To examine dopamine synthesis *in vitro*, FFK1THGC cells were cocultured with fibroblasts engineered to produce aromatic L-amino acid decarboxylase (FFK1AADC). Cocultured cells were incubated with media containing 0.01% of ascorbic acid for one hour. This media was analyzed for L-DOPA and dopamine (DA) by HPLC-ED. FFK1AADC and FFK1THGC cells cocultured with unmodified fibroblasts served as controls. FFK1THGC cells produced high levels of L-DOPA. When FFK1THGC cells were cocultured with FFK1AADC cells, there was a reduction in L-DOPA and dopamine was detected in the media.

These FFK1THGC cells were grafted into the striatum of rats depleted of DA by 6-OHDA. Immunostaining for TH in FFK1THGC cells was more robust compared to FFK1TH grafts, suggesting that BH4 may have another role in addition to acting as a necessary cofactor for its enzymatic activity. Further *in vivo* studies examining biochemical and behavioral effects of these cells are in progress.

THE EFFECTS OF A PEDICLED OMENTAL GRAFT TO THE BRAIN OF RATS WITH NIGROSTRIATAL LESIONS. N.S. Norton*, M. Brown, A.-A. Patil, A.J. Griess, B. Zumpano, and J.F. Rodriguez-Sierra. Dep't. of Cell Biology & Anat. and Div. of Neurosurg., Univ. of Neb. Med. Center, Omaha, NE 68198.

Parkinson's Disease is a debilitating illness characterized by degeneration of the dopaminergic neurons in the nigrostriatal system. The greater omentum possesses an abundant supply of dopamine and is capable of developing cortical vascular connections when transposed to the brain. We investigated the potential benefits of transplanting a pedicled graft of the greater omentum to the brain as a potential therapy in a Parkinson's animal model (PAM) since the omentum might increase the supply of dopamine to the corpus striatum and retard progression of the motor deficits. Sprague-Dawley male rats (60 days of age) were divided into four groups: 1) a control group, 2) a sham group, 3) a PAM Oil group, and 4) a PAM omental group. PAMs were produced by intracranial administration of 6-hydroxydopamine (6-OHDA). Apomorphine induced rotational studies were conducted weekly to monitor the progression of the motor deficit. Following two weeks of behavioral testing, the PAM Oil group received laparotomy followed by craniotomy over the area of the temporal lobe followed by closure of the wounds. The PAM omental animals received laparotomy and an omental flap with intact vascular pedicle, was brought to the interscapular area. Approximately one week after this surgical procedure, the proximal end of the pedicle was brought under the subcutaneous tissue and transposed to the surface of the cortical area at the level of the parietal-temporal lobe juncture. Apomorphine induced rotational studies were continued an additional three weeks. The results showed that the number of rotations was significantly less ($p<0.001$) in the PAM omental group when compared to the PAM Oil group. The results suggest that pedicled omental graft might be effective in ameliorating the progression of a PAM.

HOW FUNCTIONAL NEUROSURGICAL PROCEDURES WORK IN PARKINSON'S DISEASE: A THEORETICAL EXPLANATION. K. V. Baev*, K. A. Greene, A. G. Shetter, A. N. Lieberman. Barrow Neurological Institute, Phoenix, Arizona 85013.

In a previous publication (Baev K.V., Neurol. Res. 1994, v.17, 38-48) it was suggested that the skeletomotor basal ganglia-thalamocortical loop(s) can be considered as a functional system that models the behavior of the body and the environment during movement control. This predictory mechanism has to be tuned on the controlled object in order to function properly, *i.e.*, it has to be a learning system. The parameters of this system are tuned on the object behavior using an error signal that comes from the substantia nigra pars compacta. Minimization of the error signal is the final stage of learning process.

Therefore, Parkinson's disease (PD) has to be considered to result from degeneration of the error distribution system. Based on this theory, we make the conclusion that functional neurosurgical procedures such as pallidotomy or thalamotomy trick the controlling system in such a way that it does not recognize an error in its prediction anymore. Lesions placed in the pallidum or its projections to the thalamus make predictive signals less important so that real afferent flow from the controlled object prevails. After placement of a lesion in nonpallidal thalamic projections, the system primarily chooses predictive model afferent flow to determine the current state of the object. Therefore, these surgical procedures have to be considered symptomatic treatments: There is no real improvement of system function, only alleviation of the symptoms of PD. Chronic stimulation of basal ganglia circuitry through implanted electrodes has to be considered as adding noise to the system in addition to a functional block that it places at the stimulation site. Noise helps the system to slide down along an error surface to its global minimum when the model correctly describes the object behavior. Other methods of treatment of PD such as transplantation will be also discussed.

POSTEROVENTRAL PALIDOTOMY INDUCES MOTOR IMPROVEMENT AND DYSKINESIA IN MPTP-MONKEYS. M.R. Luquin*, J. Guillén, L. del Rio, J. Domínguez and C. Dávila. Department of Neurology, Clínica Universitaria de Navarra, Medical School, University of Navarra, Pamplona, Spain.

We have studied the effect of the lesion of the globus pallidus medialis (GPM) in 3 monkeys rendered parkinsonian by intravenous administration of MPTP. Monkeys were allowed to recover from the last MPTP injection up to 6 months and they did not receive any dopaminergic agents. Fine motor tasks were performed in all animals before MPTP administration and inmediately before surgery, when the degree of parkinsonism was considered stable. Unilateral posteroventral palidotomy was performed in 2 monkeys while in the other animal, the lesion was made in both GPM. The lesion of the GPM was made by injecting 1-2 µl of 50 nM kainic acid using a modified David Koff stereotaxic frame. Unilateral lesion of the GPM induced a contralateral amelioration of parkinsonism with a parallel improvement of fine motor tasks, but mild contralateral chorea was also observed, which persisted up to 3 months. Bilateral lesion of GPM induced severe generalized dyskinesia with improvement of parkinsonism. Post-mortem analysis showed the lesion was confined to the posterior part of the GPM, but a cell depletion was also observed in the dorsolateral part of the subthalamic nucleus homolateral to the lesion.

THE MECHANISM OF ACTION OF PALLIDOTOMY IN PARKINSON'S DISEASE (PD): CLINCAL AND PHARMACOLOGICAL RESPONSE. G. Linazasoro, J.A. Obeso, A. Gorospe, E. Ramos, R. Bakay, M. DeLong, J. Vitek*, Cliníca Quirón, San Sebastian (Spain) and Emory University Hospital, Atlanta, GA 30322

Six patients with PD were evaluated before and 3-6 months after microelectrode guided unilateral pallidotomy. Rigidity and akinesia were measured individually for each body segment, and arm and leg timed tapping tests were scored at baseline and after 24-72 hours without drugs. Pharmacological tests assessed the duration of the motor response (ON) to Sinemet (250/25 mg) and subcutaneous apomorphine (2,4,6,8 mg) and the severity and type of dyskinesias. Pallidotomy induced a marked reduction in akinesia and rigidity mainly contralateral to the lesion. The duration of the response to Sinemet was significantly prolonged and dyskinesias disappeared completely. Some body segments, i.e. shoulder, showed a permanent improvement after 24-72 hours without medication. Pallidotomy shifts the pharmacological response towards characteristics compatible with milder severity of parkinsonism. The response to dopaminergic drugs is not blocked by pallidotomy.

775.11

THE MECHANISM OF ACTION OF PALLIDOTOMY IN PARKINSON'S DISEASE (PD): PHYSIOLOGICAL AND IMAGING STUDIES. J.A. Obeso*, J.C. Rothwell, A. Ceballos-Bauman, N. Leenders, D. Brooks, P. Asselman, G. Linazasoro, J. Guridi, R. Bakay, J. Vitek, M. DeLong, Clínica Quirón, San Sebastian, Spain; MRC Motor and PET Units, London (UK), Paul Scherer Institute, Villingen (Switzerland), Emory University Hospital, Atlanta, GA

Six patients with PD were evaluated before and 3-6 months after microelectrode guided unilateral pallidotomy. Laboratory assessment included recording EEG premovement potential, magnetic cortical stimulation of the motor cortex, interonset latency (IOL) for performing sequential hand movements, simple and choice reaction time (RT), the long latency stretch reflex and the blink reflex. Positron Emission Tomography (PET) water scans (Oxygen-15) were taken while the subjects performed sequential hand movements. Following pallidotomy, all patients improved clinically but hand function remained unchanged in two. PET studies showed a significantly increased activation of the supplementary motor area (SMA), areas 6 and 4 and dorsolateral prefrontal cortex in 4 patients. The IOL for sequential hand movements was reduced by 44% and simple RT was decreased by 34%. There were no significant changes in the LLSR, blink reflex and motor cortex recovery curves and choice RT. Restoration of premotor and dorsolateral prefrontal cortex activity appears to be an important mechanism mediating the effect of pallidotomy in PD.

Characteristics Of 18F labelled ligands for Dopamine and dopamine Transport Function Using Positron Emission Tomography (PET). Bakay RAE*, Goodman MM, Boyer KL, Watts RW, Byrd L, Hoffman JM, Departments of Neurology and Neurosurgery, Emory University School of Medicine, Atlanta, GA 30322.

In order to develop and characterize Dopamine and Dopamine transport function in CNS transplantation by non-invasive techniques, a series of nonhuman primate studies were performed using PET. Fluorodopa is a standard for evaluating the dopaminergic system, but has a high signal-to-noise ratio. Dopamine transport complex is important in the regulation and synthesis of Dopamine, and is diminished in Parkinson's disease. Two distinct isotopes have been developed; fluoro-propyl-chloro-nortropane (FPCT) and fluoro-isopropyl-chloro-tropane (FIPCT). These compounds were synthesized to minimize nonspecific binding and achieve maximum specific activity. Nonhuman primate studies have been performed that characterize both blood and brain kinetic behavior of these isotopes. In combination with fluorodopa, it will be possible to completely characterize the uptake, binding, incorporation, release, and reuptake of Dopamine in vivo using PET. Data from normal, MPTP-lesioned, surgical controls and fetal mesencephalic grafted nonhuman primates will be presented. Supported by NS-24340 and R R-00165.

INCREASED DOPAMINE TURNOVER IN THE MPTP-INDUCED MODEL OF PARKINSONISM IN PRIMATES MEASURED BY PET WITH FLUORODOPA (FD). D.J. Doudet*, J.E. Holden, G. Chan, S. Morrison and T.J. Ruth. Div. Neurology, Dept. Medicine, Univ. British Columbia and UBC/Triumf PET, Vancouver, BC, Canada, V6T 2B5

The graphical analysis of PET data permits to estimate the striatal uptake rate constant (Ki) of FD. An extension of this graphical method made it possible to estimate the rate of loss of striatal signal (Kloss) during FD PET studies. Kloss is an index of the release, metabolism and outward diffusion of fluorodopamine and its metabolites. We examined the rate of loss of striatal signal in FD PET studies in normal and MPTP-treated rhesus monkeys to explore the hypothesis that dopamine (DA) metabolism is increased in parkinsonism.

Four unilaterally MPTP-treated rhesus monkeys and 4 age-matched controls were scanned in an ECAT 953B/31 tomograph for up to 4 hrs after injection of 5 mCi of FD. Metabolite analysis was performed using an alumina extraction method with anion/cation exchange columns. The extended graphical analysis was used to calcultate Kloss. Kloss was significantly ($p<0.05$) higher in the MPTP-treated striatum (0.00573 ± 0.002 min^{-1}) compared to the unlesioned striatum (0.00243 ± 0.00069 min^{-1}) and controls (0.00258 ± 0.00069 min^{-1}).

These results are in keeping with the hypothesis of compensatory increase in DA turnover in parkinsonism. Kloss as measured with FD PET may be used to explore DA presynaptic compensatory mechanisms.

[18F]6-FLUORO-L-M-TYROSINE: INITIAL STUDIES OF METABOLISM AND PHARMACOKINETICS. S. Jordan, J.L. Eberling*, H.F. VanBrocklin, J.P. O'Neil, K. Bankiewicz, W.J. Jagust. Center for Functional Imaging, Lawrence Berkeley Laboratory, University of California, Berkeley, CA 94720: Somatix Therapy Corp. Alameda, CA 94501.

[18F]6-fluoro-L-m-tyrosine (FMT) has many favorable characteristics as a Positron Emission Tomography (PET) tracer of dopaminergic function. During dynamic PET imaging with FMT in 3 rhesus monkeys we measured plasma FMT and its F18-labeled metabolites 6-fluoro-3-hydroxyphenylacetic acid (FPAC) and 6-fluoro-3-hydroxyphenylethylamine (FMA). In a separate study, 4 animals were injected with FMT and euthanized 60 and 120 mins later to determine its metabolism in brain. In both studies, samples were separated by HPLC and fractions containing labeled FMT, FPAC or FMA were counted for F18 activity. Elution times were calculated for external standards by HPLC with electrochemical detection which enabled fraction identity. These blood and brain data were used to construct a kinetic model for FMT. The major FMT metabolite in plasma was FPAC, which together with FMA accounted for over 20, 30, 40 and 50% of total plasma activity at 10, 30, 60 and 120 mins after FMT injection, respectively. FPAC was also the predominant metabolite in 60 and 120 minute post-mortem brain samples, representing over 80% total activity in both caudate and putamen. Less metabolism occurred in regions containing few dopamine terminals, such as frontal cortex (over 30% total activity was FMT), and cerebellum (over 40% total activity was labeled FMT). A three rate constant fit to a three compartmental model of FMT uptake, using the metabolite-corrected blood input function with the dynamic PET brain uptake data, revealed higher k3 values in both caudate (0.06±0.01) and putamen (0.05±0.003) than frontal cortex (0.002±0.001). Taken together these data support the use of this tracer in studying dopaminergic function in parkinsonian primates following neurografting and gene therapy.

775.15

PET [18F]6-fluoro-L-m-tyrosine Imaging of MPTP-lesioned Primates. W.J. Jagust*, J.L. Eberling, S. Jordan, H.F. VanBrocklin, J.P. O'Neil, M. Emborg, D. Rosenberg, K.S. Bankiewicz Center for Functional Imaging, Lawrence Berkeley Laboratory, University of California, Berkeley, CA 94720; Somatix Therapy Corporation, Alameda, CA 94501.

PET studies using the dopamine tracer, [18F]6-fluoro-L-dopa (F-dopa) have been used extensively to study Parkinson's disease. Interpretation of these studies has been limited because of the presence of methylated metabolites that readily enter the brain. Here we report the results of PET studies using the tracer [18F]6-fluoro-L-m-tyrosine (FMT) in 3 monkeys before and at weekly intervals after unilateral intracarotid artery (ICA) and i.v. MPTP administration. Animals were injected with approximately 10 mCi of FMT and were imaged for approximately 2 hours. Prior to MPTP administration, all animals showed preferential accumulation of the tracer bilaterally in the striatum and midbrain, but little accumulation in other brain regions. Following unilateral ICA MPTP administration (3 mg MPTP-HCl), we observed decreased signal in the striatum on the lesioned side and increased signal in the nigra/VTA complex. After i.v. MPTP administration (0.3 mg/kg) we observed a further reduction in signal in the striatum on the previously lesioned side, as well as a reduction on the contralateral side. Data were analyzed using a 3 compartment model with 3 rate constants to describe the time course of radioactivity in the striatum. Prior to MPTP administration the mean value for k3, describing FMT decarboxylation, was 0.06 (sd = 0.01) for the putamen. Following unilateral ICA MPTP administration, k3 for the putamen was 0.003 (sd = 0.001) for the lesioned side, and 0.04 (sd = 0.01) for the contralateral side. After i.v. MPTP administration there was a further decrease in k3 for the previously lesioned putamen (mean k3 = 0, sd = 0.0001), as well as a decrease on the contralateral side (mean k3 = 0.02, sd = 0.01). These values corresponded to the extent of progressive clinical deterioration. FMT produces robust estimates of dopaminergic function which are effective for tracking MPTP lesions and should be helpful in detecting grafts of genetically modified cells in this model.

ELEVATION OF TYROSINE HYDROXYLASE (TH) mRNA EXPRESSION AND FLUORO-META TYROSINE (FMT) SIGNAL MEASURED BY POSITRON EMISSION TOMOGRAPHY (PET) IN THE SUBSTANTIA NIGRA (S.N.) AFTER MPTP ADMINISTRATION IN MONKEYS. D. Nagy*, J. L. Eberling#, W. J. Jagust#, S. Jordan#, M.E.Emborg, W.W McLaughlin and K.S.Bankiewicz. Somatix Therapy Corporation, Alameda, CA 94501, #Lawrence Berkeley Laboratory, UC Berkeley, CA 94720.

Administration of 0.4 mg/kg of MPTP into one internal carotid artery (ICA) produces hemiparkinsonism (HPD) in monkeys (ms). In this study we examined TH mRNA expression in normal and 4 HPD+ ms, while 3 other ms. underwent PET scanning after FMT administration before and at weekly intervals after ICA and i.v. MPTP administration. The ms received an intracarotid infusion of 3 mg of MPTP-HCL supplemented with 0.3mg/kg i.v. to induce general parkinsonian signs in addition to HPD. These animals were able to sustain themselves without any L-DOPA administration. The in-situ hybridization (ISH) technique was applied for the detection of the TH mRNA content of the midbrain DA cells using ^{35}S labeled complementary RNA probes. Adjacent sections were stained for H&E and examined for TH-immunoreactivity (TH-IR). In the SN on the side ipsilateral to MPTP infusion very few TH-IR cells were present and contralateral SN appeared to be partially lesioned. TH mRNA expression was found higher in the SN on the partially lesioned side of the treated animals, than in the controls. In all monkeys examined with PET there was an increase of signal in SN at 7 days after ICA MPTP on treated side and at 7 days on the contralateral side after i.v. MPTP injection. High levels of the TH-mRNA expression in the partially lesioned SN cells of the MPTP-treated animals and increase of FMT signal at 7 days after MPTP administration suggests up-regulation of the remaining DA cells. These findings are consistent with increased HVA/DA ratio in striatum after MPTP administration, and indicate compensatory mechanism of the remaining and/or degenerating DA cells in SN.

[123I]ß-CIT SPECT MEASURES ARE HIGHLY REPRODUCIBLE IN PARKINSON'S PATIENTS AND HEALTHY CONTROLS.

J. Seibyl*, K. Marek, K. Sheff, P. Hoffer, R. Innis. Depts. of Diagnostic Radiology, Psychiatry, and Neurology, Yale Univ. School of Med., New Haven, CT 06520.

The monoamine transporter ligand, [123I]ß-CIT and SPECT demonstrate significant reduction of striatal uptake in Parkinson's disease (PD) patients compared with age and gender-matched controls. In order to assess the utility of SPECT for serial evaluation of disease progression in PD we performed test/retest reproducibility studies in 7 healthy subjects (HS) and 7 PD patients. **Methods:** Subjects underwent SPECT imaging at 18, 21, and 24 h post intravenous injection of 10 mCi (370 mBq) of [123I]ß-CIT. SPECT scans were repeated 7-21 days later. The ratio of specific striatal:nondisplaceable uptake (designated V_3") was obtained. Using this measure, the test/retest variability and reliability were calculated using standard statistical methods. **Results**: Both PD and HS groups demonstrated low test/retest variability for V_3" with mean measures of 12.4±4.7% and 6.8±6.8% for PD and HS groups, respectively. There were no significant differences in variability in HS and PD patient groups (p=0.28). Similarly, calculation of reliability (where 1=total reliability) showed no differences in PD and HS controls with measures of 0.99 and 0.96, respectively. These data suggest [123I]ß-CIT SPECT provides reproducible measures of DA transporters in PD patients and supports the feasibility of using the tracer for within-subject evaluation of disease progression.

775.18

A NOVEL SPECT IMAGING AGENT DETECTS TOTAL LOSS OF THE DOPAMINE TRANSPORTER IN PARKINSONIAN MONKEYS.

B.K. Madras*[1], L.M. Gracz[1], M.J. Kaufman[1], P.C. Meltzer[2], D. Elmaleh[3], A.J. Fischman[3] Harvard Medical School, Southborough, MA, 01772[1], Organix, Inc.[2], Woburn, MA, Massachusetts General Hospital[3], Boston, MA.

The dopamine transporter, localized on striatal neurons is an effective marker for Parkinson's disease. The present study highlights a novel SPECT (single photon emission computerized tomography) ligand, [123I]altropane™, that displays favorable characteristics for imaging the dopamine transporter. In human post-mortem striatum, [125I]altropane binds with high affinity (K_D: 4 nM) to the dopamine transporter and dopamine:serotonin transporter selectivity. In monkey striatum, SPECT imaging reveals selective accumulation of the ligand in striatum within 30 min and a striatum:cerebellum ratio > 10. Reversible binding is rapidly reduced by the dopamine transport inhibitor WIN 35,428. In MPTP-induced Parkinsonism, [125I]altropane binding is undetectable. These studies highlight [123I]altropane as a SPECT imaging agent for the dopamine transporter and its potential for diagnosing and monitoring dopamine neurons in Parkinson's disease and other disorders in which dopamine transporter/neurons densities are modified. NS30556, Boston Life Sci. Inc., DA06303, DA09642, MH14275, RR00168.

NEUROTOXICITY: HEAVY METALS

776.1

ALTERATIONS OF LONG-TERM POTENTIATION (LTP) AND PAIRED-PULSE POTENTIATION (PPP) IN VIVO RAT HIPPOCAMPAL DENTATE FOLLOWING DEVELOPMENTAL LEAD EXPOSURE

D.Y.Ruan*, C.Zhao, G.B.Bao, X.H.Tang, J.T.Chen, Y.N.Zhao and Y.Z.Xu

Dept. of Biology, Univ. Sci. Tech. China, P.R.China

Neonatal Wistar rats were exposed to lead from parturiution to weaning via the milk of dams drinking 0.2% lead acetate solution. The alterations in LTP and PPP of dentate gyrus in adult rats following developmental lead exposure were studied in vivo. Excitatory postsynaptic potentials (EPSPs) and population spikes (PSs) were recorded in the dentate in response to stimulation applied to the perforat path. The results showed that the LTP was induced in Pb-exposed rats with an average PS potentiation of 170±40.9%(n=11), which was significantly smaller than the increase in PS potentiations in control rats (325± 104%,n=13) (p<0.05) after tetanizing stimulation. The mean EPSPs amplitudes increased to 140.8±21.4% (n=11) for Pb-exposed rats and 174.4±7.0% (n=13) for the controls after tetanizing stimulation. The lead-induced alteration in LTP of PS potentiations was greater than that of EPSP potentiations. Paired-pulse potentiation (PPP) across a range of interpulse intervals is also depressed in Pb-exposed rats. Following pairs stimulation of perforant fiber at 250µA and an interpulse interval of 60ms, PPP for Pb-exposed rats was 157.0±42.0%(n=11) and for control rats was 213.0 ±54.0%(n= 13). Compared with controls, the mean PPP decreased 26.1% (p< 0.05). The results of this investigation demonstrated that the lead exposure in neonatal rats caused impairments in LTP and PPP of dentate gyrus. Supported by NNSFC (DYR)

776.2

ROLE OF APOPTOSIS IN DELAYED NEURONAL DEATH FOLLOWING A BRIEF EXPOSURE OF PRIMARY CULTURES OF CEREBELLAR GRANULE NEURONS TO ZINC.

E. Kharlamov, R.P. Mason* and H. Manev. ASRI, Medical College of Pennsylvania and Hahnemann University, Allegheny Campus, Pittsburgh, PA 15212.

In primary cultures of rat cerebellar granule neurons, a brief, 15 min exposure to zinc (300 µM and higher) resulted in delayed neuronal death. Cell death was assayed by measuring mitochondrial viability with the MTT assay and cell membrane integrity with the trypan blue exclusion assay. These assays did not reveal any toxicity immediately after exposing the cultures to zinc; they became positive 4 to 24 h after transient zinc treatment. The toxicity of zinc depended on maturity of neuronal cultures - it was not apparent prior to day 5, and it reached a plateau around 9-10 days *in vitro*. The latter two days in vitro were selected for further experiments. A co-treatment with zinc and calcium channel blockers (nimodipine and amlodipine) reduced the toxicity of zinc. The latter results suggest that zinc may have triggered calcium-dependent mechanisms of delayed neuronal death. One of such mechanisms is apoptotic (programmed) cell death. We assayed the cultures for the presence of DNA fragmentation (a marker of apoptosis) using the *in situ* TUNEL technique, and found an increase in the number of apoptosis-positive cells after zinc treatment. However, actinomycin D, an inhibitor of macromolecular synthesis, failed to prevent zinc toxicity. The results suggest that a calcium channel blocker-sensitive increase in endonuclease activity without a concomitant induction of protein synthesis may be operative in zinc neurotoxicity.

776.3

NEUROTRANSMITTER RELEASE IN PC 12 CELLS EXPOSED TO LEAD.

J.P. Bressler*, L. Olivi and G.W. Goldstein. Kennedy Krieger Research Institute and Division of Toxicology, Depts of Pediatrics and Neurology, Johns Hopkins University, Baltimore, MD 21205.

In children, exposure to low levels of lead (Pb) results in learning deficiencies. One hypothesis to explain this observation is that Pb impairs learning by disrupting mechanisms that control the release of neurotransmitters. The relationship between Pb and neurotransmitter release was examined by studying norepinephrine (NOR) release in PC 12 cells by using a method that takes advantage of the reuptake of [3H]NOR into vesicles. A 60 min incubation with 20 uM $(CH_3COO)_2Pb$, but not the chloride salts of Cd, Zn or Mn resulted in the release of NOR. The minimum concentration of Pb needed to provoke NOR release was 20 uM. However, if the cells were stimulated with inhibitors of microsomal Ca-ATPase or with activators of protein kinase C (PKC) the minimum concentration of Pb was reduced to 10 uM and 5 um, respectively. Neurotransmitter release was also accompanied with the release of two proteins found in secretory granules, secretogranin II and chromogranin B. A 200 uM concentration of Cd or Ni effectively blocked the release of NOR in PC 12 cells stimulated with an inhibitor of Ca-ATPase but was relatively ineffective in cells stimulated with a PKC activator. We conclude that PC 12 cells exposed to Pb release neurotransmitter. Furthermore, there appears to be at least two pathways that will heighten a cells's sensitivity to Pb, one that involves microsomal Ca-ATPase and another that uses PKC.

776.4

LOW LEVEL LEAD EXPOSURE DURING DEVELOPMENT: DOSE-DEPENDENT RUNWAY MAZE IMPAIRMENTS IN LABORATORY MICE TESTED IN EARLY ADULTHOOD.

P.W. Stewart*, R.G. Burright and P.J. Donovick. Environmental Neuropsychology Lab, SUNY Binghamton, Binghamton, NY. 13902

We investigated the effects of incremental doses of low-level Pb acetate or sodium acetate exposure during development on runway maze performance in Binghamton heterogeneous Stock (HET) mice. Mice were either untreated or received 0, 5, 10 or 25 mg/kg Pb acetate via intragastric intubation on postnatal days 6,9,12,15 & 18. No overt effects of Pb on physical development, including growth, were detected in any groups. When tested at 40-50 days of age, Pb-exposed mice exhibited a dose-dependent increase in the proportion of runway errors - with effects emerging at levels as low as 10 mg/kg. These data support growing evidence that even very low levels of Pb exposure during development may impair cognitive performance later in life.

776.5

LACK OF TOXICITY OF HUMAN NEUROMELANIN TO THE RAT BRAIN. P. L. McGeer[1], Y. Aimi[1] and T. Kawamata[2]*. 1: Kinsmen Lab. of Neurol. Res., University of British Columbia, Vancouver, B. C. Canada, V6T 1Z3. 2: Department of Neuropathology, Hyogo Institute for Aging Brain and Cognitive Disorders, Himeji, Japan, 670.

The prominence of neuromelanin in humans, and its accumulation extracellularly in Parkinson disease and other extrapyramidal disorders involving the substantia nigra, has led to speculation that neuromelanin might itself be neurotoxic. Iron is known to accumulate in the substantia nigra of Parkinsonian patients, and it has been shown that neuromelanin binds iron. Therefore, it has been even more specifically suggested that iron is neurotoxic when complexed with melanin. The proposed mechanism is oxidative stress, leading to neuronal death from toxic oxygen species. In order to test this hypothesis, as well as to learn the phagocytotic capability of microglia for neuromelanin, we extracted neuromelanin from the human substantia nigra of a normal and parkinsonian case. The extracted melanin was stereotaxically injected into the corpus striatum and substantia nigra of rats. Control injections were done with saline or brain extracts from non-pigmented brain regions. Rats were sacrificed by perfusion with aldehyde fixative at various periods after injection (3 days - 8 months). Brain sections were immunohistochemically stained with anti-tyrosine hydroxylase (TH) to reveal dopaminergic cells and processes, and OX 42 (anti C3b) to reveal microglia. Injected melanin remained even at 8 months following injection. Although some TH positive neurons were destroyed by trauma in the needle tract area in both control and melanin injected brains, TH positive neurons appeared to be completely unaffected by melanin at all time periods. There was no difference in results between normal and Parkinsonian melanin. Some melanin could be seen within a few OX42 positive microglia at all time periods, but most microglia seemed to ignore the melanin granules. The present results show that human neuromelanin is not toxic to rat substantia nigra or caudate-putamen neurons and it remains for long time periods in brain.

776.6

MANGANESE DECREASES GLUTAMATE UPTAKE IN CULTURED ASTROCYTES. A.S. Hazell* and M.D. Norenberg. Departments of Pathology and Biochemistry & Molecular Biology, University of Miami School of Medicine and VA Medical Center, Miami, FL 33101.

Manganese has recently been shown to accumulate in the basal ganglia in patients with chronic hepatic encephalopathy (HE). Ammonia and astrocytes have been strongly implicated in the pathogenesis of HE, and since we have recently shown that ammonia decreases glutamate uptake in cultured astrocytes, we examined whether manganese also affected glutamate uptake. Cultured astrocytes from newborn rats were treated with manganese (II) chloride (1-50 μM) in the absence or presence of ammonium chloride (5 mM), and glutamate uptake was determined using the non-metabolized glutamate analogue [^{3}H]-D-aspartate. Exposure times varied between 1 hr and 2 days. Treatment with manganese (50 μM) for 2 days resulted in a 11% decrease in transport of radiolabel into cells compared with controls (control 11.13 ± 2.37 vs. Mn^{++} 9.91 ± 2.66), while treatment with ammonia alone resulted in an 18% decreased uptake of [^{3}H]-D-aspartate after 48 hrs. In the presence of both manganese and ammonia, a further lowering of D-aspartate uptake was observed (34%). Preliminary data also suggested greater sensitivity of striatal cultures to the effects of manganese on glutamate transport. These results suggest that manganese alone has a detrimental action on glutamate transport into astrocytes which is additive to the ammonia effect, and may contribute to the pathogenesis of hepatic encephalopathy. INHIBITION OF NMDA RECEPTORS BY LEAD IS DEPENDENT ON THE RECEPTOR SUBUNIT COMPOSITION. I.A Omelchenko, C.S. Nelson, J.L. Marino and C.N. Allen* Cntr. for Res. on Occup. & Environ. Toxicol., Ore Hlth Sci Univ, Portland, OR 97201.

Pb^{2+} is a potent inhibitor of NMDA receptors and its action is dependent on the age of neuron. We tested the hypothesis that the vulnerability of NMDA receptors to Pb^{2+} blockade is dependent on the receptor subunit composition which changes during development. Concentration-response curves for NMDA and glutamate were generated in the presence and absence of Pb^{2+} using the two electrode voltage-clamp technique and NMDA receptors consisting of $\zeta 1\varepsilon 1$, $\zeta 1\varepsilon 2$ and $\zeta 1\varepsilon 1\varepsilon 2$ subunit combinations expressed in *Xenopus laevis* oocytes. For all three subunit compositions glutamate was a more potent agonist than NMDA. In oocytes expressing $\zeta 1\varepsilon 1$, $\zeta 1\varepsilon 2$ and $\zeta 1\varepsilon 1\varepsilon 2$ subunits Pb^{2+} inhibited glutamate-activated currents with IC_{50}s of 0.87 ± 0.25 μM; 1.21 ± 0.22 μM; 6.1 ± 0.55 μM and NMDA-activated currents with IC_{50}s of 1.37 ± 0.47 μM; 1.11 ± 0.33 μM; 6.64 ± 1.5 μM (mean $\pm$ S.E.). Pb^{2+} reduced the maximal current amplitude but did not significantly alter the EC_{50}s for glutamate or NMDA consistent with a noncompetitive block. The IC_{50}s for Pb^{2+} blockade of NMDA- or glutamate-activated currents were significantly larger for $\zeta 1\varepsilon 1\varepsilon 2$ subunits when compared to $\zeta 1\varepsilon 1$ or $\zeta 1\varepsilon 2$ combinations. These data suggest that brain regions with $\zeta 1\varepsilon 1$ or $\zeta 1\varepsilon 2$ NMDA receptors subunits would be more vulnerable to Pb^{2+} toxicity than those with $\zeta 1\varepsilon 1\varepsilon 2$ NMDA-receptors. ALTERATIONS IN N-METHYL-D-ASPARTATE (NMDA) RECEPTOR SUBUNIT mRNA AFTER LEAD TREATMENT IN NEONATAL RATS. M.A. Wilson*, J. Bressler, M.V. Johnston and G.W. Goldstein. Neuroscience Laboratory, Kennedy Krieger Research Institute and Dept. of Neurology, Johns Hopkins University, Baltimore, MD 21205

One of the primary sites of action of the environmental neurotoxin lead is at the NMDA receptor (Alkondon et al, '90); lead selectively inhibits NMDA currents, acting as a non-competitive antagonist of both NMDA and glycine (Guilarte & Miceli, '92, Uteshev et al., '93). We have examined the effects of neonatal lead exposure on NMDA receptor subunit expression in rat pups. Rat dams were administered 0.2% lead acetate in their drinking water, beginning on the day when their litters were delivered. Lead-treated and untreated control litters were culled to 8 pups at birth. Rat pups were decapitated on postnatal day 15, and *in situ* hybridization with oligonucleotide probes for NR1, NR2A and NR2B was used to evaluate NMDA receptor subunit expression in the hippocampus. Expression of NR2A mRNA was significantly reduced in the granule cell layer of the dentate hilus ($p<0.01$) and in the pyramidal layer of the CA1 region of the hippocampus ($p<0.05$). No significant changes in NR1 or NR2B expression were observed. The selective effect of lead on dentate granule cells is of special interest because these neurons have a mechanism for accumulation of the putative co-transmitter zinc that may serve to concentrate lead in this part of the hippocampus. Because NR2A expression normally increases in the forebrain between postnatal day 7 and 15, the reduced expression observed in lead treated rats may represent a developmental delay in maturation of excitatory amino acid receptors. BRAIN LIPID PEROXIDATION AND POLYDIPSIA DURING IRON OVERLOAD IN RAT. Carol A. Gunnett, James L. Hargrove, and Diane K. Hartle* Depts. of Pharmacology/Toxicology and Foods and Nutrition, The University of Georgia, Athens, GA 30602.

Brain membranes are composed of a high percentage of polyunsaturated fatty acids relative to most other tissues. The brain is therefore highly peroxidizable and at risk for oxidative free radical damage if local oxidative stress overcomes the brain's relatively moderate level of antioxidant defenses. The integrity of the blood-brain-barrier is essential to protect the brain continuously from oxidative stressors in the blood. Free iron catalyzes lipid peroxidation via Fenton reactions in vivo. Iron-catalyzed free radical formation initiates lipid peroxidation. The purpose of this study was to produce a short term oxidative stress on brain and peripheral organs using ferrous chloride (20 mg iron/kg, i.p.) and determine the extent of 1) lipid peroxidation and 2) glutathione levels in brain, liver, kidney and heart. Summary of results: Iron overload treatment caused rapid and profound polydipsia. The polydipsia was initiated within minutes of injection. Iron overload produces significant brain, liver, kidney and heart lipid peroxidation. Early time points had higher levels of lipid peroxidation relative to the 2 hr time period, presumably following rapid sequestration of free iron. Glutathione levels were not depleted in brain. EFFECTS OF *IN VIVO* CHRONIC LEAD EXPOSURE ON CA^{2+} CURRENTS IN BASAL FOREBRAIN NEURONS FROM ADULT RATS. C.A. Grover*, M.C. Jasek, W.H. Griffith, & G.D. Frye, Dept. of Medical Pharmacology & Toxicology, HSC, Texas A&M University, College Station, TX 77843-1114.

It is well known that *in vitro* acute lead treatment inhibits neuronal calcium currents. We studied the effects of chronic *in vivo* lead exposure on LVA and HVA calcium currents in basal forebrain neurons. Adult male Sprague Dawley rats were given 500 ppm lead acetate (Group Lead) or pair-fed sodium acetate (Group Control) in the drinking water for 65-75 days prior to *in vitro* electrophysiological experiments. Whole-cell patch-clamp techniques were performed on acutely isolated neurons from the basal forebrain. Current-densities were determined for all cells by normalizing Ca^{2+} currents (pA) for capacitance (pF), and current-voltage relationships were determined. From a holding potential of -80 mV Ca^{2+} currents were generated using a 2 sec prepulse to either -100 or -50 mV followed by voltage steps between -90 to +30 mV. There was no significant difference in maximum peak current-density between cells from Control ($X = 60.9 \pm 5.11$ pA/pF, n=20) and Lead ($X = 55.0 \pm 5.15$ pA/pF, n=27) treated animals. In a subset of cells rundown of maximum steady-state current-densities was significantly greater for Control ($X = 56.60 \pm 6.65$ %, n=10) than Lead rats ($X = 22.68 \pm 10.26$ %, n=10). These findings may suggest that chronic exposure to lead, like acute intracellular application of lead (Sun et al., *Soc. Neurosci. Abstr.*, 20:1719; 1994), causes a reduced rate of calcium current rundown. Supported by ES05639 (CAG), AA06322 (GDF) and AG07805 (WHG).

METHYLMERCURY (MeHg)-INDUCED INHIBITION OF WHOLE CELL POTASSIUM (K^+)-CURRENT IN RAT CEREBELLAR GRANULE CELLS. JE Sirois* and WD Atchison. Dept. Pharmacol./Toxicol., Inst. of Environ. Toxicology and Neuroscience Program, Michigan State University, East Lansing, MI 48824

MeHg is a neurotoxic metal which interacts with Na^+ and Ca^{2+} channels in a potent and apparently irreversible manner. Cerebellar granule cells are particularly sensitive to the *in vivo* effects of MeHg and provide an excellent model for studying MeHg effects on ion channels *in vitro*. The whole-cell patch clamp method was used to examine both peak and steady-state K^+-currents following culture of neonatal rat cerebellar granule cells for 7-12 days *in vitro* and to measure the effect of MeHg on these currents. From a holding potential (H_p) of -70mV, 250ms duration pulses to +30mV were given every 5 seconds. MeHg (2, 20 or 40 μM) inhibited K^+-currents in a concentration-dependent manner following exposure. Block was slow in onset and incomplete. At 2 μM MeHg was generally without effect, even following longer exposures. At 20 and 40 μM MeHg typically blocked both peak and end currents in an incomplete manner and also decreased the leakage current elicited by hyperpolarizing pulses from the H_p. The extent of block was similar following either strong (+120mV) or relatively weak (+10mV) depolarizations, demonstrating that the effect is not voltage-dependent. Initial experiments designed to examine the effect of MeHg on K^+-current activation and inactivation showed that MeHg did not alter the voltage at which the current activates, nor did it affect the rate at which the current inactivated. Thus, cerebellar granule cell K^+-channels do not appear to be a sensitive target of MeHg following *in vitro* exposure. Supported by NIH grant ES03299.

PATHWAYS MEDIATING Ca^{2+} ENTRY INDUCED BY METHYLMERCURY IN CEREBELLAR GRANULE CELLS. M. S. Marty* and W. D. Atchison. Dept. of Pharm. & Tox., Michigan State University, East Lansing, MI 48824.

Methyl mercury (MeHg) is a known neurotoxicant, hypothesized to cause cerebellar granule cell degeneration by altering Ca^{2+} homeostasis; however, the mechanism of this effect is poorly understood. Prior work demonstrated a MeHg-induced biphasic rise in intraneuronal Ca^{2+} ($[Ca^{2+}]_i$) with a large component of this rise due to influx of extracellular Ca^{2+}. This report examines potential route(s) of Ca^{2+} entry into granule cell cultures (7-10 DIV) after *in vitro* MeHg exposure. In contrast to results in NG108-15 cells, the dihydropyridine nifedipine did not significantly delay the time-to-onset of MeHg-induced elevations in $[Ca^{2+}]_i$, indicating that the routes of Ca^{2+}/MeHg entry in the two cell types may differ. Because excitatory amino acid (EAA) receptor-operated channels play a role in excitotoxicity, we hypothesized that granule cells are more susceptible to the effects of MeHg due to the presence of EAA receptor-operated channels. Thus, granule cells were exposed to 0.5 μM MeHg with and without various EAA inhibitors and changes in $[Ca^{2+}]_i$ were measured using fura-2. 6,7-Dinitroquinoxaline-2,3(1H,4H)-dione (DNQX, 100 μM), a non-N-methyl-D-aspartate (NMDA) receptor antagonist, inhibited 83% of the kainate-induced elevations in $[Ca^{2+}]_i$ but caused no delay in MeHg-induced $[Ca^{2+}]_i$ elevations. Similarly, 10 μM MK-801 and 100 μM 2-amino-5-phosphonovaleric acid (AP-5), antagonists capable of inhibiting 87% and 82% of the NMDA-induced elevations in $[Ca^{2+}]_i$, respectively, were ineffective at delaying MeHg-induced $[Ca^{2+}]_i$ elevations. These results show that EAA receptor-operated channels do not appear to be the route of MeHg/Ca^{2+} entry in granule cells *in vitro*. Supported by NIH grant ES03299.

MICROMOLAR CONCENTRATIONS OF METHYLMERCURY BLOCK VOLTAGE-ACTIVATED CALCIUM-, SODIUM- AND POTASSIUM CHANNELS OF RAT DRG-NEURONS IRREVERSIBLY. R. Leonhardt, H.L. Haas and D. Büsselberg★. Physiology II, H.-Heine-University, 40225 Düsseldorf, Germany.

Methylmercury (MeHg) readily accumulates in the nervous system and is known to cause a wide variety of neurotoxic effects, ranging from abnormal reflexes to loss of coordination and learning deficits.

Using the whole-cell patch-clamp technique, we examined voltage-activated ion currents of rat dorsal root ganglion (DRG) neurons. Cells were obtained from 2-4 day old rat pups and cultured for up to four days. Voltage-activated calcium-, sodium- and potassium channel currents were separated by selective blocking agents and specific depolarizing voltage steps. Calcium channel currents were carried by barium (10 mM). Subtypes of the three ion currents have not been distinguished. MeHg was applied by a bath perfusion system, it was added to the extracellular solution just before the beginning of each experiment. All currents were leak corrected by a P/4 protocol. Dose-response relationships were calculated by fitting the data to the Langmuir-equation.

All three types of voltage activated ion currents were reduced by MeHg in a concentration-dependent manner. Voltage-activated calcium- (IC_{50} ~2.6 μM) and potassium channel currents (IC_{50} ~2.2 μM) were ~5 times more sensitive to MeHg than voltage-activated sodium currents (IC_{50} ~12.3 μM). The calculated Hill-coefficients were ~1 for the blocking of calcium- and potassium channels and ~1.7 for the blocking of sodium channels. The reduction of calcium- and sodium channel currents appeared to be use-dependent. Independently of the external solution used, in some cases the application of higher concentrations of MeHg (≥5 μM) resulted in a biphasic change of the resting membrane current. None of the above described effects was reversible. These results indicate, that the blocking of voltage-activated ion channels may contribute to the neurotoxicity of MeHg.

DIFFERENTIAL EFFECTS OF Hg^{2+} AND METHYLMERCURY (MeHg) ON EXCITATORY AND INHIBITORY TRANSMISSION IN HIPPOCAMPAL SLICE. Y. Yuan* and W.D. Atchison. Dept. of Pharmacol./Toxicol. and Neurosci. Prgm. Michigan State University, E. Lansing, MI 48824.

Effects of Hg^{2+} and MeHg on resting membrane potentials, excitatory postsynaptic potentials (EPSPs) and inhibitory postsynaptic potentials (IPSPs) were compared in CA1 neurons of rat hippocampal slices using intracellular microelectrode recording techniques. Acute bath application of Hg^{2+} and MeHg (20 or 100 µM) caused biphasic effects on resting membrane potentials, *i.e.* they initially hyperpolarized and then depolarized CA1 neuronal membranes. However, Hg^{2+} appeared less potent in depolarizing hippocampal neuronal membranes than is MeHg. Similarly, Hg^{2+} is less potent at blocking EPSPs than is MeHg. In contrast, both Hg^{2+} and MeHg blocked IPSPs more rapidly than they blocked EPSPs at similar concentrations. However, single-electrode voltage clamp recordings of IPSCs showed that Hg^{2+} and MeHg had different effects on the time-courses and the current-voltage relationships. MeHg suppressed amplitudes of inward and outward currents at all holding potentials and shifted the I/V curve to more positive potentials, *i.e.* changing the reversal potential from about -75 mV (control) to more positive values. Hg^{2+} also suppressed both inward and outward currents, but it initially caused an increased outward current prior to suppressing it. Moreover, Hg^{2+} appeared to shift the I/V curve to more negative potentials and its overall effects on IPSC were much slower than those of MeHg. Thus, these results suggest that the mechanisms involved in these actions of Hg^{2+} and MeHg may be different. Supported by NIH grant ES03299.

STUDIES ON THE MECHANISM OF METHYLMERCURY (MeHg) TRANSPORT INTO THE BRAIN. R. Park, S. Yee and B. H. Choi*. Neuropathology, Univ. of California, Irvine, CA 92717.

Previous studies in our laboratory as well as those of others have demonstrated that transport of MeHg into brains of mature rats is enhanced by co-administration of L-cysteine. However, no significant enhancement of brain Hg uptake was noted following injection of 0.1 mM cysteine 20 minutes prior to 0.05 mM MMC injection in C57BL/6J mice. Whereas injection of ^{35}S-cysteine-MMC conjugate significantly enhanced brain cysteine uptake, separate injections of 20 mg/kg body weight of MMC and 30 µCi of ^{35}S-cysteine at 20 min. interval showed no significant enhancement of brain cysteine uptake as compared to controls. To further examine the mechanism of MeHg transport into the brain, varying doses (1, 2, 4 and 6 mM) of methylmercuric chloride (MMC), MMC-cysteine, MMC-glutathione (GSH) and MMC-β-mercaptoethanol (βME) were injected intra-peritoneally into C57BL/6J mice, and brain Hg uptake determined 3 hours thereafter. Dose-dependent increase of Hg uptake was noted in all groups. However, highly significant enhancement of Hg uptake took place in groups injected with MMC-conjugates (MMC-βME>MMC-cysteine>MMC-GSH>MMC). The kinetics of brain Hg uptake between MMC and MMC-βME groups also differed considerably. These data indicate that size and polarity of MMC-conjugates greatly influence MMC transport into the brain, and that MeHg transport into mature brains appears to take place through diverse and complex uptake systems. (Supported in part by NIEHS grant ES 02928).

CHRONIC EXPOSURE TO INORGANIC LEAD MODIFIES PKC ACTIVITY IN THE DEVELOPING RAT HIPPOCAMPUS. M. Madden & V. Miletic*. Dept. Comp. Biosci. & Environmental Toxicology Center, Univ. Wisconsin, Madison, WI 53706

The aims of this study were to characterize the subcellular distribution of protein kinase C (PKC) activity in the developing rat hippocampus, and to examine whether chronic lead exposure modifies this development. Dams were exposed to either 0 or 1000 ppm lead acetate in their drinking water and mated. Offspring were exposed *in utero*, via lactation, and directly in the drinking water after weaning. The offspring were sacrificed at postnatal days 1, 8, 15, and 29. Blood lead levels were determined at these postnatal periods and correlated to the amount of lead given. Total PKC activity was determined in the cytosolic and crude P-2 membrane fractions from each animal's hippocampus by an *in vitro* radioactive phosphorylation assay, and was expressed as picomoles of phosphate incorporated per mg of protein per min. In control rats, total PKC activity in the cytosolic fraction increased three-fold between P1 (1110 ± 283) and P8 (3296 ± 721) ($p<0.0005$), remained at these levels at P15, and then decreased somewhat at day 29 ($p<0.0025$). PKC activity in the membrane fraction of these normally developing rats also increased between P1 and P8 ($p<0.0005$), but then decreased at P15 ($p<0.0005$), and did not further change at P29. In lead-treated rats, PKC activity in the membrane fraction was significantly lower than in control rats at all measured postnatal periods ($p<0.01$ at P1, $p<0.0005$ at P8, P15, P29). In these same rats, cytosolic PKC activity was lower than in control animals at P8 and P29 ($p<0.0005$), but not at P1 and P15. These results indicate a significant modification of total PKC activity, especially in synaptosomal membrane fractions of lead-treated rats. This suggests that the modification might contribute to lead's neurotoxic action in the developing rat hippocampus. (Supported by NIH NS21278).

PRENATAL AND POSTNATAL CHRONIC EXPOSURE TO INORGANIC LEAD ATTENUATES LTP IN THE ADULT RAT HIPPOCAMPUS *IN VIVO*. A.Z. Elliott* & V. Miletic. Dept. Comp. Biosc. & Environ. Tox. Cntr., Univ. Wisconsin, Madison, WI 53706

We examined whether prenatal and postnatal chronic exposure to inorganic lead modifies the expression of long-term potentiation (LTP) in electrophysiological recordings in the adult rat hippocampus *in vivo*. Dams were given 0, 100, 500, or 1000ppm lead acetate in their drinking water beginning 2 weeks before mating. Offspring were exposed to lead via the milk and, after weaning, in the drinking water. At about 13 weeks of age, a male and a female from each litter were anesthetized with urethane (1.2-1.5 g/kg), and prepared for conventional recording of hippocampal field potentials. A bipolar stimulating electrode was lowered into the CA3 region, and the glass recording electrode (0.5-2MΩ) was positioned in the CA1 region until a maximum response to the CA3 stimulus was observed. LTP was induced by tetanic stimulation (one 400ms train of five 50ms pulses at 50Hz), and recordings of field potentials were repeated at 0.5, 1, 2, 3, and 4 hours post-tetanus. In control and 100ppm lead-treated animals (blood levels of 11.5μg/dL) an increase in the population spike (PS) amplitude of 250-300% over baseline levels was observed to persist through 4 hours. Animals given 1000ppm lead (blood levels of 31.5μg/dL) showed little LTP (PS increase <50%). Those exposed to 500ppm (blood levels of 24.6μg/dL) exhibited LTP (200% over baseline) at 1 hour, but then the PS declined to baseline levels. These data indicate that chronic exposure to lead resulting in blood levels as low as 25μg/dL prevents the full expression of LTP in the CA1 region of the rat hippocampus *in vivo*. The data further suggest that the failure to fully express LTP may contribute to lead's neurotoxic action in the developing rat hippocampus. (Supported by NIH NS21278).

CHRONIC LOW LEVEL LEAD EXPOSURE ALTERS CALCIUM CURRENT IN PHEOCHROMOCYTOMA (PC12) CELLS. C. C. Hegg* & V. Miletic. Dept. Comp. Biosci. & Environmental Toxicology Center, Univ. Wisconsin, Madison, WI 53706.

Lead is a known neurotoxin with varied and poorly understood mechanism(s) of action. We employed the whole-cell patch-clamp technique to examine the chronic effects of low level lead exposure on high-threshold voltage-dependent calcium currents in rat pheochromocytoma (PC12) cells. PC12 cells were exposed to 0, 10 or 50 μM lead-containing growth media for up to 8 weeks. At least four days prior to recording cells were plated in dishes in lead-containing media with nerve growth factor to induce differentiation. As previously reported in acute studies, chronic low level lead exposure caused a dose-dependent *decrease* in calcium current throughout a 4 week exposure. In contrast, after 5 - 8 weeks of lead exposure, both the peak and sustained components of the calcium current were *increased*. When the chronically exposed cells were further challenged with an additional 5 minute exposure to 1 μM lead a dose-dependent decrease in calcium current and an alteration in the activation and inactivation kinetics were observed. The effects of lead were only partially reversible with washing. These data suggest complex interactions of lead with calcium channels in PC12 cells. (Supported by NIH NS21278 & T32 ES07015).

EFFECTS OF *IN UTERO* METHYLMERCURY EXPOSURE ON HIGH AND LOW LUMINANCE VISUAL CONTRAST SENSITIVITY IN ADULT MONKEYS. S.G. Gilbert*, D.C. Rice, M.L. Mihali, C. Munkers, K.S. Grant-Webster and T.M. Burbacher. Dept. Environmental Health, Univ. of Washington, Seattle, WA 98195.

Both animal and human studies have shown that the visual system is sensitive to the effects of methylmercury (MeHg). The present study assessed visual function in adult monkeys (*Macaca fascicularis*) following *in utero* MeHg exposure. Maternal exposure of either 0, 50, 70, or 90 μg/kg/day of MeHg resulted in blood mercury levels at birth from 1.04 to 2.45 ppm for treated infants. There were 10, 9, 2 and 2 offspring produced, respectively. At approximately 9 to 11 years of age the monkeys were tested on an operant visual psychophysics task designed to assess spatial visual function at low and high luminance. A forced choice tracking procedure was utilized in which the monkeys faced two oscilloscope screens of equal average luminance and were required to press the button corresponding to the screen displaying a vertical sine wave grating. The following spatial frequencies were assessed: .5, 2, 4, 10, 20, and 30 cycles per degree of visual angle for high luminance and 1, 2, and 4 c/d for low luminance. Preliminary data from 12 of the monkeys at high luminance showed that some MeHg monkeys exhibited a decreased contrast sensitivity at high spatial frequency. There appear to be no treatment related effects at low luminance. That some treated individuals appear to exhibit greater visual impairment than others is consistent with previous studies of monkeys exposed to MeHg. These preliminary results, indicate that *in utero* MeHg exposure may adversely affect the spatial visual function of adult monkeys.

776.20

EFFECTS OF INTRASTRIATALLY ADMINISTERED LEAD ON EXTRACELLULAR FLUID (ECF) AMINO ACID CONCENTRATIONS IN THE STRIATUM: A MICRODIALYSIS STUDY. P. Chaiyakul*, J. Waraska, I. N. Acworth, and T. J. Maher. Division of Pharmaceutical Sciences, Massachusetts College of Pharmacy, Boston, MA 02115 and ESA Inc., Chelmsford, MA 01824.

Previous studies in our laboratory have shown that pretreatment with lead (Pb^{2+}) decreased the basal striatal ECF levels of aspartate (by 56%), glycine (by 18%) and taurine (by 23%), while increasing the K^+-evoked release of inhibitory amino acids (glycine and taurine) and decreasing excitatory amino acids (glutamate and aspartate). To further this line of investigation, we measured the ECF amino acid levels of rats intrastriatally perfused with artificial CSF (aCSF) containing concentrations of Pb^{2+} (0.1, 0.3, and 1.0 mM) using *in vivo* microdialysis. Urethane-anesthetized rats were stereotaxically-implanted with a 3 mm loop-design probe in the striatum and baseline samples collected every 20 min. for 2 hours. A Pb^{2+} containing aCSF (Mg^{2+} lowered accordingly to preserve isotonicity) was then perfused through the microdialysis probe using a liquid switch for 120 minutes. Compared to controls, aCSF containing Pb^{2+} (0.1 and 0.3 mM) significantly increased the ECF levels of all amino acids studied, but not in a dose-dependent manner. The highest concentration of Pb^{2+} (1.0 mM), where Mg^{2+} is decreased to 0 mM, significantly decreased the ECF levels of all the studied amino acids compared to controls. These data demonstrate a biphasic dose-response relationship between intrastriatal Pb^{2+} and ECF amino acid levels, suggesting that the observed changes in ECF amino acids may have partly resulted from alterations in aCSF Mg^{2+} concentrations. Additional studies on the role of Mg^{2+} and other divalent cations in the release and uptake of amino acid neurotransmitters are warranted.

REDUCED ChAT mRNA EXPRESSION IN SEPTUM OF POSTNATAL RATS FOLLOWING PERINATAL LOW-LEVEL LEAD EXPOSURE. X.Sun, X.Tian*, and J.B.Suszkiw. Dept. of Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH 45267-0576.

We investigated the effect of Pb-exposure on ChAT mRNA expression in postnatal rats. Rat pups were maternally Pb-exposed by giving 0.2% lead acetate in drinking water to dam. Septal tissue was homogenized in RNAzol ™ B (1:20, w/v). Total RNA from both control and Pb-exposed animals was extracted, quantified at OD_{260}, loaded at 20, 10, 5, 2.5, and 1.25 μg onto nylon membrane in Dot-blot manifold apparatus, and hybridized with γ ^{32}P ATP-radiolabeled 43bp ChAT antisense oligonucleotide probe or 21bp rat 18S rRNA probe, respectively. The blots were scanned and quantified with the aid of a phosphor imager SF (Molecular Dynamics). The ChAT mRNA signal was normalized to the corresponding signal obtained with a probe specific for the 18S ribosomal RNA. Relative to control levels, the ChAT mRNA in septa of PN21 and PN28 animals with Pb-exposure were reduced by 42% and 44%, respectively. These results indicate that the previously reported reduction of ChAT activity following Pb-exposure reflects the reduction of the ChAT mRNA levels. *This work was supported by NIEHS grant ES06365.*

EFFECTS OF LEAD ON CATECHOLAMINE BIOSYNTHESIS IN PC12 CELLS. A.M. Ndifor,R,R.Reams& K.Soliman*. College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL 32307.

We have previously reported that lead does not modify dopamine β hydroxylase but induces a slight enhancement in tyrosine hydroxylase activity in PC12 cells. We have further studied the effects of lead acetate on the synthesis storage and release of dopamine (DA) and norepinephrine (NE). Cells were exposed to 0.3-25μg/dl Pb^{2+} for up to 3days and the levels of DA, NE and 5HT in the cells determined by HPLC. The release of these amines and their corresponding metabolites was also observed. Pb^{2+} significantly inhibited the release of NE but not DA. It also reduced metabolic deactivation of DA to 3,4 dihydroxyphenyl acetic acid and homovanillic acid. 5HT conversion to 5-hydroxyindolacetic acid was also inhibited. DA and NE storage was only marginally reduced by lead. The inhibitory effects of lead were most prominent after 24hrs exposure and were not significant at 72hrs, suggesting the presence of an equilibrating process. These results confirm Pb^{2+} as a potent inhibitor of oxidative metabolic enzyme activity, which could result in increased accumulation of the parent compounds with potential potentiation of their neuroactivities.

SYMPOSIUM. OPIOIDERGIC MODULATION OF LONG-TERM POTENTIATION IN THE HIPPOCAMPUS: INSIGHTS INTO PEPTIDERGIC REGULATION OF SYNAPTIC PLASTICITY. C.R. Bramham, Univ. Bergen (Chairperson); C. Chavkin, Univ. Washington; J.L. Martinez, Jr., UC Berkeley; R. Nicoll, UCSF.

Opioid peptides are co-localized with the excitatory neurotransmitter glutamate in several hippocampal pathways. As is the case for most neuropeptides, a function for opioids has been difficult to define. Rapid advances have now established endogenous opioid peptides as major regulators of long-term potentiation (LTP) in the hippocampus. Similar to neuropeptides co-stored with classical transmitters in the peripheral nervous system, maximal release of opioid peptides occurs during high-frequency stimulation. Evidence indicating that activation of opioid, but not NMDA, receptors is required to induce LTP of opioid-containing pathways, including the lateral perforant path input to granule cells and CA3 pyramidal cells and the mossy fiber input to CA3 pyramidal cells, will be presented. Conflicting evidence that naloxone does not block mossy fiber LTP induction will also be discussed (Nicoll). The latest findings reveal an unexpected and intriguing complexity to opioid effects: dynorphins can act presynaptically to dampen excitatory transmission and inhibit LTP induction. Furthermore, dynorphins may be released from granule cell dendrites to act as retrograde neurotransmitters. The objective of the symposium is to synthesize what we know about the mechanisms and unique properties of opioid receptor-dependent LTP on the one hand (Bramham and Martinez), and inhibitory control of LTP by dynorphins on the other (Chavkin and Nicoll).

SYMPOSIUM. NEURAL CONTROL OF BREATHING. J.E. Remmers, Univ. of Calgary (Chairperson); D.W. Richter, Univ. of Gottingen; J.L. Feldman, UCLA; N.I. Syed, Univ. of Calgary.

The overall objective of this symposium will be to provide fundamental and comprehensive insights into both the developmental and comparative aspects of the cellular basis of respiratory rhythm generation. The first presentation will consider cellular, membrane, and metabolic factors that modulate the respiratory rhythm in adult mammals. The second presentation will review cellular and molecular mechanisms underlying respiratory rhythmogenesis in a slice preparation. The third presentation will focus on comparative aspects of respiratory chemoreception and rhythmogenesis in amphibia. The last presentation will deal with a novel approach of reconstruction of a central respiratory pattern generator and its modulation by neurotransmitters.

The approach of this session will encompass both neonates and adults in animals ranging from mammals, lower vertebrates to invertebrates. The session will be a unique opportunity to learn about the cellular basis of rhythm generation in phylogenetically and ontogenetically different species from a single ion channel to the whole animal behavior.

P300 LATENCY AT CORTICAL SITES IN VISUAL AND AUDITORY ODDBALL PARADIGMS. Ivy M. Dise Dunn*, Psychology Dept. & Beckman Institute, Univ. of Illinois at Urbana-Champaign, Champaign, IL 61820.

P300 latency was mapped during a topographic analysis of normal subjects. The objective was to determine if there is a consistent sequence in which P300 reaches peak amplitude across the cortex.

The P300 component was elicited with auditory and visual oddball paradigms in ten normal subjects. Peak latencies were ranked to show the sequence in which 18 scalp sites reached maximum amplitude. While individual variation occurred among subjects, several consistencies were seen.

The typical PZ-maximum distribution was present along the midline. In addition, a large P300-like peak occurred between 240ms - 590ms at sites away from the midline. This peak reached maximum amplitude at some sites simultaneously, but was delayed as much as 125ms at other locations. In the auditory condition, the central/parietal regions had the earliest latencies, and the latest latencies were frontal. P300 arose anteriorally in the visual condition, and terminated posteriorally. These results suggest that P300 reaches peak amplitude across the cortex in an orderly sequence. This sequence may provide insight into the cognitive processing associated with P300.

MODULATION OF FRONTAL- AND PARIETAL-LOBE ACTIVITY BY FOCUSED ATTENTION. PART I: METHOD AND PHASIC (SUB-SECOND) EFFECTS. *A.S. Gevins* & M.E. Smith. EEG Systems Laboratory & SAM Technology, One Rincon Center, San Francisco, CA, 94105.*

The strategic allocation of attention required to perform difficult cognitive tasks is reflected in corresponding phasic and tonic changes in human brain electrical activity. At present, high resolution electrophysiological methods are the only means of resolving both sub- and multi-second attentional effects in a single experiment. This may be done by analyzing the data both as discrete averaged Evoked Potential (EP) peaks, and as continuous unaveraged EEGs. An experiment suitable for both viewpoints was designed around demanding spatial and verbal tasks that required continuous maintenance and updating of representations in working memory (WM). Improved spatial resolution was obtained by recording EEGs with 115 electrodes, registering the data with anatomical models derived from each (N=8) subject's MRI, and correcting for volume conduction blurring through the skull and scalp, in effect estimating the potential distribution just above the cortical surface. For frequent, nontarget stimuli, a positive EP peak at 305ms was larger in the spatial WM condition relative to the other conditions, followed by a peak at 450ms that was larger in both spatial and verbal WM conditions relative to control conditions. The voltage maxima for the P305 and the P450 occurred over dorsalateral frontal cortex near the principal sulcus of the right- and left- hemispheres respectively. These brief (~100-200ms) events occurred in parallel with a positive slow wave, maximal over the superior parietal lobe and the supramarginal gyrus, with a slight right-hemisphere predominance. It began ~200ms after stimulus onset, returned to baseline by ~600ms post-stimulus in control conditions, and was sustained for ~1sec longer in the WM conditions than in control conditions. These results suggest that the phasic allocation of attention during WM tasks involves the momentary functional coordination of regions of frontal and parietal cortex. The relationship of these phenomena to multi-second tonic attentional processes is discussed in Part II (Smith & Gevins, this mtg.). This research was supported by NIMH, AFOSR, & ONR.

779.3

MODULATION OF FRONTAL- AND PARIETAL-LOBE ACTIVITY BY FOCUSED ATTENTION. PART II: TONIC (MULTI-SECOND) EFFECTS AND CONCLUSIONS. *M.E. Smith* & A.S. Gevins. EEG Systems Laboratory & SAM Technology, One Rincon Center, San Francisco, CA, 94105.*

When difficult tasks impose a sustained cognitive load, phasic brain electrical events are accompanied by tonic alterations in the ongoing EEG. To characterize these multi-second changes, the dataset described in Part I (Gevins & Smith, this mtg.) was spectral analyzed as 4 second epochs corresponding to single trials. Two distinct differences were reliably observed between working memory (WM) and control task conditions. First, over a restricted prefrontal region, power in the 4-7Hz (theta) band was increased in the WM tasks relative to the control tasks ($p < .02$ at peak signal intensity measured at a midline location over the superior frontal gyrus). Anatomically-registered dipole models of brain electrical currents localized the source of this signal in or near the anterior cingulate gyrus. Second, over widespread areas of cortex, but most pronounced over parietal regions, peak power in a 9-13Hz (alpha) band also differed between between WM and control tasks, with lower power in the WM conditions ($p < .001$ at a midline location over the posterior margin of the superior parietal lobule). Taken together with the Part I results, these findings suggest that a distributed network of attentional processes, with distinct timecourses in distinct neuronal populations, are required to perform the demanding WM tasks. In the frontal lobes, in conjunction with tonic focusing of awareness, increased theta activity appears to reflect engagement of medial components of the attentional system, perhaps including the anterior cingulate gyrus. In contrast, the phasic attention required for scanning and updating the contents of working memory appears to be reflected in EP enhancement in lateralized regions of dorsalateral prefrontal cortex. Finally, the sustained effort required to maintain an inter-trial internal representation of the stimuli involves modulation of activity in widespread regions of parietal cortex, and appears to be reflected both in the stimulus-locked enhancement of a posterior slow potential, and in a tonic reduction in the amplitude of the alpha rhythm. This research was supported by AFOSR, NIMH, & ONR.

COMBINED PET AND ERP STUDY OF SUSTAINED VISUAL SPATIAL ATTENTION AND VISUAL TARGET DETECTION. M.G.Woldorff*, P.T.Fox, M.Matzke, S.Veeraswamy, J.L.Lancaster, P.A.Jerabek, C.C.Martin. Research Imaging Center, Univ. of Texas Health Science Center., San Antonio, TX 78284-6240.

PET studies have indicated various brain regions involved in visual attention, but they do not provide timing information and have tended not to distinguish between sustained attention and target-related processing/attention. ERPs have differentiated between, and revealed timing of, sustained-attention vs. target-processing activation changes, but precisely specifying the sources of these effects has been difficult.

In this project, ERPs and PET scans were both recorded (separate sessions) while subjects (n=9) fixated on a small cross and *bilateral lower visual-field stimuli* were rapidly presented (~2/sec). In active runs, subjects attended covertly to a designated side to detect target stimuli on that side. There were five conditions: (1) Attend right, many targets (16%); (2) Attend left, many targets; (3) Attend right, few targets (2%); (4) Attend left, few targets; (5) Passive viewing (2% irrelevant targets). Each subject had two PET runs (15-O water-bolus) and eight ERP runs (64-chan) of each condition. PET images were analyzed using Change Distribution Analysis after spatial normalization to Talairach space.

ERPs showed enhanced positivity from 80-150 msec over *contral. occipit. areas* for both targets and nontargets in active attention conditions vs. passive. This early-positivity attention effect did not differ between many- and few-target conditions, indicating similar sustained attention. Targets in active conditions also elicited large P300 waves (320-600 msec), preceded by contral. N2b's (250-300 msec). In the PET, active attention vs. passive conditions showed strong activity in *contral. dorsal occipit. areas* (BA18/19), which also was similar in the many- and few-target conditions. In conjunction with Heinze et al. (*Nature* 1994, 372: 543-546), which found attention effects in human contral. fusiform (but *not* dorsal occipit.) for *upper* visual-field stimuli, the present results suggest *human area V4 for lower visual field* may be in dorsal occipit. cortex and a source of the early ERP attention effect. Some activation was also seen in contral. fusiform in active vs. passive conditions, which may reflect activation of a ventral parallel pathway for object analysis. The *ant. cingulate* was very active in *both the many- and few-target conditions* vs. passive, with little difference between many and few, suggesting this area is not specific to "selection for action" *per se*. *No* focal blood-flow effect was apparent as a likely *P300* source, although some indication of distributed additional activity in the many-target conditions was seen in the overall population statistics. This combined PET/ERP study indicates multiple areas activated during visual attention and provides insight into their timing and functions.

779.5

CHANGES IN AUDITORY CORTEX ACTIVATION DURING SELECTIVE ATTENTION. C.L. Grady*, J.W. VanMeter, J.M. Maisog, P. Pietrini, J. Krasuski, J.P. Rauschecker. Lab. of Neuroscience, NIA, Lab. of Psychology and Psychopathology, NIMH, Lab. of Neuropsychology, NIMH, Bethesda, MD 20892.

Previous studies have shown that attention to a particular stimulus can increase the activity of the brain area responsible for processing that stimulus. We investigated the effects of selective auditory attention in superior temporal cortex using functional MRI in 5 young subjects (3F, 2M, 26 ± 5 yrs). Echo planar images, using a 1.5 Tesla GE scanner, were obtained while subjects listened to 3 word lists. Subjects heard each list three times (for a total of 9 scans), and were instructed to count the number of times they heard a particular word during two of these presentations. For the third, they listened to the words without counting. Each scan consisted of three periods of words alternating with three periods of no stimulation, each 30 sec in length, and the order of presentation of the word lists was varied across subjects. Images obtained during stimulation were compared to those obtained during rest using an ANOVA ($p<0.01$) with a subsequent test of significance on the spatial extent of each cluster of activated voxels ($p<0.01$). All subjects showed significant areas of activation in left auditory cortex during all listening conditions compared to rest. Right hemisphere activation also was seen in 2 subjects scanned with a full-head coil. Three of the five subjects showed a mean activation during the attention conditions that was substantially larger in spatial extent than that seen during the passive listenting condition (112%, 324% and 338%). Two subjects had an equivalent number of voxels activated in the attention and passive conditions. These results provide preliminary evidence in support of an attention related enhancement of activation in auditory cortex.

779.6

A LARGE-SCALE NEURAL MODEL LINKING LOCAL NEURONAL DYNAMICS TO POSITRON EMISSION TOMOGRAPHY (PET)-REGIONAL CEREBRAL BLOOD FLOW (rCBF) DATA. M-A. Tagamets[1], B. Horwitz[1] and J. A. Reggia*[2], [1]Lab. Neurosci, NIA, NIH, Bethesda, MD, 20892 and [2]Dept. Computer Sci., Univ. Maryland, College Park, MD 20742.

In order to better understand the neural mechanisms that underlie cognitive behavior, we have developed a large-scale neural model that relates local neuronal dynamics to functional neuroimaging data [e.g., regional cerebral blood flow (rCBF)] acquired by techniques such as positron emission tomography (PET) during performance of specific visual tasks. Distinct modules of the model represent identified visual cortical areas associated with the processing of information about color and shape. The model has two general properties: 1) fast local dynamics are modeled by explicit pre- and post-synaptic processes that modulate effective connection strengths, enabling discrimination and binding of features (e.g., color, shape) presented to a module representing primary visual cortex; (2) rCBF data are modeled by integrating over time the synaptic and neuronal activities generated by the model for each cortical area. We used this model to simulate a PET study of selective attention (color vs. shape), and showed that the task can be performed using spatiotemporal encodings similar to those suggested by electrophysiological results (e.g., Singer, Ann. Rev. Neurosci., 1993). The importance of a "top-down" effect on task performance is demonstrated. We also assessed the implications of fast temporal feature binding for interpreting PET data by relating the fast local dynamics to both region-specific rCBF activations and interregional rCBF correlations.

779.7

A PET STUDY OF AUDITORY AND VISUAL ATTENTION
D.S. O'Leary,* N.C. Andreasen, R. Hurtig, L. Flashman, I. Torres, R. Hichwa, Mental Health Clinical Research Center, University of Iowa, Iowa City, IA 52242.

We have previously found that attending right or left for dichotically-presented stimuli caused asymmetric changes in rCBF in auditory cortices (O'Leary et al., *Brain and Language*, in press). The present study used simultaneously-presented visual and auditory stimuli to assess the modality-specificity of spatial attention. During different conditions of a PET study with (O-15) water, 13 normal volunteers attended left and right to visually- or auditory-presented consonant-vowel-consonants (CVCs). During visual conditions, subjects fixated centrally, but monitored left or right visual fields while ignoring dichotic stimuli. Attention to one or the other visual fields caused asymmetric rCBF changes in extrastriate cortices, but did not induce asymmetric rCBF changes in auditory cortices. The activation in auditory cortices resulting from nonattended dichotic stimuli was symmetrical. When subjects attended to dichotic stimuli, we replicated our finding that attending left or right caused asymmetric rCBF in temporal lobes, but found that rCBF in occipital cortex was unaffected. The pattern of rCBF change indicates that spatial attention is modality-specific. Regions of interest were traced on each individual's MR images which were co-registered with their PET images, allowing measurement of rCBF in Heschl's gyrus, the planum temporale, the ascending ramus of the sylvian fissure and striate cortex. These data, which will be discussed, address the anatomical location at which attentional effects occur in sensory sytems (i.e., primary vs secondary cortices).

779.8

ATTENTION MODULATES fMRI ACTIVATION IN HUMAN MT/MST. K.M. O'Craven[1,2], R.L. Savoy[1,2]*, B.R. Rosen[2]. [1]*The Rowland Institute for Science, 100 Edwin H. Land Blvd, Cambridge, MA, 02142.* [2]*MGH-NMR Center, 149 13th St., Charlestown, MA 02129* (kmo@nmr.mgh.harvard.edu)

We used functional MRI to measure the amount of activation within functionally defined regions of the human brain homologous to monkey areas MT and MST. Subjects viewed a single stimulus that consisted of both moving and stationary dots. Motion was radial, and subjects fixated a central fixation point. Initially, subjects attended to the moving dots and ignored the stationary dots. Every 20 seconds, a verbal cue instructed subjects to voluntarily switch attention between the moving dots and the stationary dots. The magnitude of the fMRI signal was significantly higher while subjects attended to the moving dots than while they attended to stationary dots and ignored the moving dots.

An additional experiment sought to quantify more precisely the modulation just described. Subjects viewed the moving-and-stationary-dot stimulus during four 20 second epochs, alternating with epochs of a stimulus in which only stationary dots were present. During two of the four epochs of moving-and-stationary-dots, subjects attended to the moving dots, and during the other two epochs, they attended to the stationary dots. Attending to stationary dots did not eliminate MT activation. Rather, MT was highly active any time a stimulus containing visual motion was present. However, when attention was directed to the stationary dots, activity was only 80-90% as strong as when attention was directed to the moving dots. This attentional modulation was significant ($p < .001$) for each of three subjects.

What does the modulation of MT activation represent? Is it *additional* activation during the "attend moving" condition, or is it *suppressed* activation during the "attend stationary" condition, because the moving dots need to be ignored? Experiments are underway to examine this question.

FUNCTIONAL MRI OF AUDITORY EFFORTFUL ATTENTION IN HUMANS. HC Breiter, LJ Seidman, JM Goodman, JM Goldstein, KM O'Craven, RM Weisskoff PWR Woodruff, R Savoy, A Jiang, D Kennedy, W Kennedy, MT Tsuang, BR Rosen*. Harvard Medical School and MGH-NMR Center, Charlestown, MA 02129.

Attention becomes effortful with increased working memory load, needs for interference control, or difficulty of target detection. Using functional MRI (fMRI), we investigated if an auditory effortful attention task would activate regions reported for visual selective attention, including brainstem and thalamus. Seven normal men had contiguous 7mm axial images covering pons to parietal cortex acquired with an asymmetric spin-echo instascan sequence. The paradigm employed an A-B-A-B design with stimulus blocks of 90 letters presented aurally one letter per second. In A, subjects responded to the letter "a" when immediately preceded by a "q" (QA). B conditions required the subject to respond to the letter "a" when preceded by a "q" four letters previously (Q3A), and ignore embedded false cues and targets. Target probability was matched between QA and Q3A conditions at 20%. Subjects were scanned three times. FMRI time series data was transformed into Talairach space and evaluated using three novel averaging techniques and nonparametric statistical mapping. Compared to QA, the Q3A condition produced, at the Bonferroni level ($p<10^{-7}$), positive change bilaterally in the parietal-occipital cortex (PPC), thalamus, superior colliculus (SC), supplementary motor area (SMA), frontal eye fields (FEF) and dorsolateral prefrontal cortex, and unilaterally in right inferior temporal cortex (ITC). Significant negative signal change occurred in the anterior cingulate (AC). This study found activation in regions proposed by Posner and Peterson to form a posterior network for orienting to sensory events (ie, PPC, thalamus, and SC), along with regions forming an anterior network for signal detection (ie, AC, SMA). Our auditory task also produced activation in visual regions such as PPC, SC, ITC and FEF; these results may relate to cognitive strategy employed. Effortful attention appears to depend on the entire distributed network implicated for selective attention, with important components being independent of sensory modality of stimulus.

779.10

rCBF IN CINGULATE, FRONTAL, AND PARIETAL CORTICES IS HIGHLY CORRELATED WITH ACCURATE DECISION RESPONSE TIME DURING TONE RECOGNITION. H.H. Holcomb*, P.J. Caudill, Z. Zhao, D.Medoff, H.T. Ravert, R.F. Dannals, C.A. Tamminga. Maryland Psych. Res. Ctr. and Johns Hopkins Med. Instit., Baltimore, MD 21228.

When trying to recognize one of two similar stimuli a subject must suppress irrelevant and distracting information, and enhance his attention to important features which help him distinguish one from another. The cingulate cortex appears to play an important role in decision physiology. We have used an auditory recognition task in conjunction with the 15-oxygen, bolus water, PET rCBF method to further understand the role of various cortical regions in making difficult auditory recognition decisions. Twelve normal volunteers were trained (3200 trials) to recognize high frequency versus low frequency tones in a forced choice recognition task. Twelve rCBF scans were obtained from each subject: 4 resting, 4 sensory-motor controlled, and 4 decision. The average accuracy for the 60 trials presented during each decision scan was 80%, median accurate response time = 683 msec. Data were registered (Woods et al, 1992) and stereotaxically normalized (Friston et al, 1995). Statistical Parametric Mapping (SPM94, Hammersmith Cyclotron Unit) was used in conjunction with other correlation matrix algorithms (Horwitz and Rapoport, 1988) to assess rCBF relationships with accurate trial response times (RT). Four regions exhibited highly significant positive correlations ($r >0.5$, $p<0.001$) with RT during decision scans: anterior cingulate, mid - frontal right, mid - frontal left, and inferior parietal lobule left. The cingulate cortex also exhibited highly significant correlations with each of the other three regions ($p < 0.001$). These associations suggest that the longer it takes a subject to make his decision the greater will be his blood flow rate to the anterior cingulate, midfrontal and left parietal cortices.

779.11

REFLEX SACCADES IN PATIENTS WITH UNILATERAL VISUAL EXTINCTION. C.A. Marzi*, A. Fanini, G. Gambina, A. Ipata, C. Miniussi, N. Smania, G. Tomelleri. Dept. of Neurological & Visual Sci., Univ. of Verona, and Neurology Div. Ospedale Borgo Trento, Verona, Italy.

Patients with unilateral left visual extinction as a consequence of right hemisphere damage centered on the parietal lobe were tested on a simple manual reaction time task with lateralized brief flashes. There were three conditions of stimulus presentation: unilateral left and right hemifield stimuli and bilateral stimuli across the vertical meridian. Ss were instructed to keep their gaze steady onto a central fixation point both before and after stimulus presentation. Following execution of the response, the patients were asked to report on the number of stimuli just seen. In spite of the instructions, there was an overall mean of about 25% reflex-like, stimulus driven, saccades following either left or right unilateral stimuli. With bilateral stimuli about two/thirds of saccades were directed to the ipsilesional hemifield. The latency peak of saccades to unilateral right stimuli was shorter (162.5 msec) than that for saccades to left stimuli (237 msec) but showed the same latency as that for right saccades following bilateral stimuli. The lack of left-directed saccades with bilateral stimuli was present in both extinguished and correct trials. The same was true for the lack of interference of the left stimuli on saccadic latency to bilateral targets. The present results suggest that the simultaneous presentation of ipsilesional stimuli has a profound inhibitory effect on reflex saccades elicited by contralesional stimuli. However, such an impairment does not seem to be related to the perceptual phenomenon of extinction.

NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS V

780.1

SEQUENTIAL EXPRESSION OF TRKS A, B AND C DURING DEVELOPMENT AND REGENERATION OF OLFACTORY RECEPTOR NEURONS A. Jane I. Roskams*, Angelyn Bethel, Laurie Williams and Gabriele V. Ronnett. Department of Neuroscience and Neurology, Johns Hopkins School of Medicine, 725 N. Wolfe Street, Baltimore MD 21205.

Nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF), and neurotrophins -3,4 and 5 (NT-3,4,5) have been identified and characterized by their ability to induce neuronal differentiation and support neuronal survival in vivo and in vitro. A family of neurotrophin receptor tyrosine kinases (Trks) mediates neurotrophin action and neurotrophin binding has been shown to stimulate homodimerization of one Trk, heterodimerization of two Trks or one Trk and the low affinity NGF receptor (LNGFR). Trk A,B,C and the lNGR are expressed in adult and developing olfactory neuroepithelium. The olfactory neuronal epithelium is capable of undergoing neuronal regeneration throughout the lifetime of the organism. When the olfactory bulb is removed, the neuroepithelium enters a state of co-ordinate regeneration, where there is a sequential expression of Trk A (precursor neurons), B (immature neurons) and C (mature neurons) within regenerating olfactory neurons at different stages of differentiation. In primary cultures of olfactory neurons Trks become specifically phosphorylated when challenged with the appropriate neurotrophin ligand and activate a signal transduction cascade that terminates in the up-regulation of immediate early genes such as fos and jun. We are currently examining the olfactory pathways of mice with a null mutation for the Trk A, B and C genes to determine whether the phenotype of these knockout mice supports the suggested in vivo role for each Trk and to examine the possibility of neurotrophin receptor redundancy during development in this system.

780.2

THE EXTRACELLULAR ACIDIFICATION RESPONSE OF TRK A EXPRESSING CELLS TO NGF IS DOWN-REGULATED BY CO-EXPRESSION OF P75 IN PC12 CELLS AND TRANSFECTED L CELLS. H. G. Wada^, J. Twiss†, G.T. Baxter*^, K.S. Fok^, E.M. Shooter†, and H. H. Sussman†. ^Molecular Devices Corp., Sunnyvale, CA 94089, †Stanford University, Stanford, CA 94305.

Neurotrophins play a central role in neuronal development and maintenance. These molecules exist primarily as dimers and bind to a family of neurotropin receptors, which include trkA, trkB, and trkC. Another receptor for neurotropins is $p75^{NGFR}$ which is a member of the TNF receptor family. We have used the Cytosensor® microphysiometer to study the role of p75 in combination with trkA, the putative high affinity receptor for NGF. The Cytosensor measures increases in extracellular acidification rate in response to receptor activation of intracellular signalling pathways. In one set of experiments, PC12 cells transfected with anti-sense sequences directed against either trkA or p75 were tested with wild type PC12 cells as controls. Anti-sense-trkA cells had a suppressed acidification response to 10 ng/ml NGF compared to the wild type PC12 cells, and anti-sense-p75 cells had an enhanced response to the same amount of NGF. It was also noted that an anti-p75 monoclonal antibody (MC192) which does not inhibit NGF binding also suppressed NGF responses in wild type PC12 cells. These data suggest that p75 has a negative regulatory function for acidification responses to NGF in PC12 cells. A similar result was obtained using L cells transfected either with trkA alone or with both trkA and p75. The trkA transfected cells gave large (80%) increases in acidification rate which were sustained over the time of neurotropin exposure, and the trkA/p75 transfected cells gave an attenuated response (15%) which rapidly returned to baseline, during the neurotropin exposure. These results suggest that p75 may have an inhibitory or desensitizing effect on trkA activation by NGF. This study was supported in part by Defense Advance Research Projects Agency, Contract MDA972-92-C-0005.

780.3

DYNAMICS OF *TRKA* PHOSPHORYLATION IN RESPONSE TO INTRACEREBRAL NGF INJECTIONS IN RODENTS. L.F. Kromer,* and D.R. Kaplan[1]. Dept. of Cell Biology, Georgetown University Medical Center, Washington, DC 20007 and [1]the National Cancer Institute, Frederick, MD 21702

Cholinergic neurons in both the septum/basal forebrain and neostriatum are responsive to nerve growth factor (NGF) and express *trkA* receptors, the high affinity receptor for NGF. Although PC12 cells have been used extensively to study NGF induced *trkA* phosphorylation and subsequent signal transduction *in vitro*, little is currently known about NGF induced signaling through *trkA* receptors *in vivo*. Thus, the present experiments were designed to evaluate the dose response and time course of NGF induced *trkA* phosphorylation in both the septum/diagonal band (S/DB) and neostriatum (NS) after intraventricular (ICV) injections of NGF in adult rats. ICV injections of NGF exhibit a clear dose response (10ng, 100ng, and 1μg) in the degree of receptor phosphorylation in both the S/DB and NS. Moreover, a single ICV injection of NGF (1 μg/2-4 μl PBS) results in a prolonged receptor activation in the S/DB and NS that can be detected by 30 min., is maximal from 2-12 hrs., and decreases to baseline levels by 24-36 hrs.. To determine whether the dynamics of this response could be altered, multiple ICV injections of NGF were administered. When 3 ICV injections of NGF are administered at 48 hr. intervals, there is a prolonged activation of *trkA* receptors in both the S/DB and NS which lasts for at least 72 hrs. This potentiation of receptor phosphorylation with multiple NGF injections has important implications for the design of possible CNS treatment therapies with neurotrophic factors. Supported by NIH grant NS-31445.

780.4

REDUCTION AND LOSS OF INNER EAR INNERVATION IN *trk*B AND *trk*C RECEPTOR KNOCK OUT MICE. B. Fritzsch*, @A. M. Fagan, #R. Smeyne, and @I. Silos-Santiago Creighton Univ., Omaha, NE 68104, @Bristol-Myers Squibb, Princeton, NJ 08543, and #Roche Inst. Molec. Biol., Nutley, NJ 07110.

The pattern of afferent and efferent innervation of the ear was investigated in embryonic and neonatal, aldehyde fixed mice homozygotic for the *trk*B or *trk*C gene deletions using DiI. $trkB^{-/-}$ mice developed innervation to all sensory epithelia by 12.5 dpc but lost it to the semicircular canals by 13.5 dpc. The utricle and saccule showed a reduction in both afferent and efferent innervation. Efferent innervation to the vestibular region developed delayed and only to areas with an afferent innervation. $trkC^{-/-}$ mice had fewer spiral ganglion cells in the cochlear basal turn. $trkB^{-/-}/trkC^{-/-}$ double knock out mice had no innervation at all by $P0_{+/-}$. Mice homozygotic for $trkB^{-/-}$ and heterozygotic for $trkC^{+/-}$ displayed the $trkB^{-/-}$ vestibular phenotype but showed only a patchy innervation of the cochlea by very few spiral ganglion cells. In contrast, mice heterozygotic for $trkB^{+/-}$ and homozygotic for $trkC^{-/-}$ showed only the phenotype of a simple $trkC^{-/-}$ mutant. These data show that TrkB and TrkC receptors are both necessary and sufficient for otic ganglion cell survival. Supported by NIH (P50 DC00215-09).

780.5

IDENTIFICATION OF A NERVE GROWTH FACTOR RECEPTOR COMPLEX BY BIOPHYSICAL APPROACHES. A.H. Ross*, C.A. McKinnon, M.-C. Daou, R.M. Stephens, D.R. Kaplan and D.E. Wolf. Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545 and NCI-Frederick Cancer Research and Development Center, Gaithersburg, MD 21701.

It has been proposed that the functional high-affinity nerve growth factor receptor is a heterodimer of two proteins gp75 and TrkA. We have obtained direct evidence of the existence of this complex by a combined approach of fluorescence recovery after photobleaching (FRAP), copatching fluorescence confocal microscopy, and site-directed mutagenesis. When gp75 is expressed alone in either mammalian PC12 cells or using baculovirus-infected insect Sf9 cells, it is highly mobile as determined by FRAP. Coexpression with TrkA causes a reduction in the mobile fraction. TrkA immobilization of gp75 is not observed, if the cytoplasmic domain of gp75 is truncated or if TrkA is mutated to inactivate the tyr-kinase domain. Analysis of diffusion coefficients in the presence and absence of NGF suggests that gp75 and TrkA are complexed, even for mutated receptors which do not bind NGF with high-affinity. Direct evidence of gp75-TrkA complex was obtained by copatching studies. It was found that patching of gp75 by crosslinking antibodies resulted in copatching of TrkA. Analysis of mutated receptors by copatching indicates receptor complexes in the absence of high-affinity NGF binding sites. Using chimeric receptors of TrkA and Tor, we determined that the extracellular domain of TrkA is critical for efficient copatching. We suggest that extracellular interactions drive complex formation, but functional high-affinity NGF binding results from a conformational change involving intracellular and extracellular domains of both receptors.

780.6

DIFFERENTIAL DEVELOPMENTAL EXPRESSION OF THE NEUROTROPHIN-3 RECEPTOR (TrkC) ISOFORMS IN THE ENTERIC NERVOUS SYSTEM. **J.D. Lewis, C.J. Davidson, J.K. Davies and L.M. Kaplan.*** Gastrointestinal Unit, Massachusetts General Hospital, Boston, MA 02114.

cDNA cloning studies have suggested the existence of multiple, neurotrophin-3 (NT-3) receptor isoforms encoded by the *trk*C gene. In the rat, alternative splicing of the primary *trk*C transcript generates four "kinase competent" isoforms that encode receptors varying by the presence or absence of 14, 25, or 39 amino acid inserts in the tyrosine kinase domain, respectively (C_0, C_{14}, C_{25}, and C_{39}). Four additional "truncated" TrkC isoforms, with identical extracellular ligand-binding domains, contain unique intracellular sequences in place of the kinase domain (TTC_{108}, TTC_{113}, TTC_{143}, and TTC_{158}). We have developed two reverse transcription polymerase chain reaction (RT-PCR) based strategies to measure specific expression of the various *trk*C isoforms. First, quantitative PCR with an easily detected, competitive mutant construct is used to quantitate total *trk*C expression. Primers flanking the kinase domain splice site competitively amplify the four kinase competent isoforms, allowing measurement of the relative expression of these mRNAs. The second assay employs similar techniques to measure expression of mRNAs encoding the truncated receptors. These studies reveal that C_0 and C_{14} are the predominant kinase competent isoforms and TTC_{158} is the predominant truncated isoform in peripheral tissues and within the gastrointestinal tract. C_{25}, C_{39}, TTC_{108},and TTC_{113} are expressed at lower levels in selected tissues. Isoform expression is strongly regulated during late stages of ENS development with selective increases in the expression of the C_{25}, C_{39} and TTC isoforms. The regulated expression of these functionally distinct isoforms suggests that response to NT-3 is determined by the developmental and physiologic state of the target neuron.

ENHANCED EXPRESSION OF trk B mRNA AND Trk B PROTEIN FOLLOWING FOREBRAIN ISCHEMIA OF RAT BRAIN K.Iihara, T. Tsukahara*, N. Hashimoto, T. Okubo, T. Taniguchi, Dept. of Cerebrovascular Surg., National Cardiovascular Center, Osaka 565; Dept. of Neurobiology, Kyoto Pharmaceutical Univ., Kyoto 606; Japan

We have shown that brain-derived growth factor (BDNF) ameliorates delayed neuronal death in the hippocampus after forebrain ischemia of rat brain. Here, we examined the expression of trk B mRNA and Trk B protein following forebrain ischemia of rat brain. Transient forebrain ischemia was induced on male Wistar rats according to the method reported by Smith et al. Northern blot analysis revealed that ischemia markedly increased the expression of trk B mRNA in the hippocampus with a peak at 4h post ischemia. In situ hybridization revealed that increased mRNA expression in the hippocampus was observed mainly in pyramidal neurons in the CA1 sector and in granular neurons in the dentate gyrus with a peak at 4h. Western blot analysis indicated that the expression of $gp^{145trkB}$ in the hippocampus increased from 30 min to 6h with a peak at 4h post ischemia. Immunohistochemistry disclosed an enhanced immunostaining for trk B protein in pyramidal neurons in the CA1 sector and in granular neurons in the dentate gyrus with a peak at 4h. Thereafter, this increased immunostaining rapidly declined, but was still moderately enhanced at 24h post ischemia. These findings revealed that forebrain ischemia markedly increases the expresssion of trk B at both mRNA and Trk B protein level especially in the hippocampus, suggesting a crucial and local role of BDNF/trk B system in the forebrain ischemia of rat brain.

ZEBRAFISH TRK RECEPTOR EMBRYONIC EXPRESSION AND LIGAND SPECIFICITY. S. C. Martin*[1], M. Hashimoto[1], R. Götz[3], J. H. Sandell[2] and G. Heinrich[1] [1]Section of Biomolecular Medicine, [2]Dept. of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA 02118. [3]Dept. of Neurology, University of Würzburg, Würzburg 97080, Germany.

We have isolated five Trk receptors from the zebrafish (Martin *et al.*, 1995 Dev. Biol., in press). The ligand specificities of these receptors has been investigated by analysis of phosphotyrosine induction in response to the neurotrophins. Each of the human neurotrophins: nerve growth factor (NGF), brain derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3) and NT-4 were tested in this assay with four of the zebrafish Trk receptors. One Trk receptor responded only to human NT-3, another only to BDNF. Experiments are underway to examine the specificity of the other Trk receptors with human and *Xiphophorous* neurotrophins.

The onset of expression of two of the zebrafish Trk receptors was examined by whole mount *in situ* hybridization. The NT-3 responsive Trk receptor was detected by *in situ* hybridization at 24 hours after fertilization in the hindbrain. In some embryos there were a total of six positive cells arranged as two rows of three cells, while in other embryos a total of 10 positive cells were found. The expression of another zebrafish Trk receptor, whose ligand has not been identified, was detected 16 hours after fertilization. A total of approximately 100 positive cells were detected in the cranial ganglia, tail and forebrain. Double labeling techniques, with markers for known cell types, are being used to investigate the identity of the positive cells. The distinct expression pattern and ligand specificities for these zebrafish Trk receptors suggests separate roles in the zebrafish nervous system. (R01-NS22422 to G.H.)

CO-LOCALIZATION OF EPH-RELATED RECEPTOR TYROSINE KINASES AND THEIR LIGANDS IN THE DEVELOPING NERVOUS SYSTEM. J.A. Holash*(1), E. Magal (2), R.A. Lindberg (2), R.J. Toso (2), D. Chang (2), H. Shao (3), V. Dixit (3) and E.B. Pasquale (1). 1) La Jolla Cancer Res. Foundation, La Jolla, CA 92037. 2) AMGEN Inc., Thousand Oaks, CA 91320. 3) Dept. of Pathology, Univ. of Michigan Med. Sch., Ann Arbor, MI 48109.

Members of the Eph-subfamily of receptor-protein tyrosine kinases are highly expressed in developing nervous tissue. This suggests that they are important in regulating the survival and differentiation of neural cells. The identification of ligands for Eph-related receptors is facilitating the investigation of their function. The relevance of receptor-ligand pairs in vivo can be assessed by determining where a receptor and its ligand are co-localized. Hypotheses regarding the receptor-ligand pair function can then be made. We have found, using immunohistochemistry, that Eck and its ligand, B61, are co-expressed in the developing rat spinal cord region. This prompted us to examine the effects of B61 on cultured spinal cord neurons. In these assays, B61, by acting through the receptor Eck, enhances neuronal survival and neurite outgrowth (Lindberg et al., CSH Symposium, 1995). In addition to the spinal cord region, B61 and Eck have overlapping patterns of distribution in the brain, as well as some cranial nerves; therefore, B61 and Eck may be active in a number of other nervous system structures. Interestingly, while the expression of Eck appears to be restricted to neuronal processes, B61 has a more diffuse pattern of expression. Because B61 is a secreted protein, it is possible that its site of production differs from the site where it is ultimately localized. We are currently immunostaining cultured neural cells to determine the cellular origin of B61 in nervous tissue.

We are also comparing the distribution of the Eph-related kinase Cek5, which is expressed in the inner plexiform and ganglion cell layers of the retina, with that of the Cek5 ligand by using both immunohistochemistry and a Cek5-Ig chimera. Our preliminary results indicate that the Cek5 ligand is co-expressed with Cek5 in the embryonic day 11 chicken retina. This suggests that Cek5 and its ligand are likely to function in the development of the visual system.

bFGF AND FGF RECEPTOR ACCUMULATE IN CELL NUCLEUS IN ASSOCIATION WITH CELL PROLIFERATION - NOVEL MECHANISM FOR CELL CYCLE REGULATION. **M.K. Stachowiak, E. Mordechai, A. Joy, K. Neary, R. Fischer*, P. Maher*, R. Florkiewicz*, E.K. Stachowiak.** Barrow Neurol. Inst., Phoenix, AZ 85013,* The Scripps Res. Inst., La Jolla CA 92037.

Sections of human brain stained with bFGF antibodies revealed the presence of bFGF in the nuclei of reactive astrocytes of the epileptic foci and in neoplastic astrocytes of glioma tumors. The mechanisms controlling induction and function of nuclear bFGF were studied in vitro. Confluent human astrocytes were quiescent and did not express nuclear bFGF. Following passage, subconfluent astrocytes re-entered cell cycle and nuclear accumulation of bFGF was observed. Glioma cells expressed nuclear bFGF and proliferated continuously independent of cell density. In an effort to determine how intracellular bFGF exerts its biological effects we discovered high affinity (kd=15 pM) ^{125}I-bFGF binding sites in the isolated nuclei. Western analysis confirmed that FGFR1 is located predominantly in the nuclei and that cytoplasm contains only trace their amounts. Intranuclear localization of FGFR1 was demonstrated by confocal microscopy. In astrocytes, the levels of nuclear FGFR1 are coregulated with bFGF in association with changes in cell density and proliferation. Glioma cells expressed nuclear FGFR1 constitutively. Glioma cell lines refractive to stimulation with exogenous bFGF, proliferated faster in response to intracellularly expressed bFGF. Increased cell proliferation coincided with nuclear accumulation of bFGF and was observed in cells expressing nuclear FGFR1, but not in cells that express only cytoplasmic FGFR1. We propose that transient nuclear accumulation of bFGF and FGFR1 proteins may promote reversible mitotic activation of quiescent human astrocytes. Deregulation of bFGF and FGFR1 expression and constitutively elevated nuclear bFGF and FGFR1 may contribute to the uncontrolled growth of glioma cells (NSF, NIH, APDA).

EXPRESSION AND DISTINCTIVE PHOSPHORYLATION OF THE CEK9 RECEPTOR TYROSINE KINASE IN THE DEVELOPING CHICKEN EMBRYO. Chandrasen Soans, Jocelyn A. Holash, Yelena Pavlova and Elena B. Pasquale*. La Jolla Cancer Research Foundation. 10901 N. Torrey Pines Road, La Jolla, CA 92037

Cek9 is a receptor tyrosine kinase of the Eph subfamily for which only a partial cDNA sequence was known (Sajjadi and Pasquale, 1993). We have obtained the entire cDNA sequence and identified a variant form of Cek9 that lacks a signal peptide. We subsequently examined the spatio-temporal expression and tyrosine phosphorylation of Cek9 during the development of the chicken embryo. Cek9 expression can be detected in many tissues and is particularly prominent in neural tissues like the cerebrum, cerebellum and retina. Immunohistochemistry reveals that Cek9 is concentrated in areas containing neuronal processes, such as the inner plexiform layer and nerve fiber layer of the retina, and the molecular layer of the cerebellum. Unlike other Eph-related kinases, Cek9 is substantially phosphorylated on tyrosine in many embryonic tissues at various developmental stages. Since we have shown that autophosphorylation of Cek9 correlates with increased *in vitro* enzymatic activity, our results suggest that Cek9 plays a role in signal transduction pathways that are active during neural development. Tyr 796, which is located in the catalytic domain of Cek9, corresponds to a tyrosine residue that is highly conserved in both cytoplasmic and receptor tyrosine kinases. The mutation of Tyr 796 to Phe leads to a dramatic reduction in the autophosphorylation of a GST-Cek9 fusion protein expressed in bacteria. Thus, Tyr 796 is important for autophosphorylation activity and/or is the major site of Cek9 autophosphorylation. (This work was supported by NIH grant HD 26351).

INSULIN INHIBITS p38 MITOGEN-ACTIVATED PROTEIN (MAP) KINASE IN CULTURED FETAL NEURONS. J.L. Kummer and K.A. Heidenreich*, Department of Pharmacology, UCHSC, and the Denver VAMC, Denver, CO 80262

The MAP kinase cascade involving Erk1/2 is a major signalling system by which cells transduce extracellular stimuli into intracellular responses. Recently, 2 other MAP kinase cascades, involving JNK/SAPK and p38/RK, have been discovered. Little is known about the regulation of these MAP kinases by neurotrophic factors. In this study, we examined the MAP kinases present in fetal chick forebrain neurons and their regulation by insulin, a potent neurotrophin for these cells. Neuronal cell lysates chromatographed on Mono Q and assayed with myelin basic protein (MBP) showed 3 peaks of protein kinase activity eluting at 30 mM NaCl (Peak 1), 170 mM NaCl (Peak 2), and 420 mM NaCl (Peak 3). Peak 1 contained JNK (assayed with a GST-c-jun fusion protein) and peak 2 contained ERK1/ERK2 (identified with ERK1/ERK2 C-terminal antibodies). Insulin (50 ng/ml, 15 min) had no significant effect on JNK or ERK1/ERK2 activities but markedly inhibited the 3rd peak of kinase activity by 80-90%. Analysis of Peak 3 by MBP-impregnated gel assays revealed a 38 kDa kinase. Like other MAP kinases, the p38 MAP kinase bound to phenyl-sepharose. However, the p38 MAP kinase was distinct from ERK1/ERK2 and JNK since it had a lower molecular weight, eluted at higher salt concentrations, and had distinct substrate specificity. p38 did not significantly phosphorylate the EGF receptor peptide or GST-c-jun, but was highly active in phosphorylating the transcription factor ATF-2. These characteristics are typical of the p38/RK kinases. In summary, insulin had no significant effect on JNK or ERK1/ERK2 MAP kinases in fetal neurons, but markedly inhibited p38 MAP kinase in these cells. Since p38 has been linked to cell apoptosis, the inhibition of this kinase by insulin may represent a mechanism by which insulin increases neuronal survival.

MEMBRANE-DELIMITED MODULATION OF NMDA RECEPTOR CHANNELS BY METABOTROPIC GLUTAMATE RECEPTORS VIA PERTUSIS TOXIN-INSENSITIVE G PROTEINS ON MOUSE CORTICAL NEURONS. S.P. Yu*, D.M. Turetsky and D.W. Choi. Department of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Med., St. Louis, MO 63110.

The excitatory neurotransmitter glutamate activates both ionotropic and metabotropic receptors (mGluRs). mGluR activation modulates many neuronal mechanisms, including the behavior of ionotropic NMDA or AMPA/kainate receptors, usually by inducing changes in the levels of the second messengers, IP_3 or cAMP. Using whole cell and single channel recordings, we studied the modulation of NMDA receptor channels by mGluRs on mouse cortical neurons. The mGluR agonists 1S-3R-ACPD (200 μM), L-CCG-I (100 μM), (S)-3-hydroxyphenylglycine (3HPG, 100 μM) and (S)-4-carboxy-3-hydroxyphenyl-glycine (4C3HPG, 100 μM) attenuated NMDA-induced whole cell current by 20-30%. However, bath-applied 3HPG (mGluR 1/5 agonist) and 4C3HPG (mGluR 2/3 agonist) showed no effect on NMDA single channel activity in cell-attached recordings. In isolated outside-out patches, 20-100 μM 3HPG but not 4C3HPG decreased the open probability (P_{open}) of NMDA receptor channels. This modulation was blocked by the mGluR antagonist, (R,S)-α-methyl-4-carboxyphenylglycine (MCPG, 500 μM), as well as $GDP_\beta S$ (200 μM), but not by pertusis toxin (PTX, 0.2mg/ml for 20-24 h). 3HPG itself is unlikely a NMDA receptor antagonist since, in HEK 293 cells lacking endogenous mGluRs, it did not affect single channel currents mediated by cloned NMDAR1/2A receptors. Present results thus provide novel evidence that mGluR 1/5 may interact locally with NMDA receptors via PTX-insensitive G proteins, without the involvement of readily diffusible messengers. This modulation may have important implication for synaptic plasticity or neurotoxicity.

DETERMINATION OF SUBUNIT COPY NUMBER OF RECOMBINANT NMDA RECEPTORS. P.Stern[2], P.Behe[2], M.Nassar[1], D.Wyllie[2], D. Colquhoun[2] and R.Schoepfer*[1,2] Laboratory for Molecular Pharmacology[1] and Dept. Pharmacology[2], University College London, WC 1E 6BT, UK.

Coexpression of wild-type and mutant subunits has been used to determine stoichiometry of neuronal nicotinic acetylcholine receptors, potassium channels and other multisubunit proteins.

We have explored whether mutant NMDA receptor subunit cDNAs expressed in *Xenopus* oocytes results in glutamate-gated channels with significantly altered single channel conductances. Coexpression of mutant N598R NR1 subunits together with wild-type NR2A subunits ($NR1^{mut}/NR2A^{wt}$) resulted in channels showing a main conductance of 2.6pS and a sublevel of 1.2pS (number of patches n=4). These are clearly distinct from the $NR1^{wt}/NR2A^{wt}$ channels which show a main conductance of 53.5pS with a sublevel of 42.3pS (n=3). Single channel conductances were determined by simultaneous least-squares fitting of the duration and amplitude of individual openings with a convolved step-response function.

Coexpression of $NR1^{mut}/NR1^{wt}/NR2A^{wt}$ subunits resulted in channels showing conductances of 15.2pS and 11.4pS (n=5) in addition to the ones found in $NR1^{wt}/NR2A^{wt}$ and $NR1^{mut}/NR2A^{wt}$ channels. These two conductances are linked by frequent direct transitions which suggests that they originate from the same channel type. This result indicates that there are at least two copies of the NR1 subunit present in one NMDA receptor molecule,

This approach to the determination of NMDA receptor stoichiometry is complicated by the need to measure very small conductances, as well as by the presence of subconductances.

ARE IONOTROPIC GLUTAMATE RECEPTORS PENTAMERIC ASSEMBLIES? A.V. Ferrer-Montiel* and M. Montal. Dept. Biology. Univ. California San Diego. La Jolla. CA 92093.

Ionotropic glutamate receptors (iGluRs) are neurotransmitter-activated ion channels that mediate excitatory synaptic transmission in the CNS. These membrane receptors are composed of multiple subunits organized around a central pore. Their subunit stoichiometry remains elusive. In analogy to the nicotinic acetylcholine receptor (AChR), the prototype of ligand-gated ion channel, iGluRs are considered to be pentamers. Recent data, however, suggest that iGluRs and AChRs may have different protein topologies. This raises the question: are iGluRs pentameric assemblies? To address this issue we used a functional assay[1] based on the differential sensitivity of two GluR1 mutant receptor subunits to open channel blockers such as PCP and MK-801. Coinjection into *Xenopus* oocytes of weakly-sensitive subunits with highly-sensitive mutant subunits produced functional receptor channels with mixed drug sensitivities. Augmenting the fraction of the sensitive subunit in the mixture increases the affinity of the complex for the channel blockers. Assuming that both classes of mutant subunits aggregate randomly, the subunit stoichiometry of GluR1 was determined to be pentameric. This finding that iGluRs are pentamers is compatible with a conserved subunit stoichiometry for the members of the ligand-gated ion channel superfamily.

DETERMINATION OF GLYCINE BINDING SITES IN THE M3-M4 LINKER OF THE NMDA RECEPTOR NR1 SUBUNIT. M.W. Wood, H.M.A. VanDongen, and A.M.J. VanDongen*. Dept. of Pharmacology, Duke Univ, Durham, NC 27710.

Initial topology models for ligand gated ion channels included four putative transmembrane domains (M1-M4). The ionotropic glutamate receptors are a subfamily of these channels for which the four transmembrane domain model has recently been rejected. NMDA receptors are a glutamate receptor subtype comprised of two subunits (NR1 and NR2). By manipulating N-glycosylation sites in the NR1 subunit, we have localized the extreme portions of the M3-M4 linker to the extracellular space. Introduction of a novel glycosylation site immediately past M3 resulted in a functional channel displaying a fractional response to glutamate, containing only contaminating amounts of the coagonist glycine. Attempts to map the M3-M4 linker region in other glutamate receptors have resulted in non-functional mutants. Despite the inability to functionally verify proper protein folding, it has been concluded that the entire M3-M4 linker exists in the extracellular space. Inconsistent with this conclusion however, is the prior determination of a functional PKA phosphorylation site in the M3-M4 linker of GluR6. In order to test for the possibility of an intracellular region within the M3-M4 linker, we introduced a canonical PKA phosphorylation consensus sequence (RRASL) into the NR1 subunit. This mutation reduced the apparent affinity for glycine by more than two orders of magnitude without affecting the apparent affinity for glutamate. The IC50 for the competitive glycine antagonist, 5,7-dichlorokynurenate (DCK) measured at the EC50 for glycine was not affected. Individual point mutations at two component residues included within the introduced PKA consensus sequence (R_1 and L) each confer a reduction of glycine affinity over an order of magnitude. Taken together, the data suggest that we have localized residues that contribute to the glycine binding site. We have now mapped both extremes as well as a central region of the M3-M4 linker in the NMDA receptor NR1 subunit to the extracellular space using functional mutations.

KAINATE RECEPTOR SUBUNITS EXPRESSED IN SINGLE CULTURED HIPPOCAMPAL NEURONS: MOLECULAR AND FUNCTIONAL VARIANTS BY RNA EDITING. J. Rossier*, D. Ruano, B. Lambolez, A. V. Paternain and Juan Lerma. C.N.R.S. 91198, Gif-sur-Yvette, France. C.S.I.C. 28002, Madrid, Spain.

Five subunits, GluR5, GluR6, GluR7, KA-1 and KA-2, belonging to the ionotropic glutamate receptors of the kainate type have been cloned. Glutamate receptors that are activated by kainate, showing a rapidly desensitizing response, but not by AMPA, have been described in cultured hippocampal neurons. To determine the kainate receptor subunits which take part of native kainate receptors, we have applied a multiplex polymerase chain reaction of cDNAs reverse transcribed from mRNA harvested from single cultured hippocampal neurons after electrophysiological recording. We found that all the cells showing rapidly desensitizing currents in response to kainate express the GluR6 subunit mRNA and that some of them also express the GluR5 subunit mRNA. No GluR7, KA-1 or KA-2 subunit mRNAs were detected. Analysis of the editing sites of the GluR6 mRNA demonstrated that the three editing sites present in these subunits are edited to a different extent, and suggested that the Q/R site from the GluR6 subunit controls functional properties of native kainate receptors, similar to recombinantly expressed homomeric GluR6 receptors.

VISUALIZATION OF GLUTAMATE-GATED CHANNEL PERMEATION: HIGH RESOLUTION MAPPING OF NEURONAL SUBPOPULATIONS. R. E. Marc*, Moran Eye Center, University of Utah, Salt Lake City, UT 84132

Virtually all retinal neurons possess glutamate (Glu) receptors but the partitioning of AMPA/kainate (AMPA/KA) and NMDA subtypes is known for but a few of over 50 known cell types. Most Glu-gated cation channels are permeable to guanidinium$^+$ derivatives, including 4-aminoguanidobutane (AGB), and Glu-gated AGB accumulation can be visualized by anti-AGB IgGs. **Objective:** Map Glu-gated AGB permeation in all retinal neurons. **Methods:** Isolated goldfish retinas were challenged 15' *in vitro* with Glu agonists / antagonists and 25 mM AGB substituted for Na^+, then analyzed with multispectral protocols for deriving quantitative amino acid and AGB immunoreactivities. **Results:** All horizontal cell types, all identifiable OFF center bipolar cells (BCs), half of all GABAergic amacrine cells (ACs) and all but one glycinergic AC type demonstrated graded, CNQX-blocked AGB permeation gated by KA (5-125 µM) but no detectable signal after NMDA (3-3000 µM) exposure with or without Mg^{+2}. In particular, the unique cholinergic/GABAergic AC cohorts responded to AMPA/KA agonists alone. ON center BCs and solitary population of glycinergic ACs possess neither AMPA/kA- nor NMDA-gated responses. A large subset of GABAergic ACs displayed strong responses to both KA and NMDA.NMDA responses were blocked by AP-7 and MK-801. Most ganglion cells appear to bear both types of receptors although a small set seems driven exclusively by AMPA/KA systems. **Conclusions:** AGB permeation is a powerful tool for partitioning the Glu-gated responses of complex neuron populations. There are three forms of Glu-gated activation in retinal neurons: (1) Pure AMPA\KA systems; (2) Dual NMDA and AMPA/KA systems; (3) Those with neither. **Support:** NIH EY02576 and a Jules and Doris Stein Research to Prevent Blindness Professorship.

TRANSIENT AND PERSISTENT PHOSPHORYLATIONS OF AMPA-TYPE GLUTAMATE RECEPTOR SUBUNITS IN CEREBELLAR PURKINJE CELLS. K. Nakazawa[1*], S. Mikawa[2], T. Hashikawa[2], & M. Ito[1]. Lab. for [1]Synaptic Function and [2]Neural Systems, Frontier Res. Prgm., The Inst. of Phys. and Chem. Res.(RIKEN), Saitama 351-01, Japan.

Ionotropic glutamate receptor (GluR) phosphorylation is postulated to play a role in receptor desensitization and long-term synaptic plasticity such as long-term potentiation (LTP) and long-term depression (LTD). To investigate the relationship of AMPA receptor phosphorylation with synaptic plasticity, we generated two kinds of antibodies against a phosphorylated peptide containing Ser-662 (that is a monoclonal antibody named **9PM**) or Ser-696 (a polyclonal antibody named **12P3**) of rat GluR2. Immunoblot analyses showed that both antibodies recognized subpopulations of cerebellar AMPA receptor subunits, which were phosphorylated. 12P3-immunocytochemistry revealed that a brief exposure of a rat cerebellar slice to AMPA leads to transient phosphorylation of the AMPA receptor subunits in Purkinje cell dendrites, providing evidence of activity-dependent receptor phosphorylation in a cell-type specific manner. An immuno-electronmicroscopic analysis showed that postsynaptic AMPA receptors at parallel fiber-Purkinje cell synapses were phosphorylated following AMPA application. Furthermore, persistent phosphorylation over 30 min was obtained when the exposure to AMPA was preceded by a 15 min perfusion of the slice with 8-bromo-cGMP, dibutyryl-cGMP or calyculin A, the stimuli causing long-term desensitization of Purkinje cell AMPA receptors. In contrast, marked 9PM-IR was observed in Bergmann glial cells regardless of stimuli causing LTD. These findings support the view that phosphorylation of GluR channels is of critical importance in the regulation of synaptic efficacy. Although our present results are inconsistent with three transmembrane model of GluR, our intracellular receptor phosphorylation might be explained if GluR membrane topology is different in a cell-type and/or subunit specific manner. Alternatively, it may be changed dynamically according to synaptic activity.

SINGLE-CHANNEL ANALYSIS OF A HIGH AFFINITY Ca^{++} AND Mg^{++} BINDING SITE IN THE PORE OF WILD TYPE AND MUTANT RECOMBINANT NMDA RECEPTORS. A. Auerbach* and L. Premkumar, Dept. Biophysics, SUNY at Buffalo, Buffalo NY 14214.

Residues at the 'QRN'site within the pore of glutamate receptors influence Ca^{++} permeability and Mg^{++} block. Mouse NMDAR ζ1 and ε2 subunits bearing either an N (wild type) or a Q at this position were expressed in oocytes and single-channel currents were recorded from outside-out patches. In the absence of Ca^{++}(1.5 mM EGTA) currents from receptors with a Q at the QRN site in both subunits (QQ) had both a main and a sublevel with conductances of 95 and 62 pS, respectively. NN receptors had a single main level with a conductance of 86 pS. These levels were differentially sensitive to Ca^{++}. The QQ sublevel conductance was reduced by 57 pS (Kd= 5 µM) and the QQ main level was reduced by 80 pS (Kd=205 µM). The NN main level conductance was biphasic with reductions in conductance of 17 pS (Kd=1.1 µM) and 32 pS (Kd=506 µM). For all forms of pore there was a residual conductance not blocked by Ca^{++} and carried by Na^+ (5,15, and 37 pS, respectively) suggesting that Na^+ can still permeate when Ca^{++} is bound. The QQ sub- and main levels were also differentially sensitive to Mg^{++}, with apparent Kds of 26 and 90 µM. Rate constants were obtained by analyses of QQ sublevel noise spectra and I/V curves. Ca^{++} binds to a site that is ~0.2 through the field (from the extracellular side) at a rate (-80 mV) of ~$4x10^9 M^{-1}s^{-1}$, unbinds at 4400 s^{-1}, and permeates at 17500 s^{-1}. Similar analyses indicate that Mg^{++} binds to a site that is ~0.28 through the field at ~$0.8x10^9 M^{-1}s^{-1}$, unbinds at 17500 s^{-1}, and permeates at 6200 s^{-1}. We conclude that the QRN site binds divalent cations with high affinity and at a high rate and defines a region near the mouth of the pore that does not require single file ion transport. Selectivity of Ca^{++} over Mg^{++} mainly arises from a higher permeation-to-unbinding ratio *(supported by NSF:IBN 9102232 BIR9403225).*

COEXPRESSION OF KA2 ALTERS THE PROPERTIES OF HOMOMERIC GLUR6 ION CHANNELS. J.R. Howe*. Department of Pharmacology, Yale University School of Medicine, New Haven, CT 065210-8066.

Patch-clamp techniques were used to compare the properties of homomeric and heterodimeric kainate-type ion channels. HEK 293 cells were stably transfected with the fully edited (VCR) version of the glutamate-receptor (GluR) subunit GluR6 or with GluR6 and the GluR subunit KA2. Steady-state currents were measured in cells pretreated with concanavalin A to remove desensitization.

As first shown by Herb *et al.* (Neuron 8: 775-785, 1992), cells co-transfected with cDNAs encoding the GluR6 and KA2 subunits responded to AMPA (0.2 to 1 mM), whereas cells transfected with GluR6 alone did not. Coexpression of KA2 also decreased the apparent affinity of kainate; the mean (±s.e.m.) EC_{50} values for kainate were 0.47 (±0.11) µM and 1.64 (±0.29) µM, respectively, in cells expressing GluR6 alone and cells co-transfected with GluR6 and KA2 (n = 7 and 4 cells). Hill coefficient (n_H) values also differed; the mean n_H value obtained from cells expressing GluR6 alone was 1.47 (±0.11) and the mean n_H value obtained from the GluR6/KA2 cells was 0.88 (±0.13). Agonist-evoked current noise was analyzed to estimate the unitary conductance (γnoise) of each type of recombinant channel. Spectral density analysis gave a mean γnoise value of 215 (±15) fS for cells expressing GluR6 alone (16 spectra from 14 cells), whereas the mean γnoise value obtained from GluR6/KA2 cells was 582 (±24) fS (16 spectra from 10 cells). The results suggest that homomeric GluR6 channels differ from heterodimeric channels formed from GluR6 and KA2 subunits both in their affinity for agonists and in their unitary conductance. (Supported by NS 30996).

EVANS BLUE SLOWS DESENSITIZATION AND INHIBITS GLUR6-MEDIATED CURRENTS IN TRANSFECTED HEK-293 CELLS. L. A. Raymond*. Dept. of Psych., U. of British Columbia, Vancouver, B.C.

The molecular cloning of several different glutamate receptor subunits has facilitated study of their structure, function, and modulation, and necessitated the development of subunit-specific antagonists in order to define the subunit composition of native neuronal receptors. Evans blue, a biphenyl derivative of 1,3-naphthalene disulfonic acid, was reported to selectively block kainate (KA)-evoked currents mediated by AMPA receptor subunits GluR1 and GluR2, but not by GluR3 or the KA-type subunit GluR6 (Keller et al., 1993). In that study in *Xenopus* oocytes, desensitization of GluR6-mediated currents was eliminated by treatment with the lectin concanavalin A (con A, 10 µM). In contrast to these results, we have found that Evans blue *does* block current through GluR6 receptors expressed in human embryonic kidney 293 (HEK-293) cells in the absence of con A. In GluR6-transfected cells, 1 µM Evans blue produced 91 ± 2 % (n=5) inhibition of the GLU or KA-gated current. Analysis of the remaining current revealed that desensitizaiton was slowed, with an increase in the decay constant (τ_D) from 7.8 ± 1.5 to 20.8 ± 4.8 msec (n=5). In agreement with the results of Keller et al. (1993), the inhibition of GluR6-mediated current by Evans blue was eliminated by pretreating the cells with 5 µM con A (which completely eliminated desensitization). Our results suggest that Evans blue may interact with more than one region of the ion channel (eg., ligand binding and desensitization domains). Furthermore, under the appropriate conditions (treatment with con A), Evans blue may prove a useful tool for differentiating neuronal AMPA and KA receptors.

EVIDENCE FOR MULTIPLE AMPA RECEPTOR COMPLEXES IN PYRAMIDAL NEURONS OF THE CA1/CA2 REGIONS OF THE HIPPOCAMPUS. R.J. Wenthold, A.S. Niedzielski*, J. Blahos and R.S. Petralia, Laboratory of Neurochemistry, NIDCD, NIH, Bethesda, MD 20892.

The four AMPA receptor subunits, GluR1-4, can form functional homomeric or heteromeric receptor complexes when expressed *in vitro*. Based on their physiological properties, it is thought that receptor complexes in neurons are heteromeric, comprised of two or more different subunits. While most neurons express multiple AMPA receptor subunits, it has not been determined if the complexes formed in any one neuron are of one type, or if the neuron is capable of forming multiple complexes which differ in their subunit compositions, and therefore, their functional properties. Hippocampal CA1/CA2 pyramidal neurons are an ideal model system for studying the composition of AMPA receptors in a neuronal population. These neurons are relatively homogenous in their functional properties and their abundant expression of GluR1, 2 &3, and a relatively pure preparation of the cell bodies and their dendrites can be obtained by dissection. Receptors were solubilized with Triton X-100. Western blots confirmed abundant GluR1, 2 &3 and low amounts of GluR4. Immunoprecipitation (IP) with anti-GluR2/3 antibodies, eliminated GluR2/3 staining on western blots, and reduced GluR1 staining to about 20% of control. To determine if this remaining GluR1 staining is due to functional receptors or disrupted or denatured complexes, ^{3}H-AMPA binding was done. IP with anti-GluR2/3 antibodies reduced binding to about 12% of controls; this could be reduced to about 3% by further IP with anti-GluR1 antibodies. This confirms the western blot data and suggests that about 10% of the ^{3}H-AMPA binding in this preparation is attributable to homomeric GluR1 receptors. IP of the solubilized preparation with anti-GluR1 antibodies eliminated GluR1 staining but reduced GluR2/3 staining only 50%. These results suggest two major populations of AMPA receptors are present in CA1/CA2 neurons, those made up of GluR1/GluR2 and those made up of GluR2 /GluR3. A population of homomeric GluR1 is also present.

781.12

DIFFERENTIATION OF GLIAL O-2A PROGENITORS REDUCES THE SENSITIVITY OF AMPA RECEPTORS TO BLOCK BY JORO SPIDER TOXIN Olimpia Meucci*, James A. Holzwarth, Alessandro Fatatis and Richard J. Miller Dept. of Pharmacol. and Physiol. Sciences, The University of Chicago, Chicago 60637 (IL).

We studied the properties of kainate-induced Ca^{2+} and Na^+ fluxes in cortical O-2A progenitor cells either before or after their differentiation into type II astrocytes. The experiments were performed using both O-2A primary cultures from rat cortex and the glial cell line CG-4 (which shares morphological and antigenic properties with O-2A progenitors and can differentiate in type II astrocytes or oligodendrocytes). Fura-2 based videoimaging and simultaneous monitoring of Ca^{2+} and Na^+ entry using microfluorimetry and whole-cell recording under voltage-clamp conditions were performed. The addition of kainate to undifferentiated or differentiated cells elicited inward Na^+ currents and large $[Ca^{2+}]i$ increases which were completely abolished by removal of extracellular Ca^{2+}, indicating the presence of Ca^{2+} permeable. Cyclothiazide, but not Con A, potentiated the effect of kainate or AMPA while GYKI 53655 prevented kainate-evoked Ca^{2+} and Na^+ fluxes, indicating the primary involvement of AMPA receptors. We examined the effect of Joro spider toxin (JSTx) and Argiotoxin 636, which only block AMPA receptors that lack GluR2(R). While these toxins were able to block kainate induced Na^+ currents and Ca^{2+} fluxes in the O-2A progenitors in a dose-dependent fashion, they were ineffective in differentiated cells. By testing the effect of JSTx during differentiation we observed a gradual increase of the number of cells insensitive to the toxin block which correlated perfectly with the expression of antigenic markers of differentiation. Thus, AMPA receptors in O-2A progenitors and type II astrocytes both flux Ca^{2+} efficiently but differ greatly in their sensitivity to spider toxins. This may indicate a change in the relative contribution of GluR2(R) subunits to individual AMPA receptors. (O.M. supported by ARIN)

INSULIN POTENTIATION OF NMDA RECEPTOR CURRENTS IN *Xenopus* OOCYTES: EFFECTS OF TYROSINE KINASES. S.J. Chen and J.P. Leonard* Department of Biological Sciences, University of Illinois at Chicago, Chicago, IL 60607.

Insulin receptors are present in mammalian brains as well as in *Xenopus* oocytes. As little as 80 nM insulin for 10 min potentiated the NMDA-activated currents on expression of heteromeric (ζ1/ϵ4) receptors in *Xenopus* oocytes. A 10X higher concentration of 0.8 μM insulin potentiated to 157% of control (157 ± 5% , n=37) reaching a maximum at 30 min. To test whether insulin potentiation was due to activation of tyrosine kinases, oocytes pre-treated for 30 min with 0.8 μM insulin were incubated in 100 μM genistein, an inhibitor of many tyrosine kinases. The insulin potentiation was reversed by genistein, but not by 100 μM daidzein, the inactive analog of genistein. We also injected exogenous tyrosine kinase pp60$^{c\text{-}src}$ into *Xenopus* oocytes expressing ζ1/ϵ4 receptors and found pp60$^{c\text{-}src}$ could potentiate NMDA receptor currents also (to 140 ± 7%, n=12). Both types of evidence indicated that tyrosine kinases were involved in potentiation of heteromeric NMDA receptor. Genistein also could inhibit the NMDA-activated currents in oocytes (to 81 ± 3% of control, n=4) in 30 min without insulin treatment. This suggests that there is basal tyrosine kinase activity in oocytes and that insulin stimulates this tyrosine kinase activity to potentiate NMDA receptor currents.

SYNAPTOPHYSIN-IMMUNOREACTIVE INNERVATION IN THE RAT PITUITARY: MODULATION WITH AGING. L.C. Saland*, D. Ramirez and A. Apodaca, Dept. of Anatomy, Univ. of New Mexico Sch. Med.,Albuquerque, NM 87131

Synaptophysin (SN) is a glycoprotein found in vesicles of mature synapses, and is considered a marker for the presence of synaptic terminals. The pituitary gland of mammals is innervated by nerve fibers of hypothalamic origin which enter both the neural (NL) and intermediate (IL) lobes, with some studies showing anterior (AL) lobe innervation. Previous studies have shown reduced tyrosine hydroxylase and GAP-43 immunoreactive (IR) innervation in the aging pituitary. We examined the glands of younger and aged rats for SN-IR to determine if relative numbers of synaptic terminals are altered with aging. Adult male Sprague-Dawley rats, ages 8, 13 and 15-17 months were halothane anesthetized, perfused intracardially with buffered paraformaldehyde, and paraffin sections of pituitary tissue were immunostained for SN, using a monoclonal antibody (dilution 1:50) from Boehringer-Mannheim. Fine, punctate staining surrounded endocrine cells in the IL, with dense staining in the NL. No stained terminals were observed in the AL. The oldest rats exhibited a reduced staining pattern in the IL when compared to younger groups, suggestive of loss of mature synapses with advancing age. Supported by NIH NS21256, GM08139.

EVIDENCE FOR AXONAL SPROUTING IN THE ANTERIOR PITUITARY FOLLOWING ADRENALECTOMY IN THE RAT. G. Ju*, C.R. Lu, F.T. Meng, L.I. Benowitz. Department of Neuromorphology, Institute of Neurosciences, The Fourth Military Medical University, Xi'an, 710032 PR China and Laboratory for Neuroscience, Children's Hospital, Harvard Medical School, Boston, MA 02115, USA.

Our previous studies have demonstrated the presence of substantial amounts of peptidergic nerve fibers in the anterior pituitary of several mammalian species, including the rat. They were found to make synaptic contacts with the gland cells, indicating a direct neural regulation of this gland. Furthermore, the number of the calcitonin gene-related peptide-like immunoreactive (LI) nerve fibers in the anterior pituitary was found to increase significantly 4 days following adrenalectomy in the rat, implying an active response to changes of the hormonal levels of the animal. The present study aimed to investigate whether axonal sprouting could account for this increase. Twelve young adult male Sprague-Dawley rats (180 - 200g) were used. Six were used as normal control and 6 with bilateral adrenalectomy. Antibody against GAP-43 was used as the probe. In the normal controls a number of GAP-43-LI fascicles could be seen. Also present were individual varicose fibers. They were distributed mainly among the gland cells, although some could be found along the blood vessels. Four days following adrenalectomy there was a great enhancement of GAP-43 immunoreactivity in the anterior pituitary. Particularly striking was the dramatic increase in the immunoreactivity around the gland cells. Large numbers of GAP-43-LI varicosities of different sizes, many fairly thick, could be seen to gather around clusters of the gland cells, seemingly in close contact with them. The results imply an active axonal sprouting following this hormone manipulation and strongly support our hypothesis of neural-humoral dual regulation of the mammalian anterior pituitary.

782.3

POPULATION ANALYSIS OF SECRETORY RESPONSES FROM INDIVIDUAL RAT SOMATOTROPES DURING GHRP-6 POTENTIATED GH SECRETION. D.A. Leong, R.G. Smith, and M.D. Leibowitz*. Univ. Virginia, Charlottesville, VA 22908, and Merck Research Labs, Rahway, NJ 07065.

Hormone-stimulated secretory responses are intrinsically mediated by single cells. We have studied the population dynamics of individual cell responses under various conditions of growth hormone (GH) secretion. Using the quantitative reverse hemolytic plaque assay, GH release *in vitro* was measured from acutely isolated, single rat anterior pituitary cells over periods of 15-90 minutes. During this time, under basal conditions there was a cumulative increase in the number of plaques formed by GH secreting cells, without an increase in the area of individual plaques (suggesting that basal GH release is a stochastic process with only some cells active at any time). Either GHRP-6 or GRF produced dose-dependent increases in the number of secreting cells, again without detectable changes in magnitude. Failure to observe changes in the magnitude of individual responses strongly suggests that cell activation is followed by inactivation. At 15 minutes, maximal concentrations of GHRP-6 and GRF were not additive, while simultaneous application of both hormones at concentrations that produced little or no effect alone produced maximum secretion. Treatment with a cell-permeant analog of cAMP produced a dose-dependent increase in the number of GH plaques. The combination of maximal concentrations of GHRP-6 and cAMP was not additive, while submaximal concentrations of GHRP-6 and cAMP failed to potentiate the number of GH releasing cells, in contrast to the combination of GHRP-6 and GRF. Since GRF activates adenylyl cyclase this observation is striking. These data suggest that GHRP potentiates the number of GRF-induced cell responses at a step prior to cAMP production. Our findings indicate that GH release is a stochastic process at the level of individual cell responses and that hormones control the overall number of responding GH cells by acting at an early step in the intracellular signaling pathway.

782.4

GLUCOCORTICOID REGULATION OF PITUITARY GH-RELEASING HORMONE RECEPTOR EXPRESSION. O. Pinhas-Hamiel, P.J. Stevens, and P. Zeitler*. Div of Endocrinology, Child. Hosp. Res. Found. Cincinnati, OH 45229.

The effect of glucocorticoids (GC) on the GH secretory axis is complex. While GC is required for basal function of the axis, chronic GC excess *in vivo* inhibits GH secretion. The mechanism of this inhibition is unknown. Among other actions, GC excess results in blunting of the GH secretory response to GH-releasing hormone (GHRH), the primary hypothalamic regulator of GH synthesis and secretion. We tested the hypothesis that GC excess results in a down regulation of the pituitary receptor for GHRH. **METHODS**: Adult male Sprague-Dawley rats (n=6) were treated daily for 8 days with either the synthetic glucocorticoid dexamethasone (DEXA, 40μg/day) or vehicle. Pituitary GHRH receptor mRNA was quantitated by ribonuclease protection assay using an antisense ^{32}P-labeled cRNA probe specific for the 3'-coding region of rat GHRH receptor (a gift of K. Mayo, Northwestern Univ.). Pituitary GH mRNA was quantitated following northern hybridization. **RESULTS**: Chronic treatment of rats with DEXA resulted in 68% decrease in pituitary GHRH receptor mRNA (52±21 vs 17±8 AU/pit, p<0.01). In addition, DEXA treatment resulted in a 36% decrease in pituitary GH mRNA (26±4 vs 16±1, p<0.05). **CONCLUSIONS**: Chronic GC excess results in decreased pituitary GHRH receptor mRNA content. Decreased receptor synthesis may account, at least in part, for the observed blunting of response to GHRH. GHRH is an important physiologic regulator of GH gene expression *in vivo*. Although GC directly induces pituitary GH gene expression *in vitro*, the down-regulation of the GHRH receptor may account for the observed decrease in pituitary GH mRNA content.

CALCIUM SIGNALLING IN NORMAL LACTOTROPES. K.Gregerson* M.Y. Ho, J.P.Y. Kao. Dept. Pediatrics, UMAB, Baltimore, MD 21201.

Intracellular [Ca^{2+}] is an important regulator of prolactin release. However, it is not known how frequency and/or amplitude of $[Ca^{2+}]_i$ fluctuations encode signalling information in lactotropes. Population responses may obscure an underlying complexity in single cells. Using fura-2, we monitored $[Ca^{2+}]_i$ in single lactotropes isolated from proestrous female rats. As previously reported, unchallenged lactotropes fell into two functionally distinct groups: those with stable $[Ca^{2+}]_i$ which was not acutely sensitive to extracellular Ca^{2+}; and those with spontaneous fluctuations in $[Ca^{2+}]_i$ which were dependent upon influx of external Ca^{2+}. There was striking variability in the $[Ca^{2+}]_i$ patterns of the latter group, ranging from irregular, noisy fluctuations to rhythmic, repetitive oscillations with characteristic rise and decay kinetics. Quiescent cells could be activated to produce $[Ca^{2+}]_i$ fluctuations by the application *and withdrawal* of 100nM dopamine. Again, the character of the induced $[Ca^{2+}]_i$ activity showed tremendous cell-to-cell variation. In contrast, in any given cell, the pattern of $[Ca^{2+}]_i$ fluctuations was remarkably characteristic in reponse to repeated challenges. The interplay of multiple mechanisms (influx, buffering, sequestration, extrusion) determine $[Ca^{2+}]_i$ patterns and may be utilized differently among functionally diverse subpopulations of lactotropes. Modulation of Ca^{2+} handling could alter the relative proportion of lactotrope subpopulations and thereby be an important mechanism in the regulation of prolactin release in varying physiological states.

Cfos/*cjun* PROTOONCOGENES MEDIATE GLUCOCORTICOID STIMULATION OF TRH GENE EXPRESSION IN HYPOTHALAMIC NEURONS. L-G Luo* and I.M.D. Jackson Division of Endocrinology, Rhode Island Hospital, Brown University School of Medicine, Providence, RI 02903.

In fetal diencephalic cell cultures, we have shown that TRH mRNA is colocalized with the *cfos*/*cjun* mRNAs and that the expression of all 3 genes is enhanced following exposure to glucocorticoids(Luo and Jackson Prog 24th Ann. Meet. Soc. for Neurosci.,1994). In order to determine whether *cfos*/*cjun* mediated glucocorticoid stimulation of TRH gene expression, we studied the effect of antisense oligonucleotides directed against the first 18 bases of *cfos* and *cjun* mRNAs following the start codon sequence. To enhance stability phosphorothioate derivatived oligonucleotides were used. After preincubation for ten days, hypothalamic neurons in monolayer culture were exposed to 10 *um* antisense oligos of *cfos* and *cjun*, both individually and together, for 24 hours, after which dexamethasone (Dex 10^{-8}M) was added to the culture medium for an additional three days. The corresponding sense oligomers were used as controls. The cell TRH peptide content was assayed by RIA, and TRH mRNA was determined by *in situ* hybridization. The cell mean intensity was analyzed by an image analysis system and expressed in arbitrary units(au). Dex enhanced TRH peptide content 1.7 - 2.3 fold compared with control (262+/-16*vs* 153+/-8 fmol/well; p<0.01) and TRH mRNA levels 1.9 - 2.6 fold (31.2+/-2.1 *vs* 15.3+/-1.1 au; p<0.01). The addition of antisense *fos* or antisense *jun* individually did not affect the capacity of Dex to increase TRH peptide or mRNA levels. However, *cfos*/*cjun* antisense oligomers, when added together, completely prevented any Dex increase in the levels of either TRH peptide (124+/-7 fmol/well) or mRNA (14.89+/-0.82 au) *vs.* Dex treated group(p<0.01).*cfos*/*cjun* antisense oligomers did not alter the unstimulated TRH peptide level. These results are similar to our findings with TRH in anterior pituitary cells (Luo & Jackson, Program 77th Annual Meeting of The Endocrine Society, Washington DC., 1995). We conclude that *cfos* and *cjun* are involved in mediating glucocorticoid stimulation of TRH gene expression in fetal rat hypothalamic neurons.

782.7

COLOCALIZATION OF AROMATASE AND ANDROGEN RECEPTOR IN NEURONS OF THE BED NUCLEUS OF THE STRIA TERMINALIS. M.Sar*[1] and E.M. Wilson[2]. Departments of Cell Biology and Anatomy[1], Pediatrics[2], and Biochmistry and Biophysics,[2] School of Medicine, University of North Carolina, Chapel Hill, NC 27599.

The conversion of testosterone to estrogen occurs in specific areas of the brain through the action of enzyme aromatase. Aromatase activity is greater in males than in females and testosterone treatment increases the activity in castrated males. In the present study we investigated whether certain aromatase neurons in the brain contain androgen receptor (AR). Co-localization of aromatase and AR was determined by dual immunoperoxidase method using antipeptide antibody aromatase (N.Harada, Japan) and AR32. Adult male rats intact or castrated, treated with testosterone propionate were perfused with Zamboni's fixative. Brains were fixed and 10μm thick serial frozen sections of preoptic-septal region were processed for dual immunostaining. Sections were first stained with AR32 antibody using diaminobenzidine tetrahydrochloride followed by immunostaining with aromatase antibody using 4-chloro-1-naphthol. Nuclear localization of AR and cytoplasmic localization of aromatase in neurons were detected in several areas of the brain including the bed nucleus of the stria terminalis. Approximately forty to fifty percentage of neurons in the bed nucleus contained AR while 20%-25% of neurons contained aromatase. Thirty to thirty-five percentage of aromatase neurons in lateral part of the bed nucleus contained AR. AR containing neurons in the medial part of the bed nucleus and in the lateral septal nucleus did not show aromatase immunoreactivity. The results demonstrate that a sub- population of aromatase neurons in the bed nucleus of the stria terminalis contain AR and further sugest androgen action in aromatase neurons (Supported by NIH Grant NS 17479).

782.8

HOMOLOGOUS UP-REGULATION OF SOMATOSTATIN RECEPTOR SUBTYPE SSTR2 EXPRESSION IN RAT ARCUATE NUCLEUS *IN VIVO*. G.S. Tannenbaum*, J. Turner, F. Guo and A. Beaudet. Depts. of Pediatrics, Neurology & Neurosurgery, McGill University, Montreal H3H 1P3, Canada.

In vitro studies using various cell systems have provided conflicting results regarding homologous regulation of somatostatin (SRIF) receptors, and information on whether SRIF regulates the expression of its own receptors *in vivo* is lacking. In the present study we examined, by *in situ* hybridization, the effects of prolonged exposure to the SRIF analog, SMS 201-995, *in vivo*, on mRNA levels of two SRIF receptor subtypes, SSTR1 and SSTR2, in rat brain using ^{35}S-labeled antisense riboprobes (kindly provided by G.I. Bell). Labeling densities in four regions - the arcuate, ventromedial (VMN) and suprachiasmatic (SCN) nuclei of the hypothalamus, and in cerebral cortex (CTX), were quantified by computer-assisted microdensitometry (Biocom). Three hours after the iv administration of 50 μg SMS 201-995 to adult male rats (n=6), there was a 46% increase (P<0.001) in the labeling density of SSTR2 mRNA-expressing cells in the arcuate nucleus compared to normal saline-pretreated controls (n=6). SSTR2 mRNA signal density was also augmented in the three other regions examined: VMN: +35%; CTX: +27%; SCN: +7%. In contrast, no changes in SSTR1 mRNA-expressing cells were observed after SMS 201-995 treatment in any of the four regions measured, consistent with the subtype selectivity of this SRIF analog (i.e. high affinity for SSTR2 but little or no affinity for SSTR1). These results demonstrate, for the first time, that SRIF preexposure *in vivo* up-regulates the expression of a subtype of its own receptors, SSTR2, within the central nervous system. Such regulation may play an important role in a variety of neural functions, including the neuroendocrine regulation of growth hormone secretion by the arcuate nucleus.

782.9

MODULATION OF CORTICOTROPIN RELEASING HORMONE RECEPTOR IN CELL CULTURE WITH ANTISENSE ODN THOMAS SKUTELLA, CHRISTIAN BEHL, JOSEPH CHRISTOPHER PROBST, ULRICH RENNER, ROBERT NITSCH*, FLORIAN HOLSBOER, Max Planck Institute of Psychiatry, Clinical Institute, Munich and Humbolt University, Institute of Anatomy, Humbolt University/Clinic Charite, Berlin, Germany

Distribution of corticotropin releasing hormone receptors (CRHR) mRNA in the brain and pituitary supports a role of CRH as a regulator of neuroendocrine and behavioral adaption to stress. To further investigate the function of CRHR 1, which is mainly expressed in the posterior pituitary, we studied effects of different encapped phosphorothioate antisense oligodeoxynucleotides (ODNs) corresponding to CRHR 1 mRNA. Antisense, sense and scrambled ODNs were tested on CRH receptor binding, ACTH release and cell survival in rat posterior pituitary and ATT20 cell cultures. Studies on uptake and intracellular distribution of encapped phosphorothioate ODN using FITC-labeled antisense and sense labeled ODN revealed that within 2-4 hours ODNs were accumulated in the cytoplasma. As revealed by rt-PCR antisense ODN produced a dose- increase in CRHR mRNA after 48-72 hours of treatment, whereas the scrambled ODN had no effect on the mRNA levels compared to untreated controls. CRH receptor binding revealed a dose-dependent reduction of CRH receptor binding after 48-72 hours of antisense treatment, while no significant effects were observed with sense and scrambled ODN controls. Further CRH-stimulated ACTH secretion and cAMP were reduced after 48-72 hours of antisense ODN treatment.72 hours after a single antisense ODN treatment a dose-dependent counterregulative increase of ACTH secretion, CRH binding and CRHR mRNA was observed, while no effects were detectable with sense and scrambled ODNs. Cellular uptake and antisense effect could be potentiated by using transfection system. Cell survival tests revealed only weak toxic effects of ODN treatment in pituitary cell culture. The results provide functional and neurochemical evidence that CRH receptor antisense ODNs produce different effects in vitro depending on parameters such as concentration, time-window and mode of application.

782.10

ORIGIN OF CORTICOTROPIN-RELEASING HORMONE INNERVATION OF THE SHEEP ADRENAL DURING FETAL, NEONATAL AND ADULT LIFE. T.J. McDonald*P.W.Nathanielsz and C.Li. Laboratory for Pregnancy and Newborn Research, Cornell University, Ithaca, NY 14853 (HD 21350)

Corticotropin-releasing hormone (CRH) immunopositive fibers are found at the adrenal cortico-medullary interface of fetal sheep starting as early as 100 days of gestation (dG) and increasing with age to adulthood (*SGI abstract #O22, 1994*). Splanchnicotomy reduces cortisol, but not ACTH secretion in acutely hypotensive fetal sheep (*Endocrinology 127:2328*) and exogenous CRH is as effective as ACTH in eliciting adrenal cortisol in hypophysectomised calves (*J. Physiol. 447:489*). These findings suggest that, in addition to endocrine control of adrenal function via pituitary ACTH, sympathetic CRH may exert direct neural control on the adrenal. Therefore the present study examined sheep spinal cord for CRH-positive neurons projecting via splanchnic nerves to the adrenal. **METHODS:** Thoracic (T_1 -T_{13}) spinal cords of 7 fetal sheep (age range 110 dG to term; term ~ 150 dG), 2 newborn lambs and 2 pregnant ewes and splanchnic nerves from 1 fetus (130 dG) and 1 ewe were immunostained using a polyclonal rabbit anti-CRH antibody. One fetus (120 dG) was injected with Fluoro-gold (200 nl, 2.5% in saline) into the left adrenal medulla, necropsied at 134 dG and immunostained for Fluoro-gold and CRH coincidence. **RESULTS:** Intermediolateral (sympathetic) CRH-immunopositive cells were found in all spinal cords: the fewest were found in the 110 dG fetus; older animals exhibited varying numbers. The splanchnic nerves from both fetus and ewe contained many immunopositive CRH fibers. Thoracic spinal sympathetic Fluoro-gold immunopositive neurons double labelled with CRH were seen only on the injected side. **CONCLUSION:** CRH immunopositive cell bodies in the sheep sympathetic spinal cord that project to the adrenal medulla via the splanchnic nerves may consititute an important pathway for modulation of adrenal function, especially in situations such as chronic stress where ACTH concentrations in peripheral plasma return to baseline but cortisol concentrations remain elevated.

782.11

RESPECTIVE ROLES OF ANGIOTENSIN II AND ANGIOTENSIN III IN THE CENTRAL REGULATION OF VASOPRESSIN SECRETION. S. Zini[1], M.C. Fournié-Zaluski, E. Chauvel, B.P. Roques, P. Corvol[1] and C. Llorens-Cortès*[1]. [1]INSERM U36 and [2]U266, 75005, Paris, France.

In the brain, evidence suggests the existence of an independent renin-angiotensin system (RAS) including angiotensin receptors, precursors and enzymes required for the formation and degradation of angiotensins. Among the effector peptides of the RAS, angiotensin II (Ang II) and angiotensin III (Ang III) are able to increase blood pressure, water consumption and vasopressin release. These effects seem to be mediated by type-1 angiotensin receptors.

In attempt to delineate the respective roles of Ang II and Ang III on the regulation of vasopressin secretion, we have first identified *in vivo* the metabolic pathways of these two peptides, then subsequently studied vasopressin release using selective inhibitors of these enzymatic pathways. For this purpose, we have recently developed selective inhibitors of aminopeptidase A (APA, EC 3.4.11.7) and aminopeptidase N (APN, EC 3.4.11.2), two enzymes which might be involved into the metabolism of Ang II and Ang III, respectively. We then infused in the mouse by the intracerebroventricularly (icv) route, [^{3}H]Ang II in the presence or absence of EC33 (3-amino-4-thio-butyl sulfonate, the APA inhibitor) or EC27 (2-amino-pentan-1,5-dithiol, the APN inhibitor) and measured levels of [^{3}H]Ang II or [^{3}H]Ang III in the hypothalamus by HPLC. These experiments indicate that *in vivo* Ang II is cleaved by APA to generate Ang III which in turn is metabolized by APN. Next, we studied the effects of EC33 and EC27 on the release of vasopressin. Ang II or Ang III (3 ng) were infused i.c.v. in the presence or absence of inhibitors (30 µg) and plasmatic vasopressin levels were estimated by RIA.

Preliminary results show that the APA inhibitor completely blocks the Ang II-induced release of vasopressin while the APN inhibitor potentiates Ang III-induced release of vasopressin. These data suggest that Ang III is one of the main effectors of the brain RAS involved in the regulation of vasopressin secretion and that Ang II possibly exerts its effect through its conversion into Ang III.

SUCKLING STIMULUS ACTIVATES BRAINSTEM NEURONS PROJECTING TO THE ARCUATE NUCLEUS OF LACTATING RATS. H.-J. Wang*, G.E. Hoffman and M.S. Smith, Department of Neurobiology, University of Pittsburgh, Pittsburgh, PA 15261

Arcuate nucleus (ARC) neuronal function changes in the presence of the suckling stimulus. This study investigated the neural pathways that may relay the somatosensory input to the ARC during lactation. Lactating rats were anesthetized on day 2 postpartum (PP) and retrograde tracer Fluoro-gold (FAu) was iontophoresed from a glass electrode into unilateral ARC. The rats recovered and continued to nurse their 8-pup litters. To introduce an acute suckling stimulus, the lactating rats were separated from their pups for 48 hr beginning on day 8 PP. On day 10 PP, pups were reunited with the dam. Two to four hr after the onset of resuckling, mother rats were sacrificed and the brainstems were processed for immunocytochemistry (ICC). The parabrachial nucleus (PB) was heavily labeled by FAu. The A1/C1 and A2/C2 areas also had many FAu-labeled cells and the majority of them were tyrosine hydroxylase (TH)-positive. Fewer FAu neurons were found in central gray, A5, A6 and the raphe nucleus; only a few labeled neurons in A5, A6 expressed TH. Double-label ICC demonstrated that the suckling stimulus activated cFos expression in many FAu-traced cells in PB and A1/C1. Fewer cFos-positive FAu cells were found in other areas. Triple immunostaining showed that a few TH neurons in A1/C1 projecting to the ARC were activated by the suckling stimulus. These data indicated that the suckling stimulus may affect ARC neuronal function primarily via the activation of PB and A1/C1 areas; other brainstem regions may also participate in this process to a lesser extent. Supported by HD14643 and NS28730.

ION CHANNELS: CELL FUNCTION III

FLUORESCENCE IMAGING OF INTRACELLULAR SODIUM IN RAT HIPPOCAMPAL ASTROCYTES. C. R. Rose* and B. R. Ransom, Dept Neurology, Yale University, Sch Med, New Haven, CT 06510.

We determined the intracellular sodium concentration ($[Na^+]_i$) and mechanisms of its regulation in cultured rat hippocampal astrocytes using fluorescence imaging (345/385 nm) of the Na^+ indicator SBFI (sodium-binding benzofuran isophthalate). Calibrations were performed in live cells after each experiment. Baseline $[Na^+]_i$ was 14.6 ± 4.9 mM (n=270) in CO_2/HCO_3^--buffered saline (T=37°C), decreasing by 0.15 ± 0.09 mM/min (n=22) following removal of extracellular Na^+ ($[Na^+]_o$).

$[Na^+]_i$ transiently increased by 4.9 ± 3.5 mM (n=23) when changing from CO_2/HCO_3^--free to CO_2/HCO_3^--buffered saline, possibly due to activation of inwardly directed Na^+-HCO_3^--cotransport. Furosemide (1 mM) or bumetanide (50 µM) decreased $[Na^+]_i$ by 2 mM indicating a steady inward transport of Na^+ via the Na^+-K^+-2Cl^--cotransporter under control conditions. Inhibition of Na^+,K^+-ATPase by ouabain (1 mM) or removal of extracellular potassium ($[K^+]_o$) caused an increase in $[Na^+]_i$ by 2.5 ± 0.9 mM/min (n=24) and 4.2 ± 1.8 mM/min (n=44), respectively.

$[Na^+]_i$ decreased with increases in $[K^+]_o$ within the range seen in the CNS during neuronal activity. Following elevation of $[K^+]_o$ from 3 mM to 8 or 13 mM, $[Na^+]_i$ declined by 5.8 ± 2.2 and 7.1 ± 2.9 mM, respectively (n=22). Perfusion with saline containing 2 mM $[K^+]_o$ increased $[Na^+]_i$ by 3.0 ± 2.3 mM (n=23). Changing $[Na^+]_o$ by 20 mM, in contrast, resulted in changes in $[Na^+]_i$ of less than 3 mM.

These results show that baseline $[Na^+]_i$ of cultured astrocytes is strongly dependent on Na^+,K^+-ATPase activity, and influenced by Na^+-HCO_3^--cotransport and Na^+-K^+-2Cl^--cotransport. The high sensitivity of $[Na^+]_i$ to changes in $[K^+]_o$ suggests a prominent role of Na^+,K^+-ATPase in extracellular K^+ homeostasis.

INVOLVEMENT OF K^+ AND Cl^- CHANNELS IN MICROGLIA FUNCTION L. C. Schlichter*, B. Ballyk, G. Sakellaropoulos, P. S. Pennefather, and D. J. Phipps, Playfair Neuroscience Unit, The Toronto Hospital, Toronto Western Division, Toronto, Ontario, M5T 2S8.

In the present study, highly purified cultures of proliferating microglia were established from neopallia of newborn rats and classified into three populations. Within 3 weeks of isolation, "primary cultured" cells that had not been treated with CSF-1 containing media expressed: (1) an inwardly rectifying K^+ current (K_{ir}) that was inhibited by micromolar concentrations of Ba^{2+} in the bathing medium; (2) an outwardly rectifying K^+ current (K_v) with many similarities to the cloned K_v 1.3 channel of lymphocytes, including block by nanomolar concentrations of charybdotoxin (ChTX) and margatoxin (MgTX); and (3) an anion current that is similar to Cl^- channels in human T lymphocytes, including permeability to Cl^- and HCO_3^- and block by flufenamic acid, NPPB (4-nitro-2-(3-phenylpropylamino)-benzoic acid) and IAA-94 (6, 7-dichloro-2-cyclopentyl-2, 3-dihydro-2-methyl-1-oxo-1H-inden-5-yl (oxy) acetic acid). Type 1 cells were passaged and maintained in culture for up to 6 weeks in the presence of CSF-1 containing supernatants from an astrocyte cell line (LM 10-5). Type 2 cells arose spontaneously in these flasks as rapidly proliferating cells that could be maintained for many weeks without added CSF-1. Both Type 1 and 2 microglia expressed K_{ir} and Cl^- current, but not K_v current. Proliferation of Type 1 and 2 microglia was stimulated by CSF-1 containing supernatants and inhibited by Ba^{2+} (K_{ir} blocker) and the Cl^--channel blockers, flufenamic acid, NPPB and IAA-94. In contrast, the K_v blockers ChTX and MgTX had no effect. These results provide evidence that K_{ir} and Cl^- channels are necessary for microglia proliferation, whereas K_v 1.3 channels do not appear to be necessary in these cultured microglia. MgTX and NPPB affected the tyrosine phosphorylation levels of several proteins before and after CSF-1 stimulation. Supported by grants from the Medical Research Council of Canada to L.C.S. and P.S.P., and a Savoy Foundation fellowship to B.B.

COMPARTMENTATION OF INTRACELLULAR NA^+ AND CL IN AN ISOLATED NERVE CELL. C. Fåhraeus, J. Schouenborg* and W. Grampp. Dept. of Physiology and Biophysics, University of Lund, Sölvegatan 19, S-223 62 Lund, Sweden.

The compartmentation of intracellular Na^+ and Cl^- in the slowly adapting lobster stretch receptor neurone was studied using electrophysiological and mathematical techniques. Measurements were made of potential shifts that could be induced by current pulses (10-100 s, 1 - 16 nA) when the neurone was superfused with GABA. Since the input resistance under these conditions is practically nil the potential shifts could be translated to Cl^- shifts close to the membrane innerface. Also, measurements were made of the pump current following intracellular Na^+ accumulation due to repetitive impulse firing (0.5 -16 s, 40 Hz). These findings gave evidence for a Na^+ shift, similar in size to the Cl^- shift, close to the membrane innerface. The data suggest that Cl^- and Na^+, under dynamic conditions, are not evenly distributed within the cell. Rather, there will be concentration gradients of 15 mM or more from the submembrane region of the cell to the inner bulk of the cell. Further, the time course for the decay of the concentration gradient is approximately 5 - 25 seconds. The slow time course indicates that there must be a diffusion hindrance close to the membrane innerface. It is noted that a diffusion hindrance in the submembrane region of the cell is functionally advantageous in that it keeps concentration changes to the submembrane region. Thereby it also amplifies ion-activated processes (pumps, channels, transporters) associated with the plasma membrane.

ABNORMALITY IN THE ACTIVATION OF Ca-ACTIVATED POTASSIUM CHANNELS REVEALED IN STUDIES OF NEUROFIBROMIN-DEFICIENT PC12 CELLS. Heidi Scrable and Diane Lipscombe*, Depts. of Neuroscience, University of Virginia, Charlottesville, VA 22908 & Brown University, Providence, RI 02912.

Individuals with Neurofibromatosis-1 (NF1) manifest electrophysiological abnormalities in transmission of nerve impulses along both peripheral and auditory nerves. As a first step toward understanding the etiology of this abnormal electrical signalling, we have used whole cell and single channel recording to characterize the ionic currents expressed in neurofibromin(Nfb)- deficient PC12 cells. We report that Nfb-deficient PC12 cells have a significantly altered ionic profile compared to their wild-type counterpart. The most prominent difference from wild-type cells was the complete lack of an Iberiotoxin-sensitive maxi-K-type current in 7/7 whole cell recordings from Nfb-deficient PC12 cells. Concomitantly, there was no K_{Ca} channel activity in single-channel recordings from patches of Nfb-deficient PC12 cells in the cell-attached mode. However, the addition of μM Ca^{2+} to the cytosolic surface of excised patches induced the activation of high conductance K_{Ca} channels, suggesting that the channel is expressed but inactive. We detected an RNA species of ~4.5 kb that hybridized to a *slow-poke* cDNA probe on Northern blots of total RNA from both mutant and wild-type cells, confirming K_{Ca} expression. Thus, our results suggest an uncoupling, in Nfb-deficient cells, of maxi-K channels from the supply of calcium normally required for activation. We are now focusing our studies on voltage-gated calcium channels, which ordinarily provide the main route of calcium entry for activation of the maxi-K during excitation. Our preliminary studies indicate that voltage-gated calcium channels are also expressed in Nfb-deficient PC12 cells and that perhaps there is a deficit in the mechanisms which govern K_{Ca}/Ca channel co-localization. We are also testing the hypothesis that these changes, in Nfb-deficient PC12 cells, are a direct consequence of mutations in the *NF1* locus by comparing the ionic properties of neurons from *NF1* heterozygous and homozygous mutant and wildtype mice.

SINGLE CHANNEL PROPERTIES OF NEUROTENSIN-INDUCED CURRENT IN CULTURED VENTRAL TEGMENTAL AREA NEURONS. P.-Y. Chien[1*], R. H. Farkas[1], S. Nakajima[2] and Y. Nakajima[1]. Dept. of Anat. and Cell Biol.[1] and Dept. of Pharmacol.[2], Univ. of Illinois at Chicago, College of Med., Chicago, IL 60612.

Neurotensin (NT) excites dopaminergic neurons cultured from the ventral tegmental area primarily by inducing a non-selective cation current. This NT-induced inward current was blocked by the non-peptide NT antagonist SR48692 (Farkas, et al., Soc. Neurosci. Abstr. 19:1263, 1993). The NT-induced current was increased by decreasing the external Ca^{2+} concentration, suggesting block by external Ca^{2+} (Chien, et al., Soc. Neurosci. Abstr. 20:1528, 1994). Therefore, Ca^{2+}-free external solution was used for single channel studies. Single channel activity induced by NT could be recorded with the outside-out patch, indicating that the channel was activated locally. The mean inward single channel current was 2.1±0.06 pA (n=7); (holding potential = -80 mV; $[Na^+]_o$ = 155 mM; $[K^+]_o$ = 5 mM; $[K^+]_i$ = 153 mM). The mean channel open time was 0.28±0.02 ms. The closed time histogram was fit by two exponentials, suggesting that these channels opened in bursts. The NT antagonist SR48692 suppressed the channel activity by decreasing the channel open probability. Thus, the activity of the channel was mediated by the NT receptor. These results indicate that this channel underlies the NT-induced non-selective current recorded with the whole-cell configuration. Supported by NSF grant IBN 9319456.

MEMBRANE STIFFNESS AND CHANNEL FUNCTION: A GENERAL MECHANISM FOR MODULATING MEMBRANE PROTEIN FUNCTION? J.A. Lundbæk[1,2], P. Birn[2], A.J. Hansen[2], and O.S. Andersen*[1]. Cornell University Medical College USA[1], Novo Nordisk A/S, 2760 Måløv, Denmark[2].

The function of voltage-dependent calcium channels is modified by a variety of amphipatic compounds, but many of these compounds modify the function of other ion channels as well. This raises the question whether the alterations in calcium channel function reflect a more general mechanism involving altered interactions between the lipid membrane and the embedded proteins.

In experiments on gramicidin channels in planar bilayers and on N-type calcium channels using patch-clamp in IMR32 cells, we show that the synthetic agents Triton X-100 and β-octyl-glucoside, which decrease the stiffness of lipid membranes, reversibly *promote* calcium channel inactivation. Cholesterol which increases membrane stiffness, *inhibits* channel inactivation. The voltage activation of the calcium channels is not affected by any of the compounds. In the concentrations used none of the compounds changed the membrane leak currents.

Alterations in membrane stiffness may constitute a general mechanism for modulating the function of membrane proteins. Changes in membrane stiffness can be predicted from the molecular shape of the membrane active compounds. This may provide for insights into the pharmacological effects of membrane-active compounds, as well as for the general effects of cell membrane lipid composition on the function of membrane proteins.

783.7

ON THE USE OF GENETIC ALGORITHMS FOR PARAMETER OPTIMIZATION IN COMPARTMENTAL MODELS OF HIPPOCAMPAL NEURONS. R. M. Eichler West* and G. L. Wilcox, Graduate Program in Neuroscience and Minnesota Supercomputer Institute, University of Minnesota, Minneapolis, MN 55455.

Most neuronal modeling to date has used parameter settings for ionic conductances derived by trial-and-error procedures. It is unclear whether these settings represent tenuous, unique spaces or robust, reasonable approximations of the values present in real neurons. This study investigated the use of *Genetic Algorithms* (GA) as a robust, efficient and reliable method for determining appropriate parameter spaces in compartmental models of hippocampal neurons. The parameters examined represent the spatial distribution of voltage-gated and/or calcium-dependent channels using kinetic equations of Traub et al (J Neurophysiol. 1991). GA represent several advantages over previous methods of parameter optimization, including convergence within a finite time (as opposed to trial-and-error or random walk methods) and the avoidance of becoming trapped in local minima (as opposed to one-step or hill-climbing methods).

Implementation required the development of a *fitness measure*, which is a score assigned to a given set of parameters based on the degree of correspondence between the extracted properties of the numerically generated time series and the "correct", or "highly fit" experimental observations. A *fitness filter* mathematically extracts properties of the simulated time series and compares them to a large number of experimental observations. These observations include, but are not limited to: resting potential, frequency-intensity plots, burst frequency plots, calcium concentration in response to somatic or dendritic stimulation, action potential (AP) threshold, AP height, AP width, input resistance, average afterhyperpolarization (AHP) voltage, and alterations in the previous measures in response to the simulated presence of a given pharmacological agent. Thus, the fitness filter contains an implicitly embedded database of experimental observations.

The data generated by the GA was also analyzed for parameter sensitivity, i.e. the range of values for which a given parameter elicits fit behaviors was determined. The results of this sensitivity analysis are of particular interest to those who study adaptive modifications in neurons.

NA^+ and CA^{2+} CHANNELS THROUGHOUT BASAL DENDRITES OF REGULAR SPIKING NEOCORTICAL PYRAMIDAL NEURONS: IMPLICATIONS OF BURSTING WITH EGTA. Paul A. Rhodes*, Rafael Yuste, and David W. Tank. Palm Beach, FL 33480 and AT&T Bell Labs, Murray Hill, NJ 07974.

It has been suggested that bursts in intrinsically bursting (IB) neocortical pyramids are driven by a Ca^{2+}-current generated depolarization of the dendrites, and that dendritic Na^+ currents must also be present in these neurons, so that somatic firing may invade the dendrites and activate dendritic Ca^{2+} channels (Rhodes and Gray 1994). Regular spiking (RS) pyramids under ordinary conditions emit only single spikes, but when Ca^{2+} chelators such as EGTA are injected, RS pyramids produce repetitive bursts (Friedman and Gutnick 1989). To explain the bursting of RS neurons with EGTA while still accounting for their single spike output under ordinary conditions, it is hypothesized that RS pyramids possess both Ca^{2+} and Na^+ currents in their basal dendrites (Yuste et al 1994; Benke and Angelides 1993), but that ordinarily their effect is masked by Ca^{2+}-gated K^+ currents. To assess the feasibility of this hypothesis, compartment model simulations of layer III and V RS pyramids were developed which 1) reproduced in detail the responses to current step characteristic of RS neurons (e.g. Mason and Larkman 1990) and which also 2) produced repetitive bursts when Ca^{2+} buffering was enhanced. The resulting models of RS pyramids satisfing these requirements included both Na^+ and Ca^{2+} channels in their dendrites, but at lower densities than in the dendrites of IB pyramids, along with fast, medium, and slow $[Ca^{2+}]$-gated K^+ currents (Schwindt et al 1988). These results suggest that since both IB and RS neurons burst under appropriate conditions, they both incorporate dendritic Ca^{2+} and Na^+ channels not only in the apical trunk (e.g. Amitai et al 1992), but also in apical oblique and basal dendrites, which are not probed by trunk impalements. Further, these results indicate the potential for processes that suppress dendritic Ca^{2+}-gated K^+ currents to shift the firing mode of neocortical regular spiking pyramidal neurons towards bursting.

783.9

MUTANT MICE FOR THE VOLTAGE-GATED POTASSIUM CHANNEL Kv3.1 ARE SMALLER AND DISPLAY A DEFICIT IN MOTOR SKILLS.

C.S. Ho* and R.H. Joho. Department of Cell Biology and Neuroscience. The University of Texas Southwestern Medical Center, Dallas, Texas 75235.

More than a dozen different voltage-gated potassium (K^+) channel genes have been cloned from mammalian tissues, however the contribution of individual K^+ channel types to cellular excitability is not known. The K^+ channel Kv3.1 is predominantly expressed in granule cells of the cerebellum, and it is first detectable around postnatal day 7 during cerebellar development. Kv3.1 also forms the *l*-type K^+ channel in T lymphocytes. To study the role of Kv3.1, we generated a Kv3.1-deficient mouse using homologous recombination in embryonic stem cells. Heterozygous mice ($Kv3.1^{+/-}$) did not exhibit an obvious mutant phenotype. Homozygous mutant mice ($Kv3.1^{-/-}$) are viable and fertile. $Kv3.1^{-/-}$ males and females have significantly lower body weights than their control littermates. Preliminary studies indicate no apparent mutant phenotype in external morphology and in the gross anatomy of the brain, including the cerebellum. $Kv3.1^{+/-}$ and $Kv3.1^{-/-}$ animals demonstrate similar spontaneous locomotor activities in the open field test. In the Rotorod test for coordinated locomotion, however, $Kv3.1^{-/-}$ animals perform worse than their heterozygous littermates in agreement with the finding that Kv3.1 is highly expressed in cerebellar granule cells. To study the role of Kv3.1 channels in autoimmune disease, the $Kv3.1^{-}$ allele is introduced in two mouse strains with inherited autoimmune disease. These experiments may provide information about the pathogenesis of the disease. (Supported by NIH grant NS-28407 and by the Kent Waldrep National Paralysis Foundation to R.H.J.)

OPIOID RECEPTORS II

784.1

CHARACTERIZATION OF MULTIPLE OPIOID BINDING SITES WITH [^{3}H]BUPRENORPHINE IN RAT BRAIN MEMBRANES.

A. Borsodi*[1], F. Ötvös[1], G. Tóth[1], C. Simon[2], S. Hosztafi[2], and S. Benyhe[1] [1]) Institute of Biochemistry and Isotope Laboratory, Biological Research Center, Hungarian Academy of Sciences, H-6701 Szeged, P.O.B. 521, and [2]) ALKALOIDA Chemical Works, H-4440 Tiszavasvari, P.O.B. 1, Hungary

Buprenorphine (Temgesic®) was radiolabelled with tritium at the positions 15 and 16. The purified end-product has 2.35 TBq/mmol (63 Ci/mmol) specific activity. The radioactive label was stable under acidic conditions, but not in the presence of strong basis. Binding characteristics of [^{3}H]buprenorphine was evaluated in particulate membrane fractions of rat brain. Specific ligand binding was of high affinity, saturable and naloxone-sensitive i.e. opioid in nature. The binding interaction displayed reversibility, and high degree of stereospecificity as measured by enantioselective opioid compounds. In kinetic experiments, equilibrium binding was achieved in 40 min incubation at room temperature, and dissociation of the receptor-ligand complex occurred readily when initiated by the addition of unlabelled opioid ligands. Homologous competition experiments reveal that [^{3}H]buprenorphine binds to an apparently single set of binding sites with a K_d value of 2.1 ± 0.4 nM. The maximal number of these sites was found to be 1.35 ± 0.27 pmol/mg protein. The binding parameters were not significantly changed in the presence of 100 mM sodium ion confirming the mixed agonist-antagonist properties of buprenorphine. In rat brain the ligand showed a relative preference for mu and kappa binding sites although opioid delta sites were found also to be labelled. The radioligand is capable of labelling kappa opioid receptors in frog brain membranes and it is a promising tool for studying ligand - receptor interaction in the opioid system.

784.2

μ-RECEPTOR ANTAGONIST BINDING OF NALOXONE BENZOYLHYDRAZONE TO STABLY EXPRESSED MOR-1 DISPLAYS G-PROTEIN DEPENDENCE.

G.P. Brown * and G.W. Pasternak. The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Departments of Neurology & Neuroscience and Pharmacology, Cornell University Medical College, New York, NY 10021

Naloxone and naloxone benzoylhydrazone (NalBzoH) are μ-opiate receptor antagonists *in vivo* and against agonist induced inhibition of adenylyl cyclase. In calf striatal and neuroblastoma cell membranes, NalBzoH binding differs from traditional G-protein receptor antagonists in that its binding to μ-receptors is highly sensitive to guanine nucleotides. Since the presence of other opioid receptors in these tissues makes it difficult to accurately assess the interaction of NalBzoH with the μ-receptor, we have examined ^{3}H-NalBzoH binding in CHO cells stably transfected with MOR-1. One selected cell line, MOR-A, has the expected profile of μ-receptor selective binding and inhibition of adenylyl cyclase. CHO cells transfected with vector alone have no opioid receptor binding or function. Naloxone and NalBzoH fully reverse the inhibition of adenylyl cyclase produced by morphine and the full agonist DAMGO while having no activity themselves, confirming their antagonist character. ^{3}H- NalBzoH binding in these cells reveals a sensitivity to guanine nucleotides similar to that observed in calf striatal or neuroblastoma cell membranes. Pertussis toxin (PTX), but not cholera toxin (CTX), affects ^{3}H-NalBzoH binding as well. The high affinity NalBzoH binding to μ-receptors is dependent upon an association with G-proteins, suggesting an unusual mechanism of antagonism and the possibility that NalBzoH is an inverse agonist.

784.3

INHIBITION OF L-TYPE Ca^{2+} CHANNELS AND ADENYLYL CYCLASE BY CLONED μ- AND δ-OPIOID RECEPTORS IN GH$_3$ CELLS.

E. T. Piros*, P. L. Prather, P. Y. Law, C. J. Evans & T. G. Hales Departments of Anesthesiology & Psychiatry., UCLA, Los Angeles., CA, 90024, and Department of Pharmacology University of Minnesota, Minneapolis, MN, 55455.

The coupling between endogenous opioid receptors and various effector systems has been studied extensively. The cloning of opioid receptor genes has facilitated research on the behavior of a single subtype of receptor. Although there is an increasing amount of data available on the binding characteristics and coupling of these receptors to adenylyl cyclase, their interaction with Ca^{2+} channels has not been tested.

To investigate the coupling of μ- and δ-opioid receptors to Ca^{2+} channels, we have stably expressed these receptor cDNAs in GH$_3$ cells. GH$_3$ cells express endogenous somatostatin (SRIF) receptors, voltage-gated Ca^{2+} and K^+ channels, but lack functional opioid receptors. Cells transfected with the μ-opioid receptor alone (GH$_3$MOR) bound both the non-selective opioid ligand diprenorphine (K_d = 0.33 nM, B_{max} = 0.39 pmoles/mg protein) and the μ-selective ligand DAMGO (K_i = 1.0 nM). DAMGO dose-dependently inhibited adenylyl cyclase activity in GH$_3$MOR cells (IC_{50} = 21.9 nM). Using the whole-cell patch-clamp technique with Ba^{2+} as the charge carrier, we have found that like SRIF, DAMGO (1 μM) also inhibits voltage-activated L-type Ca^{2+} channels (IC_{50} = 104.9 nM, INH_{max} = 26.5%). This action of DAMGO was attenuated by both naloxone and pretreatment with pertussis toxin. The δ-selective ligand DPDPE (1 μM) inhibited Ca^{2+} channel activity to a much lesser extent (3.5 ± 2.1%, n = 9). In addition to the μ-opioid receptor, GH$_3$MOR cells were transfected with the δ-opioid receptor cDNA (GH$_3$MORDOR). Expression of the δ-opioid receptor was confirmed by ligand binding studies. Like DAMGO, DPDPE also inhibited both adenylyl cyclase and Ca^{2+} channel activity. DPDPE (1 μM) reduced Ba^{2+} currents by 18.9 ± 1.1%, n = 12) in the cotransfected cells. We are investigating the mechanism(s) of action of μ- and δ-opioid receptors on Ca^{2+} channels expressed in GH$_3$MORDOR cells.

784.4

AGONIST-INDEPENDENT OPIOID RECEPTOR INHIBITION OF Ca^{2+} CHANNELS IN TRANSFECTED GH$_3$ CELLS.

T. G. Hales* and E. T. Piros. Departments of Anesthesiology and Psychiatry, UCLA, LA, CA 90025.

Agonist-independent activation of adenylyl cyclase has been observed in cells expressing cloned β2-adrenergic receptors. In addition, mutant α2C-adrenergic and m4 muscarinic receptors spontaneously inhibit adenylyl cyclase activity when expressed in non-excitable mammalian cell lines (Ren *et al.*, JBC 268:16483, 1993; Migeon and Nathanson, JBC 269:9767, 1994). Constitutive activity has not been reported for cloned opioid receptors and evidence for spontaneous coupling to ion channels is lacking. We investigated agonist independent opioid receptor coupling to native Ca^{2+} channels in GH$_3$ cells transfected with cloned μ– and δ–opioid receptors.

With Ba^{2+} as the charge carrier, the whole-cell patch-clamp technique was used to record voltage-activated Ca^{2+} channel activity from GH$_3$ cells stably transfected with both μ– and δ–opioid receptors (GH$_3$MORDOR). Ba^{2+} currents were inhibited by the μ– and δ–specific agonists DAMGO (1 μM) and DPDPE (1 μM). Inhibitions by these agonists were reversed by depolarizing prepulses (-20 to +60 mV, for 100 ms) and were blocked by intracellular GDP-β-S (2 mM). Without agonist, depolarizing prepulses caused an increase in the current evoked by a test pulse to 0 mV. This facilitation was not seen when GDP-β-S was included in the electrode solution, but was enhanced dramatically by intracellular GTP-γ-S (500 μM), suggesting that current enhancement was caused by a reversal of G-protein mediated Ca^{2+} channel inhibition. Facilitation was not observed with or without GTP-γ-S in untransfected GH$_3$ cells.

Our previous studies of opioid receptor coupling to Ca^{2+}-channels in GH$_3$MORDOR cells suggest that activation of μ- and δ- receptors causes inhibition of L-type channels via pertussis toxin sensitive G-proteins (see Piros *et al.*, this meeting). The data described here provides evidence for agonist-independent inhibition of Ca^{2+} channels by cloned μ- and/or δ-opioid receptors expressed in GH$_3$ cells. We are investigating whether the constitutive activity is a property of one or both of these receptor subtypes.

784.5

SPECIFIC *IN VIVO* BINDING OF [^{11}C]NALTRIBEN TO *DELTA* OPIOID RECEPTORS IN MOUSE BRAIN. C. D. Arnett*, M. Sajjad, E. Akgun, and P. S. Portoghese. PET Imaging Service, VA Medical Center, and University of Minnesota, Minneapolis, MN 55417.

Antinociception measures *in vivo* have demonstrated a distinction between two subclasses of *delta*-opioid receptors, termed $delta_1$ and $delta_2$. The $delta_2$-opioid receptor is selectively involved in the antinociception effected by release of endogenous opioids during cold water swim-stress and in the development of morphine dependence in mice. To investigate the two subtypes of *delta*-opioid receptors *in vivo* with the ultimate goal of selectively imaging the $delta_2$-opioid receptor in the living human brain, we labeled the nonpeptide $delta_2$-selective antagonist naltriben (NTB) with carbon-11 for use in PET imaging studies. Preliminary biodistribution studies of [^{11}C]NTB in mice demonstrated a brain uptake of 1.1 percent of the injected dose per gram (%ID/g) at 30 min after injection with a decline to 0.84 %ID/g at 60 min. Pretreatment 1.2 μmol/kg of NTB s.c. 30 min before [^{11}C]NTB reduced the brain retention of this radioligand by 65 percent at 60 min after injection. Pretreatment with 1.3 μmol/kg s.c. of the $delta_1$-selective antagonist benzylidenenaltrexone (BNTX) 30 min before [^{11}C]NTB also reduced brain retention of [^{11}C]NTB (by 45 percent) at 60 min after injection. At the doses used in this study, BNTX and NTB selectively inhibited antinociceptive activity of Leu- and Met-enkephalins administered i.c.v. or i.t., respectively, suggesting that the enkephalins mediate their antinociceptive effects through interaction at $delta_1$-opioid receptors in the brain and at $delta_2$-opioid receptors in the spinal cord (Takemori, A. E. and Portoghese, P. S. **Eur. J. Pharmacol. 242**: 145-150, 1993). The present results demonstrate specific binding of [^{11}C]NTB to mouse brain *delta*-opioid receptors. Inhibition of *in vivo* binding by pretreatment with a pharmacologically selective dose of BNTX is an interesting finding which will require further work to elucidate the respective roles of $delta_1$ and $delta_2$ opioid receptors.

784.6

CHARACTERIZATION AND APPLICATION OF A POLYCLONAL ANTISERA TO THE DELTA OPIOID RECEPTOR. T.J. Crook, A. Payne, F. Porreca and J. Lai*. Department of Pharmacology, University of Arizona, Tucson, Arizona, 85724.

The amino and carboxy terminal domains of the cloned opioid receptors show the greatest degree of sequence divergence. Fluorescent immunohistochemical analysis of NG108-15 cells with antibodies raised against the C-terminal of the delta opioid receptor (DOR) showed a granular staining in the cytoplasm near the plasma membrane, the nuclei were however devoid of staining. A 20-base sense sequence to from the DOR (nucleotides 7-26) was labeled at the 5-end with Texas red and HPLC-purified. The uptake of this oligonucleotide (ODN) into NG108-15 cells, maintained under serum-free conditions, was monitored over a 24hr period. Quantitative analysis showed that only 30-40% of the cells were labeled after 24hr, and the staining was found in both the nucleus and the cytoplasm. The uptake was both time and concentration dependent. Preicubation of the cells with either an antisense or a mismatch ODN (50μM/day) prior to the 24hr incubation with the Texas-red labeled ODN (50μM) did not significantly alter the percentage of labeled cells. When these cells were labeled with the anti-DOR antiserum a significant inverse correlation was observed between the level of the tagged ODN in a cell and the density of DOR staining after antisense pretreatment. Pretreatment with a mismatch ODN has no effect on DOR staining. We have also studied the anatomical distribution of DOR-like immunoreactivity (DOR-LI) in the brain. Mice were treated for seven days with antisense or mismatch ODN (12.5μg i.c.v.x2/day). Following treatment, mice were perfused with 4% paraformaldehyde and brains were harvested. Cryostat sections were incubated with the DOR antibody and visualized by a peroxidase reaction. High densities of DOR-LI were seen in the olfactory bulb, cortex and caudate putamen as well as a number of other sites. Administration of the antisense ODN produced a qualitative decrease in DOR-LI in many brain areas especially those around the ventricular system. Mismatch administration produced no difference in DOR-LI when compared with untreated controls.

DISTRIBUTION OF KAPPA OPIOID RECEPTOR IMMUNOREACTIVITY IN BASAL GANGLIA: A LIGHT AND ELECTRON MICROSCOPIC STUDY. J. F. McGinty*, C.K. Meshul[1], W.T. Bohler, T. A. Patterson[2] and C. Chavkin[2]. Dept. of Anatomy and Cell Biology East Carolina University School of Medicine, Greenville, NC 27858-4354, [1] V.A. Medical Center Portland, OR 97201 and [2]Dept. of Pharmacology, U. of Washington, Seattle, WA 98195.

Antisera raised against oligopeptides were used to map the presynaptic and postsynaptic locations of the kappa opioid receptor with immunocytochemistry at light and electron microscopic levels. Polyclonal, affinity purified antisera, raised in rabbits against the unique amino acid residues 371-380 (C-terminus-KT2) and 300-312 (N-terminus-KE4), were characterized as having a high titer by ELISA and as demonstrating specific recognition of the full length kappa receptor in rat brain membranes as shown by Western blot analysis. Immunoperoxidase staining in rat tissue perfused with 4% buffered paraformaldehyde revealed kappa receptor immunoreactivity (IR) in dense patches of the dorsomedial shell of nucleus accumbens and in cell bodies and fibers of the caudate-putamen, substantia nigra, and VTA. Prominent axonal immunostaining, more effectively demonstrated by the KE4 than the KT2 antiserum, was also present in the ventral pallidum, subthalamic and entopeduncular nuclei. Ultrastructural analysis revealed KT2 immunoreactivity in dendritic spines and in presynaptic terminals which made asymmetrical and symmetrical contacts with unlabeled dendrites in nucleus accumbens. The immunostaining was blocked by preadsorption with 30 μM kappa receptor peptide. This study demonstrates kappa receptor-IR in cells and fibers in the basal ganglia previously demonstrated to contain kappa receptor binding. Supported by DA 03982, DA04123 and Dept. Veteran Affairs.

KAPPA OPIOID RECEPTOR AGONIST BLOCKS POTASSIUM-STIMULATED INCREASE IN EXTRACELLULAR GLUTAMATE LEVELS IN RAT STRIATUM. S. M. Rawls*, C. T. Whitlow, W. H. Church[1] and J. F. McGinty. Dept. of Anatomy and Cell Biology and [1]Dept. of Chemistry, East Carolina University School of Medicine, Greenville, NC 27858-4354.

Kappa opioid receptor agonists decrease basal and stimulated extracellular dopamine levels in the striatum and decrease psychostimulant-induced behaviors. In addition, glutamate receptor antagonists block the development of psychostimulant-induced behavioral sensitization. Therefore, the purpose of this study was to determine whether kappa opioid receptor stimulation affects extracellular glutamate levels in the striatum as determined by *in vivo* microdialysis and HPLC coupled with electrochemical and diode array detection. Male Wistar rats were implanted with a guide cannula 4 days before insertion of a microdialysis probe into the dorsal striatum. After a 3 h. washout period, 30 min. baseline samples were collected for 2h. followed by 80 mM KCl for 30 min. to evoke glutamate release. In a second group, 100 μM of the selective kappa opiate agonist, U69,593, was perfused through the probe for 30 min. followed by U69,593 plus 80 mM KCl. Dialysates were collected for 90 min. post-treatment and each 30 min. sample was divided into an aliquot for dopamine and one for glutamate. Glutamate samples were derivatized using 2,3-naphthalene dialdehyde (NDA) before HPLC analysis. The KCl-stimulated increase in extracellular glutamate in the striatum was blocked by simultaneous perfusion with 100 μM U69,593. The kappa opioid receptor antagonist, norbinaltorphimine, will be used to test kappa receptor mediation of U69,593's effects. This study indicates that kappa opioid receptors regulate extracellular glutamate levels in rat striatum. Supported by DA 03982.

ONTOGENESIS OF δ-OPIOID RECEPTOR SUBTYPES IN RAT BRAIN AND THE STIMULATORY EFFECT OF WEANING: AUTORADIOGRAPHIC COMPETITION STUDIES. L Kitchen*, F. M. Leslie, A. Borsodi, G. Toth, P. Melchiorri & L. Negri. School of Biological Sciences, University of Surrey, Guildford, Surrey, GU2 5XH, UK & Department of Pharmacology, University of California, Irvine, CA 92717, USA

We have evidence from behavioural studies that the stimulus of weaning a mother from her rat pups at day 21 activates a subtype of the δ-opioid receptor. In addition, membrane binding and autoradiographic mapping shows that weaning activates a population of δ-receptors, primarily in the frontal-parietal cortex, recognised by [^{3}H]-deltorphin I (^{3}H-DELT I) but not by [^{3}H]- Ile^{5,6} deltorphin II (^{3}H-Ile DELT II). To determine if these sites represent receptors with distinct pharmacology we have carried out autoradiographic competition studies using Ile DELT II and [D-Ser^{2}Leu^{5}Thr^6]-enkephalin (DSLET) as displacing ligands vs. ^{3}H-DELT I and ^{3}H-Ile DELT II on sections from weaned and non-weaned 25 day old rats. Coronal sections (20μm) were cut at the level of the caudate and adjacent sections used for determination of binding with each radioligand. Sections were cut over a total distance of 460μm for competition by DSLET or Ile DELT II (0.1-300nM). Slides were pre-incubated for 30 min, and binding carried out at room temperature in 50mM Tris HCl (pH 7.4) for 90 min using 7nM of each radioligand with non-specific binding determined using naloxone (10μM). Washed and dried sections were apposed to Hyperfilm, developed after two weeks and autoradiograms quantified by video-based computerised densitometry. Preliminary quantitation (n=3) shows that DSLET and Ile DELT II compete equally effectively for δ-sites labelled with ^{3}H-DELT I or ^{3}H-Ile DELT II (IC_{50} 10-30nM) in caudate and frontal-parietal cortex. Further, there were no indications of marked differences in competition by the δ-ligands in weaned and non-weaned groups. The data suggest that the δ-receptors activated by weaning during development show a similar pharmacology with respect to competition by two δ-ligands which have been designated as subtype selective.

COCAINE-INDUCED UPREGULATION OF MU OPIOID RECEPTOR MESSENGER RNA IN NUCLEUS ACCUMBENS IS MEDIATED BY DOPAMINERGIC MECHANISMS. B.M.Cox, A.V. Azaryan, L.J. Grimm *, B.J. Clock. Department of Pharmacology, Uniformed Services University of Health Sciences, Bethesda, MD 20814

We have investigated the possibility that chronic cocaine treatment alters the levels of mRNA for mu and delta opioid receptors in brain regions rich in dopaminergic innervation. Male Sprague-Dawley rats were treated with saline or cocaine (50 mg/kg/day) for 3 days, delivered by osmotic minipump. Expression of mu and delta opioid receptor mRNA in olfactory bulb, n. accumbens and caudate putamen (caudal and rostral parts) was estimated using quantitative competitive polymerase chain reaction assays following reverse transcription. No changes in the levels of mRNA for delta opioid receptor were detected after exposure to cocaine in any of the brain regions examined. A significant increase in the level of mu opioid receptor (MOR) mRNA was detected in n. accumbens after 3 days cocaine treatment. In caudate-putamen and olfactory bulb no change in MOR mRNA was observed. In situ hybridization analysis also indicated elevated levels of MOR mRNA in n. accumbens after cocaine treatment for 3 days, with little change in other brain regions. Both SCH 23390 and eticlopride, selective antagonists of dopamine D1 and D2 receptors, respectively, block this cocaine-induced upregulation of MOR in n. accumbens.

We suggest that endogenous opioid systems in n. accumbens, the brain region specifically associated with the reinforcing properties of addictive drugs, are regulated by dopaminergic mechanisms and influenced by cocaine treatment. Opioid mechanisms may contribute to the behavioral actions of cocaine. *(Supported by a grant from the National Institute on Drug Abuse).*

SIGMA RECEPTOR REGULATION FOLLOWING CHRONIC ADMINISTRATION OF THE NOVEL SIGMA LIGAND BD1047 A.C. Zambon*, B.R. de Costa, D.D. Truong and R.R. Matsumoto. University of California Irvine, Dept. of Neurology, Irvine, CA 92717; NIDDK, Laboratory of Medicinal Chemistry, Bethesda, MD 20892.

The binding of several neuroleptics to sigma receptors has brought to question the possible involvement of these binding sites in various movement disorders. The novel sigma ligand BD1047 has been shown to have no effect on its own, but to dose dependently attenuate dystonic postures produced by the prototypic sigma ligands DTG and haloperidol, suggesting BD1047 acts as a sigma receptor antagonist. In order to further evaluate this possibility, rats were chronically treated through the lateral ventricle with BD1047 (in artificial CSF, 10 nmol/hr) and artifical CSF alone for 7 or 14 days via osmotic minipumps. Preliminary data shows that treatment for 7 days with BD1047 results in an up-regulation of sigma receptors in whole brain (increased Bmax, no change in Kd) over regular untreated and CSF alone treated rats. Receptor levels were notably higher in the cerebellum and myelencephalon, lower in the cortex and hippocampus, and unchanged in the striatum when compared to CSF treated rats, suggesting competing/dual influences of the known antagonist vs. cytotoxic effects of BD1047 following 7 days of treatment. However, after 14 days of exposure with BD1047, there was a marked decrease in sigma receptors in whole brain, suggesting that the cytotoxic effects of the compound may predominate after prolonged administration.

CELL DIFFERENTIATION AND MIGRATION VIII

DEVELOPMENT OF OLFACTORY NEURONS AND GNRH CONTAINING NEUROENDOCRINE CELLS IN THE ZEBRAFISH OLFACTORY ORGAN. K. E. Whitlock* & M. Westerfield, Institute of Neuroscience, University of Oregon, Eugene, Oregon 97403 USA.

We are interested in the process by which the olfactory placodes give rise not only to primary sensory neurons of the olfactory system, but also to neuroendocrine cells. Gonadotropin releasing hormone (GnRH) cells that migrate from the olfactory placodes to the central nervous system (CNS) are required for development of sexual maturity. Using antibodies against different forms of GnRH, we find two distinct populations of GnRH positive cells located in different positions in the CNS. One population is present between the olfactory organs and the post optic commissure, and the other population lies in the anterior commissure of the telencephalon. To investigate whether these cells originate in the olfactory placodes, we labeled olfactory placodes with DiI and followed cell migration in living embryos. DiI-labeled cells left the placodes and traveled to the locations where we observed GnRH positive cells. In addition, we ablated the olfactory placodes and showed that no GnRH positive cells migrate into the brain. These data suggest that the immunoreactive cells migrate from the olfactory placodes into the CNS.

To learn about the origins and migration of these GnRH positive cells, we transplanted olfactory placodes from labeled donor embryos to ectopic locations in unlabeled hosts. Preliminary evidence shows that cells migrate away from the transplanted placode. We are confirming the identity of these migrating cells and examining the details of their migration pathways.

Finally, we are beginning to investigate the lineage relationship between the olfactory neurons and the GnRH positive cells with the aim of understanding the developmental and evolutionary link between the olfactory and GnRH systems. This work was supported by MDA (KEW) and NIH HD22486 (MW).

TANGENTIAL MIGRATION IN THE PROLIFERATIVE ZONES OF THE DEVELOPING CEREBRAL CORTEX. N.A. O'Rourke* and S.K. McConnell Department of Biological Sciences, Stanford University, Stanford, CA 94305

Nonradial patterns of cell migration appear to disperse clonally related cells within the tangential domain of the developing cerebral cortex. Imaging studies in living cortical slices have revealed tangentially migrating cells within the intermediate zone. Analysis of the orientations of migrating cells labeled with ^{3}H-thymidine reveals even higher levels of tangential migration in the subventricular zone. In addition, within the ventricular zone the neuron-specific antibody TuJ1 stains a subset of cells with the bipolar morphology characteristic of migrating neurons in both mouse (Menezes and Luskin, J. Neurosci. 14:5399,1994) and ferret (O'Rourke et al, Devel. 121(7) 1995). Many TuJ1-stained cells are oriented parallel to the ventricular surface, suggestive of tangential migration. To ask whether cells migrate tangentially in the cortical proliferative zones, we made focal injections of DiI into the ventricular zone of living neonatal ferrets and examined their brains 24 hrs later. DiI-labeled, tangentially oriented cells with bipolar morphologies were found in both the ventricular and subventricular zones up to 500 μm from the injection sites. Cells spread tangentially along both the rostrocaudal and mediolateral planes. At least some of these cells were TuJ1-positive, supporting the notion that the TuJ1-stained cells observed previously are in fact migratory. After 24 hours, we found no evidence for the random tangential dispersion of rounded cells observed previously in the ventricular zone by Fishell et al (Nature 362:636,1992). In contrast, our evidence suggests that elongated cells migrate tangentially over long distances in linear trajectories within both the subventricular and ventricular zones. Supported by NIH MH51864.

GRANULE CELL DIFFERENTIATION IS DEPENDENT ON INTERACTIONS WITH OTHER CELLS IN THE DEVELOPING CEREBELLUM. J. Alder*, N. K. Cho, S. Temple, and M.E. Hatten, Laboratory of Developmental Neurobiology, Rockefeller University, 1230 York Ave. NY, NY 10021

To study the mechanism of granule cell fate specification in the developing cerebellum, we have isolated very early granule cell precursors from the rhombic lip where they originate. In order to determine if isolated rhombic lip cells are competent to differentiate into granule cells, we cultured purified E14 rhombic lip cells as aggregates. Although the rhombic lip cells were dividing in vitro, they failed to extend neurites or stain with the granule cell marker TAG-1. By contrast, E17 EGL cells, which have just completed their migration from the rhombic lip over the anlage to form the EGL but have not yet undergone massive proliferation, are already competent to extend neurites in vitro. Together these data may suggest that some interaction between the rhombic lip cells and another cell type in the embryonic cerebellum during this early wave of migration is important for rendering them competent to differentiate. To determine if these cells are competent to differentiate in vivo, we implanted E14 rhombic lip cells or E17 EGL cells into P6 EGL. Both cell populations were able to migrate and differentiate into granule cells, suggesting that the difference in their behavior in vitro can be rescued by the P6 environment in vivo. To determine which cell type might provide the signal which renders rhombic lip cells competent to differentiate, we have co-cultured labelled rhombic lip cells on monolayers of various cell types and assayed for neurite outgrowth. E17, P0, and P6 EGL cells can rescue neurite outgrowth of rhombic lip cells to a larger extent than cells from the whole E14 anlage whereas COS cells cannot induce neurite outgrowth at all. Interestingly, the large cell fraction of the E17 anlage which contains glial cells, Purkinje cells, and interneurons was also capable of rescuing rhombic lip cells. We are currently investigating the cellular source of the activity and whether the activity is a diffusible or membrane-bound factor.

GLIAL MEMBRANE PROTEINS IN THE PLASMALEMMAL JUNCTION BETWEEN MIGRATING NEURONS AND RADIAL GLIAL CELLS REGULATE CORTICAL NEURONAL MIGRATION. E. S. Anton*, R. Cameron and P. Rakic. Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06514

To study glial membrane proteins that may contribute to the process of neuronal migration in the developing brain, we have developed a polyclonal antiserum (D4) and a monoclonal antibody (15D7) that recognize membrane proteins present at the plasmalemmal junction between migrating neurons and their radial glial substrate (Cameron and Rakic, J. Neurosci., 14: 3139). Here we tested whether these junctional membrane proteins contribute to the regulation of neuronal migration in the cerebral cortex. E17-18 coronal sections of rat cerebrum were cultured on nitrocellulose or cell-tak coated coverslips. After 24 hours, the attached slices were lifted off, leaving behind 'imprints' of cerebral wall containing glial cells with migrating neurons attached to them. Changes in the migratory behavior of neurons in these imprint cultures were monitored before and after the addition of purified D4 or 15D7 antibodies. The rate of neuronal migration on glial substrates was significantly reduced in the presence of these antibodies to the junctional domains. Antibody exposure often led to withdrawal of leading processes, and in some instances, to detachment of neurons from their glial substrates. Exposure to control antibodies or rabbit immunoglobulins had no detectable effect on neuronal migration. These results suggest that the glial junctional membrane proteins recognized by these antibodies are crucial for the maintenance of normal neuronal migration. Dismantling of neuron-glial junctional complexes formed by these membrane proteins may underlie neuronal detachment from glial migratory substrates at appropriate positions in the developing cortical plate. DEVELOPMENTAL REGULATION OF MAP2 VARIANTS DURING NEURONAL DIFFERENTIATION IN VITRO. S. A. Przyborski and M.A. Cambray-Deakin. SPON: Brain Research Association. Dept. Biomedical Science, University of Sheffield, Sheffield S10 2TN, UK.

Microtubule-associated protein 2 (MAP2) is known to promote the assembly and stabilization of microtubules and hence may be important in neuronal differentiation. MAP2 consists of high molecular weight (HMW) proteins MAP2a, MAP2b and a low molecular weight (LMW) isoform MAP2c. These proteins are produced from a single gene by alternative splicing. In this study, we describe the expression of the various MAP2 mRNA isotypes and protein isoforms during the development of rat cerebellar granule cell neurons over a 21 day period *in vitro*. *In situ* hybridization was used to detect MAP2 mRNA isotypes which corresponded to HMW- and LMW-MAP2 proteins. The distribution of MAP2 mRNAs in the P7 cerebellar cortex compared favourably with the different stages of granule neuron development *in situ*. During early stages of neuronal differentiation *in vitro*, high levels of MAP2c mRNA were observed which gradually decreased as development progressed. Throughout the period studied, MAP2ab mRNA concentrations remained low although a small transient rise was noted during the first 14 div. The profile of MAP2 protein variants showed further developmental regulation. The expression of the LMW-MAP2c isoform closely mirrored that of its mRNA whilst HMW-MAP2b protein concentrations rose during the first 10 div and were maintained in older cultures. HMW-MAP2a appeared after 4 div and gradually increased throughout the remainder of the study. Clearly, the outline of HMW-MAP2 protein did not relate to its encoding mRNA and such disparity may be due to the operation of different transcriptional and/or posttranslational mechanisms. Immunocytochemical analyses of MAP2 variants provided further information concerning their localization during neurite outgrowth. These results describe the developmental regulation of MAP2 mRNA and protein variants and show that the profile of their expression relates to the formation of processes during the differentiation of granule neurons *in vitro*.

MEF2C ANTISENSE OLIGONUCLEOTIDES INHIBIT DIFFERENTIATION OF HIPPOCAMPAL NEURONS IN CULTURE. Dimitri Krainc*, Adriana Ferreira, Maria Carles, Kenneth S. Kosik, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital, Centèr for Neurologic Diseases, Brigham and Women's Hospital, and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

Myocyte enhancer factor 2C (MEF2C) belongs to a superfamily of transcription factors sharing a highly conserved DNA-binding domain, the MADS box. Several members of the MADS family have been shown to mediate lineage specification and differentiation. Previously, we have shown that MEF2C is induced during neuronal differentiation and activates transcription in a site dependent manner (Leifer et al., *PNAS* 1993). Here, we used cultured rat hippocampal neurons to study the role of MEF2C in neuronal differentiation and neurite outgrowth. The addition of MEF2C antisense oligonucleotides (ODNs, 50 μM) reduced MEF2C levels, as determined by immunocytochemical analysis, and almost completely prevented neurite outgrowth. Similar concentrations of sense ODNs did not affect neurite elongation. In addition, the removal of antisense ODNs from the culture medium led to a nearly complete recovery of neurite outgrowth.

These results suggest that MEF2C might play a role in the transcription of neurospecific genes involved in neuronal differentiation and neurite elongation.

THE HEAT SHOCK RESPONSE OF PC12 CELLS IS DIMINISHED UPON NEURONAL DIFFERENTIATION: RELATIONSHIP TO KEY TRANSCRIPTION FACTORS.
D. S. Dwyer*, Y. Liu, S. Miao and R. J. Bradley. Departments of Psychiatry and Pharmacology, LSU Medical Center-Shreveport, Shreveport, LA 71130.

The production of heat shock proteins (Hsps), including Hsp70, Hsp60 and Hsp90, by PC12 cells was monitored as a function of neuronal differentiation. Normal, undifferentiated PC12 cells dramatically increased the synthesis of Hsp70 and Hsp60 upon heating or exposure to ethanol. A 30 minute exposure to 42°C or 24 hours of incubation in 0.3% ethanol was sufficient to significantly elevate the levels of these inducible Hsps. In contrast, PC12 cells that were induced to differentiate with nerve growth factor (NGF) failed to produce Hsp70 or Hsp60 in response to heat or ethanol treatment. Disappearance of the heat shock response of the cells was directly relate to the extent of neuronal differentiation (as judged by neurite outgrowth and cessation of division). Cellular levels of the constitutive proteins Hsc70 and Hsp90 were unaffected by differentiation. Production of Hsps was restored in the differentiated cells by removal of NGF which coincided with loss of the neuronal phenotype. To some extent, introduction of fresh serum also rekindled the cellular stress response. Analysis of the transcriptional control of Hsp production revealed a relationship between the levels of Hsps and key transcription factors based on the differentiation state of the cells. Attenuation of the heat shock response in terminally differentiated neuronal cells may explain the increased susceptibility of neurons to the harmful effects of environmental stress.

NEUROTROPHIC ACTIVITY OF STEM CELL FACTOR AND MELANOTROPHIC ACTIVITY OF NEUROTROPHINS IN NEURAL CREST CELLS. M. Sieber-Blum* and J. Saskowski. Dept. of Cell Biology and Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226.

