15260 USA.

We have recently demonstrated the *de novo* induction of glucocorticoid receptors (GR) in AVP magnocellular neurons in the chronic hyposmolar rat (Endo. 136: 804, 1995). We have investigated the possible role for this GR in establishing osmolality-dependent steroid feedback inhibition on AVP expression, and whether this feedback regulation constitutes a direct or indirect action of GR on the AVP gene. Chemical adrenalectomy with metyrapone, an inhibitor of adrenal glucocorticoid synthesis, results in an induction of nuclear AVP hnRNA levels in hyposmolar, but not in normosmolar, rats, as measured by intron-directed *in situ* hybridization and a competitive RT-PCR assay. Preliminary results indicate, however, that the actions of metyrapone are not mimicked by RU486 treatment. Because RU486 does not antagonize the repressive actions of GR on transcription, these results may provide evidence for the direct actions of GR on the AVP gene. Furthermore, we hypothesize that the hyposmolar inhibition of AVP expression and the hyposmolar induction of GR expression are coordinately mediated by decreased nuclear levels of phosphoryl-CREB (pCREB). As measured by western analysis and immunocytochemistry, levels of pCREB were increased 2.5-fold in magnocellular AVP neurons with acute hyperosmolality and were undetectable with hyposmolality. Treatment of hyposmolar rats with naloxone predominantly blocked the induction of magnocellular GR and re-established detectable levels of pCREB (60% of control). These data support the hypothesis that pCREB is an important reciprocal regulator of AVP and GR expression. The induction of GR expression in hypothalamic AVP neurons represents a novel mechanism for the establishment of physiology-specific steroid feedback control. (NSF grant BNS-9021307)

## 347.10

**RATE-SENSITIVE GLUCOCORTICOID FEEDBACK INHIBITION IN NORMAL HUMANS AND DEPRESSED PATIENTS.** D.K. Kim\*, B.L. Kim, B.H. Yu, K.S. Hong, J. Ritchie, S. Austin, B.J. Carroll. Department of Psychiatry, Samsung Medical Center, Seoul 135-230, Korea.

This study aims to demonstrate the rate-sensitive glucocorticoid fast-feedback (FFB) inhibition of adrenocorticotrophic hormone (ACTH) with ovine corticotropin-releasing factor (oCRF) administration, and to determine the possible site(s) on which glucocorticoid exerts its FFB inhibition of ACTH secretion in humans. A third objective is to document the importance of this FFB as a confound in the CRF stimulation test in depressed patients (DEP) by comparing the ACTH response to oCRF between DEP and normal controls.

We examined the post-CRF secretory patterns of ACTH, arginine vasopressin (AVP), and cortisol in 7 normal subjects and 3 DEP with a sampling schedule of plasma at three-minute intervals. All three hormones demonstrated significant secretory responses to submaximal dose of oCRF (1 µg/kg body weight), with AVP increasing from 1.33 to 7.77 pg/ml, ACTH from 2.98 to 14.52 fmol/ml, and cortisol from 4.44 to 25.93 µg/dl. The decline in plasma ACTH followed by its initial peak coincided with the rising phase of the cortisol response in normal subjects, then a rebound of ACTH after plasma cortisol reached a high plateau level. The ACTH response to oCRF was significantly reduced by the ramp of cortisol, however, the effect of oCRF on ACTH release was more affected by the cortisol preinfusion. The DEP patients appear to shut off secretion earlier, leading to a significantly blunted integrated ACTH response in comparison with normal subjects.

This early data suggests that FFB in the oCRF test is common in human subjects. FFB is a major, uncontrolled confound in studies to date of the CRF stimulation procedure in DEP, and Pituitary gland might be the site of action of this FFB. Additional data is being collected and will be presented.

## 347.12

**EFFECT OF NEONATAL GONADECCTOMY AND ADULT HORMONE REPLACEMENT ON HYPOTHALAMIC-PITUITARY-ADRENAL STRESS RESPONSE AND BRAIN CORTICOSTEROID RECEPTOR LEVELS IN RATS.** B.E. Furey, M. Child, & C.M. McCormick\*. Department of Psychology, Bates College, Lewiston, ME 04240, USA.

Hypothalamic-pituitary-adrenal (HPA) function is influenced by circulating levels of sex steroids. However, the consequences of neonatal gonadectomy (GDX) on adult HPA function is unknown. Male and female rats were either GDX on the first day of life (neoGDX) or sham-operated. At three months, half of the shams were gonadectomized (adultGDX). All received jugular catheters and s.c. implants of either cholesterol (sham), testosterone (T: males), or estradiol benzoate and progesterone (EB-P: females). Five days following surgery, HPA function was assessed by determining plasma corticosterone (CORT) levels prior to, and at intervals following, 20 min of restraint stress. NeoGDX and adultGDX both resulted in increased levels of CORT in males, and decreased levels in females, compared to same-sex shams. EB-P increased plasma CORT levels in both neoGDX and adultGDX. In contrast, T implants caused a greater reduction of CORT levels in adultGDX than neoGDX. These differences in CORT response to stress are not explained by differences in corticosterone binding globulin (CBG) levels across the groups. Further, the differences are not related to Type I and Type II receptor levels in various brain areas: NeoGDX and intact animals did not differ in [3H]CORT or [3H]dexamethasone binding in the hippocampus, septum, frontal cortex, or hypothalamus. These data suggest that the HPA of females remains sensitive to the influence of sex hormones in adulthood despite a lack of ovarian secretions throughout development. In contrast, neoGDX in males reduced sensitivity of the HPA to testosterone. Longer regimens of T replacement are necessary to determine whether or not there are organizational effects of neonatal androgens on the development of the HPA.

## 347.13

**PROTEIN LEVELS OF THE GLUCOCORTICOID RECEPTOR, MINERALOCORTICOID RECEPTOR AND HEAT SHOCK PROTEIN-90 IN THE RAT HIPPOCAMPUS: EFFECT OF ADRENALECTOMY.** M.I. Morano\*, C.A. Caamaño, D.M. Vázquez, S.J. Watson and H. Akil. Mental Health Research Institute, University of Michigan, Ann Arbor, MI.

The hippocampal corticosteroid receptors (glucocorticoid receptor or GR and mineralocorticoid receptor or MR) are involved in the negative feedback of the hypothalamic-pituitary-adrenal axis. Furthermore, the association of these corticosteroid receptors with a protein complex which involves several heat shock proteins, including hsp-90, is thought to be critical to their ability to bind steroids. Previous *in vitro* studies demonstrate that the removal of circulating corticosterone by adrenalectomy (ADX) increases the hippocampal binding capacity of both receptors, GR and MR. In the present study we examined the GR and MR binding capacities and the protein levels of GR, MR and hsp-90 by Western blot analysis in hippocampal cytosols of rats corresponding to the following groups: 1) unhandled intact, 2) 12 h ADX, 3) 12 h SHAM, 4) 7 d ADX, 5) 7 d SHAM, 6) 7 d ADX + Dexamethasone (Dex) in the drinking water. No change in protein levels was observed in GR or MR in the SHAM-operated groups or after 12 h ADX with respect to the intact group. However, 7 d ADX up-regulated the GR and MR protein levels to more than 100 %. Dex replacement decreased the ADX effect over GR to 50 % of the control group. In contrast, the same cytosolic preparation showed similar hsp-90 protein levels in all the groups except in the ADX + Dex which exhibited a significant decrease. In sum, we conclude that the increase of GR and MR binding after adrenalectomy is due to the up-regulation of the protein levels of these receptors in the absence of glucocorticoid.

## 347.15

**BINDING CHARACTERISTICS OF CORTICOSTEROID RECEPTORS IN THE RAT HYPOTHALAMUS ARE SEXUALLY DIFFERENTIATED.** S. Hellbach, A.H.S. Hassan, V.K. Patchev, J. Deicke, D. Fischer, G.P. Chrousos\* & O.F.X. Almeida. Max Planck Institute of Psychiatry, Kraepelinstr. 2, D-80804 Munich, Germany.

We recently reported sexually differentiated responses of the hypothalamic-pituitary-adrenal (HPA) axis (Patchev et al., FASEB J., 9: 419). In this work we examined whether hypothalamic neurons cultured from juvenile (21 d.o.) male and female rats, as well as from female rats that had been neonatally-estrogenized *in vivo* (according to a protocol known to defeminize the brain), display differences in Type I and II corticosteroid receptor (CR) binding. After 10-12 days *in vitro*, binding CR sites were characterized in intact cells. We used <sup>3</sup>H-alosterone and <sup>3</sup>H-dexamethasone to label Type I and II CR, respectively. Hypothalamic cells from male, female and neonatally-estrogenized female rats showed no specific <sup>3</sup>H-alosterone binding sites. Specific and saturable dexamethasone-binding sites were found to occur in greater numbers (25-30%) in female-derived cells than in male-derived cells; this result is consistent with that already published for Type II CR gene transcription in the hypothalamus. The characteristics of dexamethasone binding sites in cells originating from neonatally-estrogenized females were similar to those found in the cells from males. These findings provide further support for the notion that the brain-organizing effects of gonadal steroids during perinatal life encompass not only the well-known neural mechanisms controlling reproduction, but also extend to the regulation of the HPA axis.

## 347.17

**TIME COURSE OF CORTICOSTEROID AND SEROTONIN RECEPTOR GENE EXPRESSION IN THE RAT HIPPOCAMPUS FOLLOWING ACUTE MDMA.** J.L.W. Yau\*, J. Noble and J.R. Seckl. Dept. Medicine. Western General Hospital Edinburgh, U.K.

Glucocorticoids and serotonin (5-HT) interact in the hippocampus, altering electrophysiological, neuroendocrine and behavioural parameters. Chronic methylenedioxymethamphetamine (MDMA) causes selective 5-HT neuronal degeneration, decreases mineralocorticoid (MR) and glucocorticoid (GR) receptor and increases 5-HT<sub>2C</sub> receptor gene expression in the hippocampus. Acutely, MDMA releases 5-HT from nerve terminals, prior to damaging axons. In the present study, we examined the effects of acute MDMA on hippocampal corticosteroid and 5-HT receptor subtype mRNA expression using *in situ* hybridisation histochemistry. Rats were killed 9h, 16h and 48h after a single injection of MDMA (20mg/kg, s.c.). Hippocampal neuronal MR mRNA expression decreased (13% fall in CA3 and CA4, p < 0.05) at 9h, increased (69% rise, p < 0.01) at 16h and returned to control levels by 48h. In contrast, hippocampal neuronal GR mRNA expression was decreased (41% fall, p < 0.01) at 9h, remaining decreased at 16h and returned to control levels by 48h. 5-HT<sub>1A</sub> receptor mRNA expression was decreased in CA1 (20% fall, p < 0.05) at all time points. 5-HT<sub>2A</sub> receptor mRNA expression remained unaltered. Effects on other 5-HT receptor gene expression are currently being examined. These results show a differential regulation of hippocampal MR and GR after acute MDMA and that induction of MR mRNA expression requires several hours following acute MDMA-induced 5-HT release. The decreased GR mRNA expression might be a consequence of the MR changes or reflects the direct effects of increased corticosterone secretion.

## 347.14

**PRENATAL ETHANOL EXPOSURE AND GLUCOCORTICOID RECEPTORS.** C.K. Kim, W. Yu, G. Edin, L. Herbert, K. Arkinstall, B. Lenger, J.A. Osborn, B. Gorzalka\* & J. Weinberg. Departments of Anatomy and Psychology\*, University of British Columbia, Vancouver, BC, Canada V6T-1Z3.

One effect of prenatal ethanol exposure is offspring hyperresponsiveness to stressors. We have previously shown that prenatal ethanol exposure does not alter hippocampal MR (mineralocorticoid receptor, Type I) or GR (glucocorticoid receptor, Type II) densities or binding affinities of male and female rats under nonstressed conditions. Furthermore, following stress, prenatal ethanol exposure did not differentially down-regulate hippocampal GRs, nor alter densities of hippocampal MRs or hypothalamic MRs and GRs in females. This study examined MR and GR densities in the hippocampus, anterior pituitary, hypothalamus and prefrontal cortex in rats that were nonstressed or exposed to chronic intermittent stress (3 wks, twice daily). The subjects were adult male and female offspring from prenatal ethanol exposed (E, 36% EDC), pair-fed (PF) and ad libitum-fed control (C) rats.

Chronic stress caused decreased body weights and increased adrenal/body weight ratios in both sexes. In males, hippocampal GR densities were lower in E than PF rats following stress, overall hypothalamic GR densities were higher in E than PF rats, and overall pituitary GRs were up-regulated in all groups following stress. In females, overall hippocampal GRs were marginally up-regulated following stress, with the up-regulation being significant only in the C group; overall hippocampal MRs were up-regulated and overall hypothalamic GRs were down-regulated in all groups following stress. Thus, this stress regimen differentially affected GR and MR densities in males and females at the different CNS sites. Importantly, there was a subtle effect of prenatal ethanol exposure on GR densities.

## 347.16

**DEXAMETHASONE SUPPRESSION OF HPA AXIS RESPONSE TO ACUTE STRESS: RELATIONSHIP TO ESTIMATES OF CORTICOSTEROID RECEPTOR OCCUPANCY IN BRAIN AND PITUITARY.** R.L. Spencer\*, P.J. Kim, M.A. Cole, B.A. Kalman. Dept. of Psychology, Univ. of Colo., Boulder, CO 80309.

Dexamethasone (DEX) is a potent synthetic glucocorticoid that has been widely used in biological psychiatry as a probe (DEX Suppression Test; DST) for testing HPA axis sensitivity to corticosteroid negative feedback. We have examined in the rat the dose-related ability of s.c. injections of DEX (1-50 µg/kg) to suppress the corticosterone response to a subsequent (90 min interval) acute stress (1 hr restraint). The 50µg/kg dose of DEX almost completely eliminated the corticosterone response (80% reduction), and the 25µg/kg dose had a partial effect (60% reduction). We also examined the effect of the high dose of DEX on available Type I and Type II corticosteroid receptors in the pituitary and the brain of rats that had been adrenalectomized for 24 h (in order to remove competing endogenous adrenal steroids). We found that DEX (50µg/kg), 30 and 90 min after injection, had no effect on available Type I or Type II corticosteroid receptor binding in the hippocampus, whereas DEX produced a selective and significant time-related decrease in available Type II receptors in the pituitary. From these studies we infer that a dose of DEX that was near maximal effectiveness in suppressing an acute stress-induced rise in corticosterone, acted by selectively occupying Type II receptors in the pituitary. These results support other studies suggesting that DEX in the context of a DST may act as a selective probe of the effects of acute activation of pituitary Type II corticosteroid receptors on HPA axis activity. Supported by UROP, JFDA and GIA programs of the Univ. of Colorado.

## 347.18

**EVIDENCE FOR REGION-SPECIFIC VARIATION IN GLUCOCORTICOID RECEPTOR EXPRESSION IN BRAIN TISSUE FROM NEONATAL PIGS.** S. Weaver\*, D. O'Donnell, W.T. Dixon, and M.J. Meaney\*. Dept. Animal Sci., Univ. of Alberta, Edmonton, Alberta, Canada T6G 2P5. Depts. of Neurology & Neurosurgery, and Psychiatry, Douglas Hosp. Res. Ctr., McGill Univ., Montreal, Quebec, Canada H4H 1R3.

Brain glucocorticoid receptors (GR) play a crucial role in the negative feedback effect of cortisol during and after exposure to a stressor. Western blotting has been used to detect the glucocorticoid receptor (GR) in a variety of tissues. Most tissues/cells exhibit a doublet with an apparent molecular weight of 90 to 97 kDa. In this study the pituitary gland, hypothalamus, frontal cortex, and hippocampus was collected from 14 day old pigs and western blotting was performed for GR receptor detection. A protein doublet of 95 and 87 kDa was detected in all regions examined with a more intense signal for the 87 kDa band in both the hypothalamus and pituitary gland. In the frontal cortex and hippocampus both bands exhibited a more uniform signal density. Hollenberg et al. (1995, Nature, 378:635) have shown that there are two isoforms of GR designated  $\alpha$  and  $\beta$  with the  $\alpha$  form electrophoretically separating at 95 kDa and  $\beta$  separating more rapidly at a lower molecular weight. In the current experiment the upper band may represent the  $\alpha$  form in that it separates at approximately 95 kDa with the lower band, which separates at 87 kDa, representing the  $\beta$  form. The two bands we have detected may represent a neural source of the two isoforms of GR and these isoforms may have distinct roles in the differential regulation of GR in the hypothalamus and pituitary gland compared to the hippocampus and frontal cortex.

## 347.19

INTRACEREBROVENTRICULAR INJECTIONS OF DEXAMETHASONE DO NOT PROMOTE INSULIN RELEASE IN LAN/CP ADRENALECTOMIZED RATS. K. DeOre, K. Kamara, C. Hansen, O. Michaelis and T. Castonguay\*Univ. of Maryland - College Park, USDA - Beltsville, MD and NIH, Bethesda, MD

Genetically obese (ob/ob) adrenalectomized (ADX) mice injected with dexamethasone ICV increase circulating insulin within 30 min of treatment. The present studies were conducted to learn if ADX LAN/CP rats would also respond to ICV dexamethasone by increasing circulating insulin. Lean and obese LAN/CP rats were individually housed in standard hanging cages and allowed free access to Purina Chow and water. Rats were assigned to one of two experimental treatments, with one half given bilateral adrenalectomies. The remaining rats were given sham operations. After surgery, all ADX rats were given saline in place of drinking water. They were allowed to recover from surgery for 4 days and were then injected ICV with 250 ng dexamethasone in 2  $\mu$ l CSF. Control rats were injected with 2  $\mu$ l CSF. Tail blood samples were collected at the time of injection, and again 15, 30, 60, 120 and 180 minutes post injection. Blood was centrifuged and plasma was assayed for insulin via RIA. Lean sham operated rats had basal insulin concentrations of  $158 \pm 30$  uU/ml. By contrast, obese sham operated rats had basal insulin concentrations of  $438 \pm 87$  uU/ml. Adrenalectomy decreased obese basal insulin concentrations ( $160 \pm 23$  uU/ml  $p < .05$ ) but not lean values ( $95 \pm 20$  uU/ml;  $p > .05$ ). Dexamethasone injections failed to promote increases in basal levels in either lean or obese ADX or sham operated groups. These data suggest that although ADX suppresses insulin in both mice and rats, the extent of glucocorticoid control over pancreatic insulin release differs between these two rodent species. Supported in part by the Howard Hughes Foundation and by NIH grant DK42446 and a grant from the Maryland Agricultural Experiment Station Competitive Grants Program.

11 $\beta$ -HYDROXYSTEROID DEHYDROGENASE (11 $\beta$ -HSD) IN HIPPOCAMPAL CELL CULTURES IS A REDUCTASE WHICH REACTIVATES INERT 11-DEHYDROCORTICOSTERONE THUS POTENTIATING KAINIC ACID NEUROTOXICITY. J. R. Seckl\* and V. Rajan. Dept. Med., West. Gen. Hosp. Edinburgh, UK.

11 $\beta$ -HSD converts corticosterone to inert 11-dehydrocorticosterone (DHC). Hippocampal 11 $\beta$ -HSD is induced by glucocorticoids *in vivo*, suggesting it may attenuate glucocorticoid neurotoxicity. There are 2 isozymes; 11 $\beta$ -HSD1, a bi-directional, NADP-dependent enzyme, and 11 $\beta$ -HSD2, an NAD-dependent exclusive 11 $\beta$ -dehydrogenase (corticosterone-inactivating). Primary fetal rat hippocampal cell cultures (~85% neurons) had 11 $\beta$ -HSD activity. This was NADP-, not NAD-dependent, and 11 $\beta$ -HSD1 mRNA was expressed. Unexpectedly, the reaction direction in intact cells was 11 $\beta$ -reduction (reactivation of inert DHC), although homogenization revealed the enzyme capable of 11 $\beta$ -dehydrogenation when removed from its cellular context. Dexamethasone ( $10^{-7}$ M) increased 11 $\beta$ -HSD activity (102% rise), increasing only 11 $\beta$ -reduction in intact cells. To determine the functional relevance of hippocampal 11 $\beta$ -reductase, glucocorticoid potentiation of kainic acid (KA,  $10^{-5}$ M) neurotoxicity was examined. Pretreatment of hippocampal cells with corticosterone ( $10^{-5}$ M) reduced survival with KA. 11 $\beta$ -HSD activity was inhibited by carbenoxolone ( $10^{-6}$ M). Carbenoxolone alone had no effect on cell survival after KA, nor altered corticosterone efficacy. DHC ( $10^{-5}$ M) also potentiated KA neurotoxicity, however this effect was lost if 11 $\beta$ -HSD was inhibited with carbenoxolone. Measures to attenuate hippocampal 11 $\beta$ -reductase may reduce neuronal vulnerability to glucocorticoids.

EFFECTS OF CASTRATION AND TESTOSTERONE ON VASOPRESSIN RELEASE. Kerry L. Swenson\*, C.D. Sladek. Finch University of Health Sciences/The Chicago Medical School, North Chicago, IL 60064.

Previous experiments demonstrated that gonadectomy prevented the increase in hypothalamic VP mRNA content induced by chronic administration of an oral salt load. However, neither posterior pituitary VP content nor hypothalamic VP mRNA content in hydrated rats was altered. Subsequent studies demonstrated that treatment of male gonadectomized rats with testosterone restored the hyperosmolar-induced increase in VP mRNA (Crowley and Amico, *Endocrinology* 133:2711-2718, 1993). Experiments were performed to determine if castration or testosterone altered osmotically stimulated VP release *in vitro*. Perfused explants of the hypothalamo-neurohypophyseal system were obtained from sham and gonadectomized male rats. There was no significant difference in VP release (determined by RIA of perfusate fractions) stimulated by a ramp increase in osmolality of the culture media (40 mosm/6 hrs) between the two groups. RIA also showed that there was no testosterone detectable in the media. Therefore, experiments were then performed to determine if the addition of testosterone to the perfusion media altered osmotically stimulated VP release. Explants were exposed to physiological levels of testosterone, 3 ng/ml, throughout the perfusion experiment. Testosterone completely inhibited the osmotically stimulated increase in VP. In contrast to the *in vivo* studies, these results suggest that castration has no effect on the osmotically induced increase in VP release and that it is inhibited by testosterone *in vitro*. Supported by NIH Grant #NS27975.

## 348.2

A ROLE FOR NON-NMDA EXCITATORY AMINO ACID RECEPTORS IN THE OSMOTIC REGULATION OF VASOPRESSIN mRNA. C.D. Sladek\* and H.E. Sidorowicz. Finch University of Health Sciences/Chicago Medical School, North Chicago, IL, 60064.

Vasopressin (VP) mRNA content is increased by chronic dehydration. This effect is mimicked by exposure of hypothalamo-neurohypophyseal explants to a ramp increase in osmolality for 6 hours. Previous studies demonstrated that this induction of VP mRNA content requires synaptic input and was blocked by kynurenic acid, a non-specific antagonist of excitatory amino acid receptors. The later observation implicated excitatory amino acids as one of the neurotransmitters involved in this response. Therefore, experiments were initiated to identify the type of excitatory amino acid receptor involved. Perfused hypothalamo-neurohypophyseal explants were exposed to a ramp increase in osmolality (40mOsm over 6 hours achieved by increasing NaCl) in the presence and absence of 10  $\mu$ M 6,7-dinitroquinoxaline-2,3-dione (DNQX), an antagonist of non-NMDA excitatory amino acid receptors. VP release (measured by RIA in timed fractions of the perfusate) and VP mRNA content (measured by RNase protection assay at the end of the 6 hour osmotic stimulus) were significantly increased by exposure to the osmotic stimulus. DNQX inhibited osmotically stimulated VP release ( $F=16.65$ ,  $p=0.0008$ ) without significantly reducing basal release. It also prevented the osmotically stimulated increase in VP mRNA content ( $p<0.05$ ). These results suggest that the synaptic regulation of VP mRNA content by osmotic stimulation is mediated at least in part by non-NMDA excitatory amino acid receptor activation. Supported by NIH grant NS27975.

## 348.3

VASOPRESSIN ANTISENSE SPECIFICALLY INHIBITS OSMOTIC STIMULATION OF VASOPRESSIN, BUT NOT OXYTOCIN RELEASE. M. Ludwig\*, M. Morris, and C.D. Sladek. Bowman Gray School of Medicine, Winston-Salem, N.C., 27157, and Finch Univ. of Health Sciences/Chicago Med Sch, North Chicago, IL, 60064.

Rapid effects of antisense oligodeoxynucleotide (ODN) on the function of the neurohypophyseal system have been reported. In this study, the effect of a vasopressin (VP) antisense ODN on osmotically stimulated release of VP and oxytocin (OT) from perfused hypothalamo-neurohypophyseal explants was evaluated. Following a 2 hr equilibration period, either an 18-mer phosphorothiodated ODN targeted to the translation start site of VP mRNA or a mixed base sequence (8  $\mu$ M) were added to the perfusate. 2 hrs later all explants were exposed to a ramp increase in osmolality (40mosm/6 hr). VP and OT release were measured by RIA in timed fractions of the perfusate. VP antisense ODN inhibited VP, but not OT release in response to the osmotic stimulus. VP release was significantly increased in explants perfused with the mixed base ODN in comparison to antisense ODN ( $F=18.54$ ,  $p=0.0026$ ). OT release was not significantly different between the mixed base and antisense groups. These observations indicate that acute exposure to VP antisense ODN interrupts osmotically stimulated VP release. The effect was specific for VP release as the OT response was not inhibited. These results are consistent with data demonstrating that antisense ODNs inhibit neurohypophyseal function in a hormone specific manner. Further studies are required to ascertain the mechanism underlying the inhibition of hormone release. Supported by NIH grants NS27975(CDS), HL43178 (MM) and NC Heart NC-92-GB-16.

## 348.4

EXPRESSION OF VASOPRESSIN MRNA DURING MATURATION IN THE RAT. M.D. Fitzsimmons\*, A.G. Robinson. Dept. of Endocrinology. Univ. of Pittsburgh, PA 15261.

Between 3 and 12 weeks of age in the rat, total vasopressin (AVP) content in the posterior pituitary increases substantially; the accumulation does not result from feedback from the posterior pituitary, nor as a consequence of increasing body weight or gonadal steroid secretion. In this experiment, we examined the pattern of AVP mRNA expression during maturation to determine the relationship between mRNA level and the accumulation of hormone in the posterior pituitary. Expressed in relative units, AVP mRNA was:  $55 \pm 5$  at 3.5 weeks,  $97 \pm 9$  at 6 weeks,  $126 \pm 11$  at 9 weeks, and  $134 \pm 14$  at 12 weeks. In order to assess the relative contribution of transcription and mRNA stability to the change in mRNA level, we measured the downregulation of AVP mRNA at 0, 1, 2, 3, 4, and 7 days after inducing hyponatremia in rats at the same ages. Since this experimental design incorporates a higher time resolution than earlier studies, we were able to detect an initial tendency for hyponatremia to stimulate AVP mRNA transcription in some age groups. This paradoxical stimulation, which may result from stress associated with surgical implantation of DDAVP osmotic minipumps, resolved within 2 days in all groups. Thereafter, all age groups exhibited similar patterns of AVP mRNA downregulation during hyponatremia; the physiologic half-life of vasopressin mRNA appears to be independent of age, to the resolution of the technique employed. We infer from these observations that the increase in hypothalamic AVP mRNA during maturation results from increased transcription and not changes in mRNA stability. In spite of higher transcription, older animals exhibit less pituitary AVP accumulation, indicating that absolute AVP secretion rate increases with age. Since the rate of pituitary accumulation is highest when mRNA content is lowest, the quantitative relationship between transcription and secretion may depend on age, with younger animals storing a higher fraction of their total synthesis. Supported by DK 16166.

## 348.5

**ENDOGENOUS HYPERINSULINEMIA SUPPRESSES VASOPRESSIN MRNA SYNTHESIS IN THE HYPOTHALAMUS.** R.H. Rao, M.D., Fitzsimmons, M.J., Sandberg, A.G., Robinson\*. Dept. of Endocrinology, University of Pittsburgh, Pittsburgh PA 15261.

Vasopressin (AVP) secretion is known to be increased in insulin deficient Type 1 diabetes mellitus, a phenomenon that has been attributed to volume depletion from osmotic diuresis induced by hyperglycemia. Nevertheless, we and others have shown that, even with volume repletion, AVP secretion is increased in insulin-deficient hyperglycemic rats. We studied the relationship between insulin and AVP in a rat model of endogenous hyperinsulinemia resulting from chronic (10 days) administration of 10% fructose in the diet. AVP mRNA (measured by RNase protection assay) was suppressed compared to rats fed a regular diet (2516±184 CPM vs. 3289±230 respectively). In a second model of endogenous hyperinsulinemia, induced by administering 10% glucose in the drinking water for 10 days, AVP mRNA was similarly suppressed compared to rats given water sweetened with saccharin (2819±249 vs. 3936±211 respectively). The relationship of these observations to peripheral insulin resistance was studied by performing euglycemic hyperinsulinemic clamps. Rats fed a 10% fructose diet had lower glucose disposal rates under equivalent clamp conditions, indicating significant insulin resistance. 10.6±5.1 µmol/kg/min vs. 31.8±7.6 in controls (n=5, p<0.05). However, glucose disposal rates during steady-state euglycemia were not impaired in rats given 10% glucose in their drinking water (23.4±3.7 µmol/kg/min, p=NS vs controls), indicating that hyperinsulinemia in these rats was not associated with insulin resistance. In summary, we have observed decreased expression of AVP mRNA after two separate hyperinsulinemia protocols (glucose feeding and fructose feeding); only the fructose diet, however, also induced peripheral insulin resistance. On the basis of these observations, and of previous studies showing that insulin deficiency increases AVP secretion, we conclude that AVP synthesis and release are responsive to insulin. Furthermore, our results indicate that the insulin responsiveness of the brain is preserved in the presence of peripheral insulin resistance.

## 348.7

**DIFFERENTIAL EXPRESSION OF NMDAR2 (NR2) RECEPTOR SUBUNITS IN VASOPRESSIN AND OXYTOCIN NEUROENDOCRINE CELLS** W.M. Al-Ghoul, R.S. Greenwood and R.B. Meeker\*. Dept. of Neurology and Neurobiology Curriculum, University of North Carolina, Chapel Hill, NC 27599

NMDA receptors consist of NR1 and NR2 subunits assembled in heteromeric configurations to form ligand gated ion channels. While the NR1 subunit of the NMDA receptor is abundant throughout the CNS, the NR2 subunits show substantial regional variation. Within the supraoptic nucleus, it has been suggested that vasopressin (VP) and oxytocin (OT) neuroendocrine cells display different NMDA receptor activities. Since NMDA receptor characteristics may be determined by NR2 subunit composition, we used immunocytochemical-*in situ* hybridization double-labeling to evaluate NR2 subunit expression in VP and OT neuroendocrine cells. Sections of rat brain were reacted with antibodies against neurophysin II or neurophysin I to identify VP and OT cells, respectively, then processed for *in situ* hybridization using <sup>35</sup>S-labeled oligonucleotides specific for NR2A, -B, -C or -D. Silver grain densities from high resolution autoradiograms were quantified over immunocytochemically identified cells to determine the relative expression of each NR2 subunit. Whereas the NR1 subunit was ubiquitously expressed in VP and OT cells, the NR2 subunits were differentially distributed with the following abundance: VP: 2B = 2C > 2D >> 2A; OT: 2B >> 2D >> 2C > 2A. VP cells were five times as likely to express the NR2C subunit and only half as likely to express the NR2B relative to OT cells. An average of 41-96% of the cells had detectable levels of each subtype indicating that some cells probably express multiple NR2 subtypes. These data indicate that VP and OT cells are likely to be controlled by distinct subtypes of NMDA receptors. Supported by NIH Grants NS13411 and NS30923

## 348.9

**GENERATION OF BURST DISCHARGE IN HYPOTHALAMIC SUPRAOPTIC NEURONS IN VITRO.** G. Böhrer, W. Greffrath, E. Martin and K. Behrend\*. Dept. of Physiology and Pathophysiology, Gutenberg University, 55099 Mainz, Germany.

In vasopressinergic neurons of the hypothalamic supraoptic nucleus hyperosmotic stimulation results in a transition from tonic to phasic discharge. The present study aimed at closer examining mechanisms involved in rhythmic generation of burst discharge. Membran potentials of supraoptic neurons of male rats were intracellularly recorded from hypothalamic slices at 32 °C using glass microelectrodes filled with 2 M potassium acetate. In supraoptic neurons spiketrains induced by current injection were succeeded by a sequence of hyperpolarizing and depolarizing afterpotentials (AHP and ADP, respectively). These afterpotentials were blocked by Cd<sup>2+</sup> and thus were considered Ca<sup>2+</sup>-activated. A fast component of the AHP was blocked by apamin whereas a slow component of the AHP was blocked by charybdotoxin. The amplitude of the posttrain depolarization depended on the interaction of the ADP and the slow AHP. Application of histamine or N-methyl-D-aspartate to the bath resulted in an increase of the amplitude of the ADP and eventually in a spiketrain. Further depolarization induced repetitive bursts of action potentials. In many supraoptic neurons fast oscillations of the membrane potential (30 to 60 Hz) occurred on top of nearthreshold ADPs and during nearthreshold depolarization induced by current injection. In spontaneously bursting neurons bursts were preceded by fast oscillations of the membrane potential. The induction of these oscillations was voltage-dependent (threshold: -58 to -48 mV). These low voltage-activated oscillations (LVAO) were blocked by TTX suggesting the activation of a TTX-sensitive, persistent Na<sup>+</sup>-current underlying LVAO. Further depolarization during continued application of TTX induced high voltage-activated oscillations (HVAO; threshold: -45 to -35 mV). HVAO were blocked by Cd<sup>2+</sup> suggesting the activation of a HVA Ca<sup>2+</sup>-current underlying HVAO. The Na<sup>+</sup>-dependent LVAO and the Ca<sup>2+</sup>-activated ADP may be important for the induction and maintenance of burst discharge in supraoptic neurons. The fast and slow Ca<sup>2+</sup>-activated AHP may be important for the termination of burst discharge and the delay of onset of the succeeding burst of action potentials.

## 348.6

**INCREASED NMDAR1 EXPRESSION IN THE HYPOTHALAMUS WITH HYPEROSMOTIC STIMULATION: QUANTITATIVE IMMUNOHISTOCHEMISTRY AND WESTERN BLOT ANALYSIS.** M.C. Curras\* and C. Decavel. Dept. of Neuroscience, University of California, Riverside.

Functional NMDA receptors have been described in rat supraoptic (SON) neurons (Hu and Bourke, 1992; Curras et al 1992). We have recently detected the NMDAR1 subunit on immunohistochemically identified magnocellular neurons of the SON (Soc. Neurosci. Abstr. 20 (1):347, 1994). Quantification of NMDAR1 immunolabeling in SON showed that expression of this subunit was increased during chronic dehydration (2% saline drinking water: 7-10 days). Another hypothalamic nucleus, which participates in water balance, the paraventricular nucleus (PVN) was tested for changes in NMDAR1 expression. Immunohistochemical detection of NMDAR1 in sections from control and saline-treated rats was done using silver-intensified gold (SIG) as a marker. Computerized analysis of labeling was performed over the posterolateral magnocellular subnucleus of the PVN of both groups. Labeling density was calculated as the ratio of the mean gray levels of PVN/ n. reunions of the thalamus, which has not been shown to be involved in water balance. This ratio was significantly greater in saline rats (1.146 ± 0.038; n=11) than in control rats (1.035 ± 0.012; n=7) at 0.01 level. Although NMDAR1 is ubiquitous in the CNS the increased NMDAR1 labeling in saline-treated rats was specifically observed in the hypothalamo-neurohypophyseal system. Western blots were performed to test if increased NMDAR1 expression would be detectable in hypothalamic homogenates from saline-treated rats. Cortex, hypothalamus and liver homogenates were loaded on a 7.5% gel (SDS-PAGE). After electrophoretic transfer onto membrane, NMDAR1 immunolabeling was found between 100-125KD. NMDAR1 expression was significantly greater in hypothalamus from saline vs control rats. Cortex showed NMDAR1 expression but no difference with saline treatment. (Quantitative image analysis was done using Quantimet 500 (Leica) customized by A. Lubarsky).

## 348.8

**LACK OF ACUTE VOLUME REGULATION IN SUPRAOPTIC NUCLEUS (SON) NEURONS ISOLATED FROM THE ADULT RAT.** S.J. Gentles, S.H.R. Oliet, P. Drapeau\* and C.W. Bourque. Centre for Research in Neuroscience, Montreal General Hospital and McGill University, Montreal, PQ, H3G 1A4, Canada.

The intrinsic osmosensitivity of SON neurons is believed to result from the modulation of stretch-inactivated cationic channels by osmotically-evoked changes in cell volume (Oliet & Bourque *Nature* 364, 1993). To behave as non-adapting osmometric transducers, however, SON neurons must lack the ability to volume-regulate. Osmotically-evoked (±mannitol) changes in cell volume were therefore examined by laser scanning or phase microscopy of neurons acutely isolated from adult rats. Examination of 16 SON neurons during strong osmotic stimulation (±93 mOsmol/kg; 64 minutes) revealed no time-dependent decay of initial osmotically-evoked volume changes. Over a more physiological range (±40 mOsm) the volume of SON neurons decreased as a linear function of external osmolality with a slope of -0.29%/mOsmol/kg (R=0.99; n=11), a value comparable to strict osmometric behaviour (-0.34%/mOsmol/kg). The volume of cortical neurons was much less sensitive to changes in external osmolality (-0.10%/mOsmol/kg; R=0.66; n=17), indicating that these cells partially regulate their volume when faced with an osmotic challenge. These observations suggest that SON neurons do not volume regulate and are consistent with a role for stretch-inactivated cationic channels in osmoreception. Supported by the Canadian Heart & Stroke Foundation and the Medical Research Council of Canada.

## 348.10

**EFFECTS OF A SALT LOAD ON ENSEMBLE UNIT ACTIVITY IN THE PARAVENTRICULAR NUCLEUS (PVN) OF THE AWAKE, BEHAVING RAT.** J.M. Paris\*, R.V. Subrahmanyam, M.F. Callahan, D.J. Woodward. Dept. Physiology/Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157-1083

Oxytocin and vasopressin neurons in the PVN respond to osmotic stimuli and to changes in plasma Na<sup>+</sup> concentrations. We hypothesized that the neural activity of a sub-population of PVN neurons should be altered in response to a chronic salt load. Three male rats were implanted with microwire recording electrodes in the PVN. Neural activity was recorded in three 2 hr sessions: 1) under control (normal water) conditions; 2) following 48 hr exposure to a 1.1% NaCl solution; and 3) after a 48 hr recovery period (normal water). Of 31 neurons simultaneously isolated in the PVN, 16 had a 20% or greater increase in firing rate after a 48 hr salt load (range 25-3260%); 11 units had a decreased firing rate, and 4 were unchanged. The increases in firing rate were associated with a mean 69±7% decrease in inter-spike interval (ISI) and a 134±60% increase in burst rate. Also, salt exposure recruited 1-4 quiescent neurons in each rat. Following 48 hrs of recovery, only 3 neurons returned to baseline firing patterns, suggesting that salt exposure may induce long-term alterations in the activity of these cells. These results represent the first characterization of osmosensitive neurons in the PVN of the awake rat. In addition to a more in-depth examination of the ensemble firing patterns of these neurons, future studies will explore concurrent alterations in blood pressure associated with various osmotic challenges. Supported by DA02338 (DJW) and NC Governor's Inst. (JMP). WWW Server: <http://biogfx.bgs.m.wfu.edu/>

## 348.11

c-FOS INDUCED BY ANGIOTENSIN AND HYPEROSMOLALITY IN SON AND PVN NEURONS EXPRESSING AT1 RECEPTOR. Z. Ying\*, S. Livreri, and J. Buggy. Dept. of Physiology, University of South Carolina, Columbia, SC 29208.

Supraoptic and paraventricular nuclei (SON, PVN) receive excitatory afferent input from subfornical organ (SFO) and organum vasculosum of the lamina terminalis (OVLT). Angiotensin II (ANG) may serve as a transmitter in these pathways and ANG type 1 (AT1) receptor immunoreactivity has been demonstrated in SON and PVN. We investigated whether neurons expressing AT1 receptors express Fos after hyperosmotic or i.v. ANG treatment in rats. Confocal laser scanning microscopy was used to co-localize fluorescent double-immunolabeling for c-fos and AT1 receptor. After i.p. hypertonic saline injection, 97.2% of AT1 neurons in SON and 97.4% in PVN expressed Fos. After ANG infusion, Fos immunoreactivity was detected in 84% of AT1 neurons in SON and 93.6% in PVN. Hyperosmotic treatment preferentially induced Fos in the OVLT cap and SFO rim whereas ANG preferentially induced Fos in the OVLT wall and SFO core and rim. AT1 receptor immunoreactivity was dense throughout SFO and OVLT but was not resolved into individual neurons for co-localization with Fos. These results demonstrate that neurons expressing AT1 receptor in SON, PVN, OVLT, and SFO were activated for Fos expression by hyperosmolality and intravenous infusion of angiotensin.

## 348.13

c-FOS AND c-JUN mRNA EXPRESSION IN RAT SUPRAOPTIC NEURONS (SON) AFTER ACUTE VERSUS REPEATED OSMOTIC STIMULATION.

J.T. McCabe\* and K. Wang. Anatomy & Cell Biology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

The proto-oncogenes, *c-fos* and *c-jun* are rapidly and transiently induced after a variety of stimuli under *in vitro* and *in vivo* conditions. Using a double-label immunofluorescence method, previous work has demonstrated that 90 min after acute hypertonic saline injection, Fos and Jun are co-expressed in 80% of SON neurons. However, when rats receive repeated hypertonic stimulation, only 17% of SON neurons have co-existent Fos and Jun immunostaining [NEUR. ABST. '94, 1567]. The induction of *c-fos* and *c-jun* mRNA was assessed using Northern blots and *in situ* hybridization. mRNA levels of both transcription factors increased within 5 min, peaked at 30-60 min, and disappeared by 180 min after acute hypertonic saline injection. *c-fos* mRNA induction was always stronger than *c-jun*. The magnitude of increased *c-fos* and *c-jun* mRNA expression was different following acute and repeated hypertonic saline injection. Similar to the response pattern observed for Fos and Jun immunocytochemistry, the induction of *c-fos* mRNA was less after repeated stimulation, and *c-jun* mRNA induction was essentially nonexistent. Gel-shift DNA binding assay supports the idea that SON protein extracts from injected rats form a complex with AP-1 oligomers.

SOMATOSTATIN ANALOG INDUCES FOS ACTIVATION IN RAT MAGNOCELLULAR NEURONS. M.J. Sandberg\*, M.D. Fitzsimmons, R.H. Rao, G.E. Hoffman, A.G. Robinson. Depts. of Endocrinology and Neurobiology, University of Pittsburgh, Pittsburgh PA 15261.

Elevated secretion of vasopressin occurs in diabetes mellitus secondary to glucose-induced osmotic diuresis, but clinical and experimental evidence indicate that, in addition, glucose acts as an osmotic agent under insulin-deficient conditions. In order to study the relative contributions of glucose and insulin on vasopressin secretion, we have developed a rat model in which octreotide (a somatostatin analog) was infused peripherally to inhibit insulin secretion with and without glucose-induced hyperglycemia. In this model, we have shown that peripheral vasopressin levels are elevated only in the hyperglycemic, insulin-deficient rats. In the present experiment, we investigate the effect of peripherally infused octreotide on sites of vasopressin synthesis in the rat brain. Non-fasted, awake, chronically catheterized 325-350g male Sprague-Dawley rats received an intravenous infusion of 140 mEq NaCl (12 ml/kg/hr) for 110 minutes. Rats also received either a 10% dextrose infusion (12 ml/kg/hr), octreotide (250 µg/kg/hr) or both. Blood was sampled from a jugular catheter at the end of the infusion. Animals were then perfused transcardially with buffered 4% paraformaldehyde/2% acrolein. The brains were removed, microtome sectioned at 25 µm, and stained for c-fos immunoreactivity. Rats receiving octreotide alone exhibited plasma glucose levels near 150 mg/dl and insulin levels of 7 ng/ml. Infusion of 10% dextrose increased plasma glucose to 950 mg/dl. Octreotide blunted the insulin response to dextrose infusion: 16 ng/ml in octreotide treated versus 39 ng/ml in rats receiving dextrose alone. Strong fos activation was found in the magnocellular neurons in the rats which received octreotide or octreotide plus dextrose, but only marginal activation in rats receiving dextrose alone. From these observations, we suggest that the peripheral octreotide infusion either stimulates magnocellular neurons directly or that a state of relative insulin deficiency triggers an osmotic response to glucose in osmosensitive neurons. Supported by DK 16166.

## OSMOREGULATION: MECHANISMS

## 349.1

ANTAGONISTIC EFFECT OF ANGIOTENSIN II AND NITRIC OXIDE ON RAT SUBFORNICAL ORGAN NEURONS

H.A. SCHMID\*, M. RAUCH and E. SIMON. Max-Planck-Institute, Kerckhoff-Institute, Parkstr. 1, 61231 Bad Nauheim, Germany.

Confirming previously published results on duck subfornical organ (SFO) neurons (Schmid et al., 1995, Neurosci. Lett. 187:149-152), 90% (n=20) of rat SFO neurons showed an excitatory response to  $10^{-6}$ M angiotensin II (ANGII) and were additionally inhibited by the nitric oxide donor sodium nitroprusside (SNP,  $10^{-4}$ M). Those data were derived using the same extracellular recording technique from slices of the rat SFO as used for the duck experiments. The antagonistic effect of ANGII and SNP on the activity of SFO neurons might represent the cellular basis for the antagonistic effect of both substances on water intake, when directly applied into the rat SFO. The inhibitory effect of SNP is presumably mediated by an activation of guanylate cyclase, because superfusion of the membrane permeable analog 8-Br cGMP ( $10^{-4}$ M) caused an inhibitory effect on neurons which could be inhibited by SNP. To further investigate the transduction mechanism underlying the effects of ANGII and SNP on those neurons, cells were acutely dissociated from the SFO of 8-16 days old rats and investigated with patch clamp recording techniques in the whole cell recording mode. After a gigohm seal had been established, the reactivity of the cells was tested by applying a brief puff of glutamate ( $10^{-3}$ M) or ANGII ( $10^{-6}$ M). In contrast to non-spiking glial cells, the cells which showed an increased action potential frequency to glutamate and/or ANGII displayed a rapidly desensitizing, TTX-sensitive (0.5mM) inward current under voltage clamp conditions and a rapidly and a slowly decaying outward current component. At a holding potential of -70mV glutamate induced a rapidly desensitizing inward current, while ANGII caused an inhibition of the rapidly and slowly desensitizing potassium current component. Supported by DFG Si 230/1.

## 349.2

COLOCALIZATION OF ANGIOTENSIN II AND NEUROPHYSIN II/VASOPRESSIN IMMUNOREACTIVITY IN THE PRIMARY CULTURE OF RAT SUBFORNICAL ORGAN. M. Jurzak\*, R. Gerstberger, F. Fahrenholz and A. K. Johnson. Dept. Psychology and Pharmacology, Univ. of Iowa, Iowa City, IA 52242-1407.

To characterize the peptide content of cultured subfornical organ (SFO) cells, specific antibodies were employed to localize angiotensin II (ANGII), neurophysin II (NPII) and vasopressin (AVP). After 5-7 days in culture, between 50 and 98 % of SFO cells with neuronal morphology revealed strong ANG immunoreactivity (n=12). Cells exhibiting the same morphology stained positive with a neuron specific enolase (NSE) antibody. In double-labeling experiments, colocalization of NPII and ANG was found in  $94 \pm 3.9$  % of cells. The two antibodies revealed a differential staining pattern, with ANG reactivity extending from the cell body into processes and NPII staining restricted to the cytoplasm. In ELISA tests the polyclonal rabbit ANGII antibody used revealed the following reactivity pattern: ANGII = ANGIII >> ANG I. The specificity of the monoclonal NPII antibody was determined in ELISA. In the tissue slice, NPII reactivity completely colocalized with AVP in magno- and parvocellular neurons of the hypothalamus. In a control experiment performed in cell culture, AVP immunoreactivity paralleled the NPII staining (> 95% colocalization). These results demonstrate the capability of cultured SFO cells to synthesize ANGII and NPII/AVP. In addition, the high percentage of colocalization suggests a strong functional relationship of both transmitter systems. Supported by A. v. Humboldt Foundation.

ANGIOTENSINERGIC PATHWAYS FROM THE SUBFORNICAL ORGAN TO THE MEDIAN PREOPTIC NUCLEUS IN NORMOTENSIVE AND HYPERTENSIVE RATS. J. Tanaka\*, A. Ushigome, I. Muguruma, S. Shimamune and M. Matsuda. Dept. of Human Dev., Naruto Univ. of Educ., Tokushima 772, Japan.

Electrophysiological properties of angiotensinergic pathways from the subfornical organ (SFO) to the median preoptic nucleus (MnPO) were investigated in normotensive Wistar-Kyoto rats (WKY) and spontaneously hypertensive rats (SHR) under urethane anesthesia. (1) The activity of SFO neurons that were antidromically activated by electrical stimulation of the MnPO was compared between WKY (n = 28) and SHR (n = 27). No significant differences were observed between WKY and SHR in the latency, conduction velocity or threshold of antidromic activation. The spontaneous firing ratio was significantly higher and the refractory period was significantly shorter in SHR. (2) Sixteen out of 46 MnPO neurons in WKY and 15 out of 47 MnPO neurons in SHR were excited by both angiotensin II (ANG II) applied iontophoretically and electrical stimulation of the SFO, and the excitatory responses were abolished by the ANG II antagonist saralasin applied iontophoretically. In these MnPO neurons that exhibited the excitation to both ANG II and SFO stimulation, the spontaneous discharge rate was significantly higher and the threshold current for the SFO stimulus-evoked excitation was significantly lower in SHR. The sensitivity to SFO stimulation was much greater in SHR than in WKY. These results provide evidence that there are marked alterations in the physiological properties of the angiotensinergic pathways from the SFO to the MnPO between WKY and SHR.

ISOTONIC VOLUME CHANGES AND OSMOTIC STIMULI EVOKE SIMILAR RESPONSES IN NEURONS OF THE RAT OVLT. H. Hiruma, D. Richard and C.W. Bourque\*. Centre for Research in Neuroscience, Montreal General Hospital & McGill University, Montreal, P.Q. Canada H3G 1A4.

Osmotically-evoked changes in membrane potential control the electrical activity of neurons in the organum vasculosum lamina terminalis (OVLT). Whole cell recordings examined the possibility that changes in volume mediate osmosensitivity in OVLT neurons acutely isolated from adult rats. Hypertonic and hypotonic stimuli ( $\pm 10$ -30 mM mannitol; n=32) evoked depolarizing and hyperpolarizing responses, respectively. Voltage-current analysis indicated that such effects result from increases and decreases in membrane conductance, with associated reversal potentials of  $-41 \pm 3$  (n=8) and  $-38 \pm 2$  (n=5) mV. Isotonic increases or decreases in cell volume caused by the application of positive or negative pressure to the inside of the patch pipette also respectively evoked depolarizing and hyperpolarizing responses. The latter were associated with increases and decreases in input conductance, with reversal potentials of  $-36 \pm 6$  (n=9) and  $-39 \pm 7$  mV (n=4). Thus, variations in cell volume evoked by either changes in pipette pressure or external osmolality appear to modulate a similar conductance pathway. Since  $E_{Cl}$  was  $< -90$  mV in our conditions, the osmosensitivity of OVLT neurons may be mediated by volume-gated nonselective cation channels. Supported by Yokohama City, the Ministry of Education, Science & Culture of Japan, The Canadian M.R.C., and the Heart & Stroke Foundation of Canada.

## 349.7

LARGE ANION CHANNELS ARE NOT ACTIVATED DURING ASTROCYTE REGULATORY VOLUME DECREASE (RVD). E. Scemes, A. Andrade-Rozental\* and D.C. Spray. University of Sao Paulo, Sao Paulo, Brazil and Albert Einstein College of Medicine, Bronx, NY 10461

Large conductance anion channels have been described in a variety of cell types, including astrocytes. We have investigated the question of whether these maxi-anion channels are involved in cell volume regulation in primary cultures of mouse astrocytes. These cells were exposed to moderate hypo-osmotic shocks (20%) and the time course of RVD was evaluated by the dye-dilution method using real time confocal microscopy. Channel activity was recorded using the cell-attached patch-clamp technique. Large conductance anion channels were observed in 17% of inside-out patches (7 of 41) obtained from astrocytes in symmetrical 140 mM NaCl, with slope conductances of 370-380 pS. Open probabilities of the channels were high at 0 mV and quite low at  $\pm 40$  mV. Such channel activity was not observed in cell-attached recordings from astrocytes exposed to 140 mM NaCl solution but appeared in only 1 of 55 of the patches at 10 min after application of the hypo-osmotic shock. Slope conductance of this channel was 150-160 pS in the cell-attached mode and after excising the patch the slope conductance was 350-360 pS. Since the time course of astrocyte RVD was 3 min, whereas channel activity was seen only once and then only at 10 min after the hypo-osmotic shock, the maxi-anion channel does not appear to play an obligatory role in astrocyte RVD under our recording conditions.

## 349.4

MEDIAN PREOPTIC NEURONS PROJECTING TO THE PARAVENTRICULAR NUCLEUS IN NORMOTENSIVE AND HYPERTENSIVE RATS. K. Kariya\*, M. Oda<sup>1</sup>, M. Kurumi<sup>1</sup>, K. Hon<sup>2</sup>, M. Nomura<sup>2</sup> and J. Tanaka<sup>3</sup>. <sup>1</sup>Res. Lab., Torii Co., Chiba 267, <sup>2</sup>Dept. of Physiol., Saitama Med. Sch., Saitama 350-04, <sup>3</sup>Dept. of Human Dev., Naruto Univ. of Educ., Tokushima 772, Japan.

Twenty-one median preoptic nucleus (MnPO) neurons in normotensive Wistar-Kyoto rats (WKY) and 18 MnPO neurons in spontaneously hypertensive rats (SHR) were antidromically activated by electrical stimulation of the hypothalamic paraventricular nucleus (PVN) under urethane anesthesia. No significant differences in the latency, conduction velocity, or threshold of antidromic activation were observed between WKY and SHR. The spontaneous firing ratio was significantly higher in SHR than in WKY. The activity of these identified MnPO units was examined for a response to intracarotid injections of isotonic (0.15 M NaCl solution, 0.05 ml) or hypertonic (0.3 M NaCl solution, 0.05 ml) saline. Injections of isotonic saline did not cause any change in the activity of all the units tested. Injections of hypertonic saline elicited an increase in the firing of 14 units in WKY and 12 units in SHR and a depression in the excitability of 3 units in WKY and 4 units in SHR, but did not affect the remaining 4 units in WKY and 2 units in SHR. The duration and frequency of excitatory response, but not the inhibitory response, evoked by the osmotic stimulation was much greater in SHR than in WKY. These results show that MnPO neurons projecting to the PVN may carry the information from osmosensitive elements, and that there is the difference between WKY and SHR in the responsiveness of these MnPO neurons to the osmotic stimulation.

## 349.6

ROLE OF  $Na^+/H^+$  EXCHANGE IN SWELLING OF GLIAL CELLS GROWN UNDER DIABETIC KETOACIDOTIC CONDITIONS. R.W. Putnam, P.B. Douglas, N. Sheibani and J.B. Dean\*. Dept. of Physiology and Biophysics, Wright State Univ. Sch. of Med., Dayton, OH 45435.

A small number of children treated for diabetic ketoacidosis (DKA) develop neurologic symptoms within hours of treatment and many of these children die. This effect has been attributed to the release from inhibition of glial cell  $Na^+/H^+$  exchange (NHE) upon correction of  $pH_i$ , resulting in increased NHE activity and glial cell swelling (Van der Meulen et al., 1987, *Lancet* ii:306-308). We tested this hypothesis by growing C6 glioma cells for 48 hr under DKA conditions: normal media + 50 mM glucose (total of 55 mM) + 6 mM  $\beta$ -OH butyrate (BHB) + 2 mM acetoacetate (AA). The day that cells were to be used,  $pH_i$  was lowered from 7.4 to 6.5 (decreased  $HCO_3^-$  at constant 5%  $CO_2$ ) for 2 hr. Changes in cell volume were measured using near-right angle laser light scattering and  $pH_i$  was measured using the pH-sensitive dye BCECF in an SLM DMX1000 Spectrofluorometer. All measurements were made in confluent monolayers of C6 cells. All experiments were done at 37°C in NaHEPES buffer in the nominal absence of  $CO_2/HCO_3^-$ . Correcting external glucose (from 55 to 5 mM) resulted in glial cell swelling with no change of  $pH_i$ . Removal of all external ketoacids resulted in a small decrease in cell volume and a marked ( $-0.67$  unit)  $pH_i$  increase. This  $pH_i$  increase was largely due to the removal of BHB and, to a much smaller extent, to the removal AA. Correcting external  $pH$  (6.5  $\rightarrow$  7.4) resulted in a small volume decrease and a rapid increase of  $pH_i$  that was largely unaffected by the NHE inhibitor amiloride. Exposure of C6 cells to insulin (up to 10 nM) did not affect  $pH_i$  nor did it increase the activity of NHE in response to cell acidification. These data indicate that neurologic symptoms associated with treatment of juvenile DKA are unlikely to be due to glial cell swelling associated with NHE activity. [Supported by the Juvenile Diabetes Foundation, International.]

## 349.8

LACK OF DELAYED VOLUME REGULATION IN RAT HIPPOCAMPAL SLICES DURING OSMOTIC STRESS. M.E. Lobinowich, E.P. Oseghobo and R.D. Andrew\*. Dept. of Anatomy and Cell Biology, Queen's Univ., Kingston, Ontario K7L 3N6.

Brain cells in culture respond to severe and maintained osmotic stress by passive volume changes followed over many seconds by some compensation. There is little evidence for or against this form of volume regulation in the intact mammalian brain. In the hippocampal slice where the neuron-glia relationship is maintained, we imaged changes in light transmittance ( $T$ ) as well as tissue resistance (both measures of cell volume change) during physiological extremes of osmotic change to detect evidence for cellular volume regulation. During superfusion of hypo-osmotic aCSF (-40 mOsm)  $T$  increased 20 to 25% in CA1 RAD (n = 6 slices). The response was maintained throughout hypo-osmotic stress over 45 min. This 'plateau' response argues against a delayed volume compensation. Moreover  $T$  did not 'undershoot' but immediately returned to baseline following re-introduction of control aCSF. A similar increase in  $T$  ( $27.7 \pm 2\%$ ) occurred at 35°C in 7 slices. In addition, the -40 mOsm aCSF reversibly increased the relative tissue resistance ( $R_{rel}$ ) measured across CA1 RAD (n = 9 slices) with a time course identical to the increase in  $T$ . Conversely, mannitol (+40 mOsm) decreased  $R_{rel}$  by 8% (n = 12 slices) and decreased  $T$  by 15.5%, again with no volume compensation over 20 min. When  $Cl^-$  was removed from the aCSF, a volume reduction occurred following initial swelling. This 'delayed' regulatory response may reflect extreme and unphysiological conditions.

To conclude, there was no evidence in the hippocampal slice for volume compensation over many minutes in the face of maintained osmotic stress at physiological extremes.

## 350.1

**ANATOMIC CHARACTERIZATION OF THE VENTRAL MEDIAL PREOPTIC AREA: INVOLVEMENT IN THE FEBRILE REACTION.** J. K. Elmquist\*, T. E. Scammell, J. E. Sherin, C. D. Breder, and C. B. Saper. Dept. of Neurology, Harvard Medical School/Beth Israel Hospital, Boston, MA 02115, and Committee on Neurobiology, Univ. of Chicago, Chicago, IL 60637.

Intravenous (iv) administration of endotoxin (LPS) induces the expression of Fos-like immunoreactivity (Fos-IR) in nuclear groups of the rat brain involved in regulation of autonomic homeostasis. One of these regions, the ventral medial preoptic area (VMPO) may be an important site for the initiation of fever. The VMPO is a small cell group located immediately adjacent to the organum vasculosum of the lamina terminalis (OVLT) and is near thermoregulatory cells of the preoptic area. Immunohistochemical analysis of VMPO revealed a GABAergic (GAD-67) cell population and the presence of neuronal cyclooxygenase-II (COX-II), the enzyme responsible for the production of prostaglandins. Furthermore, LPS administration induced COX-II-like immunoreactivity in perivascular cells in VMPO and the OVLT. The afferent and efferent projections of VMPO were assessed using small injections of a mixture of biotinylated dextrans and cholera toxin-b (CTb) into the region of VMPO. These injections revealed that VMPO neurons project to many sites including the medial preoptic nucleus, dorsomedial hypothalamic nucleus (DMH), lateral hypothalamic area, parabrachial nucleus, and the paraventricular hypothalamic nucleus (PVH). Retrogradely labeled cells were observed in regions including the DMH, suprachiasmatic nucleus, ventrolateral medulla, and the PVH. Anatomic and physiological evidence indicates that the PVH is essential for thermoregulation and initiation of fever. The potential role of the VMPO-PVH projection during the febrile response was assessed by injecting CTb into the PVH of rats, followed by iv febrile doses of LPS (5 or 125 µg/kg) 5-7 days later. Analysis of these brains demonstrated numerous retrogradely labeled cells in VMPO, many of which also contained Fos-IR. These results indicate that VMPO is activated following LPS challenge and some of these cells project directly to the PVH. These observations indicate that VMPO may be involved in the initiation of the febrile response following LPS.

**MORPHOLOGICAL CHARACTERISTICS OF HYPOTHALAMIC THERMOSENSITIVE AND TEMPERATURE INSENSITIVE NEURONS.** J. D. Griffin\* and C. B. Saper. Department of Neurology, Beth Israel Hospital and Harvard Medical School, Boston, MA 02115

Tight-seal, whole-cell recordings were made from rat hypothalamic neurons in horizontal or coronal tissue slices during changes in temperature. The intracellular stain biocytin (0.5%) was added to the tip of all recording electrodes. Neurons were classified as warm sensitive, cold sensitive, or temperature insensitive based on firing rate responses to a change in temperature. Neurons which did not show spontaneous firing rate activity were classified as silent. At the end of a recording session, tissue slices were fixed and biocytin histochemistry was done to determine the exact location and morphological characteristics of each neuron. Warm sensitive neurons in the medial preoptic nucleus (MPN), anterior hypothalamic area (AHA), and perifornical region displayed branching bipolar dendrites projecting in lateral and medial directions. Temperature insensitive neurons in the medial preoptic area, MPN, AHA, and perifornical region had primary dendrites projecting in parallel to the edge of the third ventricle (rostral/caudal or dorsal/ventral). Neurons classified as silent were located in the MPN, lateral hypothalamic area, perifornical region, and the septum. They had multipolar dendritic arborizations, averaging four primary dendrites projecting in all directions. The results of this study indicate that the dendritic orientation of neurons in the preoptic area correlates closely with their thermoreceptive properties. We hypothesize that dendritic orientation may reflect the organization of hypothalamic neurons into specific networks for thermal and related regulation.

## 350.5

**GLUTAMATE AND GLUTAMINE ANTAGONISTS ALTER HEAT-SHOCK PROTEIN EXPRESSION AND THERMAL PROFILES IN RATS EXPOSED TO MICROWAVE HEATING.** P. A. Mason\*, K. E. Purdy<sup>2</sup>, T. J. Walters<sup>3</sup>, J. M. Doyle<sup>3</sup>, J. L. Kane<sup>3</sup>, and R. Escariga<sup>1</sup>. Operational Technologies Corp., San Antonio, TX, 78229, <sup>2</sup>Trinity University, San Antonio, TX, 78212, <sup>3</sup>Systems Research Laboratories, San Antonio, TX, 78235, and <sup>4</sup>Armstrong Laboratory, Radiofrequency Radiation Division, Brooks AFB, TX, 78235

Glutamate and glutamine have putative roles in inducing heat-shock protein (hsp) expression. The effects of MK-801, a selective non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist, and L-methionine sulfoximine (L-MSO), a glutamine synthetase inhibitor, on the expression of hsps (72/73 kDa) in the rat brain after brief periods of hyperthermia were examined. L-MSO decreased basal temperatures. High-powered microwaves (2.06 GHz) delivered at 1.7 W/cm<sup>2</sup> were used to induce hyperthermia in male Sprague-Dawley rats. These rats were euthanized 6 hr after exposure. Hsp expression was quantitated in immunohistochemically-stained sections. When tympanic temperatures exceeded 40.3°C, hsp was expressed in the brains of saline-injected rats with some regions revealing dense hsp expression. MK-801 (3.0 mg/kg, i.p.), injected 90 min prior to exposure, attenuated hsp expression. MSO (150 mg/kg, i.p.), injected 3 hr prior to exposure, also attenuated hsp expression. No hsp expression was observed in sham-exposed rats receiving saline injections. MK-801 induced hsp expression in layers III & IV of the retrosplenial granular cortex of sham-exposed rats.

## 350.2

**PREOPTIC PROSTAGLANDINS AND FEVER**

T. E. Scammell\*, J. K. Elmquist, and C. B. Saper. Dept. of Neurology, Harvard Medical School / Beth Israel Hospital, Boston, MA 02115

Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) is essential in the production of fever, yet the necessary sites of PGE<sub>2</sub> synthesis and action are unknown. To determine precisely the brain regions at which PGE<sub>2</sub> produces fever, we have developed a microinjection technique that does not alter normal thermoregulation and allows temperature recording in unrestrained animals. Microinjection of PGE<sub>2</sub> into the preoptic area of male, Sprague-Dawley rats rapidly induced fever, and the largest fevers were caused by injections close to the organum vasculosum of the lamina terminalis (OVLT) and the adjacent ventromedial preoptic area. The pattern of neural activation induced by intrapreoptic PGE<sub>2</sub> was determined using Fos immunohistochemistry. As is seen during lipopolysaccharide (LPS) fever, many autonomic regulatory regions contained neuronal Fos-like immunoreactivity (Fos-IR) including the ventromedial preoptic nucleus, median preoptic nucleus, paraventricular nucleus, parabrachial nucleus, nucleus of the solitary tract, and ventrolateral medulla. In contrast, injection of artificial CSF into the preoptic area had no effect on body temperature and did not induce significant Fos-IR in any autonomic control nuclei. To determine if PG synthesis in the region of the OVLT is essential for the production of fever, we have begun to study whether preoptic injections of ketorolac, a water-soluble inhibitor of prostaglandin production, blocks LPS-induced fever. Injection of ketorolac close to the OVLT suppressed LPS fever, but injections more than 800 µm away from the OVLT had little effect on fever. Taken together, these experiments demonstrate that prostaglandins produced in the region of the OVLT contribute to the production of fever, and preoptic injection of PGE<sub>2</sub> produces fever via neural pathways similar to those activated during endotoxin fever.

## 350.4

**MODULATORY ROLE OF CYCLIC AMP IN RAT HYPOTHALAMIC NEURONAL THERMOSENSITIVITY.** A. R. Chow and J. A. Boulant\*. Department of Physiology, The Ohio State University, Columbus, OH 43210

Using rat hypothalamic tissue slices, our previous studies have shown that, in the preoptic/anterior hypothalamus, neuronal warm-sensitivity can be enhanced by drugs that elevate intracellular cyclic adenosine 3',5'-monophosphate (cAMP). The present experiments used whole-cell patch clamp recordings to examine the mechanisms of cAMP's effect on neuronal thermosensitivity. Unlike the low-slope temperature insensitive neurons, in warm sensitive neurons and moderate-slope temperature insensitive neurons, the cAMP analog, 8-bromo-cAMP (250-500 µM), enhanced the effect of temperature on the rate of depolarization of prepotentials that precede each action potential. Also, in some neurons, cAMP altered the effect of temperature on the depolarization that follows the after-hyperpolarizing potential. Both of these cAMP effects produce decreased interspike intervals and increased firing rates during warming; and, thus, they provide mechanisms for cAMP-enhanced neuronal thermosensitivity. (Supported by NIH grant NS14644.)

## 350.6

**THERMAL RESPONSIVENESS OF VENTROMEDIAL HYPOTHALAMIC NEURONS (VMH) OF COLD-AND ROOM TEMPERATURE-ACCLIMATED RATS.** Q. Li and J. Thornhill. Dept. of Physiology, Univ. of Saskatchewan, Saskatoon, Sask. Canada. S7N 5E5.

Previous work has shown that neurons in the ventromedial hypothalamic nucleus (VMH), a well-known central site that governs non-shivering thermogenesis, specifically respond to scrotal thermal stimulation (10-40°C) of room temperature (21°C) acclimatized rats (RA). The present experiments were conducted to examine the responsiveness of VMH neurons in cold-acclimated rats (CA) (4°C for 4 wks) to scrotal thermal stimulation. VMH extracellular activity was recorded with a glass-micropipette filled with 0.5 M sodium acetate in urethane-anaesthetized, male cold-acclimated Sprague-Dawley rats, when scrotal temperature was incrementally changed via a localized thermode perfused with water. T<sub>SCROTUM</sub>, T<sub>TAIL</sub> and intrascapular brown adipose tissue temperatures (T<sub>IBAT</sub>) were continuously monitored on the computer via thermistor probes and a temperature monitor. Colonic (core) temperature was maintained at 37.5°C via a servo-controlled heating blanket. Based on their thermal coefficients, VMH neurons were classified as warm-responsive (WRN), cold-responsive (CRN) and temperature non-responsive neurons (TNRN). CA-rats, but not RA-rats, showed a significant increase (P < 0.05) in T<sub>IBAT</sub>s after scrotal cooling. Compared to neurons from RA-rats, recorded VMH neurons of CA-rats displayed a higher control basal firing rate and VMH CRNs of CA-rats increased their thermosensitivity to scrotal thermal stimulation. The neuronal activity of VMH TNRNs was not altered by thermal stimulation. The results indicated that cold acclimation (1) increased T<sub>IBAT</sub>s to scrotal cooling, unlike RA rats and (2) caused associated changes in VMH neuronal activity, suggesting that VMH neurons are involved in the observed adaptive response of IBAT to cold acclimation. Supported by the MRC of Canada.

## 350.7

PROJECTIONS FROM THE PREOPTIC AREA TO THE MIDBRAIN FOR THERMOREGULATORY VASOMOTOR CONTROL IN RATS. Y.-H. Zhang, K. Yamada, M. Yanase-Fujiwara, T. Hososno, X.-M. Chen, and K. Kanosue\* Dept. of Physiology, Dept. of Basic Laboratory Science, Osaka Univ. Med. Sch., Osaka 530, Japan.

To investigate the midbrain sites innervated by neurons of the preoptic area for thermoregulatory vasomotor control we measured paw skin and tail skin temperature while stimulating midbrain areas with electrical current and with 1 mM DL-homocysteine acid and we evaluated the effects of various microknife cuts on the skin vasomotion elicited by warming the preoptic area. Experiments were made in rats anesthetized with ketamine (200 mg/kg i.p.). Electrical or chemical stimulation of sites in the ventral part of the periaqueductal grey (PAG) and in the reticular formation caused vasodilation, whereas stimulation of sites in the ventral tegmental area produced vasoconstriction. Microknife cuts rostral to the ventral tegmental area or in the PAG eliminated vasodilation by preoptic warming, whereas cuts caudal to the ventral tegmental area elicited sustained skin vasodilation. Warm-sensitive neurons in the preoptic area contribute to vasomotor control more than do cold-sensitive neurons (Zhang et al., J. Physiol., 1995), and it seems that these warm-sensitive neurons send excitatory signals to the vasodilator neurons in the PAG and in the reticular formation, while they send inhibitory signals to vasoconstrictor neurons in the ventral tegmental area.

## 350.9

INVOLVEMENT OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTORS (PPARs) IN COLD ADAPTATION. H. M. Guardiola-Diaz\*, S. Rehnmark, J.-Å. Gustafsson and S. E. H. Alexson Ctr. for Biotechnology, Karolinska Inst. at NOVUM; Dept. of Metabolic Research, Wenner Gren Institute at Stockholms Univ.; and Div. of Clinical Chemistry at the Karolinska Inst., S-141 57 HUDDINGE, Sweden.

PPARs are nuclear receptors responsive to peroxisome proliferators such as clofibrate, nafenopin and WY-14,643 as well as fatty acids. Endogenous ligand(s) for these proteins have not been identified, therefore PPARs are considered orphan nuclear receptors. Several isoforms of this receptor ( $\alpha$ ,  $\gamma$ ,  $\gamma$ 2,  $\text{nucl}(\beta, \delta)$ ) have been isolated from rodent, human and amphibian tissues. Previous reports suggest that the PPAR $\gamma$ 2 and  $\text{nucl}$  isoforms may play important roles in adipose tissue differentiation. Since this process is pivotal to the mammalian adaptation to cold we hypothesize that PPAR isoforms could be mediating important metabolic changes during cold exposure. We have tested this hypothesis by analyzing PPAR mRNA expression in rodent brown adipose tissue as a function of time in the cold (4°C). Our results demonstrate that PPAR $\gamma$ 2 and  $\text{nucl}$  mRNA levels increase after one hour exposure to cold and are then rapidly repressed (after 6 hours) below control levels. These data imply that PPARs are involved in the initial molecular changes in the cold adaptive response probably by modulating transcription of PPAR-responsive genes.

## NEUROENDOCRINE REGULATION: THYROID AND GONADAL AXES

## 351.1

LITHIUM AND CARBAMAZEPINE AFFECT INTRACELLULAR THYROID HORMONE METABOLISM IN THE RAT CNS. U. Gaio, G. Pinna, M. Eravci, C. Hassenius, A. Campos-Barros, A. Musa, J. Mihic\*, H. Meinhold and A. Baumgartner, Depts Nuclear Medicine and Psychiatry\*, Clinic B. Franklin, Free Univ., 12200 Berlin, Germany and Dept. Pharmacol., Univ. of Colorado H.S.C., Denver, CO 80262, USA.

Severe hypothyroidism may induce a host of affective symptoms in humans. Interactions between antidepressants and thyroid hormone (TH) production and metabolism are reported. Supply of T3 in brain depends mostly on the cellular uptake and intracellular deiodination of T4 by the type-II 5' deiodinase (5'D-II). 5'-III-deiodinase (5D-III) deiodinates T3 to 3,3'-T2. The effects of antidepressant drugs on the activity of the two enzymes 5'D-II and 5D-III are dependent on the time of day. We investigated at two different times during the 24 hrs cycle whether subchronic (14 days) administration of lithium (Li) and carbamazepine (CBZ) exerts an influence on TH metabolism in rat CNS. Three groups comprising 16 rats each were fed a diet containing 0.3% Li or CBZ or the same without Li or CBZ for 14 days, respectively. Eight Li- or CBZ-treated rats and 8 control rats were killed by decapitation between 4 and 5 AM, and the 8 remaining rats in each of the three groups were sacrificed between 7-8 PM. The measurement of deiodinase activities was based on the release of radioiodide from  $^{125}\text{I}$ -labelled substrates. CBZ, but not Li, enhanced 5'D-II deiodinase activity in 2 brain areas at 4 AM. In rats sacrificed at 8 PM, however, both Li and CBZ significantly increased 5'D-II activity in 7 and in 9 out of 10 brain areas, respectively. At 4 AM, 5D-III activities were inhibited after Li treatment in 6 brain areas and only in hippocampus after CBZ. At 8 PM, while CBZ had no effect, Li decreased 5D-III activities in frontal cortex and striatum. The mean serum Li concentrations were  $1.30 \pm 0.13$  mmol/L and  $1.37 \pm 0.10$  mmol/L, for CBZ  $5.8 \pm 0.5$  mg/L and  $5.3 \pm 0.51$  mg/L for the groups sacrificed in the morning and evening respectively. These results demonstrate that antidepressant treatment with Li and CBZ affect intracellular thyroid hormone metabolism in various rat brain areas. These effects are dependent on the circadian rhythm and probably result in increased T3 production. Whether or not the changes in the activities of 5'D-II and 5D-III are linked to the prophylactic properties of Li and CBZ in the treatment of affective disorders remain to be further elucidated.

## 350.8

SYMPATHETIC OUTFLOW TO INTERSCAPULAR BROWN ADIPOSE TISSUE AND NONSHIVERING THERMOGENESIS IN COLD ACCLIMATED MICE. S.A. Kirov\* and M.I. Talan, Laboratory of Behavioral Sciences, National Institute on Aging, NIH, Gerontology Research Center, Baltimore, MD 21224.

Efferent sympathetic nervous activity (SNA) from a small branch of the intercostal nerve, which ended in the interscapular brown adipose tissue, and heat production from nonshivering thermogenesis (HP) were measured in male, C57BL/6J mice under urethane anesthesia, vecuronium bromide myorelaxation, and artificial ventilation. All measurements were conducted before and during rapid (15-18 min) whole body cooling (8°C below control level). Three groups of mice were tested: (1) cold acclimated (ACCLIM) (subjected to three, consecutive, cold stress tests that resulted in improvement of cold tolerance); (2) failed acclimated (FAILED) (repeated cold stress tests did not result in improvement of cold tolerance); and (3) NAIVE.

SNA and HP increased significantly during body cooling in all mice. Animals from the FAILED group had lower SNA and lower HP before and during cold stimulation than mice from the ACCLIM group. Maximal responses to cold stimulation of ACCLIM mice exceeded those of FAILED mice by 57% for SNA and by 24% for HP. SNA and HP in the FAILED group were similar to that of NAIVE mice. These findings indicate that the sympathetic nervous system plays a primary role in cold acclimation-related changes of nonshivering thermogenesis.

## 351.2

EFFECTS OF LITHIUM ON GENE EXPRESSION OF THYROID HORMONE RECEPTORS (THRS) IN RAT BRAIN. C.-G. Hahn, A. C. Pawlyk, P.C. Whymbrow\* and S. M. Tejani-Butt, Dept. of Psychiatry, Univ. of Penn. Sch. of Med., Phila., PA 19104.

Even though lithium has received wide attention in the treatment of manic depressive illness, the mechanisms by which lithium causes its mood stabilizing effects are not yet understood. Lithium is known to interact with the thyroid axis and causes hypothyroidism in a subgroup of patients which compromises its antimanic effects. Since subchronic lithium was recently reported to alter thyroid hormone metabolism in the rat frontal cortex, the present study determined whether these effects of lithium were mediated through regulation of THR gene expression. Adult male euthyroid rats were given either a diet containing 0.25% lithium or one without lithium for 14 days. Rats were sacrificed in the evening and different brain regions were isolated and frozen. RNA was isolated from the cortex, hypothalamus and cerebellum. To quantitate the isoform specific mRNAs of THR $\alpha$ 1 and THR $\alpha$ 2, RNase protection assay as well as Northern blot analysis was employed. Repeated treatment with lithium increased THR $\alpha$ 1 mRNA in the cortex, decreased THR $\alpha$ 1 mRNA in the hypothalamus and had no effect in the cerebellum.

In contrast, THR $\alpha$ 2 gene expression was found to be unaltered in these brain regions. Thus it appears that repeated lithium regulates THR gene expression in a subtype and tissue specific manner in the rat brain. It remains to be determined whether the observed effects of lithium on THR gene expression is related to its therapeutic value in the treatment of bipolar disorder.

## 351.3

THYROID HORMONE RECEPTOR  $\alpha 2$  mRNA LEVELS ARE INCREASED IN THE HYPOTHALAMUS OF ADULT HYPOTHYROID RATS. A. C. Pawlyk, P. A. Rittenhouse\*, E. Redej and S. M. Tejani-Butti. Depts. of Psychiatry and Pharmacology, Univ. of Penn. Sch. of Med., Phila., PA 19104.

The role of thyroid hormones (TH) on brain function has been thought to be restricted to developmental influences. Although it has been suggested that thyroid hormone receptor (THR) gene expression is insensitive to alterations in thyroid status in the adult rat brain, the expression of prepro-TRH has been found to be altered in the hypothalamus in response to thyroidectomy. Therefore, changes in thyroid status may affect expression of TH responsive genes. In the present study, we examined the status of THR $\alpha 2$  gene expression in the hypothalamus of adult male rats that were rendered hypothyroid by the addition of 0.05% 6-propyl-thiouracil in their drinking water for 4 weeks. Following this period, rats were sacrificed and hypothalamic tissue was dissected and frozen. RNA was isolated and probed for THR $\alpha 2$  using Northern blots. Hypothalamic THR $\alpha 2$  mRNA levels were found to be significantly increased in hypothyroid rats when compared to euthyroid rats. Our results indicate that THR $\alpha 2$  can be regulated in the hypothalamus in response to decreased availability of TH. Since unliganded THR $\alpha 2$  can regulate gene expression, the observed increase in THR $\alpha 2$  gene expression in hypothyroid rats could have functional significance in hypothalamic gene regulation.

## 351.5

LIFELONG TREATMENT OF RATS WITH ANGIOTENSIN-CONVERTING ENZYME INHIBITOR DELAYS PUBERTY IN FEMALE RATS. R.C. Speth\*, E.E. Nilsson, D. Edwards and K.H. Berecek Washington State University, Pullman, WA 99164-6520 and Dept Physiology & Biophysics University of Alabama at Birmingham, Birmingham, AL 35294

Inhibition of the brain renin-angiotensin system (BRAS) disrupts luteinizing hormone (LH) release and ovulation in normal cycling rats. Angiotensin II (AII) receptors in regions of the brain that regulate LH release are lower in prepubertal females than in mature females, suggesting that stimulation of AII receptors in these brain areas is critical for puberty to occur. To investigate this question, female Wistar-Kyoto rats were treated throughout their lives with the angiotensin-converting enzyme (ACE) inhibitor captopril, to inhibit formation of AII. Prior to conception and through weaning, the dams were maintained on 400 mg/ml of captopril in their drinking water. Upon weaning, the pups were maintained on captopril containing water until the time at which they were sacrificed. The age at which the captopril-treated rats underwent vaginal opening and first estrus was monitored and compared to a control group of rats. Vaginal opening occurred later in the captopril treated rats, 38.6 $\pm$ 0.8 (Mean $\pm$ SD) versus 34.9 $\pm$ 1.1 days of age in the control group,  $p < 0.001$ . The age of first estrus was also similarly delayed, 43.3 $\pm$ 1.3 versus 39.0 $\pm$ 2.3 days of age ( $p < 0.001$ ) for the captopril-treated and control groups, respectively. The body weight of the control rats at time of sacrifice (the first proestrus day after the first estrus) was significantly greater ( $p < 0.025$ ) than that of the captopril-treated rats, 102 $\pm$ 7.6 versus 93 $\pm$ 6.3 grams, respectively, despite the slightly earlier age at the time of sacrifice of the control rats. These results suggest that inhibition of ACE delays puberty and slows development. Formation of AII is a major function of ACE, however, this enzyme also acts to degrade bradykinin, opioid peptides and substance P. Thus while the effects of captopril to delay puberty suggests that AII stimulation of brain AII receptors is important for the timely occurrence of puberty, other peptide substrates of ACE may also be involved in this process. Supported by NIH grants, NS21305, HL31515, HL46554.

## 351.7

SUBCELLULAR LOCALIZATION OF SPECIFIC MEMBRANE ESTROGEN BINDING SITES IN FEMALE RAT BRAIN. J. Zheng\* and V. D. Ramirez. Neurosci. Program and Dept. of Physiol. and Biophys., Univ. of Illinois, Urbana, IL 61801

In crude synaptosomal fractions (P2), we previously identified one (23 kDa) of three major (23, 28, 32 kDa) membrane estrogen-binding proteins as oligomycin-sensitivity conferring protein (OSCP), a subunit of mitochondrial FoF<sub>1</sub> ATP synthase. This unexpected finding prompted us to examine the subcellular distribution of membrane estrogen-binding proteins. We prepared crude nuclei (P1), mitochondrial (mP2) and microsomal (P3) fractions from adult female rat brain. The estrogen-binding sites were determined by radioligand binding assay using 17 $\beta$ -estradiol-6-carboxymethyl)oxime: [125I]-bovine serum albumin conjugate (17 $\beta$ -E-6-[125I]BSA). The competition assay showed K<sub>d</sub> of 12, 15, 38 nM and B<sub>max</sub> of 21, 36, 55 pmol/mg protein for mP2, P1, and P3, respectively. The specific membrane estrogen-binding proteins were further analyzed by ligand blotting using 17 $\beta$ -E-6-[125I]BSA. In the mP2 fraction, a 23 kDa protein was strongly labeled and was identified as OSCP. An additional 40 kDa estrogen-binding protein was also uniquely labeled in mP2. In the P3 fraction, three (28, 32, and 46 kDa) proteins were highly concentrated with much less presence in mP2 and P1. In addition, a 130 kDa protein was present in all fractions but highly concentrated in P1. These data suggest that, unlike the 23 kDa protein (OSCP), the 28, 32, and 130 kDa proteins are not mitochondrial proteins, but most likely plasma membrane proteins.

## 351.4

NGF LEVEL IN THE PITUITARY GLAND DURING ADULT HYPOTHYROIDISM. L. Calza\*, O.L. Giardino, S.L. Aloe. Inst. of Human Physiology, University of Cagliari; †Inst. of Neurobiology, CNR, Rome, Italy; \*Inst. Otolaryngol., University of Milano, Italy.

The involvement of nerve growth factor (NGF) in neuroendocrine regulation is supported by several lines of evidences. Recent reports indicate that NGF and NGF high affinity receptors are present in all the different cell lines in the rat pituitary gland and NGF is secreted by anterior pituitary cells *in vitro*. Adult hypothyroidism is characterized by neurochemical abnormalities involving neurotransmitters, neuropeptides, neuronal proteins and also trophic factors in different brain areas including hypothalamus and in peripheral tissues including pituitary gland. Moreover, adult hypothyroidism is characterized by other major endocrine abnormalities involving the adrenal axis, the prolactin and the growth hormone secretion. In this paper we investigated the NGF levels in several endocrine organs of adult hypo- and hyperthyroid rats. Hypothyroidism was induced by thyroidectomy after 60 days from birth, hyperthyroidism by treatment with T4 (18mg day, added to the food pellets). The experiment has been performed after 6 weeks of hypo- and hyperthyroidism. NGF levels were measured using a two-site immunoenzymatic assay. We found a 6 fold increase of NGF-IR in the pituitary gland of hypothyroid rats (control: pg/g tissue 96.6 $\pm$ 29.1; hypothyroid: pg/g tissue 620.0 $\pm$ 95.5), whereas no differences were found in testis, adrenal gland and blood. Long term hyperthyroidism does not modified NGF levels in the investigated tissues. These data could support a possible role of thyroid hormone in the regulation of NGF expression in the pituitary gland. The NGF level modification could be also an indirect consequence of long-term hypothyroidism, suggesting a possible role of NGF in the microenvironment regulation in the anterior pituitary.

## 351.6

DOES CORTICOSTERONE PLAY A ROLE IN THE EFFECT OF PROGESTERONE UPON GABAB RECEPTORS IN THE NEOCORTEX OF RAT? M.I. Al-Dahan, and R.H. Thalmann\* Dept. of Cell Biology and The Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030

We found that injection of 0.1–2.0 mg progesterone/100g body weight significantly increased the apparent GABAB receptor density that is assayed by the binding of the GABAB agonist [<sup>3</sup>H]-baclofen to well-washed membranes prepared from the cerebral cortex of ovariectomized (OVX) rats. The progestin/glucocorticoid antagonist RU 486 injected *in vivo* reduced this binding a similar amount whether or not progesterone had been injected, suggesting either a nonspecific effect, or perhaps an antagonism of the effect of endogenous corticosterone as well as injected progesterone. When progesterone was injected in adrenalectomized, ovariectomized rats (ADX,OVX), there was an increase in baclofen binding, as in the case of OVX alone. This was the case in ADX,OVX animals whether plasma corticosterone was 850nM (presumably incomplete ADX) or 245nM. Injections of corticosterone alone that produced plasma levels of 1700nM at sacrifice 4 hours later did not increase baclofen binding. Thus, so far, we have been able to implicate only progesterone in regulating GABAB receptors in a manner similar to their regulation during the estrous cycle (Brain Res. v. 640,p33). Supported by NINDS grant NS-21713.

## 351.8

KILLING OF GH<sub>4</sub>C<sub>1</sub> PITUITARY TUMOR CELLS BY 17- $\alpha$ -IODOVINYL ESTRADIOL (<sup>125</sup>IVE<sub>1</sub>) IS CELL CYCLE INDEPENDENT. C.T. Moore\*, G.S. Schneiderman, M.H. Schneiderman, E.R. DeSombre, J.F. Rodriguez-Sierra. Depts. Cell Biology and Anatomy, Radiology, UNMC, Omaha, NE and The Ben May Institute, Univ. Chicago, IL. An asynchronously growing population of the pituitary tumor cell line, GH<sub>4</sub>C<sub>1</sub>, was exposed to 17- $\alpha$ -iodovinyl Estradiol (<sup>125</sup>IVE<sub>1</sub>) to determine whether the radiotoxic potential of <sup>125</sup>I labeled estrogen, through its estrogen receptor (ER)-mediated association with DNA, was related to the cell cycle. GH<sub>4</sub>C<sub>1</sub> cells are estrogen responsive cells and secrete both growth hormone and prolactin. Estrogen binds to DNA at the site of estrogen responsive elements (EREs), thereby altering transcription of genes. Radiolabeled IUDR (<sup>125</sup>IUDR) is an analog of the nucleoside thymidine and is incorporated into the DNA of proliferating cells during the S-phase. The percentage of cells in S-phase, the labeling index (LI), can be determined by autoradiography. <sup>125</sup>I incorporated into DNA is lethal to cells so after treatment with <sup>125</sup>IUDR the survival is equal to 1 minus LI. Therefore, we tested whether <sup>125</sup>IVE<sub>1</sub>, via mediation of ER, could deliver the <sup>125</sup>I to DNA sites thereby killing the steroid sensitive cells and whether such an effect was cell cycle dependent. GH<sub>4</sub>C<sub>1</sub> cells were grown in suspension, washed, then incubated for 70 h. Suspension cultures were divided into four groups and exposed as follows: 4.92  $\mu$ Ci/ml <sup>125</sup>IVE<sub>1</sub>, 2.00  $\mu$ Ci/ml <sup>125</sup>IUDR, 2.27  $\times 10^{-4}$  M E<sub>2</sub>, or 100 $\mu$ i 100% ethanol. Two experiments were run. In the first, cultures were exposed to <sup>125</sup>IVE<sub>1</sub> for 30 min at 37°C, washed to remove any unbound treatment, then frozen at -80°C to accumulate <sup>125</sup>I decays. At various times after treatment, cells were plated, incubated for two weeks, stained and colony survival determined. In the second experiment, cultures were continuously exposed to treatment for 95 h. At various times samples were harvested, prepared for autoradiography, and plated to determine colony survival. The LI was approximately 30% after 30 min in <sup>125</sup>IUDR, indicating that approximately 30% of the cells were in S-phase during exponential growth. The length of the cell cycle, determined from the increase of the LI with time, was approximately 40 h: G1+M+G2 phases = 25 h, S-phase = 15 h. Because the survival of cells that were frozen to accumulate <sup>125</sup>I decays from <sup>125</sup>IVE<sub>1</sub> declined to near zero with increasing decays, we conclude that radiotoxicity of <sup>125</sup>IVE<sub>1</sub> to GH<sub>4</sub>C<sub>1</sub> cells is cell cycle independent. It has not escaped our attention that radiolabeled estradiol can be used as a labeling tool as well as a therapeutic agent against cells responsive to estrogen therapy in cancer.

## 351.9

**11 $\beta$ -HYDROXYSTEROID DEHYDROGENASE TYPE 2 (11-HSD2) EXPRESSION IN RAT: *IN SITU* HYBRIDIZATION STUDIES.**

B.L. Roland\*, Z.S. Krozowski and J.W. Funder. Laboratory of Molecular Physiology, Baker Institute of Medical Research, Prahran, Australia 3181.

The enzyme 11-HSD allows aldosterone occupancy of mineralocorticoid receptors (MR) by inactivating endogenous glucocorticoids. The present study examined the distribution of 11-HSD2 mRNA in rat brain and peripheral tissues by *in situ* hybridization. An <sup>35</sup>S-labeled cRNA probe was generated from a 770 base pair cDNA clone of rat 11-HSD2, from coding region 283-1052. This was linearized with Hind III and synthesized with T7 RNA polymerase. The 11-HSD2 probe was hybridized to 30  $\mu$ m brain sections and 7  $\mu$ m sections of paraffin-embedded peripheral tissues. High levels of expression of 11-HSD2 mRNA were found in kidney, parotid, ovary and rostral medulla of the brain, with moderate levels in uterus and submandibular gland and very low levels in colon and adrenal. No expression was found in liver or testis. These results, together with anatomical studies on MR distribution, suggest that 11-HSD2 may have a functional relationship with MR in some but not all of these tissues, although the specific role of 11-HSD2 is yet to be elucidated.

## 351.11

A SMALLER FORM OF ANDROGEN RECEPTOR mRNA IN BRAIN CONTAINS A TRUNCATED 5'-UNTRANSLATED REGION. R.H. Price Jr., M.E. Wilson and R.J. Handa. Dept. of Cell Biology, Neurobiology and Anatomy and Molecular Biology, Loyola Univ. of Chicago, Maywood, IL 60153.

The androgen receptor (AR) is a steroid hormone receptor present in both brain and peripheral tissues. In brain, the AR is encoded by mRNA species of two different lengths, the larger of which is approximately 11 kb and the smaller being 9.3 kb. The two forms of AR mRNA are distributed in different proportions in various brain regions. Previous results suggest that the 9.3 kb form contains a truncated or different 5' untranslated region (5'UTR). We have utilized a 5' RACE technique in an attempt to detect and amplify the 5' ends of both AR mRNA species in various brain regions and reproductive tissues of the male rat. Reverse transcription was performed using an oligo primer directed against nucleotides 2772 - 2791. ds cDNA representing both forms of AR was synthesized from ventral prostate, testis, anterior pituitary, hippocampus, cerebral cortex, and hypothalamus. PCR using AR primers targeting nucleotides 1004 - 1024 and 1228 - 1238 (both near 5' end of the coding region) and primers specific for a ds cDNA Adaptor (Clontech) ligated to the 5' ends of the AR ds cDNAs revealed two predominant amplified products. One product corresponds in size to the previously described 1 kb 5'UTR and the other reflects a significantly smaller 5'UTR of less than 100 bases. The relative concentrations of both forms of AR mRNA in the brain regions corresponds to previous findings. The existence of a shorter 5'UTR presents the possibility that there is an alternate transcription start site proximal to the amino-terminal end of the coding region. Sequence data will determine the similarity of the shorter 5'UTR with the existing, previously cloned 1 kb 5'UTR. These data may help determine region-specific regulation of AR expression in the brain. Supported by NSF IBN 9408890.

## 351.13

EFFECT OF *IN VITRO* 17 $\beta$ -ESTRADIOL (E2) ON CONCENTRATIONS OF GLUCOSE TRANSPORTER (GLUT1) IN RAT BLOOD-BRAIN BARRIER (BBB). J. Shi and J.W. Simpkins\*. Department of Pharmacodynamics & Center for Neurobiology of Aging, College of Pharmacy, University of Florida, Gainesville, FL 32610

Glucose provides the primary source of fuel in mammalian brains and a 55kDa GLUT1 glucose transporter is responsible for the passage of glucose across blood-brain barrier endothelial cells. We previously reported that 17 $\beta$ -estradiol (E2) caused a 40% increase in glucose transport across the BBB. The present study was designed to determine if E2 increases GLUT1 protein in brain endothelial cells *in vitro*. Method: 7 female rats (initial body weight 200-225gm, from Charles River, Inc.) were decapitated 14 days after ovariectomy (OVX). Cortex homogenates were separated into Ringer's solutions containing either 544 pg/ml E2 or vehicle. Microvessels were isolated and then incubated at 37°C for 4 hours in the presence or absence of E2. Protein samples were isolated, separated on SDS-PAGE gel and electrophoretically transferred to nitrocellulose membrane. Rabbit anti-rat brain glucose transporter and ECL Western blotting analysis system were used for immunoblotting and chemiluminescence, respectively. The same sample from intact rats were used as the standard for quantification. Red blood cell glucose transporter were used as reference because its motility is identical to BBB GLUT1. Results: (1) the only protein observed was 55 kDa band; (2) total cellular GLUT1 increased in the E2 group (mean  $\pm$  S.E.M., 4.917  $\pm$  .16) vs. vehicle group (3.739  $\pm$  .209) ( $p < 0.001$ ); cytosol GLUT1 increased similarly to total cellular GLUT1 (2.616  $\pm$  .148 vs. 2.021  $\pm$  .148,  $p < 0.05$ ); plasma membrane GLUT1 changed little between two groups (OVX+E2 vs. OVX, 3.477  $\pm$  .244 vs. 3.239  $\pm$  .273,  $p = .52$ ). This study shows that *in vitro* treatment with E2 increases total GLUT1 in the brain microvessel endothelial cells and that over the 4 hours incubation, this increase is confined to the cytosol with little change in the plasma membrane. (Supported by NIA grant AG 10485)

## 351.10

A DOSE RESPONSE STUDY OF DEHYDROEPIANDROSTERONE SULFATE ON DENTATE GYRUS LTP. J. Harris\*, A. Yoo, and B. Dubrovsky. Neurophysiology Laboratory, McGill University, Montréal, Québec, Canada H3A 1A1

Neurosteroids are produced peripherally by endocrine glands, as well as enzymatically in the glia from steroid hormone substrates. Control of GABA receptor sites and Ca<sup>2+</sup> channel currents are prime targets for neurosteroid actions, and their effects are concentration dependent. For this reason, and the fact that treatment with one of them, DHEAS, improves performance in tasks involving memory in aged rats, we explored the effect of this hormone on dentate gyrus LTP in a dose response mode.

Intact anesthetized rats (urethane, 1.5 g/kg) were used. Electrodes were stereotactically positioned in the perforant path and dentate gyrus for stimulation (bifocal) and recording (monofocal). DHEAS (10, 20, and 30 mg/kg, dissolved in Nutralipid 10%) was injected into the femoral vein. Twenty control animals were randomly interspersed within the experimental groups and were injected solely with Nutralipid.

The results showed a significant increase in LTP at all doses in relation to baseline values. Further, there were significant increments in amplitude at 20 and 30 mg in relation to 10 mg. However, the data did not reveal significant differences between the 20 and 30 mg treated rats. While enhancing a putative memory phenomena such as LTP, caution should be applied to the potential long-term beneficial effects of DHEAS on the consequences of aging, especially in the CNS. Neurosteroids at high concentrations behave like glucocorticoids on Ca<sup>2+</sup> channel currents (French-Mullen 1994, 1995). Activation of this channel by glucocorticoids has been linked with aging phenomena in the CNS.

## 351.12

ESTROGEN PROTECTS PRIMARY CORTICAL NEURONS FROM GLUTAMATE NEUROTOXICITY. C.A. Singer\*, T.M. Strickland, K.L. Rogers and D.M. Dorsa. Departments of Pharmacology and Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98195 and GRECC, VA Medical Center, Seattle, WA 98108

Estrogens have been shown to exert neurotrophic effects in the brain by regulating processes involved in neuronal growth, differentiation and survival. The ability of estrogen to promote neuronal survival has been shown in primary neuronal cultures from the amygdala, as well as in neuroblastoma and glial cells during serum deprivation or hypoglycemia. This leads to the possibility that estrogen might exert neuroprotective effects during other types of cytotoxic insults. Neurotoxicity mediated by the excitatory neurotransmitter glutamate has been extensively studied in primary cortical neurons and the present experiments were designed to examine the possibility that estrogen may protect these neurons from glutamate neurotoxicity. Rat primary cortical neurons were cultured for 7 to 12 days in a serum-containing medium. Twenty-four hours prior to glutamate exposure the cells were shifted to a serum-free medium containing various concentrations of 17 $\beta$ -estradiol, 17 $\alpha$ -estradiol or cholesterol. The neurons were then exposed to 50  $\mu$ M or 100  $\mu$ M glutamate for 5 minutes and maintained in a serum-free medium prior to assay. Cytotoxicity was determined by measuring lactate dehydrogenase (LDH) in the medium twenty-four hours after glutamate exposure. Results from these experiments demonstrated that 10 nM 17 $\beta$ -estradiol protects cortical neurons from exposure to glutamate. Treatment with 10 nM 17 $\alpha$ -estradiol or 10 nM of the steroid precursor cholesterol did not protect the neurons. These results demonstrate that 17 $\beta$ -estradiol can protect neurons from glutamate toxicity. The molecular basis of this protective effect, however, remains to be elucidated. Supported by the VA, AG05136, NS20311, NS07332, and NARSAD.

## 351.14

PHARMACOLOGICAL SPECIFICITY OF ESTROGEN-MODULATED ENHANCEMENT OF AMPHETAMINE-INDUCED STRIATAL DOPAMINE RELEASE. L. Xiao\* and J.B. Becker. Dept. of Psychology, Univ. of Michigan, Ann Arbor, MI 48104.

While the striatum does not appear to contain classical intracellular estrogen receptors, estradiol rapidly enhances amphetamine (AMPH)-induced striatal dopamine (DA) release. This has led to the hypothesis that estradiol acts within the striatum via a novel estrogen receptor-based mechanism(s). To determine the specificity of estrogen-modulated DA release, several estrogen analogs, metabolites and the classical antiestrogen, tamoxifen (TAM), were applied to superfused striatal tissue. Striatal tissue obtained from ovariectomized female rats was superfused with an estrogen metabolite/analog for 30 min followed by 2.5 min AMPH to induce DA release. TAM was tested alone and in the presence of 17 $\beta$ -estradiol to determine its agonistic and antagonistic properties. We demonstrate that the catechol estrogens, 2-hydroxyestradiol and 4-hydroxyestradiol, at a concentration equimolar to the effective dose of 17 $\beta$ -estradiol enhanced AMPH-stimulated striatal DA release. In contrast, estrone and estriol did not mimic the effect of estradiol. The methylated metabolite of 2-hydroxyestradiol, 2-methoxyestradiol, attenuated striatal DA release at the equimolar concentration to that of estradiol. Furthermore, TAM displayed a partial agonistic effect when administered alone, and antagonistic effect when applied with estradiol. Dose response studies of these compounds are currently underway to further examine the relative potencies of the effect. Results from this study are believed to have important implications with respect to the mechanism(s) underlying the hormonal regulation of neurochemical and behavioral indices of the mesostriatal DA system as well as the role of DA in reproductive activity in the rat. Supported by NSF #BNS9021966; and NIH #T32-HD07048.

## 351.15

**THE EFFECTS OF EXOGENOUS RELAXIN ADMINISTRATION ON C-FOS EXPRESSION IN THE BRAIN OF PREGNANT RATS. T.A.**

Heine, S. Di\*, L.L. Anderson, C.D. Jacobson. Departments of Veterinary Anatomy and Animal Science and the Neuroscience Program, Iowa State University, Ames, IA 50011.

Relaxin is a hormone involved in remodeling the gravid cervix. It is also thought to play a role in parturition. Our laboratory has been studying the effects of relaxin on *c-fos* activation in the brain. *C-fos* is a nuclear second messenger which is activated through stimulation of cellular receptors. Peak levels of expression are reached two hours after initial activation. In this study, eight adult virgin female rats were divided into two groups. Following achievement of timed pregnancy, rats were ovariectomized at eleven days of gestation, and pregnancy maintained with subcutaneously placed estradiol and progesterone capsules. Jugular cannulas were also placed at this time. On day nineteen of gestation, one group of rats received intravenous (IV) relaxin (10 µg) and the other group received an equivalent volume of isotonic saline IV. Two hours post-injection, the rats were euthanized followed by intracardiac perfusion with saline and 4% paraformaldehyde. Immunocytochemistry was used to visualize areas in the brain in which *c-fos* had been activated by the relaxin or saline administration. The supraoptic nucleus (SON) had extensive *c-fos* activity in the rats receiving relaxin, whereas minimal activity was seen in the SON of rats receiving isotonic saline. Analysis of other hypothalamic nuclei will be discussed. Studies are currently being conducted to determine if relaxin is specifically affecting oxytocinergic cells in the SON.

## 351.16

**ESTRADIOL INHIBITION OF RAT STRIATAL CALCIUM CHANNELS: G-PROTEIN MECHANISM OF ACTION. P.G.**

Mermelstein\*, J.B. Becker and D. J. Surmeier. Neuroscience Program, Psychology Dept. and Reproductive Sciences, Univ. Michigan, Ann Arbor, MI and Dept. Anatomy and Neurobiology, Univ. Tennessee, Memphis, TN.

Steroid hormones act upon cells containing intracellular receptors. However, recent evidence suggest steroids can have specific and rapid effects at the cellular membrane. Using whole-cell patch clamp techniques, 17β-estradiol reversibly blocked calcium currents in acutely dissociated and primary cultured striatal neurons. The effects were sex specific: the reduction of calcium currents was greater in neurons taken from female tissue. 17β-Estradiol primarily targeted L-type calcium channels and its inhibition was reliably seen within seconds of administration. Maximum block of 17β-estradiol occurred at picomolar concentrations. 17β-Estradiol, when conjugated to BSA, was also effective in reducing calcium current, suggesting the effects occurred on the membrane surface. Dialysis of striatal neurons with GTPγS demonstrated inhibition of calcium currents by 17β-estradiol was through G-protein activation. 17α-estradiol also reduced calcium currents, but its maximum block was significantly less than when compared to 17β-estradiol. Estradiol and 4-hydroxyestradiol were found to reduce calcium currents with similar efficacy to 17β-estradiol, while estrone and 2-methoxyestradiol were less effective. Tamoxifen served as a partial agonist as well, but did little to occlude 17β-estradiol's reduction in calcium current. These results suggest that at physiological concentrations, 17β-estradiol has immediate and specific actions upon striatal neurons altering signaling pathways independent of genome activating receptors.

## 352.1

**COMPARISON OF IL-1α DISTRIBUTION IN CVO AND NON-CVO TISSUES AFTER IV AND ICV INJECTION. S.R. Plotkin, W.A. Banks, and A.J. Kastin\*.** Veterans Affairs Medical Center and Tulane Neuroscience Interdisciplinary Program, New Orleans, LA, 70146.

Interleukin-1α (IL-1α) has been implicated in many processes within the central nervous system (CNS). IL-1α could interact with CNS tissues either by crossing the blood-brain barrier (BBB) or by interacting directly with circumventricular organs (CVOs), regions within the brain lacking a BBB. In this study, Swiss-Webster mice were given intravenous (IV) and intracerebroventricular (ICV) injections of radioactively labeled IL-1α (<sup>125</sup>I-IL-1α) and albumin, and samples of CVO tissues (pineal, median eminence, and area postrema) and non-CVO tissues (cortex and cerebellum) taken for analysis. When compared with cortex and cerebellum after IV or ICV injection, CVOs contained higher amounts of <sup>125</sup>I-IL-1α on a per gram basis, but significantly smaller amounts as a percent of total brain radioactivity. When unlabeled IL-1α was included in the injection, there was a decrease in the levels of <sup>125</sup>I-IL-1α in CVO and non-CVO tissues after IV injection but not after ICV injection, indicating that uptake can be inhibited in the blood to brain direction. These results suggest that both CVO and non-CVO brain tissues selectively take up blood-borne <sup>125</sup>I-IL-1α, although the basis for this selectivity may not be the same for both types of tissue. The results also suggest that diffusion is an important process for centrally administered cytokines. Overall, this study supports current views that blood-borne cytokines can exert some of their CNS effects either by acting directly at CVOs or by crossing the BBB and interacting with cells isolated from the periphery.

## 352.2

**SOMATOSTATIN MODULATION OF INTERLEUKIN-2 SECRETION BY ACTIVATED HUMAN T CELLS INVOLVES A SUBCLASS OF SPECIFIC RECEPTOR THAT ARE NOT DIRECTLY COUPLED BUT REQUIRES INHIBITION OF ADENYLATE CYCLASE. S. Krantic\*, A. Cardoso, C. Rabourdin-Combe.** Lab. Biol. Mol. Cell., ENS de Lyon, France.

Neuropeptide somatostatin (SRIF) displays immunomodulating properties such as complex regulation of T cell proliferation. We assessed whether such regulation involves a modulation of interleukin-2 (IL-2) secretion.

IL-2 content was quantified in the supernatants of human T cells of Jurkat line incubated in the presence of mitogens (phorbol ester 10 ng/ml+phytohemagglutinin 2 µg/ml) and SRIF. Our data show that SRIF potentiates mitogen-stimulated IL-2 secretion with an EC<sub>50</sub> of 1X10<sup>-8</sup>M.

We further analyzed kinetic and pharmacological properties of relevant SRIF binding sites by performing <sup>125</sup>I-Tyr<sup>1</sup>-SRIF14 binding assays on semi-purified plasma membrane preparations of Jurkat cells. Three types of binding sites were identified (K<sub>d1</sub>=7.8X10<sup>-11</sup>M, K<sub>d2</sub>=3.7X10<sup>-10</sup>M and K<sub>d3</sub>=1.24X10<sup>-8</sup>M). The latter binding site was a good candidate for mediating SRIF effects on IL-2 secretion since its K<sub>d</sub> is identical to EC<sub>50</sub> of SRIF action on IL-2 secretion.

Finally, we examined the coupling of Jurkat cell SRIF binding sites to adenylate cyclase. IC<sub>50</sub> value for SRIF inhibition of the enzyme was 2.2X10<sup>-11</sup>M thus suggesting the involvement of high affinity receptors.

Therefore, the putative SRIF receptor involved in regulation of IL-2 secretion is pharmacologically defined as a low-affinity receptor that is not directly coupled to adenylate cyclase. However, at SRIF concentration (about 10<sup>-8</sup>M) necessary for activation of receptor involved in neuropeptide action on IL-2 secretion, adenylate cyclase appears already maximally inhibited via activation of high-affinity receptors.

## 352.3

**INTERLEUKIN 2 (IL-2) SUPPRESSES AFFERENT SENSORY TRANSMISSION IN THE PRIMARY SOMATOSENSORY (SI) CORTEX. K.H. Lee\*, C.K. Won<sup>2</sup>, H.J. Park<sup>2</sup>, K.H. Pyun<sup>3</sup> and H.C. Shin<sup>2</sup>** Dept. of Neurosurgery<sup>1</sup>, Dept. of Physiology<sup>2</sup>, Coll. of Med., Hallym Univ. Chunchon, Immunology Lab<sup>3</sup>, KRIBB, KIST, Taejeon, Korea

Although IL-2-like immunoreactivity and IL-2 receptors are present in laminar IV of the frontoparietal cortex in the rat, the functional role of IL-2 in this brain region has not been characterized. In this study the effect of topical application of IL-2 on afferent sensory transmission to neurons in the SI cortex was determined in anaesthetized rats. Quantitative determination of the effect of IL-2 on the afferent sensory transmission to the neurons in the SI cortex was carried out by generating poststimulus time histograms of single unit responses to the subcutaneous electrical stimulation of the receptive field located in the whisker area of the face. IL-2 (0.1, 1.0, 5.0 units) significantly suppressed afferent sensory transmission in SI cortical neurons (n=19) in a dose dependent manner (0.1 U: -6.00±2.9%, p < 0.01; 1.0 U: -12.14±1.6%, p < 0.01; 5 U: -25.06±3.5%, p < 0.01; 0.1 vs. 1.0 U: p < 0.05; 1 U vs. 5 U, p < 0.01). IL-2 induced suppression fully recovered by 60 min after drug. In control experiments, saline solution containing 0.2% bovine serum albumin, used as a vehicle, did not affect afferent sensory transmission. The results of this study provide evidence that IL-2 and its receptors present in the SI cortex may participate in the processing of afferent sensory information arising from the face (supported by KOSEF 941-0700-009-2).

## 352.4

**POSSIBLE INVOLVEMENT OF CYTOSOLIC PHOSPHOLIPASE A<sub>2</sub> IN THE TNFα SIGNALING PATHWAY IN ASTROCYTES. W. Tong, M. Hannink and G. Y. Sun\*** Biochem. Dept., Univ. Missouri, Columbia, MO 65212

We have recently shown that addition of tumor necrosis factor (TNFα) to cultured astrocytes resulted in activation of DNA-binding by a RelA homodimer (JBC, 270:2703, 1995) and the induction of the group II phospholipase A<sub>2</sub> mRNA (Mol. Chem. Neuropath., in press). Although in some cells, TNFα signaling is known to involve the stimulation of an acidic sphingomyelinase and release of ceramide as second messenger, our studies suggest little or no involvement of the sphingomyelinase pathway in the TNFα signaling in astrocytes. On the other hand, our results demonstrated the ability of arachidonic acid (AA) (10 µM), lysophosphatidylcholine (LPC) and lysophosphatidic acid (LPA) (10 µM) to induce RelA/DNA binding as well as release of secretory PLA<sub>2</sub>. LPC together with AA gave a synergistic effect on PLA<sub>2</sub> release and together, they also potentiated the effect of TNFα on PLA<sub>2</sub> release. The involvement of PLA<sub>2</sub> is further supported by the observation that bromophenacylbromide, a PLA<sub>2</sub> inhibitor, resulted in complete inhibition of RelA/DNA binding induced by TNFα. These results support the notion that cytosolic PLA<sub>2</sub> leading to the release of lysophospholipids and AA is an early event associated with TNFα activation of RelA/DNA binding and PLA<sub>2</sub> release in astrocytes.

## 352.5

THE MAJOR SOURCE OF PLASMA INTERLEUKIN-6 (IL-6) ELICITED BY IMMOBILIZATION (IM) STRESS IN RAT. A. Takaki<sup>1</sup>, S. Shioda, O.-H. Huang, A. Arimura, U.S.-Japan Biomed Res Labs, Tulane Univ, Belle Chasse, LA 70037, USA; Dept of Physiol, Fac of Medicine, Kyushu Univ, Fukuoka 812, Japan.

We have recently reported that IM-induced plasma IL-6 elevation was mediated by both central and peripheral catecholaminergic mechanisms, and that adrenal corticoid suppressed this response (Takaki et al. 1995). However, the source for increased plasma IL-6 during IM stress remains unknown. Our previous study excluded the spleen, which contains many immune competent cells, as well as the adrenal and pituitary gland, as possible candidates. Since Kupffer (K) cells in the liver were suggested as a major source for the hemorrhage shock-induced plasma IL-6 (O'Neill et al. 1993), the liver was focused as the next candidate. Male CD rats (300g BW) were partially (70%) hepatectomized under anesthesia 4 days before IM stress. Awake animals were restrained for 60 min in the supine position. Plasma IL-6 response to IM was significantly attenuated by partial hepatectomy ( $p < 0.01$ ). To examine the involvement of the sympathetic innervation in the liver, the rats underwent surgical denervation of the hepatic nerve. IM-induced plasma IL-6 response in denervated rats was again attenuated as compared with the sham-operated animals ( $p < 0.01$ ). Furthermore, the tissue distribution of IL-6 like immunoreactivity (IL-6-LI) was examined histochemically using polyclonal anti-murine IL-6 antiserum (R&D system, MN) which appeared to cross-react with rat IL-6. Some K and endothelial (E) cells in the liver obtained from rats immobilized for 1 hr showed significant IL-6-LI. In addition, norepinephrine stimulated IL-6 production in K cells obtained by *in vitro* culture preparation. These findings suggest that the liver cells, especially K and E cells, are the major source of increased plasma IL-6 during IM stress, and that sympathetic innervation in the liver plays a critical role in the production of IL-6 in these cells.

## 352.7

EFFECTS OF CHRONIC INTRACEREBROVENTRICULAR ADMINISTRATION OF INTERFERON- $\alpha$  IN THE RAT BRAIN. M. Sanchez, G.E. Farrar and D. Saphier<sup>\*</sup>. Dept. of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130.

Interferon- $\alpha$  (IFN- $\alpha$ ) is an immunopotentiating cytokine produced by virus-activated leukocytes that is used clinically for its antiproliferative and antiviral activity. However, chronic administration of IFN- $\alpha$  has been found to cause cognitive, behavioral and neurological deficits that resemble those seen in HIV-disease. In fact, increased plasma and CSF concentrations of IFN- $\alpha$  have been detected in this disease, suggesting that this cytokine may be at least partially responsible for the neuropathology found in such patients. There are some changes characteristic of neurodegeneration, including: proliferation of astrocytes, changes in neuronal processes, alterations in the cytoskeleton of neurons and neuronal cell death. Thus, the aim of the present study was to further characterize the neuropathological effects of chronic i.c.v. administration of IFN- $\alpha$  ( $10^3$  U/5  $\mu$ l, three times per week), using histological and peroxidase-antiperoxidase immunohistochemistry techniques. Paraformaldehyde-fixed, frozen tissue sections of the brains of treated rats were used, and the following monoclonal antibodies were employed for the immunohistochemical studies:

- Proteins identified as components of neuronal intermediate filaments: either to the non-phosphorylated (SMI32) or phosphorylated (SMI35) epitopes in the heavy molecular weight neurofilament.
- Glial fibrillary acidic protein (GFAP).
- Heat shock protein-70 (HSP-70): both constitutive (HSP73) and inducible (HSP72). Preliminary results show some alterations in the immunoreactivity for SMI32 and/or SMI35 in the hippocampus and frontal cortex of the IFN- $\alpha$ -treated rats, although no signs of neuropathology were evident in Nissl-stained sections. In some IFN- $\alpha$ -treated animals, increased GFAP immunoreactivity was found in the substantia nigra, which paralleled some locomotor activity deficits. In order to determine if this reflects an effect on the dopaminergic cells of the region, we are currently carrying out a tyrosine hydroxylase immunohistochemical study.

## 352.9

BEHAVIORAL ACTIVATING EFFECTS OF INTERLEUKIN (IL)-2 AND IL-6. S. Zalcman<sup>1</sup>, D.M. Nance<sup>2</sup>, and A.H. Greenberg<sup>2</sup>. <sup>1</sup>Center for Studies in Behavioral Neurobiology, Dept. of Psychology, Concordia University, Montreal, Qc, Canada H3G 1M8 and <sup>2</sup>Manitoba Institute of Cell Biology, University of Manitoba, Winnipeg, Mb, Canada R3E 0V9.

We have previously demonstrated that recombinant IL-1, IL-2 and IL-6 induce cytokine-specific neurochemical alterations. Consistent with this observation is the novel finding that these cytokines differentially alter behavior. In particular, increases in the number of rears and digging episodes were evident in IL-6-treated BALB/c mice (200 or 400 ng, ip) exposed to a novel environment (i.e., a new shoebox cage). Moreover, IL-6-treated animals placed into a circular environment (i.e., a round beaker) exhibited turning behavior, tail gnawing and an increased tendency to scratch the walls of the beaker compared with vehicle-treated controls. Dopamine (DA) concentrations in the nucleus accumbens and in the caudate nucleus were reduced in IL-6-treated animals compared with controls. Hypothalamic or extra-hypothalamic norepinephrine (NE) levels were not appreciably altered in these mice. In contrast, IL-1 induced a depression of behavior that appeared to be independent of central DA changes. Moreover, IL-2-treated mice (200 or 400 ng, ip) appeared to be hypervigilant in that an increased number of nose pokes (into a hole drilled into a side of a new cage) was evident in these animals compared with control responses. These effects appeared to be associated, at least in part, with alterations of hypothalamic and extra-hypothalamic NE activity. Furthermore, exposing IL-2-treated animals to a mild stressor resulted in malformed nests 24-48 hr after treatment. It is suggested that cytokine-specific behavioral activating effects serve an adaptive purpose during an orchestrated immune response. However, pathological elevations of these cytokines (such as may occur during an autoimmune response) or cytokine-stressor interactions could result in behavioral profiles that are associated with psychopathological states. ## 352.6

BIOTINYLATED INTERLEUKIN-1 RECEPTOR ANTAGONIST BINDS TO VAGAL PARAGANGLIA IN DIVERSE VERTEBRATE SPECIES. L.E. Goehler<sup>1,3</sup>, J. Reiton<sup>2</sup>, M. Laudenslager<sup>4</sup>, S.F. Maier<sup>1</sup>, & L.R. Watkins<sup>1</sup>. <sup>1</sup>Dept Psych, Univ. Colorado, Boulder, CO 80309; <sup>2</sup>Amgen, Boulder, CO.; <sup>3</sup>Depts. of C & S Biology<sup>3</sup> & Psychiatry<sup>4</sup>, UCHSC, Denver CO.

Activation of the immune system elicits a variety of physiological & behavioral effects that are mediated by the central nervous system (CNS). This immune-to-brain communication results from the release of cytokines such as interleukin-1 (IL1) during the initial phases of the immune response. IL1 is key since IL1 receptor antagonist (IL1ra) blocks illness responses. Intriguingly, section of the abdominal vagus can also block illness responses, including elevated steroid, hypothalamic norepinephrine depletion, hyperalgesia, & fever (Watkins, Maier & Goehler. *Life Sci.* Minireview, 1995, in press). This suggests that the immune system must somehow activate vagal afferents in order to signal the brain. Indeed, we recently reported that biotinylated IL1ra (bIL1ra) selectively binds to glomus cells within abdominal vagal paranglia of the rat. These putative chemoreceptors may thus be a key link between the immune system & vagal afferents to the CNS.

Because vagal paranglia are present in diverse vertebrate species, we investigated whether glomus cells from other species also bind bIL1ra. Whole vagus nerves from monkey (*Macaca nemestrina*), bullfrog (*Rana catesbeiana*) & goldfish (*Carassius auratus*) were dissected without fixation, & incubated overnight in bIL1ra (2.95 mg/ml). Following immersion fixation & washing, the nerves were processed for avidin-biotin complex (ABC) histochemistry. Biotinylated IL1ra binding occurred in glomus cells of vagal paranglia in all three species. Omission & competition controls confirmed specificity of binding. Taken together, these results suggest that vagal sensitivity to cytokines evolved early in the vertebrate lineage, & that vagal mediation of immune to brain communication may be a fundamental feature of vertebrate bodily defenses. ## 352.8

IL-6 DOES NOT AFFECT THE VIABILITY OF RAT PRIMARY NEURONS IN CULTURE. N.S. Ranciat, L. Ramonda-Rocha, Y. Xia, R. Pal, M.L. Michaelis, E.K. Michaelis<sup>2</sup>, Dept. of Pharmacol. & Toxicol. and the Higuchi Biosci. Ctr., Univ. of Kansas, Lawrence, KS 66045.

Interleukin-6 (IL-6) is a pleiotropic cytokine which mediates signals to its target cells by binding to a receptor composed of a ligand-binding unit (IL-6R) and a signal transducer (gp130) shared with several other cytokine receptors. The presence of IL-6 in amyloid plaques of Alzheimer's patients and an IL-6 response element in the Amyloid Precursor Protein (APP) promoter led to the hypothesis that IL-6 may be involved in neurodegenerative events. We investigated the effects of IL-6 on the viability of neurons in culture and assessed expression of IL-6R's in these cultured cells and in adult rat brain. Primary cortical neurons were treated with IL-6 (25-150 U/ml) for 24 to 72 hrs. Viability was assessed by morphological criteria and 2 biochemical assays, LDH release into the medium and MTT reduction by the mitochondrial enzyme succinate dehydrogenase. Expression of the IL-6R was monitored by immunoblot analysis. IL-6 treatment did not affect the viability of rat primary cortical neurons under any of the experimental conditions tested. Immunohistochemical analyses revealed that the IL-6R is expressed in adult rat brain, but no immunoreactive IL-6R could be detected in cultured neurons. This lack of expression of IL-6R in cultured neurons may be due to the culture conditions or may reflect developmental regulation of the IL-6R in the CNS. These 2 hypotheses are currently under investigation in our laboratory (Supported by Alzheimer's Assoc. grant #94-128 and MMD-Sci. Ed. Partnership.)

## 352.10

EXPRESSION OF TYPE 1 AND TYPE 2 TUMOR NECROSIS FACTOR RECEPTORS BY RAT GLIA. J.M. Dwyer<sup>1</sup>, A. Mackenzie-Graham<sup>1</sup>, G.C. Otero<sup>1</sup>, and J.E. Merrill<sup>1,2</sup>. Dept. of Neurology<sup>1</sup>, UCLA, Los Angeles, CA, 90024; and Berlex Biosciences<sup>2</sup>, Richmond, CA, 94804.

Tumor necrosis factor alpha (TNF $\alpha$ ) and lymphotxin alpha (LT $\alpha$ ) induce pleiotropic cellular effects through low-affinity 55-kDa type 1 receptors (TNFR1, CD120a) and high-affinity 75-kDa type 2 receptors (TNFR2, CD120b). TNF $\alpha$  is present in multiple sclerosis (MS) lesions, and its secretion by microglia may contribute to oligodendrocyte injury during MS. *In vitro*, TNF $\alpha$  and LT $\alpha$  induce a diversity of effects in glial cells, ranging from proliferation to cytotoxicity. To determine whether differential expression of TNFR1 versus TNFR2 underlies the unique response of a given type of glia to TNF $\alpha$  and LT $\alpha$ , primary cultures of enriched astrocytes (99% GFAP<sup>+</sup>), microglia (97% AcLDLR<sup>+</sup>), and oligodendrocytes (95% GalC<sup>+</sup>) were used in Northern and Western blot analyses of TNFR expression. Northern blots of poly-A<sup>+</sup> RNA revealed a single 2.5-kb TNFR1 transcript in all types of glia and in the RAW 264.7 cell line; transcript levels were increased by IFN $\gamma$ . TNFR2 transcripts of approximately 3.3, 4.4, and 5.7 kb were detected in unstimulated RAW cells, in TNF $\alpha$ -stimulated microglia and, less intensely, in TNF $\alpha$ -stimulated oligodendrocytes. In Western blots, anti-TNFR1 antibodies detected a 55-kDa protein in whole-cell lysates of all types of glia and RAW cells. Anti-TNFR2 antibodies detected a 69-kDa protein in RAW cells and all glia; protein levels were downregulated by TNF $\alpha$  in astrocytes. Both antibodies also bound a 73-kDa protein in all types of cells. Cytokine-induced TNFR shedding and TNFR functions in glia are presently being analyzed. This work was supported by the Conrad N. Hilton Foundation and the Norman Cousins Program in Psychoneuroimmunology at UCLA.

## 352.11

**CENTRAL COADMINISTRATION OF THE CYTOKINES IL-2 AND IL-3: EFFECTS ON HYPOTHALAMIC-PITUITARY-ADRENOCORTICAL (HPA) FUNCTION.** U.-K. Hanisch<sup>1</sup>, W. Rowe<sup>2</sup>, J. Neuhaus<sup>1</sup>, D. van Rossum<sup>2</sup>, M.J. Meaney<sup>2</sup> and R. Quirion<sup>2</sup>. <sup>1</sup> MDC Berlin, 13122, Germany, <sup>2</sup> Douglas Hospital Research Centre, McGill University Montreal, H4H 1R3, Canada.

Chronic intracerebroventricular (i.c.v.) administration of IL-2 in rats leads to permanent HPA hyperfunction and causes damage to both glial and neuronal cells (Hanisch et al., *Endocrinology* 135: 2465-2472, 1994). In the present study, male Sprague-Dawley rats were i.c.v. infused via osmotic minipumps over a period of 14 days with either IL-2 (3 ng/hr), IL-3 (7 ng/hr), both IL-2 and IL-3, or vehicle only (as controls). IL-2 given alone led to persistently increased plasma levels of corticosterone (CORT). IL-3 itself did not alter HPA function. When IL-3 is chronically co-infused along with IL-2, IL-3 significantly inhibited the IL-2-induced rise in CORT levels. These HPA effects of central IL-2 infusion versus IL-2/IL-3 coadministration thus parallel the clinical observation that systemic IL-3 administration can block the increase in adrenal cortisol release as induced in cancer patients by high doses of systemic IL-2 (Lissoni et al., *J. Biol. Regul. Homeost. Agents* 6: 113-115, 1992). While attenuating the effect of IL-2 on the HPA axis, coadministration of IL-3 at this dose (ratio) apparently could not abolish the neural tissue injury resulting from chronically elevated central levels of IL-2. Animals receiving IL-2 only or both IL-2 and IL-3 showed brain infiltration by peripheral cells accompanied by CNS lesions, as previously reported for IL-2-infused rat CNS (Hanisch et al., *Soc. Neurosci. Abstr.* 20: 954, 1994). IL-3 alone did not affect brain tissue integrity. Taken together, the data suggest that IL-3 - although not having significant effects on its own - can modulate the neuroendocrine activity of IL-2 likely by a central mechanism. These results may, therefore, be relevant to the clinical application of IL-2 during immunotherapies. Supported by the BMFT of Germany and the MRC of Canada.

## 352.13

**ASTROCYTES EXPRESS REGIONAL HETEROGENEITY AFTER LIPOPOLYSACCHARIDE INDUCTION OF THE IMMUNO-REACTIVE PHENOTYPE**

Paul HEUSCHLING\*, Chantal FABER, Eleonora MORGA

Neuroimmunologie & Inflammation, CRP - Santé, L-1150 Luxembourg

Lipopolysaccharide (LPS) has been shown to be a strong inducer of the immuno-reactive phenotype in cultured cerebral astroglial cells. This reactive state is characterized by a strong expression of class I and II MHC antigens, an increased production of TNF- $\alpha$ , IL-1 and IL-6, and as recently shown the expression of an inducible nitric oxide (NO)-synthase. Numerous studies document that cerebral astrocytes do not constitute a homogeneous population inside the brain (for review, see Wilkin et al., 1990 TINS 13:43-46).

In this *in vitro* study, we analyzed the regional heterogeneity of primary rat astrocytes after induction of the immuno-reactive phenotype by a 48 hour-incubation in the presence of LPS. We measured the expression of MHC class II molecules, the production of NO<sup>2</sup> as nitrites, and the synthesis of TNF- $\alpha$  in astroglial cultures originating from the following brain regions: cortex, hippocampus, septum, striatum and brain stem. After LPS-induction, class II expression is highest in hippocampal and lowest in septal cultures the other regions showing intermediate values. NO<sup>2</sup> production is most intense in hippocampal and cortical astrocytes, the lowest levels appearing in cultures from brain stem. TNF- $\alpha$  synthesis was readily induced in all regions by LPS. Brain stem astrocytes show however much lower amounts than the other tested regions. We conclude that immunological activation reveals specific regional differences in the cerebral astroglial population.

## 352.15

**GANGLIOSIDE GT1b AFFECTS CONSTITUTIVE AND INDUCIBLE EXPRESSION OF TRANSCRIPTION FACTORS NF-KB, IRF-1 AND IRF-2 IN ASTROCYTES.** P. T. Massa\* and H. Wu Dept. of Neurology, SUNY-HSC, Syracuse, N.Y. 13210.

Neural-specific regulation of cytokine-inducible genes (ISGs) is controlled by transcription factors active at the interferon regulatory factor-element (IRF-E) and/or KB site in the promoter of these genes. A four hour treatment with IFN- $\gamma$  or TNF- $\alpha$  led to an increase in transcription factors NF-KB and IRF-1, but loss of IRF-2. Simultaneous treatment with GT1b caused a reversal of this cytokine effect. However, short-term treatment (10 minutes) with IFN- $\gamma$  or TNF- $\alpha$  with GT1b led to activation of  $\gamma$ -activated factor (GAF) and NF-KB, respectively, comparable to levels seen with cytokines alone, indicating no effect of GT1b on immediate cytokine signal transduction and transcriptional activation pathways. Therefore, GT1b may affect longer-term downstream events related to transcriptional or posttranslational modification of IRF-1, IRF-2, NF-KB, and GAF. The effect of GT1b may be related to inhibition of constitutive or cytokine-inducible proteolytic processing of these factors, because a calpain I/proteasome inhibitor had similar effects to GT1b. This may indicate a specific target for GT1b in neural cells. (This investigation was supported by a grant from the National Multiple Sclerosis Society).

## 352.12

**INTERLEUKIN-15 GENE EXPRESSION IN HUMAN ASTROCYTES AND MICROGLIA.** Y.-B. Lee\*, J.-I. Satoh, D.G. Walker, and S.U. Kim. Div. of Neurology, Univ. of British Columbia, Vancouver, BC, Canada

Recent studies have suggested that inflammatory cytokines such as IL-1, TNF- $\alpha$ , IFN- $\gamma$ , and IL-6 are involved in the pathogenesis of several inflammatory and degenerative neurological diseases by activating astrocytes and microglia. These cytokines also could accelerate the progression of inflammatory processes mediated by infiltrating T cells. However, the mechanisms of entry and proliferation of T cells in the CNS and possible involvement of cytokines in these processes remain unknown. Interleukin-15 (IL-15), a newly cloned cytokine which shares T cell growth activity and components of the receptor with IL-2, could play a role in T cell activation in the CNS.

To investigate the expression and cytokine-mediated induction of IL-15 in the human CNS, enriched preparations of astrocytes and microglia were established from cultures of human fetal brains (12-20 weeks' gestation). The expression of IL-15 gene by these cells was determined by reverse transcription-polymerase chain reaction (RT-PCR). Low levels of IL-15 mRNA were detected in both untreated microglia and astrocytes. Upregulation of IL-15 mRNA was demonstrated in microglia following IFN- $\gamma$  treatment and in astrocytes by IFN- $\gamma$  and IL-1 $\beta$ . In addition, IL-15 mRNA expression was downregulated by IL-6 in astrocytes. These results suggest that IL-15 produced by astrocytes and microglia plays a role in the regulation of T cell activation in the human CNS. (Supported by the Medical Research Council and the MS Society of Canada)

## 352.14

**DIFFERENT MECHANISMS INVOLVED IN THE INHIBITORY EFFECTS OF VIP ON IL-2 AND IL-4 PRODUCTION.** Z. Xin<sup>1</sup>, L. Sun<sup>2</sup>, H.Y. Wang<sup>1</sup>, H. Tang<sup>1</sup>, and D. Ganca<sup>1</sup>. <sup>1</sup>Rutgers University, Newark, NJ 07102 and <sup>2</sup>American Cyanamid, Pearl River, NY 10965.

Neuropeptides have been reported to modulate the immune response *in vivo* and *in vitro* and specific neuropeptide receptors have been reported on a variety of immune cells. Previous results from our laboratory indicated that VIP inhibits both IL-2 and IL-4 production in murine splenocytes and thymocytes. Here we investigate the mechanisms underlying the inhibition of IL-2 and IL-4 by VIP. Balb/c spleen cells and thymocytes are cultured with anti-CD3 plus PMA in the presence of VIP and Northern blots or competitive PCR are carried out for spleen cells and thymocytes, respectively. Our results indicate that VIP inhibits IL-2, but not IL-4 steady-state levels of mRNA in both spleen cells and thymocytes, suggesting transcriptional and post-transcriptional regulation for IL-2 and IL-4, respectively. Previous studies involved cAMP as a transduction pathway for IL-2 transcriptional inhibition. We compared VIP and forskolin, a known cAMP inducer, in terms of cAMP induction and IL-2 inhibition and concluded that an additional transduction pathway, besides cAMP, participates in IL-2 inhibition. Actinomycin D experiments indicate that VIP does not affect IL-2 mRNA stability, suggesting that the IL-2 transcriptional rate is affected by VIP. Posttranscriptional regulation of IL-4 production by VIP could involve different mechanisms. Our present results indicate that VIP does not affect secretion, uptake, or intracellular IL-4 stability, suggesting a specific inhibitory effect on IL-4 translation.

## 352.16

**CYTOKINE RESPONSES FOLLOWING HERPES SIMPLEX VIRUS INFECTION IN DIFFERENTIALLY HOUSED MALE BALB/C MICE.** J. D. Karp\* and J. A. Moynihan. Center for Psychoneuroimmunology Research and Department of Psychiatry, Univ. Rochester. Rochester, NY 14642.

The severity of primary and recurrent herpes simplex virus type-1 (HSV) infections have been associated with demands of the psychosocial environment in humans and animals. The immunological mechanisms responsible for this interaction are not known. Differential housing is a psychosocial manipulation that establishes neurochemical and immunological distinctions between animals. This report investigates the influence of differential housing on lymphocyte production of cytokines following sublethal infection with HSV.

BALB/c mice were housed 1 or 4 per cage for several wks before infection with HSV. Thirty-two mice were challenged with HSV in the hind footpad six and 13 days after infection and delayed type hypersensitivity (DTH) responses recorded. Splenocytes and popliteal lymph nodes from thirty-three mice were harvested seven days after infection, washed and prepared for *in vitro* analyses.

