In S-type submucosal neurons, extracellular application of ATP induces a fast and a slow depolarization by activation of cationic channels and inhibition of the membrane potassium conductance, respectively. In this study, we characterized the receptors and intracellular events associated with such ATP effects. In whole-cell recordings, ATP application evoked a rapid inward current which was antagonized by pyridoxalphosphate-6-azophenyl-2',4'-disulphonic acid (PPADS; IC<sub>50</sub>=4  $\mu$ M). Suramin potentiated these currents; whereas, reactive blue 2 was a very weak antagonist (IC<sub>50</sub>=300  $\mu$ M). In intracellular recordings, none of these three antagonists, neither pertussis toxin nor KT5720 (protein kinase (PK) inhibitor), affected the slow depolarization. Whereas, N-ethylmaleimide (uncouples receptors from G-proteins), staurosporine (non-specific PK inhibitor) and calphostin (PKC inhibitor) inhibited this response. In Fura-2/AM Ca<sup>2+</sup> imaging experiments, ATP induced a rapid increase in the intracellular free Ca<sup>2+</sup> concentration, which was completely prevented by PPADS, unaffected by staurosporine, and partially inhibited by blocking the voltage-activated Ca<sup>2+</sup> channels with Cd<sup>2+</sup>. In conclusion, the fast and slow depolarization are mediated by activation of P<sub>2X</sub>- and P<sub>2Y</sub>-purinoceptors, respectively. Activation of P<sub>2X</sub>-purinoceptors leads to an increase in intracellular Ca<sup>2+</sup>. P<sub>2Y</sub>-purinoceptors linked to G-proteins and PKC activation are likely mediating inhibition of the membrane potassium conductance. **INTERACTION BETWEEN ATP-GATED AND VOLTAGE-GATED CALCIUM CHANNELS IN THE PC12 CELL.** J.B. Keath\*, G. Balan, and F.W. Westhead, Program in Neuroscience and Behavior and Dept. of Biochemistry, Univ. of Mass at Amherst, Amherst, MA, 01003-4505.

We have investigated the possible contributions of voltage-operated calcium channels (VOCCs) to PC12 cell secretion in response to ATP stimulation. Although ATP stimulation does depolarize the cell, VOCC blockers, Nifedipine and Cadmium ion, do not inhibit the secretion of PC12 cells at either saturating or half-maximal concentrations. This suggests that the presence or absence of VOCC activity does not influence calcium concentration rise in response to ATP stimulation. Both VOCC blockers do, however, increase the rate at which the PC12 cells desensitize to ATP stimulation. This indicates that, when VOCC blockers are not present, VOCCs are opening to allow calcium into the cell. This presents us with a paradox: VOCCs open during ATP stimulation to let calcium into the cell, but this calcium does not modify the increase in internal calcium concentration that occurs in response to the ATP stimulation. To explain this quandary, we propose that both the ATP-gated calcium channels and the VOCCs are activated during ATP stimulation, but that the calcium entry is self-limiting within domains of the plasma membrane. Support for this model is provided by desensitizing PC12 cells in a solution in which the calcium is replaced with barium, which is known to induce secretion without inhibiting calcium channels. When stimulated with ATP under these circumstances, the PC12 cells desensitize even faster than they would if they were treated with VOCC blockers.

EXAMINATION OF ATP-INDUCED RESPONSES IN PC12 CELLS. INVESTIGATIONS OF P<sub>2X</sub>-RECEPTORS USING MICROPHYSIOMETER AND ELECTROPHYSIOLOGICAL TECHNIQUES

A. Rohlf, P. Salmasso, F. Fery and R. Netzer\*, Department of Electrophysiology, Battelle, CH-1227 Carouge/Geneva, Switzerland.

The response of NGF-treated PC12 cells to extracellular application of ATP was investigated using a microphysiometer and compared to electrophysiological experiments. ATP induced a rapid concentration-dependent rise of extracellular acidification with an EC<sub>50</sub> of 105 ± 9.5 μM. Preincubation with the PLC-inhibitor U-73122 did not affect the response indicating that only P<sub>2X</sub>-receptors are involved. The response was reduced by the P<sub>2</sub>-receptor antagonist suramin. The agonist αβ-methylene-ATP interacting with specific subtypes of P<sub>2X</sub>-receptors induced only marginal responses. During the electrophysiological investigations ATP induced an inward current with an EC<sub>50</sub> of 14.1 ± 1.8 μM. The application of glutamate, NMDA, AMPA and kainate induced in these cells a marginal peak decrease of relative acidification and no current in electrophysiological experiments. It is to conclude that the described microphysiometer assay serves as a non-invasive and functional system to examine effects of compounds on P<sub>2X</sub>-receptors. Support: Battelle-IR&D-fund

## LIGAND-GATED ION CHANNELS: GLUTAMATE, GABA, AND GLYCINE RECEPTORS

## 138.1

SINGLE-CHANNEL PROPERTIES OF GLUTAMATE-GATED CHLORIDE CHANNEL RECEPTOR SUBUNITS. M. Amar<sup>1</sup>, A. Etter<sup>2</sup>, K. Liu<sup>2</sup>, D.J. Beadle<sup>1</sup>, J. Arena<sup>2</sup> and I. Bermudez<sup>1</sup>. School of Biological & Molecular Sciences, Oxford Brookes University, Oxford, U. K. and <sup>2</sup>Merck Research Labs., Rahway, NJ 07065, USA.

Two subunits (GluClα and GluClβ) of a glutamate-gated chloride channel have been cloned from the free living nematode *Caenorhabditis elegans* (Cully *et al.*, Nature 371, 707-710). Homomeric GluClβ channels are sensitive to glutamate, while homomeric GluClα are not. Co-expression of GluClα with GluClβ channels shifts the glutamate dose response curve to the left, and changes the rectification properties of the whole cell currents. To gain a molecular insight into the mechanism underlying these changes we have recorded glutamate-gated channel currents from outside-out patches excised from *Xenopus* oocytes injected with GluClα and GluClβ or GluClβ specific-RNAs. Both GluClα-β and GluClβ channels exhibited a single conductance of 12 ± 0.2 pS and 15 ± 0.3 pS, respectively. GluClαβ channel open time histograms are best fitted with two exponential components, one of which is strongly voltage-dependent. The open time kinetics of the GluClβ channel is dominated by a time constant which is comparable to the voltage-dependent component of the GluClα-β channels. These results suggest that the open time kinetics of the GluClα-β channel are defined predominantly by the β subunit. Supported by the Wellcome Trust, UK.

## 138.2

INHIBITORY GLUTAMATE RECEPTORS IN A MOTOR PATTERN GENERATOR: CHANNEL PROPERTIES AND PHYLOGENETIC ANALYSIS. T.A. Cleland\* and A.I. Selverston. Dept. of Biology 0357, University of California San Diego, La Jolla, CA 92093-0357.

Inhibitory ionotropic glutamate receptors (iGluRs) are a family of ion channel proteins closely related to ionotropic glycine and GABA receptors. They are gated rapidly by glutamate; the open channel is permeable to chloride and/or potassium. They are expressed extrajunctionally on striated muscle fibers and postsynaptically in neurons across many taxa. Generally, iGluR orthologues exhibit consistent pharmacological profiles; however, some pharmacological characters are uniquely derived within discrete clades. For example, while iGluRs within other taxa are insensitive to quisqualic acid, it is a potent agonist of all known iGluRs within the pulmonate molluscs. The iGluR is a target of the insecticidal avermectins, which can modulate, activate, and block receptor gating.

Neuronal iGluRs mediate rhythmic synaptic inhibition within the central pattern generator circuits of the crustacean stomatogastric ganglion (STG). Superfusion of glutamate over voltage-clamped isolated STG neurons gated an outwardly rectifying conductance permeable primarily to chloride and pharmacologically consistent with iGluRs in related taxa. In outside-out excised patches from STG neurons, 10 μM glutamate evoked at least two unitary conductance states, the larger of which (~50 pS) was the more prevalent under experimental conditions. As glutamatergic synaptic inhibition is fundamental to the bursting properties of this oscillatory motor network, any alterations in receptor properties directly affect rhythmogenesis and consequently behavioral output.

## 138.3

THE DESENSITIZATION PROPERTIES OF NON-NMDA GLUR CHANNELS ARE ALTERED BY MEMBRANE EXCISION. M. Marquis, and C.-M. Tang<sup>1</sup> Dept of Neurology, Univ. of Maryland Sch. of Medicine.

Excised patch recordings have provided the bulk of data on the fast kinetic properties of non-NMDA GluR channels. Unfortunately, whether membrane excision alters the gating properties of these channels is not known. We addressed this issue with the use of laser induced rapid photolysis of "caged" glutamate. This approach result in identical kinetics of glutamate/receptor interaction for whole-cell and excised patch recordings. We found that membrane excision consistently and dramatically increases the extent of desensitization ( $I_{ss}/I_p$ ) and modestly increases the time constant of current decay ( $\tau_d$ ). The current decay can be fitted with a single exponential in whole cell recordings but requires two exponentials in patch recordings. Unlike in the case of NMDA GluRs the inclusion of BAPTA and ATPyS in the internal pipette solution did not prevent the changes in desensitization.

17β-ESTRADIOL POTENTIATION OF KAINATE CURRENTS: SITE OF ACTION. Qin Gu\* and Robert L. Moss. Department of Physiology, The University of Texas Southwestern Medical Center, Dallas, Texas, 75235.

Previously we reported that 17β-estradiol (E<sub>2</sub>) potentiates kainate-induced currents in acutely dissociated hippocampal CA1 neurons. This potentiation was not due to direct interaction of E<sub>2</sub> with kainate receptors but rather the activation of a second messenger system. A specific PKA inhibitor blocks the E<sub>2</sub> potentiation (Gu & Moss, 1996).

The present study was designed to investigate whether E<sub>2</sub> acts extracellularly or intracellularly to potentiate the kainate current. Experiments using standard whole-cell voltage-clamp techniques were performed on dissociated hippocampal CA1 neurons from Sprague-Dawley rats. The kainate current was elicited by applying kainate pulses (100 μM, 0.033 Hz at 0.1-1 psi for 20 ms) via a puffer electrode to the dendrite of a CA1 neuron. The effects of E<sub>2</sub>, an impermeable BSA-conjugated E<sub>2</sub> (E<sub>2</sub>-BSA), and GTP-γ-S on kainate-induced currents were tested on either side of the neuronal membrane.

Extracellular application of E<sub>2</sub> (100 nM, 3 min) significantly increased the amplitude of kainate-induced currents within 3 min, whereas extracellularly applied E<sub>2</sub>-BSA had no effect. Similarly intracellular E<sub>2</sub> also potentiated kainate currents within 12 min, but intracellular E<sub>2</sub>-BSA did not. The simultaneous application of E<sub>2</sub>-BSA on both sides of the membrane could restore the estrogenic potentiation within 3 min. Intracellular GDT-β-S suppressed the effect of E<sub>2</sub>. Extracellular E<sub>2</sub>-BSA potentiated the kainate-induced currents in the presence of intracellular GTP-γ-S, although either alone had no effect.

The results indicate that potentiation of kainate currents in rat hippocampus requires the presence of E<sub>2</sub> on both sides of the membrane. We suggest that E<sub>2</sub> acts at an extracellular site to trigger G-protein-coupled modulation, whereas E<sub>2</sub> intracellularly acts to maintain phosphorylation of kainate receptor channels. Supported by NIH grant MH 47418.

## 138.5

**AGMATINE BLOCKS NMDA RECEPTOR CHANNELS IN RAT HIPPOCAMPAL NEURONS.** X.-C. Yang\* and D.J. Reis. Dept. of Neurol. and Neurosci., Cornell Univ. Med. Col., New York, N.Y. 10021.

Agmatine (decarboxylated arginine) is an endogenous polyamine and organic cation with two positive charges at physiological pH. Agmatine is synthesized, stored and released in mammalian CNS and may be a novel neurotransmitter/modulator (Li et al., *Science*, 1994; Regunathan et al., *Soc. Neurosci. Abstr.*, 1996). Because agmatine may be taken up into neurons via some  $\text{Ca}^{2+}$  channels (Sastre et al., *Soc. Neurosci. Abstr.*, 1996), we investigated whether the amine may interact with the  $\text{Ca}^{2+}$ -permeable NMDA receptor channel. Hippocampal neurons were obtained on prenatal day 19 rats and maintained in primary culture. Ion currents through the NMDA channel were recorded using the whole-cell patch clamp technique. The  $\text{Mg}^{2+}$ -free extracellular solution contained (in mM) NaCl 140, KCl 5,  $\text{CaCl}_2$  0.2, HEPES-NaOH 10, pH 7.4, supplemented with 50  $\mu\text{M}$  NMDA and 10  $\mu\text{M}$  glycine. The electrode-filling solution contained (in mM) CsCl 145,  $\text{MgCl}_2$  2, EGTA 5, HEPES-CsOH 10, plus ATP 3, GTP 0.1, and leupeptin 0.1, pH 7.2. When applied extracellularly agmatine, at concentrations as low as 1  $\mu\text{M}$ , reversibly reduced the NMDA current at a holding potential of -60 mV. The half-block concentration of agmatine was about 100  $\mu\text{M}$ , which reduced the NMDA current by 50%. External agmatine blocked preferentially the inward NMDA current with a small blocking effect at positive voltages. As a result the linear I-V curve of the NMDA current became inwardly rectifying in the presence of external agmatine. Agmatine, possibly released presynaptically, may act to modulate ligand-gated cation channels either at the polyamine site and/or in the channel pore. (NHLBI-HL18974)

## 138.7

**Investigation of the Ethanol Site of Action on the NMDA Receptor Using Site Directed Mutagenesis.** Tooraj Mirshahi\* and John J. Woodward. Dept. of Pharmacology and Toxicology, Box 980524 Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298.

Ethanol has been shown to inhibit both native and recombinant NMDA receptors although no specific site of action has been defined. Ethanol's inhibition does not appear to be competitive with any of the known modulatory sites on the NMDA receptor. Due to its hydrophobic nature, ethanol could alter receptor function by interaction with a hydrophobic pocket on the NMDA receptor. Amino acids with large hydrophobic side chains are candidates for formation of such an ethanol binding pocket. There are several Phe (F), Leu (L) and Ile (I) residues in the NMDA receptors which could participate in formation of this pocket. We have begun to investigate this possibility using the oocyte expression system to test the ethanol sensitivity of NMDAR1 receptors with mutations at these hydrophobic sites.

Two mutant NMDAR1 receptors, F554A and F558A were expressed in combination with the NR2A subunit. Application of 100  $\mu\text{M}$  NMDA and 10  $\mu\text{M}$  glycine induced robust currents in oocytes expressing the mutant receptor combinations. NMDA-induced currents in these mutant receptors were significantly inhibited by ethanol. However the extent of ethanol inhibition of the mutant receptors was similar to that observed for wild-type (NR1/NR2A) receptors expressed in oocytes. This approach should provide valuable insights into defining a possible site of action for ethanol on the NMDA receptor. Supported by AA09986 and DA07027.

## 138.9

**BIPHASIC EFFECT OF ETHANOL ON GLYCINE CURRENTS OF CORTICAL AND HYPOTHALAMIC NEURONS.** D. Schiller, J.-H. Ye and J.J. McArdle. Depts Pharmacology & Physiology and Anesthesiology, NJ Medical School (UMDNJ), Newark, NJ 07103.

Glycine-activated current ( $I_{\text{Gly}}$ ) was recorded from freshly isolated murine cortical and hypothalamic neurons with the nystatin perforated patch technique. Approximately 40% of the cortical and 90% of the hypothalamic neurons examined responded to glycine; this current was resistant to the GABA<sub>A</sub> receptor blocking agent picrotoxin. Co-application of ethanol at concentrations of 11, 22, 43, and 65 mM reversibly potentiated peak  $I_{\text{Gly}}$  in 86% and 82% of the cortical and hypothalamic neurons, respectively. In contrast, 130 mM ethanol suppressed peak  $I_{\text{Gly}}$  of both types of neurons. At the lower concentrations ethanol potentiated  $I_{\text{Gly}}$  whether or not this current was sensitive to strychnine. The acute potentiating effect of ethanol was observed when 50, 100, 200, 300 or 400  $\mu\text{M}$  glycine induced  $I_{\text{Gly}}$ . Furthermore, pre-exposure to 65 mM ethanol for 2 min prior to the co-application of glycine and 65 mM ethanol did not alter the potentiating effect. Thus, desensitization or acute tolerance to ethanol does not occur in glycine responsive cortical neurons. Evaluation of voltage ramps revealed that the potentiation of  $I_{\text{Gly}}$  occurred in association with a rightward shift in the current-voltage relation. This suggests that ethanol may alter the conductive properties of the glycine-gated chloride channel. Finally, in 68 of the 94 neurons examined, the facilitatory effect of ethanol was associated with a decrease in the rise time of  $I_{\text{Gly}}$ . This kinetic effect suggests that ethanol may increase open probability of the glycine-gated ion channel.

## 138.6

**SENSITIVITY OF NATIVE AND RECOMBINANT GLUTAMATE RECEPTORS TO ALIPHATIC *n*-ALCOHOL INHIBITION.** B.E. Akinshola\*, R.W. Peoples, R. Stewart and F.F. Weight. Lab. Molecular and Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892-8205.

In order to compare recombinant glutamate (GluR) receptor sensitivity to alcohol with that of neurons, we used two-electrode voltage clamp and whole-cell patch clamp techniques, respectively, to study recombinant receptors expressed in *Xenopus* oocytes, and native receptors in cultured hippocampal neurons. Receptor currents in both oocytes and hippocampal neurons were measured in response to kainate as an agonist. For short-chain aliphatic alcohols from methanol to hexanol, potency for inhibition of native and recombinant receptor currents increased in proportion to chain-length or hydrophobicity, whereas inhibitory activity could not be observed with octanol for GluR1, nonanol for GluR3 (*Soc. Neurosci. Abstr.*, 21:1815,1995), and decanol for neurons. Our studies indicate that the characteristics of *n*-alcohol inhibition of neuronal currents show similarities to the inhibition of recombinant receptor subunits for alcohols from methanol to hexanol. The differences in sensitivity found with higher alcohols may be an indication of differences in the alcohol binding sites on these receptor-channels. In addition, the difference seen with the hippocampal neurons may also reflect the involvement of additional subunits. This work was supported by NIAAA, NIH.

## 138.8

**EFFECTS OF ACUTE AND CHRONIC ETHANOL EXPOSURE ON NMDA RECEPTOR EXPRESSION AND FUNCTION IN TRANSFECTED HEK 293 CELLS.** T.L. Blevins and J.J. Woodward\*. Dept. of Pharmacology/Toxicology, Virginia Commonwealth Univ., Richmond, VA 23298

The N-methyl-D-aspartate (NMDA) subtype of neuronal glutamate receptors is a multi-subunit, calcium-permeable ion channel that helps regulate synaptic activity. Previous studies have demonstrated that both native and recombinant NMDA receptors are inhibited by ethanol at behaviorally relevant concentrations (10-100 mM). In a previous study (*Neurosci. Lett.* 200:214, 1995), we observed that chronic ethanol exposure enhanced the agonist sensitivity of NMDA receptors expressed in cultured neurons. The sensitivity of these receptors to ifenprodil was also enhanced suggesting that changes in the expression of the NR2B subunit may have been involved.

To investigate the possibility that these changes occur at a post-transcriptional level, we have used a transient transfection system and monitored changes in NMDA receptor expression and function following exposure to ethanol. HEK 293 cells transfected with the NR1 subunit alone were not functionally active although significant amounts of NR1 protein were present as measured by immunoblotting and immunofluorescence. Cells transfected with NR1/NR2A, NR1/NR2B, or NR1/NR2A/NR2B subunits showed NMDA and glycine-dependent increases in intracellular calcium as measured by fura-2 imaging. In the double subunit transfected cells, both subunits appeared to be co-localized as revealed by antibody labeling and confocal imaging. This was also observed in cells transfected with an NR2 subunit and a fusion protein consisting of NR1 and the green fluorescent protein (NR1/GFP). Ethanol inhibited NMDA-induced changes in intracellular calcium with equal potency in all combinations. Chronic ethanol exposure of NR1/2A/2B transfected cells enhanced the ifenprodil sensitivity of these cells. These results suggest that some of the effects of chronic ethanol observed in neurons may result from changes in the post-transcriptional and post-translational processing of NMDA receptor subunits. Supported by AA09986.

## 138.10

**ZINC MODULATORY SITES AT THE INHIBITORY GLYCINE RECEPTOR.** B. Laube\*, J. Kuhse and H. Betz. Department of Neurochemistry, Max-Planck-Institute for Brain Research, Deutschordenstraße 46, D-60528 Frankfurt, Germany

Zinc is a divalent cation endogenously present in the synaptic cleft and released in an activity-dependent manner. The biphasic modulatory effect of extracellularly applied zinc on glycine-gated chloride currents in embryonal spinal cord neurons implicates zinc in the regulation of synaptic efficacy within glycinergic pathways (Laube et al., *J. of Physiol.* 483.3: 613-9). Glycine responses of heterologously expressed glycine receptors (GlyRs) are 2-3 fold potentiated in the presence of 0.5-10  $\mu\text{M}$  zinc, whereas >10  $\mu\text{M}$  zinc decreases the glycine response by changing the apparent agonist affinity. Single channel recording revealed that low concentrations of zinc enhance the open probability of the GlyR channel, whereas higher concentrations decrease the latter without affecting single-channel conductances. Taurine, a partial agonist of the GlyR, also showed an increased agonist potency in the presence of zinc, whereas its antagonist activity was not affected by the metal ion. Chimeric GlyR subunit constructs showed that the positive and negative regulatory effects of zinc are mediated by different regions of the GlyR protein, suggesting the existence of at least two distinct zinc binding sites. Site-directed mutagenesis of the human  $\alpha 1$  subunit identified negatively charged residues in the extracellular N-terminal region as essential determinants of high-affinity zinc binding. A model of the modulatory zinc binding sites of the GlyR will be presented.

## 138.11

**DICHLOROKYNURENIC ACID SELECTIVELY SUPPRESSES A SLOW INHIBITORY GLYCINE CURRENT.** Yi Han and Malcolm M. Slaughter\*, Departments of Biophysical Sciences, Physiology, and Ophthalmology. School of Medicine, State University of New York, Buffalo, NY 14214, USA.

The inhibitory glycine receptor (GlyR) is a pentamer of  $\alpha$ (48 KD) and  $\beta$ (58 KD) subunits. It is known that multiple isoforms exist and the distribution of GlyR subunits is inhomogeneous in the retina. This differential expression may indicate a functional diversity. We recently reported that glycine mediated chloride currents observed in retinal ganglion cells can be separated into two components which have different kinetics of activation and desensitization. These two components could be distinguished by strychnine antagonism. The fast component is blocked by strychnine with an  $IC_{50}$  of 34 nM, while the efficacy of this antagonist for the slow component is 2.2  $\mu$ M. The purpose of this study was to investigate the properties that distinguish the slow glycine receptor. Whole-cell voltage clamp techniques and a rapid perfusion system were used to study isolated ganglion cells from the amphibian retina, *Ambystoma tigrinum*. Both components were carried by chloride and had similar affinities for glycine. While the fast component was selectively suppressed by low concentrations of strychnine (<100nM), 5,7-dichlorokynurenic acid (500 $\mu$ M) manifested a selective reduction in the slow glycine current. There was little overlap between the effects of these antagonists. Several glycine analogs ( $\beta$ -alanine, L-alanine, L-serine) activated both components but had different efficacies on each component. The results suggest that there are two inhibitory glycine receptors which have distinct kinetics and pharmacologies. The slow glycine receptor has a pharmacology that is similar to that of the glycine recognition site at the NMDA receptor.

**STRUCTURAL ELEMENTS DETERMINING THE GATING OF GLYCINE RECEPTOR ISOFORMS.** J. Bormann\*, N. Rundström, H. Betz and D. Langosch. Max-Planck-Institut für Hirnforschung, D-60528 Frankfurt, Germany.

The glycine receptor (GlyR) is a ligand-gated ion channel protein that mediates synaptic inhibition in spinal cord and other CNS regions. We have analyzed the kinetic properties of human GlyR isoforms using patch-clamp recording from transfected HEK-293 cells. Elementary currents through  $\alpha 1$  or  $\alpha 2$  homooligomeric GlyRs had a burstlike appearance. Distributions of shut time and burst duration could be fitted with four and three exponential functions, respectively. The average length of long bursts was 32 ms for  $\alpha 1$ -channels, interrupted by 9.4 closing gaps. In contrast,  $\alpha 2$ -channels showed much longer bursts of 392 ms duration, containing only 2.3 closures. To identify the structural elements responsible for the different gating properties, chimera were constructed between  $\alpha 1$  and  $\alpha 2$ . The gating properties of mutant  $\alpha 1$  containing both the extracellular N-terminus and transmembrane domain M2 of  $\alpha 2$  closely resembled that of  $\alpha 2$  GlyRs. This indicates that receptor and channel both contribute to the gating properties of human GlyR isoforms. A kinetic scheme is proposed with five sequential binding steps for glycine and three open states of the channel.

**POSITIVE MODULATION OF GABA-INDUCED CURRENTS BY HISTAMINE AND RELATED COMPOUNDS IN RAT CEREBELLAR PURKINJE CELLS** I.N.Sharonova, V.S.Vorobiev, G.D. Prell and H.L. Haas\* Heinrich-Heine-Universität, Department of Physiology, Universitätsstr. 1, D-40225 Düsseldorf, Germany

We have studied the effects of histamine (HA) and some related compounds on GABA responses of voltage-clamped acutely isolated cerebellar Purkinje cells in whole-cell configuration. Conditioning application (2-10 s) of HA, histidine and the HA metabolites *tele*-methylhistamine (*tele*-MH), *tele*-methylimidazole acetic acid (*tele*-MIAA) and carnosine potentiated the current induced by 2  $\mu$ M GABA 1 s after termination of the conditioning application. This effect was spontaneously reversible; 30 s or less were typically required for 50% recovery. Both the degree of potentiation and the time constant of recovery increased with the duration of conditioning application and the elevation of tested compound concentration. Preapplication of 10  $\mu$ M histidine during 10 s doubled the GABA current, the  $EC_{50}$  was about 2  $\mu$ M. Other HA related compounds potentiated GABA-mediated currents with the following order of potency: carnosine=HA=*tele*-MH<*tele*-MIAA<L-histidine=D-histidine. *Pros*-MH and *pros*-MIAA were without effect. The divalent ion chelators EGTA (0.5 mM), EDTA (0.1 mM), iminodiacetic acid and dithion (10  $\mu$ M) also potentiated GABA responses. The effects of histidine and divalent ion chelators were not additive at high doses. HA and related compounds may thus act as endogenous potentiating modulators of GABA<sub>A</sub> receptor mediated inhibition. The effect may depend on the ability of these compounds to chelate metal ions.

## 138.12

**CONVULSANT SITE PROPERTIES IN GLYCINE RECEPTORS FROM RAT SPINAL CORD AND HIPPOCAMPAL NEURONAL CULTURES.** V.E. Wotring\* and K.-W. Yoon. Dept. of Pharmacological and Physiological Sciences and Division of Neurosurgery and Surgical Research Institute, Saint Louis University Health Sciences Center, St. Louis MO 63104.

Actions of picrotoxinin and butyrolactones were investigated in dissociated cultures from hippocampi of 1 day old or spinal cords from 12-14 embryonic day rats and kept in culture for 8-16 days and 15- 35 days, respectively. Recordings were made in voltage clamp mode using whole-cell and excised outside-out patch clamp techniques. In spinal cord, the glycine  $EC_{50}$  was 32  $\mu$ M, with a Hill slope of 1.7, while in hippocampal cells, the  $EC_{50}$  was 185  $\mu$ M and the Hill slope 2.3. Despite the difference in glycine  $EC_{50}$ , preliminary data show that cells from both hippocampus and spinal cord required similar, and relatively high, concentrations of picrotoxinin to block control glycine-elicited currents (100  $\mu$ M glycine;  $IC_{50}$ s were ~300  $\mu$ M). Unlike what has been previously reported for GABA<sub>A</sub> receptors, the picrotoxinin block of glycine showed no signs of use-dependence or voltage dependence and recoveries were rapid and complete. To further explore the possibility of a convulsant site at the glycine receptor, we used  $\alpha$ IMGBL, a substituted  $\gamma$ -butyrolactone that has been previously shown to block the convulsant site of the GABA<sub>A</sub> receptor and to reverse the picrotoxinin block of the GABA<sub>A</sub> receptor. (Yoon et al., 1993) With a relatively high concentration of  $\alpha$ IMGBL (5mM) we saw no significant effect on control glycine currents in either spinal cord or hippocampal cells (n=6, p> 0.2) or on the picrotoxinin block seen (n=6, p>0.2). We have attempted to further explore the mechanism of the picrotoxinin block of glycine receptors and to determine if the glycine receptor has activities that are similar to those associated with the convulsant site of the GABA<sub>A</sub> receptor. Potential functional roles of such a glycinergic convulsant site will be considered.

## 138.14

**MULTIPLE RESPONSES AND UNDERLYING SUBUNIT COMPOSITION OF GABA AND GLYCINE RECEPTORS IN HIPPOCAMPAL NEURONS** K.Fatima-Shad, K. Pierce, P. H. Barry & P. R. Schofield\*, School of Physiology and Pharmacology, The University of New South Wales, Sydney 2052, Australia and \*Neurobiology Division, The Garvan Institute of Medical Research, Darlinghurst, NSW 2010, Australia.

Whole cell studies of inhibitory synapses between neurons of the early post-natal rat hippocampus in dissociated culture have indicated the presence of IPSPs and IPSCs. The coincident reversal potentials for IPSCs and for GABA and glycine-evoked currents, and the sensitivity of the IPSCs to bicuculline and strychnine, indicated that the IPSCs described here were  $Cl^-$  dependent and mediated by either GABA<sub>A</sub> or glycine receptors. Heterogenous desensitization responses were observed in all cells with GABA- and glycine-gated channels. For GABA and glycine-gated receptor channels the estimated values of the receptor channel density were approximately 2 and 3 /  $\mu m^2$  respectively. This functional heterogeneity of GABA and glycine receptor channels, observed in cultured hippocampal neurons suggested the possible presence of different subunit compositions for the receptor channels. To investigate this possibility, we are coupling patch-clamp recording with Reverse Transcription followed by Polymerase Chain Reaction amplification (RT-PCR) in order to correlate the properties of GABA and glycine-gated whole cell currents with the expression of mRNAs for each subunit in individual neurons. To determine which of the GABA and glycine receptor subunit mRNAs were present, the cellular content of each neuron was aspirated into the recording pipette after the cell had been classified as "fast" or "slow". RT-PCR was performed with primers common to all known GABA and glycine cDNAs. The presence of the different subunits of the receptor in the amplified product was then investigated by restriction analysis with enzymes specific for each subunit fragment and so far has indicated the presence of  $\alpha 1$  and  $\beta 1$  subunits for these glycine receptors. Supported by the NH&MRC of Australia R.T. Hall Trust & Vincent Fairfax Family Foundation.

**MODULATION OF GABA-ACTIVATED CURRENT BY REDOX AGENTS IN CEREBELLAR PURKINJE CELLS MAY BE RELATED TO THEIR CHELATING PROPERTIES.** H.L. Haas, H.J. Luhmann\*, I.N. Sharonova and V.S. Vorobiev Department of Physiology, Heinrich-Heine University, POB 101007, D-40001 Düsseldorf, Germany

We have studied the influence of sulphydryl redox reagents on GABA-gated chloride currents in acutely dissociated Purkinje cells with concentration jump techniques. Pre-exposure to the disulfide-reducing agent, dithiothreitol (DTT, 10  $\mu$ M) during 10 s reversibly doubled the current, induced by 2  $\mu$ M GABA 1 s after DTT withdrawal. The  $EC_{50}$  for DTT potentiation was  $2.0 \pm 2$   $\mu$ M. Reduced and oxidized glutathione (GSH and GSSG) had the same effect on GABA-induced currents. The oxidizing agent 5,5'-dithiobis-2-nitrobenzoic acid (DTNB; 0.1-0.5 mM) and the thiol alkylating agent N-ethylmaleimide (0.1-1mM) had no such effect. Divalent ion chelators like EGTA (0.5 mM), EDTA (0.1 mM) and dithion (10  $\mu$ M) also augmented GABA-mediated responses. The potentiating effects of DTT and divalent ion chelators were not additive at high doses. Our observations suggest that these agents potentiate GABA-gated currents via common mechanisms. Thus, the widely used disulfide-reducing agent, DTT, can act through a mechanism different from breaking disulfide bonds. The data do not exclude a possible interaction of DTT with redox sites on the GABA receptor.

A NOVEL *DROSOPHILA* CHLORIDE CHANNEL GENE SHOWING HIGH HOMOLOGY WITH HUMAN *RHO* GENES. E.P. Semenov and W.L. Pak\*, Department of Biological Sciences, Purdue University, W. Lafayette, IN 47907-1392

Using human *rho1* cDNA as hybridization probe, we have identified a novel gene encoding a GABA receptor-like protein in *D. melanogaster*. The protein sequence contains two cysteine residues (Cys-loop) in its N-terminal extracellular portion that are conserved among chloride channels and conserved transmembrane domains within the C-terminal half. Sequence alignments show that the gene DNA sequence has highest homology with the human GABA *rho1* gene, which is expressed predominantly in the retina, rather than with other known *Drosophila* chloride channel genes. *In situ* hybridization to the fly polytene chromosomes maps the gene to a new site on chromosome 3.

## CALCIUM CHANNELS: PHYSIOLOGY, PHARMACOLOGY, AND MODULATION I

## 139.1

EXTRACELLULAR APPLICATION OF  $\beta$ -NAD<sup>+</sup> OR cADPR AFFECTS DEPOLARIZATION-INDUCED INTRACELLULAR Ca<sup>2+</sup> RISE IN CEREBELLAR GRANULE NEURONS. C.Usai\*, C.Marchetti, L.Moccagatta and A.Barberis. Istituto di Cibernetica e Biofisica, CNR, via De Marini, 6, 16149, Genova, Italy.

Experiments where cADPR was introduced in different cell types, suggested for this cyclic nucleotide the role of putative physiological ligand for the ryanodine-sensitive receptors of endoplasmic reticulum. However CD38, enzyme catalyzing the production of cADPR from  $\beta$ NAD, was localized on the external surface of the cell membrane. We studied the effect of external application of both  $\beta$ NAD and cADPR on [Ca<sup>2+</sup>]<sub>i</sub> levels in Fura2-loaded cerebellar granule cells from 8-day old rats. Neurons were incubated with different doses (10  $\mu$ M-1 mM) of  $\beta$ NAD for ten minutes and then challenged with 25 mM external KCl, after a brief washout. The peak of [Ca<sup>2+</sup>]<sub>i</sub> response was significantly increased in more than 80% of these experiments in a dose-dependent manner (12 $\pm$ 2%-47 $\pm$ 15%). In addition, a small increase in the basal calcium level was observed during 1 mM  $\beta$ NAD treatment, but not with lower doses. The enzymatically inactive form  $\alpha$ NAD failed to cause any increase in the KCl response. In a second group of experiments, cells were treated with 100  $\mu$ M cADPR for 6 minutes, then stimulated by 25 mM external KCl. This treatment did not modify the basal calcium concentration, but the peak of [Ca<sup>2+</sup>]<sub>i</sub> response to KCl induced depolarization was significantly enhanced (44 $\pm$ 18%, n=8). This effect was observed in approximately 50% of the experiments, suggesting some functional heterogeneity of the granule cells. Patch-clamp control experiments showed that  $\beta$ NAD reversibly inhibits the voltage-dependent calcium current, but potentiation of VDCC at later time after treatment was never observed. Therefore, since it has been reported that cADPR does not affect plasmalemmal calcium channel properties, both  $\beta$ NAD- and cADPR-induced increases of [Ca<sup>2+</sup>]<sub>i</sub> following depolarization can be apparently view as a potentiation of calcium-induced calcium release. The nature of the intracellular calcium stores involved in this effect has not yet been characterized.

## 139.3

STABLE TRANSFECTION OF PC12 CELLS WITH CALBINDIN-D<sub>28k</sub> REDUCES STIMULATED [Ca<sup>2+</sup>]<sub>i</sub>, INCREASES. B. S. Wong\*, M. C. Ng, A. M. Iacopino, A. McMahon and D. C. German, Dept. of Biomedical Sci., Baylor College of Dentistry, Dallas, TX 75246 and Dept. of Psychiatry, Univ. of Texas Southwestern Med. Center, Dallas, TX 75235.

The present study sought to determine whether calbindin-D<sub>28k</sub> (CB) reduces intracellular calcium concentrations [Ca<sup>2+</sup>]<sub>i</sub>, in response to drugs that elevate [Ca<sup>2+</sup>]<sub>i</sub>. PC12 cells were stably transfected with CB and four clonal lines, with different expression levels, were selected. A vector control clonal line was also isolated. [Ca<sup>2+</sup>]<sub>i</sub> was measured using the fluorescent dye fluo-3 and confocal microscopy. Bradykinin (0.5  $\mu$ M) induced a rapid, transient ~80% increase in [Ca<sup>2+</sup>]<sub>i</sub>, followed by a 35% sustained increase (to 140 sec.) in control and vector control cells. The CB clonal lines exhibited the same transient increase in [Ca<sup>2+</sup>]<sub>i</sub>; as the control cells, however, all four lines exhibited a 70-85% reduction in the magnitude of the sustained increase. The extent of the reduction, however, was not dependent upon the amount of CB in the cells. ATP (100  $\mu$ M) also caused a marked increase in [Ca<sup>2+</sup>]<sub>i</sub>, which was also significantly reduced (p<0.01) by the presence of CB. The rapid, transient elevation in [Ca<sup>2+</sup>]<sub>i</sub> was decreased 20-40% of control, as was the sustained [Ca<sup>2+</sup>]<sub>i</sub> elevation (decreased 45-64% of control). These data indicate that the presence of CB in PC12 cells reduces stimulated [Ca<sup>2+</sup>]<sub>i</sub> increases. Studies are in progress to identify the specific sources of [Ca<sup>2+</sup>]<sub>i</sub> that are altered by CB. Support by NS30406.

## 139.2

BODIPY<sup>®</sup> FL-X RYANODINE LABELING OF RYANODINE RECEPTOR CHANNELS IN RAT SYMPATHETIC NEURONS. González, C.E.<sup>1</sup>, L. Granados<sup>3</sup>, A. Cárabez<sup>2</sup> and A. Hernández-Cruz<sup>1\*</sup>. <sup>1</sup>Instituto de Fisiología Celular, UNAM, <sup>2</sup>Dept. Biología Celular, Facultad de Medicina UNAM, Ciudad Universitaria, and <sup>3</sup>Inst. Nal. Pediatría, SS, México City, México.

The plant alkaloid ryanodine (Ry) is a specific and potent modulator of ryanodine receptor (RyR) Ca<sup>2+</sup> release channels. The monosubstituted BODIPY FL-X analogue (B-Ry) was used to reveal the spatial distribution of RyRs present in cultured rat sympathetic neurons. Confocal microscopy showed cytoplasmic labeling of non-mitochondrial cisternae-like membranes. The nuclear membrane was also prominently stained. The time course of B-Ry binding was recorded with fluorescence digital microscopy. Labeling of individual neurons with 1  $\mu$ M B-Ry reached steady-state within 15-20 min, and was reversible upon wash-out with a monoexponential time constant of decay of about 10 min. Pre-incubation with non-fluorescent Ry (20  $\mu$ M, 5 min) reduced the rate of rise and peak amplitude of B-Ry binding by 60% and 50% respectively. However, non-fluorescent Ry did not increase significantly the rate of B-Ry unbinding. The basic pharmacology of B-Ry showed marked differences with normal Ry: a) it reduced, but never eliminated caffeine-induced Ca<sup>2+</sup> release in a non-use dependent manner. b) it diminished voltage-gated Ca<sup>2+</sup> influx by reversibly affecting voltage dependence and magnitude of plasmalemmal Ca<sup>2+</sup> currents. These pharmacological differences between B-Ry and normal Ry must be considered in future studies using this compound. Supported by grant 400-346-5-2366PN from CONACyT (México).

## 139.4

ALL-OR-NONE Ca<sup>2+</sup> RELEASE FROM INTRACELLULAR STORES TRIGGERED BY Ca<sup>2+</sup> INFLUX THROUGH VOLTAGE-GATED Ca<sup>2+</sup> CHANNELS IN RAT DRG NEURONS. Y.M.Usachev\* and S.A.Thayer Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455.

Ca<sup>2+</sup>-induced Ca<sup>2+</sup> release from intracellular stores (CICR) serves to amplify the [Ca<sup>2+</sup>]<sub>i</sub> signal that results from depolarization. In contrast to cardiac muscle, the amplification in neurons has previously been shown to occur in a graded manner. Now using combined indo-1-based microfluorimetry and whole-cell patch-clamp recording we show that in large DRG neurons, the stores act as a switch that when triggered by an elevation in [Ca<sup>2+</sup>]<sub>i</sub> above threshold, elicits a regenerative response. The threshold was determined by stimulation with trains of action potentials (APs) of increasing number in the presence of caffeine (2-5 mM). For subthreshold stimulation, the amplitude of the [Ca<sup>2+</sup>]<sub>i</sub> transient rose linearly with the number of APs. Suprathreshold stimulation triggered a process that was no longer proportional to the number of APs. The switch from a subthreshold to a maximal response increased dramatically both, the amplitude of the [Ca<sup>2+</sup>]<sub>i</sub> transient (from 64 $\pm$ 4 nM to 306 $\pm$ 14 nM, n=26) and the time between termination of the stimulus and the peak [Ca<sup>2+</sup>]<sub>i</sub> (from 1.2 $\pm$ 0.1 s to 16.1 $\pm$ 1.8 s, n=26). The maximal response was suppressed by ryanodine (10  $\mu$ M) and inhibitors of voltage-gated Ca<sup>2+</sup> channels (Cd<sup>2+</sup> 200  $\mu$ M and  $\omega$ -conotoxin GVIA 1  $\mu$ M) indicating that it results from CICR. This all-or-none reaction may serve as a gatekeeper that determines whether an electrical signal will be transduced into a local or widespread increase in [Ca<sup>2+</sup>]<sub>i</sub>.

## 139.5

EXTRACELLULAR SYNTHESIS OF CYCLIC ADENOSINE DIPHOSPHORIBOSE (CYCLIC ADP RIBOSE) FROM NAD BY RAT CORTICAL ASTROCYTES IN CULTURE. P.A. Rosenberg\*, L. Pawlikowska, S. E. Cottrell, M. Harms, and Y. Li. Department of Neurology, Children's Hospital & Harvard Medical School, Boston MA 02115

Cyclic ADP ribose (cADPR) is an endogenous calcium-mobilizing agent synthesized from NAD by NADases with ADP-ribosyl cyclase and cADPR hydrolase activity. In the present study, selective culturing techniques were employed in order to localize ADP-ribosyl cyclase activity and cyclic ADPR hydrolase activity to astrocytes or neurons in cultures derived from rat embryonic cerebral cortex. ADP-ribosyl cyclase activity was determined by incubating cultures with 1 mM NAD in the extracellular medium for 60 minutes at 37°C, and measuring formation of cADPR by bioassay using sea urchin microsomes and by HPLC. Astrocyte cultures and mixed cultures of astrocytes and neurons had mean specific activities of  $0.84 \pm 0.06$  and  $0.9 \pm 0.18$  nmol cyclic ADPR produced/mg protein/hr, respectively. No detectable ADP-ribosyl cyclase activity was found in neuron-enriched astrocyte-poor cultures. The extracellular localization of the ADP ribosyl cyclase activity was demonstrated by showing that this activity did not increase when cultures were permeabilized with Triton X-100 or by acetone extraction. Cyclic ADPR hydrolase activity was detectable in astrocyte cultures and in mixed cultures by incubating cultures with 300  $\mu$ M cADPR for 60 minutes at 37°C, and assaying loss of cADPR or accumulation of ADP ribose. The demonstration of extracellular ADP ribosyl cyclase and cADPR hydrolase activities associated with astrocytes may have important implications for the role of extracellular cyclic ADPR in signal transduction and in intercellular communication in the nervous system.

This work was funded by a grant from the NINDS (NS26830).

INTRACELLULAR CALCIUM DYNAMICS IN CNS MYELINATED AXONS. L. Steffensen\* and P.K. Stys, Loeb Medical Research Institute, Ottawa Civic Hospital, University of Ottawa, Canada K1Y 4E9.

As in neurons, irreversible anoxic/ischemic injury in myelinated axons of central white matter has been associated with intracellular Ca overload. Central myelinated axons have been shown to contain high total (free and bound) levels of internal Ca and although the contribution of extracellular Ca to Ca overload has been well documented, the contribution of intracellular Ca has not been well examined. Pharmacological tools were used to examine Ca stores in myelinated axons of rat optic nerve and to determine what role internal Ca plays under physiological and pathophysiological conditions. We used an electrophysiological recording technique with paired stimulation at various interstimulus intervals, which we believe reflects changes in free [Ca]. Application of caffeine (10 mM), an activator of Ca-dependent Ca release stores, caused electrophysiological changes consistent with an increase in free [Ca] in the absence of changes in the area under the compound action potential (CAP). Caffeine (10 mM) plus bepridil (30  $\mu$ M), an inhibitor of the Na-Ca exchanger, irreversibly reduced CAP area to  $69 \pm 17\%$  of control ( $n=7$ ;  $p<0.01$ ), whereas, application of bepridil alone had no effect. Ionomycin (2.5  $\mu$ M), a Ca ionophore, plus bepridil (30  $\mu$ M) caused an irreversible drop in CAP area to  $51\% \pm 11\%$  of control ( $n=8$ ;  $p<0.001$ ). Ryanodine (10 nM), a modulator of the internal Ca release channel, had no effect on resting nerves but increased free [Ca] in nerves stimulated by high frequency trains as judged by our paired stimulation protocol. These results suggest a relationship between electrical activity in axons and internal Ca dynamics, and may point to a physiological link between activity and cellular Ca-dependent metabolism. Under energy deprived conditions, release of Ca from stores may be contributing to Ca overload and irreversible injury. Supported by the Loeb Medical Research Institute.

CIRCADIAN VARIATIONS OF RYANODINE RECEPTOR IN THE SUPRACHIASMATIC NUCLEUS OF THE RAT. Myrna Den\*, Mauricio Diaz-Munoz, José Luis Chávez and Raúl Aguilar-Roblero. SPON: Brain Research Association. \*Facultad de Medicina, U. Autónoma Edo. de México, Toluca, Edo. de México 50180 and Dpto. Neurociencias, Instituto de Fisiología Celular, UNAM, México, D.F. 04510.

The hypothalamic suprachiasmatic nucleus (SCN) contains a circadian pacemaker responsible for most of the biological rhythms shown by mammals. Some reports have postulated that intracellular calcium ( $Ca^{2+}$ ) homeostasis might be playing an important role in the generation or maintaining of the SCN rhythmicity. To support this hypothesis, the properties of the ryanodine receptor (RyR) from the SCN were studied. RyR is a key element in the  $Ca^{2+}$  dynamics acting as a calcium release channel. Specific binding of [ $^3$ H]ryanodine to its receptor was performed in the SCN throughout a cycle of 12 h light/12 h darkness. The results show a significant peak in the [ $^3$ H]ryanodine specific binding to the SCN membranes at 12:00 and 15:00 h. This oscillatory pattern in the [ $^3$ H]ryanodine specific binding was detected exclusively in the SCN and not in other brain areas. IP $_3$  receptor, which is other calcium release channel, did not present any oscillatory pattern. The rhythm in the [ $^3$ H]ryanodine specific binding to SCN was still present during continuous darkness, suggesting its circadian nature. Scatchard analysis showed that the peak of [ $^3$ H]ryanodine specific binding was due to an increase in the number of RyR in the SCN, and not to an enhancement in the RyR affinity for its ligand. Immunohistochemical characterization demonstrated that the RYR present in the SCN is the type II, and that it is present mainly in neuronal cells. In conclusion, we are reporting the existence of a specific rhythm in one of the intracellular calcium release channels in the SCN which could have significant consequences in the  $Ca^{2+}$  homeostasis of this circadian pacemaker.

## 139.6

EFFECTS OF BETA-AMYLOID PROTEIN ON CALCIUM DYNAMICS IN PLATELETS AND C6 GLIOMA CELLS.

H. Ishikawa, H. Ozawa\*, K. Imoto<sup>1</sup>, H. Takemura<sup>1</sup>, T. Saito, H. Ohshika<sup>1</sup>, N. Takahata. Dept. of Neuropsychiatry and Pharmacology<sup>1</sup>, School of Medicine, Sapporo Medical University, Sapporo, Japan.

Recent studies link amyloid beta-protein (A $\beta$ ) to disruption of neuronal  $Ca^{2+}$  dynamics and the neurotoxic action in terms of Alzheimer's disease (AD) pathology. Platelets are one of the major sources of A $\beta$  in the circulation. The present study examined that the effect of A $\beta$  on free cytosolic calcium ( $[Ca^{2+}]_i$ ) in human platelets compared to C6 glioma cells. Using the fluorescent calcium probe fura-2/AM, ( $[Ca^{2+}]_i$ ) levels in platelets and cells were measured during the resting state and when stimulated by A $\beta$ . The addition of A $\beta$  fragments 25-35 (A $\beta$  25-35) gradually increased  $[Ca^{2+}]_i$  and induced aggregation in platelets. After the maximum response,  $[Ca^{2+}]_i$  decreased and then reached a sustained, higher level. The maximum  $Ca^{2+}$  response over resting  $[Ca^{2+}]_i$  after A $\beta$  25-35 stimulation (5 mmol/l) was about 160%. Similar effects were also observed with A $\beta$  1-40, whereas 1-28, 12-28 and 31-35 did not affect the  $Ca^{2+}$  response. In the absence of external  $Ca^{2+}$ , A $\beta$  25-35 caused a transient increase in  $[Ca^{2+}]_i$ , which returned to the resting level. Moreover, A $\beta$  augments the formation of inositol 1,4,5-triphosphate (IP $_3$ ) in platelets, which are similar effects to thrombin. In contrast to platelets, there were no enhancement of cytosolic calcium concentrations by A $\beta$  25-35 (up to 25  $\mu$ M) in C6 glioma cells.

These findings suggest that A $\beta$  directly induced cytosolic calcium enhancement is due to both extracellular influx and the release of intracellular  $Ca^{2+}$  stores involving IP $_3$  signal cascades in platelets not but C6 glioma cells.

## 139.8

CAFFEINE-INDUCED CALCIUM TRANSIENT IN MICE HIPPOCAMPAL NEURONS. T. Shimahara\*, P. Chameau and R. Bournaud. Laboratoire de Neurobiologie Cellulaire et Moléculaire, CNRS 91198 Gif-sur-Yvette, France.

Calcium transient induced by caffeine was studied in the cultured neurons from mice hippocampus. The calcium transient in the cell body was monitored by the fluorescent imaging analysis technique with the calcium indicator Fluo-3. In the 4-days cultured neurons, caffeine (20 mM) induced a calcium transient in 40% of neurons, while 8% of neurons showed a transient signal if caffeine application was preceded by KCl (70 mM) depolarization. The remaining neurons did not show the caffeine-induced calcium transient. In the 8-days cultured cells, the number of neurons which are sensitive to caffeine increased (70% of neurons). In these neurons, the calcium store in the endoplasmic reticulum was depleted by repetitive application of caffeine but the endoplasmic reticulum refilled spontaneously 80% of the initial  $Ca^{2+}$  stock within 4 min. Ryanodine (50  $\mu$ M), thapsigargin (2  $\mu$ M) and dantrolene (10  $\mu$ M) suppressed the caffeine-induced calcium transient. This study showed that at resting conditions the  $Ca^{2+}$  stores are continuously filled by releasable  $Ca^{2+}$ .

Supported by the grant from AFM.

## 139.10

RELEASE AND SEQUESTRATION OF CALCIUM BY RYANODINE-SENSITIVE STORES IN CA1 HIPPOCAMPAL NEURONS.

O. Garaschuk, Y. Yaari and A. Konnerth\*. Universität des Saarlandes, 66421 Homburg, Germany.

The properties of ryanodine-sensitive  $Ca^{2+}$  stores in CA1 pyramidal cells were investigated in hippocampal slices by using fura-2 based  $Ca^{2+}$  imaging combined with whole-cell recordings. Local applications of caffeine induced  $Ca^{2+}$  transients which (1) persisted in  $Ca^{2+}$ -free saline, (2) were not associated with inward currents and (3) were blocked by ryanodine, indicating that they were caused by  $Ca^{2+}$  release from ryanodine-sensitive  $Ca^{2+}$  stores. The  $Ca^{2+}$ -transients evoked by closely spaced caffeine pulses rapidly decreased in amplitude, indicating progressive depletion of the stores. The amplitude of the  $Ca^{2+}$ -transients recovered 'spontaneously' with a time constant  $\tau = 59$  s. Depleted  $Ca^{2+}$  stores did not refill in  $Ca^{2+}$ -free saline. Thus, refilling of stores depends upon extracellular  $Ca^{2+}$  influx through 'capacitative'  $Ca^{2+}$  channels in the plasma membrane. Refilling was accelerated by depolarization-induced elevations in  $[Ca^{2+}]_i$  and was blocked by bath-applied cyclopiazonic acid (CPA, 30  $\mu$ M) or thapsigargin (1-3  $\mu$ M). Even without prior store depletion, the caffeine-induced  $Ca^{2+}$ -transients disappeared after 6 min exposure to CPA, suggesting that  $Ca^{2+}$  level inside the stores is maintained by continuous  $Ca^{2+}$  sequestration. Elevations of basal  $[Ca^{2+}]_i$  markedly potentiated (up to 6-fold) the caffeine-induced  $Ca^{2+}$ -transients. The degree of potentiation was positively related to the basal  $[Ca^{2+}]_i$ . The  $Ca^{2+}$ -transients remained potentiated up to 9 min. Thus, the stores can overcharge following a transient increase in  $[Ca^{2+}]_i$ , and slowly discharge excess  $Ca^{2+}$  after basal  $[Ca^{2+}]_i$  returns to the resting level. We propose that neuronal ryanodine-sensitive calcium stores can act as either sinks or sources for  $Ca^{2+}$  when basal  $[Ca^{2+}]_i$  increases or decreases, respectively.

**METHYLSANTHINES INHIBIT SPONTANEOUS  $[Ca^{2+}]_i$  OSCILLATIONS IN THE ANTERIOR PITUITARY CELL LINE GH3.** M. Cataldi, N. Santangelo, R. Caporaso, S. Amoroso, G.F. Di Renzo and L. Annunziato. Section of Pharmacology, Dept. Neuroscience, School of Medicine, Federico II University of Naples, Via S. Pansini 5, 80131 Naples, ITALY.

The clonal anterior pituitary GH3 cells exhibit wide spontaneous oscillations of  $[Ca^{2+}]_i$ . Since methylxanthines have been reported to prevent the occurrence of  $[Ca^{2+}]_i$  oscillations in rat hepatocytes (Combettes et al. Biochem. J. 301:737,1994), in the present study the effect of these compounds on  $[Ca^{2+}]_i$  oscillations in GH3 cells was explored by fura-2 digital videomicroscopy. Both 400  $\mu$ M 3-isobutyl-methylxanthine (IBMX) and 2 mM theophylline reversibly suppressed spontaneous  $[Ca^{2+}]_i$  oscillations. The effect of methylxanthines could be attributed either to the blockade of adenosine receptors or to the inhibition of phosphodiesterases (PDE). The hypothesis that the effect of IBMX and theophylline on  $[Ca^{2+}]_i$  oscillations depends on the blockade of adenosine receptors seems unlikely since 100  $\mu$ M IBMX, a concentration reported to maximally block adenosine receptors, was ineffective. Furthermore, the adenosine receptor antagonist 8-cyclopentyl-1,3-dimethylxanthine (20 nM-1  $\mu$ M) did not induce any change in the pattern of spontaneous  $[Ca^{2+}]_i$  oscillations. By contrast, Vinpocetine (50  $\mu$ M), a selective inhibitor of type-I PDE ( $Ca^{2+}$ /Calmodulin dependent), mimicked the effect of IBMX and theophylline on the pattern of spontaneous  $[Ca^{2+}]_i$  oscillations. These results suggest that methylxanthines interfere with the pattern of spontaneous  $[Ca^{2+}]_i$  oscillations by blocking type-I PDE activity. **XESTOSPONGIN C: A POTENT CELL PERMEANT BLOCKER OF INOSITOL 1,4,5-TRISPHOSPHATE RECEPTOR CALCIUM PORE.** J. Gafni\*, J.A. Munsch\*, T. Lam\*, T.F. Molinski\*, V. Kumari\*, and I.N. Pessah\*. Depts. of Vet. Molec. Biosci., Chemistry\* and Med. Cell Biology and Human Anatomy\*, University of California, Davis, CA 95616.

Components of the phosphoinositide signaling pathway abound in the brain, with particularly high levels of inositol 1,4,5-trisphosphate receptor (IP<sub>3</sub>R) in the cerebellum. Stimulation of the IP<sub>3</sub>R results in  $Ca^{2+}$  mobilization from intracellular stores, activating many processes. Known inhibitors of the IP<sub>3</sub>R have limited uses, due to problems such as low affinity, membrane impermeability and targeting of the IP<sub>3</sub>-binding site. We show that Xestospingins A, C and D, a group of macrocyclic bis-1-oxaquinolizidines isolated from the Australian sponge, *Xestospingia* sp., are potent blockers of IP<sub>3</sub>-mediated  $Ca^{2+}$  release. IP<sub>3</sub>-induced  $Ca^{2+}$  release from rabbit cerebellar endoplasmic reticulum (ER), reveals that Xestosping C (Xest. C) is the most potent of these blockers ( $IC_{50}$ =300 nM). Competitive binding studies with [<sup>3</sup>H] IP<sub>3</sub> show that Xest. C does not bind to the IP<sub>3</sub> binding site, suggesting that Xest. C is a pore blocker. [<sup>3</sup>H] ryanodine binding studies and caffeine-induced  $Ca^{2+}$  transport assays also show that Xest. C blocks  $Ca^{2+}$  release via the ryanodine receptor with 5-30 fold lower potency. PC12 cells, a neuronal cell line which responds to bradykinin via an IP<sub>3</sub>-mediated pathway, are used to study whole cell activity of Xest. C. Calcium imaging of fura-2 loaded PC12 cells reveal that 20  $\mu$ M Xest. C decreases bradykinin-induced  $Ca^{2+}$  efflux from the ER store by 70%. Xestospingins represent a new class of potent, membrane permeable IP<sub>3</sub> blockers which exhibit a high selectivity over ryanodine receptors. Xest. C is a valuable tool for investigating the structure of the IP<sub>3</sub> pore and  $Ca^{2+}$  signaling in neuronal and non-neuronal cells. This work was supported in part by NIH grant ES05002 and Training Grant ES07059.

**LYSOPHOSPHATIDIC ACID ELEVATES INTRACELLULAR CALCIUM IN HIPPOCAMPAL NEURONS IN A NOVEL MANNER.** F.W. Holtzberg\*, M.R. Steiner, M.P. Mattson and S.M. Steiner, Univ. of Kentucky, Lexington, KY 40506.