The effect of relevant growth factors on neural crest cell development was determined by colony assay of quail neural crest cell proliferation and differentiation. Pluripotent neural crest cells are not only found in the migratory neural crest, but also at sites of terminal differentiation, including the dorsal root ganglion, the sympathetic ganglion and the developing skin. This indicates that signals from the embryonic microenvironment, such as growth factors, participate in the control of proliferation, survival and cell type specification. In the presence of stem cell factor (SCF), the following parameters were changed compared to control: 1) More colonies contained stage specific embryonic antigen-1 (SSEA-1) - immunoreactive sensory neuron precursors. 2) Colonies founded by pluripotent neural crest cells contained more cells due to a trophic influence of SCF as determined by bromodeoxyuridine incorporation studies. However, no effect of SCF on pigment cells was observed. By contrast, when SCF and one of the three neurotrophins tested (nerve growth factor, brain-derived neurotrophic factor, neurotrophin-3) were added together to the culture medium, the size of fully pigmented colonies, which are founded by committed melanogenic cells, increased. Again, this was determined to be a trophic, not a mitogenic, influence by the SCF/neurotrophin combination. SCF was required by the cells from the beginning of the culture period, whereas the neurotrophin could be added significantly later, suggesting that in the presence of SCF melanogenic cells become neurotrophin-dependent. Taken together, the data indicate that SCF can have neurotrophic activity in the sensory neuron lineage and that the well-documented trophic action of SCF on pigment cells requires the presence of a neurotrophin. DYNAMIC ANALYSIS OF TRUNK NEURAL CREST MIGRATION IN THE AVIAN EMBRYO. C. E. Krull[1]*, A. Collazo[2], S. E. Fraser[2], M. Bronner-Fraser[1]. [1]Dev. Biol. Ctr., UC-Irvine, Irvine, CA 92717; [2]Dept. of Biol., Cal. Inst. of Tech., Pasadena, CA 91125.

Trunk neural crest cells migrate through the somites in a striking segmental fashion, entering the rostral but not caudal somitic sclerotome. Various attractive and inhibitory molecules are thought to influence the patterning of trunk neural crest cells. It has been difficult, however, to observe the dynamic aspects of neural crest migration *in vivo* and perturb candidate guiding molecules due to the lack of an accessible bioassay. To this end, we have developed a novel explant system. Trunk regions of the chick embryo, placed in explant culture, continue to develop apparently normally for two days; the morphological and molecular properties of the somites are comparable to those observed in intact embryos. Neural crest cells, recognized by prelabeling with DiI or by HNK-1 immunoreactivity, migrate in the somites of the explants in their typical segmental pattern. This system allows us to follow trunk neural crest migration in situ for the first time using time-lapse videomicroscopy. Neural crest cells frequently migrated in close-knit groups of 2-4 cells, with mean migration rates of 10-14 μm/hour. The migratory trajectories of individual neural crest cells were often complex, with cells migrating in an episodic manner. Treatment of trunk explants with the lectin peanut agglutinin (PNA) altered the patterning of neural crest migration and slowed the migratory rate. Cells migrated in both the rostral and caudal halves of the sclerotome with mean rates of migration ranging from 6-13 μm/hour. These results suggest that PNA-binding molecules are required for the segmental patterning of trunk neural crest migration. Experiments to examine the potential roles that other molecules may play are in progress. *Supported by NRSA/NINDS 09459 to CEK and USPHS HD-15527 to MB-F.*

GAP JUNCTION DOWN-REGULATION IS REQUIRED FOR NEURONAL DIFFERENTIATION. R. Rozental*, M. Urban, G.I. Fishman, F.-C. Chiu, E.M. Eves, M.R. Rosner, J.A. Kessler and D.C. Spray. Depts. of Neurosci. and Neurol., A. Einstein Coll. Med., Bronx, NY 10461; Inst. Biophysics, Fed. Univ. Rio Janeiro, Brazil; Ben May Inst., U. Chicago, IL 60637.

We recently showed that electrotonic coupling is quite strong among embryonic cells destined to become neurons, and that strength of coupling changes during neuronal differentiation (*Dev. Biol.*, 167: 350-362, 1995). However, it remained unclear whether the decline in neuronal coupling is an obligatory step in this process. To address this issue, we used an SV40 Tts-immortalized rat hippocampal neuronal cell line overexpressing bcl-2 (H19-7bcl2-R10s) that can be induced to differentiate at the non-permissive temperature (39°C) in defined medium containing basic FGF (bFGF) and retinoic acid (RA). We compared the immunocytochemical and functional characteristics of cells kept at 33°C or 39°C and with cells kept at 39°C and treated with bFGF (10 ng/ml) and RA (0.3 μM); these were compared with cells transfected with Cx43 [electroporation with 20 μg DNA: 4 μg of fluorescent protein expression vector (CMV-GFP), 16 μg of either Cx43 expression construct (pGF1) or a neomycin phosphototransferase-βgalactosidase fusion protein control construct (CMV-βgal-neo)]. GFP expressing cells were identified by epifluorescence. At 33°C, both parental and transfected cells are highly coupled by Cx43 and are not excitable. However, at 39°C and with RA and bFGF, parental cells progressively uncouple, as they express neurofilament protein (NFM) and membrane excitability. Constitutive expression of Cx43 in transfectants prevents the expression of neuronal phenotype. Thus, cellular uncoupling appears to be a necessary first step for cellular differentiation early during neuronal ontogeny.

785.11

MN20/D2 CYCLIN EXPRESSION REGULATES DIFFERENTIATION OF CEREBELLAR CELLS IN CULTURE CJ MacNabb* & ME Ross, Dept of Neurology, Univ of Minnesota, Minneapolis, MN 55455.

The D type cyclins are key regulators of the G1 to S phase transition of the cell cycle, and are an integral part of cell growth and differentiation. We previously cloned from cerebellum a message form, MN20, of the D2 cyclin gene(J. Neurosci, 14:6384, '94). MN20 has a highly restricted temporal and anatomic expression pattern in brain suggesting a role in the transition of the neuroblast from proliferation to a more mature neuronal morphology. In this study, we used antisense oligodeoxynucleotides (oligos) to investigate the effect of downregulation of MN20/D2 cyclin expression on the differentiation of cerebellar granule precursors in culture. Phosphorothioate derivatized, antisense (AS)oligos complementary to sequences in the 5' end of the cDNA and their sense controls were synthesized. Cerebellar granule precursor cells were isolated from mice on postnatal day 3-5, and plated in serum-free medium. After several hours, triplicate cultures were treated with 5, 10, or 20 μM AS-oligos and morphology of the cells was examined at 10-12 hr intervals. An AS1-oligo, targeted near the translation start codon, delayed neurite outgrowth up to 42 hr, while cultures receiving no or sense-strand oligos put out neurites by 24 hr after plating. The number of cells affected by this delay increased in a dose-dependent fashion. Many of the differentiation-delayed cells died in culture by 36 hr. Surviving cells extended poorly formed neurites starting around 42 hr, as determined by immunohistochemical labeling of neurofilament. The AS1-oligo effect on cell differentiation and survival was partially rescued by bFGF. The AS1-oligo effect was sequence specific since an oligo that hybridized to a region upstream of the AUG, and therefore was not expected to interfere with translation of the cyclin mRNA, had little effect on cultures. These results suggest that proper regulation of D2 cyclin expression is required for successful differentiation and survival of cerebellar granule neurons.

785.12

THE REGULATORY PROTEINS p53 AND BAX ARE INVOLVED IN NEURONAL AND OLIGODENDROCYTE CELL CYCLE REGULATION. O. Eizenberg[1]*, E. Gottlieb[2], A. Faber-Elman[1], M. Oren[2], V. Rotter[3] and M. Schwartz[1]. Depts. of [1]Neurobiology, [2]Chemical Immunology and [3]Cell Biology, Weizmann Institute of Science, Rehovot, Israel.

This study shows that the p53 tumor suppressor gene is involved in the regulation of differentiation and programmed cell death of neurons and oligodendrocytes, two cell types which leave the mitotic cycle very early in development and undergo massive cell death upon maturation of the nervous system. Evidence is provided that in this cascade of events another regulatory protein, bax, is also involved. Specifically, we show that primary rat oligodendrocytes and neurons, as well as pheochromocytoma cells, constitutively express the p53 protein. At critical points in the development of these cells, p53 undergoes a change in its subcellular localization: it translocates from the cytoplasm to the nucleus during differentiation, while in fully mature differentiated cells it appears again in the cytoplasm. These subcellular changes in localization were found to occur concomitantly with changes in the levels of both p53 mRNA and protein. The bax, known to be up-regulated by p53, was found to be expressed constitutively in the nucleus of these cells. p53 is also shown to play a role in the apoptotic death of such cells; infection with a recombinant retrovirus encoding a C-terminal p53 miniprotein, previously shown to act as a dominant negative inhibitor of endogenous wild-type p53 activity, was found to protect neurons and oligodendrocytes from spontaneous apoptotic death. We propose that p53 is recruited into the nucleus upon receiving appropriate signals and plays a regulatory role in directing neural cells toward either differentiation or apoptosis, probably by interaction in the nucleus with bax.

The role of p35/cdk5 kinase in neuronal differentiation and neurite outgrowth

Nikolic, M., Delalle, I.*, Tsai, L-H.
Department of Pathology, Harvard Medical School, Boston MA02115.

To date all known cyclin dependent kinases (cdks) have been linked to cell cycle progression, with the exception of one - cdk5. We have previously shown that this kinase is activated when complexed to its regulatory partner, p35. The expression pattern of p35 and thus the p35/cdk5 kinase activity are exclusive to post-mitotic neurons of the developing central nervous system. The first signs of p35 expression are during the initial stages of cell migration from the ventricular zone. Subcellular localisation of both proteins is cytoplasmic; p35 is highly expressed in neuronal growth cones.

To address the role of the p35/cdk5 kinase in neuronal differentiation and neurite outgrowth we have altered levels of this kinase in rodent primary cortical cultures by means of transfection, a method established by Hank Dudek in Michael Greenberg's laboratory. P35, cdk5 or a dominant negative cdk5 mutant (dncdk5) were ectopically expressed in E17 rat embryonic cultures from the strong Cytomegalovirus (CMV) early promoter. Transfected cells were distinguished by co-transfection with a CMV-β galactosidase or retroviral LTR-alkaline phosphatase vector.

We were able to cause a dramatic reduction of neurite length in cells over-expressing dncdk5, a phenotype rescuable by co-transfection with wild type p35 or cdk5. In contrast, cells over-expressing p35 and cdk5 had increased neurite lengths in comparison to mock transfectants. The results of our experiments therefore strongly suggest a direct involvement of the p35/cdk5 kinase in neurite outgrowth.

To examine the role of p35 and cdk5 in earlier stages of differentiation, we will use proliferating cortical precursor cells. The expression of several neuronal markers will indicate their stage of differentiation.

NEUROTOXICITY II

786.1

ACUTE NEUROTOXICITY OF 2'-NH_2-MPTP: CHANGES IN REGIONAL SEROTONIN, 5-HIAA, NOREPINEPHRINE, DOPAMINE AND GFA LEVELS IN SWISS WEBSTER MICE. A. M. Andrews*, D. B. Miller, J. P. O'Callaghan and D. L. Murphy, Laboratory of Clinical Science, NIMH, Bethesda, MD 20892-1264 and Health Effects Research Laboratory, US EPA, RTP, NC 27711.

Our previous work has shown that 2'-NH_2-MPTP induces substantial depletions in cortical and hippocampal serotonin and norepinephrine lasting as long as 6 months without concomitant decreases in striatal dopamine (Andrews, A. M. and Murphy, D. L., *J. Pharmacol. Exp. Ther.* **267**, 1432-1439, 1993). In the present study, we sought to extend our observations to include the acute effects of 2'-NH_2-MPTP on regional brain neurochemistry. Administration of 1-methyl-4-(2'-aminophenyl)-1,2,3,6-tetrahydropyridine (2'-NH_2-MPTP; 4 x 20 mg/kg ip, at 2 h intervals) to mice caused large decreases in cortical and hippocampal 5-HT and NE measured 30 m, 2, 24, 48, and 72 h, and 7 and 21 days post-treatment. 5-HT was decreased by 70-90% and NE by 80-100% ($p<0.001$) at all times examined. Both 5-HT and NE were at their lowest levels within 30 m of the last injection of 2'-NH_2-MPTP. In contrast, the serotonin metabolite 5-HIAA was decreased only 20% at the earliest time-points in frontal cortex and hippocampus. 5-HIAA levels continued to fall until they were depleted ~60% at 48-72 h after treatment. Acutely, striatal dopamine was significantly decreased by 20-40% up to 48 h after the last injection of 2'-NH_2-MPTP but returned to control level by 72 h post-treatment where it remained throughout the 3 week period studied.

Astrogliosis was determined by immunoassay of time-dependent changes in glial fibrillary acidic protein in various brain regions. GFA levels were increased to 130% of control in cortex, hippocampus, and brain stem 48-72 h post-treatment ($p<0.05$); however, the observed increases following 2'-NH_2-MPTP were modest in comparison to previously reported increases on the order of 350% seen in striatal GFA at comparable times following MPTP treatment (O'Callaghan, J. P., Miller, D. B., and Reinhard, J. J., *Brain Res* **521**, 73-80, 1990).

786.2

INCREASED MANGANESE (Mn) CONCENTRATIONS AND CONCOMITANT LOSS OF POSTSYNAPTIC DOPAMINE D_2 RECEPTOR DENSITY IN PALLIDUM IN HUMAN HEPATIC ENCEPHALOPATHY (HE). R.F. Butterworth*, L. Spahr, D.D. Mousseau, G. Therrien and G. Pomier Layrargues. Liver Unit and Neuroscience Research Unit, Hopital Saint Luc, University of Montreal, Montreal, Quebec, Canada, H2X 3J4.

Pallidal lesions characterized by increased signal intensity on T_1-weighted Magnetic Resonance Imaging (MRI) have consistently been observed in cirrhotic patients with mild to severe HE. Since one potential cause of T_1 shortening is Mn deposition in brain, Mn concentrations were measured by atomic absorption spectrometry in autopsied brain tissue from 9 cirrhotic patients who died in hepatic coma and an equal number of control subjects. Mn concentrations were selectively elevated 3-fold in pallidum of HE patients (controls: 1.90 ± 0.40; HE patients: 5.40 ± 2.00 μg/g dry weight, $p<0.01$). In view of reports that chronic Mn toxicity results in alterations of the dopaminergic system, dopaminergic D_1 and D_2 receptor densities were measured by in vitro radioligand binding techniques in the same autopsy material using ^{3}H-SCH23390 and ^{3}H-spiperone, respectively. Specific ^{3}H-spiperone (D_2) binding sites were selectively decreased in pallidum of HE patients (by 44%, $p<0.01$). Mn deposition in pallidum could explain the MRI signal hyperintensity in cirrhotic patients and Mn neurotoxicity with concomitant alterations of pallidal dopaminergic function could play an important role in the pathogenesis of extrapyramidal symptoms in human HE. (Funded by MRC Canada).

786.3

RELATIVE VULNERABILITY OF NIGRAL DOPAMINE AND GABA NEURONS *IN VIVO* TO INHIBITION OF SDH P.K. Sonsalla*, L.Manzino and G.D. Zeevalk. Neurology, UMDNJ-Robert Wood Johnson Med.Sch., Piscataway,N.J.08854

In an accompanying abstract, we demonstrate that mesencephalic dopamine (DA) neurons *in vitro* are relatively more vulnerable, as compared with GABA neurons, to a mild metabolic stress. Such findings may help explain the selective loss of DA neurons in Parkinson's Disease should a generalized mitochondrial defect be found to be an underlying cause of the disease. The following study was done to determine if the same heirarchy of sensitivity of nigral DA and GABA neurons to a mild metabolic stress was maintained *in vivo*. To test this, unilateral stereotaxic injections of varying amounts of malonate, (0.25-1μmol), a reversible inhibitor of succinate dehydrogenase (SDH), or vehicle were administered into the substantia nigra (SN) of the brains of 4 mo. old Sprague Dawley rats. One week following infusion, the animals were sacrificed and DA and GABA content in the left (injected) and right nigra and striata were measured by HPLC. Malonate caused a dose dependent loss of both nigral DA and GABA on the injected side. As expected, striatal DA (from nigral projections), but not GABA, was decreased in the ipsilateral striatum. Co-administration of succinate (1.5μmol) with malonate (0.5μmol) completely prevented loss of nigral DA and GABA and striatal DA, which indicates that the effects of malonate were mediated by inhibition of SDH. Nigral DA and GABA levels were equally vulnerable to malonate. The EC_{50} for loss of DA and GABA by malonate were 0.39 and 0.42 μmol/nigra, respectively. Tyrosine hydroxylase positive neurons were significantly decreased in the nigra on the injected side. The difference in *in vivo* versus *in vitro* findings may suggest that in nigra from normal animals, mild metabolic stress *per se* does not preferentially affect DA neurons. Other factors such as increased dopamine turnover or decreased glutathione levels have been suggested as contributing factors in Parkinson's Disease and may combine with a mild metabolic stress to enhance vulnerability of the DA population. These possibilities are currently being investigated in the laboratory. This work was supported by a grant from the National Parkinson Foundation.

786.4

RELATIVE VULNERABILITY OF DOPAMINE AND GABA NEURONS IN VITRO TO INHIBITION OF SDH AND EFFECTS OF NMDA RECEPTOR BLOCKADE G.D. Zeevalk*, E. Derr-Yellin and W.J. Nicklas. Neurology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, N.J. 08854

There is evidence that metabolic defects may be a causative factor in Parkinson's (PD) as well as other neurodegenerative diseases. It is unclear at present how a generalized mitochondrial defect might result in the selective loss of dopamine (DA) neurons, a major pathological feature in PD. Here we examine the relative vulnerability of DA and GABA neurons in mesencephalic culture to inhibition of succinate dehydrogenase (SDH) by 3-nitropropionic acid (3-NPA)or malonate, irreversible and reversible inhibitors, respectively. These inhibitors produce different severities of metabolic stress. Metabolic inhibition was induced in 12 day old cultures by a 24 hr treatment with 3-NPA (0.1-0.5mM) or malonate (10-50mM). Cell death was assessed after a 48 hr recovery period by simultaneous measurement of the uptake of ^{3}[H]-DA and ^{14}[C]-GABA. 3-NPA and malonate caused a dose-dependent loss of DA uptake (EC50 0.21 and 42 mM, respectively). Exposure to 3-NPA was equally detrimental to the GABA population, whereas malonate was without affect. To determine the severity of metabolic stress imposed by 3-NPA or malonate, lactate production was measured in 12 day cultures treated with 3-NPA or malonate for 3 hr. Lactate production was 78% higher in 0.5mM 3-NPA treated cultures and 18% higher in 50mM malonate treated cultures when compared with untreated controls. Additionally, a 3 hr treatment with 0.5mM 3-NPA was sufficient to reduce DA uptake by 84% when measured after 48 hr of recovery. A 3 hr exposure to 50mM malonate did not produce toxicity. These studies suggest that 3-NPA causes a greater inhibition of oxidative metabolism. The presence of the NMDA antagonist MK-801 (1μM) during 24 hr of 3-NPA or malonate treatment completely protected against DA and GABA loss with 50mM malonate or 0.25 mM 3-NPA and partially protected versus 0.5mM 3-NPA. These studies indicate that the DA neurons *in vitro* display a relative vulnerability to mild metabolic stress as compared with mesencephalic GABA neurons. Protection by MK-801 suggests that mild metabolic stress triggers a secondary excitotoxicity mediated by NMDA receptors. This work was supported by a grant from the National Parkinson Foundation.

786.5

TIME COURSE AND MORPHOLOGY OF MPTP-INDUCED NEURONAL DEATH. V. Jackson-Lewis*, M.W. Jakowec, R.E. Burke and S. Przedborski. Dept. of Neurol., Columbia University, New York, NY 10032.

Mechanisms responsible for MPTP-induced dopamine (DA) neuronal death remains unknown and in mice it is even unclear whether neuronal death does occur. *In vitro* studies suggest that MPTP kills neurons by apoptosis. Herein, we investigated whether MPTP induces DA neuronal death *in vivo* in mice and whether the mechanism is that of apoptosis. C57/bl Mice received different doses of MPTP and were sacrificed at different time points for analyses of tyrosine hydroxylase (TH) immunohistochemistry, silver staining, and Nissl staining within the mesencephalon. We found that MPTP induces neuronal destruction in the substantia nigra pars compacta (SNpc) and the ventral tegmental area (VTA). The active phase of degeneration began at 12 hr postinjection and continued up to 4 days. During this period, there was a greater decrease in TH-defined neurons than in Nissl-stained neurons suggesting that MPTP can cause a loss in TH without necessarily destroying the neuron. Thereafter, neuronal counts by both techniques equalized and there was no further loss of DA neurons. Dying neurons showed shrunken eosinophilic cytoplasm and shrunken darkly stained nuclei. Double staining revealed degenerating neurons solely among TH positive neurons of SNpc and VTA. At no time point and at no dose of MPTP was apoptosis observed. In addition, *in situ* labeling revealed no evidence of DNA fragmentation. This study demonstrates that the MPTP mouse model replicates several key features of neurodegeneration of DA neurons in PD and provides no *in vivo* evidence that MPTP kills DA neurons by apoptosis.

786.6

INHIBITION OF BRAIN NITRIC OXIDE SYNTHASE PROTECTS AGAINST MPTP-INDUCED DOPAMINERGIC TOXICITY. S. Przedborski[1]*, V. Jackson-Lewis[1], R. Yokoyama[1] and T.M. Dawson[2]. [1]Dep. of Neurol. Columbia Univ., New York, NY 10032 and [2]Dep. of Neurosci. & Neurol. Johns Hopkins, Baltimore, MD 21287.

MPTP produces an experimental model of Parkinson's disease in a variety of animal species. The mechanism by which MPTP kills dopamine (DA) neurons is uncertain. Recent evidence has implicated nitric oxide (NO) in various neurotoxic paradigms. Thus, we have investigated whether NO is involved in MPTP-induced DA neurotoxicity *in vivo* in the mouse. C57/bl Mice received 50 mg/kg 7-nitroindazole (7-NI) to inhibit brain neuronal NO synthase (n-NOS) activity. Inhibition of n-NOS in the striatum peaked around 15 min and was still evident at 8 hr after 7-NI injection. To test the effect of n-NOS inhibition on MPTP-induced toxicity, C57/bl mice were injected with 7-NI 15 min prior to MPTP (20 mg/kg; i.p.) every 2 hr for 8 hr; mice received additional injections of 7-NI every 8 hr for 4 days following the last dose of MPTP. Mice were then sacrificed at different time points for analysis of striatal DA content by HPLC and for determination of degenerating substantia nigra pars compacta (SNpc) neuron number by silver staining. Consistent with our earlier report (Jackson-Lewis et al., 1995), this regimen of MPTP caused 94% reduction in striatal DA content and 65% destruction of SNpc neurons. In contrast, MPTP-injected mice pretreated with 7-NI showed only a 25% reduction in striatal DA content and no detectable degenerating SNpc neurons. Mice receiving 7-NI only did not show any changes in striatal DA levels. This study demonstrates that inhibition of n-NOS protects against MPTP-mediated DA damage in mice. This finding suggests that NO is involved in the MPTP neurotoxic mechanism.

THE OXIDATIVE NATURES OF DOPAMINE AND L-DOPA AND THE EFFECT OF O-METHYLATION. JW Miller*, J Selhub, JA Joseph. Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, MA 02111.

Dopamine (DA) and L-Dopa are readily oxidized to form potentially neurotoxic, pro-oxidant, reactive oxygen species which have been implicated in aging and age-related disease (e.g. Parkinson's disease). Recent evidence, however, indicates that under certain conditions, DA and L-Dopa can also serve as free radical scavenging antioxidants. In the present study, we used the Oxygen Radical Absorbance Capacity assay to demonstrate these apparent antithetical oxidative natures. In addition, we determined that O-methylation, the first step in catecholamine catabolism, produces compounds with oxidative properties different from DA and L-Dopa. The fluorescent protein porphyridium cruentum ß-phycoerythrin (ßPE) was exposed at 37 ^{0}C to either of two distinct oxidizing agents: 1. a peroxyl radical generator (2,2'-azobis[2-amidinopropane] dihydrochloride (AAPH)), or 2. $CuSO_4$. The ßPE loses its fluorescence as it is oxidized by these compounds with the rate of loss accelerated by pro-oxidants and slowed by antioxidants. Both DA and L-Dopa slowed the rate of ßPE fluorescence loss caused by AAPH in a dose-dependent manner, indicating that they acted as antioxidants. The O-methylated metabolites of DA and L-Dopa, 3-O-methylDA and 3-O-methyldopa, also slowed the rate of fluorescence loss, but to a lesser extent than DA and L-dopa, indicating that these compounds were weaker antioxidants under these conditions. Contrarily, DA and L-Dopa increased the rate of ß-PE fluorescence loss caused by $CuSO_4$, indicative of pro-oxidants. The O-methylated metabolites, however, did not increase the rate of $CuSO_4$-induced fluorescence loss, suggesting that O-methylation of DA and L-Dopa protects against their pro-oxidative effects under these conditions. These results demonstrate that DA and L-Dopa can act as either pro- or antioxidants depending on the type of oxidative stress, and suggest that O-methylation may protect against transition metal-induced catecholamine oxidation.

DOPAMINE NEUROTOXICITY: INHIBITION OF MITOCHONDRIAL RESPIRATION. D.Ben-Shachar*, R.Zuk & E.Klein, Rambam Medical Center, Fac. of Medicine, Technion, Haifa, Israel.

Abnormal dopamine metabolism is associated with several neuronal and psychiatric disorders. Oxidation of dopamine has been implicated as the main cause of its toxicity in brain. Indeed, icv injection of dopamine to rats caused a dose dependent mortality with LD_{50}=90uM. Norepinephrine was less toxic. Desferrioxamine prevented dopamine induced mortality. However we could not link dopamine toxicity to any of the conventional indicators of oxidative stress state, i.e. lipid and protein oxidation, glutathione peroxidase and reductase activities. Instead, dopamine inhibited the activity of mitochondrial NADH dehydrogenase activity with IC_{50}=8uM; that of Norepinephrine was twice as much. ATPase activity was not affected by both catecholamines. Dopamine induced inhibition of NADH dehydrogenase activity was only partially reversed by desferrioxamine while that induced by norepinephrine was not affected. The mechanism of dopamine interaction with mitochondrial NADH dehydrogenase will be further discussed. The results suggest that catecholamines can cause toxicity, not only by inducing a state of oxidative stress, but also via interaction with he electron transport system of the mitochondria. The latter was further supported by the ability of ADP+P_i to reverse dopamine induced inhibition of NADH dehydrogenase activity in a dose dependent manner.

786.9

EFFECT OF GABA, TAURINE AND FULLEROL-1 ON EXCITATORY AMINO ACID-INDUCED NEUROTOXICITY. [1]J.-Y. Wu, [1]X. W. Tang, [1]D. L. Deupree*, [1]J. Medina, [2]C.-Y. Yang and [3]L. Y. Chiang. [1]Dept. of Physiol. & Cell Biol., Univ. of Kansas, Lawrence, KS 66045, and [2]Dept. Med., Baylor College of Med., Houston, TX 77030; [3]Ctr. Condense Matter Sci., National Taiwan Univ., Taipei, Taiwan.

Primary cultures derived from 16-17 day fetal rat brain at 14 days in vitro (DIV) were used in L-glutamate-induced neurotoxicity (GNT) studies. Cultures were briefly exposed to glutamate or its agonists, e.g. kainic acid (KA) and N-methyl-D-aspartate (NMDA) for 5 min and GNT was determined 24 hrs later by measuring the release of lactate dehydrogenase (LDH) to the media. It was found that GNT was potentiated by GABA and taurine at low concentration (0.01 to 1 mM) to an extent of 50% and 100%, respectively. At high concentration, 25 mM taurine but not GABA, can effectively block GNT. The potentiation of GNT by GABA and taurine is believed to be due to their action on opening Cl^- channel since GNT as well as potentiation of GNT by GABA and taurine is greatly reduced by Cl^- channel blockers, e.g. picrotoxin, R(+)-IAA-94, niflumic acid. Fullerol-1, a C_{60} compound derivative, was found to be a potent blocker of GNT. A complete protection by Fullerol-1 against GNT induced by 0.5 mM L-glutamate was obtained at 50 μM. The mechanism of neuroprotective function of Fullerol-1 against GNT remains to be determined. (Supported by grants from Office of Naval Research; NIH, NS20978; and NSF, BNS-8820581)

786.10

TUBULIN IMMUNOSTAINING IN ORGANOPHOSPHORUS ESTER-INDUCED DELAYED NEUROTOXICITY (OPIDN). K.F. Jensen*[1], K.R. Wilmarth[2], J.K. Olin[1], M. Attia[2] & M.B. Abou-Donia[2]. [1]Neurotoxicology Div., HERL, US EPA, RTP, NC 27711 & [2]Dept. Pharmacology, Duke Univ., Durham, NC 27710

Cytoskeletal alterations occur in a variety of toxicant-induced axonopathies and may play a critical role in axonal degeneration. A single exposure to compounds such as diisopropyl phosphorofluoridate (DFP) can produce OPIDN, characterized by ataxia progressing to paralysis with a central-peripheral distal axonopathy. We previously demonstrated cytoskeletal aggregations, labeled by antibodies recognizing phosphorylated neurofilaments (PNF) and CaM kinase II (CaMKII), occur in axons early in OPIDN. The immunoreactivity for PNF and CaMKII is lost prior to the appearance of axonal varicosities characteristic of the late stages of OPIDN. To further characterize cytoskeletal alterations in this axonopathy, sections of spinal cord from control hens, and hens killed 3, 7, 10, 14 and 21 days after administration of 1.7 mg/kg DFP, were stained with a monoclonal antibody recognizing the alpha and beta subunits of tubulin. In control animals, the tubulin antibody labels the central core of axons, similar to PNF and CaMKII antibodies. The tubulin antibody also labels the cytoskeletal aggregations detectable in axons in early stages of OPIDN. But unlike PNF or CaMKII, tubulin immunostaining persists in many prominent axonal varicosities characteristic of late stages of OPIDN. These observations indicate that neurofilaments and tubulin are differentially altered in OPIDN.

786.11

EXCITOTOXIC-INDEPENDENT DNA FRAGMENTATION AND FREE RADICAL FORMATION PRODUCED BY 2-IMINOTHIAZOLIDINE-4-CARBOXYLIC ACID (2-ICA): A NOVEL HIPPOCAMPAL NEUROTOXIN. R. S. Bitner*, G. K. W. Yim and G. E. Isom. Dept. Pharmacology and Toxicology, Purdue University, W. Lafayette, IN 47097.

We previously demonstrated that 2-ICA, a minor metabolite of cyanide, produced seizures in mice that were qualitatively and quantitatively similar to seizures observed with glutamate and were blocked by glutamate antagonists. Unlike known glutamate neurotoxins, 2-ICA administered i.c.v. produced lesions primarily confined to the CA1 region of the hippocampus, similar to animal models of transient global ischemia (Bitner *et al.*, Neurotoxicol. 16:115, 1995). Failure of MK-801 or CNQX to protect against 2-ICA lesions suggested that a glutamate receptor-mediated mechanism was not involved in 2-ICA neurotoxicity. Because excitotoxicity is normally associated with delayed necrotic cell death, the goal of this study was to determine if 2-ICA produced apoptotic neuronal death, which recently has been implicated in CA1 lesions of transient global ischemia. Using a modified TdT dUTP nick end labeling (TUNEL) method, we showed that an i.c.v. injection of 2-ICA (3.2 μmol) in mice produced DNA fragmentation primarily in CA1 hippocampal neurons. We also found that 2-ICA (0.32-3.2 mM) increased the rate of formation of reactive oxygen species (ROS) in acutely dissociated neuronal culture using the fluorescent probe 2',7'-dichlorofluorescein. Consistent with an excitotoxic-independent action, the increased rate of formation of ROS by 2-ICA was not significantly reduced by MK-801 (1.0 μmol), but was blocked by the free radical scavengers, n-acetyl-L-cysteine (100 μmol) or catalase (100 U/ml). These results suggest that 2-ICA hippocampal CA1 damage may be due to DNA fragmentation caused by the formation of ROS and that 2-ICA may be useful in studying the role of apoptosis in hippocampal neurodegeneration. (Supported in part by NIEHS grant 04140).

ROLE OF A CALCIUM-ACTIVATED METALLOPROTEASE TRANSIN/STROMELYSIN IN PLASTICITY AND APOPTOSIS IN THE RAT BRAIN ?

M. Reeben, J. Arbatova, P. Riekkinen Sr and M. Saarma. Institute of Biotechnology, University of Helsinki, Helsinki, FIN-00014, Finland.

Transin/stromelysin is a neutral calcium-dependent metalloprotease (EC.3.4.24). It is known to be induced both on mRNA and protein level in rat pheochromocytoma PC12 cells during differentiation with nerve growth factor. As it degrades type IV collagen, laminin and fibronectin this suggests that transin may function to degrade the surrounding extracellular matrix during the invasive process of axonal elongation in neuronal development thereby allowing the movement of growth cones and axons toward specific targets. We were interested whether transin is expressed in adult brain and could it be regulated by neuronal activity ? As a model for neuronal activity we used seizures induced in rats by injection of glutamate analogue kainate or GABA receptor channel blocker metrazol (pentylenetetrazol). Kainic acid, but not metrazol-induced seizures lead to the induction of transin mRNA. Transin mRNA was induced in CA1 region of hippocampus, cortex, piriform cortex and amygdala region as revealed by *in situ* hybridization. The induction of transin mRNA by kainic acid was mediated by NMDA receptor and was dependent on protein synthesis. One of the possible plasticity related functions of this transin induction could be release of protease in the axon endings promoting sprouting induced by kainate. Another possibility is that transin induction by kainate may play role in neuronal damage. Differently from several other genes regulated by neuronal activity transin was not induced by metrazol and seizure activity induced by metrazol is known not to produce neuronal damage. Simultaneous DNA fragmentation in the brain regions of transin mRNA expression indicates the possible role of transin in apoptosis occuring during kainic acid-induced seizures. Transin mRNA is known to be regulated by *fos*-dependent and *fos*-independent pathways. Currently c-*fos* knockout mice are used to study the role of c-*fos* in kainic acid-induced transin mRNA induction.

ALZHEIMER'S DISEASE: MECHANISMS OF DEGENERATION II

787.1

REGIONAL SPECIFICITY OF INCREASED BASIC FIBROBLAST GROWTH FACTOR (FGF-2) IN ALZHEIMER'S DISEASE.E.G. Stopa*, V. Kuo-LeBlanc, M. Rodriguez-Wolf, M. Vitek, M. Kohls, A.M. Gonzalez and A. Baird. Brown University, Providence, RI, The Picower Institute,Manhasset,NY and The Scripps Research Institute, La Jolla, CA.

Basic fibroblast growth factor is increased in the prefrontal cortex and hippocampus of Alzheimer(AD) brains (Stopa et al.,BBRC 171:690-696,1990).Both of these regions are known to be severely affected in AD.It was therefore unclear whether bFGF would be increased in less affected areas such as the striatum.

In this study, we utilized immunodensitometry to quantitate bFGF in areas severly affected by AD: amygdala=a, A10,A20 and hippocampus=h,and areas which are less severely involved by the disease:A42 and striatum=s,in 14 control and 14AD patients.Immunodensitometry was also performed for synaptophysin and B amyloid.The immunocytochemical procedures utilized specific antibodies raised against bFGF(773), synaptophysin (Biogenex) and B amyloid (GE10).Densitometry measurements of reaction product were accomplished using NIH Image 1.51 and averaging data from 10 randomly selected 400X microscopic fields in each respective area. Immunodensitometry measurements for bFGF expressed as AD positive pixels/control positive pixels indicated a roughly 2-fold increase in affected areas A10=3.4,A20=2.8,a=2.1,h=2.2 vs less involved regions A42=1.24 and s=1.7. Immunodensitometry measurements for synaptophysin were consistent with synaptic loss in all brain regions: A10=.92andA20=.98 vs A42=.93and s=.97. Similar measurements of the amyloid burden indicated an increased deposition of Beta amyloid :A10=66.3,A20=21.0,a=33.0and h=41.7 vs A42=80.4and s=12.5.

These data indicate that bFGF is preferentially increased in brain areas severely affected by AD and suggest that this increase may be related to multiple factors including synaptic loss and B amyloid deposition.(AG10682)(DK18811)

DIFFERENTIAL BRADYKININ-INDUCED CA^{2+} ELEVATION IN FIBROBLASTS FROM ALZHEIMER'S VS. CONTROL DONORS. N. Hirashima†, R. Etcheberrigaray†, M. Racchi‡, S. Bergamaschi‡, F. Battaini‡, S. Govoni‡ and D.L. Alkon†‡* †*Laboratory of Adaptive Systems*-**NINDS**, National Institutes of Health, Bethesda MD 20892 and ‡Pharmacological Science Institute, University of Milan, Italy.

A number of studies have indicated that non-neural tissues of Alzheimer's Disease (AD) patients exhibit alterations at the cellular and molecular level. We have recently identified molecular alterations in fibroblasts from AD patients including: functional absence of a ≈ 113 pS TEA-sensitive K^+ channel, enhanced bombesin-induced Ca^{2+} release, and reduction of Cp20 (a memory-associated GTP binding protein). This study explores the bradykinin(BK)-IP_3 induced Ca^{2+} release in a new and extended population of AD and control donors. Fibroblasts were obtained from the Coriell Cell Repositories and from the Sacred Heart Hospital of Brescia, Italy. Cells were used three to four days after seeding, at comparable levels of confluence (≈ 60 to 80 cells per mm^2). Fluorescent images (fura 2-AM) at 340 and 380 nm were acquired at a rate of 2/sec. for 200 sec, with a Hamamatsu Argus 50 system. Stimulation with 100 pM BK elicited virtually no responses from control cells (N= 11 cell lines), with only one cell line responding (expressed as % of responding cells). In contrast, 12 out of 14 AD cell lines had clear responses, $p < 0.001$ (Mann Whitney). The difference between the two groups analyzed by a contingency table (response/no response) was also highly significant, $p < 0.0001$ (Fisher's exact test). Cell lines from "escapees" showed responses similar to those of control cell lines. BK concentrations of 1 and 10 nM, elicited similar responses in AD and controls. These observations confirm and extend our previous results indicating that IP_3-mediated Ca^{2+} release is enhanced in AD fibroblasts. In addition, these results provide another parameter whereby AD patients might be diagnostically differentiated from controls.

787.3

ALTERED PRESYNAPTIC PROTEIN NACP IS ASSOCIATED WITH PLAQUE FORMATION IN ALZHEIMER'S DISEASE. T. Saitoh*, A. Iwai, M. Mallory and E. Masliah Dept of Neurosciences, Sch. of Med., Univ. of California-San Diego, La Jolla, CA 92093

We have recently identified, in the brain tissue of patients afflicted with Alzheimer's disease (AD), the non-Aβ component of AD amyloid (NAC) as a new constituent of amyloid. NAC is derived from a larger precursor, NACP, a presynaptic protein. The semiquantitative immunoblotting demonstrated that the proportion of NACP/synaptophysin was more than double in the AD frontal cortex as compared to controls. NACP was localized to approximately 80% of the synaptophysin-immunoreactive boutons, presumably the presynaptic terminals, and to the dystrophic neuritic component of the plaques. Although the overall numbers of NACP-positive boutons were decreased, there was a significant increase in the intensity of NACP-immunoreactivity per bouton in AD. This increased intensity of immunoreactivity of boutons in AD was not observed with anti-synaptophysin, consistent with immunoblotting-based quantification. Antibodies against NAC immunoreacted with amyloid in 35% of the diffuse plaques and 55% of the mature plaques. Normal aged control brains containing small groups of diffuse plaques were negative with anti-NAC. Double-immunolabeling studies with Aβ antibodies showed that NAC immunoreactivity is more abundant in the center portion of amyloid than in the periphery. These studies suggest that there is a connection between metabolism of presynaptic proteins and amyloid formation, and that NAC might follow diffuse Aβ accumulation resulting in the formation of compact amyloid and mature plaques.

NACP, THE PRECURSOR PROTEIN OF NON-Aβ COMPONENT OF ALZHEIMER'S DISEASE AMYLOID, BINDS Aβ THROUGH THE HYDROPHOBIC REGION AND STIMULATES Aβ AGGREGATION.
M. Yoshimoto*, A. Iwai, D. Kang, D. A. C. Otero, Y. Xia, and T. Saitoh, Dept. of Neurosciences, University of California, San Diego, La Jolla, CA 92093-0624

NAC (Non-Aβ Component of Alzheimer's Disease Amyloid) is a peptide isolated from and immunologically localized to brain amyloid of patients afflicted with Alzheimer's Disease (AD). Molecular cloning of a cDNA encoding NAC has shown that NAC was derived from its precursor protein, NACP, of 140 amino acid residues. We found that NACP produced in *E. coli* bound with Aβ1-38 and Aβ25-35 immobilized on nitrocellulose, but did not bind with Aβ1-28 under the same conditions. The NACP binding to Aβ1-38 was abolished by the addition of Aβ25-35, but not by Aβ1-28, suggesting that the hydrophobic region of the Aβ peptide is critical to this binding. NACPδ, a deletion mutant of NACP lacking the NAC domain, did not bind with Aβ1-38. Furthermore, the binding between NACP and Aβ1-38 was decreased by the addition of peptide Y, a peptide which covers the last fifteen residues of NAC. These data indicate that NACP and Aβ peptides bind through the interaction between the C-terminal portion of NAC and the 25-35 region of Aβ peptides. In an aqueous solution, NACP formed an SDS insoluble complex with Aβ1-35 after incubation at 37°C for 72h, with a molar ratio of 1:1. Aβ1-38, on the other hand, formed an SDS insoluble aggregate when incubated with NACP at a ratio of 1:125 (NACP:Aβ), while Aβ1-38 alone or NACP alone did not aggregate under the same conditions. Thus NACP can bind Aβ peptides through the specific sequence and can promote Aβ aggregation. These data suggest that NAC or NACP may be involved in the process of amyloid formation from Aβ. This work has been funded by Alzheimer's Disease Research, a program of the American Health Assistance Foundation, and NIH grant AG05131.

INDUCTION OF HEME OXYGENASE-1 mRNA IN CEREBRAL VESSELS AND NEOCORTEX IN ALZHEIMER'S DISEASE.
D.R.D. Premkumar*, M.A. Smith, R.K. Kutty, B. Wiggert, G. Perry and R.N. Kalaria. Departments of Neurology and Pathology, Case Western Reserve University, Cleveland, Ohio and The National Eye Institute, National Institutes of Health, Bethesda, Maryland, USA

Previous studies demonstrated the specific association of heme oxygenase-1 (HO-1) protein to the pathological lesions present in Alzheimer's disease (AD). In this study, we used reverse transcription -polymerase chain reaction methods to show the increased expression of HO-1 but not heme oxygenase-2 (HO-2) mRNA transcripts in cerebral cortex and cerebral vessels from subjects with AD compared to age-matched non-AD controls. Neither HO-1 nor HO-2 mRNA was altered in the cerebellar samples; a brain region usually spared from the pathological alterations of AD. There was no clear evidence that the expression of HO-1 in these tissues was related to postmortem interval, the age of subjects or any known premortem agonal factors. The specificity of our observations was further verified by the demonstration of unchanged ß actin mRNA transcripts but increased GFAP mRNA in tissues from AD subjects compared to controls. Our findings indicate the specific induction of HO-1 mRNA and increased expression of HO-1 protein in neocortex and cerebral vessels but not HO-2, and suggest that oxidative stress is important in the pathogenesis of AD. Supported by grants from NIA and ADRDA.

DECREASES IN CEREBRAL HEMOGLOBIN OXYGENATION DURING BRAIN ACTIVATION IN PATIENTS WITH ALZHEIMER'S DISEASE MONITORED BY MEANS OF NEAR INFRARED SPECTROSCOPY (NIRS) - CORRELATION WITH SIMULTANEOUS rCBF-PET MEASUREMENTS.
C. Hock*[1], F. Müller-Spahn[1], K. Villringer[3], H. Heekeren[2], A. Ghidau[2], R. Störmer[2], S. Schuh-Hofer[2], U. Dirnagl[5], A. Villringer[5], S. Minoshima[4], S. Ziegler[3], M. Schwaiger[3]. Depts. of Psychiatry, University of Basel[1], Switzerland, and Munich[2], Germany, Depts. of Nuclear Medicine, Technical University of Munich[3] and Ann Arbor[4], Michigan, Dept. of Neurology, Humboldt University of Berlin[5], Germany.

We applied a dual channel NIRS system using two pairs of optodes placed on the left parietal cortex and on the left frontal cortex to study non-invasively changes in cerebral hemoglobin oxygenation during activation of brain function in patients with Alzheimer's disease (AD) compared to controls. Healthy elderly subjects (n=8, age 60 ± 15) showed increases in oxygenated hemoglobin [HbO_2] as well as total hemoglobin [HbT] in both frontal (mean (arbitrary units) ± SEM, 2.00 ± 1.45 and 2.37 ± 1.99, respectively) and parietal cortex (1.26 ± 1.03 and 0.23 ± 0.88, respectively) during performance of a verbal fluency task. In contrast, AD patients (n=10, age 65 ± 13 years) showed decreases in [HbO_2] and [HbT] in the parietal cortex (-2.48 ± 0.91, $p<0.02$, and -3.37 ± 1.13, $p<0.05$, respectively) and, simultaneously, increases in [HbO_2] and [HbT] in the frontal cortex (1.40 ± 2.56 and 0.31 ± 3.30, respectively). Simultaneous NIRS and ($O15\text{-}H_2O$-) PET measurements during brain activation (stroop test, n=10) showed that PET rCBF changes were paralleled by changes in [HbT] as measured by NIRS. Modeling the spatial relationship of the NIRS-measurements to the PET-image revealed best correlation assuming a NIRS sample volume covering approximately the outer 1.6 cm of the brain cortex beneath the optodes (r=0.71, p=0.021). Regional decreases in cerebral [HbT] and rCBF during activation of brain function in patients with AD may contribute to the development and the time course of neurodegeneration.

^{31}P MRS *IN VITRO* STUDY OF GRADED HYPOXIA IN FISCHER 344 RATS. R.J. McClure*, K. Panchalingam, W.E. Klunk and J.W. Pettegrew. *Lababoratory of Neurophysics, University of Pittsburgh Medical Center, W.P.I.C., Pittsburgh, PA 15213.*

Episodes of mild to moderate energetic stress could, in some individuals, trigger molecular and metabolic events that result in the biochemical findings in the brains of Alzheimer's disease (AD) patients. In this study we determined the phospholipid and high-energy phosphate metabolite levels by ^{31}P MRS at 11.7 Tesla of perchloric acid brain extracts of Fischer 344 rats that had been exposed to graded hypoxia. New born, 5 and 10 day, 1, 2, 12, and 24 month old rats were studied after 0, 15, 30, 60, 120, 300, and 600 seconds of acute hypoxia. Levels of α-glycerol phosphate (α-GP) and inositol-1-phosphate were elevated after 30 seconds of hypoxia, the greatest effect was seen in young animals. α-GP is present in very low levels in new born to 10 day old animals. Phosphocreatine (PCr) levels were found to decrease after 30 seconds of hypoxia in all age groups. There is a link between phospholipid and high-energy metabolism which is seen in the linear correlation between PCr and α-GP levels. These correlations for the different age groups are: new born, 5 and 10 day ($p=0.001$, $r=-0.84$); 1 and 2 month ($p=0.0001$, $r=-0.92$); and over 12 month ($p=0.001$, $r=-0.75$). The slope of the linear regression line for these PCr and α-GP correlations increases with age which suggest that the older animals are more susceptible to energetic stress. This connection between energetic stress and alteration in membrane phospholipid metabolism may be relevant to the pathophysiology of AD.

POSTISCHEMIC DEPLETION OF GFAP REACTIVITY IN HIPPOCAMPAL ASTROCYTES IS PREVENTED BY HWA285
A.McRae[1]*, M. Knabel[2], P. Schubert[2], K. Rudolphi[3]
[1]University of Göteborg Sweden 41390, [2]Max Planck Institute of Psychiatry Martinsried Germany, [3]Hoechst AG Frankfurt a.M. Germany

Transient (5 min) forebrain ischemia causes a reactive hypertrophy of astrocytes in the gerbil hippocampal CA1 area, reflected by an increased immunoreactivity for glial fibrillary acidic proteins (GFAP) at the 2nd postischemic (p.i.) day. In animals developing complete nerve cell death, this is followed by a depletion of GFAP staining in the CA1 stratum radiatum which appears at the 7th p.i. day as a demarcated area with a complete loss of cellular and neuropil staining. We have previously observed that pre-treatment with the neuroprotective pharmacon propentofylline (HWA285) interferes with the initiation of the astrocyte reaction preventing the ischemia-induced increase of GFAP staining. However, daily post-treatment with HWA285, started at the 2nd p.i. day was found in the present study to prevent the consecutive fading of the GFAP reactivity completed at the 7th p.i. day in the CA1 area. Here, a maintained strong GFAP staining was observed in process-bearing astrocytes, whereas neuronal damage was not prevented (as verified by MAP2 staining). We have emerging evidence that chronic HWA treatment increases GFAP reactivity in cultured astrocytes and reinforces the development of potentially neuroprotective properties by strengthening the cAMP signalling, whereas microglial activation and APP immunoreactivity are suppressed. Such a pharmacological conditioning of glial cell may provide protection against progressive, but less dramatic neuronal death than induced by ischemia, e.g. in Alzheimer or Parkinson patients.

ALPHA-1 ANTICHYMOTRYPSIN IN HUMAN OLFACTORY BULB. RG. Struble* D. Bayley, M Ghobrial. Southern Illinois University School of Medicine. Springfield, IL. 62794

Alpha-1 antichymotrypsin (ACT) is associated with senile plaques and amyloid deposition, the classic markers for Alzheimer's disease (AD). One hypothesis in AD is that senile plaques are sites of abortive sprouting representing dysfunctional control of regeneration. We hypothesized that if ACT is involved in regeneration, we should find it in olfactory bulb of normal controls. The olfactory bulb is unique because the olfactory nerve regenerates continuously throughout the life of the organism. We therefore examined the immunohistochemical localization of ACT in olfactory bulbs in humans ranging in age from 1 year to 85 years. **We found that ACT-containing perikarya, probably glia, were consistently found in regions where axonal growth could be inferred.** ACT immunoreactive glia were distributed around the olfactory nerve as it entered to bulb and throughout the granule cell layer, both regions rich in GAP43. We conclude that ACT is present in sites of axonal growth. ACT's presence in senile plaques may represent localized, abortive sprouting. If this hypothesis is correct, then treatments to induce axonal growth may be counterproductive in arresting the progression of Alzheimer's disease. Supported by NIA grant #P30 AG08014.

CHRONIC EXPRESSION OF PLATELET ACTIVATING FACTOR (PAF) AND CLUSTERIN IS ASSOCIATED WITH NEURODEGENERATION IN RAT BRAIN FOLLOWING EPILEPTIFORM SEIZURES. Bennett, S.A.L.[1,2*], Tenniswood, M.P.R.[1], and Roberts, D.C.S.[2]. [1]Alton Jones Cell Science Center, Lake Placid, NY, USA, 12946; [2]Life Sciences, Carleton University, Ottawa, Ont., Canada, K1S 5B6.

Pro-inflammatory molecules are associated with the principal lesions of a wide variety of progressive neurodegenerative disorders. It is unclear whether induction of inflammatory response molecules in the central nervous system precedes lesion formation or is a consequence of chronic exposure to non-degradable plaque elements (i.e. Periodic acid Schiff (PAS) + material). In the present study, we have investigated the relationship between clusterin, PAF, and the development of PAS + lesions following limbic status epilepticus. Clusterin is a complement regulatory protein and a prominent marker of neurodegeneration and apoptosis. PAF is a potent pro-inflammatory autacoid implicated in mediating ischemic injury and convulsive activity. In the present experiments, epileptiform seizures were elicited in male Wistar rats by IP administration of 10 mg/kg kainic acid. Brain sections were processed at various time points after seizure induction for PAS histochemistry and clusterin, PAF, and PAF receptor (PAFR) expression by immunohistochemistry and *in situ* hybridization. Apoptosis was determined by *in situ* TUNEL labelling and by evaluating DNA fragmentation. RNA was extracted from unfixed tissue blocks and regional changes in PAFR and clusterin mRNA expression evaluated by Northern analysis and RT-PCR. Results demonstrate that epileptiform seizures induce both programmed cell death and PAS staining 24-168 hr after seizure onset. Of significant interest was the finding that changes in PAF and PAFR expression were correlated with subsequent alterations in clusterin expression, PAS staining, and apoptosis. Transient PAF and PAFR expression preceded transient clusterin expression in areas that demonstrated only limited cell loss. Chronic PAF and PAFR expression occurred in those areas expressing clusterin at later time points exhibiting substantial cell loss and PAS+ lesions. These data suggest that chronic exposure to pro-inflammatory agents precedes and may, in fact, contribute to the etiology of neurodegenerative lesions. (Supported by M.R.C.)

ANTI-MICROGLIA ANTIBODIES IN SERA OF ALZHEIMER´S PATIENTS. M.R. Lemke*, M. Glatzel, A. Henneberg. Dept. Psychiatry, Medical Center, D-85049 Ingolstadt, Germany (M.R.L.), Dept. Neurology, Ulm University, D-89070 Ulm, Germany (M.G.,A.H.)

Objective: Immune mechanisms seem to be involved in tissue destruction in Alzheimer´s disease (AD). There is evidence indicating the importance of microglia in AD. In brains of AD patients the presence of complement components has been documented, that are typically activated by immune complexes. Therefore, sera of AD patients were tested for antibodies against various brain structures.

Method: In patients (n=30) with AD (according to DSM-III-R and NINCDS-ADRDA criteria, MMSE<16) and matched controls (n=30, MMSE>24) serum antibodies were measured using an indirect immunofluorescence test as published previously.

Results: In nine patients perinuclear antibodies against microglia were found in amygdala and frontal cortex. Only one of the controls showed antibody binding to microglia.

Conclusions: The results support the hypothesis of involvement of immune mechanisms in AD. Perinuclear antibodies to microglia may play a role in tissue destruction of AD. Whether these findings are specific for AD or represent a subgroup of AD needs further evaluation.

EFFECT OF ATP DEPLETION ON THE ACTIVITY OF PK40^{erk2} IN DIFFERENTIATED PC12 CELLS: IMPLICATION FOR ALZHEIMER'S DISEASE. Y.Luo, R.Mehra, L.Butler, V.M.Ingram , Dept. of Biology, Massachusetts Institute of Technology, Cambridge, MA 02139.

Hyperphosphorylated TAU is a major constituent of tangles found in Alzheimer brains; ATP is depleted in such brains. We previously reported that the brain protein kinase PK40^{erk2} can hyperphosphorylate TAU to resemble Alzheimer TAU, as found in the tangles; it is strongly inhibited by free ATP in excess over MgATP. The mitochondrial uncoupler FCCP will deplete ATP levels in differentiated PC12 cells. (1) While in-gel kinase assays show that FCCP treatment abolishes the activities of 4 MBP protein kinases by an unknown mechanism, the same assay shows the activity of another kinase to be unaffected. This appears to be PK40^{erk2} by Western blot, and by in-gel assays with hTau40 or neurofilament proteins as substrates. The increased in-vivo activity of a neurofilament kinase reported by us [Bush et al.,PNAS 1995, 92:1861] is therefore likely to be due to up-regulation of the kinase in the cell by ATP depletion [release from partial inhibition]. The PK40^{erk2} assay of ERK2-specific immune-precipitates from extracts of treated cells also shows no in-vitro increase of kinase activity. FCCP does not increase synthesis or tyrosine phosphorylation of PK40^{erk2}. (2) FCCP treatment increases, mechanism unknown, the amount of protein phosphatase PP2A in extracts. This may account for the increase in the dephosphorylated TAU-1 epitope, reported by us earlier. The results explain the late onset of TAU hyperphosphorylation in Alzheimer disease and suggest a novel mechanism for the regulation of certain kinases.

LONG-TERM POTENTIATION: PHYSIOLOGY VII

ACTIVATION OF POSTSYNAPTICALLY SILENT SYNAPSES DURING PAIRING-INDUCED LTP. D. Liao* & R. Malinow, Cold Spring Harbor Laboratories, Cold Spring Harbor, NY and *Dept. of Physiology & Biophysics, U. of Iowa, Iowa City, IA.

We have tested the hypothesis that in the CA1/subiculum region of hippocampus there exist synapses with only NMDA receptors (and thus effectively silent at resting potentials), and these synapses acquire AMPA responsivity after LTP. Consistent with this hypothesis, more synaptic failures were observed at hyperpolarizing (-65mV) than at depolarizing (+55mv) holding potentials (n=25, 52.7±4.6% Vs 20.0±2.7%). The difference in failure rate at -65mV and +55mV was blocked by 100 μM AP-5, (n=5). To stimulate just pure NMDA synapses, a (subminimal) stimulus can be set so that all trials produce failures at -65mV, but responses are seen at +55mV. We recorded 100 consecutive trials at -65mV with a subminimal stimulus. Pairing depolarization with the same subminimal stimulus produced subsequent synaptic responses at -65mV (12 of 22 experiments compared to 3 of 17 with no pairing; $p < 0.05$, Chi-test). In other experiments we could identify failures at hyperpolarizing and depolarizing potentials before and after LTP. After LTP there was a significant decrease in failure rate at hyperpolarized potentials, but no significant change at depolarized potentials (56±6% to 34±6% at -65mV vs 19±4% to 22±5% at +55mV; n=12).

LOW FREQUENCY STIMULATION INDUCES HOMOSYNAPTIC LTD IN THE CA1 REGION OF THE ADULT HIPPOCAMPUS IN VIVO. A.J. Heynen, M.F. Bear* and W.C. Abraham. Department of Psychology, University of Otago, Dunedin, New Zealand and Department of Neuroscience and HHMI, Brown University, Providence, RI 02912

Previous in vitro studies have demonstrated that low frequency stimulation (LFS; 1-5 Hz) of the Schaffer collaterals induces long term depression (LTD) of synaptic responses in CA1. This synaptic modification is input-specific, frequency-dependent, reversible and dependent upon N-methyl-D-aspartate (NMDA) receptor activation. Although homosynaptic LTD is now well characterized in hippocampal slices obtained from juvenile animals, it remains controversial whether LTD occurs in the CA1 region of adult hippocampus in vivo. The purpose of the present study was to examine LFS-induced LTD in the Schaffer collateral synapse in the intact preparation. Adult male Sprague Dawley rats (250-400 gm) under pentobarbital anesthesia (65 mg/kg) had recording and stimulating electrodes positioned in the stratum radiatum of one hemisphere. Field excitatory postsynaptic potentials (EPSP; 2-8 mV) were monitored for 30 minutes prior to application of LFS (900 pulses @ 1Hz). A lasting depression of synaptic responses was consistently observed following LFS (EPSP slope at 30 min post LFS = 84.1 ± 4 % of baseline; n = 9). LFS-induced LTD could be reversed by subsequent application of high frequency (100 Hz) stimulation. Repeated episodes of LFS saturated LTD (75.3 ± 3 % of baseline; n = 5). LTD was input-specific (homosynaptic), as responses to stimulation of afferents originating in the contralateral hemisphere (commissural input) remained unaffected by LFS of the Schaffer collateral input. Experiments in progress indicate that induction of LTD is frequency-dependent and requires NMDA receptor activation. Together, these results demonstrate that the properties of homosynaptic LTD observed in vitro also apply to the adult hippocampus in vivo. Supported in part by grants from the NZ Health Research Council.

HETEROSYNAPTIC LTP AND LTD OCCUR IN ASPINOUS CA1 INTERNEURONES. C. Stricker*, L. Reece, A.I. Cowan and S.J. Redman. Div. Neuroscience, John Curtin School of Med. Res., Australian National University, Canberra, Australia.

Synaptic specificity of LTP in CA1 pyramidal neurones has been attributed to compartmentalization of calcium in the spines associated with the activated synapses. This hypothesis was examined by testing for synaptic specificity at excitatory synapses on interneurones located in the CA1 pyramidal cell layer which are largely aspinous[1]. A standard hippocampal slice preparation from young rats (17-24 days) was used, maintained at 30°C, and bicuculline (10μM) was added to the ACSF. Intracellular recordings from interneurones were distinguished from recordings from pyramidal neurones by their short spike duration (< 1ms), pronounced spike afterhyperpolarization and lack of spike adaptation to a maintained current step. EPSPs were evoked from two stimulation sites in stratum radiatum: one near the cell body layer and the other adjacent to stratum moleculare. Stimulus strengths were adjusted to evoke EPSPs in the range 1-5 mV. EPSPs were evoked from each input at 0.5 Hz to obtain baseline responses. Independence of the two inputs was demonstrated by lack of occlusion when both inputs were stimulated simultaneously. One input was then tetanised at 100 Hz in five bursts of 20-40 stimuli while the stimulus was abolished from the other input. During conditioning the cell was depolarized until it discharged at a high frequency. Conditioned responses for both inputs were then recorded at 0.5 Hz for at least 30 mins. When one input was conditioned (n=21), the non-conditioned EPSP potentiated (10), depressed (7) or did not change (4). The conditioned EPSP potentiated (6), depressed (10) or did not change (5). The frequency of these various outcomes was independent of whether the conditioned input was proximal or distal from the soma. The heterosynaptic LTP observed in these interneurones supports the hypothesis that spines confer synaptic specificity to LTP in pyramidal cells.

788.4

INDUCTION OF HEBBIAN AND NON-HEBBIAN LTP AT THE HIPPOCAMPAL MOSSY FIBER SYNAPSE BY DISTINCT PATTERNS OF HIGH FREQUENCY STIMULATION. N.N. Urban* and G. Barrionuevo *Dept. of Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15260.*

Long trains of high frequency tetanic stimulation (L-HFS, 100 pulses at 100 Hz) delivered to the hippocampal mossy fiber (MF) input to CA3 pyramidal cells induce a form of LTP not requiring post-synaptic activation, *i.e.* a non-Hebbian form of LTP. Specifically, MF-LTP induction by L-HFS is unaffected by blockade of ionotropic glutamatergic synaptic transmission during tetanus by 10 mM kynurenic acid (Kyn) (Castillo *et al. Neuron* **12**:261), postsynaptic membrane potential, calcium chelation and CA3 cell dialysis (Zalutsky & Nicoll, *Science*, **248**:1619, Katsuki *et al., Neurosci. Res.* **12**:393, Langdon *et al., J. Neurobiol.* **26**:370).

We reported (*Soc. for Neurosci. Abstracts* **20**:302.13) that brief-HFS (B-HFS, 8 pulses at 100 Hz, 10 times at 0.2 Hz) reliably induces an NMDA-independent form of MF-LTP that is inhibited by whole-cell dialysis. We hypothesized that MF-LTP induced by B-HFS represents a Hebbian form of LTP (Jaffe & Johnston, *J. Neurophysiol.* **64**:948). We now report that, in contrast to L-HFS, B-HFS fails to induce MF-LTP in the presence of Kyn. (Post B-HFS amplitude = 97% of control, N=15). MF-LTP was induced by B-HFS after wash out of Kyn (208% of control, N=13). This result suggests that B-HFS induced MF-LTP requires the activation of the postsynaptic CA3 cell. In 5 additional experiments, NMDA receptors were blocked by both 10 μM MK-801 and 25 μM D-APV, cells were whole-cell voltage clamped at -80 mV, and dialyzed for at least 25 min with BAPTA (1 mM) and CsF (120 mM). In these experiments, B-HFS induced LTP (161% of control) of the field EPSP but not of the simultaneously measured MF-EPSC (93% of control). Taken together these data demonstrate that both Hebbian and non-Hebbian forms of NMDA-independent LTP can occur at the MF-CA3 synapse; B-HFS induces a Hebbian form of LTP while L-HFS also can induce a non-Hebbian form of LTP. SELECTIVE RECRUITMENT OF AMPA RECEPTOR MEDIATED CURRENT DURING LTP IN MEDIAL PERFORANT PATHWAY OF RAT DENTATE GYRUS. **S. Wang* and J.M. Wojtowicz. Department of Physiology, University of Toronto, Toronto, Canada, M5S 1A8**

Whether long-term potentiation (LTP) is due to enhanced AMPA receptor mediated current alone or due to the enhancement of both AMPA and NMDA receptor mediated currents is controversial. In this study, we examined the medial perforant pathway synaptic transmission during LTP to address this issue. Whole-cell voltage clamp recordings were made in rat dentate granule neurons in a standard hippocampal slice preparation. Synaptic currents were evoked by stimulating the medial perforant pathway in the middle third of the dentate gyrus molecular layer. Membrane potential was held at -65 to -75 mV. Double exponential curves fitted to the decay phase of the responses revealed a large fast component and a small slow component. Using pharmacological agents we demonstrated that the small component, constituting 14 ± 7% (n = 8) of the total response, represents the NMDA current. LTP was induced by four brief trains of stimuli at 100 Hz, paired with postsynaptic depolarization to -20 mV. The success rate of inducing LTP in individual granule neurons was only 42% but the average magnitude was large. In a representative series of nine experiments the average potentiation was 339 ± 255%. During LTP expression, only the AMPA current increased while the NMDA current was unchanged. Furthermore, the variable magnitude of LTP was directly related to the relative size of the NMDA component prior to induction of LTP. (Supported by MRC of Canada)

788.6

THE EXTENT OF NMDA RECEPTOR ACTIVATION DURING A TETANUS DETERMINES WHETHER LTP IS EXPRESSED BY AMPA OR NMDA RECEPTORS.

L. Aniksztejn and Y. Ben-Ari*. INSERM U29, 123 Bld de Port-Royal 75014 Paris (France)

Analysis whether LTP is expressed by AMPA or by AMPA and NMDA receptors is a useful approach to determine if LTP is pre- or postsynaptically mediated, but has given contradictatory results. We have now tested the hypothesis that the threshold to induce LTP mediated by AMPARs differs from that required to trigger LTP expressed by NMDARs. Extracellular recordings were made in the CA1 hippocampal region in 0.3 mM Mg^{2+}.The NMDA component of the field EPSP ($fEPSP_N$) was isolated from the AMPA component ($fEPSP_A$) by adding CNQX before and 40 min after the tetanic procedure. Three tetanic stimulation were applied (after the washout of CNQX) at weak intensity, subthreshold for eliciting $fEPSP_N$) (T_W), or at strong intensity which elicited $fEPSP_N$ of 0.3 mV (T_S). T_W induced LTP of $fEPSP_A$ (59 ± 8%, n=9) but not of $fEPSP_N$ (11 ± 2%). In contrast,T_S failed to generate LTP of $fEPSP_A$ (9 ± 3%,n =9/13) but produced LTP of $fEPSP_N$ (89 ± 17 %). In the 4 remaining cases LTP of both components were observed. In presence of the redox reagent DTNB (200 μM) or 7-Cl^--Kyn (6 μM) which reduce $fEPSP_N$ by 50 %, T_S produced LTP of $fEPSP_A$ (63 ± 8 %, n=6) but not of $fEPSP_N$ (12 ± 4%). Under the same conditions, T_W generated LTP of $fEPSP_A$ of smaller amplitude than in control (30 ± 6 %, n= 8). We conclude that i) stronger activation of NMDA receptors during a tetanic train is required for inducing LTP of $fEPSP_N$ than for $fEPSP_A$; ii) there is a bell-shaped relationship between the extent of NMDA receptor activation during the train and the magnitude of LTP of $fEPSP_A$. Therefore, these findings reinforce the hypothesis that expression of LTP is a postsynaptic process.

NMDA-MEDIATED ACTIVITY-DEPENDENT SHORT-TERM PLASTICITY OF ELECTROTONIC COUPLING. Alberto Pereda* and Donald S. Faber *Dept. of Anatomy & Neurobiology, Medical College of Pennsylvania and Hahneman University, Philadelphia, PA.*

As reported previously discontinuous tetanic stimulation of the posterior eighth nerve produces a long-term homosynaptic enhancement of both the electrotonic and chemical components of the mixed excitatory postsynaptic potential (EPSP) recorded from the Mauthner(M-) cell lateral dendrite. We report here that the same tetanizing paradigm can evoke a shorter lasting potentiation (2-10 min.), which averaged 231.4 ± 24% (± SEM) for the electrotonic and 208.9 ± 20.4% for the chemical EPSPs (n=14) when measured right after tetanic stimulation. These modifications were not non-specific, since the M-cell antidromic spike, an indicator of the neuron's input resistance, did not change significantly (mean=100.5 ± 2.7% of control). The fact that short-term potentiation of electrotonic coupling occurs in parallel with that of the chemical EPSP suggested that these transient changes might have a presynaptic origin, for example, being due to an activity-dependent increase in the presynaptic calcium concentration. To test this possibility we compared the observed effects with those evoked by paired presynaptic stimuli. However, paired pulses failed to produce significant changes in electrotonic transmission (mean=102.2 ± 2.6% of control) although it strongly facilitated the second chemical response (mean=33.1 ± 7.8% of control, n=16). In contrast, the induction of this short term potentiation rather depended upon the discontinuous or burst-like property of the tetanizing paradigm, which optimizes NMDA receptor activation while continuous stimulation (50Hz) fatigues chemical transmission. Accordingly, the short-potentiation of both components required NMDA receptor activation, as the intermittent stimulus bursts failed to induce any potentiation in the presence of the NMDA receptor blockers APV and CPP (50-100μM, n=5). These potentiations were also blocked by intradendritic injections of the calcium chelator BAPTA (5mM, n=5). Thus, while paradigms known to raise the presynaptic calcium concentration were capable of only modifying chemical transmission, NMDA-mediated postsynaptic increases in calcium could evoke transient changes not only in the chemically mediated EPSP but also in electrotonic coupling.

PRESYNAPTIC LONG-TERM POTENTIATION (LTP) OF EXCITATORY SYNAPTIC TRANSMISSION IN SINGLE GRANULE CELLS (GCS).

G.Tong*, R.C.Malenka, C.E.Jahr and R.A.Nicoll. Dept. of Cellular and Molecular Pharmacology, Physiology and Psychiatry, University of California, San Francisco, CA 94143.

Previous studies in slices suggest that mossy fiber LTP in the hippocampal CA3 region is induced and expressed presynaptically by increased cAMP dependent protein kinase (PKA) activity in presynaptic terminals. We took advantage of microdot cultures to test whether single guinea pig GCs which form autapses show LTP. GCs were distinguished from other cells by their L-AP4 sensitivity. Consistent with the results from the slice preparation, tetanic stimulation (50 Hz, 1s, 4 times) in the presence of the NMDA receptor blockers D-AP5 (50 μM) and Mg^{++} (1 mM) induced a sustained potentiation of both NMDA and AMPA components of evoked excitatory postsynaptic currents (EPSCs) that lasted at least 30 min in L-AP4 sensitive cells. In contrast, in L-AP4 insensitive cells tetanic stimulation induced no LTP. Short applications (2 min) of forskolin (30 μM) also induced a long-lasting potentiation of evoked NMDA EPSCs in L-AP4 sensitive cells but a short-term potentiation (about 10 min) in L-AP4 insensitive cells. Furthermore, preincubating neurons with a PKA inhibitor, RP-8-CPT-cAMPS (100 μM) blocked tetanus induced LTP. Finally, the frequency of spontaneous miniature AMPA EPSCs was potentiated by tetanic stimulation but the amplitude of minis remained the same. These results suggest that in single GCs, tetanic stimulation causes a presynaptic increase in cAMP leading to a long-lasting enhancement of transmitter release. This enhancement may be due to an alteration of the internal machinery that controls transmitter release.

PAIRED-PULSE FACILITATION OF DUAL-COMPONENT EPSCS IN HIPPOCAMPAL PYRAMIDAL CELLS - IMPLICATIONS FOR LTP.
Dimitri M. Kullmann* Clinical Neurology, Institute of Neurology, Queen Square, London WC1N 3BG, UK.

The coefficient of variation of the AMPA receptor-mediated component of population EPSCs in CA1 cells is consistently larger than that of the NMDA receptor-mediated component (Kullmann, 1994; Neuron 12, 1111). I have proposed that this difference arises because AMPA receptors are absent or non-functional at a proportion of synapses, but can be activated with the induction of LTP. An alternative explanation, however, is that AMPA receptors are postsynaptic to release sites with a lower average release probability than NMDA receptors. If this were so, the paired-pulse facilitation ratio (PPFR) of AMPA receptor-mediated EPSCs should be higher than that of NMDA receptor-mediated EPSCs, since PPFR varies inversely with release probability. This has indeed been described under certain conditions (Clark et al, 1994; Exp. Brain Res. 101, 272). I have tested this hypothesis by measuring PPFR for the two components at the same synapses, by recording from CA1 cells with whole-cell electrodes in guinea pig hippocampal slices. EPSCs were elicited with paired stimuli in stratum radiatum (interval: 50 ms). The AMPA component was initially recorded at a holding potential of -80 mV, and the NMDA component was then recorded at +40 mV in 10 μM DNQX. No difference was seen between the PPFRs for the two components (t-test: $p>0.5$, $n = 18$). When two presynaptic stimulating electrodes were used, the PPFR often differed between the two pathways, but the same difference was seen whether the AMPA or NMDA component was studied. These findings imply that AMPA and NMDA receptors are exposed to glutamate released with the same release probability, and that the discrepancy between the coefficients of variation reflects a non-uniform distribution of clusters of functional AMPA receptors.

788.10

Tonic and phasic retrograde signals at CA3-CA1 hippocampal synapses
J.Noel * and A.Malgaroli Scient. Inst. S. Raffaele, Dibit, Milano, Italy

Mechanism(s) of diffusive retrograde signalling at CA3-CA1 synapses and their importance for control and potentiated transmission are strongly debated. One of the main argument against this hypothesis is that LTP cannot be induced if the postsynaptic neuron is loaded with Ca^{2+} chelators, as nearby cells should still deliver diffusive signals. We investigated this problem in CA3-CA1 hippocampal cultures by monitoring miniature EPSCs (minis) (0.5 μM TTx present). Mini frequency LTP was elicited with 3 brief (200 ms) local applications of 90 mM KCl (388±37% potentiation at 50 min, n=9). LTP was prevented by loading postsynaptic neurons with either BAPTA (5-10 mM; 102±3% at 30 min, n=8) or NOS inhibitors (LNA 10 μM; 134±7% at 30 min, n=9) and by in phase application of hemoglobin (100 μM; 60 sec; 105±5% at 25 min, n=10). This strengths the idea that NO is a phasic retrograde signal required for LTP induction, but does not exclude possible additional BAPTA effects. We used a dual electrode recording approach to study the influence of postsynaptic BAPTA or NOS blockers on basal synaptic activity. Minis were monitored with a first patch pipette (WC perforated patch recording) before and after accessing the same cell with a second WC pipette to deliver compounds. Surprisingly, after the introduction of BAPTA, quantal frequency was drastically reduced (300±39% reduction, n=4) and this was not seen with NOS inhibitors (n=3). As in our culturing conditions autaptic connections are exceedingly low, we think that BAPTA also inhibits a tonic retrograde signal, which regulates quantal exocytosis and is presumably required for LTP. We conclude that presynaptic terminal functioning could be modulated by different tonic and phasic retrograde signalling mechanisms controlled by postsynaptic Ca^{2+}.

788.11

ACTION POTENTIALS PROPAGATING BACK INTO DENDRITES TRIGGERS CHANGES IN EFFICACY OF SINGLE-AXON SYNAPSES BETWEEN LAYER V PYRAMIDAL NEURONS
Henry Markram* and Bert Sakmann, Max-Planck Institute, Dept of Cell Biology, Jahnstrasse 29, Heidelberg, D-69120, Germany.

Synaptic plasticity of single-axon (sa) synapses was examined using whole-cell recordings of synaptically coupled pairs of Layer V pyramidal neurons in the rat neocortex. Neurons were identified in slices with infrared differential interference contrasts microscopy. Simultaneous pre and postsynaptic depolarisation, that resulted in a burst of action potentials (APs), triggered a long-lasting (>40 min) increase in the amplitude of saEPSPs (n=9). APs triggered in synchrony in the pre and postsynaptic neurons by brief (5ms) current pulses and at rates from 10 to 40Hz also resulted in a long-lasting increase in synaptic efficacy (n=37) that was dependent upon the activation of NMDA receptors (n=8). Postsynaptic APs in the absence of synaptic input had no effect on saEPSP (n=6). Associative subthreshold depolarisation (n=8) or depolarisation to around -20mV in QX-314- loaded neurons (n=6) during synaptic input, also failed to induce an increase in synaptic efficacy. Indeed, strong associative depolarisation resulted in a reduction in the amplitude of most saEPSPs. The maximum increase in synaptic efficacy increased with frequency of synchronous pre-postsynaptic APs, while increasing the number of APs in a burst of 20Hz did not result in larger increases than that achieved with 2APs. Only saEPSPs that collided with the backpropagating AP increased in synaptic efficacy while saEPSPs that arrived 10ms after the backpropagating AP were either unchanged or weakened (n=6). These results show that the backpropagating AP is the trigger for changes in efficacy of this synapse. The constraints of AP frequency, number and timing suggest that connectivity only between pyramidal neurons that obtain common synaptic input will be enhanced which may enable the organisation of functional neuronal ensembles.

788.12

LTP INDUCED BY NITR-5 PHOTOLYSIS IN RAT CA1 HIPPOCAMPAL NEURONS WITHOUT PRESYNAPTIC ACTIVITY.
D. Neveu[1], R.C. Malenka*[2] and R.S. Zucker[1]. [1]Neurobiology Div., Univ. of Calif., Berkeley, CA 94720 and [2]Psychiatry Dept., Univ. of Calif., San Francisco, CA 94143.

A rise in postsynaptic $[Ca^{2+}]_i$ can trigger a long-lasting form of synaptic enhancement resembling LTP in rat hippocampal CA1 pyramidal cells (Malenka *et al.*, 1988). It is unclear whether this process is the same as LTP induced by afferent stimulation. Neither its interaction with tetanically induced LTP nor its requirement for presynaptic activity have been determined.

We used photo-activation of postsynaptically injected nitr-5 to elevate postsynaptic $[Ca^{2+}]_i$ to a level of about one-half to a few micromolar. This induced an increase in the rising slope of the EPSP obtained on stimulating Shaffer collateral afferents at 0.1 Hz. An increase of up to 140% was observed (average 66% ± 35, n = 14), and remained above baseline for the duration of long recordings (>40 min, n=7). Similar effects were obtained when afferent stimulation was suspended for 3 min before and after the photo-stimulus, indicating that presynaptic activity was not required for induction of this process.

When tetanically induced LTP (2-3 sets of 2 100-Hz tetani for 1-2 s separated by 20 s) of a test pathway preceded the photo-stimulus by 25-35 min, the photo-stimulus never increased the test EPSPs; control pathways were potentiated. Occlusion of photo-activated LTP by tetanic LTP suggests that they share common processes of induction and/or expression.

These results also suggest that at least a moderate level of LTP can be induced without involvement of presynaptic activity. This result has implications for models of LTP that require the concurrent action of a retrograde messenger with presynaptic activity. Supported by NIH Grant NS 15114.

PROCESS OUTGROWTH, GROWTH CONES, AND SPROUTING VII

789.1

DEVELOPMENT OF PRIMARY AFFERENT COLLATERAL BRANCHES IN THE EMBRYONIC MOUSE SPINAL CORD.
S. Ozaki* & W. D. Snider, Department of Neurology, CSNSI, Washington University School of Medicine, St. Louis, MO 63110.

The extension of collateral branches from growing axons to their target fields is a key event in the development of neural circuits. A favorable system for analysis is the collateral branching of primary afferents in the spinal cord which occurs over several segments from the point of entry of spinal axons. Here we characterize the development of primary afferent collateral branches in the mouse spinal cord as a framework for future studies in transgenic animals. Primary afferent projections were visualized using DiI crystals placed in the brachial plexus or thoracic nerves of mouse embryos aged between embryonic day (E) 10.5 and postnatal day (P) 0. The first primary afferent axons reach the spinal cord at E10.5 and grow rostrocaudally in the primordium of the dorsal funiculus. At this stage axons are relatively smooth and growth cones are prominent. There is a delay of at least 24 hours prior to elaboration of axon collateral branches into the spinal cord. Between E12.5 and E13.5 primary afferents develop nodes at frequent intervals, and collaterals enter the gray matter by branching from parent axons at the site of these nodes. There were many more nodes than collateral branches at all developmental stages. Nodes persisted at least until P0, the latest day studied. Analysis of semi-thin sections revealed only rare non-neuronal cells in the dorsal funiculus at the time collateral branching is initiated. The relationship between collaterals and radial glial cells is under study. We correlated the onset of collateral branching with expression of neurotrophin-3 (NT-3) mRNA in the embryonic spinal cord using *in situ* hybridization. NT-3 mRNA was expressed in the motor pools at E11.5 prior to the appearance of nodes or collateral branches, making it a candidate to regulate axon collateral branching in this system.

789.2

PRENATAL DEVELOPMENT OF SPINAL CORD CIRCUITRY INVOLVED IN URINARY BLADDER FUNCTION IN THE RAT.
K.G. Ruit* and K.J. Townley, Department of Anatomy & Cell Biology, University of North Dakota School of Medicine, Grand Forks, ND 58202.

In an effort to understand how lumbar and sacral spinal cord circuitry controlling function of the urinary bladder develop during the prenatal period, a retrograde fluorescent labeling technique was used to identify and describe 1) autonomic and somatic motor neurons that provide innervation to bladder wall and sphincter musculature, and 2) the growth of vesicle (and related) primary afferents into the spinal gray matter. Crystals of the intensely fluorescent, lipid soluble tracer DiI were placed in the urinary bladders of aldehyde-fixed embryos that had been taken at different developmental stages (E13 through the day of birth) from timed-pregnant Sprague-Dawley rats. After an appropriate incubation period, the spinal cords were removed, sectioned, and examined by rhodamine epifluorescence microscopy.

By the day of birth, preganglionic parasympathetic neurons innervating the bladder have elaborated dendritic arborizations that extend medially to the central canal, into the contralateral spinal gray matter, and laterally into the lateral funiculus. Somatic motor neurons innervating sphincter musculature are located in the ventral-most regions of the spinal ventral horn and extend their dendrites in a medio-lateral plane and into the lateral and ventral funiculi. Primary afferents begin to enter the spinal gray matter on E15, and can be divided into two groups based on their morphology, 1) larger diameter fibers that enter the spinal cord more medially and descend to somatic motor neuron pools, and 2) smaller diameter fibers that enter the spinal cord more laterally and ramify densely within superficial (I and II) and deep (V and VII) laminae of the dorsal horn. The spatially- and temporally-patterned organization of the development of these neural elements suggests that, as in other systems, the development of spinal cord circuitry involved in bladder function may be regulated by the expression of centrally- or peripherally-derived trophic molecules.

TEMPORAL DIFFERENCES BUT SIMILAR DEVELOPMENTAL STRATEGIES HIGHLIGHT THE FORMATION OF AXONAL CONNECTIONS OF PERIRHINAL AND SOMATOSENSORY CORTICES. M.F. Barbe*, L. LaBarca-Meier, C. Leonard, K. Michihira, M. Salamon, P. Levitt. Dept. of Physical Therapy, Temple Univ., Phila., PA, 19140 and Dept. of Neurosci. and Cell Biol., UMDNJ, Robert Wood Johnson Medical School, Piscataway, NJ, 08854.

To investigate factors involved in the development of limbic and nonlimbic cerebral cortical circuitry, we examined the timing of thalamo-cortical and cortico-thalamic outgrowth in the somatosensory (Ss) and perirhinal (Prh) cortices. Lipophilic dye tracers, DiIC18-(3) or DiA were inserted into 4% paraformaldehyde fixed brains of rat fetuses aged embryonic day (E) 13-20. Seventy-eight rat fetuses were used. The lipophilic dyes were inserted into either presumptive Prh or Ss cortices, or the thalamus in single or double-labeling paradigms. The sections were examined for location of fibers extending from the insertion site and the presence and location of retrogradely labeled neurons. Results show that Prh cortico-thalamic axons meet the thalamo-cortical axons initially in the internal capsule on day E13.5 and probably represent the first axons from the cortex. Prh cortical axons arrive in the thalamus on E14-E14.5, a few days prior to axons from Ss cortex on E18. Axons from neurons located in lateral thalamus arrive in Prh cortex on E15 and in Ss cortex on E18, axons from neurons in midline thalamic region arrive in Prh on E18. Neurons labeled from either cortical site formed discrete clusters in thalamic areas. Axons segregated in the lateral portion of the internal capsule, with the Ss cortical-thalamic axons more dorsally situated than the Prh cortico-thalamic axons. These results show that while temporally distinct, limbic and nonlimbic cortical projections are initiated in similar, highly specific patterns. Supported by Temple University (M.B.) and NIMH grant 45507 to P.L.

EVIDENCE FOR MULTIPLE AXONS ON DEVELOPING DENTATE GRANULE CELLS. J.A. Schroer*, W. Yan, J.L. Young and J.H. Haring. Dept. of Anatomy and Neurobiology, St. Louis Univ. Sch. Med., St. Louis, MO 63104.

We have collected a sample of nearly 200 neurobiotin-filled cells from rats aged PND14 to PND120. A small number of these neurons (<10%) exhibit two axons. The prevalence of multiple axons varies as a function of age being more frequent in younger rats, but is unrelated to experimental group. All neurons seem to have morphologies consistant with that of granule cells. One axon typically arises from the soma while additional axons take origin from either proximal or distal dendrites. Examples of both axons originating from the cell body exist. Both axons may be mossy fibers regardless of their site of origin or one axon may be a mossy fiber and the second assume a distribution similar to an interneuron. In older rats, mossy fibers are seen to originate from proximal dendrites in the absence of a second axon from the soma. Similarly, cells with an axon arising from a distal dendrite and projecting within the molecular layer have been seen. These data suggest that some granule cells may express a mixed axonal phenotype during maturation and that some of these cells will retain the atypical axon.

CLONING OF N16K, A NOVEL NEURAL DIFFERENTIATION-ASSOCIATED GENE AND DEVELOPMENTAL EXPRESSION. Y. Saito*, K. Maruyama#, T.C. Saido and S. Kawashima Dept. Molec. Biol., Tokyo Metropol. Inst. Med. Sci., Bunkyo-ku, Tokyo-113, #Lab.Neurochem., National Inst Physiological Sci, Okazaki, Aichi- 444

Mouse NS20Y cells can be reproducibly differentiated into neurons upon treatment with dibtyryl cyclic AMP (dbcAMP). In order to understand the molecular mechanism and cellular events which underlie neuronal differentiation, we constracted a subtractive cDNA library made from 48hr-treated NS20Y cells. We then screened randamly selected colonies by differential hybridization using labeled cDNA probes synthesized from the dbcAMP (−) and dbcAMP (+) mRNA pools. One clone, N16K, was markedly increased in NS20Y cells after dbcAMP treatment for 48hr. Expression of N16K mRNA in adult mouse was detected only brain and spinal cord, but not in other non-neuronal tissues. N16K encodes a protein sequence of 212 amino acids. Neither the nucleotide sequence of N16K nor the deduced amino acid sequence showed appreciable homologies to known sequences in the database. Futher characterization of N16K should provide additional information about its function during neuronal differentiation. (Suppoted by the Ministry of Education, Science and Culture of Japan and by Uehara Memorial Foundation)

EXPRESSION OF *WNT-7A* IN THE CEREBELLUM SUGGESTS ITS ROLE IN GRANULE CELL MATURATION. Patricia C. Salinas* and Fiona Lucas. Developmental Biology Research Centre King's College London WC2B 5RL U.K.

Wnt genes encode secreted proteins implicated in cell fate changes during development. To begin to define the specific cell populations in which *Wnt* genes act, we chose to examine *Wnt* expression in the cerebellum which has a relatively simple structure and contains well characterized cell populations. We found that *Wnt-7A* is expressed in the adult granular cell layer. *Wnt-7A* starts to be expressed from postnatal day 6 to 22 (P6 to P22) to then declines to low levels in adult cerebellum. From P22, *Wnt-7A* expression becomes restricted to the cerebellar lobules I to VIII, showing very low levels of expression in lobules IX and X. In this posterior region, called vestibularcerebellum, granule cells receive inputs from mossy fibers of vestibular origin. These results suggest that *Wnt-7A* expression may be down regulated by vestibular mossy fibers.

To determine the factors that control *Wnt-7A* expression, we analysed the agranular cerebellum of *weaver* mutant mice in which granule cells are present in the EGL at early stages but fail to migrate and then die in the EGL. *Wnt-7A* is undetectable in the EGL of *weaver* animals even though granule cells are still present at these stages as determined by the expression of the granule cell marker, *En-2*. Thus, granule cells from *weaver* fail to express *Wnt-7A* before they die. Moreover, *Wnt-7A* is ectopically expressed in the Purkinje cell layer of P6 and P15 animals and subsequently disappears. It is of interest that in *weaver* animals, mossy fibers, which normally will make synaptic contact with granule cells, form heterologous synapses with Purkinje cells. Granule cells exposed to *Wnt-7A*-expressing cells show an increased in the number and spreading of neurites. These results suggest a role of *Wnt* genes in the maturation of granule cell neurons.

789.7

DISTRIBUTION OF TWO PRIMARY PROTEIN KINASE C (PKC) SUBSTRATES, MYRISTOYLATED ALANINE-RICH C-KINASE SUBSTRATE (MARCKS) AND F1/GAP-43 mRNAs, IN THE ADULT RAT BRAIN. R. K. McNamara[1]*, D. G. Watson[1], & R. H. Lenox.[1,2,3] Departments of Psychiatry[1], Pharmacology[2], and Neuroscience[3], University of Florida College of Medicine, Gainesville, FL, 32610-0256

MARCKS (80-87kDa) and F1/GAP-43 (B-50/neuromodulin) are major substrates for PKC and important regulators of neuroplastic events during development as well as in the adult brain, where F1/GAP-43 mRNA levels remain elevated in regions associated with a high level of plasticity (Meberg & Routtenberg, 1991). The constitutive distribution of MARCKS mRNA has not yet been documented in brain. To determine the relative distribution of MARCKS and F1/GAP-43 mRNAs in the adult rat brain, male Sprague-Dawley rats (250-300 g) were sacrificed and perfused for *in situ* hybridization histochemistry. Serial sections were hybridized with radiolabeled antisense riboprobes corresponding to bases 354-1505 of the murine MARCKS cDNA (Seykora *et al.*, 1991) or 779-1295 of the rat F1/GAP-43 cDNA (Rosenthal *et al.*, 1987). Overall, MARCKS hybridization was expressed in the majority of regions but was most pronounced in pyriform ctx, medial habenular n., paraventricular hypothalamic n., and the cerebellar granule cell layer. Consistent with earlier reports, prominent F1/GAP-43 hybridization was observed in several regions including thalamic and hypothalamic n., lateral habenular n., entorhinal ctx, raphe n., and cerebellar granule cells. Within the hippocampal formation, MARCKS hybridization was highest in dentate gyrus granule cells, moderate in CA1 pyramidal cells, and low-absent in CA3 and hilar neurons, unlike F1/GAP-43 where hybridization was highest in CA3 and hilar neurons, moderate in CA1 pyramidal cells, and low-absent in dentate gyrus granule cells. While MARCKS and F1/GAP-43 mRNAs are co-expressed in certain regions (pyriform ctx/cerebellar granule cells), their differential expression in other regions (habenular complex/hippocampus) may reflect high levels of constitutive PKC activity, which has been shown to up-regulate F1/GAP-43 mRNA (Perrone-Bizzozero *et al.*, 1993) and down-regulate MARCKS mRNA (Brooks *et al.*, 1991). [Supported by NIMH grant MH50105]

789.8

COMPARATIVE EXPRESSION OF MYRISTOYLATED ALANINE-RICH C-KINASE SUBSTRATE (MARCKS) AND F1/GAP-43 mRNAs IN HIPPOCAMPAL GRANULE CELLS FOLLOWING KAINIC ACID. S. P. Baker[2]*, R. K. McNamara[1], D. G. Watson[1], & R. H. Lenox[1,2,3] Departments of Psychiatry[1], Pharmacology[2], and Neuroscience[3], University of Florida College of Medicine, Gainesville, FL, 32610-0256.

MARCKS (80-87kDa) and F1/GAP-43 (B-50/neuromodulin) are primary substrates of protein kinase C (PKC) and have been implicated in neuronal growth and differentiation by virtue of their localization in growth cone particles, association with the cytoskeleton, and changes in expression in cultured cells following exposure to differentiating agents like phorbol esters (e.g., Perrone-Bizzozero *et al.*, 1993). We have recently demonstrated that MARCKS mRNA is constitutively expressed at high levels in hippocampal granule cells (McNamara *et al.*, 1995), unlike F1/GAP-43 mRNA which is not constitutively expressed in granule cells (Meberg & Routtenberg, 1991). Kainic acid induces F1/GAP-43 mRNA in granule cells followed by the sprouting of their axons, the mossy fibers (McNamara & Routtenberg, *in press*). In the present study, we compared the expression of MARCKS and F1/GAP-43 mRNAs in granule cells at several points following kainic acid administration using *in situ* hybridization histochemistry. Male Sprague-Dawley rats (250-300 g) were administered either kainic acid (10 mg/kg, s.c.) or the drug vehicle (1 ml/kg) and sacrificed 6 hr, 24 hr or 5 d post-injection. Consistent with previous reports, F1/GAP-43 mRNA expression was induced in granule cells at 24 hr, but not 6 hr, and declined after 5 d when supragranular mossy fiber sprouting was observed in the ventral hippocampus. MARCKS mRNA expression remained at high levels in granule cells at each of the three time points. These data demonstrate that axonal outgrowth induced *in vivo* is preceded by an elevation of F1/GAP-43 mRNA in parent neurons whereas MARCKS mRNA expression appears to remain unchanged. These findings suggest that both F1/GAP-43 and MARCKS may be required for the initiation of axonal growth processes. The role of PKC-mediated posttranscriptional mechanisms in these events remains to be determined. [Supported by NIMH grant MH50105]

EXPRESSION OF B-50/GAP-43 IN ADULT OLFACTORY NEURONS IN TRANSGENC MICE RESULTS IN MORPHOLOGICAL CHANGES IN THEIR PROJECTIONS IN THE OLFACTORY BULB. A.J.G.D Holtmaat[1,2], P.A. Dijkhuizen[1], N.M.T. van der Lugt[3], A. Berns[3], H.J. Romijn[1], A.B. Oestreicher[2], F.L. Margolis[4], W.H. Gispen*[2], J. Verhaagen[1,2]. (SPON:Eur. Neurosci. Ass.) [1]Neth. Inst. Brain. Res., A'dam, NL; [2]Rudolf Magnus Inst., Utrecht, NL; [3]Neth. Cancer Inst., A'dam, NL; [4]Roche Inst. of Molec. Biology, Nutley, NJ, USA.

To study the function of B-50/GAP-43 *in-vivo*, we created transgenic mice, that express B-50/GAP-43 in the adult olfactory system. Using the olfactory marker protein (OMP) promoter, B-50/GAP-43 expression was directed to mature olfactory neurons, which do not normally express B-50/GAP-43. Mice bearing the OMP-B-50/GAP-43 transgene exhibited B-50/GAP-43 immunoreactivity in cell bodies, dendrites and axons of numerous mature neurons throughout the olfactory epithelium. This pattern of transgene expression is consistent with the action of the OMP promoter.We find that B-50/GAP-43 expression in mature olfactory neurons results in the formation of numerous hypertrophic OMP-positive primary olfactory axons with enlarged nerve endings. Confocal laser scanning microscopy on double-immunostained sections revealed that the mature olfactory axons often terminated in dilated grape-like structures which were preferentially located on the rim of the glomeruli. Double labelling with anti-tyrosine hydroxylase (TH)demonstrated that some OMP-positive olfactory neurons exhibit ectopic projections, between the TH-positive juxtaglomerular cells or associated with extra glomerular blood vessels. These phenomena were never observed in wild type litter mates and could be confirmed by Golgi staining of individual olfactory axon terminals. These data demonstrate that continued expression of B-50/GAP-43 in adult primary olfactory neurons *in-vivo* has a direct effect on the morphology and projection territory of their axon terminals and supports a role of this growth-associated protein in nerve fiber formation.

PROMOTER ELEMENTS CONTRIBUTING TO GAP-43 GENE REGULATION IN NEURONS. J.R. Weber, G.P. Hanes, and J.H.P. Skene*. Dept. of Neurobiology, Duke Univ., Durham, NC 27710.

Previous work in this and other labs has indicated that the 5' flanking region of the rat GAP-43 gene displays a significant degree of neural specific expression, and we now show in transgenic mice that 1 kb of this region can confer a significant degree of the temporal regulation of the GAP-43 gene. As one approach to elucidating the signaling pathways which control GAP-43 expression during axon outgrowth in developing or regenerating neurons, we are now identifying individual transcription factor binding sites. We have focused on a 386 bp subfragment of the 1 kb region that drives strong expression of a reporter gene in transiently transfected neurons from developing rat cerebral cortex, but has little or no activity in non-neuronal cell lines. Deletions within this 386 bp promoter indicate that a fairly small region located downstream of the TATA box consensus sequence is required for expression in neurons. Gel shift assays have identified three sequences which bind nuclear proteins from developing rat cerebral cortex: an AP1 consensus sequence and two apparently novel sites, Cx1 and Cx2. Mutation of all three of these binding sites eliminates the majority of activity from the 386 bp promoter in cortical cultures. In contrast, gel shifts with liver nuclear extracts have shown a strong binding activity (Liv1) which overlaps with, and would likely preclude binding to, Cx1 and Cx2. These studies have identified a small cluster of transcription factor binding sites, the AP1/Cx region, which is likely to play an important role in the regulation of the GAP-43 gene in neurons. Supported by NIH grant EY07397.

ROLE OF HIGHLY CONSERVED 3' UTR SEQUENCES IN THE GAP-43 mRNA IN RNA STABILITY. N. I. Perrone-Bizzozero*, R. Thompson, K-C. Tsai, V.V. Cansino, D. T. Kohn, T. Roham, and R. L. Neve. Dept. Biochemistry, Univ. New Mexico Sch. of Med., Albuquerque NM, 87131 and McLean Hospital, Belmont, MA 02178.

We have previously shown that the mRNA for the neural-specific, growth-associated protein GAP-43 is selectively stabilized during neuronal differentiation (J. Cell Biol. 120, 1263-1270, 1993). Given the absence of known instability-conferring elements in this mRNA, we explored the role of highly conserved sequences in its 3' untranslated region (3' UTR) in mRNA stability. Between the rat and chicken GAP-43 mRNAs, the 3' UTRs show 78% of sequence identity, a level that is similar to the conservation of their coding regions. In mRNA stability assays in transfected rat PC12-N36 cells, both the rat and chicken mRNAs decayed with half-lives of about 3.5 h. The GAP-43 3' UTR was also found to destabilize the otherwise stable globin mRNA, with the half-life of the chimeric transcript comparable to that of the wild type GAP-43 mRNA. Thus, highly conserved sequences within the 3' UTR are the major determinants of GAP-43 mRNA stability. The rat and chicken GAP-43 mRNAs were also tested in RNA-binding assays with brain cytosolic proteins. Both RNAs bound equally well to the three GAP-43 mRNA binding proteins from rat brain. Also, S100 proteins from chicken brain were able to bind rat GAP-43 mRNA sequences. Based upon these results, we propose that highly conserved sequences in the 3' UTR of this mRNA contribute to the control of GAP-43 gene expression via specific RNA-protein interactions. *Supported by NIH (NS-30255, GM-08139) TSGH-NDMC, Taipei, and RAC-1090, UNM Sch. NEUROTROPHIC FACTORS: EXPRESSION AND REGULATION VII

790.1

IMMUNOHISTOCHEMICAL LOCALIZATION OF CILIARY NEUROTROPHIC FACTOR RECEPTOR α EXPRESSION IN THE RAT. A.J. MacLennan*, E.N. Vinson, L. Marks, M. Pfeiffer and N. Lee. Department of Neuroscience, University of Florida, Gainesville, FL, 32610-0244.

Ciliary neurotrophic factor (CNTF) decreases the death of neurons induced by natural causes, axotomy or genetic mutation. Molecular cloning and heterologous expression studies indicate that CNTF produces most, and possibly all, of these effects by binding to a protein referred to as CNTF receptor α (CNTFRα). Genetic "knockout" of this protein leads to significant developmental abnormalities. We used synthetic peptides corresponding to regions of the CNTFRα to raise and affinity-purify anti-CNTFRα polyclonal antibodies. The antibodies identify CNTFRα throughout the adult and developing central and peripheral nervous systems. Particularly high levels of expression were found in the olfactory bulb and the cell bodies and dendrites of cranial and spinal motor neurons, cortical pyramidal neurons, cerebellar purkinje cells and hippocampal neurons. Elevated levels were also detected in the axons of adult and developing peripheral nerves.

790.2

ONTOGENESIS OF RAT FETAL PREPROINSULIN I AND II mRNA AND INSULIN RECEPTOR mRNA WITHIN THE NERVOUS SYSTEM. R. Schechter*, D. Beju and T. Gaffney. William K. Warren Med. Res. Inst., Univ. of Okla. Health Sci. Ctr., and Dept. of Neonatology, Saint Francis Hospital, Tulsa, OK 74136.

We investigated the presence of preproinsulin I and II (PPI, PPII) mRNA within the fetal rat brain, spinal cord and dorsal root ganglia (DRG). We also studied the presence of the alpha chain of the insulin receptor (IR) mRNA in the same tissues. Total RNA was obtained from 15, 17 and 19 days gestational age rat fetal brain, spinal cord and DRG. Pancreas served as positive control for PPI and PPII mRNA, and liver for IR mRNA. Total RNA was subjected to reverse transcriptase template-specific PCR (RS-PCR) and RNAse protection assay (RPA) for PPI and PPII. IR was studied using RS-PCR. RS-PCR demonstrated a product of 381 base pair (bp) in brain, spinal cord and DRG in the 15, 17 and 19 days gestation that comigrated with the pancreatic product showing the presence of mRNA for PPI and PPII within these tissues. Semi-nested PCR products of 330 bp were obtained and further characterized with restriction enzyme digestion by HinfI and RsaI. The predicted fragments of 140 and 190 bp were obtained with HinfI for PPII, and fragments of 118 and 212 bp with RsaI for PPI. RsaI cuts only PPI, and HinfI cuts only PPII. In solution hybridization using a 32P-cRNA for PPI or PPII, followed by RPA showed bands from the 15, 17 and 19 days gestational age brain, spinal cord and DRG that comigrated with hybridized RNA from pancreas and with probe alone. RS-PCR also showed a fragment of 550 bp for IR as predicted within the brain, spinal cord and DRG for all ages studied. Fetal brain tissue was also prepared to localize insulin by electron microscopy (EM). EM showed insulin immunoreaction within the endoplasmic reticulum(ER), Golgi, cytoplasm, and cells processes. This study showed that preproinsulin I , preproinsulin II, and insulin's receptor are present within the fetal central and peripheral nervous system during nervous system development. Thus, the presence of the PPI and PPII mRNA and the immunoreaction within the ER and Golgi strongly indicate the de novo synthesis of insulin within the central and peripheral nervous system.

790.3

INSULIN-LIKE GROWTH FACTOR BINDING PROTEINS (IGFBPs) IN MOUSE SPINAL CORD DURING DEVELOPMENT. **J.Y. Ma*, I.V. Smirnova, M.N. Zoubine, M.E. Avery, S. Huibao, P.M. Arnold, B.A. Citron and B.W. Festoff. Neurobiology Research Lab., VA Med. Ctr., Kansas City, MO 64128; Dept. of Neurology, Univ. of Kansas Med. Ctr., Kansas City, KS 66160.**

IGFs are paracrine and autocrine neurotrophic factors, and both IGFs and their receptors are expressed in the mammalian spinal cord. IGFBPs are soluble polypeptides which bind to IGF to form complexes and modulate bioactivity of both IGF-I and IGF-II. Our previous studies suggested that IGF signaling system is involved in motoneuron axonal regeneration and sprouting after sciatic nerve injury. IGFBPs have been well studied in the brain during development, but the expression of IGFBPs in the spinal cord during development has not been reported. With SDS-PAGE, followed by transfer to nitrocellulose membranes and Western ligand blot with ^{125}I-IGF-II, we analyzed IGFBPs in mouse spinal cord samples during embryonic (E14, E16) and postnatal (P3, P5, P10, P15 and P30) development. An approximate 30 kDa band was found. The highest level of this IGFBP is in E14, then gradually reduces, and is barely detected after P15. Our results demonstrate a major form of IGFBP with approximate molecular weight of 30 kDa in the spinal cord is developmentally regulated. The high level of this IGFBP in an early embryonic stage suggests a potential role of the IGFBP in the spinal cord development. 790.4

GDNF mRNA IS FOCALLY EXPRESSED IN DEVELOPING MOUSE LIMB BUD IN REGIONS WHERE AXONS FORM THE PLEXUS D.E. Wright*, R.W. Gerfen, M.T. Saxena, J.C. Harding, L. Zhou and W.D. Snider. Dept. of Neurology, CSNSI, Washington University., St. Louis, MO, 63110.

The neurotrophic factor GDNF is a potent survival factor for motoneurons and is synthesized by Schwann cells and muscle. To further explore whether GDNF influences motoneurons during the early stages of peripheral innervation, we performed *in situ* hybridization on mouse embryos as motor axons enter the periphery. A mouse GDNF cDNA was PCR-amplified to synthesize 33P-labeled riboprobes. Similar to rat and human, two splice variants were amplified; the longer fragment was used to generate riboprobes. At later embryonic stages (E14-E16), GDNF mRNA was detected in non-neuronal cells along peripheral nerve and developing muscle. However at earlier stages (E10-E13), GDNF mRNA was expressed at high levels in a restricted region in the proximal limb bud. This focal expression was not observed in thoracic regions. Comparison with embryos labeled with DiI to reveal peripheral projections indicated the GDNF expression corresponds to areas where axon fascicles converge to form the plexus. The origin and identification of the cells expressing GDNF is currently being investigated. Other areas of intense GDNF expression at E11-E13 included mesodermal tissue surrounding the developing GI system and urogenital ridges. This expression may be relevant to the survival of peripheral neurons in these areas. Because GDNF belongs to the transforming growth factor (TGF)-ß superfamily, we compared GDNF expression to the patterns of related family members, including TGF-ß1, TGF-ß2 TGF-ß3, BMP-4, and BMP-6. Neither BMP-4 or BMP-6 mRNAs were detected in regions relevant to peripheral axon growth. TGF-ß1, TGF-ß2, and TGF-ß3 mRNAs were expressed in mesodermal regions adjacent to motor and sensory axons by E11. However, the expression patterns of the TGF-ßs were diffuse as compared to the focal expression of GDNF mRNA. Our results reveal that members of the TGF-ß superfamily are developmentally expressed in patterns consistent with an ability to influence axons in the periphery. The focal expression of GDNF mRNA in regions where axons converge to create the brachial and lumbar plexus suggest that GDNF may sustain motoneurons as their axons rearrange within the plexuses.

790.5

CHROMOSOMAL LOCATION AND ALTERNATIVELY SPLICED FORMS OF HUMAN GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF). D.L. Choi-Lundberg[1,*], D.A. Figlewicz[1,2] and M.C. Bohn[1]. Depts. [1]Neurobiol. & Anat. and [2]Neurology, Univ. of Rochester Med. Ctr., Rochester, NY 14642.

GDNF is a potent neurotrophic factor for lower motor neurons and midbrain dopaminergic neurons and has neurotrophic activity on several populations of peripheral neurons. It is widely expressed in rat nervous system and peripheral organs throughout development and in the adult[1], and has been detected by reverse transcription-polymerase chain reaction (RT-PCR) in the adult human nervous system[2].

To identify the human chromosome on which the GDNF gene resides, DNA from a panel of 24 somatic cell hybrids containing one human chromosome (1 to 22, X or Y) in a hamster or mouse background was amplified by PCR with primers specific for exon 2 of human GDNF. A product of the predicted size was obtained only from the somatic cell hybrid containing human chromosome 5.

Two alternative forms of GDNF mRNA were identified in human fetal astrocytes by RT-PCR with primers that span the entire cDNA sequence. These were cloned into the SrfI site of the pCR-Script SK(+) vector and sequenced. One form contains a 78 base pair (bp) deletion corresponding to 26 amino acids of the pro region of the preproprotein. The second form has a novel 79 bp sequence which replaces 78 bp of the full length GDNF cDNA deleted in the first form, resulting in a frame shift and predicted early termination of the protein product. Initiation at another AUG codon could result in a protein product lacking a signal sequence for secretion but still containing full-length mature GDNF protein. Supported by NIH grant ES01247 and MDA. [1]Choi-Lundberg, D.L., and Bohn, M.C., *Dev. Brain Res.*, 85 (1995) 80-8. [2]Springer, J.E., Mu, X., Bergmann, L.W., Trojanowski, J.Q., *Exp. Neurol.*, 127 (1994) 167-70.

ALTERNATIVE GDNF TRANSCRIPTS IN RAT BRAIN: WIDESPREAD DEVELOPMENTAL AND REGIONAL EXPRESSION. D.O. Dean*, J. Alberch†, C.F. Dreyfus & I.B. Black. Dept. of Neuroscience and Cell Biology, RWJ Medical School, UMDNJ, Piscataway, NJ 08854 and †Dept. Biologia Cel.lular i Anatomia Patologica, University of Barcelona, Spain.

Parkinson's Disease is characterized by selective degeneration of midbrain dopamine neurons. Glial cell line-derived neurotrophic factor (GDNF) has been shown to enhance the survival and differentiation of these neurons. Previously, our laboratory has found multiple GDNF-related transcripts in rat and human. We now report the developmental and regional expression of GDNF and its alternative forms in rat brain.

Using RT-PCR, we examined GDNF-related transcripts in striatum and nigra dissected on embryonic day 17 (E17), postnatal day 1 (P1) and postnatal day 32 (P32). We identified three forms; GDNF, ATF-1 and ATF-3. In striatum, GDNF and ATF-1 message levels remained constant from E17 to P32. ATF-3 peaked at P1. In nigra, GDNF and ATF-1 message levels declined from E17 to P32, whereas ATF-3 was slightly elevated at P1. The relative persistence of GDNF and ATF-1 mRNA in striatum and reduction in GDNF and ATF-1 message in nigra suggest that these forms may code for target-derived trophic factors into adulthood.

To further explore region-specific expression, we examined cerebellum, cortex, hippocampus and septum. mRNA levels of all three transcripts peaked at P1 in cortex, hippocampus and septum. In cerebellum, GDNF, ATF-1 and ATF-3 message levels were very high at E17 and thereafter slowly declined.

In sum, we have observed differential developmental and regional expression of GDNF-related transcripts. The patterns of expression of GDNF and ATF-1 in nigra and striatum are consistent with the model of a target-derived trophic factor. ATF-3 may be important perinatally, as its expression at P1 is elevated in all regions, including striatum. The high expression of GDNF-related transcripts in cerebellum suggests a potential role in the development of this structure (see Mount *et al.*, this meeting). EXPRESSION OF TRKB BUT NOT BDNFmRNA IN PARVALBUMIN CONTAINING NEURONS OF THE ADULT RAT VISUAL CORTEX. A. Cellerino, A. Burkhalter°*, L. Maffei and L. Domenici. Istituto di Neurofisiologia C.N.R. and Scuola Normale Superiore, 56127 PISA (Italy), °Dept Ana Neurobiol, Washington University Medical School, St Louis, MO 63110.

In the present study we analysed the distribution of trkB and BDNF in the adult rat visual cortex, focusing on parvalbumin (PV) positive cells, the major contingent of GABAergic neurons. Using antibodies to trkB (Santa Cruz Biotech, CA) we have found staining in both pyramidal and non pyramidal neurons. Double labelling experiments showed that most PV stained non pyramidal neurons co-localized trkB. Pyramidal neurons positive for trkB were surrounded by PV labeled boutons. Using an mRNA riboprobe for BDNF (nucleotides 147-657) and trkB (extracellular domain, nucleotides 19-412) we performed a double in situ-immuno histochemistry. We found that most PV stained cells contained trkB mRNA. Interestingly, co-localization of BDNF mRNA in PV stained non pyramidal cells was extremely rare. The present data suggest that BDNF, synthesized by pyramidal cortical neurons (Wetmore et al. Exp. Neurol. 109: 141-152, 1990), may act as postsynaptically derived neurotrophic factor or neuromodulator on PV neurons of the adult rat visual cortex.

790.8

EXPRESSION PATTERN OF FIBROBLAST GROWTH FACTOR-9 IN DIFFERENT REGIONS OF THE RAT BRAIN DURING DEVELOPMENT. Alex T. Ho*, Candace Andersson, Karl A. Kuzis, Felix P. Eckenstein. Department of Cell Biology and Anatomy, Oregon Health Sciences University, 3181 SW Sam Jackson Park Rd., Portland, OR 97201.

The members of the fibroblast growth factor (FGF) family may regulate various aspects of CNS development. Analysis of FGF receptors expression during embryonic brain development and *in vitro* experiments with cultured neuroepithelial cells, have suggested that FGFs may function as regulators of neuronal and astrocytic differentiation during the patterning of the CNS. Recent isolation and cloning of a heparin-binding growth factor from a human glioma cell line have introduced a new member of the FGF family, FGF-9. We are testing whether FGF-9 may play a role during the development and the patterning of the rat brain. We have constructed sets of PCR primers based on the published FGF-9 sequence and performed a qualitative measurement of FGF-9 expression in the developing rat brain. Furthermore, we have cloned the PCR products in order to create probes for a quantitative measurement of FGF-9 using northern blot analysis and RNase protection assays. Our PCR and northern blot data suggest that FGF-9 is expressed in the rat CNS as early as embryonic day 12. Brain distribution analysis of adult and postnatal day 1 rat brain have shown that FGF-9 expression is concentrated in the cerebellar and the spinal cord regions of the rat CNS. Currently we are culturing specific cell populations from different parts of the brain to determine which cell types in the brain express FGF-9. Our data support the hypothesis that FGF-9 may play an important role in the differentiation of these regions during the development of the rat brain.

790.9

PRENATAL ONTOGENY OF EGF RECEPTOR AND TGF α mRNAs IN RAT BRAIN. H.I. Komblum[1],*K.Tatsukawa[1], R.J. Hussain[1], C.M. Gall[2], D. Lee[3], and K.B. Seroogy[4], [1]Depts. Pharm. and Peds. UCLA, LA, CA 90095 , [2]Anat. & Neurobiol. UC Irvine, [3]Lineberger Cancer Ctr, UNC, Chapel Hill, and [4]Anat. & Neurobiol. U. Kentucky.

Transforming growth factor alpha (TGFα) is related to epidermal growth factor (EGF) and acts at the EGF receptor (EGF-R). EGF and TGFα have been demonstrated to induce neuronal differentiation and neural stem cell proliferation *in vitro*. In the present study, we examined the ontogeny of EGF-R and TGFα mRNAs during fetal development of the rat brain by *in situ* hybridization, using ^{35}S-labeled cRNAs. EGF-R mRNA was present in the ventral midbrain by E13 and was detectable within the neuroepithelia of the midbrain, anterior pons and the posterior hypothalamus by E15. The cerebellar external granule layer was also densely labeled at this age. By E17, labeling was detectable in germinal zones of the telencephalon, including those of the septum, basal ganglia and amygdala. In the brainstem and diencephalon, labeled cells were also observed at a distance from the neuroepithelial surface. By E19, hybridizing cells were present throughout most germinal zones and multiple brain areas, in a pattern similar to that found on the day of birth. TGFα mRNA was expressed in the ventral midbrain and brainstem on E13. By E15, hybridization was apparent in the ventral telencephalon, thalamus, and caudal hypothalamus. By E17, hybridization densities were very high throughout many structures of basal telencephalon and within multiple thalamic and hypothalamic nuclei. Moderate hybridization densities were apparent throughout much of the brainstem, a pattern present on the day of birth. The present study demonstrates that the distributions of EGF-R and TGFα mRNAs are overlapping during fetal development, and that the TGFα/EGF-R system may be important in the normal genesis and/or differentiation of neurons and glia.

790.10

POSTNATAL EXPRESSION OF EGF RECEPTOR mRNA IN PROLIFERATIVE ZONES OF RODENT BRAIN. K.B. Seroogy[1]*, S. Numan[1], L.A. Opanashuk[1], C.M. Gall[2], D.C. Lee[3] and H.I. Komblum[4]. [1]Dept. of Anat. & Neurobiol., Univ. of Kentucky, Lexington, KY 40536, [2]Dept. of Anat. & Neurobiol., Univ. of California, Irvine, CA 92717, [3]Lineberger Comp. Cancer Ctr., Univ. of N. Carolina, Chapel Hill, NC 27599 and [4]Depts. of Pharmacol. and Pediatrics, UCLA, Los Angeles, CA 90024.

We have recently demonstrated that epidermal growth factor receptor (EGF-R) mRNA is prominently expressed in two principal germinal zones of the postnatal rat brain, the forebrain subventricular zone and the cerebellar external granule layer (EGL) (Seroogy et al., *Brain Res.* 670: 157-164). These results, together with *in vitro* data of others, suggest a role for an EGF-R ligand in regulating the proliferation and/or differentiation of neural progenitors in these regions. To determine if expression of EGF-R is a characteristic feature of additional brain proliferative zones, the *in situ* hybridization localization of EGF-R mRNA was examined in developing postnatal rat and mouse brain using an ^{35}S-labeled cRNA probe. Expression of EGF-R mRNA was also examined in proliferative regions of transforming growth factor-alpha (TGFα)-deficient mice. In addition to prominent labeling of the subventricular zone and EGL, in neonatal brain hybridization of the EGF-R cRNA was localized mainly to dorsal aspects of the neuroepithelia of the third ventricle, cerebral aqueduct and medullary central canal. Dense labeling was also present throughout the neocortical neuroepithelium. Hybridization densities declined substantially during the early postnatal period such that, by adulthood, reduced levels of EGF-R cRNA labeling were detected only in the forebrain subventricular region. In TGFα knockout mice, EGF-R mRNA expression was altered in the forebrain subventricular zone. These results indicate that most germinal zones of the developing brain express EGF-R mRNA and that expression of the receptor may be regulated by its endogenous ligand TGFα. Supported by the American Parkinson Disease Association (K.B.S.), MH10806 (S.N.), AG00538 (C.M.G.), CA43793 (D.C.L.) and the Dana Foundation (H.I.K.).

790.11

EXPRESSION OF HEPARIN-BINDING EPIDERMAL GROWTH FACTOR (HB-EGF) mRNA IN RAT BRAIN. L.A. Opanashuk*, S. Numan, and K.B. Seroogy. Department of Anatomy & Neurobiology, University of Kentucky, Lexington, KY 40536.

Two epidermal growth factor receptor (EGF-R) ligands, transforming growth factor-alpha (TGFα) and EGF, have recently been shown to promote survival and biochemical differentiation of neural populations from several brain regions. Although the distribution of TGFα and EGF-R mRNAs in brain has been described, the presence of EGF-R ligands other than TGFα is currently unresolved. In the present study, *in situ* hybridization was used to determine whether HB-EGF, a recently discovered member of the EGF family of mitogenic polypeptides, is expressed in the developing and mature central nervous system (CNS). Rat brain coronal sections were processed for the *in situ* hybridization localization of HB-EGF mRNA at neonatal and adult ages using an ^{35}S-labeled cRNA probe. The antisense HB-EGF cRNA was transcribed from a pBluescript II KS vector containing a 258 base-pair fragment derived from the 5' end of the cloned rat HB-EGF cDNA (cDNA kindly provided by Dr. Judith Abraham, Scios Nova). Initial results have demonstrated HB-EGF cRNA hybridization within several cortical regions including the piriform cortex, hippocampus, and throughout middle layers of the neocortex. In hippocampus, labeling was most prominent in the dentate gyrus. Several thalamic nuclei, including the ventrolateral geniculate nucleus and the ventrobasal complex, exhibited HB-EGF cRNA labeling. In brainstem, expression was detected in the dorsal raphe nucleus, area postrema, and caudal ventrolateral medulla. Dense hybridization was also present in the Purkinje cell layer of the cerebellum. HB-EGF mRNA levels were substantially higher neonatally than in adulthood suggesting that expression is developmentally regulated. These results raise the possibility that the novel EGF-R ligand HB-EGF may serve functional roles in select regions of the developing and adult brain. S.N. was supported by NIMH fellowship MH10806.

790.12

COEXPRESSION OF HEPATOCYTE GROWTH FACTOR, ITS RECEPTOR (*c-met*), AND TISSUE-TYPE PLASMINOGEN ACTIVATOR IN MURINE BRAIN. D.P. Thewke, W. Sather* and N.W. Seeds. Neuroscience Prog. & Dept. of Biochem/Biophy/Genetics, Univ. of Colorado HSC, Denver, CO 80262.

Hepatocyte growth factor/scatter factor (HGF) has pleiotropic effects on cells expressing its receptor, the *c-met* proto-oncogene product. HGF is synthesized as an inactive precursor which must undergo proteolytic cleavage to become biologically active. Both tPA and uPA are capable of activating HGF. As part of a study on the roles of tPA in the CNS, the expression of HGF, *c-met* and tPA in the murine brain was investigated. In situ hybridization reveals several regions of the developing and adult brain where the expression of HGF and/or *c-met* is coincident with tPA expression. Most notably in the cerebral cortex, the hippocampus, and the olfactory bulb. During development of the cerebral cortex, HGF mRNA is observed in the ventricular and subventricular zones, while *c-met* and tPA expression are observed in the cortical subplate and marginal zone. In the postnatal brain, *c-met* mRNA is detected in layers II-III and V of the cerebral cortex and the CA1 region of the hippocampus, while HGF mRNA is most prominently observed in the ependymal linings of the ventricles and the CA2 region of the hippocampus. Low levels of tPA mRNA are observed throughout the cortex, and high levels in all regions of the hippocampus. In the adult olfactory bulb HGF is expressed in the glomerular layer (GL), *c-met* in the olfactory nerve (ONL) and mitral cell layers (MCL), and tPA in the ONL, GL, MCL and the granule cell layer. These results suggests that tPA may have a role in the development and maintenance of these structures via activation of HGF in the immediate vicinity of its receptor. (Supported in part by NIH grant NS-09818)

790.13

GDNF: A MEMBER OF A GENE FAMILY EXPRESSED IN MANY SUBPOPULATIONS OF ADULT BRAIN NEURONS. N. A-M. Pochon[1], A.D. Zurn[1], A. Menoud[1], C. Bader*[2] and P. Aebischer[1]. [1]Gene Therapy Center and Surgical Research Division, Lausanne Univiversity Medical School, [2]Division for Clinical Neuromuscular Research, Geneva University Hospital, Switzerland.

Glial cell line-derived neurotrophic factor (GDNF) was first described as a potent trophic factor expressed ubiquitously in embryonic, but not in adult rat brain. We report here that GDNF belongs to a gene family whose members are widely expressed in adult rat brain. To identify the members of the GDNF family, total RNA from adult brain has been extracted and analyzed by Northern blot and RT-PCR. In each case, several messengers larger than the GDNF mRNA have been identified with a GDNF riboprobe. With an RNAse protection assay on total RNA of the adult cerebellum, two bands are clearly protected with a Sp6 GDNF riboprobe. Furthermore, several homologous genes have been amplified by PCR from genomic DNA, using different primers and temperature conditions.

In adult rat brain, the expression of the GDNF family is neuron- specific, as shown by in situ hybridization with a DIG riboprobe. The signal intensity observed in the different brain regions suggests that there are subpopulations of neurons expressing homologous members of the GDNF family. The hybridization signal is high in the hippocampus and a neuronal subset of the striatum. Using in situ hybridization and immunocytochemistry, dopaminergic neurons of the substantia nigra synthetizing mRNAs homologous to GDNF have also been identified. In conclusion, the members of the GDNF family have a tissue specific expression and seem to have a high sequence homology.

790.14

Expression of CNTF: new perspectives revealed by a lacZ reporter gene introduced into the CNTF gene locus.

Carroll, P., Airaksinen*, M., Bock, H., Cooper, J., Meyer, M., Pera, E., Sendtner‡, M. and Thoenen, H. Max-Planck Inst. for Psychiatry, Am Klopferspitz 18a, 82152 Matrinsried. ‡Dept. Neurology, Uni. of Würzburg, 97080 Würzburg, Germany.

Although exogenously-applied ciliary neurotrophic factor (CNTF) exerts survival and differentiation effects on a variety of neuronal and glial cells in vitro and in vivo, the role played by endogenous CNTF is still incompletely understood. The high post-natal expression of CNTF in the PNS and its up-regulation after injury in the CNS has led to the proposal that CNTF may function as part of the response to damage in the nervous system. The levels and the sites of expression of CNTF during development and in adulthood are partially contraversial. To resolve these questions we have introduced the lacZ reporter gene into the CNTF coding region by homologous recombination in ES cells. Mice generated from such cells showed transient expression of the reporter gene in the developing embryonic nervous system. In the adult CNS reporter gene expression was detected in sub-populations of cells in most brain regions. In attempting to correlate the CNTF-promoter driven lacZ reporter gene expression with CNTF mRNA and protein expression patterns, we observed major differences in the expression levels of CNTF mRNA between rat and mouse in certain brain regions. Experiments are underway to identify the cells expressing CNTF.

790.15

IMMUNOLOCALIZATION OF NEUROTROPHIN NT4/5 AND ITS HIGH AFFINITY RECEPTOR TRK B IN THE RAT OLFACTORY BULB. J. C. Paz[1], J. N. Kott*[1], D. R. Kaplan[4], L.E. Westrum.[1-3] Depts. of Neurological Surgery[1], Biological Structure[2], and Psychology[3], Univ. of Washington, Seattle, WA 98195; ABL-Basic Research Program, NCI-FCRDC, Frederick MD.[4]

TrkB is the preferred high affinity receptor for the neurotrophin NT4/5 and exists in a truncated noncatalytic and full-length catalytic isoforms. Using immunohistochemistry, we are examining the developmental localization of NT4/5 and trkB in the rat olfactory bulbs (OB) of postnatal day 1, 5 (PN-1, PN-5) and adult animals. The OB is an ideal model in which to study the innervation/reinnervation process due to the unique regenerative capacity of the olfactory nerves (ON) throughout adult life. Immunoreactivity for truncated trkB remained moderate to strong throughout development in the ON and glomeruli (GL), while both full-length catalytic trkB and NT4/5 immunoreactivity were non-existent at PN-1, and strong at PN-5 and adult ON and GL. As labeling for both growth factor and receptor is found in the same fiber population, these findings may contrast with the classical theory that target-derived neurotrophins elicit trophic actions after retrograde transport back to the cell soma. The increased levels of NT4/5 and full-length catalytic trkB during the later stages of development may play a role in an autocrine and/or paracrine regulated neuronal maintenance rather than a guidance mechanism. The observation that catalytic trkB is expressed less strongly than truncated trkB suggests that truncated trkB may sequester excess NT4/5, thus limiting the diffusion of these growth factors. Supported by NIH grant NS09678 and a grant from NCI, DHHS, under contract N01-C0-4600. LEW is an affiliate of CDMRC.

790.16

DEVELOPMENTALLY REGULATED EXPRESSION OF *TRKA* AND *CHAT* IN THE RAT CAUDATE-PUTAMEN. Y. Li, D. O. Clary, L. F. Reichardt and W. C. Mobley*, Department of Neurology and Howard Hughes Medical Institute, UCSF, San Francisco, CA 94143.

TrkA, the receptor tyrosine kinase for NGF, is expressed in basal forebrain cholinergic neurons (BFCNs); its expression in development is regulated by endogenous NGF (Li et al., 1995, J Neurosci 15: 2888-2905). In the present work, we examined *trkA* expression in the developing caudate-putamen. Using double immunostaining, trkA was localized exclusively to caudate-putamen cholinergic neurons (CPCNs). TrkA mRNA was first detected at PD4 by in situ hybridization histochemistry. Northern analysis showed that trkA mRNA increased steadily from a low level at PD4 to the maximal adult level. The temporal pattern for the increase was similar to that for ChAT mRNA. By immunostaining, trkA protein was detected at PD0. Western blot showed that trkA protein increased during development and followed the pattern for the mRNA. Examining tyrosine phosphorylation of trkA in caudate-putamen triturates, we found that NGF activated these receptors at PD0 and that receptor activation was robust in older subjects. Infusion of NGF increased trkA and ChAT mRNA, as well as the size of trkA-positive neuron cell bodies. Our results indicate that trkA expression is highly regulated in CPCNs; they point to a role for NGF in CPCN morphological and biochemical differentiation.

Supported by NIH grants NS24054 and AG08938.

790.17

ACIDIC FIBROBLAST GROWTH FACTOR IS EXPRESSED BY BASAL FOREBRAIN AND STRIATAL CHOLINERGIC NEURONS. J.L. Bizon[1], J.C. Lauterborn[2], R.C. Elliott[2]*, and C.M. Gall[1,2]. [1]Dept. of Psychobiology, and [2]Dept. of Anatomy and Neurobiology, Univ. California, Irvine, CA 92717.

The basal forebrain cholinergic system is thought to be critical for the maintainance of cognitive abilities in both humans and rodents, and is susceptible to age- and injury-related degeneration. Recently, immunoreactivity for acidic fibroblast growth factor (aFGF), a substance which reportedly supports cholinergic neurons, has been localized in basal forebrain. In the present study *in situ* hybridization was used to evaluate the distribution and degree of colocalization of mRNAs for aFGF and the cholinergic marker choline acetyltransferase (ChAT) in rat forebrain. Neurons expressing aFGF mRNA were codistributed with ChAT-positive neurons throughout all fields of basal forebrain including the medial septum/diagonal band region and the striatum. Cells labeled by the aFGF cRNA also were distributed in regions not containing cholinergic neurons including lateral septum and several thalamic nuclei. Using double-labeling *in situ* hybridization, high levels of colocalization were observed in the medial septum, diagonal bands of Broca, magnocellular preoptic area and nucleus basalis of Meynert. In these fields over 85% of the cholinergic cells expressed aFGF mRNA. In striatum fewer cholinergic neurons contained aFGF mRNA and regional differences were observed. Specifically, among the ChAT-mRNA positive cells, 64% in caudate, 32% in ventral striatum (including nucleus accumbens) and 25% in olfactory tubercle expressed aFGF mRNA. These data demonstrate substantial, regionally specific, patterns of aFGF/ChAT mRNA colocalization and support the hypothesis that aFGF is an autocrine neurotrophic factor for cholinergic neurons in basal forebrain and striatum. Expression and Regulation of Neurotrophic Factors in Basal Forebrain Oligodendrocytes *in vitro* and *in vivo* P. Qu*, X. Dai, H.Wu, W. J. Friedman, I. B. Black and C. F. Dreyfus. Dept. Neuroscience & Cell Biol., UMDNJ / Robert Wood Johnson Medical School, Piscataway, NJ 08854

Previous work in our lab indicated that: (1) neurotrophic factors are expressed in cultured basal forebrain oligodendrocytes: NGF and BDNF mRNAs were detected by solution hybridization, and BDNF, NT3 and NT4/5 proteins by immunocytochemistry; and (2) the expression of BDNF mRNA can be regulated by KCl as a depolarizing signal. In order to further investigate the characteristics of the expression and regulation of neurotrophic factors under physiological conditions, and the effect of different neurotransmitters, enriched basal forebrain oligodendrocyte cultures were treated with 10 μM glutamate for 48 hours. In contrast to the effect of KCl, which increases BDNF mRNA expression, glutamate treatment caused a decrease of BDNF mRNA to nearly undetectable levels. These preliminary data suggest that different types of depolarizing signals regulate neurotrophin expression in basal forebrain oligodendrocytes via different mechanisms. To evaluate the expression of neurotrophin proteins in basal forebrain *in vivo*, immunocytochemistry has been performed to co-localize neurotrophins with the oligodendrocyte markers A2B5, MAG and MBP. Preliminary results revealed overlap of the anti-NT3 positive cells with anti-A2B5, suggesting the presence of NT3 protein in the basal forebrain oligodendrocyte precursors. Ongoing studies will determine whether NT3 is also co-localized with MAG and MBP *in vivo*. In sum, our results suggest possible mechanisms for regulating neurotrophin expression by depolarizing signals *in vitro* and the existence of neurotrophin proteins in basal forebrain oligodendrocytes *in vivo*.

SECRETONEURIN IS EXPRESSED IN DEVELOPING RAT VENTRAL PALLIDUM, ACCUMBENS, AMYGDALA AND OTHER FOREBRAIN STRUCTURES.

H. Traurig*[1], W. Kaufmann[2], J. Marksteiner[2], S.K. Mahata[3], H. Mahata[3], R. Fischer-Colbrie[3] and A. Saria[2]. [1]Anatomy and Neurobiology, Univ. of Kentucky, Lexington, KY 40536. [2]Neurochemistry Unit, Psychiatry Institute & [3]Pharmacology, Univ. of Innsbruck, A6020, Austria.

Secretoneurin(Sn), an endoproteolytic peptide derivative of secretogranin II(Sg)(aa154-186), located in large, dense core vesicles, is released from neural tissue following capsaicin or potassium stimulation. Previous data revealed intense Sn immunoreactivities(I) in adult rat forebrain, hypothalamus, amygdala, hippocampus and brain stem.

The present study examined expressions of Sn-I and SgmRNA in rat brain on fetal(F) or postnatal(P) days F14,16,18,20, P1,5 and 10. In situ hybridization probe was complementary to rat Sg mRNA (nucleotides 193-240). Sn-I were compared to substance-P- and calbindin-I.

Sn and SgmRNA signals were first detected in basal forebrain and diencephalon on F16. By F20 components of the extended amygdala (bed nuc. of stria terminalis, nuc. accumbens and centromedial amygdala) and hypothalamus showed prominent Sn-I and SgmRNA signal. Sn and SgmRNA expressions were most evident in the postnatal hypothalamus. Sn-I and SgmRNA were also expressed in basolateral amygdala and dentate gyrus interneurons.

In conclusion, components of the extended amygdala and other brain structures express Sn-I and SgmRNA at specific stages of fetal and neonatal brain maturation. These expressions probably reflect development of circuits that link limbic and striatal functions.

FUNCTIONAL HETEROGENEITY OF $GABA_A$ RECEPTOR-MEDIATED RESPONSES IN THE VENTROMEDIAL NUCLEUS OF THE HYPOTHALAMUS IN MALE AND FEMALE NEONATAL RATS. S.T. Smith,*[1] A.S. Clark[2], J. A. Lally, and L. P. Henderson[1]. [1]Depts. of Physiol. and Biochem., Dartmouth Medical School, [2]Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

Gonadal steroids act during a critical period extending from late fetal stages to approximately postnatal (PN) day 10 to induce permanent sexual dimorphisms in the ventromedial nucleus (VMN) and medial preoptic area (POA) of the rat hypothalamus. $GABA_A$-mediated synaptic transmission within these regions has been shown to play a key role in the expression of adult female sexual behavior. We have characterised $GABA_A$-mediated responses in the VMN and POA of neonatal rats (PN0-PN20) by analysis of currents elicited by rapid perfusion of high concentrations of agonist in dissociated neurons and of spontaneous inhibitory postsynaptic currents (ipscs) recorded from neurons in intact slices. Responses were elicited by rapid application of 1 mM GABA for 1-2 ms from nucleated outside-out patches. Current decays were best fitted by three exponential components with time constants of ~ 10, 60, and several hundred ms. Spontaneous ipscs were recorded in acutely isolated slice preparations in the whole-cell configuration in the presence of 20 μM CPP and 10 μM CNQX. Spontaneous ipscs were blocked by 10 μM bicuculline. Time constants of ipsc decay were similar to those for currents elicited by rapid agonist perfusion. Statistical analyses suggest that currents recorded from VMN neurons of male versus female animals show significant differences in decay kinetics. Results will be discussed with regard to sex-dependent differences in $GABA_A$ receptor composition within these regions, as assessed by the sensitivity of currents to allosteric modulators and by differential expression of $GABA_A$ receptor subunit genes. Supported by NSF IBN-9319523 (LPH/ASC).

SEX DIFFERENCES IN GLUTAMIC ACID DECARBOXYLASE (GAD) mRNA CONTENT IN THE NEONATAL RAT BRAIN. M.M. McCarthy*, D.R. Grattan, A.M. Davis & M. Selmanoff, Department of Physiology, Univ. of Maryland, Baltimore, MD 21201

Although there are sex differences and steroid effects on the inhibitory transmitter GABA in the adult brain, a role for this neurotransmitter in the sexual differentiation of the neonatal brain has not been established. Glutamic acid decarboxylase (GAD) is the rate limiting enzyme in GABA synthesis and comes in two forms: GAD-65 and GAD-67. We have used a lysate version of the RNase protection assay to quantify mRNA for both forms of GAD in tissue micropunches from specific brain regions. Data are expressed as the ratio of GAD mRNA to that of a housekeeping gene, GAPDH. GAD mRNA was quantified in the arcuate nucleus (ARC), dorsal medial nucleus (DMN), medial preoptic area (mPOA), CA1 region of the hippocampus, amygdala (AMYG) and cingulate cortex (CTX) of individual male and female brains (n=8) during early (postnatal day 1, PN1), late (PN5) and post-critical period (PN15 and PN25) for sexual differentiation of the rat brain.

At PN1, GAD-65 and GAD-67 mRNA was almost twice as high in the DMN, and was significantly higher in CA1 region of males compared to females (ANOVA; $p<.05$). GAD-67 mRNA was also significantly higher in the ARC of PN1 males. No differences were detected in mPOA or CTX. At PN5, GAD-67 mRNA was significantly lower in the mPOA of males and GAD-65 was significantly higher in ARC. There were no other differences at PN5. At PN15, GAD-67 mRNA was significantly greater in the ARC of males and both forms of GAD mRNA were higher in the AMYG of males. There were no significant differences in other brain areas and no differences at PN25.

We conclude that varying levels of GAD expression during the critical period is involved in establishment of sexually dimorphic brain regions. Additional experiments will examine sex differences in adults and the impact of neonatal hormonal manipulations on GAD mRNA levels. *Supported by SRIS Grant to MMM from Univ. of MD, School of Medicine.*

EFFECT OF EXOGENOUS ESTRADIOL ON DEVELOPMENT OF THE DOPAMINE D1 RECEPTOR IN THE RAT. J.A. Williams* and S.S. Maswood. Dept. Biol. Southeastern Oklahoma State Univ., Durant OK 74701 and Dept. Biol. Texas Woman's Univ., Denton, TX 76204.

Endogenous testosterone is aromatized within brain cells to estrogen in males at critical periods during development. Females are protected from the effects of endogenous estrogens through the presence of alpha-feto protein. However, exogenous estrogens can function like testosterone and masculinize the female brain. In this study the effect of estradiol on development of the dopaminergic system was studied. Male and female F-344 rats were injected (s.c.) on post-natal day 3 with either 1 μg estradiol benzoate or sesame oil vehicle. Animals were sacrificed between post-natal days 26-35. Brains were dissected and frontal cortex, hippocampus, and striatum removed and frozen. The dopamine D1 receptor was assayed in these tissues using [^{3}H] dopamine as radioligand and the D1 agonist (±) SKF-81297 hydrobromide as the unlabeled competitor. Levels of [^{3}H] dopamine binding to the D1 receptor subtype were decreased in cortex and hippocampus of both males and females receiving neonatal estradiol, relative to male control animals. Conversely, D1 receptor binding was increased in the striatum of estradiol treated animals. These results suggest that estradiol affects development of the dopaminergic system in a region-specific manner.

IMMUNOHISTOCHEMISTRY AND IN SITU HYBRIDIZATION HISTOCHEMISTRY OF CORTICOTROPIN-RELEASING FACTOR(CRF)-CONTAINING NEURONS IN THE FETAL RAT BRAIN. T. Fujioka[1], I. Akimura, T. Watanabe, T. Shibasaki[2] and S. Nakamura* Dept. of Physilogy and [1]Dept. of Obstetrics and Gynecology, Yamaguchi Univ. Sch. of Med., Ube, Yamaguchi 755, and [2]Dept. of Medicine, Tokyo Women's Medical College, Tokyo, Japan.

Immunohistochemistry and in situ hybridization histochemistry were used to examine prenatal development of CRF-containing neurons in the rat brain. CRF mRNA was first expressed in the lateral hypothalamus and hypothalamic paraventricular nucleus at embryonic day (E)15 (E0: sperm-positive day) in parallel with CRF immunoreactivity. As development proceeds, CRF immunoreactivity of neurons in these areas became progressively enhanced, and the number of CRF-containing neurons increased. In addition, CRF-immunoreactive neurons appeared in other brain regions including the anterior hypothalamus, arcuate nucleus, amygdala, bed nucleus of stria terminalis and septal area. CRF-immunoreactive fibers in the median eminence were detected as early as E17. These findings indicate the expression of CRF-containing neurons in various brain regions during the prenatal period. We are further investigating the possibility of the coexistence of CRF with vasopressin in fetal brain neurons. TRANSIENT SEX DIMORPHISM IN THE NUMBER OF NADPH-DIAPHORASE-POSITIVE GANGLION CELLS OF THE RAT ADRENAL GLAND DURING POSTNATAL DEVELOPMENT. C. Cracco*, S. Biasiol, G. Filogamo and A. Vercelli. Department of Human Anatomy and Physiology, Torino Univ. Sch. Med., Italy.

The rat adrenal gland (AG) contains ganglion cells able to synthesize nitric oxide, a neurotransmitter/neuromodulator involved in the control of adrenal secretory activity and blood flow. In the present study we analysed the number and distribution of nitric oxide-producing adrenal neurons during postnatal development in the two sexes by means of NADPH-diaphorase (NADPH-d) histochemistry. Wistar albino rats were perfused at various postnatal ages and the AGs processed to visualize the NADPH-d. While in adulthood positive neurons are mostly located in the medulla, at birth they are equally distributed within cortex and subcapsular region in both sexes, the medulla being practically devoid of stained nerve cells. The adult distribution of the NADPH-d-positive neurons is reached by the end of the fourth week in both sexes. A transient sex-related difference in the number of NADPH-d-positive neurons per AG is found during the second postnatal week (P7: male 463 ± 35 vs. female 192 ± 6; P10: male 473 ± 54 vs. female 260 ± 61; P15: male 369 ± 43 vs. female 278 ± 62). If newborn male rats are flutamide-injected daily, the number of NADPH-d positive adrenal ganglion cells at P10 is strongly decreased to about half of the control values. On the contrary, if newborn female rats are injected at P0 with one dose of testosterone enantate, the number of positive neurons at P10 is nearly doubled.

In conclusion, the present data demonstrate a transient sex influence on the number of NADPH-d positive neurons in the rat AG, limited to the second postnatal week, and probably related to the perinatal difference in serum testosterone in the two sexes. (Supported by MURST grants to AV)

ESTROGEN INDUCES AN INCREASE IN SINGLE CELL EXPRESSION OF PROENKEPHALIN mRNA IN THE VL-VMN OF YOUNG AND ADULT FEMALE RATS. C. Gómez[1], A. Rodríguez [1], J.L. González [1], J.A. Inserni [2]*, B.S. McEwen[3] and A.C. Segarra[1]. University of Puerto Rico, Physiology Department[1] and Neurosurgery Department[2], San Juan, PR. 00936[1] and The Rockefeller University, NY, NY 10021[3].

Estrogenic regulation of proenkephalin expression in the ventrolateral-ventromedial nucleus of the hypothalamus (VL-VMN) was studied in two age groups of female rats: juveniles and young adults. The juveniles were injected with oil or estradiol benzoate (40 μg/kg) at days 21 and 22 and sacrificed at day 23. The adult group consisted of intact and gonadectomized rats that were injected with oil or estradiol benzoate (40μg/kg) at days 72 and 73 and were sacrificed at day 74. Sections of the VMN were studied by *in situ* hybridization histochemistry at the single cell level and quantified with the assistance of an image analysis system. Estrogen plasma levels were determined by radioimmunoasay. Estrogen increased the amount of proenkephalin mRNA expressed per cell in the VL-VMN of juvenile females. We also observed an increase in the amount of cells expressing low levels of proenkephalin mRNA in these rats. In the adult, ovariectomy reduced proenkephalin mRNA expression, estrogen restored mRNA levels to those of intact females.

791.7

ESTROGEN INDUCES AN INCREASE IN SINGLE CELL EXPRESSION OF PROENKEPHALIN mRNA IN THE VL-VMN OF YOUNG BUT NOT ADULT MALE RATS. Z. Rivera[1], M. Rivera [1], J.A. Angulo[2], and A.C. Segarra[1]* University of Puerto Rico, Physiology Department[1] San Juan, PR. 00936[1] and Biology Department, Hunter College, CUNY, NY, NY[2].

Estrogenic regulation of proenkephalin expression in the ventrolateral-ventromedial nucleus of the hypothalamus (VL-VMN) was studied in two age groups of male rats: juveniles and young adults. The juveniles were injected with oil or estradiol benzoate (40 μg/kg) at days 21 and 22 and sacrificed at day 23. The adult group consisted of intact and gonadectomized rats that were injected with oil or estradiol benzoate (40μg/kg) at days 72 and 73 and were sacrificed at day 74. Sections of the VMN were studied by *in situ* hybridization histochemistry at the single cell level and quantified with the assistance of an image analysis system. Estrogen increased the amount of proenkephalin mRNA expressed per cell in the VL-VMN of juvenile males. In the adult, neither orchidectomy nor estrogen treatment had an effect on proenkephalin expression in the VL-VMN. These results and those of Romano et al. (1990) and Hammer et al. (1993) indicate that estrogenic regulation of enkephalinergic expression in the VMN of male rats changes with age and duration of estrogen exposure.

DIFFERENTIAL REGULATION OF CALCITONIN GENE-RELATED PEPTIDE AND SUBSTANCE P BY ESTROGEN IN RAT SENSORY NEURONS. S. Sarajari, J. Pickett, N. Taleghany and M.M. Oblinger* Dept. of Cell Biol. and Anat., Chicago Medical Sch., N. Chicago, IL

Calcitonin gene-related peptide (CGRP) and Substance P (SP) are co-expressed in a variety of neurons in the central as well as peripheral nervous system, including most small nociceptive neurons of the dorsal root ganglia (DRG). In regions of the nervous system that contain estrogen receptors (ER), such as pituitary and several hypothalamic regions, estrogen (E2) has been shown to augment CGRP levels and to downregulate SP levels. Recently, we have found that many of the small, but not the large-sized, DRG neurons express high levels of ER. Since many of these same neurons also express SP and CGRP, it was of interest to determine how hormonal status affects peptide expression in the DRG. Female Sprague Dawley rats were ovariectomized and either treated continuously with exogenous E2 via a subcutaneous implant of a silastic capsule filled with 17β-estradiol for 21 days (+E group) or were left untreated for that same period (ovx group). Lumbar and sacral DRGs were harvested and immunostained using a variety of polyclonal and monoclonal antibodies to CGRP, SP or ER. Results showed robust CGRP immunoreactivity (IR) in most small-sized DRG neurons, as well as in some medium to large-sized neurons; SP -IR was largely restricted to the small neurons. CGRP - IR in the DRG was markedly enhanced in the +E group relative to the ovx controls, but SP-IR appeared to be less robust in the +E group. This differential regulation of peptide expression in the DRG is consistent with findings in other ER containing neuronal populations. Studies have been recently initiated to explore the functional consequences of peptide modulation in the DRG by E2. Preliminary findings suggest that temperature/pain thresholds (tail flick response) may be influenced by gonadal steroid status.

791.10

LOCALIZATION OF NURR 1- AND NGFIB mRNA IN THE DEVELOPING AND ADULT MOUSE AND RAT CNS. R.H. Zetterström*, R. Williams, E. Lindqvist, T. Perlmann and L. Olson. Departments of Neuroscience and Cell & Molecular Biology, Karolinska Institute, S-171 77 Stockholm, Sweden.

Nurr 1 (nur-related 1) and NGFIb (nerve growth factor-inducible) are two closely related orphan receptors belonging to the steroid hormone receptor superfamily, which are both encoded by immediate early genes. The function of these two proteins is unclear, but in a recently published study the two orphan receptors have been shown to be able to modify retinoid signaling. Other recent studies have indicated that they might be involved in apoptosis. In order to further elucidate the role of these proteins we have applied in situ hybridization histochemistry to localize the possible presence of nurr 1 and NGFIb mRNA in the developing and adult mouse and rat CNS. Expression of nurr 1 mRNA was found in several regions during early development; this expression persisted throughout the pre- and postnatal period and was also found in many areas in the adult CNS. Nurr 1 mRNA was found in the olfactory bulb, several parts of the cortex, in the hippocampal formation, in the ventral tegmental area and in the substantia nigra. In contrast to nurr 1, NGFIb mRNA expression was not found in the prenatal CNS. NGFIb mRNA was first detected in newborn animals. Morover, the transcript was almost exclusively found in small groups of cells in the basal ganglia. Postnatally the NGFIb expression increased and in the adult brain NGFIb mRNA was found in many different regions, including the olfactory bulb, striatum, hippocampal formation and cortex. The interesting pattern of distribution of these two receptors imply important functions in the CNS both during development and in adulthood.

791.11

NGF-RECEPTOR IMMUNOCYTOCHEMISTRY PROVIDES EVIDENCE FOR INCREASED NEURONAL PROCESSES IN BASAL FOREBRAIN CHOLINERGIC NEURONS OF RATS RECOVERING FROM EARLY HYPOTHYROID BRAIN RETARDATION. A. Farahvar* and E. Meisami (Dept. of Physiology and Biophysics, Univ. of Illinois, Urbana, IL 61801).

Plasma thyroxine levels were suppressed in rat pups from birth by addition of PTU (propylthiouracil) in drinking water (1g/L). This neonatally induced hypothyroidism results in profound retardation of neuronal growth in brain regions. Recovery from this condition was initiated by withdrawal of PTU at 25 days of age. Animals recovering from hypothyroid show markedly increased growth rates in body and brain regions including hippocampus and dentate gyrus. Expression of low affinity p^{75} NGF-receptor (NGF-R) is thought to be largely confined to cholinergic neurons of the basal forebrain (BF) which project extensively to forebrain areas. We have shown that compared to 25-day control rats, there is a significant elevation in NGF-R levels in BF neurons of hypothyroid rats. BF neurons were stained immunocytochemically using a monoclonal antibody to NGF-R (192-IgG, Boehringer-Mannheim). Three weeks after PTU withdrawal, NGF-R immunoreactive neurons of BF in recovering rats showed markedly increased neuritic outgrowth and branching as compared to age-matched controls. This neuritic sprouting was most evident in neurons of magnocellular BF nuclei. The above results suggest regulation of NGF-R levels in BF cholinergic system by thyroid hormones may underlie the markedly increased growth rates in rat brains recovering from hypothyroid retardation.

NEUROTROPHIC FACTOR EXPRESSION IN THE ANDROGEN-SENSITIVE BULBOCAVERNOSUS MUSCLE. J. Xu and N.G. Forger*. Program in Molecular and Cellular Biology and Department of Psychology, Univ. of Massachusetts, Amherst, MA 01003.

Motoneurons of the spinal nucleus of the bulbocavernosus (SNB) of rats innervate striated perineal muscles including the bulbocavernosus (BC) and levator ani (LA). The survival of SNB motoneurons and their target muscles depends on androgen during perinatal development. As a result, the muscles and motoneurons persist in males, but degenerate in females. It has recently been demonstrated that ciliary neurotrophic factor (CNTF), can mimic some of the effects of early androgen in this system. CNTF prevents the death of SNB motoneurons and BC muscles that would normally occur in female rat pups. These observations raised the possibility that neurotrophic molecules might mediate some effects of androgen on the developing SNB system. We have used Northern blot analysis to begin to examine expression of neurotrophic factors and their receptors in the SNB system. The BC muscle of newborn male rats exhibited little or no expression of CNTF, but abundant expression of the α-component of the CNTF receptor (CNTFRα) and of TrkB, the high affinity receptor for the neurotrophins, brain-derived neurotrophic factor (BDNF) and NT-4. Expression of both CNTFRα and TrkB was very low in adult BC, indicating developmental regulation of these messages. To determine whether the expression of neurotrophic factors or their receptors might be androgen regulated, rats were treated with testosterone propionate or hydroxyflutamide, a potent antiandrogen, from embryonic day 20 (E20) through postnatal day 4 (P4). Expression of CNTF, BDNF, NT-4, CNTFRα and TrkB was then determined by Northern analysis on E20, P1 and P5 in the BC, LA, "thigh" muscle and lumbosacral spinal cord. (Supported by NIH grant HD33044-01 and the Whitehall Foundation.)

792.1

EFFECTS OF PRENATAL PROTEIN DEPRIVATION ON CORTICOSTERONE LEVELS IN ADULT RATS. P.D. Butler[1,2]*, D.A. Klugewicz[1,2], D. Ciplet[1], and J. Rotrosen[1,2]. Psychiatry Service, NYDVAMC, NY, NY 10010[1] & Dept. of Psychiatry, NYU Medical Center, NY, NY 10016[2].

Prenatal protein deprivation in rats has been used to probe long-term consequences of early nutritional deprivation. Altered hippocampal morphology and electrophysiological functioning, as well as increased 5-HT and 5-HIAA levels in a number of brain areas have been found. Corticosterone (CORT) levels are known to be regulated by brain 5-HT as well as glucocorticoid receptors in hippocampus. As part of a broader study in which we examined the behavioral, morphological and neurochemical effects of prenatal protein deprivation, we examined whether there would be long lasting changes in basal levels of CORT or CORT response to stress. Five weeks prior to breeding, SD rats were fed either a 6% or a 25% casein diet (Harlan Teklad, Madison, WI). All pups were cross-fostered to 25% dams who had given birth within the same 24 hour period, so that the experimental group was designated 6/25 and the control group 25/25. Pups were weaned at PND 25 and maintained on the 25% casein diet for the duration of the study. At PND 76-78 tail blood was obtained from a small group of rats at baseline, following 30 and 60 min of restraint, and after one hour recovery. CORT levels were measured by RIA (ICN Biomedicals). Both 6/25 (n=7) and 25/25 (n=7) animals showed a robust response to stress as seen by at least a 4-fold increase in CORT levels at 30 and 60 min. However, sample size was not sufficient to determine if the 2 groups differed in their response to stress. At PND 85, rats were sacrificed by decapitation and trunk blood collected and analyzed for CORT levels. 6/25 males (n=9) had significantly higher basal CORT levels (mean ± SEM; 215.3 ± 61.5 ng/ml) than 25/25 males (n=14; 70.2 ± 15.6 ng/ml; p=.048). 6/25 females (n=10) had a trend toward increased CORT (313.5 ± 50.5 ng/ml) compared to 25/25 females (n=14; 206.2 ± 44.5 ng/ml; p=.127). Thus, there appears to be a long lasting increase in basal levels of CORT in prenatally protein deprived rats.

792.2

EFFECTS OF CORN-FEEDING AND PROTEIN RESTRICTION ON DEVELOPMENT OF GABA-ERGIC CELLS OF THE CEREBRAL CORTEX IN RATS. HISTOLOGICAL AND IMMUNOCYTOCHEMICAL STUDIES. S.Orozco- Suàrez , A. Feria-Velasco* and A. Del Angel- Meza. Unidad de Invest. Med. en Enf. Neurológicas, H.Especialidades, CMN, S-XXI, IMSS, Mèxico, D.F. and Div. Patol. Exptl. Centro de Invest. Biomédica de Occidente, IMSS, Guadalajara, Jal. Mèxico.

Nutritional deficiency in early life affects the development of the central nervous system; there is a permanent deficit in cell number, and cell maturation is retarded in terms of axonal growth, myelination and enzymatic development. These changes are accompanied by a delay in the appearance of innate behavioral patterns, and which seem to be permanently impaired. The effects of undernutrition in early life have been recently studied in our laboratory in the following aspects: brain development, postnatal cell formation and development of GABAergic innervation of the sensorymotor cerebral cortex. Normal adult pregnant Wistar rats were fed for 6 weeks with 1) Normal diet (commercial diet for rodents, 23 % protein), 2)Hypoproteic (8 % protein) diet on a chow- purina base and 3) corn-based diet (with 8 % protein; low tryptophan and lysine diet) .The histologic studies were performed in the pups 1, 7, 14, 21, 30 and 60 days after birth. GABAergic elements were analyzed by GABA-immunocytochemistry. Radial distribution of cells and laminar numerical densities were calculated at each stage of development by photomicrographs systematically obtained from the total cortex thickness. Results of these studies showed that cortical thickness, total cellularity and the GABAergic cells were significantly reduced in the corn-fed group. The statistical significance of the difference was lower compared with the 8 % protein diet group. Results suggest that omission of essential nutrients from maternal diet has a greater inhibitory effect on postnatal brain development than that produced only by protein restriction.

792.3

EFFECTS OF PROTEIN MALNUTRITION ON HIPPOCAMPAL GABAergic CELLS. A. González-Maciel, M.A. Morales*, S. Díaz-Cintra. UISI-INP. SS. 14410, Depto. Biología Celular, IIB y Centro de Neurobiología, UNAM, México, D.F. 04510.

The effects of protein malnutrition on GABAergic cell density (GAD-positive cells) was studied in the fascia dentata and hippocampal formation of 30 and 90 days old rats. Five weeks prior to mating female rats were fed a 6% casein diet while control rats were fed a 25% casein diet. Malnutrition was established prenatally (6/25), postnatally (25/6), or both (6/6). At 30 days of age, the 6/6 malnourished group showed both a 31% significant ($p<0.0008$) reduction in the hippocampus, and a 39% significant ($p<0.0001$) decrease in the dentate gyrus GABAergic cell density. Conversely, at the same age, the 6/25 group displayed a 27% significant ($p<0.01$) increase in the fascia dentata GABAergic cell density. No significant differences were found at 90 days of age in hippocampal formation.

These data suggest that malnutrition affects the hippocampal formation morphology differentially. The increase in GABAergic cell density found at 30 days old in the 6/25 group indicates a delay in the maturation of hippocampal formation inhibitory circuitry. A severe decrease in GABAergic cell density was found in the 6/6 group in the fascia dentata and hippocampal formation. In the same group, however, a recovery was found in both structures in 90 days old rats. **Supported by DGAPA IN-204093.**

792.4

EEG POWER SPECTRA ANALYSIS BEFORE AND AFTER REM SLEEP DEPRIVATION IN NORMAL AND MALNOURISHED RATS OF 60 DAYS. L. Cintra*, P. Durán, A. Galván and S. Díaz-Cintra. Centro de Neurobiología, UNAM, A.P. 70228, México, D.F. 04510

It has been demonstrated that chronic protein malnutrition delays the maturation of the mechanisms that regulates the vigilance states. This study was designed to evaluate the effects of protein malnutrition induced by a 6% casein diet in rats, instituted 5 weeks before mating and continued during gestation and into postnatal life to their offspring, after REM-sleep deprivation in a "conflict experiment", using an inverted dark-light cycle (12D/12L). A base-line (BL) recording day at 60 days of age was followed by one day of REM-sleep deprivation by the platform technique in control and malnourished rats, followed by three recovery days. We found using EEG power spectra analysis, that the EEG relative power density of theta frequency band (4-7 Hz) was significantly increased in both light and dark phases of BL day one, during the first hour of dark phase of recovery day one and at initial hour of light phase of recovery day 2, and during first and last hour of light phase of day 3. Theta frequency band (7-12 Hz) was significantly reduced during first hour of dark phase of BL. This results suggest that malnutrition affects the mechanisms in central nervous system that regulates the theta rhythm. **Supported by DGAPA IN-208494**

PRENATAL PROTEIN MALNUTRITION ALTERS HIPPOCAMPAL LTP MEASURES AT ALL STAGES OF DEVELOPMENT. P.J. Morgane,* J.D. Bronzino, R.J. Austin-LaFrance and J.R. Galler, Center for Behavioral Development and Mental Retardation, Boston Univ. School of Medicine, Boston, MA 02118 USA.

The ability of prenatally malnourished rats to establish and maintain long-term potentiation (LTP) of the perforant path/dentate granule cell synapse was examined in freely-moving animals at 15, 30 and 90 days of age. Measures of the population EPSP slope and population spike amplitude (PSA) were calculated from dentate field potentials obtained prior to and following tetanization of the perforant path. Significant enhancement of both measures was obtained from all animals of both the diet and control groups at 15 days of age. The magnitude of enhancement obtained from the malnourished group was significantly less than that of age-matched, well-nourished controls. At 30 days of age, PSA measures obtained from approximately 50% of malnourished animals showed no significant enhancement, while measures obtained from the remaining 50% did not differ from controls. EPSP slope measures for this age group followed the same pattern. At 90 days of age, PSA measures also showed a bimodal distribution, with 50% of malnourished animals initially showing a decline in PSA measures, while the remaining 50% did not differ from controls. These results indicate that gestational protein malnutrition has an enduring impact on hippocampal neuroplasticity. **Supported by NIH/NICHD Grant # HD22539**

PRENATAL EXPOSURE TO MALNUTRITION BUT NOT COCAINE IMPAIRS ACQUISITION IN THE RADIAL ARM MAZE. J.S. Shumsky*, P.L. Shultz, J.R. Galler, and J. Tonkiss. Center for Behavioral Development & Mental Retardation, Boston University School of Medicine, 80 E. Concord St., Boston, MA 02118.

Maternal cocaine abuse is often associated with malnutrition. To explore the separate and combined effects of these two insults, the acquisition of a spatial task was examined in the adult male offspring of female rats exposed to protein malnutrition (6% casein diet) and/or cocaine (30 mg/kg) for 5 wks prior to mating and during pregnancy. Control rats were fed a 25% casein or chow diet and saline-injections were performed as drug-injection controls for all diet groups. Rats were tested using the 8-arm radial maze with 4 arms baited and were required to collect all 4 food pellets within 5 min to complete a trial. Subjects were tested for 1 trial/day until they each acquired the task. Acquisition of this task was completed when the rats attained the stringent performance criterion of obtaining 3 out of the 4 food pellets within their first 4 arm entries (while still completing the trial) over 3 consecutive days. The results showed a clear dissociation between the effects of prenatal cocaine and prenatal malnutrition. There were no significant effects due to prenatal cocaine on any measure in this procedure and there were no additive effects with prenatal malnutrition. However, prenatally malnourished rats showed impairment in two measures of acquisition: number of trials to criterion performance and task efficiency (correct arm entries/total arm entries x 100) when compared to controls. No differences were observed in the number of working or reference memory errors, suggesting that the insult produced a general impact on the acquisitional process. These results suggest that prenatal malnutrition, but not cocaine, can impair the acquisition of a radial arm maze task, when a complex procedure with a stringent performance criteria is employed. Supported by NIH grant DA 07934.

BEHAVIORAL EFFECTS OF PRENATAL PROTEIN DEPRIVATION IN PRE-WEANLING AND ADULT RATS. D.A. Klugewicz[1,2]*, P.D. Butler[1,2], D. Ciplet[1], and J.Rotrosen[1,2]. Psychiatry Service, NYDVAMC, NY, NY 10010[1] & Dept. of Psychiatry, NYU Medical Center, NY, NY 10016[2].

Recent evidence indicates that prenatal nutritional deprivation may be one early environmental exposure that increases the risk of schizophrenia. In line with a neurodevelopmental model of SCZ, we investigated the effects of prenatal protein deficiency on growth rate, developmental milestones, and dopamine mediated behaviors in pre- and post-pubertal rats using dopamine agonists and antagonists. Five weeks prior to breeding, virgin female SD rats were fed either a 6% or a 25% casein diet (Harlan Teklad, Madison, WI). All pups were cross-fostered to 25% dams who had given birth within the same 24 hour period so that the experimental group was designated 6/25 and the control group 25/25. Pups were weaned at PND 25, and maintained on the 25% casein diet for the duration of the study. Weights were measured at birth, and approximately every third day thereafter. As expected, weights of 6/25 animals did not differ from 25/25 animals at birth or anytime thereafter. From PND 1-21, pups were assessed for the attainment of developmental milestones and reflexes. Surprisingly, 6/25 animals attained several developmental milestones (i.e. righting reflex, negative geotaxis, acoustic startle, ear unfolding and incisor eruption) before 25/25 animals. At PND 35 and PND 56, stereotypy was measured in rats receiving apomorphine (0.75 mg/kg, SC). At both ages, 6/25 females (n=9), but not males, had a trend towards increased stereotypy levels compared to 25/25 females (n=15), which reached significance only at PND 56. However, d-amphetamine (1.5 mg/kg, IP) induced locomotion and haloperidol (1.0 mg/kg, IP) induced catalepsy did not differ between 6/25 and 25/25 rats at either age, though 6/25 females (n=8) showed a trend toward increased amphetamine induced locomotion at PND 56. Our results suggest that prenatal protein deprivation alters the attainment of developmental milestones, and selectively increases some dopamine-mediated behaviors in post-pubertal, but not pre-pubertal rats.

792.8

TRANSGENERATIONAL EFFECTS OF A PRENATAL TRYPTOPHAN (TRP) DIET. Moto Sakuma*, Moto R.R.C.Co., 4434 Grayton, Detroit, Mi 48224.

The manipulation of a single amino acid in pregnant laboratory rats may have an effect on their progeny. During the third trimester,five Sprague-Dawley pregnant rats were given a 3%TRP diet, and another five received a 0.3%TRP diet(control). In the preweaning period of the first generation(F1) whose mothers (F0) were given the 3%TRP diet(n=35), significant delayed growth was noted in comparison to the growth noted in the control(n=23). In the postweaning to adult period, all 35 F1 rats of F0's given the 3%TRP diet displayed significant slowness in open-field behaviors, sensitive-emotionality and heavier body weights when scored at 3,6,10 and 15 weeks of ages. Heavier brain weights were noted both birth and weaning time in these F1 rats as compared to the control. As a result of sibling mating, 59 second generation(F2) rats, whose grandmothers(F0) were given 3%TRP diet, revealed longer periods of corner crouching, higher circling,longer latency in rearing,fewer rearing counts, less defecation and heavier body weights than that of 21 control F2 rats in their postweaning to adult period. The hypoactivity and emotionality of these F2 rats were noted to be more pronounced that those observed in the F1 rats. Phenotypic evidence may be interpreted as having a transgenerational effect as the result of a prenatal TRP diet. The OPRR guidline will be followed for care.

CHRONIC PLACENTAL INSUFFICIENCY IN FETAL GUINEA PIGS AFFECTS NEUROCHEMICAL AND NEUROGLIAL DEVELOPMENT BUT NOT NEURONAL NUMBERS IN THE BRAINSTEM. S.M. Rees* and M.Tolcos. Department of Anatomy and Cell Biology, University of Melbourne, Parkville, Victoria, 3052, Australia.

It is now widely believed that infants dying of sudden infant death syndrome might have a subtle underlying immaturity of the brainstem perhaps resulting from development in a compromised intrauterine environment. In this study we have examined the effects of chronic placental insufficiency induced by unilateral ligation of the maternal artery at mid-gestation (term=66-68 days) in guinea pigs (n=29). The prenatal development of nuclei in the brainstem involved with cardiorespiratory control and swallowing was analysed using stereological procedures and immunohistochemistry. A method was devised to enable the techniques to be performed on alternate frozen sections. The total number of neurons, area of neuronal somata and volume of the hypoglossal nucleus, showed no significant difference between control and compromised fetuses. There was a proliferation of astrocytes, as determined by immunoreactivity to glial fibrillary acidic protein, in the dorsal motor nucleus of the vagus, nucleus tractus solitarius (NTS) and around blood vessels throughout the brainstem. Immunohistochemical analysis of neurochemicals in the brainstem of compromised fetuses compared to controls, revealed a decrease in substance P (SP) immunoreactivity in the spinal trigeminal tract; a significant ($p < 0.05$) increase of 33% in the number of SP-positive neurons in the NTS and an increase in met-enkephalin (ME) immunoreactive fibres in the hypoglossal nucleus. These results show that although chronic intrauterine deprivation does not alter neurogenesis, at least in the hypoglossal nucleus, there is a proliferation of astrocytes and the expression of neurotransmitters/neuromodulators is affected in nuclei involved with cardiorespiratory control and swallowing.

IMPAIRED SOCIAL RECOGNITION MEMORY IN RATS OF BOTH SEXES EXPOSED TO ALCOHOL DURING THE BRAIN GROWTH SPURT. T.D. Tran and S.J. Kelly*, Dept. Psychology, Univ. of South Carolina, Columbia, SC 29208.

A test of social recognition memory in rats involves exposing them to a juvenile conspecific for investigation during one session and after a delay, exposing them to the same juvenile for another session. A reduction in investigation time during the second session suggests memory of the juvenile. This study addressed whether alcohol exposure affects adult rats' social recognition memory. From postnatal day 2 through 10, rats in the alcohol group were intubated with 3 g/kg/day of ethanol in milk formula. Two hours later, they were given milk formula alone. Mean blood alcohol concentrations reached 255.5 ± 31.1 mg/dl. Two control groups were either intubated and not exposed to alcohol or not exposed to both the intubation and alcohol. Rats were weaned at 21 days and group-housed. No differences in body weight were found among the groups. Behavioral testing of adult rats occurred over three days. Prior to the first session of each test day, rats were placed in a cage with fresh bedding for 15 min. On day 1, a juvenile (21-30 days old) was placed in the rat's cage for 5 min and investigation time was recorded using an S&K event recorder. After a 90 min inter-exposure interval (IEI), the rat was reexposed to the same juvenile for 5 min and investigation time was again recorded. On days 2 and 3, IEIs of 30 min were used, and either the same juvenile (Day 2) or a different juvenile (Day 3) was used in the second session. Testing occurred during the light portion of the day, and females were only tested during diestrus; daily vaginal smears verified the stage of estrus. Across all groups, males spent more time investigating the juveniles in the first session than females; no differences were found among groups. Ratios of second session to first session investigation times were examined. Scores of 1.0 indicated no memory retention. There were no differences in the ratios between the sexes and when scores were collapsed across sex, alcohol-exposed rats showed marked impairment in recognizing the same juvenile in the second session after a 90 min IEI, compared to the two control groups which did not differ. Results suggest that early postnatal alcohol exposure impairs rats' social memories. (Supported by a Carolina Venture Fund Grant to S.J.K.)

ETHANOL ALTERS THE CONTENT OF PITUITARY AND BRAIN B-ENDORPHIN ON THE 20TH DAY OF FETAL LIFE IN THE RAT. H-L Li and C Gianoulakis* Douglas Hospital Research Centre Verdun, Quebec Canada H4H 1R3

At the time of birth and early postnatal life the total content and concentration of B-endorphin in the pituitary gland was lower, while the concentration of hypothalamic B-endorphin was higher in the fetal ethanol than control offspring. In the present studies the content of B-endorphin peptides in the fetal pituitary and distinct regions of the fetal brain were measured on the 20th day of gestation when the offspring are not experiencing the effects of ethanol withdrawal. Rats were fed during gestation (a) with a liquid ethanol diet ad libitum; (b) were pair-fed to the ethanol fed animals with an isocaloric liquid diet; and (c) were fed with laboratory chow and water ad libitum. On the 20th day of gestation the fetal pituitary and distinct regions of the fetal brain (accumbens, frontal cortex, septum, arcuate nucleus, amygdala, hippocampus, ventral tegmental area, and central gray matter) were dissected and extracted in 0.1 normal HCL for estimation of the content of B-endorphin peptides. Results indicated a lower content of B-endorphin in the pituitary gland, and slightly higher content of B-endorphin in the brain regions, of the ethanol exposed offspring. These ethanol induced changes in the content of B-endorphin may alter the process of neurogenesis in the fetal ethanol offspring . Supported by a grant from the NIAAA.

PERINATAL METHADONE EXPOSURE AND RAT PUP DEVELOPMENT. P.M. Kunko*, J.A. Smith, M.J. Wallace, D.T. Otey, J.R. Maher and S.E. Robinson. Dept. of Pharmacology and Toxicology, Med. College of Virginia, Richmond, VA 23298.

This study examined pup development and behavior following pre- and postnatal methadone (M) exposure, and postnatal M withdrawal. Sprague-Dawley CD rat pups, derived from dams treated with water (W) or M (9mg/kg/day) via osmotic minipumps, were cross-fostered on postnatal day 1 (PD1) to W- or M-treated dams, producing four prenatal/postnatal treatment groups: W/W, W/M, M/W, M/M (pumps implanted gestational day 7, with replacement pumps on PD10). Pups were weighed daily and examined for the appearance of developmental milestones. One group of litters (pups and dams) was challenged with naloxone (1mg/kg, s.c.) to test for physical dependence on PD19. Pups from remaining litters were examined for locomotor activity in an open field on PD21. M reduced food and water intake in the dams, but not body weight. M-treated dams had smaller litters and smaller pups and, in general, deficits persisted through PD10. Postnatal M decreased pup weight from PD7-21. Postnatal M exposure appeared to enhance some development, decreasing latency for the righting reflex in W/M pups and decreasing latency for the negative geotaxic response in W/M and M/M pups. M-treated dams and W/M and M/M pups exhibited signs of withdrawal upon naloxone challenge. M/W and M/M pups exhibited less spontaneous locomotion in the open field during the initial 5-min observation. The results suggest both transient and lasting effects of prenatal M exposure and withdrawal, and deficits associated with postnatal exposure. [Supported by 1P50 DA05274]

PERINATAL OPIOID EXPOSURE AFFECTS CHOLINERGIC DEVELOPMENT IN THE RAT. S. E. Robinson,* Q. Mo, M. J. Wallace, J. R. Maher, D. T. Otey, and P. M. Kunko. Department of Pharmacology & Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298-0613.

The present study was performed to determine whether perinatal exposure to full (methadone, M) or partial (buprenorphine, B) μ-opioid agonists delays the development of striatal cholinergic neurons. On day 7 of pregnancy, Sprague-Dawley CD rats were anesthetized with methoxyflurane and implanted s.c. with osmotic minipumps filled with M (9 mg/kg/day), B (1.5 mg/kg/day) or sterile water (W). Maternal weight, food and water intake were monitored throughout pregnancy. Within 24 h of birth, litters were culled to 10 and fostered to dams implanted with minipumps containing M, B or W, so that W/W, M/W, W/M, M/M, B/W, W/B, and B/B prenatal/postnatal exposure groups were obtained. New pumps were implanted in dams on postnatal day (PD) 10. Choline acetyltransferase (ChAT) mRNA was measured by Northern blot analysis in the striata of 10- or 22-day-old male pups, using an α-^{32}P dCTP-labelled 300 bp ChAT cDNA probe. The ratio of ChAT mRNA to 28S RNA was significantly decreased in 10-day-old pups exposed to either M or B perinatally. By PD 22, only pups with continued postnatal exposure to M had reduced ChAT mRNA. Therefore, M and B reduce expression of mRNA for ChAT, which may reflect a delay in the development of striatal cholinergic neurons. However, expression of ChAT mRNA returns to control values by PD 22 in the B-exposure group and in pups after exposure to M is stopped. [This research was supported in part by NIDA grant 1P50 DA05274].

792.14

SUBSTANCE ABUSE DURING PREGNANCY IN A HISPANIC POPULATION: PREVALENCE AND EFFECTS ON PROGENY. N.E. Del Valle[1*], Z. Rivera[1], J.A. Capriles[2], M.P. Casado[2] and A.C. Segarra[1]. University of Puerto Rico, Physiology Department[1] and Municipal Hospital, Department of Pediatrics[2], Medical Center, San Juan, Puerto Rico 00936.

A sample of newborn children in the San Juan area Municipal Hospital was taken for a prospective longitudinal study. Each week, ten neonates, 5 males and 5 females, of less than 24 hrs were randomly selected to participate in the study. Urine samples of the newborn were collected and assessed by radioimmunoassay for cocaine and nicotine. Birth parameters such as birth weight, length, head circumference and fontanel size were recorded. In our sample, no neonates tested positives for morphine, 6% tested positive for cocaine and 14% tested positive for nicotine. A decrease in birth weight and length was observed in neonates whose urine tested positive for cocaine but not in nicotine-positive neonates. No effect was observed in head circumference nor in fontanel size in these nicotine and cocaine positive neonates. We also observed a sex difference in birth weight and length, males being larger and weighing more than females. No sex difference was observed in head circumference nor in fontanel size. We are currently in the process of establishing nicotine and cocaine urine cut-off values in neonates.

792.15

THE EFFECTS OF PRENATAL NICOTINE EXPOSURE ON DEVELOPMENTAL CHANGES IN BRAIN BIOGENIC AMINE CONTENTS. K. Muneoka*, K. Kamei, S. Muraoka, R. Tomiyoshi, T. ogawa and M. Takigawa. Dept. of Neuropsychi., Faculty of Med., Kagoshima Univ., Kagoshima and Safety Research Department, Teikoku Hormone Mfg. Co., Ltd., Kawasaki-shi, Japan.

We have reported that prenatal stressful treatments such as injections, or glucocorticoids administration affected the development of serotonergic neuronal system in rat brain. On the other hand, prenatal nicotine exposure via maternal injections is a treatment inducing hypoxia and ischemia to fetus, that is mimic to the effect of maternal tobacco use. Some studies indicate that effects of nicotine itself can be discriminated from overall effects of nicotine exposure by using infusions. In the present study, we investigated effects of maternal nicotine injections(inj.) or infusions(inf.) on monoaminergic neuronal developments including serotonergic system. Pregnant SD rats were exposed to nicotine via injections twice a day (6mg/kg/day) or infusions by implanted osmotic minipumps (flow rate; 6mg/kg/day) from gestational day (GD) 4 to GD 20. In the midbrain+pons-medulla (M+P-M) and the forebrain of rat pups on postnatal day (PD) 7 and PD 15, NE, DA, DOPAC, HVA, 5HT and 5HIAA contents were measured by HPLC with ECD. Data were analyzed by two-way ANOVA (factors of treatment (inj. or inf.) and nicotine). Main significant changes are summarized below. In M+P-M, effects of inj. treatments were increases in NE, DOPAC, HVA, 5HT and 5HIAA. Effects of nicotine were decrease in HVA and increase in 5HT. In forebrain, effects of inj. were increases in NE, DOPAC, HVA and 5HIAA, and decreases in DA and 5HT. Effects of nicotine were increase in DA and decrease in DOPAC. In addition, these changes in M+P-M and forebrain were dominant in PD7 and PD15 respectively. Our results indicated that nicotine exposure affected not only dopaminergic system but serotonergic system while inj. treatment was likely to affect various aminergic systems.

792.16

SEX DIFFERENCES IN BODY WEIGHT EFFECTS OF PRENATAL NICOTINE IN RATS S. M. Nespor, E. J. Popke, M. A. Rahman, Y. Tizabi,and N. E. Grunberg* Uniformed Services University of the Health Sciences, Bethesda, MD 20814-4799; and Dept. of Pharmacology, Coll. of Med., Howard University, Washington, DC 20059

Maternal cigarette smoking during pregnancy results in decreased infant birthweight. These effects are consistent with the inverse relationship between cigarette smoking and body weight and between chronic nicotine administration and body weight. The effects of smoking on body weight in adults result from effects of nicotine on energy intake and energy expenditure and may involve effects of nicotine on plasma and hypothalamic insulin levels. The present experiment examined effects of prenatal nicotine exposure on the body weights and blood and hypothalamic insulin levels of Sprague-Dawley rat pups during the first five weeks post partum. Twenty-four pregnant dams received nicotine (6 mg/kg/day) or saline, administered by osmotic minipump, during days 4-22 of the 22-day gestation period. Body weights for the 118 male offspring and 104 female offspring were measured 18 days, 24 days, 30 days, and 34 days post partum. Blood and hypothalami from these offspring were assayed by radioimmunoassay for insulin levels. Nicotine significantly and consistently reduced the body weights and the plasma and hypothalamic insulin levels in female offspring. Nicotine slightly reduced the body weights and the plasma and hypothalamic insulin levels in male offspring. In addition, for female and males, the body weights correlated positively with the plasma and hypothalamic insulin levels ($p<0.01$). These results are consistent with previous reports that nicotine affects body weight and insulin levels and that females are more sensitive to these effects of nicotine..

IN UTERO EXPOSURE TO PAROXETINE LEADS TO ALTERED PHYSICAL AND MOTOR DEVELOPMENT. J. H. Patton*, C. H. Rayer, J. L. Langdoc. Neuroscience Program, Baylor University, Waco, TX, 76798-7334.

Previous research in our laboratory has demonstrated that in utero exposure to fluoxetine can cause morphological and behavioral teratogenic effects (Stanford & Patton, *Pharm. Biochem. & Beh.*, 1993, 45, 959-962; Patton, Langdoc, & Rayer, Poster Presented at SWPA, 1995). To test the generalizability of these effects, we exposed dams to approximately seven times the maximal human dose of paroxetine on a mg/kg basis (4.66 mg/kg) via oral gavage beginning on day seven of mating and ending the day of birth. Control animals received distilled water in similar volume by gavage during the same time period. On day three, all litters were culled to eight members, and individual pups were weighed, measured, and toe clipped for identification. Behavioral assessment began on day five. Paroxetine exposed litters had an increased number of stillbirths and neonatal deaths (Stillbirths: $t = -2.26$, $p = 0.037$, $df = 17$; Neonatal deaths $t = -2.49$; $p = 0.023$, $df = 17$). In utero paroxetine exposure had no effect on weight and length, nor upper and lower incisor protrusion time; paroxetine exposure did, however, result in earlier eye openings ($F_{1,125} = 23.043$, $p < 0.001$). Although paroxetine pups performed similarly to controls on surface righting, paroxetine exposed pups performed faster on tests of negative geotaxis (Latency: $F_{1,122} = 4.33$, $p = 0.039$; Trials to Criterion: $F_{1,126} = 4.516$, $p = 0.036$). The paroxetine pups also required fewer trials to reach criterion on cliff avoidance ($F_{1,126} = 3.218$, $p = 0.050$). Combined with our previous work with fluoxetine, results of this study suggest caution in the administration of SSRIs during pregnancy.

793.1

IDENTIFICATION OF CORTICOSTERONE-RESPONSIVE GENES INVOLVED IN HIPPOCAMPAL DEGENERATION. E. Vreugdenhil,* J. de Jong, J. S. Busscher and E.R. de Kloet. Leiden/Amsterdam Center for Drug Research, Division of Medical Pharmacology, PO box 9503, 2300 RA Leiden.

Fluctuating levels of adrenal corticoids play a pivotal role in the viability of hippocampal neurons. In animal experiments, removal as well as excess corticosteroids may result in the neurodegeneration of hippocampal neuronal circuits and consequently result in deficits in cognition and in adaptation to stress.

To investigate the molecular mechanisms underlying corticosteroid-mediated neurodegeneration in the hippocampus we have applied the differential display technique to compare the hippocampal expression profile of four groups of animals. We have used ADX rats and compared these with sham-operated animals. Furthermore, as glutamate is an important additional factor in hippocampal neurodegeneration, kainic acid was administrated to ADX rats and to sham operated rats. The display of approximately 5000 gene products results in the identification of two differentially expressed products between the ADX and sham-operated group and four between the sham-operated and kainic acid-treated animals. The comparison of the ADX, sham and kainic acid-treated groups with the ADX/kainic acid group, however, reveals 18 differentially expressed genes. These results indicate that the main mode of corticosteroid receptor-controlled gene expression in the hippocampus is interaction with other transcription factors (e.g. CREB, AP-1) and not primarily by binding to hormone responsive elements of corticosterone-specific genes. Furthermore, because corticosterone levels in the kainic acid-treated group were such that only the high-affinity MR was occupied, we suggest that the modulating effect of corticosterone on kainic acid-induced gene expression is mediated by the MR and not by the GR.

In conclusion, we will present data on the nature of some of the differentially expressed genes and discuss their possible role in hippocampal neurodegeneration.

SERUM RESCUES NEURONS FROM HYPEROSMOTIC-INDUCED PROGRAMMED CELL DEATH. **C. Dieckmann* and E.L. Feldman. Department of Neurology, University of Michigan, Ann Arbor 48109.**

SH-SY5Y neuroblastoma cells are a cloned cell line which ultrastructurally resembles developing neurons. These cells are a good model system in which to study the potential mechanisms which underlie neurotoxicity secondary to hyperglycemic, hyperosmotic exposure, as seen in diabetes. In the current study, we determined if serum could rescue neural cells from hyperosmolar induced growth arrest.

SH-SY5Y cells (9×10^4 cells/cm^2) were rinsed and plated directly in serum-free media $\pm$ 5, 20, 50, 100 and 300 mM mannitol. Cell number was measured at days 1, 2 and 3 by a colorimetric assay which detects reduction of the tetrazolium salt MTT. By day 2, 20 mM mannitol had significantly decreased SH-SY5Y cell number. The extent of growth arrest over time correlated with the severity of hyperosmolar exposure and was maximal at 300 mM mannitol. Serum rescued SH-SY5Y cells from glucose-induced growth arrest in a dose-dependent fashion with significant improvement in cell number within 24 hrs.

Programmed cell death (PCD), or apoptosis, is an active process which occurs when an essential signal is withdrawn or a noxious signal is introduced. In normosmolar media, withdrawing serum from SH-SY5Y cells did not precipitate PCD measured by flow cytometry. In contrast, approximately 25, 40, 60 and 80% of cells undergo PCD in serum-free media made hyperosmotic in 300 mM mannitol after 24, 48, 72 and 96 hrs respectively. Addition of serum rescued cells from PCD; indeed, only 6, 14, 16 and 20 % of cells underwent PCD at 24, 48, 72 and 96 hrs respectively after hyperosmotic exposure in the presence of 10% serum. Rescue was serum dose dependent and initially observed at 0.6% serum. Collectively, our results imply that a factor in serum can act as a neural osmoprotectant by rescuing cells from PCD. Sponsored by R29 NS32843 and an award from the Juvenile Diabetes Foundation International, Number 194130.

RELIABILITY AND VALIDITY OF THE PHYSICAL DISECTOR. G.J. Popken, P.B Farel*. Curriculum in Neurobiology and Dept. of Physiology University of North Carolina School of Medicine Chapel Hill, NC 27599

The analysis of many neurobiological phenomena requires accurate and reliable estimates of neuron number. The physical disector (Sterio, 1984) has been offered as an unbiased and efficient means to estimate neuron number. The disector method provides estimates of neuron number based on a small sample of cells, providing efficiency, but at a potential cost in reliability. In this study the reliability and validity of the disector method were investigated using frog dorsal root ganglia. Effects of variables related to tissue orientation, volume estimation and sample size were also considered. Recommended protocols for data acquisition by means of the physical disector were found to introduce variability in estimates of neuron number ranging from 0.7-95%. This variability could mask experimental effects or introduce spurious trends. Though recommended sampling protocols can lead to unreliable estimates, statistically reliable and valid estimates were achieved with this method when the sample size exceeded the recommended value by 3-6 times and when careful attention was paid to tissue preparation and volume measurements. Disector estimates were consistently lower than empirical estimates for ganglia cut parallel to the long axis of the dorsal root but not for ganglia cut transverse to this axis. Application of the physical disector thus requires empirical validation and careful consideration of variables that may be specific to the particular experimental situation. Supported by grants NS16030 and NS14899.

UPREGULATION OF BCL-2 FOLLOWING DEAFFERENTATION IN AVIAN NUCLEUS MAGNOCELLULARIS . L.A. Adams, D.M. Hockenbery and E.W Rubel.* Virginia Merrill Bloedel Hearing Research Cntr and Fred Hutchinson Cancer Research Cntr, Univ. of WA, Seattle WA 98195.

Interruption of VIIIth nerve activity in young chickens results in apoptotic cell death of 30% of the neurons in the ipsilateral nucleus magnocellularis (NM), the avian homolog of the mammalian anteroventral cochlear nucleus. The protooncogene bcl-2 blocks apoptotic cell death in many cell types, including neurons. To evaluate a possible role of bcl-2 in mediating cell death or survival in this system, we have used a novel antibody against chicken bcl-2 to examine the expression of the protein in NM cells at 3,6 and 12 h, and 1-5 d following unilateral cochlea removal (CR) in P11 chickens. In unoperated control animals, bcl-2 is expressed constitutively in NM cells and is localized predominately to the cell nucleus. By 3 h after CR, bcl-2 expression increases in a subset of ipsilateral(ipsi) NM neurons, and by 6 h there is an apparent increase in all ipsi NM neurons. Furthermore, at 6 h the subcellular localization of the protein has become predominately cytoplasmic. At 12 and 24 h, there are two distinct populations of ipsi cells, one with markedly lower bcl-2 levels and the other with increased protein levels in the cytoplasm; this pattern persists between 2 and 4 d. By 5 d, most of the surviving cells express low levels of bcl-2 and the subcellular localization has reverted to a predominately nuclear pattern. These results indicate that bcl-2 expression is upregulated as an early response to deafferentation injury, and suggest that those cells which survive are able to sustain elevated levels of bcl-2 during a critical post-injury period. During this critical period, bcl-2 may exert its protective effect by interacting with cytoplasmic constituents. (Supported by NIH grant DC00520).

ALTERED EXPRESSION OF BH1/BH2 FAMILY GENE(S) FOLLOWING RETINAL GANGLION CELL AXOTOMY. L. A. Levin*, K. Geszvain, R. W. Nickells. Department of Ophthalmology and Visual Sciences, University of Wisconsin Medical School, Madison, WI 53792.

Certain apoptosis-related genes, including *bcl-2*, *bcl-x*, and *bax*, share homology at the amino acid level in the BH1 and BH2 domains, through which they also interact. As part of a search for novel members of this family, we studied their expression in retinal ganglion cells after axotomy.

We designed degenerate oligonucleotide primers to the BH1 and BH2 domains, reducing multiplicity by eliminating nucleotides specific to human sequences. Total RNA was isolated from Long-Evans rat retinas at 1 and 4 days after intraorbital crush of the ipsilateral optic nerve; the contralateral retinas were used as a source of control RNA. Reverse-transcribed (RT) cDNA was amplified by the polymerase chain reaction and the products separated with a 1.5% agarose gel.

A single band of the predicted 160 bp length was seen in the control retinas; this monotonically decreased in retinas undergoing axotomy. There were no differences in levels of a control amplimer (S16 ribosomal protein). RT-negative controls demonstrated no banding. This suggests that expression of one or more members of this family decreases after axotomy, and may correlate with retinal ganglion cell apoptosis in this setting. We are currently testing this hypothesis with *in situ* hybridization studies. (Supported by NIH EY00340, Research to Prevent Blindness, and American Health Assistance Foundation.)

A NEW MINIMAL ESTIMATE OF THE MAGNITUDE OF CELL DEATH IN THE GANGLION CELL LAYER OF THE DEVELOPING RAT RETINA. L. Galli-Resta,* B. Margheritti and M. Ensini Istituto di Neurofisiologia CNR, Via san Zeno 51, 56127 Pisa, ITALY.

Overproduction of cells and the subsequent elimination of the excess are common features of nervous system development. In a typical brain region about twice as many neurons can be found in development than in adult life. However, as many investigators have already indicated, the number of dying cells could be higher than these figures suggest, since in many neuronal populations death begins when new cells are still appearing. A realistic estimate of the magnitude of cell death is missing for the lack of precise methods for assesment. However, by labelling cells according to their time of genesis with 5-bromo-2'-doexy-uridine (BrdU), we have been able to follow cells born in limited intervals of time and obtain a minimal estimate of the number of dying neurons in the rat retinal ganglion cell layer. Surprisingly, our data suggest that at least 5 times as many ganglion cells die than commonly believed, and a similar figure is obtained for displaced amacrine cells.

793.7

BASAL CELLS, IMMATURE NEURONS AND MATURE OLFACTORY RECEPTORS UNDERGO PROGRAMMED CELL DEATH IN THE RAT OLFACTORY EPITHELIUM. Thomas J. Mahalik*, Dept. of Cellular and Structural Biology. Univ. of Colorado Health Sciences Center. Denver, Colorado. 80262.

In the olfactory epithelium of the adult rodent olfactory receptor neurons are generated throughout the lifetime of an animal. Despite the continual generation of new neurons, there is no corresponding increase in the thickness of the epithelium. This means that cell death must occur in the epithelium to offset the continual generation of new cells. In the present study, a sensitive method to label nicked DNA in dying cells, was combined with immunocytochemistry to determine the identity of dying olfactory cells. In addition, the positions of apoptotic cells were mapped to provide additional information about the identity of dying cells.

Eight adult Sprague-Dawley rats were intracardially perfused with 4% paraformaldehyde. Sections through the epithelium were mounted on slides and were labeled with the TUNEL method. Sections were then labeled with antibodies against NCAM, keratin, GAP43 and OMP.

The double labeling experiments revealed that each of the olfactory cell types (i.e basal cells (keratin), immature neurons (GAP43) and mature receptor neurons (OMP)) undergo apoptotic cell death. The results of the mapping study suggest that apoptotic cell death occurs in the lower 1/3 of the olfactory epithelim. That is cell death is most likely to occur in basal cells and immature neurons.

***IN VIVO* EXAMINATION OF THE ELECTROPHYSIOLOGICAL AND ANATOMICAL PROPERTIES OF AN IDENTIFIED MOTONEURON COMMITTED TO DIE.** A. W. DeLorme°*, K. A. Klukas°, S. E. Fahrbach^, and K. A. Mesce°. Dept. of Entomology and Graduate Prog. in Neuroscience°, Univ. of Minn., St. Paul, MN 55108; Dept. of Entomology and Neuroscience Prog.^, Univ. of Ill. at Urbana-Champaign, Urbana, IL 61801.

In the abdominal ganglia of the moth *Manduca sexta*, pairs of motoneurons, the MN-12 cells, undergo programmed cell death within 4 days of adult emergence. Preliminary studies on the degeneration of MN-12's target muscle (DE-5) indicate that it degenerates early, 6 - 8 hours before the neuron is committed to die. In addition, it has been shown that there is a lag time of 8 - 14 hours from the time the MN-12 cells are committed to die, to when the first histological indications of somata deterioration are observed. Our aim was to determine if and when the anatomical and electrophysiological properties of MN-12 become altered in relation to the time of muscle degeneration and the 8 - 14 hour lag between commitment to death (at about 29 hours after adult emergence) and somata degeneration.

Neurobiotin-filled electrodes were used to examine the anatomical and electrical properties of the MN-12s. Filled cells were reacted with a Neurobiotin antibody conjugated to Cy-5, and viewed with a laser scanning confocal microscope. Thus far, we find no discernible differences in the electrical and morphological characteristics of MN-12s examined from 1 to 20 hours post ecdysis and those MN-12s older than 30 hours, even though the older MN-12s have lost their muscle targets and experienced the 'triggers' for their death hours earlier. Recordings and subsequent dye fills of both MN-12 cells in a single ganglion were sometimes obtained during cellular degeneration. We found that one of the MN-12s had a normal appearance while the other MN-12 lacked all arborizations. It appears that the MN-12 cells degenerate rapidly as the two cells are known to die in close synchrony at about 8 - 14 hours after the cell is committed to die.

PHOSPHORYLATIONS ANALYSIS IN CEREBELLAR GRANULE CELLS UNDERGOING APOPTOSIS. C. Galli, D. Mercanti, M.T. Ciotti, M. Hribal, L. Milazzo, C. Volonté* and P. Calissano.
Institute of Neurobiology CNR, Via K. Marx 43, 00137 Rome, Italy.

We have previously described and characterised cerebellar granule cells undergoing apoptosis following removal of high potassium (PNAS 90:10989-93,1993). The drop of intracellular calcium was recognised as one of the first events in the signal transduction of apoptotic message in this model (J. Neurosci. 15:1172-79,1995). In this study we have analysed by two dimensional gel electrophoresis the phosphorylation pattern of cerebellar granule cells undergoing apoptosis. The apoptotic neurons showed a pattern similar to control cells for the majority of protein product analysed. One single peptide bearing about 120kDa of molecular weight and an acidic isoelectric point showed an increase in 32P labelling triggered by shifting extracellular potassium from 25 to 5 mM. We followed the kinetic of the phosphorylative event from 0 to 2 hours after the triggering of apoptosis. The increase in 32P incorporation in the 120 KDa protein occurred in the first 20 min, a plateau was kept up to 1 hour and a slow decrease leading to basal control level was observed in the second hour of the apoptotic process. The serine threonine kinase inhibitor staurosporine selectively prevented the low potassium induced phosporylation of the 120kDa protein. The phosphatase blockers okadaic acid induced an overall augmentation of the proteins phosphorylation including the 120kDa peptide. Interestingly, forskolin and IGF-1, which block apoptosis in cerebellar granule cells, were able to prevent any change in the phosphorylation state of the 120kDa protein. These data confirm that an imbalance between kinases and phosphatases is an important step in the apoptotic biochemical pathway and describe a protein phosphorylation placed downstream the decrease of intracellular calcium in the pathway leading to neuronal programmed cell death.

DENDRITIC APOPTOSIS: A NEW MECHANISM FOR RESTRICTED NEURONAL DEATH. M. Sugimori* B.D. Cherksey and R. Llinás, Dept. Physiology & Neuroscience, New York University Medical Center, 550 First Avenue, New York, NY 10016.

While studying calcium concentration changes in Purkinje cell dendrites *in vitro* using calcium dependent fluorescent dyes, we noticed that certain manipulations resulted in the death of well defined dendritic segments. Upon further study, we found that iontophoresis of glutamic acid could trigger local release of calcium from intracellular stores even in the absence of extracellular calcium and in conditions where dendritic spikes were totally absent. When the iontophoresis injection was continuously repeated on to the same site (6 to 8 times), the calcium concentration increase became permanent and a lack of dendrite response to further iontophoresis was noticed. In order to determine whether the calcium concentration changes observed were triggered by the activation of a metabotropic glutamate ligand, most probably activating IP3 dependent calcium release from intracellular stores, we repeated these experiments after intracellular injection of heparin (500 mgms/ml). This protein prevented the secondary release of intracellular calcium during glutamatic iontophoresis.

We further observed that following glutamate iontophoresis to a given dendritic branch, the large release of intracellularly stored calcium did not, necessarily, spread to other branches within the period observed in a slice condition. These results are viewed as indicating localized release of calcium from intracellular stores may, under conditions, produce apoptosis of particular dendritic branches rather than the whole cell. There is evidence from neuropathology, especially in aging subjects, that such dendritic apoptosis is one of the main determinants of grey matter loss as opposed to the actual loss of whole neurons. Supported by NIA-AG09480.

MULTIPLE CED-3 AND CED-9 HOMOLOGUES ARE EXPRESSED IN THE MURINE NERVOUS SYSTEM. A.Sh. Parsadanian*, J.L. Elliott, and W.D. Snider, CSNSI, Dept. of Neurology, Washington University School of Medicine, St. Louis, Mo. 63110.

Recent investigations in vivo and in vitro have confirmed the central importance of ced-3 and ced-9 homologues in the regulation of neuronal survival. However, each of these families is complex and appears to contain many interacting members. Whether these molecules are expressed spatially and temporally in patterns appropriate to regulate neuron survival is unclear. We show here, using in situ hybridization, that the survival promoting ced-9 homolgues (bcl-2 and bcl-x), the death promoting ced-9 homologues (bax and bad) and the bcl-2 binding protein (BAG-1) are diffusely expressed in the murine peripheral and central nervous systems both during development and in maturity. Similarly, the ced-3 homolgue, nedd-2, is expressed by virtually all neurons at all developmental stages. In contrast, the ced-3 homolgue ICE is not expressed in the murine nervous system.

There are however, some developmental differences in expression patterns between the various family members. Temporally, mRNA for all of these molecules appears to decrease as animals mature, except for BAG-1. BAG-1 is expressed in low levels in embryonic mouse brain, then increases during early post-natal stages and into adulthood. In maturity, both ced-9 and ced-3 family members exhibit some cellular specificity in that expression is much more intense in neurons than in glial cells.

These results demonstrate that multiple ced-3 and ced-9 homologues are expressed in the murine nervous system, underscoring their central importance to regulating both naturally occurring neuronal death during development as well as neuronal survival in adult animals. These results also suggest that programmed cell death in all neurons may be regulated by similar intracellular mechanisms.

793.12

GENES ASSOCIATED WITH APOPTOSIS ARE EXPRESSED BY DYING MOTONEURONS AFTER NEONATAL AXOTOMY. R.W. Gerfen*[1], J.L. Elliott[1], E.M.[2] Johnson Jr., and W. D. Snider[1]. CSNSI, Dept. of Neurology[1] and Molecular Biology[2], Washington Univ. School of Medicine, St.Louis, Mo. 63110

Molecular mechanisms underlying neuronal programmed cell death are being clarified by the identification of genes which are associated with apoptosis in vitro. In order to assess the significance of these genes in an in vivo system, we asked whether facial motoneurons dying after neonatal axotomy exhibit morphological and molecular markers of apoptosis. After a right facial axotomy on post-natal day 1, newborn rat and mouse pups were sacrificed at 0.25, 1, 2, 3, 4, 5, 6, and 7 days. Hoechst staining revealed the presence of condensed and brightly fluorescent chromatin in facial motoneurons beginning 3-4 days after axotomy. Motoneurons exhibiting postive Hoechst staining were most numerous at days 4 -5 post axotomy, although they never comprised more than a few percent of facial neurons. Terminal transferase labeling using the Tunel method also demonstrated postive staining in facial motor neurons, again most abundant on days 4-5 after axotomy. Using ^{33}P labeled oligonucleotide in situ hybridization, we determined whether axotomized motoneurons in vivo exhibit changes in mRNA expression for transcription factors that have been linked to apoptosis in vitro. C-jun mRNA expression is heavily increased in facial motoneurons beginning at 24 hours after axotomy, remains elevated until day 3 and then declines. This increased c-jun expression appears uniformly in all axotomized motoneurons. In contrast, c-fos and NGF Ia mRNA expression begin to rise at 48-72 hours after axotomy, and remain intense even at 5 days post axotomy. Importantly, intense expression is limited to a small subset of facial motoneurons which appear shrunken and condensed. Levels of mRNA expression for other genes linked to apoptosis either decline in motoneurons post axotomy (JunD, cyclin D1, nedd-2) or are never expressed (Jun B, Fos B, ICE, Cyclin D2 & D3). These results confirm that motoneurons dying after neonatal axotomy, do so via apoptosis. In addition the temporal pattern of transcription factor expression is similar to what has been described in vitro (J. Cell Biol, 127:1717).

793.13

LONG-TERM SURVIVAL OF NEONATALLY LESIONED MOTONEURONS IN BCL-2 TRANSGENIC MICE. F. de Bilbao and M. Dubois-Dauphin* Dept. of Physiology, University Medical Center, 1211 Geneva, Switzerland.

We have previously reported that neonatal axotomized facial motoneurons which overexpress Bcl-2 were protected against neuronal death for a period of 7 days. Using the TUNEL technique, we have now observed that following facial nerve lesion in two days old wild type mice motoneurons die by apoptosis within 72 hours. In contrast, in transgenic pups apoptosis was not detected in lesioned facial motoneurons during this same period.