DTH responses were greater in individually-housed compared to group-housed mice after each challenge (p<.03). HSV-stimulated <sup>3</sup>H-thymidine incorporation by splenocytes was higher in individually-housed than group-housed mice (p<.01). Splenocytes from individually-housed mice produced more HSV-stimulated interleukin (IL)-2, IL-4 and interferon (IFN)- $\gamma$  than cells from group-housed mice after 24 hrs (each p<.01). Housing condition did not influence IL-2, IL-4 or IFN- $\gamma$  cytokine production by splenocytes at 48 or 72 hrs. No cage differences were observed in cytokine production by popliteal lymph node cells after 24, 48 or 72 hrs.

These results confirm that the psychosocial environment can influence cytokine responses of BALB/c mice to sublethal HSV infection and suggest that these influences are lost after >24 hrs of *in vitro* conditions.

## 352.17

SELF-STIMULATION FROM THE MESENCEPHALON FOLLOWING INTRAVENTRICULAR INTERLEUKIN-2 ADMINISTRATION. A. L. O. Hebb and R. M. Zacharko\*. Dept. Psychology, Carleton Univ., Ottawa, Canada

Central availability of the cytokine, interleukin-2, has been associated with altered dopamine (DA) turnover and electrophysiological activity in the medial prefrontal cortex and the mesencephalon. The alterations of central DA activity induced by IL-2 administration are, in some instances, reminiscent of the neurochemical variations induced by mild, uncontrollable stressors. These data suggest that the immune and the central nervous system communicate, in part, via a cytokine interface which may contribute to the induction of behavioral pathology. Data collected in this laboratory have revealed that mild, uncontrollable stressors provoke anhedonia from mesolimbic and mesocortical sites including the medial prefrontal cortex, the nucleus accumbens and the ventral tegmental (A10) area. The present investigation assessed whether intraventricular administration of IL-2 would provoke alterations in self-stimulation thresholds among CD-1 mice responding for brain stimulation from the A10 region. CD-1 mice were implanted with a bipolar stimulating electrode and a cannula in the lateral ventricle. Mice were trained to respond for brain stimulation at a constant current (70 uA) and a frequency range of 20-80 Hz in an ascending and descending order. Determination of half-max responding was evaluated for each animal prior to and following central IL-2 (5 ng in 1 ul PBS) or vehicle administration. Self-stimulation determinations were accomplished 15 minutes as well as 48, 72 and 168 hours following intraventricular drug application. IL-2 administration increased half-max stimulation frequencies among animals responding for brain stimulation from the dorsal A10 region while decreasing these values among ventral A10 placements. These data are consistent with the notion that sub-areas of the VTA are not only differentially responsive to stressor application but also to cytokine administration. Supported by the Gustavus and Louis Pfeiffer Research Foundation and NSERC.

## 352.19

SOMATOSTATIN MODULATES THE RELEASE OF INTERLEUKIN 6 FROM RAT CORTICAL TYPE I ASTROCYTES: pharmacological and molecular clues. M. Grimaldi, T. Florio and G. Schettini\*. Dip. Neuroscienze Sez. Farm., Univ. Napoli "Federico II", Via S. Pansini 5, I-80131 Napoli; \*Chair of Pharm., Ist. Oncologia Clinica e Sperimentale, Univ. Genova, Viale Benedetto XV 10, I-16132 Genova, ITALY.

Astrocytes release substances critical to the development of central nervous system. Among these, cytokines, such as interleukin 6, have been recently ascribed to the family of neurotrophic agents. Therefore, the study of the regulation of the release of these substances is growing in relevance. We have previously demonstrated that agents, such as VIP, that increase cAMP and activate protein kinase A, increased the release of interleukin 6 from rat cortical type I astrocytes. Here we studied the effect of the well-known neurohormone somatostatin known to inhibit adenylate cyclase, to stimulate phosphatase activity, to cause hyperpolarization in neurons, aiming to reveal its role in the regulation of interleukin 6 release by rat cortical type I astrocytes.

Somatostatin induced a concentration-related inhibition of resting interleukin 6 release with a maximal effectiveness at 100 nM. The inhibitory action of somatostatin was more effective in the presence of the direct activator of adenylate cyclase catalyst, forskolin. Indeed, forskolin stimulation of interleukin 6 release was completely blunted by somatostatin, that decreased the release of the cytokine below the basal value. This powerful inhibitory effect of somatostatin was achieved with a maximum at 1 uM concentration.

To test whether this inhibition was achieved via a G-protein-coupled mechanism we pretreated astrocytes with pertussis toxin, known to block the inhibitory G-protein mediating the inhibition of adenylate cyclase. Pertussis toxin abolished the inhibitory action of somatostatin both in basal and in forskolin stimulated conditions.

Finally we pharmacologically characterized the type of somatostatin receptor involved in this inhibitory action and typed astrocytic receptor subset by PCR, with the aim to correlate the somatostatin receptor type responsible of this inhibitory action and its coupled transduction mechanism. THE EFFECTS OF THE HIV-1 ENVELOPE PROTEIN GP120 ON THE PRODUCTION OF NITRIC OXIDE AND PROINFLAMMATORY CYTOKINES IN UNPRIMED OR INTERFERON- $\gamma$  PRIMED GLIAL CELLS. L.-Y. Kono\*, M. K. McMillan, G. Bing, P. M. Hudson, Z. Feng, Q. Qi and J.-S. Hong. Laboratory of Environmental Neuroscience, NIEHS/NIH, Research Triangle Park, NC 27709.

The neurotoxicity of the HIV envelope protein gp120 has been implicated in the neuropathology of AIDS. Nitric oxide (NO) and proinflammatory cytokines produced by microglia and astrocytes may contribute to the gp120-related toxicity. This study examined the effects and possible mechanisms of gp120 obtained from two strains, HIV-1<sub>IIIIB</sub> and HIV-1<sub>SF2</sub>, of the HIV-1 virus on the production of NO, TNF $\alpha$ , IL-1 $\alpha$ , and IL-6 in unprimed or interferon- $\gamma$  (IFN $\gamma$ ) primed glial cells. Mouse glial cells exposed to HIV-1<sub>IIIIB</sub> gp120 (10 pM to 100 nM) released increasing amounts of NO, TNF $\alpha$  and IL-6 in a dose-dependent manner, whereas IL-1 $\alpha$  was undetectable. The cells exposed to HIV-1<sub>SF2</sub> gp120 only increased the release of IL-6. The HIV-1<sub>IIIIB</sub> gp120-induced NO or cytokine productions were significantly enhanced by priming glial cells with IFN $\gamma$  (200 U/ml). However, while HIV-1<sub>SF2</sub> gp120-induced IL-6 production was increased in the IFN $\gamma$ -primed cells, the production of NO in the IFN $\gamma$ -primed cells was slightly decreased by the exposure to HIV-1<sub>SF2</sub> gp120. Typhostin A25, a potent inhibitor of tyrosine kinases, inhibited both HIV-1<sub>IIIIB</sub> gp120- and HIV-1<sub>SF2</sub> gp120-induced cytokine production, indicating that tyrosine kinases are involved in the gp120-induced signal transduction pathway(s). These results demonstrate that the production of NO, TNF $\alpha$ , IL-1 $\alpha$ , or IL-6 from both unprimed and IFN $\gamma$ -primed glial cells are differentially regulated by HIV-1<sub>IIIIB</sub> and HIV-1<sub>SF2</sub> gp120, which may provide potential insights into the roles of NO and proinflammatory cytokines in the neurotoxicity of gp120 and the neuropathology of different strains of HIV-1 viruses.

## 352.20

EXPRESSION OF IMMUNOLOGICALLY RELEVANT MOLECULES IN THE NERVOUS SYSTEM. M.L. Baker, B.M. Gebhardt, C.L. Weill\*. Neuroscience Center of Excellence, LSUMC, New Orleans, LA 70112

Neurons lack MHC Class II expression, but have a low basal expression of Class I molecules. Herpesvirus (HSV-1) infection and MHC expression are modulated by cytokines produced by lymphocytes. Interferon gamma (IFN- $\gamma$ ) has antiviral properties and is known to induce MHC expression in some cell types. Cortex and trigeminal ganglionic tissues from latently infected and uninfected mice were examined for the expression of immunologically significant markers (MHC Class II, IFN- $\gamma$ , IFN- $\gamma$  receptor, and macrophage marker) using immunohistochemical staining techniques. None of the markers

	Control		IFN- $\gamma$		examined
	Uninfected	Latent	Uninfected	Latent	
Macrophage marker	-	+	+	+	freshly obtained cortex or ganglion tissue with or without
IFN- $\gamma$	-	+	+	+	
IFN- $\gamma$ receptor	-	-	+	+	

prior infection. In the second experiment, both latent and uninfected cortex and trigeminal ganglion tissue were incubated in the presence or absence of IFN- $\gamma$  for 72 hours. After 72 hour incubation, both IFN- $\gamma$  and IFN- $\gamma$  receptors were expressed in cortex of latent and uninfected mice in the presence or absence of IFN- $\gamma$ . Macrophage marker was seen only in uninfected cortex treated with IFN- $\gamma$ . MHC Class II was not detected in cortex or ganglion tissue regardless of treatment. IFN- $\gamma$  treatment induced IFN- $\gamma$  receptor expression in both uninfected and latent ganglia. The results in the trigeminal ganglion (Table) show that IFN- $\gamma$  treatment of uninfected ganglia induces the expression of macrophage marker, IFN- $\gamma$ , and IFN- $\gamma$  receptor. ## CARDIOVASCULAR REGULATION: VAGAL PHARMACOLOGY AND PHYSIOLOGY

## 353.1

INVOLVEMENT OF NITRIC OXIDE ON BAROREFLEX REGULATION. C.J.

Tseng\*, H.W. Liu, H.C. Lin, W.J. Lo and C.S. Tung. Dept. of Medical Education and Research, VGH-Kaohsiung and Dept. of Physiology, National Defense Medical Center, Taipei, Taiwan, R.O.C..

We reported recently that nitric oxide (NO) is involved in central cardiovascular regulation of rat brainstem nuclei. In the present study, we evaluated further the baroreflex response of NO in the nucleus tractus solitarius (NTS) of rats. Male Sprague-Dawley rats were anesthetized with urethane, blood pressure and heart rate was monitored intra-arterially. Intramedullary microinjection (60 nl) of NO synthase inhibitor N<sup>G</sup>-methyl-L-arginine (L-NMMA) or normal saline was made into the NTS. Baroreflex response were elicited by increasing doses of phenylephrine (10-30  $\mu$ g/Kg i.v.) before and after intra-NTS administration of L-NMMA or normal saline. The reflex bradycardia elicited by phenylephrine was significantly inhibited by the pretreatment of L-NMMA. Furthermore, the inhibitory effects on baroreflex activation by L-NMMA were significantly reversed by pretreatment with L-arginine. These results suggest that central endogenous NO is involved in the medullary regulation of blood pressure and that NO synthase inhibitor attenuated baroreflex activation.

## 353.2

CARDIOVASCULAR EFFECTS OF NITRIC OXIDE IN THE NUCLEUS

TRACTUS SOLITARIJ OF RATS. H.C. Lin\*, H.W. Liu, W.J. Lo, C.S. Tung and C.J. Tseng. Depts. of Pharmacology and Physiology, National Defense Medical Center, Taipei, and Dept. of Medical Education & research, Veterans General Hospital-Kaohsiung, Taiwan, R.O.C..

Nitric Oxide (NO) is an endogenously synthesized effector molecular which acts as a neurotransmitter with novel properties in both central and peripheral nervous system. We previously reported that NO was involved in central cardiovascular regulation. The purpose of the present study was to elucidate the involvement of other endogenous mechanisms that could contribute to the final hemodynamic response to NO in the nucleus tractus solitarius (NTS). In normotensive Sprague-Dawley rats, intra-NTS microinjection of L-arginine (1-100 nmol/60nl) produced a dose-dependent decrease in blood pressure and heart rate. These effects were blocked by prior administration of the NO synthase inhibitor N<sup>G</sup>-methyl-L-arginine (L-NMMA) and by NMDA receptor antagonist MK-801. Similarly, prior administration of L-NMMA significantly attenuated the depressor and bradycardic effect of glutamate or NMDA. The specificity of the NO-NMDA interaction in the NTS was demonstrated with adrenergic and angiotensin receptor antagonist that did not affect the L-arginine response in the NTS. These results demonstrate a reciprocal attenuation of NO synthase inhibitor and NMDA receptor antagonist on NMDA and L-arginine responses respectively in the brainstem, and suggest that NO and NMDA may interact in central cardiovascular regulation.

## 353.3

**HEMODYNAMIC EFFECTS ELICITED BY MICROINJECTION OF GLUTAMATE (GLU) INTO THE NTS OF CONSCIOUS RATS. E. Colombari\*, R.A. Shaffer, W.T. Talman, and S.J. Lewis.** Depts. of Pharmacol. and Neurol., Univ. of Iowa & VAMC, Iowa City, IA, 52242, USA.

Microinjection of GLU into the NTS of conscious rats elicits pressor and bradycardiac responses. We sought to determine the regional hemodynamic effects that are associated with these cardiovascular effects. Blood flow in different vascular beds was measured by pulsed Doppler flowmeters in conscious rats. Relative vascular resistance (Renal: RR, Mesenteric: MR, and Hindquarter: HQR) was calculated by dividing arterial pressure (mmHg) by the Doppler shift (KHz). Microinjection of GLU (1 nmol/100 nL) into the NTS produced pressor and bradycardiac responses. The three different beds demonstrated significant vasoconstriction immediately after the microinjection (RR: +96±14%, MR: +123±21%, and HQR: +301±43%), but HQR demonstrated delayed dilatation (-29±5%, n=7). Prazosin (1mg/Kg, i.v.) essentially abolished vasoconstriction produced by GLU microinjected into the NTS (RR: +1±4%, MR: +5±4%, and HQR: +62±12%) and the pressor response observed before prazosin was replaced by hypotension (+26±5% vs -21±5%). In contrast, prazosin did not alter the delayed hindquarter dilatation elicited by GLU. However, nitric oxide synthase inhibitor L-NAME (25 µmol/Kg, i.v.) caused use dependent reduction in hindquarter dilatation. This study suggests that microinjection of GLU into the NTS of conscious rats activates cardiac parasympathetic nerves and both sympathetic constrictor and dilator fibers to arteries in the hindlimb. The use dependent reduction in hindquarter vasodilatation is consistent with release from preformed stores of a compound that causes vasodilatation and whose synthesis depends on nitric oxide synthase. ## 353.5

**IN VITRO RECORDINGS FROM AREA POSTREMA NEURONS DEMONSTRATE RESPONSIVENESS TO ANGIOTENSIN II CHOLECYSTOKININ AND GLUTAMATE Kaiqi Sun, Zhongsheng Han\*, Vicki L. Lowes and Alastair V. Ferguson.** Dept. of Physiology, Queen's Univ., Kingston, Ontario, Canada, K7L 3N6.

The area postrema (AP) lacks a normal blood brain barrier and is thus ideally suited to integrate hormonal and neuronal signals. It has been shown to play roles in regulation of cardiovascular function and food intake. Evidence suggests that angiotensin II (ANG II), glutamate and cholecystokinin (CCK) mediate these functions through AP. This study was designed to examine the responses of AP neurons to these substances in rat brain slices. Extracellular recordings were obtained from AP neurons and effects of ANG II, CCK and glutamate were examined. 106 AP neurons were tested with ANG II ( $10^{-6}$ M to  $10^{-4}$ M), of which 38.7% were excited and 13.2% inhibited. Following blockade of synaptic transmission with a low  $Ca^{++}$ , high  $Mg^{++}$  solution, effects of ANG II were maintained in all cells retaining spontaneous activity. Losartan ( $10^{-6}$ M) blocked the excitatory effects of ANG II in all 4 cells tested demonstrating these effects to be mediated by the  $AT_1$  receptors. CCK ( $10^{-7}$ M) was found to enhance the activity of 47.1% of the 34 AP neurons tested. In addition, 16 neurons were tested with glutamate ( $10^{-3}$ M), of which 7 were excited and 9 unresponsive. These results demonstrate that AP neurons are sensitive to ANG II, glutamate and CCK, findings which correlate well with the proposed role of this structure in cardiovascular function and food intake.

**Angiotensin inhibits M-type  $K^+$  currents in putative aortic baroreceptor neurons of the adult rat. A.M. Allen\*, J.T. Cunningham, M.J. Sullivan, R.E. Wachtel and F.M. Abboud.** Cardiovascular and VA Medical Centers, University of Iowa College of Medicine, Iowa City, I.A. 52242.

Angiotensin (Ang) receptors occur in the nodose ganglion and application of Ang to the isolated, whole nodose ganglion produces a small depolarization (1). We examined the effect of Ang on M-type  $K^+$  (M) currents in isolated adult rat nodose ganglion neurons co-cultured with rabbit aortic smooth muscle cells for 1-3 days. All cells studied were labelled with Dil, which had been injected into either the fat pad surrounding the aortic arch or a cuff around the aortic depressor nerve, 10-14 days prior to culture. M currents were studied under voltage clamp using whole cell patch clamp techniques. The holding voltage was -30 mV and a step was applied to -60 mV for 500 ms before returning to -30 mV. The magnitude of the M current was determined as the difference between the current at the beginning and end of the step to -60 mV. M currents, observed in 66% of labelled cells, ranged from 45 to 310 pA. Bath application of Ang ( $10^{-6}$ M) produced a  $31\pm7\%$  decrease in the current in 8/11 cells. The remaining cells showed a small (6%) increase. The inhibition by Ang was maintained for greater than 5 min. After exposure to the angiotensin receptor antagonist, Losartan ( $10^{-4}$ M) for 5-7 min, Ang produced an  $11\pm3\%$  inhibition of the M current (9 cells). We demonstrate that Ang inhibits the M current in putative aortic baroreceptors of the rat, providing a mechanism for the small depolarizing effect of Ang in the nodose ganglion.

## 353.4

**EVIDENCE THAT NMDA RECEPTORS IN NTS AND CVLM MEDIATE BAROREFLEX INHIBITION OF RVLM PRESYPATHETIC NEURONS. W-J Yuan, W-F Rong, J-J Wang, W-Z Wang, and X-Y Shen\*.** Department of Physiology, Faculty of Basic Medical Science, Second Military Medical University, Shanghai 200433; Department of Anatomy, Shanghai Medical University, Shanghai 200032, China.

Spontaneously active neurons in the RVLM were extracellularly recorded in urethane-anesthetized and artificially ventilated rats. Eighty-five units were defined as presympathetic neurons because they were inhibited by baroreceptor activation through aortic nerve stimulation or bolus intravenous injection of phenylephrine and there were cardiac rhythms in their spontaneous firing. We found that baroreflex inhibition of these presumptive presympathetic neurons were blocked by: 1) intravenous administration of ketamine (10 mg/kg), which is known to be a non-competitive NMDA receptor blocker; 2) microinjection of CPP (50 mM, 100 nL), a specific NMDA receptor antagonist, into the aortic nerve projection sites in the NTS and 3) microinjection of CPP (50 mM, 100 nL) into ipsilateral CVLM. We conclude that the baroreceptor-sympathetic reflex is mediated in the NTS and CVLM by NMDA receptors.

## 353.6

**RESPONSES OF NEURONS IN THE DORSAL MOTOR NUCLEUS TO AREA POSTREMA ACTIVATION BY ELECTRICAL STIMULATION AND ANGIOTENSIN II IN ANESTHETIZED RABBITS. L. Ou, M. Hay, E. Hassler and V.S. Bishop\*.** Dept. of Physiology, Univ. TX Hlth. Sci. Ctr., San Antonio, TX 78284-7756.

We previously demonstrated that the area postrema (AP) projects to the dorsal motor nucleus (DMN). This study was designed to determine if activation of the AP neurons by angiotensin II (AngII) alters neuronal activity of the DMN. In anesthetized rabbits, spontaneous action potentials were extracellularly recorded from DMN and neuronal activity of the DMN was examined before and after microinjection of AngII into the AP (1ng/nl, 10nl). In 27 cells, microinjection of AngII into the AP produced predominantly an inhibitory effect and reduced the mean baseline firing rate from 4.3 to 3.5 spikes/sec ( $P<0.05$ ). Seven of the cells inhibited by AngII (n=12) received excitatory baroreceptor input, suggesting that those neurons inhibited by AP injection of AngII are involved in the baroreflex regulation of heart rate. Also, electrical stimulation of the AP produced an overall inhibitory effect on an additional 32 spontaneous DMN's and reduced the mean firing rate by 27.8% ( $P<0.05$ ). In the DMN's evoked by AP stimulation (n=32), the mean latency was 15.3±1.8ms, ranging from 2 to 40 ms. Five cells were also antidromically activated by stimulation of the vagus nerves, suggesting that neurons responding to AP activation may innervate the heart. The results of this study indicate that the AP projects to the DMN and that activation of AP neurons by circulating AngII reduces neuronal activity of the DMN's. The results suggest that AngII may reset heart rate by activation of AP projections to the DMN. (Supported by NIH Grants HL36080-HL12415)

## 353.8

**MECHANOSENSITIVE (MS) ION CHANNELS IN PUTATIVE AORTIC BARORECEPTOR NEURONS (ABNs). J.T. Cunningham\*, S.A. Kraske, M.J. Sullivan, R.E. Wachtel & F.M. Abboud.** Departments of Medicine and Anesthesia, the VAMC and The Cardiovascular Center, Univ. of Iowa.

We have previously demonstrated that slow hypoosmotic stretch increases the conductance of putative ABNs in culture. This conductance was inward at and below the resting membrane potential of the ABNs and was blocked by gadolinium. In these experiments, we report the effect of rapid and direct mechanical stimulation of the neurons on the single channel. Cell attached patch clamp experiments were performed on dissociated nodose ganglia neurons from adult rats. Putative ABNs were identified by labeling the adventitia of aortic arch with the carbocyanine dye Dil 7 to 14 day prior to dissociation. Cells were tested for MS channels by applying negative pressure on the patches through the recording pipettes. In putative ABNs, MS channels were observed which were inward at the resting membrane potential of the cell using high NaCl or KCl recording solution. The activity of these channels was increased by applying 30 to 60 mmHg on the patch. The slope conductance is 114 pS and its reversal potential is 0 mV. These channels were not blocked by TEA (40 mM), TTX (1-10 µM), charybdotoxin (200 nM) or 4-AP (4 mM) but were sensitive to gadolinium (20 µM). Using standard culturing conditions, this channel was found in less than 20% of the patches tested. These observations are consistent with the macroscopic currents produced by hypoosmotic stretch. This suggests that ABNs have MS ion channels that may participate in the mechanotransduction of baroreceptor neurons.

Supported by PHS grant HL14388.

## 353.9

**Presynaptic Factors Regulating Tetanus-Induced Sustained Potentiation of Monosynaptic GABAergic Transmission in Medulla**

Steven R. Glaum<sup>1</sup>, Richard J. Miller, Penelope A. Brooks<sup>2</sup> and K. Michael Spyer<sup>1</sup>.  
<sup>1</sup>Depts. of Pharmacol./Physiol. Sci., The University of Chicago, Chicago IL 60637 and <sup>2</sup>Physiol., University College London, London UK.

Stimulation in the region of the tractus solitarius evokes monosynaptic IPSCs (evIPSCs) in dorsomedial nucleus tractus solitarius (dmNTS) neurons recorded in the presence of glutamate receptor antagonists (DNQX, 10 $\mu$ M; D-AP5, 50 $\mu$ M) with whole cell (CsCl) electrodes in coronal rat medullary slices. Tetanus (2s, 20-50Hz) reproducibly increases the amplitude of subsequent IPSCs for 20-40 min (Glaum and Brooks, *JANS*, in press, 1995).

**Recent findings:** Spontaneously occurring IPSCs are increased in frequency immediately following tetanus, however this increase does not persist for as long as the evIPSC remains potentiated. The mean<sup>2</sup>/variance of posttetanus evIPSC amplitude increased >> mean amplitude of posttetanus evIPSCs. Examination of the effects of tetanus on miniature IPSCs (mIPSCs) in the presence of tetrodotoxin (1 $\mu$ M) indicates that tetanus increases mIPSC frequency without shifting the cumulative frequency distribution.

Tetanus-induced sustained potentiation of evIPSCs was evident in slices treated (>7 min) with the N-type voltage dependent Ca<sup>2+</sup> channel (VDCC) antagonist  $\omega$ -conotoxin-GVIA (1 $\mu$ M) or L-type channel blocker nimodipine (10 $\mu$ M), but not in those slices treated with either AGA-IVA (20nM, 20 min) or  $\omega$ -contotoxin-MVHC (2 $\mu$ M). High Mg<sup>2+</sup>/low Ca<sup>2+</sup> solutions reversibly block induction of sustained potentiation.

Tetanus produces sustained potentiation of the inhibitory component of mixed EPSP/IPSP complexes recorded in dmNTS neurons in recordings (K<sup>+</sup> gluconate electrodes) made in the absence of glutamate receptor antagonists.

These results, together with earlier data, indicate a likely presynaptic locus of tetanus-induced sustained potentiation of inhibitory transmission in dmNTS which depends, in part, upon Ca<sup>2+</sup> influx through P/Q-type VDCCs. Tetanus appears to induce a sustained increase in interneuronal excitability. Underlying mechanisms and physiological relevance will be discussed.

## 353.11

**SEROTONIN EXCITES NUCLEUS TRACTUS SOLITARIUS (NTS) NEURONES RECEIVING INPUTS FROM CARDIAC VAGAL C-FIBRE AFFERENTS IN RATS.** D. Jordan<sup>1</sup>, Y. Wang, J. F. X. Jones & A. G. Ramage<sup>2</sup>. Departments of Physiology and Pharmacology<sup>1</sup> Royal Free Hospital Medical School, Rowland Hill Street, London NW3 2PF, UK.

In rats microinjection 5-HT into the NTS decreases blood pressure and heart rate by acting on 5-HT<sub>1A</sub> receptors (Itoh & Bunag, *J. Pharmacol. Exp. Ther.* 256, 1147-1153, 1991). In view of the role of the NTS in cardiovascular regulation, studies were carried out in artificially ventilated, sodium pentobarbitone-anaesthetized rats to study the effects of the ionophoretic application of 5-HT (50 mM, pH 5) and a 5-HT<sub>1A</sub> agonist, 8-OH-DPAT (20 mM, pH 4), on NTS neurones receiving either cervical vagal or cardiac vagal C-fibre inputs.

Of the 16 neurones excited by cervical vagal stimulation, ionophoretic application of 5-HT (0-10nA) increased the ongoing activity of 8, depressed the activity of 1 and did not affect the remaining. Application of 8-OH-DPAT (5-30nA) produced a similar effect. Of the 35 neurones tested, activity of 18 was increased, of 14 was depressed and 3 were unaffected. In contrast, NTS neurones excited by stimulating the cardiac vagus nerve were usually excited by ionophoretic application of 5-HT (3 of 3) and 8-OH-DPAT (4 of 5).

These results demonstrate that 5-HT has both facilitatory and depressant actions on NTS neurones but has mainly an excitatory effect on NTS neurones with cardiac vagal C-fibre afferent input. This effect is mimicked by a 5-HT<sub>1A</sub> agonist suggesting that 5-HT acts on 5-HT<sub>1A</sub> receptors in the NTS to modulate C-fibre input from the heart.

**Do Substance P Immunoreactive Afferent Nerve Terminals Influence Negative Dromotropic Vagal Motoneurons In The Rostral Nucleus Ambiguus (rNA)?** V.J. Massari<sup>1</sup>, T.A. Johnson, and P.J. Gatti. Howard U. Coll. Med., Wash. D.C. 20059

Microinjections of substance P (SP) into the NA cause bradycardia. Ultrastructural evidence indicates that SP terminals directly synapse upon negative chronotropic neurons. These morphological data suggest an anatomical substrate for the inhibitory effect of SP on cardiac rate. We have used a dual labeling histochemical and immunocytochemical method to look for potential synaptic contacts of SP terminals upon negative dromotropic neurons. Negative dromotropic neurons were labeled in the rNA of three cats following injections of a retrograde tracer into a left atrial fat pad ganglion that selectively inhibits AV conduction. Injections into the adjacent myocardium, or into the pericardium (N=2) did not result in labeling in the brain. Labeled neurons were elongated and multipolar, with a round uninflated nucleus, and abundant cytoplasm containing dense masses of rough endoplasmic reticulum. They also showed distinctive somatic and dendritic spines. Labeling was most commonly found in perikarya and proximal dendrites, however, distal dendrites as small as 0.8 $\mu$ m in diameter were also labeled. SP nerve terminals were also readily detected in these tissues. However, only 2.2% (3 of 138) could be defined as being in close apposition to negative dromotropic neurons. In no case was a clearly identified synapse formed between a SP terminal and a retrogradely labeled profile. By contrast, over 120 unlabeled terminals were observed to make synaptic contact with retrogradely labeled profiles. These data indicate that SP terminals in rNA do not synapse upon negative dromotropic neurons. The data further suggest that parasympathetic preganglionic vagal neurons controlling cardiac rate or AV conduction are modulated by CNS afferent neurons utilizing different neurotransmitters. Support by NHLBI 44922 & Howard U. Grad. Sch. Collaborative Core Program.

## 353.10

**INFLUENCE OF GABA IN THE NUCLEUS TRACTUS SOLITARIUS ON BLOOD PRESSURE IN BARORECEPTOR-DENERVATED RATS.** A.F. Sved<sup>1</sup> and S. Ito. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

We have previously reported that injection of the GABA agonist muscimol into the nucleus tractus solitarius (NTS) of chronically arterial baroreceptor-denervated (BD) rats has no effect on blood pressure, in contrast to the marked increase in blood pressure it elicits in baroreceptor intact rats (Schreihofer and Sved, *Am. J. Physiol.* 263:R258, 1992). We had interpreted that result as suggesting a lack of tonic excitation of NTS neurons in BD rats; alternatively, it could indicate that in BD rats there is tonic maximal GABA-mediated inhibition of neurons in the NTS. The present study aimed to distinguish between these two possibilities, by examining the changes in blood pressure elicited by injection of the GABA antagonist bicuculline methiodide (BMI) into the NTS of BD and control rats. In chloralose-anesthetized, paralyzed, ventilated rats, injection of 10 pmol BMI (in 100 nl of artificial CSF) into the NTS elicited minimal changes in blood pressure (-4 $\pm$ 2 mm Hg following unilateral injection, from a baseline of 117 $\pm$ 4 mm Hg, n=8). In contrast, in BD rats (complete sino-aortic denervation 7-10 days prior to experiment) injection of BMI into the NTS elicited marked reductions in blood pressure (-52 $\pm$ 6 mm Hg following unilateral injection, from a baseline of 116 $\pm$ 6 mm Hg, n=6). The maximal decrease in blood pressure elicited by BMI in BD rats was equivalent to the maximal decrease in blood pressure that could be evoked by the local injection of L-glutamate (200 pmol; -58 $\pm$ 8 mm Hg; n=6). These results suggest that the lack of a tonic role of the NTS in the regulation of blood pressure in BD rats, is a result of maximal GABA-mediated inhibition of relevant NTS neurons.

## 353.12

**CAPSAICIN DEPRESSES RAT BARORECEPTOR AFFERENTS PERIPHERALLY AS WELL AS SYNAPTIC RESPONSES TO TRACT ACTIVATION IN MEDIAL NUCLEUS TRACTUS SOLITARIUS (mNTS).** M.C. Andresen<sup>1</sup>, W. Fan and M. Yang. Dept. of Physiology, Oregon Health Sciences University, Portland, OR 97201

Capsaicin (CAP) potently depresses a range of different sensory neurons with slowly conducting axons. Of cardiovascular sensory afferents, mechanoreceptors including baroreceptors have been thought to be resistant to CAP. Here we tested the effects of CAP on axonal transmission in the aortic depressor nerve (ADN) which in the rat contains large numbers of C-fiber baroreceptors. 100-1000 nM CAP selectively depressed and then reversibly blocked the slow conduction velocity volleys in the ADN compound action potential. Reflex blood pressure and heart rate responses corresponding to C-fiber activation of ADN by low frequency, high intensity electrical stimulation were similarly blocked by CAP. Excitatory synaptic responses (EPSP) to solitary tract activation were recorded in mNTS neurons in a horizontal slice. Superfusion of the slice with 100-1000 nM CAP reduced the EPSP by 20-60%. There were additional variable effects of CAP on membrane potential and resistance. In conclusion, CAP appears to block sensory transmission at axonal sites both in the peripheral and central processes of visceral sensory neurons. The synaptic depression of sensory afferent input to mNTS is partial and is consistent with a selective, complete blockade of sensory axons with unmyelinated or lightly myelinated axons.

## 353.14

**CARDIOVASCULAR RESPONSES TO MICROINJECTION OF ARGININE VASOPRESSIN INTO THE NUCLEUS TRACTUS SOLITARIUS OF THE SPONTANEOUSLY HYPERTENSIVE RAT.** A.A. Hegarty<sup>1</sup> and R.B. Felder. Dept. of Internal Medicine and Cardiovascular Center, University of Iowa College of Medicine, Iowa City, IA 52242.

Radioimmunoassay has demonstrated a decrease in the amount of arginine vasopressin (AVP) present in the brain stem of the spontaneously hypertensive rat (SHR). The significance of this finding for cardiovascular processing in the nucleus tractus solitarius (NTS) has not been fully investigated. Previous results from this laboratory have shown that endogenous AVP in the NTS influences baroreflex control of RSNA. To determine if the cardiovascular responses to AVP are altered in the SHR, AVP was microinjected into the caudal NTS of 14 week old SHR and Sprague-Dawley rats (SDR). Changes in mean arterial pressure (MAP), heart rate (HR) and renal sympathetic nerve activity (RSNA) were recorded. In SDR (n=10), a single microinjection of 10 ng AVP in 20 nl artificial CSF into the dorsomedial NTS did not change HR (-1.1 $\pm$ 2.7 beats/min) or RSNA (-6.2 $\pm$ 2.7%) but slightly decreased MAP (-7.1 $\pm$ 2.2 mmHg). In SHR (n=4), a single microinjection of 10 ng AVP induced a significant decrease in RSNA (-16.6 $\pm$ 3.9%) and MAP (-11.5 $\pm$ 3.3 mmHg) in SHR but did not change heart rate (-6.5 $\pm$ 6.4 beats/min). In a second experiment, 4 10 nl microinjections of AVP (5 ng each) were placed in the left and right NTS 200  $\mu$ m lateral to calamus and 600  $\mu$ m lateral and rostral to calamus. Bilateral microinjection of AVP decreased HR in SDR (-35.9 $\pm$ 12.3 beats/min; n=5) and SHR (-41.4 $\pm$ 17.6 beats/min; n=4) without markedly changing MAP and RSNA. These results suggest that NTS neurons modulating RSNA may be more sensitive to exogenous AVP in the SHR than in the normotensive rat. Supported by HL-44546 and HL-08952.

C-FOS ANTISENSE IN THE NUCLEUS TRACTUS SOLITARIUS ALTERS BLOOD PRESSURE RESPONSE TO CHRONIC ARGININE VASOPRESSIN INFUSION. M.G. Sanderford, M. Hay\* and V.S. Bishop. Dept. Physiology, Univ. TX Hlth. Sci. Ctr., 7703 Floyd Curl Dr., San Antonio, TX 78284

Previous studies have shown that arginine vasopressin (AVP) inhibits its own vasoconstrictor activity through area postrema mediated sympathoinhibition resulting in little or no change in mean arterial blood pressure (MAP) during AVP infusions. Because Fos immunoreactivity increases in cells of the medial nucleus tractus solitarius (mNTS) following infusions of AVP, we postulated that *c-fos* expression in these cells might contribute to the inability of AVP to sustain an increase in MAP. To examine the potential role of mNTS *c-fos* expression during AVP infusion on the control of MAP, 200nl of vehicle (0.1M PBS), 1mM *c-fos* antisense oligonucleotides or 1mM sense oligonucleotides was injected bilaterally into the medial NTS of anesthetized rabbits instrumented for the measurement of MAP and renal sympathetic nerve activity (RSNA). Five hours after NTS injections, AVP was infused at a rate to decrease RSNA by approximately 20% and the infusion was maintained at that level. In animals receiving no *c-fos* antisense into the mNTS, 3 hour infusions of AVP ( $1.67 \pm 0.58$  mU/kg/min) resulted in a MAP change of  $-11.5 \pm 8.0$  mmHg (n=2). In contrast, in animals receiving *c-fos* antisense into the mNTS, 3 hour infusions of AVP ( $1.77 \pm 0.18$  mU/kg/min) resulted in a MAP change of  $7.1 \pm 9.3$  mmHg (n=3). The observed responses were correlated with decreased *c-fos* expression in the NTS. These results suggest that expression of *c-fos* in the mNTS is involved in AVP's central regulation of cardiovascular function. (Supported by NIH HL36080 and HL12415)

MELANOCORTIN-4 RECEPTORS (MC4-R) IN THE DORSAL VAGAL COMPLEX (DVC) MEDIATE HYPOTENSIVE AND BRADYCARDIC EFFECTS OF  $\alpha$ -MELANOCYTE STIMULATING HORMONE ( $\alpha$ MSH) S.-J. Li, K. Varga, R.D. Cone, V.J. Hruby & G. Kunos\* Dept. Pharmacol. Tox., Med. Coll. VA, Richmond, VA 23298

Proopiomelanocortin (POMC)-containing neurons projecting from the arcuate nucleus to the DVC are involved in depressor cardiovascular regulation (Neuroscience, 33:559-566, 1989). The DVC is rich in  $\alpha$ MSH and contains high levels of MC4-R, the roles of which have not been clarified. We tested the effects on blood pressure (BP) and heart rate (HR) of  $\alpha$ MSH microinjected unilaterally into the DVC of urethane-anesthetized rats.  $\alpha$ MSH, 250 pmol/100 nl, lowered BP ( $-23 \pm 8$  mmHg) and HR ( $-41 \pm 11$  beats/min). Changes in BP and HR peaked at 5 min and lasted >40 min. In other animals,  $\alpha$ -MSH was tested 10 min after the microinjection into the same site of either 10 pmol of SHU9119, a novel selective antagonist of MC4-R, or the opiate antagonist l-naloxone (140 pmol). SHU9119 did not alter BP or HR, but blocked the effects of  $\alpha$ MSH ( $-3 \pm 2$  mmHg,  $+4 \pm 12$  beats/min,  $P < 0.001$ ). Naloxone did not alter BP or HR, nor did it influence the effects of  $\alpha$ MSH ( $-17 \pm 6$  mmHg,  $-36 \pm 9$  beats/min).  $\beta$ -endorphin ( $\beta$ E, 1.25 pmol intra-DVC) also decreased BP ( $-19 \pm 2$  mmHg) and HR ( $-26 \pm 3$  beats/min), with peak changes occurring at 30-40 min postinjection. In separate animals, 10 pmol SHU9119 did not alter responses to subsequently microinjected  $\beta$ E ( $-20 \pm 3$  mmHg,  $-21 \pm 3$  beats/min), whereas 140 pmol l-naloxone blocked the effects of  $\beta$ E ( $-5 \pm 2$  mmHg,  $+14 \pm 3$  beats/min,  $P < 0.001$ ). These findings indicate that  $\alpha$ MSH and  $\beta$ E, both products of the precursor POMC, cause hypotension and bradycardia by acting at distinct MC4-R and opiate receptors in the DVC, respectively.

## CARDIOVASCULAR REGULATION: MEDULLARY RETICULAR FORMATION

## 354.1

DISTRIBUTION OF NEURONS IN THE CAUDAL VENTROLATERAL MEDULLA THAT MEDIATE THE BARORECEPTOR REFLEX RESPONSE. E. Badoert, M. McKinley, B. Oldfield, C. Chen\* and R. McAllen. Howard Florey Institute, University of Melbourne, Australia.

Until recently, electrophysiology has been the only tool available to detect barosensitive neurons in the caudal ventrolateral medulla (CVLM). A major disadvantage is that only small samples of cells can be studied. The use of the protein Fos as a marker of activated neurons has overcome this problem. The present study has utilised the Fos technique to determine the distribution of the population of barosensitive neurons in the CVLM. In anaesthetized male, sprague-dawley rats, the retrogradely transported tracer, rhodamine beads, was microinjected into the pressor area of the rostral VLM. At least 5 days later, baroreceptors were either activated in the conscious rats by raising blood pressure with phenylephrine (100ug/kg/min iv for 2hrs, n=5), or unloaded by decreasing blood pressure with diazoxide (30mg/kg subcutaneously, n=5). Saline was used in control rats (n=4 and 5 respectively). Ninety to 120 minutes after the start of the experiment, the rats were perfused with 4% paraformaldehyde. The medulla was sectioned and examined between 1mm caudal and 0.4mm rostral to the obex. Neurons that contained rhodamine (indicating they projected to the RVLM) were counted and the proportion of those that expressed Fos (ie barosensitive) was determined. Rhodamine-containing neurons and Fos positive cells were located at all rostrocaudal levels of the CVLM examined. Compared to controls, phenylephrine infusion induced a significant increase in the proportion of those neurons that expressed Fos (14% vs 1%  $P < 0.0001$ ), whilst diazoxide had no significant effect. After phenylephrine the rhodamine-containing barosensitive neurons were found mainly at the level of the obex. The results suggest there is a subpopulation of barosensitive neurons in the CVLM, confined to a small region of the rostral part of the CVLM, which are the likely interneurons mediating the baroreceptor reflex response.

IN VITRO RECORDINGS FROM AREA POSTREMA NEURONS DEMONSTRATE RESPONSIVENESS TO ADRENOMEDULLIN, A NEWLY DISCOVERED VASOACTIVE PEPTIDE. Mark A. Allen, Kaigi Sun, and Alastair V. Ferguson\*. Dept. of Physiology, Queen's Univ., Kingston, Ontario, Canada, K7L 3N6.

Adrenomedullin (ADM) is a recently discovered 52 amino acid peptide that was originally found in human pheochromocytoma. It circulates in fmol concentrations in normal plasma and has been shown to exhibit potent and long lasting vasodilatory actions *in vivo*. On the basis of these findings, it has been suggested that ADM may play a role in cardiovascular control. ADM mRNA is expressed in several tissues including the adrenal medulla, ventricle, lung, kidney and brain and ADM has been shown to exert CNS influences over the control of fluid balance. One potential site for such central actions of ADM is the area postrema (AP), a circumventricular organ which plays a significant role in cardiovascular regulation. In this study, extracellular recordings were obtained from AP neurons in rat brain slices and the effects of bath perfusion of ADM ( $10^{-7}$  M, for 200s) were examined. Of the 24 cells tested with ADM, 8 were found to increase their spontaneous spike frequencies by greater than 30% (mean increase:  $107 \pm 25\%$ ). The remaining cells were unaffected. These results suggest that in addition to its peripheral vasodilatory actions, ADM may exert its central actions by influencing AP neurons and thus cardiovascular control.

## 354.2

ROLE OF THE ROSTRAL VENTROLATERAL MEDULLA IN THE MAINTENANCE OF ARTERIAL PRESSURE IN CHRONICALLY BARORECEPTOR DENERVATED RATS. A.M. Schreierhofer\* and A.F. Sved. Department of Neuroscience, University of Pittsburgh, Pittsburgh PA 15260.

Chronically baroreceptor denervated (BD) rats, produced either by selective sino-aortic denervation or by electrolytic lesion of the projection site of all baroreceptor afferents (the nucleus tractus solitarius; NTS), have normal resting mean arterial pressure (MAP) although the lability of MAP is markedly exaggerated. The present study sought to determine whether MAP in BD rats is maintained by supraspinal drive to sympathetic vasomotor outflow, as it is in intact rats. Because the rostral ventrolateral medulla (RVLM) is the site of tonic supraspinal drive to sympathetic vasomotor outflow in intact rats, we compared the effects of inhibiting the RVLM on MAP in urethane-anesthetized BD rats and control rats. Bilateral injection of muscimol (100 pmol) into the RVLM in control rats decreased MAP from  $114 \pm 13$  mm Hg to  $47 \pm 4$  mm Hg (n=7); MAP was not further decreased by subsequent ganglionic blockade by chlorisondamine (2 mg/kg iv). Similar results were obtained in BD rats. In sino-aortic denervated rats MAP decreased from  $90 \pm 5$  mm Hg to  $49 \pm 3$  mm Hg (n=7) and in NTS-lesioned rats MAP decreased from  $99 \pm 5$  mm Hg to  $49 \pm 2$  mm Hg (n=3); chlorisondamine did not have an additional effect on MAP in either group. Dose-response curves for phenylephrine-evoked increases in MAP in ganglionic blocked BD rats and control rats were the same, indicating that sympathetically-evoked changes in vascular resistance were not altered in BD rats. These results indicate that resting MAP in BD rats is supported by sympathetic vasomotor outflow to the same extent as in intact rats. Furthermore, in BD rats, as in control rats, the RVLM is the primary source of this tonic vasomotor drive.

## 354.3

**ROLE OF VENTROLATERAL MEDULLARY PRESSOR AREA (VLPA) AND INTERMEDIAL LATERAL CELL COLUMN (IML) IN MEDIATING CARDIOVASCULAR RESPONSES ELICITED FROM THE A5 REGION.** V.K. Malhotra\* and H.N. Sapru. Depts. of Neurosurgery & Pharmacology, New Jersey Medical School, Newark, NJ 07103.

Microinjections (50 nl) of L-glutamate (1.77 nmol) into the A5 neuronal pool elicited depressor and bradycardic responses. It was hypothesized that these responses may be mediated by noradrenergic projections from the A5 neurons to the VLPA neurons or IML neurons because norepinephrine (NE; 50, 100 & 400 pmol) elicited a depressor and bradycardic response when injected into the VLPA and a bradycardic response when injected into the IML at T2. The purpose of the present study was to identify which of the afore-mentioned neuronal pools mediate the responses elicited from A5. Experiments were done in pentobarbital-anesthetized and artificially ventilated rats. Injections of muscimol (150 pmol; used as a pharmacological tool to depress reversibly the activity of neurons) into the VLPA did not alter the cardiovascular responses elicited by injections of glutamate into the A5 region. Injections of idazoxan (IDZ; 1 nmol; an  $\alpha$ -2 adrenergic receptor blocker) into the VLPA also did not alter the cardiovascular responses elicited by injections of glutamate into the A5 region. On the other hand, injections of IDZ (1 nmol) into the IML at T2 blocked the bradycardic responses to injections of glutamate into the A5 region. These results suggest that: (1) cardiovascular responses elicited by injections of L-glutamate into the A5 region are not mediated by inhibition of VLPA neurons, (2) on the other hand, inhibition of IML neurons at T2 by noradrenergic projections from A5 may be responsible for the bradycardic responses elicited from A5 region and these responses are mediated by  $\alpha$ -2 adrenergic receptors.

## 354.5

**MONOPHASIC AND MULTIPHASIC GABA RESPONSES IN NEURONS OF THE RAT ROSTRAL VENTROLATERAL MEDULLA *IN VITRO*.** A. Havar, P. Piguet, M. O. Poulter\* and P. Feltz. Lab. Physiologie Générale, Univ. Louis Pasteur, 21 rue R. Descartes, 67084 Strasbourg, France.

The GABAergic system plays an important role in baroreflex and cardiovascular regulation. The rostral ventrolateral medulla (RVL) contains reticulospinal sympathoexcitatory neurons which receive a tonic inhibition from the caudal ventrolateral medulla and from local GABAergic interneurons. Using intracellular recording in rat medullary slices, we studied the responses to pressure applied GABA agonists in electrophysiologically identified neurons within the RVL; moreover, we examined which group of neurons receives a significant GABAergic synaptic input. Neurons were classified into regular pacemaker, irregular spiking, and silent neurons. With KAc-filled electrodes, GABA (20 mM) evoked responses that ranged from a monophasic hyperpolarization to a combination of hyperpolarizing and depolarizing responses. The nature of these responses depended on the amount of the GABA delivered and on the type of neuron recorded. In regular pacemaker neurons, it consisted of a fast hyperpolarization followed by a slower depolarization that were both sensitive to SR95531 and picrotoxin. A GABA dose-dependent long lasting hyperpolarization sensitive to the GABA<sub>A</sub> antagonist CGP35348, terminated the response. In irregular spiking and silent neurons, GABA application produced usually a monophasic hyperpolarization and depolarization, respectively. The fast component of these responses was sensitive to the GABA<sub>A</sub> antagonists. Inhibitory synaptic potentials were recorded in particular in silent and regular pacemaker neurons. They sometimes occurred with a regular frequency and were reduced or blocked by the GABA<sub>A</sub> antagonists. Our data show that different groups of neurons exhibit different GABA responsiveness and that at least some of the regular pacemaker neurons recorded *in vitro* might act as local GABAergic interneurons to provide tonic inhibitory input to sympathoexcitatory neurons.

## 354.7

**Rhythmic membrane events in presympathetic neurones of the rat rostral ventrolateral medulla oblongata (RVLM).** A. Zagon\* and K. M. Spyer. Department of Physiology, Royal Free Hospital School of Medicine, Rowland Hill Street, London NW3 2PF, U.K.

Presympathetic neurones of the RVLM play a major role in generating tonic and reflex sympathetic activities. In the present study we have examined their electrophysiological characteristics that might underlie the generation of these drives.

*In vivo* intracellular recordings were made from cells of  $\alpha$ -chloralose anaesthetised, artificially ventilated Sprague-Dawley rats. Spinal projections and inputs from aortic nerve and/or vasodepressor region of the nucleus of the solitary tract (NTS) were tested. The discharge pattern of the cells and the underlying rhythmic membrane events were analysed off-line (CED 1401 system).

45 neurones received inhibitory, excitatory or excitatory-inhibitory input following aortic nerve stimulation. Based on a combination of criteria, they were defined as sympatho-excitatory or -inhibitory cells of the RVLM and were encountered both with and without direct spinal projections. A 22-26 and 33-36 Hz rhythmic oscillation of the membrane potential was observed in the majority of cells. The amplitude of the 22-26 Hz rhythm, that was most pronounced during lung deflation, could be enhanced by aortic nerve and NTS activation and cessation of ventilation. The 33-36 Hz rhythm was enhanced during depolarization when, together with an increase in firing rate, the cardiac related activity pattern of the cells diminished.

We suggest, that a 22-26 Hz oscillation is due to synaptic input while the 33-36 Hz rhythm is more likely to be generated internally.

## 354.4

**ACTIVATION OF GABA<sub>B</sub> RECEPTORS HYPERPOLARIZES RAT RVLM NEURONS AND DEPRESSES SYNAPTIC RESPONSES.** H. H. Lin\* and N. J. Dun. Dept. of Anat. & Neurobiol., Medical College of Ohio, Toledo, OH 43614

Whole-cell patch recordings were made from rostralventrolateral medulla (RVLM) neurons of brainstem slices prepared from 8-12 day old rats. Superfusing the slices with the GABA<sub>B</sub> receptor agonist (-) baclofen (3-10  $\mu$ M) hyperpolarized and decreased input resistance of RVLM neurons. Membrane hyperpolarization decreased the baclofen-hyperpolarization. Baclofen depressed the excitatory postsynaptic potentials (EPSPs) and inhibitory postsynaptic potentials (IPSPs) evoked by focal stimulation near the recording neuron. Returning the membrane potential to the resting level by injection of DC current during baclofen-induced hyperpolarization did not restore the amplitude of EPSPs and IPSPs. Spontaneous miniature EPSPs and IPSPs were recorded in some of the RVLM neurons and baclofen effectively and reversibly eliminated these spontaneous synaptic responses. Pretreating the slices with the putative GABA<sub>B</sub> receptor antagonist 2-hydroxysaclofen (20-30  $\mu$ M) partially antagonized the hyperpolarizing and synaptic depressant action of baclofen. It is concluded that GABA<sub>B</sub> receptors are present in post- and pre-synaptic sites of RVLM neurons and that their activation hyperpolarizes RVLM neurons and depresses synaptic responses. (Supported by NIH Grant HL51314).

## 354.6

**GLYCINE RELEASE IN THE RAT VENTROLATERAL MEDULLA DURING BARORECEPTOR STIMULATION.** C.V.R. De Oliveira, J.A. Assumpção, Y.Q. Confessor, L. Covolan\* and S.L. Cravo. Dept. of Physiology, Escola Paulista de Medicina-UNIFESP, 04023-900 SP, Brazil.

Although glycine has long been known as a potential neurotransmitter in the ventrolateral medulla its function remains unknown. The efflux of isotopically labelled glycine during baroreceptor stimulation in the *in vivo* superfused ventral medullary surface (VMS) was investigated. A small acrylic plastic chamber (internal volume = 30  $\mu$ L) was sealed in place over the desired position in the VMS. Isotope labelling of tissue was achieved by a 50 min closed cycle superfusion with artificial cerebrospinal fluid (CSF) containing 2  $\mu$ Ci/mL of (<sup>14</sup>C)-glycine. Subsequently the VMS was superfused during 45 min with isotope-free CSF and the superfusate collected in 3 min samples. Quench corrected radioactivity (DPM) was estimated by liquid scintillation spectrometry. Baroreceptor stimulation (BS) was carried out by increasing mean arterial blood pressure to  $\geq 160$  mmHg with phenylephrine (200  $\mu$ g/min, i.v.) during 6 min. Results obtained demonstrated that: a) baroreceptor stimulation induced a  $59 \pm 14.5\%$  increase in the spontaneous efflux of glycine in the rostral VMS (n=10); b) in previously baroreceptor denervated animals BS produced only  $7 \pm 1.8\%$  increase in spontaneous glycine efflux (n=6); c) when the superfusion chamber was placed over the caudal-medial VMS the increase in glycine efflux in response to BS was reduced to  $3 \pm 0.9\%$  (n=6). Results obtained support the hypothesis that glycine is a neurotransmitter in the VMS and suggest that it might be part of the baroreceptor reflex arch.

## 354.8

**DO SYMPATHETIC PREMOTOR NEURONS CROSSTALK?** R.M. McAllen\* and A.M. Allen. Howard Florey Institute, University of Melbourne, VIC 3052, Australia.

The bursting rhythms that characterize sympathetic whole nerve discharge may originate in the brainstem. Most ongoing sympathetic vasomotor drive is attributable to premotor neurons in the brainstem, particularly the rostral ventrolateral medulla (RVLM). One possibility is that sympathetic bursts are generated by cross-connections between, or involving, premotor neurons. Alternatively, premotor neurons may transmit bursts generated by antecedent neurons. Either way, one would expect to see short-term firing correlations between RVLM premotor neurons. We generated cross correlograms from the spontaneous activity of 35 pairs of barosensitive RVLM neurons extracellularly recorded in chloralose-anesthetized cats (by single or 2 electrode methods). One or both of each pair were proven to be bulbospinal. We found no clear evidence of direct short-term (1/few milliseconds) synaptic interactions. Two of the 35 neuron pairs showed strong synchrony within  $\pm 100$ ms, which was independent of the cardiac cycle, indicating common inputs other than baroreceptors. Five further pairs showed such synchrony very weakly. We conclude that direct crosstalk between these cells is rare, weak or absent, and that only a minority is synchronized by common drives. (Supported by NH&MRC)

## 354.9

**MODULATION OF THE CARDIOVASCULAR RESPONSES TO STATIC MUSCLE CONTRACTION BY BLOCKADE OF AMPA-GLUTAMATE RECEPTORS IN THE LATERAL RETICULAR NUCLEUS IN ANESTHETIZED RATS.** R. DiGiacco, D. Mokler\* and A. Ally. Departments of Pharmacology & Biochemistry, University of New England College of Medicine, Biddeford, ME 04005

The effects of microdialyzing CNQX (an AMPA-Glutamate receptor antagonist) into the lateral reticular nucleus (LRN), magnocellular part, on the cardiovascular responses evoked by static contraction of the triceps surae muscle were studied using chloral hydrate-anesthetized rats ( $n=5$ ). A microdialysis probe was inserted into the LRN (AP: 5.8; L: 1.5; H: 8.0) ipsilateral to the muscle being contracted using a stereotaxic guide. Contraction, elicited by stimulation of the tibial nerve (3 X motor threshold, 0.1 msec, 40 Hz) for 30 sec, increased mean arterial pressure (MAP), heart rate (HR), and tension by  $27 \pm 4$  mmHg,  $32 \pm 12$  bpm, and  $181 \pm 20$  g, respectively. Microdialysis of CNQX (2 mM) for 40 min attenuated the contraction-evoked responses, as MAP and HR increased by  $10 \pm 4$  mmHg and  $10 \pm 8$  bpm, respectively ( $P < 0.05$ ). Developed tension did not change after the administration of the drug. This suggests that neurotransmission in this area of the medulla might be involved in the central regulation of cardiovascular responses to muscle contraction. Furthermore, these results demonstrate that AMPA-Glutamate receptors within the LRN appear to play a role in mediating the cardiovascular responses to static muscle contraction.

## 354.11

**DIRECT PROJECTIONS FROM THE VENTROMEDIAL MEDULLARY REGION AND A5 PONTINE CELL GROUP TO AUTONOMIC PREGANGLIONIC NEURONS EXPRESSING NEUROKININ-1 RECEPTOR IMMUNOREACTIVITY IN THE SPINAL CORD OF RATS.** E. Polgár, J. Nagy, M. Petkó and M. Antal\*. Department of Anatomy, University Medical School of Debrecen, H-4012 Hungary.

The spinal projections of neurons in the ventromedial medullary region (VMM) and A5 pontine cell group (A5) that play a major role in the regulation of autonomic functions in general and of cardiovascular control in particular were studied in the rat by using the anterograde neural tracer Phascolus vulgaris leucoagglutinin (PHA-L). After injecting PHA-L into the VMM or A5, numerous labelled axon terminals were detected in the intermediolateral cell column (IML) of the thoracic and lumbar spinal cord. To study the postsynaptic targets of these descending fibres sections were stained for both PHA-L and calbindin-D-28k (CaB), a calcium-binding protein that has been reported to be a marker of spinal autonomic preganglionic neurons. CaB-immunoreactive neurons in the IML were found to receive multiple contacts from fibres descending from both the VMM and A5. Synaptic contacts as well as GABA- and glycine-immunoreactivity of the presynaptic terminals were identified in a correlative electron microscopic study by using postembedding immunocytochemical methods.

Combining the PHA-L labelling with the immunocytochemical detection of neurokinin-1-receptor (NK1-R; kindly provided by S. Vigna), a well known receptor for substance-P, it was found that autonomic preganglionic neurons receiving monosynaptic contacts from VMM and A5 terminals express a strong immunoreactivity also for NK1-R. Synaptic and extrasynaptic localization of NK1-R-immunoreactive membrane compartments as well as the relations of VMM or A5 terminals and NK1-R-immunoreactive membrane divisions of autonomic preganglionic neurons were investigated in a correlative electron microscopic study.

## 354.13

**CORRELATION BETWEEN THE ACTIVITY OF RESPIRATORY-MODULATED RAPHE-SPINAL NEURONES AND SYMPATHETIC NERVE DISCHARGE** S-Y. Zhou\* and M.P. Gilbey. Dept. Physiology, Royal Free Hospital School of Medicine, London NW3 2PF, UK.

A previous study from this laboratory demonstrated that in the rat some raphe-spinal neurones have their activity modulated by central respiratory drive (Gilbey, Futuro-Neto and Zhou, *J. Auton. Nerv. Syst.* 50, 263-273, 1995). In this study the correlation between the activity of these neurones and sympathetic nerve discharge was examined in the 2-6 Hz frequency band. Recordings were made in chloralose anaesthetized, paralysed, vagotomized and artificially ventilated rats. Correlations between the discharge of single units in either raphe pallidus, obscurus or magnus and cervical sympathetic nerve activity were assessed using coherence analysis (25 pairs). Peak coherence values occurred at frequencies ranging from 2.1 - 5.7 Hz. The mean peak coherence value was  $0.18 \pm 0.02$  (range 0.08 - 0.40, 32 windows). Thus all coherence values although low were significantly greater than zero (see Benignus, *IEEE Trans. Audio Electroacoustics*, AU-18, 320, 1970). Of the neurones used in the analysis sixteen of the eighteen which were tentatively identified as having axons projecting to the intermediolateral cell column had respiratory-modulated discharge patterns. Interestingly, only 2 of 19 pairs involving neurones recorded from raphe obscurus yielded coherence values of  $> 0.2$ , whereas 4 of 6 pairs comprising of neurones recorded from pallidus or magnus produced coherence values  $> 0.2$ . These data are consistent with the idea that respiratory-modulation and 2-6 Hz rhythms are relayed to the sympathetic outflow by some caudal raphe neurones. The tendency for raphe pallidus and raphe magnus neurones to have higher coherence with sympathetic nerve discharge than raphe obscurus neurones indicates that the influence of the various caudal raphe nuclei on sympathetic activity may differ. **RESPONSES OF NUCLEUS RETICULARIS PARVOCELLULARIS TO HYPOXIA AND HYPERCAPNIA.** L.M. Sexcius\*, R.M. Douglas, E.T. Anderson, and C.O. Trouth. Dept. of Physiol. & Biophysics, Howard University Coll. Med., Washington, D.C. 20059.

Maximal pressor responses to stimulation of the nucleus reticularis parvocellularis (NRP) have been reported. The integrity of the NRP is essential for the expression of the cerebral ischemic response (CIR) (Kumada et al., *Circ. Res.*, 45:63-70, 1979). In this investigation extracellular NRP neuronal activity and blood pressure were recorded from spontaneously breathing cats exposed to hypoxic (12% O<sub>2</sub>) hypercapnic (5% CO<sub>2</sub>) conditions. Cerebral ischemia (clamp. carotid and vertebral art.) leads to an increase in blood pressure and in neuronal activity recorded at NRP. Hypoxia with hypercapnia caused an increase in NRP neuronal activity and blood pressure similar to that observed with cerebral ischemia. However, hypercapnia (5% CO<sub>2</sub>) alone did not exhibit either an increase in neuronal activity or blood pressure. It appears that ischemia is more effective in inducing the CIR than hypercapnia alone.

Supported by ONR Grant # N0014-94-1-0523.

**MULTIPLE 5-HYDROXYTRYPTAMINE RECEPTORS ON RAT RVLM NEURONS.** L. L. Hwang\* and N. J. Dun. Dept. of Anat. & Neurobiol., Medical College of Ohio, Toledo, OH 43614

Rat rostromedullary lateral medulla (RVLM) exhibits a dense network of 5-HT-immunoreactive fibers. Effects of 5-HT on RVLM neurons were studied by the whole-cell patch technique in brainstem slices removed from 8-12 day old rats. 5-HT applied either by superfusion or pressure ejection elicited three types of currents: a brisk inward current, a slow inward current associated with decreased conductance, and a slow outward current associated with increased conductance. All three types of 5-HT-induced currents were blocked by the non-specific antagonist methysergide. The brisk inward current was blocked by the 5-HT<sub>2</sub> receptor antagonist MDL-72222 (10  $\mu$ M). The slow outward and inward current was made smaller with membrane hyperpolarization. The 5-HT<sub>1A</sub> agonist 8-OH-DPAT (10  $\mu$ M) caused a slow outward current similar to that of 5-HT. The 5-HT<sub>2</sub>/5-HT<sub>1A</sub> antagonist spiperone (1  $\mu$ M) and the 5-HT<sub>2</sub>/5-HT<sub>1C</sub> antagonist ketanserin (1  $\mu$ M) partially blocked the slow outward and inward current. Spontaneous miniature excitatory postsynaptic currents (mEPSCs) were recorded in some RVLM neurons. 5-HT depressed mEPSCs in some but increased the amplitude in other RVLM neurons. The result shows that 5-HT may modify the electrical activity and synaptic transmission of RVLM neurons by interacting with multiple 5-HT receptors. (Supported by NIH Grant HL51314).

**AN INTRACELLULAR STUDY OF RESPIRATORY-MODULATED CAUDAL RAPHE NEURONES AND THEIR RELATIONSHIP TO SEROTONIN-CONTAINING NEURONES IN THE RAT MEDULLA.** M.P. Gilbey\*, J. Li, P.N. Izzo and S-Y. Zhou. Department of Physiology, Royal Free Hospital School of Medicine, Rowland Hill St, London NW3 2PF, UK.

Our previous extracellular studies have demonstrated that neurones in caudal raphe (2.50 to 3.50 mm caudal to interaural line) may be involved in relaying respiratory modulation to sympathetic preganglionic neurones (Gilbey, Futuro-Neto and Zhou, *J. Auton. Nerv. Syst.* 50, 263-273, 1995). However, whether these neurones contain serotonin has not been examined. The aim of present studies was to investigate whether raphe neurones with respiratory-related activity contained serotonin. Experiments were performed on male Sprague-Dawley rats (250-350 g) anaesthetized with sodium pentobarbitone (60 mg/kg I.P.) and supplemented with i.v. chloralose (5-10 mg). Animals were paralysed (gallamine triethiodide 16 mg/kg), vagotomized and artificially ventilated. Intracellular recording and labelling were achieved using glass microelectrodes filled with 5% Lucifer Yellow (in 1 M lithium citrate) or 10% Fluorescein-Dextran (in 1.5 M potassium methyl sulphate). The brainstem was removed and post-fixed overnight. Serial coronal sections (50  $\mu$ m) of the medulla were cut on a vibrating microtome and all sections were then incubated to detect serotonin immunoreactivity using immuno-fluorescence techniques. Both intracellularly labelled and serotonin immunoreactive neurones were examined by a confocal microscope. Eight of sixteen labelled neurones located in caudal raphe had respiratory-related activity (5 expiratory - 2 inspiratory- and 1 post-inspiratory-modulated). All neurones were identified as non-immunoreactive for serotonin. These data indicate that some raphe neurones which have respiratory-related activity do not contain serotonin. (Supported by the Wellcome Trust and British Heart Foundation)

## 354.15

**CARDIOVASCULAR RESPONSES ELICITED FROM THE LOCUS COERULEUS ARE ABOLISHED BY MICROINJECTIONS OF 6-HYDROXYDOPAMINE INTO THE NUCLEUS AMBIGUUS/VENTROLATERAL MEDULLARY DEPRESSOR AREA.** H.N. Saprut\* and V.K. Malhotra, Depts. of Neurosurgery & Pharmacology, New Jersey Medical School, Newark, NJ 07103.

Microinjections (50 nl) of L-glutamate (1.77 nmol) into the locus coeruleus (LC) neuronal pool elicited depressor and bradycardic responses. It was hypothesized that these responses may be mediated by noradrenergic projections from LC to the NA/VLDA neurons because small doses of norepinephrine (NE; 0.75, 1.5, 3 & 6 pmol) elicited a depressor and bradycardic response when injected into the NA/VLDA. The purpose of the present study was to determine pharmacologically if the destruction of noradrenergic terminals (and possibly noradrenergic neurons) can abolish the cardiovascular responses elicited from the LC. Experiments were done in pentobarbital-anesthetized and artificially ventilated rats. A solution of 6-hydroxydopamine (6-OH-D, 2 µg/µl) containing ascorbic acid (0.1 mg/ml) was used for the destruction of noradrenergic nerve terminals. Five microinjections (100 nl each) were made; the interval between injections was 5 min. After a waiting period of 1 hour, tyramine (25 nmol/50 nl) was injected into the NA/VLDA; usual depressor and bradycardic responses of tyramine were absent indicating that noradrenergic terminals and/or neurons were destroyed. Subsequent injections of glutamate into the LC did not elicit the usual depressor and bradycardic responses. These results suggest that cardiovascular responses elicited by injections of L-glutamate into the LC are mediated by noradrenergic nerve terminals and/or noradrenergic neurons located in the NA/VLDA region.

**BRAINSTEM INTERNEURONS NECESSARY FOR VESTIBULAR INFLUENCES ON SYMPATHETIC OUTFLOW.** B.C. Steinbacher, Jr.\* and B.J. Yates, Depts. Otolaryngology & Neuroscience, Univ. Pittsburgh, Pittsburgh, PA 15213.

The vestibular system has prominent influences on the sympathetic nervous system and cardiovascular function, and may participate in making adjustments in circulation during movement and changes in posture. Vestibular signals are relayed to sympathetic preganglionic neurons in the spinal cord through reticulospinal neurons located in the rostral ventrolateral medulla (RVLM, Yates et al., *Am. J. Physiol.* 268, 1995). However, both anatomical and physiological studies have shown that RVLM neurons receive labyrinthine signals through polysynaptic pathways (Yates et al., *Brain Res.* 552, 1991), suggesting that vestibulohypothalamic reflexes are mediated by brainstem interneurons. The objective of this study was to determine which brainstem regions contain interneurons that are critical for producing vestibulohypothalamic responses.

Experiments were conducted on decerebrate cats, and responses were recorded from the splanchnic nerve following electrical stimulation of the vestibular nerve. Brainstem lesions were produced by microinjecting the neurotoxin kainic acid or by mechanical methods. The areas targeted for lesions included the lateral reticular formation near the obex, nucleus tractus solitarius, and the pontine parabrachial nucleus. Lesions of the caudalmost lateral medullary reticular formation abolished vestibulohypothalamic reflexes, indicating that interneurons critical for these responses are located in this area. The same lesions also attenuated most components of somatosympathetic responses elicited by stimulation of the sciatic nerve, raising the possibility that a common pool of interneurons integrates signals from muscle, skin and the vestibular system that reflect body position in space. Lesions of other brainstem areas, including more rostral parts of the lateral reticular formation, nucleus tractus solitarius, or the parabrachial nucleus had little effect on either somatosympathetic or vestibulohypothalamic reflexes, suggesting that interneurons that mediate these responses are confined to a small part of the caudal medulla.

## 354.16

**RELATIONSHIP BETWEEN THE REGULATION OF BLOOD PRESSURE AND IN VIVO NORADRENERGIC NEURAL ACTIVITIES IN THE LOCUS COERULEUS OF YOUNG SPONTANEOUSLY HYPERTENSIVE RATS.** K.H. Ko\*, Y.T. Kim\*, J.H. Lee\*, E.K. Lee, M.J. Song\*, J.W. Dailey\*, and P.C. Jobe\*, Department of Pharmacology, College of Pharmacy, Seoul National University, Seoul 151, Korea. \*Department of Basic Sciences, University of Illinois College of Medicine at Peoria, Peoria, IL 61656, U.S.A.

The purpose of the present study was to determine whether *in vivo* noradrenergic neural activity in the locus coeruleus is related to the development of hypertension. Two groups of animals were prepared, 1) young spontaneously hypertensive rats (SHR) and 2) age-matched normotensive wistar kyoto rats (WKY). At 6 weeks of age, the release of norepinephrine (NE) and 3,4-dihydroxyphenylglycol (DOPEG) from locus coeruleus of young SHR and WKY as an index of neural activity were determined by *in vivo* microdialysis along with blood pressure (BP) at three conditions: 1) normal; 2) elevated BP by systemic injection of phenylephrine and 3)  $\alpha_1$ -adrenoceptor stimulated by perfusion of phenylephrine into the locus coeruleus through microdialysis probe. Basal releases of NE and DOPEG from the locus coeruleus were  $0.415 \pm 0.089$  pg/20min,  $1.311 \pm 0.293$  pg/20min in SHR and  $0.204 \pm 0.078$  pg/20min,  $1.492 \pm 0.365$  pg/20min in WKY respectively. Basal release of NE from the locus coeruleus of SHR was significantly greater than that of WKY. Phenylephrine systemic injection caused elevation of BP in both SHR and WKY in a dose related manner. Following phenylephrine injection, the releases of NE and DOPEG from the locus coeruleus of SHR were significantly decreased, whereas there were no significant changes in the releases of NE and DOPEG in young WKY.  $\alpha_1$ -Adrenoceptor stimulation in the locus coeruleus by perfused phenylephrine through microdialysis probe caused pressor responses in both SHR and WKY, but the magnitude of pressor response in SHR was larger compared with that in WKY. The result from the present study suggests that noradrenergic neural activity in locus coeruleus may contribute as one of triggering factors for the expression of hypertension in young SHR.

## 354.18

**PROCESSING OF VESTIBULAR, HINDLIMB AND BARORECEPTOR INPUTS BY NEURONS IN THE CAUDAL VENTROLATERAL MEDULLA (CVLM).** B.J. Yates\* and B.C. Steinbacher, Jr. Depts. Otolaryngology & Neuroscience, Univ. Pittsburgh, Pittsburgh, PA 15213.

Lesions of the lateral reticular formation caudal to the obex, including the CVLM, abolish vestibulohypothalamic reflexes and substantially reduce the amplitude of somatosympathetic responses. Thus, interneurons located in this region are a critical part of the circuitry that relays vestibular and other somatic signals to descending cardiovascular-regulatory pathways. Neurons in the CVLM also play an essential role in the baroreceptor reflex pathway (Jeske et al., *Neuroscience* 65, 1995; Blessing, *News Physiol. Sci.* 6, 1991), and make direct inhibitory connections with neurons in the rostral ventrolateral medulla that project to sympathetic preganglionic neurons in the spinal cord. The purpose of this study was to determine if common neurons in the CVLM mediate baroreceptor, vestibulohypothalamic and somatosympathetic reflexes.

Recordings were made from CVLM neurons in cats anesthetized using  $\alpha$ -chloralose and urethane. Vestibular inputs were elicited by electrical stimulation of the vestibular nerve, somatic afferents were activated by stimulation of the sciatic nerve, and neurons with baroreceptor inputs were identified by having discharges correlated with spontaneous fluctuations in blood pressure during the cardiac cycle. Many neurons in the CVLM responded to vestibular nerve stimulation, frequently at short latency (1.1-1.5 ms from the effective shock). However, only a small fraction of neurons with baroreceptor inputs received labyrinthine signals. Thus, different interneurons mediate vestibulohypothalamic and baroreceptor reflexes. Many CVLM neurons with baroreceptor inputs responded to sciatic nerve stimulation, as did about half of the neurons with vestibular inputs. These data suggest that somatosympathetic responses are mediated both by neurons involved in producing baroreceptor reflexes and by neurons which lack baroreceptor inputs but which integrate a number of inputs relating to body position.

## PAIN PATHWAYS: GENE EXPRESSION

## 355.1

**LOCALIZATION OF ENKEPHALIN AND THE DELTA OPIATE RECEPTOR IN THE PONTINE PARABRACHIAL NUCLEUS: POSSIBLE INVOLVEMENT IN CFA-INDUCED NOXIOUS PERIPHERAL INFLAMMATION.** Lisa L. Bellavance\* and Alvin J. Beitz, Neuroscience Program, University of Minnesota, St. Paul, MN 55108.

Previous work from our laboratory has shown that a CFA-induced peripheral inflammatory model of nociception results in an increase in the number of cFos immunoreactive nuclei in the pontine parabrachial nucleus (PBN) of the rat. This increase in cFos-like immunoreactivity (cFos-LI) is restricted to the Kolliker-Fuse and lateral subdivisions of the PBN and suggests a role for these areas in nociception and/or antinociception. One neurochemical that is likely to participate in nociceptive/antinociceptive processes in the PBN is the neuromodulator, enkephalin (ENK). We have used both immunocytochemistry and *in situ* hybridization to determine the distribution of ENK in the lateral PBN (PBNl). Moreover, we have utilized immunocytochemical techniques to determine the comparative distribution in the PBNl of the delta opiate receptor (antibody generous gift from Dr. R. Elde; see Dado et al., 1993 and Arvidsson et al., 1995) through which ENK is likely to exert some of its cellular effects. Interestingly, the distribution of ENK mRNA and immunoreactivity is more pronounced in the medial dorsal aspects of the PBNl while immunoreactivity for the delta opiate receptor is more noticeable in the lateral ventral aspects of this subdivision. The distribution of cFos-LI seen after inflammation partially overlaps with the distributions of both ENK and the delta opiate receptor in the PBNl. Further experiments are necessary to ascertain if those neurons expressing cFos in the PBNl in response to pain also contain ENK and/or delta opiate receptor mRNA's. These experiments are in progress and will provide important data defining the neurochemical nature of the PBN's involvement in nociception and antinociception. ## 355.2

**LYMBIC AND CORTICAL EXPRESSION OF C-FOS FOLLOWING PERIPHERAL NEURECTOMY IN RATS.** Anthony L. Vaccarino, Jane E. Magnusson, Kathryn L. Ruck and Richard D. Olson\*, Department of Psychology, University of New Orleans, LA 70148.

Peripheral nerve damage often leads to pathological pain processes which persist long after healing has occurred. There is evidence that persistent pain following nerve injury is related to changes in CNS function occurring at the time of nerve damage. In the present study, the expression of c-fos was examined in various limbic and cortical areas following peripheral neurectomy. Male Long-Evans rats were anesthetized with sodium pentobarbital and the sciatic nerve from one hind paw was sectioned free and cut. In half the rats, the sciatic nerve and surrounding tissue and muscle were anesthetized with bupivacaine (0.75%) prior to nerve section. Immediately, 1 h, or 2 h after nerve section, the animals were perfused through the heart with saline followed by 4% paraformaldehyde. Brains were removed and placed in 4% paraformaldehyde for 24 h and in 30% sucrose paraformaldehyde for an additional 48 h. Frozen coronal sections (40 µm) were placed in PBSx and stained with Sheep polyclonal antibody to fos. Peripheral neurectomy resulted in c-fos expression in various limbic and cortical areas, including the periventricular nucleus of the hypothalamus, cingulate cortex and amygdaloid complex. C-Fos expression was most pronounced 2 hours after nerve section. Anesthetizing the sciatic nerve prior to nerve section resulted in decreased c-fos expression in the paraventricular nucleus and cingulate cortex. This research was supported by a Louisiana Education Quality Support Fund (LEQSF).

PREPROCHOLECYSTOKININ mRNA EXPRESSING NEURONS IN THE RAT PARABRACHIAL NUCLEUS. Ola Hermanson\*, Marin Hallbeck, Dan Larhammar and Anders Blomqvist, Dept Cell Biology, University of Linköping, S-581 85 Linköping and Dept Medical Pharmacology, University of Uppsala, S-751 24 Uppsala, Sweden.

The parabrachial nucleus (PB) is a major termination site for ascending fibers from nociceptive-responsive neurons in the spinal and trigeminal dorsal horn. Nociceptive stimuli induce the expression of the transcription factor FOS in neurons in the dorsal part of the lateral PB (Hermanson et al., Soc. Neurosci. Abstr., 1992). FOS may regulate the transcription of several neuropeptide genes, such as the CCK gene, which contains the AP-1 site. PB has been reported to contain preprocholecystokinin (ppCCK) mRNA but its distribution within PB is unknown. The aim of this study was to analyse the subnuclear localization of ppCCK-expressing neurons in PB, particularly in relation to the distribution of noxious evoked FOS.

Male Sprague-Dawley rats were killed by transcardial perfusion with 4% paraformaldehyde. The brain was cut at 20 µm on a freezing microtome. In situ hybridization was performed with a <sup>35</sup>S-labeled 0.5 kbp RNA probe complementary to ppCCK (Deschènes et al., Proc. Natl. Acad. Sci., 1984). The sections were pretreated with proteinase K, hybridized for 20 hours at 59°C, and then posthybridized under high stringency conditions, followed by autoradiography.

Several subnuclei contained ppCCK-expressing neurons. A large number of ppCCK-positive neurons was present in the superior lateral subnucleus. Many labeled neurons were also seen in the dorsal lateral subnucleus, while a moderate number of ppCCK-expressing neurons was seen in the ventral lateral subnucleus. Other parts of PB, such as the Kölliker-Fuse nucleus and the external lateral subnucleus, contained only scattered labeling.

The present findings show that the distribution of ppCCK-expressing neurons in the dorsal parts of PB is similar to the pattern of FOS-expression seen after noxious stimulation, suggesting that noxious-evoked FOS in PB may be related to ppCCK-expressing neurons.

Supported by the Swedish Medical Research Council (No. 7879).

## 355.5

DISTRIBUTION OF C-FOS IN THE BRAIN OF RODENTS AFTER NOXIOUS STIMULATION OF VISCERA. G.F. Gebhart\*, A. Solodkin\* and R.J. Traub\*, Pharmacology<sup>1</sup> and Anatomy and Neurology<sup>2</sup>, University of Iowa College of Medicine, Iowa City, IA, 52242

There is much to learn yet about the circuitry responsible for the perception of visceral pain. Identification of Fos-ir neurons has become a powerful tool to detect populations of neurons activated by different stimuli. In an attempt to elucidate some of the supraspinal areas involved in the integration of noxious stimulation from viscera, we examined c-Fos expression after noxious colorectal distention (CRD) in rats.

Using standard immunocytochemical techniques, we compared the distribution of c-Fos after three different treatments: a) CRD + loose restraint, b) loose restraint, c) no treatment.

CRD induced Fos in several brain areas. Fos was also present in some areas in the stress group but not in controls. The areas showing Fos induction after CRD are: parabrachial nucleus, ventro-lateral PAG, VPL, antero-medial and posterior nuclei in thalamus, medial and cortical amygdaloid nuclei, mammillary hypothalamic nuclei, lateral septal nucleus, infragranular cingulate and insular cortices. Areas with induction of Fos in stress and CRD conditions, with the latter showing a greater density of stained nuclei were: dorso-lateral PAG, paraventricular and suprafascicular nuclei in thalamus, cingulate, frontal, perirhinal, entorhinal and piriform cortices and hippocampal formation.

These observations show a widespread activation of brain areas after noxious stimulation of the colon. Even though there were some areas specifically activated after noxious stimulation and not stress, there were many which were activated under both conditions. These results suggest that the perception of pain is the result of parallel activation in several limbic and non-limbic areas. Supported by: NS 30604 and NS 19912.

## 355.7

ONTOGENY OF FORMALIN INDUCED C-FOS EXPRESSION IN THE RAT BRAIN. G.A. Barr\* and D.K. Yi, Biopsychology Doctoral Program, Dept. of Psychology, Hunter College-CUNY, NY, NY 10021 and New York State Psychiatric Institute, 722 W. 168th Street, NY, NY 10032.

The processing of painful stimulation differs in the young, and although it has been shown that the basic connections in nociceptive pathways are present before birth in both rats and humans, the functional ontogeny of nociception is poorly understood. In the rat, the primary afferents and the dorsal horn cells of the spinal cord that are involved in processing nociceptive information develop prenatally but undergo considerable postnatal maturation. Virtually nothing is known of the functional maturation of brain structures that, in the adult, are known to process this noxious afferent input. Following noxious stimulation of a variety of body regions, the c-fos oncogene is expressed in the spinal cord and brain of adult animals. In the infant the Fos protein is also induced in the spinal cord dorsal horn by various types of noxious stimulation as early as the day of birth. In order to study functional maturation of pain processing by brain structures, formalin or saline was injected into the forepaw or hindpaw of 0, 3, and 14 day old rat pups. After 2 hours, the pups were overdosed with a barbiturate, and perfused with 4% paraformaldehyde. The brain was dissected out, sectioned and processed for Fos immunocytochemistry. Fos-like immunoreactive cell nuclei were found in a variety of brain sites comparable to those reported by others in the adult animal. These include but are not limited to the rostral ventral medulla, periaqueductal gray of the midbrain, medial thalamic nuclei, and the hypothalamus. There was also Fos staining in some brain regions in the control rat pups. These data indicate that the brain is capable of expressing c-fos in response to a noxious stimulus as early as the day of birth. Supported by RO1 DA-07341.

## 355.4

FOS PROTEIN IN PARAVENTRICULAR THALAMIC (PVT) AND DORSAL RAPHE (DRN) NUCLEI OF MONOARTHRITIC RATS. L.E. Camacho-Corona\*, F.J. López-Muñoz\*, S.L. Cruz\*, L. Rocha\*, Depto. Farmacología y Toxicología, CINVESTAV-IPN, P.O. Box 1573, Cuernavaca, Inst. Mexicano de Investigación Científica, 76000, México, D.F.

It has been established that Fos protein appears after extracellular stimulation. We induced acute arthritis, in the same way as in the model known as Pain-Induced Functional Impairment in the Rat (PIFIR), in order to determine which brain areas of awake rats are activated.

Groups (n=4) of Male Wistar rats (250-350 g) were used: i) manipulated control group (M), ii) rats injected with vehicle (V); and iii) rats injected with 30% uric acid (UA). The injection was performed in the knee joint of the right hind limb of the rats under brief anesthesia with halothane. After an exposure period of 2.5 or 4.5 h to V or UA, the animals were anesthetized with ketamine-xylazine and then perfused. Brains were removed and cut in coronal sections (40µm) which were exposed to Fos antibody and processed by the Avidin-Biotin technique. The number of positive cells was counted and analyzed by Student's t-test. Among the areas analyzed, we found a significant increment of the number of Fos positive cells in DRN and PVT.

	DRN		PVT	
	2.5 h	4.5 h	2.5 h	4.5 h
V	38 ± 6	41 ± 4	47 ± 4	38 ± 4
UA	50 ± 3	58 ± 4*	80 ± 6*	84 ± 10*
M	33 ± 4		43 ± 7	

The temporal changes observed in DRN and PVT were closely related to functional impairment of the hind limb as registered with the PIFIR model. Thus, Fos could be used as a marker in DRN and PVT in the PIFIR model. Our data suggest that these regions might participate in a nociceptive neural pathway from knee joint.

## 355.6

FORMALIN-INDUCED C-FOS EXPRESSION IN THE SPINAL CORD OF RAT FETUSES. D. Yi\* and G. Barr, Biopsychology Doctoral Program, Dept. of Psychology, Hunter College-CUNY, NY, NY 10021 and New York State Psychiatric Institute, 722 W. 168th Street, NY, NY 10032.

Understanding the ontogeny of pain processing is an important first step in controlling and alleviating pain in neonates. It has been shown that the basic connections in nociceptive pathways are present before birth in both rats and humans. The primary afferents and the dorsal horn cells that are involved in processing nociceptive information, however, are immature at birth and undergo considerable postnatal maturation. Following formalin injection into the forepaw or hindpaw, the c-fos oncogene is expressed in the spinal cord dorsal horn as early as the day of birth. In order to study functional maturation of pain pathway before birth, we examined the expression of c-fos gene in the spinal cord of rat fetuses following formalin injection into the forepaw or hindpaw. An adult female rat was placed with a male rat for 14 hours overnight. On the following day, a vaginal smear was taken and with the presence of sperm, that day was designated as embryonic day (ED) 0. On ED 19 or ED 20, the dam underwent chemomyelotomy at L1/L2, and was placed in a holding device submerged in a warm saline bath. The uterine horns were externalized through an abdominal incision into the saline bath, and either the forepaw or the hindpaw of the fetal animal was injected with 5 µl of 10% formalin or saline. Fetuses remained in the uterine horn for 2 hours post-formalin injection, and were sacrificed at the end of the 2 hour period. ED 20 fetuses were perfused, and all animals were fixed or post-fixed by immersion in 4% paraformaldehyde. The lumbar or cervical portion of spinal cord was dissected out, sectioned and processed for Fos immunocytochemistry. No Fos labeled cells were apparent in the spinal cord of ED 19 animals. However, stained Fos nuclei were observed bilaterally in the spinal cord of ED 20 fetuses. Furthermore, very few cells in the superficial laminae were labeled and most of the labeling occurred in the deeper layers of the dorsal horn. These data indicate that the dorsal horn cells are expressing Fos protein before birth although different than the Fos staining pattern of postnatal animals. Supported by RO1 DA-07341.

## 355.8

EVALUATION OF FOS-LABELING IN THE RABBIT BRAIN FOLLOWING INDUCTION OF SINUSITIS. A.K. Roche\* and K.C. Kajander, Depts. of Pharmacology, Oral Science, Cell Biology and Neuroanatomy, and Graduate Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455.

The purpose of this study was to evaluate Fos-labeling in the rabbit brain following induction of sinusitis. The bacterium *Bacteroides fragilis* was used to induce sinusitis.

We used adult, male, New-Zealand White rabbits (2.5-3.5 kg). After onset of anesthesia, the left maxillary sinus was opened by drilling through the bony ceiling of the nasal dorsum. To prevent spread of bacteria to adjacent nasal areas, the maxillary ostium was closed using a cotton plug and cyanoacrylate ester. For induction of inflammation, 1x10<sup>8</sup> colony forming units of *Bacteroides fragilis*, suspended in 0.5 ml phosphate buffered saline, were injected onto a plug of sterile cotton placed in the left maxillary sinus. The opening in the nasal dorsum was then closed using dental resin; the skin incision was sutured, and the animal was allowed to recover. Animals were sacrificed 24 hours later for immunohistochemical localization of Fos protein.

Following induction of sinusitis, a significant increase (Student's t, p<.05) in Fos-labeled nuclei was observed in the ipsilateral subnucleus caudalis of the spinal trigeminal tract. In a previous study using WGA-HRP, we traced the central projections of nerves innervating the sinus to this subnucleus (Neurosci. Abstr., 20:1571, 1994). A complete analysis of Fos-labeling in other regions of the brain is in progress.

In this study, we used Fos-labeling to map the distribution of neurons activated by sinusitis. Our study appears to be the first to evaluate alterations in the central nervous system following induction of sinusitis.

## 355.9

DESCENDING AFFERENTS PARTIALLY SUPPRESS SPINAL DYNORPHIN mRNA AND PEPTIDE UPREGULATION INDUCED BY PERIPHERAL INFLAMMATION. **M.A. Ruda, K. Ren, E. Pfaffenroth, D. R. Kenshalo, Jr., L. MacArthur.** Neurobiology & Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892

Inflammation and hyperalgesia induce a dramatic upregulation of opioid and non-opioid mRNA and peptide levels in the spinal dorsal horn. The role of descending modulation in these events is not known. To elucidate the role of descending mechanisms in regulation of dynorphin (DYN) levels induced by tissue injury, rats received a hindpaw injection of 0.3 ml complete Freund's adjuvant (CFA) seven days after spinal transection. The L4-5 spinal segments were prepared for RNA blot analysis and immunocytochemistry 3 days after CFA. Comparisons were made between 3 groups of CFA treated rats: spinal transected (SX); sham surgery (SH); and naive (N). Paw edema was similar in all three groups (11.5mm ipsi vs 4.8mm contra). The inflamed hindpaw of SH and N rats demonstrated hyperalgesia to a radiant heat stimulus, while SX rats exhibited a withdrawal reflex to the same heat stimulus. RNA blot analysis demonstrated an 810%, 527% and 500% ipsilateral upregulation in DYN mRNA in the SX, SH and N groups respectively, as compared to the contralateral side of the SH group. Immunolabeling of colchicine treated rats showed an average of 35.8 DYN immunoreactive (DYN-IR) cell bodies /30µm section ipsilateral to the inflammation in SX rats and 34.5 cells in SH rats. These data demonstrate that descending afferents to spinal neural circuits partially suppress the DYN mRNA and peptide upregulation that occurs in response to peripheral inflammation and hyperalgesia. Since a similar number of neurons showed DYN-IR in both the SX and SH groups, it is likely that the increased DYN mRNA in the SX group reflects a more dynamic response of the same neuronal population to the painful stimulus rather than a recruitment of more neurons to the response.

## PAIN MODULATION: ANATOMY AND PHYSIOLOGY—NEUROPATHIC PAIN

## 356.1

IMPORTANCE OF THE LOCATION OF INJURY ON SYMPATHETIC DEPENDENCY OF RAT MODELS OF NEUROPATHIC PAIN. **D.H. Lee\*, K. Chung and J.M. Chung.** Marine Biomed. Inst., Depts. of Anat. & Neurosci. and Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77555.

The aim of this study was to test a hypothesis that the location of injury in the peripheral nerve is an important determinant for sympathetic dependency in rat neuropathic pain models.

Under halothane anesthesia, neuropathic injury was produced at the left L5/6 spinal nerves in three groups of rats by: 1) tightly ligating them with 6-0 silk; 2) placing loose ligatures with 5-0 chromic gut; and 3) tightly ligating half of the nerves with 6-0 silk. Behavioral tests for ongoing and evoked pain were conducted for the next 4 weeks and the degree of sprouting sympathetic fibers in the L5/6 dorsal root ganglia (DRG) was assessed.

Rats in all three groups displayed behavioral signs of ongoing and evoked pain with a similar time course. The L5/6 DRG of all three groups of rats showed large numbers of sprouting sympathetic postganglionic fibers as visualized by immunohistochemical staining with antibody against tyrosine hydroxylase. These numbers are significantly higher than those seen after distal injuries made by the same methods.

The data suggest that the proximal nerve injury, regardless of the method of injury, triggers sprouting of sympathetic postganglionic fibers into the DRG and produces sympathetically dependent neuropathic pain behaviors. (Supported by NIH grants NS31680 and NS11255)

## 356.3

SOMATOTOPICAL REDISTRIBUTION OF C-FOS NEURONS IN THE SUPERFICIAL DORSAL HORN AFTER PERIPHERAL NERVE INJURY. **C. Molander\*, J. Hongpaisan & P. Shortland.** Dept. of Neuroscience, Karolinska Institutet, S-171 77 Stockholm, Sweden.

The functional somatotopic organization in the lumbar spinal cord dorsal horn after peripheral nerve injury was studied by mapping neuronal C-FOS distribution. Electrical stimulation of the saphenous nerve at C-fiber strength was performed 5-150 days following either resection of the sciatic nerve, or combined sciatic nerve resection and saphenous nerve crush. Stimulation of the intact saphenous nerve on the contralateral side was made for comparison. Electrical stimulation of the normal saphenous nerve resulted in numerous labeled neurons in the L2-4 superficial dorsal horn. Sparse labeling was seen also in deeper laminae. Bilateral stimulation of the saphenous nerves after unilateral sciatic nerve section combined with saphenous crush resulted in an increased number of labeled cells in laminae I-II and larger distribution (in the mediolateral & caudal directions) on the injured side compared to the uninjured control side, at all survival times. Bilateral saphenous nerve stimulation after sciatic transection alone resulted in similar but less profound changes. The results indicate that chronic nerve injury is accompanied by an increased capacity of neighbouring intact or regenerating (crushed) nerves to excite postsynaptic neurons in the dorsal horn, including part of the territory of the adjacent chronically injured nerve. The timecourse of these alterations indicates that several different mechanisms, including unmasking as well as peripheral & central collateral sprouting, may be operating. Supported by Tore Nilsons fond.

EFFECTS OF AGING ON EXPRESSION OF DYNORPHIN IN RAT SPINAL CORD FOLLOWING PERIPHERAL INFLAMMATION AND HYPERALGESIA. **R.X. Zhang and M.A. Ruda\*.** Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

Dynorphin (DYN), a kappa opioid, is thought to play an important role in the modulation of nociceptive spinal neural networks. Complete Freund's adjuvant (CFA) injected into the rat hindpaw results in hyperalgesia and upregulation of DYN mRNA and peptide in the ipsilateral spinal cord. The aging process is associated with a number of physiological and biochemical changes that may impact neuronal processing of noxious inputs. This study aimed to identify age-related changes in the behavioral response and regulation of DYN mRNA and peptide in the spinal cord after CFA-induced inflammation. CFA was injected unilaterally into the hindpaw of male young (3 month, n=15) and aged (18 month, n=14) Sprague-Dawley rats. The withdrawal latency of the hindpaws to radiant heat was measured from 2 hr to 3 days after CFA. The post-CFA paw withdrawal latencies were significantly shorter ( $P<0.05$ , ANOVA) in aged rats while paw diameters, a measure of edema, were significantly larger ( $P<0.05$ , ANOVA) in aged than in young animals. At day 3, the L 4-5 spinal segments were removed and total RNA extracted. RNA blots were hybridized with a  $^{32}$ P-labeled DYN cDNA probe. In aged rats there was a significant increase (2-fold,  $P<0.05$ , ANOVA) in DYN mRNA levels in the spinal cord on the inflamed side as compared to the inflamed side in young rats. There was also a significant ipsilateral increase (3-fold,  $P<0.05$ , ANOVA) in the number of detectable DYN immunostained neurons in aged as compared to young rats. No significant differences in DYN mRNA and peptide levels were observed in the contralateral spinal cord of aged as compared to young rats. These data indicate that aged rats exhibit a more robust induction of DYN mRNA and peptide as a result of peripheral inflammation than that produced in young rats.

SYMPATHETIC SPROUTING IN AXOTOMIZED RAT DRG: ULTRASTRUCTURE. **M. Devor\*, V. Shinder and R. Govrin-Lippmann.** Department of Cell and Animal Biology, Life Sciences Institute, Hebrew University, Jerusalem, Israel 91904

Using tyrosine hydroxylase (TH) immunocytochemistry at the light microscopic level we confirmed the prior finding that following peripheral nerve injury, sympathetic postganglionic axons sprout within the corresponding dorsal root ganglia (DRGs) and in some cases form a basket-like plexus around LL sensory neuron somata. At long survival times, some axotomized DRG neurons acquire an onion bulb-like crust of glial cells which form a loose net around the normal single-layer of closely adherent satellite cells. Ultrastructural analysis, including 3D reconstruction, of TH-positive axonal baskets indicated that sympathetic axons grow on the surface of the glial cells that surround the neuron, and grow preferentially on onion-bulb layers when present. Sympathetic fibers do not contact the neuronal membrane surface directly. However, lanthanum tracer studies showed that small molecules in the bulk extracellular space have access to the soma membrane by diffusion into the seam that separates adjacent satellite cells in the adherent sheath, with subsequent spread into the satellite cell-neuron cleft. Light and EM immunocytochemistry using an antibody that specifically recognizes  $\alpha 2A$  adrenoreceptors (provided by D. Rosin, Univ. Virginia Med. Sch.) indicated that many LL and SD DRG neurons express these receptors on intracytoplasmic vesicles and on the soma membrane. There was no clear indication that nerve injury triggers receptor upregulation. Together, these observations are consistent with the hypothesis that functional sympathetic-sensory coupling in DRGs is mediated by nor-adrenalin, released non-synaptically from sprouted sympathetic fibers in the ganglion, which acts on adrenoreceptors on the soma surface after diffusion through the seam/cleft system that ensheathes the neuron.

## 356.4

NMDA, AMPA AND KAINATE RECEPTORS ARE PRESENT IN AXONS IN THE GLABROUS SKIN OF THE RAT HINDPAW. **S.M. Carlton\* and R.E. Coggeshall.** Dept. of Anatomy and Neurosciences, Marine Biomedical Institute, UTMB, Galveston, TX 77555.

It has been previously shown that AMPA, KA and NMDA receptors are expressed in the dorsal root ganglia (DRG) of rat. Based on cell size, small DRG cells immunohistochemically label with antibodies to subunits associated with all 3 glutamate receptor subclasses while large DRG cells were found to label for subunits associated with AMPA and NMDA, but not Kainate receptors. The present study addressed whether glutamate receptors were transported to the periphery, and thus could be involved in sensory processing in cutaneous axons.

Rats (male, Sprague-Dawley) were deeply anesthetized and perfused with saline, followed by mixed aldehydes. The glabrous skin from the third toe of each rat was removed and cut with a razor blade into 100µm slabs. These slabs were immunostained free-floating with antibodies which recognized the GluR1 (AMPA), GluR5,6,7 (Kainate) or the NMDAR1 (NMDA) subunits. Following immunostaining, the tissue was osmicated, dehydrated and embedded in plastic for ultrathin sectioning. At the EM level, bundles of myelinated axons and accompanying Schwann cells were found in the dermis and at the dermal-epidermal junction. Each bundle contained a varying number of labeled as well as unlabeled axons. The label consisted of dense reaction product within the axoplasm, or in some cases, along the axoplasmic membrane. It is unknown at this time if the labeled axons originated from unmyelinated parent axons or if some were myelinated axons which had lost their sheaths. These results indicate that the 3 glutamate receptor subtypes previously localized in the DRG cell bodies are transported out to the periphery. The presence of glutamate receptors on presumed sensory axons suggests that they play a role in sensory transmission. (Supported by NS11255 and 27910).

## 356.5

SYSTEMIC INJECTION OF KETAMINE ALLEVIATES PAIN BEHAVIORS IN A MODEL OF PERIPHERAL NEUROPATHY. J. Qian\*, S. Brown and S. M. Carlton. Dept. of Anatomy and Neurosciences, Marine Biomedical Inst., UTMB, Galveston, TX. 77555.

Painful neuropathies which develop after nerve injury involve central sensitization that is thought to result from activation of NMDA receptors. This hypothesis predicts that NMDA receptor antagonists will be therapeutic in alleviating neuropathic pain. In the present study, the efficacy of ketamine (KET), a non-competitive NMDA receptor-channel blocker, is assessed for relieving neuropathic pain behaviors in rats.

Male Sprague-Dawley rats (125-175 g) with tight ligations of the left L5 & L6 spinal nerves develop, within a week, increased sensitivity on the plantar surface of the left hindpaw. The nerve-injured hindpaws withdraw to innocuous and noxious von Frey hair stimulation (mechanical allodynia and hyperalgesia), application of acetone (cold allodynia), and display frequent and sustained paw withdrawals in the absence of any stimuli (ongoing pain) or when placed on a cold plate (stress-induced pain). Systemic bolus injection of 0.01 mg/kg KET transiently (15-30 min) decreases these nociceptive behaviors. KET at 1.0 mg/kg consistently attenuates all the neuropathic pain behaviors by about 50% without any noticeable side effects. Higher doses (25 & 50 mg/kg) cause motor impairment for 15-30 min, which masks KET's fast-acting analgesic properties. However, the antinociceptive effects outlast the motor deficits, reducing the pain behaviors for over an hour. In all cases, the antinociceptive effects of KET are dose- and time-dependent, reaching maximal effect within 15 min, and decaying over the next 1-2 hrs. Mechanical allodynia and hyperalgesia are most efficiently attenuated by i.p. KET, followed by cold allodynia, stress-induced pain, and ongoing pain.

The present results demonstrate that blockade of NMDA receptors can effectively alleviate pain behaviors in neuropathic rats, substantiating the important role of NMDA receptors in the mechanisms that underlie the development and maintenance of painful neuropathies. In addition, the potent analgesic efficacy of ketamine suggests that this clinically safe drug can be applied in pain management of neuropathic patients. (Supported by NS11255 and NS27910.)

## 356.7

SPROUTING OF B-HRP FILLED FIBERS OF THE L5 SPINAL NERVE FOLLOWING L5 AND L6 SPINAL NERVE LIGATION IN THE RAT. H.A. LEKAN\*, S.M. CARLTON, AND R.E. COGGESHALL. Marine Biomedical Institute, The University of Texas Medical Branch, Galveston, TX 77555-1069.

An experimental peripheral neuropathy was induced in rats by ligating the L5 and L6 spinal nerves approximately 5mm distal to the dorsal root ganglia. Previous behavioral and electrophysiological studies indicate that these animals consistently exhibit heat hyperalgesia and mechanical allodynia for a period of at least one month. To address the question of possible anatomical changes in the spinal distribution of large diameter afferent fibers, cholera toxin B subunit-horseradish peroxidase conjugate (B-HRP) was injected into the L5 spinal nerve of neuropathic animals. Three days following injection of the B-HRP, the animals were sacrificed and perfused with mixed aldehydes. Appropriate spinal cord segments were sectioned on a vibratome, and the tissue sections were processed for B-HRP labelling using tetramethylbenzidine histochemistry.

In normal rats, B-HRP filled axons (shown to be predominantly A $\beta$  fibers) enter the medial 2/3rds of lamina I and III-V of the dorsal horn, but not lamina II. Our preliminary results indicate that 2 weeks following spinal nerve ligations, B-HRP labelled fibers are now present in lamina II. If further studies support these preliminary data, then the results would suggest sprouting of A $\beta$  fibers into a region of the dorsal horn normally occupied by small diameter fibers subserving pain and temperature, similar to what has been previously reported for sciatic nerve ligation. We will now test whether the behavioral changes that characterize this model are correlated with the entrance of the A $\beta$  fibers into lamina II. This work is supported by NIH grants NS11255, NS10161, NS27910 and NS07185.

## 356.9

MORPHINE REDUCES BEHAVIORAL SIGNS OF NEUROPATHIC PAIN IN A RAT TAIL MODEL. Y.W. Yoon\*, H.S. Na, K.H. Ko, S.K. Hong and S.H. Nahm. Dept. of Physiology, Korea Univ. Med. Coll., Seoul, KOREA., 136-705.

The aim of this study was to see the effects of morphine on neuropathic pain in an experimental rat model.

Neuropathic injury was produced by resection of the inferior caudal trunk between the S3 and S4 spinal nerves unilaterally under halothane anesthesia (Neurosci. Lett., 177:50-52, 1994). Behavioral tests were performed to examine the presence of mechanical allodynia and thermal allodynia.

Operated rats showed tail-flick responses to innocuous mechanical stimuli applied to certain spot(s) of the tail with von Frey hairs as well as tail flicks or tail flick-like responses following immersion of the tail to warm (40 °C) or cold (4 °C) water. One week after the nerve injury, we examined the effects of intraperitoneally injected morphine. At 1, 3, 5 mg/kg doses, morphine reduced the responses in a dose-dependent fashion. The analgesic effect of 5 mg/kg morphine was almost completely reversed by naloxone (0.5 mg/kg; IP injection).

The present data clearly show that specific activation of opioid receptors by morphine can alleviate the neuropathic pains in our model, which seems to contradict the classical view that neuropathic pain is opioid-resistant.

## 356.6

IDENTIFICATION OF  $\alpha$ -ADRENORECEPTOR SUBTYPES EXPRESSED IN RAT DORSAL ROOT GANGLIA. S.L. Knock\*, S.G. Widen and S.M. Carlton. Depts. Humanities & Basic Science, Sealy Center for Molecular Science, Anatomy & Neuroscience, University of Texas Medical Branch, Galveston, TX 77555.

Following peripheral nerve injuries, patients can develop painful neuropathies that often become chronic and disabling. In some of these patients, the pain is sympathetically maintained and unresponsive to narcotic analgesics. Pharmacological studies strongly suggest that  $\alpha$ -adrenoreceptors play a major role in the development of this sympathetically maintained pain (SMP). Recent development of a rat model characterized by SMP and cloning of  $\alpha$ -adrenoreceptor genes provide the necessary framework for the investigation of changes in the expression of  $\alpha$ -adrenoreceptors during SMP. We hypothesize that an increase in transcription of  $\alpha$ -adrenoreceptor gene(s) provides the mechanism that results in activation of nociceptive afferents in response to adrenergic stimulation.

Using Reverse Transcriptase-Polymerase Chain Reaction (RT-PCR) techniques, we have analyzed for  $\alpha_{2A}$ ,  $\alpha_{2B}$  and  $\alpha_{2C}$ -adrenoreceptor messenger RNA (mRNA) in dorsal root ganglia, L<sub>4</sub>, L<sub>5</sub> and L<sub>6</sub>. In normal rats, we have been able to detect the expression of  $\alpha_{2A}$  and  $\alpha_{2B}$ -adrenoreceptor mRNA, but not  $\alpha_{2C}$ -adrenoreceptor mRNA. Thus, changes in the expression of these receptors in neuropathic animals may underlie SMP. (Supported by the Pearl and Aaron Forman Research Foundation, and NS11255, NS27910)

## 356.8

GLUTAMATE INJECTED INTO THE RAT HINDPAW PRODUCES MECHANICAL ALLODYNIA AND HEAT HYPERALGESIA. G.L. Hargett\*, J.F. deGroot and S.M. Carlton. Department of Anatomy and Neurosciences, Marine Biomedical Institute, UTMB, Galveston, TX 77555.

It has been demonstrated in our laboratory that AMPA, Kainate and NMDA receptors are present in axons in the rat hindpaw (see Carlton and Coggeshall). In the present study, we addressed whether activation of these peripheral receptors with exogenous glutamate (Glu) played a role in sensory transduction.

To assess mechanical allodynia, naive rats (male, Sprague-Dawley, 125-200gm) were placed on a mesh grid and behaviorally tested with von Frey filaments (9.4, 28, and 47mN). The number and quality (mild, average, robust) of each withdrawal response per 10 stimulations was recorded. Following baseline testing, animals were briefly anesthetized with halothane for injection of 20  $\mu$ l of Glu (0.01, 0.1, 1, and 5mM, n $\geq$ 5 for each dose) or vehicle (phosphate buffered saline, PBS) into the plantar skin. Animals were tested post-injection for 60 mins. at 5 min. intervals. To assess heat hyperalgesia, rats were placed on a 45 $\pm$  5 °C plate for 1 min. intervals and the elevation time of the left hindpaw recorded. Following baseline testing, animals were anesthetized as described above and 50  $\mu$ l 0.1mM Glu (n=3) or PBS (n=3) was injected into the foot pad. Rats were retested every 5 mins. for 40 mins.

Injection of PBS resulted in little change in behavioral responses to von Frey or heat stimuli. However, injection of 0.1mM Glu produced an increase in withdrawal to the 9.4 and 28mN filament while 0.1mM Glu produced an increase in withdrawal to the 28 and 47mN filament. Responses peaked within 15 mins. post-injection. Compared to PBS, 0.1mM Glu caused an increase in elevation time of the injected foot on the 45 °C plate. The results suggest that 1) there are functional glutamate receptors in the glabrous skin and 2) these receptors play a role in the transduction of mechanical and heat stimuli. (Supported by NS11255 and NS27910.)

## 356.10

CRITICAL ROLE OF CAPSAICIN-SENSITIVE NERVE FIBERS IN THE DEVELOPMENT OF THE NEUROPATHIC SYMPTOMS IN A RAT MODEL. S.K. Hong\*, H.S. Na, Y.I. Kim and K.H. Ko. Dept. Physiol., Med. Coll., Korea Univ., Seoul, KOREA.

We investigated the role of capsaicin-sensitive small diameter fibers in the development of the pain behaviors in a rat model, produced by transecting some but not all of the nerves innervating the tail.

Capsaicin (50 mg/kg, sc.) injected neonatally produced thermal hypoalgesia in the tail the degree of which was variable across individual rats. When subjected to partial denervation of the tail during adulthood, the animals with moderate thermal hypoalgesia exhibited signs of pain to normally innocuous mechanical stimuli applied to the tail with von Frey hairs (4.9-mN or 19.6-mN bending force), but not to thermal stimuli given by immersion of the tail into cold (4°C) or warm (40°C) water. The animals with marked thermal hypoalgesia, on the other hand, exhibited no signs of pain either to the mechanical or to the thermal stimuli.

These results suggest that the capsaicin-sensitive fibers are critical in the development of mechanical, as well as thermal, allodynia. (Supported by NON DIRECTED RESEARCH FUND, KRF)

## 356.11

**THE ROLE OF SIGNALS FROM DORSAL ROOT GANGLION IN NEUROPATHIC PAINS INDUCED BY NERVE INJURY.** H. S. Na\*, Y. I. Kim, K. H. Ko and S. K. Hong. Dept. Physiol., Med. Coll., Korea Univ., Seoul, KOREA.

We have developed a new rat model for peripheral neuropathy by resecting the superior caudal trunk at the level between the S1 and S2 spinal nerves under halothane anesthesia. These animals displayed much shorter tail-flick latencies following immersion of the tail to warm (40°C) or cold (4°C) water and tail-flick responses to normally innocuous mechanical stimulation to the tail with von Frey hairs. Using this new model, we examined which of the signals from the injured site of the nerve and from the dorsal root ganglion cells of the injured nerve is critical for generation of the neuropathic pains.

To block transmission of the electrical and/or chemical signals arising from the very injured site of the nerve, the neuroma produced in this site was severed with scissors or soaked with bupivacaine or colchicine. None of these manipulations resulted in alleviation of the signs of neuropathic pain. In contrast, cutting the dorsal root at the S1 level (i.e., S1 dorsal rhizotomy) significantly reduced or completely removed the neuropathic signs.

The data suggest that signals from the dorsal root ganglion cells, not from the injured site, are crucial for generation of the neuropathic pains. (Supported by NON DIRECTED RESEARCH FUND, KRF)

## 356.13

**NEUROPATHIC NERVE INJURY INDUCES SPROUTING OF A FIBRE PRIMARY AFFERENTS INTO SUBSTANTIA GELATINOSA OF THE ADULT RAT SPINAL CORD.** P. Shortland<sup>1</sup>, L. C. Yu<sup>2</sup>, T. Lundberg<sup>2</sup>, & C. Molander<sup>1</sup>. Depts. of (1) Neuroscience and (2) Physiology and Pharmacology, Karolinska Institutet, S-171 77 Stockholm, Sweden.

Two animal models have recently been developed for the study of neuropathic pain mechanisms. Rats that have a chronic constriction injury (CCI, Bennett & Xie, '88) or ligation of spinal nerves (SNL, Kim & Chung, '92) show signs of spontaneous pain, allodynia & hyperalgesia. These changes are thought to arise from altered activity levels in the peripheral nerve, dorsal root ganglion (DRG) & the dorsal horn (DH). This study investigated the central effects of neuropathic nerve injury on the A fibers, known to sprout into lamina II after nerve section (Woolf et al., '92). Adult male rats were subjected to either sciatic nerve CCI (4-0 chromic sutures or silk) or tight ligation of the L5/6 spinal nerves (4-0 silk). In CCI rats, the nerve was injected with 1% BHRP 10-14 days later proximal to the constrictions. In SNL rats, BHRP was either injected into the L5 DRG (to label injured afferents) or the sciatic nerve (to label intact L4 afferents). The contralateral uninjured side, used for control injections, showed labelling in laminae I and III-V, leaving lamina II devoid of labelling. In CCI rats, BHRP label was seen throughout laminae I-V in the L4-5 DH by 10 days post injury. There were, however, regions in lamina II that were incompletely labeled by BHRP. Adjacent sections stained for TMPase showed depletion, but not a total loss, in the sciatic region. In SNL rats, BHRP injection into the L5 DRG produced sprouting into lamina II whilst injection into the L4 spinal nerve did not. The results indicate that injured Aδ afferents sprout into SG in these models whilst intact adjacent afferents do not. Thus, injured Aδ fibers may contribute to the generation of abnormal sensations in neuropathic rats. Supported by Åke Wibergs stiftelse.

## 356.15

**POSSIBLE INVOLVEMENT OF ADRENERGIC RECEPTORS IN THE SKIN TO MODULATE MECHANICAL ALLODYNIA IN A RAT NEUROPATHIC PAIN MODEL.** D.E. Moon\*, J. Xie, and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77555.

The aim of this study was to evaluate a potential contribution of adrenergic receptors in the skin for the mediation of mechanical allodynia in a neuropathic pain state.

Under halothane anesthesia, neuropathic injury was produced by tightly ligating the left L5 and L6 spinal nerves of *Sprague-Dawley* rats. An increase in the frequency of foot withdrawals in response to repeated applications of mechanical stimuli to the plantar surface with von Frey filaments of innocuous bending force was interpreted as a sign of mechanical allodynia.

All tested rats displayed well developed signs of mechanical allodynia. Subcutaneous injection of idazoxan hydrochloride (5 µg in 20 µl), an α2-adrenergic receptor antagonist, produced a significant reduction in signs of mechanical allodynia lasting about 1 hour. Furthermore, the same drug blocked the rekindling of mechanical allodynia which was elicited by subcutaneous injection of norepinephrine in sympathectomized neuropathic rat.

The data suggest that α2-adrenergic receptors modulate the function of mechanoreceptors in the skin for mediation of mechanical allodynia in the neuropathic pain condition. (Supported by NIH grants NS31680 and NS11255)

## 356.12

**NORADRENALINE (NE) INCREASES THE EXCITABILITY OF NEURONS IN THE S1-S3 DORSAL ROOT GANGLIA (DRG) FROM A RAT MODEL OF NEUROPATHIC PAIN.** Y. I. Kim, H. S. Na, Y. W. Yoon, M. K. Lee, H. J. Kim, J.-M. Chung\*, S. H. Nahm and S. K. Hong. Dept. of Physiol., Coll. of Med., Korea Univ., Seoul, Korea.

Our rat model of neuropathic pain, produced by unilateral transection of some of the peripherally projecting nerve fibers from the sacral DRG (Na et al., 1994; Kim et al., 1995), is characterized by the noradrenergic fiber sprouting in the DRG that contain the cell bodies with the injured nerve fibers and by the sensitivity to the α-receptor blocker phentolamine (unpublished observation). In the present study we tested if bath-applied NE (30 or 100 µM) altered the excitability of neurons in the sacral DRG maintained *in vitro* by examining the injected current-voltage response (I-V) relationship. Cells in both ipsi- and contralateral DRG to the transection were subjected to the test. In 7 of 8 ipsilateral neurons, NE reduced the typical outward rectification and/or made the cells produce more spikes in response to a given level of depolarizing current step. In 3 of 6 contralateral neurons, similar or slightly weaker effects of NE were observed. The NE effects were reversible, not associated with significant changes in resting membrane potential, input resistance or time-dependent inward rectification and detected in cells exhibiting hump in the repolarizing phase of the action potential (i.e., "hump" cells) as well as in "non-hump" cells.

The present results, coupled with our unpublished observations stated above, point to the possibility that the sympathetically maintained neuropathic pain in our model is at least partly due to the NE-mediated increased excitability of cells in the sacral DRG, which involves depression of outward rectification. In addition, the data indicate that the NE effects are not limited to a certain cell type. (Supported by KOSEF and Biotech 2000)

## 356.14

**SPROUTING SYMPATHETIC FIBERS FORM SYNAPTIC ENDINGS IN THE DORSAL ROOT GANGLION OF THE NEUROPATHIC RAT.** K. Chung\* and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77555.

The purpose of this study was to determine whether sprouting sympathetic postganglionic fibers form synaptic endings/contacts in the dorsal root ganglion (DRG) of the neuropathic rat. Sympathetic axons and endings in the DRG were visualized under electron microscopy by immunohistochemical staining with antibody against tyrosine hydroxylase (TH).

Under halothane anesthesia, neuropathic injury was produced on the left L5/6 spinal nerves by tightly ligating them with 6.0 silk thread. Behavioral tests for evoked and ongoing neuropathic pain were conducted for one week postoperatively. Rats were perfused on the 7th day after surgery and the L5/6 DRG were removed, vibratome sectioned and immunostained for TH using the ABC method. The morphology and distribution of TH-immunolabeled profiles were examined on the JEOL 100-CX electron microscope.

TH-immunolabeled profiles in the DRG of injured nerve included fine unmyelinated axons and synaptic endings. These synaptic endings contained small spherical and large dense core vesicles. Some TH-immunolabeled profiles, most likely axons, were occasionally found between the soma of the DRG neuron and the satellite cells.

The data demonstrate that sprouting sympathetic fibers form synaptic endings in the DRG after spinal nerve injury. They also suggest that there is a strong possibility that the sympathetic system can modify the activities of the DRG neurons. (Supported by NIH grants NS31680 and NS11255)

## 356.16

**CORRELATION BETWEEN PAIN BEHAVIORS AND ECTOPIC DISCHARGES IN A RAT NEUROPATHIC PAIN MODEL.** H.C. Han\*, D.H. Lee, and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77555.

The aim of this study was to correlate the characteristics of ectopic discharges arising from injured afferents with behavioral signs of neuropathic pain in a rat model.

The left L5 and L6 spinal nerves of young adult male *Sprague-Dawley* rats were tightly ligated under halothane anesthesia. After surgery in two groups of rats, behavioral tests for neuropathic pain were conducted at regular intervals up to 1 or 10 weeks. Ectopic discharges were sampled in each group by electrophysiological recordings made from the L5 dorsal root, a segment previously injured.

In one week, when the neuropathic pain behaviors peaked, the total number of units showing ectopic discharges in the L5 dorsal root was estimated to be 204 ± 104 (mean ± SD). This reduced to 124 ± 56 at 10 weeks after surgery, a period when signs of neuropathic pain behavior receded considerably. However, the pattern of discharges was similar in both groups.

The data suggest that the amount, not the pattern, of ectopic discharges arising from injured afferents contribute to the severity of neuropathic pain behavior in a rat model. (Supported by NIH grants NS31680 and NS11255)

## 356.17

GABAPENTIN RELIEVES ABNORMAL PAINS IN A RAT MODEL OF PAINFUL PERIPHERAL NEUROPATHY: W.-H. Xiao and G. J. Bennett\*, Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

Gabapentin (GP; 1-(aminomethyl) cyclohexanecarboxylic acid; Neurontin®) is a novel antiepileptic with a unique binding pattern in brain, and an unknown mechanism of action. An open-label clinical trial (Mellick & Mellick, *J. Pain Symptom Mgmt*, 10:1-2, '95) in patients with reflex sympathetic dystrophy suggests that it may have efficacy in the treatment of neuropathic pain. Using rats with the chronic constriction injury (CCI) of Bennett & Xie (*Pain*, 33:87-107, '88) and an observer blinded as to drug condition, we have examined GP's effects following (2, 4 and 24 hr) i.p. and lumbar intrathecal (i.t.) bolus injections on postoperative days 6-16 (at or near the period of peak symptom severity). Prior to drug, rats had significant heat-hyperalgesia (Hargreaves' method), mechano-hyperalgesia (pin-prick test), and mechano-allodynia (v. Frey hair test). None of the drug doses produced any motor side-effects and none had any effect on the responses evoked from the control side. In a dose-response trial of i.p. GP (saline, 10, 25 and 75 mg/kg), heat-hyperalgesia and mechano-allodynia were significantly reduced in a dose-related manner for up to 4 hr. In an i.t. dose-response trial (saline, 7.5, 15, 37.5, and 75 µg; all 10 µl volume), heat-hyperalgesia was significantly reduced in a dose-related manner for up to 4 hr. An i.t. trial using 150 µg failed to reveal any efficacy against mechano-hyperalgesia; in the same animals this dose produced a significant suppression of heat-hyperalgesia and mechano-allodynia. Our results suggest that GP may be useful in the clinic and that its effects may be mediated by a spinal site of action.

## 356.19

EXPERIMENTAL PAINFUL MONONEUROPATHY: CYTOKINES IN C57BL/6J MICE AND IN MICE WITH DELAYED WALLERIAN DEGENERATION C. Sommer\* and M. Schäfers, Neurologische Klinik der RWTH Aachen und Neurologische Universitätsklinik Würzburg, Germany

This study addresses the questions whether delayed Wallerian degeneration alters the development of allodynia in mice with a unilateral sciatic nerve chronic constriction injury (CCI), and if cytokine expression differs accordingly. CCI was induced in C57BL/6J- and C57BL/wld-mice with delayed Wallerian degeneration. Allodynia, monitored by von-Frey-hair-testing, was present from day 10 after surgery, with a peak around day 16 to 20 and gradual recovery until week 11. The extent of allodynia was greater in 6J mice than in wld mice. The onset, however, was not delayed in wld mice. Sciatic nerves were harvested on day 4, 8, 12, 28, and 95 after surgery and in controls. Tissue was immunostained for TNF- $\alpha$ , IL-1 $\alpha$ , and macrophages. Myelin staining revealed mostly intact myelin sheaths in wld mice up to day 12, whereas in 6J mice, myelin sheath disruption was obvious from day 4. Macrophages were present from day 4 in 6J mice. The number and area occupied by macrophages was significantly greater in 6J mice than in wld mice on days 8 and 12. In control tissue, few IL-1 $\alpha$  immunoreactive cells were found in a Schwann cell distribution. In 6J mice, the number of IL-1 immunoreactive cells was increased from day 4, in wld mice from day 12. TNF-immunoreactivity (ir) was present to a variable degree in control tissue. On the experimental side, TNF-ir was significantly increased by day 8 in C57BL/6J, but not in C57BL/wld mice. We conclude that cytokines released in the course of Wallerian degeneration influence the degree of allodynia, and possibly other elements of neuropathic pain.

## 356.18

STRAIN DIFFERENCES IN NEUROPATHIC PAIN BEHAVIOUR IN MICE FOLLOWING CHRONIC CONSTRICTION INJURY (CCI): CORRELATION WITH NGF PRODUCTION IN INJURED NERVE? M.S. Ramer, G.D. French, M. Fahnstock and M.A. Bisby\*, Dept. of Physiology, Queen's University, Kingston, Ontario, K7L 3N6 and (MF) Dept. of Biomedical Science, McMaster University, Hamilton, Ontario, L8N 3Z5, Canada.

We compared the effects of CCI on neuropathic pain behaviours in 3 strains of mice: C57BL/Ola [Wld], which have delayed Wallerian degeneration; C57BL/6J, "normals"; and C57BL transgenics expressing the NGF gene driven by a GFAP promoter. We assessed thermal hyperalgesia, using radiant heat, and mechanical allodynia, using Von Frey hairs, before and for 21 days after a 4-ligature CCI made on the sciatic nerve. For both behavioural tests the order of sensitivity was GFAP-NGF transgenics > normals > Olas. ELISA assays of NGF in injured sciatic nerve confirm that Olas produce less NGF than normals: measurements on the transgenics are in progress. Our hypothesis is that, following CCI, NGF is produced by endoneurial cells surrounding adjacent axons which undergo Wallerian degeneration. This NGF may stimulate metabolic changes and altered central synaptic effectiveness in a dose-dependent fashion in the sensory neurons whose axons survive CCI. Supported by the Medical Research Council of Canada (MT-5198).

## PAIN MODULATION: PHARMACOLOGY—INFLAMMATION AND PROSTAGLANDINS

## 357.1

EVIDENCE FOR INVOLVEMENT OF SPINAL CORD GLIA IN DIVERSE MODELS OF HYPERALGESIA. L.R. Watkins\*, T. Deak, L. Silbert, J. Martinez, L. Goehler, J. Rellon<sup>1</sup>, D. Martin<sup>1</sup> & S.E. Maier, Dept. Psych., U CO Boulder, Boulder, CO 80309 & Amgen<sup>1</sup>, Boulder, CO.

Immune activation by inflammation or infection leads to a variety of centrally mediated illness responses, including hyperalgesia (Watkins, Maier & Goehler, *Life Sci.*, 1995 Minireview, in press). Illness responses have been proposed to result from enhanced glial synthesis & release of central cytokines such as interleukin-1 (IL-1). These studies tested if intrathecal (IT) delivery of either a glial metabolic inhibitor (fluorocitrate) or a recombinant human receptor antagonist of IL-1 (rhIL1ra) could block hyperalgesia (tail-flick test; TF) induced by either inflammation (500 µl s.c. 5% formalin) or abdominal infection (cecal ligation & puncture; CLP).

For formalin hyperalgesia, rats were tested for baseline TF latencies & then injected IT with equivalent volume vehicle (1 µl), 1 nmol fluorocitrate, or 50 µg rhIL1ra. Rats received either s.c. formalin or sham injections 10 min later. TF latencies were recorded each 5 min for 55 min. Reliable hyperalgesia was observed in IT vehicle rats receiving s.c. formalin. This hyperalgesia was abolished by either fluorocitrate or rhIL1ra. Neither fluorocitrate nor rhIL1ra affected TF latencies in sham s.c. rats.

To test CLP hyperalgesia, rats were prepared on Day 1 by sham surgery or ligating (1.5 cm segment; 4-0 silk) & puncturing (3x18 g needle; extrusion of a small amount of contents) the cecum. IT catheters & i.p. thermal telemetry probes (Minimitter) were inserted into all rats. CLP resulted in hyperthermia on Day 2. TF testing began late afternoon when core body temperatures normalized. Compared to shams, CLP rats showed reliable hyperalgesia which was blocked by IT fluorocitrate (1 nmol at 0900, 1100, 1300 & 1500 hrs Day 2). The effects of rhIL1ra are currently being tested. Histochemical analysis of potential biotinylated rhIL1ra binding sites in spinal cord is also being examined.

These data suggest that peripheral inflammation & infection induce spinal cord glia to release products such as IL-1, resulting in hyperalgesia.

INFLAMMATION MODULATES THE CONTRIBUTION OF RECEPTOR-SUBTYPES TO BRADYKININ-INDUCED HYPERALGESIA IN THE RAT. S.G. Khasar, F.J.P. Miao, H.L. Fields\* and J.D. Levine, Departments of Anatomy, Medicine, Oral and Maxillofacial Surgery & Neurology, University of California, San Francisco, CA 94143.

We have evaluated the contribution of the sympathetic nervous system to the hyperalgesia induced by bradykinin (BK), a B<sub>2</sub> agonist, and des-Arg<sup>9</sup>-bradykinin (des-Arg-BK), a metabolite of BK and a selective B<sub>1</sub> agonist. Mechanical hyperalgesia was quantified by the Randall-Selitto paw-withdrawal method. Inflammation was induced by injecting Complete Freund's Adjuvant (CFA) into the left hindpaw of the rat and testing mechanical nociception in the right hindpaw after injecting B<sub>1</sub> or B<sub>2</sub> agonists and/or antagonists. Sympathectomy was achieved by surgically removing sympathetic ganglia L<sub>1</sub>-L<sub>4</sub> bilaterally. Rats were used 48 h post-CFA injection. In the normal rat, intradermal injection of BK but not des-Arg-BK, into the dorsal surface of the hindpaw, produced a dose-dependent decrease in mechanical nociceptive threshold. NPC 17731 (NPC), a B<sub>2</sub> antagonist, but not des-Arg<sup>9</sup>-[Leu<sup>5</sup>]-bradykinin (Leu-BK), a B<sub>1</sub> antagonist, inhibited the decrease in mechanical threshold. In rats whose left paws were treated, 48 h earlier, with CFA, intradermal injection of BK or des-Arg-BK, into the right paw produced dose-dependent hyperalgesia. BK hyperalgesia was partially inhibited by NPC, and the residual part by Leu-BK. Des-Arg-BK hyperalgesia was inhibited by Leu-BK but not by NPC. 48 h after injection of CFA in sympathectomized rats, BK or des-Arg-BK failed to produce hyperalgesia.

These results suggest that B<sub>2</sub> receptors mediate BK-induced cutaneous hyperalgesia in the normal rat hindpaw. In the setting of inflammation, BK hyperalgesia is mediated by both B<sub>1</sub> and B<sub>2</sub> receptors. Intact sympathetic postganglionic neurons are required for B<sub>1</sub> and B<sub>2</sub> hyperalgesia in this model.

## 357.3

**Intramuscular Administration of Carrageenan Reduces Grip Force Strength in Rats.** L.J. Kehl\*, T.M. Trempe and K.M. Hargreaves. Depts. of Restorative Sciences and Pharmacology, University of Minnesota, Minneapolis, MN.

Subcutaneous and intra-articular injection of carrageenan produces a localized hyperalgesia in animals which can be reduced by systemic or peripheral administration of analgesic or anti-inflammatory drugs. We hypothesized that intramuscular administration of carrageenan would likewise produce muscular hyperalgesia. Development of a useful model to study muscle inflammation may have utility in studying nociceptive mechanisms of myalgia.

Male Sprague Dawley rats (100-200g) were briefly anesthetized with halothane and injected with either PBS (n=20) or carrageenan (4mg/50µl; n=20) into the triceps muscles bilaterally. Then each animal was tested at intervals over the next several hours for its capacity to exert grip force with the affected muscles using strain gauges connected via an A-D converter to an online computer. Data were analyzed by two-way ANOVA.

Bilateral injection of carrageenan into the triceps resulted in a time-dependent reduction in forearm grip force over the 8 hr observation period. Peak effects were observed at the 6-8 hour post-injection time points, with carrageenan-injected animals exerting significantly less forelimb force when compared to concurrent control animals. These initial studies are consistent with the development of carrageenan-induced mechanical hyperalgesia following injection into skeletal muscle. This model may be a useful experimental paradigm for studying mechanisms of nociceptive transmission involving muscles. (Supported by DA00240 and DE09737 to LJK and DE9860 to KMH).

## 357.5

**GLUTAMATE RELEASED INTO PERIPHERAL TISSUE DURING INFLAMMATION CONTRIBUTES TO THE DEVELOPMENT OF THERMAL HYPERALGESIA IN RATS.** D.L. Jackson\*, N.K. Groves, C.B. Graff & K.M. Hargreaves. Dept. Rest. Sci., Univ. of MN, Mpls., MN 55455

There is increasing evidence supporting the hypothesis that the excitatory amino acid glutamate contributes to the development of hyperalgesia via receptor-mediated mechanisms within peripheral tissue. We have previously demonstrated that local administration of glutamate receptor antagonists attenuates carrageenan-induced thermal hyperalgesia via a peripheral mechanism (Abs. Soc. Neurosci. 20:1390, 1994). To evaluate glutamate release into inflamed tissue, microdialysis probes (BAS; West Lafayette, IN) were inserted into the hindpaws of anesthetized male Sprague-Dawley rats and dialysate was evaluated by reversed-phase HPLC with fluorometric detection. Carrageenan-induced inflammation (2 mg ipl) was evaluated by measuring withdrawal latencies of the hindpaw from a noxious heat source (Hargreaves et al. Pain 1988; 32:77-88). At selected times following the administration of carrageenan and vehicle, groups of rats were anesthetized with halothane (1-2%) for the 30 minute dialysate collection. Data were analyzed by ANOVA and Duncan's post-hoc analysis. Carrageenan evoked a time-dependent release of glutamate relative to the vehicle treated paw, reaching a maximal difference at 180 minutes (baseline: carra: 18.9±6.4 pmol vs. veh: 20.1±1.1 pmol; 180 min: carra: 45.9±10.5 pmol vs. veh: 20.45±2.0 pmol; p<0.05). These results correspond to the development of thermal hyperalgesia which also reached a maximum at 180 minutes. By 360 minutes glutamate release from the carrageenan treated hindpaw returned to baseline (27.1±4.5 pmol) and there was a concomitant decrease in thermal hyperalgesia. Collectively, these results support the hypothesis that the local release of glutamate into inflamed tissue corresponds to the development of nociceptive behavior, suggesting that the peripheral release of glutamate participates in the development of thermal hyperalgesia. This research was funded by K16-DE0027, DE9860, and P30DE9737.

## 357.7

**WHAT UNDERLIES WIND-UP IN NORMAL AND CARRAGEENAN ANIMALS?** L.C. Stanfa and A.H. Dickenson (SPON: Brain Research Association). Dept. Pharmacology, University College London, London WC1E 6BT, U.K.

Here we investigate the transmitter systems involved in the generation of wind-up in spinal dorsal horn neurones in normal rats and following the induction of peripheral inflammation. Extracellular recordings were made from convergent dorsal horn neurones in halothane anaesthetized rats. Wind-up was induced in the neurones by a train of 16 transcutaneous stimuli (0.5Hz) applied to the hindpaw receptive field and given at 3x the C-fibre threshold. Peripheral inflammation was induced with 100µl of 2% carrageenan. The effects of the NMDA antagonist MK801, the AMPA antagonist NBQX and the nitric oxide synthase inhibitor 7-nitroindazole (7-NI) which lacks vascular effects, all given intrathecally, were tested against wind-up in normal animals and 3 hrs after the induction of carrageenan inflammation.

In normal animals, both MK801 (0.5-50µg) and 7-NI (1-100µg) preferentially inhibited the neuronal responses due to wind-up of dorsal horn neurones whilst having little effect on the constant underlying C-fibre evoked baseline neuronal response. In contrast, NBQX (5-50µg) markedly inhibited the baseline C-fibre response; wind-up was only reduced by 50µg. In the carrageenan animals MK801 was less effective against the wind-up of the neurones although more effective against baseline responses. During inflammation, wind-up remained sensitive to 7-NI which even tended to be more effective at the lowest dose. Interestingly the AMPA receptor antagonist NBQX was more effective against the evoked neuronal responses post-carrageenan, including an enhanced ability to inhibit the wind-up of the neurones.

We conclude that C-fibre evoked release of glutamate activates AMPA receptors to establish baseline responses which are then amplified by NMDA receptor activation and the production of NO in the normal rat. After inflammation wind-up is more sensitive to AMPA blockade, suggesting that this post-synaptic event is now more dependent on pre-synaptic mechanisms, conceivably via retrograde messages which may include NO.