The brain is a rich source of both lysophosphatidic acid (LPA) and the receptors for this potent lipid biomediator. Nonetheless, little is known about the intracellular signals generated by LPA in neurons. This study focuses on LPA-induced, calcium-related events in NGF differentiated PC12 cells and in primary neurons from embryonic rat hippocampus. LPA induced a rapid and transient increase in the concentration of intracellular free calcium ( $[Ca^{2+}]_i$ ) in PC12 cells. This increase was inhibited by pretreatment of the cells with pertussis toxin, phorbol myristic acid or genistein, while it was not dependent upon extracellular calcium. These data are consistent with the increase in  $[Ca^{2+}]_i$  in NGF differentiated PC12 cells resulting from signaling via a G protein coupled receptor, leading to activation of protein kinase C and a protein tyrosine kinase, which in turn result in the release of intracellular calcium stores. In contrast, in neurons, LPA stimulated a rapid and sustained increase in  $[Ca^{2+}]_i$ , which was not affected by pretreatment of the cells with any of the above inhibitors but was dependent upon extracellular calcium. This calcium response was also not affected by the addition of either cobalt or cadmium. However, treatment with the AMPA receptor antagonist, CNQX, or enzymatic depletion of extracellular glutamate partially inhibited the LPA-induced increase in  $[Ca^{2+}]_i$ . Thus, in hippocampal neurons, extracellular calcium is important in the LPA-induced increase in  $[Ca^{2+}]_i$ , which may be mediated, in part, via AMPA receptors. (Supported by the NIH & Alzheimer's Assoc.)

**WARMING INHIBITS CAFFEINE-STIMULATED  $Ca^{2+}$  TRANSIENTS IN CHICK SENSORY NEURONS.** J.L. Kenyon\* and H.R. Goff, Dept. of Physiol. & Cell Biol., University of Nevada School of Medicine, Reno, NV, 89557.

We used the amphotericin-perforated patch-clamp to measure  $I_{Ca}$  and  $I_{Ca(Ca)}$ , and indo-1 fluorimetry to measure  $Ca^{2+}_i$  in neurons isolated from 10 day old chick embryos. Step depolarizations activated  $I_{Ca}$  and  $I_{Ca(Ca)}$ , the latter showing slow deactivation upon repolarization. Warming neurons (from 20 to 37°C) increased peak  $I_{Ca}$  ( $Q_{10}=2.3\pm0.15$ , mean  $\pm$  SEM,  $n=5$ ) and the rate of decline of  $I_{Ca(Ca)}$  ( $Q_{10}=2.8\pm0.10$ ,  $n=3$ ). Below 21°C, 10 mM caffeine activated  $I_{Ca(Ca)}$  by releasing  $Ca^{2+}$  from ryanodine-sensitive stores (J. Neurophysiol. 70:710, 1993). Warming reversibly abolished the activation of  $I_{Ca(Ca)}$  by caffeine; the response disappeared and reappeared over a 3° range located between 21 and 30°C ( $n=5$ ). Similarly, below 23°C caffeine caused a rapid increase in the indo-1 fluorescence ratio. Warming to 30°C reduced the rate of rise and the amplitude of the signal (figure,  $n=4$ ). Because the affinity of indo-1 for  $Ca^{2+}$  increases with warming, these data imply that warming reduces the increase in  $Ca^{2+}_i$  caused by caffeine. These observations suggest that the release of  $Ca^{2+}$  by ryanodine-sensitive intracellular  $Ca^{2+}$  stores is less effective at raising  $Ca^{2+}_i$  at physiological temperature compared with room temperature. Possibly the stores contain less

$Ca^{2+}$  or uptake mechanisms buffer release. The "break" in the temperature-dependence of caffeine-activated  $I_{Ca(Ca)}$  suggests that a phase transition in the endoplasmic reticulum alters  $Ca^{2+}$  uptake, release, or both by intracellular stores.

Indo-1 fluorescence ratios in response to 10 mM caffeine recorded at 23° (A,B,D) or 29.5° (C).

Supported by NIH NS32144.

**TRI-ORTHO-SUBSTITUTED 2,2',3,5',6-PENTACHLORINATED BIPHENYL (PCB 95) ALTERS RAT BRAIN NEUROPLASTICITY IN VITRO THROUGH A RYANODINE RECEPTOR MEDIATED MECHANISM.** P. W. Wong, T. E. Albertson, W. F. Walby, S. L. Schantz\*, I. N. Pessah. Department of Molecular Biosciences, School of Veterinary Medicine, University of California Davis, Davis, CA 95616. \*Institute for Environmental Studies, University of Illinois, Urbana, IL 61801.

Studies have revealed that non-coplanar polychlorinated biphenyls alter intracellular  $Ca^{2+}$  signaling in both cerebellar granular cells and PC12 cells *in vitro*. Recently we have shown that several ortho-substituted PCB congeners mobilize microsomal  $Ca^{2+}$  by activation of ryanodine sensitive microsomal  $Ca^{2+}$  channel/ryanodine receptor (RyR) through a FKBP12 (FK506 binding protein 12 kDa) mediated pathway. Study of several congeners have revealed a stringent structural requirement for the activity of PCBs towards RyRs. Measurements of electrical excitability of hippocampal slices were employed to further elucidate the actions of non-coplanar PCBs in CNS. Single pulse orthodromic stimulation of Schaffer collateral/commissural (SC/C) fibers was performed by stimulating the striatum radiatum of CA1 with a bipolar electrode. Population spike (PS) and excitatory postsynaptic potential (EPSP) were recorded at striatum pyramidal. After perfusing the hippocampal slices with 25  $\mu$ M PCB 95 (channel active congener) for 30 min, PS amplitude and EPSP slope were depressed, especially at high stimulus intensities. Significant reductions in both maximal PS amplitude and EPSP slope were observed, even after the induction of long term potentiation. However, these effects were not observed in 25  $\mu$ M PCB 66 (channel inactive congener), suggesting that persistent activation of ryanodine receptor was responsible for the general depression of pyramidal cell excitability. Recently, preliminary studies on the effect of ryanodine on electrical excitability of hippocampal slice revealed that 300  $\mu$ M ryanodine caused general depressions in both PS and EPSP of pyramidal cells. The similar effects of PCB 95 and ryanodine on the hippocampus, suggests that the action of PCB 95 on hippocampal excitability is through a ryanodine receptor mediated pathway.

## 139.16

**CALCIUM-DEPENDENT PROPERTIES OF HIPPOCAMPAL PYRAMIDAL NEURONS IN TRANSGENIC MICE WITH REDUCED CALBINDIN D28K EXPRESSION.** P. Dutar\*, A. Jouvenceau, J.M. Billard, Y. Lamour (1), and S. Ferrari (2). (1) INSERM U161, 75014 Paris France; (2) Univ. di Modena, 41100 Modena, Italia.

Calbindin D28K (CaBP) is expressed in a subpopulation of CA1 pyramidal neurons of the hippocampus. We previously showed that the maintenance of long-term potentiation (LTP) is altered in the CA1 area in transgenic homozygous mice lacking CaBP expression. Using the *ex vivo* hippocampal slice preparation from wild-type and homozygous transgenic mice, we studied 1) the mechanisms of synaptic plasticity using extracellular recordings and, 2) the membrane properties of CA1 pyramidal neurons as a function of their CaBP content using intracellular recordings and immunofluorescence labelling.

1) Short-term potentiation (STP) induced by a weak tetanus (30 Hz; 0.5 sec), as well as paired-pulse facilitation of the field EPSP were not different in wild-type and homozygous mice. This contrasts with the lack of LTP maintenance and suggests the involvement of CaBP in long-term plasticity. The fEPSP slope measured as a function of stimulus intensity was significantly higher in homozygous while the afferent volley amplitude was unchanged. This suggests a modification of the synaptic efficacy of the CA1 afferent fibers in the homozygous mice.

2) Neurons recorded with sharp electrodes were filled with biocytin and the presence of CaBP in the neurons was checked using antiCaBP antibodies coupled to a fluorescent probe (FITC). In CaBP-depleted neurons from homozygous mice, a significant decrease in AHP duration as well as a reduction in spike discharge accommodation were observed. In contrast, membrane potential, membrane resistance, sodium spike amplitude and duration or EPSP and IPSP amplitude and duration were not affected. These results suggest a smaller activation of Ca-activated potassium conductance in the transgenic mice. This could be due to a stronger inactivation of  $Ca^{2+}$  currents or to an alteration in the intracellular transport of  $Ca^{2+}$ .

SPHINGOMYELIN AND ITS DERIVATIVES INCREASE VULNERABILITY TO OXIDATIVE STRESS IN PC-12 CELLS. N.A. Denisova<sup>1</sup>, I. Cantuti-Castelvetri and J.A. Joseph. USDA Human Nutrition Research Ctr. on Aging at Tufts University, Boston, MA 02111.

Previous research has shown that membrane sphingomyelin (SPM) incorporation may dramatically increase deficits in  $Ca^{2+}$  regulation induced by oxidative stress (OS) in PC-12 cells and increase conjugated diene levels. Since membrane SPM levels increase as a function of age, these findings suggest that interactions between OS and increased membrane SPM may be responsible for the age-related deficits seen in hippocampal  $Ca^{2+}$  homeostasis. Present experiments were carried out to determine whether derivatives of SPM (e.g., C2-ceramide (C2-cer), 100  $\mu$ M; sphingosine, 20  $\mu$ M; and sphingosine-1-phosphate, 1  $\mu$ M; as well as SPMase, 100 mU/mL, pretreated 1-20 min.) would have similar effects on  $Ca^{2+}$  activity. Cells were then exposed to 0 or 300  $\mu$ M  $H_2O_2$  for 30 min., loaded with Fura-2 and  $Ca^{2+}$  flux imaged. No derivatives of SPM altered effects on pre-stimulation (baseline)  $Ca^{2+}$  levels, or peak  $Ca^{2+}$  depolarization in the absence of  $H_2O_2$ . However, each derivative of SPM, except C2-cer, acted similarly to  $H_2O_2$  and significantly increased  $Ca^{2+}$ RT; C2-cer did not affect  $Ca^{2+}$ RT. These results suggest the both SPM and its derivatives could increase vulnerability to OS through initiation of  $Ca^{2+}$  dysregulation. The nature of the C2-cer differences are being explored. ALTERNATIVE SPLICING IN THE DOMAIN I-II LINKER ALTERS  $\alpha_{1A}$  Ca CHANNEL GATING AND MODULATION BY G PROTEINS. E. Bourinet<sup>1,2</sup>, T.W. Soong<sup>1</sup>, G.W. Zamponi<sup>1</sup>, A. Stea<sup>1</sup>, J. Nargeot<sup>2</sup> and T.P. Snutch<sup>1</sup>. (1)Biotechnology Laboratory, University of British Columbia, Vancouver, B.C., V6T 1Z3 Canada; (2)CRBM-CNRS UPR 9008, INSERM U249 1919 route de Mende, BP 5051, F34033 Montpellier France.

We have previously reported<sup>[1]</sup> that alternative splicing of the  $\alpha_{1A}$  gene generates calcium channels with different physiological properties ( $\alpha_{1A-b}$ ,  $\alpha_{1A-c}$ ,  $\alpha_{1A-d}$ ). Of particular interest, small amino acid alterations in the domain I-II linker influence channel kinetics. This region has also been shown to be crucial in  $\beta$  subunit binding and for modulation of Ca channels by protein kinase C. To examine the potential role of the I-II linker on channel regulation by direct G-protein interaction, we reconstituted this second messenger cascade by coexpressing rat brain  $\alpha_{1A}$  isoforms with either  $\mu$ -opioid or  $\alpha_2$ -adrenergic receptors. Application of their respective agonists, DAMGO or phenylephrine, resulted in a voltage dependent inhibition of  $\alpha_{1A}$  whole cell current. While all  $\alpha_{1A}$  splice variants exhibited a similar magnitude of agonist-induced inhibition (~20%), they differed significantly in their rate of activation. Of particular note, agonist application resulted in  $\alpha_{1A-b}$  currents that were much more slowly activating compared to  $\alpha_{1A-c}$  or  $\alpha_{1A-d}$  currents. Single channel current recordings in the absence of agonist revealed that the  $\alpha_{1A-b}$  channel is characterized by an additional mode of gating with prolonged open times. Direct G-protein modulation has been suggested to alter Ca channel gating and we are currently investigating the single channel mechanism of the differential G-protein-dependent modulation of the  $\alpha_{1A}$  splice variants. Supported by grants from the MRC of Canada, the Howard Hughes Medical Institute and the NATO.

## 140.3

CHARACTERIZATION OF  $\omega$ -AGA-IIIa BINDING TO RAT BRAIN MEMBRANES. L. Z. Yan<sup>\*</sup> and M. E. Adams. Environmental Toxicology Graduate Program and Depts. of Entomology and Neuroscience, Univ. of California, Riverside, CA 92521.

Electrophysiological studies have shown that  $\omega$ -Aga-IIIa (IIIa), an 8.5 kDa peptide toxin from *Agelenopsis aperta* spider venom, is a high affinity ( $K_d$  ~0.5-1.0 nM) antagonist of high-threshold calcium channels, but spares low threshold T-type channels. The data suggest that IIIa identifies a conserved binding site unique to high threshold channels. To further evaluate IIIa binding to mammalian CNS sites, the toxin was iodinated directly with chloramine-T method and HPLC purified. Binding experiments were conducted at 25°C in 0.5-2 ml incubation volumes containing 50 mM HEPES/NaOH (pH 7.4) and 0.1% BSA for 3 hr. Saturation assays, performed in the concentration range of 0.1-15  $\mu$ M [<sup>125</sup>I]IIIa, showed that binding to rat brain membranes is saturable and involves high and low affinity sites. The  $K_d$  for the high affinity binding site was estimated to be ~1.3 pM from Scatchard analysis. Kinetic studies showed that the ligand-receptor interaction reaches equilibrium within 1.5 hr, with an association rate constant ( $k_{on}$ ) of 0.0036 min<sup>-1</sup> pM<sup>-1</sup>, and dissociation rate constant ( $k_{off}$ ) of 0.0055 min<sup>-1</sup>, the latter corresponding to a  $t_{off}$  of 181 min. The  $K_d$  value computed from the kinetic data is estimated to be ~1.5 pM, which is in agreement with Scatchard analysis. Ongoing experiments are aimed at the characterization of IIIa binding to uniform populations of calcium channels.

## 140.2

EXPRESSION OF RECOMBINANT  $\omega$ -AGA-IVA AND MODIFICATION OF A PUTATIVE BINDING DOMAIN FOR P-TYPE Ca CHANNELS. T. M. Norris<sup>\*</sup>, V. Francis, M. Mehra, S. S. Gill and M. E. Adams. Depts. of Entomology and Neuroscience, University of California, Riverside, CA 92521.

The funnel web spider toxins  $\omega$ -Aga-IVA and  $\omega$ -Aga-IVB are high affinity antagonists ( $K_d$  ~ 1-3 nM) of P-type Ca channels in the mammalian brain. Structural analyses of Aga-IVA and Aga-IVB suggest identical disulfide-patterns and have led to a hypothesis that a cluster of conserved, highly basic residues (Arg21, 23, and 39) is important in channel binding. We have begun site-directed mutagenesis of recombinant Aga-IVA and evaluation of toxin mutants using whole-cell recording. A synthetic Aga-IVA gene was incorporated into a plasmid vector system and expressed in *E. coli* as a 6x His-Aga-IVA toxin fusion protein. The initial construct was designed to replace methionines at positions 30 and 42 with leucine residues, while a methionine was added between the His-tag and toxin gene for convenient cleavage of the fusion protein with cyanogen bromide. Replacement of methionine with leucine residues at positions 30 and 42 in the recombinant toxin had no effect on the kinetics of P-type channel block or recovery from block. The recombinant peptide blocked P-type channels with a  $K_d$  of 0.5 nM, a value almost identical to that of native Aga-IVA. Replacement of Arg39 with the less basic residue (lysine) reduced the rate of binding ( $k_{on}$ ) ~ 8-fold and increased the unbinding rate ( $k_{off}$ ) by ~ 2.5-fold, resulting in an approximate 18-fold decrease in  $K_d$  (~ 9 nM). These results suggest that Arg39 may be part of the Aga-IVA binding domain involved in P-type Ca channel antagonism.

## 140.4

DW13.3, A PEPTIDE TOXIN FROM THE SPIDER *FILISTATA*, DIFFERENTIALY BLOCKS TRANSIENTLY EXPRESSED NEURONAL CALCIUM CHANNELS. K.G. Sutton<sup>1</sup>, A. Stea<sup>1</sup>, L.D. Artman<sup>2</sup>, S. Heck<sup>3</sup>, R.A. Volkman<sup>3</sup>, M.K. Ahljianian<sup>1</sup> and T.P. Snutch<sup>1</sup>. <sup>1</sup>Biotech. Lab., Univ. of British Columbia, Vancouver, B.C. Canada, <sup>2</sup>NPS, Inc., Salt Lake City, UT, 84108, Depts. <sup>3</sup>Med. Chem. and <sup>4</sup>Neurosci., Pfizer, Inc., Groton, CT 06340.

The peptide toxin DW13.3 (Mr 8668, 74 amino acids), isolated from the venom of the spider *Filistata hibernalis* is a potent, relatively non-selective blocker of voltage-dependent calcium channels (CaCh). We have characterized the ability of DW13.3 to block rat brain  $\alpha_{1A}$ ,  $\alpha_{1B}$ ,  $\alpha_{1C}$  and  $\alpha_{1E}$  subunits coexpressed with  $\alpha_2$  and  $\beta_{1b}$  in *Xenopus* oocytes. DW13.3 produced a rapid onset of block for all classes of CaCh, however recovery from inhibition was significantly slower for  $\alpha_{1A}$  ( $\tau_{off}$  = 1738±341 s, n=5), when compared to  $\alpha_{1B}$ ,  $\alpha_{1C}$  and  $\alpha_{1E}$  ( $\tau_{off}$  = 193±73 s, 59.8±4.9 s, 43.0±6.2 s respectively, n=4/6/5). IC<sub>50</sub> values for DW13.3 block of  $\alpha_{1B}$ ,  $\alpha_{1C}$  and  $\alpha_{1E}$  were 28.4 nM, 27.3 nM and 86.7 nM. At the highest concentration used (1.15  $\mu$ M) toxin block appeared to be nearly complete for these three isoforms. In contrast, the IC<sub>50</sub> for DW13.3 inhibition of  $\alpha_{1A}$  was 4.1 nM, yet 1.15  $\mu$ M DW13.3 failed to produce total block (69.0±8.9 %, n=3). Kinetic analysis of  $\tau_{on}$  and  $\tau_{off}$  for  $\alpha_{1A}$  produced an affinity ( $K_d$  =  $k_{off}/k_{on}$  = 4.4±1.5 nM, n=5) comparable with the IC<sub>50</sub> value determined from the dose response relation. The dose response data of the  $\alpha_{1A}$  isoform is well described assuming a Hill coefficient of 1.0, although fit of the data required a model based on incomplete block. The reciprocal of the blocking time constant for  $\alpha_{1A}$  ( $1/\tau_{on}$ ) was linearly dependent upon DW13.3 concentration, consistent with 1:1 binding of the toxin molecule with the channel. This raises the possibility that DW13.3 acts on  $\alpha_{1A}$  as a partial pore blocker. DW13.3 is a potent inhibitor of all CaCh studied to date, however its effect on  $\alpha_{1A}$  contrasts with that observed for the other CaCh isoforms. Research funded by: Izaak Walton Killam Fellowship, MRC of Canada, Pfizer Central Research, NPS Pharmaceuticals.

## 140.5

EFFECT OF  $\beta_{1b}$ ,  $\beta_{2e}$ ,  $\beta_{3a}$ , OR  $\beta_{4a}$  SUBUNITS ON THE PHARMACOLOGICAL SENSITIVITY OF HEK293 CELLS STABLY TRANSFECTED WITH  $\alpha_{1A}$  SUBUNITS OF HUMAN VOLTAGE-GATED  $Ca^{2+}$  CHANNELS. K.A. Stauderman, S. Simerson, P. Brust, M. Williams\*, P. Prodanovich, C.-C. Lu, and M. Harpold. SIBIA Neurosciences, Inc., La Jolla, CA 92037.

We examined the pharmacological sensitivities of HEK293 cells stably transfected with cDNAs encoding full-length human  $\alpha_{1A-2}$  and  $\alpha_{2\delta}$  subunits together with the  $\beta_{1b}$  (cell line A68-90),  $\beta_{2e}$  (cell line E1H2),  $\beta_{3a}$  (cell line PB1-14), or  $\beta_{4a}$  (cell line 10-13) subunit. Western analysis confirmed the expression of  $\alpha_{1A}$ ,  $\alpha_{2\delta}$ , and  $\beta$  subunits in each cell line. The biophysical properties of the cell lines were also consistent with the expression of different  $\beta$  subunits in the functional  $Ca^{2+}$  channels (see Hans *et al.*, this meeting). Cells loaded with the  $Ca^{2+}$ -sensitive fluorescent dye fluo-3 responded to depolarization with 70 mM KCl with a transient increase in cytosolic  $[Ca^{2+}]$  ( $[Ca^{2+}]_i$ ) that was at least 200 nM at the peak. The KCl-induced  $[Ca^{2+}]_i$  signals were not inhibited by 1  $\mu$ M  $\omega$ -CGTx-GVIA or 5  $\mu$ M nimodipine. On the other hand, KCl-stimulated  $[Ca^{2+}]_i$  responses were inhibited by  $\omega$ -Aga-IVA in a concentration-dependent manner in all three cell lines with  $IC_{50}$  (nM) values as follows (mean  $\pm$  SEM): 51  $\pm$  9 (A68-90), 93  $\pm$  20 (E1H2), 54  $\pm$  5 (PB1-14), and 80  $\pm$  13 (10-13). Inhibition of KCl-evoked  $[Ca^{2+}]_i$  signals was also produced by  $\omega$ -CTX-MVIIIC, with mean  $IC_{50}$  (nM) values ( $\pm$  SEM) of 48  $\pm$  10 (A68-90), 105  $\pm$  12 (E1H2), 77  $\pm$  11 (PB1-14), and 113  $\pm$  10 (10-13). These data indicate that the  $\beta_{1b}$ ,  $\beta_{2e}$ ,  $\beta_{3a}$ , and  $\beta_{4a}$  subunits result in less than a 2.4-fold change in the potency of  $\omega$ -Aga-IVA and  $\omega$ -CTX-MVIIIC to block human voltage-gated  $Ca^{2+}$  channels containing  $\alpha_{1A-2}$  and  $\alpha_{2\delta}$  subunits. Although the  $\beta_{1b}$ ,  $\beta_{2e}$ ,  $\beta_{3a}$ , and  $\beta_{4a}$  subunits do not appear to influence markedly the potency of peptide toxins, the effect of  $\beta$  subunits on the potency of small non-peptidergic organic antagonists is yet to be determined.

## 140.7

ANTIBODY CROSS-REACTIVITY AND PHARMACOLOGICAL SIMILARITIES BETWEEN CHICK AND RAT SYNAPTOSOMAL N-TYPE CALCIUM CHANNELS. J.J. Geer\*, D.J. Dooley, and J. Offord. Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co. Ann Arbor, MI 48105

N-type  $Ca^{2+}$  channels have been implicated in avian synaptosomal  $Ca^{2+}$  flux due to complete inhibition of flux by  $\omega$ -conopeptide GVIA. It is well documented that rat synaptosomal  $Ca^{2+}$  flux, however, is not sensitive to these peptides despite the presence of  $\omega$ -conopeptide binding sites. These functional discrepancies were addressed by comparing avian (chick) and mammalian (rat) synaptosomal N-type  $Ca^{2+}$  channels, using methods which targeted specific extracellular and intracellular domains. Extracellular domain similarity was assessed by comparing the dissociation constants ( $K_{ds}$ ) for binding of [ $^{125}I$ ]- $\omega$ -conotoxin MVIIA to rat and chick synaptosomal membranes.  $\omega$ -Conotoxin MVIIA, a large peptide which has a complex interaction with the channel, may bind to more than one extracellular site and might be expected to show differential affinity if critical binding sites vary between the two species. The  $K_{ds}$  (rat, 1.6; chick, 2.0) were not statistically different. Additionally, the rank order of displacement of MVIIA binding by eight  $\omega$ -conopeptides and two  $\omega$ -agatoxins was found to be virtually identical in both preparations. Potencies of the peptides, as determined by the  $IC_{50}$  values, did not differ appreciably. The seven most potent inhibitors of binding were also the most potent inhibitors of  $Ca^{2+}$  flux into chick synaptosomes, although rank order varied. Intracellular similarity was probed with an antibody directed against a GST fusion protein containing the internal loop between transmembrane regions II-III of the  $\alpha_{1b}$  channel, the most highly variable region between  $Ca^{2+}$  channel subtypes. Protein from rat and chick membranes containing equal amounts of  $\omega$ -conopeptide receptor was loaded onto SDS gels and probed with the antibody. Cross-reactivity of this antibody with chick as well as rat synaptosomal membranes indicated similarity between the N-type channel in the two species. A high degree of homology has been demonstrated between avian and mammalian N-type channels both at extracellular conopeptide binding domains and at the II-III intracellular loop. Failure of the conopeptides to block  $Ca^{2+}$  flux into mammalian synaptosomes remains unexplained from these comparisons. [Supported by Warner-Lambert Co.]

## 140.9

INVOLVEMENT OF PERTUSSIS TOXIN-SENSITIVE G PROTEINS IN EVOKED TRANSMITTER RELEASE AT THE FROG NEUROMUSCULAR JUNCTION. Y. Sugiura\*, R. Tolentino and C.-P. Ko. Department of Biological Science, University of Southern California, Los Angeles, CA 90089-2520.

G proteins are thought to play an essential role in the signaling pathways of nervous system. To explore the G protein-linked modulation of neuromuscular transmission, we examined the effects of pertussis toxin (PTX), a Gi/Go inhibitor, on transmitter release at frog neuromuscular junctions (NMJs). Cutaneous pectoris muscles were incubated with, or without, PTX (2  $\mu$ g/ml) for 22-24 hr at 4°C. Intracellular recording was performed in low  $Ca^{2+}$ /high  $Mg^{2+}$  saline and end-plate potentials (epps) and spontaneous miniature epps (mepps) were collected. PTX significantly increased epp amplitude (PTX; 6.95  $\pm$  0.58 mV, n=53 vs. control; 3.78  $\pm$  0.27 mV, n=52). PTX did not affect the amplitude and frequency of mepps, indicating that the effect was presynaptic. The result is consistent with the idea that G proteins inhibit voltage-sensitive calcium channels (VSCCs). Similar presynaptic potentiation of epps by PTX was seen at regenerating NMJs 2 weeks after nerve crush (PTX; 4.05  $\pm$  0.43 mV, n=26 vs. control; 2.01  $\pm$  0.26 mV, n=25). We have previously observed that L-type VSCC blockers *potentiate* evoked transmitter release at regenerating, but not intact, frog NMJs. This potentiation at regenerating NMJ was abolished by PTX pretreatment, indicating an involvement of G proteins. The present results suggest the existence of PTX-sensitive G protein-linked modulation in evoked transmitter release at normal and regenerating frog NMJs. At the regenerating NMJ, the PTX-sensitive G protein may be a link between N-type VSCCs that mediate transmitter release and L-type VSCCs that modulate transmitter release. (Supported by NIH grant NS 30051).

## 140.6

IDENTIFICATION OF BENZ(OTHI)AZEPINE BINDING REGIONS WITHIN L-TYPE CALCIUM CHANNEL ALPHA1 SUBUNITS. R. Kraus, B. Reichl, M. Grabner, S. D. Kimball, B. J. Murphy, W. A. Catterall, and J. Striessnig\*. Institut für Biochemische Pharmakologie, Universität Innsbruck, A-6020 Innsbruck, Austria; Bristol-Myers-Squibb, Princeton, NJ 08543-4000, USA; Department of Pharmacology, University of Washington, Seattle, WA 98115, USA

To identify the binding domain for diltiazem-like  $Ca^{2+}$  antagonists on L-type  $Ca^{2+}$  channel  $\alpha 1$  subunits we synthesized the benzazepine [ $^3H$ ]benzazepam (35Ci/mmol) as a novel photoaffinity probe. [ $^3H$ ]Benzazepam reversibly labeled the benzothiazepine (BTZ) binding domain of partially purified skeletal muscle  $Ca^{2+}$  channels ( $K_d$  = 12 nM) with high yield (>66%). Antibody mapping of proteolytic labeled fragments revealed specific labeling of regions associated with segments S6 in repeats III and IV. More than 50% of the labeling was found in the tryptic fragment alanine-1023 - lysine 1077 containing IIIIS6 together with extracellular and intracellular amino acid residues. The remaining labeling was identified in a second site comprising segment S6 in repeat IV and adjacent residues. Unlike for dihydropyridines, no labeling was observed in the connecting IIIS5-IIIIS6 linker. The [ $^3H$ ]benzazepam photolabeled regions must be in close contact to the drug molecule when bound to the channel. Therefore the determinants for high affinity BTZ binding must be located within or in close proximity to segments IIIIS6 and/or IVS6. The photolabeled regions may also contain residues that control BTZ access to its binding site.

We conclude that the binding domain for BTZs is located within pore-forming regions of the channel and in close proximity to the binding domains of the other main classes of  $Ca^{2+}$  antagonists (dihydropyridines and phenylalkylamines). Our findings provide the molecular basis for the non-competitive binding interactions observed between the major  $Ca^{2+}$ -antagonist binding domains of L-type  $Ca^{2+}$  channels.

This work was supported by grants from the Austrian Science Foundation (FWF S6602 to JS) and the NIH (HL44948 to WAC).

## 140.8

IDENTIFICATION OF BENZOTHIAZEPINE BINDING REGIONS WITHIN THE  $\alpha 1$  SUBUNIT OF CALCIUM CHANNELS.

A. Kuniyasu, N. Yoshida, H. Yabana, K. Naito, K. Itagaki, A. Schwartz, H. Nakayama\*. Faculty of Pharm. Sci., Kumamoto Univ., Kumamoto, 862 Japan. Tanabe Pharm. Co., Toda, 335, Japan. LCMP, NIEHS, Research Triangles Park, NC 27709-704. Institute of Mol. Pharm. Biophys., Univ. of Cincinnati Coll. of Med. OH 45267-0828.

To identify regions which are involved in the formation of the benzothiazepine (BTZ) receptor site of skeletal muscle L-type calcium channels, the  $\alpha 1$  subunit of the channel complex was specifically labeled with a diltiazem-type photoaffinity probe, [ $^3H$ ]azidobutyl clemizem (ABC). Two photolabeled regions were located by probing labeled proteolytic fragments with several anti-peptide antibodies recognizing different segments of the  $\alpha 1$  sequence. A part of the  $\alpha 1$  associated [ $^3H$ ]ABC label was incorporated in a 13 kDa Lys-C fragment derived from the loop between S5 and S6 and the adjacent S6 segment in repeat IV (FEBS Lett., 334, 261-4, 1993). This region was partly shared with the photolabeled sites by dihydropyridine and phenylalkylamine probes. Another part of the labeling occurred in a smaller Lys-C fragment which contained in a transmembrane segment of repeat IV. Our data suggest that the BTZ site is formed by close apposition of two discontinuous regions of the  $\alpha 1$  subunit sequence in repeat IV. By identifying the BTZ binding site as the last of the three typical calcium antagonists, we can now obtain their overview and imply their allosteric interactions in the molecular model.

INHIBITION BY G PROTEINS OF N-TYPE  $Ca^{2+}$  CHANNELS EXPRESSED IN XENOPUS OOCYTES. AN ANALYSIS USING 'CUT-OPEN' METHOD.

S. Kaneko\*, Y. Mitani, T. Hata, M. Kikukawa, A. Akaike, and M. Satoh.

Depts. of <sup>1</sup>Pharmacol. and <sup>2</sup>Mol. Pharmacol., Facul. of Pharm. Sci., Kyoto Univ. Kyoto 606-01, Japan.

To investigate the intracellular modulation of N-type  $Ca^{2+}$  channels by G protein  $\beta\gamma$  subunits, 'Cut-Open' recordings were made in *Xenopus* oocytes expressing cloned N-type channels and  $\kappa$  opioid receptors. Before intracellular perfusion, application of strong prepulse to oocytes (+100 mV, 100 ms duration, 20 ms before recording pulse) significantly increased the amplitude of  $Ca^{2+}$  channel current and fastened the activation kinetics of channel opening. Intracellular perfusion with a Cesium-EGTA-GTP solution for 30 min completely abolished the effects of prepulse without run-down of the channel current. However,  $\kappa$  agonist stimulation decreased the amplitude of  $Ca^{2+}$  channel current but not influenced the activation or inactivation kinetics. These results indicate that the intrinsic retardation of channel kinetics may be mediated by a mechanism which is independent of the G protein-mediated inhibition of current amplitude.

## 140.11

REGULATION OF HUMAN NEURONAL N- AND E- TYPE  $\text{Ca}^{2+}$  CHANNELS BY G-PROTEIN  $\beta\gamma$  SUBUNITS IN HEK293 CELLS. L. R. Shekter\*, P. T. Toth, R. Taussig\* and R. J. Miller. Dept. Pharm./Phys. Sci., U. Chicago, Chicago IL 60637 & \*Dept. Biol. Chem., U. Michigan, Ann Arbor MI 48109

We previously compared receptor regulation of N ( $\alpha_{1B}$ ) and E ( $\alpha_{1E}$ ) currents in HEK293 cells (courtesy SIBIA Neurosciences). We observed strong inhibition of  $\text{Ca}^{2+}$  currents by K-opioid and SRIF agonists in  $\alpha_{1B}$  expressing but not  $\alpha_{1E}$  expressing cells containing K-opioid and SRIF receptors. In the present study we examined the effects of G-protein  $\beta\gamma$  subunit overexpression in both  $\alpha_{1B}$  and  $\alpha_{1E}$  containing cells. In  $\alpha_{1B}$  containing cells the whole-cell current was facilitated an average of  $339.7 \pm 86\%$  while the time course of activation was reduced from  $\tau = 6.00 \pm 0.54$  ms before the prepulse (p.p.) to  $\tau = 2.51 \pm 0.29$  ms after the p.p. (n=6). The I-V relationship also shifted from an average peak of +30 mV before the p.p. to +10 mV after. Interestingly, we also observed a population of cells in which there was no facilitation ( $-2.3 \pm 0.12\%$  n=7) but in which time course of activation was distinctly inhibited ( $\tau = 9.38 \pm 0.92$  ms before p.p.,  $\tau = 6.69 \pm 0.50$  ms after p.p.). Varying the p.p. duration and magnitude had no effect on G-protein relief. In untransfected cells there was no effect on either facilitation ( $1.9 \pm 0.24\%$ ; n=7) nor on time course of activation ( $\tau = 2.35 \pm 0.40$  ms before the p.p. and  $\tau = 2.51 \pm 0.50$  ms after). In  $\alpha_{1E}$  containing cells under the same conditions, a reduced but distinct facilitation was observed; the same paradigm was employed but  $V_{\text{test}}$  was 0 mV instead of +10 mV. The current was facilitated an average of  $41.2 \pm 19.7\%$  (n=5) while the time course of activation was reduced from  $\tau = 3.26 \pm 1.46$  ms to  $\tau = 1.76 \pm 0.50$  ms. In addition, the peak I-V shifted from 0 mV to +30 mV. In untransfected cells, the average peak current after the p.p. was reduced  $24.04 \pm 5.83\%$  (n=4) while the time course of activation remained essentially unchanged ( $\tau = 1.49 \pm 0.26$  ms before p.p. compared with  $\tau = 1.70 \pm 0.36$  ms after p.p.). Constitutively active forms of the G-protein subunits  $\alpha_i$  and  $\alpha_o$  were also tested for their effects on  $\alpha_{1B}$  and  $\alpha_{1E}$  expressing cells but none were observed. This work was supported by PHS Grants DA-02575, DA-02121, MH-40165 and NS-33502 to R.J.M.

HUMAN TERATOCARCINOMA-DERIVED NEURONAL NT2-N CELLS CONTAIN  $\omega$ -CGTX-GVIA AND NIFEDIPINE SENSITIVE  $\text{Ca}^{2+}$  CURRENTS. Torben R. Neelands\*, R. Scott Turner\* and Robert L. Macdonald\*. Departments of Neurology\* and Physiology\* and the Graduate Program in the Neurosciences\*, University of Michigan Health Sciences Center and Department of Veteran Affairs Medical Center\*, Ann Arbor, MI. Treatment of human NT2 teratocarcinoma cell line twice weekly for four weeks with 1  $\mu\text{M}$  retinoic acid causes them to differentiate into neuron-like NT2-N cells. We investigated whether these neuron-like NT2-N cells expressed calcium currents using whole cell voltage-clamp electrophysiological techniques. NT2-N cells were replated onto 35 mm dishes 1-7 days prior to recording. Cells were held at -80 mV in an external solution using  $\text{Ba}^{2+}$  as the charge carrier and blockers of other voltage-gated ion channels. The pipette solution contained 5 mM ATP and 0.3 mM GTP. A series of hyperpolarizing and depolarizing voltage commands were applied. Inward  $\text{Ba}^{2+}$  currents were evoked starting at -35 mV, peaking at +5 mV, and reversing at +60 mV. Individual voltage step commands to +5 mV (the peak inward current) were then repeated until the peak current had stabilized (300-600 pA). Individual 300 msec voltage commands to +5 mV were then repeated in the presence of nifedipine,  $\omega$ -CGTX-GVIA (conotoxin) or  $\text{Cd}^{2+}$ . All NT2-N cells were partially blocked by nifedipine and conotoxin and completely blocked by  $\text{Cd}^{2+}$ . The presence of N- and L-type  $\text{Ca}^{2+}$  currents in a dividing human neuronal-type cell line provides a novel model for the study of human derived calcium channel regulation. INHIBITION OF  $\text{Ca}^{2+}$ /CALMODULIN-DEPENDENT PROTEIN KINASE II REDUCES VOLTAGE-GATED  $\text{Ca}^{2+}$  CURRENT IN HIPPOCAMPAL NEURONS. E.M. Blalock and P.W. Landfield. Dept. Pharmacology, Coll. Med., U. Ky, Lexington, KY 40536.

Although several groups have found that inhibition of  $\text{Ca}^{2+}$ /calmodulin-dependent kinase II (CaMKII) prevents voltage- and  $\text{Ca}^{2+}$ -dependent facilitation of  $\text{Ca}^{2+}$  current, the basic effects of CaMKII inhibition on non-facilitated  $\text{Ca}^{2+}$  channel activity are still not well understood. Some studies have reported inhibition of voltage-gated  $\text{Ca}^{2+}$  current in peripheral tissue with KN-62, a blocker of CaMKII. However, there is some evidence that this inhibition may be due to direct block of  $\text{Ca}^{2+}$  channels, rather than inhibition of CaMKII. Here we tested the hypothesis that CaMKII modulates the amplitude of basal, non-facilitated  $\text{Ca}^{2+}$  current in hippocampal neurons.

In cultured rat hippocampal cells, KN-62 reduced whole-cell  $\text{Ca}^{2+}$  current amplitude by greater than 40% regardless of whether it was applied internally or externally (consistent with its lipophilicity). When 60 mM  $\text{Na}^{+}$  was the charge carrier through voltage-gated  $\text{Ca}^{2+}$  channels, KN-62 had no effect on current amplitude. Calmidazolium, a calmodulin inhibitor, paralleled the effect of KN-62. Single L-type  $\text{Ca}^{2+}$  channel activity was unchanged by the addition of KN-62 to the on-cell pipette solution. Together these results suggest that basal, non-facilitated  $\text{Ca}^{2+}$  current is modulated by  $\text{Ca}^{2+}$ - and calmodulin-dependent CaMKII activity; and that KN-62 does not directly block voltage-gated  $\text{Ca}^{2+}$  channels (supported by AG04542 and Bayer, Inc.).

## 140.12

CHARACTERISTICS OF G PROTEIN-MEDIATED INHIBITION OF  $\alpha_{1A}$  AND  $\alpha_{1B}$   $\text{Ca}^{2+}$  CHANNELS. J.P. Roche\* and S.N. Treistman. Dept. of Pharmacology and Mol. Tox., Program in Neuroscience, Univ. of Mass. Medical Ctr., Worcester, MA 01655.

$\alpha_{1A}$  and  $\alpha_{1B}$  calcium channels have been found to co-localize at synapses and are both thought to be capable of mediating synaptic transmission. Differential modulation of these channels by G proteins may provide neurons with mechanisms for precisely regulated exocytotic release. We have compared the characteristics of inhibition of  $\alpha_{1A}$  and  $\alpha_{1B}$  calcium currents by a tonically active G protein population in *Xenopus* oocytes, as well as after activation of a co-expressed  $M_2$  or  $M_3$  muscarinic receptor by 50  $\mu\text{M}$  acetylcholine. We have found for both the  $\alpha_{1A}$  and  $\alpha_{1B}$   $\text{Ca}^{2+}$  current, that upon removal of the initial application of acetylcholine there is a 2-3 fold rebound of current amplitude over the initial control levels. The rebound current then slowly returns towards the control current amplitude. This effect is seen with co-expression of either the  $M_2$  or  $M_3$  receptor. We conclude that the rebound is due to temporary loss of tonic inhibition based on 1) the loss of depolarizing prepulse facilitation at the peak of the rebound and 2) the correlation between the amplitude of rebound current and the amplitude of the current after treatment with either NEM or GDP $\beta$ S. Additionally, there was a significant difference in the voltage-dependence of G protein-mediated inhibition between  $\alpha_{1A}$  and  $\alpha_{1B}$  calcium currents. The reversal of G protein inhibition by depolarizing prepulses was much greater for the  $\alpha_{1B}$  channel. This may be due to a differential affinity of the G protein for the two  $\alpha_i$ 's at strongly depolarized potentials. The difference in the effects of depolarizing prepulses may indicate that the  $\alpha_{1B}$  channel plays a greater role in transmitter release in situations where high frequency trains of action potentials occur in the presynaptic neuron. In this situation the  $\alpha_{1B}$  current would more readily overcome the G protein inhibition. (This work supported by NIH grant AA05542 to S.N.T.)

## 140.14

RATE OF RE-INHIBITION OF  $\text{Ca}^{2+}$  CURRENT BY GTP- $\gamma$ -S AND 5-HT DIFFERS BEFORE AND AFTER STIMULATION OF PKC. Y. Chen and N.J. Penington\*. Pharmacol. SUNY (H.S.C.) Brooklyn N.Y. 11203.

We studied the rate of association of the G-protein subunit responsible for 5-HT-induced inhibition of current carried by  $\text{Ba}^{2+}$  in serotonergic neurons, with or without the phorbol ester PMA. We inserted a gap between the prepulse to +80 mV and the test pulse. At lower concentrations of 5-HT the re-inhibition of the  $\text{Ba}^{2+}$  current was slower (Elmslie and Jones 1994). The averaged data was fit by a single exponential of  $\tau = 56.8$  ms for 1  $\mu\text{M}$  and  $\tau = 124.9$  ms for 15 nM 5-HT. PMA (1  $\mu\text{M}$ ) reduced the percent inhibition of peak  $\text{Ba}^{2+}$  current by 5-HT (1  $\mu\text{M}$ ) and the rate of re-inhibition from 56.8 to 93.5 ms (n=7 cells). Swartz (1993) found that reversal of GTP- $\gamma$ -S effects by PMA was voltage dependent, and required a 200ms step to +80 mV every 5 seconds. In dorsal raphe (DR) neurons using this protocol, PMA did not reverse the effect of GTP- $\gamma$ -S. The average rate of re-inhibition by GTP- $\gamma$ -S had a  $\tau = 58.1$  ms (n=6) that did not change in PMA (1  $\mu\text{M}$ ). However, when PMA was added to the bath before going whole cell, GTP- $\gamma$ -S was significantly ( $p < .001$ ) less effective at slowing  $\text{Ba}^{2+}$  current activation (average facilitation=71%, reduced to 39% in PMA), and the rate of re-inhibition of the  $\text{Ba}^{2+}$  current was slowed ( $\tau = 88.5$  ms n=3). As PMA slowed the rate of re-inhibition by 5-HT, fewer activated G-protein subunits may be available to interact with the  $\text{Ca}^{2+}$  channel; appearing to rule out a direct action of PMA at that site. In DR cells, only prior PMA pretreatment can reduce the effects of GTP- $\gamma$ -S. This result suggests an action of PMA at the G-protein, but an effect on the receptor cannot be ruled out. Supported by an NIMH First award to N.J.P.

TYROSINE KINASES EXERT A TONIC CONTROL ON CALCIUM CHANNELS IN RAT HIPPOCAMPAL NEURONS. C. Rovira, B. Potier, Y. Lamour\*, INSERM U161, 2, rue d'Alésia, 75014 Paris France.

Protein phosphorylation is a major regulatory process of synaptic plasticity and calcium channels activity. Tyrosine kinases, present in large amounts in the hippocampus, play an important role in synaptic plasticity. They are activated by neurokinines and oncogene products which also cause a rise in intracellular calcium. High-Voltage-Activated calcium channels (HVA) of hippocampal pyramidal cells are substrate for serine/threonine protein kinases but it is not known whether they are modulated by tyrosine kinases. We studied the effects of genistein, a tyrosine kinase inhibitor, and orthovanadate, a tyrosine phosphatase inhibitor on HVA using whole-cell patch-clamp recordings of CA1 pyramidal neurons in hippocampal slices (300  $\mu\text{M}$  thick) from 14-20 day-old rats. Barium currents through HVA were evoked by regular (0.03 Hz) voltage steps to 0 mV from a holding potential of -60 mV. Intrapipette solution contained either BAPTA or EGTA as calcium buffers. Genistein (100  $\mu\text{M}$ ) and orthovanadate (300  $\mu\text{M}$ ) were bath applied. In the presence of intracellular BAPTA, genistein reduced the HVA by 24% (n=3) in an irreversible manner. The inactive analogue, genistin (100  $\mu\text{M}$ ), had no effect on the current amplitude. Orthovanadate reversibly increased the current amplitude by 21% (n=3). In the presence of intracellular EGTA the effect of orthovanadate was more pronounced and HVA were increased by 47% (n=2). These data show that tyrosine kinases tonically control the activity of HVA in rat hippocampal pyramidal cells.

## 140.17

**THE INHIBITORY EFFECT OF GENISTEIN ON THE ACTIVITY OF L-TYPE  $\text{Ca}^{2+}$  CHANNELS IS NOT EXERTED AT THE LEVEL OF  $\alpha_{1C}$  SUBUNIT.** A. Bassi, M. Cataldi, F. Hofmann, GF Di Renzo, M. Tagliatela\* and L. Annunziato. Section of Pharmacology, Dept. Neuroscience, School of Medicine, Federico II University of Naples, Via S. Pansini, 80131 Naples, ITALY and \*Institut für Pharmakologie und Toxikologie, Technische Universität München, München, GERMANY

Recently, we reported that tyrosine-kinase (TK) inhibitors reduce the activity of L-type  $\text{Ca}^{2+}$  channels in pituitary GH<sub>3</sub> cells (Cataldi et al. J. Biol. Chem. in press). In order to understand whether this modulation is exerted on the  $\alpha_{1C}$  subunit of this channel, expressed in GH<sub>3</sub> cells, the effect of genistein on  $[\text{Ca}^{2+}]_i$  response to  $\text{K}^+$  depolarization was studied by fura-2 single cell videomicroscopy in a cell clone stably transfected with the  $\alpha_{1C}$  subunit of L-type  $\text{Ca}^{2+}$  channels, the CHO  $\alpha_9$  cells (Bosse et al. EMBO J. 11: 2033;1992). In these cells, basal  $[\text{Ca}^{2+}]_i$  was stable ( $88.4 \pm 1$  nM) and no spontaneous  $[\text{Ca}^{2+}]_i$  oscillations were detected. When CHO  $\alpha_9$  cells were perfused with a depolarizing 55 mM  $\text{K}^+$  solution,  $[\text{Ca}^{2+}]_i$  increased by 44% over basal values. This  $\text{K}^+$ -induced  $[\text{Ca}^{2+}]_i$  increase was markedly lower than the ~400% increase observed in GH<sub>3</sub> cells. No increase in  $[\text{Ca}^{2+}]_i$  was observed when untransfected control CHO cells were exposed to high  $\text{K}^+$  concentrations. Interestingly, in CHO  $\alpha_9$  cells genistein (100  $\mu\text{M}$ ) did not exert any inhibitory action on the  $[\text{Ca}^{2+}]_i$  increase induced by 55 mM  $\text{K}^+$  (54% increase over basal values) whereas in GH<sub>3</sub> cells it blocked the  $\text{K}^+$ -induced  $[\text{Ca}^{2+}]_i$  increase by 50%. These data indicate that the effect of TK inhibitors is not exerted directly on the  $\alpha_{1C}$  subunit and that additional  $\text{Ca}^{2+}$ -channel subunits and/or modulatory proteins might be involved. (This study was supported by CNR and 40% and 60% MURST grants to L.A. and G.F.D.R.).

## 140.19

**ACTION POTENTIAL WAVEFORM-DEPENDENT MODULATION OF N-TYPE CALCIUM CHANNELS.** D. Park\* and K. Dunlap. Dept. of Neuroscience, Tufts Univ. Sch. of Med., Boston, MA 02111.

We studied GABA-mediated inhibition of N-type  $\text{Ca}^{2+}$  current evoked by command potentials derived from chick sensory neuron action potentials (APs). Voltage-dependent forms of inhibition were identified by their sensitivity to a conditioning depolarization (to 80 mV) preceding the AP. The relative proportions of voltage-dependent and -independent inhibition were studied as a function of variations in AP amplitude and duration of repolarization. As the peak of AP was decreased from 44 to -5 mV, control N current decreased by 40%. The total GABA-induced inhibition increased slightly from  $57 \pm 7$  to  $67 \pm 9$  % (mean  $\pm$  S.D.) with decrease in AP amplitude, but the proportion of voltage-dependent to -independent inhibition (~1.1) did not change significantly within the physiological range. With increases in the duration of repolarization (from 0.65 to 31.2 ms), peak N current decreased, but total charge entry through the N channel increased. GABA-induced inhibition also decreased from  $59 \pm 10$  to  $37 \pm 6$  %. This time-dependent relief of inhibition was associated entirely with the voltage-dependent component ( $33 \pm 6$  to  $16 \pm 2$  %); voltage-independent component was unchanged throughout the duration sequence. These results suggest that the extent and types of N current inhibition produced by GABA will vary under conditions of changing physiological stimuli and suggest a physiological relevance of multiple modulatory components.

## 140.18

**ROLE OF TYROSINE KINASES IN GABA<sub>B</sub>-MEDIATED INHIBITION OF N-TYPE CALCIUM CURRENT.** M. Diversé-Pierluissi\* and K. Dunlap. Departments of Physiology and Neuroscience, Tufts University School of Medicine, Boston, MA 02111.

In embryonic chick dorsal root ganglion neurons, N-type calcium current is inhibited by  $\gamma$ -aminobutyric acid (GABA) via GABA<sub>B</sub> receptors coupled to the GTP-binding protein  $\text{G}_0$ . The inhibition has two components, a voltage-dependent slowing of the activation kinetics and a voltage-independent steady-state inhibition. These inhibitory components do not appear to involve serine-threonine kinases. Here we present evidence that the steady-state inhibition induced by GABA requires the activation of tyrosine kinase. Genistein, a tyrosine kinase inhibitor, blocked the GABA-mediated steady-state inhibition. Its inactive analog, daidzein had no effect. A tyrosine kinase inhibitor containing amino acids 137-157 from the regulatory region of src kinase prevented the steady-state inhibition but not the kinetic slowing produced by GABA. This pathway is likely to be mediated by  $\alpha_0$  as a G $\beta\gamma$ -binding peptide (derived from the  $\beta\gamma$  binding domain of  $\beta\text{ARK}2$ ) failed to alter the GABA response. Recombinant  $\alpha_0$  will be used to directly test this idea. In contrast to other  $\alpha_0$ -mediated tyrosine kinase pathways (van Biesen et al. 1996, JBC 271, 1266-1269), this effect of GABA is unique in that it does not require protein kinase C.

## 140.20

**UP-REGULATION OF L-TYPE AND NON-L-, NON-N-TYPE CALCIUM CHANNELS BY PROTEIN KINASE C IN INSULIN-SECRETING RINm5F CELLS.** D. Platano, A. Pollo\*, E. Carbone and G. Aicardi\*. Dept. of Neuroscience, Univ. of Turin, Italy. (\*Dept. of Human and General Physiology, Univ. of Bologna, Italy).

We studied the effect of protein kinase C (PKC) inhibition and activation on voltage-dependent  $\text{Ca}^{2+}$  channels in rat insulinoma RINm5F cells. PKC down-regulation by chronic (24 h) treatment with the PKC activator phorbol 12-myristate 13-acetate (PMA, 1  $\mu\text{M}$ ) reduced by about 60% the  $\text{Ba}^{2+}$  currents through L-type and non-L-, non-N-type  $\text{Ca}^{2+}$  channels, indicating that PKC tonically up-regulates these channels under basal conditions. Consistently, PKC activation by acute PMA (30-300 nM) application caused only a modest increase (average 23%) of  $\text{Ba}^{2+}$  currents in a minority of cells (24%). L-type and non-L-, non-N-type channels were differently up-regulated by either basal or stimulated PKC activation. Acute cell exposure to PMA preferentially caused  $\text{Ba}^{2+}$  current increases in a voltage range in which L-type channels were mostly activated (-30 to -10 mV in 10 mM  $\text{Ba}^{2+}$ ), and the action was greatly reduced or even abolished by 5  $\mu\text{M}$  nifedipine. On the other hand, the non-L-, non-N-type channel was more effectively up-regulated under basal conditions since acute application of PKC activators caused only minor increases of the  $\omega$ -conotoxin-GVIA- and nifedipine-resistant current in a small percentage of cells. Unexpectedly, the run-up of  $\text{Ba}^{2+}$  currents during acute PMA application was followed by a progressive current decrease, which was also observed in isolation in another 24% of the cells. This action was abolished when 15 mM phosphocreatine was added to the internal perfusate, and could thus be ascribed to PKC-induced ATP depletion, rather than to a direct effect of PKC on  $\text{Ca}^{2+}$  channels. We also found that PKC-mediated phosphorylation is not involved in the voltage-dependent and voltage-independent G-protein mediated  $\alpha_2$ -noradrenergic modulation of  $\text{Ca}^{2+}$  channels in RINm5F cells (Aicardi et al., 1991, FEBS Letters 281:201-204).

## POTASSIUM CHANNELS: PHYSIOLOGY

## 141.1

**LESIONING OF THE DOPAMINERGIC NEURONS OF THE SUBSTANTIA NIGRA WITH 6-HYDROXY DOPAMINE RESULTS IN LOSS OF AN ATP-SENSITIVE  $\text{K}^+$  CHANNEL ACTIVATION.** A. McGroarty\* and S. A. Greenfield. University Dept. of Pharmacology, Mansfield Rd, Oxford, OX1 3QT, U.K.

A sub-population of neurons within the guinea-pig substantia nigra pars compacta (SNpc), which fire in a phasic fashion, show a large  $\text{K}^+$  conductance with the characteristics of an ATP sensitive  $\text{K}^+$  channel ( $\text{K}_{\text{ATP}}$ ). This channel can be activated by agents which decrease intracellular ATP levels, e.g. hypoxia and blocked by the  $\text{K}_{\text{ATP}}$  blocker tolbutamide (100-500  $\mu\text{M}$ ). We have previously investigated the effect of dopamine (DA) depleting agents on this hypoxic response using *in vitro* current clamp techniques. Previous data has shown that reserpine 6mg/kg i.p. (depletes DA storage), but not  $\alpha$ -methyl para tyrosine 200mg/kg i.p. (decreases DA synthesis) causes a loss of the response to a 5 min hypoxic insult. We now show that the DA neurotoxin 6-hydroxy dopamine (6-OHDA) has a comparable effect to reserpine. Unilateral lesions of the nigral DAergic neurons were produced by 6-OHDA injection into the medial forebrain bundle. Only the lesioned hemisphere showed loss of response. Cells recorded from this hemisphere showed a mean decrease in membrane resistance of merely  $17.99 \pm 4.44 \text{ M}\Omega$ , whereas the decrease seen in cells from the non-lesioned hemispheres was  $54.01 \pm 14.46 \text{ M}\Omega$  and indistinguishable from control ( $41.29 \pm 3.69 \text{ M}\Omega$ ) and sham operated cells ( $51.28 \pm 4.66 \text{ M}\Omega$ ). Values from 6-OHDA lesioned SNpc ( $n=7$ ) were significantly different from control ( $p<0.005$ ,  $n=5$ ), non-lesion ( $p<0.05$ ,  $n=8$ ) and sham values ( $p<0.001$ ,  $n=4$ , unpaired Student t-test). Extent of lesion was assessed using HPLC, or immunocytochemistry for tyrosine hydroxylase. We conclude that 2 quite different DA toxins cause very similar effects, strongly suggesting a link between DA systems and  $\text{K}_{\text{ATP}}$  channels in the SNpc. The results suggest that loss of DA storage could render this brain region vulnerable to further degeneration, due to the loss of  $\text{K}_{\text{ATP}}$  activity and hence of protection against metabolic insult. A.M. is supported by a Sandoz Pharma Scholarship.

## 141.2

**FUNCTIONAL ANALYSIS OF G PROTEIN  $\beta\gamma$  STRUCTURE.** B. Velimirovic\*Y. Li, D.E. Clapham and E.J. Neer. Dept. of Pharmacology, Mayo Foundation, Rochester, MN 55905 and Cardiovascular Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA 02115.

G protein  $\beta\gamma$  subunits ( $\text{G}\beta\gamma$ ) transduce signals from neurotransmitter and hormone receptors to both the classical G protein-coupled and the mitogen activated protein kinase pathways.  $\text{G}\beta\gamma$  acts directly to activate several effectors including inwardly rectifying potassium channels in cardiac ( $\text{I}_{\text{KACH}}$ ) and neuronal cells and phospholipase C  $\beta$  ( $\text{PLC}\beta$ ). Crystallographic analysis of  $\text{G}\beta\gamma$  reveal a propeller-like structure of  $\text{G}\beta$  with seven blades each made up of characteristic WD-40. In order to test what regions of the  $\text{G}\beta\gamma$  dimer are responsible for effector activation we introduced various mutations into the  $\text{G}\beta$  subunit and tested for its ability to activate recombinant  $\text{I}_{\text{KACH}}$ . Mutants were designed by substituting amino acid residues positioned on the outer surface of the dimer. The regions that were probed include the N-terminal part of  $\text{G}\beta$  contributing to the coiled-coil structure and parts of each of the seven propeller blades. This work was supported by AHA-Minnesota (BV), AHA (YL) and NIH grants (DEC and EJN).

## 141.3

**ABNORMAL CALCIUM HOMEOSTASIS IN CEREBELLAR GRANULE CELLS OF WEAVER MICE.** M.D. Womack\*, K. Thompson, E. Fanselow, G.J. Augustine and A.S. Peterson. Departments of Neurobiology and Genetics, Duke University, Durham, NC 27710. *Weaver* mice have a genetic defect that causes a drastic and selective loss of cerebellar granule cells within the first two postnatal weeks. This defect is caused by a point mutation in GIRK2, an inwardly rectifying, G-protein coupled potassium channel. We have used fluorescence imaging methods to test the hypothesis that the channel mutation leads to granule cell defects by altering the concentration of calcium ( $[Ca^{2+}]_i$ ) within granule cells.  $[Ca^{2+}]_i$  was measured in individual neurons within cerebellar slices from mice (postnatal day 4-5) via the calcium indicator fura-2. In wild type mice, the average  $[Ca^{2+}]_i$  in granule cells was about 60 nM. The average  $[Ca^{2+}]_i$  in *weaver* granule cells was nearly twice that of wild type granule cells. Elevated  $[Ca^{2+}]_i$  was observed only in *weaver* granule cells;  $[Ca^{2+}]_i$  in Purkinje cells of *weaver* mice was only slightly elevated over that of wild type Purkinje cells (also about 60 nM). This is consistent with the observation that Purkinje cells and other cerebellar neurons of *weaver* mice do not undergo the drastic cell loss characteristic of granule cells.  $[Ca^{2+}]_i$  in neurons of heterozygous mice was similar to that in neurons of homozygous *weaver* mice. Thus, at the time that cell death begins, *weaver* granule cells express both mutant GIRK2 channels and elevated  $[Ca^{2+}]_i$ . Because  $[Ca^{2+}]_i$  can regulate cell migration, neurite extension, and cell survival, elevated  $[Ca^{2+}]_i$  may comprise the link between mutant GIRK2 channels and granule cell defects in *weaver* mice. Supported by NS17771, NS34045 and the National Downs Syndrome Society. A.S.P. is a Sandoz Scholar.