Furthermore we have examined the long-term survival of these lesioned facial motoneurons overexpressing Bcl-2. Twelve weeks after the lesion in two days old pups, 74% (n=3) of facial motoneurons survived axotomy in transgenic mice (when compared to the control nucleus), whereas in wild type mice all lesioned neurons had died during the first week after the lesion. The mean diameter of control motoneurons was 26 μm whereas lesioned surviving motoneurons were smaller (13 μm, $p< 0.001$). The nucleus size of control facial motoneurons was 13 μm and 9 μm in lesioned ones ($p< 0.05$).

These results suggest that Bcl-2 confers long-term survival to the lesioned facial motoneurons. Moreover, this survival may be independent of neurotrophic factors since we have not observed facial nerve regrowth at the level of the facial musculature. However, ipsilateral to the lesion, facial nerve axons were always presents in the portion of the facial nerve travelling in the brainstem of transgenic mice.

IMMUNOBLOT AND IMMUNOHISTOCHEMICAL ANALYSES OF ISCHEMIC NEURONAL INJURIES IN THE MONKEY HIPPOCAMPUS WITH REFERENCE TO CALPAIN ACTIVATION

J.Yamano*, T. Yamashima and J. Yamashita Dep.of Neurosurgery, Kanazawa Univ., School of Med., Kanazawa 920, Japan

Calcium-activated neutral cysteine protease, calpain, is known to proteolyze fodrin or protein kinase C. However, the role of calpain in ischemic cell injuries has not been clarified. This study was performed to clarify the role of calpain in the development delayed neuronal death after transient brain ischemia in the hippocampal CA1 of the primates, using Westernblot and immunohistochemical analyses. Two male and two female monkeys weighting 7.5 to 8.5 kg were used. Monkeys were anesthetized with 1.0 to 2.0% halothane in a gas mixture of 40% oxygen and 60% nitrous oxide. Brachiocephalic artery and subclavian artery were exposed and occluded with vascular clips for twenty minutes. Rectal temperature was monitored throughout the experiment and maintained at 37°C with a heating sheet. Three antibodies that specifically recognize inactivated or activated forms of μ-calpain, and fodrin breakdown products were used. Increase of activated μ-calpain together with decrease of inactivated μ-calpain were observed especially in the perikarya of CA1 neurons after transient brain ischemia. In contrast, fodrin breakdown products, which were not observed in the control hippocampus, increased in all sectors of hippocampus after the ischemia. These results suggest that the activation of μ-calpain after brain ischemia plays an important role in the development of delayed neuronal death of the hippocampal CA1.

Key words ischemia, delayed neuronal death, calpain, hippocampus

Bcl-2 PREVENTS OXYGEN-INDUCED APOPTOSIS IN PC12 CELLS. T.Kubo*, Y.Enokido, T.Oka, N.Sato[1], Y.Uchiyama[1] and H.Hatanaka. Institute for Protein Research Osaka Univ., 3-2 Yamadaoka, and [1]1st Department of Anatomy, Osaka Univ. School of Medicine, 2-2 Yamadaoka, Suita, Osaka 565, Japan.

The brain is one of the most energy consuming organs and exclusively depends on the aerobic energy metabolism using oxygen and glucose. Thus, the neurons are always exposed to oxidative stress in their long lives. It has been reported that the oxdative damage was deeply related to Parkinson's and Alzheimer's diseases. It is therefore important to investigate the mechanisms by which the oxdative damage brings about the neuronal death. We have reported that apoptotic neuronal death was observed when embryonic rat hippocampal neurons were cultured in a 50% oxygen atmosphere (*Neuroscience*, **57**:965-972 1993). To study the mechanisms of oxygen-induced neuronal apoptosis in molecular levels, we established the system using PC12 cells. When cultured in a 50% oxygen atmosphere, PC12 cells largely died within 3 days. This cell death was prevented by protein and RNA synthesis inhibitors and the chromatin condensation was observed in cells grown in a 50% oxygen atmosphere. These results suggest that this cell death is mediated by an intracellular active death program, so called apoptosis. The high concentrations of potassium (>26 mM) in culture medium also inhibited oxygen-induced apoptosis in PC12 cells. To characterize the oxygen-induced apoptosis further, we used PC12 cells overexpressing the proto-oncogene *bcl-2*, which has been reported to prevent apoptosis in various types of cells. A large number of the *bcl-2*-transfected cells survived in a 50% oxygen atmosphere for 3 days in contrast to those transfected with the control vector. These results strongly suggest that Bcl-2 prevents oxygen-induced apoptosis in PC12 cells.

This system should be useful for analyzing the molecular mechanisms of oxygen-induced neuronal apoptosis in detail.

793.16

THE TUMOR SUPPRESSOR PROTEIN p53 MEDIATES DNA STRAND BRAKES-INDUCED APOPTOTIC NEURONAL DEATH. Y. Enokido*, T. Araki, S. Aizawa# and H. Hatanaka. Institute for Protein Research, Osaka Univ., 3-2 Yamadaoka, Suita, Osaka 565, # Institute of Molecular Embryology and Genetics, Kumamoto Univ. School of Medicine, 2-2-1 Honjyo, Kumamoto, Kumamoto 860, Japan.

The tumor suppressor protein p53 serves as a critical regulator of a G1 cell cycle checkpoint and of apoptosis following exposure cells to ionizing radiation or DNA-damaging agents. Although the physiological function of p53 in the nervous system is still unknown, recent studies have shown that p53 is surely expressed both in the PNS and CNS. Especially, it was also reported that p53 induction is associated with neuronal damage in the CNS. In this study, we focused on the effect of DNA damage on the neuronal survival, and investigated the role of p53 in DNA damage-induced neuronal death by using p53 deficient ($p53^{-/-}$) mice. When mouse cerebellar granule neurons (postnatal day 15-16) were treated with cytotoxic drugs that cause DNA damage: etoposide, a topoisomerase II inhibitor; bleomycin, which cleaves DNA; cisplatin, which creates intrastrand cross-links; and mitomycin C, an alkylating agent, massive neuronal death was observed within 12-24 hr. In contrast, neurons from $p53^{-/-}$ mice showed evident resistance to etoposide and bleomycin but not to cisplatin and mitomycin C. Although $p53^{-/-}$ neurons were also resistant to the neurotoxicity of cytosine arabinoside (AraC), neuronal death induced by low K^+ medium was similarly induced in both wild type and $p53^{-/-}$ neurons. Furthermore, in cultures continuously labeled with 5-bromo-2'-deoxyuridine (BrdU) for 24 hr, neither wild type nor $p53^{-/-}$ neurons were labeled by BrdU. These results indicate that p53 is directly involved in DNA strand brakes-induced apoptotic neuronal death and it mediates the different intracellular death cascade from low K^+ medium-induced neuronal death.

793.17

Global ischemia induces several genes associated with apoptosis in the gerbil hippocampus. J. Honkaniemi*, S.M. Massa, M. Breckinridge and F.R. Sharp. Dept. of Neurology, University of California, Department of Veterans Affairs Medical Center, San Francisco, CA 94121.

We studied the effect of global ischemia on the expression of interleukin-1ß converting enzyme (ICE), *bcl-2*, *bcl-x*, and *bax* in the gerbil hippocampus. Using *in situ* hybridization *bcl-2*, *bcl-x*, and *bax* were all found to be expressed in CA1-CA3 pyramidal region and dentate gyrus of the normal adult gerbil. Following 5 or 10 min of global ischemia *bcl-2* and *bcl-x* mRNAs were induced 24h later in CA1 neurons whereas the expression of *bax* was unchanged. At 72h following global ischemia ICE mRNA was weakly induced in the CA1 region. At this time the expression of the other genes was markedly decreased in the CA1 pyramidal cells. Using DNA nick end labelling, neurons showing DNA fragmentation were mainly localized in the CA1 neurons, although 72 h after 10 min ischemia, labelled neurons were also observed in the cortex and the CA3 region. The *bcl-2*, *bcl-x* and *bax* oligonucleotide probes detected bands of expected size on Northern blots. However, the two ICE oligonucleotide probes used detected two additional bands of 3 kb and 1.5 kb in addition to the expected prominent 2 kb band. All three isoforms of *bcl-x* were expressed in normal hippocampus as demonstrated by RT-PCR. 24 and 72 h after ischemia, the relative mRNA levels of the large isoform (*bcl-*x_L) were decreased, whereas little change was seen in the expression of the short (*bcl-*x_S) and transmembrane deleted (*bcl-*$x_{\Delta TM}$) isoforms. The induction of *bcl-2* may tend to prevent apoptosis at 1 day. However, the decrease in the protective *bcl-*x_L compared to the apoptotic *bcl-*x_S may be an important factor leading to apoptotic death. This data suggests that after global ischemia CA1 neurons express a number of genes associated with apoptosis implying that the CA1 neurons undergo apoptosis-like death with activation of endonuclease and fragmented genomic DNA.

793.18

A MONOCLONAL ANTIBODY THAT INDUCES APOPTOSIS IN NEOCORTICAL NEURONS BINDS TO A NOVEL CLASS OF DEATH RECEPTOR L.T. Zhong, L. Noterpek, J. Oh, Y.L. Ruan, L. Butcher, K.F. Faull, A.L. Fluharty and D.E. Bredesen* UCLA Neuroscience Program, Los Angeles, CA 90024, La Jolla Cancer Research Foundation, La Jolla, CA 92037

Neuronal apoptosis during development and pathogenesis of degenerative diseases may be induced by both internal and external signals. In the process of searching for these death signals and their receptors, a monoclonal antibody, designated NAIM-1 (neural apoptosis-inducing monoclonal 1; 1 out of 13,000 clones screened), was found to induce apoptosis in some rat neural primary cultures and cell lines. The killing was not due to complement related cell lysis. Bcl-2, P35, and Cu-Zn SOD, gene products which were shown to block apoptosis induced by several but not all stimuli, prevented apoptosis induced by the antibody. Histochemical staining showed no antigen expression outside the central nervous system. Within the CNS, the antibody bound predominantly to cortical neurons, especially pyramidal cells of cortical layer V. The antigen that the monoclonal antibody recognizes is not a member of the FAS-TNF receptor family. Characterization of the antigen will be presented.

793.19

APOPTOSIS CONTRIBUTES TO ISCHEMIC BRAIN INJURY IN OCCLUSION/REPERFUSION MODEL IN THE CAT Z.S. Vexler*, I.V. Klimanskaya, T.P.L. Roberts, N. Derugin, J. Kucharczyk, A. Arieff. Neuroradiology Section, Departments of Oral Biology and Medicine, University of California, San Francisco, CA 94143, USA.

Apoptosis and necrosis, two morphologically and biochemically distinguishable forms of cell death, have been implicated in neuronal loss following cerebral ischemia. The purpose of this study was to evaluate the contribution of apoptosis in brain injury in relation to the degree of hypoperfusion, using the model of focal transient middle cerebral (MCA) occlusion in the cat.

The right MCA of three cats was occluded for 2 hours followed by 10 hours of reperfusion. Diffusion-sensitive and contrast-enhanced MRI were performed every two hours and maps of the apparent diffusion coefficient (ADC) and of cerebral microcirculation ($\Delta R2^*$) were constructed. At the conclusion of experiments, triphenyl-tetrazolium chloride (TTC) was perfused intracardially. 5 μm coronal sections anatomically matching those observed on MRI were cut from formalin-fixed brain tissue. Ischemic brain damage was established using TTC and H&E staining. Presence of apoptotic cells was evaluated in situ by direct fluorescence or immunoperoxidase detection of digoxigenin-labeled genomic DNA. The contralateral MCA territory served as a control.

By two hours of MCA occlusion, the ratio of peak ΔR_2^* effects in ischemic parietal cortex and basal ganglia was decreased (17±8%) compared to anatomically matched contralateral tissues, and brain edema (30-50% drop of the ADC) was detected. Upon reperfusion, a complete restoration of cerebral microcirculation was observed. A delayed decline of the cerebral microcirculation varied in different areas. Lack of TTC staining correlated well with areas of prolonged perfusion deficit on the contrast-enhanced MRI. Cells showing digoxigenin staining were present in basal ganglia ipsilateral to the occluded MCA, regardless of the degree of disturbance of the microcirculation during reperfusion. In the cortex, cells showing digoxigenin staining were preferentially exhibited in the perifocal areas of ischemic core which were moderately perfused during reperfusion. Digoxigenin labeling was found both in pycnotic nuclei, and in the nuclei with normal morphology as revealed by double-labeling with 4,6-diamidino-2-phenylindole (DAPI) or methyl green. Our data suggest different stages of apoptotic process in individual cells.

Apoptosis appeared to be an important early contributor to ischemia-induced cell death in cats with focal transient ischemia.

793.20

LOCALIZATION OF ICE-LIKE PROTEASES, ENZYMES ASSOCIATED WITH APOPTOSIS, IN THE MAMMALIAN CENTRAL NERVOUS SYSTEM. R. Siman*, S. Trusko, R.J. DiRocco, V.R. Marcy and R.W. Scott. Cephalon, Inc., West Chester, PA 19380

Interleukin-1β converting enzyme (ICE) is a cysteine protease responsible for production of mature IL-1β. Recent molecular genetic and cell biological findings have implicated ICE and a family of homologous proteins as key mediators of programmed cell death via apoptosis. The role of apoptosis in neurodegenerative processes in the adult CNS and the involvement of members of the ICE family are not well-understood. We have used immunohistochemistry to map the distribution of members of the ICE family in the rodent CNS, and have investigated effects of neuronal injury on expression of ICE family members. Synthetic peptides were used in preparation of antisera predicted to recognize either all known members of the ICE family, or specifically react with ICE (p20 subunit) of human and mouse origin or with mouse Nedd2. In the gerbil brain, prominent ICE-like immunoreactivity was restricted to the neuropil of substantia innominata of the basal forebrain. Nedd2-like immunoreactivity, on the other hand, was broadly localized and abundant in most neurons throughout the neuraxis. Although present in the cytoplasm of neuronal perikarya, axons, and proximal dendrites, Nedd2-like immunoreactivity was most intense in neuronal nuclei. The immunostaining was specific; it was confirmed with a second antibody raised to a distinct domain, and could be preabsorbed with peptide immunogen. The effect of neuronal injury on protease content was assessed in gerbils subjected to transient global ischemia. Immunoreactivity for ICE and Nedd2 declined in hippocampal CA1 pyramidal neurons over 3 days, and began to appear in astroglia as they became reactive. These results indicate that ICE and especially Nedd2 could be involved in apoptotic mechanisms in adult central neurons, and suggest that one target of Nedd2 action may be the nucleus.

CEREBRAL CORTEX AND LIMBIC SYSTEM IV

CALBINDIN, CALRETININ AND NADPH-DIAPHORASE IN DIFFERENT CELL CLASSES IN LAYER I OF THE ADULT HUMAN NEOCORTEX. G.Meyer*,D.Galindo-Mireles,F.Carrillo-Padilla and R.Ferres Torres. Dept.Anatomia,Fac.Medicina,La Laguna, Spain.

Cajal-Retzius cells are considered the principal cell type of neocortical layer I. They are common during fetal life, but only a subpopulation survives into adulthood. We analyze here the distribution and morphology of neurons in layer I in 22 different cytoarchitectonic areas (primary sensory, motor and association cortices) of 10 human brains aged 27-96 years, by using calbindin (CB) and calretinin (CR) immunohistochemistry and NADPH-diaphorase histochemistry. Like the fetal forms, adult Cajal-Retzius cells have a long horizontal axon and dendrites restricted to layer I. They occur in all areas examined, but show a topographical preference for the bottoms of the sulci. Most Cajal-Retzius cells are CR-immunoreactive (ir), but a few ones express CB. A subgroup of Cajal-Retzius cells, located deep in the sulci around entering blood vessels, is moderately NADPH-d positive. A second class of large cells in layer I is CB-ir. These neurons, observed in the prefrontal and non-auditory temporal areas, have long smooth dendrites descending to layer III, and an apparently local axon in layer I. Their similarity with CB-ir neurons in deeper layers suggests that they do not belong to the group of Cajal-Retzius cells, but rather share the morphology, and possibly the developmental history, of neurons derived from the cortical plate.

794.2

POSTNATAL DEVELOPMENT OF LAYER IIIC PYRAMIDAL NEURONS IN THE HUMAN PREFRONTAL CORTEX: A RAPID GOLGI STUDY. H.B.M. Uylings (1), Z. Petanjek (1,2), I. Kostović (2).(SPON: European Neuroscience Association); (1) Netherlands Institute for Brain Research, Meibergdreef 33, 1105 AZ Amsterdam, The Netherlands, (2) Croatian Institute for Brain Research, Zagreb, Croatia.

We studied the dendritic development of layer IIIC pyramidal neurons in the region of Brodmann's area 9 of the human prefrontal cortex (PFC) in rapid Golgi stained sections using a 3-dimensional semiautomatic system developed at the Netherlands Institute for Brain Research. Quantitative analysis was performed on basal dendrites of 25 subjects ranging from newborn up to 91 years. Research questions are (a) which phases of developmental growth can be detected, (b) is dendritic overgrowth apparent in this crosssectional study, (c) which life-span alterations are detectable, (d) does the development of layer IIIC pyramidal dendritic processes take place later than those in layer V pyramidal neurons and (e) can data of this silver rapid Golgi study be compared with those of the mercury Golgi-Cox study. So far, the results show a rapid dendritic growth of layer IIIC pyramidal dendrites in the first year. The number of branches in basal dendrites did not increase further after the first month, but especially terminal segments elongate and as a consequence total dendritic length until 1-3 years. Somata size reached adult values around 1 year and, at the age of 6 years, two specimen showed overgrowth in size. In addition, a temporary exuberant number of spines on these pyramidal cells was detected during the period of 3-6 years (Petanjek et al., 1995). In this study no dendritic regression in normal aging was evident, although interindividual differences increased after the age of 50.

In this rapid Golgi study, the maturation of layer IIIC pyramidal cells ended no later (if not earlier) than that of layer V pyramidal cells (Petanjek et al., 1995). A similar conclusion was reached in our Golgi-Cox study (Koenderink et al., 1994). Finally this study indicates that after structural maturation of layer IIIC pyramidal dendrites, chemical maturation of these neurons will continue (Kostović et al., Neurosci. Lett. 90: 107, 1988).

CALLOSAL NEURONS AND GLIAL CELLS IN THE DEVELOPING CEREBRAL CORTEX OF HUMAN FETUSES. L. deAzevedo, R. Lent and C. Hedin-Pereira*. Instituto de Ciências Biomédicas, UFRJ, 21941-590 Rio de Janeiro, and Instituto Fernandes Figueira, FIOCRUZ, 22250-020 Rio de Janeiro, Brazil.

We have studied the morphology of developing callosal neurons and glial cells in human fetuses, by implanting DiI crystals respectively into the corpus callosum and in the marginal layer of two premature fetuses deceased at estimated ages of 28- and 33-weeks gestation. Small, paraformaldehyde-fixed blocks containing the cingulate gyrus and the callosum were dissected and implanted with crystals of DiI. The blocks remained in fixative during 4-6 months before being cut coronally at 300 μm and counterstained with DAPI. Most callosal neurons were spiny pyramids located at different depths in the cortical plate, with well-developed basal dendrites, and apical dendrites that consistently arborized within the marginal layer. Other cell types were rare, such as bipolar and multipolar neurons, and inverted pyramids. Glial cells became labelled with DiI either by the pial crystals or by contiguity with labelled callosal fibers. Three morphological types could be discerned: (1) radial glia with processes attached to the pial surface but not to the ventricular wall; (2) glial cells with short apical processes, and (3) astrocytes. Results show that by 28 weeks gestation callosal neurons are advanced in their morphological differentiation and radial glial cells are transforming into astrocytes, suggesting that radial neuronal migration has ceased in the human cerebral cortex.

CALLOSALLY-PROJECTING SUBPLATE CELLS IN FETAL HUMAN BRAINS. R. Lent*, L. deAzevedo and C. Hedin-Pereira. Instituto de Ciências Biomédicas, UFRJ, 21941-590 Rio de Janeiro, and Instituto Fernandes Figueira, FIOCRUZ, 22250-020 Rio de Janeiro, Brazil.

Subplate neurons have been implicated in the formation of cortical pathways of developing non-human mammals. To verify if these neurons project callosal axons in the developing human brain, and to study their morphology, we placed crystals of DiI into the callosal tract of two premature fetuses deceased after birth. Their estimated ages at death were respectively 28 and 33 weeks of gestation. Small, paraformaldehyde-fixed blocks of the cingulate gyrus containing the corpus callosum were dissected and implanted with crystals of DiI. The blocks remained in fixative during 4-6 months, before being cut coronally at 300 μm. Sections were counterstained with DAPI, and screened under a fluorescence microscope to identify the labelled cells and delimit the cortical subplate. Several neurons located within the subplate were detected in both brains, and were documented photographically or drawn through a camera lucida. Most of these neurons were smooth, bipolar cells with long, tangential dendrites spanning a large extent of the cingulate gyrus, and some had labelled axons that could be followed into the corpus callosum. A few were radially oriented bipolar neurons, multipolar cells with no particular orientation, and inverted pyramids. Results reveal that subplate cells in the developing human brain do project axons through the callosum. Furthermore, the characteristic tangential orientation of these cells' dendrites provides a favorable architecture for interactions with afferents.

SEX DIFFERENCES IN RESTING CEREBRAL GLUCOSE METABOLISM IN MONKEYS. M. J. Raleigh*, W. P. Melega, S-C. Huang, S. Cherry, Michael T. McGuire, and M. E. Phelps. Depts. of Psychiatry and Molecular and Medical Pharmacology, UCLA School of Medicine, Los Angles, CA 90024-1759.

This positron emission tomography (PET) study examined the relationship between sex differences in local cerebral metabolic rates for glucose (LCMRGlc) and the emergence of gender differences in behavior in developing vervet monkeys. We documented LCMRGlc in nine regions of interest (ROI) in conscious monkeys. The seven male and eight female subjects ranged two to 12 months and lived in complex, species typical social groups. Sex differences in aggression, affiliation and play were not present prior to six months of age but became prominent between six and 12 months of age. Similarly there were no sex differences in LCMRGlc in any ROI before subjects were six months old. However between six and 12 months of age, females had higher LCMRGlc than males in the orbitofrontal, dorsolateral frontal, temporal, and parietal cortex by 21%, 23%, 25%, and 23% respectively. By contrast, there were no sex differences in LCMRGlc in the visual cortex, primary motor cortex, thalamus, cerebellum, or brainstem. Thus sex differences in LCMRGlc are more pronounced in cortical association areas than in other regions and emerge coincident with the appearance of sex differences in complex social behavior. Gender may be a critical variable in specifying the links between developmental changes in LCMRGlc and behavior. Supported by the Dana Foundation, the Veterans Administration, and the NINDS.

THE ROLE OF CELLULAR ACTIVITY IN THE DEVELOPING CEREBRAL CORTEX. G.Magowan, and D.J. Price*. Department of Physiology, University Medical School, Edinburgh EH8 9AG, U.K.

An *in vitro* organotypic co-culture system was used to examine the development of the thalamocortical system. In culture embryonic day 15 thalamus innervates postnatal day 6 cortical explants and axons terminate within layer 4, as *in vivo*. Our hypothesis is that the release of neurotransmitters contributes to the determination of cell fate and target selection within this co-culture system. Neurotransmitter release may require or induce fluctuations in activity.

We either added tetrodotoxin (TTX), a sodium channel blocker, or increased potassium levels (to depolarise cells) in the developing co-culture system. TTX (10^{-6}M) resulted in increased thalamic outgrowth and eliminated the recognition of layer 4 by thalamic axons. KCl ($5x10^{-3}$M) resulted in excessive thalamic and cortical outgrowth and abolished target recognition. TTX and KCl treated co-cultures were sectioned and Nissl stained to reveal effects on cell viability. Preliminary results indicate that TTX enhances cortical cell viability, perhaps by reducing glutamate induced cell death in these co-cultures.

These experiments support a role for activity in the determination of cell fate and target recognition in the cortex. We are currently investigating whether neurotransmitters are involved in these processes, by adding specific receptor antagonists to the co-culture system.

POSTNATAL DEVELOPMENT OF ANATOMICAL AND ELECTROPHYSIOLOGICAL PROPERTIES OF LAYER I NEURONS IN RAT NEOCORTEX. Fu-Ming Zhou* and John J. Hablitz Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294.

Layer I and Cajal-Retzius (CR) cells are thought to be important in neocortical development with the CR cells thought to mature very early. Using whole cell patch clamp techniques and intracellular biocytin staining, we have studied the postnatal development of layer I neurons in the rat neocortex. Physiologically, in the first postnatal week, all layer I neurons had low resting membrane potentials, high input resistances and long membrane time constants. Action potentials (APs) were short in amplitude and long in duration. The firing frequency attained in very young cells was lower than in older ones. These parameters matured rapidly during the first 10 postnatal (PN) days. Very young layer I neurons had a prominent hyperpolarization-activated depolarizing "sag" which decreased with age. Morphologically, within the first postnatal week, bipolar horizontal neurons were prominent in layer I. These cells had very simple axonal arbors which did not extend into deep layers. Starting around PN7, these horizontal cells declined in number. Around PN10, nonpyramidal neurons with diverse morphology became the main neuronal components in layer I. Axonal collaterals of these cells were extensive and formed elaborate arbors, reaching into deep layers. These results suggest that 1) membrane properties of rat neocortical layer I neurons, including CR cells, are very immature at birth, 2) CR neurons do not show significantly earlier maturation in membrane properties than other layer I neurons, and 3) both membrane and morphological properties of layer I neurons mature rapidly in first two postnatal weeks.

DUAL COMPONENT mEPSCs IN LAYER I NEURONS OF RAT NEOCORTEX. John J. Hablitz* and Fu-Ming Zhou, Neurobiology Research, University of Alabama at Birmingham, Birmingham, AL 35294.

Dual component miniature miniature excitatory postsynaptic currents (mEPSCs) involving NMDA and AMPA receptors have been described in neocortical pyramidal cells. Using whole-cell patch clamp techniques and direct visualization of neurons, we examined the properties of mEPSCs in enigmatic layer I neurons. mEPSCs were recorded from all the layer I neurons tested. mEPSCs were prominent, occurring at rates of up to 10 Hz. In normal extracellular solution containing 1.3 mM Mg^{2+}, the inward mEPSCs consisted of fast and slow components. The slow component was absent at -70 mV, became apparent at -30 mV, was outward at +60 mV, and did not shown significant rectification. In Mg^{2+}-free solution, the slow component was observed even at -70 mV. D(-)2-amino-5-phosphonovaleric acid (D-APV) at 20 μM completely blocked the slow component indicating mediation by NMDA receptors. At -70 mV, the fast component had a rise time of about 1 ms, decayed with a single exponential time course of about 2.5 ms and was blocked by CNQX, suggesting mediation by AMPA receptors. In all layer I neurons tested (N=20), the fast component never reversed polarity even at holding potentials as positive as +80 mV. Thus, synaptic AMPA receptors on layer I neurons were highly inwardly rectifying. Bath-applied kainate (30 μM) induced an inwardly rectifying current which was blocked by CNQX. The degree of rectification of kainate responses was less than for mEPSCs. Layer I neurons have dual component mEPSCs mediated by NMDA and AMPA receptors. Synaptic AMPA-mediated responses are highly inwardly rectifying perhaps reflecting lack of GluR2 subunits.

CHAOS CONTROL IN THE DEVELOPING HIPPOCAMPUS?. J.V. Sanchez-Andres*, L. Menendez de la Prida and S. Bolea. Dept. Fsisologia, Inst. Neurociencias, Univ. Alicante, Aptdo. 374, 03080-Alicante, Spain.

Intracellular recording in hippocampal slices from rabbit shows sequential changes in the spontaneous activity of CA1 cells along early post-natal development (days 0-20 after birth). The maturation can be described as four stages: 1. Aperiodical bursting is the predominant event just after birth, accompanied by aperiodical spiking. 2. Spiking becomes more frequent and periodic while the bursting frequency decreases. 3. Bursting disappears, while periodic spiking remains. 4. Spiking frequency decreases to the level usually recorded in adult animals. The transitions among patterns are not homogeneous in the CA1 field of every single subject, pointing to an asynchronic maturation of the neurons. Independently of this heterogeneity the majority of cells behave similarly (stage 4) by the end of the studied period.

The transition from stages 1 to 3 correlates with a reduction in the afterhyperpolarization following injection of depolarizing current. This transition has been modeled with a Hodgking and Huxley formalism, showing that the reduction in the afterhyperpolarization can account for the sequential change in the pattern.

The transition from the early aperiodic to the adult-like pattern can be theoretically analyzed in terms of interspike interval maps showing a progressive degree of organization.

We hypothesize that the maturation of the afterhyperpolarization constitutes the main element in the early maturation of the pattern, while the last stage would be a consequence of both the development at the network level and of the synaptic interactions. If this process constitutes formally a case of chaos stabilization or a dynamical bifurcation would require further studies.

794.10

ONTOGENY OF THE PAIRED-PULSE INDEX: A MEASURE OF THE DEVELOPMENT OF HIPPOCAMPAL DENTATE GRANULE CELL MODULATION. J.D. Bronzino,* J.H. Blaise, R.J. Austin-LaFrance and P.J. Morgane. Dept. of Engineering and Computer Science, Trinity College, Hartford, CT 06106 USA.

Measures of hippocampal dentate granule cell field potentials recorded in response to paired-pulse stimulation of the perforant pathway applied over a range of interpulse intervals (IPI) were used to evalauate developmental changes in modulation of granule cell excitability. Population spike amplitude differences between the first and second evoked response of a pulse pair were used to construct a paired-pulse index (PPI) for chronically implanted, freely moving male Sprague-Dawley rats recorded at 15, 30, and 90 days of age. Comparison of the resulting PPIs indicated a distinct developmental progression involving the early inhibitory, facilitatory, and late inhibitory phases of granule cell modulation identified in adults. This progression was characterized by markedly less early inhibition (IPI = 20 and 30 msec.), a lower level of facilitation (IPI = 50 -150 msec.), and a complete lack of late inhibition (IPI = 300 - 1000 msec.) in 15 day old rats when compared to 90 day old animals. Values of the PPI obtained from 30 day old rats fell intermediate between the 15 day and adult groups. These results suggest that the PPI can be effectively used as an indicator of the level of functional maturation of intrinsic (i.e., GABA-ergic basket cells) and extrinsic (e.g., medial septum, median raphe, and locus coeruleus) afferent systems modulating dentate granule cell excitability. **This research supported by NSF Grant # BCS-9208128.**

ALTERATIONS IN THE PROPERTIES OF HIPPOCAMPAL NEURAL NETWORKS FOLLOWING EXPERIMENTALLY-INDUCED DECREASES IN NETWORK SIZE IN INFANCY. Karen L. Smith, Chong L. Lee and John W. Swann*. The Cain Foundation Laboratories, Department of Pediatrics, and Division of Neuroscience, Baylor College of Medicine.

A number of neurological disorders are thought to be characterized by a reduction of hippocampal pyramidal cell number in early life. Experiments were undertaken to assess the effects of reduced pyramidal cell number on hippocampal network operations in adulthood. Infant rats (3-5 days of age) were injected intrahippocampally with NMDA (5 nmoles in 50nL) and allowed to mature (50-60 days of age). Injection were made in area CA3. Histological examination of the hippocampus demonstrated a marked reduction in the size of the $CA3_A$ and $CA3_B$ hippocampal subfields. Hippocampal neuronal number was reduced. However, a well formed CA3 cell body layer was present and there was no evidence of reactive gliosis. Recordings from hippocampal slice preparations were undertaken in medium containing picrotoxin (20μM). These experiments assessed the status of pyramidal cell recurrent excitatory networks. Prolonged synchronized population discharges (3-10 sec in duration) occurred in NMDA treated hippocampus but were not observed in slices from contrateral hippocampus or vehicle injected controls. Field potential analysis and recordings from minislices suggest that the discharges arose from $CA3_C$. Paired intracellular recordings suggest that when discharges occurred in $CA3_A$ or $CA3_B$ neurons they were driven by events originating in $CA3_C$. Thus in areas of the CA3 region most altered by NMDA injections recurrent excitatory connectivity maybe poorly developed. In adjacent regions, hyper-interactive networks may exist.

ELECTROPHYSIOLOGICAL ASPECTS OF POSTNATAL DEVELOPMENT OF RAT NUCLEUS ACCUMBENS *IN VITRO*. M. Belleau and R.A. Warren*. Centre de recherche Fernand-Seguin, Montréal, Québec, H1N 3V2.

The nucleus accumbens (nAC) receives important glutamatergic input from several limbic structures. Each of these structures innervates the nAC with a characteristic pattern. These patterns are presumably achieve in part through the mutual interactions between these fibres within the nAC during development. In addition, the interactions between these different inputs may have global effects on nAC development itself. As a first step to study the influence of glutamatergic input on the development of the nAC, we have characterized the physiological properties of nAC neurons and of the hippocampal innervation of the nAC during postnatal development in rat *in vitro*.

Whole cell recording of nAC neurons was performed in parasagittal 400μm thick slices from animals aged from less than a week up to 60 days. A unipolar tungsten microelectrode was used to electrically stimulate hippocampal fibres.

Young nAC neurons displayed high input resistance, long membrane time constant, slow action potential and a poor capacity to fire repetitively as compare to neurons from older animals. The stimulation of the fimbria usually produced a dual excitatory postsynaptic potential presumably consisting of a non-NMDA and of a NMDA component in young nAC neurons. During the second postnatal week, a third late inhibitory component appears which presumably depends upon the maturation of nAC intrinsic circuitry to be expressed.

These results show that glutamatergic input is present early during postnatal life and, as a consequence, that it may have an important influence on the normal development of nAC.

INTRINSIC INTERLAMINAR CONNECTIONS IN AREA V2 OF MACAQUE MONKEYS ARE ALTERED AFTER MONOCULAR DEPRIVATION. I.Stepniewska[1], J.H. Kaas[1], and M. H. Tigges[2]*. Dept. of Psychology[1], Vanderbilt University, Nashville, TN 37240 and Yerkes Reg. Primate Res. Ctr[2]. of Emory University, , Atlanta, GA 30322

We studied the organization of intrinsic laminar connections in V2 of macaque monkeys monocularly deprived from birth, either by surgical removal of the lens (aphakic group) or by wearing a black contact lens (occluded group). Connections of cortical layers in these 2 groups and in control non-deprived monkeys were determined by making 100-200μm injections of the Fluororuby under visual control into approximately 2 mm thick cortical slices incubated 3-4h in a chamber with oxygenated Ringer's solution and then cut sagittaly into 50μm sections. One series of sections was used for fluorescent microscopy, alternate sections were reacted for CO and Nissl substance to reconstruct the laminar borders. All injections produced narrow radial bands 200-300μm in diameter of dense label within columns extending across cortical layers. Other features of transported label depended on the laminar location of the injection. Injections in supragranular layers produced the densest label in layers 2/3 and 5 that was often laterally offset from the injection's axis. Label in layers 4 and 6 was always more confined. Injections in infragranular layers led to dense, widespread label in layers 5/6 and more confined label in layers 2/3. Monocularly deprived monkeys exhibited differences from normal in density and lateral extent of horizontal connections. In comparison with controls, horizontal connections were denser in occluded and sparser in aphakic monkeys. They were unusually widespread in occluded monkeys, extending laterally up to 4mm, and often unevenly distributed, forming zones of dense and sparse label. Conversely, the extent of horizontal connections in aphakic animals was restricted in comparison with control (approx. 0.5 and 1mm from the injection site, respectively). These data show that deprivation effects can be traced into association cortex, past the geniculostriate system. {Supported by EY-09737; RR-00165 and EY-02686}.

DIRECTION SELECTIVITY OF CORTICAL NEURONS IN CATS REARED WITH CONVERGENT STRABISMUS. S. Hatta, Y.M. Chino, & E.L. Smith III*, College of Optometry, University of Houston, Houston, TX 77204-6052

Early discordant binocular visual experience disrupts the signal transfer characteristics of LGN X-cells in cats (Chino et al., *PNAS*, 1994). Specifically, contrast sensitivity of LGN units is reduced relative to their retinal inputs and substantial delays in signal transfer occur in some, but not all, LGN units. According to the 'linear summation model' for direction selectivity in simple cortical neurons (Reid & Shapley, 1991; Albrecht & Wilson, 1991; Jagadeesh & Ferster, 1993), our results in the LGN predict that the direction selectivity of simple cells is likely to be abnormal in strabismic cats. To test this prediction, unilateral convergent strabismus was surgically induced in 3-week-old kittens. Upon their maturity, extracellular single-unit recording techniques and stimulation methods with drifting or contrast-reversing sine wave gratings (24% contrast, 1.6 Hz & 3.1 Hz) were used to measure the direction selectivity of striate simple cells. We found that direction selectivity determined with drifting gratings was significantly reduced in strabismic cats compared to that in normal control cats. The reduction was directly related to alterations in the spatio-temporal summation characteristics of afferent signals revealed by contrast reversing stimuli. The results suggest that functional anomalies in LGN relay cells may be closely associated with the development of anomalous receptive field properties in cortical neurons. Supported by NIH Research Grants EY-08128, EY-03611, & RR-07146.

GENICULOCORTICAL AFFERENT ARBORS IN BINOCULARLY DEPRIVED KITTENS. A.Antonini and M.P.Stryker*, Keck Center for Integrative Neuroscience, Dept. Physiol., Univ. California, San Francisco, CA 94143-0444

In the kitten as little as 6 days of monocular deprivation by lid suture (MD) during a critical period causes a remarkable remodeling of the geniculocortical projections serving the deprived eye (Antonini & Stryker, 1993). These plastic changes correlate with physiological changes in MD animals in which visual cortical neurons become almost completely unresponsive to the deprived eye. These physiological and morphological changes may be due either to activity-dependent competitive interactions between the projections serving the two eyes or to disuse. We addressed this question by analyzing the morphology of geniculocortical arbors in binocularly deprived kittens in which the afferents serving the two eyes were equally deprived and subject to disuse, and neither had a competitive advantage.

Kittens were deprived by binocular eye-lid suture (BD) for one or two weeks prior to perfusion at 6 weeks of age. The arbors were anterogradely filled with Phaseolus lectin iontophoresed into the main laminae of the lateral geniculate nucleus. The lectin was visualized immunohistochemically, and single geniculocortical arbors were serially reconstructed in 3-dimensions. BD geniculocortical arbors were altogether indistiguishable from arbors in normal kittens or non-deprived arbors after short-term MD. They were significantly different from deprived arbors in the total length (mean: 15728 *vs* 7744μm, $p<.001$), number of branch points (mean: 150 *vs* 57, $p<.001$) and maximal density (mean: 78 *vs* 49μm/1000μm^2,$p<.02$). These results support the notion that competitive mechanisms rather than disuse are responsible for gross morphological remodeling of geniculocortical arbors.

795.4

ROBUST TWO-DAY OCULAR DOMINANCE PLASTICITY REVEALED BY SINGLE-UNIT RECORDING AND INTRINSIC SIGNAL IMAGING OF KITTEN AREA 17. TK Hensch*, MC Crair, ES Ruthazer, M Fagiolini, DC Gillespie, and MP Stryker. Dept. of Physiology, Univ. of California, San Francisco, CA 94143.

Occluding vision through one eye during a critical period in early life results in a loss of responses to the deprived (D) eye in visual cortex. D-eye geniculocortical arbor rearrangement appears to account for some of this loss, since their size is reduced by about half following 6 days of monocular deprivation (MD) (Antonini & Stryker Science '93). Anatomical effects of 4 days MD are less pronounced (A & S, pers comm), however, and varying degrees of plasticity in striate cortex have been noted for much shorter periods of deprivation. Rapid MD effects may reflect an important transitional state when D-eye afferents are anatomically present but functionally ineffective. We, therefore, investigated whether a brief MD of 2 days can consistently produce a loss of functional connections from the D eye to area 17.

Physiological recordings were carried out blind to the status of monocular vision initiated between postnatal day 27 to 31. During 48 hours of eyelid suture, kittens were either returned to their home cage or handled throughout the day to ensure that they remained alert. Ocular dominance of single units was profoundly shifted in both cases (CBI=0.10; n=107 cells, N=2 animals, and n=177 cells, N=3 animals, respectively). Robust orientation maps of intrinsic optical images from the same regions of cortex were acquired for the non-D eye but never observed for the D eye (N=4/4 cats). Our earlier work has shown that two potential initiators of plasticity, metabotropic glutamate receptors and nitric oxide synthase, do not mediate effects of 5-day MD. Similarly, neither MCPG (50mM) nor NOArg (22mM) affected the shift in single-unit responses (CBI=0.12, n=50 cells each) or the disappearance of D eye orientation maps following two days of eyelid suture.

Thus, powerful two-day ocular dominance plasticity at the peak of the critical period is indistinguishable by these analyses from week-long MD effects.

795.5

VISUALLY EVOKED POTENTIAL (VEP) ASSESSMENTS OF VISUAL FUNCTION IN A MONKEY MODEL OF TREATMENTS FOR HUMAN UNILATERAL INFANTILE CATARACTS. A.D. Aiyer, R.J. Brown, L. Stevens, and R.G. Boothe*. Division of Neurobiology and Vision, Yerkes Research Center, Emory University, Atlanta, GA 30322.

The purpose of these studies is to analyze treatment strategies for children with unilateral infantile cataracts. Infant rhesus monkeys received a lensectomy within 10 days of birth to mimic the surgical treatment that is typically given to human infants. Then infants were placed into two groups. The first (AFP-NP) wore extended wear contact lenses that focussed the aphakic eye to a far point and the fellow eye to a near point. The rationale for this treatment was to force usage of the aphakic eye when viewing far targets and the fellow eye when viewing near targets. Targets at mid distances would be expected to provide some binocular stimulation. The second group (ANP-PO) wore an extended wear contact lens on the aphakic eye that focussed it to a near point, and an occluder contact lens on the fellow eye for up to 90% of the time. The rationale for this group was to use part time occlusion to force usage of the aphakic eye. Animals in both groups were reared with the lenses until 1.5 years of age. Behavioral assessments with preferential looking methods during the rearing period indicated good acuity development in all eyes. However, VEP assessments at 3 years showed that the acuities in the aphakic eyes of the AFP-NP group had deteriorated substantially while acuities in the ANP-PO group were relatively stable. All animals exhibited directional motion asymmetry which is a marker for impaired binocular function, although strabismus was not as prominent in the AFP-NP group. It is concluded that selective defocus treatment methods are somewhat better at promoting binocular function, but part time occlusion methods are better at maintaining spatial vision. Supported by EY05975 and RR00165.

THE POSTNATAL DEVELOPMENT OF DENDRITIC MORPHOLOGY IN THE RAT VISUAL CORTICOCOLLICULAR PROJECTION. G. Prusky*, Department of Psychology, The University of Lethbridge, Lethbridge, Alberta, Canada T1K 3M4.

Previously, we have reported that rat occipital corticocollicular axons undergo predictable and significant reorganization during early postnatal development; a pattern that is altered by removing visual input. In the present study, we examine the growth of dendrites in this projection, during normal postnatal development and under visually-altered conditions, in order to elucidate the mechanisms that control the maturation of dendritic morphology.

During the first month of postnatal development, corticocollicular neurons were retrogradely labelled *in vivo* with injections of a fluorescent retrograde tracer into the superficial layers of the superior colliculus. Two -three days after these injections, between P5 and P30 at 5 day intervals, animals were perfused, their brains were fixed and sectioned, and cells were identified and intracellularly-injected with a horseradish peroxidase conjugate. The peroxidase was converted into a permanent, dark reaction product, the cellular dendrites were reconstructed and the number and centrifugal order of the branches were analyzed.

Between P5 and P15 corticocollicular dendritic arbor gradually increased in size and complexity. However, after P15 there was no significant alteration in dendritic morphology. This pattern of growth was not altered by neonatal enucleation, or by early eye opening at P7. These data suggest that the growth of corticocollicular dendrites may be guided by an intrinsic mechanism that is independent of environmental influence.

DEVELOPMENT OF CAMP-LINKED METABOTROPIC GLUTAMATE RECEPTOR (mGluR2/3) AND DARK REARING INFLUENCE ON mGluRs (1, 2/3 AND 5) IN THE CAT VISUAL CORTEX. S.N.M. Reid*, C. Romano, T. Hughes, D. Devlin and N.W. Daw. Department of Ophthalmology and Visual Science, Yale University School of Medicine, New Haven CT 06520-8061; Department of Ophthalmology and Visual Science, Washington University School of Medicine, St. Louis MO 63110.

Metabotropic glutamate receptors (mGluRs) are involved in NMDA-dependent and NMDA-independent synaptic plasticity. These receptors may also participate in sensory-dependent developmental plasticity in the visual cortex. mGluRs are coupled to various signal transduction pathways. In this study, we examined the developmental profile of cAMP-linked mGluR2/3. We also examined effects of dark-rearing on mGluR2/3 and PI-linked mGluRs (1 and 5) in the cat visual cortex. Immunohistochemical results show that the laminar distribution of mGluR2/3 changes with age. The change is different from either mGluR1α or 5. Besides laminar distribution, the quantity of mGluR2/3 also changes during postnatal development. In contrast to mGluR1 and 5, mGluR2/3 increases during the early postnatal stage. Dark-rearing increases quantity of the mGluR5 at the peak of the critical period for monocular deprivation; however, it has little effect on the quantity of mGluR1. As in the case of mGluR5, dark-rearing affects the laminar distribution of mGluR2/3. These results suggest that these receptors are probably involved in different developmental processes of the visual cortex. mGluR2/3 and mGluR5 are involved in sensory-dependent events, but mGluR1 is not. Supported by RO1 EY 00053 and HFSPO.

ALTERATION OF THE LTP/D MODIFICATION FUNCTION IN VISUAL CORTEX OF DARK-REARED RATS. A. Kirkwood* and M.F. Bear Dept. of Neuroscience and HHMI, Brown University, Providence, RI 02912.

Experience-dependent modifications of binocular connections in the immature visual cortex may employ the mechanisms of long-term potentiation (LTP) and long-term depression (LTD). Induction of both LTP and LTD require the activation of NMDA receptors. The magnitude and sign of plasticity appears to depend on the pattern and amount of NMDA receptor activation during conditioning stimulation. In visual cortex, the duration of NMDA receptor-mediated EPSCs undergoes a developmental decline that is prevented by rearing animals in complete darkness. We have tested the prediction that these changes in NMDA receptor function are paralleled by alterations in synaptic plasticity.

Slices of visual cortex were prepared from 4-6 week-old Sprague-Dawley rats that had been reared either in complete darkness or in a standard lighted environment. Synaptic responses to layer IV stimulation were recorded extracellularly in layer III. LTP was attempted with two patterns of high frequency stimulation. One pattern, theta-burst stimulation (TBS: 200 pulses delivered in 100 Hz bursts), evoked LTP of comparable magnitude in slices from dark reared (122 ± 5% of baseline at 20 min after TBS, n = 7 rats) and control rats (128 ± 4%, n = 6). However, the same number of pulses delivered in 20 Hz bursts caused significant potentiation in slices from dark-reared rats (118 ± 7%, n = 7), but little synaptic change in slices from light-reared rats (104 ± 3%, n = 6). Finally, low frequency stimulation (LFS: 1 Hz, 15 min), induced robust LTD in slices from control (82 ± 4% of baseline 30 min after LFS, n = 6), but not from dark reared rats (95 ± 3%, n = 7). These data suggest that patterns of synaptic activation are less likely to induce LTD, and more likely to induce LTP, in visual cortex of dark-reared animals. These results are consistent with the idea that the "modification threshold" -- the critical level of NMDA receptor activation at which synaptic modifications change sign from LTD to LTP -- varies as a function of the stimulation history of the visual cortex.

PROBING THE "PLASTICITY GATE" IN VISUAL CORTEX USING PAIRED-PULSE STIMULATION. H. Frank, A. Kirkwood, M.A. Paradiso* and M.F. Bear Dept. of Neuroscience and HHMI, Brown University, Providence, RI 02912.

Previous work in our lab has shown that high frequency stimulation of a site in the middle of the cortex (corresponding to layer IV), but not of white matter (WM), results in LTP of layer III field potentials (FPs) in visual cortical slices from adult rats. It has been hypothesized that inhibitory circuitry within or deep to layer IV normally acts as a "plasticity gate": a filter that constrains the types of activity patterns that can gain access to the modifiable synapses in layer III. In this study we have used paired-pulse stimulation to better understand the different patterns of synaptic activation that result from high-frequency stimulation of WM and layer IV. Extracellular FPs were recorded in layer III as different sites were stimulated. In each experiment, paired-pulse stimulation was applied to the WM while systematically varying stimulus strength and inter-stimulus interval (ISI). Then, while keeping the recording electrode in a fixed position, the stimulating electrode was moved to layer IV and the experiment was repeated. Stimulation of either site generally resulted in paired-pulse suppression (PPS) of the test response relative to the condition response, particularly at short ISIs (20-80 ms). Across these ISIs, PPS increased as stimulation intensity was increased, but this effect was far greater for white matter stimulation than for layer IV stimulation. With a 40 ms ISI, for example, low intensity stimulation of WM resulted in PPS of 89.1 ± 9 (test as % of condition response) compared with 92.6 ± 4 after stimulation of layer IV. However, at stimulation intensities yielding a FP ≥ 50% of the maximum, there was much larger PPS from WM stimulation (54.8 ± 11) than from layer IV stimulation (83.8 ± 6). The difference between WM and layer IV PPS at high stimulation intensities is significant at $P < 0.02$ (n = 8). An interpretation consistent with these data is that WM stimulation at high intensities recruits inhibition that is bypassed by stimulating layer IV.

795.10

SEQUENCE ANALYSIS OF cDNA CLONES WHOSE EXPRESSION IS ENHANCED WHEN THE VISUAL CORTEX DISPLAYS ENHANCED ACTIVITY-DEPENDANT PLASTICITY S.S. Prasad*[1], J. Hankins[1], D. Mitchell[2] and M.S. Cynader[1]. [1]Dept. of Ophthalmology., Univ. of British Columbia, Vancouver, B.C., Canada V5Z3N9 and [2]Dept of Psychology, Dalhousie University, Halifax, N.S., Canada.

It is now well established that the functional capabilities of the adult cerebral cortex are not fully mature early in postnatal life. The experience-dependant modifications of cortical connectivity and physiology in kittens have a well defined critical period which peaks at about 30 days of age. This critical period is input-dependant and can be prolonged into adulthood by restricting visual input to the cortex. This critical period for ocular dominance plasticity can be greatly prolonged simply by rearing kittens in the dark throughout the naturally-occuring critical period.

Previously we reported our initial analysis of a subtracted cDNA library comparing the 30 day old kitten visual cortex relative to the adult visual cortex. This library was screened with subtracted probes from the visual cortices of dark reared older kittens (4 months of age) that were well past the peak of their chronologically-defined critical period as well as normally reared adult animals. Together these experiments identified twenty six cDNA clones that hybridized with high intensities to both the subtracted probes for the visual cortex of young kittens, and also those of dark-reared older animals. Northern blot hybridization confirmed overexpression in kitten vs cats for ten of the clones, the other were too rare to be detected. Two of these cDNA clones detected signals only in the 30 day old kitten visual cortex . We have determined the partial nucleotide sequences for all of the differentially expressed cDNA clones in an attempt to identify any known homologies. Although four of the ten sequenced cDNA clones show sequence homologies to submitted human expressed sequence tags, our results indicate that majority of these clones have not been examined with respect to their actual function in the brain development. In order to examine the structural domains of these cDNA clones, we are screening the cDNA libraries to obtain the larger cDNA clones. Our current focus will be on those cDNA clones which are uniquely expressed in the kitten and older dark-reared visual cortex relative to the adult visual cortex.

INVOLVEMENT OF PROTEASES IN OCULAR DOMINANCE PLASTICITY IN KITTEN VISUAL CORTEX C.B. Griesinger* and C.M. Müller, Max-Planck-Institute for Developmental Biology, Tübingen, Germany

Ocular dominance stripe segregation during visual cortical development relies on selective growth and retraction of the initially overlapping geniculocortical afferents from either eye. As suggested by recent *in vitro* studies, the molecular mechanisms underlying such axonal remodeling may include the action of proteases, such as the plasminogen-activator/plasmin system (*Pittman et al., J.Neurochem., 64:566, 1995*) and thrombin (*Liu et al., PNAS, 91:10300, 1994*). We therefore investigated the role of proteases in ocular dominance plasticity by chronically infusing serine-protease inhibitors into the visual cortex of kittens by means of osmotic minipumps. Coincidently we performed monocular deprivation (MD) or reverse occlusion (RO) for 7 days. Thereafter we electrophysiologically assessed ocular dominance (OD) distribution, orientation selectivity and response strength. Leupeptin (100mM; all concentrations refer to pump reservoir) did not influence the OD shift after MD. However, the reversal of OD after RO was significantly retarded by leupeptin infusion (10.9% reversal index compared to 76% in controls). Orientation selectivity and response strength were unimpaired. Since leupeptin exhibits strong inhibitory activity against plasmin, but only weak affinity for thrombin, we tested the highly potent thrombin inhibitors hirudin (50μM) and SDZ 217-766 (100μM; gift of Sandoz LTD, Switzerland) in additional MD experiments. While hirudin failed to influence OD plasticity, the low molecular weight inhibitor SDZ 217-766 attenuated the OD shift towards the experienced eye (47% binocularity versus 21.7% in controls). The results indicate a role for leupeptin-sensitive proteases in progressive plasticity after RO, most likely mediated by the plasminogen-activator/plasmin system, known to participate in axonal growth. In contrast, thrombin might contribute to regressive changes like synapse elimination during MD. Supported by the BMFT 0316902

FAILURE TO REROUTE OR COMPRESS THALAMOCORTICAL PROJECTIONS AFTER PRENATAL POSTERIOR CORTEX ABLATIONS J. K. Niederer*, G. Maimon and B. L. Finlay. Developmental Neuroscience Group. Cornell U. Ithaca N.Y. 14853 The topographic specificity of the developing thalamocortical afferents resembles the adult pattern of connectivity from their initial entry into the cortical plate. In order to explore the nature of the cues producing this precise pattern of early innervation, we removed a large region of posterior neocortex on embryonic day 14, when the thalamic axons are just beginning to enter the subplate and before any innervation of the cortical plate has occurred.

On E14, two days before normal delivery, ablations of posterior cortex were made in hamster pups *in utero*. Under anesthesia, unilateral ventral incisions were made in the dams and 2-4 pups were exteriorized. Using the saggital and transverse sinuses as guides to the caudal and medial borders of the developing neocortex, we undercut variable amounts of the posterior neocortex with a small scalpel. Neonates were raised normally to weaning (P30). The cortex and thalamus of each animal were reconstructed to determine the extent of the cortical ablation and its subsequent effect on the thalamus. The cortex and thalamus contralateral to the ablation served as controls.

In the four experimental animals, we examined the following cortical areas, Oc1 (31-86% ablation), Te1 (0-89% ablation) and S1 (14-47% ablation), and compared their residual volume to their respective primary afferent thalamic nuclei. We found that the surface area of cortex removed was highly correlated with the volume of its remaining thalamic nucleus (r=0.87). This suggests not only that the thalamic axons are unable to innervate inappropriate cortical areas but also that they are unable to compress their projections into the remaining appropriate cortex even at this early developmental stage. DEVELOPMENT OF CORTICAL BINOCULAR DISPARITY TUNING AND CORTICOGENICULATE FEEDBACK

A. Grunewald* and S. Grossberg. Department of Cognitive and Neural Systems, Boston University, Boston, MA 02215.

The rapid processing of binocular disparity information requires highly tuned disparity-selective neural responses, yet at birth infants only show a coarse level of stereopsis. A model shows how complex cells can develop fine disparity tuning starting from coarse tuning. Competition across cortical complex cells determines a local winner, which is allowed to learn the pattern of activities that feed into the complex cell. Antagonistic rebound responses at the retina ensure that whenever learning occurs for one type of edge contrast at the complex cell stage, learning also occurs for the complementary edge contrast. In this way, complex cells develop to be insensitive to the polarity of contrast. At the same time, complex cells learn to fuse only stimuli where both eyes have the same polarity of edge. Whenever a complex cell emerges as the winner, a top-down matching, or confirmation, signal is sent to the LGN. This confirmation signal stabilizes the learning process. When the confirmation signal matches the LGN activity patterns, then the matched LGN activities are amplified. A mismatch between the the confirmation signal pattern and the LGN pattern leads to a reduction of LGN activity, so that a new winner is picked at the complex cell stage. Feedback signals are disparity-tuned, because, whenever a winner is picked at the complex cell stage, learning also occurs in the feedback pathways. Thus the model explains the importance of corticogeniculate pathways for the self-organization of disparity tuning.

A MODEL FOR THE DEVELOPMENT OF ORIENTATION SELECTIVITY BASED ON EARLY SPONTANEOUS ACTIVITY. B.A. Olshausen* and D.J. Field, Dept. of Psychology, Cornell University, Ithaca, NY 14853.

During early visual development, the retina exhibits spontaneous neural activity in the form of "waves" (Meister et al., *Science, 252*:939-943). It has previously been observed that these waves provide the type of spatiotemporal correlations that could help to refine topography within the LGN, as well as to segregate inputs from left and right eyes into different layers. Assuming that the patterns of activity in the retina are reflected to some degree in the LGN, the question then arises as to what role these waves play in cortical development, particularly since the waves contain oriented structure that could be used to develop oriented receptive fields in the cortex. In previous work we have shown that a learning algorithm that attempts to find a sparse coding of a set of images will develop wavelet-like receptive fields that are localized, oriented and multiscale when trained on natural scenes. Here, we show that when the learning rule is applied to scenes consisting of static snapshots of simulated low spatial-frequency waves, the receptive fields that emerge are oriented, localized, and low frequency. (By contrast, learning rules based on linear hebbian rules will converge to the principal components of the input stream, which are not localized and generally unoriented.) Once these receptive fields have been learned, the amount of training required on natural scenes in order to develop localized, oriented, multiscale receptive fields is substantially reduced (by at least a factor of 4). It is hypothesized that the retinal waves of activity provide the cortex with early "visual experience" that approximates the localized and oriented structure of the natural environment, and that by learning on these waves the cortex is put into a good initial state for later learning on natural visual input.

Correlation-Based Learning Model of Joint Orientation and Ocular Dominance Column Formation. E. Erwin* and K.D. Miller, W.M. Keck Center for Integrative Neuroscience, UCSF, San Francisco CA 94143.

Previously, we have shown that correlation-based competition between left- and right-eye inputs can lead to development of ocular dominance (OD) columns, while that between ON- and OFF-center inputs can lead to simple cell receptive fields (RFs) and orientation (OR) columns. Here, we study a similar model involving four input types, ON- and OFF-center inputs from left and right eyes. We assume time-invariant input correlations. We have determined the conditions for concurrent development of ocular dominance and orientation columns with preferred orientation varying continuously across OD boundaries. We are studying the relationships that then develop between the two columnar systems.

We assume symmetries between left and right and between ON and OFF. This leaves four independent correlation structures: those between input cells of same or opposite eye, of same or opposite center type. By a linear transform, the development equations decompose into four ***independent*** equations describing development of receptive fields and of maps of four synaptic weight combinations: (1) the sum of all four weight types (SUM); (2) left-eye minus right-eye strength (OD); (3) ON-center minus OFF-center strength (OR+); (4) ON-center minus OFF-center from left eye, plus OFF-center minus ON-center from right eye (OR−). Each weight combination develops independently under a distinct correlation function formed as a linear combination of the original four correlation functions. We call these functions C^{SUM}, C^{OD}, $C^{\mathrm{OR+}}$, $C^{\mathrm{OR-}}$.

Joint maps of ocularity and binocularly-correlated orientation preference develop in a large regime where (1) C^{OD} is positive over the arbor radius (radius of LGN cells converging onto a cortical cell), favoring monocular RFs; (2) the Fourier transform of $C^{\mathrm{OR+}}$ (or $C^{\mathrm{OR-}}$) has a single peak at a wavelength corresponding to 0.6–1 arbor diameter, favoring oriented RFs; (3) the principal eigenvalues associated with C^{OD} and $C^{\mathrm{OR+}}$ (or $C^{\mathrm{OR-}}$) are of comparable size and larger than the eigenvalues associated with the other two functions. These other two functions are otherwise largely unrestricted in structure.

NON-INVASIVE DOPAMINE DETERMINATION BY REVERSED PHASE HPLC IN THE MEDIUM OF FETAL MESENCEPHALIC CULTURES. A TOOL TO ENRICH GRAFT CAPACITY PRIOR TO TRANSPLANTATION.

L. Studer*, C. Spenger, B. Bühler, L. Evtouchenko, and R.W. Seiler, Dept. of Neurosurgery, Univ. of Bern, CH-3010 Bern, Switzerland.

Free floating roller tube (FFRT-) cultures allow long term maintenance of human and rat fetal ventral mesencephalic tissue (Spenger et al., 1994; J. Neurosci. Methods 54:63-73) which permits in vitro characterisation of tissue prior to transplantation. Ventral mesencephali of E13 rat embryos (n=10) were divided into 4 equally sized pieces each and were individually prepared as FFRT-cultures. After 4, 8, 12 and 16 days in vitro (DIV) medium (1ml) of each culture was collected during routine medium change and immediately stabilised adding 50 µl of orthophosphoric acid (7.5%) with 0.22mg metabisulfite. Dopamine was extracted after ultracentrifugation by an analytical kit (Chromosytems, No. 5000) and probes were determined with reversed phase HPLC using electrochemical detection (ESA, Mod. 5011).

The mean dopamine concentration in medium derived from one culture increased from 21 ± 11 pg at day 4 to 58 ± 43 pg at day 12 and decreased to 39 ± 30 pg at day 16, (n=24 each). In all cultures devoid of dopamine after 4 and 8 DIV (12.5%) levels remained below detectability at 12 and 16 DIV. There was a substantial variation in dopamine levels of medium derived from cultures of different embryos ranging from 82 to 282 pg dopamine. Statistically higher dopamine levels were detected in medium derived from cultures of the rostral part of the mesencephalon compared to that from cultures of the distal zone. After 12 and 16 days in vitro between 78% and 81% of dopamine was localised in 50% of the cultures assessed. These results show the feasibility of non-invasive individual characterisation of FFRT-cultures of fetal rat mesencephalon prior to transplantation.

HUMAN FETAL VENTRAL MESENCEPHALIC TISSUE CULTURES MAINTAINED *IN VITRO* FOR 7 TO 14 DAYS AND TRANSPLANTED TO 6-OHDA LESIONED RATS GIVE RISE TO GRAFTS RICH IN DOPAMINERGIC NEURONS.

Christian Spenger*, Lorenz Studer, Ljudmilla Evtouchenko, Beatrice Bühler, and Rolf W. Seiler, Department of Neurosurgery, University of Bern, Bern, Switzerland.

Free floating roller tube cultures of human fetal ventral mesencephalon of embryonic age (EA) 43 to 72 days post conception have been prepared (Spenger et al., 1994; J. Neurosci. Methods 54:63-73) and transplanted. After 7-14 days *in vitro* the mesencephalic tissue cultures were transplanted to the striatum of adult Wistar rats which had received unilateral injections of 6-hydroxy-dopamine into the nigrostriatal bundle 3-5 weeks prior to transplantation. Graft survival was assessed in tyrosine hydroxylase (TH) immunostained serial sections of the grafted brains between 7 to 27 days post transplantation

All transplanted animals showed large, viable grafts containing TH immunoreactive (ir) cells. The density of TH-ir neurons in these human fetal xenografts was 1949± 404 TH-ir cells / mm^3 (N=26). No significant difference was detected when TH-ir cell density of grafts derived from human foetuses EA 43 to 56 days post conception was compared to grafts from human foetuses EA 56 - 72 days post conception. This shows that ventral mesencephalic tissue from foetuses older than 8 weeks can successfully be cultured and transplanted when using the free floating roller tube technique. These results promote the feasibility of effective *in vitro* maintenance of fetal human nigral tissue prior to transplantation.

Supported by SNF No. 31-36243.92 and by BBW No. 93.0349.

NESTIN POSITIVE MULTIPOTENTIAL NON-PASSAGE EGF-RESPONSIVE NEUROSPHERES

Y. H. Chiang* and F. C. Zhou, Program in Medical Neurobiology and Dept. of Anatomy, Indiana Univ. Sch. Med., Indianapolis, IN 46202

Epidermal growth factor (EGF) screens and supports multipotential neurospheres from either adult or fetal brains (Reynolds, et at '92), and fetal sympathetic ganglia (Silani, et al, '94). To simplify previous laborious procedures of dissociation and obtain a greater number of large size neurospheres, we adopt a new non-passage culture method of procuring EGF-responsive neuropsheres for a long period of time. Undifferentiated and differentiated features of the cells derived from these non-passage neurospheres were examined by immunocytochemistry.

Single cells from cerebral cortex, striatum and mesencephalon were obtained after enzymatic dissociation of gestational day 14 fetus of Sprague Dawley rats and cultured in flasks with DMEM/F12, N2 and EGF (20ng/ml). EGF was added every 4 days. No further passage of neurospheres was made. Then, 3 to 10 month-old neurospheres of cortex, striatum and mesencephalon were subplated respectively on chamber slides with Neurobasal medium and 2% fetal calf serum (FCS) for 14 days before cells were fixed and immunocytochemically stained with antibodies against nestin, proliferating cell nuclear antigen (PCNA), microtubule associated Protein 2 (MAP2), 5-HT, 5-HT1A receptor, glutamic acid decarboxylase (GAD), glial fibrillary acidic protein (GFAP) and S-100.

Average diameter of non-passage neurospheres was about 200 - 650 µm by 3 weeks in culture. By 3 months, some of neurospheres had reached a size of more than 1 mm in diameter. After being subplated, under the Neurobasal medium and 2% FCS, cells migrated out of the neurospheres and differentiated. Nestin positive cells were found mainly inside and near the neurospheres. The size of these cells was smaller than that of nestin-negative cells. Cells both inside and outside neuropsheres were proliferative as indicated by PCNA immunostaining. Immunoreactive 5-HT, GAD, 5-HT1A receptor, MAP2 were observed on the cells with neuronal morphology. Cells with glial morphology stained positive with antibodies against GFAP and S-100. Current results suggest that EGF-responsive non-passage neuropsheres possess nestin and continuously proliferate. They can give progenies of both neuron and glia even after 3 to 10 months in culture.

HUMAN NEURONAL NTERA-2 CELLS (NT2) IMPLANTED INTO MURINE SPINAL CORD MATURE AND INTEGRATE ALONG THE HOST ARCHITECTURE INDEPENDENT OF HOST AGE OR LOCATION

R.S.Hartley*, J.Q.Trojanowski and V.M.-Y. Lee Inst. of Neurol. Sci. and Dept. of Path., Univ. of Penn. Sch. of Med., Philadelphia PA 19104

NTera-2 cells, derived from a human teratocarcinoma, were differentiated into neuron-like cells (NT2N) with retinoic acid and implanted into the spinal cords of nude mice to investigate the influence of the host milieu on the grafted cells. NT2N cells were implanted in the dorsal, ventral or central cord in either midline or lateral locations. Post-implantation survival times were varied for neonatal, young adult and adult grafts. Morphologic characteristics of the grafted cells were assessed, including nuclear size and shape and outgrowth of processes into the host parenchyma. Maturation of neurites was determined by expression of adult forms of tau and highly phosphorylated high molecular weight neurofilament (NF-H). Phenotypic characterization was also assessed by a panel of antibodies to neuronal markers, neurotransmitters and neuropeptides. No differences in NT2N grafts were observed between hosts of different ages. The phenotype, nuclear size and shape of the cells remained consistent within post-implantation survival times regardless of graft location or age of host at implantation. The morphology of neurite outgrowth mirrored that of the surrounding host tissue in all grafts. Confocal analysis suggested graft/host synapses. Robust axonal outgrowth was observed in white matter tracts at all host ages where cells were implanted in or near host tracts. Interestingly, long term neonatal grafts did not show longer outgrowth when compared to adult grafts. This may reflect a changing responsiveness to environmental cues as the NT2N cells mature in vivo. These results suggest that the engraftment of NT2N cells follows the host architecture, but not necessarily the neurotransmitter phenotype of the host neurons. Thus, the cells may mature in a self-determined manner while using the existing framework of the host to guide outgrowth. These characteristics in a human neuronal cell line may be useful for the delivery of therapeutics targeted at neurological diseases as well as for investigation of basic science questions such as process outgrowth and pathfinding.

IMMUNOHISTOCHEMICAL CHARACTERIZATION OF THE IMMORTALIZED MESENCEPHALIC CELL LINE, $1RB_3AN_{27}$

F.S.Adams*, K.N.Prasad, J.Edwards-Prasad & C.R. Freed, U. Colorado. Sch. of Med. Denver, CO 80262

The immortalized mesencephalic cell line, $1RB_3AN_{27}$ has several neuronal and dopaminergic properties that make it a candidate for neurotransplantation in Parkinson's Disease. In order to further characterize this cell line, we stained $1RB_3AN_{27}$ with antibodies directed against the neuronal marker, neuron specific enolase (NSE), the astrocytic marker, glial fibrillary acidic protein (GFAP) and a marker of neural progenitor cells, nestin. For positive controls, cultures of dissociated E15 mesencephalon containing both neurons and glia were used. Nestin immunoreactivity showed a filamentous pattern in $1RB_3AN_{27}$ and NSE showed more dense and diffuse staining. This pattern of staining was mirrored in the controls. In contrast, $1RB_3AN_{27}$ showed faint and diffuse immunoreactivity for GFAP which was unlike the controls. HPLC analysis of cell homogenates of $1RB_3AN_{27}$ revealed that in the presence of 40 µg/ml pargyline and 5 µg/ml 2-amino-6-7-dimethyl-4-hydroxy-5,6,7,8-tetrahydropteridine, an analog of tetrahydrobiopterin, these cells contained 0.73 ± 0.04 ng / (10^6 cells) of dopamine. These findings are consistent with a neuronal and dopaminergic phenotype for $1RB_3AN_{27}$.

GENETIC METHODS FOR INCREASING THE VIABILITY OF FETAL MESENCEPHALIC NEURONS *IN VITRO* AND *IN VIVO*

P.R. Borghesani[1,2], L.H. Burns[1*], D.R. Jacoby[2], J. Yu[2], F. Smith[4], X.O. Breakefield[2,3] and O. Isacson[1,2]. [1]Neuroregeneration Laboratory, McLean Hospital, Belmont, MA 02178 [2]Program in Neuroscience, Harvard Medical School, Boston, MA 02115 [3]Neurology and Neurosurgery Services, Massachusetts General Hospial, Boston, MA 02114 [4]E.K. Shriver Center, Waltham MA 02254.

In an attempt to increase the number of viable dopaminergic cells following intra-striatal implantation of fetal ventral mesencephalic (VM) tissue, two different genetic techniques are being explored. First, we have constructed both recombinant adeno-associated virus (AAV) vectors and herpes simplex virus (HSV) amplicons containing the human *bcl-2* gene. These constructs were packaged with their appropriate helper viruses and the replication incompetent particles are currently being used to directly infect dissociated E12-14 rat VM cells prior to transplantation into unilaterally 6-OHDA lesioned rats. Graft viability and functional integration are evaluated by monitoring the reduction in amphetamine-induced rotation and by characterizing immunohistologically the cellular composition and gene expression within the graft. Second, in order to stimulate stable vector-mediated gene integration/expression in post-mitotic neurons the AAV inverted terminal repeats (ITRs) have been placed flanking a transgene within an HSV amplicon. ITR flanked transgene expression and integration is being evaluated in non-mitotic cells *in vitro* in the presence and absence of the AAV *rep* gene. Other methods of direct gene transfer into fetal neurons are being investigated, including transplacental delivery of plasmids.

796.7

VESICULAR RELEASE OF GABA FROM ENGINEERED AtT-20 CELLS. R.C. Weatherwax*, A. Sandrasagra, and A.J. Tobin. Departments of Physiological Science and Neurology, Brain Research Institute and Molecular Biology Institute, University of California, Los Angeles, CA 90095.

Benzodiazepines, barbiturates, volatile anesthetics, and alcohol all act on $GABA_A$ receptors. Because such GABA mimetics are widely used to treat anxiety, seizures, and movement disorders, direct delivery of GABA itself may be experimentally and therapeutically useful. GABA, a zwitterion, cannot cross the blood-brain barrier, but transplanted engineered cells offer a method for the *in situ* delivery of GABA in experimental models of movement and seizure disorders. With this possibility in mind, we have used retroviral vectors containing GAD_{65} and GAD_{67} cDNAs to create GABA-producing cell lines. We have studied several such lines, including a number from AtT-20 cells, a tumor of mouse anterior pituitary. These engineered cells produce appropriate GADs, GAD mRNAs, and GABA. Unstimulated cells release accumulated GABA at a basal level, as determined by HPLC analysis. Treatment with 8-Br-cAMP stimulates the GABA release, but depolarization with 50 mM KCl does not. Our data suggest that, in engineered AtT-20 cells, GABA accumulates in large, dense-core vesicles that contain ACTH. (Supported by NINDS, NS22256)

796.8

TRANSPLANTATION OF TWO HUMAN TYROSINE HYDROXYLASE PRODUCING NEURAL CELL LINES INTO THE ADULT RAT BRAIN. M. Heredia*[1], A.S. Riolobos[1], J. Yajeya[1], J.M. Criado[1], A. de la Fuente[1], M. Santacana[2] [1] Dept de Fisiología y Farmacología, Univ. de Salamanca, Spain, [2] Instituto Cajal (CSIC), Madrid, Spain,

BE(2)C-M17, a human neuroblastoma cell line, and NT-2, a human teratocarcinoma cell line with the tyrosine hydroxylase (TH) gene transferred (kindly provided by Dr. R. Robbins), were stereotaxically grafted in four different regions of the rat brain; i.e., cerebral cortex, cerebellum, striatum and amygdala. Rats (n = 55) received injections of suspended M17 or NT-2 cells in HBSS (8-16 x 10^4 cells). Controls received an injection of vehicle only. At 1, 4 and 8 weeks after implantation, rats were anesthetized and perfused with 10% formaldehyde. The brains were sectioned and immunostained for TH and GFAP. The grafted M17 and NT-2 cells survived up to two months post-transplantation. NT-2 cell grafts never appeared to revert to a neoplastic state. By contrast, the M17 grafted cells generated tumors within 15 days after transplantation in 30 % of the grafted rats, generally affecting the striatum and amygdala grafts. The cells stained positively for TH *in vitro* but failed to stain *in vivo*. At 1 week post-grafting the M17 and NT-2 cells were round. At 4 and 8 weeks post-grafting most M17 cells were polygonal and extended neurite-like processes, while NT-2 cells were round or fusiform without processes. M17 cell grafts were strongly vascularized by invading host brain capillaries.

Our results show that both cell lines can survive for at least 2 months after intracerebral implantation, but they differ with respect to their pathogenicity. While the M17 cell line showed tumorigenic potential, the NT-2 cell line did not. (Supported by MEC- PB 91-0066 and DGICYT).

Non Transformed Human Stem Cell Lines Survive And Integrate Upon Transplantation Into The Embryonic Rat Brain. $E.Cattaneo, #L.Magrassi, ^R.Galli, ^P.Frolichsthal, #S.Pezzotta, #G.Butti, @S.Govoni and ^A.L. Vescovi*, $Inst. Pharmacol. Sciences, Univ. of Milan; #Dept. of Surgery, Univ.of Pavia, Policlinico San Matteo; ^Neurol. Inst. "C.Besta", Milan; @Inst. of Pharmacology, Univ. of Pavia, Italy.

We previously reported that conditionally immortalized neuronal progenitors and primary neuroepithelial cells isolated from the E14 rat striatum survive upon transplantation into the embryonic rat brain and organize into clusters of cells that progressively lose antigenic markers characteristic of immature cells (Cattaneo et al.,Dev. Brain Res.,1994). In this study we adopted the same experimental procedure to study the in vivo behavior of EGF-responsive human stem cell lines isolated from the diencephalon of 10 week old fetuses. Human donor cells were subcultured for up to two years and were exposed to 1μM BrdU, 6 days prior transplantation. On the day of the transplant, cells were also loaded with DiI. The animals were sacrificed on postnatal day 1. Following vibratome and cryostat sectioning cells were found widely dispersed and integrated into the host brain. and processes were often visible as judged by the DiI signal. The chromatin inside the nucleus of the DiI labeled cells was also distinguishable after Hoescht staining due to its more dispersed nature and lack of prominent eterochromatic spots. Despite the heterologous nature of the donor cells, no cluster segregation of the transplanted cells was ever observed following transplantation. Clear cases of BrdU and DiI double labeled cells were visible. These results indicate that fetal transplant may represent a suitable way to test for the stability and differentiation potential of non-transformed human CNS stem cells (partially supported by the Alzheimer's Association PRG-94-057 to E.C. and by funds of the Italian Ministry of Health to A.L.V.).

HOST REGULATION OF PROTEIN EXPRESSION IN INTRASTRIATAL GRAFTS OF CONDITIONALLY IMMORTALIZED NEURAL CELL LINES.
C. Lundberg and A. Björklund (SPON: Euro. Neurosci. Assoc.) Dept. of Med. Cell Res. Lund University, Lund, Sweden

Conditionally immortalized neural progenitor (CINP) cells has proven to be interesting candidates in *ex vivo* gene therapy experiments. The cells survive and integrate extensively when transplanted to the adult rat brain. Although the grafted CINP cells differentiate predominantly into glial-like cells, only 10-15% could be shown to express glial markers by immunohistochemistry when grafted to the intact brain. To investigate if a possible pool of resting, non-reactive astrocytes was present among the transplanted CINP cells we designed a study where astrogliosis was induced two weeks post-grafting of the CINP cells. The cells used in this study was HiB5 and ST14A (of embryonic hippocampal and striatal origin, respectively) created by immortalization with a replication defective recombinant retrovirus carrying a temperature sensitive allele of the SV40 Large T-antigen. The cell lines were grown under standard cell culture conditions at 33°C. After labelling with 3H-thymidine (1μCi/ml) for 72 hrs, 100 000 cells/side were injected bilaterally into the striatum of intact, adult rats as a single cell suspension. Two weeks later the animals were unilaterally lesioned either with ibotenic acid (ST14A n=4; HiB5 n=5) at the transplant site or with 6-hydroxy dopamine (ST14A n=4; HiB5 n=6) into the ipsilateral medial forebrain bundle to induce terminal degeneration around the transplant. One week later the brains were processed for immunihistochemistry for glial acidic fibrillary protein (GFAP), vimentin (VIM) or OX-42, a marker of microglia and macrophages, and processed for 3H-thymidine autoradiography. The excitotoxoic lesion induced a strong astrogliosis with up-regulation of all the markers tested. The percentage of transplanted cells expressing glial markers increased from 9% to 32% for GFAP, from 3% to 16% for VIM and from 2% to 12% for OX-42. In the 6-OHDA lesioned animals the percentage grafted cells expressing GFAP increased from 9% to 35%.while no significant changes in VIM or OX-42 was observed. in addition the GFAP-positive grafted cells changed their morphological appearance towards that of reactive astrocytes. The findings suggests that transplanted CINP cells differentiate to a large extent, respond to host derived stimuli and may take active part in the brain's reaction to injury when transplanted into the adult rat brain. .

TRANSPLANTATION OF EGF-GENERATED NEURAL STEM CELLS IN A RAT MODEL OF FOCAL ISCHEMIA. L. Santschi, D.M. Rosenbaum, R.E. Gross, S. Rybak, J.A. Kessler*. Albert Einstein College of Medicine, Bronx, NY 10461.

Neural transplantation following brain injury is a potentially promising technique for promoting functional recovery. The present study examined the feasibility of transplanting a population of EGF-responsive neural stem cells into infarcted tissue and analyzed the graft efficacy in supporting behavioral recovery. Progenitor cells isolated from E16 - E17 mouse subventricular zone were mechanically dissociated and plated in serum free medium containing EGF (Reynolds and Weiss, Science 255:1707, 1992). After 5-6 DIV, spheres of mitotically active cells growing in suspension were harvested, labeled with the DiI derivative, CM-DiI (Molecular Probes Inc.), and utilized for transplantation into the caudate/putamen of ischemic rats. Focal ischemia was induced in S-D rats by a suture model to produce MCA occlusion for 30 minutes. The cells were grafted 2 weeks after ischemia. Viable cells were clearly detected 30 days following transplantation, the latest time examined. Although most cells remained near the site of infusion, there was some migration of cells into surrounding parenchyma. We are currently examining whether cell grafting ameliorates behavioral deficits due to the stroke. Nevertheless, the survival of progenitor cell grafts in ischemic brain suggests that cell grafting may provide a means of intervening therapeutically after stroke.

NEURAL PROGENITOR TRANSPLANTATION FOR HYPOXIC ISCHEMIC (HI) BRAIN INJURY IN IMMATURE MICE. K. I. Park*, F. E. Jensen, E. Y. Snyder Depts. of Neurology & Pediatrics, Harvard Med. Sch., Children's Hospital, Boston MA 02115.

We have demonstrated that immortalized, central nervous system (CNS) progenitors (or "stem-like cells") may replace gene products & neural cells in various models of neurodegeneration. The present study was designed to explore the therapeutic potential of CNS progenitors transplanted into the brains of immature mice subjected to focal HI (FHI) or global ischemic injury. We hypothesized that stem-like cells could prove efficacious in either of 2 ways: 1) They might engraft within brain regions subjected to HI injury & differentiate into injured neural cells; 2) They might provide factors, trophins, cell-to-cell contact signals, or support structures which could promote the survival or recovery of some of the host's own injured neural cells & circuitry. Unilateral common carotid artery ligation combined with hypoxia on postnatal day 7 (P7) reliably produced FHI injury in the CD1 mouse brain with extensive ipsilateral infarction while leaving the contralateral hemisphere intact. The animal received a transplant of C17-2 neural progenitor cells within the cerebral ventricle ipsilateral to the region of infarction on P11. At maturity, there was evidence of robust engraftment & reporter gene expression by donor derived cells within the ischemic region. The donor progenitors appeared to have migrated to the region of infarction & integrated into fairly extensive areas of the infarct. Some progenitors may have differentiated into oligodendrocytes & neurons, the 2 neural cell types typically lost or compromised by HI. Other cell types were astroglial, though there was no evidence of scarring. Therefore, one strategy for the therapeutic use of neural progenitors in HI injury might be cell replacement of degenerated neural cell types & another one may involve using such cells to express therapeutic, regenerative factors (either intrinsically produced by the cells or engineered to do so *ex vivo*) within areas of infarction.

796.13

TRANSPLANTATION OF CNS STEM-LIKE CELLS AS POSSIBLE THERAPY IN A MOUSE MODEL OF SPINAL CORD DYSFUNCTION.
J. D. Flax* and E. Y. Snyder. Depts. of Neurology and Pediatrics, Harvard Medical School, Children's Hospital, Boston, MA 02115.

Spinal cord (SC) injury is characterized by a loss of neurons, glia, and myelin, and a disruption of neuronal pathways within the cord. Utilizing neonatal sciatic nerve transection as a model for depleting populations of segmental SC motor neurons (MN) in the mouse, we have sought to replace specifically those degenerated cells by transplantation of a v-myc immortalized, multipotent clonal CNS stem-like cell line. This cell line, C17-2, has been previously shown to differentiate into and replace in mature animals, cortical neurons that have been induced to degenerate (Exp. Neurol. 129:9, 1994). Preliminary studies demonstrate that C17-2 is capable of long term engraftment in the SC of sciatic nerve axotomized hosts, transplanted at 4 weeks of age, i.e. 4 weeks following injury which effectively eliminates 70% of the MNs in the ventral horn. Normally progenitors give rise to SC MNs only during fetal neural development. However in this experimental paradigm a subpopulation of these engrafted progenitors have differentiated into cells with a morphology, size, and anatomical location in the ventral horn characteristic of the degenerated MNs. These results suggest the feasibility of this lesion/transplantation paradigm to study the replacement of specific populations of injured neurons in the dysfunctional SC. Furthermore, these neural stem-like cells are capable of expression of exogenous gene products *in vivo*, allowing for the expression of candidate genes that might not only enhance differentiation and engraftment of these cells but also potentiate host SC function following insult through the regeneration of endogenous cells and circuitry. (Supported in part by grants from the APA and PVA).

796.14

EMBRYONIC STEM CELLS TRANSPLANTED TO THE ADULT BRAIN: TYROSINE HYDROXYLASE (TH) POSITIVE NEURONS DEVELOPED SPONTANEOUSLY AND BY TRANSFECTION WITH HUMAN TH GENE.
T.W. Deacon,[1*] J. Dinsmore,[2] W. Galpern[1] and O. Isacson[1] (1) McLean Hospital/Harvard Medical School, Belmont, MA 02178; (2) Diacrin, Inc., Charlestown MA 02129

Embryonic stem (ES) cells derived from mouse blastocyst and maintained in culture with leukemia inhibitory factor (LIF) were transplanted into the lateral ventricle, striatum, cerebral cortex and midbrain of adult rats and mice. Before transplantation they were subjected to 3 different treatments: a) retinoic acid (RA) treatment, b) transfection with a plasmid containing the human tyrosine hydroxylase (TH) gene, or c) left untreated. Rat hosts were immune suppressed with Cyclosporin A; mouse hosts were not immune suppressed. Untreated and RA treated cells produced grafts with variable numbers of differentiated TH-positive neurons and fibers. These were negative for dopamine-ß-hydroxylase (DßH). Effect of graft location on differentiation could not be unambiguously determined, but differences in TH cell numbers were associated with different treatments. RA treated cells produced grafts that were acetylcholinesterase (AChE) positive, while no untreated grafts expressed AChE. Transfected cell grafts showed high numbers of lightly TH-immunoreactive cells, however many cells also stained intensely TH-positive with extensive dendritic arbors and axonal outgrowth. Transfected cells and axons were DßH-negative. TH-positive axons from all ES cell grafts often exhibited varicosities, and graft axons from TH-positive cells in the striatum innervated the host striatum. These characteristics hold promise for use of ES cells as neural precursors and gene delivery vehicles for transplantation.

796.15

MOUSE EMBRYONIC STEM CELLS: IN VITRO MANIPULATION AND USE FOR INTRACEREBRAL TRANSPLANTATION.
J. Dinsmore*[1], J. Ratliff[1], C. Lindberg[1], M. Wunderlich[1] and D. Jacoby[1], T. W. Deacon[2], and O. Isacson[2]. [1]Diacrin, Inc., Charlestown, MA 02129. [2]McLean Hospital/Harvard Medical School, Belmont, MA 02178

We have developed methods to induce differentiation of mouse embryonic stem (ES) cells at high efficiency into either neurons or skeletal muscle. We wanted to use mouse ES cells as a genetic screen for novel factors capable of inducing differentiation and as a gene delivery system for the central nervous system. Mouse ES cells were transfected with the human tyrosine hydroxylase (TH) gene behind the mouse phosphoglycerate kinase promoter. To alleviate problems with down regulation of expression, plasmid vectors were used. We have obtained several ES cell clones that exhibit long term expression of the TH gene in vitro (> 2 mos.) and maintain this expression in vivo after transplantation to the CNS. To use ES cells as a screen for differentiation inducing factors, we introduced cDNA expression libraries into ES cells, selected cells induced to differentiate and isolated plasmids present within the differentiated cells. In this way, we screened large numbers of genes for involvement in cellular differentiation. One full length cDNA cloned by this method induces neuronal differentiation, and was obtained from a fetal (E17) rat hippocampal cDNA library. Expression of a truncated form of this cDNA turned on the expression of the full length endogenous ES cell gene. The DNA sequence for this gene showed no homology to any other sequences in the Genbank database, and we are currently charaterizing this gene further to identify domains within the cDNA responsible for inducing neuronal differentiation.

$^{(125)}$I DOI BINDING IN SPINAL TRANSECTED RATS.
V. Adipudi[1*], A. Radzievsky[2], M. Murray[1] and S. Croul[2]. [1] Departments of Anatomy/Neurobiology, [2]Pathology. Medical College of Pennsylvania & Hahnemann University, Philadelphia, PA 19129.

Mid-thoracic transection eliminates descending input to the lumbar spinal cord, thereby denervating target neurons. Fetal neural tissue transplanted into the lesion site permits regeneration of the descending serotonergic axons into and sometimes through the transplant into the host tissue caudal to the transplant, and thus may be expected to reverse denervation supersensitivity. 5-HT agonists improve locomotor function in animals receiving transplants as neonates or as adults through actions directly or indirectly on denervated targets (Miya et al., this volume). We characterized the serotonergic receptors in the spinal cord of spinal transected and transplanted rats. For these studies mid-thoracic transection at T6-T7 is performed in rats on postnatal day 0-2 or at 8 weeks. Transplants of E14 embryonic spinal cord were placed at the transection site in one group of animals. A separate group of normal littermates is maintained as unoperated controls. The spinal cords were harvested 2 weeks to 8 weeks postsurgery and processed for receptor autoradiography. 5-HT_2 receptors were labeled using $^{(125)}$I DOI, in spinal cord rostral and caudal to the area of transection/transplantation. In adult transected rats, we observed high levels of specific binding in lamina IX of the ventral horn, lamina I of dorsal horn and in the IML. Lamina IX caudal to transection showed significantly more binding than that seen rostral to the transection. The behavioral effects of serotonergic agonists are therefore likely to be mediated by supersensitive serotonergic targets in the ventral horn.

FETAL HIPPOCAMPAL GRAFTS IN KAINATE LESIONED HIPPOCAMPUS ESTABLISH SPECIFIC CONNECTIONS AND REDUCE ABERRANT MOSSY FIBER SPROUTING.
A. K. Shetty* and D. A. Turner. Neurosurgery and Neurobiology, Duke Univ. Med. Ctr. and VAMC, Durham, NC 27710.

Lesion-induced host factors, particularly trophic support and denervation, dramatically enhance cell survival in micrografts transplanted to adult rat hippocampus at 4 days post-Kainic acid (KA) lesion [Shetty and Turner, Neuroscience]. We hypothesize that restoration of hippocampal throughput in the KA model critically depends on the establishment of specific graft-host connections. Large suspension grafts of E19 hippocampal cells were prelabeled with 5'-bromodeoxyuridine, and were transplanted at 4 days post-KA lesion. We have measured the formation of efferent connections after 3-4 months survival using Fluorogold and DiI tracing and serial section analysis. The effect of grafts on aberrant sprouting of mossy fibers into the dentate supragranular layer (DSGL) was also quantified in Timm's stained sections.

Many neurons in grafts located in the vicinity of the degenerated CA3 cell layer established commissural connections with the contralateral hippocampus (Mean±SEM=564±328, n=7). However, such connections did not occur with ectopic grafts (<5 cells per graft, n=5). Neurons within all grafts made connections with the medial septal nucleus (451±127, n=6). Host mossy fiber ingrowth into the graft area was denser for grafts located near the degenerated CA3 cell layer than other grafts within hippocampus. The region of aberrant mossy fiber sprouting in different blades of the DSGL (measured as both width and area per length) was significantly reduced in animals with grafts near the CA3 cell layer (n=5; $p<0.01$, 58-68% reduction) compared to animals with ectopic transplants (n=5).

These results clearly show that grafted fetal hippocampal neurons both partially reconstitute the damaged circuitry following KA lesions by establishing specific point-to-point connections with the host and significantly reduce the development of post-KA abnormal circuitry in hippocampus. Supported by RO1 NS29482-01 and VAMC.

TRANSPLANTATION OF SUBVENTRICULAR ZONE CELLS FROM ADULT MICE INTO THE NEOCORTEX AND STRIATUM.
Daniel G. Herrera and Arturo Alvarez-Buylla*. Cornell Medical Center and Rockefeller University.

The subventricular zone (SVZ) of adult mice contains neuronal precursors (Lois, C. & Alvarez-Buylla, A. *Proc. Natl. Acad. Sci. USA* 90, 2074-2077 (1993), Morshead, et al. *Neuron* 13, 1071-1082 (1994)). These cells are known to migrate along a well defined pathway into the olfactory bulb where they differentiate into granular and periglomerular neurons (Lois, C. & Alvarez-Buylla, A. *Science* 264, 1145-1148 (1994)). To date there is no evidence that these cells can form new neurons outside of the olfactory bulb *in vivo*. To test whether these precursors could form neurons when grafted into neocortex and striatum, we transplanted SVZ cells from adult transgenic mice carrying the ß-Galactosidase gene attached to the neuron specific enolase (NSE) promoter (Forss-Petter, S., et al. *Neuron* 5, 187-197 (1990)). The recipients, were adult non-transgenic mice that had undergone an ischemic cortical lesion or a kainic acid-induced lesion in the striatum 1 week prior to transplantation. The SVZ was microdissected, the cells were dissociated and 30,000 to 50,000 cells were transplanted into the lesion site of the recipient mice. The animals were allowed to survive for 6 weeks. The brains were processed histochemicaly to reveal the presence of ß-galactosidase. ß-gal+ cells were present in both striatal and cortical grafts. In 2/3 striatal lesions we counted 78 and 120 ß-gal+ cells. In the ischemic lesions in cortex between 2 and 17 ß-gal+ cells were observed in each graft. These results indicate that SVZ cells from the adult brain survive and can differentiate into neurons after transplantation.

796.19

EGF-responsive neural progenitor cells survive, migrate and differentiate after transplantation into the adult rat striatum.

C. Winkler[1], J. P. Hammang *[2] and A. Björklund[1]. [1]Department of Medical Cell Research, Biskopsgatan 5, S-223 62 Lund, Sweden. [2]CytoTherapeutics, Inc., 2 Richmond Square, Providence, RI 02906.

Neural progenitors or stem cells derived from the developing rat and mouse brain with the capacity to generate both neurons and glia can be grown in culture. The aim of our study was to characterize the migrational patterns and cell differentiation of neural progenitor cells after transplantation into the striatum.

Striata of E15-transgenic mouse embryos, carrying the lac-Z reporter gene under control of the glial fibrillary acidic protein (GFAP) promoter, were triturated to a single cell suspension and cultured in serum-free medium containing 20 ng/ml Epidermal Growth Factor. The arising so called neurospheres were triturated to a single cell suspension and re-seeded every week for 14 weeks. During the last week of culture the cells were labelled with ^{3}H-thymidine and about 500.000 cells were transplanted into the striatum of intact adult Sprague-Dawley rats. The animals were immunosuppressed with cyclosporin A. Survival time was two weeks.

Autoradiography revealed good cell survival: While about 25% of the labelled cells stayed in the transplantation core, about 75% migrated throughout the whole striatum, many cells also entering the white matter tracts of the corpus callosum and the internal capsule. Cells in the core of the transplant mainly differentiated into astrocytes as revealed by immunohistochemistry for ß-galactosidase (ß-gal) and GFAP in combination with autoradiography and by the mouse specific astrocytic marker M2.

However, some cells developed a neuronal phenotype as seen by staining with the mouse specific M6-antibody. The cells which had migrated away from the core were ß-gal negative and only a few cells stained for GFAP. Experiments determining the identity of the migrated cells are currently under investigation.

AGING PROCESSES: MOLECULAR CHARACTERISTICS

797.1

THE EFFECT OF AGE AND GONADAL STEROIDS ON THE EXPRESSION OF GLIAL FIBRILLARY ACIDIC PROTEIN IN THE CEREBELLUM. J. E. Anderson, B. C. Jones*, J. P. O'Callaghan, J. R. Day. Depts. Of Biology and Biobehavioral Health, The Pennsylvania State Univ. University Park, PA 16802 and the Neurotoxicology Div., Health Effects Lab., U.S. E.P.A., Research Triangle Park, NC 27711.

Glial fibrillary acidic protein (GFAP) is an astrocyte-specific intermediate filament protein which is used as an index of reactive gliosis and neurodegeneration. GFAP increases in response to brain injury and normal aging, and its expression can be manipulated by altering circulating adrenal and gonadal steroids. Gonadal steroids decrease in women at the age of menopause, and testosterone concentrations are often reduced in older men. One hypothesis is that lower levels of gonadal steroids might render the brain more susceptible to neurodegeneration. The purpose of this study is to examine the effects of gonadal steroid manipulation on GFAP in the rat brain during aging. Three age groups (3, 12, or 24 mo) of male, Fisher 344 rats were castrated and given hippocampal lesions. Castrated animals received either testosterone implants or blank implants, resulting in marked differences in the concentration of circulating testosterone. In this preliminary study, GFAP immunoreactivity in the cerebellum (a region not effected by the lesion) was measured by ELISA and compared between age and hormone treatment groups. The results indicated that 3 and 12 mo intact and castrated animals had lower GFAP content than their respective 24 mo groups. Testosterone implants in castrated rats reversed this age-related increase in GFAP immunoreactivity. These data show that the exogenous testosterone suppressed the age-related increase in GFAP in the cerebellum, a brain region not generally associated with steroid hormone sensitivity. These data support the hypothesis that changes in gonadal steroid hormones during aging might render the brain more susceptible to neurodegeneration. Also, these data suggest that hormone replacement therapy might have value in neurodegenerative disease intervention. This study was funded by an AFAR research grant to JRD.

AGE-RELATED INCREASE IN TGF-ß1 mRNA IN RAT HIPPOCAMPUS IS LOCALIZED TO ACTIVATED MICROGLIA. N.R. Nichols*, C.E. Finch and T.E. Morgan. Andrus Gerontology Center, Dept. of Biological Sciences, Univ. Southern Calif., Los Angeles CA 90089-0191.

Increased TGF-ß1 expression occurs in adult brain in response to injury and disease and may mediate neurotrophic effects of glia. Previously, we showed by RNA blot hybridization that TGF-ß1 mRNA was up regulated in rat and human brain with advanced age. We also showed that TGF-ß1 was up regulated after lesioning of rat brain and was localized to activated microglia following both deafferenting and neurotoxic lesions. Several reports indicated that microglial numbers increased during aging and that microglia in the aged brain exhibited an activated morphology (shortened, thickened processes and increased expression of complement receptor 3 and MHC class II antigen). Collectively, these data suggested that the age-related increase in TGF-ß1 mRNA could be due to the increased number of microglia or to increased expression per cell. Therefore, TGF-ß1 mRNA was quantified in the hippocampus and cortex on a per cell basis in young (7 mo) and old (24 mo) F344 male rats following in situ hybridization with a [35]S-labeled cRNA probe. TGF-ß1 grain density (grains/cell) increased 59% ($P < 0.01$) in hippocampus and 55% ($P < 0.05$) in cortex of old compared with young rats. We also performed combined immunocytochemistry with antibodies against glial markers and in situ hybridization for TGF-ß1 mRNA. TGF-ß1 mRNA in old rats is predominantly localized to OX-42+ microglia with increased expression of complement receptor 3 compared with young rats. In contrast, TGF-ß1 mRNA in old rats did not co-localize with GFAP+ astrocytes. These data indicate that increased TGF-ß1 mRNA prevalence is a marker of activated microglia in the aged hippocampus and cortex. If increased TGF-ß1 peptide is secreted from activated microglia, this peptide may contribute to the neurotrophic activity of microglia in the brain during aging. Supported by AG-07909 (CEF) and AFAR (TEM).

797.3

TRANSFORMING GROWTH FACTOR (TGF)-ß1 AND THE MICROGIAL RESPONSE TO AGING. T.E. Morgan*, I. Rozovsky, T.H. Hogan, and C.E. Finch. Andrus Gerontology Center, Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191.

Unlike microglia in young adult mammalian brain, microglia in aged brains appear to be in an activated state that we hypothesize may contribute to the age-related susceptibility to neurodegeneration through altered response to TGF-ß1. TGF-ß1 is a pleiotrophic peptide that increases during the brain's response to neurodegeneration and aging. In cultured microglia from neonatal rats, TGF-ß1 effectively suppresses activation, proliferation, and major histocompatibility factor class 2 expression. These studies examine the effects of TGF-ß1 on cultured microglia from aged rat brains. As observed in vivo, cultured microglia from 24 month old rat brain ("aged") are morphologically distinct from their "young" (3 month old) counterparts and appear to be in an activated state. The mitotic index (MI), calculated from ^{3}H-thymidine labeling, of "aged" cultured microglia is 4 times higher than the MI of "young" cultured microglia. TGF-ß1 (1 ng/ml, 24 hours) treatment does not inhibit the increased proliferation of "aged" cultured microglia. Furthermore, TGF-ß1 (1 ng/ml, 24 hours) failed to inhibit the lipopolysaccharide (LPS)-induced formation of reactive nitrogen intermediates (nitrite concentration in medium) in "aged" cultured microglia. Therefore, "aged" microglia are less responsive to the deactivating effects of TGF-ß1, which may be a factor in age-related diseases, such as Alzheimers disease. Supported by AG-07909 (CEF) and AFAR (TEM).

797.4

FOCAL SITES OF DEMYELINATION AND REMYELINATION (MICROPLAQUES) IN PERIPHERAL NERVES OF AGED CATS. C. Bertolotto*, J.K. Engelhardt, F.R. Morales and M.H. Chase. Department of Physiology, Department of Anatomy and Cell Biology and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

Previous morphological studies in our laboratory have demonstrated that segmental demyelination and remyelination are present in the peripheral nerves of old cats (Bertolotto C. et al. Soc. Neurosci. Abstr. Vol. 20; part 2, p. 1710, 1994). In the process of examing myelin alterations during aging, we found that demyelination and remyelination exhibited a consistent pattern along the fibers of peripheral nerves of old cats, which is the subject of this abstract.

Two adult cats (1 to 3 years-old) and three old cats (17 to 19 years-old) were used in this study. These animals were given a lethal dose of sodium pentobarbital and perfused with a saline solution and a fixative (2% paraformaldehyde and 2% glutaraldehyde in 0.1 M phosphate buffer at pH 7.4). Teased fiber preparations of the hindlimb nerves were stored in 100% glycerin. The fibers were mounted in pure glycerin and examined with a light microscope.

Teased myelinated fibers from the adult cats exhibited a smooth myelin surface with intact nodes of Ranvier. The internodes of each individual fiber were of similar thickness and length. The teased fiber preparations from the old cats exhibited regions that contained clusters of two or more adjacent fibers where demyelination or remyelination had occurred. These regions were delimited by apparently normal myelin. We refer to these regions, that appeared as small patches of abnormal myelin, as "microplaques".

These focal abnormalities in adjacent myelinated fibers in the peripheral nerves, to our knowledge, have never been described before in aging animals or in peripheral neuropathies. However, we believe they were present in previous studies of others because published microphotographs exhibit the same phenomena that we have described in the present report. The presence of microplaques suggests that, during aging, there is a focal process that affects clusters of Schwann cells which are located in close proximity to each other. *Supported by USPHS Grant AG 04307.*

797.5

DISTRIBUTION OF APOLIPOPROTEIN E PLAQUES AND GLIOSIS IN THE AGING RHESUS MACAQUE TEMPORAL CORTEX. S.G. Kohama* and H.F. Urbanski. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, Oregon, 97006.

Expression of the astrocyte marker, glial fibrillary acidic protein (GFAP) increases during aging and neuropathology. Similarly, the expression of apolipoprotein E (ApoE) increases with age in nonhuman primates in association with amyloid deposits. Because of the potential role of both of these markers in Alzheimer's Disease, the relative distributions of GFAP and ApoE were examined in the temporal cortex of the aging Rhesus macaque (*Macaca mulatta*).

The distribution of GFAP in the temporal cortex of young and middle-age adult monkeys was similar, with high levels seen in the molecular layers of the dentate granule cells, Ammon's horn and glial limitans. In some older monkeys (>25 years), hypertrophic astrocytes could be visualized in the hippocampal pyramidal and deeper layers of the temporal cortex.

ApoE expression was only seen in the older monkeys. Although a few plaques were seen scattered in the hippocampus of several of these animals, the majority of plaques were seen in the temporal cortex. Thus the more generalized distribution pattern of reactive astrocytes overlaps with that of the ApoE plaques, suggesting that a causal relationship may exist between astrogliosis and ApoE deposition.

ALTERATION OF MULTIPLE GENE EXPRESSION IN INDIVIDUAL HIPPOCAMPAL CA1 NEURONS AS A FUNCTION OF AGING. Y. Cao* and J. H. Eberwine. Depts. of Pharmacology, School of Medicine, University of Pennsylvania, Philadelphia, PA 19104.

Aging is recognized as a multifactoral event. The study of the interactions between these factors is essential to understand the fundamental mechanisms of the aging process. Using the antisense RNA amplification (aRNA) technique, we were able to simultaneously analyze multiple gene expression in individual cells in live acutely cultured slices of the hippocampal CA1 field. 3-month-old, 12-month-old and 24-month-old of Fischer 344 and Brown Norway F1 hybrid rats were used in the present study. We found that the mRNA levels for individual subunits of the glutamate receptor family were altered; specifically GluR2, GluR5 and GluR7 mRNAs decreased as a fraction of total composition of these receptor subunits as a function of age while GluR1, GluR3, GluR4 and GluR6 mRNAs had no significant compositional changes. Superoxide dismutase (SOD) mRNA also showed age-related changes, and interestingly the type II glucocorticoid receptor mRNA had higher expression in some but not all neurons from aged hippocampal slices. Presuming that protein levels parallel mRNA levels, then it is reasonable to postulate that coordinate changes in gene expression are reflective of functional significance.

AGE-ASSOCIATED CHANGES IN CNS TRANSCRIPTION FACTOR ACTIVITY. T. Toliver*, J. Papaconstantinou and R. Perez-Polo. Dept. of Human Biological Chemistry and Genetics, Univ. of Texas Medical Branch, Galveston, Texas 77555-0652.

Age-related cognitive deficits are usually associated with a loss of cholinergic function. Transcription factors may play an integral role in regulating cholinergic homeostatic gene expression. In the present study, we tested the hypothesis that transcription factor nuclear factor κB (NFκB) activity is altered in the basal forebrains and hippocampi of aged rats. Nuclear extracts prepared from basal forebrains and hippocampi of 3 and 30-month old Fischer-344 Brown Norway rats were used to measure NFκB activity by electrophoretic mobility shift assay. Basal levels of NFκB binding to cognate DNA consensus sequences were significantly higher in hippocampi ($p \leq 0.01$) and basal forebrains ($p < 0.05$) of aged rats. Basal AP-1 activity was also measured and showed no significant difference between age groups. NFκB activity in cerebellum and frontal cortex was also measured and there appear to be no significant differences between age groups. The data demonstrate increased basal levels of NFκB activity in the basal forebrain and hippocampus of the aged rat. The regional differences suggest a possible relationship between altered NFκB activity and decreased neurotrophin action and cholinergic function associated with aging. AGEING-RELATED DECREASE IN PSA-NCAM IS NOT RELATED TO COGNITIVE DEFICITS. D.N. Abrous*, M.F. Montaron, [1] K.G. Petry, [2] G. Rougon, M. Darnaudéry, M. Le Moal, H. Simon, and W. Mayo. [1] INSERM U259, Bordeaux, France. [2] INSERM U394, Bordeaux, France. [2] CNRS-UMR 9943, Marseille, France.

Age-dependent spatial memory impairments have been related to a decline in hippocampal plasticity. It has been shown that highly polysialylated neuronal cell adhesion molecule (PSA-NCAM) are highly expressed during adulthood within regions associated with ongoing neurogenesis such as the hippocampus. Furthermore, NCAM defcient mice lack PSA-NCAM and show deficits in spatial learning when tested in the Morris water maze. The aim of the present study was to examine the effect of ageing on the expression PSA-NCAM within the hippocampus and other various brain regions using immunohistochemistry. In addition in order to investigate whether age-dependent changes in expression of PSA-NCAM were accentuated in aged rats with learning impairment, animals were in a first step assessed for their memory capability using a Morris water maze. Seven-month old and 24-month old rats were tested in the Morris water maze. Three weeks later animals were sacrificed and sections were processed for PSA-NCAM immunohistochemistry. Ageing was accompanied by an overall decrease in PSA-NCAM-immunoreactivity (IR) within the forebrain with a dramatic decrease of the number of PSA-NCAM-IR perikarya within the hippocampus and the piriform cortex. These results were confirmed by western blot analysis. No difference was observed in aged rats with or without spatial learning impairment. It is concluded that PSA-NCAM expression is dramatically reduced during ageing, very likely reflecting a decrease in neurogenesis. Although these PSA-NCAM changes parallel the decrease in cognitive abilities, our data did not evidenced a causal relationship between these two parameters.

BDNF AND SOMATOSTATIN GENE EXPRESSION IN THE PRIMATE BRAIN: DECREASED LEVELS OF mRNA DURING AGING. M. HAYASHI* and K. SHIMIZU. Department of Cellular and Molecular Biology, Primate Research Institute of Kyoto University, Inuyama, Aichi 484, Japan.

BDNF (Brain Derived Neurotrophic Factor) is one of the neurotrophic molecules for the various neurons in the vertebrate central nervous system. A recent study showed a marked decrease of BDNF gene expression in the hippocampus in Alzheimer's disease. Furthermore, in the rat cerebral cortex, BDNF was reported to enhance the level of mRNA of the neuropeptide somatostatin, suggesting that BDNF may be a regulatory molecule for the expression of the somatostatin gene. In the present study, using the northern blot analysis, we investigated BDNF and somatostatin mRNA expression in the central nervous system of the macaque monkey (*Macaca fuscata fuscata*) during the aging process. BDNF and somatostatin mRNA (1.6 and 4.0 kb transcripts for BDNF, 0.65 kb transcript for somatostatin) were detected in various cerebral subdivisions (the frontal cortex, the temporal cortex, the motor cortex, the somatosensory cortex and the visual cortex) and the hippocampus. During the aging process (2 years, 10 years and >30 years), the levels of BDNF and somatostatin mRNA significantly decreased in the cerebral subdivisions and the hippocampus. These findings suggest that the decrease in the gene expression of BDNF may cause the levels of somatostatin mRNA to decline in the primate brain during the aging process. Supported by Grant-in-Aid (04268103) from the Ministry of Education, Science and Culture, Japan.

CALCIUM BINDING PROTEINS AND SYNAPTIC VESICLE PROTEINS IN AGING RETINA. T.Yamaguchi*[1], P.Papazafiri[2], P.Podini [2]and J.Meldolesi[2]. [1]Dept. of Biochem. Tokyo Women's Medical Coll.,Tokyo Japan and [2] DIBIT, San Raffaele Scientific Institute , Milano Italy.

The changes of calcium homeostasis have been noticed to be one of an important aspect responsible for morphological and molecular deterioration in aging neurons. The functional alteration in aging retina has not yet been investigated from the point of calcium homeostasis. A high affinity calcium binding protein ,calretinin has been identified from retina which is densely distributed in sensory neurons besides retina and various subsets of cortical neurons was detected in the aging retina from 2 weeks to 30 months old rat. These changes were compared to that of another family member of calcium binding protein ,calbindin D28K ,in the retina as well as in the visual cortex. The synaptic vesicle proteins , synapsin and synaptophysin were also detected in the retina and cortex as marker proteins of synaptic function in aging neurons. Both synaptic marker proteins showed an age-dependent decrease only in the retina while calretinin ,densely distributed in the inner plexiform layer did not show any change in aging retina . Howerver, calbindin D28K, localized at the outer plexiform layer showed a comparable change in synaptic marker proteins in the retina. A dramatic decrease of synapsin at the inner plexiform layer which started after 12 month old was the most prominent change in aging retina,while in the cortices including occipital cortex,no decrease was observed. As a whole, age-dependent decrease is evident in synaptic marker proteins and calbindinD28K but not calretinin in the retina .On the contrary, in the cortex, none of these molecules showed age-depedent change.The role of these changes in aging retina remains to be disclosed.

INCREASING AGE ALTERS TRANSBILAYER FLUIDITY AND CHOLESTEROL ASYMMETRY IN SYNAPTIC PLASMA MEMBRANES OF MICE. U. Igbavboa, N. A. Avdulov, F. Schroeder, and W. G. Wood*. VA Med Ctr, GRECC and Univ of MN, Dept. of Pharmacology, Minneapolis, MN 55417.

Previous studies on age differences in membrane structure have reported on the total or average change in membrane structure. The present experiments determined fluidity and cholesterol distribution of the exofacial and cytofacial leaflets of brain synaptic plasma membranes (SPM) from 4-5, 14-15, and 24-25 mo old C57BL/6NNia mice using trinitrobenzenesulfonic acid quenching techniques and fluorescent probes. The exofacial leaflet of SPM from young mice was significantly more fluid as compared to the cytofacial leaflet. The large difference in fluidity between the two leaflets was abolished in SPM of the oldest age group. Age differences in leaflet fluidity were related to the distribution of cholesterol in the two leaflets. The exofacial leaflet contained substantially less cholesterol than the cytofacial leaflet (13% vs 87% respectively) in SPM of young mice. This asymmetric distribution of cholesterol was significantly modified with increasing age. There was approximately a two-fold increase in exofacial leaflet cholesterol in the oldest group when compared with the youngest age group. The bulk SPM cholesterol/phospholipid molar ratio did not differ among the three age groups. Transbilayer fluidity and cholesterol asymmetry were altered in SPM of older mice. This approach is a new and different way of viewing how aging modifies membrane structure. Age differences in SPM leaflet structure may contribute to modification of membrane function. Supported in part by AG11056 and Dept. of Veterans Affairs.

DISTRIBUTION OF OMP mRNA IN THE CILIARY-DENDRITIC, SOMAL AND AXONAL COMPARTMENTS OF HUMAN OLFACTORY RECEPTOR NEURONS. T.V. Getchell[*1], N.S. Rama Krishna[2], O.I. Buiakova[3], F.L. Margolis[3] and M.L. Getchell[2]. Depts. of [1]Physiology and [2]ENT Surgery, Univ. of Kentucky College of Medicine., Lexington, KY 40536, and [3]Roche Institute of Molecular Biology, Nutley, NJ 07110.

Differential localization of mRNAs in subcellular compartments may indicate a specific role for extrasomal protein synthesis in neuronal function. The localization of OMP mRNA and protein was examined in olfactory receptor neurons in tissue obtained at autopsy from humans who ranged in age from 26 weeks of gestation to 85 years of age, including three subjects with Alzheimer's disease. Quantitative *in situ* hybridization was performed on 10 µm-thick sections using ^{35}S-labeled antisense cRNA probes as described previously (Buiakova et al., *Genomics* 20:452, 1994; Rama Krishna et al., *NeuroReport* 6:817, 1995). The mean grain density was 1.7 X greater in the ciliary-dendritic, 4.0 X greater in the somal and 2.6 X greater in the axonal compartments than in the background. Also, the olfactory nerve layer-glomerular compartment in the olfactory bulb had a substantially higher grain density than tissue background. The mean grain density in the somal compartment increased systematically with age except in subjects with Alzheimer's disease where it was significantly less than in age-matched controls. The localization of grains over the compartments corresponded to the presence of mature olfactory receptor neurons as determined by OMP immunoreactivity at all ages studied. Our results indicate that OMP mRNA is localized in the ciliary-dendritic, somal and axonal compartments of human olfactory receptor neurons and that OMP mRNA is substantially reduced in subjects with Alzheimer's disease.

EXPRESSION OF HEAT SHOCK PROTEINS IN AGING. M.C. Wilson, S.B. Maggirwar, T.J-F. Lee* and V. Ramkumar. Dept. of Pharmacology, Southern Illinois Univ. Sch. Med., Springfield, IL 62702

The expression of heat shock proteins by the cell helps it to cope with rapid changes in its environment such as exposure elevated temperatures, oxidants and toxins. In this study, we have assessed the expression of two heat shock proteins (hsp), a constitutive form (hsp70) and an inducible form (hsp72), in the brains of adult (3 month old) and aged (18, 24 month old) rats. The levels of hsp70, quantitated by Western blotting, in the 18 and 24 month old rats were 92 ± 8% and 83 ± 20% (mean ± SE) of the 3 month old, respectively. The basal levels of hsp72 for the 18 and 24 month old animals were 103 ± 3 and 124 ± 8% of 3 month old, respectively. Exposure of these different groups of rats to heat stress (37°C, 1 h) resulted in substantial age-related differences in the induction of hsp72 following 8 h of recovery. Increases in hsp72 elicited by heat stress were 815 ± 17%, 202 ± 14% and 101 ± 8% compared to the naive 3, 18 and 24 month old control, respectively. Increases in hsp70 were negligible under identical conditions, being 109 ± 6%, 100 ± 9% and 107 ± 6% of the respective naive age-matched controls. These studies demonstrate that the aging brain has a markedly reduced response to stress, which might make it more susceptible to damage following adverse changes in its local environment.

● THE DISTRIBUTION OF UBIQUITIN-PROTEIN CONJUGATES IN VARIOUS REGIONS OF RAT BRAINS ● E. R. Mesco*
Department of Biology, Moorhead State University, Moorhead, Minnesota 56563

The accumulation of varied molecular compounds is seen during the course of normal aging. In addition, specific lesions are associated with various age-related neuropathologies. These age-associated accumulations may, in part, be the result of alterations in proteolytic processing. The ATP-dependent ubiquitin proteolytic system is one candidate for such changes. Studies were performed using young (1 to 3 months old) Sprague-Dawley rats, both male and female. Brain tissue was isolated from cortex, cerebellum, hippocampus, striatum, and thalamus. Analysis of proteins was done using SDS-PAGE and immmunological identification with anti-ubiquitin antibodies. Profiles from the different brain regions were determined in order to establish baselines for future comparison to aged brain samples.

797.15

CELLULAR STORES OF THE IRON- AND ALUMINUM-BINDING PROTEIN, L-CHAIN FERRITIN, ARE MASSIVELY ELEVATED IN OLD HIPPOCAMPUS. S.R. Robinson[1,2] D.F. Noone[1,2] and T.A. Day[2]*
[1]Vision, Touch & Hearing Research Centre; and [2]Department of Physiology and Pharmacology, University of Queensland, St. Lucia, QLD, 4072. Australia.

Neuronal damage and loss in the aging brain may be caused by chronic exposure to free radicals. The generation of free radicals is rate-limited by the availability of iron and aluminum, which are stored within cells by ferritin. We have compared the distribution and intensity of immunolabeling for ferritin in the hippocampus of adolescent (3 months; n=7) and old (>20 months; n=7) male rats. Rats were euthanased with sodium pentobarbitol (60mg/kg; IP), perfused transcardially with 4% paraformaldehyde in 0.1M phosphate buffer (pH 7.2), and their hippocampal formations sectioned at 100µm on a Vibrotome. Sections were incubated in L-chain ferritin antisera for 5 days (1:2500; ICN), then in secondary antisera and finally with streptavidin-HRP-DAB.

In adolescent rats, cells with weak ferritin immunoreactivity are common in the stratum radiatum of CA2, but not elsewhere. There are no significant differences between individual rats in the total numbers of labeled cells ($p>0.1$; 2-tailed t-test). In old rats, the hippocampus contains more L-chain ferritin than any other brain region. Large numbers of strongly labeled cells are found in the stratum radiatum of CA2, CA3, CA4 and, to a lesser extent, the subiculum. The total number of ferritin-immunoreactive cells in old hippocampus is 6.5-fold higher than in adolescent hippocampus ($p<0.0001$; 2-tailed t-test), with CA4 showing a 78-fold increase. CA1 is consistently devoid of labeled cells. The total number of labeled cells differs significantly between individual old rats ($p<0.05$; 2-tailed t-test). Comparisons with different titrations of the primary antisera indicate that the maximal intracellular concentration of ferritin in old hippocampus is an order of magnitude higher than in adolescent hippocampus. At both ages, most ferritin-immunoreactive cells resemble resting microglia. Microglia may be implicated in age-related hippocampal degeneration through their storage of iron and aluminum, or through an associated production of free radicals.

DECREASE IN LIPOPIGMENTATION IN HEARTH AND SYMPATHETIC GANGLION BY NITROCATECHOLS NITECAPONE AND ENTACAPONE. A. Hervonen, S. Lahtivirta, O. Kajander, M. Savola*, L. Sopanen# and P. Pohto#. Lab. of Gerontol., Univ. of Tampere, 33101 Tampere, Finland and # Orion Corporation, Orion-Farmos Pharmaceuticals, Helsinki, Finland.

Nitecapone and entacapone are new COMT-inhibitors with antioxidant properties. We studied lipopigmentation after two year administration of nitecapone and entacapone to Spraque-Dawley rats. Intragastric administration of nitrocatechols was used as a basic method of a toxicological study. Both male and female rats and three different doses were used. Left ventricle of hearth (LV) and superior cervical sympathetic ganglion (SCG) have been analyzed by now. The tissues were freeze-dried, fixed with paraformaldehyde vapor and embedded in paraffin. Lipopigmentation was measured using image analysis system connected to a fluorescence microscope. Both nitecapone and entacapone diminished the area covered by lipopigments both in SCG and LV. The pigment granule size was smaller in nitrocatechol groups. This decrease was more drastic in females and especially with entacapone. The best results with low lipopigmentation were obtained with intermediate doses (80-90 mg/kg) of nitrocatechols. In female intermediate groups the area covered by lipopigments was about 50% of the control value. This may be due to the antioxidative properties of nitecapone and entacapone. The compounds may provide protection against oxidative stress in a lifelong experiment.

EXPRESSION OF INDUCIBLE NITRIC OXIDE SYNTHASE (iNOS) IN SPINAL MOTOR NEURONS AFTER AXOTOMY AND IN AGING F344 RATS. **O. Hanson-Painton*, P. Grammas and J.M. Jacob. Depts. of Pathology and Anat. Sci., Univ. of Oklahoma HSC, OKC, OK 73190.**

Nitric oxide (NO) has been shown to be both an important neuromodulator and neurotoxin in the CNS. The objective of this study was to examine the effects of age and axotomy on iNOS expression in spinal motor neurons. In 6 month F344 rats, the sciatic nerve was cut and iNOS expression examined at 1-7 days after axotomy. The retrograde tracer Fluorogold was used to locate the motor columns supplying the right sciatic nerve. Using a polyclonal antibody directed against iNOS and avidin-biotin enhanced DAB to visualize protein immunoreactivity (IR), the distribution and temporal expression of iNOS-IR was determined. The data demonstrate iNOS-IR was increased by day 2 and maximally upregulated by day 3; by day 7, iNOS-IR was reduced but still above control levels. Also, a comparison of 6 and 24 month spinal motor neurons showed a marked increase in iNOS-IR. These data demonstrate an upregulation of iNOS after axotomy and in aging, suggesting increased production of NO with axonal injury and age. Supported by grants to PG (NS 30457) and JMJ (AFAR).

AGE-DEPENDENT INCREASE IN INDUCIBLE NITRIC OXIDE SYNTHASE IN CEREBRAL MICROVESSELS. **M.A. Dorheim*, W.R. Tracey and P. Grammas. Dept. of Pathology, Univ. of Oklahoma HSC, Oklahoma City OK 73104, Dept. of Cardiovascular and Metabolic Diseases, Central Research Division, Pfizer Inc., Groton CT 06340**

Vascular endothelial cells are a quantitatively important producer of nitric oxide (NO) and could be a source of this mediator/neurotoxin in the brain. We have previously demonstrated that isolated rat brain microvessels possess both constitutive (ecNOS) and inducible nitric oxide synthase (iNOS). The objective of this study was to compare iNOS levels in microvessels from 3 month-old adult rats to that present in microvessels isolated from aged (18-23 months) animals. Intact microvessels were isolated from rat cerebral cortices, homogenized and supernatants collected. Immunodetection was performed using an anti- iNOS antibody (#8196, 1:1000) and a peroxidase labelled secondary antibody. Slot blot quantitation was performed by scanning densitometry. iNOS protein was found to be >12-fold higher in the microvessels from the aged rats compared to the 3 month-old rats. These data suggest that increased expression of iNOS and a concomitant elevation of NO production may contribute to neuronal damage in the aged brain. (Supported in part by NIH NS30457 and OCAST)

CHLORIDE AND OTHER CHANNELS

798.1

A CALCIUM-DEPENDENT CHLORIDE CURRENT IN MOUSE SYMPATHETIC NEURONS . F. de Castro, E. Geijo-Barrientos and R. Gallego*. Instituto de Neurociencias y Departamento de Fisiología, Universidad de Alicante, 03080-Alicante, Spain.

Axotomized rat sympathetic neurons show a depolarization after spike firing (ADP), which is generated by a calcium-dependent chloride current (Sánchez-Vives & Gallego, *J. Physiol.* 475: 391, 1994). In normal cells this conductance may be located in the dendrites and only become evident in somatic recordings after the dendritic retraction induced by axotomy. Therefore, we have investigated whether this current is present in non-axotomized mouse sympathetic neurons which have shorter dendrites than similar cells in the rat. The experiments were done in an "in vitro" preparation of the superior cervical ganglion using single-electrode current- and voltage-clamp techniques and intracellular staining with neurobiotin. In the presence of TTX (1 μM) and TEA (25 mM), inward peaks and outward currents were recorded during 50-200 ms depolarizing pulses from -50 mV, followed by slowly decaying inward tail currents that lasted 400-800 ms. The tail current was blocked by anthracene-9-carboxylic acid (2 mM), a selective blocker of chloride channels, and its reversal potential shifted in accordance with the Nernst equation when the extracellular chloride concentration was changed. Calcium-free solution or $CdCl_2$ (200 μM) abolished both, the inward peak and the tail current. In current-clamp recordings, a train of spikes evoked a marked ADP in the majority of the cells. The amplitude of the ADP for a given neuron was inversely correlated with the number and total length of dendritic branches. These results suggest that mouse sympathetic neurons have a calcium-dependent chloride current localized in the distal dendrites.

Supported by Grant PB92-0347 from the DGICYT (Spain).

SEROTONIN-ACTIVATED Cl^- CURRENT IN RAT BRAIN STEM NEURONS

R.A.Davidoff[*,#], J.C.Hackman[#], S.R.Whittmore[$] and A.Y.Valeyev[#] Neurophysiology Laboratory, Veteran's Administration Medical Center[], Department of Neurology[#] and Miami Projec[$] University of Miami, Florida 33101, USA.

We studies RN46A cells, a serotonergic neuronal cell line derived from E13 rat raphe (White et al., J.Neurosci,1994). Intracellular recordings in the whole-cell configuration were made at room temperature using CsCl-filled micropipettes. 5-HT receptor agonists and antagonists were applied either by pressure pulses from closely positioned pipettes or by gradual diffusion in the extracellular medium. Applications of 5-HT evoked a dose-dependent inward current when holding membrane potentials were negative. When the equilibrium potential for Cl^- was set near 0 mV, current responses to 5-HT reversed polarity near 0 mV suggesting a dominant role for Cl^- ions in the conductance response. Bicuculline and strychnine had no effect on 5-HT activating current while picrotoxin blocked the Cl^- current. The slow kinetics of activation of the Cl^- conductance suggest the participation of second messengers in this process. (Supported VAMC MRIS #1769 and 3369 and USPHS #NS 17577).

798.3

GABA AND PENTOBARBITAL ACTIVATED CURRENT IN HUMAN DRG CELLS

A.Y.Valeyev*[],J.C.Hackman[#], P.M.Wood[+] and R.A.Davidoff[#] Neurophysiology Laboratory, Veteran's Administration Medical Center[#], Department of Neurology[] and Miami Project[+], University of Miami Miami, Florida 33101

Cells were cultured from embryonic (E) day 72 and adult human dorsal root ganglia (DRG). Neurons were grown for 5 or more days in serum-supplemented medium. Intracellular recordings in the whole-cell configuration were made at room temperature. $GABA_A$ receptor agonists and modulators were applied by pressure pulses from closely positioned pipettes. All cells responded to micromolar concentrations of GABA and the general anesthetic pentobarbital, but not the steroid anesthetic alphaxalone (3α-hydroxy-5α-pregnane-11,20-dion). When the equilibrium potential for Cl^- was set near 0 mV, current responses to GABA and pentobarbital reversed polarity near 0 mV, which corresponds to E_{Cl^-} calculated from the Nernst equation and suggests a dominant role for Cl^- ions in the response. Currents activated by GABA and pentobarbital were blocked by bicuculline and picrotoxin. Remarkably, diazepam had no modulatory effect on GABA-activated current. Noise analysis of membrane current variance shows that the open times of Cl^- channels activated by GABA and pentobarbital are different. (Supported by VAMC MRIS #1769 and 3369 and USPHS #NS 17577).

798.4

COMPARISONS OF AND INTERACTIONS BETWEEN THREE TRANSMITTER-INDUCED CL-DEPENDENT RESPONSES IN *APLYSIA* NEURONS. J.S Kehoe* and C.A Vulfius. Lab. de Neurobiologie, Ecole Norm. Sup., 46 rue d'Ulm, 75005 Paris

King and Carpenter (Neurosci. Lett. 82:343-348, 1987) observed that transmitter-induced Cl-dependent responses in *Aplysia* neurons often "interact" with one another: they cross-desensitize, and are often blocked by the same antagonists. We have studied the Cl-dependent responses of the Medial cells of the pleural ganglion to fast perfusion application of ACh, GABA and Glutamate. None of these responses, studied in whole-cell patch clamp, could be selectively blocked by the antagonists tested (strychnine, picrotoxin, bicuculline, and tubocurarine). Furthermore, each of these transmitter-induced responses desensitized with prolonged agonist application, and a "desensitizing" pulse of any one of the three transmitters caused a significant cross-desensitization of the responses induced by the other two. Even when using ATP- GTP-free solutions in very low resistance whole-cell pipettes, all three responses, as well as their cross-desensitizing interactions, persist.

In spite of the marked interaction between the GABA response and those elicited by ACh and Glutamate, the GABA response appears to be mediated by a different channel. When sulphate was used as the anion in the pipette solution, the GABA response was reduced by about 70-80% whereas the responses to ACh and Glutamate remained unchanged. In contrast, when Cl was used, all three responses, measured at a fixed number of mV less negative than ECl, remained unchanged. It thus appears that the interactions between these transmitter-induced responses are not simply the result of a common activation of a single receptor-channel complex.

798.5

SELECTIVE ANION PERMEABILITIES DISTINGUISH SUBCELLULAR CALCIUM POOLS IN RAT BRAIN.

Stephen L. Facchina and Ajay Verma*,Depts. of Neurology and Anesthesiology,Uniformed Services Univ. of the Health Sciences Bethesda, Maryland 20814

The anion selectivity of rat brain intracellular, nonmitochondrial $^{45}Ca^{2+}$ sequestering compartments was studied using rat brain microsomal fractions and fresh frozen sections. Mg-ATP dependent $^{45}Ca^{2+}$ transport in sodium azide containing buffers showed a strict requirement for anion cotransport as no $^{45}Ca^{2+}$ uptake occurred in buffers containing the impermeant gluconate as the sole anion. Prominent $^{45}Ca^{2+}$ accumulation was observed with oxalate, fluoride and phosphate as the sole anions and intermediate accumulation using acetate or chloride. By using a number of Ca^{2+} transport inhibitors two distinct compartments could be distinguished, each showing unique anion preferences. Thapsigargin (Tg), cyclopiazonic acid (CPA) and 2,5-di-*tert*-butyl-hydroquinone (tBQ) potently blocked oxalate, fluoride,or phosphate supported Ca^{2+} transport. Inhibition of Mg-ATP dependent chloride supported $^{45}Ca^{2+}$ uptake, however, required much higher concentrations of these inhibitors. Autoradiographic localization of $^{45}Ca^{2+}$ sequestering compartments using fresh frozen rat brain sections revealed unique anatomical distributions for the chloride selective pool with enrichment in brain stem, deep cerebellar nuclei and spinal cord. $^{45}Ca^{2+}$ uptake supported by oxalate, fluoride or phosphate was instead much more prominent in forebrain structures and cerebellar cortex.

798.6

RINGER CONDITIONS DETERMINE THE STABLE EXPRESSION OF WHOLE-CELL CHLORIDE CURRENT IN RAT ASTROCYTES.

C.D. Lascola* & R.P. Kraig, Dept. of Neurology, The University of Chicago, Chicago, IL

Increases in $[Cl^-]_i$ accompany astroglial depolarization in intact slices and primary cultures[1-2], suggesting a role for Cl^- in many activity-dependent processes. The dominant hypothesis based on whole-cell, excised and cell-attached patch clamp recordings, however, is that astroglial chloride channels are normally inhibited in culture by some constitutive intracellular factor[3].

Cultures of astrocytes were prepared from neonatal rat pups, and maintained in DMEM (10% FBS), following standard techniques. Whole-cell patch-clamp recordings were made at 22-25°C using 140mM NMDG-Cl bath and 40mM NMDG-Cl/ 100mM NMDG-gluconate pipette solutions, both of which also contained Mg^{2+}. Following a >1 hour incubation of cells at 37° C in standard Ringer solution (10 mM dextrose; 140mM NaCl), we observed whole-cell chloride currents in 83% of cells 2-20 days after plating (n=24). Cells were voltage-clamped from -100 mV to +100 mV in 20 mV increments to reveal outward rectifying chloride currents as expected in asymmetrical Cl^- solutions. The mean peak amplitude was 780 pA and the current reversal potential was -26.6 ± 9.4 mV (n=20). When gluconate was substituted for 100 mM Cl^-, the reversal potential was 8.6 ± 5.0 mV (n=5), and the current-voltage (I-V) relationship was linear, suggesting no voltage-dependence. When gluconate was substituted for all but 8 mM Cl^-, the reversal potential depolarized to 31 ± 5.1 mV (n=4), and the I-V became inwardly rectifying. Chloride currents were completely but reversably blocked by 1mM Zn^{2+} (n=3), a known chloride channel blocker. In cells that were introduced to recording solutions at 22-25°C after removal from DMEM, no whole-cell chloride current was observed (n=19).

These results demonstrate that removal of cells from serum-containing media and possibly temperature are important determinants of chloride current expression in cultured astrocytes. 1. Ballanyi et. al., *J. Physiol.*, **382**, 1987; 2. Walz & Mukerji, *Exp. Neurol.*, **99**, 1988; 3. Barres et. al., *Annu. Rev. Neurosci.*, **13**, 1990.

798.7

SWELLING-ACTIVATED AMINO ACID EFFLUX IN THE HUMAN NERUROBLASTOMA CELL LINE CHP-100.

S. Basavappa[1], C. Huang[1], A.W. Mangel[2], K. Kirk[1], P.N. Leigh[3,*] and J.C. Ellory[1]. [1]University Laboratory of Physiology, University of Oxford, Oxford OX1 3PT, UK , [2]Departments of Medicine and Cell Biology, Duke University Medical Center, Durham, NC, USA, and [3]Department of Neurology, Institute of Psychiatry, London SE5 8AF, UK.

Pathological disturbances (such as hyponatermia or ischemia) may result in significant changes in neuronal cell volume which have not been investigated in detail. The present studies evaluated the effects of hypoosmotic stress on cell volume and amino acid efflux in the human neuroblastoma cell line CHP-100. Using a Coulter Multisizer, CHP-100 cells were found to swell by ~35% ± 5% when the osmolarity of the extracellular solution was decreased from 290 to190 mOsm/kg H_2O. The rapid swelling was followed by regulatory volume decrease (RVD) with the cell volume approaching the isoosmotic value over 15 min. In cells loaded with ^{14}C-taurine, a similar hypoosmotic shock increased taurine efflux to 299% ± 22% (n=23, $p<0.05$) of control values. This efflux was inhibited by the chloride channel blockers 5-nitro-2-(3-phenyl-propylamino)-benzoic acid (NPPB), 4,4'-diisothiocyanatostilbene-2,2'-disulfonic-acid (DIDS), and niflumic acid, and was also dependent upon extracellular calcium. Hypo-osmotic stress also caused a significant increase in ^{14}C-glycine efflux, that was sensitive to NPPB. By contrast, efflux of ^3H-glutamate was not significantly affected by hypoosmotic exposure. It is concluded that CHP-100 cells undergo RVD when confronted with hypoosmotic stress and efflux of taurine and glycine may contribute to this process via a calcium-dependent anion permeability pathway.

LITHIUM PRE-TREATMENT PREVENTS ACTIVATION OF VOLUME-SENSITIVE CHLORIDE CHANNELS IN BOVINE CHROMAFFIN CELLS.

P.A. Doroshenko*. Loeb Res Inst, Ottawa Civic Hosp, Ottawa, Ontario K1Y 4E9, Canada

The role of phosphatidylinositol 4,5-bisphosphate (PIP2) hydrolysis in activation of volume-sensitive chloride (VolS Cl) channels was studied in bovine chromaffin cells using whole-cell patch clamp. Its involvement is implicated by inhibition of the VolS Cl channels by intracellular neomycin (Doroshenko & Neher, 1991) which is known to selectively bind PIP2 making it unavailable as a substrate for PIP2-specific enzymes (e.g. phospholipase C-γ). It has also been reported that hypotonic swelling of astrocytes intensified PIP2 hydrolysis, while its inhibition resulted in suppression of regulatory volume decrease (Bender *et al.*, 1993). The ability of bovine chromaffin cells grown in primary culture to generate the Cl current in response to intracellular administration of 100 μM GTPγS was tested during their incubation in the presence of 10 mM LiCl. Because LiCl is a potent inhibitor of inositol monophosphatase involved in replenishment of the limited membrane pool of PIP2, its presence is expected to cause a depletion of PIP2 in the cell membrane. From about 10 cells tested from each coverslip treated with LiCl, only the first cells tested within 10 min after the drug addition to the bath produced the current, while those tested after longer exposures did not. These results support the hypothesis that activation of VolS Cl channels in bovine chromaffin cells involves stimulation of PIP2 hydrolysis and suggest the role for lipid-derived second messengers in volume-regulatory processes.

MECHANISM OF ACTION OF FLUFENAMIC ACID ON Ca-ACTIVATED CHANNELS.

L.D. Partridge*R.J. Lee, T. Shaw Depts. of Physiol. & Path., Univ. of New Mexico, Albuquerque, NM 87131

Non-steroidal anti-inflammatory drugs (NSAIDs) are well known to produce anti-inflammatory effects through actions on prostaglandins, but their mechanism of analgesic action is less well understood. We have shown previously that the NSAID, flufenamate (FFA) transiently activates both a Ca-activated nonselective (I_{CAN}) and a Ca-activated outward ($I_{o\text{-}slow}$) current in neurons and that this is paralleled by a maintained rise in $[Ca]_i$. These effects are specific and not shared by two other fenamates.

In this study, we investigated the mechanism of action of FFA on $[Ca]_i$ and these two currents. A rise in $[Ca]_i$ is still observed following FFA application in dinitrophenol or thapsigargin but the transient increase in I_{CAN} and I_{slow} is reduced. Application of protein kinase inhibitors and membrane permeable cAMP analogs suggest that the effect on membrane currents is not through channel phosphorylation. Both the $[Ca]_i$ response and the current activation process were fully recovered after a 20 min wash following FFA application.

We conclude that FFA causes a release of Ca from mitochondria and ER that activates these Ca-activated currents and that these stores can be rapidly refilled. The reduction in I_{CAN} in the presence of a maintained elevation of $[Ca]_i$ does not appear to result from channel phosphorylation.

These are the first descriptions of the mechanism of action of this NSAID on neuronal Ca-activated channels. These actions may underlie some of the analgesic actions of this drug.

798.10

CALPAIN ACTIVATED CHLORIDE CHANNELS IN EXCISED PATCHES OF MYOTUBES AND NEURONS.

G. C. McCarter* and R. A. Steinhardt Dept. of Molecular and Cell Biology, Univ. of Calif., Berkeley, CA 94720

We have previously reported that exogenous calpain activates chloride channels when applied to the cytoplasmic face of about half of excised patches from mouse myotubes. We now report a similar activation in cerebellar granule cells and provide evidence that a membrane-resident protease may be responsible for activating the channel when it arises spontaneously. The channel in both cell types is outwardly rectifying, has a conductance between 30 and 90 pS and is blocked by 5-nitro-2-(3-phenylpropylamino)-benzoate (NPPB), similar to channels seen in cells from airway epithelium and several other tissues. Channels are also activated when bath calcium is raised from 0.18 to 1.8 mM, again in about half of excised myotube patches, and this effect is blocked by the presence of the protease inhibitor leupeptin. Cytochalasins have been reported to activate chloride channels in myoballs and other cells and we report here such an activation in neurons. This and the fact that cytoskeletal proteins are known to be calpain substrates suggest that proteolytic activation of the chloride channel may be mediated via a cytoskeletal regulation of the channel.

DEVELOPMENTAL EXPRESSION OF AN INWARDLY RECTIFYING CHLORIDE CONDUCTANCE IN RAT BRAIN. G.H. Clayton*, R.L. Smith, K.J. Staley, and C.L. Wilcox. Dept. of Neurology, UCHSC, Denver, CO 80262 and Dept. of Microbiology, CSU, Fort Collins, CO 80523.

A voltage sensitive, inwardly rectifying chloride channel, which has been shown to play a significant role in the modulation of neuronal responses to $GABA_A$ activation, is present in the same neurons that express mRNA for a previously cloned chloride channel (ClC-2) with similar properties. These results strongly suggest that ClC-2 is the source of the inwardly rectifying conductance. Using digoxigenin labeled riboprobes, we have examined the expression of ClC-2 during early postnatal development of rat brain and have found rapid changes in the pattern of developmental expression of ClC-2. In hippocampus and in cortex, expression is more wide spread in neonatal animals than in adult rats and can be found in proliferative layers. Similarly, ClC-2 was expressed in neurons of caudoputamen in the early stages of post natal development but was essentially absent in adult animals. In contrast, in cerebellum, the expression of ClC-2 is a relatively late post-natal event occurring between 7 and 14 days after birth during the period of purkinje cell synaptogenisis. To summarize, ClC-2 is expressed extensively in developing rat brain neurons including cells within germinal layers and becomes more restricted in the adult. These results suggest that ClC-2 may subserve functions which are different during migration and synaptogenesis than in the adult.

CALCIUM CHANNELS: MISCELLANEOUS BLOCKERS

799.1

NIMODIPINE INHIBITS A PERSISTENT CALCIUM CURRENT IN CHRONICALLY DEPOLARIZED CEREBELLAR GRANULE NEURONS C.Usai*, C.Marchetti, A.Barberis and L.Moccagatta. Istituto di Cibernetica e Biofisica, CNR, via De Marini, 6, 16149, Genova, Italy.

High $[K^+]_o$ in the culture medium is a standard technique for maintaining *in vitro* viability of neurons in defect of appropriate neurotrophic factors. Survival promotion by high $[K^+]_o$ is a long term phenomenon; cells, indeed, live for weeks in absence of trophic factors. This effect is thought to be mediated by a chronic membrane depolarization inducing a sustained elevation of free $[Ca^{++}]_i$. The nature of the voltage-dependent Ca^{++} channel responsible for this persistent elevation was investigated in cultured cerebellar granule neurons from 8-day old rats, by measurements of $[Ca^{++}]_i$ in Fura2-loaded cells. Cultures, routinely maintained in 25 mM KCl to enhance survival, were incubated with Fura2 either in 25 mM (chronic depolarization) or 5.4 mM KCl (control solution). In 25 mM KCl, $[Ca^{++}]_i$ was 155± 32 nM (n=13), and quickly decreased to 43±19 nM (n=9) when $[KCl]_o$ was lowered to 5.4 mM. Saturating doses of nimodipine (>10 nM) reduced $[Ca^{++}]_i$ to the *same level* as in control solution. The IC_{50} of this effect was 0.39±0.09 nM. In contrast, agatoxin IVA (200-500 nM) was ineffective. In 5.4 mM KCl the basal calcium level was 36±15 nM (n=95), and acute depolarization with 25 mM KCl induced a $[Ca^{++}]_i$ elevation larger (≈300 nM) than in chronic depolarization, suggesting the presence in the last case of channel inactivation. In neurons depolarized with 15-75 mM KCl, nimodipine strongly inhibited the $[Ca^{++}]_i$ rise. The dose-dependence of this effect was best approximated by a two site curve with $IC_{50}(1)$=0.27 nM and $IC_{50}(2)$=65 nM. In agreement with previous findings in different tissues, these values might represent the affinities of the drug for two different states of the channel, namely closed (or resting) and open state. Chronic depolarizations activate DHP-sensitive Ca^{++} channels: the high level of $[Ca^{++}]_i$ due to the Ca^{++} influx through these channels is somehow responsible for the enhanced survival of granule cells.

799.2

EFFECTS OF NEFIRACETAM AND OTHER NOOTROPICS ON NEURONAL CALCIUM CHANNELS AND PERIPHERAL-TYPE BENZODIAZEPINE RECEPTORS. S. Watabe*[1], Y. Nakamoto[2], M. Yoshii[2], and T. Shiotani[1]. [1]Tokyo R & D Center, Daiichi Pharmaceutical Co., Ltd., Tokyo 134 and [2]Dept. of Neurophysiology, Tokyo Institute of Psychiatry, Tokyo 156, Japan.

We have previously reported that neuronal Ca^{2+} channels were blocked by the peripheral-type benzodiazepine receptor (PBR) agonist Ro 5-4864, whereas they were activated by the nootropic nefiracetam (DM-9384), although this compound has a binding affinity to PBR. In the present study, we have further investigated the effects of nefiracetam on the Ca^{2+} channel and PBR by using various nootropic agents. Ca^{2+} channel currents were optimally enhanced by nefiracetam at 1 μM and less potently by aniracetam at 10 μM. The currents were not affected by oxiracetam or piracetam, or chemically-unrelated cognitive enhancers such as idebenone and bifemelane. Unlike nefiracetam and aniracetam, these compounds inhibited the currents at higher concentrations. Binding of ^{3}H-PK 11195, a PBR antagonist, to the mouse brain was inhibited by nefiracetam and aniracetam with IC_{50}'s of 0.39 and 1.59 mM, respectively, whereas it was not inhibited by oxiracetam and piracetam. The results suggest that PBR is a low-affinity site for nefiracetam and aniracetam and may be involved in their drug actions at high concentrations, whereas PBR is not involved in drug actions of other cognitive enhancers such as oxiracetam and piracetam.

799.3

FACILITATORY ACTION OF THE NOOTROPIC NEFIRACETAM (DM-9384) ON CALCIUM CHANNELS IS MEDIATED BY INHIBITORY G-PROTEINS IN NG108-15 CELLS. M. Yoshii*[1], S. Watabe[2], T. Nukada[3], T. Shiotani[2] and M. Tanaka[2]. [1]Dept. of Neurophysiology, [3]Dept. of Neurochemistry, Tokyo Institute of Psychiatry, Tokyo 156 and [2]Tokyo R & D Center, Daiichi Pharmaceutical Co., Ltd., Tokyo 134, Japan.

We have recently reported that the cognitive enhancer, nefiracetam (DM-9384), increases L-type Ca^{2+} channel currents in NG108-15 cells and that the effect is inhibited by pertussis toxin (PTX), suggesting that inhibitory G-proteins (Gi/Go) mediate the drug action (Yoshii and Watabe, *Brain Res.* **642**, 123-131, 1994). In the present study, we have further examined whether stimulatory G-proteins (Gs) are involved in the action of nefiracetam using the whole-cell patch-clamp technique. Under the condition that L-type currents were blocked by nifedipine (10 μM), the remaining high voltage-activated long-lasting currents were recorded. Leu-enkephalin (50 nM), which is known to activate Gi/Go, reduced the currents in a PTX-sensitive manner. The inhibited currents were reversed by nefiracetam (1 μM). On the other hand, PGE1 (10 μM), which is known to activate Gs, similarly reduced the currents, whereas dibutyryl cAMP (1 mM) did not affect the currents. The inhibited currents by PGE1 were not recovered by nefiracetam. The results suggest that the nefiracetam action is mediated by inhibitory G-proteins (such as Gi/Go), but not by stimulatory G-proteins (Gs).

LIFARIZINE BLOCKS VOLTAGE SENSITIVE NEURONAL CALCIUM CHANNELS. C.J. Siok,* R.D. Williams, L.F. Lanyon, R.J. Post, D. Yohannes M.K. Ahlijanian and A.H. Ganong Pfizer Inc, Central Research Division, Groton, CT 06340.

Lifarizine (RS 87476) is a use- and voltage-dependent sodium channel blocker (*Br. J. Pharmacol.*, 113:600, 1994) which also blocks the effects of calcium channel activators in smooth muscle (*Br. J. Pharmacol.*, 104:156P, 1991) and is neuroprotective (*Radiology*, 179:221, 1991). We examined the effects of lifarizine on several classes of neuronal calcium channel in both rat and human tissue. In rat SCG cells, using a holding potential of -100 mV, 10 μM lifarizine blocked 70±2% (n=3) of the nifedipine resistant current while 1 μM blocked 25±1% (n=6). The N-channel blocker conotoxin GVIA blocks approximately 70% under the same conditions. When the holding potential was lowered to -50 mV, the block by 1 μM lifarizine significantly increased to 47±4% (n=6; p<.001). Against P-type calcium channels in acutely dissociated rat cerebellar Purkinje cells 10 μM lifarizine blocked 52±5% (n=3) of the ω-Aga-IVA-sensitive current at a holding potential of -80 mV. The effects of lifarizine on human calcium channels were tested using fura-2 fluorescence measurements in the human IMR32 neuroblastoma cell line. Lifarizine blocked the ω-conotoxin GVIA-sensitive (N-channel) KCl-induced calcium increase with an IC_{50}=3.4 μM and nifedipine-sensitive (L-channel) increase with an IC_{50}=2.8 μM. At 10 μM, lifarizine also blocked 98% the current remaining in these cells after treatment with saturating concentrations of both nifedipine and GVIA. These data indicate lifarizine is a non-specific, voltage dependent blocker of neuronal calcium channels which, along with its ability to block voltage sensitive sodium channels, may play an important role in its neuroprotective activity.

799.5

VERAPAMIL AND LIDOCAINE PRODUCE A VOLTAGE-DEPENDENT BLOCK OF CLASS B CALCIUM CHANNELS EXPRESSED IN XENOPUS OOCYTES. M.L. WEBER*[1], G.W. CAMPBELL[1], C.P. TAYLOR[1], J. OFFORD[2] AND D.M. ROCK[1] [1]Neuroscience Therapeutics and [2]Biotechnology, Parke-Davis Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

There are a variety of subtypes of voltage-gated Ca^{2+} channels that have been described using electrophysiological and molecular techniques. One subtype of Ca^{2+} channels, designated as N-type, is found predominantly on neurons and has been shown to be important in mediating neurotransmitter release as well as neuronal excitability. Expressed Ca^{2+} channels that contain α_{1B} (Class B) have pharmacological and biophysical properties that are similar to N-type Ca^{2+}channels. Voltage-dependent blockers of N-type Ca^{2+} channels may be useful in the treatment of neurological disorders, including stroke.

Microinjection of cRNAs encoding for human neuronal α_{1B}, human neuronal β and rabbit skeletal muscle α_2 subunits produced high voltage-activated Ca^{2+} channels in Xenopus oocytes, whose activity was measured using two electrode voltage-clamp techniques. The block of expressed channels by lidocaine and verapamil was done at holding potentials where there was a small degree (5%) of steady state inactivation (-80 mV) and at depolarized holding potentials (-55 mV) where approximately 50% of the channels were inactivated. Using these two holding potentials we found a 5-50 fold increase in the potency of these two compounds when inducing current from the more depolarized holding potential. The ω-conotoxin GVIA tested in the same paradigm blocked Class B Ca^{2+} channels, but showed no voltage-dependency. Lidocaine and verapamil are non-selective ion channel blockers, producing voltage-dependent blocks of sodium and L-type calcium (verapamil) channels.

These results suggest that lidocaine and verapamil interact with a common site on Na^+ and Ca^{2+} channels that is revealed under depolarization or inactivation.

799.6

ω-CONOTOXIN GVIA AND SPERMINE CAUSE THE SAME EFFECT ON HIPPOCAMPAL FIELD POTENTIALS, BUT SPERMINE DOES NOT PREVENT CONOTOXIN BINDING. P.A. Ferchmin*; E.M. Rivera and V.A. Eterović. *Center for Molecular and Behavioral Neuroscience, Department of Biochemistry, Univ. Central del Caribe, Bayamón, PR 00960.*

When stimulating in area CA1 of hippocampal slices with paired pulses, 1μM ω-conotoxin GVIA (ω-CTX) inhibited irreversibly the first, or conditioning population spike (PS) and increased paired-pulse facilitation. Similar but reversible effects were observed with 1-3 mM spermine, suggesting that it too inhibits N-type Ca^{++} channels. However, spermine did not protect PS from irreversible inhibition by ω-CTX, which suggests a binding site on the channel not overlapping with that of ω-CTX. Upon complete inhibition of PS by ω-CTX, increased stimulation restored a full PS but did not decrease the degree of paired-pulse facilitation. This restored PS was inhibited by spermine with an IC_{50} similar to that seen with naive slices. Since ω-CTX block is irreversible, strong stimulation could have recruited other types of Ca^{++} channels or induced a voltage-dependent relieve of ω-CTX inhibition; since spermine potency did not change, it may act as a general inhibitor of voltage-dependent Ca^{++} channels. Supported by NIH-MBRS GM50695 and NIH-RCMI RR03035.

INTERACTIONS BETWEEN VOLATILE ANESTHETICS AND VOLTAGE DEPENDENT CALCIUM CHANNELS IN ISOLATED RAT BRAIN SYNAPTOSOMES. F. Xu, J. Zhang, V. White, H.C. Hemmings, Jr.*, T.J.J. Blanck, Dept. of Anesthesiology, Cornell University Medical College, NY 10021.

Presynaptic depression of Ca^{2+} entry through CNS voltage dependent Ca^{2+}-channels (VDCC) leading to inhibition of neurotransmitter release may be a primary effect of volatile anesthetics (VA) during general anesthesia. This work describes a parallel inhibition of binding and Ca^{2+} influx caused by halothane and isoflurane and demonstrates interactions between VAs and inhibitors of L- and N-type VDCC. Halothane and isoflurane (0.25-1.5 mM) inhibited dose-dependently K^+-stimulated Ca^{2+} influx into rat cortical synaptosomes to 55% and 65% of control value, respectively. Both anesthetics also depressed [^{3}H]isradipine binding to synaptosome membranes dose-dependently over the same concentration range. In equilibrium binding studies, an increase of K_d and a decrease of B_{max} were observed in presence of 1.5 mM halothane or isoflurane compared to the control values. In the absence of volatile anesthetics, nitrendipine (NTP, an L-type Ca^{2+}-channel antagonist) caused a slight increase in K^+-stimulated Ca^{2+} influx into rat synaptosomes, whereas the N-type Ca^{2+}-channel blocker ω-conotoxin GVIA (CTX) inhibited Ca^{2+} influx dose-dependently. Simultaneous treatment with 1 μM NTP and 200 nM CTX resulted in an intermediate inhibition of Ca^{2+} influx. The inhibitory effect of halothane on Ca^{2+} influx was potentiated by NTP, by CTX, or, more strongly, by NTP and CTX simultaneously. In contrast, the inhibitory effect of isoflurane on Ca^{2+} influx was potentiated by simultaneous use of NTP and CTX, but not by NTP or CTX alone. These results suggest that the inhibitory effect of halothane and isoflurane on depolarization-evoked Ca^{2+} influx in rat cortical synaptosomes involves L- and/or N-type VDCC located on synaptosomal plasma membranes. Inhibition of VDCC may play an important role in the CNS effects of VAs.

799.8

MECHANISM OF ACTION OF CISSUS SICYOIDES WATERY EXTRACT ON MALE GUINEA PIG AORTIC RINGS. E. Gijón*, L. Cartas, M. Lorenzana-Jimenez, and X. García. Dept. of Physiology and Dept. of Pharmacology, School of Medicine. UNAM. México D.F. 04510. México.

The extract of Cissus sicyoides (Cs) from dry leaves 1:10 w/v produces vasoconstriction in aortic rings without endothelia in a dose dependent manner (1). As this could be explained by calcium movilization trough voltage dependent channels or receptor dependent channels, we tested several potassium chloride (KCl) concentrations. KCl 7.7-10 mM increased Cs contractil response while KCl 20-77 mM decreased this response. Cs vasoconstriction dose response curve may be observed in calcium free solutions with EGTA 0.2 mM and 3 mM and caffeine 5 and 50 mM. Caffeine blocked Cs contraction dose dependent. These suggests that Cs contraction depends on calcium channels activated by membrane voltage changes and on internal calcium deposits.

LAMBERT-EATON MYASTENIC SYNDROME IgGs INHIBIT NON-L, NON-N Ca^{2+}-CHANNELS IN RAT INSULINOMA RINm5F CELLS. C. Grassi*, V. Magnelli^, E. Sher°, G.B. Azzena and E. Carbone^ Institute of Human Physiology, UCSC , Rome, Italy. ^Dept. of Anatomy and Human Physiology, University of Turin, Italy. °Center of Citopharmacology, CNR, Milan, Italy

Lambert-Eaton myasthenic syndrome (LEMS) is an autoimmune disease characterised by a widespread disorder of neurotransmitter release, which has been attributed to down-regulation of presynaptic Ca^{2+}-channels. We have recently shown that LEMS IgGs reduce Ca^{2+}-currents through N-type channels and this might account for impairment of the autonomic functions observed in this syndrome (Grassi et al., *Neurosci. Lett.* 181:50-56, 1994). However, acetilcholine release at level of the mammalian neuromuscular junction has been proposed to be due to activation of non-L non-N Ca^{2+}-channels. In the present study we investigated the action of LEMS IgGs on Ca^{2+}-currents in RINm5F cells, which show a high percentage (30-35%) of non-L non-N Ca^{2+}-channels (Magnelli et al., *Pflügers Arch.*, 1995 in press). High-voltage activated (HVA) Ca^{2+}-currents were recorded in 10mM Ba^{2+} from cells incubated (12 h) with IgGs (2 mg/ml) of either LEMS or control subjects. After ω-CTx-GVIA-treatment (3.2μM for 15 min) and in the presence of nifedipine (5 μM), current amplitude was 84±12pA (S.E.M., n=18) in LEMS IgG-treated cells and 160±20pA (n=19) in controls (47% depression, P< 0.01). Activation and inactivation kinetics were not modified by LEMS IgGs. The channel voltage-dependency in control- and LEMS-IgG treated cells did not exhibit significant difference, derived from the absence of shift in the current-voltage (IV) curve. Our data suggest that LEMS IgGs target non-L, non-N Ca^{2+}-channels as well as other HVA Ca^{2+} channels thus probably causing the impairment of acetilcholine release at the neuromuscular junction level observed in LEMS patients.

PROPOFOL INDUCES EXTRA CELLULAR ACIDIFICATION IN NEURONS.

K Björnström[1], H Eriksson[2], Å Schippert[3], A Sjölander,[3] C Eintrei[1]*
Departments of Anaesthesiology[1] and Cell Biology[3],University Hospital, S-581 85 Linköping and Astra[2], Södertälje, Sweden

The site of action of the anaesthetic drug propofol (Diprivan®) is still unknown. We have previously shown that propofol induces changes in the cytoskeleton arrangement after an intracellular calcium rise (1). Our hypothesises is that anaesthetic drugs interact with the cell membrane which change the state of the ion channels and induce changes in the cytoskeleton.

We have used a microphysiometer (2) to measure the amount of proton excretion in primary culture of neurons after stimulation with propofol in the concentration of 0.3, 3 and 30 μg/ml respectively. We used medium or 10% Intralipid® as controls.

To further investigate how the propofol-induced rise in intracellular calcium occur we used the tyrosine kinase inhibitor herbimycin A, incubated for 30 min, and thereafter measured intracellular calcium in single cells as described previously (1).

The results shows dose dependent and reversible changes in the extracellular acidification. We believe this acidification is caused by acidic metabolites leaving the cell through open ion channels, probably calcium channels. The intracellular calcium rise was reduced when herbimycin A was added. The reduction was caused by reduced influx of calcium ions. This shows that tyrosine kinase has a roll in the intracellular pathways caused by propofol.

GENETIC DISRUPTION OF THE M1 MUSCARINIC RECEPTOR IN MICE S. E. Hamilton*, M. Qi, G. S. McKnight, N. M. Nathanson, R. L. Idzerda. Department of Pharmacology, University of Washington, Box 357280, Seattle WA 98195-7280

The m1 muscarinic receptor is found in high concentrations in the hippocampus where it is thought to be involved in memory and learning. It is also present in sympathetic ganglia where it regulates synaptic transmission through the ganglia from the central nervous system (CNS) to the heart and blood vessels. We are generating mouse strains deficient in the m1 receptor in order to determine its function in the nervous system. An allele of this gene was "knocked-out" in mouse embryonic stem (ES) cells by homologous recombination using a 7 kb fragment of the mouse m1 gene in which the sequence corresponding to the N-terminal 56 amino acids was replaced with the sequence for the positive selectable marker, neomycin phosphotransferase. In addition the gene encoding HSV thymidine kinase was incorporated at one end of our construct as a marker for negative selection. After introducing the construct into ES cells by electroporation, colonies were grown in the presence of G418 and gancyclovir and were screened using both PCR and Southern analyses. Two of our cell lines deficient in m1 yielded chimeric mice and the mutant m1 gene was transmitted through the germline. The resulting heterozygotes are being bred to obtain homozygotes deficient in both copies of the m1 gene. We will verify the loss of m1 protein expression using an m1 specific polyclonal antibody we have generated and will use these mice to elucidate the role of m1 receptors in the CNS.

PRESENCE OF M_4 AND M_1 MUSCARINIC RECEPTOR SUBTYPES IN RAT OLFACTORY BULB AND M_4 MEDIATES BIMODAL CONTROL OF CYCLIC AMP FORMATION. H. Ladinsky*, G.B. Schiavi, M. Gil Quintero, M. Turconi, M.C. Olianas[1] and P.L. Onali[1]. Research Department, Boehringer Ingelheim Italia, Milan, Italy 20139 and [1]Department of Neurosciences, University of Cagliari, Cagliari, Italy 09124.

The pharmacology of muscarinic receptor (mAChR) sites in the rat olfactory bulb (OB) was characterized by use of a series of displacing ligands. In binding experiments against [^{3}H]NMS, regression analysis of the shallow inhibition curves produced by M_1-selective antagonists pirenzepine, guanylpirenzepine, DAG 5600 and DAG 5198 showed that M_1 mAChRs make up 47.4±2% of total receptors, and those produced by M_4/M_2-discriminating compounds DAU 6385 and DAU 6387 indicated that M_4 receptors comprise 45.2% of all mAChRs. The M_1+M_4 mAChRs thus make up 93% of the total population in OB. None of the affinity constants of the drugs indicated the presence of M_2 binding sites. Both carbachol-stimulated, and carbachol-inhibited Ca^{2+}/calmodulin- and forskolin-stimulated adenylate cyclase activity in OB homogenates were blocked by the above antagonists as well as by AF-DX 116, himbacine and AQ-RA 741. The inhibition constants of the antagonists, determined by Schild analysis, correlated highly ($R = 0.95$) with the binding affinities of the antagonists for the m4 mAChR in NG 108-15 neuroblastoma-glioma hybrid cells but not with those for the rat cortical M_1 ($R = 0.31$) or cardiac M_2 ($R = 0.76$) mAChRs. The results thus provide evidence that the M_4 subtype mediates the cholinergic bimodal regulation of cyclic AMP formation in OB.

m5 MUSCARINIC RECEPTORS ON MICROGLIA: IMPLICATIONS FOR CHOLINERGIC NEURON-MICROGLIAL COMMUNICATION. G. Ferrari-DiLeo and D.D. Flynn*. Dept. of Pharmacology, Univ. of Miami School of Medicine, Miami, FL 33101

Microglia, the resident macrophages of the CNS, are involved in both protective and destructive processes important for neuronal survival. The close association of microglia with basal forebrain cholinergic neurons and the presence of cholinergic muscarinic receptors on microglia suggest possible unique cholinergic neuron-microglia interactions. While there is evidence to suggest that microglial activation may be, in part, controlled by neurotransmitters and neuropeptides, little is known about the signal transduction mechanisms involved. We have previously demonstrated that the m5 subtype is the predominant muscarinic receptor on microglia isolated from adult and newborn brains and on blood macrophages (Ferrari-DiLeo & Flynn, *Life Sci.* 56:1037, 1995). In order to elucidate cholinergic regulation of microglia function, we have characterized the coupling of muscarinic receptor activation to signal transduction mechanisms in microglia. These studies are the first to examine m5 receptor signalling properties in a preparation that endogenously expresses this subtype. Carbachol stimulation of microglia results in the activation of PLC and release of inositol phosphates but not in the activation of PLA_2 or release of arachidonic acid. The efficiency of coupling of muscarinic receptor stimulation to nitric oxide synthase activation is being investigated. In order to examine putative microglia-to-neuron signalling, we determined the effects of microglia secreted factors on muscarinic receptor binding and second messenger responses. Cells exposed to microglia-conditioned media demonstrated decreased responses to carbachol. These studies suggest that not only do microglia respond to cholinergic stimulation but that microglia may modulate cholinergic neurotransmission.

SODIUM NITROPRUSSIDE INDUCES INTERNALIZATION OF MUSCARINIC RECEPTORS R. Maggio*, P. Barbier, F. Fornai, F. Vaglini and G. U. Corsini. Institute of Pharmacology, School of Medicine, University of Pisa, Italy.

In the present study we have extensively characterized the internalization of muscarinic acethylcholine receptors induced by the nitrogen monoxide (NO) generating compound sodium nitroprusside (SNP). When CHO cells stably transfected with the m4 muscarinic receptor subtype were incubated for 1 h in the presence of 700 μM SNP, the number of receptors, measured in intact cells with the hydrophilic ligand [^{3}H]N-methylscopolamine ([^{3}H]NMS), was reduced by 30 %. This effect was dose dependent, beginning with concentration of SNP as low as 45 μM. Receptor diminution induced by SNP was very fast ($t_{1/2}$ ranged between 10 and 20 min). Removal of SNP from the incubation medium did not result in a recovery of the binding sites measured with [^{3}H]NMS. The phenomenon was temperature dependent (it did not occur at 4 °C), and was blocked by the muscarinic antagonist atropine. Moreover, the effect of SNP was not observed in cell homogenate indicating that the integrity of the cell was required. Receptor diminution was not detected when the number of binding sites was evaluated with the lipophilic antagonist [^{3}H]quinuclidynil benzilate. This indicates that SNP induces a redistribution of the muscarinic receptors between the plasma membrane and an internal compartment of the cell. Receptor loss was readily reversed by the treatment with the sulphydryl reducing agent diethyldithiocarbamate (10 μM). Our data indicate that muscarinic receptors are internalized by SNP through the oxidation of sulphydryl groups; moreover they suggest that NO could play a role in muscarinic receptor desensitization.

CONSTITUTIVELY ACTIVE MUSCARINIC RECEPTORS PRODUCED BY RANDOM MUTAGENESIS OF THE SIXTH TRANSMEMBRANE DOMAIN. T. A. Spalding*, E. S. Burstein, D. Hill-Eubanks, M. R. Brann. Department of Psychiatry, University of Vermont, Burlington VT 05405 and Receptor Technologies, Winooski, VT 05404.

Libraries of recombinant m5 muscarinic receptors were constructed containing random mutations in regions of the receptor thought to be involved in ligand binding and G-protein coupling. Functional receptors were identified based on their ability to amplify NIH-3T3 cells in a ligand-dependant manner. We have isolated constitutively activated receptors which are able to amplify NIH-3T3 cells in the absence of ligand. This constitutive activity is inhibited by atropine and other classical muscarinic antagonists. The receptors remain sensitive to carbachol, which is ten to fifty times more potent on constitutively activated receptors compared to wildtype.

We have constructed libraries of receptors containing mutations in the third, fifth and sixth transmembrane regions, the N and C terminii of the third internal loop and the second internal loop of the receptor. However, all of the constitutively activated receptors identified to date contain multiple mutations in the sixth transmembrane domain. We are currently performing site directed mutagenesis studies to determine whether individual amino acid substitutions can cause the constitutive activation of the receptor.

NOVEL HIGH THROUGHPUT ASSAYS OF CLONED RECEPTOR PHARMACOLOGY IN LIVING MAMMALIAN CELLS. Terri L. Messier, Christine M. Dorman, Hans Braüner-Osborne, David Eubanks, S.V. Penelope Jones*, and Mark R. Brann. Receptor Technologies Inc. 276 East Allen Street Winooski, VT 05404.

An innovative high throughput assay of cloned receptor pharmacology has been developed based on the observation that many receptors stimulate proliferation of NIH 3T3 cells in a ligand dependent manner. We report application of this assay to evaluate the pharmacology of ligands for cloned receptors belonging to a wide range of functional and pharmacological classes. These include muscarinic, adrenergic, neurokinin, prostanoid, endothelian and neurotrophin receptors. Our assay involves the co-expression of an enzyme marker with the receptor of interest. The cloned receptor ligand stimulates proliferation of the cells and the induced effect is assessed by measurement of the co-expressed β-galactosidase. This assay is called Receptor Selection and Amplification Technology (R-SAT, patent pending). R-SAT offers significant advantages compared to other methods for evaluating receptor pharmacology. A colormetric change is measured in a 96-well plate format providing the ability to easily screen many ligands for activity toward one or more receptors in a single assay. A positive correlation is shown when we compare ligand activity in our assay and more traditional assays. In addition, our assay can measure the response of ligands toward a receptor in a relatively short period (4-6 days). This assay strategy facilitates screening of large compound libraries and can reliably discriminate between agonist, partial agonist, and antagonist. R-SAT, a novel high throughput assay provides a simple, rapid, and economical method of reliably screening compounds and receptors.

Isolation and Characterization of the chick m2 and mouse m1 muscarinic acetylcholine receptor promoters.

Marc L. Rosoff*[1], Jai Wei[1], Robert A. Shapiro[2], Neil M. Nathanson[1], [1]Dept. Pharmacol., Univ. Washington, Seattle, WA 98195; [2]Bristol-Meyers Squibb Pharmaceutical Research Institute, Seattle WA 98121

We are interested in the molecular mechanisms and signal transduction pathways involved with the transcriptional regulation of muscarinic acetycholine receptors (mAChR's). We have isolated genomic regions containing the putative chick m2 (cm2) promoter and the putative mouse m1 (mm1) promoter.

Constructs containing the putative promoters drive the expression of the firefly luciferase gene when transiently transfected into IMR-32 human neuroblastoma cells. Treatment of cells for 8 hrs. with leukemia inhibitory factor (LIF) or ciliary neurotrophic factor (CNTF) results in an increase in cm2 driven luciferase expression while mm1 driven luciferase expression remains unchanged. Treatment with nerve growth factor (NGF) had no effect on expression of either reporter constructs. We have begun to compare the regulation of the endogenous mAChR levels and their respective mRNAs with the regulation of the reporter gene constructs.

Initial studies indicate the putative cm2 promoter will drive luciferase expression in transiently transfected chick heart primary cultures (>8 fold above vector alone). We are currently investigating the regulation of the cm2 luciferase constructs in this system.

DISTINGUISHING BETWEEN STERIC HINDRANCE AND ORDINARY COOPERATIVE RECEPTOR MODELS.

C.-M. Staschen *[1], L.D. Homer and S.T. Ahlers. [1]Naval Medical Institute, Kopperpahler Allee 120, 24119 Kronshagen, Germany; Naval Medical Research Institute, Bethesda, MD 20889-5607, USA.

Radioligand binding studies are often carried out to distinguish among alternative kinetic models of receptor binding. When there is knowledge of the 3-dimensional molecular structure of the receptor it may be possible to express the structural features in terms of kinetic rate constants. This specialized model may then be compared to a more general model to obtain statistical verification or rejection of the adequacy of the specialized, structurally-based model. As an example we compare between an ordinary cooperative receptor model and a cooperative receptor model with steric hindrance as recently proposed by Proska and Tucek (Mol. Pharmacol. 45: 709-717, 1994).

The starting parameters used for the models were obtained from real kinetic experiments of radiolabeled N-methyl-scopolamine at M2-muscarinic receptors of the rat heart as published by Proska and Tucek. Nonequilibrium pseudodata with random error (4%) were generated. Parameters were estimated by minimizing a weighted sum of squared errors with simultaneous analysis of pooled kinetic pseudodata. Statistical significance between the two models was calculated using the partial F-test. Successful statistical discrimination between the two models was obtained with a design consisting of association experiments performed with several different radioligand and several different inhibitor concentrations. In contrast, simulated pooled equilibrium experiments or pooled association experiments using only 1 radioligand concentration even with several inhibitor concentrations failed to distinguish between the two receptor models.

IDENTIFICATION OF SINGLE AMINO ACID RESIDUES DETERMINING SELECTIVE ACTIVATION OF $G_{q/11}$ BY THE m3 MUSCARINIC ACETYLCHOLINE RECEPTOR.

N. Blin, J. Yun and J. Wess*. National Institutes of Health, NIDDK, Lab. of Bioorganic Chemistry, Bethesda, MD 20892.

A large body of evidence suggests that the specificity of receptor/G protein interactions is determined by multiple intracellular receptor domains. To gain deeper insight into the molecular mechanisms governing receptor/G protein coupling selectivity, specific amino acids which are of particular importance for proper G protein recognition need to be identified. Towards this goal, the present study was undertaken to identify single amino acids required for selectively coupling the m3 muscarinic acetylcholine receptor to G proteins of the $G_{q/11}$ family. Distinct intracellular segments/amino acids of the m3 receptor were systematically substituted into the structurally closely related m2 muscarinic receptor which does not couple to $G_{q/11}$ but to $G_{i/o}$ proteins. The resultant mutant receptors were expressed in COS-7 cells and studied for their ability to induce agonist-dependent stimulation of phosphatidyl inositol hydrolysis, a response known to be mediated by G proteins of the $G_{q/11}$ class. Using this approach, we identified four amino acids in the second intracellular loop and four amino acids at the C-terminus of the third intracellular loop of the m3 muscarinic receptor which are essential for efficient $G_{q/11}$ activation. We could demonstrate that these amino acids, together with a short segment at the N-terminus of the third intracellular loop, fully account for the G protein coupling preference of the m3 muscarinic receptor. Taken together, our data strongly suggest that only a rather limited number of amino acids, located on different intracellular regions, are required to determine the functional profile of a given G protein-coupled receptor.

CHARACTERIZATION OF A CHICK m5 MUSCARINIC ACETYLCHOLINE RECEPTOR

S. Creason, K. Tietje, and N.M. Nathanson*. Department of Pharmacology, University of Washington, Seattle, WA. 98195

A partial length cDNA clone coding for a muscarinic acetylcholine receptor was isolated from chick heart using PCR and degenerate oligonucleotide primers. Sequence analysis showed this fragment to have 91% similarity and 88% identity with the third cytoplasmic loop of the rat m5 receptor. This fragment was used to probe a chicken genomic library to obtain a full length clone encoding the chick m5 (cm5) muscarinic receptor. The cm5 receptor, like all other vertebrate muscarinic receptors cloned to date, did not contain any introns in the coding region of the gene. cm5 specific oligonucleotides were used in reverse transcription PCR assays to demonstrate that the cm5 receptor is expressed in both chick heart and chick brain.

When expressed in stably transfected CHO cells, the cm5 receptor exhibited high affinity for the muscarinic receptor specific antagonist 3H-QNB. Ligand binding assays with perinzipine, AF-DX 116, and carbachol show this receptor to have pharmacological properties similiar to other cloned muscarinic receptors. Functional studies demonstrate the ability of this receptor to stimulate phospholipase C and increase carbachol stimulated phosphatidylinositol hydrolysis in stably transfected CHO cells.

SITE-DIRECTED MUTAGENESIS OF THE m1 MUSCARINIC RECEPTOR: ROLE OF B-B-X-X-B MOTIF IN RECEPTOR-G-PROTEIN COUPLING.

N.S.M. Geoghagen, R.T. Cline, C.M. Fraser and N.H. Lee*. Department of Molecular and Cellular Biology. The Institute for Genomic Research, Gaithersburg, MD 20878.

Seven transmembrane domain (7tmd) receptors modulate the activity of their effector enzymes via G-proteins. Examples of single tmd receptors that functionally interact with G-proteins are also known. Of interest is the finding that the cytoplasmic regions of these two structurally diverse class of receptors contain a B-B-X-X-B motif (where B is a basic amino acid and X is a non-basic amino acid) which is postulated to be the G-protein activator domain. Agonist-stimulation of m1 muscarinic acetylcholine receptors (m1mAChRs), belonging to the 7tmd receptor family, results in hydrolysis of phosphoinositides (PI). The carboxyl-terminal, cytoplasmic domains of m1mAChRs contain two of these G-protein-activator motifs, $KRTPR^{141}$ and $KKAAR^{365}$ (where the number indicates position of the last amino acid) in the 2nd and 3rd intracellular loops, respectively. We have mutated the basic amino acids to alanine (A) to access their role in receptor-G-protein coupling. Antagonist binding and expression levels (1-2 pmol/mg protein) of mutant receptors where comparable to wild-type m1mAChRs. The $AAAAA^{365}$, but not the $AATPA^{141}$, mutant receptor was functionally uncoupled for agonist-stimulated PI hydrolysis. The $AKAAR^{365}$ and $KKAAA^{365}$ mutant receptors exhibited decreased potency and efficacy to stimulate PI hydrolysis compared to wild-type m1mAChRs, respectively. The $KAAAR^{365}$ and $KAAAA^{365}$ mutants exhibited both decreased potency and efficacy to stimulate PI hydrolysis. These data demonstrate that the $KKAAR^{365}$ motif is the G-protein activator domain with each basic amino acid contributing to agonist-stimulated PI hydrolysis.

STRUCTURE OF THE m4 MUSCARINIC RECEPTOR GENE AND ITS PROMOTER.

Avtar. Roopra, Ian.C. Wood, Christina.A. Harrington* and Noel J. Buckley, Wellcome Laboratory for Molecular Pharmacology, University College London, London WC1E 6BT, U.K.

G-protein coupled receptors are encoded by one of the most diverse gene families in the mammalian genome, accounting for as much as 1% of the entire genome. Most, if not all, of these gene products have a unique distribution within the nervous system and hence it is of interest to determine how these expression profiles are brought about i.e. What determines the receptor repertoire of individual neurones?

Cholinergic muscarinic receptor genes are members of this gene superfamily. The m4 gene is expressed mainly in telencephalic regions of the CNS, autonomic ganglia and lung; Activation of m4 receptors can lead to closing of N-type voltage sensitive Ca^{2+} channels, activation of K^+ channels and inhibition of adenylyl cyclase. Analysis of the m4 gene has shown that it contains a 460bp non-coding exon separated from the single coding exon by a 4.8kb intron. A rat cosmid clone containing the m4 gene and 20kb of upstream sequence was found to be sufficient to direct expression of the m4 gene in a cell type specific manner when transfected into cell lines. A DNA sequence analysis of the 5'flanking region of the m4 promoter showed that this region is *gc* rich, does not contain a TATA or CAAT box and has several consensus sequences for enhancer elements including AP-2, AP-3 and E-Box binding sites. Transient transfection of a series of luciferase reporter constructs into different cell lines demonstrated that 600bp of 5'flank was capable of driving cell specific expression. Present studies are aimed at defining those *cis* elements which are responsible for driving cell specific expression of the m4 gene and functionally assessing their role both *in vitro* and in transgenic mice.

m1-m4 MUSCARINIC RECEPTOR PROTEINS IN RAT DENTATE GYRUS AND AFFERENT PROJECTION NEURONS. S.T. Rouse* and A.I. Levey. Dept. of Neurology, Emory Univ. Sch. of Med., Atlanta, GA 30322

Acetylcholine (ACh) has a variety of modulatory roles in the hippocampus, which are mediated by a family of five mAChR subtypes (m1-m5). To establish the anatomical basis of ACh actions, we studied the expression of mAChRs in the dentate gyrus (DG) using light microscopic immunocytochemistry (ICC) (Levey, 1991). m1-m4 subtypes are found in the neuropil of the molecular layer, but with differential laminar distributions. m1 and m3 are expressed throughout the molecular layer and in granule cell bodies, suggesting, at least in part, the postsynaptic distributions of these subtypes. m2 is concentrated in a very thin band at the junction of the inner and middle third of the molecular layer. m4 is enriched in the inner third of the molecular layer, suggesting localization in associational/commissural projections. All 4 subtypes were identified in hilar neurons.

To identify the receptor proteins in hippocampal projection neurons, we injected retrograde tracer (WGA-HRP) unilaterally into the DG, combined with mAChR ICC. Multipolar hilar cells of the contralateral hippocampus that comprise the commissural pathway express m1, m3 and m4, but not m2. Septohippocampal neurons express the m2 subtype. Raphe cells that project to the DG express the m1 subtype. Cells in layer 2 of the entorhinal cortex, that comprise the perforant pathway, express m1, m2 and m4. These results indicate mAChR subtypes are differentially expressed in DG and its afferent projection neurons. Future studies will delineate the pre- and postsynaptic distributions of the subtypes in these circuits.

MUSCARINIC CHOLINERGIC RECEPTOR (Hm1) INTERNALIZES VIA CLATHRIN-COATED VESICLES. L.M. Tolbert, R.I. Cone* and J. Lameh, Departments of Pharmacy and Pharmaceutical Chemistry, University of California, San Francisco, CA 94143-0446.

Upon exposure to agonists such as carbachol, muscarinic receptors quickly internalize to a significant degree. The mechanism of muscarinic receptor internalization is poorly understood. We have used immunofluorescence confocal microscopy to identify the pathway by which muscarinic receptors are internalized. Using human embryonic kidney cells (HEK 293) transfected with the Hm1 (human muscarinic subtype 1) receptor tagged with the epitope EYMPME, we have seen that acid treatment, which has been shown to inhibit internalization via clathrin-coated vesicles, inhibits carbachol-stimulated internalization. PMA, on the other hand, which inhibits caveolae-mediated endocytosis, has no effect on carbachol-induced endocytosis. Double-labeling studies with clathrin; α-adaptin, which links endocytosed proteins to clathrin; and transferrin, which recycles through clathrin-coated vesicles, show that each of these proteins is colocalized with Hm1 following agonist treatment. Conversely, in double-labeling studies with caveolin, the protein that comprises caveolae, no colocalization between Hm1 and caveolin was observed. These results suggest that agonist-induced internalization of the Hm1 receptor occurs by a clathrin-mediated pathway. Supported by MH 00996. L.M.T. supported by AFPE and GM08338.

EFFECT OF CARBACHOL ON MORPHOLOGICALLY CHARACTERIZED AMYGDALOID NEURONS: ANALYSIS "IN VITRO". J. Yajeya*[1], A. de la Fuente Juan[1], M. Merchán[2], I. Plaza[2], M. Heredia[1], A.S. Riolobos and J.M. Criado. Depts de Fisiologia y Farmacologia[1] and Biología Celular y Patología[2]. Universidad de Salamanca. 37007 Salamanca. Spain.

The cholinergic system of neurotransmission has been implicated in processes of attention, learning and memory. This system is connected with the amygdala, a structure also implicated in such processes. Using the slice technique, we have made intracellular recordings and tracer injections to determine: 1) the effects and action mechanisms of carbachol on basolateral neurons, 2) the morphological features of the neuron types affected. In 85 % of the one hundred and twenty-three neurons studied, carbachol (20 μM) induced a slow depolarization of 5-10 mV. Sometimes the cell attained the firing threshold This response was maintained under perfusion with Ba^{2+} (1mM) and using cesium acetate (3M) filled electrodes. The addition of flunarizine (10 μM) or the perfusion with low Ca^{2+} (0.2 mM) and high Mg^{2+} (2.4 mM) solutions did not block the depolarizing effect of carbachol, but changed the time course. The response was blocked under perfusión with T.E.A. (5 mM); it was also reduced in amplitude with T.T.X. (1 μM) perfusion or in solutions with a low Na^+ (58.5 mM). Biocytin-injected, carbachol affected neurons are multipolar, with spiny dendrites and pyramidal appearance, possibly corresponding to type I of McDonald. These results suggest that carbachol effects on basolateral amygdaloid neuron are mediated by modification of Na^+ and K^+ conductances. The Ca^{2+} ion may be involved in the maintenance of the long time course of the response under physiological conditions.

THREE TYPES OF ATROPINE-SENSITIVE RESPONSES TO CARBACHOL IN ACUTELY ISOLATED SEPTAL NEURONS OF THE RAT. L. R. Sun and J. B. Suszkiw*. Dept. of Molecular and Cellular Physiology, Univ.of Cincinnati College of Medicine, Cincinnati, OH 45267-0576.

Using whole cell current-clamping and voltage-clamping techniques, we investigated the responses of septal/diagonal band neurons to carbachol. Recordings were made from large (diameter ≥ 25 μm), acutely dissociated neurons from 14-22 day old Sprague-Dawley rat pups. Carbachol was applied (100 μM, 100 ms) to the cell via a puffer pipette before and following bath superfusion with 10 μM atropine. Responses to glutamate (100 μM, 100 ms) were measured as well. Glutamate elicited depolarizing, inward currents in all cells tested (50/50). Carbachol induced hyperpolarizing, outward currents in 27/50 (54%) of cells and depolarizing, inward currents in 6/50 (12%) of cells. In 5/50 (10%) of cells, carbachol increased membrane resistance that was accompanied by a increased firing frequency of action potential. All the responses were attenuated in the presence of atropine. Twenty four percent of the cells (12/50) didn't show any responses to carbachol. These results indicate that majority of large neurons in the septum are cholinoceptive and that three types of atropine-sensitive responses can be distinguished.

A VOLTAGE AND CALCIUM-DEPENDENT CATION CURRENT UNDERLIES THE DEPOLARIZATION AND DEPOLARIZING AFTER-POTENTIAL ELICITED BY MUSCARINIC ACTIVATION IN RAT CORTEX. S. Haj-Dahmane* and R. Andrade. Dept. of Pharmacol. and Physiol. Science, St. Louis Univ. School of Med. St. Louis, MO 63104.

Muscarinic stimulation depolarizes pyramidal neurons of the rat prefrontal cortex and induces the appearance of a slow calcium-activated afterdepolarization (sADP). We have previously shown that both of these effects reflect the activation of cation-nonselective currents. We now have examined the relationship of the currents underlying these two responses.

Whole cell recordings were obtained from layer V pyramidal neurons of rat prefrontal cortex in brain slices. Administration of carbachol elicited an inward current that increased steeply in amplitude above rest (approx -70 mV). Blocking calcium influx using cadmium greatly reduced this voltage dependence. Buffering of the intracellular calcium with 10 mM EGTA or BAPTA had no effect on the carbachol induced current (I_{CARB}) at rest. However it strongly reduced the amplitude of this current at depolarized potentials as well as the current underlying the after-depolarization (I_{ADP}). This indicated that the voltage dependence of I_{CARB} was due, at least partly, to calcium influx. Moreover it suggested the sADP resulted from a calcium induced enhancement of the current responsible for the depolarization. Consistent with this possibility, administration of TEA(2-3 mM), which blocks of depolarization, also inhibited the sADP.

These results suggest that muscarinic receptors activate a voltage and calcium-dependent cation current to depolarize cortical pyramidal cells. Calcium influx during one or more action potentials enhances this current and results in the appearance of a depolarizing afterpotential. Supported by MH 49355.

MUSCARINIC RECEPTORS MEDIATING INWARD AND OUTWARD CURRENTS IN RAT DORSOLATERAL SEPTAL NEURONS. T. Akasu*[1], H. Hasuo[1] and J. P. Gallagher[2] [1]Dept. Physiol., Kurume Univ. Sch. Med., Kurume 830, Japan and [2]Dept. Pharmacol. & Toxicol., Univ. Texas Med. Br., Galveston, Texas 77555, U.S.A.

Cellular mechanism and receptor type responsible for the muscarine-induced currents in dorsolateral septal nucleus (DLSN) neurons were investigated by using slice patch-clamp technique. Bath-application of muscarine (3-100 μM) caused either inward current (I_{mi}) or outward current (I_{mo}) in DLSN neurons. These currents were associated with increase in membrane conductance and were voltage-independent. The reversal potentials of I_{mi} and I_{mo} were -17.0±5.3 mV (n=14) and -90±4.3 mV (n=28), respectively. In subpopulation of neurons, muscarine caused the inward current by suppression of a voltage-dependent, non-inactivating K^+ current, the M-current. The I_{mi} was concentration-dependent; the EC_{50} of I_{mi} and I_{mo} were 23 and 7 μM, respectively. Atropine (0.2 μM) completely reduced both I_{mi} and I_{mo}. Pirenzepine (PZP) also reduced the I_{mi} and the I_{mo} in a competitive manner. Schild plot showed that the Kd for PZP was 120 nM (n=5) in the I_{mi}. Methoctramine (1 μM) competitively depressed the I_{mi} with Kd of 230 nM. AF-DX 116 (1 μM) produced no significant inhibition of the I_{mi}. In contrast, the Kd value for PZP was 54 nA in I_{mo}. AF-DX 116 inhibited the I_{mo} in a competitive manner with Kd of 410 nM. McN-A-343 produced neither inward nor outward current. Intracellular dialysis with GTPγS, a non-hydrolyzable analogue of GTP, irreversibly depressed both the I_{mi} and the I_{mo}. Pre-treatment of DLSN neurons with pertussis toxin (PTX) did not prevent the I_{mi} (n=8), while it completely depressed the I_{mo} (n=8). These data suggest that muscarine causes non-selective cation and K^+ currents acting at M_3 and M_4 subtype receptors, respectively, through different types of G-proteins in DLSN neurons.

A QUINUCLIDINE DERIVATIVE INDUCES AN INWARD CURRENT ASSOCIATED WITH M-POTASSIUM CURRENT INHIBITION IN m1-MUSCARINIC RECEPTOR-TRANSFORMED NG108-15 CELLS.

H. Kishida[a], K. Yamamoto[a], Y. Fuse[a], M. Noda[b], and H. Higashida[b]*. [a]Takasago Res. Lab., Kaneka Corp., Takasago 676, and [b]Depart. of Biophys., Kanazawa Univ. Sch. of Med., Kanazawa 920, Japan

3-(m-phenoxybenzylidene)-quinuclidine (KST-5452) is an M_1-specific ligand with an affinity constant of about 23 nM for rat cerebral cortical membrane. Oral administration of KST-5452 to rats with basal forebrain lesions improves passive avoidance performance. This suggests that KST-5452 has an ameliorating action on amnesia, probably through an effect on the cholinergic central nervous system. The electrophysiological effects of KST-5452 were studied in NG108-15 neuroblastoma x glioma hybrid cells transfected with m1 muscarinic acetylcholine receptor (mAChR) cDNA. Application of 0.1-1 mM KST-5452 (3 µl) on NGPM1-27 cells induced a long-lasting inward current accompanied by a fall in membrane conductance. The average amplitude of the inward current elicited by 1 mM KST-5452 was 0.6 ± 0.3 nA (n=19). Outward current was not observed in 19 NGPM1-27 cells tested. The inward current was accompanied by an inhibition of the amplitude of M-current relaxations (49 ± 11 %, n=10). The results show that KST-5452 mimics only an excitatory part of the ACh-inducd responses in m1-transformed cells and suggest that the ameliorating effect of KST-5452 on amnesia may be due to the increased membrane excitation in brain neurones which results from the inhibition of the M-current.

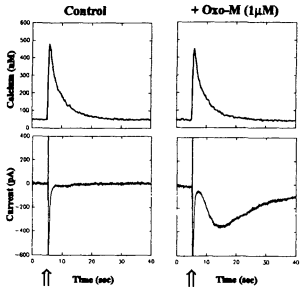
MUSCARINIC ENHANCEMENT OF A NOVEL NEURONAL CHLORIDE CONDUCTANCE.

S. J. Marsh, J. Trousland, J. L. Leaney, C. Stansfeld* & D. A. Brown. Department of Pharmacology, University College London, Gower Street, London WC1E 6BT. UK.

Experiments on cultured mamalian sympathetic neurons, using combined techniques of voltage-clamp perforated-patch recording and microfluorimetric measurements of intracellular Ca^{2+} with indo-1, have disclosed a delayed Cl-current that is synergistically regulated by the actions of raised intracellular Ca^{2+} and muscarinic (m1) receptor-mediated activation of protein kinase C (PKC).



In voltage-clamped (-60mV) Cs-loaded cells at 32 °C, bath application of the muscarinic receptor agonist oxotremorine-M (Oxo-M) did not change the resting intracellular Ca^{2+} concentration or membrane conductance but augmented a slowly developing inward current following an intracellular Ca^{2+} transient induced by a voltage-step (0.2s to 0mV, ⇑ in figure). This effect was mimicked by phorbol esters and blocked by down regulation of PKC and the PKC inhibitor calphostin C. Chloride channel blockers and ion substitution experiments suggest that the slow inward current results from an increased Cl^- conductance.

We also found that a brief application of acetylcholine could induce the delayed chloride current through a conjoint action on both nicotinic receptors (to produce a change in $[Ca^{2+}]_i$) and muscarinic receptors (to increase DAG levels and thereby activate PKC). This demonstrates an unusual form of synergism between two effects of a single transmitter

ACETYLCHOLINE RECEPTOR MUSCARINIC: AGONIST/ANTAGONIST FOR RECEPTORS

801.1

MUSCARINIC RECEPTOR INHIBITION OF AGONIST-STIMULATED CYCLIC AMP IN GUINEA PIG ILEUM.

R. S Ostrom and F. J. Ehlert*. Dept. of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

The longitudinal muscle of the guinea pig ileum contains both M_2 and M_3 muscarinic receptor subtypes. The M_3 subtype couples to phosphoinositide hydrolysis and elicits a direct contraction, whereas the more abundant M_2 subtype inhibits adenylate cyclase and has an indirect role in contraction. In rat ileum only forskolin, isoproterenol, PGE_1 and PGE_2 increased cAMP accumulation, and of these, only responses elicited by forskolin and isoproterenol could be opposed by the M_2 receptor (Griffin *et al., J. Pharmacol. Exp. Ther.* 263(1): 221-5, 1992). The purpose of this study was to characterize similar relationships in the guinea pig ileum. We investigated the ability of oxotremorine-M (oxo-M) to inhibit cAMP accumulation in slices of the guinea pig ileum in the presence of various agonists known to stimulate adenylate cyclase. Appreciable stimulation of cAMP (>50% over basal) was observed with maximal concentrations (1-10 µM) of forskolin, isoproterenol, PGE_1, PGE_2 and PGI_2, with fold stimulations over basal of 14.93, 2.51, 2.27, 2.28 and 1.52, respectively. Moderate cAMP stimulation (25 - 50% over basal) was seen using dopamine, 5-HT, 5-methoxytryptamine, dimaprit and VIP. Little or no effect (<25% over basal) was observed with SKF-38393, 2-chloroadenosine, CGS-21680, PGD_2, secretin and vasopressin. Oxo-M (1 µM) inhibited cAMP accumulation by 35% under basal conditions, while forskolin- and isoproterenol-stimulated cAMP was inhibited by 73 and 61%, respectively. Oxo-M inhibited PGE_1- and PGE_2-stimulated cAMP by 48 and 56%, respectively, but only inhibited PGI_2-stimulated cAMP by 33%, a value no greater than the oxo-M effect on basal cAMP. Oxo-M inhibition of cAMP accumulation in the presence of the other agonists with moderate or no stimulation of adenylate cyclase was less than or equal in magnitude to its effects on basal cAMP. Our results show that only forskolin, isoproterenol, PGE_1, and PGE_2 cause an appreciable increase in cAMP that is opposed by muscarinic stimulation, suggesting that the relaxing effects of these agents may be specifically inhibited by the M_2 receptor. (Supported by NIH grant NS30882)

801.2

Sequestration of muscarinic acetylcholine receptors.

H. Tsuga, E. Okuno, K. Kameyama, and T. Haga*, Inst. for Brain Research, Univ. of Tokyo, Tokyo 113, Japan.

Sequestration of muscarinic acetylcholine receptors (m1-m5), which was assessed as loss of [^{3}H]N-methylscopolamine binding activity from the cell surface, was examined in COS-7 cells that had been transiently transfected with muscarinic receptors and G protein-coupled receptor kinase (GRK2 = βARK1) or GRK2 dominant-negative mutant (DN-GRK2). The agonist-dependent phosphorylation and sequestration of m2 receptors were facilitated by co-expression of GRK2, and reduced by co-expression of DN-GRK2. The sequestration of m4 receptors was observed by treatment with 10^{-5} M or higher concentrations of carbamylcholine and 40% of m4 receptors were sequestered by treatment with 10^{-4}-10^{-3} M of carbamylcholine for 2 hours. When GRK2 was co-expressed, 35% of m4 receptors were sequestered by treatment with 10^{-6} M of carbamylcholine and 65% of m4 receptors were sequestered by treatment of 10^{-4} -10^{-3} M of carbamylcholine for 2 hours. Co-expression of DN-GRK2 reduced the sequestration of m4 receptors to less than 25%. For m1, 3, 5 receptors, only less than 25% of receptors were sequestered by treatment of 10^{-4} -10^{-3} M of carbamylcholine for 2 hours. These results indicate that the phosphorylation of m2 and m4 receptors by GRK2 facilitates their sequestration and the mechanism of sequestration may be different between m2, 4 receptors and m1, 3, 5 receptors.

801.3

BUTYLTHIO[2.2.2]: AN ORALLY ACTING MUSCARINIC ANTINOCICEPTIVE IN RODENTS.

M. D. B. Swedberg*[1], M. J. Sheardown[1], P. Sauerberg[1], P. Olesen[1], P. D. Suzdak[1], F. P. Bymaster[2], J. S. Ward[2], C. H. Mitch[2], D. O. Calligaro[2] and H. E. Shannon[2]. Novo Nordisk, Drug Discovery, Neuroscience, Malov, Denmark (1), and Eli Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN, U.S.A. (2).

Butylthio[2.2.2](+)-3-[4-(butylthio)-1,2,5-thiadiazol-3-yl]-1-azabicyclo [2.2.2]octane) is a muscarinic agonist/antagonist at muscarinic receptors in vitro. The analgesic effect of butylthio[2.2.2] was assessed in the Grid Shock, Tail Flick, Hot Plate, and Writhing tests in mice 30 min after s.c. or p.o. administration. ED_{50}'s (mg/kg) ranged from 0.12 - 3.5 (s.c.) and 1.15 - 19.0 (p.o.), yielding s.c./p.o. ratios of 5 - 20. ED_{50}'s (mg/kg) for the muscarinic side effects salivation or tremor were 13.5 (s.c.) and >60 (p.o.), yielding therapeutic windows > 50. Butylthio[2.2.2] was equieffective too, and 3 - 23 times more potent than morphine. Butylthio[2.2.2]'s duration of action was similar to morphine's (160 min). The dose response curve was shifted to the right by the muscarinic antagonist scopolamine but not by the opioid antagonist naltrexone. After 6.5 days repeated dosing there was marked tolerance to morphine, but less, if any, to butylthio[2.2.2]. In the rat Grid Shock ED_{50}'s (mg/kg) of 0.3 (s.c.) and 22.0 (p.o.) mg/kg were obtained. These data show that butylthio[2.2.2] potently and efficaciously produces antinociception after s.c and p.o. administration in mice and rats.

MOLECULAR STUDIES OF AGONIST INTERACTIONS WITH m1 MUSCARINIC RECEPTORS.

W.S. Messer, Jr.*, M.A.N. Edgar, B. Ojo, H. Zhang, J.J. Huzl, III and A.A. El-Assadi Department of Medicinal & Biological Chemistry, Center for Drug Design & Development, College of Pharmacy, The University of Toledo, Toledo, OH 43606

Selective muscarinic agonists might be useful in the treatment of Alzheimer's disease. Previous studies identified several amidine derivatives as efficacious m1 agonists. For example, 5-(3-methyl-1,2,4-oxadiazol-5-yl)-1,4,5,6-tetrahydropyrimidine (CDD-0098) displays high activity at m1 receptors. To explore the structure activity relationships of muscarinic receptor ligands, a novel isoxazole derivative was synthesized and tested for m1 receptor affinity and activity in A9 L cells.

5-(3-Methyl-isoxazol-5-yl)-1,4,5,6-tetrahydropyrimidine (CDD-0190) inhibited [^{3}H]-(R)-QNB binding to m1 receptors in a biphasic manner with 59 % of the sites at 1.6 µM and 41 % at 60 µM. CDD-0098 displayed higher affinity; 31 % at 21 nM and 69 % at 2.3 µM. CDD-0190 also stimulated PI metabolism through m1 receptors with an EC_{50} of 92 µM and maximal stimulation at 290 % above basal levels. CDD-0098 was both more potent (5.4 µM) and efficacious (640 %) in stimulating PI turnover in A9 L cells.

Molecular modeling studies, using a model of the m1 muscarinic receptor developed by Nordvall and Hacksell (*J. Med. Chem.* **36**:967-976, 1993), suggested that the isoxazole exhibits lower activity due to the loss of a hydrogen bonding interaction with threonine192 of the m1 receptor. The data provide the basis for a systematic evaluation of the molecular features important for binding and activity at muscarinic receptor subtypes.

801.5

FUNCTIONAL CHARACTERIZATION OF A SERIES OF NOVEL 1,4,5,6-TETRAHYDROPYRIMIDINE DERIVATIVES AS SELECTIVE MUSCARINIC AGONISTS. A.A. El-Assadi*, S.M. Abunada, R. Sehgal, K. Ryan, M.A. Shepherd and W.S. Messer, Jr. Department of Medicinal & Biological Chemistry, Center for Drug Design & Development, College of Pharmacy, The University of Toledo, Toledo, OH 43606

Selective muscarinic agonists might be useful in the treatment of Alzheimer's disease. Previous studies identified several amidine derivatives as selective and efficacious m1 agonists. 5-Ethyloxycarbonyl-1,4,5,6-tetrahydropyrimidine (CDD-078), 5-propargyloxycarbonyl-1,4,5,6-tetrahydropyrimidine (CDD-097), and 5-(3-ethyl-1,2,4-oxadiazol-5-yl)-1,4,5,6-tetrahydropyrimidine (CDD-102) display high efficacy at m1 receptors and lower activity at m3 receptors expressed in A9 L cells.

Functional selectivity for M_1 receptors was confirmed through a series of biochemical and behavioral studies. Pirenzepine was more effective than either AF-DX 116 or p-F-HHSiD in blocking the stimulation of PI turnover in rat cerebral cortex by each agonist. Pharmacological screening indicated few cholinergic side-effects (e.g., salivation, hypothermia) for each agonist following i.p. injections in mice. Finally, i.p. injections of CDD-097 (1.0 mg/kg) reversed spatial memory deficits induced by i.c.v. administration of hemicholinium-3 (5 µg) in a modified Morris water maze task. Taken together, the data indicate the functional selectivity of these compounds, which warrant further development as M_1 agonists for the treatment of Alzheimer's disease.