## 357.4

**PRE-TREATMENT BUT NOT POST-TREATMENT WITH AN NK-1 RECEPTOR ANTAGONIST ATTENUATES HINDPAW INFLAMMATION-INDUCED HYPERALGESIA IN THE RAT.** R.J. Traub\* and D. Brozoski. Dept. Pharmacology, University of Iowa, Iowa City, IA 52242

The mechanism(s) of generation and maintenance of hyperalgesia and spinal dorsal horn hyperexcitability subsequent to peripheral injury is not fully understood. Current hypotheses propose a central role for excitatory amino acids, but the role of neuropeptides is still in question. We examined the role of substance P (SP) in the generation of hyperalgesia. The NK-1 receptor antagonist CP-96,345 (100, 50, 25 nmol), the inactive CP-96,344 (100 nmol) or saline was administered into the intrathecal space of rats 10 min before unilateral hindpaw injection of carrageenan (2 or 6 mg) or formalin (1 or 5%). Rats were tested for thermal and mechanical hyperalgesia over 24 hrs (carra) or observed for 1 hr (form). CP-96,345 dose-dependently attenuated thermal and mechanical hyperalgesia (2 mg carra) for up to 5 hrs; 6 mg carra hyperalgesia was unaffected (100 nmol). 300 nmol CP-96,345 caused temporary paralysis. Neither 100 nmol CP-96,344 or saline had any effects, nor did 100 nmol CP-96,345 4 hrs after 2 mg carrageenan. 125 nmol CP-96,345 partially attenuated the phase 2 formalin (1% and 5%) response but did not affect the phase 1 response. CP-96,344 had a small effect on the phase 2 response. These results suggest that SP contributes to the generation but not maintenance of hyperalgesia in 2 models of inflammation. However, in some cases the magnitude of the inflammation can override the effects of the antagonist. Further, the inactive enantiomer produced a small effect in the formalin model, suggesting that slightly different mechanisms may produce central sensitization in these models. ## 357.6

**INFLAMMATION-INDUCED CHANGES IN ALPHA-2-ADRENERGIC REGULATION OF PAIN.** H.Mansikka and A.Pertovaara\*. Depts. of Physiology, Univs. Helsinki and Turku, Finland.

We studied changes in alpha-2-adrenergic regulation of secondary hyperalgesia brought about by neurogenic inflammation, following mustard oil treatment of the skin in rats. An alpha-2-adrenoceptor agonist (medetomidine=MED) or antagonist (atipamezole=ATI) were administered systemically (s.c.), intracerebrally or intrathecally (i.t.). Mustard oil induced a marked secondary hyperalgesia to mechanical test stimuli in intact but not in spinalized rats. MED s.c. reversed the hyperalgesia at normally sub-antinociceptive doses. ATI s.c. paradoxically reversed the hyperalgesia in a non-monotonic fashion. MED i.t. produced antinociception at very low doses, whereas in the medullary lateral reticular nucleus (LRN) MED enhanced hyperalgesia. ATI in the LRN, but not in the nucleus raphe magnus nor i.t., produced a paradoxical antinociceptive effect. The results indicate that supraspinal structures are involved in the spinal hyperalgesia induced by neurogenic inflammation. Following inflammation, the enhanced antinociceptive potency of MED is due to a direct spinal action whereas the paradoxical antinociceptive effect of ATI is due to action on the LRN.

## 357.8

**DIFFERENTIAL ANALGESIC AND STIMULUS PROPERTIES OF SELECTIVE BRADYKININ B<sub>1</sub> AND B<sub>2</sub> ANTAGONISTS IN MODELS OF INFLAMMATORY NOCICEPTION IN RATS.** J.T. Roach\* and K.J. Sufka. Departments of Psychology and Pharmacology, University of Mississippi, Oxford, MS 38677.

Research has documented the differential role of bradykinin (BK) receptors (B<sub>1</sub> & B<sub>2</sub>) in the mediation of temporal aspects of inflammatory nociception. This work suggests that selective BK antagonists may have therapeutic potential against chronic inflammatory pain. In addition to the demonstration of differential antinociceptive effects of B<sub>1</sub> and B<sub>2</sub> antagonists on the formalin test (2.5%), the present study sought to further define the stimulus properties (via the conditioned place preference paradigm) of the selective B<sub>1</sub> antagonist des-Arg<sup>9</sup>, [Leu<sup>8</sup>]-BK (0.0, 0.03, 0.1 & 0.3 mg/kg, sc) and the selective B<sub>2</sub> antagonist HOE-140 (0.0, 0.1, 0.5 & 1.0 µmol/kg, sc) in the Freund's adjuvant (0.10 ml, ipl) model of chronic inflammatory nociception. Neither antagonist affected the early phase of the formalin response. In the late phase of the formalin response, Des-Arg<sup>9</sup>, [Leu<sup>8</sup>]-BK exhibited dose-dependent antinociceptive effects while HOE-140 exhibited only modest antinociceptive effects. In the conditioned place preference paradigm, des-Arg<sup>9</sup>, [Leu<sup>8</sup>]-BK, but not HOE-140, exhibited negatively reinforcing effects (i.e., analgesia) in adjuvant-inflamed rats and aversive effects in non-inflamed rats. Neither compound exhibited positively reinforcing effects (i.e., abuse potential). These results further define the stimulus properties of these BK antagonists and provide additional evidence of the therapeutic potential of B<sub>1</sub> antagonists against conditions of chronic inflammatory pain.

## 357.9

THE CONTRIBUTION OF PERIPHERAL BRADYKININ B<sub>2</sub> AND HISTAMINE H<sub>1</sub> RECEPTORS TO CARRAGEENAN EVOKED INFLAMMATION AND SPINAL C-FOS EXPRESSION IN THE RAT. J. Buritova, V. Chapman, P. Honoré, M.-C. Lombard\* and J.-M. Besson, INSERM U.161, 75014 Paris, France.

The effects of intraplantar HOE140 and thiazinanium, selective antagonists of the bradykinin B<sub>2</sub> and the histamine H<sub>1</sub> receptor respectively, on carrageenan evoked Fos-like immunoreactive (FLI) spinal neurons and peripheral inflammation were studied. Three hours after the intraplantar carrageenan (6mg in 150µl of saline), FLI neurons was observed in the L4-L5 segments of the lumbar spinal cord, with both superficial (I-II) and deep laminae (V-VI) neurons being densely FLI labelled.

Intraplantar HOE140 (0.1, 1 and 10µg in 50µl of saline), co-administered with carrageenan, dose-relatedly ( $r^2=0.434$ ;  $p<0.01$ ) reduced the total number of spinal FLI neurons ( $23\pm5\%$  reduction of controls,  $p<0.01$ ,  $35\pm6\%$  and  $50\pm5\%$ ,  $p<0.001$  for both, respectively). 1 and 10µg of HOE140 produced similar effects on both the number of superficial ( $33\pm6\%$  and  $51\pm6\%$ ;  $p<0.001$  for both) and deep ( $35\pm8\%$  and  $48\pm7\%$ ;  $p<0.001$  for both) laminae FLI neurons.

Intraplantar thiazinanium (25, 50 and 100µg in 50µl of saline), co-administered with carrageenan, dose-relatedly ( $r^2=0.558$ ;  $p<0.001$ ) reduced the total number of spinal FLI neurons ( $32\pm5\%$ ,  $41\pm3\%$  and  $55\pm2\%$ ;  $p<0.001$  for all, respectively). 25µg of thiazinanium produced similar effects on the number of superficial ( $22\pm7\%$ ;  $p<0.01$ ) and deep ( $39\pm6\%$ ;  $p<0.001$ ) FLI neurons. However, 50 and 100µg of thiazinanium had significantly stronger effects on the number of deep FLI neurons ( $50\pm4\%$  and  $63\pm3\%$ ;  $p<0.001$  for both) as compared to the number of superficial FLI neurons ( $28\pm5\%$  and  $43\pm4\%$ ;  $p<0.001$  for both).

The HOE140 and thiazinanium mediated reductions of the number of FLI neurons were associated with sequential reductions of the inflamed paw and ankle diameters. These results confirm that peripheral bradykinin and histamine contribute to carrageenan inflammation and that selective antagonism of these inflammatory mediators results in a parallel reduction of the spinal expression of c-Fos.

## 357.11

LYSINE ACETYLSALICYLATE INHIBITS COMPOUND ACTION POTENTIALS IN THE RABBIT RETINA. Kenneth I. Maynard\*, Volker Limmroth, Pablo M. Arango, Christopher S. Ogilvy, Neurosurgical Service, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

Although lysine acetylsalicylate (ASA) is a widely used analgesic agent, it remains unclear whether its action is partially mediated by the central nervous system (CNS), and whether the antinociceptive effect of ASA is entirely due to its anti-inflammatory action. We examined whether ASA affects the CNS using the *in vitro* rabbit retina preparation. Four retinas were stimulated by dim light flashes (1 s), which evoked "ON" AND "OFF" compound action potentials (CAPs) recorded from the optic nerve, and the electroretinogram (ERG), measured transretinally. ASA (6, 60, 180, 670, 1800 µM) inhibited "OFF" CAPs ( $77\pm8$ ,  $81\pm30$ ,  $62\pm6$ \*,  $0\pm0$ \* &  $0\pm0$ \* % of control responses respectively, \* =  $P<0.05$ ). Although at low concentrations (6, 60 & 180 µM) ASA tended to increase "ON" CAPs ( $101\pm4$ ,  $110\pm8$ , &  $121\pm26$  % of control responses respectively), at higher concentrations (670 & 1800 µM), it reduced these responses ( $47\pm25$  &  $10\pm1$ \* % of control responses respectively, \* =  $P<0.05$ ). ASA did not affect the light-evoked PIII of the ERG at any of the concentrations examined. In summary, ASA affects neurotransmission (i.e. light-evoked CAPs), but not phototransduction (i.e. light-evoked PIII of the ERG) in a concentration-dependent manner in this *in vitro* CNS preparation. Whether this effect is due to the anti-cyclooxygenase activity of ASA or some other mechanism remains to be elucidated.

## 357.13

PARACETAMOL DIFFERENTLY AFFECTS NOCICEPTION AND HYPERALGESIA IN THE RAT. M. Bianchi and A.E. Panerai\*, Dept. Pharmacology, Sch. of Med., Univ. of Milano, 20129 Milano, Italy

The classical models usually employed for the study of analgesic drugs in the experimental animal allow to evaluate their ability to enhance nociceptive thresholds. However, it is well known that, differently from nociceptive pain, clinical pain does not only represent a protective response to noxious stimuli, but is characterized by the appearance of an abnormal hypersensitivity. For this reason, experimental models of hyperalgesia seem to be more predictive than classical models of the clinical efficacy of analgesic drugs. We studied the effects of low doses (25, 50, and 100 mg/kg p.o.) of the non-steroidal anti-inflammatory drug paracetamol on "central" inflammatory hyperalgesia (by tail-flick test), on "peripheral" inflammatory hyperalgesia (by Randall-Selitto test), on inflammatory edema (by plethysmometry), and on nociceptive thresholds (by tail-flick test), in rats. Both inflammatory edema and hyperalgesia were induced by the injection of a suspension of 10% brewer's yeast in the plantar part of the left hindpaw. At the lowest dose, paracetamol reduced only "central" hyperalgesia. At the doses of 50 and 100 mg/kg, the drug reduced also "peripheral" hyperalgesia. Moreover, it enhanced nociceptive thresholds to a mechanical stimulus in the non-inflamed paws. Neither paw inflammatory edema, nor tail nociceptive thresholds to a thermal stimulus in the non-inflamed animals have been modified by paracetamol administration. Our results suggest that paracetamol can reduce hyperalgesia without affecting physiological nociception and inflammation.

## 357.10

PERIPHERAL INFLAMMATION CHANGES THE NMDA RECEPTOR FUNCTION IN SPINAL NOCICEPTIVE SYSTEMS SHOWN WITH DIRECT NERVE STIMULATION. L.J. Rygh, A. Tjølsen\* and K. Hole, Dept. of Physiology, University of Bergen, 5009 Bergen, Norway.

Single unit activity in the dorsal horn of the spinal cord was recorded extracellularly in urethane anesthetized, intact rats by means of tungsten microelectrodes. All cells responded to noxious stimulation of the left hind paw. The posterior tibial nerve was stimulated electrically (16 pulses, 2 ms, 0.5 Hz) at 1.5x threshold for C fibre response (2.7-10.0 mA). The responses were counted separately for A<sub>β</sub>, A<sub>δ</sub> and C fibre response and postdischarge according to the response latencies. NMDA was dissolved in saline and applied onto the spinal cord in a volume of 50 µl.

Experiments were done after 16-24 hours of inflammation in the receptive field, induced by s.c. injection of 100 µl of 2% λ-carrageenan in saline, and in controls.

NMDA increased (0.05-5 nmol) and reduced (50 nmol) the A<sub>δ</sub> and C fibre response and postdischarge of the dorsal horn cells in a biphasic manner. In addition NMDA seemed to increase wind up (WU) of cells with a low control WU and reduce WU of the cells with a high control WU. Inflammation clearly increased the effect of NMDA on post discharge (0.5 nmol). Generally the cells of the carrageenan injected rats had a greater control WU and the effect of NMDA on WU was reduced. Inflammation clearly increased the receptive field for touch, and raised the threshold for C fibre response.

These results indicate that activation of NMDA receptors affects nociceptive responses in the spinal cord in a biphasic manner. Thus, previous results on NMDA effects are confirmed using stimulation directly on the peripheral nerve, showing the effects to be located in the CNS. Inflammation gave changes in dorsal horn cells in parameters like postdischarge, WU, threshold and receptive field that suggest that NMDA receptor mechanisms are involved in chronic pain states.

## 357.12

MODULATION OF A TTX-RESISTANT NA<sup>+</sup> CURRENT AS A MECHANISM OF PRIMARY AFFERENT NOCICEPTOR SENSITIZATION. M. S. Gold\*, D. B. Reichling, M. J. Shuster and J. D. Levine, Depts. of Medicine, and Oral Surgery and Division of Neuroscience, UCSF, Box 0452A, San Francisco CA 94143-0452

Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), an inflammatory mediator released at sites of tissue injury, has been shown to produce hyperalgesia and sensitization of primary afferent nociceptors. While PGE<sub>2</sub> may increase nociceptor excitability in nodose ganglion neurons through the modulation of a specific Ca<sup>2+</sup>-dependent K<sup>+</sup> current, the apparent absence of that current in dorsal root ganglion (DRG) neurons raises the possibility that sensitization may involve other currents. We tested the hypothesis that a voltage-gated Na<sup>+</sup> current specific to small-diameter primary afferent neurons (a tetrodotoxin-resistant Na<sup>+</sup> current: TTX-R I<sub>Na</sub>) is a target for PGE<sub>2</sub>. We studied the effects of PGE<sub>2</sub> on voltage-gated Na<sup>+</sup> currents in acutely isolated DRG neurons from the adult rat using conventional whole-cell and cell-attached patch clamp techniques. In whole-cell configuration, PGE<sub>2</sub> dose-dependently decreased the activation threshold and increased the magnitude of TTX-R I<sub>Na</sub> in 52% (16 of 31) of DRG neurons that expressed the TTX-R I<sub>Na</sub>. These changes were specific for TTX-R I<sub>Na</sub> as they were not observed for TTX-sensitive I<sub>Na</sub>. The lowest concentration of PGE<sub>2</sub> that induced changes was approximately 1 nM. The decrease in activation threshold induced by 1 µM PGE<sub>2</sub> was associated with a hyperpolarizing shift in the voltage-conductance relation of TTX-R I<sub>Na</sub> (V<sub>1/2</sub> of activation curve decreased  $5.2 \pm 0.8$  mV,  $n = 8$ ; Mean  $\pm$  SEM) and the peak current was increased  $24 \pm 3.2\%$  ( $n = 16$ ); no changes were observed in the steady-state inactivation curve of TTX-R I<sub>Na</sub>. The changes observed with the cell-attached patch configuration were similar to those observed with whole cell recording, except the magnitude of the changes were larger: 1 µM PGE<sub>2</sub> hyperpolarized the V<sub>1/2</sub> of activation by  $14.5 \pm 3.6$  mV ( $n = 4$ ) and increased the peak current to  $225 \pm 38\%$  ( $n = 8$ ). Since the PGE<sub>2</sub>-induced changes in TTX-R I<sub>Na</sub> should increase nociceptor excitability, we suggest that modulation of TTX-R I<sub>Na</sub> is an ionic mechanism underlying nociceptor sensitization.

## 357.14

EFFICACY OF TWO NON-STEROIDAL ANALGESICS ON RELIEF OF NEUROMUSCULAR TMD PAIN. A. ESHENAU, J. BUXBAUM, N. MYSLINSKI\* AND F. PARENTE, Department of Oral Craniofacial Biological Sciences, Physiology Section, Dental School, University of Maryland, Baltimore, MD 21201

Pain of temporomandibular origin (TMD) is frequently managed by the use of NSAIDs. The purpose of this double-blind study was to compare the effectiveness of Etodolac vs. Ibuprofen in reducing TMD pain, and to examine EMG measures as physiologic correlates to pain. Twenty-four TMD subjects were randomly assigned to 1 of 6 treatment sequences. All subjects received Etodolac, Ibuprofen, and placebo. EMG was used to quantify masseter muscle pain, and a visual analog scale (VAS) was used to quantify perceived pain. Nine additional subjects were treated with an increased dose of Etodolac only. Changes in EMG parameters were analyzed with multivariate analyses. Although both Ibuprofen ( $F=4.64$ ,  $p<0.048$ ) and Etodolac ( $F=4.74$ ,  $p<0.046$ ) significantly reduced pain, there was no significant difference in efficacy between the 2 agents ( $F=2.535$ ,  $p<0.13$ ). EMG measures accounted for 14% of the shared variance of the pain scores. At low pain and drug levels (<5" on VAS), there was little correlation between change in EMG measures and change in VAS. At high pain and drug levels (>5" on VAS), band width and power were predictive of change in VAS. The results indicate that this protocol was sensitive enough to segregate the analgesics from placebo, and that Fourier power and band width were reliable predictors of pain. This study was supported by a grant from the Wyeth-Ayerst Corporation.

PROSTAGLANDIN  $E_2$  SUPPRESSES A POTASSIUM CURRENT IN RAT SENSORY NEURONS. A.R. Evans, M.R. Vasko and G.D. Nicol\*, Dept. of Pharmacology and Toxicology, Indiana Univ. School of Medicine, Indianapolis, IN 46202.

Prostaglandins enhance the sensitivity of sensory neurons to excitatory chemical agents by altering the levels of excitability. To investigate the cellular mechanisms mediating this prostaglandin-induced hypersensitivity, we utilized the whole-cell patch-clamp technique to examine the effects of prostaglandin  $E_2$  ( $PGE_2$ ) and prostaglandin  $F_{2\alpha}$  ( $PGF_{2\alpha}$ ) on neuronal excitability. Sensory neurons were dissociated from the dorsal root ganglia (DRG) of 15-17 day-old rat embryos and grown in culture for 5-7 days. At the end of each recording the cell was exposed to capsaicin; data from only capsaicin-sensitive neurons are reported here. Treatment with 1  $\mu M$   $PGE_2$  for 10 and 20 min increased in the number of action potentials elicited by a current ramp by about two-fold. To further explore this enhanced excitability, addition of 1  $\mu M$   $PGE_2$  caused a time-dependent decrease in the outward potassium current ( $I_K$ ) recorded from neurons bathed in N-methylglucamine Ringer's. After 10 and 20 min treatments,  $G_{max}$  was reduced to  $0.59 \pm 0.05$  and  $0.47 \pm 0.05$  ( $n=10$ ) of the control value. Measurements obtained from the current-voltage relation between -60 and -40 mV, demonstrated a 1.5- and 1.9-fold increase in membrane resistance at these times. Neither the amplitude of  $I_K$  nor the membrane resistance was altered by treatment with 1  $\mu M$   $PGF_{2\alpha}$  over the 20 min exposure times. Assessment of  $I_K$  inactivation indicated two populations of neurons; one having ~40% inactivation for a prepulse to +20 mV and another having only ~15% inactivation. The inactivation profile of either type was unaffected by treatment with  $PGE_2$ . These findings suggest that  $PGE_2$  may act, in part, to enhance the excitability of these sensory neurons through modulation of a potassium current(s). Supported by NIH Grant NS30527.

## RETINAL SUBCELLULAR MECHANISMS II

## 358.1

CHANGES IN THE SENSITIVITY AND RECEPTIVE FIELD PROPERTIES OF RETINAL GANGLION CELLS IN RESPONSE TO NITRIC OXIDE DONORS. T.A. Ojala\*, R.E. Miller, Graduate Program in Neuroscience and Dept. of Physiology, University of Minnesota, Minneapolis, MN 55455.

The effect of nitric oxide in the retina of the neotenus tiger salamander (*Ambystoma tigrinum*) was investigated by applying a nitric oxide donor, S-nitrosocysteine (SNC), to perfused whole eyecup preparations while recording either the electroretinogram (ERG) or the extracellular spikes of ganglion cells. Fresh SNC significantly reduced (50-60%) the *b* and *d* waves of the ERG, while day-old solutions had almost no effect. Fresh SNC caused a change in the sensitivity and receptive field size of some ganglion cell subtypes, as determined by spot summation experiments. This latter result suggests that some components of the receptive field may display differential sensitivity to exogenous nitric oxide. Supported by NIH grant GM08471 to TAO and grant EY03014 to RFM.

## 358.3

GLUTAMATE RELEASE FROM GOLDFISH RETINAL SLICES. K. Dorst & G.S. Ayoub\*, Dept of Biology, Westmont College, Santa Barbara, CA 93108

Glutamate is the principle excitatory neurotransmitter in the vertebrate CNS, and is considered the primary transmitter candidate for retinal photoreceptors and bipolar cells. To determine the patterns of release of this amino acid within the goldfish retina, we used an enhanced fluorometric assay for glutamate in conjunction with retinal slices. In this way, glutamate released from retinal neurons could be localized to the immediate location of the specific neurons, thus confirming not only which cells release glutamate, but also where the release sites are localized.

Retinal slices of 125  $\mu m$  thickness were prepared using the procedure described by Wu (1987). The slices were maintained in an oxygenated saline solution and visualized under red light using Nomarski interference optics. Photographs of the slices were made using a SBIG 61 cooled CCD camera, and were saved to the computer disk. An assay solution containing GDH and GPT was introduced to the chamber, in a solution containing D-aspartate to prevent glutamate re-uptake by the cells. In the presence of glutamate, NAD in the solution was catalyzed to NADH, and the fluorescence of NADH was localized within the slice using the CCD camera. We observed several bands of fluorescence in the inner plexiform layer of the retinal slice, as well as a more diffuse band of fluorescence in the outer plexiform layer. Thus, endogenous glutamate is likely released by bipolar cells and by photoreceptors of the goldfish retina.

## 358.2

SYNAPTIC PROTEINS IN THE OUTER PLEXIFORM LAYER OF THE MAMMALIAN RETINA. J.H. Brandstätter\*, C.W. Morgans, H. Betz and H. Wässle, Max-Planck-Institut für Hirnforschung, Frankfurt, Germany.

The two synaptic layers (outer and inner plexiform layer), the clearly defined cell types and the distinct types of synapses (conventional and ribbon synapses) make the retina an attractive model system for correlating structure and function of synapses. We studied by immunocytochemistry the expression of synaptic vesicle-associated proteins (synaptophysin, synaptoporin and synapsin I/II) and a presynaptic plasma membrane protein (syntaxin) in the outer plexiform layer (OPL) of rat, rabbit, cat and monkey.

The synaptic vesicle protein homologs, synaptophysin and synaptoporin, were found to have different distributions in the OPL across species. Synaptophysin was concentrated in the photoreceptor terminals in all species examined. Synaptoporin, on the other hand, was absent from the OPL in rat and cat, but was present in the OPL of rabbit in horizontal cells suggesting the presence of vesicular synapses in these cells.

To confirm this, we examined the distribution of synapsin I/II and syntaxin in the OPL since both proteins are constituents of conventional synapses and are known to be absent from photoreceptor terminals. Consistent with previous reports, we saw very little immunoreactivity for synapsin I/II and no immunoreactivity for syntaxin in the OPL of rat and cat. In contrast, strong labeling for both proteins was observed in the OPL of rabbit and monkey in a pattern possibly reflecting conventional synapses of horizontal cells. These data raise the possibility that vesicular release of neurotransmitter occurs from horizontal cells.

## 358.4

LOCALIZATION AND FUNCTION OF DOPAMINE D1 RECEPTORS IN RAT RETINA. M.L. Veruki\* and H. Wässle, Max-Planck-Institut für Hirnforschung, Frankfurt, Germany.

Much work has been done to determine the role of dopamine in the outer retina, however, relatively little is known about the action and localization of dopamine receptors in the inner retina, particularly in mammals. Therefore, we have chosen two approaches to study the role of dopamine in the inner retina of the rat. Patch clamp experiments were aimed at determining the effects of dopamine on amacrine cells, and immunocytochemistry was used to identify neurons that express D1 receptors.

Ligand- and voltage-gated currents were monitored in the whole-cell mode from amacrine cells in retinal slices. Test substances were applied via pressure through a puffer pipet. GABA- and glycine-gated currents elicited in amacrine cells were both decreased by application of the D1 receptor antagonist SCH-23390. Additionally, voltage-gated potassium currents in amacrine cells, generated by depolarizing voltage steps, were found to be decreased by SCH-23390. The intracellular mechanisms underlying these actions are currently being studied.

Antibodies to the D1 receptor (the generous gift of S. Grünewald, MPI-Biophysik) labelled membranes of cell bodies and processes of neurons in the inner nuclear layer and most neurons in the ganglion cell layer. Colocalization studies with antibodies against parvalbumin, tyrosine hydroxylase and choline acetyl transferase demonstrated that AII, dopaminergic, and cholinergic amacrine cells display D1 receptor immunoreactivity at the soma and the origin of the primary dendrites.

Our results suggest that dopamine may modulate many, if not all, cells in the inner nuclear and ganglion cell layers of the rat retina.

## 358.5

RABBIT STARBURST AMACRINE CELLS CONTAIN THE 67kDa ISOFORM OF GLUTAMATE DECARBOXYLASE. C. Brandon\*, Department of Cell Biology and Anatomy, Chicago Medical School, North Chicago, IL 60064.

Rabbit retinal starburst amacrine neurons almost certainly release acetylcholine as a neurotransmitter. They may also be GABA neurons: they contain immunoreactive GABA, and they accumulate muscimol, but the presence of glutamate decarboxylase (required for the biosynthesis of GABA) has proven difficult to demonstrate unequivocally. Many GABA-containing displaced amacrine cell bodies (Mosingier '85, '87), as well as the dendrites of displaced cholinergic amacrine (Brandon '87), do not appear to contain immunoreactive GAD.

To resolve this discrepancy, rabbit retinas were examined for the presence of two known molecular-weight isoforms of GAD. Rabbit retinas were labeled with DAPI *in vivo*, then fixed and cut into tangential sections that were stained with antisera specific to GAD65 (Brandon '85) or to GAD67 (Kaufman '91).

The GAD67-specific antiserum labeled a large number of apparent amacrine cell bodies in the ganglion cell layer. The presence of DAB reaction product within these cells blocked the normal DAPI fluorescence, indicating a complete co-localization of DAPI and GAD67. On the basis of DAPI labeling, size (ca. 10-11 microns), cell density, nuclear morphology, and (where visible) radial dendritic morphology, most of the GAD67-immunoreactive cells appeared to be displaced starburst (cholinergic) amacrine. Therefore, rabbit retinal starburst amacrine use the 67kDa isoform of GAD, but not the 65kDa isoform; other (GABAergic) displaced amacrine neurons appear to contain both isoforms.

Supported by USPHS RO1-EY05601.

## 358.7

DARK- AND LIGHT-INDUCED CHANGES IN GLUTAMATE RELEASE BY THE PHOTORECEPTOR LAYER OF THE XENOPUS RETINA.

P. Witkovsky\*, Y. Schmitz, J. Ng, Department of Ophthalmology, NYU Medical Center, 550 1st Avenue, New York, NY 10016, USA

Our goal is to investigate the light/dark dependence and the mechanisms of glutamate release by photoreceptors. For this purpose, we use a preparation in which the inner retinal layers are removed by Triton-X and distilled water treatment (Cahill & Besharse 1992, *Vis. Neurosci.* 8:487). The remaining layer of pigment epithelium, photoreceptors and some adherent horizontal cells is cultured up to 24 hours in a superfusion chamber (1.75 ml/h). The glutamate concentration in superfusate samples is measured by a fluorimetric bacterial luciferase assay (Fosse et al. 1986, *J. Neurochem.* 47:340). This method is highly specific for glutamate, as we found that aspartate, glutamine and GABA gave no response. First we investigated the viability of the preparation. Electron microscopy revealed normal morphology of photoreceptor terminals and photoreceptors excluded the vital dye trypan blue. Intracellular recordings demonstrated that rods had typical dark potentials and responded to light with normal kinetics. A few light-evoked responses were obtained from horizontal cells indicating intact synaptic transmission. Baseline dark release of glutamate was  $7.16 \pm 3.31$  nMol/retina/min. Exposure to bright white light (ca.  $30 \mu\text{W}/\text{cm}^2$ ) attenuated glutamate release by 55%. With the superfusion rate of 1.75 ml/h and 10 min samples, the lowest glutamate values were obtained 30 min after light onset. Thereafter release in the light increased by about 10% over the next 90 min. With these baseline values, we are now able to investigate prolonged adaptational changes, calcium-dependence and modulation of glutamate release from photoreceptors. Supported by a fellowship from the DFG to Y.S. and NIH grant EY 03570 to P.W.

## 358.9

(RS)-3,4,5-TRIHYDROXYPHENYLGLYCINE: A POTENTIAL ANTAGONIST AT L-AP4 RECEPTORS IN AMPHIBIAN ON BIPOLAR CELLS. J. Gottesman\*, W.B. Thoreson\*, D.E. Jane\*, J.C. Watkins\*, and R.F. Miller\*. Physiology Dept. & Graduate Program in Neuroscience, Univ. of Minn. Minneapolis, MN 55455; \*Ophthalmology Dept., Univ. of Nebraska Med. Cent. Omaha, NE 68198; \*Pharmacology Dept. Sch. of Med. Sci., Univ. of Bristol, Bristol, UK.

Antagonists to the L-2-amino-4-phosphonobutyric acid (L-AP4) receptor of ON bipolar cells, believed to be mGluR6, have yet to be identified. However, since phenylglycine derivatives can act as antagonists at a variety of other metabotropic glutamate receptors, the actions of an new phenylglycine derivative, (RS)-3,4,5-trihydroxyphenylglycine (THPG), were tested at L-AP4 receptors in ON bipolar cells in the mudpuppy and tiger salamander retinas. Actions of THPG were assessed via whole cell recording in an amphibian retinal slice preparation and field potential recordings of the ERG in the eyecup.

Consistent with L-AP4 receptor antagonism, in whole cell recordings from ON bipolar cells, THPG (1mM) reduced the outward current evoked by L-AP4 (5 $\mu\text{M}$ ). THPG applied alone also evoked inward currents which reversed near 0 mV. Amphibian ON bipolar cells do not possess ionotropic glutamate receptors nor does AMPA (50 $\mu\text{M}$ ) mimic the effect of THPG. THPG inward currents when applied alone may therefore reflect antagonism of endogenous glutamate. Concentration/response data were obtained using the ERG b-wave as an assay for ON bipolar cell activity.  $\text{IC}_{50}$  for THPG was  $\sim 700 \mu\text{M}$ .

This is the first report of a compound whose action is consistent with that of an antagonist for the ON bipolar cell receptor. Further study will be required to verify the mechanism of action and the specificity of THPG for the ON bipolar versus other metabotropic glutamate receptors.

## 358.6

IMMUNOSTAINING FOR GLUTAMATE RECEPTOR SUBUNITS IN MAMMALIAN RETINA. K. Morigiwa\*, N. Vardi, and P. Sterling. Dept. Neuroscience, U. Penn, Phila. PA 19104

We studied the immunolocalization of various subunits of the major families of glutamate receptor in retinas of cat, rat, and monkey. Frozen and vibratome sections were labeled with antibodies recognizing GluR2/3, 2/4, 4, 6/7, NMDAR1, mGluR1 $\alpha$  and mGluR6. In the outer plexiform layer staining patterns were similar: horizontal cells stained with antibodies against GluR2/3, 2/4, 4, and 6/7 but not NMDAR1 or mGluRs. Bipolar dendrites did not stain for GluR6/7 or NR1 but some did stain for GluR2/3, 2/4, and 4. In rat, but not in cat or monkey, other bipolar dendrites (presumed depolarizing) stained for mGluR6. Most amacrine cells stained for GluR2/3, 2/4, and NMDAR1. A smaller amacrine population stained for GluR4, 6/7, and mGluR1 $\alpha$ . Most ganglion cells stained for all of the GluRs, NMDAR1, and mGluR1 $\alpha$ , but not mGluR6. Both in outer and inner plexiform layers, processes were most distinctly stained for GluR4 and GluR6/7. Staining for NMDAR1 was more restricted than has been observed by *in situ* hybridization, suggesting that some cell types expressing its mRNA do not translated it into protein. On the other hand mRNA for GluR6/7 has not been seen in horizontal cells despite their immunostaining. Possibly an edited version of GluR6/7 is expressed that was not probed for by *in situ* hybridization.

## 358.8

AMPA-PREFERRING RECEPTORS MEDIATE EXCITATORY SYNAPTIC INPUTS TO RETINAL GANGLION CELLS. P.D. Lukasiewicz\*, J. Wilson, J.E. Lawrence. Depts. of Ophthalmology and Anatomy & Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Pharmacological studies were performed to determine whether AMPA- and/or kainate (KA)-preferring receptors mediate excitatory synaptic inputs to tiger salamander retinal ganglion cells. Excitatory postsynaptic currents (EPSCs), evoked by light or by stimulating bipolar cells with puffs of K<sup>+</sup>, were measured using whole cell recording techniques in the retinal slice. The AMPA/KA component of the EPSCs was isolated by including strychnine (2 $\mu\text{M}$ ), picrotoxin (150 $\mu\text{M}$ ), TTX (0.5 $\mu\text{M}$ ) and AP7 (50 $\mu\text{M}$ ) in the bath.

The AMPA receptor antagonist, GYKI-52466, (100 $\mu\text{M}$ ) reduced the ON, light-evoked EPSCs and puff-evoked EPSCs to  $2 \pm 1\%$  and  $6 \pm 0.3\%$  of control. The mean  $\text{IC}_{50}$  values were 3.6 $\mu\text{M}$  and 4.2 $\mu\text{M}$  for the light- and puff-evoked responses, respectively. GYKI also reduced KA-evoked currents (1mM) in a concentration-dependent manner ( $\text{IC}_{50} = 12 \mu\text{M}$ ). Concanavalin A (300 $\mu\text{g}/\text{ml}$ ), a compound that preferentially potentiates responses mediated by KA-preferring receptors, did not enhance either EPSCs or KA responses. By contrast, cyclothiazide, which selectively enhances AMPA-preferring receptor mediated responses, was found to enhance both EPSCs and KA-evoked currents (Lukasiewicz et al., 1995, *Invest Ophthalmol & Vis Sci*, 36:S406). Our results indicate that the non-NMDA component of ganglion cell EPSCs is mediated predominately by AMPA-preferring receptors. Supported by NIH Grants EY08922, EY02687 and RPB, Inc.

## 358.10

EFFECTS OF IONOTROPIC GLUTAMATE RECEPTOR AGONISTS ON RAT RETINAL BIPOLAR CELLS. E. Hartveit\* Dept. Neurophysiol., Univ. Oslo, Norway.

Several lines of evidence suggest that in the mammalian retina, the glutamatergic photoreceptor input to rod bipolar cells and ON-cone bipolar cells is mediated by an APB-sensitive metabotropic receptor, whereas the input to OFF-cone bipolar cells is mediated by an ionotropic receptor. Direct physiological evidence for this scheme in the intact mammalian retina is still lacking. From experiments on isolated rod bipolar cells (*in situ* hybridization, electrophysiology), there is also evidence that these cells might express ionotropic glutamate receptors. This raises the question whether ON-bipolar cells receive visual input through ionotropic as well as metabotropic receptors. I have therefore compared the effects of application of AMPA, kainate and NMDA on rod and cone bipolar cells in the rat retina. For reliable identification of bipolar cells in electrophysiological experiments, a database of different bipolar cells was first established by injection of Lucifer Yellow in bipolar cells in lightly fixed retina slices, largely confirming the recent findings of Euler & Wässle (1994). Whole-cell voltage clamp recordings (int: cesium gluconate, TEA; ext: 100 $\mu\text{M}$  picrotoxin, 10 $\mu\text{M}$  strychnine, 2.5-5 mM  $\text{Co}^{2+}$ ) were obtained under visual control (IR-DIC videomicroscopy) from all 3 classes of bipolar cells in vertical slices of the rat retina. Responses to glutamate agonists were obtained by pressure application from a multibarrel pipette. No cells responded to NMDA. Responses mediated directly by non-NMDA-type ionotropic glutamate receptors ( $E_{\text{rev}} \sim 0$  mV) have only been obtained from cone bipolar cells with axonal terminals stratifying in the distal part of the IPL (presumed OFF-cone bipolars). For rod bipolar cells and cone bipolar cells with axon terminals stratifying in the proximal part of the IPL (presumed ON-cone bipolar cells), no evidence for responses mediated directly by conventional ionotropic glutamate receptors was observed. Where responses to non-NMDA agonists could be obtained, they were reversed close to the equilibrium potential for chloride ions, suggesting that they were indirectly mediated by GABA<sub>A</sub> receptors. The results suggest that ionotropic glutamate receptors are involved only in mediating photoreceptor input to OFF-cone bipolar cells, not to rod bipolar cells or to ON-cone bipolar cells.

## 358.11

## 5HT7 RECEPTOR ISOLATED FROM RABBIT RETINA.

K. Pootanakit<sup>1</sup>, S.R. Wheeler<sup>1</sup>, D.D. Hunter<sup>2</sup> and W.J. Brunken<sup>\*1</sup>.<sup>1</sup>Department of Biology, Boston College, Chestnut Hill, MA 02167.<sup>2</sup>Neuroscience Program, Tufts Univ. Sch. of Med., Boston, MA 02111.

Previous studies have shown that the serotonergic system is associated with the rod pathway; for example, radioligand binding and electrophysiological studies implicate 5HT1, 5HT2 and 5HT3 receptor subtypes in retinal processing. Recently, a new receptor subtype -5HT7- with a high affinity for serotonin has been cloned from rat and mouse brain. We are particularly interested in this receptor because it has a pharmacological profile similar to the 5HT1a receptor. In contrast to 5HT1a, 5HT7 is positively coupled to adenylyl cyclase. Such a receptor would be more consistent with the effects of serotonin and selected agonists on adenylyl cyclase activity in rabbit retina.

First, we determined whether the 5HT7 transcript is present; RT-PCR was performed on RNA isolated from rabbit retina using oligonucleotide primers made from a highly conserved region of mouse and rat sequences. After PCR, a single distinct band of the expected length was obtained; the product was subcloned into a plasmid vector and the sequence determined. The sequence shows >90% sequence identity with both rat and mouse 5HT7. We are currently performing *in situ* hybridizations using this probe; our preliminary data suggest that a population of bipolar cells express these transcripts. Since the presence of a transcript does not necessarily mean that the cell will express the protein, we plan to make antibodies against 5HT7 receptor using the deduced amino acid sequence of the clone we have obtained.

Supported by NIH EY06776 (WJB); Boston College Undergraduate Research Program; DDH is a Fellow of Sloan Foundation.

**IS IP<sub>3</sub> A TERMINAL TRANSMITTER IN LIMULUS PHOTORECEPTORS?** M. Dörflöcher\*, G. Stommel, K. Kosfeld, M. Klemeit, C. DellaCorte, H. Stieve. Inst. für Biologie II, RWTH Aachen, 52074 Aachen, FRG, and Monell Chemical Senses Center, Univ. Pennsylvania, Philadelphia, PA 19104, U.S.A.

IP<sub>3</sub>-gated cation channels in the plasma membrane have been found in olfactory cells in vertebrate (Restrepo et al., Science 249:1166, 1990) and invertebrate species (Fadool & Ache, Neuron 6:907, 1992). In *Limulus* ventral photoreceptors IP<sub>3</sub> causes calcium release from internal stores. In addition, influx of external Ca through plasma membrane channels has been postulated (Stommel et al., Proc. Göttingen Neurobiol. Conf., 1994). Are these channels gated by IP<sub>3</sub>? We injected antibodies against the plasma membrane form of the IP<sub>3</sub> receptor in vertebrates (courtesy of L. Kalinoski; Kalinoski et al., Soc. Neurosci., 1993) into ventral photoreceptors and measured light-induced receptor currents (ReC) and cytosolic Ca increase using arsenazo. In 3 cells, ReC were reduced in amplitude and current time integral by up to 40%. The latency of arsenazo signals was longer by up to 50%, and the rising phase was slowed down. Controls with anti tetanus toxin antibodies showed no effects. Anti IP<sub>3</sub> antibodies detected protein bands of about 60-80 kDa in Western blots of *Limulus* ventral nerve and lateral eye preparations. The specificity of this binding is currently being tested. These results suggest that IP<sub>3</sub> may directly mediate the opening of plasma membrane channels and thus be one of the terminal transmitters in the transduction cascades in *Limulus* photoreceptors.

## 358.15

**ROLE OF PRESYNAPTIC CALCIUM CHANNEL GATING IN DIVALENT BLOCK OF TRANSMISSION AT THE PHOTORECEPTOR SYNAPSE.** D. Kureny<sup>1</sup>, M. Wilkinson<sup>1</sup>, G. Thurlow<sup>\*1</sup>, A. Pignatelli<sup>2</sup>, F. Sappia<sup>2</sup>, M. Piccolino<sup>2,3</sup>, A. Byzov<sup>4</sup> and S. Barnes<sup>1</sup>. <sup>1</sup>Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1; <sup>2</sup>Dipartimento di Biologia, Università di Ferrara, 44100 Ferrara, Italy; <sup>3</sup>Istituto di Neurofisiologia del C.N.R., 56100, Pisa, Italy; <sup>4</sup>Institute for Problems of Information Transmission, Moscow, Russia.

Divalent cation-induced block of synaptic transmission from photoreceptors to horizontal cells was reversed when [Ca<sup>2+</sup>] was reduced, a paradoxical result since the blocking divalent was still present. We studied the presumed presynaptic mechanisms of these effects by voltage-clamping isolated cone photoreceptors. Cells were bathed in standard solutions with 2 or 3 mM CaCl<sub>2</sub>. Ca current activation curves were obtained by dividing leak-subtracted current-voltage relations by the driving force and normalizing. In 2 mM Ca<sup>2+</sup>, 5 μM Zn<sup>2+</sup> produced a positive shift of the Boltzmann-fitted activation curve midpoint of 3.7 ± 0.3 mV and decreased conductance to 91% ± 7% (mean ± s.d., n=5). Lowering [Ca<sup>2+</sup>] to 0.5 mM then produced a negative activation shift of -5.4 ± 0.8 mV and further decreased conductance to 48% ± 4% of control. Similar shifts were seen with 10 μM Zn<sup>2+</sup>, 5 μM Cd<sup>2+</sup>, 50 μM Ni<sup>2+</sup> or 10 μM Co<sup>2+</sup> added to 2 or 3 mM Ca<sup>2+</sup>, and during reduction of divalent strength to 0.5 mM Ca<sup>2+</sup> or 0.75 mM Ca<sup>2+</sup> (n=14). The negative shift of Ca channel activation brought about by lowering [Ca<sup>2+</sup>], restores Ca<sup>2+</sup> influx in the "synaptic window" (below -35 mV), in spite of the reduced Ca<sup>2+</sup> conductance, and thus restores glutamate release and transmission of the light response.

## 358.12

**NEUROGENESIS OF NICOTINIC ACETYLCHOLINE RECEPTORS IN THE CHICK RETINA.** P.F. Gardino<sup>\*1</sup>, K.C. Calaza<sup>1</sup>, D.E. Hamassaki-Britto<sup>2</sup>, J.M. Lindstrom<sup>3</sup>, L.R.G. Britto<sup>4</sup> and J.N. Hókoç<sup>1</sup>. <sup>1</sup>Lab. Neurobiologia da Retina, 21949-900, Brazil; <sup>2</sup>Dept. of Hystol. and Embryol., ICB/USP-SP, Brazil; <sup>3</sup>Dept. of Neurosci., Univ. of Pennsylvania, USA; <sup>4</sup>Dept. of Physiol. and Biophys., ICB/USP-SP-Brazil.

The development of cells containing neuronal nicotinic acetylcholine receptors (nAChRs) in the chick retina revealed different ontogenetic patterns for α3 and α8 nAChR subunits (Hamassaki-Britto et al., J. Comp. Neurol., 347:161, 1994). In this study, the neurogenesis of these cells was evaluated by combining the autoradiographic technique of [<sup>3</sup>H]-thymidine incorporated into dividing cells with the immunohistochemical technique of using antibodies directed against α3 and α8 nAChR subunits. Alpha3-like immunoreactive cells (α3-LI) in the ganglion cell layer (GCL) are generated from embryonic day 2 (E2) to E6, while α8-LI in the GCL is generated from E1 to E6. In the GCL, the results show that the neurogenesis period of α8-LI begins one day before the generation of α3-LI. The neurogenesis of both α3 and α8-LI amacrine cells (AC) extend from E2 to E9, whereas α3-LI displaced ganglion cells (DGC) are generated from E3 to E9. The time course of generation of each α3-LI populations in the inner nuclear layer has a different rate. The majority of DGCs leave the cell cycle earlier than ACs. Alpha8-LI bipolar cells begin to be generated late, from E5 to E10, indicating that these cells are the last ones to enter and leave the mitotic cycle. These results suggest that the neurogenesis of α3 and α8 cells follow the general pattern of cell generation during development of the chick retina. **DEVELOPMENT OF SUBSTANCE P (SP)-CONTAINING CELL POPULATIONS IN THE POSTNATAL RABBIT RETINA**

G. Casini\*, L. Trasarti, A. Grassi and P. Bagnoli, Dept. of Environmental Sciences, Tuscia University, 01100 Viterbo, and Dept. of Physiology and Biochemistry, University of Pisa, 56123 Pisa, Italy

In the mammalian retina, SP is likely to be involved in regulatory and/or modulatory actions in the plexiform layers. To contribute to the knowledge of the maturation of transmitter-identified retinal cell types, we used immunohistochemical methods to visualize SP-immunoreactive (IR) cells in rabbit retinas from birth (postnatal day -P- 0) to adulthood. During the first postnatal week, SP immunoreactivity is confined to large and small cell bodies in the ganglion cell layer (GCL) and to a few somata in the inner nuclear layer (INL). At P6, many SP-IR processes run obliquely or vertically oriented in the inner plexiform layer (IPL), and they are characterized by the presence of a growth cone at their distal end. At P11 (eye opening), SP-IR somata in the INL are more numerous than at P6. SP-IR processes are longer and confined to laminae 1, 3 and 5 of the IPL. Growth cones are still observed. Some immunolabeled fibers originating from SP-IR somata in the INL reach the outer plexiform layer, where they form sparse arborizations, suggesting the presence of SP in interplexiform cells. Long bundles of SP-IR processes (likely ganglion cell axons) are also seen in the ganglion cell axon layer. At P14, no growth cones are present on SP-IR processes and no further changes are observed up to the adult age. Our results demonstrate the presence of SP in amacrine, displaced amacrine, interplexiform and ganglion cells. In addition, consistent with other studies on developing retinal cell populations, mature characteristics of SP-IR neurons are established by eye opening, which represents a critical period in retinal maturation.

Li<sup>1</sup> and M.K. Walton<sup>2</sup> Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892<sup>1</sup>; and Div. of Clinical Trial Design and Analysis, OTRR, CBER, FDA, Rockville, MD 20852<sup>2</sup>.

Retinal neurons express GABA receptors with diverse pharmacological properties. With a potentiometric probe, such properties can be localized to specific cell types. Oxonol, a negatively charged lipophilic dye, slowly partitions (1-5 min) into depolarized, and out of, hyperpolarized neurons (Walton et al., 1993\*), and signals membrane potential changes in rod bipolar cells (RB's) and other retinal neurons (round cells) dissociated with papain from adult Sprague-Dawley rats. GABA (25-100 μM) evoked fluorescence changes in 23% of RB's and 29% of round cells. Fluorescence decreases (-0.3 to -3 log units), reflecting membrane hyperpolarizations, predominated (80%). Bicuculline methyl bromide (BCC, 100-200 μM) blocked GABA responses in only 20% of responding cells. Picrotoxin (PTX, 50 μM) was rarely effective, and failed to block GABA responses in cells sensitive to BCC. Muscimol (50 μM) was less effective than GABA, evoking predominantly fluorescence decreases in 16% of RB's and 19% of round cells. In a given cell, responses to muscimol were smaller than to GABA. CACA (50 μM) was nearly ineffective. This pharmacology resembles descriptions of GABA-gated Cl<sup>-</sup> currents in rat RB's (Feigenspan et al., 1993\*). Thus both RB's and round cells in rat retina exhibit unique GABA physiologies: 1) BCC-insensitive and conforming neither to GABA<sub>A</sub>, nor to GABA<sub>C</sub> patterns, and 2) BCC-sensitive and GABA<sub>A</sub>-like, but not blocked by PTX.

DOPAMINE ACTS AS A CIRCADIAN CLOCK EFFECTOR BY ACTIVATING D4 RECEPTORS IN FISH RETINA. S. C. Mangel\* and Y. Wang. Univ. of Alabama Sch. of Med., Birmingham, AL 35294.

In fish retina, cone horizontal cells (HCs) receive synaptic contact from cones and not from rods. A circadian clock regulates cone HC light responses so that cone input predominates during the subjective day and rod input predominates during the subjective night (Mangel and Wang, 1994). To determine whether dopamine acts as a circadian clock effector, the effects of dopamine and dopamine drugs on L-type cone HC light responses were studied during the subjective day and night. Following 14 days of a 12/12 hr light/dark cycle, goldfish were maintained in constant darkness for 24-48 hrs. Surgery was performed under dim red or infrared light. HCs were impaled without the aid of any light flashes. Superfusion of dopamine (0.01-1  $\mu$ M) or quinpirole (1  $\mu$ M), a D2-like agonist, during the subjective night increased cone input and eliminated rod input to the cells, a state typically observed during the subjective day. In contrast, application of spiperone (1-10  $\mu$ M), a D2-like antagonist, clozapine (1-10  $\mu$ M), a preferential D4 antagonist, or forskolin (10  $\mu$ M), an activator of adenylate cyclase, during the subjective day reduced cone input and increased rod input. Eticlopride (50  $\mu$ M), a D2 antagonist, and SCH23390 (10  $\mu$ M), a D1 antagonist, were without effect. Destruction of dopaminergic cells following 6-hydroxydopamine treatment increased rod input and decreased cone input during the subjective day. Because D4 receptors are found on photoreceptor cells, but not on HCs (Cohen et al., 1992), these results suggest that a circadian clock regulates rod and cone input to cone HCs by modulating rod-cone coupling. The clock increases dopamine levels during the day so that D4 receptors on photoreceptor cells are activated. This in turn decreases rod-cone coupling via a decrease in cAMP. Supported by grants from the NIH and NSF.

## 358.18

CIRCADIAN RHYTHMICITY AND ADRENERGIC STIMULATION ARE INVOLVED IN THE GENETIC REGULATION OF MELATONIN SYNTHESIZING ENZYME (HIOMT) AT THE TRANSCRIPTIONAL LEVEL IN RAT PINEAL AND RETINA. Chenli M. Craft\* and François Gauer, Mary D. Allen Laboratory for Vision Research, Doheny Eye Inst., Dept. Cell & Neurobiol., Univ. Southern Calif. Sch. of Med., Los Angeles, CA 90033.

Hydroxyindole-O-methyltransferase (HIOMT) is the final enzyme in the melatonin synthesis pathway and is highly expressed in rat pineal and retina. To address the environmental and the circadian regulation of melatonin, we investigated the molecular expression and localization of rat HIOMT in pineal and compared it to the retina, utilizing a cDNA encoding the rat HIOMT. Because rat HIOMT mRNA expression was not detectable in retina by Northern analysis, we devised a sensitive Ribonuclease Protection Assay (RPA). The analysis revealed a RPA protected fragment of HIOMT mRNA with 40 fold lower expression per  $\mu$ g total RNA isolated from retina compared to pineal. Transcription of an HIOMT mRNA at 6 timepoints throughout a 24-hr period was determined and was significantly higher in expression levels during nighttime in pineal and retina. Pineal HIOMT mRNA transcriptional levels persist in constant darkness (mid-day vs. mid-dark) and with exogenous adrenergic stimulation (isoproterenol 4mg/kg, 30-150 min after injection). The tissue localization and fluctuations of these mRNAs was confirmed by *in situ* hybridization. In conclusion, the mRNA for rat HIOMT is expressed on a daily basis in the rat retina and pineal. Although only modest changes occur in rat HIOMT enzyme and protein levels, the mRNA has a distinct, circadian rhythm and is under adrenergic regulation, reflecting the synthesis of melatonin. The physiological and genetic relevance of this HIOMT transcriptional regulation is now under investigation.

## VISUAL CORTEX: EXTRASTRIATE—FUNCTIONAL ORGANIZATION I

## 359.1

ORGANIZATION OF VISUAL CORTEX IN THE MONGOLIAN GERBIL (*Meriones unguiculatus*). EVIDENCE FOR MULTIPLE VISUAL AREAS. J. L. Cudmore\* and C. G. Ellard. Department of Psychology, University of Waterloo, Waterloo, Ontario, CANADA N2L 3G1.

The visual cortex has been shown to have distinct architectonics as well as a unique pattern of connections with other visual structures. However, the question of the number of visual areas that exist in posterior neocortex and whether different mammalian species differ in the number of visual areas remains in doubt. This study attempted to address the issue of visual cortex organization by investigating this area in the Mongolian gerbil (*Meriones unguiculatus*). Small quantities (0.2-0.3  $\mu$ l) of three different fluorescent tracers (RITC, Fluorogold, Fast Blue) were pressure injected into the right occipital area of the brain. Following a survival period of 7 days, gerbils were perfused. Brains were removed and prepared for flatmount sectioning. Sections were cut at 40 $\mu$ m and were mounted unstained for fluorescent microscopy. Results demonstrated that the injection of multiple tracers labeled some distinct areas in lateral and medial extrastriate cortex and these areas appeared to be retinotopically organized. These distinct regions were consistently labeled from animal to animal. Despite this consistency, there was also a noticeable amount of variability between brains in the extent of extrastriate cortex containing labeled cells. It is thought that the gerbil visual cortex is organized as multiple visual areas but that individual differences in the connections of these areas are a feature of this organization.

This research was funded by a grant to CGE from the Natural Sciences and Engineering Research Council of Canada.

## 359.2

VISUAL AREAS IN THE EXTRASTRIATE CORTEX OF THE MARMOSET M.G.P. Rosa, L.M. Schmid, J.C. Clarey\*. Vision, Touch & Hearing Research Centre, The University of Queensland, Brisbane, QLD 4072, Australia

The visuotopy of extrastriate cortex was studied by electrophysiological recordings in ten marmosets anaesthetised with sufentanil and nitrous oxide. Large portions of cortex were studied in each animal with penetrations 300-800  $\mu$ m apart. In the dorsomedial cortex, we identified four visuotopic representations between the second visual area, V2, and posterior parietal cortex. The zone of densest myelination coincided precisely with the dorsomedial area (DM). Within DM, the lower quadrant representation is continuous, with central vision represented laterally, peripheral vision medially, the horizontal meridian caudally and the vertical meridian rostrally. In contrast, the upper quadrant representation is split, with the central portion represented at the lateral edge of DM on the dorsal surface, and the periphery along the midline. Three other visual field representations, including both quadrants, surrounded DM. These were named the dorsointermediate (DI) and medial (M) areas, based on similar areas in the owl monkey, and the dorsoanterior area (DA), rostral to DM. In caudal temporal cortex, the middle temporal area (MT) contained a precisely organised visuotopic map, and ventral to MT there was another systematic representation of both quadrants, perhaps corresponding to the dorsal subdivision of FST (FSTd). Lateral cortex, between foveal V2 and MT, contained multiple representations of the fovea and lower visual field. Our results reveal a highly complex visuotopy in primate cortex, with local discontinuities in representation, and borders between areas that are often not coincident with either the horizontal or vertical meridians. In these aspects, the visual areas of the marmoset resemble those of cats. However, there was no evidence of visual areas with partial representations of the visual field, such as those described in cats and macaques.

## 359.3

DIFFERENTIAL INPUT FROM AREA V2 TO AREAS V4, MT AND PO IN CEBUS. S. Nascimento-Silva, R. Gattass, M. Fiorani Jr., A. P.B. Souza\*. Lab. Neurobiologia III, IBCCF, UFRJ, Ilha do Fundão. Bl. G. 21949- 900. Rio de Janeiro, RJ, Brasil.

To investigate the differential inputs from area V2 to areas V4, MT and PO in Cebus monkeys we injected multiple retrograde tracers in nine hemispheres and analysed the distributions of labeled neurons in V2. We sectioned one hemisphere in the parasagittal plane, two in the coronal plane and in the remaining ones we used flattened preparations of cortex. After injections in V4, MT and PO we found labeled neurons located in stripes running orthogonal to the V1/V2 border in flattened preparations. As in the macaque MT-projecting neurons were located in the cytochrome oxidase-rich thick stripes, and V4-projecting neurons were located both in thin stripes and interstripes regions. The PO-projecting neurons were found both in thick stripes and in the interstripe regions. The laminar distribution of the neurons in V2 that project to V4 and MT are different from those that project to PO. V4- and MT-projecting neurons are located in upper layers (2, 3), while PO-projecting neurons are located both in upper (2, 3) and lower (5, 6) layers. These results indicate that three distinct visual pathways arise from different sets of modules in V2. They also support the hypothesis of a subdivision of the dorsal stream of visual information processing into a dorsolateral projecting to MT and a dorsomedial projecting to PO, as suggested by Gattass et al., 1990, Brazilian J Med Biol Res, 23:375-393.

## 359.4

CALLOSAL CONNECTIONS INTERLINK ANATOMICALLY CORRESPONDING REGIONS IN VISUAL AREA V2 OF MACAQUE MONKEY. P.L. Abel\*, B.J. O'Brien, and J.E. Olavarria. Department of Psychology, University of Washington, Seattle, WA 98195.

In visual area V2 of the macaque monkey accumulations of callosal projecting neurons are found along the V1/V2 border and within finger-like regions extending 7-8 mm into area V2. The extent of this distribution raises the question of whether or not callosal fibers interlink anatomically corresponding regions in V2. We addressed this issue by analyzing the distribution of retrogradely labeled cells in V2 following tracer injections that were positioned at different locations from the V1/V2 border in contralateral V2.

Small injections of different fluorescent tracers were made into dorsal area V2 of adult monkeys (*Macaca fascicularis*). In order to reach regions of area V2 buried within the lunate sulcus, a portion of the prelunate gyrus was removed. Data were analyzed in sections cut parasagittally or tangentially to the cortical surface, and the position of labeled cells and injection sites was measured relative to the V1/V2 border revealed by Nissl staining or cytochrome oxidase histochemistry.

We found accumulations of labeled callosal cells predominantly in supragranular layers. Analysis of these labeling patterns demonstrated that the distances from the fields of labeled cells to the V1/V2 border were similar to the distances from the corresponding injection sites to the V1/V2 border. However, small numbers of labeled cells were also observed near the V1/V2 border after some injections placed distant from the V1/V2 border. Thus, our results suggest that callosal projecting neurons in area V2 predominantly interlink anatomically corresponding regions. This pattern of connections may facilitate interactions between cortical regions representing visual fields located on opposite sides of the vertical meridian.

## 359.5

CORTICOTHALAMIC CONNECTIONS OF EXTRASTRIATE REGIONS IN RHESUS MONKEYS. E.H. Yeterian\* and D.N. Pandya. Dept. of Psychology, Colby College, Waterville, ME 04901, E.N.R.M. V.A.M.C., Bedford, MA 01730, and Boston University School of Medicine.

Corticothalamic connections of extrastriate visual areas were studied using the autoradiographic anterograde tracing technique. The results show that the medial extrastriate region above the calcarine sulcus projects mainly to the lateral pulvinar (PL), medial pulvinar (PM), and lateral posterior (LP) nuclei. In addition, the dorsal portion of the medial region has connections to the lateral dorsal (LD) as well as to intralaminar nuclei. The dorsolateral extrastriate region projects strongly to the PL and LP nuclei, to the PM and inferior pulvinar (PI) nuclei, and to the LD and intralaminar nuclei. The lateral extrastriate region above the inferior occipital sulcus (IOS) has strong connections to both the PL and PI nuclei, and has minor projections to the PM and oral pulvinar (PO) nuclei. The ventrolateral extrastriate region below the IOS projects mainly to the PI nucleus, to the caudal portion of the PL nucleus, and has some projections to the PM nucleus. The ventromedial extrastriate region, medial to the occipitotemporal sulcus, has strong connections with the ventral and medial sectors of the PI nucleus. This region also projects to the caudal portion of the PL nucleus, and has minor connections to the LP nucleus. Finally, the annectant gyrus projects to the PL nucleus, to the rostral portion of the PI nucleus, and has minor connections to the PM nucleus. Thus, the medial and dorsolateral extrastriate regions are related mainly to the PL and LP nuclei, as well as to intralaminar nuclei. In contrast, the ventrolateral and ventromedial regions are connected strongly with the PI nucleus. This connectational organization appears to reflect functional differentiation at the cortical level (Supported by the Dept. of Veterans Affairs, NIH grant 16841, and Colby College Social Science grant 01 2239.)

## 359.7

INPUTS TO VISUAL AREAS V1, V2, AND MT FROM THE MACAQUE PULVINAR AND THEIR RELATIONSHIPS TO CHEMOARCHITECTONIC SUBDIVISIONS. M.M. Adams<sup>1</sup>, M.J. Webster<sup>1</sup>, R. Gattass<sup>2</sup>, P.R. Hof<sup>1</sup> and L.G. Ungerleider<sup>1</sup>. <sup>1</sup>Lab. Neuropsych., NIMH, Bethesda, MD 20892; <sup>2</sup>Inst. Carlos Chagas Filho, Univ. Fed., Rio de Janeiro, Brazil; <sup>3</sup>Dept. Neurobiol., Mount Sinai Sch. Med., New York, NY 10029.

Previously, we defined three fields in the pulvinar based on projections from MT (Ungerleider et al., JCN 223:368,1984): P1, which is located primarily in the inferior pulvinar (PI) but extends into a portion of the adjacent lateral pulvinar (PL); P2, which surrounds P1 and is entirely in PL; and P3, which is found posteromedially in PI but also includes small portions of PL and the medial pulvinar that lie dorsal to the brachium of the superior colliculus. Both P1 and P2, but not P3, contain clear retinotopic maps of the visual field. In the present study, we investigated the inputs from these fields to V1, V2, and MT and related this information to chemoarchitectonic subdivisions based on calbindin (CB) immunostaining. V1 and V2 were injected with retrograde tracers in retinotopically matched visual field representations in 6 monkeys, and MT was injected in an additional 3. Retrogradely labeled cells resulting from V1 and V2 injections were completely overlapping and organized into two separate fields, one in P1 and another in P2. The locations of these cells, which were rarely double-labeled, were in register with the visual field maps of P1 and P2. The P1 field, but not other parts of P1, was characterized by moderate CB staining and seems to correspond to the lateral subdivision of PI described by Gutierrez et al. (Soc. Neurosci. Abstr., 20:770,1994). Cells projecting to MT were also found in P1 and P2 but were mainly concentrated in the most medial portion of P3, which was largely devoid of CB staining and may correspond to the medial subdivision of PI described by Gutierrez et al. The lateral portion of the P3 field was characterized by dense CB staining, devoid of MT- and V1-projecting cells, and contained only a few projecting to V2. The cortical connections of this subdivision of P3, which appears to correspond to the central subdivision of PI described by Gutierrez et al., remain to be determined.

## 359.9

FUNCTION OF FEEDBACK FROM EXTRASTRIATE TO STRIATE CORTEX IN THE CAT: COMPARISON OF COOLING AND LESION EFFECTS. Y.P. Danilov, R.J. Moore, V.R. King, and P.D. Spear\*, Dept. of Psychology and Ctr. for Neuroscience, Univ. of Wisconsin, Madison, WI 53706.

Stimulation of the far surround (outside the classic receptive field) alters the responses of striate cortex cells to receptive-field center stimulation. We examined the effects of reversibly cooling lateral suprasylvian (LS) extrastriate cortex on this far-surround effect. Prior to cooling, 47% of the cells (N=45) showed an inhibitory far-surround influence and 6% showed a facilitatory influence on responses to gratings of optimal orientation and spatial frequency. Cooling LS cortex had no significant effect on the far-surround influence. We were concerned that this was because the cooling device may not have inactivated a large enough area of visual-field topography deep in the LS sulcus. Therefore, we tested additional striate cortex cells (N=43) after a large LS cortex lesion. Only 7% of these cells showed an inhibitory far-surround effect, and 26% showed a facilitatory effect. In normal controls (N=33), 45% of the cells showed an inhibitory effect and 15% showed facilitation.

These results led us to compare the three groups in terms of spatial-frequency (SF) tuning, which had been determined prior to testing the far-surround influence. In cats with an LS lesion, responses to low SFs were decreased and responses to high SFs were increased compared to normal. Conversely, among cells tested prior to cooling, responses to low SFs were increased and responses to high SFs were decreased. There also were opposite effects on maximal response and contrast sensitivity.

These results suggest that LS cortex inhibits far-surround influences and modifies the spatial-frequency tuning of striate cortex neurons. In addition, ablation and cooling of LS cortex can have different effects, perhaps because of post-cooling rebound. (Supported by R01 EY01916)

## 359.6

SYNCHRONOUS FIRING LEADS TO EFFECTIVE NEURONAL INTERACTIONS IN A MODEL OF THE THALAMOCORTICAL SYSTEM.

E. D. Lumer\*, G. Tononi, The Neurosciences Institute, 10640 John Jay Hopkins Drive, La Jolla, CA 92121

Many efforts at understanding cortical functioning assume the existence of codes based on either mean firing rate or temporal coincidences. In this report, we describe a model based on the anatomy and physiology of the thalamocortical system, the behavior of which cannot be accounted for purely in terms of either firing rates or temporal coincidences. This conclusion is derived from the responses of the model both before and after perturbations affecting either one of these variables. The model contains a lower and a higher visual area, two corresponding specific thalamic sectors, and a thalamic reticular nucleus. Cortical neurons, both excitatory and inhibitory, are organized in three laminae corresponding to supragranular layer, infragranular layer, and layer 4. The connectivity includes various sets of intra- and interlaminar, interareal, thalamocortical, and corticothalamic connections. Different cell types are modeled as integrate-and-fire elements with membrane time constants  $\tau$  of 8-20msec, each equipped with appropriate sets of synaptic channels. When presented with visual patterns, the simulated model showed transient episodes of population oscillations as well as synchronous firing. These episodes were highly dependent on the mean firing rate of the activity transmitted across multiple intra- and interareal recurrent loops. To address the role of temporal coincidences, a random jitter in the timing of action potentials was introduced, with a spread that was varied systematically from 2msec to several times  $\tau$ . A jitter with a spread on the order of the membrane time constant led to a decrease of mean firing rates, an impaired detection of specific features of visual stimuli, and a disappearance of episodes of coherent activity. These experiments demonstrate that firing rate and synchrony of firing both contribute to causally effective interactions within the thalamocortical model in an interdependent way.

## 359.8

FEEDFORWARD AND FEEDBACK CORTICOCORTICAL PROJECTIONS IN THE MONKEY VISUAL SYSTEM DISPLAY DIFFERENTIAL NEUROCHEMICAL PHENOTYPE. P.R. Hof<sup>1</sup>, L.G. Ungerleider<sup>2</sup>, M.J. Webster<sup>2</sup>, R. Gattass<sup>3</sup>, M.M. Adams<sup>2</sup>, C.A. Saulstad<sup>1</sup>, W.G.M. Janssen<sup>1</sup> and J.H. Morrison<sup>1</sup>.

<sup>1</sup>Dept of Neurobiol., Mt Sinai Sch. Med., New York, NY 10029; <sup>2</sup>Lab. of Neuropsychol., NIMH, Bethesda, MD 20892; <sup>3</sup>Inst. Carlos Chagas, Rio de Janeiro, Brazil.

Previous studies of the primate cerebral cortex have shown that neurofilament protein (NFP), and glutamate receptor subunit proteins (GluRs) are present in pyramidal neuron subpopulations displaying specific regional and laminar distribution patterns. To define the neurochemical phenotype of the neurons of origin of feedforward and feedback corticocortical projections linking areas V1, V2, V3, V4 and MT of the monkey visual system, we performed a quantitative analysis of the distribution of NFP and various GluRs using tract-tracing combined with immunohistochemistry and computer-assisted morphometry. Injections of Fast Blue and Diamidino Yellow were placed either within areas V4 and MT or areas V1 and V2 in 13 adult rhesus monkeys. The brains were cut in a series of 40  $\mu$ m-thick coronal sections that were incubated with specific antibodies to NFP, or to the GluR5-7 (kainate), GluR2(4) (AMPA), or NMDAR1 subunits. There was a higher proportion of neurons projecting from layers III and V/VI of V1, V2, and V3 that were NFP-positive projecting forward to MT (58-100%), than to V4 (25-36%). Comparable results were obtained with GluR5-7 (68-100% vs 48-56%). Contrasting with these differences, the feedback projections from MT, V4, and V3 to V1 and V2 originated mostly from layer VI neurons, and contained consistently high proportions of NFP and GluR5-7 (80-100% independently of the projection). In all projections analyzed, AMPA and NMDAR1 subunits appeared to be present in nearly all retrogradely labeled neurons. These results indicate that NFP and GluR5-7 are present in select neuronal populations that are differentially represented among feedforward and feedback projections in the monkey visual system. These specific distribution patterns across corticocortical projections also suggest the existence of differential neurochemical coding of the magno- and parvocellular visual streams. Supported by NIH AG06647 and MH52154.

## 359.10

FEEDBACK CONNECTIONS CONTRIBUTE TO CENTER-SURROUND INTERACTIONS IN NEURONS OF MONKEY AREAS V1 AND V2. A.C. James, J.-M. Hupé, S.L. Lomber, B. Payne, P. Girard and J. Bullier\* Cerveau et Vision INSERM U371 18 avenue du Doyen Lépine 69500 Bron/Lyon, France.

Corticocortical connections can be classified as feedforward and feedback. Nothing is known concerning the role of feedback cortical connections. We have tested the role of feedback connections in shaping the receptive field properties of visual cortical neurons by inactivating reversibly higher-order areas. Two preparations were used. In one case, we inactivated the entire extent of area MT and the surrounding areas of the superior temporal sulcus by cooling and we recorded neurons in area V2. In the other, we inactivated a limited extent of area V2 by small GABA injections and recorded in area V1. In both cases we assessed the center-surround interaction by presenting a variety of center-only and center-surround stimulus configurations and comparing the neuron responses to these stimuli.

The data show changes in the interactions between center and surround. In some neurons, inactivation of the higher-order areas produced a disfacilitation. In other cases, we observed a desuppression, which in some cases was total.

These results suggest that feedback connections act upon the integration of information concerning neighbouring regions of the visual field.

## 359.11

## COMPUTER SIMULATIONS OF THE ROLE OF RECURRENT INTERACTIONS IN MEDIATING CONTEXTUAL ASPECTS OF COLOUR VISION.

J. Wray\* and G. M. Edelman. The Neurosciences Institute, 10640 John Jay Hopkins Drive, San Diego, CA 92121.

It is known that the perceived colour of an object depends both on the context in which it is viewed and on its physical properties. What is not known, however, is how this perceptual construction is achieved. The hypothesis underlying the present study is that a process of reentry mediated by long range, reciprocal connections within and among visual cortical areas results in the integration of context into the colour percept. To test this hypothesis, a computer model was constructed based on known anatomical and physiological properties of visual cortex, in particular those of areas V2 and V4. Both areas were modelled as topographic maps containing excitatory and inhibitory units tuned to respond maximally to red, yellow, green and blue. An extensive pattern of reciprocal connections was also modelled. The architecture of the model took account of physiological data, such as the nonclassical receptive field properties of visual cortical neurones, and anatomical data, such as the spread of intracortical horizontal connections and the extent of intercorical forward and backward connections. The model was evaluated using stimuli, obtained via a video camera, that are analogous to those used in psychophysical colour induction and colour constancy experiments. Simulation experiments revealed that the modelled system gave rise to population firing patterns that varied continuously when the hue and saturation of a stimulus was varied continuously. Interactions among units in V2 and V4 produced response patterns that were influenced by visual context in a fashion compatible with human psychophysical data on colour induction and colour constancy. Interruption of intrinsic paths within V4 severely compromised the model's properties of colour constancy and colour induction. Disruption of V2 intrinsic connections and V4 → V2 backward connections showed a smaller but measurable effect on contextual integration. These simulations illustrate a potential role in colour vision of recurrent signalling within V4 and V2 and between V4 and V2.

## 359.12

## SELECTIVE INTEGRATION: A MODEL FOR DISPARITY ESTIMATION.

M. S. Gray\*, A. Pouget, R. S. Zemel, S. J. Nowlan, and T. J. Sejnowski. UC-San Diego, Howard Hughes Medical Institute, The Salk Institute, PO Box 85800, San Diego, CA 92186-5800.

Because local disparity information is often sparse and noisy, there are two conflicting demands when estimating disparity in an image region: the need to spatially average to get an accurate estimate, and the problem of not averaging over discontinuities. We have developed a network model of disparity estimation based on disparity-selective neurons, such as those found in the early stages of processing in visual cortex. The model can accurately estimate multiple disparities in a region, which may be caused by transparency or occlusion.

The model consists of several stages and computes its output using only feedforward processing. One-dimensional binocular retinal input is preprocessed with disparity energy filters at a range of spatial frequencies and phases. The output of these disparity energy filters forms the input to two separate pathways: the local disparity pathway, and the selection pathway. The local disparity pathway computes an estimate of the disparity in a local region of the image. Because these local disparity measurements may be unreliable, a process is needed to determine which signals to integrate. The selection pathway fulfills this role by selectively gating those disparity signals that reliably indicate the true disparity of the object. The output of this stereo model is a distributed representation of disparity.

This selective integration of reliable local estimates enables the network to demonstrate stereo hyperacuity (i.e., sub-pixel disparity estimation from pixel-based inputs) on normal and transparent random-dot stereograms. Analysis of the model suggests that the selection units appear to respond to disparity contrast — that is, edges in depth. We predict that neurons in visual area MT will demonstrate a similar selectivity to disparity contrast.

## VISUAL CORTEX: EXTRASTRIATE—FUNCTIONAL ORGANIZATION II

## 360.1

## CORRELATED ACTIVITY BETWEEN NEURONS IN AREA 17 AND LATERAL SUPRASILVIAN AREA STUDIED BY CROSS-CORRELATION ANALYSIS IN THE CAT. N. KATSUYAMA, H. SATO, Y. HATA\*, AND T. TSUMOTO. Dept. Neurophysiol., Biomed. Res. Ctr., Osaka Univ. Med. Sch., Suita, Osaka, 565, JAPAN.

The posterior medial lateral suprasylvian area (PMLS) of cerebral cortex is one of extrastriate visual areas in the cat and thought to be involved in motion perception, stereopsis and eye movements. Previous anatomical studies have revealed that area 17 and PMLS are connected through corticocortical projection fibers. PMLS also receives thalamocortical inputs from visual thalamic nuclei such as the lateral posterior nucleus (LP), lamina C of the lateral geniculate nucleus (LGN) and the medial interlaminar nucleus (MIN). To assess functional connectivity between area 17 and PMLS physiologically, we recorded single unit activities simultaneously from both areas and carried out cross-correlation analysis of neuronal spike trains. Adult cats were anesthetized with a mixture of 70 % N<sub>2</sub>O, 30 % O<sub>2</sub> and 0.3-0.5 % halothane. In PMLS, recordings were done from the posterior part of suprasylvian sulcus so that the center of receptive field of each cell was located in foveal and parafoveal areas. We studied a total of more than two hundred and fifty neuron pairs, of which about 10 % had significant peaks in their cross-correlograms. Significantly correlated activities were often observed in cell pairs with following features: 1) their receptive fields were overlapped, 2) their preferred direction of motion of visual stimuli differed by less than 90 degrees from each other, and 3) they were located mostly in supragranular or granular layers of the cortices. In some cell pairs we observed asymmetric peaks which indicated that PMLS neurons fired earlier than area 17 cells. These results suggest that cell populations with similar properties in area 17 and PMLS were functionally connected and they process visual information cooperatively.

## 360.2

## DYNAMIC PATTERNS OF SYNCHRONIZATION BETWEEN NEURONS IN AREA MT OF AWAKE MACAQUE MONKEYS

A. K. Kreiter\* and W. Singer. Max-Planck-Institut für Hirnforschung, D-60528 Frankfurt, F.R.G.

Recent models of visual information processing suggest that neuronal assemblies, representing sensory stimuli, are defined by the synchronous spiking of their constituting neurons. To investigate the dynamic properties of neuronal synchronization and the conditions for their occurrence, multi-unit responses to moving bar stimuli were recorded with multiple electrodes in area MT of awake fixating macaque monkeys. We analysed the relation between the temporal patterning of individual spike trains and the probability of occurrence of cross-correlations between two recording sites. It was found that cross-correlations are rare and weak if one or both of the spike trains exhibited a flat auto-correlogram which suggests a poisson-like firing pattern of the corresponding multi-unit activity. In contrast, the auto-correlograms of correlated spike trains showed a 5 to 10 ms broad centre peak, indicating synchronization between discharges of different simultaneously recorded neurons. To assess the influence of response strength on synchronization, the cross-correlation was computed as a function of time and compared with the time course of the PSTHs. In periods, where activity rises in one recording site and decays in the other, fast systematic shifts of up to 12 ms of the correlation peak position are found. If, on the contrary, the response strength changes in parallel at both sites, then the correlation peak position stays constant. In almost all cases these shifts follow the rule that the more strongly activated neurons lead over those responding more weakly.

These results suggest that local synchronisation is a prerequisite for synchrony between spatially segregated neurons and that fast graded changes of the temporal phase of synchrony could be exploited to represent graded relations among members of the same assembly.

## TEMPORAL CORRELATION OF FMRI SIGNALS MAY REVEAL BRAIN CONNECTIVITY B. Biswal, E.A. DeYoe, F.Z. Yetkin, V.M. Haughton, S. Rao\*, J.S. Hyde. Medical College of Wisconsin, Milwaukee, WI.

In this study, we mapped the temporal correlation of FMRI signals between pairs of voxels in the visual and motor areas in 12 alert human subjects under resting and task conditions. Series of 512 sequential gradient recalled echo-planar images were obtained under 3 conditions: 1) Rest: The subjects were specifically asked not to perform or imagine any motor, sensory or cognitive tasks. 2) Visual stimulation: Subjects viewed a flashing checkerboard at 8 Hz for 10 sec alternating with 10 sec of a fixation point. 3) Motor task: Subjects were asked to sequentially tap their fingers in both hands for 20 sec alternating with 20 sec of rest. For conditions 2) and 3) a synthetic time course representing the stimulus or task alteration frequency was used in a cross-correlation analysis to identify task-activated voxels. For each activated voxel, the time course of the rest state signal was temporally cross-correlated with the rest state signals from all other voxels in order to identify pairs of foci having inherent temporal correlation. Maps of voxels activated in the task conditions were highly similar to maps of correlated voxels in the rest state (0.73 spatial correlation in visual cortex, 0.87 correlation in motor cortex). In both visual and motor cortices, statistically significant resting correlation was found between patches of activated voxels in roughly corresponding positions in each hemisphere, but not among non-activated voxels. The mean correlations in functionally related regions during task activation and rest state were 0.59 and 0.37, respectively. This was substantially higher than in non-activated regions ( $r < 0.1$ ). In addition, voxels in extrastriate visual area, MT, in lateral occipitotemporal cortex correlated with voxels in calcarine V1. Similarly, it was found that, in primary motor cortex, voxels not only correlated with corresponding foci in contralateral motor cortex but also with foci in the supplementary motor area. Although known anatomical connectivity (callosal and ipsilateral cortico-cortical) suggests a possible anatomical substrate, it is not clear if the resting correlations reflect causal connectivity between foci or some common input such as arousal or attentional factors or common vascular control signals.

## 360.4

MULTIPLE SINGLE UNIT RECORDING USING TETRODES IN MACAQUE VISUAL CORTEX: ELECTRODE DESIGN AND SPIKE IDENTIFICATION J. S. Pezaris<sup>1</sup>, M. Sahani<sup>1</sup>, K. L. Grieve<sup>2</sup>, & R. A. Anderson<sup>1,2</sup>. <sup>1</sup>Computation and Neural Systems Program, <sup>2</sup>Division of Biology, Caltech, Pasadena, CA 91125.

We have adapted the McNaughton-Wilson tetrode for use in the awake behaving monkey preparation. Our design combines a standard guide tube for puncturing dura with a much finer carrier tube to hold the tetrode bundle. The assembly is manipulated using standard hydraulic microdrives, assuring good positional accuracy.

Eleven penetrations were made into parietal cortex. Tetrodes were made with 15 and 25 micron insulated commercial nichrome wire running in oil-filled 33 gauge stainless steel carrier tubes. Two control penetrations were made with standard tungsten wire electrodes. Direct digital recordings were made of the four-channel waveforms.

Histology shows that the tetrode wire runs straight up to our maximum extension of 12 mm, and that the carrier tube does not cause excessive neural trauma. Tracks left by the three electrode types are nearly identical.

Coarse analysis of recorded data shows the tetrode wires compare favorably against traditional coated tungsten electrodes in terms of impedance (0.5–0.7 MΩ vs. 0.8 MΩ), signal pickup, and signal to noise ratio (15:1 vs. 23:1).

Finer analysis of recorded data shows clearly separable multi-unit activity. Initial analysis was done by clustering four-channel peak height. We observed that false clusters were created by simultaneous firing of distinct units. Additional analysis was done using M. S. Lewicki's Bayesian waveform classification tools. This resulted in classification consistent with the peak height analysis, while resolving simultaneous activity.

CLUSTERS IN RESPONSES OF VISUAL NEURONS. O. Ruksenas, R. Satinskis and P. Kaufmann. Dept. of Biochemistry and Biophysics, Vilnius University, Ciurlionis 21, 2009 Vilnius, Lithuania.

The time course of neuronal response to presentation of a static and a moving light slit was investigated in the Clare-Bishop area of the cat cortex. Five parameters were used to estimate neuronal response: the total number of impulses, the number of clustered impulses, the number of isolated impulses, the number of clusters, and the maximum frequency of the poststimulus histogram.

Our experimental data demonstrate that: (1) only two neurons of the 56 units tested had no inherent clustered activity; (2) the number of clusters is the best parameter of neuronal response for estimating the orientation and direction selectivity of neurons; (3) clustered impulses contribute up to 44% of the total response, whereas in the case of spontaneous activity they contribute only up to 25%; (4) variability of clustered constituents is as much as twice that of other parameters; (5) a decrease of stimulus orientation/direction optimality causes a quantitative decrease of neuronal response parameters which is most reliably expressed in terms of the number of clusters; (6) increasing the level of stimulus illumination causes an increase in the number of clusters, but the number of impulses forming a cluster does not depend on the level of illumination - this increase is accompanied by a decrease in the latency of the first cluster and in the average interval between clusters; (7) increasing the speed of stimulus movement causes changes in the structure of neuronal response similar to the changes caused by increasing the level of stimulus illumination.

## 360.7

INACTIVATION OF THE STRIATE-RECIPIENT ZONE OF LP INFLUENCES THE RESPONSES OF ONLY A FEW CELLS IN PMLS CORTEX. K. Minville, T. Savard, and C. Casanova. Departments of Ophthalmology and of Physiology and Biophysics, Faculty of Medicine, University of Sherbrooke, Sherbrooke, Quebec, Canada.

Removal of the primary visual cortex has little effect on the spatial frequency (SF) sensitivity of cells in the posteromedial lateral suprasylvian (PMLS) cortex (Guido *et al.*, *J. Neurophysiol.* 5: 1636, 1990). Neuroanatomical studies have shown that neurons in the striate-recipient zone (LPI) of the lateral posterior-pulvinar complex project to layer IV in PMLS. Since cells in LPI and PMLS share similar spatio-temporal properties, we have investigated the possibility that the LPI could contribute to the spatial frequency sensitivity of cells in the PMLS area. Experiments were performed with anesthetized normal adult cats. Receptive fields of 110 PMLS units were characterized with drifting sine-wave gratings presented at saturation and half-maximum contrast. An injecting-recording microelectrode filled with GABA (200µM) or Xylocaine (2%) was placed in the LPI. A total of 45 cells was successfully tested. Results indicate that 1) only a few cortical cells (22%) were affected by the inactivation of the LPI. 2) In almost all cases, the responses were reduced (up to 80%) at all SF tested. 3) We did not observe any change in tuning function, nor in the cells' spatial resolution (except for one unit). These results suggest that, in normal cats, the LPI is not strongly involved in spatial frequency processing of most PMLS cells. It is possible however that afferents from the two other main parts of the LP-pulvinar complex (LPM and pulvinar) may contribute to the spatial frequency properties in the PMLS area. *Supp. by Grant MT-10962 of MRC of Canada, FRSC and FCAR.*

## 360.9

MORPHOLOGY OF REWIRED LGN NEURONS PROJECTING TO MIDDLE SUPRASylvian CORTEX FOLLOWING REMOVAL OF IMMATURE AREAS 17 AND 18 IN CATS. M. A. MacNeil, G. Einstein, & B.R. Payne. Department of Anatomy & Neurobiology, Boston University School of Medicine, Boston, MA 02118.

Removal of cats areas 17 and 18 early, but not late, in postnatal development results in the sparing of reflexive and non-reflexive visually-guided behaviors. These spared behaviors are accompanied by a massive compensatory rewiring of geniculocortical projections to middle suprasylvian (MS) cortex. However, little is known about the types of visual signals relayed along these pathways. The purpose of our study was to reveal the morphologies of the neurons participating in the rewired circuits and relate them to the morphologies of functionally characterized neurons described by others. In lightly fixed tissue slices, LGN neurons retrogradely labeled from MS cortex with fluorescent microspheres, were intracellularly filled with Lucifer Yellow. Reconstructed neurons were classified according to a battery of parameters including soma size and shape, and dendritic field-form and specializations. In normal cats, thalamic neurons projecting to MS cortex comprised types I-IV of Guillery (1966). However, in adult animals that had incurred removal of areas 17 and 18 on the day of birth, only class I and IV neurons were identified. Moreover, these neurons had changes to their dendrites that resulted in broader and more profuse dendritic arbors. In normal animals, type I and IV neurons transmit Y and W visual signals, and these are the same types of signals we suspect are transmitted to MS cortex along the rewired pathways. These signals are likely to influence the types of behaviors spared by early lesions of areas 17 and 18. (Supported by NIMH, NINDS and R29EY07840).

## 360.6

TEMPORAL COMPETITION MECHANISM PRODUCING NEURAL RESPONSES OF THE SUPERIOR TEMPORAL SULCUS. Kiyohiko Nakamura. Grad. Sch. of Info. Syst., Univ. of Electro-Communications, Chofu, Tokyo 182, Japan.

Neurons of the superior temporal sulcus are capable of discriminating visual stimuli in about a hundred milliseconds (Oram & Perrett 1992). This study tests the hypothesis that cortical processing of that time range is performed by competition of the first spikes delivered by neuronal populations. MODEL: The visual pathway of form recognition, cortices V1-V2-V4-PIT-CIT-AIT-STPa, was modeled by a sequence of 7 arrays of 5 × 5 neuronal populations. Each population included three types of neurons: pyramidal, stellate, and inhibitory neurons. There were 100 neurons for each type in every population. Behavior of single neurons was given by a Hodgkin-Huxley type of model. PROCEDURE: Model parameters were given according to physiological data. The experiment by Oram & Perrett was simulated. RESULTS: (1) The empirical data on neural responses of visual discrimination were quantitatively reproduced by the model cortex. (2) The model showed that their analysis on firing latencies was inadequate and predicted that firing latencies should decrease with selectivity of stimuli for each neuron. The empirical data partially support the prediction. (3) Cell responses of other experiments such as oscillatory activity were explained by the model. CONCLUSION: These support the present hypothesis of competitive cortical processing.

## 360.8

INCREASED OXIDATIVE METABOLISM IN MIDDLE SUPRASylvian CORTEX FOLLOWING REMOVAL OF AREAS 17 & 18 IN NEWBORN CATS. K.D. Long, S.G. Lomber and B.R. Payne. Laboratory for Visual Perception and Cognition, Department of Anatomy and Neurobiology, Boston Univ. School of Medicine, Boston, MA 02118.

Based on electrophysiological and behavioral data, middle suprasylvian (MS) cortex has been implicated in the sparing of visually guided behaviors following early ablation of areas 17 & 18. In this study, we sought to measure changes in metabolic activity that could be related to changes in inputs to MS cortex following early area 17 & 18 damage. We measured changes in cytochrome oxidase (CO) activity in MS cortex in intact cats and cats with areas 17 and 18 removed in adulthood (P180), postnatal day 28 (P28) or postnatal day one (P1). After at least a nine month interval to allow for any potential reorganization to occur, brain sections were prepared and reacted for the presence of CO. The density of CO reactivity in each of the 6 cortical layers in MS cortex was measured and standardized against densities from ventral periaqueductal gray on the same section. Significant increases in CO activity occurred in deep layer III and in layer IV of cats which incurred lesions on P1. In contrast, there were no significant differences in the level of CO activity among intact, P28 or P180 cats for any of the cortical layers, and all were lower than the P1 levels. In the P1 ablated group, the increase in activity was restricted to the medial bank of the MS sulcus, including all of area PMLS and part of AMLS. The metabolic change in the P1 ablated group can be linked to a number of rewired pathways and further implicates the region in the sparing of certain visual functions after early brain damage. Supported by NS07152 and MH44647.

## 360.10

PHYSIOLOGICAL DEGRADATION IN VISUAL NEURONS OF MULTIMODAL AND NONPRIMARY CORTICAL AREAS IN BINOCULARLY DEPRIVED CATS. J. Gershon and U. Yonon. *Physiol. Lub., Goldschleger Eye Res. Inst., Sheba Med. CTR., Tel-Aviv Univ. Fac. Med., Tel-Aviv, 69978, Israel.*

The activity of cortical cells was physiologically studied in visual primary (VI,17), nonprimary (SSS: AMLS, PMLS) and multimodal (MS: AMSA, PMSA) cortical areas. Extracellular unit recordings were performed in 12 cats binocularly deprived (BD) at age of 1 week, in 7 cats monocularly deprived (MD) at ages of 1-11 weeks, and in 31 normal (NOR) controls. The cats were anesthetized and paralyzed, the receptive fields (RFs) were mapped and classified (incomplete, diffuse, habituation) and PSTHs were computed.

Cortical area	Total no. of cells			Responsive cells, %			Irregular RFs, %		
	BD	MD	NOR	BD	MD	NOR	BD	MD	NOR
VI	189	64	429	33.7	81.2	85.6	32.5	6.2	3.5
SSS	311	122	398	25	50.4	55.7	70.8	23.4	20.4
MS	191	164	362	25.1	50.7	52.2	85.8	11.3	13.5

While a remarkable reduction was found in the responsiveness of the VI, MS and SSS areas in the BD cats, it was similar in the MD and NOR cats (see table). Accordingly, the percentage of cells with irregular RFs increases in all areas of BD cats, compared with the MD and NOR cats. There is also a consistent degradation of function in the multimodal and nonprimary areas compared with the primary areas. This is also consistent with previous results (Soc. Neurosci. Abstr., 20:1742, 1994), showing reduction in selectivity both for orientation and direction in multimodal and nonprimary areas compared with the primary area. In conclusion, the degradation of function in the multimodal and nonprimary areas is facilitated by the early absence of vision.

## 360.11

COMPARISON OF LATERAL EXCITATORY AND INHIBITORY CONNECTIONS IN CORTICAL ORIENTATION MAPS OF THE CAT. Z.F. Kisvárdy\*, E. Tóth, M. Rausch, U.T. Eysel, Ruhr-Universität Bochum, Institut für Physiologie, 44780 Bochum, Germany.

We asked whether the existing controversy in the literature concerning the orientational topography of corticocortical connections (Gilbert and Wiesel, 1989; Matsubara et al, 1985) could be explained by the difference in the topography of lateral excitatory and/or lateral inhibitory connections. Accordingly, orientation maps were obtained with multiunit recordings and corticocortical connections were revealed with biocytin injections and analyzed in horizontal sections. In order to distinguish putative excitatory boutons from putative inhibitory boutons a battery of morphological features were taken into account: the pattern and fine morphology of parent axons of the labeled boutons, bouton size and shape and for inhibitory boutons of basket cells the presence of perisomatic contacts onto neighboring neurons. All labeled boutons were classified as either excitatory or inhibitory and reconstructed from the entire cortical thickness with the help of a 3-dimensional reconstruction system (NeuroLucida). The resulting anatomical maps were compared with smoothed orientation maps using an interpolation procedure and dissected into iso- ( $\pm 30^\circ$ ), oblique- ( $\pm[30-60]^\circ$ ) and cross- ( $\pm[60-90]^\circ$ ) orientational zones with respect to the orientation preference at the injection site.

The results for areas 17 and 18, respectively, showed that (a) of the excitatory boutons an average of 53 and 59% occupied iso-zones, 30 and 30% oblique-zones and 17 and 11% cross-zones, (b) of the inhibitory boutons an average of 48 and 46% occupied iso-zones, 28 and 39% oblique-zones and 24 and 15% cross-zones, (c) no significant differences in the corresponding proportions between the two areas were found. The distribution of boutons as a function of lateral distance from the center of the injection site - we used this as the measure of functional impact - revealed that lateral iso-excitation and iso-inhibition in both areas are strongest in the close vicinity of the injection site, lateral oblique-excitation and oblique-inhibition follow a broad spectrum and lateral cross-excitation and cross-inhibition are strongest at half a hypercolumn distance. The ratio between the absolute number of excitatory and inhibitory boutons in each orientation zone at different distances did not vary up to the hypercolumn distance beyond which the number of inhibitory boutons rapidly declined. The only significant difference between the two areas was that the hyper-column distance in area 18 was ~1.4 times larger than that of area 17.

We conclude that corticocortical connections in areas 17 and 18 follow the same topographical principles, excitatory connections are biased in connecting similar orientations and inhibitory connections are biased in connecting dissimilar orientations. This work was supported by the Deutsche Forschungsgemeinschaft (Ey 8/23).

## 360.13

ORIENTATION CENTERS REVEALED WITH OPTICAL IMAGING AND THEIR CONNECTIONS IN AREA 18 OF THE CAT. T. Yousef, U.T. Eysel, M. Rausch, M. Lappe\*, Z.F. Kisvárdy\*, Ruhr-Universität Bochum, Institut für Physiologie, 44780 Bochum, Deutschland, Ruhr-Universität Bochum, Institut für Allg. Zool. und Neurobiologie, 44780 Bochum, Deutschland.

Orientation centers are intriguing locations in the orientation map where a broad spectrum of orientation columns meet in a small volume of cortex. We studied the orientational topography of corticocortical connections at orientation centers. Orientation maps were obtained with optical recording of intrinsic signals evoked by the optimal visual stimulus and the exact topographic location of orientation centers was determined with respect to the vascular pattern of the imaged cortex. Under microscope control the tip (12-16  $\mu$ m) of an injection glass pipette was guided into an orientation center and fluorescent latex-beads were pressure injected (40-70 nl) into layer III over a period of 10 min. After 1-2 days, the animals were perfused with 4% paraformaldehyde and horizontal sections (30  $\mu$ m) were prepared. The topography of retrogradely labeled somata were reconstructed from the entire cortical depth using an image reconstruction system (NeuroLucida). The results showed that the overall distribution of the labeling was patchy and 12-15 distinct patches (400-600  $\mu$ m in diameter) could be distinguished. Patch-to-patch distance was 1.2-1.4 mm. The labeling spanned an overall distance of 8-10 mm in AP and 5-6 mm in LM direction. Qualitative comparison between the orientation map and the anatomical map showed that the patches largely avoided orientation centers although a few labeled neurons were found in orientation centers. In order to make a quantitative comparison between the topography of the orientation map and the topography of the labeled somata the orientation was dissected into iso- ( $\pm 30^\circ$ ), oblique- ( $\pm[30-60]^\circ$ ) and cross- ( $\pm[60-90]^\circ$ ) orientational zones with respect to the average orientation preference at the injection site. The proportion of labeled somata within each patch was then calculated according to iso-, oblique- and cross-orientations. It was found that different patches occupied regions possessing different orientations, respectively. The proportional variations of the orientational distribution of the labeling between different patches were the following: iso-(19-75%), oblique-(12-30%), cross-(9-60%). These results indicate that the functional topography of corticocortical connections at orientation centers might be radically different from that of orientation domains (Tóth E., Bonhoeffer T., Eysel U.T., Kisvárdy Z.F., in this volume). It would be interesting to know whether a similar difference is also present between the axonal topography of individual cells of orientation domains and of orientation centers.

This work was supported by the Deutsche Forschungsgemeinschaft (Ey 8/23).

## 360.15

NEURAL CORRELATES OF CUE-INVARIANT BOUNDARY PERCEPTION. Y.-C. Wang\*, D. Liu, S.J. Ault, and A.G. Leventhal, Dept. of Neurobiology and Anatomy, Univ. of Utah Sch. of Med., Salt Lake City, UT 84132.

The purpose of this study was to determine if cue invariant (CI) cortical cells can integrate multiple cues that simultaneously define a boundary. We tested the responses of CI cells to boundaries defined by texture, relative motion, illusory contours and luminance in various combinations. The salience of the boundaries was varied by altering the texture, motion, illusory contour generating stimuli and luminance levels defining the boundaries. CI cells in area 18 of cat visual cortex responded more strongly to more salient stimuli. This was true when the increased salience resulted because a more salient cue was used (i.e. a more salient texture versus a less salient texture) as well as when two or more less salient cues (i.e. a less salient texture combined with a less salient motion or a less salient luminance) defined the boundary. Clear orientation and direction selective responses could be evoked when a texture boundary that was not salient enough to elicit a response (subthreshold texture) was combined with a motion or luminance boundary that was not salient enough to elicit a response (subthreshold motion or subthreshold luminance).

Our results indicate that CI cortical cells can extract and integrate linear and directional information about boundaries using multiple cues simultaneously. These cells may provide the neural substrate for cue invariant boundary perception. Supported by EY04951 to A.G.L.

## 360.12

CORTICOCORTICAL CONNECTIONS SHOW LOW ORIENTATIONAL SPECIFICITY IN AREA 18 OF CAT VISUAL CORTEX. E. Tóth\*, T. Bonhoeffer, U.T. Eysel, Z.F. Kisvárdy\*, Ruhr-Universität Bochum, Institut für Physiologie, 44780 Bochum, Germany, Max-Planck Institut für Psychiatrie, Am Klopferspitz 18A, 82152 München, Germany.

In area 17, corticocortical connections were shown to link similar orientation preferences (Gilbert and Wiesel, 1989) while in area 18 were shown to link dissimilar orientation preferences (Matsubara et al, 1985). We revisited this conundrum by examining the orientational specificity of excitatory and inhibitory connections in an orientation map obtained with optical imaging of intrinsic signals. In the center of an orientation domain biocytin was iontophoretically injected into layer III. All labeled structures were reconstructed in a horizontal plane from the entire depth of the cortex with the help of a 3-dimensional reconstruction system (NeuroLucida). Labeled excitatory boutons and somata were distinguished from labeled inhibitory boutons and somata on the basis of morphological features (Kisvárdy et al., in this volume). Additionally, parvalbumin (PV) immunohistochemistry was applied to determine the distribution of GABAergic somata contacted by labeled inhibitory basket axons (Kisvárdy et al, 1993). The resulting anatomical maps were aligned and quantitatively compared with the corresponding orientation map. The orientation map was dissected into iso- ( $\pm 30^\circ$ ), oblique- ( $\pm[30-60]^\circ$ ) and cross- ( $\pm[60-90]^\circ$ ) orientational zones with respect to the average orientation preference at the injection site. The results showed that: (a) of the excitatory boutons an average of 48.1% occupied iso-, 30.3% oblique- and 21.6% cross-zones, (b) of the inhibitory boutons an average of 35.1% occupied iso-, 36.8% oblique- and 28.1% cross-zones. Retrogradely labeled somata showed the following distribution at iso-, oblique- and cross-orientation sites, respectively: of the pyramidal type 63%, 22.3% and 14.5%, of the inhibitory type (large basket cell) 31.3%, 25% and 43.7%, of the unknown type 87.7%, 5.8% and 6.5%, in total (all types included) 72.3%, 15.1% and 12.6%. Immunopositive PV somata receiving basket cell input showed almost equal distribution regarding iso- (33.1%), oblique- (33.1%) and cross-orientation (33.8%).

In summary: (i) although the remote patches of excitatory corticocortical connections are centered on similar orientations (Kisvárdy et al, 1993) on the global scale they are less specific showing only a bias to similar orientations, (ii) inhibitory corticocortical connections by large basket cells also target regions of all orientations, however, with a bias to dissimilar orientations. Interestingly, the network of PV-positive cells contacted by basket cells showed no specificity at all orientational zones. This work was supported by the Deutsche Forschungsgemeinschaft (Ey 8/23).

## 360.14

CUE-INVARIANT ORIENTATION AND DIRECTION SENSITIVITY OF CELLS IN EXTRASTRIATE VISUAL CORTEX. D. Liu, Y.-C. Wang, S.J. Ault, and A.G. Leventhal\*, Dept. of Neurobiology and Anatomy, Univ. of Utah Sch. of Med., Salt Lake City, UT 84132.

The purpose of this study was to determine if cortical cells have the computational power to analyze complex stimuli that give rise to the perception of a boundary in the absence of a luminance boundary. The stimuli we employed included boundaries defined by relative motion (motion-defined boundaries), differences in textures (texture-defined boundaries), illusory contours, and luminance-defined boundaries (bars and gratings).

We find that many complex cells in area 18 of cat visual cortex respond to boundaries defined by motion, texture, illusory contours and luminance. Individual cells responded to boundaries regardless of the cue defining the boundary. Cue invariant (CI) cells exhibited clear orientation and direction selectivity when tested with all types of boundaries. The degree of selectivity did not vary significantly when individual CI cells were tested with boundaries defined by different cues. In addition, when boundaries were made more salient by varying the texture, motion, illusory contour or luminance defining them, the responses of CI cells increased accordingly.

Our results indicate that cells responding selectively to boundaries in a cue invariant fashion occur at relatively early stages in visual cortex. Supported by EY04951 to A.G.L.

## 361.1

PARALLEL TIME COURSES OF AGE-RELATED ANATOMICAL CHANGES IN THE ANTEROVENTRAL COCHLEAR NUCLEUS AND PROGRESSIVE HEARING LOSS IN MICE. J.F. Willott\* and L.S. Bross. Dept. Psychology, Northern Illinois Univ., DeKalb, IL 60115.

This study tests the hypothesis that cochlear pathology modulates age-related neuronal changes in the anteroventral cochlear nucleus (AVCN). Measurements of AVCN neuronal number, size, and neuropil volume were made on mice of the DBA/2J (DBA) and C57BL/6J (C57) strains at ages ranging from 15 days to 2 years and on CBA/J (CBA) mice aged 1 month to 2 years. DBA and C57 mice possess genes that cause progressive cochlear pathology and hearing loss. DBA mice exhibit some threshold elevations by 4 weeks of age and this becomes severe by 2 months. C57 mice hear well through 1-2 months of age then exhibit hearing loss progressing gradually over the next 12 months. CBA mice hear well through 2 years of age. The hypothesis predicts that the time course of AVCN changes would parallel that of cochlear dysfunction, and this was supported by the results. The period between 2 and 3 weeks of age appeared to be one of growth in both DBA and C57 mice, as AVCN volume increased. In DBA mice, AVCN volume decreased after 23 days and significant neuronal loss occurred by 31 days, coinciding with the early onset of progressive hearing loss. In C57 mice, changes were not significant until 7 months of age. In CBA mice, AVCN volume continued to increase for the entire first year of life, and no loss of neurons was observed. Another observation was that the age-related loss of volume and neurons were greater in DBA mice than in C57 mice.

Supported by NIH grant 1 R37 AG07554-7.

## 361.3

TEMPORAL ACUITY FOR ACOUSTIC TRANSIENTS FOLLOWING AUDITORY CORTICAL LESIONS IN RODENTS, IN COMPARISON TO AGE EFFECTS. D.Y. Lin, J.R. Ison, M.K. Taylor, G.P. Bowen, & W.E. O'Neill\*. Departments of Psychology and Physiology, University of Rochester, Rochester NY 14627.

Age-related decrements in speech perception ("presbycusis") can be attributed to peripheral changes in audibility or to distortion, perhaps with a central neural component. Temporal lobe damage also diminishes speech recognition ("word deafness"), which has been attributed to a high-level deficit in language processing. Recent reviews (Phillips & Farmer, 1990, Beh Brain Res) suggest, however, that word deafness lies in the central processing of acoustic transients, as is seen, e.g., in temporal acuity for gaps in noise. Using startle reflex modulation audiometry, we find that rats with temporal lobe lesions and substantial medial geniculate degeneration lose noise-gap detection, with no change in light-gap detection or peripheral function. (These data capture a case report in Buchtel & Stewart, 1989, Brain & Lang). Noise increment deficits were apparent at first but recovered in 3 months, while gap detection only partly recovered. Old CBA mice (> 24 vs 3 mo) also showed deficits in noise gaps with near normal responses to noise increments, and differed from brain damaged rats largely in their having ABR and noise offset deficits. The data reveal that gap detection is not solely provided by the increment in noise that ends the gap, but depends further on an active inhibition of neural activity within the gap to provide contrast at noise onset. The overall outcome supports the idea that inhibitory deficits at central auditory sites are responsible for a loss of temporal acuity and the resulting distortion of complex acoustic input in brain damaged and aged rodents and humans.

(Supported by NIH Grants AG09524 & EY01319, & RCHSR)

## 361.5

AGING-RELATED CHANGES IN CONNECTIONS TO A FUNCTIONALLY-CHARACTERIZED REGION OF THE INFERIOR COLLICULUS OF THE CBA MOUSE MODEL OF PRESBYCUSIS. R.D. Frisina\*, J.P. Walton, M.A. Lynch-Armour and J.D. Byrd. Otolaryngology Div., Univ. Rochester School of Medicine, Rochester, NY 14642-8629, USA.

Explorations of the neural basis of presbycusis have implicated changes in the cochlea and brain. We previously discovered that the proportion of neurons capable of encoding short noise gaps (1-2 ms) in central nucleus of the inferior colliculus (ICC) of old CBA mice declines relative to young adults (Walton *et al.*, *Assoc. Res. Otolaryngol. Abstr.*, 17:83, 1994). To start to ascertain why this occurs, injections of HRP were made following these recordings in dorsomedial ICC in 18-24 kHz region of CBA mice, 3 ages: Young adult, 2-4 mon (N=5); Mid age, 14-16 mon (N=4); Old, 22-27 mon (N=5). Retrogradely labeled perikarya were found in the brainstem. Analyses revealed: 1) The density of HRP in retrogradely stained perikarya declined with age; 2) The number of labeled cells in some nuclei such as the superior olivary complex (SOC) remained stable, whereas others decreased with age. The latter included statistically significant reductions in all 3 contralateral cochlear nucleus (CN) divisions and the ipsilateral anterolateral periolivary nucleus of the SOC. Cell counts and output analyses of other regions are currently being analyzed. Declines in inputs from the CN and other areas may underlie physiological and psychophysical degradations in temporal and speech processing, characteristic of presbycusis. Supported by NIH Grant P01 AG09524 and the International Center for Hearing & Speech Research - Rochester, NY.

## 361.2

SPEECH RECOGNITION PERFORMANCE IN NOISE BY PRESBYCUSIC SUBJECTS. D.R. Frisina, D.G. Sims and J.R. Ison\*. Dept. of Communications Sciences, Rochester Institute of Technology, Rochester, NY 14623-0887, USA.

Previous speech recognition experiments with presbycusic subjects have suggested changes in the cochlea and central auditory pathways. This study is part of a larger multi-disciplinary program-project effort to determine the role of the central auditory system in presbycusis. We explored speech recognition aging-effects with three measures used under two intensity levels and two types of background noise. Age-effects on speech recognition in noise performance were evaluated in two groups of young and old normal-hearers (N=40), matched for absolute hearing sensitivity. In addition, the effect of hearing loss on speech recognition in noise performance was examined by comparing the performance of old subjects with mild hearing impairment (N=30) to that of the old normal-hearing group. Speech recognition in noise performance results revealed reduced performance of aging subjects with otherwise normal absolute sensitivity thresholds relative to the young subjects. In addition, the effect of mild hearing loss was explored in old subjects. This study begins to examine functional assessment of aging changes in the peripheral and central components of the human auditory system.

## 361.4

PARADOXICAL GAP DETECTION THRESHOLDS OF MOUSE INFERIOR COLLICULUS NEURONS IN BACKGROUND NOISE. W.W. Wilson\*, J.P. Walton and R.D. Frisina. Div. of Otolaryngology, Univ. of Rochester, Rochester, NY 14642-8629, USA.

A common psychophysical measure of auditory temporal acuity is the detectability of a silent gap in an ongoing signal. Gap detection thresholds measured psychophysically decline when background noise is added to the silent interval (Forrest and Green, 1987, JASA 82(6)). We recorded the response of IC neurons in 2 month old C57BL/6 mice to a gap-detection paradigm in a search for physiological correlates to this psychophysical degradation of temporal processing in background noise.

Neurons were characterized by their best frequency, threshold for tones and wideband noise, rate/intensity functions, and minimal gap threshold (MGT). "Gap series" typically consisted of two wideband noise bursts at 65 dB SPL, separated by a silent gap ranging from 0 ms (control) to 96 ms long. MGT was defined as the shortest gap duration capable of eliciting a discrete neural response evident in PST histograms. After determining MGT in quiet, gap series were run in continuous background noise at 6 dB intervals below the signal level. Recording sites were verified by HRP histochemistry.

Phasic and tonic units typically had MGTs under 10 ms and background noise tended to increase MGT. Inhibitory units had much higher MGTs, corroborating findings in the avian forebrain (Buchfeller *et al.*, 1989; J Comp Physiol A: 164). Surprisingly, MGTs improved in poor signal/noise conditions for inhibitory units. MGT was shortest for the highest background noise conditions and gradually became longer with increasing signal/noise ratio. Inhibitory units may therefore play an important role in auditory temporal processing under poor signal/noise conditions. NIH-NIA Grant P01 AG09524 and the International Center for Hearing and Speech Research, Rochester, NY.

## 361.6

CALCIUM BINDING PROTEIN AND GABA IMMUNOREACTIVITY IN THE INFERIOR COLLICULUS OF THE AGED CBA/J MOUSE MODEL OF PRESBYCUSIS. M.L. Zettel\*, W.E. O'Neill\*, R.D. Frisina. Depts of Surgery (ENT Div.) & Physiology, University of Rochester School of Medicine, Rochester, N.Y. 14642-8629, USA.

As part of ongoing research to examine the auditory system of the aged mouse model of presbycusis we have analyzed the inferior colliculus (IC) using antibodies against the inhibitory neurotransmitter GABA and the calcium binding proteins calretinin (CR), calbindin (CB), and parvalbumin (PV). Following measurement of ABR audiograms and gap detection thresholds in a startle response inhibition paradigm, the brains of young (4-6 mon. old) and old (>24 mon. old) CBA/J mice were immunoreacted with an antibody against GABA (5 mice each age group) or with antibodies against CR, CB and PV (5 mice each age group). In the old mice ABRs showed an average flat loss of 20-30 dB from 4 to 80 kHz and gap detection showed deficits consistent with a loss of central inhibitory mechanisms involved in temporal processing.

GABA is abundant in the IC and may be important for temporal acuity. GABA(+) cells were numerous and evenly scattered throughout the IC in both age groups. However, four of the five old mice showed an average 24% decrease in the number of GABA(+) cells in the central nucleus of the IC (ICC); the fifth mouse showed an increase. Calcium binding proteins are abundant in the auditory system, and are a possible protective or regulatory mechanism against calcium induced neurotoxicity. CR(+) cells were numerous in the dorsal cortex, external cortex, commissural nucleus, and the brachium of the IC. They were rare and widely scattered in the ICC. A 26% increase in the number of CR(+) cells was observed in the old IC. An analysis of CR(+) cell types is underway. PV staining was intense in both cell bodies and neuropil in all divisions of the IC while CB antibody stained only a few scattered cells. Comparative counts and densitometry are in progress. Supported by NIA P01-AG09524 and the International Center for Hearing and Speech Research.

**AUDITORY PATHWAYS OF A SONIC FISH (*Pollimyrus*).**

James Kozloski, John D. Crawford,\* Inst Neurological Sci & Psychology Dept, U of Pennsylvania, Philadelphia, PA 19104.  
*Pollimyrus* (Mormyridae) has been of interest in neuroethological studies of hearing and communication because of its specialized ears and simple acoustic repertoire. Neurophysiological studies have focused on the response properties of the midbrain nucleus MD, and have revealed complex specificity which likely plays a role in processing communication signals. In an effort to understand both the emergence of these properties and the fate of information extracted in the midbrain, we have investigated anatomically both inputs from the medulla and outputs to the diencephalon and optic tectum. Using double barrel electrodes, we have physiologically characterized auditory areas then injected biotin-based pathway tracers at recording sites within the auditory pathway. Biocytin injections into MD revealed multiple areas in the medulla which project to MD via an organized fiber sheet within the lateral lemniscus (LL). Groups of cell bodies were labeled contralateral to the injection site near the LL and MD (ie. nLL), further posterior on the midline at the ventral margin of the cerebellar crest cell layer (cc), and bilateral and slightly ventral relative to cc (Bell's nucleus octavus). In addition to these three groups of cell bodies presumably afferent to MD, bilateral terminal fields were labeled more ventral, possibly a nucleus receiving descending inputs from the midbrain. Physiological recordings from these medullary sites revealed clear transformations along this pathway, from the medulla to the midbrain. [NIDCD R01 1252; PAL HRF GA1205; U of P Res F]

## 361.9

**CELL DEATH IN THE NUCLEUS LAMINARIS AND NUCLEUS MAGNOCELLULARIS OF THE BARN OWL (*Tyto alba*).** D. P. Massoglia, C. E. Carr\*, Dept. of Zoology, Univ. of Maryland, College Park, MD 20742.

During embryonic development of the chicken auditory system there is approximately 80% cell death in the Nucleus Laminaris (NL) and 30% cell death in the Nucleus Magnocellularis (NM) (Rubel, Smith & Miller, 1975). The Barn Owl (*Tyto alba*) has a specialized auditory system, and substantially more cells in NL and NM than in the adult chicken (Winter & Schartzkopf, 1961). At least two mechanisms may underlie this hypertrophy: an increase in cell proliferation and/or a decrease in cell death. Since cell birth in the owl NL and NM is complete by E8 (Carr & Cohen, unpublished observations), owl embryos were examined after E15, when cells were considered post-mitotic and migration to the nuclei complete. Embryo ages were also chosen to correspond with the onset of cell death observed in the chicken (E9, or 40% of incubation time). Owl embryos of age E8,17,18,20,22,23 and 35 post fertilization and an adult brain were either embedded in paraffin (10µm), or plastic (8µm; E18, E20) and counterstained. Nuclear profiles in both NL and NM were counted in every other section, and corrected total counts were obtained for each series (Coggeshall, 1992). At E18, the owl NL and NM contain a larger number of neurons than the E9 chicken. Substantial cell death was also observed. Thus the hypertrophied auditory brainstem of the adult Barn Owl appears to be regulated by increased cell proliferation and by cell death. At present we do not know whether the rate of cell death is less than that observed in the chicken.

## 361.11

**THE DEVELOPMENT OF POSTNATAL OLIVOCOCHLEAR NEURONS: IS IT COMPETITION OR A WAITING PERIOD?** D.D. Simmons\*, J.H. Kim, and N. Moore, Dept. of Physiological Science and Brain Research Institute, UCLA, Los Angeles, CA 90095-1527.

As neurons grow toward their target cells, they synthesize specific neurotransmitters that are important for mature function. Previous studies have suggested that periolivary (PO) olivocochlear (OC) neurons wait for a defined period below inner hair cells (IHCs) in the cochlea before growing towards the outer hair cells. The OC system is the major efferent pathway to the cochlea and is responsible for modulating activity of the cochlear nerve. Choline acetyltransferase (ChAT), calcitonin gene-related peptide (CGRP), and glutamate decarboxylase (GAD) serve as neurochemical markers for OC neurons. Standard immunocytochemical techniques were used to study the development of neurotransmitter expression in OC neurons that were defined on the basis of tracer injections into the crossed OC bundle.

ChAT-immunoreactive cells were first detected in the superior olive around postnatal days (P) 5-6. ChAT-positive cells in PO regions had larger somal sizes and had multipolar shapes with an average of 3 primary dendrites while ChAT-positive cells in the lateral superior olive (LSO) were smaller and had more fusiform shapes with an average of 2 primary dendrites. CGRP-positive cells co-labeled with ChAT-positive cells in the LSO. GAD-positive cells in the LSO were identified at P12.

ChAT immunoreactive terminals in the cochlea were first detected at P4 in basal regions below IHCs. CGRP-positive terminals did not label until P6. GAD-positive terminals were not present below IHCs at P6 but were found below IHCs at P12.

Thus, ChAT expression occurs just prior to CGRP expression, at a time when GAD expression is absent. This raises the possibility that cholinergic OC neurons may competitively interact.

## 361.8

**THREE-DIMENSIONAL MORPHOLOGY OF SPECIALIZED SYNAPSES IN COCHLEAR NUCLEI OF THE NEWLY HATCHED CHICKEN.** E.G. Dobbins\* & G. Laurent, Division of Biology, 139-74, California Institute of Technology, Pasadena, CA 91125.

The cochlear branch of the eighth cranial nerve (VIII<sub>n</sub>) innervates both nucleus angularis (NA) and magnocellularis (NM) in the owl (Carr & Boudreau, *J. Comp. Neurol.* 314(91):306-318; Köppl, *J. Comp. Neurol.* 339(94):438-446) and chicken (Jhaveri & Morest, *Neurosci.* 7(82):809-836). Although single axons have collaterals to both nuclei in owl, this has not been established in chicken. Biotinylated dextran amines (m.w. 10,000) were injected into the cochlea of newly hatched chickens. After survival times of two weeks, the chickens were perfused and brainstems processed with avidin-biotin and cobalt-intensified '3'3'5'5' Diaminobenzidine. The afferent and synaptic morphology was analyzed with light and laser scanning confocal microscopy. The afferents enter the rostral medulla in a dorsolateral position, ascend dorsomedially between the two nuclei, and branch, entering each nucleus from its dorsal aspect. Single axons send collaterals to NA and NM in chicken. Each of these collaterals supports synapses with different morphology in the two nuclei: boutons in NA and end-bulbs in NM. Three-dimensional reconstructions of a single synapse in NM, from confocal microscopy, show its highly specialized character. Supported by NIMH and NSF-PFF (GL).

## 361.10

**CALCITONIN GENE-RELATED PEPTIDE IMMUNOREACTIVITY IN THE CHICK BRAINSTEM.** R.A. Cude\*<sup>1</sup>, M.S. Darr and C.E. Carr

Dept. of Zoology, Univ. of Maryland, College Park, MD 20742-4415 and <sup>1</sup>Dept. of Biology, Texas Woman's University, Denton, TX 76204-3799.

In the mammalian brainstem, calcitonin gene-related peptide-immunoreactivity (CGRP-I) is found within neurons of cranial motor nuclei, preganglionic parasympathetic motoneurons, in vestibular efferent neurons and in some olivocochlear (OC) neurons. Within the OC system, CGRP-I is localized primarily within cell bodies, nerve fibers and terminals of the lateral OC (LOC) division which terminate on auditory nerve endings under inner hair cells in the ipsilateral cochlea. In contrast, most neurons of the medial OC (MOC) division, which project predominantly to the base of outer hair cells in the contralateral cochlea, lack, or have much lower levels of, CGRP-I. Both LOC and MOC neurons are immunoreactive for choline acetyltransferase (ChAT), the biosynthetic enzyme for acetylcholine. In the chick, ChAT-immunoreactive (ChAT-I) neurons projecting to the inner ear are also found in two groups in the brainstem. We wished to determine whether chick cochlear efferent neurons could be divided into two neurochemically distinct groups based on their CGRP-immunoreactivity. We combined immunohistochemistry using antisera to ChAT and CGRP with the retrograde transport of rhodamine dextran amine from the inner ear. CGRP-I was found in neurons of cranial motor nuclei and scattered around the superior olive. Unlike mammals, however, chick cochlear efferent neurons do not appear to contain CGRP-I, or they have CGRP levels that are too low to be detected immunohistochemically.

The ChAT antiserum was kindly provided by Dr. Miles Epstein, U. Wisconsin Madison; the CGRP antibody was donated by Dr. Catta Sternini, UCLA. This work was supported by NIDCD grants DC01867 (RAC), DC00436 (CEC) and a Howard Hughes Fellowship (MSD).

## 361.12

**DEVELOPMENTAL CHANGES IN GLUTAMATE RECEPTOR SUBUNIT IMMUNOCYTOCHEMISTRY IN THE NEONATAL GERBIL COCHLEAR NUCLEUS.** J.R. Schwartz\* and P.R. Eager, Dept. of Surgery/Otolaryngology, Yale Univ. Sch. of Med., New Haven, CT 06520

Cryostat sections of aldehyde fixed brains from neonatal gerbils (at postnatal day (P) 7,14,21,28) & adult animals were incubated with antibodies (Ab) recognizing the glutamate receptor subunits GluR1, 2/3, or 4 (Chemicon) and examined light microscopically.

In the youngest animals there was a high level of diffuse staining throughout the cochlear nucleus (CN) and the entire brainstem. With increasing age, the brain showed a decrease in this diffuse stain more marked in some areas. With GluR1 and 2/3, lightly stained somata were present close to the ependymal surface of the dorsal CN (DCN) at P7 and there was a thin region of slightly darker diffuse staining in the region of the molecular (ML) & cellular (CL) layers. At P14 the ML & CL of the DCN were notably darker than the deep layer (DL). Diffuse staining of DL decreased progressively from P7-P28. Diffuse staining of ML & CL was most intense at P14 & P21 with some decrease at P28. GluR4 produced little if any differential diffuse staining of ML & CL compared to DL at all ages.

Medium sized somata scattered throughout the ML & CL, including those with the size and distribution of cartwheel cells, were progressively more darkly stained by GluR1 & 2/3 from P7-P21, with a slight decrease at P28. More somata and their dendrites were darkly stained by GluR2/3 than GluR1 in the ML & CL, their size and location suggesting that they were both cartwheel and fusiform cells. With GluR4 cellular staining in DCN was relatively light. GluR1 & 2/3 produced little staining of cells in the octopus cell area (OCA) compared to GluR4. OCA cells stained progressively more darkly with GluR4 from P7-P21, and slightly less darkly at P28. Diffuse staining of the OCA neuropil declined from P7 to 28 with all Abs.

While GluR1,2/3 & 4 may all be present in DCN cartwheel cells, comparison of sections from a single animal indicate that at P14 GluR1 is preferentially present in cartwheel cells, GluR2/3 in fusiform cells & dendrites and GluR4 in octopus cells. The increase in staining at P14 & P21 is consistent with the development & functional maturation of synapses over this time. The decreased somatic and neuropil staining at P21 & P28 probably reflect the incorporation of subunits into functional receptors at the synapses and their removal from the cytoplasm. Supported by NIDCD DC00132.

## 361.13

**DIFFERENTIAL CELL BIRTH OF THE PERIOLIVARY NEURONS IN THE RAT.** M. Kudo<sup>1</sup>, Y. Kitao<sup>1</sup> and S. Higo<sup>2</sup>\*

<sup>1</sup>Dept. of Anatomy, Sch. of Med., Kanazawa Univ., Kanazawa 920, Japan and <sup>2</sup>Dept. of Morphological Neural Sci., Kumamoto Univ. Med. Sch., Kumamoto 860, Japan.

In a recent study (Kudo et al. 1992) we provided evidence that neurons having different laterality of projections have different birthdays in the lateral (LSO) and the medial (MSO) superior olive. The present study is aimed at examining the birth dates of the periolivary nuclei neurons which exhibit various morphology and different laterality of projections to the inferior colliculus (IC). Rat fetuses were exposed to 5-bromodeoxyuridine (BrdU), the thymidine analogue, in utero to label neurons proliferated at different embryonic days (E). Upon reaching adulthood, rats were given injections of Fluoro-Gold (FG) into the IC unilaterally to identify the laterality of the projection and the cell morphology by the retrograde labeling. The results indicate that neurogenesis in the periolivary nuclei are between E12 and E16. The superior paraolivary nucleus (SPN) neurons were generated on E12 and E14 with a strong peak on E13. The medial nucleus of the trapezoid body (MTB) neurons were generated mainly on E14, although they did not project to the IC (BrdU+ and FG-). In the ventral nucleus of the trapezoid body (VTB), many of the IC projecting neurons (BrdU+ and FG+) were produced on E14, while non-IC projecting neurons (BrdU+ and FG-) were on E15.

## 361.15

**AGE-DEPENDANT DEGENERATION OF SPIRAL GANGLION CELLS IN WILD TYPE MICE.** S. Dazert, M.L. Feldman and E.M. Keithley\*. Division of Otolaryngology, UCSD Sch. of Med., La Jolla, CA 92093-0666.

Age-related hearing loss in humans typically shows a bilateral sensorineural hearing impairment, predominantly with high-frequency sounds. In coincidence with the audiometrical findings histological examinations of temporal bones show pathological changes at the basal end of the cochlea. Investigations of pathological changes in rodent cochleas as a function of age revealed varying results in different species. In aging rats and gerbils a decreased number of spiral ganglion cells (SGCs) was mainly detected in both the basal and apical turns of the cochlea. In contrast to these findings other investigators described genetically inbred C57BL/6 aged mice with the main loss of SGCs in the basal turn.

The aim of this study was to investigate the cochlea and especially the SGC density as a function of age in wild type pigmented mice to determine the pattern of degeneration. Three groups of different ages ranging from 2 to 31 month were studied. Each group contained 3 or 4 animals. Either the left or right ear was chosen randomly and prepared for histological examination of plastic sections using light microscopy. In middle aged wild type mice (18-19 month old) the main loss of SGCs occurred in the basal turn (49% loss compared to 2-3 month old animals) followed by the apical turn (31%). The greatest SGC losses in 28-31 month old wild type mice were present at the apical region of the cochlea (76%) followed by the basal turn (74%). The mid-region showed a 45% decrease of SGCs. The oldest animals also had degenerative changes in the stria vascularis in the apical turn.

These findings lead to the assumption that age-dependent degeneration of the spiral ganglion in mammals including humans occurs over the entire length of the cochlea with emphasis on the both ends of the cochlea.

## 361.17

**P<sub>1</sub> PURINOCEPTOR AGONIST STIMULATES ANTIOXIDANT ENZYMES IN THE COCHLEA OF CHINCHILLA.** M.S. Ford, S.B. Maggirwar, C. Whitworth, L.P. Rybak, D.M. Caspary\* and V. Ramkumar. Dept. of Pharmacology, Southern Illinois Univ. Sch. of Med., Springfield, IL 62704

In an initial step towards assessing the role of purinergic receptors in the peripheral auditory system, we have begun to characterize the subtypes of P<sub>1</sub> purinoceptors in the cochlea. Both the A<sub>1</sub> and A<sub>3</sub>, adenosine receptor (AR) were detectable in membranes prepared from the cochlea, using [<sup>3</sup>H]CPDPX and [<sup>125</sup>I]APNEA, respectively. The estimated number of A<sub>1</sub> and A<sub>3</sub>AR (B<sub>max</sub>) were 368 and 175 fmol/mg protein with equilibrium dissociation constants (K<sub>d</sub>) averaging 5.6 and 9.9 nM, respectively. In membrane preparations, R-phenylisopropyladenosine (R-PIA, 1 μM) elicited a small degree of inhibition of adenylyl cyclase activity, which was only partially blocked by theophylline (100 μM). Activation of the cochlear ARs by round window application of R-PIA had no effects on auditory measures such as endocochlear potential and compound action potential. However, treatment of R-PIA for 1 h elicited significant increases in the activities of antioxidant enzymes such as superoxide dismutase, catalase and glutathione peroxidase which were reversed by theophylline (1 mM). These studies suggest that while adenosine may not contribute directly to the propagation of an auditory signal, it might provide cytoprotection against oxidative damage to structures in the cochlea intimately involved in the processing of auditory signals.

## 361.14

**GROWING AUDITORY AFFERENTS IN THE TRAPEZOID BODY RECOGNIZE THE MIDLINE.** L.S. Ross\*

Neurobiology Program, Dept. of Biological Sciences, Ohio University, Athens, OH 45701.

During development of the auditory system, axons from the cochlear nucleus must make connections with a number of specific auditory nuclei in the superior olivary complex of the brainstem. Many of these axons bypass ipsilateral olivary nuclei, cross the midline, and innervate contralateral olivary nuclei. The cues that guide these outgrowing auditory axons are poorly understood. Using Dil as a neuronal tracer, I have investigated the morphology of axonal growth cones at various points along the trapezoid body in the developing mouse embryo. During embryonic days 12-18, labeled growth cones were found throughout the trapezoid body and auditory nuclei. Growth cones within auditory nuclei were larger and had more filopodia than growth cones in fiber tracts. Growth cones also displayed a more complex morphology at the midline and appeared to defasciculate from other axons at this point. As axons reached the midline, they did not cross directly; rather they made a dorsal turn, crossing the midline at an angle, and then refasciculated and returned to a more ventral trajectory. Acetylcholinesterase histochemistry revealed a population of cells residing at the midline that differentiate just prior to the arrival of these auditory afferents. These results suggest that outgrowing auditory afferents may recognize and use the midline as a guidance cue.

**4-METHYLTHIOBENZOICACID PROTECTION AGAINST CISPLATIN OTOTOXICITY: CORRELATION OF AUDITORY BRAINSTEM RESPONSES AND THE ANTIOXIDANT SYSTEM.** C. Morris, K. Husain, C. Whitworth, L. Evenson, S.M. Somani, and L.P. Rybak\*. Department of Pharmacology and Surgery, Southern Illinois University School of Medicine, Springfield, Illinois 62794-9230.

This study investigates the auditory brainstem responses and antioxidant system in cisplatin-induced ototoxicity and the otoprotection with 4-methylthiobenzoic acid (MTBA). Male Wistar rats were injected with 1) saline for control animals, 2) cisplatin (16 mg/kg, i.p.), 3) MTBA (250 mg/kg/i.p.), 4) cisplatin plus MTBA. Rats were subjected to auditory brainstem response (ABR) recording prior to sacrifice (three days post-treatment) and cochlae were isolated and were analyzed for lipid peroxidation (MDA), superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GSH-Px) and glutathione reductase (GR). Glutathione (GSH) and oxidized glutathione (GSSG) were also analyzed in the cochlea. Cisplatin elevated the ABR thresholds and increased the cochlear MDA level (20%) whereas reduced glutathione (GSH) level, SOD, CAT, GSH-Px and GR activities decreased 23, 43, 15, 22, and 48% respectively. Pretreatment with MTBA demonstrated smaller ABR threshold shifts and normalized the activities of antioxidant enzymes, GSH, and MDA levels. These results suggest that MTBA provides otoprotection against cisplatin-induced ototoxicity by enhancing antioxidant system. Supported by NIH RO1 DC 0239601.

## 362.1

GLUTAMATERGIC AND GABAERGIC POSTSYNAPTIC RESPONSES OF STRIATAL SPINY NEURONS TO INTRASTRIATAL AND CORTICAL STIMULATION. H. Kita\*, Dept. Anatomy, and Neurobiol. Coll. of Med., Univ. of Tennessee, Memphis, TN 38163.

Glutamatergic and GABAergic responses of the neostriatal (Str) spiny neurons to Str and cortical (Cx) stimulation were characterized by intracellular recording in slice preparations. Single Str or Cx stimulation induced a fast AMPA/kainate-receptor mediated PSP followed by a slow NMDA-receptor mediated PSP. The NMDA-response was small in neurons at resting membrane potential but became a significant component when the neurons were depolarized to subthreshold membrane potential. Repetitive Str or Cx stimulation induced a large, long duration depolarization with spikes in Str spiny neurons. Application of CPP reduced the amplitude of the response to the subthreshold level of spike generation. BMI, on the other hand, greatly increased the response amplitude and the number of spikes. The AMPA/kainate-response, which was isolated by BMI and CPP, alone can not induce sustained depolarization in spiny neurons to repetitive stimulation. Application of NBQX abolished GABA<sub>A</sub>-response of spiny neurons to Cx stimulation, indicating that, in order for Str spiny neurons to respond with GABA<sub>A</sub>-response after Cx stimulation, the AMPA/kainate-response must be induced in the GABAergic secondary neurons in the Str.

This study indicates the main synaptic driving forces of Str neurons include AMPA/kainate-, NMDA- and GABA<sub>A</sub>-responses. Although AMPA/kainate-response is the main synaptic input, the generation of action potentials in Str neurons is greatly influenced by both GABA<sub>A</sub>- and NMDA-responses. Supported by NS-25783 and NS-26473.

## 362.3

ADENOSINE A1 RECEPTOR MODULATION OF CORTICO-STRIATAL SYNAPTIC POTENTIALS. D.R. Stevens\*, I. Flügge and H.L. Haas Physiologisches Institut II, Heinrich-Heine-Universität, Postfach 101007, Düsseldorf, D-40001 Germany

The striatum contains relatively high levels of adenosine receptors. We have therefore examined the role of adenosine in the striatum using intracellular recording in a rat corticostriatal slice.

Adenosine reversibly reduced corticostriatal EPSPs in most neurons. This action was mimicked by the A1 agonist N<sup>6</sup>-cyclopentyl adenosine (CPA) but not by the A2 agonist 5'-(N-cyclopropyl) carboxyamido-adenosine. Adenosine did not decrease input resistance. DPCPX (an A1 antagonist) blocked the action of adenosine and enhanced EPSPs. Inhibition by CPA, but not by adenosine, was accompanied by enhanced paired-pulse facilitation. The lack of enhancement during adenosine treatment may indicate a competing action at an A2 receptor. These results are consistent with the reported inhibition of corticostriatal EPSPs by adenosine and suggest that endogenous adenosine acting at A1 receptors modulates activity and may be protective against excitotoxicity in the striatum.

In neurons not exhibiting the properties of principal neurons, adenosine did not depress evoked EPSPs. Corticostriatal activation of cholinergic interneurons is spared under these conditions and may result in increased vulnerability of interneurons to excitotoxicity.

Supported by SFB 194.

## 362.5

PERIODIC AND STOCHASTIC COMPONENTS OF THE SUBTHRESHOLD MEMBRANE POTENTIAL OF CORTICOSTRIATAL AND STRIATAL NEURONS RECORDED *IN VIVO*. E.A. Stern\* and C.J. Wilson, Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, TN.

*In vivo* recordings of identified corticostriatal projection neurons and striatal medium spiny neurons in rats anesthetized with urethane show that these neurons exhibit spontaneous, subthreshold membrane potential shifts. The depolarized (Up) state of the neurons results from convergent synaptic activity interacting with the membrane rectification properties.

Fourier analysis of the membrane potential in the  $\leq 100$  Hz range reveals three constituent parts of the spectrum: A periodic component of  $\sim 0.1$ -1 Hz contributed to the timing of the spontaneous subthreshold shifts. The presence of a stochastic component was indicated by low-frequency noise with approximately 1/f decay, which was present primarily in the Up state. An additional white noise component was present in both the Up and Down (hyperpolarized) states. In corticostriatal neurons, the 1/f component often showed a significant peak at  $\sim 40$  Hz.

The frequency components of the membrane potential state transitions are within the range described for cortical slow oscillations. However, the pattern of state transitions could not be approximated by a single periodic function. The Up and Down state durations are stationary within each neuron, enabling classification of the two-state activity as renewal processes. The intensity functions of the Up state transitions are modeled as doubly stochastic point processes, with one stochastic variable being the state of the neuron (Up or Down) and the other being the strength of the synaptic input.

Supported by NS20743.

## 362.2

PARVALBUMIN-IMMUNOREACTIVE NEURONS IN RAT GLOBUS PALLIDUS: A LIGHT AND ELECTRON MICROSCOPE STUDY. J.Q. Ren\* and H. Kita, Dept. Anatomy, and Neurobiol. Coll. of Med., Univ. of Tennessee, Memphis, TN 38163.