**POTASSIUM SPATIAL BUFFER EXPLORED BY DIFFUSION ANALYSIS AND BARIUM IN NEOCORTEX.** W. Schwandt\*, C.-K. Tong and C. Nicholson. Dept. of Physiology & Neuroscience, NYU Medical Center, New York, NY 10016. Prominent among proposed mechanisms for brain potassium ( $K^+$ ) homeostasis is spatial buffering (SB) by glial cells (Orkand et al. 1966, *J. Neurophysiol.* 29: 788; Gardner-Medwin 1983, *J. Physiol.* 335: 393). The relative importance of SB for  $K^+$  homeostasis was assessed using diffusion analysis and applying  $Ba^{2+}$  (0.5 to 5 mM) to block the inward rectifier  $K^+$  channel ( $K_{IR}$ ) in rat neocortical slices. Slices were cut at 400  $\mu$ m from Sprague-Dawley rats.  $K^+$  and the extracellular probe tetramethylammonium ( $TMA^+$ ) were iontophoresed from microelectrodes and monitored about 100  $\mu$ m away with ion-selective microelectrodes. Diffusion analysis (Nicholson 1993, *J. Neurosci. Meth.* 48: 199) in 0.3% control agarose gel yielded the free diffusion coefficient  $D = 1.86 \pm 0.03 \times 10^{-5} \text{ cm}^2 \text{ s}^{-1}$  (mean  $\pm$  SEM, 34  $^{\circ}\text{C}$ ). In slices it provided extracellular volume fraction  $\alpha$ , apparent diffusion coefficient ( $D^*$ ), tortuosity factor  $\lambda = (D/D^*)^{0.5}$  and non-specific uptake  $k'$ . In normal conditions  $\lambda_{K^+} = 1.77 \pm 0.04$ . It was unaffected by  $Ba^{2+}$  and similar to that obtained with  $TMA^+$  ( $\lambda_{TMA^+} = 1.78 \pm 0.04$ ). In contrast, the apparent  $\alpha_{K^+} = 0.62 \pm 0.02$  declined to  $0.43 \pm 0.01$  with  $Ba^{2+}$  while  $\alpha_{TMA^+} = 0.22 \pm 0.01$ . Non-specific uptake was exceptionally low ( $k'_{K^+} = 7.24 \pm 2.5 \times 10^{-3} \text{ s}^{-1}$ ) and  $Ba^{2+}$  induced a rise to  $k'_{K^+} = 4.6 \pm 0.6 \times 10^{-3} \text{ s}^{-1}$ , matching  $k'_{TMA^+} = 4.9 \pm 0.9 \times 10^{-3} \text{ s}^{-1}$ .  $Ba^{2+}$  did not affect parameters measured with  $TMA^+$ . Surprisingly, despite the postulated presence of SB,  $K^+$  diffusion curves could be fitted accurately by standard diffusion theory. However,  $\alpha_{K^+}$  and  $k'_{K^+}$  deviated substantially from those obtained with  $TMA^+$  as shown in the *in vivo* rat (Nicholson et al. 1979, *Brain Res.* 169: 580-84). The threefold larger value of  $\alpha_{K^+}$ , compared to  $\alpha_{TMA^+}$ , suggests that  $\alpha_{K^+}$  is not measuring true extracellular space. Furthermore, although the presumed blocking of the  $K_{IR}$  reduced  $\alpha_{K^+}$ , it did not lead to normal values (i.e.  $\alpha_{TMA^+}$ ). Thus SB seems to contribute to  $K^+$  homeostasis but is apparently not the only mechanism involved. Regarding  $k'$  it was striking again that SB, a mechanism based on  $K^+$  entering glial cells, was not characterized by a high uptake. But  $k'_{K^+}$  did increase to values comparable to  $k'_{TMA^+}$  when the  $K_{IR}$  was presumably blocked. Finally we note that  $\lambda_{K^+}$  was similar to  $\lambda_{TMA^+}$  and unchanged by  $Ba^{2+}$ . These paradoxical findings emphasize the need for detailed modeling of these SB experiments. Supported by NIH Grant NS 28642.

**CONTRIBUTIONS OF THREE POTASSIUM CURRENTS TO FREQUENCY-DEPENDENT SPIKE BROADENING OF APLYSIA R20 NEURONS.** M. Ma\* and J. Koester. Center for Neurobiology and Behavior, Columbia University, N.Y., NY 10032. The R20 neurons of *Aplysia* exhibit frequency-dependent spike broadening. We had previously identified three  $K^+$  currents that mediate action potential repolarization: a transient A-type  $K^+$  current ( $I_{Adepol}$ ), a delayed rectifier current ( $I_{K-v}$ ), and a  $Ca^{2+}$ -sensitive  $K^+$  current ( $I_{K-Ca}$ ). A major constraint in the earlier study was the lack of completely selective blockers for  $I_{Adepol}$  and  $I_{K-v}$ , resulting in an inability to assess directly the effects of their activation and inactivation on spike broadening. In the present study, the dynamic clamp technique, which employs computer simulation to inject biologically realistic currents into a cell under current clamp conditions, was used either to block  $I_{Adepol}$  or  $I_{K-v}$  or to modify their inactivation properties. The data lead to the following hypothesis for the mechanism of spike broadening in the R20 cells. As the spike train progresses, the primary responsibility for spike repolarization gradually shifts from  $I_{Adepol}$  to  $I_{K-v}$  to  $I_{K-Ca}$ . This sequence can be explained on the basis of the relative rates of activation and inactivation of each current with respect to the constantly changing spike durations, the cumulative inactivation of  $I_{Adepol}$  and  $I_{K-v}$ , and the progressive potentiation of  $I_{K-Ca}$ . Positive feedback interactions between spike broadening and inactivation contribute to the cumulative inactivation of both  $I_{Adepol}$  and  $I_{K-v}$ . The data also illustrate that when two or more currents have similar driving forces and partially overlapping activation characteristics, selectively blocking one current under current clamp conditions can lead to a significant underestimate of its normal physiological importance, due to the interplay of different currents via their effects on spike shape. (This work was supported by NIH grant NS14385.)

**EFFECTS OF SHAKER K CHANNEL (Kv1.1)-NULL MUTATION ON CEREBELLAR PHYSIOLOGY IN MICE.** C.L. Zhang\*, A. Messing, and S.Y. Chiu. Dept. of Neurophysiology and Vet. Medicine, Univ. of Wisconsin, Madison, WI 53706. In the cerebellum, the output of the Purkinje cells is subjected to inhibitory control by basket cells that release GABA onto the Purkinje cell body. The mechanism that regulates this release is unknown, but likely involves voltage-gated  $K^+$  channels. Immunohistochemistry shows that Kv1.1 & Kv1.2, two Shaker  $K^+$  channels, are co-localized to the basket-cell-Purkinje-cell junction. In this study, we used Kv1.1-null mutant mice to assess the role of Kv1.1 (as well as the compensatory role of Kv1.2) in regulating the tonic inhibition of Purkinje cells. Whole-cell patch clamp recordings of spontaneous inhibitory postsynaptic currents (IPSCs) were made from Purkinje cells in thin cerebellar slices from P10-P13 Kv1.1-null mutants using wild type littermates as control. In normal saline solutions, mutation caused a specific increase in the frequency (~2 fold) but not the amplitude of IPSCs. Mutation had no effects on the IPSCs measured in TTX. The IPSCs in the mutant were blocked by bicuculline (10  $\mu$ M) but not affected by CNQX (10  $\mu$ M) and APV (100  $\mu$ M). In wild type slices, Shaker channel blockers 4-AP (0.3 mM), TEA (0.3 mM) and DTX (0.8, 8 nM) mimicked null-mutations by causing a differential increase of frequency over amplitude of the IPSCs. The role of residual Shaker  $K^+$  channels (like Kv1.2) in modulating IPSCs in the mutant was investigated by applying these blockers to mutant slices. Interestingly, TEA (0.3 mM) and DTX (0.8 nM) were without effects on the mutant IPSCs. Granted that Kv1.2 is more sensitive than Kv1.1 to these blockers at these concentrations, a negligible role of Kv1.2 in the mutant is suggested. We conclude that Kv1.1 plays an important role in regulating spontaneous GABA release onto Purkinje cells, with limited ability from a closely related member Kv1.2 to compensate for the loss of function. Supported by NIH grant 23375.

## 141.6

**ELECTROPHYSIOLOGICAL PROPERTIES OF RAT MEDIAN RAPHE NEURONS.** Y. Nishimura\*, Y. Yoshioka, K. Ito, H. Kitagawa, M. Lin, T. Asahara and T. Yamamoto. Dept. Physiol. Sch. Med. Mie Univ. Tsu, Mie 514 Japan. Electrophysiological properties of the median raphe neurons were investigated by intracellular recording and whole-cell patch clamp techniques. Slices of 400  $\mu$ m for intracellular recording and of 150-200  $\mu$ m for whole-cell patch clamp were made from the young rat (2 - 21 d. o.). The intracellular recording was performed using micro-pipet filled with Biocytin or Lucifer yellow. The whole-cell patch clamp was employed after cleaning the surface of the soma. TEA (20 mM) prolonged the action potential in the depolarized membrane potential, though it affected the spike duration little in the resting membrane potential. Action potential was prolonged by 4-AP (300  $\mu$ M) in the resting membrane potential. Firing patterns induced by long outward current (500ms duration) were grouped into regular spiking and phasic spiking.  $Ca^{2+}$  channel blockers (replacement of  $Ca^{2+}$  with  $Co^{2+}$ ,  $Ni^{2+}$ ) increased the firing rate in the regular spiking cells but not in the phasic spiking cells. These agents did not alter the phasic spiking patterns. The phasic spiking patterns, however, were changed into the regular spiking patterns by 4-AP. The 4-AP sensitive outward current was transient and was easily inactivated by depolarizing prepulses. The TEA-sensitive outward current showed weak inactivation. The outward current blocked by  $Ca^{2+}$  channel blockers was persistent. In the median raphe neurons the spike repolarization was controlled by mainly 4-AP sensitive current. The firing rate in the regular spiking cells was controlled by  $Ca^{2+}$ -mediated  $K^+$  current. This study was supported by Ministry of Education, Science and Culture of Japan.

**OUTWARD POTASSIUM CURRENTS OF MAGNOCELLULAR NEUROSECRETORY CELLS ISOLATED FROM THE SUPRAOPTIC NUCLEUS OF THE ADULT GUINEA PIG.** M. D. Hlubek\* and P. Cobbett. Dept. of Pharmacology and Toxicology and The Neuroscience Program, Michigan State University, East Lansing, MI 48824. A necessary prerequisite to understanding the mechanisms which underlie firing patterns of oxytocinergic and vasopressinergic magnocellular neurosecretory cells (MNCs) is a thorough characterization of the specific ionic conductances present in the membrane of these cells. Using whole-cell patch clamp techniques, we have identified four different outward  $K^+$  currents in MNCs acutely isolated from the SON of the adult guinea pig. Depolarizing steps from a holding potential ( $V_h$ ) of -40 mV produced a long-lasting, slowly-activating  $K^+$  current which activated at test potentials more positive than -20 mV. This voltage-activated delayed  $K^+$  current was preferentially blocked by extracellular tetraethylammonium (TEA). In addition, extracellular  $Cd^{2+}$  significantly reduced this sustained current, suggesting the presence of a long-lasting  $Ca^{2+}$ -dependent  $K^+$  current. An additional, more rapidly activating and decaying outward  $K^+$  current which activated at test potentials more positive than -60 mV was recorded during depolarizing steps from  $V_h$  -90 mV. This voltage-activated transient  $K^+$  current was preferentially blocked by extracellular 4-aminopyridine (4-AP). In many recordings from MNCs, a transient, 4-AP-insensitive outward current was evoked by depolarizing voltage steps from  $V_h$  -40 mV. This transient  $K^+$  current was abolished by extracellular  $Cd^{2+}$ , suggesting that it is a transient  $Ca^{2+}$ -dependent  $K^+$  current. Supported by NINDS (NS28206) and Neuroscience Training Grant NINDS (NS07279).

**GATING KINETICS OF  $D_2$  DOPAMINE RECEPTOR-MODULATED  $K^+$  CHANNELS ON RAT STRIATAL NEURONS.** Gabriela J. Greif<sup>1</sup> and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., and <sup>1</sup>Dept. Neurobiology, Harvard Medical School, Boston, MA 02115.

We used cell-attached patch-clamp recording to characterize the kinetics of activation of an 85 pS inwardly rectifying  $K^+$  channel by  $D_2$ -like dopamine receptors on freshly dissociated rat caudate-putamen neurons. Previous studies indicated that channel activation has an absolute requirement for the presence of  $D_2$ -like dopamine agonists, and occurs in a membrane-delimited fashion. At concentrations near the dissociation constant (1-10 nM), the  $D_2$  agonist quinpirole elicited isolated brief openings and short bursts, while increasing the quinpirole concentration to 10  $\mu$ M markedly prolonged burst durations. Within a burst, there was a single population of open dwell times, which increased in duration as a function of quinpirole concentration, and two populations of closed dwell times, which were insensitive to agonist concentration. Similar results were obtained with a different agonist, 7-OH-DPAT, and with the G-protein activating peptide mastoparan, but not when the channel was metabolically activated independently of the receptor by rotenone. These results suggest that dopamine receptor-dependent activation of this channel stabilizes a burst-opening state. (Supported by NIH grant MH-48545.)

**ROLES OF VOLTAGE-DEPENDENT TRANSIENT POTASSIUM CURRENT IN THE EXCITABILITY OF SUPRACHIASMATIC NUCLEUS NEURONS.** Rong-Chi Huang. Department of Physiology, Chang Gung College of Medicine and Technology, Taiwan, ROC

The purpose of this study is to investigate the physiological roles of a voltage-dependent transient potassium current ( $I_A$ ) in electrical excitability of suprachiasmatic nucleus (SCN) neurons. Experiments were performed on isolated hypothalamic slices using the extracellular recording technique, and neuronal excitability of SCN neurons was examined by evoking population action potentials (PAP) with a bipolar electrode located at the optic chiasm near SCN.

Addition of TTX and total substitution of choline<sup>+</sup> for Na<sup>+</sup> completely eliminated the evoked PAP, indicating that the PAP is due to activation of the voltage-dependent Na<sup>+</sup> current in these neurons. Double pulses stimulation suppressed the amplitude of the second PAP as opposed to that of the first control PAP, and the degree of suppression decreased with longer interpulse intervals. Recovery from suppression was complete in about 1 second, similar to the time course of recovery from Na<sup>+</sup> current inactivation. Addition of 1 mM 4-aminopyridine (4-AP) decreased the amplitude and slope of PAP, and markedly prolonged the duration of PAP. Furthermore, 4-AP greatly enhanced the double pulse suppression at short interpulse intervals. The results indicate that the 4-AP-sensitive  $I_A$  current participates in setting the duration of action potential and more importantly in regulating firing rate of SCN neurons. This work was supported by Chang Gung Medical Research Foundation (CMRP506).

**EVIDENCE THAT SMOCS RESULT FROM THE ACTIVATION OF  $K_{Ca}$  CHANNELS BY CALCIUM RELEASED FROM RYANODINE SENSITIVE CALCIUM STORES.** L.A. Merriam, J.C. Hardwick and R.L. Parsons. Dept. of Anatomy & Neurobiology, Univ. of VT., Burlington, VT 05405.

Spontaneous miniature outward currents (SMOCs) are thought to result from the release of  $Ca^{2+}$  from intracellular stores, which then activates clusters of large conductance  $K_{Ca}$  channels. In vascular smooth muscle cells, the  $Ca^{2+}$  is released from a ryanodine-sensitive store located close to the sarcolemma. Less is known about the  $Ca^{2+}$  store responsible for these transient currents in neurons. We have extended the previous observations of Satin and Adams (1987) to test if the  $Ca^{2+}$  which initiates SMOCs is released from an intracellular ryanodine-sensitive  $Ca^{2+}$  store. We recorded SMOCs from dissociated mudpuppy parasympathetic postganglionic neurons using the perforated patch technique in the presence of 200  $\mu$ M  $CdCl_2$  to block voltage-dependent  $Ca^{2+}$  influx. At -10 mV, ryanodine (10 or 50  $\mu$ M) caused an increase in SMOC frequency followed by a concentration dependent elimination of SMOC activity as  $Ca^{2+}$  stores became depleted. During exposure to ryanodine, SMOC configuration changed as would be expected from ryanodine locking the  $Ca^{2+}$ -induced release channel in an open, subconductance state. Thapsigargin (100 nM), which inhibits endoplasmic reticulum  $Ca^{2+}$ -ATPase, also eliminated SMOCs. Exposure to low concentrations of caffeine (<3 mM) increased SMOC frequency; following multiple challenges with 30 mM caffeine, SMOCs were eliminated. These results suggest that neuronal SMOCs result from  $Ca^{2+}$  released from ryanodine-sensitive stores. Using immunofluorescence microscopy, we also demonstrated ryanodine receptor-immunoreactivity in these neurons. Supported by NS 23978.

**POTASSIUM CURRENTS IN NEURONS FROM THE VENTRAL LATERAL MEDULLA (VLM) OF RATS.** J.W. Peters\*, J. S. Allard, and C.O. Trough. Dept. of Physiology & Biophysics, Howard Univ., Wash., DC 20059.

Central respiratory  $CO_2$ /pH chemosensitivity has been described on the ventrolateral brainstem (VLM) surface. These studies were undertaken to identify  $K^+$  currents present in developing VLM neurons. Cells were isolated for whole-cell patch-clamp recording, without the use of enzymes, by placing the surface of a tissue section in a petri dish coated with high molecular weight poly-lysine. The tissue slice was removed after 30-180 minutes and cells adhering to the coating were cultured overnight. The reversal potential was  $-33 \pm 3.3$  mV (mean  $\pm$  SEM; N=16); increasing  $K_o$  by 35 mM resulted in a depolarizing shift of  $15.8 \pm 1.7$  mV (N=13). Preliminary results indicate a variety of  $K^+$  channel types and combinations that are present in these neurons. Inwardly rectifying  $K^+$  channels were found in 7 of 16 cells tested. A slowly inactivating potassium current ( $I_{Ks}$ ) was found in 12 of 15 cells examined. JWP and JSA were supported by ONR Grant # N00014-94-1-0523.

**CARDIAC CELLS ALTER THE EXPRESSION OF POTASSIUM CURRENT IN CHICK SYMPATHETIC NEURONS.** D.A. Przywara\* and A.R. Wakade. Department of Pharmacology, Wayne State University, Detroit, MI 48201.

The pharmacologic behavior of sympathetic neurons (SN) in culture is different from their counterparts growing in the body. The  $K^+$ -channel antagonist tetraethylammonium (TEA) has little effect on evoked release of [<sup>3</sup>H]norepinephrine ([<sup>3</sup>H]NE) from cultured SN, but acts in the expected manner seen in mature neuroeffector organs when SN are co-cultured with heart cells (Wakade et al., J.Physiol. 488, 1995). We examined the effects of several  $K^+$ -channel antagonists in SN grown alone and with cardiac cells. Action potentials (AP) of SN and co-cultured SN had similar shape and duration ( $3.7 \pm 1$  and  $3.0 \pm 0.4$  ms at 50% repolarization). TEA caused 8 to 10 fold increase in AP duration (APD) in co-cultured SN but had little effect on SN alone. 4-aminopyridine (4-AP, 1 mM) which blocks  $I_A$  in SN had little effect on APD in mono or co-cultured SN, suggesting that differential expression of  $I_A$  was not involved. Charybdotoxin caused a small increase in evoked [<sup>3</sup>H]NE release under both culture conditions and produced similar block of isolated, voltage-clamped  $K^+$  current. Outward current in the presence or absence of  $Ca^{2+}$  also showed similar density in SN alone or with cardiac cells, suggesting that  $Ca^{2+}$ -dependent  $K^+$  current was not differentially expressed. However,  $Ca^{2+}$  current density was significantly lower in SN plus cardiac cells compared to SN alone ( $0.19 \pm 0.03$  and  $0.61 \pm 0.13$  pA  $\mu m^{-2}$ , respectively) and when [ $Ca^{2+}$ ]<sub>o</sub> was buffered to  $\leq 100$  nM in SN, TEA increased APD 8 to 10 fold. These data support the conclusion that cardiac cells control TEA sensitivity of SN  $K^+$  channels via altered voltage-dependent  $Ca^{2+}$  entry.

**LOW POTASSIUM SALT BRIDGES RECTIFY ANOMALOUS RESULTS.** G.G. Schofield, J.T. Weber\* and M.J. Mason. Depts of Physiology and Anatomy, Tulane University Medical School, New Orleans, LA 70112.

During initial patch-clamp investigations of possible stretch-induced activation of rat basophilic leukemia cells, we employed drug application from a large diameter micropipette to single cells in a static bath. To reduce possible junction potential errors we grounded the preparation via 3 M KCl salt bridge. Under these conditions, application of control solution from either glass or polyethylene micropipettes induced a dramatic reduction of whole-cell inward rectifier ( $I_{K_{in}}$ ) currents (see figure). This decrease in the amplitude of  $I_{K_{in}}$  resembled channel block by a contaminant released from the micropipette. However, a concomitant negative shift of the reversal potential of the ramp current suggested an alteration of the [ $K^+$ ] bathing the cell. Flame photometry confirmed  $K^+$  accumulation in the chamber over a 15 min period from 3.0 mM to 7.4 mM (n = 4). Raising extracellular [ $Ca^{2+}$ ] from 1 to 5 mM also induced a dramatic decrease in the amplitude of  $I_{K_{in}}$ , but without a shift of reversal potential. These data demonstrate the extreme sensitivity of  $I_{K_{in}}$  to change in external [ $K^+$ ] and an unexpected sensitivity of  $I_{K_{in}}$  to external [ $Ca^{2+}$ ]. Thus, a small junction potential (< 5 mV) from a low  $K^+$ -containing salt bridge may be preferable to the effects of uncontrolled accumulation of external [ $K^+$ ] which can occur when using a 3 M KCl salt bridge to obviate junction potential correction. Supported by LEQSF.

## 141.15

**Ca<sup>2+</sup>-ACTIVATED K<sup>+</sup> CHANNELS OF SYMPATHETIC NEURONS FROM ADULT HYPERTENSIVE RATS.** Walter P. Robertson and Geoffrey G. Schofield, \*Dept. of Physiology, Tulane University Medical Center, New Orleans, LA 70112.

Essential hypertension has been linked with hyperexcitability of sympathetic neurons. Since K<sub>Ca</sub> channels of adult rat sympathetic neurons have not been characterized, we examined if altered K<sub>Ca</sub> channel properties underlie neuronal hyperexcitability in hypertensive rats (SHR). In excised patches bathed in symmetrical 130 mM K<sup>+</sup>, single K<sub>Ca</sub> channel I-V relationships were linear between -50 and +50 mV and reversed near 0 mV. Mean slope conductances were 126±4 pS for SHR (n=6) and 124±16 pS for normotensive WKY neurons (n=4). With 0.1 μM cytoplasmic [Ca<sup>2+</sup>], channels activated positive to -50 mV and reached half maximal P<sub>o</sub> near -20 mV in both rat strains. Preliminary estimates of Ca<sup>2+</sup> binding affinities of K<sub>Ca</sub> channels were 630 nM and 203 nM at -50 and -30 mV, respectively, for SHR (see figure), and 643 nM and 233 nM in WKY neurons. Based on these data, altered steady-state properties of K<sub>Ca</sub> channels cannot explain sympathetic neuron hyperexcitability in the SHR.

Figure. Calcium dependence of P<sub>o</sub> for a K<sub>Ca</sub> channel from an SHR. P<sub>o</sub> calculated as the fraction of time spent in the open state at -50 mV (circles) and -30 mV (squares) is plotted against cytoplasmic [Ca<sup>2+</sup>]. Solid lines are least-squares fits of the data to a single site binding isotherm. The apparent affinity of K<sub>Ca</sub> channels for Ca<sup>2+</sup> increases with depolarization.

Supported by NIH and LEQSF.

## 141.17

**EFFECTS OF INTRACELLULAR CALCIUM CHELATION ON THE TRANSIENT POTASSIUM CHANNEL (K<sub>A</sub>) IN NEOCORTICAL PYRAMIDAL NEURONS** L. Jiang<sup>1</sup> and J. Kang<sup>2</sup>, <sup>1</sup>Department of Hepatitis Clinic, People Hospital of Liaoning, Shenyang, Liaoning 110015, P.R. China and <sup>2</sup>Department of Cell Biology and Anatomy, New York Medical College, Basic Science Building, Valhalla, NY 10595

To investigate influence of intracellular Ca<sup>2+</sup> on the K<sup>+</sup> channel for A-current (K<sub>A</sub>) during neuronal spiking, single large layer V pyramidal neurons in visualized neocortical slices were patched by two electrodes: a whole-cell current clamp and a cell-attached patch. Electrodes for whole-cell recordings were filled with K-MeSO<sub>4</sub> plus a Ca<sup>2+</sup> chelator, 1,2-bis (2-aminophenoxy) ethane-N,N,N',N'-tetraacetic acid (BAPTA, 10 mM). Before membranes in whole-cell electrodes were ruptured, spikes were induced by depolarization pulses delivered to whole-cell electrodes. Activities of K<sub>A</sub> channels and a small conductance Ca<sup>2+</sup>-activated K<sup>+</sup> channel (SK<sub>Ca</sub>) were observed following spikes in cell-attached patch recordings. K<sub>A</sub> channel openings immediately followed each spike and contributed to repolarization and the fast afterhyperpolarization (AHP). After breaking the membrane in whole-cell patches, cell-attached patch recordings showed an inhibition of SK<sub>Ca</sub> channel activity and an enhancement of K<sub>A</sub> channel activity by intracellular BAPTA. Meanwhile, whole-cell current clamp recordings showed that spiking adaptation was inhibited and the fast AHP was increased by intracellular BAPTA. The results indicated that depolarization-induced increase in intracellular Ca<sup>2+</sup> levels not only activated SK<sub>Ca</sub> channels but also inhibited K<sub>A</sub> channel activity. The inhibitory effect of intracellular Ca<sup>2+</sup> on K<sub>A</sub> channels may play roles in neuronal bursting properties.

## 141.19

**CHARACTERIZATION OF FAST AND SLOW POTASSIUM CURRENTS IN THE CELL BODIES OF IDENTIFIED CUTANEOUS AFFERENT DORSAL ROOT GANGLION (DRG) NEURONS.** B. Everitt<sup>1</sup>, M. A. Rizzo and J. D. Kocsis, Dept. of Neurology, Yale Univ. Med. Sch., New Haven, CT. 06510, and Neuroscience Res. Ctr., VAMC, West Haven, CT. 06516.

The present study was undertaken to characterize K<sup>+</sup> currents on the cell bodies of DRG neurons as a precursive examination of their injury-induced plasticity. DRG neurons from adult female Wistar rats were dissociated and short-term cultured for examination 16-24 hrs. later. Whole cell patch clamp recordings were obtained from medium-size (39-49 μm diameter) cells, retrogradely labelled with Fluorogold. K<sup>+</sup> currents were isolated by blocking Na<sup>+</sup> and Ca<sup>2+</sup> currents with appropriate ion replacement and channel blockers. Stable recordings of up to 50 min were obtained at a holding potential of -80 mV. Depolarization-activated K<sup>+</sup> currents were routinely recorded during 300 ms voltage steps to potentials positive to -40 mV, from conditioning potentials ranging from -120 to -40 mV. The neurons displayed complex K<sup>+</sup> currents composed of distinct kinetic and pharmacological properties. Separation of these components was achieved on the basis of sensitivities to 4-aminopyridine (4-AP), dendrotoxin (DTx), and by the response to variation in conditioning voltage. Concentrations as low as 10 μM 4-AP could be seen to reduce peak current by as much as 70%, with a recovery up to 85% of the total peak after 15 min wash. With subtraction of traces, recorded before and after 10 μM 4-AP, a rapidly activating K<sup>+</sup>-current, sensitive to low doses of 4-AP, was revealed. High concentrations of 4-AP (6mM) were seen to extinguish all inactivating current, thus isolating I<sub>K</sub>. Perfusion with 1 μM DTx blocked slowly inactivating transient current (I<sub>h</sub>) while sparing most of the initial fast transient current (I<sub>A</sub>). A reversible effect of DTx was to significantly reduce input resistance. At least three components of K<sup>+</sup> current, in varying ratios, were defined in identified cutaneous afferent DRG neurons. Supported in part by the VA and the NIH.

## 141.16

**BK CHANNELS IN EMBRYONIC RAT NEUROEPITHELIUM ARE STRETCH SENSITIVE.** GD Lange<sup>2</sup>, JL Barker<sup>1</sup> and J-M Mienville<sup>1</sup>, <sup>1</sup>Lab of Neurophysiology & <sup>2</sup>Instrumentation and Computer Section, NINDS, NIH, Bethesda, MD 20892.

The mechanosensitive properties of large-conductance Ca<sup>2+</sup>-activated K<sup>+</sup> (BK) channels from embryonic rat neuroepithelium were investigated with the cell-attached and inside-out configurations of the patch-clamp technique. The channels were activated in both recording configurations by negative pressures applied to the patch electrode, but reversal of the effect was total and immediate in inside-out patches whereas it was incomplete and delayed in on-cell patches. This mechanosensitivity was not mediated by Ca<sup>2+</sup> ions or fatty acids, suggesting that it is an intrinsic property of these channels. Cytochalasin B did not affect mechanosensitivity in on-cell patches but increased it in inside-out patches. Kinetic studies showed that stretch increased the mean open time of the channels and decreased the slowest time constant of their closed-time distributions. The present as well as previous results suggest complex interactions between embryonic BK channels and their membranous and submembranous environment.

## 141.18

**PATCH-CLAMP RECORDINGS OF AN OUTWARD K<sup>+</sup> CURRENT IN RETINAL GLIAL CELLS.** T. Pannicke and W. Reichelt\*, Paul-Flechsig-Inst. Brain Res., University of Leipzig, 04109 Leipzig, Germany.

We performed cell-attached patch-clamp recordings from isolated, non-cultivated retinal (Müller) glial cells from guinea pigs. Bathing solution contained 3 mM K<sup>+</sup>, whereas the pipette solution contained 0.5 to 20 mM K<sup>+</sup>.

Recordings were performed from 330 patches, but only 23.6% of the patches displayed a current at depolarizing voltage steps, whereas hyperpolarizing voltage steps did never evoke any current. The current was exclusively macroscopic, with an amplitude of 19.1±12.8 pA at a 90 mV step, except once, when unitary current transients were found with a conductance of 4.8 pS. An average (51 trials) of the single channel traces, containing transients from 4 channels, resembled the macroscopic currents found in the other patches. Those had a time-to-peak of 15.2±6.7 ms during an 80 mV step and 6.3±2.6 ms during an 150 mV step, and were partly inactivating to about one third of their peak amplitude. The potentials for half-maximal steady-state activation and inactivation were +16.6 mV and -15.5 mV, respectively. Steady-state inactivation was incomplete over the tested voltage range of up to +30 mV. During the recording procedure the currents were running down and disappeared after a period of several minutes.

The current features are characteristic for a delayed rectifier channel, which is partly inactivating due to the activity of a β-subunit. Obviously, the channels are arranged in small clusters all along the cell membrane. At present the function of these channels remains elusive.

POTENTIATION OF CLONED  $\text{Ca}^{2+}$ -ACTIVATED  $\text{K}^+$  (mSLO) CHANNELS BY A SERIES OF N-ALKANOLS DEMONSTRATES CUTOFF. B. Chu\* and S. N. Treistman, Department of Pharmacology and Molecular Toxicology and Program in Neuroscience, University of Massachusetts Medical Center, Worcester, MA, 01655.

Using electrophysiological methods, our laboratory has shown that EtOH (10-100mM) rapidly and reversibly potentiates the activity of both native neurohypophyseal and cloned dSlo and mSlo  $\text{Ca}^{2+}$ -activated  $\text{K}^+$  (BK) channels. Cutoff describes the phenomenon where in a homologous series of anesthetic agents, one observes a direct correlation between potency and hydrophobicity until a sudden loss of anesthetic efficacy among higher members occurs in spite of high lipid solubility. It has been argued that cutoff results from the inability of large hydrophobic alcohols to interact with hydrophobic pockets on channel proteins. To determine whether the potentiation of mSlo channels by alcohols displays a cutoff, we measured the degree of potentiation by a series of n-alkanols of mSlo BK channels expressed in *Xenopus* oocytes. Currents were elicited by stepping the voltage from -80mV to +50mV in the two electrode voltage clamp configuration. Ethanol, butanol, hexanol, and heptanol rapidly and reversibly enhanced the current. Nonanol (1-3mM) did not significantly potentiate the current. Interestingly, the degree of potentiation by ethanol was less than that seen in excised patches. Ethanol (8, 25, 50, 100, 200mM) enhanced the current by 9, 12, 17, 36, and 66% respectively; butanol (5, 10, 20, 30mM) by 17, 31, 59, and 71%; hexanol (0.5, 1, 2, 3mM) by 19, 29, 46, and 45%; and heptanol (0.25, 0.5, 1, 2, 3mM) by 16, 20, 27, 33, and 62%. 50mM ethanol was previously shown by our laboratory to potentiate mSlo channels expressed in *Xenopus* oocytes by ~100% in excised patches. Our results indicate that 1) cloned mSlo BK channels demonstrate a cutoff and 2) intracellular modulators such as kinases or G-proteins may modulate the sensitivity of mSlo BK channels to ethanol. Supported by NIH grant AA08003.

COPPER INDUCES CALCIUM-DEPENDENT NEUROTRANSMITTER RELEASE FROM CATECHOLAMINERGIC NERVE TERMINALS. J.K.T. Wang\*, Department of Neuroscience, Tufts University School of Medicine, Boston, MA 02111.

Rat hippocampal or striatal synaptosomes, preloaded with  $^3\text{H}$ -norepinephrine (NE) or  $^3\text{H}$ -dopamine, respectively, were exposed to 3-100  $\mu\text{M}$   $\text{Cu}^{2+}$  under superfusion.  $\text{Cu}^{2+}$  caused the release of labeled transmitters in a concentration- and time-dependent manner. At 100  $\mu\text{M}$   $\text{Cu}^{2+}$ , transmitter release rises at 1 min, peaks at 2 min, and is sustained over a period of 5 min. This time course is slower than that of  $\text{K}^+$ -depolarization or that of the  $\text{K}^+$  channel blocker 4-aminopyridine (4AP), but the amount of release induced by  $\text{Cu}^{2+}$  over the 5 min period is similar to that induced by  $\text{K}^+$  or 4AP.  $\text{Zn}^{2+}$  and  $\text{Ni}^{2+}$  (0.1-1mM), but not  $\text{Cd}^{2+}$  or  $\text{Co}^{2+}$ , also induced transmitter release, but their effects were much smaller than that of  $\text{Cu}^{2+}$ . The effect of  $\text{Cu}^{2+}$  is dependent on extracellular  $\text{Ca}^{2+}$  and  $\text{Na}^+$ , since it was eliminated by omitting  $\text{Ca}^{2+}$  from the superfusion buffer, or by substituting  $\text{Na}^+$  with choline Cl. Moreover, 3  $\mu\text{M}$  TTX also inhibited the  $\text{Cu}^{2+}$ -induced NE release. The effect of 4AP is similarly dependent on extracellular  $\text{Ca}^{2+}$  and  $\text{Na}^+$ . These results suggest that  $\text{Cu}^{2+}$  and certain divalent heavy metals may block  $\text{K}^+$  channels in catecholaminergic nerve terminals, leading to opening of voltage-gated  $\text{Na}^+$  channels, membrane depolarization, opening of voltage-gated  $\text{Ca}^{2+}$  channels, and transmitter release. These events, and the possible resultant changes in neuronal functions, may occur *in vivo* when the levels of heavy metals are modified by physiological or pathological processes. Supported by grant R01NS0590 from the NIH.

## 142.5

VOLTAGE AND CALCIUM DEPENDENCE OF PAXILLINE BLOCK IN NEURONS AND ENDOCRINE CELL LINES. D.E. Johnson\*, H. Wieland, S. Terhart-Krabbe, M. Neuberg, R.T. McCarthy\* and R. Wittka, \*Institute for Dementia Res., Bayer Corp., West Haven, CT 06516 and Institute for Neurobiology, Troponwerke GmbH & Co. KG, D-51063 Koeln, F.R.G.

The indole alkaloid fungal mycotoxin paxilline was examined for effects on large conductance calcium activated potassium channels (BK) in a variety of cell types. In an *in vitro* slice preparation of rat cortical neurons, paxilline (100 nM) markedly broadened the action potential duration (APD). The mechanism of toxin block was studied in  $\text{GH}_3$  and undifferentiated PC12 cell lines using whole cell, cell attached and excised patch recording techniques. Results demonstrated that paxilline was a potent blocker of BK channels in both cell lines. Furthermore, paxilline inhibition of BK current was both calcium and voltage dependent. Paxilline block displayed a unique voltage dependence such that current inhibition was pronounced at hyperpolarized holding potentials ( $V_H < -30$  mV) but diminished at depolarized potentials ( $V_H > -20$  mV). Examination of toxin block at hyperpolarized potentials revealed that paxilline inhibited BK current at concentrations as low as 6 nM in the presence of low intracellular calcium ( $\text{Ca}_i = 1\mu\text{M}$ ). Increasing  $\text{Ca}_i$  to 50  $\mu\text{M}$  reversed paxilline block. These results suggest that paxilline broadens the cortical action potential by inhibiting BK channels which play a critical role in cortical repolarization. (Bayer)

INTERNALLY APPLIED GLUCONATE REVERSIBLY INHIBITS  $\text{I}_{\text{K}}$ ,  $\text{I}_{\text{AHP}}$ ,  $\text{I}_{\text{h}}$  AND  $\text{I}_{\text{Ca}}$  IN RAT HIPPOCAMPAL PYRAMIDAL NEURONES. A.A. Velumian\*, L. Zhang, P. Pennefather, P.L. Carlen, Playfair Neuroscience Unit, Toronto Hospital and University of Toronto, Toronto, Ontario M5T 2S8, Canada

Earlier we reported that the spike frequency adaptation and slow afterhyperpolarization (sAHP) in hippocampal pyramidal neurons highly depend on the nature of anions used in the patch pipette solution. In particular, we showed that gluconate (Gluc<sup>-</sup>), an anion widely used in whole-cell recording experiments, causes a fast rundown of the sAHP and of spike frequency adaptation, while methylsulphate was found to be a suitable anion to preserve these cellular features. Here we show, using internal perfusion of patch pipettes in whole-cell recording experiments on hippocampal CA1 neurons in brain slices, that inhibitory effects of Gluc<sup>-</sup> on spike frequency adaptation and on sAHP are reversible. Contrary to what might be expected based on Gluc<sup>-</sup> binding of  $\text{Ca}^{2+}$ , the sAHP and its underlying current could be temporarily enhanced by adding 1-3 mM of calcium chelator BAPTA to internal solution in the presence of Gluc<sup>-</sup>. Moreover, the sAHP could be "revived" by BAPTA after its complete rundown in the presence of Gluc<sup>-</sup>. Replacement of internal methylsulphate with Gluc<sup>-</sup> did not affect the membrane resting potential or the amplitude and duration of action potentials, but reversibly increased the cell input resistance and, accordingly, decreased the threshold current for spike generation. Internally applied Gluc<sup>-</sup> reversibly inhibited several cationic currents: the hyperpolarization-activated current ( $\text{I}_{\text{h}}$ ), the depolarization-activated delayed rectifier  $\text{K}^+$  current ( $\text{I}_{\text{K}}$ ), the high voltage-activated  $\text{Ca}^{2+}$  current and the  $\text{Ca}^{2+}$ -activated  $\text{K}^+$  current ( $\text{I}_{\text{AHP}}$ ) that underlies the sAHP. While the mechanisms of these effects remain to be elucidated, our data indicate that Gluc<sup>-</sup> should be used with caution in experiments where the above membrane currents are involved.

## 142.4

THE INACTIVATING INWARD-RECTIFYING POTASSIUM CURRENT IN  $\text{GH}_3\text{B}_6$  CELLS IS HIGHLY SENSITIVE TO THE CLASS III ANTIARRHYTHMIC AGENT E-4031. F. Weinsberg, C.K. Bauer and J.R. Schwarz\*, Inst. Physiol., Univ. Hamburg, D-20246 Hamburg, Germany

Clonal rat anterior pituitary cells ( $\text{GH}_3\text{B}_6$  cells) exhibit an inward-rectifying potassium current ( $\text{K}_{\text{IR}}$ ), characterized by a voltage-dependent and sodium-independent inactivation during hyperpolarizing voltage pulses (Bauer et al., J. Physiol. 429: 169, 1990).  $\text{K}_{\text{IR}}$  is relatively insensitive to TEA and barium.

We now report that  $\text{K}_{\text{IR}}$  is effectively blocked by the class III antiarrhythmic agent E-4031.  $\text{K}_{\text{IR}}$  was activated by voltage pulses to -110 mV from a holding potential of -40 mV (bath solution: isotonic KCl). The maximum block of the transient inward current was 65%, achieved with 100 nM E-4031; increasing the concentration up to 10  $\mu\text{M}$  induced no further reduction. The  $\text{IC}_{50}$  value was 3 nM. The voltage-dependence of  $\text{K}_{\text{IR}}$  steady-state inactivation was not altered by 10 nM E-4031. The maximal reduction of the holding current in isotonic KCl at -40 mV was 26% ( $\geq 100$  nM E-4031), suggesting the presence of additional ionic currents at this potential. Inward and outward currents of  $\text{GH}_3\text{B}_6$  cells in normal Ringer's solution (holding potential: -80 mV, test pulse: 0 mV, prepulse: -120 mV) were not affected by 100 nM E-4031.

E-4031 is a selective blocker of  $\text{K}_{\text{IR}}$  in  $\text{GH}_3\text{B}_6$  cells, with an  $\text{IC}_{50}$  value much lower than those reported for other potassium currents. Supported by the Deutsche Forschungsgemeinschaft (Schw 292; Ba 1436).

## 142.6

TETRAHYDROBERBERINE INHIBITS ACETYLCHOLINE-INDUCED  $\text{K}^+$  CURRENT IN ACUTELY DISSOCIATED RAT HIPPOCAMPAL CA1 PYRAMIDAL NEURONS. P.X. Chen, J. Wu, and Chibing Xu\*, Dept. Physiol., Sun Yat-Sen Univ. Med. Sci., Guangzhou, 510089, P.R. China, and \*Dept. Neurol. Univ. New Mexico Sch Med., Albuquerque, NM 87108

It is well established that tetrahydroprotoberberines (THPBs) is a novel class of dopamine (DA) receptor antagonists. In this study, effects of THPBs on acetylcholine (ACh)-induced current were investigated in freshly dissociated CA1 pyramidal neurons from rat hippocampus using nystatin perforated patch-clamp whole-cell recording technique under voltage-clamp model. At the holding potential ( $V_H$ ) of -20 mV, ACh evoked an outward current ( $\text{I}_{\text{ACh}}$ ) with the half-maximum effective concentrations ( $\text{EC}_{50}$ ) of  $2 \times 10^{-6}$  M. I-V relationship curve showed that the reversal potential of  $\text{I}_{\text{ACh}}$  was -82 mV which was close to the  $\text{K}^+$  equilibrium potential of -86 mV calculated from the Nernst equation, and  $\text{K}^+$  channel blocker, TEA, clearly inhibited the  $\text{I}_{\text{ACh}}$ , indicating that ACh-induced outward current is mainly carried by  $\text{K}^+$ . THB, but not *l*-THP or *l*-SPD, clearly inhibited  $\text{I}_{\text{ACh}}$  in a concentration-dependent manner with the  $\text{IC}_{50}$  of  $1.3 \times 10^{-3}$  M. THB suppressed the maximum of concentration-response curve of  $\text{I}_{\text{ACh}}$  without change of the Hill coefficient, suggesting a noncompetitive inhibition. In addition, THB also inhibited caffeine- or strychnine-induced outward  $\text{K}^+$  currents. It is concluded that THB inhibits ACh-induced  $\text{K}^+$  current underlay the blockade of the membrane  $\text{K}^+$  channels. Supported by National Natural Sciences Foundation of China (No. 39270775).

## 142.7

ANANDAMIDE, THE ENDOGENOUS CANNABINOID RECEPTOR AGONIST, IS RELEASED IN RAT HIPPOCAMPUS AND DECREASES THE POTASSIUM M-CURRENT. P. Schweitzer\*, S.G. Madamba, G.R. Siggins and D. Piomelli<sup>1</sup>. Neuropharmacology, The Scripps Research Instit, La Jolla, CA 92037, <sup>1</sup>The Neurosciences Institute, San Diego, CA 92121.

Cannabinoids have powerful psychoactive properties and alter many physiological processes. Such effects are believed to be mediated through specific binding sites in the brain, with one of the highest densities found in the hippocampus. Anandamide (arachidonyl ethanolamide) is described as an endogenous ligand for cannabinoid receptors, but its existence and role in adult brain tissue is still poorly documented. Therefore, we assessed anandamide formation in adult rat hippocampus by incubating transverse slices with the calcium ionophore ionomycin (1  $\mu$ M; 10 min) in the presence of PMSF (100  $\mu$ M), an inhibitor of the enzyme that degrades anandamide. We subjected the incubation media and slices to lipid extraction and fractionated the extracts by HPLC, and analyzed the HPLC fractions by GC/MS. Anandamide, identified by its GC retention time and full mass spectrum, was present in the slices and incubation media, and its mass was increased by ionomycin treatment. We used the hippocampal slice preparation to perform intracellular voltage-clamp recordings in the presence of 1  $\mu$ M tetrodotoxin. Superfusion of R-1 methanandamide (M-AEA), a non-degradable form of anandamide, onto CA1 pyramidal neurons decreased the non-inactivating voltage-dependent potassium M-current ( $I_M$ ) by about 30% (1  $\mu$ M;  $n = 3$ ) to 50-60% (5  $\mu$ M;  $n = 3$ ). We also observed an  $I_M$  decrease with the cannabinomimetic drug WIN 55,212-2 (0.5-2  $\mu$ M;  $n = 6$ ). Prior treatment of the slices with the cannabinoid receptor antagonist SR141716A (1  $\mu$ M) prevented the effect of M-AEA ( $n = 3$ ) and WIN ( $n = 4$ ) on  $I_M$ .

Our results provide evidence for the formation and release of anandamide in the adult rat hippocampus, and show that such cannabinoid substance can post-synaptically modulate the excitability of CA1 pyramidal neurons. Supported by NIH (MH 44346 and AA 06420) and Neurosciences Res. Foundation.

## 142.9

$\kappa$ -CONOTOXIN PVIIA, A CONUS PEPTIDE TARGETED TO POTASSIUM CHANNELS. R. Jacobsen<sup>1</sup>, M. Stocker<sup>2</sup>, H. Terlau<sup>2</sup>, K. Shon<sup>3</sup>, M. Grille<sup>1</sup>, W. R. Gray<sup>1</sup>, W. Stühmer<sup>2</sup> and B. M. Olivera<sup>1\*</sup>. Dept. of Biology, Univ. of Utah, Salt Lake City, UT, 84112; Molekulare Biologie Neuronaler Signale, Max-Planck-Institut für Exp. Medizin, D-37075, Göttingen, Germany; Dept. of Physiology and Biophysics, Case Western Reserve Univ., Cleveland, OH, 44106.

A novel 27 amino acid Conus peptide with 3 disulfide bonds,  $\kappa$ -conotoxin PVIIA, was recently purified and characterized from *Conus purpurascens* venom (Terlau, et al., *Nature*, 381:148-151, 1996). The peptide inhibits the *Shaker* K<sup>+</sup> channel, but has no effects on any voltage-gated Na<sup>+</sup> or Ca<sup>2+</sup> channel tested.  $\kappa$ -Conotoxin PVIIA has been chemically synthesized; the synthetic material is identical to the natural material by both chemical criteria and biological activity. Although the peptide rapidly inhibits the *Shaker* K<sup>+</sup> channel, the rat brain Kv1.1 K<sup>+</sup> channel is resistant to the toxin. Chimeras between the *Shaker* and Kv1.1 channel reveal that the peptide is generally targeted to the region of the channel between the fifth and sixth transmembrane domains. For the fish-hunting *Conus purpurascens*,  $\kappa$ -conotoxin appears to be part of an excitotoxic shock strategy generally used by venomous predators to very rapidly immobilize their prey. For rapid prey immobilization to occur, both the  $\kappa$ -conotoxin and a  $\delta$ -conotoxin, which delays voltage-gated Na channel inactivation, are required. (Work supported by Grant PO1 GM 48677 NIGMS and SFB 406.)

## 142.11

THE A-CURRENT IS NOT BLOCKED BY INTRACELLULAR CESIUM IN GUINEA PIG LATERODORSAL TEGMENTAL NEURONS. R.M. Sanchez\*, A. Surkis, and C.S. Leonard, Center for Neural Science, New York University, 4 Wash. Pl., NY, NY 10003.

LDT neurons exhibit a prominent transient potassium current ( $I_A$ ).  $I_A$  has been reported to be blocked by intracellular Cs<sup>+</sup> in various neurons, including rat LDT neurons. Unexpectedly, whole-cell voltage-clamp recordings of guinea pig LDT neurons in a brain slice preparation revealed an apparent  $I_A$  which persisted despite internal Cs<sup>+</sup> dialysis. LDT neurons recorded with Cs<sup>+</sup>-based pipette solutions exhibited a transient inward current which resembled a T-type Ca<sup>2+</sup>-current as previously reported (Kamondi et al. 1992, *J Neurophys.* 68:1359). However, this current reversed near -35 mV and it was inhibited by 4-aminopyridine (4-AP), suggesting that it was  $I_A$  after cesium dialysis had shifted  $E_K$  positively, rather than a T-current. Increasing [K]<sub>o</sub> caused a further positive shift in the reversal potential for the transient current, and Ringer containing 0 Ca<sup>2+</sup>/4mM EGTA/TEA did not reduce the current, although the voltage-dependence of activation shifted negatively, resulting in larger inward 4-AP-sensitive currents. The mean time constant of inactivation removal was 15.5 ms, indicating that the Cs<sup>+</sup>-resistant current was not  $I_p$ . Boltzmann fits were used to estimate the voltage-dependence of  $I_A$  and indicated an activation  $V_{1/2}$  of -43mV and an inactivation  $V_{1/2}$  of -59mV. The influence of dendritic filtering and series resistance on these estimates was also examined by computer simulation of morphologically realistic LDT neurons. These data indicate that guinea pig LDT neurons express a novel  $I_A$  which has a Cs-resistant ion permeation mechanism. It will be of interest to learn if this feature is correlated with other functional properties, such as sensitivity to neuromodulators. Further study may also reveal this property to be diagnostic of a particular Kv gene subfamily. Supported by NS27881

## 142.8

LITHIUM BLOCK AND PERMEATION OF DOPAMINE-MODULATED K<sup>+</sup> CHANNELS ON RAT STRIATAL NEURONS. Yong-Jian Lin<sup>\*1</sup>, Xueguang Chen, and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115 (and <sup>1</sup>Dept. Anesthesiology, Cornell Medical Center, New York, NY 10021).

Using cell-attached patch-clamp recording from freshly dissociated rat caudate-putamen neurons, we have studied the blockade properties of an inwardly rectifying 85 pS K<sup>+</sup> channel, which is activated by D<sub>2</sub>-like dopamine receptors. Previous studies showed that this channel was sensitive to block by cesium ions. In addition, Cs<sup>+</sup> weakly permeated the channel at voltages near the K<sup>+</sup> reversal potential, introducing an anomalous negative slope conductance into the current-voltage relationship. Here, we have studied the effects of 0.5-1.0 mM LiCl within the patch pipette upon this channel, and report results similar to those for CsCl. These concentrations of Li<sup>+</sup> partially blocked 85 pS channel currents near the resting membrane potential, and also carried small currents near the K<sup>+</sup> reversal potential. Li<sup>+</sup> block was flickery and voltage-sensitive, and nearly complete at 1 mM. Notably, Li<sup>+</sup> displayed these effects at concentrations corresponding to tissue levels attained at therapeutic dosages, rather than at the higher, toxic concentrations needed to block many other ion channels. These results raise the possibility that effects on this dopamine receptor-modulated K<sup>+</sup> channel may contribute to lithium's mechanism of action in the treatment of bipolar disorder. (Supported by NIH grant MH-48545.)

## 142.10

THE REGULATION OF HUMAN (*h*slc) CA<sup>2+</sup>-ACTIVATED K<sup>+</sup> CHANNELS BY REDOX REAGENTS. T. J. DiChiara\* & P.H. Reinhart. Dept. of Neurobiology, Duke Univ. Medical Center, Durham, NC 27710.

Cloned human Ca<sup>2+</sup>-activated K<sup>+</sup> channels (*h*slc) channels contain at least 25 cysteine residues, raising the possibility that reduction or oxidation of disulfide bonds in the channel protein could have functional consequences. We have investigated the influence of sulfhydryl redox reagents on *h*slc (hbr5) channels in a stably transfected HEK293 cell line using inside-out macropatch analysis. Intracellular application of the reducing agent dithiothreitol (DTT, 1 mM) has three effects: first, the voltage of half-maximal activation ( $V_{0.5}$ ) is shifted an average of  $18.3 \pm 1.8$  mV ( $n=8$ ) to more negative potentials without affecting the slope of the voltage dependence. The time course of this potentiation can be fit with a single exponential having a mean time constant of  $7.5 \pm 0.6$  min ( $n=8$ ). Second, reduction by DTT consistently slows the rate of channel "run-down," measured as a right-shift in macroscopic conductance-voltage curves, from an average of 2.2 mV/min to 0.17 mV/min ( $n=13$ ). Third, DTT increases current activation kinetics by  $32.7 \pm 4.2\%$  ( $n=8$ ). In contrast to DTT treatment, application of the reduced form of glutathione has no significant effect on *h*slc currents ( $n=2$ ), while the oxidized form shifts  $V_{0.5}$  values to more positive potentials ( $n=3$ ). A similar shift is observed upon oxidation with 5-5'-dithio-bis(2-nitrobenzoic acid) (DTNB, 1 mM). These data show that *h*slc Ca<sup>2+</sup>-activated K<sup>+</sup> channels can link cellular metabolism to excitability by means of one or more redox modulatory site(s) that significantly influence channel function. Supported by NIH grants to PHR (NS31253) and TJD (MH10930).

## 142.12

ETHANOL HAS OPPOSITE EFFECTS ON THE ACTIVITY OF TWO CLONED LARGE CONDUCTANCE, CA<sup>2+</sup>-ACTIVATED K<sup>+</sup> (*bslo* AND *mslo*) CHANNELS. A.M. Dopico and S.N. Treisman\*. Dept. Pharmacol. & Mol. Toxicol., and Program in Neurosci., Univ. Mass. Med. Ctr. Worcester, MA 01655.

The activity of large conductance, Ca<sup>2+</sup>-activated K<sup>+</sup> (BK) channels regulates arterial tone. Ethanol (EtOH) either increases or decreases arterial tone, depending upon the vascular net considered. We previously found that 10-200mM EtOH increased the activity ( $NP_o$ ) of mouse brain (*mslo*) BK channels expressed in *Xenopus* oocytes. However, 50mM EtOH does not activate BK channels in aortic smooth muscle. To examine whether this differential effect of EtOH on BK channels is attributable to differences between the two BK channel proteins or to other components of the membrane, we report here the effects of EtOH on BK channels (*bslo*) cloned from aortic smooth muscle, and expressed in the oocyte system, using single channel recordings from inside-out patches. *Bslo* has been reported to be >99% identical to *mslo* (Biophys. J. 68: A29). *Bslo* channels showed a reversal potential of 0.8 and 30 mV in symmetric 145 mM [K<sup>+</sup>]<sub>o</sub> and 145/45 mM [K<sup>+</sup>]<sub>i</sub>/[K<sup>+</sup>]<sub>o</sub>, respectively. The main unitary conductance was 270 pS in symmetric 145 mM [K<sup>+</sup>]<sub>o</sub>, with at least one subconductance state.  $NP_o$  increased when [Ca<sup>2+</sup>]<sub>i</sub> was increased and/or at more positive potentials (59 mV per e-fold change in  $NP_o$ , at low  $P_o$ ). EtOH (50-100mM) reversibly decreased *bslo* channel  $NP_o$  (-66%), without modifying unitary conductance, reversal potentials, or voltage-sensitivity. Since *mslo* and *bslo* channels were embedded in the same oocyte membrane, these results suggest that the differential action of EtOH is attributable to differences between the channel proteins.

Supported by grants from ABMRF (AMD) and NIH AA-08003 (SNT).

## 142.13

EFFECT OF CHARYBDOTOXIN, A POTASSIUM CHANNEL BLOCKER, ON OVERT BEHAVIOUR AND LOCAL CEREBRAL GLUCOSE UTILISATION. S.M.Cochran\* and J.A.Pratt. Dept. of Physiology and Pharmacology, University of Strathclyde, Glasgow, G1 1XW, U.K.

Charybdotoxin (CTX) is a polypeptide neurotoxin isolated from scorpion venom *Leiurus quinquestriatus*. It is a high affinity blocker of voltage- and  $\text{Ca}^{2+}$ -dependent  $\text{K}^+$  channels, although it is thought to predominantly block transient "A" channels within the rat brain (Schweitz *et al.*, *Biochem* 28:9708-9714, 1989). A dose response trial was designed in order to establish sub-convulsive doses of CTX after bilateral icv administration. A pilot study demonstrated that a dose of 50pmoles/5µl caused convulsions. In the present study, no seizures were observed at a dose of 25 pmoles/5µl, or lower (12.5 and 6.25 pmoles/5µl).

The 2-Deoxyglucose Method (Sokoloff *et al.*, *J. Neurochem.* 28:897-916, 1977) was then used to investigate the effects of CTX on functional activity, as reflected by changes in local cerebral glucose utilisation (LCGU). The structures investigated were the hippocampus, related limbic structures and the basal ganglia. At a dose of 12.5 pmoles/5µl (bilateral icv injection) CTX evoked heterogeneous changes in LCGU, with significant increases seen in 18 out of 26 structures (One-Way Anova,  $p < 0.05$ ). Significant increases were seen, for example, in the perforant pathway, with LCGU increasing from  $71 \pm 2$  to  $96 \pm 2$  µmol/100g/min ( $n=4$ , mean  $\pm$  SEM; saline vs CTX treated groups) in the entorhinal cortex, and from  $88 \pm 3$  to  $103 \pm 1$  µmol/100g/min in the molecular layer of dentate gyrus. In the basal ganglia, LCGU increased from  $87 \pm 3$  to  $107 \pm 3$  µmol/100g/min in the caudate nucleus but no change was seen in the globus pallidus ( $57 \pm 2$  vs  $55 \pm 1$  µmol/100g/min). Preliminary data indicates that CTX may improve functional activity in selected structures rather than cause a global increase in activity throughout the brain.

This work was supported by The Smith's Trust and SHERT.

## 142.15

RESTING ('LEAK')  $\text{K}^+$  CHANNELS IN RAT HIPPOCAMPAL PYRAMIDAL NEURONS INHIBITED BY EXTERNAL  $\text{Ba}^{2+}$  AND INTERNAL  $\text{Ca}^{2+}$ . A.A.Selyanko, J.A.Sim\* and D.A.Brown. Dept.Pharmacol., University College, London, WC1E6BT, UK.