MUSCARINIC AGONIST STIMULATION OF CYCLIC AMP ACCUMULATION IN PERTUSSIS TOXIN-TREATED CHO-m4 CELLS. Kris Eckols and Neil DeLapp*, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Indiana 46285

Of the five molecularly defined subtypes of muscarinic receptors, the m2 and m4 proteins are negatively coupled to adenylate cyclase. However, Jones et. al.(Mol Pharm 40: 242-247, 1991) reported a large atropine-inhibitable increase in cAMP formation induced by the muscarinic agonist carbachol in CHO-m4 cells that had been treated with pertussis toxin (PTX). The purpose of the present study was to characterize the pharmacology of muscarinic-mediated cAMP accumulation in PTX-treated CHO-m4 cells. Subconfluent CHO-m4 cells were treated for 18 hours with 100 ng/ml PTX. Cells were harvested with trypsin and were incubated in suspension for ten minutes in the presence of 1 µM forskolin ± the compounds tested. Incubations were terminated by boiling and cAMP was determined with an enzyme immunoassay. Antagonist dose-response curves were determined for reversal of stimulation by 10 µM oxotremorine M. Oxotremorine M stimulated an 8-10 fold increase in cAMP formation (EC50: 2.2 ± 1.1 µM) that was blocked by 1 µM atropine. A series of standard agonists exhibited a wide range of partial agonist activities (relative to oxotremorine M as 100): acetylcholine, 106; carbachol, 92; arecoline, 77; S-aceclidine, 69; muscarine, 63; bethanechol, 42; McN-A-343, 33; R-aceclidine, 13; pilocarpine, 11; and RS 86, 7. Estimated Ki's for antagonists were: atropine, 1.3; 4-DAMP, 3.6; dicyclomine, 40; PFHHSiD, 175; pirenzepine, 180; and AFDX 116, 1490. The rank order of antagonist potencies was the same as reported for m4-mediated inhibition of adenylate cyclase in rat striatum (Olianas and Onali, J. Pharm. Exp. Ther. 259: 680-686, 1991). Thus, in CHO-m4 cells lacking a functional Gi protein, the robust muscarinic stimulation of cAMP formation (16-20 fold over inhibition of forskolin-stimulated cAMP formation in non-PTX-treated cells) has a typical m4 pharmacology and readily discriminates full from partial muscarinic agonists.

NEOSTIGMINE APPEARS TO ACTIVATE MUSCARINIC RECEPTORS ON MUDPUPPY PARASYMPATHETIC POSTGANGLIONIC NEURONS. J.C. Hardwick, R.L. Parsons and S.B. Backman.* Dept. of Anatomy & Neurobiology, University of Vermont, Burlington, Vermont, 05405 and Dept. of Anaesthesia, Royal Victoria Hospital, McGill University, Montreal, Quebec, H3A 1A1.

Indirect evidence from *in-vivo* studies in cats suggests that the bradycardia produced by systemic administration of the anticholinesterase neostigmine may be mediated, in part, by direct activation of muscarinic receptors on cardiac parasympathetic postganglionic neurons (J Pharm Exp Ther 1993 265:194). In the present investigation, this possibility was examined more directly by studying the effect of direct application of neostigmine to individual parasympathetic postganglionic neurons of the mudpuppy (*Necturus maculosus*) cardiac ganglia. Previous studies in these neurons have shown that muscarinic agonists activate an inwardly rectifying potassium conductance via m2 receptors (Neuropharmacol 1992 31:1311). Neurons were impaled with an intracellular recording electrode and the voltage responses to brief (1-3 sec) pressure ejections of either neostigmine (10^{-4}M) or the muscarinic agonist oxotremorine (10^{-4}M) were examined. Neostigmine and oxotremorine applications produced hyperpolarizations of 20.4 ± 3.2 mV, n=10 & 30.2 ± 3.3 mV, n=8, respectively). Neither response was affected by superfusion with the nicotinic antagonist hexamethonium (100 µM). However, the neostigmine-and oxotremorine-induced hyperpolarizations were reversibly inhibited by both non-selective (atropine 1 µM) and selective m2 (gallamine 20 µM; AFDX-116 1 µM) muscarinic antagonists. The neostigmine-induced hyperpolarization was associated with a decrease in input conductance and appeared to reverse near the potassium equilibrium potential. These results suggest that neostigmine may activate m2 receptors on cardiac parasympathetic postganglionic neurons, independent of its anticholinesterase activity. NOVEL MUSCARINIC M1 RECEPTOR AGONISTS PROMOTE SURVIVAL OF CNS NEURONS IN PRIMARY CELL CULTURE. J. Alberch*[1,2], D. Gurwitz[3,4], A. Fisher[3] and H.T.J. Mount[1]. [1]Dept. of Neuroscience and Cell Biology, Robert Wood Johnson Medical School-UMDNJ, Piscataway, NJ 08854, [2]Dept. de Biologia Cel.lular i Anatomia Patologica, Univ. Barcelona, Spain, [3]Israel Institute for Biological Research, Ness-Ziona, Israel and [4]Sackler Faculty of Medicine, Tel-Aviv University, Israel.

We reported previously that muscarinic receptor (mACh-R) activation increases survival of cultured Purkinje cells, grown in the presence of NGF (Mount *et al.* 1994, J. Neurochem. *63*, 2065). In the present study, we examined the trophic potential of a novel series of specific m1ACh-R partial agonists in primary cultures of cerebellum and striatum. These compounds (AF150(S), AF151(S) and AF102B) stimulate release of arachidonic acid and activate phospholipase C, but do not affect adenylyl cyclase in cell lines transfected with m1AChR gene.

Dissociated cultures of gestational day 18 (E18) rat cerebellum were grown for 6 days in the presence of drug +/- NGF. The m1AChR agonists elicited dose-dependent increases in Purkinje cell survival, that were pirenzepine (10 nM) sensitive. NGF potentiated the trophic action of low agonist concentrations (1-10 µM). NGF also improved Purkinje survival, when administered in combination with exogenous arachidonic acid.

To examine whether muscarinic mechanisms regulate survival in other brain areas, agonists were tested in cultures of E18 striatal neurons. AF150(S) elicited dose-dependent increases in cell number, at 7 days *in vitro*. Improvements in survival were paralleled by enhancement of [^{3}H]GABA uptake, suggesting that GABAergic neurons were affected.

In sum, m1ACh-R activation improves survival of diverse populations of cultured primary neurons. Receptor coupling to phospholipase C and/or arachidonic acid release may underlie these actions. (Supp: Medical Research Council [Canada] and Ministerio de Educacion y Ciencia [Spain].)

METHOXYPHENETHYLAMINE-ERGOLINE "HYBRIDS": NOVEL MUSCARINIC LIGANDS. M.A. Mayleben[1*], A. Monte[2], W. Roeske[3], H. Yamamura[3], R.B. Mailman[1], and D.E. Nichols[2]. Univ. of North Carolina[1], Chapel Hill, NC 27599, and Purdue Univ.[2], W. Lafayette, IN. 47907, Univ. of Arizona[3], Tempe, AZ

Among the deficits seen in Alzheimer's Disease are decreased levels of acetylcholine (ACh) in several brain regions. Attempts to remedy this deficit using either increased dietary choline or cholinesterase inhibitors have had very limited success. Direct pharmacotherapy has been plagued by the lack of selectivity of available drugs in discriminating among the five muscarinic receptors (m1-m5) that have been cloned to date. All of these receptors are in the G-protein superfamily, with the m1 and m3 receptors linked to PI hydrolysis, and the m2 and m4 receptors negatively coupled to adenylate cyclase (AC). Localization studies indicate that the muscarinic receptors are found in the heart (mostly m2), salivary and sweat glands, and brain. In the brain, m2 receptors are found predominantly presynaptically, while the m1 receptors are found postsynaptically. This pattern has suggested that an ideal Alzheimer's drug would be an agonist at the m1 receptor while having no affinity or even antagonistic effects at the m2 receptor. During the screening of aminotetrahydronapthofurans (NAPs) designed as serotonergic ligands, certain members were found to have nanomolar affinity at the m1 muscarinic receptor in brain, with seven times lower m2 and little m3 activity. These compounds were studied further in a murine fibroblast cell line (B82) transfected with either the m1 or the m2 receptor. In these lines, bromoNAP had higher affinity (m1 K_I = 14 nM; m2 K_I = 30 nM) than the parent drug (NAP) (m1 K_I = 149 nM; m2 Ki = 335 nM), whereas a second analog (N,N-dimethylNAP) had little affinity for these receptors (m1 K_I = 846 nM; m2 K_I = 943). Functional studies at both the m1 and m2 receptors demonstrated that all of these drugs were antagonists. Although these functional characteristics suggest the compounds will not have utility as therapy in AD, this class is unusual for high affinity muscarinic ligands in that they are primary amines.

801.10

IN VIVO EFFECTIVENESS OF SELECT M_2 ANTAGONISTS. M.J. Stillman*[1], B. Shukitt-Hale[1], A. Levy[2], and H.R. Lieberman. Military Performance and Neuroscience Division, United States Army Research Institute of Environmental Medicine, Natick, MA 01760-5007, [1]GEO-CENTERS, INC., Newton Centre, MA 02159, and [2]IIBR, Ness Ziona, ISRAEL.

The central cholinergic system has been shown to exhibit presynaptic modulation of acetylcholine (ACh) release. Although still under investigation, evidence from physiological and pharmacological studies suggests that the M_2 receptor subtype acts as a negative autoreceptor. This *in vivo* microdialysis study examined the effects of the M_2 antagonists, methoctramine, AF-DX 116, AF-DX 384, and AQ-RA 741, on hippocampal extracellular ACh levels. Drug (2, 4, 8, or 16 µM) or vehicle (Ringer's solution) was perfused via a microdialysis probe into the CA1 hippocampal region of freely-moving male Fischer 344 rats. Levels of ACh were assessed by HPLC-EC. All compounds significantly elevated ACh levels. When the dose-response functions were expressed as Kd multiples, the drugs were found to be on the same linear dose-response curve, with certain exceptions. These results support the concept that the proposed presynaptic mechanism of action of these drugs is M_2 receptor-based.

801.11

AN AGONISTIC EFFECT OF ATROPINE. P.S. Guth*, F.R. Domer, C.H. Norris, S. Masetto and P. Valli. Dept. of Pharmacol., Tulane Med. Sch., New Orleans, LA 70112 and Ist. Fisiol. Gen. Univ. Pavia, Pavia, Italy.

According to pharmacological theory (Paton, 1961) even antagonists should cause receptor activation, initially, before tight binding occurs. Hanf *et al.* (1993) reported on just such an agonistic effect of atropine (Atr) on muscarinic receptors of cardiac myocytes. The present observation occurred when Atr was used in an attempt to identify the receptor involved in an effect of acetylcholine (ACh) on sensory cells (hair cells) isolated from the frog saccule. The application of Atr (nM-μM) produced changes in currents similar to those produced by ACh in voltage-clamped isolated hair cells. Further, ACh and Atr seemed to be additive in their effects. We then went on to demonstrate that Atr had agonistic effects in vestibular organs *in vitro*. In both semicircular canal and saccule, Atr (pM-nM) facilitated afferent firing rates similarly to ACh. The saccule was significantly more sensitive to Atr's effect than the semicircular canal. Denervation of the efferent, cholinergic innervation of these organs did not alter their responses to Atr. At higher concentrations, Atr has been shown to antagonize the facilitatory effects of ACh in vestibular organs (Housley, *et al.* 1990; Guth *et al.* 1994). Thus, Atr exerts an ACh-like agonistic effect in these organs. Supported by Grant DC 00303 of the N.I.H.

801.12

HEPARIN INTERACTION WITH MUSCARINIC RECEPTORS; SUBTYPE SELECTIVITY AND MECHANISM OF ACTION. Esam E. El-Fakahany*, Shou Zhen Wang and Randee Edmundson. Division of Neuroscience Research in Psychiatry, University of Minnesota Medical School, Minneapolis, MN 55455.

The selectivity of heparin in its positive cooperative effects in influencing binding of antagonist muscarinic receptor ligands was investigated at the five known subtypes of muscarinic receptors. The effects of heparin on binding of [^{3}H]N-methylscopolamine at equilibrium was studied in CHO cells which express each of the individual muscarinic receptor subtypes and in membranes prepared from these cells. Heparin significantly increased equilibrium binding of subsaturating concentrations of the ligand only in membranes of CHO-m2 cells. These effects of heparin were similar to those obtained in cardiac membranes. Heparin did not influence ligand binding to m2 receptors in intact cells, suggesting an action of heparin at a cytoplasmic domain of the receptor or at an intracellular protein which is coupled to m2 muscarinic receptors. The positive cooperative effects of heparin at m2 muscarinic receptors were nearly abolished upon treatment of cells with pertussis toxin. These results suggest that the effects of heparin on ligand binding to m2 muscarinic receptors require an intact interaction between the receptor and G-proteins.

801.13

ANTICHOLINERGIC ANTIPARKINSON DRUGS ARE POTENT ANTAGONISTS OF MUSCARINIC INHIBITION OF D1-STIMULATED ADENYLYL CYCLASE IN RAT STRIATUM. P.Onali* and M.C. Olianas, Dept. of Neurosciences, Univ. of Cagliari, Cagliari, Italy.

Antimuscarinic drugs have long been used for the treatment of Parkinson's disease and extrapyramidal motor disturbances caused by neuroleptics. However, the mechanisms underlying this therapeutic benefit have not been elucidated. Previously, we have reported that in rat striatum muscarinic receptor activation inhibits dopamine (DA) D1 receptor function, as indicated by the reduced DA stimulation of adenylyl cyclase. In the present study we have investigated the ability of various antimuscarinic drugs currently used in the treatment of Parkinson's disease to antagonize the carbachol (CCh) inhibition of adenylyl cyclase activity stimulated by the selective DA D1 agonist (±) SKF 82958. We have found that trihexyphenidyl, benztropine, biperiden, procyclidine and ethopropazine are potent antagonists of CCh inhibitory effect with Ki values ranging from 4.0 to 30 nM. Moreover , there is a good correlation (r = 0.95) between the Ki values and the average clinical doses of the drugs. These data suggest that the removal of a muscarinic inhibitory tone on D1 receptor activity may be one of the mechanisms by which the anticholinergic drugs exert their antiparkinsonian effect.

801.14

STRUTURAL BASIS OF ANTAGONIST BINDING TO m1 AND m2 MUSCARINIC RECEPTORS USING SITE-DIRECTED MUTAGENESIS. M.A.B. TICE*, L.A. TAYLOR, T. HASHEMI AND R.D. McQUADE. CNS Pharmacology, Schering-Plough Research Institute, Kenilworth, NJ 07033

Pharmacological characterization of the muscarinic receptors has been based on affinity for the M1 and M2 selective antagonists, pirenzepine (PZ) and AFDX-116, respectively. The molecular cloning and sequencing of the five muscarinic receptor genes have advanced our ability to investigate receptor binding using such tools as site-directed mutagenesis. In an attempt to map antagonist binding and to probe receptor selectivity, we have performed site-directed mutagenesis on the human m1 and m2 receptor genes. Corresponding sequnces were exchanged between the receptor genes. Mutants were constructed that replaced uncharged residues in m1 (Leu174-Ala175-Gly176-Gln177) with the corresponding charged residues of the m2 sequence (Glu172-Asp173-Gly174-Glu175). Another mutant involved the replacement of the charged Glu397 in m1 with Asn of m2. A similar mutant was constructed in m2 which changed Asn419 to Glu. Radioligand binding studies conducted with these mutants show 2 to 3 fold increase in affinity for PZ by the m2 mutants and a 2 fold increase in affinity of the m1 mutant Asn 397 for the m2 selective antagonist, himbacine.

Site-directed mutagenesis studies performed by Fraser,et al. Mol. Pharm. 36:840(1989) on conserved aspartate residues of the m1 receptor revealed the importance of Asp105 for antagonist binding. We like others have investigated the effect of mutation of conserved amino acids around this pivotal residue. Mutation of the conserved Trp residue in m1 and m2 at positions 101 and 99, respectively, have been constructed. Construction of mutants in the muscarinic receptor family have given insight into the basis of receptor selectivity for various antagonists.

ACETYLCHOLINE RECEPTOR MUSCARINIC: RECEPTORS—EXPRESSION

802.1

***IN SITU* HYBRIDIZATION STUDIES OF THE EXPRESSION OF MUSCARINIC RECEPTOR SUB-TYPE mRNA IN AGED MEMORY-IMPAIRED AND UNIMPAIRED LONG EVANS RATS.** H. Le Jeune*, J-G. Chabot, W. Rowe, M. Meaney and R. Quirion. Douglas Hospital Res. Ctr., Dept. Psychiat. McGill Univ., 6875 Boul. LaSalle, Montreal, Canada H4H 1R3.

We recently reported that the apparent densities of muscarinic M2-like / [^{3}H]AF-DX 384 binding sites are not decreased, but indeed increased, in various cortical and hippocampal areas of 24-25 month-old memory-impaired (AI) vs aged memory-unimpaired (AU) Long Evans rats behaviorally-assessed using the Morris Water Maze (Quirion et al., J. Neurosci., 15:1455, 1995; Aubert et al., Neuroscience, in press). Increases in M2-like receptor binding densities were correlated with altered acetylcholine release, and behavioral improvements were noted following treatment with a potent antagonist, BIBN99 (Quirion et al., ibib). In order to determine if changes in M2-like receptor levels were of genomic/transcriptional nature, the expression of molecularly-defined m1, m2, m3 and m4 receptor mRNAs was studied in the AI/AU model using quantitative *in situ* hybridization and ^{35}S-labeled riboprobes complementary to human muscarinic receptors cDNA sequences (Bonner et al., Science 237:527-532, 1987). Specific mRNA transcripts for each of these four muscarinic receptors are expressed in the rat brain according to a unique profile of distribution globally, but not fully, in accordance with earlier results obtained with oligonucleotides. The apparent level of expression of each mRNA transcript was not significantly different in any regions of the AI vs AU rat brains or between 6-month old Long Evans adult rats and 24-25-month old aged animals. Accordingly, increases in [^{3}H]AF-DX 384 binding sites are not associated with changes in the expression of the m2 and m4 transcripts, the two genes coding for pharmacological-defined M2 receptors recognized by [^{3}H]AF-DX 384. It thus suggests post-transcriptional and/or receptor recycling modifications leading to apparent increases in receptor protein levels in the AI group. Supported by MRCC.

802.2

IN VIVO UPTAKE OF I-123 QNB STEREOISOMERS IN HUMAN BRAIN. R. Coppola*, M.B. Knable, D.W. Jones, J. Gorey, K.S. Lee, D.R. Weinberger. NIMH, IRP, CBDB, 2700 M.L. King Jr. Ave., S.E., Washington, D.C., 20032

I-123 QNB, a radioligand antagonist for muscarinic receptor imaging, has four stereoisomers which have not been fully characterized in vivo in humans. Two normal subjects (aged 34 and 75), underwent SPECT studies with the RS, RR, SR and SS stereoisomers of I-123 QNB in separate scanning sessions. Prolonged time-activity data over a period of 22 hours were obtained . Regions of interest (ROIs) were drawn on MRI scans co-registered with SPECT scans. All isomers produced scans with no detectable binding in the cerebellum. The RS isomer produced scans with the most rapid accumulation of specific binding. The RR isomer produced scans with a slower accumulation and lower peak of specific binding. The SR and SS isomers yielded scans with an early peak of few counts and little anatomic segregation of ligand distribution. The table displays the peak binding for both subjects in cpm/mCi/ml.

	RS		RR		SR		SS	
	young	old	young	old	young	old	young	old
Thalamus	1.4	48.3	5.4	5.5	5.2	6.8	1.4	1.2
Putamen	35.2	139.5	10.1	47.3	4.8	8.8	1.6	1.5
Occ. Ctx.	14.0	134.5	7.2	24.2	3.4	6.3	0.49	0.78

These data, in combination with previous in vitro work (Gibson, J. Nuc. Med., 1984), suggest that the RS and RR isomers have different affinities at the M1 and M2 receptor subtypes that may be discernible in vivo. Also, there appears to be an age related increase in the number of unoccupied M1 and M2 receptor subtypes.

802.3

SUBTYPE-SPECIFIC REGULATION OF MUSCARINIC RECEPTOR EXPRESSION AND FUNCTION BY HETEROLOGOUS RECEPTOR ACTIVATION. D. A. Jackson* and N. M. Nathanson, Department of Pharmacology, University of Washington, Seattle, Washington 98195.

Incubation of cultured embryonic chicken heart cells with the β-adrenergic agonist isoproterenol resulted in a dose-dependent increase in the number of mAChR on the surface of intact cells. The isoproterenol-mediated increase in mAChR number was time-dependent and reached a maximum by 48 hours. Chick heart cells treated with isoproterenol exhibited a greater than 6 fold increase in the sensitivity for carbachol-mediated inhibition of adenylyl cyclase activity as compared to control. Stimulation of cultured heart cells for 24 hours with isoproterenol resulted in a 25-35 % increase in cm2 mRNA levels as compared to control cm2 mRNA levels. In contrast, the level of cm4 mRNA was not significantly affected by isoproterenol treatment. cm2 mRNA levels were maximally elevated by fifteen hours following isoproterenol stimulation and remained elevated for up to 72 hours. Incubation of cells with isoproterenol in the presence of Rp-cAMP, an inhibitor of cAMP-dependent protein kinase, blocked the increase in the level of cm2 mRNA. Thus, prolonged activation of β-adrenergic receptor results in an increase in mAChR number and muscarinic responsiveness in chick heart cells due to a cAMP-dependent protein kinase mediated increase in cm2 mRNA levels.

802.4

LOCALIZATION OF MUSCARINIC ACETYLCHOLINE RECEPTOR SUBTYPES IN HUMAN BRAIN USING BY SUBTYPE SPECIFIC ANTIBODIES. Shiozaki K.[1], Uchiyama H.[2] and Nakata H.*[3] [1] Fukushimura Hospital, 19-14 Yamanaka Noyoricho Toyohashi 441 Japan [2]Dept. of Neurosurgery, Hamamatsu Redcross Hospital [3]Dept. of Pharmacology, National Defence Medical College.

We have attempted to generate subtype specific antibodies against muscarinic acetylcholine receptor subtypes(mAChR, m1-m4) and to examine their distributions in human brain. Large regions of the third cytoplasmic loops(i3) of the porcine(m1, m2) and rat(m3,m4) receptors were expressed as fusion proteins and used for immunization. Each antiserum immunoprecipitated each subtype of mAChR expressed in Sf-9(m1, m2 and m4) or CHO(m3) cells in a subtype-specific manner. Membrane fractions were prepared from postmortem human brains(80 year old male, 85 year old female, 91 year old male), histopathologically diagnosed as normal aging. Concentrations of mAChRs in different regions of the brain of these preparations as determined by ^{3}[H]QNB binding were 1250±66(frontal cortex), 1028±159 (hippocampus), 1685±329(caudate nucleus) and 984±119(thalamus) f mol /mg protein. mAChRs were prelabeled with ^{3}[H]QNB, then solubilized with 1% digitonin and 0.1% cholate and immunoprecipitated with antisera. The proportions of specifically precipitated mAChR subtypes were estimated as the differences in the amounts of bound ^{3}[H]QNB precipitated with specific antibody and those precipitated with non immune serum. The estimated percentages were as follows:frontal cortex (m1:38.1±1.3, m2:9.1±0.9, m3:6.3±1.1, m4:5.8±3.3), hippocampus(m1:40.2±2.4, m2:9.0±0.3, m3:5.6±0.6, m4:4.9±2.7), caudate nucleus(m1:43.7±2.4, m2:12.5±2.4, m3:4.1±0.9, m4:7.0±3.1) and thalamus(m1:3.6±6.4, m2:46.0±6.8, m3:4.6±2.8, m4:-1.3±0.8).

EXPRESSION OF MUSCARINIC M3 RECEPTORS mRNA IN HUMAN BRAIN MICROVASCULAR FRACTIONS, ASTROCYTES AND VASCULAR CELLS IN CULTURE. D.G. Linville*[1], Z. Cohen[2], A. Olivier[2], W.V. Yong[2], D. Stanimirovic[3], and E. Hamel[2]. [1]Mercyhurst Coll, Erie, PA, 16546 USA, [2]Montreal Neurological Institute, McGill Univ, Montréal, QC, Canada H3A 2B4 and [3]National Research Council of Canada, Ottawa, ON, Canada.

Subtype specific muscarinic acetylcholine receptors (mAChR) have been identified pharmacologically in human isolated cerebral microvessels (MVs) and capillaries (CAPs), of which the M3 subtype is thought to mediate relaxation (Linville & Hamel, *Naunyn-Schmied. Arch. Pharmacol.*, in press). We investigated the expression of m3 mAChR mRNA by reverse-transcriptase/polymerase chain reaction (RT/PCR) and/or IP_3 production in isolated human cortical MVs and CAPs obtained post-mortem, astrocytes cultured from human fetal brain (HFBA) and subcloned endothelial (HBEC) or primary cultures of smooth muscle (HBSM) cells. The latter were respectively dissociated from CAPs (< 112μm) or MVs (> 112 or > 350μm) isolated from human temporal lobe excised at surgery for the treatment of epilepsy. MVs, CAPs and HBEC were all enriched in γ-glutamyl transpeptidase and alkaline phosphatase. HBEC and HFBA were respectively and selectively immunopositive for Factor-VIII and GFAP. Gel electrophoresis of the PCR products generated with specific m3 mAChR oligonucleotide primers yielded a band of the expected size in preparations of human MVs (n=3), CAPs (n=3), HBFA (n=3), HBSM (n=2), but not HBEC (n=4). However, mAChR agonist bethanechol (1mM) moderately increased (~70%) IP_3 production in HBEC. These results show that m3 mAChR mRNA is expressed in freshly isolated human cortical MVs, CAPs as well as in astrocytes and primary cultures of smooth muscle cells, and that HBEC express mAChRs couple to phospholipase C activation. Further work is needed to explain to apparent discrepancy between HBEC and freshly isolated CAPs (mainly enriched in endothelial cells) in m3 mAChR expression. Supported by MRC and NRC of Canada and a McGill major studentship (Z.C.).

OXIDATIVE BURST IN NEURONAL CELLS AFTER MUSCARINIC STIMULATION. J. Naarala*, P. Tervo, J. Loikkanen and K. Savolainen[1]. National Public Health Institute, Department of Toxicology, P.O.B. 95, FIN-70701 Kuopio, and [1]Department of Environmental Sciences, University of Kuopio, Finland.

The effects of a muscarinic receptor agonist, carbachol (CCh), on the production of reactive oxygen metabolites (ROM) and the levels of the intracellular glutathione (GSH) were studied in human SH-SY5Y neuroblastoma cell line. ROM and GSH were measured by using fluorescent probes, dichlorofluorescin (DCF) and monochlorobimane (MBCL), respectively. The translocation of protein kinase C (PKC) to the cell membrane was measured by phorbol dibutyrate (PDBu) binding and muscarinic receptor number was assayed by using quinuclidinylbenzilate (QNB) binding in intact SH-SY5Y cells. One millimolar CCh increased ROM production 1.87 fold at 60 min, 2.37 fold at 120 min, and 3.0 fold at 180 min as compared to the control values. However, CCh, at a concentration of 500 μM, caused only a slight increase in ROM production, and values obtained with 100 μM CCh remained at control levels. Intracellular GSH levels decreased by about 25% when the cells were incubated for 120 min with 1 mM CCh. However, GSH levels returned back to the control level after 180 min incubation. PDBu binding (B_{MAX}) increased by 73% after 20 min incubation with 1 mM CCh as compared to the control cells. Also 500 μM CCh increased in PDBu binding 33-54% as compared to corresponding controls, i.e. PKC translocation to the membrane was enhanced. QNB binding (B_{MAX}) increased by 166% after 60 min incubation with 1 mM CCh, and returned back to the control level after 180 min incubation. We conclude that muscarinic receptor stimulation with CCh may cause oxidative stress in human neuroblastoma cells. Oxidative burst in neuronal cells may be partially routed through PKC, because increase in PDBu binding is a prerequisite for the production of ROM. However, there may be other effector mechanisms that have to be activated prior to the production of ROM. Supported by the Academy of Finland.

MUSCARINIC ACETYLCHOLINE RECEPTOR EXPRESSION IN DIABETIC RAT BRAIN. M.E. Morton*, T.N.Clancy, D.W. Laidlaw, and C.E. Sanz, Department of Biology, College of the Holy Cross, Worcester, MA 01610.

Current evidence suggests that neuropathies are a common complication associated with human insulin-dependent diabetes mellitus (IDDM). Although structural and functional changes occur in neural tissues in individuals with diabetes, the molecular mechanisms responsible for aberrant neural function and structure in diabetes are not understood. The BB diabetic rat is an appealing system in which to study these mechanisms since the BB rat model closely resembles human IDDM. The muscarinic acetylcholine receptor (mAChR) is the major receptor for acetylcholine in the brain and its expression has been shown previously to be affected by insulin. Therefore, the neuronal mAChR pathway is most likely affected in diabetes. To investigate the expression of the mAChR and downstream targets in diabetes in order to begin to dissect the role of altered mAChR function in the development of diabetic neuropathies, [^{3}H]QNB binding analysis was performed on brain tissue homogenates from male diabetic BB rats vs. age- and sex-matched control rats. Diabetic rats were provided with insulin up to 30 hours prior to analysis. The data demonstrate a two-fold increase in expression of mAChR in diabetic rat brain This change is specific for mAChR expression and not downstream components of the signaling pathway since neither G-protein (Gβ, Giα1, Giα2, Giα3, Gs, or Go) nor voltage-gated calcium channel (α2 subunit) expression is altered in the hippocampus, cortex, brainstem, or cerebellum of diabetic rats. Supported by a grant from NIH (NINDS) #31757-01.

ACETYLCHOLINE (ACh) STIMULATES THE RELEASE OF NITRIC OXIDE FROM RAT SPINAL CORD IN VITRO. Z Xu, C Tong, JC Eisenach*, P Li, The Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1009

Previous in vivo studies suggest that Nitric Oxide(NO) may mediate the actions of ACh on spinal sympathetic neuronal activity and on antinociception in the spinal cord dorsal horn. In this study we utilized a novel bioassay for NO release to examine the effect of ACh perfusion of rat spinal cord in vitro on NO release. Following Animal Care Committee approval, adult male Sprague-Dawley rats were euthanized, the spinal cord removed, and spinal cord slices placed in tissue chambers perfused continuously with oxygenated Krebs solution which exited the chamber to fall on endothelium denuded aortic rings. Successful removal of endothelium was tested by lack of relaxation to ACh. After preconstriction with phenylephrine, ACh (10^{-12} to 10^{-4} M) alone or with other drugs (all 10^{-5} M) were added into the perfusion solution, with continuous recording of the detector ring's tension. Data are expressed as % relaxation (mean ± SEM), and were analyzed by 2-way ANOVA on the full dose response curves, with $P < 0.05$ considered significant. Perfusion directly on detector rings of ACh caused no change in their tension, whereas perfusion over rat spinal cord tissue with ACh resulted in a dose-dependent relaxation of the detector ring, with maximum relaxation of 55%. This relaxation was blocked by n-methyl-l-arginine (NMLA), hemoglobin, or methylene blue. ACh-induced relaxation was also blocked similarly by the muscarinic antagonists, atropine, pirenzepine, or AFDX-116. This study showed that ACh causes release of a vasodilator from spinal cord slices in vitro which shares the pharmacology of NO (active on endothelium-denuded rings, blocked by the NO synthase inhibitor, NMLA, the NO scavenger, hemoglobin, and the guanylate cyclase inhibitor, methylene blue), and involving both M1 and M2 receptors activation.
Supported in part by GM35523.

EFFECT OF FORSKOLIN ON CARBACHOL-INDUCED SIGNAL TRANSDUCTION IN CANINE CULTURED TRACHEAL SMOOTH MUSCLE CELLS. C. M. Yang*. Department of Pharmacology, Chang Gung College of Medicine and Technology, Kwei-San, Tao-Yuan, Taiwan.

The effect of elevating cyclic AMP on carbachol-induced generation of inositol phosphates (IPs) and rise in intracellular Ca^{2+} ($[Ca^{2+}]i$) was investigated in canine cultured tracheal smooth muscle cells (TSMCs). Pretreatment of TSMCs with either cholera toxin, forskolin, or dibutyryl cyclic AMP inhibited carbachol-stimulated Ca^{2+} mobilization and IPs accumulation. The inhibitory effects of these agents produced both depression of the maximal response and a shift to the right of the concentration-response curve of carbachol without changing the EC_{50} values. Even after treatment with forskolin for 24 h, the cells retained the ability to respond to carbachol-induced Ca^{2+} mobilization to the same extent as the control group. The K_b and Bmax values of the muscarinic receptor (mAChR) for [^{3}H]N-methyl scopolamine binding were not significantly changed by forskolin treatment, suggesting that the inhibitory effect of forskolin is distal to the mAChR. The AlF_4^--induced IPs accumulation was inhibited by forskolin, supporting that G protein(s) are directly activated by AlF_4^- and uncoupled to phospholipase C by forskolin treatment. We conclude that cyclic AMP elevating agents inhibit carbachol-stimulated responses in TSMCs. Since generation of IPs and increase in $[Ca^{2+}]i$ are very early events in the activation of mAChRs, attenuation of these events by cyclic AMP elevating agents might well contribute to the inhibitory effect of cyclic AMP on tracheal smooth muscle function.

Hippocampal Sympathetic Ingrowth and Cholinergic Denervation Differentially Alter Hippocampal Muscarinic Receptors Over Time. M.R. Roberson, K. Kolasa, D.S. Parsons, L.E. Harrell*. Alzheimer's Disease Center, Depts. of Psychology and Neurology, VA and Univ. Alabama Med. Ctr., Birmingham, AL 35294

Degeneration of forebrain cholinergic neurons and hippocampal neuronal reorganizations both occur in Alzheimer's Disease (AD). Our laboratory has been utilizing the model of hippocampal sympathetic ingrowth (HSI), which has been suggested to occur in AD, to investigate the functional effects of cholinergic denervation (CD) and hippocampal rearrangements. In this model, peripheral sympathetic fibers, originating from the superior cervical ganglia, grow into the hippocampus, after cholinergic denervation via medial septal lesions (MSL). In this study we examined the long-term effects of these treatments on muscarinic cholinergic receptors (mAChR), by examining [^{3}H]-QNB, a nonselective mAChR antagonist, binding in hippocampal membranes 3 months post lesion. Four groups of animals were employed: Controls (sham MSL + sham ganglionectomy (Gx); HSI (MSL + sham Gx); CD (MSL + Gx); Gx (sham MSL + Gx). In dorsal hippocampal membranes, binding affinity (K_D) was found to be significantly decreased in HSI ($p < .002$) and CD ($p < .01$) groups as compared to controls, while number of mAChR (Bmax) was found to be significantly increased in HSI as compared to controls ($p < .02$) and CD ($p < .01$) groups. These results suggest that long-term cholinergic denervation (found in both HSI and CD groups) decreases mAChR affinity, while the presence of sympathetic fibers increases the number of mAChR. Thus, both HSI and cholinergic denervation affect mAChR, a bit differently. Further, these results may provide some insight into why cholinomimetic therapies are ineffective for most AD patients, in that a decrease in mAChR affinity would reduce agonist efficacy at the mAChR.

802.11

EFFECT OF (±)-EPIBATIDINE ON THE RELEASE OF CATECHOLAMINES: BIOCHEMICAL AND BEHAVIORAL EVIDENCE IN RATS. A.I. Sacaan*, F. Menzaghi, J.L. Dunlop, L.C. Correa, K.T. Whelan, and G.K. Lloyd
SIBIA, 505 Coast Boulevard South, La Jolla, CA 92037-4641

The present study determined the effect of (±)-epibatidine (Epi), a neuronal nicotinic acetylcholine receptor (NAChR) agonist on catecholamine release. (±)-Epi (3-300 nM) produced a concentration-dependent increase in [^{3}H]-dopamine release from rat striatal slices, and [^{3}H]-norepinephrine release from rat hippocampal and thalamic slices, with differential sensitivity to various NAChR antagonists as shown below:

Tissue	EC_{50} (nM)	Mec 3 (uM)	d-TC 100 (uM)	DHβE 100 (uM)	TTX 1 (uM)
Striatum	37 ±10	+	-	+	+
Hippocampus	20 ±2.6	+	+	-	+
Thalamus	23 ±5.3	+	+	-	+

In addition, (±)-Epi (1-3 ug/kg, s.c.) and nicotine (350 ug/kg, s.c.) produced ipsilateral turning in the unilaterally 6-hydroxy-dopamine lesioned rat, consistent with the stimulation of dopamine release from the intact nigrostriatal dopamine pathway. This effect was blocked by mecamylamine (mec) (3 mg/kg, s.c.). Moreover, (±)-Epi (1-3 ug/kg, s.c.) increased locomotor activity in a dose-dependent manner. This effect was blocked by mec as well as the D1 and D2 receptor antagonists, SCH23390 and eticlopride, respectively. These results demonstrate that, in addition to the previously reported analgesic activity, (±)-Epi displays NAChR agonist activity in the rat central nervous system and that certain effects may be mediated via NAChR-stimulated catecholamine release, and subsequent activation of corresponding receptors.

CONSTITUTIVE ACTIVATION OF MUSCARINIC RECEPTORS BY THE G-PROTEIN G_q E. S. Burstein*, T. A. Spalding, H. Bräuner-Osborne, M. R. Brann, Department of Psychiatry, University of Vermont, Burlington VT 05405 and Receptor Technologies, Winooski, VT 05404.

In the absence of ligands, G-protein coupled receptors interconvert between active and inactive conformations. These conformations are stabilized by agonists and antagonists, respectively. Like agonists, G-proteins are thought to preferentially associate with receptors in the active conformation and should therefore be able to promote their formation in the absence of agonist. We show that overexpression of $G_{\alpha Q}$, but not $G_{\alpha 12}$ induces constitutive activation of compatible (m1, m3, and m5 but not m2) muscarinic receptors and this activity is blocked by muscarinic antagonists. Gq also increases the potency and efficacy of agonists. The phenotypes of receptors activated by G-proteins are very similar to the phenotypes of mutationally activated receptors. These results indicate that regulation of G-protein levels has a profound impact on receptor control of cellular physiology, even in the absence of agonist ligands.

G PROTEIN βγ SUBUNITS MIMIC THE MUSCARINIC REGULATION OF ADENYLYL CYCLASE OF RAT OLFACTORY BULB. M.C. Olianas*[1], H. Hamm[2] and P. Onali[1], Dept. of Neurosciences, University of Cagliari, Italy [1] and Dept. Physiol. and Biophys., Univ. of Chicago, IL 60680[2].

In membranes of rat olfactory bulb activation of muscarinic receptors enhances basal and neurotransmitter-stimulated adenylyl cyclase activities but inhibits Ca^{2+}/calmodulin and forskolin (FSK) stimulations of the enzyme. In the present study we show that this bimodal control of cyclic AMP formation can be reproduced by the G protein βγ subunits. Thus, incubation of olfactory bulb membranes with the βγ subunits of transducin elicited a concentration-dependent increase of basal adenylyl cyclase activity with an EC50 of about 100 nM. The βγ stimulatory effect was not additive with that produced by maximal activation of muscarinic receptors. Moreover, as observed with muscarinic receptor agonists, the βγ subunits significantly potentiated the stimulation of cyclic AMP formation by vasoactive intestinal peptide and inhibited the adenylyl cyclase activity stimulated by FSK with an IC50 of about 40 nM. These data support the idea that in rat olfactory bulb muscarinic receptors exert a bimodal control on cyclic AMP formation by promoting the release of G protein βγ subunits which then differentially affect the various molecular forms of adenylyl cyclase.

803.1

HYDROGEN PEROXIDE AND HYDROXYL RADICAL, BUT NOT SUPEROXIDE, PROMOTE A CONCENTRATION-DEPENDENT INHIBITION OF GLUTAMATE UPTAKE BY ASTROCYTES. O. Sorg and F.E. Bloom*. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Glutamate uptake (Glu up) by astrocytes is a very important function which prevents the potential neurotoxicity of this neurotransmitter after its release by neurons. Recently, Volterra et al. showed that H_2O_2 induced an inhibition of Glu-up by primary astrocytes in cultures. Using the same model, we tried to define the role of three main reactive oxygen species in Glu up inhibition, as well as the efficiency of endogenous protection mechanisms. H_2O_2 promotes an inhibition of Glu up in a concentration-dependent manner. O_2-, by itself, has no effect, suggesting that the reactive species in the xanthine/xanthine oxidase system is a combination of H_2O_2 and ·OH radical produced by the Haber-Weiß reaction. The Glu up inhibitory effect of H_2O_2 is potentiated by adding CuSO4 and ascorbate - a condition known to produce ·OH radical - or N-ethylmaleimide. The latter compound could act as a thiol-modifier group of the glutamate transporter and/or as a glutathione peroxidase I inhibitor; these possibilities are under investigation. (Supported by MH 47680).

803.2

INCREASED GLUTAMATE UPTAKE BY GLIAL CELLS DURING ATP DEPLETION IN HIPPOCAMPAL SLICES. J.E. Madl*. Department of Anatomy & Neurobiology, CSU, Ft. Collins, CO 80523.

Diverse metabolic insults can cause neuronal damage via the release of excitatory amino acids (EAAs), including glutamate (Glu). Severe ATP depletion releases EAAs by reversal of cotransporters that normally act to clear the synapse of transmitter EAAs. However, many metabolic insults produce only mild to moderate ATP depletion. Therefore, the effects of moderate ATP depletion on EAA uptake were determined. Uptake of the EAA analog D,L threo-b-hydroxyaspartate (OH-Asp) was used as an indicator of Glu uptake. OH-Asp uptake and the ATP content of rat hippocampal slices were measured by HPLC. Moderate ATP depletion (80% ≥ ATP ≥ 40% of control) increased uptake of OH-Asp. In contrast, more severe ATP depletion (ATP<40% of control) decreased OH-Asp uptake and increased release of endogenous Glu, suggesting reversal of cotransporters. Selective depletion of ATP from glia using fluoroacetate and fluorocitrate resulted in a similar increase in uptake of OH-Asp, suggesting that much of the increased uptake occurred in glial cells. Immunocytochemical localization of Glu in metabolically insulted slices indicated that Glu was decreased in nerve terminal-like puncta and increased in cells with glial-like morphology, suggesting that glial cells accumulate EAAs released by neurons. Increasing extracellular phosphate blocked the increased uptake of EAAs, suggesting that the increases of intracellular phosphate induced by ATP depletion may increase the phosphate gradient and potentiate EAA uptake. The increased uptake of EAAs during mild to moderate ATP depletion suggests that during many moderate insults, such as partial ischemia, a decrease in extracellular Glu might contribute to loss of CNS function.

803.3

GLUTAMATE UPTAKE BY HIPPOCAMPAL ASTROCYTES IS INHIBITED BY FERROUS CHLORIDE. J. H. Pizzonia*, E. O'Conner and D. L. Kraemer. Dept. of Surgery, (Neurosurgery), Yale University School of Medicine, New Haven, CT. 06520

Iron-complexed to blood breakdown products has been implicated in the pathogenesis of stroke and reperfusion injury, trauma and epilepsy. Excessive accumulation of iron during aging has also been implicated in several neurodegenerative diseases. We hypothesized that iron may affect neuronal injury by inhibiting glutamate transport mechanisms. As astroglial regulation of glutamate is primarily responsible for modulated synaptic glutamate activity, we examined the effect of iron on glutamate uptake and efflux in astrocytes. Hippocampal astrocytes were prepared from neonatal rats and preincubated in HEPES buffer containing 50 μM ferrous chloride for 30 minutes before the addition of ^{3}H-glutamate. Uptake was determined from 2-60 minutes and total radioactivity determined from cell lysates. Ferrous chloride decreased glutamate uptake by 50% at 10 minutes (n=4, p<.05), and by 70% after 60 minutes (n=4, p<.001) compared to control cells incubated in HEPES buffer without iron. In separate experiments the rate of ^{3}H-glutamate efflux was not changed by addition of 50 μM ferrous chloride. Preincubation with the calcium channel blocker, lanthanum chloride, (1 μM) did prevent inhibition of ^{3}H-glutamate uptake by 50 μM ferrous chloride. We conclude that iron inhibits glutamate uptake into astrocytes and thereby may induce neurotoxicity by a mechanism independent of transmembrane calcium influx.

803.4

EXCITOTOXICITY BY TRANSPORTER-MEDIATED GLUTAMATE EFFLUX FROM NEURONS AND GLIA IN NON-ISCHEMIC CONDITIONS A. Volterra*, P.Bezzi, B. Lodi Rizzini, D. Trotti & G. Racagni Ctr Neuropharmacol, Inst Pharmacol Sci, Univ Milan, 20133, Italy

Uptake in neurons and astrocytes by distinct transporter subtypes keeps low (≤1 μM) extracellular glutamate concentration ($[GLU]_o$) with crucial implications for excitatory synaptic transmission. In ischemia, loss of the physiological ion gradients causes transporters to function in reversed mode pumping out GLU up to neurotoxic levels. We have reported that addition of a competitive GLU uptake inhibitor, t-pyrrolidine-2,4-dicarboxylate (PDC, 200 μM, 30' in normal salt buffer with 1 mM Mg^{++}) to cortical neuroglial co-cultures, induces rapid increase of cell-released $[GLU]_o$ (from 1 to 5 μM) and, as a consequence, delayed (1 day) neurotoxicity (Volterra et al., Soc.Neurosci.Abs.20:271,1994). Toxicity is prevented by the NMDA-antagonist APV (100 μM) and attenuated (40-60%) by AMPA/kainate (CNQX, 10 μM) and metabotropic (MCPG, 500 μM) blockers. Surprisingly, both $[GLU]_o$ increase and neurotoxicity with PDC are largely (70%) unaffected by 1 μM TTX, despite that TTX abolishes excitatory synaptic activity in the culture, as recorded by whole-cell current-clamped neurons. However, in the presence of TTX, we observe GLU release from astrocytes of sister glial cultures in response to PDC (200 μM, 30'), an effect abolished by replacement of Na^+_o with Li^+. Moreover, Li^+ substitution reduces by >80% the TTX-insensitive component of $[GLU]_o$ increase observed in co-cultures. Therefore, our data indicate that: (1) transporter-mediated (Li^+-sensitive) GLU efflux from both glia and neurons, in addition to reduced reuptake of synaptically released GLU, accounts for PDC-induced $[GLU]_o$ rise and neurotoxicity; (2) reversed GLU transport function can be activated even under normal, non-ischemic conditions (e.g. via heteroexchange) with direct neuroexcitotoxic consequences.

HUMAN NERVE TISSUE-SPECIFIC GLUTAMATE DEHYDROGENASE ADAPTED TO FUNCTION UNDER LOW ENERGY STATES AND INCREASED GLUTAMATE RELEASE. P. Shashidharan*, Donald D. Clarke[1], and Andreas Plaitakis. Department of Neurology, Mount Sinai School of Medicine, One Gustave L Levy Place, New York, N.Y., 10029, [1]Dept. of Chemistry, Fordham University, Bronx, New York.

Human glutamate dehydrogenase (GDH) exists in nerve tissue-specific and housekeeping isoforms encoded by distinct genes. We have obtained both these proteins in pure form by expressing the corresponding cDNAs in Sf9 cells using the baculovirus expression system. The specific expression of each GDH isoproteins by the corresponding cell lines was verified by the N-terminal amino acid sequencing. Heat inactivation studies revealed that the nerve-tissue specific GDH was heat-labile and the housekeeping enzyme heat stable. In the absence of allosteric effectors, the two isoenzymes differed markedly in their ability to interconvert glutamate to α-ketoglutarate. The nerve-specific enzyme was largely inactive whereas the housekeeping GDH showed 40-50% of its maximal activity. ADP induced a concentration-dependent (10-1,000 μM) activation that was proportionally greater (200 - 6,000%) for the nerve tissue-specific than the housekeeping GDH (50-260%). GTP, known to be present in brain at relatively high levels, inhibited the housekeeping GDH but had little effect on the nerve tissue-specific enzyme. Since GDH is highly concentrated in synaptic astrocytes where it is involved in transmitter glutamate metabolism, these allosteric properties evidently represent an adaptation enabling the brain-specific GDH to oxidize increased loads of transmitter glutamate upon extensive hydrolysis of ATP to ADP that may occur in energy failure and/or increased glutamate release.

803.6

REGULATION AND PATHOLOGY OF KYNURENINE PATHWAY METABOLISM IN RAT BRAIN. J. Luthman*, Eva Vänerman, Göran Fredriksson and Bodil Fornstedt-Wallin. Astra Arcus AB, Södertälje, Sweden.

The kynurenine pathway, which is the principal route of hepatic L-tryptophan (TRY) metabolism, also appears to play an important role in brain function. A kynurenine pathway metabolite of particular interest in this regard is quinolinic acid (QUIN), which acts as a NMDA receptor agonist and excitotoxin. Endogenous QUIN and its biosynthetic enzyme 3-hydroxyanthranilic acid dioxygenase (3-HAO) occur in the brain and QUIN levels have been shown to increase in various neurodegenerative processes. In cultures of rat brain tissue, exposure to QUIN and the precursor 3-hydroxyanthranilic acid (3-HANA) produce neuronal loss. Furthermore, administration of QUIN or the precursor *in vivo* to rats leads to cerebral damage. However, the knowledge about the relative contribution of peripheral and central kynurenine pathway enzymes in the *in vivo* regulation of cerebral QUIN is limited. In Sprague-Dawley rats, intracerebroventricular (i.c.v.) administration of 3-HANA, but not other precursors of QUIN, induced a major increase in hippocampal QUIN, that was saturable at high doses and peaked at 2h after administration. Co-administration with a 3-HAO inhibitor blocked the 3-HANA-induced increase in QUIN. Systemic administration of tryptophan, 3-HANA and QUIN itself increased cerebral QUIN, while much smaller effects were seen after administration of L-kynurenine and 3-hydroxykynurenine. Systemic, but not i.c.v., administration of the 3-HAO inhibitor partially counteracted the increase of cerebral QUIN after systemic TRY or 3-HANA. However, in animals with brain damage, such as ischemia and neurotoxin-induced lesions, i.c.v. administration of the inhibitor decreased cerebral QUIN. This indicates that, although cerebral QUIN levels are regulated by the availability of precursors in the periphery, cerebral synthesis plays a significant role when central QUIN levels are enhanced under pathological conditions.

INTRACEREBRAL GLUTAMATE AND CEREBRAL BLOOD FLOW DURING CHRONIC HYPOXEMIA IN THE NEAR-TERM OVINE FETUS

J. Henderson, D. Penning*, J. Reynolds and F. Dexter
Dept. of Obstetrics and Gynecology and Dept. of Anesthesiology
University of Iowa College of Medicine, Iowa City, Iowa.

Using chronic *in utero* microdialysis (ref.), we examined the relationship between change in cerebral blood flow (CBF) and glutamate (Glu) efflux from the parasaggital parietal cortex (PSPC) in the near term ovine fetus during chronic fetal hypoxemia.

Six near-term ovine fetuses (2 control, 4 experimental) were chronically instrumented with vascular catheters and a microdialysis probe inserted in the PSPC. An adjustable vascular occluder was placed around the common uterine artery. After a 3 day recovery and a 24 hour probe equilibration period the vascular occluder was tightened in experimental animals to reduce the fetal 0_2 saturation by 50% for a 24 hour period without progressive metabolic acidemia. Fetal CBF was determined by injection of radiolabelled microspheres at 0, 8, 16 and 24 hours . Microdialysate samples were collected at 28 minute intervals and the concentration of Glu determined by HPLC.

Basal Glu efflux was 102 ± 64 ng/ml and basal CBF was 227 ± 61 ml/100 g · min. In 3 of 4 experimental animals there was an increase in CBF and Glu efflux in the PSPC while in 1 experimental animal and both controls the CBF and Glu were unchanged. All fetuses experienced an increase in Glu efflux post mortem.

In this preliminary study, ovine fetuses responding to hypoxemia by increasing CBF also show an increase in PSPC Glu efflux. Glu did not increase in animals that failed to show an increase in CBF.

LONG-TERM CHANGES IN BRAIN FOLLOWING CONTINUOUS PHENCYCLIDINE ADMINISTRATION: STUDIES USING 2-FDG, FLUNITRAZEPAM, KETANSERIN, MAZINDOL, QNB, AND LIGANDS FOR AMPA AND PCP RECEPTORS. G. D. Ellison* and A. KEYS. Department of Psychology, UCLA, 405 Hilgard Ave., Los Angeles, CA 90024

When given continuously for several days, NMDA antagonists such as phencyclidine (PCP) and dizocilpine (MK-801) induce neural degeneration in a variety of limbic structures such as retrosplenial cortex (RSCx), entorhinal cortex (ENTCx), dentate of hippocampus (DEN), and olfactory regions. This has been demonstrated using a variety of measures, including silver-stains. Further autoradiographic studies were conducted in animals at both 24 hours and 21 days after binge PCP administration using 2-FDG and a variety of receptor ligands.

24 hours after pellet removal there were still large increases in glucose uptake in these same limbic structures, and many of these regions were still present after 21 days of recovery. These alterations were accompanied by decreased flunitrazepam but increased mazindol binding in many of these same limbic regions. QNB and AMPA binding was decreased but TCP binding increased in many brain regions, including striatum. These studies may indicate an anatomical substrate for the persisting psychoses which sometimes occur following PCP.

HIPPOCAMPAL EXCITATION AND TOXICITY PRODUCED *IN VIVO* BY DOMOIC ACID. *P.M. Gross*[1,5] T.M. Polischuk,[2] D.S. Wainman[1], & D.F. Weaver[3,4]*
Depts. [1]Surgery (Neurosurgery), [2]Anatomy & Cell Biology, [3]Chemistry, [4]Medicine (Neurology), & [5]Physiology, Queen's Univ. and Kingston Gen. Hospital, Kingston, Ont., Canada K7L 3N6.

Excitotoxic processes are implicated in many conditions of neuronal damage, including Alzheimer's and Huntington's disease, epilepsy, traumatic head injury, and stroke. Domoic acid (DOM), a glutamate analog from seaweed that contaminates shellfish, is a potent neurotoxin that putatively stimulates glutamate AMPA/kainate receptors (T.M. Polischuk and R.D. Andrew, this meeting). Microinjection of DOM (25-100 pmol) into the lateral cerebral ventricle of conscious rats produced convulsive signs such as tonic tail and forelimb extension, forepaw flexion, exophthalmos, hypoactivity (unresponsiveness), and hyperventilation. Within 5-20 min, DOM evoked increases in mean arterial pressure, plasma glucose levels, and heart rate. Using the quantitative autoradiographic [^{14}C]deoxyglucose technique to measure rates of tissue glucose metabolism, we determined the neuroexcitatory responses of various brain regions to DOM at 4 doses: 100, 50, 25, and 0 pmol. Subregions of the hippocampal formation, ipsilateral (but not contralateral) to the injection site, had dose-dependent, elevated rates of glucose metabolism, including Ammon's horn (+68% in CA1, +130% in CA2, and +194% in CA3), dentate gyrus (+46%), and the fimbria (+49%) (mean responses to 100 pmol DOM are shown). Upon histological inspection by light microscopy, we found that neurons in the pyramidal layer of CA3 ipsilateral to injection were hyperchromatic, irregularly shaped, and surrounded by enlarged extracellular spaces. These findings are pathological signs consistent with excitotoxic cell damage. The caudate, lateral septal, and septofimbrial nuclei also displayed substantial metabolic stimulation near the injection site (>100% increase in ipsilateral metabolic rate). Together, the metabolic and histological results reveal that DOM is a potent, dose-dependent neuroexcitant and toxin in the intact brain.

DIFFERENTIAL SUSCEPTIBILITY TO DOMOIC ACID INDUCED TOXICITY IN THE DEVELOPING RAT: A BEHAVIOURAL STUDY. S.M. Strain, G.V. Allen* and R.A.R. Tasker*. Dept. Anat. & Physiol., Atlantic Vet. College, UPEI, Charlottetown, PEI, C1A 4P3 and *Dept. Anat. & Neurobiology, Dalhousie Univ, Halifax, NS B3H 4H7, Canada

Domoic acid (DOM) is an excitatory amino acid that has been identified as a potent neurotoxin in both people and experimental animals. The effects of DOM in the mature brain have been well documented but little information is available concerning its action in the immature brain. This study was designed to assess the toxic effects of systemically administered domoic acid in developing male and female Sprague-Dawley rats. Intraperitoneal injections of five doses (n=6 for each) of domoic acid or saline were administered on postnatal days 0, 5, 14, 22, 30 (f) and 50 (m). Dosages ranged from (0.05 - 2.0 mg/kg) depending on the developmental age. Each animal's behaviour was recorded each minute for 120 minutes post injection using a 3 point scale of increasing severity. Dose response curves as a function of age were generated and statistically compared for parallelism and potency. Prior to weaning pups were found to be significantly more susceptible to domoate induced toxicity, as indicated by both increased potency and the occurrence of convulsive behaviours involving both fore and hind limbs. Post-weaning the more classic limbic seizure was observed and was characterized by the occurrence of forelimb tremors in a reared position and masticatory movements. Data indicate that susceptibility to domoic acid toxicity in the developing rat may be dependent upon establishment and maturation of limbic system circuitry.

803.11

Neuropathology of Subchronic Oral Administration of Domoic Acid (DA) in the Rat. **O.Pulido*;R.Mueller;J.Truelove;F.Iverson;P.Rowsell and M.Bujaki.**
Pathology Section, Toxicology Research Div., Bur. of Chemical Safety; Food Dir., HPB, Ottawa, Ont., Can. K1A 0L2.

Amnesic shellfish poisoning (ASP) is caused by eating shellfish containing elevated levels of DA. This study aimed at determining the effect of repeated consumption of DA. Male and female Sprague-Dawley rats were dosed by gavage for 64 days with 0, 0.1 or 5 mg/kg/day of DA. Treated animals showed no clinical changes over the 64 days, including urinalysis, haematology and serum chemistry. At the end of the study and under anesthesia, rats were exanguinated and perfused with neutral buffered formalin (NBF) or with 2% glutaraldehyde (GL): 2% paraformaldehyde (PF). Tissues were then processed for light microscopy (LM) or for electron microscopy (EM). LM results were unremarkable, including the area postrema, hippocampus and retina which are considered target sites for DA toxicity. Glial fibrillary acid protein (GFAP) and glutamate receptor immunohistochemistry (GluR1-4) did not show visually detectable difference between treated and control rats. EM of the CA3 field of the hippocampus from the high dose (5mg/kg/day) group revealed neuronal damage: cytoplasmic vacuolation, neuronal shrinkage, dilatation of dendritic and astrocytic processes and formation of electron dense profiles. This dose was equivalent to the estimated maximum human dose during the Canadian ASP incident in 1987 and is seven times less than that required to cause overt clinical signs in the rat. No significant changes were observed at the dose of 0.1 mg/kg, estimated as the dose resulting from the consumption of one 250 mg portion of mussel meat containing the present limit for DA of 20ug/g of shellfish meat.

803.12

SERUM CLEARANCE OF DOMOIC ACID IS UNALTERED FOLLOWING MULTIPLE EXPOSURES IN MICE.

Y.G. Peng, H.F. Martin* and J.S. Ramsdell. Marine Biotoxins Program, National Marine Fisheries Service and Marine Biomedical & Environ. Sciences, Medical University of South Carolina, Charleston, SC 29412.

Domoic acid (DA), a tricarboxylic amino acid, is a rigid analogue of the neurotransmitter L-glutamate and has been demonstrated to be an environmental neurotoxin to humans. Previous studies in rodents and primates indicate that DA is cleared from serum within four hours after a single dose. In the present study, we have determined the concentration of DA in serum after single or multiple dose exposure and correlated this with stereotypic neurological effects in mice. Mice were intraperitoneally administered 2.0 mg/kg DA either in multiple doses (every other day i.p. for 4 times in 7 days) or a single dose on the same day of the last multiple exposure dose. DA levels were monitored as serum concentration and measured at 60 min and 120 min using the DA radioreceptor assay. Serum DA levels did not differ at 60 min in single (0.59 ± 0.04 µg/ ml) and multiple (0.50 ± 0.05 µg/ml n= 8) exposures, or at 120 min (single 0.124 ± 0.005 µg/ml, multiple 0.123 ± 0.004 µg/ml, respectively n= 7). The onset of stereotypic neurological effects in the form of scratching was also similar in each group (20.2 ± 0.5 min & 22.4 ± 1.1 min, respectively) although the duration of scratching lasted longer in mice with a single dose (30-45 min) than those with multiple exposure (20-35 min). Convulsive behavior, evident with a single 2.0 mg/kg dose, was not observed after the second dose in the multiple exposure group. This study indicates that multiple exposures of DA to mice does not alter DA clearance from the serum and does not appear to lead to a more neurotoxic response.

DISTRIBUTION OF $GABA_A$ RECEPTOR α1-SUBUNIT POLYPEPTIDES IN THE GUINEA PIG HIPPOCAMPUS. E.M. Barnes, Jr.*, M.E. Díaz, L.V. Colom, J.D. Miranda, B.J. Baumgartner, and M.H.J. Tehrani, Depts. of Neurology and Biochemistry and Div. of Neuroscience, Baylor Col. of Med., Houston, TX 77030.

In order to conduct a histochemical examination of $GABA_A$ receptors in various brain tissues, we have prepared polyclonal antibodies against a selective intracellular loop region of the α1 subunit. The chick $GABA_A$ receptor α1(331-381) subunit sequence was expressed as a fusion protein containing a hexahistidyl leader peptide, purified by Ni^{2+}-affinity chromatography, and used for rabbit immunizations. The corresponding α1-subunit antiserum immunoprecipitated 66% of ^{3}H-flunitrazepam binding to extracts from guinea pig hippocampus and reacted with a single 50-kDa polypeptide on Western blots. The strong cross-species reactivity was expected from the 88% sequence identity in the α1(331-381) region between chicken and rodents. The pattern of immunoreactivity on 50 μm sections of guinea pig hippocampus was examined using rhodamine-labeled anti-rabbit IgG and confocal laser microscopy. Immunofluorescent labeling of $GABA_A$ receptor α1 subunits was observed on pyramidal cells and putative interneurons in the CA1 and CA3 regions. The α1 subunit was located in the soma and apical dendrites of pyramidal cells. This distribution was similar for the both the CA1 and CA3 layers. Putative interneurons of the stratum oriens, pyramidale, and radiatum also showed immunoreactivity of α1 subunits.

ANTIBODIES TO THE β-SUBUNITS OF $GABA_A$ RECEPTORS. Ming Li* and Angel L. De Blas. Div. Mol. Biol. and Biochem., School of Biological Sciences, University of Missouri-Kansas City, Kansas City, MO 64110-2499.

Antisera to the β_1, β_2 and β_3 subunits of rat $GABA_A$ receptor have been made by immunizing rabbits with either synthetic peptides or bacterial fusion proteins. The peptides corresponded to amino acid residues 382-393, 382-393 and 380-391 of the rat $ß_1$, $ß_2$, and β_3 subunits respectively. The large intracellular loop (IL) located between the putative transmembrane domains M3 and M4 of the rat β_1, β_2 or β_3 were expressed as staphylococcal protein A fusion proteins. The antisera specifically reacted with the corresponding peptide or IL fusion protein in ELISA. The antibodies immunoprecipitated the solubilized $GABA_A$/Benzodiazepine receptors from rat brain. Quantitative immunoprecipitation showed that in the rat cerebral cortex β_2 is the most abundant of the ß subunits whereas in the hippocampus the most abundant is $ß_3$. Immunoprecipitation studies in several brain regions showed a good correlation between the relative abundance of $ß_1$, $ß_2$, and β_3 peptides and mRNA expression. The antibodies were affinity-purified on immobilized peptide or IL protein. The latter was purified after controlled protease cleavage of the fusion protein. The affinity-purified antibodies are being used for receptor characterization by immunoblotting and immunocytochemistry.

804.3

DISTRIBUTION OF $GABA_A$/BENZODIAZEPINE-RECEPTORS IN THE BRAIN OF GOLDFISH (*CARASSIUS AURATUS*) AND SALMON (*SALMO SALAR*). M. Anzelius*, B. I. Holmqvist and P. Ekström. Dept. of Zoology, University of Lund, Sweden.

The antibody bd-17 was used for immunocytochemical detection of $GABA_A$/benzodiazepine receptor $ß_2/ß_3$-subunits (bd-17ir) in the brain of the goldfish. The relative density and regional distribution of bd-17ir were analysed by computerized image analysis and were compared with our previous results from the salmon. In the goldfish bd-17ir is mostly found as a diffuse labelling of circumscribed areas corresponding with cytoarchitectonally defined "nuclei". Strong labelling is located in the telencephalon, pretectum, optic tectum, hypothalamus and torus semicircularis. Several nuclei of the hypothalamus and posterior tuberculum show strong labelling (e.g. the preglomerular nuclei, n. anterior tuberis, n. posterior tuberis, lobi inferiores). The stratum periventriculare, stratum griseum centrale and stratum fibrosum et griseum superficiale of the optic tectum display bd-17ir. Perikaryal labelling was observed in the torus longitudinalis and in the granular layer of different subdivisions of the cerebellum. In the brain stem the central grey is strongly immunoreactive. The bd-17ir in the goldfish brain is in general similar to that found in the salmon, but in the goldfish labelling generally correlates better with cytoarchitectonic entities, particularly in the hypothalamus and posterior tuberculum. The labelling in the central grey is not present in the salmon brain.

IMMUNOCYTOCHEMISTRY OF A NOVEL GABA RECEPTOR SUBUNIT

K. Aronstein, S. Carlson* & R. H. ffrench-Constant. Departments of Neuroscience and Entomology, University of Wisconsin-Madison, Madison, Wisconsin 53706

Following our recent cloning of a novel γ-aminobutyric acid (GABA) receptor subunit gene *Resistance to dieldrin* or *Rdl* from the cyclodiene resistance locus in *Drosophila melanogaster*, we were interested in defining its pattern of expression during development. Here we report the raising of an anti-*Rdl* polyclonal antibody that recognizes a single protein of the expected 65 kDa size in immunoblots of *Drosophila* head homogenates. *In situ* hybridization using *Rdl* cDNA probes and the anti-*Rdl* antibody shows that *Rdl* message and protein are expressed globally in the developing central nervous system (CNS) of 15-17 hr embryos. No message can be observed on or before 12-13 hr. Interestingly, despite the use of GABA in both the peripheral and CNS of insects, *Rdl* GABA receptor subunits appear to be confined to the CNS. Detailed immunocytochemistry of *Drosophila* brain sections showed particularly strong anti-*Rdl* antibody staining in the optic lobes, ellipsoid body, fan shaped body, ventrolateral protocerebrum and the glomeruli of the antennal lobes. Results are compared with the distribution of staining observed in the insect CNS with antibodies against GABA itself, synaptotagmin (a synaptic vesicle protein) and a second *Drosophila* subunit which appears to be a homolog of the vertebrate $GABA_A$ receptor β subclass.p

FUNCTIONAL COMPARTMENTALIZATION OF $GABA_A$-RECEPTOR SUBTYPES IN THE RAT SPINAL CORD. H. Mohler*, J.M. Fritschy, and S. Bohlhalter. Institute of Pharmacology, University of Zürich, CH-8057 Zürich, Switzerland.

To assess the significance of the structural heterogeneity of $GABA_A$-receptors, we analyzed immunohistochemically the subunit composition and cellular localization of $GABA_A$-receptor subtypes in the rat spinal cord. The regional distribution of the subunits α1, α2, α3, α5, β2,3, and γ2 was investigated with subunit-specific antibodies, and their co-localization within individual neurons visualized by double-immunofluorescence staining. The results reveal a widespread and almost ubiquitous expression of the subunits α3, β2,3, and γ2 in the spinal cord, suggesting that most receptors comprise the subunit triplet αx/βx/γ2, which forms functional receptors amenable to benzodiazepine modulation. An "atypical" $GABA_A$-receptor subtype, containing the subunits α2/γ2 only, was detected in preganglionic and somatic motoneurons. Further heterogeneity arose from the differential, lamina-specific distribution of the subunits α1 and α5 in layers III-VIII. Thus, in lamina III, most neurons contained either the subunit α1 and/or α5, along with β2,3 and γ2. In laminae IV-V, the most frequent α-subunit was α1, whereas in laminae VII-VIII, the subunit α5 predominated (along with the subunits α3/β2,3/γ2). However, the α3- and α5-subunits were located to distinct cells. Hot-spots of immunoreactivity, suggestive of a postsynaptic localization of $GABA_A$-receptors, were seen frequently on neuronal somatic and dendritic membranes. In addition, an intense and diffuse staining was observed for the subunits α2/α3/β2,3/γ2 in laminae I-III, localized presumably on primary afferent terminals. These results demonstrate the existence of different $GABA_A$-receptor subtypes in distinct compartments of the spinal cord, suggesting that $GABA_A$-receptor heterogeneity may be of relevance for the modulation of sensory inputs, nociception, and motor control at segmental levels.

804.6

DIFFERENTIAL DISTRIBUTION OF $GABA_A$ RECEPTOR SUBUNITS IN THE RAT INFRALIMBIC CORTEX: RELEVANCE TO NOVEL ANTIPSYCHOTIC DRUG TREATMENT. E.Dunn*, J.M.Fritschy[1], D.B.Carter and K.M. Merchant, CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001 and [1]Institute of Pharmacology, Univ. of Zurich.

The prefrontal cortex has been implicated in manifestation of negative symptoms and cognitive deficits in schizophrenic patients. Several studies of postmortem human tissue indicate that there is a loss of GABAergic interneurons and an increase in $GABA_A$ receptor binding in the prefrontal cortical regions of schizophrenics. These data suggest that disturbances in GABAergic neurotransmission in limbic cortex of schizophrenic patients may contribute to the pathophysiology of schizophrenia, and that specific GABAergic agents may be therapeutically useful. To evaluate this possibility, we have performed a detailed analysis of distribution of $GABA_A$ receptor subunits in the rat medial prefrontal cortex (infralimbic, IL, region). Mapping of α_1, α_2, α_3, α_5 and β_{2+3} subunits was carried out by immunocytochemistry with previously characterized, subunit-specific antibodies. The α_1 and β_{2+3} subunit antibodies immunostained all layers (I, II, III, V, and VI) of the IL cortex, with layers II and III displaying what appeared to be small interneurons. In contrast, α_2, α_3 and α_5-like immunoreactivity was restricted to a single layer of the IL region; layer I displayed labelling for α_2 and layer VI for α_3 and α_5 subunits. Both α_3 and α_5 antibodies immunostained large cell bodies, resembling pyramidal cells, which appeared to be restricted to layer VIb for the α_5 subunit. Such studies may help design pharmacological agents with subunit selectivity to modulate GABA neurotransmission in a regionally-selective manner.

COMPARISON OF DISTRIBUTION PATTERNS OF GABA AND GABA$_A$ RECEPTORS IN THE RAT NUCLEUS TRACTUS SOLITARIUS.

K. Terai[1,2], I. Tooyama[2*], H. Kimura[2] and P. L. McGeer[1].
1: Kinsmen Lab. of Neurol. Res., Univ. of British Columbia, Vancouver, B.C., Canada, V6T 1Z3. 2: Inst. of Mol. Neurobiol., Shiga Univ. of Med. Sci., Otsu, Shiga, Japan.

GABA, an inhibitory neurotransmitter, plays an important role in the nucleus tractus solitarius (NTS). The nucleus is associated with taste sensation, general visceral input and regulation of the autonomic nervous system. Previous immunohistochemical studies have demonstrated that GABA-positive terminals and neuronal somata are richly distributed in the NTS.

In this study, we examined the immunohistochemical localization of GABA$_A$ receptors in the rat NTS using a monoclonal antibody against the b-subunit. The pattern of distribution was compared with that of presynaptic GABA terminals. Immunoreactivity for GABA$_A$ receptors was confined to the surface of neuronal somata and processes. These positive structures were distributed mainly in the rostral part of the NTS, where GABA terminals were also abundant. In the intermediate and caudal parts of the NTS, however, positive staining for GABA$_A$ receptors was located in the ventrolateral part of the NTS, particularly in the ventrolateral subnucleus. In these regions, GABA-positive terminals were rather sparse. In addition, few if any cells positive for GABA$_A$ receptors were seen in the medial part of the NTS, including the medial subnucleus where GABA-positive terminals were dense. The results clearly indicate that GABA neurons probably act in the rostral NTS via GABA$_A$ receptors but that their actions in the intermediate and caudal parts of the NTS appear to be mediated by receptors that are not detected by the monoclonal antibody used.

Ba^{2+}-SENSITIVITY OF MONOSYNAPTIC AND 4-AP-INDUCED GABA$_B$ IPSPs IN CA1 PYRAMIDAL CELLS OF RAT HIPPOCAMPAL SLICES.

T.M. Pham* and J.-C. Lacaille. Center for Research in Neurological Sciences and Department of Physiology, University of Montréal, Montréal, Qc, Canada H3C 3J7.

GABA$_B$ receptors in hippocampal pyramidal cells may be coupled to heterogeneous K^+ conductances that are differentially sensitive to Ba^{2+}. The aim of this study was to examine with intracellular recordings the effects of barium on GABA$_B$-mediated inhibitory postsynaptic potentials (IPSPs), pharmacologically isolated in the presence of GABA$_A$, NMDA and non-NMDA receptor antagonists, in conventional rat hippocampal slices. In a first series of experiments, monosynaptic GABA$_B$ IPSPs were evoked by stimulation of GABA fibers/cells in str. radiatum, lacunosum-moleculare or oriens. These IPSPs displayed the following characteristics (mean ± sem): amplitude -5.4±0.5 mV, peak latency 150±22 ms, and recovery time 386±37 ms (n=15). The E_{rev} of these IPSPs was -91.6±2.2 mV (n=12). Bath application of 1mM Ba^{2+} completely suppressed monosynaptic GABA$_B$ IPSPs to -35.9±16.0% of control amplitude (n=12; p<.001). Ba^{2+} effects were reversible upon washout (42.0±19.4% of control amplitude; n=4). In a second series of experiments, spontaneous GABA$_B$ IPSPs were induced by bath application of 100 µM 4-aminopyridine (4-AP). Spontaneous 4-AP induced GABA$_B$ IPSPs had the following properties: amplitude -8.1±0.6 mV, rise time 215±20 ms, recovery time 1.8±0.4 s (n=10). Their E_{rev} was -107.2±3.6 mV (n=7). Synchronized GABA$_B$ IPSPs were progressively abolished by bath application of Ba^{2+} (n=8). Spontaneous GABA$_B$ IPSPs recovered after washout of Ba^{2+} (64.8±5.4% of control amplitude, n=7). These results indicate that GABA$_B$ IPSPs, either evoked monosynaptically or synchronously induced in 4-AP, were mediated by K^+ conductances sensitive to Ba^{2+}. Thus, synaptically released GABA may not activate postsynaptic GABA$_B$ receptors linked to Ba^{2+}-insensitive K^+ conductances.

KINETIC PROPERTIES OF EVOKED MONOSYNAPTIC FAST IPSCS IN NEOCORTICAL PYRAMIDAL CELLS.

D.S.F. Ling*[,1] and L.S. Benardo[1,2]. Depts. of Pharmacology[1] and Neurology[2], SUNY-Health Science Center, Brooklyn, NY 11203.

Previously, we examined the recruitment properties of fast IPSCs in neocortical layer V pyramidal cells (PCs) and found that the magnitude of fast GABAergic inhibition is absolutely limited. However, overall inhibitory strength is also determined by IPSC kinetics. For example, if IPSC time decay is prolonged as a consequence of volume transmission, an increase in total charge transfer results. We have, therefore, examined the kinetic properties of fast IPSCs using whole-cell techniques to record from layer V PCs in slices (400µm) of somatosensory cortex from young (P15-30) rats. Fast IPSCs were evoked with graded stimuli applied to layer V/VI. Cesium-gluconate electrode solutions were employed to block slow GABA$_B$-mediated IPSCs and excitatory synaptic transmission was blocked with CPP and CNQX (10µM). Isolated IPSCs were best fit with an equation describing second-order activation and single-exponential current decay. There was no apparent correlation between IPSC kinetics and stimulus intensity. When IPSCs reached maximal amplitude, further increases in stimulus intensity did not cause significant changes in either IPSC rise or decay. The consequences of these kinetic properties for limited fast inhibition and the underlying pre- and postsynaptic mechanisms will be discussed. (Supported by MH51677)

DUAL MODULATION OF GABA$_A$ RECEPTORS BY EXTERNAL H^+ IONS IN ACUTELY ISOLATED RAT HIPPOCAMPAL NEURONES

Michael Pasternack*, Sergei Smirnov and Kai Kaila.
Department of Biosciences, Division of Animal Physiology, University of Helsinki, P.O.BOX 17, FIN-00014 Helsinki, Finland

We have studied the effect of extracellular H^+ on the GABA$_A$ receptor-mediated chloride conductance in acutely isolated pyramidal neurones from the rat hippocampus under whole-cell voltage clamp in HCO_3^--free solutions. The conductance evoked by saturating concentrations (500-1000 µM) of GABA showed a marked sensitivity to variations in external pH (pH_o) around 7.4. A rise in pH_o between 6.4 and 8.4 decreased the conductance by about two-fold per pH unit. However, when evoked by low GABA concentrations (1-10 µM) the conductance showed an equally marked increase upon an increase in pH_o. At an intermediate concentration of GABA (around 30 µM), the GABA$_A$ conductance was not affected by external H^+. The concentration-response relationship was flat between 50-100 µM GABA, consistent with the presence of at least two functionally distinct GABA$_A$ receptors with different affinities. The effect of pH_o was best described as a combination of two effects: i) a downmodulatory effect of H^+ seen as a parallel shift to the right in the concentration-response curve of the higher affinity GABA receptor, and ii) an upmodulatory effect of H^+ seen as a non-competitive potentiation of both the higher and the lower affinity receptor populations. Zn^{2+} (1-50 µM) inhibited in a concentration-dependent manner the conductance induced by saturating GABA concentrations. In addition, at pH_o 8.4 Zn^{2+} induced a parallel positive shift in the GABA concentration-response curve. In the presence of Zn^{2+} the GABA$_A$ conductance was upmodulated by H^+ at both high and low agonist concentrations. The above data implie a coexistence in these cells of two functionally distinct GABA$_A$ receptor populations with different affinities to GABA and different sensitivities to H^+ and Zn^{2+}. The high sensitivity of GABA$_A$ receptors to H^+ suggests that the efficacy of central inhibition depends on the regulation and modulation of interstitial pH in the brain.

804.11

GABAergic MODULATION OF NEURONS FROM THE HORIZONTAL LIMB OF THE DIAGONAL BAND OF BROCA (hDBB) THAT PROJECT TO THE HIPPOCAMPUS.

J.C. Easaw*, B.S. Jassar, K.H. Harris and J.H. Jhamandas. Department of Medicine (Neurology) and Division of Neuroscience, University of Alberta, Edmonton, Alberta, Canada.

Anatomical data indicate reciprocal projections between the hDBB and the hippocampus. GABA has been identified as a major transmitter in these pathways, which have been implicated in the generation and maintenance of the hippocampal theta rhythm. We have examined the actions of GABA receptor agonists on acutely, dissociated rat hDBB neurons using the whole-cell patch-clamp technique. Fluorescein-labelled latex microspheres were injected into the hippocampus to retrogradely label cells in the hDBB. Three to four days later, cells were acutely dissociated using enzymatic treatment and visualized under fluorescent microscopy to identify the labelled neurons. Current-voltage relationships of the labelled hDBB neurons were similar to those recorded from unlabelled cells. Under voltage-clamp conditions, bath applied muscimol (10µM), a GABA$_A$ receptor agonist, evoked a current that reversed at -69 mV (n=4). Baclofen (10µM), a GABA$_B$ receptor agonist, evoked no response (n=4). These results suggest that GABAergic afferents modulate the activity of the hDBB neurons projecting to the hippocampus through the GABA$_A$ receptor.

INHIBITORY POSTSYNAPTIC POTENTIALS IN RAT SUBICULAR BURSTING NEURONS.

D. Mattia*, H. Kawasaki and M. Avoli Montreal Neurological Institute and Department of Neurology and Neurosurgery, McGill University, MONTREAL, Canada H3A 2B4

Intracellular recordings from rat subicular bursting neurons (BNs, n=35) were made in an in vitro slice preparation to evaluate the inhibitory component of the response to single-shock extracellular stimuli delivered in different portions of the CA1 subfield. Stimulation of the CA1 alveus and CA1 stratum radiatum evoked a sequence of depolarizing-hyperpolarizing potentials in 17 BNs, whereas only a monophasic depolarization was observed in 16 BNs. Stimuli applied either to the CA1 stratum pyramidale or stratum lacunosum-moleculare induced in the same cells (n=2) a depolarizing potential and a depolarizing-hyperpolarizing sequence of potentials, respectively. When varying the resting-membrane potential the stimulus-induced hyperpolarization behaved as expected for an inhibitory postsynaptic potential (IPSP), had a reversal potential of -81 ± 5 mV (n=10) and was associated with an increase in membrane conductance of 25 ± 14 nS (n=5). Shunt of the action potentials induced by prolonged depolarizing current injection occurred when hyperpolarizing IPSPs were elicited by concomitant synaptic stimulation. Bath application of the GABA$_A$ receptor antagonist BMI (10µM, n=4) reduced both the IPSP amplitude and the associated increase in membrane conductance. These findings suggest that only a subset of subicular BNs respond with a hyperpolarizing IPSP when activated by the stimulation of different portions of the CA1 subfield. They also indicate that this hyperpolarizing IPSP is mainly due to the postsynaptic activation of GABA$_A$ receptors located on BNs. Supported by Savoy Foundation and MRC of Canada.

804.13

A BICUCULLINE- AND SACLOFEN-RESISTANT GABA CURRENT IN SUBSTANTIA GELATINOSA OF THE RAT SPINAI CORD *IN VITRO*. M. Yoshimura*, H. Baba, Y. Yajiri and H. Higashi. Dept. Physiol., Kurume Univ. Sch. Med. Kurume 830, Japan.

Stimulation of Aδ afferent fibers evoked a GABAergic IPSP via the $GABA_A$ receptor. In many SG neurons, however, the GABA-induced response was in part resistant to bicuculline and saclofen. To study the property of the GABA response, blind patch clamp recordings were made from SG neurons in the transverse spinal cord slices of the adult rat. Bath applied GABA (0.1 - 1 mM) produced an outward current which consisted of an initial peak and a slowly decaying plateau. The initial peak current was depressed by bicuculline (10 - 100 μM), while the plateau current was hardly affected. $GABA_B$ receptor antagonist, phaclofen (500 μM) and saclofen (500 μM) also had no significant effect on the plateau current. Picrotoxin (60 - 100 μM) depressed the GABA current by more than 60 %. Both the initial peak and plateau currents were reversed in polarity near the Cl^- equilibrium potential. It appears, therefore that the plateau current has a similar property to the $GABA_C$ current reported recently in visual system. The $GABA_C$ receptor analog, *trans*-4-aminocrotonic acid (CACA, 0.5 - 1 mM), in fact, produced in SG neurons a response similar to the GABA response The CACA-induced current was, however, completely abolished by bicuculline (20 μM). These observations provide an idea that SG neurons may express a novel GABA receptor which has a different pharmacological property from the $GABA_C$ receptor and that this receptor may be involved in modulation of nociceptive transmission in the spinal dorsal horn.

MUSCIMOL INDUCES TWO DISTINCT ELECTROPHYSIOLOGICAL RESPONSES IN RAT SUPRACHIASMATIC NUCLEUS NEURONS *IN VITRO*. J.A. Zidichouski*, S.B Kombian and Q.J. Pittman Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada.

The Suprachiasmatic Nucleus (SCN) is implicated as an important hypothalamic site involved in the synchronization of physiological functions that are circadian by nature. Sleep/wake cycles, body temperature, cardiovascular and digestive functions are influenced by cues obtained from the environment. Circadian rhythms are affected by light, the pineal hormone melatonin, and by a variety of pharmacological agents. For example, benzodiazapines cause a significant phase advance in wheel running activity in rodents. GABA immunoreactivity is evident throughout the SCN and GABAergic interneurons are thought to mediate inhibitory postsynaptic potentials recorded within this nucleus. The present study, therefore, examined the electrophysiological effects of exogenous application of the $GABA_A$ receptor agonist muscimol in an in vitro SCN slice preparation (400 μm coronal slices). The whole-cell nystatin patch clamp technique was used and recordings were made from 21 cells located in the dorsal aspect of the SCN. Bath application of muscimol (5-100μM) produced two distinct electrophysiological responses. In 13 of 21 (62%) SCN neurons, a membrane depolarization or inward current was observed. This "atypical" response reversed at -57.7 ±2.1 mV (n=6) and was accompanied by a marked decrease in membrane resistance (26.4% of control ±9.7, n=7). A typical muscimol-induced hyperpolarization or outward current that reversed at -73.8 ±1.1mV (n=6) was observed in the 8 remaining SCN neurons. The mean change in input resistance was 72.3% of control (±7.5% n=3). Both responses were, however, attenuated by the $GABA_A$ channel blocker picrotoxin (25-100μM). PENTOBARBITAL MODULATION OF GABA-A RECEPTOR KINETICS USING ULTRAFAST ACTIVATION IN EXCISED PATCHES OF MOUSE CORTICAL NEURONS. J.J. TINGEY, A.M. LAVOIE, J.R. BARINGER* & R.E. TWYMAN. Programs in Neuroscience, Human Molecular Biology & Genetics, Depts of Neurology & Pharmacology, Univ. of Utah, Salt Lake City, UT

Steady state applications of pentobarbital (PB) have previously been shown to increase GABA-A mediated chloride current by increasing single channel open duration without changing open frequency [Macdonald et al., J. Physiol., 1989]. An ultrafast ligand exchange system (100μs exchange time) was used to examine the effects of PB on GABA binding and gating kinetics (channel activation and relaxation). Outside-out patches from cultured fetal mouse cortex contained >10 channels and were voltage clamped at -75mV in symmetrical chloride solutions at room temperature. GABA (10μM-10mM) alone or in the presence of PB (50μM) was applied to patches using either a series of repeated brief pulses (800μs) or single step applications (50ms-2s). Chloride currents were sampled at 20-100kHz and filtered at 2-10kHz. Current onset (10-90% rise time) and decay time constants (τ) were analyzed individually and as patch ensemble averages.

Pre-application of PB was necessary to see an alteration of kinetics, suggesting that PB binds the receptor more slowly than GABA. As we previously reported for diazepam, PB did not alter channel maximal opening rates. Unlike diazepam, PB prolonged current relaxation indicating that PB increases time spent in one or more bursting states, similar to that seen for steady state single channel recordings.

NEUROPEPTIDE LOCALIZATION: CNS REGULATION

805.1

DISTRIBUTION OF THE NEUROPEPTIDE Y Y2 RECEPTOR mRNA IN RAT BRAIN. E.L. Gustafson*, M.M. Durkin, K.E. Smith, C. Gerald, Y. She, A.I. Illy, R.W. Weinshank and T.A. Branchek. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

The expression cloning of the human NPY Y2 receptor cDNA and the subsequent cloning of the rat homologue (C. Gerald et al., K.E. Smith et al., Soc. Neurosci. Abstr. 1995) have made it possible to localize the mRNA encoding this NPY receptor subtype in rat tissues. We have carried out *in situ* hybridization studies using [^{35}S]dATP-labelled oligonucleotide probes to the rat Y2 receptor mRNA to determine the distribution of Y2 mRNA in the rat brain and peripheral tissues.

Probe specificity was confirmed by testing the radiolabelled oligonucleotides in transfected cells. In rat forebrain, Y2 mRNA is most abundant in the CA3 region of the hippocampus, the medial nucleus of the amygdala, and in the arcuate nucleus and tuber cinereum of the hypothalamus. Hybridization signals are also observed over the olfactory tubercle, the lateral septal area, the basomedial and cortical nuclei of the amygdala, the dorsomedial and ventromedial hypothalamus, the dorsal and ventral premammillary nuclei, the piriform cortex, and the centromedial and paraventricular nuclei of the thalamus. Caudally, hybridization signals for the Y2 mRNA are restricted to the dorsal and caudal linear raphe, the pontine nucleus, and the posterior dorsal tegmental nucleus. In the spinal cord, labelling is observed over scattered large neurons in lamina 9. A subpopulation of large neurons in the dorsal root ganglia also exhibit a low hybridization signal for the Y2 mRNA.

The present results indicate that the mRNA encoding the Y2 receptor is discretely localized in the rat brain. In some areas, colocalization of this novel receptor with NPY itself appears likely, particularly in the arcuate nucleus of the hypothalamus. The distribution of this NPY receptor subtype mRNA suggests involvement in multiple physiological roles.

ASSOCIATIONS BETWEEN NEUROPEPTIDE Y NEURONAL ELEMENTS AND MICROVESSELS IN RAT AND HUMAN CEREBRAL CORTEX. R. Abounader* & E. Hamel, Montreal Neurological Institute, McGill Univ, Montréal, QC, Canada H3A 2B4

Neuropeptide Y (NPY) constricts cerebral intracortical arterioles (Dacey *et al.* 1988 *J. Cereb Blood Flow Metab* 8: 254) and NPY-containing nerve terminals have been incidentally observed in apposition with such intracortical microvessels (Aoki & Pickel 1989 *J Neurosci* 9: 4333). To assess the morphological basis for a putative role of NPY in the regulation of microvascular functions, we performed a quantitative study of the associations of NPY neuronal elements with microvessels in human and rat cerebral cortex, respectively fixed by immersion after surgical removal and by intra-aortic perfusion. Brain sections were immunostained for NPY and analysed using light microscopy. On 20 μm-thick sections, the overall association of NPY neurons with local intracortical microvessels was evaluated. On semithin (2 μm-thick) sections, the total number of NPY neuronal elements, blood vessels and perivascular NPY punctate structures were counted on photomicrographs. Only neuronal elements which directly touched a vessel wall were considered to be perivascular. In the 20 μm-thick sections of rat cerebral cortex, many NPY-containing neurons showed associations with intraparenchymal vessels, these were more frequent between NPY processes and vessel walls than between cell bodies and vessels. On semithin sections in the rat, 3.6% of all NPY punctate structures (n=4709) were perivascular. Also, of all vessels counted (n=476), 22.5% were contacted by at least one NPY element with 7.6% of the vessels having 2 or more NPY processes. In man, an extremely dense network of NPY-containing neuronal elements with very few cell bodies was observed in both thick and semithin sections. Due to the inability to visualize all intracortical vessels and to the very high density of the NPY-innervation in the human cortex, a quantitative analysis was not performed. However, many of the processes, most likely nerve terminals, were apposed to a vessel wall in semithin sections. These morphological data may indicate that cortical microvascular functions are regulated by NPY neuronal mechanisms. Further studies at the ultrastructural level would help define these NPY neurovascular relationships. Supported by Dr Karl Thomae GmbH/Bio-Mega and the MRC of Canada through a University-Industy grant.

PRIMARY HIPPOCAMPAL NEURONAL CULTURES CO-EXPRESS NPY-LIKE IMMUNOREACTIVITY AND NPY Y1 RECEPTORS: A POSSIBLE SELF-AUTOREGULATORY MECHANISM? J.-A. St-Pierre*, Y. Dumont, and R. Quirion. Douglas Hosp. Res. Ctr. and Dept. Neurol. and Neurosurg., and Psychiatry, McGill University, Montréal, Québec, Canada, H4H 1R3.

Neuropeptide Y (NPY) and its homologues induce complex effects in the hippocampal formation that include the modulation of glutamatergic neurotransmission (Colmers and Bleakman *TINS* **17**:373,1994) and sigma receptor systems (Monnet et al. *JPET* **263**:1219, 1992; Bouchard et al. *J. Neurosci.* **13**:3926,1993). At least two classes of NPY receptors, Y1 and Y2 , mediate these functional effects as both sub-types are expressed in the rat hippocampus, albeit each according to a unique anatomical profile (Dumont et al., *J.Neurosci.***13**:73, 1993). In order to investigate further the respective role of the Y1 and Y2 receptors at the cellular and molecular levels, a rat embryonic primary hippocampal neuronal cell culture model was developed and shown to be uniquely enriched with Y1/[^{125}I][Leu^{31},Pro^{34}]PYY binding sites (St-Pierre et al. *Soc. Neurosci. Abst* **20**:85, 1994). The aim of the present study was to establish the phenotype(s) of Y1 receptors-bearing hippocampal neurons using a combined immunocytochemical/emulsion receptor autoradiographic method and focusing first on the possible existence of NPY-immunoreactive neurons in the cultures. Dissociated hippocampal cells from embryonic days 18-19 rats were grown for 20 days on cover-slips. Emulsion receptor autoradiography was then performed using the selective Y1 radioligand, [^{125}I][Leu^{31},Pro^{34}]PYY (35pM), followed by NPY immunocytochemistry (ABC method, Vector) with a highly specific NPY antibody (generously provided by G. Pelletier, Laval Univ.). Most interestingly, a significant proportion of bipolar and pyramidal-like neurons were clearly NPY-immunoreactive and expressed the Y1 receptor sub-type. These results suggest the possible existence, via Y1 receptors, of an autoregulatory mechanism governing NPYergic neurotransmission in the rat hippocampal formation. 805.4

PREPRO-NEUROPEPTIDE Y mRNA EXPRESSION AND RECEPTOR AUTORADIOGRAPHY IN BRAIN FROM HYPERTENSIVE AND NORMOTENSIVE RATS K. J. McLean, B. Jarrott and A. J. Lawrence*. Dept. of Pharmacology, Monash Univ., Clayton, Victoria, 3168, Australia.

Neurons containing neuropeptide Y (NPY) may participate in central cardiovascular control by tonically suppressing the baroreceptor reflex pathway, possibly by influencing barosensitive neurons within the nucleus tractus solitarius (NTS) (1). The present study has employed both in situ hybridization histochemistry and receptor autoradiography, to visualise the expression of preproNPY mRNA in the forebrain and to determine the NPY receptor subtype/s in the brainstem, respectively. Specific hybridization signals to a preproNPY antisense oligonucleotide probe were visualized in the cortex, dentate gyrus, hippocampus and reticular thalamus from age-matched spontaneously hypertensive rats (SHR) and normotensive Don Ryu rats (DRY) and Wistar-Kyoto rats (WKY). Differences in the expression of preproNPY mRNA were only observed in the hypothalamic arcuate nucleus, where densitometric analysis of images revealed values of 4.21 ± 0.39 (SHR; n=7), 1.81 ± 0.53 (DRY; n=8) and 1.42 ± 0.15 dpm/mm^2 (WKY; n=8). Autoradiography using ^{125}I-Bolton Hunter-NPY (BH-NPY, 15 pM) demonstrated NPY binding sites in the dorsal vagal complex and inferior olive. NPY (1 µM) and peptide YY (1 µM), but not [Leu^{31}, Pro^{34}] NPY (10 - 100 nM), fully inhibited the binding of ^{125}I-BH-NPY. These results indicate that NPY receptors of the Y_2 subtype predominate in the dorsal vagal complex. While all three rat strains appear to have the same receptor subtype in the brainstem, the relevance of the differential NPY gene expression in the arcuate nucleus regarding central cardiovascular control mechanisms and /or the pathogenesis of hypertension remains to be elucidated.

[^{3}H]BIBP3226, A NEWLY DEVELOPED NON-PEPTIDE NEUROPEPTIDE Y Y_1 RECEPTOR ANTAGONIST RADIOLIGAND: BINDING CHARACTERISTICS AND QUANTITATIVE AUTORADIOGRAPHY.

Y. Dumont* and R. Quirion. Douglas Hospital Research Center, Dept. Psychiatry, McGill University, 6875 LaSalle Blvd., Montréal, Québec, Canada, H4H 1R3.

Rudolf et al. (Eur. J. Pharmacol., 271: R11-R13, 1994) recently reported the development of a highly selective non-peptide neuropeptide Y (NPY) Y_1 receptor antagonist, devoid of activity on the Y_2 and Y_3 (Jacques et al., Eur. J. Pharmacol. in press) receptor subtypes. This suggests that BIBP3226, in a radiolabelled form, could prove most useful as the first antagonist radioligand to investigate Y_1 receptor binding parameters. Entzeroth et al. (Eur. J. Pharmacol., in press) have just developed [^{3}H]BIBP3226. This new radioligand was studied here using both rat brain membrane binding assays and receptor autoradiography according to protocols described earlier (Dumont et al., J. Neurosci., 13: 73-86, 1993). Unlabelled BIBP3226 competed with high affinity for rat brain Y_1 (Ki of 1 nM) but not Y_2 (> 1 µM) binding sites. Autoradiograms revealed that 100 nM BIBP3226 competed for at least 75 to 90% of 30 pM [^{125}I][Leu^{31},Pro^{34}]PYY/Y_1 agonist binding sites in most brain regions including in the superficial layers of the cortex, various thalamic nuclei, the dentate gyrus of the hippocampus and the cerebellum. In contrast, few areas such as the glomerular layer of the olfactory bulb, lateral septum, nucleus tractus solitarius (NTS) and area postrema are rather resistant (<30%) to BIBP3226. The direct use of [^{3}H]BIBP3226 (5 nM) as radioligand confirmed and extended these findings with high specific labelling concentrated in cortical areas and in the thalamus for example, but not in the NTS and the area postrema. Taken together, these results may suggest the possible existence of Y_1 receptor subtypes, one being highly sensitive to BIBP3226. Supported by an MRCC Industry/University Grant jointly with Thomae GmbH/Bio-Mega.

NEUROPEPTIDE Y Y_1 AND Y_2 RECEPTOR BINDING SITES IN THE RAT AND HUMAN SPINAL CORD: EFFECT OF SURGICAL MANIPULATIONS AND AMYOTROPHIC LATERAL SCLEROSIS (ALS). D. Jacques[1], Y. Dumont[1], S. Kar[1], C. Krieger[2], A. Fournier[3], S. St-Pierre[3] and R. Quirion[1]. [1]Douglas Hospital Res, Ctr, Dept. Psychiatry, McGill University, Montreal, Canada, H4H 1R3; [2]University of British Colombia, University Hospital, Vancouver, Canada; [3]INRS-Santé, 245 Boul Hymus, Pointe-Claire, Canada, H9R 1G6.

Autoradiographic studies have shown that following sciatic nerve sectioning, [^{125}I]BH-NPY binding decreased while [^{125}I]PYY labelling increased in the superficial laminae of the ipsilateral dorsal horn (Kar and Quirion, Brain Res.,574:333, 1992; Zhang et al., Eur. J. Neurosci., 7:367, 1995). In order to determine the neuropeptide Y (NPY) receptor subtypes involved, the respective distribution of the Y_1 and Y_2 receptors was investigated in the rat and human spinal cord using recently developed selective radioligands (Dumont et al., J. Pharmacol. Expt.Ther. 272: 673, 1995). Another series of experiments were carried out to determine whether Y_1 and Y_2 receptor binding sites are differentially altered following sciatic nerve lesion and in ALS spinal cord. Autoradiographic studies revealed that high levels of both Y_1/[^{125}I][Leu^{31},Pro^{34}]PYY and Y_2/[^{125}I]PYY$_{3\text{-}36}$ binding sites are present in laminae I and II of the dorsal horn of the adult rat spinal cord. Deeper laminae and the ventral horn are more heavily labelled with Y_2 ligand. Following unilateral sciatic nerve section (14 days), specific Y_1 binding decreased while Y_2 labelling increased in the superficial laminae of the ipsilateral dorsal horn. In contrast to the rat spinal cord, Y_1/[^{125}I][Leu^{31},Pro^{34}]PYY and Y_2/[^{125}I]PYY$_{3\text{-}36}$ binding sites are rather similarly distributed in the normal human spinal cord with labelling particularly concentrated in laminae I and II, and the ventral horn expressing low but still significant levels of binding sites. No significant alterations were noted in the distributional profile and/or density of Y_1 or Y_2 receptor subtypes in the ALS cord. Taken together, these results suggest that both the Y_1 and Y_2 receptor subtypes are expressed in the rat and human spinal cord, and are differentially regulated following sciatic nerve lesioning. Supported by the MRCC and an Industry-University grant.

DISTRIBUTION OF [^{3}H]-NEUROTENSIN RECEPTORS IN HUMAN BRAIN. Steven R. Daviss*, Carol A. Tamminga, and Robert A. Lahti. Maryland Psychiatric Research Center, University of Maryland School of Medicine, P.O. Box 21247, Baltimore, MD 21228.

The distribution of receptors for neurotensin in human brain are distributed primarily in so-called limbic areas, with a distribution that appears to be distinct from that of dopamine receptors. We have examined dopamine receptor subtype distributions within human brain, and would like to compare these distributions with that of neurotensin receptors in brain tissue from normal controls. We present here autoradiographic data using [^{3}H]-neurotensin (^{3}H-NT) to locate NT receptors in normal human brain. Two coronal hemi-blocks were cut at the level of the head of the caudate and at the level of the hippocampus from frozen human brain tissue from three individuals with no known psychiatric or neurologic illnesses. Each hemi-block was divided into 3 smaller blocks, and these were sectioned at 20µm on a cryostat, thaw mounted, incubated in ^{3}H-NT, and developed on tritium-sensitive film. Digitized images were used to estimate specific binding across blocks and cases. Areas of intense binding include anterior cingulate cortex (ACC), insular cortex, and entorhinal cortex (ERC), with moderate binding in caudate, amygdala, subiculum, and prefrontal cortex (PFC). Binding within ACC and PFC superficial cortical layers was about twice that in deep layers. Discrete areas of intense binding within the superficial layers of ERC were consistent with localization to the layer II cellular islands. These data are consistent with previous reports of distribution of [^{125}I]-NT receptors in human brain tissue.

NEUROTENSIN RECEPTOR mRNA LOCALIZATION IN HUMAN MIDBRAIN, BASAL GANGLIA, CINGULATE CORTEX AND HIPPOCAMPAL FORMATION BY IN SITU HYBRIDIZATION. S.S. Wolf[1]*, S.E. Bachus[1], B.L.Kinkead[2], M.J. Owens[2], C.B. Nemeroff[2], J.E. Kleinman[1], T.M. Hyde[1]. [1]NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032 and [2]Dept. of Psychiatry and Behavioral Sciences, Emory University School of Medicine, Atlanta, GA 30322

Neurotensin (NT) is a putative CNS neurotransmitter which may be implicated in certain neuropsychiatric disorders. High concentrations of NT receptors are present in specific brains regions, including the substantia nigra (SN), ventral tegmental area (VTA), entorhinal and cingulate cortices, with moderate concentrations in the basal ganglia. Recently, human midbrain and striatal NT receptor mRNA was localized by *in situ* hybridization (Yamada et al., *Neuroscience* 64: 405-417, 1995). We have corroborated these findings and further examined select limbic regions in which NT receptors have previously been reported to be concentrated. Utilizing a ^{35}S-labelled antisense riboprobe, we examined several rostro-caudal levels of 8 normal human midbrains. High levels of NT receptor mRNA signal were detected in the substantia nigra pars compacta and in the paranigral subnucleus of the VTA. In contrast, faint signal was detected in other subnuclei of the VTA and other mesencephalic structures. No significant signal was observed in striatum. In the hippocampal formation, moderate signal was seen in the dentate gyrus, with light labeling of layer II of the entorhinal cortex. Pregenual cingulate cortex revealed only faint signal in a homogenous pattern. The association of high NT receptor mRNA signal with dense NT receptor concentrations in some regions, such as SN, is consistent with a perikaryal localization of NT binding sites. In contrast, the significant mismatch of moderate or high receptor density in striatum, cingulate and entorhinal cortices, with faint, or absent, mRNA signal suggests that these regions may represent terminal NT binding sites.

805.9

COEXISTENCE OF VASOACTIVE INTESTINAL PEPTIDE mRNA AND NEUROTENSIN RECEPTOR mRNA IN MANY NEURONS OF THE SUPRACHIASMATIC NUCLEUS IN THE FEMALE RAT.

E. Bartolák-Suki, M.J. Alexander*, and S.E. Leeman. Dept. of Pharmacology & Exper. Therapeutics, Boston University School of Medicine, Boston, MA 02118.

Vasoactive intestinal peptide (VIP)-synthesizing neurons in the suprachiasmatic nucleus (SCN) are implicated in the regulation of gonadotropin-releasing hormone (GnRH) secretion. Recently, it has been suggested that neurotensin (NT) binding sites are closely associated with VIP-containing neurons in the SCN (Francois-Bellan et al., *Synapse* 10:282, 1992). The goal of the present study was to investigate whether, and to what extent, VIP neurons in the SCN express mRNA encoding the high-affinity NT receptor (NTR). Coronal sections were prepared from the brains of adult female rats (n = 8), and double-label *in situ* hybridization histochemistry with digoxigenin-labeled and radiolabeled (^{35}S or ^{33}P) cRNA probes was used for simultaneous detection of VIP mRNA and NTR mRNA in individual cells. As expected, both mRNAs were detected primarily in the ventral SCN, where the regional distribution of VIP mRNA labeling coincided with that of NTR mRNA labeling at all rostrocaudal levels. Although single-labeled cells of either type were observed, the vast majority of VIP mRNA-labeled cells also displayed NTR mRNA labeling. Our results provide definitive evidence that neurons capable of synthesizing VIP are by far the predominant cell type in the SCN that expresses NTR mRNA. Moreover, these results suggest that VIP-synthesizing neurons are the major cell type in the SCN in which NTR levels are reduced by estrogen, as shown in previous studies. We speculate that NT-mediated hormonal input and photic/circadian inputs are integrated in the SCN by certain VIP-synthesizing neurons which directly regulate the activity of GnRH neurosecretory cells. Supported by NIH Grant DK 29876.

DISTRIBUTION AND SEASONAL VARIATION OF VIP-LIKE PEPTIDES IN THE NERVOUS SYSTEM OF *HELIX POMATIA*.

A. Hermann*, W. Kaufmann and H. Kerschbaum. Dept. of Animal-Physiology, Univ. of Salzburg, Inst. of Zoology, Hellbrunnerstr. 34, A-5020 Salzburg, Austria.

The distribution of neuropeptides immunologically related to vasoactive intestinal peptide (VIP) and its precursor peptide preproVIP(111-122), was studied in the central and peripheral nervous system of the snail, *Helix pomatia*, by use of immunocytochemical methods. VIP and preproVIP-related immunoreactivity were present in somata and nerve fibres in subpopulations of neurons in all central ganglia. Hibernating snails contained on average a total of 670 VIP- and 763 prepro-VIP-immunoreactive neurons. The number of immunoreactive cells was substantially reduced by more than 50% in active snails during summer with an average of 289 VIP- and 356 prepro-VIP-immunoreactive neurons. Antiserum against VIP labelled nerve fibres next to blood vessels and smooth muscle cells, whereas prepro-VIP-like material was localized in nerve fibres and endocrine-like cells. VIP-immunoreactive material was also found in accessory ganglia of small and large tentacles, ganglia of the lips, the sensory epithelium of the tentacles, free nerve endings between skin epithelial cells, neuronal cells in the retina and in the sensory epithelium of statocysts.

The cell-specific distribution and the seasonal variation of VIP- and preproVIP-like peptides suggests that they may act as transmitters or modulators in the nervous system and may be involved in the physiological adaptation of central neurons during long-term resting periods of snails.

The number of striatal neurons with CCK-like immunoreactivity is ipsilaterally increased in unilateral 6-OHDA lesioned rats

R. Schade, K. Brăntigam, H. Grasmo, C. Pfister, K.M. Bode-Greuel*
Institute of Pharmacology and Toxicology, Department of Medicine (Charité), Humboldt-University of Berlin, Bayer AG, Wuppertal, Germany

The existence of striatal CCK-ergic neurons is controversial discussed in literature. There is evidence both for striatal perikarya with CCK-like immunoreactivity (CCK-IR) and CCK mRNA in this rat brain region. Other studies failed to demonstrate perikarya with CCK-IR or CCK transscription material in basal ganglia of the rat brain. Previously, we have described a new avian antibody (Ab) raised against the sulphated CCK-8. Using this antibody neurons of different size and shape can be visualized in the striatum. Since CCK and dopamine (DA) were found to be colocalized in neurons of the mesencephalon of rats, it was speculated that CCK may have a neuromodulatory influence on DA. The 6-OHDA-lesion is a tool used commonly to investigate the influence of any neuronal substance on the DA function.. Thus, using the new avian anti CCK-Ab the present study was aimed to investigate whether or not a 6-OHDA (MFB) lesion has any influence on the distribution pattern of striatal CCK-IR structures.

It could be found that the number of CCK-ergic neurons significantly is increased ipsilaterally (150 %) to the lesioned hemispere 3 months following the 6-OHDA-lesion. No differences could be observed between the both hemispheres 1 month after the lesion. The increasing number of visualized CCK-ergic neurons seen in the lesioned hemisphere is interpreted as a functional parallel with receptor up/down regulation. The observed difference between both hemispheres may reflect a quite similar phenomenon but on a different level of functional brain organization. This response may also due to compensatory mechanisms which develop time dependently. Despite of our limited insight in neuronal interactions in general, the present results further substantiate the hypothesis of a nigrostriatal (and vice versa) regulatory CCK/DA relation (directly or indirectly).

THE ORIGIN OF CCK IN CAUDATE AND NUCLEUS ACCUMBENS: COMBINED MICRODIALYSIS, RETROGRADE TRACING AND IN SITU HYBRIDIZATION ANALYSES.

A. E. Kresse*, A. Reyes, P. Micevych and N. T. Maidment. Neurobiology and Psychiatry, UCLA, Los Angeles, CA 90024.

Contrary to several anatomical reports we have been unable to provide evidence for a dopaminergic midbrain origin for caudate (CPu) and nucleus accumbens (Acb) extracellular CCK measured by microdialysis (Soc. Neurosci. Abstr. **18**, 1369, 1992). Morino et al (1992) provided evidence for a cortical origin of extracellular CCK in the CPu. The current experiments were carried out to substantiate these findings and to extend them to the Acb using both microdialysis and histochemical approaches. Male Sprague Dawley rats were anaesthetized with Halothane. Kainic acid was injected bilaterally into a wide cortical area (total of 32 1ul injections). 10 days later rats were implanted with dialysis probes in CPu and Acb. After a 2h equilibration period samples were collected every 30 min. CCK release was evoked by incorporation of veratridine (50 µM) in the perfusion medium for 10 min and measured by RIA. Evoked release of CCK was reduced to 6% of naive control rats. Rhodamine-labeled latex beads were injected into the medial CPu or Acb shell. In situ-histochemical detection of CCK mRNA expression was achieved using a ^{35}S-labeled synthetic oligonucleotide probe. Retrograde tracing analysis revealed ipsi- and contra-lateral input from many regions of the neocortex and substantia nigra compacta (SNC). Also a massive projection from the medial and central amygdala, as well as the anterior dorsal and midline nuclei of the thalamus was observed. About 90% of the retrogradely labeled neocortical neurons also expressed CCK mRNA while this co-localization could be found only occasionally in the amygdala, SNC and thalamus. While very few retrogradely labeled neurons were found in the neocortex following Acb injection, several cortical amygdaloid nuclei, as well as the ventral part of the subiculum (S) and the ventral tegmental area (VTA) showed large numbers of ipsilateral projection neurons. Those in S and VTA were also found to express CCK.

805.13

IMMUNOLOCALIZATION AND QUANTITATION OF FIBROBLAST GROWTH FACTOR RECEPTOR-1 IN THE HUMAN PERIPHERAL NEUROMA.

Q. Ma, R.W. Beuerman*, S. Zhao, L. Pedroza, H. Tran, D. Nguyen, D.G. Kline. Dept. of Ophthalmology, LSU Eye Center, New Orleans, LA 70112

Immunocytochemical localization of fibroblast growth factor receptor-1 (FGFR-1) was studied in the cultured cells (passage 4 or 5) from human neuroma tissue obtained at the time of surgery. The cultured cells consisted of large numbers of fibroblasts and a few Schwann cells identified by anti-NGF receptor. The results showed that the fibroblasts were positively stained using an immunohistochemical procedure with a monoclonal antibody to recognize FGFR-1. Further, the subcellular location of FGFR-1 in the cells was investigated by electron microscopy using pre-embedding indirect immunogold double labeling. The particles (15 nm gold probe for FGFR-1) were found to be arranged regularly along the cell membranes at an average distance of 1.3±0.5 µm from the receptors, and particles (5 nm gold probe for basic fibroblast growth factor) were also present in the cytoplasm. It is interesting that the numbers of gold particles (for FGF receptor-1) were dramatically reduced after administration of basic fibroblast growth factor in the binding test. FGF membrane receptors were quantitated by flow cytometry using microbeads as the standard. The receptor density was calculated to be about 5600 per cell. The results will be useful for determining the function of FGF receptors in the formation of neuromas. Supported in part by DAMD17-93-V-3013.

805.14

DISTRIBUTION OF IMMUNOREACTIVE NERVE GROWTH FACTOR IN THE BRAIN AND PITUITARY GLAND OF *XIPHOPHORUS*.

L. Magliulo-Cepriano[1], M.P. Schreibman[2]* and M. Schartl.[3] State University of New York, Farmingdale[1], Brooklyn College Biology Department, C.U.N.Y., Brooklyn, NY 11210[2], Universitat Wurzburg, Germany[3].

Antisera generated against Xiphophorus neurotropin-6 was utilized to study the distribution of immunoreactive (ir)- nerve growth factor (NGF) in the brain and pituitary gland of *Xiphophorus maculatus*, the platyfish, at different stages of sexual development. In both immature and mature animals, ir-NGF was found in an intensely stained cluster of perikarya in the anterior lateral nucleus lateralis tuberis (NLT). Processes of these cell bodies extended ventromedially toward and through the infundibulum and into the neurohypophysis of the pituitary gland. In the pituitary, immunoreactivity was seen in the pars intermedia and in the gonadotropic zone of the caudal pars distalis. Immunoreactivity was also noted in the hindbrain of mature animals. In neonatal animals, ir-granules were also noted around cells of the anterior olfactory lobe. These data suggest that NGF is involved in pituitary gland physiology, from very early in neonatal life, into sexual maturity. [Supported by NASA (NAGW-1704) and BARD (IS-2149-92)]

805.15

A COMPREHENSIVE ANALYSIS OF THE DISTRIBUTION OF FGF-2 AND FGFR1 IN THE RAT BRAIN. A.M. Gonzalez*, M. Berry†, P.A. Maher, A. Logan§, and A. Baird. The Scripps Research Institute, Dept. of Cell Biology, La Jolla, CA; †UMDS (Guy's Campus) London, UK; §Dept. of Clinical Chemistry, Univ. of Birmingham, UK

We examined the distribution of basic fibroblast growth factor (FGF-2) and its receptor (FGFR1). The results confirm the widespread distribution of both, and different regions express distinct patterns of protein: neuronal and non-neuronal cells show different subcellular distributions that vary according to the area where they are located. The intensity of staining and hybridization also varies according to the loci examined and the cell type involved. Astrocytes contain the highest levels of FGF-2 and FGFR1 mRNAs, and possess high levels of nuclear ir-FGF-2. Amongst non-neuronal cells, oligodendrocytes do not contain significant levels of ir-FGF-2; however they do express FGFR1 mRNA. In these cells, ir-FGFR1 is mainly associated with the myelin sheaths of neuronal fibers. In ventricular systems, ependymal cells synthesize and contain ir-FGFR1, but only cells lining the lateral wall of the III ventricle express FGF-2 mRNA. Subependymal cells contain high levels of both ir-FGF-2 and ir-FGFR1. Neurons express low levels of FGF-2 mRNA and ir-FGF-2 is localized predominantly to the perikaryon. However, select populations of neurons, (CA2 field of the hippocampus) show high levels of FGF-2 mRNA, in which the nucleus is strongly immunopositive. Similarly, high levels of FGFR1 mRNA are localized to select populations of neurons, (*e.g.*, amygdala). ir-FGFR1 is mainly associated with myelinated fiber tracts (*e.g.*, striatum), and some neurons show immunoreactivity in the perikaryon (*e.g.*, hippocampus), the nucleus (*e.g.*, mesencephalic trigeminal nucleus), or in axonal projections (*e.g.*, hypothalamus). In many areas, FGF-2 and FGFR1 mRNA and/or their translated protein do not co-localize in neurons (*e.g.*, neo-cortices) or even in the same regions of the brain (*e.g.*, substantia nigra). In other instances, mRNAs colocalize (*e.g.*, supraoptic nucleus). The highly specific anatomical distribution of ir-FGF-2 supports the notion that it plays a multifunctional role in the CNS. This comprehensive analysis should resolve numerous disparate findings described in the literature.

805.16

DIFFERENTIAL EXPRESSION OF CHROMOGRANIN A (CgA) HIGHLIGHTS ASTROCYTIC HETEROGENEITY. D.G.Munoz* and D.X. Deng. Dept. Pathology, University of Western Ontario, London, Ontario, Canada N6A 5C1

The neuropeptide CgA is subjected to cell type-specific proteolytic processing in many varieties of endocrine cells and neurons. McAuliffe and Hess reported that rat Bergmann glial cells are labelled by the antihuman CgA monoclonal antibody LK2H10. We now rule out cross-reactivity by demonstrating that LK2H10 does not recognize in western blots of rat brain any protein not present in adrenal medulla. We also immunostained the entire brains of adult male Sprague-Dawley rats with LK2H10 and polyclonal antibodies to the C-terminal sequence of rat CgA, and rat pancreastatin, a CgA-derived peptide. All three antibodies labelled Bergmann glia, as well as a subset of astrocytes. While all extracerebellar astrocytes expressing C-terminus (representing uncut CgA) and pancreastatin were restricted to the white matter, LK2H10 labelled a much wider population, including in addition astrocytes in the motor nuclei of cranial nerves, the molecular layer of cerebral cortex, the posterior (but not anterior) hypothalamus, and the stratum lacunosum-moleculare (but not radiatum) of hippocampus. Colocalization in the same cells of vesicular CgA and GFAP was confirmed by confocal microscopy. These observations show that astrocytes express CgA, and that region-specific populations differentially process CgA, suggesting a remarkable degree of functional heterogeneity, which may be related to CgA's modulatory actions on dendritic growth.

805.17

DIFFERENTIAL PROTEOLYTIC PROCESSING OF CHROMOGRANIN A IN RAT BRAIN NEURONS. D.X. Deng, C. Gibson* and D.G. Munoz. Dept. Pathology, University of Western Ontario, London, Ontario, Canada N6A 5C1

Chromogranin A (CgA) is a prohormone subjected to proteolytic processing. Cell type-specific differential expression of CgA-derived peptides has been observed in endocrine cells. To investigate whether differential processing of CgA takes place in neurons the entire brains of male Sprague-Dawley rats were immunostained with sequence-specific polyclonal antibodies to the CgA-derived peptides ß-granin and pancreastatin, and the C-terminus of CgA, and with 2 monoclonal CgA antibodies. Immunoreactivity for the C-terminus, representing uncut CgA, was widespread in perikarya, except for most neurons in cerebral neocortex, thalamus, neostriatum, and cerebellar cortex. All other antibodies labelled partially overlapping subsets of this population, and of synaptic terminals. For example, LK2H10 intensely labelled perikarya in the supraoptic and paraventricular nucleus, and ß-granin the central nucleus of the amygdala. In addition ß-granin was expressed in a subset of myelinated axons in the brain stem, and pancreastatin in circumventricular and subpial varicose fibers. These results indicate that CgA is proteolytically processed in neurons prior to axonal transport of large dense core synaptic vesicles. The differential expression of CgA fragments in neuronal populations suggests distinct functional roles for each CgA-derived peptide.

PEPTIDES: PHYSIOLOGICAL EFFECTS IV

806.1

INCREASED VASOPRESSOR ACTIONS OF NEUROPEPTIDE Y-(13-36) IN SPONTANEOUSLY HYPERTENSIVE VERSUS NORMOTENSIVE RATS MAY BE DUE TO INCREASES IN Y_2 RECEPTOR BINDING IN THE NUCLEUS TRACTUS SOLITARIUS. P. B. Hedlund*, J. A. Aguirre[1], J. A. Narváez[1], and K. Fuxe. Dept. of Neuroscience, Karolinska Institutet, S-171 77 Stockholm, Sweden and [1]Dept. of Physiology, Univ. of Málaga, Málaga, Spain

The C-terminal NPY fragment (13-36) [NPY-(13-36)], a NPY Y_2 receptor agonist, elicits vasopressor responses upon central administration. We have studied the cardiovascular responses of NPY-(13-36) and the distribution of NPY receptor subtypes within the nucleus tractus solitarius (nTS) in spontaneously hypertensive rats (SHR). NPY-(13-36) was injected intracerebroventricularly in different doses (7.5 to 3000 pmol) in awake, unrestrained rats to evaluate the cardiovascular effects. NPY receptor subtypes were studied by autoradiography using [^{125}I]peptide YY ([^{125}I]PYY) as a radioligand and by masking the Y_1 and Y_2 receptor subtypes with unlabelled [Leu^{31},Pro^{43}]NPY and NPY-(13-36) respectively. In both male SHR and age-matched male normotensive Wistar-Kyoto rats (WKY) NPY-(13-36) injections elicited vasopressor effects. In WKY this effect was dose-dependent and became significant at doses from 75 pmol, whereas in the SHR the vasopressor effect had a longer duration than in the WKY and became significant at lower doses (25 pmol) but associated with the development of an early ceiling effect. The heart rate was unaffected in both groups of rats. Total specific [^{125}I]PYY binding in the nTS was 25% higher in SHR than in WKY rats. By masking the Y_1 and Y_2 receptor subtypes respectively it could be shown that this difference was due to an increase in Y_2 receptor binding within the nTS. The present results give evidence for an increased potency but not an increased efficacy of NPY-(13-36) in inducing a pressor response in the SHR associated with a longer duration as compared with the WKY rats. These enhanced vasopressor effects may partly be explained on the basis of an increased density of Y_2 receptor (vasopressor effects) versus Y_1 receptor subtypes (vasodepressor effects) leading to a dominance of Y_2 over Y_1 transduction in the SHR. The peak activity of NPY-(13-36) in SHR may not be increased due to the already high blood pressure levels in these rats.

806.2

NEUROPEPTIDE Y mRNA IS INCREASED IN THE ARCUATE AND HIPPOCAMPAL HILUS AFTER ACUTE STRESS. C.D. Conrad* and B.S. McEwen. The Neuroendocrinology Lab, The Rockefeller University, New York, New York 10021

Arcuate and hilar NPY mRNA expression has been shown to be regulated by adrenalectomy (ADX) and a 1 week infusion of adrenal steroids (Wantanabe et. al., Mol Brain Res. (1995) 28: 135-140). ADX caused an increase in NPY mRNA whereas NPY mRNA decreased in the arcuate. We investigated whether acute stress would also exert a differential effect on NPY mRNA expression in the hippocampal hilus and arcuate nucleus. Male rats were acutely stressed by placing them in wire mesh restraints for 1 hour. Rats were decapitated at 0 (no stress), 1, 6 and 24 hrs after restraint. In situ hybridization was used to determine NPY mRNA levels. Film analysis of the autoradiograms indicated that NPY mRNA increased in the arcuate 24 hrs after one exposure to restraint stress, $F(3,35)=3.427$, $p<0.05$. NPY message was not elevated 1 and 6 hours after restraint compared to non stressed rats (10 rats/group). NPY mRNA increased in the dentate hilus 6 and 24 hrs after restraint compared to the non stressed and 1 hr groups, $F(3,19)=3.747$, $p<0.05$ (5-6 rats/group). Preliminary data from grain count analysis concur with the film results. Corticosterone (CORT) levels indicated that serum CORT was elevated immediately following the stressor (1 hr rats = 41.6 μg/dl) and that these levels declined by 6 hours. These data indicate that exposure to one hour of restraint stress is sufficient to elevate NPY mRNA levels in both the arcuate nucleus and hippocampal hilus. Furthermore, acute stress did not differentially alter NPY mRNA expression between the arcuate and hilus. Supported by grants MH10804 to CC and MH41256 to BM.

EFFECTS OF NEUROPEPTIDE Y AND SIGMA RECEPTOR ANTAGONISTS ON NMDA-STIMULATED [^{3}H]DA RELEASE FROM SLICES OF RAT PREFRONTAL CORTEX AND STRIATUM. D.T. Ault* and L.L. Werling. Depts. of Neuroscience and Pharmacology, The George Washington University Medical Center, Washington, DC 20037.

Although the identity of the endogenous ligand for sigma receptors is controversial, various neuropeptides and steroids have been shown to compete for binding to these receptors. Among endogenous sigma receptor ligand candidates is neuropeptide Y (NPY) which mimics electrophysiological preparations of some sigma ligands. We have previously shown that prototypical sigma agonists such as (+)pentazocine and BD737 inhibit stimulated [^{3}H]DA release in various brain regions. Using a superfusion system, we compared the effect of NPY on stimulated [^{3}H]DA release to the effects of these ligands. In contrast to (+)pentazocine- and BD737-mediated inhibition of release, NPY enhanced release at nM concentrations. Several sigma antagonists reversed the enhancement. Effects of NPY receptor antagonists are currently being tested. (Supported by a NIDA grant to LLW.)

BLOOD PRESSURE CHANGES INDUCED BY ANGIOTENSIN ANALOGUES DESIGNED TO INTERACT WITH THE AT$_1$ RECEPTOR SUBTYPE. J.W. Wright*, A.J. Bechtholt, S.L. Esser and J.W. Harding. Departments of Psychology and VCAPP, Washington State University, Pullman, WA 99164-4820.

Three angiotensin receptor subtypes have now been identified and characterized within the brain renin-angiotensin system (RAS). Of these, the AT$_1$ subtype appears to be responsible for mediating the classic physiologies and behaviors associated with the brain RAS, namely pressor and drinking responses, vasopressin release, salt appetite, and sexual behavior accompanied by cyclic regulation of reproductive hormones. It has been assumed that angiotensin II (AngII) activates the AT$_1$ receptor subtype, although there is evidence that angiotensin III (AngIII) may also act at this site (reviewed by Chiu et al., 1993). The present investigation utilized three metabolically stable angiotensin analogues in an effort to determine the form of angiotensin that activates the centrally mediated pressor response. Each of these analogues was modified at the N-terminus with a hydroxylethylamine group ($CHOHCH_2NH$) amide bond. This bond primarily differs from the peptide bond in that it permits free rotation of the backbone bonds, it is 1.67 angstroms longer, and it significantly increases the half-life of each molecule.

Intracerebroventricular infusion of each analogue (100 pmol/min) for 10 min in alert rats indicate maximum mean (+SEM) systemic blood pressure elevations of 20+5.7, 21+2.6, and 17+0.9 mm Hg for AngII, III, and IV pseudopeptide analogues, respectively. Comparable values for native AngII, III, and IV were 24+2.2, 21+3.1, and 15+1.1 mm Hg. These results suggest that native AngII and III are equipotent at the AT$_1$ receptor subtype, while AngIV is less potent. The advantage offered by AngII over AngIII may be that it activates this receptor as AngII, and is then converted to AngIII that also activates the receptor, followed by conversion to AngIV which is briefly activated. AngIII does not offer this "multiple-ligand" effect.

THE EFFECTS OF ESTROGEN ON ANGIOTENSIN II STIMULATED PROLACTIN SECRETION IN VITRO. W. Bryant, K. Zechiel and P. Callahan*, Dept of Zoology, Center for Neuroscience, Miami University, Oxford, Ohio 45056.

The role of Angiotensin II (AII) in the physiological regulation of Prolactin (PRL) release is unknown. The purpose of these studies was to determine the effect of estrogen on the AII - induced PRL secretory response from dispersed anterior pituitary cells. Female rats were ovariectomized (ovx) at 4-6 weeks of age and divided into 2 groups. One group of ovx females received estrogen replacement pellets (ovx + E), while a second group received placebo (ovx). A third group of female rats was left intact. Two months later, the stimulatory effects of AII on PRL release were determined *in vitro*.

Administration of AII significantly stimulated PRL release in cells obtained from intact female donors. AII did not stimulate PRL secretion from cells obtained from ovx + E treated females and was only weakly stimulatory to cells obtained from ovx rats. These results indicate that estrogen alone is not responsible for the sensitivity to AII stimulation observed in cells from intact female rats. Also, AII did not stimulate PRL secretion from cells obtained from male rat donors. Scatchard analysis of Sar^1-Ile^8 AII binding revealed no difference between K_d and B_{max} values in male and female anterior pituitaries.

Thus, it appears that anterior pituitary cells from female rats are sensitive to AII stimulation, but that estrogen is not solely responsible for this sensitivity. This response to AII stimulation does not appear to be a receptor mediated phenomenon since there was no difference in receptor binding characteristics (K_d and B_{max} values) between pituitaries obtained from male or female rats. (Supported by NIH grant DK 48023 to PC).

GLUCOCORTICOID REGULATION OF THE VASOPRESSIN V1a RECEPTOR IN THE SEPTUM OF RAT BRAIN

J. J. Watters*[a], C. W. Wilkinson[b], C. F. Ferris[c] and D. M. Dorsa[b]

Departments of Pharmacology [a], Psychiatry and GRECC [b], VAMC Seattle and American Lake, Univ. of WA, Seattle WA 98195 and Dept. Psychiatry Univ. Mass., Worcester, MA [c]

Vasopressin is intimately involved in the hypothalamo-pituitary adrenal axis. V1a vasopressin receptors (V1aR) , the primary subtype expressed in the brain, and their mRNA, are expressed in WRK-1 mammary tumor cells. Both the receptor and its mRNA are enhanced by dexamethasone (DEX) treatment. To examine the molecular basis of this effect, we have isolated a genomic clone encoding the rat V1aR. Approximately 3.5kb have been sequenced revealing the presence of 3 putative glucocorticoid response elements (GREs) in the 5' flanking region of the gene. Gel mobility shift assays using these putative GREs and nuclear extract from DEX treated WRK-1 cells indicate that 2 of the 3 putative GREs are active in protein binding and might mediate transcriptional effects of glucocorticoids. The septum of the rat brain expresses a vasopressin V1aR which has been impicated in various rodent behaviors. In order to examine in vivo effects of adrenal steroids on septal V1aRs, we bilaterally adrenalectomized (ADX) male rats and hormone replaced them with either DEX in different concentrations, or with aldosterone. The effects were evaluated in the septum of these animals using a radiolabelled specific V1aR antagonist ^{125}I Sar^7-AVP. ADX significantly decreases ($p<0.05$) V1aR binding site density below those of the sham ADX controls. Additionally, DEX, but not aldosterone, was able to restore V1aR binding in ADX animals to levels comparable to those of sham controls. Studies are currently in progress to determine the effects of these steroids on V1aR mRNA in the septum. (Supported by NS20311, the VA and Pharmacological Sciences Training Grant 670489).

PHYSICAL AND EMOTIONAL STRESSORS STIMULATE THE RELEASE OF VASOPRESSIN WITHIN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS OF RATS: A MICRODIALYSIS STUDY. C. T. Wotjak, M. Kubota, M. Engelmann, I. Neumann and R. Landgraf. Max Planck Institute of Psychiatry, Clinical Institute, D-80804 Munich, Germany.

The neuropeptide arginine vasopressin (AVP) is thought to play an important role in HPA axis regulation at the level of the paraventricular nucleus (PVN). The release of AVP within the PVN in response to physical and emotional stressors was monitored by microdialysis in adult Wistar rats. Compared to pre-stress values (0.1-1.0 pg/30-min dialysate), swimming in the Morris water maze increased AVP release (380%, $p<0.01$, n=8). Intra-PVN release of the neuropeptide peaked also during social defeat (226%, $p<0.01$, n=11), but was just slightly increased during exposure to "milder" stressors (exposure to a juvenile: 160%, n.s.; novel environment: 137%, n.s., n=8 each). These data provide evidence that both physical and emotional stressors are potent to evoke intranuclear AVP release and confirm the hypothesis of an involvement of the intracerebrally released neuropeptide in coping with intense stress. Since plasma corticosterone demonstrated a substantial activation of the HPA axis in response to all stressors used (Morris water maze: 574%, $p<0.01$, n=6; social defeat: 510%, $p<0.01$, n=6; juvenile exposure: 250%, $p<0.01$, n = 10; novel environment: 424%, $p < 0.01$, n = 6) further studies have to investigate to which extent AVP release within the PVN contributes to the regulation of the HPA axis activity. Supported by VW.

SPINAL CORD OXYTOCIN MEDIATES THE PUPIL DILATATION RESPONSE TO VAGINOCERVICAL STIMULATION IN THE RAT. G. Sansone*, E.V. Kruck, M. Ganduglia-Pirovano and B.R. Komisaruk. Institute of Animal Behavior, Rutgers The State University of New Jersey, Newark, N.J. 07102.

The present study was designed to investigate whether oxytocin (OT), which is released into the spinal cord after vaginocervical stimulation (VS), mediates responses to VS. Ovariectomized, estrogen-primed (10 µgEB/100 g bw, SC x 3 d) rats were used. OT (10 and 25 µg in 5 µl saline) was administered intrathecally (i.t.) at the lumbar level and all rats were tested for responses to VS (i.e. facilitation of lordosis, analgesia, pupil dilatation, increase in blood pressure and heart rate). A selective OT receptor antagonist [d(CH_2)$_5$-Tyr(Me)^2-Thr^4-Tyr-NH_2^{9}] OVT (OTA, 25 µg in 5 µl saline) was then administered i.t. and VS (300 g force) was applied to the cervix to determine which responses, if any, previously mimicked by i.t. OT, could be blocked. RESULTS: Administration of OT i.t. (10 or 25 µg) produced a significant increase in pupil diameter (PD) within 1 min ($p < 0.05$, ANOVA). Significant PD persisted for 20 min (10 µg OT) and for 25 min (25 µg OT) post-injection, respectively. When OTA was injected i.t., the magnitude of the increase in PD in response to VS compared to the saline control was significantly reduced within 3 min post-injection ($p < 0.05$, ANOVA). The antagonistic effect of OTA was still present 60 min post-injection ($p < 0.05$, ANOVA). No effect of OTA alone was observed. OT also significantly increased blood pressure ($p = 0.001$, ANOVA); however, administration of OTA did not antagonize the hypertensive effect of VS. No change in heart rate, analgesia, or lordosis was induced by either OT or OTA. CONCLUSION: The present findings suggest that OT is a central nervous system transmitter that mediates specifically VS-produced PD by stimulating the autonomic (sympathetic division) outflow from the spinal cord. Support: NIH - Fogarty International Center - 1RO3-TW00394 (BRK).

OXYTOCIN ANTISENSE REDUCES SALT INTAKE IN THE BARORECEPTOR DENERVATED RAT. M. Morris*, P. Li, C. Barrett, M.F. Callahan. Dept. of Physiology and Pharmacology and The Hypertension Center, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157

Interruption of baroreceptor input to the brain produces a state of salt sensitivity. In view of the role of oxytocin (OT) in the control of salt intake and excretion, experiments were performed to evaluate the effect of central injection of OT antisense oligomers on reduced salt intake shown in sinoaortic denervated rats (SAD). Paraventicular injection of OT antisense (AS) decreased intake of 2% NaCl in the SAD, but not in the sham operated (SO)controls. The SAD rats consumed 22±4 ml after mixed base control injection as compared to 8±4 ml after the OT AS injection ($p < 0.05$). There was no difference in the response of the SO controls. The SAD animals demonstrated an increase in the plasma OT response to 24 hours salt loading (3.2±0.7 to 6.9±0.8 pg/ml as compared to 2.8±0.9 to 4.4±0.9 pg/ml, SAD vs SO). The increased endocrine response occurred even though salt intake was lower in the SAD animals. There were no group differences in plasma electrolytes or posterior pituitary OT content. Results demonstrate a specific effect of OT antisense in the denervated animal, suggesting that central OT stimulates salt intake in this model.

EFFECT OF CENTRAL NEUROTENSIN ADMINISTRATION ON FOS EXPRESSION IN THE RAT BRAIN - RELATING FUNCTION TO ANATOMY. T.D. Ely*P.D. Lambert, R. Gross, C.B. Nemeroff and C.D. Kilts. Dept. of Psychiatry, Emory Univ. Sch. of Med., Atlanta, GA 30322.

The central administration of the neuropeptide neurotensin (NT) is associated with robust behavioral, neuroendocrine and hypothermic responses. The neural substrates and sites of NT-induced alterations in brain function are unclear. The expression of the immediate early gene c-fos has been described as a monitor of neuronal activation in response to a range of stimuli. We have used immunohistochemistry to localize cells activated by the intracerebroventricular (icv) administration of NT and attempted to correlate brain regional Fos responses with endocrine or hypothermic effects to determine related sites of action. Groups of male Sprague-Dawley rats (n=5) received single icv injections of artificial CSF or NT (0.3, 3 or 30μg). 90 minutes following injection, brains were removed, 40μm slices were cut and stained for Fos. NT administration produced a dose-dependent hypothermia, increase in serum corticosterone and increase in the number of Fos-positive cells within the central (Ce) and basolateral nuclei of the amygdala and the paraventricular and supraoptic hypothalamic nuclei. Injection (i.p.) of the selective NT antagonist SR48692 30 minutes before icv injection of NT completely abolished the increase in corticosterone and attenuated the increase in Fos-positive cells within the amygdala. A strong correlation was found between the number of Fos-positive cells in the Ce and the serum corticosterone level for each animal tested (n=16, r=0.72). These data show that central NT activates neurons within the amygdala and the hypothalamus and that the effect of NT to increase serum corticosterone is mediated via an action involving the Ce. Our data further suggests the existence of multiple central NT receptor subtypes.

ASTRESSIN, A POTENT CYCLIC CRF ANTAGONIST J. Rivier, J. Gulyas, M. H. Perrin, S. C. Koerber, S. Sutton, A. Corrigan, S. L. Lahrichi, A. G. Craig, R. Evans*, W. Vale and Catherine Rivier. The Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037.

Predictive methods, physicochemical measurements (NMR, CD) and structure activity relationships studies suggest that corticotropin-releasing factor (CRF) and its family members (urotensins and sauvagine) assume an α-helical conformation when interacting with the CRF receptor(s). We have scanned the r/hCRF sequence with several constraining modalities such as an i-(i+3) and i-(i+4) bridge consisting of the D or L-Glu-Xaa-Xaa-(Xaa)-D or L-Lys scaffold. From this series we have identified a unique substitution that resulted in an antagonist, Astressin (a 30 -peptide) that is >100 times more potent than the α-helical CRF_{9-41}, 42 times more potent than [DPhe^{12},Nle^{21,38}]r/hCRF_{12-41}, our present standard, and 400 times more potent than the corresponding linear analog in an *in vitro* pituitary cell culture assay. As expected, Astressin had very low affinity for the CRF binding protein and very high binding affinity in a specific receptor assay. *In vivo*, Astressin is significantly more potent and longer acting than any previously tested antagonist at inhibiting basal or stimulated ACTH secretion. Indeed, Astressin blocked stress-induced ACTH release at less than 0.3 mg/kg, iv in the rat. In an agonist (a 38-peptide), this structural modification resulted in a 2-fold increase in potency as compared to the parent linear analog. The differences in relative potency in the agonist (2-fold loss) and antagonist (400-fold loss) series between the linear and cyclic forms suggest that the bridge reinstates a structural motif in the antagonist equivalent to that brought about by an unaltered N-terminus octapeptide in the agonist.

CATECHOLAMINE RECEPTORS: GENETICS

807.1

THE STATUS OF THE DOPAMINE D_2 RECEPTOR (DRD2) LOCUS AS A SUSCEPTIBILITY FACTOR IN AUTISM: FAMILY ASSOCIATION STUDIES. S.D. Flanagan*[1], E. Cook[2], E. Courchesne[3], A. Lincoln[3], C. Lord[2], B. Leventhal[2], R. Gysin[1] and R. Courchesne[3]. [1]Beckman Res. Inst. of the City of Hope, Duarte, CA; [2]University of Chicago Hospitals, Chicago, IL; and [3]Children's Hospital, San Diego, CA.

Case-control studies support the hypothesis that a genetic variant at the DRD2 locus contributes significantly to risk for autism. The hypothesized DRD2 susceptibility factor is neither necessary nor sufficient to cause autism and probably interacts with other factors, genetic or non-genetic. Linkage disequilibrium with the DRD2 *Taq*A1 allele is the subject of considerable controversy concerning its role as a risk factor in severe alcoholism. Much of the controversy revolves around limitations inherent in any genetic association study utilizing the case-control design. In severe alcoholism, there is the additional problem that variations in subject recruitment could select for alcoholics possessing different risk factors, explaining the wide divergence in various reports. By contrast, autism as diagnosed by well established ADI and ADOS criteria, is unlikely to be affected by vagaries of subject recruitment; furthermore, the parents of autistic subjects are readily recruited providing the opportunity for the calculation of haplotype relative risk in the powerful family association design. We recruited 31 sets of autistic patients and their parents (Courchesne lab), and found a trend for elevated transmission of the DRD2 *Taq*A1 allele to probands (χ^2=3.05, p=0.08). Data for the DRD2 *Taq*B1 allele, which lies in strong linkage disequilibrium with the *Taq*A1 allele, were as follows: 12 B1 and 50 B2 parental alleles were transmitted to probands; 3 B1 and 59 B2 alleles were not transmitted (Fisher exact, one-tailed, p=0.01). We have now recruited a separate, replication sample of 27 sets of probands and parents (Cook lab) to test our hypothesis that the association of autism with DRD2 *Taq*B1 allele exists. *A portion of this work was supported by the Wacker Foundation.*

GENDER, HERITABILITY AND D_1 RECEPTOR BINDING. S. Kanes*, S. Sanderson, M. Silverman, E. Rasmussen, L. Cipp, K. Dains, B. Hitzemann, and R. Hitzemann. Departments of Psychiatry, Neurobiology and Pharmacology, SUNY at Stony Brook, NY 11794-8101.

The D_1 dopamine receptor specific binding of ^{125}I-SCH 23382 was determined in discrete brain regions of both male and female C57BL/6 (B6), DBA/2 (D2), B6♀D2♂ F_1 cross and F_2 cross mice. Data were obtained for the substantia nigra zona reticulata (SNr), the core and shell of the nucleus accumbens (NAc) and both the lateral and dorsomedial aspects of the caudate-putamen (CPu). N = 12/sex for the parental strains and the F_1 cross and 30/sex for the F_2 cross. Variance in receptor binding for the F_2 cross is derived from both heritable and non-heritable causes. The non-heritable or environmental component (V_E) was estimated from the variances seen in the parental strains and the F_1 cross. For the F_2 males, significant broad sense heritability was found in the NAc core (0.75) and the NAc shell (0.60). For the F_2 females, significant heritability was detected only in the NAc shell (0.71). In comparison to the males, V_E for the females was significantly higher in both the NAc core and the SNr; in the SNr, the difference in variability was > 300%. D_1 receptor binding was generally higher in the D2 strain, a difference (60%) which was most marked for the males in the NAc shell. The most marked gender effect was seen in the SNr; receptor binding for the B6 females was > 100% higher than that of the B6 males. The F_2 cross was genotyped for *D13Mit13*, a microsatellite which is polymorphic between the B6 and D2 strain and which is closely linked to *Drd1*. No association was detected between receptor binding and genotype.

807.3

GENDER, HERITABILITY AND D_2/D_3 RECEPTOR BINDING. L. Cipp*, S. Sanderson, M. Silverman, E. Rasmussen, J. Gatley, S. Kanes, K. Dains, B. Hitzemann, and R. Hitzemann. Departments of Psychiatry, Neurobiology and Pharmacology, SUNY at Stony Brook, NY 11794-8101.

The receptor specific binding of ^{125}I-epidepride was determined in discrete brain regions of both male and female C57BL/6 (B6), DBA/2 (D2), B6♀D2♂ F_1 cross and F_2 cross mice. Epidepride binds with a high affinity to D_2 and D_3 but not D_4 dopamine receptors. Data were obtained for the substantia nigra zona compacta (SNc), the ventral tegmental area (VTA), the core and shell of the nucleus accumbens (NAc) and both the lateral and dorsomedial aspects of the caudate-putamen (CPu). The binding of ^{3}H-7-hydroxy-DPAT was used to determine that D_3 receptor binding is < 5% of the total epidepride binding in all brain regions except the NAc. In general, there was no difference in the heritability of receptor binding between F_2 males and females. Collapsing the data across gender, the broad sense heritability was SNc (0.56), VTA (0.50), NAc core (0.52), NAc shell (0.62), dCPu (0.56) and lCPu (0.60). In the NAc core and shell, binding was modestly higher (10-25%) in the B6 as compared to the D2 strain. Further, compared to the B6 males, the B6 females showed a significantly higher receptor binding in the core (+25%). In both the SNc and VTA, receptor binding was markedly (> 50%) higher in the D2 strain; there were no gender effects in these regions. The F_2 cross (N=100) was genotyped for *D9Mit22*, *D9Mit4* and *D9Mit21*, microsatellites which are polymorphic between the B6 and D2 strains and which are closely linked to *Drd2*. The results show that for both the striatum and midbrain, the D2 allele is associated with higher receptor density.

807.4

GENDER, HERITABILITY AND DOPAMINE TRANSPORTER (DAT) BINDING. E. Rasmussen*, S. Sanderson, M. Silverman, L. Cipp, B. Hitzemann, and R. Hitzemann. Departments of Psychiatry, Neurobiology and Pharmacology, SUNY at Stony Brook, NY 11794-8101.

The DAT specific binding of ^{125}I-RTI 55 was determined using quantitative receptor autoradiography in the nucleus accumbens (NAc) core and shell of both male and female C57BL/6 (B6), DBA/2 (D2), B6♀D2♂ F_1 cross and F_2 cross mice. N = 12/sex for the parental strains and the F_1 cross and 30/sex for the F_2 cross. Variance in receptor binding for the F_2 cross is derived from both heritable and non-heritable causes. The non-heritable or environmental component (V_E) was estimated from the variances seen in the parental strains and the F_1 cross. For the F_2 males, significant broad sense heritability was found in the NAc shell (0.80) and the NAc core (0.75). For the F_2 females, significant heritability was detected only in the NAc shell (0.76). There were no significant differences in V_E between males and females in either brain area. In the NAc shell, DAT binding was significantly higher in the D2 as compared to the B6 strain; this difference was most marked for the females (+ 57%). The shell F_1 and F_2 data suggest that the B6 genotype is dominant but that significant epistatic effects are also present i.e. the F_2 phenotype is significantly higher than would be predicted on the basis of a simple dominance/recessive model. The strain differences in the core are less marked and only significant for the males (D2 > B6). DAT binding is significantly higher for females in both brain regions. In the core the difference is most marked for the B6 strain (+ 36%) and in the shell for the D2 strain (+ 63%). DAT binding is markedly higher in the core; collapsing across strain and gender, the average difference is 125%.

807.5

GENETICS AND THE ORGANIZATION OF CHOLINERGIC NEURONS IN THE MOUSE CAUDATE-PUTAMEN: CONFIRMATION OF TWO QTL. K.M. Dains*, B.A. Hitzemann and R.J.Hitzemann. Departments of Neurobiology and Behavior and Psychiatry and Behavioral Science, SUNY at Stony Brook, NY 11794.

The broad sense heritability of cholinergic cell density, as high as 78% in some areas of the caudate-putamen (CPu), was determined from the analysis of C57Bl/6J (B6) and DBA/2J (D2) inbred mouse strains and B6D2 F_1 and F_2 hybrid crosses. In order to identify genes associated with this phenotype, quantitative trait locus (QTL) analysis was performed using 25 strains of the BXD/Ty series. Confirmation of the putative QTL was accomplished using 50 B6D2 F_2 hybrids phenotyped for cholinergic cell number. Two possible candidate QTL were revealed by this analysis, *D9Mit21* on chromosome 9, near *Drd2*, the D_2 dopamine receptor gene, and *D12Mit7* on chromosome 12, near *c-fos*. *Drd2* is associated with neuroleptic-induced catalepsy and D_2 dopamine receptor density. *c-Fos* is induced by muscarinic agonists and antagonists as well as dopamine antagonists such as haloperidol. Further, as reported elsewhere at this meeting (Patel et al.), in comparison to the B6 strain, the haloperidol sensitive D2 strain shows a more marked Fos response in most regions of the striatum. Overall, the QTL associated with *D9Mit21* and *D12Mit7* are considered good candidates a) for additional confirmation in other F_2 crosses, b) for the formation of congenic lines and c) for eventual positional cloning of the relevant gene(s).

807.6

GENETICS AND THE HALOPERIDOL-INDUCED INCREASE OF FOS IN THE MOUSE STRIATUM. N. Patel, B. Hitzemann, and R. Hitzemann*. Departments of Psychiatry, Neurobiology and Pharmacology, SUNY at Stony Brook, NY 11794-8101.

Haloperidol and related antipsychotic drugs (those which induce extrapyramidal symptoms {EPS}) increase striatal Fos expression. The Fos response in the caudate-putamen (CPu) is blocked by anticholinergic drugs and markedly reduced after the administration of atypical antipsychotic drugs such as clozapine. These data support the notion that the Fos response is predictive of EPS. An alternative method to test this hypothesis is to compare the Fos response among inbred strains of mice which are differentially sensitive to haloperidol-induced catalepsy (catalepsy is the murine equivalent of EPS). The ED_{50} for haloperidol-induced catalepsy in the DBA/2 (D2) strain is 0.4 mg/kg and in the C57BL/6 (B6) strain is 4.0 mg/kg. Male D2 and B6 mice were administered 0.3 and 1.0 mg/kg of haloperidol, sacrificed 1 hour later and Fos expression was measured in the rostral striatum using standard immunocytochemical methods. In the lateral CPu, Fos expression in response to both doses was on average >100% higher in the D2 strain. The pattern was the same in the core of the nucleus accumbens (NAc) but the magnitude of the difference was less (ca. 50%). In the shell of the NAc, the difference between the D2 and B6 strains was the same as in the core at 0.3 mg/kg but began to reverse at 1.0 mg/kg. In the dorsomedial CPu and depending on the rostral/caudal level sampled, there was either no difference between strains or the B6 strain showed a greater Fos response. Thus, only in some brain regions does the Fos response parallel the behavioral differences in strain sensitivity.

SEROTONIN RECEPTORS: 5-HT$_3$

808.1

FUNCTIONAL AND BINDING STUDIES OF PHOSPHORYLATION AND GLYCOSYLATION SITE MUTANTS OF 5-HT$_3$ RECEPTORS: **E.J. Fletcher, M.I. Sepulveda, T. Green, R. Pinnock* and S.C.R. Lummis. Division of Neurobiology, LMB and Department of Zoology, University of Cambridge, Cambridge, UK..**

5-HT$_3$ receptors, members of the family of ligand-gated ion channels (Maricq et al.,1991), possess a number of potential phosphorylation and glycosylation sites. We have used site-directed mutagenesis of these sites to examine their function in homomeric 5-HT$_3$ receptors. In particular we have explored the function of phosphorylation in generating differences observed in the two splice variants of the 5-HT$_3$ receptor, which differ by 6 amino acids and a potential phosphorylation site. Full length 5-HT$_3$R-As (short) DNA was obtained from N1E-115 mRNA using PCR. Coding sequence for the additional 6 amino acids in the 5-HT$_3$R-A (long) subunit was inserted using site-directed mutagenesis, as were mutations to remove potential phosphorylation and glycosylation sites. Sequences were inserted into the eukaryotic expression vector pRc/CMV and transfected into HEK 293 cells using calcium phosphate precipitation. Mutants were characterised using radioligand binding and whole cell patch clamp electrophysiology. Radioligand binding studies with [^{3}H]granisetron showed that relative potencies of a selection of 5-HT$_3$ receptor selective ligands were similar (GR65630 > mCPBG > MDL72222 > 5-HT) in long, short and functional mutant receptors. However patch clamp studies showed differences in agonist affinity and efficacy (long > short); binding studies also distinguished between the splice variants: K_d = 0.38 ± 0.03 and 0.24 ± 0.02 (n=4) for long and short forms respectively. Phosphorylation was not responsible for this observed change in affinity. The results from the glycosylation studies show that only one of the potential glycosylation sites (N191) is crucial for ligand binding and function.

IDENTIFICATION OF AMINO ACID RESIDUES INVOLVED IN AGONIST/ANTAGONIST LIGAND RECOGNITION BY THE 5-HT$_3$ RECEPTOR. J.A. Steele, F.G. Boess†, L.J. Steward, M. Davies* & J.L. Martin. Department of Pharmacology, University of Alberta, Edmonton, Alberta, Canada T6G 2H7; †F. Hoffmann-La Roche AG, Department PRPN, P.O. Box CH-4002, Basel, Switzerland.

The 5-HT$_3$ receptor is a member of the ligand-gated ion channel family. To investigate the importance of certain amino acids in agonist/antagonist ligand recognition, we have performed site-directed mutagenesis on the 5-HT$_3$-aL cDNA isolated from NG108-15 cells. 5-HT$_3$ receptor mutants were transiently expressed in HEK 293 cells and characterized using whole-cell patch clamp electrophysiology and radioligand binding.

The E106D mutation caused a 10-fold reduction in the Kd of [^{3}H]GR65630, while there was a 100-fold reduction in the Ki for 5-HT in competition with this ligand, compared to wild type. There was no change in the EC_{50} value for 5-HT measured with electrophysiology. However, the Ki and EC_{50} values for the E106N mutation were decreased 40-fold and 10-fold, respectively, when compared to wild type.

E106 appears to be particularly important in agonist recognition for the high affinity desensitized conformation of the receptor which is measured by binding, but less so for the low affinity resting conformation, which is measured by electrophysiology and is integral to channel activation.

SOLUBILISATION OF THE 5-HYDROXYTRYPTAMINE$_3$ RECEPTOR RECOGNITION SITE EXPRESSED IN PIG CEREBRAL CORTEX

S Fletcher* & NM Barnes. Department of Pharmacology, The Medical School, University of Birmingham, Edgbaston, Birmingham B15 2TT UK

5-Hydroxytryptamine$_3$ (5-HT$_3$) receptor recognition sites were solubilised from homogenates of pig cerebral cortex (1 g original wet weight/mL in 25 mM Tris, pH 7.45) by addition of an equal volume of buffer (25 mM Tris, 2 mM EDTA, 100 µM PMSF, 10 µg/mL bacitracin, 10 µg/mL sodium azide, 10 µg/mL soybean trypsin inhibitor, pH 7.45) containing 0-4% Triton X-100. Maximum yield (35.8% ± 3.2; % mean ± SEM, n=5) was obtained using Triton X-100 at a final concentration of 0.4%.

Preliminary studies suggest that the pharmacological profile of solubilised 5-HT$_3$ receptor sites is similar to that obtained for the receptor sites in the crude homogenates. For example, the antagonists ondansetron and tropisetron, and the agonist 5-HT, compete for [^{3}H]-(S)-zacopride binding to solubilised receptor preparations giving similar pKi values to those obtained in crude homogenate preparations; 8.09± 0.08, 7.33 ± 0.21 and 6.43 ± 0.12 (mean ± SEM, n=3) respectively, compared to values of 7.71 ± 0.16, 7.44 ± 0.05 and 6.28 ± 0.02 (mean ± SEM, n=3-6) obtained in crude homogenates.

We conclude that the 5-HT$_3$ receptor recognition site expressed in pig brain has been successfully solubilised, which is an essential prerequisite for purification of the receptor.

S. Fletcher is recipient of an AJ Clark Studentship from the British Pharmacological Society.

808.4

IN VIVO INHIBITION OF K$^+$-EVOKED ACETYLCHOLINE RELEASE BY 5-HT3 RECEPTOR ACTIVATION. P. Blandina, I. Ceccarelli, R. Corradetti*, G. Pepeu & M.G. Giovannini. Dipartimento di Farmacologia Preclinica e Clinica, Universitá di Firenze, Firenze, Italy

Although 5-HT3 receptors are present in the cortex and hippocampus, their physiological role is not clearly defined. We show here that 5-HT modulates the release of ACh from cortex and hippocampus of freely moving rats using the microdialysis technique. Perfusion flow rate was 3 µl/min. Twenty four hours after implantation with dialysis fiber, hippocampus or cortex of male Wistar rats (250 g) released spontaneously 2.5±0.1 pmol/10 min ACh (N=87), measured by HPLC with electrochemical detection. Two identical 100 mM K$^+$ stimulations, given through the dialisys fiber at a 90 min interval, each almost doubled ACh release. 5-HT (1-50 µM) inhibited K$^+$-evoked release of ACh up to about 50% from cortex and hippocampus. The 5-HT3 agonists phenylbiguanide (0.1-10 µM) and 1-m-Cl-phenylbiguanide (1-10 µM) mimicked 5-HT effect in cortex, but not in hippocampus. The effects of both 5-HT and phenylbiguanide in cortex were completely antagonized by the 5-HT3 antagonist ICS 205-930 (0.5 mg/kg s.c.), but not by methiotepin, antagonist at 5-HT1-like and 5-HT2 and not at 5-HT3 receptors. Thus, 5-HT3 receptors may contribute to the role of ACh in controlling the cortical but not the hippocampal functions.

5-HT$_3$ RECEPTOR AGONISTS REDUCE GLUTAMATE NEUROTRANSMISSION IN THE HIPPOCAMPUS OF THE RAT. K. Batsche*, and R.Y. Wang. Dept. of Psychiatry, SUNY Stony Brook, Stony Brook, NY, 11794.

We have previously shown that the 5-HT$_3$ receptor agonist 2-methyl-5-HT reduces both EPSP's and IPSP's of CA1 pyramidal cells evoked by stimulation of the Schaffer collaterals. This action is receptor specific and concentration dependent. However, others have suggested that activation of 5-HT$_3$ receptors in the hippocampus can increase GABA release at interneuron terminals. In the present study, we further examine the role of 5-HT$_3$ receptors in this area using the more selective and potent 5-HT$_3$ receptor agonist SR 57227A (SR), appplied either iontophoretically or via bath. Glutamatergic neurotransmission was elicited either by Schafffer collateral stimulation or local iontophoresis of glutamate. We used whole cell current- and voltage-clamp recordings from CA1 pyramidal neurons. Glutamate was pulsed with an ejecting current adjusted to produce short depolarizations of 7-15 mV. Similar to the action of 2-methyl-5-HT, SR consistently reduced PSP's elicited by Schaffer collateral stimulation without changing the membrane properties of the cells. Further, local iontophoresis of SR reduced glutamate-induced depolarizations to about 50% of control values, while not altering the kinetics of glutamate uptake or receptor activation or the input resistance of the cell. These actions of SR were blocked by the selective 5-HT$_3$ receptor antagonists BRL43694 and tropisetron but not the 5-HT$_{1A}$ receptor antagonist (+)-WAY100135. The 5-HT$_{1A}$ receptor agonist 8-OH-DPAT also inhibited glutamate-induced depolarizations, which was blocked by (+)-WAY100135. In several cells, SR produced a slow hyperpolarization of the cell's resting potential that did not desensitize. It appears from these experiments that 5-HT, acting at 5-HT$_3$ receptors, will modulate glutamatergic currents in the CA1 area of the hippocampus in a manner not directly involving the opening or closing of membrane ion channels. 808.6

POTENTIATION OF THE INHIBITORY ACTION OF DOPAMINE BY THE SEROTONIN$_3$ RECEPTOR AGONIST SR57227A ON MESO-CORTICOLIMBIC DOPAMINE TARGET NEURONS IN RATS. Jian Yu Zhang*, Bryan Horan and Rex Y. Wang. Dept. of Psychiatry and Behavioral Sciences, SUNY at Stony Brook, Stony Brook, NY 11794-8790.

We have previously shown that 5-HT$_3$-like receptors in the medial prefrontal cortical (mPFC) have a permissive role in regulating or gating the inhibitory action of dopamine (DA). In the present study, we examined further the effect by which a potent and selective 5-HT$_3$ receptor agonist SR 57227A modulates the depressant action of DA on cells in the mPFC, hippocampus and nucleus accumbens (NAc), using the techniques of single cell recording and iontophoresis. We have previously demonstrated that SR 57227A produced a current-dependent depression of the firing of hippocampal CA1 pyramidal cells and this effect was blocked by the selective 5-HT$_3$ but not other receptor antagonists. The iontophoretic application of DA (5-80 nA) produced a current-dependent depression of both spontaneously active and glutamate-evoked firing of cells in the mPFC, NAc and hipocampus. When SR 57227A was iontophoresed concurrently with DA at a subthreshold current, it significantly potentiated the inhibitory action of DA but not GABA. The potentiation was blocked by the selective 5-HT$_3$ receptor antagonist BRL 46470A. Our results support and extend the previous finding that 5-HT$_3$ receptors play an important role in modulating the DA's action. Since the 5-HT$_3$ receptors are primarily localized in the mesocorticolimbic structures, it is possible that the simultaneous blockade of DA and 5-HT$_3$-like receptors by clozapine may partially account for its preferential interaction with the mesocorticolimbic DA system. In addition, this may also contribute to clozapine's higher therapeutic efficacy (Supported by MH-41440).

808.7

ABILITY OF TRICHLOROETHANOL TO MODIFY 5-HYDROXYTRYPTAMINE$_3$ RECEPTOR MEDIATED DEPOLARISATION OF THE ISOLATED RAT VAGUS NERVE. KR Bentley*, KD Johnston, RL Stowe and NM Barnes. Dept of Pharmacology, Medical School, University of Birmingham, Birmingham B15 2TT UK.

In the present study we assess the ability of trichloroethanol (TCE) to modulate the function of the 5-HT$_3$ receptor expressed in rat vagus nerve measured by extracellular recording (Blake JF et al. Br J Pharmacol 95; 291-299, 1988).

5-HT (10 nM-30 µM) induced depolarizations of the rat vagus nerve (EC_{50} = 0.97 ± 0.13 µM, (mean ± SEM, n = 5)) that were antagonized by the selective 5HT$_3$ receptor antagonist ondansetron (20 nM; pK_B = 8.9).

TCE (5 mM) significantly increased the potency and maximal response of 5-HT to depolarize the vagus nerve (5-HT; EC_{50} = 0.5 ± 0.12 µM, mean ± SEM, n = 5). TCE (0.1-10 mM) maximally increased the response to a submaximal concentration of 5-HT (0.3 µM), TCE pEC_{50} = 2.55 ± 0.13, (mean ± SEM, n = 3). 5-HT (0.3 µM)-induced depolarisations in the presence of TCE at concentrations above 10 mM were submaximal.

The selective 5-HT$_3$ receptor agonist, phenylbiguanide (PBG) induced depolarizations of the isolated rat vagus nerve with near the same potency as 5-HT (EC_{50} = 1.49 ± 0.33 µM, mean ± SEM, n = 3) and these were also potentiated by TCE (5 mM) (PBG; EC_{50} = 0.28 ± 0.07 µM, maximal response relative to PBG alone = 124 ± 20% mean ± SEM, n = 3, $p < 0.05$, Students paired t-test). Similarly, TCE (5 mM) significantly increased the size of the depolarisation induced by the low intrinsic activity partial agonist quipazine (300 nM) whereas, even in the presence of TCE (5 mM), we failed to detect a response on application of (S)-zacopride (300 nM). The present study has identified that TCE enhances the potency and the maximal response of 5-HT$_3$ receptor agonists to depolarize the isolated rat vagus nerve.

DISTRIBUTION OF 5-HYDROXYTRYPTAMINE3 RECEPTOR EXPRESSION IN THE HUMAN FOREBRAIN

R.M.C. Parker*[1], J. Ge[1], P.C. Barber[2], N.M. Barnes[1] and J.M. Barnes[1] Dept of [1]Pharmacology & [2]Pathology, Medical School, University of Birmingham, Birmingham B15 2TT UK.

The distribution of 5-hydroxytryptamine3 (5-HT3) receptor expression in the human forebrain was assessed using quantitative receptor autoradiography with [^{3}H]-(S)-zacopride and Northern blot analysis to detect 5-HT3 receptor-A/As receptor subunit mRNA levels using [^{32}P]riboprobes generated from 5-HT3-As cDNA (Hope et al, Eur J Pharmacol 245, 187-192, 1993).

5-HT3 receptor expression was differentially distributed with highest levels in the hippocampus (autoradiographic studies revealed that within heterogeneous structure, the levels of expression (fmol/mg tissue equivalent; Amersham; mean±SEM, n = 3-7) were highest in the dentate granule cell layer (16±2), dentate molecular cell layer (8.1±1.2)) and the extrapyramidal system (autoradiographic studies; caudate nucleus (4.3±0.8), putamen (4.3±0.8), substantia nigra (2.3±0.6), mean±SEM, n = 3-7). No 5-HT3 receptor expression was detected in the cerebellar cortex.

In the present studies, 5-HT3 receptor expression in the human forebrain was highest in the hippocampus and striatum (caudate nucleus and putamen). Ongoing in situ hybridisation studies may reveal which neurones express the 5-HT3 receptor.

We are grateful to Drs A.G. Hope, J.A. Peters and Prof. J.J Lambert for the gift of 5-HT3-As cDNA. Supported by the MRC.

NEUROCHEMICAL COMPOSITION OF NEURONS EXPRESSING THE 5-HT$_3$ RECEPTOR. M. Morales*, E. Battenberg and F. E. Bloom. The Scripps Research Institute, Neuropharmacology. 10666 N. Torrey Pines Rd., La Jolla CA 92037.

The type 3 serotonin receptor (5-HT$_3$R) is a ligand-gated ion channel whose presence in the central nervous system has been established by radioligand binding and *in situ* hybridization analysis.

In a previous study (Soc. Neurosci. Abstr., 20:1156), we combined *in situ* hybridization and immunocytochemistry techniques to identify neurotransmitters present in 5-HT$_3$R expressing cells. We detected a substantial number of neurons expressing both 5-HT$_3$R and gamma-amino butyric acid (GABA) throughout the brain. To further characterize the 5-HT$_3$R/GABA expressing neurons we investigated if the neuropeptides somatostatin (SS) or cholecystokinin (CCK) were present in 5-HT$_3$R expressing neurons. While SS was not found in 5-HT$_3$R expressing neurons, co-expression was found for 5-HT$_3$R and CCK. As subpopulations of GABAergic cells might contain different Ca^{2+}-binding proteins (calbindin, calretinin or parvalbumin) we sought to determine if any of these proteins were present in 5-HT$_3$R expressing cells. We found that while calbindin did not co-localize with 5-HT$_3$R transcripts, limited co-localization was found for calretinin, whereas, parvalbumin (PV) was often found in cells expressing 5-HT$_3$R.

We conclude that the inhibitory 5-HT$_3$R/GABA interneurons may be basket cells that coexist with parvalbumin or CCK. Our data on the presence of 5-HT$_3$R/CCK-containing neurons in cortex and hippocampus provide anatomical evidence that activation of local 5-HT$_3$R/CCK expressing cells might participate in the release of CCK in cortex and the hippocampus.

SELECTIVE MODULATION OF TRYPTOPHAN HYDROXYLASE AND TYROSINE HYDROXYLASE EXPRESSIONS BY S-20342 IN THE RAT BRAIN. S. Raison[1], D. Weissmann[1], M.C. Rettori*[2], H.-P. Husson[3], P. Renard[2], B. Guardiola-Lemaitre[2] and J.-F. Puiol[1]. [1]CNRS-UCB, UMR 105, Rue G. Paradin, 69372 Lyon; [2]I.R.I.SERVIER, 6 Pl. des Pléiades, 92415 Courbevoie; [3]Laboratoire de Chimie Thérapeutique, 4 ave de l'Observatoire, 75006 Paris, FRANCE.

S-20342 (-N-[(1R,4R,9aS)-4-phenyl octahydropyrido [2,1-c] [1,4] oxazin-1-yl] 3,4,5-trimethoxybenzamide) is a new chemical entity with an unexpected neurochemical and behavioral profile: although devoid of any affinity for 5HT and DA receptor subtypes, it produced in animal models anxiolytic-like and antipsychotic-like effects[(1)]. In this study, tryptophan hydroxylase (TpOH) protein was quantified by dot blot analysis in steady-state conditions and 12 hours after a single injection of *p*-chlorophenylalanine (ip; 300 mg/kg), to estimate the apparent disappearance rate of TpOH protein, in control and S-20342 treated rats (ip; 30 mg/kg). This quantitative analysis was performed in the mesencephalic serotoninergic cell body groups, the raphe dorsalis (RD) and centralis (RC) nuclei as well as in their respective terminal areas, the neostriatum and the hippocampus. The timecourse effect, performed 1, 2, 3, 4 and 6 days after S-20342 injection showed a significant increase in the steady-state content of TpOH in the RD at day 4. The turnover rate of TpOH was highly enhanced in both RD and RC, by 18% and 21% respectively, at day 1, and by 57% and 45% at day 4. Furthermore, a highly significant increase in TpOH mRNA content was quantified by *in situ* hybridization, 12 hours after S-20342 injection, in the RD. A slight increase in TpOH protein content was observed in the hippocampus but no modification was measured in the neostriatum. Interestingly, tyrosine hydroxylase protein was significantly increased at day 3 in the ventral tegmental area but neither in substantia nigra nor in locus coeruleus. These results suggest that S-20342 would potentially induce TpOH protein, which is of particular interest to further study the regulation of TpOH expression.

EVIDENCE FOR PRESYNAPTIC COMPENSATORY CHANGES IN SEROTONERGIC NEURONS FOLLOWING DESTRUCTION WITH 5, 7-DIHYDROXYTRYPTAMINE. A.C. DeVries, F.S. Hall, M. Linnoila* and A. Pert. NIMH and NIAAA, Bethesda, MD 20892.

Following selective neurotoxin induced lesions of the nigro-striatal dopamine (DA) system, it has been found that presynaptic compensatory changes take place in the remaining populations of DA neurons sufficient to normalize the extracellular concentrations of striatal DA. The purpose of the present study was to determine whether the serotonergic (5-HT) system has similar characteristics following neuronal destruction. Rats implanted with microdialysis guide cannulae in the striatum received intracerebroventricular injections of either 0, 50, 100, 150, or 200 µg of 5,7-dihydroxytryptamine (5,7-DHT, a selective 5-HT neurotoxin). Two to three weeks later the animals were tested behaviorally, and then had a CMA-11 microdialysis probe introduced into the striatum. Twenty four hours later microdialysis samples were collected at 30 min intervals and analyzed for 5-HT content with standard HPLC-EC procedures using a microbore column. Lesions produced by the highest concentrations of 5,7-DHT (200 µg) proved to be anxiolytic while lesions produced by lower concentrations of 5,7-DHT (150 and 100 µg) were anxiogenic as assessed with an elevated plus-maze. Low and medium doses of 5,7-DHT failed to alter significantly extracellular levels of 5-HT in the striatum while reducing tissue levels across a variety of terminal and perikaryal regions. Only the highest dose of 5,7-DHT was able to decrease striatal extracellular 5-HT, which was also accompanied by sustantial striatal depletions of tissue 5-HT. It appears that presynaptic compensatory changes take place in 5-HT neurons following lesioning similar to those seen in the dopaminergic systems.

AN ANTISENSE OLIGONUCLEOTIDE TO TRYPTOPHAN HYDROXYLASE HAS DIFFERING EFFECTS ON INDICES OF SEROTONERGIC FUNCTION. F. S. Hall*, A. Pert, D.A. Nielsen, M. Linnoila Laboratory of Clinical Studies/DICBR, NIAAA and Biological Psychiatry Branch, NIMH, Bethesda, MD 20892

The effects of an antisense phosphothioate oligonucleotide aimed at position 123 of rat tryptophan hydroxylase mRNA (5' TGT CTT CAA TCA TGG 3') was compared to a random sequence (5' TCG AAT CGT TAA TCG 3'). The compounds were administered directly into the median raphe nucleus via an injector inserted into an indwelling guide cannula (AP -7.7, ML +0.0, DV -7.5) in male Sprague Dawley rats. Subjects received 3 injections of 1 nmol oligonucleotide in 1ul of saline at 12 hour intervals. Twenty-four hours after the last injection the subjects were decapitated and discrete brain regions were dissected from the tissue: frontal cortex, ventral striatum, dorsal striatum, hypothalamus, hippocampus, dorsal raphe nucleus, and median raphe nucleus. Tissue samples were subsequently analyzed for serotonin, dopamine, norepinephrine and 5-hydroxytryptophan content using HPLC-EC. Prior to sacrifice, food consumption was found to be increased in antisense-treated subjects and open-arm entries in the elevated plus maze were decreased compared to control subjects. In these subjects tissue serotonin, 5-hydroxytryptophan, dopamine and norepinephrine content were unaltered. Investigations are underway to examine other neurochemical indices of serotonin function which might account for the observed behavioral differences in antisense-treated subjects.

Effect of Estrogen (E) and Progesterone (P) on the Expression of Tryptophan Hydroxylase (TPH) mRNA in the Raphe Nucleus of Non-human Primates. M. Pecins-Thompson, N.A. Brown, C.L. Bethea*, Division of Reproductive Sciences, Oregon Regional Primate Research Center, Beaverton, OR 97006

P increases prolactin secretion in E-primed female monkeys through a neural mechanism and serotonin (5HT) is a stimulatory transmitter for prolactin. This laboratory has shown that E induces progestin receptors in 5HT neurons. To determine whether E or P alters the function of 5HT neurons, the expression of mRNA for tryptophan hydroxylase (TPH) was examined in ovariectomized (ovx)-control, E treated (28 days) and E+P treated monkeys (14 days E + 14 days E+P) using *in situ* hybridization and a 248 bp TPH probe generated with RT-PCR (n=3 animals/group). Perfusion fixed midbrain sections (10µ) were hybridized at 40°C with ^{35}S antisense cRNA directed against the 5' substrate binding domain of monkey TPH. Adjacent sections were immunostained for 5HT to confirm the location of the dorsal raphe (DR). After a final wash in 0.1X SSC at 50°C, sections were opposed to tritum sensitive film for 14 days. Densitometric analysis with graylevel thresholding was performed at 3 or 4 levels of the DR. The number of pixels exceeding background in defined areas was obtained (*pixel number*) and normalized by the total number of pixels counted (*pixel fraction*). There was a 10 fold increase in TPH mRNA signal represented by both pixel number and pixel fraction in E treated macaques compared to ovx controls ($p < 0.05$). Supplemental P treatment reduced TPH mRNA expression from E levels in 2/3 animals but the average TPH mRNA level in E+P treated animals remained 4 fold higher than in ovx controls. These data indicate that E induces TPH gene expression in non-human primates. The effect of E+P on TPH mRNA was variable with the average level falling between the ovx group and the E treated group. EFFECTS OF ALTERED L-TRYPTOPHAN AVAILABILITY ON THE BRAIN RELEASE AND TURNOVER OF SEROTONIN IN PORTACAVAL SHUNTED RATS AS ASSESSED BY IN VIVO MICRODIALYSIS. P.B.F. Bergqvist*, S. Hjorth, G. Apelqvist, and F. Bengtsson, Depts of Clin Pharmacol, Lund Univ Hosp, 221 85 Lund, and Pharmacol, Univ of Gothenburg, 413 90 Gothenburg, Sweden.

A large body of evidence suggests that the neuropsychiatric syndrome seen in liver failure, hepatic encephalopathy (HE), is associated with an increased brain turnover (t.o.) of serotonin (5-HT). However, in a recent study we showed an unaltered neuronal release of 5-HT in chronic HE as reflected by unchanged dialysate 5-HT levels in the brain of portacaval shunted (PCS) rat. In the present study we studied the frontal neocortical extracellular levels of 5-HT and its main metabolite 5-HIAA at basal HE conditions and after a provocation of the 5-HT system by systemic administration of the precursor amino acid L-tryptophan (L-TRP; 1 loading dose of 280 mg/kg i.p. followed 3 hours later by 5 consecutive iterations of 50 mg/kg during 5 hours). Brain 5-HT t.o. was also determined by studying brain extracellular accumulation of 5-HIAA following systemic administration of probenecid (200 mg/kg i.p.), an inhibitor of the brain outtransport mechanism of 5-HIAA. While the basal extracellular 5-HT levels were unaffected by the PCS procedure the 5-HIAA levels were elevated ($p<0.05$) in the PCS rats compared with controls confirming the contention that increased brain 5-HT t.o. in HE is not associated with an increased neuronal release of 5-HT. Following the L-TRP administrations the 5-HT levels did not change either in PCS or control rats. The 5-HIAA levels, however, increased both in the PCS rats but especially in the controls. This finding may indicate that the 5-HT t.o. in the control rats are more susceptible to increased L-TRP availability. The probenecid treatment resulted in a similar 5-HIAA accumultaion in PCS and control rats. This similar time-course for the 5-HIAA accumulation might indicate that the increased extracellular 5-HIAA levels and, hence, the increased 5-HT t.o., is a phenomenon partly due to inhibition of the brain 5-HIAA outtransport.

SEASONAL VARIATION IN NEUROENDOCRINE AND MOOD RESPONSE TO L-TRYPTOPHAN INFUSION IN DEPRESSED PATIENTS AND HEALTHY SUBJECTS. A. Cappiello*, R. T. Malison, C. J. McDougle, S. Vegso, D. S. Charney, G. R. Heninger, L. H. Price. Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06519.

Recent reports suggest that seasonal variation of mood disorders might be related to alteration in rhythmicity of serotonin [5-HT] function. In this study we examined seasonal effects on the neuroendocrine and mood responses to i.v. infusion of the 5-HT precursor L-tryptophan (L-TRP) in depressed patients and healthy subjects. Methods: 126 drug-free patients with DSM-III-R major depression and 58 healthy comparison subjects participated. After an overnight fast, subject received an i.v. infusion of L-TRP 7 g. Blood was obtained for determination of serum prolactin (PRL), growth hormone (GH), and tryptophan levels. Visual analogue scales were used to assess mood. Results: Cosinor analysis revealed seasonal variation in peak change (Δ) PRL in the combined depressed patients ($p<.02$) and in unipolar ($p<.04$), nonmelancholic ($p<.003$), and nonpsychotic ($p<.007$) subgroups, with winter acrophases and summer troughs; healthy subjects showed no seasonality. Peak Δ GH showed seasonal variation in healthy subjects (April acrophase and February trough, $p<.01$), but not in depressed patients. Baseline tryptophan levels demonstrated summer peaks and winter troughs in the combined depressed group ($p<.01$) and in unipolar ($p<.009$), nonmelancholic ($p<.02$), and nonpsychotic ($p<.03$) subgroups. A negative correlation was found between peak Δ PRL and tryptophan levels in combined depressed ($p<.02$) and unipolar patients ($p<.04$). Baseline GH levels also manifested seasonal variation in the combined depressed ($p<.01$) and in bipolar ($p<.01$), melancholic ($p<.001$), nonpsychotic ($p<.04$), and psychotic ($p<.007$) patients. Conclusions: Our data are consistent with previous evidence that central 5-HT function is abnormal in depressed patients and further suggest a seasonal variability of such abnormalities that is absent in healthy subjects. Seasonal patterns of 5-HT function confined to specific diagnostic subgroups suggest that the pathophysiologies of clinically discrete mood disorder subgroups may be heterogeneous.

THE STIMULATION OF FORWARD LOCOMOTION ELICITED BY MK-801 IS ABOLISHED BY LOW DOSES OF THE 5-HT_{2A} ANTAGONIST MDL 100,907 P. Martin*, N. Waters, S. Holm, A. Carlsson and M. L. Carlsson.

Division of Pharmacology, Univ. of Göteborg, Medicinareg. 7, S-413 90 , Sweden.

1. In a previously published report (P. Martin *et al.*, J Neural Transm [Gen Sect] 1994; 95 :113-121), the dopamine D-1-antagonist SCH 23390, was more efficient than the D-2-antagonist raclopride, in counteracting the hyperactivity induced by the non-competitive NMDA-receptor antagonist MK-801. However, SCH 23390, besides its D-1 affinity, has been shown to have affinity for 5-HT_2-receptors. 2. Here, 3 compounds selective for the D-1, D-2 and 5-HT_{2a}-receptors, respectively, were tested concerning their effect on normal locomotion and MK-801-induced (0.3 mg/kg i.p.) hyperlocomotion in mice. 3. The D-1 antagonist SDZ 219-958 (0.017-0.15-1.35 mg/kg i.p.) dose-dependently counteracted the MK-801-induced locomotor stimulation. However, this was also the case for the 5-HT_{2a}-receptor antagonist MDL 100,907 (0.001-0.01-0.1 mg/kg i.p.), which even abolished (0.1 mg/kg) the MK-801-induced hyperlocomotion, with relatively less influence on locomotion in normal animals. 4. Finally, the effect in normal and MK-801 pretreated mice, of the concomitant administration of either of the D-1 or the D-2 antagonist (raclopride) with the 5-HT_{2a}-antagonist, was investigated. Protocols based on orthogonal design matrices were used. Data was subjected to multiple regression and the results presented as 3-dimensional response surface graphs. The main finding of these experiments was that regression coefficients for MDL 100,907, being insignificant in normal mice, became larger and highly significant in mice pretreated with MK-801. 5. In conclusion, low doses of the 5-HT_{2a}-receptor antagonist MDL 100,907 given alone or during simultaneous blockade of D-1 or D-2 receptors, have a strong inhibitory effect on MK-801-induced hyperlocomotion in mice. The equally strong inhibitory effect, in this respect, reported earlier with SCH 23390, is not explained solely by its D-1 antagonistic properties, and might partly be due to its affinity for 5-HT_2-receptors.

809.8

ROLE OF NITRIC OXIDE (NO) IN PENILE ERECTION AND YAWNING INDUCED BY 5-HT_{1C} RECEPTOR AGONISTS. A. Argiolas* & M.R. Melis. Bernard. B. Brodie Dept. Neurosci., Cagliari Univ., 09124 Cagliari, Italy.

The effect of N^G-nitro-L-arginine methyl ester (NAME) and N^G-monomethyl-L-arginine (NMMA), two inhibitors of NO synthase, given into a lateral ventricle (i.c.v.) on penile erection and yawning induced by 1-(3-chlorophenyl)-piperazine (m-CPP) and N-(3-trifluoromethylphenyl)-piperazine (TFMPP) two selective 5HT_{1C} receptor agonists, was studied in male rats. Both NO synthase inhibitors (50-500 μg) prevented dose-dependently the behavioral responses induced by m-CPP (0.5 mg/kg s.c.) or by TFMPP (1 mg/kg s.c.), NAME was about 4-5 times more potent than NMMA while D-NMMA, which does not inhibit NO synthase, was ineffective. The inhibitory effect of NAME on m-CPP and TFMPP responses was prevented by the co-administration of L-arginine (1 mg i.c.v.). m-CPP- and TFMPP-induced penile erection and yawning was prevented also by the i.c.v. administration of LY 83583 (50-200 μg) or methylene blue (50-400 μg), two inhibitors of guanylate cyclase but not by reduced hemo-globin (50-400 μg), a NO scavenger. The results suggest that central NO is involved in 5-HT_{1C} receptor agonist-induced penile erection and yawning.

809.9

THE SEROTONIN 5-$HT_{2A/2C}$ SELECTIVE AGONIST, DOI ELICITS HEAD TWITCH FOLLOWING DIRECT INJECTION INTO THE MEDIAL PREFRONTAL CORTEX OF RATS. David L. Willins* and Herbert Y. Meltzer, Laboratory of Biological Psychiatry, Case Western Reserve University, Cleveland, Ohio 44106

The systemic administration of selective serotonin-2 (5-HT_2) receptor agonists produces a characteristic head twitch response (HTR) in rodents. The selective 5-$HT_{2A/2C}$ agonist, DOI produces a HTR following bilateral injection into the medial prefrontal cortex (mPFCx) of male, Sprague-Dawley rats. This response was dose-dependant for doses ranging from 0 to 57 nmoles/0.5 μl/side, and was reversed by pretreatment with ketanserin (2.5 mg/kg, i.p.). In addition, pretreatment of rats with either clozapine (1 mg/kg, i.p.), amperozide (5 mg/kg, i.p.), remoxipride (10 mg/kg, s.c.) or SCH23390 (50 μg/kg, s.c.) also inhibited DOI-induced head twitch. Intra-cortical administration of MK-212, a serotonin agonist which has 100-fold greater selectivity for the 5-HT_{2C} receptor than the 5-HT_{2A} receptor, did not produce a HTR when administered at a dose of 34 nmoles/0.5 μl/side. Chronic treatment of rats with antipsychotic drugs has been shown to alter both serotonergic and dopaminergic receptors. Twenty-one day treatment of rats with either clozapine (20 mg/kg/d, p.o.) or haloperidol (0.5 mg/kg/d, p.o.) inhibited the HTR to DOI. Finally, pretreatment of rats with baclofen, a $GABA_B$ receptor agonist, was shown to produce a bi-phasic alteration of the HTR to DOI. While a higher dose of baclofen (3 mg/kg, sc) produced a marked inhibition of DOI-induced head twitch, a low dose (0.6 mg/kg, sc) potentiated this response. These data suggest that activation of 5$HT2_A$ receptors in the mPFCx stimulates a HTR which may involve dopaminergic as well as GABAergic mechanisms. VOLTAMMETRIC MEASUREMENT OF SEROTONIN IN THE SUBSTANTIA NIGRA PARS RETICULATA OF FREELY MOVING RATS. J.L. Góngora-Alfaro*, S. Hernández, F. Heredia, J.L. Bata, G. Arankowsky, J. Aceves and D. Martínez-Fong, Centro de Investig. Regionales, Universidad Autónoma de Yucatán, México, 97000.

The substantia nigra pars reticulata (SNr) receives serotonergic innervation from the raphe nuclei. Using differential pulse voltammetry with carbon fiber microelectrodes (CFM) we have measured the extracellular concentration of serotonin (5-HT) in the SNr of freely moving rats (n=5). Thirty six hours after implanting the CFM, an oxidation peak was measured at +277 mV. Allopurinol (20 mg/kg, i.p.) reduced the peak height to 55 ± 4%, indicating the contribution of uric acid (15.5 ± 4.4 μM) to the oxidation peak. Pargyline (40 mg/kg, i.p.) caused a further reduction of the peak height to 32 ± 3%, indicating that 5-HIAA (1 ± 0.1 μM) also contributes to the peak. The remaining peak was considered to be 5-HT because it appeared at +307 ± 6 mV and was increased by the 5-HT reuptake blocker duloxetine. The basal concentration of 5-HT (45.6 ± 10.8 nM) could be an overestimation due to the inhibition of 5-HT metabolism by pargyline. It is concluded that 5-HT is released in the SNr. (Supported by grant 1831-M9211 from CONACyT, México.)

Neurochemical and behavioral correlates in post-hypoxic myoclonus: an *in vivo* microdialysis study. A.G. Kanthasamy*, T.Q. Vu, S.P. Jaw and D.D. Truong, Parkinson & Movement Disorders Laboratory, Dept. of Neurology, Univ. of California, Irvine, CA 92717.

To evaluate the neurochemical dynamics of serotonergic and dopaminergic systems in post-hypoxic myoclonus, the extracelluar release of serotonin (5-HT), dopamine (DA) and their metabolites were determined using *in vivo* microdialysis. Basal and stimulated release of 5-HT, 5-HIAA, DA and DOPAC were monitored in the prefrontal cortex of a stimulus-sensitive myoclonus model. KCl (100 mM) or NMDA (500 μM) were locally infused to evoke the release of neurotransmitters. Basal levels of these neurotransmitters were unaffected among the three groups (control, post-hypoxic, post hypoxic-recovered rats). A significant reduction ($p < 0.01$) in KCl- and NMDA-stimulated release of 5-HT and DA was observed between control and post-hypoxic rats. The depolarization-induced reduction in 5HIAA was markedly elevated in post-hypoxic rat as compared to controls. These neurochemical changes returned close to normal levels in post hypoxic-recovered rats. A linear relationship was obtained between neurochemical alterations and behavioral quantitation of myoclonus. These data suggest that a synergistic hypofunctioning of stimulus-induced serotonergic and dopaminergic terminals in mesocortical regions may contribute to the behavioral expression of post-hypoxic myoclonus. (Supported by Myoclonus Research Foundation).

SEROTONERGIC MODULATION OF AUDITORY EVOKED POTENTIALS IN BEHAVING CATS. G. Juckel, M. Mölnar, U. Hegerl, V. Csepe, G. Karmos (SPON: European Neuroscience Association). Depts. Psychophysiology, Freie Universität Berlin (Germany) and Academy of Sciences Budapest (Hungary).

Several findings suggest that the stimulus intensity dependence of auditory evoked potentials is modulated by the brain serotonin system Epidural recordings over the primary and secondary auditory cortex were conducted in chronically implanted cats under drugs influencing the serotonergic system administered either i.v. or by local injection into the dorsal raphe. The intensity dependence was increased after blocking serotonergic activity presynaptically and decreased after stimulating this activity. Postsynaptically, modifications of 5-HT_{1a} and 5-HT_2 receptors, but not of 5-HT_{1c} receptors, changed the intensity dependence. The serotonergic modulation of the intensity dependence was stronger in the primary than in the secondary auditory cortex, possibly corresponding to the known different serotonergic innervation of the two areas. The serotonergic system seems to modulate the initial stage of auditory processing, since only the first component of the evoked potentials was affected by the serotonergic interventions.

809.13

EFFECT OF REPEATED EXPOSURE TO FORCED SWIMMING STRESS ON EXTRACELLULAR LEVELS OF 5-HT IN THE RAT. L. Kirby* and I. Lucki. Departments of Psychiatry and Pharmacology, Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Previous work using *in vivo* microdialysis demonstrated that forced swimming produces regionally-selective changes in extracellular 5-hydroxytryptamine (5-HT) in rats (Kirby et al., Brain Res., 1995, in press). Swimming produced increases of 5-HT in striatum, decreases of 5-HT in amygdala and lateral septum, and did not change 5-HT in frontal cortex and hippocampus. This study examined these neurochemical changes after repeated exposure to the swim stress. Cannulae were implanted under surgical anesthesia into either striatum or lateral septum. One week later, dialysis probes were lowered through the cannulae and dialysis samples collected before, during, and after a 15 min swim exposure. This dialysis procedure and swim exposure was repeated the following day. Dialysate content of 5-HT and 5-hydroxyindole-acetic acid (5-HIAA) were measured by HPLC. On the first test day, swim produced an elevation of extracellular 5-HT by 60% over baseline in striatum and a reduction to 40% below baseline in lateral septum. On the second day, swim had no effect on 5-HT in either brain region. On both days, however, swim produced decreases in 5-HIAA in both regions to 40-50% below baseline. These results suggest that there is an adaptation of the regionally-specific effects of forced swimming on extracellular 5-HT, but not of 5-HIAA, over repeated exposure to the stress. *Supported by USPHS grants MH 17168, MH36262, and MH 48125*

809.14

EFFECT OF FORCED SWIMMING STRESS ON EXTRACELLULAR LEVELS OF 5-HT IN THE DORSAL RAPHE NUCLEUS OF THE RAT. J. M. Chou*, L. G. Kirby, and I. Lucki. Depts. of Psychiatry and Pharmacology, Inst. of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

The effect of forced swimming for 30 minutes on extracellular levels of 5-hydroxytryptamine (5-HT) and its major metabolite, 5-hydroxyindoleacetic acid (5-HIAA) were examined in the dorsal raphe nucleus, a region containing 5-HT cell bodies. Extracellular levels of 5-HT and 5-HIAA were measured using *in vivo* microdialysis with electrochemical detection with 10 min resolution. A dialysis probe was implanted into the dorsal raphe nucleus under surgical anesthesia on the day prior to the study. The next day, dialysate samples were collected for 70 min to establish baseline. Forced swimming initally produced a 40% decrease in raphe extracellular concentrations of 5-HT and 5-HIAA. 5-HT concentration remained supressed for approximately 2 hours following the swim. 5-HIAA concentration remained reduced for 30 min, but rebounded to increase 20% above baseline 2 hours after the swim. This indicates that 5-HT metabolism in the dorsal raphe nucleus was likely increased while 5-HT release was reduced by the forced swim. Previous work in our laboratory has shown that forced swimming produced a regionally- selective pattern of changes in extracellular 5-HT (Kirby et al., Brain Res., 1995, *in press*). Since forced swimming is used as a screen for antidepressant drug effects, it is possible that regional changes in levels of 5-HT may play a selective role in mediating the behavioral effects of antidepressant drug treatments. *Supported by USPHS grants MH 17168, MH36262, and MH 48125*

PERIPHERAL AND CENTRAL INDICES OF SEROTONIN FUNCTION AND IMPULSIVITY. C. Reist*, D. Helmeste, L. Albers, S.W. Tang. UC-Irvine, Psychiatry Service, VA Medical Center, Long Beach, CA, 90822.

A large body of literature exists implicating serotonin in psychiatric and behavioral disorders. There is evidence for its role in suicide, aggression and other behaviors characterized by impulsivity. Efforts continue to refine serotonergic challenge paradigms and to develop new tools to examine this system at the molecular level. In the present study hormonal response to oral paroxetine was examined for use as a serotonergic challenge agent in a group of healthy subjects. Platelet $5HT_{2A}$ mediated intracellular calcium response to serotonin was also measured to assess signal transduction. Paroxetine elicited a robust cortisol response which was directly correlated with the magnitude of platelet calcium response. Both of these measures were inversely correlated with the trait of impulsivity as measured by the Barratt Impulsivity Scale. These results suggest that paroxetine has utility in studying serotonergic systems.

810.1

ATP-INDUCED OSCILLATIONS OF CYTOSOLIC CA2+ ACTIVITY IN CULTURED ASTROCYTES AND IN GLIOMA CELLS. G. Reetz*. Institute of Neurobiochemistry, University of Magdeburg, Leipziger Str. 44, 39120 Magdeburg, Germany.

Continuous stimulation with ATP induced $[Ca^{2+}]_i$ oscillations (1-2/min) in cultured astrocytes from newborn rats and in rat glioma cells (C6-4-2). The initial $[Ca^{2+}]_i$ response to ATP resulted from $InsP_3$-induced Ca^{2+} release, whereas the subsequent oscillations were dependent on both $InsP_3$-sensitive Ca^{2+} stores and Ca^{2+} influx. Depolarization by 50 mM $[K^+]_{ex}$ resulted in a transient Ca^{2+} response in astrocytes, presumably due to activation of voltage-dependent Ca^{2+} channels. In C6-4-2 glioma cells, $[Ca^{2+}]_i$ oscillations were also induced by bradykinin. Simultaneous recording of membrane potential showed that the oscillations of $[Ca^{2+}]_i$ and of membrane potential in glioma cells were synchronous. The oscillations were affected by the K^+ equilibrium potential and by blocking $K^+(Ca^{2+})$ channels, indicating a potentiation of Ca^{2+} influx by membrane hyperpolarization. Whole-cell patch-clamp experiments indicate a conductance for Na^+ and for Ca^{2+}.

The oscillations were also influenced by hypotonic and by hypertonic medium in glioma cells as well as in astrocytes. We conclude that in glial cells there is a feedback regulation between cell volume and $[Ca^{2+}]_i$. The experiments indicate a possible physiological function of Ca^{2+} oscillations in volume regulation of glial cells.

810.2

A DETERGENT, CYTOCLEAN, HAS SELECTIVE ACTIONS ON LIGAND-GATED ION CHANNELS EXPRESSED IN XENOPUS OOCYTES. T.K. Machu*[1], S.J. Mihic[2], X.-P. Qian[1], and J.E. Dildy-Mayfield[2] [1]Dept. of Pharmacology, Texas Tech University Health Sciences Center, Lubbock, TX 79430 [2]Dept. of Pharmacology, University of Colorado Health Sciences Center and VA Medical Center, Denver, CO 80262

Cytoclean was observed to have selective actions on ligand-gated ion channels. Responses of α1 and α2 glycine receptors expressed in Xenopus oocytes were 3 to 5 fold higher with solutions prepared in glassware that had been washed with Cytoclean than with solutions prepared in glassware that had been extensively washed with ethanol and Nanopure water. Cytoclean (0.001%-0.01%) potentiated 50 μM glycine responses in oocytes expressing α2 glycine receptors by 23 ± 7% to 342 ± 43%. Cytoclean is composed of 4 reagents dissolved in water, and these reagents were tested individually for their abilities to modulate responses of oocytes expressing α2 glycine receptors. Tetrapotassium phosphate, sodium xylene sulfonate, and Triton X-100 (1-10 fold of their respective concentrations in Cytoclean) minimally potentiated 50 μM glycine mediated currents. Approximately 10% of Cytoclean is composed of Biosoft D62, which at concentrations of 0.00005%-0.001%, potentiated 50 μM glycine responses by 13±1% to 474±50%. Biosoft D62 is composed of ethanol (29%) and linear alkylbenzene sulfonate (>95% C12 chain). Dodecanol is used in the synthesis of Biosoft D62 and represents no more than 1.5% of this reagent. Neither the concentration of ethanol (~5 mM) nor dodecanol (~ 4 μM) that is present in the highest concentration of Biosoft D62 tested had any effect on 50 μM glycine mediated currents, suggesting that the reagent responsible for the potentiation of glycine receptor function is linear alkylbenzenesulfonate. The effects of Cytoclean were examined on 5-HT_3, $GABA_A$, and kainate/AMPA receptors expressed in Xenopus oocytes. Cytoclean had no effect on 5-HT_3 nor GluR6 receptor function, but Cytoclean (0.005% and 0.01%) inhibited GluR3 mediated currents by ~21% and 41%, respectively. Enhancement of $GABA_A$ receptor function ranged from 21±2.3% to 458±142% with Cytoclean (0.0001% to 0.01%), respectively. These results suggest that trace amounts of Cytoclean adhering to glassware may confound experimental results.

810.3

EXAMINATION OF BOVINE APO-OPSIN AS A MODEL OF LIGAND BINDING RECEPTORS. W.A. Clark*, J.C. Gutierrez, and J.K. Northup. Lab of Cell Biology, National Institute of Mental Health, Bethesda, MD 20892-4090.

Rhodopsin and the associated G-protein transducin have been utilized by numerous investigators to examine the mechanism of receptor-G-protein interaction. We have extended this work using apo-opsin to serve as a model for ligand binding seven transmembrane receptors. Bovine rhodopsin-containing rod outer segment disc membranes were depleted of chromophore using hydroxylamine at basic pH. In an established *in vitro* transducin activation assay (Fawzi et al., JBC 266:12194, 1991), the resultant apo-opsin demonstrated ~50-fold lower activity than rhodopsin. Reconstitution of this opsin with 9-*cis*- or 13-*cis*-retinal in the dark results in a significant inhibition of opsin activity below basal. Upon exposure of this "inverse agonist"-bound state of opsin to light, full rhodopsin activity is achieved. Furthermore, apo-opsin responds to all *trans*-retinal in a dose dependent manner to form a reactivated rhodopsin species indistinguishable from native rhodopsin in the transducin activation assay. Data are presented demonstrating the effects of transducin in modulating the apparent affinity of opsin for all *trans*-retinal. These studies utilizing opsin provide novel insights into the functioning of this class of receptors.

CAFFEINE-INDUCED FOS PROTEIN EXPRESSION IN THE RAT BRAIN. H.J. Bennett*, J. Burns and K. Semba. Dept. of Anatomy & Neurobiology, Dalhousie University, Halifax, N.S., CANADA B3H 4H7.

Caffeine is a methylxanthine which has a mild stimulatory action in the CNS. Its action is thought to be mediated primarily by antagonism at adenosine receptors. Extracellular adenosine has been demonstrated to have a tonic inhibitory effect at a number of presynaptic and postsynaptic sites. Previous studies have shown that high doses (>75 mg/kg, i.p.) of caffeine increase c-fos mRNA in the striatum of the rodent brain. In order to investigate the effects of caffeine at lower doses and in extrastriatal structures, male Wistar rats were injected with caffeine (1, 5, 10 or 75 mg/kg, i.p.) or saline, perfused 2 hrs later, and their brains were processed for Fos immunohistochemistry. Basal expression of Fos was observed in a number of brain regions after saline injection. The distribution seen with 1 or 5 mg/kg caffeine was not significantly different from the basal expression. In contrast, following 10 mg/kg injection greater numbers of Fos-positive neurons were seen in the medial prefrontal, cingulate and pyriform cortices, olfactory tubercle, hypothalamic nuclei, paraventricular thalamic nucleus, supragenual nucleus, and cochlear nuclei. With 75 mg/kg caffeine, in addition to the above regions Fos-immunoreactive neurons were observed in the lateral striatum, globus pallidus, substantia nigra pars reticulata, central nucleus of the amygdala, paraventricular and supraoptic hypothalamic nuclei, lateral parabrachial nucleus, locus coeruleus, ventrolateral medullary reticular formation, and nucleus of the solitary tract. Behaviourally, increased activity was seen after 5 or 10 mg/kg, whereas activity was reduced after 75 mg/kg; no change was observed with 1 mg/kg. These results indicate that caffeine induces c-fos expression in a dose-related manner in more widely distributed brain regions than previously reported, including those involved in limbic, autonomic, and motor functions. Supported by the MRC of Canada.

ENZYMATIC HYDROLYSIS OF AGMATINE TO PUTRESCINE IN RAT BRAIN. M. Sastre*, S. Regunathan and D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

We have recently discovered that agmatine (decarboxylated arginine), an endogenous ligand for imidazoline receptors, and its biosynthetic enzyme, arginine decarboxylase (ADC), are expressed in mammalian brain (Li et al., *Science* 263: 966-969, 1994). In bacteria, the major metabolic pathway for agmatine is hydrolysis by agmatinase to putrescine, the precursor of polyamines, and urea. We sought to determine whether agmatine can be metabolized by a similar pathway in rat brain. Agmatinase was assayed by measuring hydrolysis of guanido^{14}C-agmatine to ^{14}C-urea and putrescine and subsequent trapping of $^{14}CO_2$ released by urease from ^{14}C-urea. Incubation of guanido^{14}C-agmatine with rat brain homogenates resulted in a substantial hydrolysis of agmatine (7.6 to 11.8 nmol/hr/mg protein). Activity is reduced (up to 75%) by boiling while ~25% of total activity remained in non-homogenate controls due to non-enzymatic degradation of agmatine. With subcellular fractionation of rat brain, agmatinase activity was maximal (48.1 nmol/hr/mg protein) in the soluble fraction of the P2 pellet (synaptosomal/mitochondrial). Further fractionation of the P2 pellet resulted in enrichment of agmatinase in the mitochondrial (327.8 nmol/hr/mg protein) vs. synaptosomal (31.2 nmol/hr/mg protein) fractions. Agmatinase activity in the P2 pellets varied regionally in brain: hypothalamus (133 nmol/hr/mg protein) > hippocampus (88) > medulla (64.5) > cerebellum (47.5) > striatum (35.8) > cerebral cortex (30.2). We conclude: (a) rat brain expresses agmatinase which can convert agmatine to putrescine and urea; (b) the enzyme is soluble and associated with mitochondria; (c) the agmatine-putrescine pathway suggests a novel metabolic pathway for polyamine biosynthesis in brain.

"CAGED" CARBON MONOXIDE: MOLECULES FOR PHOTO-RELEASING FREE CARBON MONOXIDE IN SITU. Joseph P. Y. Kao, D. Weinreich†* & Paul F. Keltz. Medical Biotechnology Center, and Depts. of Physiology, and †Pharmacology & Experimental Therapeutics, School of Medicine, University of Maryland, Baltimore, MD 21201.