Light and electron microscopic analysis of parvalbumin immunoreactive neurons (PV-neurons) in the GP was performed. Approximately two-thirds of the GP neurons were PV-positive. The somata of PV-neurons were, on average, larger than PV-negative ones. The proximal dendrites of PV-neurons were smooth and often lay parallel to the border between the GP and the neostriatum. Distal dendrites of PV-neurons were varicose. Thin PV-positive fibers with large boutons were observed in the neuropil of the GP.

Electron microscopic observations revealed that PV-neurons contained deeply indented nuclei and a large volume of cytoplasm. The somata of PV-negative neurons were occupied by deeply indented nuclei and a small volume of cytoplasm. Both PV-positive and negative neurons received synaptic boutons identical to the known striato-pallidal, subthalamo-GP, and local collateral boutons. The PV-positive boutons contained small round or elongated vesicles and often more than one mitochondrion. Most of the boutons (i.e., 86%) formed symmetric synapses with somata and large dendrites, and the others (14%) formed asymmetric synapses with small dendrites.

The study indicated that GP projection neurons can be divided into two subgroups according to their PV-immunoreactivity. PV-positive and negative neurons received similar extrinsic synaptic inputs and both types of neurons were connected through their local collateral axons. Supported by NS-25783 and NS-26473.

THE SPACING OF SYNAPSES ALONG CORTICOSTRIATAL AXONS. A.E. Kincaid\*, T. Zheng, and C.J. Wilson, Dept. Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, TN 38163.

Convergence of excitatory synaptic activity of corticostriatal (CS) neurons is a major determinant of the firing of neostriatal (NS) projection neurons. Each NS cell receives several thousand corticostriatal synapses. The number of CS axons that contribute synaptic input to each NS neuron is not known. To obtain an upper limit to the number of synapses made by one axon onto single NS neurons, we measured the number of varicosities along the course of single CS axons as they traverse the dendritic fields of neostriatal neurons.

CS axons were labeled by intracellular injection of biocytin or by small extracellular injections of biocytin or BDA. Selected tissue sections from these same animals were processed for electron microscopy, and the diameters of labeled CS axons were measured at synaptic and nonsynaptic regions for comparison to the diameters of varicosities and non varicose segments seen in the light microscope.

The average diameter of labeled CS axons containing vesicle accumulations and synaptic specializations was  $0.53 \mu\text{m}$  and for CS axons without vesicles or synaptic specializations was  $0.18 \mu\text{m}$ . Thus the axonal varicosities identified with the light microscope represented synapses. The average intervicosity distance for CS axons was the same in the patch and matrix compartment ( $10.6 \mu\text{m}$  and  $11.6 \mu\text{m}$  respectively). Individual branches of single axons generally were separated by more than the diameter of a spiny cell's dendritic tree. Thus, if all possible contacts were made onto one spiny cell, from a single CS axon would be 30-40, and the minimum number of CS axons contacting a single NS neuron would be at least 250-300. If connections were made upon spiny cells at random, the average number of connections would be about 0.04, and each NS cell would receive inputs from about 10,000 different CS axons. Supported by NS20743.

## 362.6

PREDICTED RESPONSES OF NEOSTRIATAL SPINY NEURONS TO CURRENT STEPS BASED ON PROPERTIES OF THEIR IONIC CONDUCTANCES. Charles J. Wilson\*, Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, TN 38163.

Voltage clamp studies of striatal spiny neurons have provided accurate measurements of the voltage dependence and kinetics of several ionic conductances that are believed to be important for these neurons. However, the best descriptions of these conductances have been obtained using dissociated striatal neurons, while most conventional intracellular recording has been done on striatal tissue slices. To determine the degree to which available quantitative descriptions of ionic conductances can predict the responses of striatal spiny neurons, computer simulations of standard intracellular recording experiments were performed using quantitative descriptions of ionic conductances obtained from dissociated neurons. Application of ion channel blockers was simulated by reducing channel density according to dose-response curves obtained in voltage clamp experiments. The results were directly compared with intracellular recording data from slices.

All 4 potassium conductances known to be active at subthreshold membrane potentials (I<sub>ir</sub>, I<sub>As</sub>, I<sub>AF</sub>, and I<sub>K</sub>) were required to reproduce the control responses of spiny neurons to subthreshold current pulses. These were also sufficient to account for the alterations in subthreshold responses seen after partial K channel blockade with 4-AP, TEA, or cesium. These channels, in combination with somatic Na channels were sufficient to account for some, but not all of the repetitive firing properties of the cells.

## 362.7

**DOPAMINE D<sub>1</sub> RECEPTOR STIMULATION SELECTIVELY DEPRESSES A SLOWLY INACTIVATING K<sup>+</sup> CURRENT IN STRIATAL NEURONS.** E.S. Nisenbaum\*, C.J. Wilson and D.J. Surmeier. Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee-Memphis, Memphis, TN 38163.

Evidence indicates that D<sub>1</sub> receptor activation can modulate the spike discharge properties of striatal neurons. Although this modulation may result from effects on several different ionic conductances, outward K<sup>+</sup> currents are likely candidates due to their critical role in regulating spike discharge. Striatal neurons possess three types of depolarization-activated K<sup>+</sup> currents, including fast (I<sub>AF</sub>) and slowly (I<sub>AS</sub>) inactivating A-currents and a noninactivating current. The present experiments investigated which of these currents were modulated by D<sub>1</sub> receptor stimulation using whole-cell voltage-clamp recording from acutely isolated rat striatal neurons.

Depolarizing voltage steps (0.5-2 s in duration) from -80 mV to +35 mV evoked I<sub>AF</sub>, I<sub>AS</sub>, and the noninactivating current. Application of the D<sub>1</sub> receptor agonist, 6-chloro-APB (APB, 10 μM) reduced the amplitude of the total outward K<sup>+</sup> current by approximately 30%. The effect of APB application was rapid and completely reversible having onset and offset time constants of 1.1 ± 0.3 s and 1.7 ± 0.3 s (n=6), respectively. Subtraction of the currents evoked before and after application of APB yielded the APB-sensitive current which activated rapidly (τ=4 ms) and inactivated relatively slowly (τ=625 ms). These kinetics of activation and inactivation are very similar to those previously described for I<sub>AS</sub> in striatal neurons.

These results suggest that D<sub>1</sub> receptor stimulation preferentially depresses I<sub>AS</sub> in striatal neurons. In light of our previous studies, a D<sub>1</sub> receptor-mediated decrease in the availability of I<sub>AS</sub> would be expected to shorten that latency to discharge and increase the frequency of firing of striatal neurons in response to long (e.g., ≥ 500 ms) periods of depolarization. Support: NS26473

**DOPAMINE-ACETYLCHOLINE INTERACTIONS IN A BIOPHYSICALLY-BASED MODEL OF THE NEOSTRIATUM.** J.R. Gabbel\*. Department of Cognitive Science, UC San Diego, La Jolla, CA 92093-0515.

Although it is generally accepted that the actions of dopamine and acetylcholine in the neostriatum are somehow complementary, the details of their interaction remain unclear. Based on voltage-clamp studies, Surmeier suggested specific actions of these neuromodulators on ion currents which could account for the nature of this interaction. Surmeier's results were incorporated into a computational simulation using the GENESIS simulator. Striatal medium spiny cells and giant aspiny cholinergic cells were both simulated at a moderate level of detail, with degenerate morphology, but with a fairly complete complement of conductances.

The model neurons have firing patterns which closely resemble the real cells. The model medium spiny cells, in particular, exhibit the characteristic bistable membrane potential pattern seen in real spiny neurons.

As suggested by Surmeier, acetylcholine tends to stabilize the model spiny neurons at either the "up" or "down" membrane potential levels, while dopamine facilitates shifting from one state to the other.

When placed into a network based on the cytoarchitecture of the neostriatum, the medium spiny cells and cholinergic interact in a way that allows the structure to function as a simple working memory. It is suggested that this could be the basis for the role of the striatum in encoding "set" in action sequences. A deficit in establishment and maintenance of set is one of the signal characteristics of Parkinson's disease, a phenomenon which maps naturally to the characteristics of the model presented here.

## 362.11

**ALTERATIONS IN NEOSTRIATAL NEURONAL RESPONSES TO DOPAMINE RECEPTOR AGONISTS IN A MUTANT MOUSE LACKING D<sub>1A</sub> DOPAMINE RECEPTORS.** M.S. Levine\*, K.L. Allemus, C. Cepeda, H.C. Cromwell, C.A. Crawford, J. Drago\*, D.R. Sibley\* and H. Westphal\*. MRRC, UCLA, LA, CA 90024, \*Anat. Dept. Monash University, Clayton Victoria, Australia, \*Exptl. Ther. Br., NINDS, \*Lab. Mammal. Genes and Dev., NICHD, Bethesda, MD 20892.

Previously, we have shown that dopamine (DA) enhances N-methyl-D-aspartate (NMDA)-induced responses in neostriatum. This effect is mimicked by the D<sub>1</sub> agonist, SKF 38393 and blocked by the D<sub>1</sub> antagonist, SCH 23390. This study uses a genetic approach to further examine this role of D<sub>1</sub> receptors. Homologous recombination was used to generate mutant mice lacking functional D<sub>1A</sub> DA receptors (Drago et al., 1994, PNAS, 91:12564-12568). Intracellular recordings were made from neostriatal neurons in brain slices from mutant and wild-type control mice. In one set of experiments, we used iontophoresis of NMDA and DA combined with bath application of SKF 38393. NMDA induced depolarizations accompanied by action potentials in all neurons. In wild-types, DA or SKF 38393 markedly potentiated NMDA-induced responses. In mutants, DA produced only a small enhancement and SKF 38393 had no effect. In a second set of experiments, we assessed the effect of SKF 38393 on depolarizing synaptic responses (DPSPs) induced by activation of cortical afferents. In standard artificial cerebrospinal fluid (ACSF), this response is mediated by non-NMDA receptors. When cells are exposed to Mg<sup>2+</sup>-free ACSF and 6-cyano-7-nitroquinoxaline-2,3-dione, a non-NMDA receptor antagonist, the DPSP is primarily mediated by NMDA receptors. SKF 38393 (5-20 μM) had little effect on the amplitude of the DPSP (3% increase) in mutants but increased the amplitude in wild-types (34%). Taken together, these results support the hypothesis that DA's ability to potentiate NMDA-induced responses is mediated by D<sub>1</sub> receptors. Supported by USPHS Grants HD 05958 and AG 10252.

## 362.8

**Long-term synaptic plasticity in the striatum: Distribution of response patterns and modulation.** F.A.S. Villar and J.P. Walsh\*, Andrus Gerontology Center & Dept. of Physical Therapy, University of Southern California, Los Angeles, CA 90089-0191.

The present study examined the distribution of long-term synaptic plasticity response patterns under conditions of differing stimulation intensity. Elimination of dopaminergic innervation with 6-OHDA and block of metabotropic glutamate receptors. A set of aged animals (>24 mo.) were also examined.

When tetanus stimulation intensity equalled the test stimulus intensity (no action potentials were evoked), 60% of cells from young animals showed LTD, 35% showed LTP and 5% showed no change (n=17). In aged animals, 83% showed LTD, 17% LTP and 0% no change (n=6). Increasing the stimulation intensity during the tetanus to twice the test intensity increased the synaptic depolarization and reliably generated action potentials. Under these conditions, 90% of young cells showed LTD, 10% LTP and 0% no change (n=10). In aged animals, 80% showed LTD, 0% LTP and 20% no change (n=5). Data reflects 20 min posttetanus sampling. ±5% of control was categorized as no change.

Elimination of DAergic input to the striatum by nigral 6-OHDA injections shifted the distribution toward LTP, with 29% of cells showing LTD, 71% LTP and 0% no change (n=7) in response to same intensity stimulation. Block of met-GLU receptors with AP-3 did not affect the distribution of responses, with 67% of cells showing LTD, 33% LTP and 0% no change (n=3). These data indicate that: (1) LTP can be generated in some cells under "normal" conditions, (2) postsynaptic action potentials and activation of met-GLUR are not absolute requirements for LTD induction, and (3) DAergic lesions increase the probability of expressing LTP even though some cells still show LTD.

Supported by NIA grant AG09793.

## 362.10

**NMDA-INDUCED EXCITOTOXICITY IN VISUALLY IDENTIFIED NEOSTRIATAL NEURONS IN SLICES. MODULATION BY DOPAMINE.** C. Cepeda\*, Q. Yu, C.S. Colwell, N.A. Buchwald and M.S. Levine. Mental Retardation Research Center, University of California, Los Angeles, CA 90024.

This study examined dopamine's (DA) ability to modulate excitotoxicity induced by activation of N-methyl-D-aspartate (NMDA) receptors. Nomarski optics and infrared videomicroscopy were used to visualize individual neostriatal neurons in thick slices (350 μm) obtained from rat pups (12-18 days of age). Bath application of NMDA (25, 50, and 100 μM) induced cell swelling in a dose-dependent manner. This effect was blocked by 2-amino-5-phosphonovaleate (AP5) (10-20 μM), an antagonist of NMDA receptors. DA (20-50 μM) or its receptor agonists, SKF 38393 (20-30 μM) (D<sub>1</sub> agonist) and quinpirole (20 μM) (D<sub>2</sub> agonist), had no effect on neostriatal neurons when applied alone. However they modified NMDA-induced swelling. DA (50 μM) produced a 20% enhancement of NMDA-induced cell swelling. This effect was mimicked by SKF 38393 suggesting the enhancement is mediated by activation of D<sub>1</sub> receptors. Furthermore, SCH 23390, a D<sub>1</sub> receptor antagonist, reduced cell swelling (15% instead of 30%) alone or in combination with DA. In contrast, quinpirole conferred some protection against the swelling (20% instead of 30% increase). These results indicate that DA and its receptor agonists and antagonists can effectively modulate NMDA-induced cell swelling. DA, via D<sub>1</sub> receptors, enhances NMDA's effects. In contrast, activation of D<sub>2</sub> receptors reduces NMDA-induced swelling. These observations agree with our previous electrophysiological findings in which selective activation of D<sub>1</sub> receptors potentiates electrophysiological responses induced by activation of NMDA receptors while activation of D<sub>2</sub> receptors tends to attenuate NMDA-induced responses. Supported by USPHS Grant HD 05958.

## 362.12

**THE EFFECTS OF SEROTONIN AND THE SELECTIVE SEROTONIN REUPTAKE INHIBITOR FLUOXETINE ON STRIATAL NEURONS RECORDED IN VITRO.** J.S. Verbanac\* and A.A. Grace. Departments of Neuroscience and Psychiatry, Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

The neostriatum is known to receive a substantial serotonergic innervation from the raphe. The physiological role of this neurotransmitter in the regulation of striatal cell activity and its relationship to other striatal afferents is presently not well understood. In the present study, the physiological and pharmacological effects of the selective serotonin reuptake inhibitor fluoxetine was investigated using current clamp techniques in striatal slices. Intracellular recordings were made *in vitro* from neostriatal neurons. Perfusion of fluoxetine (1 μM) in the bath resulted in a modest reduction in input resistance (8%) and hyperpolarization of the membrane (-6.5 mV). Fluoxetine administration also resulted in a shortened spike latency (15%) and an increase in the number of spikes evoked by constant current depolarizing pulses. This latter effect may possibly be due to an observed decrease (39%) in the afterhyperpolarization of neostriatal neurons. Following the administration of fluoxetine, serotonin (50 μM) was added through the bathing medium. Administration of serotonin following fluoxetine augmented the response observed after fluoxetine in neostriatal neurons, suggesting that the effects of fluoxetine may be due to potentiation of the effects of endogenous serotonin within the slice. Supported by MH42217, MH45156, MH01055.

## 362.13

**ION MECHANISMS OF DOPAMINERGIC INHIBITION IN NEOSTRIATAL NEURONS.** S. Hernández, J. Bargas, A. Reyes and E. Galarraga\*. Instituto de Fisiología Celular, UNAM. POBox: 70-253, México City DF 04510 México.

Intracellular recordings in a brain slice preparation of the rat brain were performed to explore the actions of dopamine and dopaminergic agonists on the firing response of neostriatal neurons. The most reproducible effect of dopamine or D1-agonists upon the firing response of neostriatal neurons is a decrease in firing rate (100% of cases,  $n > 50$  neurons) together with an increase in the current needed to achieve threshold for action potential firing. This effect was accompanied by a decrease in slope input resistance in the subthreshold voltage range with a reversal potential between -80 and -90 mV. These actions persisted in the presence of 10mM TEA or TEA+TTX (10mM, 1  $\mu$ M) suggesting that: 1) the effects are direct on the post-synaptic cell, and 2) not due to TTX- or TEA-sensitive conductances. However, here we report that, 5 mM Cs<sup>+</sup> completely abolished most inhibitory action of dopamine or D1-agonists upon the firing response. This suggests that dopamine actions mainly depend on a Cs<sup>+</sup>-sensitive conductance, which once blocked, occludes the effect on the firing rate. In fact, some cells showed an increase in firing rate after dopamine agonists and Cs<sup>+</sup>. Other D1-agonists effects which may in part explain an inhibitory action upon firing response were: 1) an increase in the amplitude and duration of the afterhyperpolarizing potential (AHP) which follows an action potential, and 2) an enhancement of the calcium plateau potential induced by 10-20 mM TEA which correlates with an increase in inward calcium current. This last effect was probably mediated by channels of the L-type as it was occluded by BayK8644. Both effects may be related because part of the AHP is activated by Ca<sup>2+</sup> entry. Financed in part by DGAPA-UNAM and CONACyT (México).

## 362.15

**ACTIONS OF NEUROPEPTIDES ON LARGE ASPINY NEURONS OF RAT NEOSTRIATUM IN VITRO.** Toshihiko Aasaki\* and Yasuo Kawaguchi. Lab. Neural Circuits, Inst. Phys. & Chem. Res. (RIKEN), Nagoya, Aichi 456, Japan.

Whole-cell patch clamp recordings were performed in a brain slice preparation to study the actions of substance P (SP) and opioids on large aspiny neurons of the rat neostriatum. All of the neurons fit well with physiological properties of large aspiny neurons described by Kawaguchi (1992) and some of them were further identified morphologically. Intrastriatal stimulation (20 Hz, 0.5 ms pulses for 500 ms) evoked spike discharges followed by a slow excitatory, or inhibitory postsynaptic response lasting for about 1 min (11/14 cells; 10 excitatory, 1 inhibitory). Antagonist of SP, [D-Arg<sup>1</sup>, D-Pro<sup>2</sup>, D-Trp<sup>7,9</sup>, Leu<sup>11</sup>]SP, suppressed the slow e.p.s.c.(p.) (4/5 cells) and, in 2 cells (2/4), unmasked the i.p.s.c. In one cell, i.p.s.c. was evoked and the antagonist enhanced its amplitude, due to blockade of masked e.p.s.c. by the antagonist. Bath-application of SP transiently evoked an inward current (24/25, 100-200 pA, ED<sub>50</sub>, 0.1  $\mu$ M) in a dose-dependent manner. The excitatory effect of SP was mostly accompanied by a decrease (23/24) in input resistance. At holding potential of -50 to -70 mV, SP current was unchanged even in the presence of K-channel blockers (Cs<sup>+</sup>, TEA, Ba<sup>2+</sup>, 4-AP) and a Ca-channel blocker (Co<sup>2+</sup>). However, replacement of extracellular Na<sup>+</sup> with choline substantially suppressed it and that of extracellular Cl<sup>-</sup> with Na isethionate had no effect. The effect of SP on I<sub>h</sub> was variable and its blockade by Cs<sup>+</sup> had no effect on SP current. It is therefore suggested that the SP current was mainly elicited by opening of non-selective cation channels at the resting membrane potential. On the other hand, bath-application of [Met<sup>1</sup>]-enkephalin (10  $\mu$ M) reversibly evoked an outward current in 2 cells (2/2), which also showed an inward current evoked by SP. DAMGO (1  $\mu$ M, 4/4),  $\mu$ -receptor antagonist, and K-selective antagonist, U-50488 (1  $\mu$ M, 2/2), had no effect on the outward current, whereas  $\delta$ -selective antagonist, DPDPE (10  $\mu$ M, 2/2), suppressed it. These results suggest that SP, released from striatonigral neurons, and enkephalin, from striatopallidal neurons, may reciprocally regulate the activity of large aspiny neurons of the striatum.

## 362.17

**INCREASED SUBTHALAMIC NEURONAL ACTIVITY IN DOPAMINERGIC LESIONED RATS NOT RELATED TO A DECREASED PALLIDAL INHIBITION.** J.Féger\*, M.Mouroux and O.K.Hassani. Lab. de Pharmacologie, Fac.Pharmacie, Paris, France.

There is a general agreement to describe an increased activity of the subthalamic neurons in the animal models of Parkinson's disease: MPTP-treated monkeys or 6-OHDA-induced dopaminergic lesion in rats. In this last species, this lesion induces an increase of neurochemical index in the inhibitory striatopallidal neurons. Inhibition of the pallidal neurons is believed to release the activity of the subthalamic neurons. Following this proposal, a pallidal or a dopaminergic lesion should induce the same quantitative and qualitative changes in subthalamic neurons. Unit activity were recorded in the subthalamic nucleus in three groups of anesthetized (urethane) rats: control, rats with a pallidal or midbrain dopaminergic lesion. The lesion of the globus pallidus was induced by a microinjection of ibotenic acid (20 nmol in 400 nl). The dopaminergic midbrain lesion was obtained with a microinjection of 6-OHDA (8  $\mu$ g in 2  $\mu$ l) in the substantia nigra. In the control rats, the pattern of firing was slightly irregular with a mean value of  $14.7 \pm 0.4$  spikes per second. In the rats with a pallidal lesion performed 8 to 10 days before, the activity was more regular than in the control rats and the discharge rate was between 13.7 and 22.6 sp/sec with a mean value of  $17.6 \pm 0.6$  sp/sec ( $p < 0.05$ ). In the 6-OHDA-lesioned rats three weeks before, the pattern of activity was clearly irregular with bursts and pauses. The discharge rate was between 22.3 and 36.7 sp/sec with a mean value of  $30.3 \pm 1$  sp/sec ( $p < 0.001$ ). The activity of the pallidal neurons was recorded in control and 6-OHDA-lesioned rats. The mean value were  $29.5 \pm 1$  in control rats and  $25.2 \pm 2.8$  with an irregular and bursting activity in the dopaminergic lesioned rats. The differences in the increase of the discharge rate of the subthalamic neurons, 19.5% versus 105.7% and in their pattern of unit activity dispute the importance of an inhibition/disinhibition process in the relation between the striatum and the subthalamic nucleus in midbrain dopaminergic lesioned animals. These results fit well with anatomical and neurochemical data suggesting that the globus pallidus is more than a simple relay in the striato-pallido-subthalamic circuit.

**POTASSIUM CHANNEL BLOCK INDUCES DYE COUPLING IN NEOSTRIAT NEURONS.** A. Reyes, E. Galarraga, D. Tapia and J. Bargas\*. Instituto de Fisiología Celular, UNAM. POBox: 70-253, México City DF 04510 México.

According to the "equivalent cylinder" (EC) model (Rall, 1977), the charge function of dendritic neurons can be approximated to a sum of exponential functions. The "electrotonic length" (L) is a function of the proportion between the longest time constant ( $\tau_d$ ) and the equalizing ones ( $\tau_e$ ). The "equalizing time constants" represent dendritic charge redistribution. In our case:  $L_{\text{pass}} (\mu \pm \text{SD}) = 1.72 \pm 0.02$  ( $n=46$ ) (including  $R_m$  heterogeneity, e.g., Durand, 1984). Thus, if only one exponential can be extracted from a charge function, it cannot be differentiated from the isopotential case ( $L=0$ ); meaning that charge transfer from soma to dendrites occurs virtually instantaneously. Here we report that (in mM): 5Cs<sup>+</sup>, 10TEA, or 5Ba<sup>2+</sup> increase  $R_m$  and induce  $L=0$  in most neurons. However: 1) Not all blockers increased  $R_m$  in the same proportion, suggesting that just some resting K<sup>+</sup>-channels need to be blocked in order to have  $L=0$ , 2) Different classes of K<sup>+</sup>-channels may produce the same effect, 3) The neurons that did not become "isopotential" during blockers appeared to be dye coupled with neighboring neurons after anatomical reconstruction (intracellular biocytin)(42%). As the probability of dye coupling in control slices is very low (2%), it appeared to be significantly increased after K<sup>+</sup> blockade, 4)  $C_m$  and  $A_m \approx (\tau_d/R_m)/(1\mu\text{F}/\text{cm}^2)$  determined after isopotential charge functions during Ba<sup>2+</sup>, coincided with anatomical measurements (Wilson, 1993), 5)  $A_m$  together with somatic resistance and capacitance calculated from anatomical methods and whole-cell recordings of isolated somas coincided to give and independent measure of  $\rho (\approx 20)$ . Supported by DGAPA/PADEP-UNAM and CONACyT (México).

## 362.16

**THREE CLASSES OF GABAergic INTERNEURONS IN RAT NEOSTRIATUM.** Y. Kubota\* and Y. Kawaguchi. Lab for Neural Circuits, Bio-Mimetic Control Research Center, RIKEN, Atsuta, Nagoya, Aichi 456, Japan.

In the neostriatum aspiny interneurons containing a calcium binding protein, parvalbumin, had been known as GABAergic. The purpose of the present study is to show other striatal interneurons are also GABAergic. Male Wistar rats (weight 100-200g) were used. Using mirror image immunohistochemical methods with antiserum against GAD67 (one of the two forms of synthetic enzyme for GABA) revealed that two other classes of interneurons were also GABAergic in the neostriatum of colchicine treated rat. Those were nitric oxide synthase-(NOS), which also contained somatostatin, and calretinin- (another calcium binding protein) positive cells. We also investigated GABA immunoreactivity in the terminals of striatal interneurons of untreated rats. Aspiny interneurons were identified in isolated slices of striatum from young rats (18-22 days postnatal) by whole cell, current-clamp recording, followed by intracellular injection of biocytin. Three types of neostriatal interneurons were identified, which were long-lasting afterhyperpolarization (LA) cells, fast spiking (FS) cells, and low-threshold spike (LTS) cells and those corresponded to cholinergic large aspiny cells, parvalbumin-containing cells, and NOS-containing cells, respectively. After overnight fixation, the slices were histochemically processed and embedded in Epon. Electron microscopic observations of postembedding GABA staining revealed that the terminals of FS cells and LTS cells were immunoreactive for GABA, however, the terminals of LA cells did not show GABA immunoreactivity. These results suggest that GABAergic interneurons are heterogeneous in neostriatum.

## 362.18

**SUBTHALAMIC ABLATION REVERSES CHANGES IN BASAL GANGLIA OXIDATIVE METABOLISM AND MOTOR RESPONSE TO APOMORPHINE INDUCED BY NIGROSTRIATAL LESION.** E. Blandini\*, M. Garcia-Osuna, J.T. Greenamyre.

Neurological Institute "C. Mondino", University of Pavia, Italy\*; Departments of Neurology, Neurobiology & Anatomy, and Pharmacology, University of Rochester Medical Center, Rochester, NY

In Parkinson's disease (PD), dopaminergic denervation of the striatum leads to a cascade of functional alterations in basal ganglia circuitry which causes overactivity of the output nuclei of the circuit, substantia nigra pars reticulata (SNr) and medial globus pallidus (MGP). Increased firing of the subthalamic nucleus (STN), which sends excitatory projections to both SNr and MGP, seems to be mainly responsible for this phenomenon. The pivotal role of STN is further suggested by the fact that reduction in STN activity is associated with amelioration of PD symptoms. The aim of this study was to investigate the effect of selective STN ablation on basal ganglia oxidative metabolism, as well as on the motor response to apomorphine, in rats with prior nigrostriatal lesion. Sprague-Dawley rats received a unilateral stereotaxic injection of 6-hydroxydopamine in the substantia nigra pars compacta (SNc) and medial forebrain bundle. Eight months later, the same animals underwent an ipsilateral STN lesion by means of an N-methyl-D-aspartate injection (25 nmol). Histochemical staining for succinate dehydrogenase and cytochrome oxidase were performed on slide-mounted brain sections. Side-to-side differences in staining intensity were analyzed by means of computerized densitometry. Rotational response to i.p. apomorphine was tested before and after STN ablation.

The nigrostriatal lesion alone induced ipsilateral increases in enzymatic activity of both SNr and entopeduncular nucleus (the rodent homologue of human MGP). This phenomenon was completely abolished, or reversed, by STN ablation. Complete STN lesion also abolished apomorphine-induced rotational behaviour. These results confirm the pivotal role of STN in the modulation of basal ganglia output and shed further light on the neural basis of the beneficial effect of STN manipulation on PD symptomatology.

## 362.19

**SUBTHALAMIC NUCLEUS NEURONAL ACTIVITY IS INCREASED BY DOPAMINE D<sub>1</sub> RECEPTOR AGONISTS.** D.S. Kreiss\*, L.A. Anderson, J.R. Walters. NIH, NINDS, ETB, Bethesda, MD 20892.

By providing links from the cortex and globus pallidus to the substantia nigra and entopeduncular nucleus, the subthalamic nucleus (STN) plays an integral role in the transmission of information through the basal ganglia. The regulation of STN neuronal firing rates by dopamine (DA) D<sub>1</sub> receptors was investigated using *in vivo* extracellular single unit recording techniques in locally anesthetized, paralyzed male rats. STN neuronal firing rates were dose-dependently increased by the selective D<sub>1</sub> receptor agonist SKF 38393 (1.25-20 mg/kg, iv); 20 mg/kg increased firing rates to 269% of basal rates. A similar increase was produced by the D<sub>1</sub> agonist SKF 82958 (0.43 mg/kg, iv). SKF 38393- and SKF 82958-induced increases in firing rates were reversed by the D<sub>1</sub> antagonist, SCH 23390 (0.5 mg/kg iv). STN neuronal firing rates were also increased by the nonselective DA agonist apomorphine (0.32 mg/kg, iv), but not by the indirect acting DA agonist amphetamine (1.6, 5.0 mg/kg, iv). Apomorphine-induced firing rate increases could be prevented by SCH 23390 or chloral hydrate or ketamine anesthesia. Local administration of SKF 82958 (3.0 µg/0.3 µl) into the STN increased STN neuronal firing rates 2 to 3-fold; these increases could be reversed by systemic SCH 23390 (0.5 mg/kg, iv). Local administration of SCH 23390 (0.3 µg/0.3 µl) into the STN prevented systemic SKF 38393 (20 mg/kg, iv) from increasing STN firing rates. These results support an excitatory role of D<sub>1</sub> agonists on STN neuronal activity, which is mediated, at least in part, by D<sub>1</sub> receptors located within the STN itself. These findings contradict current models of basal ganglia function which predict an indirect inhibitory effect of DA on STN neuronal activity resulting from disinhibition of globus pallidus neuronal activity.

## CEREBELLUM: BEHAVIOR, DEVELOPMENT, MODELS

## 363.1

**VISUALLY GUIDED REACHING WITH THE FORELIMB CONTRALATERAL TO A "BLIND" HEMISPHERE: CONTRIBUTIONS OF THE CEREBELLUM.** H.E. Savaki\*, C. Kennedy\*, L. Sokoloff\* and M. Mishkin\*. Dept. Basic Sciences, Div. Medicine, Univ. of Crete, Iraklion, Crete, Greece 71110, and \*NIMH, Bethesda, MD 20892.

The 2-[<sup>14</sup>C]deoxyglucose method was used to map local metabolic activity in the cerebellar cortex as well as its major inputs and targets in monkeys performing visually guided reaching with the left forelimb. The study was carried out both in normal (N) monkeys and in monkeys that had the right cerebral hemisphere deprived of visual input by right optic tract section combined in some cases with forebrain commissurotomy (TC). The metabolic mapping revealed significant activations of the left cerebellar hemispheric extensions of vermal lobules V, VI, and VIII in all monkeys. In the N monkeys, however, the activations were somewhat smaller in the lateral ("visual") than in the paravermal ("motor") zones of these hemispheric extensions, whereas in the TC monkeys the activations in these two zones were equally large. The findings suggest that the activated loci in the left cerebellum combine (i) visual information about the target relayed by either cerebral hemisphere and (ii) sensorimotor information concerning intended and actual movements of the left forelimb relayed by the right cerebral hemisphere and the limb, and then send this integrated information back to the motor system of the right cerebral hemisphere, which is thus enabled to guide the left forelimb to the visual target whether it is visually intact or "blind" (Savaki et al., *J. Neurosci.* 13:2772-2789, 1993).

## 363.3

**CEREBELLAR INACTIVATION ABOLISHES THE CAPABILITY OF CATS TO COMPENSATE FOR UNEXPECTED BUT NOT EXPECTED PERTURBATIONS OF A REACH MOVEMENT.** Yu. Shimansky\*, J.-J. Wang, V. Bracha, J.R. Bloedel. Barrow Neurological Institute, Phoenix, AZ 85013.

The purpose of this study was to determine the effects of inactivating concurrently the interposed and dentate nuclei on the capacity of cats to compensate for the perturbation of a forelimb reaching movement. Cats were trained to reach for a vertical bar and move it to a food reward zone through a straight groove in a horizontal template. During the reach a perturbation was applied consisting of an external force that was engaged at a certain point during the reach and transiently modified the trajectory of the limb. Once engaged, the force increased linearly as the paw moved towards the bar. Perturbations were applied either on successive trials (predictable) or randomly (unpredictable). Normal cats compensated for predictable perturbations in a few trials and for unpredictable perturbations over 1-2 days. The animals with the interposed and dentate nuclei inactivated by focal 1 µl injections of muscimol (800 ng/µl) required significantly more trials to adapt to the predictable perturbation, and they were unable to compensate for unpredictable perturbations applied at low enough frequencies to be unexpected. However, when the perturbation probability was higher than 50%, compensatory behavior was present in every trial independent of whether a perturbation actually was applied. After considerable practice, the compensation consisted of a motor pattern that was effective in both perturbation and non perturbation trials. Furthermore, the strategy employed to compensate for unpredictable perturbations during cerebellar nuclear inactivation was qualitatively different than the strategy employed by control animals. The data suggest that the cerebellum is necessary for implementing adaptive motor strategies requiring short-latency modifications of ongoing movements on a trial by trial basis. Supported by NIH grants NS30013 and NS21958.

## 363.2

**IMPAIRMENTS IN PLANNING, COORDINATION, AND ADAPTATIVE ADJUSTMENTS OF REACHING PRODUCED BY ANTERIOR AND POSTERIOR INTERPOSITUS AND RED NUCLEUS INACTIVATION.** J.H. Martin\*, A. Hacking, S. Cooper, C. Ghez. Ctr. Neurobiol. & Behav., Columbia Univ. and NYS Psychiatric Institute, New York, NY 10032

To investigate cerebello-rubral control of limb movement we studied the effects of muscimol inactivation of AIP, PIP and RN on performance of a reaching task in the cat. Animals reached into a narrow food well at various heights, distances and inclinations to grasp a small piece of beef.

AIP inactivation produced under-reaching, wrist and tip paths that were more curved and variable, and increased movement time. Animals were unable to reprogram paw kinematics to reach over obstacles. While elbow scaling to target height was preserved, associated motions of shoulder, wrist and digits, needed to linearize paw path and to adapt the paw to the food well, were reduced or eliminated. PIP inactivation produced over-reaching but did not impair obstacle avoidance. While paths were more variable, like AIP, path linearity, limb deceleration, and movement time were unaffected. As noted previously for AIP, (Cooper, et al; 1993) impairments in interjoint coordination and end-point biases during PIP inactivation also resulted, in part, from failure to take account of interjoint interaction torques.

Trajectory variability was increased during RN inactivation but without biases in movement end-points or increases in movement time. Rubral inactivation also produced deficits in interjoint coordination and reaching over obstacles that resembled those during AIP inactivation.

Our results support the idea that the intermediate cerebellum and the red nucleus, play a critical role in several aspects of forelimb control needed to assure spatially accurate paw paths, especially in specifying muscle contractions and joint torques. We have previously reported (Martin and Ghez, 1993) that impaired obstacle avoidance and over-reaching occur during rostral motor cortex inactivation, suggesting a role for the corticospinal system in expressing some of these deficits. (NS31391)

## 363.4

**EFFECT OF CEREBELLAR INACTIVATION ON THE ACQUISITION AND RETENTION OF PRISM ADAPTATION DURING GOAL-DIRECTED REACHING IN CATS.** M.S. Milak\*, M. Kozicki, V. Bracha, J.R. Bloedel. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

Experiments were performed to test the hypothesis that adaptation to optical prisms could occur during the inactivation of the interposed and dentate nuclei in cats and that inactivation performed after acquisition would not eliminate retention. After cats were trained to reach for a vertical bar under normal vision and pull it through a straight groove to a reward zone, they were adapted to 20 degree Fresnel prisms which displaced the image to the right. Throughout the experiment the cat could visualize its paw during the terminal phase of the trajectory. While recording the time course and kinematics of the reach, the effects of injecting 1 µl buffered saline simultaneously in the interposed and dentate nuclei on the adapted behavior, extinction, and readaptation to a novel prism (40 degrees in the opposite direction) were determined. Using the same protocol, nuclear inactivation (1 µl of a 800 ng/µl muscimol solution) produced a very brief (2-4 trials) decrease in the animals' capacity to reach the bar, after which they resumed the performance of accurate reaches despite the ataxia. Furthermore, during nuclear inactivation the cats were able to adapt quickly to the novel 40° prism. Thus, in this paradigm the inactivation of the intermediate and lateral cerebellar nuclei in cats did not eliminate the previously acquired adaptation, nor did it block their adaptation to novel prisms. Supported by NIH grants NS 30013 and NS 21958.

## 363.5

INVOLVEMENT OF THE CEREBELLAR INTERPOSED NUCLEUS IN REFLEXIVE AND VOLUNTARY FORELIMB MOVEMENTS. N.K. Winters, K.B. Irwin, F.P. Kolb, J.R. Bloedel\*, V. Bracha. Barrow Neurological Institute, Phoenix, AZ 85013.

Our previous studies in the cat demonstrated that the cerebellar nucleus interpositus (NIP) is involved in the expression of classically conditioned and unconditioned withdrawal reflexes (WR) in several skeleto-muscular effector systems. Recently, we suggested that WR circuits are implemented by the nervous system in the execution of more complex voluntary limb movements. This hypothesis predicts that inactivation of the NIP should result in qualitatively similar performance deficits within the same effector system regardless of the nature of the movement.

To test this notion, we compared the NIP inactivation-induced deficits in forelimb WR to the deficits in forelimb movements during different modes of locomotion and reaching. The effects of muscimol inactivations of the NIP on the forelimb WR were: a) reduced amplitude of flexion; b) changes in the limb's trajectory; c) impaired precision placement of the limb during transition from withdrawal to a quadruped stance; and d) hypermetria of associated corrective postural responses. Qualitatively similar deficits were observed in forelimb movements during reaching and locomotor tasks. The similarity of NIP inactivation-induced deficits in a variety of forelimb movements could be at least partly attributed to a dysfunction of shared reflex substrates.

NIH Grants NS 30013 and NS 21958.

## 363.7

CEREBELLAR COMMUNICATIONS WITH THE PREFRONTAL CORTEX: EFFECT ON HUMAN COGNITIVE SKILLS. A.L. Leiner, H.C. Leiner, and C.R. Noback\*. Channing House, 850 Webster Street (635), Palo Alto, CA 94301; & Dept. of Anatomy and Cell Biology, Columbia University, College of P&S, 630 West 168 Street, New York, NY 10032.

Recent discoveries about the structural and functional connections of the cerebellum to cognitive areas of the cerebral prefrontal cortex have led us to analyze how the neural projections from the neocerebellum can convey complex messages to the cerebral cortex. These neural projections are organized into small bundles of fibers, called fascicles, which can convey not merely a sequence of signals over each individual fiber but also various combinations of signals over each individual fascicle. In information-processing terms, such combinations of signals are termed "symbols"; and the various "symbols" comprise the neural "alphabet" by which the fascicle can communicate what to do and when to do it. The cerebellum, by learning to project such messages to the proper areas of the cerebral cortex at the proper times, can help the cerebro-cerebellar system to automatize some human motor, cognitive, and language skills.

## 363.9

A MODEL FOR HOW THE CEREBELLUM ANTICIPATES SENSORY INPUTS AND MODULATES THE VESTIBULO-OCULAR REFLEX (VOR). Oliver J.M.D. Coenen\* and T.J. Sejnowski. UC San Diego, Howard Hughes Medical Institute, CNL, The Salk Institute, PO Box 85800, San Diego, CA 92186-5800.

The gain of the VOR in monkeys is modulated by many inputs including eye position, target distance and otolith signals. We have developed a kinematic equation for the VOR that describes how the signals from the vestibular canals and otoliths can be combined with eye position and vergence angle signals to give the ideal VOR response for any head rotation and translation in three dimensions. By simulating head rotations for different locations of the axis of rotation, and by including delayed otolith and canal inputs, we obtain results which quantitatively match the VOR dynamics observed in monkeys (Snyder & King; J. Neurophys. 67:4, 1992).

We have also developed a dynamic model for how the nonlinear modulation of the VOR could be learned. Snyder & King (Vision Res. 32:3, 1992) have shown that the gain of the VOR changes in anticipation of vergence movements and have suggested that a central command signal could drive the vergence system and the VOR response via the cerebellum. Our adaptive cerebellar model describes how such a central command signal can 1) become associated with the modulation of the VOR and 2) produce anticipatory modulation of the VOR to compensate for retinal slips which may occur hundreds of milliseconds later. The model is a dynamical neural network represented by a set of differential equations. Computer simulations of the model show how the cerebellum may construct predictive representations of the retinal slip signals which can modulate the gain of the VOR in anticipation of new behavioral conditions.

## 363.6

BUFFER KINETICS INFLUENCE THE FIRING PROPERTIES OF A PURKINJE CELL MODEL WITH REALISTIC CALCIUM DYNAMICS. P. Smolen\* and E. De Schutter. Born Bunge Foundation, University of Antwerp, 2610 Antwerp, Belgium.

Previously used compartmental modeling to characterize the electrophysiology of cerebellar Purkinje cells (De Schutter and Bower, J. of Neurophysiology: 71, 375-400, 1994), had primitive (single-pool) calcium dynamics. We have now incorporated more realistic calcium handling, and updated channel kinetics, into this Purkinje cell model. Calcium diffuses radially between cylindrical shells (but not longitudinally between compartments), with diffusible buffers incorporated, and with channels and pumps in the outer shell. K-Ca channels are coupled to the calcium in the outer shell. We simulate responses to somatic current injection.

At moderate current injections, we find that a typical pattern of slow dendritic Ca bursting can only be obtained if most of the calcium buffer has slow kinetics (relaxation time on the order of 100 ms). The bursting pattern becomes unphysiological upon increasing the proportion of fast buffers, which are however known to dominate Ca buffering in the cytoplasm of some other cell types. Also, K-Ca channels must be sensitive to calcium on the order of 1  $\mu$ M to drive dendritic bursting. Given these conditions, typical dendritic bursting is obtained for 2-3 seconds. In this model, large gradients of calcium do not develop within spiny or smooth dendritic compartments due to their narrow diameter. We are exploring an alternative hypothesis that K-Ca channels and Ca channels are clustered such that K-Ca channels are exposed to localized peaks of high "domain" calcium.

Regarding channel properties, a very high density of somatic NaF channels and a low density of somatic CaP channels are both required to properly reproduce somatic spiking.

Supported by NFWO (Belgium) and NIMH grant 1-R01-MH52903-01.

## 363.8

A QUALITATIVE MODEL OF CEREBELLAR PLASTICITY THAT LEARNS TEMPORAL PATTERNS. J.L. Krichmar\*. PMI Incorporated, 11744 Parklawn Dr., Rockville, MD 20852.

A qualitative computer model of the cerebellar cortex is presented to investigate the ability of the cerebellum to learn sequences. The cerebellum provides control to motor areas of the nervous system by issuing sequences of commands. The cerebellum must decide which motor command is appropriate based on sensory afferents. The vast array of sensory information that converges on a Purkinje cell (PC) makes the cerebellum suitable for pattern recognition. This study proposes that: 1) associative learning occurs by correlating mossy fiber (MF) sensory afferents with MF motor efference copy, 2) climbing fiber input signifies a learning phase by gating in sensory input for evaluation, and 3) the cerebellum learns a motor program that is made up of sequences of motor commands. A biologically plausible model of a PC population is developed using the artificial intelligence technique "Qualitative Reasoning". The qualitative reasoning neuronal model (QRN) is significantly more computationally efficient than differential equation models of neurons, yet unlike artificial neural networks, QRN does not abstract important aspects of neural function. QRN qualitatively describes the dynamics and kinematics of the channels existing in a PC. The simulated PC population employs a learning rule based on current evidence of Long-Term Depression at the parallel fiber-PC synapse. QRN models calcium spikes in the PC dendritic tree as well as sodium spikes in the PC soma. The output, membrane potential as a function of time, is derived from the qualitative interaction between the model's parameters. QRN demonstrates the ability to learn multiple sequences by making associations from its inputs. The model suggests that the role of the climbing fiber is to divide cerebellar motor control into a motor phase and an evaluation phase. The QRN modeling technique may be a useful tool for addressing other open questions in neuroscience.

## 363.10

THE EFFECT OF CORRELATED INPUTS ON SPIKE TRAINS IN A PURKINJE CELL MODEL: D. Jaeger\*, E. De Schutter\*, and J.M. Bower. Div. of Biology 216-76, Caltech, Pasadena, CA 91125 and U. of Antwerp - UIA\*, Belgium

Electrophysiologists frequently use the cross-correlation method to examine functional connectivity between two simultaneously recorded cells. Classical analysis suggests that the shape and amplitude of peaks in cross-correlograms is indicative of reciprocal or shared input. In the present study we use a previously constructed realistic Purkinje cell model (De Schutter and Bower, J. Neurophysiol. 71: 375-419) to examine how single cell properties may influence the expression of input correlations in cross-correlograms.

Cross-correlograms were constructed between the spike trains of two simulation runs with controlled correlations in synaptic input superimposed on random background synaptic activation. As expected from classical analysis, the presence of simultaneous excitatory inputs was associated with a narrow peak in the cross-correlogram, while simultaneous inhibitory inputs lead to a much broader peak. However, the size of peaks in our cross-correlograms was dependent on multiple variables and therefore was not a good indicator of the strength of input correlations. In addition, the same set of shared inputs could lead to peaks of different amplitude and shape depending on the pattern of uncorrelated input. For example, if one simulation had a slower baseline spike rate than the other, the peak in the cross-correlogram due to simultaneous excitation had an offset of several msec from the center bin due to dendritic properties of the cell. Such a delayed peak is frequently interpreted as indicating an excitatory connection from one cell onto the other, which would be erroneous in the present case. Overall, the present study indicates that observed cross-correlations in spike trains can be strongly influenced by single cell properties, thus confounding the interpretation with respect to synaptic input.

## 363.11

**A NETWORK MODEL OF THE SAGITTAL OLIVO CEREBELLAR COMPLEX.** J.L. Contreras-Vidal<sup>1</sup>, J.R. Bloedel, and G.E. Stelmach. Lab. of Motor Control, Arizona State University, Tempe, AZ 85287 - 0404 and Barrow Neurological Institute, Phoenix, AZ.

The goal of this study is to assess the operational role of the cerebellum during on-going motor behavior by developing a network model of this system. The model explores the spatiotemporal interactions involving the sagittal organization of the cerebellar cortex, cerebellar nuclei, and inferior olive. Non-linear ordinary differential equations are used to model the membrane potential for each cell type (short-term activations), and their physiological action (inhibitory or excitatory). The network 1) differentiates between granule cell ascending axons and parallel fibers; 2) characterizes the Purkinje cell dendritic tree as a single summing node at the soma; 3) accounts for the short-term enhancement of Purkinje cell response to inhibitory and excitatory inputs; and 4) models electrotonic coupling at the inferior olive.

The dynamic response generated by the model was compared with actual physiological results. The model was able to produce spatiotemporal patterns of activity similar to those recorded physiologically in response to brief natural stimulation, and provides theoretical support for the Dynamic Selection Hypothesis regarding the functional basis for the sagittal organization of the cerebellum.

Supported by RS Flinn Foundation and NIH grant NS21958. Contreras - Vidal is on leave from Monterrey Institute of Technology, México.

## 363.13

**THE POSTEMBRYONIC DEVELOPMENT OF THE CEREBELLUM IN GYMNOTIFORM FISH.** G.K.H. Zupanc\*, I. Horschke, R. Ott and G.B. Rascher. Department of Physical Biology, Max Planck Institute for Developmental Biology, D-72011 Tübingen, Federal Republic of Germany.

In contrast to mammals, in teleost fish the capability for the production of new neurons and glial cells during adulthood is very pronounced in many brain regions. A previous quantitative mapping of the proliferation zones in the brain of adult *Apteronotus leptorhynchus* (Teleostei, Gymnotiformes) has shown that 75% of all mitotic active cells are situated in the cerebellum [Zupanc and Horschke, *J. Comp. Neurol.* 353, 213-233, 1995]. By employing the thymidine analogue 5-bromo-2'-deoxyuridine, we have, in the present study, investigated the postembryonic development of this brain region in detail.

In the corpus cerebelli and the valvula cerebelli, the vast majority of newborn cells originates in the respective molecular layers. Within the first few days of their life, these cells migrate towards specific target areas, namely the respective granule cell layers. Ten days after birth, more than 80% of them have reached the granule cell layers of the corpus cerebelli, valvula cerebelli pars lateralis, and valvula cerebelli pars medialis. In the caudal part of the cerebellum, the granule cell layer of the eminentia granularis pars medialis displays the highest mitotic activity. From there, the cells migrate through the adjacent molecular layer to the granule cell layer of the eminentia granularis pars posterior, and within 10 days 70% of the newborn cells have reached this target area. Time-lapse experiments employing survival times between 1 hour and 161 days after the administration of 5-bromo-2'-deoxyuridine ( $n = 48$  fish) demonstrated that a high percentage of the newly generated cells survives for long periods of time. Volumetric measurements of the various cerebellar subdivisions in fish of different sizes ( $n = 12$  fish) indicate that a large fraction of these cells is added to the population of already existing cells, thus resulting in a permanent growth of the target areas and their associated structures.

## 363.12

**SIGNAL TRANSDUCTION IN A CEREBELLAR GRANULE CELL: A MODELING APPROACH.** Huo Lu\*, F.W. Prior<sup>1</sup> and L.J. Larson-Prior. Dept. of Neuroscience & Anatomy, Dept. of Radiology<sup>1</sup>, Penn State Univ. College of Med., Hershey, PA 17033.

The cerebellar granule cell (GC) receives sensory data from incoming mossy fibers which synapse at the tip of the GC dendrite within the glomerulus. Cerebellar granule cell axons may take their origin from the soma, but more frequently arise from one of the dendrites (Palay and Chan-Palay (1974) *Cerebellar Cortex Cytology and Organization*). This architecture may preferentially weight signals on the dendrite from which the axon arises. Thus, differences in the location of the axon hillock region may have a significant impact upon the transduction of synaptic input.

A fifteen compartment model of a cerebellar granule cell, modified from Gabbiani *et al.* (*J. Neurophysiol.* (1994) 72:999) was developed and accurately predicts GC behavior. The model was validated by simulation of voltage clamp responses that matched those experimentally derived from recordings of rat cerebellar GCs (Cull-Candy *et al.*, *J. Physiol.* (1989) 414:179; De Waard *et al.*, *Eur. J. Neurosci.* (1991) 3:771), and by current clamp simulations which matched reported GC firing patterns.

The model explicitly includes compartments for the axon hillock and proximal axon. Four dendrites are modeled, each consisting of two compartments and a terminal bulb on which all synaptic contacts are made. One proximal dendritic compartment contains active conductances. The axonal compartments were placed either at the soma or on the active dendritic compartment and tested for their responses to synaptic activation at each terminal bulb. Inputs varied in their number, frequency and phase relationships and were transduced via activation of ionotropic (AMPA and NMDA type) and metabotropic glutamate receptor subtypes. Supported in part by Penn. State Univ. and NS 30759 (LLP).

## 363.14

**AN EARLY CRITICAL PERIOD IN OLIVOCEREBELLAR INTERACTIONS DEFINED BY TARGETED ABLATION OF PURKINJE CELLS.** T. Chu<sup>1,2</sup> and J. Oberdick<sup>2,3</sup>. <sup>1</sup>Neuroscience Program, <sup>2</sup>The Neurobiotechnology Center, and <sup>3</sup>The Department of Cell Biology, Neurobiology and Anatomy, The Ohio State University, Columbus, OH 43210.

In last year's abstract we reported that olivary neurons (ONs) begin to degenerate at P4 in the novel mouse mutant L7ADT as observed in Nissl preparations, and that by P15 few ONs are detectable (T. Chu *et al.* 1994, Soc. Neurosci. Abstr.). However, using an olive-specific probe (Brn-3), we now show by *in situ* hybridization that there are clearly Brn-3 positive ONs in P41 mutants. The size of the mutant olive at this relatively late age is reduced along the rostrocaudal, the mediolateral and the dorsoventral axes, with uniformly distributed cell loss. In contrast, at P4 the most severe cell loss occurs at the medial accessory olive (MAO). We further performed TUNEL assay, an assay that detects "apoptotic" cell death, on P4 brain sections and found specific nuclear labeling in only the caudal olive, especially the MAO. The caudal olive has been shown to project to the medial cerebellum (M. Paradies *et al.* 1993, Dev. Dynam. 197:125-145), which is the part of the cerebellum which first shows Purkinje cell (PC) degeneration in our mutant. Thus these data suggest an early target-dependent and topographically oriented interaction between ONs and PCs. TUNEL assay using P7 or older brain sections, however, fails to detect any specific nuclear labeling above that in wild-type mice, even though the data from Nissl stain and *in situ* hybridization demonstrate that ON loss continues as the animal approaches adulthood. Therefore, we propose that ONs are most vulnerable to PC loss during the first four or five postnatal days in the mutant and that the severity of this dependence tapers off as the animal ages. This is consistent with the observation of a period of olive cell loss in normal development that extends from P3 to P5 in the rat (N. Delhaye-Bouchaud *et al.* 1985, J. Comp. Neurol. 232:299-308.). Supported by NSF # IBN-9309611.

## CEREBELLUM: CLINICAL STUDIES

## 364.1

**KINESTHETIC CONTROL OF MOVEMENT IN CEREBELLAR DISEASE.** Stephen E. Grill<sup>1</sup>, Mark Hallett<sup>1</sup>, and Lisa M. McShane<sup>2</sup>. Human Motor Control Sect.<sup>1</sup>, Biometry and Field Studies Branch<sup>2</sup>, NINDS, NIH, Bethesda, MD 20892.

Normal subjects use kinesthetic information to control movement (Cordo *et al.* 1993). Cerebellar dysfunction may be in part due to improper use of kinesthetic information. We evaluated the ability to use kinesthetic information during movement in 14 patients with cerebellar degenerations and 14 normal controls.

Subjects were seated with the right index finger connected to a rotary torque motor and the left hand holding a switch triggered by the thumb. They viewed an oscilloscope on which one beam represented the right index finger angle and the other corresponded to a joint angle at which they were to trigger the switch. Initial finger position was 18 deg extended relative to the trigger angle. In training, 500 ms after a tone the index finger was moved at 20 deg/s in the flexor direction. After each trial, subjects received feedback on the oscilloscope showing how much they undershot or overshot. Further training used the same velocity but the beams vanished at trial onset, and reappeared upon completion to give feedback. For the experimental session 200 flexor movements ranging from 10 to 88 deg/s were imposed on the index finger in pseudorandom order. Subjects adjusted the timing of triggering depending on the velocity. An additional 200 similar trials were run in which subjects reacted as quickly as possible to perception of movement. EMG was recorded from the flexor pollicis brevis muscle in a subset of the subjects.

Cerebellar patients performed much worse compared to controls. Although able to trigger accurately when the movements were slow, they triggered too late for faster movements. The difference between the minimum reaction time and the minimum time to produce coordinated triggering reflects kinesthetic processing time and was not different in patients and controls. Poor patient performance was instead due to prolonged reaction times which the EMG recordings indicate was partly due to longer time from onset of EMG to switch press.

## 364.2

**PERFORMANCE OF CEREBELLAR PATIENTS IN A MULTI-JOINT, VISUOMOTOR ADAPTATION TASK.** S.J. Shanhag\*, J. Matsumoto, E. Ahlskog, R.F. Poppele, and T.J. Ebner. Departments of Neurosurgery and Physiology and Graduate Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455, and Department of Neurology, Mayo Clinic, Rochester, MN 55905.

The role of the cerebellum in motor learning and adaptation remains a controversial issue. We have examined the influence of the cerebellum in motor learning through the use of a visuomotor adaptation task to assess the motor learning deficits in human patients with acute cerebellar damage. Subjects were seated in front of a video display and controlled the movement of a cursor on the display using a planar, 2-joint manipulandum. A sling supported the elbow to restrict movement to the horizontal plane. Subjects were required to hold the cursor in a central "start box" until one of eight equidistant "target" boxes appeared; the cursor then had to be moved to and held inside the target box within a movement time window. After a practice period on a normal hand-cursor movement relationship, the X and Y cursor gains were reversed. At the end of this learning period, the initial gains were restored. Our previous study with this task in normal subjects (Shanhag & Ebner, *Soc Neurosci. Abstr.* 1994) showed that learning may be characterized by two phases of movement kinematics. The first, feedforward phase is rapidly reorganized during the learning of the visuomotor transformation while the second phase, which utilizes visual feedback, is modified more gradually. Patients with isolated, stable cerebellar lesions did not display these characteristics, but instead showed increased movement times and multiple corrective movements as a result of dysmetria. However, quantification of the initial direction of movement under the different gain conditions suggests that the patients are able to adapt to the changes in the hand-cursor relationship. Supported by NIH grants NS-18338 and NS-28633.

## 364.3

LOCALIZATION OF SPECIFIC REGIONS OF THE CEREBELLAR SYSTEM INVOLVED IN PRISM ADAPTATION. T.A. Martin\*, J.G. Keating, H.P. Goodkin, A.J. Bastian, and W.T. Thach. Dept. of Anatomy and Neurobiology and IWJ Rehab. Res. Inst., Washington University School of Medicine, St. Louis, MO, 63110.

To test prior assertions that the cerebellum is involved in wedge prism adaptation of limb movements directed to visual targets (Baizer and Glickstein, 1974; Weiner et al., 1983), we studied patients with cerebellar damage. Our preliminary results (Thach et al., Soc. Neurosci. Abs. 551.2, 1991) supported the hypothesis that the olivocerebellar system plays an important role in this visuomotor adaptation. Further studies of patients with specific lesions of the cerebellum or its inputs or outputs have been done to localize the regions of the olivocerebellar system that are necessary for normal prism adaptation.

Patients with generalized cerebellar atrophy, lesions of the superior vermis, damage of the inferior olive, infarcts in the distribution of the posterior inferior cerebellar artery (PICA; possibly with inferior cerebellar peduncle involvement), and focal infarcts in the contralateral basal pons or ipsilateral middle cerebellar peduncle had absent or impaired ability for prism adaptation. This group often showed mild or no limb ataxia. By contrast, subjects with infarcts in the distribution of the superior cerebellar artery territory (SCA; involving the anterior superior surface of the cortex and the dentate nucleus) or in the cerebellar receiving zones of the thalamus usually adapted normally. This group often had marked limb ataxia.

These results implicate climbing fibers from the contralateral inferior olive via the ipsilateral inferior cerebellar peduncle, mossy fibers from the contralateral pontocerebellar nuclei via the ipsilateral middle cerebellar peduncle, and superior vermal cerebellar cortex as being critical for this adaptation. Not necessary are lateral hemisphere cortex and the dentato-thalamic projection. (Supported by ONR N00014-92-J-1827 and NIH Grant NS12777)

## 364.5

RESPONSES TO REPEATED LOCOMOTOR PERTURBATIONS IN CEREBELLAR PATIENTS.

M.K. Rand\*, D.A. Wunderlich, P.E. Martin, G.E. Stelmach, J.R. Bloedel. Arizona State Univ., Tempe, AZ, 85287; Barrow Neurological Institute, Phoenix, AZ, 85013.

The cerebellar patients' locomotor behavior in response to treadmill perturbations was studied to test whether they can establish strategies for responding to unexpected perturbations that minimize alternations of gait. The perturbation, which lasted about 1.5 sec and consisted of a sudden slowing of the treadmill followed by a sudden increase in speed up to the original speed, was given repeatedly at random intervals during treadmill walking. The cerebellar patients participating in this study had recovered from mass lesions affecting the cerebellum extensively enough so that no clinical locomotor deficit was apparent in normal over-ground walking.

Age matched control subjects could modify their gait in a manner that permitted them to locomote with near normal stepping and EMG pattern in the gastrocnemius and anterior tibial muscles after adaptation to the perturbation. In contrast, cerebellar patients attempted to compensate for the perturbation with a variety of strategies, none resulting in the re-establishment of a relatively normal gait pattern with minimal variability in EMG amplitude over the time period of the perturbation. The results suggest that, although the cerebellar patients can adapt their behavior in response to the perturbation, they cannot establish a consistent, efficient strategy for overcoming the imposed modification in treadmill movement.

## 364.7

CEREBELLAR INVOLVEMENT IN MOTOR PREPARATION: A PET-REACTION TIME (RT) STUDY. B. Horwitz\*<sup>1</sup>, M.P. Deiber\*<sup>2</sup>, V. Ibanez\*<sup>2</sup>, N. Sadato\*<sup>2</sup>, M. Hallett\*<sup>2</sup>. <sup>1</sup>Lab. Neurosci, NIA, <sup>2</sup>Motor Control Section, Medical Neurol. Branch, NINDS, NIH, Bethesda, MD, 20892.

Regional cerebral blood flow (rCBF), measured by [<sup>15</sup>O]-water and PET, and RTs were obtained during performance of two tasks in which 13 right-handed subjects responded with one of two right finger movements in one of two dimensions after receiving either complete (full condition) or no advanced (none condition) visual information as to finger and dimension (Deiber et al., Soc. Neurosci. Abstr. 1994, 20: 443). RT was significantly longer during the none condition than during the full condition. Correlations between RT and normalized rCBF were obtained using a pixel-based method (Horwitz et al., Beh. Brain Res. 1995, 66: 187-193). Significant negative correlations between cerebellar rCBF and RT were found for both conditions, but not for other motor cortical structures (primary motor, supplementary motor, premotor). Comparing the none vs. full conditions, the right cerebellum (ipsilateral to the movements) was the only brain structure for which the change in RT significantly correlated with the change in rCBF ( $r = -0.686$ ,  $p < .01$ ). These results demonstrate that faster RT during tasks primarily concerned with movement preparation is related to higher cerebellar rCBF, but not to rCBF in cortical motor structures. They further suggest that the cerebellum plays a major role in allowing subjects to react quickly in the absence of advanced information needed for preparation of specific movements.

## 364.4

SCHEMATIC MODEL OF SHORT- AND LONG-TERM ADJUSTMENTS OF EYE-HAND COORDINATION IN THROWING. W.T. Thach\*, T.A. Martin, J.G. Keating, H.P. Goodkin, and A.J. Bastian. Dept. of Anatomy and IWJ Rehab. Res. Inst., Washington University School of Medicine, St. Louis, MO, 63110.

In throwing at a visual target while wearing laterally displacing wedge prisms, subjects may undergo two types of adjustment of the gaze-throw angle. Over a short term (10-50 throws), the subject changes this angle to a new calibration value (Kane and Thach, 1989; Thach et al., 1992). The new calibration is retained for a day or longer. Over a longer term (6000 throws, 6 weeks) of alternate prism/no-prism throws, the subject acquires a second prism calibration in addition to the no-prism calibration. He hits the target upon each first throw, prism or no-prism. The two calibrations are retained without practice for 18 months or longer.

To determine the anatomic components of the gaze-throw recalibration in two long term prism/no-prism trained subjects (Martin et al., 1993), we video-recorded positions of head-in-space and shoulders-in-space while throwing with and without prisms. Knowing that eyes foveated the target and that throws hit the target, we computed the angular positions of eyes-in-head, head-on-trunk, and trunk-on-arm. We found that for both subjects, the gaze adjustment was not confined to any one set of 2 members (e.g. eyes-in-head), but instead was distributed across all 3 sets of coupled body parts. Moreover, each subject had a different distribution of coupling changes across the 3 sets of coupled body parts.

We have created a schematic model based on the knowledge that the cerebellum plays roles both in the coordinated movement of multiple body parts and in motor learning and the assumption that the inferior olive climbing fiber discharge is sensitive to the direction of visually-detected error of movement and can adjust movement performance through LTD of pf-Pc contacts. The model uses these features to account for (1) the distribution of the gaze-throw short- and long-term adjustments across multiple body parts, (2) the privacy of adaptation to the trained body parts or task, (3) the differences between short-term adaptation and long-term acquisition of skills. ## 364.6

VERBAL FLUENCY IMPAIRMENT IN PATIENTS WITH

CEREBELLAR LESIONS. M.G. Leggio\*, A. Solida, M.C. Silveri, G. Gainotti, and M. Molinari. Experimental Neurology Lab, Neuropsychology Service, Institute of Neurology, Catholic University, Largo A. Gemelli 8, 00168 Roma, Italy.

Emerging evidence suggests that Cerebellar computational properties may be important for cognitive functions. Recently we have reported a single case of agrammatism after focal cerebellar damage. Aim of the present study was to investigate verbal output in cerebellar patients by means of a timed verbal task requiring naming production under forced (phonemic or semantic) conditions. Cerebellar patients ( $n=25$ ) affected by right ( $n=6$ ) or left ( $n=13$ ) focal lesions or with cerebellar atrophy ( $n=6$ ) have been compared to age and education matched controls ( $n=30$ ). Cerebellar patients produced significantly fewer words in both tasks although with poorer performances under phonemic conditions. To better define the production patterns semantic and phonemic clusters analysis was performed. Cerebellar patients displayed clear difficulties in phonemic clustering. Although right lesioned patients presented the most affected performances, comparison between right and left lesioned groups fail to reach statistical significance. Statistically significance difference were observed between atrophic and focal lesioned groups, with poorer performances for the focal group. The present findings indicate that cerebellar patients are impaired in verbal production with specific difficulties to utilize phonemic retrieval strategies. This defect may represent a specific impairment of verbal skills or a disturbance of correct timing and planning for the access to information.

## 365.1

DISTRIBUTION OF SPONTANEOUSLY ACTIVE NEURONS IN MEDIAL AND LATERAL VESTIBULAR NUCLEI OF RAT BRAINSTEM SLICES. Y. Sun<sup>1</sup>, H. J. Waller<sup>2</sup>, D. A. Godfrey<sup>1</sup>, and A. M. Rubin<sup>1</sup>. Depts. of Otolaryngology<sup>1</sup> and Neurological Surgery<sup>2</sup>, Medical College of Ohio, Toledo, OH 43699.

Spontaneous neuronal firing is prominent in some brainstem structures *in vitro*, but uncommon in others. However, the functional significance of spontaneous activity and its relationships to membrane, interneuronal, and neurochemical variables are largely unknown. In this study, we have explored the medial (MVN) and lateral (LVN) vestibular nuclei with extracellular microelectrodes to determine the locations of spontaneously active neurons.

Transverse or horizontal slices of rat brainstem were cut with a Vibratome at 550  $\mu$ m, and the location and firing pattern of each spontaneously active neuron were recorded. 266 neurons were found in 1166 penetrations of MVN, 15 neurons in 433 penetrations of LVN. In horizontal sections, relatively more neurons were found in the rostral half (0.46 neurons/penetration) than the caudal half (0.18 neurons/penetration) of MVN. In transverse sections, relatively more neurons were found in the medial half (0.26 neurons/penetration) than the lateral half (0.10 neurons/penetration) of MVN.

Most of the neurons showed regular patterns (97% in MVN, 73% in LVN). Mean firing rates were similar in MVN and LVN ( $22.5 \pm 12.0/s$  and  $19.4 \pm 10.7/s$  respectively), but MVN neurons showed greater regularity (coefficients of variation of intervals:  $0.11 \pm 0.27$  in MVN,  $0.25 \pm 0.17$  in LVN,  $P < 0.05$ ). In contrast with dorsal cochlear nucleus (Waller and Godfrey, 1994), no neurons showed bursting patterns. We conclude that there are marked regional differences in the relative numbers of spontaneously active vestibular neurons, but only small differences in the characteristics of their discharge.

## 365.3

NITRIC OXIDE SYNTHASE LOCALIZED IN A SUBPOPULATION OF VESTIBULAR EFFERENTS WITH NADPH DIAPHORASE HISTOCHEMISTRY. M. Singer and A. Lysakowski<sup>1</sup>. Dept. of Anatomy and Cell Biology, Univ. of Illinois College of Medicine, Chicago, IL, 60612.

Nitric oxide (NO) has recently been discovered to be both a second messenger and a neurotransmitter in a wide variety of physiological systems. Recent reports indicate it may play an important role in the vestibular periphery. One report (Chen and Eatock, *Biophys. J.*, A430, 1994) has shown that NO-producing agents inhibit a low-voltage-activated potassium current ( $I_{K,L}$ ) specific to type I hair cells. Other reports claim nitric oxide synthase (NOS) is present in rat vestibular ganglion cells and in boutons throughout the sensory epithelium (Lyon et al., *Neurosci. Abst.*, 20:969, 1994; Harper et al., *OHNS* 111: 430, 1994). Vestibular bouton afferents have a restricted distribution, namely the peripheral zone of the crista (Fernández et al., *J. Neurophysiol.* 60:167, 1988, 73:1253, 1995). We decided to investigate the distribution of NOS to clarify the role of NO in the vestibular periphery.

No known single neurotransmitter colocalizes with NOS. NADPH diaphorase histochemistry has been used to selectively label NOS neurons because fixation of tissue with paraformaldehyde appears to inactivate all NADPH-dependent oxidative enzymes, except for NOS (Dawson et al., *PNAS*, 88: 7797, 1991; Matsumoto et al., *Neurosci. Lett.*, 155: 61, 1993).

The vestibular endorgans and brainstem of adult chinchillas (*C. laniger*) and Long-Evans rats were reacted using NADPH diaphorase histochemistry. Diaphorase-positive staining was present in hair cells of both types (mainly at the apex of the crista), in boutons at the basal end of hair cells, and in a subpopulation (20%) of the lateral vestibular efferent brainstem group. Label was markedly absent from calyces and ganglion cells. In ultrastructural material, the reaction product was seen in efferent boutons. (Supported by NIDCD DC-01474 and DC-02290.)

## 365.5

CALCIUM-BINDING PROTEIN STAINING REVEALS DIFFERENCES IN THE DISTRIBUTION OF PRIMARY AFFERENT AND PURKINJE CELL TERMINALS IN THE VESTIBULAR NUCLEI. Golda Anne Kevetter<sup>1</sup> and Robert B. Leonard<sup>2</sup>. Depts. Otolaryngology, Anat. and Neurosciences, Physiology and Biophysics, Univ. TX Med. Br., Galveston, TX 77555

Previously we have shown staining for calcium-binding proteins in the vestibular nuclei. The distribution of staining suggests these proteins stain at least the primary afferents, cerebellar Purkinje cells, or both. To distinguish these possibilities we made lesions either in the vestibular nerve central to Scarpa's ganglion or the cortex of the cerebellum. Immunohistochemistry with antibodies for calretinin or calbindin was performed. Analyses concentrated on the medial vestibular nucleus (MVN). Calretinin-staining was substantially reduced after lesion of the nerve. Staining was most reduced over the magnocellular portion of MVN. Changes in labeling adjacent to the ventricle could not be determined since a population of neurons in this location, possibly intrinsic, stain with calretinin histochemistry. No reduction of staining was seen after lesion of the cerebellum. This was not surprising since neither Purkinje cells nor cells in the cerebellar nuclei stain with calretinin. Staining with calbindin was different. After lesion of the nerve, calbindin staining was also significantly reduced in the magnocellular MVN. However, a dense area of terminal staining was apparent in the medial MVN, especially along the ventricular border and the ventral border with the nucleus prepositus hypoglossi. After lesion of the cerebellum, staining was reduced in those areas. Remaining fibers and terminals that stained positive for calbindin were concentrated in the lateral and magnocellular MVN. These preliminary experiments indicate that select populations of afferents to the vestibular nuclei may possess different chemical properties. (Supported in part by NIH grant DC0052 and Deafness Research Foundation)

## 365.2

NMDA RECEPTOR-MEDIATED INHIBITION OF THE BRAINSTEM VESTIBULAR SYSTEM IN VESTIBULAR COMPENSATION IN RATS. T. Kitahara, N. Takeda<sup>1</sup>, T. Kubo<sup>2</sup> and H. Kiyama<sup>2</sup>. Depts. of Neuroanatomy & ORL, Osaka Univ. Med. Sch., Suita, Osaka 565, Japan.

After unilateral labyrinthectomy (UL), Fos-like immunoreactive (-LIR) neurons appeared in the ipsi-MVe, contra-PrH and contra-IO beta, and then gradually disappeared in accordance with the development of vestibular compensation. This finding means that the activation of these nuclei is the initial event of vestibular compensation. By means of retrograde tracing, it was revealed that a part of the Fos-LIR neurons project their axons to the vestibulocerebellum.

Before vestibular compensation is accomplished, injection of MK801, an antagonist of NMDA receptor, caused reappearance of UL-induced behavioral deficits (decompensation) and Fos expression in the contra-MVe, ipsi-PrH and bilateral-IO beta. These findings indicate that the neurons in which Fos was expressed by MK801 had been inhibited after UL by glutamatergic synapses driving inhibitory neurons via NMDA receptors and that disinhibition of these neurons induced by MK801 caused decompensation. Accordingly, it is suggested that the NMDA receptor-mediated inhibition of the brainstem vestibular system plays an important role for the initial processes of vestibular compensation. Cerebellar afferents are mediated by NMDA receptors and cerebellar efferents are GABAergic. Therefore, it may be further suggested that the vestibulocerebellum is a component of the NMDA receptor-mediated inhibition.

## 365.4

CALRETININ IS NOT SPECIFIC FOR CALYCEAL AFFERENTS IN THE SEMICIRCULAR CANALS OF *PSEUDOMYS SCRIPTA*. G. Monk and E. H. Peterson<sup>1</sup>. Dept. Biological Sciences and Neurobiology Program, Ohio University, Athens, OH 45701.

The calcium-binding protein calretinin has been reported to stain calyx afferents selectively in the vestibular endorgans of rodents. The reason for this selectivity is unknown. Calyx afferents in mammals typically have larger axon diameters than other afferent types. Thus, two interpretations of calretinin staining patterns are possible: calretinin may be selective for (a) calyx afferents or (b) large diameter afferents.

To distinguish between these possibilities, we assayed calretinin-like activity in the posterior canal of the turtle, *P. scripta*. *Pseudomys* is unusual among amniotes in possessing a population of bouton afferents with axons as large or larger than calyx afferents ( $\beta$ -bouton afferents; Brichta and Peterson, 1994, *J. Comp. Neurol.*, 344:481-507); they are located preferentially toward the canal center.

Two types of afferents were labeled following immunocytochemical demonstration of calretinin-like activity. Calyx afferents were stained throughout the central zones of each hemicrista; their distribution and structure were consistent with our earlier description of these neurons (Brichta and Peterson, 1994). In addition, a small number of very large diameter bouton afferents were labeled near the canal center; their numbers, structure, and distribution suggests that they correspond to  $\beta$ -bouton afferents.

Our data demonstrate that calretinin-like activity is not restricted to calyx afferents in *Pseudomys*. Thus, calretinin may be selective for very large diameter afferents, independent of type.

## 365.6

QUANTITATIVE DISTRIBUTION OF CHOLINE ACETYLTRANSFERASE ACTIVITY IN RAT VESTIBULAR NUCLEAR COMPLEX. H. Li<sup>1</sup>, A. B. Squire, D. A. Godfrey, and A. M. Rubin<sup>1</sup>. Dept. of Otolaryngology-Head and Neck Surgery, Med. Col. of Ohio, Toledo, OH 43699-0008.

Cholinergic structures in and near the rat vestibular nuclear complex (VNC) probably include secondary projections from the VNC to cerebellar cortex (Barmack et al., 1992), centrifugal fibers to the vestibular labyrinth (Schwarz et al., 1986), and innervation from unidentified sources (Burke and Fahn, 1985). In order to estimate the prominence of these cholinergic structures, choline acetyltransferase (ChAT) activity was mapped at 3 rostral-caudal levels through the VNC, by microdissection of freeze-dried sections and radiochemical assay. The overall ChAT activity in the VNC was

	$\mu$ mol/kg dry wt/min (mean $\pm$ SE, n=4 rats)
MVN dorsal	145 $\pm$ 11
MVN ventral	133 $\pm$ 20
LVN dorsal	64 $\pm$ 13
LVN ventral	86 $\pm$ 12
SuVN	67 $\pm$ 10
SpVN	68 $\pm$ 4

only about 1/4 of that of the cochlear nucleus, about 1/6 of that of whole rat brain, and about 1/50 of that of the cholinergic facial motor nucleus. Among VNC regions, ChAT activity (see Table) was higher in the medial (MVN) than in the lateral (LVN), superior (SuVN), or spinal (SpVN) nuclei. Activity tended to be highest in the most superficial part of MVN, but no rostral-caudal gradient was found. ChAT activity among the main group of vestibular efferent neurons was about twice that in the nuclei containing olivocochlear neurons. It is suggested that: 1) The activity of ChAT in rat VNC is lower than previously estimated. 2) Cholinergic structures are more prominent in MVN than in other VNC regions. 3) Cholinergic mechanisms are important in vestibular centrifugal control. (NIH grant R01-DC2550)

## 365.7

**CONSTITUTIVE AND INDUCED NITRIC OXIDE SYNTHASE IN THE VESTIBULAR COMPLEX AND GANGLION.** Dale W. Saxon\* and Alvin J. Beitz. Dept. of Vet/Pathobiol., Univ. of Minn., St. Paul, MN, 55108. The enzyme nitric oxide synthase (NOS) is responsible for the production of nitric oxide, a gaseous molecule now widely believed to be involved in neurotransmission in the CNS and PNS. In addition to its widespread distribution in the nervous system under normal circumstances NOS has recently been shown to be induced in neurons of precerebellar nuclei (Saxon and Beitz, '94). Using NADPH-diaphorase as a marker, the distribution of neurons containing constitutive (cNOS) and induced NOS (iNOS) was investigated in the vestibular complex and vestibular (Scarpas) ganglion. Neurons containing cNOS in the vestibular complex were largely confined to the medial vestibular nucleus (MVN) with a small number of faintly stained neurons occasionally encountered in nucleus X. cNOS neurons were distributed along the entire length of the MVN although the rostral part of the nucleus contained only a sparse population. Except for the presence of a network of positively stained fibers which permeate the neuropil of the entire vestibular complex, vestibular nuclei other than the MVN lacked perikaryal staining. The vestibular ganglion contained very little constitutive NOS. However, following lesions to the cerebellar cortex and survival times of 7 days or greater, neurons containing induced NOS were found in the inferior, lateral and superior vestibular nuclei. In addition, induced neurons were found in the nucleus of Roller, nucleus X, nucleus linearis, lateral reticular nucleus and external cuneate nucleus. Lesion/fluoro-Gold injections into the midline cortex resulted in double-labeled neurons in several precerebellar nuclei including the inferior vestibular nucleus. Although the MVN contained numerous retrogradely labeled neurons, particularly in the caudal half of the nucleus none of these neurons were found to contain NOS. Following cerebellar lesions that included damage to the vestibular complex induced NOS was evident in cell bodies of the vestibular ganglion and in axonal profiles in the root of the VIII nerve ipsilateral to the lesion. The impact of induced NOS on the function of the vestibular system remains to be elucidated, but the present study provides the groundwork for the undertaking of such future studies. This work was supported by NIH Grant #NS31318.

## 365.9

**SYNAPTIC INTERACTIONS IN THE VESTIBULO-OCULAR PATHWAYS OF GUINEA PIG STUDIED IN AN IN VITRO WHOLE BRAIN PREPARATION.** A. Babalian, N. Vibert, M. Scrafan, M. Mühlethaler and P.-P. Vidal\*, I.P.P.A., CNRS-Colège de France, 15 rue Ecole de Médecine, 75006 Paris, France; 2 Dpt. Physiologie, CMU, 1 rue Michel-Servet, 1211 Geneva 4, Switzerland.

The isolated and perfused whole brain of guinea-pig is a powerful tool to tackle various neurophysiological problems. It combines the advantages of *in vitro* preparations (stable recording conditions, control of the extracellular medium, etc...) with the preserved connectivity of an intact brain. We studied on this preparation synaptic transmission between vestibular afferents and second-order vestibular neurones. Both extracellular field potentials and synaptic responses of single neurones were recorded within the vestibular nuclei (mainly the medial one) following stimulations of vestibular nerves. Using a low  $Ca^{2+}$ /high  $Mg^{2+}$  solution which blocks chemical transmission, we assessed the pre- and postsynaptic components of field potentials. They were similar to those observed *in vivo*, with delayed latencies (by 30 to 40%) due to lower recording temperature (29°C). Stimulation of the ipsilateral vestibular nerve produced monosynaptic EPSPs (latency 1.1-1.8 ms) in all three main cell types previously identified in slices (A, B and B+LTS neurones). Type A and B neurones revealed regular and irregular spontaneous discharges, respectively, implying that they might correspond to the tonic and phasic vestibular neurones described *in vivo*. Both synaptic field and EPSPs were largely blocked by CNQX, indicating AMPA receptor-mediated synaptic transmission. The remaining component was generally blocked by APV, suggesting involvement of NMDA receptors. In some cases however, a small synaptic component resistant to both antagonists was observed. We have furthermore studied the vestibulo-oculomotor interactions by recording: a) discharges of abducens and oculomotor nerves; b) synaptic field potentials in the antidromically-identified abducens and oculomotor nuclei; c) postsynaptic potentials in abducens motoneurons following stimulation of vestibular nerves. It confirmed the existence of strong bilateral, disynaptic inputs (latencies of synaptic events 2.1-3.1 ms) from vestibular afferents to abducens and oculomotor nuclei.

## 365.11

**DEVELOPMENT OF A NOVEL, REVERSIBLE LABYRINTHECTOMY MODEL: BEHAVIORAL AND ANATOMICAL CORRELATES.** A.J. Beitz\*, D.W. Saxon and J.H. Anderson. Dept. of Vet. Pathobiology and Dept. of Otolaryngology, Univ. of Minnesota, St. Paul, MN 55108.

Previous studies of the effects of unilateral labyrinthectomy (UL) have used models in which the labyrinth is destroyed surgically or by injection of toxic chemicals into the middle or inner ear. In the present study we have developed a reversible UL procedure in which 25  $\mu$ l (0.3 mM) of tetrodotoxin (TTX), a voltage sensitive sodium channel blocker, is injected into the middle ear of adult Long-Evans rats. This procedure is adapted from that described by Rubel and colleagues for blockage of cochlear nerve activity. Compared to saline injected controls, the effects of TTX were evident within 10-20 min following injection, as evidenced by the typical behavior signs: nystagmus, tonic head tilt, and ataxic gait combined with circling of the animal toward the side of injection. These vestibular signs lasted for up to 24 hr. Two groups of rats were perfused with fixative at 3 hr and 24 hr postinjection, respectively, and the brains were processed for immunocytochemical localization of the immediate early gene, Fos. In TTX-treated rats sacrificed at 3 hr Fos expression was prominent bilaterally in the prepositus hypoglossi and the rostral portion of the SVN, contralaterally in the rostral portion of the medial vestibular nucleus (MVN), and ipsilaterally in the IVN, the Y-group and the caudal portion of the MVN. By 24 hr post-injection Fos immunolabeling decreased throughout the vestibular complex, except in the caudal MVN and contralateral prepositus hypoglossi. In addition to the vestibular complex, there was Fos expression in various subnuclei of the ipsilateral inferior olivary complex and in the fastigial nucleus and the granule cell and molecular layers of lobules 9 and 10 of the cerebellum. These data support and extend previous studies examining Fos expression following UL and indicate that this new TTX model may be useful for future studies of UL. Supported by NIH grants NS31318, DCD 01086 and DCD 00110.

## 365.8

**IMMUNOCYTOCHEMICAL STUDY OF GLIAL REACTION IN THE IPSI AND CONTRALATERAL VESTIBULAR NUCLEI OF HEMI-LABYRINTHECTOMIZED RATS.** C. de Waele\*, A. Campos Torres, R. Pochet, P. Josset, P.P. Vidal, I.P.P.A., CNRS-Colège de France, Paris, Lab. Anatomy and cytology, Hôpital Trousseau, Paris, France and Lab. Histologie, ULB, B 1070, Bruxelles, Belgique.

Vestibular compensation is an attractive model for investigations of cellular mechanisms underlying post-lesional plasticity in the adult central nervous system. Immediately after hemilabyrinthectomy, the spontaneous activity in the deafferented second-order vestibular neurons falls to zero, resulting in a strong asymmetry between the resting discharge of the vestibular complexes on the lesioned and intact sides. After about fifty hours, the deafferented vestibular neurons recover a quasi normal resting activity, which is thought to be the key of the compensation of the static vestibular syndromes observed at the acute stage. In this study, we investigated by means of different monoclonal and polyclonal antibodies whether a glial reaction is involved during the vestibular compensation process. Potential degenerating axons were also studied using a silver impregnation method. Adult rats were hemilabyrinthectomized and the appearance of reactive astrocytes was studied at 1, 2, 4, 8 and 21 days post-lesion by means of selective monoclonal GFAP and Vimentin antibodies. Specific antibody binding sites were visualized using the avidin biotin method and the 3'-3'-diaminobenzidine as a peroxidase substrate. Double labelling experiments were performed using secondary fluorescent antibodies. Finally, GFA and Vimentin protein levels were assessed by dot immunoblot techniques. In the normal rats, the vestibular nuclei were devoid of vimentin-positive glial cells and GFAP-positive astroglial cells were uniformly distributed within all the vestibular nuclei. In the hemilabyrinthectomized rats, although very few degenerating axon terminals could be detected, numerous vimentin-positive astroglial cells appeared within the deafferented vestibular nuclei. This reaction became evident between 1 and 2 days following the lesion, peaked at about three days and then declined during the following days. In conclusion, the decrease of the resting discharge of the deafferented central vestibular neurons most probably induced this glial reaction. It remains to be determined the exact role of these reactive astrocytes in the vestibular compensation process.

## 365.10

**IMMUNOHISTOCHEMICAL STAINING FOR CALCIUM BINDING PROTEINS: POTENTIAL CORRELATIONS WITH ANATOMICAL AND/OR PHYSIOLOGICALLY DEFINED VESTIBULAR PRIMARY AFFERENTS.** R.B. Leonard\* and G.A. Kevetter. Departments of Anat. & Neurosci., Physiol. & Biophysics, and Otolaryn., Univ. of TX Medical Branch, Galveston, TX 77555

Vestibular primary afferents in several mammalian species have been subdivided using a combination of physiological and morphological properties of the endings within the sensory neuroepithelium (e.g., Lysakowski et al., '95; Fernandez et al., '95). Other than intracellular labeling of single axons, anatomical techniques used to examine the central projections label all types of afferents. We have been exploring the possibility that staining for various calcium binding proteins can be used to identify types of afferents in gerbils. In initial experiments, we have examined staining for calretinin and calbindin in both the cristae and maculae.

Currently, the results for calretinin are the clearest. Stained fibers progress through the middle of the cristae to reach the sensory epithelium of the central zone. There the fibers form clear, well-stained calyx endings. The stained fibers appear to correspond to the largest fibers seen in plastic embedded sections. No boutons were observed. The same statements apply to the maculae. It is hard to escape the conclusion that these afferents correspond to the calyx-only, highly irregular fibers, originating from the apex of the cristae. Calbindin stains afferents occupying a wider region of the crista. Axonal staining is less intense, but the axon diameters appear to be more variable than seen with calretinin. Calyx endings are readily apparent in the central and intermediate zones and can be found in the peripheral zone. Structures that appear to be boutons can be seen, although continuity with the parent axon is difficult to detect. These statements also apply to the maculae. This pattern suggests that calbindin stains primary afferents with dimorphic endings. (Support by Deafness Res. Fnd)

## 365.12

**ONTOGENY OF VESTIBULAR COMPOUND ACTION POTENTIALS IN THE CHICKEN.** T.A. Jones\* and S.M. Jones. ENT Vestibulo-cochlear Research Lab, University of Missouri, School of Medicine, Columbia, Missouri 65212.

Compound action potentials of the vestibular nerve were measured from the surface of the scalp in 72 chickens (*Gallus domesticus*). Ages ranged from approximately -48 hours (traditional E19) to 336-hours-old (14-days-post-hatch). Zero-hours-old was defined as the time of hatch. Responses were elicited using 2ms duration cranial linear acceleration pulses. Stimuli were expressed in units of jerk (g/ms) or in dB relative to 1.0g/ms. Traditional signal averaging was used to resolve vestibular responses out of the background activity.

Response thresholds decreased systematically up to approximately 200 hours of age. Amplitudes of early peaks (P1, N1, P2) increased linearly as a function of age presenting a rate of maturation of  $0.11 \pm 0.02 \mu V/day$  (mean  $\pm$  sd). Response latencies decreased with increasing age up to 350-hours-old (rate =  $-28.1 \pm 8.5 \mu s/day$ ). Responses were not resolved at ages younger than -52-hours-old (late E18). These data suggest that functional development continues after all major morphological structures are in place. Functional improvement may correspond to neural myelination and synaptic maturation, two of many possible explanations for the findings. (Supported by NASA NAGW 1275, 3910)

## 365.13

CONTRIBUTION OF TONIC INPUT FROM THE LABYRINTH TO THE POSTURAL CONTROL IN THE RAT. T. Deliagina\*, L. Popova, G. Grant, G. Orlovsky. Department of Neuroscience, Karolinska Institute, S-171 77, Stockholm, Sweden.

Removal of a vestibular organ (unilateral labyrinthectomy, UL) results in severe motor disorders. Two principally different primary causes are responsible for them: a considerable loss of the sensory (vestibular) information and a loss of tonic excitatory inflow from the labyrinth. In the present study, a role of the tonic inflow was investigated. For this purpose, the effect of electrical stimulation of the transected vestibular nerve on different motor disorders, evoked by UL was studied in freely behaving rats. This stimulation was used to "substitute" the lost tonic vestibular input. Six UL-evoked motor disorders were investigated. They appeared in a fixed order after surgery: (1) body twisting, (2) rolling, (3) extension of limbs contralateral to UL, (4) circling, (5) head roll tilt, (6) spontaneous ocular nystagmus. Stimulation of the vestibular nerve in UL-rats completely abolished the symptoms (1-5), and reduced considerably the symptom (6). Thus, an artificial tonic input from the vestibular nerve, not depending on movements of the animal and on its position in space, can abolish most motor disorders evoked by UL. In addition, postural disorders evoked by electrical stimulation of the vestibular nerve in the rats subjected to bilateral labyrinthectomy, were studied. By increasing gradually the strength of current stimulating the vestibular nerve, we could evoke all the UL-symptoms, but in a reversed order. Thus, a loss of tonic input from the labyrinth, rather than a loss of specific vestibular information, is the cause for most motor disorders evoked by UL in the rat.

PROGRESSIVE FUNCTIONAL DECLINE OF VESTIBULO-OCULAR REFLEX AFTER INTRA-OTIC ADMINISTRATION OF GENTAMICIN IN THE CHINCHILLA Christian Head, Karl Beykirch, Alan Greenfield, Ivan Lopez, Larry Hoffman\* UCLA School of Medicine, Los Angeles, CA 90095

Vestibulo-ocular reflexes were measured in the chinchilla to document the functional decline after intraotic gentamicin (GM) administration. The time course of functional loss was correlated with the histological evidence of hair cell loss from the sensory epithelium. Eye movements induced by rotation about the yaw axis in the dark (VOR) were measured in adult animals pre- and post-GM treatment. Sinusoidal rotational stimuli at .0125, .05, .2 and .8 Hz and 120 °/sec peak velocity were used to characterize the VOR pre- and post- GM administration. Following the collection of normative data, the animal subjects received bilateral intra-otic administration of GM. VOR testing was resumed one day post GM treatment (PT). These results were compared to findings from a parallel histologic evaluation of the crista sensory epithelium. Data obtained over a period of six days following GM administration were fit to the standard first order high pass VOR model. The gain obtained from these fits declined exponentially during this period. At one day PT the mean gain declined to 78% of the normal value. The histological data on day one indicated initial damage in hair cells with signs of cytoplasmic vacuolization, nuclear pyknosis and swelling. By day four the mean gain had decreased further to 12% of the normal value. The morphology on day 4 showed a significant increase in destroyed HCs. By day 6 the VOR gain in all three animals at the tested frequencies was  $0.003 \pm 0.001$ . This paralleled histologic findings in animal subjects sacrificed at 7 days post-administration demonstrating HC loss in the sensory epithelium. Our study demonstrates that there is a progressive decline in vestibular function as measured by VOR, after local administration of GM. This progressive loss of VOR also correlates well with the histological time course of HC loss and cellular damage to the sensory neuroepithelium. ENDOLYMPHATIC POLARIZATION AND MECHANICAL STIMULI REVEAL DIVERSITY IN THE ACTIVATION OF SEMICIRCULAR CANAL HAIR CELLS IN THE TOADFISH, *OPSANUS TAU*. R.D. Rabbitt\*<sup>1,4</sup>, S.M. Highstein<sup>3,4</sup> and R. Boyle<sup>2,4</sup> <sup>1</sup>Dept. Bioeng. Univ. Utah, Salt Lake City, UT; <sup>2</sup>Dept. of Otolaryngol. and Physiol., OHSU, Portland, Oregon; <sup>3</sup>Dept. Otolaryngol., Anat. and Neurobiol., Wash. Univ., St. Louis, MO; <sup>4</sup>Marine Biological Laboratory, Woods Hole, MA.

Extracellular responses of individual afferents were recorded for electrical polarization of the endolymphatic space and for micro-mechanical indentation of the limb of the horizontal semicircular canal in the oyster toadfish, *Opsanus tau*. Results delineate the relative contributions of mechanical and post-transduction-current (PTC) mechanisms to the sensory process. The indentation stimulus was designed to mimic physiological head rotation, and the electrical stimulus was designed to bypass the mechanics and drive the transduction current via the Nernst-Planck potential. Overall transfer functions reflect the entire cascade of events from the stimuli to the neural spike train. PTC processing is equivalent for the electrical and mechanical stimuli and hence differences between the afferent responses reflect mechanical events taking place prior to the PTC segment. The mechanical segment leading to gating of hair-cell transduction currents was thereby isolated from the overall process. Results for the mechanical activation of hair cells confirm existence of a purely mechanical lower-corner frequency <0.1 Hz. Above ~0.5 Hz, results show a systematic inter-afferent diversity in both the gain and phase of mechanical activation of hair cells that acts in concert with PTC processing to determine the overall afferent response. For afferents typed as low gain (see Boyle and Highstein, J. Neurosci. 10, 1990), a phase lag in the mechanical activation of hair cells is canceled by a phase lead in PTC to generate responses that align with angular head velocity. In contrast, acceleration type afferents combine a phase lead in the mechanical activation with additional phase lead in PTC to achieve responses that align with angular head acceleration. High-gain type afferents fall in between these two extremes. Commensurate differences in the relative contributions of mechanical and PTC processing are observed in the gain. ## OCULOMOTOR SYSTEM: SACCAD—BEHAVIOR AND IMAGING

## 366.1

FIXATION AND THE GENERATION OF EXPRESS SACCADIES IN HUMANS. M. Biscaldi, D. Cavegn, B. Fischer\*. Brain Research Unit, Institute of Biophysics, University of Freiburg, 79104 Freiburg, Germany

A large incidence of express saccades (ES; latency about 100 ms) without training paralleled by an inability to suppress ES to suddenly appearing stimuli has been observed in a subgroup of dyslexics, but only very rarely in normally reading subjects (Biscaldi et al., 1994 *Invest Ophthalmol & Vis Sci* 35:1951). We studied the latency and the metrical properties of saccades in an adult, non-dyslexic subject. The subject produced 65-95% ES in the gap (fixation point removed 200 ms before target onset) as well as in the overlap (fixation point remains on) paradigm with the target randomly at 4° to the left or right. The number of ES increased when the fixation foreperiod, the gap duration, and the possible target locations varied from trial to trial as compared when they remained fixed. In the gap paradigm, the gain of saccade amplitude was normal. In the overlap paradigm, we observed in some ES an amplitude transition function with the smallest gain at the longest latency. In the antisaccade and memory-guided saccade paradigms, the subject often erroneously reacted with ES to the target, the gain of these ES also systematically decreased with increasing latency. Our findings can be interpreted by a selective dysfunction of the collicular fixation system. A deactivation of the collicular fixation neurons in monkeys results in a strong increase of ES and a loss of fixation control; saccades executed during electrical stimulation of the fixation neurons are strongly hypometric (Munoz & Wurtz, 1993 *J Neurophysiol* 70:576).

## 366.2

GAP-EFFECTS IN DUAL TASK EXPERIMENTS WITH ISO/ANTI TASK CONDITIONS. A. Rolli<sup>1</sup>, W. Wolf<sup>1</sup>, M.M. Wierzbicka\*<sup>2</sup>

<sup>1</sup>Bundeswehr University, Munich, Germany, <sup>2</sup>Brockton/West Roxbury VA Medical Center & Harvard Medical School, Boston MA 02132.

Saccadic and manual reaction times were measured in single and dual task experiments. The target (LED), presented 8° left or right from the fixation point, appeared at the instant when the fixation point was switched off (gap 0) or 200 ms later (gap 200). In the single task condition, subjects responded by either horizontal saccades or forefinger isometric movements as fast as possible, where movement direction requested was to (iso) or opposite to (anti) the target direction in separated sessions. In the dual task condition both movements were required, in which the direction of eye and finger movements could be the same or opposite. We tested all possible combinations of iso and anti direction of the two movements.

The aim of this study was to compare the gap-effect (i.e. shorter reaction times in the gap 200 condition) of saccadic and manual reaction times in single and in dual task experiments in view of a dependence between both movements. We were interested in the relation between target and movement directions, and also in the relation between the directions of the two movements in dual task trials.

In addition, we compared the gap-effects in elderly people (60 years or older) to those in subjects aged below 40 to see if there was the same amount of prolongation of the reaction time as it was seen before in single task studies (Tedeschi et al., *Functional Neurology* 4(4), 1989).

## 366.3

**Brain oscillations: the origin of express saccades?**

K. Kirschfeld\*, R. Feiler and F. Wolf-Oberhollenzer

Max-Planck-Institut für biologische Kybernetik, Spemannstr. 38, D-72076 Tübingen, Germany

The time that elapses between the appearance of a target toward which the eye is supposed to move and the beginning of the eye movement is rather long: 200 ms. According to Carpenter (in Eye Movements: Cognition and Visual Perception, ed. D. F. Fischer; Hillsdale, New Jersey: Erlbaum 1981) the appearance of the target generates a signal that loads an integrator, and once the integrator value reaches a certain threshold, a saccade is triggered. Under a specific experimental paradigm ("gap conditions"), the latency of the (slow) regular saccades is shortened, and the latency-histogram can become multimodal. Saccades with latencies in the region of the first peak are called *express saccades*, those associated with the second peak *fast regular saccades*. The different peaks have been ascribed to different anatomical pathways, operating with individual time delays (Fischer and Weber, Behavioral and Brain Sciences 16, 553-610, 1993). We present a different model based on the idea that shortening of saccadic latency results from a threshold reduction and multimodality from threshold oscillations in the saccade-generating pathway. To oscillate in response to a stimulus is a general property of the CNS. It can be ascribed to feedback loops, the gain in which is high - on the verge to instability - in order to make the system fast.

## 366.5

**OCCURRENCE OF ANTICIPATORY SACCADIC AS A FUNCTION OF EXPECTANCY FOR INFORMATION.** L. Wang\* and J.A. Stern. Dept of Psychology, Washington Univ. St. Louis, MO 63130.

Expectancy for information in this study refers to attentionally anticipating information imparted in forthcoming visual events. Timing and frequency of anticipatory saccadic gaze shift was examined as a function of such expectancy.

Subjects participated in a Continuous Performance Task (CPT). A visual stimulus sequence consisted of 1440 randomly permuted digits. Fifteen target-sequences of three unequal digits with isoparity (target-parity), odd or even, were randomly imbedded in each quarter of the stimulus sequence. The stimuli were presented one digit at a time for 300 ms at a stimulus onset asynchrony (SOA) of 2500 ms. The stimulus locations jumped across the display at the spatial interval of about eight degrees of visual angle from left to right and then reversed, and so on. The participant's task was to press a button when they had detected a target-sequence. They were also informed that the target-sequence would be followed by a digit with non-target-parity.

It was assumed that expectancy for the occurrence of a target-sequence would gradually build up following presentation of relevant stimuli. For example, one's expectancy for the next unequal target-parity digit would be higher after seeing two preceding unequal target-parity digits than after seeing one.

**RESULTS** Anticipatory saccades occurred earlier on trials immediately following two preceding unequal target-parity digits than on other trials. For trials following the target-sequences, anticipatory saccades occurred later, and the frequency of the anticipatory saccades was lower than on the other trials.

**CONCLUSIONS** Expectancy for information affects visual strategies of information acquisition. Gaze shift is facilitated by the expectation to acquiring information, while inhibited by the expectation that the next stimulus will be one not requiring processing.

## 366.7

**SACCADIC LATENCY DEPENDS ON TARGET DIRECTION, NOT ECCENTRICITY.** E. Leslie Cameron and Peter Lennie\*. Center for Visual Science, University of Rochester, Rochester, NY 14627.

Measurements of saccadic latency are generally used to characterize the performance of the oculomotor system. Here we explore some of the decision processes underlying saccadic latency. The main goal was to assess how the amount and form of target uncertainty affect the latency of saccades. To do this we varied the number and distribution of possible target locations. A gap between fixation offset and target onset is known to reduce latency (the gap effect). A second goal was to establish whether spatial uncertainty influences the gap effect.

We monitored eye position with an SRI dual-Purkinje eye tracker. The amount of target uncertainty was varied by setting the number of possible targets between one and twenty. The form of uncertainty was varied by specifying the placement of potential targets in three different ways: (1) variable direction and eccentricity, (2) variable direction, fixed eccentricity and (3) fixed direction, variable eccentricity. We measured the latency of saccades under gap, no gap and overlap conditions.

Saccadic latency increases when the number of possible targets increases from one to two, but shows little increase in latency when the number of possible targets increases beyond two. Latency is longest when direction is variable, regardless of whether eccentricity is variable. When direction is fixed, latency is short, regardless of whether eccentricity is variable. We conclude that direction is more important than eccentricity in determining latency. Our results can be understood in the context of a model of saccade initiation in which the direction and amplitude are programmed in parallel (Becker and Jürgens, Vision Res., 1979, 19, 967). Spatial uncertainty has no influence on the gap effect. Supported by NIH grants EY04440 and EY01319.

## 366.4

**PERCEIVED VISUAL DIRECTION AFFECTS SACCADIC GAIN.**

D.R. Lucas\* and W.A. Hershberger. Psychology Department, Northern Illinois University, DeKalb, IL 60115.

The saccadic eye movement system responds to unusual re-fixation errors by modifying its gain (saccade amplitude/target eccentricity). This adaptive repair mechanism can be invoked in the laboratory by physically displacing the visual target during saccades. We reported in a preliminary study (Lucas & Hershberger, IOVS 35:2033, 1994) that saccadic gain can also be invoked without physical target displacement. Here, we extend our findings to a sample of subjects increased eightfold. On 2-target trials, subjects made horizontal saccades from a central visual fixation target (FT) to a saccade target (ST) displaced 8° rightward, and flashed for 1 ms as soon as FT was extinguished. On 3-target trials, we presented a perisaccadic target (PST) after ST. The PST was displaced 10°, 8°, or 6° rightward from FT and was flashed near the beginning or end of the initial saccade, for a short (1 ms) or long (1 s) duration. Each subject participated in 2 blocks of 30 3-target trials. Before and after each 3-target trial block, subjects participated in blocks of 10 2-target trials (to measure gain changes caused by the 3-target trials). Sixteen subjects served in each of 4 groups defined by factorial combination of PST onset (begin or end) and duration (short or long). PST-10° trials caused gain increases for all groups; PST-6° trials caused gain decreases except for the begin-short group; PST-8° trials caused no gain changes except for the begin-short group. In both exceptional conditions, the begin-short group had gain increases. We propose these increases were caused by the perceptual displacement of the PST known as the perisaccadic illusion of visual direction: Visual targets briefly presented near the beginning of a saccade are seen as displaced in the direction of a saccade. Our results imply that the perisaccadic illusion of visual direction can alter the size of the very saccades that occasion the illusion.

## 366.6

**SACCADIC TO REMEMBERED LOCATIONS DURING TRACKING OF ILLUSORY TARGET MOTION** A.Z. Zivotofsky, K.G. Rottach, A.A. Kori, L. Averbuch-Heller, V.E. Das, C.W. Thomas, S. Kamran and R.J. Leigh\* Ocular Motor Lab., VAMC and Case Western Reserve Univ., Cleveland, OH 44106

Using the magnetic search coil technique, we measured the accuracy of saccades to remembered target locations that were flashed at eccentricities of up to 10.5 deg on a 20 X 30 deg random dot display that was either stationary or moving horizontally sinusoidally at 0.3 Hz. Saccades that were made to targets flashed on a stationary background were accurate (average RMS error of 1.7 deg). When targets were flashed as subjects smoothly pursued a laser spot that moved vertically across the stationary background, saccadic gain was also good (average RMS error of 2.1 deg). The vertical saccade size was closely correlated to spatial, not retinal, error. When saccades were made to targets flashed during attempted fixation of a stationary spot while the background was moving horizontally, the saccades were noticeably inaccurate horizontally for 3 of the 4 subjects (average RMS error for the 3 was 4.6 deg). When targets were flashed as subjects smoothly pursued a laser spot that moved vertically across the horizontally moving background (a condition that induces a strong illusion of diagonal target motion), saccades were strikingly inaccurate horizontally (average RMS error of 5.3 deg), but quite accurate vertically. The horizontal saccadic mislocalization of targets flashed during illusory, diagonal target motion was correlated with both the position of the background at flash and the distance the background traveled subsequent to the flash. In general, the error decreased significantly from the first saccade in darkness to the final position reached by the eye in darkness (an average 18%). ## 366.8

**CONTEXT-SPECIFICITY OF HUMAN SACCADIC ADAPTATION.**M. FUJITA<sup>1,2\*</sup>, A. AMAGAI<sup>3</sup>, F. MINAKAWA<sup>1</sup> Communications Research Laboratory, Koganei, Tokyo 184, Japan<sup>1</sup>, Grad. Sch. Inf. Sys., Univ. Electro-Communications, Chohu, Tokyo 182, Japan<sup>2</sup>.

Response of the visually guided saccade (V-sacc) is well known to be under adaptive control in metrical aspects such as gain and direction. Adaptive modifications are specific to higher-level context aspects as well as to spatial parameters such as to the direction of the response (Deubel, 1993). Present study shows how widely context-specificity of saccadic adaptation works.

There are at least three types of saccades, a memory-guided saccade (M-sacc) made to a remembered target position, and by classifying V-sacc into two types, a visually guided and externally triggered saccade (VE-sacc) which pursues a jump-like target displacement, and a visually guided and internally initiated saccade (VI-sacc) which is initiated to a stationary visible target.

Firstly, adaptive modifications in either M-sacc or VI-sacc could be induced by intrasaccadic target shifts as in Deubel's paradigm. Each session comprised of adaptive phase, and pre- and post-adaptive phase. For adaptation, subjects had to follow displacements of a target of LED (light-emission diode) on a panel. Step-like intrasaccadic target shifts were systematically elicited at the saccade offset and in the opposite direction with respect to the saccade. Saccadic gain decreased fast during the first 100 trials and seemed to reach plateau after 500 trials in individual sessions.

Secondly, adaptive modification in one type of saccades, M-sacc, VI-sacc, or VE-sacc was transferred little to another type of saccade.

Thirdly, delay was introduced up to 400 ms between the offset of a primary saccade and the presentation of a shift target. Although being late in modification, even at 400 ms latency, still appeared adaptation in VE-sacc or M-sacc we investigated.

These findings have important implications for oculomotor learning. They suggest that VE-sacc, VI-sacc and M-sacc may have different motor pathways, and adaptation must have taken place more likely during primary saccades than during corrective saccades, since corrective saccades were led by visual target shifts in every type of saccade.

## 366.9

OPPOSITE GAIN ADAPTATION IN EQUAL-DIRECTION REFIXATIONS WITH DIFFERENT DEPTH COMPONENTS. J.A.M. Van Gisbergen\* and V. Chaturvedi. Medical Physics & Biophysics, KUN, Nijmegen, The Netherlands.

Primates show direction-specific plastic gain adaptation of saccades when the target is repeatedly displaced intra-saccadically. A different paradigm, wearing glasses with unequal magnification, has been used to show adaptation of the depth component in binocular refixations. In order to gain more insight into the adaptive capacity of gaze shifts in 3D space, we investigated whether it is possible to adapt the depth component of binocular refixations with the target displacement paradigm. In addition, we tested whether refixations with equal version but different vergence components can be adapted in gain independently.

Binocular eye movements to LEDs were recorded in three human volunteers using the coil technique. In the depth-adaptation experiment, the target was first presented in the frontal plane at the left and then switched intra-saccadically to a more nearby LED at the same eccentricity. In the differential saccade-gain adaptation experiment, we first adapted saccades to a far target on the left using the gain-shortening version of the target-shifting paradigm. When gain reduction was clearly established, we continued these gain-shortening trials and alternated them with gain-increase trials to a nearby target at the same eccentricity.

The depth adaptation experiment yielded a gradual change in the depth component of the refixation that subsided gradually when the intra-saccadic depth displacement of the target was discontinued. The second experiment showed that the system can manifest opposite gain changes in saccades to different depths. We conclude that the effectiveness of the intrasaccadic displacement paradigm is not limited to the frontal plane and that it can reveal not only directional specificity of gain adaptation in the frontal plane, but also depth specificity.

## 366.11

DOES THE SHORT TERM ADAPTATION IN SACCADIC EYE MOVEMENTS INFLUENCE IMAGINED HEAD POINTING?

J. Kröller\*, D. Pélisson, C. Prablanc, INSERM, Unité 94, 6500 Bron, France

When during ongoing eye saccades the visual target is displaced from one position to another, the oculomotor system adapts to the changed situation after several trials and performs a single saccade to the second target position. To study whether this adaptation influences head movements 10 experiments were done in humans. Each experiment consisted of a pre- and a post-adaptation test and the adaptation period. During the pre- and post-tests the subjects were asked to perform head rotations according to verbal instructions starting always from a LED in front of them (the center target). During the adaptation phase the subjects were requested to perform saccades from the center target to LEDs in the periphery on both sides, while only the targets on the right side changed their position during the saccades. The position-shifts were directed toward the center LED. The subjects were instructed to not move the head during adaptation. Head position and EOG were monitored on-line. This insured that a sufficient degree of adaptation was achieved before the post-adaptation test was commenced.

The results show that head pointing to both sides, the perturbed and the unperturbed one, do not differ significantly. Compared to the pre-test in the post-test some subjects exhibited smaller head movements while others increased the amplitude of head rotations. We could not find clear asymmetries in this 'expansion/shrinkage' pattern. This indicates that, in all likelihood, remembered head pointings are not affected by adaptation of saccadic eye movements. We conclude that the internal representation of the visual surround and the performance of non-targeting head movements are processed outside brain structures which are involved in saccadic short term gaze adaptation.

## 366.10

MODEL-BASED ALGORITHMS FOR TRACKING EYE ORIENTATION USING A VIDEO BASED APPROACH D. Zhu, T. Raphan\*. Institute of Neural & Intelligent Systems, Dept. of CIS, Brooklyn College of CUNY.

To bypass the invasive nature of the coil system in measuring eye movements in three dimensions, there have been a number of investigations on the use of cameras and video-based techniques (Parker et al, 1985; Hatamian et al, 1983; Vieville et al, 1987; Clarke et al, 1991; Moore et al, 1994). The methodology developed by Moore et al (1994) uses a three dimensional rotation model to find the eye orientations in three dimensions. It is based on finding the orientation of the optic axis by computing the center of mass of the pupil and then computing the rotation about the optic axis utilizing variation in intensity along an iral arc. This methodology is dependent on maintaining a fixed pupil size in order not to have changes in the iral striation patterns which would cause errors in computing torsional eye position. In addition, the algorithm for computing the orientation of the optic axis is based on finding the center of mass of the pupil. This too is dependent on pupil size variation and orientation of the eye. The purpose of this study was to derive an algorithm based on a more global model of how circular contours which describe the pupil and iris are mapped to elliptical contours under a rotation and projection mapping, i.e., affine transformations. We have implemented an edge detection algorithm that determines the contour at each given eye orientation. The orientation of the optic axis relative to the axis of the image plane is computed by finding the best fitting ellipse for this contour. The shape of the ellipse can then be related to the orientation of the optic axis. Torsion about the optic axis is computed by using a minimum distance pattern matching algorithm on the totality of the iral signature. This more global approach to computing the torsional component of eye orientation tends to be immune to artifacts which arise when the eye moves into positions where there is partial lid occlusion. The algorithms developed are also robust with regard to pupil size and illumination conditions.

## 366.12

BINOCULAR COORDINATION OF EYE MOVEMENTS DURING WAKEFULNESS, NON-REM AND REM SLEEP IN MONKEYS. Wu Zhou\* & W.M. King. Neuroscience Program, U. Rochester, Rochester, NY 14642 and Depts. of Neurology and Anatomy, U. Mississippi Med. Ctr., Jackson, MS 39216

Binocular coordination of eye movements is important for normal fusion and stereopsis in animals with frontal eyes. Hering's Law of Equal Innervation has been interpreted to imply that binocular coordination is anatomically hard wired (Westheimer, 1977). Alternatively, Helmholtz argued that binocular coordination is not "an obligatory anatomical mechanism" (Helmholtz, 1910). To address this issue, we have examined binocular coordination in monkeys during three states of consciousness: wakefulness (in light and dark), non-REM sleep and REM sleep. We found that the visual axes of the eyes intersected at a single point in space (the fixation point) whenever monkeys were awake. During sleep, however, the eyes were often (80% of the time) diverged horizontally and vertically beyond infinity so that there was no single fixation point. During non-REM sleep, drifting eye movements and occasionally saccadic eye movements were observed in one eye but not in the other eye. During REM sleep, both eyes moved synchronously during saccades. Rapid eye movements during REM sleep, however, were often disjunctive rather than conjugate as described by classical studies (Aserinsky & Kleitman, 1955). It has been suggested that REMs during sleep are related to "watching" dream content (Roffwarg et al, 1962). Since the eyes of our subjects were often diverged beyond infinity during sleep, the lines of sight did not intersect at a single fixation point. Thus, each eye was often directed at different parts of visual field during REM sleep. These observations suggest that REMs may be an epiphenomena related to the dream state, but not to the visual content of the dreams themselves. Finally, these results suggest that binocular coordination is not necessarily hardwired, but rather is a distinguishing characteristic of the awake state. (Supported by EY04045 to Dr. W.M.King)

## OCULOMOTOR SYSTEM: CLINICAL STUDIES

## 367.1

SCHIZOPHRENIC PATIENTS WITH DEFICIT SYNDROME HAVE ABNORMAL SMOOTH PURSUIT EYE MOVEMENTS. D.E. Ross\*, G.T. Thaker, R. Buchanan, A. Lahti, M. Moran, D. Medoff. Maryland Psychiatric Research Center, P.O. Box 21247, Baltimore, MD 21228

Previous studies in patients with schizophrenia and related phenomena have found an association between abnormal smooth pursuit eye movements and psychopathology which may be related to the deficit syndrome of schizophrenia, which is characterized by primary and enduring negative symptoms. **Objective:** The purpose of this study was to examine the potential relationship between abnormal smooth pursuit and the deficit syndrome of schizophrenia. **Methods:** 16 normal controls, 11 schizophrenic patients with deficit syndrome and 22 non-deficit patients were assessed with infrared oculography. The target consisted of a series of foveal and foveal step-ramps. Measures of smooth pursuit function included initial acceleration, velocity during pursuit maintenance and, in response to the foveal target, initial saccadic response. **Results:** MANOVA revealed that the three groups differed significantly with respect to the dependent variables, Wilk's lambda = 0.69,  $F(2,20) = 4.4$ ,  $p = .025$ . Post-hoc Tukey's tests revealed that the patients with deficit syndrome had abnormally decreased initial acceleration, velocity maintenance, and, in response to the foveal target, increased initial saccadic latency (all  $p$ 's < .05). The oculomotor performance of the non-deficit patients was generally intermediate between that of normal controls and deficit patients. **Conclusion:** These findings are consistent with and extend previous ones by showing that abnormal smooth pursuit eye movements in schizophrenic patients are strongly associated with the deficit syndrome. Eye tracking disorder and deficit syndrome in schizophrenia may share a common pathophysiology and/or etiology, probably involving cortical-subcortical circuits.

## 367.2

DEFICITS OF SMOOTH PURSUIT INITIATION IN SCHIZOPHRENIC PATIENTS. D. Schoepf, W. Heide, V. Arolt, K. Junghanns and D. Kömpf. Dep. of Psychiatry and Neurology, University of Lübeck, FRG. (SPON: European Brain and Behaviour Society).

Abnormalities of smooth pursuit (SP) eye movements have frequently been reported in schizophrenic patients. To evaluate, if this could be due to deficits of SP initiation or of cortical visual motion processing we recorded ocular motor responses to unpredictable horizontal step-ramp movements of a foveal laser target, using infrared reflection oculography. Step-ramps with initial steps of 3° and 8° succeeded by constant foveofugal (FF) and foveopetal (FP) constant velocity-ramps of 10, 15 or 30°/s were administered. We assessed position errors (PE) and latencies of the primary and secondary saccades in response to a step-ramp target, postsaccadic SP velocity (PV) and in case of presaccadic pursuit initiation pursuit latency and initial eye acceleration. The maximum velocity of pursuit maintenance (PM) was determined 300 to 500 msec after the target step. The control condition was the PE for saccades to stationary visual targets and the pursuit responses to predictable (periodic) stimuli of comparable velocities. Data from 15 subacute schizophrenic patients and 15 age-matched normals were analysed. **Statistically significant differences** between patients and normal subjects in the step-ramp paradigm were: (1) a reduced gain of PM at all velocities of step-ramps but a comparably higher gain of predictive pursuit; (2) a reduced PV with fast FF ramps (30°/s); (3) an increased number of catch-up saccades; (4) an elevated PE of the primary and secondary saccades at most ramp velocities in contrast to a normal amplitude of saccades to stationary targets. The latency of the first saccade, the latency of pursuit initiation, the PV at 10 and 15°/s and the initial eye acceleration were within normal limits. The present data demonstrate that schizophrenia affects the pursuit response to unpredictable targets more than to predictable targets, but leaves the parameters of pursuit initiation largely intact. In addition, saccadic dysmetria to moving targets implies a defective use of visual motion information by the saccadic system.

## 367.3

## EYE TRACKING DYSFUNCTIONS IN SCHIZOPHRENIC AND DEPRESSED PATIENTS

A. Mackert, K.-M. Flechtner, R. Sauer, B. Steinacher, S. Traversi, J. Kasper\*  
Dept. Psychiatry, Free University of Berlin, 14050 Berlin, Germany

Although eye tracking dysfunctions (ETD) have received much attention as a biological marker for vulnerability to schizophrenia, some studies, however, have failed to find a significant difference between ETD in patients with schizophrenia and affective disorder.

We examined tracking performance of 43 schizophrenics and compared them with 33 depressed patients and 42 healthy volunteers. Subjects were asked to follow a red laser light point moving sinusoidally with a frequency of .4 Hz and an amplitude of  $\pm 10^\circ$ . Eye movements were recorded with a high resolution infrared scleral reflection technique. We counted the number and amplitudes of saccades during SPEM and determined the average gain (ratio stimulus velocity to eye velocity). Compared to normals, mean number of saccades was significantly increased and mean gain was reduced in schizophrenic patients. However, depressed patients also showed ETD in a minor degree.

Our results strengthen the hypothesis that ETD may not be specific to schizophrenic disorders in psychiatric populations.

## SACCADIC EYE MOVEMENTS IN HUMANS WITH ATTENTION-DEFICIT HYPERACTIVITY DISORDER. J.E. Goldring, K.A. Hampton, D.P. Munoz\*, MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ontario, Canada.

Attention-deficit hyperactivity disorder (ADHD) is a common disease characterized by abnormal patterns of attention, impulsivity, and hyperactivity. Normally, when fixating a visual stimulus, visuospatial attention is actively engaged upon the point of fixation. This active visual fixation must be disengaged before the generation of a saccade, and this process influences saccadic reaction time (SRT). Because ADHD children have difficulty keeping their attention engaged on a task, we hypothesized that they would have shorter SRTs. We studied the saccadic eye movements in children with ADHD as well as control children and adults. Subjects initially fixated a central visual stimulus (fixation point-FP). A target stimulus then appeared to the right or left of the FP. Subjects were told to look to (pro-saccade task) or away from (anti-saccade task) the target. The target was presented while the FP was on (overlap condition), or 200 ms after it was turned off (gap condition). ADHD subjects had considerable difficulty maintaining steady fixation on the FP, and tended to generate many extraneous saccades. These movements were reduced when taking their prescribed drug, methylphenidate (ritalin). There was no significant difference in mean SRT between the control and ADHD children, however there was an increase in the variability of SRTs in ADHD children. We predicted that they would make more mistakes in the anti-task (difficulty suppressing pro-saccades), however once again, they did not differ from the control children. Both control and ADHD children triggered many directional errors in the anti-task whereas control adults did not. Surprisingly, although ritalin decreases impulsivity and increases the ability to concentrate, it had no significant effect on the number of mistakes made on the anti-task. Rather, the ability to perform the anti-task with few mistakes was dependent upon subject age.

## UNEQUAL SACCADIC IN STRABISMICS AFTER EXPOSURE TO ANISEIKONIA. Z. Kapoula\*, M.P. Bucci, T. Eggert and L. Garraud\*, LPPA, CNRS-College de France, Paris, Douarnenez Hospital, Brittany, France.

In normals, saccadic inequality is induced immediately when the image is made larger for one eye. Such disconjugacy reduces disparity at the point of fixation; it persists under monocular viewing which suggests a fast learning mechanism. We examined this mechanism in 8 subjects with long-standing convergent strabismus. Four of them had a small squint (4 to 18 pd) and maintained peripheral fusion and gross stereopsis. The other four had larger squint (22 to 30 pd), no fusion and no stereopsis. No subject had amblyopia. All subjects wore an afocal magnifier (8%) in front of their preferred eye, and a prism in front of the other eye that reduced the squint. They viewed a random dot pattern and made saccades (typically  $8^\circ$ ) for 20 minutes. Binocular recordings of horizontal saccades were made with an IR device.

In subjects with partial binocular vision saccades became larger in the eye wearing the magnifier immediately (0.88°); this disconjugacy persisted under monocular viewing (0.67°), suggesting that fast learning is preserved. Subjects with no binocular vision also made large changes in saccadic disconjugacy (1.52°) that persisted under monocular viewing (1.09°). These changes, however, were not correlated with the change required by the magnifier. Most likely, the use of the prism caused the non-preferred eye to take up fixation thereby modifying the baseline disconjugacy.

We conclude that fast disconjugate changes in saccade amplitude are possible in all strabisms, with or without partial binocular vision. In the former, saccadic disconjugacy responds to the disparity and aims to maintain peripheral binocular vision. By contrast, in subjects without binocular vision, disconjugate changes seem to be driven by monocular visual input.

## EFFECTS OF GABAPENTIN ON PENDULAR OCULAR OSCILLATIONS. J.S. Stahl\*, K.G. Rottach, L. Averbuch-Heller, R.D. von Maydel, S.D. Collins, R.J. Leigh Ocular Motor Lab. VA Medical Center and Case Western Reserve University, Cleveland OH 44106

Spontaneous, quasi-sinusoidal oscillations of the eyes (acquired pendular nystagmus) that occur in humans may represent instability in feedback loops between the cerebellum and brainstem. The neurotransmitter gamma-aminobutyric acid (GABA) might be involved in the control of such feedback, since 1) GABA<sub>A</sub> is important for normal functioning of the neural integrator for horizontal eye movements; 2) GABA<sub>B</sub> is involved in the inhibitory control of "velocity storage" by the nodulus and uvula; 3) the GABA<sub>B</sub> agonist baclofen is able to abolish periodic alternating nystagmus and may also improve downbeat nystagmus. We measured the effects of the drug gabapentin, which is structurally similar to GABA, on vision and eye movements in three patients with acquired pendular nystagmus. A single oral 600 mg dose of gabapentin reduced the ocular oscillations and improved visual acuity in all three patients by a factor of  $\geq 2$ . The effect was sustained after five weeks of treatment in two patients who elected to continue taking it. Two normal subjects who took a single 600 mg dose developed gaze-evoked nystagmus in darkness. The drug effect might be exerted via modification of GABA metabolism in the cerebellar-brainstem circuits. Alternatively, the drug could act similarly on the optic nerve, affecting visual feedback. These preliminary results suggest that a systematic, blinded evaluation of the effects of gabapentin on normal human eye movements and pathological oscillations should be carried out. ## BEHAVIORAL INHIBITION DEFICITS IN MEDICATION-NAIVE CHILDHOOD OBSESSIVE COMPULSIVE DISORDER PATIENTS

D. Rosenberg\*, D. Averbach, K. O'Hearn, B. Birmaher and J.A. Sweeney. Neurobehavioral Studies Program, Univ. Pittsburgh Sch. of Med., Pittsburgh, PA 15213.

Obsessive Compulsive Disorder (OCD) is characterized by recurrent intrusive thoughts and repetitive ritualistic behaviors. Approximately 50% of all OCD cases have onset in childhood, and its lifetime prevalence is two to three times greater than schizophrenia and bipolar disorder. Neuroimaging studies implicating orbital prefrontal cortical and striatal region involvement in OCD, together with the apparent inhibitory deficit suggested by the symptomatology of OCD, suggest that a deficit in response suppression may be a central neurocognitive deficit in these patients. Seventeen medication-naïve, non-depressed OCD patients 8-20 years of age, and 17 age and sex case-matched healthy comparison subjects performed an oculomotor delayed response task, an antisaccade task as well as a control visually guided saccade task. While no differences were observed between childhood OCD patients and controls in the latency, accuracy or peak velocity of reflexive visually guided saccades, a higher percentage of response suppression failures was observed in childhood OCD patients on both the oculomotor delayed response task and antisaccade task. On the oculomotor delayed response task, pediatric and adult controls performed equally well on all parts of the task regardless of the delay period duration, while on the antisaccade task, pediatric controls performed more "poorly" on the most difficult part of the task. Detection of such deficits depends on age-related ability to inhibit responses, as well as task difficulty and characteristics. The findings in this study suggest that there is a basic disturbance of neurobehavioral inhibition in OCD that may underlie the repetitive symptomatic behavior that characterizes the illness.

## 367.8

## THE ROLE OF VISUAL STIMULI IN PREDICTIVE SACCADIC ELICITED AT VARIOUS RATES. C. Kennard\*, E. O'Sullivan, S. Shaunak, M. Hawken, T. Crawford and L. Henderson. Academic Unit of Neuroscience, Charing Cross and Westminster Medical School, London W6 8RF, U.K.

Saccades of patients with mild Parkinsonian disease (PD) are said to be abnormal in the absence of a concurrently visible target or when they are part of a rapid sequence of eye movements. We tested this hypothesis by using a predictive saccade paradigm in which target visibility is withdrawn for a period, but the subjects are requested to continue tracking as if the target had remained visible. Three rates of target alternation were used (0.25 Hz, 0.5 Hz and 1.0 Hz). The PD patients rapidly developed predictive behaviour at all three frequencies of target presentation. Withdrawal of target visibility brought out the extremes of primary saccadic gain, most undershoot (hypometria) being displayed at the lowest frequency, whereas the gain was greatest - actually overshooting the target location - at the highest frequency. The control group showed similar but greater overshoot resulting in a markedly hypermetric final eye position which was independent of frequency. These results demonstrate that the spatial error of Parkinsonian saccades does not invariably take the form of hypometria when part of a rapid sequence of eye movements and that they can be hypermetric relative to the target location.

## 367.9

SPONTANEOUS EYE-BLINKING AS A FUNCTION OF VISUAL ATTENTION IN SCHIZOPHRENIA. S. Windmann, I. Curio and I. Jurna\*. Medical and Clinical Psychology, University of the Saarland, 66421 Homburg/Saar, Germany.

Elevated dopaminergic transmission in mesolimbic and mesocortical pathways have long been discussed as a direct or indirect cause for schizophrenic symptoms, such as attention deficits. Pharmacological studies in animals as well as human clinical studies point to a positive link between dopaminergic transmission and eye-blink rate. However, the neurophysiological mechanisms of spontaneous eye-blinking are not yet fully understood. Psychophysiological eye-blinking can be described as a function of the perceptual demands of the situation. We examined eye-blinking in 14 schizophrenic subjects and 17 normal controls under three experimental conditions, in which the subject's visual attention was i) externally controlled (by means of an intermittent flash light); ii) completely internally controlled (free talk); and iii) alternating (filling in a form) in an intrasubject replication design. Among all three conditions, MANOVA-results showed consistent and stable increased blink-rates in schizophrenic patients (no interaction effects and no effects for repeated measurements were found). Effects were even marked in several descriptors of the blink-interval-distribution. The findings are interpreted in terms of the blink-alpha-neuro-circuit (BANC) postulated by Karson (1990, Schizophrenia Bulletin, 16, 345-354). Applicability of parameters of spontaneous eye-blinking as diagnostic and prognostic indicators or even as biological markers of psychopathology is discussed.

## 368.1

GABAERGIC ORIGIN OF THE MONOSYNAPTIC PAD EVOKED IN SINGLE GROUP I MUSCLE AFFERENTS BY INTRASPINAL MICROSTIMULATION. J.N. Quevedo\*, J. Lomeli, P. Linares and P. Rudomin. CINVESTAV-IPN, México, D.F. 07000.

We have shown previously that in the anesthetized cat, intraspinal microstimulation (IS- $\mu$ St) with strengths below threshold for spike generation, produces a monosynaptic depolarization of single afferent fibers (MS-PAD). This PAD has been attributed to direct activation of last-order GABAergic interneurons (*Exp. Brain Res.* 91:29, 1992). Simultaneous measurement of the intraspinal threshold of two collaterals of the same afferent fiber has shown that IS- $\mu$ St with low strengths, may produce a MS-PAD that is restricted to one collateral only, while higher stimulus strengths produce a MS-PAD in both collaterals (*Brain Res.* 643:328, 1994). This has raised the question on whether the MS-PAD that is restricted to one of the two collaterals is due to monosynaptic activation of GABAergic interneurons, or, instead, to local responses produced by the electrical pulse. The MS-PAD produced by IS- $\mu$ St that was restricted to one collateral only, had an onset latency shorter than 1.5 ms and lasted up to 100 ms. In two cases this PAD was depressed 20-40 min after PTX (1 mg/kg i.v.) by 50 and 100% of control, respectively. In one case, low strength IS- $\mu$ St produced a MS-PAD in both collaterals that was depressed 20 min after PTX by 73% and 100% of control, respectively. These observations suggest that the MS-PAD evoked by IS- $\mu$ St either in one or in both collaterals of the same afferent fiber has a GABAergic component. They further indicate that the excitability increase produced by IS- $\mu$ St in one collateral may not necessarily spread to nearby collaterals of the same afferent fiber, suggesting that presynaptic inhibition due to activation of GABA<sub>A</sub> receptors can be rather selective. *Partly supported by NIH NS09196 and CONACyT 039-N9107.*

## 368.2

TONIC INHIBITION OF SPINAL PRESYNAPTIC INHIBITION BY DESCENDING NORADRENERGIC NEURON. Y. Hasegawa, H. Araki\* and H. Ono. Dept. of Pharmacy, Branch Hosp., Faculty of Med., Univ. of Tokyo, Tokyo 112, Japan. \*Dept. of Pharmacol., Res. Cent., Taisho Pharmaceutical Co., Ltd. Saitama 330, Japan.

Presynaptic inhibition was induced by conditioning stimulation of the L4 dorsal root (DR) was measured in terms of the reduction in the amplitude of the monosynaptic reflex (MSR) in the L5 ventral root which was evoked by test stimulation of the L5 DR in anesthetized rats. Depression of the MSR was evoked within a conditioning-test stimulation interval of 5 - 30 msec. This depressant response was inhibited by the direct application of bicuculline (100  $\mu$ M), but not strychnine (100  $\mu$ M), to the spinal cord surface. Thus, this depressant response most likely represents presynaptic inhibition. A significant difference was recognized between the percent presynaptic inhibition in intact (26%) and spinalized (69%) rats. In intact rats in which noradrenaline had been depleted by DSP-4 (50 mg/kg, i.p.), presynaptic inhibition was significantly enhanced to 67%. In spinalized rats, L-DOPA (5 mg/kg, i.v.) with prazosin-HCl (0.5 mg/kg, i.v.) inhibited presynaptic inhibition. The  $\alpha_2$ -adrenoceptor agonist clonidine-HCl (0.1 mg/kg, i.v.) significantly inhibited presynaptic inhibition, and this effect was antagonized by the  $\alpha_2$ -adrenoceptor antagonists idazoxan (0.5 mg/kg, i.v.) and yohimbine-HCl (0.5 mg/kg, i.v.). These results suggest that descending noradrenergic neurons inhibit presynaptic inhibition, and this action is mediated via  $\alpha_2$ -adrenoceptor.

FACILITATION OF MEPPS IN RAT TRIGEMINAL MOTONEURONES IN-VITRO. Ming-Yuan Min, John C. Curtis and Kwabena Appenteng. (SPON: Brain Research Association) Dept. of Physiology, Univ. of Leeds, Leeds, UK.

Plots of the amplitude distribution of mEPSPs (i.e. EPSPs recorded in the presence of tetrodotoxin) reveal clear, equidistant, peaks with small coefficients of variation. Changes in the mean spacing and probability of the peaks can thus be used to infer changes in postsynaptic and presynaptic function. Transmission at excitatory synapses on trigeminal motoneurons has been reported to be subject to a tonic inhibition which has been suggested to be mediated by GABA. We have found that bath application of the GABA<sub>A</sub> receptor antagonist 2-OH-saclofen (50-100  $\mu$ M) produces increases in quantal amplitude and release probability, indicating the presence of postsynaptic and presynaptic GABA<sub>A</sub> receptors (Fig.1: open bars; peaks, in a motoneurone, in absence of drug; filled bars; peaks in presence of drug). The changes are transient when (whole-cell) patch electrodes not containing the sodium salts of GTP or ATP are used, but are sustained when electrodes containing both salts are used, with the activity returning to control levels after washout of drug. However, use of electrodes containing GTP alone can result in increases in mEPSP amplitude which are sustained for over 4 hours after washout of saclofen.

ASSAYS OF GLYCINE RECEPTOR FUNCTION IN THE ISOLATED SPINAL CORD OF OSCILLATOR MUTANT MICE. E. S. Simon\* and R. E. Burke. Lab. Neural Control, NINDS, NIH, Bethesda, MD 20892.

As part of an investigation of the function of inhibitory glycine receptors (GlyRs) in spinal networks, we examined oscillator (*spd<sup>01</sup>*) mice, a mutant with a deletion in the gene encoding the  $\alpha 1$  GlyR subunit (Buckwalter et al. Hum. Mol. Genet. 3:2025,1994). During the 2nd postnatal week, oscillator homozygotes, identified by molecular genotyping (ibid), exhibit progressive tremor, rigidity, gait abnormalities, and myoclonus that worsen until death at P18-P21. *In vitro* preparations of lumbar spinal cords were examined in P11-P13 normal (wild type) mice and oscillator homozygotes. In normals, strychnine-sensitive (glycinergic) recurrent inhibitory postsynaptic potentials (RIPSPs; approx. reversal potential -60 mV) were evoked by ventral root (VR) stimulation and recorded in motoneurons (MNs) with sharp intracellular electrodes. In 15/16 MNs from the oscillator mice, RIPSPs were undetectable even during long de- and hyperpolarizing current pulses. Synchronized 5-15 Hz sinusoidal oscillations in VR and MN records were found in normal spinal cords after bath application of strychnine (Simon, Neurology, in press) but were present in oscillator spinal cords without drug treatment. In both normal and mutant cords, these network-generated sinusoidal oscillations were markedly and reversibly attenuated by bath-applied glycine (1-2 mM). In oscillator, the absence of glycinergic RIPSPs in MNs contrasts with the potent effects of glycine on network oscillations. Network oscillations appear to represent a more sensitive assay for the presence of functional GlyRs at P11-P13.