Channels responsible for setting the resting potential of most neurons remain elusive. In hippocampal pyramidal neurons the resting ('leak') conductance is inhibited by  $\text{Ba}^{2+}$  (Storm & Heliessen, 1989: Soc.Neurosci.Abstr., 15,77). We have identified corresponding  $\text{Ba}^{2+}$ -sensitive single channels in CA1/CA3 pyramidal neurons dissociated from 7 day-old rats and cultured in vitro for 8-25 days (Alger *et al.*, 1994: Neurosci.Lett., 168,23). Whole-cell recording revealed a voltage-insensitive component of membrane current between -120 and -50 mV inhibited by 1 mM  $\text{Ba}^{2+}$  and reversing at -105 mV in 2.5 mM  $[\text{K}^+]_{\text{out}}$ . Single  $\text{K}^+$  channels active at rest potential, with a slope conductance of  $12.2 \pm 2.0$  pS ( $n=5$ ;  $[\text{K}^+]_{\text{out}} = 2.5$  mM), were detected in 11 cell-attached patch recordings. When excised into outside-out mode channels were inhibited  $91.1 \pm 1.1\%$  ( $n=4$ ) by 1 mM  $\text{Ba}^{2+}$  but were unaffected by 1 mM TEA or 0.5 mM 4-AP. Channel activity persisted and increased on excision of patches into inside-out mode and was then reversibly inhibited by internal  $\text{Ca}^{2+}$  ( $\text{IC}_{50}$  118 nM). This effect persisted in MgATP-free solution so probably did not involve phosphorylation/dephosphorylation. Channel activity in cell-attached patches was enhanced in  $\text{Ca}^{2+}$ -free bathing solution and was inhibited during spontaneous spiking in  $\text{Ca}^{2+}$ -containing solution, leading to a  $\text{Ca}^{2+}$ -dependent post-spike inward current. Inhibition of these channels may therefore be responsible for spike after-depolarization.

APAMIN, A BLOCKER OF CALCIUM ACTIVATED POTASSIUM CHANNELS INDUCE NEURODEGENERATION OF PURKINJE CELLS IN CEREBELLUM. C. Mourre\*, B. Soumireu-Mourat. CNRS-URA 372, Lab Neurobiologie des Comportements, F-13388-Marseille, France.

Apamin induces characteristic epileptiform seizures. We used convulsive doses of apamin to determine a possible neuronal damage. Patterns of cell loss and neurodegeneration were studied using a Fink-Heimer silver staining procedures.

Following acute and unilateral intracerebroventricular injection (icv) of 1 ng apamin, the rat brains presented, after 48h survival times, a bilateral damage in cerebellum exclusively. The argyrophilic cells were Purkinje cells in flocculus, paraflocculus and paramedian lobules. No neurodegeneration was found in the others lobules and cerebellar nuclei. After 0.7 ng apamin icv injection, no seizures and no neuronal damage were observed.

Three doses of apamin were used for chronic apamin injections with osmotic pumps (Alzet, 0.5µl/h, 14 days): 0.2, 0.4, 0.6 ng/µl. At 0.2 ng/µl apamin dose, no damage were found but animals were hypersensitive to noise especially. During 0.4 and 0.6 ng/µl apamin infusions, the rats showed typical seizures during five first days. They appeared restless during the time course of the infusions. The two highest doses of apamin induced a neurodegeneration only in Purkinje cells of the cerebellum. The pattern was identical with that observed after acute icv 1 ng apamin injection.

In conclusion, these data demonstrate that the inactivation of small conductance  $\text{Ca}^{2+}$ -activated  $\text{K}^+$  potassium channels by apamin induce a particular neuronal damage in rat brain that was very different from neurodegenerations, frequently limbic, induced by convulsive drugs like kainate acid and dendrotoxin, a blocker of type A potassium channels.

HERG CURRENTS ARE REDUCED BY KETOCONAZOLE, ERYTHROMYCIN, AND TERFENADINE, SUGGESTING MULTIPLE MECHANISMS FOR CARDIOTOXICITY. M.-L. Roy\*, J. Kiehn, R. Dumaine, and A.M. Brown. Rammelkamp Center for Research, MetroHealth Med. Center, Case Western Reserve University Sch. of Med., Cleveland, OH 44109.

The HERG potassium channel, first identified in hippocampus, has also been reported in various cardiac tissues. Terfenadine (Seldane), a widely-used antihistamine, has been associated with arrhythmias when simultaneously administered with fungicides (i.e. ketoconazole) or macrolide antibiotics (i.e. erythromycin). We have recently shown that nanomolar concentrations of terfenadine block HERG currents as expressed in *Xenopus* oocytes (*Circulation*, in press).

We heterologously expressed Kv1.5 and HERG channels in *Xenopus* oocytes to compare their sensitivities to ketoconazole and erythromycin. Currents were recorded using the two-electrode voltage-clamp technique. Ketoconazole reduced HERG and Kv1.5 currents with comparable  $K_d$  values of 30 µM and 60 µM, respectively, without use- or voltage-dependent block for either channel. These values are physiologically significant, as plasma concentrations of ketoconazole have been reported in the low micromolar range. In the whole oocyte, erythromycin (1-1000 µM) did not alter either HERG or Kv1.5 currents, whereas application of erythromycin to inside-out patches blocked HERG current with an estimated  $K_d$  value of 150 µM. Our results indicate that, in addition to slowing the metabolism of terfenadine, ketoconazole and erythromycin may provoke cardiovascular complications. Thus, as HERG and Kv1.5 are expressed in neuronal and glial cells, respectively, similar compounds may alter these channels in the CNS.

MORPHOLOGICAL AND MORPHOMETRIC ANALYSIS ON IMPAIRED PARALLEL FIBER-PURKINJE CELL SYNAPSE FORMATION IN *Glurδ2*-KNOCKOUT MICE.

H. Kurihara, M. Watanabe, M. Mishina\*, and Y. Inoue\*. Dept. of Anat., Hokkaido Univ. Sch. of Med., Sapporo 060, and \*Dept. of Pharmacol., Tokyo Univ. Faculty of Med., Tokyo 113, Japan.

The glutamate receptor channel subunit  $\delta 2$  is localized specifically in the Purkinje cell (PC) spines, and plays important roles in development of PC synapses, long-term depression, and motor coordination. In the present study, we quantitatively analyzed the parallel fiber-Purkinje cell (PF-PC) synapses in the vermis of the *Glurδ2*-mutant and wild-type cerebellum at 5 weeks of age. The number of the PCs in the mutant were almost comparable to that in the wild-type (98% of the wild-type). However, the numerical density of PC spines in the mutant was reduced to 75% of that in the wild-type. Serial electron micrographs demonstrated that 63% of the PC spines in the mutant were in contact with the PF terminals, whereas the rest failed to form synaptic contacts. These free or "naked" spines were completely surrounded by sheets of the Bergmann astrocytes. In the wild-type, on the other hand, all PC spines were contacted with the PF terminals. Based on these data, it was estimated that the total number of the PF-PC synapses per PC in the mutant mouse was remarkably reduced to 47% of the wild-type mouse. Moreover, the mean number of contacted spines per PF terminal was significantly reduced:  $1.10 \pm 0.03$  in the mutant and  $1.45 \pm 0.03$  in the wild type ( $p < 0.0005$ ). These findings suggest that the  $\delta 2$  subunit may be involved in stabilization process of the PF-PC synapses, leading to a successful integration of all PC spines formed during development into synaptic structure.

## 143.2

CELLULAR DISTRIBUTION OF NMDA GLUTAMATE RECEPTOR SUBUNITS IN THE HUMAN CEREBELLUM. C.R. Scherzer, J.A. Kerner, D.G. Standaert, Z.R. Hollingsworth\*, J.B. Penney, Jr., A.B. Young, G.B. Landwehrmeyer. Dept. of Neurology, Mass. Gen. Hosp., Boston, MA 02114.

NMDA receptors are composed of proteins from two families: NMDAR1, which are required for channel activity, and NMDAR2, which modulate properties of the channels. We have used a quantitative *in situ* hybridization method with human ribonucleotide probes to examine the regional and cellular distribution of the NMDA receptor subunit mRNA in the human cerebellum.

Purkinje cells showed intense labeling for NMDAR1 mRNA and NMDAR2A mRNA probes, whereas labeling for the NMDAR2D mRNA probe was moderate. Granule cells showed high hybridization signals for the NMDAR1 and NMDAR2C mRNA and moderate signals for the NMDAR2D mRNA. In addition, intense labeling for the NMDAR2B probe was observed in medium sized neurons with chromophilic cell bodies in the upper part of the granule cell layer, most likely representing Golgi cells. Neurons in the molecular layer, i.e. basket cells and stellate cells, showed high hybridization signals for NMDAR1 and NMDAR2D, moderate signals for NMDAR2B and low signals for NMDAR2C. While the NMDAR2D mRNA probe was found to label all neurons in the molecular layer equally, the expression of the other subunit mRNAs in this cerebellar layer seemed to be heterogeneous.

NMDAR composition in the cerebellum appears to be distinctly different from composition in the cortex, with the NMDAR2C expression prominent in the cerebellum in contrast to the NMDAR2B expression prominent in the cortex. We conclude that each type of neuron analyzed displays a distinct NMDAR2 subunit profile. Supported by USPHS grant AG11337.

## 143.3

GLUTAMATE RECEPTORS POSTSYNAPTIC TO CORTICAL TERMINALS IN CORTEX AND THALAMUS. Y.N.Kharazia\*, K.Phend, R.J.Weinberg and A.Rustioni. Dept. of Cell Biology & Anatomy, UNC, Chapel Hill, NC 27599.

Excitatory corticocortical and corticothalamic projections are both from axons of pyramidal cells. Though both appear to use glutamate as transmitter, postsynaptic effects may differ in these two projections. We here report an electron microscopic study of receptors postsynaptic to these projections. To supplement tentative morphological identification of cortical terminals, anterograde tracers were used, including WGA-HRP, PHA-L, and biotinylated dextran, injected into deep layers of rat S-I cortex. Labeled synapses were identified in ipsi- and contralateral S-I cortex, and in the ipsilateral ventrobasal thalamus. Anesthetized rats were perfused with mixed aldehydes. Following histochemistry for tracer, tissue was embedded and processed for postembedding immunogold (Phend et al., '95) for AMPA, NMDA and metabotropic glutamate receptors. Analysis of immunostained material revealed that in both cortex and thalamus all three types of receptors could be found at synapses made by cortical terminals. AMPA receptors appeared to be more often postsynaptic to cortical terminals in cortex than in thalamus, whereas NMDA was more prominent in thalamus than in cortex. This work was supported by NIH awards 16264 (to AR) and 29879 (to RJW).

## 143.5

AMPA AND NMDA RECEPTORS IN MOTONEURONS OF THE SPINAL CORD AFTER SCIATIC NERVE TRANSECTION A. Rustioni\*, A. Popratiloff, V.N. Kharazia, and R.J. Weinberg. Dept. of Cell Biology & Anatomy, UNC, Chapel Hill, NC 27599.

Transverse sections through the fourth and fifth lumbar segments of rat spinal cord were immunocytochemically processed using antibodies specific for AMPA receptor subunits GluR1-4, and for the NMDA receptor subunit NMDAR1. Changes in immunostaining for glutamate receptors in the ventral horn were observed after 3-14 days on the side ipsilateral to a lesion of the sciatic nerve. GluR2/3 staining was markedly decreased in injured motoneurons, which were concentrated in dorsolateral lamina IX. No obvious changes in staining of motoneurons were detected for the other AMPA subunits tested. Changes in GluR4 expression were conspicuous: numerous GluR4-positive microglial cells appeared in on the lesioned side within 3 days after the lesion and became more prominent after longer survival. Many of these intensely GluR4-positive microglial cells enveloped motoneurons. NMDAR1 staining became apparent in glia close to motoneuronal somata after 14 days survival. These NMDA-positive cells were identified as astrocytes, on the basis of their intense staining for GFAP. Down regulation of glutamate receptors in motoneurons may be associated with the loss of synaptic input known to occur after axotomy. Supported by NIH grant NS 12440.

## 143.7

REGIONAL CONCENTRATIONS OF AMPA RECEPTOR SUBUNIT mRNAs SUGGEST RECEPTOR CLASSES. S.J. Gold<sup>1</sup>, J. Ambrose, Ingerson<sup>1,3</sup>, J.R. Horowitz<sup>2</sup>, G. Lynch<sup>1,3</sup>, C.M. Gall<sup>1,2</sup>. Depts. of <sup>1</sup>Psychobiology, <sup>2</sup>Anatomy & Neurobiology and <sup>3</sup>CNLM, Univ. of Calif., Irvine, CA 92717.

In situ hybridization was used to assess regional concentrations of AMPA receptor (AMPA) subunit mRNAs in adult rat brain to determine if subunit mRNA ratios, suggestive of different AMPAR subunit compositions, recur across brain areas. Four patterns of subunit mRNA content were observed and named AMPAR-1, AMPAR-2, AMPAR-2,3 and AMPAR-1,2 (numbers indicate subunit mRNAs most enriched for each class). Categories were resolved by agglomerative hierarchical clustering and statistically validated. Subunit mRNA ratios were of the AMPAR-1 type in habenula and lateral mammillary bodies; the AMPAR-2,3 type in thalamic sensory relay and pontine nuclei; and the AMPAR-2 type in piriform cortex, neocortex, and medial mammillary bodies. GluR2 mRNA represented a substantial fraction of total GluR mRNA in all regions, but was highest in the AMPAR-2 class where it attained 57% of total GluR mRNA. The AMPAR-1,2 class, expressed in neuronal layers of hippocampus, ventromedial hypothalamus and numerous amygdaloid nuclei, was the most prevalent pattern across regions surveyed. These results suggest four regionally recurring AMPAR subunit stoichiometries. The relative GluR concentrations presented here should 1) aid in identifying pathway-specific AMPAR features, and 2) provide a template for recombinant modeling of native AMPARs (supported by AG00538 and BNS9024143).

## 143.4

GLUTAMATE RECEPTORS POSTSYNAPTIC TO THALAMOCORTICAL TERMINALS IN SI. R.J.Weinberg\* and V.N.Kharazia. Dept. of Cell Biology & Anatomy, UNC, Chapel Hill, NC 27599

Pharmacological and immunocytochemical studies suggest that thalamocortical afferents use glutamate as neurotransmitter. We have used immunocytochemistry for ionotropic glutamate receptors to study thalamocortical transmission in primary somatic sensory cortex (SI) of rats. LM immunocytochemistry of barrel cortex suggests that thalamocortical transmission is mainly via NMDA receptors, whereas electrophysiology indicates that AMPA receptors play the primary role. Since LM cannot unambiguously identify synaptic receptors, we used immunogold EM techniques to study glutamate receptors postsynaptic to thalamocortical terminals in SI. Terminals were identified both on morphological grounds and by EM anterograde transport methods. Histochemistry for tracer was followed by an embedding procedure designed to optimize antigen retention (Phend et al., '95). Both AMPA and NMDA receptor subunits could be found at synapses made by thalamocortical fibers; however AMPA subunits were more often postsynaptic to thalamocortical terminals than were NMDA subunits. This evidence suggests that thalamocortical transmission is predominantly via AMPA receptors. This work was supported by NIH award 29879 (to RJW).

## 143.6

LOCALIZATION OF GLUTAMATE RECEPTORS IN THE LOCUS CERULEUS OF RHESUS MACAQUES. H.F. Urbanski\* AND S.G. Kohama. Division of Neuroscience, Oregon Regional Primate Research Center, 505 N.W. 185th Avenue, Beaverton, Oregon, 97006.

Noradrenergic innervation of major brain areas, such as the hypothalamus and cerebral cortex, originates in part from the locus ceruleus (LC) located in the hindbrain. The LC is theoretically under the control of excitatory glutamatergic afferents, since this area can be stimulated by exogenous glutamate. Therefore, this study examined the localization of ionotropic glutamate receptors in the LC of perfused fixed rhesus monkey brains (*Macaca mulatta*). Both the NMDA and AMPA classes of receptors were examined by immunocytochemistry (ICC) and *in situ* hybridization (ISH). The LC was localized initially in coronal sections by ICC for tyrosine hydroxylase (Boehringer-Mannheim), the rate limiting enzyme in the catecholamine synthesis pathway. Neighboring sections were then immunostained for NR1, the NMDA receptor subunit found in all NMDA receptor complexes, and for GluR1 and GluR2/3, major subunits of AMPA receptors (Chemicon Int.). In all cases, immunostaining for NR1, GluR1 and GluR2/3 subunits were found in neurons of the LC. To corroborate these results, ISH for NR1, GluR1, GluR2 and GluR3 subunits were performed on sections containing the LC. Coronal sections were initially postfixed, digested with proteinase K, acetylated, then hybridized overnight at 60 ° C with 35-S-labelled cRNA probes generated from rat cDNA templates. Sections were subsequently washed, treated with RNase A, then further rinsed, with a final stringency wash at 70° C in 0.1 X SSC. The LC was visualized on exposed β-max films (Amersham) and emulsion-dipped slides (Kodak). Again, all subunits examined were found in the LC, with NR1 and GluR1 giving the most robust signals. Both GluR2 and GluR3 mRNA were also found in LC neurons, corroborating the immunostaining seen with the GluR2/3 antibody. Grant Support: NIH HD-29186 and RR00163

## 143.8

DISTRIBUTION OF mRNA CODING FOR AMPA RECEPTOR SUBUNITS DURING OVINE CNS DEVELOPMENT. D.T. Theophilopoulos, T.S. McGraw, M.S. Sapper, J.J. Mitchell, D.J. Burchfield, and K.J. Anderson\*. Departments of Pediatrics, Physiological Sciences and Neuroscience, University of Florida, Gainesville, FL 32610.

**Introduction:** The AMPA receptor is one of three major ionotropic glutamate receptors that has been cloned and consists of four subunits (GluR-A-D) that are expressed in alternatively spliced isoforms termed flip and flop. AMPA receptors containing predominantly flip isoforms are associated with enhanced responses to L-glutamate and thought to play a role in excitotoxicity. Glutamate receptors are present in both fetal humans and fetal sheep, but not in fetal rodents, the most commonly used model for excitotoxicity. **Hypothesis:** Early in ovine CNS development, the flip isoforms of AMPA receptors predominate which may render the immature brain more vulnerable to excitotoxicity. **Methods:** *In situ* hybridization using <sup>35</sup>S labeled probes to all four subunits and both flip and flop isoforms was performed on sheep brains at 0.8 term, term, 2 days, 10 days and adult ages to determine the distribution and density of the different AMPA receptor subunit mRNAs. **Results:** In the neocortex and cerebellum, mRNA for the flip isoforms of all four subunits is prominent prenatally and then declines into adulthood. In the hippocampus, mRNA for the flip isoforms of GluR-A and GluR-D is also prominent prenatally and similarly declines into adulthood. The flip isoform of GluR-D, previously reported only in the cerebellum of adult rats, is also found in the neocortex prenatally. Flop isoforms are expressed in a constant fashion, prenatally through adulthood. **Conclusion:** The flip isoforms of the AMPA receptor, which are associated with an enhanced response to L-glutamate, are prevalent prenatally and may render the immature brain more vulnerable to excitotoxicity. ## 143.9

**CALCIUM SIGNALING PATHWAYS LINKED TO AMPA RECEPTOR ACTIVATION IN CULTURED PURKINJE NEURONS.** D.L. Gruol\*, J.G. Netzeband, and K.L. Parsons. Dept. Neuropharmacol., The Scripps Research Institute, La Jolla, CA 92037.

We have used FURA-2 microscopic  $\text{Ca}^{2+}$  imaging and electrophysiological techniques to investigate the contributions of extracellular and intracellular  $\text{Ca}^{2+}$  to the  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazole propionate (AMPA)-induced  $\text{Ca}^{2+}$  signal or voltage response of cultured rat Purkinje neurons (> 16 days in vitro). Rapid microperfusion of AMPA (10  $\mu\text{M}$ ; 1 s) elicited an immediate depolarization ( $35 \pm 1$  mV,  $n=15$ ), whereas the  $\text{Ca}^{2+}$  signal peaked (soma:  $74 \pm 6$  nM,  $n=66$ ; dendrites:  $40 \pm 4$  nM,  $n=44$ ) 6–11 s after stimulation. The peak  $\text{Ca}^{2+}$  signal corresponded in time to a plateau in the depolarization, but both the  $\text{Ca}^{2+}$  levels and the depolarization recovered within about 1 min following AMPA application. The depolarization was followed by a smaller but more prolonged hyperpolarization (peak =  $13 \pm 1$  mV; duration =  $490 \pm 55$  s). Removal of extracellular  $\text{Ca}^{2+}$  prolonged the depolarization by 92% and shortened the hyperpolarization by 50% ( $n=5$ ). In contrast, similar treatment abolished the  $\text{Ca}^{2+}$  signal to AMPA ( $n=12$ ). The  $\text{Ca}^{2+}$  signal was also greatly attenuated by the P-type  $\text{Ca}^{2+}$  channel antagonist  $\omega$ -agatoxin-IVA (200 nM;  $n=19$ ). Intracellular ryanodine-sensitive  $\text{Ca}^{2+}$  stores also contributed to the AMPA-mediated  $\text{Ca}^{2+}$  signal as the ryanodine-receptor antagonist dantrolene (10  $\mu\text{M}$ ) decreased the  $\text{Ca}^{2+}$  signal by 70% ( $n=9$ ). Similar data were obtained with caffeine (20 mM,  $n=31$ ) which depletes ryanodine-sensitive  $\text{Ca}^{2+}$  stores. In contrast, DTBHQ (10  $\mu\text{M}$ ), an inhibitor of the  $\text{Ca}^{2+}$ -ATPase responsible for  $\text{Ca}^{2+}$  re-uptake, had no effect on the peak  $\text{Ca}^{2+}$  signal. Interestingly, DTBHQ did alter the time course of the electrophysiological response ( $n=6$ ), whereas dantrolene did not ( $n=6$ ). These data show that both extracellular and intracellular  $\text{Ca}^{2+}$  contribute to the AMPA-induced  $\text{Ca}^{2+}$  and voltage signals in Purkinje neurons. Supported by AA 06665 and AA 05421.

## 143.11

**AMPA RECEPTOR SUBUNITS IN RAT SUBSTANTIA GELATINOSA AFTER PERIPHERAL NERVE INJURY** A. Popratiloff\*, R.J. Weinberg and A. Rustioni, Dept of Cell Biology & Anatomy, UNC, Chapel Hill, NC 27599.

Increased excitability and decreased inhibition of superficial laminae of the spinal cord may contribute to the abnormal pain consequent to peripheral injury. We here report initial results on changes in AMPA receptors after peripheral nerve injury. Three rats with 14 d survival were used for light microscopy. Tissue was processed for immunofluorescence; digitally captured images from superficial laminae were analysed. Quantitative analysis suggested that staining with antibody to sequence shared by GluR2 and GluR3 subunit (GluR2/3) was stronger on the side ipsilateral to the lesion. Another group of rats were perfused with mixed aldehydes 7–60 days after transection of the sciatic nerve; tissue was prepared for electron microscopy and processed for postembedding immunogold. Gold particles coding for GluR2/3 subunits were counted from active zones at type II primary afferent terminals (underlying small myelinated fibers). GluR2/3 labeling was significantly increased on the side ipsilateral to the lesion. This increase could be detected at 7 d survival and became more prominent with 14 d. These results suggest that increased GluR2/3 expression may produce increased excitability of superficial laminae neurons after peripheral nerve injuries. Supported by NIH grant NS 12440.

## 143.13

**HIPPOCAMPAL, SUBSTANCE P-, ENKEPHALIN- AND CALRETININ-INNervation OF AMPA RECEPTOR-CONTAINING NEURONS IN THE RAT LATERAL SEPTUM.** F. Varoquaux and C. Leranth\*, Dept. of Obstetrics & Gynecology and Section of Neurobiology Yale University, New Haven, CT 06520

Neurons of the lateral septum (LS) receive glutamatergic inputs from the hippocampus and from supramammillary calretinin (CR)-containing neurons. They are also innervated by other supposedly excitatory inputs from Leu-enkephalin (L-Enk)-containing axons originating in the perifornical area and Substance-P (SP)-immunoreactive fibers arriving from the laterodorsal tegmental area.

This study investigated the presence of ionotropic AMPA receptor subunits GluR1 and GluR2/3 in LS neurons targeted by these pathways. Single immunostaining for GluR1 and GluR2/3 was performed on septal sections of fimbria-fornix transected animals; double immunostaining for AMPA subunits and SP, L-Enk, and CR was carried out on septal sections of intact rats.

Neurons containing GluR1 and GluR2/3 were abundant and homogeneously distributed in the LS. GluR1 was most intensively expressed in dendrites and somatic and dendritic spines, while GluR2/3 was exclusively associated with the soma and proximal dendrites. Hippocampal, SP, and CR fibers terminated on both GluR1- and GluR2/3-containing neurons. All enkephalinoceptive neurons contained both GluR1 and GluR2/3. Degenerated hippocampal-septal boutons formed asymmetric synapses on GluR1-containing spines. In contrast, only a very few hippocampal fibers were seen in contact with GluR2/3 stained profiles. SP-, L-Enk-, and CR-immunoreactive boutons established asymmetric synaptic contacts with the soma and dendritic shafts of both GluR1- and GluR2/3-immunoreactive neurons.

Regarding the differential intracellular distribution of AMPA receptor subunits, these observations suggest that hippocampal input on GluR1-containing spines can elicit a much higher calcium influx than the ascending hypothalamic and tegmental afferents, that terminate on the predominantly GluR2/3-containing perisomatic area. Supported by NS 26068

## 143.10

**CALCIUM SIGNALING PATHWAYS INVOLVED IN THE RESPONSE TO METABOTROPIC GLUTAMATE RECEPTOR-1 (mGluR1) AGONISTS IN CULTURED PURKINJE NEURONS.** J.G. Netzeband\*, K.L. Parsons, D.D. Sweeney and D.L. Gruol. Dept. Neuropharmacol., The Scripps Research Institute, La Jolla, CA 92037.

The purpose of the present studies was to investigate the role of extracellular and intracellular  $\text{Ca}^{2+}$  on both the  $\text{Ca}^{2+}$  signal and electrophysiological response to mGluR1 agonists. Both inositol trisphosphate (IP3)-gated and ryanodine-gated intracellular  $\text{Ca}^{2+}$  stores were examined. FURA-2 microscopic  $\text{Ca}^{2+}$  imaging or current clamp recordings were used to record the  $\text{Ca}^{2+}$  signal or voltage response of cultured rat Purkinje neurons (>16 days in culture) to the mGluR1 agonists (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (ACPD; 300  $\mu\text{M}$ ), 3,5-dihydroxyphenylglycine (DHPG; 200  $\mu\text{M}$ ), glutamate (50  $\mu\text{M}$ ), and quisqualate (Quis; 1–5  $\mu\text{M}$ ). The mGluR1 agonists were applied by rapid microperfusion (1 s). In  $\text{Ca}^{2+}$ -free solution, Quis ( $n=27$ ) and glutamate ( $n=6$ ) elicited small, but reproducible increases in  $\text{Ca}^{2+}$  levels in both the soma and dendrites. Similar results were obtained with a concentration of  $\text{La}^{3+}$  (100  $\mu\text{M}$ ) which blocks all  $\text{Ca}^{2+}$  channel activity. These data show that mGluR1 agonists mobilize  $\text{Ca}^{2+}$  from intracellular stores.  $\text{Ca}^{2+}$  signals to Quis were attenuated (40–50%) by 2,5-di(*t*-butyl)-1,4-hydroquinone (DTBHQ; 10  $\mu\text{M}$ ;  $n=33$ ) or thapsigargin (1  $\mu\text{M}$ ;  $n=11$ ), inhibitors of the  $\text{Ca}^{2+}$ -ATPase responsible for re-uptake of  $\text{Ca}^{2+}$  into IP3-gated stores. Similarly, the ryanodine receptor antagonist dantrolene (10  $\mu\text{M}$ ;  $n=9$ ) reduced the peak  $\text{Ca}^{2+}$  signal to ACPD by 40–65%. In contrast, thapsigargin (but not dantrolene) reduced the electrophysiological signal to ACPD. Thus, both IP3- and ryanodine-gated stores contribute to the  $\text{Ca}^{2+}$  signal to mGluR1 agonists in cultured Purkinje neurons. However, the data also suggest that the electrophysiological response is more heavily dependent on  $\text{Ca}^{2+}$  release from IP3-gated stores. Supported by AA 06665 and AA 05421.

## 143.12

**THE RELATION OF THE HETEROMERIC CONSTRUCTION OF GLU SUBUNITS AND THE NEURON SPECIFIC CALCIUM BINDING PROTEINS IN THE MURINE CEREBRAL CORTEX**

M. Kondo<sup>1,2</sup>, H. Kamogawa<sup>2\*</sup>, R. Sumino<sup>2</sup> and H. Okado<sup>1</sup>.

<sup>1</sup>Dept. of Neurobiology, Tokyo Metropolitan Inst. for Neurosci., Fuchu 183; <sup>2</sup>Dept. of Physiology, Sch. of Dent., Nihon Univ., Chiyoda 101, Japan.

The AMPA receptors in the central nervous system play an excitatory synaptic transmission mechanism. The AMPA receptors in the majority of neurons are weakly permeable to  $\text{Ca}^{2+}$ , while the absence of GluR2 subunit increases the  $\text{Ca}^{2+}$  permeability. To determine the distribution of the type 1 (with GluR2 subunit) and type 2 (without GluR2 subunit) neurons in the cerebral cortex of the rat, we performed double stainings, combining nonradioactive *in situ* hybridization and immunocytochemistry. In addition, we analyzed the immunoreactivity of the neuronal calcium binding proteins, parvalbumin and calbindin D-28k in these two types of neurons. The type 2 neurons, which were immunoreactive with anti-GluR1 antibody and lacked GluR2 mRNA, were almost nonpyramidal cells, whereas the type 1 neurons, which contained GluR2 mRNA, were mainly pyramidal ones and a part of neurons were nonpyramidal ones. Some type 2 neurons, which showed nonpyramidal shape, were stained for parvalbumin immunoreactivity. The pyramidal type 1 neurons with weak level expression of GluR1 were lightly stained for calbindin D-28k immunoreactivity and the nonpyramidal type 1 ones with intensive expression of the GluR1 revealed the strong calbindin D-28k immunoreactivity. It was suggested that the varied combinations of GluR subunits were related to the expression of the differential calcium binding proteins.

## 143.14

**AMPA RECEPTOR SUBUNIT EXPRESSION IN PARVALBUMIN AND CALRETININ POSITIVE NEURONS OF THE HIPPOCAMPUS.** M.V. Catania<sup>1</sup>, M. Bellomo<sup>2</sup>, R. Giuffrida<sup>2\*</sup>, and V. Albanese<sup>1</sup>. <sup>1</sup>Istituto di Bioimmagini e Fisiopatologia del Sistema Nervoso Centrale (IBFSNC), CNR, Piazza Roma 2, 95123 Catania and <sup>2</sup>Istituto di Fisiologia Umana, Univ. Catania, 95125 Catania, Italy.

Recent studies suggest a functional diversity of native AMPA receptors (AMPA) with respect to their  $\text{Ca}^{2+}$  permeability and kinetic properties. In interneurons, AMPARs are characterized by higher  $\text{Ca}^{2+}$  permeability and faster kinetics than AMPARs in principal cells, possibly due to a low GluR-B and a high GluR-D subunit expression, respectively. We studied the mRNA expression profile of AMPAR subunits in the hippocampal parvalbumin (PV) and calretinin (CR) positive cells, which are different populations of non-principal cells. A double-labeling approach was used: non-radioactive *in situ* hybridization and immunohistochemistry.

The majority of PV-positive neurons were characterized by a predominant expression of GluR-A, -C and -D mRNAs and low or undetectable expression of GluR-B mRNA throughout the hippocampus. CR-positive cells were characterized by a different regional expression of AMPAR subunits. In the hilus and CA3 region, large CR-positive neurons exhibited high levels of GluR-A and -D, whereas in the other regions CR-positive neurons were moderately or weakly labeled for GluR-A and -D. CR-positive neurons were generally weakly labeled for both GluR-B and -C, although some big hilar neurons occasionally exhibited moderate levels of GluR-B and -C subunit.

This study indicates that the coexistence of GluR-A, -C and -D is a common feature of hippocampal PV positive cells and suggests the presence of AMPARs with fast kinetics and high  $\text{Ca}^{2+}$  permeability. On the contrary, AMPAR subunit expression was dissimilar in CR positive neurons suggesting the existence of at least two cell populations with different location and electrophysiological properties.

## TETANIC STIMULATION OF EXCITATORY SYNAPTIC INPUTS TO CA3 STRATUM RADIATUM INTERNEURONS

F. Laezza\* and R. Dingledine. Dept. of Pharmacol., Emory Univ., Atlanta, GA.

In the CA3 str. radiatum of the rat hippocampus two types of GABAergic interneurons can be identified based on the properties of the AMPA receptor mediated EPSCs. In type I neurons, EPSCs show linear I-V relationships and are not affected by the polyamine toxins Joro spider toxin (JSTX) or N-(4-Hydroxy-phenyl-propanoyl)-spermine (NHPP), while in type II cells EPSCs are characterized by inwardly rectifying I-V relationships and are suppressed by JSTX or NHPP, suggesting a prominent expression of  $Ca^{2+}$ -permeable AMPA receptors in type II neurons. To determine whether  $Ca^{2+}$  entry through synaptic AMPA receptors triggers forms of synaptic plasticity, we studied the effect of tetanic stimulation of excitatory synaptic inputs to type I and II neurons. EPSCs were evoked by electrical stimulation of CA3 pyramidal cells in the presence of 10  $\mu$ M bicuculline and 50  $\mu$ M D-APV, in the hippocampal slice preparation. Biocytin (~0.4%) was added in the intracellular solution for morphological verification following whole cell recording. After 5-15 minutes of low frequency (0.16 Hz) control stimulation, tetanic stimulation (usually 3x100 Hz, 0.3s) was applied while the neuron was voltage clamped at -70/-80 mV. High frequency stimulation was followed in type II neurons by synaptic depression (n=3) lasting up to 50 minutes and short or long term potentiation (n=2). In two type II neurons no clear effect was detectable, although a trend to synaptic depression was present. In contrast, no change in EPSC amplitude was detected after high frequency stimulation in type I neurons (n=3). JSTX or NHPP (10  $\mu$ M) applied in the bath solution 40-60 minutes after tetanic stimulation reduced EPSC amplitude >35% in type II (n=3) and <12% in type I (n=2) neurons. These results suggest that type II neurons might possess some forms of synaptic plasticity induced by high frequency stimulation, probably mediated by  $Ca^{2+}$  flux through AMPA receptors. ## IMMUNOHISTOCHEMICAL LOCALIZATION OF METABOTROPIC GLUTAMATE RECEPTORS (mGluRs) IN THE RAT BASAL GANGLIA C.M. Testa\*, S.W. Weiss and D.G. Standaert. Dept. of Neurology, Mass. Gen. Hosp., and Harvard Medical School, Boston, MA 02114.

mGluRs, which couple glutamate to second messengers, have important roles in basal ganglia function. We used two polyclonal antisera to investigate mGluR1 and mGluR2/3 localization in rat basal ganglia. Using confocal laser microscopy, mGluRs were visualized in combination with tyrosine hydroxylase (TH), MAP2 (dendritic marker), or SV2 (presynaptic marker) immunoreactivity (ir). In neostriatum, punctate mGluR1-ir was present in the neuropil. This staining did not colocalize with MAP2 or SV2, and was not altered by decortication or unilateral 6-OHDA lesions. In the globus pallidus (GP) and substantia nigra pars reticulata (SNpr), however, mGluR1-ir was tightly clustered along large, MAP2-ir dendrites. In contrast, punctate mGluR2/3-ir staining was observed within the neuropil of all basal ganglia structures. In striatum these puncta were abundant; some colocalized with SV2-ir. Striatal mGluR2/3-ir puncta were markedly reduced in number after decortication, but not altered by 6-OHDA lesions. Unlike mGluR1, mGluR2/3-ir in the GP and SNpr was not associated with MAP2-ir dendrites. Neither mGluR1-ir nor mGluR2/3-ir could be detected in TH-ir soma within substantia nigra pars compacta, or in TH-ir striatal terminals.

Overall mGluR2/3-ir is similar in pattern across the basal ganglia whereas mGluR1 has distinct subcellular localizations, and therefore possibly distinct functions. These data support a presynaptic location for mGluR2/3 in striatum, and a postsynaptic location for mGluR1 on large GP and SNpr dendrites. Supported by the National Parkinson Foundation & NS31579.

## 143.19

## DETERMINATION OF DISTRIBUTION OF mGLUR4a AND mGLUR7 DURING DEVELOPMENT WITH SUBTYPE-SPECIFIC ANTIBODIES. S. R. Bradley\*, A. I. Levey, A. I. Uyoe, and P. J. Conn. Departments of Neurology and Pharmacology, Emory University School of Medicine, Atlanta, GA 30322.

Polyclonal antibodies that specifically react with two subtypes of metabotropic glutamate receptors (mGluRs), mGluR4a or mGluR7, were produced and characterized by immunoblot analysis and immunocytochemistry. Antibodies were generated against the C-terminal domains of mGluR4a and mGluR7 using synthetic peptide immunogens. Both antibodies recognized native proteins in rat brain with molecular weights similar to the molecular weights of the bands in mGluR-transfected cell lines. Immunoblot analysis revealed that the levels of mGluR7 are differentially regulated in different brain regions during development. For instance, in the hippocampus, cortex, and midbrain, mGluR7 immunoreactivity is higher at postnatal days 7, 14, and 21 than in adults. In contrast, mGluR7 immunoreactivity is high at postnatal day 7 in cerebellum and pons/medulla, but is relatively low at postnatal days 14, 21, and in adults. Immunocytochemistry and western blot analysis revealed that mGluR4a and mGluR7 are widely but differentially distributed throughout the rat brain, and also that they are localized in specific cellular sites. Strong mGluR4a immunoreactivity was observed throughout the brain whereas the distribution of mGluR7 immunoreactivity was more varied, with heavy staining in cortical and limbic regions and light staining in pons/medulla and cerebellum. Analysis at the electron microscopy level revealed that mGluR7 immunoreactivity is largely presynaptic, though postsynaptic mGluR7 staining was also observed. In contrast, mGluR4a immunoreactivity was present on both presynaptic and postsynaptic elements. These data are consistent with the postulated role of mGluR4 and mGluR7 as presynaptic autoreceptors in a variety of brain regions and suggest that mGluR4 may also have a postsynaptic function. Supported by a NIH NRSA postdoctoral fellowship (SRB) and NIH NINDS grant NS31373 (PJC).

## 143.16

## METABOTROPIC GLUTAMATE RECEPTORS SUPPRESS EXCITATORY SYNAPTIC INPUTS TO DENTATE INTERNEURONS.

J. Doherty\*, and R. Dingledine. Dept. of Pharmacol., Emory Univ., Atlanta, GA.

The effects of subtype selective metabotropic glutamate receptor (mGluR) agonists on interneurons at the granule cell/hilar border in the dentate gyrus (DG) were examined under whole-cell voltage clamp using slices of neonatal rat hippocampus. We have previously shown that the mGluR antagonist (+) MCPG (500  $\mu$ M) attenuates hypoxic suppression of excitatory input to DG interneurons. Therefore, we investigated which mGluRs were capable of mediating suppression of excitatory inputs to DG interneurons. Individual interneurons were morphologically identified with Hoffman modulation contrast optics and confirmed by a biocytin staining protocol following electrophysiological study. Minimal electrical stimulation of either DG granule cells or CA3 pyramidal cells generated AMPA and NMDA receptor mediated excitatory postsynaptic currents (EPSCs) in DG interneurons. Excitatory input from DG granule cells was suppressed by the nonselective mGluR agonist, ACPD (10-100  $\mu$ M) and selective group I (DHPP, 20-50  $\mu$ M), group II (DCG-IV, 1  $\mu$ M), and group III (L-AP4, 100  $\mu$ M) agonists. In contrast, excitatory input from CA3 was suppressed by selective group I and III agonists, but not the group II agonist. 1S,3R-ACPD and DHPP evoked inward currents in dentate interneurons and increased the frequency of spontaneous EPSCs. Suppression of excitatory input to DG interneurons by mGluRs, as occurs during transient hypoxic episodes, may modulate synaptic inhibition in the DG by regulating the output of feedback inhibitory interneurons. The differential sensitivity of input from the CA3 and DG granule cells to group II mGluRs may provide a mechanism to selectively enhance the effectiveness of feedback inhibition from the CA3 to DG during conditions when mGluRs are active. This work was supported by NS17771.

## 143.18

SUBTYPE-SPECIFIC IMMUNOHISTOCHEMICAL LOCALIZATION OF METABOTROPIC GLUTAMATE RECEPTORS 2/3, 5 AND 7 IN THE RAT OLFACTORY BULB. Y. Sahara\*, T. Kubota\*, N. Noro\*, M. Ichikawa\* and Y. Nakamura\*. <sup>1</sup>Dpt. Physiol., Fct. Dent., <sup>2</sup>Schl. Allied. Hlth. Sci., Tokyo Med. & Dent. Univ., <sup>3</sup>Dpt. Pharmacol., Schl. Med., Univ. Tokyo, Tokyo 113, <sup>4</sup>Dpt. Anat. & Embryol., Tokyo Metropol. Inst. Neurosci., Tokyo 181 Japan.

Anti-peptide antibodies directed to metabotropic glutamate receptors (mGluRs) 2/3, 5 and 7 were used to study the precise distribution of mGluRs-immunoreactivities in the rat olfactory bulb. Each antibody was subtype-specific and selectively stained different elements in the olfactory bulb. In the main olfactory bulb, light microscopic analysis revealed intense mGluR2/3 and mGluR5 staining in the periglomerular region and the external plexiform layer, while cell bodies of the mitral cell and the granule cell lacked of staining. In electron microscopic analysis, immunoreactivities of mGluR2/3 and mGluR5 were recognized in dendrites of the granule cell. The mitral cell bodies were strongly immunoreactive for mGluR7, which was associated with endoplasmic reticulum and Golgi apparatus. In the accessory olfactory bulb, the mitral/tufted cell layer as well as the granule cell layer were intensely stained with mGluR2/3 and mGluR5 antibodies, and were also immunoreactive for mGluR7. Cell bodies of the mitral/tufted cell were not immunoreactive. In electron microscopy, immunoreactivities of mGluR2/3, 5 and 7 were recognized in dendrites of the granule cell. The glomerular layer was immunoreactive for mGluR 5. These results suggest that each subtype of mGluR plays a specific functional role in olfaction. Supported by Uehara Memorial Foundation.

## 143.20

## EXPRESSION OF GROUP I METABOTROPIC RECEPTORS BY POPULATIONS OF NEURONS IN THE RAT NEOSTRIATUM.

J.A. Kerner, D.G. Standaert, J.B. Penney, Jr., A.B. Young\*, and G.B. Landwehrmeyer. Dept. of Neurology, Mass. Gen. Hosp., Boston, MA 02114.

In the striatum, metabotropic glutamate receptors (mGluRs) couple to second messenger systems via G-proteins. The mGluRs can be divided into three groups based on homology and pharmacology. We studied expression of group I mGluRs (mGluR1 and mGluR5) in rat striatum using a quantitative RNA probe *in situ* hybridization method. Radiolabeled probes for mGluR 1 or 5 were hybridized with digoxigenin probes for somatostatin (SOM), preproenkephalin (ENK), preprotachykinin (SP), glutamic acid decarboxylase 67 (GAD67), parvalbumin (PARV), or choline acetyltransferase (ChAT).

mGluR5 mRNA was very abundant in the striatum. Projection neurons were intensely labeled, SP neurons more than ENK neurons. Of the interneuron populations studied, only GAD67 positive cells exhibited a significant mGluR5 signal; the intensity was about half that seen in the projection neuron populations. The intensity of the mGluR1 signal in the striatum was much less than that of mGluR5. The strongest signal was seen in SP-positive neurons. ENK-positive projection neurons as well as ChAT, PARV, GAD67 and SOM positive interneurons were also labeled by the probe for mGluR1 mRNA.

Group I mGluR's have been implicated in excitotoxicity because of their ability to regulate intracellular calcium. The differential expression of mGluR1 and mGluR5 by distinct types of striatal neurons may contribute to their selective vulnerability in neurodegenerative disease and neural injury. Supported by USPHS grants NS31579 and AG11337.

## 144.1

**Differential cellular and regional distributions of the glutamate transporters GLT1 and EAAC1: an in situ hybridization analysis in the rat brain.** Torp, R., Danbolt, N.C., Storm-Mathisen, J., Ottersen, O.P. Dep. of Anatomy, University of Oslo, P.O. Box 1105, N-0317 Oslo 3, Norway.

The cellular and regional distribution of mRNA encoding the newly cloned glutamate transporter EAAC1 (the rat homologue of rabbit EAAC1) was investigated by nonautoradiographic in situ hybridization using digoxigenin labelled riboprobes. The distribution of this mRNA species was compared with that of mRNA coding for GLT1. The two transporters showed very different expression patterns. The probe recognizing EAAC1 mRNA labelled exclusively neuronal cells. GLT1 mRNA was predominantly glial, but some neuronal populations were labelled, including many thalamic and neocortical neurons. The neurons containing the GLT1 transcript exhibited a distribution that was different from, and at some sites complementary to, the distribution of neurons containing EAAC1. In the subiculum, for example, neurons positive for GLT1 and EAAC1 were found in the deep and superficial cell layers, respectively, while in the parietal neocortex GLT1 predominated in layer VI and EAAC1 in layer V. Very few neuronal populations, most notably cells in hippocampal subfields CA3 and CA4, and in layer II in the entorhinal cortex, appeared to be equipped with both transcripts. In the cerebellum, GLT1 mRNA was restricted to astrocytes, while EAAC1 was found in granule cells and occurred in particularly high concentrations in some Golgi neurons and neurons in the cerebellar nuclei. It can be concluded that the two glutamate transporters show highly differentiated distributions in rat brain and that they may prove useful targets in future attempts to modify glutamatergic transmission in select brain regions and nerve pathways.

## 144.3

**ATP-INDUCED RELEASE OF EXCITATORY AMINO ACIDS FROM CULTURED ASTROCYTES IS CALCIUM-DEPENDENT.** S. Jętriniak\* and K. Jętriniak, Department of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011, USA.

The specific objective of this study was to study the mechanism by which ATP releases excitatory amino acids (EAA) from cultured astrocytes. Dissociated cortical glia cultures were grown on polylysine coated coverslips. Cultures were mounted in a perfusion chamber and perfused at a rate of 200  $\mu$ l/min, with gassed Ringer solution at 36 $\pm$ 1 $^{\circ}$ C. Quantification of amino acids was performed by high performance liquid chromatography utilizing fluorescence detection and pre-column OPA-derivatization. Following a period of culture equilibration, 1 min, 200  $\mu$ l samples were collected. Baseline concentrations of Asp and Glu in astrocyte cultures were 28 $\pm$ 12 nM (mean $\pm$ SD; n=12) and 38 $\pm$ 18 nM, respectively. Perfusion application of 100  $\mu$ M ATP for 2 min to astrocytes resulted in an 179 $\pm$ 4% increase of Asp and 212 $\pm$ 10% increase of Glu release. A second application of ATP 10 min after first application resulted in a increase in the release of both EAA's that was at the level of 64% of that from the first application. Ten min application of ATP to glial resulted in a peak increase in the release followed by a decline to a plateau significantly higher than baseline release. Bath application of adenosine (100  $\mu$ M) was without effect on release of EAA suggesting involvement of P2 receptors. Suramine, a competitive antagonist at P2 receptors, produced a block of the response to ATP. The release of EAA evoked by ATP was not abolished in low Ca-EGTA solution. Pretreatment of the astrocyte cultures with 50  $\mu$ M BAPTA-AM abolished the effect of ATP. U73122, a PLC inhibitor, abolished stimulatory effect of ATP suggesting involvement of an IP3-sensitive calcium store. An anion transport blocker, furosemide, blocked ATP-induced glutamate release. Our results show that ATP selectively evokes the release of EAAs from cultured glia by activating intracellular calcium stores.

## 144.5

**DETERMINATION OF CALCIUM (Ca<sup>2+</sup>)-INDEPENDENT COMPONENT OF GLUTAMATE (GLU) AND GABA RELEASE BY MINIMIZATION OF PRE-SYNAPTIC Ca<sup>2+</sup> INFLUX.** S.M. Lasley\* and M.C. Green. Dept. Biomed. and Therapeutic Sci., U. Illinois Coll. of Medicine, Peoria, IL 61656.

The amounts of GLU and GABA measurable in brain extracellular fluid (ECF) emanate from multiple sources. Ca<sup>2+</sup>-dependent release was defined as the difference between GLU/GABA measured in the presence of Ca<sup>2+</sup> (total release) and its absence (Ca<sup>2+</sup>-independent release). This experiment was designed to accurately identify the Ca<sup>2+</sup>-independent component by microdialysis perfusion of brain tissue with Ca<sup>2+</sup>-free solutions in awake rats. Bilateral guide cannulae were stereotactically implanted under anesthesia in dorsal hippocampus, and dialysis initiated 2-4 days later by insertion of probes that extended 2 mm beyond the cannula tips. Animals were perfused with a modified Ringer's solution on one side (for total release) and the same solution with Mg<sup>2+</sup> replacing Ca<sup>2+</sup> with or without Ca<sup>2+</sup> channel blockers on the opposite side. After establishing basal levels of ECF GLU and GABA, release was stimulated by switching perfusion to Ringer's containing 150 mM K<sup>+</sup> (no Na<sup>+</sup> to maintain isotonicity). 40 min later perfusion was returned to the initial solution. Removal of Ca<sup>2+</sup> from the perfusate significantly elevated basal levels of GLU and GABA and further enhanced K<sup>+</sup>-stimulated release by 20-30% compared to rats dialyzed with modified Ringer's. Addition of 1 mM Cd<sup>2+</sup> to the Ca<sup>2+</sup>-free perfusate effectively diminished K<sup>+</sup>-evoked release but markedly increased basal levels of GLU (28-fold) and GABA (11-fold). Inclusion of 1 mM methoxyverapamil (MVP) in the Ca<sup>2+</sup>-free medium significantly decreased basal levels of GABA and blocked K<sup>+</sup>-stimulated GLU and GABA release. With use of MVP the proportion of total release that was Ca<sup>2+</sup>-dependent was found to be 82% for GLU and 95% for GABA. These results suggest that dialysis with simple Ca<sup>2+</sup>-free solutions is insufficient to identify Ca<sup>2+</sup>-independent release, and indicate that the preferred Ca<sup>2+</sup> channel blocker is one that does not also support exocytosis. (Supported by NIH ES06253)

## 144.2

**THE EFFECTS OF GLUTAMATE ON THE DENDRITE OUTGROWTH OF CULTURED HIPPOCAMPAL NEURONS: ELECTRON MICROSCOPIC EXAMINATION OF THE CYTOSKELETON.**

Charles H. Keith\* and Mark T. Wilson. Cellular Biology, University of Georgia, Athens, GA 30602.

Glutamate-induced increases in Ca<sup>2+</sup> have been shown to cause dendrite retraction in cultured hippocampal neurons. This effect of glutamate is dendrite specific and may be important for modulating dendrite outgrowth during neuronal development in the hippocampus. Various cytoskeletal changes must occur after glutamate exposure, however, previous studies have not examined these changes at the ultrastructural level.

In the present study, hippocampal neurons were dissected from E17-18 rat (*sprague dawley*) embryos and co-cultured for 2 days with astrocytes before exposure to glutamate. The axons and dendrites of control and experimental neurons were measured and then fixed for electron microscopic examination.

After 4 hours of glutamate exposure dendrites stopped growing. Twelve hours after glutamate exposure dendrites were reduced in length, as compared to pre-glutamate dendrite lengths. Axons continued to grow after both 4 and 12 hours of glutamate exposure. Ultrastructural examination of the dendrites from control and experimental neurons displayed no obvious difference in microtubule morphology or distribution. The lack of changes in dendritic microtubules after glutamate exposure may implicate the actin filaments as the primary targets of glutamate-induced dendrite retraction.

## 144.4

**THE EAAT4 IS A PURKINJE CELL-SPECIFIC, POST-SYNAPTIC GLUTAMATE TRANSPORTER IN THE BRAIN.**

K. Yamada, M. Watanabe, T. Shibata\*, K. Tanaka<sup>1</sup>, K. Wada<sup>1</sup>, Y. Inoue.

Dept. of Anat., Hokkaido Univ. Sch. of Med., Sapporo 060. <sup>1</sup>Dept. of Degenerative Neurological Diseases, National Institute of Neurosci., NCNP, Kodaira 187, Japan.

The glutamate transporter plays important roles in termination of the glutamate receptor activation and in protection of neurons from the glutamate excitotoxicity. The EAAT4 is the fourth subtype of the glutamate transporter, with properties of ligand-gated chloride channel activities. To clarify the expression and localization, in situ hybridization and immunohistochemistry were applied to the mouse brain. Antisense oligonucleotide probes labeled with <sup>33</sup>P-dATP demonstrated its specific expression in cerebellar Purkinje cells. The transcripts were detected in Purkinje cell layer of the posterior cerebellum as early as embryonic day 15. Immunohistochemistry with anti-peptide antibody revealed that the distribution of the EAAT4 was restricted to the molecular layer of the cerebellum. In the layer, the strong immunoreactivity was observed as numerous punctate stainings, while perikarya and thick dendrites of the Purkinje cells were labeled only weakly. No immunoreactivity was detected in the axons nor terminals. By immunoelectron microscopy, the antibody labeled dendritic spines of the Purkinje cells. These findings indicate that the EAAT4 is a Purkinje cell-specific glutamate transporter localized at the post-synapse. Taken together with previous results on dense localization of the GluT-1 and GLT1 on the Bergmann astrocytes, the Purkinje cell synapses are thus provided with distinct transporter subtypes at discrete synaptic elements.

## 144.6

**EXTRACELLULAR GLUTAMATE INDUCES LEUKOCYTE ADHERENCE TO PIGLET PIAL VENULES.** A.B. Shah, J.M. Gidday, J.W. Beetsch, E.R. Gonzales, Y.-B. Lee, R.G. Maceren, M.J. Noetzel\*, T.S. Park. Departments of Neurology and Neurological Surgery, and St. Louis Children's Hospital, Washington University School of Medicine, St. Louis, MO 63110

Glutamate release is important in the induction of several neurochemical cascades that promote tissue injury following cerebral ischemia. An inflammatory response to cerebral ischemia with leukocyte recruitment is gaining recognition as another important factor contributing to ischemic injury. We tested the hypothesis that glutamate can initiate an inflammatory response in the cerebral circulation. Anesthetized newborn pigs were equipped with closed cranial windows for epifluorescent videomicroscopy of rhodamine 6G-labelled leukocyte dynamics. Glutamate (1  $\mu$ M, 10  $\mu$ M, or 100  $\mu$ M in CSF) was superfused (50  $\mu$ l/min) continuously through the window in separate animal groups (n=4 each), and leukocyte adherence was measured after 30, 60, and 120 minutes of superfusion. Relative to a control group (n=8), we found no increases in adherence with 1  $\mu$ M or 10  $\mu$ M glutamate, but 100  $\mu$ M glutamate caused a progressive, significant increase in adherence over time. The extent of adherence induced by 100  $\mu$ M glutamate did not differ from that observed in response to complete global ischemia (n=5). These findings indicate that extracellular glutamate, at a concentration similar to that measured in brain following ischemic insults, can induce an inflammatory response in cerebral venules that, in turn, is associated with increases in vascular permeability (see ER Gonzales et al., this volume). Leukocyte adherence may be secondary to glutamate-induced oxygen free radical formation and/or stimulated production of other inflammatory mediators. This mechanism, and its role in secondary brain injury following ischemia, have yet to be determined. (NINDS 21045 and 32568).

## 144.7

A1, mGluR2 Auto AND GABAB HETERORECEPTORS COMODULATE PURINE AND EAAs RELEASE FROM RAT HIPPOCAMPAL SYNAPTOSOMES. A. Poli\*, P. Di Iorio, F. Caciagli, R. Ciccarelli, P. Giuliani, P. Ballerini, R. Lucchi and F. Nicoletti. Dept Biology, Univ. Bologna, Italy. \*Inst. Pharmacology, Univ. Chieti, Italy. ^Inst. Pharmacology, Univ. Catania, Italy. Previous our findings indicate that presynaptic A1 adenosine (Ado) receptor and class II metabotropic glutamate receptors (mGluR2 and 3) co-operate in inhibiting the evoked release of purines and excitatory amino acids (EAAs) from slices and synaptosomes of rat hippocampus. In the present study, we evaluated whether presynaptic A1, mGluR2 as well as the GABAB receptors are involved in this modulatory mechanism for the purine and EAA release as well as that of GABA from rat hippocampal synaptosomes likely through a common signal transduction mechanism. K-induced release of endogenous Ado, glutamate (Glu) and GABA was increased in a concentration-dependent fashion. The fluorescent probe bisoxonol (0.5 µM) confirmed that K<sup>+</sup> caused a dose-dependent membrane depolarization, which was significantly reduced by the pretreatment with CCPA, DCG-IV and (±)baclofen respectively. All these agonists reduced the evoked release of Ado and Glu in a dose-dependent fashion (IC50 25 nM for CCPA, 4 µM for DCG-IV and 70 µM for baclofen), and this effect was less than additive when the drugs were used in combination. On the contrary, K<sup>+</sup>-evoked GABA release was unaffected either by CCPA or by DCG-IV, whereas (±)baclofen was able to reduce GABA release only at doses 200 µM. The A1 and mGluR2 antagonists DPCPX (100 nM) and MCCO-I (300 µM) counteracted the inhibitory effects of the respective agonists on the K<sup>+</sup>-evoked release of both Ado and Glu. Phaclofen (1 mM), the GABAB autoreceptor antagonist, did not modify the baclofen-induced inhibition of K<sup>+</sup>-evoked Glu and Ado release, whereas completely prevented that of GABA release. These findings suggest that presynaptic A1 Ado receptor and mGluR2 as well as GABAB heteroreceptor exert an inhibitory control on the release of both purines and EAAs.

## 144.9

GLUTAMATE, ASPARTATE AND CALBINDIN IN THE MEDIAL THALAMUS: AN IMMUNOHISTOCHEMICAL STUDY IN THE RAT. M. Bentivoglio\*, C. Frasson<sup>2</sup>, R. Spreafico<sup>2</sup>. <sup>1</sup>Inst. Anat. Histol., Univ. Verona, 37134 Verona, <sup>2</sup>Neurological Institute "C. Besta", 20133 Milan, Italy.

Topographical and quantitative features of medial thalamic neurons in which aspartate (ASP) or glutamate (GLU) may serve a neurotransmitter role were investigated in the rat. The calcium binding protein calbindin D-28k (CB) was exploited as a marker of neuronal subsets, thus allowing also to study the relationships between the CB-containing thalamic neurons and those immunoreactive (ir) to excitatory amino acids. Double immunocytochemistry of ASP and CB, or GLU and CB, was performed in 40 µm thick sections. The three markers were distributed, with regional variations, in the thalamic midline and medial nuclei, where ASP-ir neurons appeared more numerous than the GLU-ir ones; ASP-CB or GLU-CB double immunostained neurons were evident. ASP-, GLU-, CB-ir cells were then quantitatively evaluated in 5 µm thick consecutive sections. Interindividual variations and different anti-ASP and anti-GLU antibodies did not result in significant differences. ASP and GLU were not co-localized. Single ASP- or GLU-ir neurons accounted for 60% of the total number of immunostained cells; ASP-ir cells represented more than half of these neurons. Half of the CB-ir cells were double immunostained. The proportion of double CB-ASP-ir neurons was sevenfold higher than that of the CB-GLU-ir ones. These results suggest that ASP may act as excitatory neurotransmitter in a relatively high proportion of medial thalamic neurons, in which ASP frequently coexists with CB. About 50% of the CB-ir cells did not contain either ASP or GLU, suggesting that some medial thalamic neurons may utilize a different excitatory neurotransmitter.