We report the design, synthesis, and application of NF-CO, NV-CO, and NP-CO, a family of three "caged CO" compounds —photosensitive reagents that release the messenger molecule carbon monoxide when illuminated with long-wavelength ultraviolet light. The caged CO's are useful as Na^+ or K^+ salts, which can be bath-applied or introduced into cells via patch pipets, respectively. The caged CO's can also be readily loaded into living cells by incubation with the acetoxymethyl (AM) ester forms of the reagents. The light-induced "uncaging" reaction is characterized by $t_{½} \approx 80$ μs. Carbon monoxide photoreleased from intracellular caged CO is as effective as exogenous gaseous CO in activating intracellular guanylyl cyclase.

The photosensitive "cages" in these caged CO compounds are based on *o*-nitrobenzyl chemistry—the most widely-used caging chemistry in biology. Common mercury or xenon light sources are thus sufficient to activate photorelease of CO. Because photorelease offers the dual advantages of spatial and temporal control of messenger molecule delivery, these caged CO's are ideal for applications in signalling studies.

A LYSINE RESIDUE OF THE CANNABINOID RECEPTOR IS CRITICAL FOR RECEPTOR RECOGNITION BY SEVERAL AGONISTS BUT NOT WIN55212-2. Z. H. Song* and T. I. Bonner. Lab. of Cell Biology, NIMH, NIH, Bethesda, MD 20892.

Lysine192 in the third transmembrane domain of the human CB1 cannabinoid receptor was converted to an alanine to study its role in receptor recognition and activation by agonists. HU-210, CP-55940, WIN55212-2, and anandamide, four cannabinoid agonists with distinct chemical structures, were used to characterize the wild-type and the mutant receptors. In 293 cells stably expressing the wild-type receptor, specific binding to [^{3}H]WIN55212-2 and inhibition of cAMP accumulation by cannabinoid agonists were demonstrated, with different ligands exhibiting the expected rank orders of potency and stereoselectivity in competition binding and functional assays. In cells expressing the mutant receptor, the binding affinity of the receptor for [^{3}H]WIN55212-2 was only slightly affected (the K_d for the mutant receptor was twice that of the wild-type), and the ability of WIN55212-2 to inhibit cAMP accumulation was unchanged. However, HU-210, CP-55940 and anandamide were unable to compete for [^{3}H]WIN55212-2 binding to the mutant receptor. In addition, the potencies of HU-210, CP-55940 and anandamide in inhibiting cAMP accumulation were reduced by more than 100-fold. These results demonstrate that lysine192 is critical for receptor binding by HU-210, CP-55940 and anandamide. Since lysine192 is not important for receptor binding and activation by WIN55212-2, WIN55212-2 must interact with the cannabinoid receptor through at least one point of interaction that is distinct from those of the three other agonists.

WHOLE CELL PATCH-CLAMP MEASURED ANGIOTENSIN II-INDUCED CURRENT CHANGES IN BRAIN SLICES F.P. Martial*, A. Goucham, S.N. Thornton, S. Nicolaïdis. Neurobiologie des Régulations, Collège de France, 11 place Marcelin Berthelot, 75231 Paris CEDEX 05, France.

Previous experiments on anesthetized rats have shown that many neurons in the *septo-preoptic continuum* are sensitive to Angiotensin (AII) and/or Losartan (Los).

Neuronal post-synaptic currents evoked by short time step depolarizations were recorded in slice preparations of the *septo-preoptic continuum* from juvenile rat brains using the whole cell patch-clamp technique. The effect of the specific non-peptidic antagonist of the angiotensin Type-1 receptor, Losartan (DUP 753), was also tested.

Rats weighed between 60 and 100 g on the day of the sacrifice. The temperature of the perifusion *milieu* was 25 ± 1°C. For each cell several step depolarization series (increasing by 20 mV) were applied under control conditions and then after bath application of AII or Los.

Preliminary results showed that at least two types of units were recorded. In the first type, the presence of AII in the bath produced an outward current composed of two distinct phases: one rapidly inactivable phase, and a second non-inactivable but saturable phase. In this type of unit Los could partially antagonize the effect of AII, and this lasted several minutes or more.

The second type of unit observed showed, under control conditions, weak, voltage dependant, rapidly inactivable, inward currents. These currents disappeared in the presence of AII but remained unaffected application of Los in the bath.

These results are consistent with several observations made previously in our laboratory with extra-cellular recordings and micro-iontophoresis as well as in behavioral studies. The variability of the responses to iontophoretic application of AII as well as the long term action of Los already observed in our laboratory were quite puzzling. Now, these whole-cell recordings show that AII should must not be seen as a mere neurotransmitter but rather as a subtle neuromodulator capable of acting on different receptors, pre as well as post-synaptically. Los, on the other hand, has a much longer, and apparently more complicated, action on these receptors.

810.9

CHARACTERIZATION OF A LOW AFFINITY BINDING SITE ON THP-1 MONOCYTES USING PEPTIDE AND NON-PEPTIDE NEUROKININ LIGANDS. S.L. Yates*, J.M. Kocsis, and K.R. Brunden. Gliatech, Inc., 23420 Commerce Park Rd., Cleveland, OH 44122.

Substance P (SP) typically initiates signal transduction through its binding to neurokinin 1 (NK1) receptors. SP is known to increase the production of interleukin-1 from human monocytes; however, these cells are devoid of high affinity NK1 receptors. Jeurissen *et al.* (J Immunol, 1994, 152:2987) have recently identified a low affinity non-NK1 receptor on human monocytes. To further characterize the properties of this receptor, we have examined the binding of the non-peptide NK1 antagonist, L-703,606, to human myeloid leukemia (THP-1) cells. The THP-1 cells were stimulated with lipopolysaccharide for 48 hr, subsequently harvested, and membrane homogenates were prepared. Binding of ^{125}[I]L-703,606 was performed at 4°C in Tris buffer, pH 7.4, containing a cocktail of protease inhibitors. Association analysis revealed that ^{125}[I]L-703,606 binding saturated within 10 to 15 min. Unlabeled L-703,606 inhibited the binding of ^{125}[I]L-703,606 with an apparent affinity of ~200 nM. Interestingly, SP did not inhibit ^{125}[I]L-703,606 binding, nor did a variety of NK peptide antagonists and agonists. To clarify these observations, additional studies were conducted as above using ^{125}[I]SP. Unlabeled SP caused a dose-dependent inhibition of ^{125}[I]SP binding, revealing a low affinity binding site. L-703,606 and the other NK compounds tested above were able to compete for ^{125}[I]SP binding. These data provide evidence of a low affinity NK-like receptor on THP-1 cells which may have a distinct non-peptide regulatory/modulatory binding site in addition to a peptide binding site.

810.10

CLONING AND CHARACTERIZATION OF BRAIN CYSTEINE SULFINIC ACID DECARBOXYLASE. X.W. Tang, Y. Sun, C.C. Hsu, C.-Y. Yang[1] and J.-Y. Wu*. Dept. of Physiol. & Cell Biol., Univ. of Kansas, Lawrence, KS 66045, and [1]Baylor College of Med., Houston, TX 77030

Taurine is one of the most abundant free amino acids found in mammalian CNS, and is believed to play many important physiological functions. The rate limiting enzyme in taurine biosynthesis in the brain is believed to be cysteine sulfinic acid decarboxylase (CSAD). Despite its importance, little is known regarding the molecular nature and mode of regulation of CSAD. Here we report the purification of CSAD to homogeneity from porcine brain by a combination of column chromatographies of hydroxylapatite, DE-52 and Sephadex G-100 and polyacrylamide gel electrophoresis(PAGE). The purified CSAD has a molecular weight of 86-90 kDa and 43 kDa on non-denaturing gradient PAGE and SDS-PAGE, respectively, suggesting that the CSAD is a homodimer of 43 KDa. A cDNA encoding CSAD has been cloned from porcine brain cDNA library using anti-CSAD as probe. The clone was further verified by showing CSAD activity when it was expressed in bacteria. Partial DNA sequence of the CSAD cDNA has been obtained. In regard to the mode of regulation, CSAD activity was found to increase to an extent of 50%, 120%, 690% when crude synaptosomes were treated with 5 mM ATP, 0.2 mM vanadate, or 2mM EDTA/EGTA respectively. Furthermore, when crude CSAD preparations were incubated with alkaline phosphatase, CSAD activity decreased to 75% of its original value, indicating that the CSAD activity might be regulated by phosphorylation. (Supported by grants from Office of Naval Research; NIH, NS20978; and NSF, BNS-8820581)

810.11

ZINC PROTOPORPHYRIN IX (ZnPP) INHIBITS RELAXATION AND SECOND MESSENGER ACTIVATION IN THE RAT AORTA IN A MANNER DISTINCT FROM INHIBITION OF HEME OXYGENASE (HO). *Lars Ny,* Lars Grundemar and Karl-Erik Andersson, Department of Clinical Pharmacology, Lund University Hospital, S-221 85 Lund, Sweden.* Carbon monoxide (CO), which can be produced by HO through degradation of heme has been claimed to be a neuronal messenger and a regulator of the vascular tone. We examined whether the HO inhibitor ZnPP and other porphyrins affects vasodilation evoked by various agents in the rat aorta. ZnPP (0.1 mM) virtually abolished the relaxation evoked by vasoactive intestinal peptide (VIP), atrial natriuetic peptide (ANP) and attenuated the relaxation induced by acetylcholine (ACh). In contrast, ZnPP did not affect the relaxation evoked by forskolin and 3-morpholino-sydnonimin, agents which directly activate adenylate cyclase and guanylate cyclase, respectively. Also SnPP and PP attenuated the VIP-evoked relaxation. ZnPP also abolished the elevation of cAMP and cGMP levels evoked by VIP and ANP, respectively. Neither ZnPP nor PP affected the contraction evoked by phenylephrine. Thus, ZnPP inhibits relaxation induced by VIP, ANP and ACh, probably by interfering with membrane receptor-coupled dilatory signal transduction pathways. This effect does not seem to be dependent upon inhibition of HO. It appears that the lack of specificity of the HO inhibitors makes them less suitable as tools in the investigation of a messenger role of CO.

810.12

HEME OXYGENASE ISOENZYMES AND EFFECTS OF CARBON MONOXIDE IN THE FELINE LOWER ESOPHAGEAL SPHINCTER.

Lars Grundemar[1], Lars Ny[1], Bengt Larsson[1], Per Alm[2], Peter Ekström[3] and Karl-Erik Andersson[1], Departments of [1]Clinical Pharmacology, [2]Pathology and [3]Zoology, Lund University, Lund, Sweden.*

Carbon monoxide (CO) has, like nitric oxide, recently been suggested to be a gaseous messenger in the brain and periphery. The distribution of the CO producing enzymes heme oxygenase (HO)-1 and -2 were examined in the feline lower esophageal sphincter (LES). Also HO activity in homogenates and motor effects of CO in the LES were investigated. HO-2 immunoreactivity (IR) was observed in nerve cell bodies in the submucosal and myenteric plexus, nerve fibers, non-neuronal cells surrounding smooth muscle bundles, and in the endothelium of some arteries. HO-1-IR was confined to non-neuronal cells in the smooth muscle layer. HO activity, measured as CO production was demonstrated in LES homogenates. This activity was inhibited by the HO inhibitor zinc protoporphyrin. Exogenously administered CO evoked a concentration-dependent relaxation and increased cyclic GMP levels in LES strips. These results show that HO-2 as well as HO-1 are present in the LES and suggest that CO can be generated by neuronal and non-neuronal cells and may possibly have a role as a peripheral messenger.

810.13

EXPRESSION OF HO2 IN DIFFERENTIATED PC12 CELLS. E.E. Thompson* and S.H. Snyder The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Heme oxygenase (HO) catalyses the oxidation of heme to biliverdin and carbon monoxide (CO). Since CO can activate soluble guanylate cyclase, it is likely that HO plays a role in cGMP mediated signal transduction. When differentiated with NGF, PC12 cells express the neuronal isoform of heme oxygenase, HO2. HO2 enzyme activity in cellular sonicates after 6 days of NGF treatment is 5 nmol/mg/hour, which is higher than that in total brain homogenates. Also, as early as day three of NGF treatment, there is a cGMP signal by immunoassay that is sensitive to ZnPPIX, an inhibitor of HO, but not to nitroarginine. These data suggest that as PC12 cells differentiate into their neuronal phenotype, they synthesize HO2 which is used in cGMP mediated signal transduction. This makes PC12 cells an interesting model system in which to study the role of neuronal HO2.

810.14

IMMUNOCYTOCHEMICAL LOCALIZATION OF HEME OXYGENASE-2 IN RAT BRAIN. M. Yamanaka[1], Y. Nishimura*[2], R. Semba[1]. [1]Dept. of Anatomy II, [2]Dept. of Physiology II, Mie University School of Medicine, Tsu, Mie 514, Japan.

Carbon monoxide is a membrane-permeable gas that has been suggested to play a signaling role in the brain. It is formed by the enzyme heme oxygenase-2 during conversion of heme to biliverdin. In the present study, we raised antisera against the synthesized N-terminal fragment of this enzyme and studied cellular distribution of the enzyme in the rat brain by an immunocytochemical method. Heme oxygenase-2 immunoreactivity was observed only in neurons. Though immunoreactive neurons were ubiquitous to the brain, intensely stained neurons were rich in the olfactory bulb, layers III and V of the cerebral cortex, hippocampus, locus coeruleus, pontine nucleus and cerebellum. In the pyramidal cells of the hippocampus and Purkinje and basket cells of the cerebellum, immunoreactivity was manifested in the dendrite and the perikaryon rather than in the axon terminal, suggesting the function of HO-2 as a generator of a retrograde messenger.

810.15

HEME OXYGENASE-2 IN SENSORY AND AUTONOMIC NEURONS OF THE GUINEA-PIG. W. Kummer*, R. Vollerthun and B. Höhler. Inst. Anat. & Cell Biol., JLU, D-35385 Giessen, FRG

Heme oxygenase-2 (HO-2) is the major carbon monoxide (CO) generating enzyme constitutively expressed in the brain. In view of the potential role of CO as a neurotransmitter the distribution of HO-2 in the peripheral nervous system was investigated by immunohistochemistry, and the immunoreactive protein was characterized by western blotting using an antiserum raised against rat testicular HO-2. All neuronal cell bodies in sensory ganglia (trigeminal, petrosal, jugular, nodose, and dorsal root ganglia), regardless of their size, exhibited intense immunoreactivity to HO-2. Immunoreactivity was confined to the perikaryon and did not extend into the axon. Similarly, all neuronal cell bodies of sympathetic ganglia (superior cervical, stellate, inferior mesenteric, and lumbar chain ganglia), and submucosal and myenteric ganglia of the small intestine of the guinea-pig were HO-2 immunoreactive. Peripheral tissues and organs so far investigated by immunohistochemistry (visceral arteries, fat tissue, skin) were devoid of HO-2 immunoreactive axon terminals. Western blots revealed an HO-2 immunoreactive protein with an apparent molecular weight of 36 kDa in cerebellum, sympathetic and dorsal root ganglia. The present findings establish an HO-2 immunoreactive protein as an ubiquitous component of sensory and autonomic neurons in the guinea-pig. Its molecular weight corresponds to that of brain HO-2 which is 6 kDa smaller than that of testicular HO-2. The ubiquitous distribution excludes a specific association with a particular functionally defined subset of neurons. The prominent localization in the perikaryon suggests a role in the catabolism of the numerous heme proteins synthetized and utilized by peripheral neurons. (supported by the DFG, Ku 688/2-2)

810.16

BIOLOGICAL EFFECTS OF ENDOTHELIN-1 ON ASTROCYTES ARE MEDIATED BY ET_B RECEPTOR THROUGH SEVERAL G PROTEINS. S. Cazaubon[1], P. Lacombe[2]*, A.D. Strosberg[1], P.O. Couraud[1] [1]CNRS UPR 0415, Institut Cochin de Génétique Moléculaire, and [2]CNRS UA 641, Faculté de Médecine Villemin, Paris, France

Astrocytes have been shown to express endothelin-1 (ET-1) receptors functionally coupled, via different heterotrimeric G-proteins, to several intracellular pathways. It is reported here that both receptor subtypes, ET_A-R and ET_B-R, mRNAs were detected in primary cultures of astrocytes. To assess the relative contribution of each subtype in the astrocytic responses to ET-1, effects of BQ-123, an antagonist selective for ET_A-R, and IRL1620, an agonist selective for ET_B-R, were investigated. Binding experiments indicated that ET_B-R is the predominant subtype in these cells. Inhibition of the forskolin-stimulated cAMP production was observed under ET_B-R stimulation. *Bordetella pertussis* toxin pretreatment completely abolished this effect, indicating that this pathway is coupled to ET_B-R via Gi protein. Increase of tyrosine phosphorylation of cellular proteins, stimulation of mitogen-activated protein kinase (MAPK) and DNA synthesis were also found to be mediated by ET_B-R, but through PTX-insensitive G protein. IRL1620-induced MAPK activation involved the adapter proteins Shc and Grb2, and the serine/threonine-kinase Raf-1. This study reveals that the various effects of ET-1 in astrocytes are mediated by ET_B-R which couples to multiple signaling pathways via distinct G proteins.

UPTAKE AND TRANSPORTERS: MISCELLANEOUS

811.1

STUDY OF THE FUNCTIONAL ROLE OF N-LINKED GLYCOSYLATION SITES IN GAT-1 GABA TRANSPORT AND REQUIREMENTS FOR GLYCOSYLATION IN ADDITION TO THE CANONICAL SEQUENCE. J. A. Clark*. Laboratory of Cell Biology, NIMH, Bethesda, MD 20892-4090.

Isolation of Na^+/Cl^--dependent transporter cDNAs has made it possible to study the structure and function of these important proteins, with the goal of attaining a better understanding of how these carriers work. Canonical sites for N-linked glycosylation are found in the large extracellular loop that connects transmembrane domains three and four in nearly all members of this transporter family. Although the role of N-linked oligosaccharides may be trivial for the function of some proteins, the role is significant and varied in the function of many proteins. Studies have been undertaken to understand the role that glycosylation plays in GAT-1 GABA transporter function. Mutation of Asn residues 455, 460, and 463 to Gln residues results in no detectable GABA transport in intact transiently transfected CV-1 cells. The nature of this loss of transport activity will be described.

In vitro translation of a GAT-1 construct resulting in truncation of the protein at Gln residue 209 results in expression of a nonglycosylated protein. However, truncation of GAT-1 at Trp residue 285 results in a glycosylated product. These data suggest that something in addition to the canonical site is necessary for N-linked glycosylation of GAT-1.

811.2

COCAINE INHIBITS GABA TRANSPORT AT NEURONS IN THE DORSOLATERAL SEPTAL NUCLEUS (DLSN). S. Shoji and J.P.Gallagher.* Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX 77555.

To investigate the action of cocaine, we applied cocaine to brain slices, in vitro, and conducted intracellular recordings from neurons in the DLSN. Brain slices were obtained from drug naive rats (NR) or chronically cocaine treated rats (CR, 15 mg/kg, IP, 2X daily for 14 Days). In NR, superfusion of cocaine produced a membrane potential hyperpolarization in only 50% of sampled neurons, while slightly prolonging the duration of evoked IPSPs ($GABA_A$ and $GABA_B$). On the other hand, 100% of DLSN neurons recorded from CR exhibited a hyperpolarization to cocaine (3 μM) with a significant prolongation in the duration of IPSPs. The cocaine induced-membrane potential hyperpolarization, which is due to an activation of both potassium and chloride conductances, was TTX-insensitive and persisted in zero calcium solution. Lowering the extracellular sodium (35 mM) or chloride (7.4 mM) blocked the cocaine induced-hyperpolarization. Higher concentrations of the potent GABA uptake blocker NO-711 (10 μM), which itself induced a membrane potential hyperpolarization and greatly prolonged the duration of IPSPs, blocked the cocaine induced-hyperpolarization.

These results suggest that cocaine inhibits GABA uptake in DLSN neurons. Moreover, in brains from CR, cocaine inhibition of GABA uptake is greatly potentiated compared to NR. This latter potentiating effect of chronic cocaine may be a cellular electrophysiological correlate of behavioral "SENSITIZATION". Supported by DA-07190.

811.3

MULTIPLE GABA PLASMA MEMBRANE TRANSPORTERS ARE EXPRESSED IN THE VERTEBRATE RETINA.
J. Johnson*, T.K. Chen, C. Evans, D. Rickman, and N. Brecha. Depts. of Neurobiol., Med. and Psych., UCLA and VAMC-WLA, LA, CA 90073; Dept. Ophth., St. Louis Univ., St. Louis, MO 63104.

The purpose of this study was to determine the cellular expression pattern of three GABA transporters (GATs) in the rat retina using affinity purified polyclonal antibodies directed to the C-terminus of GAT-1, GAT-2 and GAT-3. Antibody specificity was tested by preadsorption of the primary antibody with 10^{-5}M C-terminal peptides of known GABA and glycine transporters. Numerous GAT-1-immunoreactive (IR) amacrine cell bodies are in the proximal inner nuclear layer (INL). A few IR displaced amacrine and rare ganglion cell bodies are in the ganglion cell layer (GCL). GAT-1-IR processes are densely distributed to all inner plexiform layer (IPL) laminae. Weak GAT-1-IR is also present in Müller cell endfeet and processes in the outer retina. GAT-2-IR is localized to retinal pigment and ciliary epithelia. GAT-3-IR is expressed predominantly by Müller cells. Some GAT-3-IR cell bodies are found in the proximal INL and IR processes are densely distributed to all IPL laminae. These data indicate that whereas GAT-1-IR is prominently expressed by neurons, and weakly expressed by Müller cells, GAT-3-IR is prominent in Müller cells, and GAT-2-IR is confined to non-neuronal cells. GAT-1 and GAT-3 are therefore likely to mediate high affinity uptake of GABA in the retina and influence synaptic activity. In contrast, GAT-2 may participate in fluid balance in the retinal pigment and ciliary epithelia.

811.4

CHARACTERIZATION OF NEUROTRANSMITTER TRANSPORTER-HOMOLOGOUS cDNA CLONES IN *DROSOPHILA*.
W. S. Neckameyer,* K. Driscoll and A. Pruett. Dept. of Pharmacological & Physiological Science, St. Louis University School of Medicine, St. Louis MO 63104.

Several independent cDNA clones were previously isolated from a *Drosophila melanogaster* adult head cDNA library using a hybridization probe derived from a highly conserved region of the norepinephrine and γ-aminobutyric acid transporters (Neckameyer, Neurosci. Abstr. 19: 1122, 1993).

Sequence analysis of one *Drosophila* cDNA clone displays remarkable conservation with the cloned rat GABA transporter. Two other cDNA clones fall into the same major class by Southern hybridization analysis of *Drosophila* genomic DNA; however, these clones have different restriction enzyme patterns and mRNA transcription patterns, suggesting they are related but independent transporters. The second class of cDNAs shares homology by Southern analysis but not at the DNA sequence level. Further characterization of these cDNAs will be presented.

811.5

Mammalian Brain-Specific L-Proline Transporter: Preferential Localization of Transporter Protein to Glutamatergic Nerve Terminals in Rat Forebrain.
R.T. Fremeau, Jr.*, J. Chan, A. Pohorille, J.V. Nadler, T.A. Milner, and V.M. Pickel. Depts of Pharmacol. & Neurobiol., Duke Univ. Med. Ctr., Durham, NC 27710; and Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021

A high affinity mammalian brain-specific L-proline transporter (PROT) has been cloned. PROT is a member of the Na^+-(and Cl^-)-dependent plasma membrane transporter family that includes transporters for several neurotransmitters, osmolytes, and nutrients. Previous *in situ* hybridization studies localized rPROT mRNA to subpopulations of glutamatergic neurons in rat brain. However, no direct morphological evidence exists about the regional and subcellular distribution of the PROT protein. Thus we used an affinity-purified antipeptide antibody directed against the carboxy-terminus of this transporter for the light and electron microscopic immunolocalization of the PROT protein in rat forebrain. Immunoperoxidase labeling revealed abundant, punctate PROT immunoreactivity in forebrain regions that receive dense glutamatergic innervation including the olfactory bulb, piriform cortex, hippocampal formation (HF), amygdala, caudate-putamen (CPu), thalamus, and hypothalamus. Within HF, prominent immunolabeling was observed in the inner and outer thirds of the dentate molecular layer and in strata oriens and radiatum of the CA3 and CA1 regions. Electron microscopic immunogold detection of PROT in CPu revealed prominent labeling of axon terminals forming asymmetric, excitatory-type synapses with dendritic spines. Unexpectedly, the majority of gold particles were observed overlying vesicular organelles within the axonal cytoplasm. In most cases, at least one or two gold particles were in contact with the plasma membrane adjacent to the synapse. These findings raise the possibility of a novel presynaptic regulatory role for PROT in excitatory transmission. High affinity L-proline uptake may regulate the synthesis and/or release of glutamate in specific excitatory nerve terminals. Alternatively, high affinity uptake may limit postsynaptic actions of L-proline by reducing its extracellular concentration in synaptic and/or surrounding spaces. Supported by NIH grants NS32501, NS16064, MH42834, MH40342, DA04600, and NSF 9310965.

811.6

MOLECULAR CHARACTERIZATION OF A TAURINE TRANSPORTER CLONED FROM MOUSE RETINA.
V. Sarthy*[1], H. Sarkar[2], X. Qian[2] and H. Egal[1], Dept. of Ophthalmology, Northwestern University, Chicago, IL 60611; and Dept. Of Physiology, Baylor College of Medicine, Houston, TX 77030.

The high intracellular taurine levels in ocular tissues are maintained by high affinity, Na^+-dependent taurine transport systems. In the course of screening a mouse retina cDNA library for neurotransmitter transporters, we isolated a cDNA clone whose predicted protein sequence showed strong homology to known taurine transporters from rat brain (98.4%) and human placenta (94.7%). RNA transcribed *in vitro* from the cDNA clone induced Na^+ and Cl^--dependent, ^3H-taurine uptake in microinjected *Xenopus* oocytes. Whereas taurine uptake rate varied hyperbolically with external taurine or Cl^- concentration, the uptake rate showed a sigmoidal dependence on external Na^+ concentration. Hill plots suggested that the taurine transporter required 2 Na^+ and 1 Cl^- per taurine molecule. Taurine uptake was inhibited 50% or more by 100 μM β-alanine, hypotaurine, guanidinoethanesulfonic acid and guanidinopropionic acid. Homotaurine and glycine, however, did not block uptake. Furthermore, taurine uptake was inhibited by the phorbol ester, PMA but not by its inactive analog, 4-α-PDD suggesting a role for phosphorylation in taurine transport. Finally, *in situ* hybridization studies showed that the taurine transporter was highly expressed in the ciliary body and to a lesser extent in the mouse retina.

LEUCINE INFUSED INTO THE BRAIN BY MICRODIALYSIS COMPETES FOR THE IN VIVO LARGE NEUTRAL AMINO ACID TRANSPORTER.
H. R. Zielke*, Y. Huang, C.L. Zielke, Peter Baab and J.T. Tildon. Dept. of Pediatrics, University of Maryland, Baltimore, MD 21201.

The effect of leucine on the interstitial concentration of the large neutral amino acids in rat brain was examined using a microdialysis delivery system and HPLC analysis of the eluant. Microdialysis probes were inserted stereotaxically into the hippocampus of rats. Leucine [0.5, 2, 5 and 10 mM in artificial CSF] was infused into the awake, free-moving rat and the eluate from the probe was analyzed for 20 amino acids. The infusion of leucine rapidly increased the concentration of phenylalanine, tyrosine, methionine and tryptophan to higher steady state levels. A 2-4 fold increase in concentration in these amino acids was observed at 10mM leucine with minor changes in other amino acids, except glutamine which doubled in concentration. The response to leucine was concentration dependent. Inclusion of 2 mM phenylalanine or tyrosine in the artificial CSF (instead of leucine) increased leucine and tyrosine (or phenylalanine with 2 mM tyrosine), methionine and tryptophan. The data suggest that leucine, known to accumulate in Maple Syrup Urine Disease, interferes with the uptake of the amino acid precursors for serotonin and catecholamine biosynthesis. The reduced uptake may explain some of the neurological and developmental defects observed in this disease. Finally, the increase in interstitial glutamine observed in the presence of leucine is consistent with the published data of Yudkoff et al. (J. Neurochem. 62:1192-1202, 1994) who showed that leucine is an amino donor for glutamine formation. (NIH grant 16596)

IMMUNOCYTOCHEMICAL ANALYSIS OF AMINO ACID TRANSPORT INTO NEURONS AND GLIAL CELLS IN THE RABBIT RETINA USING SPECIFIC ANTIBODIES AGAINST AMINO ACID ANALOGUES AND STEREOISOMERS.
D. V. Pow, D.K. Crook, I.R. Keast* and D.I. Vaney. Vision, Touch and Hearing Research Centre, Department of Physiology and Pharmacology, University of Queensland, Brisbane, Queensland 4072.

Neurons appear to be dependent upon extracellular supplies of substrates for the formation of amino acid transmitters such as glutamate and GABA, and for the formation of amino acid-derived compounds such as nitric oxide. To determine which cells in the retina exhibit high-affinity uptake of amino acid transmitters and their precursors, we have developed highly specific antibodies to molecules such as D-aspartate, D-glutamine and L-NAME; these molecules do not occur naturally in mammals, but are transported by glutamate, glutamine and arginine transporters, respectively. Thus transport of these molecules into cells can be distinguished immunocytochemically from pools of endogenous molecules. Retinae were isolated from rabbits that had been killed by an intravenous overdose of sodium pentobarbital (80 mg/kg). Retinae were incubated with test compounds (40 μM) dissolved in a physiological saline solution (Ames medium), then fixed and processed for immunocytochemistry, using 0.5 μm semithin sections. This paradigm results in high resolution labelling of specific classes of cells. Examination of serial semithin sections permitted the identification of endogenous molecules. For instance, D-arginine is strongly accumulated in a subset of retinal neurons, including some GABAergic amacrine cells; D-arginine also accumulates in a population of amacrine cells that contain neither GABA nor glycine. By contrast, D-glutamate is taken up mainly by glial cells, where it is converted into D-glutamine. This D-glutamine is then exported to subsets of neurons including the glutamatergic retinal ganglion cells. We believe that this immunocytochemical approach to demonstrating amino acid transport is a powerful tool both for analysing the cell specificity of uptake and for examining any activity-dependence of these transport systems.

DISTRIBUTION OF mRNA CODING FOR THE MAMMALIAN BRAIN-SPECIFIC L-PROLINE TRANSPORTER. T.S. McGraw*, R.T. Fremeau, Jr. and K.J. Anderson, Depts. Physiol. Sci. & Neuroscience, Univ. Florida, Gainesville, FL 32610; Dept. Pharmacol. & Neurobiol., Duke Univ. Med. Ctr., Durham, NC 27710.

The presence of a high affinity Na^+-dependent synaptosomal uptake system for L-proline (PROT) has generated interest in the possible role of this transporter in synaptic function. Initial reports on the cloning and distribution of PROT demonstrated that it was expressed in subpopulations of glutamatergic pathways in the CNS, further suggesting that this transporter may modulate excitatory synaptic transmission. We have utilized in situ hybridization to further characterize the anatomical distribution of PROT mRNA in the CNS. Oligonucleotide cDNA probes (45mer) were constructed that were complimentary to the published sequence of PROT. Probes were screened against GenBank to ensure specificity and labelled with [^{35}S]ATP for film and emulsion-based in situ hybridization. Rat brains were sectioned in the horizontal, coronal and saggital planes and hybridized with labelled probes. Control probes consisted of sense strands from the same sequence. PROT mRNA was found in high abundance in the olfactory bulb mitral cell layer, external plexiform layer neurons, olfactory tubericle and anterior olfactory nucleus. Within the thalmus, specific nuclei were labelled including the anterior dorsal, lateral posterior and lateral doral nuclei. In the hippocampal formation, intense labelling was seen in pyramidal neurons of CA1-4, while granule cells of the dentate gyrus were lightly labelled. Labelling was observed in cerebral cortical layers III and V of the somatosensory cortex. Intense labelling was seen in neurons of layers II-III of the entorhinal cortex. Diffuse labelling was seen in the brainstem and cerebellum. These findings are consistent with previous observations that PROT is found in some, but not all, glutamatergic pathways in the CNS. The localization of PROT to specific populations of excitatory neurons may provide another means to regulate excitatory neurotransmission. Supported by AG-08843, NS32501, and NSF 9310965.

CHARACTERIZATION OF ASPARTATE RELEASE VIA REVERSAL OF CLONED HUMAN EXCITATORY AMINO ACID TRANSPORTER SUBTYPES [1,2]V.R. Roettger*, [2]J.L. Arriza, and [1,2]S.G. Amara, [1]Howard Hughes Medical Institute and [2]Vollum Institute , Oregon Health Sciences University, Portland, OR

Excess glutamate release may contribute to ischemic brain damage; the mechanism for this release is probably reversal of one or more Na^+-dependent glutamate transporters (Roettger and Lipton, Soc. for Neurosci. Abst., 20, 1994). We used stably transfected HEK293 cells independently expressing three excitatory amino acid transporter subtypes (EAAT1-3) isolated from human motor cortex (Arriza et al., J of Neurosci., 14:5559, 1994) to deteermine which subtype(s) may be involved. In addition, different release paradigms were examined to determine which conditions can trigger excess release during ischemia.

Methods: Cells expressing EAAT1, EAAT2 , EAAT3, or vector alone (vector control) were loaded with ^{3}H-D-Aspartate (D-ASP) for 30'; EAAT transfected cells accumulated D-ASP at levels greater than 5-fold over that accumulated by vector control cells. Release was stimulated by exposure to either: (1) combined sodium azide (Az - 20mM) and iodoacetate (IAA - 0.5mM) which lowers cellular ATP; (2) gramicidin D (GD - 50ug/ml) which increases internal Na^+; or (3) nigericin (NIG - 20uM) which exchanges external H^+ for internal K^+; all these conditions occur during ischemia. Results: Az/IAA or GD exposure stimulated D-ASP release from transporter-transfected cells to approximately the same level for all subtypes (2-fold greater than release from vector control cells). However, NIG exposure stimulated D-ASP release from EAAT1 and EAAT2 transfected cells to a larger degree over vector control cells (>3-fold) than release from EAAT3 transfected cells (<2-fold greater than vector control cells). This suggests that EAAT subtypes may be differentially regulated by H^+ ions.

These results indicate that the stimulus required to release glutamate via reversal of uptake may differ between cloned transporter subtypes and suggest that all transporter subtypes may not be involved in ischemia-induced glutamate release to the same extent.

LOCALIZATION OF A NEUTRAL AND BASIC AMINO ACID TRANSPORTER IN RELATION TO NITRIC OXIDE SYNTHASE IN RAT FOREBRAIN. V.M. Pickel*, A. Pohorille, J. Chan, S.S. Tate, and M.J. Nirenberg, Depts. of Neurology and Neuroscience and Biochemistry, Cornell University Medical College, New York, NY 10021.

The neutral and basic amino acid transporter (NBAT) is one of two known members of a novel class of proteins involved in sodium-independent transmembrane transport of amino acids. NBAT is highly expressed in renal and intestinal brush border membranes, and has also been localized to enteric neurons and to selective neurons in brainstem and spinal cord in a distribution similar to that of nitric oxide (NO). In addition, L-arginine, the precursor for NO-synthesis is a potent NBAT substrate. Thus, to further establish the potential role of NBAT in regulation of substrate availability to NO-containing neurons, we examined the localization of a previously characterized antiserum against NBAT in relation to neurons immunolabeled for NO synthase (NOS) in rat forebrain. NBAT immunoreactive perikarya seen by light microscopy had many morphological similarities to the NOS-labeled cells including the presence of one or more processes in contact with blood vessels. Perikarya and processes containing NBAT were prominently distributed in the striatum, amygdala, and deep cortical laminae. In the striatum, electron microscopic dual labeling showed immunogold-labeling for NBAT frequently associated with plasma membranes of unlabeled dendrites. Although few of these dendrites or perikarya were dually labeled for NOS, many were directly apposed to NOS-immunoreactive processes. We conclude that NBAT may be involved in neuronal uptake of amino acids, which in turn regulates the availability of arginine and other substrates to NO neurons. (Supported by grants MH00078; MH40342; and HL 18974).

INSULIN REGULATES 14C-CREATINE UPTAKE IN GLIAL AND MUSCLE CELL LINES. Tea N. Kekelidze and Mario D. Saltarelli.* Department of Neurology, Emory University School of Medicine, Atlanta, GA 30322.

Creatine and its phosphorylated derivative creatine phosphate (CP) play an important role in the maintenance of intracellular ATP levels. Creatine is phosphorylated by creatine kinase to form CP, which is believed to be used for the regeneration of ATP pools. An adequate supply of creatine is required for the maintenance of CP levels. Creatine is selectively accumulated from the extracellular space by a sodium-coupled high-affinity creatine transporter (CREAT) located in the cellular plasma membranes from brain, muscle, and other peripheral tissues. CREAT has been shown by recent cloning studies to be structurally related to the norepinephrine/GABA transporter family. Insulin has been shown to influence the metabolism of creatine and phosphocreatine, and rapidly alters creatine accumulation in muscle.

We have recently shown that CREAT velocity increases 5-10 fold when either C6 glioma or L6 myoblast cell lines are incubated in creatine-free medium, when compared with cells grown in the presence of 5 mM creatine (McClatchey et al. (1995), ISN Abstracts, J. Neurochem.). Northern analysis of RNA isolated from creatine-starved and creatine-fed cells showed no change in the relative amounts of CREAT RNAs, supporting the existence of post-translational regulatory mechanisms involved in the maintenance of intracellular creatine levels.

To further clarify the mechanisms involved in CREAT regulation, we assessed creatine uptake in C6 and L6 cells exposed to insulin (0.1 μM). After preincubation in serum-free medium, acute (5, 10, 30 min) insulin treatment resulted in a 40 ± 6% (X ± S.E.M.; N=5; $p < 0.002$) reduction of sodium-dependent 14C-creatine uptake, when compared with vehicle-treated control cells. These studies will allow further clarification of the role of receptor tyrosine kinases in the post-translational regulation of creatine transport activity. Supported by NINDS CIDA NS01651.

CHARGE MOVEMENT ASSOCIATED WITH GLYCINE UPTAKE. Stéphane Supplisson*, Claude Bergman. Laboratoire de Neurobiologie, Ecole Normale Supérieure, 46 rue d'Ulm, 75005 Paris, France.

Relationships between the non linear capacitive current and the steady-state current associated with glycine uptake were analyzed for two glycine transporters showing 96% identity in their primary sequences (rGLYT1b and hGLYT1b) and expressed in *Xenopus* oocytes. As for several previously cloned Na^+/coupled transporters, relaxation currents were recorded in response to voltage steps; in the presence of substrate they disappeared while steady-state currents developed. The relaxation currents are assumed to reflect electrical charge movement within the carrier associated with partial reactions in the transport cycle. For a given voltage step, the time integral of the single exponential current relaxation (*i.e.* the amount of charge (Q) displaced) is the same at the onset of the pulse and on membrane repolarization; it decreases with increasing glycine concentration ("charge masking"). The Q/V relationship can be fitted by a Boltzman equation with $z\delta$=0.5 and $V_{0.5}$=-20mV. Current relaxations show Na^+ and Cl^- dependence. Replacing Na^+ by Choline$^+$, TEA$^+$, or N-Methyl-Glucamine$^+$ decreases the amount of mobile charges by 80%. In the presence of Li^+ (which does not promote glycine uptake) Q is reduced by only 40%. Relaxation time constants show little voltage dependence; they are, however, significantly shorter for rGLYT1b than for hGLYT1b. At 20μM glycine, the ratio between the steady-state current and the amount of masked charges is independent of the voltage and found higher for rGLYT1b than for hGLYT1b. For the same amount of displaced charges, the rat transporter produces a 2 times larger steady-state current than the human transporter.

GENE EXPRESSION OF THE RAT VESICULAR ACETYLCHOLINE TRANSPORTER R. Cervini, S. Berrard*, L. Houhou, P.-F. Pradat and J. Mallet, Lab. Génétique Moléculaire de la Neurotransmission et des Processus Neurodégénératifs, UMR C9923 C.N.R.S., F-91198 Gif-sur-Yvette, France.

The gene encoding the vesicular acetylcholine transporter (VAChT) has recently been localized within the first intron of the gene encoding choline acetyltransferase (ChAT) in both nematode and mammals, including man. The conserved structure of the ChAT/VAChT locus is unique, since both genes lie in the same transcriptional orientation and both their products are required to express the cholinergic phenotype.

We have previously shown that rat VAChT is encoded by several mRNAs. Two of them share a common 5' exon (R) with one ChAT mRNA and are therefore generated by alternative splicing of a ChAT/VAChT primary transcript. We now demonstrate that the first intron of the rat ChAT gene contains two promoters, each used to generate one VAChT mRNA. We have also identified a fifth VAChT mRNA species containing the sequence between exon R and the VAChT translation initiation codon. The existence of these five forms of VAChT mRNA with different 5'-noncoding ends can now be correlated to the size diversity of the VAChT mRNAs that we previously observed by Northern analysis.

PROTON INTERACTIONS WITH THE ACETYLCHOLINE TRANSPORTER OF SYNAPTIC VESICLES. M. L. Nguyen, H. J. Carlisle* and S. M. Parsons, Department of Chemistry, University of California, Santa Barbara, CA 93106.

The acetylcholine transporter (AChT) of synaptic vesicles exchanges internal protons for cytoplasmic ACh. The effects of protons on both faces of the AChT were studied using purified *Torpedo* synaptic vesicles and a hyposmotic lysis-resealing technique. The rate of proton leak from acidified vesicles is slowed about two-fold by vesamicol, which is an allosteric inhibitor of the AChT, but it is not affected significantly by saturating ACh. This suggests that the AChT mediates a large fraction of the permeability of vesicular membrane to protons and that it "slips". When the internal pH is set at 5.1 and the external pH is varied, uptake of subsaturating ACh decreases toward 0 at lower external pH with an apparent pK_a of 7.6±0.2. The major kinetics effect of low external pH is an increased Michaelis constant for ACh, consistent with competition of ACh with a proton for binding to the outwardly oriented AChT. When the external pH is set at 7.8 and the internal pH is varied, uptake of subsaturating ACh decreases toward 0 at higher internal pH with an apparent dependence on the second power of the proton concentration and a pK_a of about 5.6. The major kinetics effect of higher internal pH is decreased V_{max} for ACh with a smaller effect on the Michaelis constant. There is no D_2O solvent kinetic isotope effect on the rate of ACh uptake, but there is substantial slowing of the rate of the proton leak through the AChT. A model for binding of a proton or ACh alternately to the transport site and a second proton to an internal allosteric activating site that mediates a leak through the AChT by site-to-site hopping will be presented.

811.16

VESAMICOL BINDING STUDIES OF THE CLONED RAT VESICULAR TRANSPORTER FOR ACETYLCHOLINE. A. Roghani*[1], S.M. Parsons[2], and R.H. Edwards[1]. [1]Dept. of Neurology, UCLA, Los Angeles, CA 90024 & [2]Dept. of Chemistry, UCSB, Santa Barbara, CA. A large body of evidence has implicated acetylcholine (ACh) in the pathogenesis of neurodegenerative disorders such as Alzheimer's disease(AD). ACh and other transmitters are stored into synaptic vesicles from which their release is regulated in response to neural activity. This storage requires active transport from the cytoplasm. Genetic studies in the nematode *C. elegans* recently identified a putative vesicular ACh transporter (*Unc-17*). This protein shows sequence homology to previously cloned vesicular amine transporters and its distribution suggests a role in cholinergic transmission. Using RT-PCR, we have recently isolated homologous transporters, first from *Torpedo californica*, and then from rat spinal cord (rVAChT) (PNAS *91*, 10620). The full length rVAChT was expressed transiently in COS cells. After 4 days of growth in culture, the cells were homogenized and high speed membrane samples prepared and used for [^{3}H]vesamicol binding assays. Incubation of membranes with various amount of vesamicol (0 to 75 nM) under equilibrium conditions resulted in high affinity and specific binding of vesamicol (Kd=5.5 nM and Bmax=12 pmol/mg protein) to membranes from the VAChT-transfected cells, but not to those transfected with vesicular amine transporter. In a separate experiment, keeping the vesamicol concentration at 1 nM, the vesamicol binding increased rapidly with time to reach maximal levels in 15 min. Repeating this experiment in the presence of ATP or CCCP did not alter the binding profile, suggesting that the vesamicol binding to VAChT did not depend on a H^+-electrochemical gradient. Furthermore, the amount of vesamicol bound to the membrane from transfected cells was significantly less when the binding was performed in the presence of ACh, but not in presence of choline or GABA. Moreover, incubation of the membrane with varying amounts of vesamicol and ACh at equilibrium showed that, as the vesamicol concentration was raised to higher and higher values, it overcame the binding inhibition by ACh in a competitive manner. The latter results are consistant with vesamicol binding to the site of substrate recognition on the VAChT protein.

811.17

PRODUCTION AND CHARACTERIZATION OF ANTI-FUSION PROTEIN ANTIBODIES TO THE RAT VESICULAR ACETYLCHOLINE TRANSPORTER. M.L. Gilmor*, C.J. Heilman, A. Roghani, N.R. Nash, H.D. Rees, H. Yi, S.M. Hersch, R.H. Edwards, A.I. Levey. Department of Neurology, Emory Univ. School of Medicine, Atlanta, GA 30322 and Department of Neurology, UCLA School of Medicine, LA., CA 90024

A cDNA for the putative rat vesicular acetylcholine transporter (VAT) has recently been cloned, but little is known about the encoded protein. We produced rabbit polyclonal antibodies to VAT in order to characterize VAT protein. A glutathione S-transferase/VAT C-terminus fusion protein was used as immunogen and for affinity-purification of antibodies. Western blot analysis revealed specific reactivity with bands in HeLa cells transfected with VAT cDNA and which were absent in mock transfected cells. In Western blots of rat brain homogenates, VAT-immunoreactive bands were predominant in striatum, neocortex and hippocampus, with low levels in cerebellum. Immunoreactivity was eliminated with preabsorbtion on the fusion protein. Immunohistochemistry demonstrated VAT immunoreactivity in neuronal perikarya in known cholinergic cell groups, while non-cholinergic neurons were not immunoreactive. Dense VAT terminal fields and fibers were present in cholinergic projection sites, including cortex, hippocampus, basolateral amygdaloid nucleus, and many other regions of the brain. In electron micrographs, VAT C-terminus reactivity was associated with synaptic vesicles in cholinergic terminals in rat striatum and hippocampus. These studies demonstrate VAT is a selective marker of cholinergic neurons, and specifically, cholinergic synaptic vesicles and axon terminals.

811.18

THE HIGH-AFFINITY CHOLINE TRANSPORTER IS MODULATED IN VIVO BY db-cAMP. V. Vogelsberg*, N.H. Neff and M. Hadjiconstantinou, M. Departments of Psychiatry, Pharmacology and The Neuroscience Program, The Ohio State University College of Medicine, Columbus, OH 43210.

The high-affinity choline transport (HACT) is considered by many researchers to be the rate-limiting step for the synthesis of acetylcholine (ACh). The mechanism(s) involved in regulation of the transporter are not understood. We studied the effect of cAMP-dependent pathways on HACT. db-cAMP was administered i.c.v. to mice and at various time points choline (Ch) uptake, ACh synthesis and choline acetyltransferase (ChAT) activity were measured in synaptosomes from hippocampus, striatum and frontal cortex. At 1 hour db-cAMP increases choline uptake in hippocampus and frontal cortex and slightly in striatum. Choline uptake remains elevated up to 6 hours later and then returns to baseline. The change in uptake is attributed to an apparent increase in V_{max}. ChAT activity was not altered in any of the brain regions studied, but ACh synthesis was increased in all areas after 1 hour treatment with db-cAMP. Cycloheximide did not prevent the increase in HACT activity at 1 hour, indicating a mechanism other than protein synthesis is involved. Administration of okadaic acid had no effect on basal or db-cAMP activated Ch uptake, while a protein kinase A inhibitor prevented the cAMP induced increase.

811.19

INFLUENCE OF ESTROGEN ON HIGH AFFINITY CHOLINE UPTAKE IN RAT BRAIN SECTIONS. M.L. Caspers*, B.E. Deverman and M.J. Fu. Dept. of Chemistry, Univ. of Detroit Mercy, Detroit, MI 48219.

Estrogen may exert a protective effect on several enzymes of acetylcholine metabolism. The uptake of choline is the rate-limiting step in acetylcholine biosynthesis. Ovariectomized female, Fischer-344 rats (2 mo) had either 17β-estradiol (0.5 or 5 mg) or placebo pellets implanted in the nape of their necks. Placebo and 17β-estradiol-treated animals were sacrificed after 2 or 3 weeks, 24μm frozen sections of the brains were prepared and treated with hemicholinium-3 (HC-3), a competitive inhibitor of the high-affinity choline transporter. Autoradiographic studies showed high levels of specific HC-3 binding in the caudate putamen (CP) and the nucleus accumbens. Computer-assisted densitometry indicated specific HC-3 binding was 65.5% of total HC-3 binding. An 11% ($P<0.04$) decrease in HC-3 binding in the CP occurred in rats treated with 0.5 mg 17β-estradiol pellets for 3 weeks when compared to the placebo-treated group. In rats receiving 5 mg 17β-estradiol pellets, a 16% ($P<0.04$) decrease in HC-3 binding in the CP was noted after 2 weeks and a 20% ($P<0.002$) decrease was seen after 3 weeks. (Supported by a grant from the Amer. Fed. Aging Res. and a gift from J. Rose.)

ELECTROGENIC Na^+-K^+ PUMP IN THE DISSOCIATED MAMMALIAN CNS NEURONS. Mitsutoshi Munakata*, Mika Fujimoto and Norio Akaike. Department of Physiology, Kyushu University Faculty of Medicine, Fukuoka 812-82, Japan.

Active Na^+-K^+ transport maintains intracellular ionic conditions and involves in the cell excitability with the distinct electrogenicity. We investigated the basic properties of the electrogenic Na^+-K^+ pump in neurons freshly dissociated from the rat neostriatum by the use of the nystatin-perforated patch technique. In current-clamp mode, ouabain (10 μM) depolarized neurons, suggesting that Na^+-K^+ pump functions well under the present experimental conditions. In the voltage-clump mode (V_H= -40 mM) with the pipette solution containing 40 mM Na^+, raising $[K^+]_o$ evoked an ouabain sensitive outward current in a concentration-dependent manner (EC_{50}=0.74 mM) under the suppression of K^+ and voltage dependent Ca^{2+} channels, Na^+-Ca^{2+} exchanger. Tl^+, Rb^+, NH_4^+ and Cs^+ also could evoke the outward current in the order of EC_{50}: $Tl^+ > K^+ > Rb^+ > NH_4^+ > Cs^+$. The pump activity had slight voltage dependency and decreased in hyperpolarized membrane potential. The pump activity was temperature dependent (Q_{10}=3.1). The sensitivity to ouabain was also temperature dependent, and the IC_{50} of ouabain was 7.07 μM at 20 °C and 1.3 μM at 30 °C. Interestingly, the pump activity was still observed even with the Na^+-free pipette solution. However, such activity reversibly diminished when Na^+ was completely removed from the external solution, suggesting that Na^+ ions are continuously leaking into the cell, resulting in activating the pump. A mitochndiral uncoupler, FCCP (1 μM), also eliminated the pump current. These results indicate that neuronal Na^+-K^+ pump functions in concert with ion dynamics across the cytoplasmic membrane.

811.21

SODIUM-GLUCOSE COTRANSPORTER IS PRESENT AT THE ABLUMINAL MEMBRANE OF THE BOVINE BLOOD-BRAIN BARRIER. W-J Lee, D.R. Peterson, V. Burmeister, C.E. M°Cormack*, E.J. Sukowski, and R.A. Hawkins. Physiology Department, Finch Univ. of Health Sciences/The Chicago Med. Sch., North Chicago, IL 60064.

The use of brain endothelial membrane vesicles is a unique approach in the study of glucose transport across the blood-brain barrier (BBB). Membrane vesicles were isolated from bovine brain microvessels and characterized as previously described by Sanchez del Pino *et al* (J. Biol. Chem. 267: 25951-25957, 1992). Luminal membrane vesicles showed enrichment of the enzyme gamma-glutamyl transpeptidase, while abluminal membrane vesicles exhibited System-A amino acid transport activity. The uptake of radiolabeled D-glucose was determined by rapid filtration. In the absence of an inwardly-directed sodium gradient, luminal and abluminal membrane vesicles showed similar initial rates of glucose uptake. However, in the presence of a sodium gradient, abluminal membrane vesicles exhibited the ability to transiently concentrate glucose above the equilibrium value (overshoot). The intravesicular glucose concentration fell back towards the equilibrium value upon dissipation of the sodium gradient. This phenomenon was not seen in luminal membranes in the presence of sodium. The addition of phlorizin, a specific inhibitor of the sodium-glucose cotransporter, abolished the overshoot in abluminal membrane vesicles. Kinetic analysis of glucose transport in abluminal membrane vesicles, showed the presence of 2 distinct carriers; a high-affinity, low capacity sodium-glucose cotransporter, and a passive low-affinity high capacity facilitative transporter. Luminal membranes possess only a passive facilitated carrier. These results indicate that glucose transport across the BBB is more complex than initially thought, and that the abluminal sodium-glucose transporter may be important in regulating glucose flux into and out of the extra-cellular fluid of the brain. (Supported by NIH grants NS31017 and DK42331).

Characterization of Na^+-Dependent P_i Uptake in Cultured Fetal Rat Cortical Neurons. M. Glinn*, B. Ni and S. M. Paul. Lilly Res. Labs., Lilly Corp. Ctr., Indpls., IN 46285.

We have recently demonstrated the existence of a brain-specific Na^+-dependent inorganic phosphate (P_i) cotransporter which is constitutively expressed in neurons of the rat cerebral cortex, hippocampus and cerebellum[1]. Characterization of Na^+-dependent P_i uptake in cultured fetal rat cortical neurons revealed that such transport is low up to DIV 11, but is fully developed after DIV 12 (when > 90% of saturable P_i uptake is Na^+-dependent). Na^+-dependent P_i uptake rates were initially increased and attained steady state more rapidly at 37 °C as compared with 22 °C or 4 °C, and were inhibited at low as compared with neutral or alkaline pH. Kinetic analyses revealed a K_m for P_i of 54 ± 12.6 μM and for Na^+ of 35 ± 4.2 μM. The V_{max} was 1.54 ± 0.48 nmoles/min/mg protein. The pH sensitivity and kinetic parameters observed for neuronal P_i transport were similar to those reported for P_i transport in renal-derived cells and membrane vesicles[2-6]. A reduction in extracellular Ca^{2+} markedly decreased (> 60%) Na^+-dependent P_i uptake, with a threshold for maximal P_i import of 1-2.5 mM $CaCl_2$. Cultures incubated in medium where equimolar concentrations of choline were substituted for Na^+ had lower levels of ATP and ADP and higher levels of AMP than did those incubated with Na^+. The largest fraction of $^{32}P_i$ imported with Na^+ was concentrated in the adenine nucleotides. Omission of glucose from the incubation medium for up to 18 hours did not affect Na^+-dependent $^{32}P_i$ uptake. However, depletion of ATP by incubation in choline-containing medium, or with metabolic inhibitors, dramatically decreased $^{32}P_i$ import rates. These data support the hypothesis that a major function of the Na^+-dependent P_i transporter is the import of P_i required for the production of high-energy compounds vital to neuronal metabolism.

811.23

REGIONAL DISTRIBUTION OF THE Na^+/Cl^--DEPENDENT "ORPHAN" TRANSPORTERS, RXT1 AND V-7-3-2, IN THE RAT CENTRAL NERVOUS SYSTEM. J. Masson, Z. Aïdouni, M. Pohl, B. Giros, M. Hamon and S. El Mestikawy*. INSERM U288, faculté de Médecine Pitié-Salpêtrière, 75013 PARIS, France

Rxt1 and V-7-3-2 are two members of the membrane-bound protein family which includes monoamines (dopamine, noradrenaline and serotonine)- and aminoacids (GABA, glycine, proline and taurine)-transporters. However, the substrates of Rxt1 and V-7-3-2 have not yet been identified. Northern blot studies already demonstrated that these two "orphan" transporters are exclusively synthesized in the CNS. Further studies on regional distributions of mRNA encoding Rxt1 and V-7-3-2 were presently performed by means of in situ hybridization with specific [^{35}S]cRNA antisense probes. In general, both distributions superimposed each other with high to moderate densities of Rxt1 and V-7-3-2 mRNAs in the hippocampus, cerebellum, pontine nucleus, olfactory tubercle and bulb, and spinal cord. However, differences were also noted since Rxt1 mRNA was abundant in the thalamus whereas V-7-3-2 mRNA was hardly detected in this region. Furthermore, within the substantia nigra, mRNA encoding V-7-3-2 was found exclusively in the pars reticulata whereas that encoding Rxt1 was visualized only in the pars compacta. At the hippocampal level, the pyramidal (CA1-3) and granular cell layers were found to express both mRNAs, but only Rxt1 mRNA was observed in the hilus of the dentate gyrus. Complementary immunohistochemical studies with specific polyclonal antibodies showed that the Rxt1 protein was concentrated in brain regions receiving glutamatergic and/or GABAergic inputs. At the ultrastructural level, Rxt1 was found to be associated exclusively with nerve endings. Current studies on the cellular and subcellular distributions of the V-7-3-2 protein with specific antibodies should help in further assessing the differences versus similarities between these two "orphan" members of the same transporter family.

SECOND MESSENGERS: KINASES

812.1

A NOVEL KINASE (DLK) IS EXPRESSED IN NEURONS. M. Mata*[1], G. Jiang[1], D.J. Fink[1], and L.B. Holzman[2]. [1]Department of Neurology, University of Pittsburgh, Pittsburgh, PA 15261, and [2]Department of Medicine, University of Michigan, Ann Arbor, MI 48109.

DLK (dual leucine zipper bearing kinase) is a serine-threonine protein kinase in the family of mixed lineage kinase that was identified and found in brain, kidney, and ovary (Holzman et al. 1994).

Non-radioactive in situ hybridization with a riboprobe generated from a PstI (1790-3460) cDNA fragment demonstrated a high level of expression of DLK in most neurons of the cerebral cortex, dentate gyrus and CA regions of hippocampus, basal ganglia and brain stem nuclei, cerebellar Purkinje cells, spinal cord and dorsal root ganglion neurons.

Western blot analysis of protein from cerebral cortex, hippocampus, brain stem and spinal cord, using an antibody to the carboxy terminal region of the fusion protein revealed a 130 kd protein corresponding to the translation of the DLK mRNA. Sub-cellular fractionation of tissue from rat cerebral cortex revealed that DLK appeared to be associated with the 100,000g membrane fraction, despite lacking a transmembrane domain, and is found enriched in synaptosomes isolated from rat forebrain.

In brain aggregating cultures, DLK appeared as a doublet by reducing SDS-PAGE electrophoresis. Inhibition of serine-threonine protein phosphatases by okadaic acid (5nM and 200nM) reduced its electrophoretic mobility suggesting that DLK phosphorylation is probably under the regulatory control of PP1.

This results suggest that DLK is synthetized in neurons, is membrane associated, and found in synaptosomes. DLK may play a role in signal transduction a the synapse.

812.2

Role of C1 and C2 domains in the *cis*-fatty acid activation of protein kinase C. Feleke Eshete, Hyun Chung and Kentaro Murakami*. Department of Biochemical Pharmacology, SUNY-Buffalo, NY 14260

Protein kinase C (PKC) has been shown to participate in the regulation of synaptic plasticity in the brain. *cis*-Unsaturated fatty acids (cFA) such as arachidonic acid activate PKC independently or synergistically with diacylglycerol (DAG) *in vitro*. Recent studies using slice preparations showed that the synergistic activation of PKC by cFA and DAG is also operative in the hippocampus (Chen and Murakami, Neuroscience, in press). A tandem repeat of cysteine rich zinc finger-like sequence present in the C1 regulatory domain in PKC has been considered to be the DAG interaction site, as atypical PKC such as PKC ζ which lacks one of these cysteine rich domains is insensitive to phorbol esters and DAG. The nature of interaction of cFA with PKC and the basis for the synergistic interaction with DAG in the activation of PKC is not yet known. To address these questions, we have generated PKC mutants in which C1 or C2 regulatory domain is deleted and expressed in COS-7 cells. Comparison of the biochemical characteristics of these mutated enzymes with wild type PKC shows that the alteration of the regulatory domain significantly affects the sensitivity of PKC to cFA. Further studies are underway to determine the role of C1 and C2 domains in synergy of cFA with DAG, translocation to the membrane and substrate specificity. (Supported by NIH MH48973)

PURIFICATION AND CHARACTERIZATION OF PKMζ, THE CATALYTIC FRAGMENT OF THE PROTEIN KINASE C ζ ISOFORM. E. Sublette*, S. Hrabetova, T.C. Sacktor. Depts. of Pharmacology and Neurology, State University of New York Health Science Center, Brooklyn NY 11203.

We have previously described a brain-specific, constitutively active carboxy-terminal fragment of PKCζ (PKM), which has been implicated as an important element in hippocampal long-term plasticity: levels of PKMζ increase in LTP (Sacktor *et al.* PNAS **90**: 8342, 1993) and decrease in LTD (see Hrabetova and Sacktor, these abstracts). Physiological experiments with chelerythrine, a specific inhibitor of the catalytic domain of PKC, provide further evidence that PKMζ is required for the maintenance of both LTP and LTD (*ibid.*).

Here we present a characterization of rat brain PKMζ, purified with DEAE-Sepharose, heparin-Sepharose and hydroxyapatite column chromatography. PKMζ was isolated from all other PKC isoforms, as well as from full-length PKCζ. PKMζ shows catalytic activity toward a number of substrates, including Aε pseudosubstrate peptide and histone IIIS. Inhibitory properties of chelerythrine are also examined with respect to PKMζ. An understanding of the characteristics of PKMζ may lead to more precise approaches for elucidating the function of this molecule in long-term synaptic plasticity.

812.4

ENDOGENOUS FACILITATION OF NORADRENALINE RELEASE FROM SYMPATHETIC NERVES THROUGH PHOSPHOLIPASE C GENERATION OF DIACYLGLYCEROL AND ACTIVATION OF PROTEIN KINASE C. H. Majewski*, A. Hoare & T.V. Murphy Prince Henry's Institute of Medical Research, P.O. Box 5152, Clayton, Victoria 3168, Australia.

We have previously shown that inhibition of protein kinase C (Musgrave & Majewski, 1989; Naunyn Schmiedeberg's Arch. Pharmacol. 339, 48-53) or protein kinase C down-regulation (Foucart et al., 1991 Molec Neuropharmacol. 1, 95-101) attenuates high but not low frequency release of noradrenaline from sympathetic nerves, suggesting that high output noradrenaline release is maintained by endogenous activation of protein kinase C. The present study was to investigate this hypothesis further in rat atria whose transmitter stores were radiolabelled with [^{3}H]noradrenaline. When the atria were field-stimulated at 10 Hz for 5, 10 or 15 s, there was a progressive increase in noradrenaline release and the protein kinase C inhibitor polymyxin B (21 μM) inhibited noradrenaline release at the long (10 and 15 s) but not the short (5s) duration stimulation. This suggests that activation of protein kinase C increases during the stimulation train. The phospholipase C inhibitor U73122 (3 μM) significantly inhibited noradrenaline release at the longer trains and polymyxin B added with U 73122 had no further effect suggesting that both drugs operate through the same pathway. The diacylglycerol kinase inhibitor R-59949 (1 μM), which prevents the breakdown of endogenous diacylglycerol, significantly elevated noradrenaline release evoked by the longer stimulations. However, in the presence of polymyxin B, R-59949 had no effect on noradrenaline release suggesting the involvement of protein kinase C. From these results we suggest that during a train of stimuli there is progressive activation of phospholipase C which results in diacylglycerol formation which in turn activates protein kinase C to facilitate noradrenaline release.

812.5

A NOVEL MEK KINASE ACTIVATES TWO DISTINCT MAP KINASE SIGNALING CASCADES. E.M. Elliott*, J.L. Blank, P. Gerwins, S. Sather, and G.L. Johnson. Div. Basic Sci., Natl. Jewish Ctr., Denver, CO 80206

MAP kinase (mitogen-activated protein kinase) activation defines a kinase cascade initiated by extracellular ligands binding to particular growth-factor and G_i-coupled receptors. A novel component of this kinase cascade termed MEKK2 (MAPKK kinase) has been cloned and sequenced. Two in-frame termination codons are located in the 5′ untranslated region followed by an initiation methionine. The cDNA encodes a protein of 619 amino acids, corresponding to a molecular size of 69 kD.

The MEKK2 protein was expressed in HEK 293 cells to determine its role in the MAP kinase signaling cascades. Expression of MEKK2 activates MEK1 and MKK4 (both MAPKK) and ERK1 and JNK (both MAPK). Thus, MEKK2 activates two distinct MAP kinase cascades: (1) MEK1→ ERK1 and (2) MKK4→ JNK. Both ERK and JNK activate transcription factors thereby completing the transduction of extracellular signals to the nucleus for the control of specific gene transcription.

812.6

ISOZYMIC DIFFERENCES IN THE INACTIVATION OF CA^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE II DURING AUTOPHOSPHORYLATION. A. Hudmon*, S. J. Kolb, J. Aronowski† and M. N. Waxham. Dept. of Neurobiology and Anatomy, †Dept. of Neurology, University of Texas Health Science Center, Houston, Texas 77025.

Purified forebrain Ca^{2+}/calmodulin-dependent protein kinase II (CaM-kinase) undergoes a time-dependent inactivation that is sensitive to the conditions of autophosphorylation. We extend these findings by demonstrating that isozymes of CaM-kinase containing different ratios of alpha (50 kDa) and beta (60 kDa) subunits produce differential time-courses of enzyme inactivation during conditions of autophosphorylation. Purified forebrain CaM-kinase (3:1, alpha:beta) loses approximately 80% of its activity, while purified cerebellar CaM-kinase (1:4, alpha:beta) was observed to lose less than 30% of its activity during autophosphorylation in identical conditions. This observation was extended to both cytosolic preparations and crude homogenates of forebrain and cerebellar enzyme. Recombinantly expressed alpha or beta subunits of CaM-kinase undergo alterations in enzyme activity that parallel the dominant isozymic traits associated with forebrain and cerebellar CaM-kinase. These data indicate that differences in the ratio of alpha and beta subunits composing the holoenzyme produces isozymes of CaM-kinase with different apparent rates of inactivation, indicating that the beta subunit is not as susceptable to autophosphorylation-associated enzyme inactivation as the alpha subunit.

812.7

DOMAIN ANALYSIS OF ASSOCIATIONS BETWEEN CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II (CaMKII) SUBUNITS USING A YEAST TWO-HYBRID SYSTEM S.J.Kolb*, A.Morris†, A.Hudmon, and M.N.Waxham Dept. of Neurobiol. and Anatomy, †Dept. of Integrative Biology, Univ. of Texas Med. Sch. Houston, TX 77030.

CaMKII subunits form functionally important protein-protein interactions with other CaMKII subunits to form holoenzymes. We have analyzed the association of the two major neuronal isoforms, α and β in intact cells using a yeast two-hybrid system. Expression of these subunits in mammilian cell culture has suggested, in one study (Yamauchi et al., (1989) JBC, 264 p19108) that β subunits do not polymerize unless coexpressed with α. We detect α–α, α–β, and β–β associations between hybrid proteins in yeast. The detection of the β–β association is supported by electron microscopy studies involving purified subunits from rat brain that have suggested that pure α-containing holoenzymes and pure β-containing holoenzymes exist (Kanaseki et al (1991) JCB 155, p1049). By deletion analysis, we have confirmed that the C-terminal domain is essential and sufficient for subunit association. Moreover, associations between different domains within the same subunit, including the unique domain in the β subunit, are currently under investigation. Our findings suggest that the yeast two-hybrid system is a useful addition to current techniques designed to study the interactions within CaMKII subunits and holoenzymes.

812.8

NMDA RECEPTOR ACTIVATION LEADS TO PHOSPHORYLATION OF ELONGATION FACTOR-2: A POTENTIAL ROLE FOR NMDA RECEPTORS IN CONTROLLING PROTEIN SYNTHESIS. A.J. Scheetz*, A. Nairn# and M. Constantine-Paton · Yale University, Department of Biology and # Rockefeller University.

We are studying NMDA receptor-stimulated protein phosphorylation in the developing tadpole tectum, where structural synaptic plasticity is prominent. Using an in situ phosphorylation assay, we have previously detected 5 proteins whose phosphorylation is stimulated by NMDA receptor activation. One of these proteins, NARPP-90, has an isoelectric point and molecular mass similar to that of elongation factor 2 (EF-2), which is an enzyme that catalyzes the translocation of peptidyl-tRNA from the A site to the P site on the ribosome during protein synthesis. Phosphorylation of EF-2 by a novel calcium and calmodulin-dependent kinase (CaM kinase III) eliminates EF-2's ability to support translation and is associated with mitogenic transformation in some non-neuronal cells. Using antibodies specific to the phosphorylated form, we have examined whether EF-2 becomes phosphorylated when NMDA receptors are stimulated in the tadpole retinotectal projection. Stimulation of tecta with 50 μM NMDA + 10 μM glutamate (NMDA treatment) caused a minimum of 30-fold increase in phospho-EF-2 as detected by western blotting. Furthermore, like NARPP-90, EF-2 phosphorylation was not stimulated by application of either 60 μM AP-5 + 10 μM glutamate or 10 μM glutamate alone. As with NARPP-90, NMDA treatment of adult frog tecta, where synaptic plasticity is greatly attenuated, does not lead to EF-2 phosphorylation. Finally, western blotting of 2-dimensional gels with a pan-EF-2 antibody revealed that EF-2 comigrates with NARPP-90. These data indicate that NARPP-90 and EF-2 have similar properties and may be the same protein. They also suggest that NMDA receptor stimulation may transiently prevent protein synthesis which could be permissive for the transition of young synapses from an immature state to a more stable form.

812.9

CLONING AND EXPRESSION OF A NOVEL BRAIN-SPECIFIC P21-ACTIVATED PROTEIN KINASE (PAK2). K.J. Ivins*, M.R. Kozlowski, S.P. Manly, N. Freshney, L. Feig, R.L. Neve. Molecular Neurogenetics Laboratory, McLean Hospital, Belmont MA 02178; Geron Corporation, Menlo Park, CA; Tufts University, Boston, MA; Bristol Myers Squibb PRI, Wallingford, CT.

The p21 GTP-binding protein (p21) ras mediates the activation of the MAPK pathway following stimulation of extracellular growth factor receptors. The ras-related p21s of the rho family (rho, rac, and cdc42) mediate parallel pathways of signal transduction that are thought to modulate cytoskeletal function; but the components of these pathways have not been identified. We have cloned a rat hippocampal cDNA encoding a novel 61-kD p21 activated kinase (PAK2) that is 83% identical to a previously identified p65 PAK (Manser et al., Nature 367:40, 1994). RNA blot analysis showed that the 11 kb RNA encoding PAK2 is preferentially expressed in the nervous system. At least 4 alternatively spliced 5' UTR sequences have been identified, suggesting possible translational control of PAK2 expression. In situ hybridization histochemistry (ISSH) demonstrated that PAK2 RNA is widely distributed in adult rat brain, with high levels in hippocampus, amygdala, cortex, and the raphe nucleus; moderate levels in thalamus; and low levels in the caudate nucleus and cerebellum. In the E18 rat nervous system, PAK2 RNA is expressed at high levels in spinal cord and dorsal root ganglia as well as in brain, suggesting that PAK2 may also have a role in development. In pull-down assays using GST-p21 fusion proteins, ^{35}S-PAK2 was precipitated by GST-rac1-GTPγS and by GST-cdc42-GTPγS, but not by GST-rhoA-GTPγS or by any of the GST-p21 fusion proteins loaded with GDPγS. These results suggest that GTP-bound rac1 and cdc42 interact directly with PAK2. Furthermore, myc-tagged PAK2 expressed in COS-7 cells was immunoprecipitated with anti-myc antibody. Immunoprecipitated myc-PAK2 phosphorylated myelin basic protein in the presence of rac1-GTPγS and cdc42-GTPγS, but not in the presence of rac1-GDPγS or cdc42-GDPγS. Therefore, PAK2 is a functional kinase likely to be involved in neuronal signal transduction mediated by rac1 and cdc42.

812.10

ATP-EVOKED INOSITOL PHOSPHATE FORMATION THROUGH ACTIVATION OF P_{2U} AND P_{2Y} PURINERGIC RECEPTORS IN ASTROCYTES: REGULATION BY PKC SUBTYPES α, δ AND θ. C.C. Chen* and W.C. Chen. Institute of Pharmacology, College of Medicine, National Taiwan University, Taipei, Taiwan.

ATP-induced phosphoinositide (PI) hydrolysis were studied in cultured astrocytes. To characterize the P_2 purinergic receptor-mediated effects of ATP, subtype specific agonists 2-methylthio ATP (2-MeSATP), UTP and α,β-methylene ATP were comparatively studied. ATP, UTP or 2-MeSATP induced a dose-dependent increase of inositol phosphate (IP) accumulation, α,β-methylene ATP had no effect. Cross-desensitization experiments indicated that ATP interacts with both P_{2U} and P_{2Y} receptors. The effect of ATP, UTP or 2-MeSATP was inhibited markedly by pretreatment of cells with pertussis toxin (PTX). All these results suggested that ATP interacts with P_{2U} and P_{2Y} receptors coupled to PLC through PTX-sensitive G protein to mediate PI response in astrocytes. Short-term (10 min) treatment of cells with 1 μM TPA attenuated ATP, UTP and 2-MeSATP-induced PI breakdown, however, long-term (24 h) pretreatment resulted in marked potentiation of ATP and UTP responses and restoration of 2-MeSATP response. Further analyze the effect of TPA, 10 and 90 min pretreatment attenuated ATP and UTP-induced PI breakdown, but this inhibitory action was lost after 3 h treatment. Both 6 and 24 pretreatment resulted in a marked potentiation. Western blot analysis showed translocation of PKCα, PKCδ and PKCθ from the cytosol to the membrane following 10 and 90 min treatments and restoration to basal levels in the membrane fraction was seen after 3 h treatment. On the other hand, partial and complete down-regulation of these two isoforms were seen after 6 and 24 h treatment, respectively. However, PKCη was translocated but not down-regulated by TPA. These results suggested that PKCα, PKCδ and PKCθ but not PKCη may exert a tonic inhibition on P_{2U} receptor-mediated PI turnover in unstimulated astrocytes.

812.11

PHORBOL 12,13-DIACETATE (PDAc) CAN MIMIC THE NEURONAL EXCITATORY ACTION OF PHENYLEPHRINE (PhE). L.-M. Kow*, S.N. Carson, and D.W. Pfaff. The Rockefeller University, 1230 York Ave., New York, NY. 10021.

PhE can facilitate lordosis in female rats primed with estrogen and excite neurons in hypothalamic ventromedial nucleus (VMN) through the activation of α_1-adrenergic receptors, which are coupled to the phosphoinositol second-messenger pathway. We previously showed that PhE's behavioral effect could be mimicked by TPA (Brain Res. 660:241, 1994), and now used in vitro electrophysiological approach to see if the same also applied to its neuronal action. When the activity of single units recorded from VMN in hypothalamic slices was excited by PhE, a phorbol ester or related agent was infused into the chamber bathing the slice. Applications of PDAc excited 8 of the 10 (8/10) PhE-excited neurons at 10 μM, 3/5 at 5 μM, 2/3 at 2.5 μM and 5/8 at 1.0 μM. However, as the concentration decreased, the excitation became less steep and the latency to excitation prolonged. In contrast, applications of inactive phorbol esters (0/12 units at 10 μM, 0/2 at 5 μM and 0/3 at 1 μM) or the solvent DMSO (0/7 at 0.043% for 10 μM phorbol esters) was never effective. Surprisingly, administration of 12-O-tetradecanoyl phorbol 13-acetate (TPA) excited only 1/17 units at 10 μM and 0/5 at 5 μM. To see if the activation of protein kinase C (PKC) was involved, hypothalamic slices were incubated with phorbol esters or control agents at 34-37°C for ≥18 hours. In slices incubated with PDAc (10 or 20 μM) to deplete PKC, PhE excited 4/13 neurons. This responsiveness is significantly lower than the 9/12 and 6/8 from slices incubated with the inactive 4α-PDAc (10 or 20 μM) or DMSO (0.043%), respectively. Thus, the excitatory action of PhE can be mimicked by PDAc but not by TPA, and the action appears in part to involve the activation of PKC. PDAc and TPA might differ in their effectiveness and/or selectivity of PKC isoform activation. (Supported by PHS NS30824 from NINDS)

812.12

MUSCARINIC RECEPTOR ACTIVATION POTENTIATES LITHIUM-INDUCED DOWN-REGULATION OF THE PKC SUBSTRATE MARCKS IN IMMORTALIZED HIPPOCAMPAL CELLS. R.H. Lenox[1,2,3]* and D.G. Watson[1]. Departments of Psychiatry[1], Pharmacology[2] and Neuroscience[3], University of Florida College of Medicine, Gainesville, FL 32610.

We previously reported that chronic exposure of an immortalized hippocampal cell line (HN33 cells) to lithium chloride (1-10mM) produces a dose-dependent down-regulation of the PKC substrate MARCKS (**M**yristoylated **A**lanine-**R**ich **C**-**K**inase **S**ubstrate). Additionally, it was determined that the lithium-induced reduction in MARCKS protein was dependent upon the concentration of inositol, and was reversed in the presence of high inositol concentrations. In the present study we have examined the effect of muscarinic receptor activation on the expression of MARCKS protein in lithium-treated HN33 cells. Using [^{3}H]NMS binding we have determined that HN33 cells express muscarinic receptors (B_{max}: 48 fmol/mg protein) which are coupled to an IP_3/DAG response. Carbachol stimulation of [^{3}H]inositol-loaded HN33 cells produces a dose-dependent accumulation of inositol phosphate in the presence of lithium chloride. When HN33 cells were exposed to lithium chloride (1-5mM) under limiting inositol conditions, addition of 1mM carbachol significantly potentiated the lithium-induced down-regulation of the MARCKS protein. The magnitude of the MARCKS protein down-regulation following carbachol stimulation was greater in the membrane-bound fraction relative to the soluble fraction. Lithium's proposed action on PKC-mediated events, such as expression of MARCKS protein in brain, appears to be related to inositol concentration and receptor mediated signalling through the IP_3/DAG pathway. (Supported by NIMH grant MH50105).

CYCLIC GMP-DEPENDENT PROTEIN KINASE TYPE II EXPRESSION IN THE RAT BRAIN; AN RT-PCR AND *IN SITU* HYBRIDIZATION STUDY. A. El-Husseini*, C. Bladen and S. R. Vincent. Division of Neurological Sciences, Department of Psychiatry, The University of British Columbia, Vancouver, Canada, V6T 1Z3.

Cyclic GMP is produced in neurons through the activation of cell surface guanylyl cyclases by the atriopeptides, and soluble guanylyl cyclase by nitric oxide. Cyclic GMP can alter cellular responses by regulating many proteins including cGMP-dependent protein kinases, phosphodiesterases and ion channels. Immunohistochemical studies have shown that cGMP-dependent protein kinase type I is expressed in Purkinje cells and in the basal ganglia. We have used the reverse-transcription-polymerase chain reaction (RT-PCR) and *in situ* hybridization techniques to examine the expression of cGMP-dependent protein kinase type II (cGK II) in the brain. A PCR product with the size predicted from the cDNA for cGK II was detected in various regions of the brain, with highest expression in the thalamus. The amplified product of this cDNA was subcloned, sequenced and shown to be cGK II. *In situ* hybridization with riboprobes derived from the cloned cGK II PCR product indicated that this kinase was highly expressed in the outer layers of the cortex, the septum, amygdala and olfactory bulb with highest levels in the thalamus. High amounts of cGK II mRNA were also found in specific brain stem loci including the medial habenula, the subthalamic nucleus, the locus ceruleus, the pontine nucleus, the inferior olivary nuclei, and the nucleus of the solitary tract. Only low levels of cGK II mRNA were detected in the striatum, cerebellum and hippocampus. These data suggest that the effects of guanylyl cyclase activators, such as nitric oxide and the atriopeptides, in various regions of the central nervous system may be mediated through cGK II, which is widely expressed in the brain.

812.14

NITRIC OXIDE REGULATES CYCLIC GMP-DEPENDENT PROTEIN PHOSPHORYLATION IN RAT BRAIN. C. Bladen, A. El-Husseini and S.R. Vincent.* Division of Neurological Sciences, Department of Psychiatry, The University of British Columbia, Vancouver, B.C. Canada V6T 1Z3.

Nitric oxide acts via its receptor, soluble guanylyl cyclase, to increase cGMP levels and regulate various proteins including cGMP-dependent phosphodiesterases, ion channels and protein kinases. Two cGMP-dependent protein kinases have been identified in the mammalian brain, Type I, in Purkinje cells and the basal ganglia, and the recently identified Type II, which is more widely expressed throughout the brain, particularly in the thalamus (El-Husseini et al., *J. Neurochem.* in press). We have compared the regulation of protein phosphorylation in the cerebellum and thalamus by the NO-cGMP signal transduction system. Phosphorylation experiments were carried out *in vitro* on the soluble and particulate fractions of both these tissues using γ-^{32}P-ATP, and labeled proteins were examined following separation on 5-20% SDS-PAGE and exposure to X-ray film. One group of animals was injected with 20 mg/kg 7-Nitroindazole, 1 h prior to preparation of the fractions for protein kinase assays, in order to inhibit endogenous NO production in the brain. This treatment dramatically decreased the *in vitro* phosphorylation of a soluble 72kD protein. This appears to represent the autophosphorylation of the Type II cGMP-dependent protein kinase, since it was unaffected by *Rp*-8-bromo-cGMP, which is an inhibitor of the Type I, but a weak agonist of the Type II kinase. In the thalamus, this autophosphorylation could be restored, and indeed, significantly enhanced, by the addition of cGMP to the phosphorylation reaction. The labeling of this protein was even greater in the presence of 8-bromo-cGMP or cGMP plus IBMX. Labeling of a particulate protein of 46 kD was also reduced in both tissues following inhibition of NO synthase, and this could again be reversed by exogenous cGMP or 8-bromo-cGMP. These results indicate a role for endogenous NO in the regulation of protein phosphorylation by Type II cGMP-dependent protein kinase in the brain.

812.15

STAUROSPORINE, Gö-6976, AND K-252a ENHANCED KCl-EVOKED RELEASE OF 3H-NE FROM HUMAN NEUROBLASTOMA SH-SY5Y CELLS. D.B. Hawver*, A. Rashid, G. Chen, H.K. Manji, and W.Z. Potter, Section of Clinical Pharmacology , Experimental Therapeutics Branch, NIMH, and PRAT Program, NIGMS, NIH, Bethesda, MD 20892.

To explore the role of kinases in the regulation of neurotransmitter release, we have studied the effects of various kinase activators and inhibitors on the release of 3H-NE from cultures of human neuroblastoma SH-SY5Y cells. We found that the non-specific kinase inhibitor, staurosporine (STR), strongly enhanced the amount of 3H-NE released during a 7 min incubation with 100 mM KCl, without affecting basal release. Maximal effect required a preincubation of 1 hour and a dose of 50-70 nM. Two STR analogues, Gö-6976, and K-252a, similarly enhanced release. Another analogue, GF-109203X, thought to be a more specific inhibitor of Protein Kinase C (PKC), inhibited 3H-NE release at 2 μM. The PKC activators, PMA and thymeleatoxin (THM), enhanced KCl-evoked release when preincubated 14 min at 100 nM and 1 μM, respectively, and these effects appeared to be additive to those of STR, Gö-6976, and K-252a, suggesting that the activators and inhibitors may act via separate pathways. Moreover, downregulation of PKC isozymes α and ε by 24 hr treatment with 100 nM PMA or 1 μM THM abolished the enhancement of release by PMA or THM, but left intact the effects of STR, Gö-6976, and K-252a. Twenty-four hr treatment with 1 μM PMA, however, did abolish the enhancement induced by these agents, implying that there may be a PKC-sensitive step in their mechanisms, also. Finally, since both KN-62 (10 μM), a CaM Kinase II inhibitor, and Genistein (50 μM), a tyrosine kinase inhibitor, significantly inhibited KCl-evoked 3H-NE release, it appears that multiple kinases are involved in the regulation of transmitter release in this system.

813.1

ACTIVATION OF THE PERIPHERAL CANNABINOID RECEPTOR (CB2) INHIBITS ADENYLATE CYCLASE

Bayewitch M.[1], Avidor-Reiss T.[1], Levy R.[1], Mechoulam R.[2], Barg J.[1], and Vogel Z.*[1], Dept. of Neurobiology[1] Weizmann Institute of Science, Rehovot, Israel, Department of Natural Products[2], Faculty of Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel.

Two types of cannabinoid receptors have been recently cloned. The brain cannabinoid receptor (CB1) and the peripheral cannabinoid receptor (CB2). The CB2 receptor was shown to be expressed in the HL-60 promyelocytic leukemia cell line after differentiation with TPA and it is not present in brain (Munro et al., Nature 365:61-65). Activation of CB1 with tricyclic cannabinoids or with endogenous cannabinoid ligands, the anandamides, was shown to inhibit adenylate cyclase (AC) activity in rat brain homogenates, in $N18TG_2$ neuroblastoma cells, and in cells transfected with CB1. We have recently established a stable CHO cell line that expresses CB2. Using this cell line we found that the receptor binds a variety of tricyclic cannabinoid ligands as well as anandamides. In addition, we found that activation of CB2 leads to inhibition of AC (stimulated by forskolin, PGE_1, or cholera toxin). The maximal level of inhibition was approximately 50%. The EC_{50} values were 3, 47, and 350 nM for HU210, HU293a, and HU293 respectively. The inhibition of AC by cannabinoids was abolished by pretreating the cells with 100 ng/ml pertussis toxin indicating that CB2 couples to the G_i/G_o family of GTP binding proteins. *Supported by a grant from the Forschheimer Center for Molecular Biology.*

TRANSMEMBRANE SIGNAL TRANSDUCTION SYSTEMS MEDIATING CHOLINERGIC REM SLEEP GENERATION. ML Capece, MA Fleegal, HA Baghdoyan, and R Lydic*. Department of Anesthesia, Pennsylvania State University, College of Medicine, Hershey, PA 17033

The cholinergic regulation of REM sleep has been studied in detail, yet the complex signal transduction pathway(s) responsible for REM sleep generation are unknown. Considerable data show that muscarinic receptors in the medial pontine reticular formation (mPRF) are important for REM sleep generation (*NeuroReport* 5:1631,1994). Most recently, Gi and Gs-like G-proteins have been shown to act as transducers in the ability of mPRF carbachol administration to cause a REM sleep-like state (*Am. J. Physiol.* 269:(in press),1995). As an initial step toward identifying the second messengers involved in REM sleep generation, the present study is testing the hypothesis that increasing cAMP in the mPRF will block cholinergic REM sleep generation. Cats (N=3) were implanted with standard electrodes for measuring states of waking, non-REM and REM sleep and with guide tubes for mPRF drug administration. Polygraphic recordings were made for 2 hrs following mPRF microinjection (n) of saline (control, n=13); carbachol (8.7mM, n=12); forskolin, an activator of adenylate cyclase and a stimulator of cAMP (7mM, n=8); carbachol following forskolin pretreatment (n=9); dibutyryl cAMP, a cAMP analog (87mM, n=6); and carbachol following dibutyryl cAMP pretreatment (n=6). After all microinjections of forskolin, 2 hr recordings were made 24 hr (n=17) and 48 hr (n=17) post-injection and 24 hr (n=12) after dibutyryl cAMP. The carbachol-induced REM sleep-like state was significantly ($p<0.05$) decreased by mPRF pretreatment with forskolin (-34.7%) and dibutyryl cAMP (-49.5%). In contrast, forskolin alone and dibutyryl cAMP alone had no immediate or long term effect on natural REM sleep. These data suggest that cholinergic REM sleep generation is mediated, in part, by pontine adenylate cyclase and cAMP.

GONADAL STEROID MODIFICATIONS OF RECEPTOR-INDUCED RESPONSES IN CULTURED NEURONAL CELLS. I. López-Coviella, R. Alonso*, & F. Hernández-Díaz. Lab. of Neuroendocrinology, University of La Laguna Medical School, 38320 S/C de Tenerife, Spain.

The generation of second messengers following receptor activation may depend on receptor sensitivity, coupling of agonist-bound receptor to GTP-binding proteins, and extent of activation of effector proteins. Steroid hormones may affect each one of these steps. Incubation of GnRH producing neurons (GT1-7 cell line) for 48 hours with 100 nM estradiol (E_2) completely suppressed norepinephrine-induced intracellular cAMP accumulation. This effect was completely reversed by a 15-minute incubation period with 100 nM progesterone (Pg) or progesterone-3-BSA (Pg-BSA; a derivative that does not cross cell membranes), prior to norepinephrine (NE) treatment. The addition of 1 μM colchicine to the medium of E_2-untreated cells, 1 hour before harvesting, produced a 35% increase in basal cAMP levels. This increment did not occurred in E_2-treated cells. However, colchicine increased cAMP levels in the presence of E_2, when cells had been stimulated with NE. Thus, as Pg and Pg-BSA, colchicine also reversed the effect of E_2. These results may constitute the first indication of a direct effect of ovarian steroids on the response of GnRH neurons to a neurotransmitter, and suggest that genomic and non-genomic effects of gonadal steroids could alter receptor-effector coupling by different mechanisms. Data on steroid receptors and cytoskeletal proteins that may be regulating these events in this and other cell lines are presented. (Supported by DGICYT PM92-0160, GAC 92-069, & GAC 93-002)

CHRONIC ANTIDEPRESSANTS TREATMENT ENHANCE ROLIPRAM INDUCED BEHAVIORS IN RATS H. Ozawa*[1], H. Kamada[1], M. Yamamoto[1], N. Amemiya[2], S. Hatta[2], T. Saito[1], H. Ohshika[2] and N. Takahata[1]. Dept. of [1]Neuropsychiatry and [2]Pharmacology, Sapporo Medical University, School of Medicine, Sapporo 060, Japan.

It has been reported that treatment with rolipram, a selective cAMP phosphodiesterase inhibitor which reflects the enhanced availability of cAMP in the brain, results in an extraordinary behavioral syndrome characterized by head twitches (HT), forepaw shaking (FS), grooming and hypothermia in the rat. These particular behavioral alterations in rats induced by rolipram contribute to the enhanced availability of cerebral cAMP. The goal of the present study is to examine the connection between the second messenger system and animal behaviors induced by psychotherapeutic drugs. Sprague-dawley male rats were injected (i.p) once daily for 1-21 days with saline and amitriptyline (10mg/Kg), imipramine (10mg/Kg), clomipramine (10mg/Kg), milnacipran (20mg/Kg), fluoxetin (10mg/Kg), fluvoxamine (25mg/Kg), trazodone (20mg/Kg), chlorpromazine (10mg/Kg) or lithium (3mEq/kg). The numbers of rolipram (10 mg/Kg) induced HT, FS and Gr actions were counted 15min after rolipram injection for 45 min. Rectal temperature was measured immediately before and 50 min. after rolipram administration. Administration of chronic (14-21days) but not acute tricyclic antidepressants and atypical (trazodone) or novel antidepressants (SSRIs or milnacipran) augmented rolipram-induced behaviors (especially HT). Contrary to the effects of antidepressants, chronic chlorpromazine or lithium administration decreased those behaviors. These findings provide symptomatic documentation that elevation of the cAMP cascade system may have an important role in antidepressive effects .

FUNCTIONAL CHARACTERIZATION OF A2b ADENOSINE RECEPTORS EXPRESSED BY HUMAN NONPIGMENTED EPITHELIAL (NPE) CELLS *S. Mehdi Rezazadeh*, Felicia Terry and Michael W. Martin*. Department of Pharmacology, University of North Texas Health Science Center at Forth Worth, Fort Worth, Texas 76107.

Activation of A1 and A2 adenosine (ADO) receptors results in either inhibition or stimulation of adenylyl cyclase (AC), respectively. In the present study, we characterized the AC responses of human NPE cells to a series of ADO receptor agonists and antagonists. Accumulation of cyclic AMP (cAMP) was determined by measuring the conversion of ^{3}H-ATP to ^{3}H-cAMP after pre-labelling cells with ^{3}H-adenine. Cells incubated in serum-free media had low levels of cAMP and the PDE inhibitor RO20-1724 increased these levels only marginally. Addition of the isoproterenol (ISO) or the receptor-independent activator forskolin (FSK) markedly elevated cAMP levels. No evidence for A1 receptor-mediated inhibition of basal, ISO-, or FSK-stimulated AC activity was observed. In fact, the A1-selective agonist 6-chloro-N^6-cyclopentyladenosine stimulated AC activity at concentrations >10 μM and in the presence of 1 μM FSK synergistically activated cAMP accumulation, even at nanomolar concentrations. Adenosine stimulated cAMP accumulation but with relatively low potency (EC_{50} = 54 μM). The rank order of potency of other receptor agonists was NECA > R(-)PIA > CGS21680. 5'-N-ethylcarboxamidoadenosine (NECA)-stimulated (1μM) cAMP accumulation was competitively antagonized by both xanthine (8-cyclopentyl-1,3-dipropylxanthine [CPX] and 8-(3-chlorostyryl)caffeine [CSC]) and non-xanthine (CGS 15943A) ADO antagonists. The rank order of potency was CSC>CGS 15943>CPX. These data indicate that NPE cells express a "low affinity" A2b receptor subtype. (Supported by NIAAA-A06890 and UNTHSC Grants).

PK 11195 BLOCKS THE INHIBITORY EFFECT OF BENZODIAZEPINES ON FORSKOLIN-STIMULATED ADENYLATE CYCLASE ACTIVITY IN STRIATUM. C.C. Tenn*, J.M. Neu and L.P. Niles. Department of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

In this study, we investigated the effects of benzodiazepine (BZ) receptor antagonists, on the inhibition of forskolin-stimulated adenylate cyclase (AC) activity by various BZs in the rat striatum. Male Sprague Dawley rats (200-250g) were maintained under a 12L:12D lighting regimen and sacrificed approximately 3 hours after lights on. Saturation studies using [^{3}H]flunitrazepam revealed a single binding site in the striatum (K_D = 5.1 ± 0.3 nM) which significantly decreased in affinity in the presence of GTP (K_D = 10.2 ± 1.0 nM) with no change in B_{MAX}. Functional studies in the striatum revealed a biphasic inhibition of forskolin-stimulated AC activity by the peripheral type agonist, Ro5-4864. The first phase of the AC inhibition is consistent with a G_i-coupled receptor-mediated action, whereas the second phase appears to involve a direct effect on the enzyme itself. The first phase of the inhibition (10^{-11}- 10^{-5} M) had an EC_{50} of 66 nM, with the second phase (10^{-4}-5 x 10^{-4} M), an EC_{50} of 3.2 x 10^{-4} M. In the presence of flumazenil (1 μM), a central-type BZ receptor antagonist, a shift to the left was observed with the first phase of inhibition (EC_{50} = 46nM) with no significant change in the second phase.

In the presence of 5 μM of PK 11195 (a peripheral-type BZ receptor antagonist), Ro5-4864-induced inhibition of the AC activity of the first phase was reversed with no significant effect on the second phase. The peripheral antagonist similarly blocked the inhibitory effect of other BZs (flunitrazepam and diazepam) and indoleamines (melatonin and 2-iodomelatonin) on stimulated AC activity. These results provide further evidence of a G_i-coupled BZ receptor in the rat striatum. (Supported by a NSERC Strategic grant).

MODULATION OF STRIATAL *C-FOS* EXPRESSION BY DIAZEPAM. L.P. Niles*, L.J. Smith and C.C. Tenn. Department of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Diazepam, a non-selective benzodiazepine (BZ) receptor agonist, inhibits cyclic AMP (cAMP) production, particularly in the rat striatum, via a putative G_i-coupled BZ receptor. Since phosphorylation of a cAMP response element binding protein (CREB), by a cAMP-dependent protein kinase (PKA), results in *c-fos* activation, the effect of diazepam on the expression of this immediate-early gene was examined. Male Sprague Dawley rats (about 150-250 g) were maintained for at least one week under a 12L:12D lighting cycle with lights on from 7 am to 7 pm. They were randomly assigned to groups and injected with vehicle or drugs 4 - 5 hours after lights on. Two hours later, animals were killed and striata dissected on ice and frozen overnight at -20° C. Subsequently, striata were homogenized in sucrose (containing Mg^{2+} and Hepes) and nuclear fractions isolated by centrifugation. Proteins were separated by SDS/PAGE followed by Western blot analysis using a polyclonal anti-c-FOS antibody. Following incubation with an HRP-conjugated second antibody, FOS and related proteins were detected by chemiluminescent autoradiography.

Preliminary studies indicate that diazepam (5 mg/kg, ip) induces *c-fos* expression when administered alone. However, pretreatment with diazepam (5 mg/kg, ip) caused a significant attenuation of the effect of amphetamine (5 mg/kg, ip), which by itself is a potent *c-fos* inducer. The sites and mechanisms underlying the modulatory effects of diazepam on neuronal activation, as indicated by *c-fos* induction in the striatum, await clarification. (Supported by a NSERC Strategic grant).

IN VIVO INHIBITION OF CA^{2+}/CALMODULIN STIMULATION OF TYPE I ADENYLYL CYCLASE BY SOMATOSTATIN. Mark D. Nielsen, Enrique C. Villacres*, and Daniel R. Storm, Department of Pharmacology, University of Washington, Seattle, WA 98195

In vitro evidence has demonstrated that the type I Ca^{2+}/calmodulin-sensitive adenylyl cyclase (I-AC) is inhibited by both the α_i and $\beta\gamma$ subunits of guanine nucleotide-binding proteins (G proteins). However, *in vivo* evidence concerning the ability of extracellular hormones to inhibit the Ca^{2+}/calmodulin stimulation of I-AC is lacking. Here, we describe concentration-dependent inhibition of Ca^{2+}/calmodulin stimulation of I-AC *in vivo* by the tetradecapeptide hormone somatostatin. Treatment of human embryonic kidney 293 (HEK 293) cells stably expressing I-AC with the muscarinic agonist carbachol or the Ca^{2+} ionophore A23187 resulted in 3-or 20-fold increases in intracellular cAMP levels, respectively. Utilizing the endogenous somatostatin receptors expressed in HEK 293 cells, we found that somatostatin inhibited these cAMP increases 40-50%. Forskolin stimulation of I-AC was also inhibited by a similar amount. Maximal inhibition of I-AC occurred at approximately 200nM somatostatin, with an IC50 of ~25nM. Additionally, inhibiton of Ca^{2+}/calmodulin stimulation of I-AC was prevented by overnight pretreatment with pertussis toxin, suggesting that G proteins of the G_i/G_O class are involved. These results demonstrate that extracellular hormones are capable of inhibiting Ca^{2+}/calmodulin stimulation of I-AC via inhibitory G proteins *in vivo*.

cAMP-DEPENDENT PROTEIN KINASE A INCREASES THE EXCITABILITY OF EXPIRATORY NEURONS OF CAT. O.Pierrefiche, A.M. Bischoff, P.M. Lalley* and D.W. Richter. II. Institute of Physiology, University of Göttingen, FRG and Department of Physiology, University of Wisconsin, Madison, USA.

The cAMP/PKA system is known to control neuronal excitability by altering neurotransmitter- and voltage-controlled conductances. In this study, we set out to determine whether the cAMP-PKA system modulates the excitability of late expiratory (E2) neurons in the caudal brainstem. We injected wiptide, an inhibitor of PKA, into E2 neurons in pentobarbital-anesthetized, paralyzed and artificially ventilated adult cats, and analyzed various cellular properties in single electrode current (SECC) and voltage (SEVC) clamp. Wiptide reduced neuronal input resistance, hyperpolarized the membrane potential, reduced rate of depolarization to threshold and depressed action potential discharge. Action potential duration was reduced whereas their after-hyperpolarizations increased in magnitude and duration. Inspiratory- and postinspiratory-phased synaptic outward currents increased greatly and expiratory-phased synaptic inward currents seemed slightly depressed.

The results indicate that the cAMP/PKA system is tonically active and increases excitability of E2 neurons. Possible mechanisms for these effects include blockade of persistant potassium and GABA-A receptor-controlled currents, as well as augmentation of glutamate receptor-controlled currents

ACETYLCHOLINESTERASE MODULATES DOPAMINE - STIMULATED CYCLIC AMP ACCUMULATION IN *APLYSIA* GILL.

Srivatsan, M.*, Fuller, L. Z., Jackson, B. A. and Peretz, B.
Dept. of Physiology, Univ. of Kentucky Medical Center, Lexington, KY 40536.

Acetylcholinesterase (AChE) has functions in addition to acetylcholine (ACh) hydrolysis as supported by studies of AChE regulating dopaminergic receptor responsiveness in substantia nigra (Greenfield, S.A., 1985). Our recent studies have demonstrated that AChE inhibition affects a non-cholinergic component of the siphon-gill withdrawal reflex in *Aplysia*. Dopamine (DA), enhances muscle contraction in gill apparently by elevating cyclic AMP (cAMP) levels (Ruben et al., 1979). AChE is widely present in *Aplysia* gill and is released when gill is exposed to DA suggesting a non-cholinergic functional interaction between DA and AChE in the gill. The aim of the present study was to determine if AChE inhibition in the gill alters DA-dependent cAMP accumulation, as measured by RIA. DA dose-dependently increased cAMP levels in isolated gill pinnules incubated in *Aplysia* saline. Incubation in the presence of AChE inhibitor BW284c51, which binds to both the catalytic site and a peripheral anionic site of AChE, dose-dependently attenuated cAMP accumulation in response to a maximum stimulatory dose (30μM) of DA. Total inhibition of AChE with 100μm BW284c51 reduced DA-dependent cAMP by 68%. In contrast, total inhibition of AChE with 1mM edrophonium chloride, which binds only to the catalytic site of AChE, did not reduce DA stimulated cAMP levels. Also, incubating in carbachol (10 and 100μM) had no effect on cAMP levels in pinnules. These results show that AChE modulates DA-dependent cAMP accumulation in *Aplysia* gill through a non-cholinergic mechanism involving its peripheral site. AChE's modulation of DA's effects in *Aplysia* gill and nigral neurons in higher vertebrates suggests that this function of AChE is conserved across species.

cAMP IMAGING REVEALS GLUTAMATE RECEPTOR-MEDIATED REDUCTION OF [cAMP] IN PRIMARY CULTURES OF HIPPOCAMPAL NEURONS. B.J. Bacskai[1] and R.Y. Tsien*[1,2]. [1]Dept. of Pharmacology and [2]Howard Hughes Medical Institute, University of California San Diego, La Jolla, CA 92093-0647.

The role of cAMP in neuronal plasticity in the hippocampus is receiving considerable attention. However, traditional radio-immunoassays measure total cAMP at a single time point, usually in the presence of phosphodiesterase inhibitors, in homogenates of brain which contain neurons, astroglia, and other cell types. Using a fluorescently labeled cAMP-dependent protein kinase (FlCRhR), cytosolic [cAMP] was measured in morphologically identified neurons in primary cultures of rat hippocampus in real time. Individual neurons were microinjected with FlCRhR and stimulated with a variety of glutamate receptor agonists. Resting [cAMP] was high enough to cause partial activation of the kinase, and rapidly decreased to negligible levels following a 1-5 min pulse of 10-100 μM glutamate. NMDA (100 μM) and AMPA (100 μM) also elicited decreases in [cAMP]. Ca^{2+} entry seemed necessary but not sufficient, because reductions in [cAMP] required extracellular Ca^{2+}, and nitrendipine blocked the reduction in [cAMP] induced by AMPA, but not that by NMDA. However elevation of Ca^{2+} by high K^+ or ionomycin had no effect. Forskolin (25 μM), which normally elicited maximal increases in [cAMP], had no effect when applied within 20-30 minutes after glutamate or NMDA addition. The metabotropic glutamate receptor agonist trans-ACPD had no effect on basal or forskolin-stimulated [cAMP]. Bath application of glutamate or NMDA led to rapid, transient cytosolic acidification from pH 7.0 to pH 6.5, in the range where FlCRhR fluorescence is partially sensitive to pH, but acidification alone cannot completely account for the measured decreases in FlCRhR ratio, nor the inhibition of forskolin-stimulated increases in [cAMP]. Inhibitory crosstalk between glutamate receptors and cAMP may be important for neuronal plasticity.

ENDOGENOUS PROTEIN KINASE A INHIBITOR (PKIα) MODULATES SYNAPTIC ACTIVITY

L.de Lecea[1*], J.R.Criado[2], S. Rivera[3], S.J. Henriksen[2], C.M. Gall[3] and J.G. Sutcliffe[1]. Depts. of Molecular Biology[1] and Neuropharmacology[2] The Scripps Research Institute La Jolla, CA 92037[3].Dept. of Anatomy and Neurobiology. University of California Irvine, CA 92717

Protein kinase A (PKA) has long been known to be involved in major regulatory mechanisms underlying synaptic plasticity and complex behaviors such as learning and memory. PKIα has been extensively used as an extremely specific and potent inhibitor of PKA and the PKA-mediated signal transduction. Clear functions 'in vivo' for PKIα, however, remain to be established. Here we report that several forms of synaptic stimulation in the rat hippocampus cause a 50% decrease in the concentration of PKIα. Furthermore, infusion of antisense oligonucleotides against PKIα into the rat brain results in dramatic changes in the electrophysiology of hippocampal neurons, including the blocking of long-term potentiation suggesting a stimulus-dependent regulatory role for PKIα in PKA signal transduction.

PHOSPHORYLATION OF DARPP-32 AND INHIBITOR-1 BY CYCLIN-DEPENDENT PROTEIN KINASES. J.A. Bibb[1], J.P. O'Callaghan[1], S.L. Pelech[2], J.-A. Girault[3], A.C. Nairn[1]*, J. H. Wang[4], P. Greengard[1] and A.J. Czernik[1]. [1]Lab. of Molecular & Cellular Neuroscience, The Rockefeller University, New York, NY 10021; [2]University of British Columbia, Vancouver, Canada; [3]INSERM U114, Paris, France; University of Calgary, Calgary, Canada.

DARPP-32 (D-32) and inhibitor 1 (I-1) are homologous inhibitors of protein phosphatase 1 (PP-1). Their ability to function as inhibitors is dependent on phosphorylation of threonine 34 and threonine 35 of D-32 and I-1, respectively, by cAMP-dependent protein kinase. For D-32, which is highly enriched in dopaminoceptive neurons of the basal ganglia, this activated state is modulated through phosphorylation at additional sites by casein kinases I and II. Here, we report that *in vitro*, D-32 and I-1 serve as substrates for phosphorylation by the cell-cycle dependent kinase cdc 2 as well as the neuronal cdc 2-like kinase cdk 5. The stoichiometries of phosphorylation by cdc 2 purified from sea star oocytes have been determined for D-32 and I-1, respectively. Two-dimensional phosphopeptide mapping of thermolytic and tryptic digests of D-32 and I-1 revealed distinct maps for each. Amino acid analysis identified the residues phosphorylated as threonine for D-32 and serine for I-1. Sequence analysis of phosphopeptides purified by HPLC was used to identify the phosphorylation sites and direct the generation of phosphorylation-state-specific antibodies. The antibodies are being used to evaluate the state of phosphorylation of these sites in tissue slices. Neuronal cdk 5 purified from bovine brain appears to phosphorylate the same site as cdc 2 based on phosphopeptide mapping. The expression of various cdks in striatal tissue was shown to be developmentally regulated by immunoblot analysis. Notably, of the kinases studied, only cdk 5 was detected in adult rat striatal tissue.

813.14

EXPRESSION OF PKI ISOFORM mRNAS IN DEVELOPING RAT NERVOUS TISSUE; LOCALISATION OF mRNA SPECIES IN BRAIN. L. F. Donaldson*, M. R. Hanley and D. A. Walsh Dept. of Biological Chemistry, UCDavis, Davis Ca 95616

The mRNAs for the two known isoforms of the cAMP-dependent protein kinase (PKA) inhibitor protein (PKIα and PKIβ) are known to have a differential distribution in developing rat tissues, particularly in brain and testis. As these tissues are heterogenous in cell type, we have investigated the cellular expression of PKIα and PKIβ mRNAs in developing rat brains using a specific in situ hybridisation technique. Male Wistar rats were sacrificed at 5 day intervals, beginning at day 5 of age and ending at day 60. Whole brains were removed, hemisected along the sagittal plane and rapidly frozen on dry ice. 10μm sections were hybridised with cRNA probes complementary to the mRNAs encoding PKIα and PKIβ. Film autoradiography showed high expression of PKI mRNAs in cerebellum and hippocampus from days 15 to 60. In immature rats (d5) PKIβ mRNA expression was high in individual cortical and hippocampal neurons. In adults PKIβ mRNA was appparent in cortical, hippocampal, and cerebellar granular neurons. This expression was detectable from day 15, increased to a plateau by day 25 and remained constant until day 60. No specific hybridisation was detectable in cerebellum or hippocampus before 20 days, or in sections hybridised with sense cRNA probes. PKIα was also localised in cerebellar granule cells and hippocampus in adult rat brain. PKA has been shown to be of importance in the maintenance of long term potentiation and response of hippocampal neurons to anoxia, suggesting that PKI may play an important role in the function of the hippocampus.

813.15

BILATERAL DOPAMINE LESIONS IN THE NUCLEUS ACCUMBENS MODIFIES CYCLIC AMP-DEPENDENT PHOSPHOPROTEINS. L. Churchill*, Kari J. Johnson and P.W. Kalivas. Dept. of Veterinary & Comparative Anatomy, Pharmacol. & Physiol. Washington State University, Pullman, WA 99164-6520.

Previous analyses revealed that cyclic-AMP dependent back phosphorylation of a 35 kD nucleus accumbens protein was reduced at 32 days after bilateral 6-hydroxydopamine lesions in the nucleus accumbens. Two-dimensional gel electrophoretic analyses verified that a 35 and a 56 kD protein showed a significant decrease in cyclic AMP-dependent phosphorylation *in vitro*. Also a protein with a molecular weight of 45 kD showed a significant enhancement in the dopamine-depleted nucleus accumbens. These results indicate an increase in the phosphoproteins with molecular weights of 35 and 56 kD as well as a decrease in the phosphoprotein at 45 kD after a bilateral dopamine lesion. The phosphoprotein of 35 kD might be DARPP-32 as evidenced by the changes in phosphorylation that occurred 17 days after a unilateral dopamine lesion in the striatum with dopamine priming (Barone et al., 1994, *Neuroscience* 61:867). The differences between this study and ours may be due to differences between the nucleus accumbens and striatum, the longer time period studied, or the bilateral vs. unilateral lesion. A further question is whether the μ-opioid agonist induction of behavioral augmentation after the dopamine lesion will also alter phosphoproteins in the nucleus accumbens. This work was supported in part by USPHS grants #DA06612 (LC) and #MH40817, #DA0396, #DA00158 (PWK).

ISOLATION AND CHARACTERIZATION OF cAMP-SPECIFIC, ROLIPRAM-SENSITIVE PHOSPHODIESTERASE (PDE IV) FROM PIG BRAIN CYTOSOL. Gudrun Pahlke and Herbert H. Schneider* Research Laboratories, Schering AG, 13342 Berlin, Germany.

Rolipram is a selective and stereospecific inhibitor of type IV PDE. Using a rapid and specific purification procedure we have purified the cytosolic form of a rolipram sensitive "low K_m" cAMP PDE from pig brain cortex. The enzyme was isolated by affinity batch chromatography followed by MonoQ and Superose6 chromatography. The purification was approx. 5000-fold at 1% yield based on ^{3}H-rolipram binding capacity. The protein had a native MW of 180 kDa and a denatured MW of 90 kDa, suggesting a dimeric structure. K_D (0.2 nM) and n_H near 1 of ^{3}H-rolipram binding were similar throughout purification steps in the presence of a factor derived from boiled tissue extract. In its absence B_{max} decreased drastically with unchanged K_D and n_H. It is a thermostable, lipophilic and Mg^{++}-dependent protein which modulates the binding of ^{3}H-rolipram to the protein in a positive or negative manner, depending on concentration. The sensitivity of the PDE activity to inhibition by (-)-rolipram improved from 300 nM (IC_{50}) in crude brain extract to 0.7nM in the purified preparation. It decreased further to 0.15nM in the presence of factor. IBMX, ICI 63.197, Ro 20-1724 and denbufylline were active with IC_{50}s of 740, 140, 33 and 5nM. Cilostamide inhibited enzyme activity significantly only at 100μM. Between 0.1-100μM, cGMP neither inhibited nor activated the purified enzyme. Calmodulin stimulated PDE activity in crude extracts 2-fold, no effect was seen in MonoQ fractions. The isolated protein revealed complex enzyme kinetic behavior. Depending on substrate concentration K_m and V_{max} values varied between 2.8 and 7.3 μM and V_{max} between 13 and 26 μmoles/min/mg. The type of enzyme inhibition by (-)-rolipram was of a hyperbolic mixed type, probably because of the endogenous mixture of PDE IV isoenzymes.

814.1

ALPHA-IFN MODULATES THE RESPONSE TO GABA AND GLUTAMATE ON NEURONS FROM LATERAL HYPOTHALAMUS. V. Mendoza-Fernández, P. Pérez-Arellano, M. Herrera-Ruíz and C. Reyes-Vázquez*. Depto. Fisiol. Fac. Med., UNAM, México, D.F., México

Both, systemic and microiontophoretic application of α-interferon (α-IFN) exerts long lasting effects on the electrical activity of several brain nuclei; particularly, the lateral hypothalamic nuclei had shown to be very sensitive to the effects of this cytokine. In these neurons α-ifn elicits changes in the pattern, size and frequency of discharge, of the electrical signals recorded extracellularly. These effects started few seconds after α-IFN application and always outlasted the administration for several min. However, the relation between this effect and the physiologic response to other substances, is unknown. In the present study we analyzed the effects of GABA and glutamate, applied before and after an α-IFN administration, on the electrical activity of lateral hypothalamic neurons. The recordings were made from brain slices obtained from male Wistar rats. Slices preparation and recording techniques of the extracellular activity were made using conventional methods. Alpha-IFN elicited effects in 82% of the recorded neurons. Approximately 64% of these neurons showed a decrease of their discharge with changes in the size and the pattern of the action potentials. When applied before α-IFN administration, GABA and Glutamate showed a dose dependent decrease and increase; respectively, of the frequency of discharge. Such effects lasted exclusively the time of drug application, and once it ended, the frequency of discharge returned to control levels without changes in the size or the pattern of response. However, when these drugs were applied after α-IFN administration, the effects were increased importantly, both, in intensity and duration. This potentiation action started between 10 and 15 min after α-IFN application and lasted several hours. After that, the sensitivity of these neurons to these drugs returned to normal. The results show that α-IFN modifies the sensitivity and response pattern to other substances from hypothalamic neurons.

814.2

MODULATION OF NMDA RESPONSES BY INTERFERON-α IN THE PREOPTIC ANTERIOR HYPOTHALAMUS. S.Take, T.Katafuchi, S.Duan and T.Hori. Dept of Physiology, Faculty of Medicine, Kyushu University, Fukuoka 812-82, Japan

The brain and the immune system share the ligand-receptor systems which enable them to communicate with each other. Interferon-α (IFN-α) is one of such ligands that are produced in the both systems, which is known to induce a variety of central symptoms. The preoptic anterior hypothalamus (POA) is one of the sites of action of central IFN-α. We previously reported that IFN-α's modulatory effect on glutamate- and NMDA-induced whole cell currents in the POA. In the present study, we investigated the mechanisms of IFN-α-induced suppression of NMDA responses in the POA neurons voltage-clamped at -60mV using 120μm hypothalamic slices of 10-20 days old WKA rat. Inward currents induced by pressure-ejected NMDA (200μM, 200msec) were markedly suppressed by perfusion of recombinant human IFN-α (100-200U/ml, 2 min) with a few minutes latency for more than one hour. This IFN-α-induced suppression of NMDA currents was partially blocked by simultaneous application of naloxone (10μM), and the bath application of [Tyr-(D-Ala)-Gly-(N-Me-Phe)-Gly-ol]-enkephalin (DAGO, 2μM), μ receptor selective opioid agonist, suppressed NMDA currents just as IFN-α did, suggesting the involvement of opioid receptors. Although bath application of sodium salicylate (SALC, 10μM) reversed suppression of NMDA currents, prostaglandin E2 (2μM) did not affect NMDA responses. Concurrent application of superoxide dismutase (SOD, 200U/ml) with IFN-α almost completely abolished IFN-α's action on NMDA currents and hydrogen peroxide (1mM) mimicked it, suggesting the involvement of reactive oxygen intermediates (ROIs). Neither SOD nor SALC affected DAGO-induced suppression of NMDA currents. Nω-nitro-L-arginin (100μM) slightly attenuated the suppression of NMDA currents, suggesting the involvement of nitric oxide which is known to interact with ROIs.

These results suggest that opioid receptor mechanism and ROIs are independently involved in IFN-α-induced suppression of NMDA currents in the POA neurons.

PROLONGED STIMULATION WITH INTERFERON-α REGULATES CATECHOLAMINE SECRETION IN CULTURED BOVINE ADRENAL CHROMAFFIN CELLS. Y.Toyohira, N.Yanagihara, K.Minami[1], Y.Uezono and F.Izumi*. Depts of Pharmacology and [1]Anesthesiology, Univ. of Occup. & Envir. Health, School of Medicine, Kitakyushu 807, Japan.

Interferons(IFNs) are a group of molecules that have antiviral and immunoregulatory functions. Recent studies have reported that several neurological side effects are observed in IFN-treated patients. To investigate whether IFN can modulate the neurosecretory functions, the effects of two IFNs, human leukocyte IFN-α and recombinant human IFN-γ, were studied in cultured bovine adrenal chromaffin cells. Treatment of cultured cells with IFN-α(1000U/ml) for 48 hr increased an accumulation of catecholamines in the cultured medium, but not with IFN-γ(1000U/ml). The IFN-α-induced response was observed in time (8-48 hr)- and concentration (10-1000 U/ml)-dependent manners. The stimulatory effect of IFN-α was not inhibited by protein kinase C inhibitor (H-7) and NO synthase inhibitor (L-NMMA), both of them were previously reported as the second messenger in catecholamine secretion. These results suggest a possibility that IFN-α acts as a neuromodulator during immune responses.

AVP release by acetylcholine or norepinephrine: region-specific and cytokine-specific regulation. J.Raber*, G.F.Koob, and F.E.Bloom, Department of Neuropharmacology, The Scripps Research Institute, 10666 North Torrey Pines Rd., La Jolla, CA 92037.

Arginine vasopressin (AVP) containing neurons of the magnocellular hypothalamic nuclei and limbic structures, including the hippocampus and amygdala may be influenced by cytokines. Interferon-α (IFN-α) and transforming growth factor-β1 (TGF-β1) have been detected in the brain, suggesting their possible regulatory functions. An *in vitro* paradigm was used to investigate the influence of these cytokines on the release mechanisms of AVP in the hypothalamus and amygdala. Previous work established that *in vitro* AVP is released, in a calcium-dependent manner from both sites, and that this release is responsive to acetylcholine (ACh), norepinephrine (NE), IL-1, IL-2, IL-6 or high KCL (60 mM). IFN-α enhanced AVP and CRF release from both hypothalamus and amygdala. Dibutyryl cGMP also stimulated AVP release. Blockade of nitric oxide synthase antagonized the IFN-α-induced AVP release from the amygdala but not from the hypothalamus. TGF-β1 had no effect on basal release of AVP, nor on the AVP-release induced by IFN-α, IL-2 or NE, but selectively blocked the ACh-induced release in both hypothalamus and amygdala. TGF-β1 also inhibited the ACh-induced CRF release from both brain regions. When the release of AVP induced by IFN-α, IL-2, ACh and NE was probed with inhibitors of guanylate cyclase, the interactions exhibited regional selectivity: neither the IL-2-induced AVP release from hypothalamus, nor the NE-induced release of AVP from either amygdala or hypothalamus were affected by guanylate cyclase inhibitors, but all other AVP releasers were blocked. These data suggest that in addition to CRF, AVP release by IFN-α may also contribute to the activation of the hypothalamic pituitary axis. The ability of TGF-β1 to diminish the AVP and CRF released by ACh could mediate some of this cytokine's capacity to rescue damaged neurons. The extension of these neurotransmitter-cytokine interactions to the amygdala may provide an additional basis for interactions between neuronal and immune systems. (supported by grant MH 47680).

LOCAL LYMPH NODE APPLICATION OF 6-HYDROXYDOPAMINE (6-OHDA) DENERVATES LYMPHOID ORGANS WHILE SPARING INNERVATION TO THE JOINTS: A MODEL FOR STUDYING NEURAL-IMMUNE INTERACTIONS IN EXPERIMENTAL ARTHRITIS (EA). D. Lorton*, D.L. Bellinger, S.Y. Felten, and D.L. Felten. Hoover Arthritis Research Center, Sun Health Research Institute, Sun City, AZ 85351 and Dept. of Neurobiol. and Anat., Univ. of Rochester Sch. of Med., Rochester, NY 14642.

Numerous studies document that NE can modulate chronic inflammatory responses and joint destruction associated with rheumatoid arthritis (RA). These studies have employed systemic methods of NA denervation which denervate several potential sites where NE may act, including the joints and lymphoid organs. We propose that NA innervation is playing a dual role: modulating the severity of RA by innervation of 1) the joints and 2) the lymphoid organs. We have developed a model to explore the role of NA innervation of lymphoid organs in the development of EA.

The fatpads that sequester the popliteal and inguinal lymph nodes (PLN and ILN, respectively) were isolated on each side of eight male Lewis rats, and two 4 μl injections of 6-OHDA (150 μg/ml sterile saline plus 0.1% ascorbic acid) or vehicle were administered 10 minutes apart into each fatpad. Lymph nodes (LN), spleen, sciatic nerve and heart were taken 1, 5, and 14 days following localized 6-OHDA injection and NE content was determined using HPLC to quantitate levels of NE. By one day following local 6-OHDA application into ILN and PLN, NE levels were reduced by approximately 87% and 82% compared to control values, respectively. Reduced ILN and PLN NE levels persisted over the fourteen day time period. In contrast, LN application of 6-OHDA did not significantly reduce NE concentration in the sciatic nerve. The local 6-OHDA injection did, however, result in a significant reduction of NE content in the spleen and heart over fourteen days. Thus, local ILN and PLN application of 6-OHDA reduced NE levels in the relevant LN and spleen, and spared the NE innervation of the hindlimbs. This method of denervation will be a useful model for dissecting out the functional role of NA innervation of lymphoid organs versus the joints in the onset and progression of EA.

814.6

SYMPATHETIC NORADRENERGIC INNERVATION OF SPLEEN, THYMUS AND MESENTERIC LYMPH NODES (MLN): A COMPARISON BETWEEN SPRAGUE-DAWLEY, LEWIS AND FISCHER 344 RATS. S.S. Dimitrova, S.Y. Felten and D.L. Felten*. Department of Neurobiology and Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642

Primary and secondary lymphoid organs are innervated by sympathetic postganglionic noradrenergic (NA) nerve fibers. We have shown that the NA nerves in the spleens of Fischer 344 (F344) rats progressively decline with age, paralleled by an age-related decline in cell-mediated immunity. The histocompatible inbred Lewis (LEW) strain is susceptible to autoimmune disorders and shows exacerbated autoimmune reactivity following sympathectomy. This study was undertaken to compare the NA innervation of spleen, thymus and MLNs in young adult, male and female, F344, LEW and Sprague-Dawley (SD) rats, using anatomical and neurochemical assessment. Both strain and sex effects were observed in splenic innervation. LEW rats have higher NE concentration than both SD and F344 rats. NE concentration is higher in females of all strains compared to males. The F344 strain has lower total NE content in spleen than each of the other two strains, but no male/female differences were noted. The distribution of NA nerve fibers in the spleens of the three strains was similar and followed the compartmentation reported previously. The density of innervation correlated well with the neurochemical analysis (SD>LEW>F344). In the thymus, total NE was greater in LEW than F344 rats. No sex differences were found. In the MLN, the NE concentration in the SD strain is higher than in F344; for total NE content, SD>LEW>F344.

This study demonstrates that male F344 rats have the most sparsely innervated spleens, the lowest NE concentration in spleen and MLN, and the lowest NE content in the lymphoid organs examined. This observation may be important for interpreting aging studies in rodents, where the male F344 rat is the single best available model at present. The more dense NE innervation of secondary lymphoid organs in LEW rats may be important in the regulation of autoimmune reactivity. (Supported by R37 MH 42076 and a Markey Charitable Trust Award).

NGF MODULATES SYMPATHETIC INNERVATION OF LYMPHOID TISSUES. Sonia L. Carlson*, Kathryn M. Albers[§], Daniel J. Beiting, Mark Parish, James M. Conner[†], & Brian M. Davis. Dept. of Anatomy and Neurobiology & [§]Dept. of Pathology, Univ. of Kentucky College of Medicine, Lexington, KY 40536-0084 and [†]Dept. of Biology, Univ. of California, San Diego, La Jolla, CA 92093-0601

Immune tissues are known to be innervated by the sympathetic nervous system, but little is known of what directs the innervation to specific tissue compartments. We have examined the sympathetic innervation of immune tissues in transgenic mice that overexpress nerve growth factor (NGF) in skin and other epithelial structures. NGF transgenic mice exhibited dramatic hyperinnervation in the splenic marginal zone, and the medulla and capsule of peripheral lymph nodes. In contrast, the transgenic mesenteric lymph nodes showed no hyperinnervation. This difference correlated with the location of these nodes; peripheral lymph nodes drain skin where the transgene was expressed while mesenteric lymph nodes drain non-transgene expressing structures. In addition, the level of innervation correlated with the level of NGF peptide content as assayed by ELISA and immunocytochemistry. RT-PCR showed that the NGF transgene was not being expressed in the immune tissues, suggesting that immune tissues can concentrate transgene-produced NGF. In addition, the change in innervation had functional consequences. The mitogen response to concanavalin A (Con A) by spleen cells was decreased in the transgenics suggesting that elevated catecholamines or NGF can modulate the proliferative response of these cells. These mice demonstrate that NGF can modulate the sympathetic innervation and function of the immune system. Supported by MH48644 to SLC and NS31826 to BMD & KMA.

ROLE OF PROTEOLYTIC ENZYMES AND PLASMA INHIBITORS IN CONTROLLING OPIOID PEPTIDES-MEDIATED IMMUNOMODULATION. L. Bongiorno-Borbone*, A. Urbani, M. Marini, L. G. Roda. Dept. Medicina Sperimentale, Universita' "Tor Vergata", 00133 Roma, Italy.

Circulating immunocompetent cells release soluble proteolyses active in degrading peptides of limited molecular size, notably opioid peptides. Together with soluble plasma enzymes and with those embedded in the membrane of immunocompetent cells, these enzymes regulate the active concentration of neuromodulatory-active plasma peptides. The proteolytic activity of immunocompetent cells is controlled by stimulation: in stimulated PBMC, both the release of soluble enzymes and the enzymes exhibited by the cells' membrane are increased (Bongiorno, L., Marini, M., Urbani, A., Ausiello, C.M. & Roda, L.G. (1993) Int. J. Immunopharmac. 15:621-629). In addition, stimulation modifies the ratio between the three classes of enzymes involved in enkephalins' hydrolysis: aminopeptidases, dipeptidylaminopeptidases and dipeptidylcarboxypeptidases. The activity of all soluble plasma enzymes is controlled by the proteolysis inhibitors present in this tissue (Bolacchi, F., Marini, M., Urbani. A. & Roda, L.G. Neurochem. Res., in press). It moreover seems likely that the direction and intensity of the peptide-mediated neuroimmune interactions is modulated by the immune system activation as well. The interactions of these factors have been studied with the specific aim of ascertaining the role of proteolytic enzymes and of their inhibitors in the regulative processing of plasma peptides, specifically of opioid peptides. The role of proteases and of their inhibitors has been studied in cultured lymphoid cell lines liable to stimulation, antigen-specific clones of immunocompetent cells and human volunteers. Results obtained indicate that the variations of hydrolysis measurable under different conditions are controlled by variations of both the population of the enzymes released by immunocompetent cells and of the plasma inhibitors. These results can be interpreted as indicating that plasma inhibitors play a role in controlling the short-term variations of neuropeptides hydrolysis evidenced in response to changes in the environmental parameters (e.g. Shulteis, G. & Martinez, J.L., Jr. (1993) Peptides 14:161-167).

BOTH BRAIN AND LYMPHOCYTE DERIVED β-ENDORPHIN EXERT IMMUNOSUPPRESSION. P.Sacerdote*, B.Manfredi and A.E. Panerai. Dept.Pharmacology, University of Milan, Milano, Italy.

We previously showed that the opioid receptor antagonists naloxone and naltrexone enhance the proliferative responses of human and rat lymphocytes (1). In the present study we wanted to evaluate the role of central, pituitary and immunocyte-derived β-endorphin (BE) in the inhibitory effect of the peptide on splenocyte proliferation in the rat. The intracerebroventricular (icv) administration of BE (1,5,10 ng/rat) induced a significant inhibition of PHA induced proliferation, while the icv administration of an anti BE antiserum potentiated the response. Also the intravenous (iv) injection of the BE antiserum induced an increase of splenocyte proliferation. Since the pituitary can be considered the major source of circulating BE, in order to verify the effect of immunocyte derived BE we evaluated the effect of the administration of the i.v. antiserum in hypophysectomized rats. In these animals the BE antiserum is still able to enhance the splenocyte proliferation. Our data suggest that BE exerts a tonic inhibitory effect on proliferation acting both centrally and peripherally, where immunocyte derived BE can inhibit proliferation throughout a paracrine/autocrine mechanism.

ROLE OF NOREPHINEPHRINE IN ANTIBODY PRODUCTION: SUPPRESSED IgG PRODUCTION IN EPILEPSY-PRONE MICE. Julia M. Green-Johnson[1], Steve Zalcman[2], Catherine Y. Vriend, Svetlana Dolina, Dwight M. Nance and Arnold H. Greenberg. The Manitoba Institute of Cell Biology and Dept. of Pathology, University of Manitoba, Winnipeg, MB, R3E 0V9; [1]Biology Dept, Acadia University, Wolfville, NS. B0P 1X0[2] Center for Studies in Behavioural Neurobiology, Concordia University, Montreal, PQ. H3G 1M8.

To determine whether chronic neurochemical alterations could influence antibody production, the responses of two substrains of Balb/c mice [Epilepsy Prone (EP) and Epilepsy Resistant (ER)] to immunization with sheep red blood cells (SRBC) were examined. Significant differences in levels of SRBC-specific IgG were found between the two substrains. In addition, significant differences in splenic NE levels between the two substrains were observed, in both non-immunized and in immunized mice at several time points after immunization. The EP substrain showed elevated splenic NE levels and suppressed IgG production relative to the ER substrain. Treatment of ER mice with the β_2 adrenergic agonist (β_2AR) terbutaline on days 4, 5 and 6 after immunization resulted in a significant decrease in IgG production relative to saline treated controls. This suggests that elevated splenic NE acting through β_2AR is capable of mediating the suppression of the IgG response as seen in the EP strain. Taken together with previous studies indicating that the effect of elevated NE at the initiation of the immune response can have an enhancing effect on antibody production, these data suggest a dual role for NE in the immune response.

MURINE ANTI-NEURONAL IgG AUTOANTIBODIES ALTER ION CHANNEL CURRENTS OF NEUROBLASTOMA CELLS. J.Crimando, K.Cooper, and S.A.Hoffman* Ariz. St. Univ. Tempe AZ 85281.

Neurobehavioral manifestations in both human and murine models of systemic lupus erythematosus (SLE) have been correlated to diverse brain-reactive autoantibodies (BRAA). It is suggested that subsets of BRAA, especially IgG, bind to neuronal surface components and alter specific functions which may lead to some of these deficits. Using a natural murine models of SLE, we examined whether monoclonal IgG BRAA and anti-neuronal IgG autoantibodies from sera are capable of altering voltage-gated sodium (Na^+) and potassium (K^+) channel currents of neuroblastoma NBP_2 cells. Monoclonal IgG BRAA produced from a 2 mo. BXSB mouse bound brain membrane antigens of 58, 32, and 30kD, a 105kD NBP_2 membrane antigen, and reacted against neuronal cell bodies in cortex, hippocampus, and hypothalamus. Cultured NBP_2 cells were incubated with the monoclonal BRAA or anti-neuronal IgG for two hours. Inward Na^+ and outward rectifying K^+ currents were analysed by whole-cell patch-clamp recording. Though the monoclonal IgG BRAA did not affect these currents, one of the six samples of autoimmune IgG from BXSB sera did inhibit inward currents by 65% ($P<0.001$) compared to controls, while outward currents were unaffected. This demonstrates that subsets of anti-neuronal IgG exist which have specific functional effects on neuronal cells. These are hypothesized to be significant in the pathogenesis of immune-mediated neurobehavioral involvement in immunologic disorders.

THE EFFECTS OF SEX AND ESTROUS PHASE ON SURGERY-INDUCED INCREASES IN TUMOR CELL RETENTION AND ITS ATTENUATION BY MORPHINE G.G. Page*, S.A. Boun and S. Ben-Eliyahu. Ohio State Univ. College of Nursing, Columbus, OH 43210.

The vast majority of studies investigating the effects of surgery on immunity and tumor metastasis have used male subjects. We recently reported that morphine attenuates the metastatic-enhancing effects of surgery in male F344 rats. Given the differing hormonal environments between females and males and recent findings indicating that females in proestrus/estrus (PE, high estrogen levels) are more susceptible to tumor metastasis than are females in diestrus (Di), these studies explored whether there were sex- or estrous-related differences in the metastatic-enhancing effects of surgery and in the effectiveness of morphine in attenuating this outcome. A mammary adenocarcinoma cell line, MADB106, syngeneic to the F344 rat was used. MADB106 cells metastasize only in the lungs, a process known to be controlled by natural killer cells. In Exp 1, females in PE or Di and males were randomly assigned to the surgery (standard abdominal laparotomy under halothane anesthesia), anesthesia only, or control group. In Exp 2, PE or Di females and males were either subjected to abdominal surgery with anesthesia or anesthesia alone, and were either treated or not with morphine (pre- and postoperatively in saline or a slow release suspension, respectively). Radiolabeled MADB106 cells were injected i.v. 5 h after surgery and lungs were removed 13 h later to assess their radioactive content. Surgery resulted in a 3-fold increase in tumor cell retention in all 3 sex/estrous groups, an effect that was additive to the above-mentioned differences observed in the PE vs Di females in both the anesthesia only and control groups. This finding may have important implications in the timing of surgical interventions for breast cancer. Morphine administration similarly benefitted the males and females, evidenced by a significant interaction between the effects of surgery and of morphine. Supported by the Oncology Nursing Society and NIH grant NR03829.

EFFECT OF CAPSAICIN INTRAPERITONEAL ADMINISTRATION ON MESENTERIC AND PERITONEAL MAST CELLS. Y.H. Wang, J.Y. Wei and V.L.W. Go , A. Scheibel Brain Res Inst and CURE/Gastroenteric Biol Ctr, UCLA Los Angeles, CA 90024-1782.

Using video imaging and vital fluorescent probes to visualized mast cell's activation (NeuroImage 1:313-324, 1994) we have reported that electrical stimulation of splanchnic nerve activated mesenteric mast cells (MeMCs) (Neurosci Abst 20:052, 1994) and that capsaicin-sensitive splanchnic afferents is important for the action (Gastroenterology 1995, in press). Topical application of low dose capsaicin has been used to selectively excite the sensory terminals of thin primary afferents (Pharmacol Rev 43:147-148, 1991). Aim: to further determine the effect of capsaicin i.p. administration on the MeMCs and peritoneal mast cells (PMCs). Sulforhodamine B (200 μg/ml with capsaicin 5 X 10^{-5} M, 20 ml) was i.p. injected into urethane anesthetized rats and kept in situ for 20 min. Laparotomy was performed, pieces of mesentery were mounted on teflon tambours for MeMC examination and peritoneal lavage was harvested for PMC. Images of MeMCs (n=18 to 87, median 45.5 cells) were randomly captured from each tambour, and PMCs (n=50 to 138, median 72 cells) from dish. For each experiment the stained cells of two tambours and two dishes were counted, normalized and expressed as mean $\pm$ SD%. Data from three vehicle experiments were compared to three experimental trials. Results: capsaicin i.p. activated 76 $\pm$ 5.7% MeMCs as compared to 10.1 $\pm$ 4.3% N=6 vehicle trials ($p < 0.001$ two-tailed paired t test), whereas for PMCs the activated cell number is 9.7 $\pm$ 2.2% vs 10.6 $\pm$ 4.8% N=6 ($p > 0.7$ two-tailed paired t-test). The results indicated that capsaicin (5 X 10^{-5}) i.p. activated MeMCs but not PMCs, suggesting the important of neural element involvement in the effect. Neuropeptides leading to MeMC activation are further investigated. (Supported by NIH Grant NS 28433)

EXPRESSION OF NITRIC OXIDE SYNTHASE TYPE II IN THE SPINAL CORD UNDER CONDITIONS PRODUCING THERMAL HYPERALGESIA. D. Grzybicki*, A. Loihl, S. Kardos, G. Gebhart and S. Murphy. Depts. of Pharmacology and Pathology*, Univ. of Iowa, Iowa City, IA 52242.

Peripheral tissue injury or nerve damage result in a thermal hyperalgesia believed to be mediated via the production of nitric oxide (NO). Attention is on NO derived from Type I NO synthase (NOS) but sustained production of NO via the NOS II isoform may be involved in the mediation of a transient thermal hyperalgesia produced in rats after intrathecal administration of proinflammatory cytokines.

Male Sprague Dawley rats with an intrathecal sterile catheter were infused with IL-1β (10 ng) and IFN-γ (1000 U) and then sacrificed at various times. Segments of spinal cord (1 cm) centered around the lumbar enlargement were excised. Expression of NOS II mRNA was detected by RT-PCR and confirmed by ribonuclease protection assay. Western blotting revealed NOS II protein at 4 and 8 hours after cytokine injection. Expression was scattered diffusely throughout gray and white matter in cells which morphologically represent perivascular macrophages and/or vascular cells, glia, and small neurons. Immunohistochemical studies are in progress to identify these cells. There was no evidence of gliosis or infiltration by macrophages.

We conclude that endogenous cells in the CNS can be induced *in vivo* to express NOS II and that its expression in the spinal cord may play a role in transient thermal hyperalgesia. Supported by NS29226.

INTERLEUKIN-1ß INHIBITS *IN VIVO* AND *IN VITRO* ß-ENDORPHIN SECRETION FROM HYPOTHALAMIC NEURONS BY ACTIVATING NITROUS OXIDE SYNTHASE. N. Boyadjieva, A. Dey, S.J. Fung* and D.K. Sarkar. Dept. of Veterinary and Comparative Anatomy, Pharmacology and Physiology, Washington State University, Pullman, WA 99164-6520.

Interleukin-1ß (IL-1ß) is localized in the hypothalamus and responds positively after endotoxine administration. IL-1ß positive neuronal terminal fields included those in the arcuate nucleus. Since the arcuate nucleus contains a large population of ß-endorphin (ß-EP) neurons, we determined the effect of IL-1ß on *in vitro* and *in vivo* release of ß-EP from these neurons. Furthermore, the role of nitrous oxide synthase in the IL-1ß-regulated ß-EP secretion is determined, because nitrous oxide, which is produced by this enzyme, has been shown to mediate IL-1ß actions on various hypothalamic neuropeptides. *In vitro* release of ß-EP was studied using primary cultures of rat fetal mediobasal hypothalamic cells. IL-1ß concentration-dependently decreased the release of ß-EP from the cultured neurons. The inhibitory effect of IL-1ß was completely prevented by a nitrous oxide synthase blocker L-NAME. The blocker alone caused an increase in basal release of ß-EP from the cultured hypothalamic neurons. In agreement with these findings, IL-1ß and L-NAME significantly altered hypothalamic ß-EP release into the blood of pituitary portal vessels in ovariectomized rats. IL-1ß inhibited while L-NAME increased ß-EP levels in the blood of pituitary portal vessels. L-NAME also prevented the inhibitory effect of IL-1ß on pituitary portal blood levels of ß-EP. These data suggest that IL-1ß and nitrous oxide may interact to regulate ß-EP secretion from the hypothalamus. Supported by the National Institutes of Health Grant AA08757.

POTENTIATION OF CYTOKINE-INDUCED NITRIC OXIDE SYNTHASE ACTIVITY BY cAMP IN D30 MURINE ASTROCYTES. K.L. Burgher*, J. A. Heroux, and G. E. Ringheim, Neuroscience Product Group Unit, Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ 08876.

The effects of cyclic nucleotides on the expression of the inducible nitric oxide synthase (i-NOS) were investigated using an immortal astrocyte cell line (D30) derived from the mouse cerebellum. The expression of i-NOS activity from these cells was dependent upon co-stimulation with interleukin-1β (IL-1β) and interferon-γ (IFN-γ), and was not induced by either cytokine alone. The induction of i-NOS mRNA over basal levels was not apparent until 24 h and remained elevated out to at least 72 h. Accumulation of nitrite in the media from stimulated i-NOS activity was significant versus control cells by 48 h and continued to increase out to the latest time tested (72 h). Co-stimulation with 8-bromo-cyclic GMP (100 nM-100μM) alone or in combination with IL-1β and/or IFN-γ did not have any affect on the levels of i-NOS activity. Similarly, the addition of 8-bromo cyclic AMP (8-Br-cAMP), alone or in the presence of IL-1β or IFN-γ, did not result in detectable increases of i-NOS activity. In the presence of both IL-1β and IFN-γ, however, 8-Br-cAMP increased both enzyme activity and mRNA levels. The potentiation of i-NOS activity observed from co-stimulation with IL-1β and IFN-γ, either in the absence or presence of 8-Br-cAMP, was inhibited by preincubating the cells with L-N^5-(1-iminoethyl)ornithine, an irreversible i-NOS inhibitor. These results indicate that cAMP-mediated processes can synergize with cytokines to stimulate i-NOS expression in astrocytes. Moreover, since the requirement for either IL-1β and IFN-γ was not replaced by 8-Br-cAMP, additional signal transduction pathways are likely involved in the IL-1β and IFN-γ induced i-NOS expression.

IMPROVED PROCEDURE FOR IDENTIFYING NERVE FIBERS AND INDUCIBLE NITRIC OXIDE SYNTHASE IN RAT SPLEEN. J.C. Meltzer*, P.C. Grimm, A.Jansen, A.H. Greenberg, and D.M. Nance. Depts. of Anatomy, Pathology, Pediatrics, and Manitoba Inst. of Cell Biol., Univ. of Manitoba, Winnipeg, MB R3E 0W3.

Neuroimmune studies have demonstrated a critical role for the sympathetic innervation of the spleen as well as norepinephrine (NE) and neuropeptide Y (NPY) in modulating splenic immune function. As part of our analysis of neural regulation of splenic macrophage function, we have found that endogenous peroxidase activity (EPA) often precluded application of PAP immunohistochemistry to immune organs. We report procedures to reduce EPA and offer alternatives based upon alkaline phosphatase (AP) or Cy3 immunofluorescent detection systems. Rats were given splenic nerve cuts or sham surgeries and injected i.v. with saline or endotoxin and sacrificed at various intervals. Sections were digested with proteinase K (PK), placed in antibodies to the NE-synthesizing enzymes DBH and TH, NPY or inducible nitric oxide synthase (iNOS), and then developed with the various detection systems. Results indicated that protein digestion with PK increased the intensity and quantitiy of immunostaining and splenic nerve cuts eliminated TH, DBH and NPY fibers. Sensitivity with PAP, AP and Cy3 were similar for fiber staining, but EPA impeded interpretation of cellular iNOS staining induced by endotoxin. Thus, PK can be a valuable tool for antigen unmasking and AP and Cy3 offer an alternative detection system for organs with high levels of EPA such as the spleen. Supported by the MRC of Canada and the NIMH.

815.1

STATIC FORCE REPRESENTATION BY THE POPULATIONS OF MOTOR CORTICAL NEURONS IN THE JOINT-RELATED COORDINATE SYSTEMS.

S. Tanaka*. Dept. of Electrical Eng., Sophia Univ., Tokyo 102, Japan

Dynamics representation in the motor cortex has long been suggested. Experiments by Kalaska et al. (J Neurosci 1989) provided deeper insights into the relations of the activities of motor cortical neurons to dynamics parameters. The objective of the present research is to investigate theoretically static force representation in the motor cortex. In order to do it, the descending circuit from the motor cortex to the spinal cord is modelled, which relates the population activity of M1 pyramidal cells to that of motor neurons. The activities of the cortical neurons are modulated sinusoidally by the direction of static force represented in the intrapersonal, joint-related coordinate system (Tanaka, NSL 1994). The major consequences of the present theory are: (a) The populations of M1 cells code static force of the arm; (b) The direction of the force is coded distributedly throughout the whole populations; (c) The magnitude of the force is regulated by changing the depth of modulation of the activities of the M1 pyramidal cells; (d) The descending circuit transforms the static force coded in the motor cortex into static joint torques, which are coded by paired motoneuron pools in the spinal cord; (e) Change of the static joint torques with the postural change of the arm is provided by changing the activities of the pyramidal cells, rather than by changing the synaptic strengths of the neuronal circuit; (f) A substantial proportion (but not more than half) of the pyramidal cells has negative correlation with the static force, which was observed in experiments (for example Maier et al., J Neurophysiol 1993).

815.2

DISCRIMINATION AND CORRELATION OF EEG BRAIN ACTIVITY WITH STATIC TORQUE EXERTIONS IN THE UPPER EXTREMITY OF HUMAN SUBJECTS. J.P.A. Dewald*, A.L. Ricamato and J.D. Given. SMPP, Rehab. Inst. of Chicago, and Dept. of PM&R, Northwestern University Medical School, Chicago, Il.

We have combined EEG and EMG recordings during mechanically controlled static torque exertions in specific directions for the investigation of muscle synergies in the upper extremity of three subjects. Analysis of resulting spatial EMG profiles have shown that consistent muscle coactivation patterns exist across subjects. This work investigates the existence of similar distinct spatial organization at the level of the brain.

Subjects were seated with their wrist casted to a 6 degrees of freedom (D.O.F) load cell which measured the respective elbow and shoulder torques. Subjects were trained to produce elbow and shoulder torque ramps of 2 seconds duration followed by a 1.5 sec steady state hold using visual torque feedback. Four target directions, spaced apart by 90° and corresponding to elbow flexion-extension and shoulder abduction-adduction torques, were used in our paradigm. EMGs were recorded from 2 elbow and 6 shoulder muscles using surface electrodes. EEG signals were recorded from a total of 120 electrodes placed in a cap on the subject's head. The head and EEG electrode placements were digitized to permit additional EEG analysis. 80-100 trials of recorded EEG epochs were first aligned using either EMG or torque onsets and then ensemble averaged for each direction yielding SNR's > 15.

Alignment of EEG epochs using EMG onsets produced erroneous shifts of up to 200 ms between peak EEG motor potentials. These shifts disappeared when EEG ensemble averaging was realized using torque onsets. A comparison of subject specific 3D voltage maps, constructed from ensemble averaged EEG data and recorded head and EEG electrode 3D coordinates, showed differences in topographic brain activity as a function of target direction. However, for the same subject, topographical brain activity was consistent when repeating the same target direction.

These results indicate that ensemble averaging of EEG motor potentials is best achieved using torque onsets since torque provides the best measure of total motor output of the shoulder-elbow system. Furthermore, 3D voltage maps do indicate differences in brain mapping as a function of torque direction. This may indicate differences in topographical organization at the level of the brain prior to and at the start of the execution of different muscle synergies in the upper extremity. CELL ACTIVITY IN MONKEY DORSAL PREMOTOR (PMd) AND PARIETAL AREA 5 CORTEX ARE ALTERED BY CHANGES IN ARM POSTURE FOR MOVEMENTS WITH SIMILAR HAND TRAJECTORIES. S.H. Scott, L.E. Sergio* & J.F. Kalaska. CRSN, Dépt. de Physiologie, Univ. de Montréal, Montréal, PQ, CANADA H3C 3J7

We have shown previously that neuronal activity in monkey primary motor cortex (M1) is altered by changes in arm posture for movements with similar hand trajectories (Scott & Kalaska, Neurosci. Abst. 20:982, 1994). The present study tested the effect of arm posture on cell activity in parietal area 5 (A5) and dorsal premotor (PMd) cortex. We trained two monkeys to move a pendulum-like handle to visual targets using two different arm postures- the 'natural' posture in the sagittal plane, and abducted approximately 80° into the horizontal plane in order to grasp and move the handle. The two arm postures changed the mechanical state (i.e. length and EMG activity) of muscles that span the shoulder and elbow joints. In both postures, the hand position remained at shoulder height. In both cortical areas, the activity of individual cells was usually not identical in the two postures. Tonic cell activity often significantly increased or decreased (PMd: 100/169 cells; A5: 45/80; M1: 390/539; F-test, $p<0.05$). The direction tuning of cells also often changed (PMd: 117/169; A5: 65/80; M1: 458/539; F-test, $p<0.05$) and the mean change in direction was less in PMd (22.6°) than in A5 (42.1°) or M1 (42.5°). Overall, the effect of arm posture was less for cells in PMd than in A5, and both these areas were less affected when compared to M1 or to mathematical models based on intrinsic movement attributes. MAPPING MOTOR CORTEX OUTPUT ZONES WITH STIMULUS TRIGGERED AVERAGING OF EMG ACTIVITY: DISTAL AND PROXIMAL FORELIMB MUSCLE REPRESENTATIONS IN THE RHESUS MONKEY. JH Karrer*, BJ McKiernan, J Marcario, A Belhaj Saïf and PD Cheney Physiology Dept & Smith MRRC, Univ Kansas Medical Center, Kansas City, KS 66160

Using repetitive ICMS (intracranial microstimulation with high frequency trains) to evoke movements or EMG activity, others have reported significant areas of overlap in MI output zones representing distal and proximal muscles (e.g., Donoghue et al., Exp. Brain. Res. 89: 1, 1992). Such zones of overlap may serve as substrates for activation of functional muscle synergies underlying coordinated multi-joint movements. The goal of this study was to apply a more sensitive output mapping method – stimulus triggered averaging of EMG activity – to identity MI zones representing distal and proximal forelimb muscles. Two rhesus macaques were trained to perform two motor tasks: 1) a reaching and prehension task, and 2) a targeted push pull task. Averages of rectified EMG activity were computed from individual microstimuli (10-20 μA, 10-20 Hz) delivered to MI cortex in penetrations placed at 0.5 mm spacing. EMG activity was recorded from a total of 22 forelimb muscles including 11 proximal muscles (5 shoulder, 6 elbow) and 11 distal muscles (4 wrist, 5 forearm digit and 2 intrinsic hand muscles). Of the 728 stimulation sites tested, 464 produced effects in one or more of the target muscles. Of these sites, 157 produced effects exclusively in proximal muscles, 193 exclusively in distal muscles and 114 in both distal and proximal muscles. Consistent features were observed in MI output maps confirming work of others (Strick and Preston J. Neurophysiol. 48: 139,1982; Kwan et al., J.Neurophysiol. 41: 1120,1987). A primary distal output zone formed a central core that was surrounded medially, rostrally, and laterally by a horseshoe shaped proximal muscle representation. The medial arm of the proximal muscle representation showed overlap with the primary distal muscle representation. We conclude that stimulus triggered averaging of EMG is a sensitive method that can be used to map both excitatory and inhibitory zones in MI. Supported by NINDS grant #552096.

INPUT-OUTPUT PROPERTIES AND CHANGES OF RECRUITMENT GAIN OF THE CORTICOSPINAL PATHWAY. H. Devanne, B. A. Lavoie and C. Capaday*. Centre de Recherche en Neurobiologie, Université Laval, Québec, (Qc), Canada, G1J 1Z4.

Experiments were done to determine the form of the input-output relation of the corticospinal pathway to the motoneuron pools of the first dorsal interosseus (FDI) and the tibialis anterior (TA), respectively. The motor cortex was excited by focal transcranial magnetic stimuli (TCM). In both muscles the form of the input-output relation (i.e. stimulus intensity vs. response amplitude) was sigmoidal. The steepness of the relation increased whereas the threshold decreased with increasing tonic background activation up to about 30-40% of the maximum tonic effort. The plateau level was not influenced by the background activation level, except that it could not be reached when no background activity was present. This was probably due to the limitation of the stimulator maximum output. However, this finding may reflect a change in the intrinsic excitability of the motor cortex in going from rest to activity, or that convergent inputs from different descending systems are required for maximal activation of motoneuron pools. The sigmoidal input-output relation implies that the amount of facilitation or inhibition of a test EMR is a function of the test EMR amplitude and that in fact there is no range over which the amount of facilitation or inhibition is either constant, or relatively so, as has been suggested for monosynaptic spinal reflexes (see Crone et al., Exp. Brain Res., 81:35-45, 1990). The increase of the steepness of the relation with the background level of activity demonstrates that the recruitment gain (Kernell and Hultborn, Brain Res., 507:176-179, 1990) of the motoneuron pool changes as a function of the recruitment level even for the same qualitative task. This implies that adjustment of the stimulus intensity to compensate for the effect of changes of the background activity on EMR amplitude is not a valid procedure to insure that the amount of facilitation or inhibition be independent of the test EMR amplitude.

MODULATION OF NEURONAL ACTIVITY IN THE PRIMARY MOTOR CORTEX DURING PASSIVE TEXTURE DISCRIMINATION IN THE AWAKE MONKEY. **W. Jiang* and C. E. Chapman. CRSN, Université de Montréal, Canada.**

Previous studies have shown that area 4 neurones can encode surface texture and it was suggested that such sensory information is important in the control of precision grip under different conditions. The present study investigated the sensory properties of area 4 neurones while a monkey discriminated a change in the texture of surfaces passively applied to the contralateral fingertips. The monkey was trained to discriminate a standard surface (raised dots, 2 mm spatial period (SP) over the entire length) from 3 other surfaces in which the SP was proportionally increased to 3, 4 or 5 mm over the second half (surfaces physically continuous). Following the presentation of each surface, the monkey indicated the presence or absence of the change in texture by, respectively, pulling or pushing a lever with the opposite hand to obtain a juice reward. 41 out of 53 neurones tested either had a receptive field (RF) that included the scanning digit tips (14 touch, 8 pressure, 9 joint) or were vigorously active during discrete movements involving the scanning digits yet had no RF (n=10). Overall, 37 of the 41 units showed increased discharge to the presentation of the textured surfaces (4 cells not modulated) during the discrimination task. Texture change-related discharge was seen in only 3/37 neurones in the task, and all 3 had a cutaneous RF. 6 of the remaining 34 units were also tested for texture-sensitivity outside the context of the task (monkey not working; distracted with random drops of juice). 2/6 units (both had a cutaneous RF) now displayed texture-related discharge. The results indicate that texture-related information is indeed relayed to area 4, but texture sensitivity can vary as a function of the context within which the surfaces are presented. Supported by the MRC and Université de Montréal.

IMPORTANCE OF STIMULUS INTENSITY ON THE TIME COURSE AND MAGNITUDE OF MOVEMENT-RELATED SUPPRESSION OF TACTILE DETECTION IN HUMANS. Williams S.R., Shenasa J. and Chapman C.E*, CRSN, Université de Montréal, Montréal, Québec, Canada, H3C 3J7

Much debate surrounds the relative merits of active and passive touch. Previous studies have shown that active movement is accompanied by a reduction in the transmission of tactile cutaneous inputs. In order to evaluate the effect of a simple active movement on tactile detection of low intensity cutaneous stimuli, perceptual performance was examined in humans during the execution of a motor task, abduction of the right index finger. Stimuli were delivered to the glabrous tip of the right index finger. The intensity of stimulation was initially set at a level where 90% of the stimuli were stimuli were perceived at rest (P_{90}, 32 subjects). Four other stimulation intensities (1.25X P_{90} , 1.5X P_{90}, 1.75X P_{90} and 2X P_{90}) were examined in separate blocks of trials for 10 of the subjects. Data from individual subjects were pooled and the time course and amplitude of any movement-related suppression of tactile perception was examined in relation to two peripheral events: the onset of movement and the onset of movement-related electromyographic (EMG) activity. The time at which the first significant decrease in perception occurred increased from 210 ms before movement onset (190 ms before EMG onset) with stimuli of intensity P_{90} to 10 ms before movement onset (30 ms after EMG onset) at intensity 2x P_{90}. The minimum proportion of stimuli detected during movement trials varied between 0% (complete abolition of stimulus detection) at intensity P_{90} and 87% at intensity 2X P_{90}. These results indicate that movement-related suppression of tactile detection is highly dependant on the intensity of the stimulus being detected. Movement strategies in active touch could be designed to take advantage of this effect by optimising the signal to noise ratio in conditions where there is a widespread increase in absolute detection threshold.

FUNCTIONAL CONNECTIVITY OF NEURONS IN THE SENSORY-MOTOR SYSTEM CHANGES DEPENDING ON THE PATTERNS OF VIBRISSAL MOVEMENTS IN RATS: ANALYSIS BY TIME DEPENDENT SCATTER DIAGRAMS. E. MIYASHITA[1]*, Y. HAMADA[2], M. OGURA[1] AND S. MORI[1]. [1]Lab. Neurobiol., Natl. Inst. Physiol. Sci., Okazaki, Aichi 444, Japan, [2]Lab. Neural Model., Fron. Res. Pro., RIKEN, Wako, Saitama 351-01, Japan

Functional connectivities among neurons in the rat vibrissal motor (MCx), sensory (SCx) cortices and the superior colliculus (SC) were studied in relation to the changes in patterns of vibrissal movements. In three rats, formvar-coated Nichrome wire electrodes (øout: 25 µm) were chronically implanted into the MCx, SCx and SC under ketamine hydrochloride anesthesia. After recovery from the anesthesia, multi-unit activities were recorded through these electrodes during sniffing movements of the vibrissae and during passive movements of them. Single unit activities were classified using a cluster cutting analysis. Functional connectivities of these units were analyzed by time dependent scatter diagrams (ref.: Y. Hamada et. al. in Brain Res. 660 (1994) 209–215). During sniffing movements of the vibrissae, both the neurons in the MCx and SCx had excitatory functional connectivities with neurons in the SC and the neurons in the MCx had inhibitory functional connectivities with the ones in the SCx. During passive movements of the vibrissae, both the neurons in the MCx and SCx had inhibitory functional connectivities with neurons in the SC and the neurons in the SCx had inhibitory functional connectivities with the ones in the MCx. These results suggest that the functional connectivities change depending on the behavioral states of the animals and the pattern of the changes is unique to a given behavioral state.

NEURONAL ACTIVITY IN MOTOR CORTEX OF CATS DURING THE PERFORMANCE OF FORELIMB MOVEMENTS. J.M. Criado*, A. de la Fuente, M. Heredia, A.S. Riolobos and J. Yajeya. Departamento de Fisiología y Farmacología, Universidad de Salamanca, Spain.

Findings from studies using recording from single neurons in awake animals, have revealed some specific functions for motor cortex. Our aim is to study the participation of motor cortex in different aspects of a voluntary movement. With this purpose, unitary activity has been recorded in motor cortex of cats previously trained in an associative conditioning. The process of conditioning consists in the presentation of an auditory stimulus (free field) with a random variable range of intensity (40dB, 70dB, or 100dB SPL). Three seconds later, the animal has access to the food by opening automatically a trap door. To eat, the cat must perform an extension movement of the forelimb followed by a flexion to get the food. Following this experimental protocol we studied the cellular discharge before and after the onset of movement of forelimb. Our results show that from twenty-eight cells tested, fifteen responded when the cat has the possibility to get the food. Onset latencies were in a great majority of cells circa 250 ms. Thirteen cells of them, keep their increased simple spike discharge during 1-2 sc, peaking circa one second after the trap door was opened. Also we have two cells which responses appeared before the opening of the trap. The results suggest two kinds of populations cells in motor cortex, ones related with voluntary movements and other with aspects related with the anticipation actions. (Supported by DGICYT Research Project PB 91-0421).

RETRODICTING SENSORY STIMULI AND PREDICTING MOTOR BEHAVIOR FROM NEURAL ACTIVITY

G. Gaál*, L.M. Kay and W.J. Freeman, University of California, Berkeley

Estimation of Jacobian matrices in nonlinear systems can be used to model visuomotor tasks and study population coding. Based on multiunit recordings in a visuomotor task from primate motor cortex, we developed a model for the task of reaching and tracking in a plane and showed how the model relates to recent population coding algorithms (Gaál, Physica D, 1995). Adaptive feedback control of joint angles of a three-joint arm was used. Visual error was combined with the transpose of the Jacobian matrix of the direct kinematic equation to determine the control signal. At first we simulated small movements at reference locations to estimate the Jacobian matrix. Then we estimated the matrix for simulated data by "reading off" changes in joint angles and x-y coordinate values of the hand from continuous simulated arm movement. In the present study, we apply the method of estimating Jacobian matrices for nonlinear functions of neural activity. We use "training" data sets recorded in an operant conditioning task from behaving rats. The rats presssed bars on olfactory cue for water reward (Kay and Freeman, Soc. Neurosci. Abstr., 1995). We then use the estimated matrices to retrodict sensory stimuli and predict behavior from "test" data sets.

SINGLE NEURON ACTIVITIES DURING A SENSORIMOTOR DECISION **J. Zhang*[1], A. Riehle[2], S. Kornblum[1] and J. Requin[2] Department of Psychology, University of Michigan, Ann Arbor[1] and Cognitive Neuroscience Lab, CNRS, Marseille, France[2]**

A monkey was trained to perform wrist extension/flexion movements to align a pointer with a visual target while single unit activities in primary motor cortex (MI) were being recorded. The stimuli consisted of colored LEDs presented either to the left or right of a central starting position. Depending on the color of the LED, the monkey had to point either directly at it (compatible condition), or at LED on the opposite side (incompatible condition). Compatible and incompatible trials were blocked during training sessions, and were randomized within blocks during recording sessions. Neuronal activities in the four types of correct trials (left/right x compatible/incompatible) was analysed to determine whether such activity was more related to stimulus side, response side, or the compatibility rule that maps one onto the other. A 3-D vector was constructed to orthogonally decompose the *pattern* of neuronal activity (across four trial types) into the sensory, motor, and rule aspects of the task. The direction of the vector is represented by a point on the unit sphere that describes the functional loci of the activity (whether related to stimulus, to response, to rule, or to the monkey's "decision"), while the length of the vector reflects the differential activity (i.e., variance) across trial types and therefore its task-relevance. For each neuron, the peak differential activity during a trial was identified along with its spherical (functional) locus. We find that the peak spherical loci of the recorded population (156 units) in MI are clustered and evolve from sensory -> "decision" -> motor "landmarks" as a trial progresses, reflecting the monkey's sensorimotor transition during a trial of the task.

CONDITIONING OF MONKEY MOTORCORTICAL UNIT BIDIRECTIONALITY BY COMPLEXITY OF TRAINING PROGRAM. SA Sahrmann*, MH Clare, TW Anderson, M Yamaguchi, EB Montgomery, Washington University School of Medicine, Physical Therapy Pgm, Neurology Dept, St. Louis, MO 63110.

Motor cortical neuron discharge patterns have been related to movement elements such as force and direction. The relationship of the training task to the discharge patterns has not been studied. In this study, units in animals performing a complex repertory of graded and reversal ankle forces were compared with units in animals performing a simpler set of fixed force and direction tasks. Four rhesus monkeys were trained to perform ankle isometric force tasks in response to signal lights indicating magnitude and direction of force. Two animals performed a complex set of 4 tasks involving large and small forces and reversals of force. Two monkeys performed a simple two task set of unidirectional large forces. Standard extracellular recording techniques were used to record from hindlimb motor cortical area. Related cells (667) had a significant increase in firing rate ($p<.01$) timed with the large force phase, from rest to dorsal (D) or to plantar (P). Chi square was used to assess significant increase in unit firing rate and the distribution of cell types classified as unidirectional (UNI), D or P, or bidirectional (BI) both. Monkeys trained with the complex schedule had a greater proportion of BI units than those with the simple repertory ($p<.001$). The uni/bi ratios for complex training were 148/107 (1.38) and for simple training 311/101 (3.07). The proportion of Bi units for the small force task (Uni, 82; Bi, 50; ratio = 1.64) was similar to that of the large force task in the complex trained monkeys.

EFFECT OF A VIRTUAL REALITY ILLUSION ON MOTOR CORTICAL POPULATION VECTORS DURING DRAWING. D.W. Moran, A. Kakavand and A.B. Schwartz*. Barrow Neurological Institute, 350 W. Thomas, Phoenix, Arizona 85013; The Neurosciences Institute, 10640 John J. Hopkins Drive, San Diego, California 92121.

A motor illusion paradigm in a virtual reality environment was used to ascertain the relationship between visual, movement, and cortical population trajectories. A rhesus monkey was outfitted with stereographic goggles and trained to draw computer generated objects in free space. The 3D position of the monkey's hand was tracked in real time and downloaded to a graphics workstation that generated a virtual representation of the monkey's hand (spherical cursor) as well as the desired object to be drawn. The drawing task required the monkey to trace five continuous revolutions of a computer-generated ellipse. During the first two revolutions, the ratio of movement gains in the medial/lateral and superior/inferior directions was unity. During the third revolution, the movement gain in the medial/lateral direction was quasistatically increased such that a 1.0 cm hand movement caused a visual displacement of 1.8 cm. Given that the ellipse had a major/minor axis ratio of 1.8, the monkey visually perceived an elliptical trajectory during the remaining revolutions while, kinematically, its hand was moving in a circle. During repeated drawing tasks, single-cell recordings were obtained from the contralateral primary motor area. A population vector trajectory was constructed and compared to both the visual and movement trajectories.

Preliminary results from the analysis of 130 primary motor cortical cells in one hemisphere showed that the population trajectory was elliptical during the unity gain portion of the task and circular when the gain changed. Therefore, the population trajectory always matched the hand's trajectory. This suggests that motor cortical activity encodes the actual hand trajectory instead of the perceived movement. Supported by NIH (NS 26375).

CODING OF TARGET MOTION AND HAND MOVEMENT PARAMETERS IN MOTOR CORTEX DURING TARGET INTERCEPTION. W. Kruse*, N. Lindman Port, A.P. Georgopoulos. Brain Sciences Center, VAMC, and Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55417

We recorded the activity of 380 cells in the arm area of the motor cortex while a monkey intercepted a moving target on a computer screen using a 2D articulated manipulandum. The target accelerated, decelerated or traveled at a constant velocity for 0.5, 1 or 1.5 s. A multiple linear regression was used to relate the ongoing cell activity to the evolving position, velocity and acceleration of the target and hand movement. Since the interception movement was always upwards, the trial-by-trial time course of cell discharge at time t, was expressed as a function of the y-component of position, velocity and acceleration of the target, at time $t+k$, and the hand, at time $t+l$, where k and l were independent time shifts (-120 to $+140$ ms). The R^2 was calculated for each 10 ms shift. We found that in 378/380 cells the regression model was statistical significant at the combination of shifts with the highest R^2 (median $R^2 = 0.149$). In practically all cells both target and hand effects were significant; in only 1/378 cells there was only a significant hand but not target effect, and in only 2/378 cells there was a significant target but no hand effect. These results indicate that the motor cortex processes dynamically time-varying information concerning both target and hand movement. The same analysis was performed between the average (across cells) target and hand movement parameters and the y-component of the time-varying neuronal population vector. The highest R^2 (0.951) was obtained at $k = -90$ ms and $l = +100$ ms. The regression coefficients for position and velocity of target and hand movement were statistically significant ($p<10^{-4}$) but not those for target or hand acceleration. These results indicate that the moving target exerts an ongoing, dynamic influence on population activity with a latency of 90 ms, and that, in turn, the neuronal population exerts an influence on the hand movement with a latency of 100 ms.

816.3

CODING OF MOVEMENT PARAMETERS IN MOTOR CORTEX AND AREA 5: A COMPARISON USING TIME SERIES, MULTIPLE REGRESSION ANALYSIS. A.P. Georgopoulos*, J. Ashe. Brain Sciences Center, VAMC, and Departments of Physiology and Neurology, University of Minnesota Medical School, Minneapolis, MN 55417

A multiple linear regression model has been used to relate the ongoing cell activity in motor cortex and parietal area 5 to evolving parameters of movement (position, velocity, acceleration, and target direction) during 2D arm movements (Ashe, J. and Georgopoulos, A.P., Cerebral Cortex 6: 590, 1994). In the model the trial-by-trial time course of cell discharge at time $t+\tau$, was expressed as a function of the XY components of the target direction (unit length vector), and position (m), velocity ($m.s^{-1}$) and acceleration ($m.s^{-2}$) of the hand at time t, where τ was a time shift (-200 to +200 ms). The R^2 was calculated for each 10 ms shift. The regression coefficients of the XY components of each parameter can be used to construct a resultant vector the length of which describes the magnitude of the relation between the cell activity ($imp.s^{-1}$) and the particular movement parameter for each cell. Here we present the results of this analysis for 290 cells in the motor cortex and 207 in area 5 at the time shift for which R^2 was highest. In motor cortex and area 5, respectively, the magnitude (mean$\pm$SEM) of these vectors for the different parameters were as follows: position (124.4 ± 5.91 vs. 112.7 ± 6.70), velocity (31.2 ± 1.82 vs. 29.4 ± 2.07), acceleration (3.6 ± 0.24 vs. 3.3 ± 0.23), and target direction (15.0 ± 0.75 vs. 12.6 ± 0.76). Of these comparisons only the last one (target direction) was statistically significant ($P<0.05$, t test). These results indicate that the processing of time-varying movement parameter information is very similar in the motor cortex and area 5, except for target direction which exerts a stronger effect on motor cortical than on area 5 cell activity. (Supported by VA and NIH grants).

816.4

SET-RELATED ACTIVITY IN THE DORSAL PREMOTOR AREA REFLECTS TARGET LOCATION RATHER THAN LIMB TRAJECTORY. L. Shen* and G.E. Alexander. Dept. of Neurology, Emory Univ. Sch. Med., Atlanta, GA 30322.

The dorsal premotor area has been implicated in the preparation for movement, but the precise contribution of this region to motor control processes remains unclear. Single neuron activity was sampled from the dorsal premotor area and from primary motor cortex in two macaque monkeys while the subjects performed a visually-instructed, delayed reaching task. Subjects used the right forelimb to move a joystick, whose position was reflected by a cursor presented on a video display in front of the animal. Direct vision of the limb was prevented by an occluding collar. Each trial began with the illumination of a fixation point in the center of the display. After the subject had aligned the cursor with the fixation point, four radially arranged peripheral targets were also illuminated. After a variable delay, the subject was instructed, by the brief dimming of the appropriate peripheral target, which of the four would be the "correct" target for that trial. A second variable delay then ensued until the fixation point dimmed, which served as the movement- triggering stimulus. At this point, the subject was required to align the cursor with the correct peripheral target by moving the joystick in the appropriate direction. The direction of the target (relative to the fixation point) was dissociated from that of the hand/limb trajectory by varying the spatial mapping between joystick and cursor. This made it possible to determine whether the set- related activity that preceded the movement to capture the peripheral target was preferentially related to the direction of the forthcoming hand/limb movement or to the spatial properties of the target. Of the dorsal premotor area neurons with directional, set-related activity, nearly all showed directional tuning that reflected the direction/location of the target rather than that of the hand's trajectory. In contrast, in primary motor cortex roughly one half of the neurons with directional, set-related activity showed directional tuning that reflected the hand's trajectory while the other half reflected the direction/location of the target.

PHASIC RESPONSES TO SENSORY CUES IN THE DORSAL PREMOTOR AREA REFLECT ABSTRACT FEATURES OF THE INSTRUCTED MOVEMENT RATHER THAN SPECIFIC DETAILS SUCH AS MOVEMENT TRAJECTORY. G.E. Alexander* and L. Shen. Dept. Neurology, Emory Univ., Atlanta, GA 30322.

Previous studies have shown that neurons in the dorsal premotor area may respond to visual cues that serve as instructions or as triggers for the guidance of limb movements. There is general agreement that these responses are strongly conditioned by the motor instructional content of the stimulus, so that a premotor neuron may respond differentially to the same physical stimulus when it serves as the instruction for two different motor acts. Here we present evidence that this conditioning effect is based on a relatively abstract representation of the movement, namely the goal of the movement, rather than specific details such as the intended limb trajectory. Single neuron activity was sampled from the dorsal premotor area in two macaque monkeys while the subjects performed a visually-instructed, delayed reaching task. On each trial, the subject moved a joystick to align a cursor with a central fixation point, at which time four peripheral targets were also illuminated. After a variable delay, one of the four peripheral targets dimmed briefly. This served as the subject's spatial cue, instructing which target would be the "correct" one for that trial. A second variable delay then ensued until the fixation point dimmed, which served as the movement-triggering stimulus. The subject then aligned the cursor with the correct peripheral target by moving the joystick in the appropriate direction. To dissociate the direction of the target from that of the limb's trajectory, we varied the spatial mapping between joystick and cursor. Phasic neuronal responses to the spatial cue, when directional, were always tuned to the direction of the target, rather than that of the instructed limb movement. Phasic responses to the trigger stimulus were often directional as well, even though this stimulus contained no directional information. Like the responses to the spatial cue, directional responses to the trigger stimulus were always tuned to the direction of the target and not to the direction of the limb movement itself.

REPRESENTING SPATIAL INFORMATION FOR LIMB MOVEMENT: ROLE OF AREA 5 IN THE MONKEY. E. Guigon, F. Lacquaniti, L. Bianchi, S. Ferraina, R. Caminiti* INSERM CREARE, UPMC, 75005 Paris, France; Istituto Scientifico S. Lucia, 00179 Rome, Italy; Istituto di Fisiologia Umana, Universita La Sapienza, 00185, Rome, Italy.

How is spatial information for limb movement encoded in the brain? Computational and psychophysical studies suggest that hand position at start, via-points and targets is specified relative to the body to afford a comparison between the sensory (e.g. kinesthetic) reafferences and the commands that generate limb movement. Here we propose that the superior parietal lobule (Brodmann area 5) might represent a substrat for a body-centered positional code. Monkeys made arm movements in different parts of three-dimensional space in a reaction-time task. We found that the activity of area 5 neurons can be related to either the starting point, the final point, or combinations of the two. Neural activity is monotonically tuned in a body-centered frame of reference, whose coordinates define the azimuth, elevation and distance of the hand. Each spatial coordinate tends to be encoded in a different subpopulation of neurons. This parcellation could be a neural correlate of the psychophysical observation that these spatial parameters are processed in parallel and largely independent of each other in man.

COMPARISON OF THE NEURONAL ACTIVITY IN SMA AND IN THE VENTRAL CINGULATE CORTEX DURING PREHENSION IN THE MONKEY. G.Cadoret* and A.M.Smith, C.R.S.N, University of Montreal, Quebec, Canada.

A total of 92 neurons in the cingulate cortex, and 115 neurons in SMA were found to be active in association with grasping and lifting in 2 *M.fascicularis* monkeys. Neurons in SMA were located in the medial wall, just caudal to the genu of the arcuate sulcus; neurons in the cingulate cortex were clustered in the ventral fundus of the cingulate sulcus caudal to the hand representation of SMA, in area 23c. The number of cells with proprioceptive fields was considerably higher than that of cells receiving cutaneous afferents in both the cingulate cortex (29:8) and the SMA (27:3). Hand movements could be evoked by ICMS at 8 recording sites in the cingulate cortex and at 12 sites in SMA. In the 2 samples of cells, the majority of the neurons increased their firing rate between 100 and 600 msec. before the grip onset, with the same distribution of onset times. The proportion of phasic cells observed in the 2 regions (62% in SMA and 65% in the cingulate cortex) was higher than in the motor cortex (52%). The proportion of phasic-tonic cells was lower in the cingulate cortex than in SMA. Force-pulse perturbations applied to the object during the holding phase elicited excitatory responses in 19% of the SMA neurons and 32% of the cingulate neurons, at a mean latency of 49 msec. in both groups of cells. No evidence of preparatory responses to the perturbation was found in the cingulate cortex, and only 5 cells in SMA exhibited a preparatory response. These results indicate that these 2 medial areas share some features and are involved in the sensorimotor control of the hand. However both regions seem to be insensitive to the preparatory grip force increases in anticipation of the perturbation. Supported by MRC of Canada.

DIFFERENTIAL INVOLVEMENT OF M1 AND A PREMOTOR AREA IN A MOTOR TASK. N. Picard*[1] and P.L. Strick[1,2]. [1]VAMC and [2]Depts. of Neurosurgery and Physiology, SUNY-HSC, Syracuse, NY 13210.

We examined activation of the cortical motor areas in monkeys performing motor tasks using the 2-deoxyglucose (2DG) method. Two monkeys were trained to perform remembered sequences of reaching movements for a juice reward (REM task). An additional two monkeys were trained on a Control task which required them to sit in a primate chair and lick juice rewards delivered at time intervals comparable to that of the REM task. Using serial sections spaced 90-100 μm apart, we generated flattened maps of 2DG uptake in motor areas located on the lateral surface and the medial wall of the hemisphere.

In animals performing the Control task, activation within the motor areas was largely confined to regions of face representation in the supplementary motor area (SMA) and primary motor cortex (M1). Activation related to licking also was present in animals performing the REM task. In addition, these animals had separate sites of activation in motor areas on the medial wall and lateral surface. The most extensive and intense activation was found bilaterally on the medial wall in the caudal cingulate motor area on the dorsal bank of the cingulate sulcus (CMAd). A smaller focus of activation was present in the rostral cingulate motor area (CMAr). On the lateral surface, activation was present contralaterally in the arm representation of M1. However, this activation was largely restricted to the anterior bank of the central sulcus. Surprisingly, the activation in M1 was modest in extent and intensity compared to that in the CMAd. In fact, the activation in the arm area of M1 was less intense than the activation in the face area associated with licking. Thus, the REM task appears to differentially recruit M1 and a premotor area (CMAd). Supported by the VA Medical Research Service, USPHS 24238 (PLS), and Medical Research Council of Canada (NP).

DIRECTION OF SACCADES EVOKED BY INTRACORTICAL MICROSTIMULATION (ICMS) OF SUPPLEMENTARY EYE FIELD (SEF) IS DEPENDENT ON BEHAVIORAL TASK CONDITION. N. Fujii [1,2], H. Mushiake [1], M. Tamai [2], J. Tanji*[1]. Department of Physiology [1], Department of Ophthalmology [2], Tohoku University School of Medicine, Sendai, 980, Japan.

In previous reports, the direction of saccades evoked by ICMS of the SEF has been characterized as goal directed, but at times as fixed vector. We report here that properties of saccades differ greatly depending on what oculomotor task the animal performs. A monkey (Macaca fuscata), facing a panel with five LEDs, performed a visually triggered saccade task with delay. When the animal placed its hand on a hold plate, an LED was turned on as a fixation target. If fixation was maintained for 1200-1600 ms (fixation period), the fixation LED was dimmed as a GO signal. An LED, serving as a saccade target, appeared about 500 ms before the GO signal, hence there was a delay between the appearance of saccade target and the GO signal. ICMS was delivered to the SEF at two different phases of the behavioral task. 1) During fixation, 500 ms after the initiation of the fixation. 2) immediately (50-100 ms) before the GO signal (pre-GO signal).

During fixation, the direction of stimulus evoked saccades was always contralateral to cortical stimulus sites, e.g., from the left SEF, the evoked saccades were directed rightward. The saccade trajectory appeared either goal directed or constant vector, with a mean latency of 124.7 ms. In contrast, when the pre-GO ICMS was applied, the direction of evoked saccades altered depending on the position of the precued target. Thus, the animal captured the target with a saccade, despite the presence of the ICMS. If the saccade target was presented contralateral to the stimulus site, the interval between the GO signal and the saccade onset was <100 ms. If the target appeared ipsilaterally, the interval ranged from 150-300 ms.

A MODEL FOR SHIFTING RECEPTIVE FIELDS BASED ON GAIN-MODULATION AND HEBBIAN LEARNING. E. Salinas, and L.F. Abbott*. Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Multimodal cortical neurons implicated in a number of spatial tasks involving coordinate transformations exhibit two types of receptive fields: (1) gain-modulated and (2) shifting. Gain-modulated responses can be modeled as the product of a conventional receptive field and a variable gain factor (Andersen et al., Science, 1985). Neurons in parietal area 7a combine visual, eye-position and head-position information in this manner (Andersen et al.). In contrast, some neurons in premotor cortex responsive to somatosensory and visual stimuli have visual receptive fields that shift when the arm or head moves, but not when the eyes move (Graziano et al., Science, 1994). In area LIP, visual receptive fields that shift in anticipation of a saccade have been recorded (Duhamel et al., Science, 1992). Auditory receptive fields that shift with eye position have also been reported (Stricanne et al., Neurosci. Abstr., 1994).

We show, using theoretical methods and computer simulations, that neurons receiving inputs from gain-modulated cells can automatically develop shifting receptive fields if input synapses are subject to a Hebbian or correlation-based synaptic modification rule. No dynamic reconnection or other type of switching mechanism is necessary if the presynaptic neurons have gain-modulated responses. This is consistent with the fact that gain-modulated cells project extensively into areas that exhibit shifting receptive fields. The synaptic weights needed to produce shifting responses develop spontaneously without any supervision or error signal. The model makes testable predictions about how the responses of neurons with shifting receptive fields might be modified by training. In general, gain-modulated neurons provide a powerful coordinate-free representation from which downstream networks can extract the information relevant to their function by means of correlation-based synaptic modification. Supported by grant NSF-DMS9208206.

OSCILLATIONS IN MONKEY MOTOR CORTEX DURING VISUALLY- AND MEMORY-GUIDED REACHING MOVEMENTS. B. Acuna*, C. Ojakangas, J.N. Sanes and J.P. Donoghue. Department of Neuroscience, Brown University, Providence, RI 02912.

We previously described γ-range (25-50 Hz) local field potential oscillations LFPs) in monkey primary motor cortex (MI, Sanes and Donoghue, PNAS 90:4470, 1993). The γ-LFPs occurred throughout a pre-movement delay period, ceasing around movement onset. They also emerged when the monkey changed behavior from quiet sitting to task engagement, suggesting that they are related to motor preparatory states. The current experiment tested the hypothesis that MI γ-LFPs encode remembered movement direction. We recorded γ-LFPs in MI through chronically implanted microwires in a monkey performing visually guided reaching movements to 1 of 3 targets represented on a video monitor. At first, the monkey position the hand at a central zone for an initial hold period in each of two tasks. In the *memory task*, 1 of 3 visual targets was then illuminated for 800 ms. After a 4 s "pre-cue" period, all targets were displayed, and the monkey was required to move a position feedback cursor to the instructed target within 600 ms after the go-cue. In the *visual task*, the target remained illuminated throughout the pre-cue period. In both conditions, distinct γ-LFPs were evident during both the hold and pre-cue periods, but they diminished around movement onset and remained low throughout the movement. We conclude that γ-LFPs are not related to preparation for a specific movement direction because they occurred during the hold period (before movement direction was specified), and they showed no directional tuning. Additionally, no apparent difference in the pattern or occurrence of γ-LFPs was seen between the memory and visual tasks. Synchronously active γ-LFPs were sometimes evident across multiple sites, but these were not temporally locked to any task event. These findings indicate that oscillations are not related to details of upcoming learned motor actions or to memory processes that might occur within MI, but that they are inversely related to motor execution. DYNAMIC INTERACTIONS BETWEEN NEURONS OF THE MONKEY MOTOR CORTEX IN RELATION TO BEHAVIORAL EVENTS. A. Riehle[1]*, S. Grün[2], A. Aertsen[2], J. Requin[1]. [1]Cognitive Neuroscience Lab., CNRS, Marseille, France; [2]Dept. Neurobiol., Weizmann Inst. of Science, Revohot, Israel.

Simultaneous recording of adjacent motor cortical neurons reveals rapid modifications in their synchronized activity during the execution of various motor tasks. These modulations are time-locked to the occurrence of either external events, such as the presentation of visual stimuli, or internal events, such as the time when the stimulus is expected and/or the movement is executed. Coincident firing enhances the probability that the receiving neuron will be activated. Hence, coincident firing might be considered as a potential neural code used to bind otherwise disparate activity into a coherent entity. Dynamics of interactions between neurons were studied both by using trial-averaged measures (Joint PSTH [1]) and by analyzing, trial by trial, individual epochs of synchronized firing ("unitary events" [2]). "Unitary events" were defined as activity constellations that occur more often than expected by chance on the basis of the firing rates of the neurons. The presence and significance of these events were evaluated, taking also into consideration the non-stationarity in the firing rates of the neurons involved. The results suggest that the degree of synchronization in groups of motor cortex neurons might play a role in the neuronal computations underlying the execution of a motor task. Furthermore, the time structure of the interaction between neurons supports the hypothesis that a single neuron might participate in different neuronal groups by rapidly changing its coupling to other neurons as a function of computational demands.

PRECISE SPATIO-TEMPORAL FIRING PATTERNS IN THE FRONTAL CORTEX OF BEHAVING MONKEYS: EXISTENCE AND CORRELATION TO BEHAVIOR. Y. Prut, E.Vaadia*, H. Bergman, I. Haalman, H. Slovin, and M. Abeles. Dept. of Physiology and the Center of Neural Computation, The Hebrew university, Jerusalem 91010, Israel

The possibility that temporally precise events participates in cortical information processing was tested. Multiple single units were recorded in the frontal cortex of Rhesus monkeys during performance of a delayed response task. We searched for firing patterns (FPs), defined as repeated spike-triplets with specific time intervals (with jitter of ±1 ms). The estimation of significance took into account the firing rates and the pairwise correlation amongst the units.

We found that: **(1)** FPs were composed of spikes of one or more units, spanning few to hundreds ms. A given triplet of units exhibited FPs, of different temporal structure.**(2)** Many FPs appeared in relation to behavior. Moreover, different FPs of the same units could appear preferentially during different behavioral modes. **(3)** FPs tended to appear in clusters, each dominated by a different set of units. The clusters were also related to the behavior. **(4)** Cross-correlations (CC) were computed for spike trains and compared to the corresponding 'FPs triggered' CCs. For about 60% of the neuronal pairs, the two CCs had different shapes. **(5)** The range of observed time intervals in FPS of a given neuronal pair, was either broad (presumably corresponding to a weak coupling) or narrow (presumably corresponding to a strong coupling). **(6)** Some FPs appeared more frequently in association with the occurrence of certain other FPs.

The findings support the hypothesis that information processing is mediated by synchronous activations of neuronal groups, allowing single neuron to participate in different computational processes.

NEURAL NETWORK MODELING OF MOTOR CORTICAL OPERATIONS DURING MENTAL ROTATION AND MEMORY SCANNING TASKS. A.V.Lukashin*, B.R.Amirikian, V.L.Mozhaev and A.P.Georgopoulos. Brain Sciences Center, VA Medical Center, Minneapolis, MN 55417

We propose a neural network model that reproduces quantitatively the spiking activity of motor cortical cells recorded in behaving monkeys during performances of two different visuomotor tasks: (i) the mental rotation task, which required the production of a movement at an angle from a stimulus direction, and (ii) the memory scanning task, which required the selection of an appropriate movement direction, depending on the serial position of stimuli in a sequence. In the present study, the ensemble of directionally tuned motor cortical cells is simulated by a recurrent network of interconnected, stochastic spiking neurons. The key point of the model is that a large repertoire of neural activity is permanently stored in the connectivity matrix in such a way that, once it is initiated, a particular neural dynamics evolves in time as a self-sustained dynamic attractor of the network. Our simulations demonstrate that specific patterns of motor cortical activity observed in experiments using paradigms (i) and (ii) can be stored in the connectivity matrix and can be initiated by specific external inputs of short duration.

HIGHLY NONLINEAR PROCESSING OF TEMPORAL INPUT FLUCTUATIONS BY REALISTICALLY MODELED CORTICAL BURSTING NEURONS P.H. Bedenbaugh* and M.M. Merzenich, *Keck Center for Integrative Neuroscience, Univ. of California at San Francisco, San Francisco, CA*

Analytical models of spiking neurons, MacGregor (1987) model neurons, and sigmoid elements all misrepresent and nonlinearly distort temporally fluctuating inputs (Bedenbaugh, 1993). Inputs to these models must therefore be highly synchronous to produce synchronous outputs. All of these models have simple dynamics dominated by the kinetics of post-synaptic potentials. Through computer simulation, we studied whether or not the richer intrinsic properties and longer time constants (*eg.*, as provided by calcium exchange, diffusion and modulation) of a bursting neuron would represent temporally fluctuating inputs more accurately than do these simpler models.

A one-compartment model of a cortical bursting neuron based on a model of Lytton and Sejnowski (1991) was simulated with NEURON. Pairs of model neurons received input from partially overlapping pools of Poisson spike trains. Simulations were run with both low variance input (1000 presynaptic neurons) and high variance input (100 presynaptic neurons). For both sets of simulations, the synaptic strength was varied to evoke firing rates ranging from less than 4 spikes per second to over 90 spikes per second. We measured the output correlation coefficient as a function of the fractional shared input. These quantities would be equal for a system that represents temporally fluctuating inputs well.

In every case, the output correlation coefficient was far less than the fraction of shared input, just as for the more simplified models. We conclude that neurons that behave like this model neuron are better suited for responding unambiguously to particular synchronized spatial input patterns than to accurately representing fluctuating inputs with a fluctuating output spike train.

Special thanks to Michael Hines for help with NEURON. Thanks to Bill Lytton for the calcium pump/diffusion model. Supported by NIH DC00144 and Pittsburgh Supercomputing Center.

NON-LINEAR DYNAMICS OF SPONTANEOUS NEOCORTICAL FIELD POTENTIALS RECORDED DURING ANESTHETIZED AND AWAKE STATES IN CHRONICALLY IMPLANTED RATS. Mark E. Jackson* and Larry J. Cauller, GR41, Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083-0688.

Nonlinear dynamics provides a means of analyzing multi-variable, complex systems that were formerly considered either random or too complex to understand. The analysis of the correlation dimension of a one-dimensional time series can reveal the deterministic nature of the complex system and allows an estimation of the minimum number of variables necessary to describe that system. We are using non-linear dynamics to analyze the cortical activity of rats with the goal of determining the essential neurophysiological constituents of functional cortical activity. This study developed an intact rat preparation with chronically implanted electrodes in SI, MI, and AI neocortex. Spontaneous field potentials were recorded during deep Nembutal anesthesia and during non-moving, alert activity. The autocorrelation function showed a slow fall-off and an extended range of positive correlation and the power spectrum showed broadly spaced peaks, typical of a fractal signal. Samples of the time series (32 sec at 1 msec sampling interval) were analyzed using the Grassberger-Procaccia method to determine the correlation dimension. The dimension in the awake state was higher than the anesthetized state (≈2.9 vs. 1.2). We plan to use this preparation to study cholinergic modulation in the neocortex of awake, behaving rats. Supported by a grant from the Whitehall Foundation.

BLOCKADE OF HALOPERIDOL-INDUCED CATALEPSY BY 8-OH-DPAT IS MEDIATED BY FOREBRAIN RECEPTORS. K. Eberle-Wang*, R.J.A. Banks and M-F. Chesselet. University of Pennsylvania, Department of Pharmacology, Philadelphia, PA 19104.

Peripheral administration of the prototypical dopamine receptor antagonist, haloperidol, elicits catalepsy in rats. Studies by Neal-Beliveau et al. (1993) demonstrated that systemic administration of the 5-HT_{1A} agonist, 8-OH-DPAT, blocked haloperidol-induced catalepsy. The location of the 5-HT1A receptors mediating this response is unknown. In the present study, we have compared the effects of 8-OH-DPAT administration into the lateral ventricles (to act on forebrain 5-HT_{1A} receptors) vs. infusion into the cisterna magna (to act on spinal chord 5-HT_{1A} receptors) on haloperidol-induced catalepsy. Male Sprague-Dawley rats were implanted with chronic guide cannulae for intracerebroventricular (ICV) or intracisternal (ICM) drug administration. All rats received 3 once-daily injections of haloperidol (2.0 mg/kg, s.c). Five days later, the animals received the same dose of haloperidol and catalepsy was recorded at 1, 2, 3 and 4 hours after injection. To test for catalepsy, rats were placed with forepaws resting on a horizontal bar 11 cm above the bench top and the latency to replace both forepaws on the bench top was measured (max 300 sec). Fifteen min prior to the 3 hour observation, 8-OH-DPAT (10 µg/5 µl) or saline was administered ICV or ICM according to a within-subjects design. ICV infusion of 8-OH-DPAT significantly decreased by 81% the duration of catalepsy at the 3 hour time point, 15 min after its infusion. However, catalepsy returned to control levels by the fourth observation period, 75 min after 8-OH-DPAT infusion. In contrast, ICM infusion of the same dose of 8-OH-DPAT had no effect of haloperidol catalepsy. These data confirm and extend previous studies demonstrating that 5-HT_{1A} agonists block haloperidol-induced catalepsy in the rat. Furthermore, the data suggest that 5-HT_{1A} receptor mechanisms in the forebrain, rather than in the spinal chord, are responsible for mediating the anticataleptic effect of 8-OH-DPAT. ΔFosB PARTICIPATES IN THE MEDIATION OF PRIMING G.S. Robertson* and M. Morelli[2] Dept. of Pharmacology[1], University of Ottawa, Ottawa, Ontario, Canada, K1H 8M5. Dept. of Toxicology[2], University of Cagliari, Viale A Diaz 182, Caligari 09100, Italy.

Administration of dopamine receptor agonists to rats with unilateral 6-hydroxydopamine (6-OHDA) lesions of the nigrostriatal pathway produce changes in the denervated striatum that enable a subsequent injection to elicit more vigorous circling. This behavioural phenomenon is termed priming. D1-like dopamine receptor agonists profoundly elevate immediate-early gene (IEG) expression in the denervated striatum. IEGs encode transcriptional regulating factors suggesting they may participate in gene signalling pathways that mediate priming. Indeed, we have recently discovered that chronic alterations in dopaminergic neurotransmission persistently enhance expression of the IEG product ΔFosB in the striatum. In order to determine whether ΔFosB is involved in priming, we examined whether (A) levodopa-induced priming and ΔFosB expression have similar time courses and (B) if inhibition of ΔFosB synthesis with an antisense oligonucleotide reduces levodopa-induced priming. ΔFosB expression in the 6-OHDA-denervated striatum peaked 3 days after levodopa administration and returned to preinjection levels at 10 days. This time course is similar to that for levodopa-induced priming. Moreover, intrastriatal injection of an antisense, but not a random, oligonucleotide against Δ*fos*B mRNA 14 hours prior to levodopa administration significantly reduced circling to a subsequent injection of the selective D1-like agonist SKF 38393. Taken together, these findings suggest that ΔFosB may play a role in those intracellular events which mediate levodopa-induced priming.

THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS AS A STRIATAL OUTPUT STATION. I. EFFECTS OF MICROINJECTIONS OF GABA AGONISTS AND ANTAGONISTS ON STEREOTYPED BEHAVIOR. L.F. Allen,* M.P. Latimer, R.I.J. McConnell, A.S. Walls and P. Winn. School of Psychology, Univ. St Andrews, Fife, Scotland KY16 9JU.

Excitotoxic lesions of the PPTg disinhibit orofacial stereotypy stimulated by *d*-amphetamine in the ventrolateral caudate-putamen (VLCP) *(Allen LF and Winn P, Exp. Brain Res. 1995, in press)*. Anatomical and behavioral evidence indicates that outflow from both dorsal and ventral striatum is processed through the PPTg but it is not clear what particular role this structure fulfils. There are several VLCP outflow sites from which orofacial stereotypy can be stimulated by microinjecting GABAergic drugs. In the present experiments we have sought to first, confirm that microinjections of GABA drugs into the substantia nigra pars reticulata (SNr) elicit orofacial stereotypy; and second, examine the effects of various doses of the GABA agonist muscimol and the antagonist picrotoxin microinjected into the PPTg. In each case rats' performance was videotaped and scored using a checklist. In the first experiment, 75ng/0.5µl muscimol injected into anterior SNr stimulated licking and biting, directed mainly at the cage environment. Injections into posterior SNr had significantly less effect. 75ng/0.5µl picrotoxin had no effect on orofacial activity when injected into either anterior or posterior SNr. In the second experiment, 15, 30 and 45ng/0.3µl of either muscimol or picrotoxin microinjected into the compact portion of PPTg had no effect on orofacial stereotypy. Small changes in the incidence of sniffing and rearing were observed. These data suggest that while loss of the PPTg disinhibits orofacial stereotypy stimulated from the VLCP, manipulating GABA transmission in the PPTg in the absence of other stimulation does not induce significant changes in orofacial or other forms of unconditioned behavior.

817.4

THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS AS A STRIATAL OUTPUT STATION. II. EFFECTS OF PPTg LESIONS ON REACTION TIME MEASURES IN A CONDITIONED VISUAL DISCRIMINATION TASK. P. Winn,* M.P. Latimer, V.J. Brown and P.J. Brasted. School of Psychology, Univ. St Andrews, Fife, Scotland KY16 9JU.

Anatomical, functional imaging and behavioral data indicate that the PPTg is an important output station for the dorsal striatum and related structures. In the present experiments we examined the role of the PPTg in mediating reaction time (RT) responses in a conditioned visual discrimination task known to be sensitive to dorsal, but not ventral, striatal dysfunction. Rats were trained in a nine-hole box to make responses from a central start-point: bright stimulus lights signalled a right side response, dim lights a left side response. Correct responses were rewarded by 45mg food pellets. The time taken to leave the central start point after stimulus onset was recorded as RT. Before lesions were made there were no differences between rats in RT; bilateral ibotenate lesions of PPTg were then made (0.12M: 2 X 0.2µl injections/hemisphere; sham lesions 2 X 0.2µl PBS; unilateral lesions were made, followed 24h later by lesions on the contralateral side). After surgery significant differences were found. Lesioned rats were significantly slower in RT whereas control operated rats showed no change from preoperative performance. Histological analysis showed that both cholinergic (identified by NADPH diaphorase histochemistry) and non-cholinergic PPTg neurons had been damaged. These data (i) confirm that the PPTg is involved in the mediation of dorsal striatal processes; (ii) can be explained by suggesting either an interference with striatal outflow systems (principally directed through non-cholinergic PPTg neurons) or by suggesting that arousal and/or activational processes mediated by PPTg cholinergic neurones have been affected.

Behavioral Effect of Focal Inhibition of the Subthalamic Nucleus. D. Dybdal, K. Japikse, D. Burnhill, and K. Gale*. Dept. Pharmacology, Georgetown Univ. Med. Ctr., Washington DC, 20007.

Previous electrophysiological studies have suggested that the subthalamic nucleus (STN) is an important source of excitatory glutamatergic input into substantia nigra (SN). To evaluate the functional significance of these inputs in the awake, behaving rat, we compared the effects of focal pharmacological inhibition of STN with the effects of blocking glutamate receptors within SN. Infusion of muscimol (200pmol), a $GABA_A$ agonist, unilaterally into STN induced a pronounced contraversive postural asymmetry without stimulation of locomotor activity. A similar response was evoked by the direct infusion of kynurenate (100nmol), a glutamate antagonist, unilaterally into SN. These results are consistent with the hypothesis that excitatory glutamatergic inputs into SN regulate postural control and that the STN is a source of these inputs .

The absence of locomotor stimulation following the inhibition of STN or blockade of glutamate transmission in SN was in clear contrast to the marked locomotor stimulation (in addition to postural asymmetry) induced in the same animals following direct unilateral application of muscimol in SN, an effect that has been previously well characterized. It therefore appears that while STN-derived glutamate inputs regulate postural adjustments, non-glutamatergic excitatory influences derived from regions other than STN must contribute to the nigral regulation of locomotor activity.

MODULATION OF METABOTROPIC GLUTAMATE AGONIST INDUCED ROTATION BY ADENOSINE AGONISTS AND ANTAGONISTS. J. Feeley Kearney* and R. L. Albin. Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor, MI, 48109-1687.

Metabotropic glutamate receptors (mGluRs) are a major class of excitatory amino acid receptors. Eight mGluR subtypes coupled to a variety of effector systems have been cloned. Binding studies have shown that the striatum and subthalamic nucleus (STN) possess a high density of mGluR binding sites (Albin et al, 1992, Neurosci, 46, 35). Unilateral intrastriatal and intraSTN infusion of the mGluR agonist 1-aminocyclopentane-1S,3R-dicarboxlyic acid (ACPD) induces vigorous contralateral rotation in rats. There is a high density of adenosine A_2 receptors in the striatum (Jarvis et al, 1989, Eur J Pharmacol, 18, 243), and some of the effects of striatal mGluR activation may be mediated by modulation of adenosine effects. We performed a series of experiments to determine if the contralateral rotation induced by unilateral striatal mGluR activation can be modified by activation or blockade of adenosine receptors.

Pretreatment with the adenosine antagonist theophylline (25mg/kg) significantly decreases contralateral rotation induced by unilateral intrastriatal ACPD (1µmol). Intrastriatal and intraSTN coinjections of theophylline (5mM) and ACPD (1µmol) significantly decrease contralateral rotation suggesting that mGluRs and adenosine receptors interact locally. These appear to be adenosine A_2 effects as the selective A_2 antagonist 8-(3-chlorostyryl)caffeine (CSC) (3mg/kg) also decreases contralateral rotation induced by unilateral intrastriatal and intraSTN ACPD, while the selective A_1 antagonist 8-cyclopentyl-1,3-dipropylxanthine (DPCPX) (5mg/kg) has no effect. Pretreatment with the selective A_2 agonist CGS 21680 potentiates contralateral rotation induced by unilateral striatal ACPD, whereas pretreatment with the selective A_1 agonist N6-cyclopentyl-adenosine (CPA) has no effect. These results suggest that mGluR effects may be due, in part, to modulation of adenosine action.

Supported by NS19613 and 2T32-NS07222.