## 368.5

**RECIPROCAL INHIBITION OF EXPIRATORY NEURONS IS GLYCINERGIC AND NOT REQUIRED FOR RHYTHM GENERATION.** J.L. Feldman\* & X.M. Shao. Systems Neurobiology Laboratory, Dept. of Physiological Science, UCLA, Los Angeles, CA, 90095-1527

Does respiratory rhythm generation require phasic inhibitory interactions between inspiratory and expiratory neurons? In *en bloc* *in vitro* neonatal rat brainstem, rhythmic motor outflow is relatively unaffected by global perturbation of Cl<sup>-</sup> or K<sup>+</sup> channels, or GABA<sub>A</sub> and glycine receptors (Feldman & Smith, NY Acad. Sci., '89; Onimaru, et al. Pflug. Arch '90). To extend these studies to single neurons, we whole cell patch clamped expiratory neurons in rhythmically active medullary slices from neonatal rats (P0-P4) (Smith et al. Science, '91). We recorded from 6 neurons in the preBötzinger Complex (preBötC) which generated impulses during expiration and were silent—with IPSPs—during inspiration. Application of bicuculline (bath: 10 μM; local injection into preBötC: 0.2-0.4 mM) had no effect on inspiratory inhibition. The phasic inhibitory activity disappeared following strychnine application (bath: 5 μM; local injection: 0.1 mM) or using a bathing solution with Cl<sup>-</sup> replaced by isothionate. Following local injection of strychnine (0.4 mM) or bicuculline (0.2-0.4 mM) in preBötC or XII nucleus, changes in XII nerve respiratory pattern—irregular seizure-like discharge on top of the relatively unchanged rhythm—were observed. These results suggest that: i) the inspiratory-modulated inhibitory synaptic input to preBötC expiratory neurons is glycinergic, but not required for rhythm generation, and, ii) *in vitro*, endogenous GABA and glycine affect respiratory pattern within preBötC and XII nucleus. Supported by NIH Grant HL 40959.

## 368.7

**ACTIVATION OF ADENOSINE A<sub>1</sub> AND A<sub>2</sub> RECEPTORS DIFFERENTIALLY MODULATES CALCIUM CHANNELS AND GLYCINERGIC SYNAPTIC TRANSMISSION IN RAT BRAINSTEM.** M. Umemiya\* and A.J. Berger. Dept. Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195-7290

Multiple types of calcium channels are responsible for evoked transmitter release at the presynaptic terminal in the mammalian CNS. To test the contribution of each calcium channel type to synaptic modulation, we recorded unitary glycinergic postsynaptic currents in rat hypoglossal motoneurons. Activation of A<sub>1</sub> adenosine receptors inhibited synaptic transmission. The data suggested that synaptic inhibition was mediated by inhibition of N-type calcium channels at the presynaptic terminal because 1) ω-conotoxin GVIA sensitive synaptic transmission was more sensitive to A<sub>1</sub> receptor activation than ω-conotoxin GVIA resistant synaptic transmission, 2) when recorded from the soma of presynaptic interneurons, N-type calcium channels were more sensitive to A<sub>1</sub> receptor activation than were ω-conotoxin insensitive calcium channels. In contrast, activation of A<sub>2</sub> adenosine receptors predominantly potentiated ω-conotoxin GVIA resistant synaptic transmission. As ω-conotoxin GVIA resistant synaptic transmission was more sensitive to the activation of A<sub>2</sub> receptors, we conclude that A<sub>2</sub> receptor activation facilitates synaptic transmission through potentiating P/Q-type (ω-Agatoxin IVA sensitive) calcium channels. Thus, it is likely that N-type and P/Q-type calcium channels play different roles in synaptic modulation by neurotransmitters in the CNS. (Supported by NS 14857)

## 368.9

**CLONIDINE REDUCES I<sub>h</sub> IN HYPOGLOSSAL MOTONEURONS (HMs).** M.A. Parks\* and A.J. Berger. Dept. of Physiology and Biophysics, University of Washington, Seattle, WA 98195-7290

We used intracellular recording techniques in 400 μm-thick brainstem slices from juvenile rats to investigate the effects of clonidine, an α<sub>2</sub>-adrenoceptor and non-adrenergic imidazoline receptor agonist, on HMs *in vitro*. In current clamp, clonidine (10-100 μM) elicited a slow hyperpolarization and increased input resistance (R<sub>in</sub>) in all 14 HMs tested (R<sub>in</sub> in 10 μM clonidine = 142 ± 23% of control, n=4). Concurrently, the time course of the depolarizing "sag" of the voltage response to hyperpolarizing 250-msec current steps was slowed. This effect on the sag was not altered by 0.5 mM TTX (n=2), indicating that it was direct.

Since this sag represents the activation of a hyperpolarization-activated inward current, I<sub>h</sub> (Bayliss et al., J. Neurophys. 71:119, 1994), we investigated clonidine's effect on I<sub>h</sub> using single electrode voltage clamp (SEVC). In SEVC, I<sub>h</sub> was activated by applying a series of hyperpolarizing steps from a holding potential of -60 mV. Clonidine decreased the amount of I<sub>h</sub> activated at any given potential, thus shifting the I<sub>h</sub> activation curve more negative. A first order exponential fit of the activation time course of I<sub>h</sub> revealed that clonidine increased the activation time constant, τ, in all cells (n=6). In steps to -90 mV, average τ increased from 160 ms in control to 253 ms in clonidine.

Yohimbine (10-100 μM), an α<sub>2</sub>-antagonist, did not block clonidine's effect on the depolarizing sag (n=4) or, in SEVC, on I<sub>h</sub> (n=1). This suggests that the effect of clonidine on I<sub>h</sub> is not mediated by α<sub>2</sub>-adrenoceptors, but may involve imidazoline receptor activation. Supported by HL 49657.

## 368.6

**EXCITATION OF UPPER AIRWAY MOTONEURONS BY IONTOPHORETIC APPLICATION OF SEROTONIN.** V. Fenik, L. Kubin, S. Okabe, A.J. Pack, and R.O. Davies\*. Dept. of Animal Biology and Center for Sleep and Respiratory Neurobiology, University of Pennsylvania, Philadelphia, PA 19104

Our earlier studies led us to propose that the hypotonia of upper airway muscles observed during sleep, especially REM sleep, is dependent on the serotonergic innervation of motoneurons (mns) to the upper airway muscles. Serotonin (5HT) excites upper airway mns and this excitation is withdrawn during REM sleep, when the firing of medullary serotonergic neurons is reduced. We hypothesized that the sensitivity of different groups of upper airway mns to 5HT could be related to the magnitude of their depression during REM sleep, e.g., pharyngeal dilator mns would be more sensitive than laryngeal mns. Experiments were done on decerebrate, vagotomized, paralyzed and artificially ventilated cats. Hypoglossal (XII) and vagal (X) nerves were prepared for recording and the medulla exposed. Five-barrel pipettes (7 μm tip diameter) were filled with: 3 M NaCl for recording, 3 M NaCl for current balancing, 10 or 20 mM 5HT, 10-75 mM glutamate, and 5 mM methysergide. Mns were identified by spike-triggered averaging the corresponding whole nerve activity, and characterized by their activity pattern with respect to phrenic nerve activity. To date, 59 XII mns have been studied (40 inspiratory, 9 expiratory, 10 tonic) and 13 X mns (3 inspiratory, 10 expiratory). In all mns types, 5HT produced a gradually developing and long-lasting excitation that could be blocked by methysergide. In an attempt to quantify the sensitivity to 5HT, 14 XII inspiratory mns and 5 X expiratory mns having similar control firing rates were tested with small 5HT currents (15-25 nA, mean: 18 nA ± 4.5 (SD)) applied for 3 min from a barrel containing 10 mM 5HT and 150 mM NaCl. Under these standardized conditions, the maximal firing rate increase was 10 Hz ± 5 (SD) in XII mns and 2.5 Hz ± 1.3 (SD) in X mns (p < 0.004). Thus, the sensitivity to the excitatory effects of 5HT varies among functionally different airway mns. This may be related to different receptor densities, receptor location, or local differences in 5HT reuptake mechanisms. (Supported by HL-42236 and HL-47600)

## 368.8

**PRESYNAPTIC DEPRESSION OF GLUTAMATERGIC EPSCs IN RAT HYPOGLOSSAL MOTONEURONS (HMs) BY MUSCARINIC RECEPTORS IS NOT DUE TO INHIBITION OF N- OR P-TYPE CALCIUM CURRENTS.** M.C. Bellingham\* and A.J. Berger. Department of Physiology and Biophysics, University of Washington, Seattle, WA 98195-7290.

Cholinergic modulation of synaptic inputs is significant in regulation of motor responses. Whole-cell patch-clamp recordings were made from young adult rat HMs (n = 17), visually identified using Nomarski optics and infrared transillumination of transverse brainstem slices. Electrical stimulation lateral to the hypoglossal motor nucleus evoked short-latency excitatory postsynaptic currents (EPSCs), which were markedly suppressed or abolished by bath application of kynurenic acid (2 mM; n = 4), showing that they were glutamatergic. Bath application of carbachol (10 μM), a cholinergic agonist, reversibly reduced EPSC amplitude to 37 ± 17% (mean ± SD, n = 11) of control, caused an inward holding current (-65 ± 59 pA) and a small decrease (14 ± 13%) in input resistance. The muscarinic receptor antagonist atropine (1 μM) blocked EPSC reduction (n = 4). Postsynaptic currents evoked in HMs by focal pressure injection of L-glutamate (500 μM, n = 3) were not significantly reduced by carbachol, while spontaneous glutamatergic miniature EPSCs were significantly (P < 0.01, n = 3) reduced in frequency without reduction in amplitude, indicating that excitatory glutamatergic inputs to rat HMs are modulated by muscarinic receptors at a presynaptic site. Bath application of ω-conotoxin (ω-CgTx, 2 μM, n = 4), a blocker of N-type calcium channels, then ω-agatoxin-IVA (ω-AgaTx, 200 nM, n = 8), a blocker of P-type calcium channels, reversibly reduced EPSC amplitude to 62 ± 12% and 37 ± 23% of control, respectively. Sequential blockade of N- and then P-type calcium channels did not significantly alter the reduction of the remaining EPSC by carbachol, which reduced EPSCs to 33 ± 9% (n = 4) after ω-CgTx (cf. reduction to 32 ± 8% of control before ω-CgTx) or to 32 ± 10% (n = 4) after ω-AgaTx (cf. reduction to 32 ± 8% of control before ω-AgaTx). We conclude that muscarinic modulation of presynaptic N- or P-type calcium channels is not essential for the mechanism(s) by which activation of presynaptic muscarinic receptors depresses excitatory synaptic transmission to HMs. Supported by Parker B. Francis Foundation, NS 14857, HL 49657.

## 368.10

**MODULATION OF CAUDAL RAPHE NEURONS BY SEROTONIN: 5-HT<sub>1A</sub> RECEPTOR-MEDIATED INHIBITION OF CALCIUM CURRENT AND ACTIVATION OF AN INWARDLY-RECTIFYING K<sup>+</sup> CURRENT.** Douglas A. Bayliss\*. Department of Pharmacology, University of Virginia, Charlottesville, VA 22908.

Raphe neurons of the caudal medulla oblongata provide a major descending influence onto spinal motoneurons and sympathetic preganglionic neurons, yet little is known regarding intrinsic ionic conductances or neuromodulation in those raphe cells. Whole-cell recordings were made from visually identified neurons in a rat medullary thin-slice preparation in order to determine effects of serotonin (5-HT) on voltage-activated calcium currents and inwardly-rectifying K<sup>+</sup> currents in caudal raphe cells. Currents through calcium channels were evoked by steps to 0 mV from a holding potential of -70 mV. In the majority of caudal raphe neurons, 5-HT decreased peak current dose-dependently; inhibition at a maximally effective concentration of 5-HT (1 μM) averaged 49.4 ± 3.1%. Calcium current inhibition was apparently mediated by a 5-HT<sub>1A</sub> receptor, as it was mimicked by the 5-HT<sub>1A</sub> receptor agonist 8-OH-DPAT and blocked by the 5-HT<sub>1A</sub> antagonist NAN-190, but unaffected by ketanserin, a 5-HT<sub>2</sub> antagonist. Caudal raphe neurons expressed N-type (ω-Conotoxin GVIA-sensitive) and P-type (ω-Agatoxin IVA-sensitive) calcium current, both of which were inhibited by 5-HT. In addition to its effects on calcium currents, 5-HT also caused a membrane hyperpolarization and/or outward current. The current activated by 5-HT (I<sub>5HT</sub>), measured during hyperpolarizing ramp potentials from -40 mV, was strongly inwardly-rectifying. In elevated external K<sup>+</sup>, the reversal potential of I<sub>5HT</sub> was shifted in the depolarizing direction and the conductance induced by 5-HT was enhanced, peak I<sub>5HT</sub> in 6-mM external K<sup>+</sup> averaged 16.7 ± 2.9 pA with an attendant 6-fold increase in conductance. Effects of 5-HT were mimicked by 8-OH-DPAT, suggesting that they were also mediated by a 5-HT<sub>1A</sub> receptor. These results indicate that 5-HT<sub>1A</sub> receptors inhibit N- and P-type calcium currents and activate inwardly-rectifying K<sup>+</sup> currents in caudal raphe neurons; such effects may underlie 5-HT-mediated autoinhibition of caudal raphe cells. (Supported by NS33583).

## 368.11

PONTINE MICROINJECTION OF THE M2 MUSCARINIC ANTAGONIST METHOCTRAMINE BLOCKS BETHANECHOL-INDUCED REM SLEEP (REM-BETH). H.A. Baghdooyan\* and J.L. DiVittore. Department of Anesthesia, The Pennsylvania State University, College of Medicine, Hershey PA 17033.

Activation of muscarinic cholinergic receptors (mAChRs) in the medial pontine reticular formation (mPRF) is known to be important for generating rapid eye movement (REM) sleep. Currently, there is much interest in specifying the precise roles of individual mAChR subtypes in REM sleep generation. Recent *in vitro* receptor autoradiographic studies have demonstrated the presence of M2 binding sites in feline mPRF (*NeuroReport* 5:1631-1634, 1994). Therefore, the present study is testing the hypothesis that mPRF administration of methoctramine (METH) will block cholinergic REM sleep generation. To date, 11 control recordings (no injection) and 57 microinjections of bethanechol alone (BETH, 4.3 µg/25 µl, 87 mM) and bethanechol following METH pretreatment (6 doses of METH ranging from  $10^{-12}$  M to  $10^{-2}$  M) have been made in 3 conscious cats. All injections were made during quiet wakefulness, and polygraphic recordings were obtained for 2 hrs post-injection to quantify sleep and wakefulness. Following mPRF microinjection of BETH alone, cats spent an average of 74% of the total recording time in the REM sleep-like state (REM-BETH), representing a 466% increase over control REM sleep levels. Microinjection of METH 15 min prior to BETH significantly reduced REM-BETH ( $F=20.09$ ;  $df=7,67$ ;  $p<0.001$ ), and the ability of METH to block REM-BETH was dose-dependent. A 22% decrease in REM-BETH was obtained following pretreatment with  $10^{-10}$  M METH, but a concentration of  $10^{-4}$  M METH was required to significantly ( $p<0.05$ ) block REM-BETH and return REM sleep to control levels (13%). The present data are consistent with previous anatomical studies localizing M2 receptors to the mPRF (*NeuroReport* 5:1631-1634, 1994), and provide functional evidence that M2 receptors in the mPRF contribute to generating the BETH-induced REM sleep-like state. *Support: Department of Anesthesia and MH45361.*

## SPINAL CORD AND BRAINSTEM: ANATOMY

## 369.1

IDENTIFICATION OF GLUTAMATE, GABA AND PARVALBUMIN-CONTAINING TRIGEMINAL PREMOTOR NEURONS IN THE RABBIT. A. Koltia\*, K.G. Westberg, P. Clavelou, D. Veilleux and J.P. Lund. RIKEN institute Wako, Japan; and Univ. of Montreal, CRSN, Mt. P.Q., Canada, H3C 3J7.

This study was designed to histochemically identify excitatory and inhibitory trigeminal premotor neurons in the rabbit. Last-order interneurons were retrogradely-labeled with rhodamine conjugated dextran-amines injected into the Vth motor nucleus (NVmt). As in other species, many premotor neurons were found throughout the rostro-caudal extent of the reticular formation (RF). By far the largest projection originated from the parvocellular region (Rpc) including pars  $\alpha$  (Rpca) (64% of all reticular projections). Within the trigeminal system proper, last-order interneurons were found mainly in the regio h of Meessen and Olzchewski (comprising the supra-NsV, juxta-NsV and inter-trigeminal (NintV) areas) and the subnucleus oralis of the spinal V tract (NVspo) (respectively 46 and 23% of trigeminal projections). Fewer projections arose from the main sensory nucleus, the subnucleus caudalis of the spinal V tract and the contralateral NVmt. All of the above groups were bilateral with the exception of NVmt. The contralateral olivary complex also provided a massive innervation of trigeminal motoneurons. Glutamate-containing premotor neurons were found across all areas of the RF, with again the highest proportion in Rpc and Rpca. Some of the retrogradely-labeled neurons in medial NsV, NVspo and the Olive were also glutamate immunoreactive. GABA immunopositive premotor interneurons were localized in lateral NsV, NintV, Rpc, Rpca and the gigantocellular and lateral RF. The distribution of parvalbumin-containing neurons paralleled closely that of GABA immunoreactive neurons in the RF but not in regio h, suggesting that these may be physiologically different populations of GABAergic interneurons. These results provide anatomical evidence for the existence of several populations of excitatory and inhibitory interneurons innervating the trigeminal motoneurons of the rabbit.

## 369.3

SEROTONIN<sub>1A</sub> AND  $\alpha_1$ - AND  $\alpha_2$ -NORADRENERGIC RECEPTORS IN THE SPINAL CORD OF SPINALIZED CATS. N. Giroux, R.S. Aloyz, S. Rossignol and T.A. Reader\* *Centre de recherche en sciences neurologiques, Département de physiologie, Faculté de médecine, Université de Montréal, Montréal (Québec) Canada.*

The serotonin (5-HT) antagonist cyproheptadine reduces spasticity and improves locomotor function of spinal cord injured patients. In chronic spinalized cats, the 5-HT agonists quipazine and 5-MeODMT increase the amplitude of activity in flexor and extensor muscles during locomotion. Also, in spinalized cats as well as in spinal cord injured patients, the  $\alpha_2$ -noradrenergic agonist clonidine improves recovery of locomotion. To establish a basis for locomotor pharmacotherapy the fate of monoamine receptors was examined after a complete spinal transection in cats. The distribution of 5-HT<sub>1A</sub>,  $\alpha_1$ - and  $\alpha_2$ -noradrenergic receptors was studied in the lumbar spinal cord of six control cats and in animals with different survival times (13, 33, 70, 165, 279 and 409 days) after spinalization at thoracic L3 level. The 5-HT<sub>1A</sub> receptors were localized with [<sup>3</sup>H]8-OH-DPAT in the gray matter; the highest densities were in laminae III and IV, and around the central gray (lamina X). After spinalization, [<sup>3</sup>H]8-OH-DPAT binding increased, mainly in laminae III and IV at 33 days. For the other laminae, there were no differences when compared to control cats. The  $\alpha_1$ - and  $\alpha_2$ -noradrenergic receptors were labelled with [<sup>3</sup>H]prazosin and [<sup>3</sup>H]idazoxan, respectively. Both receptors showed a similar pattern of distribution; the highest levels were in the dorsal horn (laminae II-III) but also in laminae IX and X, with moderate labelling in the remaining laminae. [<sup>3</sup>H]prazosin binding increased after 33 and 70 days following spinalization in laminae I, II-III, and after days 70 and 165 in laminae II-III and IX. At longer survival times, i.e.: 279 days or more, [<sup>3</sup>H]prazosin binding was lower than in control cats for all laminae. There was also an up-regulation of  $\alpha_2$  receptors, especially at 13 and 33 days of survival, followed by a decrease at longer survival periods. The pronounced and acute up-regulations observed in the lumbar region suggests that mechanisms involving 5-HT<sub>1A</sub>,  $\alpha_1$ - and  $\alpha_2$ -noradrenergic receptors may be important after spinalization.

## 369.2

EFFECTS OF A COMPLETE SPINAL TRANSECTION ON NMDA RECEPTORS IN CAT SPINAL CORD. R.S. Aloyz, N. Giroux, S. Rossignol, T.A. Reader and H.H. Jasper\* *Centre de recherche en sciences neurologiques, Département de physiologie, Faculté de médecine, Université de Montréal, Montréal (Québec) Canada.*

Excitatory amino acids have been shown to mediate locomotion in paralyzed decerebrate cats, in *in vitro* neonatal rats and in lampreys. In chronic spinal cats, the N-methyl-D-aspartate (NMDA) receptor antagonist AP5 can block locomotion and NMDA can restore locomotion after AP5, suggesting that NMDA receptor activation may be important for the expression of locomotion. The distribution of amino acids and glutamate receptors of the NMDA subtype was studied in the lumbar spinal cord in four control cats and in four animals with different survival time (13, 33, 70 and 279 days) after spinalization at T13. The localization and changes of glutamate NMDA receptors were examined in the different cytoarchitectonic laminae of the lumbar spinal cord, by quantitative autoradiography using [<sup>3</sup>H]MK-801. In control cats, the highest densities of NMDA receptors were in laminae II-III, followed by lamina I and X, and with lower densities in the rest of the gray matter. After spinalization, there was an up-regulation at 13 and 33 days after spinalization in the dorsal horns (laminae I-IV) with no variation in the other laminae. At longer survival times, i.e. 70 and 279 days post spinalization, there was a return to normal values in the spinalized cats. Samples of spinal cord from the same cats were also used to measure amino acids by HPLC; one of the most abundant amino acids found in the lumbar spinal cord of control cats was glutamic acid (GLU) with endogenous levels of 14.1 µmoles/mg protein. On day 13 following complete spinalization, there was a decrease in GLU (8.7 µmoles/mg protein), but at longer survival times, i.e. 33 days post spinalization, the levels had returned to control values (13.5 µmoles/mg protein). The receptor changes reported could eventually be correlated to the alterations in the levels of amino acids, and to the effects of administration of NMDA agonists and antagonists in this animal model of functional recovery. [Supported by the MRC(C) and the Neuroscience Network]

## 369.4

LOCALIZATION OF CALCIUM-DEPENDENT PROTEIN PHOSPHATASE (CALCINEURIN) IN THE BRAIN STEM AND SPINAL CORD OF THE RAT.

F.F. Ebner\*, B.E. Wadzinski\* and S. Strack\* *Institute for Developmental Neuroscience and \*Dept. of Pharmacology, Vanderbilt University, Nashville, TN 37203.*

Calcineurin (CaN) is a brain enriched protein phosphatase that has been implicated in synaptic transmission, cytoskeletal dynamics and other calcium-regulated events. We have studied the distribution of the major,  $\alpha$ -isoform of CaN in the rat spinal cord and brainstem with a polyclonal antibody raised against a peptide sequence present in  $\alpha$ CaN. Quantitative immunoblot analysis showed that  $\alpha$ CaN is present in the spinal cord at 3 to 4 fold lower concentration than in the forebrain. Light microscopic immunohistochemistry revealed a strikingly restricted pattern of  $\alpha$ CaN staining. In the brain stem, high  $\alpha$ CaN immunoreactivity was observed in a subset of large neurons in several motor nuclei: the trigeminal (V), facial (VII), and the perihypoglossal nucleus of Roller. Axons, dendrites and the soma excluding the nucleus were immunoreactive. Some axons in cranial nerves were also stained. Neurons in the hypoglossal nucleus and throughout the reticular formation were faintly labeled. Terminal field-like staining in the nucleus trigeminalis interpolaris was present in clusters which likely correspond to the "barrelettes" of whisker pad afferents. In the spinal cord,  $\alpha$ CaN was found in a subset of large motoneurons in the lateral aspects of the ventral horn and diffusely in the superficial laminae of the dorsal horn. Dorsal root ganglion neurons stained faintly; axons in the dorsal and ventral roots were largely unlabeled. In the white matter, the corticospinal tract is faintly stained. A small fiber tract running ventrolateral of the dorsal horn was strongly immunoreactive and was identified as the spinocervical tract, an ascending tract that carries somatosensory information from dorsal horn lamina IV neurons to the cervical nucleus. The staining pattern was qualitatively similar in cervical, thoracic and lumbar segments of the spinal cord. (Supported by NS13031 to F.F.E. and GM51366 to B.E.W.)

## 369.5

## GAP JUNCTIONS ARE ABUNDANT ON NEURONS THROUGHOUT ADULT RAT SPINAL CORD

J. E. Rash\*, R. K. Dillman, B. L. Bihartz, L. R. Whalen, H. S. Duffy, and T. Yasumura. Anatomy and Neurobiology, Colo. State U., Fort Collins, CO 80523

Using confocal "grid-mapped" freeze-fracture, we have visualized and mapped 81 gap junctions (GJs) on motor neurons and interneurons in laminae IV-IX from lumbosacral, thoracic, and cervical regions of adult rat spinal cord. GJs were found in 29 clusters on 27 neurons, primarily on somata and proximal dendrites, forming "mixed" (chemical and electrical) synapses. Most neuronal GJs were very small (mean = 87 connexons; median = 52; range = 6-704). GJs were present in neuronal plasma membranes at an average density of  $1/34 \mu m^2$  in the lumbosacral enlargement, and at  $1/158 \mu m^2$  in the cervical enlargement. Thus, we calculate that the average neuron in the ventral horn of rat spinal cord contains 300-1000 GJs. Since most neuronal GJs are less than  $0.06 \mu m$  in diameter, they are too small to have been detected previously by thin-section TEM methods or by conventional immunocytochemical staining techniques. Most neuronal GJs in the spinal cord are too small for direct intercellular propagation of action potentials. However, they may provide pathways for metabolic coupling at mixed synapses or for electrical modulation of chemical synaptic transmission. Contrary to published reports, GJ are a general component of neuronal plasma membranes in adult rat spinal cord -- they were present in all levels examined, they were in all laminae examined, and they were present on interneurons and motor neurons. New electrophysiological monitoring strategies may be required to ascertain the role of neuronal GJ in spinal cord function.

## PHRENIC MOTONEURONS ADAPT TO INACTIVITY. G.C. Sieck\*,

W.Z. Zhan, H. Miyata, Y.S. Prakash & K.G. Smithson. Depts. of Anesthesiology, and Physiology & Biophysics. Mayo Foundation, Rochester, MN 55905

Motoneuron (MN) plasticity may be influenced by the level of activation and/or by interactions between MN and muscle fibers (MF). The goal of this study was to examine phrenic MN adaptations to diaphragm (DIA) muscle inactivity, and to determine the effect of mismatched MN and MF activities on such adaptations. Two models of DIA inactivity were compared in the rat: 1) spinal isolation (SI) by hemisection at C2 where MN and MF activities were matched; and 2) tetrodotoxin (TTX) nerve blockade where MN activity increased and was mismatched with MF inactivity. Fluorescent dextran (3000 MW) or cholera toxin B-fragment (CTB) were injected into the DIA to retrogradely label phrenic MNs. Following 2 weeks of paralysis, cervical spinal cords were excised. Fluorescently-labeled MNs were optically sectioned using confocal microscopy and MN somal volumes were measured. CTB was detected using a peroxidase reaction and dendritic architecture was assessed using computerized camera-lucida analysis. Compared to controls, phrenic MN somal volumes decreased with SI, but increased with TTX. Dendritic arborization increased with both SI and TTX, but to a greater extent with TTX. These results suggest that morphological adaptations of phrenic MNs are dependent on a match between MN and muscle activities. Supported by NIH grants HL34817 and HL37680.

## ULTRASTRUCTURE OF PHYSIOLOGICALLY IDENTIFIED JAW-MUSCLE SPINDLE AFFERENT TERMINATIONS ONTO RETROGRADELY LABELED JAW-ELEVATOR MOTONEURONS. P. Luo\* and D. Dessem. Dept. of Physiology, University of Maryland Dental School, Baltimore, MD 21201.

Synaptic relationships between rat jaw-muscle spindle afferents and jaw-elevator motoneurons were studied with combined retrograde and intracellular labeling. Initially motoneurons were retrogradely labeled by injecting horseradish peroxidase (HRP) into the jaw-elevator muscles. After 2 days, jaw-muscle spindle afferent axons were physiologically identified by their response to stretching of the jaw muscles and intracellularly stained with biotinamide. 243 intracellularly stained jaw-muscle spindle afferent boutons were examined which synapsed either with retrogradely-labeled motoneurons (n=85) or unlabeled structures (n=158) in the jaw-elevator motoneuron pool. 68% of stained spindle boutons synapsed with large or medium sized, retrogradely-labeled motoneuron dendrites. 86% of these synapses were asymmetric; 14% were symmetric. 32% of identified spindle boutons formed axosomatic synapses of which 78% were symmetric and 22% were asymmetric. Approximately 24% of the stained spindle boutons comprised the intermediate element of a synaptic triad sandwiched between an unlabeled presynaptic P-type bouton and a postsynaptic HRP-labeled motoneuron dendrite or soma. Numerous unlabeled S-, F-type, and dense-cored vesicle containing boutons (n=831) converged onto the same motoneuron elements which received spindle afferent synapses. 53% of these unlabeled boutons were F-type (n=444), 28% were S-type (n=230) and 19% (n=157) contained dense-cored vesicles. Most dense-cored vesicle containing boutons terminated on motoneuron somata (81%, n=129) rather than dendrites (19%, n=28). These data indicate that jaw-muscle spindle afferent synapses onto motoneurons are both morphologically and spatially diverse and that a smaller percentage of these synapses may be under presynaptic control than in the spinal cord. These data also imply that premotor neurons containing inhibitory neurotransmitters, catecholamines and neuropeptides may modulate trigeminal motoneuron excitability. Supported by NIH DE10132.

## 369.6

## GROWTH OF DENDRITIC TREES OF NECK MOTONEURONS IN ADULT CATS FOLLOWING AXOTOMY. P.K. Rose\* and M. Odlozinski, MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, ON Canada K7L 3N6

Long term axotomy leads to several major structural alterations in spinal motoneurons, including loss of synapses on the cell body. Since most synapses on motoneurons are located on the dendritic tree, the initial goal of the present study was to determine the rearrangement of synapses located on different regions of the dendritic trees. Following a 12 to 16 week permanent axotomy, motoneurons supplying the cat neck muscles, biventer cervicis and complexus, were antidromically identified and intracellularly stained with horseradish peroxidase. In preparation for the electron microscopic studies, dendrites were systematically reconstructed at the light microscopic level. Three of the 9 motoneurons examined appeared normal, but, unexpectedly, the other motoneurons showed evidence of growth. Some distal dendrites gave rise to complex appendages that consisted of tangled branches, some fine, some swollen. Other distal dendrites had long segments that were unusually swollen ( $3 - 4 \mu m$ ) and displayed a nonuniform staining pattern similar to that seen in myelinated axon collaterals. A quantitative comparison of the dendritic trees of three axotomized and three control motoneurons demonstrated that the total number of dendritic branches increased by 60 to 350%. Some dendrites from the axotomized cells terminated more than  $3200 \mu m$  from the soma, compared to a maximum dendritic length of  $2,050 \mu m$  in the control cells. Two of the axotomized motoneurons had surface areas more than 50% larger than the control cells.

These results indicate that the dendritic trees of some neck motoneurons expand following long-term axotomy. The results contrast with comparable studies of axotomized hindlimb motoneurons whose dendritic trees shrink by 35%. The additional membrane may provide a site for additional synaptic contacts or may represent aberrant axonal growth. (Supported by MRC and MDAC)

## 369.8

LIGHT AND ELECTRON MICROSCOPE STUDY ON SYNAPTIC CONTACTS MADE BETWEEN MUSCLE-SPINDLE AFFERENT TERMINALS AND  $\alpha$ -MOTONEURONS IN THE CAT TRIGEMINAL MOTOR NUCLEUS. N.H. Yabuta, Y.C. Bao\*, A. Yoshida, M. Takemura\* & Y. Shigenaga. Dept. of Oral Anatomy II, Osaka Univ. Faculty of Dentistry, Suita, Osaka 565, Japan, \*School of Dentistry, Kyungpook University, Taegu, Korea

We have previously reported that jaw-closing spindle afferents can be classified as type I and type II which may represent Ia and secondary afferents. This study aimed to investigate the spatial distribution of contacts made by spindle afferents upon motoneurons light microscopically, and to examine ultrastructures of their terminals in the central and peripheral Vmo dl. HRP was injected into single spindle afferent(s) and a motoneuron in the same preparation. The type I terminals made contacts on the more proximal dendrites than the type II terminals did. The average number of contacts made by a spindle afferent upon a motoneuron was about two. For electron microscope study, 76 boutons in peripheral Vmo dl and 105 in central Vmo dl were analyzed. Two characteristics were common to labeled boutons in the two regions. First, all the labeled boutons were densely filled with clear, spherical, synaptic vesicles. Second, neither the part of the collateral branch proximal to the bouton, or the intermediate fiber connecting the boutons, were seen to participate in a synaptic specialization. However, following differences were observed: (1) the total number of contacts per bouton was significantly fewer ( $P < .05$ ) in central Vmo dl neuropile than in peripheral one, (2) labeled boutons made significantly higher numbers of synaptic contacts on proximal dendrites in the former than in the latter region, and (3) the number of labeled boutons postsynaptic to axon terminals containing pleomorphic synaptic vesicles was higher in the latter than in the former regions. These data demonstrate that the spatial distribution of synaptic contacts made by spindle afferent fibers upon motoneurons is different between primary and secondary spindles.

## 369.10

## COMPARATIVE SYNAPTIC ULTRASTRUCTURE OF CAT AND MACAQUE TRIGEMINAL MOTONEURONS. N.F. Capra\*, J.M. Bermanke and P.J. May. DOCBS, U. of Maryland, Baltimore, MD 21201, Dept. of Anatomy, U. of Mississippi Med. Ctr., Jackson, MS 39216.

The central morphological correlates for the species specific coordination of jaw muscle activity indicated by behavioral and electrophysiological data have not been fully elucidated. This study compares the synaptic ultrastructure of trigeminal motoneurons in cats and monkeys. A mixture of WGA-HRP/HRP was injected into either the masseter, temporalis, or anterior digastric muscle of 4 cats and 5 macaque monkeys. Within the monkey trigeminal motor nucleus (Vmot), temporalis and masseter motoneurons were broadly distributed, but a small injection into posterior temporalis produced a discrete focus of label. In cat, these two motoneuron pools were located in the dorsolateral Vmot. In both species, anterior digastric motoneurons were more ventromedial. The somata and proximal dendrites of neurons, labeled from each muscle injection, were examined with the EM. Boutons on all the motoneurons studied contained either small clear spherical vesicles (Type 1), small-flattened vesicles (Type 2) or a mixture of clear vesicles and large dense-cored vesicles (Type 3). The largest terminals were generally associated with subsynaptic cisterns. Descriptions of bouton types are remarkably consistent regardless of species or motoneuron population. Thus, bouton morphology and motoneuron somatopy do not seem to provide sufficient bases for structure-function correlation. However, in cat, specific differences were identified in the relative synaptic density and in the distribution of bouton types on motoneurons supplying different muscles. For example, Type 2 terminals were more numerous on digastric neurons, while Types 1 and 3 were more common on masseter neurons. Ongoing analysis is directed at determining how the synaptic distribution on identified macaque motoneurons compares with that found in the cat. Supported by NIH grants DE06027 & EY09762.

## 369.11

ULTRASTRUCTURAL CHARACTERIZATION OF ESOPHAGO-MOTOR AND PHARYNGO-MOTOR NEURONS IN THE NUCLEUS AMBIGUUS OF THE RAT. T. HAYAKAWA<sup>1</sup>, Y. YAJIMA<sup>2</sup> and K. ZYO<sup>1</sup>. Dept. of Anatomy<sup>1</sup> and Physiology<sup>2</sup>, Hyogo Coll. of Med., Nishinomiya, Hyogo 663, JAPAN.

The viscerotopic organization of the upper alimentary tract in the nucleus ambiguus has been well studied, but there is little information about the morphology of each neuron innervating the pharynx or the esophagus. We studied the ultrastructure of pharyngo- (PH), cervical esophago- (CE) and subdiaphragmatic esophago-motor (SDE) neurons labelled by retrogradely transported WGA-HRP. The WGA-HRP was injected into the lower pharynx, the cervical or subdiaphragmatic esophagus of male S-D rats. The PH neurons were large-sized, polygonal, and containing well-developed cell organelle with a round nucleus. Both the CE and the SDE neurons were medium-sized, oval, and containing well-developed cell organelle, but the SDE neuron was larger than the CE neuron. The average number of axosomatic terminals in a sectional plane was 30.8 in the PH, 7.9 in the CE, and 4.2 in the SDE neurons. The number of Gray's type I and type II terminals in the axosomatic terminals was almost equal in the PH and the CE neurons, but there were few Gray's type II terminals in the SDE neurons. Desmosome-like junctions between dendro-dendritic or somato-dendritic appositions were often present in the area surrounding the SDE neurons. There were also unlabeled small interneurons in the compact formation of the nucleus ambiguus.

## 369.13

PONTINE AND MEDULLARY AFFERENT PROJECTIONS TO THE NUCLEUS RETROAMBIGUUS: A WGA-HRP AND AUTORADIOGRAPHIC TRACING STUDY IN THE CAT. Peter O. Gerrits\* and Gert Holstege, Department of Anatomy and Embryology, University of Groningen, Oostersingel 69, Medical School, 9713 EZ Groningen, The Netherlands.

The nucleus retroambiguus (NRA) is a premotor interneuronal cell group in the lateral part of the most caudal medulla. It projects to a set of motoneuronal cell groups which take part in respiration, vocalization, vomiting, and lordosis. The NRA receives strong afferent input from the periaqueductal gray (PAG), and the PAG-NRA pathway has been shown to be crucial for vocalization. Structures rostral to the PAG seem not to project to the NRA. To determine whether there exist NRA afferent projections other than those originating in the PAG, a combined retrograde and anterograde transport study was carried out in the cat. Injections of WGA-HRP were centered on the NRA, and [<sup>3</sup>H]-leucine injections were placed in various brainstem sites. The results demonstrated that NRA afferents not only originate in the PAG but also in the lateral tegmental field, i.e. the ventrolateral parabrachial and Kölliker-Fuse nuclei, the retrotapezoid nucleus, the solitary nucleus, and the ventrolateral part caudal to the facial nucleus (VII). Afferents also originate in two cell groups in the ventral part of the medullary medial tegmental field, one at the level of VII and one just rostral to the hypoglossal nucleus. The results indicate that virtually all respiratory related cell groups have strong access to the NRA. The cell groups in the medial tegmental field might be involved in eating and drinking related behaviors during which respiratory control is necessary.

## 369.15

CENTRAL AUDITORY AND TRIGEMINAL NERVE PROJECTIONS REVEALED BY IN VITRO TRANSPORT OF NEUROBIOTIN IN TURTLE. J. Keifer\* and J. L. Herrick. Dept. of Anatomy and Structural Biology, Univ. of South Dakota School of Medicine, Vermillion, SD 57069.

One aim of our laboratory is to examine the feasibility of developing an *in vitro* model of the classically conditioned eye-blink reflex to be used for cellular studies of conditioning. Recent studies in the turtle have demonstrated that a neural correlate of the eye-blink reflex can be generated in the *in vitro* brainstem-cerebellum by stimulation of the trigeminal nerve while recording responses in the abducens nerve (Exp. Brain Res. 97: 239, 1993). Evidence also suggests that paired stimulation of the auditory and trigeminal nerves results in classically conditioned activity in the abducens nerve (J. Neurosci., 1995). The aim of the present study was to examine the central projections of auditory and trigeminal nerve inputs in this species in order to reveal neural pathways that might underlie conditioning.

Neurobiotin (4%, 0.1-0.5 µl) was pressure injected into the cut end of either the trigeminal or posterior eighth nerve of the *in vitro* brainstem-cerebellum preparation from the turtle *Chrysemys picta*. Transport times ranged from 3-17 hr and tissue was processed using standard methods. The results of the trigeminal nerve injections showed retrogradely labeled motor V neurons, axons in spinal V and terminal label in the trigeminal nucleus following 3 hr transport time. After 6 hr, these regions labeled in addition to neurons in the principal and accessory abducens nucleus. Longer transport times resulted in projections to the cerebellum and labeled neurons in contralateral red nucleus. Injections of the eighth nerve showed terminal label in the ipsilateral cochlear nucleus and the cerebellum in 6 hr. Longer transport times resulted in labeled neurons in the ipsilateral cochlear nucleus and fibers that crossed the midline to the superior olivary and cochlear nucleus. Terminal label was observed in the abducens nuclei and extensive label was observed in the region of the trigeminal nucleus. These data suggest that Neurobiotin was transported transneuronally with times >6 hr. Furthermore, the results suggest that brainstem as well as cerebellar sites receive direct input from the auditory (CS) and trigeminal (US) nerves during conditioning. Supported by a USD Migrant and USDSM Parson's Research Fund.

## 369.12

QUANTITATIVE ANALYSIS OF SYNAPSES FORMED BY INDIVIDUAL RETICULOSPINAL FIBERS ON LUMBAR MOTONEURONS OF FROG. A.E. Dityatev<sup>1</sup>, N.M. Chnykhova<sup>2</sup>, A.L. Babalin<sup>2</sup>, G.V. Dityatva<sup>1</sup> and H.P. Chamann<sup>1</sup>. Department of Physiology, University of Bern, Switzerland<sup>1</sup> and Institute of Evolutionary Physiology and Biochemistry, St. Petersburg, Russia<sup>2</sup>.

Although much is known about the effects and connections of descending tracts on spinal neurons, little is known about the spatial pattern of interaction between individual elements. Such knowledge is needed for an understanding of complex information transfer. In this work, several pairs formed by a reticulospinal fiber contacting a lumbar motoneuron were intracellularly stained after identification of the contacting elements. Pairs were reconstructed using a computer-assisted camera lucida (Eutectic NTS) with high resolution (10x100x, N.A.=1.4). The simplest contact system (5 contacts) was formed by 2 collaterals with total path lengths of 7045 and 4490 µm resp. on a rather simple motoneuron (membrane surface 136880 µm<sup>2</sup>). The collaterals had similar average densities of boutons (62/mm). Boutons were mostly found on fine terminal branches (density = 220 bouton/mm). The diameter of terminal boutons (28 % of all boutons) was smaller than that of en passant boutons (1.1±0.33 µm vs. 1.3±0.35 µm). The most complicated connection had 19 contacts formed by 4 collaterals (total path length 16404 µm) on a very complex motoneuron (275560 µm<sup>2</sup>). Sizes and distribution of boutons were similar to the first connection. Mean distance from collateral origin to any bouton was 566±215 µm. Action potentials must pass 11 branch point on average to get there. Boutons contacting motoneurons were 558±212 µm from the origin of the collateral and 311±154 µm from the motoneuron soma. Over half the dendritic surface was more than 500 µm from the soma. The collaterals of an axon stained with neurobiotin formed 6 contacts on the proximal dendrites of the motoneuron (surface 192050 µm<sup>2</sup>). The axon had a relatively high density of boutons (84/mm), which were 1.48±0.45 µm thick. Only 18% were end boutons. These data allow quantitative comparison of reticulospinal connections with the synapses formed by fibers having other supra- and intraspinal origin. Supported by the Swiss NF.

## 369.14

FUNCTIONAL ORGANIZATION OF THE BULBAR RETICULAR FORMATION IN THE MALLARD, ANAS PLATYRHYNCHOS.

J.L. Dubbeldam, A.J. Tellegen, R.G. Bouw (Spon: European Brain and Behaviour Society). Institute of Evolutionary and Ecological Sciences, Leiden University, 2300 RA Leiden, The Netherlands.

The bulbar reticular formation contains part of the premotor systems for jaw, tongue and neck muscle motor nuclei. It is also recipient of input from various sensory systems. We analysed the pattern of afferent and efferent connections using a combination of anterograde and retrograde tracing techniques. Roughly, the reticular formation can be subdivided in three longitudinal zones: a dorsolateral and a ventromedial parvocellular zone (RPcdl and RPcvm) and a medioventral gigantocellular zone (RGc). A plexus of Horsley cannot be distinguished in normal material of the mallard brainstem. RPcdl and RPcvm receive trigeminal input from the nuclei of the descending trigeminal system. The mesencephalic trigeminal nucleus projects to the rostral part and the caudal part of RPcdl leaving an intermediate compartment free of input. The rostral and caudal compartments of RPcdl send projections to ipsilateral motor nuclei innervating jaw closing and jaw opening muscles respectively. The ventromedial zone of RPcvm and the adjoining laterodorsal zone of RGc receive vestibular input, the medial zone of RGc receives visual input through the decussating tectobulbar tract. There seems to be no overlap of these two zones of sensory input. RPcvm projects bilaterally to motoneurons of the jaw muscles; RPcdl and RPcvm both project to (mainly ipsilateral) motor nuclei of the tongue muscles, whereas RPcvm and RGc both project to motor centers innervating neck muscles. This pattern of afferent and efferent reticular connections strongly suggests the existence of functionally defined zones in the bulbar reticular formation.

## 370.1

**ENTORHINAL FIBERS TO THE INNER MOLECULAR LAYER AND HILUS OF THE DENTATE GYRUS: A PHAL TRACING STUDY.**

T. Deller<sup>1</sup>, R. Nitsch<sup>2</sup>, A. Martinez<sup>3</sup>, and M. Frotscher<sup>1</sup>. Anat. Institute, Univ. of Freiburg, F.R.G. (1), Anat. Institute, Charité, Berlin, F.R.G. (2), and Dep. de Bioquímica y Fisiología, Univ. Barcelona, Spain (3).

Entorhinal fibers to the molecular layer of the dentate gyrus are believed to be strictly confined to the outer two thirds. These fibers arise from layer II stellate neurons in the entorhinal cortex (EC) and curve upwards to more rostrally located portions of the hippocampal formation. Another entorhinal projection terminates in the hilus of the dentate gyrus (Köhler, C. (1985) *Neurosci. Lett.* 56:13-19). These axons originate from neurons located in layers IV-VI and are believed to project horizontally to the hippocampal formation. It has been suggested that these fibers reach the hilus of the dentate gyrus via CA3. Using anterograde tracing with PHAL we unraveled another trajectory of entorhinal fibers that originate from neurons located in layers IV and VI and reach the hilar area via the inner molecular layer of the dentate gyrus. These fibers enter the outer two-thirds of the molecular layer, traverse the inner molecular layer and the granule cell layer, and finally arborize subjacent to the granule cell layer. This projection is strongest in the temporal portion of the ipsilateral hippocampus and almost absent septally. Electron microscopy revealed that these fibers form asymmetric synapses on dendrites in the inner molecular layer, somatic spines of granule cells, and spineless dendrites beneath the granule cell layer. Postembedding immunogold staining indicates that entorhino-hilar fibers do not contain the inhibitory neurotransmitter GABA. These data demonstrate that not all entorhino-dentate fibers follow the classical laminar organization of afferents in the rat fascia dentata. While entorhinal fibers from the superficial layers terminate exclusively in the outer zone of the dentate gyrus, entorhinal fibers arising from deeper layers are not confined to laminar boundaries (SFB 528, Ni 322/1-2, SFB 1523, Fr 620/4-2, Leibniz Program).

## 370.3

**EFFERENT PROJECTIONS OF THE CLAUSTRUM TO THE AMYGDALA: AUTORADIOGRAPHIC ANALYSIS IN THE MACAQUE MONKEY. K. Coleman-Meschke\* and D. G. Amaral.** The Center for Behavioral Neuroscience, SUNY at Stony Brook, Stony Brook, NY 11794-2575.

The mammalian claustrum is a large, narrow sheet of gray matter with dorsal and ventral enlargements. The dorsal claustrum is extensively interconnected with the neocortex bilaterally, whereas the ventral claustrum has reciprocal projections with a variety of subcortical structures and limbic cortical regions. We have examined the projections from the claustrum to the amygdaloid complex after injections of a mixture of 3H-leucine and 3H-proline into the claustrum in Macaca fascicularis monkeys. Injection into the ventral portion of the claustrum demonstrated a heavy ipsilateral projection to the magnocellular division of the basal nucleus throughout the rostral-caudal extent, and light-to-moderate projections to the intermediate division of the basal nucleus. Moderate labeling was also noted over the dorsal portion of the lateral nucleus. The ventral-most injection also demonstrated light-to-moderate projections to the lateral division of the central nucleus. There were no significant projections to any other nucleus within the amygdaloid complex. Nor was there any labeling of the contralateral amygdala. Injections into the dorsal portion of the claustrum revealed no projections to any nucleus within the amygdaloid complex at any rostral-caudal level. Injections of the anterograde tracers Phaseolus vulgaris leucoagglutinin or 3H-amino acids into the magnocellular division of the basal nucleus revealed a heavy return projection to the ventral claustrum. This projection innervated mainly the ventral enlargement of the claustrum. These findings will be discussed in relation to published information on claustricocortical connections and the implications for the nature of the amygdalocortical interactions.

## 370.5

**ORGANIZATION OF PROJECTIONS FROM THE BASOMEDIAL NUCLEUS OF THE AMYGDALA: A PHASEOLUS VULGARIS-LEUCOAGGLUTININ STUDY IN THE RAT. G. D. Petrovich\*, P. Y. Risold and L. W. Swanson.** NIBS Program and Dept. of Biol. Sci., USC, Los Angeles, CA 90089-2520.

PHAL was injected stereotactically into 30 rats to describe the overall pattern of efferent projections from the basomedial nucleus of the amygdala (BMA). The anterior and posterior parts of the BMA, recognized on cytoarchitectonic grounds, were shown to display significantly different patterns of projections.

Within the amygdala, the anterior basomedial nucleus (BMAa) heavily innervates the central, medial, and anterior cortical nuclei. In contrast, the posterior basomedial nucleus (BMAp), sends a dense input to the lateral nucleus, and to restricted parts of the central and medial nuclei.

Extraamygdalar projections from the BMA may be divided into ascending and descending components. The former end in the cerebral cortex, striatum, and septum. The BMAa mainly innervates primary olfactory cortical areas (piriform, transitional) while the BMAp innervates association cortical areas (perirhinal, entorhinal) and the medial prefrontal cortex (infralimbic, prelimbic areas). Within the striatum, the BMAa densely innervates the striatal fundus and olfactory tubercle, while the nucleus accumbens receives a heavy input from the BMAp. Both parts of the BMA send massive inputs to distinct regions of the bed nuclei of the stria terminalis.

Descending projections from the BMA end primarily in the hypothalamus, where the BMAa mainly innervates the lateral hypothalamic area, while the BMAp projects especially heavily to the ventromedial nucleus.

In conclusion, the cytoarchitectonically distinct anterior and posterior parts of the BMA are also hologically distinct. Thus, the BMAa and BMAp form parts of anatomical circuits that probably mediate different functions.

## 370.2

**POSTNATAL DEVELOPMENT OF GRANULE CELLS AND THEIR**

**AFERENT SYNAPSES IN THE DENTATE GYRUS OF RHESUS MONKEYS. L. Seress\*, B.J. Baumgartner and C.E. Ribak.** Dept. of Physiol., Univ. Med. Sch., Pécs, Hungary and Dept. of Anat. & Neurobiol., Univ. of Calif., Irvine, CA 92717.

Granule cells, the molecular layer and subgranular zone of the hilus were examined in both developing and adult rhesus monkeys. Total dendritic length and the properties of the dendrites were measured by a computer assisted 3-D tracing system. Spine density was counted for dendrites under oil immersion (100X obj.). Vertical probes through the molecular layer and horizontal probes in the hilus were obtained with electron microscopy to count the number of synapses per unit area in the developing neuropil. The total dendritic length of granule cells displayed a significant increase from birth until the 6th postnatal month. It was followed by a smaller increase until 1 year. No decrease was observed in adults. The spine density on dendrites of granule cells increased from birth to 3 months of age where it then remained at a level observed at all older examined ages. The number of asymmetric synapses per unit area in the molecular layer was highest between 3 and 7 months. A similar peak in synapse number per unit area was observed in the hilus. Between 7 months and 1 year of age, the number of asymmetric synapses per unit area decreased to a level that was found in newborn monkeys. There was no significant change in the number of both axosomatic symmetric synapses for granule cells and axodendritic symmetric synapses in the molecular layer between birth and 1 year. These data suggest that the inhibitory innervation of granule cells develops prenatally whereas the excitatory innervation undergoes significant postnatal changes. Both dendritic length and spine density of granule cells steadily increase from birth until they reach the mature stage. The transient peak in the number of asymmetric synapses per unit area in the dentate gyrus may be explained by a "dilution" caused by the increased volume of the dentate gyrus and the increase in the number and size of glial processes.

Supported by U.S.-Hungarian Joint Fund 186/91 and NIH Grant NS-15669.

## 370.4

**SYNAPTIC INPUT FROM THE RAT ENTORHINAL CORTEX, AMYGDALA, MIDLINE THALAMUS AND PREFRONTAL CORTEX ONTO STRIATAL NEURONS. D.M. Finch.\*** Department of Neurology and Brain Research Institute, University of California, Los Angeles, CA 90095-1761.

Tracing studies have shown that projections from the entorhinal cortex, amygdala, midline thalamus and infralimbic cortex all terminate in the same general region of the striatum, particularly the nucleus accumbens (Acb). Physiological responses of striatal neurons to stimulation of these areas were examined. Sprague-Dawley albino rats were anesthetized with chloral hydrate (400 mg/kg i.p.) and extra- and intracellular recordings from Acb and caudate putamen neurons were obtained. A retrograde tracer (WGA-APoHRP-Gold) was deposited in some animals in the vicinity of recording sites to confirm that stimulating electrodes were located near cells that projected to the striatum. Excitatory responses to stimulation of all of the areas were obtained. In many cases, excitatory responses were intermittent and intracellular recordings showed that even large EPSPs could be insufficiently large to trigger action potentials except in the presence of "spontaneous" depolarizations. Some cells showed short term frequency potentiation, in which 5/sec stimulation increased the probability of spike firing. Recordings from spontaneously active cells showed a period of spike suppression lasting hundreds of msec after stimulation. A number of cells showed responses to more than one stimulating locus and in a subset of these cases it was possible to show synaptic interactions. These results indicate that functional influences from diverse areas can converge onto single Acb neurons to effect synaptic integration. Supported by NIH Grant DA09543.

## 370.6

**INTRINSIC CONNECTIONS OF THE RAT AMYGDALOID COMPLEX: PROJECTIONS ORIGINATING IN THE ACCESSORY BASAL NUCLEUS. V. Savander<sup>1</sup>, J.E. LeDoux<sup>2</sup>, C.-G. Go<sup>2</sup>, A. Pitkanen<sup>1,3</sup>.** <sup>1</sup>Dept. of Neurology and <sup>2</sup>A.I. Virtanen Institute, Univ. of Kuopio, P.O.Box 1627, FIN-70211 Kuopio, Finland and <sup>3</sup>The Center for Neural Science, New York University, NY 10003, USA.

The aim of present study was to determine the distribution and topography of the intra-amygdaloid projections originating in the accessory basal (basomedial) nucleus of the rat amygdala. The anterograde tracer, *Phaseolus vulgaris* leucoagglutinin was iontophoretically injected into different rostrocaudal levels of the accessory basal nucleus. The distribution of labelled terminals was analyzed from immunohistochemically stained sections. On the basis of the cytoarchitectonics and the connectational data arising from the present study, we divided the accessory basal nucleus into two divisions, the magnocellular and the parvocellular division. The main projections originating in the magnocellular division terminated in the medial division of the lateral nucleus, in the periamygdaloid cortex and in the capsular division of the central nucleus. The parvocellular division projected to the medial division of the lateral nucleus, the central division of the medial nucleus, the capsular and medial divisions of the central nucleus, the medial division of the amygdalohippocampal area and to the posterior cortical nucleus. The present study shows that the projections originating in the accessory basal nucleus, like those originating in the lateral and basal nuclei (Pitkanen et al., 1995; Savander et al., 1995) are topographically organized to a greater extent than previously thought.

## 370.7

**THE LATERAL NUCLEUS OF THE RAT AMYGDALA IS RECIPROCALLY CONNECTED WITH ITS MAIN INTRA-AMYGDALOID TARGET NUCLEI.** A. Pitkanen<sup>1, 3\*</sup>, J. E. LeDoux<sup>2</sup>, C. G. Go<sup>2</sup>, V. Savander<sup>1</sup>. <sup>1</sup>Dept. of Neurology and <sup>3</sup>A. I. Virtanen Institute, Univ. of Kuopio, P.O. Box 1627, FIN-70211 Kuopio, Finland and <sup>2</sup>The Center for Neural Science, New York University, New York, NY 10003, USA.

*Phaseolus vulgaris* leucoagglutinin (PHA-L), an anterograde tracer, was used to investigate the intra-amygdaloid afferent connections of the lateral nucleus of the rat amygdala. PHA-L was iontophoretically injected into the basal nucleus, the accessory basal nucleus and the periamygdaloid cortex of the rat amygdaloid complex. The results obtained from the present study revealed that the lateral nucleus received substantial projections from its main intra-amygdaloid target areas: the basal nucleus, the accessory basal nucleus and the periamygdaloid cortex. We also observed that the afferent projections were organized in a manner that supports the idea of dividing the lateral nucleus into three divisions, namely, the medial, dorsolateral and the ventrolateral divisions. The medial division received projections from the accessory basal nucleus and the periamygdaloid cortex. The ventrolateral division received projections from the parvocellular division of the basal nucleus and the periamygdaloid cortex. The dorsolateral division, instead, did not receive any projections from the nuclei investigated. The present study demonstrates that the organization of the information flow within the amygdaloid complex is not as unidirectional as previously thought.

## 370.9

**PROJECTIONS FROM THE PARAVENTRICULAR NUCLEUS OF THE THALAMUS TO THE LIMBIC CORTEX.**

T. van Groen\*, I. Kadish and J.M. Wyss. Dept. of Cell Biology, University of Alabama, Birmingham, AL 35294-0019

Previous studies indicate that the paraventricular (PV) nucleus of the thalamus projects primarily to the prelimbic cortex (area infraradiata; IRb), and to the ventral striatum. However, our anterograde tracing studies suggest that many axons extend beyond these areas to synapse in more caudal limbic cortical areas. The present study used anterogradely and retrogradely transported tracers to characterize the projections of PV. Injections into PV label axons and terminals in the frontal polar, agranular insular, medial orbital and IRb cortices, in the anterior olfactory nucleus and in the basolateral, central and lateral amygdaloid nuclei. In the caudal limbic cortex, labeled axons extend to the caudal piriform, and to perirhinal and entorhinal cortices, and the ventral subiculum. In addition to the cortical projections, PV projects to a number of subcortical areas; PV injections label a dense terminal field in the ventral striatum (nucleus accumbens) and a sparse terminal field in the olfactory tubercle and in the lateral part of the lateral septal nucleus. Further, labeled axons and terminals are in the rostroventral reticular nucleus of the thalamus and sparsely to the dorsal periaqueductal gray. Neurons in different parts of PV have distinct projections, e.g., only rostral parts of PV project to the subicular and entorhinal cortices. Axons of PV terminate primarily in layers I and V in most cortical areas, but the projections to the entorhinal and perirhinal cortices terminate in deep layers (i.e., layers V-VI). These results demonstrate that PV projects to functionally distinct limbic areas, e.g., regions implicated in learning and memory versus regions involved in cardiovascular regulation and control of emotions.

## 370.11

**ANATOMICAL EVIDENCE FOR A POSSIBLE VISCERALLY-RELATED PREMOTOR AREA IN THE LATERAL FRONTAL CORTEX OF THE RAT** M.D. Cassell\* & C.-J. Shi. Dept. of Anatomy, University of Iowa, Iowa City, IA 52242

The rostral medial agranular frontal cortex (AgM) in the rat is connected with somatosensory, posterior parietal insular and motor cortices and the ventrolateral part of the mediodorsal thalamic nucleus (MD). It is usually considered to function as a premotor area mediating sensory-guided voluntary movements. Corticocortical projections arising from gustatory/viscerosensory areas of the anterior parietal insular cortex terminate heavily in a band of dysgranular insular cortex on the lateral frontal surface (dorsolateral orbital and lateral frontal polar cortices) that is continuous with AgM rostrally. To determine if this cortical area has similarly organized connections as AgM, microinjections of biocytin were made at all levels of its rostrocaudal extent. Projections to the thalamus targeted the ventromedial parts of caudal MD, and the centromedian and parafascicular nuclei. Cortical projections were directed at head and forelimb regions of motor cortex, as well as viscerosensory parts of the parietal insular cortex. Strong projections to the rostral caudate-putamen and lighter projections to the anterior basolateral amygdaloid nucleus were also observed. The organization and extent of these projections parallel those arising from AgM, with projections targeting motor-related cortical and subcortical areas, but indicate a strong relationship with the anterior parietal insular cortex. As behavioral studies have consistently shown deficits in appetitively-guided motor activity following lesions of this area, we suggest this area of prefrontal insular cortex may function as a viscerally-related premotor zone. Supported in part by NS25139.

## 370.8

**INTRACELLULARLY LABELED HIPPOCAMPAL HILAR INTERNEURONS IN VIVO.** A. Sik, M. Penttonen, A. Ylinen\* and C. Buzsaki. CMBN, Rutgers University, Newark, NJ 07102

Interneurons in the dentate area were characterized physiologically and filled with biocytin in urethane anesthetized rats. The neurons were double stained for various peptides and calcium binding proteins. In some cases the PV target cells were investigated. The labeled interneurons were divided into subgroups. (1) NPY-containing interneuron, with very spiny dendrites in the hilar region. The axon collaterals covered the 2/3 of the dentate gyrus (septo-temporally) innervating the outer half of the entire extent of the molecular layer. In addition, boutons contacted more than 1000 PV positive targets. (2) Calbindin positive cell, with axon collaterals mostly in the stratum oriens and radiatum of the entire dorsal CA3. A secondary axon penetrated into the hippocampal fissure, giving rise several collaterals in the CA1 radiatum and the subicular area. (3) Basket-like cell in the granule cell layer with axon collaterals in the granule cell layer, and the inner molecular layer. (4) Interneuron in zone 3 innervating the granule cell layer and inner/middle molecular layer of both upper and the lower blades. (5) Bistratified interneuron in CA3 pyramidal layer innervating the stratum oriens and radiatum. The subgroups had characteristic and different physiological response properties.

## 370.10

**HYPOTHALAMO-THALAMO-CORTICAL CIRCUITS INFLUENCED BY PHEROMONAL INFORMATION, AND INVOLVED IN REPRODUCTIVE AND DEFENSE BEHAVIORS.** P.Y. Risold\*, L.W. Swanson. NIBS Program, Dep. of Biol. Sci., USC, Los Angeles, CA 90089-2520.

Recently, dense projections from the highly interconnected anterior (AHN), ventromedial (VMH), and dorsal preamunillary (PMD) nuclei of the hypothalamic medial zone were identified to the anterior nucleus reuniens (RE) and the ventral anteromedial nucleus (AMv) of the rat thalamus. In this study, simultaneous injections of PHAL and fluorogold (FG) were placed in the RE. The distribution of retrograde labeling confirmed afferents to this nucleus from the AHN, VMH, and PMd, while an analysis of the distribution of PHAL-labeled axons showed that through this pathway the same hypothalamic nuclei may influence ventral regions of the hippocampal formation (SUBv and field CA1v). However, projections from the RE were also found to the cingulate cortex and, in particular, a small terminal field was identified in the lateralmost part of the agranular retrosplenial area (RSPagl). Connections of the RSPagl were subsequently analyzed by the PHAL-FG procedure. Moderate afferents from the RE were confirmed, but interestingly, the RSPagl was found to be connected densely with the AMv as well as with the rostromedial part of the lateral posterior nucleus. In addition, this area was found to innervate brainstem centers involved in head and eye movements (including the superior colliculus), and the periaqueductal gray, which receives dense descending inputs from the AHN, VMH, and PMd.

The AHN and VMH are known to be targeted by very dense medial amygdala projections. The AHN is also bidirectionally connected with the ventral lateral septal nucleus, which is a major terminal field for SUBv and CA1v projections. Thus, via these thalamocortical pathways, the AHN, VMH, and PMd may participate in attentional responses, probably initiated in part by pheromonal information. These circuits may also play an important role in the initiation and coordination of goal-oriented behaviors in which the AHN, VMH, and PMd are suspected to be involved (e.g., reproductive and defensive).

## 370.12

**HODOLOGICAL FRONTO-HIPPOCAMPAL INTERACTION: RE-DISCOVERING THE CINGULUM BUNDLE.**

R. Morris\*, M. Petrides and D.N. Pandya. Montreal Neurological Institute, McGill University, Montreal, CANADA and Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA, USA

Evidence from the clinical literature has shown that certain aspects of memory depend on the integrity of both the frontal cortex (FC) and the hippocampal system (HS) as well as on their functional interaction. Small surgical removal of the anterior portion of the temporal region including the entorhinal cortex (EC) is not sufficient to disrupt that fronto-hippocampal relationship. More radical temporal removal, however, including a considerable extent of the HS disrupts that reciprocal communication. These clinical data strongly suggest that the interaction between the FC and the HS is not exclusively dependent upon the integrity of the EC. Thus, the source of frontal inputs to the HS that might bypass the EC was investigated by means of autoradiography in the macaque monkey. The origin and course of the cingulum bundle have been carefully examined to see if this fiber system could sustain such fronto-hippocampal interaction. The results have revealed that the cingulum bundle links the FC with the HS. This hodological affiliation originates in the mid-dorsolateral portion of the FC that lies above the sulcus principalis. The presubicular component of the HS is the final recipient of the cingulum projection originating in the mid-dorsolateral FC. The results are discussed in the context of the cognitive deficits observed after surgical removals from frontal and temporal lobes for the treatment of pharmacologically intractable epilepsy.

## 370.13

**DIFFERENTIAL PROJECTION FROM THE FRONTAL CORTEX TO THE ROSTRAL TEMPORAL LOBE IN THE FASCICULARIS MONKEY. A RETROGRADE TRACING STUDY.** R. Insausti\*, E. Sanz, A. Insausti and L.M. Gonzalo. Dept. Anatomy, University of Navarra, Apdo. 273, 31080 Pamplona, SPAIN.

The rostral temporal lobe of the monkey is made up of several cytoarchitectonic areas (tip, area 36p or temporopolar cortex; ventromedial aspect, perirhinal cortex; ventrolateral aspect, rostral area TE and dorsal aspect TS1), as shown in cytoarchitectonic studies. Given the importance of the rostral temporal lobe in visual (rostral area TE), memory (perirhinal cortex, temporopolar cortex), and emotional (temporopolar cortex) processing, we have attempted to individualize differences in connectivity of the various components of the rostral temporal lobe. We report here the differences found in the frontal cortex input. Retrograde tracers (1% WGA-HRP, 3% Fast Blue or 2% Diamidino Yellow) were injected after exposure of the temporal pole (two cases), rostral perirhinal cortex (three cases) and rostral area TE (one case). After appropriate survival, animals were perfused transcardially and the brain serially cut at 50 µm. One section every 500 µm was analyzed and the location of neurons recorded with a digitizing system. Labeling was charted onto two-dimensional reconstructions of the frontal cortex in each case. Our results can be summarized as follows: The orbitofrontal cortex is the only cortical area projecting to all the components of the rostral temporal lobe, being the temporal pole the region recipient of the largest projection both in extent and density. The rostral portion of area TE is the only one receiving input from the ventral lateral frontal cortex (Area 46 and area 12). Perirhinal cortex receives the least projection and only from the orbitofrontal cortex. Thus, the anatomical and functional heterogeneity of the rostral temporal lobe is enhanced by the different patterns of frontal cortical projection, what suggests that both the frontal and the rostral temporal lobe are connected in such a way that favors the functional segregation of the frontal lobe. Supported by grant DGICYT PM92-1166.

## 370.15

**Limbic cortex and astrocytic gliosarchitectonics: retrieval of Golgi-like GFAP immunoprecipitation from formalin fixed brain.** B. Quinn\*. Division of Neuropathology, NYU Medical Center, New York, NY 10016.

Recent studies focus new attention on the potentially diverse roles of astrocytes in neuromodulation, including calcium wave propagation, perisynaptic ion modulation, glutamate release and metabolism, amyloid processing, neurotrophin production, and neuromodulatory microvasculature control<sup>1</sup>. Traditional pathologic studies recognize fibrous and protoplasmic astrocytes, while in vitro studies demarcate Type I and Type II astrocytes. However, rare classical Golgi studies recognized many astrocytic subtypes with complex, intriguing regional architectonics<sup>2</sup>. We have developed a nearly Golgi-like "immuno-impregnation" from human brain both routinely immersion fixed for weeks, or alcohol fixed, using PEG embedding, hydrated autoclave treatment of floating sections sandwiched between lens paper and slides, GFAP or CD44 immunostaining of thick floating sections, and a novel silver immunointensification of the DAB product. Our preliminary studies have defined at least seven reliable astrocytic forms in human meso-temporal lobe/hippocampus; this morphologic diversity seems to increase from rodent to man. Other limbic areas such as cingulate and orbital cortex reveal highly distinctive laminar glial architectures. The findings invite correlation with molecular differentiation markers, for example analysis of glial heterogeneity in neocortical regions with different predispositions to amyloid plaque formation, and the comparative study of limbic system gliosarchitectonics in schizophrenia and controls. Sponsored by the Stanley Foundation and the NYU Alzheimer Disease Center. (1) Smith, Prog. Brain Res. 94, 1992. (2) Retzius, Biol. Untersuch., 1894.

## 370.14

**LAMINAR ORIGIN OF THE SUBICULAR CORTEX PROJECTION TO THE BED NUCLEUS OF THE STRIA TERMINALIS IN THE RAT.** K. Sripanidkulchai and J.W. Brown\*. Department of Anatomy, Khon Kaen University, Khon Kaen Thailand and Department of Cell Biology, University of Alabama at Birmingham, Birmingham, AL 35294.

Previous studies have demonstrated that the hippocampal formation projects to the bed nucleus of the stria terminalis in the rat. Whereas the projection from the entorhinal cortex to nuclei near the bed nucleus (e.g. nucleus accumbens) has been shown to originate in layer V, the origin of the projection to the bed nucleus from the hippocampal formation is less well documented. This study characterized these projections using the retrograde transport of fluoro-gold and fast blue. In 30 male Sprague-Dawley rats, a 30-40 nl injection of one of the dyes (4% in dH<sub>2</sub>O) was placed into a small area of the bed nucleus of the stria terminalis and the rat was sacrificed 10 days later. The brains were perfused, sectioned and stained for AChE, Nissl or left unstained. The results demonstrate that the projection from the presubiculum and parasubiculum to the bed nucleus of the stria terminalis originates in the AChE rich layer V. The projection neurons are all pyramidal in shape and ipsilateral to the injection in the bed nucleus. Further, the data indicate that only the medial subdivision of the bed nucleus receives this projection. These data demonstrate a topographic projection from pre- and parasubiculum to the bed nucleus of the stria terminalis in the rat.

## ASSOCIATION CORTEX AND THALAMOCORTICAL RELATIONS: ANATOMY

## 371.1

**MUSCARINIC m2 ACETYLCHOLINE RECEPTOR EXPRESSION IN SELECTED PROJECTION AND LOCAL CIRCUIT NEURONS IN THE MONKEY CEREBRAL CORTEX: AN IMMUNOHISTOCHEMICAL AND IN SITU HYBRIDIZATION ANALYSIS.** L. Mrzljak\*, A.I. Levey, S. Belcher and P.S. Goldman-Rakic. Section of Neurobiology and Dept. of Pharmacol., Yale Sch. of Med., New Haven, CT 06510 and Emory Univ. Sch. of Med., Atlanta, GA 30332.

Pharmacological and physiological studies have emphasized the role of the muscarinic m2 acetylcholine receptor as an autoreceptor on cholinergic afferents that modulates the release of acetylcholine in the cerebral cortex. Using an antibody against acetylcholine m2 muscarinic receptor protein, we have recently described postsynaptic as well as presynaptic localization of this receptor in the cerebral cortex (Levey et al. J. Neurosci. 11:3218-3226, 1991; Mrzljak et al. Proc. Natl. Acad. Sci. 90:5194-5198, 1993). We have now combined immunohistochemistry and in situ hybridization using <sup>35</sup>S labeled riboprobes to validate postsynaptic localization and evaluate the expression of m2 protein and mRNA in prefrontal and premotor neurons. In nine rhesus monkeys ranging from 4 months to 15 years of age immunohistochemistry revealed either a positive band of labeling across layer V in areas 9, 10, 11 and 46 or a bilaminar pattern of labeling in layers III and V of areas 6, 8, SMA and 24. A subset of nonpyramidal neurons exhibiting the characteristics of local circuit neurons in layers II-VI expressed m2 protein indicating a role of this receptor in inhibitory intracortical projection. However, pyramidal neurons in layers III and V were the most predominant cell type stained. The apical dendritic trees of these pyramidal neurons were intensely labeled, whereas immunolabeling in the cell bodies was barely detectable. In situ hybridization revealed m2 mRNA expression in numerous layer III and V cells and further displayed the same areal banding pattern. The postsynaptic localization of m2 receptor protein in deep layer pyramidal neurons suggest a selective role of this receptor in the regulation of corticofugal (corticostriatal, corticocortical) projections.

## 371.2

**DIVERSE MESENCEPHALIC DOPAMINERGIC CELL GROUPS PROJECT TO THE MACAQUE FRONTAL CORTEX.** Patricia S. Goldman-Rakic\* and S. Mark Williams. Section of Neurobiology, Yale University School of Medicine, 333 Cedar Street, C303 S.H.M., New Haven, CT 06510.

Although the topography of the mesocortical DA system has been extensively studied in rodents, few studies have examined the origin of this projection in primates. We have employed a combination of retrograde tracing, using fluorescent dyes, and tyrosine hydroxylase (TH) immunohistochemistry to identify frontal cortex projecting DA neurons. Injections of fast blue (FB) were made in areas 46, 9d, 8B, 6M, 4, 24 and the prelimbic area (PL) of the rhesus monkey. Neurons containing both FB and TH (FB/TH+) were plotted from the level of the mammillary bodies to the locus coeruleus. Although it is commonly assumed that the ventral tegmental area (VTA) is the major source of DA afferents to the neocortex, our results demonstrate that the frontal cortex is innervated by a widespread continuum of neurons distributed in all three of the mesencephalic DA cell groups (A9, A10 and A8, corresponding to the substantia nigra pars compacta [SN], VTA, and the retrorubral area [RRA], respectively). For all frontal areas examined, approximately 1/3 of midbrain FB/TH+ were located caudally and dorsally to the SNpc, in the dorsal retrorubral area. The remaining 2/3 of FB/TH+ neurons were distributed primarily in the full medial-lateral extent of the dorsal SN and in the n. parabrachialis pigmentosus of the VTA. Although, this pattern of distribution is observed for all frontal areas examined, some evidence of topography was evident. The medial prefrontal cortex (area PL) receives more DA input from the midline VTA and less from the lateral SN and RRA than do dorsolateral prefrontal areas (e.g. area 46). As has been reported in other species, a large number of retrogradely-labeled neurons in the ventral mesencephalon are non-dopaminergic (FB/TH-). These cells are primarily distributed in the rostromedial VTA; however, FB/TH- are observed in A8 and A9 as well. The evidence of robust projections of DA neurons from the A8 and A9 cell groups to the primate frontal cortex implicates midbrain regions beyond the VTA in the modulation of neocortical processes.

## 371.3

**OVARECTOMY AFFECTS MONOAMINE INNERVATION IN PRIMATE PREFRONTAL CORTEX.** M. Kritzer\*, Dept. of Neurobiology & Behavior, SUNY at Stony Brook, Stony Brook, N.Y.

The association cortices have well known roles in memory, motivation, and emotion. Monoaminergic circuits are critical to these processes, and are implicated in their dysfunction in cognitive/affective disorders. However, gender differences noted in some of these same functions and disorders indicate that gonadal hormones also influence association cortex. Findings are presented suggesting this influence could stem from hormone modulation of monoamines.

Immunolabeling for tyrosine hydroxylase (TH) and serotonin (5-HT) in the prefrontal cortex of an adult rhesus monkey ovariectomized (OVX) eight months before sacrifice, and two age-matched controls revealed striking differences in monoamine innervation. Thus, whereas labeling in controls corresponded to published descriptions, immunolabeling in the OVX case was qualitatively and/or quantitatively different. TH labeling in layer I, for example, which is normally divided into inner and outer strata of high and low fiber density, was uniformly dense in the OVX case. Quantitative analysis revealed that TH-innervation was decreased in OVX cortex in all but layer Ia, with fiber density reduced by more than 50% in layer II, and by 10-30% in remaining layers. 5-HT labeling on the other hand was more dense in every layer of the OVX vs. control cortex, with density increased by 15% in layer I, and by 40-60% in remaining layers.

The opposing effects of OVX on 5-HT vs. TH argues against roles for non-specific factors, e.g., tissue preservation, in producing observed differences in immunolabeling, and argues for layer- and transmitter-specific effects of the hormonal milieu on monoamines in prefrontal cortex. This influence may be important in gender differences seen in the maturation, adult function and dysfunction of the association cortices in human and non-human primates.

## 371.5

**SELECTIVE CONNECTIONS OF THE SUPERIOR TEMPORAL AUDITORY REGION WITH THE PREFRONTAL CORTEX IN THE MACAQUE MONKEY.** L.M. Romanski\*, J.F. Bates and P.S. Goldman-Rakic, Yale Univ. Sch. Med. Section of Neurobiology, New Haven, CT 06510.

A recent study from this laboratory has revealed multiple, parallel anatomical pathways linking specific visual areas in the temporal lobe with particular regions of the prefrontal cortex (Bates et al., 1994). To examine the possibility that similarly organized processing streams exist in the auditory domain we have examined the connections between the superior temporal gyrus (STG) and the supratemporal plane with the prefrontal cortex. WGA-HRP was placed into cytoarchitecturally defined regions within the frontal lobes of rhesus monkeys and the retrograde cells and anterograde terminals were localized within cytoarchitecturally defined areas of the superior temporal auditory region (Pandya and Sanides, 1973). Most regions of the prefrontal cortex had connections with some portion of the STG or the supratemporal plane. However, prefrontal cortical areas I2 lateral, I1/I2 orbital and the frontal pole (area 10) showed the greatest connectivity with superior temporal auditory regions with retrograde cell labeling being densest in areas TS2 and TS3 of the STG. In addition, many regions of the prefrontal cortex were connected with area TPO, the polysensory area located in the dorsal bank of the STS. In all cases, retrogradely labeled cells in the superior temporal region were most prominent in layers III and V. Terminal labeling was apparent in all areas which had retrograde cells. This labeling was particularly dense in layer I but columns of terminals which spanned all layers of the cortex were also present. Our results confirm and extend previous studies detailing the connections of the superior temporal auditory regions with the prefrontal cortex in the primate. These temporo-frontal connections indicate that there may also be multiple, parallel processing streams to convey auditory information to the prefrontal cortex in a similar manner as that seen with visual processing.

## 371.7

**CORTICOTHALAMIC PROJECTIONS FROM DIFFERENT LAYERS OF THE CINGULATE CORTEX TO THE ROSTRAL RETICULAR NUCLEUS AND RELATED THALAMIC NUCLEI.** C. Lizio, S. DeBiasi and G. Battaglia\*, Dept. of Neurophysiology, Neurological Institute "C. Besta", Milano, Italy; University of Milano, Italy.

The anatomical connections between the cortex and the thalamus have been traditionally regarded as strictly ipsilateral. Recent studies, however, revealed extensive crossed corticothalamic projections from limbic cortical areas (Lizio et al., 1994), and commissural intrathalamic connections arising from the rostral pole of the reticular nucleus (Raos and Bentivoglio, 1993; Battaglia et al., 1994). The present work reinvestigated, by means of sensitive retrograde and anterograde axonal tracers, the corticothalamic projections from different layers of the rat cingulate cortex. Small iontophoretic injections of Fluorogold (FG) or biotinylated dextran amine (BDA) were delivered in different regions of the rostral reticular nucleus, or in different layers of the cingulate cortex, respectively. After a survival time of 7 to 10 days, the rats were perfused, and the brains coronally cut with a vibratome. The sections were then processed with an antibiotin antibody to reveal the anterogradely transported BDA, or directly observed with a fluorescence microscope for the retrogradely transported FG.

After FG injections in the medial region of the rostral pole of the reticular nucleus, retrogradely labeled neurons were found in the ipsilateral cingulate cortex (CG1 and CG3; Zilles, 1985), mainly concentrated in the inferior part of layer VI. After injections in the lateral region of the rostral pole, retrogradely labeled neurons were found in the same ipsilateral cingulate area, particularly concentrated in the superficial part of layer V. These results were confirmed by the anterograde tracing data: after BDA injections in the deep layer VI of CG1, labeled terminals were found in the medial region of the ipsilateral rostral pole of the reticular nucleus, and bilaterally and almost symmetrically distributed in the anterior, intralaminar, and midline nuclei. After injections in superficial layer V, labeled fibers were confined to the lateral rostral pole, and predominantly distributed in ipsilateral dorsal thalamic nuclei.

The present results reveal a different anatomical organization of the corticothalamic pathways arising from different limbic cortical layers, and suggest an important role for the deep layers of the cingulate cortex in the subcortical link between the cerebral hemispheres.

## 371.4

**OVERLAP AND SEGREGATION IN PREFRONTAL TERRITORIES CONNECTED WITH PARIETAL AND TEMPORAL VISUAL ASSOCIATION AREAS IN MACAQUE MONKEYS.** C. Cavada\*, J. Tejedor, A. Hernández-González and F. Reinoso-Suárez, Dept. Morfología, Fac. Medicina, Univ. Autónoma de Madrid, 28029 Madrid, Spain.

The dorsolateral and ventrolateral sectors of the prefrontal cortex are usually related to the posterior parietal and temporal visual cortices, respectively, regarding both connections and function. However, following injections of HRP-WGA in either sector, neuronal and terminal labeling was present in both posterior parietal and temporal areas. This observation led us to examine whether there is segregation, overlap, or both, in the prefrontal cortical territories connected with visual association areas of the parietal and temporal lobes. Multiple labeling experiments were performed using anterograde and retrograde tracers placed in posterior parietal areas 7a and 7ip, and in the temporal areas STP (superior temporal polysensory area), TE and TEO. Following pairs of injections in 7a and intermediate or posterior STP, segregation was the rule in the prefrontal labeled territories. These were often interdigitated, and some mingling of projection neurons was only observed in restricted portions of the dorsolateral prefrontal convexity, lower bank of the principal sulcus and area 45 in the anterior bank of the lower limb of the arcuate sulcus. Conspicuous overlap of connectional territories was observed, however, following injections in the posterior parietal areas and anterior STP, TE and TEO. Overlap was most prominent in the cortex of the principal and arcuate sulci, again in the lower bank of the former and anterior bank of the latter. Pairs of injections in 7ip and TE additionally produced overlap of connectional territories in the ventrolateral prefrontal convexity. These territories where projections to and from posterior parietal and temporal cortices coincide may play a key role in global visual perception through integration of both spatial and object-related visual cues.

## 371.6

**DIRECT COMPARISON OF THE ORIGINS OF THALAMOCORTICAL PROJECTIONS TO AREAS 4, 6 AND 46: MULTIPLE NEUROANATOMICAL TRACING IN SINGLE MONKEYS.** E.M. Rouiller(1)\*, V. Morel(1), J. Tanne(2), N. Zeller(2) and D. Bussac(2) (1) Institute of Physiology, Univ. of Fribourg, 1700 Fribourg, Switzerland; (2) Vision et Motricité, INSERM U94, 69500 Bron, France.

To clarify to what extent the various subdivisions of the cortical areas 4, 6 and 46 receive segregated or overlapping thalamocortical inputs, multiple retrograde tracing experiments were conducted in individual monkeys. Typically, distinct retrograde tracers were deposited in the hand representations of the primary (M1) and supplementary (SMA) motor areas, in the anterior (PMda) and posterior (PMdp) zones of the dorsal premotor cortex, in the ventral premotor cortex (PMv), and in the superior (46s) and inferior (46i) zones of area 46. The corresponding clusters of labeled thalamocortical neurons formed complex mosaics in the thalamus, transgressing cytoarchitectonic boundaries. PMdp and SMA received inputs from thalamic territories presenting a large degree of overlap: their main nucleus of origin was VL0, but projections also came from VA, VLm, VPLo, VLc, CL, CM and MD. The origins of inputs to 46i and 46s often overlapped, but were clearly segregated from those reaching PMdp and SMA, occupying more medial regions of the thalamus (mainly in MD). As a general rule, thalamic territories directed to 46i were larger than those projecting to 46s. Inputs to M1 originated from territories located in the same thalamic nuclei as those directed to PMdp and SMA, but the degree of overlapping was less prominent (about half of the cross-sectional area): the main nucleus of origin of the projection to M1 was VPLo. The inputs to PMv originated mainly from the area X where they partially overlapped with those to PMda. In other thalamic nuclei these inputs to PMv only partially overlapped with those directed to PMdp, SMA and M1. The thalamocortical projections to these various cortical areas, in spite of the complex arrangement of the thalamic territories of origin, exhibit distinct patterns of segregation and/or overlapping, consistent across monkeys.

## 371.8

**CORTICAL CONNECTIONS OF THE RETROSPLENIAL GRANULAR B CORTEX.** J.M. Wyss\* and T. van Groen, Dept. of Cell Biology, University of Alabama, Birmingham, AL 35294

Although the retrosplenial cortex is situated in a critical position between the hippocampal formation and the neocortex, few studies have examined its cortical connections. The present experiments used anterograde tracing techniques to characterize the efferent and afferent cortical connections of the retrosplenial granular B cortex (Rbg). Rbg projects to the ipsilateral anterior cingulate (infradiata, IR), retrosplenial dysgranular (Rdg), Rga, postsubicular and presubicular cortices, and to the contralateral Rbg, Rdg, Rga, and postsubicular cortices. The axons from Rbg terminate in specific cortical layers, in IRβ predominantly in layer I and V, in Rbg in I and III/V, in Rga in layers I and III, in postsubiculum in layers I and V, however, in presubiculum predominantly in layer I. Axons from contralateral Rbg form a dense terminal plexus in layers IV and V of Rbg, with a smaller number of terminals in layers I and VI. Rbg projections to the thalamus terminate primarily in the anteroventral, and the laterodorsal nuclei with less dense projections to anterodorsal nucleus. Cortical projections to Rbg originate in the ipsilateral area infradiata, Rdg and Rga cortices, the dorsal subiculum, and in contralateral Rbg. Each cortical projection to Rbg terminates in distinct layers of the cortex. The axons arising from Rdg terminate primarily in layers I and III-V, the axons from Rga terminate predominantly in layers I and II-III, the projections arising from the subiculum mainly end in layers II-III. The axons arising from the thalamus terminate in layers I and III/IV. Together, these data provide insight into the connections that link Rbg to the limbic learning and memory circuit.

## ANALYSIS OF CORTICAL ORGANIZATION AND INDIVIDUAL VARIABILITY USING COMPUTERIZED FLAT MAPS.

H.A. Drury<sup>1</sup>, D.C. Van Essen<sup>1</sup>, S. Joshi<sup>2</sup>, M.J. Miller<sup>2</sup>, C.H. Anderson<sup>1</sup>, and T. Cogan<sup>1</sup>. <sup>1</sup>Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO, USA. <sup>2</sup>Department of Electrical Engineering, Washington University, St. Louis, MO, USA

We illustrate several ways in which computerized three-dimensional reconstruction and automated flattening of the cerebral cortex can facilitate the analysis of cortical organization and of variability across individual brains. Our analysis was based on reconstructions of the right hemisphere from two macaque monkeys. Both hemispheres were flattened using a multi-resolution approach reported at last year's meeting (Anderson et al., Soc. Neurosci. Abstr. 20:428, 1994). The two hemispheres were similar in total surface area of neocortex (60 cm<sup>2</sup> vs. 69 cm<sup>2</sup>), which is significantly smaller than previous estimates of neocortical surface area based on manually flattened cortical maps. The pattern of sulcal and gyral folding, represented by maps of mean curvature in the three-dimensional reconstruction, were broadly similar in the two maps, but there were numerous differences in detail. The borders of different cortical areas can be readily displayed on individual sections, in the three-dimensional reconstruction, and on the flat cortical map. Alternative partitioning schemes can be directly overlaid in order to facilitate precise comparisons between different schemes.

Comparisons between different individual hemispheres can be facilitated using shape-based warping algorithms that transform one structure to match the shape of another (Miller et al., PNAS 90: 11944, 1993). Application of this method to two-dimensional maps, using sulcal and gyral boundaries to drive the warping process, represents an efficient transformation strategy that preserves topological relationships on the transformed surface. It can be applied in conjunction with a surface-based coordinate system to establish a valuable alternative to standard (three-dimensional) stereotaxic coordinate systems.

## ASSOCIATION CORTEX AND THALAMOCORTICAL RELATIONS: PHYSIOLOGY

## 372.1

## OPIOID PEPTIDES INHIBIT THALAMIC RELAY CELLS

S. Charkpak\* and J. Brunton. Dept of Physiology, University Medical Center, 1211 Geneva 4, Switzerland

In rat brain slices, we used the whole-cell recording technique, in current and voltage-clamp modes, to characterize the response of thalamic relay neurons to opioid peptides. Of 89 cells located in the centrolateral nucleus, 82 were inhibited by [D-Ala<sup>2</sup>, NMePhe<sup>4</sup>, Gly<sup>5</sup>]enkephalin (DAMGO), the agonist selective for  $\mu$ -opioid receptors. In current-clamp mode, the inhibition resulted in a hyperpolarization accompanied by a decrease in membrane input resistance. The effect of DAMGO was reversible, concentration-dependent (a 23 % decrease in input resistance was measured at the ED<sub>50</sub> (about 2.5  $\times 10^{-7}$  M)) and was antagonized by CTOP. No cell tested (n=11) responded to either [D-Pen<sup>2</sup>, L-Pen<sup>5</sup>]enkephalin (2.5  $\mu$ M) or to U50469 (2.5  $\mu$ M), respective agonists for  $\delta$  and  $\kappa$ -opioid receptors. The response to DAMGO could be reversed at potentials negative to -90 mV and the reversal potential shifted with the extracellular K<sup>+</sup> concentration according to the Nernst equation. Our results demonstrate that opioid peptides inhibit centrolateral neurones principally through an increase of a voltage-independent potassium conductance. Relay cells located in the reunions, rhomboid, ventrolateral, ventromedian and ventroposterior nuclei were similarly inhibited by DAMGO. We thus hypothesize that morphine-like agonists induce a specific brain state where the thalamo-cortical inputs are globally depressed.

## 372.2

## DEPTH-PROFILE ANALYSIS AND SPATIAL EXTENT OF SYNCHRONY OF FAST (20-40 Hz) AND SLOW (&lt;1 Hz) CORTICOTHALAMIC OSCILLATIONS. E. Amzica\* and M. Steriade. Lab. Neurophysiol., Sch. Med., Laval University, Quebec, Canada G1K 7P4.

Coherent fast activities were recorded within intracortical and corticothalamic networks (Steriade et al., this meeting). Here we report the temporal and spatial relations of fast (generally 20 to 40 Hz) and slow (<1 Hz) activities. Data resulted from multisite extracellular and field potential recordings in cortical and related thalamic foci, in cats implanted chronically or anesthetized with ketamine and xylazine. Fast oscillations were present throughout activated patterns (waking and REM sleep, or after stimulating midbrain activating systems), and were related to the depolarizing phase of the slow (<1 Hz) sleep oscillation. Simultaneous recordings at different depths in the same cortical column showed high, in-phase synchrony between fast activities at all levels, from most superficial to deep cortical layers. In contrast, the depolarizing and hyperpolarizing components of the slow (<1 Hz) sleep oscillation were annulled at, and reversed below, a depth of  $\approx 300$   $\mu$ m. This suggests a uniform vertical distribution of fast oscillating pools of neurons, and a massive cortical sink of the slow oscillation below 300  $\mu$ m. The negative waves composing the fast oscillations were crowned by action potentials throughout the cortical depths. In some instances, however, in a circumscribed deep cortical region, around 0.8 mm, negative field potentials of fast oscillations, overridden by action potentials, showed phase opposition with related surface activities. The horizontal, intracortical synchrony was conversely affected by the distance and the observation time. The coherence of fast rhythms was almost abolished at distances exceeding 5 mm, while the coherence of the slow oscillation extended over the whole cortical surface. Spontaneous fast activities may remain synchronous beyond 5 mm, if only short epochs (<1 s) are observed. This led us to the development of an analysis paradigm that discloses the dynamic evolution of synchronized processes.

Supported by MRC grant MT-3689 and FRSQ.

## 372.3

## FAST (20-40 HZ) SPONTANEOUS OSCILLATIONS ARE SYNCHRONOUS IN CORTICOTHALAMIC NETWORKS DURING BRAIN-ACTIVATED EPOCHS. M. Steriade\*, E. Amzica and D. Contreras. Lab. Neurophysiol., Laval Univ., Sch. Med., Quebec, Canada G1K 7P4.

We present experimental evidence that, in contrast to the widely used term of "EEG desynchronization" defining arousal and REM sleep, fast activities are coherent within intracortical and corticothalamic networks. Extracellular and intracellular activities were recorded, together with local field potentials, from multiple sites in sensory, motor and association neocortical areas and related thalamic nuclei of cats under ketamine & xylazine anesthesia as well as in chronically implanted, unanesthetized cats. The electrographic patterns of quiet sleep in behaving animals were similar to those during anesthesia. Natural arousal or EEG activation elicited by stimulation of mesopontine cholinergic nuclei were associated with the blockade of sleep oscillations (<15 Hz) and the occurrence of fast rhythms (generally 20 to 40 Hz) whose coherency among various cortical foci or between simultaneously recorded cortical and thalamic sites was assessed by means of cross-correlation analyses. The strength of corticothalamic synchronization depended on the presence of direct reciprocal projections between cortical and thalamic recorded sites, as identified by conventional physiological procedures. The synchronized fast activities were also observed during sleep patterns; however, they were selectively suppressed during the prolonged, rhythmic, simultaneous hyperpolarizations of cortical, thalamic reticular and thalamocortical neurons. This aspect contrasted with the sustained fast rhythms during brain-activated states when all these neuronal types were depolarized. These results on spontaneously occurring, state- and voltage-dependent fast rhythms, challenge the notion that fast rhythms are contingent on optimal sensory stimuli and are exclusively generated intracortically. Our data also indicate that "EEG desynchronization" is an obsolete term, since fast spontaneous activities are synchronized within corticothalamic circuits.

Supported by MRC grant MT-3689, FRSQ and Savoy Foundation.

## 372.4

## THALAMOCORTICAL FOS EXPRESSION AND BEHAVIOURAL ACTIVATION: MODULATION BY CATECHOLAMINE DEPLETION. M. Bubser\*, M. G. P. Feenstra, E. B. H. W. Erdtsieck-Ernste, M. H. A. Botterblom, H. F. M. Van Uum. Graduate School Neurosciences Amsterdam, Netherlands Institute for Brain Research, 1105 AZ Amsterdam, The Netherlands.

The medial prefrontal cortex (PFC) is characterized by converging input from thalamic and dopaminergic afferents. We used the transsynaptic expression of the immediate early gene c-fos (measured as Fos-like immunoreactivity [Fos-LI]) and behavioural parameters to analyze the interaction of these afferent systems in freely moving rats. To this aim we compared the effects of activating the thalamocortical pathway in intact rats and in rats with 6-hydroxydopamine (6-OHDA) lesion of the right ventral tegmental area. A dialysis probe that was implanted into the mediadorsal thalamus was perfused with the GABA-A antagonist bicuculline (20 min, 0.03 or 0.1 mM) which induced Fos-LI in the mediadorsal and more pronounced in the midline thalamic nuclei. In the PFC the transsynaptic expression of Fos-LI was dose-dependently increased both in controls and in 6-OHDA-lesioned rats which had a unilateral reduction of dopamine (-70%) and noradrenaline (-80%) in the PFC and of dopamine in the dorsal and ventral striatum (-90%). In lesioned rats perfused with 0.1 mM bicuculline the amount of Fos-LI was increased when compared to correspondingly treated controls. Bicuculline perfusion also induced a dose-dependent behavioural activation consisting of stationary (0.03 mM) or ambulatory (0.1 mM) activity that was not modified by 6-OHDA lesion. These findings confirm that forebrain catecholamines exert an inhibitory control over thalamocortical functions and they indicate that the interaction of prefrontal afferent systems can be shown *in vivo* at the level of immediate early gene expression.

Supported by the Van den Houten Foundation.

## 372.5

COLUMNAR AND LAMINAR TRANSMISSION OF THE ACTIVITY IN THE MONKEY PREFRONTAL CORTEX REVEALED BY OPTICAL IMAGING IN VITRO. K. Nakamura<sup>1</sup> and T. Sawaguchi<sup>1,2</sup>. <sup>1</sup>Department of Behavioral and Brain Sciences, Primate Research Institute, Kyoto University, Inuyama, Aichi 484, Japan. <sup>2</sup>PRESTO, Research Development Corporation of Japan.

To examine local transmission of the activity in the prefrontal cortex (PFC) of primates, we examined the spread of neuronal activity followed by an electrical stimulation in slice preparations of the monkey PFC, using an optical recording technique. Slices (400  $\mu$ m) were prepared from the principal sulcal region (area 46) of the PFC and were stained with an absorptive voltage-sensitive dye, RH482 (0.1 mg/ml). The electrical stimulation (single pulse, 0.3 ms in duration, usually 200  $\mu$ A) was applied at various layers and neuronal excitation was optically recorded using a 128 x 128 photodiode array covering an area of 4 x 4 mm (Fuji Film Microdevice, SD1001). We found that excitation of neurons spread in a columnar fashion from the stimulated site to the surface and bottom of the cortex when the site was at middle layers (layers III and IV). The width of the column increased as the current intensity of stimulation was increased (40-300  $\mu$ A) but it was saturated at  $\sim$ 600  $\mu$ m when the current intensity exceeded a certain level (i.e.,  $>160$   $\mu$ A). The stimulation at different sites usually activated different columns, and there appeared to be discrete, perpendicular boundaries between columns. When stimulated sites were close in horizontal distance ( $<0.3$  mm), almost the same area was activated. Further, the spread of the activity differed in direction and range by the stimulation at different layers. The stimulation at deep layers (V and VI) activated deep layers, that at middle layers (III and IV) activated all layers, and that at upper layers (II and III) activated upper and middle layers. The activation disappeared when an antagonist of excitatory amino acid, CNQX (40  $\mu$ M), was applied on the slice preparation. These findings suggest that the PFC of monkeys consists of relatively distinct functional columns formed by excitatory connections and the activity transmits lamina within the columns.

## 372.7

OSCILLATORY AUTO-STIMULATION OF THALAMIC NEURONS IN VITRO, USING FICTIVE RECURRENT INHIBITION (FRIN) REVEALS A NEW TYPE OF INTRINSIC PLASTICITY. R. Llinás and R. Rall<sup>\*</sup>. Dept. Physiology & Neuroscience, New York University Medical Center, 550 First Avenue, New York, New York 10016.

The electrophysiology of thalamic relay neurons was investigated using *in vitro* guinea pig brain slices. The bridge amplifier was modified such that a thalamic neuron action potential would trigger an inhibitory feedback current injection resembling the amplitudes and time courses of GABA<sub>A</sub> and GABA<sub>B</sub> IPSPs. Single action potentials in the recorded neurons were used to trigger the fictive recurrent inhibitory current pulse (FRIC). Such transient return feedback did not trigger rebound responses sufficiently robust to ensure oscillatory firing at all membrane potentials and for all fictive IPSP durations and amplitudes. At membrane potentials negative to the resting level, the auto-stimulating frequencies could be from as low as 0.5 Hz to near 2 Hz. As the duration of the inhibitory current was reduced, the frequencies for any given resting potential increased until the cell was incapable of supporting an oscillatory event. In tabulating the frequencies of oscillation as a function of FRIC amplitude, time course, and cell resting potential, it became clear that some frequencies are favored by these neurons. These are the ultra-low 0.5 Hz, and 2 Hz, 4 Hz, 10 Hz and 40 Hz. These oscillatory frequencies correspond quite nicely to those seen in thalamic neurons in other preparations and under other recording conditions. Surprisingly, certain frequencies, when entrained for a short time, resulted in subthreshold oscillations which persisted after the stimulation was discontinued. This occurred particularly at high frequencies (35 to 55 Hz) where driven oscillations lasting on the order of 5 seconds could produce continuing oscillations for up to 4 to 6 seconds. This 40 Hz oscillation may be important for thalamocortical re-entry pathway function. Indeed, the issues of a computational optimization believed to be implemented by thalamocortical resonance and its possible relation to sensory binding would be greatly facilitated by such intrinsic plasticity. ## 372.9

SUSTAINED ATTENTION AND HABITUATION: A COMBINED PET AND EEG STUDY. T. Paus<sup>\*</sup>, R.J. Zatorre, J. Gotman, Z. Caramanos, M. Petrides, A.C. Evans. Montreal Neurological Institute, McGill University, Montreal H3A 2B4, Canada.

This study investigated changes in rCBF and EEG during the performance of an auditory sustained-attention test. Eight healthy male volunteers listened for 60 min to 1-sec tones randomly varying in intensity (ISI:2 sec; total number:1200). The subjects' task was to detect a 5-dB decrement occurring during the last 100 ms of the tone (target probability: 0.05). With the <sup>15</sup>O-H<sub>2</sub>O bolus technique, six 60-sec CBF scans were obtained at 1, 10, 20, 30, 40, and 50 min from the start of the test. EEG was recorded concurrently. Time-trend analysis of the normalized CBF data revealed highly significant time-dependent (across scans) CBF decreases in the thalamus. In addition, CBF decreases were observed in the prefrontal, secondary-auditory, and parietal cortex of the right hemisphere. On the other hand, time-dependent CBF increases were found in the fusiform gyrus bilaterally. Time analysis of the EEG spectrum showed subtle but significant increase in the theta and decrease in the gamma relative amplitude. There was also highly significant reduction of blood flow in the temporalis muscle bilaterally. No significant decline in the number of the detected targets was observed. We conclude that the above pattern of CBF and EEG changes is due to (1) habituation of the neural response to the repeated auditory stimulation, (2) an associated shift from an alert to a relaxed state, and (3) changes in a cognitive network related to auditory attention.

## 372.6

CURRENT SOURCE DENSITY ANALYSIS OF NEOCORTICAL SLEEP SPINDLES, SPIKE-AND-WAVE EPILEPSY, DELTA, AND GAMMA WAVES IN THE FREELY MOVING RAT. A. Kandel<sup>\*</sup> and G. Buzsáki. CMBN, Rutgers University, Newark, N.J. 07102.

Thalamocortical neuronal oscillations underlay various field potential patterns that are expressed in the neocortex. Many of these patterns are thought to be initiated in the thalamus and/or in discrete regions within the neocortex. The thalamus is known to be the initiator of various neocortical patterns (e.g. sleep spindles and high voltage spike-and-wave spindles (HVS)) and is believed to be involved in other patterns as well (e.g. delta waves, slow waves, and 40 Hz oscillations (gamma)). In this study a 16-site silicone probe (100  $\mu$ m site intervals) was fixed to a moveable platform and implanted medial to the barrel cortex. Animals were able to move freely and field potentials and extracellular unit recordings were obtained simultaneously during sleep spindles, HVS, delta, and gamma wave EEG activity patterns. Current source density (CSD) analysis of the spike component of HVS and sleep spindles indicated sinks in the dorsal most aspect of layer IV, which corresponds to the location of major inputs from thalamic relay cells. Another possible current sink was in layer I/II with corresponding sources in layers I and III, where non-specific thalamocortical efferents diffusely synapse. CSD for delta and gamma waves suggests that they have current sink-source pairs located in layers I/II/III, as well as in layers V/VI, the major neocortical pyramidal cell layers. Extracellular units fired preferentially with the spike components of sleep spindles and HVS in each electrode. The results of this study support previous hypotheses regarding thalamic relay inputs to layer IV as the site of origin of sleep spindles and HVS in the neocortex but also postulates the involvement of layers I/II. These results suggest that specific and non-specific thalamic relay cells are differentially involved in various thalamocortical oscillation patterns.

## 372.8

ANTICIPATORY HEAD-DIRECTION CELLS IN THE ANTERIOR THALAMUS OF THE RAT. H.T. Blair<sup>\*</sup> & P.E. Sharp. Dept. of Psychology, Yale University, New Haven, CT 06520-8205

A head-direction cell fires action potentials only when a rat's head is facing in a specific, preferred direction with respect to the static surrounding environment. Head-direction cells have been observed in several regions of the rat brain, including postsubicular cortex (PSC) (Ranck, 1984, *Soc Neurosci Abstr*), and the anterodorsal nucleus (ADN) of the thalamus (Taube, 1995, *J Neurosci*). Here, we recorded head-direction cells from PSC and ADN of freely-moving rats. Neural activity was analyzed in relation to both head direction and angular head velocity. We found that 17 of 19 cells in PSC maintained the same preferred firing direction, regardless of the angular head velocity. By contrast, 15 of 21 cells in ADN shifted their directional preference systematically to the left during clockwise head turns, and to the right during counterclockwise head turns, by an amount proportional to the angular speed of head turning. This firing pattern suggests that ADN cells were anticipating that the head would face a specific direction in the near future. By contrast, the behavior of PSC cells suggests that they fired only when the head was presently facing a specific direction. Supporting this conclusion, it was found that ADN cells had their best directional tuning function in relation to the rat's future head direction (at a future time displacement of about 40 msec), whereas PSC cells had their best tuning function in relation to the rat's present head direction.

PSC and ADN are reciprocally connected to form a thalamocortical circuit (van Groen & Wyss, 1990, *Brain Research*). Since PSC contains both head-direction cells and neurons that encode the angular velocity of the head (Sharp, in press), ADN cells might be able to anticipate the future head direction by combining information about the present head direction, and the angular motion of the head. The anticipatory head-direction signal from ADN might then be sent back to PSC, where it could be used in computing the rat's present head direction.

SIGNAL TRANSDUCTION AND NEURAL ASSOCIATION IN NEURONAL DISORDERS: FUNCTIONAL IMAGING BY POSITRON EMISSION TOMOGRAPHY. T. Kusuki, Y. Imahori<sup>\*</sup>, Y. Ohmori, and S. Ueda. Dept. of Neurosurgery, Kyoto Prefectural University of Med.

To determine the associating function of neuronal domains in human brain, we obtained signal transduction imaging by positron emission tomography and evaluated these images with neural disorders. In normal neuronal action, C-11 labeled diacylglycerol (DAG) was incorporated into phosphoinositide selectively by DAG kinase and sequential phosphorylation enzymes, and the membrane bound radioactivity reflected its activity.

In the normal resting cerebrum (n=7), lateralization of heteromodal association areas was noted in each domain, and this tendency was more notable in the right brain. In patients with thalamic pain (n=2), high activity was observed in putamen and thalamus in the affected side, rather than frontal association area. And the treatment by extradural electric stimulation to the affected side of the motor area removed the pain and raised bilateral prefrontal activity of phosphatidylinositol (PI) turnover. After analgesic stimulation, suppression effect was observed in the respective area for the long time. In contrast, dysinhibition was observed in the contralateral side. In patients with Parkinson's disease (n=4), potentiation of thalamus in the lesioned side was observed, and exercise loading of flexion caused suppression of the thalamic activity through GABA from putamen. In patients with cerebral ischemic disease (subcortical infarction, n=6), the signalling activity was kept in normal range in the domain of the respective cortex. After the therapy using mAChR-agonist for the long period, signalling activity of the corresponded cortex was activated, in other words, the associating domain was increased.

According to these results, it was showed that associating function is always rebuilded in cerebral association area and each domains. And it was also showed that long-term potentiation (LTP) and long-term depression (LTD), with PI turnover and protein kinase C, were highly concerned in the rebuilding of the association.

## 372.11

CEREBRAL CORTICAL AREAS INVOLVED IN A GO/NO-GO VISUAL DISCRIMINATION TASK REVEALED BY PET IMAGING IN MONKEYS. K. Kubota, I. Ando, T. Sawaguchi\*, A. Mikami, K. Nakamura, K. Sawaguchi, Watanabe, E. Yoshikawa, T. Kakiuchi, and H. Tsukada. Central Research Laboratory, Hamamatsu Photonics K.K., Shizuoka 434; Dept. of Behavioral & Brain Sciences, Primate Res. Inst., Kyoto Univ., Aichi 484, Japan.

To examine which cerebral cortical areas are involved in the conditional selection between execution or inhibition of forelimb movement, regional cerebral blood flow (rCBF) was measured with  $^{15}\text{O}$ -labeled  $\text{H}_2\text{O}$  positron emission tomography (PET) in two rhesus monkeys that performed a GO/NO-GO visual discrimination task with wrist movement. The task was initiated by the monkeys pressing a hold lever by their right hands and consisted of a warning period of 1-3 s (a white square on a CRT), a cue period of 0.5 s (a yellow or blue square), a response period (a red square), and a final reward period. The monkeys were to release the lever within 0.8 s after the onset of the response period when the preceding cue was blue (GO) or continue to hold the lever for 1.8 s when the preceding cue was yellow (NO-GO). rCBF was measured for 2 min using a PET scan associated with each of the following conditions: the GO/NO-GO, GO, and NO-GO conditions (SHR-2400, Hamamatsu Photonics, 2.7 mm in-plane resolution). The rCBF measurements were performed repeatedly during the three conditions, and the rCBF findings in each condition were compared using a subtraction method to detect brain regions with rCBF increases specific to the GO/NO-GO condition. The PET images were superimposed onto the MR images that were fitted to Nissl-stained sections to obtain anatomical information. Significant increases in rCBF associated with the GO/NO-GO condition were found bilaterally in the prefrontal cortex (areas 46 and 8), dorsal and ventral premotor cortices (area 6), parietal cortex (area 7), temporal cortex (TE), cingulate cortex (areas 23 and 24), and peri-hippocampal regions. Among them, the prefrontal and premotor cortices appeared to be the most activated during the GO/NO-GO condition. Thus, the prefrontal-premotor system may recruit mnemonic and sensory information from other cortical areas to make the conditional selection between execution or inhibition of forelimb movement.

## 372.13

ISLAND BIOGEOGRAPHY IN CEREBRAL CORTEX: Shaping Up New Cerebral Codes in Functional Archipelagos. WILLIAM H. CALVIN\*, Univ. of Washington, Seattle 98195-1800.

While a darwinian process has six essential features (a pattern that copies with variants which compete for a limited workspace biased by a multifaceted environment, with this selective survival to reproductive maturity skewing the next generation's variants), another half-dozen features affect the speed (or stuck-in-a-rut stability) of evolutionary processes. We are all familiar with what the French call *l'esprit d'escalier*, thinking of the right response only after leaving the party. If plans of quality are to be shaped up within the situational "windows of opportunity," some accelerating and equilibrium-escaping features may prove essential for mental versions of a darwinian process.

A well-known feature of island biogeography is relative speed, as in the differentiation of Darwin's finches unbuffered by large continental gene pools. When rising sea level converted part of the European coastline into an island (Jersey), the red deer trapped there underwent a rapid dwarfing in only 10,000 years. A second accelerating feature of islands is that a species can go extinct locally. This creates an "empty niche" which, when rediscovered, provides enough resources for even the rarer variants of the species for awhile. Should disease or climate change then shrink this boomtime population, some of those rarer variants may prove to have the right combination of features to survive the bottleneck and repopulate the island. Archipelagos allow for many parallel experiments. Episodes that recombine the islands (as when sea level temporarily lowers) create winner-take-most tournaments.

Triangular mosaics of synchronized cortical neurons not only provide the six essentials but form temporary "islands" with finchlike variant patterns; changes in cortical excitability may play a parcellation-then-tournament role similar to sea level in speeding the evolution of novel cerebral codes. (See W. H. Calvin, *Soc. Neurosci. Abstr.* 1992-94, and *Scientific American* 10/94).

## 372.12

MAGNETIC FIELD RESPONSES IN PARIETAL ASSOCIATION CORTEX TO VISUAL STIMULATION IN SPACE.

S. Murakami\*, S. Kuriki, J. M. Fujii, R. Fukatsu and N. Takahata.

Dep. of Neuropsychiatry, School of Medicine, Sapporo Medical University, Sapporo 060 Japan and 1) Res. Institute of Electronic Science, Hokkaido University, Sapporo 060 Japan

It was much reported that the parietal association cortex (PAC) was related to the function of visuo-spatial cognition. In human, the neural mechanism of the PAC was not revealed because it was difficult to record the neural responses noninvasively. However, we reported the magnetic field responses to visual stimulation in PAC (*Neurosci. Res.* 16 (1993):225). In this study, we investigated the magnetic field responses to visual stimuli in PAC for the purpose to reveal the neural function of visuo-spatial cognition in space. The subjects were 5 healthy adults and in a magnetically shielded room. The magnetic field responses to visual stimuli were recorded by a 37-channel SQUID magnetometer system (BTi). The LEDs lined at 3 degree interval at horizon, vertical and depth were used for the gazing (for eye position) and for the stimulating (for retinal stimuli), which located at 50 cm away from the eye. The combination of the gazing and the stimulating LEDs was #1 stimulated retinal position change in horizon at the same eye position, #2 stimulated retinal position change in vertical and depth at the same eye position and #3 eye position change in orbit under stimulating the same retinal position. Magnetic field responses were observed at 90-120 (M120), 120-170 (M170) and 180-220 (M220) msec latency after stimulating LED onset. The magnetic field responses of M170, which were observed in all subjects, were almost stable under stimulating the same retinal position at various eye position of #3 experiment but were change under stimulating the various retinal position at the same eye position of #1 and 2. The estimated current dipole sources of these magnetic field responses of M170 of #1, 2 and 3 located at the deep area of PAC, along the intraparietal sulcus. These results suggest that the retinotopic topography was main in PAC.

DISRUPTION OF DECREMENTAL ATTENTIONAL PROCESSING BY SELECTIVE REMOVAL OF HIPPOCAMPAL CHOLINERGIC INPUT. M. G. Baxter\*<sup>1</sup>, M. Gallagher<sup>1,2</sup>, and P. C. Holland<sup>3</sup>. <sup>1</sup>Curriculum in Neurobiology and <sup>2</sup>Department of Psychology, Univ. North Carolina, Chapel Hill, NC, 27599; <sup>3</sup>Department of Psychology: Experimental, Duke Univ., Durham, NC 27708.

Recent studies with the selective cholinergic immunotoxin 192 IgG-saporin have indicated that lesions of the medial septal area (MSA) which selectively remove cholinergic innervation of the hippocampus do not disrupt spatial learning, unlike less selective lesions of the MSA or lesions of the hippocampus itself. The hippocampal formation is also involved in decremental attentional processing; studies from our laboratories have demonstrated that hippocampal lesions disrupt decremental attentional processing of conditioned stimuli in Pavlovian conditioning paradigms (Han, Gallagher, and Holland, submitted). We sought to determine if 192 IgG-saporin lesions of the MSA would mimic the effects of hippocampal lesions on decremental attentional processing. Male Long-Evans rats received microinjections of either 192 IgG-saporin (LES) or vehicle (CON) into the MSA. Each rat was tested in a latent inhibition paradigm in which one of two conditioned stimuli (CSs) was preexposed in the absence of reward, followed by a conditioning phase in which both CSs were (independently) paired with a food reward. The percent of conditioned responses during CS presentation in the conditioning phase was determined for both the preexposed and novel CSs. CON rats showed less conditioned responding to the preexposed CS than to the novel CS (latent inhibition), indicating that decremental attentional processing of the preexposed CS had occurred. MSA-LES rats showed equal degrees of conditioned responding to the preexposed and novel CSs, indicating that decremental processing of the preexposed CS did not occur. Studies are currently in progress to determine the effects of these lesions in a conditioning paradigm that produces both incremental and decremental processing of conditioned stimuli. ## 373.2

C-FOS INDUCTION DURING AN INCREMENTAL CHANGE IN ATTENTION. D. J. Bucci\*<sup>1</sup>, A. A. Chiba<sup>2</sup>, P. C. Holland<sup>3</sup>, and M. Gallagher<sup>1,2</sup>. <sup>1</sup>Curriculum in Neurobiology and <sup>2</sup>Dept. of Psychology, University of North Carolina, Chapel Hill, NC 27599 and <sup>3</sup>Dept. of Psychology: Experimental, Duke University, Durham, NC 27708.

Induction of the immediate-early gene, *c-fos*, was monitored during an incremental change in attention within an associative learning paradigm. Male Long-Evans rats were trained in a procedure developed by Wilson et al. (1992), in which attention is manipulated when a consistent predictive relation between two cues is shifted to a less predictive relationship. In the first conditioning phase, all rats were exposed to serial conditioning trials in which a light-then-tone sequence was followed by food half of the time (light→tone→food and light→tone trials). Rats in the "consistent" condition continued to receive these trials during the second phase of conditioning. In a second set of rats, those in the "shift" condition, the tone was omitted on non-reinforced trials, altering the predictive accuracy of the light and thereby increasing attention to that stimulus. Attention to the light was assessed during the third phase of conditioning, in which the light was paired directly with food. Increased attention to the light was evidenced by more rapid light-food conditioning in the shift-group relative to the consistent-group. The induction of *c-fos* was determined immunocytochemically in six animals from each training condition after one session of Phase 2 training, when the predictability of the light was initially altered in the shift condition but not the consistent condition. More Fos-like-immunostaining was evident in several cortical regions of rats in the shift-group as compared to those in the consistent-group. These regions were associated with the basal forebrain corticopetal system, and included both frontal and parietal cortex, and the substantia innominata. Comparable levels of Fos-like-immunostaining were observed for both groups in other areas, including the hippocampus and ventral tegmental area. ## 373.3

ALTERED SELECTIVE ATTENTION IN RATS WITH CHOLINERGIC LESIONS OF THE SUBSTANTIA INNOMINATA. A.A. Chiba<sup>1</sup>, P.J. Bushnell<sup>2</sup>, W.M. Oshiro<sup>2</sup>, and M. Gallagher<sup>1</sup>. <sup>1</sup>Department of Psychology, University of North Carolina, Chapel Hill NC 27599. <sup>2</sup>Neurotoxicology Division, US EPA, Research Triangle Park, NC 27711.

Current research has implicated a role for the basal forebrain cholinergic system in the modulation of attention on a variety of behavioral tasks in rats, monkeys, and humans. A spatial orienting task, modeled after Posner's covert orienting paradigm, was used to investigate the allocation of attention to a visual target in rats with selective cholinergic lesions of the substantia innominata (SI) or intact control rats. A given trial of the spatial orienting task required each rat to press a lever in response to the illumination of one of two visual targets in order to obtain a food reward. The targets were located on opposite sides of a test chamber and 70% of targets were preceded by a visual cue (a flash of light contiguous with a target location). On a given trial, the cue either accurately predicted the location of the target (valid cue) or appeared in the location opposite to that of the target (invalid cue). Target detection was facilitated by valid cues and degraded by invalid cues. Following pretraining on this task, eight of the rats received selective lesions of the cholinergic neurons in the SI by local infusion of 192 IgG-saporin and nine of the rats served as surgical controls. On trials in which a target was preceded either by a valid cue or by no cue, performance of SI-lesioned rats was equivalent to that of intact control rats. However, on trials in which a target was preceded by an invalid cue, SI-lesioned rats displayed reduced accuracy and prolonged latency to respond to a target, relative to intact control rats. These data support the hypothesis that the basal forebrain cholinergic system plays a modulatory role in mediating selective attention. ## 373.5

DOUBLY DISSOCIABLE EFFECTS OF SELECTIVE MEDIAN RAPHE AND DORSAL RAPHE LESIONS ON VISUAL ATTENTION. A.A. Harrison, B.J. Everitt and T.W. Robbins. (SPON: EUROPEAN NEUROSCIENCE ASSOCIATION) Dept. of Experimental Psychology, University of Cambridge, Cambridge, UK

We have previously reported that global forebrain 5-HT depletion resulted in enhanced probability of responding and reduced latencies to respond correctly without affecting discriminative accuracy as measured by a 5-choice serial reaction time task. The current set of experiments assessed the behavioural effects of selective median raphe and dorsal raphe lesions on the same behavioural task.

Rats were trained to detect brief flashes of light presented randomly in a spatial array of five apertures with food reinforcement. When performance stabilised (>80% correct, <20% omissions) animals received infusions of either 5,7 dihydroxytryptamine or vehicle solution to either the median or dorsal raphe. The lesions induced different patterns of 5-HT depletion primarily in the hippocampus and striatal areas respectively.

Median raphe lesions produced a transient increase in premature responding and a more robust reduction of the latency to collect the reward. These results are suggestive of enhanced motivation in these animals.

Lesions of the dorsal raphe, however, induced a similar but not identical pattern of behaviour to that observed following global forebrain 5-HT depletion. Enhanced probability of responding as indexed by both increased premature responding and reduced numbers of omitted trials resulted from 5-HT depletion in striatal areas. Dorsal raphe lesioned animals also transiently exhibited superior accuracy of detection of the visual stimuli on baseline task parameters, compared to control.

The results indicate that the two ascending 5-HT systems mediate different behaviour on this task and that impulsive responding observed following global forebrain 5-HT depletion is primarily mediated by dorsal raphe 5-HT transmission.

## 373.4

OVERT ORIENTING IN THE RAT: EFFECTS OF UNILATERAL LESIONS OF BASAL FOREBRAIN CHOLINERGIC NEURONS ON SELECTIVE ATTENTION. P.J. Bushnell<sup>1</sup>, A.A. Chiba<sup>2</sup>, W.M. Oshiro<sup>1</sup>, and M. Gallagher<sup>2,3</sup>. <sup>1</sup>Neurotoxicology Division, US EPA, Research Triangle Park, NC 27711. <sup>2</sup>Department of Psychology, University of North Carolina, Chapel Hill NC 27599.

Detection of a peripheral visual target by rats can be modulated by a visual or auditory cue presented prior to the target stimulus. Detection is facilitated by (valid) cues spatially contiguous with the target and degraded by (invalid) cues in the contralateral visual field. Rats (n=6) were trained to press either of two targets (backlit pigeon keys: PKs) for food reward. Rats initiated each trial with a press on a central food cup door; 500 msec later, a cue (a 400 msec flash of light) was presented 10, 150, 450 or 900 msec before the target. Cues occurred on 70% of the trials; 70% of the cues were valid and 30% invalid. Effects of cues were quantified in relation to responses on no-cue trials. After training, each rat received a unilateral infusion of the immunotoxin 192 IgG-saporin into the substantia innominata (SI). Two kinds of changes in target detection were observed after the lesion. First, responses to targets in the visual field contralateral to the lesion were faster and less accurate than those to targets in the ipsilateral field, particularly with short (<1 sec) targets. Second, there was a tendency for invalid cues to reduce accuracy more for contralateral targets than for ipsilateral targets. Thus unilateral lesion of the cholinergic neurons in the SI degraded detection of visual targets in the contralateral visual hemifield, particularly when cues were presented in the ipsilateral hemifield (i.e., when targets in the contralateral hemifield were invalidly cued). These results support research indicating that the cholinergic projections from the basal forebrain to the cortex play a role in mediating selective attention to visual targets. <sup>3</sup>Supported in part by a Human Frontiers in Science Award and a Research Scientist Award (K05-MH01149). <sup>4</sup>Supported in part by an NRSA (F32-MH1099).

## 373.6

UNILATERAL EXCITOTOXIC LESION OF THE NUCLEUS BASALIS OF MEYNERT INDUCES CONTRALATERAL NEGLECT IN THE RAT. B. Lannes, T. Humby and T.W. Robbins (SPON: European Neuroscience Association). Department of Experimental Psychology, University of Cambridge, U.K. CB2 3EB.

Previous work in this laboratory has provided evidence for a role of the cholinergic nucleus basalis of Meynert (NBM) in attentional processes. As the NBM sends projections in particular towards cortical regions implicated in neglect, such as the posterior parietal cortex and the prefrontal cortex, we investigated whether unilateral lesions of the NBM could induce a neglect syndrome in the rat.

Rats were trained in a task in which they have to sustain a nose poke in a centre hole for one of 4 variable foreperiods. At the end of each foreperiod, a stimulus appeared in either of 2 locations on one side or the other. After the stimulus appeared, the rats were required to report its presence by responding at a panel at the rear of the chamber for food reward. When rats had reached a criterion of 70% correct over at least 3 consecutive sessions, unilateral NBM lesions were performed using the excitotoxin AMPA (0.01M). The lesions were performed against the preferred eye as determined, where possible, from the baseline performance. When tested after 2 weeks of recovery, the NBM lesioned rats displayed neglect contralateral to the lesion, exhibited as a slowing of reaction or response time to contralateral stimuli. The magnitude of the deficit depended upon the baseline degree of side dominance. Results will be discussed in the context of theories of neglect and the role of ascending cholinergic projections in attentional function.

## 374.1

A FUNCTIONAL MAGNETIC RESONANCE STUDY OF SELECTIVE AND DIVIDED ATTENTION DURING VISUAL DISCRIMINATIONS OF SHAPE, SPEED AND COLOR. G. Bush, B. Rosen, J. Belliveau, J. Reppas, S.L. Rauch, D. Kennedy, J. Sutton, R. Tootell. NMR Center, Massachusetts General Hospital-East, CNY-9, Charlestown, MA 02129.

Attention is the cognitive mechanism by which humans select which of a myriad of sensory stimuli to process at any given moment. We used functional magnetic resonance imaging (fMRI) to examine the modulatory effects of selective and divided attention on regional cerebral activation during a visual discrimination task.

Four normal human subjects were scanned while engaged in the visual task developed for a similar PET study by Corbetta et al. (J. of Neuroscience, 1991, 11, 2383-2402). The subject's task was to indicate by button-press if two frames of computer-generated small bars were the same or different with respect to the cued attribute. At the start of a block, subjects were cued to attend either only to subtle (threshold) changes in shape, speed, or color (selective attention), or to changes in any parameter (divided attention). A passive-viewing/random button press block was used as a control. All subjects were scanned on two separate occasions to evaluate test-retest reliability. Three of the subjects also were scanned in a third session to directly identify extrastriate regions activated by visual, smooth pursuit, saccade, motion detection and object-recognition tasks.

Activation patterns were qualitatively similar to those of the aforementioned PET study, i.e. we found analogous discrete regions in extrastriate visual cortex which were activated by each of the selective attention conditions, and confirmed activation of right dorsolateral prefrontal and anterior cingulate cortex in the divided attention condition. While intrasubject test-retest reliability was strong, there was wide intersubject variability in activation patterns.

Selective and divided attention modulated neuronal activity in extrastriate and extravisual regions. The data support a top-down enhancing modulation theory of attention. Advantages of using fMRI included the ability to examine issues of test-retest reliability and intersubject variability, and to directly compare regions characterized by tests of visual function.

## 374.2

ARE THE SAME ATTENTIONAL MECHANISMS USED FOR TARGETS DEFINED BY COLOR, ORIENTATION, AND MOTION? M. Girelli and S.J. Luck. Department of Psychology, University of Iowa, Iowa City, IA, 52242-1407.

Previous studies have shown that the N2pc component of the event-related potential (ERP) waveform reflects an attentional filtering process that operates during color and form discrimination, and the present study sought to determine if this same attentional process is used for targets defined by motion. We recorded ERPs from young adults in a visual search paradigm using stimulus arrays composed of either 8 vertical green bars moving in a downward direction (homogeneous arrays) or 7 of these bars and 1 bar that differed in its color, orientation, or direction of motion (pop-out arrays). One of the three pop-out types was the target for a given trial block, and the homogeneous arrays and other pop-out types served as nontargets. A robust N2pc component was observed for all three target dimensions, indicating that the same neural attentional systems are used across dimensions. In addition, we found that motion pop-outs elicited an N2pc component even when another feature was the target, whereas color and orientation pop-outs elicited an N2pc only when they were targets. This result suggests that motion pop-outs might automatically attract attention, even when they are not task-relevant. Together, these results indicate that: a) information from the parvo and magno streams converges before the stage of attentional filtering indexed by the N2pc component; and b) stimuli within the magno stream may attract attention more automatically than stimuli within the parvo stream.

## 374.3

THE EFFECTS OF DORSOLATERAL PREFRONTAL LESIONS ON VISUAL SEARCH. D.L. Woods\* and K.H. Ogawa, Dept. of Neurology and Neurosciences Center, UC Davis, Northern California System of Clinics, Martinez, CA 94553.

Dorsolateral prefrontal (DLPF) cortex is thought to play a key role in the control of visuospatial attention. In the current experiments, we compared performance of patients with DLPF lesions and age-matched control subjects in visual search tasks. Rectangular bars were presented in equiluminant displays of 4, 9 or 16 elements varying randomly in color (green, red, or yellow) and orientation (right-diagonal, horizontal, and vertical). In different conditions, subjects detected targets defined by Color, Orientation, or by the Conjunction of color and orientation features. Search rates were similar for DLPF patients and controls in single feature conditions. However, in Conjunction conditions DLPF lesions impaired (1) the detection of targets at peripheral display positions; and (2) the discrimination of targets from distractors of target color. These results suggest that the DLPF lesions narrow the focus of attention in both spatial and feature domains.

Supported by NS32893 and the VA Research Service.

## 374.5

A POSITRON EMISSION TOMOGRAPHY (PET) STUDY OF ATTENTION TO AUDITORY STIMULI. M.L. Kesler\*, D.S. O'Leary, R.R. Hurtig, and N.C. Andreasen, Mental Health Clinical Research Center, Dept. of Psychiatry, University of Iowa College of Medicine, Iowa City, Iowa 52242.

A correlational analysis approach was used to relate attention-associated changes in superior temporal gyrus (STG) blood flow to changes in blood flow in other brain regions. Regional Cerebral Blood Flow (rCBF) was measured with PET in 16 right-handed control subjects using eight bolus injections of  $^{15}\text{O}$ -labelled water. Cognitive activation tasks involved the detection of a target during the binaural or dichotic presentation of different types of auditory stimuli, and allowed examination of directing attention to the left or right ear. The baseline task involved monitoring for an infrequent tone. Dorsolateral frontal, inferior parietal, and STG regions of interest (ROIs) were drawn on magnetic resonance (MR) images, followed by individual registration of the MR scans with the PET scans. Using BRAINS software, average rCBF in each ROI was calculated for each of the eight PET conditions per subject. Spearman partial correlations (controlling for whole brain flow) were computed for pairs of regions across subjects. For these 16 subjects, there was a significant correlation between left STG flow and right inferior parietal flow during the attend-left condition ( $r=0.75$ ,  $p<.01$ ), as well as during the attend-right condition ( $r=0.93$ ,  $p<.01$ ). No such correlation was significant for the baseline condition. This suggests that the left STG - right inferior parietal coupling might be involved in selective attention or complex target detection. Alternately, this association may be the result of complex auditory stimulus processing, which was not required in the baseline task.

## 374.7

MULTIMODAL AND UNIMODAL SENSORY INTEGRATION IN HUMANS: BEHAVIORAL AND ERP EVIDENCE. D. Costin\*, H.J. Neville, A.M. Meredith, B.E. Stein, UCSD Cog Sci, La Jolla, Ca, \*Med Col of VA, \*Bowman Gray Sch Med, Wake Forest Univ, Winston Salem, NC.

In our previous studies ERPs elicited by multimodal stimuli (auditory and visual) displayed components not observed during the presentation of each unimodal stimulus alone: coincident multimodal stimuli elicited new patterns of activation when compared to ERPs elicited by stimulation with the separate unimodal components, or when compared to the addition of the separate unimodal responses. Moreover, the effects of spatial disparity on these additional ERP components were similar to those observed in single-cell responses of multimodal cells in the cat superior colliculus and polysensory cortex (anterior ectosylvian sulcus). Behavioral measures in both cats and humans have also shown similar effects of coincidence and disparity, providing further evidence that similar organizing principles may govern multimodal stimulus processing across species and levels of analysis.

In this study we compared ERP components elicited by multimodal stimuli with those elicited by multiple different stimuli within the same modality in order to distinguish activation patterns linked to multimodal processing from those that may be indices of general integration processes. Multiple unimodal stimuli consisted of concurrent presentations of red and green lights or noise and tone sounds at the same location. Multimodal stimuli consisted of one light and one sound at the same location.

Overlap in the ERP activity elicited by multiple unimodal stimuli and multimodal stimuli may index activity linked to modality-independent integration processes. Patterns of activation elicited by multimodal stimuli that are distinct from those elicited by multiple unimodal stimuli may provide evidence for distinct multimodal integration processes. These ERP indices will allow further characterization of multisensory integration processes. (McDonnell-Pew Grad, DC 00128, NS 22543)

## 374.4

COMMON AREAS OF PARIETAL ACTIVATION FOR SHIFTS OF SPATIAL ATTENTION AND TASKS INVOLVING THE CONJUNCTION OF VISUAL FEATURES. D.L. Hutton, M. Corbetta, G.L. Shulman, F.M. Miezin, and S.E. Petersen\*, Washington Univ. Sch. of Med., Box 8111, St. Louis, MO 63110.

Theories of visual search postulate that tasks showing an increase in search functions involve either a serial analysis of objects in the field or a spatially parallel system that has reduced efficiency with an increase in the number of items analyzed. We have previously reported that areas in the superior parietal lobule (SPL) are active when attention is shifted across different visual locations. We used PET to determine whether SPL is differentially active during feature vs. conjunction tasks in two experiments.

In expt 1, subjects saw a display consisting of four square windows containing moving colored dots. In the color task, subjects searched for the presence of red-orange dots, in the motion task for the presence of fast moving dots, and in the conjunction task, for the combination of red-orange fast moving dots. Behaviorally only the conjunction task produced search times increasing with display size. In expt 2, subjects saw a similar display containing four differently colored rectangles. They searched for targets defined either by color, or the combination of a color and orientation. In both experiments, more activity was apparent in SPL for conjunction than for feature tasks. Coordinates obtained from the previous study on spatial attention were tested on the present data sets for replication. SPL was consistently more active in the conjunction than feature tasks, with one locus on the right ( $x,y,z=21,-61,50$ ) showing significant differences between conditions in both experiments. This correspondence provides functional anatomical evidence that increasing search functions can involve shifts of spatial attention, and supports serial models for visual search.

## 374.6

A FRONTO-PARIETAL NETWORK FOR RAPID VISUAL INFORMATION PROCESSING: A PET STUDY OF SUSTAINED ATTENTION AND WORKING MEMORY. J.I. Coull\*, C.D. Frith and P. Grasby, Wellcome Dept. of Cognitive Neurology, MRC Cyclotron Unit, Hammersmith Hospital, DuCane Road, London W12 0NN, UK.

The Rapid Visual Information Processing (RVIP) task is a test of sustained attention, which also requires working memory (WM) for its successful execution. It is known to be sensitive to manipulations of the cholinergic and noradrenergic neurotransmitter systems, both of which have been widely implicated in the modulation of attention. Previous neuroimaging studies have implicated the frontal and parietal cortices in performance of simple sustained attention tasks. However, the neuroanatomical substrates of RVIP performance are not yet known. Therefore, this study investigated the functional anatomy of the RVIP task using Positron Emission Tomography (PET) derived measures of rCBF in 6 healthy volunteers. Subjects were required to perform variants of the RVIP task which manipulated the level of WM load and the speed of stimulus presentation. Changes of rCBF induced by these cognitive challenges were compared to that produced by a control and a rest condition. Comparison of all RVIP tests to the control condition produced increases in rCBF in the right inferior frontal cortex/precentral gyrus, the right inferior parietal cortex, and the lateral occipital cortex bilaterally. Conversely, significant decreases in rCBF were observed in the cingulate gyrus, Sylvian sulcus bilaterally, and the left middle temporal gyrus. A specific comparison of fast versus slow rates of stimulus presentation produced additional increases in rCBF in the lateral occipital cortex. These results support a fronto-parietal network for sustained attention, and provide the basis for investigating the neuroanatomical correlates of the noradrenergic modulation of attention.