## 144.8

IMMUNOCYTOCHEMICAL CHARACTERIZATION OF HOFMANN NUCLEI NEURONS.

A.L. Eide\*, R. Torp. Inst. Basic Medical Sciences, University of Oslo, Norway.

Hofmann Nuclei (HN) neurons are commissurally projecting neurons in the spinal cord of birds. Recent tracing studies have established the detailed projection pattern of these neurons and their anatomical input (Eide, 1996). The cells have been suggested as a useful model for studies of intersegmental connectivity in the spinal cord; physiologically as well as developmentally. Yet little is known about the function of the neurons.

We have made an attempt to characterize the transmitter substances involved in these spinal circuits by use of antibodies directed to some of the well established amino acid transmitters. The separate location of the HN neurons in segmentally iterated clusters attached on the lateral surface of the spinal cord make the cells a favourable population in which to use immunocytochemical methods.

Chicken embryos at d18 were fixed and prepared for immunocytochemistry. For both LM and EM neighbouring sections were incubated in primary antisera to glutamate, GABA, and glycine.

The HN soma stained positive for glutamate and glycine indicating that these amino acids are colocalized within the neuron.

Punctuate staining around the cells at LM level indicated that the cells received glutamatergic input. This was confirmed with an immunogold technique at EM level where identified terminals making contact with the soma were enriched with glutamate like immunoreactivity.

## 144.10

QUANTITATION OF BLOOD CONTRIBUTIONS TO QUINOLINIC ACID CONCENTRATIONS IN BRAIN AND SYSTEMIC TISSUES. M.P. Heyes, K.E. Beagles, M.A. Zito, M.G. Proescholdt, S.P. Markey and P.F. Morrison. Section on Analytical Biochemistry, Laboratory of Clinical Science NIMH, and Biomedical Engineering, NCR, Bethesda MD 20892-1262.

The source of the neurotoxin quinolinic acid (QUIN) in brain and systemic tissues under normal and pathologic circumstances reflects either *de novo* synthesis from L-tryptophan and other precursors, or entry of QUIN itself from the blood. To quantify the relative contributions of blood versus tissue-derived QUIN, [<sup>13</sup>C<sub>7</sub>]-QUIN was infused in gerbils via osmotic pumps placed subcutaneously (30 mM at 0.55 µL/h), and the fraction of QUIN in tissue (Ti; measured in tissue homogenates) derived from blood (Bl; measured in serum) was calculated by the formula ([<sup>13</sup>C<sub>7</sub>]-QUIN<sub>Ti</sub> / QUIN<sub>Ti</sub>) / ([<sup>13</sup>C<sub>7</sub>]-QUIN<sub>Bl</sub> / QUIN<sub>Bl</sub>). In normal gerbils, blood QUIN contributed 40-50% of total QUIN in brain, 70% in CSF, >95% in spleen, lung, liver and intestine, and between 40-70% in kidney, heart and skeletal muscle. Systemic endotoxin (450 µg/kg) administration increased blood, brain, CSF and systemic tissue QUIN levels at 24 h. The relative proportion of QUIN derived from blood in brain, spleen, lung and intestine was unchanged by endotoxin, but increased in kidney, heart and skeletal muscle. In contrast, cerebral ischemic injury (10 min carotid artery occlusion) resulted in an increase in regional brain QUIN concentrations at four days, with a proportional increase in the amount of QUIN derived endogenously by brain. In the hippocampus for example, brain QUIN levels increased from 48±4 to 1571±453 pmol/g, and 94.6 % of QUIN was synthesized by tissue. There were no changes in the post-ischemic gerbils in systemic tissue or blood QUIN levels, or changes in the relative proportions of blood- versus tissue-derived QUIN. These results establish that the brain normally synthesizes QUIN, and that the rate of this formation increases in conditions of brain and systemic immune activation. The design of drugs to attenuate QUIN accumulations as potential therapeutic strategies needs to target appropriate tissue QUIN sources.

## CATECHOLAMINES: DOPAMINE I

## 145.1

IONTOPHORESIS OF AMPHETAMINE IN THE NEOSTRIATUM AND NUCLEUS ACCUMBENS OF AWAKE, UNRESTRAINED RATS. E.A. Kiyatkin\* and G.V. Rebec, Program in Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

The ability of amphetamine (AMPH) to enhance dopamine (DA) transmission in the neostriatum and nucleus accumbens is believed to play a critical role in the behavioral and psychogenic actions of this drug. To assess the direct effects of AMPH on neostriatal and accumbal neurons under naturally occurring behavioral conditions, single-unit recording was combined with iontophoresis in awake, unrestrained rats. Brief (15 - 20 s) applications of AMPH inhibited both spontaneously active and glutamate (GLU)-activated neurons, but the inhibition was stronger on the latter group. The inhibitory effect of AMPH occurred at low ejection currents (5 - 10 nA) and was dose-dependent. Onset (4 - 12 s) and offset (6 - 24 s) latencies were relatively brief. When applied for prolonged periods (2 - 4 min), AMPH exerted a powerful inhibition of the GLU response, resulting in a complete blockade of the response at higher currents (≥ 20 nA). Although systemic AMPH is known to activate many neostriatal and accumbal neurons in ambulant rats, this effect appears to require GLU afferents from cerebral cortex (Tschanz et al., Eur. J. Pharmacol., 257:161, 1994). AMPH iontophoresis, in contrast, may selectively increase the local accumulation of DA. Comparisons with iontophoretic DA obtained in previous work (Kiyatkin and Rebec, J. Neurophysiol., 75:142, 1996), however, indicate that AMPH is more potent than DA in terms of number of responsive cells, threshold currents, and magnitude of inhibition. This difference may reflect an action of AMPH on other monoaminergic systems, including serotonin. It appears, therefore, that local applications of AMPH do not mimic the systemic actions of this drug on neostriatal and accumbal neurons. Supported by NIDA (DA 02451).

## 145.2

GABA<sub>B</sub> RECEPTORS MODULATE THE FIRING PATTERN OF DOPAMINE NEURONS IN THE VENTRAL TEGMENTAL AREA

J.M. Mathé\*, K. Chergui, G. Engberg and T.H. Svensson. Dept. of Physiology and Pharmacology, Div. of Pharmacology, Karolinska Institutet, 171 77 Stockholm, SWEDEN

Our previous studies demonstrate the fundamental role of the firing pattern, rather than the average firing rate, of dopamine (DA) neurons for the regulation of DA release as well as in the DA effect on postsynaptic neurons. Here we have analyzed the role of GABA<sub>B</sub> receptors in the control of the firing pattern of DA neurons in the ventral tegmental area (VTA). Extracellular single cell recordings were obtained from VTA DA neurons in male chloral hydrate anesthetized SD rats. Discriminated action potentials were recorded by computer for analysis of firing rate, burst firing and regularity of firing, as assessed by the variation coefficient. Systemic administration of relatively low doses of baclofen (<8 mg/kg, i.v.), a selective GABA<sub>B</sub> agonist, dose-dependently reduced burst firing and increased the regularity of firing in VTA DA neurons. However, the firing rate was significantly reduced only after administration of high doses (≥8 mg/kg) of baclofen. The above effects were effectively antagonized by pretreatment with the selective GABA<sub>B</sub> antagonist CGP 35348 (100 mg/kg, i.v.), which did not affect the firing pattern of VTA DA cells when given alone. Local, microiontophoretic application on VTA DA cells of the above compounds induced essentially identical effects on the firing pattern as seen after systemic administration. Thus, GABA<sub>B</sub> receptors, similarly to NMDA receptors, can specifically control the firing pattern of mesolimbic and/or mesocortical DA neurons, without affecting their average firing rate. Since we have shown that specific alterations in firing patterns of midbrain DA neurons change gene expression in their target areas, GABA<sub>B</sub> receptors probably exert a prominent influence upon information processing in DA circuitries in brain. WHOLE CELL RECORDINGS FROM VISUALLY IDENTIFIED MESOCORTICAL DOPAMINE NEURONS IN BRAIN SLICES. W.-X. Shi\*, P. Zheng and B. S. Bunney. Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06510

Mesocortical dopamine (MC DA) neurons may play a key role in the development and treatment of schizophrenia. However, our knowledge of MC DA cells is still very limited, partially due to the technical difficulties of studying these cells. Thus far, MC DA cells have only been recorded *in vivo* with extracellular electrodes. To study MC DA cells in more detail and to overcome some of the limitations associated with an *in vivo* preparation, we developed a brain slice preparation in which MC cells in the VTA were first retrogradely labeled *in vivo* with fluorescent microspheres and then visually identified and recorded in slices under an upright fixed-stage fluorescence microscope. We made whole cell recordings from 16 identified MC cells. Half of them showed a hyperpolarization response to DA. Preliminary data suggest, however, that these cells are less sensitive to DA than nigral DA cells. Like SN DA cells, MC DA-responding cells had broad action potentials, large AHPs, and a strong time-dependent inward rectification during hyperpolarization. Unlike nigral DA cells, however, they had a much higher input resistance and longer membrane time constant. Most of them also lacked the transient outward rectifier and showed a fast rising LTS-like potential at the end of a hyperpolarization step. Most strikingly, MC DA-responding neurons were capable of firing at a much higher rate than SN DA cells without developing depolarization inactivation. Compared with MC DA-responding cells, MC DA non-responding neurons had a shorter membrane time constant and a lower input resistance. These cells also showed an inward rectifier during hyperpolarization. However, compared with that observed in MC DA-responding cells, the inward rectifier in MC DA non-responding cells was much faster in developing, thus giving rise to only a moderate degree of sag in response to a hyperpolarization step. The DA status of these two populations of MC cells is currently under investigation using double-staining for tyrosine hydroxylase.

D-AMPHETAMINE INHIBITS THE SPONTANEOUS ACTIVITY OF TWO- TO THREE-WEEK-OLD NIGRAL DOPAMINE NEURONS IN THE MIDBRAIN SLICE. Amy J. Barron\*, Mark W. Lewis and David K. Pitts. Department of Pharmaceutical Sciences, College of Pharmacy & Allied Health Professions, Wayne State University, Detroit, MI 48202.

Previous *in vivo* studies of nigral dopamine neuron responses to D-amphetamine (AMP) during the early postnatal period have suggested that AMP either exerts anomalous effects (Trent, Nakamura and Tepper, Eur. J. Pharmacol. 204:265, 1991) or has more typical adult-like inhibitory effects on spontaneous activity (Pitts and Zhang, Soc. Neurosci. Abstr. 19: 928, 1993). However, Pitts and Zhang (1993) reported that the long-loop inhibitory forebrain feedback pathway that is activated by AMP in adult animals, and in part responsible for the inhibitory response, may not be fully functional in 2-week-old animals. The *in vitro* response to AMP has not been studied in the midbrain slice preparation of young animals, where the long-loop feedback pathway is not present. Under these conditions, the major effects of AMP are likely to be exerted through the release of DA from nigral dendrites and the subsequent stimulation of somatodendritic DA autoreceptors, i.e. short-loop feedback. In the present study the response of nigral DA neurons from 2- or 3-week-old midbrain slices to 5  $\mu$ M AMP was examined. In all cases 5  $\mu$ M AMP elicited inhibitory responses which ranged in magnitude from 39% to 100% ( $n=7$ ). These results strongly suggest that the short-loop feedback loop is operational during this early postnatal period. Additional studies will further characterize the postnatal development of this response and determine the mechanism. (Supported by MH47857 to DKP).

REVERSIBLE BLOCKADE OF AN APAMIN-SENSITIVE AFTERHYPERPOLARIZATION BY (+)-TUBOCURARINE INDUCES BURSTING ACTIVITY IN NIGRAL DOPAMINE NEURONS IN VITRO. S.T. Connelly, H.-X. Ping and P.D. Shepard\*. MD Psychiatric Res. Cntr. & Univ. of MD. School of Med., Baltimore, MD 21228.

SK-type,  $Ca^{2+}$ -activated  $K^{+}$  channels are responsible for the medium and slow components of the post-spike afterhyperpolarization (AHP) exhibited by mesencephalic dopamine (DA)-containing neurons *in vitro*. Apamin (APA), a potent antagonist of this conductance, increases neuronal excitability and leads to the appearance of bursting activity resembling that observed spontaneously *in vivo*. Although APA-induced bursting has been attributed to its ability to suppress the AHP, the irreversible nature of the blockade has made it difficult to establish the specificity of the toxin's actions. In the present series of experiments, (+)tubocurarine (d-TC), a neuromuscular blocking agent with affinity for the APA binding site, was tested for its effects on the (1) AHP complex and (2) firing pattern exhibited by DA neurons in nigral brain slices. d-TC (500  $\mu$ M) blocked or reduced the APA-sensitive component of the AHP ( $61.0 \pm 6.3\%$  decrease) without affecting spike width. Extracellular recordings revealed a marked alteration in neuronal activity during d-TC application. The coefficient of variation (CV = standard deviation/mean), computed from interspike interval distributions, was used to assess drug-induced alterations in firing pattern. Of the 55 control cells analyzed, 53 exhibited CVs  $< 18\%$  (mean  $\pm$  SEM:  $11.3 \pm 0.5\%$ ) indicative of a pronounced pacemaker-like discharge. By contrast, the majority of cells treated with d-TC (38/64) exhibited CVs  $\geq 18\%$  (mean  $\pm$  SEM:  $40.0 \pm 4.6\%$ ). Bursting activity was detected in 17% of the d-TC treated cells. d-TC induced alterations in both the AHP complex and firing pattern were fully reversed within 45 minutes of washout from the recording chamber. These data strongly suggest that alterations in firing pattern observed following APA and d-TC result from selective blockade of the post-spike AHP. Supported by USPHS grant MH-48543.

## 145.4

L-ARGININE AND NITRIC OXIDE MODULATION OF NMDA-INDUCED BURST FIRING OF DOPAMINE NEURONS IN RAT MIDBRAIN SLICE. B.A. Cox\* and S.W. Johnson. Department of Physiology and Pharmacology, OHSU, Portland, OR, 97201.

Intracellular recordings of dopamine (DA) neurons in rat midbrain slices were performed to examine the effects of L-arginine (3-10 mM) and nitric oxide donor diethylamine/nitric oxide complex (DEA/NO, 0.05-1 mM) on NMDA (30  $\mu$ M)/apamin (100 nM)-induced burst firing.

L-arginine caused a hyperpolarization (5-10 mV) which inhibited oscillations so that burst firing switched to slower single spike firing and eventually quit firing ( $n=4$ ). L-arginine, applied together with GABA<sub>B</sub> antagonist CGP35,348 (300  $\mu$ M) and GABA<sub>A</sub> antagonist bicuculline (30  $\mu$ M,  $n=3$ ), depolarized the cell 2-3 mV and inhibited firing, but had no effect on burst-related oscillations.

DEA-NO caused DA neurons to switch from burst firing to rapid single spike firing followed by a large depolarization (10-25 mV) which inhibited firing ( $n=3$ ). However, DEA-NO, applied to the bath with CGP35,348 and bicuculline, resulted in a hyperpolarization (4-24 mV) which subsequently inhibited both firing and oscillations ( $n=4$ ).

The results indicate that L-arginine inhibition of burst firing is partially due to L-arginine-induced potentiation of GABA synaptic currents (Cox, *et al.* Soc. Neurosci. Abstr., 21:1088, 1995), and that another mechanism is also involved. Additionally, the data suggest that there is a GABA component to DEA-NO modulation of burst firing. ## 145.6

SPONTANEOUSLY ACTIVE NIGRAL DOPAMINE NEURONS ARE BOTH EXCITED AND INHIBITED BY 8-BROMO-CYCLOC-AMP IN THE MIDBRAIN SLICE. Mark W. Lewis\*, Amy J. Barron and David K. Pitts. Department of Pharmaceutical Sciences, College of Pharmacy & Allied Health Professions, Wayne State University, Detroit, MI 48202.

Little is known about the influence of cAMP on the pacemaker activity of nigral dopamine neurons. The membrane permeable analog of cAMP, 8-Bromo-cAMP (1-2 mM), was administered via the artificial CSF perfusate into a brain slice chamber, and the electrical activity of single nigral DA neurons was monitored using standard extracellular electrophysiological recording techniques. Brain slices from rats aged 2- ( $n=16$ ), 3- ( $n=18$ ), 4- ( $n=10$ ) and 5-weeks-old ( $n=2$ ) were examined and nigral DA neuron responses categorized as: excitation (50.0%), inhibition (28.3%), biphasic (excitation/inhibition: 19.6%) or none (2.1%). No age-dependent effects were detected, however, the 4- and 5-week-old sample sizes are small. The predominant response was excitatory, and the relative proportion of excitatory responses to inhibitory or biphasic responses was found to be concentration dependent (log-linear analysis: response category  $\times$  concentration interaction,  $P < 0.05$ ). The excitatory response predominated at the lower concentration (80% at 1 mM; 35.5% at 2 mM). There was an increase in inhibitory responses at the higher concentration (13.3% at 1 mM; 35.5% at 2 mM). Biphasic responses (29.0%) were only seen with the 2 mM concentration. The mechanism for these effects is currently under investigation. Preliminary evidence suggests that stimulation of adenylate cyclase by 5  $\mu$ M forskolin elicits excitatory and inhibitory responses similar to that of 8-Bromo-cAMP. IONIC MECHANISMS UNDERLYING BURSTING PLATEAU POTENTIALS IN NIGRAL DOPAMINE NEURONS IN VITRO. H.-X. Ping\* and P.D. Shepard. MD Psychiatric Res. Cntr. & Univ. of MD. School of Med., Baltimore, MD 21228.

Mesencephalic dopamine (DA)-containing neurons exhibit a  $Ca^{2+}$ -dependent, sinusoidal oscillation in membrane potential that underlies the ability of these cells to maintain spontaneous activity in the absence of afferent synaptic input. Recent studies have shown that an SK-type  $Ca^{2+}$ -activated  $K^{+}$  channel is principally responsible for the falling phase of the autogenous pacemaker oscillation (Ping and Shepard, NeuroReport, 1996). Apamin-induced blockade of this conductance results in the emergence of a voltage-sensitive plateau potential capable of driving a rhythmic bursting discharge similar to that observed spontaneously *in vivo*. In the present series of experiments, sharp electrode intracellular recording techniques were used to investigate the ionic mechanisms contributing to generation of the bursting plateau potentials exhibited by DA neurons in nigral brain slices. Depolarizing current pulses applied in the presence of TTX (2  $\mu$ M) and apamin (100-200 nM) evoked a ramp shaped, slow depolarization with a trajectory identical to that preceding spike generation in control media. When applied from negative holding potentials (-64 mV), low intensity current pulses were followed by a plateau potential exhibiting all-or-none characteristics. Increases in stimulus strength (duration or amplitude) reduced the duration of the voltage response without significantly affecting its amplitude. Addition of TEA (20-30 mM) to bathing solutions containing TTX and apamin increased the input resistance of the cell and the duration of the plateau potential; however, TTX + TEA were incapable of evoking a similar response in the absence of apamin. Bath application of  $Cd^{2+}$  (200-400  $\mu$ M) or removal of  $Ca^{2+}$  from the bathing media fully blocked the plateau potential without affecting the initial ramp-shaped component of the voltage response. These data suggest plateau potentials underlying apamin-induced bursting *in vitro* are mediated by a voltage-sensitive  $Ca^{2+}$  conductance which may possess self-limiting properties. This research was supported by USPHS grant MH-48543.

## 145.9

**MICRODIALYSIS PROBE IMPLANTATION INTO STRIATUM DISRUPTS HALOPERIDOL-INDUCED DOPAMINE CELL DEPOLARIZATION BLOCK**  
 C.L. Todd, H. Moore, D.G. Harden and A.A. Grace. Depts. of Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh PA 15260.

Depolarization block (DB), the cessation of spontaneous activity due to sustained hyperexcitation, develops in midbrain dopamine (DA) neurons during repeated administration of neuroleptics. Although DB has been well-characterized electrophysiologically, microdialysis studies have provided inconsistent data regarding changes in DA levels in the striatum during DB. Such variability could reflect regulation of extracellular DA by compensatory mechanisms as well as by lowered DA cell activity. An additional possibility is that implantation of the dialysis probe disrupts striatal cell activity, an effect which has been shown to reverse DA cell DB. This study examined the effects of striatal implantation of a microdialysis probe on DA cell activity in the SN in rats that had been treated repeatedly with haloperidol (HAL). Intact rats treated with HAL for 21-22 days showed a marked reduction in the number of spontaneously-active cells in the substantia nigra (SN). Five to 90 min after lowering the dialysis probe into the striatum, the number of active DA cells in the ipsilateral SN was increased. An increase in the number of active DA cells was also apparent at 24-48 hours following probe implantation. The number of DA cells that had apparently recovered from DB depended on the interval between implantation and testing, and whether or not HAL was withdrawn during this interval. These results show that implantation of a microdialysis probe can reverse DA cell DB. Thus, although microdialysis may be useful in determining the effects of DB on the extracellular levels of DA in the striatum, the experimental design, particularly the timing of probe implantation relative to withdrawal of treatment and dialysis measurement may be critical. ## 145.11

**OPTICAL IMAGING OF EXTRACELLULAR DIFFUSION IN SUBSTANTIA NIGRA AND VENTRAL TEGMENTAL AREA.**  
 C. Nicholson\*, S. J. Cragg, L. Tao and M. E. Rice. Dept. Physiology & Neuroscience, NYU Medical Center, 550 First Avenue, New York, NY 10016.

Dendritic release of dopamine (DA) and other neurochemicals in the substantia nigra (SN) and ventral tegmental area (VTA) represents a novel form of cell-cell communication. DA in particular is thought to diffuse from release sites to mediate volume transmission in these areas. We determined regional differences in diffusion properties of the SN pars compacta (SNc), pars reticulata (SNr), and VTA in slices of guinea pig midbrain. Fluorescent-labeled 3 kDa dextran was co-diffused with DA after pressure microinjection. The dextran was monitored with integrative optical imaging while DA was simultaneously detected using fast scan cyclic voltammetry at a carbon fiber microelectrode 100  $\mu$ m from the source. This technique permitted visualization of isotropic and anisotropic diffusion and evaluation of how regional variations in uptake influence the diffusion of DA (see Abstract by Rice et. al.). We found significant regional differences in the geometric parameter, tortuosity ( $\lambda = (D/D^*)^{0.5}$ ), where  $D$  is the free, and  $D^*$  the apparent, diffusion coefficient in brain). Diffusion in SNc ( $\lambda = 1.76$ ) was less restricted than in VTA ( $\lambda = 2.03$ ) or SNr ( $\lambda = 1.95$ ) ( $P < 0.001$ ). Regional differences in  $\lambda$  had similar effects on the diffusion of both DA and dextran. Optical imaging of dextran migration showed that extracellular diffusion in VTA was isotropic. By contrast, dextran diffusion in SNc was anisotropic, with a preferred direction along the intrinsic lateral dendrites and channeling along dendrites extending into the SNr. These data suggest that the structure of the extracellular microenvironment in the SNc, SNr and VTA will influence how DA and other neurochemicals mediate volume transmission in each region. Supported by NS-28642 (CN) and NS-28480 (MER).

Lew<sup>2</sup>, Xi He<sup>2</sup>, Stan Watson<sup>5</sup>, Björn Tengroth<sup>6</sup> and Kjell Fuxe<sup>1</sup>

<sup>1</sup>Department of Neuroscience, Karolinska Institutet, 171 77 Stockholm, Sweden, <sup>2</sup>Dept Behavioural Neuroscience, University of Pittsburgh, Crawford Hall, Pittsburgh, PA 15260, USA, <sup>3</sup>St. Eriks Eye Hospital, 112 82 Stockholm, Sweden, <sup>4</sup>Neurochemistry Research Unit, New York University, Medical Centre, 560 First Avenue, New York, N.Y. 100 16, USA, <sup>5</sup>European Graduate School for Neuroscience in Brain Behaviour, University of Limburg, Dept. Psychiatry and Neuropsychology, Maastricht, The Netherlands, <sup>6</sup>Mental Health Research Institute, The University of Michigan, Ann Arbor, Michigan 48109, USA

The study was designed to determine whether dopaminergic neurotransmission in the retina can operate via volume transmission. Using double immunolabelling, a mismatch as well as a match was demonstrated between tyrosine hydroxylase (TH) and dopamine (DA) immunoreactive (ir) terminals and cell bodies and DA D2 receptor-like ir cell bodies and processes. The match regions were located in the inner nuclear and plexiform layers. The mismatch regions were located in the ganglion cell layer, the outer plexiform layer, and the outer segment of the photoreceptor layer. Analyzing D1 receptor like ir processes versus TH ir nerve terminals, mainly a mismatch could be demonstrated, with the D1 like ir processes present in the outer plexiform layer and the outer segment. The demonstration of a mismatch between the localization of the TH terminal plexus and the DA D2 and D1 receptor subtypes suggests that DA may reach the D2 and D1 mismatch receptors via diffusion in the extracellular space. After injecting DA into the corpus vitreum, DA diffuses through the retina, and strong catecholamine (CA) fluorescence appears in the entire inner plexiform layer and outer plexiform layer where DA probably is bound to D1 and D2 receptors. The DA receptor antagonist chlorpromazine fully blocks the appearance of the CA fluorescence. Thus, the amacrine and/or interplexiform DA cells can operate via volume transmission to influence the outer plexiform layer and the outer segment, as well as other layers such as the ganglion cell layer. Supported by grants from St Eriks Eye Hospital, (04X-715) the Swedish Medical Research Council, USPHS MH50314, Marianne and Marcus Wallenberg foundation, the American Parkinson Disease Association.

## 145.10

**INHIBITION OF DOPAMINE RE-UPTAKE: SIGNIFICANCE FOR THE FIRING RATE AND FIRING PATTERN OF NIGRAL DOPAMINE NEURONS.** A. Elverfors\*, G. Engberg, J. Jonason and H. Nissbrandt. Department of Pharmacology, Göteborg University, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

In the present study the effects of inhibition of the re-uptake of dopamine (DA) were analysed with respect to DA release and to the firing pattern of DA neurons in the substantia nigra (SN). Intravenous administration of GBR 12909 (0.5 - 8 mg/kg), a specific and potent inhibitor of DA re-uptake, was found to dose-dependently increase the DA concentration both in the SN and in the striatum, as measured by microdialysis. However the drug failed to significantly affect the firing rate of the nigral DA neurons. In contrast, GBR 12909 dose-dependently induced a regularisation of the firing pattern, concomitant with a reduction in burst activity. An acute hemisection of the brain, which by itself produced a slight regularisation of the firing pattern of the nigral DA neurons without changing the firing rate or the ability of the DA neurons to fire in bursts, was found to prevent the regulatory action of GBR 12909. Pretreatment with the selective GABA<sub>B</sub>-receptor antagonist CGP 35348 (200 mg/kg, i.v., 5 min) did not significantly affect the firing rate, the regularity of the DA neurons, or their ability to fire in bursts. However CGP 35348 markedly antagonised the ability of GBR 12909 to induce pacemaker-like firing or a decrease in burst activity of the nigral DA neurons.

The results of the present study suggest that a striatonigral projection may serve to control the activity of nigral DA neurons not primarily by regulating the firing rate, but, preferably, by modulating the firing pattern of the neurons. In this regard, activation of somatodendritic GABA<sub>B</sub>-receptors may form the final link in this feedback inhibitory control system.

## 145.12

**DIFFUSION AND UPTAKE OF DOPAMINE IN SUBSTANTIA NIGRA AND VENTRAL TEGMENTAL AREA.** M. E. Rice\*, S. J. Cragg, S. A. Greenfield and C. Nicholson. Dept. Physiology & Neuroscience, NYU Medical Center, 550 First Avenue, New York, NY 10016.

Dopamine (DA) released from somatodendritic sites in the substantia nigra pars compacta (SNc) and ventral tegmental area (VTA) may reach receptors through extrasynaptic communication (volume transmission). These regions contain few DA synapses and so the time course and sphere of influence of DA will be determined by the diffusion and uptake properties of the extracellular microenvironment. We examined DA uptake properties in SN and VTA in guinea-pig *in vitro* following local pressure microinjection of DA. DA was detected using fast-scan cyclic voltammetry at a carbon-fiber microelectrode 100  $\mu$ m from the source. Most DA diffusion curves were adequately fitted using with linear uptake (i.e. uptake =  $k' \times$  concentration), though an improvement is expected with Michaelis-Menten kinetics. Overall  $k'$  was similar in SNc ( $k' = 0.10 \text{ s}^{-1}$ ) and VTA ( $k' = 0.10 \text{ s}^{-1}$ ) but significantly less in SN pars reticulata ( $k' = 0.02 \text{ s}^{-1}$ ). Inhibition of DA uptake with GBR 12909 significantly decreased  $k'$  in SNc and VTA, but to a rate in SNc ( $k' = 0.03 \text{ s}^{-1}$ ) that was half that in VTA ( $k' = 0.06 \text{ s}^{-1}$ ) ( $p < 0.05$ ). Inhibition of uptake at the norepinephrine transporter with desipramine slightly decreased  $k'$  in SNc ( $k' = 0.07 \text{ s}^{-1}$ ) and VTA ( $k' = 0.09 \text{ s}^{-1}$ ). While overall kinetics were similar, the data reflected regional heterogeneity in uptake characteristics which may have important implications for the role of DA in the physiology and pathophysiology of DA cells. Uptake via the DA transporter is more avid in SNc than VTA; in parallel, populations of SNc are more vulnerable to degeneration than VTA in idiopathic and MPTP-parkinsonism, the latter of which depends on DA uptake for toxin accumulation.

Supported by NS-28480 (MER) and NS-28642 (CN).

**CHARACTERISTICS OF EXTRACELLULAR DOPAMINE FORMED FROM EXOGENOUS L-DOPA IN THE INTACT AND DOPAMINE-DENERVATED STRIATUM OF THE RAT.** D.W. Miller\* and E.D. Abercrombie. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

*In vivo* microdialysis was used to examine the effects of exogenous L-DOPA on extracellular dopamine (DA) in the striatum of intact and DA-depleted rats. Extensive unilateral lesions (>95%) of the nigrostriatal DA neurons were accomplished by injecting 6-OHDA (6 $\mu$ g) into the medial forebrain bundle. A microdialysis probe was implanted into the ipsilateral striatum 2 weeks following the lesion. Previous work from this group suggested that in intact rats, L-DOPA (50mg/kg) induces a small increase in striatal DA which is impulse-independent. However, DA uptake in the intact striatum has been shown to mask the effects of L-DOPA on striatal DA efflux (Wachtel & Abercrombie, Neurosci. Abstract 126.18, 1994). The present studies examined the effect of impulse activity blockade on DOPA-induced striatal DA efflux in two experimental paradigms. The first condition incorporated DA uptake blockade via systemic administration of GBR-12909 (20mg/kg) in intact rats. The second condition examined the effect of impulse blockade in the DA-denervated striatum where DA uptake does not exert a strong influence on DOPA-induced extracellular DA efflux. Impulse activity was blocked via infusion of 1 $\mu$ M tetrodotoxin (TTX) through the microdialysis probe. A small TTX-insensitive component was revealed in both cases. We hypothesize that this component is similar to the small amount of DA released in the intact striatum following L-DOPA administration in absence of DA uptake blockade. In both conditions, there also exists a larger component that is TTX-sensitive, as revealed in the intact rat when DA uptake is blocked. Thus, there are two components of DOPA-induced striatal DA efflux (a small impulse-independent component and a large impulse-dependent component) in the intact striatum when DA uptake is blocked and in the DA-denervated striatum. The source of the regulated (TTX-sensitive) release is yet to be determined. [Supported by USPHS Grant NS 19608]

## 145.15

**EFFECT OF WITHDRAWAL DURATION AFTER CHRONIC AMPHETAMINE ON STRIATAL ACETYLCHOLINE RESPONSE TO ACUTE AMPHETAMINE CHALLENGE** Michael J. Bickerdike\* & Elizabeth D. Abercrombie, Center for Molecular & Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Chronic intermittent amphetamine (AMPH) administration to rats results in behavioral sensitization to a subsequent AMPH challenge. Behavioral sensitization develops during chronic treatment and is apparent to a varying degree after any period of withdrawal. However, potentiated dopamine (DA) release in response to AMPH is consistently reported only after withdrawal of a week or more. The present microdialysis study assessed the effect of short (2 day) and long (2-3 week) withdrawal from chronic AMPH (4mg/kg i.p.; b.i.d; 12 days) on striatal acetylcholine (ACh) release in male rats administered an AMPH challenge (4mg/kg i.p.). Behavioral studies of locomotion showed that sensitization developed throughout chronic AMPH treatment - this effect was greatest after long withdrawal, but clearly apparent at short withdrawal. Systemic AMPH did not significantly affect striatal ACh efflux in naive or chronic saline treated rats, either after short or long "withdrawal". However, AMPH challenge resulted in a significant and prolonged increase in striatal extracellular ACh after both short and long withdrawal from chronic AMPH. After short withdrawal, striatal ACh increased from 69.5 fmol/20µl (basal) to a maximal level of 97.5 fmol/20µl after 135 min. After long withdrawal, striatal ACh increased from 65.6 fmol/20µl to a maximal level of 118.8 fmol/20µl after 120 min. Preliminary results indicate that DA release in response to AMPH is not significantly affected by long withdrawal from chronic AMPH (87.3 pg/20 µl increase post AMPH, versus an 87.8 pg/20 µl increase in chronic saline controls), while after short withdrawal, striatal DA efflux in response to AMPH was attenuated (61.6 pg/20 µl increase post AMPH, versus 103.8 pg/20 µl for controls). Taken together these data suggest that the behavioral sensitization observed in these studies, particularly at the short withdrawal time point, may relate to increased ACh release in striatum. Further studies are underway to investigate the hypothesis that an increase in glutamate drive to striatum is important in mediating these alterations in striatal ACh function. **DOPAMINE MODULATES BOTH EXCITATORY AND INHIBITORY SYNAPTIC TRANSMISSION IN THE SUPERFICIAL LAYERS OF RAT PREFRONTAL CORTEX.** G.M. DiBlest\*, G. Gonzalez-Burgos and G. Barrionuevo, Department of Neuroscience and Center for the Neural Basis of Cognition, University of Pittsburgh, Pittsburgh, PA.

In the rat, the prelimbic/infralimbic cortices of the frontal lobes receive dorsomedial thalamic nucleus projections as well as a dense subcortical dopamine (DA) innervation; therefore, this region of rat cortex is a good model of the primate medial prefrontal cortex (mPFC). The objective of these studies was to characterize the effects of exogenous dopamine on synaptic transmission within the local mPFC circuitry at the cellular and synaptic levels. To further simplify the cortical circuitry, we used the rat mPFC cortical slice preparation for the *in vitro* study of dopaminergic neuromodulation. Synaptic responses were evoked by bulk stimulation of the underlying white matter alternating with stimulation of the parallel local gray matter. Complex postsynaptic potentials (PSPs) were recorded using sharp-electrode intracellular techniques. The waveforms were evoked as the postsynaptic membrane potential (Vm) was altered by constant injections of current. PSP-Vm plots reveal multiple components to the synaptic responses which can be separated based on their reversal potentials. Responses were collected before and during the application of 50 µM dopamine in the bath.

The hyperpolarizing components of the responses evoked at depolarized membrane potentials increased with dopamine treatment (n=4) as was predicted based on the *in vivo* literature. However, the apparent depolarizing components of the responses showed a either increases or decreases (n=2 each). Pharmacological manipulations are currently being used to investigate the effects of dopamine on the individual components of the synaptic waveform. CNQX (1-10 µM) will be used to eliminate the bulk of glutamatergic transmission, and bicuculline (1-5 µM) will be used to eliminate the bulk of fast inhibitory transmission.

This work was supported by MH45156 and an Andrew Mellon Foundation predoctoral fellowship (GMD).

## 145.19

**DOPAMINE DEPRESSES EXCITATORY SYNAPTIC TRANSMISSION ONTO LAYER V PYRAMIDAL CELLS IN RAT PREFRONTAL CORTEX.** A.T. Gullledge\* and D.B. Jaffe, Div. of Life Sci., Univ. of Texas at San Antonio, San Antonio, TX 78249.

The prefrontal cortex is an area of associational cortex important for working memory function. The PFC of both primates and rodents is highly innervated by dopaminergic fibers and has elevated dopamine receptor expression when compared to other cortical areas.

We have been examining the effects of dopamine on excitatory synaptic transmission onto prefrontal layer V pyramidal cells. Excitatory postsynaptic potentials (EPSPs) were evoked in disinhibited slices containing medial prefrontal cortex obtained from the brains of 14 to 28 day old rats. The stimulating electrode was placed in layer V, within 75 µM of the soma of the pyramidal cell to be recorded.

Bath application of dopamine (30 or 60 µM) decreased the initial slope of EPSPs  $21\% \pm 3.5$  (mean  $\pm$  SEM, n=10). Reduction in EPSP slope was reversible in 4 of 5 cells in which washout was attempted.

Excitatory postsynaptic currents recorded under voltage-clamp displayed paired-pulse depression (PPD). Application of 100 µM dopamine decreased the magnitude of PPD  $20.43\% \pm 9.98$  (n=8). These data suggest that dopamine may be acting presynaptically to reduce excitatory synaptic transmission.

This work was supported by a Faculty Research Award from UTSA.

## 145.16

**ONTOGENETIC EFFECTS OF NOMIFENSINE ON DOPAMINERGIC MODULATION OF STRIATAL ACETYLCHOLINE RELEASE IN MALE RATS:** C.A. Bolanos\*, S.L. Abel and D. Jackson, Psychology Department, Northeastern University, Boston, MA 02115.

Previous research has shown that periadolescent rats approximately 30- to 40-days old are generally less sensitive to pharmacological challenges when compared with younger or older animals. For example, studies have illustrated that periadolescent rats exhibit attenuated responses to the behavioral effects of dopaminergic drugs such as cocaine, amphetamine, or apomorphine. The neurobiological basis for these periadolescent effects are still unresolved; but several possibilities have been proposed, including the development of dopamine (DA) autoreceptors. In the present study, the lack of sensitivity shown in the periadolescent rats was further assessed by measuring DA inhibition of acetylcholine (ACh) release in striatal slices. It was hypothesized that superfusion with 10 µM nomifensine, a DA reuptake blocker, would not alter the evoked ACh efflux from periadolescent rats (PD35), while it would inhibit the electrically-evoked ACh release in striatal slices prepared from young (PD20) and adult (PD80) animals. ACh release studies were conducted with slices (350 µm) that had previously been labeled with  $^3\text{H}$ choline. Basal and electrically-evoked tritium efflux were used as measures of ACh release. Surprisingly, superfusion with nomifensine resulted in an inhibition ( $-61 \pm 18\%$ ) of electrically-evoked ACh release in striatal slices prepared from the PD35 rats. The magnitude of this effect was not significantly different from that observed in the PD20 ( $-63 \pm 15\%$ ) or the PD80 ( $-56 \pm 19\%$ ) rats. In summary, periadolescent rats show the same magnitude of DA reuptake when compared with PD20 and PD80 animals. Future studies will examine the effects of lower doses of nomifensine (0.1 and 1 µM) as well as the effects of other DA reuptake blockers (cocaine or amphetamine) and DA receptor agonists in order to assess saturation of the DA transporter and to examine the potential differences in autoreceptor sensitivity in the three age groups, respectively.

## 145.18

**DOPAMINE MODULATION OF HIPPOCAMPAL INPUT TO THE RAT PREFRONTAL CORTEX.** D.B. Carr\*, S.R. Sesack, and A.A. Grace, Departments of Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

Afferents to the prefrontal cortex (PFC) from the hippocampal formation and from dopamine neurons in the ventral tegmental area (VTA) have been implicated in working memory processes and in the pathogenesis of schizophrenia. Previous anatomical investigations in our laboratory have demonstrated that both hippocampal and dopamine terminals synapse on dendritic spines of presumed pyramidal cells in the PFC. In addition, these afferents are often in direct apposition to one another. In order to determine whether dopamine afferents modulate hippocampal input to individual pyramidal neurons, we have examined the responses of PFC neurons, recorded extracellularly in anaesthetized rats, to fornix stimulation before and after stimulation of ascending dopamine afferents from the VTA. Our preliminary results indicate that single-pulse stimulation of the fornix produces both short and long latency excitatory responses in PFC neurons. Prior stimulation of the VTA (10 Hz train, 300 ms duration) attenuates the excitatory response of some PFC neurons to hippocampal stimulation. Pharmacological studies are in progress to examine the dopamine receptor subtype involved in this modulatory response. This work is supported by USPHS grants MH45156 and MH50314.

## 146.1

IDENTIFIED 5-HT-LABELLED FIBERS AND THE LATERAL GIANT INTERNEURON OF CRAYFISH. B.E. Musolf and D.H. Edwards\*  
Dept. of Biology, Georgia State University, Atlanta, GA 30302-4010

The Lateral Giant (LG) interneurons form a tightly coupled ladder-like network that provides a command system for the tailflip escape response in crayfish. In each abdominal hemiganglion, the dendrites of an LG neuron receive inputs from mechanosensory afferents and interneurons. The LG axon projects to the next rostral ganglion where it excites both the LG in that hemiganglion and the fast flexor (FF) motoneurons. The LG is excited through a strong axo-axonic electrical connection, and the FFs are excited both directly and indirectly, through an intervening interneuron, the segmental giant (SG).

We found earlier that LG's response is modulated by superfused serotonin according to the social dominance status of the animal (Yeh, *et al.*, 1996, *Science* 271: 366). Recently we identified a pair of 5-HT-immunoreactive fibers that project caudally from the thorax to the terminal abdominal ganglion. Each 5-HT fiber has a set of short lateral branches in each ganglion that end in terminal varicosities along the ventral surface of the adjacent LG axon, where the axon excites SG and the FF motoneurons. The ganglionic LG neuron receives few contacts at its initial axon segment and none in the dendrites. We also found that superfused serotonin enhances the FF response to an LG spike in dominant crayfish. The 5-HT fibers are likely candidates for modulating FF responses to LG spikes, and also for modulating LG's responses to mechanosensory inputs. Supported by grants from NIH and NSF to DHE.

## 146.3

A LIBRARY SCANNING CLONING PROCEDURE FOR THE ISOLATION OF BIOGENIC AMINE RECEPTOR GENES FROM THE HONEY BEE. P. R. Ebert\*, J. Rowland, B. Meadows. Depts. of Biochemistry and Entomology, University of Queensland, St. Lucia, QLD 4072 Australia.

Degenerate, biogenic amine specific primers were used to isolate receptor genes from the honey bee. The utility of PCR-based gene cloning was greatly enhanced by performing PCR reactions on 200 individual subpools of both genomic and cDNA libraries containing approximately 100 clones each. By this method, a total of seven biogenic receptor genes have so far been isolated. Standard PCR reactions using total head cDNA as template only produced two receptor clones while genomic DNA template failed to produce any amplification product. DNA homology suggests that the cloned genes represent serotonin, dopamine, tyramine/octopamine and noradrenergic receptors. Gene regulation with respect to social and caste-specific behaviour is currently being investigated.

## 146.5

LIGAND-SPECIFIC COUPLING OF A NOVEL CLONED *DROSOPHILA* DOPAMINE RECEPTOR WHEN EXPRESSED IN *XENOPUS* OOCYTES. P.D. Evans\*, V. Reale\*, F. Hannan\*, G. Feng\* and L.M. Hall\*. The Babraham Institute Lab. Molecular Signalling, Dept. Zoology, Univ. Cambridge, Cambridge, CB2 3EJ, U.K. and \*Dept. Biochem. Pharmacol., State Univ. of New York, Buffalo, USA.

In insects dopamine receptor subtypes may be involved in memory and learning. Dopamine receptors belong to the G-protein coupled receptor superfamily of seven transmembrane domain proteins. Five distinct classes of dopamine receptor have been identified by cloning in mammals. These fall into two broad pharmacological categories D1-like and D2-like. A D1-like receptor affecting adenylyl cyclase activity has already been identified in *Drosophila* (Gotzes *et al.*, 1994, *Receptors and Channels* 2:131-141; Sugamori *et al.*, 1995, *FEBS Lett.* 362:131-138). We have recently cloned a novel G-protein coupled dopamine receptor (DopR99B), expressed in *Drosophila* heads, which may define a novel class of dopamine receptors (Feng *et al.*, 1996, *J. Neurosci.*, in press). We report here that when expressed in *Xenopus* oocytes the activated DopR99B increases intracellular  $Ca^{2+}$  levels and also increases cyclic AMP levels. The rank order of potency for biogenic amines in stimulating both second messenger effects is dopamine > norepinephrine > epinephrine > tyramine. Octopamine and 5-hydroxytryptamine are not active at concentrations up to 100  $\mu$ M. The pharmacological profile for synthetic antagonists on both second messenger responses was identical and suggested that DopR99B is a D1-like dopamine receptor. The pharmacological profile for synthetic agonists again suggests a D1-like dopamine receptor, but was different for the two second messenger systems assayed. Thus, DopR99B exhibits the "ligand-specific" form of agonist-specific coupling to different second messenger pathways, a phenomenon exhibited by a range of other aminergic and peptidergic G-protein coupled receptors from both invertebrates and vertebrates (see Evans *et al.*, 1995, *Prog. Brain Res.* 106:259-268).

## 146.2

CHARACTERISATION OF THE SEROTONERGIC NEURONES IN THE FIRST ABDOMINAL GANGLION OF THE CRAYFISH. Linda J. Anderson\*, Michael Hörner & Donald H. Edwards. Dept. of Biology, Georgia State University, Atlanta, GA 30302.

Previous work in our laboratory has shown that the crayfish escape tailflip is modulated by serotonin, and the modulation is affected by the social status of the animal (Yeh *et al.*, *Science* 271, 366-369, 1996). Immunohistochemical experiments have identified a pair of serotonin-immunoreactive (5HT-IR) neurones in the first abdominal ganglion (a1). In lobster, homologous neurones receive input from the escape circuit (Hörner *et al.*, this meeting). The crayfish neurones may contribute to the serotonin responsible for the modulation of the tailflip. Therefore, this study was undertaken to examine the synaptic connections between these neurones and elements of the tailflip escape circuitry. Electrical stimulation of the terminal abdominal ganglion afferents evoked either an EPSP or an IPSP in the 5HT-IR neurones; the latencies of these responses differed, suggesting two discrete pathways. Similarly, stimulation of the first root of a1, which contains the axon of the segmental giant, an interneurone which receives input from the command neurone responsible for the tailflip (lateral giant, or LG), also produced either an EPSP or an IPSP. However, in the majority of preparations (70 %), stimulation of LG did not evoke a response in the 5HT-IR neurones. In the remaining preparations, a small EPSP was evoked. Experiments are continuing to discover further connections in this system.

## 146.4

POTENTIATION OF B38-EVOKED CONTRACTIONS BY 5HT AND THE SCPS HAS A SIGNIFICANT POSTSYNAPTIC COMPONENT. L. E. Fox\* and P. E. Lloyd. Committee on Neurobiology, University of Chicago, Chicago, IL. 60637

*Aplysia* anterior buccal muscle 3 (I3a) is innervated by 2 excitatory glutamatergic motor neurons (B3 and B38). B38 also expresses the SCPs while B3 expresses FMRFamide. I3a is also innervated by a modulatory serotonergic neuron C1 (or the MCC). Intracellular stimulation of B38 evokes contractions of I3a that are potentiated by both 5HT and the SCPs. While the short-term effects of 5HT and the SCPs are similar, there is a dramatic difference in the duration of their modulatory effects. The effects of the SCPs reverse on wash out while the effects of 5HT persist for several hours after wash out. The short-term potentiation of B38-evoked contractions by 5HT and the SCPs as well as the persistent effects of 5HT appear to be due, in part, to postsynaptic actions of the modulators. 5HT and the SCPs potentiated contractions of isolated I3a muscle evoked by the bolus application of glutamate. SCPs (1  $\mu$ M) increased the excitability of the muscle and increased the bolus-evoked contractions ~4 fold. 5HT (1  $\mu$ M) increased the excitability of I3a dramatically, usually causing the muscle to contract rhythmically. Lower concentrations of 5HT (0.1  $\mu$ M) also increased the excitability of the muscle and increased the bolus-evoked contractions ~5 fold. Again, the effects of the SCPs reversed on wash out while the effects of 5HT persisted several hours after wash out.

B38-evoked excitatory junction potentials (EJPs) were also persistently potentiated by 5HT. Methiothepin (30  $\mu$ M) a 5HT antagonist known to act on *Aplysia* 5HT receptors coupled to phospholipase C, inhibits the persistent potentiation of EJPs, but not short-term potentiation produced by 5HT. Supported by F31 MH10656 and NSF IBN 9418815.

## 146.6

DEPLETION OF ENDOGENOUS DOPAMINE ALTERS THE DENSITY OF D1-LIKE DOPAMINE RECEPTORS IN THE BRAIN OF THE HONEY BEE, *APIS MELLIFERA*.

M.T. Purnell, I.C. Kokay, D.J. Taylor and A.R. Mercer\* Department of Zoology and Centre for Neuroscience, University of Otago, Dunedin, NZ.

Two distinct dopamine (DA) receptor subtypes have been identified in the brain of the honey bee (I. Kokay and A. Mercer (1996) *Brain Research* 706: 47-56). Both are present in the brain early in metamorphic adult development and exhibit significant changes in density during the lifetime of the bee (I. Kokay and A. Mercer (1995) *Soc. Neurosci. Abstr.* 21: 632). The effects of depleting brain DA levels on the density of one of these two DA receptor subtypes, namely the D1-like DA receptor in the brain of the bee, have now been examined. We have found that brain DA levels can be reduced significantly by a single 10  $\mu$ l (250  $\mu$ g) injection of  $\alpha$ -methyl-tyrosine (AMT) into the haemolymph of the bee. Maximum depletion of DA was observed 3 h after treatment. DA levels in the brain of the bee returned to normal 24 h after AMT injection. Injection of saline alone into the haemolymph of the bee did not alter the levels of DA in the brain. *In vitro* assays using the D1-specific DA receptor radioligand  $^3$ H-SCH 23390 were used to monitor the effects of amine depletion on D1-DA receptor densities. Non-specific binding was defined as binding in the presence of  $5 \times 10^{-6}$  M cis-(Z)-flupentixol. No significant change in DA receptor density was apparent 30 min after treatment with AMT. However, 3 h after injecting this drug, depletion of DA caused a significant reduction in the density of D1-like DA receptors in the brain of the bee. [Supported by ORG MFZB77]

## 146.7

AGE DEPENDANT DOPAMINE DISTRIBUTION IN THE CNS GANGLIA OF APLYSIA CALIFORNICA. D. Daniels, J. M. Flinn, & V. Chandhoke\*. Department of Psychology & The Shared Research Instrumentation Facility, George Mason University, Fairfax, Virginia.

Previously, we have demonstrated age dependant changes in the dopamine levels of the ring and abdominal ganglia of *Aplysia californica*. The relationship between age and dopamine levels is complex with a maximum at five months and a secondary peak at ten months. This study seeks to investigate the distribution of the dopamine in the individual ganglia of *A. californica* as a function of age.

Twenty animals in each of five age groups (five, six, seven, eight, and ten months post-hatch) were obtained from The *Aplysia* Facility at the University of Miami. The animals were anaesthetized, dissected and the CNS removed. The following ganglia were isolated for examination: cerebral, buccal, abdominal, left pleural-pedal, and right pleural-pedal. Individual ganglia were then weighed and suspended in TBS. The protein content of each sample was measured by a BioRad protein assay. Dopamine levels were measured by reverse phase HPLC and normalized by the protein content. Preliminary data show that the pattern of dopamine distribution in the six month animals was different from the distribution in the ten month animals. At six months, the left pleura-pedal ganglia had the highest levels, followed by the abdominal, cerebral, right pleural-pedal, and buccal ganglia respectively. The dopamine levels of the left pleural-pedal ganglia were much greater than that of the right pleural-pedal. At ten months, the left pleural-pedal still had the highest values, followed by the right pleural-pedal, buccal, cerebral, and abdominal ganglia respectively. The left pleural-pedal and the abdominal ganglia, which had the highest dopamine levels at six months, showed the greatest decrease between six and ten months.

## 146.9

CLONING AND SEQUENCING OF TYRAMINE BETA-HYDROXYLASE IN *MANDUCA SEXTA*. K. Mace and H. K. Lehman\*. Dept. of Biology, Univ. of Nevada, Las Vegas, NV 89154.

Tyramine beta-hydroxylase (TBH) is the putative rate-limiting enzyme controlling the biosynthesis of octopamine in the insect nervous system. TBH appears to be developmentally regulated in the terminal abdominal ganglia of *Manduca*, and the increase in TBH activity during metamorphosis is coincident with the appearance of a subset of octopaminergic neurons. Furthermore, the steroid hormone 20-hydroxyecdysone is necessary and sufficient for the developmental increase in TBH activity. To better understand the role of steroid hormones in the regulation of TBH, we have attempted to clone and characterize TBH from the nervous system of *Manduca sexta*.

We have performed RT-PCR using degenerate primers based on conserved regions of mammalian dopamine beta-hydroxylase to amplify and clone TBH from terminal abdominal ganglia poly (A)<sup>+</sup> RNA taken from late pupa. Following PCR amplification and agarose gel analysis, several products of the approximate expected size were cloned using a TA cloning kit (Invitrogen). Sequence analysis (Sequenase, Amersham) of several products revealed a single clone 578 bp in length with high homology (50% identity) to mammalian dopamine beta-hydroxylase at the amino acid level. Northern blot analysis is currently underway to verify that this sequence is expressed in the nervous system and in-situ hybridization will be used to determine the tissue distribution of this sequence within the nervous system. Supported by the NSF (IBN-9496168).

## 146.11

DEVELOPMENT OF THE DOPAMINERGIC SYSTEM IN THE ANTENNAL LOBES OF THE BRAIN OF THE HONEY BEE

B.S. Kirchhof<sup>1</sup>, U. Homberg<sup>2</sup>, and A.R. Mercer<sup>1</sup>. <sup>1</sup>Department of Zoology and Centre for Neuroscience, University of Otago, Dunedin, New Zealand <sup>2</sup>Institut für Zoologie, Universität Regensburg, 93040 Regensburg, Germany

Dramatic growth and reorganization of the primary antenno-sensory centres (antennal lobes, AL) of the brain is associated with the metamorphic adult development of the honey bee, *Apis mellifera*. In the adult worker bee, the AL neuropil is innervated by a small population of dopamine-immunoreactive (DA-IR) neurons (S Schäfer and V Rehder (1989) *J Comp Neurol* 280:43-58). We have used immunohistochemistry and HPLC, respectively, to examine the development of DA-IR neurons in the AL and changes in endogenous DA levels associated with the development of the AL neuropil. The DA antibody used in this study was generously supplied by Dr. R.M. Buijs, Netherlands Institute for Brain Research, Amsterdam. DA-IR somata in the brain could first be detected at pupal stage 1 (P1) of the 9 stages of metamorphic adult development, but no immunoreactive processes were observed in the AL neuropil at this stage. DA-IR processes first became prominent in the developing neuropil of the AL at pupal stage 3, coinciding with the onset of protoglomerular formation in the AL. During subsequent stages of metamorphosis, the density of DA-IR processes increases. Although most of these processes remain restricted to the inner margins of the glomeruli, some extend also into the glial borders that surround each glomerulus. Changes in endogenous DA levels correlate well with the appearance of DA-IR in the AL. DA was first detected in the developing AL at pupal stage 3 (P3), and peaked at pupal stage 4 (P4). Previous studies have shown that the percentage of pupal AL neurons *in vitro* that express D2-like DA receptors peaks also at P4 (B Kirchhof and A Mercer (1995) *Soc Neurosci Abstr* 21:406). The early appearance of DA and DA receptors in the AL of the bee brain is consistent with the possibility that DA plays a role in regulating the development of the highly structured AL neuropil. [Supported by ORG MFZB77]

## 146.8

OCTOPAMINE IMMUNOREACTIVITY IN THE STOMATOGASTRIC GANGLION OF *HOMARUS AMERICANUS*, *PANULIRUS INTERRUPTUS*, AND *CANCER BOREALIS*. V.L. Kilman\* and E. Marder. Vollen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Octopamine powerfully modulates a wide range of behaviors in decapod crustacea. One example of this is the modulation of the motor pattern generating networks responsible for feeding in the stomatogastric ganglion (STG) of *P. interruptus*, *H. americanus*, and *C. borealis*. While central octopamine-containing neurons have been described in the ventral nerve cord and brain of *H. americanus*, and biochemical studies have shown octopamine in the STG of *P. interruptus*, the source of octopamine input to the STG has not been determined. In this study we immunocytochemically localized octopamine in sections of paraffin- and plastic resin-embedded STG of crabs (*C. borealis*) and lobsters (*H. americanus*, *P. interruptus*). While the neuropil of *C. borealis* and *P. interruptus* STG contain octopamine immunoreactivity, the STG of *H. americanus* does not. As octopamine modulates rhythmic activity in the STG of *H. americanus*, the lack of octopamine immunoreactivity in *H. americanus* neuropil suggests that octopamine reaches STG targets in this animal via neurohemal release. In contrast, octopamine immunoreactivity in *P. interruptus* and *C. borealis* suggests that the source of some octopamine input is local release from the fibers stained in the ganglion. Experiments are in progress to determine what other modulators may be colocalized with octopamine.

## 146.10

OCTOPAMINERGIC MODULATION OF SYNAPTIC TRANSMISSION AT THE *DROSOPHILA* LARVAL NEUROMUSCULAR JUNCTION. M.J. Coleman\* and L.C. Griffith. Brandeis University, Dept. of Biology & Vollen Center, Waltham, MA 02254.

Glutamate is the major excitatory transmitter at the larval neuromuscular junction of the fruit fly, *Drosophila melanogaster*. Several neuromodulators, including octopamine, have been immunocytochemically localized to subsets of the nerve terminals innervating these muscle fibers. However, the physiological function of these modulators is not well-understood.

Octopaminergic modulation of evoked excitatory junctional potentials (EJPs) in larval body wall muscle fibers was examined by bath-application of octopamine. In muscles that are innervated by octopaminergic motor neurons (muscle 12), octopamine increased the EJP amplitude by 14±0.1% relative to control (p<0.01), but did not significantly alter the decay rate of the EJP (N=3). In addition, octopamine appeared to reversibly decrease the input resistance of individual muscle fibers by 32±0.1% (p<0.05). Interestingly, we found that octopamine also modulated EJPs in muscles that are not innervated by octopaminergic motor neurons (muscle 6). In these muscles, although octopamine did not produce an increase in EJP amplitude, it increased the EJP decay rate by 20±0.1% (p<0.01, N=4). These data suggest that at the *Drosophila* larval neuromuscular junction, octopamine may act both as a modulatory transmitter and as a neurohormone.

To begin examining the second messenger pathways involved in octopaminergic modulation, we are studying the effects of octopamine in a mutant with decreased CaM kinase activity. We found that the amplitude of EJPs in muscle 6 of this mutant was 19±0.1% larger than in control (p<0.01), but the decay rate was not significantly different (N=4). These data suggest that octopaminergic modulation of decay rate may involve CaM kinase activity.

LCG is an Alfred P. Sloan Fellow. Work supported by NSF grant IBN9421360 (LCG) and NIH grant NS07293 to Brandeis (MJC).