THE LOCATION OF AN IBOTENIC ACID LESION IN THE DORSAL STRIATUM AFFECTS THE BEHAVIOURAL DEFICIT OBSERVED. R.A. Fricker*, L.E. Annett, E.M. Torres and S.B. Dunnett MRC Cambridge Centre for Brain Repair, University of Cambridge, UK

The excitotoxic model of striatal damage has been used extensively in the rat to test motor deficits both in whole body asymmetries and in skilled limb movements. However, conflicting results of both the type and extent of behavioural deficits have been reported. Unilateral excitotoxic lesions of the dorsal striatum, typically give rise to ipsilateral rotation in response to both amphetamine and apomorphine. Conversely, recent studies have claimed that a lesion in the rostral striatum induces a marked contralateral rotation in response to apomorphine. Bilateral excitotoxic lesions placed in the dorsolateral striatum cause a marked impairment in reaching movements of the forelimbs and tongue and lesions to more ventrolateral regions result in impairments in the initiation and execution of these movements. The present study investigated the effect of unilateral ibotenic acid lesions in the dorsal striatum on rotation in response to both amphetamine and apomorphine and in the "staircase test" of skilled forelimb use. In a 2x2 matrix design experiment, adult female Sprague-Dawley rats received a double unilateral lesion of 0.5 µl 0.06M ibotenic acid at 2 sites in either the anterior, posterior, medial or lateral striatum. Rats which received posterior lesions showed a marked ipsilateral rotation in response to both amphetamine and apomorphine, while animals receiving anterior lesions showed little ipsilateral or a slight contralateral bias. Rats receiving lateral lesions showed a marked impairment of contralateral paw use on the "staircase test" while animals with medial lesions showed no significant difference to control unoperated animals. These results confirm the somatotopic organisation of the dorsal striatum in its role in motor functions and indicate the necessity for design of lesion and transplantation studies to take into account the locus of an excitotoxic lesion in order to evaluate the behavioural deficits and recovery which result.

PREFERENTIAL LOCALIZATION OF SELF-STIMULATION SITES IN STRIOSOMES/PATCHES OF RAT CAUDATE-PUTAMEN. N.M. White* and N. Hiroi, Department of Psychology, McGill University, Montreal, Quebec, Canada.

The striatum consists of two histochemically distinguishable compartments: "patches" or "striosomes", surrounded by a "matrix". As a test of the hypothesis that the striosome/patch compartment may have reward-related functions, this study examined the role of the two striatal compartments in electrical self-stimulation of the brain. Rats were implanted with monopolar electrodes aimed at the medial portion of the caudate-putamen. After recovery from surgery they were trained to bar press for 0.5 sec trains of 60Hz sine-wave stimulation. Training consisted of placing the rats in the test cage and "shaping" them to press the bar by administering trains of stimulation contingent upon behaviors that approximated the bar pressing response. Following each training session each rat remained in the cage for 30 min to test for spontaneous bar pressing. All rats were trained until they reached a self-stimulation criterion -- at least 100 spontaneous responses in 30 min on 3 consecutive days -- or for a maximum of 11 - 15 days. After attaining or failing to attain the criterion the animals' brains were stained for calbindin or calretinin. Animals with electrodes that were in or touching areas of light calbindin (Gerfen, et al, Proc.Natl.Acad.Sci.USA 82:8780-8784,1985) or heavy calretinin (Hiroi, in preparation) staining, indicating contact with a patch/striosome, acquired self-stimulation behavior more reliably than animals with electrodes terminating exclusively in tissue expressing heavy calbindin or light calretinin staining (matrix). The results provide *in vivo* evidence that the striosome/patch compartment is functionally differentiated from the matrix compartment. Direct stimulation of striosome/patch compartment, but not of the matrix, led to acquisition of bar pressing behavior, either because striosome stimulation has rewarding consequences, or because stimulation of this area promotes the storage of new information.

INTRASTRIATAL DNQX INDUCES CONTRALATERAL ROTATION AND GLOBUS PALLIDUS FOS IN DOPAMINE-DENERVATED RATS J.J. Schuller* and J.F. Marshall, Dept. of Psychobiology, University of California, Irvine, 92717.

The striatopallidal and striatonigral projections are the two major output pathways of the striatum. These pathways both use GABA as a neurotransmitter, and are influenced by glutamatergic and dopaminergic afferents. Several measures of neuronal activity indicate that interruption of dopaminergic neurotransmission in the striatum leads to increased basal activity in striatopallidal neurons. We have examined the role of striatal glutamate in mediating the striatopallidal hyperactivity by combining local glutamate antagonist application with behavioral quantification and immunocytochemical localization of Fos in the globus pallidus (GP) as an index of striatopallidal activity. Rats were given unilateral 6-OHDA lesions of the nigrostriatal pathway. 24 d post-lesion, each rat was implanted unilaterally with a guide cannula aimed at the anterior portion of the denervated striatum. Unlesioned control rats were also implanted with striatal cannulae at this time. 3-4 d following cannula implantation all rats were infused intracerebrally with the AMPA receptor antagonist DNQX (0.75, 1.5, or 3 ug) or vehicle (1ul), and perfused 2 h later. The fixed brains were sectioned and processed for Fos immunoreactivity. Rats with 6-OHDA lesions displayed dose-dependent contralateral rotation in response to DNQX, but not to its vehicle. Unlesioned control rats were unresponsive to either DNQX or its vehicle. DNQX dose-dependently induced Fos in the GP of 6-OHDA-lesioned rats but not in unlesioned control rats. Vehicle did not induce significant GP Fos in either lesioned or unlesioned rats. Based on these data we conclude that glutamate acting at striatal AMPA receptors contibutes to DA-denervation-induced hyperactivity in the striatopallidal pathway. Furthermore, the disinhibition of pallidal neurons may play an important role in the expression of motor behavior.

TIME- AND DOSE-DEPENDENT EFFECTS OF THIO END-CAPPED ANTISENSE OLIGONUCLEOTIDES ON AMPHETAMINE-INDUCED STRIATAL *c-FOS* EXPRESSION AND BEHAVIOUR IN THE RAT. M. Hong*, B.J. Chiasson, K.M.A. Murphy and H.A. Robertson, Department of Pharmacology, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4H7

Previous work demonstrated that a single intrastriatal infusion of fully thio substituted antisense oligonucleotides (s-ODNs) targeted to *c-fos* mRNA attenuates striatal *c-fos* expression and results in ipsiversive rotational behaviour in rats challenged with amphetamine. However, multiple infusions of these s-ODNs into the brain were found to produce neurotoxic damage. Although a reduction in the number of thio substitutions may minimize neurotoxicity, few studies have examined the effectiveness of partially substituted antisense s-ODNs *in vivo*. In the present study, the effects of single and double end-capped s-ODNs targeted to *c-fos* mRNA on amphetamine-induced striatal *c-fos* expression and rotational behaviour were examined in rats. Intrastriatal infusions of a single end-capped s-ODN (2 nmol) 1, 2.5 or 5 but not 10 hours prior to amphetamine challenge (5 mg/kg i.p.) attenuated striatal *c-fos* expression and resulted in ipsiversive rotational behaviour in a time-dependent manner. Similarly, infusions of a single or double end-capped s-ODN (0.5 - 6 nmol) 2.5 hours prior to amphetamine challenge resulted in similar effects in a dose-dependent manner. However, at the higher doses of these antisense s-ODNs (4 - 6 nmol) some animals demonstrated seizure activity and increased *c-fos* expression was observed in the cortex, thalamus and lateral striatum in addition to an atypical pattern of amphetamine-induced *c-fos* expression in the contralateral striatum. Thus, the present data suggest that infusion of low dose single or double end-capped s-ODN is effective in attenuating striatal *c-fos* expression and inducing ipsiversive rotational behaviour in amphetamine challenged rats while at higher doses both s-ODNs lead to seizure activity in some animals.

ANTISENSE OLIGODEOXYNUCLEOTIDES: COMPARISON OF THE UPTAKE AND LOCALIZATION OF PARTIAL AND FULL PHOSPHOROTHIOATE DERIVITIVES IN BRAIN. H.A. Robertson*, Lab. Molecular Neurobiology, Dept. Pharmacology, Dalhousie Univ., Halifax, Nova Scotia, Canada B3H 4H7

Antisense oligodeoxynucleotides (ODNs) represent a powerful new technique for manipulating gene expression *in vivo*. Endo- and exonucleases present in tissues rapidly degrade antisense ODNs thus limiting their effectiveness and in general, most people have worked with antisense ODNs where the phosphodiester bond is modified to a phosphorothioate bond. However, we and others have found fully-phosphorothioate derivitized ODNs to be toxic when administered chronically. In an attempt to reduce toxicity, we have studied antisense ODNs which have only a single phosphodiester linkage at the 5' and 3' ends of the ODN modified to phosphorothioate derivatives (chimeric ODNs). Behaviourally, we observed that the onset of activity for such chimeric antisense ODNs directed against *c-fos* was much quicker than for the fully phosphorothioated ODNs. This has been examined using FITC labelled antisense ODNs. Rats were injected directly into the striatum with 2 μl of distilled water containing 1 nmol of either a chimeric antisense ODN to *c-fos* or a fully phosphorothioated antisense ODN to *c-fos*. At various times up to 24 hr after injection, the animals were perfused, sections cut and the uptake and localization of the antisense ODN was followed using fluorescence microscopy. The chimeric antisense ODN to *c-fos* appeared to diffuse more rapidly in striatum and was completely gone at 24 hr; the fully derivitized ODN was still present at 24 hr. Interestingly, both the chimeric and the fully phosphorothioated ODNs appear to be selectively taken up by neurons in globus pallidus. INDICES OF ON-LINE AND PREPROGRAMMED CONTROL OF OPERANT RESPONSE FORCE IN RATS. A. B. Slifkin* and J. Brener, Dept. of Psychology, SUNY, Stony Brook, NY 11794-2500.

Research on human subjects has shown that control of Peak response Force (PF) by Time to Peak Force (TPF) reflects the operation of feedback (FB) processes, whereas control of PF by the Rate of Rise of Force (dF/dt) reflects the operation of feedforward (FF) processes. The current study tested whether TPF and dF/dt have the same relationships to FB and FF control of response force in rats. Knowledge-of-Results (KR) (Immediate or Terminal) and Force Contingency [LOW (2 g) or HIGH (18 g)] were examined in a 2 x 2 between-subjects design. Under conditions of Immediate KR, food reward delivery occurred at the moment during response execution that the imposed force requirement was achieved. This afforded the opportunity for response force to be regulated by the available external FB. It was anticipated that if rats make use of the Immediate KR in controlling PF, then HIGH-LOW differences in PF would be determined by HIGH-LOW differences in TPF. Under Terminal KR, use of information about response correctness during response execution was prevented since food for responses meeting the imposed force requirement was delivered at response end. Under these conditions therefore, rats were forced to rely on FF control and it was anticipated that HIGH-LOW differences in PF would be determined by HIGH-LOW differences in dF/dt. Both expectations were confirmed indicating that in rats, as in other species, modulation of PF by TPF reflects FB control whereas modulation of PF by dF/dt reflects FF control.

817.13

CONTROL OF RESPONSE FORCE IN RATS: EFFECT OF BILATERAL PARTIAL 6-OHDA NIGRAL LESIONS AND DOPAMINERGIC DRUGS. J. Brener*, R.E. Strecker†, and X. Liu, Depts of Psychology and †Psychiatry, SUNY, Stony Brook, NY 11794-2500.

The cardinal signs of Parkinson's disease (PD) include bradykinesia and tremor. In addition, PD patients show deficits in isometric force production and the temporal features of individual movements. To understand the mechanism of these behavioral deficits we examined changes in both the force and timing of individual isometric responses in a rat model of PD (Liu et al., this volume). Hungry rats were trained to apply force to a central beam for 2 s. Following beam release, visual stimuli were presented to signal which of two other beams (left or right) should be pressed. A sugar water reward was made available if the left beam was pressed with low force (< 3g), or if the right beam was pressed with high force (>50g). On each session rats made approximately 80 long-duration responses, 100 high-force responses and 100 low-force responses.

Bilateral, partial 6-OHDA nigral lesions resulted in significant increases in the numbers of low-force and high-force errors. These errors were entirely due to loss of control over the rate of rise of force (df/dt): Response timing was uninfluenced either during responses that demanded force control or during responses that required duration control. These results are attributed to a deficiency in the programming of response force rather than to deficiencies in the on-line regulation of motor output (see Slifkin & Brener, this volume). Related results from pre-lesion drug probes with apomorphine, haloperidol and amphetamine will also be reported.

817.14

DEFICITS IN RESPONSE SELECTION PRODUCED BY BILATERAL PARTIAL 6-OHDA NIGRAL LESIONS AND DOPAMINERGIC DRUGS. X. Liu*, R.E. Strecker†, and J. Brener, Depts of Psychology and †Psychiatry, SUNY, Stony Brook, NY 11794-2500.

A sensitive behavioral test was developed to track changes in sensorimotor capacity produced by partial nigral lesions in rats. Hungry rats were trained to apply force to a central beam for 2 s. Following beam release, visual stimuli were presented to signal which of two other beams (left or right) should be pressed. A sugar water reward was made available if the left beam was pressed with low force (< 3g), or if the right beam was pressed with high force (>50g). Following collection of the reward, stimuli instructed the animal either to repeat the last response or to start a new sequence by pressing the central beam. The task was designed to measure simple and choice reaction times as well as to record various sorts of response errors.

After bilateral 6-OHDA nigral lesions, which resulted in a loss of DA neurons in substantia nigra and 50-80% forebrain DA depletions, RT lengthened as an inverse function of stimulus probability. Thus, data showed that simple RTs lengthened least and RTs to the most improbable stimuli lengthened most. This is consistent with the interpretation that the timing of basic sensory and motor processes were uninfluenced by the lesions, but that the processes of response selection were profoundly slowed. Error data relevant to this interpretation as well as pre-lesion data obtained during drug probes [apomorphine (.01, .03, .1 mg/kg, sc), amphetamine (.03, .1, .3 mg/kg, ip) and haloperidol(.01, .03, .1 mg/kg, ip] will be reported.

BASAL GANGLIA AND CEREBELLAR INPUTS TO SUPERIOR COLLICULUS CONTROL HEAD AND MOUTH MOVEMENTS ELICITED BY FORMALIN INJECTIONS INTO THE RAT HIND PAW. S. Wang, N. Wood, M. Simkins and P. Redgrave*. Dept. Psychology, University of Sheffield, Sheffield, S10 2TP, U.K.

The dorsolateral substantia nigra reticulata (DL- SNR) projects directly to the parvicellular medullary reticular formation (PCRt), an oral premotor region, and to the lateral intermediate layers of the superior colliculus (L-SC), which participate in head control. Both the L-SC and the PCRt also receive direct projections from the lateral deep cerebellar nucleus (L-DCN). The purpose of the present study was first, to characterise in more detail anatomical connectivity from DL-SNR and L-DCN to the L-SC and PCRt, and second, to establish the role of this circuitry in a task requiring precise co-ordination of the head and mouth.

Multiple retrograde and anterograde transport of tracers was used to investigate neural connectivity at the light microscopic level. The main findings were: (i) In rostral DL-SNR a high proportion (>70%) of retrogradely labelled cells were double labelled following some of the injections of fluorescent dyes into L-SC and PCRt. (ii) In L-DCN segregated populations of single labelled cells were found following similar injections of fluorescent tracers into L-SC and PCRt. (iii) Simultaneous injections of PHA-L into DL-SNR and biotinylated dextran into L-DCN produced intermingling patterns of anterograde terminal label in L-SC which surrounded cells retrogradely labelled with cholera toxin B injected into PCRt.

An injection of 50µl of 4% Formalin into the hind paw of a rat produces a reliable biphasic response in which the animal turns to lick and bite the injected paw. This response was suppressed in a dose-dependent manner by bilateral injections of the GABA agonist muscimol into the L-SC (12.5-50ng: 0.5µl/side). Interestingly, the animals' attention and activity were redirected from lower to upper regions of space when doses of muscimol >20 ng were injected into L-SC.

These data suggest that: i) premotor circuits controlling the head and mouth receive converging input from both basal ganglia and cerebellum; and (ii) the integrity of this circuitry is essential for effective performance of a task requiring movements of the head and mouth. *Supported by Wellcome Trust grant 038011/Z/93 to PR*

CEREBELLUM: GENETIC MODELS

818.1

INHIBITION OF DEEP CEREBELLAR NUCLEI NEURONS IN DYSTONIC RATS. J.J. Fu* and J. F. Lorden. Dept. of Psychology, Univ. Alabama at Birmingham, Birmingham, AL 35294

In the genetically dystonic (dt) rat, a model for torsion dystonia, the deep cerebellar nuclei (DCN) have been identfied as a site of abnormality. This study used extracellular single unit recording and microiontophoresis to test the sensitivity of DCN neurons to inhibitory input. Under urethane anesthesia, GABA (0.1M, pH 4.5), taurine (0.5M, pH 3.0), and bicuculline (5mM, pH 3.0), the GABA antagonist, were applied to DCN neurons in dt rats and unaffected littermates, aged 18-25 days. In littermates, all DCN neurons tested (n=17) were inhibited by GABA. Inhibition was defined as a reduction in firing rate of at least 50% at ejection currents of 90 nA or less. In the dt rats, only 79% of the neurons tested (n=24) responded. Unresponsive cells were located mainly in the n. interpositus. In responsive cells, reduced sensitivity in comparison with littermates was noted in the lateral nucleus. In littermates, 56% of the neurons tested (n=18) were inhibited by taurine. In dt rats, however, only 23% of the cells tested (n=22) responded. All cells tested showed increases in firing rate to application of bicuculline. These results are consistent with studies showing decreased binding of ^{3}H-muscimol in the DCN of dt rats and indicate reduced inhibitory control in the dt DCN. INCREASED SOMATAL PARVALBUMIN AND GLYCINE IMMUNOREACTIVITY IN THE CEREBELLAR TARGETS OF PURKINJE CELL DEGENERATION MUTANTS. J. Bäurle and U. Grüsser-Cornehls. (SPON: European Neuroscience Association). Dept. Physiol., Freie Univ. Berlin, 14195 Berlin, Germany

The complete loss of Purkinje cells (PC) in Purkinje cell degeneration (PCD) mutant mice removes the major inhibitory input to the deep cerebellar (DCN) and vestibular nuclei (VN). Neuronal activity, however, is not enhanced in the VN, suggesting compensatory reactions of other inhibitory neurons, but the total number of GABAergic cells is not increased and the density of GABAergic terminals is greatly reduced compared to wildtypes. In the present study we show that the number of Parvalbumin-immunopositive (Parv+) somata, which are absent in the DCN and at a very low level in the VN of normal wildtypes, increases massively in these nuclei of PCD mutants. This increase is closely correlated temporally and spatially with the PC loss. In addition, Glycine-immunopositive (Gly+) neurons are drastically more packed in the DCN of PCD, and even after correcting for nuclear shrinkage (≈50%) the total number of Gly+ cells remains significantly higher by 1/3 compared to wildtypes. Moreover, the size and density of Gly+ terminals contacting DCN neurons are increased in PCD. Double labeling shows that Parv, which often colocalizes with GABA, is highly localized in small and medium-sized Gly+ neurons of the DCN and VN in PCD mutants. Taken together, the increase in Parv+ neurons that mainly colocalize with Gly and in terminal size and density of Gly+ small and medium-sized neurons reflect most probably an enhanced inhibitory activity and, as these are presynaptic to the large output neurons, a reduction in turn of the activity of the latter. This mechanism is likely to compensate for the PC loss and contribute to the mild motor deficit in PCD mutants, as a somatal Parv increase can also be evoked in single subdivisions of the DCN and VN by discrete cerebellar lesions in wildtypes, and in Weaver mutants where motor impairment is improved by this operation.

c-fos EXPRESSION IN THE CEREBELLUM OF *SHAKER* MUTANT RATS WITH HEREDITARY PURKINJE CELL DEGENERATION. D.L. Tolbert*, P. Sharp, M. LaRegina and P. McCulloch. Depts. Anat. &. Neurobiol. and Surg. Saint Louis Univ. and Div. Comp. Med. Washington Univ, St. Louis, MO. 63104

Three month old *Shaker* mutant rats are characterized by coincident degeneration of lobule I-IX Purkinje cells and motor ataxia. Immunochemistry was used to assess c-fos activity in the cerebella from *Shaker* mutant and normal rats. Fos immunoreactivity was observed in the cortex, white matter, and deep nuclei in mutant rats. In the cortex clusters of Fos immunopositive cells were located in the granule cell layer of lobules I-IX. There were no immunopositive cells located in other cortical layers. Subjacent to the clusters of Fos positive cells in the granule cell layer Fos immunoreactive cells were frequently present in the white matter. In other areas clusters of positive cells were located in the white matter at the base of folia and lobules. Fos immunoreactive cells were present throughout the cerebellar nuclei. These cells were more numerous and grouped together in regions deafferented of inhibitory corticonuclear input. Comparable patterns of Fos immunoreactivity were not observed in normal cerebella. These findings of increased cerebellar activity in *Shaker* mutant rats could be the basis for the ataxia and tremor seen in these animals. (Supported by NIH grants RR07013 and NS20227).

818.4

DEVELOPMENT AND QUANTIFICATION OF ATAXIC GAIT IN THE SHAKER MUTANT RAT. B.R. Clark*, A.J.Bastian, T. Weatherspoon, and W.T. Thach. Program in Physical Therapy, Dept. of Anatomy, Wash. Univ. Sch. of Med., St. Louis, MO. 63108, and McNair Entry Fellowship Program, Knox College, Galesburg, ILL. 61401.

The shaker mutant rat spontaneously demonstrates Purkinje cell and inferior olive degeneration (LaRegina et al., Lab. Animal Sci. 42: 19-26, 1992). Clinically shaker rats are classified as strong shakers or mild shakers depending on the presence or absence of tremor. We were interested in determining whether gait deficits in the strong shaker mutants correlated with the described progression of Purkinje cell degeneration (Tolbert et al., J. Comp. Neurol., in press). At regular intervals between 1-6 months of age, we evaluated gait by having normal and shaker rats traverse a clear plexiglass tunnel. Hindfeet were marked with black ink and forefeet were marked with red ink for footprint identification. Measurements of stride length, step length, and stride width were made. Spatial distribution of hindlimb footprints relative to ipsilateral forelimb footprints were measured. Landmarks on the hip, scapulae, wrist, and ankle were marked with black ink. Left forelimb and hindlimb kinematics were videotaped and analyzed using Peak Performance.

At 1 month of age, shaker gait appeared normal. By 3-4 months of age, walking track analysis of shaker gait revealed decreased step and stride length, increased hindlimb stride width, and increased variation of hindlimb placement relative to ipsilateral forelimb placement. Videotape analysis of kinematic gait abnormalities showed forelimb high stepping, highly varied ankle path during hindlimb swing phase, larger and more variable hip displacement, increased time spent in stance phase, and disturbed temporal and spatial pattern of footfalls. Hildebrand plots revealed a lack of temporal synchrony in both the lateral sequence and diagonal couplet that characterizes normal rat gait. At 6 months of age these deficits are more pronounced. In addition, the rats fell more frequently and took extra footfalls uncoupled with footfalls of the ipsilateral limb. These results are consistent with the described time course and extent of Purkinje cell degeneration in shaker rats (Tolbert, ibid). (Supported by the Program in P.T.)

818.5

INFERIOR OLIVARY NEURON NUMBER IN DEVELOPING NORMAL AND *LURCHER* MICE. J. A. Heckroth*. Department of Anatomy and Neurobiology, St. Louis University Medical School, St. Louis, MO 63104-1028.

The number of neurons which comprise the inferior olivary complex has been estimated in wild-type and *lurcher* mice at 10, 20, and 30 days of age. Current results reflect neuronal number estimates in three mice of each genotype at each age. Serial 50μm frozen sections were stained with cresyl violet and analyzed using a Neurolucida® system. Boundaries were drawn around each of four olivary subdivisions (caudal and rostral medial accessory olives, dorsal accessory olive, and principal olive) in every other section, and these outlines were used by Neurolucida® to generate volume estimates of each subdivision. Neuron density in each of the subdivisions was estimated by counting the number of neuronal nuclei within a randomly positioned 125,000 μm^3 cube of tissue in each section. Average density values were multiplied by the volume to provide neuronal number estimates of each subdivision. The number of neurons in the wild-type inferior olive remains relatively constant (about 13,000) over the period examined. The number of *lurcher* olivary neurons is already reduced by about 30% at 10 days of age, and falls to about 30% of normal by 30 days. Although a previous study demonstrated homogenous olivary atrophy in adult *lurcher* mice, the present results suggest a differential rate of loss from the olivary subdivisions. Most notably, the current data suggest a relative sparing of neurons in the caudal medial accessory olive during the period investigated. This work was supported by NINDS grant NS33969.

818.6

COMPENSATORY MECHANISMS IN WEAVER MUTANT MICE AFTER LESIONS OF THE CEREBELLAR VERMIS. C. Grüsser, J. Bäurle and U. Grüsser-Cornehls. (SPON: EUROPEAN NEUROSCIENCE ASSOCIATION). Dept. Physiol., Freie Univ. Berlin, 14195 Berlin, Germany

Recent investigations in Weaver mutant mice, which suffer from an almost complete loss of cerebellar granule cells, a portion of the Purkinje-cells (PCs, mostly in the anterior vermis) and a degeneration of dopaminergic cells in the substantia nigra, have shown that ablation of the cerebellum improved the poor motor performance (severe ataxia, instability of gait, posture and balance) significantly. Electrophysiological experiments revealed a disorganized and faulty output of the surviving PCs and a disinhibition of type i vestibular nuclei cells. On the basis of these findings we removed the anterior vermis in young animals. Their motor performance was observed in an arena divided into 10 x 10 cm squares and the number of tumblings counted within a 5 min walking period in relation to the squares traversed (t/k). T/k improved by 77% in relation to the preoperative values and manoevering on a slanted wire and wooden bench recovered dramatically.

Immunocytochemical investigations revealed an increase in GABA- and Parvalbumin-positive soma labelling of small and medium-sized neurons in the deep cerebellar (Fastigius) and Deiter's nuclei, both projection sites of the anterior vermis. Parvalbumin is a Ca^{2+}-binding protein and thought to indicate high activity levels of the respective neurons. Since a large portion of the small and medium-sized neurons are inhibitory, a tentative assumption is that by removing the total population of PCs in a restricted cerebellar area, a shift in the inhibitory power occurs, leading probably to the better motor compensation in the operated Weaver. The same mechanism is observed in PCD mice, which have an almost complete lack of PCs and in normal wildtypes in which again a portion of the cerebellum was removed.

818.7

GROOMING IN WEAVER MUTANT MICE. R. Lalonde* and C. Strazielle. Université de NANCY I et Université de Montréal, Centre de recherche en sciences neurologiques, Université de Montréal, Montréal (Qc) Canada H3C 3J7

Since electrical stimulation of the medial parts of the cerebellum (vermis and fastigial nucleus) elicits grooming in normal rats, we wished to determine to what extent cerebellar atrophy affects the grooming response. Weaver mutant mice, characterized by degeneration of cerebellar atrophy affects the grooming response. Weaver mutant mice, characterized by degeneration of cerebellar granule cells and midbrain dopamine neurons, were compared to normal mice during self-grooming after water immersion. There were no intergroup differences for grooming episodes, grooming sequences, and grooming episodes per sequence. One grooming component appeared less frequently in weaver mutants: face washing and one more frequently: abdomen licking. Normal mice began a sequence by grooming an anterior body part on 68.9% of occasions, whereas this pattern was reduced (32.5%) in weavers.

AN ELECTRON MICROSCOPIC ANALYSIS OF NORADRENERGIC INNERVATION OF THE WEAVER CEREBELLUM. L.C. Abbott* and C. Sotelo. Dept. of Vet. Anat. & Public Hlth., Texas A&M Univ., College Station, TX 77843, USA and INSERM U.106, 47 Blvd. de l'Hopital, 75651 Paris, FRANCE

Although monoaminergic (MAergic) systems can form classical synaptic junctions in many central regions, the vast majority of MAergic axon terminals are "non-junctional", which correlates with the paracrine action exerted by these systems. To assess the influence of the cellular environment on synaptic modeling of cerebellar MAergic axons, noradrenergic innervation of the wild type mouse cerebellum was compared with that of the weaver (agranular) cerebellum. Noradrenergic axons were ultrastructurally identified using immunocytochemistry for tyrosine hydroxylase (TH), with an antibody provided by R. Reinhardt. In wild type and weaver cerebella, almost all TH+ varicosities were non-junctional and their density was much greater in weaver than in wild type cerebella. From large samples of TH+ varicosities, neuronal elements apposed to noradrenergic axon terminals were identified and quantified. 80% of the TH+ varicosities were apposed to dendritic profiles, of which about half belonged to Purkinje cell dendrites. 60% of the TH+ varicosities were apposed to other axon terminals. In wild type mice, 45% of the dendritic profiles apposed to TH+ varicosities were synaptically contacted by apposed TH- axon terminals, whereas in the weaver mouse this percentage decreased to 22%.

These results emphasize that cerebellar noradrenergic innervation is almost exclusively of the non-junctional type, and that Purkinje cells do not appear to be the only target of this innervation. Granule cell absence does not change the fate of the noradrenergic innervation, because it does not evolve from a mostly non-junctional into a junctional input. This is in contrast to the report for serotonin axon terminals in a rat phenocopy of the weaver mutation (Beaudet and Sotelo, Brain Res. 206:305, 1981).

CONTROL OF POSTURE AND MOVEMENT: HUMAN LOCOMOTION

819.1

SYNCHRONIZATION EFFECTS OF AUDITORY RHYTHM ON GAIT IN HEALTHY ELDERLY AND PARKINSON'S DISEASE PATIENTS. M.H.Thaut*[1], G.C.McIntosh[1], S.H.Brown[2], R.R.Rice[3], C.A.Mezza[1], R.A. Miller[1]. Center for Res. in NeuroRehab., Colorado State Univ.[1]; Center for Human Motor Res., Univ. Michigan[2]; Poudre Valley Hospital[3]; Fort Collins CO 80523.

The effect of auditory rhythm on stride timing in Parkinson's disease (PD) was studied in a frequency entrainment design. Twenty-one PD patients on dopaminergic medication (ON), 10 PD patients off medication (OFF), and 10 healthy elderly (HE) subjects completed 4 tasks: (1) 30 m baseline walking at preferred speed; (2) walking with rhythmic cue matched to their baseline cadence; (3) walking with rhythmic cue 10% faster than baseline; (4) walking with rhythm faded.

Rhythmic signal frequency entrained gait cadence across all frequencies in all subjects except 2 ON-PD patients exhibiting continuous step-to-cue phase drift. Rhythmic cuing decreased variability of stride intervals (IRI) in the OFF-PD group by 62%, and between 10 and 30% in the HE and ON-PD group. Rhythmic stimulus interval (ISI) and IRI were closely matched across all frequencies. Offset values ranged from 8 to 40 ms. OFF-PD patients had larger synchronization errors (SE) (matched cuing: 125 ms; faster cuing: 142 ms) than ON-PD patients (75 ms; 98 ms) and HE subjects (72 ms; 92 ms). Phase angle transformations of SE to normalize for ISI differences showed the same results. SE variability was similar between OFF-PD and ON-PD groups (40.5 vs 47.3 ms) and increased slightly with faster cuing in both groups (45.9 vs 48.2 ms). We conclude that timekeeper entrainment occurred in the HE and both PD groups, however with larger and more variable synchronization offsets in the OFF-PD group.

819.2

FORCE SYMMETRY FEEDBACK TRAINING ON THE BICYCLE IN PATIENTS WITH UNILATERAL CEREBROVASCULAR ACCIDENTS. K.L. Perell,[1] R.J. Gregor,*[2] A.M.E. Scremin.[1] [1]PM&RS, WLA VAMC, LA, CA 90073 & [2]Georgia Tech, Atlanta, GA 30322.

The purpose of this study was to examine the ability of subjects with unilateral cerebrovascular accidents (CVAs) to utilize kinetic feedback to modify pedaling techniques. The relationship between performance and neurophysiological parameters such as sensation, propriception, kinesthesia, and cognition were explored. Eight male subjects with unilateral CVAs were randomly assigned to two groups. The bicycle apparatus was a recumbent bicycle with pedals capable of measuring normal and tangential components of the applied force. Training consisted of twelve one-minute trials with one minute rest between trials, three times a week for four weeks. Feedback consisted of visual and verbal feedback regarding patterns approximating the effective force bilaterally after each trial during the rest periods. The no-feedback (NF) group received no feedback. No feedback was given during the pre/post testing sessions. Effective pedaling was determined by the amount of positive crank work involved/noninvolved (I/N) leg ratio. The NF group showed improvement in this parameter, but the FB group did not. Possible explanations for the lack of improvement in the FB group are: 1) the cyclical nature of cycling allowed for natural patterns to develop without feedback; 2) with feedback, frequent trial-to-trial changes interfered with the development of natural patterns; 3) the feedback may have been too complicated for this population; and 4) development of error-detection mechanisms by integrating the visual feedback and kinesthetic variables was limited by the compromised learning and integrating abilities of these subjects. Further, subjects with subcortical lesions tended to perform better than those with cortical lesions. In the three most important effective pedaling parameters, the majority of the subjects who had I/N ratios closer to 1.0 (complete symmetry) had subcortical lesions.

THE EFFECTS OF CHEMOTHERAPY ON GAIT PATTERNS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA. V.Galea*, C.Mark, J.A.Halton and M.R.Pierrynowski. Human Movement Lab., McMaster Univ., Hamilton, ON, Canada L8N 3Z5.

The majority of children receiving treatment for acute lymphoblastic leukemia (ALL) develop abnormalities of gait, reduced weight bearing and, in severe cases, wheelchair confinement (Halton, et al, 1993). Children with ALL admitted to the McMaster University Medical Centre are treated on the Dana Farber Cancer Institute Protocol, having a prospective of cure approximating 80%. Upon presentation, patients are categorized as either high or standard-risk of relapse (HR or SR) based on (primarily) total white blood cell count and age. Patients in the HR category receive 3X the dosage of corticosteroids (Dexamethasone) than those in the SR category and are cranially irradiated in addition to receiving the SR consolidation and maintenance protocol. SR males receive cranial irradiation but the standard steroid dose.

Complete, kinetic gait analyses were performed on 21 patients who were at various stages of the 24 month treatment protocol. In addition, total serum protein, creatine phoshokinase, serum 3-methylhistidine and hydroxyproline levels were monitored in an effort to assess myofibrillar and collagen degradation secondary to administration of Dexamethasone. The HR females (N=6) were the most severely affected , with the maximum hip joint power at toe-off showing a definite decline as treatment progressed. Those least affected were the SR males (N=7) whose hip joint powers at toe-off did not show a decline as treatement progressed. . SR females (N=5) and HR males (N=3) showed progressive declines in hip powers but to a much lessor extent then the HR females.. Serum 3-methylhistidine and hydroxyproline levels correlated well with maximum hip powers (r=0.748 and 0.891, respectively). Knee and ankle joint powers at toe-off were not affected to the same extent. These findings suggest that the observed gait abnormalities in these children could be attributed to a corticosteroid induced myopathy affecting the large ,proximal lower limb muscles.

EFFECT OF PARESIS ON GAIT INITIATION AFTER STROKE. F. Malouin*, C.L. Richards, F. Dumas, C. Bonneau, F. Comeau and S. Lavoie. Lab. Neurobiology and Physiotherapy Dept., Laval Univ., Quebec City, PQ, G1J 1Z4, Canada.

The initiation of gait is controlled centrally by a motor program (Crenna & Frigo 1991) that releases preparatory adjustments (PAs) to propulse the body forward and toward the stance limb. The aim of this study was to determine if PAs are preserved after a stroke. The activations of soleus (S), tibialis anterior (TA), and the ground reaction forces were recorded bilaterally in nine subjects (mean of 56 yrs) who had sustained a first stroke. Subjects initiated gait under two conditions: 1) with the paretic limb as the swing limb (PSW) or 2) with the non paretic limb as the swing limb (NPSW) while they stood with one foot on each of two force platforms (AMTI). The latency of PAs, and peak values of the centre of pressure (CP), normalized to the length of the base of support, were compared between conditions and to results from a control group (n=6) walking slowly. The two paretic subjects with highest gait velocity (99, 104 cm/s) displayed characteristics PAs (bilateral TA pre-activation, S inhibition, and displacement of the CP backward and to the swing limb) for the two conditions, but the magnitude and timing of the PAs differed from controls. In the other subjects with a slower gait (28-69 cm/s) only the TA from the NP limb was pre-activated in either conditions. The TA from the NP limb was also activated first whether gait was initiated with the PSW (245 ± 70 ms) or the NPSW (216 ± 98 ms) limb. In addition to this fixed order of recruitment, the latency of TA was longer than controls (140 ± 24 ms) suggesting a bilateral involvement in the planning process of the gait initiation program after stroke. While controls had displayed a nearly symmetrical backward shift (peak CPx) under the swing (12.4%) and the stance (14.2%) limbs, patients had smaller CPx on the P side (4% and 8.8%) compared to the NP side (8.8% and 10.9%) for conditions 1 and 2, respectively. Present results suggest that strategies involving the NP side compensate for impaired feedforward control of gait initiation after stroke (Supported by NHRDP).

EFFECTS OF INCREASED SPEED AND WORKLOAD ON THE CONTROL OF MOVEMENT IN PERSONS WITH HEMIPLEGIA. D.A. Brown*, S.A. Kautz, and C.A. Dairaghi. Motor Control Physiology Lab. Rehabilitation Research and Development Center at the Palo Alto Veterans Affairs Medical Center (153), Palo Alto, CA 94304 *Funded in part by Foundation for Physical Therapy, Inc.*

Controversy surrounds the once-widely accepted theory that undue exertion during exercise should be avoided because it may exacerbate impaired motor performance in spastic hemiplegia. We hypothesized that the motor performance measured during pedaling in hemiplegia is related to the level of exertion associated with workload and speed. We examined specific measures of motor performance during pedaling for a relatively homogeneous population of hemiplegic stroke patients and compared these with a group of age-matched, neurologically-normal individuals. We measured pedal force output and EMG activity in seven muscles at combinations of five workloads (0, 40, 80, 120, and 160 Joules) and three speeds (25, 40, and 55 rpm). Results demonstrated that stroke patients responded to increased workloads by increasing the force output of both the plegic and nonplegic limbs without increasing the amount of negative work done by joint torques. This result is also accompanied by increased EMG activity in the power generating muscles of both limbs. Interestingly, subjects with poor motor recovery showed better motor performance at lower speeds. We conclude that, during hemiplegic exercise, challenging workloads can enhance motor output without impairing motor performance. However, exercise at challenging movement speeds should be approached with caution.

THE DYNAMICS OF HUMAN LOCOMOTION: HYSTERESIS AT THE WALK-RUN TRANSITION. F. J. Diedrich* and W. H. Warren, Jr. Department of Cognitive and Linguistic Sciences, Brown University, Providence, RI 02912

Why do humans switch from walking to running as speed increases? According to the dynamic theory, the shift between gaits behaves as a bifurcation between two attractors (Diedrich & Warren, 1995). This theory predicts that the transition should exhibit hysteresis, which is a tendency for the walk to run transition to be made at a higher speed than the run to walk transition. Strong evidence for hysteresis has been found in experiments in which speed was varied in a step-wise manner through the transition region (e.g., Hreljac, 1993). In contrast, in trials in which speed was continuously varied, results concerning hysteresis have been mixed (Diedrich & Warren, 1995). Therefore, in order to clarify these findings, six participants performed transition trials in which the time scale of the change in the control parameter was varied. Specifically, transition trials were performed in the following conditions: 1) speed was continuously varied, 2) speed was changed in steps of 10 s, and 3) speed was changed in steps of 20 s. These trials were analyzed with respect to the direction of the transition, thus resulting in a more complete evaluation of hysteresis.

WALKING AS INFLUENCED BY DIMENSIONAL CHANGES IN ENVIRONMENTAL OBSTACLES. J. R. Higgins*, B. C. Bennett, J. W. Doyle, S. Higgins. Department of Kinesiology, San Francisco State University, San Francisco, CA 94132

Increasingly, descriptions of the mechanisms of motor control are being cast in a dynamical systems framework. From the dynamical systems perspective walking can be considered an attractor state (a stable pattern) for locomotion. Perturbations of a stable attractor can illuminate the principles and processes that contribute to shifts and stabilities in movement pattern. Subjects walking a linear path in their preferred rate and style, were perturbed by having to traverse an obstacle of various dimensions placed in the path. We looked for phase shifts in the temporal and kinematic organization of the movement and in the strategies chosen to traverse the obstacle. The level platform was 20 cm high. The width of the platform, the critical parameter for the designed task, varied from 1 cm to 75 cm, a range that at times either compels stepping over or stepping upon the platform to traverse it, or that affords either strategy. The width of the platform was varied in random order; increasing to decreasing order; and, decreasing to increasing order. Analysis of the movement strategies and kinematics of the gait in this motor task revealed the presence of hysteresis. That is, in regions where the width of the platform affords the subject either stepping upon or over to traverse it, the individual's recent history determines which movement solution will be chosen and how selected temporal and kinematic variables vary to support these strategies. In addition, the kinematic analysis of the subjects' gait revealed systematic adaptation to the direction of change in platform dimension. These data support the existence of a region of bistability between two stable attractor states in which the individual may opt for either state. The transformations and shifts between the two stable attractor states in a hysteretic fashion, argues strongly for context and experience as integrated in the control of movement.

ROLE OF BINOCULAR VISION IN OBSTACLE AVOIDANCE DURING LOCOMOTION. A.E. Patla[1]*, M.A. Goodale[2], S. Rietdyk[1], A. Adkin[1], C. Silcher[1], & J.J. Marotta[3] [1]Dept. of Kinesiology, Univ. of Waterloo, Waterloo, Canada, [2]Dept. of Psychology, Univ. of Western Ontario, London, Canada, [3]Neuroscience Program, Univ. of Western Ontario, London, Canada.

We are interested in determining how binocular vision influences the kinematics of obstacle avoidance during locomotion. Young healthy subjects (n=7) were asked to estimate heights of obstacles verbally, and following that subjects (n=6) were required to step over obstacles of three different heights (Low-0.5cm, Medium-18cm, High-38cm) during locomotion under monocular and binocular viewing conditions. Head and lower limb kinematics were monitored using an OPTOTRAK system. Verbal estimation of obstacle height was similar under two viewing conditions, although the variability in slope of the regression line between the estimated and actual height was more variable under monocular viewing. Choice of leading limb was affected by monocular viewing but only for the high obstacle: when the right eye was patched subjects preferred (approx. 2 to 1) to lead with the left limb and vice versa. Leading limb toe clearance was affected by monocular viewing, but only for the high obstacle (15.4 vs 12.7cm). Trailing limb toe clearance was higher for the monocular viewing condition for all three obstacle heights (H-13.6 vs 12.8cm; M-14.3 vs 12.3cm; L-6.1 vs 4.9cm). Viewing strategies differed among subjects. For 3 subjects relative head pitch angle (with respect to the trunk) over the obstacle was affected by monocular viewing: they looked down more for the high obstacle (20.6° vs 16.1°). Maximum pitch angle occurred before the obstacle in the monocular viewing condition and after the obstacle in the binocular viewing condition. Supported by grants from NSERC Canada.

CONTROL STRATEGIES FOR VISUALLY GUIDED STEPPING

M.A.Hollands and D.E.Marple-Horvat (SPON: Brain Research Association.)
Department of Physiology, University of Bristol, UK

Human subjects performing a task that requires visual guidance of each step onto irregularly placed 'stepping stones' usually foveate the next target of footfall just before they lift the foot to be repositioned ie towards the end of stance. When asked to negotiate the same walkway without ambient lighting, and with each stone's location indicated by a central light spot (LED), subjects' stepping and eye movements are unchanged. Under conditions of intermittent visual denial, in which all LEDs were temporarily extinguished at irregular intervals, a proportion of steps are affected, but not all, suggesting that uninterrupted on-line visual feedback is not crucially important, even when (as here) each step required visual guidance. In an affected step, the effect is primarily on stance, rather than swing, and is an increase in stance duration, suggesting an effect on planning during stance of the next step (next swing towards the next target) rather than on execution of the ongoing step (current swing). Under 400 and 500 ms denial, there is no effect when the target disappears in the first 100ms of stance; this implies that crucial planning does not take place until near the end of stance of the foot to be repositioned. Accurate saccades, followed by accurate steps, to the next footfall target are often made when it is invisible. This implies that saccade generation might itself be useful even though it does not result in a foveal image ie the neural processing preceding a saccade to a target is used in planning the next step. We propose that a task such as this is executed under central nervous control operating as a feedforward visuomotor control system that is robust during periods of visual denial of up to 800ms. Analysis of eye movements recorded during this experiment (currently underway) should further elucidate the underlying control strategies used in this locomotor task.

CONTROL OF TIMING OF HEALTHY ADULT GAIT DURING WALKING AT VARYING CADENCES. S. J. Lee*. Department of Physical Therapy, National Yang-Ming Univ. Taipei, Taiwan, ROC.

Schmidt's invariant phasing theory of motor control (1976, 1985, 1988) is a theory of strict central control of timing in which the proportional duration of the kinematic events of a well-learned or an innate movement pattern is invariable while the overall period of time to complete the movement pattern varies. This study attempted to assess the applicability of Schmidt's invariant phasing theory in mature human locomotor movements by determining if consistency exists in the proportional duration of selected 2 hip, 4 knee and 4 ankle kinematic events in the sagittal plane of healthy adult gait while walking at varying cadences. A computerized videotape gait analysis system was employed. Sixteen repeated stride cycles at preferred, fastest, and slowest cadences, respectively, for each of 18 healthy adults (Mean age=27±6 years, 9 males and 9 females) were analyzed.

The results of this study showed a high degree of consistency in the proportional duration of selected kinematic events during the total stride cycle within repeated trials of each of the walking conditions at preferred, fastest, and slowest cadences. This finding indicates that the control of timing of healthy adult gait within a specific walking cadence is essentially central. However, significant differences ($p < .05$) were found in the proportional duration of all selected kinematic events during the total stride cycle among different walking conditions at preferred, fastest, and slowest cadences. This part of findings indicates that the central control of timing of healthy adult gait is not strict at varying cadences. The results of this study, taken as whole, is better interpreted in light of the view of a task-related control mechanism of timing in mature human locomotor movements. It also suggests a need to refine Schmidt's invariant phasing theory.

SEGMENTAL COORDINATION DURING HOPS USING ONE OR TWO FEET IN CHILDREN AND ADULTS. P.A. McKinley[1]*, C. Assaiante[2], B. Amblard[2], and L. Pelland[1]. McGill University, Sch. of P.O.T., Montreal Quebec H3G 1Y5[1] & UPR Neurobiologie et Mouvements, CNRS, Marseille France[2]

The main purpose of this study was to investigate the development of segmental coordination during single hops using one foot or two feet in children of two ages (5.5-6 and 7-7.5yrs) and adults (n=6/group). Kinematics of the legs, trunk and head, kinetics at takeoff and landing, and EMG of the trunk, lower limb and neck were collected using an integrated motion analysis system (ELITE, BTS). Results were analyzed separately for 3 phases - takeoff, flight and landing - and indicated the following: 1) for head/trunk control, the children differed from adults, but not from each other, while at the lower limb, the three groups used different modes of advancing the body; 2) children use significantly more trunk and head motion to advance the body during bipedal hops than during unipedal hops and as compared to adults; 3) head stabilization in space is phase dependent, while trunk stabilization is phase independent in all subjects. It is suggested that poor timing of, and lack of adequate propulsion during the takeoff phase in children may be responsible for the observed differences. Similarities in head/trunk stabilization in space suggest that the trunk may contribute a stable reference frame from which balance control is organized. Supported in part by NSERC & FRSQ

MODULATION OF RECIPROCAL INHIBITION DURING WALKING AND VOLUNTARY MOVEMENT IN HUMANS. B. A. Lavoie*, H. Devanne and C. Capaday. Centre de Recherche en Neurobiologie, Université Laval, Québec (Qc) Canada, G1J 1Z4

These experiments were designed to evaluate task dependent control of reciprocal inhibition during natural motor activities. We measured the effect of tibialis anterior (TA) activation on the amplitude of the soleus (SOL) H-reflex during the swing phase of walking (SW), one leg stepping (OLS), phasic TA contraction (PC) and tonic TA contraction (TC). Linear regressions of the mean TA rectified EMG vs. SOL H-reflex amplitude were compared to determine whether slopes or y-intercepts (y-int.) differed significantly between these tasks. During PC and TC, the H-reflex amplitude stayed well above zero at all TA EMG levels. During SW and OLS the amplitude of the SOL H-reflex was reduced to, or near, zero during ankle dorsiflexion at all TA EMG levels. When we compared SW and PC, we found that the slopes were not significantly different but the y-int. were significantly higher for PC. When we compared SW and TC the y-int. were always significantly greater for TC. Capaday et al. [J. Neurophysiol. 64: 607-616, 1990] showed that there was no difference in the amount of reciprocal inhibition acting on the active SOL between voluntary tonic activity and the stance phase of walking. In complement to that study, the present results suggest a strong task dependent modulation of reciprocal inhibition onto the inactive SOL (i.e. when it acts as an antagonist). In summary, there was a difference between SW and PC or TC, but not between SW and OLS. The strong reciprocal inhibition occurring in a task in which the SOL is stretched (SW, OLS, PC) could be due to increased presynaptic inhibition of Ia-afferents onto SOL α-motoneurons, or increased hyperpolarization of SOL α-motoneurons. As for the lack of difference between SW and OLS, this could be due to a fine tuning of reciprocal inhibition in order to ensure clearing of the foot off the ground.

H REFLEX MODULATION IN TIBIALIS ANTERIOR DURING PASSIVE PEDALLING. J.D. Brooke, W.E. McIlroy*, M. Miklic, W.R. Staines and J.E. Misiaszek. Department of Human Biology and Nutritional Sciences, University of Guelph, Ontario, Canada N1G 2W1

Soleus H reflex gain is strongly modulated, leading to marked attenuation, consequent to passive movement of the human leg. We addressed the lack of information about any other H reflex of the leg with such movement, hypothesizing that attenuation also occurs for tibialis anterior (TA), in antiphase to the firing pattern this muscle shows during active pedalling. With eight subjects, thirty TA H reflexes were collected at four equispaced phase positions with two passive movement velocities (20 and 60 rpm of the pedal crank). M waves indicated stimulus stability. TA was tonically contracted throughout the cycle, at 5- 15% of the EMG for a maximum voluntary contraction. No significant movement-induced attenuation, or phase modulation of the reflex, occurred for either velocity. Mean maximum depression was 19% of controls, at full extension ($p > .05$). This lack of modulation for the TA H reflex contrasts with typical reductions of up to 80% of control for soleus. Such marked contrasts in sensorimotor gain control between the Ia autogenic pathways for muscles of the human leg may indicate functional differences in the spinal reflexes they serve. Supported by NSERC (CANADA).

819.14

H REFLEX MODULATION DURING REVERSE PASSIVE PEDALLING. S.P.Dukelow, J.D.Brooke*, K.B. Adamo, J.Cheng, W.R. Staines and J.E. Misiaszek. Department of Human Biology and Nutritional Sciences, University of Guelph, Ontario, Canada N1G 2W1

The gain of the soleus H reflex attenuates to the rate of passive movement of the human leg. The attenuation is maximal at the end of leg flexion. In this phase, maximum flexion of the hip and knee occur at different positions. We asked, 'Will the gain changes still occur when the direction of movement is reversed, so as to reverse those positions?' In four subjects, reverse passive pedalling movements of the legs were studied at two velocities, 10 and 30 rpm. Ten H reflexes per subject were elicited from TN stimulation in the popliteal fossa, at eight equispaced positions around the cycle. M waves were used as indicators of stimulation stability. For each subject, greatest reflex attenuation occurred in the flexion phase ($p < .01$), but unlike forward movement, it peaked before full flexion of the knee. Movement velocity continued to determine the degree of inhibition ($p < .05$). The reverse versus forward difference in the position of the peak inhibition likely reflects differences in conditioning receptor discharge from hip and knee extensor muscles, due to differing kinematic profiles for the two movements. Supported by NSERC (CANADA).

819.15

MOVEMENT KINEMATICS MODULATE SOMATOSENSORY EVOKED POTENTIAL (SEP) AMPLITUDE. W.R. Staines*, J.D. Brooke and J.E. Misiaszek. Human Neurophys. Lab, Human Biology Dept., University of Guelph, Guelph, ON, Canada, N1G 2W1.

Gating of SEPs becomes more pronounced with increased movement velocity. Also, the gain of the soleus H reflex correlates with the rate of tissue stretch around the knee during passive cycling. We hypothesized that SEP gain would be similarly dependent on the rate of stretch of the knee extensors. SEPs from Cz' and Cz, referenced to Fpz', along with soleus H reflexes were elicited by electrical stimulation of the tibial nerve at the popliteal fossa in 6 subjects. Combinations of rates and ranges of cyclical passive movement of the right leg were used to obtain two sets of three conditions with equivalent estimated rates of stretch of the knee extensors (4 and 16 mm/s). SEPs sampled during passive movement leading to the greater estimated rate of stretch were significantly depressed compared to those sampled during the lower rate of stretch and the stationary controls ($p<0.05$). The maximum attenuation across all conditions was 40% of the stationary controls. There was also a significant rate effect ($p<0.05$) between the conditions with equivalent rates of stretch. Thus, it appears that, at least for mild attenuation, the controls for SEP gain read both movement range and rate, and not simply the rate of extensor muscle stretch. Supported by NSERC (Canada).

EXPERIMENTAL REMODELLING OF LOCOMOTOR PATHWAY CONTROL. K Weber, WAF Fletcher, C Gordon, G Melvill Jones*, E Block. University of Calgary, Dept. of Clinical Neurosciences, Calgary, Alberta, Canada, T2N 4N1

In a previous study we described an experimental paradigm which adaptively remodelled non-visual control of curvature in the trajectory of forward locomotion in such a way that when trying to walk straight ahead, blindfolded subjects invariably described strongly curved pathways (Gordon et al 1995, EBR 102). In the present study we chose "stepping-in-place" rather than forward locomotion as a means of measuring long-term post-adaptive effects. Six normal subjects participated in 7 trials each, during which they "stepped-in-place" (ie. without turning relative to space) on the center of a horizontal disc which was turning at rates ranging from 11.25 - 90 deg/sec and for durations ranging from 7.5 - 60 min. Following this adaptation procedure, blindfolded subjects attempted "stepping-in-place" on the stationary floor. Results: Post-adaptation all subjects turned relative to space without any perception of rotation, the direction of turn being the same as that of stepping relative to the turning disc. The initial response (up to 20 deg/sec) was linearly related to the velocity of the turning disc (slope=0.41, r=0.79) up to 45 deg/sec after which the response plateaued. The initial response was independent of stimulus duration over the range tested. Two additional response characteristics were: 1) an early (first min) depression (likely due to vestibular stimulation), and 2) a subsequent response decline best fitted by a double exponential curve of short and long time constants on the order of minutes and hours respectively. Presumably this novel, adaptive system normally serves to maintain proper calibrations in the non-visual, ground-based control of locomotor trajectory curvature during forward locomotion.

A SEX DIFFERENCE IN HUMAN TURNING BIAS. L.A. Mead* and E. Hampson. Dept. of Psychology, University of Western Ontario, London, Ontario, Canada N6A 5C2.

Extensive research with rodents has clearly established the existence of individual differences in the preferred direction of spontaneous and induced rotation. Sex differences also exist, in that female rats demonstrate stronger rotational biases than males. In an attempt to generalize these findings to humans, the "human rotometer" has been developed which is capable of measuring spontaneous rotational movement in humans (Bracha et al., 1987). We report here a new method for measuring turning bias in humans which is fast, reliable, and performed under controlled laboratory conditions. Four tapedecks were arranged on tables surrounding an open square area, 3 m across. Every 5 s, one of the tapedecks emitted a 1 s tone, to which subjects responded by approaching the tapedeck and checking a response sheet. Half of the 160 trials were "critical trials" in which the tone was heard from directly behind the subject. The experimenter recorded the direction the subject turned on each trial. Sixty-one right-handed, medication-free subjects (35 males, 26 females) were tested using this paradigm. On average, both males and females demonstrated rightward turning biases on the critical trials, however the tendency to turn to the right was significantly stronger for females. Among 43 subjects who returned for a second session, we found a significant correlation of .77 between the turning biases measured at the two sessions. These findings support the existence of a sex difference in turning bias in humans, and suggest that the rotation task described here is a reliable and valid method of measuring this bias.

819.18

SAGITTAL PLANE HEAD STABILIZATION DURING LOCOMOTION. R.L. Cromwell*. Dept. of Physical Therapy, Temple University, Philadelphia, PA 19140.

The anatomic architecture of the head and neck is one of instability. However, head stability is essential for maintaining gaze during daily activities such as locomotion. In the horizontal plane during locomotion, subjects successfully maintained head stability (Cromwell, Soc. Neurosci. Abstr., 1994). This was accomplished by head with respect to trunk gains < 1 and relative phases $\leq 180°$ at frequencies near 1 Hz. At higher frequencies, gains were now 1 and relative phases were 180° indicating a greater challenge to head stability at these frequencies. A somewhat different picture has emerged in the sagittal plane. Ten subjects walked at their natural cadence while angular velocities of the head and trunk were measured in the sagittal plane. Preliminary results of four subjects showed average peak head velocities of 60.4 °/s toward flexion and 42.1 °/s toward extension. Frequency analyses demonstrated a frequency range of .24 to 8.3 Hz related to this motion. Subjects showed head with respect to trunk gains near 1 and relative phase values of 180° at all frequencies with few exceptions. These frequency and velocity characteristics indicate that the challenge to head stability in the sagittal plane is greater than that of the horizontal plane. Therefore, even at low frequencies in the sagittal plane, head motion perfectly compensates trunk motion in order that head stability is maintained. In the sagittal plane, gravity exerts a greater effect as the head increasingly deviates from vertical. The larger average peak velocity in the flexion direction is an indication of the gravitational effect on head motion in this plane. *Supported by grant DC01125.*

GLUCOSE ENHANCEMENT OF COGNITIVE PERFORMANCE IN COLLEGE STUDENTS. D.L. Korol*, F.J. Lexcen, M.B. Parent, M.E. Ragozzino, C.A. Manning and P.E. Gold. Univ. Virginia, Charlottesville, VA 22903.

In healthy elderly subjects, Alzheimer's patients and other patient populations, glucose ingestion enhances performance on several tests of memory. Similar findings in young adults, however, have not been evident. Perhaps the tests used to demonstrate facilitation of memory in aged and other populations have lacked the sensitivity or difficulty needed to observe glucose enhancement in young subjects. In the present study, we addressed whether glucose facilitates memory and attention in young adults on more difficult tests. A counterbalanced, crossover design was used, with each subject tested on 2 occasions: after glucose (50 g) and after saccharin ingestion. A series of cognitive tests was administered to assess memory for narrative prose and delayed recognition of faces and words (Squire and Zouzounis, 1993), working memory for words (Salthouse, 1992) and attention (Minnesota clerical number checking test). Significant enhancement of performance by glucose was found on both immediate and delayed recall of the narrative prose passage. Scores on narrative prose and attention tests were positively correlated with peak change in blood glucose after glucose consumption. Facilitation was also seen on completed correct items in the attention test, but only when blood glucose rose to levels greater than 60 mg/dl above baseline. These data suggest that glucose enhances cognitive performance in young subjects when both task load and blood glucose levels are sufficiently increased. In addition, under some conditions, glucose enhances performance on tests that emphasize attention as well as memory. Supported by ONR (N0001489-J-1216), NINDS (NS32914) and NIA (AG07648).

ODOR IDENTIFICATION IN HUMANS BEFORE AND AFTER RESECTION FROM A TEMPORAL LOBE. M. Jones-Gotman* & R.J. Zatorre. Montreal Neurological Institute and McGill University, Montreal, Quebec, Canada, H3A 2B4.

Mild deficits in odor identification are observed after temporal-lobe resections in patients tested birhinally (Jones-Gotman & Zatorre, *Neuropsychologia* **26**, 387-400, 1988) and monorhinally (Jones-Gotman et al, *Epilepsia* **33**, 135, 1992) using the University of Pennsylvania Smell Identification Test (UPSIT). In this study, we investigated the contribution of possible pre-existing deficits to performance on the UPSIT in 45 epileptic patients tested monorhinally before and after excision from the left or right temporal lobe.

Results showed impairments in both groups before surgery without significant difference between the nostrils, and an overall decline in the left-resection group after surgery. The right-resection group, although still impaired postoperatively, showed a slight gain rather than a loss after surgery.

The postsurgical loss in left-resection patients underlines the strong verbal component in this olfactory task. The pre-operative deficits in both groups show that an epileptic focus in either temporal lobe is sufficient to disrupt normal odor identification. Funded by MRC MT-10314 to MJ-G and RZ.

THE DEVELOPMENT OF FACE DISCRIMINATION CONTINUES INTO ADULTHOOD: AN ERP STUDY. T.D. Alvarez* and H. J. Neville. UCSD Depts. of Neuroscience and Cognitive Science, La Jolla, Ca 92093.

Clinical, behavioral and electrophysiological studies have led to the proposal that, in adults, specialized mechanisms within the right hemisphere are preferentially involved in the discrimination of faces. Moreover, several studies suggest that adults use these specialized systems in the discrimination of upright but not inverted faces. Comparatively little is known about the developmental time course of the neural and cognitive substrates underlying face discrimination. While some studies suggest that a specialized mechanism for face processing exists even in newborns, behavioral studies have shown that children may not use the same mechanisms as adults in face discrimination tasks. For example, it has been reported that children do not show better performance for upright than for inverted faces, or the left visual field advantage for upright faces seen in adults. These studies have suggested that this adult pattern emerges relatively late in development, sometime in early adolescence.

The present study used behavioral and electrophysiological techniques to examine the development of face discrimination from the age of 9 to adulthood. Event related potentials (ERPs) were recorded from 9, 13, 16 year old, and adult subjects performing a face matching task.

Behavioral findings showed that performance on the task improved with age, and was better for upright than for inverted faces in all age groups. ERP data provided clear evidence of major developmental changes in the processes underlying face discrimination over the age range studied. As in adults, ERPs recorded from children displayed a negativity around 250-450 ms to the second member of a pair of faces. This negativity was greater for mismatched than for matched faces. However, the ERPs of the child groups did not display the hemispheric asymmetry or the difference between upright and inverted faces that was observed in adults. These results suggest that the adult pattern of face discrimination develops gradually, and appears at a much later age than previously believed (> 16 years).

820.4

LATERAL AUDITORY INPUT ALTERS VISUAL PERCEPTION: CROSS-MODAL HEMISPHERE ACTIVATION. Roger A. Drake*, Lisa R. Myers, and Boris A. Marshinin. Dept. of Psychology, Western State College, Gunnison, Colorado 81231, USA and Institute of Psychology, Russian Academy of Sciences, Yaroslavskaia str. 13, Moscow, Russia.

Visual perception was measured by line bisecting. Dividing a horizontal line to one side of the true center indicates a greater relative activation of the contralateral cerebral hemisphere. This perceptual error results from the more-active hemisphere overestimating the length of the line segment in the opposite visual field. Subjects heard audiotaped oral messages about which line to bisect next, in only one ear via full-coverage stereophonic headphones.

The Net measure produced means of -.92 for left-ear input and +.57 for right-ear input, $F(1,26)=4.30$, $p<.05$. The Index measure showed means of -30.77 and +18.00, $F(1,27)=5.41$, $p<.03$.

These results show the power of induced lateral orientation of attention to selectively activate one cerebral hemisphere relative to the other, as previously measured by rCBF (Malamed & Larsen, 1977), cognitive processing (Drake, 1990) EEG (De Toffol et al., 1992), and evoked potentials (Tressoldi & Cusumano, 1992).

820.5

PERCEPTION OF COMPOUND VISUAL STIMULI AND HEMISPHERIC SPECIALIZATION IN HUMANS AND BABOONS. J. Fagot, J. Requin* & C. Deruelle. CNRS, Lab. of Cognitive Neurosciences, Marseille, France.

A matching-to-sample task was used to assess the ability of baboons (n=8) and humans (n=14) to process the global and local information of compound visual stimuli. During the test, a compound sample stimulus, such as a large square made of smaller circles, was displayed for 120 ms in the left (LVF) or right (RVF) visual half-field. Sample presentation was followed by the display of two comparison forms, one matching the sample at either the global or local level, the other being neutral. By manipulating a joystick, the subjects had then to select the comparison form matching the sample. The two species exhibited a LVF (right hemisphere) advantage for global matching, and a reversed but unsignificant RVF (left hemisphere) advantage for local matching. In humans, scores were better and speed faster, when matching had to be made at the global level. In contrast, baboons showed a significant score and speed advantage for local matching. This species difference was replicated in 2 additional experiments, in which effects of stimulus element sparsity and subject familiarization with the forms were assessed. Overall, results suggest (1) that global dominance is not mandatory in nonhuman species, and (2) that this effect in humans has some strong cognitive, rather than purely perceptual (peripheral) bases.

820.6

CONSTRUCTION OF THE SPATIAL COGNITIVE MAP DOES NOT REQUIRE ACTIVE EXPLORATION OF THE ENVIRONMENT. D.B Matthews*, A.M. White, E.D. Brush & P.J. Best. Center for Neuroscience Research and Dept. of Psychology, Miami University, Oxford OH 45056.

When navigating, rats use distal, spatial cues to construct a spatial cognitive map (O'Keefe & Nadel, 1978). This map facilitates navigation and is apparently constructed even if the animal has never physically navigated through the entire environment. Recently, this idea has been challenged by Sutherland et al. (1987) who report that rats trained in the Morris Water maze with barriers restricting their exploration were not able to escape from a novel start location that was located within the restricted region. However, their study included severe alterations in the environment on the test day that may have impaired performance merely by a stimulus generalization decrement. The current study shows that when the rats are trained in the water maze with barriers are that are faded after the animal learns the task, escape performance is not impaired when the rats are started from a novel start location. However, when the barriers were not faded during training and were removed during testing (a method similar to Sutherland's), the animals performance was impaired. Hence, the spatial cognitive map can be used to support spatial navigation regardless of the level of exploration.

820.7

DOES THE LEVEL OF BRAIN ACTIVITY REFLECT THE PERFORMANCE OBTAINED IN TEMPORAL TASKS? L. Casini, F. Macar and O. Pascalis*. Lab. de Neurosciences cognitives, CNRS, 13420 Marseille cedex 20, France.

Attentional models of time perception assume that temporal judgments are based on mechanisms that depend on attentional resources. In order to better understand these mechanisms, slow brain potentials were recorded during different temporal tasks. The relative level of activity asssociated with correct responses was compared to that obtained with incorrect responses to study the relation between performance and brain activity. Slow brain potentials were recorded over 16 electrodes placed over the prefrontal areas.

In the first experiment subjects were tested on a temporal reproduction task: Four As appeared on a video screen for 3 or 4 sec and were then replaced by four Bs. Subjects had to press a button when they thought that the Bs had remained on the screen as long as the As. The B periods were grouped into different categories depending on their duration and three categories were compared: Accurate responses centered on the target, short responses (underestimation of 1 sec) and long responses (overestimation of 1 sec). In the second experiment, four As were presented on a video screen either with a short (2.5 sec) or a long (3.5) duration and subjects had to decide if the presented duration was the short or the long one. Correct and incorrect responses were compared.

In both experiments, correct responses were correlated with a significantly lower level of activity suggesting that efficient temporal processing is related to reduced prefrontal activation. This relation between the subject's performance and the level of brain activity suggests that the errors correspond to increased "cortival noise".

NEURAL SYSTEMS IN TEMPORAL INFORMATION PROCESSING: THE BASAL GANGLIA AND THE CEREBRAL HEMISPHERES **D.L. Harrington, K.Y. Haaland, and W.D. Stofer* Veterans Affairs Medical Center and University of New Mexico, Albuquerque, NM 87108**

Controversy exists about whether timing is localized (i.e., cerebellum) or is a distributed process regulated by many neural systems. The present study examined the role of the cerebral hemispheres and the basal ganglia in timing, as these neural structures have been linked to timing functions. Twenty right-hemisphere (RH) and 20 left-hemisphere (LH) stroke subjects, 30 subjects with Parkinson's disease (PD), and 43 control subjects were studied using procedures of Keele and colleagues (1985; 1989) for isolating timing operations. Subjects completed two motor timing tasks (i.e., a constant 300 or 600 ms intertap interval [ITI]), two perceptual timing tasks (i.e., a 300 and 600 ms SOA between tone pairs), and an auditory processing control task (i.e., frequency perception). The total variability in motor timing was partitioned into clock and motor implementation sources of variance using the methods of Wing and Kristofferson (1973). The PD group was impaired in the clock, but not the motor source of variance in the motor timing task, regardless of the ITI. Only the clock component of motor timing was impaired in the stroke groups, but a hemispheric asymmetry was found such that the RH group showed the greatest clock variability at the 600 ITI and the LH group showed the greatest clock variability at the 300 ITI. Perceptual timing was impaired in all patient groups. Only the two stroke groups were impaired on the frequency perception control task. The results implicate the basal ganglia and/or the thalamocortical circuits in timing. In addition, the findings are consistent with models that propose hemispheric biases for processing frequency information, and this asymmetry is further explored in analyses of intrahemispheric lesion location.

A PREDICTIVE MODEL FOR DIFFUSE SYSTEMS MATCHES HUMAN CHOICES IN A SIMPLE DECISION-MAKING TASK. D.M. Egelman, C. Person, P.R. Montague*. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Recent physiological work in alert primates suggests that firing rate changes in a subset of mesencephalic dopamine neurons carries information about expectations of future rewarding events. These neurons also have access to the precise time at which a reward will be delivered. We have previously proposed that the output of these neurons represents ongoing errors between the expected amount of reward and amount delivered, shown how such errors could be constructed in a real brain, and related the resulting algorithm to methods of optimal control (Quartz *et al.*, Soc. Neuro. Ab. 18:1210 (1992)). We have now used the model to bias action choice through control of noise sensitivity of target neurons. Both humans (n=9) and networks were given a simple two deck card choice task where the amount of reward from both decks was not stationary and depended on the history of choices from the decks. The networks converged quickly so as to match the relative rate of return from the two decks. The majority of humans (n=7) settled into the same 'matching' strategy while a minority performed near the optimum (n=2). Our proposed model provides one possible bottom-up description of how diffuse systems could establish constraints that favor event matching while not excluding other more complicated reward-seeking strategies. This may explain why it is difficult for animals, however rational they may be, to maximize long-term rewards and why under appropriate circumstances they display risk averse behavior.

A THEORY OF PERCEPT PROCESSING L.D. Partridge* L.D. Partridge Dept of Biomed. Eng. Univ. of Memphis, Memphis TN 38152 and Dept. of Physiol. Univ.of New Mexico, Albuquerque NM 87131

Any cognitive theory that attempts to explain sensory percepts must deal with the integration of information across sensory modalities. The ability to parse the sensory world into discrete identifiable objects is a very individual process that relies on both genetic predisposition and neuronal plasticity. As such it forms the basis for the individual's unique cognitive interaction with the world.

A useful description of processing of sensory information utilizes the concept of specific percept attractors. The set of all inputs that can activate a given attractor constitutes the basin of that attractor. Adjacent basins are separated at sepatrixes. A percept attractor is a characteristic and multidimensional neuronal path that can be loosely linked to other percept attractors in either a mutually inhibitory or nested manner. It is proposed that there is a range of attractors, from those that can be fully activated by an input of a single dimension in one sensory modality, to those that are activated by varying inputs from multiple dimensions over several sensory modalities. Individual inputs to these attractors can merely bias neurons toward a state in which an activity trajectory is sustained transiently.

We present here a theory of orders of progressively more complex sensory basins approximately representing the drive of fixed action patterns and of simple reflexes, and simple perceptions and an integrated perceptual space. The from-bottom-up meta control of sepatrix fields in the integrated perceptual space may in turn be the basis for primary consciousness.

820.11

SOLVING THE PUZZLES OF HUMAN PERCEPTION.
Y. Shapiro*. TBD. Cambridge, MA 02138.

The puzzles of perception that emerge from the computational models, which are based on Helmholtz's theory of perception, include: How must the brain compute 2D retinal images into 3D representations? Given the foveal blind spot, how must the brain compute so that we see the objects without the hole/s corresponding to the blind spot? Given the blood vessels in the retina, how must the brain compute so that we see the objects whose surfaces are not laced with the lines corresponding to the vessels? While more puzzles are certainly in the coming from the students of computer vision, the puzzle of puzzles - "fusion" has another problem yet. Purves & White (1994) tested the hypothesis of and present experimental evidence for monocular habit in normal distance viewing. Their finding is well explained by the well known fact: most neurons of primary visual cortex have preferential response to the stimulation of one eye or the other, but it contradicts the explanation of perception as "fusion". As Purves & White (1994) point out, the explanation is suspect anyway: it cannot explain either "double vision" or ocular rivalry, and it is at odds with the preferential response. "Fusion" or "the inner eye" is invoked to explain the unity of perception which begins in two retinal images of the brain that must compute retinal images. And to compute the brain must store, as it must in the new biological models of Calvin (1990) and Edelman (1989, 1992), according to which retinal images are superfluous. The assumption that neurons compute and store requires two classes of neurons for which we have no morphological, chemical, or other evidence. LTP provides no convincing evidence for LTM (Shapiro, 1994). To solve all the puzzles, a new theory of perception is badly needed and will be presented.

MONOAMINES AND BEHAVIOR: DOPAMINE II

821.1

6-OHDA LESIONS OF MEDIAL PREFRONTAL CORTEX POTENTIATE STRESS-INDUCED ANALGESIA IN THE RAT. C.A. Sorenson* and J.L. Bloom. Neuroscience Program, Amherst College, Amherst, MA 01002.

Previous research has shown that 6-OHDA lesions of medial prefrontal cortex (MPFC) produces hyperdopaminergia in the mesolimbic DA system characterized by elevated D2 receptor density, an increase in the stress-related release of DA, and an increase in behaviors linked to mesolimbic activity. Evidence also suggests a role for mesolimbic DA neurons in the production of analgesia. This study was undertaken to test whether animals receiving MPFC injections of 6-OHDA would show potentiation of stress-induced analgesia, as measured by an increase in tail flick latency (TFL) scores to mild stressors (.2 ma footshock or 60 sec. of an audiotape of rat pain-induced vocalization). Twenty-four male Sprague-Dawley rats received bilateral MPFC injections of either 6-OHDA or the ascorbate vehicle. 6-OHDA animals displayed a significantly greater increase in TFL scores following exposure to either stressor than did controls. In addition, the locomotor response to amphetamine was significantly greater in 6-OHDA animals, and there was a highly reliable correlation between locomotor activity score and the increase in TFL produced by vocalization. These findings suggest that mesolimbic DA neurons may modulate aspects of the stress response, such as analgesia, and therefore implicate these neurons in the control of emotional reactivity.

821.2

CHRONIC IN VIVO MONITORING OF EXTRACELLULAR DOPAMINE USING ELECTROCHEMISTRY. G. C. Parker* and P. B. S. Clarke. Pharmacology & Therapeutics, McGill Univ., Montreal, PQ, Canada H3G 1Y6.

We have developed a technique to monitor the changes in interstitial dopamine (DA) with a high temporal frequency in a preparation that provides consistent measurements over months rather than days. Nafion-coated carbon paste 'working' electrodes were tested after chronic implantation in the rat nucleus accumbens. In a typical session, voltammetry is used to characterise the voltage-current relationship for that implant and determine the parameters to be used in chronoamperometry. By comparing the voltammogram to the measured current at various potentials using chronoamperometry, we have demonstrated that at the sweep speed used, the voltammogram correctly describes the optimal potential to use in the chronoamperometric experiments. A session can last several hours with a stable baseline, sampling as often as every 3 sec on the device we use (GMA Echempro). Electrochemical selectivity was tested as follows. The monoamine oxidase inhibitor pargyline (100 mg/kg IP) increased the signal, whereas the D1/D2 agonist pergolide (0.6 mg/kg IP) decreased it. Uncoated electrodes monitored opposite changes from a higher baseline. The 5-HT uptake inhibitor fluoxetine (10 mg/kg IP) did not alter the signal at Nafion-coated electrodes. By reference to literature microdialysis reports, our results are consistent with the Nafion-coated electrodes measuring DA with minimal interference from DOPAC, ascorbate, 5-HT or 5-HIAA at the parameters used. Using a modification of a reference electrode design (Kruk et al., Soc Neurosci Abstr 19: 384.14) our preparation is still stable and selective more than two months after surgery. This technique provides a valuable tool for behavioural and pharmacological analyses requiring a chronic preparation, sampling with a temporal resolution higher than is commonly available using microdialysis.

821.3

HETEROGENEITY OF PRESUMED DOPAMINE NEURONS IN THE VENTRAL TEGMENTAL AREA IN AWAKE, UNRESTRAINED RATS. E. A. Kiyatkin* and G. V. Rebec, Prog. in Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

Mesocorticolimbic dopamine (DA) neurons play a pivotal role in the regulation of behavioral processes. Although much is known about these cells in anesthetized and in vitro preparations, information on the mechanisms regulating their activity under natural conditions is very limited. To assess this issue, single-unit recording combined with microiontophoresis was used in awake, unrestrained rats to study the electrophysiological properties of neurons in the ventral tegmental area (VTA) and their responses to DA and glutamate (Glu). In contrast to the traditional differentiation of VTA units into two groups -- DA and non-DA cells (long vs. short spike and low vs. high rate of activity) -- we found substantial diversity in both spontaneous impulse activity and responsivity to the applied compounds. Although an analysis of our data revealed at least five types of VTA neurons, two of these appeared to be DA-containing. Type I cells, localized in lateral and deep areas of the VTA, had relatively long bi- or triphasic spikes, low rate of nonbursting spontaneous activity with minimal changes after presentation of simple activating stimuli and/or during movement. These cells were highly sensitive to DA, but the threshold for the Glu response was high, and the magnitude of Glu-induced activation was small with profound rebound inhibition. Type II cells, localized throughout the dorso-medial areas of VTA, had a triphasic spike of shorter duration and discharged with a bursting pattern at a highly variable rate. These cells typically show powerful activation characterized by bursting, decreasing spike magnitude and, on occasion, episodes of depolarization inactivation, after stimuli presentation and during spontaneous motor behavior. Type II cells were highly sensitive to Glu-induced activation and consequent depolarization block, but the threshold for the DA-induced inhibition was much higher than in Type I cells. Although the reasons and mechanisms underlying this heterogeneity are unknown, VTA DA cells of both types appear to be governed by strict self-regulatory mechanisms minimizing their response to direct afferent stimulation. Supported by NIDA (DA 02451).

EFFECTS OF HALOPERIDOL AND SCH 23390 ON JUVENILE RAT SOCIAL BEHAVIOR: IMPLICATIONS FOR THE ROLE OF DOPAMINE. S. L. Bucher-Yiannoutsos*, S. Kilroy, L. Lassow, & J. D. Salamone Department of Psychology, University of Connecticut, Storrs, CT., 06269-1020

The effects of various doses of haloperidol (HP; 0.025 mg/kg, 0.05 mg/kg, 0.1 mg/kg, 0.2 mg/kg, vehicle) and SCH 23390 (SCH; same doses) on juvenile rat social behavior were assessed. In two experiments, the effects of systemic drug administration on rough-and-tumble play (RT play) vs. non-playful social (NP social) activity were investigated via a modified paired-encounters paradigm. Two hundred dyads (n = 100 dyads per experiment) were tested according to dose of HP or SCH administered, and whether one or both members of the pair (1MEM or 2MEM) received an injection. Subjects were observed for 15 rather than 5 minutes, and the frequency of NP social activities (e.g., sniffing) was evaluated. Results indicate that the modified paradigm is useful in characterizing the complex nature of juvenile social behavior, as well as delineating the behavioral effects of pharmacological compounds. Haloperidol selectively affected RT play for the 2MEM sample in a dose-dependent fashion, with the 0.05 mg/kg dose resulting in excitation, and the 0.2 mg/kg dose inducing significant behavioral suppression. By contrast, HP did not significantly affect either the 1MEM sample or NP social activity at any dose administered. SCH also induced a dose-dependent decrease in RT play, and had no effect on NP social activity. Unlike HP, lower doses of SCH did not result in higher levels of playful behavior. Taken together, these results indicate that brain dopamine may be critical for the execution of RT play, but appears to be less critical for the expression of NP social behavior.

821.5

SOCIAL REACTIVITY IN INBRED MOUSE STRAINS: MEDIATION OF FEAR BEHAVIOR BY D_1 AND D_2 DOPAMINE RECEPTORS

P.L. Gendreau[1], J.M. Petitto[2], J.-L. Gariépy[1], and M.H. Lewis[2]*. [1]Department of Psychology, University of North Carolina, Chapel Hill, NC, 27599, [2]Department of Psychiatry, University of Florida, Gainesville, FL, 32610.

In previous experiments we observed that dihydrexidine (DHX), a full efficacy dopamine agonist with a 10 fold selectivity for D_1 vs. D_2 sites, markedly increased social reactivity in isolated ICR mice. This response was correlated with an isolation-induced increase in striatal D_1 density. In this study we hypothesized that these effects would be particularly robust in inbred mouse strains characterized as high in emotionality. Given the importance of motor activity in the expression of emotional behavior, two inbred mouse strains (A/J and C57BL/6J) high in emotionality and low and high, respectively, in motor activity were chosen. Isolated mice were administered either a D_1 (DHX, 10 mg/kg) or D_2 (quinpirole, 1.0-3.0 mg/kg) agonist and their behavior was assessed in a social interaction test. Both agonists induced a marked strain dependent social reactivity. In C57BL/6J mice, DHX significantly increased escape behavior whereas quinpirole (3.0 mg/kg) had only marginal effects on this measure and other measures of social reactivity. Conversely, quinpirole induced a striking increase in almost all measures of social reactivity (e.g., defensive kicking, jump, vocalization) in A/J mice. This heightened reactivity was also observed following DHX, albeit to a much lesser degree. These findings highlight the importance of dopamine receptors in the expression of fear-related behaviors. They also suggest differences in receptor subtype mediation of social reactivity as a function of strain. Supported by NSERC of Canada and MH45371.

821.6

ELECTROPHYSIOLOGICAL AND PHARMACOLOGICAL CHARACTERIZATION OF SINGLE NEURONS IN THE VENTRAL TEGMENTAL AREA OF THE RAT.

Kosobud, A.E.K.[1], and Chapin, J.K.[2] [1]Prog. Neural Sci., Dept. Psych., Indiana Univ., Bloomington, IN 47405, USA; [2]Dept. Anat. and Neurobiol., Med. Coll. of Penn./Hahnemann Univ., Philadelphia, PA, 19102, USA.

The ventral tegmental area (VTA) is a central element in a neural system that mediates the reinforcing properties of natural stimuli (such as food), brain stimulation and drugs of abuse. While VTA dopaminergic neurons appear to be of particular importance, the VTA also contains interneurons and non-dopaminergic projecting neurons whose role in VTA function and influence on dopamine release are relatively unknown. Using multiple chronically implanted microwire electrodes, it is possible to record from many VTA neurons simultaneously. In preparation for studies of the functional interaction of VTA neurons, we have been developing criteria for identification and subgrouping of recorded neurons. In the present studies, bundles of 4-8 microwire electrodes were chronically implanted in the VTA of male Wistar rats. Following recovery from surgery, recordings were obtained in awake and anesthetized rats during administration of drugs including apomorphine (a mixed D1/D2 agonist), morphine or alfentanyl (μ opiate agonists), and midazolam or diazepam ($GABA_A$ agonists). Signals reflecting the activity of single neurons were identified by uniformity of waveform, and decreasing probability of unit firing observed around the node of the autocorrelation histogram. Neurons broadly classifiable as dopaminergic (long duration, irregularly shaped waveforms, relatively slow firing rates, inhibited by apomorphine, excited by μ opiate and $GABA_A$ agonists) and non-dopaminergic (short duration, biphasic action potentials, excited by apomorphine, inhibited by μ opiate and $GABA_A$ agonists). Furthermore, the heterogeneity observed within these two broad categories suggests that it may be possible to further subdivide these neurons, for instance into non-DA interneurons and projecting neurons, and also into subtypes of DA neurons. Supported by NIDA DA 08349 and Hahnemann University RIG 990414.

821.7

DOSE-DEPENDENT EFFECTS OF ASCORBATE ON CONDITIONED AVOIDANCE RESPONSE. J. M. Gulley* and G. V. Rebec, Program in Neural Science and Dept. of Psychology, Indiana University, Bloomington, IN 47405.

Pretreatment with ascorbate, a known modulator of dopamine transmission in the striatum, enhances the ability of haloperidol, a dopamine antagonist, to induce catalepsy and to block the behavioral effects of amphetamine (Rebec and Pierce, Prog. Neurobiol., 43:537, 1994). In the present study, we extended this line of work to the lever-release version of the conditioned avoidance response (CAR) task, which is highly sensitive to changes in striatal dopamine (White and Rebec, Neurosci. Protocols, in press). Increases in dopamine transmission enhance CAR performance, while decreases have the opposite effect. Adult, male rats were trained to avoid footshock by releasing a lever within 500 msec of tone onset. We tested the effects of low (100 mg/kg) and high (1000 mg/kg) dose ascorbate both alone and in combination with haloperidol (.01 and .05 mg/kg). Consistent with previous results, high dose ascorbate alone impaired CAR performance and increased response latency without altering the latency of the escape response. The low dose of ascorbate, in contrast, failed to impair CAR performance by itself and attenuated the detrimental effects of haloperidol. Collectively, these results confirm and extend reports that ascorbate modulates dopamine-mediated behavioral responses. Our data suggest, however, that this effect of ascorbate is dose-dependent such that low doses enhance and high doses impair striatal dopaminergic mechanisms.

Supported by NSF IBN 91-12055.

821.8

EFFECTS OF L-DOPA, METHAMPHETAMINE AND APOMORPHINE ON SHUTTLE AVOIDANCE LEARNING IN NEONATALLY 6-OHDA-TREATED RATS. M. Takasuna*[1], T. Okauchi[2] and T. Iwasaki[2]. [1] Yamano College of Aesthetics, Tokyo 192-03, Japan. [2] Institute of Psychology, Univ. of Tsukuba, Tsukuba 305, Japan.

Neonatal depletion of brain dopamine produces various behavioral deficits including hyperactivity as well as learning impairment of active avoidance task (Takasuna et al, 1995). To investigate the drug effects on shuttle avoidance learning in the dopamine-depleted rats, L-DOPA (5 or 25 mg/kg, i.p., pretreated with benserazide), methamphetamine (1 or 2 mg/kg, i.p.) and apomorphine (0.5, 1.0 or 10 mg/kg, i.p.) were injected before the training session. Rats were treated with 6-hydroxydopamine (6-OHDA; 35 μg/3 μl/ventricle, pretreated with desipramine) on Days 2 and 4 after birth. The avoidance training (50 trials x 3 days) began on Day 90 after 5-min open-field test. Though each drug elicited a dose-dependent alteration of activity in the open-field, none of the drugs increased the number of avoidance responses in 6-OHDA-treated group. In particular, the increase of intertrial shuttling responses after the injection of higher dose of L-DOPA was not accompanied with improvement of avoidance performance. These results suggested that the performance of 6-OHDA-treated rats was not affected by the activity-stimulating effect of the drugs.

821.9

EXPOSURE TO AMPHETAMINE *IN VIVO* LEADS TO ENHANCED AMPHETAMINE-INDUCED DOPAMINE RELEASE BY DOPAMINE NEURON TERMINALS *IN VITRO*. M. O'Neill, J. Wang and P. Vezina*. Department of Psychiatry, University of Chicago, Chicago, IL 60637.

Experiments investigated the effect of prior exposure to systemic injections of amphetamine on the subsequent release of dopamine (DA) evoked by amphetamine from DA neuron terminals in the rat nucleus accumbens (N.Acc.) and dorso-lateral striatum (Dl.Str.) *in vitro*. Different groups of rats were administered five injections of amphetamine (3.0 mg/kg, i.p.) or saline, one injection every third day. Two weeks following the last injection, rats were decapitated, their brains rapidly removed, the N.Acc. and Dl.Str. bilaterally dissected out and the tissue incubated in oxygenated sodium bicarbonate buffer. Tissue was incubated repeatedly for five minutes in 400 μl of medium and exposed in successive incubations to different concentrations of amphetamine (0-10 μM). Prior exposure to amphetamine *in vivo* led to significantly enhanced, concentration dependent, amphetamine-induced DA release from both N.Acc. and Dl.Str. DA neuron terminal tissue *in vitro*. The two groups did not differ when no amphetamine was present in the medium: basal DA release *in vitro* was not altered by amphetamine preexposure *in vivo*. These results confirm and extend those of previous reports (Kolta *et al.*, Neuropharmacol., 1985, 24, 823; Castaneda *et al.*, Life Sci., 1988, 42, 2447). Together with other findings indicating that amphetamine acts in the cell body region of midbrain DA neurons to produce sensitization, these results support the view that exposure to such injections leads to long term changes in midbrain DA neuron function.

821.10

MK-801 BLOCKS THE DEVELOPMENT OF SENSITIZATION TO THE LOCOMOTOR AND DOPAMINE ACTIVATING EFFECTS OF AMPHETAMINE. D.C. Jolly* and P. Vezina. Department of Psychiatry, University of Chicago, Chicago, Illinois 60637.

Repeated intermittent administration of amphetamine has been shown to produce an enhanced locomotor and nucleus accumbens (N.Acc.) dopamine (DA) response to a subsequent challenge injection of amphetamine, when testing is done sufficiently long after the last drug injection. This study used *in vivo* microdialysis and measured locomotor activity in rats to examine whether these effects would develop in the presence of NMDA receptor blockade by MK-801. Four groups of rats were tested. During preexposure, rats in each group received 2 injections (separated by 30 min.) per session. These were conducted every third day. Rats in the S-S group received two injections of saline. Rats in the S-A group each received saline and amphetamine (1.0 mg/kg, i.p.). Rats in the M-S group received MK-801 (0.3 mg/kg, s.c.) and saline. Finally, rats in the M-A group received MK-801 and amphetamine. This procedure was repeated five times. Two to three weeks after the last injection, all animals were given amphetamine (1.0 mg/kg, i.p.) and their locomotor and N.Acc. DA response measured. The S-A rats showed a significantly greater locomotor and N.Acc. DA response in comparison to S-S rats, reflecting sensitized responding by S-A animals. In contrast, the locomotor and N.Acc. DA response of M-A rats did not differ significantly from those of M-S. rats. These results suggest that NMDA receptor activation is a necessary component of the development of sensitization to amphetamine. Interestingly, both the locomotor and N.Acc. DA responses of animals having been preexposed to MK-801 were higher than those of S-S rats. This may reflect an additional and separate long-term effect of exposure to this NMDA receptor antagonist.

821.11

CROSS-SENSITIZATION IN THE PREWEANLING RAT: THE EFFECTS OF DIZOCILPINE ON AMPHETAMINE AND NPA. M.A. Duke, C.A. Bolanos, G.M. Garmsen, M.A. Clair, S.A. McDougall*. Dept. of Psychology, California State Univ., San Bernardino.

Repeated exposure to a variety of direct (NPA) or indirect (amphetamine; AMPH) DA agonists produces sensitization in young and adult rats. NMDA antagonists (dizocilpine; DIZ) block the induction of sensitization in adults, suggesting that DIZ and the DA agonists AMPH and NPA share a common locus of action. To further assess this possibility, we attempted to determine, using the preweanling rat, whether (1) DIZ would block the sensitization induced by AMPH and NPA; and (2) whether DIZ, AMPH, and NPA are capable of inducing cross-sensitization. 17-day-old rats were injected on four consecutive days with DIZ (0.3 mg/kg) or saline. After 30 min, rats were then given AMPH (2.5 mg/kg), NPA (1.0 mg/kg), DIZ, or saline. A final test day occurred 2 days later, with activity, sniffing, and rearing being measured after AMPH, NPA, or DIZ treatment. The results showed that pretreatment with DIZ blocked the sensitization induced by AMPH and NPA. Curiously, DIZ, AMPH, and NPA did not induce cross-sensitization in the 17-day-olds. For example, repeated treatment with AMPH had no effect on the behavioral actions of DIZ or NPA. Thus, these results show that DIZ, AMPH, and NPA are each capable of inducing sensitization, but that the sensitization produced by these drugs may be mediated by different mechanisms.

821.12

CUES SPECIFICALLY UNPAIRED WITH AMPHETAMINE ATTENUATE THE DEVELOPMENT OF LOCOMOTOR SENSITIZATION TO THE D-2 DOPAMINE RECEPTOR AGONIST QUINPIROLE. C. Jake-Matthews* and P. Vezina. Department of Psychiatry, University of Chicago, Chicago, IL 60637.

Experiments were conducted to determine whether prior exposure to amphetamine enhances the subsequent development of sensitization to the locomotor effects of the D-2 dopamine receptor agonist quinpirole. Because conditioned drug effects have been shown to influence the expression of sensitization to amphetamine, the role of such effects in the development of sensitization to quinpirole were also assessed.

Three groups of rats were first administered injections of either amphetamine (1.5 mg/kg, i.p.) or saline. Animals in one group (PAIRED) received amphetamine in locomotor activity measuring boxes and, the following day, saline in their home cage. Animals in a second group (UNPAIRED) received saline in the activity boxes and amphetamine in their home cage. Animals in a third group (CONTROL) received saline in both environments. All animals were left undisturbed on the third day. This procedure was repeated five times. Seven to ten days following the last injection, all animals were administered quinpirole (0.5 mg/kg, s.c.) in the activity boxes and their locomotor response measured. These injections were repeated every four days for a total of 10 quinpirole injections.

Prior exposure to amphetamine had no effect on the subsequent development of sensitization to the locomotor effects of quinpirole. Both PAIRED and CONTROL group animals displayed a similar development of sensitization to quinpirole when this agonist was administered repeatedly. Interestingly, the development of sensitization to quinpirole over days in UNPAIRED group animals was significantly retarded relative to the other two groups. These results suggest that while different mechanisms likely contribute to the locomotor sensitization observed with amphetamine and D-2 dopamine receptor agonists, both instances are dramatically affected by conditioned stimuli specifically unpaired with drug.

821.13

LONG-TERM, BI-WEEKLY TREATMENT OF LESIONED RATS WITH QUINPIROLE LEADS TO BEHAVIORAL SENSITIZATION TO BOTH D1 AND D2 DA RECEPTOR AGONISTS AND TO L-DOPA. K.E. Asin*, L. Bednarz and A. Nikkel, Neuroscience Res. D-47U, Pharmaceutical Products Division Abbott Laboratories, D-47U, Bldg AP9A, Abbott Park, IL 60064

Reports indicate that daily, repeated administration of selective D1 and D2 dopamine (DA) receptor agonists to lesioned rats may lead to the development of behavioral tolerance or sensitization in response to an acute drug challenge. Since sensitivity changes are dependent on dose and treatment schedule, we investigated the consequences of intermittent, repeated treatment of lesioned rats with vehicle (**V**), D1 or D2 DA agonists on rotation after acute D1 and/or D2 agonist challenges.

Male Sprague-Dawley rats were given unilateral injections of 6-OHDA into the MFB. Following recovery, rats were tested for rotation after apomorphine (0.3 mg/kg), divided into 4 groups (N=17-18/grp), and given 43, bi-weekly injections of either **V**, the D1 agonist **A-85653** (0.09mg/kg), quinpirole (0.15mg/kg) (**Quin**) or A-85653 (0.03mg/kg) + Quin (0.05 mg/kg) (**COMBO**); rotation was examined periodically. After this repeated treatment phase (RTP), animals were challenged with various doses of either A-85653, Quin, or L-DOPA and rotation was measured.

During the RTP, all but **V** rats demonstrated behavioral sensitization. Repeated **A-85653** led to behavioral tolerance in response to acute, low doses of A-85653, but response sensitization following a higher dose compared to rats given **V** during the RTP. Rotation levels were unchanged compared to **V** following any challenge dose of Quin, but the behavioral response to L-DOPA was diminished. In contrast, rats given **Quin** during the RTP showed enhanced rotation in response to all compounds, including A-85653. The effects of repeated **COMBO** treatment were compound- and dose -dependent and tended to reflect the additive effects of repeated A-85653 and Quin. HPLC analysis indicated that rats sustained 95% striatal DA depletions.

Our results indicate that repeated quinpirole treatment leads to behavioral supersensitivity in rats following an acute injection with a D1 or D2 receptor agonist or L-DOPA. In contrast, repeated A-85653 treatment produces dose-dependent changes in behavioral sensitivity to itself, but not to quinpirole or L-DOPA.

821.14

CORRELATION OF STRIATAL DYNORPHIN mRNA EXPRESSION AND BEHAVIORAL SENSITIZATION FOLLOWING REPEATED D1 AGONIST INJECTION. J.F. Bejar, M.B. Harrison, and J.M. Trugman* Department of Neurology, Univ. of Virginia, Charlottesville, VA 22908

Repeated injections of D1 dopamine agonists have been shown both to elicit behavioral sensitization and increase striatal dynorphin mRNA expression but the correlation between dynorphin expression and sensitization has not been established. Rats with unilateral 6-hydroxydopamine nigral lesions received 1, 2, 4, or 8 daily injections of the D1 agonist SKF 38393 (10 mg/kg ip). Contralateral rotation was observed for 2 hours following each injection and after the last injection the brains were processed for dynorphin mRNA expression by *in situ* hybridization. Rotation increased as a function of the number of injections with a maximal response achieved after 5 injections (repeated measures ANOVA, $P<0.05$). Dynorphin mRNA expression was markedly increased in the dopamine deafferented striatum after 4 and 8 injections of D1 agonist with the most prominent effect seen in the dorsolateral quadrant (up 250%). Dynorphin expression and rotation both positively correlated with injection number (linear regression analysis, $P<0.05$) and there was a positive association of dynorphin expression and rotational response (Spearman rank-order correlation, $P<0.05$). These results are consistent with the hypothesis that increased striatal dynorphin contributes to the enhanced motor response resulting from repeated D1 agonist injection.

821.15

STRIATAL DOPAMINE CONCENTRATIONS FOLLOWING AN ACUTE TREATMENT WITH AMPHETAMINE IN A NOVEL VERSUS HOME ENVIRONMENT. K. E. Browman *, A. Badiani, J. J. Lalley and T. E. Robinson. Department of Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI 48104.

The magnitude of amphetamine-induced rotational behavior is greater in rats treated in a NOVEL versus HOME environment (Badiani et al. 1993). We hypothesized that the environment may influence the behavioral response to amphetamine by modulating striatal dopamine concentrations. In a previous studies, however, we found no HOME versus NOVEL differences in the effects of amphetamine on dopamine concentration in the NAcc-Core. These experiments were to determine whether HOME versus NOVEL differences in amphetamine-stimulated dopamine may be found in the NAcc-Shell or in the Caudate.

Rotational behavior in rats with a unilateral 6-OHDA lesion of the mesostriatal dopamine system was used as an index of the psychomotor activating effects of amphetamine. The animals were implanted contralaterally with a microdialysis probe aimed at either i) the NAcc or the Caudate (Experiment 1), or ii) the NAcc-Shell (Experiment 2). One day later the animals received 2 mg/kg of amphetamine IP, either in their HOME cage or in a NOVEL test cage. Rotational behavior was quantified for 100 min. and simultaneously samples of dialysate were collected every 20 min. In Experiment 1 we found that, although amphetamine-induced rotational behavior was enhanced in the NOVEL environment, there were no differences in NAcc or Caudate dopamine. Experiment 2 is in progress, and data will be reported at the meeting.

821.16

THE DEVELOPMENT AND EXPRESSION OF AMPHETAMINE SENSITIZATION ARE ATTENUATED BY REMOVING TREATMENT ASSOCIATED CUES. Hans S. Crombag*, Aldo Badiani and Terry E. Robinson. Department of Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI 48104.

The development and expression of sensitization to the psychomotor stimulant effects of amphetamine (AMPH) is significantly attenuated if rats are given drug treatments in their HOME cage relative to rats receiving the same treatments in a physically identical but NOVEL test cage (Badiani, 1993). One difference between the HOME and NOVEL environment is the salience of cues that predict drug administration. We hypothesized, therefore, that removal of all cues predictive of drug administration would further attenuate the development and expression of sensitization. We tested this hypothesis by comparing AMPH sensitization in two groups of rats. One group received an unsignalled intravenous (i.v.) infusion of AMPH (1.0 mg/kg) each day for six consecutive days at HOME using a remotely activated infusion pump. The second group received the same treatment but in a NOVEL environment. The psychomotor response to AMPH was quantified by measuring rotational behavior in unilaterally DA-denervated rats. Repeated AMPH treatment produced a progressive increase in drug response in rats that received i.v. infusions in the NOVEL environment. In contrast, the same dose of AMPH produced a very small acute response in the HOME environment and there was no evidence of sensitization. These results further implicate the role of environmental factors in the development and expression of behavioral sensitization.

821.17

FURTHER STUDIES ON THE ENHANCING EFFECTS OF A NOVEL VERSUS HOME ENVIRONMENT ON AMPHETAMINE SENSITIZATION. A. Badiani* and T. E. Robinson. Department of Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI 48104.

Sensitization to the psychomotor activating effects of amphetamine is greater in rats treated in a NOVEL versus HOME environment (Badiani et al. 1993), as indicated by a greater rate of sensitization (i.e., the progressive increase in amphetamine effects over consecutive test sessions). In the present study we report on NOVEL versus HOME differences in the effects of intermittent amphetamine on two other indices of amphetamine sensitization.

Rotational behavior in rats with a unilateral 6-OHDA lesion of the mesostriatal dopamine system was used as an index of the psychomotor activating effects of amphetamine. In Experiment 1 HOME and NOVEL rats received seven consecutive IP injections of either saline or 2 mg/kg amphetamine. Following one week withdrawal the rotational response to 2 mg/kg amphetamine IP was compared in saline versus amphetamine pretreated animals. Although both HOME and NOVEL groups did sensitize, the magnitude of sensitization was greater in NOVEL rats. In Experiment 2 a dose-effect curve (0.75, 1.5, 3.0, and 6.0 mg/kg amphetamine IP) was quantified before and after six IP injections of 4.0 mg/kg amphetamine. Sensitization was indicated by a parallel shift to the left of the dose-effect curve in both groups, but this shift was about 3.5 times greater in the NOVEL group than in the HOME group.

821.18

CHANGES IN DIALYSIS MEASURES OF STRIATAL MONOAMINES AND AMPHETAMINE-EVOKED ROTATIONAL BEHAVIOR AFTER ELECTROLYTIC LESION OF THE NIGROSTRIATAL BUNDLE. E. Castañeda*, I.Q. Whishaw, M. Davidson, L. Schuster, T. Daugherty and Y.-H. Li. Arizona State University, Tempe, AZ 85287-1104.

Adult male Long-Evans rats were tested for basal levels of dopamine (DA), its major metabolites and 5-hydroxyindoleacetic acid (5-HIAA) using removeable microdialysis probes implanted bilaterally into the caudate nuclei. Following baseline measures, an electrolytic lesion was created in the nigrostriatal bundle within the lateral hypothalamus using a previously implanted monopolar electrode (2 mA, 20 sec) and testing continued for 3 hr. The next day, rats received an injection of d-amphetamine (AMPH, 1.5 mg/kg, s.c.) during dialysis testing. Afterwards, the probes were removed and animals were returned to their home cages. On day 14 post-lesion, rats were tested again for basal and AMPH-evoked changes in extracellular monoamine levels. Quarter turns were measured throughout testing. Immediately after the lesion, DA levels declined in the damaged hemisphere and this was accompanied by transient rotational behavior ipsilateral to the lesion. The next day, basal DA levels remained low in the damaged side but AMPH-stimulated levels were enhanced relative to the intact side and rats turned predominantly contralateral to the damaged side. Two weeks later, the enhancement in AMPH-evoked DA was no longer observed, although animals now turned predominantly in an ipsiversive direction. There were no hemispheric differences in DA metabolite levels at any time, but 5-HIAA levels were significantly attenuated in the damaged side on day 14 post-lesion. The present results will be discussed with regard to novel insight about loss/recovery of function.

821.19

CEREBRAL HEMISPHERE-DOMINANCE INFLUENCES BEHAVIORAL RECOVERY AFTER FETAL MESENCEPHALIC GRAFTING IN THE RAT PARKINSON MODEL. C. Rosenthal[1], J. Oertel[2], A. Brandis[2], M. Samii[1], G.F. Walther[2], G. Nikkhah[1]* [1]Neurosurgical Clinic, Nordstadt Hospital, Haltenhoffstr. 41, D-30617 Hannover [2]Institute of Neuropathology, Hannover Medical School, Konstanty-Gutschow-Str.8, D-30625 Hannover, Germany.

The improvement of spontaneous sensorimotor functions after unilateral grafting of fetal ventral mesencephalon in Parkinson patients as well as in the respective animal-models has so far been incomplete and variable. Usually, there is no good correlation between behavioral recovery and transplant survival or graft-derived reinnervation. Therefore we have investigated, whether the extent of forepaw handedness (preference) influences the level of functional recovery in tests of skilled forelimb use and stepping behaviour. 120 female Sprague Dawley rats were divided into left-handed, right-handed and ambidextrous animals on the basis of their skilled forelimb performance. The rats received unilateral 6-hydroxydopamine lesions of the nigrostriatal pathway either ipsi- or contralaterally to the preferred paw. Rotational and sensorimotor behaviour was assessed post lesion and 5, 18, 32, 45 and 58 weeks post grafting. Finally, the number of surviving dopaminergic neurons and graft volumes were determined. The results showed a significant differences in the extent of behavioral recovery between animals grafted into the dominant vs non-dominant hemisphere. In accordance with previous studies, morphological parameters did not seem to correlate with behavioral performance.
The findings of the present study indicate that the extent of functional recovery induced by dopaminergic grafts is, at least partly, influenced by cerebral hemisphere dominance.

INTRAVENTRICULAR INJECTION OF ANTI-DβH-SAPORIN: PRELIMINARY BEHAVIORAL FINDINGS. C. C. Wrenn*, M. J. Picklo, D. Robertson, R. G. Wiley. Dept. of Pharmacology, Vanderbilt Univ., Nashville, TN 37232.

Lesions have long been used to surmise neural function from the associated changes in behavior. Anti-neuronal immunotoxins offer an efficient way to produce highly specific lesions. The objective of the current study was to examine some behavioral effects of intraventricular (i.c.v.) injection of the anti-neuronal immunotoxin anti-DβH-saporin (α-DβH-sap). This immunotoxin (IT) consists of a monoclonal antibody to the noradrenaline synthesizing enzyme dopamine β-hydroxylase (DβH) coupled by a disulfide bond to saporin, a ribosome inactivating protein. α-DβH-sap is expected to produce selective neural lesions because DβH is an enzyme located in the membrane of synaptic vesicles and nerve terminals of noradrenergic and adrenergic neurons.. Groups of rats (n=7) received injections into the left lateral ventricle of 5μg or 10μg of α-DβH-sap. These doses were chosen based on previous experiments in which we observed that the locus coeruleus could be completely lesioned with sparing of A5 neurons at a 5μg dose while both populations are killed at 10μg. One week after surgery both groups of the IT-injected rats lost weight in a statistically significant, dose-dependent manner. By two weeks, only the 10μg group differed significantly in weight loss from controls. Approximately two weeks after surgery, tail flick behavior and exploratory activity (day and night) of the groups was examined. None of the groups differed in the latency to flick the tail in response to a noxious stimulus (heat). Night-time exploratory activity was significantly decreased in both immunolesioned groups while the decrease observed during the day did not reach statistical significance. Grooming bouts were also counted during activity monitoring and were found to increase dose dependently although statistical significance was obtained only during the day between the 10μg group and control group. We conclude that i.c.v. injections produce profound and selective destruction of CNS noradrenergic neurons resulting in subtle but significant changes in behavior. Rats treated with i.c.v. α-DβH-saporin should prove useful in a variety of studies of CNS noradrenergic neural systems. (Supported by Dept. Of Veterans Affairs).

REMOVAL OF MEDIAL TEMPORAL-LIMBIC REGIONS RESULT IN ABNORMAL DOPAMINE NEUROTRANSMISSION IN THE RHESUS MONKEY.
B.S. Kolachana*, R.C. Saunders, J. Bachevalier † and D.R. Weinberger. Clinical Brain Disorders Branch, NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032 and †Dept. Neurobiol. & Anat. , Univ. Texas Sch. Med. Houston, TX 77225.

We demonstrated previously that neonatal limbic lesions of the medial temporal lobe area result in abnormal dopamine neurotransmission in the caudate nucleus in adult rhesus monkeys. The present study compared the effects of neonatal limbic lesions with similar lesions made in adult monkeys on dopamine neurotransmission using *in vivo* microdialysis. Three groups of adult monkeys were used in the investigation: normal adults (N=3), monkeys who had undergone surgical removal of limbic areas including the hippocampus and entorhinal cortex in adulthood (N=2), and monkeys with similar lesions made in the first 3 weeks of their post-natal life (N=3). Extracellular dopamine overflow was measured in the caudate nucleus in response to low (20mM) and high (50mM) dose potassium (K+) challenges after gas anesthesia. Microdialysis probes were positioned into the caudate nucleus, perfused with normal CSF with samples collected and analyzed for dopamine. Each study was replicated twice in each animal with a minimum of 2 probes per study. After establishing a stable baseline, a 20mM K+ challenge was given for 25 min., followed by perfusion with normal CSF for 3 hr., followed by a 2nd K+ (50mM) challenge. Samples were collected for an additional 2 hr before termination of the study. 20mM potassium challenge resulted in 56% increase in normal adults and 37% increase in monkeys with neonatal lesions. 50mM K+ challenge resulted in 505% in normal adults and 247% increase in monkeys with neonatal lesions. In contrast, no changes in caudate dopamine overflow were observed in monkeys with adult limbic lesions following either low or high potassium challenge. These results suggest that limbic lesions in rhesus monkeys have profound effects on caudate dopamine transmission that vary in magnitude depending on age when the lesion occurred.

821.22

EFFECTS OF DISTRACTION, DELAY DURATION AND DRUG TREATMENTS ON DELAYED RESPONSE PERFORMANCE IN NORMAL MONKEYS USING AN AUTOMATED BEHAVIORAL TESTING SYSTEM.
Z.-Q. Sun* and J.S. Schneider. Depts. of Anat. and Neurobiol. and Neurology, MCP and Hahnemann University, Philadelphia, PA 19102.

Normal macaque monkeys were trained to perform an automated delayed response (DR) task with or without cue (attention) or delay (memory) distractors, or with variable duration delays, ranging from 0.1 sec. to 30 sec. Cue distractors negatively affected task performance while delay distractors had no effect on performance. Distractors presented during response choice also had no effect on performance. Performance deteriorated with long duration delays. Interestingly, performance did not significantly deteriorate with short duration cue presentations. Methylphenidate further impaired DR performance with cue distractors while LY-171555 and dihydrexidine had no significant positive or negative effects on DR performance. Neither methylphenidate, LY-171555, nor dihydrexidine further affected performance of long delay DR trials. Scopolamine (0.01 mg/kg) significantly impaired DR performance but the deficit did not appear to be delay dependent. IDRA 21 (0.5 mg/kg), which prevents AMPA receptor desensitization and increases excitatory synaptic strength, had no effect on task performance alone but when given 10 min. prior to scopolamine, blocked the detrimental effects of scopolamine on DR performance. These results demonstrate the utility of our automated behavioral testing system for assessing attention, memory, and pharmacological manipulations of behavior in non-human primates.

MONOAMINES AND BEHAVIOR: NOREPINEPHRINE

822.1

IMPACT OF PSYCHOSOCIAL STRESS ON CENTRAL ALPHA$_2$-ADRENOCEPTORS.
G. Flügge* and E. Fuchs. German Primate Center, 37077 Göttingen, Germany

Alpha$_2$-adrenoceptors are supposed to function as autoreceptors and to regulate the activity of the nor/adrenergic system in the brain. We have previously shown in male tree shrews (*Tupaia belangeri*) that under psychosocial stress (PSS), when the nor/adrenergic system is activated, binding sites for the subtype non-selective antagonist ^{3}H-rauwolscine are down-regulated. In the present study we investigated binding of the alpha$_{2A}$-subtype preferring ligand ^{3}H-RX 821002 after different durations of PSS by in vitro receptor autoradiography. Down-regulation of alpha$_{2A}$-adrenoceptors is region-specific and depends on the duration of PSS: In the locus coeruleus, the receptor number is reduced after 2, 10, and 21 days of PSS and returns to normal levels thereafter. In the prefrontal cortex, the receptor number is only slightly reduced on day 2 of PSS and is normal thereafter. In contrast, in the solitary tract nucleus and the dorsal motor nucleus of the vagus, down-regulation occurs only after 21 and 28 days of PSS. Our data demonstrate the dynamic changes in alpha$_{2A}$-adrenoceptors under PSS and indicate that in different brain regions, receptor regulation underlies different mechanisms.

822.2

EFFECT OF ACUTE OR CHRONIC RESTRAINT STRESS ON BEHAVIOR AND BRAIN NOREPINEPHRINE SYSTEM IN WISTAR-KYOTO (WKY) RATS.
S. M. Tejani-Butt[1], H. M. Zafar[1] and W. P. Pare*[1,2]. [1]Dept. of Psychiatry, Univ. of Penn. Sch. of Med., Phila., PA 19104 and [2]VA Medical Center, Perry Point, MD 21902.

We have reported that WKY rats develop more restraint-induced gastric ulcers and exhibit more depressive behavior than several other rat strains. Recently we have shown that repeated exposure to novel stressors for 21 days not only exacerbates depressive behavior in WKY rats but also alters ß-adrenoceptors (ß-ARs) and norepinephrine transporter (NET) sites in several limbic brain regions when compared to Sprague-Dawley rats. The present study examined whether these effects would be elaborated following an acute stress and whether WKY rats would demonstrate adaptation after repeated stress. Rats were subjected to a 2h supine restraint stress either for 1 or 8 consecutive daily sessions. Open field behavioral data were collected before the first day and immediately after the seventh session. Rats were sacrificed following their last session, brains removed, frozen and sectioned for autoradiographic analysis of ^{125}-I-pindolol binding to ß-ARs and ^{3}H-nisoxetine binding to NET sites in discrete brain regions. Acute stress resulted in a significant drop in body weight and an inhibition of behaviors in the open field. These effects were also sustained following chronic restraint stress. In contrast, while acute stress had no effect on the NE system, chronic stress decreased ß-ARs in the cortex, hippocampus and caudate putamen and decreased NET sites in the hypothalamus and locus coeruleus.

822.3

MICROINJECTION OF NOREPINEPHRINE (NE) INTO THE MEDIAL PREOPTIC-ANTERIOR HYPOTHALAMUS (MPOA-AH) REGULATES AGONISTIC BEHAVIOR IN FEMALE SYRIAN HAMSTERS.
A.C.Harmon, K.L.Huhman, T.O.Moore* and H.E.Albers. Lab. Neuroendocrinol. & Behav., Depts. Biol. and Psychol., Georgia State Univ., Atlanta, GA 30303: Dept. Psychol. Morehouse College., Atlanta, GA 30314.

Vasopressin (AVP) within the MPOA-AH is involved in the regulation of aggressive behavior and flank marking. In females, injection of NE into the MPOA-AH inhibits the ability of AVP to induce flank marking. The present study examined whether NE injected into the MPOA-AH can alter agnostic behavior in female hamsters. Female hamsters were allowed to establish stable dominant/subordinate relationships. Dominant females were implanted with guide cannulae aimed at the MPOA-AH and injected with NE 300ng in 200nl saline or vehicle in a counterbalanced order. Following injection of NE, dominant behaviors (e.g. attacks, bites) significantly declined (Saline: 5.5±2.25; NE: 0.17±0.15; $p<0.05$) and subordinate behaviors (e.g. retreats, defensive postures) significantly increased (Saline: 0.33±0.14; NE: 4.0±1.63; $p<0.05$). No significant changes were observed in a range of other behaviors unrelated to dominance/subordinance. These data support the hypothesis that injection of NE into the MPOA-AH can regulate agonistic behavior in female hamsters.

DEFENSIVE BEHAVIOR INCREASES MAO-A ACTIVITY IN THE LOCUS COERULEUS OF THE RAT.
C. Quinn, D. Benjamin, L.A. Pohorecky*. Laboratory of Neuropharmacology, Center of Alcohol Studies, Rutgers Univ., Piscataway, NJ 08855.

The objective of this study was to determine if monoamine oxidase (MAO) activity in rats changes as a result of an aggressive interaction. Male Sprague Dawley rats (450-500g) were allowed to establish residence in large wire cages over a period of 10 days. Naive intruders (250-275g) were introduced into the resident's cage for a period of 30 min and sacrificed immediately after the interaction. During this period, 4.75±1.03 roll-tumble fights occurred. Control rats from the same group as the intruders were sacrificed without being subjected to an intruder experience. Brain sections from the level of the locus coeruleus (LC) were assayed for MAO-A, while brain sections from the level of the dorsal raphe nucleus (DRN) were assayed for MAO-B. A histochemical, coupled peroxidatic oxidation assay utilizing nickel enhanced DAB staining was employed (Maeda et al., Cell Mol Bio., 33:1-11). The amount of DAB staining within individual cell bodies of the LC and DRN was digitized to provide a semi-quantitative measurement of MAO activity, with precise anatomical localization. MAO-A activity in the noradrenergic cell bodies of the LC was found to be 25% greater in intruders than in controls. MAO-B activity in the DRN cell bodies did not differ between intruders and controls. These results suggest the existence of a rapid mechanism for MAO-A activation in the LC which is triggered by intruder status (Supported by ASPET, Sigma Xi, and the Smithers Foundation).

822.5

DSP-4 LESIONS IMPAIR ORIENTING BEHAVIOR IN RATS.
C. Yu and R.N. Holdefer*. Dept. of Biology, Hong Kong Univ. of Science and Tech., Hong Kong.

The orienting reflex (OR) is an early stage of sensory information processing seen as a decrease in heart rate and desynchronization of the EEG in response to a salient sensory stimulus, and may involve the locus coeruleus-norepinephrine pathway (LC-NE). For example, a role for the LC-NE in attention and vigilance has been hypothesized, and neurons in the LC-NE of awake animals respond best to salient sensory stimuli (Aston-Jones, 1985). Stimulation of the LC-NE desynchronizes EEG and slows heart rate (Berridge *et al.*, 1993; Miyawaki *et al.*, 1991).

Rats were chronically implanted for ECG and EEG recordings. The OR was elicited by taped rat vocalizations in a sound attenuating chamber. Norepinephrine was depleted by DSP-4 injections (50 mg/kg, i.p.), a selective neurotoxin for norepinephrine, and tested for an OR 11-16 days after injection.

In control animals (n=9) there was an 8.5% decrease ($p<.05$) in heart rate (HR) 4 s after the onset of the orienting stimulus (rat vocalizations), as compared to baseline HR (6 s before the orienting stimulus). HR decreased by a maximum of 10% ($p<.01$) at 13 s after the orienting stimulus and remained significantly decreased throughout the 60 s testing period, although some habituation was seen. In the DSP-4 pre-treated rats (n=8) there was a small, non-significant decrease in HR during the testing period.

Central NE concentrations in control and DSP-4 treated rats were determined by HPLC with electrochemical detection. NE concentrations were reduced in the DSP-4 animals by 31% in frontal cortex, 87% in parietal cortex, and 59% in the hippocampus.

We conclude that there is an involvement of central NE in the orienting reflex of rats.

822.6

TIME COURSE OF CHANGES IN HYPOTHALAMIC AND HIPPOCAMPAL NOREPINEPHRINE DURING AMPHETAMINE WITHDRAWAL.
D. M. Camp*, D.K. DeJonghe and T. E. Robinson. Dept. of Psychology and Neuroscience Program, Univ. of Michigan, Ann Arbor, MI 48109.

Following the discontinuation of an escalating dose amphetamine (AMP) pretreatment regimen rats exhibit a decrease in spontaneous nocturnal motor activity that persists for 1-2 weeks. Furthermore, these transient changes in behavior are associated with depletion of hypothalamic norepinephrine (NE) concentrations (Paulson et al., *Psychopharmacol.* 1991, *103*, 480-492). In the present experiment we used in vivo microdialysis to further characterize NE neurotransmission during AMP withdrawal. Animals received an escalating dose AMP pretreatment regimen (1→10 mg/kg) over 10 consecutive days and then were withdrawn for either 24 hrs or 30 days prior to determination of NE in either the hypothalamus or hippocampus during basal 'resting' conditions and also following a challenge injection of 2.0 mg/kg d-AMP i.p.. It was found that during the early withdrawal period, basal extracellular NE was significantly elevated in both brain regions, relative to saline-pretreated rats. In addition, in the hypothalamus there was a significant attenuation in AMP-stimulated NE release. Following 30 days of withdrawal, basal hypothalamic extracellular NE did not differ from controls, but there was a significant enhancement in AMP-stimulated NE release in this brain region. These results are consistent with the idea that alterations in NE neurotransmission may contribute to both post-AMP withdrawal 'behavioral depression' and the persistent effects of AMP on behavior (i.e. behavioral sensitization).

822.7

ALPHA-2 ADRENERGIC FUNCTION AND VISUAL SELECTIVE ATTENTION IN MONKEYS.
P. Rämä*, J.K. Hietanen. Institute of Biomedicine, Department of Physiology, P.O. Box 9, FIN-00014 University of Helsinki, Finland.

Catecholinergic innervation of the cerebral cortex may have an important function in controlling attention. The well documented ability of alpha-2 agonists to improve working memory may, at least in part, be due to the memory being protected from irrelevant or distractive stimulation (Arnsten & Contant, *Psychopharmacology*, 180:159-169, 1992). This indicates that alpha-2 agonists may also have a beneficial effect on attentive functions. In the present study the monkeys (*Macaca arctoides*) were trained to perform spatially selective manual responses (left/right) in a task in which the stimulus colour (green/red) and its spatial location (left/central/right) were relevant and irrelevant stimulus dimensions, respectively. The location of the colour stimulus was compatible, incompatible or neutral with respect to the direction of the response. The different types of stimulus conditions were presented in random order within the block of testing. The effects of medetomidine, an alpha-2 agonist, and its antagonist atipamezole were studied by comparing their effects on saline control performance separately in each stimulus condition. The role of alpha-2 adrenergic function will be discussed in the context of visual selective attention.

STIMULATION OF MEDIAL SEPTAL NORADRENERGIC β-RECEPTORS INDUCES BEHAVIORAL AND FOREBRAIN EEG ACTIVATION.
C.W. Berridge*[1] and S.L. Foote[2]. [1]Psycholology Dept., Univ. Wisconsin, Madison, WI 53706; [2]Psychiatry Dept., Univ. California, San Diego, La Jolla, 92093.

We previously demonstrated that acute, selective manipulations of locus coeruleus (LC) neuronal activity elicit robust alterations in forebrain EEG in halothane-anesthetized rat. Similar EEG responses are observed following small infusions of noradrenergic β-agonists and antagonists into the basal forebrain region encompassing the medial septum and vertical limb of the diagonal band of Broca (MS) in anesthetized rat. The present studies assessed whether the EEG activational effects induced by activation of MS β-receptors are observed in the absence of anesthesia, and if so, whether concomitant behavioral effects are observed. Rats were implanted with a guide cannula aimed at MS or adjacent regions. On the day prior to testing, rats were singly housed in sound attenuated chambers. On the day of testing, a 33 ga. infusion needle was inserted and attached to the cannula via plastic threaded sleeves and videotaping of the rat's behavior began 30 min later. 60 min following the onset of behavioral recording, an infusion (150 nl) of either vehicle or the β-adrenergic agonist isoproterentol (ISO; 25 ug/ul) was made without disturbing the animal. EEG was simultaneously recorded in a subset of animals. MS vehicle infusions, or ISO infusions, placed outside MS did not alter EEG measures or the amount of time spent awake compared to the preceding hour. In contrast, MS ISO infusions resulted in hippocampal/cortical EEG activation and within 3-10 min, increased the time spent awake in the hour following the infusion (5 vs. 34 min). EEG responses preceded the behavioral responses and were present at the latter portions of the behavioral response which were often characterized by brief and frequent bouts of lying down interrupted by shifts of body position and brief periods of locomotor activity. These results indicate that the LC-noradrenergic system exerts an excitatory influence on behavioral and EEG measures of arousal in the unanesthetized rat, via actions within MS.

IMPROVED VIGILANCE PERFORMANCE IN MONKEY ASSOCIATED WITH ALTERED LOCUS COERULEUS (LC) ACTIVITY AFTER CLONIDINE.
J. Rajkowski*, S. Ivanova, P. Kubiak & G. Aston-Jones, Dept. Psychiatry, Hahnemann Univ., Philadelphia, PA 19102.

The effect of the alpha2 agonist, clonidine (5, 20 or 40 ug/kg), on activity of LC neurons was studied in 4 Cynomolgus monkeys while they performed a vigilance task requiring sustained focused attention (see Kubiak et. al, this volume). Behavioral effects of clonidine were dose-dependent: 5 ug/kg (im) had no effect on task performance, 20 ug/kg (im, sc) resulted in drowsiness or mild sedation with continued but improved performance, and 40 ug/kg (im) produced strong sedation.

In 3 monkeys who performed well before clonidine (< 5% errors of commission or false alarms; FAs), clonidine administration reduced errors (increased ß) but also increased bar release latency. LC discharge was unaffected by 5 µg/kg clonidine, but was consistently reduced by the higher doses. There was an inverse relationship between tonic LC activity and task performance after clonidine. However, if LC neurons became totally quiescent animals became drowsy and performance ceased.

Clonidine produced an unexpectedly strong effect in the fourth monkey. This animal exhibited hyperactive behavior throughout training (FAs ~ 30%). Clonidine (20 µg/kg, sc) produced prolonged epochs of near-perfect performance (5% FAs; increased ß and d'), alternating with epochs of drowsiness. By 2 h after clonidine, performance had deteriorated to preinjection levels and motor hyperactivity returned. Overall, task performance correlated strongly with the level of LC tonic activity: Whereas poor performance before clonidine invariably corresponded to elevated tonic LC activity, improved performance after clonidine was associated with low-frequency LC discharge. Phasic LC responses to CS+ cues, typically small in this monkey, increased markedly after clonidine.

These results support other findings of improved sustained attention after clonidine, especially notable in hyperactive animals, and suggest the possibility that alterations in LC activity may be a causal factor. Clonidine will be microinfused into the LC to selectively inhibit LC neurons as a test of this hypothesis. Supported by AFOSR grant F49620-93-1-0099.

CONTRASTING RESPONSES OF MONKEY LOCUS COERULEUS (LC) NEURONS TO CONDITIONED VS. UNCONDITIONED STIMULI: RELATIONSHIP TO AROUSAL, PERFORMANCE AND VIGILANCE.
P. Kubiak*, S. Ivanova, J. Rajkowski and G. Aston-Jones. Div. Behav. Neurobiol., Dept. Psychiatry, Hahnemann Univ., Philadelphia, PA 19102

We previously reported that performance degrades with prolonged behavior on a vigilance task, and varies over shorter epochs within the task, in association with altered LC responses to CS+ cues. We now report that LC responses to conditioned vs. unconditioned stimuli exhibit converse changes during naturally occurring drowsiness, or during inattentiveness associated with high arousal. LC neurons were recorded from 3 Cynomolgus monkeys performing a vigilance task. Animals were required to foveate a central fix spot to initiate each trial of stimulus presentation; such foveation ensured attentiveness to the task. Animals were trained to release a pedal after infrequent CS+ stimuli and withhold responding to frequent CS- stimuli. LC neurons were phasically activated at a short latency (~120 msec) by CS+ stimuli but not by other task events. During occasionally occurring periods of drowsiness task performance deteriorated, as evidenced by decreased frequency of foveation of the fix spot, increased errors of omission, and longer latencies of lever release. During drowsiness the tonic discharge rate of LC neurons decreased and LC responses to CS+ stimuli were significantly smaller. In contrast, LC responses to unconditioned auditory stimuli (white noise bursts; 70 msec, 75 db) were of greater magnitude during drowsiness and poor task performance. Similarly, LC responses decreased for CS+ cues, but increased for unconditioned stimuli, during epochs of inattentiveness and poor performance associated with high arousal and apparent agitation. These results reveal that (1) a close relationship exists between attentiveness, LC tonic and phasic activities, and performance of a vigilance task, (2) LC responses to CS+ cues decrease during inattentiveness associated either with drowsiness or with high arousal and agitation, and (3) responsiveness of LC neurons to unconditioned stimuli is magnified during these same periods of inattentiveness. Our findings indicate that LC responsiveness depends on the state of attention and support the role of LC in attention and vigilance. Supported by AFOSR grant F49620-93-1-0099.

822.11

A COMPUTATIONAL MODEL OF LOCUS COERULEUS INFLUENCE ON PERFORMANCE IN A VISUAL DISCRIMINATION TASK

M. Usher, J.D. Cohen, D. Servan-Schreiber, R. Zemel*, Dept. Psychology, Carnegie Mellon Univ., Pittsburgh, PA 15213, P. Kobiak, J. Rajkowski and G. Aston-Jones, Hahnemann Univ.

A computational model is proposed that accounts for the relationship between patterns of tonic and phasic Locus Coeruleus (LC) activity and behavioral performance during a vigilance task: improved performance during periods of lower tonic activity together with phasic bursts after target stimuli. The model shows how the relationship between patterns of LC firing and behavioral performance can be explained by changes in electrotonic coupling within LC. Specifically, it demonstrates that an increase in electrotonic coupling results in a more synchronous (i.e., phasic) pattern of firing that is triggered by target but not by distractor stimuli, and that is also associated with a lower spontaneous (i.e., tonic) firing rate. This results in tighter coupling of neocortical NE release to target stimuli, which in turn improves task performance (a reduction in false alarms without an increase in response latency to targets). The model provides an account of the influence of LC cells and NE on performance in a cognitive task, suggesting a specific role for electrotonic coupling within LC and neuromodulatory influence of NE in selective attention.

IS A CONNEXIN INVOLVED IN NEURAL CONTROL OF LUMINESCENCE IN THE CNIDARIAN *RENILLA KOELLIKERI*? G. Germain and M. Anctil*. Dept. Sci. Biol., Univ. de Montréal, Montréal, Québec, Canada H3C 3J7.

Of the three classes of the phylum Cnidaria, Hydrozoa but neither Scyphozoa nor Anthozoa possess ultrastructurally identifiable gap junctions. We present evidence that the bioluminescence system of an anthozoan, the sea pansy, which is believed to be coordinated by a nerve-net but which is also adrenergically controlled via cells neighboring the light-emitting cells (photocytes), requires gap junction-like coupling to effect light emission. Gap junction blockers such as octanol and heptanol reversibly eliminated in situ luminescent responses but not those of dissociated photocytes. An anti-connexin43 monoclonal antibody (anti-Cx43) loaded in permeabilized cells abolished the luminescent responses. Western blot analysis revealed the presence in sea pansy tissues of a Cx43-like protein. We also visualized Cx43-like punctate immunoreactivity in some epithelial layers and in the nerve-net, with greater abundance in the luminescent endoderm. Ultrastructural observations revealed only small "close appositions" but not recognizable gap junctions. These results suggest that a Cx43-like gap junction protein exists in the sea pansy and is involved in transmission of bioluminescent signaling, but does not aggregate in typical large plaques. THE ALPHA1-ADRENOCEPTOR ANTAGONIST PRAZOSIN ANTAGONIZES MK-801 EVOKED STIMULATION OF MESOLIMBIC DOPAMINE ACTIVITY: ELECTROPHYSIOLOGICAL, BIOCHEMICAL AND BEHAVIORAL CORRELATES J.M. Mathé, G.G. Nomikos, B.E. Hildebrand, K. Chergui, P.Hertel, A.A. Mathé' and T.H. Svensson Dept. Physiology & Pharmacology, Div. Pharmacology, Karolinska Institutet, 171 77 Stockholm, SWEDEN.

The effects of the potent alpha-1-adrenoceptor antagonist prazosin were investigated on electrophysiological, biochemical and behavioral action of the psychotomimetic, NMDA-receptor antagonist MK-801 related to the mesolimbic dopamine (DA) system in the rat.

Extracellular single-cell recordings were obtained from A10 DA neurons in chloral hydrate anaesthetized rats. Action potentials were fed into a computer for analysis of firing rate, burst firing and regularity of firing, as assessed by the variation coefficient. In addition, levels of DA and its metabolites were measured in the n. accumbens (NAC) with microdialysis in freely moving rats. Locomotor activity was assessed in rats in an open field. Rats were pretreated with either vehicle or prazosin (0.3-1.0 mg/kg), 20 min prior to MK-801 (0.05-0.3 mg/kg) administration.

Administration of prazosin 1) effectively blocked the increased burst firing, but did not affect the average firing rate of A10 DA neurons 2) antagonized the increased DA, DOPAC and HVA levels in the NAC, and 3) blocked hyperlocomotion, as induced by MK-801.

Thus, behavioral stimulation by MK-801 is indeed associated with increased presynaptic activity in the mesolimbic DA system. Moreover, a potent and selective alpha-1-adrenoceptor antagonist can specifically block this, subcortically evoked DA activity without any significant effect on basal DA release in the same region. Supported by the Medical Research Council of Sweden and the Karolinska Institutet.

LONG-TERM EFFECTS OF PSYCHOMOTOR STIMULANTS ON APPETITIVE AND CONSUMMATORY SEXUAL BEHAVIORS IN THE MALE RAT. M.F. Wilkins*, L. Schattmann, and J.G. Pfaus. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montréal, QC, Canada.

Amphetamine and cocaine are generally believed to enhance human sexual desire, arousal, and performance, whereas long-term use of these drugs is associated with a deterioration of sexual function. Surprisingly, these effects have not been studied extensively in animals. We examined the acute and long-term effects of cocaine hydrochloride (5, 10, or 20 mg/kg) or *d*-amphetamine sulfate (1.25, 2.5, or 5 mg/kg) on sexual behavior in sexually experienced male rats. Amphetamine or cocaine were injected prior to tests conducted every 4 days in bilevel chambers. Acute amphetamine increased anticipatory level changes, but decreased the proportion of rats that mounted, intromitted and ejaculated. Long-term amphetamine decreased anticipatory level changes secondarily to the induction of stereotypy, and also further decreased the proportion that mounted, intromitted or ejaculated. These effects reversed during withdrawal, but declined following challenge dosages of amphetamine. In contrast, acute cocaine did not affect anticipatory level changes or the proportion of rats that mounted, intromitted or ejaculated. However, cocaine increased mount and intromission latencies, decreased ejaculation latencies, and decreased the number of intromissions before ejaculation. Although tolerance accrued to these effects, challenge dosages after withdrawal further reduced the number of intromissions and the ejaculation latencies. Thus, acute and long-term administration of amphetamine or cocaine differentially affect sexual behavior in the male rat.

NEUROPEPTIDES AND BEHAVIOR III

823.1

THE EFFECT OF NPY ADMINISTERED TO EITHER THE VMN OR THE PVN ON LORDOSIS AND FEEDING. C. Bauer and J.E. Thornton*, Neuroscience/Biopsychology Program and Department of Biology, Oberlin College, Oberlin, OH 44074

Recently we have shown that neuropeptide Y (NPY) increases lordosis in female guinea pigs. The effect of NPY on feeding in guinea pigs has not been examined. The present experiment determined whether NPY might act on either the ventromedial nucleus (VMN) and/or the paraventricular nucleus (PVN) of the hypothalamus to affect lordosis and feeding in female guinea pigs.

Ovx female guinea pigs had a cannula implanted into either the VMN or the PVN. For lordosis tests, estrogen-and progesterone-primed females were infused with 100 pmol NPY or saline vehicle in a repeated measures, counterbalanced design, and tested for lordosis behavior. NPY significantly increased lordosis when it was administered to the VMN but not the PVN. For feeding tests, ovx females were infused with 100 pmol NPY or vehicle and feeding was examined. NPY administered to either the PVN or the VMN significantly increased both the number of grams eaten and the frequency of feeding. It is suggested that NPY acts at the VMN to affect lordosis and at both the VMN and the PVN to affect feeding in the female guinea pig.

823.2

DRINKING INDUCED BY MICROINJECTIONS OF PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE (PACAP38) INTO THE LATERAL HYPOTHALAMUS (LH) OF NONDEPRIVED RATS. M.Puig de Parada*, M.A.Parada, and L.Hernández. Department of Physiology, School of Medicine, Universidad de los Andes, Mérida 5101-A, Venezuela.

PACAP38 increases cAMP levels in rat pituitary cells and sulpiride increases cAMP in neurons bearing dopamine D2 receptors. Sulpiride induces also several behaviors when bilaterally administered in the perifornical LH (pfLH). The present study tested if bilateral pfLH PACAP38 microinjections could reproduce the behavioral effects of sulpiride. PACAP38 (1 nmol/0.5 µl) administered in the vicinity of the pfLH selectively induced drinking (19.7±4.1 ml of water) during the hour following the injection. In the same rats (n=12) sulpiride (45 nmol/0.5 µl) had milder effects (7.8±1.4 ml/hr). The difference between both effects was statistically significant ($t = 3.61$; $df=11$; $p<0.005$). Neither sulpiride nor PACAP38 promoted drinking when injected (n=10) 1.3 mm behind the effective zone. This negative result is an evidence of the neuroanatomical specificity of the dipsogenic effect of both drugs. The dipsogenic effects of sulpiride and PACAP38 were well correlated [$R = 0.821$; $F(1/20) = 41.5$; $p<0.0001$] suggesting that both substances trigger drinking by activation of the same hypothalamic mechanisms. These results suggest that PACAP38 in the pfLH could be an integrative neuropeptide regulating drinking behavior.

CHOLECYSTOKININ ATTENUATES GROOMING VIA AN ATYPICAL RECEPTOR TYPE. J.M. Van Kampen* and A.J. Stoessl. Clin. Neurol. Sci., University Western Ontario, Ont., Canada.

The neuropeptide cholecystokinin (CCK) is known to interact with dopamine in various ways. We have demonstrated that CCK-8S effectively attenuates dopamine D1-mediated vacuous chewing movements (VCM's) and stereotypic grooming. Our work has shown a clear role for the CCK-A receptor in the attenuation of **VCM's** but the receptor type mediating this effect on **grooming** remains unclear. While a selective CCK-B agonist was effective in attenuating grooming, the CCK-A rather than the CCK-B antagonist blocked the attenuating effects of a general agonist. Similar anomalous results have been found by others in studies of anxiety and analgesia. To further explore this issue we examined the effects of selective CCK antagonists on the attenuation of grooming by a CCK-B agonist. Administration of SKF 38393 (5mg/kg,s.c.) to male Sprague Dawley rats resulted in a significant increase in grooming which was reduced to control levels by the peripheral administration of the selective CCK-B agonist CCK-4 (20µg/kg,i.p.). Pretreatment with **both** the CCK-A antagonist, MK-329, and the CCK-B antagonist, L-365,260, significantly blocked this attenuation over a range of doses (20µg/kg,100µg/kg, 500µg/kg;i.p.). SKF 38393-induced VCM's were unaffected by CCK-4 or either of the antagonists. Further study has ruled out possibile influence from anxiogenic properties of CCK-4 or direct effects of the antagonists themselves. We also examined the effects of vagotomy on the actions of CCK-8S. Vagotomy abolished suppression of both VCM's and grooming. Taken together, these findings suggest a predominant peripheral 'A' receptor mediated effect of CCK but CCK-4 may be acting at a novel receptor subtype.

823.4

FETAL MOTOR BEHAVIOR AND RESPONSIVENESS TO PERIORAL CUTANEOUS STIMULATION: INVOLVEMENT OF V1 RECEPTORS. E.I. Varlinskaya & E.S. Petrov, Inst. for Exptl. Med., St. Petersburg, Russia and W.P. Smotherman*, Ctr. Dev. Psychobiol., Binghamton University - SUNY, Binghamton, NY.

Arginine-vasopressin (AVP) injected into the cisterna magna of the E20 rat fetus increases motor activity, including the relatively uncommon patterns of mouthing, licking and facial wiping. The AVP effect is mediated by V1 receptors in the brain stem and spinal cord. The effect of AVP on fetal motor behavior can be potentiated by intrahemispheric (IH) injection of the V1 antagonist [ß-mercapto-ß,ß-cyclopentamethylene-propionyl^1,O-Me-Tyr^2,Arg^8]-vasopressin. These findings suggest that there are at least two populations of V1 receptors: one in the spinal cord/brain stem that has an excitatory effect and a second in the brain hemispheres that has an inhibitory effect on fetal motor behavior. Fetal responses to perioral cutaneous stimulation including the presentation of an artificial nipple also are influenced by manipulation of V1 receptors in the spinal cord/brain stem and brain hemispheres. IC injection of the V1 antagonist reduces fetal responsiveness while blockade of V1 receptors by IH injection has the opposite effect and potentiates responsiveness to perioral cutaneous stimulation including oral capture and grasping of the artificial nipple. These findings indicate that AVP plays a role in regulating fetal motor behavior including responsiveness to perioral cutaneous stimulation and suggests that AVP may affect behavior immediately after birth in the context of suckling.

WPS is supported by an MERIT Award from NIH (HD 16102-11).

NO EFFECT OF CENTRALLY ADMINISTERED CCK-8S ON RETENTION OF INHIBITORY AVOIDANCE IN FEMALE RATS AS A FUNCTION OF ESTRUS STATE. L. J. Wichlinski*, C. Dietrich, A. Mayer, C. Wesely, L. Flaten, B. Hogan, C. Kulawik, A. Sparks, M. Cervera, and M. Dedricks. Dept. of Psychology, Carleton College, Northfield, MN 55057.

In previous experiments from our laboratory, centrally administered cholecystokinin (CCK)-8S produced a significant enhancement of retention performance in the one-trial inhibitory avoidance task in male but not female rats. In this experiment we sought to determine the role of the estrus cycle in the failure of CCK-8S to produce memory enhancement in female rats. Adult female Sprague-Dawley rats were implanted stereotaxically with guide cannulae one week before training. Immediately following training on the one-trial inhibitory avoidance task (0.6 mA, 1.0 sec) rats were infused i.c.v. with either CCK-8S (800 pmoles) or vehicle. Testing took place 24 hr later. Rats were assigned to one of four estrus states (metestrus, pro-estrus,estrus, or diestrus) based on light microscope assessments of vaginal epithelial cells collected prior to training. Behavioral results were matched to estrus groups in a blind fashion after testing. Again, CCK-8S failed to enhance retention performance relative to vehicle treatment, regardless of estrus state. Also, vehicle results alone did not vary as a function of estrus state. Possible reasons for the absence of CCK-8S effects include: insensitivity of the task to CCK-8S modulation in female rats, a low threshold for suppression of CCK-8S by circulating ovarian steroid hormones, differential dose-response curves for female and male rats, and interactions between CCK-8S and testosterone. Ovariectomy experiments are in progress to explore this issue further.

823.6

MODULATION OF CORTICOTROPIN-RELEASING FACTOR (CRF) RELEASE BY NMDA AND 5HT$_{1a}$ RECEPTORS IN PRIMARY CULTURES OF FETAL RAT AMYGDALA. D.L. Birkle*, V. Suski, M.S. Cratty, R.W. Gabr, H.A. Mason, M.G. Villanueva, A.K. Salm. Department of Pharmacology and Toxicology, Department of Anatomy, WVU School of Medicine, Morgantown, WV 26506.

Previous immunocytochemical studies from our laboratory have demonstrated the presence of corticotropin-releasing factor (CRF)-positive neurons in primary cultures of fetal rat amygdala neurons. We have also previously shown Ca^{2+}-dependent, depolarization-induced release of CRF in these preparations, and CRF release in response to the excitatory amino acid neurotransmitter, glutamate. We now have evidence that glutamate-induced CRF release is mediated primarily by activation of NMDA receptors. NMDA (EC_{50}, 5 µM) stimulated CRF release. The effects of both glutamate and NMDA were blocked by AP-5 (IC_{50}, 30 µM), or by restoring $[Mg^{2+}]_{out}$ to 1 mM. Kainic acid (EC_{50}, 0.5 µM) also stimulated CRF release, and was partially antagonized by AP-5, suggesting that its effects are mediated in part by the release of glutamate in the cell culture. Activation of 5-HT$_{1a}$ receptors with the agonist, 8-OH-DPAT, reduced both basal and depolarization-induced (60 mM K^+) release of CRF (EC_{50}, 1 nM). These studies demonstrate stimulatory (via NMDA receptors) and inhibitory (via 5HT$_{1a}$ receptors) modulation of CRF release from fetal amygdala neurons in primary culture. Supported by NSF (IBN-9222263).

FORCED-SWIM TEST REDUCES CYCLO(HIS-PRO) LEVELS IN RAT BRAIN. A.E. Pekary*, R.L. Lloyd, M. Chilingar, A. Sattin. Psychiatry, Medicine (Endocrinology) & Research Services, West Los Angeles VA & UCLA School of Medicine, Los Angeles, CA 90073.

Electroconvulsive seizures (ECS) elevate the levels of both thryotropin releasing hormone (TRH) and TRH-Gly (pGlu-His-Pro-Gly), a TRH precursor, in the limbic system of rats. We have reported significant correlations between results from the forced swim test (a test used to predict efficacy of antidepressant drugs and ECS) and post-ECS TRH and TRH-Gly levels in four anterior limbic regions dissected from male Wistar rats (Ann NY Acad Sci, 739:135, 1994). Because TRH and TRH-Gly are readily converted to cyclo(His-Pro) (cHP), we have studied the effects of ECS and forced swimming on the brain levels of this metabolically stable cyclic dipeptide. cHP has a number of CNS effects including the induction of hypothermia and suppression of motor activity which may influenced, and in turn be influenced by ECS and forced swim. The rat groups were: untreated controls, swim only, ECS only, and swim+ECS. Below are the cHP levels (ng/g wet wt.) for pyriform ctx. (PYR), striatum (STR) and anterior ctx. (AC)(mean ± SD):

	Control + ECS only (18)	Swim only + (Swim+ECS) (16)	p
PYR	60.9 ± 29.5	39.4 ± 11.1	<0.01
STR	46.6 ± 19.6	29.7 ± 9.6	<0.004
AC	54.9 ± 57.3	29.1 ± 13.3	n.s.

Forced swim testing significantly decreased cHP in 2 of the 3 regions tested. ECS did not affect mean cHP levels in these regions (not shown). Mechanisms of this effect are unknown. It is known that cHP can be derived from sources other than TRH. We thank Dr. Ivor Jackson for the cHP antiserum. Supported by VA Research Service.

THE EFFECTS OF NGF, b-FGF AND CEREBROLYSIN ON SPATIAL NAVIGATION AFTER BILATERAL LESIONS OF THE SENSORIMOTOR CORTEX: A. Gschanes, V. Valouskova, M. Windisch and H. Xiong*. Center of Animal Biology, Medical School, Roseggerweg 48, A-8036 Graz, Austria.

Damage of the sensorimotor cortex causes spatial navigation deficits in rats. Lesions of this brain region were made with suction and the subsequent behavioral effects measured in a Morris water maze apparatus. bFGF, NGF or Cerebrolysin (CER) a nootropic peptidergic drug, were infused by osmotic minipumps unilaterally into cavities made by suction or intraperitoneally (ip). For comparison, other unlesioned rats were injected ip with saline or CER. Animals were tested in the water tank 13 days after surgery for 3 consecutive days. The length of the trajectory to a submerged platform, as well as the speed of swimming, were measured. The trajectory of lesioned animals was significantly longer than of controls but none of the treatments changed this parameter. However, all groups treated ip and the NGF group infused centrally swam faster towards the platform in comparison to the corresponding lesioned or intact controls. The same animals were evaluated 8 months after treatments. Only FGF-treated animals showed a significant improvement in comparison to the lesioned controls. We conclude that, in the short-term, CER improves spatial memory in lesioned and intact animals whereas FGF leads to more long-lasting effects.

CONVERGENT MODULATION OF A NEUROMUSCULAR JUNCTION BY NINE NEUROHORMONES. J.C.Jorge-Rivera* and E.Marder, Volen Center, Brandeis University, Waltham, MA 02254

Despite numerous examples of invertebrate neuromuscular junction (NMJ) modulation by amines and peptides, little is known about the physiological organization of NMJ modulation by multiple substances.

We have found that a stomatogastric NMJ in the crab Cancer borealis is modulated by 9 neurohormones: Red Pigment Concentrating Hormone (RPCH), Proctolin (PROC), TNRN- and SDRN-FLRFamide, Serotonin (5-HT), Octopamine (OCT), Dopamine (DA), D-Allatostatin-3 (D-AST-3), and Histamine (HIS). We studied the effect of each modulator on agonist-mediated contractions, nerve-evoked contractions, high K^+ contractions, nerve-evoked excitatory junctional potentials (EJPs), and excitatory junctional currents (EJCs). Changes in muscle fiber input resistance were also investigated in current clamp and voltage clamp conditions. While 7 modulators enhanced the efficacy of this NMJ, 2 of them were inhibitory. For example, PROC enhances nerve-evoked muscle contraction by 500%±100% (n=3) whereas D-AST-3 reduces contractions by 60%±7% (n=7). It is likely that this NMJ is targeted by different complements of modulators under different physiological contexts in vivo. Pairs of modulators (RPCH and PROC, 5-HT and AST, FLRFamides and HIS) produce different responses when coapplied than when either is applied alone.

INCREASES IN CYCLIC-GMP OCCUR AT ECDYSIS IN AN EVOLUTIONARILY CONSERVED INSECT NEURONAL NETWORK. J. Ewer and J.W. Truman*, Zoology Dept., U. of Washington, Seattle, WA 98195.

In the moth *Manduca sexta*, the neuropeptide eclosion hormone (EH) is released at the end of each molt and triggers ecdysis, the shedding of the old cuticle. Just in anticipation of ecdysis a network of 25 pairs of peptidergic neurons shows a dramatic increase in cGMP-immunoreactivity (cGMP-IR; Ewer et al.(1994) J. Neurosci., **12**: 7704-7712). This network includes 5 pairs of neurons in the subesophageal ganglion, and two pairs in each of the thoracic and first 7 abdominal ganglia. In moths the abdominal neurons contain Crustacean CardioActive Peptide (CCAP).

A homologous neuronal network becomes cGMP immunoreactive during ecdysis in a variety of insects. In the most ancestral insects, such as silverfish (Zygentoma) and grasshoppers (Orthoptera), some of the abdominal CCAP neurons are present but do not show the cGMP response. Other insects like crickets (Orthoptera), meal worms (Coleoptera), and mosquitoes (Diptera) have the full complement of 50 cells participating at ecdysis. Higher Diptera (*Drosophila, Sarcophaga, Musca*) are exceptional in that the ecdysial cGMP response is absent although most, if not all, of the CCAP neurons are present. We will discuss how variation in the pattern of cGMP expression in this network may relate to differences in ecdysis behaviors.

823.11

AMPLITUDE REDUCTION OF EVOKED HIPPOCAMPAL FIELD POTENTIALS DURING SEXUAL BEHAVIOR IN THE FEMALE RAT. Grossman, K., Burstein, U., Zeppelin, D., Ward, T., Sween, K., Brittin, L., Carder, S., Kelley, S., Wolfson, W., Smock, T*. Behav. Neuroscience Prog., Dept. of Psych., Univ. of Colorado, Boulder, CO 80309.

These studies were designed to investigate the influence of sexual behavior on the amplitude of evoked hippocampal field potentials. Ovariectomized Sprague- Dawley rats underwent chronic electrode implant surgery. The stimulating electrode was placed in the stratum radiatum (near CA3) and the recording electrode was placed in CA1. Biphasic 0.5ms constant current square wave pulses were delivered every five seconds. Evoked potentials (EP) were reduced 30% below maximum and recorded before (B), during (S) and after four testing conditions (TC): sexual-social (receptive fem. +male, n=10); non-sexual social (non-receptive fem.+ male, n=8 & non-receptive fem.+ fem. n=11); and non-sexual non-social (non-receptive fem.+ food, n=8). Amplitude reduction (AR) during the TC was measured as the change in the average amplitude between B and S. AR for specific behaviors (i.e. locomotion, grooming) was measured as the change in the average amplitude between B and the behavior. The results suggest that there may be a greater AR in the sexual-social TC during the overall S period compared to the AR in the other three TC. There was a significantly greater AR during locomotion in the sexual-social TC compared to the receptive fem.+male TC. However, there were no differences in AR during locomotion compared to other specific behaviors within TC. AR during locomotion is attributed to the difference between the highest and lowest locomotion AR. The results suggest that the females in the sexual social TC may be non-specifically more aroused than in the other TC and that the AR may reflect this difference.

823.12

PROFILE OF CGRP-, AMYLIN- AND SALMON CALCITONIN-INDUCED DEPRESSION OF LOCOMOTION FOLLOWING INTRACEREBRO-VENTRICULAR INJECTIONS D. van Rossum*[1,2] and R. Quirion[2]. [1]Max-Planck Institute for Brain Research, 60528 Frankfurt/M, Germany, [2]Douglas Hospital Research Centre, McGill University, Montréal, Canada, H4H 1R3.

Calcitonin gene-related peptide (CGRP)-, amylin- and calcitonin-like immunoreactivity, as well as respective binding sites, are widely distributed in the CNS. Few brain areas, including the nucleus acumbens, are enriched with binding sites for all three peptides (van Rossum *et al., J. Pharmacol. Exp. Ther.* **270**, 1994). The central administration of either CGRP, amylin or calcitonin induces specific neurobehavioral profiles. In the present study, we investigated the effects of each of these peptides on amphetamine-induced (2 mg/kg) as well as on spontaneous locomotor activities. Locomotion was recorded by photocell interruptions in activity chambers for 3 hrs following animal treatment. Intracerebroventricular injections of each peptide (0.04-20 µg/10µl) decreased, in a dose dependent manner, the amphetamine-induced locomotion. All three peptides showed similar maximal effect (~ 40 %) in decreasing amphetamine-induced locomotion. However, salmon calcitonin revealed to be most potent (0.16 µg) followed by rat amylin (1.25 µg) and human CGRPα (hCGRPα, 2.5 µg). A similar potency profile was observed on spontaneous locomotion. Interestingly, the injection of bicuculline (0.5 mg/kg), a $GABA_A$ receptor antagonist, selectively blocked the decrease in spontaneous locomotion induced by hCGRPα while having no significant effects on rat amylin and salmon calcitonin-induced decrease in spontaneous locomotor activity. The present findings thus support the existence of functionally distinct receptor subtypes for CGRP *vs.* those of amylin and salmon calcitonin to modulate locomotor activity in the rat brain. Supported by the MRC of Canada.

CONDITIONED BLOOD GLUCOSE CHANGES IN HUMANS: CENTRAL INSULIN EFFECT OR PERIPHERAL EFFECTOR? G. Fehm-Wolfsdorf*, J. Pohl and W. Kerner. Institute of Psychology, University of Kiel, D-24098 Kiel, Germany.

Classical conditioning of changes in blood glucose level has been repeatedly demonstrated in animal experiments, and more recently in human studies (Fehm-Wolfsdorf et al., 1993, Physiol Behav, 54,155). In their model of drug-induced conditioning Eikelboom & Stewart (1982, Psychol Rev, 89,507) discuss two possibilities for the unconditioned stimulus and response: in glycemic conditioning they consider a direct action of insulin on a peripheral effector mechanism or a CNS mediated activation of effectors. The present study aimed to compare these possibilities directly within a yoked-control design: the "peripheral group" (PG) was infused with insulin (infusion rate 1.5 mIE/kg/min) until they clearly noticed symptoms of hypoglycemia (mean duration 24 min), then the CS (a strange mixture of odours) was given for 10 min while blood glucose was held constant by a clamp technique (group mean 2.3mM/L). Subjects of the "central group" (CG) were matched with the subjects of the PG relative to the decrease of blood glucose following insulin injection in a previous matching session. During the acquisition sessions the yoked partner in the CG was infused with the identical amount of insulin, but in addition received glucose to maintain stable blood glucose levels (group mean 5.1mM/L). The CS was given to the CG at the hypothetical time of a central insulin effect, i.e. 5 min after start of infusion for 10 min. 30 male healthy drug-free non-smoking volunteers participated in 6 sessions each: a matching session, 4 conditioning sessions and a test session with saline infusions for all subjects. Within the test session a CR was defined as a change from baseline by >0.45mM/L blood glucose. In the PG 40% and in the CG 47% of the ss showed a CR, half of them hypo- or hyperglycemia. From this result we would conclude that conditioning occurs as an effect of insulin and results in a disturbance of homeostatic regulation of blood glucose. Research was supported by a grant from the DFG.

INHIBITION OF NOVELTY-INDUCED LOCOMOTOR ACTIVITY BY INTRA-VTA INJECTION OF NEUROPEPTIDE FF, AN ANTI-OPIOID PEPTIDE. Marco N., Cador M., Stinus L.*, Le Moal M. and Simonnet G. INSERM U.259 - Rue Camille Saint-Saëns 33077 Bordeaux, France

The neuropeptide FF (NPFF) is a mammalian neuropeptide with some antiopioid properties such as anti-analgesic effects. Brain NPFF receptors are different from opioid receptors and are present at the Ventral Tegmental Area (VTA) level on non-dopaminergic cells. We have previously shown that intra-VTA injection of NPFF was able to inhibit intra-VTA morphine-induced locomotor activity. Thus, the presence of both NPFF and opioid systems at the VTA level suggest that these two opposing systems may participate to a physiological regulation of the activity of the mesocorticolimbic dopaminergic system. To test this hypothesis, we have studied the locomotor activity elicited by a novel environment since it has been reported that the mesocorticolimbic dopaminergic system is required for the expression of novelty-induced locomotor activity. In this study, we have shown that intra-VTA injection of naloxone methobromide induced a biphasic inhibition of the locomotor activity triggered by novelty, indicating that opioid peptides are released when rats are placed into a novel environment. During an early phase (0-30 min) naloxone only partially inhibited novelty-induced locomotor activity (-30%), indicating the existence of both opioid and non-opioid components. During a second period (30-90 min) naloxone totally blocked novelty-induced locomotor activity showing an essential role for opioids at the VTA level. When injected in the VTA, NPFF inhibited in a dose dependent manner (1 to 10 µg/0.5 µl) the novelty-induced locomotor activity. The highest dose (10 µg) totally blocked the hyperactivity induced by novelty. These results indicate that this neuropeptide has both opioid and non-opioid blocking effects at the VTA level suggesting that NPFF may be a modulator of the mesocorticolimbic dopaminergic system activity.

ALCOHOL-INDUCED BEHAVIORAL DEFICITS AND REGIONAL BRAIN WEIGHT REDUCTIONS DEPEND ON TIMING OF ALCOHOL EXPOSURE DURING THE NEONATAL BRAIN GROWTH SPURT IN RATS. J.D. Thomas[1]*, C.M. Esparza[2], D.E. Moritz[2], G. Lopez[2], E.A. Wasserman[1] & J.R. West[2]. [1]University of Iowa, [2]Texas A & M University

Prenatal exposure to alcohol can produce permanent CNS dysfunction expressed as a wide spectrum of behavioral deficits; however, the nature and severity of this dysfunction varies greatly. Developmental timing of alcohol exposure is believed to be one important determinant of alcohol's teratogenic effects. Using a rat model system, the present study investigated the behavioral and CNS consequences of brief episodes of alcohol exposure during varying periods within the neonatal brain growth spurt, a time of rapid CNS development equivalent to the human third trimester. Sprague-Dawley rats were exposed to alcohol (6.6 g/kg) in a binge-like manner on two consecutive days via an artificial rearing procedure. One group was exposed to alcohol on postnatal days (PD) 4 and 5, another group on PD 6 & 7, and a third group on PD 8 & 9. A fourth group served as a calorically matched, artificially reared control, and a fifth group comprised normally reared suckle controls. Subjects were tested from PD 25-43 on a series of behavioral tasks including a motor task and a reversal training learning task. All alcohol-exposed groups were significantly impaired on the motor task; however, early exposure (PD 4/5) produced more severe deficits than later exposure. An opposite pattern for deficits was observed on the learning task. On this behavioral measure, severe deficits were observed in the groups following late exposure to alcohol (PD 6/7 & PD 8/9), but not earlier. This dissociation in the temporal pattern of behavioral vulnerability corresponded with the temporal vulnerability of regional brain weight reductions. Reductions in cerebellar weight, an area involved in motor performance, were most severe following early alcohol exposure (PD 4/5), whereas reductions in forebrain weight, which includes areas involved in cognitive tasks, were most severe following later exposure (PD 6/7 and PD 8/9). Thus, the pattern of behavioral deficits is consistent with the temporal vulnerability of various brain regions. Supported in part by NIAAA grant AA05523.

EFFECTS OF PRENATAL ALCOHOL EXPOSURE AND AGING ON AUDITORY FUNCTION IN THE RAT. M.W. Church*, E.L. Abel, J.A. Kaltenbach and G.W. Overbeck. Fetal Alcohol Research Center, Depts. Ob/Gyn and Audiology, Wayne State Univ. Sch. Med., Detroit, MI 48201.

The present study investigated select aspects of peripheral and central auditory dysfunction, as well as the pathological effects of aging, in an animal model of the fetal alcohol syndrome (FAS). Pregnant rats consumed liquid alcohol diets containing 0%, 17.5%, or 35% ethanol-derived calories, from gestation day 7 to parturition. A fourth group was untreated. Offspring of these mothers were tested for auditory and neurological function, using the auditory brainstem response (ABR) at 6, 12 and 18 months of age. The ABR provided evidence of both peripheral and central auditory disorders. Specifically, some animals in the alcohol-exposed groups showed a peripheral auditory disorder in the form of congenital sensorineural hearing loss. This was correlated with punctate lesions of and malformed stereocilia on the auditory sensory receptor cells in the inner ear. Alcohol-exposed animals also showed a central auditory processing disorder characterized by prolonged transmission of neural potentials along the brainstem portion of the auditory pathway. Animals in the highest dose group also showed an augmentation in the age-related deterioration of auditory acuity. Thus, increased peripheral and central auditory dysfunction and pathological deterioration of auditory function in old age may be sequelae of FAS. Such morbidities have important implications for the long-term clinical assessment and management of FAS patients.

BEHAVIORAL AND IMMUNOLOGICAL CONSEQUENCES OF BRIEF EMBRYONIC EXPOSURE TO NICOTINE OR ALCOHOL IN DOMESTIC FOWL CHICKS. R. A. Hughes[1]*, M. R. Baker[1], N. Nollen[1], S. H. Chou[2], K. A. Nordyke[2], and J. E. Cunnick[1,2]. Depts. Psychology[1], Microbiol. Immunol. Prevent. Med[2]., Iowa State Univ. Ames, IA 50010-3180.

Fertile eggs of domestic fowl (Gallus gallus) received injections into the egg air space of either nicotine tartrate (NIC; 0.0, 0.025, 0.25, 2.5, or 5.0 mg/ml/kg egg) or ethyl alcohol (ETOH; 10, 20, 30, or 40% 1 ml/kg egg) on incubation days 10-12. NIC (5.0 mg/kg) significantly ($p < .05$) affected hatch rate and hatchling survival but other NIC and ETOH amounts did not. Chick body weights at hatch were not significantly affected by either NIC or ETOH.

Indices of social distress vocalizations & activity) defensive (tonic immobility induction and duration), and immunologic responses (leukocyte proliferation to mitogen stimulation; ConA, LPS, PWM; blood thymus and spleen) were measured successively in surviving chicks at one (social measure), 14 (tonic immobility measures), and 17 (immune system measures) posthatch. On the social test neither NIC nor ETOH altered distress vocalizations but both drugs decreased activity in a dose dependent manner. On the tonic immobility test ETOH groups required fewer inductions than controls but duration was equivalent; NIC did not affect the immobility measures.

Preliminary analysis of the immune system data suggest significant effects of NIC and ETOH on leukocyte proliferation that depend, in part, upon dose and sex gender.

BINGE-TYPE ALCOHOL EXPOSURE DURING THE FIRST TWO TRIMESTERS EQUIVALENT IN THE RAT FAILED TO PRODUCE A DEFICIT IN CEREBELLAR PURKINJE CELL NUMBER USING STEREOLOGICAL METHODS. Susan E. Maier* & James R. West, Anatomy & Neurobiology, Texas A&M University Health Science Center, College Station, TX 77843-1114

Women who binge drink throughout pregnancy have an increased risk for delivering babies with Fetal Alcohol Syndrome or Alcohol-Related Birth Defects. In the rat, cerebellar Purkinje cells are extremely susceptible to alcohol-induced cell death as a consequence of third trimester equivalent exposure (postnatal days 4-9). Whether alcohol exposure during the first two trimesters equivalent results in similar Purkinje cell deficits is the question we addressed. Timed pregnant rats received one of three treatments daily from gestation days (GD) 1-20; alcohol gavage (6 g/kg, 22.5% v/v), Maltose-Dextrin gavage + pairfed to alcohol, or standard lab chow. Offspring from treated dams were perfused with fixative on GD33 (postnatal day 10), had their cerebella removed and processed for plastic embedding using Historesin®. Serial sagittal sections were cut through the entire cerebellum and mounted on slides for counting using Cavalieri's principle and the optical disector. Even though peak blood alcohol concentrations (BAC) reached 334 mg/dl late in gestation, there were no differences between the three groups in estimates of volume, density, or Purkinje cell number. Taken together with previous findings, these results suggest that cerebellar Purkinje cells are considerably less susceptible to alcohol-induced deficits during the first two trimesters equivalent than during the third trimester equivalent, even when alcohol exposure during the third trimester equivalent encompasses a substantially shorter duration (6 days) and results in a considerably lower peak BAC (~250 mg/dl). Supported by Grant AA10090.

ALCOHOL-INDUCED HIPPOCAMPAL ABERRANT MOSSY FIBER PROJECTIONS DEPEND ON THE PATTERN OF EARLY POSTNATAL ALCOHOL EXPOSURE IN RATS. D. M. Smith and C. R. Goodlett*. Dept. of Psychology, IUPUI, Indianapolis, IN 46202.

Continuous exposure to alcohol (EtOH) in artificially reared neonatal rats during the first ten postnatal days has been shown to produce aberrant mossy fiber projections into the distal intra- and infrapyramidal zone of mid-temporal hippocampal field CA3 (West & Hamre,*Dev. Brain Res.*, 1985). This experiment examined whether induction of aberrant mossy fibers depends on the daily pattern of neonatal alcohol exposure.

Harlan Sprague-Dawley rats were randomly assigned to one of the following treatments administered on postnatal days 1-9: one of three alcohol treatments (using artificial rearing methods); an artificially reared control; or a suckle control. Alcohol was given in three different patterns, as follows: Continuous 1 (a replication of the original West & Hamre treatment) received 2.8% v/v EtOH in each of 8, 15-min daily feedings (n=5); Continuous 2 received 2.8% v/v EtOH (n=3) or 3.2% v/v EtOH (n=5) in each of 12, 20-min daily feedings; Binge received 10.2% v/v EtOH in 2 consecutive of the 12, 20-min daily feedings (n=5). Artificially reared controls were given feedings calorically matched to the experimental groups (total n=11), and suckle controls (n=25) were reared normally by dams. Continuous 1 treatment produces more rapid increases in blood alcohol concentration (BAC) per feeding, compared to Continuous 2, because a larger volume of EtOH is delivered in a shorter feeding time. The Binge treatment produces a high peak BAC (~250 mg/dl) that falls to 0 before the end of the day. Rats were sacrificed on PD 45; frozen horizontal sections (35 µm thick) were processed with the Timm stain for heavy metals and evaluated microscopically for the presence of distal intra-and infrapyramidal mossy fibers.

In the Continuous 1 condition, 2 of the 5 cases were found to have aberrant mossy fiber projections (compared to 7 out of 8 in West & Hamre, 1985). None of the remaining groups had subjects with aberrant mossy fibers. These data suggest that the rapid and continuous presence of high BACs in the early neonatal period is critical to the development of aberrant mossy fiber projections. (Supported by AA09596)

ETHANOL-GABA$_A$ RECEPTOR INTERACTION IN DEVELOPING RAT CEREBELLAR PURKINJE CELLS: γ2L vs. γ2S mRNA EXPRESSION. H.H. Yeh*, E.V. Grigorenko and T. Y. Rikhter. Dept. Physiology & Pharmacology, Bowman Gray Sch. Med., Winston-Salem, NC 27157.

The modulation of the GABA$_A$ receptor by ethanol may be dependent on GABA$_A$ receptor subunit composition. Since the expression of many GABA$_A$ receptor subunits are developmentally regulated, such dynamics should reveal to advantage as to whether ethanol sensitivity is related to GABA$_A$ receptor subunit make-up. Here, we combined patch clamp recording and RT-PCR in single immature Purkinje cells to link ethanol-GABA interaction with GABA$_A$ receptor subunit mRNA expression, focusing on the long and short splice variants of the γ2 subunit (γ2L &γ2S).

Purkinje cells acutely dissociated from postnatal day(PD)-1, -3, -5, -7, -9 and -11 rat cerebella, were chosen for study. At each age examined, GABA-activated whole-cell current responses were potentiated upon co-application of 50 mM ethanol. Profiling of GABA$_A$ receptor subunit mRNAs in these cells revealed the expression of α, β and γ subunit mRNAs. The γ subunit expressed prior to PD-7 was that of γ2S. The expression of γ2L was not evident in individual Purkinje cells until PD-7. In whole cerebellar tissue, γ2S mRNA expression was found throughout postnatal development but that of γ2L mRNA only beyond PD-5. Other subunit messages also appear developmentally regulated.

Our results indicate that ethanol modulation of GABA$_A$ receptor function in cerebellar Purkinje cells is present prior to the emergence of, and thus independent of, γ2L mRNA expression and that the dynamics of neuroreceptor expression in development can provide insights into the specificity of ethanol-neuroreceptor interactions.

PRENATAL ETHANOL EXPOSURE ALTERS MODULATION OF THE $GABA_A$ RECEPTOR CHLORIDE CHANNEL COMPLEX IN ADULT OFFSPRING. D.D. Savage, L.L. Paxton, H. Wu, and A.M. Allan* Dept. of Pharmacology, Univ. of New Mexico H.S.C., Albuquerque, NM 87131-5316

The amino acid neurotransmitters glutamate and GABA have been implicated as neurochemical correlates underlying the electrophysiological and behavioral deficits observed in Fetal Alcohol Syndrome. To further investigate prenatal ethanol-induced changes in the GABA system, we measured the ability of GABA and four modulatory agents that affect $GABA_A$ receptor-stimulated ^{36}chloride ion flux in membrane vesicles prepared from hippocampus, cerebellum and frontal cortex of adult offspring from *ad lib* chow, pair-fed and ethanol fed rat dams. Prenatal ethanol treatment involved the consumption of a liquid BioServ diet containing 5% (v/v) ethanol by rat dams throughout gestation.

Dose dependent GABA-stimulation of chloride flux was not significantly affected by the prenatal ethanol exposure in any of the brain areas examined. In the frontal cortex, prenatal ethanol exposure significantly attenuated both the positive modulatory effects of flunitrazepam (FLU; 25 μM) and alphaxalone (ALPH; 25 μM) as well as the negative modulation by the inhibitory neurosteroid, 5 α-pregnan-3 β -ol- 20-one sulfate (PS; 25 μM) and the benzodiazepine inverse agonist FG-7142 (FG; 10 μM) on GABA-stimulated $^{36}Cl^-$ flux. In the cerebellum, prenatal ethanol exposure diminished the modulatory influences of the benzodiazepines but not the neurosteroids. In hippocampus, prenatal ethanol exposure enhanced the effect of positive modulators (FLU and ALPH) but diminished the effects of negative modulators (FG and PS). These findings suggest that prenatal ethanol exposure produces long-lasting effects on the modulatory sites of the $GABA_A$ receptor complex. Further studies will be required to determine whether these alterations are a compensatory mechanism in response to the early ethanol insult or if these alterations contribute to the electrophysiological and behavioral deficits observed in fetal ethanol exposed offspring.

824.8

EFFECT OF PRENATAL ALCOHOL EXPOSURE ON SEROTONIN TRANSPORTER BINDING SITES IN RAT BRAIN. H. M. Zafar , S. Shelat, E. Redei and S. M. Tejani-Butt*. Depts. of Psychiatry and Pharmacology, Univ. of Penn. Sch. of Med., Phila., PA 19104.

Fetal alcohol exposure (FAE) is known to have long-term effects on behavior which include hyperactivity and altered stress response. FAE has also been reported to decrease serotonin (5-HT) levels, turnover, release and uptake, as well as alter 5-HT receptor sites in several brain regions of offsprings. Since presynaptically located 5-HT transporter (5-HTT) sites serve as markers of 5-HT innervation, the present study examined the effects of FAE on 5-HTT binding sites in several discrete brain regions of the developing male and female offspring. Time-pregnant dams were fed liquid ethanol diet, isocaloric diet without ethanol or normal rat chow. Male and female offspring were sacrificed at 21, 40 and 60 days of age. The brains were removed and sectioned for autoradiographic analysis of ^{3}H-cyanoimipramine (^{3}H-CNIMI) binding to 5-HTT sites. The results indicate that FAE had a significant time and sex dependent effect on 5-HTT sites. In FAE-females, 5-HTT sites were decreased in the amygdala and hypothalamus and increased in the hippocampus and dorsal raphe nucleus as early as day 21. However, 5-HTT sites increased in the amygdala in day 40 FAE-females, and this increase persisted in the amygdala and hippocampus in adulthood. In contrast, 5-HTT sites were found to be unaltered in immature FAE-males, but decreased in the amygdala and hypothalamus and increased in the hippocampus and dorsal raphe nucleus in adult FAE-males; a pattern similar to immature FAE-females. (Research funds from USPHS grant NS 31699 and AA 07389).

824.9

EFFECT OF PRENATAL ETHANOL EXPOSURE ON POSTNATAL EXPRESSION OF GLUTAMATE RECEPTORS AND PHYSIOLOGICAL RESPONSES IN BARREL FIELD CORTEX. V. Rema*, W. Huang and F. F. Ebner. Institute for Developmental Neuroscience, Vanderbilt University, Kennedy Center, Nashville, TN 37203.

Prenatal ethanol exposure leads to alterations in the expression of glutamate receptors in postnatal rat cortex. There is reduced expression of NMDA receptor subunits NR1, NR2A/B as detected by immunocytochemical analysis, which is maintained for at least 3 months after birth. However we do not see a similar reduction in the expression of AMPA receptor subunits at the ages examined. Compared to normal animals the cortex of rats prenatally exposed to ethanol showed an increase in GluR1 immunostaining at P21 and P30, whereas GluR2/3 immunoreactivity was lower at P21 and higher by P30 compared to normal. The expression of GluR4 does not seem to be effected by prenatal ethanol exposure at P21 and P30. We are currently examining the effect of these subunit changes on physiologically recorded plasticity. Extracellular single unit recording suggests that neuronal responses in the primary somatosensory cortex of adult rats are altered following exposure to alcohol during gestation. The main differences compared to normal animal are in the level of spontaneous activity, the amplitude of evoked responses in the center and surround receptive fields and the response latencies. (Supported by NS 13031 and HD 1052)

CORPUS STRIATUM HISTOLOGICAL ALTERATIONS IN ADULT MICE PRENATALLY TREATED WITH DIAZEPAM A. Márquez-Orozco*, M.C. Márquez-Orozco, M.V. Gazca-Ramírez and G. de la Fuente-Juárez. Embryol Dept. School of Medicine UNAM, POB 70-553 México 04510 D.F. México.

Diazepam accumulates in the fetal human and mice corpus striatum, where it produces a delay in the neuroblastic differentiation. An atypical chromatin distribution and less number of fibers. We investigated if the histological alterations of the fetal corpus striatum occurs in adult mice. Single daily doses (2.7 mg/kg) of diazepam were sc. administrated to CD-1 strain female mice, from gestation day 6 to 17. A control received equivalent volumes of saline solution. The offspring's were wet-nursed by non-treated mice, weaned and kept for 240 days. The motor activity and swimming pattern were periodically measured from the 6th day until the 8th month. Mice were deeply anesthetized, perfused with 10% formaline, and the brains were removed, fixed and stained for myelin, nerve cells, and axons identification; a selected blocks were impregnated with the fast-Golgi technique. Light microscopy demonstrated in diazepam mice atypical distribution of neurons, less number of fibers, and accumulation of glial cells around vessels, and in the bundles fibers. Behavioral analysis of the experimental group (swimming, and spontaneous motor activity) correlated well with the persistent histological alterations.

824.11

PERSISTING EFFECTS OF PRENATAL EXPOSURE TO DIAZEPAM ON SEXUAL BEHAVIOR OF FEMALE MICE. L.A.I. Hernández-Alvarez*, A. Martínez-Vargas, B. Victoria-Romero, A. Márquez-Orozco and M.C. Márquez-Orozco. Unit for Research in reproduction. School of Medicine, BUAP and Dept. of Embryology. School of Medicine, UNAM, México 04510 D.F., México.

We have shown in forgoing works, effects of prenatal exposure to diazepam (DZP) on sexually dimorphic reproductive behaviors. In this work, we assessed the sexual behavior of senile females CD-1 strain mice exposed to DZP during gestation. One group of female mice was s.c. treated with DZP (2.5 mg/kg/d) from the 6th to the 17th days of gestation and a control group received saline sol. On the 27th month of age, the spontaneous female sexual activity to males from the same breeds was tested and videorecorded under red light. Precopulating and copulating activities were evaluated. No difference was found in precopulating behaviors from both groups, but during copulating stage lordotic indexes and proportion of lordotic females were greater in experimental animals. Results indicate persistent and long-lasting mating facility patterns of prenatal exposure of DZP on sexual behaviors which could be due to permanent modification of neurotransmission by the drug during development.

824.12

HISTOLOGICAL CHANGES IN THE RETINA OF MOUSE FETUSES EXPOSURE TO DIAZEPAM. M.C. Márquez-Orozco*, A. Márquez-Orozco, M.V. Gazca-Ramírez and G. de la Fuente-Juárez. Embryol. Dept. School of Medicine UNAM, POB 70-553 México 04510 D.F. México.

We investigated if diazepam (DZ) 1.0 mg/kg dose produces similar histological effects in the fetal retina as with 2.7 mg/kg dose. Three gestating CD-1 strain mice groups were injected daily sc. from day 6 to 17, the first group with single daily DZ doses (2.7 mg/kg), the second group with single daily DZ, doses (1.0 mg/kg) the third group received saline solution (S). A fourth group was non-treated (NT). All were killed with CO_2 atmosphere the 18th. day, and the fetus removed. Their eyes were fixed with 2.5% glutaraldehide, post-fixed in OsO_4 and embedded in epoxy resin. The semifine sections were stained with toluidine blue and observed under the light microscope. The fetal retina in both DZ groups revealed in the neuroblastic layers delay cellular differentiation. A greater nuclear density of the retinal cells were observed. The cells showing nuclei with clumps of heterochromatin atypically distributed. S and NT groups exhibited neither histological differences in the retina and the cells showing nuclei with normal heterochromatin typically distributed. Results give evidence that both DZ doses produces histological changes in the fetal retina.

EFFECTS OF FLUMAZENIL BENZODIAZEPINE DEPENDENCE IN MAN. S. W. Woods*, M. I. Rosen, L. H. Price, H. R. Pearsall, F. A. Hameedi, D. W. Gallager, D.S. Charney, G. R. Heninger, T.R. Kosten. Yale University, 34 Park Street, New Haven, CT 06519

Preclinical studies suggest that the benzodiazepine (BZ) receptor antagonist flumazenil (FLU) in single doses can reduce established BZ dependence. The goal of this ongoing study is to determine whether FLU has this effect in BZ dependent human subjects (Ss). Barbiturate pretreatment is employed to attenuate FLU- induced acute withdrawal. Method: Thus far, 10 methadone maintained polysubstance abuse inpatient Ss have been randomly assigned to FLU (n=5) or placebo (PLA, n=5) groups. FLU Ss were dependent on BZs for 3.0±0.7 yrs and were stabilized for 18±7 d on 5.6±2.2 mg/d alprazolam (ALP) equivalent. After stabilization, a single dose of phenobarbital (PBS) at 30 times (x, n=3) or 60x (n=2) the ALP daily stabilization dose was administered p.o. followed after 2.5 hrs by FLU 1.5 mg i.v. per S over 15 min. PLA Ss dependent on BZs for 6.8±6.0 yrs were stabilized for 18±6 d on 6.0±1.9 mg/d ALP equivalent. These Ss also received PBS at 30x (n=3) or 60x (n=2) the ALP dose, but PBS was followed by double-blind placebo (PLA) i.v. over 15 min. One hr after FLU/PLA, BZ was abruptly discontinued via single blind placebo substitution in both groups. Abstinence symptoms were rated using the Ribicoff Abstinence Rating Scale (RARS) for the next ten days. Results: Results to date indicate that FLU was well tolerated in these BZ dependent Ss when given after PBS. RARS scores after BZ discontinuation peaked as expected at 2-3 days in both groups but are approximately 50% lower in the FLU-treated Ss. "Escape" medication doses were lower for FLU (0.6±0.9 mg ALP equivalent/10d) than for PLA (3.2±3.1 mg) Ss. Discussion: These results suggest that FLU in a single dose when administered with PBS may be able safely to reduce established BZ dependence in man. Further research is needed to investigate dose-response relationships.

824.14

THE EFFECT OF INTRA-AMYGDALOID ADMINISTRATION OF FLUMAZENIL IN DIAZEPAM-DEPENDENT RATS. J.W. SLOAN*, E.P. Wala, X. Jing. Dept. of Anesthesiology, College of Medicine, Univ. of KY., Lexington, KY 40536

The amygdala is an important brain site for the anxiolitic and anticonvulsant actions of benzodiazepines (BZS). Autoradiographic studies indicate a high density of BZ receptors (BZR) (predominantly type-2) in the basolateral amygdaloid nuclear complex. The aims of the present study were to test the ability of the BZR antagonist, flumazenil (FLU), to precipitate an abstinence syndrome in the ventromedial lateral (LaVM) and basolateral (BLA) amygdaloid nuclei in diazepam (DZ)-dependent rats. The rats were exposed for 3 wks to DZ (540 mg/wk) slowly released from subcutaneously implanted silastic capsules. FLU (25 ug) and DMSO vehicle were microinjected into LaVM (AP=5.7; RL=4.8; V=2) (n=6) and BLA (AP=5.7; RL=4.8; V=1)(n=5). The abstinence signs, behavioral activities and EEG were recorded for 10 min before and 40 min after microinjections. The Precipitated Abstinence Score (PAS), Behavioral Score (BS) and the changes in Total Power (TP) of the EEG recorded at the sites of microinjections were determined. FLU did not produce either a significant PAS or a significant BS in BLA and LaVM. FLU evoked clonic convulsions (1 rat) and twitches and jerks (P<.05) in BLA. No signs of abstinence were precipitated by FLU in LaVM. FLU tended to increase TP of low and high frequency bands in BLA but not in LaVM. DMSO did not alter TP in BLA and LaVM. The present data indicate that except for convulsive signs a surprisingly mild abstinence was evoked by FLU in both nuclei of lateral amygdala in rats dependent on DZ. INTRATHECAL (IT) ADMINISTRATION OF FLUMAZENIL AND PK11195 PRODUCE AN ABSTINENCE SYNDROME IN DIAZEPAM-DEPENDENT RATS. E.P. Wala,* J. W. Sloan, X. Jing, P.H. Holtman, Dept. of Anesthesiology, College of Medicine, Univ. of KY., Lexington, KY 40536.

The actions of central and peripheral benzodiazepine receptor (BZR) antagonists, flumazenil (FLU) and PK11195 (PK), at the spinal level were determined in rats subcutaneously implanted for 3 wks with silastic capsules filled with diazepam (DZ) (540 mg/wk). Control rats were exposed to empty capsules. The rats were implanted with EEG electrodes into the ventral thalamic nucleus (Th), CA1 area of hippocampus (H) and parietal (PC), frontal (FC) and cerebellar (CbC) cortices and with an intrathecal (IT) catheter into the spinal subarachnoid space (vicinity of T-12). After recovery, FLU (0.1 mg/kg), PK (0.05 mg/kg) and vehicle were injected (10ul) IT. The EEG, abstinence signs and behavioral activities were recorded. The Precipitated Abstinence Score (PAS), Behavioral Score (BS) and changes in Total Power (TP) for slow (4-12Hz) and fast (18-26Hz) frequency bands were determined. Intrathecal FLU and PK precipitated a significant PAS but not a significant BS in DZ dependent rats. Intrathecal PK decreased TP of fast waves in Th,H,PC and CbC but not in FC. FLU did not alter TP. In control rats PAS, BS and changes in TP were not significant. Thus, in the spinal cord both central (predominantly type-2) and peripheral BZR are involved in dependence on DZ as indicated by the PAS produced by FLU and PK. The lack of effect of IT FLU on EEG may be related to the low density of type-1 BZR in the spinal cord. (NIDA grant DA02195).

CONTINGENT TOLERANCE, BUT NOT WITHDRAWAL SYMPTOMS, IS MAINTAINED FOR 14 DAYS WITHOUT TREATMENT FOLLOWING DIAZEPAM EXPOSURE IN KINDLED RATS. Kippin, T.E.[1], St. Denis, M.[2], Kalynchuk, L.E.[2], & Pinel, J.P.J.[2] 1. Centre for Studies in Behavioral Neurobiology, Concordia Univ., Montreal, Que; 2. Dept of Psych, Univ. British Columbia, Vancouver, B.C.

Tolerance to a drug's effect and symptoms of withdrawal are often considered to be different manifestations of the same underlying mechanisms, however, few adequate attempts to dissociate these phenomena have been made. In the present study, amygdala-kindled adult male Long-Evans rats were used to examine tolerance to the anticonvulsant effects of and symptoms associated with withdrawal from diazepam (2.5 mg/kg). Following kindling, rats were divided into three groups. On each of 10 treatment trials, rats received either diazepam 1 hr before (drug-before group) or after (drug-after group) a convulsive stimulation or vehicle 1 hr before or after convulsive stimulation (vehicle-control group). Then, all rats received convulsive stimulations 1 hr following diazepam (tolerance test) and 1 hr following vehicle (stimulation tests). Consistent with previous reports, tolerance to diazepam's anticonvulsant effects was contingent upon receiving a convulsive stimulation during drug exposure--only drug-before rats were tolerant. However, both the drug-before and drug-after groups displayed significant withdrawal effects as demonstrated by increased duration and severity of convulsions on stimulation tests--larger withdrawal effects were displayed by the drug-before rats than the drug-after rats. Following a 14-day retention interval (without drug or stimulation), all rats received a second series of tolerance and stimulation tests. As previously reported, contingent tolerance was still present in drug-before rats. However, neither the drug-before nor the drug-after rats displayed any evidence of withdrawal effects. The finding that contingent tolerance, but not withdrawal effects, was maintained over the retention interval suggests that different mechanisms underlie these phenomena.

824.17

EFFECTS OF DIAZEPAM ON $GABA_A$ RECEPTOR FUNCTION IN THE TOLERANT AND WITHDRAWAL RATS. S. Toki, T. Saito*, A. Nabeshima, H. Ozawa, S. Hatta[1], M. Watanabe, and N. Takahata Department of Neuropsychiatry and Pharmacology[1], School of Medicine, Sapporo Medical University, Sapporo, 060 Japan

Alterations in $GABA_A$ receptor function were studied in diazepam (DZP)-dependent rats. Physical dependence on DZP was induced in male Fischer rats by the drug-admixed food (DAF) method. Using the DAF method, severe physical dependence on DZP is characterzed by spontaneous convulsions during DZP withdrawal developed. In comparison with control rats, 10μM GABA-dependent $^{36}Cl^-$ influx in withdrawal rats wassignificantly increaced, whereas there was no significant difference between the tolerant and control rats. While enhancement of GABA-dependent $^{36}Cl^-$ influx by the addition of EtOH and flunitrazepam (FZ) was recognized in the control, there was no such effect of EtOH or FZ in the DZP-tolerant animals. On the other hand, GABA-dependent $^{36}Cl^-$ influx was enhanced by FZ in the withdrawn group. In a [^{3}H] FZ binding assay to benzodiazepine (BZ) receptors, Bmax values were significantly increased in DZP-withdrawn animals, but decreased in the DZP-tolerant group as compared with the control. When [^{3}H] muscimol binding was examined, the Kd of high affinity sites of the $GABA_A$ receptor in withdrawn rats was significantly lower than in the control. In low-affinity binding sites, the values of Kd and Bmax were significantly decreased as compared with those in the control. The present study indicates that GABAergic transmission involving the regulation of GABA-dependent chloride channels is altered in DZP-dependent rats.

GENDER-SPECIFIC CHANGES IN CRF CONTENT AND CORTICOSTERONE LEVELS FOLLOWING CHRONIC BENZODIAZEPINE EXPOSURE IN RATS. M. A. Wilson* and R. Biscardi. Department of Pharmacology, Univ. South Carolina School of Medicine, Columbia, SC 29208.

Acute stress induces sex-specific changes in GABA/benzodiazepine (BZ) receptors and corticosterone release in rats. Gender-related differences have also been observed in GABA/BZ responses after chronic benzodiazepine exposure. The present study compared changes in CRF content and corticosterone release following benzodiazepine exposure in ovariectomized female (OVX) and sham-operated male rats. After treatment with vehicle or diazepam-filled (DZ) silastic capsules for 3 days (acute) or 3 weeks (chronic), CRF content in punches from eight brain areas and serum corticosterone were determined in groups of unstressed (habituated to sacrifice procedures) and swim-stressed (10 min prior to sacrifice) rats. In OVX females, acute and chronic DZ exposure attenuated the stress-induced increase in corticosterone by 31% and 32%, respectively ($F=13$, $p<0.002$ for DZ effect). Males showed nonsignificant decreases in corticosterone levels (15%) after acute and chronic DZ exposure. Chronic diazepam exposure significantly increased CRF content in amygdala of unstressed OVX females, but not males ($F=8$, $p=0.01$ for sex-DZ interaction). Median eminence levels of CRF were reduced by chronic DZ treatment in unstressed males, but not in OVX females ($F=6.5$,$p=0.02$ for interaction). Several brain areas (preoptic area, locus coeruleus, paraventricular nucleus) showed male-OVX differences in CRF levels, but no effect of DZ exposure. CRF content in some areas was not altered by gender or DZ treatments. The results suggest BZ agonists attenuate stress-induced corticosterone release to a greater degree in females than males, but that tolerance does not develop to this effect. Chronic benzodiazepine exposure appears to modulate CRF content of certain brain areas in a gender-specific manner. (Support: DA05932 to MAW).

DRUG DISCRIMINATION ANALYSIS OF PARTIAL AGONISTS AT THE BENZODIAZEPINE (BZ) MODULATORY SITE. N. A. Ator*, M. A. Kautz, C. A. Sannerud[1], and R. R. Griffiths. Johns Hopkins Univ. Sch. Med. and [1]Natl. Inst. on Drug Abuse, Balt., MD 21224.

The discriminative stimulus effects of partial agonists at the Bz site were studied in rats and baboons trained to discriminate Bz or pentobarbital. In a two-lever drug versus no drug procedure, bretazenil, imidazenil, and U-78875 reliably occasioned drug-appropriate responding in animals trained to discriminate diazepam and pentobarbital but there was less reliable generalization in animals trained to discriminate lorazepam. In rats trained to discriminate two doses of midazolam under a three-lever procedure, bretazenil occasioned 100% drug-appropriate responding only on the lever paired with the 0.32 mg/kg dose but not the 3.2 mg/kg dose. In rats trained to discriminate lorazepam from pentobarbital under a three-lever procedure, imidazenil occasioned responding on both drug-paired levers; although, across the dose range, responding was higher on the lorazepam lever for rats trained to discriminate lorazepam first and pentobarbital second. In interaction studies in rats, U-78875 antagonized the effects of lorazepam, had little effect on diazepam, and potentiated the effects of pentobarbital. There appeared to be a behavioral component to the ability of U-78875 and bretazenil to antagonize lorazepam's effects in baboons: the compound antagonized lorazepam when the baboon did not generalize to it but potentiated lorazepam if the partial agonist shared discriminative effects with lorazepam. Supported in part by NIDA DA04133.

ALPRAZOLAM DEPENDENCE PREVENTED BY SUBSTITUTING WITH THE ß-CARBOLINE ABECARNIL G. Pinna, R. Galici, H.H. Schneider, D.N. Stephens* and L. Turski. Research Laboratories of Schering AG, D-13342 Berlin, Germany.

Abrupt termination of the treatment of humans with benzodiazepines (BDZs) leads to a rapid-onset discontinuation syndrome. For this reason, there is considerable interest in discovering means of weaning patients away from BDZs without the risk of discontinuation syndrome. We have employed methods for electroencephalographic (EEG) monitoring of seizures, for electromyographic monitoring of muscle tone, and for detecting anxiety-like behavioral changes after discontinuation of long-term treatment with sedative drugs in mice for controlled and standardized assessment of dependence liability of alprazolam. Alprazolam, a BDZ with a short half-life, was chosen because it has replaced diazepam as the most prescribed anxiolytic drug since the end of eighties. Male NMRI mice, 20-24 g, were subjected to s.c. injections of 6 mg/kg of alprazolam or vehicle given twice daily for 12 days. Long-term treatment with alprazolam led to a rapid loss of its depressant action on exploratory activity in non-habituated mice. Monitoring of withdrawal signs started on the day following the last administration of alprazolam or vehicle. The intensity of the discontinuation syndrome (EEG seizures, rigidity, anxiety) increased slightly over first 2-3 days of withdrawal, the symptoms were most pronounced during the next 7-14 days, and abated slowly up to withdrawal days 21-28. Replacement of alprazolam treatment with the ß-carboline selective agonist abecarnil (6 mg/kg/d for 7 d) prevented the occurrence of withdrawal signs; when replacement treatment with abecarnil was subsequently terminated no signs of dependence were detected. Replacement of alprazolam treatment with the ß-carboline antagonist ZK93426 (ethyl-5-isopropoxy-4-methyl-ß-carboline-3-carboxylate; 20 mg/kg/d for 7 d) did not prevent the discontinuation syndrome. Replacement therapy with abecarnil after long-term treatment with the BDZs offers novel method for rapid tapering. The use of the BDZ antagonists for tapering long-term treatment with BDZs is not justified by the experimental data.

NATURALLY OCCURRING BENZODIAZEPINE-LIKE COMPOUNDS IN FOOD AND PLANTS: THEIR IMPLICATION IN HEALTH AND DISEASES. R. Avallone, L. Corsi, D. Braghiroli, C. Parenti, M. Di Bella,, I Venturini°, M.L. Zeneroli° and M. Baraldi*. Depts of Pharmaceutical Sciences and of Internal Medicine°, Modena University, Italy.

Since the identification of the Benzodiazepine (Bz) receptors many studies have been performed to search for natural Bz receptor ligands for these recognition sites. Many substances have been found to act either specifically or nonspecifically at Bz receptors. Recently, however, some investigators have described the presence of Diazepam, Nordiazepam and other halogenated Bz in human and animal brain tissues. Several authors gathered further chemical evidence of the presence of Bz and metabolites in natural sources like serum and milk. Since synthetic pathway for the production of halogenated Bz are not yet found in animal tissues, it is likely to surmize that these Bz are of exogenous source. The presence of halogenated Bz have been described in plants and in food. It must be stressed however that there are also other Bz-like compounds, and among them the so called "endozepines" which are nonhalogenated substances, which are still poorly characterized. Herein we report that using extraction protocol, HPLC purification, receptor binding displacement and selective antibenzodiazepine antibody we identified several Bz-like compounds in foods such as carobs and potatoes and in medicinal plants such as Matricaria Chamomilla with mean concentrations of 0.5 - 2 ng/g depending on the analyzed part of the vegetable. The presence of Bz-like compounds detected in plants, food stuffs and milk seems to support the hypothesis that exogenously supplied Bz-like compounds could be regarded as exogenous agents which when introduced through the alimentary chain subserve the function to basically activate the Bz receptors for their physiological function. There are however pathological conditions where Bz compounds have been found to accumulate because of the altered metabolism by the liver such liver cirrhosis and fulminant hepatitis. In these pathological conditions we know that caution must be taken to avoid the administration of commercial Bz due to an increased GABAergic tone. The data presented indicate also that the administration of food containing natural Bz must be avoided in order to prevent the occurrance of episodes of encephalopathy in patients with severe liver diseases.The rise of Bz in plasma and in brain might play a role as precipitating factor of hepatic encephalopathy.

CHARACTERIZATION OF CHLORIDE EFFLUX FROM GT1-7 NEURONS: LACK OF EFFECT OF ETHANOL ON $GABA_A$ RESPONSE AT 4° C. M.A. Javors*, T.S. King, X. Chang, C. Levinson, and M.K. Ticku. Departments of Psychiatry, Pharmacology, Physiology, and C&SB, University of Texas HSC, San Antonio, TX 78284.

GT1-7 hypothalamic neurons, which synthesize and secrete GnRH (gonadotrophin releasing hormone), were immortalized from transgenic mice and have been shown to express functional $GABA_A$ receptors. Our previous experiments showed that stimulation of these receptors with muscimol produced an increase of cytosolic [Ca^{2+}] and the release of GnRH. Our previous experiments also showed that ethanol enhanced $GABA_A$-mediated increase in [Ca^{2+}] despite the fact that GT1-7 neurons do not express a γ subunit. GT1-7 neurons were grown to confluence in 100 mm diameter culture dishes and loaded with ^{36}chloride overnight. The next morning cells were washed extensively. The extracellular medium was then sampled to determine chloride efflux. Our results show that chloride efflux increased with increased temperature (tested at 4°, 23°, and 37° C; 4° C was used for the rest of our experiments to minimize background). DIDS, an inhibitor of anion exchange, reduced chloride efflux by 65% with an IC50 of 100 µM. Bumetanide, an inhibitor of Na:K:2Cl cotransport, had no effect on chloride transport at concentrations up to 200 µM. Muscimol, a $GABA_A$ agonist, stimulated chloride efflux with an IC50 equal to 0.5 µM. Bicuculline, a $GABA_A$ antagonist, reversed the muscimol effect with an IC50 of 13 µM. Ethanol (46 mM) had no effect on muscimol-induced chloride efflux at 0.5, 1.0, and 10 µM muscimol. Our results suggest that stimulation of $GABA_A$ receptors causes an efflux of chloride from GT1-7 neurons. The lack of an effect of ethanol under these conditions (4° C) is consistent with the current hypothesis that a γ subunit may be necessary for the effects of low concentrations of ethanol at $GABA_A$ receptors. (Supported by NIAAA grant AA10112.)

EVALUATION OF THE DISCRIMINATIVE STIMULUS EFFECTS OF GABAERGIC DRUGS IN MUSCIMOL-TRAINED RATS. Hendree E. Jones and Robert L. Balster*. Department of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298-0310.

The discriminative stimulus effects of GABAergic drugs were evaluated in rats trained to discriminate the direct $GABA_A$ agonist, muscimol (1.0 mg/kg I.P.), from saline under a two-lever fixed ratio (FR) 32 schedule of food reinforcement. Another direct $GABA_A$ agonist, THIP, produced full substitution for muscimol. Diazepam, an allosteric modulator of GABA-mediated postsynaptic inhibition, yielded a maximum of 54% muscimol-lever responding at a dose which decreased rates of responding. Partial substitution for muscimol (maximal levels of 71% muscimol-lever responding) was also produced by the GABA agonist progabide. The GABA uptake inhibitor, tiagabine, produced no greater than 48% muscimol-lever responding. Valproic acid, a reversible GABA transaminase inhibitor, failed to substitute for muscimol and vigabatrin, an irreversible GABA transaminase inhibitor, yielded a maximal 46% muscimol-lever responding. These results demonstrate the pharmacological specificity of muscimol discrimination by showing that only direct agonists for the GABA site on the $GABA_A$ receptor complex produce full substitution. GABA agonists acting by other mechanisms can be distinguished from muscimol and THIP in this procedure. (Research supported by NIDA grants DA-01442 and DA-05665).

CHARACTERIZATION OF GLUTAMIC ACID DECARBOXYLASE PROTEIN FUNCTION AND mRNA CONTENT IN GENETIC MODELS OF SEVERE OR MILD WITHDRAWAL NEUROEXCITABILITY. K.J. Buck*, T. Lischka and D. Wu. Department of Medical Psychology, Oregon Health Sciences University, Portland, OR 97201-3098, USA.

Physical dependence and withdrawal from ethanol and other central depressants shows the influence of heritable factors, but none of the genes responsible has been identified. By association and interval mapping, we identified a quantitative trait locus (QTL) which accounts for more than 40% of the genetic variance in ethanol withdrawal neuroexcitability in C57BL/6J (B6) X DBA/2J (D2) recombinant inbred (BXD RI) strains. Analyses using a B6D2F2 intercross confirmed that a QTL affecting withdrawal severity is linked to the microsatellite marker *D2Mit9*, which localizes to the same region of chromosome 2 as *Gad-1* (37-43 cM). *Gad-1* encodes glutamic acid decarboxylase (GAD), which catalyzes the rate limiting step in the synthesis of the major known inhibitory neurotransmitter γ-aminobutyric acid (GABA). Numerous studies have implicated the synaptic actions of GABA in neuroadaptation to ethanol associated with physical dependence and withdrawal.

DBA/2J mice are a well characterized genetic animal model expressing severe ethanol dependence and withdrawal neuroexcitability, whereas B6 have mild withdrawal reactions. We found that D2 mice demonstrate lower GAD enzyme activity as compared to B6 mice. Northern blot analyses using RNA isolated from ethanol-naive and ethanol-dependent B6 and D2 mice show that GAD mRNA content (3.7 kb and 5.7 kb isoforms, encoded by *Gad-1* and *Gad-2*, respectively) is regulated by chronic ethanol treatment. These results indicate that genetic differences in ethanol withdrawal neuroexcitability may be mediated, in part, by differences in GAD expression and function. ETHANOL INCREASES $GABA_A$ RECEPTOR-MEDIATED CURRENTS IN CEREBELLAR PURKINJE NEURONS IN RAT BRAIN SLICES. W.R. Proctor* and T.V. Dunwiddie, Dept. Pharmacol., Univ. Colo. Hlth. Sci. Ctr. and Vet. Adm. Med. Ctr., Denver, CO

This study was designed to determine if GABAergic responses evoked in cerebellar Purkinje cells are modulated by ethanol, and to further examine the cellular mechanisms that might be involved. Brain slices were prepared from the cerebellar vermis, maintained under *in vitro* conditions, and Purkinje neurons were readily visualized using DIC optics. The slices were stored and recorded at room temperature, drugs were added to the superfusing aCSF, and patch electrodes containing K^+ or Cs^+- gluconate were used while recording in current-clamp or voltage-clamp modes. Stimulation of the parallel fibers in the molecular layer produced either epsp, ipsp or epsp/ipsp responses. The ipsps were rapidly and reversibly blocked by 10 μM bicuculline and were usually enhanced (10-30%) by superfusion of 80 mM ethanol. Epsps and membrane resistance did not appear to be significantly altered, whereas the spontaneous firing rate was typically depressed by ethanol. In addition, the local pressure application of GABA (10 μM) to the proximal dendritic region resulted in outward current responses that were greatly depressed by bicuculline but were not significantly affected by ethanol, whether short (5-10 msec) or long (1 sec) pressure applications were used. Pretreatment of the slice with the ß-adrenergic agonist, isoproterenol (500 nM), did not seem to enhance the effects of ethanol. The finding that ethanol enhances bicuculline-sensitive ipsp responses in Purkinje neurons under these *in vitro* conditions, suggests that $GABA_A$ receptor-mediated events are involved in ethanol action in the cerebellum.