## 374.8

DIFFERENTIAL EFFECTS OF SPATIAL AND EXPECTANCY CUES ON COVERT SHIFTS OF ATTENTION. D.R. Gitelman\*, S. Weintraub, Z.M. Gruijic, J.R. Meyer, A.M. Farina, E.J. Russell, M.M. Mesulam, Center for Behavioral & Cognitive Neurology, Northwestern University, Chicago, IL 60611

The focus of visual attention can be shifted covertly, i.e. without shifting visual fixation, permitting study of spatial attention without eye movements. Mechanisms that control covert attentional shifts include peripheral cues to prime spatial locations for targets, and central cues to generate directional expectancy for target appearance. We investigated the effects of cue type on reaction times (RTs), in two patients with right hemisphere strokes and their matched controls.

Eye movements were monitored via an infrared reflection system. We found that: 1) Valid expectancy cues (central arrow pointing towards subsequent target site) generated faster RTs than valid spatial cues (change in luminance at site of subsequent target) in all subjects. 2) In one patient with a right fronto-parietal-cingulate lesion, RTs were 25% slower towards the left vs. right for valid expectancy cues, but only 8% slower towards the left for valid spatial cues. 3) In a second patient with a right frontal-parietal but not cingulate lesion, the opposite pattern was obtained. RTs were 32% slower towards the left for valid spatial cues vs. 11% slower towards the left for valid expectancy cues. 4) Invalid expectancy cues (central arrow pointing opposite to subsequent target site) produced 72% slower leftward RTs in the first patient, but only 20% slower RTs to the left in the second patient.

These results indicate that peripheral space-priming cues and central expectancy-generating cues influence covert shifts of spatial attention through potentially different mechanisms. Attentional shifts in response to expectancy cues may be particularly vulnerable to lesions in cingulate cortex as part of a proposed distributed network for spatial attention.

## 374.9

MULTIMODAL HEMISPATIAL EXPLORATORY-MOTOR NEGLECT FOLLOWING DAMAGE TO THE BASAL GANGLIA. Z.M. Gruić\*, D.R. Gitelman, S. Weintraub, J.R. Meyer, A.M. Farina, E.J. Russell, M.-M. Mesulam, Center For Behavioral & Cognitive Neurology, Northwestern Univ. Sch. of Med., Chicago, IL 60611.

The substrate of spatial attention takes the form of a distributed network with interconnected cortical (frontal, parietal, cingulate) and subcortical (striatal, and thalamic) components. We had predicted that damage affecting the frontal component of this network (or the striatum with which it is interconnected) would cause a predominantly exploratory-motor neglect whereas injury to the parietal component would cause a predominantly sensory-representational neglect.

A stroke patient with a right subcortical lesion was studied with computerized paradigms designed to selectively probe the exploratory and representational components of neglect. The lesion involved the caudate nucleus, the internal capsule, and the ventrolateral nucleus of the thalamus.

There was no auditory, visual, or tactile extinction. No disengagement asymmetry was seen during covert shifts of attention, but reaction times were 15% slower to left valid cues, suggesting the existence of a mild left hemispatial deficit in the sensory-representational component of spatial attention. Exploratory-motor deficits in the left hemisphere were much more prominent. On a blindfolded manual exploration task (using the unaffected right hand) the patient omitted 30% of the targets on the left (compared to 10% of the targets on the right), and touched 18 targets in the left field compared to 33 targets in the right. On a target detection task requiring visual search she was 34% slower in the left space than in the right, although simple lateral eye movements were symmetrical and normal. Our results show that there can be a dissociation between behavioral components of neglect, and that exploratory-motor neglect can have multimodal manifestations that involve manual as well as oculomotor exploration.

## 374.11

VISUAL ATTENTION INDUCED BOTTOM UP AND TOP DOWN SIGNAL MODULATION IN FMRI. W. Chen<sup>1</sup>, S. Ogawa<sup>2</sup>, P. Mitra<sup>2</sup>, X. Hu<sup>1</sup> and K. Ugurbil<sup>1</sup>. <sup>1</sup> Univ. of Minnesota Med. School, Minneapolis, MN 55455 and <sup>2</sup> AT&T Bell Laboratories, Murray Hill, NJ 07974

Using fMRI (echo planar multi slice imaging at 4T) of the human brain, we studied feed-forward and feed-backward effects on the signal activation associated with visual attention. Colored box patterns on a screen were presented to a subject during the measurement. He was instructed to pay attention to a cue to a box pattern flickering at the center of the screen (1x2 degrees in the visual field) and count the event where a pair of patterns (200 msec on and 200 msec apart and the pair appeared at every sec.) had the same color. The periods (45 sec each) of attention and non-attention were alternately repeated 3 times in an experiment. During the period of not paying attention to the visual pattern, the subject kept fixating at a cross at the center of the screen but listened to the sound generated by the field gradient during the imaging. With paradigm I where the screen presentation was always on, there was not appreciable modulation due to the attention-non attention task performance at the forvia area of V1. Although the task did not involve spatial information in any special way, activation patterns associated with the visual attention was observed at areas 7, 39, 40 in the parietal area in 6 subjects among 8 tested. A typical activation time course of a site at area 39 is shown in Fig. 1.

With paradigm II, where attention and no attention periods were separated by a dark (no screen display) period, sustained activation in the V1 area during each task period was larger with attention than without. With the same display as in paradigm II but without attention, such signal modulation due to attention was not observed in V1 area nor parietal area. This work done at U. of MN was supported by NIH grant RB08079.

## 374.13

EVENT-RELATED POTENTIAL (ERP) CORRELATES OF UNEXPECTED JUMPS OF A CONTINUOUSLY MOVING AUDITORY STIMULUS

Wolfgang Teder<sup>1</sup>\*, István Winkler<sup>2</sup>, Risto Näätänen<sup>3</sup>. <sup>1</sup>Dept. of Neurosciences, Univ. of California, San Diego, La Jolla, CA 92093-0608, USA. <sup>2</sup>Institute for Psychology, Hungarian Academy of Sciences, H-1394 Budapest, P.O. Box 398, Szondi u. 83/85, Hungary. <sup>3</sup>Cognitive Psychophysiology, Dept. of Psychology, P.O. Box 11 (Ritarikatu 5), FIN-00014 University of Helsinki, Finland.

Multichannel ERPs were recorded from human subjects participating in an auditory free-field experiment. A total of nine equally spaced loudspeakers were arranged to form a semi-circle of an arc of about 120°, facing the subject at a distance of about 1.2 m. The typical stimulus sequence consisted of brief broadband noise bursts shifted through consecutive spatial locations from left to right and vice versa, thereby producing the illusion of a train passing. Occasionally, the perceived moving stimulus would violate the pattern and skip two spatial locations instead of moving continuously onwards as expected. Control sequences presented the same stimuli in other patterns that did not create expectancies for continuous movement.

The ERP elicited by the stimuli marking the violation of the sequential ordering showed a distinct waveform, as compared to the ERP elicited by the same spatial location in one of the control conditions. ERPs to violations were more negatively displaced at a latency of about 130 ms and showed a broad frontocentral scalp distribution. The results are discussed in terms of a mismatch-type brain process that is elicited in a broad range of situations where expectancies are violated.

## 374.10

DISSOCIATION OF OVERT FROM COVERT SHIFTS OF SPATIAL ATTENTION IN PATIENTS WITH FOCAL LESIONS OF THE RIGHT HEMISPHERE. S. Weintraub\*, D.R. Gitelman, Z.M. Gruić, A.M. Farina, M.-M. Mesulam, Center for Behavioral and Cognitive Neurology, Northwestern University Medical School, Chicago IL 60611

The focus of visuospatial attention can shift through overt changes in the line of gaze or through covert shifts that do not involve eye movements. Studies in two patients with supranuclear ophthalmoplegia (Rafal et al, 1988) suggested that the two mechanisms may be linked in patients with brainstem disease but the generality of this phenomenon has not been investigated systematically in patients with other types of lesions.

Reaction times to peripheral targets were measured in 3 right hemisphere stroke patients and in 9 control subjects with paradigms that elicited overt or covert shifts of attention. In the covert shift paradigms, subjects maintained central fixation and gave a rapid response to left- or right-sided targets that were preceded by a preparatory cue which was either a peripheral change of luminance or a central directional arrow. Control subjects did not show significant left-right asymmetries of reaction time in either type of task. In two patients with right hemisphere lesions and clinical left hemispatial neglect, reaction times were significantly prolonged to validly cued targets in the left side in covert attentional shifting paradigms whereas no asymmetry was detected in the overt attentional paradigm. In one patient without hemispatial neglect, a right hemisphere lesion caused a slight prolongation of leftward overt attentional shifts but no asymmetry in covert attention shifts. These initial observations in patients with hemispheric lesions suggest that the mechanisms for shifting spatial attention covertly can be dissociated from mechanisms for shifting the line of gaze and focus of attention through overt eye movements.

## 374.12

ERP MEASURES OF AUTOMATIC ATTENTIONAL ORIENTING. J.B. Hopfinger, G.R. Mangun\*. University of California at Davis, Department of Psychology & Center for Neuroscience, Davis, CA 95616.

Attentional cueing studies have shown that at short cue-to-target intervals, a non-predictive peripheral cue appearing at the location of a subsequent target (valid trial) facilitates response times to the target. At longer cue-to-target intervals, however, responses are actually slower for valid as compared to invalid targets (i.e., Inhibition of Return - IOR). The mechanisms which underlie these effects remain unresolved. In this experiment, we used ERPs elicited by valid and invalid targets to investigate the mechanisms underlying the facilitation and inhibition seen in peripheral cueing tasks.

A left or right field peripheral cue (offset and onset of four marker dots) preceded each target (a "tall" or "short" bar), but did not predict target location. The cue preceded the target at either a short (68-268 msec) or long (600-800 msec) cue-to-target interval (i.e., SOA). ERPs recorded over occipital scalp sites showed differential modulations of early, sensory-evoked components, as a function of cue validity and SOA condition. In the short SOA condition, validly cued targets showed an enhanced amplitude P1 component (110-130 msec) relative to invalidly cued targets. However, in the long SOA condition, the P1 to validly cued targets was reduced in comparison to the invalidly cued targets. These data suggest a possible facilitation of early visual processing at the cued location immediately following a peripheral cue, which is replaced later in time by a relative inhibition at this same location. Such a pattern implies that reaction time patterns obtained in similar peripheral cueing studies may be the result of spatial attention effects on early visual processing.

## 374.14

SEQUENTIAL CHANGES IN AUDITORY EVOKED POTENTIALS DURING TARGET DETECTION IN HUMANS. A. Starr\*, T. Aguinaldo and H. J. Michalewski. Department of Neurology, University of California, Irvine, California 92717-4290.

The amplitude of potentials evoked by non-target signals change in an orderly manner as a function of their position relative to the target. The negative components, N100 and a pre-stimulus negativity (Readiness Potential, RP) are markedly attenuated to non-targets immediately following the target, and then regain their amplitudes to subsequent non-targets in an exponential manner for N100 and a linear manner for the RP. In contrast, the amplitude of the positive potentials (P50 and P200) increase immediately following the target but are of normal amplitude thereafter. The effects of instruction ("press to targets" or "count targets") influenced these sequential amplitude changes on component amplitudes for the negative but not the positive potential changes. Thus, there are dynamic changes in both traditional sensory and in Readiness Potentials to stimuli that follow a detected target.

## 374.15

EYE BLINK RATE AS A PRACTICAL PREDICTOR FOR VIGILANCE. S. R. Quartz\*, M. Stensmo, S. Makeig<sup>1</sup> and T. J. Sejnowski. Howard Hughes Medical Institute, The Salk Institute, 10010 North Torrey Pines Road, La Jolla, CA 92037. U.S.A. <sup>1</sup>Naval Health Research Center, P.O. Box 85122, San Diego, CA 92186, U.S.A.

Performance on signal detection tasks depends on a subject's state of alertness. We are developing methods to automatically assess the state of alertness of human subjects using electrooculogram (EOG) signals. Eye movements were monitored on human subjects in 28-minute sessions during which they responded to randomly-occurring targets (rate 10/min) consisting of barely audible noise-bursts. The responses were used to compute a local error rate (percent of recognized targets during the past minute). Ten subjects performed two or more experiments on different days. The vertical EOG (VEOG) signal was analyzed to extract eye closure and opening events, which were also translated into per minute rates. In an initial study only eye closure events were used. This simple measure of alertness nonetheless showed good correlation over the entire sessions to local error rate (max. -0.85). Further analysis of the VEOG showed that error rate was also correlated with amplitude and blink rate (where a blink is defined as an eye closure followed by an opening within 1 second). We trained a nonlinear neural network predictor on the first experiment session, and tested it by prediction of the local error rate from blink events on the second session, for six subjects with meaningful blink rate/performance correlations in both sessions. We were able to predict the local error rate of the subjects with an average accuracy of  $0.176 \pm 0.03$  s.d. root-mean-square error. This was not significantly different from the accuracy of estimates based on spectral data from two channels of the electroencephalogram (EEG),  $0.156 \pm 0.05$  s.d. Psychophysical experiments from other laboratories support our findings. However, our study is, so far as we know, the first in which eye blink data were used to predict as well as analyze error rates. A measure based on eye blinks, and also perhaps eye movements, could be used in a practical device to monitor the alertness of, e.g., sonar operators, truck drivers or air-traffic controllers.

## 374.17

COGNITIVE INHIBITION OF OBJECT VERSUS LOCATION IN YOUNG AND OLD ADULTS. P.M. Simone\*, Department of Psychology, Santa Clara University, Santa Clara, CA 95053

Selective attention involves activation of a target and inhibition of any distractors. Some evidence suggests that older adults are not as able as young adults to inhibit distractors. Connelly & Hasher (1993) found that this cognitive inhibition can be associated with the distractor object OR its location. Additionally, older adults are impaired only when required to inhibit the object, and not the location of the distractor.

This study explored young (18-22) and older adults' (55-74) ability to inhibit the object or location of distracting information. Negative priming trials were presented in prime and probe pairs. Stimuli were 9 colored squares. A target and distractor were presented for 150 msec. After a 500 msec delay subjects were presented with 4 colored squares and were to press the target as quickly as possible. A similar probe trial began 500 msec later. The probe target was either the same color as the prime distractor but in a new location, a new color located in the same position as the prime distractor, or the two were unrelated. Sustained inhibition was measured in the probe trial.

As predicted, older adults did not inhibit the distractor object but did show effects of sustained inhibition when required to inhibit the location of the distractor. Young adults also showed a differential pattern of responding when the distractor object or location was inhibited. These results suggest that separate mechanisms exist for the inhibition of an object and the inhibition of a location.

## 374.19

ATTENTIONAL ORIENTING ALTERED BY NICOTINE FROM TOBACCO SMOKE. E.A. Witte\*, J.T. McCracken, and J. Wilkins, Psychiatry Department, University of California, Los Angeles, CA 90024.

Attentional orienting, as measured by performance in a cued covert target detection task has been shown to be affected by alterations in nicotinic cholinergic transmission<sup>1,2</sup>; the difference in reaction times between validly and invalidly cued trials (validity effect) was reduced by nicotine administration. While these studies have established a preliminary link between facilitation of nicotinic cholinergic neurotransmission and altered attentional orienting, they did not examine the dose-response relationship between these variables.

To this end, we examined the relationship between salivary nicotine levels and measures of attentional orienting, alerting, and overall response times in five smokers and five nonsmoker controls. Smokers were tested after an overnight abstinence from smoking, and then one, two, three, five, and seven hours after beginning *ad libitum* smoking on that day. Nonsmoker controls were tested at the same intervals. At each session, a saliva sample was collected for later analysis for nicotine levels (ng/ml).

The results of this study show a clear relationship between nicotine levels and the validity effect. No apparent relationship was observed between nicotine levels and the alerting effect (difference in reaction times between non-cued trials and double-cue trials), as would be predicted by previous research<sup>1,2</sup>.

This study provides important support for a direct role of the nicotinic cholinergic system in mediating attentional orienting. However, increases in nicotine levels did not affect the alerting measures.

## 374.16

CNV IS AFFECTED BY UNILATERAL FRONTAL EXCISION IN HUMANS. C. Verkindt, M. Robert and F. Richer\*. Labo. Neuroscience Cognition, Université du Québec, Montréal, QC, H3C-3P8.

We examined the hypothesis of a frontal lobe involvement in the generation of the contingent negative variation by recording slow potentials in frontal lobectomy patients performing delayed conditional response tasks. nine patients who had undergone a unilateral frontal excision for the relief of epilepsy were compared to 9 temporal lobectomy patients and 9 age-matched controls. Subjects were tested on two tasks involving speeded responses to a visual stimulus (S2) which followed another visual stimulus after a 4-sec delay. One task required a two-alternative color discrimination at S1 and delaying response until S2, whereas the second task involved the color discrimination at S2 and a neutral stimulus as S1. Response times (but not error or omission rates) were increased in both patient groups compared to controls. Compared to the other two groups, 6 frontals showed a large attenuation of both the early and the late portion of the slow potential in the S1-S2 delay. The three other frontal patients presented a normal early CNV. One of them exhibited a moderate attenuation of the late portion of this potential while the two others did not. The young age of these subjects at operation (12-16 years old), suggests that some plasticity effect may contribute to the reduced lesion effects in these frontal patients. Although all the frontal lesions were unilateral, no lateralization of the potential attenuation was observed. This absence of asymmetry in frontal lesion effect was previously found on attentional waves (Knight et al. 1981). The present results may indicate that the integrity of both frontal lobes is necessary to preserve some neural mechanisms leading to the generation of the CNV.

## 374.18

THE EFFECT OF DISTRACTORS ON VISUALLY GUIDED REACHING BY PATIENTS WITH HEMISPATIAL VISUAL NEGLECT

L.L. Baylis, Dept. Psychology, Presbyterian College, Clinton, SC 29325, G.C. Baylis\*, Dept. Psychology, University of South Carolina, Columbia, SC 29208, and R.D. Rafal, Dept. Neurobiology, U. C. Davis, Davis, CA 95616.

Patients suffering from left hemispatial visual neglect following damage to the right parietal lobe were tested on a visually guided reaching task. In this task, nine locations (in a 3 x 3 array) could be illuminated red (target items) or green (distractor items).

Consistent with the observed neglect, reaction times to reach to targets located to the patients left were elevated compared to central or right targets.

In addition, it was found that the location of irrelevant distractor items could affect reaction times to reach to targets. So, for target items located directly in front of the patient, reaction times were elevated when distractors were located to the right of them, but were reduced when distractors were located to their left.

These results suggest that both relevant (target) and irrelevant (distractor) information are used preattentively to demarcate visual space. Neglect represents a failure to allocate attention within this parsed visual space.

## 375.1

**DENTATE GYRUS GLYCOGEN METABOLISM IS INVERSELY CORRELATED WITH EEG THETA ACTIVITY.** A. Uecker\*, G. Rao, C.A. Barnes, B.L. McNaughton and E. Reiman. ARL Division of Neural Systems, Memory and Aging, Univ. of Arizona, Tucson, AZ 85724 and Samaritan Pet Center, Good Samaritan Regional Medical Center, Phoenix, AZ 85006.

Glycogen phosphorylase a (GP<sub>a</sub>), an enzyme marker of neuronal activity, has been used to study behaviorally-related metabolism in the hippocampus (Wallace, 1982; Harley & O'Keefe, 1986) and other brain regions. GP<sub>a</sub> activity is least in the molecular layer of the dentate gyrus in exploring animals and greatest in anesthetized animals (Uecker et al., 1993), and is also systematically reduced by different levels of restraint (exploration < manual restraint < towel restraint < anesthetization; Uecker et al., 1994). Thus, GP<sub>a</sub> activity appears to be inversely correlated with behaviors associated with the theta rhythm. We addressed this question directly in nine 6 month old Long-Evans female rats with electrodes implanted in the region of the hippocampal fissure. During 10 behavioral sessions, 5 minute recordings were made of hippocampal EEG during exploration, manual restraint, towel restraint, and rest. Power in the theta frequency (6-10 Hz) exhibited a significant decline in amplitude across these conditions. Molecular layer glycogen metabolism increased across behavioral conditions (as observed previously) and was inversely correlated with the theta rhythm ( $r = -.50$ ). Although it is known that hippocampal CA1 pyramidal cells are more active during rest than during exploration (Thompson & Best, 1989; Ranck, 1973), Foster et al. (1989) found that CA1 CS cells became almost completely silent during towel restraint. If this effect occurs also in the granule cells it would suggest that it is the theta rhythm or factors associated with it, rather than cell discharge *per se* that regulates the metabolic rate in the dentate gyrus granule cells. Supported by the Flinn Foundation and MH01227.

## 375.3

**IDENTIFICATION OF IEGs DIFFERENTIALLY REGULATED BY LTP-INDUCING STIMULI IN YOUNG AND OLD RATS.** B. Pierchala, A. Lanahan, G. Lyford, P.F. Worley, G.S. Stevenson\* and C.A. Barnes. Depts Neurosci & Neurol Johns Hopkins Univ, Baltimore, MD 21205 and Depts Psych & Neurol and ARL Division NSMA, Univ Arizona, Tucson, AZ 85724.

Several lines of evidence suggest that activity-dependent mechanisms are altered with aging and that these mechanisms may contribute to age-dependent memory decline. For example, the durability of LTP in the hippocampus is reduced in aged rats and this deficit is associated with impaired performance on hippocampal-dependent spatial learning tasks. Because the initial induction of LTP appears normal in aged rats, attention is focused on the cellular mechanisms underlying long-term plasticity. In previous studies, we have used differential cloning techniques to identify genes that are rapidly induced by physiological synaptic activity and by stimuli that induce LTP in the hippocampus. We now use these same techniques to identify rapid response genes that are differentially induced following LTP in young versus aged rats. Dentate gyri were microdissected and used to prepare radiolabeled cDNA. Panels of candidate genes were then probed using the reverse Northern strategy. Most of the known IEGs are similarly regulated in young and old animals, however a small set of genes have been identified that appear to be differentially regulated. We are presently working to determine whether this pattern of results holds in larger populations of young and old rats. It is anticipated that an understanding of this gene regulation will lead to identification of signaling pathways that are functionally altered with aging. Additionally, our previous work indicates that many of these rapid response genes play a direct role in modification of signaling capacity of neurons. Thus, identification of these genes should provide insights into the cellular basis of age-dependent changes in synaptic plasticity. Supported by AG09219 and MH01227.

## 375.5

**HIPPOCAMPAL THETA AND THE SPATIAL FIRING OF DENTATE GYRUS GRANULE CELLS.** W.E. Skaggs\*, J.J. Knierim and B.L. McNaughton. ARL Division NSMA, Univ. of Arizona, Tucson, AZ 85724.

Two recent findings warrant a re-examination of the relations between the theta rhythm and firing of dentate gyrus granule cells. First, granule cells are not, as once thought, high-rate "theta cells", but rather low-rate cells with highly specific place fields (Jung and McNaughton, 1993); second, a robust interaction exists between place-related firing of complex spike cells in CA1 and theta phase (phase precession, O'Keefe and Recce, 1993; Skaggs et al., submitted). Phase precession implies that different cells are active at the beginning and end of the theta cycle. If this occurs in one area, it is likely to induce differences in downstream areas. Therefore, a simple strategy for locating the source of the precession is to backtrack upstream from CA1 until an area is found that does not show precession. We have used parallel recording techniques to record simultaneously from granule cells and CA1 CS cells in rats running for food reward on a narrow track. CA1 CS cells fire their first spikes, as the rat enters a place field, near the end of the theta cycle, and bursts of spikes gradually precess to the beginning of the theta cycle as the rat passes through the place field. Granule cell spatial firing also shows clear phase precession, but their first spikes, as the rat enters a place field, appear approximately 90 degrees earlier in the theta cycle than would be the case for a CA1 cell; also, unlike CA1 cells, granule cells are virtually silent during approximately the last quarter of the theta cycle. Thus, the phase of peak population activity for granule cells is advanced about 90 degrees from that of CA1 cells. Furthermore, in two rats in which the fascia dentata was lesioned by multiple injections of colchicine, phase precession could still be seen in some CA1 complex spike cells. Pending verification of lesions, this suggests that phase precession may originate prior to the fascia dentata, possibly in the entorhinal cortex. Supported by MH46823 and NS09052.

## 375.2

**BEHAVIORAL CORRELATES OF RAT PREFRONTAL CORTICAL UNITS DURING SPATIAL WORKING MEMORY TASKS.** M.W. Jung\*, Y.-L. Qin, B.L. McNaughton and C.A. Barnes. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Single units were recorded with "tetrodes" in regions of the prefrontal cortex, including those which are targets of hippocampal afferents, while rats were performing an 8-arm radial maze, spatial working memory task or a figure-8 maze, delayed spatial alternation task. Virtually no place-specific firing was observed on the 8-arm maze among approximately 200 recorded units, except to the extent that different spatial locations were related to distinct phases of the task. A small, but significant number of cells exhibited spatially biased firing on the figure-8 maze. Also, few units showed continuous neural activities that might mediate working memory of spatial locations. The units had diverse behavioral correlates that were generally associated with different stages of the task, such as intertrial intervals, onset or end of trials, selection of arms on the 8-arm maze, delay periods, approach to or departure from goals, and selection of paths on the figure-8 maze. Some units were essentially silent during the tasks while others were active but had no discernible task-related behavioral correlate. Among the units that were recorded in both tasks, the majority showed no obvious relationship between behavioral correlates in the two tasks. These results, while preliminary, are consistent with previous behavioral studies that suggest a prefrontal cortical role in encoding "rules" (i.e., structural features) of a task but not in encoding allocentric spatial information or memory. Given that the hippocampal projection to this region is capable of undergoing LTP (Laroche et al., 1990), our data lead to the hypothesis that the role of this projection is not to impose spatial representations upon prefrontal activity, but to provide a mechanism for learning the spatial context in which particular behaviors are appropriate. Supported by the McDonnell-Pew Foundation and MH01227.

## 375.4

**PRESERVED LTP INDUCTION IN CA1 OF AGED F-344 RATS.** G. Rao\*, J. Shen, C.A. Barnes and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

With supramaximal, high-frequency stimulation, no differences in magnitude of LTP induction have been observed between young and old animals in either CA1 or the fascia dentata; however, using weak stimulation both Deupree et al. (91) and Moore et al. (93) did observe a reduction in LTP induction in CA1, suggesting a deficit when more "physiological" stimulation is employed. We have previously shown a reduction in evoked, population AMPAR and NMDAR EPSPs in aged F-344 rats but no change in unitary EPSPs or apparent quantal sizes. This suggests that CA1 may undergo a loss of synapses in aging with no change in the receptor content of individual synapses, and possibly no differences in the intrinsic capability of individual synapses to express LTP. Under this interpretation, the apparent age effect would be a consequence of activation of fewer synapses, and consequently less effective postsynaptic depolarization. To test this, we paired weak orthodromic stimulation with postsynaptic depolarization via direct, intracellular current injection, in order to bypass the possible variable level of presynaptic activation with electrical stimulation. The evoked EPSP (stimulating electrode in s. radiatum) was paired with an ascending series of intracellular depolarizing current pulses (100 msec, 0 to 4 nA, 2 nA steps). LTP was not different across age groups (% increase in EPSP slope: young =  $35.6 \pm 3.6$ ; adult =  $37.9 \pm 4.21$ ; old =  $36.6 \pm 4.25$ ). A replication of Moore et al. (n=11 rats, 9 mos; n=11, 23-28 mos) confirmed reduced LTP in old rats when using primed burst stimulation (% increase in EPSP slope: adult =  $24.7 \pm 2.9$ ; old =  $13.4 \pm 2.1$ ). This deficit in LTP induction may arise from insufficient depolarization by orthodromic stimulation, perhaps as a result of synapse sparsity, and appears not to reflect an intrinsic age difference in LTP induction mechanisms. Supported by AG03376 and MH01227.

**DIFFERENTIAL EFFECTS OF DENTATE GYRUS LESIONS ON PYRAMIDAL CELL FIRING IN 1- AND 2-DIMENSIONAL SPATIAL TASKS.** J.J. Knierim\* and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Destruction of the dentate gyrus with colchicine leaves place-specific firing on an 8-arm maze relatively intact (McNaughton et al., 1989). In the present experiments, similarly lesioned rats were trained to forage for food in a gray cylinder (76 cm diam., 51 cm high) with a single white cue card (Muller et al., 1987). After training, CA1 and/or CA3 pyramidal cells were recorded over 4-6 days. Few cells displayed normal spatial selectivity. Some fired strongly in a ring at the edge of the cylinder, whereas others fired weakly in fuzzy "doughnut" or "crescent" shaped regions of the cylinder. In contrast, when the rats were subsequently trained to run back and forth on a linear track, with a moveable goal box at one end and a stationary goal location at the other, many cells displayed normal behavioral/spatial correlates (see Gothard, Skaggs, and McNaughton, this session). The same cells showed little selectivity when the rats foraged in the cylinder or on an open circular platform. It thus appears that in a task in which directional behavior was highly constrained, CA1/CA3 cells did not require an intact dentate gyrus in order to express normal selective activity. In a two-dimensional apparatus, in which directional behavior was less stereotyped and unconstrained, pyramidal cells apparently had access to information about distance to the edge of the cylinder/platform, but were unable to use the available heading information. These results remain preliminary pending histological verification of the lesion, but they nonetheless provide clear evidence of a differential effect of damage to the hippocampal system on place cell firing in tasks that provide different sources of heading information. Supported by NS09052 and HFSP.

## 375.7

**INTERACTIONS BETWEEN MULTIPLE SPATIAL REFERENCE FRAMES IN THE RAT HIPPOCAMPUS.** K.M. Gothard\*, W.E. Skaggs and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Hippocampal CA1 cells were recorded from five rats, trained to run on a 1.5 m rail between a fixed food cup at one end (goal) and a sliding box containing a food cup at the other. On each trial, the rats ran from the box to the goal, and then back to the box, which, in the meantime, was moved to a different position. Each trial started at one of five equally spaced box locations and ended at another. Two main classes of cells were observed: (1) cells that fired in relation to the moveable box (box-inward and box-outward cells) and (2) cells that fired in relation to the goal and/or the global spatial reference frame (place cells), indicating that both the goal and the box defined discrete reference frames. Most cells were unidirectional in their firing, regardless of which reference frame they were bound to. The firing of cells bound to one reference frame appeared to occlude the firing of cells bound to the other. In all rats, box-outward cells, which fired in the immediate vicinity of the box, were unaffected by the location of the box, whereas those that fired at greater distances from the box showed a systematic shift and shrinkage of firing field as a function of the proximity of the box to the goal. These cells may either represent position as a fixed fraction of the distance between start and the goal, or else encode the distance from the most recently visited reference point, modulated by the proximity of the goal. These results suggest that in this behavioral context, (a) hippocampal cells represent position in multiple reference frames (the fixed frame of the goal, the moving frame of the box and a fractional frame between box and goal), (b) only one reference frame is active at a time, and (c) a given reference frame is associated reliably across rats with the same part of the task. Supported by ONR.

## 375.9

**RECENT EXPERIENCE STRENGTHENS PRE-EXISTING CORRELATIONS BETWEEN HIPPOCAMPAL NEURONS DURING SLEEP.** H.S. Kudrimoti\*, B.L. McNaughton, C.A. Barnes and W.E. Skaggs. ARL Division NSMA, University of Arizona, Tucson, AZ 85724.

During slow-wave sleep, patterns of correlated neuronal firing that occurred during the preceding behavior are reactivated in rat hippocampus (Wilson and McNaughton, 1994). We confirmed and extended this result in 22 of 24 recording sessions from 3 rats in which 60-90 CA1 CS cells were recorded per session. Correlations between all cell-pairs were computed during awake behavior, and during 20-60 min sleep episodes recorded before and after each behavior session, as  $\text{Cov}(x,y)/\sigma_x\sigma_y$ ,  $x$  and  $y$  being the firing rate vectors (100 ms bins) of any two cells in the sample. Correlations between cells that were strongly correlated during behavior (reflected in overlap of their fields) were significantly higher in the sleep period following maze running than a) correlations between the same cell-pairs in the preceding sleep session, or b) correlations between cells that were active but uncorrelated during behavior. The correlation increases returned to baseline in about 1 hr. Also, when two separate environments were visited sequentially, the effects of the earlier of the two experiences were still evident in the subsequent sleep, suggesting that not much decay occurs during waking. Firing rates did not change significantly during sleep following the experience; however cells that had place fields on the apparatus had substantially higher rates during sleep both before and after the behavior. There was a significant linear relationship between the correlations between cell-pairs during behavior and the corresponding correlations during prior sleep, even in cases in which the subsequent behavior was in a novel apparatus. This suggests that the probability that two cells will have overlapping place fields in any given environment is partly a function of a preexisting synaptic weight distribution. Support: MH46823 and MH01227.

## 375.11

**MATCHING PURSUIT ANALYSIS ENABLES TEMPORAL-LOCALIZATION OF FREQUENCY/PHASE PATTERNS OF HIPPOCAMPAL EEG AND THEIR RELATIONS TO THE NEURONAL STATE VECTOR DURING SLEEP.** B. Shen, B.L. McNaughton and C.A. Barnes\*. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

EEG signals embed a wide range of patterns over the time-frequency domain. Linear expansions in a single complete basis, (e.g., Fourier, wavelet), can provide accurate characterization in either the time or frequency domain, but not in both simultaneously. Matching pursuit analysis (Mallat and Zhang, 1993) provides a decomposition of signals into components that are simultaneously localized in both time and frequency. The output of this analysis, which can be appreciated visually in 3-D Wigner plots of relative energy in both frequency and time, can provide a powerful basis for automated EEG analysis, for example, the characterization of transitions between hippocampal theta and LIA.

During REM sleep, theta oscillations in the hippocampal EEG were decomposed into relatively discrete segments of different dominant frequencies and phases. We examined the dynamics of a population of 54 simultaneously recorded CA1 pyramidal cells during these frequency/phase transitions. Firing rates were binned in 100 ms intervals and the state vector correlation matrix was constructed. As shown previously (Moore et al., Soc. Neurosci Abs, 1994), this matrix is characterized by periods in which the firing rate vector is relatively stationary over time, punctuated by rather abrupt transitions to different regions of neuronal state space. We observe that these state transitions tend to be correlated with the transitions of the frequency/phase of the theta rhythm during REM revealed in the matching pursuit analysis. Supported by MH46823 and the McDonnell-Pew Foundation.

## 375.8

**CONTEXT-DEPENDENT BINDING OF HIPPOCAMPAL "PLACE CELLS" TO DIFFERENT FEATURE-CENTERED REFERENCE FRAMES.** B.L. McNaughton\*, K.M. Gothard and W.E. Skaggs. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Hippocampal CA1 cells were recorded from three rats, trained for two different tasks in two different rooms but with an overlapping set of behaviorally relevant objects. In the first task, rats ran back and forth on a 1.5 m rail, with a fixed food cup (goal) at one end and a sliding box (containing a food cup) at the other. While the rat was at the fixed goal, the box was moved to a new position, so that each trial started at one, and ended at another of 5 equally spaced box locations on the rail. In the second, analogous task, which was performed on a 1.2 x 1.2 m open platform, rats ran from the same box to a goal location adjacent to a cylindrical landmark. There were three possible goal locations along one edge of the platform, and 3 box locations along the opposite edge. The box and landmark locations were independently randomized. Of 43 cells with correlates on at least one task, only 29 showed any behavioral correlate in both tasks. The correlates were: (1) location-specific firing (place cells), box-related firing, (inside-box, box-outward, and box-inward cells; see Gothard et al., this session) and goal-related firing. From the 29 cells, only 4 showed the same behavioral correlate for both tasks; the other 25 were allocated in an apparently nonsystematic way to different reference frames. Although the same box and food cups were used in both environments, only one cell was bound to the box in both environments. These results suggest that binding to a feature frame is not maintained across environments and tasks, and further supports the notion that the hippocampus generates orthogonal representations for similar experiences. Supported by ONR.

## 375.10

**REACTIVATION DURING SLEEP OF CORTICO-CORTICAL AND HIPPOCAMPUS-CORTICAL CORRELATION STATES FROM PRECEDING BEHAVIOR.** Y.-L. Qin\*, B.L. McNaughton, W.E. Skaggs and C.A. Barnes. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Hippocampal cells that fire together during behavior exhibit enhanced correlations during subsequent slow-wave sleep (Wilson and McNaughton, 1994; Kudrimoti et al., this meeting), indicating that information acquired during behavior is reexpressed in hippocampal circuits during sleep, as postulated by some theories of memory consolidation (Marr, 1971; McClelland, McNaughton and O'Reilly, 1995). If hippocampus reinstates patterns in neocortex, as postulated by this theory, then correlations between neocortical cells during behavior should also reemerge during sleep. This should also be true for correlations between hippocampal and neocortical cells. Parallel recordings were made either within posterior neocortex (HL), within CA1, or simultaneously in both areas. Each session involved an initial episode of sleep (S1), a period of behavior on a simple, triangular maze (M1) and a subsequent sleep episode (S2). All pairwise correlations ( $\text{Cov}(x,y)/\sigma_x\sigma_y$ ) between rates (100 ms bins) were computed for each of the 3 states. For both cortico-cortical and hippocampo-cortical interactions, the correlations during S2 were significantly more strongly predicted by the correlations during M1 than were the correlations during S1, indicating that information about the experiences during M1 was reexpressed during S2. This suggests that traces of recent experience are reexpressed in both hippocampal and neocortical circuits during sleep, and moreover, that at any given moment during slow-wave sleep, the representations in the two areas tend to correspond to the same experience. It remains to be determined whether the effect in one area depends on the other. Supported by MH46823.

## 375.12

**ON THE PHASE RELATION BETWEEN EXCITATORY AND INHIBITORY POPULATIONS DURING HIPPOCAMPAL THETA RHYTHM.** M. Tsodyks\*, W.E. Skaggs, T.J. Sejnowski and B.L. McNaughton. Computational Neurobiology Lab, Howard Hughes Medical Institute, The Salk Institute, La Jolla CA 92037 and ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson AZ 85724.

We examine the dynamical behavior of a neural network consisting of two groups of cells, one whose members are excitatory to all other cells and the other inhibitory, with external oscillatory inhibitory input to the inhibitory population such as is known to occur in the septal GABAergic input to hippocampal interneurons (Freund and Antal, 1988). Using simulations and phase plane analysis, we find that over a substantial range of parameters, the behavior of the network is apparently paradoxical, in that increasing the direct external inhibitory input to the inhibitory cells leads them (as well as the excitatory cells) to synchronously increase their activity, and thus to oscillate out of phase with the external drive. The range of parameters over which this occurs corresponds closely to the range in which the excitatory network is unstable when all inhibition is removed. In the opposite regime, the inhibitory population oscillates in phase with the external drive, and out of phase with the excitatory population.

For a network operating in the vicinity of the transition between these two regimes, the inhibitory population exhibits intermediate phase shifts relative to the excitatory one. This phenomenon may be important for understanding the behavior of inhibitory interneurons ("theta cells") during the hippocampal theta rhythm, where unit recordings have revealed all three possible situations. The model may also be relevant to understanding the effects of neuromodulation in several brain regions, including the neocortex. Supported by MH46823 and the McDonnell-Pew Foundation.

## 375.13

COOPERATIVE ROLE OF PERIODIC DRIVING AND RANDOM BACKGROUND INPUT IN GOVERNING THETA CELL OUTPUT IN RAT HIPPOCAMPUS. D.R. Chialvo, C.A. Barnes, B.L. McNaughton, K.M. Gothard and M. Mehta. ARL NSMA, Univ. of Arizona, Tucson, AZ 85724.

The interspike interval distributions of hippocampal interneurons vary continuously between Poisson-like (random) and multimodal (periodic) as a function of behavioral state. This suggests the simultaneous presence of both oscillatory and random inputs. The theory of stochastic resonance predicts that a cell's response can be exponentially sensitive to the uncoherent (noise) input, but only quadratically sensitive to the oscillatory source (Chialvo, J. Stat. Phys. 70:1993). We analyze the spike time-series of theta cells from rats during either sleep or running for food on a rectangular track. We define the spectral density of the point process at the theta frequency as  $\text{Signal}(S)$  and the background spectral density as  $\text{Noise}(N)$ . The quantity  $10 \cdot \log_{10}(S/N)$  estimates the signal to noise ratio (SNR), reflecting how many spikes are coherent with the periodic input compared with how many are not. From this we derive the input magnitude due to  $N$  and  $S$ . We find, paradoxically, that during both activity and sleep, as the noise increases, there is a substantially larger increase in the SNR, even for rather small changes in mean rate. This paradoxical improvement of the coherent spiking in the presence of augmented noise is the signature of stochastic resonance (SR), a phenomenon in which noise and periodic modulation play a cooperative role. Although SR has been demonstrated artificially in a variety of systems, our results are the first evidence of this phenomenon occurring spontaneously in a living system. These results suggest that SNR as defined here is a more sensitive indicator of changes in the state of theta cells than mean firing rate, and may be useful in characterizing physiological changes that occur in hippocampal networks during abnormal states such as drug-states, disease or aging. ## 375.15

MILLISECOND TEMPORAL STRUCTURE OF MEMORY REPRESENTATIONS AND HIPPOCAMPAL-DEPENDENT COGNITIVE MECHANISMS. A. Samsonovich\* and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Experimental studies of hippocampus and neocortex show temporal correlations of spikes at the scale of milliseconds. The ability of a network of spiking units to store and to retrieve such patterns has been demonstrated numerically (W. Gerstner et al., Biol. Cyb. 69, 503, 1993). The present study investigates possible neural mechanisms of information processing that depend on the millisecond temporal structure of memory representations. A model network of leaky integrate-and-fire neurons with dynamic delayed Hebbian synapses has been studied numerically in discrete time. Two basic kinds of dynamics are observed: (quasi) periodic and chaotic spatio-temporal patterns of spikes. The period is estimated analytically. Different self-developed periodic spatio-temporal patterns were stored in the network and selectively retrieved later. Retrieval was possible by initiation of the temporal sequence as well as by a steady stimulation with the appropriate spatial distribution. The period of the pattern can be set by global sinusoidal modulation of neuronal thresholds and tends to be commensurate with the period of modulation (i.e., the period ratio is a rational number). Endowing spatially correlated patterns with fixed uncorrelated temporal structures may substantially reduce their interference thus substantially increasing the memory capacity of the network. In addition, the obtained results imply that formation of cyclic attractors in the phase space of the CA3 network may account for such phenomena as phase precession of place cell firing during the theta rhythm (O'Keefe and Recce, 1993) and formation of archetypal spatial maps. Supported by the McDonnell-Pew Foundation.

## 375.17

REVISITING THE PAPEZ CIRCUIT: THE ROLE OF HIPPOCAMPUS AND ITS AFFERENT AND EFFERENT STRUCTURES IN RODENT NAVIGATION. A.D. Redish\* and D.S. Touretzky. Computer Science Dept. and Center for the Neural Basis of Cognition, Carnegie Mellon Univ., Pittsburgh PA. 15213.

We present a hypothesis compatible with the neurophysiological, anatomical, and lesion literature, which details the role of hippocampus and its afferent and efferent structures in rodent navigation. Place cells in hippocampus are sensitive to sensory information, which can enter from cortical areas via deep entorhinal cortex into the superior layers, and thence into hippocampus proper. But place cells continue to show place fields in the dark. We have suggested elsewhere that this is driven by path integration. We suggest here that the path integrator is located in post-subiculum and cingulate cortex, and that path integrator information enters hippocampus via connections from post-sub to sup-EC.

If place cells are involved in navigation, rodents must have a means of combining place information with information about current goals to generate motor actions. We suggest nucleus accumbens as a good candidate, receiving place information via the fornix and goal information from hypothalamus.

Although head direction cells have been found in a number of places, we suggest that these different anatomical structures are performing different functions: lateral dorsal thalamus integrates orientation cues from multiple external stimuli (represented individually in parietal cortex), while HD cells in anterior thalamic nuclei and post-subiculum are updated by intrinsic cues.

When an animal enters a familiar environment, head direction or path integrator coordinates may be reset by external cues. In this hypothesis, the place code is recombined with local view information in subiculum, and then sent to the head direction and path integration systems.

Novelty is assumed to be encoded by acetylcholine levels reaching hippocampus from the septal nuclei. New environments require dentate gyrus, while familiar ones can be processed by the perforant path.

## 375.14

ACCURACY OF HIPPOCAMPAL PLACE FIELDS IN PREDICTING LOCATION IS ENHANCED IN THE PRESENCE OF THETA RHYTHM. J.L. Gerrard\*, J. Ginzburg, C.A. Barnes, T.J. Scjowski and B.L. McNaughton. Howard Hughes Medical Institute, Salk Institute, La Jolla, CA 92037 and ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Theta rhythm recorded from the hippocampus is observed mainly when a rat is running or exploring its environment. It has been observed that the place-specific activity of single hippocampal pyramidal cells is more robust in the presence of theta rhythm in the EEG (Kubie et al., Soc. Neurosci. Abst., 1984), but no quantitative analysis has been performed on how this change affects the accuracy of a population of place cells in predicting the rat's location in space. We have estimated the effectiveness of the hippocampal place cells in coding for the location of the rat in space in two conditions: (1) the place fields are defined using only spikes that appear when theta rhythm is present in the EEG, and (2) the place fields are defined using all the spikes that occurred when the rat is running on the maze. We analyzed data from a large ensemble of simultaneously recorded hippocampal cells and reconstructed the path made by the rat when running in the maze, using the population activity vector, as described by Wilson and McNaughton, 1993. The reconstruction error is reduced by 40% when using only the spikes that appear when theta rhythm is present in the EEG, in comparison to the case when all spikes are taken into account. Clearly, the presence of theta rhythm is well correlated with relatively high accuracy of the place fields in predicting location. Supported by MH46823, AG12609 and MH01227.

## 375.16

TOWARDS A COMPUTATIONAL MODEL OF THE HIPPOCAMPAL FORMATION INCORPORATING REALISTIC ANATOMICAL CONNECTIVITY: AMMON'S HORN AREA CA1 AND THE SUBICULUM. P. Patton\* and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

A computational model of the rat hippocampal region incorporating realistic anatomical connectivity is being developed. This report focuses on Ammon's horn area CA1 and the subiculum. Each of these structures is represented as a rectangular sheet, through which points, representing neurons, are distributed. CA1 is assumed to contain 380,000 pyramidal cells and the subiculum 280,000 (West et al., Anat. Rec. 231: 482-497). Intrinsic circuitry of area CA1 and inputs from area CA3 are based on Ishizuka et al. (JCN 295: 580-623) and Bernard and Wheal (Hippocampus 4(5): 497-529). Major connections of CA1 and the subiculum with each other and the entorhinal cortex (EC) are also included in the current model. These connections are topographically organized with respect to a septotemporal axis running parallel to the boundaries between the cytoarchitectonic subdivisions, and a perpendicular proximodistal axis, with proximal being the direction towards area CA3 along the hippocampal surface. Fibers originating in the medial EC (MEC) terminate in the proximal half of area CA1 and distal half of the subiculum, and lateral EC (LEC) fibers terminate in an opposite fashion (Witter, Hippocampus 3:33-44). CA1 projects to the subiculum, with more proximal portions projecting more distally (Tamamaki and Nojyo, JCN 291:509-519). CA1 and the subiculum project to the EC, with the proximal portion of CA1 and distal portion of the subiculum projecting to MEC and opposite portions to LEC (Witter *ibid.*). The connectivity matrices resulting from these anatomical models will serve as a basis for models of operations such as associative memory. Supported by MH42683.

## 375.18

INTRA-CORTICAL LONG-TERM POTENTIATION IN SUPERFICIAL LAYERS OF LATERAL ENTORHINAL CORTEX INDUCED BY THETA-PATTERN STIMULATION. M. Protomastro\* and T. Otto. Program in Biopsychology and Behavioral Neuroscience, Dept. of Psychology, Rutgers University, New Brunswick, NJ, 08855.

It has previously been demonstrated that the entorhinal cortex (EC), a primary cortical target of the hippocampal formation, is capable of robust long-term potentiation (LTP) induced by theta-bursting stimulation (TBS) of ipsilateral CA1. The present study sought to determine the capacity within the EC itself to induce and maintain LTP. Five urethane-anesthetized rats were implanted with a bipolar stimulating electrode and a recording electrode in the superficial layer of lateral EC (LEC). Responses were characterized by a latency to peak of 6 ms. The mean maximum response was 0.9 mV (mean stim. int. = 590 uA), and all responses showed paired-pulse facilitation and followed brief trains of high frequency (4-5 pulses at 70-100 Hz) stimulation. During baseline recording, EPSPs (mean amplitude of 0.2 mV, mean stim. int. = 200 uA) were evoked every 15 sec for 15-20 min; initial slope and peak amplitude were recorded on-line by computer. TBS of LEC (2 bouts of 14 bursts [4 pulses at 100Hz], 140ms between bursts [7Hz], 10 sec between bouts) was then delivered at twice the baseline stimulation intensity, and its effect on the EPSP was assessed by continued low-frequency stimulation (every 15 sec) for 60 min. TBS produced stable LTP in LEC; the average potentiation at 60 min was 140.4% of the baseline response. Histology is presently being conducted to verify placement of electrodes in the superficial layers of the LEC.

## 375.19

HIPPOCAMPAL NEURONS ENCODE BOTH LOCAL AND DISTAL STIMULI IN RATS EXPLORING A CUE-CONTROLLED ENVIRONMENT. **M.L. Shapiro**<sup>1</sup>, **H. Tanila**<sup>2</sup>, & **H. Eichenbaum**<sup>2</sup>. <sup>1</sup>Dept. of Psychology, McGill Univ., Montreal, Canada, <sup>2</sup>Cntr. for Behavioral Neuroscience, SUNY Stony Brook, NY.

Sensory and behavioral correlates of hippocampal complex-spike cell (CS) activity in rats are often assessed in environments with many distal extra-maze, but few local intra-maze stimuli. In such cases, CS cells usually respond to the constellation of extra-maze stimuli. Conversely, CS activity recorded while rats explore environments rich with intra-maze stimuli and reduced extra-maze stimuli is often correlated with the intra-maze stimuli. In the present experiment, male Long Evans rats explored a 4-arm radial maze surrounded by curtains holding large, easily discriminated visual stimuli, and in addition, each arm of the maze was covered with a unique set of visual, tactual, and olfactory cues. CA1 and CA3 CS cells were recorded using tetrodes, and the arm entries were rewarded with lateral hypothalamic stimulation. After recording CSs in a standard configuration (baseline trials), the arms and the distal stimuli were rotated 90° in opposite directions around the maze center. After determining whether local or distal cues controlled CS activity, each element of the relevant stimulus set was removed one at a time in recording trials interspersed between baseline trials.

As many CS cells fired in relation to the local as to the distal stimuli, with some influenced strongly by a single local or distal cue. Groups of CS cells recorded simultaneously were influenced by the same stimulus set. Furthermore, some cells changed their firing pattern during the course of these manipulations, becoming most influenced by fixed, uncontrolled room stimuli. Thus, hippocampal neurons encode all salient features of the environment, including local intra-maze stimuli as well as distal extra-maze stimulus configurations, and many change their coding properties rapidly, ultimately learning to encode the most stable aspects of the environment. Supported by the NIMH and NIA.

## 375.21

NEURONAL ACTIVITY IN THE PARAHIPPOCAMPAL REGION OF RATS PERFORMING A DELAYED NON-MATCHING TO SAMPLE TASK. **B.J. Young**<sup>\*</sup>, **T. Otto**, **G.D. Fox** and **H. Eichenbaum**, Center for Behavioral Neuroscience, SUNY at Stony Brook, NY 11794.

Neuropsychological and electrophysiological evidence indicates that the parahippocampal region (perirhinal and entorhinal cortex) plays a critical role in recognition memory. The present study sought to further examine the role of the parahippocampal region in recognition memory by characterizing perirhinal and entorhinal neural activity in rats performing an odor-guided continuous delayed nonmatching to sample task that requires parahippocampal function. Analyses focused on the extent to which cells demonstrated odor selective responses during memory cue sampling and at the end of the memory delay just prior to the recognition test.

Our initial analyses of 147 perirhinal and 71 lateral entorhinal cells revealed that more than 90% of the cells recorded from each area fired selectively during specific behavioral events. Greater than 40% of the cells from each area fired maximally around the time the rat sampled odor memory cues, with the activity of 11.6% of perirhinal and 28.1% of entorhinal cells displaying a statistically significant degree of odor-selective activity. Of particular importance, the activity of 8.2% of perirhinal cells was significantly influenced immediately prior to the recognition test by the odor that had to be remembered across the preceding delay. The results of this latter analysis are not yet available for entorhinal cells. These data show that neurons of the parahippocampal region encode to-be-remembered odors and that specific memory codings are maintained or reestablished at the time of a subsequent recognition test. Supported by NIA & NIMH.

## 375.20

HIPPOCAMPAL PLACE FIELDS IN AGED RATS WITH SPATIAL MEMORY DEFICIT. **H. Tanila**<sup>\*</sup>, **M. Shapiro**, **H. Eichenbaum**, Cntr. Behav. Neuroscience, SUNY at Stony Brook, NY 11794-2575.

As a part of an ongoing study to characterize hippocampal neural coding, place cells in aged rats (26 months) identified as spatially-impaired or intact by water maze test were compared with those of young rats (4-5 months). Previous work has shown that hippocampal cells of aged rats have place fields, suggesting intact spatial coding, but it is not clear whether this firing is determined by relationships between distal spatial cues, or rather is controlled by single distal or local cues as occurs after explicit damage to hippocampal connections. In the present study rats performed a radial-arm maze task for lateral hypothalamic stimulation. Local cues were provided by removable arm inserts distinguished by visual, tactile, and olfactory stimuli. Distal cues were provided by different removable visual patterns on a blank curtain surrounding the maze. Place cells were characterized by response to independent rotation, deletion, and transposition of local and distal cues as described in the accompanying abstract.

In both spatially-impaired and -intact aged rats, most place fields rotated with the distal cues when local and distal cues were rotated independently, and the spatial firing patterns were not disrupted by deletion of single distal cues. Furthermore, as found in young rats, hippocampal cells of aged rats became more dependent on stable cues after repeated manipulations of other cues. Thus, although the present study did not determine whether the rate of such "learning" is slower in hippocampal place cells, it is clear that encoding of spatial relationships is accomplished by the hippocampus even in aged rats that are severely impaired in spatial learning. Supported by NIA.

## LEARNING AND MEMORY: PHYSIOLOGY II

## 376.1

A SIMULATION OF EPISODIC MEMORY FUNCTION IN THE HIPPOCAMPAL FORMATION.

**Michael E. Hasselmo**<sup>\*</sup> and **Milos Cekić** Department of Psychology and Program in Neurosciences, Harvard University, Cambridge MA 02138.

Models of hippocampal subregions are combined in a network simulation which can sequentially store highly overlapping patterns representing component features of behavioral episodes, and can recall these patterns given partial cues. In the simulation, Hebbian modification of perforant path synapses and feedforward inhibition in the dentate gyrus and region CA1 establishes sparse self-organized representations of patterns presented sequentially to entorhinal cortex. Dentate gyrus activity passes via the mossy fibers to region CA3, where excitatory recurrent synapses mediate auto-associative memory function with attractor dynamics due to a balance of feedback excitation and inhibition (Hasselmo et al., *J. Neurosci.* in press). Activity then spreads to region CA1 via the Schaffer collaterals, which mediate storage and recall of associations between activity in region CA3 and region CA1 (Hasselmo & Schnell, *J. Neurosci.* 14: 3898-3914). In region CA1, this allows sequential comparison of recall from region CA3 with afferent input from the entorhinal cortex, as measured by the sum of activity in region CA1. Region CA1 output regulates cholinergic modulation from the medial septum to set appropriate dynamics for learning of novel patterns or recall of previously stored memories (Hasselmo, *Behav. Brain Res.* 67: 1-27).

Brain slice experiments tested the cholinergic suppression of synaptic transmission at the backprojections from region CA1 to subiculum and entorhinal cortex. In the model, combining self-organization of perforant path input with associative memory function of backprojections to entorhinal cortex required cholinergic suppression at these synapses. Extracellular synaptic potentials were recorded in the pyramidal cell layer of the subiculum during stimulation of stratum oriens in CA1. Perfusion of the cholinergic agonist carbachol (100µM) suppressed these synaptic potentials by 66.4% ± 3.54 (n=5). This supports the theory that cholinergic modulation allows combined self-organization and associative memory function in the hippocampus. Supported by ONR N00014-93-1-595 and NIMH R29 MH52732-01.

## 376.2

REVERBERATING CIRCUIT IN THE ENTORHINAL-HIPPOCAMPAL SYSTEM REVEALED BY REAL-TIME IMAGING.

**T. Iijima**<sup>\*</sup>, **M.P. Witter**<sup>†</sup>, **M. Ichikawa**, **T. Tominaga**, **R. Kajiura** and **G. Matsumoto** Electrotechnical Lab. Ibaraki, Tsukuba 305, Japan, <sup>†</sup>Vrije University, Amsterdam 1081 BT, Netherlands

Among the mechanisms proposed to underlie memory formation in the central nervous system, long lasting changes in synaptic efficacy (LTP and LTD) as well as reverberation of activity along a closed loop of excitatory neurons are considered promising candidates. Although the hippocampal formation is believed to be a crucial structure for memory processes, results of recent behavioral and electrophysiological experiments have indicated that the closely associated entorhinal cortex may execute a specific role as well.

The dynamics of neuronal circuits in the entorhinal-hippocampal system were studied in slices with the use of optical imaging with high spatio-temporal resolution. Following a focal electrical stimulation in the superficial layers of the entorhinal cortex, we detected reverberation of neural activities within the entorhinal cortex, which apparently enables this area to hold information for a certain period of time. Reverberation was more prominent and lasted longer, up to 500 msec, when the inhibition due to gamma-aminobutyric acid was slightly suppressed by applying 1 - 5 µM bicuculline. In this situation, we also occasionally observed transfer of entorhinal activity along the various routes of the perforant pathway into the various components of the hippocampal formation. The entorhinal neuronal circuit may thus contribute specifically to memory processes taking place in the entorhinal-hippocampal system by holding information and selectively gating the entry of information into the hippocampus. The latter finding may be in line with previous observations that the transmission of neural activity to the hippocampal formation is frequency dependent (Jones R.S., *TINS*, 16, 58-64, 1993).

A COMPUTER CONTROLLED APPARATUS FOR GENERATION OF SLOPE GUIDED PLACE NAVIGATION IN RATS. M. Moghaddam, Yu. Kaminsky, A. Zahalka and J. Bures (SPON: ENA). Institute of Physiology, Academy of Sciences, Prague, Czech Republic.

Cue directed locomotion is usually defined as approach to visible targets, but can also be studied in darkness when the goal emits non-visual signals (odor, sound). A special situation arises when the slope of terrain is used as the orienting gradient the steepness and direction of which is assessed by vestibular system and proprioception. Rats can be trained in darkness to find a feeder placed on the top of a low cone (1m diameter, 4 cm high). A device allowing continuous generation of slope guided locomotion consists of a 1m arena on the floor of which rests a styrofoam disk (1m dia) equipped with 3 equidistant feeders 17 cm from its center. A 1-5 cm long vertical rod raised under one of the feeders opens its cover and tilts the disk (balanced by solenoid operated counterweights) in a plane passing through the feeder, rat's center of gravity and a point at the disk periphery contacting the floor of the arena. The multitude of such planes generated by the rat's locomotion forms the surface of a virtual cone the top of which is represented by the feeder. A computerized infrared tracking system monitors the rat's position in darkness, closes the feeder after the rat has spent 5 s in its vicinity and returns the disk to horizontal position. After a 10 s interval the computer raises the feeder most remote from the position of the rat and the sequence is repeated. Relative path length (ratio of distance travelled to rat-target distance at the time of feeder opening) is inversely related to inclination (0° to 8°) and is a sensitive measure of performance in this type of vestibular navigation. MODELS OF DENDRITIC SPINES CONTAINING ACTIVE CONDUCTANCES DISPLAY COMPLEX TEMPORAL PROCESSING CAPABILITIES. BE Peterson, EA Gale, RV Jensen and GM Shepherd. Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510

Models of dendrites with spines containing active conductances were previously used to demonstrate how these conductances can enable an arbor to perform logical functions on coincident inputs (Shepherd and Brayton, 1987). We have used similar models to investigate how such systems behave over a range of spatiotemporal input patterns. Recent work verifying the existence of active conductances in dendrites has provided evidence for the possibility of such mechanisms (Stuart and Sakmann, 1994; Magee and Johnston, 1995; Spruston et al., 1995). Theoretical work along these lines has postulated that these active conductances can have important functional roles in the way information is processed in the dendritic arbors of neurons (Softky, 1994). In particular, these properties can limit integration time and can therefore force an arbor to act as a local coincidence detector of its synaptic inputs. Our results indicate that within the model there are complex interactions between arbor and spine morphology, channel kinetics, synaptic strengths, and effective output of the system. Changing the synaptic conductance by 27% in a typical model resulted in a change of integration time from 0.4ms to 2ms. We have also found that these properties can effectively insert delays between inputs from spatially distributed spines without increasing the integration window. This mechanism could be employed by neurons to process temporally complex signals in a more sophisticated manner than simple coincidence detection. Supported by NIDCD, NIMH & NASA (Human Brain Project).

## 376.7

SOLUTIONS OF THE SHORTEST PATH PROBLEM FROM NETWORKS OF DIRECTIONALLY SELECTIVE PLACE CELLS. M. Stead and R.U. Muller. Department of Physiology, SUNY-Brooklyn, Brooklyn, NY 11203.

In previous work, we showed that recurrent (CA3-like) networks of place cells connected by Hebbian synapses can store enough information to solve spatial problems. The key idea is that synaptic resistance (inverse synaptic strength) is proposed to monotonically increase with the distance between the firing fields of a pair of place cells. A cell pair with overlapping fields should fire together in time, so synaptic resistance should be low. In contrast, a cell pair with separated fields will not fire together, and synaptic resistance should stay high. When synaptic resistances are set in this way, shortest paths can be extracted from the network with standard graph theoretic algorithms.

The stated synaptic modification scheme assumes that place cells are omnidirectional, as is true in open areas surrounded by walls (Muller et al, J. Neurosci. 14; 7235-7251, 1994). Muller et al also showed that place cells show directional selectivity on an 8-arm maze. It is therefore important to test if optimal paths can be found when discharge depends on head direction as well as position.

In a first order scheme, synaptic resistance was set according to the distance between the fields of the cell pair multiplied by the similarity in the directional tuning of the two cells. When resistance is set in this way, straight-line paths between arbitrary pairs of points can still be calculated; the representational method is robust despite a fundamental change in the spatial firing properties of the underlying cells. The "behavior" along the path is, however, peculiar: the fake rat need not point in the direction in which it moves. In a more sophisticated method, resistance is lowered only if the two cells are tuned to similar directions AND the direction from the field of the presynaptic cell to the field of the postsynaptic cell is similar to the tuning direction. This method, which better mimics the behavior of real rats, yields more realistic paths.

## 376.4

AN INFORMATION SYSTEM FOR NEURONAL PATTERN ANALYSIS J.R. Payne\*, S.J. Quinn, M. Wolske, M. Gabriel, M.E. Nelson Beckman Institute, University of Illinois, Urbana, IL 61801.

There has been an explosion of data in the neuroscience community in recent years owing to rapid developments in multi-neuron recording techniques, computer-based data acquisition systems and large scale neuronal modeling studies. This has led to a disproportionate amount of time being spent archiving, cataloging, and searching through datasets—time that could be more productively spent on data analysis and interpretation. In addition, existing software tools are usually tailored to the specific formats of individual laboratories, forcing research groups to reinvent tools and making it difficult to share data between groups. The Information System for Neuronal Pattern Analysis (ISNPA) is being developed by neuroscientists at the Beckman Institute in collaboration with NCSA in order to address these problems.

ISNPA consists of three primary interrelated components: 1) The *database component*, a SYBASE database engine running on a Sun Sparc 10 server with 300 Gb of online storage capacity. Users interact with the database engine by means of an extensive and individually customizable graphical user interface that allows the user to search hierarchically-organized descriptive information (metadata) about the experimental datasets. 2) The *Time Series Data Protocol (TSDP)*, which allows neuronal time series data to be stored, manipulated and transported via the internet from one computer platform to another, independent of the format of the source data. 3) A suite of *analysis and visualization tools* based on TSDP that provide a flexible, intuitive and efficient means of processing and interacting with large amounts of data. ## 376.6

GEOMETRIC DETERMINANTS OF HIPPOCAMPAL PLACE FIELDS. J. O'Keefe\* and N. Burgess. Department of Anatomy, University College London, London WC1E 6BT, U.K.

Why do place cells fire where they fire? We examined the firing fields of 16 well-isolated place cells from 3 rats while they searched for food in quadrangular boxes formed by identical walls arranged in 4 configurations: a large square (122x122cm), a small square (61x61cm), and 2 rectangles (61x122cm) whose long side was either parallel to the long axis of the (rectangular) testing room, or perpendicular to it. 14 cells had a single field in 2 or more of the configurations, and 2 cells had two fields in 2 or more of the configurations. No cells had fields exclusively in the large and small squares, or exclusively in the two rectangles. Fields were quantified by calculating the centroid and standard deviation of the spatial firing rates in the 2 orthogonal directions defined by the axes of the boxes. The component of the centroid in each direction was measured in 3 ways: as a distance relative to a testing room wall (M1), as a distance relative to a box wall (M2), and as a proportion of the distance between two opposite box walls (M3). The measurement with the minimum variance across configurations was taken as the major determinant of the component of the field location in that direction. The most common combinations of measurements determining field location were M2 in both orthogonal directions (4 fields), and M2 in one direction with M3 in the other (7 fields). 5 fields had M1 as the determinant in one direction combined with M2 or M3 in the other. We assume that these cells were influenced by elongated features outside of the box, e.g. the testing room walls. The fields of neighbouring neurons may have differing determinants. The results show that a place field's location is the result of at least two vector computations involving the distance in an allocentric direction to an extended cue.

## 376.8

THE FIRING OF HIPPOCAMPAL PLACE CELLS IS EITHER NOISY OR SIGNALS MORE THAN JUST POSITION. A.A. Fenton\*, J.L. Kubie, R.U. Muller. SUNY Brooklyn, NY, 11203.

Current ideas of place cell (PC) properties are based mainly on time-averaged positional firing distributions, which are very smooth for long recordings. We find, however, that PCs may fail to fire as the rat crosses the firing field through its center, suggesting that firing in time is more variable than expected from averages. This impression was tested by comparing the observed spike time series to one generated by a Poisson model. The probability of a spike in each 1/60 sec interval was calculated from the average firing rate in the pixel. The match of observed to predicted spike times was good on a scale of tens of seconds but poor on a scale of 1-3 seconds, about what it takes a rat to cross the field; spikes were more clustered than predicted from the average rate.

To formally demonstrate excess firing variance, we did a Monte Carlo analysis (100000 repeats) of the number of spikes expected along a path, given the time-averaged rate in each pixel. (A path is a time series of positions.) Only paths through the field center were studied. A t-value was got for each path by seeing where the observed number of spikes fit into the Monte Carlo distribution. Such t-values were much larger (positive or negative) than t-values got from seeing where a single additional Monte Carlo run fit in the Monte Carlo distribution. An F-test of the 2 t-value distributions revealed that the variance of the observed was much greater than of the expected. The excess variance could not be explained by the tendency of PCs to fire complex spikes, by drift in average firing rate or by details of the paths. Interestingly, when firing on single field paths was compared for simultaneously recorded PC pairs with overlapping firing fields, the t-values from the two cells were uncorrelated. Thus, either the positional signal of PCs is very noisy and not modulated by any aspect of the general state of the rat, or individual PCs carry a signal in addition to position.

## 376.9

PERFORMANCE DIFFERENCES IN THE P AND NP SELECTED LINES OF RATS IN PLACE LEARNING IN THE MORRIS MAZE. C. R. Goodlett<sup>1</sup> and S. L. Morzorati<sup>2</sup>, <sup>1</sup>IUPUI and <sup>2</sup>Indiana Univ. School of Medicine, Indianapolis, IN 46202.

The P (alcohol-preferring) and NP (alcohol-nonpreferring) rats, selectively bred for differences in voluntary alcohol consumption, also differ in the generation of hippocampal theta rhythm. NP rats generate a consistently higher peak theta frequency than P rats during REM sleep, still-alert waking, and ambulation (Morzorati *et al.*, *Alcohol*, 1994; Breen *et al.*, *Alcoholism: Clin. Exp. Res.*, 1993). Frequency-specific theta activity is correlated with exploration and learning in rats, and theta sets the optimal conditions for induction of long-term potentiation in the hippocampus. Because the theta frequency generated by NP rats is higher than is typical found in outbred rat stocks, the present study compared P and NP lines on acquisition of spatial learning in the Morris water maze, a task known to depend on hippocampal function.

Adult, male P (n=10) and NP (n=9) rats were trained on the following sequence in the water maze: cue-guided learning using a visible platform (2 days); simple place learning using a submerged platform in a designated location (7 days, plus probe trials); and, place learning set with the submerged platform in a different location each day (5 days). For cue learning (conducted in a separate room), latency to escape was the dependent measure. Data for the place learning trials were acquired using a computerized video tracking system which collected escape latency, path length, swimming speed, perimeter time, and time in each quadrant (on probe trials).

No differences were found on the visible platform task, and both lines had escape latencies under 10 sec by the second day. Throughout the place training, NP rats swam slower than P rats, leading to a dissociation of escape latencies and path lengths. The NP rats had significantly longer escape latencies (but not path lengths) during acquisition of the simple place learning and, more prominently, during the first 2 days of learning set training. The markedly longer escape latencies when novel spatial contingencies were instituted, and the slower swimming during place but not cue-guided learning, suggests the NP rats adopt slower search behavior in the Morris maze to compensate for altered spatial processing. ## 376.11

THE RESPONSE OF HEAD DIRECTION CELLS TO NON-VISUAL CUES. J.P. Goodridge\*, K.A. Worboys, P. Dudchenko and J.S. Taube, Department of Psychology, Dartmouth College, Hanover, NH 03755.

Previous research has shown that head direction (HD) cells in both the anterior thalamic nuclei and the postsubiculum discharge in relation to prominent visual landmarks in the environment. In particular, when a familiar visual cue in the environment is rotated, the HD cell's preferred firing direction shifts by a corresponding amount. This study assesses whether HD cells are similarly responsive to non-visual cues in the environment.

Five female, Long-Evans rats were trained to retrieve food pellets thrown randomly into a gray, cylindrical chamber in which an auditory click emanating from one side of the cylinder served as the only prominent orientation cue. Following training, a recording electrode array was implanted into either the anterior thalamic nuclei or the postsubiculum. Eight HD cells were identified and recorded in a control session with the room lights off. Then, with the animals removed from the cylinder, the auditory click was rotated 90° and the animals were returned to the cylinder. All HD cells failed to shift in accordance with the click rotation. In addition, four HD cells, each in a different animal, were tested for their response to rotation of a large white card which was taped to the inside cylinder wall and which the animal had never seen before. The preferred firing direction of these cells all shifted in accordance with the card rotation. Thus, despite the fact that the animal was given extensive experience with the auditory click, it was not able to exert stimulus control over the preferred firing direction of these cells in the same manner as the cue card.

The response of three HD cells to non-visual cues was also assessed in three different blindfolded rats. Even after the animal was blindfolded, the preferred firing direction of two of the three cells remained stable while the third cell stabilized after 20 minutes. In addition, when the floor paper (on which urine spots could be identified) and the cylinder (from which the cue card had been removed) were rotated together, the preferred firing direction of two of the three cells shifted by a corresponding amount. These findings suggest that HD neurons are responsive to olfactory information as well as visual information.

## 376.13

HEAD DIRECTION CELLS RECORDED FROM RATS WITH HIPPOCAMPAL LESIONS. E.J. Golob\* and J.S. Taube, Department of Psychology, Dartmouth College, Hanover, NH 03755.

Neurons have been identified in the postsubiculum (PoS) and anterior thalamic nuclei (ATN) which discharge as a function of the animal's allocentric head direction in the horizontal plane (HD cells). Previous studies have also shown the presence of location-specific discharge in hippocampal cells. This study was designed to determine how HD cell activity would be affected by lesions of the hippocampus.

Six female, Long-Evans rats were trained to forage for food pellets dropped randomly into a gray cylindrical chamber containing a prominent white cue card. After training, bilateral ibotenic acid lesions were made in the hippocampus and an electrode recording array was implanted in the PoS (n=4) or the ATN (n=2). Following recovery animals were screened for cells daily within the cylinder. Eleven HD cells were identified in the lesioned animals, with at least one cell per animal. Previous experiments have shown that when an animal is introduced to a novel enclosure having a different shape, such as a rectangle, the HD cell's preferred firing direction (PFD) will often shift relative to the PFD within the cylinder. We tested whether lesioned animals, when presented with a novel enclosure, were able to maintain this new PFD across repeated sessions over several days. The variation in PFD for 7 HD cells did not appear to differ from control animals. The absolute difference between the PFD on the first and second days were  $14.6 \pm 3.34^\circ$  for 7 cells in the cylinder and  $11.6 \pm 4.93^\circ$  for 5 cells recorded in a novel enclosure. However, preliminary results show that the PFD of lesioned animals may be less stable as the animal walks from a familiar to an unfamiliar environment compared with control animals. Taken together, these findings indicate that the hippocampus may not be necessary for establishing and maintaining stable HD cell firing when landmarks are present, but may be important for processing path integration information.

## 376.10

ALTERED INHIBITION OF DENTATE GRANULE CELLS DURING SPATIAL LEARNING IN AN EXPLORATION TASK. E.J. Moser\*, Centre for Neuroscience, University of Edinburgh, Edinburgh EH8 9LE, U.K., and Dept. of Neurophysiology, University of Oslo, Norway.

Spatial learning may require precise control of the impulse flow through the hippocampal formation. The inhibitory interneurons in the dentate gyrus may be important in this respect. To study whether inhibition on the dendrites and somata of dentate granule cells is altered during spatial learning in an exploration task, field potentials were recorded in the dentate gyrus in response to paired stimulation of the perforant path while rats explored or rested (20 ms interstimulus interval, wide range of intensities). A population spike in the first potential was consistently associated with a suppression of the field EPSP as well as the population spike of the second waveform. The suppression is likely to reflect recurrent inhibition on the dendrites and the somata of the granule cells, respectively.

During exploration, the suppression of the EPSP was enhanced relative to reference potentials sampled at the same brain temperature while the rat was resting in its home cage. The difference did not disappear when the potentials were matched with respect to the EPSP slope or the spike amplitude of the first potential. Below the spike threshold, no change in the paired-pulse ratio was observed. The suppression was largest at the start of the exploration, after which it decayed gradually. It was still present at 15 min. On the other hand, the suppression of the population spike seemed to be relaxed during the exploration. The population spike of the second waveform was significantly enhanced relative to that of temperature-matched reference potentials. This enhancement showed no decay during the session. The results suggest that exploration of an unfamiliar environment may be accompanied by a dual change in recurrent inhibition on the granule cells: Interneurons projecting to the molecular layer may be more excitable, whereas interneurons contacting the somatic region may exert less inhibition.

## 376.12

THE EFFECTS OF LESIONS OF THE POSTSUBICULUM ON HIPPOCAMPAL PLACE CELL ACTIVITY. P. Dudchenko\*, J.P. Goodridge, and J.S. Taube, Department of Psychology, Dartmouth College, Hanover, NH 03755.

The presence of cells in the postsubiculum (PoS) and other regions of the brain which code for an animal's allocentric head direction in the horizontal plane has been well established. The PoS projects directly to layers of entorhinal cortex which in turn project to the hippocampus. Recent work in our lab, described in a separate abstract (Golob and Taube), has shown that head direction cell activity in the PoS is generally not disrupted by lesions of the hippocampus. The current study examined the converse relationship: Are place cells in the hippocampus affected by lesions of the PoS?

To assess this question, bilateral ibotenic acid lesions were made in the PoS of Long-Evans female rats and moveable recording electrodes were implanted to assess neuronal activity in the CA1 hippocampal region. Upon recovery, animals were screened daily for place cells in a cylindrical apparatus containing a white cue card. Our preliminary results suggest that place cells can be identified in the hippocampus following destruction of the PoS, although these cells appear to possess higher rates of background firing. In addition, the firing rate maps of these place cells are less robust in terms of spatial coherence and information content when compared to values reported from place cells in the dorsal hippocampus of normal animals (Poucet *et al.*, 1994). If these preliminary findings are borne out in subsequent animals, it may be hypothesized that head direction cells in the PoS provide an input which is necessary for the optimal firing of hippocampal place cells.

## 376.14

INFLUENCE OF VESTIBULAR SYSTEM LESIONS UPON ANTERIOR THALAMIC HEAD-DIRECTION CELL ACTIVITY. R.W. Stackman\* and J.S. Taube, Department of Psychology, Dartmouth College, Hanover, NH 03755.

Single-unit analyses have identified a subset of neurons, in the rat anterior thalamic nucleus (ATN) (Taube, 1995), that discharge as a function of the rat's head direction (HD) in the horizontal plane. HD cells may be an integral component of a neural network that supports spatial navigation. It has been hypothesized that vestibular information may be critical for acquiring an internal representation of space and for maintaining that representation in the absence of a familiar landmark. Further, vestibular lesions disrupt spatial navigation under conditions in which landmarks are not present. Given the potential contribution of the vestibular system to HD cells, we investigated the influence of vestibular system lesions upon the activity of HD cells.

Female Long-Evans rats were trained to retrieve food pellets thrown randomly into a cylindrical apparatus that included a white cue card that served as an orientation cue. Following acquisition of this task, rats were implanted with chronic recording electrodes directed at the ATN. Rats also received bilateral intratympanic injections of either the vestibular system toxin, sodium arsenite (30 mg/0.1 ml/side) or 0.9% saline. Following recovery, rats were tested each day for vestibular function using a contact righting test, and then cellular activity was monitored in the cylinder to determine directional, and other spatial or behavioral correlates. Vestibular-lesioned rats exhibited persistent deficits of contact righting. Although HD cells were identified in control-treated rats, no HD cells were isolated in vestibular-lesioned rats. Cells from vestibular-lesioned rats exhibited higher background firing rates and appeared to fire in bursts, although these bursts did not correlate with the animal's HD. These data appear to suggest an important contribution of the vestibular system in the maintenance of the directional firing properties of ATN neurons.

## 376.15

**HEAD DIRECTION CELL ACTIVITY IN THE ANTERIOR THALAMIC NUCLEI, BUT NOT THE POSTSUBICULUM, PREDICTS THE ANIMAL'S FUTURE DIRECTIONAL HEADING.** J.S. Taube<sup>1</sup> and R.U. Muller<sup>2</sup>. <sup>1</sup>Dept. of Psychology, Dartmouth College, Hanover, NH 03755 and <sup>2</sup>Dept. of Physiology, SUNY Health Science Center, Brooklyn, NY 11203.

Previous studies have identified two distinct populations of neurons which discharge as a function of the animal's head direction (HD) in the horizontal plane. One population is in the postsubiculum (PoS); the second is in the anterior thalamic nuclei (ATN). These two brain areas are reciprocally connected with one another, making it hard to determine which area is primarily responsible for organizing HD cell discharge. To help understand the origin of the HD signal, we performed a time shift analysis where the spike series was shifted forwards and backwards in time with respect to the animal's head direction in 1/60th sec intervals. A sample of 20 PoS and 17 ATN cells were selected from 8 min recording sessions during which Long-Evans rats performed a food foraging task in a cylindrical apparatus containing a single visual polarizing cue. For each cell, firing rate vs. head direction plots were computed for each shift of the spike series and two parameters were measured from each plot: peak firing rate and half-width of the directional firing range (see Taube et al., 1990). It is our argument that determining the time shift which produces the optimal value for each parameter lets us determine which brain structure "leads" HD cell firing. We found that the optimal time shifts for peak firing rate and half-width were  $40.00 \pm 4.23$  and  $34.45 \pm 5.50$  msec for ATN cells, respectively. In contrast, PoS HD cells had optimum values of  $-0.83 \pm 9.72$  and  $-1.67 \pm 9.43$  msec, respectively. These results are consistent with preliminary experiments showing that lesions of the ATN disrupt HD cell discharge in the PoS, while lesions of the PoS do not interfere with HD cell discharge in the ATN. Taken together, these findings suggest that the HD cell signal, which was first identified in the PoS, actually originates in the ATN, and predicts the animal's future directional heading by about 37 msec.

## 376.17

**VISUAL AND VESTIBULAR INFLUENCES ON HEAD-DIRECTION CELLS IN THE ANTERIOR THALAMUS OF THE RAT.** P.E. Sharp\* & H.T. Blair. Dept. of Psychology, Yale University, New Haven, CT 06520-8205

Head-direction cells were recorded from the anterodorsal thalamic nucleus as rats navigated freely in a cylindrical recording chamber. The wall and floor of the cylinder could be rotated independently of one another, to deliver different combinations of visual and vestibular movement information. The wall was painted with an alternating pattern of eight vertical black and white stripes, so that any 90° rotation of the wall and/or floor left the environment visually unchanged.

We measured the responses of head-direction cells to several different rotations of the apparatus, including: 1. **Wall Alone 90°**. As the stripes on the wall moved around the animal, a change of head direction was signalled by visual motion cues, but not by vestibular cues. 2. **Wall+Floor 90° (fast)**. The entire apparatus was rotated, and the animal along with it. Vestibular signals indicated a change of head direction, but visual motion cues did not, since the wall rotated with the animal. 3. **Floor Alone 90°**. The animal moved along with the floor, but the wall was stationary as the animal moved. Both visual and vestibular cues indicated a change of head direction. 4. **Wall+Floor 90° (slow)**. As in #2, the entire apparatus was rotated, but the rotation was below vestibular threshold. Thus, a change of head direction actually occurred, but was signalled by neither visual nor vestibular cues.

In manipulations #1 and #2, visual and vestibular cues provided contradictory information, and cells variably rotated their preferred direction in agreement with visual cues, vestibular cues, or a partial combination of both. In manipulations #3 and #4, visual and vestibular cues provided complementary information, and cells always responded in the same way. In manipulation #3, cells never rotated their preferred firing direction, and in manipulation #4, cells always rotated their preferred firing direction along with the apparatus. These results indicate that visual and vestibular signals cooperatively influence the rat's head-direction system.

## 376.19

**DIFFERENTIAL EFFECTS OF SPATIAL REFERENCE AND WORKING MEMORY TESTING ON SYNAPTIC EFFICACY IN THE LATERAL SEPTUM OF MICE.** R. Garcia, R.M. Vouimba and R. Jaffard\*. Lab. Neurosciences Comportementales & Cognitives, CNRS URA 339, Univ. Bordeaux I, Ave. des Facultés, 33405 Talence, France.

The efficacy of synaptic transmission from the fimbria to the lateral septum of freely moving C57 BL/6 mice was monitored electrophysiologically over 9 days of training in either a spatial discrimination task (Reference memory: RM) or a delayed nonmatching-to-place task (Working memory: WM) in an 8-arm radial maze. The learning specificity of the observed changes was assessed using a control group exposed to muscular effort (treadmill). Results showed that RM testing induced a progressive and persistent increase in the amplitude of the N3 averaged evoked potentials in the LS, the magnitude of which was significantly greater in fast learners than in slow learners. Conversely, WM testing induced an inverse pattern of effect. Specifically, each daily training session induced a slight but significant decrease in the amplitude of N3 with respect to the control group. Moreover, a significant correlation was observed between the magnitude of this decrease and response accuracy. The observed bidirectional effect of RM and WM testing on synaptic transmission in the LS were also observed using a task in which, on each trial, animals were forced to visit, one at a time, each arm of the radial maze. In this task animals were divided into two groups. In the first group, the probability of finding food in a given arm was either 1 (the four constantly baited arms) or 0 (the four never baited arms); in the second group, the probability of finding food in each of the 8 arms was 0.5. Preliminary results indicate that each type of testing induced opposite changes in the amplitude of N3: the first (i.e., "invariant") group displayed a persistent increase in N3, whereas the second (i.e., "variant") group displayed an opposite pattern of change (i.e., a depression). These changes in testing-induced hippocampo-septal septal glutamatergic synaptic transmission might play a role in the previously observed task-specific (WM vs RM) testing-induced alterations of hippocampal cholinergic activity (Manighetto et al., Behav. Brain Res., 1993, 56: 133-144; Pharmacol. Biochem. Behav., 1994, 49: 689-699).

## 376.16

**THE POSITIONAL FIRING OF PLACE CELLS IS CONTROLLED MORE STRONGLY BY CARDS ON THE WALL THAN BY 3-DIMENSIONAL OBJECTS INSIDE THE ARENA.** B. Poucet\*, A. Cressant & R.U. Muller. Lab. Cognitive Neuroscience, CNRS, Marseille, 13402 France, and Dept. Physiology, SUNY, Brooklyn, NY.

Place cells recorded from the dorsal hippocampus of freely-moving rats fire the most intensely in a region of space called the firing field. Previous work has shown that a single white cue card attached to the wall of a recording cylinder controls the angular position of firing fields; when the card is rotated, fields rotate equally. In the present study, we asked whether similar control could be exerted by 3-dimensional objects placed directly in the recording arena. Single cell recordings were made while hungry rats chased pellets in a gray cylinder with 2 or 3 different, heavy objects on the floor; the locations of the objects relative to each other and their distances from the cylinder wall were fixed. Recordings were made under 2 conditions, first with the objects in a "standard" position relative to the laboratory frame and second with the objects rotated as a rigid set around the center of the cylinder. In contrast to the stability of firing field positions across sessions when the white card was in a standard position, firing fields often rotated and changed in other ways across sessions when the objects were in the standard position. Moreover, when the objects were rotated between sessions, the new angular position of the firing field was unpredictable, in contrast to the reliable control over angular position exerted by the card. Finally, when both the card and the objects were simultaneously present and rotated equally, the ensemble of stimuli exerted nearly ideal control over angular firing position. Nevertheless, when the card was withdrawn, the objects were still ineffective in controlling field position. These results suggest that the rat hippocampus is not sufficiently powerful to do the spatial processing needed to use as landmarks objects that can be viewed from all angles.

**NONLINEAR DYNAMICAL MODEL OF HIPPOCAMPAL FIELD CA3 WITH REVERBERATING SHORT-TERM MEMORY.** S. P. Wicke<sup>1</sup>, M. Taketani<sup>2</sup>, J. Ambros-Ingerson<sup>3</sup>, G. Lynch<sup>3</sup>, and R. Granger<sup>3</sup>. <sup>1</sup>Center for Neural Science, New York University, New York, NY 10003. <sup>2</sup>RCE2, Central Research Laboratories, Matsushita Electric Industrial Co., Ltd., 3-4 Hikari-dai, Seika-cho, Soraku-gun, Kyoto 619-02 Japan. <sup>3</sup>ICS Department and Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717.

The hippocampal formation can be viewed as a roughly serial chain of structures, each performing a distinct information processing operation on the input which is passed through this "assembly line." Centrally located in this pathway, the unusually dense recurrent associational system of CA3 suggests that its operation may be one of time dilation (i.e. sustained input-specific dynamical activity). Incorporation of hippocampal field CA3's dense local connectivity along with its mossy fiber, septal, and perforant path afferents and the differential time courses of excitatory and inhibitory postsynaptic potentials into a mathematical model gave rise to a system of neuronal ensembles or "patches" which exhibit oscillatory activity in response to brief excitatory input. Simulations reveal the persistence of a patch's oscillatory response to transient (~milliseconds) afferent stimulation to be dependent on (i) the strength of the converging information-bearing signal and (ii) the time of its arrival relative to the phase of ongoing periodic septal and mossy fiber input, the optimal frequency for maintaining the oscillatory activity being that of theta rhythm. Thus in the present model, the pattern of actively oscillating CA3 patches, which also cycle at theta rhythm, reflects the specific spatial and temporal characteristics of the afferent signal and extends information about the input across the duration of the recurrent activity (~seconds). The hypothesis is forwarded that this unusual form of transient memory may render CA3 capable of holding fleeting neuronal traces encoding sensory cues over the seconds-long time courses of behavioral actions via input-specific standing periodic responses.

## 376.20

**SPATIAL REPRESENTATION IN MONKEY SEPTAL NUCLEI.** H.Nishijo\*, T.Kita, T.Ono, K.Nakamura and K.Terasawa. Dept. Physiol., Fac. Med., Toyama Medical & Pharmaceutical University, Sugitani, Toyama 930-01, Japan.

It has been reported that septal lesion resulted in deficits of various types in place navigation tasks. In the present study, neuronal activity in the monkey septal nuclei was recorded during performance of a place-dependent Go-NoGo (PGN) task in which reward contingencies were variable with reference to the spatial location of a monkey's cab in one of four places in an experimental room. The task was initiated by a sight presentation of a place (place phase) followed by presentation of an object (object phase). A bar-press was reinforced only if each object was seen in one corresponding place (Go-trial), and the same object was never reinforced in other places (NoGo-trial). Of 349 septal neurons recorded, 42 responded differentially to location during the place phase (place-differential neurons), and 72 responded differentially to Go/NoGo responses during the object phase. The multidimensional analysis of place-phase responses of these 42 place-differential neurons indicated that the four places distributed in a two-dimensional space at relative positions were similar to those in the real experimental room. Furthermore, the distance between possible two places in the two-dimensional space significantly correlated to behavioral performance defined as a % of correct trials during discrimination of the given pair of places. These results suggest that functional subpopulation of monkey septal neurons could encode some behavioral aspects of a place.

## 376.21

\*ELECTRICAL STIMULATION OF THE SEPTAL REGION OF AGED RATS IMPROVES PERFORMANCE IN AN OPEN FIELD MAZE. F. Jiang, J. Turnbull\* and R. Racine. Dept. of Medicine and Psychology, McMaster Univ. Hamilton, Ontario, Canada L8N 3Z5.

\* Memory deficits of age and disease may result from dysfunction of the temporal lobes and functionally associated structures. We have proposed that iatrogenic rhythmic electrical stimulation of the deep septal nuclei, which project to the hippocampal formations of the temporal lobes, might moderate these memory deficits. We show here that this is the case. Septal stimulation of very old rats leads to a marked improvement in performance in an open field maze task. Unilateral stimulation of the projection from the entorhinal cortex to the hippocampus was less effective. The frequency of stimulation was important: stimulation at 5 Hz and 50 Hz was effective, while 0.5 Hz was less effective (though still significantly better than control). Hippocampal (dentate) EEG did not change significantly with septal stimulation frequency. These results may bear on the memory deficit of old age in humans. The results may also bear on the memory deficits seen in human disease states such as Alzheimer's disease, though this cannot be readily verified in the absence of a suitable animal model.

## LEARNING AND MEMORY: PHARMACOLOGY IV

## 377.1

PHARMACOLOGICAL MANIPULATION OF HIPPOCAMPAL PLACE CELL FIRING WITH MICRODIALYSIS IN THE RECORDING SITE. N. Ludvig\*, B.T. Altura, B.M. Altura and S.E. Fox. Dept. of Physiology, State University of New York, Brooklyn, NY 11203.

This study was devoted to exploring whether the microdialysis-coupled unit recording method (Ludvig et al., *J. Neurosci. Meth.* [1994] 55:31-40) can be used for studying hippocampal place cells, and whether the firing pattern of these cells can be changed by perfusing drug solutions in the recording site.

Complex-spike cells (pyramidal cells) displaying the characteristic location-specific firing of place cells could be readily detected in behaving rats during microdialysis with artificial cerebrospinal fluid (ACSF) in the microenvironment of the neurons. This provided evidence that the microdialysis procedure, although it causes unavoidable damage in the hippocampal circuitry, leaves a substantial number of neurons in the dialysis area functionally intact.

The effects of exposing identified place cells to 10 min perfusions of ACSF with high concentration (50 mM) of K<sup>+</sup> were also examined. These recording/dialysis sessions were preceded by *in vitro* tests to determine the time when the high concentration of K<sup>+</sup> solution reaches the tip of the microdialysis probe, and to measure the amount of K<sup>+</sup> that diffused out of the probe. For these tests, ion selective electrodes were utilized. The generated data enabled us to know exactly the time-frame and magnitude of the K<sup>+</sup>-exposures. We have found that such exposures mostly increase the firing rate of the recorded neurons, and often activate "silent" pyramidal cells within the recording/dialysis site. Place cells appeared to fire more intensely out of their firing field than before and after the K<sup>+</sup>-challenge. Importantly, the overall behavior of the rats were not affected by these procedures, and in each recording/dialysis session place cells could be studied for as long as 2 days.

The described method may provide a way to examine some aspects of the synaptic and molecular mechanisms that regulate place cell firing.

## 377.3

THE EFFECTS OF NIMODIPINE ON THE ACQUISITION AND RETENTION OF A REFERENCE MEMORY TASK. K.A. Kane<sup>1</sup> and G.B. Robinson\*<sup>2</sup>. <sup>1</sup>Dept. of Psychology, University of New Brunswick, Fredericton, NB, E3B 5A3 and <sup>2</sup>Dept. of Surgery, Louisiana State University Medical Centre, Shreveport, LA, 71130-3932.

Manipulation of neuronal calcium has been found to affect learning and memory systems. The calcium channel antagonist, nimodipine, for example, improves working memory in both young and aged animals (LeVere & Walker, *Neurobiol. Aging*, 12:63, 1991; Levy et al., *Pharm. Biochem. & Behav.*, 39:781, 1991). There is, however, some question as to whether or not nimodipine administration also improves reference memory (e.g., McMonagle-Strucko & Fanelli, *Pharm. Biochem. & Behav.*, 44:827, 1993). In the present study, we investigated the effects of nimodipine administration on the performance of young rats on a circular platform reference memory task. The effects of nimodipine on both task acquisition and task retention were examined.

Male Long-Evans hooded rats (3-4 months old) were subcutaneously implanted with either nimodipine (n=14) or placebo (n=14) sustained-release pellets. Nimodipine pellets contained 30 mg of drug, slowly released over approximately 30 days. Animals received 2 trials/day on the maze until acquisition criterion (3 or fewer errors/trial over 5 consecutive trials) was met. Fifteen days after reaching the acquisition criterion, retention was tested in a subset of the rats administered nimodipine (n=6) and placebo (n=7). Retention criterion was 3 or fewer trials over 3 consecutive trials. Rats administered nimodipine required an average of 9.5 ± 0.2 acquisition trials to reach criterion compared to 13.5 ± 0.1 trials for controls. This difference was significant (p < .01). Nimodipine administration also decreased the number of trials required to meet the retention criterion from 5.0 ± 0.2 for controls to 3.0 ± 0.0. This difference was also significant (p < .05). These results suggest that nimodipine administration facilitates reference memory acquisition and retention in young rats. Supported by NSERC.

## 377.2

EFFECTS OF T-588, A NOVEL COGNITIVE ENHANCER, ON ACETYLCHOLINE AND MONOAMINE RELEASES AND SECOND-MESSENGER SYSTEMS IN RATS. S. Ono\*, M. Mackawa, T. Kimura, A. Takagi, A. Nakamura, K. Kondo, H. Miyazaki, K. Mozumi, N. Matsui and H. Narita. Research Laboratories, Toyama Chemical Co. Ltd., Toyama 930, Japan.

Previous studies demonstrated that T-588 (3 mg/kg, po) ameliorated the memory and learning impairment in embolized and ischemic rats to the performance level of sham-operated rats by daily administration at the chronic phase. We have also shown that T-588 (0.1 mg/kg, iv) improved the scopolamine-induced EEG changes in rabbits. To examine the mechanism for T-588, we investigated the effects of T-588 on acetylcholine (ACh) and monoamines releases and on phosphoinositide (PI) hydrolysis and cyclic AMP formation in rat brains. Oral administration of T-588 (3 and 10 mg/kg) caused a significant increase of microdialysate ACh and noradrenaline (NA) releases from the frontal cortex and hippocampus. T-588 produced a concentration-dependent increase in the spontaneous efflux of [<sup>3</sup>H] dopamine, [<sup>3</sup>H]NA and [<sup>3</sup>H]serotonin in the cortical, hippocampal and striatal slices. These effects were still fully detected when slices were incubated with a calcium-free medium or tetrodotoxin. T-588 (1-10 mM) stimulated PI hydrolysis and cAMP formation in a concentration-dependent manner in the cortical and hippocampal slices. 2-Amino-3-phosphonopropanoate or N-ethylmaleimide blocked T-588's actions, while atropine, prazosin, propranolol, ketanserin or SCH23390 did not. T-588 (3 and 10 μM) enhanced isoproterenol-stimulated cAMP formation without altering the cAMP level by itself. These results suggest that T-588 enhances the neuronal transmitter system not only by increasing ACh and NA releases, but also by facilitating PI hydrolysis and cAMP formation.

## 377.4

A COMPARISON OF THREE CLASSES OF CALCIUM CHANNEL ANTAGONISTS ON MEMORY IN MICE Victoria Garcia deSoria, Kevin Phelan\* & David Quartermain Lab. Behavioral Neurology, NYU Medical Center and Pfizer Inc. New York, N.Y.

Calcium channel antagonists (CCA's) of the dihydropyridine class such as Nimodipine, Amlodipine and Nifedipine can facilitate learning and memory but little information is available on the other types of CCA's. The purpose of the present study was to compare the effects on memory of drugs representing the three main classes of CCA's. The following drugs were used: Amlodipine, Nimodipine, Nifedipine (Dihydropyridines), Verapamil (phenylalkalkylamines) and Diltiazem (Benzothiazepines). 1. Different doses of the drugs were injected immediately after training in a passive avoidance task. Results showed that all agents improved retention in a dose dependent manner with Verapamil producing the weakest effects. 2. The most effective doses of each drug were injected immediately after training (5 trials) in an spatial discrimination task. Results indicated that all drugs enhanced retention with the dihydropyridines showing the strongest effects.

## 377.5

A COMPARISON OF THE EFFECT OF CALCIUM CHANNEL ANTAGONISTS ON SHORT AND LONG TERM MEMORY. David Quartermain\* & Victoria Garcia deSoria. Lab. of Behavioral Neurology, NYU Med. Cntr. New York, N.Y.

Short and long term memory was studied using a spontaneous alternation task in a T maze. Mice were given either 1 or 4 forced choices to one arm followed by a single free choice trial at intervals ranging from 10 min to 5 d. after training. Mice given 1 trial exhibited STM (ie chose the opposite arm) at all intervals out to 20 min. but not beyond. Animals given 4 trials showed good memory (80% to 90% correct choices) at all intervals to 24 h. By 3 d. performance had declined to 70% and became random 5 d. post training. Various Ca channel antagonists were administered before the training trial. Results showed that amlodipine, nimodipine, diltiazem verapamil & flunarazine improved STM with amlodipine showing the strongest enhancement effects. Only amlodipine and nimodipine significantly improved LTM.

## 377.7

CALCIUM ENTRY BLOCKER AMELIORATE NEURONAL DAMAGE AND PLACE LEARNING IMPAIRMENT OF RATS WITH TRANSIENT FOREBRAIN ISCHEMIA. R. Tamura\*, Y. Nakada, Y. Takamura and T. Ono. Dept. Physiol., Fac. Med., Toyama Medical and Pharmaceutical University, Toyama 930-01, Japan.

Effects of ( $\pm$ )-1-(3,4-dimethoxyphenyl)-2-(4-diphenylmethyl-piperazinyl) ethanol dihydrochloride (tamolarizine), a calcium entry blocker, on ischemic neuronal damage (selective neuronal death in the hippocampal CA1 subfield) and place learning impairment were studied in rats with transient forebrain ischemia. Rats were subjected to forebrain ischemia (occlusion of the bilateral common carotid and vertebral arteries) for 15 min, and received an intraperitoneal injection of tamolarizine (40 mg/kg) or saline just after restoration of blood flow. Place learning was tested in a spatial navigation task in which rats were required to alternate between 2 circular areas located diametrically in a circular open field to obtain intracranial self-stimulation (ICSS) rewards. In this task, rats in the ischemia+saline group showed severe learning impairment and, during the test period (30 days), they did not reach the same performance level as normal rats, while rats in the ischemia+tamolarizine group showed mild learning impairment, but reached the normal performance level. There were no significant differences of spontaneous locomotor activity and sensitivity to ICSS rewards between the ischemia+saline and ischemia+tamolarizine groups. The extent of selective neuronal death in the hippocampal CA1 subfield of rats in the ischemia+tamolarizine group was remarkably weaker than that of rats in the ischemia+saline group. These results indicate that blockade of calcium entry by tamolarizine treatment suppresses selective neuronal death in the hippocampal CA1 subfield, which consequentially prevents the impairment of place learning.

## 377.9

EFFECTS OF L-ARGININE ON SPATIAL MEMORY IN RATS: ROLE OF NITRIC OXIDE. K. Sato and T.J. Maher\*. Div. Pharm. Sci., Massachusetts College of Pharmacy/AHS, Boston, MA 02115.

While much information is available regarding the role of nitric oxide (NO) in synaptic events measured in *in vitro* systems that are thought to play a role in learning and memory, little information exists documenting the effects of NO in whole animal behavioral paradigms. Thus, the present study attempted to manipulate NO neurotransmission via the administration of the NO precursor L-arginine (L-ARG) alone, or in combination with, the NO synthase inhibitor N-nitro-L-ARG methylester (L-NAME), while determining performance in a spatial memory task utilizing rats. Parameters of performance in the Morris water maze (latency to locate platform, swim path length, and time spent in the platform quadrant during the probe trial) were significantly improved by pretreatment with L-ARG (100-400 mg/kg, i.p.) when compared to controls ( $p < 0.05$ ). L-NAME alone, 500 mg/kg, but not 300 mg/kg, significantly ( $p < 0.05$ ) impaired performance. None of the above treatments produced their observed effects via alterations in swimming ability as determined by measuring swim speed. Co-administration of either dose of L-NAME with L-ARG (200 mg/kg) significantly ( $p < 0.05$ ) attenuated the previously observed performance enhancement. These studies document the spatial memory enhancing abilities of the amino acid L-ARG in rats, and provide further evidence for a role of NO in these behaviors.

Supported in part by a grant from the Center for Brain Sciences and Metabolism Charitable Trust.

## 377.6

EFFECT OF CHRONIC ADMINISTRATION OF THE CALCIUM CHANNEL BLOCKER AMLODIPINE ON LEARNING AND RETENTION IN MICE. Michael Reilly, Victoria Garcia deSoria, Anne Shemer\* & David Quartermain Pfizer Inc. & Lab. of Behavioral Neurology NYU School of Medicine.

The calcium channel antagonist Amlodipine (AM) can facilitate memory when administered acutely immediately after training. The effect of chronic administration is not known. This study reports three experiments which show that AM does not lose its effectiveness as a memory enhancer with chronic administration. 1. Mice were injected daily with 5 mg/kg AM for 14 days prior to training on a spatial discrimination. Immediate post training AM was as effective in enhancing retention as it was in a group treated chronically with saline. 2. Mice trained to 4/5 avoidances in a one way active avoidance (AA) task showed substantial forgetting 14 days later. This forgetting was alleviated in mice treated daily with AM for 14 days. 3. Mice given AM daily prior to training showed an increased rate of learning of AA. These results show that chronically administered AM can facilitate retention and prevent spontaneous forgetting.

## 377.8

INHIBITION OF ENDOGENOUS NITRIC OXIDE SYNTHESIS FACILITATES ASSOCIATIVE LEARNING. W. Du\*, A.G. Romano, V.A. Aloyo and J.A. Harvey. Div. of Behavioral Neurobiology, Dept. of Pharmacology, The Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA 19129.

Nitric oxide (NO) has been suggested to play an important role in synaptic plasticity and learning. We examined the effects of L-NAME, a specific and competitive inhibitor of NO synthetase, on classical conditioning of the rabbit's nictitating membrane response. Rabbits received injections of saline ( $n=11$ ) or L-NAME (25 mg/kg,  $n=11$ ), 60 min prior to each of 4 daily conditioning sessions. Standard conditioning procedures employed a tone CS and an air puff US. L-NAME-treated animals demonstrated an enhanced acquisition of CRs across conditioning days as compared with controls. L-NAME treated animals required 54 fewer trials to achieve the criterion of 5 ( $p < 0.001$ ) and 47 fewer trials to achieve the criterion of 10 ( $p < 0.05$ ) consecutive CRs. The enhanced acquisition of CRs produced by L-NAME was not due to an effect on nonassociative processes or changes in blood pressure. Thus, inhibition of endogenous NO synthesis results in facilitation of associative learning. These results suggest that NO normally functions as a tonic inhibitory modulator of associative learning and that procedures aimed at decreasing its production may provide a novel approach for improving learning. This work was supported by NIMH grant MH16841.

## 377.10

THE ROLE OF NITRIC OXIDE IN DIZOCILPINE-INDUCED IMPAIRMENT OF SPONTANEOUS ALTERNATION BEHAVIOR IN MICE. K. Yamada\*, Y. Noda and T. Nabeshima. Department of Neuropsychopharmacology and Hospital Pharmacy, Nagoya University School of Medicine, Nagoya 466, Japan.

We investigated the role played by nitric oxide in the dizocilpine-induced impairment of both spontaneous alternation behavior in a Y-maze and of passive avoidance performance in a multiple passive avoidance task in mice. Dizocilpine impaired the spontaneous alternation behavior, and the retention of passive avoidance, without affecting acquisition, in the multiple passive avoidance task.  $N^G$ -nitro-L-arginine methylester (L-NAME), an inhibitor of nitric oxide (NO) synthase, dose-dependently impaired the spontaneous alternation behavior, but had no effect on either the acquisition or retention of passive avoidance. The inhibitory effect of L-NAME on the spontaneous alternation behavior was completely reversed by the co-administration of L-arginine. Pretreatment with L-arginine ameliorated the dizocilpine-induced impairment of spontaneous alternation behavior, but not the impairment of the retention of passive avoidance. Finally, the impairment of spontaneous alternation behavior caused by dizocilpine was significantly diminished by pretreatment with dibutyryl cyclic GMP. These results suggest that, although N-methyl-D-aspartate receptors play a critical role in both spatial working memory and long-term memory processes, assessed by spontaneous alternation behavior and the passive avoidance, respectively, different neuronal mechanisms may be involved in these two processes. Further, it is suggested that the NO/cyclic GMP system may play a role in spatial working memory.

## 377.11

EFFECTS OF PROPENTOFYLLINE, A NERVE GROWTH FACTOR (NGF) SYNTHESIS STIMULATOR, ON CHOLINERGIC DYSFUNCTION INDUCED BY THE INFUSION OF ANTI-NGF ANTIBODY INTO RAT'S SEPTUM. I. Nabeshima\*, Y. Ogiwara, A. Nitta, J. Onishi and Y. Noda. Department of Neuropsychopharmacology and Hospital Pharmacy, Nagoya University School of Medicine, Nagoya 466, Japan.

Alzheimer's disease (AD) is characterized by the loss of cholinergic neurons. Since nerve growth factor (NGF) plays an important role in the survival and maintenance of cholinergic neurons in CNS, NGF may have some beneficial effects in the patients with AD. We investigated the effects of oral administration of propentofylline, having potent stimulatory effects on NGF synthesis and secretion in mouse astrocytes, on the cholinergic dysfunction induced by the continuous infusion of anti-NGF antibody into the septum. The deficits of performance in water maze, habituation and passive avoidance tasks were produced by the infusion of anti-NGF antibody (10 µg/rat for 14 days). Further, when choline acetyltransferase (ChAT) and cholinesterase (ChE) activities, regarding as the cholinergic marker enzymes, were measured after the behavioral studies, both activities were reduced. The impairment of learning and memory of water maze task, and reduction of ChAT and ChE activities in the anti-NGF antibody-infused rats were recovered when administration of propentofylline (10 and 25 mg/kg p.o., once a day for 19 days) was commenced 3 days before the implantation of mini-osmotic pump, and continued through the period of learning and memory tasks. These results suggest that propentofylline, a NGF synthesis stimulator, may provide a new therapeutic approach to the patients with AD.

## 377.13

AIT-082 DELAYS THE ONSET OF AGE-INDUCED WORKING MEMORY LOSS. R.F. Ritzmann\*<sup>1,2</sup>, A.J. Glasky<sup>1,2</sup>, J. Prisceari<sup>2</sup>, and M.P. Rathbone<sup>3</sup> <sup>1</sup> Adv. ImmunoTherapeutics, Tustin, CA 92680, <sup>2</sup> Olive View/UCLA MC, Sylmar, CA 91342 and <sup>3</sup> Depts. Biomed. Sci. and Medicine, McMaster U., Hamilton, Ontario L8N 3Z5

AIT-082, a purine derivative, has been shown to improve working memory in the win-shift test (Pharmacol. Biochem. Behav. 47:325-329, 1994). This test employs a T-maze and by increasing the time of the interval between trials, the duration of memory trace can be determined. In normal adult C57B/6 mice, the longest delay that these mice can remember is 120 seconds; AIT-082 (30mg/kg) increased the duration to over 180 seconds. NG-Nitro-L-arginine methyl ester (L-NAME), an inhibitor of NO production, at 30mg/kg inhibited memory in the win-shift test but the inhibition was blocked by AIT-082. Thus, AIT-082 acts downstream from nitric oxide. Normal mice show a progressive deficit after 16 months of age and by 20 months can no longer perform at a 10 second interval. AIT-082 (30 mg/kg/day) administered in the drinking water beginning at 14 months (prior to the appearance of any age-induced deficit), maintained the average duration of the memory trace of 60 minutes at 21 months. This demonstrated a 3 month delay in the onset of age-induced deficits. Analysis of the data showed that the age-induced deficit although delayed occurred in only half the subjects. The remaining mice continued to perform at normal level at 21 months of age. The neurochemical basis for this differences in responsiveness is under investigation. In vitro, studies have suggested a carbon monoxide/guanylate cyclase site for the action of AIT-082. (Supported by NIA AG09911 and the Hospital for Sick Children Foundation)

## 377.15

FACILITATIVE EFFECT OF GLUCOSE ON OBJECT RECOGNITION MEMORY IN MICE. C. Messier\* and V. Pelletier. School of Psychology, U. of Ottawa, (Ont) Canada K1N 6N5.

The memory-improving effect of glucose has been demonstrated in rodents and humans. In rodents, this effect has been observed using a variety of memory tests that have no direct equivalent in humans. Similarly, glucose improvement of memory in humans was observed in tests that cannot be applied to rodents. In the present experiment, we have examined in mice the effect of post-training glucose on the memory for objects. Animals were first placed in an empty open field for two 3-min habituation periods. The next day, the animals are placed for 3 min in the open field that now contained two identical objects. The time taken to observe and explore the objects was recorded. Immediately after, the animals were given either a saline or glucose (500 mg/kg) injection. Two additional groups received a glucose injection one or five hours post-training and one group of mice received no treatment. The next day, animals were placed again for 3 min in the open field with one of the previously observed object and one new object. The objects exploration time was again recorded. Results showed that the animals that received the immediate glucose injection spent more time exploring the new object while no such effect was observed for the various control groups. These results suggest that glucose retroactively improved the memory for previously observed objects in the same way as it has been shown to improve memory in other behavioral tasks.

INHIBITION OF NITRIC OXIDE SYNTHASE DISRUPTS THE EXTINCTION OF CONDITIONED FEAR IN THE RAT. P.L. Malen\* & P.E. Chapman. Graduate Program in Neuroscience and Department of Psychology, University of Minnesota, Minneapolis, Minnesota, 55455.

Inhibition of nitric oxide synthase (NOS) affects the induction of some forms of long-term potentiation and disrupts the acquisition of different forms of learning. We have reported that systemic administration of an NOS inhibitor disrupts the extinction of conditioned fear in rats. To more fully characterize the effects of NOS inhibition on conditioned fear, we have used a conditioning paradigm designed to isolate different components of conditioned fear. Our results indicate that NOS inhibitors administered directly to the brain are as effective as those given systemically at retarding the extinction of cued conditioned fear.

Male rats were maintained on a 22-hour water restriction schedule throughout the experiment. Rats received conditioning in a distinctive chamber designated context A. A conditioning session consisted of ten pairings of a 60 second tone coterminating with a footshock. Following testing of cued conditioned fear levels in a different chamber (context B), animals received extinction training in context A that consisted of five 60 second tones and no footshocks. The level of cued conditioned fear was then measured in context B. The conditioned fear response to the tone was measured as a relative decrease in drinking during the tone. We considered fear conditioning extinguished when animals licked at baseline levels following the repeated tone-alone presentations.

Systemic administration of 75 mg/kg L-NAME (a NOS inhibitor) significantly disrupted the extinction of cued conditioned fear ( $p < 0.05$ ). Direct infusion of 500 nmols of L-NAME into the lateral ventricle also significantly disrupted the extinction of cued fear ( $p < 0.05$ ). Our results, although preliminary with respect to the contextual component of conditioned fear, indicate that the effects of NOS inhibition appear to be specific for the extinction of cued conditioned fear. (Supported by Whitehall Foundation & NSF grants to PFC.)

ICV INSULIN INCREASES PERFORMANCE ON A PASSIVE-AVOIDANCE TASK. C.R. Park\*, R.J. Seeley, and S.C. Woods. Depts. of Behavioral Neuroscience and Psychology, University of Washington, Seattle, WA 98195-1525

Woods and Strubbe have proposed that associative factors are major regulators of ingestive behavior. Animals may become conditioned to ingesting food when exposed to certain external or internal cues which have become associated with food presentation. Since food intake is followed by increased insulin levels, an effect of insulin on hippocampal processes involved in memory could enhance the ability to learn such an association. This experiment determined whether insulin has a modulatory role on memory formation.

Naive, Long-Evans rats ( $n=25$ ) were implanted with third ventricular cannula. The animals were trained on a step-through, passive avoidance procedure, in which latency to enter a darkened compartment was the dependent measure. On the training trial, after entering the darkened compartment, the animals received a mild foot shock. The animals were then removed and received an injection of either 4 mU insulin, heat-deactivated insulin or saline vehicle (4 µl). After 24 hours, the animals were tested in the apparatus again.

Compared to saline or heat-deactivated insulin, animals receiving standard insulin had a statistically significant increased latency to enter the dark compartment when retested ( $p=0.037$  and  $p=0.001$  respectively). This difference is consistent with an increased ability to remember the negative consequences of entering.

## 377.16

INFLUENCE OF GLUCOSE AND GLUCOREGULATION ON HUMAN MEMORY IN OLDER SUBJECTS. R. Curwin\*, M. Gagnon, V. Knott and C. Messier. School of Psychology, U. of Ottawa, (Ont) Canada K1N 6N5.

We examined changes in cognitive performance following drinking a glucose (50 g) or saccharin solution (50 mg) in fasted older male and female subjects. Blood glucose levels were measured and a recovery index was computed: it was used to categorized poor and good recovery subjects within each sex. For the Wechsler paragraph immediate recall, a significant interaction was observed between gender, recovery, and glycemic (glu/sacc) condition. Post hoc analysis revealed that poor recovery males showed significantly poorer performance on immediate recall of the first paragraph under the glucose condition. Males with good recovery and females with both poor and good recovery displayed no significant differences of immediate recall between glycemic conditions. For the ADAS word list learning trials, a similar interaction was also observed for the second and third learning trials. Post hoc analysis revealed that good recovery males tended to benefit from glucose consumption in learning word lists whereas poor recovery males and both good and poor recovery females did not. There were no significant differences on the first learning trial between gender, recovery or glycemic condition. With delayed recall of paragraphs, no significant differences were observed. Nevertheless, poor recovery males tended to do poorer than good recovery males and both poor and good recovery females on delayed recall. No significant differences were found for other memory measures such as verbal paired associate learning and recognition memory.

## 377.17

CONTEXT-DEPENDENT EFFECTS OF GLUCOSE AND TIME-DEPENDENT EFFECTS OF FRUCTOSE ON THE MODULATION OF A REACTIVATED MEMORY. W. A. RODRIGUEZ\*, C. A. HORNE, and J. PADILLA. Psychobiology Lab, New Mexico Highlands Univ., Las Vegas, NM 87110.

A passive avoidance-to-active avoidance negative transfer paradigm was used to investigate the context-dependent effects of glucose and the time-dependent effects of fructose on reactivated memories in rats. In both experiments, memory reactivation consisted of re-exposing the rats 24 after passive avoidance conditioning to environmental cues present during training; and post-reactivation injections of glucose (100 mg/kg, sc) and fructose (100 mg/kg, sc) or saline were followed 24 h later by active avoidance (reversal) conditioning. In Experiment 1 glucose or saline was administered immediately after one of three reactivation-context treatments: experimental context + US (footshock), experimental context only, or novel context + US. Glucose administered in the experimental context, but not in the novel context, impaired active avoidance conditioning (i.e., enhanced passive avoidance memory) compared with saline treatment. In Experiment 2, fructose or saline was administered in the experimental context 0, 2, 5, or 30, min, or in the colony room 60 min, after reactivation. The results showed a time-dependent decrease in the ability of fructose to modulate a reactivated memory. Together, these results indicate that modulation by sugars of old (reactivated) memories depends on where and when the sugar is administered.

## 377.19

DIETARY SATURATED FATTY ACIDS IMPAIR LEARNING AND MEMORY IN RATS. C.E. Greenwood<sup>1,2\*</sup> and G. Winocur<sup>2</sup>. Dept. Nutr. Sci.<sup>1</sup>, Univ. Toronto, Toronto, Ont., Canada M5S 1A8; Rotman Inst.<sup>2</sup> and Dept. Food & Nutr. Services<sup>3</sup>, Baycrest Centre for Geriatric Care, North York, Ont., Canada M6A 2E1.

At one month of age, Long Evans rats (n= 8/group) were placed on one of four high fat diets (20 % wt/wt) varying in fatty acid (FA) composition or chow (4.5% fat). The saturated fatty acid (SFA) levels of experimental diets ranged from 9.5% to 3% of total diet, with fat blends allowing for the dissociation of the effects of the SFAs from those of either monounsaturated (MUFA) or polyunsaturated (PUFA) fatty acids. After three months of feeding, rats were tested on a variable interval delayed alternation task. Impairment in both the ability to learn the basic alternation rule as well as remembering trial-specific information over time was observed in all animals fed the experimental diets relative to those consuming chow. The degree of impairment was highly associated with the level of SFAs fed and independent of the levels of either the MUFAs or PUFAs provided. Brain membrane phosphatidylcholine FA profile was altered by the different dietary fats fed. However changes in FA profile across diets showed no direct association with the cognitive impairment. The results provide evidence that cognitive impairment in weanling rats is directly associated with intake of SFAs and suggest that the mechanism whereby SFAs mediate their effect is independent of brain membrane compositional changes. (NSERC)

## 377.21

THE INFLUENCE OF NICARDIPINE AND IFENPRODIL ON THE BRAIN FREE ARACHIDONIC ACID LEVEL AND BEHAVIOR IN HYPOXIA-EXPOSED RATS. V. Eraković\*, G. Župan, J. Mršić, A. Simonić, J. Varljen\*. Department of Pharmacology, Department of Chemistry and Biochemistry\*, Medical School, University of Rijeka, Braće Brannetia 20/I, Rijeka, Croatia.

Cerebral hypoxia is associated with increase of intracellular calcium concentration and free arachidonic acid (FAA) level and followed by various behavioral disturbances. The aim of this study was to investigate the effect of calcium channel blockers, nicardipine and ifenprodil, on the brain FAA level and learning ability in rats exposed to hypoxia. The study was carried out on Hannover-Wistar rats weighing 250 g. They were injected with 0.03; 0.1; 0.3 or 1 mg/kg of tested drugs i.p.. Thirty minutes later the learning ability was tested in a passive avoidance task according to the step-through procedure. Immediately after the training trial, the animals were subjected to a period of oxygen deprivation hypoxia until losing of the righting reflex. The retention trial was carried out 24 hours later. Other group of animals was pretreated with mentioned substances before hypoxia-exposure. Fifteen minutes after losing of the righting reflex they were decapitated and brains were frozen in liquid nitrogen. The FAA level was quantified by gas chromatography. Our results show that both nicardipine and ifenprodil were effective in preventing a memory decline in hypoxia-exposed rats. Nicardipin did not prevent the accumulation of the brain FAA contrary to ifenprodil which produced statistically significantly decrease of the brain FAA level in hypoxia-exposed rats.

## 377.18

INTRA-SEPTAL INFUSIONS OF A MU OPIOID RECEPTOR AGONIST IMPAIR SPONTANEOUS ALTERNATION PERFORMANCE: CONCURRENT GLUCOSE INFUSIONS ATTENUATE THE DEFICIT. M.B. Parent\*, F.J. Lexcen, M.R. Stefan, V.A. Louis, P.T. Laurey, & P.E. Gold. Dept. of Psychology, Univ. of Virginia, Charlottesville, VA 22903.

Infusions of the opioid agonist morphine into the rat medial septum impair spatial working memory, including performance on a spontaneous alternation task. The morphine-induced performance impairments are blocked by concurrent administration of glucose, injected either systemically or intra-septally. The present study sought to identify the opioid receptor subtype(s) which may participate in these effects. With evidence that the medial septum contains a high density of  $\mu$  opioid receptors, the effect of intra-septal infusions of the selective  $\mu$  opioid agonist [D-al<sup>2</sup>, N-Me-phe<sup>4</sup>, gly<sup>5</sup>]-enkephalin (DAMGO) on spontaneous alternation performance was examined. Intra-septal infusions of DAMGO (0.3 nmol), administered 30 min prior to testing, significantly impaired spontaneous alternation performance. Concurrent intra-septal infusions of glucose (16.7 nmol) attenuated the DAMGO-induced deficit. These results indicate that activation of  $\mu$  opioid receptors in the medial septum impairs spatial working memory. These findings suggest that intra-septal morphine infusions may impair spontaneous alternation performance via activation of  $\mu$  opioid receptors. Combined with other evidence from our laboratory indicating that glucose does not reverse memory impairments induced by central injections of noradrenergic antagonists or GABAergic agonists, these findings further suggest that glucose may interact primarily with  $\mu$  receptor-mediated processes to influence learning and memory. [Supported by NIA (AG 07648), NINDS (NS32914), and NIH (HD07323)].

## 377.20

THE INFLUENCE OF NIMODIPINE AND MK-801 ON THE BRAIN FREE ARACHIDONIC ACID LEVEL AND THE LEARNING ABILITY IN HYPOXIA-EXPOSED RATS. J. Mršić\*, G. Župan, V. Eraković, A. Simonić, J. Varljen. Department of Pharmacology, School of Medicine, B. Brannetia 20/I, Rijeka, Croatia.

A number of reports indicated that a disturbance in calcium homeostasis induced by hypoxia is accompanied with increase in free arachidonic acid (FAA) level and behavioral deficits. The purpose of this study was to investigate the effects of calcium channel blockers, nimodipine and MK-801 on the brain FAA level and learning ability in hypoxia-exposed rats. The study was carried out on Hannover-Wistar rats weighing 250 g. They were injected with 0.03; 0.1; 0.3 or 1 mg/kg of tested drugs. Thirty minutes later the learning ability was tested in a passive avoidance task according to the step-through procedure. Immediately after the training trial, the animals were subjected to a period of oxygen deprivation hypoxia until the loss of the righting reflex. The retention trial was carried out 24 hours later. A part of animals was pretreated with calcium channel blockers tested and exposed to the hypoxic conditions. Fifteen minutes after losing the righting reflex they were decapitated and brains were frozen in liquid nitrogen. The FAA was separated by thin-layer chromatography, methyl esters were prepared by methanolysis and quantified by gas chromatography. The level of FAA was measured. It has been found that nimodipine was effective in reversing the significant increase of the brain FAA level and memory decline in hypoxia-exposed rats. MK-801 prevented the accumulation of the brain FAA, but did not improve the memory deficit in hypoxic animals.

## 378.1

LEFT LATERAL ORBITOFRONTAL ACTIVATION DURING AVERSIVE OLFACTORY STIMULATION. D. H. Zald, P. J. Pardo\* & J. V. Pardo. Psychiatry PET Unit, Psychiatry Service, VAMC, Dept. of Psychology and Division of Neuroscience Research, Department of Psychiatry, University of Minnesota, Minneapolis, MN

The perception of olfactory stimuli is dominated by a hedonic (pleasantness-unpleasantness) dimension. We utilized this hedonic characteristic of olfactory perception to study the neural correlates of emotional processing in humans. Ten psychiatrically healthy female subjects were exposed to aversive, moderately pleasant, or no odor conditions while cerebral blood flow (rCBF) was measured with a slow bolus  $H_2^{15}O$  technique and PET. Exposure to aversive olfactory stimuli produced the greatest rCBF increase in the left lateral orbitofrontal cortex (Brodmann's area 47). The increase in rCBF in this region was highly statistically significant when the aversive condition was compared to either the pleasant odor or the no odor condition. Preliminary data from experiments with affectively valenced gustatory stimuli indicate that this same area is activated during aversive gustatory stimulation. These data provide evidence that the left lateral orbitofrontal cortex plays a role in the processing of aversive chemical stimuli.

This research was supported by the Department of Veterans Affairs and an Eva O. Miller Fellowship from the University of Minnesota.

## 378.3

RECRUITMENT AND RETENTION OF HISPANIC ELDERLY IN A MUSCULOSKELETAL STUDY. R. Ramirez-Delav\*, M.L. Villa and R. Marcus. Stanford University and PAVAMC, Palo Alto, CA 94304.

Scant information exists concerning recruitment and retention of minority elders into clinical studies, although survey non-participation is high among general elderly groups. We are conducting a study that enjoys a retention rate of 95% after 3 years, and explored reasons why subjects decided to participate and continue participation. 152 healthy Mexican-American women aged 60-85 years enrolled in a 5 year study of osteoporosis. Volunteers were recruited through community agencies, churches and word of mouth, from 4/92 to 3/93 from a group of 257 women interviewed during the recruitment campaign. Following enrollment, all subjects were contacted monthly. At the screening interview, all were asked how they heard about the study. Responses were compared with the answer to the same question 2 years later when 135 of the original cohort were interviewed. Other questions included: reasons for participation; perception of personal benefit; and opinions about quality of attention received. Subjects averaged  $66 \pm 6$  yr. of age and 9.5 yr. of education; 22% spoke Spanish only; 19% mostly Spanish; 30% both languages equally; 29% mostly English; and less than 1% English only. Average acculturation score (Espino and Maldonado) was  $2.1 \pm 0.9$ . Social network (friends and community centers) was reported as the primary source of study information by 71% of subjects at time of initial contact, compared to 67% recalled at the 3rd visit. The primary reason for participation and the most important benefit received from participation was information concerning health status (62%); 95% reported benefits from participation; 80% rated quality of attention received as very good and 19% as good. Conclusion: These Hispanic elders enrolled primarily due to a local community recruitment approach. Retention was enhanced by perception of personal benefit and continuity in follow-up. Funded by the NIA and the Research Service of the Dept. of Veterans Affairs.

## 378.5

FUNCTIONAL ANATOMY OF GO/NO-GO DISCRIMINATION IN MAN -A PET STUDY-. R. Kawashima\*, H. Itoh, S. Ono, K. Satoh, S. Furumoto, R. Gotoh, M. Koyama, S. Yoshioka, K. Takahashi\*, T. Takahashi\*, T. Yanagisawa\*, H. Fukuda. Dep. Nucl. Med. & Radiol., IDAC, Tohoku Univ. Sendai, 980-77 JAPAN, #Dep. Radiol., Iwate Medical Univ. Morioka, 020 Japan.

The purpose of this study was to identify the functional fields activated in relation to the NO-GO decision. Nine healthy subjects participated in the study which consisted of two test positron emission tomography scans, GO/NO-GO (GNG) task and response selection (RS) task, and one control scan. In the RS task, subjects were asked to flex their thumb of the right hand when a light emitting diode (LED) placed 60 cm from their eyes turned on red and to flex their index finger of the right hand when LED turned on green. In the GNG task, subjects were asked to flex their thumb when the LED turned on red, however, they were asked not to move their fingers when LED turned on green. In the control state, they were asked simply to look at the LED without any movement of finger during the course of the scan. The mean regional cerebral blood flow (rCBF) change images for each task minus control and task minus task were calculated and fields of significant rCBF changes were identified. Several fields in the prefrontal cortex of the right hemisphere were specifically activated in relation to the GNG task. The results indicate that the prefrontal cortex of the right hemisphere may be a key structure to make a decision not to move.

## 378.2

SHOCK INDUCED ANTICIPATORY ANXIETY: IMPACT OF RIGHT OR LEFT HEMISPHERIC LESIONS IN HUMANS. B. Slomine, D. Bowers\*, K. M. Heilman, R.M. Bauer, & M. Bradley. Depts. of Neurology & Clinical Psychology, University of Florida College of Medicine, Gainesville, FL 32610.

When shown pictures of affective scenes, patients with right parietal lesions fail to display normal autonomic aroused (e.g., SCR). Because such lesions are associated with visuo-perceptual and hemispatial attentional disturbance, reduced autonomic reactivity to emotional pictures may be secondary to perceptual/attentional difficulties. To circumvent the "visuo-perceptual" explanation, we evaluated 24 focal stroke patients (12 right, 12 left) and 24 controls on a *shock induced anticipatory anxiety task*. In this task, onset of one target tone signaled that the S would receive a mild electric stimulus 6 seconds later (shock condition), whereas onset of another target tone indicated that no shock would be forthcoming (control condition). Psychophysiological data were collected over 40 trials along with verbal ratings of subjective affective state. During anticipation of shock, the LH and control Ss showed increased SCR arousal in conjunction with increased negative ratings of their emotional state. In contrast, the RH patients displayed a dissociation between SCR and verbal report: they failed to show increased SCR when awaiting shock, although their subjective ratings reflected increased negativity. This dissociation suggests that lesions of RH can disrupt generation of autonomic arousal during aversive situations, while leaving operational the appraisal of one's subjective affective state. Supported by NIMH48861.

## 378.4

CORTICAL AROUSAL PATTERNS IN RESPONSE TO EMOTIONAL AND NEUTRAL AUDITORY STIMULI. M. Vaninjan\*, and J. Panksepp. Dept. of Psychology, Bowling Green State University, Bowling Green, OH 43403.

Previous work has demonstrated that event related synchronization (ERS) is a sensitive index of dynamic cortical arousal patterns. In the present research ERS analysis was used as a method for discriminating neurophysiological affective states. Cortical activity was measured in 10 adult females with a standard EEG array of 19 electrodes. Responses to happy and sad music, female voice and white noise were analyzed.

It was found that the ERS analysis in the alpha frequency band (8-12 Hz) differentiated cortical arousal in response to happy versus sad music. Overall, a trend was found for smaller synchronization increases during the sad versus happy music. The most robust statistical differences appeared during the third and fourth seconds following music-onset. More specifically, during the third second there was greater synchronization during sad versus happy music at electrode site F4. During the fourth second there was less synchronization during sad versus happy music at electrode sites F3 and C3.

The ERS analysis also unambiguously differentiated cortical responses to a female voice versus white noise. There was less synchronization at all electrode sites, at all times, in response to the voice versus noise. The most robust statistical differences appeared during the second and third seconds following stimulus-onset. During the second second, the synchronization increase was smaller during voice versus the noise conditions at electrode sites P3, F7 and T4. One second later there was less increased synchronization during the voice versus noise at electrode sites Fp2, F3, F4, C3, P3, P4, T5, Fz, Cz, Pz, O1 and O2.

The results suggest that the ERS analysis is one method for determining different cortical arousal patterns in response to affective and neutral stimuli.

## 378.6

TRYPTOPHAN DEPLETION AND AGGRESSIVE RESPONDING IN HEALTHY MALES. F.G. Moeller\*, D.M. Dougherty, A.C. Swann, D. Spence, C.M. Davis, and D.R. Cherek. Human Psychopharmacology Laboratory, Dept. of Psychiatry and Behavioral Science, The University of Texas - Houston, Houston, TX 77030.

In order to study the effect of decreasing plasma tryptophan levels on aggressive responding in a controlled laboratory setting, we administered two doses (25 g and 100 g) of a tryptophan-free amino acid mixture to 10 healthy male subjects after 24 hours of a low tryptophan diet. Subjects were screened for current or past psychiatric, or non-psychiatric medical illness. Aggressive responding on a free-operant laboratory measure of aggression, (the Point Subtraction Aggression Paradigm), and plasma tryptophan levels were measured before and after drinking the amino acid mixture. There was a significant increase in aggressive responding after the 100 g mixture and a non significant increase in aggressive responding after the 25 g mixture. There was also a significant decrease in plasma tryptophan at 5 hours after ingestion compared to baseline for both doses of the amino acid mixture. This study supports the hypothesis that tryptophan depletion increases aggressive responding in healthy males in a laboratory setting, probably by decreasing brain serotonin.

## 378.7

## CORTICAL EVOKED POTENTIAL AND fMRI MEASURES OF EMOTIONAL PERCEPTION.

P. J. Lang\*, B. N. Cuthbert, M. M. Bradley, and J. R. Fitzsimmons, Center for the Study of Emotion and Attention, Department of Clinical and Health Psychology, University of Florida, Gainesville, Florida 32610.

Two related experiments were performed to study brain and autonomic responses to pictures varying along affective dimensions of valence and arousal. In one study, 81 subjects viewed 18 pleasant, 18 neutral, and 18 aversive pictures selected from the International Affective Picture System, each presented for 6 s. Cortical potentials were measured with a 10-s time constant from 9 sites along frontal, vertex, parietal, and occipital rows. Vertical and horizontal eye movements were also recorded for removal of eyeblink and saccadic eye movement effects. Slow potentials were positive throughout most of the picture viewing period at frontal, vertex, and parietal sites. These potentials were further modulated by the arousal dimension of picture content, with pleasant and unpleasant pictures (both highly arousing) showing significantly more positivity at all leads compared to neutral content. In contrast, occipital leads showed only a late positive complex peaking at about 400 msec, with minimal subsequent positivity; further, differences among affective contents were minimal. These results suggest that slow waves provide a topographically sensitive measure of affective picture processing. A second fMRI study, assessing reactions to these pictures in a 1.5T GE Signa scanner, was conducted to compare responses in these two measurement domains.

## 378.8

## PROCESSING OF REWARD-RELATED INFORMATION IN PRIMATE ORBITOFRONTAL NEURONS. L. Tremblay and W. Schultz\*, Institut de Physiologie, University of Fribourg, CH-1700 Fribourg, Switzerland.

The involvement of the frontal cortex in the motivational control of behavior was investigated by recording the activity of orbitofrontal neurons (areas 11 and anterior 13) in monkeys performing in a conditional motor task. Animals performed, or refrained from performing, an arm movement in response to a trigger signal depending on a preceding instruction. In order to differentiate reward-related from movement-related activity, movement trials were either rewarded with fruit juice or unrewarded (correct performance indicated by a sound), depending on the preceding instruction. Correct performance in non-movement trials was also rewarded with fruit juice. All trials included delays between 1) the instruction and trigger and 2) the trigger and the reinforcer (reward or sound). Over 400 neurons were recorded from two monkeys, with about half of them exhibiting task-related activity. This study had 3 principal results. 1) Very few neurons showed delay-related activity preceding the behavioral reaction. 2) Reward-related activity was common in orbitofrontal cortex, with half of recorded neurons having activity directly associated with the expectation or reception of primary reward. This activity was absent in unrewarded trials, indicating a true relationship to juice delivery and not to a "correct" or end-of-trial signal. 3) About half of the neurons responded to the instruction. Two thirds of these responses were preferential or selective for one or two trial types, mostly for both rewarded trials (movement and non-movement) or for unrewarded movement trials. These neurons discriminated stimuli based on their reward or non-reward associations. In conclusion these results indicate that, while other prefrontal regions have been implicated in the "what" and "where" of behavioral reactions, the orbitofrontal cortex may be involved in the question of "why" a behavioral reaction is performed.