## 147.1

**cAMP-GATED Na<sup>+</sup> CURRENT IN MOLLUSC CNS: MODULATION OF MOTOR NETWORKS, COINCIDENCE DETECTION, AND IN VIVO ENZYMOLOGY.** R. Gillette, L. Sudlow, L.L. Moroz, J. Jing, and M. Gillette\*. Dept. of Molecular and Integrative Physiology, Univ. of Illinois, Urbana IL 61801

Sodium currents gated directly by cAMP ( $I_{Na,cAMP}$ ) are the most prominent ion currents stimulated by cAMP in many molluscan neurons.  $I_{Na,cAMP}$  is found in effector neurons and interneurons of the motor networks for feeding, gill movement, locomotion and escape swimming, where it may mediate excitatory neuromodulatory effects lasting seconds or more.  $I_{Na,cAMP}$  shows different characteristics in different neurons. In neurons of the feeding network of *Pleurobranchaea*,  $I_{Na,cAMP}$  is increased with depolarization from the resting membrane potential in the pacemaker region via lifting of a depolarization-sensitive Ca<sup>2+</sup> block, is markedly enhanced by applications of nitric oxide (NO), and is sensitive to changes in pH, pentylenetetrazol and oxidized glutathione. In contrast,  $I_{Na,cAMP}$  in locomotor neurons is reduced by depolarization via a mechanism dependent on intracellular Ca<sup>2+</sup>, and is not sensitive to NO, pH, pentylenetetrazol, nor thiol oxidant. The sensitivity of the feeding neurons'  $I_{Na,cAMP}$  to NO confers coincidence detection ability and specifically suggests a role in arousal of feeding behavior. Kinetic characters of  $I_{Na,cAMP}$  lend it to quantitative analysis of cAMP metabolism in living neurons, such that the effects of 5-HT and NO on cAMP synthesis, degradation and concentrations can be precisely measured with conventional voltage clamp methods. Supported by NIH (RO1 NS26838) to R.G.

## 147.3

**NITRIC OXIDE AND ORTHOGRADE NEUROTRANSMISSION IN THE CNS OF THE SNAIL LYMNAEA STAGNALIS.** Michael O'Shea\* and Ji-Ho Park, Sussex Centre for Neuroscience, School of Biological Sciences, University of Sussex, Brighton, East Sussex, BN1 9QG, UK

Nitric oxide (NO) is synthesized in the snail by a calcium/calmodulin activated nitric oxide synthase (NOS) that has been localised to identifiable neurons in the buccal ganglion. One of these is the giant B2 motor neuron. This cell is peptidergic and cholinergic (Paul Benjamin, pers. comm) but also contains NOS. Another identified motor neuron, B7, is excited by the B2 neuron. Stimulation of a train of action potential in B2 produces a constant latency (~200ms) slow depolarisation in B7 but not in other neurons. The B2 induced EPSP in B7 cannot be blocked by hexamethonium but it is reversibly blocked by the NO scavenger haemoglobin at 500µM. Met-haemoglobin, which cannot scavenge NO, has no effect. Also the EPSP is eliminated by the NOS inhibitor L-NAME (1 mM) but is unaffected by D-NAME. Solutions of NO and NO donors were pressure ejected from a micropipette onto neurons in the buccal ganglion. This causes depolarisation of B7 leading to action potentials but the B2 neuron does not respond to local pressure ejection of NO donors or NO solutions. The B7 cell is the only neuron in the vicinity of B2 to respond to the NO ejection. When the solutions of NO donors are de-gassed using a 24hr delay between preparation and the use of the solution and nitrogen aeration, there is no depolarisation. Together this evidence indicates that there is a central synaptic interaction between the B2 and the B7 interneuron and the transmitter is NO. In previous experiments we demonstrated that NO can activate the central pattern generator for feeding (Elphick et al, J Neurosci, 15(11): 7653-7664). It may also be involved in synaptic interactions between motoneurons that are driven by the feeding CPG. Supported by BBSRC Grant GR/J3234 to MO'S.

**PRODUCTION OF NITRIC OXIDE (NO) IN INVERTEBRATE CENTRAL NERVOUS AND PERIPHERAL TISSUES: AN ELECTRON PARAMAGNETIC RESONANCE STUDY.** L.L. Moroz\*, S.W. Norby, R.B. Clarkson and R. Gillette, Dept. Molecular and Integrative Physiology, EPR Center, Univ. Illinois, Urbana, IL, 61801.

We measured NO formation in CNS and peripheral tissues by combining electron paramagnetic resonance and spin trapping techniques for eight molluscan genera chosen for diverse ecological adaptations and systematic relationships (*Gastropoda*: *Pleurobranchaea*, *Aplysia*, *Tritonia*, *Phestilla*, *Lymnaea*, *Planorbis*; *Cephalopoda*: *Octopus*, *Loligo*), for an annelid (*Lumbricus*), two arthropods (*Homarus*, *Limulus*) and two poriferans (*Terpios*, *Lencetla*). A spin trap complex of sodium N-methyl-D-glucamine dithiocarbamate with FeSO<sub>4</sub> was employed for intact tissues and homogenates. We have found: 1) NO is present and its production is L-arginine-dependent in CNS and some peripheral tissues of all genera investigated; 2) There is a correlation between NO synthesis rate and NADPH-diaphorase activity for all tissues investigated, with the exception of the *Tritonia* CNS; 3) Estimated endogenous NO concentrations in CNS and some peripheral tissues were 0.4-10 µM; 4) The NO synthase inhibitors L-NAME, L-NA, and L-NMA did not suppress NO signals, and in some cases enhanced them; 5) The seemingly paradoxical effects of the NO synthase inhibitors are explainable by observations that the inhibitors themselves act as substrates for non-enzymatic NO production in the presence of the reducing compounds NADPH, DTT, L-cysteine and L-ascorbate. Supported by NIH RO1GM42208 grant to R.B.C. and NIH RO1NS26838 grant to R.G.

## 147.2

**THE NO/cGMP PATHWAY MEDIATES MUSCARINIC RESPONSES IN THE CNS OF *Manduca sexta*.** B.A. Trimmer\* and S. Qazi, Dept. of Biology, Tufts University, Medford, MA 02155.

Biochemical and physiological studies were performed to describe the role of nitric oxide (NO) in the muscarinic stimulation of cGMP levels in whole abdominal nerve cords of *Manduca sexta* larvae. Incubations were all performed in the presence of 3-isobutyl-1-methylxanthine (IBMX), to inhibit phosphodiesterase breakdown, this resulted in a 3 fold increase in basal accumulation of cGMP (136 ± 23, fmol/nerve cord (fm/c), n=14) measured by radioimmunoassay. Addition of a muscarinic agonist, oxotremorine-M (oxo-M) further increased cGMP levels (214 ± 42 fm/c, n=11; one way anova, contrast,  $F_{(1,113)} = 5.84$ ,  $p = 0.017$ ). Treatment of nerve cords with the nitric oxide synthase inhibitor, nitroarginine (NA, 1mM) reduced the basal levels of cGMP to 37 ± 1.6 fm/c (n=6, contrast,  $p < 0.0001$ ). Furthermore, NA blocked the oxo-M evoked increase in cGMP (NA+oxo-M = 43 ± 3.0 fm/c,  $p < 0.0001$ ). The suppression of cGMP levels was not caused by inhibition of GC, because direct activation of GC with a NO donor compound, sodium nitroprusside in the presence of NA resulted in high levels of cGMP (945 ± 87 (n=6) fm/c). Therefore the muscarinic activation of guanylate cyclase (GC) appears to require NO. To determine the physiological role of the NO/cGMP pathway during muscarinic activation of abdominal motoneurons, extracellular recordings were made of activity in the lateral branch of the ventral nerve (VNL). Instantaneous spike frequencies were averaged over a 40 sec recording period. Perfusion with 1µM oxo-M resulted in a significant increase in VNL activity (34 ± 5.7 to 134 ± 15.2 spikes/sec; n=10; one way anova,  $F_{(1,36)} = 21$ ,  $p < 0.0001$ ). When ganglia were pretreated with NA, VNL activity was suppressed (NA + oxo-M = 39 ± 17 spikes/sec, n=6). This suggests that muscarinic activation of NO/cGMP pathway modulates motoneuron activity.

## 147.4

**NITRIC OXIDE ENHANCES cAMP-GATED Na<sup>+</sup> CURRENT IN NEURONS OF THE FEEDING NETWORK OF THE PREDATORY SEA-SLUG**

*PLEUROBRANCHAEA CALIFORNICA*. L. Sudlow\*, L.L. Moroz and R. Gillette, Dept. of Molecular and Integrative Physiology, Univ. of Ill, Urbana IL 61801

cAMP-gated Na<sup>+</sup> current ( $I_{Na,cAMP}$ ) is a prominent mediator of neuro-modulatory arousal in motor networks of feeding, locomotion and escape swimming. These same motor networks exhibit strong histochemical evidence of nitric oxide synthase (NOS) activity (Moroz and Gillette, 1996, J.Comp.Neurol. 367:607). Earlier, it was shown that nitric oxide (NO) donors stimulate buccal motor output both in intact animals and isolated CNS. We sought to examine possible interactions between  $I_{Na,cAMP}$ , cAMP and NO. Here we find that NO gas and NO donors (spermine/NO, DEA/NO, SNAP, S-Nitrosocysteine, final concentrations of 0.1 - 1 mM) markedly potentiate the  $I_{Na,cAMP}$  response to injected cAMP in neurons of the buccal ganglion. DEA/NO caused a 4-fold increase in the maximum  $I_{Na,cAMP}$  and a 30% decrease in the  $K_m$  of the current for cAMP. Application of 8-Br-cGMP did not mimic the effects of NO donors on  $I_{Na,cAMP}$ .  $V_{max}$  and  $K_m$  of phosphodiesterase (PDE) in the buccal neurons were also altered as a result of application of NO donors. PDE  $V_{max}$  decreased by 50% after application of DEA/NO while the  $K_m$  decreased by 40%. In contrast, NO donors did not enhance  $I_{Na,cAMP}$  in the pedal ganglion G-cluster neurons. It was previously shown that  $I_{Na,cAMP}$  also differs between the feeding and locomotor neurons in voltage dependence and sensitivity to Ca<sup>2+</sup>, H<sup>+</sup>, and thiol reagents.  $I_{Na,cAMP}$  appears to serve as a coincidence detector for cAMP and NO via a cGMP-independent mechanism. Supported by NIH RO1 NS26838 to R.G.

## 147.6

**NITRIC OXIDE SYNTHESIS IN CENTRAL AND PERIPHERAL TISSUES OF THE TROPICAL SEA SLUG, *Phestilla sibogae***

(Nudibranchia, Aeolidiida). D.Yu. Budko\*, L.L. Moroz\*, M. Hadfield\* and R. Gillette\*. \*Kewalo Marine Lab., Univ. Hawaii, Honolulu, HI, 96813; \*Dept. Molecular and Integrative Physiology, Univ. Illinois, Urbana, IL, 61801.

Nitric oxide (NO) production and NO synthase (NOS) localization was studied in the CNS and peripheral tissues of the nudibranch *P. sibogae*. Electron paramagnetic resonance (EPR) of specific NO spin traps was used to measure NO, while NOS was localized using NADPH-diaphorase (NADPH-d) histochemistry in the buccal mass, esophagus, rhinophores, tentacles and gills. NADPH-d activity was strongly resistant both to glutaraldehyde and paraphormaldehyde fixation, but distribution patterns of NADPH-d activity were dissimilar in the different fixatives, suggesting the presence of at least two distinct isoforms of NOS. Only a few cells in the CNS were labelled; the majority were localized in the peripheral tissues. Hundreds of intensely stained multipolar neurons were observed in the buccal mass and esophagus. *P. sibogae* appears to be alone among more than 30 molluscan species examined (Moroz and Gillette, 1995) in possessing a plexus of NADPH-d reactive neurons in the buccal mass. We suggest that these cells are modulator and/or motor neurons. EPR detected a high level of NO production in both buccal mass and esophagus. NO is a potent neuromodulator of the feeding program in molluscs; thus, NO production might underlie the virtually chronic feeding activity characteristic of *P. sibogae*. Moderately labelled NADPH-d reactive neurons were observed in peripheral sensory structures (rhinophores, tentacles, mouth area) as well as in the rhinophoral ganglia, where NO signals were also detected by EPR, suggesting an involvement of NO in chemosensory processing. Supported by NIH RO1NS26838 grant to R.G. and by Office of Naval Research grant N00014-94-10524 to M.H.

## 147.7

LOCALIZATION OF NITRIC OXIDE SYNTHASE BY NADPH-DIAPHORASE HISTOCHEMISTRY AND IMMUNOCYTOCHEMISTRY IN THE BRAINS OF THE FLY, *SARCOPHAGA BULLATA*. M.K. Walsh and H. Itagaki<sup>2</sup>. Dept. of Biology, Kenyon College, Gambier, OH 43022.

Nitric oxide (NO), a free radical gas, has been shown to play a major signalling role in the vertebrate immune, vascular, and nervous systems. It is synthesized from L-arginine by a family of enzymes, the nitric oxide synthases (NOS), that also has NADPH diaphorase activity (Hope *et al.*, 1991). By using either antisera to NOS, or a histochemical method to detect the NADPH diaphorase activity, it is possible to localize NOS in various tissues.

Among invertebrates, other investigators have found evidence of NOS in the central nervous systems of a variety of Mollusca, as well as insects (e.g. *Drosophila*, locusts, honeybees). In addition, the *Drosophila* NOS gene has recently been cloned and sequenced by Regulski and Tully (1995).

In this study, we used both histochemical and immunocytochemical methods to localize NOS in the brain and subesophageal ganglia of adult *Sarcophaga bullata*, the blowfly. We found heavy NOS activity in the antennal lobes and in the central bodies, while we found little staining in the mushroom bodies. Our results are congruent with the results of the earlier work on *Drosophila* (Müller and Buchner, 1993). However, the NOS activity patterns are different from the work on locusts (Elphick *et al.*, 1995) in that we found little activity in the mushroom bodies. Our results also support the hypothesis that NO is involved in olfactory processing in insects.

## 147.9

EFFECTS OF NITRIC OXIDE ON AFFERENT RESTING ACTIVITY IN THE CEPHALOPOD (*SEPIA OFFICINALIS*) STATOCYST.

Y. Tu, T.D. Snell and B.U. Budelmann<sup>1</sup>. Marine Biomedical Inst., Univ. Texas Medical Branch, Galveston, TX 77555-1163.

The effects of nitric oxide on the resting activity (RA) of afferent crista fibers were studied in isolated statocysts (n=98) of the cephalopod cuttlefish *Sepia officinalis* by bath application. L-Arginine (precursor of nitric oxide; threshold  $10^{-6}$ M) caused either a decrease of RA, or first a short increase and then a long lasting decrease, or in a few cases an increase only. Application of D-Arginine had no effect. Similar effects to L-Arginine were seen after application of  $10^{-6}$ M to  $10^{-4}$ M 8-Bromo-cGMP sodium (permeable analog of cyclic GMP), and the nitric oxide sources Sodium nitroprusside (SNP,  $10^{-6}$ M to  $10^{-4}$ M), Diethylamine sodium ( $10^{-5}$ M to  $10^{-4}$ M), and 3-Morpholinodimethylamine (SIN-1,  $10^{-6}$ M to  $10^{-4}$ M). When nitric oxide synthase was blocked by  $10^{-5}$ M to  $10^{-3}$ M N<sup>G</sup>-Nitro-L-arginine methyl ester (L-NAME) or  $10^{-5}$ M to  $10^{-4}$ M N<sup>G</sup>-Nitro-L-arginine (L-NOARG),  $10^{-4}$ M L-Arginine was no longer effective, but the effects of 8-Bromo-cGMP sodium and the above nitric oxide sources still occurred. After application of  $10^{-4}$ M Methylene blue or  $10^{-4}$ M Cystamine, L-Arginine and the above nitric oxide sources had only excitatory effects.

These data suggest that in the cuttlefish statocyst a Nitric oxide-cyclic GMP pathway exists with a mainly inhibitory effect on RA. Additional data will be presented on a possible interaction between the cyclic GMP and cyclic AMP systems.

## 147.8

INVOLVEMENT OF NITRIC OXIDE IN THE SYMBIOTIC RELATIONSHIP BETWEEN DINOFLAGELLATE ALGAE AND ANTHOZOANS.

H. Trápido-Rosenthal<sup>1,2</sup>, L. Fraser-Smith<sup>1</sup>, H. Holder, C. Morrall<sup>1,2</sup>, and Z. Billingham<sup>1,3</sup>. (<sup>1</sup>Bermuda Biological Station for Research, Bermuda, University of Plymouth<sup>2</sup>, UK, and <sup>3</sup>University of York, UK).

Cnidarians of the class anthozoa, such as anemones and corals, can live in symbiotic relationships with dinoflagellate algae (zooxanthellae) of the genus *Symbiodinium*. Such symbioses are at least in part chemically mediated (Gates *et al.*, PNAS, 1995). When living in a symbiotic relationship, the free amino acid pools of zooxanthellae are dominated by arginine, the cells have a high arginine transport capacity; and they possess an inducible nitric oxide synthase (NOS) activity (Bester *et al.*, Chem. Senses, in press). We report here the results of investigations into the NOS activity present in the tissue of *Aiptasia pallida*, an organism that maintains populations of *Symbiodinium* in its tentacles.

We assayed for NOS activity by monitoring the ability of *Aiptasia* homogenates (from which algae had been removed) to convert arginine to citrulline. We found that *Aiptasia* possess NOS activity, and that this activity is localized in the soluble fraction of homogenates. Calcium, calmodulin, and NADPH are required for maximal activity, which is inhibited by N-arginine methyl ester and by nitroarginine, but not by valine.

In response to stresses such as heat shock or mechanical agitation, anemones retract their tentacles by contracting their muscles. Such stressed animals have lower NOS activity than do unstressed controls. Treatment of *Aiptasia* with NOS inhibitors can also cause tentacular retraction, while treatment with the NOS substrate arginine can inhibit this response to stress. Taken together, our results suggest that (1) NO may be involved in the anemone's control of tentacular deployment, and that (2) NO derived from symbionts has the potential to contribute to the behavior of the host organism.

Supported in part by a contract from Boehringer-Mannheim Corporation and a grant from the NIH (1-R03-DE11916-01).

## 147.10

DOES NITRIC OXIDE INHIBIT METAMORPHOSIS IN A LARVAL MOLLUSC? S. Froggett and E.M. Leise<sup>1</sup>. Dept. of Biol., U. of N. Carolina Greensboro, Greensboro, NC 27412.

In metamorphically competent larvae of the gastropod *Ilyanassa obsoleta*, the apical ganglion maintains a higher level of staining for NADPH-diaphorase than all other ganglia throughout pre-metamorphic development (Lin, M. and Leise, E. M., *J. Comp. Neurol.* in press). Staining intensities increase in all neuropils during this stage, however neuropil staining decreases in all ganglia at metamorphosis.

To elucidate the function of nitric oxide (NO) during metamorphosis, we bath-applied NO donors and a nitric oxide synthase (NOS) inhibitor, in combination with a known metamorphic inducer, serotonin, to competent larvae. NO donors or the NOS inhibitor were applied once or replaced every 6 hrs to maintain high activity during the experiment. Metamorphosis was scored at 24 and 48 hrs.

The NO donor SNAP inhibits metamorphosis at  $10^{-3}$  M to  $10^{-5}$  M at 24 hrs and  $10^{-3}$  M to  $10^{-4}$  M at 48 hrs. The NOS inhibitor L-NAME does not affect metamorphic induction. Our results suggest that NO may be an endogenous inhibitor of metamorphosis. The lack of significant results with L-NAME suggests that this compound is not actively taken up by larvae. Injection experiments and further use of other NO donors are needed to confirm the SNAP results.

This research was supported by grants from UNC-G.

## TRANSPORTERS I

## 148.1

EFFECTS OF VARIOUS ANTIDEPRESSANTS ON GABA TRANSPORTER SUBTYPES EXPRESSED IN COS7 CELLS. M. Nakashita\*, K. Sasaki, C. Matsuyama, N. Sakai and N. Saïto. Laboratory of Molecular Pharmacology, Biosignal Research Center, Kobe University, Kobe 657, Japan

The discovery of the tricyclic and tetracyclic antidepressants, which are known to inhibit the reuptake of two biogenic amines, noradrenaline and serotonin, has revolutionized the therapy of the depression, but the molecular mechanism of these drugs has not yet been elucidated. Molecular cloning of neurotransmitter transporters revealed that the tricyclic and tetracyclic antidepressants act on the presynaptic serotonin and noradrenaline transporters, and that the antidepressants has different affinity for the two biogenic amine transporters. It was also shown that GABA uptake is also altered by antidepressants and some antidepressant have anticonvulsive effects. We here examined the effects of various antidepressants on the GABA uptake through three subtypes of GABA transporters (GAT1, GAT2 and GAT3) expressed in COS7 cells.

IC<sub>50</sub> value of 11 antidepressants for serotonin transporter (SET) and three GABA transporters was examined. Desipramine, maprotiline, amitriptyline and nortriptyline proved to have similar inhibitory potency for GAT1 and GAT3 to that for SET. According to the previous uptake study using synaptosomal fraction, amitriptyline has similar value of IC<sub>50</sub> for serotonin uptake to noradrenaline uptake among these four antidepressants. These results suggested that amitriptyline acts on three neurotransmitter transporters (GABA, noradrenaline and serotonin transporters) at the similar concentration and that the inhibitory effect of amitriptyline on GABA uptake should be mentioned clinically.

## 148.2

EXPRESSION OF GABA TRANSPORTERS IN THE RAT THALAMUS.

S. De Biasi\*, L. Vitellaro-Zuccarello and N. Brecha<sup>2</sup>. Dip. Fisiol. Biochim. Gen. Sez. Istologia e Anatomia Umana, Univ. Milano, Milano, Italy; <sup>2</sup>Dept. Neurobiology, UCLA, Los Angeles, CA 90095-1763, USA.

GABAergic transmission is terminated by the uptake of GABA into neuronal and glial processes through GABA plasma membrane transporters. The three GABA transporters (GAT-1, GAT-2 and GAT-3) isolated from the rat nervous system share structural similarities but have distinct pharmacological properties and tissue distributions.

The localization of GAT-1 and GAT-3 in rat thalamus has been studied by immunocytochemistry with anti-peptide antibodies raised in rabbits against the C terminal portion of the transporters (Minelli *et al.*, 1995, 1996). Vibratome sections of the thalamus of rats perfused under anesthesia with mixed aldehydes were processed for the visualization of GAT-1 and GAT-3 immunoreactivity (GAT ir) by a standard ABC-DAB procedure. Representative sections containing the reticular, ventrobasal and dorsal lateral geniculate nuclei were also processed for electron microscopy.

At light microscopy the two antisera labeled the thalamic neuropil with a distinct pattern of intensity, as GAT-1 ir was generally faint whereas GAT-3 ir was very intense throughout the thalamus. At the electron microscope GAT-1 ir and GAT-3 ir were always confined to astrocytic cell bodies and their proximal and distal processes. Astrocytic processes were scattered throughout the neuropil, where they surrounded blood vessels and unlabeled neuronal profiles, including axonal terminals making either symmetric or asymmetric synapses. The present results indicate that in rat thalamus both GABA transporters are involved in the uptake of GABA into glial cells. Supported by MURST 40%, NIH EY04067 and VA Merit Review Funds.

## 148.3

**INFLUENCE OF STRUCTURAL ANALOGUES ON MOUSE BRAIN SYNAPTOSOMAL TRANSPORT OF  $\gamma$ -HYDROXYBUTYRATE.** G. Tunnickliff, S.J. McCormick and R.D. Stith\* Laboratory of Neurochemistry, Department of Biochemistry & Molecular Biology, Indiana University School of Medicine, Evansville, IN 47712.

$\gamma$ -Hydroxybutyrate is a metabolite of  $\gamma$ -aminobutyric acid (GABA), the prime inhibitory neurotransmitter in the brain, and has pronounced neuropharmacological actions, such as the induction of somnolence and general anesthesia. Further, it inhibits neuronal activity in cultured cells, and induces a generalized absence seizure-type EEG activity in experimental animals. In addition to possessing a specific receptor site in the brain,  $\gamma$ -hydroxybutyrate possesses a high-affinity transport system in synaptosomes which might represent an uptake mechanism responsible for removing  $\gamma$ -hydroxybutyrate from the synaptic gap. This transport system displayed saturation kinetics and was substantially activated in the presence of pyridoxal 5'-phosphate.

One way to characterize a transport system is to study the effects of inhibitors. The structure of these inhibitors and their mechanism of action can shed light on the nature of the recognition site on the transporter. This study measured the action of several  $\gamma$ -hydroxybutyrate and GABA structural analogues, as well as the  $\text{Na}^+$  antagonist, harmaline. The GABA transport inhibitors nipecotic acid, guavaicaine and  $\beta$ -alanine had no effect on  $\gamma$ -hydroxybutyrate synaptosomal uptake. However, the  $\gamma$ -hydroxybutyrate analogues 2-hydroxycinnamic acid, fulylactic acid and citrazinic acid were all competitive inhibitors of transport, with  $K_i$  values of  $74 (\pm 14) \mu\text{M}$ ,  $130 (\pm 16) \mu\text{M}$  and  $222 (\pm 35) \mu\text{M}$ , respectively. Harmaline was a competitive inhibitor with respect to  $\text{Na}^+$ . These results show that the  $\gamma$ -hydroxybutyrate transporter is pharmacologically distinct from the GABA transporter, and that structural analogues can compete for binding at the  $\gamma$ -hydroxybutyrate recognition site on the transport protein. Funded by IUSM

## 148.5

**RXT1, AN «ORPHAN»  $\text{Na}^+/\text{Cl}^-$ -DEPENDENT TRANSPORTER, IS LOCATED ON AXON TERMINALS OF CORTICO-STRIATAL GLUTAMATERGIC NEURONS IN THE RAT BRAIN.** S. El Mestikawy<sup>(1)</sup>, J. Masson<sup>(1)</sup>, L. Kerkerian<sup>(3)</sup>, P. Kachidian<sup>(3)</sup>, Z. Aidouni<sup>(1)</sup>, P. Gaspard<sup>(2)</sup> and M. Hamon<sup>(1)</sup>. <sup>(1)</sup> INSERM U288 and <sup>(2)</sup> INSERM U109 Institut Fédératif des Neurosciences de la Pitié-Salpêtrière. PARIS 75013, France; <sup>(3)</sup> CNRS-UPR 9013, MARSEILLE 13402, France.

Rxt1 was cloned thanks to its sequence homology with the well characterized  $\text{Na}^+/\text{Cl}^-$ -dependent transporters for neurotransmitters such as the dopamine-, norepinephrine-, serotonin- and GABA- transporters. However, its transported substrate has not yet been identified. The development of specific probes (cRNA, polyclonal antibodies) allowed the demonstration that Rxt1 is expressed exclusively by central neurons whose distribution in the rat brain suggests that they may correspond mainly to those using glutamate as neurotransmitter. In particular, a high concentration of the Rxt1 protein but only low levels of the Rxt1 mRNA were found in the striatum as expected of the addressing of the «orphan» transporter to the terminals of cortico-striatal glutamatergic projections. Several complementary approaches were used in order to directly assess this possibility. Firstly, electrocoagulation was applied to the cerebral cortex for inducing a massive degeneration of cortico-striatal afferents. This electrolytic lesion resulted in the parallel decrease in both the density of striatal glutamatergic terminals (quantified by the measurement of synaptosomal [ $^3\text{H}$ ]glutamate uptake) and the striatal levels of the Rxt1 protein (estimated by western blot). Secondly, cortical neurons projecting to the striatum were retrogradely labeled by fluorogold injections into the striatum. Combined *in situ* hybridization with a specific cRNA probes showed that the vast majority of retrogradely labeled cortico-striatal neurons contained Rxt1 mRNA. Thirdly, immunolabeling at the electron microscope level indicated that the Rxt1 protein was present in axon terminals of cortico-striatal projections identified by the anterograde transport of HRP-tracer. Altogether, these data demonstrated that Rxt1 is located on the striatal terminals of glutamatergic neurons originating in the cerebral cortex. Therefore, Rxt1 may play a key role in glutamate-dependent modulations of striatal (motor and cognitive) functions.

## 148.7

**ALTERATIONS IN HIGH AFFINITY CHOLINE UPTAKE IN RAT BRAIN SECTIONS DUE TO 17 $\beta$ -ESTRADIOL.** M.L. Caspers\*, B.E. Deverman and M.J. Fu, Dept. of Chemistry, Univ. of Detroit Mercy, Detroit, MI 48219.

We have shown that a decrease in high affinity choline uptake occurs in ovariectomized (OV) rats exposed to either 0.5 or 5 mg 17 $\beta$ -estradiol pellets for 2 or 3 weeks (Soc. Neurosci. Abstr. 21 (1995) 2064). In this study, young (2 mo) OV rats were sacrificed 5 or 8 wks after implantation of 17 $\beta$ -estradiol (0.5 or 5 mg) or placebo pellets, 24  $\mu\text{m}$  frozen brain sections were prepared and treated with [ $^3\text{H}$ ]hemicholinium-3 (HC-3), a competitive inhibitor of the high-affinity choline transporter. Autoradiographic studies with computer-assisted densitometry indicated an 18.6% ( $P < 0.001$ ) and a 13.7% ( $P < 0.0005$ ) decrease in HC-3 binding in the caudate putamen (CP) of rats treated with 0.5 mg 17 $\beta$ -estradiol pellets for 5 and 8 wks, respectively. In rats receiving 5 mg 17 $\beta$ -estradiol pellets, an 11.1% ( $P < 0.04$ ) and 12.7% ( $P < 0.001$ ) increase in HC-3 binding in the CP was noted after 5 and 8 wks, respectively. After 3 wks, non-OV and OV, old (15 mo) rats treated with 0.5 mg estradiol pellets had a 7.1% and an 8.4% ( $P < 0.003$ ) decrease in HC-3 binding, respectively. After 5 wks of exposure to 5 mg 17 $\beta$ -estradiol pellets, a 29.1% ( $P < 0.002$ ) decrease and a 9.9% ( $P < 0.001$ ) increase in HC-3 binding was noted in non- and OV old rats, respectively. (Supported by an Amer. Fed. Aging Res. grant).

## 148.4

**CHARACTERIZATION OF GLYCINE TRANSPORT IN CULTURED MÜLLER CELLS FROM THE RETINA.** A. Gadea, M. Romo-De-Vivar\* and A. M. López-Colomé. Instituto de Fisiología Celular, Universidad Nacional Autónoma de México, Apartado Postal 70-253, México, D.F., 04510, México.

Rapid termination of the synaptic action of glutamate (glu) and glycine (gly) is achieved by uptake into the presynaptic terminal and glial cells. In the vertebrate CNS, gly acts both, as an inhibitory neurotransmitter and as a glu modulator or coagonist at postsynaptic N-methyl-D-aspartate receptors. We have previously described NMDA receptors in Müller cells of chick retina coupled to the phosphoinositide cascade, the entry of calcium and the activation of PKC (López-Colomé et al., 1993). A colocalization of gly transporters and NMDA receptors has been reported in brain tissue (Smith et al., 1992); since the concentration of gly could participate in the modulation of glu excitatory transmission in the vertical pathways of the retina, transport of gly in confluent monolayer cultures of Müller cells from 7-day-old chick embryos was studied. Uptake was measured at 37 °C in Krebs-Ringer Bicarbonate buffer containing [ $^3\text{H}$ ]gly/1:25000. Gly transport into an osmotically-sensitive compartment reaches equilibrium at 30 min. Process is energy-requiring, since iodoacetate (1mM), ouabain (200  $\mu\text{M}$ ), and potassium cyanide (1mM), inhibited transport 23%, 58% and 15% respectively; 2,4-dinitrophenol (50  $\mu\text{M}$ ) had no effect. Sarcosine (1mM) competitively inhibited transport, whereas 1mM taurine, D-serine, GABA and  $\beta$ -alanine were ineffective. Gly transport was pH-sensitive with an optimum at pH 7.4. Kinetic analysis of the saturation curve for gly in a concentration range from 0.01 mM to 2 mM ([ $^3\text{H}$ ]gly/1:5000), revealed two transport systems: low affinity with a  $K_m$  579  $\mu\text{M}$ ,  $V_{max}$  2.3 nmol/min/mg protein, and high affinity with a  $K_m$  of 43.8  $\mu\text{M}$ ,  $V_{max}$  0.55 nmol/min/mg protein. Ion dependence was investigated for both systems, replacing NaCl with choline chloride or LiCl in the case of  $\text{Na}^+$ , or with  $\text{Na}^+$  gluconate in the case of  $\text{Cl}^-$ . Both systems were highly dependent on the presence of  $\text{Na}^+$ ; the high-affinity system proved also dependent on  $\text{Cl}^-$  ions in the external medium. This work was partially supported by Grant 3375-N from CONACYT.

## 148.6

**CONTROL OF NMDA RECEPTOR ACTIVATION BY A GLYCINE TRANSPORTER.** S. Supplisson\* and C. Bergman. Laboratoire de Neurobiologie, Ecole Normale Supérieure, 75005 Paris, France.

Cotransporters accumulate specific substrates inside the cells using ionic electrochemical gradients. They can also lower the substrate concentration outside the cell membrane if the passive diffusion from the bulk solution towards the membrane does not compensate the uptake. Such a depletion could be of physiological importance for the regulation of the synaptic glycine concentration at glutamatergic synapses and the control of N-Methyl-D-Aspartate receptors (NMDAR). To study the capacity of a glycine transporter (GLYT1b) to control NMDAR, we coexpressed both proteins in *Xenopus* oocytes. We previously reported that in such a system stopping the superfusion flow in the presence of glycine and glutamate resulted in a dramatic decrease of the NMDA-induced current. This inhibition was interpreted as resulting from a local (juxtamembrane) decrease of [Gly] due to glycine uptake. We show now that even in a fast perfusion mode, the activity of GLYT1b is sufficient to lower significantly the extracellular glycine. This conclusion is drawn from the comparison of concentration-response curves for glycine activation of the NMDAR in oocytes expressing NMDAR with or without GLYT1b. In the presence of GLYT1b, the glycine  $\text{EC}_{50}$  of NMDAR is shifted from 2.2  $\mu\text{M}$  to 8-10  $\mu\text{M}$ . That this shift is only apparent is indicated by the fact that the  $\text{EC}_{50}$  of D-serine (a non transported glycine agonist of NMDAR) remained unchanged. We calculate that even in the fast perfusion mode, the transporter can lower the glycine concentration at the membrane by a factor of 4 to 5. Supported in part by EC grant BMH4CT950571.

**DIFFERENCES IN THE DEVELOPMENTAL EXPRESSION OF THE VESICULAR ACETYLCHOLINE TRANSPORTER AND CHOLINE ACETYLTRANSFERASE IN THE RAT BRAIN.** Thomas Holler<sup>1</sup>\*, Brygida Berse<sup>1</sup>, Jennifer Marie Cermak<sup>1</sup>, Marie-Françoise Diebler<sup>2</sup> and Jan Krzysztof Blusztajn<sup>1</sup>. <sup>1</sup>Department of Pathology, Boston University School of Medicine, Boston, MA 02118; <sup>2</sup>Département de Neurobiologie Cellulaire, CNRS, 91190 GIF-sur-Yvette Cedex, France

The neurotransmitter acetylcholine (ACh) is synthesized by the enzyme choline acetyltransferase (ChAT) and then transported into synaptic vesicles by the vesicular acetylcholine transporter (VAcHT). Since the VAcHT gene is located within the first intron of the ChAT gene, it is likely that expression of the two genes is coregulated. We compared the developmental expression of VAcHT and ChAT mRNA and protein in rat brain. ChAT mRNA and enzyme activity increased by almost 10-fold from embryonic day 19 to adulthood, with the most pronounced increase occurring after birth. In contrast, VAcHT mRNA increased by only about 2-fold from late embryonic stages to adult levels. However, VAcHT protein followed the developmental pattern of ChAT activity, revealing a large excess of VAcHT mRNA over VAcHT protein during early stages of development. The results are suggestive of differential mechanisms of ChAT and VAcHT regulation during brain development, and of possible translational control of VAcHT expression.

## 148.9

**$\beta$ -AMYLOID INHIBITS GLUCOSE UPTAKE IN CULTURED RAT ASTROCYTES.** A. Párpura-Gill\*, C. Martens, D. Beitz and E. Uemura. Dept. of Veterinary Anatomy, Neuroscience Program and Dept of Animal Science, Iowa State University, Ames, IA 50011.

Astrocytes possess cytoplasmic membrane glutamate uptake carrier which normally keeps extracellular levels of glutamate below neurotoxic concentrations. The process of glutamate uptake is energy dependent, and the capacity of astrocytes to continue with this function during pathologic conditions may have significant consequences on neuronal survival. Glycolysis is the major source of that energy. Any inhibition of this ATP-producing process could result in diminished glutamate uptake in astrocytes. Investigation of the cerebral glucose metabolic rate in AD patients determined that glucose oxidation in these patients was significantly lower than in normal, age-matched patients. This suggests lower ATP production in AD patients which might have direct effect on astrocytic glutamate uptake. In this study, we investigated  $\beta$ -amyloid effect on astrocytic glucose uptake. Purified astrocyte cultures were prepared from hippocampi of P2-5 Sprague-Dawley rats. Cells were plated onto tissue culture plates coated with  $\beta$ 25-35 peptide (1mg/ml). At postplating day 7  $^{14}$ C-glucose was added. The reaction was stopped after 1 hour, and radioactivity was measured in cell lysates. We found that  $\beta$ 25-35 peptide significantly inhibits glucose uptake in astrocytes. Our data suggest that  $\beta$ -amyloid might play a role in neuronal cytotoxicity by lowering efficacy of glutamate uptake carrier via decreasing glucose uptake, thus disrupting energy production essential for the glutamate carrier functioning. Supported by Alzheimer's Association #93048.

**EXCITATORY AMINO ACIDS STIMULATE GLYCOLYSIS IN ASTROCYTES VIA ACTIVATION OF THE  $\text{Na}^+/\text{K}^+$  ATPase** L. Pellerin\* and P.J. Magistretti. Laboratoire de Recherche Neurologique, CHUV et Institut de Physiologie, Université de Lausanne, Switzerland.

Several lines of evidence indicate that astrocytes may play a pivotal role in coupling neuronal activity with energy metabolism (Magistretti & Pellerin *Cerebral Cortex* 6:50-61 1996). We have observed that excitatory amino acids (EAAs) like glutamate and aspartate increase 2-deoxyglucose (2-DG) uptake and phosphorylation by mouse cortical astrocytes in culture. The stimulatory effect of EAAs is mediated by a  $\text{Na}^+$ -dependent glutamate transporter. Since the effect on 2DG uptake can be prevented by ouabain, an inhibitor of the  $\text{Na}^+/\text{K}^+$  ATPase, we have engaged in a more direct demonstration of the involvement of the pump. Using  $^{86}\text{Rb}$  uptake as an index of the activity of the  $\text{Na}^+/\text{K}^+$  ATPase, we have found that L-glutamate increases Rb uptake into astrocytes in a concentration-dependent manner with a  $K_m$  of 72  $\mu\text{M}$ . Both D- and L-aspartate, but not D-glutamate exert a similar effect, further indicating a transporter-mediated effect. In addition, the possibility of a massive  $\text{Na}^+$  influx due to opening of voltage-dependent  $\text{Na}^+$  channels can be excluded since TTX is without effect. As for 2-DG uptake, the effect of L-glutamate is prevented by 100  $\mu\text{M}$  ouabain, further supporting a functional link between these two processes. Since EAAs also increase lactate release by astrocytes, these observations also strongly support the view that EAAs stimulate glycolysis in astrocytes via activation of the  $\text{Na}^+/\text{K}^+$  ATPase. When viewed within their physiological context, these data suggest that upon cortical activation, EAAs released by activated neurons provide a direct signal for astrocytes to take up glucose and metabolize it to lactate, which can be used by neurons as an energy source.

**The Mammalian Brain-Specific, High-Affinity, L-Proline Transporter: Identification of Cysteine Residues Important for Transport.** I.W. Miller\*, SE Renick, RT Freneau, Jr. Dept. of Pharmacol., Duke Univ. Med. Ctr., Durham, NC 27710.

The cloned, mammalian brain-specific, high-affinity L-proline transporter (PROT) is a member of the gene family of  $\text{Na}^+$ - (and  $\text{Cl}^-$ )-dependent plasma membrane transport proteins that includes transporters for several neurotransmitters, osmolytes, and metabolites. We report that the sulfhydryl reagent *p*-hydroxymercuriphenylsulfonic acid (pHMBs) is a potent inhibitor of high-affinity L-proline uptake in PROT-transfected HeLa cells ( $\text{IC}_{50} \sim 5 \mu\text{M}$ ). pHMBs is an organomercurial compound which is membrane impermeable and covalently modifies cysteine residues. Therefore, one or more externally accessible cysteine residues within the PROT protein may be important for substrate binding and/or translocation. To investigate this hypothesis, we used site-directed mutagenesis to individually replace each of eleven cysteine residues conserved between the human and rat PROT homologs with isosteric serine residues. We then examined whether any individual cysteine residue is required for the transport function of mammalian brain PROT. The eleven  $\text{C}_{10}\text{S}_1$  mutants were transiently transfected into HeLa cells and  $^3\text{H}$ -L-proline uptake was measured. Three mutants (C50S, C54S, C431S) exhibited  $\leq 50\%$  L-proline uptake as compared to the wild type PROT; four mutants (C86S, C220S, C231S, C547S) exhibited 60-80% uptake; and four mutants (C218S, C470S, C483S, C501S) exhibited 100% uptake. We are currently investigating the molecular basis of the transport defects in those mutants expressing reduced transport. We are also determining the effect of each mutation on transport inhibition by pHMBs. Preliminary data indicate that one mutant is less sensitive to pHMBs inhibition than wild type PROT. This residue may be located in the PROT permeation pathway. Grant support: Neurobehavioral Sciences Training Grant PHS MH15177, and NIH NS32501.

## 148.10

**DIFFERENTIAL DISTRIBUTION OF LACTATE TRANSPORTERS AND LACTATE DEHYDROGENASE (LDH) ISOZYMES: EVIDENCE FOR AN ASTROCYTE-NEURON LACTATE CYCLE.** G. Pellegri, P.G. Bitar, J.-L. Martin and P.J. Magistretti\* Institut de Physiologie, Université de Lausanne, Switzerland.

There is experimental evidence indicating that lactate and pyruvate are adequate substrates for brain tissue and that lactate is produced by astrocytes and utilized by neurons. This metabolic exchange requires the presence of a lactate transport system and a selective distribution of LDH isoenzymes. Two monocarboxylate transporters have been cloned in peripheral tissues (MCT1 and MCT2). We have used cDNA probes to study the regional and the cellular distribution of MCT mRNAs in the mouse brain. The expression of MCT1 and MCT2 mRNAs is developmentally regulated, reaching a peak during the second postnatal week (P15). *In situ* hybridization experiments revealed a differential distribution of MCT1 and MCT2 mRNAs in P15 brain. Thus, MCT1 is particularly expressed in the vascular endothelial cells, while MCT2 labelling is observed in hippocampal and cortical neurons. In contrast, in the adult mouse brain, MCT1 and MCT2 mRNAs are expressed throughout the whole brain, with no endothelial labelling and no colocalization with GFAP; this suggests that in the adult brain MCT1 and MCT2 are predominantly expressed in neurons. The cellular distribution of the MCT1 and MCT2 mRNAs was also examined in primary cultures of cortical astrocytes and neurons. Northern blot analysis indicates that MCT1 mRNA is predominantly localized in astrocytes, while MCT2 is more abundant in neurons. Further suggesting the existence of an astrocyte-neuron lactate cycle is the selective distribution of LDH isoenzymes. Indeed, the A subunit, which is predominantly found in lactate-producing tissues, is exclusively detected in certain populations of astrocytes in the adult human brain while neurons are labelled exclusively by antibodies raised against the B subunit which is enriched in lactate-consuming tissues. Our findings suggest that lactate produced in astrocytes may passively diffuse into the extracellular space and be avidly taken up by neurons possessing MCT1 and MCT2, thus providing an energy substrate for those cells. ## 148.12

**DEVELOPMENTAL EXPRESSION OF ORPHAN TRANSPORTERS rB21a AND v7-3 mRNAs IN EMBRYONIC RATS.** K. Inoue<sup>1</sup>, S. Shimada<sup>1</sup>, K. Sato<sup>1</sup>, G. R. Uhl<sup>2</sup> and M. Tohyama<sup>1</sup>. <sup>1</sup>Dept. of Anat. & Neurosci., Osaka Univ. Med Sch., Osaka, 565. JAPAN.

<sup>2</sup>Mol. Neurobiol. Br., IRP, NIDA, NIH, Dept. Neurol. & Neurosci., JHUSM, Balto., MD21224

Orphan transporters rB21a and v7-3 are members of a new subfamily of  $\text{Na}^+$ ,  $\text{Cl}^-$  dependent neurotransmitter transporters with two large extracellular loops. We have investigated developmental expression of orphan transporters rB21a and v7-3 mRNAs in rats by *in situ* hybridization histochemistry. Both mRNAs exhibited unique regional and temporal developmental expression profiles. As a characteristic feature, rB21a mRNA was expressed strongly in liver during development, but diminished markedly to undetectable levels around birth. Intense expression of v7-3 mRNA in choroid plexus also faded around birth. In the adult rat brain, rB21a mRNA was localized in pineal gland, pia matter and choroid plexus, whereas v7-3 was widely distributed in central nervous system neurons. These developmental expression patterns may suggest possible candidate substrates for the orphan transporters that could even differ from embryonic development to adulthood.

## 148.14

**EFFECTS OF ENDOGENOUS MONOCARBOXYLATES (PYRUVATE & LACTATE) ON THE PRESERVATION OF RAT HIPPOCAMPAL SLICES UNDER HYPOGLYCEMIC CONDITIONS** A. M. Benz, Y. Izumi, D. B. Clifford\*, & C.F. Zorumski. Depts. of Psychiatry and Neurology, Washington Univ., School of Med., St. Louis, MO 63110.

In rat hippocampal slices, dark cell appearance is a characteristic histological change during glucose deprivation. We have previously shown that the dark cell appearance by glucose deprivation was prevented by the application of alternative energy substrates other than glucose (*NeuroReport* 1994;5:617. *Society for Neuroscience* 1994;20:1320.). Among these substrates, lactate and pyruvate from glia may function as endogenous energy substrates in the central nervous system. If this is the case, monocarboxylates are particularly important for the preservation of neuronal integrity when glucose is unavailable. To address the question of whether endogenous monocarboxylates participate in the preservation of neurons during hypoglycemia, we examined the effects of cytochalasin B (CCB) and  $\alpha$ -cyano-4-hydroxycinnamate (4CIN) in hippocampal slices. CCB and 4CIN are inhibitors of glucose- and monocarboxylates-transport, respectively.

Administration of 200  $\mu\text{M}$  4CIN for 90 min in the presence of 10 mM glucose did not produce histological change (N=6), suggesting that monocarboxylates are not essential energy substrates for neurons when glucose is available. However, the combination of 50  $\mu\text{M}$  CCB and 200  $\mu\text{M}$  4CIN produced remarkable shrinkage in pyramidal cells (N=6). Although 50  $\mu\text{M}$  CCB alone for 90 min revealed some dark cell appearance, the degree of changes was less compared to the effects of the combination (N=6). This result indicates that when glucose utilization is impeded endogenous monocarboxylates play an important role in neuronal preservation.

CHANGES IN EXTRACELLULAR [KCl] ALTERS GLUCOSE UTILIZATION IN CEREBELLAR GRANULE NEURONS. E.M. Kochler-Stee\*, T.M. Davies-Hill, J.A. Simpson, EDMNS, DB, NIDDK, NIH, Bethesda, MD 20892

Cerebellar granule neurons (CGN) are normally cultured in high KCl [25mM] media to allow for optimal growth and differentiation. Under these conditions, the expression of glucose transporters (GLUTs) 1 and 3 and the rate of glucose transport/utilization are maximal. If CGNs are grown in serum-free low KCl [5.6mM] media, the rate of differentiation and GLUT expression are slower. Transferring differentiated CGNs from a high to low KCl environment leads to apoptotic cell death. In this study, the effect of acute exposure of differentiated CGNs, grown in media containing high KCl and serum, to a low KCl solution on glucose transport/utilization was measured by the 2-deoxyglucose (2DG) method. Transfer of CGNs (day 8 *in vitro*) to low KCl Lockes buffer increased the apparent rate of 2DG uptake which was maximal after 9 min and remained elevated for up to 30 min. Addition of energy substrates (i.e. lactate (1mM), pyruvate (1mM) or glucose (100μM)) blunted the apparent increase in 2DG uptake. In contrast, transfer of CGNs to high KCl Lockes buffer did not induce an increase in the rate of 2DG uptake but rather decreased uptake over time; addition of energy substrates appeared to block this effect. To determine if the increase in the apparent rate of 2DG uptake in cells incubated in the low KCl buffer resulted from an increase in glucose transport activity or GLUT translocation, 3-O-methylglucose transport as well as photoaffinity labelling techniques were used, respectively. There was no difference in 3-O-methylglucose uptake in cells incubated for 0 or 9 min in low KCl buffer +/- 100μM glucose nor was there any change in the number of GLUTs present on the cell surface after 30 min incubation in the low KCl buffer. Thus, the apparent increase in 2DG uptake is not a result of GLUT activation and/or translocation but rather reflects the ambient energy status of the cells following ionic manipulations which results in an increased phosphorylation of 2DG. ## 148.17

CALCIUM AND CALMODULIN DEPENDENT PROTEIN KINASE II REGULATION OF BRAIN MICROSOMAL  $Ca^{2+}$  UPTAKE MEDIATED BY  $Mg^{2+}/Ca^{2+}$  ATPase. J. T. Parsons\*, S. B. Churn\*, and R. J. DeLorenzo<sup>1, 2, 3</sup>, Departments of Biochemistry<sup>1</sup>, Neurology<sup>2</sup>, and Pharmacology<sup>3</sup>, Medical College of Virginia, Richmond, VA 23298.

Multifunctional Calcium and Calmodulin Dependent Protein Kinase II (CaMKII) regulates a multitude of brain functions. CaMKII is also a ubiquitous enzyme that has been shown to stimulate cardiac microsomal  $Ca^{2+}$  uptake by phosphorylation of  $Mg^{2+}/Ca^{2+}$  ATPases. In order to determine whether CaMKII regulates brain  $Mg^{2+}/Ca^{2+}$  ATPases, we examined the effect of various kinase inhibitors on endogenous microsomal CaMKII activity and  $Ca^{2+}$  uptake mediated by  $Mg^{2+}/Ca^{2+}$  ATPase. Microsomes were isolated from rat brain homogenates by differential centrifugation. Endogenous CaMKII activity was measured by  $^{32}P$  incorporation into the 50 kDa alpha subunit (autophosphorylation) of the enzyme.  $Mg^{2+}/Ca^{2+}$  ATPase mediated  $Ca^{2+}$  uptake was measured by scintillation counting of  $^{45}Ca^{2+}$  accumulation in the microsomes.  $Ca^{2+}$  uptake was performed under conditions that resulted in significant CaMKII autophosphorylation activity. The calmodulin antagonists chlorpromazine and W-7 resulted in 62 % and 71 % inhibition respectively of CaMKII activity. The nonspecific kinase inhibitor H-7 caused 81 % inhibition of CaMKII autophosphorylation. In addition, the CaMKII specific calmodulin antagonist peptide [CPI(290-309)] inhibited 64 % of CaMKII autophosphorylation activity. These compounds also had similar inhibition of microsomal  $Ca^{2+}$  uptake. Chlorpromazine and W-7 caused 41 % and 78 % decrease in  $Ca^{2+}$  uptake respectively. H-7 resulted in microsomal  $Ca^{2+}$  uptake inhibition of 64 %. Finally, CPI(290-309) demonstrated an inhibition of  $Ca^{2+}$  uptake of 32 %. The data suggest that CaMKII either directly or indirectly regulates neuronal microsomal  $Ca^{2+}$  uptake mediated by  $Mg^{2+}/Ca^{2+}$  ATPases. This work was supported by NIH grant R01-NS23350.

## 148.19

THE SITES OF  $^3H$ -HISTIDINE UPTAKE WITHIN AN ARTHROPOD EYE RAISE QUESTIONS ABOUT THE SYNTHESIS OF HISTAMINE, THE PHOTORECEPTORS' NEUROTRANSMITTER. J.R. Morgan and A.E. Stuart\*, Dept. of Physiology, Univ. of North Carolina, Chapel Hill, NC 27599-7545.

Histamine (HA), the proposed neurotransmitter at arthropod photoreceptor (PR) synapses, is synthesized from histidine (Hd) by decarboxylation. We examined the uptake of  $^3H$ -Hd into barnacle PRs and surrounding glia using autoradiography and biochemistry. No cellular domain of the PRs (somata, axons, or synaptic terminals) labeled after incubation in  $^3H$ -Hd (0.2, 2, or 20 μM, 15 min, 15°, flashing light). Glia labeled intensely, however, as did non-PR axons in the ocular nerve. To determine whether  $^3H$ -Hd was converted to  $^3H$ -HA in the glia and supplied to the PRs, preparations were incubated in  $^3H$ -Hd (15 min), washed, and either homogenized or fixed for autoradiography 1, 5, or 24 hrs later. Even after 24 hrs, radioactivity ran with Hd and not HA in thin layer chromatography, indicating that  $^3H$ -HA was not synthesized by glia. Autoradiographic label remained confined to glia and non-PR axons. Attempts to deplete the PRs of HA by stimulating release with high  $[K^+]$ , while blocking HA uptake with chlorpromazine did not change the pattern of  $^3H$ -Hd label. Since the PRs do not take up  $^3H$ -Hd (under our incubation conditions), the pathway by which their HA is supplied remains a puzzle. Supported by NIH grant EY03347 to AES.

## 148.16

GLUCOSE TRANSPORTER, GLUT 5, EXPRESSION IN CULTURED MICROGLIAL CELLS OF RAT. J. Payne\*, J. Simpson and P. Davies, Dept. of Pathology, Albert Einstein College of Medicine, Bronx, N.Y. 10461; NIDDK, NIH, Bethesda, MD 20892.

Glut 5 is a member of a group of related facilitative glucose transporter proteins that are involved in enhancing transportation of glucose and/or fructose across plasma membranes. Although some isoforms are present in non-CNS tissue, GLUT 5 is one of three isoforms present in human and rat brain. We have shown, using immunocytochemical techniques, that Glut 5 is expressed exclusively in microglial cells of human and rat brain. In the present study we examined the expression of Glut 5 in cultured microglial cells from rat brain. Antibody to Glut 5 was raised to a 20 amino acid synthetic peptide specific for the C terminal region of the rat Glut 5 sequence. The anti-rat Glut 5 antibody was affinity purified. Mixed cell cultures were prepared from 4 day postnatal rats, and microglia were isolated from day 7-9 cultures. For immunocytochemistry, purified microglial cells were grown on glass coverslips and treated with the following antibodies: 1) OX 42, a microglial marker, 2) ISO B4, a lectin that labels all forms of microglia, 3) Anti-rat Glut 5. Protein from the membrane and cytosol fractions of cultured microglial cells was used for Western blotting. Control experiments included no primary antibody as well as peptide absorption experiments. The results show that Glut 5 is expressed in cultured microglial cells of rat. Western and immunocytochemical data show that the protein is found not only in the plasma membrane but also seems to be expressed in the cytosol. This is a novel finding because other glucose transporters (Glut 1-4) are present in the plasma membrane (Glut 1-3) or in cellular vesicles (Glut4). The regulation of this transporter is currently being investigated. Supported by NIMH 38623

## 148.18

AGMATINE IS TRANSPORTED BY A SPECIFIC UPTAKE SYSTEM INTO RAT BRAIN SYNAPTOSOMES. M. Sastre\*, S. Regunathan and D.J. Reis, Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell University Medical College, New York, NY 10021.

Agmatine, a polyamine is synthesized by decarboxylation of arginine in rat brain (Li et al., *Science*, 1994). The facts that agmatine is stored in specific neuronal systems and is released from synaptosomes (Regunathan et al., *Soc. Neurosci. Abstr.*, 1996) suggest it has properties of a novel neurotransmitter/neuromodulator. We investigated whether neurons contain an uptake system for agmatine. The uptake of guanido  $^{14}C$ -agmatine (4.2 μM) was measured ( $P_2$  fractions) for 10 min at 37°C in Krebs buffer in synaptosomes prepared from rat brain. The reaction was stopped by centrifugation, pellets washed extensively and radioactivity counted. The uptake of agmatine was temperature-dependent and saturable only at high concentrations ( $K_m$  of  $18.8 \pm 3.3$  mM and  $V_{max}$  of  $4.78 \pm 0.67$  nmol/mg prot/min). Treatment with ouabain (a  $Na^+/K^+$  ATPase inhibitor) or replacement of extracellular  $Na^+$  did not attenuate the uptake. Agmatine uptake was not inhibited by various amino acids, polyamines or monoamines. Of various ion-channel modulators, only  $Ca^{2+}$  channel blockers inhibited whereas reduction of extracellular  $Ca^{2+}$  increased uptake. Some drugs acting at imidazoline receptors, e.g. idazoxan ( $K_i = 0.24$  mM) and phentolamine ( $K_i = 0.22$  mM) were strong non-competitive inhibitors of uptake. We conclude that synaptosomes can take up and concentrate agmatine by a mechanism differing from common amino acid, polyamine or monoamine transporters and might be mediated/regulated by calcium channel activity.

Effects of Inorganic Phosphate Concentration on ATP Metabolism in Cultured Fetal Rat Cortical Neurons. M. Glinn\*, B. Ni and S. M. Paul, Lilly Research Laboratories, Lilly Corp. Center, Indpls, IN 46285

Our laboratory has recently characterized saturable  $Na^+$ -dependent  $P_i$  import into cultured fetal rat cortical neurons, and shown that a substantial fraction of the  $P_i$  so accumulated is incorporated into ATP. We now report that the ATP content of cortical neurons after incubation with extracellular  $P_i$  ( $[P_i]_e$ ) strongly correlates with the intracellular  $P_i$  level ( $[P_i]_i$ ). Both  $[P_i]_i$  and  $[ATP]$  were dependent upon  $[P_i]_e$  and rose significantly after incubation with  $[P_i]_e \geq 10$  μM and 80 μM respectively. Both increases were maximal above 160 μM  $[P_i]_e$ . In the absence of  $[P_i]_e$ , both  $[ATP]$  and  $[P_i]_i$  declined with time.  $[ATP]$  strongly correlated with  $[P_i]_i$  over time in the presence of  $[P_i]_e$ ; however, in the absence of  $[P_i]_e$ , the correlation decreased in parallel with absolute metabolite levels. The ratio of  $[ATP]:[P_i]_i$  also rose after incubation with  $[P_i]_e$ , indicating a stimulation of ATP biosynthesis which was abolished when glucose was omitted from the uptake medium. Omission of  $Ca^{2+}$ , which inhibits  $P_i$  uptake (Glinn et al., 1995), resulted in a rapid decline in  $[ATP]$  which was not ameliorated by addition of  $[P_i]_e$ ; nevertheless, the correlation between  $[ATP]$  and  $[P_i]_i$  remained strong in the presence of  $[P_i]_e$  independently of the presence of external  $Ca^{2+}$ . These results demonstrate that  $[P_i]_e$  effects a concentration-dependent stimulation of ATP biosynthesis which is not solely a result of increased substrate availability, and that  $[P_i]_i$  correlates with  $[ATP]$  after incubation with  $[P_i]_e$  independently of the presence of extracellular  $Ca^{2+}$ .