CHRONIC ETHANOL EXPOSURE AND WITHDRAWAL SELECTIVELY INCREASE DIAZEPAM-INSENSITIVE [^{3}H]RO 15-4513 BINDING IN MOUSE CEREBELLUM. H.C. Becker* and M.F. Jarvis, Med. Univ. of South Carolina and VAMC, Charleston, SC 29425 and Rhône-Poulenc Rorer Central Research, Collegeville, PA.

The partial benzodiazepine inverse agonist, RO 15-4513 has been shown to block some behavioral and biochemical effects of ethanol (EtOH). [^{3}H]RO 15-4513 labels two classes of recognition sites in the mammalian cerebellum, a diazepam-sensitive (DZ-S) site and a diazepam-insensitive (DZ-IS) site that may represent a novel subtype of the GABAa receptor. The present studies were conducted to examine the effects of chronic EtOH exposure on both total and DZ-IS [^{3}H]RO 15-4513 binding in cerebellum from C3H mice. Mice received either 64 hr EtOH intoxication via inhalation chambers (BEC = 165-185 mg/dl) or no EtOH exposure. Mice were sacrificed at the end of the EtOH exposure (HR 0) or 8 hours post-withdrawal (HR 8). Ligand saturation studies (0.3-50 nM) were conducted on pooled cerebellar tissue from 3-4 mice. In control mice, the binding parameters for [^{3}H]RO 15-4513 were Kd = 3.9 ± 1.1 nM, Bmax = 3220 ± 300 fmol/mg protein. The binding parameters for [^{3}H]RO 15-4513 in the presence of 10 μM DZ (DZ-IS) were Kd = 3.0 ± 0.4 nM, Bmax = 953 ± 108 fmol/mg protein. Neither EtOH intoxication (HR 0) nor EtOH withdrawal (HR 8) significantly altered total [^{3}H]RO 15-4513 binding in the mouse cerebellum. However, DZ-IS [^{3}H]RO 15-4513 binding density was significantly increased (60%) by EtOH intoxication and by (75%) EtOH withdrawal. These results suggest that chronic EtOH exposure and withdrawal selectively increases DZ-IS [^{3}H]RO 15-4513 binding sites in mouse cerebellum. These data agree with other studies indicating an increase in mRNA and protein levels for the α6 subunit, which encodes DZ-IS RO 15-4513 binding at GABAa receptors in cerebellum.

CHRONIC ETHANOL TREATMENT DECREASES CENTRAL-TYPE BENZODIAZEPINE RECEPTORS IN RAT BRAIN. X. Ren, S.C.Pandey, M.R.Piano, J.M.Davis*, G.N.Pandey. Department of Psychiatry, University of Illinois at Chicago, IL 60612.

The benzodiazepine receptor is an allosteric modulatory site present on most gamma-aminobutyric acid (GABA) receptor channels. Several lines of evidence suggest that some of the central effects of alcohol may be mediated by the GABA-benzodiazepine-chloride channel receptor complex. The results of benzodiazepine receptor studies in the brain after chronic ethanol exposure appear to be inconsistent. To further examine the role of central benzodiazepine receptors in alcohol dependence, we studied the effect of 60 days of ethanol treatment on central benzodiazepine receptors in the rat cortex. Male Sprague Dewley rats were fed the Lieber-Decarli liquid diet containing ethanol (9% v/v) or control liquid diet for 60 days. Rats were sacrificed and cortices were separated out for measurement of binding indices of central benzodizepine receptors by binding techniques using [^{3}H]-R015-1788 as ligand. We observed that maximum binding sites (B_{max}) of [^{3}H]-R015-1788 binding (763 ± 75 fmol/mg protein) were significantly lower (26%) in the cortex of ethanol-fed rats compared to B_{max} (1026 ± 104 fmol/mg protein) in the cortex of pair-fed control rats. There were no significant changes in Kd values among the groups. These results suggest that decreased central benzodiazepine receptors may be involved in the process of alcohol dependence.

825.7

THE IMIDAZOBENZODIAZEPINE INVERSE AGONIST RO19-4603 (RO19) ATTENUATES ETHANOL (EtOH) ORAL SELF-ADMINISTRATION (OSA) IN SPRAGUE-DAWLEY RATS. G. G. Blakley*, M. E. Paterson, H. L. June, and M. J. Lewis
Neurobehavioral Laboratory, Dept. of Psychology, Temple University, Philadelphia, PA 19122 and IUPUI, Indianapolis, IN 46202

Benzodiazapine (BDZ) inverse-agonists have been reported to antagonize several of EtOH's actions including its reinforcing properties. RO19 is a potent imidazobenzodiazepine inverse agonist. Although having a half-life of 15-60 min, a single dose of RO19 has been reported to suppress EtOH OSA in alcohol preferring (P) and non-preferring (NP) rats for as long as 32 hrs. The present experiment examined the effect of RO19 upon OSA of EtOH in a limited access paradigm in randomly bred, free-feeding Sprague-Dawley rats. Animals were given daily, 1 hr concurrent access to H_2O and gradually increasing EtOH concentrations (1%-10%) (v/v). After stable preference of a 10% solution was established, animals were pretreated with i.p. injections of 0.00g/kg, 0.025g/kg, 0.075g/kg, and 0.150g/kg of RO19. RO19 showed a dose-dependent attenuation of EtOH consumption over several hours. These data are consistent with previous research on RO19 in selected rats and suggest that brief occupation of $GABA_A$/BDZ receptor sites by such compounds may alter EtOH reinforcement. (Supported in part by AA06263 and RR08016 and Temple University.)

825.8

ETHANOL SUBSTITUTES FULLY FOR A DIAZEPAM-KETAMINE MIXTURE.

J. Jenkins, Y. Egilmez, B. Rocha and M. Emmett-Oglesby*. Dept Pharmacology, University of North Texas Health Science Center, Fort Worth, TX 76107

When ethanol (EtOH) is trained as a discriminative stimulus, drugs that enhance GABAergic neurotransmission (e.g., diazepam, DZP), and drugs that uncompetitively antagonize glutamate neurotransmission at NMDA receptors (e.g., ketamine, KET), substitute for EtOH. However, when drugs from either of these classes are trained as discriminative stimuli, EtOH fails to substitute fully for either type of drug. The present study tested the hypothesis that in rats trained to discriminate a mixture of DZP (5.6 mg/kg) and KET (10 mg/kg) from saline, EtOH would substitute fully for this training mixture. The mixture was trained using a two-lever choice procedure in which food served as a reinforcer under a fixed-ratio 10 schedule. After the discrimination was acquired, dose-effect testing showed full substitution with: the mixture, DZP alone, KET alone, pentobarbital, chlordiazepoxide, dizocilpine and EtOH. These data support the hypothesis that simultaneous activation of GABAergic neurotransmission and blockade of glutamate neurotransmission are critical in producing an EtOH life stimulus. Supported by R01 AA9378.

825.9

SELECTIVE DRUG ANTAGONISM BY LOW LEVEL HYPERBARIC EXPOSURE SUGGESTS A NEW HYPOTHESIS FOR ETHANOL'S INITIAL SITES OF ACTION: ALLOSTERIC MODULATORY PATHWAYS IN LIGAND GATED ION CHANNELS. R.L. Alkana*, D.L. Davies, M.B. Bolger and R.D. Brinton. Alcohol and Brain Research Lab., Department of Molecular Pharmacology and Toxicology, School of Pharmacy, University of Southern California, Los Angeles, CA 90033.

Exposure to low level hyperbaric (≤ 12 times normal atmospheric pressure–ATA) helium-oxygen gas (heliox) antagonizes a broad spectrum of ethanol's acute and chronic behavioral effects. Considerable evidence indicates that the antagonistic mechanism is direct and meets predictions based on a competitive pharmacological model. Our recent *in vivo and in vitro* work found that pressure antagonism is selective: exposure to 12 ATA antagonized the effects of drugs which act through allosteric modulation of $GABA_A$ receptors (ethanol, n-propanol), but did not antagonize the effects of drugs that act via high affinity binding as direct agonists or channel blockers (e.g., GABA, picrotoxin and morphine). This work also demonstrated that pressure antagonized allosteric modulatory drugs (diazepam and pentobarbital) that initiate their allosteric effects by high affinity binding. This selective pattern of pressure antagonism, taken in context with: 1) the similar behavioral and pharmacological profiles for ethanol, diazepam and pentobarbital and 2) the mechanistic link for these drugs to allosterically mediated potentiation of $GABA_A$ receptor function, suggests structural or functional elements that represent likely targets for ethanol's initial actions. These sites are the allosteric modulatory pathways which transduce binding events on ligand gated ion channels. The characteristics that make an allosteric pathway sensitive to ethanol may be unique to specific binding sites within a ligand gated ion channel (e.g., $GABA_A$) or may extend to other ligand gated ion channels sensitive to ethanol (e.g., NMDA and/or $5HT_3$). Our current research is directed toward testing this hypothesis (Supported by NIH, NIAAA research grants AA03972 and AA05234).

825.10

THE EFFECTS OF LOW LEVEL HYPERBARIC EXPOSURE ON 4,5,6,7-TETRAHYDROISOXAZOLO-PYRIDIN-3-OL (THIP)-, PENTOBARBITAL- AND ETHANOL-INDUCED LOSS OF RIGHTING REFLEX DURATION IN MICE. D.L. Davies*, A. Manolescu, N.M. Pecolatto, J.A. McCuin and R.L. Alkana. Alcohol and Brain Research Lab., Department of Molecular Pharmacology and Toxicology, School of Pharmacy, University of Southern California, Los Angeles, CA 90033.

Exposure to 12 atmospheres absolute (ATA) helium oxygen gas (heliox) antagonizes behavioral effects of ethanol, n-propanol and diazepam, but not morphine, isoniazid, picrotoxin and *dl*-allylglycine. Recent biochemical studies found that exposure to 12 ATA heliox antagonized ethanol-potentiation of GABA-activated ^{36}Cl uptake in mouse cerebrocortical membrane vesicles (microsacs) without altering GABA-activation *per se*. The pattern of the antagonism indicates that exposure to 12 ATA heliox acts in a selective manner on drugs that act through allosteric modulation. The present study further investigates the selectiveity of low level hyperbaric exposure. C57BL/6J mice were injected ip. with 55 mg/kg THIP (GABA agonist), 60 mg/kg pentobarbital ($GABA_A$ receptor allosteric modulator) or 3.6 g/kg ethanol. When LORR occurred, the mice were placed in cylindrical, stainless steel 18 liter hyperbaric chambers and exposed to either 12 ATA heliox or to control atmospheric conditions of 1 ATA air and/or 1 ATA heliox at ambient temperatures selected to offset drug- and helium-induced hypothermia. Exposure to 12 ATA heliox significantly reduced LORR duration induced by pentobarbital and ethanol but did not significantly reduce LORR duration induced by THIP. These results add to the evidence that low level hyperbaric exposure selectively antagonizes the effects of drugs which act through allosteric modulation of $GABA_A$ receptors (e.g., ethanol, diazepam and pentobarbital) but does not antagonize the effects of drugs that act via high affinity binding as direct agonists or channel blockers (e.g., GABA, picrotoxin and morphine) and suggest that allosteric modulating pathways which transduce binding events on $GABA_A$ and other ligand-gated ion channels may represent initial sites of action for ethanol. QUANTITATIVE AUTORADIOGRAPHIC ANALYSIS OF $[^3H]MK801$ BINDING TO NMDA RECEPTORS IN BRAINS OF RODENTS DIFFERENTIALLY SENSITIVE TO ETHANOL. M.J. Velardo* and N.R. Zahniser. Neuroscience Program and Dept. of Pharmacol., Univ. Colo. Health Sci Ctr., Denver, CO 80262.

Initial sensitivity to ethanol has been linked to its action at several classes of brain ligand-gated ion channels. At low concentrations, ethanol inhibits the actions of glutamate at N-methyl-d-aspartate (NMDA) receptors. Therefore, the analepsis observed in response to ethanol may be mediated, at least in part, by NMDA receptors. Long sleep (LS) and short sleep (SS) mice and high alcohol sensitivity (HAS) and low alcohol sensitivity (LAS) rats have been selectively bred to exhibit differential initial sensitivity to the hypnotic effects of ethanol. Using these rodent lines, specific binding of a K_d concentration of $[^3H]MK801$ (10 nM) was determined using quantitative autoradiography. Assays contained saturating concentrations of glutamate, glycine, and spermine in the presence of EDTA. In the mice, specific $[^3H]MK801$ binding in hippocampus was twice that in cerebral cortex, whereas in the rats, binding in the two brain regions was equivalent. Surprisingly, the ethanol-insensitive SS mice showed higher binding (10-20%) in both hippocampus and cortex. No differences were observed between the HAS and LAS rats in either brain region. Our results suggest that differences in NMDA receptors exist in specific regions of LS and SS mouse brain. However, the HAS/LAS rat results weaken the association between the observed differences in $[^3H]MK801$ binding sites and initial ethanol sensitivity. (Supported by AA 03527)

WITHDRAWAL FROM CHRONIC ETHANOL EXPOSURE INCREASES SENSITIVITY TO N-METHYL-D-ASPARTATE (NMDA) IN RAT NUCLEUS ACCUMBENS NEURONS.
Z. Nie, S.G. Madamba, and G. R. Siggins*. Dept. of Neuropharmacology and Alcohol Research Center, The Scripps Research Institute, La Jolla, CA 92037.

Behavioral studies suggest that the nucleus accumbens (NAcc) is a brain area involved in the rewarding effects of ethanol (EtOH). We recently reported that low EtOH concentrations decreased NMDA-induced currents in NAcc core neurons *in vitro* (Nie et al., JPET 271:1566, 1994). Several lines of evidence suggest that chronic EtOH treatment alters NMDA function. To determine whether such treatment alters NMDA receptor sensitivity in NAcc neurons, we used voltage-clamp recording in a rat brain slice preparation to compare the NMDA receptor sensitivity of NAcc core neurons taken either from rats maintained in ethanol vapor chambers for 3-4 weeks and then withdrawn for 8-12 hours (EtOH treated; mean BALs: 71-138 mg%), or from rats held for the same period in chambers without ethanol vapor (controls). We rapidly superfused NMDA for 3 min, in the presence of 10 μM CNQX, 1 μM tetrodotoxin and 30 μM bicuculline to prevent indirect or non-NMDA responses. We studied 14 cells (mean RMP: -87; mean spike size: 118 mV). There was no apparent difference in spike size or RMP between neurons of control and EtOH treated rats. At holding potentials around -65 mV, 1 μM NMDA superfusion elicited inward currents in only 1 of 6 NAcc neurons from control slices. However, in slices from EtOH treated rats, 1 μM NMDA evoked clear, reversible inward currents (mean: -41 pA) in all 8 neurons studied, and 0.5 μM NMDA evoked -50 pA inward currents in 1 neuron. These data provide new electrophysiological evidence that withdrawal from chronic EtOH exposure in NAcc core neurons increases the responsivity of NMDA receptors, an effect that could underlie the increased behavioral excitability seen in ethanol-withdrawn animals.

THE ANTI-CRAVING AGENT ACAMPROSATE ENHANCES NMDA-MEDIATED EPSPs IN RAT NUCLEUS ACCUMBENS NEURONS.
[1]F. Berton, [1]W. Francesconi, S.G. Madamba*, [2]W. Zieglgänsberger, and G.R. Siggins, Dept. of Neuropharmacology and Alcohol Research Center, Research Institute of Scripps Clinic, La Jolla, CA 92037, [1]University of Pisa, Italy, and [2]Clinical Inst., Max-Planck-Institute of Psychiatry, D-80804 Munich, Germany.

Acamprosate (calcium acetylhomotaurinate; LIPHA) is a new drug shown in European clinics to prevent relapse in weaned alcoholics. However, the mechanisms underlying this action are unclear. Therefore, we studied the effects of acamprosate in a slice preparation of the nucleus accumbens (NAcc), a brain region thought to play a role in drug reinforcement. Recent studies in our laboratory (Nie et al., JPET, 271: 1566, 1994) demonstrated that ethanol (EtOH) inhibits glutamatergic NMDA- and non-NMDA-mediated synaptic transmission in the NAcc. We used current- and voltage-clamp recordings of NAcc core neurons and isolated locally-evoked NMDA- and non-NMDA glutamatergic EPSP components with 20 μM CNQX and 30-60 μM APV, respectively. Bicuculline 30 μM was also present to block $GABA_A$ receptors. We recorded from 20 neurons with a mean resting membrane potential (RMP) of -80 mV, mean spike size of 110 mV, and mean input resistance of 40 MΩ. Superfusion of 300 μM acamprosate did not alter RMPs or the input resistance of these neurons. However, acamprosate significantly increased NMDA-EPSPs and -EPSCs in 70% of neurons tested ($n = 10$; $F(1,31) = 7.646$; $p = 0.0096$; 3 neurons showed no effect). In contrast, acamprosate (300 μM) slightly reduced or had no effect on the evoked non-NMDA EPSPs in 7 cells. Washout of acamprosate returned both NMDA and non-NMDA EPSPs to control values. These results are compatible with previous findings in hippocampus (Madamba et al., in submission) and in cortex (Zeise et al., Eur. J. Pharmacol. 231: 47, 1993) suggesting that the clinical efficacy of acamprosate may result from modulation of glutamatergic neurotransmission. *Supported by grants from NIH (AA06420) and Groupe LIPHA (Lyon, France).*

THE EFFECTS OF PHENCYCLIDINE ON A MULTIPLE SCHEDULE OF ETHANOL AND SACCHARIN SELF-ADMINISTRATION. K.L. Shelton* and R.L. Balster Dept. of Pharmacology/Toxicology, Medical College of Virginia, Richmond, VA 23298-0310

Antagonism of the NMDA subtype of glutamate receptors has been implicated in the discriminative stimulus and reinforcing properties of ethanol. Recent studies have shown that systemic injections of a nonselective glutamate antagonist and intraaccumbens injections of competitive NMDA antagonists will decrease ethanol self-administration. We have developed a multiple schedule of ethanol and saccharin self-administration in which selective drug effects on ethanol-reinforced responding can be demonstrated. Adult male Long-Evans rats were trained using a post-parandial drinking procedure to lever press during daily 60-min sessions for 0.05 ml of 10% ethanol (w/v) and 0.1% saccharin solutions under an alternating fixed-ratio 4 multiple schedule. The present study was designed to examine the ability of repeated administration of the noncompetitive NMDA antagonist, phencyclidine (PCP), to selectively attenuate ethanol self-administration. Ascending doses of 1, 2 and 4 mg/kg of PCP were given i.p. 15 min prior to the self-administration session for six consecutive days. Six-day blocks with pre-session saline injections intervened between testing each PCP dose. Doses of 1 and 2 mg/kg of PCP failed to significantly alter the number of either PCP or saccharin deliveries. The 4 mg/kg dose of PCP significantly decreased both ethanol and saccharin self-administration. Levels of saccharin responding quickly returned to control levels during the saline control sessions following the 4 mg/kg dose of PCP, however ethanol responding remained depressed for at least 10 sessions. These results indicate that systemic administration of PCP does not selectively attenuate ethanol self-administration, but a high dose may have selective effects on relapse. We are currently testing the competitive NMDA antagonist CPPene in the same multiple schedule to determine if it has effects similar to that of PCP. DISCRIMINATIVE STIMULUS EFFECTS OF THE NOVEL NEUROSTEROID, CO 8-7071, IN PENTOBARBITAL-TRAINED RHESUS MONKEYS. J. K. Rowlett* and W. L. Woolverton. Department of Psychiatry and Human Behavior, University of Mississippi Medical Center, Jackson, MS 39216.

Co 8-7071 (3α,21-dihydroxy-3β-triflouromethyl-5β-pregnan-20-one, 21-hemisuccinate) is a water-soluble, orally-bioavailable neurosteroid pro-drug. The purpose of this study was to assess the discriminative stimulus (DS) effects of Co 8-7071 in rhesus monkeys (N=2) trained to discriminate pentobarbital (PB, 10 mg/kg, i.g., 60 min pre-session) from saline. Lever pressing was maintained under a discrete-trials shock avoidance schedule of reinforcement (30 trials/day, 30-sec ITI, FR 5). During test sessions, in which responding on either lever was reinforced, the monkeys were given PB (3.0-17 mg/kg, i.g., 60 min pre-session) or Co 8-7071 (3.0-30 mg/kg, i.g., either 60 or 120 min pre-session). Administration of PB resulted in a dose-related increase (0-100%) in the percentage of responses emitted on the drug-appropriate lever with a dose-related decrease in response rate (resp/sec). Co 8-7071 produced drug-appropriate responding in both monkeys, depending on pre-session time. At 60 min pre-session, Co 8-7071 (3.0-17 mg/kg) produced a dose-related increase (0-100%) in drug-appropriate responding in one monkey, but not in the second monkey. At 120 min pre-session, Co 8-7071 (3.0-30 mg/kg) produced a dose-related increase (0-100%) in drug-appropriate responding in the one monkey tested to date. No systematic effects on response rate were seen after Co 8-7071 treatment. These results suggest that Co 8-7071 may share some DS effects with PB in rhesus monkeys. (Supported by NIDA grant DA-09139).

BEHAVIORAL PHARMACOLOGY OF NEGATIVELY-PUNISHED RESPONDING IN THE RAT. J.M. Rhoads, T.A. Tatham* . Dept. of Psychiatry, Uniformed Services University of the Health Sciences, Bethesda, MD, 20814.

Behavior may be suppressed by both postive and negative punishment. Positive punishment consists of *presentation* of response-contingent *aversive* events such as shock. In contrast, negative punishment suppresses behavior by response-contingent *removal* of access to *positive reinforcement* (timeout). The effects of CNS drugs on positively-punished behavior have been extensively characterized, while the behavioral pharmacology of negative punishment is virtually unknown. This study examines the effects of drugs on negatively-punished responding with emphasis on indentifying similarities and differences in the effects of drugs on responding punished by negative versus positive punishment.

Initially the lever-pressing of 4 rats was maintained by a fixed-interval (FI) schedule in which the 1st response after 1 min produced a food pellet. Negative punishment was subsequently introduced so that every 5th response produced a timeout during which the response lever was retracted and inoperable, and the 1-min fixed-interval timer was paused. After 1 min the lever was re-extended into the chamber, and timing resumed. Introduction of punishment decreased the reponse rate from .623 responses/sec to .168 responses/sec. Once responding stabilized, drugs were administered before some sessions. The following drugs increased punished responding: the psychomotor stimulant *d*-amphetamine > the sigma and PCP recptor agonist MK-801 (dizolcipine) > the benzodiazepine chlordiazepoxide. The opiate morphine, the barbituate pentobarbital, and the 5-HT1A receptor agonist 8-OH-DPAT failed to reliably increase rates. Results resemble those typically obtained with positive punishment in that responding in both procedures is increased by chlordiazepoxide and MK-801, and 8-OH-DPAT and morphine fail to increase rates. However, effects differ in that pentobarbital increases only positively-punished responding, and *d*-amphetamine increases only negatively punished responding. The results suggest distinct pharmacological profiles for the two forms of punishment despite similarity in their behavioral effects.

EFFECTS OF CHLORDIAZEPOXIDE AND BUSPIRONE ON BEHAVIOR SUPPRESSED BY PRESENTATION OF TIMEOUT FROM FOOD. F.van Haaren* and K.G. Anderson, Dept. of Psychology, Univ. of Florida, Gainesville, FL 32611-2250.

Six rats were exposed to a two-component multiple schedule. In one component (A), lever presses were followed by pellet presentation on a RI 30-s schedule, in the other component (B), pellet presentation occured on the same schedule, but lever presses also resulted in timeout presentation (10 sec) on a RI 2-s schedule (conjoint RI 30-s food, RI 2-s timeout). The two components were presented in an A-B-A-B-A sequence. Once responding had stabilized subjects were injected with different doses of chlordiazepoxide (CDP, 1, 3, 10, 17 and 30 mg/kg, IP, -15 min), or different doses of buspirone (BUSP, 0.1, 0.3, 1.0, 1.7, 3.0 or 4.2 mg/kg, IP, -15 min). Response rates during the conjoint component of the schedule were considerably lower than those in the other component. Low doses of CDP and BUSP produced a small increase in RI responding. Suppressed responding was greatly increased by low doses of CDP, but hardly affected, or decreased by low doses of BUSP. Higher doses of CDP (= > 10 mg/kg) and BUSP (= > 1.0 mg/kg) suppressed responding in both components of the multiple schedule.

DRUGS OF ABUSE: AMPHETAMINES AND OTHER STIMULANTS V

EFFECTS OF SYSTEMIC AND INTRACRANIAL CAFFEINE ON DOPAMINE OVERFLOW IN ANESTHETIZED AND FREELY-MOVING RATS: *IN VIVO* MICRODIALYSIS STUDIES.
Enrico Museo* and Agu Pert. Biological Psychiatry Branch, National Institute of Mental Health, Bethesda, MD 20892.

The neurochemical basis of caffeine's psychomotor stimulant actions is not completely understood. The possibility has been raised that as with other psychomotor stimulants (eg. nicotine, amphetamine, and cocaine), the effects of caffeine are in part due to the activation of dopaminergic substrates. We studied the effects of caffeine on extracellular levels of dopamine (DA) in the nucleus accumbens of either anesthetized or freely-moving rats. Dialysate samples were collected at 20-min intervals and DA levels were quantified using HPLC with electrochemical detection. Caffeine was administered systemically (0, 20 or 40 mg/kg, i.p.) or directly into the nAcb (0, 10, 100, 1000 μM). In anesthetized rats, systemic administrations of 40 mg/kg, but not 20 mg/kg, of caffeine increased DA overflow in the n. accumbens. In unanesthetized rats, however, both doses increased locomotor output while having no effect on n. accumbens DA. When administered directly into the n. accumbens caffeine (1000μM) facilitated DA overflow in unanesthetized as well as anesthetized rats. In the former case, caffeine also had a locomotor stimulant effect. Even though caffeine can facilitate DA overflow in the n. accumbens under certain conditions (at high concentrations or under anesthesia) the relevance of such effects to its behavioral actions is not apparent. Because systemic injections of caffeine (20 & 40 mg/kg)had behavioral effects without altering DA overflow, it seems that caffeines behavioral effects are not dependent on the facilitation of DA overflow in the n. accumbens.

826.2

NMDA-TYPE GLUTAMATE RECEPTOR INVOLVEMENT IN CAFFEINE'S LOCOMOTOR STIMULANT EFFECTS AND TOLERANCE TO THESE EFFECTS. K.R.Powell* and S.G.Holtzman Dept. of Pharmacology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

The involvement of NMDA-type glutamate receptors in caffeine's locomotor stimulant effects and the development of tolerance to these effects was examined in rats. Rats were administered caffeine and dizocilpine (MK-801), a competitive NMDA receptor antagonist, alone and in combination. Both caffeine and dizocilpine increased dose-dependently locomotor activity in rats. When combined with caffeine, the highest dose of dizocilpine, that alone did not increase locomotor activity (0.1 mg/kg), enhanced the locomotor stimulant effects of caffeine. Lower doses of dizocilpine (0.01-0.03 mg/kg) did not alter the effects of caffeine. During the tolerance phase of the study, rats were exposed to caffeine using scheduled access to a caffeinated drinking solution (1.0 mg/ml) and were implanted with osmotic minipumps (Alzet Corp.) containing either dizocilpine (0.1 mg/kg/day infusion) or saline for a period of 7 days. The effects of caffeine on locomotor activity were examined before, during and following chronic exposure to caffeine to measure the development of tolerance to these effects. Dizocilpine did not alter the development of tolerance to caffeine's effects. These data indicate a supraadditive interaction between the acute effects of caffeine and dizocilpine and suggest that NMDA-type glutamate receptors may be involved in the mechanisms underlying locomotor stimulant effects of caffeine. On the other hand, these data suggest that NMDA-type glutamate receptors are not involved in the development of tolerance to caffeine's locomotor stimulant effects in rats. (Supported by DA 03413)

826.3

VENTRAL PALLIDAL 6-OHDA LESIONS IMPAIR AMPHETAMINE SELF ADMINISTRATION AND LOCOMOTOR ACTIVITY. N.J. DeSousa, J.N. Nobrega[1], and P.J. Fletcher[1]*. Dept. of Psych., Univ. of Toronto, Toronto, Canada, *M5S 1A1*; and [1]Clarke Inst. Psychiatry, Toronto, Canada, *M5T 1R8*.

Recent studies have suggested a role for the ventral pallidum (VP) in drug self administration and locomotor activity. However, the possible contribution to these behaviours of ascending mesopallidal dopamine (DA) neurons has not yet been evaluated. The present experiments sought to examine the role of VP DA in amphetamine (AMP) self administration (SA) and locomotion in rats.

Rats were trained to intravenously self administer AMP (50 µg/kg/infusion) on an FR1 schedule (1hr/day) until response rates had stabilized. Rats were then treated bilaterally with either intra-VP 6-OHDA (2.4 µg/0.3 µl) or ascorbic acid vehicle. Immunohistochemical results from pilot studies have indicated reliable VP DA depletions without affecting DA content in the ventral tegmental area, frontal cortex, or nucleus accumbens. In expt. 1, following a 1 week recovery period, animals were again given access to AMP (50 µg/kg/infusion) and allowed daily 1 hr SA sessions for 10 days. In expt. 2, an AMP (100, 50, 25, 12.5, 6.125, and 0 µg/kg/infusion) dose response analysis was conducted over the subsequent 6 days. Finally, rats were tested for the expression of AMP-induced (1.0 mg/kg ip) locomotor activity in photobeam-based activity monitors in expt. 3.

Results from expt.1 showed that rats treated with 6-OHDA administered significantly fewer amphetamine infusions than control animals over the last 5 days of testing. Further, results from expt. 2 revealed that 6-OHDA treated rats displayed a dampened inverted-U dose response curve, administering significantly fewer infusions across middle range doses. In expt. 3, results indicated that animals treated with 6-OHDA were significantly less responsive to the locomotor activating effects of AMP. These results suggest the involvement of VP DA in the rewarding and locomotor activating effects of psychostimulant drugs.

826.4

CONDITIONED INCREASES IN MOTOR ACTIVITY AND DOPAMINE CONCENTRATIONS IN THE NUCLEUS ACCUMBENS OF THE RAT FOLLOWING REPEATED ADMINISTRATION OF COCAINE OR *d*-AMPHETAMINE. P. Di Ciano, C.D. Blaha and A.G. Phillips* Department of Psychology, University of British Columbia, Vancouver, B.C., Canada V6T 1Z4

One of the terminal regions of the mesotelencephalic dopamine (DA) pathway, the nucleus accumbens (N.Acc.), has been implicated in the primary and secondary reinforcing properties of drugs of abuse. This study demonstrates that repeated pairings of either cocaine or *d*-amphetamine (amph) with a compound environmental stimulus (odour, light) produced conditioned increases in both locomotor activity and extracellular DA concentrations in the N.Acc., when rats were exposed to the compound CS in the absence of the drug. *In vivo* chronoamperometry was used to monitor extracellular levels of DA in the N.Acc. Motor activity was recorded as the number of photocell beam crossings in the test chambers. Compared to controls, both cocaine and amph significantly increased motor activity (mean maximum: 880 and 470 photocell counts, respectively) in the first 10 min after drug administration. Significant increases were also seen in associated DA oxidation currents that plateaued at 2nA and 3.75nA after cocaine and amph administration, respectively. When compared to controls, rats that had previously received either cocaine or amph paired with the CS showed significant increases in motor activity, upon presentation of the compound CS, that were of comparable magnitude (~200/ 10min), for animals treated with either drug. Associated changes in extracellular DA concentrations in the N.Acc. were significantly elevated ~20 min after presentation of the CS, to levels between 2-3nA and 3-4nA for the cocaine and amph-treated rats, respectively. The present experiments provide support for the hypothesis that DA in the N.Acc. is involved in the conditioned incentive effects of drugs of abuse.

826.5

DOSE-DEPENDENT EFFECT OF METHAMPHETAMINE ON NEUROTENSIN RELEASE IN STRIATUM AND NUCLEUS ACCUMBENS. J.D. Wagstaff*, J.W. Gibb and G.R. Hanson. Dept.of Pharmacology & Toxicology, University of Utah, Salt Lake City, UT 84112

Central neurotensin (NT) systems are thought to play an important role in the modulation of dopaminergic pathways. Stimulants of abuse such as methamphetamine (METH) dramatically alter tissue levels and synthesis of this neuropeptide. However, the regulation of NT release has been difficult to study *in vivo* as extracellular levels of NT are extremely low. We previously measured extracellular NT by microdialysis in awake animals, and demonstrated regulation by D-2 receptors. The present study examines the effect of METH on NT release from striatum and nucleus accumbens, and characterizes the role of dopamine D-1 and D-2 receptors in mediating METH-induced alterations. METH altered extracellular NT in a dose-dependent manner. At a low dose (0.5 mg/kg), METH increased NT release from both regions to approximately 200% of control. An intermediate dose (5.0 mg/kg) increased extracellular NT to 150% in the striatum and 140% in the accumbens. At 15 mg/kg, METH had no affect on NT release. The role of DA receptor subtypes was assessed in the striatum by combining selective D-1 (SCH-23390) and D-2 (eticlopride) antagonists with the low and high doses of METH. Eticlopride (0.5 mg/kg) alone decreased NT release ≈20-30% and completely blocked the effect of low dose METH. SCH-23390 (0.5 mg/kg) alone had no effect on basal NT release, but the combination of D-1 blockade with 15 mg/kg METH increased NT release to ≈150% of control. These data indicate that the effect of low dose METH on NT release is mediated through stimulation of D-2 receptors, while the lack of effect of high dose METH is due to D-1 activation. (Supported by USPHS grants DA 34471 and DA 00869)

826.6

INCREASED DOPAMINE D1 RECEPTOR SITES OF THE SUBSTANTIA NIGRA RETICULATA SUBSEQUENT TO INTERMITTENT PRETREATMENT WITH METHAMPHETAMINE. Y.Zhang and J.A.Angulo*, Department of Biological Sciences, Hunter College, NY.

We have assessed the effect of intermittent methamphetamine (METH) pretreatment on haloperidol-induced effects on neostriatal neuropeptide mRNA abundance and dopamine receptor levels. Rats received a total of five METH injections (1.5 mg/kg), one injection every third day. Fifteen days after the last METH injection, rats received daily injections of haloperidol for seven consecutive days. Treatment with METH did not afftect neostriatal ^{3}H-spiperone (dopamine D2) binding sites, but METH pretreatment significantly potentiated haloperidol-induced increases of D2 receptor sites in ventrolateral caudate-putamen (vlCPu) and nucleus accumbens (NAc). In contrast, METH treatment decreased ^{3}H-SCH 23390 (D1 receptor) binding sites in the NAc. Haloperidol treatment of METH-pretreated rats significantly decreased D1 sites in vlCPu, anterior CPu (aCPu) and NAc. In the midbrain ventral substantia nigra reticulata (vSNr), METH pretreatment increased D1 receptor sites (202% above control). In addition, haloperidol treatment of saline-pretreated rats increased D1 receptor sites of the vSNr 58% relative to controls. METH pretreatment enhanced haloperidol-induced changes in neostriatal preproenkephalin (PPE) or preprotachykinin mRNA abundance. The present results show that pretreatment with METH increases dopamine D1 receptor sites in the midbrain substantia nigra pars reticulata and potentiates haloperidol-induced alterations of dopamine receptors and neuropeptide mRNA abundance in the caudate-putamen and nucleus accumbens of the rat brain.

826.7

METHAMPHETAMINE (M)-STIMULATED STRIATAL DOPAMINE (DA) RELEASE AS MEASURED BY MICRODIALYSIS DECLINES RAPIDLY OVER TIME AFTER PROBE INSERTION. B. Gough*, J. Bowyer and R. Holson. National Center for Toxicological Research, Jefferson, AR 72079.

Three experiments were conducted to investigate the striatal response to repeated M exposure in male rats. In all three experiments, M exposure occurred for one group three times at two-hr intervals, with the first exposure occurring 2 hr after probe insertion. Independent of route of administration (1 mg/kg M ip, or 20 µM of M for 10 min via the microdialysis probe), the DA peak elicited by the third M exposure was only 50 % as large as that elicited by the first exposure, 4 hrs earlier. This reduction in the response to M was a function of time post probe-insertion, and not of prior M exposure. When probes were inserted at 0700 hrs but the first M infusion did not occur until 1300 hrs, striatal DA levels were as low as the 1300 hr peak in rats given infusions at 0900, 1100 and 1300 hrs. Conversely, when the probe was inserted 1 hr before the third ip M injection, the DA released by the third injection was as great as that in response to the first injection, measured 2 hr after probe insertion. Finally, ip M-induced DA peaks 24 hr after probe insertion were only 10 % of those seen 2 hr after probe insertion, and these much smaller peaks did not decline over repeated injection. It is concluded that the magnitude of M-stimulated striatal DA release declines rapidly over the first 24 hours following probe insertion.

METHAMPHETAMINE-INDUCED REGULATION OF STRIATAL AND CORTICAL NMDA RECEPTORS. A.J. Eisch*, S.J. O'Dell and J.F. Marshall, Psychobiology Dept., University of California, Irvine, CA 92717-4550.

Methamphetamine (m-AMPH) produces long-lasting damage to dopaminergic and serotonergic terminals in the striatum and cortex of the rat. Evidence also suggests that m-AMPH is toxic to non-monoaminergic cortical neurons. We used quantitative autoradiography to investigate changes in the dopaminergic and glutamatergic systems in striatal and cortical regions after a neurotoxic regimen of m-AMPH. Rats were given i.p. injections of saline (1 mg/ml) or m-AMPH (4 mg/kg of free base) every two hours for four injections. One week or one month later, regions of the striatum, prefrontal and parietal cortices were examined for m-AMPH-induced changes in [3H]mazindol (MAZ) binding to striatal dopamine (DA) transporters and [3H]glutamate (GLU) binding to NMDA receptors. One week after m-AMPH, both [3H]MAZ binding and [3H]GLU binding to NMDA receptors were decreased in striatal subregions. Specifically, the ventral and lateral sectors of the striatum showed the greatest decreases in [3H]MAZ and [3H]GLU binding, while the nucleus accumbens showed no significant m-AMPH-induced damage. One month after m-AMPH, striatal [3H]MAZ binding was still significantly decreased, while NMDA receptors had returned to control levels. The parietal cortex also showed m-AMPH-induced changes. One week after m-AMPH, a significant *increase* in [3H]GLU binding to NMDA receptors was seen in layers II/ III and IV. One month after m-AMPH, only layers II/III showed a significant increase in [3H]GLU binding. In contrast, regions of the prefrontal cortex showed no changes in NMDA receptor density either one week or one month after m-AMPH. This is the first demonstration that forebrain NMDA receptors are altered by a neurotoxic regimen of m-AMPH. These results support the view that repeated m-AMPH adminstration affects excitatory amino acid transmission in selected cortical and striatal regions.

826.9

METHAMPHETAMINE EFFECTS ON BRAIN ENERGY METABOLISM: COMPARISON BETWEEN EXTRACELLULAR LACTATE IN STRIATUM AND PREFRONTAL CORTEX. S.E. Stephans*, T.S. Whittingham, A.J. Douglas and B.K. Yamamoto Departments of Psychiatry, Neuroscience, and Neurological Surgery, Case Western Reserve Univ., Cleveland, OH 44106.

A high dose of methamphetamine (METH) can lead to depletion of tissue dopamine in the striatum (STR). In contrast, the medial prefrontal cortex (PFC) is relatively resistant to the toxic effects of METH. The mechanisms underlying this selective effect are unknown; however, energy depletion has been linked to METH-induced decreases in striatal dopamine content. To further extend this finding, microdialysis coupled with an enzymatic fluorometric assay was utilized to assess *in vivo* the dynamic changes in extracellular lactate concentrations after METH in awake rats. Lactate concentration in the dialysate was measured and used as an index of possible energetic stress in STR and PFC during a neurotoxic dosing regimen of METH (10.0 mg/kg, i.p., every 2 hours for a total of 3 injections) or saline. There was a significant increase (228% of baseline) in extracellular lactate in STR over time beginning immediately after the first METH injection and persisting up to 4 hours after the third injection ($p<0.02$). There was no significant change in striatal lactate over time in saline injected rats. Extracellular concentrations of lactate in the PFC were not significantly different between METH and saline injected rats. DA tissue content measured 4 days following administration of METH was significantly depleted in STR but not PFC ($p<0.05$). Overall, these data are evidence that METH enhances energy consumption more in the STR than in the PFC. This effect may be due to the greater density of DA terminals in STR. It is possible that the acute and sustained enhancement in energy utilization is related to the long-term dopamine depletions produced by METH.

BEHAVIORAL SENSITIZATION TO 7-OH-DPAT: EFFECTS OF SELECTIVE DOPAMINE ANTAGONISTS. B.A. Mattingly*, S. Fields, M. Langfels, M. Cecil, & D. Giovannini. Department of Psychology, Morehead State Univ., Morehead, KY 40351.

Repeated treatments with the dopamine (DA) D_2-type agonists, bromocryptine and quinpirole, result in the development of behavioral sensitization. This sensitization effect, however, may be prevented by the co-administration of either DA D_1 or D_2 antagonists. The primary purpose of this study was to determine whether DA D_1- and D_2-type antagonists would also block the development of sensitization to the putative DA D_3 agonist, 7-OH-DPAT. In Exp. 1, rats were tested for 2 hrs in photocell activity arenas daily after treatment with 7-OH-DPAT (0, .01, .10, or 1.0 mg/kg). All doses initially inhibited activity, but with repeated treatment, the 1.0 mg/kg dose resulted in sensitization. No cross-sensitization to cocaine was observed. In Exps. 2 & 3, rats were co-administered 7-OH-DPAT (1.0 mg/kg) and either the D_2-type antagonist, eticlopride (ETIC, 0.3 mg/kg) or the D_1-type antagonist, SCH 23390 (SCH, 0.2 mg/kg), and tested for activity. Both antagonists significantly suppressed activity and prevented the progressive 7-OH-DPAT-induced increase in activity over sessions. ETIC, but not SCH, also blocked the development of sensitization. That is, after a 7-OH-DPAT challenge injection, rats pretreated with ETIC and 7-OH-DPAT did not differ from vehicle pretreated rats. Rats pretreated with SCH and 7-OH-DPAT, however, were significantly more active than rats pretreated with only 7-OH-DPAT.

826.11

THE D_3 AGONIST 7-OH-DPAT GENERALIZES TO THE DISCRIMINATIVE STIMULUS EFFECTS OF AMPHETAMINE IN RATS. R. A. Bevins*, M. C. Bradley, J. E. Klebaur, & M. T. Bardo. Psychology Dept, Univ of Kentucky, Lexington, KY 40506-0044.

Rats were first trained to discriminate between 1 mg/kg amphetamine and saline (ip) using a two-lever drug discrimination procedure. Following acquisition of the discrimination, generalization to a range of amphetamine doses (0.0625, 0.125, 0.25, 0.5, 1.0, and 2.0 mg/kg) was examined in 4-min extinction tests. The degree of amphetamine-appropriate responding varied directly with the dose of amphetamine. Response rates decreased systematically with greater amphetamine doses. We then assessed the ability of the putative D_3 agonist 7-OH-DPAT (0, 0.01, 0.03, 0.1, 0.3, and 1.0 mg/kg) to occasion amphetamine-correct responding. In a balanced manner, all rats were tested twice with each dose; on one test the 7-OH-DPAT was injected ip and in the other test it was injected sc. Regardless of injection route, the higher doses of 7-OH-DPAT fully generalized to amphetamine. However, 7-OH-DPAT injected sc occasioned greater amphetamine-correct responding at lower doses than when injected ip. 7-OH-DPAT also produced a dose-dependent decrease in barpress rates with both injection routes. The D_2 antagonist eticlopride (0.01 and 0.05 mg/kg; ip) partially blocked the amphetamine-appropriate responding induced by 7-OH-DPAT. This latter results argues that the generalization of 7-OH-DPAT may be mediated, at least in part, by dopamine D_2 receptors.

826.12

DOSE-DEPENDENT EFFECTS OF THE D3-PREFERRING AGONIST 7-OH-DPAT. J. L. Neisewander*, T. V. Khroyan, and D. A. Baker. Department of Psychology, Arizona State University, Box 871104,Tempe, AZ 85287-1104.

Dose-dependent effects of 7-OH-DPAT (DPAT) on motor behaviors and conditioned place preference (CPP) were assessed. Two-day conditioning trials were conducted. On one day, animals received one of 8 doses of DPAT (0-5 mg/kg, s.c) and were placed into a distinct compartment for 40 min. On the other day, they were injected with saline and immediately placed into a different compartment for 40 min. Three trials were conducted over consecutive days. Locomotion, sniffing, and yawning were measured following the first and last injection of DPAT. CPP was then assessed by recording the amount of time animals spent in each compartment when given free-access to both for 15 min. DPAT produced a U-shaped dose-dependent change in locomotion and sniffing with the greatest decreases observed at 0.01 and 0.03 mg/kg. DPAT also produced an inverted U-shaped dose-dependent change in yawning with the greatest increases observed at 0.03 and 0.1 mg/kg. DPAT-induced yawning was sensitized at a dose of 0.1 mg/kg. The 5 mg/kg dose of DPAT produced CPP. None of the other doses (0.003-1 mg/kg) produced CPP, and in fact there was a trend for place aversion at 0.3 mg/kg. DPAT has a 100-fold greater affinity for D3 receptors relative to D2 receptors. Thus, it is possible that the low doses (0.01-0.1 mg/kg) that increased yawning and decreased locomotion and sniffing may preferentially occupy D3 receptors. Furthermore, these putative D3-preferring doses of DPAT do not produce CPP and may produce place aversion. (Supported by DA07730)

826.13

EFFECTS OF 7-OH-DPAT ON AMPHETAMINE-INDUCED STIMULANT BEHAVIORS AND CONDITIONED PLACE PREFERENCE. T. V. Khroyan *, D. A. Baker, R. A. Fuchs and J. L. Neisewander. Department of Psychology, Arizona State University, Box 871104, Tempe, AZ 85287-1104.

Putative D3-preferring doses of 7-OH-DPAT (0.01-0.1 mg/kg) produce a decrease in locomotion and sniffing and do not produce conditioned place preference (CPP). This study examined the effect of these doses on amphetamine-induced behaviors and CPP. Three 2-day conditioning trials were conducted over consecutive days. On one day of each trial, animals received an injection of either amphetamine (1.0 mg/kg) coadministered with 7-OH-DPAT (0- 0.1 mg/kg) or saline and were placed into a compartment for 40 min. On the other day, animals were injected with saline and placed into a different compartment for 40 min. Locomotion, sniffing, and headbobbing were measured following the first and third drug injections. Following conditioning, CPP was assessed by recording the amount of time animals spent in each compartment when given access to both. Amphetamine increased locomotion after the first injection, and this effect was attenuated by 0.03 mg/kg 7-OH-DPAT. Amphetamine-induced locomotion was decreased dose-dependently by 7-OH-DPAT after the third injection due to the emergence of dose-dependent headbobbing, a behavior not observed in animals receiving amphetamine alone. Amphetamine coadministered with 0-0.03 mg/kg 7-OH-DPAT produced CPP, whereas amphetamine coadministered with 0.1 mg/kg 7-OH-DPAT did not produce CPP. These results suggest that 7-OH-DPAT potentiates the stimulant properties of amphetamine and alters the rewarding properties (supported by DA07730 and HHMI).

REPEATED PHENCYCLIDINE TREATMENTS ACTIVATE CHOLECYSTOKININ SYSCTEMS IN RAT BRAINS. H.Shibuya*1, K.Yamada1, T.Yoshikawa1, T.Nabeshma2, M.Toru1, 1;Department of Neuropsychiatry, Tokyo Medical and Dental Univ., 1-5-45, Yushima, Bunkyo-ku, Tokyo, 113, Japan, 2;Nagoya Univ., School of Medicine, 45, Tsurumacho, Showa-ku, Nagoya, 466, Japan,

Reported findings on cholecystokinin(CCK) immunoreactivity in the postmortem brain and cerebrospinal fluind, CCK receptor bindings and clinical therapeutic trials with CCK related substances suggest functional alterations of CCK systems in the schizophrenic brain. Meanwhile, phencyclidine(PCP) is known to produce positive and negative psychotic symptoms in human. We assumed the PCP treated rat as the schizophrenic animal model and determined the CCKmRNA and CCK immunoreactivities in various brain areas in order to investigate the functional state of CCK in schizophrenia. Single administration of PCP (7.5mg/kg,ip) promptly and transiently decreased CCK immunoreactivities in many brain areas and CCKmRNA in the hippocampus and parieto-occipital cortex. However, repeated administrations of PCP increased the synthesis of CCK. These findings would suggest that CCK systems are hyperactive in schizophrenic brain and play roles to produce some schizophrenic symptoms.

ACUTE AND LONG-TERM NEUROCHEMICAL EFFECTS OF METHCATHINONE, A NEW STIMULANT OF ABUSE. M.P. Gygi, J.W. Gibb, and G.R. Hanson.*Dept. of Pharmacology and Toxicology, Univ, of Utah, Salt Lake City, UT 84112.

Methcathinone (CAT), a synthetic derivative of cathinone, emerged as an illicit drug of abuse in the U.S. during the early 1990s. Because of ease of synthesis, CAT is preferred by some over cocaine or methamphetamine (METH). Multiple doses of CAT were shown to be toxic to brain dopamine (DA) and 5-hydroxytryptamine (5HT) neurons (Martello et al., Soc Neurosci 419.15, 1994). In striatum, a single dose of CAT decreases the activity of tryptophan hydroxylase (TPH), the rate-limiting enzyme in the synthesis of 5HT. To characterize further the time course of these effects, rats were given 4 doses of CAT (30 mg/kg) 4 h apart, and sacrificed 72 h or 30 d following the last dose. In the 72 h group, striatal TPH activity was decreased. The activity of striatal tyrosine hydroxylase (TH), the rate-limiting enzyme in DA synthesis, was also decreased. Striatal concentrations of DA and 5HT and their metabolites were reduced as well. Both TH and TPH activites returned to control by 30 d after treatment. Because drug-induced increases in mesostriatal dopaminergic activity elevate striatal levels of neurotensin, the response of this peptide to CAT was assessed and compared to METH, a known releaser of DA. Rats were given either 4 doses of CAT (30 mg/kg), METH (15 mg/kg) or saline 4 h apart, and sacrificed 18 h after the last dose. Both METH and CAT increased striatal levels of neurotensin to greater than 200% of control. These data demonstrate that CAT affects monoaminergic parameters in the striatum. These effects do not appear to be permanent. Since striatal neurotensin levels were elevated by CAT, it is possible that the neurochemical response is due to CAT-induced DA release. S(-)METHCATHINONE AS A DISCRIMINATIVE STIMULUS: EFFECTS OF OTHER CNS STIMULANTS.
R. Young* and R.A. Glennon. Dept. Med. Chem., MCV/VCU, Richmond, VA 23298

Methcathinone ("Cat") is a CNS stimulant that is a very significant drug of abuse in the former Soviet Union. It also has appeared on the clandestine market in the US and has been recently classified as a Schedule I substance. We have shown[1] previously that racemic methcathinone and its two optical isomers all produce both amphetamine- and cocaine-like discriminative stimulus effects in rats trained to discriminate S(+)amphetamine and cocaine, respectively, from saline. In those studies, S(-)methcathinone was almost twice as potent as S(+)amphetamine and more than eight times more potent than cocaine. In the present study, using rats, S(-)methcathinone (0.5 mg/kg, i.p., 15 min. pretreatment) was employed as the training drug in a two-lever discrimination task. Once established, the S(-)methcathinone stimulus was shown to have a rapid onset to action (5 min pre-session injection interval=89% drug-lever responding) and a duration of effect of approximately 90-120 min. In tests of stimulus generalization, the S(-)methcathinone-stimulus (ED50=0.11mg/kg) generalized to R(+)-methcathinone (ED50=0.39 mg/kg), S(+)amphetamine (ED50=0.20 mg/kg), and cocaine (ED50=1.47 mg/kg). Thus, the present results re-confirm our previous conclusion that S(-)methcathinone is a very potent CNS stimulant with amphetamine- and cocaine-like effects. (DA-01642)[1]Pharm. Biochem. Beh., 50, 601-606, 1995.

PHARMACODYNAMIC ANALYSIS OF KETAMINE ACTION IN SCHIZOPHRENIA. D. Medoff*, A.C. Lahti, H.H. Holcomb, M. Zhao, C.E. Priebe, C.A. Tamminga. MPRC, University of Maryland School of Medicine, and the Department of Mathematical Sciences, Johns Hopkins University.

The noncompetitive NMDA antagonist ketamine produces a short lived discrete activation of psychotic symptoms in schizophrenia. To study regional neural activity that corresponds to ketamine administration, we administered .3mg/kg of ketamine to five medicated schizophrenic inpatients and measured regional cerebral blood flow (rCBF) using $H_2{}^{15}O$ and positron emission tomography (PET) before (x3) and at seven time points after ketamine administration. The post ketamine administration time points ranged from 6 to 66 minutes. After image registration, a 12 mm three dimensional Gaussian filter was used to smooth the data. Data were analyzed using the Statistical Parametric Mapping (SPM94) software program, MRC Cyclotron Unit, Hammersmith Hospital. Significant patterns of blood flow change over time were detected in several regions. The lingual gyrus shows an immediate drop in blood flow at six minutes and a swift return to baseline by sixteen minutes. The hippocampus also shows an immediate drop in blood flow, but a more gradual return to baseline at 56 minutes. The anterior cingulate, inferior frontal cortex, thalamus, and the cerebellum all showed increases in blood flow, but in distinctly different patterns. It is noteworthy that the areas of ketamine-altered rCBF are circumscribed, limited in number, and much more restricted than the distribution of NMDA/PCP receptors. Based on the localization of blood flow response to ketamine in these subjects, we suggest that limbic brain regions are important in mediating the behavioral actions of ketamine. These data implicate an abnormality of glutamatergic-transmission in psychosis.

AMYGDALA LESIONS THAT BLOCK SENSITIZATION TO BROMOCRIPTINE FAIL TO BLOCK SENSITIZATION TO BROMOCRIPTINE PLUS MK-801. W. A. Carlezon, Jr.*, F. A. Guarraci, and R. A. Wise Center For Studies in Behavioral Neurobiology, Concordia Univ., Montréal, QC, CANADA H3G 1M8

Repeated intermittent administration of the dopamine (D_2) agonist bromocriptine (BRO; 5.0 mg/kg, IP) causes progressive increases in sensitivity to the locomotor-stimulating actions of the drug in rats; this "sensitization" is context-specific, such that rats repeatedly given BRO in one environment show no evidence of sensitization when tested in a different environment. We now report that electrolytic lesions of the basolateral amygdala eliminate BRO sensitization without altering sensitivity to the acute stimulant effects of the drug, suggesting that the drug-environment associations that contribute to BRO sensitization are processed at some level in the amygdala. Similar lesions of the amygdala fail to block the progessive increases in locomotion that occur when MK-801 (0.25 mg/kg, IP) is co-administered with BRO, under conditions that do not produce sensitization to MK-801 alone. However, there is no evidence of sensitization when animals (lesioned or sham-lesioned) accustomed to receiving the combination of MK-801 plus BRO subsequently receive either drug alone. Thus it is the *absence* of MK-801 in animals accustomed to the combination of drugs that precludes expression of sensitization. These findings suggest that MK-801 makes responses learned under its influence "discriminative cue-specific", and that such cues can facilitate experience-dependent changes in drug sensitivity even when the amygdala is damaged.

FASCICULUS RETROFLEXUS LESIONS INCREASE SELF-ADMINISTRATION OF AMPHETAMINE. Carol A. Murphy and Marion Murray*. Department of Anatomy and Neurobiology, Medical College of Pennsylvania and Hahnemann University, 3200 Henry Avenue, Philadelphia, 1PA 19129.

Disruption of the efferent pathway of the habenular nuclei, the fasciculus retroflexus (FR), produces behavioral and physiological changes that reflect a state of increased arousal, including increased open field activity and chronically elevated basal levels of corticosterone. Within a normal population of Sprague-Dawley rats, similar responses to stress are positively correlated with increased self-administration of amphetamine. Because habenular projections through the FR tonically inhibit the activity of dopaminergic (DA) neurons in the ventral tegmentum, and intake of psychostimulant drugs is tightly linked to forebrain DA activity, we tested whether rats with FR lesions would self-administer higher doses of amphetamine. Two months after receiving either FR or sham lesions, female Sprague-Dawley rats were prepared with catheters in the external jugular vein and tested for intravenous self-administration of d-amphetamine sulfate (10ug/injection) in both nose-poke and lever-press operant response paradigms. Rates of amphetamine self-injection and the incidence of behavioral stereotypy were assessed during daily 1-hour sessions. Our results show that FR-lesioned animals initially self-administered greater amounts of amphetamine than sham controls over the first several days of testing but that their drug intake gradually decreased to near-control levels. Stereotypic responses to amphetamine were also greater after FR lesion and remained elevated with respect to controls for the duration of the experiment. These results suggest that habenular regulation of DA reward systems may normally provide an important negative feedback mechanism which moderates the intake of psychostimulant drugs. Supported by NIMH award MH53635-01.

827.1

SINGLE-UNIT RESPONSES OF HIPPOCAMPAL CA1 PYRAMIDAL NEURONS TO 5-HT1A AGONIST DRUG ADMINISTRATION IN UNANESTHETIZED, UNRESTRAINED RATS. N.Ueda[1], K. Tada[1]*, K. Kasamo[1], T. Kojima[1] and K. Ishikawa[2]. Dept. of Neuropsychiat[1]. and pharmacol[2]., Nihon Univ. Sch. of Med., 30-1 Oyaguchi Kamimachi Itabashi, Tokyo 173, Japan.

Previous electrophysiological experiments demonstrated that 5-hydroxytryptamine (5-HT)1A agonists inhibited spontaneous pyramidal cell activity in anesthetized rats. Since all the 5-HT1A agonists thus far tested act as partial agonists post synaptically, it is important to know whether these 5-HT1A agonists inhibit hippocampal pyramidal cell activity under conditions in which 5-HT neurons are activated. So we examined the effects of 5-HT1A agonists on single-unit activity of hippocampal CA1 pyramidal neurons in unanesthetized,unrestrained rats. Subcutaneous administration of the selective 5-HT1A agonists, 8-hydroxy-2-(di-n-propylamino) tetralin (8-OH-DPAT), buspirone, ipsapirone produced a dose-dependent inhibition of hippocampal CA1 pyramidal cell activity. The order of potency was 8-OH-DPAT (ED50 for 8-OH-DPAT=0.07 μ g/kg)> buspirone(ED50 for buspirone=0.19 μ g/kg) which is in agreement with previously reported behavioral, electrophysiological and biochemical studies. The 5-HT1A antagonist, 1-(2-methoxyphenyl)-4-[4-(2-phthalimido) butyl]piperazine (NAN190) inhibited the effect of buspirone(1mg/kg) on single-unit activity of hippocampal CA1 pyramidal neurons. Present results provides further evidence for post synaptic site of action of anxiolytic 5-HT1A agonists.

827.2

MKC-242, A NOVEL 5-HT1A RECEPTOR AGONIST, REPRESENTS DIFFERENT PROFILES FROM AZAPIRONES IN THE ANIMAL MODELS.
M. Abe, R. Tabata, #H. Nakai, #T. Komatsu, K.-I. Saito* and M. Egawa. Pharmaceuticals Lab. I, # Pharmacokinetics and metabolism Research Lab., Mitsubishi Chemical Co., Yokohama Research Center, Yokohama, 227.

MKC-242 (5-[3-[[(2S)-1,4-benzodioxan-2-ylmethyl]amino]propoxy]-1,3-benzodioxol HCl) is a potent and selective 5-HT1A receptor agonist. It showed anxiolytic-like and antidepressant-like effect at very low doses (0.0625-3 mg/kg, p.o.) in some animal models. MKC-242 is structuraly differed from azapirones. In the present study, we investigated two different profiles of MKC-242 from azapirones.

First, the effect of MKC-242 on the immobility time in the forced swimming test in male rats was investigated comparing with buspirone and tandospirone. MKC-242 (0.3-3 mg/kg, i.p.) reduced the immobility time. However buspirone and tandospirone did not. The effect of MKC-242 was antagonized by administration of WAY100135, a 5-HT1A receptor antagonist. In addition, the effect was also antagonized by administration of 1-(2-pyrimidinyl)piperazine, a major metabolite of azapirones.

Second, the effect of MKC-242 on the shock induced fighting behavior in male mice was investigated comparing with the reference compounds. MKC-242 reduced the fighting behavior in a dose dependent manner and the effect lasted for 3 hrs at non-sedative doses (ED50 = 1.7-5 mg/kg,p.o.). Buspirone and tandospirone also reduces the fighting behavior 1 hr after the administration at non-sedative doses (ED50 = 42 and 80 mg/kg, p.o., respectively). However, these compounds were effective 2 hrs after the administration at only sedative doses (ED50 = 160 and 320 mg/kg, p.o., respectively). The serum AUC for MKC-242 was about 400-fold higher than that for buspirone in rats.

In conclusion, MKC-242 showed more potent antidepressant-like effect and longer-lasting anxiolytic-like effect comparing with buspirone and tandospirone. These characters might be due to the structural difference and pharmacodynamic difference from azapirones.

EFFECTS OF CHRONIC AZAPIRONE TREATMENT ON SEROTONERGIC SYSTEMS. G. K. Matheson*, C.Michel, M. Weiberg, and J. Thomas. Neurobiology Laboratory, Indiana University School of Medicine. Evansville, IN 47712.

Buspirone or ipsapirone (3 mg/kg, b.i.d., *s.c.*) was administered to Long-Evans rats for ten days. On day ten, the effects of various concentrations of buspirone or ipsapirone on the inhibition of spontaneous single-unit neural activity or the hypothalamic-pituitary adrenal axis (HPAA) were tested. Acute animals did not receive the drug pretreatment. Serotonergic neurons generating single-unit activity were identified by their location, discharge frequency (0.5-2.5 spikes/sec), wave-form characteristics, and spontaneous activity. Drug effects were determined by comparing the average rate of discharge recorded over one minute before drug administration with the rate recorded during the sixth post-injection one minute interval. In the chronic and single treatment studies, buspirone and ipsapirone were equally efficacious and totally inhibited the spontaneous activity of serotonergic single-unit neurons in a dose-dependent manner. For buspirone the potency (ED_{50} value) was 134 µg/kg for the acute study and 1800 µg/kg for the chronic study, a thirteen fold increase in the required dose. For ipsapirone the ED_{50} value was 700 µg/kg for the acute study and 1200 µg/kg for the chronic study. Chronic buspirone or ipsapirone administration increased the tolerance of the HPAA following a challenge by each drug. The ED_{50} for elevation of plasma corticosterone levels was increased from 4.0 to 7.6 mg/kg for buspirone and 6.2 to 8.0 mg/kg for ipsapirone. The data suggests chronic administration may lead to possible differences in ligand-receptor affinity, metabolic rates, and/or the cyclic AMP-G-protein mechanism.

827.4

CP-93,393, A NOVEL ANXIOLYTIC/ANTIDEPRESSANT AGENT WITH BOTH 5-HT1A AGONIST AND ALPHA-2 ADRENERGIC ANTAGONIST PROPERTIES: *IN VITRO* STUDIES. A.W. Schmidt*, C.B. Fox, J. Lazzaro, S. McLean, A. Ganong, D.W. Schulz, K. Desai, G.M. Bright and J. Heym. Central Research Division, Pfizer Inc., Groton, CT. 06340.

CP-93,393, ((7S,9aS)-2-(2-pyrimidinyl)-7-(succinimido-methyl) 2,3,4,6,7,8,9,9a-octahydro-1H-pyrido[1,2-a]pyrazine), is a novel anxiolytic/antidepressant agent that combines 5-HT1A agonist activity and α2 adrenergic antagonist features. Like buspirone, CP-93,393 lacks affinity for benzodiazepine receptors and would therefore not have the sedative and/or addictive properties of anxiolytics such as diazepam and alprazolam. In rats, CP-93,393 potently inhibits dorsal raphe firing by activating presynaptic 5-HT1A autoreceptors (Reynolds,L.S. et al., this meeting). CP-93,393 binds with moderate affinity (Ki = 100 nM) to postsynaptic 5-HT1A receptors, but displays differential efficacy as an agonist depending on the tissue preparation. For example, adenylate cyclase studies reveal CP-93,393 to be a partial agonist (67% compared to 5-HT, EC50 = 600 nM) in HeLa cells expressing human 5-HT1A receptors, while both CP-93,393 and buspirone behave as full agonists when guinea pig hippocampal membranes are utilized. In recordings of 5-HT mediated hyperpolarizations from CA1 neurons in guinea pig hippocampal slices, CP-93,393 displayed partial agonist activity (52% effect compared to 5-HT, EC50 = 1.8 µM). In addition, CP-93,393 binds with appreciable affinity to human α2A, α2B and α2C adrenergic receptors transfected in CHO cells (Ki = 10 - 50 nM). In adenylate cyclase studies in the α2A clone, CP-93,393 (1 µM) produces a competitive rightward shift of the UK-14,304 dose-response curve, indicating that it acts as an α2A adrenergic antagonist. CP-93,393 has a unique combination of 5-HT1A agonist and α2 adrenergic antagonist properties that may lead to improved efficacy as an anxiolytic/antidepressant agent.

827.5

IN VIVO PROFILE OF CP-93,393: EVIDENCE OF COMBINED 5HT1A AGONIST AND α2 ANTAGONIST ACTIVITIES. L.S.Reynolds*, J.P.Braselton, J.S.Sprouse, H.Rollema, T.Clarke, S.McLean, W.Horner, and J.Heym. Central Research Division, Pfizer Inc. Groton CT. 06340

CP-93,393 is a novel anxiolytic/antidepressant compound possessing both $5HT_{1A}$ and α2 adrenergic properties. In recordings from rat dorsal raphe, CP-93,393 was a potent agonist at the $5HT_{1A}$ autoreceptor, inhibiting the spontaneous firing of serotonergic neurons in a dose dependent manner (ED_{50} =14 µg/kg i.v.) while displaying only moderate affinity for the $5HT_{1A}$ receptor (K_i=92±6 nM, rat cortex). In keeping with its action as a potent presynaptic agonist, this compound also produced a dose-dependent decrease in extracellular serotonin (ED_{50}=1.6 mg/kg s.c.) and 5-hydroxy indole acetic acid (5HIAA) levels as measured by *in vivo* microdialysis in rat hippocampus. In addition to affecting the $5HT_{1A}$ receptor, CP-93,393 also acted as an α2 ligand with significant binding affinity for α2 adrenoreceptors in rat (K_i=35±6 nM). As expected with α2 antagonist activity, levels of the NE metabolite 3-methoxy-4-hydroxy-phenylglycol (MHPG) were increased dose-dependently in rat forebrain. In addition, the spontaneous firing rate of NE-containing neurons in rat locus coeruleus was increased by CP-93,393, possibly through an α2 mechanism. This combination of decreased serotonergic activity and increased NE transmission produced by CP-93,393 could be effective in the treatment of anxiety and affective disorders.

827.6

ANXIOLYTIC ACTIVITY OF CP-93,393: ENHANCED EFFICACY VIA COMBINED 5-HT1A AGONIST AND α2-ADRENERGIC ANTAGONIST ACTIVITIES. P.A. Seymour*, K. Desai and G.M. Bright. Departments of Neuroscience and Medicinal Chemistry, Central Research Division, Pfizer Inc, Groton, CT 06340.

The anxiolytic/antidepressant, CP-93,393, is a 5-HT1A agonist that is both chemically and biologically distinct. Unlike members of the buspirone class its novel azabicyclic structure incorporates α2-adrenergic antagonist activity into the parent molecule. CP-93,393 was discovered using a modification of the Vogel conflict test designed to identify compounds with improved efficacy. After i.p. administration CP-93,393 showed a MED comparable to gepirone (1.78 mg/kg), but yielded much greater efficacy (780 vs 320% of control), which was comparable to that observed with diazepam. Since α2-antagonists have also been shown to have anticonflict activity in a similar paradigm (Gower and Tricklebank, 1988), the interaction between 5-HT1A agonism and α2-antagonism was investigated. It was found that subthreshold doses of the α2-antagonist, idazoxan (IDZ), significantly enhanced the anticonflict effects of submaximal doses of CP-93,393, other 5-HT1A agonists, and benzodiazepines. Moreover, it was found that 8-OH-DPAT, which was inactive at any dose tested when administered alone, elicited robust activity when combined with subthreshold doses of IDZ, indicative of synergy between these two compounds. These data support the hypothesis that the enhanced efficacy observed with CP-93,393 may be due to the combination of 5-HT1A agonist and α2-adrenergic antagonist activities, and suggest that CP-93,393 may show improved efficacy in the clinic as well.

827.7

ADAPTATION OF NMDA RECEPTORS IN ANIMAL MODELS OF DEPRESSION: CHRONIC MILD STRESS (CMS). G.N. Nowak*[1], M. Papp[2] and I. A. Paul[1]. Lab. Neurobehav. Pharmacol. & Immunol., Depts. of Psychiatry and Pharmacology, Univ. of Miss. Med. Ctr., Jackson, MS 39216, USA[1] and Inst. of Pharmacology, Pol. Acad. of Sci., Krakow, Poland[2].

NMDA receptor antagonists are as efficacious as clinically active antidepressants (AD) in both preclinical behavioral paradigms sensitive to ADs and in animal models of depression. Moreover, 10-14 d. continuous administration of ADs is required to produce a dose-dependent adaptation of the NMDA receptor complex in rodents. Specifically, chronic AD administration results in a 2-4 fold reduction in the potency of glycine to displace [^{3}H]5,7-dichlorokynurenic acid from the strychnine-insensitive glycine recognition site of the NMDA receptor complex. In addition, chronic AD treatment results in a 40-100% reduction in the proportion of high affinity, glycine-displaceable [^{3}H]CGP-39653 binding to the glutamate recognition site of the NMDA receptor complex. These effects are not observed following chronic administration of structurally related non-AD treatments. A limitation of these earlier studies is that adaptation of the NMDA receptor complex was observed following AD administration in naive animals. We therefore tested the hypothesis that animal models of depression would result in AD-reversible adaptation of the NMDA receptor complex. We administered imipramine (IMI - 10 mg/kg x 28 days) to rats subjected to CMS. As previously reported, 28 days CMS resulted in reduced consumption of a sucrose solution. This was reversed by administration of IMI. Moreover, we now report that CMS results in adaptation of the NMDA receptor complex and that this adaptation is reversible by chronic IMI treatment. These data lend support to the hypothesis that AD activity is associated with adaptation of the NMDA receptor complex and that "depression" or "anhedonia" in animals is associated with an AD-reversible dysfunction of the NMDA receptor complex.

SAFETY AND EFFICACY OF THE CCK_B ANTAGONIST CI-988 IN GENERALIZED ANXIETY DISORDER John J. Sramek, Jerome R. Costa, Judith Bammert Adams, Alison MacPherson, and Neal R. Cutler*. California Clinical Trials, Beverly Hills, CA 90211 and Parke-Davis Division of Warner-Lambert, Ann Arbor, MI

CI-988 is a novel peptoid CCK antagonist with affinity for brain CCK_B and gastrin receptors. This study investigated the efficacy of this compound in patients with generalized anxiety disorder (GAD). We report results from one site (n=32) in a multicenter study (n=88). Sixteen patients who had had at least a six-month duration of symptoms were randomized to 300 mg/day CI-988 and 16 to placebo. Twenty-nine patients completed all four weeks of study treatment. The primary efficacy measures were the Hamilton Rating Scale for Anxiety (HAM-A) and the Clinical Global Impression (CGI) scale. Patients on CI-988 showed a greater decrease (p=0.06) in HAM-A scores than did patients on placebo at the end of the study, with mean change in HAM-A total at week 4 of -7.69 (-32.0%) for CI-988 and -4.19 (-18.6%) for placebo. The HAM-A change favoring CI-988 was primarily due to improvement in somatic symptoms of anxiety. There were no significant differences on the CGI between the patients treated with CI-988 versus placebo (mean changes of -0.88 and -0.34, respectively, in impression of severity score, and mean changes of 0.92 and 0.94, respectively, in impression of change scores). All adverse events were rated mild or moderate. One patient on CI-988 discontinued due to moderate abdominal pain; two patients on placebo discontinued for personal reasons. Our findings indicate that CI-988 given for four weeks has a potential anxiolytic effect, though the small sample size limits any certainty. These findings were not reflected in the overall multicenter results; one center favored placebo and the other favored neither group. Given the acceptable tolerability of CI-988 seen here, testing of higher oral doses in patients with GAD may be warranted.

LYSOSOMOTROPIC DRUGS SLOWLY ACCUMULATE IN HUMAN BRAIN TISSUE. RELATIONSHIP TO THERAPEUTIC LATENCY OF ANTIDEPRESSANT AND NEUROLEPTIC DRUGS? J. Kornhuber*, W. Retz, P. Riederer. Dept. of Psychiatry, University of Würzburg, 97080 Würzburg, Germany.

The mechanism of therapeutic latency of antidepressant (AD) and neuroleptic (NL) drugs is not clearly understood. Current hypotheses include slow adaptive processes after fast access to primary drug targets. Here, we present a hypothesis explaining therapeutic latency by slow accumulation of the drugs in acidic intracellular compartments. We have studied the pharmacokinetics of amantadine, a lysosomotropic model substance. It's fast therapeutic response is mediated by fast access to cell surface receptors. However, it slowly accumulates intracellularly in human brain tissue. Half-maximal and plateau concentrations are reached after 8 and at least 70 days of treatment, respectively. The concentration in brain tissue relative to CSF and serum is about 20:1. The high storage capacity of brain tissue is probably related to lysosomotropic properties of amantadine. This means that amantadine, as other lysosomotropic substances, is trapped by protonation in acidic intracellular compartments and may disturb biochemical processes that require an acidic milieu, such as the proton-driven transport of monoamines into synaptic vesicles. The mean daily oral dose of amantadine is low compared to the high storage capacity of brain and other tissues thus explaining the slow accumulation. Many psychotropic drugs including AD and NL substances also have lysosomotropic properties. A slow accumulation in brain tissue is therefore likely for many AD and NL drugs and has been directly demonstrated for fluoxetine. While lysosomotropism alone is not a sufficient explanation for AD or NL properties of a certain drug, it contributes to high storage capacity and slow accumulation in brain tissue and results in alterations of several biochemical processes.

DIFFERENT ANXIOLYTIC-LIKE PROFILES OF NOVEL ANTIPSYCHOTICS IN RODENTS. C. Sánchez and J. Arnt*. H. Lundbeck A/S, DK-2500 Copenhagen, Denmark.

An add-on anxiolytic effect is desirable for neuroleptic drugs, as emotional disturbances are frequently accompanying symptoms in schizophrenic patients. The non-classical neuroleptic sertindole shows potent anxiolytic-like effects in rodents and the marmoset[1]. In the present study we have compared the profiles of haloperidol and clozapine with the newer antipsychotics sertindole, risperidone, olanzapine, seroquel and ziprasidone in 3 animal models, i.e. facilitation of exploratory behaviour of rats in a two-compartment black and white box (**B/W**), inhibition of footshock-induced ultrasonic vocalization in adult rats (**USV**) and inhibition of isolation-induced aggressive behaviour in male mice (**AGGR**). Sertindole is the only compound with an anxiolytic-like profile in the **B/W** test (i.e. increased exploration of the white compartment relative to the black). Olanzapine shows an anxiogenic-like profile, and the other compounds are inactive or weakly anxiogenic-like. Clozapine, risperidone, seroquel and olanzapine inhibit **USV**, whereas sertindole and ziprasidone are inactive. Haloperidol is also inactive, even at doses that inhibit locomotor activity markedly. Sertindole, clozapine, risperidone and seroquel inhibit **AGGR**, whereas olanzapine is inactive. Haloperidol is also inactive, even at doses that inhibit locomotor activity of non-aggressive mice markedly. In conclusion, the classical neuroleptic haloperidol is inactive, and the newer antipsychotics and clozapine constitute a heterogenous group with regards to anxiolytic-like effects in rodents.

QUIPAZINE PARTIALLY REVERSED THE RHYTHM SLOWING AND FORCE DECREASING EFFECTS OF CLOZAPINE ON RATS' TONGUE MOVEMENTS DURING LAPPING BEHAVIOR. S. Das* and S.C. Fowler. Dept. of Pharmacology & Toxicology, Univ. of Kansas, Lawrence, KS 66045.

In order to investigate the putative role of serotonin receptor blockade in the slowing of rats' lick rhythm induced by low doses of clozapine (Das & Fowler, Psychopharmacology, 1995), the nonselective serotonin agonist quipazine was administered to rats treated acutely with clozapine. Thirsty rats (n=29) were trained to lap water from a force-sensing disk in 2-min sessions, and Fourier analysis of the resulting force-time recordings provided for the quantification of lick rhythm. By itself, quipazine (0.25, 0.5, 1.0, 2.0 mg/kg, ip. 30 min) significantly quickened the lick rhythm at the lowest 3 doses. Clozapine (1.5, 3.0 mg/kg, ip., 30 min) robustly reduced lick rhythm, and quipazine coadministration partially, but significantly reversed the clozapine-induced slowing. The results were consistent with the hypothesis that serotonin receptors are involved in clozapine's effects on rats' orolingual behavior. Supported by MH43429.

827.12

A SINGLE INJECTION OF IBOGAINE PRODUCES SIGNIFICANT ELEVATIONS IN CORTICOSTERONE LEVELS AND SELECTIVE CHANGES IN THE DOPAMINERGIC SYSTEM IN RAT BRAIN. S.F. Ali*, G.D. Newport, W. Slikker, Jr., R.B. Rothman and M. H. Baumann Neurochemistry Laboratory, Division of Neurotoxicology, NCTR/FDA, Jefferson, AR 72079, and Addiction Research Center, NIDA, Baltimore, MD 21224.

Recently, we reported that a single injection of ibogaine (IBG) produced significant alterations in nitric oxide synthase activity and monoamines levels in mouse brain. Other reports suggest that IBG has moderate binding affinity for the opioid receptors (kappa and sigma). The neurochemical mechanism(s) and its role as a treatment medication for drug addiction is still unclear. The present study was designed to evaluate the effect of IBG on corticosterone levels and the dopaminergic system. Adult SD rats were dosed with 50 mg/kg IBG, ip, and sacrificed 15, 30 minutes 1, 2 and 24 hr later. Trunk blood was collected for hormone levels and brain was dissected for neurochemical analyses. IBG produced significant elevations in corticosterone levels 15 minutes after drug administration that increased with time up to 2 hr and returned to control levels 24 hr after dosing. Dopamine (DA) concentrations in striatum decreased significantly at 30 minutes, 1 and 2 hr after drug administration, however, it returned to control levels at 24 hr. DA metabolites DOPAC and HVA concentration increased in a time dependent manner up to 2 hr. At 24 hr DOPAC concentrations were below control values whereas, HVA returned to control levels. Concentrations of serotonin and its metabolite 5-HIAA were decreased only at 1 hr after the dose administration. These data suggest that a single injection of IBG can produce significant elevations of corticosterone and depletion of DA in a time-dependent manner. Future experiments will determine if these effects are mediated through the kappa or sigma receptors.

THE PUTATIVE 'ENDABUSE' IBOGAINE INTERACTS WITH THE PCP AND SIGMA BINDING SITES IN RAT BRAIN. Yossef Itzhak* and Syed F. Ali, University of Miami School of Medicine, Miami FL 33101 and Division of Neurotoxicology, NCTR/FDA, Jefferson, AR 72079.

Although the alkaloid ibogaine is a potent hallucinogenic agent some indications suggest that it may be useful for the treatment of opioid and cocaine addiction. The neurochemical mechanism(s) underlying ibogaine effects remain unclear. In the present study we investigated the interaction of ibogaine with the PCP site located in the ionophore of the NMDA receptor complex, with the NMDA receptor binding site, and with sigma binding sites. In well-washed membrane preparations of rat *cortex* and *cerebellum*, the PCP sites were labeled with [^{3}H]MK-801 or [^{3}H]TCP, and the NMDA receptor with [^{3}H]CGP 39653. The sigma-1 and sigma-2 binding sites in rat cortex and cerebellum were labeled with [^{3}H]pentazocine and [^{3}H]DTG, respectively. Results indicated that ibogaine interacts with High and Low affinity PCP binding sites in the cortex: Ki(H) = 0.01-0.05 μM; Ki(L)=2-4 μM, and only with low affinity sites in the cerebellum: Ki=2-4 μM. In contrast, ibogaine (> 100 μM) had no affinity for [^{3}H]CGP 39653 binding sites (cortex and cerebellum). The affinity of ibogaine for sigma-1 and -2 binding sites in cortex and cerebellum ranged from 1.5 - 3 μM. Since NMDA receptor antagonists (e.g., MK-801) are thought to attenuate opiois withdrawal symptoms and cocaine sensitization, it is possible that binding of ibogaine to the PCP sites contributes to its potential 'endabuse' properties. In turn, ibogaine interaction with sigma binding sites may be associated with its adverse effects.

827.14

DANTROLENE DIMINISHED FORELIMB FORCE EMISSION IN A PRESS-WHILE-LICKING BEHAVIORAL TASK. J.A. Stanford* and S.C. Fowler. Dept. of Human Development, Univ. of Kansas, Lawrence, KS 66045.

The peripherally acting striate muscle relaxant, sodium dantrolene, was evaluated as a potential means for modeling reduced muscle tone in freely behaving rats. Animals were trained to use a single forelimb to exert continuous downward pressure on a force-sensing operandum, and water reward was made available to the rat as long as forelimb force was maintained above 20g. Dantrolene (5.0, 7.5, 10.0 mg/kg, ip., 45 min before sessions) significantly and dose-dependently reduced the rats' force output during the hold, but not the initiation segment of forelimb responses. Fourier analysis of the hold segment force-time records indicated that dantrolene diminished power above 5 Hz, but did not slow the oscillatory phenomena quantified by this method. Time on task was not affected by these doses of dantrolene. Together the data suggest that dantrolene can reduce striate muscle force production at doses that have negligible motivational consequences.

EFFECTS OF CHRONIC LITHIUM, VALPROIC ACID, AND CARBAMAZEPINE ON THE EXPRESSION OF THE PKC SUBSTRATE MARCKS IN IMMORTALIZED HIPPOCAMPAL CELLS. D.G. Watson[1]*, R.K.McNamara[1], and R.H. Lenox[1,2,3]. Departments of Psychiatry[1], Pharmacology[2], and Neuroscience[3], University of Florida College of Medicine, Gainesville, FL 32610.

Studies in our laboratory and others have provided evidence for a role of PKC in mediating the effects of chronic lithium in the brain (Manji and Lenox, 1994). We have previously reported that chronic lithium alters the expression of a major PKC substrate, MARCKS (**M**yristoylated **A**lanine-**R**ich **C**-**K**inase **S**ubstrate), in both rat hippocampus (Lenox *et al*, 1992), and in immortalized hippocampal cells in culture (Lenox *et al*, 1993). In addition, exposure to phorbol esters also induces a rapid down-regulation of MARCKS protein via a PKC-dependent mechanism (Watson *et al*, 1994). In the present investigation we have compared the effects of chronic exposure to the anti-manic agents lithium, valproic acid, and carbamazepine, on the expression of MARCKS protein in immortalized hippocampal HN33 cells. HN33 cells were grown in inositol-free DMEM media supplemented with 5% fetal bovine serum. Following exposure to lithium chloride (1-10mM), sodium valproate (0.5-1.5mM), and carbamazepine (2.5-100μM), cells were collected, fractionated into soluble and membrane fractions, and MARCKS protein assayed by western blot analysis. Both lithium chloride and sodium valproate exposure produced a significant dose-dependent reduction in MARCKS protein in both the soluble and membrane fractions, following long-term exposure (3-7 days). No alterations in MARCKS protein levels were observed following acute exposure to either agent. In contrast, no changes in MARCKS protein levels were detected following long-term exposure to carbamazepine. Regulation of MARCKS protein may represent a pharmacological property shared by mood stabilizers with therapeutic efficacy in the prophylactic treatment of manic-depressive illness. (Supported by NIMH grant MH50105).

CPP AND NBQX FAIL TO POTENTIATE DOPAMINE D1 AND D2 AGONIST-INDUCED RESPONSES IN THE 6-OHDA MODEL OF PARKINSON'S DISEASE. A.T. Shropshire* and K.L. Marquis. Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543.

Loschmann et al. (J Neural Transm (1992) [Suppl] 38:55-64) proposed that AMPA antagonists may be useful for the symptomatic treatment of Parkinson's disease. Additionally, Wachtel et al. (Neuroscience Letters, 142 (1992) 179-182) proposed that AMPA antagonists and competetive NMDA antagonists may be suitable as adjuvants for the treatment of Parkinson's disease. This was based on (i) the amelioration of parkinsonian symptomology in the MPTP-treated marmoset upon co-administration of the selective AMPA antagonist NBQX and the competetive NMDA antagonist CPP with threshold doses of l-DOPA, and (ii) the potentiation, by NBQX and CPP, of the turning responses produced by threshold doses of the dopamine agonists, apomorphine and lisuride, in substantia nigra lesioned rats. In the current experiment, we examined the effect of combinations of the dopamine D1/D2 agonist, apomorphine, and the D2 agonist, quinpirole, with different doses of NBQX and CPP on turning behavior in rats with unilateral 6-OHDA lesions of the substantia nigra. Our results fail to support the hypothesis of Loschmann et al. or Wachtel et al. Neither NBQX (0.4 and 1.56 mg/kg ip) nor CPP (0.1 and 0.4 mg/kg ip) potentiated the turning behavior produced by apomorphine (0.05 mg/kg ip or sc) or quinpirole (0.05 mg/kg ip). Both antagonists slightly reduced the dopamine agonist-induced turning in substantia nigra lesioned rats. These results tend to lend support to the findings of Morelli and Di Chiara (Eur J Pharmacol, 182 (1990) 611-612) that blockade of NMDA transmission reduces D2 responses. However, we found no evidence to support their claim that blockade of NMDA transmission potentiates D1 responses in the 6-OHDA model of Parkinson's disease.

PROGESTERONE METABOLISM IS REGULATED BY CARBAMAZEPINE VIA EFFECTS ON 5α-REDUCTASE IN C6 GLIOMA AND NEUROBLASTOMA CELLS. B.S.Pan*, H.K.Manji and W.Z.Potter, Section of Clinical Pharmacology, ETB, NIMH, NIH, Bethesda, MD 20892

Despite the widespread use of carbamazepine (CBZ) in the treatment of both neurological and psychiatric disorders, its mechanisms of action remain to be elucidated. In recent years, considerable research has demonstrated significant effects of neuroactive steroids on the regulation of neuronal excitability. It is thus noteworthy that we have previously demonstrated that CBZ increases the levels of pregnenolone (a precursor of neuroactive steroids) in a time- and dose-related manner in C6 cells. Although preliminary evidence suggests that these effects may be mediated via peripheral-type benzodiazepine receptors, CBZ has also been postulated to interact with 5α-reductase, the enzyme which converts progesterone to 5α-dihydroprogesterone (DHP); since DHP plays an important role in regulating neuronal activities, we investigated the effect of CBZ on progesterone metabolism in both cultured rat C6 glioma cells and in neuroblastoma cells (since 5α-reductase activity is higher in neurons). We have found that CBZ alters 5α-reductase activity and therefore the ^{3}H-progesterone conversion rate in both C6 cells and neuroblastoma cells. The mechanism(s) by which CBZ regulates 5α-reductase activity, and the potential differences of progesterone conversion in neuronal and glial cells is currently under investigation.

NON-COMPETITIVE NMDA ANTAGONISTS IMPAIR SPATIAL DELAYED ALTERNATION PERFORMANCE IN RATS: REVERSAL BY ANTIPSYCHOTICS, Anita Verma* and Bita Moghaddam, Department of Psychiatry, Yale University School of Medicine, VA Medical Center 116A/2, West Haven, CT 06516

In the present study, the effect of non-competitive NMDA antagonists on a prefrontal cortex (PFC) sensitive task was examined using a spatial delayed alternation (SDA) paradigm in rats. In addition, *in vivo* microdialysis was used to assess the effect of exposure to ketamine on extracellular dopamine levels in PFC and striatum. The non-competitive NMDA antagonists, ketamine (10, 20 and 30 mg/kg) and MK 801 (0.1 and 0.5 mg/kg), impaired the SDA performance as illustrated by the decrease in the number of correct responses during sessions with 15 sec inter-trial interval, as compared with the corresponding vehicle-treated control group. A significant increase in extracellular levels of dopamine was observed in PFC as compared with striatum following ketamine (30 mg/kg) administration. The disruptive effect of ketamine on SDA performance was reversed by haloperidol (0.1 mg/kg) but not by SCH 23390 (0.1 mg/kg). Raclopride (0.1 and 0.5 mg/kg) produced partial reversal of ketamine-induced impairment of spatial working memory performance. These data suggest impairment of PFC-sensitive SDA performance by non-competitive NMDA antagonists. A modulatory role for dopamine receptor subtypes in ketamine-induced disruption of spatial working memory is also suggested.

828.1

NEUROPHYSIOLOGICAL AND BEHAVIORAL EVALUATION OF TREMBLER MICE BETWEEN 1 AND 2 MONTHS OF AGE. J.A. Gruner* and A.K. Yee. Dept. of Pharmacology, Cephalon, Inc., West Chester, PA 19380.

The Trembler mouse (heterozygous TR-J+, Jackson Laboratories) is considered a model of Charcot-Marie-Tooth (CMT) disease. Both humans with CMT and Trembler mice have homologous mutations in the PMP-22 gene (Suter et al., *TINS 16*:50, 1993). Functional impairment of TR-J+ and wild type littermates was assessed at 37, 51, and 65 days of age to determine whether the relative age of onset and progression of the pathology were similar in mice and humans. Behavioral impairment was assessed by determining the latency for mice to traverse a 60 cm x 19mm rod. Electrophysiological measures included conduction velocities (CV) and amplitudes of sciatic, sural, and caudal nerves. Behavioral and electrophysiological deficits in Trembler mice were apparent at 37 d of age and did not markedly progress (see table; *= $p<0.05$ vs control). Behavioral impairment in TR-J+ mice was indicated by an increased latency to traverse the rod. Conduction velocity deficits for sural and caudal nerves were similar to those shown below for the sciatic n. Amplitude measures for all three nerves were reduced by 68% or more in TR-J+ mice and did not significantly change over time.

Measure	Rod Latency (s)			Sciatic CV (m/s)		
Age	37d	51d	65d	37d	51d	65d
TR-J+	6.5±1.0*	5.2±0.8*	5.5±0.5*	6.2±0.3*	6.9±0.3*	7.8±0.6*
control	3.1±0.6	1.8±0.2	2.0±0.1	24.5±1.8	29.8±0.2	30.1±1.2

In contrast to these data, human neurological symptoms of CMT typically are not seen until late childhood and progress to moderate disability by age 30. We conclude that the Trembler mouse may be an appropriate model for assessing the ability of agents to reverse the neurologic deficits of CMT. However, since neurological deficits in the Trembler mouse appear early and fail to progress, this model is inappropriate for evaluating agents intended to affect the pathogenesis of CMT.

828.2

ALTERED SCHWANN CELL PHENOTYPE ASSOCIATED WITH PMP-22 PRODUCTION IN TREMBLER-J MICE. L. Notterpek, G.J. Snipes* and E.M. Shooter. Depts. of Neurobiol. and Neuropathol., Stanford Univ. Sch. of Med., Stanford, CA 94305

Peripheral myelin protein (PMP-22) is a Schwann cell glycoprotein found in compact myelin of the peripheral nervous system. Mutations, duplications or deletions of the PMP-22 gene are associated with peripheral neuropathies in mouse and human. The Trembler-J (Tr-J) mouse mutant carries the same single point mutation that has been identified in an affected human pedigree. Tr-J animals show severe hypomyelination and reduced steady-state levels of PMP-22 mRNA. The specific aim of our studies is to determine how the Tr-J mutation alters normal processing of PMP-22. Genotyped Tr-J Schwann cells were isolated and cultured in parallel with normal litter mates. Compared to normals, Tr-J Schwann cells exhibit distinct morphology and decreased rate of proliferation when cultured in the presence of forskolin and glial growth factor. Double immunolabeling with polyclonal PMP-22 antisera and monoclonal organelle markers indicate differences in the level and localization of PMP-22 in Tr-J Schwann cells. In normal Schwann cells PMP-22 levels are low and the highest level of immunoreactivity is concentrated in the perinuclear region of the ER. In Tr-J, intense PMP-22 like immunoreactivity extends throughout the cytoplasm, including apparent colocalization with lysosomal structures. These data suggest that increased levels of PMP-22 protein (mutant and wild-type) are associated with decreased proliferation of Tr-J Schwann cells in culture. Studies are in progress to identify further differences in processing and translocation of normal and mutated PMP-22 protein when Schwann cells are cocultured with dorsal root ganglion neurons and induced to myelinate.

CORTICAL GLIA FROM TS16 TRISOMIC MICE REDUCE CHOLINERGIC EXPRESSION IN CULTURED NEURONS. P.G. Nelson, D.v. Agoston, S.C. Fitzgerald. Lab. Dev. Neurobiol., NICHD, NIH; S. Rapoport*, Z. Galdzicki, Lab. Neurosci., NIA, NIH, Bethesda, MD 20892.

Cultures of mouse ventral spinal cord express choline acetyltransferase (ChAT), detected as enzyme activity in homogenates or immunocytochemically in individual neurons. Glia-neuron interactions important for neuronal survival and cholinergic expression have been demonstrated in this system. We studied cholinergic expression of cultured neurons grown on cerebral cortical glia derived from either normal or TS16 trisomic animals. The TS16 trisomy is of particular interest in that it is homologous to the human Trisomy 21 (Down syndrome). The ChAT enzymatic activity of neurons grown in the TS16 glia was reduced to 54% of control values. Total neuronal counts were no different in the two conditions. TS16 neurons grown on TS16 glia expressed ChAT levels 37% of normal. When TS16 neurons were grown on normal glia, ChAT levels were 63% of normal. This was significantly greater than the values for TS16 neurons growing on TS16 glia. We hypothesize that glial cells derived from TS16 animals are either deficient in some cholinergic trophic agent or, more probably, produce some material with a negative effect on neuronal function with some specificity for cholinergic neurons.

828.4

MONOCYTE RECRUITMENT IN BRAINS OF TRANSGENIC MICE EXPRESSING MONOCYTE CHEMOTACTIC PEPTIDE-1 (MCP-1) IN THE CENTRAL NERVOUS SYSTEM. M.E. Fuentes, M.R. Swerdel, S. Durham, M. Barbacid*, R. Bravo, S. Lira. Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ 08543.

It has been postulated that chemokines mediate cell migration to the central nervous system (CNS) during pathological conditions. Monocyte chemoattractant peptide (MCP-1), a member of the C-C chemokine subfamily, has been shown to have a potent chemoattractant activity for monocytes *in vitro* and to be expressed during the development of experimental immune encephalomyelitis, an animal model of multiple sclerosis. In order to study the biological role of MCP-1 *in vivo*, and to examine its role in the development of brain inflammation, we developed a transgenic model system in which MCP-1 expression is driven by the myelin basic protein promoter. In such transgenic mice, we observed maximal transgene expression (RNA) at three weeks of age throughout the white matter, as expected for this oligodendrocyte-specific promoter. Coincident with the temporal and spatial pattern of transgene expression, we found a significant infiltration of mononuclear cells. The recruited cells were predominantly perivascular in orientation with a modest degree of parenchymal infiltration. The vast majority of the cells recruited were monocytes/ macrophages, according to histological and immuno-histochemical criteria.

These results clearly demonstrate that MCP-1 can direct monocyte trafficking *in vivo*. Furthermore, they establish these transgenic mice as important models to study inflammatory cell recruitment to the CNS and the involvement of chemokines in the ethiopathology of inflammatory brain disease.

828.5

GENOTYPIC INFLUENCES ON CYTOKINES EXPRESSION IN ASTROCYTES. THE ROLE OF THE COMPLEMENT COMPONENT C5. M.G. De Simoni[1], P. Mascarucci[1], T.H. Hogan[2], S.A. Johnson[3*] and G.M. Pasinetti[2]. [1]Mario Negri Research Institute, Via Eritrea 62, Milano, Italy 20157; [2]Division of Neurogerontology, Andrus Gerontology Center, USC, Los Angeles, CA 90089; [3]Cortex Pharmaceutical, Irvine, CA 92718.

Many proinflammatory complement (C) components are associated with amyloid deposits in Alzheimer disease (AD) brain. However, the role of C in AD is little understood and may be pertinent to the recruitment and activation of inflammatory cells. Because astrocytes express C5a receptor (C5aR) and because of the C5 derived anaphylatoxin C5a control of cytokine expression in peripheral cells, we further explored the secretion of TNF and IL-6 in astrocytes of C5 deficient ($C5^-$) mice and compared with astrocytes from congenic C5 sufficient ($C5^+$) mice. We found that monotypic cultures of cortico-hippocampal astrocytes originated from neonatal $C5^-$ mice secrete >8 times more TNF and IL-6 than astrocytes from congenic $C5^+$ mice 24 hrs after endotoxin stimulation (10 μg/ml). No detectable TNF and IL-6 signal was found in conditioned medium of control endotoxin free astrocyte cultures of both genotypes. These data suggest that the lack of C5 (C5a?) might predispose astrocytes to a more reactive state in vitro. These data are consistent with the >2 fold higher induction of the astrocytic markers GFAP and apoE mRNAs in hippocampus of $C5^-$ mice following excitotoxic kainic acid lesions, compared to $C5^+$. These studies give basis for further exploration of the role of recombinant and native C5a anaphylatoxins on cytokine gene expression, glial activation in C5aR knockout mice. This work was supported by the Nathan W. & Margaret T. Shock Aging Research Foundation to GMP.

GENOMIC IMPRINTING AND AUDIOGENIC SEIZURES IN MICE. M.Banko, K.Allen , S.Dolina, P.Neumann and T.N.Seyfried*Boston College, Boston MA 02167.

Audiogenic seizures (AGS) are severe convulsions induced in some strains of mice by loud, high-frequency sound. AGS susceptibility in DBA/2J (D2) mice is maximum at 21 days of age and gradually subsides with adulthood. Epilepsy prone (EP) mice were selected for high AGS susceptibility in a BALB/c line. Unlike D2 mice, EP mice are maximally AGS susceptible at 30 days of age, and this susceptibility persists into adult ages. The seizure phenotype is similar in both the EP and D2 mice. Crosses were generated between the EP and D2 mice to determine the genetic mechanisms that may account for the difference in seizure susceptibility at 30 days of age. Although EP and D2 mice exhibit high susceptibility to AGS at 30 days of age (86% and 53% seizing, respectively), the reciprocal EPD2F1 and D2EPF1 hybrids were mostly seizure resistant, (14% and 16% seizing, respectively), suggesting that AGS susceptibility in these mice is inherited as a recessive trait. In the EP X EPD2F1 backcross, significant associations were found between AGS susceptibility and several markers near Asp-3 on proximal Chromosome 7. In the reciprocal EPD2F1 X EP backcross, however, no significant associations were found between AGS susceptibility and these markers. These data suggest that genomic imprinting may influence the expression of gene(s) on Chromosome 7 involved with AGS susceptibility. Moreover, these findings indicate that different genetic factors are responsible for AGS susceptibility in the EP and D2 mice, further substantiating interallelic heterogeneity for audiogenic seizure susceptibility in mice. PROGRESSIVE COGNITIVE IMPAIRMENT IN DISCRIMINATED AVOIDANCE PERFORMANCE IN GFAP-IL6 TRANSGENIC MICE. L.H. Gold*, C.J. Heyser and I.L. Campbell. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Transgenic mice that express the pro-inflammatory cytokine IL-6 in the CNS under the regulatory control of the glial fibrillary acidic protein promoter (GFAP) develop progressive neurodegenerative disease. The relationship between the neurological disease exhibited by these mice and functional neurobehavioral outcomes was examined. Heterozygous or homozygous GFAP-IL6 mice and control littermates were repeatedly tested at different ages in a Y-maze task for their ability to learn a nonconditional spatial discrimination to avoid the onset of a mild footshock (5 trials/day for 6 days). Both the number of correct avoidances and errors were used as an index of learning performance. When tested at 3 months of age heterozygous mice were able to learn at the same rate as control mice, whereas homozygous mice were significantly slower to acquire the avoidance response. At 6 months of age, heterozygous mice exhibited a deficit in the ability to learn the avoidance response intermediate to that of the controls and homozygotes. At 12 months of age the performance of both heterozygous and homozygous mice had declined even further. At this age both groups failed to demonstrate acquisition of the avoidance response and made significantly more errors when compared to age-matched controls and their own performance at 3 and 6 months of age. No correlation was observed between motor function/coordination and the impaired learning ability of the transgenic groups and no differences were observed between the groups in a test of shock sensitivity. These data demonstrate a progressive learning disability in the GFAP-IL6 mice which is correlated with the progressive neuropathological changes observed in these animals and is not consequent to impaired motor or somatosensory function.

EFFECT OF THE WEAVER MUTATION ON THE EXPRESSION OF DOPAMINE TRANSPORTER IN NEURONS OF THE SUBSTANTIA NIGRA PARS COMPACTA. C. Adelbrecht, Y. Agid and R. Raisman-Vozari*. INSERM U 289, 75013 Paris, France.

Under physiological conditions, the reuptake dopamine transporter (DAT), located at the plasma membrane, is responsible for dopamine (DA) transport from the synaptic cleft back into the cytoplasm, where they may be repackaged by the vesicular transporter (VAT) into storage organelles, enabling further removal of DA from the synaptic cleft and protection from degradation. Thus, DA transporters play an important role in neurotransmission and could be targets for pathological and/or pharmacological agents. Although the mechanisms involved in dopaminergic cell loss in the homozygous weaver mice (wv/wv) are still unknown, the earliest and largest defect of the dopaminergic system is the decrease in striatal DA uptake (Simon et al., J. Neurochem. 62,543,1994). The cause of this decrease remains unclear but it could be the consequence of an abnormal expression of uptake- and/or storage-related proteins induced by the weaver mutation. Quantitative in situ hybridization of DAT, VAT and tyrosine hydroxylase (TH) mRNAs, carried out on surviving DA cells of the substantia nigra pars compacta (SNC) from two months old weaver mice (wv/wv) showed a significant decrease of DAT expression (-60%) when compared to normal control mice (+/+). DAT mRNA also decreases in SNC cells in heterozygous weaver mice (wv/+) although differences are not significant. In contrast the expression of VAT and TH mRNAs was not affected in the remaining DA neurons of the weaver mice (wv/wv). The specific decrease of DAT mRNA in the surviving neurons of the adult weaver mice could result from a feed-back regulation due to a deficient interaction between dopaminergic nerve terminals and striatal targets. Nevertheless, a genetic alteration of DAT can not be excluded. Studies of DAT expression at early stage during post-natal development are now underway to answer these questions.

A NEW SPONTANEOUS MOUSE MUTATION RESEMBLING HUMAN NIEMANN-PICK TYPE C DISEASE. B. Kosaras, A. Li and R.L. Sidman* Div. of Neurogenetics, New England Regional Primate Research Center, Harvard Medical School, Southborough, MA 01772-9102.

Several filial generations after a C57BL/6J x BALB/cByJ cross, a single female mouse in a litter of five was noted at 45 days of age (P45) to show weakness of hindlimbs, tremor, and instability of gait. The motor disorder progressed, the mouse lost weight, and died at P90. Similarly affected mice of both sexes were produced by her sibs, and in subsequent generations in this pedigree. Affected mice have not generated offspring, but the 23/109 affected progeny to date from phenotypically normal carriers strongly suggests autosomal recessive inheritance. At autopsy, the liver color is pink to yellowish-white. Many liver cells are enlarged with multiple vacuoles and granules, some staining with sudan black B for lipids and with the fluorescent filipin reagent for unesterified cholesterol. Macrophages rich in cytoplasmic granules are prominent in spleen, lymph nodes, and lung. Large cells in bone marrow smears showed intense cytoplasmic fluorescence with filipin. Staining of paraffin sections of formalin-fixed tissues with the periodic acid-Schiff method is variable from cell to cell in many organs, but is never strong. Brain weight was about 80% of normal. Somas and dendrites of large neurons in dorsal root ganglia, spinal cord, cerebellum, cerebral cortex and retina were distended with lysosome-sized granules that vary in EM appearance from membrane-bound homogeneous organelles to granules rich in myelin-like membranes. Many myelinated and unmyelinated axons in CNS and PNS are dramatically distended focally to 5–10 times their normal diameter with similar granular inclusions. Cerebellar Purkinje cells are reduced in number. These features are consistent with descriptions by others of mouse and human inherited disorder(s) classified as Niemann-Pick Type C disease. Chemical, genetic and tissue culture tests are in progress.

828.10

CHROMOSOME LOCALIZATION OF THE NEUROLOGICAL MOUSE MUTATIONS TOTTERING (*tg*), PURKINJE CELL DEGENERATION (*pcd*), AND NERVOUS (*nr*). D.B. Campbell* and E.J. Hess. Department of Neuroscience & Anatomy, The Pennsylvania State University College of Medicine, Hershey Medical Center, Hershey, PA 17033.

Tottering (*tg*), Purkinje cell degeneration (*pcd*), and nervous (*nr*) are all recessive neurological mutations in the mouse. The mutated gene has been identified in none of these mutants. Positional cloning allows the identification of mutant genes without *a priori* knowledge of the biochemical function of the gene product or the anatomical site of mutant gene expression. Instead, this cloning method identifies abnormal genes based on their physical location in the genome. However, a major rate-limiting step in positional cloning has been the identification of an exact chromosomal location for the gene of interest. We have developed a strategy to rapidly identify the precise chromosomal regions containing the mutant genes of interest. Our strategy takes advantage of the existence of congenic strains: many mutations in the mouse arose spontaneously in one inbred strain and were subsequently backcrossed onto a different inbred strain. After several generations of backcrossing, the only DNA retained from the original strain should be that immediately surrounding the mutant locus; this DNA is readily distinguishable by simple sequence length polymorphisms (SSLPs) between the original strain and the backcross strain. By screening SSLPs in congenically bred mutant mouse strains, we have pinpointed the chromosomal locations of *tg*, *pcd*, and *nr*. The *tg* mutation lies within the 1.1 centimorgan (cM) interval distal to *D8Mit103* and proximal to *D8Mit79*, *D8Mit105*, and *D8Mit283* on mouse chromosome 8. The *pcd* locus maps to the 3.8 cM region between *D13Mit140* and *D13Mit67* on chromosome 13. The *nr* locus maps between *D8Mit155* and *D8Mit18*, a 5.6 cM interval of chromosome 8. In addition to providing specific map positions for these loci, the tightly-linked molecular markers also allow genotyping of *tg*, *pcd*, and *nr* mutant pups, making feasible developmental studies of the late-onset neurological phenotypes caused by these mutations. A PRELIMINARY EXAMINATION OF THE ROLE OF LTP/LTD IN AMYGDALA KINDLING USING TRANSGENIC CaMKII-Asp 286 MICE. D.P. Cain* and Mark Mayford. Dept. Psychology/Neuroscience Program, Univ. Western Ontario, London, N6A 5C2 Canada and Howard Hughes Medical Institute/Dept. Neurobiology and Behavior, Columbia Univ., 722 West 168th St., New York, N.Y. 10032.

The role of long term potentiation (LTP) has been hypothesized to be important in the kindling model of epileptogenesis. The role of long term depression (LTD) in kindling is not known. The availability of a line of transgenic mice with a mutant form of calcium calmodulin-dependent protein kinase II, resulting in the production of LTD instead of LTP in response to 5-10 Hz stimulation (Mayford et al., submitted), allows an examination of the role of LTP/LTD in epileptogenesis. Therefore we surgically implanted indwelling electrodes into the amygdala and applied a 1-sec train of pulses once daily to evoke after-discharge (AD), a predominant frequency of which was in the 5-10 Hz range. The duration of evoked AD was nearly twice as long in mutants as in wild-type mice in both the stimulated and contralateral amygdala. Despite this, the rate of kindling to the first generalized convulsion did not differ between the groups (mutants = 12.0 ADs, wild-type = 10.9 ADs). The kindled state was retained equally well by the two groups after a 4-wk stimulation-free interval. These results indicate a partial disconnection between AD duration and rate of kindling development. This suggests that a reduction in LTP associated with epileptiform spiking in the range of 5-10 Hz may be linked with the failure of the mutants to develop kindled seizures more rapidly than wild-type mice. Supported by NSERC and HHMI.

TARGETING OF THE DOPAMINE D_3 RECEPTOR GENE IN EMBRYONIC STEM CELLS: ENRICHMENT FOR HOMOLOGOUS RECOMBINATION BY DESTABILIZING SELECTION MARKER TRANSCRIPTS FROM RANDOM INTEGRATION SITES. B.V. Skryabin* and C. Schmauss. Dept. Psychiatry & Brookdale Center for Molecular Biology, Mt. Sinai Sch. of Med., New York, NY 10029.

Successful gene targeting by homologous recombination is largely determined by the relative frequency of homologous vs. non-homologous recombination events. A widely used selection method for homologously recombinant ES cells is a positive-negative selection (PNS) which typically involves the placement of the thymidine kinase (TK) gene outside of the targeted homology and the addition of antiviral drugs to the ES cell-selection media. However, the toxicity of such drugs (gancyclovir or FIAU) is thought to impair the ability of ES cells to colonize the germ line. An alternative to the use of antiviral agents in conjunction with G-418 for PNS is to destabilize only that portion of the neomycin phosphotransferase II mRNA that derives from random integration sites (positive selection). We have targeted the dopamine D_3-receptor gene locus in mouse ES cells with 5 different replacement targeting vectors. Four vectors contained one of the following sequence elements that are thought to destabilize the neomycin-resitance-gene (neo^r) transcript: 1.) A poly (A^+) less neo^r-cassette; 2.) a neo^r ribozyme with proven catalytic activity, 3.) a mutant ribozyme placed outside of the targeted homology (control); and 4.) an antisense neo^r sequence. A control vector contained the TK gene placed outside of the targeted homology. Our initial results indicate that these strategies are effective alternatives to the selection with antiviral agents. GENE TRANSFER AND THE EXPRESSION OF AN EXOGENOUS GENE IN VIVO USING THE HEMAGGLUTINATING VIRUS OF JAPAN–LIPOSOME METHOD. K. Kato [a,b], and S. E. Fraser[b,*a] Nara Institute of Science and Technology, 8916-5 Takayama, Ikoma, Nara, 630-01, Japan; [b]Division of Biology, Caltech, Pasadena, CA 91125.

We have established a simple and efficient method for gene transfer in vivo in post-mitotic neurons of adult rat brain using nuclear protein, liposomes, and hemagglutinating virus of Japan (HVJ; sendai virus). Simple plasmid DNA and nuclear protein (HMG1: non-histone chromosomal protein high mobility group 1) that co-encapsulated in liposomes were co-introduced into cells by HVJ-mediated membrane fusion. The DNA was then carried into the nuclei of nondividing cells with the aid of the nuclear transport system of HMG1.

HVJ-liposomes containing the *E.coli* β-galactosidase gene under control of a chicken β-actin promoter were stereotaxically injected into various brain areas of adult rats, such as hippocampus, cerebellum, cerebral cortex, or caudate putamen. Neuronal cells that expressed the β-galactosidase gene were detected only in the target area of the injected brain of adult rat for 10 days by light microscopic analysis. Electron microscopic analysis revealed that the product of the histochemical reaction were associated with the nuclear membrane and the endoplasmic reticulum of positive cells; it appeared that the products were translated endogenously. Moreover, the products were observed in typical neuronal cells with large, round, and pale nuclei, and with direct axo-somatic and axo-dendritic synaptic contacts.

We are currently applying this system to investigate rhombomere development in the chicken embryo hindbrain.

DIRECT cDNA SELECTION BY HYBRIDIZATION OF MOUSE CEREBELLAR LIBRARIES AGAINST MICRODISSECTED DNA POOLS FROM THE MMU16 C3-C4 REGION. J.J. Wei, M.E. Hodes, Y. Wang, Y. Feng, B. Ghetti and S.R. Dlouhy*, Depts. of Pathology and Lab. Medicine and of Med. and Mol. Genetics, Indiana Univ. Sch. of Med., Indianapolis, IN 46202.

The distal one third of mouse chromosome 16 is homologous to a part of human chromosome 21 and contains the murine mutant *weaver* (*wv*). The molecular basis of this disorder remains unknown. In this study, cDNA segments were selected directly by hybridization of newborn mouse cerebellar cDNA against genomic DNA pools generated by microdissection of the MMU16 C3-C4 region. Following two rounds of PCR-based DNA-cDNA hybridization, cDNA fragments were cloned into PCR II. About 15% of 300 recombinants analyzed do not contain repetitive sequence and 75% of these unique sequences were mapped to the microdissected chromosome by analysis of somatic cell hybrids and/or by genetic linkage analysis. More than 60% of such cDNA clones (as assessed by RT-PCR) represent transcripts that are expressed in adult mouse cerebellum and northern blots show that some of these are brain- specific. The cDNAs should be useful reagents for further neuromolecular studies (e.g., as *wv* candidates). One selected cDNA clone appears to represent the glutamate receptor, Glur5, which is specifically expressed in postnatal mouse cerebellum and was mapped previously to MMU16. Seventeen of our cDNAs have been mapped genetically within a 20 cM interval on distal MMU16. We conclude that direct cDNA selection from microdissected materials is a practical way of constructing a transcription map of this region. (Supported by USPHS P01 NS27613 and R01 NS14426)

CYTOCHROME OXIDASE ACTIVITY IN THE NAPLES HIGH- AND LOW-EXCITABILITY RAT LINES: A STUDY OF BRAIN ACTIVITY DIFFERENCES IN A GENETIC MODEL. K. Nixon*, D. Hu, F. Gonzalez-Lima, and A.G. Sadile[1] Dept. of Psychology and Inst. for Neuroscience, University of Texas at Austin, Austin, TX, 78712, USA; [1]Inst. of Human Physiol., 1st Medical School, University of Naples, Naples, Italy.

Quantitative Cytochrome Oxidase (C.O.) histochemistry, a metabolic marker for neural activity, was used here, for the first time, to detect functional brain differences between three different genotypes. The Naples High-Excitability (NHE) and Naples Low-Excitability (NLE) rat lines were selectively bred according to the frequency of rearings and corner-crossings during forced exposure to spatial novelty, both of which are hallmarks of hippocampal dysfunction. Although several neuro-behavioral studies have shown these animals to be a plausible model for hippocampal function, these results need to be confirmed by other means. Using quantitative image analysis, six areas of interest within the hippocampal formation, including the CA fields, the inner blade, and the outer blade of the dentate gyrus, were sampled in naive rats. Significant differences in C.O. activity were detected between the NHE and random bred controls in the area of the inner blade of the dentate gyrus. Previous research has shown a similar decrement in activity in this same area during high behavioral arousal. These findings support the NHE and NLE rats as models for hippocampal function, and, perhaps, a generalized genetic model of hyperactivity.

ASSESSMENT OF THYMIDINE KINASE DEFICIENT HERPES SIMPLEX VIRUS TYPE 1 AS A TRANSFER VEHICLE INTO SYMPATHETIC PREGANGLIONIC NEURONS. M.A. LeVatte', G.A. Dekaban and L.C. Weaver, Neurodeg. Research Group, Robarts Research Institute, London, Ontario, N6A 5K8.

The sympathetic nervous system discretely controls blood pressure as well as blood flow to different visceral organs. Long term improvements in faulty control of discrete functional groups of spinal sympathetic preganglionic neurons (SPNs) might be accomplished by introducing corrective genes into these cells using replication-defective herpes simplex virus type 1 (HSV-1). Our initial experiments assessed the suitability of HSV-1 as a transfer vehicle into SPNs. The *Escherichia coli* β-galactosidase (β-gal) gene or the human placental alkaline phosphatase (AP) gene was inserted into the thymidine kinase gene, generating replication-defective TK-β-gal or TK-AP (thymidine kinase mutant of HSV-1 expressing β-gal or AP, respectively). To assess whether these mutants retained their neurotropic properties, TK-β-gal was directly inoculated into the spinal cord of hamsters at thoracic (T) segment 6-8. At 3 or 5 days post-inoculation, neurons and numerous oligodendrocytes in the spinal cord were infected with TK-β-gal. To target only SPNs and to assess uptake and retrograde transport of this replication defective HSV-1 into the cord, the TK-AP was inoculated into the left adrenal gland of hamsters. Two, four or five days later, the spinal cords were removed and examined for the presence of TK-AP using AP histochemistry. At 2 days, many SPNs expressing AP were found in T6-9. Very few oligodendrocytes were infected and few inflammatory infiltrates were visible upon counterstaining the cord. At 4 days, fewer SPNs expressing AP were detectable and infiltrates were present. At 5 days, very few SPNs expressing AP were found and inflammatory infiltrates were more abundant. In more preliminary experiments TK-β-gal also was retrogradely transported from the adrenal gland to the spinal cord. These studies demonstrate that a TK-HSV-1 can be retrogradely transported from the periphery to the spinal cord to transduce limited groups of SPNs specifically. Supported by MRC Canada.

DEVELOPMENTAL DISORDERS III

QUANTIFICATION AND SPECIFICITY OF HIPPOCAMPAL NEURONAL LOSS FOLLOWING NEONATAL INFECTION WITH LCMV B.D. Pearce*, S.C. Steffensen, S.J. Henriksen, M.J. Buchmeier, J.R. Baldridge, A. Paoletti, A.H. Miller Emory Univ Sch of Med, Atlanta, GA 30322; Scripps Res Inst, La Jolla, CA 92037

While a perinatal viral insult has been implicated as a potential causative factor in developmentally-derived hippocampal pathology, the mechanism by which a viral infection during development could disrupt hippocampal structure and function has not been defined. Accordingly, we infected neonatal rats i.c. with lymphocytic choriomeningitis virus (LCMV) and measured electrophysiological and neuropathological changes in the hippocampus. In rats studied at 84-102 days post infection, virus was cleared from dentate granule neurons, yet, Nissl stained cells in the dentate granule layer were decreased by 67.5% (internal limb) and 74.5% (external limb) in LCMV-infected rats. ($p<0.002$). In addition, in vivo electrophysiological measures, recorded from the hippocampal dentate granule layer in response to paired-pulse stimulation of monosynaptic afferents, revealed a marked decrement in the GABA-mediated recurrent inhibition to dentate granule cells, suggesting that dentate granule cells were receiving enhanced excitatory input, perhaps due to an early loss of GABAergic inhibitory interneurons. A subset of GABAergic interneurons in the dentate gyrus contain parvalbumin which may protect these cells from Ca^{++}-induced damage. Quantification of interneurons stained for parvalbumin revealed a 72% loss of these cells in the dentate gyrus of LCMV-infected rats ($p<0.05$). Since rats were infected prior to the developmental stage at which parvalbumin appears, immature neurons (those lacking their protective parvalbumin) may have been particularly vulnerable to the early effects of the virus. These data suggest a novel neuropathogenic mechanism involving an early virus-induced loss of inhibitory interneurons resulting in an unleashing of excitotoxic synapses on dentate granule cells (with resultant cell death), and thus perpetuation of a pathologic cascade which continues in the absence of detectable virus.

829.2

EFFECT OF CHRONIC HYPOXIA ON CORTICAL CELL NUMBERS AND VASCULAR DENSITY. W.B.Stewart*, M.A. Salvatore, V.V. Pathy, G.G. Haddad, L.R. Ment, and M.L. Schwartz. Depts of Surgery (Anatomy), Pediatrics, Neurology and Neurobiology. Yale Univ. Sch. of Med. New Haven CT 06517.

Premature infants often undergo chronic hypoxic episodes. In order to examine the effects of hypoxia on brain development, we have raised rats from postnatal day 3 to 33 in a chamber where O2 levels were controlled at 9 to 10%. The rats were sacrificed and their brains removed for a quantitative study of cells and microvessels of the neocortex. Cell counts were performed on Nissl stained sections using the optical dissector method. Neurons and glial were counted separately, using nuclear morphology to assign them provisionally to either category. Microvessels were counted using the dissector method in unstained, wet-mounted, randomly oriented cortical sections.

Hypoxic rats (N=5) had smaller cortical volumes than control rats (N=5) (127 mm3 vs 156 mm3, $p<.0.03$). Also, the density of neuronal-like cells was higher in the hypoxic rats (174,000 / mm3 vs 96,000 / mm3, $p<0.02$). Despite the smaller cortical volume, there were more of these cells in hypoxics than controls (22.2 million vs 14.9 million, $p<0.06$). By contrast, the number of glial-like cells were similar (2.6 million - hypoxic vs 2.2 million - control). Hypoxic rats had a higher density of capillaries than controls (518 cap. / mm2 vs 400 cap. / mm2, $p<0.03$).

We conclude that neonatal brain has a number of adaptive responses to hypoxia. These include increased vascular density and alterations in programmed cell death. Definitive analysis of this latter possibility is currently being examined using immunohistochemical methods to discriminate between neurons and glia. In addition, these changes in cortical volume and cell density suggest that there may also be decreases in the volume of the neuropil or the extracellular space. This work was supported by NS32578.

PRENATAL γ-IRRADIATION REDUCES PREPULSE INHIBITION OF STARTLE RESPONSE IN RATS. M. Mintz, A. Gigi, S. Ben-Eliyahu, & M. Myslobodsky*, Psychobiology Res. Unit, Dept. of Psychology, Tel Aviv Univ., Ramat Aviv, Israel

The pathophysiology of behavioral anomalies caused by prenatal irradiation is frequently obscured by the complexity of behaviors used in such studies. To simplify the experimental models we explored changes in the prepulse inhibition (PPI) in Sprague-Dawley rats submitted to whole body γ-irradiation (Theratron 780 ^{60}Co source at 1.5 Gy and a dose rate of 0.15 Gy/min) on Days 15, 17, or 19 of gestation (G). Sham-irradiated rats served as controls. At postnatal day 25 (P25), startle response was assessed to a train of white-noise bursts (122 dB; 40 msec). Following habituation, rats were exposed to a white-noise prepulse (20 dB; ISI=100 msec). At P25 all irradiated groups had higher startle response to the first noise burst compared to controls ($F_{3,36} = 4.1$, $p<.02$). In G15, startle amplitude remained elevated throughout the whole session. By contrast, other irradiated groups habituated to control level at the same rate. PPI was reduced in all irradiated groups. The retest of startle at P55, showed its facilitation in G17 and G19 groups. In G19, habituation to control levels was markedly delayed ($t_{18}=6.8$, $p<.01$). PPI remained decreased in both irradiated groups (animals irradiated on day 15 were not available for analysis) but not at statistical significance level. The possibility is discused that reduced PPI is associated with deficient telencephalic structures, perhaps the prefrontal cortex and hippocampus that are implicated in PPI of startle response.

ON THE MECHANISM OF NEONATAL TOLERANCE TO ENERGY DEPRIVATION IN CNS WHITE MATTER. B. R. RANSOM*[1] P. DAVIS & R. FERN[1,2] Dept. of Neurology[1], Yale University School of Medicine, New Haven, and Neuroscience Research Center[2], VA Medical Center, West Haven. CT.

The neonatal CNS is relatively resistant to anoxic injury. Prolonged perinatal anoxia/ischemia, however, causes neurological dysfunction by preferentially damaging white matter. We studied the mechanism of neonatal white matter resistance to anoxia/ischemia using the isolated rat optic nerve, a CNS white matter tract. Optic nerve integrity was monitored electrophysiologically by recording the supramaximal compound action potential (CAP). Neonatal nerves (P6-10) were injured as severely as adult nerves by 60 min of combined anoxia/0-glucose (ischemic conditions). This suggested that adult and neonatal nerves had a similar innate susceptibility to injury from near total energy deprivation (i.e. loss of both aerobic an anaerobic metabolism). Removal of either O_2 or glucose for 60 min, however, produced non-reversible CAP loss in adult but not in neonatal optic nerves. Susceptibility to injury from removal of O_2 or glucose developed rapidly between P10-20. Optic nerves survived if glucose was replaced by lactate, and glycogen contained in astrocytes (none is present in axons) could be a source of lactate in 0-glucose. Block of lactate transport with α-cyano-4-hydroxycinnamic acid potentiated the effect of 0-glucose in both adult and neonatal nerves, which supported this hypothesis. These data suggested that astrocytes protected axons from 0-glucose injury by exporting lactate, presumably following glycogen breakdown, via the extracellular space, to axons. This mechanism could not act to protect neonatal nerves from combined anoxia/0-glucose because lactate metabolism requires the presence of O_2. This mechanism allowed neonatal nerves to survive more effectively than adult nerves in 0-glucose, possibly because of a lower energy requirement in neonatal white matter. Although P6-10 nerves were as prone to injury from combined anoxia/0-glucose as adult nerves, preliminary data indicated that nerves from P1-4 rats were resistant to these conditions. Supported by NIH grants.

NEUROANATOMICAL ANOMALIES IN MICE EXPOSED TO PRENATAL RADIATION S.L. Schmidt* (1,2), M.H.F. Souza (1), and Y. Abreu-Vilaça (1). (1)Dept Fisiologia, Universidade do Estado do Rio de Janeiro, RJ, 20551030, Brasil. (2)Dept. Psychology, University of Alberta, Canada.

In adult mice, prenatal ionizing irradiation at 16, 17 and 19 days of gestation with 3Gy causes reduction of the corpus callosum (CC). Here, we reported the short-term effects after irradiation at E16 with 3Gy and the effects in adult animals after irradiation at E15 with doses lower than 3 Gy (0.5, 1.5, 1.75, 2.0, 2.5 Gy). To study the short-term effects, offspring of control and irradiated mothers were obtained at E17, E19, PND1 and PND5. The brains were sectioned and stained with either cresyl-violet or Bodien silver-stain. The brains of adult animals irradiated at E15 were cut and stained with cresyl-violet. In normal E17 mice, some cells in the subventricular zone formed a sling across the midline. One day after irradiation, the subventricular zone was disrupted, the sling was not detected and a great number of pyknotic figures was seen in the cortical plate but not in the thalamus (in particular, the dorsal lateral geniculate nucleus seemed normal). At E19, PND1, and PND5, the corpora callosa were reduced or absent in most cases, there was a decrease in cellular density in the cortex, and the thalamus did not present any anomalies. Aberrant fibers were seen after E19 whereas ectopic neurons were found only on PND5. Adult mice irradiated at E15 with 1.5 Gy presented periventricular ectopias and agenesis of the caudal portion of the CC. A dose of 1.75Gy caused CC defects in all cases (75% total callosal agenesis; 25% absence of the caudal portion of the CC), presence of ectopias (100%), a pattern that resembled aberrant fibers, and presence of the longitudinal aberrant bundle (50%). Ectopic neurons in layer I were detected in the 1.75Gy group and were commonly seen in the 2 Gy group. Animals irradiated with doses greater than 2 Gy did not present the pattern that resembled aberrant fibers, but CC defects and periventricular ectopias were consistently found. These data show an association with CC defects and ectopias and suggest that prenatal irradiated mice may be a convenient neuropathologic model of callosal agenesis. In humans, callosal agenesis is usually associated with heteropias and polymicrogyria, often at a frequency higher than can be explained solely by chance.

INHIBITION OF L1-MEDIATED CELL-CELL ADHESION BY ETHANOL. R. Ramanathan, G. Perides M. E. Charness*, *Dept Neurology, Harvard Medical School, VA Medical Center, West Roxbury, MA 02132.*

Mental retardation, hydrocephalus, and agenesis of the corpus callosum are observed both in fetal alcohol syndrome and in human disorders associated with mutations in the gene for the neural cell adhesion molecule (CAM) L1. We showed previously that ethanol inhibits cell-cell adhesion in neural cells treated with human osteogenic protein-1 (OP-1), a powerful inducer of the genes for L1 and N-CAM (*J. Biol. Chem.* **269**, 9304, 1994). To determine whether ethanol inhibits adhesion mediated by an individual class of immunoglobulin CAMs, we produced stable transfectants of mouse L cells expressing human L1. L cells were transfected with a modified pRc/RSV vector (Invitrogen) containing a cDNA for human L1, selected by growth in G418 medium, and subcloned from single colonies. Stable expression of L1 was demonstrated by Northern blot, Western blot, and immunofluorescence. L1-transfected fibroblasts exhibited increased adhesiveness in a short-term aggregation assay as compared with non-transfected cells and cells transfected with the vector alone. Ethanol (5-50 mM) caused a dose-dependent inhibition of cell-cell adhesion in L1-transfected fibroblasts. The dose response curve for ethanol inhibition of cell-cell adhesion in human L1-transfected fibroblasts was similar to that observed for OP-1 treated neural cells. Ethanol's inhibition of L1-mediated cell-cell interactions could contribute to the nervous system lesions of fetal alcohol syndrome. Moreover, because L1 is required for long-term potentiation (*Nature* **372**, 777 ,1994), inhibition of L1-mediated synaptic plasticity could also play a role in alcohol-associated memory disorders.

MEDIAL SEPTAL ATROPHY IN AGED MICE EXPOSED TO A SINGLE DOSE OF ALCOHOL IN UTERO. I. Lee, R. Dumas, M.H. Lee and A. Rabe*. New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314

It has been demonstrated that mice exposed to a single of dose of alcohol during neurulation, although while remaining free of gross malformations, show a precipitous deterioration of long-term memory in middle and old age. In order to determine whether the behavioral deterioration is related to anatomical changes in specific brain structures, we performed morphometric analyses in several forebrain structures.

C57Bl/6J mice were exposed on gestation day (GD) 9 to a single oral dose of 5.8 g/kg alcohol (E), which produced approximately 700 mg/dl BAC 1 hour after gavage. Control mice were intubated with isocaloric and isovolumic dextrose solution substituted for alcohol (D). The brains were sampled at 24 months of age. The number of neurons was counted and neuron size was measured in the occipital cortical layers, hippocampus, and medial septum. The only measure yielding a significant group difference was the neuron size in the medial septum: They were significantly smaller in the E than D mice. The diminished neuron size is consistent with the findings that structures along the midline are particularly susceptible to alcohol exposure on GD 9. The involvement of the medial septum in long-term memory has been documented, and the atrophic medial septal neurons in the E mice may account for the premature memory decline reported previously by our laboratory (Dumas and Rabe, 1994).

ANATOMICAL MALFORMATIONS OF SPINAL CORD AXONAL TRACTS IN A RETINOIC ACID-INDUCED SPINA BIFIDA IN THE RAT EMBRYO. Nathalie Valdés, Stéphane Woerly, Louise Bertrand and Raymond Marchand*. Centre de recherche en neurobiologie, Hôp. de l'Enfant Jésus, Univ. Laval; Canada G1J 1Z4.

Most of the congenital malformations taking place at the level of the spinal cord result from a defective closure of the neural plate. This malformation is commonly refered to as spina bifida. We have developed a model of lumbo-sacral spina bifida with myeloschisis (spina bifida aperta) after administration of retinoic acid (RA). RA induces spina bifida when administred in 3 consecutive forcible feedings each containing 13mg of RA/kg at $E10_0$, $E10_6$ and $E10_{12}$. The objectives of the present work were to study the morphology and organization of the spina bifida (SEM and classical histology) as well as the anatomical organization of the axonal tracts (dextranamine injections) in spina bifida embryos. The detailed study of the descending projections associated to the malformation allowed us to identify defective axonal tracts. For example, a dextranamine injection at a caudal thoracic level shows that some axonal tracts do present an abnormal trajectory at the level of the spina bifida. Axons enter the spina bifida but do not extend beyond it. At the level of the malformation, axons cross the midline and form a U-shaped tract that ascends in the contralateral side. NEUROBIOLOGICAL MODEL FOR TOURETTE SYNDROME CENTERED ON THE NUCLEUS ACCUMBENS. G.N.O. Brito* and M.N. Azevedo. Setor de Neurociencias, Univ. Fed. Fluminense, Niteroi, Brasil.

Tourette syndrome (TS) is a genetic disorder characterized by chronic multiple motor and vocal tics with a fluctuating course and modulated by internal and external environmental events. TS is more prevalent in males than females, and is commonly associated with behavioral disorders such as obsessive-compulsive disorder and attention deficit hiperactivity disorder. TS symptoms are attenuated by DA antagonists and usually exacerbated by psychostimulants. We propose that dysfunction centered on the nucleus accumbens (NAC) represents the neurobiological basis of TS. NAC is divided into a shell and a core region with distinct anatomical relationships. Additionally, recent evidence indicates that NAC has a micro-organization characterized by modules of distinct neurochemical and neuroanatomical features. These modules could interact via closed parallel and open interconnected circuits as suggested by Joel and Weiner (1994) for the basal ganglia. Our model assumes that events (e.g., maternal stress, steroids, hormones and neurotransmitters) occurring during the development of the nervous system interact with products derived from the expression of the putative gene for TS thereby inducing modular changes in NAC. The clinical presentation, associated behavioral disturbances and response to drugs would depend on the pattern of modular dysfunction.

NONLINEAR DYNAMICS OF RESPIRATORY PATTERNING IN INFANTS WHO SUCCUMB TO THE SUDDEN INFANT DEATH SYNDROME. V.L. Schechtman*, M.Y. Lee, A.J. Wilson, D.P. Southall and R.M. Harper. *Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90095.*

Aberrations in cardiac variability appear in infants who later succumb to the sudden infant death syndrome (SIDS); however, overall respiratory variability in SIDS victims is comparable to that of control infants. We assessed non-linear dynamic characteristics of breath-to-breath intervals collected during sleep in 16 recordings of apparently-healthy infants who subsequently died of SIDS and 35 recordings of age-matched control infants. One-interval/next-interval plots (Poincaré Plots) were used to assess nonstationary aspects of respiratory rate variation. Next-breath dispersion was determined following short, intermediate, and long breath-to-breath intervals, and dispersion at each rate was expressed as a percentage of overall respiratory rate variation. ANOVA was used to identify differences between the SIDS victims and control infants. During quiet sleep, SIDS victims showed increased next-breath dispersion following short respiratory intervals, relative to surviving infants. The findings indicate differences in breath-to-breath patterning of respiration in infants who succumb to SIDS that occur preferentially at high respiratory rates and do not affect overall respiratory variability.

SUPPLEMENTARY MOTOR AND PREMOTOR OVERACTIVITY IN STUTTERING: A PET STUDY OF STUTTERING AND INDUCED FLUENCY. P.T. Fox*, R.J. Ingham, J. Costello Ingham, H. Downs, T. Hirsch, J.L. Lancaster Research Imaging Center, University of Texas Health Science Center at San Antonio, TX, 78284-6240

The neural-systems whose dysfunction underlies developmental stuttering are unknown. To address this question, we compared stuttered speech to induced fluency (1) using positron-emission tomography (PET).

Twenty, right-handed men participated: ten developmental stutterers and ten normal controls. In each subject, brain blood flow was imaged 3 times per condition in each of 3 conditions: Solo reading, Chorus reading and Rest. In both Solo and Chorus, subjects read aloud from a passage presented on a video monitor. In Solo, reading was unaccompanied; in Chorus, reading was accompanied by a tape-recording of the same passage. All stutters stuttered frequently during Solo but were stutter-free during Chorus. Controls were stutter-free in both conditions. PET imaging used 15-O, water-bolus methods and Change-Distribution Analysis.

Stuttering elicited strong activations in SMA (medial BA6) and right, superior-lateral premotor cortex (lateral BA6). Chorus reading greatly reduced these abnormal activations. In normal subjects, motor-systems activations in both conditions were similar to those of stutterers during induced fluency. We conclude that developmental stuttering may be caused by excessive neural activity in medial and lateral premotor cortex.

ANOMALOUS CENTRAL AUDITORY PROCESSING IN MAN.

D. M. Daly*. Box 210855, Dallas, TX 75211.

In processing complex sounds such as in speech people exploit systems common at least to mammals. We report using sets of synthesized sounds[1] to test auditory processing in people with normal pure-tone and speech audiometrics and confirmed history of anomalous auditory processing.

1. An American journalist who could read and write German but was unable to understand or speak it intelligibly classified certain sets anomalously ($p<0.0001$); a daughter fluent in German and tested concurrently performed without difficulty.
2. An 11 yr. boy who had difficulty with spoken but not written material in school classified **gy** sets anomalously; his father, a pilot, performed similarly and reported lifelong difficulties with regional accents (particularly in certain ATC sectors).
3. A mother and daughter classified **gy** and **bw** clearly and similarly, but differently from father and another daughter. Each pair reported the other spoke imprecisely; both pairs differed significantly from normal controls.
4. A father and daughter consistently distinguished as many as 4 classes where normal controls found at most 3. These did not correspond to normal classes nor could normal classes be composed from them.
5. An 11 yr. old boy with articulatory difficulties (palate shape) had normal comprehension; his father had undergone surgery for similar problems as a child. Both performed normally ($1\text{-}p < 0.0001$) over 6 hr. of testing

Cases 1-4 demonstrate a range of stable, anomalous auditory processing which affects ability to understand sounds of a foreign or even native language. Cases 1 and 3 preclude appeal to early environment. Analogous to the anatomic origins in Case 5, Case 4 appears to involve anomalous end organ (possibly basilar membrane) geometry.[2] We believe this method can be used to assess dynamic aspects of auditory functioning as well as central auditory processing.

EPILEPSY: KINDLING

830.1

AMYGDALA-KINDLING LEADS TO LOSS OF GABA-IMMUNOREACTIVE NEURONS IN A TINY AREA OF THE PIRIFORM CORTEX. H. Lehmann, U. Ebert and W. Löscher (SPON: European Neuroscience Association), Dept. of Pharmacology, Toxicology and Pharmacy, School of Veterinary Medicine,D-30559 Hannover, Germany

Female Wistar rats weighing 260-280 g were electrically kindled via bipolar electrodes, which were implanted unilaterally into the basolateral amygdala, until 10 fully kindled seizures were elicited. After an unstimulated period of 40 days the rats were sacrificed and a immunohistochemical preparation of brain tissue was performed by using a monoclonal *anti*-GABA antibody. Quantification of GABA-immunoreactive (IR) neurons was carried out in the basolateral amygdala, piriform cortex, dentate gyrus, CA1 and CA3. A kindling ($n=10$) versus a sham-group ($n=6$), which received electrode implantation, but no electrical stimulation, and a naive group ($n=10$) were compared. At the stimulation site i.e. the nucleus of the right basolateral amygdala, a significant loss of GABA-IR neurons was observed in kindled rats that ranged between 31-52%. The extent of cell loss was similar ipsi- and contralateral to the stimulation site. Along the rostro-caudal extension of the piriform cortex a distinct area between +0.2 and -0.8mm from Bregma ipsilateral to the stimulation site showed a significant reduction of GABA-IR cells by 17-26%. In contrast, the hippocampal formation showed no changes in GABA-immunoreactivity. In the sham-group no alterations in any of the above areas were evident. We conclude that amygdala-kindling is associated with permanent GABAergic cell loss the site of stimulation, but also at a circumscribed site of the piriform cortex, which is evidently involved into the phenomenon of kindling.

PERSISTENT SPONTANEOUS EPILEPTIFORM DISCHARGES EVOKED BY KINDLING-LIKE STIMULATION IN PIRIFORM CORTEX *IN VITRO*. M. R. Pelletier* and P. L. Carlen, Playfair Neuroscience Unit, Bloorview Epilepsy Research Program, Toronto Hospital, Toronto, ON, M5T 2S8.

Interictal discharges appear first, and with greater frequency, in the piriform cortex after kindling, and this region (layer II) is highly susceptible to neuronal damage after kindling-induced status epilepticus. Brain slices containing the piriform cortex, rostral to the septal pole of the hippocampus, were prepared from Wistar rats. Field potentials were recorded in the endopiriform nucleus with NaCl-filled microelectrodes and evoked via a bipolar stimulating electrode placed inferior to layer II (association fibres). Weak stimulation produced a small amplitude potential (p1). Increasing the stimulation intensity evoked p1 and also a second potential (p2) of greater amplitude and occurring at a latency of 50-100 ms from p1. Increasing further the stimulation intensity decreased progressively the latency of p2. The p2 response was polysynaptic in origin, because only p1 was evoked when stimulation was delivered at 1 Hz. Responses were evoked (0.05 Hz) with the test intensity, which was the threshold intensity required to evoke p2. The slice was tetanized (TET) every 10 min: 100 Hz, 2 sec, twice the test intensity. Stimulation was terminated after the 10th TET and spontaneous discharges were monitored. Spontaneous discharges prior to the first TET were recorded in only 4/14 slices. The frequency of spontaneous discharges increased progressively and persisted for the duration of experiments (longest time recorded 120 min after 10th TET). Evoked responses increased in both amplitude and duration and the threshold to evoke p2 decreased after TET. Bath application of the NMDA antagonist, APV (50 μM; $n=3$), the benzodiazepine agonist, midazolam (1 μM; $n=3$), or the antagonist, flumazenil (500 nM; $n=3$) were without effect on the frequency of spontaneous discharges. This novel model of epilepsy is similar to conventional kindling; decreased threshold to evoke discharges, spontaneous discharges, and persistent.

830.3

IBOTENIC ACID LESIONS OF THE HIPPOCAMPUS REDUCE "WET SHAKES" ASSOCIATED WITH AMYGDALOID KINDLING IN THE RAT. J.L. Meyerhoff*, L.E. Jarrard and D.D. Walczak. Div. Med. Neurosci., Walter Reed Army Institute of Research, Wash., D.C. 20307; Dept. of Psychol., Washington and Lee Univ., Lexington, VA 24450 and Solvay Pharmaceut., Marietta, GA 30062.

"Wet Dog Shakes" (WDS) are associated with kindling of the septum, hippocampus (HC), entorhinal cortex (ERC) or amygdala (Squillace, et al., 1980; Le Gal La Salle et al., 1981; Lerner-Natoli et al, 1984). Injection of colchicine into the HC suppressed by 95% the WDS elicted via ERC kindling (Frush & McNamara, 1986). We evaluated the effect of ibotenic acid (IA) lesions of the HC on WDS elicited by amygdaloid kindling. Bilateral stereotaxic injections of IA into the HC were performed in anesthetized male SD rats and chronic amygdaloid electrodes were placed (Meyerhoff, et al. 1985). IA lesions destroy neurons without affecting fibers of passage. Although lesions did not affect no. of stimulations required to elicit stage 5 seizures, the no. of WDS observed was reduced by 68%. Injection of (TRH) i.c.v. synchronizes HC EEG (Kalivas, 1980) and elicits WDS (Drust & Crawford, 1983). Although other neurohumors might be involved in WDS, kindled seizures increase brain levels of TRH (Meyerhoff, et al, 1990) and HC levels of TRH mRNA (Rosen et al., 1992; Kubek et al., 1993).

830.4

THE EFFECTS OF COMPLETE AND PARTIAL BILATERAL LESIONS OF THE CEREBELLAR DEEP NUCLEI ON AMYGDALOID KINDLING IN THE RAT. G.C. Teskey*, J.K. Min and P.A. Valentine. Behav. Neurosci. Res. Grp., Dept. of Psychology, Univ. of Calgary, Calgary, AB, Canada T2N 1N4.

The role of hindbrain mechanisms involved in the acquisition of electrically induced forebrain seizures has received relatively little attention. While an anti-epileptic influence of the cerebellar fastigial nuclei (CFN) has been documented, conflicting observations have been reported for the cerebellar dentate nuclei (CDN), and interpositus nuclei (CIN). This study was undertaken to facilitate a direct comparison of the role of the cerebellar fastigial, dentate and interpositus nuclei in mediating amygdaloid kindling.

Male, Long-Evans hooded rats were chronically implanted with bipolar electrodes in the amygdala, and one of the CDN, CFN, or CIN were bilaterally electrolytically lesioned. Following a two-week recovery, an afterdischarge threshold was determined. This was achieved by the application of 50 μA stimulation trains consisting of 1.0 msec biphasic square wave pulses at 60 Hz for one second. Failure to elicit a discharge resulted in increasing the current in 50 μA steps until the threshold was surpassed. Daily kindling stimulation was applied at 100-150 μA above threshold until two stage 5 convulsions were elicited. The duration, amplitude, and frequency of evoked afterdischarges (ADs) were measured.

Lesions of the cerebellar deep nuclei influence both the kindling rate and afterdischarge characteristics. Our preliminary results indicate that complete lesions resulted in a reduction in the number of sessions to elicit a stage 5 convulsion, decreased AD durations and an atypical progression through the behavioural stages. Partial lesions were typically associated with an increase in the number of sessions to elicit a stage 5 convulsion and increased AD durations. Supported by NSERC.

830.5

THE EFFECTS OF PICROTOXIN AND ATROPINE ON INTERICTAL SPIKING DURING AMYGDALA KINDLING IN THE GENETICALLY FAST AND SLOW KINDLING RAT STRAINS. J.A. Grabowski* and D.C. McIntyre. Psychology Dept., Carleton Univ., Ottawa, Ont., Canada K1S 5B6.

In this study, two rat strains with naturally different kindling rates and disposition to develop interictal spiking (IIS) were examined. Although IIS is the hallmark of an epileptic focus, the kindling resistant (SLOW) rats showed significantly more IIS during all stages of amygdala kindling than the kindling prone (FAST) rats. In the present study, we examined the IIS, the convulsive seizure (ictal event) and the postictal spike (PIS) for their pharmacological sensitivity in both the FAST and SLOW kindling strains. Rats were amygdala kindled daily at their afterdischarge threshold intensity. Once IIS was established, rats were injected with either drug or saline in a latin square design and the IIS rate was observed for 20 min. Subsequently, the ictal event was triggered, which provoked PISs. The GABA antagonist, picrotoxin (0.5 mg/kg), significantly increased the IIS rate, yet had little effect on the ictal event in both strains, while it slightly depressed the PIS rate in the SLOW rats. Like picrotoxin, the cholinergic antagonist, atropine (25 mg/kg), increased the IIS rate in both strains, but strongly suppressed the ictal event in the SLOW but not the FAST strain, and increased the PIS rate in the SLOW but not the FAST strain. Clearly, both IIS activity and kindling rate show a genetic predisposition, but surprisingly their relationship is inverse. It is also clear that IIS, ictal and PIS events are neither similar in the two strains nor in their sensitivity to pharmacological manipulation.

830.6

AXONAL TRANSPORT VELOCITY CHANGES IN THE AMIGDALINE FIBERS IN THE ANTERIOR COMISSURE BY AMIGDALOID KINDLING. Martinez-Lorenzana G, Talavera E, León-Olea M, Condés-Lara M. and Sitges M*. Dpto. Neurofisiología. Instituto Mexicano de Psiquiatría. Calz. México-Xochimilco No. 101 C.P 14370 México D.F.

Studies have shown that the neuronal activity influences both the uptake and axonal transport processes. Kindling, an experimental model in which the neuronal excitability is enhanced, is achieved following repetitive low intensity subconvulsive electrical stimulations in some cerebral regions, mainly in the limbic system (Goddard et al. Exp. Neurol. 25:295-330.1969). Evidence suggests that the neuronal hyperactivity produced by electrical stimulation involves the following processes: endocytosis, exocytosis, mechanisms related to axonal transport and proteic synthesis. In this study, axonal transport velocity during the neuronal hyperexcitability produced by amygdaloid kindling was investigated using a retrograde tracer such as Wheat Germ Agglutinin coupled to Horseradish Peroxidase (HRP-WGA). The fibers analized were the amigdalae fibers crossing in the anterior commissure. Male Wistar rats were divided into three groups: 1)kindled, 2)Sham and 3)Control. Rats were injected with 10% HRP-WGA (10-20 nl) in the right basolateral amygdaloid nucleus, contralateral to the stimulated amygdala. The survival time was 48 h. Coronal sections comprising the areas from the injection site to the anterior commisure were selected. The HRP-WGA reaction was carried out using TMB according with Mesulam (1982) proceding. The brain sections were analyzed under a light microscope. Our results indicated that the kindled group had an increase in axonal transport of HRP-WGA. This means a greater density of labelled fibers and the localization of labelled neurons at a greater distance from the injection site. The enhanced axonal transport was evident when comparing this group with the sham and control groups. Our results suggest that the increment in neuronal activity, due to full kindling seizures, correlates with an increase in the uptake and transport of HRP-WGA.

830.7

AMYGDALA KINDLING PRODUCES MORE "DEFENSIVE" BEHAVIOR THAN HIPPOCAMPAL OR CAUDATE KINDLING IN RATS. J.P.J. Pinel*, L.E. Kalynchuk, and D. Treit[1]. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C., V6T 1Z4 and [1]Dept. of Psychology, Univ. of Alberta, Edmonton, Alberta, T6G 2E9.

We have previously reported that amygdala-kindling in rats results in elevated levels of several defensive behaviors (Kalynchuk et al., 1995). The purpose of this experiment was to investigate whether this effect would also occur after kindling different brain sites. Bipolar electrodes were implanted in the basolateral amygdala, dorsal hippocampus, or caudate nucleus of 81 male, Long-Evans rats. These rats were divided into six groups: amygdala kindled, amygdala control, hippocampal kindled, hippocampal control, caudate kindled, and caudate control. All rats then received 99 convulsive (kindled) or sham (control) stimulations. One day after its last stimulation, each rat was placed in an open field for 5 minutes and then tested for its resistance to capture from the open field. The following day, each rat was tested on an elevated-plus maze. The site of stimulation had a significant effect on the results of these tests. During the first minute in the open field, the amygdala-kindled rats engaged in less exploration than both the hippocampal or caudate-kindled rats. In addition, the amygdala-kindled rats were more resistant to capture from the open field than the hippocampal or caudate-kindled rats. Finally, the amygdala-kindled rats engaged in more open arm activity and escape behavior from the elevated-plus maze than the hippocampal or caudate kindled rats did. Thus, amygdala kindling results in increased emotionality and defensiveness compared to hippocampal or caudate kindling. This suggests that heightened emotionality in kindled rats may be a consequence of repeated seizure activity in or near the amygdala, rather than the kindled state per se. These findings may be relevant in understanding the fear and affective disturbances often experienced by temporal lobe epileptics. HIPPOCAMPAL KINDLED SEIZURES DISRUPT PERFORMANCE IN THE MORRIS WATER MAZE. T.H. Gilbert* & M.E. Corcoran. Dept. of Psychology, Univ. of Victoria, POB 3050, Victoria, BC, Canada, V8W 3P5.

The hippocampus is thought to play an important role in the processing of spatial information, in that interference in normal hippocampal functioning can produce deficits in performance of a wide variety of tasks that use spatial navigation for optimal performance. The effects of hippocampal kindling on subsequent learning and memory of a spatial task have been assessed in several studies. Although the studies vary in procedure and site of stimulation, their results fairly consistently suggest that epileptiform activity within the hippocampal formation impairs performance. We have attempted to assess the spatial performance of rats in the Morris water maze task during kindling of hippocampal field CA1.

We used two procedures: (1) seizures were kindled with stimulation of CA1 prior to daily training in the water maze (acquisition); and (2) maze training was imposed until performance stabilized, and then seizures were kindled with stimulation of CA1 prior to daily testing in the maze (retention). In both cases, stimulation of field CA1 was applied 25-45 min prior to daily testing in the maze. Only nonconvulsive afterdischarge (AD) was kindled in some rats in the experimental group, whereas in other rats generalized convulsive seizures were kindled. Yoked controls carried electrodes but did not receive stimulation.

We found that CA1 kindled seizures significantly disrupted water maze performance during both acquisition and retention. Similar effects were produced when either nonconvulsive seizures (AD) or convulsive seizures were evoked. Our findings are consistent with previous results suggesting that kindled epileptiform activity in the hippocampus impairs performance in tasks sensitive to spatial learning and memory. (Supported by NSERC)

830.9

THE EFFECTS OF AMYGDALA KINDLING ON T-MAZE PERFORMANCE IN EPILEPTOGENETICALLY FAST AND SLOW KINDLING RAT STRAINS. W. S. McLeod and D. C. McIntyre*. Depart. of Psychology, Carleton Univ., Ottawa, Canada, K1S 5B6.

Kindling, an animal model of epilepsy, was investgated for having acute and chronic effects on memory. Genetically FAST and SLOW kindling rat strains were tested for working and reference memory in a T-maze before, during and after amygdala kindling. Maze performance was monitored 23 hours after eliciting stage 1 through 5 kindled convulsions, then 1 hour versus 10 minutes after stage 5 convulsions in fully kindled animals. After a seizure free period of 10 days and beyond, maze performance was retested with increasing levels of difficulty in the working memory task. Results indicated that kindled convulsions and kindling *per se*, have acute and chronic effects, respectively, on working memory performance. Working memory was more susceptible to disruption than reference memory. Additionally, the FAST rats were less capable than the SLOW rats on the working memory task before kindling, and showed greater impairment during and after kindling. Discussed are neuropharmacological differences between limbic areas of FAST and SLOW rat strains that may account for the differential sensitivity of working memory to kindling disruption.

830.10

SEIZURE AND SPIKE ACTIVITY INTERRELATIONS DURING RAPID KINDLING IN RABBITS. Olga A. Timofeeva* and Gary M. Peterson. Dept Anatomy & Cell Biology, East Carolina Univ Sch Med, Greenville, NC 27858.

Seizures and interictal spikes are considered to be basic components of epileptic activity, but the relationship between these is poorly understood. The present study examines the relationship between seizure and spike activity using closely-spaced recurrent hippocampal seizures ("rapid kindling"). This model provides an opportunity for examining electrographic epileptic reactions in response to electrical stimuli applied at different stages of seizure susceptibility. Twelve adult rabbits with chronically implanted electrodes were stimulated in the hippocampus once every 5 min to achieve a condition of rapidly recurring seizures. EEG was monitored continuously during the experiment (3-6 h). Electrical stimulations produced progressive seizure development in 8 of the 12 animals. Seizures were induced more frequently with increasing numbers of electrical stimulations. Interictal spiking was observed in 5 of the 8 animals and in all (n=4) rabbits which did not develop seizures. Spiking developed at different stages of kindling. A latency for spike onset following each electrical stimulus train significantly fluctuated due to changes in seizure susceptibility. Two kinds of spike onset latency were distinguished: "short-term" (< 50 s) and "long-term" (> 70 s). "Short-term" spike latency was observed predominantly in 3 situations: in the early phase of a prolonged refractory period (5 min after triggering seizure), when seizure decay occurred, and during an "unsuccessful" kindling procedure. "Long-term" spike latency was observed predominantly in the last phase of a prolonged refractory period (5 min before triggering seizure) and always during the development of ictal events. These data showed that "short-term" latency for spike onset correlated with low susceptibility to seizure whereas "long-term" latency correlated with enhancement of seizure susceptibility. These results suggest that seizure priming and triggering mechanisms temporarily inhibit spike activity.

830.11

Regional Increases in the β Subunit but not the α Subunit of Calmodulin Kinase II mRNA in Kindling. K. Sato[1,2], K. Kashihara[3], K. Morimoto[4] and T. Hayabara[2]. [1]Department of Neuropsychiatry and [3]Department of Neurology, Okayama University Medical School, Okayama 700, Japan. [2]Clinical Research Institute, National Sanatorium Minamiokayama Hospital, Okayama 701-03, Japan. [4]Department of Neuropsychiatry, Kagawa Medical School, Kagawa 761-07, Japan.

Levels of the mRNAs for the α and β subunits of calmodulin (CaM) kinase II were studied in the kindling model of epilepsy. Using in situ hybridization and ^{35}S-labeled oligonucleotide probes, induction of these mRNAs was evaluated in the rat brain just after and 0.5, 1, 2, 4, 8 and 24h after generalized seizures induced by daily electrical stimulations of the amygdala. Four to 24h after the seizures, kindling significantly increased levels of the β subunit of CaM kinase II mRNA in the hippocampus compared with controls which had undergone a sham procedure. Four to 24h after the last stimulation, levels of the β subunit of CaM kinase II mRNA increased significantly by 18 to 28 % in the granule cell layer on each side of the dentate gyrus and by 18 to 30 % in the pyramidal cell layer of the ipsilateral CA2. In the pyramidal cell layer of the ipsilateral CA3, levels increased significantly by 22 % 4h after the seizures. There were no detectable changes in levels of the β subunit of the enzyme mRNA in other areas, which included the amygdala, pyriform cortex, perirhinal cortex and temporal cortex. In contrast, no significant changes in levels of the α subunit of CaM kinase II mRNA were observed in the regions examined after kindling-induced generalized seizures.

These results indicate that the increases in CaM kinase II-dependent protein phosphorylation may be associated with changes in synaptic biochemistry in kindling, and suggest that CaM II kinase may mediate the molecular processes underlying kindling-induced epileptogenesis.

830.12

DIFFERENTIAL EXPRESSION OF GABA AND GLUTAMATE TRANSPORTER SUBTYPES IN FULLY KINDLED ANIMALS T.D. Hernandez*(1), A.E. Kline(1), M. Nakashita(2), H. Obata(2) and N. Saito(2). Department of Psychology(1), Univ. of Colorado, Boulder, CO, 80309 and Laboratory of Molecular Pharmacology(2), Biosignal Research Center, Kobe Univ., Kobe 657, Japan.

Alterations in excitatory and inhibitory neurotransmitter activity have been shown in humans with epilepsy and in animal models of the disorder. In general, there is evidence for upregulation of excitatory transmission coupled with downregulation of inhibitory transmission. While these changes have been noted in terms of receptor function, little is known about seizures and amino acid transporters. Glutamate and GABA are each taken up by specific subtypes of transporters located on pre- or post-synaptic terminals or glia. Alterations in the distribution or concentration of these transporters in an animal model of epilepsy (i.e. electrical kindling) should provide clues as to how the brain responds to recurrent seizure activity. To this end, animals were chronically implanted with a bipolar stimulating electrode in the amygdala and kindled once daily until each responded with a Stage 5 seizure. One week later, animals were sacrificed and prepared for immunocytochemical examination of the cellular distribution of the GABA and glutamate transporter subtypes. The glial type of glutamate transporter (GLT-1) was increased in the kindled side of the piriform cortex, while no significant change was observed in other glutamate transporters. None of the three GABA transporters showed obvious change after kindling. These data will be discussed in the context of how alterations in amino acid transporters might underlie the enhanced seizure susceptibility that is produced via the kindling process.

830.13

AN AUDITORY STIMULUS PRESENTED PRIOR TO AMYGDALA KINDLING ALTERS THE RATE OF SEIZURE PROGRESSION: CONTINUOUS EXPOSURE IS NOT REQUIRED FOR THIS REGION-SPECIFIC EFFECT. A.E. Kline*, V. Revilla, and T.D. Hernandez. Department of Psychology, University of Colorado, Boulder, CO 80309.

Prior work has shown that an antecedent tone presentation during every kindling trial significantly delays the rate of amygdala kindling (Hernandez, Warner, Kline, & Kahler, 1995). The specific aim of this study was, therefore, to alter the presence of the tone and investigate this manipulation on kindled seizure development. To achieve this goal, male Long-Evans rats were implanted with an electrode in the right amygdala and assigned to either a *Tone, No Tone*, or *Tone Discontinued* group and kindled daily. The *Tone* group received the tone on every trial while the *Tone Discontinued* group received it for only the first 5 days and subsequently kindled the same as the *No Tone* group (i.e., not exposed to the tone while receiving the kindling stimulation). The results revealed that prior exposure of the tone significantly delayed Stage 5 seizure development for subjects kindled in the central nucleus and significantly accelerated Stage 5 seizures for those kindled in the amygdalostriatal transition area; this finding was observed whether the tone was presented at each trial or discontinued early during the kindling process. These findings indicate that an auditory stimulus presented prior to amygdala kindling alters (i.e., delays or accelerates) the rate of seizure progression. Furthermore, the alteration is not contingent on continuous exposure to the tone, but does appear to be region-specific. Lastly, the data suggest there is an early critical period during kindling that may be amenable to manipulations. Further research is necessary to determine the nature of these manipulations and what effects they might have on seizure genesis.

AUDIOGENIC KINDLING INDUCES INCREASED BURST FIRING RESPONSES TO ACOUSTIC STIMULI IN NEURONS OF THE MEDIAL GENICULATE BODY OF GENETICALLY EPILEPSY-PRONE RATS. P. N'Gouemo* and C. L. Faingold. Dept. Pharmacol. Southern Illinois University School of Medicine, Springfield, IL 62794.

Repetitive audiogenic seizures (AGS) result in expansion of the brainstem neuronal network to forebrain structures, including the medial geniculate body (MGB). We previously observed an increase in acoustically-evoked action potentials (AP) in inferior colliculus (IC) neurons with such an AGS kindling paradigm in genetically epilepsy-prone rat (GEPR-9). The medial part of MGB (MGM) receives input from IC. The present study examined acoustically-evoked MGM neuronal responses in "kindled" GEPR-9 as compared to non-kindled GEPR-9 and normal Sprague-Dawley rats. Each stimulated rat received the electric bell (122 dB SPL) twice daily until the onset of convulsion (GEPR-9 mean latency:14.5 sec) or for 15 sec in control. Each kindled GEPR-9 exhibited 14 AGS. Other GEPR-9s (non-kindled) were used after one AGS. MGM extracellular AP were recorded in anesthetized (ketamine/xylaxine, 85/3mg/kg; i.p.) rats 24h after the last stimulation. Acoustic stimulation consisted of 50 stimuli (½ sec, 12 kHz tone bursts) effective in evoking AGS. Responses were analyzed using poststimulus time histograms (PSTH). Recordings involved 11 neurons in kindled GEPR-9, 10 neurons in non-kindled GEPR-9, and 10 neurons in normals. Over 50% of MGM neurons in the GEPR-9 showed burst firing, as compared to 10% of non-kindled GEPR-9 and normal MGM neurons. The mean number of AP per PSTH of MGM unit bursts was significantly elevated in the kindled GEPR-9 (209±47.5, S.E.M.) at 68 dB SPL in comparison to non-kindled GEPR-9 (97.1±9.7) or control (71.9±19.3). The burst responses in GEPR-9 MGM neurons may be a critical neuronal mechanism of AGS kindling that subserves the increase in AGS severity.(Support NIH NINDS NS 21281)

831.1

PROEPILEPTIC EFFECT OF VALPROIC ACID IN RAT HIPPOCAMPAL CA1 PYRAMIDAL NEURONS. S. Otoom and K. A. Alkadhi*, Department of Pharmacological and Pharmaceutical Sciences, University of Houston, Houston, TX 77204-5515.

This study was designed to investigate a proepileptic effect of valproic acid (VPA) in hippocampal slices. Studies were performed on brain slices from male Sprague-Dawley rats using conventional intracellular recordings in hippocampal CA1 pyramidal neurons. Action potentials were evoked in response to brief intracellular current pulses (20 ms, 0.5 nA). Veratridine (0.2-0.3 μM) was used to induce epileptiform discharge in response to these pulses. Large concentrations of VPA (0.5 mM) had a biphasic effect on veratridine-pretreated neurons. VPA initially caused an inhibition of evoked bursting activity but soon the bursting reappeared at a higher frequency. The wash-out of the drug was also biphasic. During the early wash-out of VPA with veratridine-containing artificial cerebrospinal fluid (veratridine-ACSF), a complete inhibition of the bursting was noticed. Prolonged wash-out of VPA restored control-like evoked rhythmic bursting. VPA at concentrations of 2 mM or higher enhanced veratridine-induced bursting and the inhibition phase of the drug was not seen. The wash-out of this VPA concentration was still biphasic, the early wash-out with (veratridine-ACSF) produced inhibition of the epileptiform discharges while prolonged washing restored the rhythmic bursting. Membrane potential and membrane input resistance were measured befor and during the epileptic phase of the drug in the presence of veratridine. VPA (0.5-2 mM) produced a small but non significant decrease in membrane input resistance accompanied by a small (non significant) membrane depolarization in the veratridine-pretreated neurons. These results indicate that VPA in large concentrations have a proepileptic effect in rat hippocampal CA1 pyramidal neurons treated with veratridine.

831.2

THE EFFECTS OF VALPROIC ACID ON PMA-INDUCED REGULATION OF PROTEIN KINASE C ACTIVITY AND NMDA-EPSP IN THE RAT HIPPOCAMPUS. **G. Y.-P. Lee*, T. J. Teyler, and L. M. Brown, Depts. Neuro. and pharm., NE Ohio Univ. Coll. of Med., Rootstown, OH 44272-0095.**

The anti-convulsant drug valproic acid suppressed the NMDA induced [3H]-NE efflux in rat cortical slices (Brown et al., 1994). Chronic incubation of glioma cells with valproic acid (0.6 mM) resulted in decreased PKC activity in both membrane and cytosolic fractions (Chen et al., 1994). Incubation with 1 μM phorbol 12-myristate 13-acetate (PMA) for 10 min resulted in a loss of PKC activity in the cytosolic fraction with a concurrent increase in membrane-associated PKC activity (Watson et al., 1994). We investigate the effect of valproic acid on the PMA-induced translocation of PKC from cytosol to membrane, and the effect of valproic acid on NMDA-EPSP. Brain slices (350 μm) from the hippocampus of adult Long-Evans hooded rats were studied. Control slices were incubated in oxygenated ACSF, and experimental slices were incubated in ACSF containing 100 μg/ml (0.6 mM) valproic acid for 20 min and 1 μM PMA for 10 min. After the treatment, hippocampal slices were washed in PBS, homogenized, and prepared for PKC phosphorylation assay (PKC assay kit, Gibco Co.). 400 μm hippocampal slices were used for extracellular NMDA-EPSP recordings with 10 μM bicuculline and 20 μM DNQX in ACSF. The experimental slices were perfused with valproic acid. Results showed that PMA increased PKC activity in the membrane fraction more than in the cytosolic fraction. Valproic acid decreased this enhancement by PMA, and it also suppressed the population NMDA-EPSP amplitude by 10%.

EFFECTS OF CARBAMAZEPINE ON $GABA_B$-RECEPTORS: INCREASE OF FIELD POTENTIAL CHANGES. J.v.Wegerer,[1,2] I.S.Roed[3] and J. Walden[1]*; 1:Psychiatr.Univ.-klinik, Hauptstr.5, Freiburg; 2:Inst.f.Biol.III, Schänzlestr.1, Freiburg, 3:Bayer AG, Köln, Germany

Nowadays carbamazepine (CBZ) is established in the treatment of epilepsies as well as of affective and schizoaffective disorders. In former studies of the group calciumantagonistic effects of CBZ were found to be a possible common mechanism of action in both diseases. In this study we investigated a possible interference of the action of CBZ on GABAergic neurotransmission, since an attenuation of GABAergic inhibition is discussed to be involved in both illnesses. Extracellular recordings were carried out from areas CA1 and CA3 of the hippocampal slice (guinea pig). GABA and its subtype agonists were applied by conventional local pressure application technique. CBZ was systemically administered. Results: 1) CBZ produced a small increase in the amplitude of field potential changes (EFP) induced by GABA (9 % after the 6th application during 30 minutes; n = 18). 2) CBZ showed no effect on EFP induced by the $GABA_A$-agonist muscimol (n = 5). 3) CBZ produced an increase in the amplitude of EFP induced by the $GABA_B$-agonist baclofen (18 % after the 6th application during 30 minutes; n = 12). The effects were completely reversible. This may be explained either by a direct action on $GABA_B$-receptors, a positive feedback caused by presynaptic $GABA_B$-autoreceptors or by an interference with postsynaptic intrinsic mechanisms. Further studies must reveal whether this effect contributes to the beneficial effect of CBZ in both diseases.

831.4

EFFECTS OF LEVETIRACETAM (LO59) ON CA3 NEURONS IN THE RAT HIPPOCAMPAL SLICE. S. Birnstiel*, E. Wülfert and S.G. Beck, Dept. Pharmacol., Loyola Univ. Med. Ctr., Maywood, IL 60153.

Levetiracetam is a highly effective novel anticonvulsant with an unknown mechanism of action. To test the hypothesis that levetiracetam exerts its actions by an interaction with gabaergic or glutamatergic neurotransmission, intracellular recordings were obtained from the CA3 pyramidal cell layer of transversal slices of rat hippocampus. Synaptic potentials were evoked by stimulation of the septal pathway. Levetiracetam in a concentration of 10 μM did not significantly alter the membrane potential, input resistance or the amplitude of the normal subthreshold synaptic potential consisting of a fast EPSP and IPSP. In contrast, the area under synaptically evoked epileptiform bursts in the presence of 10 μM bicuculline was decreased by levetiracetam. This inhibition in bursting could be due to an enhancement of slow synaptic inhibitory transmission or a decrease of slow synaptic excitatory transmission by levetiracetam. Levetiracetam (10 μM) did not alter the response to 3-10 μM baclofen. Experiments on a possible interaction of levetiracetam with NMDA- or metabotropic glutamate mechanisms are currently in progress. Supported by UCB Pharma.

AUTORADIOGRAPHIC STUDY OF FELBAMATE EFFECTS ON $GABA_A$ AND NMDA RECEPTORS.
A. Kume* and R.L. Albin. Dept. of Neurology, Univ. of Michigan, Ann Arbor, MI 48104.

Antiepileptic drug felbamate effects on $GABA_A$ and NMDA receptors were investigated autoradiographically in rat brain. For $GABA_A$ receptor, felbamate produced dose-dependent inhibition of [^{3}H]t-butylbicycloorthobenzoate (TBOB) binding with IC_{50} values approximating 250 μM. Saturation analysis in the presence of felbamate revealed a change in K_d and B_{max}. Dissociation initiated by picrotoxin was accelerated by felbamate. The regional pattern of [^{3}H]TBOB binding inhibition by felbamate was heterogeneous. For NMDA binding, felbamate produced dose-dependent inhibition of [^{3}H]MK-801 binding with the maximal inhibiton of 80% at 1-3 mM and IC_{50} values approximating 800 μM. Saturation analysis in the presence of felbamate revealed a decrease in K_d and B_{max}. The regional pattern of [^{3}H]MK-801 binding inhibition by felbamate was heterogeneous. [^{3}H]glycine binding was not affected by felbamate. High-dose glycine only partially antagonized the felbamate inhibition of [^{3}H]MK-801 binding. Combining our results with reported electrophysiological data suggests that felbamate has effects on both $GABA_A$ and NMDA receptors at clinically relevant concentrations.

Actions of Felbamate in the corticostriatal system: beyond antiepileptic effects.
A. STEFANI, A. PISANI, A. SINISCALCHI, E. ONGINI *§ and P. CALABRESI.
Clinica Neurologica, Università di Roma Tor Vergata, Rome, Italy
§ Schering Plough, Comazzo, MI, Italy

Felbamate (FBM) is a new anticonvulsant which has been shown to interact with the glycine site of the NMDA receptor. The mechanisms underlying the FBM capability to elevate the seizure threshold and to exert neuroprotective effects are not entirely known. Therefore, we have studied the FBM responses in two brain areas - neocortex and striatum - which are involved in both the seizure propagation and neurodegenerative processes. In particular, we have characterized the effects of FBM on: i) high-voltage-activated (HVA) Ca^{2+} currents in pyramidal and striatal cells, ii) the firing properties of neostriatal neurons, iii) the glutamatergic corticostriatal transmission. Patch-clamp whole-cell recordings on isolated neurons and current-clamp intracellular recordings from brain slices were performed with standard techniques. Our main findings can be summarized as follows:

1) FBM dose-dependently reduced HVA Ca^{2+} currents in either cortical and striatal cells. IC_{50} for this action was respectively 298 nM and 15 M; the FBM modulation of Ca^{2+} conductances was blocked by nifedipine (dihydropyridine-antagonist), not by -conotoxin (blocker of N-type channels),

2) FBM inhibited the high-frequency repetitive firing of striatal neurons; this effect was dependent upon the inactivation of the voltage-dependent sodium current,

3) FBM significantly reduced the cortically driven striatal EPSP only after removal of the magnesium block, therefore suggesting that the NMDA component of the transmission was selectively depressed.

Taken together, these findings strongly support the usefulness of FBM not only as an antiepileptic drug but also as a neuroprotective agent.

THE EFFECTS OF THE ANTICONVULSANT REMACEMIDE HYDROCHLORIDE AT NEURONAL SODIUM CHANNELS. D.Y. Sanchez* and E.W. Harris. Biology Department, Fisons Pharmaceuticals, PO Box 1710, Rochester, NY 14603.

Whole-cell voltage clamp experiments were performed to measure the effects of remacemide hydrochloride and a metabolite, FPL 12495, on neuronal sodium channels.

Cells were dissociated from rat pups 1 - 8 days of age. A voltage clamp protocol designed to mimic rapid firing of action potentials in the brain was used to measure the use-dependent block of sodium current. Slow inactivation was defined as the amount of inactivation 30ms after the end of the depolarizing pulse. The time course of development of slow inactivation was determined. In addition, slow inactivation was measured following 60s of conditioning at -100 mV and -60 mV.

IV plots showed no effect on activation of sodium channels by either compound. The time course of individual currents in response to depolarizing pulses was not affected by either drug. However, the development of slow inactivation was speeded up and the amount of steady-state slow inactivation was enhanced in the presence of either drug. In addition, both compounds caused an accumulation of sodium channel block with high frequency stimulation. FPL 12495 accumulated block at 30μM whereas remacemide hydrochloride required approximately 100μM for significant accumulation of block.

These findings directly demonstrate that remacemide hydrochloride and its metabolite, FPL 12495, act to block sodium channels. This may explain their ability to suppress epileptic activity.

831.8

EFFECTS INDUCED BY GABAPENTIN ON THE ELECTROPHYSIOLOGICAL PROPERTIES OF BURSTING NEURONS IN THE RAT SUBICULUM IN VITRO. H. Kawasaki, D. Mattia, C. Zona* and M. Avoli, Montreal Neurological Institute, Dept Neurology and Neurosurgery, McGill University, 3801 University St, MONTREAL, QC, Canada H3A 3B4

Sharp-electrode intracellular recordings in current-clamp mode were made from pyramidal-like bursting cells of the rat subiculum in a slice preparation to study the effects of the antiepileptic drug Gabapentin. Gabapentin (100μM) induced a small hyperpolarization (4.2 ± 3.1, $n = 14$) of the resting membrane potential (RMP in control = -60 ± 4.6 mV) and reduced the ability of these neurons to generate bursts of action potentials during depolarizing current pulses ($n = 6$). Such intrinsic bursting ability is thought to be caused by a voltage-gated, Na^+-mediated mechanism (*J Neurophysiol* 70 (1993) 1244-1248). The effect on bursting was also seen when the RMP was brought to control values with intracellular steady injection of depolarizing current. In 11 out of 15 cells, Gabapentin decreased by $16.1 \pm 9.7\%$ the sag that is recorded in subicular neurons during hyperpolarizing current pulses. This sag was reduced and eventually blocked by extracellular application of Cs^{2+}. In spite of this effect, which made hyperpolarizing pulses become larger in amplitude, the tendency to generate rebound bursts was decreased by Gabapentin. The effects of Gabapentin were still observed up to two hours after washout. Our findings indicate that Gabapentin can modify the intrinsic excitability of rat subicular neurons. Some of these effects might be caused by the blockade of an inward current that in current-clamp recordings is apparent during hyperpolarizing current pulses, while the burst depression might be due to an interaction of Gabapentin with voltage-gated sodium channels. Supported by MRC of Canada.

831.9

EFFECT OF GABAPENTIN (GBP) ON AMINO ACIDS (AA) IN RAT HIPPOCAMPAL SLICES *IN VITRO*. I.M. Kapetanovic*[1], C.P. Taylor[2], W.D. Yonekawa[1] and H.J. Kupferberg[1]. [1]Epilepsy Branch, NINDS, NIH, Bethesda, MD 20892 and [2]Dept. Neurosci. Therapeutics, Parke-Davis Research, Ann Arbor, MI 48105.

GBP (1-(aminomethyl)cyclohexaneacetic acid; Neurontin®) is a recently approved anticonvulsant, but its mechanism of action remains unclear. The balance between the activity of inhibitory (GABA) and excitatory (L-glutamate, GLU and L-aspartate, ASP) neurotransmitter AA is important for normal neurological function and may play a crucial role in the pathogenesis and potential treatment of epilepsy. This study examined the effects of GBP on these amino acids as well as L-glutamine (GLN) which is closely related to them by the "GLU-GLN" and "GABA-GLU-GLN" cycles. Because of compartmentation, concentrations of newly synthesized (NEW) AA were examined in addition to the total tissue (BASAL) AA. Isotopic enrichment, after incubation with stable isotopically labeled precursors ($^{13}C_6$-glucose, $^{13}C_2$-GLU, $^{13}C_2$-GABA, or $^{15}N_1$-GLN), was used to measure NEW amino acids. BASAL and NEW amino acids were determined by GC-MS. Due to the known delay in its onset of action, GBP (50 or 100 µM) was added at least 60 min before the incubation with labeled precursors. In some cases, animals were also given a 100 mg/kg i.p. bolus of GBP 1 hr prior to slices. There was no effect of GBP on the uptake of $^{13}C_2$-GABA or $^{13}C_2$-GLU or conversion of $^{13}C_2$-GLU to $^{13}C_1$-GABA. Therefore, these data suggest that GBP does not influence GLU decarboxylase, GLU dehydrogenase or GABA transaminase in this paradigm. However, GBP consistently decreased both BASAL and NEW GLN by about 20-30%. This effect may be due to the inhibition of the system L neutral amino acid transport. In the presence of ^{13}C,^{15}N-leucine, GBP decreased NEW but not BASAL GLU. Previous studies suggest this could be caused by GBP inhibition of system L transport or cytosolic branched-chain amino acid aminotransferase.

831.10

THE EFFECTS OF D-23129 (ADD 230001) AND STANDARD ANTICONVULSANTS ON THE PAIRED-PULSE PARADIGM IN RAT HIPPOCAMPUS *IN VITRO*. W.D. Yonekawa*, I.M. Kapetanovic and H.J. Kupferberg, Epilepsy Branch, NINDS, NIH, Bethesda, MD 20892.

The Antiepileptic Drug Development (ADD) Program is investigating the mechanism(s) of action of clinically used and experimental anticonvulsant drugs using standard electrophysiological techniques. The paired-pulse paradigm consisted of measuring the percent increase of the second CA1 EPSP and population spike (PS) after two consecutive stimulations separated by interstimulus intervals varying between 10 to 200 ms. Results were compared before and after drug addition to the ACSF in a standard submerged slice chamber. The results indicate that the standard anticonvulsant drugs, phenytoin and VPA, had minimal effects on paired-pulse facilitation of both PS and EPSP. The experimental drug, D-20443, the hydrochloride salt of D-23129 (*N*-[2-amino-4-(4-fluorobenzylamino)phenyl]carbamic acid ethyl ester) from AWD GmbH/ASTA Medica AG, Germany, did appear to attenuate the facilitation of the conditioned PS and to a lesser extent, the EPSP slope. The attenuation was greatest at half maximum stimulation. While these data might be indicative of a D-23129 presynaptic effect, the different time profile for EPSP attenuation indicates other mechanisms may be involved. These results do show that it is possible to differentiate among various anticonvulsant drugs using the paired-pulse procedure, permitting speculation on possible mechanisms of action.

TRAUMA: TREATMENT I

832.1

EFFECT OF A OF COMBINATION OF ANTAGONISTS OF NMDA AND NON-NMDA RECEPTORS ON FUNCTIONAL DEFICITS RESULTING FROM SPINAL CORD TRAUMA. Jean R. Wrathall* and Yang Dong Teng, Neurobiology Div., Dept. Cell Biology, Georgetown Univ., Washington, DC 20007.

Ionotropic glutamate receptors play a significant role in secondary injury processes after spinal cord trauma. We have shown that both NBQX, a potent and highly selective antagonist of the AMPA/kainate subtypes of glutamate receptors, and CPP, an antagonist of NMDA receptors, focally administered at 15 min after a standardized traumatic spinal cord injury (SCI), result in an increase in the speed of recovery and reduction in long-term hindlimb deficits. NBQX is also effective when administration is delayed until 4 hrs after SCI. We have now examined the effect of combining CPP administered at 15 min and NBQX at 4 hrs. A weight-drop device was used to produce a standardized incomplete thoracic SCI in rats, and CPP (40 nmoles, 1.68 µl) or vehicle (VEH) alone, administered focally at the injury site at 15 min. At 4 hrs post-injury (p.i.), NBQX (15 nmoles, 1.68 µl), or VEH alone, was similarly injected. Behavioral tests of hindlimb functional deficits were performed at 1 day and weekly thereafter for 9 weeks. The group treated with CPP and NBQX demonstrated a reduction in hindlimb functional deficits compared to VEH-VEH controls that was significant beginning at 2 weeks p.i., as we saw previously with CPP alone. The group receiving VEH-NBQX showed reduced deficits beginning at 3 weeks p.i., as seen previously with NBQX administered at 4 hours However, there was no significant difference in the degree of reduction of long-term deficits between the CPP-NBQX and VEH-NBQX groups from 3 - 9 weeks p.i. These results suggest that there are separate mechanisms involved in the antagonists' effects on speed of recovery from SCI as distinct from their effects on long-term functional deficits. ACTIONS OF SYSTEMIC THEOPHYLLINE ON HEMIDIAPHRAGMATIC RECOVERY IN RATS FOLLOWING CERVICAL SPINAL CORD HEMISECTION. K.D. Nantwi*, A. El-Bohy and H.G. Goshgarian. Department of Anatomy and Cell Biology, Wayne State Univ., Sch. of Med., Detroit, MI 48201

This study assesses the effects of theophylline on functional hemidiaphragmatic recovery after C2 spinal cord hemisection in adult female rats using electrphysiological techniques. Twenty four hours following anesthesia with choral hydrate (400 mg/kg, i.p.) and C2 spinal hemisection, rats were reanesthetized. A tracheostomy and bilateral vagotomy were performed, and the femoral artery and vein cannulated for monitoring blood pressure and drug administration respectively. The phrenic nerve ipsilateral to cord injury was placed on bipolar recording electrodes. The animal was then paralyzed and artificially ventilated. The ventilator was turned off and nerve activity recorded until it ceased. After 30 min, theophylline was administered and the procedure repeated. In another group (spontaneously respiring), both phrenic and diaphragmatic activities were monitored after the drug. In a third group of rats (spontaneously respiring) , activity in both phrenic nerves was recorded simultaneously.

In these experiments, (n=6) theophylline induced biphasic effects; i.e. at a low dose (15 mg/kg) it evoked excitation while at a high dose (30 mg/kg) depression predominated. In the first group of spontaneously respiring animals (n=5), a standard dose of theophylline (15 mg/kg) induced activity in both the phrenic nerve as well as the left hemidiaphragm ipsilateral to the hemisection. In the second spontaneouslyrespiring group (n=9), activity was induced in the nerve ipsilateral to the hemisection and enhanced in the intact phrenic nerve for up to three hours.

These results show for the first time that theophylline can activate a latent motor pathway and thus restore the respiratory drive to phrenic motor neurons which was lost by spinal cord injury. Respiratory activity is not only reestablished in the phrenic nerve made quiscent by hemisection, but it is also enhanced in the contralateral phrenic nerve.

EFFECTS OF MODEST SYSTEMIC HYPOTHERMIA IN A RAT MODEL OF CONTUSIVE SPINAL CORD INJURY (SCI). A. Martinez-Arizala*, D.H. Hesse, J. V. Perrone, B.A. Green. The Miami Project, Dept. of Neurology and Dept. of Neurological Surgery, Univ. of Miami School of Med., Miami, FL 33136.

Past studies suggest that hypothermia, in the form of local spinal cord cooling, is beneficial in SCI. These studies required surgical access to the spinal cord and cord temperature (temp) was lowered in the range of 10°C. Recent studies in experimental brain ischemia have shown that modest lowering of brain temp (1-3°C) can significantly lessen the degree of tissue damage. Such decreases may be achieved by using systemic hypothermia, which in contrast to local cord cooling does not require surgical access to the spinal cord. To investigate if modest decreases in temp are also beneficial in SCI, thoracic spinal contusive injuries (T8) of moderate severity were produced in S-D rats using the weight drop technique. Following injury, rats were subjected to systemic hypothermia (n=11; core temp=33°C for four hours), or normothermia (n=9; core temp=37°C for four hours). Following SCI, epidural temp remained one degree higher than core temperature. The mean epidural temp was 34.26 ± 0.16°C (±s.e.m.) and 37.69 ± 0.15°C in the hypothermic and normothermic groups, respectively. Hindlimb Tarlov motor scores one month post-SCI were higher in the hypothermic group, 2.9 ± 0.3, when compared to the normothermic group, 2.4 ± 0.2, although it was not statistically significant (p=0.15). The righting reflex time was significantly better in the hypothermic group; 1.56 ± 0.18 sec compared to 2.8 ± 0.47 sec for the normothermic group (p=0.28). However, inclined plane scores, beam balance performance, and sensory scores were similar in both groups. These results suggest a mild positive trend for this regimen of systemic hypothermia. Detailed histological analysis of the lesions is being used to evaluate the degree of tissue sparing, particularly of the segmental grey matter.

REDUCTION OF NaCl AMELIORATES ULTRASTRUCTURAL DAMAGE TO DENDROTOMIZED MAMMALIAN SPINAL NEURONS. D. G. Emery*, L. J. Rosenberg and J. H. Lucas. Dept. of Zoology and Genetics, Iowa State Univ., Ames, IA 50011 and Dept. of Physiology, Ohio State Univ., Columbus, OH. 43210

In low Ca^{++} conditions Na^+ and Cl^- influx after dendrotomy causes dilation of the smooth endoplasmic reticulum (SER) and Golgi apparatus in cultured spinal neurons (Exp. Brain Res. 86:60-72). Reducing NaCl by 50% (sucrose substitution) increases neuronal survival after dendrotomy from 28% to 68%, while 100% replacement of NaCl reduced survival to 2% (Neurosci. Abst. 20:353.3). We have examined the ultrastructural damage exhibited by neurons within 30 min. of dendrotomy in serum-free, HEPES buffered medium with 50% or 100% replacement of NaCl by sucrose, in the presence of normal (1.8mM) Ca^{++}. Total replacement of NaCl eliminated Golgi/SER swelling but exacerbated mitochondrial swelling, a putative lethal insult. Replacement of 50% of the NaCl reduced but did not eliminate Golgi/SER swelling but seemed to have no effect on mitochondrial swelling. The sodium component of the injury current may contribute to the elevation of cytosolic free Ca^{++} after dendrotomy by stimulating release of mitochondrial Ca^{++} or imparing the Na^+/Ca^{++} antiporter. Cl^- following Ca^{++} into the SER contributes to osmolysis of this organelle, further disrupting Ca^{++} homeostasis. Interventions which preserve the integrity of the SER may have therapeutic value. The effects of longer survival times and specific Na^+ or Cl^- substitutes on ultrastructural damage and survival after dendrotomy are currently being investigated. Supported by PHS grant NS29683 to JHL

832.5

ULTRASTRUCTURE OF MAMMALIAN SPINAL CORD (SC) NEURONS LESIONED UNDER HYPOTHERMIC CONDITIONS. G. Craenen, D.G. Emery[1], and J.H. Lucas*. Dept of Physiology, The Ohio State University, Columbus, OH 43210. [1]Dept of Zoology, Iowa State University, Ames, IA 50011.

There is considerable interest in the potential of CNS cooling to limit tissue damage during surgery and after traumatic injury. This laboratory has developed a model of nerve cell physical injury in which a UV laser microbeam is used to create defined lesions in murine SC neurons grown in tissue culture (standard injury: transection of a primary dendrite 100 µm from the soma; J. Neurotrauma 4: 231-55, 1985). Studies with this model found that a protocol of carefully controlled cooling (2h at 17°C followed by rewarming to 37°C) after dendrotomy significantly increased neuronal survival (J. Neurotrauma 11: 35-61, 1994). Protection was lost when the period at 17°C was extended. Cooling below 17°C caused a N-methyl-D-aspartate (NMDA) receptor-linked injury.

The present study compared the ultrastructural damage that developed in the perikarya of neurons lesioned at 10°C, 17°C, 27°C and 37°C (8-14 cells/group). D-2-amino-5-phosphonovalerate (10 µM) was added to the medium in all experiments to prevent NMDA-linked hypothermic injury. Cells were fixed 5-25 min after surgery. In general, dilation/vesiculation of the Golgi/endoplasmic reticulum in lesioned neurons decreased as the temperature was reduced. The incidence of cytoplasmic condensation, which may be an early indicator of lethal injury (J. Neurotrauma 4: 231-55, 1985), also decreased with cooling (0% at 10°C, 36% at 17°C, 55% at 27°C and 50% at 37°C). However, somal mitochondria of neurons lesioned at lower temperatures exhibited more stress (lucent matrix foci and/or general dilation) than neurons lesioned at 37°C. A study of the damage that develops in neurons cooled after dendrotomy at 37°C, is in progress. Supported by PHS 29683-04 from NINDS to JHL.

REDUCTION OF EXTRACELLULAR Na+ INCREASES SURVIVAL OF SPINAL CORD (SC) NEURONS SUBJECTED TO DENDROTOMY. L.J. Rosenberg*, D.G. Emery†, and J.H. Lucas. Dept of Physiology, The Ohio State University, Columbus, OH 43210. †Dept of Zoology, Iowa State University, Ames, IA 50011.

A modified ionic environment (MIE) that limits neuronal deterioration would be useful in situations of trauma or surgery. Previous studies in low Ca+2 MIE's found that Na+ and Cl- contribute to osmolysis of the smooth endoplasmic reticulum (SER) and Golgi in SC neurons subjected to dendrite transection with a UV laser microbeam (Emery et al., Exp. Brain Res. 86, 1991). The SER can provide significant Ca+2 buffering even when intracellular levels exceed 10 µM (Carafoli and Penniston, Sci. Amer. 253, 1985). Survival was significantly higher when neurons were lesioned and maintained for 12h in Hepes buffered, serum-free MIE's with a 50% reduction of NaCl (sucrose substitution, normal Ca+2; Lucas et al., Soc. Neurosci. Abst. 20, 844). The present studies investigated the individual contributions of Na+ and Cl- (normal Ca+2) to neuronal degeneration after dendrotomy.

Study I Na+ substituted MIE's were toxic to unlesioned SC neurons and glia when exposure times exceeded 2h. No visible stress was observed in cultures exposed for 2-12h to Cl- substituted MIE's.

Study II Neurons were lesioned in various MIE's (50-80 cells/group). The normal ionic environment was restored 2h post surgery and survival was evaluated at 24h by erythrosin B.

120 mM NaCl	60 mM NaCl	Na+ substitutes	Cl- substitutes
34%±11	67%±17	Choline 74%±13	Isethionate 30%±12
		*NMDG 63%±17	D-gluconate 32%±12

*NMDG = N-methyl-D-glucamine

Study III of the effects of Na+ and/or Cl- reduction on the ultrastructural damage that develops in lesioned neurons, is in progress. Supported by PHS 29683-04 to JHL.

COMPARISON OF SCIATIC NERVE GRAFTS AND SYNTHETIC TUBES AS BRIDGES IN SPINAL CORD INJURY REPAIR. J.A. McLane* and J. M. Kerns. Rehabilitation R&D Center, Edward Hines Jr. VA Hospital, Hines, IL 60141 and Department of Anatomy, Rush-Presbyterian St. Lukes Medical Center, Chicago, IL 60612.

Although it has been shown that central nervous system neurons are capable of vigorous attempts at regeneration, functional regeneration is seldom successful because of the formation of a dense scar and the presence of inhibitor factors. There are few exceptions to date in experimental models. Peripheral nerve autografts have been shown to enhance regenerative processes within the optic nerve and other injured central nervous system axons. However, the supply of peripheral nerve to use as autografts is very limited. Therefore, synthetic tubular prostheses are being investigated as a means of enhancing and directing regeneration of neurites in the corticospinal tract of the spinal cord following injury.

In these studies, the corticospinal tracts of rats were cut in the midthoracic region of the spinal cord. At the time of injury one end of an artificial nerve consisting of a 1.2 mm i.d. polysulfone tube (Amicon) filled with 30% Matrigel was implanted at the injury site. The other end of the tube was implanted deep into the spinal cord to approximate the ventral horn at a site caudal to the initial injury. Regeneration of axons within these tubes was compared to regeneration of axons within a similarly grafted segment of fresh or predegenerated, isogeneic peripheral nerve. Comparisons were based upon immunocytochemical and morphometric evaluations.

The synthetic tubes supported a cable of organized cells filling more than 50% of the tube volume. This cable was composed of a mixture of cell types, including fibroblasts, glial cells, and a few bare or loosely ensheathed neurites. The cable was highly vascularized and wrapped by a layer of connective tissue. The nerve grafts contained many neurites which were ensheathed by either Schwann cells or myelin.

PROTECTIVE EFFECT OF GLUTATHIONE GLYCOSIDE IN EXPERIMENTAL SPINAL CORD INJURY. S. Etebar, R. C. Kim*, B. H. Choi. Neuropathology, DVA Med Ctr, Long Beach, CA 90822 and Univ. of Calif., Irvine, CA 92717.

Secondary tissue damage developing subsequent to traumatic or ischemic CNS injury is thought to be related at least in part to the generation of reactive oxygen species (ROS). To determine the effectiveness of the potent antioxidant glutathione (GSH), in comparison to that of methylprednisolone (MP), in protecting against oxidative stress following spinal cord injury, the thoracic spinal cords of Sprague-Dawley rats were compressed by a Sugita aneurysm clip; 15 min later, animals were given either a GSH-glycoside (GSH-gly), a newly synthesized compound in our laboratory, or MP intraperitoneally. Thiobarbituric acid-reactive substances (TBARS) and hydrogen peroxide (H_2O_2) levels were measured in animals sacrificed at 6 hr. Spinal cord TBARS levels were significantly lower in GSH-gly- or MP-treated than in control animals. Tissue H_2O_2 levels were also lower in both treatment groups, although the difference was statistically significant only in those given GSH-gly. In addition, neurological assessment, using the Tarlov grading scale, Rivlin-Tator inclined plane testing and tail-flick response, showed functional recovery to be greater in GSH-gly-treated than in untreated animals. These findings, therefore, suggest that GSH-gly is effective in protecting against ROS-mediated damage following spinal cord injury.

COMPLEX ENVIRONMENT ATTENUATES SPATIAL MEMORY DEFICITS FOLLOWING CORTICAL CONTUSION. S.A. Baldwin*, T.R. Gibson, R.W. Brown, P.J. Kraemer and S.W. Scheff. Center on Aging and Dept. Psychology, Univ. Kentucky, Lexington, KY 40536.

Exposing weanling rats to a complex environment (CE) can alter brain anatomy by increasing brain weight, cortical thickness, dendritic branching and vasculature. Environmental enrichment has been implicated as an aid in recovery from lesion-induced functional impairments in rats. An animal model for cortical contusion has been developed which manifests many of the neuropathologies seen in human closed head injury. The model involves an electronic controlled pneumatic impact device which can deliver very precise and controlled cortical contusions to an animal. This model can be used to study the effects of environmental enrichment on compensation following injury.

Weanling CE rats were housed together in a large cage filled with novel objects that were changed daily. Isolated condition (IC) rats were kept in standard laboratory cages without the objects. Forty days following CE or IC rearing the rats were anesthetized and subjected to a unilateral cortical injury. Seven days after brain trauma, the animals were tested for spatial memory in a Morris Water Maze. The CE group was significantly better on the spatial memory task. Morphological analysis revealed a significant increase in the cortical thickness for the enriched animals as compared to those in the isolated condition.

While it is unclear at present why the CE group performs better, these animals may have a better General Adaptive Capacity (GAC). The complex environment increases the GAC and thus allows the CE animals to perform better. These animals appear to show a greater compensation ability following the trauma. Supported by NS31220

MEASUREMENTS OF DELAYED CELL DEATH FOLLOWING CORTICAL CONTUSION INJURY IN RATS.

S.L. von Stück*, S.M. Lee, D.A. Hovda and D.P. Becker.
Division of Neurosurgery, UCLA Sch. of Med., Los Angeles, CA 90024.

Previous work from our laboratory has demonstrated significant neuronal death (up to 73% cell loss) at 2 weeks following a lateral pneumatic piston injury. There is a sequence of secondary insults including biochemical and metabolic alterations immediately after injury that may increase functional impairment as well as induce cell death. This study utilized cytochrome oxidase histochemistry and cellular cytoarchitecture analysis to examine the time course of pathological changes following a lateral pneumatic piston induced injury in 19 male rats. Under general anesthesia (2.0-2.5 mL/min enflurane; 100% O2) a cortical contusion was produced using a 5 mm diameter flat tip (centered at -3.4 mm from bregma) driven to a depth of 2 mm beneath the cortical surface at a velocity of 1.6 m/s. The development of cavity formation and neuronal necrosis were evaluated immediately, 1 h, 6 h, 1 d, and 3 d following injury. Alternate 20 mm sections were stained with cresyl violet and cytochrome oxidase. Immediate cell death was produced by the mechanical shearing at the rim of the impact site (~20% of impact site) and tearing occurred in the white matter below the site. The cells in the remaining 80% of the impact site have morphological characteristics of viable cells up to 1 d post-injury. This core showed slight depression (80% of contralateral) in cytochrome oxidase staining at 6 h but significant depression (50%) at 1 d and 3 d post-injury. This depression was not present at sites distal from the impact site at any time post-injury. These results indicate a potential relationship between secondary tissue damage and altered physiological states. It suggests a window of optimal effectiveness for pharmacological intervention that will rescue injured cells.

AMPHETAMINE ENHANCES METABOLIC RECOVERY FOLLOWING MODERATE AND SEVERE CONCUSSIVE HEAD INJURIES IN ADULT RATS. A. Panigrahy*, S.M. Lee, N. Balady, D.A. Hovda, and D.P. Becker. Division of Neurosurgery, UCLA School of Medicine, LA, CA 90024.

Catecholamine stimulation, via amphetamine (AMPH) administration, has been shown to alleviate the metabolic depression typically seen after brain injury in the rat. Previous work from our laboratory has shown that following a moderate fluid percussion (F-P) brain injury, the local cerebral metabolic rates for glucose (LCMRglc) remain depressed as compared to sham-injured values in several neocortical areas, lasting up to 10 days post-injury. We have also found that increasing the levels of severity of F-P brain injury results in a prolonged metabolic depression. In this study, we assessed whether AMPH administration after F-P brain injury would enhance metabolic recovery from a F-P brain injury, in a dose dependant manner, depending on the level of severity of injury. Fifteen adult male Spraque Dawley rats (250-350g) were F-P injured at moderate or severe injury levels while under general anesthesia. AMPH (2 mg/kg BW) was administered 3h after injury for single treatment experiments and 3,6, and 9 h after injury for multiple treatment studies. After 1 day post-injury, LCMRglc was determined by [^{14}C] 2-deoxy-D-glucose autoradiographic methods. LCMRglc for injured animals without AMPH administration served as control values. Moderate-injured animals (n=3), with a single treatment, exhibited LCMRglc values 13%-32% greater than untreated moderate-injured animals (n=4) in different regions of the neocortex (frontal, parietal, and occipital cortex). Severe-injured animals (n=3), with a single treatment, exhibited LCMRglc values that did not significantly differ from untreated severe-injured animals (n=3) in the cortical regions examined. Severe-injured animals (n=2), with multiple treatments, exhibited LCMRglc values 14-20% greater than untreated severe-injured animals in the cortical regions examined. These results suggest that AMPH administration enhances metabolic recovery in a dose-dependant manner; multiple treatments may be require to enhance metabolic recovery with a more severe injury. Supported by NS30308, Lind Lawrence Foundation, and a Howard Hughes Medical Student Research Training Fellowship.

KININ B_2 BUT NOT B_1 RECEPTOR ANTAGONIST TREATMENT REVERSES I.C.V. ENDOTOXIN-INDUCED HYPERALGESIA AND FEVER IN THE RAT.

M. Perkins*, K. Walker, & A. Dray. Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN, U.K.

The pro-inflammatory effects of bradykinin (Bk) B_1 and B_2 receptor stimulation have been extensively studied in models of peripheral inflammation. However all of the components of the kinin system are also present in the CNS (Walker *et al.*, 1995, *Neurochem. Int.*, 26:1-16). The present study examined whether inhibition of kinin activity could also alleviate some effects of CNS inflammation. We have investigated the development of hyperalgesia and fever following i.c.v. injections of *E. Coli* lipopolysaccharide (LPS). Rats received a single i.c.v. injection of LPS (200 ng) under enflurane anaesthesia. Rectal temperature (RT), thermal hyperalgesia and mechanical hyperalgesia were measured before and at 2 h intervals following LPS (n = 6/group). RT, thermal and mechanical hyperalgesia were maximal 6 h after LPS injection. LPS-induced increases in RT, thermal and mechanical hyperalgesia were reversed ($P < 0.05$) by the i.c.v. co-administration of the B_2 receptor antagonist, HOE 140 (10-30 pmol), but not by co-administration of B_1 receptor antagonists, des-Arg^9-Leu^8 Bk (0.1-1 nmol) or des-Arg^{10} HOE 140 (0.1-1 nmol). Systemically administered HOE 140 (0.01-1 µmol/kg, i.v.) produced no significant effect. However LPS-induced fever, thermal and mechanical hyperalgesia were inhibited by either i.c.v. (10 nmol) or i.v. (0.1-1 µmol/kg) administered indomethacin. These results indicate that administration of endotoxin to the CNS induces the development of hyperalgesia and fever and that these responses involve the activity of kinins, via the stimulation of centrally located B_2 receptors, and the formation of prostanoids.

ADENOSINE PROVIDES PROTECTION FROM CA1 TRAUMATIC NEURONAL INJURY TO HIPPOCAMPAL SLICES. S.J. Stamos*, K.L. Panizzon and R.A. Wallis, Dept. of Neurology, UCLA, Los Angeles, CA 90024 and Sepulveda VAMC, Sepulveda, CA 91343.