## BIOLOGICAL RHYTHMS AND SLEEP: PHYSIOLOGY I

## 379.1

## CYCLIC SPONTANEOUS LIMB MOVEMENTS IN NEONATAL RATS AND THEIR RELATION TO BEHAVIORAL ACTIVITY STATES.

M. Dyer\* and C. R. Almli, Developmental Neuropsychobiol. Lab., Washington Univ. Med. Sch., St. Louis, MO, 63108.

Cyclic spontaneous motility is ubiquitous prenatally and postnatally in most species. A 1-3 min cyclicity/periodicity has been found during prenatal and early postnatal development. It has been proposed that the 1-3 min periodicity is an expression of REM sleep states. The present study examined cyclic motility in 1 day old rats as a function of behavioral states.

At PN1, individual rats were videotaped for 20-30 min. Videotapes were scored for numbers of movements of individual limbs, and for duration of active and inactive behavioral states. Active behavioral states were scored when pups displayed ambulation, grooming, or righting movements, i.e., behaviors that appeared homologous to behaviors seen in adult rats. Inactive behavioral states were scored using REM sleep criteria, e.g., limb twitches. Limb movements that occurred during active or inactive behavioral states were analyzed for periodicity with spectral analysis. Results showed that movements were more likely to be cyclic when rats were behaviorally active. When rats were behaviorally inactive, movement periodicities tended to be attenuated or abolished.

These results do not support the proposition that cyclicity of movements in the neonatal rat is restricted to REM sleep states.

## 379.2

## HOW DOES THE STATE OF VIGILANCE MODIFY FREQUENCY RECEPTIVE FIELDS (FRF) IN THE GUINEA-PIG AUDITORY THALAMUS? E. Hennevin\*, Y. Manunta &amp; J.-M. Edeline, NAM URA 1491, Univ. Paris XI, 91405 Orsay cedex, France.

It is well known that thalamocortical neurons display a burst discharge in slow-wave sleep (SWS) and a tonic discharge in both wakefulness (W) and Paradoxical Sleep (PS). However, it is unknown how sensory processing is modified by these changes in functional states of thalamic neurons. In the present experiment, auditory thalamus neurons were studied during W, SWS and occasionally PS phases. Single units were recorded from restrained guinea-pigs via chronically implanted tungsten electrodes. The animals were undrugged and never sleep deprived. EEG (cortical and hippocampal) and EMG activity were continuously monitored during FRF determination. FRF was tested by presenting 11 ascending frequencies to the contralateral ear via a calibrated earphone. Up to 6 intensities were used to test each cell.

During SWS, spontaneous activity was significantly decreased in 14/27 cells (increased in 4/27). Evoked activity was decreased in 15/27 cells (increased in 2/27). The Signal/Noise ratio (S/N) was unchanged. During PS, spontaneous activity was increased in 7/16 cells (decreased in 2/16), while evoked response was decreased in 7/16 cells (increased in 2/16). The S/N ratio was significantly decreased.

Quantification of the frequency selectivity at different intensities should allow a better characterisation of sensory processing during the sleep states.

## 379.3

## FREQUENCY AND VOLTAGE OF THETA WAVES IN THE HIPPOCAMPUS AND CORTEX AS RELATED TO DREAMING PATTERNS IN THE RAT. C. Timó-laria\*, A. C. Valle, K. Sameshima, G. Ballester, L. V. Venturini and V. L. L. Missen, Univ. São Paulo Medical School and Fed. Univ. São Paulo Medical School (EPM), 01246-903 São Paulo SP, Brazil.

Instantaneous voltage and frequency of hippocampal and cortical theta waves were analyzed as related to dreaming behaviors (DB) of the rat. Head (H), rostrum (R), eyes (O), ears (E) and fore- and hindlimbs (L<sub>f</sub>, L<sub>b</sub>) movements were recorded simultaneously with the EEG of several cortical areas and hippocampal fields. It was found that: 1) a DB may be expressed as H, R, O, E, L<sub>f</sub> and L<sub>b</sub> movements alone or as the various possible combinations among them (HR, HO, HRO etc.); 2) during a DB sustained desynchronization occurs only in the frontal cortex and theta waves occur over most cortical areas and in the hippocampal fields; 3) theta frequency and voltage usually increase (typical values: 140  $\mu$ V and 7.5 Hz) during a DB but often both variables augment before and decrease to 5.5 or 6 Hz after DB until a new episode occurs; 4) while DB is in course both variables keep high but voltage changes continuously in distinct areas; 5) when DB is intense frequency increases while voltage decreases for either a few seconds or a few hundred milliseconds, paralleling DB duration. COMMENTS: The increase of both variables before a DB is displayed probably reflects configuration and identification of a dream. The brief dissociation between theta voltage and frequency is in fact a short desynchronization. Desynchronization of the frontal electro-oscillograms in rats and of almost the entire neocortex in primates, including man, is an electrophysiological manifestation of attentive wakefulness and of dreaming activity. Since the frontal cortex and desynchronization are phylogenetically recent acquisitions, the drop in theta voltage while frequency goes up in the rat desynchronized sleep may be related to a high degree of attention to a dream, just as desynchronization in attentive wakefulness. Supported by FAPESP, CNPq, HCFMUSP, FFM.

## 379.4

## UNIQUE DYNAMICS OF RAT HIPPOCAMPAL ELECTROGRAM IN RELATION TO REM SLEEP. J. M. Gaztelu\*, C. Barrenechea and M. Romero, Neurología Experimental, Dpto. Investigación, Hospital Ramón y Cajal, 28034-Madrid.

The aim of this study was to characterize the dynamics of hippocampal and cortical EEGs with respect to rapid-eye-movement sleep (REM) in the rat. Albino male rats were implanted with skull screws for recording the cortical EEG and with electrodes for recording the hippocampal EEG and the temporalis muscle EMG. Data were sampled continuously during 24-48 h and stored. Power spectral density (PSD) in the delta (1-4 Hz) and theta (5.5-8.5 Hz) bands was averaged in periods ranging from 2 to 48 sec. The vigilance states [wakefulness, non-REM sleep, and REM] were scored in two-sec epochs.

Although there was considerable waxing and waning of EEG power in the sec to sec range, there was a rising trend in the hippocampal EEG PSD in the theta band in the sleep epochs preceding REM, state in which it reached a maximum. When REM episodes lasted ca. 1.5-7 min, the rising trend continued during REM well above the mean theta PSD in the 8 min preceding REM onset. In the cortical EEG, theta PSD decreased sharply after REM onset, to continue during REM below the corresponding 8 min pre-REM average. Conversely, both structures showed similar trends in delta power in the epochs before and during REM. Therefore, the hippocampus shows unique dynamics in EEG theta PSD during sustained REM, although it shares with the cortical EEG the dynamics in delta power.

Aided by FIS 95/0048-01.

## 379.5

EFFECTS OF SLEEP DEPRIVATION ON PLASMA FREE AMINO ACIDS IN THE RAT. R.K. Zoltski\* and P. Ramm, Dept. of Psychology, Brock U., St. Catharines, ON L2S 3A1, Canada.

We investigate the metabolic consequences of sleep and sleep deprivation. In this study, we examined plasma free amino acid profiles associated with different conditions of sleep deprivation. A 24 hour island platform deprivation condition (n=16) used medium-sized islands over water. Island platform deprivation replicates the classic REM deprivation paradigm. A computer-scored and driven rocker condition (n=14) produced total sleep deprivation (>99%). A third condition (n=41) was created by manually arousing rats for 4-6 hours. This established a fairly uniform group of minimally-deprived animals with a high level of sleep need. Prior to deprivation, rats received EEG/EMG electrodes and cannulae in the femoral vein and artery. Three days of post-surgical recovery were allowed.

Following the deprivation period and a 3 hour fast, the EEG was recorded for 45 mins and blood samples were taken at 0, 5, and 45 mins. Glucose, haematocrit, the animal's state of vigilance, and fourteen free amino acids were analyzed. The three deprivation conditions are associated with different profiles in five of these amino acids (Table).

Amino acid	Mild dep. (1)	Island (2)	Rocker (3)	(p < 0.05)
glutamine	574.8±13.8	315.5±19.8	290.7±40.6	1'2, 1'3
glycine	374.0±14.0	308.8±13.5	289.5±24	1'2, 1'3
methionine	18.2±1.4	34.0±1.2	16.9±3.9	1'2, 2'3
tyrosine	52.1±1.3	58.1±1.4	62.4±3.4	1'3
histidine	70.0±2.7	71.4±1.1	54.3±4.06	1'3, 2'3

Island and rocker deprivation differ in their effects upon levels of circulating amino acids, and may be targeting different physiological processes.

## 379.7

SLEEP ARCHITECTURE IN KITTENS AFTER BILATERAL MESENCEPHALIC LESIONS THAT ELIMINATE PONTO-GENICULO-OCCIPITAL (PGO) WAVES IN THE LATERAL GENICULATE NUCLEUS (LGN). James P. Shaffery\*, Thomas Fitch, Samuel G. Speciale, Howard P. Roffwarg, Roseanne Armitage and Gerald A. Marks, Dept. of Psychiatry, University of Texas Southwestern Medical Center at Dallas, 75235.

We previously reported that reducing the time kittens spend in rapid eye-movement (REM) sleep during the critical period of visual system development leads to morphological changes in LGN cells. Bilateral mesencephalic lesions severing the ascending pontine cholinergic fibers that are thought to produce PGO-waves, a cardinal feature of REM sleep, while eliminating PGO in LGN, are reported to have no effect upon subsequent sleep amounts. It is possible, however, that such lesions may affect more subtle aspects of sleep architecture in these young animals.

After confirming PGO-waves in baseline records, kittens were anesthetized (Ketamine and Xylazine) and bilateral electrolytic lesions (5mA for 20 s) were performed (P2, L2 5, 3, 5, 11-1). Baseline sleep micro-architecture data are compared with that from post-lesion days three and seven. We report on the structure of sleep bouts and REM sleep cycles. We also quantify ECoG activity within sleep states utilizing a digital period analysis (DPA) algorithm that includes full zero-cross (sensitive to slow frequency events), first derivatives (to detect fast frequency events occurring upon a background of slow waves) and power-in-frequency measures in the following frequency bands: delta 0.5-4Hz, theta 4-8Hz, alpha 8-12Hz, sigma 12-16 Hz, and beta 16-30Hz.

These bilateral brainstem lesions effectively eliminated PGO-waves for the seven days of the experiment. Post-lesion REM sleep measures of bout and cycle, number and length remained at baseline levels. Slow wave sleep (SWS) measures were only slightly increased over baseline, by 10%. Total power was increased over baseline about 20% in both sleep states, resulting largely from increased beta power in SWS (~31%) and REM (~10%) over baseline relative to other power measures. The DPA data suggest that removal of the modulatory influence of pontine cholinergic-generated PGO-waves results in an increase in fast frequency cortical ECoG activity.

EFFECTS OF REM SLEEP ON EXPERIENCE-DEPENDENT MORPHOLOGICAL DIFFERENCES IN THE VISUAL CORTEX. K.E. Armstrong\*, P. Sinha, C. Solomon, S. Han, W.T. Greenough, Departments of Psychology and Cell and Structural Biology, Neuroscience Program, Beckman Institute, University of Illinois Urbana-Champaign, IL 61801.

Rapid eye movement (REM) sleep has been thought to play a critical role in information processing and memory consolidation. In animals the initial REM sleep episode following any learning task is the most important for the learning and consolidation of that information. A novel method for manipulating REM sleep, ambient temperature variation, was used (Szusiak and Satinoff, 1985). This technique is ideal for measuring morphological changes associated with sleep manipulations because it appears to minimize stress effects relative to other nonpharmacological sleep deprivation procedures. Environmental Complexity (EC) and Individual Cage (IC) rearing conditions were used to vary the opportunity for learning. Previous studies using this paradigm found an increase in occipital cortical thickness in the EC rats (Bennett et al, 1964; Greenough et al, 1985). Our preliminary findings suggest that following as few as 10 days of EC/IC exposure, coupled with ambient temperature manipulations, the increased occipital cortical thickness seen in non-sleep deprived EC rats was reduced in rats deprived of sleep immediately following a 2hr daily exposure to the EC environment. Animals receiving delayed temperature manipulations (4 h after EC exposure) had a thicker visual cortex than did their immediate deprivation counterparts. Supported by MH35321.

## 379.6

THE DEVELOPMENT OF SLEEP HOMEOSTASIS IN THE RAT. M. G. Frank, H. C. Heller, W. C. Dement\*, Dept. of Biological Sci., Stanford Univ., Stanford, CA. 94305

Increases in non-REM sleep (NS) slow wave activity (NSWA) after sleep deprivation (SD) provide an index of sleep homeostasis in adult and juvenile rats. We investigated the effects of SD on sleep homeostasis in neonatal rats during the period of initial NS maturation (P12-P24).

Rat pups were implanted for EEG/EMG recording and sleep deprived for 3h at light onset using forced locomotion. SD in P12-P20 rats increased NS and suppressed REM sleep in the first 2h of recovery. Spectral analyses, however, revealed that NSWA did not significantly increase until P24. These findings suggest that P12-P20 neonatal rats respond to SD by increasing NS time and not NS intensity. Therefore sleep homeostasis may be present in neonatal rats but its manifestation as increased NSWA is absent until the fourth postnatal week.

## 379.8

A DEVELOPMENTAL AND COMPONENTIAL ANALYSIS OF ACTIVE SLEEP. M. S. Blumberg\* and D. E. Lucas, Department of Psychology and Neuroscience Graduate Program, University of Iowa, Iowa City IA 52242.

A wide variety of hypotheses have been put forth that address the functional significance of active sleep. Despite, however, the well-accepted fact that active sleep expresses itself predominantly in the perinatal period, the vast majority of these functional hypotheses are applicable largely, if not exclusively, to the adult. We build on the developmental approaches of previous researchers and propose that the individual components of active sleep (e.g., myoclonic twitches, rapid eye movements) exhibit unique developmental and phylogenetic histories and may serve independent functions in the developing organism. This dynamic perspective leads to specific experimental approaches aimed at the developmental roles of these components in the neonate, their maintenance roles in the adult, and the means by which these various components coalesce temporally in what is commonly referred to as a behavioral state.

## 379.10

DIFFERENTIAL PERIODIC EFFECTS OF BRIGHT LIGHT ON TEMPERATURE AND PERFORMANCE RHYTHMS IN RHESUS MONKEYS DEPEND ON THE TIMING OF THE LIGHT PULSE. L.A. Schultz and W.N. Tapp\*, Neurobehavioral Unit, V.A. Medical Center, East Orange, NJ 07018.

Five rhesus monkeys housed in constant light were given single 2 h pulses of 1000 lux bright light (BL) at several points in their day. Each monkey earned all of its daily food aliquot by correct responding on a task that combined a measure of vigilance ability (VIG) with a measure of short-term memory (delayed same/different or DSD). Monkeys were implanted with transmitters that allowed us to continuously monitor body temperature (Tb). BL applied at the start of alpha phase-advanced the Tb rhythm while bright light at the end of alpha phase-delayed the Tb rhythm. In contrast, BL given during the middle of subjective day or during the middle of subjective night did not reliably alter the phase of Tb. The phases of the performance measures were insensitive to light given at any point.

BL also altered the period of Tb and performance rhythms. BL pulses given at the onset of alpha had similar effects on the period of Tb, VIG, and DSD though the direction of the effect varied between monkeys. However, while the direction of the period change in Tb following BL exposure at the end of the subjective day was identical to that following exposure at the start of alpha, BL had a differential effect on the direction of period changes in the performance rhythms. That is, lengthened Tb periods as a result of BL were associated with lengthened DSD periods, but with shortened VIG periods compared to baseline. Likewise, shortened Tb periods following BL exposure at the end of alpha were associated with shortened DSD periods, but lengthened VIG periods.

## 379.11

DAILY SCHEDULED EXERCISE CAN ADVANCE, DELAY OR INVERT ENTRAINMENT TO SKELETON PHOTOPERIODS IN HAMSTERS. Sinclair, S.V., Mistlberger R.E.\* and Marchant, E.G. Psychology, Simon Fraser University, Burnaby, B.C., V5A 1S6.

Daily schedules of exercise can shift the phase of photic entrainment in hamsters. This study utilized a skeleton photoperiod (SPP, two 30 minute light pulses) to better simulate natural dawn and dusk light exposure patterns, and to facilitate observation of transients indicative of possible oscillator decoupling. Sixty-eight adult male Syrian hamsters were housed in cages with activity wheels in a 14:10 LD SPP. Exercise (3h locked in a novel running wheel) was scheduled at one of 5 phases of the SPP. Some of the animals exercised in the middle of their inactive period (ZT4-7) showed 180° inversion of their activity rhythms. Inversion in one animal appeared to be achieved by partition. Animals that did not invert showed small phase advances ( $\bar{x} = .65h \pm .72h$ ). Exercise near the end of the active period (ZT21-24) caused large phase delays of entrained rhythms ( $\bar{x} = 3.29h \pm 5.24h$ ). Exercise at other phases late in the activity period (ZT19-21 and ZT20-23) had minimal effects. Exercise near the beginning of the activity period (ZT9.5-12.5) on average caused phase delays ( $\bar{x} = .64h \pm 1.35h$ ); but, some advances were also observed. The period of free-running rhythms recorded in subsequent constant dark was longer in hamsters that phase-delayed in the ZT9.5 condition, but was not otherwise related to the phase of the prior exercise schedule. There was no evidence that exercise could stably uncouple an activity component from the entrained activity bout (i.e. free-running rhythms were not split in DD). These experiments demonstrate that exercise can have powerful effects on phasing of activity rhythms entrained to SPPs that may better simulate patterns of light exposure in nocturnal and diurnal animals, such as humans, that may spend most of the day shielded from natural light. Supported by NSERC, Canada.

## 379.13

COLD EXPOSURE PHASE-SHIFTS CIRCADIAN RHYTHMS IN HAMSTERS: ROLE OF ACTIVITY AND SEROTONIN. E.G. Marchant\*, S. Sinclair and R.E. Mistlberger. Psychology, Simon Fraser University, Burnaby, BC V5A 1S6.

Circadian rhythms in rodents can be phase-shifted by appropriately timed activity. This may be dependent on the motivational stimulus for activity; running induced by a novel cage or social interaction is effective, whereas running induced by cold has been reported to be less or ineffective. We report here, however, that cold exposure in the home cage (no novelty) induces large phase-shifts that are dependent on activity induction, despite modest activity induction. Adult, male Syrian hamsters (N=24) were housed in plastic cages with activity wheels (17cm) in a ventilated refrigerator. Every 10-14 days, LD (14:10) was replaced by 3-4 days of dim red light (DD). On the first day of DD, 6 h before usual dark onset, the refrigerator was cooled to 4°C for 3 h. Phase shifts of circadian rhythms were quantified by comparing daily activity onsets before and after the cold pulse. By contrast with control tests, cold exposure induced significant phase advances of the wheel-running rhythm ( $106 \pm 53$  min vs.  $15 \pm 21$  min,  $p < .001$ ). Hamsters ate during the cold pulse, but food deprivation did not prevent shifts (N=7). Most hamsters also ran during and after cold exposure (3h total  $486 \pm 652$ , 6h total  $1367 \pm 1335$ , range 0-4003 revolutions). These levels are low by comparison with thresholds for activity-induced phase shifts defined in previous studies, and some hamsters exhibited phase-shifts despite little running. Nonetheless, locking the wheel for 6 h prevented phase-shifting ( $24 \pm 53$  min,  $p > .1$ , N=7). These data indicate that cold-induced running is an effective nonphotic zeitgeber, and contradict the best evidence that motivational contexts determine the phase-shifting value of physical activity. Although 5HT1A agonists induce phase shifts similar to cold-induced running, we have not been able to attenuate cold or novelty induced shifts by preinjections of the 5HT1A antagonist WAY100478 sc. at doses up to 15 mg/kg. Supported by NSERC, Canada.

## 379.15

MEALS INCREMENTALLY AND INSTANTANEOUSLY RESET CIRCADIAN ACTIVITY PATTERNS IN SUPRACHIASMATIC NUCLEUS LESIONED RATS J.M. White\*, W. White and W. Timberlake. Dept. of Psychology and Prog. in Animal Behavior (RTG), Indiana University, Bloomington, IN 47405

The nature of meal-engendered circadian processes of rats with complete lesions of the suprachiasmatic nucleus (SCN) was studied. After receiving electrolytic lesions, female Sprague-Dawley rats were housed, in constant dim light, in stations containing a running wheel, a nest, and pellet and water dispensers. In Experiment 1 rats were arrhythmic when fed ad lib, wheel turned prior to both mealtimes when fed from 1000 to 1100 and from 1600 to 1700, but wheel turned primarily around the early mealtime (the meal time preceded by the long intermeal interval) during two consecutive days of food deprivation. In Experiment 2 the rats failed to wheel turn prior to two meals scheduled at 19 or 31 hr periods (6 and 13 hr and 6 and 25 hr intermeal intervals). While these noncircadian schedules were in effect, a component of activity with a 24 hr period and a "peak" between 1000 and 1200 was observed. This component appeared to be an oscillating after-effect of the 24 hr period feeding schedule. The component was not observed when an animal was maintained on a 12/12 hr light-dark cycle and fed ad lib for 6 weeks before being placed on noncircadian schedules. When the 31 hr schedule was in effect, rats were especially active 24 hr after every early meal. Rats with complete lesions of the SCN can simultaneously manifest two meal-engendered circadian processes, each associated with an independent circadian activity pattern. Meals appear to incrementally adjust the time course of one process (Stephan, J. Bio Rhythms, 1989) and instantaneously reset the time course of the other.

## 379.12

PHASE RELATIONSHIP OF EVENING AND MORNING OSCILLATORS REGULATES PHASE RESPONSIVITY: COMPARATIVE STUDY BETWEEN WILD-TYPE AND  $\tau$  MUTANT HAMSTERS. S. Yamazaki\*, K. Shimomura and M. Menaker. Dept. of Biology, Gilmer Hall, Univ. of Virginia, Charlottesville VA 22903.

The length of the activity phase ( $\alpha$ ) of the hamster's circadian wheel-running rhythm is regulated by two coupled oscillators, the evening oscillator (E) which controls activity onset and the morning oscillator (M) which controls the end of activity. Kawato (personal communication) predicted that the phase relationship between E and M should regulate circadian period and phase responsivity. The hamster's  $\alpha$  gradually lengthens in constant darkness, by inference the result of decoupling of E and M. We applied 1 h light pulses and measured the relationship between  $\alpha$  and the magnitude of the phase shift that they produced. In  $\tau$  mutants (period = 20 h), the magnitude of the phase delay produced by a light pulse at circadian time (CT) 14 was strongly correlated with  $\alpha$ . The critical  $\alpha$  (CA) at which the phase delay increased dramatically was about 9.5 circadian hour (CH). However, the CA for phase advance (light pulse at CT 18) was about 12 CH. In wild-type (period = 24 h), we could not find a CA for phase delay, but the CA for phase advance was about 10 CH. CAs of heterozygous mutants (period = 22 h) were 12 CH for phase delay and 12.5 CH for phase advance.

Fig. 1 Phase delays produced by light pulses

## 379.14

IMPAIRED CIRCADIAN RHYTHM RESPONSE FOR BODY TEMPERATURE AND ACTIVITY OF OBESE ZUCKER RATS TO REVERSAL OF THE LIGHT-DARK CYCLE. T.A. Lennie, P.J. Rowsey, B. Cimprich\*, and B.L. Metzger. The University of Michigan, Ann Arbor MI, 48109-0482

As part of a larger study, we compared the ability of female Sprague-Dawley and obese Zucker rats to reentrain circadian rhythms for body temperature and activity following complete reversal of the light-dark cycle (12h/12h). Body temperature (Tb) and spontaneous cage activity were measured by surgically implanted biotelemetry devices (Mini-Mitter, Sunriver, OR). Following a baseline period, the light-dark cycle was reversed at the onset of the dark cycle resulting in 24 hours of light. The rats were left undisturbed except for a brief daily inspection for an additional 5 days during which body temperature and activity were continuously monitored and recorded every 10 minutes (Dataquest III, Data Sciences). During baseline, body temperatures of the Zucker rats averaged about 0.3°C lower than Sprague-Dawley rats. However, there were no differences in the period, amplitude, or phase of the circadian rhythm for Tb. Baseline circadian activity patterns were also similar between the groups. Following reversal of the light cycle, the Sprague-Dawley rats demonstrated a more rapid response to the light cycle change. By Day 5, the Tb rhythm was entrained to the new light cycle. In contrast, reentrainment was delayed in the Zucker rats with the nadir for Tb still occurring during the light cycle on Day 5. Reentrainment of activity patterns in the Sprague-Dawley rats was noted by Day 4. The pattern of activity in Zucker rats was flat following light change. Moreover, the level of activity progressively decreased such that total activity on Day 4 was 27% lower than baseline. By Day 5, only a 4 hour phase advance in the nadir for activity was noted. These results indicate that obese Zucker rats have an impaired ability to respond, both behaviorally and metabolically, to changes in environmental zeitgebers.

## 379.16

SHALLOW AND DEEP TORPOR ARE DIFFERENTIALLY ASSOCIATED WITH FOOD INTAKE AND BODY WEIGHT IN SIBERIAN HAMSTERS. C.C. Purvis and M.J. Duncan. Dept. of Anatomy and Neurobiology, Univ. of Kentucky Med. Center, Lexington, KY 40536.

Torpor is a thermoregulatory adaptation exhibited by many small rodents in response to one or more environmental stimuli, e.g., short photoperiod, cold exposure and reduced food availability. In Siberian hamsters, short photoperiod (SD)-induction of daily torpor depends upon the pineal gland. This study examined the effect of lesions of melatonin-receptor containing thalamic nuclei, the paraventricular nucleus (PVT) and reunions nucleus (RE), on food intake and the display of torpor. Adult male hamsters were subjected to sham surgery (controls) or received stereotaxic injections of ibotenic acid into the RE or PVT, sparing the rostral pole. One week later, animals were transferred to SD (10L:14D); after 12 weeks, they were transferred to a cold room (7°C) and daily torpor was monitored for 60 days. Then the hamsters were perfused transcardially with fixative, brain sections were prepared and the lesion sites were verified histologically. This study detected two distinct behavioral states of torpor characterized by different core body temperatures: shallow (27°C) and deep (17°C) torpor. Lesions of either the PVT or RE had no significant effect, as compared to controls, on the expression of either shallow or deep torpor. However, statistical analysis revealed that the incidence of deep but not shallow torpor was inversely correlated with food intake ( $p < 0.0001$ ) and final body weight ( $p < 0.001$ ). These results suggest that these two states of torpor are regulated by different underlying mechanisms, in particular, differential coupling to metabolic state.

## 379.17

COUPLING BETWEEN LIGHT- AND FOOD-ENTRAINABLE CIRCADIAN OSCILLATORS IN PIGEONS. M.E. Rashotte\* and F.K. Stephan. Program in Neuroscience, Department of Psychology, Florida State University, Tallahassee, FL 32306-1051.

Two experiments were conducted to determine whether pigeons have a separate food-entrainable oscillator (FEO) and to assess the coupling strength between the FEO and the light-entrainable oscillator (LEO). Two pigeons were housed in a LD12:12 cycle with food available 9h after light onset. Body temperature (T<sub>b</sub>), O<sub>2</sub> consumption and CO<sub>2</sub> production were monitored. T<sub>b</sub> and O<sub>2</sub> increased prior to light onset and food presentation. When the LD cycle was phase delayed or advanced by 4h while feeding time remained unchanged. T<sub>b</sub> and O<sub>2</sub> rises showed the expected delaying or advancing transients with respect to light-onset. The T<sub>b</sub> and O<sub>2</sub> rises prior to feeding also delayed or advanced for several days but then returned to their proper phase position. In a second experiment, food was presented at 23.5h intervals for 10 days while the LD cycle continued with a 24h period. Entrainment to the LD cycle was unaffected. Both T<sub>b</sub> and O<sub>2</sub> consumption continued to rise prior to feeding but with a reduced lead time. Feeding time was then delayed by 5h. T<sub>b</sub> and O<sub>2</sub> consumption with regard to the LD cycle was unaffected, but both measures showed delaying transients until they re-entrained to the new feeding time. This experiment also provided some evidence for a circadian modulation of the respiratory quotient (CO<sub>2</sub>/O<sub>2</sub>). The results provide strong support for the existence of a separate FEO in pigeons and indicate asymmetrical coupling between the LEO and FEO, with the former having a stronger effect on the latter.

## 379.18

TIME SERIES ANALYSIS OF PERIODICITIES IN INTERSCAPULAR BROWN FAT TEMPERATURE PATTERNS. L. Kelly\* and C. Bielaiew. School of Psychology, Neuroscience group, University of Ottawa, Ottawa, Ont. K1N 6N5 Canada.

There is evidence that brown adipose tissue (BAT) thermogenesis contributes to the ultradian warming patterns of core temperature (Closa et al, 1991). Indeed, ultradian cycles in BAT activity have been suggested as a pivotal factor underlying the feeding bouts of ad-lib schedules (Himms-Hagen, 1994). Diurnal patterns in BAT activity have been described by examining changes in sympathetic firing rate (Sakaguchi et al, 1988) and GDP-binding levels (eg. Redlin et al, 1992); however, results are equivocal. We chose to investigate the chronic BAT temperature pattern. A radio-frequency disc transmitter (Mini-Mitter, Inc.) was implanted in each 400g male rat, either by bonding it directly to the muscle under the interscapular deposit or to a piece of surgical teflon which was then sewn in place. After one week of recovery, BAT temperatures were recorded throughout the 24 h cycle (12h light:dark) for up to six days. Spectral analysis was performed on the raw data (half-hour intervals) and again after removing the circadian component from the series ("deseasoning"); this procedure reduces interference from harmonic frequencies. As expected, all data show a strong circadian cycle, but the ultradian rhythms are less clear. The 8h and 4h cycles are most consistent, appearing in 3, and 2, respectively, of the 8 spectral graphs. The 4h cycle may be stronger as it persists in 3 graphs when deseasoned data are used. As ultradian cycles appear less stable than circadian ones, simultaneous recording of BAT temperature and food intake/hormonal profiles, etc. would be useful in assessing the potential significance of the 4h cycle reported here.

## BIOLOGICAL RHYTHMS AND SLEEP: PHYSIOLOGY II

## 380.1

PREOPTIC/ANTERIOR HYPOTHALAMIC (POAH) COOLING SUPPRESSES SLEEP IN RATS. D. McGinty<sup>1\*</sup>, Md. Noor Alam<sup>1</sup>, S. Morairty<sup>2</sup> and R. Szymusiak<sup>3</sup>, Dept. Veterans Affairs Medical Center, Sepulveda, CA 94343, Depts. Psychology<sup>1</sup>, Neuroscience<sup>2</sup> and Medicine<sup>3</sup>, Univ. Calif., Los Angeles, CA.

Excitation of POAH warm-sensitive neurons (WSNs) and/or suppression of cold-sensitive neurons (CSNs) can facilitate NREM sleep, but some evidence suggests that POAH hypnogenic effects can be independent of thermoregulatory output. Noting that the majority of POAH neurons are insensitive to local temperature changes, we used bilateral POAH cooling (1.5°C) with water-perfused thermodes to selectively inactivate WSNs and activate CSNs in the rat. During three hour cooling periods in the middle of the usual daily sleep period (CT 3.5-6.5) total sleep time was reduced by 85%, including both NREM and REM sleep. EEG delta activity was also sharply reduced during cooling, but was enhanced during the first 2 hours following cooling. Body temperature was elevated during and one hour after POAH cooling. Since POAH cooling produces selective effects on thermosensitive neurons, our finding suggests that these neurons are essential for the hypnogenic output of this site leading to spontaneous sleep.

## 380.2

EFFECTS OF PARADOXICAL SLEEP DEPRIVATION ON THERMOREGULATION IN THE RAT. P. Shaw, B. Bergmann, C. Landis\* and A. Rechtschaffen, Dept. of Psychiatry, U. of Chicago, Chicago, IL 60637

Rats subjected to total sleep deprivation (TSD) by the disk-over-water method have shown three thermoregulatory changes: an elevated thermoregulatory setpoint (T<sub>set</sub>); excessive heat loss; a reduction of wake-sleep temperature differences (dT). The present study evaluated which of these changes may be achieved by the loss of paradoxical sleep (PS) alone, and which required loss of the NREM component of total sleep as well. Hypothalamic temperature (T<sub>hy</sub>) was continuously monitored in 5 rats selectively deprived of PS (PSD) and their yoked controls (PSC). All were provided with a continuously available operant to control ambient temperature (T<sub>a</sub>). Unlike TSD rats, PSD rats did not show significant increases in T<sub>hy</sub> or operant responses for heat, thus supporting previous inferences that elevated T<sub>set</sub> in TSD rats resulted from the loss of the NREM sleep component. That T<sub>hy</sub> remained near baseline in spite of large increases in metabolic rate is consistent with previous inferences that PSD alone can cause excessive heat loss. Large progressive decreases of dT from 0.6°C during baseline to 0.2°C near the end of deprivation in PSD rats, but not in PSC rats, confirms earlier indications that PSD alone is sufficient to reduce wake-sleep temperature differences.

## 380.3

DISCHARGE DURING WAKEFULNESS AND SLEEP OF RAT PREOPTIC/ANTERIOR HYPOTHALAMIC (POAH) NEURONS. Md. Noor Alam<sup>1</sup>, R. Szymusiak<sup>2</sup>, T. Steininger<sup>1\*</sup> and D. McGinty<sup>1</sup>. Dept. Veterans Affairs Medical Center, Sepulveda, CA 94343, <sup>1</sup> Dept. Psychology and <sup>2</sup> Dept. Medicine, UCLA.

Neurons in the POAH participate in the regulation of both body temperature and sleep-waking states. A significant proportion of POAH neurons recorded in cats have elevated spontaneous discharge rates during sleep with EEG synchrony (nonREM sleep) compared to waking. We have recently reported that activity of POAH thermosensitive neurons in cats is modulated by sleep. Discharge rates and thermosensitivity of most warm-sensing neurons are elevated in nonREM sleep. Activity of cold-sensing neurons is reduced during sleep.

We have extended our analysis of POAH neurons to the rat. Extracellular POAH unit activity was recorded using chronic microwire technique. In a sample of 46 cells, 30% were nonREM sleep-related (i.e., spontaneous discharge rate in nonREM sleep > 120% of waking discharge rate), 15% were waking-related, and the discharge rate of 54% did not vary across the sleep-waking cycle. Of a small sample of thermosensitive neurons studied to date, the majority of warm-sensing neurons also displayed elevated spontaneous rates in nonREM sleep.

These preliminary results indicate that sleep-wake discharge of POAH neurons in rats is similar to that previously described in cats. They also support a hypothesized role for hypothalamic thermosensing cell types in sleep-wake regulation in this species.

## 380.4

DEVELOPMENT OF CIRCADIAN RHYTHMS OF BODY TEMPERATURE AND ACTIVITY IN SPRAGUE-DAWLEY RAT PUPS. I. M. Hoban, Higgins, D. M. Murakami, C. Fermin\* and C. A. Fuller. Section of Neurobiology, Physiology and Behavior, Univ. of California, Davis, CA 95616-8519.

Twenty-four albino rat pups were implanted with intraperitoneal telemetry transmitters on postnatal day 17. Immediately after surgery, they were individually housed with *ad lib* food and water. Body temperature was recorded at 10 minute intervals until postnatal day 90. Twelve of the animals (7 male, 5 female) were maintained in a light-dark cycle consisting of 12 hours of light followed by 12 hours of darkness (LD 12:12). The remaining 12 pups (6 male, 6 female) were housed in constant light of 0.5-1 lux (LL). Data were analyzed for amplitude, mean and phase of the circadian rhythm of body temperature. Small amplitude rhythms were visible on postnatal day 17. Amplitude continued to increase until days 40-50 when it reached a mature steady-state. The absence of an external light-dark cycle did not delay the appearance of rhythmicity in the pups maintained in LL. Interestingly, the pups in LL attained a mature homeostatic level of temperature regulation sooner than did the pups in LD. All pups evidenced robust rhythms in both lighting environments for the duration of the study. There was no difference between males and females in free-running period. (Supported in part by NASA Grant NCC2-886.)

## 380.5

THE DEVELOPMENT OF THE PHOTIC INDUCTION OF C-FOS IN THE RETINA AND SCN. D. M. Murakami\*, I.-H. Tang, T. M. Hoban-Higgins and C. A. Fuller. Section Neurobiology, Physiology, and Behavior, Univ. of California, Davis, California 95616-8519.

The retinohypothalamic tract (RHT) is an important neural pathway for light to entrain and phase-shift circadian rhythms. The development of the RHT was studied by examining the ability of light to induce c-Fos reactivity within the retina and suprachiasmatic nucleus (SCN) at different ages. Rats were housed in a standard vivarium environment of LD 12:12 (weaned at P21). At CT 13 rats (ages from P1 to P35) were moved to an isolation chamber. The experimental group was exposed to a 1 hour light pulse (300 lux), while controls did not receive a light pulse. All rats were immediately sacrificed, brains and eyes removed, sectioned through the retina (5mm) and SCN (50mm), immunohistochemically stained for c-Fos, and counterstained. Rats at P1 & P3 did not exhibit the photic induction of c-Fos within the retina or SCN. However, by P7 the SCN exhibited an adultlike pattern of photically induced c-Fos reactivity. Retinal c-Fos reactivity exhibited significant photic induction within the outer and inner nuclear layers and ganglion cells. These results suggest that highly significant maturation of the RHT occurs between P3 and P7. (Supported in part by NASA Grant NAGW-2195.)

## 380.7

MODULATION OF c-Fos EXPRESSION IN ORGANOTYPIC CULTURES FROM THE RAT BRAINSTEM. S.H. Winston, D.G. Rainnie, P. Shiromani, B. O'Donnell\*, R.W. Greene, and R.W. McCarley. Dept. of Psychiatry, Harvard Medical School and Brockton VAMC, Brockton, MA 02401.

We have previously shown that microinjection of carbachol into the pontine reticular formation *in vivo*, causes c-Fos expression in a subset of neurons in the brainstem. The purpose of this study was to develop an *in vitro* brainstem preparation that could be used to study this phenomenon.

Organotypic cultures were prepared using a modification of the method of Stoppini *et al.* (1991). In sterile conditions, 8-10 day old Long-Evans rat pups were anaesthetized by hypothermia and decapitated. Brains were rapidly removed and placed in ice-cold MEM containing 25 mM HEPES and 10 mM TRIS, pH 7.35. A block of tissue containing the entire rostral-caudal aspect of the dorsal Raphe nucleus was prepared, 250  $\mu$ m coronal slices cut on a Sorvall TC-2 tissue slicer, and transferred to 35mm culture dishes containing dissection medium at 27°C. Individual slices were transferred to (30 mm) Millicell-CM inserts in 100 mm petri dishes containing 5 ml of culture medium and maintained at 36°C in an incubator with a 5% CO<sub>2</sub> atmosphere. Culture medium contained 50% MEM with 25mM HEPES, 25% horse serum, and 25% Hanks solution buffered with 5 mM TRIS and 4 mM NaHCO<sub>3</sub> to pH 7.2. After 3-5 days cultures were washed with sterile, serum-free, ACSF (containing in mM: NaCl 124; KCl 3.75; KH<sub>2</sub>PO<sub>4</sub> 1.25; MgCl<sub>2</sub> 1.3; CaCl<sub>2</sub> 2.5; NaHCO<sub>3</sub> 26; and glucose 10) for 4 hrs, and then cultured overnight in fresh ACSF. After drug treatment, slices were fixed with 4% paraformaldehyde and stained for Fos-Li activity with a rabbit anti-Fos antibody (Santa Cruz) and visualized with DAB staining. ACSF alone caused no c-Fos expression, addition of carbachol (200  $\mu$ M) evoked regionalized expression of c-Fos, which could be modulated by atropine (200  $\mu$ M). Experiments are in progress to determine the mechanisms underlying carbachol-induced activation of c-Fos in the brainstem.

## 380.9

ELICITED DIAPHRAGMATIC FRACTIONATIONS AND PGO WAVES ACROSS STATES. W. K. Hunt, L. D. Sanford, A. R. Morrison, R. J. Ross\*, and A. I. Pack. Lab. for Study of the Brain in Sleep, Dept. of Psych., and Ctr. for Sleep and Resp. Neurobio., Univ. of Penna., Philadelphia, PA 19104

Fractionations (FR) are 20-100 ms pauses in diaphragm activity that occur spontaneously during rapid eye movement sleep (REM), often in association with ponto-geniculo-occipital (PGO) waves. Tones elicit FR and PGO waves during REM, non-REM, and waking with similarities in timing suggesting generation by the same neural mechanisms. We examined elicited PGO waves and FR across states. Cats (n=4) were implanted with electrodes to record EEG, EOG, neck EMG, diaphragm EMG, and PGO waves from the lateral geniculate nuclei. Auditory tones (n=50-150, 90dB, 20ms duration) or blanks were presented in mid-inspiration across a 4-8 hr recording session. Tones elicited PGO waves and FR at similarly high rates across all states (62-79% of trials). The majority of stimuli elicited both a PGO wave and a FR (60-68% of trials), but each could be elicited alone. The latencies and durations of elicited FR were similar across states ( $\bar{x}$  latency: 23-25ms,  $\bar{x}$  duration: 21-25ms), but the mean latency of elicited PGO waves in REM ( $\bar{x}$  = 63  $\pm$  7ms) was longer ( $p < .01$ ) than in waking or non-REM ( $\bar{x}$  = 37  $\pm$  7ms and 41  $\pm$  7ms, respectively). In addition, a second, long-latency FR (LFR) ( $\bar{x}$  latency: 82  $\pm$  6ms and  $\bar{x}$  duration: 22  $\pm$  2ms) was elicited at a higher ( $p < .05$ ) rate in REM (35% of trials) than in other states (5% of trials in waking, and 3% in non-REM). We found that elicited FR consistently occur with shorter latencies than elicited PGO waves, in contrast to spontaneous FR which have a variable relationship to PGO waves, but usually occur 10-40 ms after the onset of the PGO wave. The LFR elicited during REM resembles a spontaneous FR in its relationship to the PGO wave and its prevalence in this state may reflect the bias toward motoneuronal inhibition characterizing REM. In conclusion, this study suggests that PGO waves and FR may be generated by different neuronal populations that are similarly influenced by auditory stimuli. EFFECTS OF UNILATERAL OPTIC NERVE TRANSECTION ON MAMMALIAN CIRCADIAN TIMING SYSTEM. I.-H. Tang, D. M. Murakami, C. A. Fuller\*. Section of Neurobiology, Physiology and Behavior, University of California, Davis, California 95616-8519

This study investigated the effects of unilateral optic nerve transection (UONX) on the golden hamster's circadian rhythms and light induced c-Fos in the SCN. One group of six animals was housed under a square-wave LD (SQ/LD) cycle(14:10). Another group of six animals was exposed to a simulated natural LD(SN/LD) cycle composed of a 4 hr linearly ramped dawn-mimicking period, a 6 hr full light intensity day period, a 4 hr linearly ramped dusk-mimicking period. Unilateral optic nerve transection was performed on half of the animals from each group after stable entrainment had been established. Then all animals were kept under the SN/LD cycles. The body temperature and ambulatory activity rhythms of animals previously exposed to the SN/LD became arrhythmic for up to 4 weeks after the surgery and gradually restored circadian rhythmicity to a new circadian pattern as previously described. However, animals housed under SQ/LD before UONX retained their circadian rhythmicity and gradually established a new circadian rhythms under the SN/LD. All animals, intact and UONX, received one hour light pulse at 1500 hour and were then sacrificed at 1600 hour. c-Fos expression in the SCN was examined. Animals with UONX showed weaker c-Fos expression and different spatial distribution of the c-Fos immunoreactive cells in the SCN. (Supported in part by NASA Grant NAG2-795.)

## 380.8

EFFECTS OF THE OPIATE RECEPTOR ANTAGONIST NALOXONE ON IPSPs EVOKED IN LUMBAR MOTONEURONS FOLLOWING STIMULATION OF THE NUCLEUS RETICULARIS GIGANTOCELLULARIS DURING CARBACHOL-INDUCED ATONIA. M.-C. Xi\*, R.-H. Liu, J. Yamuy, F.R. Morales and M.H. Chase. Department of Physiology and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

Anatomical data demonstrate that spinal cord motoneurons are richly innervated with axon terminals containing the peptide enkephalin (ENK) (Aridsson *et al.*, *Synapse*, 1992, 11:85-104). Functionally, ENK and other opioid peptides suppress the spontaneous and evoked activity of cat spinal motoneurons (Zieglensberger *et al.*, *Brain Res.*, 1976, 115:111-128). These data have led us to hypothesize that opioid peptides may be involved in modulating the activity of motoneurons during active sleep. We were therefore interested in examining the large amplitude, long-latency, glycinergic IPSPs which are induced in lumbar motoneurons by electrical stimulation of the medullary nucleus reticularis gigantocellularis (NRGc). Specifically, we wanted to determine whether these IPSPs, which are evoked exclusively during active sleep and carbachol-induced atonia, would be affected by ENK.

Intracellular recordings were obtained from lumbar motoneurons in the decerebrate cat during atonia induced by the microinjection of carbachol into the rostral pontine reticular formation. The non-selective opioid peptide receptor antagonist naloxone was applied, juxtacellularly, to the recorded cells. Electrical stimulation of the NRGc elicited IPSPs in lumbar motoneurons with a mean amplitude of  $1.8 \pm 0.3$  mV (S.E.M.), a latency to onset of  $28.8 \pm 1.8$  ms, a latency to peak of  $53.2 \pm 1.8$  ms, a half-width of  $27.6 \pm 1.5$  ms and a duration of  $57.1 \pm 1.5$  ms (n=8). Naloxone, when applied microiontophoretically (50-400 nA, 4-11 min), reversibly reduced by 33% the amplitude of these NRGc-induced IPSPs (to  $1.2 \pm 0.3$  mV; n=8;  $p < 0.01$ ), but had no effects on the resting membrane potential, or the latency or time course of the IPSPs. The mean latency of the naloxone effect on the NRGc-induced IPSPs was  $2.3 \pm 0.4$  min (n=8).

The present results suggest that opioid peptides modulate the NRGc-induced IPSPs during carbachol-induced atonia, and that they may participate in the regulation of lumbar motoneuron inhibition during active sleep. Supported by USPHS Grants NS 23426, NS 09999 and MH 43362.

## 380.10

AFFERENT STIMULUS-INDUCED IPSPs ARE TIME-LOCKED TO PGO WAVES FOLLOWING THE INJECTION OF CARBACHOL INTO THE NUCLEUS PONTIS ORALIS. K.A. Kohlmeier, F. López-Rodríguez, F.R. Morales and M.H. Chase\* Neuroscience Interdepartmental Program, Dept. of Physiology, Dept. of Anatomy & Cell Biology, and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90095.

We have recently found that auditory clicks and sciatic nerve stimulation result in the generation of IPSPs in masseter motoneurons in the  $\alpha$ -chloralose-anesthetized cat (*Sleep Research* 1995 24:9; *Soc. Neuro. Abs.* 1994 20:1218). The production of these IPSPs by afferent stimuli is state-dependent insofar as they occur only in conjunction with the carbachol-induced state and its accompanying pattern of muscle atonia. Consequently, we were interested in determining (1) whether afferent stimuli elicit PGO waves in the  $\alpha$ -chloralose preparation following carbachol-induced muscle atonia in order to demonstrate whether such stimuli activate the startle network (*Acta Neurobiol. Exp.* 1975 35:821) and, if so, (2) whether there is a temporal relationship between the afferent stimuli-induced increase in inhibitory drive on motoneurons and afferent stimuli-elicited PGO waves. Following the microiontophoresis of carbachol (200 mM) into the nucleus pontis oralis (NPO) in seven cats anesthetized with  $\alpha$ -chloralose (40 mg/kg I.V.), either an auditory click (1.5 ms duration, 95 dB) was presented or the sciatic nerve was stimulated via an implanted nerve cuff at an intensity sufficient to induce an H reflex. Both types of afferent stimuli were found to produce PGO waves. The average latencies to onset of the stimuli-induced PGO waves were not significantly different (sciatic nerve stimulation-induced PGO wave,  $21.6 \pm 1.2$  ms; n=27; click-elicited PGO wave,  $21.4 \pm 0.6$  ms; n=35;  $p > .05$ ). The sciatic nerve stimulation- and click-induced IPSPs also had similar latencies to onset ( $30.4 \pm 1.7$  ms and  $32.1 \pm 0.8$  ms, respectively). The delay between the onset of the sciatic nerve stimulation-elicited IPSP and the click-elicited IPSP from the foot of the elicited PGO wave was  $8.8 \pm 0.7$  ms and  $10.9 \pm 0.8$  ms, respectively. This delay was not significantly different from the latency to onset of 1) the spontaneous IPSPs which are time-locked to PGO waves in the  $\alpha$ -chloralose-anesthetized cat following the injection of carbachol into the NPO ( $p > .05$ ) and 2) the IPSPs that are time-locked to the PGO waves which are present during spontaneously-occurring active sleep in the chronic cat (Kohlmeier *et al.*, submitted for publication; *Brain Research* 1994, 653:31). The data in this report suggest that the spontaneous production of PGO waves during active sleep represents the neuronal signature of internal activation of the startle network.

## 380.11

**CORTICAL EEG-RELATED ACTIVITY OF BASAL FOREBRAIN NEURONS AND THEIR RESPONSES TO BRAINSTEM AND SENSORY STIMULATION IN URETHANE-ANESTHETIZED RAT.** K. Semba\*, L. Déjari and D.D. Rasmussen. Depts. of Anat. & Neurobiol.(K.S.) and Physiol. & Biophys.(D.D.R.), Dalhousie Univ., Halifax, N.S. B3H 4H7 Canada; Dept. of Comp. Physiol., Eötvös Loránd Univ., Budapest, Hungary (L.D.).

The cholinergic projection from the basal forebrain to the cerebral cortex has been suggested to have a crucial role in cortical activation. The activity of basal forebrain neurons appears to be regulated by ascending inputs from the brainstem. In this study we examined the effects of electrical stimulation of the pedunculopontine tegmental (PPT) and the dorsal raphe (DRN) nuclei as well as sensory stimuli (tail pinch) on the activity of desynchronization (D)- and synchronization (S)-active basal forebrain neurons under urethane anesthesia (initial dose: 1.25-1.35 g/kg, i.p.). Fifty-two of 169 basal forebrain neurons tested were identified as D-cells and 14 as S-cells on the basis of correlation between firing rate and EEG power. Single pulses to PPT and DRN elicited short-latency (2-13 msec), short-duration (9-15 msec) excitatory responses in most of D- (73%) and S-cells (67%). Inhibitory responses, longer in duration (24-131 msec), were seen only in 8% of D-cells but more frequently (22%) among S-cells. In contrast, short train stimulation (0.5 sec, 100 Hz) of the same structures or tail pinch (1-2 sec) excited most D-cells (80-96%) but inhibited the majority of S-cells (55-67%). These results indicate that the majority of basal forebrain neurons showing EEG-related firing patterns increase their activity during cortical EEG desynchronization. Together with previous anatomical and physiological data, the predominantly excitatory effects of PPT and DRN stimulation on D-cells suggest that, in addition to the well known cholinergic and serotonergic projections, glutamatergic or other excitatory pathways from these structures to the basal forebrain may be important for cortical activation. **SINGLE UNIT RECORDING FROM THE MESOPONTINE TEGMENTUM DURING DIFFERENT BEHAVIORAL STATES** Chiara M. Portas, Mahesh Thakkar\* and Robert W. McCarley. VA Medical Center and Harvard Medical School, 940 Belmont St, Brockton, MA 02401

Neurons of the mesopontine tegmentum play a significant role in the control of behavioral states; it has been proposed that projections from cholinergic neurons in the laterodorsal and pedunculopontine tegmental nuclei to the thalamus and medial pontine reticular formation are crucial to the regulation of REM sleep. In order to clarify the firing characteristics of neurons in these regions across different behavioral states, we have recorded single units in freely behaving cats.

Male adult cats, anesthetized with sodium phenobarbital (35 mg/kg), were implanted with chronic sleep recording electrodes and a mechanically driven microdrive targeted at the mesopontine tegmentum. Two bundles of 7 microwires (32 µm each) were used to record single units. 7-10 days were allowed for post-operative recovery before recordings began. Extracellular single unit activity was amplified and fed into a window discriminator. The microwires were advanced in steps of 25-50 µm until a single neuron spike with a signal to noise ratio of at least 3:1 was encountered. Once an acceptable single unit was found, neuronal activity was recorded along with polygraphic indicators of behavioral states viz. EEG, EOG, and EMG. The cat was continuously observed by video (without disturbance) throughout the recording session. Two to five wake/slow-wave sleep/REM cycles were recorded for the units reported here. Histological verification of the recording site is pending.

Polygraphic records were classified into active waking, quiet waking, slow-wave sleep, REM sleep with eye movements and REM sleep without eye movements. The firing patterns of all recorded neurons were then categorized in relation to behavioral state. Preliminary results from this study show a low firing rate for most neurons and that majority of these alter their firing rate with regard to sleep and wakefulness. Majority of these neurons showed increased firing during wakefulness and REM.

## 380.15

**INTERACTION BETWEEN TWO PHOTORECEPTORS SYSTEM IN CRAYFISH PROCAMBARUS.** V. Inclán-Rubio\* and A. Borghonio-Aguilar. Departamento de Fisiología. Facultad de Medicina, UNAM. AP. 70-250, CP 04510 Mexico, D.F. MEXICO.

It is known that white-light stimuli on the caudal photoreceptors of the sixth abdominal ganglion (6th AG) in the crayfish increase the electric activity along the abdominal chain, evoking an inhibitory effect on the amplitude of the electric response to the light of the visual photoreceptors (electroretinogram, ERG). The objective of this research was to study the capability of monochromatic light applied to the 6th AG to synchronize the ERG circadian rhythm. We worked with adult crayfish *Procambarus clarkii*. The ERG was obtained with the conventional registration technique under a L:D (12:12) photoperiod. In the 4th day of registration, a monochromatic-light stimulus (590nm) of one-hour duration and 400 lux intensity on the 6th AG, at four different circadian times (6, 12, 18 and 24 CT), six more days after were analyzed the changes. Results show changes in the ERG circadian rhythm, which are made evident by (a) a decrease in the amplitude of the ERG after the stimulation, (b) the appearance of a transitory state lasting from 36 to 40 h, and (c) a change of phase that depends on the moment of the application of the stimuli, (advance: 12, 18 and delay at 6, 24 CT). These results show a functional communication between the extraretinal photoreceptors of the 6th AG and the retinal photoreceptors in the compound eye. (PAPIIT-DGAPA:IN204593).

## 380.12

**HIGH FREQUENCY BURST FIRING IN BASAL FOREBRAIN NEURONS RECORDED IN VIVO: RELATIONSHIP TO SLEEP-WAKING STATE.** R. Szymusiak<sup>2\*</sup>, Md. Noor Alam<sup>1</sup> and D. McGinty<sup>1</sup>. Dept. Veterans Affairs Medical Center, Sepulveda, CA 94343, <sup>1</sup> Dept. Psychology and <sup>2</sup> Dept. Medicine, Univ. Calif., Los Angeles, CA 90024.

Cholinergic neurons of the basal forebrain (BF) recorded *in vitro* display the voltage-dependent calcium current  $I_{Ca}$  that underlies high frequency burst (HFB) firing (Khateb et al., *Neurosci.* 51:489, 1992).  $I_{Ca}$  is also present in thalamocortical relay cells, and HFB firing in relay cells recorded *in vivo* occurs primarily during sleep (Steriade et al., *Science* 262:679, 1993). Using chronic microwire technique, we compared extracellular single unit discharge within the thalamus and BF of adult cats and rats to look for evidence of sleep-related HFB firing in BF neurons.

In cats, 76% of a population of thalamic neurons displayed HFB firing during nonREM sleep and tonic, single spike firing in waking. Presence of sleep-related HFB firing was indicated by a > 50% increase in the variance about the mean discharge rate (calculated in 250 msec bins) during sleep compared to waking. Analysis of BF neurons was confined to those displaying relatively tonic discharge (> 5 Hz) in waking. In a sample of 64 such neurons, 16% had a state-dependent pattern of discharge variability comparable to that found in the majority of thalamic neurons. In rats, a similar proportion of BF neurons (14%) displayed evidence of HFB firing in sleep. Extracellularly recorded HFB firing during sleep may be useful for identifying BF cholinergic neurons recorded *in vivo*.

## 380.14

**EFFECTS OF DISCRETE IBOTENIC ACID LESIONS OF MESOPONTINE TEGMENTUM ON SLEEP AND WAKING STATES IN THE RAT.** M. Thakkar, W.L. Inglis, D.G. Rainnie, R.W. Greene, R.W. McCarley\* and K. Semba. Dept. Psychiatry, Harvard Medical School & VAMC, Brockton MA 02401, USA, and Dept. Anatomy & Neurobiology, Dalhousie University, Halifax NS, Canada B3H 4H7.

Several lines of evidence indicate that the cholinergic neurones in the laterodorsal (LDTg) and pedunculopontine (PPTg) tegmental nuclei play a crucial role in the control of behavioral state. It is possible to make relatively circumscribed lesions in the rat mesopontine tegmentum using ibotenic acid (e.g. Inglis et al., *Neuroscience* 58, 817-833). Using a similar lesion protocol, this study investigates the extent to which neurons in the PPTg or LDTg are involved in the regulation of sleep and wakefulness.

Rats were implanted with EEG electrodes on occipital and frontal cortices, wires into the neck muscles for EMG measurements, and bilateral guide cannulae aimed at either LDTg or PPTg. Following recovery from surgery and habituation to the test environment, 2 or 3 baseline recordings of 4h were taken during the same period of each day, in order to establish normal activity patterns for each rat. Lesions were made by lowering a microinjection needle through a guide cannula into the mesopontine tegmentum under pentobarbitone anaesthesia, and pressure-injecting 0.1 M ibotenic acid into the region. Polygraphic recordings were made, during the same 4 h period as baseline recordings, on days 1 and 4 after excitotoxic infusion and thereafter at weekly intervals for up to two months. Polygraphic records showed that lesioned rats spent more time awake or in a drowsy state and their sleep pattern was more fragmented. EEG power spectral analysis revealed striking changes in activity within identifiable frequency bands (<25 Hz) in different. These data indicate that destroying either the PPTg or LDTg is sufficient to disrupt the pattern of sleep and wakefulness and alter cortical EEG patterns in characteristic ways. Supported by The Wellcome Trust (038117/Z/93), MRC of Canada (MT-11312) and the Veterans Administration.

## 381.1

MODELLING AND MEASURING THE ACOUSTICAL FEATURES OF THE MIDDLE-EAR OF THE ZEBRA FINCH. H.-P. Rangel & W. Plassmann\*  
 ZOOLOGISCHES INSTITUT, J. W. GOETHE-UNIVERSITÄT, FRANKFURT AM MAIN, FRG  
 The middle-ear cavities of the Zebra Finch *Taeniopygia guttata castaneotis* have an inter-connection by pneumatizations of the bony skull which can be considered as an inter-aural pathway: Sound which is incident to one tympanic membrane travels to the inner side of the other tympanic membrane. This causes an action of the soundwave on both sides of the tympanic membrane. This mechanism of sound receiving is described in acoustical terms as a pressure-difference-receiver.

The directionality and frequency-sensitivity of this mechanism can be used to distinguish it from pressure-receiver-mechanisms. The features are physically well understood and can be used to construct physical and mathematical models to evaluate the values of pressure-difference-receivers with different geometrical dimensions and in different sound-fields.

We have designed a mathematical and physical model for pressure-difference-receivers, checked it with hardware-models and have done physiological measurements with the Zebra Finch. We recorded with three probe-microphones, two of them inserted through holes into the middle-ear cavities of the bird resp. into the interconnecting tube of the hardware-model. We measured the directionality on a turntable at every 10° rotation angle up to 360° azimuth. Afterwards the transferfunctions between the microphones were evaluated and compared with the calculated values.

The results show that the middle-ear of the Zebra Finch acts as a pressure-difference-receiver with good agreement to the theoretical expectations about directionality and frequency-sensitivity. The comparison of the measurements with published behavioural studies about hearing-range and directionality from other labs shows good agreement too.

## 381.3

CHARACTERIZATION OF SLOW INHIBITORY POTENTIALS IN NUCLEUS HVC OF ADULT MALE ZEBRA FINCHES. Marc F. Schmidt\* and D. J. Perkel. Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

Nucleus HVC of songbirds is anatomically situated at the intersection of motor and auditory pathways. It is thought to be a primary candidate for integrating song motor activity and auditory feedback. Chronic neural recordings from adult zebra finches (McCasland and Konishi, 1981) have shown that auditory responses in HVC become inhibited during and following singing. Because auditory feedback is critical for song learning, it has been hypothesized that this vocalization-induced inhibition may not occur until the onset of song crystallization since such inhibition would prevent auditory feedback to HVC during learning. To investigate possible cellular mechanisms by which this inhibition may occur, we used a slice preparation to record intracellularly from adult HVC neurons.

Electrical stimulation of fiber tracts outside of HVC, or directly within the nucleus, elicited relatively rapid GABA<sub>A</sub> receptor-mediated IPSPs as well as two types of slow IPSPs. Both of these slow IPSPs were best elicited by brief stimulus trains rather than single pulses. The first IPSP had a duration of 200-400 msec (consistent with GABA<sub>B</sub> receptor-mediated events). The second type of slow IPSP was much longer in duration with a time course of several seconds. Its duration was similar to the time course of vocalization-induced inhibition of auditory responses.

To investigate candidate neurotransmitters which might mediate these slow IPSPs, we have tested various agonists for their ability to hyperpolarize HVC neurons. The GABA<sub>B</sub> receptor agonist baclofen (30  $\mu$ M; n=5/5), the metabotropic glutamate receptor agonist 1S-3R-trans-ACPD (100  $\mu$ M; n=4/4) and serotonin (30  $\mu$ M; n=6/7) all caused hyperpolarizations of 5-10 mV. These changes were associated with a decrease in input impedance. Pharmacological characterization of the observed slow IPSPs will be crucial for testing their role in vocalization-induced inhibition of auditory responses.

## 381.5

INNATE CONTRIBUTIONS TO SELECTION OF ACQUIRED SONG DURING VOCAL LEARNING IN WHITE-CROWNED SPARROWS. C.S. Whaling\*<sup>1</sup>, M. Solis<sup>2</sup>, G. Carrillo<sup>2</sup>, J.A. Soha<sup>1</sup>, P. Marler<sup>1</sup> and A.J. Doupe<sup>2</sup>. <sup>1</sup>Section of Neurobiology, Physiology, and Behavior, UC Davis, Davis, CA 95616 and <sup>2</sup>Keck Center and Depts of Psychiatry and Physiology, UCSF, San Francisco, CA 94143.

Young, naive sparrows tutored with tape recordings of both conspecific and heterospecific song preferentially learn conspecific song. We investigated the acoustic and physiological basis for this learning preference using both behavioral and neurophysiological techniques. White-crowned sparrows (wesp; *Zonotrichia leucophrys nuttalli*), were collected as nestlings and raised by hand in acoustic isolation. In behavioral experiments, we measured the vocal response of fledglings to a variety of song stimuli (Nelson and Marler, 1993). These songs included normal wesp song, "isolate" songs from wesp raised in acoustic isolation, and heterospecific songs. We found that normal white-crown song and "isolate" songs are equally potent in eliciting a vocal response in fledglings and are more potent than heterospecific songs. The strong response to isolate songs, which are composed of a series of whistles, suggests that whistles may be critical for song recognition in this species. To investigate the neurophysiological basis of this innate preference, we recorded single and multi-unit auditory responses of neurons in HVC and auditory neostriatum of fledgling wesp. We found many neurons that responded strongly to whistles of both normal and isolate song. Some neurons also responded well to pure tone bursts of the same duration as wesp whistles but did not respond to the same tone bursts when their duration was shorter than normal whistle length. These results suggest that the innate ability of naive fledglings to select conspecific song from an array of stimuli may depend on the presence of whistles, which are universal in normal wesp songs. Consistent with this hypothesis, whistles are effective stimuli for evoking neuronal responses in the auditory neostriatum of naive wesp. Supported by NIMH 14651 and Klingenstein and Sloan Research Fellowships.

## 381.2

FUNCTIONAL HIERARCHY DEFINED BY SINGLE UNITS IN SINGING BIRDS: HVC REPRESENTS SYLLABLES, AND RA REPRESENTS NOTES. A.C. Yu, D. Margoliash\*, Com. Neurobiol., Univ. of Chicago, Chicago, IL 60637

We have characterized the motor properties of single neurons in forebrain nuclei of the song system in male zebra finches. Birds chronically implanted with electrodes mounted on miniature microdrives were recorded during singing.

Single unit study of HVC activity confirmed prior results (Yu and Margoliash, 1993). In all cases, neuronal activity in HVC preceded each syllable of song, and was dominated by tonic excitation. Histograms of neuronal activity were unique for each syllable type and independent of the position of the syllable in the song.

In contrast, activity of RA neurons was characterized by strong inhibition and highly phasic excitation, producing very precise sequences of 1-7 distinct bursts/syllable. The number of bursts was related to syllable complexity. Bursts appeared to be associated with notes (subunits of syllables) or individual acoustic features of a syllable, although activity was also dependent on the position of the syllable within the song. Syllables that shared notes also shared the corresponding bursts. The time-registry of sequences of bursts from pairs of vocalizations was improved by aligning the spike traces using the "warp-path" derived from dynamic time warping of the syllable acoustics. Within bursts, timing was more variable for introductory syllables, whereas the number of spikes and the inter-spike interval (ISI) in bursts associated with major syllables were highly consistent across vocalizations (e.g., between pairs of spikes ISI = 1.4 ms  $\pm$  106  $\mu$ s SD). For such bursts, typically the first ISI was longer than the rest, and the second and following spikes exhibited increasingly diminished amplitude.

In zebra finch, HVC is organized at a syllable-type level, and is independent of the context within a song. The motor code in RA is organized around notes or smaller acoustic features of a syllable, and depends on song context. Context-dependent RA activity suggests a coarticulation mechanism for song production.

## 381.4

SENSITIVITY TO AUDITORY TEMPORAL CONTEXT INCREASES SIGNIFICANTLY FROM FIELD L TO HVC. M.S. Lewicki\* and B.J. Arthur. Computation and Neural Systems Program, Division of Biology, Caltech, Pasadena, CA 91125

Neurons in the songbird forebrain nucleus HVC have responses that are highly dependent on the auditory temporal context and can integrate information over periods of hundreds of milliseconds. An example of this integration is temporal combination sensitivity (TCS) where the response of the neuron is sensitive to both the combination and order of pairs of song syllables. Whether these properties arise in HVC or already exist in the afferent neurons is not known.

To address this issue, we compared the degree of context and temporal combination sensitivity of HVC neurons with their auditory afferents in field L (L1, L2a, L3, L2b, and L). Extracellular physiological recordings were made from adult male zebra finches. Single units were isolated with conventional methods and with spike discrimination software. The anatomical location of the recording sites was determined from electrolytic lesions.

Context sensitivity was measured by comparing the response to forward song with the response to the same syllables presented in reverse order. Neurons that showed a significant response to the bird's own song were selected for analysis. In HVC, half of these neurons showed a significant difference between the response to forward song and the response to the syllables in reverse order (15/31). This effect was seen less frequently in neurons in field L (5/25).

TCS was determined by whether a neuron showed 1) a response dependent on the temporal order of a syllable pair and 2) a difference between the response to the syllable pair and the sum of the responses to the individual syllables. Syllable pairs were selected for presentation by comparing the response to syllable pairs in the forward song to the same syllable pair in the reverse syllable order song. Neurons that showed a significant response to the syllable pair were selected for analysis. TCS was not seen in any of the field L neurons (0/13), whereas TCS was present in one third of the selected population of HVC neurons (5/15).

## 381.6

NEUROPHYSIOLOGICAL EVIDENCE FOR SONG DISCRIMINATION IN SONGBIRD NUCLEUS HVC. S.F. Volman\*, Department of Zoology, The Ohio State University, Columbus OH 43210.

Almost all neurons in the song-system nucleus HVC respond preferentially to a bird's own song (Margoliash, 1986). Most hypotheses about the function of this selectivity assume that a bird's song could serve as a useful reference, or "matched filter," for discriminating among the similar songs of other birds. Songbirds do solve this difficult auditory task, because they recognize other individuals by song, and there is often a large amount of song sharing among birds within a local area. I have tested this idea by comparing HVC auditory responses among groups of sibling zebra finches, using the songs of all siblings, and the father, as stimuli. Because song is learned, these songs are highly similar. In the HVC of each bird, the relative responses to the songs were consistent across multiple recording sites. The response profile -- i.e. the relative response strength across stimuli -- was unique in each bird, although, e.g., in a group of 4 brothers, two birds could share a similar profile, which was different from that of the other two birds. Songs that produced the most response in one bird could be the worst stimulus in another. Thus, the response profiles cannot be explained by the general nature of the stimuli, but only by reference to their similarities and differences from a bird's own song. These data support the hypotheses that the unique tuning properties of HVC are useful for audition. Furthermore, because HVC neurons acquire their selectivity during song learning (Volman, 1993), this nucleus appears to be a kind of build-it-yourself perceptual filter, similar to the acquisition of phonemic categorical perception during speech learning in humans. Supported by NIMH grant R29-MH47330

LEARNED SONG DISCRIMINATION AT THE SINGLE CELL LEVEL IN ZEBRA FINCH CAUDOMEDIAL NEOSTRIATUM (NCM). R. Stripling<sup>1</sup>, S.F. Volman<sup>2</sup>, and D.F. Clayton<sup>1</sup>.

<sup>1</sup>Beckman Institute, Urbana, IL, 61801 & <sup>2</sup>Dept. of Zoology, Ohio State Univ., Columbus OH 43210.

The caudomedial neostriatum (NCM) of songbird forebrain responds to playbacks of recorded birdsong with a large and rapid induction of the immediate early genes *zenk* and *c-jun*, both of which have been implicated in learning and memory processes. We set out to investigate the biological significance of these events by recording the electrophysiological responses of single units in the NCM of awake, unanesthetized zebra finches during song playback (Stripling, et. al., Soc Neurosci Abstr, 1994). Here we show that single units in NCM can reduce their response to a song if that song is repeated, without altering their responses to other songs. This learned discrimination develops rapidly within the first few presentations, and approaches an asymptote within ~10 minutes, when one song is presented repeatedly (~2 s of song every 10s). Of particular interest, the acquired response selectivity remains in an apparently labile state for up to 30 minutes, during which time it can be disrupted or abolished by presentations of other songs. The timecourse for consolidation of this learned discrimination parallels the timecourse for consolidation observed in other systems, and may be related to the time required to produce and transport the proteins that are synthesized as a result of the genomic response to stimulation.

SENSORY ACQUISITION IN ZEBRA FINCHES REQUIRES ACTIVATION OF NMDA RECEPTORS IN THE ANTERIOR FOREBRAIN. M.E. Basham<sup>\*</sup>, E.J. Nordeen and K.W. Nordeen, Dept. of Psych. and Neurosci. Program, Univ. of Rochester, Rochester, NY 14627

Activation of NMDA receptors has been implicated in experience-dependent behavioral and neural plasticity. In zebra finches systemic injections of NMDA receptor antagonists during exposure to a song tutor impair song development. In the present study NMDA receptors in one song region, the IMAN, were selectively inactivated during restricted access to a song tutor. The results suggest that song memorization requires activation of NMDA receptors located in or near the IMAN.

Zebra finch chicks were isolated from song until 30 days of age, when they received bilateral cannulae directed at either the IMAN or the cerebellum, or were given sham surgeries. They were then visually isolated from other birds and acoustically isolated from adult male song except during tutoring sessions. Between 32 and 52 days of age all birds were exposed to an adult male tutor and his mate for 90 minutes every other day. Half of the IMAN group and all of the cerebellum group received AP5 infusions (2.5 µg in .1 µl) through the cannulae 5-15 minutes prior to tutoring. The remaining IMAN birds received AP5 infusions only on non-tutoring days. At 90 days of age songs were recorded and the birds were then sacrificed and cannula placement verified. Birds that received AP-5 infusions directed at the IMAN immediately prior to tutoring were impaired in two measures of vocal learning (% of the bird's song learned from the tutor, and % of the tutor's song learned). These birds learned significantly less than shams, cerebellum infused birds or IMAN birds infused on non-tutoring days. In other birds, AP5 infusions into the IMAN did not impair the ability to discriminate zebra finch from canary song. Taken together, these results suggest that song memorization requires activation of NMDA receptors in or near the IMAN. (supported by NIMH #MH45096)

PHYSIOLOGICAL EVIDENCE FOR A SELECTIVE NEURONAL LEARNING PROCESS IN SONGBIRD AUDITORY FOREBRAIN. D.S. Vicario<sup>\*</sup>, F. Nottebohm, and S.J. Chew, Lab. of Animal Behavior, The Rockefeller University, New York, NY 10021.

We are interested in the mechanisms that allow a bird to remember and recognize a familiar vocal signal. Neurons in the caudomedial neostriatum (NCM) of adult songbirds give vigorous auditory responses to playbacks of conspecific song, but these responses decrease (habituate) when the same novel song is repeated many times (Chew et al. 1995).

The establishment and duration of this stimulus-specific habituation depended both on the nature of the auditory stimulus and on the exposure paradigm. Repeated presentation of novel complex auditory stimuli (conspecific and heterospecific songs, conspecific male and female long calls) produced habituation, but pure tone sequences did not. When each stimulus was initially presented 200 times with an 11s inter-stimulus interval (ISI), habituation was maintained for >20h for conspecific song and female calls, 17h for male calls, and <3h for heterospecific stimuli. When short ISIs (<3.5s) were used, no habituation occurred. When the bird heard only 50 presentations of a conspecific song, habituation lasted only 6h. However, if the 50 stimuli were presented in groups of 10, spaced 10 mins apart, the habituation lasted >20h.

Related work has shown that this long-lasting neuronal memory for conspecific vocalizations depends on gene expression within NCM at critical times after exposure to a novel stimulus (Chew et al. 1995). It is possible that forgetting of specific classes of stimuli after characteristic delays may be due to the lack of induction of new genes at those times. We now predict that the manner of presentation of a stimulus also influences gene expression, and through it, memory duration. (MH40900, MH18343)

## 381.8

THE DEVELOPMENT OF SONG- AND ORDER-SELECTIVITY IN THE ANTERIOR FOREBRAIN OF JUVENILE ZEBRA FINCHES. M.M. Solis<sup>\*</sup> and A.J. Doupe, Neuroscience Graduate Program, Keck Center, Depts of Psychiatry and Physiology, UCSF, San Francisco, CA 94143

Auditory experience of both the tutor song and the bird's own plastic song is crucial to song learning. The anterior forebrain pathway (AFP) could be a site of auditory feedback, since it is also required for normal song development, and in adult birds it contains auditory neurons that are highly selective for the bird's own song. This selectivity clearly emerges during development, because these neurons respond equally well to all song stimuli in 30d. zebra finches. To understand the origin of song-selectivity in neurons of the AFP, juvenile zebra finches were studied at an intermediate stage of development, when the sensory phase was closing, and the plastic song of the sensorimotor phase was well underway.

Single unit recordings were made in LMAN and X of 60d. male zebra finches. The acoustic stimuli presented included the bird's own plastic song (BOS), its tutor song, conspecific and heterospecific songs. BOS and tutor song stimuli were the most effective stimuli for neurons, consistently eliciting stronger responses than conspecific and heterospecific songs. Responses to BOS were usually greater than those to tutor song; however, a minority of neurons preferred tutor to BOS stimuli. A small population of neurons remained untuned, responding equally well to many song stimuli. Neurons also exhibited order-selectivity for BOS and tutor song, showing weak responses when these songs were presented in reverse. Neurons in X were often less selective than those in LMAN.

These results show that neurons in the AFP change dramatically between 30 and 60 days of age. Despite the immature quality of the plastic song, BOS selectivity was already displayed by these neurons. In addition, tutor song selectivity was found, a feature not present in younger juveniles. Finally, order-selectivity had developed. Such selective properties at an intermediate stage of song learning support an auditory role for the AFP during song acquisition. Studies of birds in which motor learning has been delayed or altered, thus interfering with the similarity between juvenile and tutor song, will clarify the origin and role of selectivity in the AFP.

## 381.10

IMMUNOCYTOCHEMICAL ANALYSIS OF ZENK GENE INDUCTION BY SONG STIMULATION IN THE ZEBRA FINCH BRAIN. Claudio V. Mello<sup>\*</sup>, Laboratory of Animal Behavior, The Rockefeller University, NY, 10021

The ZENK gene (also known as *zif-268*, *egr-1*, *NGFI-A*, or *Krox-24*) encodes a transcriptional regulator and is induced by song playbacks in specific portions of the forebrain of songbirds. ZENK induction is highest for conspecific songs, lower for heterospecific songs, and absent for pure tones (Mello et al., 1992). ZENK expression peaks at 30 min and returns to control levels about 60 min after stimulus onset. Mapping of ZENK expression in the brain after song playbacks by in-situ hybridization reveals induction in areas closely related to auditory pathways, especially in the caudomedial neostriatum (NCM), but, surprisingly, not in the song control circuit (Mello and Clayton, 1994). The study of regulation of the ZENK gene has now been extended to the protein level. An antiserum that recognizes the carboxy-terminal of the protein predicted by the ZENK sequence has been used in an immunocytochemical assay for the ZENK protein. This antibody detects a nuclear protein in telencephalic neurons of zebra finches after song or metrazole-induced depolarization. This method is being used to determine the time course of expression and anatomical distribution of ZENK protein in the brain of zebra finches hearing playbacks of conspecific song. Defining when and where ZENK protein is present is an essential step in the search for genes that may be targets of ZENK action.

## 381.12

LONG-TERM NEURONAL MEMORIES FOR NOVEL CONSPECIFIC SONGS REQUIRE NEW GENE EXPRESSION IN AVIAN AUDITORY FOREBRAIN. S.J. Chew<sup>\*</sup>, E.D. Jarvis, C.Y. Mello, D.S. Vicario and F. Nottebohm, Lab. of Animal Behavior, The Rockefeller University, New York, NY 10021.

Song playbacks induce expression of an immediate early gene, ZENK, in the caudo-medial neostriatum (NCM) of songbirds; this induction is higher for conspecific than for heterospecific songs. Multi-unit recordings in NCM of zebra finches have demonstrated vigorous auditory responses that habituate to repeated presentation of a novel song stimulus; this physiological memory is long-lasting for conspecific, but not heterospecific, songs.

The present study assessed the role of new gene expression in long-term habituation to song by injecting inhibitors of RNA (actinomycin-D, or ACT) and protein (cycloheximide, or CYC) synthesis, and antisense RNA molecules into NCM at the site of electrophysiological recordings. ACT, CYC and ZENK anti-sense had no effect on short-term habituation of NCM neurons. However, ACT and CYC disrupted long-term habituation (tested 3-24h after training) when injected at 1-3h, 6-7h, 15h, and 17h after training. ZENK antisense disrupted long-term habituation when injected up to 1h after training. Control injections of ZENK sense or of anti-sense to another gene not induced by song playback, but known to be expressed in the tissue, had no effect. Immunocytochemistry showed that ACT, CYC and ZENK anti-sense injections block production of the ZENK protein in a limited subregion of NCM, but ZENK sense does not; we are now determining the specificity of this anti-sense effect. Our results show that the long-term auditory memory for conspecific songs depends on new RNA and protein synthesis in NCM at defined intervals after training, and suggest that the induction of the ZENK gene is a necessary step in the establishment of this memory. (MH40900, MH18343, GM12562)

## 381.13

EXPRESSION OF THE ZENK GENE IN CANARY FOREBRAIN IS IMPLICATED IN THE MEMORIZATION OF VOCAL SIGNALS THAT REGULATE GOAL-DIRECTED BEHAVIOR. E.D. Jarvis\*, S.J. Chew, C.V. Mello, M.V. Rivas and F. Nottebohm. Laboratory of Animal Behavior, The Rockefeller University, NY 10021.

Birds exposed to song paired with a mild shock give fear responses to the song and eventually learn to avoid the shock by hovering in the air when they hear the song. This training induces expression of the immediate early gene ZENK in the auditory NCM-HVCM region above levels seen in yoked-unpaired controls or in birds hearing song alone. Expression in other hyperstriatal subdivisions (HD, HA, rostral HV), LPO, and Hippocampus occurred from the shock alone. We examined whether the enhancement of ZENK expression in NCM-HVCM of trained birds is related to attention or to associative learning. Birds overtrained to associate song with shock gave 80-100% avoidance responses to the song stimulus and by then presumably had little new to learn about the paired stimuli. These birds jumped precisely before the shock was given, indicating that they were paying close attention to the song. In-situ analysis of brain sections hybridized with ZENK riboprobes revealed an inverse relation between the amount of overtraining and the level of ZENK expression. Lesions in NCM-HVCM impaired learning of the avoidance response but not of the fear response. Likewise, injections of ZENK antisense RNA into NCM-HVCM impaired long-term retention of the avoidance response but not of the fear response. Taken together, our results and other published data suggest that ZENK expression in NCM-HVCM is related to higher order processing and memorization of naturally occurring communication signals that regulate goal directed behaviors.

## 381.15

PCR-BASED mRNA DIFFERENTIAL DISPLAY REVEALS ENRICHMENT OF ALDEHYDE DEHYDROGENASE IN THE HIGH VOCAL CENTER AND IN TWO OTHER NUCLEI OF THE SONG SYSTEM OF SONGBIRDS. N. Denisenko\*, F. Nottebohm and C. Mello. Laboratory of Animal Behavior, The Rockefeller University, NY, 10021.

HVC (High Vocal Center) is necessary for the acquisition and production of learned vocalizations in song-birds. PCR-based mRNA differential display was used to screen for mRNAs enriched in the HVC of adult male zebra finches. HVC and its underlying "shelf" region were dissected out for comparison in three birds and RNAs were isolated. Approximately one third of the possible primer combinations described by Liang and Pardee (Science, 257:967-970, 1992) were used to PCR-amplify mRNAs from HVC and "shelf" samples; 23 primary candidates for differentially expressed mRNAs were detected. Using in situ hybridization to brain sections containing HVC and the "shelf" region in a secondary screening procedure, we identified six clones that were expressed at higher levels in HVC than in the rest of the forebrain. Expression of one of these clones was particularly high in HVC, high in anterior neostriatum (including IMAN), lower in RA and very low or absent elsewhere in the forebrain. IMAN and RA are part of the song system and, as is the case for HVC, are necessary for the acquisition or production of learned song. Sequence analysis revealed significant homology to aldehyde dehydrogenase (ALDH) of several species. ALDH function has been linked to catecholamine metabolism and retinoic acid synthesis. We are currently investigating the possible role of ALDH in the acquisition and production of learned song.

EFFECTS OF NEUROMODULATORS ON EXCITATORY SYNAPTIC TRANSMISSION IN NUCLEUS RA OF THE ZEBRA FINCH. D. J. Perkel\* Div. Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

Nucleus RA is a prominent brain region crucial for vocal production and learning in songbirds. Modulation of synaptic strength in RA is a leading candidate mechanism underlying behavioral plasticity. As part of a long-term goal of understanding the cellular substrates of learning, I am characterizing synaptic transmission and putative modulators of synaptic strength in RA.

Coronal brain slices were prepared from male zebra finches just beginning to sing (30 - 45 days old), and whole-cell voltage-clamp recordings were obtained from RA neurons in those slices. Antidromic stimulation of RA output fibers permitted selective activation of recurrent collaterals, which give rise to the major class of excitatory synapse (> 75%) in RA. These synapses were compared with previously described inputs from nuclei HVC and L-MAN.

The collateral synapses in RA were found to resemble those arising from HVC fibers and to differ from L-MAN connections: application of the glutamate receptor (gluR) antagonists CNQX and APV showed that transmission is dually mediated by NMDA and non-NMDA postsynaptic gluRs; transmission was blocked by activation of GABA<sub>A</sub> receptors; and transmission was relatively insensitive to norepinephrine (NE). In addition, activation of metabotropic gluRs by bath application of 1S-3R-trans-ACPD (100  $\mu$ M) reversibly blocked synaptic transmission in all three (HVC, L-MAN and recurrent) synaptic populations.

The pharmacological similarity of synapses made by collaterals in RA to those made by HVC fibers is consistent with a major role for intrinsic RA circuitry in the primary motor pathway for song production. These findings extend previous observations of differential effects of neuromodulators on inputs to RA; in particular, they suggest additional complexity of modulation by selective or global adjustment of synaptic strength.

## 381.14

SEASONAL REGULATION OF IMMEDIATE EARLY GENE EXPRESSION IN THE SONG CONTROL NUCLEI OF THE MALE CANARY FOREBRAIN. Fernando Nottebohm\* and Erich D. Jarvis. Laboratory of Animal Behavior, The Rockefeller University Field Research Center, Millbrook, NY 12545.

Adult male canaries undergo seasonal periods of song plasticity. During the late summer/early fall new song syllables are acquired, others are modified and still others disappear. We investigated whether these changes in vocal behavior were accompanied by changes in expression of the immediate early gene ZENK, which has been implicated in the formation of song auditory memories. 1 to 2 year old male canaries were sacrificed at different months of the year. Brains were removed and in-situ hybridizations were performed with 35S-ZENK riboprobes. In the fall, over 40% of the birds showed ZENK expression in the song nuclei HVC and RA at levels 2-7 times higher than the barely detectable levels seen in the spring. The highest expression occurred during the month of October which coincides with 1) the peak in the recruitment of new neurons into HVC, 2) a rise in blood testosterone levels and 3) consolidation of newly learned syllables. Because expression was seasonally higher in RA, where there is no adult neurogenesis, and also in the large X projecting cells of HVC, which are not formed in adulthood, ZENK regulation does not appear to be directly related to neurogenesis. Since HVC and RA are necessary for the acquisition and production of learned song, our observations suggest that ZENK expression in the song system is related to circuit changes that underlie the long-term acquisition of new song memories.

## 381.16

Synelfin mRNA Expression is Differentially Regulated in Nucleus IMAN of Zebra Finches Raised Under Acoustic Isolation

H. Jin, D. F. Clayton\* Cell and Structural Bio., U. of Illinois, Urbana, IL, 61801

Male zebra finches form a model of a tutor's song during a "critical period" in juvenile development. Under normal conditions, the critical period for song model acquisition ends by ~35d after hatching. The closure of the critical period may be delayed, however, if birds are raised in auditory or visual isolation from potential tutors (R.G. Morrison & F. Nottebohm, J. Neurobiol., 24: 1045-1064, 1993). We recently described the identification of a gene -- synelfin -- whose expression is regulated in IMAN, a telencephalic nucleus implicated in song model acquisition (Soc. Neurosci. Abstr., 19:807, 1993). Synelfin mRNA is highest early in the critical period, but then drops sharply at 30-35d. In order to examine the linkage between the differential regulation of synelfin and the progression of the critical period, we compared the levels of synelfin mRNA in IMAN in males raised either in a normal aviary or in acoustic isolation, by means of RNA *in situ* hybridization. Pilot data indicate that birds reared in isolation had significantly higher synelfin mRNA levels in IMAN at 30d than did the normal birds ( $p=0.01$ ,  $n=2$  normal birds,  $n=4$  isolated birds). Additional replications of this experiment are currently being analyzed, and will be described. This preliminary result suggests that increased synelfin mRNA levels may be closely linked to increased functional plasticity in IMAN, and that a decrease in synelfin may be correlated with closure of the critical period for song model acquisition. The potential ability of environmental manipulations to alter synelfin expression is of particular interest, since synelfin's human homolog has recently been implicated as a molecular participant in the pathology of Alzheimer's Disease. (Supported by NIH grant NS25742)

## 381.18

DEVELOPMENTAL STUDIES OF GLUTAMATE RECEPTOR AND PEPTIDE IMMUNOREACTIVITY IN THE ZEBRA FINCH SONG SYSTEM. G. Carrillo and A. J. Doupe\*, Psychiatry/Physiology Depts., UCSF, San Francisco, CA 94143

Sensory exposure during a critical developmental period is essential for normal song learning in songbirds. During this period, lesions of the anterior forebrain pathway (AFP) disrupt song learning, while similar lesions in adults have no effect. To understand further the changing role of this pathway in song learning, we studied the development of neurotransmitters in the AFP, using immunohistochemical staining for the R1 subunit of the NMDA receptor and for two peptide neurotransmitters, leu-enkephalin and Substance P.

In 20d old male zebra finches, LMAN cell bodies and their dendrites showed intense NMDAR1 labelling, and were indistinguishable in immunoreactivity from the surrounding neostriatum. In contrast, in adult finches LMAN neurons showed a striking reduction in R1 immunolabelling, and stained much less intensely than the surrounding cells. In 40d birds, R1 immunoreactivity in LMAN was intermediate between that of 20d and adult birds. This result is in agreement with previous studies of LMAN using MK-801 autoradiography (Aasmund et al., 1993). Furthermore, in 20d old finches, the entire parafactory lobe (LPO), including Area X, was also immunoreactive for R1. By adulthood, however, Area X showed a marked decrease in immunolabelling relative to the surrounding LPO. This developmental decline in receptor labelling in both LMAN and X may be linked to the decreased role of the anterior forebrain sensory circuit as birds mature and learn. Peptide immunoreactivity showed similar developmental changes in some song nuclei. Area X and RA were more strongly enkephalin-immunoreactive in 20 and 35d old birds than in adults, while HVC, LMAN, and NIF were well-labelled at all ages. Substance P immunoreactivity was prominent in Area X at all ages, but appeared to decrease in intensity with age. Increased knowledge of the transmitters involved in the song system and of how they change during ontogeny should lead to a more mechanistic understanding of song acquisition and suggest manipulations to assess the role of these molecules in development and learning.

## 381.19

DEVELOPMENTAL INCREASES IN TYROSINE HYDROXYLASE IMMUNOREACTIVITY AND CATECHOLAMINE LEVELS IN MALE ZEBRA FINCH SONG NUCLEI. J.A. Soha<sup>1</sup>, T. Shimizu<sup>2</sup>, and A.J. Doupe<sup>3</sup>. <sup>1</sup>Dept. of Neurobiology, Physiology and Behavior, UC Davis, CA 95616, <sup>2</sup>Dept. of Psychology and Surgery, Univ. of So. Florida, Tampa, FL, 33620, and <sup>3</sup>Keck Center and Depts. of Psychiatry and Physiology, UCSF, San Francisco, CA 94143

Several of the interconnected brain nuclei which mediate song learning and production in the male zebra finch (*Taeniopygia guttata*) have been shown to contain catecholamines (CA), both by direct chemical assay and by immunolocalization of tyrosine hydroxylase (TH), the synthetic enzyme for CA. Neuro-modulatory roles have been proposed for CA both in the adult song system and in a number of other neural systems, particularly during experience-dependent plasticity. We therefore investigated the appearance of CA in song nuclei of male zebra finches during posthatch development, i.e. the period during which song learning occurs. Using immunohistochemical staining, we examined the intensity of TH-immunoreactivity in the song nuclei HVC, LMAN, RA, and Area X in young males aged 20, 35, and 60 days as well as in adults (>90 days). We also visualized catecholamines directly in Area X using CA histochemistry. Both TH immunoreactivity and CA histochemistry were initially low in Area X relative to the surrounding parabrachial lobe (LPO), and then increased during development to become more intense than LPO by day 60-90. Similarly, TH immunoreactivity in HVC was initially low relative to the surrounding neostriatum, then increased during development to become more intense than the surround by day 60. RA and LMAN also showed large increases in TH immunostaining over the same period. These results show that CA levels increase in song nuclei during development and thus raise the possibility that these transmitters play a role in the development of the song system and/or in song learning. Supported by the Markey Charitable Trust, NSF IBN9209538, and a Caltech Summer Undergraduate Fellowship.

## 381.20

CHANGES IN CATECHOLAMINE LEVELS AND TURNOVER IN THE BRAINS OF MALE ZEBRA FINCHES OVER DEVELOPMENT. C.F. Harding<sup>\*</sup>, S.R. Barclay, and S. Waterman. Biopsychology Program, Hunter College, CUNY, New York, NY 10021

Catecholamine (CA) levels and turnover were quantified in ten behaviorally-relevant brain nuclei (6 vocal control [VCN], 2 auditory [AN], 2 hypothalamic [HN]) at four critical points during development of the VCN and the period of song learning. Aviary-housed finches were sacrificed at 25, 35, 55, and 90 days of age. Some birds were pretreated with  $\alpha$ -methyl-para-tyrosine ( $\alpha$ MPT) to allow estimation of CA turnover, and CA levels in microdissected nuclei were quantified using high performance liquid chromatography with electrochemical detection.

Patterns of CA function in VCN and AN were quite different from those in HN in which CA function showed gradual changes and no striking peaks. Norepinephrine (NE) levels and/or turnover changed significantly over development in 5 VCN, 1 AN, and 1 HN. In all VCN and AN in which significant changes were found, NE levels and/or turnover showed a striking peak at day 25, suggesting a possible role in song memorization. DA levels and/or turnover also varied significantly over the 4 time points in 5 VCN, 2 AN, and 1 HN. However, DA peaked later than NE--between days 35 and 55, suggesting a possible role in vocal practice.

In contrast to hypothalamic areas, peak NE and DA levels and turnover rates in most VCN and AN during development were dramatically higher than those seen in these areas in adulthood, reaching levels never seen in adults. In four cases, when CA synthesis was blocked by use of  $\alpha$ MPT, tissue levels of NE and/or DA in these areas were exhausted within an hour.

## NEUROETHOLOGY: SONGBIRDS II

## 382.1

TESTOSTERONE MODULATION OF GABA<sub>A</sub> RECEPTOR DENSITY IN THE ZEBRA FINCH VOCAL CONTROL SYSTEM. W.R. Perlman<sup>\*</sup>, J.M. Castro, D.J. Bernard and G.F. Ball. Dept. of Psychology, Behavioral Neuroendocrinology Group, Johns Hopkins University, Baltimore, MD 21218

Zebra finches (*Taeniopygia guttata*) possess a neural circuit consisting of discrete nuclei that mediate the learning and production of song. The production of song in males is influenced by testosterone (T): castration greatly reduces song rate. In order to identify neurotransmitter systems involved in the production of song and their possible modulation by T, we mapped the distribution of GABA<sub>A</sub> receptors with the use of an *in vitro* quantitative receptor autoradiography procedure employing the GABA<sub>A</sub> agonist [<sup>3</sup>H] muscimol as the ligand. Receptors were labeled in adult (> 90 days) male and female intact birds and in castrated, and T-treated castrated, male finches. The highest densities of GABA<sub>A</sub> receptors were detected in the paleostriatum primitivum, the lateral archistriatum, and the granule layer of the cerebellum. Within the vocal control system the High Vocal Center (HVC) and area X could be defined by their high receptor density in comparison to the surrounding structures. The robust nucleus of the archistriatum and the magnocellular nucleus of the neostriatum were characterized by receptor densities that are among the lowest detected anywhere in the telencephalon. Significant effects of castration were detected in HVC, an area that contains androgen receptors, but not in other song control areas. T-treated castrates exhibited a higher receptor density than untreated controls. Previous studies in birds and mammals have demonstrated that steroid hormones influence GABA<sub>A</sub> receptor density in steroid-sensitive areas of the hypothalamus. The localization of GABA<sub>A</sub> receptors in vocal control nuclei and their modulation by T suggests that GABA may be involved in song production.

## 382.2

LATERALIZATION OF SYRINGEAL FUNCTION IN TESTOSTERONE-TREATED FEMALE CANARIES. R.S. Hanley<sup>\*</sup>, M. S. Chinn and N. E. E. Ullrich. Biology Department, Seattle University, Seattle, WA 98122.

Male canaries (*Scrinus canaria*) produce most of their song syllable types on the left side of the syrinx, the two-sided vocal organ. Female canaries, which seldom sing, produced small repertoires (7-14 syllable types per bird) when treated with testosterone propionate (T). To learn whether left syringeal dominance occurs in T-treated female canaries, we cut the tracheosyringeal nerve on either the right or left side, to disrupt syllable production on that side of the syrinx. Pre- and post-operative syllable types were recorded and identified visually on spectrograms by their frequency structures and repetition rates. Right nerve cuts had minor effects on the syllable repertoires of three birds (88%, 89% and 92% of syllable types remained), whereas left nerve cuts had severe effects on the syllable repertoires of three birds (22%, 27% and 29% of syllable types remained). Two additional birds, one with a right nerve cut and one with a left nerve cut, had partially altered syllable repertoires (64% and 50% of syllable types remained, respectively). We conclude that most, but not all, female canaries generate the majority of their syllable types with the left syrinx.

## 382.3

SEX DIFFERENCES IN VOCAL BEHAVIOR IN BUDGERIGARS ARE NOT ASSOCIATED WITH A SEX DIFFERENCE IN THE VOLUME OF THE TELENCEPHALIC VOCAL CONTROL NUCLEUS, LPOm. A. A. Nespor<sup>\*</sup>, G. F. Ball & R. J. Dooling. Dept. Psych., Univ. of Maryland at College Park, College Park, MD 20742 & Dept. Psych., Johns Hopkins Univ., Baltimore, MD 21218.

Budgerigars (*Melopsittacus undulatus*) produce a complex learned vocal repertoire that includes a long rambling song called warble. Both males and females warble, but there are marked sex differences in the amount of song produced. Males warble daily at a high rate, while females rarely sing. Previous investigations on songbirds have shown that sex differences in vocal behavior are associated with sex differences in the volume of song control nuclei with the volume usually being larger in males. Such relationships between sex differences in brain and behavior have not been investigated in any psittacine species such as the budgerigar. The goal of the present study is to determine if budgerigars possess a sex difference in the volume of the magnocellular nucleus of the parabrachial lobe (LPOm) a telencephalic vocal control nucleus. This nucleus was chosen because it appears to be analogous to area X, a subdivision of the parabrachial lobe in the song bird vocal control circuit, that exhibits a large sex difference in volume in many species. We employed two techniques to delineate the boundaries of LPOm and re-construct its volume. Sections (25µm) were collected from male and female budgerigars and either Nissl stained or were labeled for muscarinic cholinergic (MC) receptors with the use of an *in vitro* autoradiography procedure. The MC antagonist, N-methyl scopolamine served as the ligand. As previously reported by Striedter (1994 JCN 343:35-56) the boundaries of LPOm were apparent in the Nissl stained sections by the more darkly staining large cells evenly interspersed among the more numerous small cells characteristic of the rest of the LPO. In the autoradiogram, the boundaries of LPOm were defined by the higher density of MC receptors in comparison to the surrounding LPO (Ball, 1994 Brain, Behav, Evol 44:234-246). When the volume of LPOm was re-constructed with either histochemical marker, no significant sex difference in volume was detected. Thus, sex differences in vocal behavior in budgerigars are not associated with differences in LPOm volume.

## 382.4

SEASONAL CHANGES IN THE VOLUME OF SONG CONTROL NUCLEI IN FREE-LIVING MALE AND FEMALE EUROPEAN STARLINGS

D.J. Bernard<sup>\*</sup> and G.F. Ball, Behavioral Neuroendocrinology Group, Department of Psychology, Johns Hopkins University, Baltimore, MD USA

Temperate zone songbirds sing most during the breeding season and less often at other times of year. Brain nuclei in the neural circuit controlling song learning and production undergo changes in morphology that parallel these behavioral changes. In the laboratory, birds housed on long, spring-like photoperiods have larger song control nuclei than birds on short, winter-like day lengths. Long days also induce increases in circulating testosterone (T) levels, and the observed volume changes may be mediated by T-dependent mechanisms. Because no studies to date have systematically investigated plasticity in the song control system under natural conditions, it is unclear to what extent the volume changes observed in the lab reflect changes as they occur in the wild. In the present study, we measured the volume of song nuclei in adult male and female European starlings (*Sturnus vulgaris*) collected from the field every month from March 1994 through February 1995. Based on laboratory results, we predicted that song nuclei would be largest during the breeding season when T levels were elevated. The volume of three song nuclei, the high vocal center (HVC), nucleus robustus archistriatalis (RA), and area X were significantly larger in males than in females in every month of the study. In both sexes, area X volume decreased during the breeding season (May-July), was large during the late summer and fall when T levels were low, and decreased again in volume in January and February when T levels were increasing in males. The volumes of HVC and RA did not change significantly over the study period, although the largest volumes for both nuclei were observed in April when T levels peaked. In sum, the form and magnitude of changes in volume of song nuclei differ in laboratory and field contexts in European starlings.

**HORMONAL AND BEHAVIORAL CORRELATES OF SEASONAL PLASTICITY IN THE SONG NUCLEI OF A WILD SONGBIRD.** G.T. Smith\*†, E.A. Brenowitz†, M.D. Beecher†, S.E. Campbell†, and J.C. Wingfield†. Departments of †Zoology (NJ-15) and ‡Psychology (NI-25), University of Washington, Seattle, WA 98195

Song control nuclei are larger in captive male songbirds that are housed in breeding, vs. nonbreeding, conditions. Few studies have asked whether these changes occur in wild songbirds, and none have asked what the behavioral correlates of these changes are in species that lack adult song learning. We measured seasonal changes in the song nuclei and song behavior in wild song sparrows (*Melospiza melodia*) to address these questions.

We captured adult male song sparrows at four times of year: (1) March 1-31 (prebreeding), (2) April 1- May 15 (breeding), (3) September 1- October 15 (postmolt), and (4) December 1-31 (late fall). We collected blood samples to measure plasma testosterone (T) concentrations. We perfused the birds and measured the size of their song nuclei. We also recorded the song repertoires of the same five adult male song sparrows at each time of year to determine if there were changes in repertoire size, within-song type stereotypy, or syllable morphology.

We found seasonal changes in the size of song nuclei that were temporally correlated with changes in plasma T concentrations and with changes in within-song type stereotypy, but not repertoire size. These results demonstrate seasonal changes in the song nuclei of wild songbirds and suggest that seasonal plasticity in the song nuclei is associated with seasonal changes in song stereotypy. GTS is a HHMI predoctoral fellow.

## 382.7

**BRAIN SPACE FOR LEARNED SONG IN BIRDS DEVELOPS INDEPENDENTLY OF SONG LEARNING.** E. Brenowitz\*, K. Lent, and D. Kroodsmma. Depts. of Psychol. & Zool., Univ. of WA, Seattle, WA 98195 & Dept. of Biology., Univ. of MA, Amherst, MA 01003.

In numerous species of songbirds, individuals or species that sing larger numbers of song types have larger song control nuclei in their brains. The direction of the cause and effect relationship between the complexity of song behavior and brain space is unknown, however. The hypothesis that birds that learn large song repertoires develop large song nuclei was therefore tested with a songbird, the marsh wren (*Cistothorus palustris*).

Males were hand-reared and tutored in the laboratory with either small ( $n = 8$  males heard 5 song types) or large ( $n = 8$  males heard 45 song types) repertoires. When the birds were adults, the number of song types each male sang was first determined. The birds were then sacrificed and the volume and cellular attributes of the forebrain song nuclei HVC and RA were measured from Nissl-stained sections.

Adult males in the small repertoire tutor group produced 5-6 song types, and males in the large repertoire group produced 36-47 song types. Despite these large behavioral differences in the size of their learned song repertoires, the two groups did not differ in either the volumes of HVC and RA or in neuronal size, number, or density within these nuclei. These results suggest that the relationship between behavioral song complexity and brain space found in this and other species develops largely independently of early song learning experience and the later production of those songs.

## 382.9

**A PARALLEL CIRCUIT LINKING IMAN AND AREA X IN THE AVIAN SONG SYSTEM** A.D. Perera, F.Hunger, M. Gahr and J. M. Wild\*. Dept. of Anatomy, Univ. of Auckland, New Zealand, and Max Planck Institute, Seewiesen, Germany.

The "recursive loop" that links the thalamic nucleus DLM to IMAN and Area X in the forebrain is thought to be necessary for song learning in the developing bird but not for song production in the adult. The neuronal pathways linking these nuclei have been described, but our data suggest that the previously published circuit may be incomplete. The experiments show that neurons in IMAN that send axons to RA also send axons to Area X, thereby establishing a "parallel" link between IMAN and Area X. Injections of biotinylated dextran amine (BDA) or fluorescent tracers into different parts of Area X in juvenile and adult zebra finches or canaries retrogradely labeled cells in IMAN. The BDA injections also produced terminal fields in different parts of RA. In comparison, injections into RA produced retrogradely cells within IMAN but only a very sparse terminal field within Area X. This latter observation was in sharp contrast to injections into IMAN which resulted in dense terminal fields in both RA and Area X. These data suggest that the nature of the axonal terminations of IMAN neurons in RA differs from that of the terminations in Area X. Furthermore, these results imply that only some of the IMAN neurons that project to Area X also send axons to RA. Double-labelling experiments are required to determine the proportion of IMAN neurons that send axons to both of these two nuclei. (Supported by the Whitehall Foundation, Inc.)

## 382.6

**PHOTOPERIOD REGULATION OF CELL DEATH IN ADULT AVIAN TELENCEPHALON.** J.R. Kirm\* & H. Schwabl. \*Biology Dept., Wesleyan University, Middletown CT 06459, and Rockefeller University Field Research Center, Millbrook, NY 14857.

The High Vocal Center (HVC) in adult male canaries exhibits neuronal loss and replacement at a higher rate in fall than in spring (Kirm et al., PNAS, 91: 7844-48, 1994). In the present experiment, the effect of day length on HVC cell survival was explored as a step toward addressing the possibility that photoperiod regulates the seasonal death and recruitment of neurons. All birds experienced a photoperiod regime corresponding to natural, seasonal changes in photoperiod (in NY State) for at least 1 yr. prior to the experiment. In May, adult males (1-2 yrs. old) were either transferred from long days (14.5 hr / 9.5 hr L/D) to short days (8 hr / 16 hr) or were kept on long days for 2 weeks. Birds were then overdosed with anesthetic, perfused with 0.9% PBS followed by 4% paraformaldehyde in PBS and their brains processed for light microscopy. The number of pyknotic, degenerating cells/mm<sup>2</sup> in HVC was quantified in 10-12 Nissl-stained 6  $\mu$ m sections from each bird. The density of dying cells was nearly 5 times higher in short day birds (mean  $\pm$  SE =  $1.41 \pm 0.31$ ;  $n=5$ ) compared to long day birds ( $0.29 \pm 0.13$ ;  $n=5$ ;  $t(8) = 3.33$ ;  $p = .01$ ). These results indicate that changes in photoperiod can induce HVC cell death and suggest further that seasonal cell death in the HVC of adult canaries is regulated by naturally occurring variation in photoperiod.

## 382.8

**THE AUDITORY PATHWAY THROUGH NUCLEUS BASALIS IN OSCINE SONGBIRDS DOES NOT APPEAR TO BE CONNECTED TO THE VOCAL MOTOR SYSTEM.** G.F. Striedter\* and S. Young. Division of Biology, California Institute of Technology, Pasadena, CA 91125.

Oscine songbirds and parrots have independently evolved the ability to learn complex vocalizations and have evolved different pathways to convey auditory feedback to the vocal motor system. Specifically, previous anatomical studies have suggested that auditory information is conveyed to the vocal motor system via Field L in songbirds, but via nucleus basalis in parakeets. The auditory pathways through Field L and nucleus basalis coexist in parakeets, but it was not known whether songbirds also possess an auditory pathway through nucleus basalis.

We therefore injected biotinylated dextran into the physiologically identified auditory portion of nucleus basalis ( $n=3$ ) in zebra finches. Cells were retrogradely labelled in the intermediate nucleus of the lateral lemniscus (LLi) bilaterally and terminal arborizations were labelled in the contralateral nucleus basalis. This projection pattern suggests that individual cells in LLi project bilaterally to the caudal portion of nucleus basalis. Terminal arborizations were also labelled in the ipsilateral frontal neostriatum adjacent to the caudal nucleus basalis. Tracer injections that included this portion of the frontal neostriatum ( $n=2$ ) labelled terminal arborizations in the caudal pole of the ipsilateral neostriatum. An injection into this portion of the caudal neostriatum retrogradely labelled cells in the ipsilateral frontal neostriatum, confirming the hypothesis that the auditory pathway courses from nucleus basalis through the frontal neostriatum to the caudal neostriatum. None of these injections yielded labelling in the nuclei of the so-called oscine song system. These data suggest that an auditory pathway through nucleus basalis exists in songbirds but does not play a major role in the control of vocalization. The data also support the hypothesis that parrots and songbirds are using non-homologous auditory pathways to provide auditory feedback to the vocal motor system. ## 382.10

**DIFFERENT KINDS OF PLASTICITY IN THE ZEBRA FINCH FOREBRAIN.**

A. Rellenhagen and H.-J. Bischof. Universität Bielefeld, Fakultät Biologie, Postfach 100131, 33501 Bielefeld, F.R.G. (Sponsor: EBBS)

The hyperstriatum accessorium (HIA), the medial neo-hyperstriatum (MNII), the lateral neo-hyperstriatum (LNII) and the archi-neostriatum caudale (ANC) of the zebra finch forebrain are activated in arousing situations (Bischof and Herrmann, 1986, 1988).

Within these four areas changes in spine density due to rearing conditions and the first courtship encounter can be observed by means of the Golgi method. Rearing birds in isolation decreases the density of spines (compared to social rearing) within HIA and ANC, and increases the spine density within MNII and LNII. Short social contact (7 days) after isolated rearing enhances spine density in HIA and ANC, and reduces the density of spines in MNII and LNII. The spine density returns to isolation values within HIA and ANC, but not within MNII and LNII if the birds are isolated again after social contact. The acoustic field I and the visual ectostriatum are not activated by arousal situations, and do not show any alterations.

Our results show that plastic changes due to the social environment can only be observed in areas activated in arousing situations, and that both, reduction and enhancement, is possible. We assume that the complexity of the HIA and ANC neuronal nets mirrors the complexity of the social environment. The reduction of spines within MNII and LNII, in contrast, may be the anatomical manifestation of an imprinting process which has been shown to occur in the same experimental situation as we used in our present study (e.g. Bischof and Clayton, 1991).

## 382.11

DEVELOPMENT OF SONG SYSTEM STRUCTURES IN NORMAL AND SONG DEPRIVED ZEBRA FINCHES. C. E. Collins\*, T. E. Ahmad, S. Das and T. J. DeVoogd  
Developmental Neuroscience Group, Uris Hall, Cornell University, Ithaca, NY 14853

Song development in zebra finches (*Taeniopygia guttata*) takes place during a juvenile sensitive phase. Songs heard during this early sensitive phase are used as models for the song the young male bird will later produce. As adults, only male zebra finches produce song.

To address song-specific neural development, zebra finches were raised deprived of the opportunity for song learning and compared with finches which had learned song normally. Opportunity for song learning is manipulated by removing adult males from the aviary when the oldest hatchling is 5d old. Volumes of two song structures, HVC (high vocal center) and RA (robust nucleus of the archistriatum) were measured to assess gross anatomical changes associated with song development. The volume of a non-song-related telencephalic area, ectostriatum, was measured as an experimental control. Zebra finches were perfused at 35d and 55d of age. Volume data were collected from 40 µm thick, Cresyl violet stained sections using NIH Image software.

Preliminary data from 55d old zebra finches (N=12) suggest no volumetric differences in song structure HVC, but do indicate significant differences in RA, with the deprived finches showing smaller RA volumes. Measures of control area, ectostriatum, indicate no significant differences in volume, suggesting no general telencephalic effects of song deprivation. Recent research on white-throated sparrows (*Zonotrichia albicollis*) demonstrate variations in RA volume with amount of song production (DeVoogd et al., 1995). We are currently investigating whether observed differences in RA volume between song-deprived and normally raised zebra finches correlate with amount of song produced.

## 382.13

EVIDENCE FOR A NOVEL REAFFERENT PATHWAY IN THE VOCAL MOTOR SYSTEM OF SONGBIRDS. G.E. Vates\*, D.S. Vicario, & E. Nottebohm. Lab. of Animal Behavior, The Rockefeller University, New York, NY 10021.

Songbirds learn their song by reference to auditory information. However, once song is learned, deafening has no immediate effect on the stereotypy of the learned repertoire. We wanted to test the possibility that the efferent pathway for song production receives other feedback about ongoing motor commands. The efferent pathway goes from the High Vocal Center (HVC) to the robust nucleus of the archistriatum (RA), which in turn innervates mesencephalic and medullary nuclei involved in vocalization. Neural tract tracers (biotinylated dextran amines, rhodamine-linked dextran amines, and fluorogold) were used to show that the RA of adult male canaries sends a strong projection to a part of the dorsal thalamic complex (previously named DMP), which includes many neurons that innervate the medial portion of the magnocellular nucleus of the anterior neostriatum (mMAN), which in turn innervates HVC. A weaker projection from RA was seen to another dorsal thalamic nucleus, DLM. Initial results indicate that this projection to the dorsal thalamus originates in the dorsal subregion of RA, which is known to project preferentially to the midbrain and to a lateral medullary region involved in respiratory control of song. A similar pattern of connections was seen in zebra finches, although the projection from RA to the dorsal thalamic complex does not appear to be as robust. Thus, HVC may receive feedback about specific aspects of the motor program it generates via the loop through RA, DMP and mMAN. This feedback pathway could be essential for song learning or production.

## 382.15

ORGANIZATIONAL FEATURES OF BUDGERIGAR VOCAL CIRCUITRY RELATIVE TO SONGBIRDS: A DISTRIBUTED VERSUS A HIERARCHICAL SYSTEM. S.E. Durand\*, J.T. Heaton and S.E. Brauth. Dept. of Psychology, UMCP, College Park, MD, 20742

Vocal control circuitry of the oscine forebrain consists of a direct and an indirect pathway onto the robust nucleus of the archistriatum (RA). These two pathways are interconnected but are unidirectional and unilaterally organized. The indirect pathway onto RA incorporates nuclei within, respectively, the lobus parolfactorius (LPO), dorsal thalamus and anterior neostriatum (NA). Absence of a comparable circuit in budgerigar has been proposed as a distinguishing feature of parrot vocal pathways (Streidter, G.F., 1994, JCN 343:35-56). Using pathway tracing we have identified at least 3 such circuits by which parrot RA is connected to forebrain nuclei other than parrot "high vocal center" (HVC). These circuits incorporate nuclei within LPO, NA and dorsal thalamus, that appear comparable to oscine vocal control nuclei, as well as additional cell groups: the oval nucleus of the anterior hyperstriatum ventrale (HVo) (Streidter, 1994) and a peri-n. ovoidalis (OV) region that may provide input from accessory auditory pathways. Thus, it is not the absence of a comparable circuitry that distinguishes the parrot system but rather an organization that is distributed and more elaborate. DMm: magnocellular nucleus of the dorsomedial thalamus; nXIIIts: tracheosyringeal portion of the hypoglossal nucleus; \* bilateral pathway

## 382.12

DORSAL THALAMUS OF ZEBRA FINCHES RECEIVES INPUTS FROM HYPOTHALAMUS AND ARCHISTRIATUM E. F. Foster\*, Ritvik P. Mehta and S. W. Bottjer. USC, Los Angeles, CA 90089-2520

The medial magnocellular nucleus of the anterior neostriatum (mMAN), is one of several afferent inputs to the High Vocal Center (HVC) in songbirds. We have previously shown that mMAN of zebra finches receives its major source of afferent input from the posterior dorsomedial nucleus of the thalamus (DMP). To determine the trans-synaptic afferent inputs of DMP, injections of the fluorescent dye, Dil, were made in DMP of adult male zebra finches. Our results confirm the existence of a projection from DMP to mMAN, which travels within the lateral forebrain bundle (LFB). In addition, DMP projects to the area of the medial neostriatum immediately dorsal and ventral to mMAN. Sparse fiber label was visible in the ventro-medial aspects of the parolfactory lobe (LPO), and scattered retrogradely labeled cells were seen dorsal to mMAN in accessory hyperstriatum (HA). Labeled cells were also seen in the lateral septal nucleus (SL), and within the lateral forebrain bundle (LFB) at the level of the septum. Many labeled cells were seen in the dorso-lateral region of the archistriatum immediately lateral to the robust nucleus of the archistriatum (RA) in a region of dorsal archistriatum (Ad), that receives input from the shell region of IMAN. In the diencephalon, retrogradely labeled cells were visible in a region of the hypothalamus corresponding to the external cellular stratum (SCE). Scattered labeled cells were also seen in the brainstem at the level of the pons. These results have not yet been confirmed in the anterograde direction, however, they strongly suggest that DMP is a source of convergent inputs to the song control system via the DMP-to-mMAN-to-HVC pathway. These results are of particular interest because they are the first report of hypothalamic regions in communication with song control regions.

## 382.14

CONNECTIONS BETWEEN VOCAL CONTROL NUCLEI AND THE BASAL FOREBRIN IN THE BUDGERIGAR. W. S. Hall\*, K. K. Cookson, J. T. Heaton, S. E. Durand, W. Liang and S. E. Brauth. Dept. Psychology, Univ. MD, College Park, MD.

We used pathway tracing, acetylcholinesterase (AChE) histochemistry, choline acetyltransferase (ChAT) and enkephalin (ENK) immuno-histochemistry to investigate basal forebrain input to four vocal control nuclei in the budgerigar: the robust nucleus of the archistriatum (RA), higher vocal center (HVC) and oval nuclei of the hyperstriatum ventrale (HVo) and anterior neostriatum (NAo). HVo and NAo contain high levels of AChE, ENK, and many ChAT fibers and puncta. RA and HVC contain moderate levels of AChE, ENK, and some ChAT fibers.

The ventral paleostriatum (VP) is a likely source of both cholinergic and enkephalinergic input to these vocal control nuclei. VP contains many ChAT and ENK immunoreactive fibers and somata. Tracer injections into RA and HVC retrogradely labeled neurons within VP, and a tracer injection into VP anterogradely labeled fibers in the rostral forebrain, including the regions of vocal control nuclei. We hypothesize that VP is an important source of both cholinergic and enkephalinergic input to vocal control nuclei.

VP lesions in nestlings disrupt the transition from unlearned food begging calls to flexible call learning (Brauth, et al., 1994). Basal forebrain projections to vocal control nuclei may provide an important input for vocal learning.

## 382.16

LMAN LESIONS DECREASE INDUCED SONG PLASTICITY IN THE ADULT ZEBRA FINCH. H. Williams\* and N. Mehta. Biology Department, Williams College, Williamstown, MA 01267.

Zebra finch males raised communally crystallize song at 90 days and do not change their song thereafter. However, changes to adult song do occur after denervation of the vocal organ (syrinx). These changes can take the form of silenced song syllables (syllables that disappear from the song but leave a silent interval in their place), deleted song syllables (syllables removed from the song with no remaining silent interval), and added song syllables (Williams & McKibben, 1992, Behav. Neur. Biol. 57:67-78). We bilaterally lesioned LMAN, a nucleus that is required for song development but not for song maintenance in adults (Bottjer et al., 1984, Science 224: 901-903), and subsequently denervated the right half of the syrinx of adult male zebra finches in order to determine whether adults can change their songs in the absence of LMAN.

Neither LMAN lesions nor sham operations were followed by changes in the songs of adult male zebra finches followed for 18 weeks postop. Five birds that received LMAN lesions followed four weeks later by right-side syringeal denervation silenced a total of four syllables over the course of 14 weeks but neither deleted nor added song syllables. Five birds that received sham surgery followed four weeks later by right-side syringeal denervation silenced 1 syllable, deleted 4 syllables, and added 6 syllables to their songs. Hence the song changes that require alterations in the timing of the respiratory pulses that drive phonation did not occur unless LMAN was intact. These results indicate that adult zebra finches that have crystallized their songs can reactivate the branch of the song system that normally affects song only during development.

## 382.17

LESIONS OF A VOCAL CONTROL NUCLEUS IN THE BUDGERIGAR DISRUPT PRODUCTION BUT NOT PERCEPTION OF CONTACT CALLS. J.T. Heaton\*, M.L. Dent, R.J. Dooling & S.E. Brauth. Univ. of Maryland, College Park, MD 20742.

In budgerigars (*Melopsittacus undulatus*), as in songbirds, the expression of learned features of calls and warble song depend on a robust nucleus of the archistriatum (RA) which receives input from a higher vocal center (HVC). In songbirds, some HVC and RA neurons respond selectively to elements of the birds own song, and there is evidence that lesions of HVC result in perceptual deficits involving species-typical vocalizations. We used standard operant conditioning procedures to test budgerigars on several different perceptual tasks involving learned vocal signals before and after bilateral lesion of RA. First, we measured detection and discrimination thresholds for simple tones. Then we examined more difficult discriminations involving natural and synthetic species-specific contact calls. We also tested RA and Field L lesioned birds on a recognition task to determine whether lesioning affected a bird's ability to remember - not just discriminate - new calls.

Birds receiving RA lesions showed the expected disruption in contact call production; however, lesions had only small, insignificant effects on pure tone thresholds and call discrimination tests. Lesioned subjects continued to perform normally on difficult discriminations between natural contact calls and computer synthesized analogs. In addition, RA lesioned birds required the same number of trials to recognize new calls as intact birds, and subsequent Field L lesions caused only transient deficits in performance. These results demonstrate that the processing of species-specific contact calls in budgerigars does not require an intact song circuit. Budgerigars may differ from songbirds in this regard. Supported by Grants MH-10417 to JTH, NIH DC-00198 and MH-00982 to RJD, and MH-40698 to SEB.

## 382.19

EFFECTS OF HVC LESIONS ON MOTOR CORRELATES OF COWBIRD SONG. S.L. Rich\*. Program in Neural Science, Indiana University, Bloomington, IN 47405.

Adult brown-headed cowbirds (*Molothrus ater ater*) produce 2 - 6 stereotyped songs. Each song type is composed of 2-4 stereotyped expiratory bursts, corresponding to groups of notes (note clusters) and a final whistle. Song production is thought to depend on a telencephalic pathway including a "higher vocal center" (HVC).

Subsyringeal air sac pressure and vocal output were recorded in male cowbirds before and after receiving electrolytic, unilateral lesions within the rostral half of HVC. These lesions affected song production by distorting: 1) respiratory pressure patterns 2) temporal patterns of song elements and 3) the acoustic structure. The best song attempts during the first 2 days after the lesion included only one partially intact note cluster accompanied by a pressure pattern which was stereotyped but did not match pre-operative patterns. The remaining note clusters and/or the final whistle were absent. During the first 3 days after the lesion vocal intensity and sound frequency decreased and acoustic structure deteriorated until day 3 when the characteristics of preoperative song were unrecognizable. The acoustic structure and temporal patterns of the song then began to improve. By day 5 song often included 2 note clusters followed by a final whistle each accompanied by a stereotyped pressure pattern. Within the improved note clusters, notes produced by the side of the syrinx ipsilateral to the lesion were often absent or distorted while notes produced by the intact side were less affected. Throughout the post-lesion period, attempts to sing typically began with 1 or more silent expiratory bursts. Supported by NS 29467.

## 382.21

EFFECTS OF LATERAL SEPTUM ABLATIONS ON AGGRESSION AND COURTSHIP IN MALE ZEBRA FINCHES (*Taeniopygia guttata*). J. L. Goodson, A. C. Dukes, R. P. Eibach, M. S. Friedman, E. Adkins-Regan. Department of Psychology, Cornell University, Ithaca, New York, 14853

The role of the lateral septum in courtship and aggression has been investigated extensively only in mammals. The present study was conducted to 1) determine lateral septum behavioral function in a bird and 2) investigate functional similarities and differences in septal function between birds and mammals. Male zebra finches (*Taeniopygia guttata*) received bilateral electrolytic ablations of the lateral septum (n=7) or sham surgery (n=10), followed the next day by 5mm silastic tubule implants of testosterone propionate (s.c.). A series of tests began one week post-surgery in which the following behaviors were measured: chases, pecks, beak fences, beak wipes, directed songs, undirected songs, allopreening, solicitation of allopreening, mounts, following females, dances, and behaviors indicative of pairing in a series of four colony tests. Ablations were histologically verified, and were largely limited to the lateral septum, with little collateral damage. Overt aggression (chasing other males in a colony) was significantly lower in the experimental group (0.111 chases/min  $\pm$  .032) than in the control group (1.117 chases/min  $\pm$  .365; two-tailed t-test, p<.05). Septal ablated birds tended to be slower to pair; only one ablated bird had paired by the second colony test, compared to seven of the control birds, a difference which approached significance (Fisher's exact probability test, p<.08). We conclude that the lateral septum is necessary for the normal expression of aggression, as is the case in mammals, and may be involved in the pairing process.

## 382.18

EFFECTS OF LESIONING NUCLEUS INTERFACIALIS ON ADULT ZEBRA FINCH SONG. E. T. Vu\*, Y. Kuo, and F. S. Chance. Division of Biology, California Institute of Technology, Pasadena, CA 91125.

The nucleus interfascialis (NIf) in the songbird forebrain is thought to play a role in the control of learned vocalizations because the firing rate of neurons in NIf is elevated during singing and is time-locked to vocalizations (McCasland, 1987). We have tested the necessity of NIf in adult song control by lesioning it bilaterally with the neurotoxin ibotenic acid (6  $\mu$ g/ $\mu$ l), which spares fibers of passage.

Animals with more than about 70% of NIf lesioned bilaterally (including two with complete bilateral lesions) produced altered songs as soon as they were recorded on the second day following surgery. Both the acoustic structure of individual song notes and the stereotyped sequencing of notes were compromised. However, in all cases (N = 16), a stereotyped sequence of notes returned within 10 days after lesioning. The acoustic structure of the notes recovered fully. In some animals, certain notes were sung less frequently 10 days after lesioning than before the lesion, resulting in a consistently shorter song phrase (or motif) than before. This relatively rapid song recovery was not mediated by auditory feedback because it was also observed in deafened animals (N = 7).

In some animals, the sparing of fibers of passage in the lesion area was confirmed by injecting a retrograde label, biotinylated dextran amine, into nucleus HVC, to which both NIf and the thalamic nucleus Uvaeformis (Uva) project. Uva fibers travel near and through NIf before terminating in HVC. A normal number of Uva neurons were retrogradely labeled in these NIf-lesioned animals.

These results suggest that neurons in area NIf do not play a necessary role in generating the song of adult zebra finches. We are investigating the nature of the transient impairment of song following NIf lesioning, and the process of relatively rapid song recovery. We are also determining whether NIf neurons are important for young birds during the process of song learning by vocal practice.

## 382.20

SYRINGERAL MUSCLE ACTIVITY DURING SONG IN BROWN-HEADED COWBIRDS. S.E. Allan\* and F. Goller. Medical Sciences Program and CISAB, Indiana University, Bloomington, IN 47405.

Song in adult brown-headed cowbirds (*Molothrus ater ater*) consists of 2-3 bilaterally generated introductory note clusters, separated by inspirations, followed by a high frequency whistle (6-12 kHz) produced on the right side. We recorded electromyographic activity in up to 4 syringeal muscles together with subsyringeal air sac pressure and vocal output in 8 spontaneously singing cowbirds.

During the introductory note clusters, EMG activity in dorsal muscles (*musculus tracheobronchialis dorsalis* and *m. syringealis dorsalis*) is high during periods of full ipsilateral adduction. This activity is particularly striking at the beginning of each expiratory burst where both sides are closed. However, during the whistle EMG activity in the left dorsal muscles is weak even though that side is fully adducted, suggesting that cowbirds use different syringeal motor patterns to close the left syrinx during the whistle as compared to introductory note clusters.

EMG activity in right *m. syringealis ventralis* (vS) increases exponentially with the fundamental frequency of the ipsilaterally generated sound. Fundamental frequency of notes produced on the left side range from 300-1200 Hz and accompanying EMG activity in the left vS is variable. Much higher EMG amplitudes in the left vS were recorded during the right side generated whistle than during ipsilateral sound production. Supported by NIH #NS29467 & #NS09229 and Austrian Programme for Advanced Research and Technology.

## 382.22

LEARNED ENGLISH VOCALIZATIONS AS A MODEL FOR STUDYING BUDGERIGAR (*Melopsittacus undulatus*) WARBLE SONG. P.A. Banta\* and L.M. Pepperberg. Program in Neuroscience, University of Arizona, Tucson, AZ 85721.

It is commonly known that budgerigars are capable of reproducing human speech. What is not known, however, is whether such behavior can be exploited to investigate the mechanisms of budgerigar vocal production. The purpose of the present study was to determine the extent to which budgerigars can be taught English vocalizations and to assess whether these vocalizations can be used to study the vocal control system of these birds.

Seven budgerigars were taught English vocalizations using the Model/Rival technique (Pepperberg, 1981) and a variation of this technique. During training, either one or two experimenters modeled target vocalizations for the birds. Target vocalizations were single words (e.g. "cork" and "paper") and short phrases (e.g. "you be good" and "come here").

Budgerigars learned many target and non-target vocalizations and produced them singly, as elements incorporated in their warble song, or in response to presented objects. Vocalizations incorporated in the warble song were produced with high frequency (up to 13 words or phrases/min) and were also produced in a highly stereotyped manner. Learned vocalizations recognizable by ear were visually analyzed on a Kay 5500 Sonagraph with respect to fundamental frequency, first and second formants, vocalization duration and overall pattern. Three naive raters independently compared vocalization sonagrams and matched them to pre-determined vocalization classes with 90% accuracy.

We contend that the frequent and stereotypic nature with which learned English vocalizations are produced by budgerigars makes this model uniquely amenable for studying the role of specific vocal control nuclei in the production of warble song. We intend to investigate the effects of lesions in vocal control nuclei on the production of these words and phrases. Supported by the Whitehall Foundation.

INTESTINAL INFUSIONS OF FATTY ACIDS INDUCE C-FOS IN THE PARABRACHIAL N., PARAVENTRICULAR N. AND CENTRAL N. OF THE AMYGDALA. J. McCaffery, S.J. French, D. Greenberg, A.J. Strohmayer\*, and T.A. Houpt. E.W. Bourne Behav. Res. Lab., Dept. Psychiatry and Neurology, Cornell Univ. Med. Coll., White Plains, NY 10605.

Induction of c-Fos-like immunoreactivity (c-FLI) in the nucleus of the solitary tract (NTS) by intraduodenal infusions of fats correlates with the satiating potency of the fats in food intake tests (McCaffery et al., 1994). Because the NTS is the first central relay for afferent information from the gut and projects to many rostral brain regions that may participate in the processing of visceral satiety signals we mapped neuronal activation using c-FLI in the pontine parabrachial n. (PBN), the supraoptic n. (SON) and paraventricular n. (PVN) of the hypothalamus, and the central n. of the amygdala (CeN) after intraduodenal infusions of fats.

Adult male rats were surgically equipped with gastric cannulas and duodenal catheters. Rats were randomly assigned to 5 groups which received one of the following intestinal infusions (10ml; 0.44ml/min): 0.15M NaCl (Sal), 5 kcal Intralipid (IL), 0.65 kcal oleic acid, 0.65 kcal linoleic acid, 0.65 kcal linolenic acid. Infusions were performed after stomach lavage and with cannulas open allowing stomach contents to drain. One hour after intestinal infusions ended, rats were sacrificed and processed for c-FLI. The PBN, SON, PVN, and CeN were qualitatively scored for density of c-FLI-positive cells and compared to c-FLI induction in the NTS.

The induction of c-FLI in the PBN, PVN, and CeN by intraduodenal infusions of a mixture of fats (IL) or by specific long-chain fatty acids qualitatively paralleled the induction of c-FLI in the NTS. In the SON, c-FLI was infrequently observed and did not appear correlated with the type of infusion. Infusions of Sal induced little or no c-FLI in any of the brain regions. The induction of c-FLI in rostral projection sites of the NTS may represent functional activation of neuronal circuits mediating behavioral satiety caused by intestinal infusions of fat.

GASTRIC LOADS OF AN AMINO ACID MIXTURE BUT NOT GLUCOSE ALTER EXTRACELLULAR AMINO ACID PATTERNS IN THE PARAVENTRICULAR NUCLEUS AS MEASURED BY *IN VIVO* MICRODIALYSIS. N. Chang, P.J. Currie and G.H. Anderson\*. Department of Nutritional Sciences, Faculty of Medicine, University of Toronto, Toronto, Ontario, Canada M5S 1A8.

Brain amino acids are hypothesized to play a role in the regulation of food intake, and it is established that central amino acid concentrations are affected by the macronutrient composition of the diet. In this study, microdialysis was used to examine the profile of extracellular amino acids in the paraventricular nucleus (PVN) of awake, freely-moving rats following gavage of equicaloric loads of anhydrous glucose (0.89 g) or an amino acid mixture (0.85 g patterned after 1 g of chicken egg albumin). The microdialysis probe (perfused at a rate of 2 µl/min) was implanted into the PVN 2 hours prior to gavage and dialysates were collected every 20 min starting from 1 hr prior to and 3 h after treatment. Dialysate amino acids were derivatized with o-phthalaldehyde and determined fluorometrically after HPLC separation. Administration of a balanced amino acid mixture evoked significant increases in dialysate levels of many essential amino acids, as well as alanine. While extracellular levels of alanine and leucine exhibited immediate (first 20 min aliquot) increases, elevations of isoleucine, methionine, phenylalanine, tyrosine, and valine were detected in the second 20 min aliquot. The concentration of most amino acids peaked within 40 min of treatment, with the exception of alanine and threonine which peaked 60 min after gavage. Most amino acids showed an increase of 125%-190% of baseline. However, dialysate levels of valine reached a maximal increase of 230%. The extracellular amino acid profile in the PVN was, in general, unaffected by glucose administration. These findings imply that dietary composition may influence the amino acid profiles of the extracellular fluid in brain (Supported by NSERC).

## 383.5

EXPRESSION OF C-FOS-LIKE IMMUNOREACTIVITY IN THE RAT BRAIN ONE WEEK AFTER BILATERAL ABDOMINAL VAGOTOMY. G.P. Smith\*, R.A. Berlin, and T.A. Houpt. E.W. Bourne Behav. Res. Lab., Dept. Psychiatry, Cornell Univ. Med. Coll., White Plains NY 10605

Total subdiaphragmatic vagotomy eliminates much of the afferent information flow from the gut to the brain. Although the drinking response to angiotensin II (sc) is decreased after vagotomy (Simansky & Smith, 1983), the drinking response to hypertonic saline (ip) does not decrease until 7-10 days after vagotomy (Jerome & Smith 1984). Gradual changes in neuronal activity may account for the delayed changes in the response to hypertonic saline. To search for changes in central neuronal activity after abdominal activity, we used c-Fos-like immunohistochemistry (c-FLI) to identify cells in the medulla, pons, and forebrain that were activated 1 week after vagotomy.

Both major vagal trunks of adult male rats (n=5) were cut between 2 silk ligatures below the diaphragm and above the hepatic, accessory celiac, and celiac branches. Control rats (n=5) were sham-vagotomized. One week later, rats were overnight food-deprived, perfused, and the brain processed for c-FLI.

Numerous c-FLI-positive cells were observed in the caudal nucleus of the solitary tract (NTS) and area postrema. The pattern of c-FLI expression in the NTS appeared to parallel the receptive fields of subdiaphragmatic vagal afferents. The lateral parabrachial nucleus, the central nucleus of the amygdala, the hypothalamic paraventricular nucleus, and the supraoptic nucleus also showed intense c-FLI staining. Little or no c-FLI cells were seen in sham-vagotomized rats in these regions.

Because c-FLI was observed not only in the receptive field of the vagus in the NTS but also in rostral projection sites of the NTS, some of the c-FLI observed must have been induced transsynaptically. Explanations for c-Fos expression 1 week after vagotomy include persistent activation of axotomized afferent vagal fibers, or a release of NTS neurons from inhibition. Because c-Fos can regulate gene expression, it may participate in intracellular mechanisms mediating neuronal plasticity after vagotomy.

## 383.2

INITIAL HYPOPHAGIA CAUSED BY AN IMBALANCED AMINO ACID DIET (IAAD) IS ABOLISHED IN DORSOMEDIAL HYPOTHALAMIC NUCLEUS LESIONED (DMNL) RATS. L.L. Bellinger\* and D.W. Gietzen. Dept. of Biomedical Sci., Baylor College Of Dentistry, Dallas, TX. 75246 and Vet. Med. Anat. Phys. & Cell Biol. Univ. of Calif., Davis, CA 95616.