## 149.1

MUTATIONAL ANALYSIS OF THE VESICULAR MONOAMINE TRANSPORTERS IDENTIFIES RESIDUES THAT INFLUENCE SUBSTRATE AFFINITY AND DRUG SENSITIVITY. J.P. Finn III, D. Peter, T. Vu, and R.H. Edwards\*, Departments of Neurology and Physiology, UCSF School of Medicine, San Francisco, CA 94143.

Vesicular monoamine transporters (VMATs) are required for the packaging of monoamine neurotransmitters into vesicles. Two VMATs (VMAT1 & VMAT2) have recently been cloned and show a high degree of sequence similarity (62% identity) but substantial differences in apparent substrate affinity and drug sensitivity. VMAT2 has a higher affinity for all amine transmitters, especially histamine, and a greater sensitivity to the inhibitor tetrabenazine (TBZ). Functional chimeras have identified two domains of VMAT2 responsible for these differences, one from transmembrane domain 5 (TMD5) to the beginning of TMD8 and another from the end of TMD9 through TMD12. Mutational analysis of these two domains now identifies specific residues responsible for histamine recognition and TBZ sensitivity. (Supported by NIH)

## 149.3

CHEMICAL MODIFICATION OF DOPAMINE TRANSPORTER (DAT): ROLE OF HISTIDINE RESIDUES IN COCAINE ANALOG BINDING. AP Patel\*, TA Kopajtic, and MJ Kuhar, Food and Drug Administration, Office of Generic Drugs, Rockville, MD 20855, NIDA/IRP, Balto., MD 21224, Yerkes Primate Center, Emory University, Atlanta GA 30322.

The rat DAT gene predicts the presence of 12 histidine residues, 5 of which are in the large second extracellular loop, one each in extracellular loops 4, 5, and 6, two in intracellular loop 4 and two in the C-terminus tail. We tested if these residues were involved in (125-I)RTI-55 binding by treating LLC-PK1 cells that stably express DAT with diethylpyrocarbonate (DEPC), a reagent that specifically modifies histidine residues, prior to binding studies.

DEPC inhibited DAT ligand binding in a time- and concentration-dependent fashion. Half maximal inhibition occurred with 3 mM DEPC at room temperature after a 5 min treatment, and >90% inhibition occurred after 60 min. The inhibition was dependent on pH of the media, and slightly greater inhibition occurred at pH 7.4 than at 6.0. These results suggest that histidine residues are part of the ligand binding domain of DAT. Supported by NIDA/IRP.

## 149.5

DETERMINATION OF NOREPINEPHRINE TRANSPORTER AMINO-ACIDS THAT ARE INVOLVED IN TRICYCLIC ANTIDEPRESSANT BINDING. C. Roubert, M. Hamon\* and B. Giros, INSERM U-288, 91, Bd. de l'Hôpital, 75013, Paris, France.

Transporters for biogenic amines regulate the concentration of neurotransmitters in the synaptic space by a process of rapid and efficient reuptake. Therefore, blockade of the uptake mechanisms will potentiate the nerve transmission, with profound *in vivo* consequences. Widely used in the clinic, tricyclic antidepressants (TA) are specific blockers of the norepinephrine- and serotonin-transporters (NET and 5-HTT), but they have no action at the dopamine transporter (DAT). Taking advantage of this observation, and on the recent molecular cloning of these transporters, we constructed a series of chimeric proteins between NET and DAT, which allowed to localize the binding domain of TA to transmembrane domains (TM) 6 to 8 of the NET (Giros et al., *J. Biol. Chem.*, 1994, 269, 15985-15988). In order to have more precise and relevant informations of the structure-activity relationships of the TA binding sites on NET, we have constructed a set of mutated NET, using a PCR-aided mutagenesis strategy. All the amino-acids contained in TM domains 6 to 8 of NET were systematically mutated toward their counterpart of the DAT. The 10 mutants are: Mut1 (Ser288>Ile, Asn289>Asp, Asn 292>Arg), Mut2 (His296>Ser), Mut3 (Lys303>Cys), Mut4 (Phe316>Cys), Mut5 (Asp336>Thr), Mut6 (His370>Gln, Glu371>Lys, Lys372>Ser, Asn374>Pro), Mut7 (Glu376>Gly, Glu381>Asp, Ala383>Pro), Mut8 (Ser395>Ala, Ser398>Pro, Gly399>Leu), Mut9 (Phe402>Ala) and Mut10 (Ser419>Ala). All these mutants will be transiently expressed in LLC-PK cells, and their pharmacological profile will be compared with those of the native DAT and NET. As a consequence of this study, we should be able to determine which amino-acid in the NET are important for high affinity binding of the TA.

## 149.2

TARGETING OF THE HUMAN VESICULAR MONOAMINE AND ACETYLCHOLINE TRANSPORTERS TO SECRETORY ORGANELLES IN RAT PC-12 CELLS. H. Varoqui and J.D. Erickson\*, Sec. Mol. Neurosci., Lab. Cell Biology, NIMH, Bethesda, MD 20892.

The neuroendocrine PC-12 cell line is useful to study the molecular basis for preferential targeting of the vesicular monoamine transporter isoforms (VMAT1 and VMAT2) and the vesicular acetylcholine transporter (VACHT) to large dense core vesicles (LDCVs) and small synaptic vesicles/synaptic-like microvesicles (SLMVs), respectively (PNAS 93, 3547).

We have generated stable PC-12 cell lines which express the human neuronal VMAT2 isoform (hVMAT2) or human VACHT (hVACHT) and compared their subcellular distribution with that of the endogenous endocrine-specific VMAT1 isoform (rVMAT1) and VACHT (rVACHT). Expression of the human transporters in PC-12 cells could be distinguished from the rat vesicular transporter proteins using species-specific antisera. In addition, the VMAT2 isoform selectively binds <sup>3</sup>H-dihydrotetrabenazine. Homogenates from control and transfected PC-12 cells were fractionated on equilibrium sucrose density gradients and assayed by biochemical methods. In control PC-12 cells, transport of <sup>3</sup>H-5HT was predominantly in a heavy fraction which contained secretogranin, a marker of LDCVs. The binding of <sup>3</sup>H-vesamicol was found in a lighter fraction which contained synaptophysin, a marker of small synaptic vesicles, as well as in intermediate fractions (presumably endosomal). The expression of hVMAT2 and hVACHT paralleled that of the endogenous rVMAT1 and rVACHT with the preferential targeting of the VMAT isoforms to LDCVs and VACHT to SLMVs.

Chimeras between hVMAT2 and hVACHT have been constructed to identify structural domains which direct the trafficking of these proteins in PC-12 cells. The intraluminal glycosylated loop and cytoplasmic tails, poorly conserved between VMATs and VACHT, may contain targeting information. Unique restriction sites have been added to conserved regions of these proteins by site-directed mutagenesis and the chimeras tested for functional activity in a transient expression assay in CV-1 fibroblasts. Stable PC-12 cell lines expressing these chimeras have been made to determine what role the glycosylated loop or the cytoplasmic tails of these proteins play in the preferential targeting of these proteins to LDCVs or SLMVs. (Support: NIMH Intramural Research Program)

## 149.4

DOPAMINE TRANSPORTERS WITH TRANSMEMBRANE DOMAIN PHENYLALANINE MUTATIONS. Z. Lin, R. Revay, T. Kopajtic, & G.R. Uhl\*, Molec. Neurobiol., NIDA IRP & Dept. Neurol. & Neurosci., JHUSM, Baltimore, MD 21224

Dopamine transporter (DAT) recognition of cocaine, cocaine analogs such as carboxyfluorotropane (CFT) and dopamine may involve hydrophobic interactions. Aromatic DAT transmembrane domain (TM) residues could play roles in DAT recognition of catecholamine catechol groups, cocaine phenyl groups, and the halogenated phenyl group of CFT. They could also orient DAT TMs, helping to direct the correct amino acids toward ligand- and substrate-recognizing pockets. To address possible roles played by TM aromatic residues in such interactions, we have constructed DATs with alanine (A) substitutions for more than 10 of the 26 phenylalanines (F) lying in postulated TMs. TM 1 and 2 F-A substitutions reduced dopamine uptake and [<sup>3</sup>H]-CFT binding. In transiently-expressing COS cells, these receptor mutants as well as mutants in TM domains yielded periauclear DAT immunoreactivity indicating abnormal cellular trafficking of even these single amino acid mutants. Mutants in TMs 4, 7, 8, and 11, on the other hand, produced nearly-normal patterns of cellular expression. These studies elucidate contributions of aromatic amino acids to the correct DAT folding necessary for plasma membrane targeting, and may also identify residues essential for cocaine recognition and/or dopamine uptake.

## 149.6

THE FUNCTIONAL EFFECT OF THE SECOND TRANSMEMBRANE LEUCINE ZIPPER MOTIF OF THE DOPAMINE TRANSPORTER.

F. R. Sallee, N. S. Vrindavanam, M. George\*, S. A. Hamamdzc, J. X. Ma, Dept. of Psychiatry, MUSC, Charleston, SC 29425

The dopamine transporter [DAT] is a dopamine reuptake protein found exclusively on dopaminergic neurons. The DAT cDNA has been cloned, expressed and studied. Potential regulatory regions identified in sequence data of the DAT include two leucine zipper motifs, one in the second transmembrane region and the other in the ninth transmembrane region. The third leucine of the second transmembrane region was mutated to an alanine. This mutant form was then cloned into an eukaryotic expression vector pcDNA3 and expressed in COS-7 cells. Expression of the mutant form was confirmed by Northern and Western blots. Radiolabelled substrate uptake and ligand binding assays were performed on these cells and compared to non mutated forms. The mutation had a differential effect on dopamine [DA] uptake and WIN 35,428 binding. It is noted that the mutation changes the functional characteristics of the transporter by making it at least thirty percent more efficient in substrate uptake and decreasing ligand binding by approximately the same margin. The results suggest that the leucine zipper mutation makes the transporter more efficient for substrate transport and decreases WIN 35,428 binding. This suggests that the second transmembrane leucine zipper motif may play a significant role in the functional regulation of the transporter involving substrate translocation and also in ligand binding.

## 149.7

**TYROSINE-533 IS CRITICAL FOR THE FUNCTION OF THE RAT DOPAMINE TRANSPORTER.** S. Kitayama\*, C. Mitsuhashi, G.R. Uhl# and T. Dohi. Dept. of Pharmacology, Hiroshima Univ. Sch. of Dent., Hiroshima 734, Japan, #Mol. Neurobiol. Branch, ARC/NIDA/NIH, Baltimore, MD21224.

Sodium- and chloride-coupled dopamine transporters (DAT) located in the plasma membrane of dopaminergic nerve terminals act to terminate synaptic transmission by reaccumulating released dopamine (DA). We have investigated the role of polar amino acids located in putative transmembrane regions (TM). Using site-directed mutagenesis we have demonstrated that serines and tyrosine located in 11th TM are involved in substrate discrimination [S. Kitayama et al., Synapse 15, 58-62(1993)]. In this region, the rat DAT contains tyrosine-533 while corresponding amino acid in human is phenylalanine. Since transport activities of the human and rat DATs and their sensitivities to various substances including drugs of abuse differ subtly, we have investigated the role of tyrosine-533 of rat DAT in substrate transport and in sensitivity to drugs including cocaine. Tyrosine-533 replacement by alanine caused a marked increase in ability to transport DA and 1-methyl-4-phenylpyridinium (MPP<sup>+</sup>), a Parkinsonism-inducing neurotoxin. Cocaine's potency in inhibiting DA uptake was unchanged. Replacement by phenylalanine yielded small increases in DA and MPP<sup>+</sup> uptake, but increased cocaine's potency in inhibiting DA uptake. Expression levels and targeting to the plasma membrane of the mutant DATs appeared normal, as indicated by unchanged Bmax values for binding [<sup>3</sup>H]CFT, a cocaine analogue, to expressing cells. Tyrosine-533 is critical for the DAT function, and may be implicated in species differences of transporter functions including differential sensitivities to cocaine in human and rat.

**MUTUALLY EXCLUSIVE BINDING DOMAIN FOR WIN 35,428 AND MAZINDOL ON THE CLONED HUMAN DOPAMINE TRANSPORTER.** Q. Xu and M.E.A. Reith. Dept. of Biol., Illinois State Univ., Normal, IL 61790; Dept. of Biomedical and Therapeutic Sci. Univ. of Illinois Coll. Med., Peoria, IL 61656.

It has been suggested that cocaine and mazindol bind to separate sites on the dopamine transporter. The present study addresses this issue by examining the inhibition by mazindol of the binding of the cocaine analog [<sup>3</sup>H]WIN 35,428 ([<sup>3</sup>H]CFT), and the inhibition by CFT of [<sup>3</sup>H]mazindol binding to membrane preparations of the cloned human dopamine transporter expressed in C6 glioma cells. Inhibition curves were constructed at 6 widely spaced radioligand concentrations, enabling the distinction between the nonlinear hyperbolic competition (i.e., negative allosteric) model and the apparent competitive (i.e., mutually exclusive binding) model, as opposed to the common approach using a single inhibitor/radioligand concentration where negative allosteric interactions can masquerade as simple competitive inhibition. Nonlinear computer curve fitting analysis indicated that the data were described equally well by the hyperbolic model with an allosteric constant  $\beta$  of ~100 or greater and the mutually exclusive model ( $F_{1,33-39} < 1.1$ ). Among data sets, there was a strong correlation between equilibrium dissociation constants fitted by the allosteric model and those fitted by the mutually exclusive model ( $r=0.999$ ,  $P < 0.00001$ ), and the average equilibrium dissociation constant was 13 nM for [<sup>3</sup>H]CFT and 7 nM for [<sup>3</sup>H]mazindol. The present results show that when negative allosterism becomes extreme ( $\beta$  of 100 or more), it is indistinguishable from mutually exclusive binding ( $\beta = \infty$ ). Complexities in cocaine/mazindol interaction are more likely to be found at the level of substrate translocation and transporter reorientation than at the level of recognition. Supported by NIDA 08379.

## 149.11

**INDUCED EFFLUX AT THE NOREPINEPHRINE TRANSPORTER BY TYRAMINES AND PHENYLETHYLAMINES** K.S. Danek\*, J.W. Kable, J.B. Justice Jr. Department of Chemistry, Emory University, Atlanta, GA 30322.

Rotating Disk Electrode Voltammetry (RDEV) was utilized to measure the transport of catecholamines and other nonelectroactive substrates in suspensions of LLC-NET cells. Dopamine (DA) (1  $\mu$ M) or dihydroxybenzylamine (DHBA) (1  $\mu$ M) was initially added to a suspension of cells and the clearance of the substrate from solution was monitored by a glassy carbon electrode at an applied potential of +450mV vs. Ag/AgCl. Subsequent addition of a second nonelectroactive substrate induced immediate efflux of DA or DHBA. The data were expressed as the ratio of initial rate of efflux to initial rate of uptake.  $\beta$ -Phenylethylamine (10  $\mu$ M) induced efflux of DA at 45% of the initial rate of DA uptake ( $n=8$ ). However, the D- and L- $\alpha$ -Phenylethylamines produced almost no DA efflux.  $\beta$ -Phenylethylamine induced efflux of DHBA at only 13% of its initial uptake rate ( $n=7$ ). These results indicate that shortening the side chain length reduces transport. D- and L-Amphetamine had DA efflux/uptake ratios of 22% and 45%, respectively ( $n=6$ ). Meta-Tyramine (10  $\mu$ M) induced efflux of DA at 19% of the uptake rate ( $n=4$ ) whereas para-Tyramine was slower (13%) ( $n=3$ ) at this and 1  $\mu$ M and 100  $\mu$ M added concentrations. This suggests that the presence of the hydroxy group on the phenyl ring also causes a decrease in transport. The distance between the amine and phenyl functionalities appears to be more influential than the hydroxy ring substituent in the transport process.

## 149.8

**CHARACTERIZATION OF DRUGS WHICH DISCRIMINATE BETWEEN UPTAKE AND LIGAND BINDING SITES AT THE DOPAMINE TRANSPORTER PROTEIN** Carol W. Tiffany\*, Jennifer L. Olkowski, Kevin L. Tays, Keith M. MacIain, Paul F. Jackson, and Barbara S. Slusher. Guilford Pharmaceuticals, Inc. 6611 Tributary Street, Baltimore, MD 21224

Dopamine uptake and cocaine binding occur at distinct sites on the dopamine transporter protein (DAT), making it possible to design drugs which specifically inhibit cocaine recognition by the DAT while permitting the transporter to maintain its function of dopamine accumulation. To explore this possibility, we analyzed the potencies of several drug classes in inhibiting [<sup>3</sup>H]dopamine uptake ( $K_{i_{uptake}}$ ) and [<sup>3</sup>H]CFT binding ( $K_{i_{bind}}$ ) in CHO cells stably expressing the human DAT. Because others have shown that  $K_{i_{uptake}}/K_{i_{bind}}$  ratios different than unity can result when the assays are conducted under different conditions, we conducted the two assays under identical conditions of time, buffer and temperature. Using these assay parameters, we identified several series of compounds having  $K_{i_{uptake}}/K_{i_{bind}}$  significantly greater than unity including local anesthetics (procaine, dibucaine, tetracaine, dyclonine, oxethazine, dipiperidone, lorcanide), antipsychotic agents (desipramine, imipramine), methylphenidate, and diuretics. Under these assay parameters, GBR 12909 was found to have a  $K_{i_{uptake}}/K_{i_{bind}}$  ratio of two. By chemically dissecting GBR 12909 into distinct regions, we have determined which moieties are important for binding at the cocaine site, and which were important for dopamine uptake inhibition. Several novel derivatives of this compound were found to be more selective than GBR 12909 at binding to the cocaine site when compared to their ability to inhibit dopamine uptake. The utility of compounds with  $K_{i_{uptake}}/K_{i_{bind}}$  ratios greater than unity are currently being explored in animal models of addiction.

## 149.10

**DOPAMINE TRANSPORTER (DAT) LIGANDS: N-SUBSTITUTED PHENYLPROPANES (NSPTs) AS LIGANDS FOR RAPID PET/SPECT STUDIES**, T. Kopajtic\*, U. Scheffel, J. Lever, P. Abraham, K. Parham, W.B. Mathews, F.I. Carroll, and M.J. Kuhar. NIDA/IRP, The Johns Hopkins Univ., Balto MD, Research Triangle Institute, Raleigh-Durham NC, and Yerkes Primate Cent, Emory Univ., Atlanta GA.

Phenylpropans are superb binding ligands for DAT. In this study, we examine NSPT derivatives of RTI-55 as in vivo binding ligands. The methyl group on the nitrogen was substituted with propyl (RTI-310), allyl (RTI-311), butyl (RTI-312) or fluoropropyl (RTI-313) groups. In vitro binding revealed nanomolar potency at DAT with reasonable high potency at 5HT and NE transporters. Maximal in vivo Striat./cerebel. ratios in mice were about 5 for RTI-311, RTI-312 and RTI-313, and about 6.4 for RTI-310. The ratios peaked most rapidly for RTI-311 and RTI-313. Pharmacological studies indicated that these compounds were binding to DATs. These findings suggest that NSPTs may be excellent in vivo binding ligands for rapid PET/SPECT studies. Supported by NIDA/IRP, Guilford Pharm., DA06309, and DA08870.

## 149.12

**SYNTHESIS AND EVALUATION OF METHYLPHENIDATE ANALOGS AS POTENTIAL TREATMENT AGENTS FOR COCAINE ABUSE.** M.M. Schwen\*, S.G. Holtzman, Q. Shi, Z. Liu, and H.M. Deutsch. \*Mercer Univ. Sch. Medicine, Macon, GA 31207; Emory Univ. Sch. Medicine, Atlanta, GA 30322; Sch. Chem. Biochem., GA Tech, Atlanta, GA 30332-0400.

Cocaine (CC) is thought to exert its reinforcing effects by inhibiting carrier-mediated neuronal re-uptake of dopamine (DA). Derivatives of the stimulant drug *threo*-( $\pm$ )-methylphenidate (MP) containing modifications of the piperidine, ester, and/or aromatic ring functions were synthesized as part of a program aimed at developing a site-directed antagonist of CC which will block the binding of CC to the DA transporter, yet spare DA uptake. The potency of the test compounds to inhibit synaptosomal [<sup>3</sup>H]DA uptake and [<sup>3</sup>H]WIN 35,428 binding to the CC receptor were determined using rat striatal tissue. Conversion of the aromatic ring to a naphthyl ring increased potency in both assays. Replacement of the ester function by -CH<sub>2</sub>OH, -CH<sub>2</sub>OCOCH<sub>3</sub>, or -CONH<sub>2</sub> caused parallel 6- to 20-fold losses in potency against both uptake and binding. While all of the N-methyl substituted compounds also underwent absolute losses in potency, the relative potency of N-Me, p-Me MP to inhibit [<sup>3</sup>H]WIN 35,428 binding increased to more than x 7 its potency to inhibit [<sup>3</sup>H]DA uptake.

Most of the MP analogs tested were found to substitute for CC in rat drug discrimination studies, although N-Me,p-Me MP exhibited a unique biphasic dose-response curve. Due largely to the differential effect of N-Me,p-Me MP on binding and uptake, the ED<sub>50</sub>'s of the compounds for CC discrimination correlated better with their potency to block [<sup>3</sup>H]DA uptake than with their potency to block [<sup>3</sup>H]WIN 35,428 binding.

This data suggest that synaptic DA contributes to the discriminatory properties of CC in the rat, and that it is feasible to synthesize a CC antagonist which can block CC binding and spare DA uptake.

Mutagenesis of the dopamine transporter (DAT), the principle site for cocaine reward and euphoria, provides evidence that sites for cocaine and dopamine may overlap but may not be identical. Candidate compounds that might block cocaine, minimally interfere with dopamine transport, and thus provide useful cocaine antagonism were selected based on DAT modeling and tested for potencies in blocking dopamine uptake and inhibiting binding of the cocaine analog carboxyfluorotropane (CFT). Trihexyphenidyl (THP) displayed dopamine transport sparing cocaine antagonism with up to 7-10-fold greater potency in CFT binding inhibition than in uptake blockade. Structure-activity studies reveal THP features important for its differential potencies. Both substitutions for the THP piperidine ring, including replacement with diethylamine, and halogenation of the THP phenyl enhance potency in dopamine uptake inhibition and thus reduce the compounds' selectivities for blocking CFT binding in rat striatal and/or expressed recombinant human DATs. Phenyl substitution for THP's cyclohexyl ring, conversely, exerts modest effects on potency ratios. The prototype dopamine sparing cocaine antagonist, THP highlights the strict structural requirements at several positions likely to be required of a pharmacologically-useful cocaine antagonist.

**INVOLVEMENT OF CATECHOL SUBSTRATE RELATED PROTON TRANSFER REACTIONS IN THE STRIATAL TRANSPORT OF DOPAMINE.** Tamera Stobb<sup>\*</sup>, Martin T. Morocco, and James O. Schenk. Depts. of Chemistry and Biochemistry/Biophysics, Programs in Pharmacology/Toxicology and Neuroscience, Washington State University, Pullman, WA 99164.

Deuterium oxide solvent isotope effects on the transport velocities of a series of catechol derivatives (dopamine, 4-ethylcatechol, and 3-methoxytyramine) were measured by rotating disk electrode voltammetry to determine that a rate limiting step in the dopamine transporter-mediated translocation involved a catechol proton transfer. Acid-base titrimetry with linear potential sweep voltammetry and glass electrode potentiometry was also conducted to assess the relative pK<sub>a</sub> values of catechol- and amine-derived protons on dopamine. The results suggest that the catechol protons of dopamine are at least as strong as the ammonium protons on the side chain and when looked at in the absence of side chain basic functionality may be stronger by about 0.8 pK<sub>a</sub> units than the ammonium form of the ethylamine. These results lend credence to the possibility that catechol proton transfer is an important mechanistic feature of recognition and translocation of dopamine by the striatal transporter for dopamine. (Supported by National Institutes on Drug Abuse (NIDA) grant, DA07384. J.O.S. is also the recipient of a NIDA Research Scientist Development Award, KO2 DA00184.)

## 149.17

**RELATIONSHIPS BETWEEN CATECHOL SUBSTRATE BINDING SITE AND AMPHETAMINE (AMP) AND COCAINE (COC) BINDING SITES IN A KINETIC MODEL OF THE STRIATAL TRANSPORT OF DOPAMINE (DA).** Hollie K. Wayment<sup>\*</sup> and James O. Schenk. Depts of Chem. and Biochem./Biophys., Washington State Univ., Pullman, WA 99164.

Previously this laboratory (*J. Neurochem.* 63: 1683-1692, 1994) described results of kinetic studies designed to test whether a number of inhibitors of DA transport bind at the same site as COC on the striatal DA transporter. Experiments were not conducted to determine how COC or S(+)-AMP binding sites relate to each other and the catechol substrate site mediating translocation of DA by the transporter. Here we address this question by showing that *m*-tyramine (TYR) and S(+)-AMP act as substrate analogs for DA by competitively inhibiting inwardly-directed, striatal DA transport as measured by rotating disk voltammetry. Both compounds caused release of DA from intracellular stores at concentrations  $\geq$  ten-fold larger than those observed to inhibit inwardly-directed transport of DA from the extracellular compartment. In separate studies it was found that S(+)-AMP and *m*-TYR inhibited the transport of DA by competing for a common binding site whereas COC was found to inhibit the transport of DA by binding to a site separate from that of the substrate analogs. However, binding sites of COC and substrate analogs were found to be mutually interactive with an equilibrium constant in the  $\mu$ M range suggesting that the COC binding site on the DA transporter is distinct from that of hydroxyphenethylamines. These results suggest that an antagonist for COC binding may be useful in blocking COC binding while minimizing inhibition of DA transport. This may be accomplished by developing agents which maximize the negative interaction between inhibitor binding sites and minimize the action at the catechol substrate site. However, it leaves unresolved the question of how the action of the AMP's and other drugs of abuse that act as substrate analogs may be antagonized. ## 149.14

**KINETIC ANALYSES OF STRIATAL DOPAMINERGIC TRANSPORT *IN VITRO*: LINKAGE TO METABOLISM AND VESICULAR SEQUESTRATION.** Jennifer J. Parish and James O. Schenk<sup>\*</sup>. Depts. of Biochemistry/Biophysics and Chemistry, Programs in Pharmacology/Toxicology and Neuroscience, Washington State Univ., Pullman, WA 99164.

The membrane dopamine transporter functions to take up dopamine (DA) into the cytosolic compartment of a dopaminergic neuron following neurotransmission. Once inside the cell, dopamine can be packaged into vesicles, remain in the cytoplasm or become metabolized. We suspected that the rate at which dopamine is transported into the cell may be related to these intracellular processes. Specifically, this research focused on the kinetic relationship of dopamine uptake to: 1) transport into synaptic vesicles or 2) metabolism to 3,4-dihydroxyphenylacetic acid (DOPAC) by monoamine oxidase. These data indicate that these two intracellular processes did not affect initial rate measurements ( $<30$  s) in apparent *zero trans* entry experiments, but did affect the kinetics of dopamine reuptake examined during longer time intervals (30s- $<200$ s) when intracellular dopamine was allowed to accumulate in *low to infinite trans* experiments. In the latter experiments removal of the synaptic vesicles, as well as inhibiting vesicular sequestration, caused an increase in the K<sub>m</sub> and V<sub>max</sub> of the transporter. Inhibition of monoamine oxidase caused a decrease in the K<sub>m</sub> and V<sub>max</sub> of the transporter. Thus, under certain conditions these two cytosolic biochemical processes were found to be linked to the kinetic activity of the transporter and may alter the magnitude and timing of chemical neurotransmission. (Supported by National Institutes on Drug Abuse (NIDA) grant, DA07384. J.O.S. is also the recipient of a NIDA Research Scientist Development Award, KO2 DA00184 and J.J.P. was supported by the Howard Hughes Foundation and a Barry Goldwater Fellowship.)

## 149.16

**MEASUREMENTS OF DOPAMINERGIC TRANSPORTER-MEDIATED OUTWARDLY-DIRECTED TRANSPORT OF DOPAMINE (DA) BY PROGRAMMED ROTATION RATE AT THE ROTATING DISK ELECTRODE.** Cynthia Earles<sup>\*</sup> and James O. Schenk. Depts. of Chemistry and Biochemistry/Biophysics, Programs in Pharmacology/Toxicology and Neuroscience, Washington St. Univ., Pullman, WA 99164.

The outward function of the DA transporter in reserpine- and pargyline-treated striatal tissue from the rat *in vitro* was investigated by measuring the current responses for the oxidation of DA as a function of rotation rate at a glassy carbon rotating disk electrode. The release of DA via the transporter and its subsequent electrochemical detection is analogous to a chemical reaction - electron transfer (CE) kinetic model in electroanalytical chemistry. Data was found to fit the CE mechanism and a pseudo-first order rate constant of dopamine release was measured. Amphetamine, a drug known to inhibit DA uptake as a substrate analog, increased the outwardly-directed transporter rate constant in a concentration dependent manner. In contrast, cocaine, a compound not thought to be a substrate analog, had no effect on the outwardly directed transporter rate constant. The results of these experiments suggest that: (a) the apparent outward rate constant of the dopamine transporter can be kinetically resolved and measured and (b) the differing mechanisms of action of two different drugs of abuse can be observed. (Supported by National Institute on Drug Abuse grants, DA07384 and KO 2 DA07384, to J.O.S.)

**A THERMODYNAMIC STUDY OF THE DOPAMINE TRANSPORTER ION-COUPLING MECHANISM.** H. H. Gu<sup>\*</sup> and G. Rudnick. Department of Pharmacology, Yale University School of Medicine, New Haven, CT 06510

We previously described the stable expression of dopamine (DA), norepinephrine, serotonin, and gamma-aminobutyric acid (GABA) transporters (DAT, NET, SERT and GAT, respectively) in LLC-PK<sub>1</sub> cells and determined the ion coupling stoichiometry for NET in plasma membrane vesicles from those cells using SERT and GAT as internal controls. A preparation of plasma membrane vesicles from MDCK cells expressing DAT now allows us to employ the same approach to study the transport mechanism for DAT. DA accumulation into DAT vesicles was stimulated by inward Na<sup>+</sup> and Cl<sup>-</sup> gradients and required external Na<sup>+</sup> and Cl<sup>-</sup>, suggesting that these ions are co-transported with DA. An outward K<sup>+</sup> gradient did not stimulate transport, and the complete removal of K<sup>+</sup> from both sides of the vesicle membrane had little effect on DA accumulation, suggesting that K<sup>+</sup> is not involved in DAT-mediated transport. Addition of valinomycin to vesicles with an outward K<sup>+</sup> gradient resulted in a 5 to 6 fold increase of substrate accumulation into DAT vesicles, compared to a 1 to 2 fold increase in GAT and NET vesicles. This result suggests that DAT transport is electrogenic and that at least two charges are moved across the membrane in each transport cycle (GAT and NET each transports a single charge per cycle). The Na<sup>+</sup> gradient dependency of DAT was more similar to that of GAT than to that of NET, suggesting a Na<sup>+</sup>:DA ratio of two. In addition, the K<sub>m</sub> for DAT transport was not significantly affected by changing external pH from 6.5 to 7.5 (increasing the neutral form of DA 10-fold), suggesting that cationic DA was the predominant substrate. Therefore, we conclude that DAT co-transporters one DA<sup>+</sup> molecule with one Cl<sup>-</sup> and at least two Na<sup>+</sup> ions, that K<sup>+</sup> is not involved, and that two (or more) net positive charges are transported with each molecule of DA.

This work is supported by a grant from NIDA.

## 150.1

**TRANSLLOCATION OF  $\gamma$ -SUBTYPE OF PROTEIN KINASE C -DIRECT VISUALIZATION IN LIVING CELLS USING FUSION PROTEIN WITH GREEN FLUORESCENT PROTEIN.** N.Sakai\*, S. Sumioka, C. Hasegawa, K. Sasaki, H. Obata and N. Saito. Lab. of Mol. Pharmacol., Biosignal Res. Ctr., Kobe Univ., Kobe 657, Japan. The protein kinase C- $\gamma$  (PKC- $\gamma$ ), a neuron specific subtype of PKC, is known to be translocated from cytosol to membrane by various stimulus including phorbol ester and  $\text{Ca}^{2+}$ . The green fluorescent protein (GFP), isolated from jellyfish *Aequorea victoria*, have fluorescent activity without additional substrates and co-factors. To directly observe the translocation of PKC- $\gamma$  in living cells, a cDNA, encoding a GFP sequence following the 3' end of the PKC- $\gamma$ , was constructed using PCR, subcloned into expression plasmids and PKC- $\gamma$ -GFP fusion protein was expressed in various cell lines. The significant fluorescence of PKC- $\gamma$ -GFP fusion protein was observed in the cytosol of cells using confocal laser scanning fluorescent microscope. The treatment of 5  $\mu\text{M}$  TPA produced the translocation of PKC- $\gamma$ -GFP fusion protein to plasma membrane within 30 min. A23187, a  $\text{Ca}^{2+}$  ionophore, first translocated PKC- $\gamma$ -GFP to membrane more rapidly than TPA and finally patchy signals were observed in both membrane and perikarya. These findings revealed the diverse mechanism of the translocation of PKC in the difference of activators.

## 150.3

**EFFECTS OF ESTRADIOL ON PROTEIN KINASE C ACTIVITY IN FEMALE RAT BRAIN.** M. A. Ansonoff\* and A. M. Etgen. Depts. Neurosci. & Psychiat., Albert Einstein Coll. Med., Bronx, NY 10461. Previously we demonstrated that  $\alpha_{1B}$ -adrenergic receptor mRNA is elevated in hypothalamic, but not cortical tissue of ovariectomized, estrogen-treated female rats (J. Neuroendocrinol., in press). Protein kinase C (PKC) has been shown to affect  $\alpha_{1B}$ -adrenergic receptor mRNA levels (JBC 268:3610-3615, 1993) and to be estrogen-regulated in some estrogen-sensitive tissues (Lab. Inv. 68:472-480, 1993). Because PKC may be important in regulation of the  $\alpha_{1B}$ -adrenergic receptor mRNA, PKC activity was measured in hypothalamic and cortical extracts. This was accomplished by quantifying  $^{32}\text{P}$  incorporation into a synthetic peptide substrate containing the optimal consensus sequence for PKC-mediated phosphorylation. PKC activity increased approximately two-fold in the hypothalamus of ovariectomized female rats treated with 2  $\mu\text{g}$  of estradiol benzoate (EB) at 24 and 48 hr prior to sacrifice in comparison to ovariectomized female rats treated with peanut oil ( $n = 5$ ,  $p < 0.01$ ). In cortical tissue, PKC activity was much greater than in hypothalamus, and EB treatment did not affect PKC activity ( $n = 5$ ,  $p > 0.10$ ). Estrogen enhancement of PKC activity may thus influence  $\alpha_{1B}$ -adrenergic receptor mRNA levels in female rat hypothalamus. Future studies will determine if this enhancement of PKC activity is due to an increase in the amount of PKC enzyme or an enhancement of enzyme activity. Furthermore, it must be determined if estrogen's enhancement of PKC activity is isoform-specific. Supported by grants MH 41414, RSDA MH 00636 and T32 AG00194

**BIOCHEMICAL AND BEHAVIORAL CORRELATES OF CHRONIC CONSUMPTION OF LOW DOSES ETHANOL: FOCUS ON PROTEIN KINASE C ACTIVITIES.** A. Pascale, M. Persichella\*, F. Battaini\*, V. Cuomo\* and S. Govoni\*. Inst. of Pharmacol. Sci., Univ. of Milano; \*Inst. of Pharmacology, Univ. of Bari; \*Dept. Exptl. Med. and Biochem. Sci., Univ. of Roma Tor Vergata; #Inst. of Pharmacology, Univ. of Pavia, Italy. Several studies have been focused on detecting biochemical and physiological alterations produced by ethanol. Multiple receptor functions and signalling pathways are modulated by this substance, among these, the PLC-mediated hydrolysis of phosphoinositides seems to be particularly sensitive to ethanol. Along this line the related protein kinase C (PKC) system has been reported to be affected at brain level by chronic ethanol intake. We have previously demonstrated that chronic low doses ethanol (3% v/v in drinking water for two months) does not induce tolerance or dependence. The lack of toxicity is indicated by no changes in body weight and other vital parameters (bilirubin,  $\gamma$ -glutamyl transferase, serum transaminases). In addition treated rats perform better than controls in a two-way avoidance task [Govoni et al., *Alcohol*, 11: 241-246, 1994]. Few data are available on the neurobehavioral and neurochemical consequences of chronic consumption of low doses of ethanol. The aim of the present study was to explore the effect of this treatment on both calcium-dependent and -independent PKC activities in rat cortex and hippocampus. We also investigated whether ultrasonic calls (UCs), a significant parameter for evaluating emotional and motivational states of the animal, correlate with PKC activities. The results indicate that ethanol exposure produces a reduced vocalization, an effect reminiscent of that of benzodiazepines, and a decrease in PKC activities both in the cortex and in the hippocampus. In addition, only at cortical level, in ethanol-treated rats we observed a correlation between calcium-dependent activity and UCs. Our data suggest that low doses ethanol affect PKC activity and that this enzyme may be an important target of the ethanol action in modulating emotional and motivational behaviours. Research in part supported by a grant from the Nutrition Foundation of Italy.

## 150.2

**THE TARGET OF PKC INDUCED SUPPRESSION OF ADENOSINE INHIBITION OF GLUTAMATE EXOCYTOSIS FROM SYNAPTOSOMES IS DOWNSTREAM OF THE A1 RECEPTOR AND G-PROTEIN COUPLING.** M. McLaughlin, D.C. Budd and D.G. Nicholls\*. Neurosciences Institute, Dept. of Pharmacology, Ninewells Medical School, Dundee, DD1 9SY, UK. Glutamate exocytosis from isolated cortical terminals from rat brain (synaptosomes) can be inhibited by the activation of the adenosine A1 receptor. The inhibitory action is mediated by decreasing the influx of  $\text{Ca}^{2+}$  after clamped depolarization with high  $\text{K}^{+}$ , suggesting a  $\text{Ca}^{2+}$  channel locus. Adenosine inhibition can be suppressed by activation of PKC with phorbol esters and also with the physiological activator diacylglycerol produced by metabotropic receptor activation. This study explored the mechanism(s) by which suppression of the inhibitory pathway by PKC is/are achieved. Synaptosomes were prepared and aliquots used to confirm phorbol dibutyrate (PDBu) induced suppression of adenosine A1 inhibition of glutamate exocytosis. The remaining synaptosomes were incubated with vehicle (control) or PDBu and the membranes and cytosol fractionated. Western blot analysis of various PKC isoforms demonstrated a positive translocation of the PKC(s) from the cytosol to the membrane in PDBu treated samples. PDBu treatment however failed to alter basal or A1 agonist induced stimulation of GTPgammaS binding and GTPase activity associated with heterotrimeric G-proteins. These findings suggest that the A1 receptor coupling to the G-protein and the G-protein activation/deactivation cycle are not compromised by kinase action. Thus, the locus of PKC action appears to be downstream of heterotrimeric G-proteins. (This work was supported by the MRC and an EU network grant)

## 150.4

**EFFECT OF CHRONIC TREATMENT WITH DEXAMETHASONE ON [ $^3\text{H}$ ]PHORBOL DIBUTYRATE BINDING AND EXPRESSION OF PROTEIN KINASE C ISOZYMES IN THE RAT CORTEX.** Y. Dwivedi\* and G.N. Pandey. Psychiatric Institute, Department of Psychiatry, University of Illinois at Chicago, Chicago, IL 60612. The mechanisms of the upregulation of serotonin (5HT) $_{2A}$  receptors in the postmortem brain of suicide victims and in platelets of depressed patients are unclear. Since dysregulation of functions of the hypothalamic-pituitary-adrenal (HPA) axis has been observed in depressed and/or suicidal patients, it is possible that increased levels of cortisol may cause the upregulation of 5HT $_{2A}$  receptors. Another possible mechanism may be increased phosphorylation of 5HT $_{2A}$  receptors by protein kinase C (PKC). In an earlier study, we observed that corticosterone or dexamethasone (DEX) treatment caused a significant increase in 5HT $_{2A}$  receptors in the rat brain. To further investigate the mechanism of upregulation of 5HT $_{2A}$  receptors, we studied the effects of DEX on [ $^3\text{H}$ ]PDBU binding and the expression of PKC isozymes ( $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ , and  $\epsilon$ ) in membranar and cytosolic fractions of the rat cortex. Male Sprague-Dawley rats were treated with DEX (1.5 mg/kg) or vehicle subcutaneously for 10 days. The animals were sacrificed on the 10th day of injection. [ $^3\text{H}$ ]PDBU binding was determined by the radioligand binding technique, whereas expression of PKC isozymes was determined by the Western blot technique. We observed that DEX treatment caused a significant increase in  $B_{\text{max}}$  of [ $^3\text{H}$ ]PDBU binding to cytosolic PKC but had no effect on membranar PKC. Immunolabeling results showed that the increase in cytosolic PKC is isoform specific. DEX treatment caused a significant increase in levels of only the  $\gamma$  and the  $\epsilon$  isoform in the cytosolic fraction but had no effect on the expression of PKC isozymes in the membranar fraction. These results thus suggest that PKC is involved in the mechanism of upregulation of 5HT $_{2A}$  receptors and plays an important role in depression and suicidal behavior.

## 150.6

**PB $^{2+}$  BOTH ACTIVATES AND INHIBITS PROTEIN KINASE C PURIFIED FROM RAT BRAIN AND IN NEURONAL CELL CULTURE.** W.R. Mundy\*, T.J. Shafer and T.R. Ward. Neurotoxicology Division, NHEERL, U.S. EPA, RTP, NC 27711. Environmental exposure to the toxic metal Pb $^{2+}$  has been identified as a major hazard to the health of children in industrialized nations. Although Pb $^{2+}$  is a well-recognized neurotoxin which can produce neurobehavioral deficits at blood levels as low as 10  $\mu\text{g}/\text{dl}$  ( $0.5 \times 10^{-4}$  M), the molecular target(s) is unclear. Identifying these targets is essential for the development of biologically based dose-response (BBDR) models. Several lines of evidence suggest that Pb $^{2+}$  neurotoxicity may result from interference with intracellular signaling systems which depend on  $\text{Ca}^{2+}$ . Pb $^{2+}$  has been reported to either activate or inhibit the calcium- and phospholipid-dependent enzyme protein kinase C (PKC) in a number of different systems. We examined the effects of a wide range of Pb $^{2+}$  concentrations on highly purified (>90%) PKC from rat brain. Free Pb $^{2+}$  concentrations of  $10^{-11}$  to  $10^{-6}$  M activated PKC ( $K_m = 1.7 \times 10^{-12}$  M, maximal activity = 295 nmol/mg protein/min) as compared to activation by free  $\text{Ca}^{2+}$  concentrations of  $10^{-4}$  to  $10^{-4}$  M ( $K_m = 6.3 \times 10^{-7}$  M, maximal activity = 475 nmol/mg protein/min). Concentrations of free Pb $^{2+}$  greater than  $10^{-6}$  M inhibited PKC activity.  $\text{Ca}^{2+}$ -stimulated ( $5 \times 10^{-4}$  M) PKC activity was also inhibited by Pb $^{2+}$  at concentrations of  $10^{-7}$  to  $10^{-4}$  M ( $\text{IC}_{50} = 1.5 \times 10^{-6}$  M). In rat primary cortical cell cultures the binding of [ $^3\text{H}$ ]phorbol ester was used to estimate the translocation of PKC from the cytosol to the membrane *in situ*. Pb $^{2+}$  (1-10  $\mu\text{M}$  total concentration) stimulated phorbol ester binding in both the absence and presence of  $\text{Ca}^{2+}$  in the media. When phorbol ester binding was stimulated by ionomycin, Pb $^{2+}$  inhibited this binding with an  $\text{IC}_{50}$  of 1.3  $\mu\text{M}$ . These results suggest that low concentrations of Pb $^{2+}$  can interfere with PKC activity both *in vitro* and in cell culture.

## 150.7

THE PROTEIN KINASE C PATHWAY IS ENDOGENOUSLY ACTIVE IN EXPIRATORY NEURONS OF CATS A. Haji, O. Pierrefiche, P.M. Lalley\* and D.W. Richter II. Inst. Physiol., Univ. Göttingen, Humboldtallee 23, 37073 Göttingen, FRG

We studied the functional role of intracellular signal pathways involving protein kinase C (PKC) in the process of respiratory pattern generation in expiratory neurons of anesthetized, paralyzed and vagotomized cats. Measurements in current- and voltage-clamp were performed with fine-tipped electrodes while the specific PKC blocker (NPC 15-437) was intracellularly injected before and after extracellular application of TEA. Intracellular blockade of PKC reversibly hyperpolarized expiratory neurons throughout the respiratory cycle, reduced synaptic drive potentials and spontaneous action potential discharge. Neuronal input resistance was decreased during inspiration and increased during expiration. Blockade of PKC decreased spontaneous excitatory synaptic drive currents. This effect became more prominent after  $K^+$  conductances were blocked by TEA. Under such conditions, injection of NPC 15-437 evoked a decrease of both excitatory and inhibitory synaptic drive currents. Stimulation induced post-synaptic currents and potentials were decreased after blockade of PKC, with or without TEA application.

These results demonstrate that PKC is endogenously active and acts throughout the respiratory rhythm by modulating three different currents: 1) it upregulates  $Ca^{2+}$ -mediated inhibitory synaptic currents and 2) it upregulates excitatory synaptic currents, 3) it downregulates persistent  $K^+$  currents.

## 150.9

SUBSTRATE SPECIFICITY AND GENOMIC STRUCTURE OF CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE I (CaM KINASE I) M.R. Picciotto\*, J. Elliott, A.J. Czernik and A. C. Nairn. Dept. of Psychiatry & Peptide Synthesis Facility, Yale Univ. Sch. of Med., New Haven, CT 06510. & Lab. of Mol. and Cell. Neurosci., Rockefeller Univ., N.Y., NY 10021.

CaM kinase I was originally identified in rat brain based on its ability to phosphorylate site 1 of synapsin I. In order to define a consensus phosphorylation site for the enzyme we have used purified bovine brain CaM kinase I, bacterially produced recombinant CaM kinase I and cAMP-dependent protein kinase (PKA) to phosphorylate a number of peptide substrate analogs based on the phosphorylation site of synapsin I. We have also used site directed mutagenesis to identify a residue in CaM kinase I that is important for substrate interaction and overall enzyme activity. The CaM kinase I cDNA was used to clone the genomic DNA encoding the enzyme in order to identify alternatively spliced exons that might encode CaM kinase I variants. The intron-exon boundaries and overall genomic structure were determined. Preliminary experiments are underway to define the CaM kinase I promoter, with the aim of elucidating the regulatory elements that control CaM kinase I expression in neurons as well as in other expressing tissues. These experiments will enhance our understanding of the mechanisms underlying the interaction of CaM kinase I and its substrates, and could contribute to the identification of new substrates and regulatory mechanisms for the enzyme.

Supported by Yale University and Rockefeller University funds.

## 150.11

ASSOCIATION OF SRC-FAMILY TYROSINE KINASE LYN WITH GLANGLIOSIDE GD3 IN RAT BRAIN. K. Kasahara\*, Y. Watanabe, T. Yamamoto\*, Y. Sanai.

Department of Biochemical Cell Research, Tokyo Metropolitan Institute of Medical Science, Bunkyo-ku, Tokyo, Japan, #Institute of Medical Science University of Tokyo, Japan

Gangliosides are membrane-bound glycosphingolipids containing sialic acids that are found in high concentrations on the central nervous system. The carbohydrate moieties of gangliosides undergo profound changes during development and differentiation, suggesting that they may play fundamental roles in these processes. To clarify the function of gangliosides, we have undertaken identification of ganglioside-specific binding proteins.

In the present study, we demonstrated that monoclonal antibody (mAb) to ganglioside GD3 coimmunoprecipitated src-related protein tyrosine kinase Lyn in rat brains. *In vitro* kinase assay of the mAb immunoprecipitates there were phosphorylated proteins of 53/56 kDa. The phosphoamino-acid residue of p53/56 was tyrosine. p53/56 were identified as Lyn by reimmunoprecipitation with anti-Lyn antibody. The mAb also coprecipitated Lyn in rat cultured cerebellar neurons. This identification was confirmed using the cDNA expression system in CHO cells which express sole ganglioside GM3, the enzymatic substrate of ganglioside GD3 synthase. Cotransfection with GD3 synthase and lyn expression plasmids resulted in the association demonstrated by coimmunoprecipitation. These ganglioside GD3-Lyn tyrosine kinase interactions could be the mechanism by which ganglioside modulate cellular functions.

## 150.8

DYNAMIC REGULATION OF CALMODULIN AVAILABILITY BY CAM-KINASE II: COMPUTER SIMULATION ANALYSIS.

M. D. Mauk\* and M. N. Waxham. Department of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77030

Given the numerous and often opposing cellular processes regulated by calcium/calmodulin (CaM), how are these processes activated selectively for different calcium influxes? Until recently it was generally held that activation of different CaM-dependent enzymes is controlled simply by the level of calcium influx. However, evidence suggests that i) the diffusion of CaM is severely restricted, ii) autophosphorylation of calcium/CaM-dependent protein kinase (CaMK-II) dramatically decreases the off-rate of CaM, effectively "trapping" CaM, and iii) CaMK-II is abundant in neurons. These observations suggest that CaM-trapping by CaMK-II can regulate the local availability of CaM for binding to other enzymes in a complex and time-dependent manner. This may favor the selective activation of particular CaM-dependent enzymes depending on the pattern, not just the level, of calcium influx. We have used simulations of CaMK-II to test these and related hypotheses. Results suggest that the frequency and magnitude of calcium influx can influence the activation of CaM-dependent enzymes competing with CaMK-II for a limited supply of CaM. Results also suggest that the ability of different enzymes to compete with CaMK-II for CaM is extremely sensitive to the on- and off- rates that comprise the enzymes' affinities for CaM, even when the affinities are identical. Thus, CaMK-II regulation of CaM availability may allow selective activation of other CaM-dependent enzymes depending on the specific calcium dynamics.

INHIBITION OF CaM KINASE CASCADE BY cAMP DEPENDENT PROTEIN KINASE Gary A. Wayman, Hiroshi Tokumitsu and Thomas R. Soderling\*

Vollum Institute, Oregon Health Sciences University, Portland, Oregon 97201

$Ca^{2+}$ /Calmodulin dependent protein kinase IV (CaM KIV), and CaM kinase kinase (CaM KK) are neurally expressed members of the CaM kinase family that are involved in transcriptional regulation. Phosphorylation of CaM KIV by CaM KK increases the total as well as the  $Ca^{2+}$ /CaM independent activity of the enzyme. In this study we examined the regulation of the CaM kinase cascade by cAMP dependent protein kinase (PKA). Here we report that phosphorylation of CaM KK by PKA *in vitro* as well as *in vivo* inhibits CaM KK and thereby inhibits activation of CaM KIV. PKA phosphorylates purified rat brain CaM KK on multiple residues, but does not phosphorylate CaM KIV *in vitro*.

Phosphorylation of CaM KK inhibits the ability of CaM KK to activate CaM KIV *in vitro*. Activators of PKA also inhibit CaM KK activity *in vivo*. CaM KK expressed in COS-7 cells is inhibited by both forskolin as well as Sp-5,6-DCI-cBIMPS, an analog of cAMP. Likewise, the endogenous CaM KK in both PC12 cells and primary hippocampal neurons is also inhibited by activation of PKA. The inhibition of CaM KK *in vivo* is blocked by H89, further supporting a role for PKA in the inhibition. Omission of protein phosphatase inhibitors from the homogenization buffer reverses forskolin induced inhibition of CaM KK by PKA in PC12 cells. These data suggest that CaM KK/CaM KIV signaling cascade may be inhibited by the activation of the cAMP/PKA signaling pathway *in vivo*. This crosstalk may allow neurons to fine tune transcriptional activity depending on the pairing or sequence of signals received. (supported: NIH GM41292)

## 150.12

REGULATION OF CYCLIC AMP-DEPENDENT PROTEIN KINASE IN CATH.A AND SH-SY5Y CELL LINES. V.A. Boundy\*, J.S. Chen, and E.J. Nestler. Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Increasing evidence indicates a role for chronic morphine-induced upregulation of the cAMP pathway in mediating aspects of opiate tolerance, dependence, and withdrawal in locus coeruleus neurons. This upregulation is manifested by increases in adenylyl cyclase levels, cAMP-dependent protein kinase (PKA) activity, and phosphorylation of specific protein substrates. *In vivo*, the alterations of PKA activity are associated with increases in immunoreactivity of the catalytic subunit (Cα/β) and regulatory subunit RII (α/β) as well as in the message levels of catalytic subunit Cβ. In an effort to understand the mechanisms underlying the regulation of PKA in the locus coeruleus, the effects of perturbations of the cAMP pathway on PKA were examined in the LC-like Cath.a cell line and the human neuroblastoma SH-SY5Y cell line. Exposure of Cath.a cells to forskolin (5μM) resulted in a decrease in the immunoreactivity of Cα/β. This downregulation occurred in a time-dependent fashion with a 25% decrease seen after 2 hours and a recovery to near basal levels by 48 hours. Exposure of SH-SY5Y cells to forskolin also resulted in a time-dependent decrease in the immunoreactivity of Cα/β with a maximal decrease of 50-60% seen by 12-18 hours and maintained up to at least 48 hours. Following differentiation of SH-SY5Y cells to a more neuronal state with retinoic acid (10μM), exposure to forskolin resulted in a biphasic curve of Cα/β immunoreactivity similar to that seen for Cath.a cells. The 40% decrease in Cα/β immunoreactivity detected at 4-6 hours was not attenuated by pretreatment of the SH-SY5Y cells with the protein synthesis inhibitor, cycloheximide (100μg/ml, 1 hour), suggesting that new protein synthesis is not required for the observed downregulation. We are currently investigating the effects of perturbations of the cAMP pathway on the regulatory subunit proteins, RI and RII, as well as on the message levels of the PKA subunits. (USPHS DA 07290 and 08227.)

## 150.13

CHRONIC HYPOXIA DECREASES cAMP-DEPENDENT PROTEIN KINASE ACTIVITY IN PC12 CELLS. D. Beitner-Johnson\* and D. Millhorn. Department of Cellular and Molecular Physiology, University of Cincinnati, Cincinnati, OH 45267-0576.

The intracellular signaling pathways involved in hypoxia are poorly understood, and very little is known about the effects of long-term hypoxia. Acute hypoxia is known to increase synthesis and release of dopamine. PC12 cells are oxygen-sensitive catecholaminergic cells that express dopamine D<sub>1</sub> and D<sub>2</sub> receptors and thereby provide a useful system to study the effects of oxygen deprivation. To evaluate the effect of long-term hypoxia on intracellular signaling mechanisms, PC12 cells were exposed to 5% oxygen for various times between 0 and 48 hours. Cells were then harvested and assayed for cAMP-dependent protein kinase activity. Chronic (24 and 48 hours), but not acute hypoxia decreased cAMP-dependent protein kinase activity by ~30% from control levels. Both basal and 8-bromo-cAMP stimulated cAMP-dependent protein kinase activity were decreased by chronic hypoxia, suggesting that prolonged oxygen deprivation down-regulates the total amount of the enzyme. This effect was not due to hypoxia-induced alterations in cell number or cell viability. These data suggest that down-regulation of the cAMP signaling pathway is one mechanism by which PC12 cells adapt to hypoxia. Further studies are currently underway to evaluate the role of dopamine receptor function in hypoxia. This work was supported by HL33831 and HD28948.

## 151.1

ALTERATION IN CALCIUM/CALMODULIN-SENSITIVE ADENYLYL CYCLASE ACTIVITY IN THE CEREBRAL CORTEX OF STROKE-PRONE SPONTANEOUSLY HYPERTENSIVE RATS. S. Hattai<sup>1</sup>, H. Togashi<sup>2</sup>, H. Ozawa<sup>3</sup>, H. Saito<sup>2</sup>, and H. Ohshika<sup>1</sup>. Depts. of <sup>1</sup>Pharmacology and <sup>2</sup>Neuropsychiatry, School of Medicine, Sapporo Medical University, <sup>3</sup>First Dept. of Pharmacology, Hokkaido University School of Medicine, Sapporo 060, Japan

Stroke-prone spontaneously hypertensive rats (SHRSP) are a genetic animal model of severe hypertension with cardiovascular and cerebrovascular complications. Recently, we have reported that SHRSP exhibited behavioral impairment in the passive avoidance task and dysfunction in the hippocampal cholinergic system, suggesting that SHRSP is a useful animal model for the study of vascular dementia. Several recent studies have suggested that Ca<sup>2+</sup>/calmodulin-sensitive type I adenylyl cyclase (AC) may be important for neuroplasticity and spatial memory. In the present study, the function of adenylyl cyclase was examined in the cerebral cortex of SHRSP. Male SHRSP (25-week-old) was used for the experiment, and age-matched Wistar-Kyoto rats (WKY) were used as genetic control. GppNHP-stimulated and forskolin-stimulated AC activities were not different between WKY and SHRSP. There were no significant differences in the amount and function of Gs, estimated by immunoblotting and guanine nucleotide photoaffinity labeling, respectively, between WKY and SHRSP. However, Ca<sup>2+</sup>/calmodulin-sensitive AC activity was slightly but significantly decreased in SHRSP compared with that in WKY. These results suggest the possibility that the function of Ca<sup>2+</sup>/calmodulin-sensitive, presumably type I, AC was impaired in the brain of SHRSP. (Supported by a grant from the Hokkaido Government, Japan.)

## 151.3

THE EFFECTS OF CTOP AND NALTRINDOLE ON DYNORPHIN A<sub>1-17</sub>-INDUCED INHIBITION OF BASAL AND FORSKOLIN STIMULATED ADENYLYL CYCLASE ACTIVITY IN RAT CAUDATE PUTAMEN. L.H. Clave, A. Ho, and M.J. Kreek\*. The Rockefeller University, New York, NY 10021.

Adenylyl cyclase activity is used as one functional measure of opioid receptor-mediated signal transduction. The naturally occurring opioid peptide, Dynorphin A<sub>1-17</sub>, is the primary endogenous ligand of the  $\kappa$  opioid receptor. Previous studies using the selective  $\kappa$  opioid receptor antagonist, nor-BNI, have suggested that dynorphin's effects are not solely  $\kappa$  receptor-mediated. The aim of the present study was to determine the extent to which Dyn A<sub>1-17</sub> exerts its  $\kappa$ -mediated effects on cyclase activity in rat caudate putamen, an area known to contain a heterogeneous population of opioid receptors. Adenylyl cyclase activity was determined by measuring cAMP production in membranes prepared from caudate putamen of naive male Fischer 344 rats using a cAMP radioligand binding assay. Dyn A<sub>1-17</sub> (10<sup>-9</sup> - 10<sup>-5</sup> M) produced a significant dose-dependent inhibition of both basal and forskolin-stimulated (10<sup>-5</sup> M) adenylyl cyclase activity. Although the forskolin-stimulated values were approximately 9-10 fold higher than basal values as was expected, the percentage changes which were negligible in this assay were similar. The ability of CTOP (10<sup>-8</sup> - 10<sup>-5</sup> M) and naltrindole (10<sup>-8</sup> - 10<sup>-5</sup> M), selective  $\mu$  and  $\delta$  antagonists, respectively, to attenuate Dyn A<sub>1-17</sub>-induced inhibition of cyclase was determined. Preliminary findings show that both CTOP (10<sup>-5</sup> M) and naltrindole (10<sup>-5</sup> M) are able to block, in part, the inhibition of cyclase caused by Dyn A<sub>1-17</sub>. ## 151.2

OPIATE-INDUCED ADENYLYL CYCLASE SUPERACTIVATION: STUDY IN TRANSFECTED CELLS. I. Nevo, Z. Vogel\*, R. Levy, D. Sava, M. Bayewitch and T. Avidor-Reiss. Dept. of Neurobiology, Weizmann Institute of Science, Rehovot 76100, Israel.