Extracellular increases in adenosine concentration during hypoxia-ischemia have been found to be neuroprotective. Several cytotoxic mechanisms mediating hypoxic-ischemic injury have been shown to be active in traumatic neuronal injury as well. Therefore, to assess the possible neuroprotective role of adenosine against traumatic neuronal injury, we investigated whether exposure to adenosine would prevent CA1 neuronal injury from fluid percussion trauma in the hippocampal slice. Treatment with 1.0 mM adenosine begun within one min. after trauma, improved recovery at 95 min. of CA1 orthodromic population spike (PS) from 11% ± 5 to 91% ± 4, and improved recovery of CA1 antidromic PS from 13% ± 2 to 91% ± 3. Tetanic stimulation of 100 Hz for 1 second at supra-maximal threshold given 95 min. following trauma, produced a significant increase in CA1 orthodromic PS of 132% ± 10 over baseline after recovery with adenosine treatment. This increase persisted during one hour of additional monitoring consistent with preserved long-term potentiation. Neuroprotection against trauma was also seen with the A1 receptor agonist, N^6-cyclohexyladenosine (20 µM) which increased CA1 PS orthodromic and antidromic recoveries to 93% ± 2 and 92% ± 3, respectively. These findings indicate that direct adenosine application and more specifically, A1 receptor stimulation, provide protection against CA1 traumatic neuronal injury. This work also suggests that elevations of extracellular adenosine concentration may be a preventive factor against the development of neuronal injury after head trauma. Supported by the VA Research Service.

P-SELECTIN BLOCKADE AFTER FLUID PERCUSSION INJURY: BEHAVIORAL AND ANATOMIC SEQUELAE. D.O. Maris, R.F. Cody, H. Seckin, S.R. Sharar[1], M.S. Grady*. Depts. of Neurological Surgery and Anesthesiology[1], Univ. of WA Sch. of Med., Seattle, WA 98104.

Ischemia and reperfusion promotes neutrophil migration into brain parenchyma, resulting in free radical formation which is in part responsible for neuronal injury. Traumatic brain injury is frequently associated with ischemia. We examined the effect of blockade of cell adhesion molecules (CAMs; important in neutrophil margination and migration across endothelium)on the anatomic and behavioral sequelae of traumatic brain injury in the rat. Lateral fluid-percussion injury (FPI) was used as the injury model. A standard Morris water maze was used as the behavioral task. A blocking antibody to P-selectin (a CAM important in causing neutrophils to attach to endothelium; Cytel, San Diego) and a non-blocking P-selectin antibody were used as treatments. Thirty-two adult male Sprague-Dawley rats were randomly divided into four groups: injury-only; injured/inert vehicle; injured/CAM antibody; sham injury (all n=8). Rats were given moderate FPI with those rats in the treatment groups immediately receiving an intra-arterial injection. Subjects were "place" tested in the Morris water maze at 7 and 14 days post-injury for spatial learning. Rats were perfused at 14 days post-injury and their brains sectioned. Immunocytochemistry was performed on the forebrain for ChAT and GABA, and on the hippocampus using GFAP, OX-42, OX-6, and ED-1. A separate group of 16 animals underwent identical preparation for myeloperoxidase (MPO) determination in the brain parenchyma.

Rats in the injured-only group performed poorly compared to the sham-injured group ($p < .01$), indicating a spatial learning deficit. Using multiple performance indices, a slight treatment effect was seen for rats in the CAM-blockade group ($p<.05$) in cumulative distance and quadrant time measures; latency values were not significant. No significant differences were observed in any performance index between the control antibody and injury-only groups. Analyses of MPO and anatomical data are currently being conducted. This study suggests that administration of a CAM-blocking agent following injury may attenuate the behavioral effects of TBI. (Supported by NIH P 50 NS30305).

LIPOSOME-MEDIATED BDNF cDNA TRANSFER IN INTACT AND TRAUMATICALLY INJURED RAT BRAIN. [1]K.Yang*, [1]Y.Iwamoto, [1]X.S.Mu, [1]N.Mu, [1]C.E.Dixon, [1]J.S.Whitson, [2]J.R.Perez-Polo, [1]G.L.Clifton, [1]R.L.Hayes. [1]Neurosurgery, U of TX Health Science Ctr., Houston, TX 77030; [2]Human Biochem. & Genetics, U of TX Medical Branch, Galveston, TX 77555.

The therapeutic potential of various neurotrophins for treatment of the injured central nervous system is widely recognized (Barinaga, et al., Science 264:772-774, 1994). The transient expression produced by liposome-mediated gene transfection may limit its application in diseases caused by genetic defects. However, liposomal transfection of neurotrophin may prove useful for treatment of CNS injury. Our laboratory recently reported reduced neurofilament loss in traumatized septo-hippocampal primary cell cultures by liposome-mediated BDNF cDNA gene transfer (Hayes, et al., Neurosci. Lett. in press; Hayes, et al., this meeting). To further explore the potential of gene therapy in brain injury, we are conducting systematic studies of liposome-mediated neurotrophin gene transfer in uninjured rats and in rats following experimental cortical impact injury. Eight μg of pCMV/BDNF plasmid DNA was mixed with 20μl of commercially available liposomes (DOTMA and DOPE: Gibco-BRL) and either liposomes alone or cDNA/liposomes injected (1.2 μl/min) stereotactically into the right hippocampus of uninjured rats with a microsyringe pump. Rats were sacrificed at various time points up to 6 days following injections. PCR analyses were able to detect BDNF cDNA in hippocampi injected with liposomes complexed with cDNA for BDNF from one to six days after injection. Immunohistochemistry studies indicated that expression of BDNF protein (turkey anti-BDNF: Amgen) extended beyond the injection site. Similar profiles of BDNF gene transfection were seen when liposomes or liposomes/cDNA were injected ten minutes after cortical impact injury. Our results suggest that liposome-mediated transfection of neurotrophin cDNA can be a practical gene transfer method for treatment of brain injury. (Supported by NIH grants PO1 NS31998 and RO1 NS21458)

832.16

LIPOSOME-MEDIATED TRANSFECTION OF NEUROTROPHIN cDNA ENHANCES RECOVERY OF NEUROFILAMENT LOSS AND CHOLINE ACETYLTRANSFERASE (ChAT) ACTIVITY AFTER INJURY TO SEPTO-HIPPOCAMPAL CELL CULTURES. R.L. Hayes*, K. Yang, J.S. Whitson, W. Le, J.J., Xue, C.E. Dixon, G.L. Clifton, A. Kampfl. Dept. of Neurosurgery, University of Texas Houston Health Science Center, Houston, TX 77030.

Enhancing the availability of neurotrophins following brain injury may have significant therapeutic potential. Thus, we used primary septo-hippocampal cell cultures to study liposome-mediated BDNF and NGF gene transfer following depolarization injury (6.0 min depolarization with 60 mM KCl in the presence of 2.8-5.8 mM Ca^{++}). BDNF or NGF cDNA were subcloned onto a unique Not1 site under the control of the CMV promoter. BDNF or NGF cDNA was complexed with liposomes (1.0-3.0 μl lipofectin:1.0 μg cDNA) and transferred to septo-hippocampal cell cultures one day after neuronal injury. Transfection control cultures were incubated with the equivalent volumes of liposomes without cDNA. Three days after depolarization injury, ChAT activity was determined, or Western blot and immunohistochemical analyses examined losses of neurofilament proteins. In non-transfected cultures, we observed approximately 30% loss of ChAT activity following depolarization injury. Depolarization cultures transfected with NGF cDNA did not manifest any significant ChAT activity loss. Depolarization also produced significant loss of neurofilament proteins in non-transfected cultures. Both Western blot analyses and immunohistochemical studies confirmed that BDNF transfection significantly enhanced the recovery of neurofilament proteins three days following depolarization injury. Liposome-mediated transfection of neurotrophins may be useful for treatment of cytoskeletal derangements and disturbances in cholinergic neurotransmission following central nervous system injury (also see Yang, et al., this meeting). (Supported by NIH grants PO1 NS 31998 and RO1 NS 21458)

EVOLUTION OF THE ALTERATIONS ON ORAL ACETAMINOPHEN PHARMACOKINETICS INDUCED BY SPINAL CORD INJURY IN THE RAT. P. García-López, G. Castañeda-Hernández, G. Guízar-Sahagún and I. Madrazo*. Proyecto Camina A.C. Calz. Tlalpan 4430, 14050 México, D.F., Mexico.

There is evidence that drug kinetics are altered by spinal cord injury (SCI). Notwithstanding, it is not known if such changes are permanent or evolve during the acute, subacute and chronic phases following SCI. Therefore, we studied acetaminophen kinetics after a single oral 100 mg/kg dose 1, 12 and 50 days after spinal cord contusion at the T8 level in rats. Peak plasma concentration in μg/ml (Cmax), area under the blood concentration against time curve in μg h/ml (AUC) and half-life in h (T1/2) were 115±10, 106±7 and 3.8±0.2 respectively in sham-lesioned control rats. 1 day after SCI Cmax was 54±9*, AUC was 76±7 and T1/2 was 5.6±0.6* (* denotes $p<0.05$ compared to control values), the significant reduction on Cmax indicates a decrease in absorption, whereas the significant longer T1/2 suggests an impaired elimination. As a results, bioavailability, indicated by AUC, did not change significantly. 12 days after SCI Cmax was 77±8*, AUC was 78±7 and T1/2 was 3.9±0.3. This suggests that the effect on elimination was reverted, but not that on absorption. 50 days after SCI Cmax was 133±16, AUC was 129±21 and T1/2 was 4.5±0.3. It appears that, both, absorption and elimination were recovered. It is concluded that SCI results in important pharmacokinetic alterations which, however, revert with time. It then appears that, although dosage regimens should be changed after a recent SCI, fixed regimens are not recommended and hence dosing should be continuously adjusted.

832.18

DELAYED ADMINISTRATION OF AMPHETAMINE IMPROVES SPATIAL LEARNING FUNCTION AFTER LATERAL FLUID PERCUSSION INJURY IN THE RAT. M.R. Prasad,* J. M.Dose, H.S. Dhillon and P. Kraemer. Departments of Surgery and Psychology, University of Kentucky Medical Center, Lexington, Ky 40536.

Several studies indicate that the administration of amphetamine at 24 hr after sensorimotor cortex ablation injury and the practice during drug intoxication facilitate the functional recovery of animals. In the present study, we examined the effects of separate administrations of amphetamine (that can enhance the release of norepinephrine), prazosin (an alpha 1-adrenergic receptor antagonist and methoxamine (an alpha 1-adrenergic receptor agonist) at 24 h after lateral fluid percussion (FP) brain injury on the neurologic motor and cognitive outcome of brain injury. Male Sprague Dawley rats (325-350 g; N=44) animals were pretrained to perform beam walk task. The next day the rats were treated with atropine, anesthetized with sodium pentobarbital (60 mg/kg, IP) and subjected to lateral FP brain injury of moderate severity (2.1-2.2 atm.). At 24 h after injury, after obtaining baseline beam walk scores, animals were injected with saline (N=11) or amphetamine (4 mg/kg, N=12) or prazosin (4 mg/kg, N=11) or methoxamine (10 mg/kg, N=10). None of the above drugs significantly affected the beam walking ability of animals during practice (1 h, 2 h and 6 h after drug treatment) and on days 2 through 10 after brain injury. Amphetamine, but not prazosin and methoxamine, treated animals demonstrated significant ($p<0.05$) improvement in spatial learning ability than those of saline treated animals. These results suggest that amphetamine-improved outcome of FP brain injury may involve a combination of receptors along with alpha 1-adrenergic receptor (Supported by NIH Grant NS 31816).

832.19

MK801 PRETREATMENT NORMALIZES MEMORY DEFICITS BUT NOT ALTERED PHOSPHOINOSITIDE METABOLISM 15 DAYS AFTER MODERATE TRAUMATIC BRAIN INJURY. T.M.DELAHUNTY', J.Y.JIANG, Q-Z. GONG, L.L.PHILLIPS, R.J.HAMM, B.G.LYETH. Division of Neurosurgery, Medical College of Virginia, Richmond, VA 23298.

Traumatic brain injury (TBI) produces significant memory impairment and cognitive deficits at 15 days after injury that are reduced by pretreatment with the NMDA receptor antagonist MK801. We have demonstrated altered muscarinic receptor coupling at 15 days after injury. This study examines the effect of MK801 pretreatment on altered muscarinic receptor coupling. Rats were given (i.p.) a single bolus of MK801 (0.3/mg/kg) and injured 15 minutes later by a 2.0 atmosphere lateral fluid percussion impact. After 15 days survival the rats were sacrificed and hippocampal tissue from injured and sham-injured controls was labelled with [^{3}H]-myoinositol and challenged with 250μM Carbachol. The response of injured animals was compared to that of sham-injured animals. In untreated animals, basal inositol phosphates on the side contralateral to the injury cannula were unchanged by injury but on the side ipsilateral to the injury cannula basal levels were enhanced by 26% ($p=0.01$). The response to carbachol was enhanced by 8% on the contralateral side but diminished by 11% on the ipsilateral side ($p=0.02$). In MK801 pretreated animals basal inositol phosphates were unchanged by injury on the side contralateral to the injury cannula but were enhanced by 46% ($p=0.01$) on the side ipsilateral to the injury cannula. The response to carbachol in treated animals remains enhanced by injury 9% on the contralateral side and diminished by 20% on the ipsilateral side ($p=0.05$). Thus, blockade of NMDA receptors does not protect against alterations in muscarinic responses and exacerbates injury induced changes on the side ipsilateral to the injury cannula. Supported by NIH grants NS 12587 and NS 29995.

TACRINE SLOWS COGNITIVE RECOVERY AFTER TRAUMATIC BRAIN INJURY AND A MUSCARINIC M2 ANTAGONIST REDUCES ITS EFFECT. B.R. Pike*, R.J. Hamm, D.M. O'Dell, M.D. Temple, and B.G. Lyeth. Dept. of Psychology and Division of Neurosurgery, Virginia Commonwealth Univ./Medical College of Virginia, Richmond, VA 23284-2018.

Posttraumatic neuronal depression is hypothesized to contribute to the long-term cognitive deficits following traumatic brain injury (TBI). Postinjury blockade of the presynaptic muscarinic M2 autoreceptor with BIBN 99 amplifies ACh release and improves cognitive performance following TBI in rats. This investigation tested the effects of tacrine (THA), a cholinesterase (AChE) inhibitor, on cognitive performance following central fluid percussion TBI. In addition, effects of combined administration of BIBN 99 and THA on cognitive performance was also tested. In experiment 1, injured rats (2.1 atm) were injected (i.p.) daily for 15 days with either saline (n=8) or 3.0 mg/kg THA (n=10) beginning 24 h after injury. Cognitive performance was assessed on days 11-15 after injury in the Morris water maze (MWM). ANOVA indicated that there was no difference on MWM latencies over days between Saline and THA treated animals. However, to examine rate of recovery, regression lines were calculated and compared by a t-test. This analysis showed that the THA group recovered at a slower rate than the Saline group ($p<0.01$). In experiment 2, injured rats (2.3 atm) were injected daily with either saline (n=7) or the combination of 0.5 mg/kg BIBN 99 (s.c.) and 3.0 mg/kg THA (i.p.) (n=7) according to protocol of experiment 1. ANOVA indicated that there was no difference on MWM latencies over days between Saline and BIBN 99+THA treated animals. However, a t-test on the regression lines was significant ($p<0.05$) indicating that the combined treated animals recovered at a faster rate than the Saline treated animals. These results suggest that AChE therapy slows cognitive recovery following rodent TBI. Cholinergic amplification with presynaptic M2 muscarinic antagonists appears to be a more efficacious strategy for improving cognitive outcome following TBI. (Supported by NS 12587)

NERVE GROWTH FACTOR ATTENUATES THE LOSS OF CHOLINERGIC NEURONS IN THE MEDIAL SEPTAL NUCLEUS WHICH OCCURS AFTER FLUID-PERCUSSION BRAIN INJURY IN THE RAT. G. Sinson, E.S. Flamm*, T.K. McIntosh. Division of Neurosurgery, University of Pennsylvania, Philadelphia, PA 19104.

Neurotrophins have potential therapeutic applications in a number of neurodegenerative diseases. Previously we have shown that cortical infusions of NGF can attenuate memory deficits in rodents subjected to lateral fluid-percussion brain injury. This study attempts to establish a histopathologic correlation for these cognitive improvements.

Male Sprague-Dawley rats underwent lateral fluid-percussion brain injury of moderate severity (2.1-2.3 atm.). Twenty-four hours after injury, a mini-osmotic pump was implanted to infuse NGF (n=9) or vehicle (n=5) directly into the region of maximal injury. Infusions continued in all animals for 2 weeks, at which time the pumps were removed. Two weeks later (4 weeks after injury) the animals were sacrificed and compared histologically with uninjured animals (n=5). Measurements of the area (mm2) of the septal nuclei demonstrated significant losses in all injured animals ($p<0.05$). Immunohistochemical identification of cholinergic neurons in the medial septal nucleus also demonstrated a significant loss of these neurons in all injured animals ($p<0.05$). The loss of these cholinergic neurons was significantly less in those injured animals which had received NGF infusion after injury ($p<0.05$). Acetylcholinesterase histochemical staining in the hippocampus was also greater in those animals which had received NGF infusion (but still less than uninjured animals). No differences in the size of the cortical injury were noted.

These data suggest that NGF administration, beginning 24 hours after fluid-percussion brain injury, attenuates the loss of cholinergic neurons in the medial septal nucleus. (Supported, in part, by NIH NS26818 and 08803)

MCPG TREATMENT OF TRAUMATIC BRAIN INJURY IN THE RAT. Q-Z. Gong, T.M. Delahunty, R.J. Hamm, and B.G. Lyeth*. Division of Neurosurgery, Medical College of Virginia, Richmond, Va 23298-693.

Numerous studies have demonstrated the involvement of ionotropic glutamate receptors in traumatic brain injury (TBI) pathophysiology. This study examined the involvement of metabotropic glutamate receptors (mGluRs) in TBI. Of the seven cloned mGluRs, $mGluR_1$ and $mGluR_5$ are coupled to phospholipase C signal transduction, whereas the other five are negatively coupled to adenylate cyclase. Pharmacological studies have demonstrated that (+)α-methyl-4-carboxyphenylglycine (MCPG) acts as a selective antagonist for $mGluR_1$ and $mGluR_2$, while the (−)MCPG isomer is relatively inactive.

In this study, a single 5.0 μl injection of (+)MCPG (0.02 μM, n=8, 0.2 μM, n=10), (−)MCPG(0.2 μM, n=10) or CSF-vehicle (n=11) was administered into left lateral ventricle 5 minutes prior to TBI. A 2.1 atmosphere fluid percussion pulse was delivered through a 2.6 mm diameter injury cannula centered over the right cortex (bregma -5.0, lateral 3.0 mm). Performance on sensory motor tasks was assessed prior to injury and for 5 days after TBI with beam-balance, beam-walking and rotarod tasks. Memory performance was assessed on days 11-15 after TBI with Morris water maze. TBI produced significant motor and memory deficits in the CSF-treated group. High-dose (+)MCPG-treated rats had significantly smaller deficits compared to CSF-treated rats on beam-walking ($P<0,05$) and memory ($P<0.01$), but did not differ from CSF-treated rats on either systemic arterial blood pressure or heart rate responses to injury. Neither the low-dose (+)MCPG nor (−)MCPG affected behavioral deficits. These results suggest that TBI-induced activation of $mGluR_1$ and/or $mGluR_2$ contributes to TBI morbidity. Blockade of those receptors with (+)MCPG may reduce certain components of TBI morbidity.

COMPENSATORY PLASTICITY OF THE BRAIN AFTER TRANSCRANIAL POLARIZATION IN CHILDREN WITH CEREBRAL PALSY. M.Sinyaya*[1], D.Pinchuck , M.Katisheva, E. Sidorenko. [1]Pavlov Institute of Physiology of RAN, Inst. of Exp.Medicine, St.Petersburg, Russia,199034,

Local transcranial polarization was used for correction of motor dysfunctions in children with CP. The state of the brain and spinal cord were examined by analysis of EEG, EMG and habituation. Muscle tonus was recorded by new miotonometer that was developed in the lab. of Ontogenesis in the Inst. of Exp.Med. The clinical effects were depended on scalp location of electrodes, the method (mono or bipolar) of stimulation, strengh of the current and its duration. It was shown that the polarization of the brain has led to the decrease in the variation of EEG, restoration of stability of the interhemispheric connections, formation of normal patterns of EEG and the increase in the role the α-rhythm. We estimated that the muscle tonus, the manipulate test, the habituation process on verbal stimulation, asymmetry of the brain changed after polarization, parallel with the restoration of motor functions. Our methods allow for the control of the rehabilitation process dynamics and for the compensatory ability of the brain and spinal cord to be altered.

INHIBITORY EFFECT OF NYA ON NOS INDUCTION IN AN ANIMAL MODEL OF CEREBRAL HEMORRHAGE. Z.-C. Peng*[1,3], X.-Q. Li[2], Q.-H. Liang[2], C.-X. Zhu[2], X.-X. Yan[1], X.-Y. Hu[2]. [1]Dept. Anat., [2]Inst. Trad. Chinese & Western Med., Hunan Med. Univ., P.R. China; and [3]Inst. Anat. & Histol., Univ. Verona, Italy.

Nao Yi An (NYA), a complex deriving from Traditional Chinese Medicine, has been found to be effective in the recovery of movement deficits in patients suffering from cerebral hemorrhage. We studied the modification of nitric oxide synthase (NOS) activity in an animal model of cerebral hemorrhage, and the effect of NYA, by means of NADPH-diaphorase (NDP) histochemistry. NYA (4.38 g/kg body weight) was orally administered to adult Wistar rats 2 h before autologous blood injection into the right internal capsule (IC) (T Group rats); NYA administration was then repeated daily until perfusion. NYA was not administered in other animals which received blood injection in the IC (C group). Rats were perfused 2, 4, 7, 14, and 28 days after the operation and brain sections were processed for NDP-histochemistry. NDP-positive non-pyramidal neurons were seen in the cerebral cortex, as normally present. In addition, in the C group of rats, numerous NDP-positive pyramidal neurons and endothelial cells were seen throughout the ipsilateral and contralateral cortex, especially in the operated hemisphere, 2 days after surgery. NDP-positive non-neuronal cells, presumably macrophages and astrocytes, were also seen In the C group in the operated hemisphere, close to the needle track. NDP-positive pyramidal neurons were only seen in the ipsilateral cortex 4 days after the operation, when very few NDP-positive non-neuronal cells were still detectable. NDP-positive non-neuronal cells disappeared afterwards. The number of NDP-positive pyramidal neurons decreased progressively 7 days after the operation and they were not visible after 28 days. Non-neuronal NDP-positive cells were not detected in the T group, in which very few NDP-positive pyramidal neurons were detected only in the area close to the needle track in the earliest stage. Thus, our data indicate that autologous blood injection into the brain may induce NOS expression, and that NYA may inhibit such induction.

METHYLPREDNISOLONE BLOCKS MEMBRANE LIPID PEROXIDATION BUT DOES NOT SCAVENGE FREE RADICALS. DANXIA LIU* AND LIPING LI. Marine Biomedical Institute and Department of Human Biological Chemistry and Genetics, University of Texas Medical Branch, Galveston, TX 77555-1143

Methylprednisolone (MP) reduces impairment in human and experimental animals following traumatic spinal cord injury. To study the mechanisms whereby MP reduces secondary injury, prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$, 0.2 mM in ACSF), a product of membrane lipid degradation, was administered into rat spinal cord through a microdialysis fiber. $OH^{\bullet}$ formation was measured by also administering salicylate (0.5 mM in ACSF) through the fiber as a trapping agent and measuring the products 2,3- and 2,5- dihydroxybenzoic acid by HPLC and electrochemical detection. Malondialdehyde (MDA), an end product of membrane lipid peroxidation, was also measured from dialysates by HPLC and fluorometric detection. We found that $OH^{\bullet}$ and MDA both increased dramatically in response to $PGF_{2\alpha}$ administration. In the MP-treated group, 30 mg/kg and 60 mg/kg body weight of MP completely blocked $OH^{\bullet}$ formation and MDA release respectively. This demonstrates that $PGF_{2\alpha}$ induces $OH^{\bullet}$ formation, thereby causing membrane peroxidation to release MDA and that MP blocks the pathway of $PGF_{2\alpha} \rightarrow OH^{\bullet}$ and subsequent MDA production. Next, we generated $OH^{\bullet}$ by administering Fenton reagents into the rat spinal cord and measured MDA release caused by $OH^{\bullet}$ generation. We found that MDA dramatically increased in response to $OH^{\bullet}$ generation. However, MP (30 mg/kg) had no effect on MDA release. This further demonstrates that MP acts as an antioxident to reduce peroxidative injury, but not as a free radical scavenger. Supported by the Paralyzed Veterans of America Spinal Cord Research Foundation (#1025).

PROGESTERONE TREATMENT REDUCES GENDER DIFFERENCE IN MORRIS WATER MAZE PERFORMANCE AFTER MEDIAL FRONTAL CORTICAL CONTUSION. R.L. Roof*, J.W. Heyburn, J. Baez, & D.G. Stein. Brain Research Lab, Inst. of Animal Behav., Dept of Psych, Rutgers Univ. Newark NJ 07102.

We previously reported that progesterone (P) reduces cerebral edema associated with cortical contusion in male and female rats[1]. In males this leads to an amelioration of cognitive deficits as well as a reduction of neuronal death in the thalamus[2]. To determine whether the females' injury-induced cognitive deficits are also improved with P treatment, 44 female Sprague-Dawley rats were given medial frontal cortical contusions on the day of proestrus. P or oil injections (4 mg/kg,) were given beginning at 1h after injury, and once each 24h period for 1 week.

Beginning 7 days after surgery, each rat was tested for 10 days in the Morris water maze. Contused females took significantly more time and used a longer path to find the hidden platform compared to sham females. Contused females receiving P injections performed better than females treated with the oil vehicle.

These data were compared to that of male rats previously reported[2]. Sham males and females performed equally well on the MWM, however, after cortical contusion, oil-treated females performed significantly worse than oil-treated males. P treatment reduced this gender difference, and females performed as well as P-treated males.

As with the males, cell density measures demonstrated significant neuronal loss associated with the contusion in the medial dorsal thalamus (MD)as well as in cortical areas adjacent to the contusion area. Reduction of the MD cell loss was seen in P-treated lesion rats. There were no gender differences in cell loss or rescue.

EFFECT OF IMMUNE PRIMING ON BORNA DISEASE A. J. Lewis[1], J. L. Whitton[2], U. Ngo[3], S. van den Noort*[3] and W. I. Lipkin[3] Depts of Anatomy and Neurobiology[1] and Neurology[3], Univ. of California, Irvine, CA 92717; Scripps Research Institute[2], La Jolla, CA 92037.

Borna disease was first described as an encephalitic disease of horses and sheep in southern Germany. The etiological agent has since been found to be a non-segmented, negative strand RNA virus. Borna disease virus (BDV) causes an immune-mediated neurologic disorder in a wide range of host species. The N protein of BDV, p40, is one of the most abundant viral proteins present in infected cells and tissues and elicits a strong antibody response. A vaccinia virus vector expressing p40 (VVp40) was used to prime an immune response in male Lewis rats prior to challenge with BDV infection. Control animals received either a vaccinia vector expressing an irrelevant antigen or PBS. Six weeks later animals were inoculated intranasally with BDV. Clinical observations were made daily. Animals receiving VVp40 showed intensification of clinical disease when compared with both control groups. At 14, 21, 31 and 36 days post BDV challenge brains were collected for histology and RNA analysis. Examination of inflammation in hematoxylin and eosin stained brain sections showed increased perivascular infiltration. Northern hybridization showed a dramatic decrease in expression of viral RNAs in the experimental group. Immunization with VVp40 resulted in an apparent increase in viral clearance, however encephalitis and clinical symptoms were exacerbated.

834.2

BORNA DISEASE VIRUS-SPECIFIC ANTIBODIES ARE PRESENT IN THE CNS OF INFECTED RATS C. G. Hatalski*[1,3], W. F. Hickey[2], W. I. Lipkin[3] Department of Anatomy & Neurobiology[1], Neurovirology Laboratory[3], Univ. of Cal. Irvine, Irvine, CA 92717; Department of Pathology[2], Dartmouth Hitchcock Medical Center, Lebanon, NH 03756

To study the role of antibodies in the CNS during Borna disease virus (BDV) infection, brain sections from male Lewis rats at different times post-infection (acute 4-6 weeks, chronic 15-25 weeks) were analyzed for detection of IgG. Immunohistochemistry using anti-rat IgG antibodies showed diffuse staining throughout the brain, primarily in gray matter areas and neuropil during both the acute and chronic phases of infection. A few small cells both in the parenchyma and in perivascular cuffs stained intensely; these cells are likely to be plasma cells. Additionally, a few cells with neuronal morphology showed intracellular staining. Western blot analysis was performed to compare the levels of IgG in rat brains from the acute and the chronic phase of infection. The intensity of staining with anti-rat IgG in Western blot suggests that there is an increase in the amount of IgG in the CNS from the acute to the chronic phase of infection. To determine if antibodies in the CNS are directed against BDV, CSF and sera from three rats in the chronic phase of infection were analyzed by ELISA for antibodies directed against three BDV-encoded proteins (p40, p23, and gp18) and for capacity to neutralize BDV infectivity. Antibodies were present in the CSF that detected p40, p23 and gp18 and had neutralization activity. However, antibody titers to BDV proteins were lower in the CSF than in the serum (CSF/serum 3-15%). The titers of neutralizing antibodies were also lower in the CSF than in the serum (CSF/serum 16-37%). These results suggest that BDV-specific antibodies are present in the CNS; whether these antibodies play a role in modulation of infection or immunity remains to be determined.

RETROVIRUS-INDUCED ASTROCYTIC NITRIC OXIDE (NO) PRODUCTION FOLLOWING INFECTION WITH NEUROPATHOGENIC ts1 MoMuLV : A MECHANISM FOR NEURONAL DEATH AND PATHOLOGICAL CHANGES IN SPONGIFORM POLIO-ENCEPHALO-MYELOPATHY OF FVB/N MICE

J.M. Vann, P. Szurek and B.R. Brooks* Neurol & Research Svc, Wm S Middleton Memorial VAMC, Madison, WI 53705-2286 and Neurology Dept, University of Wisconsin Medical School

Background: NO-mediated neuronal or oligodendroglial damage by HIV-1 in AIDS has been postulated to require NO-producing neurons or macrophages, but the effect of retroviral infection on astrocyte (As) inducible nitric oxide synthase (iNOS) is unknown.

Methods: Subcortical As NO production *in vitro* was monitored by measurement of nitrite formation with Griess reagent before and after ts1 infection. Lipopolysaccharide (LPS) and gamma-interferon (gIFN) effects on mock-infected and ts1-infected As NO production were studied separately and together.

Results: Basal NO production by ts1-infected As was higher than in mock-infected As from 72 hr pi. LPS [10-10,000 ng/ml], but not gIFN, increased NO production in mock-infected and ts1-infected As. LPS [1 ug/ml] / gIFN [100 U/ml] together stimulated significantly higher NO production in ts1-infected As than mock-infected As. L-N-monomethyl-arginine (LNMMA), an inhibitor of iNOS, blocked these effects.

Conclusions: NO production by retrovirus-infected As provides an added source for indirect neuronal/oligodendroglial death.

***IN VITRO* AND *IN VIVO* ANTIVIRAL ACTIVITIES OF HUMAN RECOMBINANT MONOCLONAL ANTIBODIES TO HSV-1 AND -2**

P.P. Sanna*[1], R.A. Williamson[2], A. De Logu[1], M.E. Samson[1], F.E. Bloom[1], and D.R. Burton[2,3]. Depts. of Neuropharmacology[1], Immunology[2] and Molecular Biology[3], The Scripps Res. Inst., La Jolla, CA.

Herpes simplex viral disease is an important cause of morbidity and mortality in man. Although the availability of drugs with high therapeutic indexes has greatly improved the management of herpetic infections, the emergence of drug-resistant viral strains, especially in the immunocompromised subjects, has become a cause of serious concern and underscores the importance of developing new and alternative prophylactic and therapeutic tools.

We have isolated large panels of human recombinant monoclonal antibodies to HSV by antigen selection ('panning') from combinatorial phage display libraries. Some such antibodies displayed neutralizing activity *in vitro*. A type common antibody specific for glycoprotein D, antibody ACHSV8, neutralized very effectively both laboratory strains and clinical isolates of HSV-1 and -2 and was capable of inhibiting cell-to-cell transmission of these viruses *in vitro* as an Fab fragment. This antibody acts through first order kinetics and appears to bind monovalently to its epitope. In addition, this antibody more than doubled survival times ($p<0.0001$) when administered to athymic nude mice infected with HSV-1. Such prolongation of survival was seen even when the antibody was administered up to 24 hours post-infection, a time when the virus is already in the PNS.

To improve the implementation of this approach, we have now modified this affinity-based cloning technique to allow for more facile isolation of recombinant antibodies to specific viral proteins in their native conformation. With the modified method, phage display libraries are panned against viral glycoproteins 'captured' from infected cell extracts with immobilized monoclonal antibodies. Using this strategy we isolated six novel neutralizing human recombinant antibodies to HSV glycoproteins D or B. Partially supported by MH - 47680.

HERPES SIMPLEX VIRUS IN POSTMORTEM MULTIPLE SCLEROSIS BRAIN TISSUE. V.J. Sanders*, A.E. Waddell, S.L. Felisan, W.W. Tourtellotte, M.D., Ph.D. Neurology Research, West L.A. V.A. Med. Ctr., Los Angeles, CA 90073

Objective: To test for the presence of herpes simplex virus 1 and 2 (HSV) in postmortem brain samples from patients with multiple sclerosis (MS) and controls using polymerase chain reaction/Southern blot hybridization methodology (PCR/SB). Background: HSV is a common neurotropic virus capable of long latencies. It can cause focal demyelination in animals. Methods: Dissected plaque tissue classified as active or inactive and unaffected white matter (WM) and gray matter (GM) from 37 MS cases were screened for HSV by PCR/SB. WM and GM from 22 Alzheimer's disease, 17 Parkinson's disease and 22 cases without neuropsychiatric disease served as controls. Results: 46% (17/37) of the MS cases and 28% (17/61) of the control cases had samples positive for HSV ($p=.109$). 41% (9/22) of active MS plaques were positive for HSV. 20% (6/30) of inactive plaques had virus. 24% (9/37) and 14% (5/37) of MS cases had HSV in WM and GM, respectively. 27% (14/61) and 13% (8/61) of non-MS cases had HSV in WM and GM, respectively. No significant differences were found between all subgroups ($p= .097$). Conclusions: HSV was present in a greater frequency of MS cases compared to control cases. A greater frequency of active plaques had HSV present compared to inactive plaques. Virus in MS WM and GM as well as controls makes an association to the MS disease process uncertain. Future: Cellular localization of virus and its relationship to pathology and latency may reveal an association with disease.

THE USE OF A SMALL ANIMAL MODEL FOR CMV RETINAL INFECTION: IN SITU MOLECULAR BIOLOGY.((E.S. Lazar[1], L Epstein[1], Jr., W. Britt[2], B. Blumberg[1], A. Jones[1], M. del Cerro[1]*))U. of Rochester Medical School[1], Rochester, NY; U. of Alabama, Birmingham School of Medicine[2], Birmingham, AL.

Human cytomegalovirus (HCMV) is an important cause of morbidity and mortality in patients infected with HIV, and little is known about the pathogenesis associated with this virus. No models have been developed to study HCMV infection of human neural tissue in vivo. We have developed an animal model which will aid in delineating this problem. We sought to detect the presence of HCMV in human retinal xenografts in SCID mice using immunocytochemistry (ICC) and In Situ Hybridization(ISH). As HCMV is specific for the human genome, *in vivo* infection of human cells into an animal model is a valuable tool in following the course of the disease. Human fetal retina was transplanted into the anterior chambers (AC) of eyes of SCID mice and infected with HCMV. (ICC) was performed with monoclonal antibodies targeted against early, middle, and late replication phase proteins and other gene products. Peroxidase/anti-peroxidase ICC was performed using an Elite Vector ABC and DAB Peroxidase Substrate Kit. ISH was performed using a 500bp random-primed digoxigenin labeled dsDNA probe which targeted a specific region of CMV DNA. This technique and the process of in situ polymerase chain reaction was tested on AD 169, Coff, and Crump strains of HCMV. 30 days post-infection, the grafts are differentiated with detection of intranuclear and intracytoplasmic viral components. ISH was successful at detecting positive cells with the use of the labelled probe which specifically targeted a region of the CMV genome. This shows that active infection is occurring in the transplanted tissue and that we are infecting human tissue with HCMV. The AD 169 strain was much more reactive than the Coff and Crump strains of HCMV. This animal model allows the study of HCMV replication in nervous tissue and the specific effects of HCMV on human retinal cells. In vitro molecular immunohistochemical and ISH techniques are suited to the detection of HCMV infected retinal cells. Here, we use the AC immune privilege and the immune status of the SCID to mimic HCMV infection in AIDS patients.

CELL TYPE-SPECIFICITY AND INDUCIBILITY OF THE HUMAN CYTOMEGALOVIRUS MAJOR IMMEDIATE EARLY PROMOTER IN BRAINS OF TRANSGENIC MICE. J.M. Fritschy*[1], S. Brandner[2], A. Aguzzi[3], B. Lüscher[1], and P. J. Mitchell[2]. [1]Institute of Pharmacology, [2]Institute of Molecular Biology II, University of Zürich, CH-8057 Zürich; [3]Institute of Neuropathology, University Hospital, CH-8091 Zürich, Switzerland.

Human cytomegalovirus (HCMV) has been associated with a variety of pathologies including CNS infections. We showed previously that the HCMV immediate early (IE) promoter directs *lacZ* gene expression in transgenic mouse embryos specifically to sites correlated with known target tissues of congenital HCMV infection in human fetuses (Koedood et al., 1995). Thus, cell type-specific transcription factors that regulate the IE promoter appear to be conserved between humans and mice and to play an important role in determining HCMV infection targets. Here, we analyzed brain-specific IE-*lacZ* expression in our transgenic mice with a view towards identifying potential HCMV infection targets in the neonatal and adult CNS. Immunohistochemical analysis revealed IE-*lacZ* expression in choroid plexus, some endothelial and ependymal cells, and in several neuron populations, notably in brainstem, cerebellum, cerebral cortex, hippocampus, olfactory bulb, and thalamus. Double-labeling with GFAP antibody showed that the IE promoter was inactive in most astrocytes, but was dramatically induced in astrocytes of the ipsilateral cortex and striatum during gliosis induced by a stab lesion of the neocortex. The IE promoter activity pattern in the murine CNS is consistent with clinical data on human HCMV brain infection targets and suggests a model for HCMV progression in the CNS whereby astrocytes become permissive for infection in response to tissue damage caused by infection of primary targets.

834.8

EFFICIENT TRANSDUCTION OF HUMAN NEURONS WITH AN ADENO-ASSOCIATED VIRUS VECTOR. B. Du, P. Wu*, D.M. Boldt-Houle, J. Watters, and E.F. Terwilliger. Divisions of Infectious Disease and Hematology/Oncology, New England Deaconess Hospital, Harvard Medical School, Boston, MA 02215

An adeno-associated virus (AAV) vector containing a lacZ gene under the control of the CMV immediate early promoter was evaluated with respect to its transduction efficiency and integration ability in nondividing human NT neurons. Using dual staining immunocytochemistry with monoclonal antibodies to neurofilament proteins and ß-galactosidase (ß-gal), we were able to demonstrate: 1) the co-localization of neurofilaments and ß-gal in the same cells; and 2) a dosage-dependent pattern of AAV vector transduction efficiency, with up to 100% of the neurons expressing ß-gal. The efficiency found in NT neurons was equal to or greater than the AAV transduction efficiency in 293 cells, which are a highly sensitive cell line to AAV. This indicates that the human NT neurons are readily susceptible to AAV-mediated transduction. No neurotoxicity was detectable by a MTT assay. Further, quantitative PCR analyses of high molecular weight cellular DNA from the transduced neurons indicated that the copy number of the AAV ß-gal genome increased not only in a dose-dependent but in a time-dependent manner, the latter suggesting a slow progressive rate of integration of the vector over a period of days following transduction. In summary, this study demonstrates that AAV-based vectors can efficiently transduce, express and integrate a foreign gene into postmitotic human NT neurons.

EXPRESSION OF CYTOKINES AND NITRIC OXIDE SYNTHASE BY ASTROCYTES IN CHRONIC DEMYELINATION CAUSED BY MHV-JHM IN SUSCEPTIBLE MICE Ning Sun* and Stanley Perlman Department of Pediatrics and Microbiology, University of Iowa, Iowa City, IA 52242

Intranasal inoculation of C57BL/6 mice with mouse hepatitis virus (MHV), strain JHM under the appropriate condition results in a chronic demyelinating disease characterized clinically by hindlimb paralysis (HLP). Expression of cytokines, nitric oxide synthase (iNOS), MHC class I and II antigen and their possible cellular sources were investigated in this study. Cytokines TNF-α, IL-6, IL-1β and iNOS were all up-regulated in the spinal cords of HLP mice as revealed by immunocytochemistry. Double-label studies demonstrated that cells expressing these cytokines and iNOS were astrocytes. Most astrocytes expressing cytokines and iNOS were not infected by virus but were distributed in the white matter of spinal cord near virus and demyelinating lesions. Also in additional experiments, the spatial relationship of virus-infected cells and the activated astrocytes was analyzed. The analysis showed that 15% of all infected cells in these chronically infected mice was astrocytes. The expression of cytokines and iNOS in astrocytes in these mice is in significant contrast to findings in mice with the acute encephalomyelitis caused by MHV-JHM. In acutely infected animals, TNF-α, IL-6 and iNOS are found mainly in macrophage-like cells. In addition, MHC class I and II antigen are also up-regulated in the spinal cords of chronically infected mice, although not in astrocytes. The results of this study demonstrate that expression of different cytokines and nitric oxide synthase in the astrocytes is a feature unique to the chronic as opposed to acute infection caused by MHV-JHM. The concordance of the present results with findings in other animal models of demyelinating disease and in patients with multiple sclerosis suggests that astrocytes play a major role in chronic demyelination.

INTRACEREBROVENTRICULAR ADMINISTRATION OF IL-1β IN DOGS PRODUCES CSF LEUKOCYTOSIS BUT NOT FEVER. G.S.F. Ling*, B. Goodman, and D.F. Hanley. Division of Neurosciences Critical Care, Dept. of Neurology, Johns Hopkins Medical Institutions, Baltimore, Maryland 21287.

Il-1β has a well-recognized role in initiating and perpetuating inflammatory cellular responses and in producing fever. Clinically, fever is often the first objective sign of systemic illness. In this study, we examined the effect of intracerebroventricular (i.c.v.) administration of Il-1β on cerebrospinal fluid (CSF) white blood cell count (WBC) and fever.

Beagle dogs (n=6) were each surgically prepared with an indwelling i.c.v. catheter system. After at least one month of recovery, human Il-1β was given i.c.v. in doses of 50, 100 and 200 ng/kg. Controls received 0.1% BSA in normal saline. Blood and CSF specimens were obtained before and for 3 hours after dosing. Body temperature was measured continuously throughout. Biofluid analyses used standard manual methods and an automated hematology counter.

Results demonstrated a rapid increase in CSF leukocyte count. By 5 min. after administration, peak cell counts were obtained. For the 100 and 200 ng/kg groups, the WBCs were 36 ± 8.7 mm^3(Mean $\pm$ SEM) and 89 ± 39.3 mm^3, respectively. These results were significantly different from control ($p < 0.05$, t-test). Over the next hour, these levels gradually decreased back to baseline. At 5 min., the white cells were noted to be predominately mononuclear, approximately 75% of total WBCs. Body temperature did not significantly increase from baseline.

In conclusion, following i.c.v. administration in dogs, Il-1β leads to CSF leukocytosis that is predominantly mononuclear. This effect is dose-dependent. In addition, at the doses tested, there was no pyrogenic response. These findings suggest that disorders that lead to a predominantly CSF monocytosis (such as aseptic meningitis) may be mediated by Il-1β. In addition, it appears that fever requires a higher level of this cytokine or possibly another mechanism is involved.

834.11

NORMAL NEURONAL EXCITABILITY AND SYNAPTIC TRANSMISSION IN PRION PROTEIN GENE ABLATED MICE. P.-M. Lledo*, S. J. DeArmond¶, S.B. Prusiner† and R.A. Nicoll. *Depts. of Cellular & Molecular Pharmacology, ¶Pathology & †Neurology, Biochemistry & Biophysics; UCSF, San Francisco, CA 94143.*

The physiological function of the cellular prion protein (PrP^C) remains obscure. To investigate whether the loss of PrP^C could affect neuronal excitability and/or synaptic transmission in the CNS, we have used hippocampal slices and recorded in the CA1 region from PrP knockout mice ($Prnp^{o/o}$). Field potential recordings have revealed a normal level of synaptic inhibition since in response to stimulation in *stratum radiatum*, responses from $Prnp^{o/o}$ mice consisted of a single population spike similar to the one recorded from control mice and the plot of field EPSP slope versus the population spike amplitude showed no difference between the two sets of data (n = 12). Intracellular recordings also failed to detect any difference in electrical membrane properties and the reversal potential for IPSPs was unchanged (-70.1 ± 1.9 mV in 10 control and -69.5 ± 2.3 mV in 8 $Prnp^{o/o}$ mice). The study of the IPSC kinetics also reveals no modification (n = 14). In another set of experiments, we examined whether LTP was altered and found that no statistical difference existed between the two groups of animals (n = 5). Our findings differ from published results in which the level of inhibition was reported to be impaired in the $Prnp^{o/o}$ mice (Collinge *et al.*, Nature 370: 295-297; 1994), but agree with the earlier detailed behavior studies in which no impairment in $Prnp^{o/o}$ mice could be demonstrated (Büeler *et al.*, Nature 356: 577-582; 1992). *Supported by NATO, the CNRS and the NIMH.*

THE PRION PROTEIN BINDS TO PSF, AN ESSENTIAL SPLICE FACTOR. Bruno Oesch*, Paul Jenö, and Edith Gubler. Brain Research Institute, University of Zürich, August Forelstr. 1, 8029 Zürich, Switzerland, and Dept. of Biochemistry, Biozentrum, 4056 Basel

Interaction of the prion protein (PrP) with other cellular proteins on ligand blots has led to the identification of two PrP ligands of 45 and 110 kDa (Pli 45 and Pli 110, respectively). Here, we report the identification of Pli 110 as PSF, a splice factor associated with the polypyrimidine-tract binding protein. Pli 110 was purified using sucrose gradient centrifugation followed by chromatography on carboxy methyl cellulose, reverse phase and hydrophilic interaction columns. Tryptic peptides of bovine Pli 110 were sequenced revealing extensive homology to human PSF. Binding to PrP was confirmed with recombinant PSF. Using anti-PSF antibodies, we were able to show the presence of PSF in our most purified preparations of Pli 110. In addition, the binding pattern of PrP to unfixed sections was similar to the distribution of PSF i.e. the signals were strongest in areas of high density of cell bodies.

These results suggest that either PSF may have an alternative function at the membrane or that PrP is not exclusively located at the cell surface. Recently, an intracellular 60 kDa PrP isoform has been identified and shown to be more abundant in scrapie-infected animals suggesting that this isoform may aid the generation of disease-specific PrP^{Sc} or infectious particles. We are currently investigating whether the 60 kDa form of PrP copurifies with PSF.

834.13

NECROTIC, NOT APOPTOTIC, CHANGES IN THE PITUITARY OF FEMALE HAMSTERS INFECTED WITH THE 139H STRAIN OF SCRAPIE. X. Ye*[1], R.I. Carp[2], [1]Div of Neurotoxicology, FDA/NCTR, Jefferson, AR, 72079, [2]NYS Institute for Basic Research for Developmental Disabilities, 1050 Forest Hill Road, Staten Island, NY, 10314.

Previous studies have shown that 139H-infection of hamsters causes obesity and marked histopathological changes in the islets of Langerhans and pituitary. Using routine EM, we now report more details of the histopathological changes in the pars distalis of the pituitaries of 139H-infected hamsters. Dilation and vacuolation were first observed in the mitochondria and rough endoplasmic reticulum (RER). The subsequent abnormal events seen included vacuolation and breakdown of the secretory vesicles, lysosomal breakdown and finally cell digestion and lysis. In some damaged cells the nucleus remained attached to the cellular membranes, suggesting that it was protected to some degree from the effects of cytoplasmic toxins by the nuclear membrane. Based upon these observations, we conclude that the cellular death seen in the pituitaries of 139H-infected hamsters is due to necrosis rather than apoptosis.

THE MOLECULAR PATHOGENESIS OF THE TUBULO-FILAMENTOUS PARTICLES: EVIDENCE OF A HOMOLOGOUS SINGLE-STRANDED DNA IN SPONGIFORM ENCEPHALOPATHY. H. Narang*. Dept. of Psychiatry, School of Medicine, SUNY, Stony Brook NY 11794.

Scrapie, bovine spongiform encephalopathy (BSE) and Creutzfeldt-Jakob disease (CJD) with six other diseases have been grouped together as spongiform encephalopathies (SEs). No simple genetic susceptibility factor for SEs has been identified in human or animals. Existence of at least 20 genetically stable strains in SEs appears to be incompatible both with PrP by itself or with a specific point mutation seen in the PrP gene being the agent. The evidence presented so far suggests that SE is an infectious disease and not a genetic disorder. Unique virus-like tubulofilamentous particles termed nemavirus (NVP) have been consistently observed in SE brains by EM. In a blind study, a scrapie-infected and a normal hamster brain were examined at 3, 5, 7, 10, 14, 18, 21, 24 and 28 days post-inoculation. Examination of grids prepared from both left and right sides of the brain at 3, 5 and 7 days revealed no NVP or SAF. However, at 10 days scrapie-infected hamster brains from the inoculated right side revealed both NVP and SAF. From 18 days post-inoculation the NVP and SAF were observed in both sides of the brain which would suggest that replication of the agent starts at the local site of inoculation. No NVP or SAF were seen in any of the preparations from normal brains. Nucleic acid was purified from the content of enriched preparations of mitochondria/NVP. The ssDNA was synthesized into double stranded DNA and inserted in Puc 18, cloned and sequenced. An unusual palindromic six base (TACGTA) 10 repeat sequence was obtained, as observed in scrapie, which revealed no significant homology to other sequences. A probe prepared reacted with a band of about 1.2 kb in scrapie, CJD and BSE but not with control normal DNA specimens.

834.15

BACTERIAL ENDOTOXINS INDUCE NEUROLOGICAL SYMPTOMS IN ADULT WISTAR RATS. R. F. Brown and M. Kiernan.*
Psychology Dept., The University of New South Wales, Australia, 2052.

The present experiments investigated the novel finding that bacterial endotoxins can induce neurological symptoms in adult wistar rats. Neurological symptoms typically appeared 6 - 24 hr post endotoxin administration (ivi. and ip.), persisted for 24 - 36 hr, and then spontaneously resolved. These symptoms appeared in approximately 85 % treated animals, although symptom severity was variable. Mildly affected rats presented with mainly proprioceptive deficits, which manifested as an abnormal gait; moderately affected rats presented with proprioceptive and mild motor deficits; and severely affected rats presented with proprioceptive, motor (paralysis/paresis), and sensory (reflex) deficits. Further experiments were conducted to: investigate the generalisation of this syndrome across a number of different rat strains, and between sexes; localise the site(s) of pathology mediating this syndrome; and, determine which endotoxin-induced chemical pathway(s) might be mediating this syndrome.

834.16

PNEUMOCOCCAL CELL WALL COMPONENTS RELEASE TNF-α FROM CEREBRAL ASTROGLIAL AND ENDOTHELIAL CELL CULTURES M. Weih*, D. Freyer, J. R.Weber, P. Scholz, A. Meisel, K. Angstwurm,W. Bürger, U. Dirnagl. Dept. of Neurology, Dept. of Microbiology, Charité, Humboldt University Berlin and Schering AG, Berlin, Germany.

Astroglial cells and cerebral endothelial cells have been shown to produce tumor necrosis factor-alpha (TNF-α) upon stimulation with cytokines like IFN-γ, IL1-β or bacterial lipopolysaccarides (LPS). The cell wall of Streptococcus pneumoniae (PCW) has been shown to cause meningeal inflammation,which might be mediated in part by pro-inflammatory cytokines like TNF-α. TNF-α has also been found in cerebrospinal fluid in experimental menigitis and in humans. We tested whether astroglial or endothelial cells could account for this TNF-α release. Addition of PCW to cultured rat astroglial cells increased TNF-α in the supernatant significantly after 4h from 3 ± 0,63 pg/ml to 9,8 ± 1,6 pg/ml and was inhibited by dexamethasone (10^{-6} M). TNF-α release from astroglial cells, as determined by the L929 bioassay, was dose-dependent in a range shown to cause meningeal inflammation in vivo. TNF-α production in cerebral endothelial cells after 12 h was higher than in astrocytes (117 vs. 45 pg/ml) and also inhibitable by dexamethasone.Our results suggest astroglial, microglial and endothelial cells as sources of TNF-α, a pro-inflammatory cytokine, which could mediate vascular and antimicrobial response in the early phase of experimental pneumococcal meningitis leading to recruitment of blood leucocytes and finally breakdown of the blood-brain-barrier (This work was supported by the DFG).

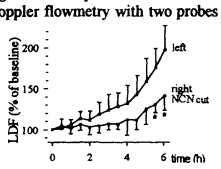
IS THERE A ROLE OF NEUROGENIC INFLAMMATION IN THE rCBF RESPONSE IN BACTERIAL MENINGITIS? J. R. Weber, K. Angstwurm, R. Empson*+, G.M. Bove #, K.M. Einhäupl, U. Dirnagl and M.A. Moskowitz #.
Depts. of Neurology and +Physiology, Charité, Humboldt University, 10098 Berlin, Germany, #Massachusetts Gen. Hosp., Harvard Medical School, Boston.

Headache and nausea are the most relevant clinical symptoms in early bacterial meningitis (BM). The hypothesis that headache in BM may result from trigeminal activation is strongly supported by observations in the early phase of experimental meningitis which is characterized by a dramatic regional cerebral blood flow (rCBF) increase and inflammation within the first 6 hours. We undertook this study to examine a possible role of trigeminal axons in the rCBF response.

In 5 male wistar rats the nasociliary nerve (NCN), which innervates the meninges over the frontal lobe was cut on the right side 10 days before the experiment. Meningitis was induced by intracisternal injection of pneumococcal cell wall components (equivalent of 10^7 cfu Streptococcus pneumonae PnR-527, Jena). Physiological parameters were monitored throughout the experiment. rCBF was measured continuously over 6 hours with laser Doppler flowmetry with two probes bilaterally over the right and the left frontal lobe of the cortex through the thinned skull

LDF % / side	*0h*	*3h*	*6h*
right, NCN cut	100	123 ± 7	197 ± 29
left	100	106 ± 19	140 ± 17*

(p< .05) Students t-test, mean ± SD

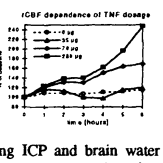


Denervation of the meninges attenuates the rCBF increase in BM. The study provides first evidence for a role of a neurogenic mechanism in rCBF response in acute inflammation of the CNS. We speculate that neuropeptides released from trigeminal C-fibers may be involved in mediating rCBF increase in BM.

834.18

INTRACISTERNAL INJECTION OF TUMOR NECROSIS FACTOR ALPHA (TNFα) INCREASES REGIONAL CEREBRAL BLOOD FLOW (rCBF). K.Angstwurm, M.Weih, D.Freyer, K.M. Einhäupl, P.Scholz[1], G.Ransmayr[2]*, U.Dirnagl, J.R.Weber. Dept. of Neurology, Humboldt-University, [1]Schering AG, Berlin, Germany,[2]Dept. of Neurology, Univ. of Innsbruck, Austria.

TNFα is a pleiotrophic cytokine, which is thought to be a central mediator of various CNS diseases. Its role in bacterial meningitis, for example, is still under controversial discussion. We tested the effect of intracisternal injection of recombinant rat specific TNFα on rCBF, intracranial pressure (ICP), pleocytosis and brain water content in rats. TNFα (activity: 3 10^7 units/mg) was applied in three dosages (35µg (n=3); 70µg (n=4); 280µg (n=3) per animal). In control animals saline i.c. was injected. rCBF measurement was performed by laser Doppler flowmetry through the thinned right parietal bone. Within the observed 6h post i.c. injection no differences were seen in blood pCO2, pO2, and pH of treated and untreated rats. In TNFα i.c. injected animals a systemic effect was leukopenia. Otherwise the 35µg TNFα group did not differ from saline i.c. injected. An injection of 70µg or 280µg TNFα increased rCBF significantly beginning 2h after i.c. injection compared to the lower dosages. 4,5h and later rCBF of 280µg TNFα group was higher than of all other groups (mean±SD 6h after i.c. injection: 0µg: 115±17; 35µg: 120±10; 70µg: 170±39; 280µg: 248±28. p<0,05, ANOVA, Student-Newman-Keuls). Animals with the two higher dosages showed mild pleocytosis (400/µl, p<0,05). No significant differences were found concerning ICP and brain water content. Conclusions: 1.CNS inflammation requires more mediators than just TNFα, 2. TNFα is a possible mediator for systemic effects of CNS inflammation. The role of NO in TNFα mediated rCBF response has to be eluciated in future.



834.19

TROPHISM OF *TOXOPLASMA* FOR ASTROCYTES IN A HUMAN FETAL NEURAL CULTURE. S.K. Halonen and F.C. Chiu*. Dept. of Neurology, Albert Einstein College of Medicine, Bronx, N.Y. 10128.

Toxoplasma gondii is an intracellular parasite that is one of the most common opportunistic infections of the CNS in AIDS patients, causing an often fatal encephalitis. Treatment of this disease is hampered by a lack of information about the basic biology of this parasite in neuronal cells. In this study primary cultures from human fetal brain were used to study the behavior of Toxoplasma in neural cells. Toxoplasma was able to infect both astrocytes and neurons but growth of the parasite in astrocytes was approximately 10-fold higher than in neurons. The behavior of Toxoplasma also differed drastically in astrocytes vs. neurons. In astrocytes, Toxoplasma replicated every 4-6 hrs, with an average of 22-24 parasites/host cell at 48 hrs. In neurons however, parasites replicated only 1-2 times over this same 48 hr period. There was evidence that some of the infected neurons were necrotic 24 hrs after infection. However, approximately 10% of the infected neurons were able to support replication of the parasite. These results indicate that 1) astrocytes support the majority of the proliferation of the parasite in the brain and 2) neurons exhibit a differential susceptibility to infection with Toxoplasma. A better understanding of the trophism for astrocytes and of the differential behavior of Toxoplasma in neurons may yield insights into the mechanisms underlying toxoplasmic encephalitis.

835.1

NMDA RECEPTOR DOMAINS IN POSTMORTEM BRAINS OF SCHIZOPHRENIC PATIENTS. T. Matsunaga*[1], A. Shimada[2], A. G. Mukhin[1], D. K. Ingram[2], S. R. Zukin[3], J. Kleinman[4], M. Casanova[5] and E. D. London[1]. Intramural Research Programs, [1]NIDA and [2]NIA, Baltimore, MD 21224; [3]Albert Einstein Col. Med., New York, NY; 10461; [4]Intramural Research Program, NIMH, Washington, DC 20032; and [5]Med. College of Georgia, Augusta, GA 30912.

Growing evidence suggests that aberrant glutamatergic systems interacting with dopaminergic systems may be involved in the pathophysiology of schizophrenia. The NMDA receptor is a heteropolymeric complex that has distinct domains, including NMDA and glycine recognition sites and channel binding sites. Furthermore, the subunit composition of the receptor displays regional variations in brain.

[H-3]CGP39653, [H-3]dichlorokynurenic acid and [H-3]dizocilpine were used to assay specific binding to NMDA and glycine recognition sites and channel sites, respectively, in membranes from the orbital gyrus (OG) and superior temporal gyrus of postmortem brain samples from normal control subjects and patients with schizophrenia and bipolar disease.

The specific binding of [H-3]CGP39653 to OG membranes was higher in samples from schizophrenic and bipolar patients (+66%) than that in controls. The difference between the schizophrenic and control samples was significant ($p<0.05$ by ANOVA and Scheffe's test). There were no other statistically significant differences. Correlations between specific binding of any of the radioligands in either brain region and the intervals between death time and freezing time were not statistically significant.

These findings are consistent with frontal cortical glutamatergic hypofunction and consequent up-regulation of NMDA recognition sites in schizophrenia, but do not exclude the possibility that the effect seen is due to neuroleptic treatment.

835.2

DISTRIBUTION OF CCK mRNA IN PREFRONTAL CORTEX OF SCHIZOPHRENICS. T.Takahashi[1,2], H.Arai[2], R.Inoue[2], A.Matsumoto*[2],†, P.Mckenna[3] and P.C.Emson[1] 1)Dept. of Neurobiol., The Babraham Inst., Babraham, Cambridge CB2 4AT, UK 2)Dept. of Psychiat. & Anat. †, Juntendo Univ. Sch. of Med. Hongo, Tokyo 113, Japan 3)Dept. of Psychiat., Univ. of Cambridge, Cambridge CB2 2QQ, UK

Cholecystokinin(CCK) mRNA is present in large amounts in the human cerebral cortex. CCK-immunoreactivity and mRNA has also been detected in dopaminergic neurons of the substantia nigra, pars compacta and the ventral tegmental area suggesting a possible involvement of CCK in the pathology of schizophrenia. In this study we have used *in situ* hybridization technique with an antisense oligonucleotide probe specific for CCK mRNA to detect sites of CCK mRNA in post-mortem human prefrontal cortex (Brodmann areas 9, 10 and 11). The distribution and numbers of cells expressing CCK mRNA have been determined using computer assisted image analysis in brains from neurologically normal controls. CCK mRNA was expressed with similar laminar pattern in all cases. On film autoradiography there was no significant differences in amounts of CCK mRNA between schizophrenics and controls, however that of schizophrenics tended to be reduced than controls. On emulsion autoradiography CCK mRNA was expressed in large amounts in populations of small neurons in cortical layers II-VI, in addition a number of larger pyramidal cells in layers II and V also contained CCK mRNA albeit at lower levels. As the results of counting silver grains, schizophrenics were significant reduced in cellular levels of CCK mRNA in layer V and VI in area 9, in layer III in area 10, and in layer III in area 11. These results suggest that the ability of CCK biosynthesis in the region of prefrontal cortex of schizophrenics may be downregulated.

835.3

WITHIN-SUBJECT CHANGES IN STRIATAL D2 RECEPTOR BINDING POTENTIAL ARE RELATED TO CHANGES IN SCHIZOPHRENIC SYMPTOMS. M.B. Knable*, R. Coppola, D.W. Jones, J. Gorey, K.S. Lee, D.R. Weinberger. NIMH, IRP, CBDB, 2700 M.L. King Jr. Ave., S.E., Washington, D.C., 20032

Ten schizophrenic patients underwent prolonged IBZM SPECT studies while free from neuroleptic drugs (mean 150; range: 7- 730 days) and a measure proportional to peak D2 receptor binding potential (BP) was determined as previously described (Knable, et al., J. Nuc. Med., 1995). Sixteen healthy controls were studied for comparison. For schizophrenic patients, the peak BP for the left and right striata were 0.67±0.25 and 0.68 ±0.20 respectively, and for normal controls these values were 0.73±0.21 and 0.71±0.21. Although peak BP tended to be less in schizophrenics, this difference was not statistically significant. There were no significant differences between the left and right striata for either group. There were no significant correlations between peak BP and positive symptoms, negative symptoms, movement disorder, age, or illness duration. Four of the schizophrenic patients were able to complete two SPECT studies during the drug free period. Percent change in peak BP was significantly correlated with change in positive symptoms (rho=0.80) and change in negative symptoms (rho=1.0). This association was not explained by persistent D2 receptor occupancy by neuroleptic drugs during the first scan, since there was an inverse relationship between the drug free period at the first scan and change in peak BP. These data suggest that increased D2 receptor density is not present as a trait marker in schizophrenia, but that D2 receptor number covaries with the severity of certain symptoms characteristic of the illness.

835.4

PERINATAL IBOTENATE INJECTIONS PRODUCE ANATOMICAL AND BEHAVIORAL CHANGES SIMILAR TO SCHIZOPHRENIA. R. A. Devo*, J. L. Gerson, K. L. Marshall, and J. M. Hittner. Dept. of Psychology, Winona State Univ., Winona, MN 55987.

The glutamate theory of schizophrenia proposes a relationship between degeneration of glutamatergic neurons and the behavioral deficits associated with schizophrenia. This study evaluates the effects of perinatal lesions of hippocampal glutamatergic neurons and subsequent changes in learning and social behavior.

Twenty-two male Long-Evans hooded rats received bilateral hippocampal injections of ibotenic acid (IBO) or PBS (controls) on day five postpartum.

Social-Play Testing (Day 28). Rats were individually housed for 72 hr prior to testing. IBO rats played significantly less (made fewer pins) than controls $F(1,19)= 4.70$, $p<.05$.

Eight arm radial maze training (Day 70). Subjects were placed in the hub and allowed to enter each arm for 10 sessions. Performance was significantly poorer in the IBO group $F(1,18) = 16.927$, $p<.001$.

Extinction testing (Day 80). Rats were trained to barpress to a criterion of 400 responses followed by 3 extinction sessions. IBO treated rats demonstrated resistance to extinction.

Histology. Brains were fixed (10% formalin), sectioned (20 μm) and stained using cresyl violet. IBO decreased the size of the dorsal hippocampus and enlarged the lateral ventricles.

These data suggest that hippocampal IBO injections produce anatomical and behavioral deficits similar to schizophrenia.

835.5

M1, M2, M3 DISTRIBUTION IN THE THALAMUS OF POSTMORTEM HUMAN BRAIN

J. H. Callicott, A.M. Murray, T.M. Hyde, A.de Bartolomeis, M.M. Herman, R.C. Saunders,* J.E. Kleinman
CBDB, NIMH Neuroscience Center at St. Elizabeths, NIH, Washington, D.C., 20032

The thalamus is a crucial synaptic relay point for limbic system processing. In particular, the anterior and medial thalamic nuclear groups are key intermediaries in the connections between medial temporal and frontal cortical areas. As part of an ongoing investigation of neurochemistry of schizophrenia and suicide, we studied the distribution of muscarinic receptor subtypes in the "limbic" subdivisions of the thalamus -- anterior and mediodorsal nuclear groups.

Using quantitative autoradiography, we labeled M1 ([^{3}H]pirenzepine), M2 ([^{3}H]NMS), and M3 ([^{3}H]NMS) receptors in human postmortem tissue for normal controls, schizophrenics, suicides, and neuroleptic controls. Using one factor ANOVA comparisons, M2 and M3 receptors were of equal abundance and both greater than M1 in anterior and mediodorsal thalamic nuclei in the normal control group. Similar patterns were observed in the schizophrenic and neuroleptic control groups. The only significant finding was a marked elevation of M1 receptors in both the anterior and mediodorsal thalamic nuclei of the suicide group when compared to the other groups. M1 receptor density in suicides was elevated approximately 4-fold over controls. Urine toxicology screens for all of the suicides were negative for tricyclics or neuroleptics, thus suggesting that this relative upregulation of M1 receptors may be a reflection of underlying affective illness rather than medication effect. These results conform to the pattern of M1receptor changes in suicide in human striatum previously reported by Murray et al. (submitted).

835.6

GABA-A RECEPTOR BINDING CHANGES IN SCHIZOPHRENIA: DORSOLATERAL PREFRONTAL AND CINGULATE CORTICES

A.M. Deveney, A.M. Murray, T.M. Hyde*, M.M. Herman and J.E. Kleinman, Clinical Brain Disorders Branch, IRP, NIMH, St. Elizabeths Hospital, Washington, DC 20032.

GABA neurons constitute the major subtype of intraneuron in the human cortex. Reports of GABA-A receptor abnormalities in schizophrenia have major implications since GABA intraneurons mediate 5HT input and glutamatergic output in the cortex, both of which are reportedly abnormal in schizophrenia. Furthermore, there have been reports of abnormalities in cortical GABA-A receptors density in schizophrenia. Tissue mounted 14 µm thick sections from DSMIII-R diagnosed schizophrenics (n=8, mean age=59.25±5.3, PMI=19.4±3.8), normals (n=9, mean age=54.8±5.2, PMI=25.5±4.5), non-schizophrenic suicides (n=9 mean age=57.2±7.9, PMI=20±10), and neuroleptic treated controls (n=7, mean age=51.8±7.2, PMI=30.0±6.9), were used for receptor autoradiography of dorsolateral prefrontal cortex and anterior cingulate cortex. Binding was carried out according to the method of Benes et al., (1992) with 5 nM [^{3}H]muscimol as the radioligand. Non-specific binding was determined in the presence of 10 µM GABA or 100 µM (+)-bicuculline. For purposes of anatomical analysis the pre-frontal cortex was divided into layers II-III and IV-VI. The cingulate cortex was analyzed in three divisions (layers I, II-III and IV-VI). There was no difference between schizophrenics and control groups for GABA-A receptors in dorsolateral prefrontal or anterior cingulate cortex. Scatchard analysis was carried out on a separate cohort of schizophrenics (n=12, mean age=54.5±4.6, PMI=17.4±8.0), and controls (n=9, mean age=47±4.4, PMI=18±1.8), in anterior cingulate cortex. Homogenate binding was performed using the ultracentrifugation method of Yang and Olsen, (1987). Again [^{3}H]muscimol (1.25-35nM) was used as the radioligand. Non-specific binding was determined by 100 µM GABA. There was no difference in kD and Bmax between controls and schizophrenics. Non-specific binding was considerably higher when (+)-bicuculline was utilized compared to GABA, using both autoradiography and homogenate binding techniques. This data does not support the notion that GABA-A receptor density is abnormal in dorsolateral prefrontal or cingulate cortex in schizophrenia.

835.7

CHOLINERGIC NEUROCHEMISTRY OF THE CEREBRAL CORTEX IN SCHIZOPHRENIA.

S.M. Gabriel*, V. Haroutunian, P. Powchik, M. Davidson, K. L. Davis. Departments of Psychiatry, Mount Sinai School of Medicine, New York, NY 10029 and Bronx VA Hospital, Bronx, NY 10468.

A common symptom of chronically institutionalized elderly schizophrenics is severe cognitive impairment. To determine the neurochemical correlates of cognitive dysfunction in elderly schizophrenics, neurochemical studies were performed in 41 schizophrenic patients receiving extensive cognitive and neuropsychiatric evaluations in life. Cases were specifically selected to be free of neuropathologic lesions and to vary extensively with respect to the cognitive dementia rating (CDR) scale and to the positive and negative syndrome scale (PANSS). Of the ten cerebral cortical regions examined, we found that cognitive decline in elderly schizophrenics was correlated with the activity of the acetylcholine marker enzyme, choline acetyl transferase (ChAT), in the parietal cortex only. Levels of ChAT in schizophrenia were not comparable to the reduced levels observed in Alzheimer's disease. These data indicate that diminished cholinergic activity may contribute to the severe cognitive impairment associated with schizophrenia.

835.8

GENERATING MICE OVEREXPRESSING D4 DOPAMINE RECEPTOR AND LACKING NMDA RECEPTOR NR2B SUBUNIT BY TRANSGENIC TECHNIQUE.

Toshikuni Sasaoka*, and Susumu Tonegawa, Center for Cancer Research, MIT, Cambridge, MA 02139

According to a current dopamine hypothesis of schizophrenia the hyperactivity in the mesolimbic dopamine system contributes to schizophrenic symptoms. To study the involvement of hyperactivity in mesolimbic dopamine system in schizophrenia we have used a transgenic mouse approach to generate mice overexpressing the D4 dopamine receptor (DRD4). Growing evidence suggests the contribution of an abnormal glutamate system to schizophrenia. Phencyclidine, which results in effects that resemble schizophrenic symptoms, is a non-competitive antagonist of the NMDA receptor. As the NMDA receptor subunit NR2B is expressed specifically in the forebrain, disruption of the NR2B gene could ablate NMDA receptor function selectively in the forebrain and thus affect glutamate-mediated synaptic transmission in the region. We have used the gene targeting approach to mutate the NR2B gene in mice.

We made the human DRD4 transgene construct containing 12.5 kb of 5'-flanking region, 4 kb of the whole coding sequence and 1 kb of 3'-flanking region. The transgene construct was introduced into (C57BL/6J x CBA/J) F2 eggs by microinjection. We generated 8 DRD4 transgenic lines. The expression levels of the DRD4 transgene are being assessed.

D3 ES cells were transfected with the NR2B targeting construct in which the coding sequences of transmembrane domain 4 were deleted by replacement with a neomycin resistance gene. After selection in G418, one targeted clone out of 192 G418-resistant clones was identified by Southern analysis. Chimeric mice were generated with this ES clone, and bred to get ES cell derived progeny. Preliminary data on the phenotype of the mutant mice will be presented. (Supported by Stanley Foundation)

835.9

ANALYSIS OF DOPAMINE (D2, D3 AND D4) RECEPTORS AND DOPAMINE TORANSPORTER GENE VARIANTS IN SCHIZOPHRENIA.

Y. FUJIWARA*, K. YAMAGUCHI, K. KASHIHARA[1], Y. SHIRO,[1], K. SATO[2], S. KURODA, Depts. of Neuropsychiatry and [1]Neurology, Okayama Univ. Med. Sch., [2]Clin. Res Instit., Natl. Sanatorium Minamiokayama Hosp., Okayama, 700, Japan

We report data from four studies on variants of the D2 receptor gene (Ser311→Cys), BalI polymorphism in D3, 48-nucleotide repeat Polymorphism in D4, and 40-nucleotide repeat polymorphism in the dopamine transporter gene, in patients with schizophrenia (Sc) (n=69), mood disorder (n=10), neurological disease (n=40) and controls (n=29). Each polymorphism was typed by amplification of genomic DNA by PCR and agarose gel electrophoresis. Seven individuals were heterozygous for Cys/Ser311 of D2 and two of them were Sc patients with a family history of the illness. Two patients with Sc were homozygous for the mutant form of D3 and showed a stuporous state at disease onset. We detected four-fold and two-fold repeats in D4, and ten-fold, nine-fold and seven-fold repeats in the dopamine transporter gene. There was no evidence for association between each variant and reactivity to pharmacotherapy for Sc.

835.10

SUBICULAR MAP-2 IMMUNOREACTIVITY IN SCHIZOPHRENIA.

G. Rosoklija, M.A. Kaufman, D. Liu, A.P. Hays, N. Latov, C. Waniek, J.G. Keilp, A. Wu, S.A. Sadiq, J. Gorman, I. Prohovnik, A.J. Dwork*, N.Y. State Psychiatric Institute and Columbia University, New York, NY 10032

We studied MAP-2 immunoreactivity on paraffin sections of hippocampal formation from autopsies of 15 unselected schizophrenics, mean age 73, 14 unselected psychiatric controls, mean age 78, and 6 non-psychiatric patients without neuropathological abnormalities, mean age 51. Psychiatric diagnoses were determined by standardized review of clinical records (Keilp *et al.*, Schiz. Res., in press). Complete neuropathologic examinations were performed and included thioflavine S stain and immunohistochemistry with Alz 50 and an antibody to paired helical filaments. Immunoperoxidase staining for MAP-2 was performed on paraffin sections, and intensity was evaluated by densitometry. Among the schizophrenics, immunoreactivity in subiculum was significantly lower than in CA4 ($p<.05$, 2-tailed paired t-test), while in each control group, immunoreactivity was slightly more intense in subiculum than in CA4 (not significant). The difference between immunoreactivity in subiculum and immunoreactivity in CA4 was affected by a diagnosis of schizophrenia but not by age, neuropathologic diagnosis, post mortem interval, or senile plaque or neurofibrillary tangle counts. Pronounced loss of subicular immunoreactivity was present in 6 (40%) of the schizophrenics, 3 (21%) of the psychiatric controls, and none of the non-psychiatric controls. Thus, in our hands, loss of subicular MAP-2 is strongly associated with schizophrenia but is not a specific or sensitive marker. Our results extend the original observation of this association by Arnold *et al.* (PNAS 88:10850, 1991). The association of schizophrenia with diminished subicular MAP2 immunoreactivity is one of the few results in the post mortem study of schizophrenia to be confirmed in independent laboratories studying different samples of subjects. *Support: AG 10638 & The Stanley Foundation.*

DETECTION OF SENILE DEGENERATION IN OLD BRAIN SPECIMENS FROM A PSYCHIATRIC COLLECTION. A.J. Dwork, D. Liu*, M.A. Kaufman, I. Prohovnik. N.Y.S. Psych. Inst. & Columbia U, New York, NY 10032

Conflicting reports have been published regarding the prevalence of neuropathologic changes of Alzheimer's disease (AD) in brains of older individuals who suffered from schizophrenia. Large samples and valid histologic techniques are needed to resolve this issue; for example, an observed AD rate of 5% among controls and 10% among schizophrenics would require over 200 subjects in each group to be statistically significant ($X^2 = 3.841$, df = 1, $p < .05$). Psychiatric brain samples of this size can in general be obtained only from collections of specimens accrued over many years. Since we are in the process of studying AD in such a collection, we began by determining which staining procedures could be applied to material that had been in formalin or paraffin for many years. We found that: (1) Plaque and tangle counts from contemporary thioflavine S staining on tissue that had been in formalin for 50 years or paraffin for at least 31 years (the oldest samples examined) were entirely consistent with those obtained from von Braunmuhl stains performed at the time of the original neuropathologic examinations. (2) In the same specimens, senile degenerative changes were easily recognized by immunohistochemistry with antibodies to paired helical filaments, ß-amyloid, or ubiquitin. (3) Compared to thioflavine S staining, immunoreactivity with Alz 50 was well demonstrated after 9 years in formalin, weaker after 20 years in formalin, and absent after 30 years in formalin. Alz 50 immunoreactivity was well preserved in paraffin blocks 31 years old. (4) In contrast to staining for senile degenerative changes, immunohistochemistry for MAP2 and synaptophysin was significantly impaired after several years of storage in formalin. We conclude that a variety of staining techniques for senile degenerative changes can be applied reliably to archival material, but that each method must be validated individually. *Supported by AG 10638.*

CHOLINERGIC PEDUNCULOPONTINE NEURONS IN SCHIZOPHRENIA: FAILURE TO FIND INCREASED CELL NUMBERS. K.F. Manaye*, R. Zweig, D. Wu and D.C. German. Dept Psychiat, UT Southwestern Med Sch, Dallas, TX 75235-9070, Dept Biochem, Univ Kentucky, Lexington, KY 40536, and Dept Neurol, LSU Med Cntr, Shreveport, LA, 71130.

The number of cholinergic pedunculopontine (PPN) neurons has been reported to be increased in the brains of schizophrenics, based upon examination of post-mortem brains with a stain for NADPH-diaphorase (Karson et al., 1991). The present study sought to examine PPN neurons using an antibody against choline acetyltransferase (ChAT), and computer imaging procedures to map the cell locations. In 3 schizophrenic and 6 control cases, there were no differences in the total number of ChAT-containing cells in the Ch5d, Ch5c or Ch6 regions; in controls there were about 20,000 total cells, unilaterally. Also, in 8 schizophrenic and 11 control cases, there was no difference in the number of Nissl-containing PPN cells through the dense portion of the nucleus (Ch5c); in schizophrenic cases there were 577 ± 97 (mean ± SEM) cells per section, and in control cases there were 583 ± 70. In both control and schizophrenic cases, there were twice as many Nissl-stained cells as ChAT-immunostained cells. These data do not support the hypothesis that there are increased numbers of cholinergic PPN neurons in schizophrenia.

DIFFERENTIAL REGULATION OF $GABA_A$ AND BENZODIAZEPINE RECEPTOR BINDING IN THE HIPPOCAMPAL FORAMTION OF SCHIZOPHRENICS. S.L. Vincent*, Y. Khan, R. Wickramasinghe, and F.M. Benes. Department of Psychiatry and Program in Neuroscience, Harvard Medical School and Laboratory for Structural Neuroscience, McLean Hospital, Belmont, MA 02178.

Recent postmortem studies have reported a marked upregulation of $GABA_A$ receptor binding (RB) activity in the anterior cingulate and prefrontal cortices of schizophrenic (SZ) subjects. Because the hippocampal formation has also been implicated in the pathophysiology of SZ, the current study has examined $GABA_A$- and benzodiazepine- (BZ) RB in this region from control (N=15) and SZ (N=8) subjects. Low-resolution analysis of $GABA_A$-RB showed an increase for SZs in the area dentata, CA4, CA3, CA2, subiculum, and presubiculum. The magnitude of these differences ranged from 22% to 91%, and was largest for stratum oriens (91%) and stratum pyramidale (57%) of CA3, and lowest in all layers of CA1 (22-36%). In contrast, BZ-RB showed more modest increases in CA3 (stratum oriens, 32%), CA1 (stratum oriens, 13%), subiculum (25%), and presubiculum (48%). High-resolution analysis of $GABA_A$-RB for CA3 showed no change on pyramidal cells (PNs), but a 170% increase on nonpyramidal cells (NPNs), while for CA1 there was a 43% increase on PNs and no change on NPNs. In contrast, a similar analysis of BZ-RB showed no change on either PNs or NPNs of CA3. These differential changes of $GABA_A$-RB by subregion and cell type are consistent with a model in which there are discreet alterations in disinhibitory GABAergic modulation in CA3 of SZs. Although $GABA_A$ and BZ binding sites are believed to share the same macromolecular receptor complex, the present finding of a disparity for RB-activity between these two sites suggests they may be differentially regulated in SZ brain. Gene expression for NMDA receptor subunits in the prefrontal and parieto-temporal cortex of schizophrenics and controls. E.G. Jones[1] S.Akbarian[1]* D. Bradley[1], D.Trinh[1], S.G. Potkin[2], W.E. Bunney Jr[2], N.J.Sucher[3]. *[1]Dept. of Anatomy and Neurobiology and [2]Dept. of Psychiatry and Human Behavior, Univ. of California, Irvine, CA 92717 and [3]Dept. of Neurology, Children's Hospital, Harvard Medical School, Boston MA 02115*

NMDA receptor channel blockers potentially induce a psychosis with psychopathological symptomes that are frequently observed in patients with schizophrenia, but evidence for a defect in NMDA receptor mediated signal transmission in brains of schizophrenics has remained inconclusive. Using in situ hybridization histochemistry and optical densitometry, the present study analysed in 15 schizophrenics and 15 matched controls the genetic expression pattern of all 5 NMDA receptor subunit genes (NR1, NR2A-D) in the prefrontal cortex, a brain region thought to be primarily involved in the pathophysiology of the disease. Comparative studies were conducted on the parieto-temporal cortex of the same specimens. Both in schizophrenics and controls, levels of mRNA for NR1, NR2A, NR2B and NR2D subunit polypeptides were overall 40% higher in the prefrontal cortex, in comparison to the parieto-temporal cortex. The prefrontal , but not the parieto-temporal cortex of schizophrenics showed a signficant change in the stoichiometric composition of mRNAs for the NR2 subunit gene family, due to a selective increase in the proportion of NR2D subunit mRNA (schizophrenics: 34.6 ± 4.0%, controls: 23.4 ± 2.5%, $p = 0.031$). Given the fact that NR2D subunit appears to enhance the excitability of the NMDA receptor (Monyer et al., 1994), the increased expression of the mRNA for NR2D polypeptide in the prefrontal cortex of schizophrenics may be a compensatory response to the functional hypoactivity and to the assumed deficits in NMDA receptor mediated signal transmission. Supported by grant no. MH 44188 from the NIMH.

CHANGES IN GENE EXPRESSION IN RAT BRAIN AFTER CHRONICAL NEUROLEPTIC TREATMENT. N. Dahmen, V. Fischer, M. Fickova, S. Reuss, G.D. Bartoszyk* and C. Hiemke. Departments of Psychiatry and Anatomy, University of Mainz, Germany and Department of CNS-Research*, E. Merck, D-64271 Darmstadt, Germany

The administration of antipsychotic drugs has been demonstrated in rat and human brain to alter the pattern of gene expression. Among the genes regulated are those that encode for dopamine receptors, various neuropeptides and immediate early genes. To test the hypothesis that further changes in neuronal gene expression are involved in the longterm effects of chronically administered neuroleptic drugs, rats were treated orally for 3 weeks with haloperidol, 2 mg/kg per day, and clozapine, 100 mg/kg per day. After that time, animals were decapitated and haloperidol and clozapine serum levels measured in truncal blood by radio receptor assay and HPLC, respectively. Total RNA was extracted from whole brains and subjected to RNA differential display. This method is a tool to identify and clone differentially expressed genes and involves the reverse transcription of mRNAs with oligo-dT primers anchored to the beginning of the poly(A) tail, followed by PCR reaction in the presence of a second 10mer arbitrary in sequence and analysis of amplification products on a sequencing gel. Comparison of gel patterns derived from treated and control animals resulted in reproducible differences in the three groups. In particular, one transcript was observed that only appeared in samples derived from control and haloperidol treated animals but not from clozapine treated animals. Our results support the study hypothesis of a modulation of neuronal gene expression by neuroleptic drugs and suggest that gene regulation is relevant to the treatment and/or the pathophysiology of schizophrenia.

835.16

DEVELOPMENTAL EXPRESSION OF ALPHA-3 INTEGRIN, A MOLECULE IMPLICATED IN SCHIZOPHRENIA. **Vicente A. Honer WG, Nobrega J*, Kennedy JL. Clarke Institute of Psychiatry, Toronto, Ontario M5T 1R8, Canada.**

Accumulating structural and molecular evidence suggests that a neurodevelopmental disturbance may be a cause of schizophrenia. In brains of schizophrenics, several limbic structures show altered cell numbers and/or disrupted cell orientation. Also, several neurodevelopmental molecules are changed in these regions, such as NCAM, NMDA receptors, and synaptic vesicle proteins. We have been investigating the role, in schizophrenia, of molecules involved in brain development and in the synaptic plasticity events that occur during brain maturation. Using an antibody that binds differentially to schizophrenia versus control brain homogenates, a human cDNA clone, WH4, was isolated and showed a 96% homology to the α_3 subunit of $\alpha_3\beta_1$ integrin. Integrins are cell membrane receptors that bind the extracellular matrix, promoting communication between the intra and extracellular environments, and are crucial for cell movement. We have found strong α_3 subunit (WH4) expression in rat brain and have analysed its mRNA distribution in the adult animal, and during postnatal development by *in situ* hybridization. We have found a widespread distribution of the mRNA throughout the adult brain, with higher levels in hippocampus, pyriform cortex, amygdala, hypothalamus and cerebellum. Preliminary results indicate higher levels of expression in 1 day old rat brains, which decrease to adulthood levels after 7 days. This pattern of expression is consistent with a role of the molecule in plasticity events during brain maturation and the involvement of α_3 integrin in schizophrenia remains intriguing .

LOCALIZATION OF D4 DOPAMINE RECEPTORS IN RAT BRAIN. A.M. Murray*, T.M. Hyde, B.K. Lipska, G.K. Wood, J.E. Kleinman and D.R. Weinberger, Clinical Brain Disorders Branch, IRP, NIMH, St. Elizabeths Hospital, Washington, DC 20032.

Studies in human brain have demonstrated a mismatch for mRNA localization for D4 receptors. There is neglible D4 mRNA in the striatum/nucleus accumbens but abundent D4 receptor binding. It is possible that D4 receptors are not synthesized in the basal ganglia, but rather have a presynaptic localization on afferent terminals in the striatum. Prefrontal cortex contains the largest amount of D4 mRNA in the human brain. If the receptors are located on projection neurons to the striatum, a lesion of these neurons should result in a decrease in D4 receptor number. Adult Sprague-Dawley rats recieved infusions of ibotenic acid or vehicle into the medial prefrontal cortex. This region projects to the nucleus accumbens (core and shell). Rats were killed 6 weeks later. Brain sections (20 µm) were preincubated and then incubated with 1 nM [^{3}H]YM 09151-2. Adjacent sections were preincubated with 200 µM Gpp(NH)p and incubated with 6 nM [^{3}H]Raclopride. (+)-Butaclomal (10 µM) was used to determine non-specific binding in both assays. Mean optical density in the dorsolateral (DLS), ventromedial striatum (VMS), nucleus accumbens (NAC), NAC-core and NAC-shell were converted to fm/mg protein. Specific [^{3}H]raclopride binding was subtracted from specific [^{3}H]YM 09151-2 binding to estimate putative D4 receptor density. There was no effect of lesion for either ligand or for the calculated D4 receptor density in any region. These results suggest that D4 receptors are not located on cortico-striatal neurons projecting from medial prefrontal cortex to nucleus accumbens (core/shell). The limitations of using [^{3}H]YM 09151-2 minus [^{3}H]raclopride subtraction technique to measure D4 receptors will be discussed.

NEONATAL VENTRAL HIPPOCAMPAL DAMAGE CHANGES CORTICOSTERONE AND CENTRAL DOPAMINERGIC RESPONSES TO ACUTE FOOTSHOCK. S.J. Chrapusta, B.K. Lipska, M.F. Egan, R.J. Wyatt*, G.K. Wood and D.R. Weinberger. NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

Neonatal ibotenic acid ventral hippocampal (VH) damage enhances behaviors linked to dopamine (DA) system(s) in Sprague-Dawley rats, e.g. acute stress-induced locomotor activity, stereotypic and locomotor responses to DA agonists, etc. The VH-lesioned rats demonstrate an enhanced haloperidol challenge-induced DA release following chronic haloperidol treatment. However, they respond to chronic saline injections with a reduction of DA release in brain regions implicated in stress. We used continuous footshock (0.45 mA for 0, 20, and 60 min) to study the effects of this lesion on DA responses to acute stress in frontal cortex (FC), nucleus accumbens (NA), and striatum (ST). As an index of DA release, regional 3-methoxytyramine levels 10 min after pargyline hydrochloride injection (75 mg/kg, i.p.) were compared in microwave-fixed brains of the VH-lesioned and sham rats. Serum corticosterone (CORT) was measured as a peripheral index of stress. Basal DA release was attenuated in the NA but not in the FC or ST in the VH-lesioned rats. Footshock increased ST and NA DA release in the lesioned but not sham rats at both 20 and 60 min. In the FC, footshock-induced increases in DA release were found in both VH-lesioned and sham rats. The FC DA release normalized towards the end of the footshock session in the sham rats, but not in their VH-lesioned counterparts. Basal CORT levels were similar in the VH-lesioned and sham rats. Footshock increased CORT levels in both VH-lesioned and sham rats, but the patterns differed in that there was no attenuation over time in the VH-lesioned rats. Our observations indicate that the VH lesion interferes with the homeostatic systems involved in stress management in the rat, and delays adaptation to acute stress, which may potentiate detrimental effects of such event(s).

835.19

DOPAMINE RECEPTOR CHANGES IN RATS WITH NEONATAL VENTRAL HIPPOCAMPAL LESION ARE ONLY OBSERVED AFTER CHRONIC STRESS

G.K. Wood, B.K. Lipska, A.M. Murray, M.E. Knable, L.B. Bigelow*, D.R. Weinberger. Clinical Brain Disorder Branch, IRP, NIMH, Neuroscience Center at St. Elizabeths, Washington, DC 20032.

Neonatal exocitotoxic lesions of the rat ventral hippocampus (VH) produce postpubertal emergence of motoric hyperactivity to dopamine-related behavioral stressors. The accumulation of 3-methoxytyramine was reduced in the nucleus accumbens (NAC), striatum (STR) and medial prefrontal cortex (MPFC) in chronically stressed lesioned but not sham-operated rats. We now determined if stress-induced changes are associated with alterations of dopamine receptors in the MPFC, NAC and STR. On postnatal day 7 (PD7), the VH was lesioned with ibotenic acid. To test for age effects at baseline, rats were sacrificed at PD35 or PD56. In another group rats were stressed (daily saline injections for 3 weeks from PD35 to PD56) or untreated. Brain sections for autoradiography were incubated with [3H]raclopride (6.0nM), [3H]YM-09151-2 (YM, 1nM) or [3H]SCH-23390 (3nM). Raclopride and YM binding in the STR and raclopride binding in the MPFC decreased with age in all rats. At baseline, there was no difference between sham and lesioned rats at any age. Stress significantly increased the binding of raclopride in MPFC and YM in STR in lesioned but not in sham rats. Stressed lesioned rats had higher MPFC SCH23390 binding than stressed sham rats. The data suggest that previously reported behavioral hyperresponsiveness to acute stress in neonatally VH lesioned rats is not produced by increased D1, D2/D3 receptor levels. However, chronic stress upregulates D1 and D2/D3 levels in lesioned but not in control rats.

835.20

ALTERED INDUCTION PATTERNS OF c-FOS mRNA AFTER CLOZAPINE AND HALOPERIDOL IN RATS WITH NEONATAL HIPPOCAMPAL LESIONS. B. K. Lipska*, S. M. Lillrank, G. K. Wood, D. R. Weinberger. Clinical Brain Disorders Branch, IRP, NIMH, Neuroscience Center at St. Elizabeths, Washington, DC 20032.

Previous studies have indicated that neonatal (postnatal day 7) ibotenic acid lesions of the ventral hippocampus in the rat can be useful in modeling some aspects of schizophrenia. This developmental lesion results in postpubertal emergence of multiple abnormalities suggesting altered dopamine responsivity to environmental and pharmacological stimuli that can be ameliorated with antipsychotic drugs, clozapine (CLOZ) and haloperidol (HAL). In the present study we examined the effects of acute (i.p.) and chronic (via osmotic minipumps, 28 d) treatment with vehicle, CLOZ and HAL on c-fos expression in infralimbic region of medial prefrontal cortex (IF), dorsolateral (DLS) and ventromedial (VMS) striatum, and nucleus accumbens (NAC) in rats with neonatal hippocampal lesions. The effects of acute injections were drug-, lesion- and region-specific. In controls, acute HAL (0.2 mg/kg) increased c-fos mRNA by 30% (IF), 118% (DLS), 71% (VMS), 39% (NAC), $p<0.05$ vs vehicle. The response of lesioned rats to HAL was attenuated but significantly increased over vehicle, except for IF. Lesioned HAL-treated rats had significantly reduced c-fos mRNA in DLS, VMS and NAC, but not in IF, as compared to HAL-treated controls. In contrast, acutely CLOZ-treated lesioned rats showed reduced c-fos mRNA in IF and increased c-fos in VMS and NAC as compared with CLOZ-treated controls. There were no significant effects of chronic treatment on c-fos mRNA suggesting tolerance to both drugs. These data indicate that this developmental lesion differentially alters regionally-specific c-fos mRNA response to acutely administered neuroleptics.

835.21

EXPRESSION OF LIMBIC SYSTEM-ASSOCIATED PROTEIN (LAMP) IN RATS WITH NEONATAL EXITOTOXIC HIPPOCAMPAL LESIONS.

1)SM Lillrank*, 1)BK Lipska, 2)P Levitt, 2)AF Pimenti and 1)DR Weinberger 1Clinical Brain Disorders Branch, NIMH, Neuroscience Center at St Elizabeths, Washington DC 20032. 2Dept. Neuroscience and Cell Biology, UMDNJ, Robertwood Johnson Med School, Piscataway, NJ 08854

We have previously demonstrated that rats with neonatal (day 7 after birth, PD7) ibotenic acid damage in the ventral hippocampus (VH) express postpubertally (PD56) a variety of abnormal behaviors related to mesolimbic and nigrostriatal dopaminergic and prefrontocortical dysfunction. We have hypothetized that the behavioral abnormalities elicited in this model might have resulted from an interaction of an early VH lesion with subsequent developmental maturation and with the development of anomalous limbic circuitry. LAMP is expressed preferentially by neurons in limbic structures or in neurons that receive direct projections from structures of the limbic system. It was shown previously that there is a critical period for cortical neurons to express LAMP. We studied the expression of the rat LAMP mRNA using in situ hybridization technique in adult rats with neonatal VH lesions. LAMP was expressed in all rats in the cingulate,- medial prefrontal and piriform cortex, nucleus accumbens, medial and lateral septal nuclei and claustrum. In adults there were no differences in LAMP expression between sham operated and neonatally lesioned animals in terms of optical density mesurements. These data support earlier studies indicating that the LAMP mRNA is expressed predominantly in the limbic regions. It also shows that the developmental VH lesion at PD7 does not permanently change the expression of LAMP mRNA in adult rats. We are currently examining LAMP mRNA expression in shorter time periods post lesion.

835.22

AMPA SPLICE VARIANT EXPRESSION IN MEDIAL TEMPORAL CORTEX IN SCHIZOPHRENIA AND CONTROLS . J. T. Noga,* S. E. Bachus, T. M. Hyde, M. M. Herman, D. R. Weinberger, J. E. Kleinman. NIMH, DIRP, Clinical Brain Disorders Branch, NIMH Neuroscience Center at St. Elizabeth's Hospital, Washington, DC 20037

The neurodevelopmental hypothesis of schizophrenia is supported by cortical cytoarchitectural abnormalities and volume decreases (localized and global) in the absence of gliosis. Receptor density and gene expression abnormalities in glutamatergic (and other) neurotransmitter systems have also been reported. These abnormalities have been concentrated primarily in prefrontal, medial temporal, and striatal structures. In this study we tested neurodevelopmental aspects of receptor gene expression in schizophrenia by examining the relative presence of ontogenetically regulated flip and flop isoforms of AMPA receptor mRNA in medial temporal structures of postmortem brains from adult schizophrenics (n=6, mean age 56.8 ± 16.3 years), normal controls (n=6, mean age 50.8±12.2), and medicated nonschizophrenic psychiatric controls (n=8, 46.8±16.7) using in situ hybridization of [^{35}S]-labelled oligonucleotide mRNA probes with 20 µm thin frozen sections. ANOVA results of densitometric analysis revealed a main effect of isoform type consistent with previous literature reports, namely that the flip isoform predominated in the regions measured (entorhinal cortex, deep intermediate/lateral ($p<.0002$) and superficial intermediate/lateral ($p<.07$), and deep ($p<.0002$) and superficial ($p<.0002$) sulcal subregions; dentate gyrus ($p<.0002$); and subiculum ($p<.0002$)) in all diagnostic groups. The schizophrenia group did not differ from the other 2 diagnostic groups in the density of flip or flop isoforms or in their ratio ($p>.2$). We conclude that there is no apparent abnormality in the expression of GluR3 flip or flop isoforms in this sample of schizophrenia v. control subjects. These results do not support the presence of an aberration in GluR3 splice variant ontogeny in schizophrenia. GluR1,2, and 4 isoforms are being studied as well in this group of brains and will be reported.

835.23

rCBF PATTERN DIFFERENCES BETWEEN SCHIZOPHRENIC PATIENTS WITH AND WITHOUT DEFICIT SYMPTOMS. W.T. Carpenter, Jr.*, A.C. Lahti, H.H. Holcomb, P.J. Caudill, M. Zhao, D.R. Medoff, C.A. Tamminga. MPRC, University of Maryland School of Medicine, P.O. Box 21247, Baltimore, MD 21228

We previously reported that schizophrenic patients with deficit symptoms (primary negative symptoms) were distinguished from non-deficit patients and normals in a PET/FDG study by reduced metabolism in thalamus and in frontal and parietal cortex (Tamminga et al, 1992). We now report $H_2{}^{15}O$ PET data on drug-free schizophrenic patients with (N=5) and without (N=5) deficit symptoms and normals (N=12). Rest, sensory-motor control (SMC), and tone discrimination task scans were obtained on each subject, four of each. Task difficulty was manipulated to assure a comparable accuracy of 80% in each subject group. Statistical Parametric Maps (SPM 94 MRC Cyclotron Unit, Hammersmith Hospital) were created to contrast rCBF activity patterns between groups. Preliminary analyses show that while normal volunteers show physiologically appropriate patterns of activation, deficit and nondeficit patients have different patterns from normals at rest and during tasks. In normals, during the tone discrimination task, right middle frontal and anterior cingulate cortices are activated. In patients, deficit patients have reduced parieto-occipital flow at rest and reduced frontal cortex flow during the tone discrimination task, compared with nondeficit schizophrenic patients.

HIGH GLUCOCORTICOID LEVELS DECREASE SOME ANTIOXIDANT ENZYME ACTIVITIES IN THE ADULT RAT BRAIN. L.J. McIntosh,* K.E. Hong and R.M. Sapolsky. Dept. of Biological Sciences, Stanford Univ., Stanford, CA 94305

Due to its high oxygen consumption, the brain may be particularly vulnerable to oxidative damage and degeneration. Substances affecting neuronal oxidative homeostasis would therefore be expected to alter the ability of the brain to defend itself against oxidative damage. High levels of glucocorticoids (GCs), the adrenal hormones secreted in response to stress, can change metabolic capacity in various brain regions by decreasing energy uptake and elevating intracellular calcium, thereby altering intracellular oxidative homeostasis. We have recently shown that GCs enhance oxygen radical-associated neurotoxicity in vitro, supporting previous in vivo studies demonstrating that GCs potentiate neurodegeneration following oxidative insults (e.g. stroke, hypoglycemia, seizure). To investigate whether GCs affect the enzymatic component of intracellular oxidative defenses, we assayed Cu/Zn- and Mn-superoxide dismutase, catalase, and glutathione peroxidase in the livers and several brain regions of rats which had been either adrenalectomized (ADX) to remove circulating GCs, or supplemented with GCs to achieve high physiological levels. GCs altered enzyme activity in a pattern unique for each enzyme. For example, catalase activity in GC-treated rats was decreased 50% in liver and 66% in cortex, and did not change significantly in hippocampus and cerebellum as compared to ADX rats. Glutathione peroxidase activity decreased 50% in hippocampi of high GC animals, but was essentially unchanged in liver and cortex. Western blotting is being used to determine whether changes in activity are a genetic or epigenetic effect. Our results indicate that stress hormones may directly affect pathways involved in oxygen radical toxicity in adult brain, and imply that the GC potentiation of damage seen after oxidative insults is due in part to a decrease in the cellular enzymatic antioxidant defenses.

836.2

KETAMINE INHIBITS GLUTAMATE INDUCED NEURONAL DEATH. 1)Masanori YAMAUCHI, 1)Akiyoshi NAMIKI, 2)*Takahumi NINOMIYA 1)Dept. of Anesthesiology, Sapporo Medical University 2)Dept. of Anatomy Sect. I, Sapporo Medical Universit

We studied the effect of ketamine, non-competitive NMDA-receptor antagonist, on glutamate-induced neuronal death in cultured rat cortical neurons. After 7 days in culture, the neurons were exposed to 1mM of glutamate or both glutamate and 10-1000μM of ketamine. After 24-hr. exposure, they were stained with a monoclonal anti-microtuble-associated protein 2 antibody. The number of surviving cultured neurons was decreased by a exposure of glutamate. Concomitant exposure of glutamate and ketamine did not decrease the number of neurons in a concentration-dependent manner. Ketamine likely protects the glutamate-induced neuronal death.

836.3

TROLOX INHIBITS CELL DEATH FOLLOWING COMBINED OXYGEN AND GLUCOSE DEPRIVATION IN MIXED NEURONAL/GLIAL CORTICAL CULTURES. A.W. Probert*, F.W. Marcoux and P.A. Boxer. Parke-Davis Pharmaceutical Res., Div. of Warner-Lambert Co., Ann Arbor, MI 48105.

Exposure of mixed neuronal/glial cortical cultures to increasing intervals of combined oxygen [1%] and glucose [1 mM] deprivation (COGD) results in a gradual rise in neuronal cell death measured 18-22 hours post COGD. Injury-onset (LDH release) first appears following 135 to 150 minutes of COGD, climaxing after 240 to 255 minutes of deprivation. Treatment with the vitamin E analog, Trolox, a free radical scavenger, increased the deprivation intervals required to initiate COGD-induced neuronal death. This postponement of injury-onset was concentration dependent, delaying the induction of cell death by 30 to 60 minutes for Trolox concentrations of 10 μM to 1000 μM. Trolox did not alter the deprivation interval required to achieve maximal injury. Co-treatment with Trolox (100 μM) and the NMDA competitive antagonist, CPP (3(2-carboxypiperazine-4-yl)propyl-1-phosphonic acid, 100 μM), produced a synergistic effect, prolonging deprivation intervals required to induce both injury-onset and maximal death. In both cases, deprivation intervals required to override CPP's protection were increased by 30 to 45 minutes with Trolox co-treatment. Results suggest free radical formation may contribute to the early stages of neuronal injury initiated by oxygen and glucose deprivation.

836.4

CALBINDIN-D28k IS PRESENT IN MIDBRAIN DOPAMINERGIC NEURONS THAT ARE LESS VULNERABLE TO MPTP-INDUCED DEGENERATION. C.-L. Liang, C.M. Sinton*, P.K. Sonsalla, and D.C. German. Dept Psychiat, UT Southwestern Med Cntr, Dallas, TX 75235-9070, and Dept Neurol, UMDNJ RW Johnson Med Sch, Piscataway, NJ 08854.

The calcium-binding protein, calbindin-D28k (CALB), is in nerve cells in midbrain regions where dopaminergic (DA) neurons reside that are less vulnerable to degeneration in Parkinson's disease (PD), and in an animal model of PD (the MPTP-treated mouse). In order to determine whether the CALB-containing DA neurons are less vulnerable to degeneration in the MPTP-treated mouse, immunohistochemical staining and computer mapping techniques were employed. Male C57BL/6 mice were treated with saline or MPTP (4x20 mg/kg on Day 1, and 3x20 mg/kg on Day 3) and sacrificed on Day 9. Ten μm coronal sections were cut through the midbrain, and sections were double immunostained for CALB and tyrosine hydroxylase. The locations of all TH, and TH+CALB cells in a midbrain region were mapped. In animals treated with MPTP (n=5), compared to controls (n=3), there was a 72% reduction in TH-containing cells ($p < 0.001$), but only a 30% reduction in TH+CALB-containing cells ($p < 0.02$). These data support the hypothesis that DA cells that contain CALB are less vulnerable to MPTP-induced degeneration than DA cells lacking CALB.

G_{M1} GANGLIOSIDE INFUSION PRODUCES INCREASED GFAP IMMUNOREACTIVITY IN THE ABSENCE OF NEUROPATHOLOGY.
G. P. H. Ballough*,[2], P. R. Patel[2], J. P. Makowski[2], M. A. O'Connor[2], F. J. Cann, C. D. Smith[1] and M. G. Filbert[1]. [1]Neurotoxicology Branch, U.S. Army Medical Research Institute of Chemical Defense, Edgewood Area - Aberdeen Proving Ground, MD 21010-5425. [2]Department of Biology, La Salle University, Philadelphia, PA, 19141.

Glial fibrillary acidic protein (GFAP) immunodetection, as a marker of reactive astrocytosis, has become a mainstay of modern neurotoxicology. It is well established that increased GFAP immunostaining is a sensitive, early index of neurotoxic insult. As part of an ongoing study to evaluate the effectiveness of G_{M1} administration to ameliorate brain damage resulting from soman-induced seizures, we observed an apparent induction of reactive astrocytosis in the absence of neuropathology. Male Sprague-Dawley rats received G_{M1} (5 mg/kg/day, for 5.0 ± 0.5 days) through a permanent cannula implanted intracerebroventricularly (i.c.v.) and connected to an osmotic minipump. Controls received saline infusions or were sham operated. Rats from each of these groups received either soman (83 µg/kg, i.m.) or saline injections 4.0 ± 0.5 days following initiation of G_{M1} infusions. GFAP immunostained brain sections were assessed both visually and using optical density image analysis. These results demonstrate a significant and marked increase in GFAP immunostaining in the G_{M1} infused non-soman group compared to the other groups; this finding was not associated with neuropathology (determined on H&E-stained serial sections). Elevations in GFAP were most pronounced in the hippocampi of these non-seizing animals. This study provides new information concerning GFAP as a marker for brain damage, and indicates the possibility that astrocytic reactions may be uncoupled from neuropathology.

CHRONIC G_{M1} GANGLIOSIDE ADMINISTRATION PROTECTS AGAINST SOMAN-INDUCED SEIZURE-RELATED BRAIN DAMAGE.
M. G. Filbert, F. J. Cann, C. D. Smith, C. E. Kling, J. S. Forster, J. S. Graham, B. E. Hackley* and G. P. H. Ballough^. Neurotoxicology Branch, U.S. Army Medical Research Institute of Chemical Defense, Edgewood Area - Aberdeen Proving Ground, MD 21010. ^Department of Biology, La Salle University, Philadelphia, PA, 19141.

Soman (pinacolylmethylphosphonoflouridate) is an irreversible acetylcholinesterase (AChE) inhibitor which produces seizure-related brain damage in mammals. In the present study, we examined possible ameliorative effects of chronic G_{M1} administration on brain damage resulting from soman administration. Male Sprague-Dawley rats received G_{M1} (5 mg/kg/day, for 5.0 ± 0.5 days) through a permanent cannula implanted intracerebroventricularly (i.c.v.) and connected to an osmotic minipump. Controls received saline infusions or were sham operated. Rats from each of these groups received either soman (83 µg/kg, i.m.) or saline injections 4.0 ± 0.5 days following initiation of G_{M1} infusions. Damage was assessed using H&E and cresyl violet (CV) histochemistry as well as glial fibrillary acidic protein (GFAP) and microtubule associated protein-2 (MAP2) immunohistochemistry. These results show that two mechanisms of neuroprotection were produced by chronic GM_1 infusion: First, GM_1 administration interfered with the development of seizures and status epilepticus; in these situations, no brain damage was observed. Secondly, brain damage resulting from sustained seizures was significantly attenuated in GM_1 treated rats.

INHIBITION OF BRAIN NITRIC OXIDE SYNTHASE BY S-METHYL-ISOTHIOUREA
X. Xu*, F. Zhang and C. Iadecola, Lab. of Cerebrovascular Biology and Stroke, University of Minnesota, Minneapolis, MN 55455.

S-methyl-isothiourea (SMT) is a relatively selective inhibitor of inducible nitric oxide (NO) synthase (iNOS) that improves survival in a rodent model of septic shock (PNAS, 91, 12472, 1994). Because, iNOS induction may contribute to some forms of brain injury, including ischemic damage (Iadecola et al., this meeting), it would be important to determine whether SMT could be used as a selective iNOS inhibitor in brain. Calcium-dependent (cNOS) and independent (iNOS) NOS activities were measured in brain homogenates using the citrulline assay. iNOS was induced in the rat cerebral cortex by thermal lesions and in systemic organs by i.p. administration of lipopolysaccharide antigen (LPS). SMT (0.01-1000µM) attenuated cNOS activity of brain homogenates in a dose-dependent manner (EC_{50}=0.9µM). SMT was nearly as potent as nitro-L-arginine (L-NA; EC_{50}=0.7) and was, respectively, 11 and 814 times more potent than monomethyl-L-arginine (L-NMMA) and aminoguanidine (AG). SMT attenuated iNOS activity in lung homogenates of LPS-treated rats (EC_{50}=0.09) and was 12, 115, and 1152 times more potent than L-NMMA, L-NA and AG, respectively. We then evaluated the ability of SMT to inhibit cNOS and iNOS in brain *in vivo*. SMT (1-100 mg/kg; i.p.; n=4 per dose) inhibited brain cNOS dose-dependently and up to 34±4% (100 mg/kg). Higher SMT doses (500, 1000mg/kg) produced seizures and death. In contrast, L-NA (40 mg/kg; i.p.) inhibited cNOS by 75±2% (n=4). SMT (100 mg/kg) failed to attenuate iNOS activity in homogenates of thermal brain lesions (p>0.05 from vehicle). Thus, the *in vitro* data suggest that SMT is a more potent inhibitor of iNOS than L-NA, L-NMMA or AG. However, *in vivo*, SMT inhibits only brain cNOS and less effectively than L-NA. We conclude that SMT is a potent iNOS inhibitor *in vitro*. However, its lack of effectiveness *in vivo* limits its usefulness in models of iNOS-dependent brain injury. (Supported by AHA and NIH)

LOW DOSE SELEGILINE TREATMENT MEDIATES NEURONAL RESCUE IN RAT PERIPHERAL SYMPATHETIC NERVOUS SYSTEM. T. Salonen, A. Haapalinna #, E. Heinonen #, J. Suhonen + and A. Hervonen *, Univ. of Tampere, School of Public Health, Dept. of Gerontology, FIN-33101 Tampere, FINLAND; # ORION Corp., FARMOS Research, Dept. of Neurological Products, FIN-20101 Turku, FINLAND; + The Salk Institute, La Jolla, CA 92093, USA

Selegiline (SEL) is a selective and irreversible monoamine oxidase type B (MAO-B) inhibitor. It has been shown to protect against toxic effects of aminergic neurotoxins. Recent animal studies have suggested that low doses of SEL has also neuronal rescue and antiapoptotic effects after neuronal damage or withdrawal of trophic factors, respectively. The purpose of this study was to determine the effect of SEL on the recovery of adrenergic nerve fibres after 6-OHDA-induced degeneration. The animals were treated with 6-OHDA (50 mg/kg i.p.) and 24 hours after that the treatments with SEL (0.03, 0.1 and 1 mg/kg s.c.) or distilled water were started and then continued daily. The animals were killed one or two weeks after the 6-OHDA administration and the SCG's and SMG's were dissected. The treatment with 6-OHDA had significantly decreased the number and length of the nerve fibres in the SMG. Subchronic SEL treatment had enhanced recovery rate and there was a statistically significant difference between SEL 0.1 mg/kg group and 6-OHDA treated control group in SMG innervation at two week time point. The degenerative effect of 6-OHDA on the ganglion cell somata was detected in this experiment similar to the previous experiments. The somata of the cells seemed to prefer the highest dose of SEL for the fastest recovery.

THE NEUROTOXIN MPTP INCREASES CALBINDIN-D_{28K} LEVELS IN MOUSE MIDBRAIN DOPAMINERGIC NEURONS.
[1]May C. Ng, [1]Anthony M. Iacopino, [1]E. Matthew Quintero, [1]Florentina Marches, [¶]Patricia K. Sonsalla, [§]Chang-Lin Liang, [§]Samuel G. Speciale and [§]Dwight C. German*. [1]Department of Biomedical Sciences, Baylor College of Dentistry - Dallas, TX 75266-0677; [¶]Department of Neurology, UMDNJ Robert Wood Johnson School of Medicine - Piscataway, NJ 08854; [§]Department of Psychiatry, University of Texas Southwestern Medical Center - Dallas, TX 75235.

The calcium-binding protein calbindin-D_{28k} (CALB) has been localized in high concentration in several neuronal populations within the CNS and is believed to act as an intracellular calcium (Ca^{2+}) buffer. There has been much interest and speculation concerning its potential neuroprotective function. However, there is little direct evidence linking CALB content of individual neurons to Ca^{2+} buffering ability, resistance to Ca^{2+}-mediated excitotoxicity, or vulnerability to Ca^{2+}-mediated degeneration. It is necessary to demonstrate these relationships on a cellular level so that more definitive conclusions can be made. We have utilized immunocytochemical and Western blot techniques to determine whether cellular CALB content is altered in the nucleus A10 dopaminergic region of the midbrain following administration of the neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Our data demonstrate a significant increase in the CALB content of nucleus A10 neurons (up to 227 ± 23% above control) 3 and 6 hours after MPTP treatment. CALB elevation demonstrated both time and dosage dependency as 6 hour groups exhibited larger increases than 3 hour groups, and a 60mg/kg dosage induced a larger increase than a 20mg/kg dosage. The time course of CALB elevation is consistent with upregulation of gene transcription. These data support the hypotheses that MPTP is neurotoxic by causing increases in intracellular Ca^{2+} and that increased CALB in midbrain dopaminergic neurons is a protective response to elevated intracellular free Ca^{2+}.

K252A, K252B AND STAUROSPORINE INCREASE HIPPOCAMPAL NEURON SURVIVAL AND IMPROVE WATER MAZE PERFORMANCE AFTER KAINATE LESION.
V. L. Smith-Swintosky*[1], P. Kraemer[2], N. McCants[1], R. Brown[2], A. Maki[2] and M. P. Mattson[1]. [1]Dept. of Anatomy and Neurobiology and Sanders-Brown Research Center on Aging, [2]Dept. of Psychology, University of Kentucky, Lexington, Kentucky, 40536-0230.

Staurosporine, K252a and K252b are low molecular weight alkaloids which act as protein kinase inhibitors that antagonize the effects of neurotrophic factors at high concentrations (µM); but have neuroprotective activities at low concentrations (fm-nM). We found that systemic administration of K252a, K252b or staurosporine (1µg/kg) significantly protected rat hippocampal neurons against both unilateral and bilateral hippocampal kainic acid (KA) lesions. Twenty-four hr pretreatment with K252b or staurosporine significantly protected CA3 neurons against unilateral KA lesion ($p<0.05$). Chronic administration of these agents for 2 mos further increased CA3 neuron survival after KA lesion by 1220% and 720%, respectively. Seven day pretreatment with either K252a, K252b, or staurosporine led to a significant increase in CA1, CA3 and hilar neuron survival after bilateral KA lesion ($p<0.05$). Moreover, these compounds improved either learning or performance on the Morris water maze. In addition, we found with western blots that 24 hr treatment with K252b or staurosporine led to a distinct change in excitatory amino acid receptor levels in vitro and in vivo, such that the NMDA receptor subunit NR1 was decreased and the AMPA receptor subunit GluR1 was increased. The ability of these lipophilic alkaloids to be given systemically and have a central neuroprotective effect against excitotoxic/metabolic insults may have profound implications for treatment of several neurodegenerative disorders.

***IN VITRO* STUDIES ON ANTIOXIDANT PROPERTIES OF METALLOTHIONEIN AND ITS POSSIBLE ROLE IN NEUROPROTECTION.**
S. HUSSAIN*, W. SLIKKER Jr. AND S.F. ALI. Neurochemistry Laboratory, Division of Neurotoxicology, National Center for Toxicological Research/FDA, Jefferson, AR 72079

Metallothionein (MT) is a low molecular weight (6-7 kd) metal binding protein found in biological systems. Its role as an antioxidant is still unclear. The present study was designed to examine the *in vitro* antioxidant properties of commercially available MT and to compare with MT isolated from mouse brain. Different concentrations of MT I and II have been used to determine their capacity to scavenge $O_2^{\cdot-}$ generated from the xanthine/xanthine oxidase (X/XO) system that is based on the i aaaaaaassnhibition of nitrite formation. Other -SH containing molecules e.g. cysteine and GSH, were also used to assess superoxide scavenging properties and to compare with MT. In addition, we have also isolated MT-like protein from mouse brain that inhibits nitrite formation. The results show the concentration dependent $O_2^{\cdot-}$ scavenging properties of MT and MT II has a three- fold higher capacity than MT I. The order of superoxide scavenging properties was found as follows: MTII> CYS> GSH> MTI. A positive control experiment was run with pure SOD that is known to scavenge $O_2^{\cdot-}$ to confirm the X/XO system. The reduction of -SH groups could be due to their oxidation by $O_2^{\cdot-}$. The -SH groups of brain protein fraction were detected qualitatively by dot blotting using a DIG protein kit from Boehringer. Results from this experiment show that a substantial number of -SH groups may be involved in scavenging $O_2^{\cdot-}$. In conclusion, the present study suggests that MTs and MT-like proteins isolated from mouse brain scavenge the superoxide radical *in vitro*. Further, *in vivo* experiments are in progress to substantiate the antioxidant properties of metallothioneins.

PROTECTIVE EFFECTS ON NEURONAL CELLS BY ANTIOXIDATIVE AGENTS OF MICROBIAL ORIGIN.
J.-S. Kim, K. Shin-ya*, Y. Hayakawa and H. Seto. Institute of Molecular and Cellular Biosciences, The University of Tokyo, Bunkyo-ku, Tokyo 113, Japan

A number of neuronal disorders such as brain ischemic injury, Alzheimer's disease and amyotrophic lateral sclerosis (ALS) have proven to be caused by oxygen free radicals. In the course of our screening for antioxidant microbial substances to prevent or ameliorate these diseases using an *in vitro* glutamate-toxicity model, we isolated several potent microbial metabolites (Shin-ya *et al.*, *Tetrahedron Lett.*, **34**: 4943-4944 (1993)). Here, we report the effects of those compounds on neuronal survival.

Cultured rat hippocampal neurons maintained in serum free media were exposed to L-glutamate and other glutamate receptor agonists with or without antioxidants of microbial origin. Some of those antioxidants effectively prevented neuronal cell death by lowering levels of intracellular oxygen radicals with concentrations around 20-200 nM, whereas vitamin E showed little effect with concentration 50 mM. These compounds also protected primary hippocampal neurons and PC12 cells from apoptosis induced by trophic factor deprivation. Since antioxidants were reported to protect against amyloid β toxicity (Behl *et al.*, *Cell*, 77, 817-827 (1994)), we also assessed the activities of those compounds against Aβ toxicity in primary hippocampal neurons and Aβ induced-decrease of MTT reduction in PC12 cells. NADPH oxidase inhibitors like diphenylene iodonium were not effective; only vitamin E type antioxidants protected against Aβ toxicity in our system. Taken together, these findings confirmed the importance of oxygen radicals in neuronal cell death and the usefulness of antioxidant application to neuronal cell survival.

836.13

PROTECTION OF NEURONAL VIABILITY AND INHIBITION OF LIPID HYDROPEROXIDE FORMATION BY TIRILAZAD MESYLATE.
H.M. Scherch*, J.R. Zhang, P.K. Andrus, B.S. Lutzke, P.F. VonVoigtlander, and E. D. Hall. CNS Diseases Research, The Upjohn Co., Kalamazoo, MI 49001.

The 21-aminosteroid, tirilazad mesylate (U-74006F), has demonstrated neuroprotection in a variety of CNS injury models, most likely, through inhibition of lipid peroxidation. In the present study, the compound has been shown to improve neuronal viability in an *in vitro* model of iron-induced lipid peroxidation. Utilizing HPLC-chemiluminescent technology, a correlation has been established between U-74006F protection of neuronal viability and a decrease in lipid hydroperoxide (LOOH) formation. Exposure of murine spinal cord neuronal cultures to 30 μM ferrous ammonium sulfate (FAS) for 20 minutes resulted in an increase in phosphatidylcholine, phosphatidylethanolamine, and free fatty acid LOOH formation. LOOH levels increased 6, 50 and 28 fold, respectively. Prior to iron insult, cell cultures were treated for 60 minutes with U-74006F in half-log concentrations ranging from 0.3 to 30 μM. LOOH levels were reduced significantly in a concentration dependent manner. A 30 μM concentration of U-74006F essentially decreased LOOH levels to control levels and maintained cellular viability near 100%. Correlation between cell death and LOOH formation provides further confirmation of the mechanism of action of U-74006F.

836.14

DIFFERENTIAL EXPRESSION OF CALMODULIN AND CALMODULIN-BINDING PROTEINS AFTER KAINIC ACID ADMINISTRATION TO THE MOUSE.
C.Solà, M. Vendrell*, J.M. Tusell[1] and J. Serratosa. Dept. Pharmacol. and Toxicol. and Dept. Neurochem.[1] CID-CSIC. Barcelona. Spain.

An increase in intracellular calcium has been repeatedly involved in the development of neuronal damage. Calmodulin (CaM), a major calcium binding protein in mammalian brain, is expressed by three different genes (CaM I, CaM II and CaM III) that encode an identical protein. Nevertheless, little is known about the regulation of these genes or about their role in calcium mediated neuronal damage. In turn, CaM mediates its action through its union to different CaM-binding proteins (CaMBP) and among them the calcium-CaM dependent protein kinase II (CaMKII) and the phosphatase calcineurin are highly enriched in the brain.

We studied the expression of the three CaM genes and the two CaMBP above mentioned in the mouse brain after intraperitoneal administration of kainic acid (KA) by means of *in situ* hybridization histochemistry, in several brain regions and at different times of the administration (5 h, 24 h, 2 d and 4 d). The role of CaM and CaMBP following this neurotoxic insult has not been characterized until now.

In general, our results show that KA treatment induced a transient increase in CaM I mRNA hybridization signal in mouse brain 5 h after KA. On the contrary, KA treatment produced a decrease in CaM II mRNA hybridization signal 24 h following the administration in most brain regions considered, while CaM III mRNA signal was mostly unaffected. In addition, a decrease in CaMKII mRNA hybridization signal was observed in regions of cerebral cortex and hippocampus, effect already observed at 5 h of KA and still present in some regions 4 d after. Mainly, these results suggest a differential response of CaM genes to neurotoxic insult.

836.15

EFFECTS OF GLUTAMATE-INTOXICATION ON VOLTAGE- AND TRANSMITTER-GATED ION CURRENTS IN CULTURED CORTICAL NEURONS:COMPARISON WITH DIZOCILPINE-TREATED CULTURES
T. Weiser, A. Rohlfs#, R. Netzer#, M. Wienrich*. #Battelle Geneva, Switzerland; Boehringer Ingelheim, Germany

Voltage- and transmitter-induced currents were investigated in cultured cortical neurons of fetal rats after an exposure to glutamate (10 and 100 μM for 20 h) using the whole-cell configuration of the patch-clamp technique. Voltage-gated currents were induced by voltage steps from -60 to +30 mV; transmitter-gated currents were induced by pulse applications of glutamate (500 μM), NMDA (100 μM), AMPA (50 μM), kainate (1 mM) or GABA (10 μM). The results were compared to those of cultures co-exposed to glutamate and dizocilpine (1 μM).

Exposure to glutamate (100 μM) destroyed 69±4% of the neurons. Surviving cells showed the following changes: The capacity of the cell membrane as a parameter for cell size was reduced. The sodium peak current was reduced from a mean of -3095 pA to -380 pA; the potassium steady state current decreased from a mean of 1857 pA to 614 pA. The relative GABA-induced current was reduced from 25 pA/pF to 9.7 pA/pF. All these effects were significant ($p<0.05$).

These changes induced by glutamate exposure were abolished by co-incubation with the NMDA-antagonist dizocilpine (1μM).

The currents induced by pulse applications of glutamate, NMDA, AMPA and kainate were not significantly different between glutamate-intoxicated and control cells.

These results demonstrate that glutamate intoxication selectively influences certain functional parameters of cultured neurons, and that these changes can be counteracted by the application of a non-competitive NMDA-antagonist.

This work was supported by the BMFT (0319520A)

KAINATE AND AMPA RECEPTORS AND DOPAMINE RELEASE IN EXPERIMENTAL HEPATIC ENCEPHALOPATHY.
S.S. Oja*, H.D. Borkowska, J. Albrecht and P. Saransaari. Tampere Brain Research Center, Tampere University Medical School, Tampere, Finland, and Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland.

Salient features of hepatic encephalopathy (HE) include extrapyramidal symptoms, such as rigidity and tremor. Our working hypothesis was that these symptoms may be associated with an impaired glutamatergic regulation of dopamine release in the striatum. We thus investigated how the functions of kainate and 2-amino-3-hydroxy-5-methyl-4-isoxazolepropionate (AMPA) receptors and the release of dopamine are altered in the frontal cerebral cortex and striatum in experimental HE induced in male Wistar rats with repeated intraperitoneal injections (300 mg/kg) of a hepatotoxin thioacetamide. In HE, the bindings of both AMPA and kainate to synaptic membranes were increased in the frontal cerebral cortex. The release of dopamine evoked by kainate was correspondingly enhanced. In the striatum the binding of kainate was reduced and the kainate-evoked release of dopamine depressed in HE. Of the binding parameters, K_D was generally affected less than B_{max}, e.g., B_{max} for AMPA increased twofold in the frontal cerebral cortex and B_{max} for kainate decreased to the same degree in the striatum, whereas no significant changes were discernible in K_D. The mechanism of dopamine release was not itself compromised in HE, as indicated by persisting potassium stimulation of the release in both brain regions studied. The present results demonstrate that the glutamatergic regulation of brain dopaminergic systems is indeed impaired in HE and the neurological symptoms are thus likely to stem from this defect.

EFFECT OF NITRIC OXIDE ON STP IN CA1 AND CA3 AREA OF RAT HIPPOCAMPAL SLICES CHRONICAL EXPOSURE TO LEAD.

Y.Z.XU*, Y.WU, W.F.WU, A.L.KE, D.Y RUAN DEPT.OF BIOLOGY, UNIV. OF SCIENCE AND TECHNOLOGY OF CHINA,HEFEI,ANHUI 230026 , P.R.CHINA.

Neonatal Wistar rats were exposed to lead from parturition to weaning via the milk of dams drinking 0.2% lead acetate solution. Previous studies in our lab had shown that lead-exposed rats led to a significant reduction on STP in CA1 area and a significant increase on STP in CA3 area (Neursoi.Abst. 885.18, 1993). IN this study we tested the effect of the NO-generating compound Sodium Nitroprusside (SNP) on STP by recording field excitatory postsynaptic potentials (EPSPs) extracellularly in hippocampal slices from control and lead-exposed rats. By bath application of 1mM SNP, STP in CA1 area of control rats were significantly increased in magnitude from 187±39% (n=8) to 270±101% (n=8, $p<0.05$) and that in lead-exposed rats were significantly increased from 129±14% (n=8) to 297±104% (n=8, $p<0.01$). While in CA3 area of control rats, by bath application 1 mM SNP, the magnitude of STP were significantly increased from 119±18% (n=8) to 146±27% (n=8, $p<0.05$) and that in lead- exposed rats were not significantly increased from 187±35% (n=8) to 201±78% (n=8). This data suggest that NO may be a messenger molecule both in CA1 and CA3 area. There are effect of lead on the retrograde messenger system in postsynaptic neurons in CA1 area and on the inhibitory interneuron in CA3 area. Supported by NNSFC (DYR).

***IN VIVO* VERSUS *IN VITRO* EXPRESSION OF RAT INDUCIBLE NITRIC OXIDE SYNTHASE BY ACTIVATED MICROGLIA AND REACTIVE ASTROCYTES.** C.G. Pilapil*, C.E. Nolan, M.A. Collins, R. Tracey, and R.B. Nelson, Dept. of Neuroscience, Pfizer Central Res., Groton, CT.

The two endogenous CNS inflammatory response cells are microglia and reactive astrocytes. Both of these inflammatory response cells from rat can be stimulated *in vitro* with non-specific pro-inflammatory factors (opsonized zymosan or lipopolysaccharide) to release micromolar quantities of nitric oxide (NO), synthesized by an inducible nitric oxide synthase (iNOS). We have also determined in co-culture bioassays that microglia and astrocytes stimulated with pro-inflammatory factors kill adjacent hippocampal neurons, an effect completely abrogated by NOS inhibitors. Little is known about the *in vivo* regulation of iNOS expression in microglia or astrocytes. To begin characterizing the circumstances under which iNOS is expressed in rat brain, we induced unilateral glial reactivity in area CA3 of the rat hippocampal formation via kainic acid administration in the lateral ventricle. We found that by 2 days post-lesion, iNOS immunoreactivity (based on 2 different iNOS-specific antibodies) appeared in cells around the lesion site having reactive astrocyte morphology. Cells of the same size, location, and morphology stained immuno-positive for the astrocyte marker GFAP, and for NADPH-diaphorase activity (a non-specific NOS marker). Cresyl violet staining verified the near-complete destruction of area CA3 pyramidal cells on the injected side. The staining intensity of all 3 of the above markers was increased by 5 days post-lesion and later timepoints are being examined. In animals receiving only vehicle injection, the same 3 markers appeared by 2 days in cells of reactive astrocyte morphology along the cannula tract. Staining of OX-42, a marker for activated microglia, also greatly increased as a result of the kainate lesion, but only a few of the iNOS-positive cells had a morphology or size consistent with OX-42 staining. These results indicate that: 1) both astrocytes and microglia from rat can express iNOS *in vitro*; 2) differential iNOS expression by these cells can occur *in vivo*; and 3) rat brain injury induces predominantly astrocytic iNOS expression.

FREE RADICAL AND NON FREE RADICAL MEDIATED ALTERATIONS IN Ca^{2+} FLUX IN PC-12 CELLS. J.G.Strain, N.D.Jimenez, G.Cao* and J.A.Joseph. USDA-Human Nutrition Research Center on Aging at Tufts University, Boston, MA 02111.

Previous research has suggested that the initial effects of cellular free radical neurotoxic insult involve large increases in intracellular Ca^{2+}. However, the exact role of oxidative stress on the various parameters involved in these increases has not been specified, especially in the case of low, non lethal concentrations of H_2O_2. Present experiments were carried out to examine these parameters in PC-12 cells exposed to 300 uM H_2O_2 for 30 minutes in growth medium alone or containing either nifidipine (L-type Ca^{2+} antag.), conotoxin (N-type antag.), trolox (Vitamin E analog), or *n*-tert-butyl-α-phenylnitrone (nitrone trapping agent, PBN). Fluorescent imaging was used to visualize intracellular Ca^{++} changes in individual Fura II-loaded cells. Baseline (pre-30 mM KCl) Ca^{++} levels were significantly increased by H_2O_2 treatment (200%), while the rise in free intracellular Ca^{++} following KCl stimulation was decreased (50%) and the cell's ability to clear the excess Ca^{++} (i.e., Ca^{2+} recovery time, Ca^{2+}RT) following depolarization was signifcantly increased. Nifidipine, conotoxin, trolox and PBN prevented the initial increase in Ca^{++}, and with the exception of conotoxin, antagonized the H_2O_2-induced decreases in Ca^{++} flux following KCl stimulation. Interestingly, not only were none of these agents effective in protecting against H_2O_2-induced decreases in the cell's ability to clear excess Ca^{++} following depolarization, all of these agents except PBN increased Ca^{2+}RT without H_2O_2 and in fact, acted synergistically with H_2O_2 on this parameter.

836.20

INDUCTION OF CELLULAR STRESS BY INHIBITION OF SUPEROXIDE DISMUTASE OR HEAT SHOCK ALTER UBIQUITIN CONJUGATION IN PC12 CELLS. S.J.Flann, P.W.Beesley* and C.C. Rider, School of Biological Sciences, Royal Holloway, University of London, Egham Hill, Egham, Surrey TW20 OEX, U.K.

Ubiquitin is a low molecular weight polypeptide which is commonly found conjugated to a wide range of target proteins via the ϵ-amino group of lysine. A major role of this conjugation is to target proteins for rapid degradation, although ubiquitination has other functions, as yet not clearly defined. Ubiquitin is a heat shock protein and its mRNA levels are elevated by a number of stress conditions. We have, therefore, studied the effect of cellular stress induced by inhibition of superoxide dismutase (SOD) or heat shock, on ubiquitin conjugates in differentiated PC12 cells. Elevated free radical levels were induced by inclusion of the SOD inhibitor diethyldithiocarbamic acid (DDTC) in the culture medium, at concentrations varying from 10^{-3} to 10^{-5} M. Ubiquitin conjugates were detected by immunodevelopment of Western blots using an anti-ubiquitin monoclonal antibody. Within 1 h the level of high molecular weight conjugates ($Mr > 60$ kD) is elevated at all inhibitor concentrations relative to control. At 10^{-5} M DDTC, these levels remain elevated for at least 4 h but return to control levels by 24 h. Little loss of cell viability, measured by dye exclusion, was observed. In contrast, at 10^{-3} M DDTC the conjugate levels are still elevated at 24 h, at which time there is marked loss of viability. A concomitant decrease in the level of a putative ubiquitin-histone conjugate was observed. Induction of sublethal stress by heat shock of PC12 cells for 3 h at 43°C, also caused a rapid marked elevation in the level of high molecular weight conjugates for up to 24 h, relative to control cells. These results show that ubiquitin-conjugation is a regulated process and can alter rapidly in response to conditions which induce stress in neurone-like cells.

THE ROLE OF HIPPOCAMPAL Cu, Zn-SUPEROXIDE DISMUTASE (SOD-1) IN KAINIC ACID-INDUCED NEURONAL DEGENERATION. H. C. Kim[1]*, S. J. Kim[2], G. Bing and J. S. Hong. [1]College of Pharmacy, Kangwon National University, Chuncheon, 200-701, KOREA, [2]Lab. of Chemoprevention, NCI/NIH, Bethesda, MD 20892 and LEN, NIEHS/NIH, Research Triangle Rark, NC 27709, USA.

We examined the immunocytochemical distribution of cytosolic Cu, Zn-superoxide dismutase (SOD-1), the expression of SOD-1 mRNA and the activities of SOD-1, glutathione peroxidase (GSHPx) and catalase (Cat) in the rat hippocampus after systemic injection of kainic acid (KA). Intense immunoreactivity of SOD-1 was seen in the pyramidal cell layer 3·5 days after injection of KA, while weak immunoreactivity for SOD-1 was observed in the pyramidal cell layer in control rats. The increased immunoreactivities and mRNA levels for SOD-1 were consistent with the enhanced enzyme activities of SOD-1 following KA. However, the increased activity of SOD-1 after KA treatment was not accompanied by adaptive rises in the activities of GSHPx and Cat. High levels of SOD-1, and low levels of GSHPx and Cat, may increased the intracellular accumulation of H_2O_2. This increased H_2O_2 might faciliate the lipid peroxidation of hippocampal neurons. An altered balance in the antioxidant enzyme systems following KA could mediate the neurodegenerative process.

NITRIC OXIDE SYNTHASE-CONTAINING CELLS IN THE RAT HIPPOCAMPUS ARE RESISTANT TO TRIMETHYLTIN. H. Kanai*, M. Ikeda, M. Akaike, S. Tsutsumi, Y. Takahashi, M. Sadamatsu, A. Masui, and N. Kato, Dept. of Psychiatry, Shiga Univ. of Med. Sci., Otsu 520-21, Dept. of Physiol. Chem., Tokyo M & D Univ. Graduate School, Tokyo 113, and Drug Develop. Res. Labs., Hoechst Japan Ltd., Kawagoe 350-11, Japan.

Nitric oxide (NO) is implicated both in the physiology and the pathology in the hippocampus. We studied change in NO activity in the hippocampus of rats treated with trimethyltin hydroxide (TMT; 9mg/kg, p. o.), by means of morphological NADPH-diaphorase staining and biochemical enzymatic determination of NO-synthase. TMT was known to induce selective loss of CA3/4 pyramidal cells in the hippocampus.

The rats were sacrificed 5 and 16 days after TMT treatment . TMT exposure caused the typical behavioral changes of TMT intoxication such as hyperactivity, aggression, and tail-mutilation, as well as the hippocampal damage as reported previously. The interneurons scattered in the hilus and CA3/4 were found strongly positive in NADPH-diaphorase staining. The CA1 pyramidal cells, which were reported to contain endothelial NO synthase, also had weak positive staining. Both positive cells were not affected by TMT treatment. NO synthase activity was measured by the conversion of [3H] arginine to [3H] citrulline. [3H] citrulline was separated from [3H] arginine by high-performance liquid chromatography and counted by liquid scintillation. There was no significant change in NO synthase activity in the hippocampus between control and TMT-treated rats. Despite these behavioral and morphological changes, NADPH diaphorase staining remained unchanged, which was further substantiated by no change in NO synthase activity. These results suggest the resistance of NO synthase-containing neurons to TMT.

EXPRESSION OF NOS ISOFORMS IN THE DEVELOPING AND DEGENERATED RAT BRAIN: MORPHOLOGICAL; RT-PCR; WESTERN BLOT AND MICRODIALYSIS STUDY

G. Keilhoff, B. Seidel, H. Noack, J. Calka, R. Bökelmann, W. Schmidt*, G. Wolf
Inst. Med. Neurobiology, Univ. Magdeburg, D-39120 Magdeburg, Germany

Nitric oxide synthase (NOS) in the brain is present in different isoforms, which possess a histochemically detectable NADPH-diaphorase (NADPH-d) activity. To test when these isoforms first appear during ontogenesis, mRNA and protein levels of brain (b), endothelial (e) and inducible (i) NOS in tissue samples from pre- and postnatal rat brains were determined and compared with the ontogenetic pattern of NADPH-d activity obtained by histochemistry. Starting with the embryonic day (ED) 10 the mRNA-levels of all isoforms showed no or only minor changes until adult state in all brain regions except i-NOS, which temporally declined by 17th ED. In contrast to the permanent expression of the specific RNAs, but in line with the ontogenetic pattern of the NADPH-d at the light microscope, detectable amounts of b- and i-NOS in the Western blots appeared first at ED 15 and increased considerably until adult state. Endothelial-NOS protein, however, was expressed during all developmental stages and increased moderatly until adult state. Ultrastructurally, NADPH-d labeling was seen in the brain pallium of 13-day-old embryos. The reaction product was deposited on membranes of the nuclear envelope. Cells of ED 10 were, as a rule, free of formazan.

Exposure to quinolinic acid led to a massive loss of neuronal cells in the striatum. Parallel to this depletion a striking proliferation of reactive microglia/macrophages and astroglia was seen. Most of IB_4 positive macrophages showed NADPH-d reaction product deposited on membranes, whereas the population of highly phagocytotic cells displayed cytosolic staining, which seems to be the inducible isoforms. Parallel microdialysis studies showed a significant increase in citrulline 7 days after intoxication by which the induction effect on NOS production is further substantiated.

NEURO-ONCOLOGY: TUMOR BIOLOGY

BROMODEOXYURIDINE UPTAKE IN RG-2 RAT BRAIN TUMORS: LIMITATIONS OF A PROLIFERATION MARKER.

A.C. Itskovich*, H.H. Engelhard, D.R. Groothuis. Northwestern University Institute for Neuroscience, Evanston, IL 60201.

Bromodeoxyuridine (BrDU) is used as a proliferation marker and radiosensitizer in brain and other tumors. We looked at incorporation of ^{14}C-BrDU into a nonextractable tissue fraction in normal and neoplastic tissue. RG-2 gliomas were transplanted into 12 male Fischer-344 rats. Each animal received a 50 μCi bolus of ^{14}C-BrDU in a femoral vein; multiple blood samples were collected in 10, 30, and 60 min experiments. Total ^{14}C activity and BrDU concentration was measured in plasma. The amount of labeled BrDU in 20 μm thick sections was measured with quantitative autoradiography, before and after washing with methanol. We calculated a plasma half-life of BrDU, an apparent blood-to-tissue transport value (K_{1app}), and an incorporation quotient (Q). Plasma half-life was < 10 min. The K_{1app} decreased rapidly in RG-2 tumor, from 15 μl/g/min at 10 min to 5 μl/g/min at 60 min. In cortex, K_{1app} peaked at 30 min at 3 μl/g/min. Q in RG-2 tumor was constant from 10 to 30 min, at 3 μl/g/min, and peaked at 30 min in cortex at 3 μl/g/min. BrDU is rapidly metabolized ; its availability is limited by capillary permeability. In rapidly proliferating tissue with low permeability, BrDU uptake is likely to underestimate the true rate of proliferation.

837.2

EXPRESSION OF DIAZEPAM BINDING INHIBITOR AND MITOCHONDRIAL BENZODIAZEPINE RECEPTOR IN HUMAN ASTROCYTOMAS: RELATIONSHIP TO CELL PROLIFERATION.

H. Miettinen, J. Kononen, H. Haapasalo, P. Hélen* and H. Alho. Laboratory of Neurobiology, University of Tampere, Finland.

A polypeptide capable of displacing benzodiazepine binding from both central- and peripheral-type receptors has been purified from the brain and liver of different species and has been designated as diazepam binding inhibitor (DBI). The expression of diazepam binding inhibitor and mitochondrial benzodiazepine receptor (MBR) were studied in human astrocytic tumors using immunocytochemistry and *in situ* hybridization. Both MBR and DBI were prominently expressed in neoplastic cells, whereas low or undetectable levels were present in normal brain. Immunocytochemical double-staining demonstrated that MBR and DBI were present in the same cells, suggesting that DBI may act in an autocrine manner in these cells. Analysis of 86 cases showed that MBR expression was statistically significantly associated with tumor malignancy grade (p=0.004) and proliferative index as determined by MIB-1 immunocytochemistry (p=0.004). Patients having tumors with high number of MBR immunoreactive cells had shorter life expectancy than patients whose tumors showed lower MBR expression (p=0.024). These results suggest that MBR might be useful in evaluating malignancy in brain tumors.

837.3

VASOACTIVE INTESTINAL PEPTIDE IMMUNOREACTIVITY AND mRNA ARE PRESENT IN A HUMAN ASTROCYTOMA CELL LINE.

J. Y. Wu*, G. W. Glazner and R. A. Alvero, Lab. Dev. Neurobiol., NICHD, NIH, Bethesda, MD, 20892,

Vasoactive intestinal peptide (VIP) is a potent neuroendocrine mediator with a wide range of biological activities. In addition to its role as a neurotransmitter, VIP is a potent survival factor for cultured cortical neurons, and has been shown to stimulate mitosis in primary astrocytes and cultured mouse embryos. VIP immunoreactivity is present in many human tumors, and VIP receptors have been found in colonic adenocarcinomas, breast cancers, melanomas, neuroblastomas, and pancreatic carcinomas. In the CNS, VIP is present in neurons, but has not been found in primary astrocytes. Given the vigorous growth factor effects of VIP, and the prevalence of VIP in other tumor cells, we investigated the presence of VIP in a human astrocytoma cell lines. The grade IV human astrocytoma cell line U373 was grown in minimal essential medium with 10% fetal bovine serum. Conditioned medium was obtained by incubating for 6 hours in serum-free media. Total RNA was extracted from cell pellets, and reverse transcription- polymerase chain reaction (PCR) was performed using primers highly specific for VIP mRNA. PCR products were obtained from these samples within 30 cycles. The identitiy of PCR products was verified using nested primers. In addition, VIP peptide immunoreactivity in both U373 cell pellets and conditioned media was investigated using radioimmunoassay. VIP immunoreactivity in cell pellets was detected and correlated with density, increasing from 162.5 pg/flask with 30-40% confluence, to a mean of 812.7 pg/flask with 100% confluence. In the media, VIP immunoreactivity was also found at a level of 15 pg/ml regardless of confluence. These data indicate that a human astrocytoma cell line has both mRNA and immunoreactivity for VIP.

REVERSE-TRANSCRIPTASE POLYMERASE CHAIN REACTION (RT-PCR) ANALYSIS OF SOMATOSTATIN RECEPTOR (SST) EXPRESSION IN NEUROBLASTOMA.

A.R. Albers, M.S. O'Dorisio, and A.J. Yates*, Dept. of Pediatrics, The Ohio State Univ. College of Med., Columbus, OH 43205.

Somatostatin receptor (SST) expression indicates good prognosis in neuroblastoma†. Five SST genes (SST1-5) have been cloned. This study investigated the expression of SST1-5, somatostatin peptide (SMS), and a control gene (c-abl) in neuroblastoma. RT-PCR was used to analyze SST1-5, SMS, and c-abl gene expression in total RNA isolated from 13 neuroblastoma tumor samples, 3 neuroblastoma cell lines, and 3 control tissues: pituitary, brain, and adrenal. The tissues were provided by the Cooperative Human Tissue Network at Children's Hospital and The Ohio State University Hospitals. Tissues were kept at -80°C with or without cryoprotectant. RNA was demonstrated to be free of genomic DNA (gDNA) using primers for the c-abl gene designed to span an intron. The c-abl cDNA product but no gDNA product was demonstrated in 13 neuroblastoma samples, 3 cell lines and 3 control tissues. Eight of 13 neuroblastoma tumors, 3/3 control tissues and 2/3 neuroblastoma cell lines demonstrated SST2 expression. No neuroblastoma tumors or cell lines tested to date have expressed SST1, SST3, SST4, or SST5. Pituitary expressed SST1, SST3, and SST4 but not SST5. Brain expressed SST1, SST4, and SST5. The cDNA product for SMS was demonstrated in 12/13 neuroblastoma samples and in none of the cell line samples. The current study suggests that RT-PCR SST expression analysis of total RNA extracted from small tissue samples, eg. tumor biopsies, provides a powerful assay to use 1) in determining prognosis in cancer and 2) as a basis for choosing to use somatostatin analog therapy in cancer.

EFFECT OF INTERFERON AND NERVE GROWTH FACTOR ON GLIOMA GROWTH CORRELATES WITH ALTERATION OF CELL SIZE. M. Wiranowska[1], S.Saporta[2], J.Moore[2], S.Phuphanich[1] and M.F. Nolan[2]*. Departments of Neurology[1] and Anatomy[2], College of Medicine, University of South Florida, Tampa, FL., 33612.

The effects of interferon (IFN), nerve growth factor (NGF) and IFN+NGF on human astrocytoma U-373, human melanoma A-375 and mouse glioma G-26 cell growth, size and differentiation evaluated here. Cells were incubated for 3 days with NGF at 0.1-10 µg/ml, 5-5x10^4 IU/ml of human recombinant IFNα-2b or 8x10-8x10^4 IU/ml of mouse IFNα/ß, or with a combination of NGF and IFN. Cell growth was evaluated by incorporation of 3-H thymidine and cell cycle by analysis with flow cytometry. Morphology and cell size were evaluated microscopically and with a Coulter Multisizer. It was found that homologous IFNs inhibited growth of all evaluated cells in a dose-dependent manner, while NGF inhibited only glioma cells showing synergy with IFN. Following NGF/IFN treatment, the number of smaller glioma cells increased while the number of large cells decreased. Unique "spider-like" cells with long processes were seen microscopically following NGF/IFN treatment. Cell differentiation was evaluated by expression of glial fibrillary acidic protein (GFAP) by Western immunoblotting. The GFAP levels of NGF/IFN treated mouse glioma G-26 cells increased, compared to the controls, which have a low initial expression of GFAP. Human U-373, which expresses high initial GFAP, demonstrated no detectable change in GFAP levels. It is postulated that the synergistic inhibitory activity of NGF/IFN on glioma proliferation correlates with the increased number of small glioma cells, which may be an indication of glioma cell differentiation into a non-proliferative phenotype.

ALTERATIONS IN CYCLIN B1 EXPRESSION AND CELL CYCLE KINETICS IN HUMAN GLIOMA AND MEDULLOBLASTOMA FOLLOWING RADIATION AND CHEMOTHERAPY. AJ Janss*, A Maity, GD Kao, RJ Muschel, WG McKenna, PC Phillips. Div. of Neurology, Children's Hospital of Philadelphia and Depts. of Radiation Oncology and Pathology and Laboratory Medicine, Univ. of Pennsylvania Medical Center. Philadelphia , PA.

Cell cycle check points mediate responses to DNA-injury in proliferating cells. Cyclin B1 has been implicated in the regulation of cellular commitment to mitosis (G2/M transition) in eukaryotic cells yet little is know about its role in treatment-induced G2 delay in brain tumors. Gliomas are common, treatment-resistant brain tumors in adults, while medulloblastomas are common, relatively treatment-sensitive brain tumors in children. To study cyclin B1 in these brain tumors we treated synchronized U251 glioma cells and DAOY medulloblastoma cells during S phase with 6Gy radiation (RT) or 100nM camptothecin (CPT; 1 hr exposure). Cell cycle kinetics were evaluated using flow cytometry, cytotoxicity using clonogenic assays, nuclear integrity and membrane integrity, and expression of cyclin B1 mRNA and protein using northern and western blot analysis, respectively. Glioma cells exposed to RT or CPT were delayed in G2 and had decreased cyclin B1 protein and mRNA. Medulloblastoma cells exposed to CPT also exhibited G2 delay and decreased cyclin B1 mRNA. In contrast, irradiated medulloblastoma cells had little G2 delay and a less marked decrease in cyclin B1 mRNA. CPT produced nuclear fragmentation and loss of membrane integrity in medulloblastoma cells within 48 hr or treatment, while RT did not. We conclude that cyclin B1 is involved in production of treatment-induced G2 delay in both human glioma and medulloblastoma cells. We speculate that lack of cyclin B1 protein alterations and G2 delay in medulloblastoma cells after RT may be one mechanism explaining the relative sensitivity of medulloblastomas to RT. Check points in cell cycle progression may represent important targets for anti-tumor therapy as they may modulate cellular sensitivity to DNA-damaging agents.

mdm2 GENE INDUCES THE EXPRESSION OF mdr1GENE AND P-GLYCOPROTEIN IN A HUMAN GLIOBLASTOMA CELL LINE S. Kondo*[1], G. H. Barnett[1], T. Morimura[2] and J. Takeuchi[2]. [1]Department of Neurosurgery/S80, Brain Tumor Center/Cancer Center, The Cleveland Clinic Foundation, 9500 Euclid Avenue, Clevaland, OH 44195, U.S.A.; [2]Department of Neurosurgery, National Utano Hospital, Ukyo-ku, Kyoto 616, Japan.

The overexpression of multidrug resistance (mdr1) gene and its product, P-glycoprotein (Pgp), is thought to limit the successful chemotherapy of human tumors. Recent studies demonstrate that mutations of the tumor-suppressor gene p53 may enhance the expression of mdr1 gene and Pgp. However, as there are some human tumors that overexpress both mdr1 gene and Pgp but reveal no mutations of p53, the mechanism by which mdr1 gene and Pgp are overexpressed in human tumors is not yet clear. In this report, we show that mdm2 (murine double minute 2) gene induces the expression of mdr1 gene and Pgp in human glioblastoma U87-MG cells expressing neither MDM2 nor Pgp. Furthermore, mdm2 confers the resistance of U87-MG cells to apoptotic cell death induced by etoposide (VP-16) and adriamycin. These findings suggest the possibility that mdm2 may play an important role in the development of MDR phenotype in human tumors.

NEUROBEHAVIORAL TESTING AS A PREDICTOR OF TUMOR VOLUME WITHIN THE RODENT CAUDATE NUCLEUS. P.D. Sawin, R.M. Roach, V.C. Traynelis*. The University of Iowa College of Medicine, Iowa City, IA 52242

Introduction: Brain injury resulting from intracranial tumor growth is dynamic and progressive. The purpose of this study was to correlate neurobehavioral findings with tumor volume in a rodent model of intracranial glioma.

Methods: 24 adult male Fischer 344 rats were assigned randomly to one of four groups. In Groups 1-3, a 36B10 glioma (5000 cells/inoculum) was implanted into the dominant caudate nucleus of each animal. Group 4 animals served as sham-operated controls. Animals in Groups 1, 2, and 3 were sacrificed at 8, 12, and 16 days post-implantation, respectively. Tumor size was quantified by computerized volumetric analysis. All animals underwent a battery of neurobehavioral tests preoperatively and immediately prior to sacrifice.

Results: All implanted animals developed viable tumors. Mean tumor volume increased over time (1.67±0.80 mm^3 @ 8 days, 3.54±1.98 mm^3 @ 12 days, 9.98±4.29 mm^3 @ 16 days). No significant difference in Bederson motor performance was noted between groups. Dual simultaneous stimulation (tape test) revealed greater contact and removal asymmetry with greater tumor size. Parallel bar testing demonstrated deterioration in performance with increasing tumor size ($p=0.005$). Native rotational behavior was reduced in tumor-bearing animals ($p<0.001$). Apomorphine enhanced turning behavior in these animals ($p=0.001$), and increased the magnitude of contralateral rotation bias ($p=0.02$). Sham animals did not demonstrate increased rotation with apomorphine.

Conclusions: Neurobehavioral changes induced by an enlarging lesion within the rodent caudate are subtle. Increasing tumor volume is associated with progressive tape test asymmetry, decline in parallel bar performance, and altered rotational activity. These neurobehavioral findings facilitate estimation of tumor volume *in vivo*, enhancing the utility of rodent brain tumor models.

NEURO-ONCOLOGY: TREATMENT

GENE THERAPY FOR BRAIN TUMORS BY AUTOLOGOUS VACCINATION WITH ENGINEERED GM-CSF SECRETING TUMOR CELLS. J.S. Yu, J.A. Burwick, G. Dranoff, E.A. Chiocca* and X.O. Breakefield Neurosurgery Service and Molecular Neurogenetics Unit, Massachusetts General Hospital, Charlestown, MA 02129 and Dana-Farber Cancer Insitute, Boston, MA 02125

We have developed an ex vivo gene therapy paradigm for the treatment of brain tumors using granulocyte-macrophage colony-stimulating factor (GM-CSF). The murine B16 melanoma and the GL 261 glioma lines were infected with MFG recombinant retrovirus containing the mouse GM-CSF cDNA. The tumor lines were confirmed to secrete GM-CSF by ELISA. Subcutaneous vaccination of syngeneic mice with irradiated GM-CSF-secreting B16 melanoma cells completely protected animals from subsequent intracranial B16 tumor inoculation. Histologic evaluation revealed the presence of neutrophils, eosinophils and lymphocytes in the intracerebral inoculation site. In contrast, animals vaccinated with irradiated B16 cells or not vaccinated succumbed to intracranial tumor within 3 weeks after inoculation. Treatment of established intracranial B16 melanoma tumors with subcutaneous injection of irradiated GM-CSF secreting B16 cells increased median survival as compared to injection of irradiated B16 cells or no treatment. In addition, treatment of intracerebral glioma with subcutaneous vaccination with irradiated, GM-CSF-secreting autologous cells also increased survival compared to controls. Histologic examination revealed a dramatic perivascular lymphocytic infiltrate beginning 3 days after treatment with GM-CSF transduced cells which was not found in controls.

EXTENDED TRANSFER OF HSV-TK GENE INTO DISSEMINATED 9L BRAIN TUMORS BY INTRAARTERIAL AND INTRAVENTRICULAR DELIVERY OF A HERPES VECTOR. C.M. Kramm, N.G. Rainov, M. Chase, M. Sena-Esteves, E.A. Chiocca, X.O. Breakefield*. Molecular Neurogenetics Unit, Massachusetts General Hospital, Boston, MA.

The aim of the present study was to improve delivery of therapeutic herpes simplex virus type 1 thymidine kinase (HSV-TK) gene into disseminated brain tumor masses by intraarterial and intraventricular injection of vectors. The herpes vector hrR3 was used because highest gene transfer efficiency was achieved after intratumoral application in our laboratory with this vector, as compared to retrovirus or adenovirus vectors. hrR3 bears the HSV-TK and the E. coli *lacZ* reporter gene and has a deletion in the ribonucleotide reductase gene, which allows selective virus replication in dividing cells. Two different models of disseminated 9L brain tumors were established 5-7 days before intraarterial or intraventricular injections of hrR3. For intraarterial application bradykinin was injected prior to the vector to disrupt selectively the blood-tumor-barrier. Transfer efficiency of the HSV-TK and *lacZ* genes was investigated in multiple tumor foci throughout both hemispheres. Intraventricular delivery of hrR3 was achieved via stereotactical injections into the cisterna magna, and distribution of the HSV-TK and *lacZ* genes was evaluated in a model with a right frontal lobe tumor and extensive leptomeningeal tumor spread throughout the CSF pathways. HSV-TK and *lacZ* gene delivery was assessed in tumor masses and in normal brain at different time points by immunohistochemical and histochemical detection of the gene products. With intraarterial application of hrR3 following selective disruption of the blood-tumor barrier by bradykinin, transfer of the HSV-TK and *lacZ* genes was found almost exclusively in the periphery of all disseminated tumor foci. Normal brain was not affected, and no toxicity was observed. Intraventricular delivery of the vector resulted in expression of the HSV-TK and *lacZ* genes in the intracerebral and the leptomeningeal tumor masses. Some toxicity was observed with intensive leptomeningeal inflammation and temporary infection of periventricular areas of the brain. Intratumoral HSV-TK and *lacZ* expression was strongest within the first 2 days after intraarterial or intrathecal herpes injection, but was still detectable up to at least 16 days after virus application, consistent with vector replication in the tumors. Both application strategies provide a marked extension of TK gene transfer efficiency, as compared to intratumoral delivery. [Study supported by NINDS grant NS24279. CMK is a fellow of the Deutsche Krebshilfe. NGR is a Wilhelm-Toennis-scholar.]

838.3

REPLICATION OF HERPES SIMPLEX VIRUS-1 GAMMA 34.5 DELETION MUTANT IN MURINE BRAIN TUMORS.

S. Kesari[1,2*], B. Randazzo[1], S.M. Brown[3], A.R. MacLean[3], V.M.-Y. Lee[2], J.Q. Trojanowski[2] and N.W. Fraser[1].
[1]Wistar Institute, [2]Dept. of Pathology, Univ. of Penn., Philadelphia, PA 19104. and [3]MRC Virology Unit, Glasgow, Scotland.

Herpes simplex virus γ- 34.5 deficient viruses are being considered as candidates for use as cancer therapy vectors. Studies have shown that the neurovirulence factor γ-34.5 appears necessary for replication in the central nervous system. Previously we have shown the efficacy of HSV type I (HSV-1) strain 1716, which has a deletion in the γ34.5 neurovirulence gene, to induce selective lysis of human tumor cells in the nude mouse brain. We are expanding these studies to immunocompetent mouse tumor models to determine the effects of a functional immune system on viral therapy. Preliminary immunohistochemical and in situ hybridization studies suggest that tumor lysis does occur in the presence of an inflammatory response. We are currently determining the role of this response in modulating the efficacy in viral therapy.

838.4

IMMUNIZATION AND GANCICLOVIR TREATMENT DELAY THE FORMATION OF HSV-TK EXPRESSING BRAIN TUMORS IN RATS THROUGH IMMUNOLOGIC SUPPRESSION.

U. Blömer, D. Barba, D.A. Petersen[1*], and F.H. Gage[1], Dept. of Neurosurgery UCSD, 200 West Arbor Drive, San Diego, CA 92103-8893. [1]The Salk Institut, 10010 North Torrey Pines Road, La Jolla, CA 92037-1099

Immunity to tumors develops following ganciclovir (GCV) treatment of brain tumors expressing the Herpes Simplex Virus-thymidine kinase (HSV-TK) gene. To study if HSV-TK by itself might contribute to the anti-tumor immunogenicity, the growth of non-immunogenic D74 tumors, wild type (D74-w.t.) and TK-modified D74 (D74-TK) brain tumor cells, were studied in naive rats and rats previously treated and cured of 9L tumors by HSV-TK and GCV treatments. Formation of the D74-TK tumors were significant reduced in both naive and pretreated rats, even though the *in vitro* growth rate of these tumors was similar. Analysis of immune cells infiltrating the tumors revealed a significant increase in the CD4 positive cells in TK-modified tumor cells in the previously treated rats. Furthermore the regression of the D74-TK tumors was greater in the previously treated rats. These findings suggest that even in non immunogenic tumors, the expression of HSV-TK slows the tumor formation, that can be associated with the immune response. This immunity could be exploited by vaccination strategies to increase tumor regression seen with HSV-TK and GCV treatments.

Supported by Deutsche Forschungsgemeinschaft (BL-389 1/1).

838.5

ADENOVIRUS-MEDIATED GENE TRANSFER INTO EXPERIMENTAL RAT GLIOMAS.

A. Kammesheidt *[1], M.R. Graf [2], G. Granger [2], L.P. Villarreal [2], and K. Sumikawa [1]. Dept. of Psychobiology [1], Dept. of Molecular Biology and Biochemistry [2], Univ. of California, Irvine, CA. 92717.

Adenovirus-mediated transfer of cytokine genes is a novel technique which may have therapeutic value in the treatment of central nervous sytem neoplasms. It has not been established however, that viral recombinants can transduce different brain tumors with similar efficiency. Also, we wanted to investigate whether direct viral-mediated transfer of cytokines into a pre-established tumor could elicit signs of tumor rejection due to increased activation of the host's immune system. In order to address these issues, we transduced five different rat glioma cell lines with two different adenoviral recombinants, one carrying the βgal reporter gene (AdCMVβgal), and the other containing the cDNA for human interleukin-2 (AdCMVIL2). Even at a multiplicity of infection of 1000 we observed a strong difference of infectability between the different glioma cell lines as indicated by X-gal histochemistry and by the level of Il-2 released into the culture media. This variance was consistent for both adenoviral recombinants. The degree of infection efficiency of the gliomas from highest to lowest was D74 > F98 > C6 > 9L > T9. X-gal histochemistry revealed that approximately 95% of D74 cells were transduced as compared to approximately 1% of T9 cells. In addition, we are testing for the ability of AdCMVβgal to transduce *in situ* gliomas. Adenoviral-mediated cytokine transfer into established gliomas will be discussed.

838.6

A NOVEL GENE THERAPY APPROACH TO PITUITARY ADENOMAS.

A. Freese*, M. During, M. Kaplitt, B. Davidson, K. O'Malley, E. Flamm, T. Gennarelli, and P. Snyder. Div. Neurosurg. Univ. Pa. Phila., PA 19104; Div. Neurosurg. Yale Univ., New Haven, CT 06520; Dept. Med. Univ. Iowa, Iowa City, IA 52242; Dept. Neurosurg., Hahnemann Univ., Phila., PA 19146

Although dopamine (DA) receptor agonists play a role in managing prolactinomas, there are significant side-effects. We are developing a gene therapy approach to prolactinomas which would eliminate the need for such drugs and which has applications to other adenomas. We have constructed viral vectors containing genes encoding DA biosynthetic enzymes, including tyrosine hydroxylase (TH) and amino acid decarboxylase (AADC). By introducing such vectors into a prolactinoma, DA levels might increase locally, inhibit prolactin secretion and shrink the tumor.

Using an Adenovirus vector with a TH gene (AdCMVth), transfection of human prolactinoma cultures resulted in transgene expression, as monitored by immunocytochemistry. Increases in dopamine release were observed in cultures treated with AdCMVth, compared to controls. Significant and sustained reductions of secreted prolactin were also observed in AdCMVth treated cultures, compared to controls.. Similar results were obtained using an Adeno-associated virus vector which contains transgenes encoding both human TH and AADC.

Viral vectors might be used for gene therapy in other pituitary adenomas by introducing transgenes encoding proteins which modulate hormone secretion and tumor growth patterns. Unlike strategies based on introducing cytotoxic genes into tumors, our approach doesn't require that virtually all tumor cells are transfected to achieve these effects.

838.7

INHIBITION OF GLIOMA GROWTH IN RATS TREATED WITH INTERLEUKIN 2 GENE-MODIFIED ENDOTHELIAL CELLS.

M.J. Nam*, P. Johnston, R. Indurti, and J. Laterra Dept. of Neurology and The Kennedy Krieger Institute, Johns Hopkins Sch. of Med., Baltimore, MD 21205

Interleukin-2 (IL-2) is known to be secreted by T helper cells and to stimulate cytotoxic T cells and natural killer cells, affecting antitumor responses. The antitumor effects of IL-2 were examined in rats implanted with 9L glioma cells. As a delivery vehicle of IL-2, rat brain endothelial cells immortalized with adenovirus E1A gene and modified to express the *lac Z* (RBEZ) were used. RBEZ cells have been shown to survive for greater than 1 month after implanting to brain tumors. RBEZ-IL2 cells were obtained by transfection with pBCMG-hygro-IL2, a BPV expression vector containing murine IL-2 cDNA under the transcription control of a cytomegalovirus promoter. 9L cells ($1X10^5$) with either RBEZ-hygro (control) or RBEZ-IL2 cells ($2X10^6$) were injected subcutaneously into flanks of rats and tumor volumes sequentially measured. RBEZ-IL2 treatment inhibited tumor growth (at 27 days, 13635 ± 2883 vs 170 ± 144 mm^3, n=10, p=0.001). 9L gliomas were also injected stereotactically into left cerebral hemispheres concurrent with either RBEZ-hygro or RBEZ-IL2 cells. After 14 days, rats were sacrificed and cross-section areas and tumor volumes were determined. Endothelial-based IL-2 delivery prevented intracranial glioma formation as estimated by cross-section area (35 ± 3 vs 6 ± 5 mm^2, n=3, p=0.006) and tumor volume (214 ± 32 vs 26 ± 25 mm^3, n=3, p=0.005). RT-PCR for IL-2 was performed to document IL-2 gene expression in vivo. IL-2 specific PCR products were detected at 5 days post-implantation in hemispheres receiving RBEZ-IL2 cells but not in contralateral hemispheres. These findings establish that genetically modified endothelial cells can be stably engrafted to growing gliomas and effectively deliver antitumor agents.

ANTIPROLIFERATIVE EFFECT OF C-MYC ANTISENSE PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDES IN RAT GLIAL TUMOR CELLS.

Z.J.Chen, W.C.Broaddus*, S.Prabhu, W.G.Loudon. Division of Neurosurgery, Medical College of Virginia, Richmond, VA 23298

Antisense oligodeoxynucleotides (ODNs) offer the potential to block the expression of specific genes within cells. c-myc is an immediate early response gene induced by various mitogens, suggesting that its protein product may play a role in numerous signal transduction pathways, including those modulating cell division. Rat-specific phosphorothioate 15-mer ODNs were synthesized by the Nucleic Acids Synthesis and Analysis Laboratory of the Massey Cancer Center. The antisense c-myc sequence used was as follows: 5'-CACGTTGAGGGGCAT-3'. Three concentrations of ODNs (1uM, 3uM, 10uM) were added to the media of cultures of RT-2 cells (a rat glioblastoma cell line), and cell growth was assessed by MTT assay one to four days after adding the ODNs. Compared to cultures containing standard media, antisense oligodeoxynucleotide was found to significantly inhibit the growth of glioma cells, while sense and scrambled sequence ODNs did not significantly affect cell growth at the concentrations tested. Western blot analysis showed that expression of immunoreactive c-myc protein was also reduced in the antisense ODN-treated cells (and not in sense-, scrambled- or control-treated cells). Flow cytometry and immunocytochemistry studies are ongoing. These results suggest that c-myc plays a critical role in glioma cell proliferation, and support a potential role for antisense strategies designed to inhibit c-myc expression in the treatment of malignant gliomas in clinical settings.

Suppression of Human U87 Glioblastoma Tumor Growth in the Flank of Nude Mice with Antisense Oligonucleotides to the *c-myb* Oncogene. W. C. Low*, C. You, E. P. Flores, L. Chiang, J. A. Conrad, X. Q. Liu, D.Y.K. Wen, and W. A. Hall. *Departments of Neurosurgery and Physiology, and Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455*

c-myb is a proto-oncogene which encodes a nuclear protein involved in the regulation of the cell cycle. This oncogene is typically over expressed in various types of cancer. Previous studies in our laboratories demonstrated that antisense oligonucleotides to the *c-myb* oncogene can suppress the proliferation of human medulloblastoma and glioblastoma cells grown *in vitro*. In the present study, we have examined the effects of antisense administration *in vivo* using nude mice as tumor transplant recipients. Human glioblastoma of the U87 cell line were injected into the flank of nude mice (5×10^6 cells). Ten days after the injection of the tumor cells, animals received injections of either *c-myb* antisense or nonsense (100 μM), or Hank's balanced salt solution (HBSS) in 50 μl volumes directly into the tumor. Antisense oligos were designed for codons 182-188 of the *c-myb* oncogene. Antisense injections were given at days 10, 12, 14, and 16 after the transplantation of the tumor cells. Tumor volume (mm^3) was measured daily for each animal over a period of 17 days. Animals given injections of HBSS exhibited tumors at day 17 which significantly increased in size to 217% ($p < 0.05$) of the volume prior to HBSS administration. Animals given nonsense oligonucleotides also exhibited tumors which significantly increased in size by 210% ($p < 0.05$). In contrast, animals receiving *c-myb* antisense exhibited no significant increase in tumor size with tumors only 128% of their pre-antisense treatment size. These results suggest that the administration of antisense to codons 182-188 of the *c-myb* oncogene can suppress U87 tumor growth *in vivo*, and may thus be an effective form of therapy in treating human brain tumors. *(Supported by a grant from the American Cancer Society).*

LAZAROIDS INHIBIT PROLIFERATION OF CULTURED HUMAN BRAIN TUMOR CELL LINES. P. Arora, Y.S. Lee, T.C. Origitano and R.D. Wurster*. Neuroscience Program, Depts. of Physiology and Neurological Surgery, Loyola Medical Center, Maywood IL 60153.

Lazaroids (or 21-aminosteroids) are potent lipid peroxidation inhibitors having antioxidant properties (i.e. scavengers of reactive active species, ROS) similar to glucocorticoids and vitamin E. ROS, at low levels, are shown to activate signal transduction pathways (Ca^{2+}, PKC and arachidonic acid) and induce expressions of certain proto-oncogenes (c-fos, c-jun, c-myc) that are involved in cell proliferation. In this study cultured human brain astrocytoma (U-373 MG) and neuroblastoma (SK-N-MC) cell lines were used to determine if two representative lazaroid compounds (U-74389G and U-83836E) could affect tumor cell proliferation. Alpha-tocopherol (or vitamin E, a potent antioxidant) and steroids (methylprednisolone and dexamethasone) were also tested under similar experimental conditions. Cell viability was assessed by counting viable cells in a hemocytometer using the trypan blue exclusion method. Results obtained show that both lazaroids effectively inhibit proliferation of U-373 MG and SK-N-MC in a dose-dependent manner. The steroids and alpha-tocopherol were also antiproliferative but at higher doses. In addition to their antioxidant effects, the antiproliferative effects of lazaroids may also be attributed to their ability to chelate iron and decrease membrane fluidity. In summary, lazaroids have significant growth-inhibitory properties that may have potential clinical use in the treatment of certain brain tumors, especially where ROS are known to be involved in tumor promotion. They would be clinically advantageous as their actions are devoid of the usual side effects of steroid therapy and are more potent than alpha-tocopherol.

838.11

INHIBITION OF GLIOMA GROWTH WITH PROTEIN TYROSINE KINASE INHIBITOR: METHYL 2,5-DIHYDROXYCINNAMATE. S Yazdani, CG Caday*, X Alvarez and A Nanda. Division of Neurosurgery, Department of Surgery and Biomedical Research Institute, Louisiana State University Medical Center, Shreveport, LA 71130.

Many protein tyrosine kinases (including growth factor receptors and oncogenes) are overexpressed in human gliomas. Thus, selective inhibition of specific protein tyrosine kinases (PTK) is a potential therapeutic approach to inhibit glioma proliferation. Erbstatin selectively inhibits epidermal growth factor receptor (EGFR) tyrosine kinase activity, but it is unstable. Repeated treatment with methyl 2,5-dihydroxycinnamate (MDHC), a more stable member of the erbstatin family of PTK inhibitors, inhibited glioma growth in culture with an IC_{50} of 2-3 μM. More than 90% of cell growth was inhibited following repeated treatment with 5 μM MDHC. In contrast, glioma cultures that were treated once with MDHC (at concentrations as high as 20 μM) were able to overcome the MDHC inhibition and regrow. The IC_{50} of MDHC showed that it was a more potent inhibitor than the structurally homologous tyrphostins which inhibited gliomas with an IC_{50} of 20-40 μM [Miyaji *et al.* 1994 J Neurosurg 81: 411-419]. MDHC-treated glioma cells did not appear to die by necrosis. MDHC-treated cells showed retraction of glial processes, cell shrinkage and enhanced DAPI staining. The potential use of members of the erbstatin family for glioma therapy requires development of more stable analogues with more specific tyrosine kinase activity.

Induction of programmed cell death by 1,25-dihydroxyvitamin D3 in C6.9 rat glioma: A role for 1,25-(OH)2D3 in the control of brain tissular homeostasis? D. Wion, C. Baudet, P. Naveilhan, G. Chevalier, P. Brachet* INSERM U 298, CHU Angers, F-49033 Angers, France.

1,25-dihydroxyvitamin D3 (1,25-(OH)2D3) is a seco-steroid hormone which exerts its principal biological activities through specific nuclear receptors (VDR). Accumulating evidence, including the presence of VDR in several brain areas, the synthesis of 1,25-(OH)2D3 by activated microglial cells and the regulation of neurotrophins expression by 1,25(OH)2D3 in astrocytes, suggests that the brain is a target for this hormone.

We have previously reported that 1,25-dihydroxyvitamin D3 exerts a toxic effect in rat C6 and human GHD glioma cell lines (Naveilhan et al. J. Neurosci. Res. (1994), 37, 271). In view of the well known heterogeneity of C6 cells, a C6 subclone called C6.9, isolated by the method of limiting dilution, was used to investigate the underlying mechanisms by which 1,25-(OH)2D3 acts on glioma cells. When C6.9 cells cultured in a serum-free medium were treated during 24 hours with 10^{-7}M 1,25-(OH)2D3, cell death occured 5-7 days later. An increased expression of c-myc, gadd 45, and p53 genes is observed at day 3. Apopototic DNA fragmentaion is also observed on day 6. However, nuclear fragmentation, which is the morphological criteria for apoptosis, was not observed. Taken together these data suggest that 1,25-(OH)2D3 induces a programmed cell death in C6.9 cells which shares the biochemical but not the morphological features of apoptosis. They also offer new therapeutic perspectives in the treatment of gliomas. Furthermore, they raise the possibility that the synthesis of 1,25-(OH)2D3 by activated microglial cells could limit the appearance of brain tumors and then add another clue on the possible roles of 1,25-(OH)2D3 in the nervous system.

OLIGOSACCHARIDE INHIBITION OF GLIOMA GROWTH M. Nieto-Sampedro, C. Bailón, A. Fernández-Mayoralas, M. Martín-Lomas, B. Mellström, and J.R. Naranjo*, Cajal Institute and Institute for Organic Chemistry, CSIC, Madrid, Spain.

α–D-GalNAc-(1→3)-β-D-Gal-(1→4)-[α–L-Fuc-(1→3)]-β-D-GlcMe (TS4; Me, methyl), a synthetic analogue of an antimitotic present in brain[1], was cytostatic for cultured primary rat astrocytes and rat C6 glioma cells at μM concentrations[2], but showed no cytotoxicity at concentrations 100-fold above the ID50. The growth of tumors formed after C6 transplantation in brain was, as expected, inhibited by continuous infusion of TS4 (10 μg/hour). In addition, treated tumors appeared necrotic, suggesting that TS4 may have activated cell-mediated destruction mechanisms. Natural killer (NK) cell activation, requires binding of an oligosaccharide ligand to the receptor lectin NKR-P1; these ligands have a structure[3] very similar to TS4. On the other hand, TS4-induced conexin 43 overexpression, could enhance C6 immunogenicity and cause cytotoxic lymphocyte activation. TS4 and sialyl-Lewis are closely related to blood groups and selectin ligands. Their antimitotic properties[2] suggests a role for blood group carbohydrates and may account for contact inhibition of cell proliferation. This work introduces a new class of antimitotics and potential antimetastatics. Supported by grants SAF 0212-92 from the CICYT, Spain, and by Boehringer Ingelheim España, S.A..

BRAIN GLIOMA TREATMENT BY MONOCLONAL ANTIBODIES TO HUMAN CHORIONIC GONADOTROPIN. M.L. Leavitt*, E.A. Acevedo, H.F. Acevedo, A. Krichevsky, R. Gorewit, and J.C. Maroon. Allegheny-Singer Research Inst., Medical College of Pennsylvania and Hahnemann Univ., Pittsburgh, PA 15212 and InVitro Technologies, Inc., Pittsburgh, PA 15238.

We have demonstrated expression of membrane-associated human chorionic gonadotropin (hCG) by cultured human cancer cells of the nervous system and the rat C-6 glioma cell line. Monoclonal antibodies (MAbs) reacting with some hCG epitopes have shown cytolytic effects on human cancer cells. This study investigated whether intratumoral (IT) infusion of a MAb to hCGβ (CTP-103) would prolong survival of brain glioma-bearing rats. One million C-6 cells were infused via a chronic plastic guide cannula directed towards the striatum. The presence of intracerebral tumor was confirmed by magnetic resonance imaging (MRI) before submitting rats to infusion of either CTP-103 (12 μg/day) or PBS vehicle. Intratumoral infusion (0.5 μl/hr) was performed by means of a subcutaneous (sc) osmotic minipump connected to a 23g needle inserted through the guide cannula. A mean (± SEM) post C-6 cell implantation survival time of 23.6 ± 1.4 days with a range of 17-29 days was observed in a group of 8 non-treated C-6 cell-implanted rats. Rats infused with PBS IT or with CTP-103 sc died in 24 days. In contrast, 3 out of 4 IT CTP-103 treated rats are currently alive at 42, 88, and 91 days. Post-treatment MRI revealed the absence of tumor and the presence of necrosis and edema. Histological examination of an IT CTP-103 infused rat euthanized 78 days following tumor cell implantation confirmed the absence of tumor which had been observed by MRI prior to the start of treatment. These preliminary findings suggest that therapy for brain gliomas based on hCG MAbs may be effective. CONCENTRATION DEPENDENT EFFECTS OF NEOSTIGMINE ON d-AMPHETAMINE INDUCED INCREASES IN STRIATAL ACETYLCHOLINE RELEASE. E. Acquas* and H. C. Fibiger. Division of Neurological Sciences, Dept. of Psychiatry, University of British Columbia, Vancouver, B. C., V6T 1Z3 Canada.

There is considerable evidence based on *in vivo* brain microdialysis that systemically administred d-amphetamine increases acetylcholine (ACh) release in the striatum. This increase is mediated by dopamine D_1 receptors, since it can be blocked by the D_1 receptor antagonists SCH 23390 and SCH 39166. In contrast, when d-amphetamine is applied directly to the striatum it decreases ACh release by its dopamine mediated actions on striatal D_2 receptors. Here, we report that the effects of d-amphetamine (2 and 10 mg/kg) on striatal ACh release are strongly influenced by the concentration of a cholinesterase inhibitor (neostigmine bromide) in the perfusion fluid. In the presence of neostigmine 10^{-7} M, d-amphetamine (2 mg/kg) significantly stimulated striatal ACh release (max increase 54% above baseline), while at 10^{-8} M this dose of d-amphetamine did not significantly change striatal ACh output (max 16% above baseline). Administration of a higher dose of d-amphetamine (10 mg/kg) significantly increased striatal ACh output in the presence of neostigmine 10^{-7} M (max 68% above baseline), while it decreased striatal ACh release (max 27% below the baseline) in the presence of 10^{-8} M neostigmine. In contrast to the neostigmine concentration dependent effects of d-amphetamine, enhanced ACh release produced by the full D_1 agonist A-77636 (4 μmol/kg) was not influenced by the level of cholinesterase inhibition. These findings indicate that the effects of d-amphetamine on striatal ACh release depend critically on the concentration of neostigmine in the perfusion fluid and demonstrate that microdialysis conditions can critically influence dopamine-mediated effects on striatal ACh release.

IN VIVO AND IN VITRO ACTIONS OF LINOPIRDINE AND NOVEL NEUROTRANSMITTER RELEASE ENHANCING AGENTS L.O. Wilkinson,*T. Smith, A. Ramirez, P. Seymour, S. McCarthy, L. Chambers, K. Ward, S. DeMattos, D. Liston, J. Lazzaro, A. Ganong, J. Lee, T. Schaeffer, D. Johnson, B. Volkmann, A. Villalobos, S.D. Heck, D.M. Nason, M.H. Lee, K. Coffman, G.M. Bright, J. Jasys, and W. F. White. Pfizer Central Research, Eastern Point Road, Groton, CT 06360

Linopirdine (DuP-996) is the first example of a novel class of compounds which increase the stimulated release of neurotransmitters in brain slices. Its ability to influence acetylcholine suggests utility in the treatment of Alzheimer's disease. We report here on the in vivo and in vitro activity of a number of succinimide and alcohol based compounds which, like DuP-996, modulate stimulated neurotransmitter release. As previously demonstrated, DuP-996 increased K+ stimulated release of acetylcholine from the striatum, displaying an inverted-U-shaped dose-response curve. In our succinimide and alcohol based series, a U-shaped dose-response curve was also observed. Structural modifications influenced maximal efficacy, but not potency. A comparison of the ability of these compounds to influence ACh release in the striatum and hippocampus revealed smaller effects in hippocampus than striatum, but the rank order of efficacy correlated in the two brain regions. To evaluate in vivo activity, ACh release from hippocampus was measured using the dialysis technique. Activity in this model correlated with in vitro efficacy and CSF drug concentration. These neurotransmitter release enhancers also produced a constellation of symptoms akin to those seen after treatments which increase cholinergic neurotransmission (fasiculations, salivation, tremors and seizures), and potentiated the ability of a pentylenetetrazol challenge to induce seizures in mice. The effects in all three of these in vivo models occurred in the same dose range; the rank order of potency of 7 compounds was the same in all three models. The close correlation between the effects of these compounds on ACh release in vivo and their ability to induce undesirable side-effects suggests that they occur through a similar mechanism.

839.3

IN VIVO MODULATION OF RAT CORTICAL ACETYLCHOLINE RELEASE BY NMDA RECEPTORS. M.G. Giovannini, L. Giovannelli, P. Blandina* and G. Pepeu. Dipartimento di Farmacologia, Università di Firenze, Firenze, Italy.

The transversal microdialysis technique was used to investigate the modulation of cortical cholinergic neurons by glutamatergic inputs in the rat *in vivo*. Male albino Wistar rats (250-300 g) were used. Under chloral hydrate anesthesia a transversal microdialysis membrane was positioned in the parietal cortex. Drugs were administered either through the dialysis membrane or i.c.v. The competitive NMDA antagonist CPP (5 nmol/5 µl saline) administered i.c.v. to rats elicited a long lasting increase in cortical ACh output by100%. This effect was not abolished by administration of NMDA (200 µM) to the cortex through the membrane. In some experiments a second membrane was inserted either in the medial septum or in the nucleus basalis magnocellularis (NBM). CPP (100 µM), locally administered to NBM, decreased cortical ACh release. CPP (100 µM) administered to the septum increased cortical ACh release by 82%, this effect being abolished by concomitant administration of 50 µM muscimol, while bicuculline alone (50 µM) increased cortical ACh release by 190%. These data indicate that cortical ACh release is indirectly modulated by a glutamatergic input. Retrograde tracing using Fluoro-Gold administered to the cortex *via* the dialysis membrane showed the presence of numerous labelled neurons in the nucleus basalis, an area known to project to the cortex, as well as sparse fluorescent cell bodies in the medial septal nuclei. Double labelling of the sections with an anti-ChAT antibody showed that the highly fluorescent neurons present in the medial septal nuclei and projecting to the cortex are not cholinergic. Further experiments using an anti-parvalbumin antibody will be performed to verify the nature, possibly GABAergic, of these neurons which might be responsible for the indirect modulation of cortical ACh release by glutamatergic inputs.

This project was supported by a Grant from MURST.

IS BUTYRYLCHOLINESTERASE PRESENT IN PRIMITIVE CHORDATES? L. Pezzementi*, R. Jotani, B. Mathews, D. Milner and W. Soong. Div. of Science and Mathematics, Birmingham-Southern College, Birmingham, Alabama, 35254.

Previously, we reported that a single cholinesterase (ChE), with properties intermediate to acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE), was present in the cephalochordate amphioxus in globular and asymmetric forms. Sequence analysis of a PCR-generated 1kb genomic fragment was consistent with this identity (*Soc. Neurosci. Abstr.* 19, p. 917, 1993). Now, we find that two ChE activities can be distinguished kinetically by the irreversible inhibitor Iso-OMPA. A rapidly-inactivated fraction comprises 70% of the esterase in total high ionic strength detergent-containing extracts and resembles AChE, hydrolyzing acetylthiocholine almost exclusively. The residual slowly-inactivated enzyme resembles atypical BuChE found in cartilaginous and bony fishes, hydrolyzing butyrylthiocholine at 30% of the rate of acetylthiocholine. Most diagnostic ChE inhibitors do not distinguish the two esterases. The two activities are solubilized in different proportions by sequential extraction in low ionic strength (80% AChE/20% BuChE), low ionic strength detergent-containing (40%/60%), and high ionic strength detergent-containing buffers (70%/30%). We are determining the molecular forms of the enzymes. We have also used PCR with degenerate oligonucleotide primers to obtain a 1.5 kb ChE-like genomic sequence from amphioxus, which we are currently sequencing. In the agnathan vertebrate *Myxine glutinosa* we have found that globular and asymmetric forms of AChE are present in skeletal muscle, but that liver contains atypical BuChE; we have not yet characterized its molecular forms. Of the diagnostic inhibitors tested, only ±ambuterol distinguishes the two activities. In contrast, we have found only globular forms of AChE in the urochordate *Styela plicata*. These data require a reevaluation of the evolution of chordate AChE and BuChE. Supported by an NSF RUI grant to L.P.

REGULATION OF THE CHOLINERGIC GENE LOCUS BY RETINOIC ACID RECEPTOR ALPHA, cAMP, AND CNTF/LIF SIGNALING PATHWAYS IN A MURINE SEPTAL CELL LINE.
B. Berse[1], S.L. Wertheim[2]* and J.K. Blusztajn[1], [1]Boston University School of Medicine, Boston, MA 02118, and [2]University of Massachusetts Medical School, Worcester, MA 01655.

The genes encoding two proteins critical for the cholinergic phenotype: choline acetyltransferase (ChAT) and the vesicular acetylcholine transporter (VAChT) are closely linked - with the VAChT coding sequence contained within the first intron of the ChAT gene. By means of differential promoter use and alternative RNA splicing, the two genes generate two distinct classes of mRNA. This unusual genomic organization suggests that transcription of these two genes is co-ordinately regulated. Using Northern analysis and molecular probes specific for ChAT and VAChT, we have been studying the modulation of their expression in a murine septal cell line, SN56, by three groups of agents: retinoids, growth factors of the CNTF/LIF family, and cAMP. Messenger RNA levels of both ChAT- and VAChT were increased up to 3.5-fold by treatment with 9-cis- or all-trans-retinoic acid (RA, 1 µM, 48 h). This effect was mimicked by an RA receptor alpha (RARα) agonist (Ro 40-6055) and prevented by a specific antagonist (Ro 41-5253), indicating that it was mediated by RARα. ChAT- and VAChT-specific transcripts were also induced (up to 3-fold) by treatment with CNTF or LIF (20 ng/ml, 48 h), as well as by increasing intracellular [cAMP] (e.g. with 10 µM forskolin, which activates adenylate cyclase, or with 1 mM dibutyryl cAMP for 48 h). cAMP had a greater effect on the level of VAChT mRNA (4-fold induction) than on the level of ChAT mRNA (2-fold induction), suggesting a quantitatively differential transcriptional regulation of the two genes by the cAMP pathway. The effects of the three groups of agents studied were additive, pointing to several independent mechanisms by which the cholinergic properties of septal neurons can be modulated. REGULATION OF CHOLINERGIC FUNCTION IN *CAENORHABDITIS ELEGANS*. D. Frisby, J. Duerr*, J. McManus, and J. Rand, Program in Molecular and Cell Biology, Oklahoma Medical Research Foundation, Oklahoma City, OK 73104.

The *cha-1* and *unc-17* genes in *Caenorhabditis elegans* encode choline acetyltransferase and a vesicular acetylcholine transporter respectively. These genes were shown in our laboratory to comprise a eukaryotic "operon"; the *unc-17* gene is completely nested within the first intron of *cha-1*, and their cognate mRNAs are produced by alternative splicing of a common transcription unit. Analysis of the upstream region of *cha-1/unc-17* suggests the existence of a regulatory element (located within a 747 bp region approximately 2.4 kb upstream of exon-1) that is required for proper expression in most, but not all of the body cholinergic neurons (i.e., posterior to the pharynx). Expression of both genes in cholinergic neurons anterior to the nerve ring, however, does not appear to be altered in the absence of this putative "body control region." The upstream position of this region is consistent with the location of three independently isolated regulatory mutations which result in a phenotype similar to a deletion of the "body control region."

ELECTRICAL STIMULATION OF THE DORSAL RAPHE NUCLEUS INCREASES ACETYLCHOLINE RELEASE IN RAT FRONTAL CORTEX: AN *IN VIVO* MICRODIALYSIS STUDY.

H. Hirano* and H.C. Fibiger. Division of Neurological Sciences, Department of Psychiatry, The University of British Columbia, Vancouver, B.C., Canada V6T 1Z3

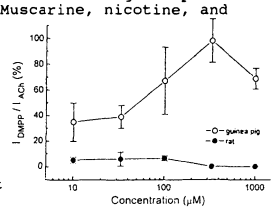
The effects of electrical stimulation (ES: frequency=60 Hz, stimulation duration=0.2 sec, interstimulus interval=2.1 sec) of the dorsal raphe nucleus (DRN) on cortically-projecting cholinergic neurons were studied using *in vivo* microdialysis to measure extracellular acetylcholine (ACh) in the frontal cortex of freely moving rats.

ES of the DRN for 20 min significantly increased cortical ACh concentrations in a current-dependent manner. Thus, ES at both 25 μA and at 50 μA significantly increased extracellular ACh levels, while ES at 12.5 μA failed to do so. Pretreatment with ketanserin, a 5-HT_{2A} receptor antagonist, failed to block ES (25 μA)-induced increases in cortical ACh release. Similarly, pretreatment with the selective dopamine D_1 antagonist SCH 23390 also failed to block the ES (25 μA)-induced increases in cortical ACh release. These results indicate that ES of DRN enhances cortical cholinergic function. However, neither 5-HT_{2A} nor D_1 receptors appear to be involved in this phenomenon.

839.8

PHARMACOLOGICAL DIFFERENCES IN THE CHOLINERGIC RECEPTOR ON OUTER HAIR CELLS OF RAT AND GUINEA PIG. C.Chen*, C. LeBlanc and R.P.Bobbin. Dept. of Otolaryngology, LSUMC, New Orleans, LA 70112.

The cholinergic receptor on outer hair cells (OHCs) in guinea pig has an unusual nicotinic-like receptor pharmacology (Erostegui et al., Hear. Res. 74: 135, 1994). The pharmacology of the acetylcholine (ACh) receptor cloned from rat cochlea (α_9 subunit) approximates but does not match the pharmacology obtained for the ACh receptor in guinea pig OHCs (Elgoyhen et al., Cell, 79: 705, 1994). The purpose of the present study was to compare cholinergic receptor agonist-induced responses in OHCs from rat to OHCs from guinea pig using the whole-cell variant of the patch-clamp technique. ACh caused the largest outward current in both groups of the cells recorded at 0 mV when stepped from a holding potential of -60 mV. Carbachol- and suberyldicholine-induced responses in cells from guinea pig were similar to those from rat. However, 1,1-dimethyl-4-phenylpiperazinium (DMPP) produced very little response in rat OHCs and a large response in guinea pig OHCs (see Fig.). Muscarine, nicotine, and cytisine induced very little response in guinea pig OHCs and none in rat OHCs. The pharmacology of the ACh receptor on OHCs of rat is similar to that obtained with the α_9 subunit in Xenopus oocytes, but different from the ACh receptor on OHCs of guinea pig.



Supported by an NIH grant R01-DC00722.

THE EFFECT OF AF64A ON CHOLINE ACETYLTRANSFERASE (ChAT) GENE EXPRESSION IN THE SEPTO-HIPPOCAMPAL PATHWAY IN VIVO.

Q. Fan, L.R. Santiago and I. Hanin*Dept. of Pharmacology, Loyola Univ. Chicago, Stritch School of Medicine, Maywood, Il 60153.

AF64A, a selective cholinergic neurotoxin, has been used to produce an animal model of cholinergic hypofunction (El Tamer et al., Neuropharmacology 31:397-402, 1992). We have, therefore, further focused our studies on the effect of AF64A on ChAT in the septo-hippocampal cholinergic pathway. Following a single administration of AF64A (i.c.v., bilaterally, 1 nmol/lateral ventricle), there was a transient increase in ChAT activity in the septum. This increase peaked (+164%, $p<.01$) at day 7, and was back to control levels at day 14. Concurrently, there was a long-lasting ($\geq$ 28 days) decrease (-40%, $p<.01$) in ChAT activity in the hippocampus. To determine if this change in ChAT activity was due to an effect of AF64A on gene expression of the cholinergic neuron, we quantified ChAT mRNA levels using the reverse-transcription polymerase-chain reaction approach. Histone mRNA was used as an internal standard. In septum, a significant increase (+165%, $p<.05$) in ChAT mRNA levels was observed as early as 1-2 days after the administration of AF64A, followed by a significant decrease (-54%, $p<.05$) at day 7. This reduction in septal ChAT mRNA levels was still observed at day 28. These combined data suggest that the long term effect of AF64A on the septo-hippocampal cholinergic pathway may, at least in part, be due to an action of AF64A on gene expression in the cholinergic neuron.

CHOLINESTERASE INHIBITORS INTERACTION WITH CORTICAL NEUROTRANSMITTERS. G. Cuadra and E. Giacobini*. Dept. Pharmacology, Southern Illinois Univ. Sch. Med., P.O. Box 19230, Springfield, IL 62794-9230 USA.

In previous investigations, we have demonstrated that cholinesterase inhibitors (ChEI) such as physostigmine (PHY) and heptylphysostigmine (HEP) elicit a significant and simultaneous increase in acetylcholine (ACh) and norepinephrine (NE) levels in rat cortex. This effect is enhanced by idazoxan (IDA), a selective α_2-antagonist. These data suggest that a combination of cholinergic and adrenergic drug may improve the pharmacological effect of ChEI on cortical neurotransmitters (NT) such as ACh-NE. In order to obtain additional information on cortical NT interaction, we evaluated, in the cerebral cortex of the rat, the effect of PHY and HEP in animals pretreated with clonidine (CLO), a selective α_2-agonist, on ACh, NE, dopamine (DA) and 5-hydroxytryptamine (5-HT, serotonin) extracellular levels. We detected no effect of systemic or intracortical CLO administration on ACh levels, but NE, DA and 5-HT levels were all decreased. Clonidine co-administration reduced the effect of PHY on ACh levels, on the contrary, HEP administered to animals pre-treated with CLO produced a stronger effect than HEP alone. A possible explanation for this difference is the variation in duration of the two drugs on ACh elevation and receptor desensitization. In conclusion, our data suggest that co-administration of a selective α_2-agonist such as CLO with ChEI does not represent a favorable pharmacological and therapeutical alternative. Considering our previous results with IDA (Cuadra and Giacobini, 1995), we suggest that combination of an α_2-antagonist with HEP may represent a more favorable alternative in order to improve the clinical efficacy of ChEIs in AD treatment.

CAFFEINE ENHANCES ACETYLCHOLINE RELEASE *IN VIVO* BY SELECTIVE ANTAGONISM OF ADENOSINE A_1 RECEPTORS. A.J. Carter*, W.T. O'Connor, M.J. Carter and U. Ungerstedt. Dept. of Biological Research, Boehringer Ingelheim KG, D-55126 Ingelheim/Rhein, Germany and Dept. of Physiology and Pharmacology, Karolinska Institute, S-17177 Stockholm, Sweden.

Caffeine is a commonly used drug which increases arousal, a condition associated with increased cholinergic activity in the mammalian cerebral cortex including the hippocampus. We have used the technique of microdialysis in association with microbore high-performance liquid chromatography to investigate the effects of caffeine on the extracellular levels of acetylcholine in the hippocampus of awake, freely moving rats. The oral administration of caffeine dose-dependently (3 - 30 mg/kg) increased the extracellular levels of acetylcholine. This increase was completely blocked when the microdialysis probe was perfused with the Na^+-channel blocker TTX, and strongly attenuated when a Ca^{2+}-free Ringer solution was employed. The effect of caffeine on hippocampal acetylcholine release was concentration-dependently counteracted by local perfusion of the A_1 receptor agonist N^6-cyclopentyladenosine (0.1 - 1 µmol/L), but not by the A_2 receptor agonist CGS 21680 (10 µmol/L). Neither agonist affected baseline acetylcholine release at these concentrations. These results demonstrate that acetylcholine release in the hippocampus is under tonic inhibitory control of the endogenous neuromodulator adenosine, and that orally administered caffeine enhances action potential-dependent vesicular acetylcholine release by antagonism of local A_1 receptors. Hence, the data provide a possible link between adenosine A_1 receptors in the hippocampus, increased cholinergic activity and the psychostimulant effects of caffeine.

MODULATION OF RAT CORTICAL ACETYLCHOLINE (ACh) RELEASE *IN VIVO* BY α2 ADRENOCEPTOR AGONISTS AND ANTAGONISTS. S. Tellez, F. Colpaert and M. Marien*, Centre de Recherche Pierre Fabre, Castres 81100, France.

Cortical ACh release in conscious guinea pigs was shown to be reduced by noradrenaline and clonidine (Moroni *et al.*, 1983, JPET 227, 435). The antagonism of this effect by yohimbine (a non-selective α2 adrenoceptor antagonist) suggested a mediation by α2 adrenoceptors. Recently we have shown that (+)-efaroxan, a highly selective α2 antagonist, increases cortical ACh release in the conscious rat, as measured by microdialysis (Eur. J. Pharmacol., in press). To further characterize this response, we have examined the effects of other α2 adrenoceptor ligands in the same model. The α2 antagonists (mg/kg), (+)-efaroxan (0.63), atipamezole (2.5) and idazoxan (2.5), increased cortical ACh outflow by 300, 230 and 220%, respectively, over a 3 h period following injection. In contrast, the α2 adrenoceptor agonist UK14,304 (2.5 mg/kg) decreased ACh outflow by 60%. The cholinesterase inhibitor tacrine had no significant effect on ACh outflow at 2.5 mg/kg i.p., increased outflow by 350-450% at 5 mg/kg, and was lethal at 10 mg/kg in 2 out of 3 rats. These results support the notion that cortical ACh release *in vivo* can be modulated by α2 adrenoceptors. Selective α2 adrenoceptor antagonists such as (+)-efaroxan may have a therapeutic potential in neurological disorders involving deficits in cortical ACh release.

DEPOLARIZATION-INDUCED BREAKDOWN OF CYTOSOLIC ACETYLCHOLINE IN RAT HIPPOCAMPAL NERVE TERMINALS: EFFECT ON ACETYLCHOLINE SYNTHESIS IN THE CYTOSOL. P.T. Carroll,* TTUHSC, Lubbock, Texas 79430.

Rat hippocampal minces were loaded with [acetyl 1-^{14}C] acetylcholine ([^{14}C] ACh) in the presence of echothiophate and the effect of high K^+ and veratridine depolarization determined on the subcellular storage and release of [^{14}C] ACh and its metabolites. Depolarization of tissue for 5 minutes released [^{14}C] acetate and decreased the ratio of [^{14}C] ACh to its metabolites in the cytosol (S_3) without stimulating the release of [^{14}C] ACh. When paraoxon was used instead of echothiophate, depolarization of tissue no longer released [^{14}C] acetate or decreased the ratio of [^{14}C] ACh to its metabolites in the S_3 fraction. Depolarization of tissue still did not release [^{14}C] ACh . However, when tissue was depolarized with veratridine for 10 minutes in the presence of echothiophate, [^{14}C] ACh was released. Also, the ratio of [^{14}C] ACh to [^{14}C] acetate in the S_3 fraction was reduced to the same extent as the ratio of [^{14}C] ACh to [^{14}C] acetyl CoA was increased, effects which were blocked by paraoxon. These results suggest that depolarization of hippocampal nerve terminals accelerates the breakdown of cytosolic ACh and thereby speeds up the "forward" reaction of cytosolic ChAT (BN581179758; NINDS 2R01N521289-10).

KEY WORD INDEX

The *Abstracts* volume 21 Key Word Index is printed on the following pages. This subject index uses a permutation process to create an index entry for every key word in the abstract title. Key words are placed at the beginning of the center column of the index and the program numbers in the right column. Text reading left and right of the key word is retained for understanding in context. A slash (/) shows the end and the beginning of the author's title. Space limitations do not permit the full abstract title to be printed. Words with limited search value are not listed as key words. The BioSciences Information Service Subject Index is used by many scientific organizations and has become the standard in computerized scientific indexes.