Rats show food intake (FI) suppression in as little as 3 h after giving an IAAD; this decrease in FI can be attenuated by giving Tropicisetron (TROP) a 5HT<sub>2</sub> receptor antagonist. Wang et al., showed c-Fos expression in the DMN 2 h after giving rats an IAAD. In the present study male S. D. rats were given DMNL or sham operations (SHAM). The rats were placed on chow for 8 d and then basal diet for 10 d; the DMNL rats were hypophagic (p<0.01) compared to SHAM rats. On day 11 the rats were injected i.p. with saline (SAL) 1 h prior to lights out and FI recorded 3, 6, 12 and 24 h later. On day 12 the rats were weighed and injected with SAL or TROP (9mg/kg): Grp 1, SHAM + SAL (161g BW, n=9); Grp 2, SHAM + TROP (163g BW, n= 10); Grp 3, DMNL + SAL (145g BW, n=7); and Grp 4, DMNL + TROP (146g BW, n=9) and 1 h later presented with an isoleucine IAAD; the DMNL groups weighed less (p<0.01) than the SHAMs. At 3 h, intakes (expressed as a % of their basal intake) were: Grp 1, 60%; Grp 2, 158%; Grp 3, 135% (P<0.01 greater than Grp 1); and Grp 4, 223% (P<0.01 greater than Grp 2). Similar cumulative intake differences were noted at 6 h, however by 12 h Grp 1 and 3 and Grp 2 and 4 were consuming similar amounts. Grp 2 and 4 intakes remained higher (P<0.01) than Grp 1 and 3 at 12 and 24 h. On day 2 IAAD intake of the four groups was similar and on day 3 they began to adapt, i.e., eat more of the IAAD. On days 4-7 the DMNL rats didn't adapt compared to the SHAMs. BW changes were reflective of FI. The data show that DMNL: 1. abolish the initial, but not later, FI suppression caused by the IAAD, 2. doesn't interfere with TROP's ability to enhance the intake of an IAAD and that the lesion and drug effects are additive. ## 383.4

HIGHLY SENSITIVE BRAINSTEM TISSUE SITES FOR GLUCOPRIVIC STIMULATION OF FEEDING. T.T. Dinh\* and S. Ritter. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520 USA.

Glucoreceptors controlling food intake are known to be centrally located since administration of glucoprivic agents directly into the brain elicits feeding. Additional evidence suggests that glucoreceptors are located in the caudal hindbrain. The present study mapped the hindbrain of rats caudal to the facial nerve (n=63) for sites where feeding could be elicited by localized glucoprivation. The antimetabolic glucose analogue, 5-thioglucose (5TG, 24 µg in 200 nl) or 0.9% saline (200 nl) were injected through small diameter cannulas and food intake was measured at hourly intervals for 4 hrs. Positive sites were found in the ventrolateral medulla in the vicinity of the C1 adrenergic cell group, where feeding was increased to  $1.9 \pm 0.3$  g above saline baseline. Positive sites were also found in the vicinity of the nucleus of the solitary tract, but the most positive sites were found at various dorsal/ventral levels within a 1 mm extent along the midline just rostral to the area postrema, an area that includes many C2 adrenergic neurons. At these sites, rats consumed  $3.87 \pm 0.5$  g in response to 5TG and  $0.9 \pm 0.4$  g in response to saline. Sites positive for feeding were similar to those at which 5TG stimulates adrenal medullary secretion and Fos expression. Certain hindbrain catecholamine neurons may be important effectors for glucoprivic feeding. Whether they or other neurons in close proximity to them are the putative glucoreceptor cells for feeding will require additional experimentation.

## 383.6

CENTRAL cFOS EXPRESSION INDUCED BY MILK DEPRIVATION AND INGESTION IN NEONATAL RATS. L. Rinaman\*, J.G. Verbalis, & E.M. Stricker. Depts. of Neuroscience & Medicine, University of Pittsburgh, Pittsburgh, PA 15260.

During the first week of postnatal life in rats, dehydration is the sole stimulator of independent ingestion and gastric distension is the sole inhibitor. We analyzed central expression of cFos in 3-day-old rats following mild dehydration (induced by milk deprivation) and gastric distension (induced by feeding after deprivation) to localize neurons whose activity is heightened by these conditions. Control pups (n=4) were removed from their dam, anesthetized, and perfused with fixative; their stomachs contained varying amounts of milk (0.36±0.13g) at sacrifice. Other pups (n=6) were deprived of their dam for 5 hr and then were anesthetized and perfused; their stomachs contained no milk at sacrifice. A third group of pups (n=5) was deprived of their dam for 5 hr and then was allowed to suckle for 30 min. These deprived-refed pups were anesthetized and perfused 1 hr after completion of suckling; their stomachs were moderately distended with milk (0.71±0.12g) at sacrifice. Brain sections from control, deprived, and deprived-refed pups were processed for immunocytochemical detection of cFos. Some sections also were processed for detection of oxytocin (OT), vasopressin (VP), or tyrosine hydroxylase (TH). Little cFos was seen in the forebrain or caudal medulla of non-deprived controls. In contrast, cFos was elevated in osmosensitive forebrain regions and in hypothalamic OT and VP neurons in deprived pups, although cFos remained sparse in the caudal medulla (similar to controls). In deprived-refed pups, forebrain cFos was similar to that in deprived pups, as expected (since cFos remains detectable for several hr after induction). However, in contrast to the lack of medullary cFos in control and deprived pups, many TH-positive neurons and other neurons in the nucleus of the solitary tract, area postrema, and ventrolateral medulla exhibited cFos in refed pups. SUMMARY: Mild fluid deprivation activates specific forebrain neurons but appears not to activate caudal medullary neurons in neonates, suggesting that forebrain activation is sufficient for stimulating ingestion at this age. In contrast, refeeding does activate medullary vagal relay neurons in neonates, implicating these neurons in distension-induced inhibition of ingestion.

## 383.7

INTEGRATION OF ORAL AND GASTRIC SIGNALS: C-FOS ANALYSIS. Emond, M.\* & Weingarten, H.P. Dept. Psychology, McMaster University, Hamilton, Ontario, Canada, L8S 4K1.

Control of food intake requires the coordination of oral and gastric afferent signals. We used Fos immunohistochemistry, as an index of neural activity, to identify properties of neuronal populations activated during oral and gastric stimulation presented in isolation or in combination. We tested nine triads of male rats that were 24 hr food deprived before, and anaesthetized with urethane (1.2 g/kg) during, the experiment. Animals with restricted oral stimulation had 1 M sucrose perfused over the tongue at a constant rate of 0.63 ml/min for 19 min; gastric stimulation was accomplished by identical infusions directly intragastrically. The third member of every triad received the oral and gastric infusions simultaneously. 90 min later rats were killed, the brains were removed and processed for Fos-like immunoreactivity (FLI) using standard protocols. FLI was assessed by counting the number of Fos-labelled cells in the caudal, medial and rostral levels of the nucleus of the solitary tract (NST) and dorsal motor nucleus (DMN) and in the paraventricular nucleus (PVN). Overall, the isolated oral and gastric infusions produced similar degrees of Fos activation. However, in the PVN and all 3 levels of the NST the combined infusions resulted in significantly less FLI than either infusion presented alone. Overall, there were no differences in FLI across treatments in the DMN. Our results indicate first, that Fos expression can be elicited in anaesthetized rats and the profile of results replicate our previous finding in freely-behaving rats that combined oral and gastric stimulation results in significantly less FLI in NST than oral stimulation alone. Second, our results suggest the conclusion that preparations used frequently to isolate the roles of oral (sham feeding) or gastric (IG loads) afferents may not adequately capture the contribution of these signals when they are embedded in the context that approximates normal eating, i.e. these signals in combination.

## 383.9

BEHAVIORAL ACTIVITY AND MEAL INTAKE ELICITED BY PERIFORNICAL HYPOTHALAMIC INJECTION OF 8-BROMOADENOSINE 3',5'-CYCLIC MONOPHOSPHATE (8-br-cAMP) IN THE RAT. E.R. Gillard\*, B. Mouradi and B.G. Stanley Dept. of Neurosci. & Psychol., Univ. of CA, Riverside, CA 92521, USA.

We have shown that 8-br-cAMP elicits robust feeding when injected into the perifornical hypothalamus (PFH) and nearby lateral hypothalamus, suggesting that some neurotransmitters known to influence feeding in these regions may do so via the cyclic AMP second messenger system. To begin to address whether injection of 8-br-cAMP simulates a process that may occur in PFH neurons during normal feeding, we examined meal patterns and behavioral activity in male rats for 4 hrs following injection of 8-br-cAMP (100 nmol/0.3 µl) into the PFH. 8-br-cAMP injected animals consumed 90% of their total intake in a large ( $11.9 \pm 4.3$  g), short-latency (all but one subject ate within 6 min.) first meal lasting an average of 7 minutes; this was followed by a much smaller meal occurring in the second hour postinjection. Behavioral observations showed that these animals spent significantly more time ( $30 \pm 7\%$  of total time) eating during the first 10 minutes than did controls (0%). In contrast, neither drinking nor gnawing behavior were stimulated by 8-br-cAMP injection. Activity level was increased in 8-br-cAMP injected animals relative to controls during the 2 hrs following injection, with a consequent decrease in the time spent resting and sleeping. However, peaks in activity occurred later than the dramatic stimulation of eating observed in the first 10 minutes postinjection. These findings suggest that stimulation of the cAMP second messenger system in PFH neurons might contribute to intense, rapid eating responses, such as those elicited by food deprivation.

## 383.11

EFFECTS OF HYPONATREMIA ON FOS-LIKE IMMUNOREACTIVITY (FLI) IN THE SUBFORNICAL ORGAN AND MAGNOCELLULAR NUCLEI IN THE RAT. L. Han\*, N.E. Rowland, B.-H. Li & G.C. Smith Dept. Psychology, Univ of Florida, Gainesville, FL 32611

The subfornical organ (SFO) and the supraoptic (SON) and paraventricular (PVN) nuclei are key brain structures in the control of fluid balance. We previously found that treatment with the natriuretic agent, furosemide, which causes salt appetite, was associated with FLI expression, a marker of neuronal activation, in the SFO but not in the SON and PVN. This study was designed to determine whether the absence of FLI in the SON and PVN after furosemide treatment is caused by hyponatremia subsequent to water ingestion. Male adult SD rats, either on regular or sodium (Na)-free diet for 2 days, received either saline or furosemide (two SC injections of 5mg, 2 hr apart). Water was then withdrawn from half of the subjects. A 1-hr, two-bottle (water vs. salt) drinking test was performed 22 hrs after furosemide treatment. Two weeks later, all the rats were treated the same way as above, except that they were perfused for Fos immunocytochemical staining 22 hours after receiving furosemide without the drinking test. It was found that 1) there was no difference between regular diet groups and Na-free diet groups in terms of plasma renin activity, urine sodium or FLI expression; 2) furosemide significantly increased salt intake, but not water intake, whether water was withdrawn or not; 3) furosemide induced a strong FLI in the SFO in all rats, whether or not allowed to drink; 4) when water was withdrawn, furosemide-treated rats showed weaker FLI in the SON and PVN than saline-treated rats. The results suggest that a 3-day Na-free diet dose not enhance FLI expression in the SFO after furosemide treatment, and that hyponatremia caused by water intake contributes to inhibiting FLI expression in the SON and PVN.

## 383.8

METABOTROPIC GLUTAMATE RECEPTOR INVOLVEMENT IN FEEDING STIMULATION: EVIDENCE FROM LATERAL HYPOTHALAMIC INJECTION OF ACPD. M.A. Duva\*, L.C. Spears & B.G. Stanley Departments of Neuroscience & Psychology, University of California, Riverside, CA 92521.

We have recently shown that agonists of several ionotropic glutamate receptors elicit intense eating when injected into the lateral hypothalamus (LH) of satiated rats. To investigate whether metabotropic glutamate receptors, which can modify gene expression, enzyme pathways, and cellular growth, might be involved in feeding stimulation, we employed LH injections of the metabotropic agonist 1S,3R-1-aminocyclopentane-1,3-dicarboxylic acid (1S,3R-ACPD). Adult male Sprague-Dawley rats with chronically implanted LH cannulas were injected with 1S,3R-ACPD (0.1, 1, 10, 33, 100 or 300 nmol/0.3 µl) or vehicle in ascending order and food intake was measured 1, 2, and 4 hrs later. Injections of 1S,3R-ACPD produced dose-dependent feeding responses, with 33 nmol to 300 nmol doses yielding mean intakes of 3.9 to 4.6 gm 1 hr postinjection, and 6.3 to 6.8 gm at 4 hrs postinjection. To examine the consistency of the response, tests with 100 nmol of 1S,3R-ACPD were repeated every 2 to 3 days. The feeding response declined somewhat after the first test and was consistent thereafter. To examine the chemical specificity of this effect, we also tested 33 to 300 nmol doses of the less active stereoisomer 1R,3S-ACPD and found that it was significantly less effective, producing a maximum eating response of 3.7 gm 4 hr after injection of the 300 nmol dose. These findings suggest that metabotropic glutamate receptors may be involved in the stimulation of eating behavior.

## 383.10

EFFECTS OF FEEDING AND INSULIN ON EXTRACELLULAR ACETYLCHOLINE IN THE AMYGDALA OF FREELY MOVING RATS. Andras Hajnal<sup>a,b</sup>, Emmanuel N. Pothos<sup>a\*</sup>, Gregory P. Mark<sup>a</sup>, Pedro V. Rada<sup>a</sup>, Laszlo Lenard<sup>b</sup> and Bartley G. Hoebel<sup>a</sup>. <sup>a</sup>Department of Psychology, Princeton University, Princeton, NJ, 08544 and <sup>b</sup>Neurophysiology Research Group of the Hungarian Academy of Sciences at the Institute of Physiology, Pecs University, Medical School, H-7643 Pecs, Hungary.

Extracellular levels of acetylcholine (ACh) were measured in the central nucleus of the amygdala (AMY) by using microdialysis in 20 min intervals before, during and after 1 hr feeding in 20 hr food-deprived rats. The effects of peripheral injections of glucose or "low" (200 mU/kg) and "high" (1 U/kg) doses of insulin on ACh in the AMY were also observed in non-deprived animals. Feeding caused a 40% increase in extracellular ACh in the AMY which recovered 1 hr after feeding. Injections of both glucose and insulin resulted in an increase in ACh levels (50-60%) but the dynamics were different: glucose caused ACh to plateau within 80 min after the injection; whereas both doses of insulin caused a peak in ACh release in the first 20 min interval followed by a two step recovery. The "low" and "high" doses of insulin had similar effects on ACh release even though they had different hypoglycemic potency. These results suggest that ACh in the AMY is involved in feeding, and that peripheral insulin may influence ACh in the AMY in a way that is partially unrelated to hypoglycemic effects. Initiated and supported by the James S. McDonnell Foundation and supported by USPHS grant NS30697 (to B.G.H.) and an OKTA F 012978 (to A.H.)

## 383.12

CHRONIC INTRACEREBROVENTRICULAR (ICV) MICROINFUSION OF CYTOKINES: i) DIFFERENTIAL EFFECTS ON FEEDING; ii) PROFILE OF Gα-PROTEIN SUBUNIT SUBCLASSES IN THE VENTROMEDIAL HYPOTHALAMIC NUCLEUS (VMN). C. R. Plata-Salamán<sup>\*</sup>, G. Sontjé, C. D. Wilson<sup>2</sup> and J. M. H. French-Mullen<sup>1</sup>. <sup>1</sup>Sch. Life Hlth Sci., Univ. Delaware, Newark, DE 19716, and <sup>2</sup>Dept. Pharmacol., Zeneca Pharmaceuticals, Wilmington, DE 19897.

Anorexigenic cytokines include IL-1, IL-6, IL-8 and TNF-α. Increased levels of cytokines in the CSF are present during various diseases. Cytokine-induced feeding inhibition is proposed to participate in the long-term anorexia observed during disease. We studied in rats the effects of the chronic ICV (into the third ventricle) infusion of various cytokines for 7 days (through osmotic minipumps) on behavioral parameters. The results during the 7-day pump period were: IL-1β decreased nighttime feeding dose-dependently (0.5 ng/24 h, n=8; 2.0 ng/24 h, n=10; 8.0 ng/24 h, n=10) relative to the vehicle infusion (n=11) (p<0.001). The decrease of feeding and body weight persisted during the 7-day infusion (contrary to the peripheral IL-1β chronic infusion which has been associated with tolerance); feeding and body weight increased toward baseline following the end of IL-1β infusion. Total daily food intake decrease was less prominent relative to the nighttime decrease because daytime food intake did not change or increased. Water intake was not decreased in any group suggesting specificity of action. Chronic ICV administration of TNF-α (20 ng/24 h, n=9; 100 ng/24 h, n=8; 300 ng/24 h, n=7), IL-6 (100 ng/24 h, n=9), or IL-8 (20 ng/24 h, n=9) was significantly less effective than IL-1β to induce behavioral modifications. Computerized analysis also showed specific effects on the behavioral patterns. Immunoblots of VMN from normal rats (n=8) showed that the levels of GαO protein subunit are >30 fold higher relative to those of Gαi1-i3. The chronic ICV microinfusion of IL-1β (2.0 ng/24 h/72 h) increased the levels of Gαi1 and Gαi2 protein by 3.8-fold detected in immunoblots of VMN (n=6). No effect was observed on GαO and Gαi3 protein levels suggesting specificity. The results suggest that IL-1β, at estimated pathophysiological concentrations in the CSF, may induce long-term anorexia and may modify specific signalling systems.

## 383.13

BRAIN AREAS ACTIVATED BY INGESTION USING FUNCTIONAL MRI OF AWAKE RATS. E. Tabuchi<sup>1,2</sup>, T. Yokawa<sup>1</sup>, T. Ono<sup>2</sup>, A. Nijima<sup>3\*</sup> and K. Torii<sup>1</sup>. <sup>1</sup>ERATO, R&D Corp. of Japan, Yokohama 221, <sup>2</sup>Dep. of Physiology, Toyama Med. & Pharmaceut. Univ., Toyama 930-01, <sup>3</sup>Dep. of Physiology, Niigata Univ. Sch. of Med., Niigata 950, Japan.

To understand spatial and temporal dynamics of activated areas in the brain, functional magnetic resonance imaging (fMRI) was undertaken using awake rats. Under anesthesia, each rat had a receptacle put on its head to immobilize the animal's skull to be later fixed painlessly in the correct stereotaxic position. After recovery, they were trained to accept the restraint in a stereotaxic apparatus without struggling, and were allowed to lick a solution from a spout when manually extended close to its mouth, following water deprivation for one day. T2\* weighted MRIs, in which intensity increases in area with high consumption of oxygen (oxy-hemoglobin), were then taken before (control), during, and after ingestion of various solutions; water, saline, 5% glucose, 0.2 M lysine, 0.15 M MSG, 0.05 M arginine, 0.5 M glycine, and 0.05 M histidine. During ingestion of most solutions, the signal intensity in T2\* weighted MRI raised in most brain areas and increased significantly in the lateral hypothalamic area, the ventromedial nucleus of the hypothalamus, the central nucleus of the amygdala, the piriform cortex, and the CA1 subfield of the hippocampus, and it gradually returned to the control level after ingestion. These findings directly indicate that these brain regions cooperate and work in parallel during drinking behavior.

## 383.15

EFFECTS OF ARCULATE NUCLEUS LESIONS ON BODY WEIGHT, FOOD INTAKE, & REPRODUCTIVE BEHAVIOR IN OBESE ZUCKER FEMALE RATS. C.L.M. Bivens\* & D.H. Olster. Dept. of Psychology & Neuroscience Research Institute, Univ. of Calif., Santa Barbara, CA. 93106.

Genetically obese Zucker female rats are hyperphagic, overweight, and infertile. It has been speculated that overproduction of neuropeptides in the cell bodies of the arcuate nucleus of the hypothalamus may contribute to obesity and infertility in obese Zucker rats. To test this hypothesis ovariectomized (OVX) adults received either bilateral, electrolytic lesions (0.2 mA, 30 sec, obese Zucker) or sham-lesions (no current, 30 sec, obese and lean Zucker) in the arcuate nucleus and subsequently monitored for food intake and body weight for 7 weeks. Twenty-four hour food intake in lesioned obese females was lower than that observed in sham-lesioned obese females, but not different to that found in their sham-lesioned lean counterparts (e.g., week 5, lesioned obese 60±2 g; sham-lesioned obese 76±2 g; sham-lesion lean 54±4 g, p<0.0001). Furthermore, body weights were lower in lesioned obese, compared to sham-lesioned obese females (e.g., at 7 weeks, 522±11 g sham lesion vs. 477±10 g lesion, p<0.02). At 8 weeks postsurgery, OVX adults received either 15 µg/kg estradiol benzoate (EB) or EB plus 2 mg/kg progesterone (P) and tested for sexual receptivity and proceptivity. All groups showed uniformly low levels of lordosis after EB alone. However, following EB plus P treatment obese lesioned females and sham-lesioned lean females displayed increased sexual receptivity as compared to sham-lesioned obese females (LQ= 38±6%, 56±11%, 23±6%, p<0.02, respectively). These data suggest that the arcuate nucleus contributes to hyperphagia, weight gain, and suppressed reproductive behavior in obese Zucker females. It is proposed that neurochemicals overproduced by the arcuate nucleus, such as neuropeptide Y and β-endorphin, may contribute to the obesity and infertility in obese Zucker females (Supported by NIH HD 28636 and American Psychological Association)

## 383.17

Activational Hormones Are Not Necessary For Expression Of Prolactin's Sexually Dimorphic Effects On Food Intake In Rats. S.H. Heil\* & C.P. Cramer. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

Exogenous prolactin (PRL) administration increases food intake only in female rats (Heil and Cramer, 1992). The present experiment was designed to examine what role adult gonadal hormones play in PRL's sexually dimorphic effects on food intake. Ten male and ten female Long-Evans rats were gonadectomized at 30 days of age, before the commencement of puberty. In addition, at 85 days of age, ten intact females were implanted with subcutaneous Silastic capsules filled with testosterone propionate, to test the possibility that male insensitivity to PRL is due simply to circulating testosterone. Gonadectomized males and females were implanted with blank capsules of the same dimensions.

At 90 days of age, animals were housed in hanging cages with ad lib access to water and a jar of ground chow. Food intake was measured daily for five days of baseline, followed by ten days of PRL injections. Injections were administered twice daily at 0800 and 1900 hours at a dose of 1 mg/kg. Results were analyzed by repeated measures ANOVA.

Both gonadectomized females and intact females + Silastic testosterone significantly increased intake in response to exogenous PRL injections. Gonadectomized males' intake was not significantly different from baseline intake. Thus, activational hormones are not necessary for the expression of PRL's sexually dimorphic effects on food intake, nor is male insensitivity to PRL due solely to circulating testosterone. Moreover, these results suggest that the dimorphism in response to PRL is organized much earlier in development, a possibility we are currently testing.

## 383.14

THE EFFECT OF AD LIB FOOD PLACEMENT ON BODY WEIGHT FOLLOWING MEDIAL SEPTAL LESIONS IN RATS. A. Poplawsky\*. Dept. of Psychology, Bloomsburg Univ. of Penna., Bloomsburg, PA 17815.

To assess changes in body weight, rats with control operations or medial septal lesions were weighed for 120 days following surgery. At the end of this period, rats with medial septal lesions weighed less than rats with control operations. For the next 25 days, half the rats from each group received their ad lib food in a feeder attached to the outside of the cage, while the remaining rats continued to have their food placed inside the cage. Placing the food outside the cage resulted in a decrease in body weights for control rats that became equivalent to medial septal rats, while the rats with medial septal lesions were not affected by this change. This suggests that ad lib food placement can interact with the effects of medial septal lesions on body weight regulation.

## 383.16

INTRA-PARAVENTRICULAR INJECTIONS OF PROLACTIN INCREASE FOOD INTAKE IN FEMALE RATS. D. Sauv  \* and B.C. Woodside. Centre for Studies in Behavioral Neurobiology, Concordia University, Mtl., Canada, H4B 1R6

Lactation in mammals is characterized by a marked hyperphagia and significantly elevated levels of Prolactin (PRL). Several recent studies in our laboratory have provided evidence for a causal relationship between PRL and the hyperphagia of lactation. For example, PRL injected intracerebroventricularly (twice daily for ten days to virgin females rats) produced a dose-dependent increase in food intake without disrupting vaginal cyclicity. Doses of 2 and 10 µg were effective in increasing food intake, whereas doses of 400 and 800 ng were not. Recently, PRL receptors have been located in the paraventricular nucleus of the hypothalamus (PVN) an area that has also been implicated in the control of food intake. In this study, therefore, the effect on food intake of prolactin administration into the PVN was determined. Doses that were ineffective when administered into the ventricles, were injected directly into the PVN of virgin female Wistar rats, and food intake monitored. Results revealed that whereas 400 ng of PRL did not cause increases in food intake, 800 ng produced a robust effect. These results confirm once more that PRL has a central effect on food intake, and that it is highly likely that the hyperphagic effect of PRL is mediated, at least in part, by the PVN.

## 383.18

REGULATION OF RENAL OXYTOCIN (OT) RECEPTORS BY ADRENAL STEROID HORMONES. L.M. Flanagan-Cato\*, R.R. Sakai, C.N. Moga, and S.J. Fluharty. Depts. Psychology, Animal Biology and Institute for Neurological Sciences, University of Pennsylvania, Philadelphia, PA, USA. Supported by MH43787.

Aldosterone, released in response to sodium deficiency, promotes sodium retention in the kidney and augments sodium appetite in the brain. In contrast, OT released in response to hypernatremia promotes natriuresis in kidney while inhibiting sodium appetite centrally. The present study tested the hypothesis that aldosterone-induced sodium retention may in part reflect blunted natriuretic mechanisms. Previous studies had indicated that in a renal cell line, LLC-PK<sub>1</sub>, OT receptor binding was reduced by treatment with aldosterone. We determined whether *in vivo* aldosterone reduced the levels of OT receptor binding in the kidney. Three groups of adult male rats were studied: control (C, n=6), 4 day adrenalectomized (ADX, n=6), and 4-day desoxycorticosterone acetate treated (DOCA; 2.5 mg/day, n=5). OT receptor binding studies were performed on kidney membranes. Results demonstrated that after ADX, there was a significant increase in the levels of OT receptors detected, whereas after DOCA treatment there was a significantly reduced number of OT receptors detected. More specifically, compared with control, OT receptor binding was increased by 43.2 ± 11.9 % in ADX rats (p<0.005), and decreased by 29.1 ± 9.3 % in DOCA-treated rats (p<0.02). Taken together, these results suggest that the increased level of renal OT receptor binding in the ADX group represents a disinhibition from endogenous aldosterone. Thus, it appears that aldosterone has the complementary actions of blunting OT-mediated natriuresis and directly stimulating sodium retention. This would parallel the effects of adrenal steroids in the brain to simultaneously stimulate and disinhibit sodium appetite.

## 383.19

BRAIN OXYTOCIN (OT) RECEPTOR ANTAGONISM DISINHIBITS SODIUM APPETITE IN PREWEANLING RATS. S.Y. Chow\*, S.J. Fluharty and L.M. Flanagan-Cato. Depts. Psychology, Animal Biology, Pharmacology, and Institute for Neurological Sciences, University of Pennsylvania, Philadelphia, PA, USA. Supported by MH43787.

Adrenalectomy (ADX) stimulates sodium appetite in the adult rat, mediated in part by angiotensin II (AngII) activity in the brain. This behavioral response to ADX does not emerge until postnatal day 12 (PN12). However, as early as PN3 AngII receptors are present in brain, and these animals are physiologically responsive to ADX, as demonstrated by elevated plasma levels of AngII. The absence of sodium appetite until PN12, therefore, has not been readily explained. In the adult rat, centrally-released OT inhibits sodium appetite. We examined whether this inhibitory signal may prevent neonatal rats from displaying sodium appetite in the face of an excitatory stimulus. PN10 rat pups were infused intraorally with 4% NaCl, and intakes were determined by measuring changes in body weight. Prior to the intraoral infusions, pups were pretreated icv with either vehicle, AngII (5 ng), or AngII plus the OT receptor antagonist ornithine vasotocin (OVT; 5 µg). Central AngII increased intake of NaCl ( $0.7\% \pm 0.3$  vs.  $2.2\% \pm 0.3$ ;  $p < 0.005$ , intakes expressed as % change in body weight). This intake was further enhanced by giving OVT in conjunction with AngII ( $3.2\% \pm 0.3$ ,  $p < 0.05$  compared with AngII alone). When sodium appetite was induced by ADX in PN10 rats, OVT also augmented intakes ( $1.7\% \pm 0.2$  vs.  $2.6\% \pm 0.3$ ,  $p < 0.05$ ). Together these results suggest that endogenous OT may mediate the inhibition of sodium appetite in the preweanling rat. Release from this oxytocinergic inhibition reveals a previously unsuspected ability of PN10 rats to display sodium appetite after ADX.

## DRUGS OF ABUSE: AMPHETAMINES AND OTHER STIMULANTS I

## 384.1

BEHAVIORAL SENSITIZATION TO AMPHETAMINE AND THE CHOLINERGIC SYSTEM. J.B. Bedingfield, L.D. Calder, L.H. Thai and R. Karler\*. University of Utah School of Medicine, Salt Lake City, Ut 84132

The results of our previous studies suggest that sensitization consists of at least two pharmacologically separable components, induction and expression, and that both of these components involve a dopaminergic-glutamatergic-GABAergic interaction within the striatum. The present study was designed to investigate the role of the cholinergic system in sensitization to amphetamine-induced stereotypy in CF-1 mice. The nicotinic antagonists, mecamylamine and DBE given systemically were ineffective against amphetamine-induced stereotypy in naive mice, but they blocked both the induction and expression of sensitization. The antagonists administered intrastratially also blocked induction but were ineffective against expression. The systemic data indicate that sensitization involves the recruitment of at least one neuroeffector system not normally involved in the action of amphetamine. The intrastratial data imply that the striatum is a locus for the nicotinic involvement in induction and that the nicotinic role in expression occurs at a different brain locus. These data add support to the concept that behavioral sensitization involves the interaction of multiple neuroeffector systems in multiple brain loci. (Supported by NIDA grant DA00346.)

## 384.3

ATTENUATION OF THE LOCOMOTOR ACTIVATING EFFECTS OF D-AMPHETAMINE, COCAINE, AND SCOPOLAMINE BY POTASSIUM CHANNEL MODULATORS. S. Rosenzweig-Lipson\*, S. Thomas, J.E. Barrett. Wyeth-Ayerst Research, CNS-Biology, Pearl River, NY 10965.

The locomotor activating effects of  $\alpha$ -amphetamine, cocaine, and scopolamine were determined alone and after pretreatment with K-channel modulators in mice. When administered alone,  $\alpha$ -amphetamine (1-30 mg/kg) and cocaine (3-56 mg/kg) produced inverted U-shaped dose-effect curves characteristic of psychomotor stimulant drugs. Low to intermediate doses produced dose-dependent increases in locomotor activity, whereas high doses either increased locomotor activity less than an intermediate dose or decreased locomotor activity. When administered alone, scopolamine (3-56 mg/kg) also produced dose-dependent increases in locomotor activity but these effects plateaued, with similar increases in locomotor activity induced by 10 - 56 mg/kg of scopolamine. Pretreatment with the K-channel blockers 4-aminopyridine (0.3-1.7 mg/kg), quinine (30-100 mg/kg) or apamin (0.3-1 mg/kg) attenuated the locomotor increases induced by  $\alpha$ -amphetamine, cocaine, and scopolamine. Pretreatment with the K-channel openers cromakalim (1-3 mg/kg) and pinacidil (3-10 mg/kg) also attenuated the locomotor increases induced by  $\alpha$ -amphetamine and scopolamine but did not modify the locomotor activating effects of cocaine. These results demonstrate that K-channel modulation can modify the behavioral effects of  $\alpha$ -amphetamine, cocaine, and scopolamine and suggest that K-channels may play an important role in central nervous system pharmacology. Further, K-channel openers differentially alter the behavioral effects of  $\alpha$ -amphetamine and cocaine, suggesting a fundamental difference in the manner in which K-channel openers interact with the neurochemical mechanisms related to these two psychomotor stimulant drugs.

## 384.2

SCOPOLAMINE PREVENTS BEHAVIORAL SENSITIZATION TO METHAMPHETAMINE. T. Ohmori\*, T. Abekawa and T. Koyama. Dept. Psychiatry, Hokkaido Univ. Sapporo 060 Japan

Cholinergic neurotransmission has been implicated in various forms of neural plasticity such as kindling and learning. We have previously shown that blockade of muscarinic cholinergic receptors prevents the development of locomotor sensitization to methamphetamine (Life Sci 56: 1223-29,95).

The present study was conducted to examine whether scopolamine, a muscarinic cholinergic antagonist, would also block augmentation of stereotypy induced by chronic methamphetamine (MA) treatment. Rats treated with MA (2.5 mg/kg, sc) for 10 days indicated significantly enhanced stereotyped behavior when tested with MA (2.5 mg/kg) after a 7-8 day withdrawal. Pretreatment with scopolamine (3 mg/kg) prior to MA administration prevented the augmentation of stereotypy. Rats treated with scopolamine alone showed no difference in MA-induced stereotypy compared to those treated with saline. Scopolamine methylbromide, a derivative of scopolamine that does not easily cross the blood-brain barrier, had no effect on the augmentation of stereotypy.

These results suggest that stimulation of central muscarinic cholinergic receptors plays a role in the development of sensitization to the stereotypy stimulating effect of methamphetamine.

## 384.4

EFFECTS OF THE 5-HT<sub>2A/C</sub> ANTAGONIST RITANSERIN ON AMPHETAMINE-STIMULATED DOPAMINE RELEASE IN THE RAT PREFRONTAL CORTEX. E.A. Pehek\* and Y. Bi. Dept. Psychiatry, Case Western Reserve University and Cleveland VAMC, Brecksville, OH 44106.

Administration of relatively high doses of ritanserin (RIT) has been reported to increase extracellular concentrations of dopamine (DA) in the rat medial prefrontal cortex (mPFC). However, the mechanism for this effect is unknown. One possibility is that blockade of cortical 5-HT<sub>2</sub> receptors enhances impulse-dependent DA release. It is known that the D<sub>2</sub> antagonist haloperidol enhances impulse-dependent DA release in the striatum, and potentiates the effects of agents like amphetamine (AMPH) that act on the DA transporter to enhance DA efflux. The present study examined whether RIT acts similarly to augment AMPH-stimulated DA efflux in the mPFC. *In vivo* microdialysis coupled with HPLC/ED was used to collect and assay extracellular fluid in the mPFC for DA content before and after drug treatment. A dose of RIT was chosen (1.0 mg/kg s.c.) that does not alter basal extracellular DA levels by itself but should effectively block 5-HT<sub>2</sub> receptors. 2-4 days following implantation of chronic, indwelling guide cannulae, microdialysis probes were lowered through these cannulae into the mPFC of awake rats. Following collection of baseline samples, RIT or vehicle was administered 30 min before d-AMPH (5.0 mg/kg i.p.). AMPH increased basal extracellular DA levels from 1.41 pg/20 µl to 4.52 pg/20 µl 60 min following AMPH injection (n = 7). In the group pretreated with RIT, basal extracellular DA levels increased from 1.34 pg/20 µl to 3.78 pg/20 µl 60 min following AMPH injection (n = 7), a non-significant difference from the AMPH alone group. Thus, at this dose, RIT did not potentiate carrier-mediated DA release in the mPFC and thus behaves differently than drugs which enhance impulse-dependent DA release in the striatum.

## 384.5

**PHENTERMINE AUGMENTS THE LONG-TERM SEROTONIN DEPLETING EFFECTS OF (±) FENFLURAMINE IN THE RAT.** R. Lew\* and L.S. Seiden. Department of Pharmacological & Physiological Sciences, University of Chicago, 947 E58th St Chicago IL 60637.

Clinical studies have reported that the appetite suppressants phentermine (DA releaser) and (±) fenfluramine (5-HT releaser) are more effective together for weight reduction than either drug alone. However, the present study demonstrates co-administration of these drugs in rats causes significantly greater depletion of CNS 5-HT levels than either drug alone and cautions against their clinical use. Male Holtzman Sprague-Dawley rats (275 - 300 g) were injected ip at 1 hr intervals for a total of 4 injections with one of the following treatments: 1) saline (0.9 % NaCl), 2) phentermine (20 mg/kg; PHEN), 3) Low (±) Fenfluramine (3.125 mg/kg; Lo-FEN), 4) High (±) Fenfluramine (12.5 mg/kg; Hi-FEN), 5) Phentermine (20 mg/kg) & Low (±) Fenfluramine (3.125 mg/kg; Phen/Lo-Fen) and 6) Phentermine (20 mg/kg) & High (±) Fenfluramine (12.5 mg/kg; Phen/Hi-Fen). After 7 days recovery, animals were sacrificed and brain regions assayed for 5-HT. PHEN/Lo-FEN and PHEN/Hi-FEN treated animals showed a significantly greater weight reduction (86 - 87% of initial body weight) than animals treated with PHEN, Lo-FEN or Hi-FEN (91-95%) ( $P < 0.05$ ). In 5-HT studies, PHEN reduced 5-HT levels in striatum and hippocampus but not in other brain regions. Lo-FEN and Hi-FEN significantly reduced 5-HT in a dose-dependent manner in all brain regions, with Hi-FEN causing approximately 80 % depletion. Serotonin depletion by PHEN/Lo-FEN in all brain regions was significantly greater than Lo-FEN alone ( $P < 0.05$ ) and was comparable with Hi-FEN. Serotonin depletion by PHEN/Hi-FEN was not different from Hi-FEN alone. In conclusion, the present study cautions against the combined use of these drugs due to their severe depleting effect on central 5-HT levels. Further studies examining the long-term and neurotoxic effects of these drugs are in progress. (This work was supported by research grant DA00085; L.S.S. is supported by RSA MH-105 62)

## 384.7

**DOI DOES NOT MODIFY, 5-HT-ACTIVATED K<sup>+</sup>-OR Ca<sup>2+</sup> CURRENTS, OR EXCITATION BY AMINO ACIDS IN ACUTELY ISOLATED RAT SEROTONERGIC NEURONS** N.J. Penington\* Dept. of Pharmacol. SUNY (H.S.C) Brooklyn, NY. 11203.

Previous studies of the phenethylamine hallucinogenic drugs have reported that i.v. injection of DOI produced an inhibition of the firing rate of serotonergic dorsal raphe (DR) neurons of the rat. Direct application by iontophoresis demonstrated only weak non-specific effects, but injection into the nucleus produced slowing of cell firing, possibly due to the reduction of on-going synaptic excitation. The effect of DOI (10 μM) was tested on adult isolated DR neurons that responded to 5-HT with the activation of an inwardly rectifying K<sup>+</sup> current, but it was without effect. Under conditions that isolated Ca<sup>2+</sup> current that could be inhibited by 5-HT; DOI (10 μM) was similarly without effect, neither blocking nor mimicking the action of 5-HT. Brief applications of glutamate produced an inward current similar to those elicited by synaptic excitation, but DOI (10 μM) failed to influence the size or duration of these responses. These results suggest that DOI does not directly influence the cell bodies of DR neurons. Further studies using DR slices, subject to synaptic influences, will be required to reveal the mechanism that may underlie the effects of DOI on DR neurons. (Supported by the Aaron Diamond Foundation).

## 384.9

**ANTAGONISM OF 3,4-METHYLENEDIOXYMETHAMPHETAMINE-INDUCED FACILITATION OF BRAIN STIMULATION REWARD BY A D<sub>2</sub>, BUT NOT A 5HT<sub>2</sub>, ANTAGONIST.** S.L. Fledderjohn, C.J. Schmidt, R.A. Frank\*. Department of Psychology, University of Cincinnati, Cincinnati, OH, 45221-0376, and Marion Merrill Dow Research Institute, 2110 E. Galbraith Rd., Cincinnati, OH, 45237.

The effect of 3,4-Methylenedioxymethamphetamine (MDMA), known colloqually as "ecstasy," "X," or "XTC", on central reward mechanisms was measured using thresholds for brain stimulation reward (BSR). Since MDMA is self-administered, is structurally similar to amphetamine, and releases both dopamine and serotonin, it was predicted that it would facilitate BSR. Specific D<sub>2</sub> and 5HT<sub>2</sub> antagonists were used to determine how MDMA-induced release of dopamine and serotonin contribute to the hypothesized facilitation of BSR.

Bipolar stainless steel electrodes were implanted into the ventral tegmental area (VTA) of Sprague-Dawley rats that were then trained to nose poke for stimulation. The number of pulses delivered in each train of stimulation was then varied from 0 to 15 to determine self-stimulation threshold using a modified version of the method of constant stimuli. Once the rats achieved a stable BSR threshold, the first phase of the study began. In this phase, rats ( $n=24$ ) were injected with three doses of MDMA (1.0, 3.0 and 6.0 mg/kg, IP) on successive days with the dose of MDMA randomized across subjects. MDMA produced significant, dose-dependent decreases in self-stimulation thresholds which was similar to those produced by amphetamine, nicotine and cocaine.

In the second phase of the study, the effects of the specific D<sub>2</sub> antagonist, eticlopride, and the specific 5HT<sub>2</sub> antagonist, MDL 100,907, on MDMA-induced facilitation of BSR were evaluated. Eticlopride (0.066 mg/kg) blocked the effects of MDMA, while MDL 100,907 (2.0 mg/kg) had no effect. These data are consistent with the hypothesis that the rewarding effects of MDMA are mediated by dopaminergic rather than serotonergic systems.

This research was supported by NIDA grant DA04483; RA Frank, PI.

## 384.6

**POTENTIATION OF THE PATHOLOGICAL EFFECTS OF SUBTOXIC DOSES OF SUBSTITUTED AMPHETAMINES BY INHIBITION OF MONOAMINE OXIDASE TYPE-A.** E.T. Kokotos Leonardi\*, H.K. Kramer, X.P. Hou, and E.C. Azmitia. Department of Biology, New York University, New York, New York, 10003.

MDMA, PCA and FEN have been reported to be selective inhibitors of MAO-A, the subtype found outside serotonergic cells. These agents, therefore may increase levels of extracellular serotonin by stimulating carrier-mediated release, blocking re-uptake and inhibiting serotonin catabolism. Increased levels of extracellular serotonin are believed to stimulate protein kinase C (PKC) activity and glycogenolysis in astrocytes. We now describe the potentiation of the pathological effects of sub-toxic doses of substituted amphetamines by prior inhibition of MAO-A.

An established fetal raphe microculture system was used to determine whether inhibition of MAO-A would potentiate the toxicity of the ring substituted amphetamines, MDMA, MDE, MBDB. Briefly, amphetamines at  $10^{-7}$  M to  $10^{-5}$  M with or without  $10^{-10}$  M clorgyline were added into 8 day old raphe cultures and left in the culture plates for four days. The toxicity of these agents to fetal raphe neurons was determined by measuring uptake capacity with 50 nM [<sup>3</sup>H]-5-HT. MDA, MDE and MBDB toxicity was significantly potentiated in the presence of  $10^{-10}$  M clorgyline. The role of MAO-A inhibition in the toxic mechanism of the substituted amphetamines FEN and MDMA was determined *in vivo*. Animals were pretreated with clorgyline 3 hr prior to administration of FEN or MDMA. Four experimental groups were established: saline controls, FEN at 2 mg/kg, clorgyline at 1 mg/kg and a final group receiving both FEN and clorgyline ( $n=4$  per group). Animals were injected (s.c.) at 10 hr. intervals and killed by decapitation 2 weeks after the last injection. The density of serotonergic terminals in cortex was quantified by [<sup>3</sup>H]-paroxetine binding. Neither FEN nor MDMA resulted in a reduction of paroxetine binding sites. However, clorgyline pretreatment significantly potentiated the toxicity of FEN and MDMA ( $p < 0.05$ , 0.01). These results support the involvement of MAO-A inhibition in the mechanisms by which substituted amphetamines produced serotonergic neuropathies. (NIDA# 271-90-7403)

## 384.8

**IN VIVO EVIDENCE FOR CARRIER-MEDIATED RELEASE OF SEROTONIN BY 3,4-METHYLENEDIOXYMETHAMPHETAMINE.** J.F. Nash\* and G.A. Gudelsky\*. \*The Procter & Gamble Co., 11511 Reed Hartman Hwy., Cincinnati, OH 45241 and \*Dept. of Psychiatry and Pharmacology, Case Western Reserve University, Cleveland, OH 44106.

*In vivo* microdialysis was used to determine whether the 3,4-methylenedioxymethamphetamine (MDMA)-induced increase in the extracellular concentration of serotonin (5-HT) involves a carrier-mediated process and to further investigate the state-dependent interaction between 5-HT and dopamine (DA). A concentric microdialysis probe was inserted into the striatum (A: 1.2, L: 3.1, V: -6.5) on the morning of the experiment and dialysate samples were collected every 30 min after a 2 hour equilibration period. MDMA (2.5 - 20 mg/kg, ip) produced a dose-dependent increase in the extracellular concentration of 5-HT. The administration of 20 mg/kg MDMA resulted in extracellular concentrations of 5-HT that were at least 25 times those determined during the baseline period; 5-HT efflux remained significantly elevated for at least 180 min after drug administration. Treatment with the 5-HT uptake inhibitor, fluoxetine (10 mg/kg, ip), alone did not significantly alter the extracellular concentrations of 5-HT or DA. However, the increase in both 5-HT and DA produced by MDMA was attenuated significantly by treatment with fluoxetine. Infusion of the sodium channel blocker tetrodotoxin (TTX 10 μM) through the dialysis probe did not alter MDMA-induced 5-HT release. In contrast, TTX significantly diminished MDMA-induced DA release, consistent with previous reports. The co-administration of carbidopa (25 mg/kg, ip) and L-5-hydroxytryptophan (5-HTP; 50 mg/kg, ip) resulted in a marked increase in 5-HT efflux (e.g., 65 times basal concentrations) but no increase in DA release. The administration of MDMA to rats treated with carbidopa and 5-HTP resulted in a synergistic elevation of 5-HT and DA. These data are consistent with the view that MDMA increases the extracellular concentration of 5-HT by facilitating carrier-mediated 5-HT release which can be enhanced greatly under conditions in which 5-HT synthesis is stimulated. Moreover, these data are supportive of a stimulatory role of 5-HT on state-dependent DA release.

## 384.10

**LONG-TERM ATTENUATION OF INHIBITORY EFFECTS OF SEROTONIN AND DOPAMINE ON GLUTAMATE-EVOKED FIRING OF NUCLEUS ACCUMBENS CELLS FOLLOWING REPEATED INJECTIONS OF METHYLENEDIOXYMETHAMPHETAMINE (MDMA).** S. R. White\*, K. M. Imel and T. Obradovic. Dept. of Vet. & Comp. Anat., Pharmacol. and Physiol., Washington State Univ., Pullman, WA 99164.

MDMA ("ecstasy") releases both dopamine and serotonin from forebrain axon terminals when applied acutely and appears to be selectively neurotoxic to fine-diameter serotonin terminals in the forebrain when administered repeatedly (Steele, et al., *Addiction*, 1994, 89:539-551). The purpose of this study was to investigate whether repeated exposure to MDMA might alter serotonin and dopamine neurotransmission in the nucleus accumbens (NAc), a forebrain region that is an important component of brain reward circuitry. Male Sprague-Dawley rats received twice daily injections of MDMA (20 mg/kg, s.c.) or saline for 4 successive days. Two weeks later, the rats were anesthetized with urethane and effects of microiontophoretically applied serotonin, dopamine or the D<sub>1</sub> agonist SKF38393 on glutamate-evoked firing of cells in the nucleus accumbens core were tested. The inhibitory effects of all three drugs were markedly attenuated in the MDMA-pretreated rats compared to the saline-pretreated control rats. For example, dopamine (40 nA, 60 s) decreased glutamate-evoked firing  $47.5 \pm 3.4\%$  for cells from the saline-pretreated rats compared to only  $21.7 \pm 3.5\%$  for cells from the MDMA-pretreated rats. Similarly, serotonin (40 nA, 60 s) decreased glutamate-evoked firing  $37.5 \pm 6.8\%$  in control rats compared to  $14.2 \pm 4.1\%$  in MDMA-pretreated rats. These findings indicate that repeated exposure to MDMA produces long-term alterations in responses of NAc cells to serotonin and dopamine. Since both of these monoamines have been implicated in depression and psychosis as well as drug abuse, alterations in their effects on cells in the NAc (and perhaps other forebrain areas) following repeated exposure to MDMA might be expected to have wide-ranging consequences. (Supported by DA08116)

## 384.11

DIFFERENTIAL EFFECTS OF METHYLENEDIOXYMETHAMPHETAMINE (MDMA) IN THE NUCLEUS ACCUMBENS CORE AND SHELL. T. Obradovic\*, K. M. Imel and S. R. White. Dept. of Vet. & Comp. Anat., Pharmacol. and Physiol., Washington State Univ., Pullman, WA 99164.

The nucleus accumbens (NAc) has been partitioned into core and shell regions based on differences in neuronal morphology, anatomical connections, neurotransmitter distribution and receptor distribution. It is well-established that the NAc is an important locus for mediating the rewarding properties of abused drugs, but little is known about whether these drugs may have differential effects in the shell and core. This study compared the effects of the euphoria-producing amphetamine derivative MDMA ("ecstasy") on glutamate-evoked firing of cells in the shell (54 cells) and core (102 cells) regions of the NAc using microiontophoresis combined with extracellular recording of single unit activity. Because MDMA increases extracellular concentrations of monoamines in the accumbens, effects of serotonin, dopamine, and the selective D1 agonist SKF 38393 were also tested in the shell and the core. MDMA (20-60 nA, 60 s) inhibited glutamate-evoked firing of cells in a dose-dependent manner in both core and shell. However, the magnitude and duration of the inhibition was significantly greater in the core than the shell. Dopamine, SKF 38393 and serotonin also inhibited firing of the NAc cells, but, in contrast to MDMA, these drugs did not have a differential effect in the core and shell regions. Therefore, the differential effect of MDMA in the two regions did not appear to be mediated by differences in serotonin or dopamine receptors. Whether MDMA may have a differential effect on monoamine release and/or reuptake from terminals in the shell compared to the core is not known. Although the mechanisms responsible for the differential effects of MDMA on core and shell cells remain to be determined, the results of this study indicate that abused drugs may have markedly different effects on neuronal excitability in the subregions of the NAc. (Research supported by grant DA08116.)

## 384.13

FURTHER CHARACTERIZATION OF THE EFFECT OF AMPHETAMINE ON EXTRACELLULAR GLUTAMATE LEVELS IN THE VENTRAL TEGMENTAL AREA. J. Ng\*, C.J. Xue and M.E. Wolf. Dept. of Neuroscience, Finch Univ. of Health Sciences/The Chicago Medical School, N. Chicago, IL 60064.

Considerable evidence supports the idea that excitatory amino acid (EAA)-containing projections from the prefrontal cortex to the ventral tegmental area (VTA) are important in the development of behavioral sensitization to amphetamine (AMPH). To determine whether AMPH activates this pathway, *in vivo* dialysis was used to measure extracellular levels of glutamate (GLU) and aspartate (ASP) in VTA after systemic administration of AMPH. We have reported previously that low AMPH doses (1-2.5 mg/kg, s.c.) fail to alter extracellular GLU or ASP levels in VTA. A higher dose (5 mg/kg, s.c.) similarly failed to produce immediate alterations in GLU or ASP, but resulted in a delayed increase in GLU levels which attained statistical significance 3 hrs after AMPH injection. The magnitude of this delayed increase was similar in control and AMPH sensitized rats. It is possible that repeated elevation of GLU levels in VTA leads to compensatory alterations in EAA receptors on VTA dopamine (DA) neurons, ultimately resulting in increased excitatory drive to VTA DA neurons and thereby contributing to the initiation of sensitization. Consistent with this hypothesis are: 1) the ability of intra-VTA MK-801 to prevent sensitization (Kalivas and Alesdatter, JPET 267:486, 1995), 2) the increase in sensitivity to GLU exhibited by VTA DA neurons in sensitized rats (White et al., JPET 273:445, 1995), and 3) the increased firing rate and autoreceptor subsensitivity exhibited by VTA DA cells in sensitized rats (White and Wang, Brain Res. 309:283, 1984). Studies are underway to characterize the pharmacological basis of the delayed increase in GLU levels elicited by AMPH, and to determine whether inhibitors of the GLU transporter unmask additional effects of AMPH on GLU or ASP levels in the VTA. Support: DA 07735.

## 384.15

EXPRESSION OF mRNA FOR GLUTAMATE RECEPTOR SUBUNITS IN NUCLEUS ACCUMBENS AND PREFRONTAL CORTEX OF AMPHETAMINE SENSITIZED RATS. C.J. Xue, L.M. Monteggia, H.Y. Chen, J.R. Mathiasen\*, W.X. Lu and M.E. Wolf. Dept. of Neuroscience, Finch University of Health Sciences/The Chicago Medical School, N. Chicago, IL 60064.

Electrophysiological studies have shown that sensitization to amphetamine (AMPH) is accompanied by altered responsiveness of both ventral tegmental area dopamine neurons and nucleus accumbens (NAc) neurons to iontophoretically applied glutamate, suggesting sensitization-related alterations in glutamate receptor function (White et al., JPET 273:445, 1995). The function of both AMPA and NMDA receptors is known to be affected by differential incorporation of subunits. We therefore compared levels of mRNA for AMPA and NMDA receptor subunits in rats treated for 5 days with water or 5 mg/kg AMPH. Brain tissue was perfused 3 or 14 days after the last injection. A novel *in situ* hybridization protocol that allows quantification of mRNA levels was employed (see abstract by Wolf, Chen and Lu). <sup>35</sup>S-labeled oligonucleotide probes to AMPA subunits GluR1,2,3,4 and NMDA subunits NR1,2A,2B,2C were obtained from DuPont. NIH Image software was used for quantitative analysis of autoradiographs. In NAc, preliminary data suggest decreased levels of GluR2 mRNA and no change in GluR1 and GluR3 mRNAs in AMPH sensitized rats at 3 days off. At 14 days off, no differences between water and AMPH treated rats were apparent for GluR 1-3 mRNAs. In prefrontal cortex (PFC), there was no change in GluR1,2,3 mRNAs at 3 days off, but modest increases in GluR1 and GluR3 mRNAs at 14 days off. GluR4 mRNA levels in NAc and PFC were very low. Studies with NR1,2A,2B,2C probes are in progress; preliminary data suggest alterations in NR1 mRNA levels in both NAc and PFC of AMPH sensitized rats. Thus, altered levels of AMPA and NMDA receptor subunit mRNAs may play a role in AMPH sensitization. Support: DA 07735.

## 384.12

INDUCTION OF LOCOMOTOR ACTIVITY BY GLUTAMATE ANTAGONIST (DNQX) INJECTED IN THE VENTRAL TEGMENTAL AREA. A. Dalia\*, N.J. Uretsky and L.J. Wallace. Division of Pharmacology, College of Pharmacy, Ohio State University, Columbus, OH 43210.

The ventral tegmental area (VTA) dopamine neurons (A10) play a critical role in the etiology of schizophrenia as well as in the reinforcing properties of drugs of abuse. Since AMPA injected into the VTA elicits locomotor activity (LMA) similar to that of amphetamine (AMPH). Therefore, we hypothesized that AMPA/KA receptors in the VTA might control DA neuronal activity. To test this hypothesis, DNQX, an antagonist of these receptors, was injected bilaterally into the VTA immediately before the administration of AMPH (1.0 mg/kg). Contrary to our hypothesis, bilateral injection of DNQX (1.0 µg) into the VTA of both control and AMPH-treated rats increased LMA. In addition, unilateral injection of DNQX produced contraversive turning. Experiments were then designed to determine if dopamine is involved in this effect of DNQX. The locomotor stimulation produced by DNQX was not associated with a change in DOPAC/DA level in the nucleus accumbens or the striatum. However, complete dopamine depletion achieved by administration of α-methyl-para-tyrosine and reserpine blocked DNQX induced LMA. These results suggest that basal activity but not activation of dopamine neurons is required for the locomotor response to DNQX. (Supported by DA07722 and DA06776).

## 384.14

INCREASE IN DOPAMINE TRANSPORTER mRNA IN THE VENTRAL TEGMENTAL AREA OF AMPHETAMINE SENSITIZED RATS. W. X. Lu\* and M.E. Wolf. Dept. of Neuroscience, Finch Univ. of Health Sci./The Chicago Medical School, North Chicago, IL 60064.

Because of the importance of the dopamine transporter (DAT) in the action of psychomotor stimulants such as amphetamine (AMPH) and cocaine (COC), there has been interest in the possibility that behavioral sensitization to psychomotor stimulants involves alterations in DAT function. Studies of the effect of repeated COC administration on DAT function have yielded inconsistent results, depending on the COC treatment regimen and the length of withdrawal. However, it seems clear that repeated COC can alter the expression of the DAT. In contrast, very few studies have examined the effect of repeated AMPH on DAT levels. We have therefore examined the effect of AMPH sensitization on DAT mRNA levels in rat midbrain. Rats were treated for 5 days with water or 5 mg/kg AMPH, and perfused 3 or 14 days after the last injection. Using a new quantitative method of *in situ* hybridization (see abstract by Wolf, Chen and Lu), coronal brain sections were hybridized with a <sup>35</sup>S-labeled oligonucleotide probe for the DAT. Preliminary data suggest increased levels of DAT mRNA in the ventral tegmental area (VTA) of AMPH sensitized rats at both 3 and 14 days off. The region with increased DAT mRNA, which includes the paraventricular nucleus, the interfascicular nucleus and a portion of parabrachial pigmented nuclei, is lateral and dorsal to the rostral interpeduncular nucleus and medial to substantia nigra. These data suggest that altered DAT levels in dopaminergic projections originating in the VTA may contribute to AMPH sensitization. Supported by USPHS Grant DA 07735.

## 384.16

EFFECTS OF DOPAMINERGIC AND GABAERGIC MANIPULATIONS OF VENTRAL PALLIDUM ON VTA SELF-STIMULATION. W. Gong\*, D. B. Neill and J. B. Justice, Jr. Depts. of Psychology and Chemistry, Emory University, Atlanta, GA 30322

The ventral tegmental area (VTA) dopamine systems have well established roles in drug reward. Ventral pallidum (VP) receives a GABAergic projection from nucleus accumbens (NAS), which receives a massive dopaminergic projection from VTA. In addition, VP also receives a smaller dopaminergic projection directly from VTA. The aim of the present study was to examine the involvement of VP dopaminergic and GABAergic neurotransmissions in VTA electrical self-stimulation reward in rats. We used the autotitration procedure, in which the intensity of VTA stimulation was stepped down 3 uA every fifth depression of a stimulation lever. The rat was free to travel to another lever that, when depressed, reset the intensity to the maximum value for that rat. The major variable of interest was the stimulation intensity at which the rat reset. VP drug injections of 0.5 µl were bilateral. Amphetamine (2.5-10 µg) produced a dose-dependent decrease in reset current threshold without significantly changing total lever pressing in the 20 min test session. Picrotoxin (0.05-0.2 µg), on the other hand, did not significantly change the reset current or total lever pressing. These findings suggest that dopamine at VP is involved in VTA self-stimulation reward but GABA is not, which is consistent with our previous findings that intra-VP injection of amphetamine induced conditioned place preference but intra-VP injection of picrotoxin did not.

**MICRO-INJECTION OF CHOLERA TOXIN INTO THE VENTRAL TEGMENTAL AREA PRODUCES ENHANCED LOCOMOTOR RESPONSES TO SUBSEQUENT AMPHETAMINE ADMINISTRATION.** J.J. Byrnes, D.M. Weinstein, N.J. Uretsky, and L.J. Wallace. Neuroscience Program and Division of Pharmacology, The Ohio State University, Columbus, OH 43210.

The neural substrates involved in behavioral sensitization to psychostimulants include the dopamine (DA) neurons in the ventral tegmental area (VTA) and their axon terminals in the nucleus accumbens (N.Acc). In the VTA, activation of DA D1 receptors appears necessary for the development of sensitization as this phenomenon is blocked by intra-VTA administration of a D1 receptor antagonist (Stewart and Vezina, 1989). In many brain regions D1 receptors are positively coupled to adenylyl cyclase (AC) activation. Therefore, we tested the hypothesis that sensitization to psychostimulants requires enhanced AC activity in the VTA. On Day 0, rats received bilateral injections of cholera toxin (CTX), a known activator of AC, or its vehicle into the VTA followed by either repeated (Days 1, 3, 5, 7, and 18) or acute (Day 18 only) administration of AMPH (0.5 mg/kg, i.p.). On Day 19, tissue slices of the VTA and N.Acc were prepared and AMPH-induced [<sup>3</sup>H]DA release was measured. CTX (0.1-1.0 µg/site) treatment resulted in a dose-dependent enhancement of AMPH-stimulated locomotor activity on Day 1. The locomotor responses to subsequent AMPH treatments in high dose CTX-treated animals were markedly augmented beyond the response seen on Day 1. This long-lasting sensitivity to AMPH was associated with increased AMPH-induced [<sup>3</sup>H]DA release in the VTA but not the N.Acc. Interestingly, there was no effect of CTX treatment on either AMPH-stimulated locomotor activity or [<sup>3</sup>H]DA release when the first AMPH treatment was on Day 18. Moreover, repeated treatment with this low dose of AMPH in the absence of CTX pretreatment did not produce a sensitized locomotor response. These results indicate that intra-VTA CTX treatment facilitates sensitization to low doses of repeated AMPH which is associated with the increased ability of AMPH to release DA in the VTA. In addition, these effects may be mediated by alterations in cellular mechanisms linked to D1 receptors in this brain region. (Supported in part by DA07722, DA06776, and Sigma Xi)

## 384.19

**ENHANCED RESPONSES TO DIRECT ACTING DOPAMINERGIC AGONISTS AFTER PRETREATMENT WITH PERTUSSIS TOXIN IN THE VENTRAL TEGMENTAL AREA.** S. Narayanan, L.J. Wallace, and N.J. Uretsky. Division of Pharmacology, College of Pharmacy, The Ohio State University, Columbus, OH 43210.

The development of sensitization to psychostimulant drugs may involve a transient reduction in the G/G<sub>i</sub> proteins linked to D<sub>2</sub> receptors in the ventral tegmental area (VTA). Supporting this hypothesis is the observation that the administration of pertussis toxin (PTX), which inactivates the G/G<sub>i</sub> proteins, into the ventral tegmental area (VTA) results in an enhanced locomotor response to the systemic administration of amphetamine (Steketee et al. 1991). We have demonstrated that the administration of PTX into the VTA also produces an enhanced locomotor response to apomorphine administered either systemically or directly into the nucleus accumbens, suggesting that postsynaptic as well as presynaptic changes have developed at dopaminergic synapses in the N.Acc. The purpose of the present study was to evaluate the role of postsynaptic D<sub>1</sub> and D<sub>2</sub> receptors in the N.Acc in the enhanced response to dopaminergic agonists in PTX-treated rats. Rats injected bilaterally with PTX (0.3 µg) into the VTA showed an enhanced locomotor response to amphetamine (0.5 mg/kg, i.p.) 2 weeks after PTX administration. The stimulant effects of amphetamine in these animals were antagonized by SCH23390 (0.1 mg/kg), a D<sub>1</sub> receptor antagonist, but not by eticlopride (0.1 mg/kg), a D<sub>2</sub> receptor antagonist. Both compounds antagonized the effects of amphetamine in vehicle-treated animals. In addition, the PTX-treated animals showed a markedly magnified locomotor response to SKF38393, a D<sub>1</sub> receptor agonist administered either systemically or directly into the nucleus accumbens at doses (10 mg/kg i.p. and 0.1 µg/site respectively) which produced minimal effects on the locomotor activity of the vehicle-treated control animals. High doses of quinpirole (1 mg/kg, s.c.), a D<sub>2</sub> receptor agonist induced a small but significant locomotor response in PTX-treated animals. These results suggest that the administration of PTX into the VTA produces an increase in sensitivity of postsynaptic D<sub>1</sub> and D<sub>2</sub> dopamine receptors in the N.Acc.

## 384.18

**COMPARISON OF SENSITIZED LOCOMOTOR BEHAVIOR IN RATS ELICITED BY AMPHETAMINE AND PERTUSSIS TOXIN.** D.M. Weinstein, S. Narayanan, J.J. Byrnes, L.J. Wallace, and N.J. Uretsky. Division of Pharmacology, College of Pharmacy, The Ohio State University, Columbus, OH 43210.

Amphetamine (AMPH) administered in a repeated, intermittent fashion produces a persistent, enhanced behavioral response to a subsequent challenge dose of AMPH. Administration of pertussis toxin (PTX) into the ventral tegmental area (VTA) has also been shown to produce an enhanced behavioral response to an acute challenge of AMPH. The question arises as to whether AMPH and PTX produce comparable behavioral responses and thus can be considered equivalent models of the same phenomenon. We therefore conducted experiments designed to compare sensitizations elicited by AMPH and PTX in the context of the magnitude of enhanced response to an AMPH challenge. Rats pretreated with 4 doses of AMPH (5mg/kg i.p.) showed a 70% elevation of locomotor activity relative to control in response to a 0.5mg/kg AMPH challenge dose given 10 days later. However, rats pretreated bilaterally in the VTA with PTX (0.3µg/site) and challenged with AMPH (0.5mg/kg i.p.) 15 days later, exhibited locomotor activity greater than 900% over control. To determine whether we could approach the level of activity produced by PTX pretreatment, we implemented 2 additional AMPH pretreatment paradigms: 10mg/kg i.p. or escalating 5, 10, 15, 20mg/kg i.p. every other day for 4 doses. Rats were challenged with AMPH, 0.5mg/kg i.p., 7 days later. Although these animals also exhibited sensitized behavior, the magnitude was not different than the original amphetamine regimen of 5mg/kg, suggesting a maximal locomotor response to AMPH had been reached. These results suggest that AMPH-based locomotor sensitization plateaus well below that of the PTX-based response, and hence may imply that AMPH and PTX produce sensitized behavior through disparate mechanisms. Further studies are underway to investigate the *in vitro* dopamine release characteristics of these two drug models. (Supported in part by DA07722 and DA06776)

## 384.20

**ROLE OF VENTRAL TEGMENTAL AREA cAMP SYSTEMS IN BEHAVIORAL SENSITIZATION TO AMPHETAMINE.** B.K. Tolliver\*, K. Hsu, L. Ho, and S.P. Berger. University of California, San Francisco and SFVAMC, San Francisco CA 94121.

Considerable evidence has implicated ventral tegmental area (VTA) G protein signal transduction systems in the development of behavioral sensitization to psychostimulants. Sensitization has been associated with alterations in G proteins in the VTA following chronic stimulant treatment, and can be induced by persistent inactivation of G<sub>i</sub> proteins following VTA microinjection of pertussis toxin. A recent report of sensitization following microinjection of cholera toxin into the nucleus accumbens has demonstrated that cAMP systems may be involved in this process. However, the role of cAMP systems of the VTA in sensitization have not been elucidated. In the present study, bilateral microinjection of cholera toxin (500 ng / 500 nl / side) into the VTA of male Sprague-Dawley rats resulted in a significant baseline hyperactivity and sensitized locomotor response to 1.5 mg/kg d-amphetamine relative to rats receiving bilateral VTA microinjections of saline (500 nl / side) when assessed 24 hours after microinjection. In addition, the development of sensitization evident 72 hours after a single bilateral VTA microinjection of d-amphetamine (5 µg / 500 nl / side) was prevented by coadministration of the cAMP-dependent / cGMP-dependent protein kinase inhibitor H8 (at a dose of 10 µg / 500 nl / side, but not at 5 µg / 500 nl / side). These results extend previous studies which have established the importance of the ventral tegmental area in the development of behavioral sensitization and suggest that cAMP systems in the VTA may play a crucial role in this neuroadaptive response to psychostimulant drugs. (Supported by USPHS Grant DA 07376-04)

## DRUGS OF ABUSE: AMPHETAMINES AND OTHER STIMULANTS II

## 385.1

**AMPHETAMINE, COCAINE AND MORPHINE PRODUCE LARGER INCREASES IN DOPAMINE RELEASE IN THE N. ACCUMBENS OF ROMAN HIGH-AVOIDANCE (RHA) VS. LOW-AVOIDANCE (RLA) RATS.** M.G. Corda\*, O. Giorgi, D. Lecca, G. Carboni, V. Frau, G. Piras, V. Valentini and G. Di Chiara. Dept. Toxicol., Univ. of Cagliari, Italy.

RHA and RLA rats are selected and bred for rapid versus poor acquisition of two-way avoidance behavior in a shuttle box. Numerous behavioral studies have found that RLA rats are more "emotional" than RHA rats. Further, anxiolytics improve the performance of RLA rats in different behavioral tests. The present study was undertaken to analyze line-related differences in the effects of psychotropic drugs with rewarding properties. To this aim, we used brain microdialysis to compare the effects of amphetamine (AMPH, 0.25 mg/kg, s.c.), cocaine (COC, 5 mg/kg, s.c.), and morphine (MORPH, 0.5 mg/kg, s.c.) on the release of dopamine (DA) in the n. accumbens (NA) in both rat lines. No line-related differences were observed in the basal DA release (RHA: 73 ± 4, RLA: 67 ± 3). The effect of AMPH on DA release was more robust in RHA rats (maximal increase above basal value 40 min after treatment: RHA, +200%; RLA, +125%, p < 0.05). Likewise, the maximal increment caused by COC at 20 min after injection was more pronounced in RHA (+117%) than in RLA rats (+55%), whereas the peak effect of MORPH 80 min after treatment was +64% and +24% in RHA and RLA rats, respectively. These line-dependent differences persisted for 2 h with AMPH and COC and 4 h with MORPH. Interestingly, no significant line-related differences were observed with larger doses of AMPH and MORPH. Because the mesolimbic DAergic system plays a pivotal role in operant behavior by giving motivational relevance to environmental and pharmacological stimuli, our results suggest that RHA and RLA rats may have different dependence liabilities when exposed to drugs of abuse.

## 385.2

**PARALLEL STRAIN-DEPENDENT DIFFERENCES FOR AMPHETAMINE-INDUCED LOCOMOTION AND DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS AS MEASURED BY TRANSCEREBRAL MICRODIALYSIS IN FREELY MOVING MICE.** A. Zocchi\*, C. Orsini, S. Cabib and S. Puglisi-Allegra. Dip. Psicologia, Università "La Sapienza", and Istituto di Psicobiologia e Psicofarmacologia (CNR) Roma, Italy

Mice DBA/2 and C57BL/6 are known to respond differently or even in opposite ways to DA agonists. In particular C57 show higher sensitivity to the stimulant effects of amphetamine on locomotor activity (Cabib S. Behavioral Pharmacology, 1993, 4, 367-374). The present study investigated the role of mesolimbic Dopamine (DA) release in the different sensitivity to the psychomotor stimulant effects of amphetamine in mice of the C57 and DBA inbred strains. Male mice (8-10 week old) living in groups of 6 in standard breeding cage were implanted with transversal microdialysis tubes within the nucleus accumbens and singly housed for 48 hr before testing. On the test day the home cage of each mouse was placed on an activity meter (ANIMEX) and basal levels of activity and DA outflow were collected each 15 min for at least 180 min, then mice were injected (i.p.) with either saline or D-amphetamine (2.5 mg/kg). Samples and activity scores were collected every 15 min for 120 min. Saline injection did not affect either activity or DA outflow in any strain. Amphetamine significantly enhanced DA outflow and activity beyond saline levels in mice of the C57 strain. The effect of amphetamine on activity and DA outflow was time-dependent, peaking 45 min following injection. By contrast no significant effects were found in DBA mice. These results strongly suggest that these strain-dependent differences relate to a different susceptibility of the mesolimbic DA system to the psychostimulant.

## 385.3

COMPARISON OF METHAMPHETAMINE-HCl AFTER INHALATION AND I.V. ROUTES OF ADMINISTRATION IN MICE. Y. Meng, A.H. Lichtman, D.T. Bridgen and B.R. Martin\* Department of Pharmacology and Toxicology, Medical College of Virginia-Virginia Commonwealth University, Richmond, VA 23298.

Smoking of methamphetamine has been a very popular method of administration among drug users. The purpose of the present study was to investigate the volatilization and pyrolysis of methamphetamine-HCl, and to compare the relative pharmacological potencies and the biodisposition of this drug between inhalation and i.v. routes of administration in mice. At 200°C, 46% of the drug was volatilized, and the formation of pyrolytic products was insignificant. In the inhalation studies, 6 mice at a time were exposed to various amounts of volatilized methamphetamine-HCl for 5 min, and then assessed for locomotor activity. The maximum stimulation of activity was approximately 8 fold after either i.v. injection (ED<sub>50</sub>=0.88 µg/kg) and inhalation exposure (ED<sub>50</sub>=3mg) to methamphetamine-HCl. In addition, the biodisposition for the ED<sub>50</sub> doses of methamphetamine-HCl by i.v. or inhalation route of administration were very similar. Intravenous injection of 1 mg/kg and inhalation exposure of the volatilization of 3 mg of methamphetamine-HCl resulted in drug equivalents of 1.2 and 1.0 µg/g in the brain, 1.0 and 0.8 µg/g in the whole body, and 0.24 and 0.28 µg/ml in the plasma, respectively. These data suggest that inhalation exposure and i.v. injection are equipotent routes of administration for methamphetamine. This research was supported by NIDA grant DA-02396.

## 385.5

INDIVIDUAL DIFFERENCES IN NOVELTY SEEKING ON THE PLAYGROUND MAZE PREDICTS AMPHETAMINE-INDUCED LOCOMOTOR ACTIVITY. J.E. Klebaur, P.A. Abner, and M.T. Bardo. Dept. of Psychology University of Kentucky, Lexington, KY 40506-0044.

Previous research has shown that a rat's level of activity in a novel environment can predict the strength of amphetamine-induced locomotor behavior and self-administration, but not amphetamine conditioned place preference. The increase in activity observed when a rat is exposed to an inescapable novel environment is thought to reflect escape behavior due to stress. To assess approach to novelty in a free-choice test, we have examined the ability of a new test the playground maze (Nicholls, Springham, & Mellanby, 1992), to predict individual differences in response to amphetamine (0.25 or 1.0 mg/kg). Using the playground maze to categorize rats as either high or low novelty seekers, it was found that high novelty seekers were more sensitive to the locomotor stimulant effects of amphetamine, but not to amphetamine conditioned place preference. These results suggest that individual differences in a free-choice test of novelty preference can predict the psychostimulant effects of amphetamine, but not the rewarding effects.

## 385.7

INTRAPERITONEAL 3-NITROPROPIONIC ACID (3-NPA) AND AMPHETAMINE (AMPH) CAN COMBINE TO PRODUCE DAMAGE TO TERMINALS AND CELL BODIES IN THE STRIATUM AND MUSCLE RIGIDITY. J.F. Bowyer, W. Slikker Jr., L. Schmued, Z. Binienda, A.C. Scallet, and P. Clausen. Div. of Neurotoxicol., NCTR/FDA, Jefferson, AR 72079-9502.

Neither 2 doses (2 hrs apart) of 3.75 mg/kg AMPH alone nor a single dose of 30 mg/kg 3-NPA i.p. produced signs of neurotoxicity in the striatum or lowered striatal dopamine content in adult rats. Administration of a higher dose of 3-NPA alone (40 or 50 mg/kg) produced either lethality within 24 hrs or, in surviving rats, minimal neurotoxicity in the striatum. However, when 30 mg/kg 3-NPA was administered with 2 doses of 3.75 mg/kg AMPH a wide range of neurotoxicity to the striatum was produced. Over 30% of the rats showed muscle rigidity/cataplexy, decreased food consumption for several days after dosing and degeneration of axons and cell bodies in the medial caudate/putamen of the striatum with little damage to the globus pallidus, cerebral cortex, hypothalamus or thalamus. The 5% that exhibited hind-limb paralysis and survived 24 hrs after combined dosing had axonal and neuronal degeneration in the caudate/putamen, globus pallidus, thalamus and cerebellar nuclei. In 30% of the rats dosed with both AMPH and 3-NPA only transient torpidity with minimal muscle rigidity was observed 1 to 3 hrs after the combined dosing. Such rats did not show prominent histological signs of neuronal degeneration in the striatum but did show dopamine depletions (50% of control) 8 to 10 days after exposure. The combined effect of mitochondrial dysfunction produced by 3-NPA along with the activation of specific neuronal pathways by AMPH may have predisposed axons and cell bodies in these pathways to degeneration.

## 385.4

SENSITIZATION TO LOCOMOTOR EFFECTS OF METHYLPHENIDATE IS INFLUENCED BY THE TIME OF ADMINISTRATION. O. Gaytan, A. Swann, and N. Dafny\* Dep. of Neurobiology, UT Medical School at Houston, P.O. Box 20708, Houston, TX 77225

Chronic administration of stimulants has been reported to produce reverse tolerance, or sensitization, to its effects on motor activity an stereotypy. This adaptation may be related to the pathophysiology of recurrent psychiatric disorders. Since disturbances in circadian rhythms are also found in many of these disorders, the relationship between sensitization and chronobiological factors became of interest. This study was designed to investigate the effect of repeated treatment with methylphenidate (MPD) on the circadian pattern of motor activity, and whether the development of sensitization differs if MPD is given at different times of the light/dark cycle. Male Sprague-Dawley rats were housed in activity monitoring system test cages after 7 days of acclimation to L:D cycle (07:00:19:00) and monitored continuously for 16 days as follows: Baseline (Day 1-2), Saline Injection (Day 3), Challenge Doses (Day 4) - either 0.6, 2.5, or 10 mg/kg of MPD, Maintenance dose (Day 5-9) - 2.5 mg/kg once a day, Withdrawal (Days 10-14), Re-Challenge (Day 15) - same doses as day 4. This regimen was run at 4 times (0800, 1400, 2000, 0200). Two locomotor parameters are presented (Horizontal Activity and Total Distance). In general, sensitization occurred at all the time points, and the parameter of total distance was more affected. There were differences between the time points with the 2000 displaying the weakest sensitization. Administration during the middle, but not at the beginning, of the light and dark phase (1400 & 0200) caused changes in the levels of diurnal activity. In conclusion, the development of sensitization and daily pattern of motor activity were dependent on the time of administration.

## 385.6

INDIVIDUAL DIFFERENCES IN RESPONSE TO AMPHETAMINE. P. Clausen, S.A. Ferguson, and J.F. Bowyer. NCTR/FDA, Jefferson, AR 72079-9502.

In spite of efforts to minimize experimental variation, considerable individual differences in response to amphetamine (AMPH) are commonly observed. To further elucidate this phenomenon we recorded the behavior of adult male Sprague-Dawley rats after 1 x 2.5 mg/kg AMPH s.c., and simultaneously determined extracellular AMPH-levels in the caudate/putamen. The pharmacokinetic profile revealed the existence of "LOW AMPH" rats with peak AMPH concentrations less than 80 pg/ul microdialysate and "HIGH AMPH" rats with peak AMPH concentrations up to 150 pg/ul microdialysate. The "HIGH AMPH" group dissociated into RESPONDERS and NONRESPONDERS according to their behavior after AMPH administration. Circling (i.e., the number of complete turns) in the microdialysis bowl was used as an accurate behavioral criterion which can be easily recorded. RESPONDERS exhibited a significant positive correlation (r=0.875, p=0.023, n=6) for peak number of Circlings vs. peak AMPH levels in the microdialysate. Currently we are conducting experiments to see if the same individuals which are behavioral NONRESPONDERS after 1 x 2.5 mg/kg also display an attenuated hyperthermic response after multiple doses of 5 mg/kg AMPH. In conclusion, earlier suggestions (Segal & Kuczenski, J. Pharmacol. Exper. Ther. 242:917-926, 1987) that a pharmacokinetic explanation is inconsistent for individual differences in behavioral response to AMPH are partially corroborated. It needs to be determined if NONRESPONDERS have lower extracellular dopamine levels or if they have the same levels but are less sensitive to dopamine.

## 385.8

METHAMPHETAMINE DEPLETES DOPAMINE AND DECREASES GLUTAMATE IMMUNOREACTIVITY WITHOUT INDUCING TERMINAL DEGENERATION. K. B. Burrows\* and C. K. Meshul. Dept. of Medical Psychology and Pathology, Oregon Health Sciences University, and VA Medical Center, Portland OR 97201.

Methamphetamine (METH) treatment results in long-lasting depletion of dopamine (DA) in the striatum (Str). Glutamate (GLU) is believed to play a role in METH neurotoxicity. Blockade of GLU overflow or pretreatment with GLU antagonists protects against DA depletion. The goal of this study was to determine if METH effects the concentration of GLU in presynaptic nerve terminals in rats. METH treatment (4.5 mg/kg X 2 hrs X 4 inj) depleted striatal DA (40% of control) and decreased the density of GLU immunolabeling in presynaptic terminals as determined by post-embedding immuno-gold electron microscopy. Decreased immunoreactivity was present 24 hrs after METH treatment only in Str. Significant decreases were found 72 hrs after METH in Str, nucleus accumbens (NAc), and motor cortex (Ctx). The reduction in GLU immunoreactivity suggests that METH treatment may result in either prolonged release, or decreased uptake and/or synthesis of GLU. Although it has been assumed that METH results in the destruction of DA-containing terminals in Str, there is little direct electron microscopic evidence to support this hypothesis. Therefore, the effect of METH (4.5 mg/kg X 2 hrs X 4 inj) on synaptic morphology in the Str, NAc, and Ctx was examined. Despite the loss of DA observed in the current study, no evidence of cell body, terminal, or axonal degeneration was found ultrastructurally. (Supported by Dept. of Veterans Affairs and a N.L. Tartar Fellowship)

**BEHAVIORAL AND BIOCHEMICAL ASPECTS OF GM<sub>1</sub> ATTENUATION OF MDMA-INDUCED NEURONAL TOXICITY.** E. P. Finnerly\*, B. Dunbar and D. Hoganson. Univ. of Osteopathic Med. & Health, Sciences and Drake University, Des Moines, IA 50312

MDMA (Ecstasy), a methylamphetamine derivative, has been found to produce severe and somewhat selective damage to CNS serotonergic (5-HT) neurons. This damage, though extensive, does not involve cell death. The ganglioside GM<sub>1</sub> has demonstrated potential neurotrophic properties which may enhance the rate of recovery of the neurons from the MDMA-induced effects. To assess this GM<sub>1</sub> effect, MDMA (20 mg/kg x 4 days), GM<sub>1</sub> (40 mg/kg), MDMA and GM<sub>1</sub> or saline was injected (i.p.) into male rats. Behavioral activity was determined for 24 hours on day 5 or day 12 following the beginning of the injections. A general increase in activity on day 5 was noted for the MDMA group (consistent with a release of 5-HT and/or catecholamines) while the activity of the MDMA/GM<sub>1</sub> group was lower, at the level of the control. At day 12 the MDMA group's activity was decreased relative to the control (consistent with a 5-HT depletion) while the MDMA/GM<sub>1</sub> group's activity was at or above that of the control. Biochemical analysis of brain tissue obtained from the animals sacrificed on day 7 or 14 following the beginning of the injections demonstrated a profound depletion of 5-HT, dopamine and norepinephrine with administration of MDMA. The MDMA/GM<sub>1</sub> group also showed this depletion, though to a smaller degree, suggesting some attenuation of the toxic effects.

We gratefully acknowledge FIDIA Pharmaceutical Co. for their generous gift of the GM<sub>1</sub>.

## 385.11

**INVOLVEMENT OF SUPEROXIDE RADICALS IN METHAMPHETAMINE INDUCED AP-1 DNA BINDING ACTIVITIES.** P. Sheng\*, X.-B. Wang, B. Ladenheim, C. Epstein, and J. L. Cadet. Molecular Neuropsychiatry and Molecular Neurobiology Sections, Division of Intramural Research, NIH/NIDA IRP, Baltimore, MD 21224

Stimulants are known to cause increases in immediate early genes. The mechanisms by which they do so have not been completely characterized. In the present study, we tested the idea that this activation might involve production of free radicals by using nontransgenic (Non-Tg) and CuZn SOD transgenic (SOD-Tg) mice. Methamphetamine (METH) caused dose-dependent increases in AP-1 DNA-binding activity in both Non-Tg and SOD-Tg mice. However, the increases in SOD-Tg mice were less prominent than those observed in Non-Tg animals. The time-course of METH-induced AP-1 changes was similar in both strains of mice. The AP-1 binding activity showed an initial increase at 1 hour, peaked at 3 hours, and then gradually declined. AP-1 binding activity was back to normal by the 72-h time point. Regional analyses of METH effects revealed increases in the caudate-putamen, frontal cortex, and cerebellum, with the striatum showing relatively higher METH-induced AP-1 DNA-binding activation. These regional effects were also attenuated in the SOD-Tg mice. These data indicate that METH-induced stimulation of AP-1 DNA-binding depends on cellular redox status. These results are consistent with *in vitro* studies that have reported that several transcription factors are regulated through redox mechanisms.

## 385.13

**BCL2 EXPRESSING DOPAMINERGIC CELLS ATTENUATE METHAMPHETAMINE- NO- AND CO- INDUCED TOXICITY** C. CERRUTI\* and J.-L. CADET. Molecular Neuropsychiatry Section, NIDA/ARC, Baltimore, MD.

Dopaminergic systems are very sensitive to chemically very different toxic agents. Methamphetamine (METH) is one of such neurotoxins. We have shown that METH-induced toxicity in DA neurons involves the formation of free radicals such as superoxide and nitric oxide (NO). We then investigated whether METH-induced toxicity can be attenuated by BCL2 expressed in a dopaminergic cell line. Toxicity was assessed by trypan blue exclusion.

METH-induced toxicity was dose dependent in wild type and BCL2 cells. However, the percentage of dead cells was significantly higher in wild type cells. Moreover, exposure to sodium nitroprusside, a NO-releaser, induced a dose dependent toxicity which was significantly more pronounced in wild type cells. Interestingly, the application of a medium enriched in CO also induced a more pronounced toxicity in control cells. Thus, the neurotoxicity induced by METH or the direct exposure to NO or CO, can be attenuated by the expression of BCL2 gene in dopaminergic cells. The survival of dopaminergic neurons in a context such as transplantation, could be dependent on the expression of such genes that confer a resistance to toxic environment.

## 385.10

**Bcl-2 PROTECTS NEURAL CELLS FROM METHAMPHETAMINE-INDUCED NEUROTOXICITY IN VITRO.** S. Ordonez\*, J. Ordonez, J. Cadet. Molecular Neuropsychiatry Section, Division of Intramural Research, NIH/NIDA IRP, Baltimore, MD 21224

Methamphetamine (METH) causes neurotoxic effects on monoaminergic neurons. Previous studies from this laboratory had suggested a role on oxidative stress in METH-induced toxic effects. Specifically, transgenic mice with high superoxide dismutase (SOD) activity are protected against these deleterious effects of the drug. We have to continue to dissect the pathway through which superoxide radicals cause the changes after METH administration. In order to do so, we have used immortalized bcl-2 neural cells in which the proto-oncogene has been introduced because bcl-2 is known to work in an oxidant pathway to protect cells against oxidative stress. We predicted that these neural cells expressing bcl-2 will be protected against METH-induced toxicity. Cells expressing bcl-2 and cells expressing vector alone were treated with various doses of METH for various time points. Flow cytometry was then used to assess cellular viability. All cells exposed to METH develop cytoplasmic vacuoles. In addition, METH caused dose-dependent increase in cell death which was observed both after 24 and 48 hours of exposure. However, bcl-2 inhibits these toxic effects of the drug. These results provide further evidence of a role of an oxidant pathway in METH-induced neurotoxicity. Data will be presented to document if cell death caused by METH is via apoptosis or necrosis.

## 385.12

**PROTECTION OF 3,4-METHYLENEDIOXYMETH-AMPHETAMINE(MDMA)-INDUCED NEUROTOXICITY BY PHENYL-T-BUTYL NITR ONE (PBN), BUT NOT BY SALICYLATE (SALI), IN RATS.** S. Y. YEH\*, Neuropsychiatry lab. Div. Intramural Research, NIDA/NIH, P.O. Box 5189, Baltimore, MD 21224

MDMA-induced neurotoxicity is hypothesized to be due to hydroxyl free radicals and/or metabolites of MDMA. PBN was used to trap possible free radical metabolites of MDMA and other free radicals while SALI was used to trap hydroxyl free radicals. Rats received two doses of PBN (50, 100, 200 and 400 mg/kg dissolved in 25% of ethanol, 50 mg/ml, i.p.) and MDMA (20 mg/kg, s.c.) given concurrently 6 h apart. Control rats received saline or 25% ethanol as vehicle. For the SALI studies, SALI (3, 6, 12, 25, 50, 100, 200 mg/kg dissolved in saline) was injected i.p. 1 h prior to the s.c. injection of MDMA (20mg/kg for acute study; 10mg/kg x 2 doses x 4 days for chronic study). Rectal temperature was measured before drug and after the first injection for 5 h. Rats were sacrificed 5 or 7 days after the last injection for the PBN or SALI, respectively. Brain tissues were dissected and frozen until used for measurement of monoamines by HPLC. Rectal temperature of rats treated with PBN decreased whereas PBN plus MDMA, ethanol (0.5 to 2 ml/kg) and ethanol plus MDMA were not significantly altered. Temperature increased after SALI plus MDMA. Levels of monoamines in the frontal cortex, hippocampus, striatum and brain stem of rats treated with PBN and MDMA were not significantly changed as compared with saline and vehicle controls. Administration of SALI failed to attenuate the toxic effects of MDMA. These results suggest that the neurotoxicity of MDMA might be related to MDMA metabolite free radicals other than hydroxyl radicals.

## 385.14

**INVOLVEMENT OF THE NITRIC OXIDE IN AMPHETAMINE-EVOKED CHANGES IN THE PRODYNORPHIN SYSTEM ACTIVITY.** B. Przewlocka, J. Turchan, W. Lason\* and R. Przewlocki. Dept. Neuropeptide Research, Inst. Pharmacology, 31-343 Kraków, Poland.

A growing body of evidence suggests involvement of the prodynorphin system in the neurochemical mechanism of psychomotor stimulants. To better understand this issue, in a time-course study we measured the prodynorphin mRNA and  $\alpha$ -neoendorphin tissue levels, as well as the *in vitro* release of the peptide in the nucleus accumbens and caudate putamen of rats treated with amphetamine (5mg/kg i.p., twice a day for 5 days). Acute and chronic amphetamine administration increased the prodynorphin mRNA level in both those structures, that effect being associated with an increase in the  $\alpha$ -neoendorphin tissue level and *in vitro* release. The amphetamine-induced increase in the prodynorphin mRNA was attenuated in rats pretreated with the nitric oxide synthase inhibitor L-NAME (10 and 50 mg/kg i.p.). The obtained results indicate that amphetamine increases the prodynorphin system activity; moreover, the drug-induced prodynorphin gene expression appears to be under regulatory control of the nitric oxide.

## 385.15

ROLE OF NITRIC OXIDE ON BEHAVIORAL CHANGES INDUCED BY PHENCYCLIDINE IN MICE. Y. Noda<sup>1</sup>, K. Yamada<sup>2</sup>, Y. Komori<sup>2</sup>, H. Sugihara<sup>2</sup>, T. Kameyama<sup>3</sup>, H. Furukawa<sup>3</sup> and T. Nabeshima<sup>1</sup>. <sup>1</sup>Dept. of Neuropsychopharmacol. and Hosp. Pharm., Nagoya Univ. Sch. of Med., Nagoya 466, Japan. <sup>2</sup>Dept. of Microbiol., <sup>3</sup>Chem. Pharmacol., and <sup>4</sup>Med. Chem., Faculty of Pharmaceut. Sci., Meijo Univ., Nagoya 468, Japan.

The role played by nitric oxide (NO) on the behavioral changes induced by phencyclidine (PCP) in mice was investigated by using a NO synthase inhibitor, N<sup>G</sup>-nitro-L-arginine methyl ester (L-NAME). Acute PCP treatment induced hyperlocomotion, motor incoordination, sniffing, head movement and ataxia in a dose-dependent manner. Hyperlocomotion and ataxia induced by acute PCP (3 mg/kg s.c.) treatment were enhanced by L-NAME (50 mg/kg i.p.), the effects were reversed by L-arginine (1 g/kg i.p.). In mice treated with PCP repeatedly (10 mg/kg/day s.c., once a day for 14 days), the ataxia and motor incoordination induced by acute PCP (10 mg/kg) treatment were attenuated (indicating development of tolerance) whereas hyperlocomotion was enhanced (indicating development of sensitization). Tolerance to PCP-induced ataxia and motor incoordination was significantly attenuated by combined treatment with L-NAME (50 mg/kg/day i.p.), while sensitization to PCP-induced hyperlocomotion was further enhanced. NO synthase activity in the cerebral cortex and cerebellum, but not in the striatum and hippocampus, was significantly decreased by acute PCP (10 mg/kg) treatment, and such changes in activity in the cerebral cortex and cerebellum were reversed by subacute PCP treatment. These results suggest the involvement of central NO production in the mediation of behavioral changes induced by acute and subacute PCP treatment in mice.

## 385.17

EFFECTS OF VARIOUS PHARMACOLOGICAL AGENTS ON METHAMPHETAMINE-INDUCED HYPERTHERMIA AND NEUROTOXICITY IN MICE. L. Manzano<sup>\*</sup>, D.S. Albers and P.K. Sonsalla. Dept. Neurology, UMDNJ-RWJ Med. Sch., Piscataway, NJ 08854.

The administration of methamphetamine (METH) to experimental animals causes a significant increase in core temperature. The damage sustained to dopaminergic nerve terminals can be reduced by attenuating the METH-induced hyperthermia by environmental cooling or pharmacological manipulation. The purpose of the present study was to determine if the protection from METH-induced decrements in striatal tyrosine hydroxylase activity and DA content by several pharmacological agents with diverse actions could be attributed to the blockade of this hyperthermia. Core temperature was significantly increased in mice during the treatment period with METH. Concurrent treatment of mice with METH and neuroprotective agents (DA receptor antagonists, dizocilpine, fenfluramine, propranolol, phenytoin,  $\alpha$ -methyl-p-tyrosine) prevented this hyperthermic response. Moreover, agents which were unable to suppress the METH-induced temperature elevation whether from normal basal temperature (ibuprofen, salicylate, 8-OH DPAT) or from a drug-induced hypothermia (reserpine), were unable to protect against the neurotoxic actions of METH. Taken together, these data suggest that the rapid induction of core temperature by METH contributes to its neuropathology regardless of basal temperature.

## 385.19

ALTERED AMPHETAMINE (AMP) METABOLISM AND ABUSE LIABILITY IN A RAT PHENOCOPY OF THE HUMAN CYTOCHROME P450 2D6 (CYP2D6) DEFICIENCY. E.M. Sellers, T. Bems, W.A. Corrigan, D.M. Tomkins, J.B. Kamien<sup>\*</sup>, N. Joharchi, R.F. Tyndale and S.V. Otton. Depts. Pharmacology & Psychiatry, Univ. of Toronto; & Addiction Research Foundation, Toronto, Canada.

Humans missing CYP2D6 (about 8% of Caucasians) may have altered drug dependence characteristics because this enzyme is important in the metabolism of some drugs of abuse including AMPs. In rats d-AMP conversion to 4-OH AMP is by CYP2D1. Quinine (QN) and bupropion (B) are inhibitors of male Wistar rat CYP2D1 metabolism of dextromethorphan and d-amphetamine by liver microsomes ( $K_i = 190$  nM and  $1.8$   $\mu$ M). *In vivo* QN (20 mg/kg i.p.) and B (10 mg/kg i.p.) increased the plasma AUC of d-AMP (5 mg/kg i.p.) by 290% and 260% respectively (and decreased 4-OH d-AMP by 68% and 88%) compared to AMP alone ( $p < 0.01$ ). QN and B increased and prolonged rat locomotor activity after d-AMP (0.3 mg/kg i.p.) compared to controls ( $p < 0.01$ ) in a pattern paralleling the observed changes in plasma kinetics of d-AMP. In a two-choice drug discrimination study, QN but not B increased generalization of low AMP doses to d-AMP ( $p < 0.05$ ) and both prolonged the duration of  $> 90\%$  d-AMP-appropriate responding up to 90 min post d-AMP injection. In contrast, in self administration studies, B but not QN caused a parallel shift to the left of the number of infusions vs. d-AMP injection dose response curve ( $p < 0.05$ ). These studies indicate that d-AMP  $> 4$ -OH AMP is responsible for the behavioral effects seen in rats. In humans, CYP2D6 phenotype should be important for AMPs that undergo substantial ring hydroxylation or O-demethylation. Deficient individuals should show higher AMP toxicity at a fixed dose and use lower doses during chronic abuse. Conversely, individuals with high enzymatic activity may have lower AMP (but higher metabolite) toxicity and use higher doses than individuals with lower or absent CYP2D6 activity. Supported by NIDA Grant DA 086889.

## 385.16

PROTECTION AGAINST MDMA-INDUCED SEROTONIN NEUROTOXICITY IN RATS PRETREATED WITH KETANSERIN AND ALPHA-METHYL-PARA-TYROSINE: ROLE OF HYPOTHERMIA. J.E. Malberg<sup>\*</sup>, K.E. Sabol and L.S. Seiden. Dept. of Pharmacology and Physiological Sciences, University of Chicago, Chicago IL 60637.

We looked at the role temperature plays in protection against MDMA-induced serotonin depletions. This study demonstrates that the hypothermia seen in alpha-methyl-para-tyrosine and ketanserin-pretreated rats is an important factor in protection against neurotoxicity. We administered MDMA (40 mg/kg, s.c.) to male Holtzman rats pretreated with either alpha-methyl-para-tyrosine (AMPT; DA synthesis inhibitor, 75 mg/kg, s.c. 1 and 5 hrs prior to MDMA) or ketanserin (KET; 5-HT<sub>2</sub> antagonist, 6 mg/kg, 1 hr prior to MDMA). Body temperature was measured in all rats using a peritoneally implanted temperature probe and one week after injections rats were sacrificed and brain regions analyzed by HPLC. When rats pretreated with AMPT or KET were injected with MDMA, a significant hypothermia of 2.3°C was seen 20 minutes after the MDMA injection which continued for 2 1/2 hours. The KET and AMPT pretreatment significantly ( $p < 0.05$ ) protected against decreases in 5-HT and 5-HIAA levels in the frontal cortex, somatosensory cortex, striatum, and hippocampus seen in rats treated with MDMA alone. The transmitter levels of pretreated rats did not differ from saline controls, and AMPT or KET alone had no effect on temperature nor transmitter levels. In a second experiment, rats were given the same drug treatments and placed under a heat lamp immediately after the MDMA injection. The temperature of these rats was maintained at 38.5-39.0 for 4 hours to prevent the hypothermic response. The KET and AMPT pretreated rats whose body temperature was maintained had levels of 5-HT and 5-HIAA that were significantly ( $p < 0.05$ ) lower than saline controls and the drug-pretreated rats that exhibited hypothermia. This demonstrates that prevention of the hypothermia abolishes protection against neurotoxicity. One hypothesis is that the hypothermia exerts its protective effect by preventing oxidative stress or other reactions that lead to neurotoxicity. (Supported by NIDA Training Grant DA-07255-01)

## 385.18

THE NEUROPATHOLOGY PRODUCED BY METHAMPHETAMINE OR MPTP IN MICE IS POTENTIATED BY INTRASTRIATAL MALONATE. D.S. Albers<sup>\*</sup>, G.D. Zeevalk and P.K. Sonsalla. Dept. Neurology, UMDNJ-RWJ Med. Sch., Piscataway, NJ 08854.

The treatment of mice with neurotoxic doses of methamphetamine (METH) or 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) produces damage to nigrostriatal dopaminergic neurons and causes a transient loss in striatal ATP levels. These observations suggest that perturbations of energy metabolism may contribute to their neurotoxicity. The purpose of the present study was to determine if reduced energy production would potentiate the neurotoxic actions of systemically administered METH or MPTP. Mice received a unilateral infusion of saline or malonate (0.5-3.0  $\mu$ mol), a reversible inhibitor of succinate dehydrogenase, into the striatum prior to treatment with METH or MPTP at doses which produced no significant DA loss. Malonate, by itself, produced minimal or no decrease in striatal DA content in animals sacrificed 5-7 days after treatment. However, in combination with METH or MPTP, malonate dose-dependently potentiated the DA depletion in the infused side (by 30-70%) compared to the contralateral side. These data suggest METH-induced perturbations of energy metabolism create a state of metabolic stress for dopaminergic neurons which may ultimately contribute to the neurodegenerative effects of METH. Furthermore, the potentiation of MPTP toxicity by malonate is consistent with the widely held view that MPTP-induced neurotoxicity is mediated by energy impairment due to the blockade of Complex I by MPP<sup>+</sup>. This work was supported by a grant from the National Institute of Drug Abuse.

## 385.20

PROTECTION AGAINST METHAMPHETAMINE-INDUCED DEPLETION OF STRIATAL DOPAMINE IN RATS BY GDNF. W.A. Cass<sup>\*</sup> and D.M. Gash. Department of Anatomy and Neurobiology, University of Kentucky, Lexington, KY 40536.

Repeated methamphetamine (METH) administration to animals can result in decreased dopamine (DA) levels, tyrosine hydroxylase activity and DA uptake sites in the striatum. These effects appear to be long-lasting and in the rat may still be present six months after treatment. Glial cell line-derived neurotrophic factor (GDNF) has pronounced effects on dopaminergic systems *in vivo*, including partial neuroprotective effects against 6-OHDA and MPTP-induced degeneration of DA neurons. The present study examined the ability of GDNF to prevent METH-induced reductions in striatal DA. Male rats were administered METH (4 mg free base/kg, s.c.) or saline 4 times in one day at 2 hour intervals. One week later the animals were killed and striatal DA levels determined by HPLC. The METH treatment produced decreases in DA levels of 30-40% in the dorsal striatum and 50-60% in the ventral striatum. Using *in vivo* electrochemistry, similar decreases were found in potassium-evoked release of DA in the striatum of METH-treated animals. In another group of animals GDNF (Synergen Inc., Boulder, CO) was injected into the right striatum (10  $\mu$ g in 2  $\mu$ l buffer at a rate of 0.2  $\mu$ l/min) 24 hours prior to the METH treatment. GDNF completely prevented the reduction in striatal DA levels on the right side of the brain, while levels on the left side were still decreased. While these results are preliminary they suggest that GDNF can prevent the toxic effects of METH on DA neurons. *In vivo* electrochemistry experiments are underway to determine if GDNF can also prevent METH-induced reductions in potassium-evoked DA release.

## 386.1

EFFECTS OF CHRONIC FLUOXETINE AND TIANEPTINE ADMINISTRATION ON MONOAMINE LEVELS AND TURNOVER IN DISCRETE BRAIN NUCLEI. C.R. McKittrick\*, M. Frankfurt, C.J. Schindler, B.S. McEwen, and V.N. Luine. Laboratory of Neuroendocrinology, Rockefeller University and Department of Psychology, Hunter College, New York, NY 10021.

We investigated the effects of chronic antidepressant treatment on serotonin (5HT) and norepinephrine (NE) levels and metabolism in brain regions involved in affective states. Fluoxetine and tianeptine are both clinically active antidepressants even though they have opposing effects on 5HT reuptake: fluoxetine inhibits 5HT reuptake, while tianeptine increases it. Tianeptine (10 mg/kg), fluoxetine (10 mg/kg) or saline were administered i.p. to male rats daily for 21 days. Forty-eight hours after the last injection, half of each treatment group were injected with the monoamine oxidase inhibitor, pargyline (75 mg/kg) to assess the rates of 5HT and NE accumulation. Monoamine levels in discrete brain nuclei were measured by HPLC. Following tianeptine treatment, NE levels in frontal cortex (FCTX) were decreased by 44% compared to control, while NE turnover was increased, suggesting enhanced synaptic release of NE; tianeptine also increased 5HT turnover in FCTX by 83%. Fluoxetine, on the other hand, had no effects on 5HT or NE turnover in this region. However, in median raphe, fluoxetine increased both 5HT and NE turnover, while tianeptine also tended to increase NE turnover in this area. Finally, fluoxetine increased 5HT levels by 71% in dorsal raphe, with tianeptine having no effect. These data suggest that the therapeutic effects of the two drugs may be mediated by alterations of both 5HT and NE neurotransmission. [Supported by GM07524-18 (CRM) and PSC-CUNY 666244 (VNL)]

## 386.3

CHRONIC CITALOPRAM AND FLUOXETINE TREATMENTS UP-REGULATE 5-HT<sub>2C</sub> RECEPTORS IN THE RAT CHOROID PLEXUS. A. Laakso, E.-P. Pälviämäki, M. Kuoppamäki, M. Koulu\*, E.K.G. Svrälähti and J. Hietala. Dept. of Pharmacology, Univ. of Turku, Turku, Finland.

The effects of chronic (for 14 days) citalopram and fluoxetine treatments with three doses (2.5, 10 and 20 mg/kg) and withdrawal times (24 hours, 68 hours and 14 days) on 5-HT<sub>2C</sub> (formerly 5-HT<sub>2C</sub>) receptors in the rat brain choroid plexus were studied with quantitative receptor autoradiography in two separate experiments. Chronic citalopram treatment caused a consistent and dose-related increase in the density of 5-HT<sub>2C</sub> receptors (up to 90 %). This effect was slightly more pronounced when measured with an antagonist ligand ([<sup>3</sup>H]mesulergine) compared to measurements with an agonist ligand ([<sup>125</sup>I]DOI). The up-regulation was most evident 24 hours after the last dose and disappeared thereafter rather rapidly. Chronic fluoxetine treatment also increased the density of 5-HT<sub>2C</sub> receptors 24 hours from the last dose, but the increase was accompanied by a reduced affinity and was less marked than that observed with citalopram. The changes in receptor characteristics were not observed consistently after the 68 hour withdrawal from fluoxetine. Furthermore, the up-regulation of fluoxetine appeared not to be dose-related, nor reflected by an increase in agonist binding. In conclusion, the results show that chronic citalopram and fluoxetine treatments induce an up-regulation of choroid plexus 5-HT<sub>2C</sub> receptors, but the effect is more marked with citalopram. The data also suggest that 5-HT<sub>2C</sub> receptors are significantly occupied during chronic fluoxetine treatment (by fluoxetine or more likely by an active metabolite, norfluoxetine), proposing that the actions of chronic fluoxetine treatment may not reside only in serotonin uptake inhibition. This direct interaction by fluoxetine may trigger additional regulatory mechanisms of the 5-HT<sub>2C</sub> receptor leading to pharmacodynamic differences between chronic citalopram and fluoxetine treatments.

## 386.5

REGULATION OF BDNF AND trkB IN RAT BRAIN BY CHRONIC ANTIDEPRESSANT TREATMENTS. M. Nibuya\*, S. Morinobu, and R.S. Duman. Lab. of Molecular Psychiatry, Dept. of Psychiatry and Pharmacology, Yale Univ. Sch. Med., New Haven, CT.

Recent studies demonstrate that chronic antidepressant treatments (ADTs) activate the cAMP signal transduction system. This includes increased expression of CREB (cAMP response element binding protein), suggesting that ADTs regulate specific target genes (see Duman et al., this volume). One potential gene target is brain derived neurotrophic factor (BDNF), a possibility supported by the finding that CREB antisense oligonucleotides block the induction of BDNF in hippocampus (see Duman et al., this volume). Previously we reported that chronic electroconvulsive seizures (ECS) enhance the induction and prolong the expression of BDNF and its receptor, trkB. We now report that chronic (21 d), but not acute (1 d), administration of antidepressant drugs, including tranylcypromine, sertraline, fluoxetine, desipramine, or mianserin, also significantly increase the expression of BDNF and trkB mRNA in hippocampus by 30-75%. In contrast, chronic administration of nonantidepressant drugs, including morphine, cocaine, or haloperidol, did not increase levels of BDNF and trkB in this brain region. Chronic (21d), but not acute (1d), pretreatment of rats with antidepressants (i.e., ECS, tranylcypromine, sertraline, or desipramine) also completely blocked restraint stress-induced down-regulation of BDNF in hippocampus. The results indicate that expression of BDNF is a common gene target of different types of ADTs. Regulation of BDNF may lead to neuronal plasticity and thereby increase the survival and function of neurons, a hypothesis that is currently under investigation (see Vaidya et al., this volume).

## 386.2

# FLUOXETINE IMPAIRS ACQUISITION OF AN AVOIDANCE RESPONSE IN RATS

Christina J. Nelson and Wesley P. Jordan\*

Psychology, St. Mary's Col. of Md., St. Mary's City, MD 20686

Selective-serotonin reuptake inhibitors such as fluoxetine (Prozac) have become one of the most common treatments for clinical depression. While investigating the effects of fluoxetine within a learned-helplessness paradigm, control animals not made helpless but receiving fluoxetine (10mg/kg daily) were unable to learn to shuttle over and back across a low barrier to escape footshock. Of ten animals, only one successfully escaped on more than 33% of the trials during 3 days of training (mean=13%, median=1%). A majority of the vehicle animals always escaped the shock within 30s (mean=66%, median=100%).

Although a few studies have noted impairments in avoidance learning following fluoxetine administration, none have systematically investigated the extent of the debilitating effects. Subsequent tests in the present study appear to rule out changes in sensory threshold or motor dysfunction as causes for the impairment in the avoidance task. Latency to lick a hindpaw when placed on a 45°C hotplate was unaffected by daily injections of either 5 or 10mg/kg fluoxetine. Tests of jump thresholds to footshock are underway. Open field behaviors also were unaffected by an acute dose of fluoxetine (10mg/kg).

If peripheral effects do not account for fluoxetine's impairment in the avoidance task, central motivational or learning mechanisms may be affected adversely by doses of fluoxetine used in clinical applications.

## 386.4

A-80426, A POTENT AND SELECTIVE  $\alpha_2$ -ADRENOCEPTOR ANTAGONIST WITH SEROTONIN UPTAKE BLOCKING ACTIVITY AND PUTATIVE ANTIDEPRESSANT-LIKE EFFECTS. W.J. Giardina\*, S.A. Buckner\*, M.E. Brune\*, A.A. Hancock\*, C.T. Wismer\*, J. Milicic\*, A.J. Rattin\*, S. Roux\*, J.G. Wettstein\*, M.D. Meyer\*, R.D. Porsolt\*, J.F. Kerwin, Jr.\* and M. Williams\*. Neuroscience Discovery, Abbott Laboratories, Abbott Park, IL 60064 and \*ITEM-Labo, 93 ave de Fontainebleau, 94276 Le Kremlin-Bicetre Cedex, France.

A-80426 [N-[2-(benzofuran-6-yl)ethyl]-N-(R)-(+)-5-methoxy-1,2,3,4-tetrahydro naphthalen-1-yl methyl]-N-methylamine) is a selective inhibitor of serotonin synaptosomal uptake and an antagonist of [<sup>3</sup>H]-paroxetine binding to serotonin uptake sites and [<sup>3</sup>H]-rauwolscine binding to  $\alpha_2$ -adrenoceptors (Hancock et al. FASEB, 1995, 9:A408). A-80426 was evaluated *in vivo* for its ability to block serotonin uptake and  $\alpha_2$ -adrenoceptors; its antidepressant potential was also assessed. In rats, A-80426 significantly reduced p-chloroamphetamine-induced hyperactivity, a measure of *in vivo* blockade of serotonin uptake, after acute (ED<sub>50</sub>=13  $\mu$ moles/kg, po) and chronic (14 day) (ED<sub>50</sub>= 4.1  $\mu$ moles/kg, po) dosing. At doses of 6.7 and 22  $\mu$ moles/kg, po, A-80426 was effective in this test procedure for at least 12 hours. Doses of 6.7 to 224  $\mu$ moles/kg, ip, of A-80426 failed to block hypothermia and hypoactivity produced by the  $\alpha_2$ -adrenoceptor agonist, clonidine, and doses of 100 and 300  $\mu$ moles/kg, po, were required to block clonidine-induced mydriasis. A-80426 reversed the step-down passive avoidance deficit in olfactory bulbectomized rats (ED<sub>50</sub>= 7.1  $\mu$ moles/kg, po), a finding suggesting that the compound has antidepressant potential. It was, however, inactive in the tail suspension and forced swim behavioral despair models of antidepressant activity in mice at doses up to 72  $\mu$ moles/kg, ip. Despite its favorable *in vitro* profile, A-80426 is not an effective  $\alpha_2$  blocker *in vivo* and is inactive in classical animals models of depression. It is unlikely that A-80426 would have antidepressant activity equivalent to other serotonin uptake inhibitors.

## 386.6

CHRONIC ELECTROCONVULSIVE SEIZURE ALTERS CYTOSKELETAL PROTEINS (NEUROFILAMENTS, NF-200, NF-160 AND NF-68) IN THE RAT HIPPOCAMPUS. V.A. Vaidya\*, S.M. Strittmatter and R.S. Duman. Neuroscience Program, Lab of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508

Previous work has shown that chronic electroconvulsive seizure (ECS) and antidepressant drug treatments lead to an increase in BDNF and trkB within the hippocampus (Nibuya et al., this volume). Since BDNF is reported to promote the growth, differentiation and function of hippocampal neurons, these findings suggest that ECS and antidepressant drugs, via regulation of BDNF, may influence neuronal growth and structure in the hippocampus. Following administration of ECS for 10 days we observed decreases in neurofilament immunoreactivity by western blotting. These decreases, ranging from 20-50%, were observed for all three forms of neurofilaments, NF-200 (NF-H), NF-160 (NF-M) and NF-68 (NF-L). There were no alterations in levels of glial fibrillary acidic protein (GFAP). In the peripheral nervous system it is known that neurofilament levels decrease and GAP-43 levels increase during nerve regeneration. In order to determine if similar changes are occurring in the CNS we are now characterizing effects on GAP-43 following chronic ECS. In addition, morphometric studies of single hippocampal neurons (i.e. CA3 pyramidal cells and dentate granule cells) are under way. Given the reports (Watanabe et al. Brain Res.1990;588:341-345; Uno et al. J.Neurosci 1989;9(5):1705-11) that chronic stress leads to the atrophy of CA3 pyramidal neurons, these results suggest that the action of ECS as well as antidepressant drugs might be related to their ability to influence neuronal morphology or to induce synaptic remodeling.

## 386.7

**CHRONIC ANTIDEPRESSANT TREATMENTS INCREASE THE FUNCTION AND EXPRESSION OF CREB.** R.S. Duman\* and M. Nibuya. Lab. of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. Sch. Med., New Haven, CT.

Recent studies demonstrate that chronic antidepressant treatments (ADTs) activate the cAMP signal transduction system, including increased levels of adenylyl cyclase and nuclear translocation of cAMP-dependent protein kinase (PKA). These findings raise the possibility that ADTs regulate CREB (cAMP response element binding protein). The function of CREB is regulated by PKA, as well as  $Ca^{2+}$ -activated protein kinases, and may be influenced by regulation of total CREB expression. The present study demonstrates that chronic administration of electroconvulsive seizures (ECS) for 10 d or tranylcypromine, sertraline, fluoxetine, or desipramine for 21 d significantly increased the expression of CREB mRNA in hippocampus. Chronic ECS also increased levels of CRE binding, determined by gel shift analysis, demonstrating a corresponding increase in levels of functional CREB. One potential gene target of CREB is brain derived neurotrophic factor (BDNF), which is increased by chronic ADTs (see Nibuya et al., this volume). To directly determine the role of CREB in regulation of BDNF, we employed an antisense (AS) oligonucleotide strategy. Local infusion of CREB AS, but not sense, oligonucleotides decreased basal and ECS-induction of BDNF mRNA in hippocampus. CREB AS did not influence c-jun expression, which is independent of CREB, and blockade of BDNF induction was reversible, demonstrating that there was no permanent cellular damage by AS treatment. The results demonstrate that CREB expression is increased by ADTs, and indicate that CREB mediates the regulation of target genes, such as BDNF, in response to chronic ADTs.

## 386.9

**SEROTONERGIC MECHANISMS INVOLVED IN THE EFFECTS OF FLUOXETINE IN THE RAT FORCED SWIMMING TEST (FST).**

M.J. Detke\*, L. Kirby and I. Lucki. Departments of Psychiatry, Pharmacology and Psychology, University of Pennsylvania, Philadelphia, PA 19104.

Fluoxetine has previously been shown to reduce immobility and increase swimming in the Porsolt behavioral despair test or FST using a time-sampling scoring technique (Detke, Rickels and Lucki; *Psychopharmacology*, in press). This behavior was used to examine serotonergic mechanisms involved in fluoxetine's antidepressant effects. Water depth was 30 cm, to prevent the rats from supporting themselves with tails or hind limbs. After a 15-min pretest, drugs were administered 24, 5, and 1 hr prior to the 5-min swim test.

Fluoxetine (20 mg/kg SC) reduced immobility and increased swimming in a dose-dependent manner. These effects were prevented by pretreatment with p-chlorophenylalanine (PCPA, 150 mg/kg, IP X2), which produced a 95% reduction of serotonin content in the frontal cortex. Fluoxetine's effects were also blocked by pindolol (2 mg/kg SC) and propranolol (5 mg/kg SC), but not WAY 100,478 (10 mg/kg SC), NAN 190 (1 mg/kg SC), ketanserin (3 mg/kg SC), or ondansetron (3 mg/kg SC). None of the antagonists had any effects on their own. Behavioral effects similar to fluoxetine's were produced by 8-OH-DPAT (0.125 - 0.5 mg/kg SC) and CGS 12066 (1 - 10 mg/kg SC), but not by bromo-dimethoxyamphetamine (DOB; 1 mg/kg SC) or phenyl bi-guanide (PBG; 30 mg/kg SC). Low doses of pindolol (0.06 - 2 mg/kg SC) did not enhance the effect of fluoxetine (20 mg/kg SC) in this animal model of depression.

These results confirm earlier findings showing that SSRIs produce antidepressant-like effects in the FST, and that these effects are behaviorally specific. The PCPA experiment demonstrates that serotonin is necessary for these effects. The other experiments suggest that the 5-HT<sub>1A</sub> and 5-HT<sub>1B</sub> receptors mediate the antidepressant-like effects. The preliminary findings with pindolol do not agree with the findings of Artigas et al. (1994) in depressed humans.

**BEHAVIORAL EFFECTS OF ANTIDEPRESSANT DRUGS IN RATS SELECTIVELY BRED FOR LOW ACTIVE RESPONDING IN THE SWIM TEST.** C.H.K. West\*, L.M. Lester and J.M. Weiss. Lab. of Behavioral Neuroscience & Neuroimmunology, Dept. Psychiatry, Emory Univ. Sch. Med., Atlanta, GA 30306.

To attempt to study aspects of reduced active responding seen in human clinical depression by constructing an animal (rodent) model, rats have been selectively bred for low activity in a swim test (SwLo); these animals now show little struggling and much floating in the swim tank. In parallel, animals showing high activity (much struggling, little floating) have also been selectively bred (SwHi). The effect of antidepressant (AD) treatment was tested on SwLo rats; drugs were also administered to SwHi rats for comparison. Groups of SwLo males were administered vehicle, 3 non-AD psychoactive compounds and 7 ADs (from several pharmacological classes) for 1, 12, or 26 days via osmotic pumps. In response to 5 of the 7 ADs [desipramine (DMI), imipramine, venlafaxine, phenelzine (PHE) and bupropion (BUP)], SwLo's showed a pattern of no significant change in struggling at 1 day but significant enhancement of struggling at 12 and 26 days of AD treatment, consistent with the clinical observation that therapeutic effectiveness of ADs appears only after prolonged treatment. Fluoxetine and amitriptyline failed to increase struggling in the SwLo's. The non-ADs produced either little effect on struggling (haloperidol, caffeine) or the largest effect at 1 day (amphetamine). ADs that increased struggling also decreased floating, but usually to a lesser degree. These two effects were not correlated as DMI produced the largest increase in struggling whereas PHE and BUP produced the largest decreases in floating. Unlike swim test behaviors, activity in the open field was not consistently affected by AD treatment. These results suggest that struggling behavior of SwLo rats is increased by prolonged, but not acute, treatment with most types of ADs and that other, perhaps less vigorous, behaviors (floating, open field activity) are affected by ADs in a manner less reflective of therapeutic potential.

**ANTIDEPRESSANT-INDUCED c-FOS IN CENTRAL AMYGDALA AND PARAVENTRICULAR NUCLEUS.** J. Demotes-Mainard, C. Henry, J. Arsaut, R.M. Bluthé\*, M. Bourgeois#, E. Amauld, INSERM U-394 and # Department of Psychiatry, Université de Bordeaux II, 33077 Bordeaux, France.

Tricyclic antidepressants are known to impair both serotonin (5-HT) and norepinephrine (NE) reuptake, but their exact neural and molecular targets remain poorly understood. Both 5-HT and NE systems are widely distributed within the brain, and the corresponding receptors exhibit a wide molecular diversity. Antidepressants act on both somatic and axonal transporters, interfering with pre- and post-synaptic actions of monoamines on their receptors. However 5-HT and NE receptors are coupled, through various transduction pathways, to transcription factors whose induction reflects the resultant action of a given drug on both 5-HT and NE systems. Therefore we investigated in mice, through *in situ* hybridization using a [<sup>35</sup>S]-labelled oligonucleotide probe, the induction of the transcription factor c-fos by the tricyclic antidepressant clomipramine. Forty-five minutes after a single injection of clomipramine (30mg/kg, i.p.), c-fos induction was prominent in two forebrain structures, namely the central nucleus of the amygdala and the paraventricular nucleus. There was no evidence for desensitization since a similar pattern of c-fos induction persisted after repeated injections of clomipramine (30mg/kg/day, i.p.) for 15 days. This observation emphasizes the role of central amygdala and paraventricular nucleus as targets of antidepressant actions on the limbic system and hypothalamo-pituitary-adrenal axis, respectively, and suggests that the delayed therapeutic effects of antidepressants may depend on drug-induced transcription and subsequent alterations of neuronal phenotype.

## 386.10

**LONG-TERM TREATMENT WITH MOCLOBEMIDE NORMALIZED THE BEHAVIOR OF COGNITIVELY IMPAIRED TRANSGENIC MICE WITH REDUCED GLUCOCORTICOID RECEPTOR FUNCTION.** A. Montkowski, N. Barden\*, J.M.H.M. Reul, R. Landgraf and F. Holsboer, Max Planck Institute of Psychiatry, Clinical Institute, Kraepelinstr. 2-10, D-80804 Munich, Germany and CHUL Research Centre, Québec, Canada.

Impaired cognitive function and enhanced activity of the hypothalamic-pituitary-adrenocortical system are among the cardinal symptoms of major depression in humans that resolve after successful antidepressant treatment. To test the hypothesis that reduced GR function could cause these clinical disturbances, we used a transgenic mouse model expressing antisense RNA complementary to glucocorticoid receptor (GR) mRNA. The transgenic mice have elevated plasma corticosterone concentrations in response to stress and show profound behavioral changes in a number of tests that are indicative of cognitive impairment. Both the behavioral deficits and the hormonal alterations disappeared after long-term treatment with moclobemide, a reversible inhibitor of monoamine oxidase type A that is used clinically as an antidepressant. Following moclobemide treatment, the behavior of transgenic mice no longer differed from that of normal mice in both the elevated plus maze, which is used as a test of anxiety in animals, and in the forced swim test. Furthermore, the deficient olfactory short-term memory of transgenic mice, as assessed in the social recognition paradigm, was significantly improved by moclobemide. The behavior of normal mice was not influenced by antidepressant treatment. These observations suggest that a transgenic mouse with GR dysfunction may be a useful model for investigation of drug effects on both cognitive and neuroendocrine aspects of depression.

## 386.12

**A COMPARISON OF THE EFFECT OF IMIPRAMINE ON ICSS OF VTA AND LATERAL HYPOTHALAMUS.** K. Sweet, S. Murray, and D. Neill\*. Dept. Psychology, Emory Univ., Atlanta, GA 30322.

Anhedonia, the loss of the appreciation of pleasure, is a notable component of severe depression in humans. We examined whether administration of the classical tricyclic antidepressant imipramine would enhance the reward value of electrical self-stimulation of the ventral tegmental area and lateral hypothalamus. Sprague-Dawley rats bearing electrodes in one of these sites were trained on autotitration self-stimulation. In our version of this procedure, the intensity of the 100 pps, 0.5 msec biphasic stimulation dropped 3  $\mu$ A every 5th lever press. A single response on a separate lever reset the intensity to an individually-determined maximum. We found that daily treatment with 10 mg/kg imipramine HCl, I.P., 20 hr before testing, produced resetting at lower intensities in both LH and VTA groups. For the LH group, this enhanced reward was very small (3  $\mu$ A), and slowly developed over 7-10 days. For the VTA group, the enhanced reward was larger (8 - 10  $\mu$ A) and developed within 2 days. We interpret these results as indicating differential effects of the drug on non-dopaminergic hypothalamic and dopaminergic mesolimbic reward systems.

## 386.13

CHRONIC FLUOXETINE TREATMENT ALTERS 5-HT<sub>1A</sub> MEDIATED RESPONSE IN AREA CA1, BUT NOT AREA CA3, OF HIPPOCAMPAL SLICES. S.G. Beck, K. Choi, S. Birnstiel, W. A. Pouliot, J. Crayton\*, Departments of Pharmacology and Psychiatry, Loyola University Medical Center, and Hines VA Biological Psychiatry, Maywood, IL 60153.

The 5-HT neurotransmitter system and the raphe-hippocampal pathway are implicated in regulating complex emotional responses such as depression. The raphe-hippocampal 5-HT system is a likely target for psychoactive drugs used to treat such disease states. To obtain information on the discriminant action of antidepressant drugs, 5-HT receptor-elicited responses were recorded by intracellular recording techniques in areas CA1 and CA3 of the hippocampus. SD rats were treated with vehicle or the anti-depressant fluoxetine in 50% DMSO by mini-pumps at an average dose of 6.8 mg/kg for three weeks. Rats were decapitated, trunk blood collected for plasma fluoxetine and norfluoxetine determinations, and brain slices prepared for electrophysiological recording. The EC<sub>50</sub> for the 5-HT<sub>1A</sub>-mediated hyperpolarization was shifted to the left, i.e., more potent, in cells from fluoxetine treated rats. In CA3 there were no significant differences in the Emax, EC<sub>50</sub> or slope of the 5-HT<sub>1A</sub> concentration-response curves between cells from sham and fluoxetine treated rats. There was no change in the 5-HT<sub>4</sub>-mediated inhibition of the slow afterhyperpolarization elicited by a train of action potentials in area CA1 between cells from sham and fluoxetine treated rats. These results support our hypothesis that antidepressant treatment can have discriminant actions on different 5-HT receptor subtype-mediated responses (i.e., 5-HT<sub>1A</sub> versus 5-HT<sub>4</sub>) and on a particular 5-HT receptor evoked response (i.e., 5-HT<sub>1A</sub> between CA1 and CA3). This differential action may be important for understanding the clinical efficacy of antidepressant drugs. Supported by PHS NS28512 and MH 00880 to SGB.

## 386.15

PHARMACOLOGICAL DIFFERENTIATION OF SELECTIVE SEROTONIN REUPTAKE INHIBITORS (SSRIs) BY RECEPTOR PROFILING. J. Lancaster, T. Hartman, S. Faraci<sup>1</sup>, P. Sweetnam<sup>1</sup> and J. Ferkany\*. NovaScreen, A Division of Oceanic Biosciences Corp., Hanover, MD 21076 and <sup>1</sup>Dept. of Explor. Lead Discovery, Pfizer Central Research, Groton CT 06340.

The antidepressants fluoxetine, paroxetine, and sertraline elicit their therapeutic action by the inhibition of serotonin reuptake, K<sub>i</sub>'s = 1 nM, within synapses. SSRI's provide a therapeutic benefit with a low incidence of side effects although a comprehensive receptor selectivity profile for each of these compounds has not been reported. Such a profile will be valuable as these drugs are further evaluated for their utility in the treatment of obsessive compulsive disorder and premenstrual syndrome. All three structurally distinct compounds were tested in over 70 different receptor binding assays to assess receptor selectivity. A comparison and contrasting of these profiles is reported here. Briefly, the data show all three to be highly selective reuptake inhibitors. However, each appears to interact with other receptors types, IC<sub>50</sub> values ≤ 1 μM. The rank order potency for sertraline at these ancillary receptors is [3H]IDTG(sigma), [3H]WIN35,428 (dopamine), and [3H]GR65630(5HT<sub>3</sub>); for paroxetine [3H]pirenzepine(M1), [3H]WIN35,428(dopamine), [3H]AF-DX384(M2), [3H]IDTG(sigma), [3H]GR65630(5HT<sub>3</sub>), and [3H]batrachotoxin (sodium site 2); and for fluoxetine [3H]IDTG(sigma), [3H]ketanserin(5HT<sub>2</sub>), and [3H]pirenzepine(M1). The minor differences in selectivity profiling can be used to develop an even more selective second generation SSRI's.

## 386.17

FLUOXETINE INCREASES PLASMA LEVELS OF ALLOPREGNANOLONE IN DEPRESSED PATIENTS. A. Pasini\*, G. Spalletta, F. Di Michele, C. Furnari, P. Fucci, N. Ciani, and E. Romeo\*, Dept. San. Pubblica and "Dept. Med. Sperimentale, "Tor Vergata" Univ., Roma, Italy 00133. Acute fluoxetine treatment was reported to increase allopregnanolone (ALLO) content in rat brain (D.Uzonov et al. Neuroscience Abst. 1995). Here we examined in DSM-IV depressed patients, whether the treatment with fluoxetine (20mg/day) may alter the synthesis of neurosteroids. The plasma levels of progesterone (PROG), 3α and 3β isomers of ALLO (3α-ALLO, 3β-ALLO), pregnenolone (PREGN), 5α-dehydroprogesterone (DHP), were measured by gas chromatography-mass spectrometry. After a wash-out period of 7 days, blood samples were taken on days 0, 10, 20, 30, 40, 50, 60 of fluoxetine administration. On the same days patients were administered auto and hetero evaluation psychometric tests to measure depression, anxiety and aggressiveness. On day 0 the plasma levels of 3α-ALLO (250-300pg/ml) were below the control values (800-1000pg/ml), while the 3β-ALLO levels (300-400pg/ml) were increased compared to control values (10-50pg/ml). After fluoxetine administration, 3α-ALLO levels showed a progressive increase until day 30 after which they stabilized at control values. Conversely 3β-ALLO levels normalized progressively between day 20 and 30. The content of PROG and PREGN was not altered by fluoxetine, while the levels of DHP, the immediate precursor of ALLO, slightly decreased until day 30. A highly significant negative (3α-ALLO) and positive (3β-ALLO) correlation existed between ALLO and symptoms of anxiety and depression. These data support the hypothesis that fluoxetine may selectively provide a fine control in the production of 3α and 3β ALLO through DHP. Since 3α-ALLO is a potent positive modulator of GABA<sub>A</sub> receptors, our working hypothesis is that the antidepressant, antidiaphoric action of fluoxetine could be in part mediated by GABA<sub>A</sub> receptors active neurosteroids.

## 386.14

NEONATAL CLOMIPRAMINE (CLI) DECREASES ACOUSTIC STARTLE IN ADULT RATS. J.L. Stafford-Segert\*, S. Dickerson, & J. Inghram, Dept. of Psychology, Univ. of Missouri, Columbia, MO 65211

Neonatal exposure to CLI has been shown to produce behavioral symptoms in adult rats which mimic those of human endogenous depression: e.g. altered activity levels, sleep patterns, and pleasure-seeking behavior (Vogel, et al., 1990). We examined the effect of neonatal CLI on the acoustic startle response in adult rats. Male Sprague-Dawley rats were injected with CLI (15mg/kg, s.c.) twice daily for 14 days, beginning at post-natal day 8; control rats received equivalent vehicle injections. Whole body startle was tested at age 3 months. All rats were first tested in 30 min sessions consisting of 90 presentations of a 115-dB, 90 ms white noise stimulus on a 20 sec ISI. Next, rats were tested following administration of the serotonin agonist drug 5-methoxy-N,N-dimethyltryptamine (5-MeODMT; 2mg/kg, i.p.), which has been previously shown to increase acoustic startle. Preliminary data indicate that the CLI-treated rats show a smaller baseline startle response compared to controls. 5-MeODMT increased startle in the control rats, but not in the CLI-treated rats. These data suggest that neonatal CLI exposure may produce alterations in adult serotonin neurotransmission, supporting the validity of this as an animal model of depression.

## 386.16

RANDOMIZED CONTROLLED TRIAL OF PINDOLOL IN TREATMENT NAIVE AND TREATMENT REFRACTORY DEPRESSION. R.M. Berman, A.M. Darnell, H.L. Miller, A. Anand, D.S. Charney\*, Affective Disorders Program, West Haven VA Medical Center, West Haven, CT 06516

We now report our preliminary findings from two double-blind, placebo-controlled trials examining the use of pindolol, a serotonin<sub>1A</sub> antagonist, in treatment naive (Study A) and treatment refractory (Study B) depressed patients. In Study A, treatment naive patients are concurrently started on fluoxetine and either active pindolol (2.5 mg po tid) or placebo. In Study B, fluoxetine-refractory patients are maintained on fluoxetine with the addition of either active pindolol (2.5 mg po tid) or placebo; after 3 weeks, the placebo group is placed on active pindolol.

To date of this writing, 33 patients have finished Study A, all but 2 completing at least two weeks on protocol: After two weeks of medication, 3 of 15 patients on active pindolol demonstrated ≥50% decreases in Hamilton Depression Rating Scores (HDRS). At the same time point, 3 of 18 patients on placebo demonstrated ≥50% decrease in HDRS. Response (defined by ≥50% HDRS reduction and HDRS ≤15) rates in patients completing at least 4 weeks of medication were comparable in groups receiving active versus placebo pindolol (8 of 11 vs. 8 of 12, respectively). Six patients have completed study B: HDRS decreases of ≥50% were noted in 2 patients after 3 weeks on pindolol and another patient after 6 weeks on pindolol. A fourth patient demonstrated a robust response after 3 weeks on pindolol with a HDRS decrease from 28 to 15. None of 2 patients randomized to a placebo period responded by three weeks on placebo. Small sample sizes in these ongoing studies limit statistically valid conclusions; however, analyses with more subjects will be presented.

## 386.18

5-HT<sub>1A</sub> AUTORECEPTOR ANTAGONISTS RESTORE SEROTONERGIC NEURONAL ACTIVITY AFTER ACUTE FLUOXETINE TREATMENT IN BEHAVIOR CATS. C. A. Fornal\*, C. W. Metzler, F. J. Martin and B. L. Jacobs, Prog. in Neuroscience, Princeton University, Princeton, NJ 08544.

The lack of clinical antidepressant efficacy of selective serotonin reuptake inhibitors (SSRIs) after acute treatment may be due to a reduction in the activity of central serotonergic neurons resulting from the indirect activation of somatodendritic 5-HT<sub>1A</sub> autoreceptors. It has been hypothesized that the co-administration of a 5-HT<sub>1A</sub> autoreceptor antagonist with an SSRI might lead to a more rapid or more effective antidepressant response by attenuating the feedback action of serotonin at the 5-HT<sub>1A</sub> autoreceptor. The present study examined the effects of two selective 5-HT<sub>1A</sub> receptor antagonists (WAY-100635 and (S)-WAY-100135) on the activity of serotonergic neurons after acute treatment with the SSRI fluoxetine. Serotonergic neurons in the dorsal raphe nucleus were recorded and identified using methods previously described (Fornal et al., JPET 270: 1345-1358, 1994). Administration of fluoxetine (5 mg/kg, i.v.) decreased neuronal activity to approximately 5% of baseline values. Administration of WAY-100635 (0.1 mg/kg, i.v.) rapidly reversed this suppression, and increased neuronal activity above pre-fluoxetine baseline levels. Unit activity gradually returned to fluoxetine pretreatment levels within 2 hr after WAY-100635 administration. Subsequent injections of the same dose of WAY-100635 produced similar effects. (S)-WAY-100135 (0.5 mg/kg, i.v.) also reversed the effect of fluoxetine on neuronal activity, but was less effective and had a shorter duration of action (~30 min) than WAY-100635. These results indicate that (S)-WAY-100135 and in particular WAY-100635 block the action of endogenous serotonin at 5-HT<sub>1A</sub> autoreceptors and increase the firing rate of serotonergic neurons during sustained reuptake inhibition. Supported by grants from NIMH, AFOSR, and Miles Laboratories.