Acute stimulation of opiate receptors inhibits adenylyl cyclase (AC) and reduces cAMP levels in the cell. Chronic activation of opiate receptors leads to a progressive increase in cAMP. This phenomenon, particularly manifest upon withdrawal of the opiate agonists, is referred to as AC superactivation and was previously observed in several neuronal cultures. We reconstituted the ability of opiates to induce AC superactivation using CHO and COS-7 cells transfected with opiate receptors. Such cells can serve as a useful model for studying the signal transduction of opiates, especially the modulation of AC activity. We found that AC superactivation is due to prolonged activation of the receptor and is gradually reversed by exposure to antagonist. AC superactivation seems to be the primary mechanism for the apparent morphine tolerance in chronically treated cells. AC superactivation is mediated via pertussis toxin-sensitive G proteins (G<sub>i/o</sub>). G $\beta\gamma$  dimers, which dissociate from G $\alpha$  following GTP-binding protein activation, have an important role in this process. AC superactivation can be obtained following chronic stimulation by several other inhibitory agonists, demonstrating the generality of the phenomenon. We are currently investigating the AC isoforms involved in the process. Supported by NIDA (DA6265), Israeli Ministry of Health, and Forschheimer Center for Molecular Genetics.

## 151.4

$\alpha_2A/D$ -ADRENOCEPTOR COUPLING TO ADENYLYL CYCLASE II, III AND IV: ENZYME TYPE-SPECIFIC MODIFICATION BY PROTEIN KINASE C ACTIVATION. A. Mariamaki\* and S.M. Lanier. Depts of Pharmacol., Univ. of Turku, Finland and MUSC, Charleston, SC USA.

$\alpha_2A/D$ -adrenoceptor ( $\alpha_2$ -AR) coupling to adenylyl cyclase (AC) was examined in DDT1-MF2 smooth muscle cells (stably transfected with  $\alpha_2$ -AR) before and after ectopic expression of AC types II, III or IV. AC expression was determined by mRNA analysis and functionality. Relative to control cells, basal activity was increased in only ACII transfectants (5-fold), whereas maximal enzyme activity (FSK/GTP $\gamma$ S/Mn<sup>2+</sup>) was increased by 7 (ACII), 4 (ACIII) and 2 (ACIV) fold. In intact cells, FSK stimulation was augmented 4 (ACII), 3 (ACIII) and 3 (ACIV) fold versus control, whereas isoproterenol-induced (100 $\mu$ M) increase in cellular cAMP levels were minimally altered. However, in ACII and ACIV transfectants the effect of  $\alpha_2$ -AR activation was biphasic, inhibiting isoproterenol stimulation at lower  $\alpha_2$ -AR agonist concentrations. The stimulatory and inhibitory effects of  $\alpha_2$ -AR activation were blocked by pertussis toxin and the overall effect likely represents a balance between inhibitory input (G $\alpha_i$ ) and enzyme stimulation by G $\beta\gamma$  synergizing with G $\alpha_s$ . Protein kinase C (PKC) activation did not modify  $\alpha_2$ -AR coupling to AC III. However, PKC activation identified distinct properties of ACII and ACIV relative to their regulation by Gi/Go-coupled receptors. PKC activation blocked  $\alpha_2$ -AR inhibition of isoproterenol effects in ACII transfectants, but not ACIV transfectants. Although types II and IV share several regulatory properties, these data suggest that PKC phosphorylation differentially affects stimulatory and inhibitory input to these two enzymes. (Supported by NS 242821/CTR 2235).

## 151.5

PERFUSION OF NEOCORTICAL SLICES WITH PROGESTERONE AFFECTS CYCLIC AMP AND GABA<sub>B</sub> RECEPTORS. R. H. Thalmann\*, M. I. Al-Dahan and M. H. Jalilian Tehrani, Baylor Coll. of Med., Houston, TX 77030.

Baclofen inhibition of cyclic AMP may be enhanced by proestrus levels of plasma progesterone in vivo (Al-Dahan et al, this meeting). We have attempted to study the effects of progesterone in vitro upon GABA<sub>B</sub> receptors and this messenger system. neocortical slices of rats that had been ovariectomized at least one week were incubated in a Krebs buffer (bubbled with 95%O<sub>2</sub>, 5%CO<sub>2</sub>). Exposure of slices to progesterone (1/2 max 30nM for 4 hours) increased baclofen binding to GABA<sub>B</sub> receptors up to two fold. Although 100nM progesterone did not affect basal levels of cyclic AMP, it did facilitate (3uM) forskolin stimulated cyclic AMP levels when introduced along with forskolin. However, when forskolin was introduced 45 minutes following progesterone, there was no such facilitation. Thus progesterone seems to produce a short-latency, transient facilitation of forskolin-stimulated cyclic AMP that would seem to require an unconventional or membrane progesterone receptor. This effect may reflect a progesterone interaction with this messenger system that could couple progesterone to cellular effects such as the increase in GABA<sub>B</sub> receptors that progesterone produces. Supported by National Institutes of Health grant NS21713

## 151.7

CIRCADIAN RHYTHM IN THE CALCIUM-INHIBITABLE ADENYL CYCLASE ACTIVITY OF THE RAT STRIATUM. Y. Chem\*, E. H. Y. Lee, H.-L. Lai, H.-L. Wang, Y.-C. Lee and Y.-H. Ching. Division of Neuroscience, Institute of Biomedical Sciences, Academia Sinica, Taipei 11529, Taiwan, R. O. C.

To elucidate the neuronal significance of the Ca<sup>2+</sup>-inhibitable adenylyl cyclase (AC), we investigated the circadian regulation of the Ca<sup>2+</sup>-inhibitable AC in the rat striatum. Under our experimental conditions, almost 90 % of the forskolin-evoked AC activity in the striatum was Ca<sup>2+</sup>-inhibitable. Intriguingly, the Ca<sup>2+</sup>-inhibitable AC activity in the striatum exhibited a daily oscillation with a peak occurring around 10:00. This circadian fluctuation of the Ca<sup>2+</sup>-inhibitable AC activity remained largely unchanged in those cyclase assays in which GDPβS and MnCl<sub>2</sub> were substituted for GTP and MgCl<sub>2</sub>. Therefore, regulation of the effector enzyme itself, but not Gα<sub>s</sub> protein, may lead to the circadian variation of the Ca<sup>2+</sup>-inhibitable AC activity. A circadian fluctuation of the AC activity evoked by an A<sub>2a</sub> adenosine-selective agonist (CGS21680) was also observed in the striatum. Intrastriatal injection of an A<sub>2a</sub>-selective adenosine agonist or antagonist at the interval (9:30- 10:30) in which the Ca<sup>2+</sup>-inhibitable AC activity was at its peak, resulted in a more significant alteration of locomotor activity than those observed at a later interval (16:30-17:30) when the Ca<sup>2+</sup>-inhibitable AC activity was relatively low. Taken together, we have characterized a marked circadian variation in the Ca<sup>2+</sup>-inhibitable AC activity localized in the striatum which appears to cause a circadian fluctuation of at least one neuromodulator's action. This work was supported by grants from National Science Council (NSC 84-2331-B-001-029), Taiwan.

CHARACTERISATION OF CB1 RECEPTORS ON RAT NEURONAL CELL CULTURES: BINDING AND FUNCTIONAL STUDIES USING THE SELECTIVE ANTAGONIST, SR 141716A. M. Jung, R. Calassi, M. Rinaldi-Carmona, P. Chardenot, G. Le Fur\*, P. Soubrie and F. Oury-Donat. Sanofi Recherche, 34184 Montpellier, France.

This study was undertaken to provide a further characterization of central cannabinoid receptors on rat primary neuronal cell cultures from selected brain structures. Using [<sup>3</sup>H]-SR 141716A, the specific CB1 receptor antagonist, we demonstrated the presence of a relatively high density of specific binding sites (B<sub>max</sub> = 139 ± 9 fmol/mg of protein) displaying a high affinity (K<sub>d</sub> = 0.76 ± 0.09 nM) on cortical neurones. Furthermore, the two cannabinoid receptor agonists, CP 55940 and WIN 55212-2, inhibited in a concentration-dependent manner cyclic AMP production induced by either 1 μM forskolin or isoproterenol with EC<sub>50</sub> values in the nanomolar range (4.6 and 65 nM on forskolin and 1.0 and 5.1 nM on isoproterenol for CP 55940 and WIN 55212-2, respectively). Moreover, on striatal neurones and cerebellar granule cells, CP 55940 also reduced the cyclic AMP accumulation induced by 1 μM forskolin with a potency similar to that observed on cortical neurones (EC<sub>50</sub> values of 3.5 and 1.9 nM on striatum and cerebellum, respectively). SR 141716A antagonized the CP 55940- and WIN 55212-2-induced inhibition of cyclic AMP accumulation suggesting the CB1 receptor specific mediation of these effects on all primary cultures tested. Furthermore, CP 55940 was unable to induce MAP kinase activation either on cortical or on striatal neurones. In conclusion, our results showed nanomolar efficiencies for CP 55940 and WIN 55212-2 on cyclase activity with no effect on any other signal transduction pathway investigated on primary neurone cultures.

## 151.6

CYCLIC AMP AND PROTEIN KINASE A IN THE PONTINE RETICULAR FORMATION CONTRIBUTE TO CHOLINERGIC RAPID EYE MOVEMENT (REM) SLEEP GENERATION. M.L. Capece\*, M.A. Flegel and R. Lydic. Department of Anesthesia, Pennsylvania State University, College of Medicine, Hershey, PA 17033.

Microinjection of the cholinergic agonist carbachol into the medial pontine reticular formation (mPRF) of cat produces a REM sleep-like state by way of a signal transduction pathway involving muscarinic receptors (*Neuropsychopharmacol* 2:67, 1989), pertussis toxin sensitive G-proteins, and adenylate cyclase (*Am. J. Physiol.* 269:R308, 1995). The present study is testing the hypothesis that cAMP and protein kinase A (PKA) regulate cholinergic REM sleep generation. Four cats received unilateral microinjections (n) of saline (n=17); carbachol (n=18); 8-bromo-cAMP (n=9), a cAMP analog; 8-bromo-cAMP as a pretreatment to carbachol (n=9); Sp-cAMPS (n=3), an activator of PKA; Sp-cAMPS as a pretreatment to carbachol (n=6); Rp-cAMPS (n=4), an inhibitor of PKA; and Rp-cAMPS as a pretreatment to carbachol (n=6). After each microinjection, 2 hr recordings were made of percent time spent in waking, non-REM sleep, and REM sleep. Carbachol enhanced REM sleep (67.8%) and this enhancement was significantly decreased by pretreatment with 8-bromo-cAMP (48.8% REM sleep) or Sp-cAMPS (40.3% REM sleep). Rp-cAMPS did not decrease the carbachol-induced REM sleep-like state. These data suggest that stimulation of the cAMP/PKA pathway can significantly decrease cholinergically-induced REM sleep. The results are consistent with previous studies which microinjected dibutyl cAMP, pertussis toxin, and forskolin into the mPRF. Taken together, these data suggest that REM sleep generation involves a muscarinically-activated cAMP/PKA pathway.

## 151.8

SYNERGISTIC ACTIVATION OF ADENYL CYCLASE IS DEPENDENT UPON PHOSPHOLIPASE C-MEDIATED PROCESSES IN HUMAN NEUROBLASTOMA SK-N-BE(2)C CELLS. Kyung-Tai Kim\* and Byung-Chang Suh. Department of Life Science, Pohang University of Science and Technology, Pohang, 790-784, Republic of KOREA

U-73122, an inhibitor of processes involved in the activation of phospholipase C (PLC), was used to assess the role of PLC activation in the synergistic elevation of cAMP induced by carbachol and prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) in human neuroblastoma SK-N-BE(2)C cells. Pretreatment of the cells with U-73122 resulted in inhibition of carbachol-induced intracellular Ca<sup>2+</sup> ([Ca<sup>2+</sup>]<sub>i</sub>) rise and inositol 1,4,5-trisphosphate (InsP<sub>3</sub>) generation, with maximal and half maximal inhibition (IC<sub>50</sub>) occurring at approximately 15 μM and 3.2 μM, respectively. U-73122 also inhibited the synergistic enhancement of cAMP accumulation induced by carbachol and PGE<sub>2</sub> in a concentration-dependent manner with maximum and IC<sub>50</sub> at 12 ± 4 μM and 3.4 ± 0.3 μM, respectively. However, U-73122 does not significantly inhibit PGE<sub>2</sub>-induced production. While BAPTA/AM treatment decreased the synergistic cAMP accumulation by 28%, addition of U-73122 further decreased it down to complete inhibition. Furthermore, GTPγS- and AlF<sub>4</sub><sup>-</sup>-induced InsP<sub>3</sub> generation in digitonin-mediated permeabilized cells was also inhibited by U-73122 treatment. Pretreatment of the cells with neomycin, another blocker of the PLC pathway, also resulted in inhibition of the synergistic cAMP accumulation. These results suggest that the increase in [Ca<sup>2+</sup>]<sub>i</sub> and the coupling process between muscarinic receptor-linked G protein and PLC are important for the synergistic activation of adenylyl cyclase in SK-N-BE(2)C cells. (Supported from the POSTECH and the KOSEF)

## 151.10

EFFECTS OF FORSKOLIN ADMINISTRATION ON BEHAVIORAL RESPONSE TO FORCED SWIMMING IN THE RAT. H. Maeda, H. Ozawa, N. Amemiya, K. Kaneta\*, T. Saito, N. Takahata. Dept. of Neuropsychiatry and Pharmacology<sup>1</sup>, School of Medicine, Sapporo Medical University, Sapporo, Japan.

Our previous studies showed that GppNHp-stimulated adenylyl cyclase (AC) activity is increased subsequent to the chronic administration of tricyclic antidepressants (TCA), electroconvulsive shock and selective serotonin reuptake inhibitors (SSRIs) suggesting enhanced cAMP signal transduction system by these treatments (Ozawa and Rasenick, Mol. Pharm. 1989, J. Neurochem. 1991, Ozawa et al, Neurosci Abst 95).

Forskolin increases intracellular cAMP formation in a neurotransmitter receptor-independent manner by direct activation of catalytic subunit of AC or stabilizing between Gs and AC. The Porsolt behavioral despair test or the forced swimming test (FST) is an animal behavior test sensitive to discover new types of antidepressant agents. The present study investigated the effect of forskolin on behavioral responses to FST compared to TCA. Wistar male rats were injected (i.p.) with saline and amitriptyline (15mg/Kg), forskolin (15mg/Kg). Water depth 37 cm to prevent from supporting themselves with tail or hind limbs. The behaviors in the swim were recorded on videotape. Following a 15 min pretest, drugs were administered 1hr prior to the 5 min swim test. Forskolin decreased ratings of immobility and increased swimming which is similar effects to amitriptyline treatment. In addition, water soluble forskolin also reduced immobility.

These data are consistent with hypothesis that elevation of the cAMP cascade system may have an important role in antidepressant effects.

## 151.11

FORSKOLIN EVOKES EXTRACELLULAR ADENOSINE ACCUMULATION IN RAT CORTICAL CULTURES. Y. Li, X. Gan\*, and P.A. Rosenberg, Department of Neurology, Children's Hospital & Harvard Medical School, Boston MA 02115

Previous studies have shown that  $\beta$ -adrenergic receptor agonists increase extracellular adenosine by stimulating the transport of cyclic AMP from astrocytes into the extracellular space, where it is sequentially hydrolyzed to AMP and adenosine. In this study, we investigated the effect on extracellular adenosine concentration of direct and maximal activation of adenylyl cyclase by forskolin. Forskolin evoked intracellular and extracellular cAMP accumulation as well as extracellular adenosine accumulation. In order to test whether cAMP transport was required for forskolin stimulated extracellular adenosine accumulation, we attempted to block adenosine accumulation using probenecid, an inhibitor of cAMP transport. Probenecid at 1 mM blocked forskolin stimulated extracellular cAMP accumulation ( $90.4 \pm 2.1$  inhibition in 3 experiments), and also blocked forskolin stimulated adenosine accumulation ( $62 \pm 10\%$  inhibition of excess adenosine accumulation due to forskolin; 3 experiments). Next, we tested whether the accumulation of adenosine in response to forskolin could be blocked by the cyclic nucleotide phosphodiesterase inhibitor RO 20-1724. Adenosine accumulation due to forskolin in the presence of 180  $\mu$ M RO 20-1724 was only  $19 \pm 11\%$  of the value due to forskolin in the absence of this inhibitor ( $n = 3$ ). Finally, the accumulation of adenosine in response to forskolin could also be blocked by the 5'-ectonucleotidase inhibitor GMP, at 500  $\mu$ M. These results demonstrate that forskolin can increase extracellular adenosine levels, and suggest that this adenosine is ultimately derived from cAMP.

This work was funded by a grant from the NINDS (NS28830).

## 151.12

EXPRESSION OF THE bZIP DOMAIN TRANSCRIPTION FACTORS C/EBPs AND ATF-4 IN HIPPOCAMPAL NEURONS AND THEIR REGULATION BY THE CYCLIC AMP SIGNAL TRANSDUCTION PATHWAY. J.C. Lopez-Garcia\*, D. Baranes, Y.-Y. Huang, H. Golan, T. Tanaka, K. Takeda, S. Akira and K. Yukawa, Center for Neurobiology & Behavior, Columbia Univ., New York, NY 10032 and Hyogo College of Medicine, Hyogo 663, Japan.

The *Aplysia* CCAAT enhancer-binding protein (ApC/EBP) has been found to be an essential transcription factor activated by the cAMP signal transduction pathway during the consolidation phase of long-term facilitation. By contrast, ApCREB2 acts as a repressor for other bZIP factors including CREB1 and C/EBP. To explore whether mammalian homologues of these bZIP transcription factors play a role in the molecular processes leading to long-term memory, we initially examined the expression of C/EBPs and ATF-4, a mammalian homologue of ApCREB2 and the inducibility of these bZIP factors by the cAMP pathway in hippocampal neurons. Among several C/EBP isoforms identified in mammals, only C/EBP $\beta$  and CHOP-10 are expressed in dissociated hippocampal neurons in culture. Expression of both C/EBP $\beta$  and CHOP-10 are augmented 2-4 hours after forskolin treatment. Immunocytochemical and *in situ* hybridization analysis similarly indicate that ATF-4 mRNA and protein are expressed in hippocampal neuron and are significantly increased by forskolin treatment. To directly examine the roles of these transcription factors in synaptic plasticity, we are beginning to analyze long-term potentiation and long-term depression in the hippocampus of C/EBP $\beta$  knock-out (k/o), CHOP-10 k/o and ATF-4 k/o mice. Supported by HHMI & grants from the Ministry of Education of Japan.

## SECOND MESSENGERS AND PHOSPHORYLATION II

## 152.1

ROLE OF NEUROFIBROMIN 1 IN SIGNAL TRANSDUCTION MEDIATING NEUROPEPTIDE RESPONSE. F. Guo<sup>†</sup>, J. The A. Bernards, I. Hariharan, Y. Zhong<sup>†\*</sup> Cold Spring Harbor Lab Cold Spring Harbor, NY 11724; MGH cancer center-Harvard Medical School, Charlestown, MA 02129

The NF1 gene, which is altered in patients with type 1 neurofibromatosis, encodes a protein homologous to the ras GTPase activating protein (GAP). To understand its physiological function, the mutants of *Drosophila* NF1 homolog were examined.

It has been shown that PACAP38-like neuropeptide induces a 100-fold enhancement of K<sup>+</sup> currents (Zhong and Pena; Neuron 14:527; 1995) by coactivation of the Ras/Raf and adenylyl cyclase/cAMP pathways at the larval neuromuscular junction (Zhong; Nature 375:588, 1995). This 100-fold enhancement of K<sup>+</sup> currents was eliminated in NF1 mutants and the defect was rescued by expression of the normal NF1 transgene. In contrast, the PACAP38 response was not affected by GAP mutations. This NF1 defect appears not result from an alteration of the Ras pathway rather from the failure of activation of adenylyl cyclase to synthesize cAMP. This is strongly supported by the observation that PACAP38 could induce a normal-like response in NF1 mutants if membrane permeable cAMP analogs or forskolin (stimulating adenylyl cyclase) was supplied. It is suggested that the NF1/Ras complex may be important in controlling activation of adenylyl cyclase by G protein.

## 152.2

MODULATION OF ION CHANNEL ACTIVITY BY TYROSINE PHOSPHORYLATION. S. Catarsi, L. Aniksztein and P. Drapeau\* Centre for Research in Neuroscience, McGill University and Montreal General Hospital, Montreal, PQ, Canada H3G 1A4.

Pressure (P) sensory neurons of the leech possess a cation channel whose activity is increased by serotonin through protein kinase C. Soon after a serotonergic Retzius neuron comes into contact with the P cell, the cation channel loses the serotonin modulation at the sites of contact. This event, which requires tyrosine phosphorylation, leads to the specific recognition of the two cells, to the selection of the correct serotonin response and eventually to the formation of an inhibitory synapse. We have examined the possible direct modulation of the channel by tyrosine phosphorylation. In cell-attached configuration, bath application of the tyrosine kinase inhibitor genistein, but not of its inactive analog daidzein, induced a 6 fold increase of the open probability of the channel (Po) without altering its conductance or its mean open time; this effect was blocked by sodium pervanadate, a membrane permeable inhibitor of tyrosine phosphatases. In inside-out configuration, a protein tyrosine phosphatase (TCAC11.PTPase) induced a 10 fold increase of Po; this effect was totally blocked by the specific phosphatase inhibitor sodium orthovanadate. Incubation with either orthovanadate or pervanadate did not provoke any significant variation in the activity of the channel.

These data suggest that the cation channel is directly phosphorylated by a tyrosine kinase under resting conditions in order to maintain a low basal level of activity. Future experiments will try to clarify the possible interactions between tyrosine phosphorylation and protein kinase C as well as the role of tyrosine phosphorylation in modulation and synaptogenesis.

Supported by the MRC and FRSQ of Canada and by INSERM and Ministère de la Recherche Française.

## 152.3

NEFIRACETAM, A NOOTROPIC AGENT, INHIBITS Ro 5-4864-INDUCED MITOCHONDRIAL DEPOLARIZATION AS EXAMINED BY RHODAMINE 123 FLUORESCENCE IN NG108-15 CELLS. S. Watabe<sup>1,2</sup>, M. Yoshiji<sup>2</sup>, T. Nukada<sup>3</sup>, T. Shiotani<sup>1</sup> and M. Tanaka<sup>1</sup>. <sup>1</sup>Tokyo R & D Center, Daiichi Pharmaceutical Co., Ltd., Tokyo 134 and <sup>2</sup>Dept. of Neurophysiology, <sup>3</sup>Dept. of Neurochemistry, Tokyo Institute of Psychiatry, Tokyo 156, Japan.

We have recently reported that the peripheral-type benzodiazepine receptor (PBR) in brain has an affinity to nefiracetam, a nootropic agent (Watabe et al., Soc. Neurosci. Abstr. 21, 2034, 1995). It remains to be seen, however, whether nefiracetam influences the membrane potential of mitochondria which might be regulated by the mitochondrial benzodiazepine receptor (MBR). In the present study, mitochondrial membrane potentials ( $\psi_m$ ) were measured fluorometrically in NG108-15 cells using rhodamine 123 (5  $\mu$ M/ml) and the effects of nefiracetam on  $\psi_m$  were investigated. Ro 5-4864, a specific agonist for PBR, induced a depolarization of  $\psi_m$  at concentrations higher than 25  $\mu$ M. In contrast, PK 11195, a specific antagonist for PBR, exerted no effect on  $\psi_m$  but prevented the agonist-induced depolarization. Similarly, nefiracetam (50  $\mu$ M) did not affect  $\psi_m$  but prevented Ro 5-4864-induced depolarizations. The results suggest that nefiracetam may act as a stabilizer of the mitochondrial membrane potential possibly by interacting with MBR.

## 152.4

AGONIST-INDUCED MU OPIATE RECEPTOR PHOSPHORYLATION IS DEPENDENT ON THE POTENCY OF OPIATE LIGANDS Y. Yu, L. Zhang\*, H. Sun, G. R. Uhl<sup>†</sup> and J. B. Wang. Dept. of Pharmaceutical Sciences, Sch. of Pharmacy, Univ. of Maryland at Baltimore, Baltimore, MD 21201, <sup>†</sup>Lab. of Molecular and Cellular Neurobiology, NIAA/NIH, Bethesda, MD 20892, <sup>†</sup>Molecular Neurobiology Branch, NIDA/NIH and Depts. of Neurol. and Neurosci., Johns Hopkins Univ., Sch. of Med., Baltimore, MD 21224.

Mu opiate receptor phosphorylation can be induced upon opiate agonist activation. In order to understand the mechanisms of this phosphorylation event, we examined the effects of a variety of opiate ligands on mu receptor phosphorylation, mu receptor mediated adenylyl cyclase inhibition, and mu receptor mediated activation of a G protein linked K<sup>+</sup> channel. Mu receptor phosphorylation was assessed by <sup>32</sup>P-labeling of Chinese hamster ovary cells stably expressing the cloned human mu receptor (h $\mu$ CHO) which was immunoprecipitated with a specific anti-mu receptor peptide polyclonal antibody. Among 22 tested opiate ligands, sufentanil, dihydroetorphin, etorphine, and DAMGO caused the strong mu receptor phosphorylation; methadone, morphine,  $\beta$ -endorphin<sub>(1-13)}, enkephalins and dynorphin A<sub>(1-17)} produced a ranged intermediate effect; while the partial agonist buprenorphine and several other "mixed agonist-antagonists" had little effect on mu receptor phosphorylation. Correlation between the potencies and intrinsic activities of opiate ligands and receptor phosphorylation that they induced suggests that the extent of agonist-induced mu receptor phosphorylation relates to the nature or agonist activities at these receptors.</sub></sub>

Supported by Sch. of Pharmacy, UMAB and NIH intramural program.

## 152.5

ENDOTHELIN (ET) STIMULATES PHOSPHORYLATION OF ETS-1 IN GLIAL CELLS. L.E. Fleischman and D.W. Fink, Jr.\* Lab. of Neurotrophic Factors, Div. of Cytokine Biol., CBER/FDA, Bethesda, MD 20892.

The 51 kDa isoform of Ets-1, a putative transcription factor that binds the DNA target sequence GGAATA, has been detected in cells of glial lineage. Phosphorylation of Ets-1 is elicited by a variety of peptidergic and neurotransmitter substances that evoke increases in intracellular calcium. It is reported here that the potent vasoconstrictor, ET, stimulates Ets-1 phosphorylation in glial cells. In C6 glioma cells, incubation with ET-1 stimulated Ets-1 phosphorylation in a dose-dependent manner. Similarly, dose-dependent phosphorylation of Ets-1 was elicited by ET-2, whereas ET-3 was without effect. Induction of Ets-1 phosphorylation by ET-1 and ET-2, but not ET-3, suggests these effects are mediated through ETA-type receptors. ET-1 stimulation of Ets-1 phosphorylation could be detected at 5 min and was sustained for at least 15 min. Pretreatment with the cell permeant, myosin light chain kinase-selective inhibitor KT5926 prevents ET-1/ET-2-mediated Ets-1 phosphorylation. Addition of ET-1 to cultures of primary rat astrocytes derived from neonatal cortex resulted in a weak but discernible dose-dependent stimulation of Ets-1 phosphorylation. Increases in Ets-1 phosphorylation were also observed following addition of ET-1 and ET-2, but not ET-3, to RN-22 cells derived from a rat schwannoma. This effect of ET in RN-22 cells was inhibited by KT5926, analogous to observations made in C6 glioma cells. For all cell types tested, Ets-1 in untreated control cells was largely in the unphosphorylated 51 kDa form; thus, ET-stimulated increases in phosphorylation were assessed against backgrounds devoid of detectable endogenous Ets-1 phosphorylation. ET has been reported to promote DNA synthesis and stimulate neurotrophin expression in astrocytes. These data suggest Ets-1 regulated processes may be involved.

## 152.7

ACUTE HALOPERIDOL INCREASES THE ACTIVITY AND PHOSPHORYLATION OF TYROSINE HYDROXYLASE AT SPECIFIC SERINE SITES *IN VIVO*. K. Harada<sup>1</sup>, J.Y. Lew<sup>1</sup>, A. Garcia-Espana<sup>1</sup>, J. Platt<sup>1</sup>, M. Goldstein<sup>1</sup>, J.W. Haycock<sup>2</sup> and A.Y. Deutch<sup>3</sup>, <sup>1</sup>Neurochem. Res. Labs., NYU Med. Ctr., New York, NY, <sup>2</sup>Dept. Biochem. Molec. Biol., LSU Med. Ctr., New Orleans, LA and <sup>3</sup>Dept. Psychiatry and Pharmacol., Yale Univ., Sch. of Med., New Haven, CT.

Acute administration of haloperidol is known to increase the activity of striatal tyrosine hydroxylase (TH), but it is not yet known whether this is associated with changes in the phosphorylation of the enzyme. Using antibodies that specifically recognize TH phosphorylated at different sites, namely anti-ThpSer19 and anti-ThpSer40, we have determined the effects of a single injection of haloperidol upon the *in vivo* phosphorylation of TH at Ser19 and Ser40 and correlated this with changes in TH activity. Striata were dissected from rats sacrificed at 10 and 60 min after treatment. Blot immunolabeling analysis revealed that haloperidol increased the phosphorylation of TH at both Ser19 and Ser40, and these increases were associated with a concomitant increase in TH activity. Immunohistochemical studies revealed that the anti-ThpSer40 did not result in staining in the striatum of vehicle-treated rats, but did label dopamine terminals in the dorsal striatum of haloperidol-treated rats. These data indicate that haloperidol activates TH by phosphorylating the enzyme at both Ser19 and Ser40 sites, and thus suggests that acute activation of TH by the D2 antagonist occurs through both activation of CAM kinase II and PKA. These antibodies should prove useful in determining the degree to which depolarization-induced activation of TH is modified after chronic antipsychotic drug treatment. Supported by USPHS grants MH2717 and NS6801 (M.G.), NS25134 (J.W.H.), and MH45124 (A.Y.D.), and the National Parkinson Foundation Centers of Excellence at NYU and Yale Univ.

## 152.9

TYROSYL-PHOSPHORYLATION IS ASSOCIATED WITH MORPHOLOGICAL PLASTICITY OF RG-2 ASTROGLIAL CELLS. K.D. Ramsell<sup>1</sup>, S.W. Watts, D.F. Matesic, and P. Cobbett, Depts. of Pharmacology & Toxicology and Pediatrics & Human Development and The Neuroscience Program, Michigan State University, East Lansing, MI 48824.

Serum modulates cAMP-dependent morphological changes of neurohypophyseal astrocytes (Ramsell *et al.*, 1996) and glioma-derived astrocytes (Koshel and Tas, 1993) *in vitro*. Serum has also been shown to cause tyrosyl-phosphorylation of cytoskeletal elements in cultured fibroblasts (Chrzanoska-Wodnicka and Burridge, 1994). This study was designed to test the hypothesis that the effect of serum on astrocytic morphology is mediated by modulation of tyrosyl-phosphorylation of cytoskeletal proteins. Western blot analysis revealed that RG-2 cells incubated in serum (2-10%) containing medium exhibited strong tyrosyl-phosphorylation of proteins of approximately 125 kDa and 66 kDa, which correspond in molecular weight to the cytoskeletal proteins Fak125 and paxillin respectively. Tyrosyl-phosphorylation of these proteins was decreased by approximately 60% when cells were incubated in serum-free medium and was decreased to a greater extent when cultures were incubated in serum-free medium containing either forskolin (5  $\mu$ M), or genistein (50  $\mu$ M), a tyrosine kinase inhibitor. Cells in cultures with high levels of tyrosyl-phosphorylation of 125 kDa and 66 kDa proteins were mostly non-stellate (<2%). Cultures incubated in genistein or forskolin containing medium not only contained cells with low levels of tyrosyl-phosphorylation of these proteins but also had a significantly increased proportion of stellate cells. These data show that astrocytic morphology is not only dependent on cAMP levels but also on the status of tyrosyl-phosphorylation of presumed cytoskeletal proteins. Supported by NINDS (NS 28206).

## 152.6

THE PHOSPHORYLATION STATE OF TYROSINE HYDROXYLASE AT SERINE 40 PARALLELS DOPAMINE AUTORECEPTOR-MEDIATED CHANGES IN DOPA BIOSYNTHESIS. C.W. Aretha<sup>1</sup>, M.P. Galloway<sup>1</sup>, M. Goldstein<sup>1</sup>, and J.W. Haycock<sup>2</sup>, <sup>1</sup>Dept. Psychiat. Behav. Neurosci., Wayne State Univ. Sch. Med., Detroit, MI., <sup>2</sup>Neurochem. Res. Lab., NYU Med. Ctr., New York, NY, <sup>3</sup>Dept. Biochem. Molec. Biol., LSU Med. Ctr., New Orleans, LA.

Dopamine (DA) agonists decrease the rate of basal and stimulated DA biosynthesis in corpus striatum and, in a previous study, these effects were associated with a decrease in overall <sup>32</sup>P incorporation into tyrosine hydroxylase (TH). Activation of the nigrostriatal pathway, however, increases the phosphorylation of striatal TH at multiple sites. Thus, in the present studies, we examined the effects of DA agonists upon DOPA biosynthesis and the phosphorylation state of TH-Ser19 and TH-Ser40 (using quantitative blot immunolabeling with site- and phospho-specific antibodies) in rat striatal slices. In control slices, forskolin (1  $\mu$ M, 5-40 min) increased the stoichiometry of Ser40, but not Ser19, phosphorylation while elevated K (+30 mM, 40min) increased both Ser19 and Ser40 phosphorylation. Both treatments increased DOPA synthesis. Pretreatment with DA agonists (7-OH-DPAT and Quinpirole, 1  $\mu$ M) decreased DOPA synthesis in both treated and untreated slices. These reductions were associated with decreases in the phosphorylation state of Ser40, whereas Ser19 phosphorylation was relatively unaffected. Preincubation with the DA antagonist eticlopride (1  $\mu$ M) essentially blocked the effects of quinpirole. [Supported by DA04210 and the Joe Young, Sr. Research fund (MPG), MH2717 and NS6801 (MG), NS25134 and MH00976 (JWH)]

## 152.8

17- $\beta$  ESTRADIOL PREVENTS CREB DECLINE IN THE RAT HIPPOCAMPUS FOLLOWING SEIZURE AND HYPOXIA. K.S. Panickar<sup>1,2</sup>, M.E. Hosford<sup>1</sup>, M.A. King<sup>3</sup>, G. Rajakumar<sup>1</sup>, P. Persaud<sup>1</sup> & J.W. Simpkins<sup>1</sup>, Center for Neurobiology of Aging and Department of Pharmacodynamics<sup>1</sup>, Department of Pharmacology and Therapeutics<sup>2</sup>, Department of Neuroscience<sup>3</sup>, University of Florida, Gainesville, FL 32610.

We have reported that CREB concentrations in the male rat hippocampus is reduced at 90 minutes after hypoglycemia-induced seizure (Soc. for Neurosci. Abstr. 1995, p.1947). In Experiment 1, of the present study, two groups of rats were ovariectomized (OVX) but one group received 17- $\beta$  estradiol (E2) treatment for 1 week. Hypoglycemic seizure was induced by injecting Insulin (12.5 U/kg, IP) and the rats sacrificed at 90 minutes following seizure. When compared to E2-treated animals OVX animals revealed a 53% decrease ( $p < 0.05$ ) in the number of CREB immunoreactive neurons in the CA1 pyramidal cell layer and a 56% decrease ( $p < 0.05$ ) in the dentate granule cell layer of the hippocampal region. In the CA3 region there was a 30% decrease in OVX versus E2-treated rats (NS). In Experiment 2, hippocampal slices from OVX and E2-replaced animals were subjected to hypoxia for 30 minutes and slices were collected at different time points following hypoxia. Western Blot analysis revealed an initial decline in CREB protein levels by 60% and 25% in OVX and E2-replaced animals, respectively, with a recovery phase beginning at 2.5 hrs following hypoxia. More importantly, the recovery of CREB protein level was increased to 25% above the control level in the E2-treated animals. These results suggest that 17- $\beta$  estradiol may be beneficial in preventing CREB decline and in facilitating CREB recovery following an insult. (Supported by NIH AG 10 485 to JWS).

## 152.10

THE RAS ACTIVATOR CDC25<sup>Mm</sup>/RAS-GRF: EXPRESSION IN THE CENTRAL NERVOUS SYSTEM AND MECHANISM OF SIGNAL TRANSDUCTION. R. Zippel, E. Mancinelli, S. Denis-Dorimi\*, E. Martegani, C. Ferrari, N. Gnesutta, S. Orecchia and E. Sturani, Dept. General Physiology and Biochemistry, University of Milan, 20133 Milan, Italy

CDC25<sup>Mm</sup>/Ras-GRF is a guanine nucleotide exchange factor of Ras reported to be expressed in the brain. We show that it is highly expressed in different area of the brain and, at a reduced level, in the spinal cord. It is localized in neuronal cells of the CNS and absent both in glial cells and in dorsal root ganglia. Subcellular fractionation of mouse brain shows that CDC25<sup>Mm</sup> is present in synaptosomes and highly enriched in postsynaptic densities. In primary cultures of hippocampal cells the p140 Ras-GRF is phosphorylated and associated with calmodulin. This association can be modulated by different stimuli. We have previously shown that the constitutive expression of CDC25<sup>Mm</sup> in fibroblasts potentiate a signalling cascade mediated by pertussis toxin sensitive-Gi proteins (Zippel *et al.*, Oncogene, 1996, in press). Investigations have been undertaken to elucidate the pathways in which Ras-GRF is involved in neuronal cells.

This investigation was partially supported by CEE BIO2CT-93005.

## 152.11

DISTRIBUTION OF THE mRNA FOR C-JUN NH<sub>2</sub>-TERMINAL KINASE KINASE (JNK/SEK1) IN THE ADULT AND DEVELOPING RAT BRAIN. L. Carboni, R. Carletti, S. Tacconi, E. Bettini, F. Ferraguti\*. Dept. of Pharmacology, Glaxo Wellcome S.p.A., Medicines Research Center, 37135 Verona, Italy.

At least three different Mitogen Activated Protein Kinase (MAPK) pathways mediate the transduction of extracellular signals to cellular responses in mammalian cells. The activation of Stress Activated Protein Kinases (SAPKs), also named c-Jun NH<sub>2</sub>-Terminal Kinases (JNKs), a recently discovered subfamily of MAPKs, induces the phosphorylation and trans-activation of c-Jun and other transcription factors. SAPK/JNK is activated via Thr and Tyr phosphorylation mediated by a dual specificity kinase, named SEK1/JNKK. We studied the mRNA distribution of SEK1/JNKK in the adult rat CNS using *in situ* hybridization with 45mer radiolabeled oligonucleotide probes. Film images were analyzed by means of a computer-assisted image analysis system. Strong signal intensity was observed in the hippocampal formation, in the medial habenular nucleus, in the granular layer of the cerebellar cortex, in some brain stem nuclei; intermediate expression levels were detected in the cerebral cortex and in thalamic and hypothalamic nuclei; hybridization signal was low in the basal ganglia. SEK1/JNKK mRNA distribution was compared to the hybridization pattern obtained using a SAPK specific probe: the localization of the two mRNA species was overlapping. SEK1/JNKK mRNA distribution was also studied at days 1, 3, 6, 9, 12, 15, 18 and 21 of post-natal development and compared to that found in the adult. The pattern of expression during development appeared to be similar to the adult animal. mRNA levels were low at P1, but increased the following days to reach, at P21, values similar to the adult animal. This study demonstrate a discrete distribution of SEK1/JNKK and a co-localization of this kinase with its substrate SAPK/JNK, suggesting a physiological role of the SAPK/JNK pathway in rat CNS.

## 152.13

ISOFORM-SPECIFIC LOCALIZATION OF CALCINEURIN IN HUMAN CONTROL AND ALZHEIMER HIPPOCAMPUS T. Kawamata<sup>1</sup>\*, T. Hashimoto<sup>1</sup>, K. Maeda<sup>1</sup>, P. L. McGeer<sup>2</sup>, E. G. McGeer<sup>2</sup>, and C. Tanaka<sup>1</sup>. <sup>1</sup>Hyogo Institute for Aging Brain and Cognitive Disorders, Himeji 670, Japan, and <sup>2</sup>Kinsmen Laboratory of Neurological Research, Univ. of B. C., Vancouver V6T 1Z3, Canada

Calcineurin (CN), an ionized calcium (Ca<sup>2+</sup>)/calmodulin-dependent protein phosphatase, has been recognized as a key element in cellular signal transduction pathways. It is enriched in the central nervous and immune systems. To determine whether it might be involved in the pathogenesis of Alzheimer disease (AD), we investigated the localization of both the  $\alpha$  and  $\beta$  subunits of the catalytic domain of CN in human brain tissues. Eight postmortem brains of AD cases were compared with 5 control brains. Polyclonal antibodies against the two subunits were raised in rabbits, affinity-purified, and used for immunohistochemistry.

The isoforms were differently distributed in the hippocampus. Strong CA1-subiculum neuron and mossy fiber zone staining was obtained with the CN- $\alpha$  antibody, with weaker staining of almost all neurons. Strong staining of granule and pleomorphic neurons, as well as mossy fiber zone, was obtained with the CN- $\beta$  antibody. CN- $\beta$  was more associated than CN- $\alpha$  with such neuritic pathology as neuropil tangles, degenerative neurites and intracellular neurofibrillary tangles in AD brains. Some glia with astrocytic profiles immunoreactive for CN- $\alpha$  or CN- $\beta$  were prominent in AD hippocampus.

These findings indicate that the two subunits may also differ in both their normal physiological roles and their involvement in AD pathology.

## 152.15

CLONING AND EXPRESSION PATTERN OF RAT G-PROTEIN COUPLED RECEPTOR KINASE 6 (GRK6) Ch. Fehr, S. Reuss<sup>1</sup>, Ch. Hiemke and N. Dahmen<sup>2</sup>. <sup>1</sup>Departments of Psychiatry and Anatomy<sup>2</sup>, University of Mainz, 55131 Mainz, Germany.

Phosphorylation of G-protein coupled receptors at intracellular amino acid residues by G-protein coupled receptor kinases (GRKs) is believed to be involved in receptor regulation. To facilitate studies on G-protein coupled receptor kinase 6 (GRK6) in rodents, we cloned rat GRK6 cDNA by a modified 5' and 3'-RACE technique. We obtained a 2817 bp rat GRK6 cDNA, with an open reading frame of 1731 bp and a partial termination site at position 2543. Sequence comparison with human GRK6 revealed a 77.8% identity of the cDNA in the 5'-UTR, 89.5% in the CDS, 77.5% in the 3'-UTR and 96.2% on the protein level. Comparison with other GRK family members showed a closer relationship to GRK5 (78.6% in the N-terminal, 87.4% in the catalytic and 80.3% in the C-terminal domain) than to GRK2 (47.6% in the N-terminal, 69.8% in the catalytic and 67.7% in the C-terminal domain).

RT-PCR experiments demonstrated the occurrence of GRK6 mRNA in all samples investigated: brain, muscle, heart, aorta, liver, lung, thymus, stomach, uterus and kidney. To quantify brain expression of GRK6 in different brain regions we performed quantitative RT-PCRs with increasing amounts (10<sup>2</sup>-10<sup>8</sup> copies) of a truncated *in vitro* transcribed GRK6 RNA standard added to the brain RNA samples (400 ng each reaction). These experiments demonstrated similar expression patterns of GRK6 (10<sup>4</sup>-10<sup>5</sup> copies/ng RNA) in cortex frontalis, cortex occipitalis, striatum, thalamus, hypothalamus, pons, cerebellum and cervical spinal cord. Taken together, our findings suggest a role for GRK6 in receptor phosphorylation and regulation in various tissues and brain regions.

## 152.12

REGIONAL DIFFERENCES IN CANNABINOID RECEPTOR CATALYTIC ACTIVATION OF G-PROTEINS IN RAT BRAIN. C. S. Breivogel<sup>1</sup>\*, L. J. Sim, and S. R. Childers. Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

Cannabinoid receptor activation of G-proteins can be measured by WIN 55212-2 (WIN)-stimulated [<sup>35</sup>S]GTPγS binding in brain membranes or sections with excess GDP. In autoradiographic studies, although receptor binding and agonist-stimulated [<sup>35</sup>S]GTPγS binding were generally parallel, a lack of correlation was found between these two parameters in some regions, with some areas providing relatively less [<sup>35</sup>S]GTPγS stimulation than predicted from receptor binding. To quantify these differences, membranes from different brain regions were assayed by Scatchard analysis of net WIN-stimulated [<sup>35</sup>S]GTPγS binding and [<sup>3</sup>H]WIN binding, to calculate catalytic amplification factors (ratio of activated G-protein B<sub>max</sub> to receptor B<sub>max</sub>) for each region. Results showed significant differences between regions, in agreement with the results from autoradiography. Cannabinoid receptors in frontal cortex and brain stem exhibited the greatest catalytic amplification, with approx. 1.6 G-proteins activated per receptor. The lowest levels of amplification were in the cerebellum and sensorimotor cortex, with values of approximately 0.8 G-proteins per receptor. These results suggest that cannabinoid receptors may exhibit varying levels of amplification in different regions with respect to G-protein activation.

Supported by DA-06784 and DA-07246 from NIDA.

## 152.14

DISTRIBUTION AND REGULATION OF ACTIVATED MAP KINASES ERK1 AND ERK2 IN RAT CNS. D. S. Cameron<sup>1</sup>, J. W. Haycock<sup>2</sup>, E. Schaefer<sup>3</sup>, and A. Y. Deutch<sup>1</sup>. <sup>1</sup>Depts. of Psychiat. and Pharmacol., Yale Univ. Sch. Med. and VA Medical Center, New Haven, CT 06516, <sup>2</sup>Dept. of Biochem., LSU Medical Center, New Orleans, LA 70119, and <sup>3</sup>Promega Corp., Madison, WI, 53711.

Extracellular signal-Related protein Kinases (ERKs) are widely distributed in brain, and mediate a broad spectrum of effects, ranging from mediation of growth hormone actions to activation of catecholamine biosynthesis. ERKs possess both phosphorylated Tyr (pY) and Thr (pT) residues. Although anti-pY antibodies have been used to identify activated ERK, phosphorylation of both residues is required for ERK activity. We used an antibody (Promega) that specifically recognizes the diphosphorylated forms of ERK1 and ERK2 to map the distribution and regulation of ERK in the rat. Diphospho-ERK-immunoreactivity (ppERK-ir) was regionally heterogeneous. Cortical neurons (layers II/III) were intensely labeled, particularly in the entorhinal and perirhinal cortices. Dense cytoplasmic staining resulted in full visualization of processes in these cells, and in lightly-stained sections nuclear ppERK-ir was apparent. Densely-stained neurons were also seen in the central amygdaloid (CAN) and hypothalamic paraventricular (PV) nuclei; few somata were seen in the hippocampus. Acute ECS treatment increased the numbers of cortical ppERK-ir neurons, but in contrast enhanced neuropil staining in the hippocampus. ECS resulted in the virtual disappearance of ppERK-ir somata in the CAN and PV; only a few weakly-stained nuclei were observed. An increase in neuropil staining in the hippocampus was also seen after icv infusion of the PKC activator phorbol 12,13 dibutyrate but not the inactive 4 $\alpha$ -phorbol ester. These data suggest that ERK activation may result in association of ppERK with an intracellular substrate that masks ppERK antigenicity. The pattern of ECS-elicited changes suggests that ERK activation may be important in stress-elicited changes in cellular function. Supported by MH45124, MH00967, NS25134, NPF.

STIMULATION OF MUSCARINIC M<sub>1</sub> RECEPTORS LEADS TO MULTIPLE SIGNALING EVENTS: EVIDENCE USING THE CYTOSENSOR® MICROPHYSIOMETER K. De Moor & S. Pitchford\*. Molecular Devices Corp., Sunnyvale, CA 94089.

The stimulation of many G-protein coupled receptors results in the initiation of multiple signaling pathways, often through the recruitment of different G-protein subunits. We used the Cytosensor Microphysiometer System, which measures the excretion of acid products of cell metabolism and homeostasis in real time, as a continuous monitor of the cellular response to muscarinic M<sub>1</sub> receptor activation while adding agents that interfere with different signaling pathways. Activation of the M<sub>1</sub> receptor transfected into CHO cells (classically known to couple via a G<sub>q</sub> protein) with the agonist carbachol resulted in a biphasic increase in the extracellular acidification rate (ECAR) in a concentration-dependent manner (EC<sub>50</sub>: 2.44 ± 0.19  $\mu$ M). The initial response was completely inhibited by blockers of the sodium-hydrogen exchanger (NHE) and by the kinase inhibitor, staurosporine. The response was slightly attenuated in cells that had been treated for 18 hours with 100 nM PMA or pre-treated for 30 minutes with 25  $\mu$ g/ml genistein. The response was unaltered, however, by separate pertussis toxin or KN-62 treatments and, more importantly, by treatment with U73122, an inhibitor of PLC. Treatment with wortmannin, an inhibitor of PI-3-kinase, resulted in an ECAR response larger than that to carbachol alone. This suggests that the coupling of the M<sub>1</sub> receptor to the extracellular acidification response may involve pathways other than the classical G<sub>q</sub>/PLC path.

## 152.17

AN ESTROGEN RECEPTOR THAT NONGENOMICALLY UNCOUPLES G-PROTEIN COUPLED RECEPTORS. A.H. Lagrange\*, Y. Tong, L. Yu, O.K. Ronnekleiv, and M.J. Kelly. Dept. of Physiol. & Pharm. OHSU, Portland OR 97201 and Dept. Genetics, IU. Sch. Med. Indianapolis, IN

$\mu$ -Opioid peptides (e.g.  $\beta$ -endorphin) hyperpolarize hypothalamic neurons by activating a  $K^+$  inward-rectifier (GIRK). In a subpopulation of cells, 17 $\beta$ -estradiol ( $E_2$ ) rapidly ( $\approx 10$  min) activates PKA which uncouples this system, causing a four-fold increase in the  $EC_{50}$  of the  $\mu$ -selective agonist, DAMGO. To study this estrogen receptor (ER), we used intracellular recordings of arcuate neurons from *in vitro* hypothalamic slices from ovariectomized guinea pigs. Inhibition of protein synthesis with 200  $\mu$ M cycloheximide did not block the effects of  $E_2$  (DAMGO  $EC_{50} = 123$  nM  $\pm$  27 nM;  $E_2$  alone = 115  $\pm$  10 nM; controls = 59  $\pm$  3 nM), thus implying that  $E_2$  acts nongenomically. The  $EC_{50}$  for  $E_2$ 's effect was 8 nM and the biologically inactive isomer, 17 $\alpha$ - $E_2$  had no effect.  $E_2$  appears to act at an intracellular receptor, since the membrane-impermeant conjugate BSA- $E_2$  did not alter DAMGO potency.  $E_2$ 's effects were blocked by the antiestrogen ICI 164,384 and Schild analysis estimated that the affinity for ICI 164,384 was identical to the classical ER. Furthermore,  $E_2$ -sensitive cells were immunocytochemically stained for the classical ER. In addition, we expressed the  $\mu$ -receptor, GIRK and the rat ER in oocytes. Using the same paradigm that we used for the slice experiments, the DAMGO  $EC_{50}$  was not altered by  $E_2$  treatment (8.3 nM  $\pm$  0.6 in controls; 6.3 nM  $\pm$  0.5 after  $E_2$ ). Therefore, these nongenomic actions may represent either a novel ER or a novel action of the classical ER that requires multiple components and/or subcellular organization that are not reproduced in the oocyte expression system. PERTUSSIS TOXIN ADP-RIBOSYLATION OF BRAIN AND SPINAL CORD INHIBITORY G-PROTEINS USING [ $^3$ H] NAD AS SUBSTRATE. N.W. DeLapp\*, D. E. Womer and H. E. Shannon. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

Pertussis toxin (PTX) blocks inhibitory G-protein (Gi/o) function by ADP-ribosylation. ADP-ribosylation *in vitro* is usually determined using [ $^{32}$ P] NAD as substrate coupled with SDS-PAGE and autoradiography to identify labeled Gi/o. An alternative method is described.

Rat brain and mouse spinal cord membranes were solubilized by sonication in Tris buffer containing 1% sodium cholate followed by centrifugation to remove insoluble material. PTX was activated by incubation in 50 mM DTT. The ADP-ribosylation reaction (50  $\mu$ l) contained 25 mM Tris HCl pH 8.0, 1 mM ATP, 100  $\mu$ M GDP( $\beta$ )S, 10 mM thymidine, 1 mM EDTA, 12.5 mM DTT, 0.025% SDS, 1.25  $\mu$ g activated PTX, 15  $\mu$ M [ $^3$ H] NAD (3 Ci/mmol), and 20-100  $\mu$ g of protein. Reactions were carried out for one hour at 30 degrees C and samples were prepared for electrophoresis. G-proteins were separated by SDS-PAGE, transferred to nitrocellulose and immunoblotted with an anti-Gi/o antibody. Immunoreactive bands on the blot corresponding to 40 Kd MW were cut out, dissolved in scintillation fluid, and counted. Incorporation of ADP-ribose was 20-30 fold greater using cholate-solubilized compared to suspended membrane preparations. A dose dependent increase in labeling of Gi/o was obtained between 20-80  $\mu$ g of soluble protein/assay. ADP-ribosylation of spinal cord Gi/o was reduced by 62% in samples taken from mice 7 days after intrathecal injection of 0.3  $\mu$ g/Kg of PTX. ADP-ribosylation of cholate-solubilized membranes using [ $^3$ H] NAD coupled with scintillation counting of bands identified by immunoblotting provides a rapid, quantitative method not requiring [ $^{32}$ P].

## 152.18

Effects of pertussis toxin and G $\alpha$  protein specific antibodies on phosphoinositide hydrolysis in rat brain membranes after cholinergic denervation and hippocampal sympathetic ingrowth. K.KOLASA\*, D. PARSONS, M. ROBERSON AND L.E. HARRELL. VA Med. Ctr. and University of Alabama at Birmingham Med. Ctr.

Following cholinergic denervation (CD) of the hippocampus by medial septal lesions (MSL), an unusual neuronal reorganization occurs in which peripheral adrenergic fibers arising from the superior cervical ganglia grow into the hippocampus (hippocampal sympathetic ingrowth-HSI). We have previously reported that CD and HSI differentially affected cholinergically stimulated phosphoinositide (PI) turnover and the affinity of muscarinic acetylcholine receptors (mAChR) as measured with non-specific and specific antagonists. We have also reported that GTP $\gamma$ S- as well as GTP $\gamma$ S+carbachol-stimulated PI hydrolysis were differentially changed by CD and HSI, which would indicate an alteration in G proteins and/or the entire receptor function. To examine the type of G protein which may be involved in these effects, we have preincubated rat hippocampal membranes with pertussis toxin (PTX) in the presence of GTP $\gamma$ S and GTP $\gamma$ S+carbachol. Our results indicate that PTX reduced both GTP $\gamma$ S- and agonist-stimulated PI hydrolysis but significant effect was obtained only in CON and CD group. This may suggest that PTX-sensitive G proteins are involved in the mediation of PI hydrolysis. To confirm this hypothesis membranes were preincubated with monoclonal antibodies to G $\alpha_{o1112}$  and with polyclonal antibody to Gq/11. It was found that the G $\alpha$  antibody significantly decreased GTP $\gamma$ S stimulated PI hydrolysis in all experimental groups. G $\alpha$  antibody also induced a significant decrease in GTP $\gamma$ S+agonist-stimulated PI, but only in HSI group. Impairment of GTP $\gamma$ S- and agonist-stimulated PI hydrolysis was also significant in all experimental groups when preincubated with a specific antibody to PTX-insensitive G protein- Gq/11. The results suggest that the mechanisms by which HSI and CD induced alterations in mAChR affinity and PI hydrolysis are probably mediated by changes in the coupling between AChR and possibly 2 different types of G proteins, or by their differential activation.

EXISTENCE OF PROTEIN VARIANTS OF RAT BRAIN 14-3-3  $\zeta$  ISOFORM. K. Murakami\*, S.Y. Situ and F. Eshete. Dept. of Biochemical Pharmacology, State University of New York at Buffalo, NY 14260

The 14-3-3 protein is highly enriched in the central nervous system, consisting of approximately 1% of the total cytosolic proteins in the brain. Despite such high abundance, the function(s) of the protein is poorly understood. Recent studies indicate that the 14-3-3  $\zeta$  mediates diverse cellular functions, including arachidonic acid-specific PLA2 activity, PKC regulation, and Raf-1 activation and translocation to the membrane. Increase in the immunoreactivity of Raf-1 during LTP has also been reported. These observations suggest that the 14-3-3 mediates a pivotal step in signaling pathways that involves arachidonic acid, PKC as well as MAP-kinase. However, substantial controversies exist regarding its PLA2 activity and effects on PKC regulation. To closely examine the contradictory issues, we have cloned the 14-3-3  $\zeta$  from the rat hippocampal cDNA library for expression studies in mammalian cells. Our DNA sequencing analysis of the clone shows that there are protein variants present in the 14-3-3  $\zeta$ . These are missense mutations, which lead ACG (Thr) to ATG (Met) and CGT (Arg) to GCT (Ala) conversions at amino acid residues 88 and 109, respectively. Respective amino acid residues of rat 14-3-3  $\zeta$  isolated from hippocampal, pineal and brain cDNA libraries are Met/Ala, Thr/Ala and Thr/Arg at these positions. It is thus apparent that rat 14-3-3  $\zeta$  has three distinct protein variations. Such mutation is an important indication for the diverse functions of this protein, and may also contribute to the recent contradictory observations regarding the role of the 14-3-3  $\zeta$  subtype. ## SECOND MESSENGERS AND PHOSPHORYLATION III

## 153.1

MEASUREMENT OF MITOCHONDRIAL [ $Ca^{2+}$ ] IN CULTURED RAT NEURONS TRANSFECTED WITH MITOCHONDRIAL-TARGETED AEQUORIN. R.A. Padua\*, C. Campbell and S.A. Thayer. Dept. of Pharmacology, University of Minnesota, Minneapolis, MN 55455.

The mitochondrial  $Ca^{2+}$  concentration ( $[Ca^{2+}]_{mt}$ ) was measured directly in cultured rat hippocampal and dorsal root ganglion neurons. Neurons were transfected with the gene encoding the  $Ca^{2+}$ -binding photoprotein apoaequorin fused to the mitochondrial targeting sequence of cytochrome C oxidase. Gene transfer was mediated by a replication-deficient adenoviral vector that carried the apoaequorin gene construct. In DRG neurons, high  $[K^+]_i$  and caffeine elicited cytosolic  $Ca^{2+}$  ( $[Ca^{2+}]_i$ ) increases that produced concomitant  $[Ca^{2+}]_{mt}$  transients as detected by aequorin bioluminescence. Both depolarization- and caffeine-elicited  $[Ca^{2+}]_{mt}$  transients were blocked by application of the mitochondrial uncoupler FCCP although  $[Ca^{2+}]_i$  was still increased. Furthermore, depolarization-induced  $[Ca^{2+}]_{mt}$  transients were inhibited by combined addition of antimycin A1 and oligomycin B. In hippocampal neurons, NMDA elicited  $[Ca^{2+}]_i$  transients that were paralleled by increases in  $[Ca^{2+}]_{mt}$ . Similar to DRG neurons,  $[Ca^{2+}]_{mt}$  transients in hippocampal neurons were inhibited by FCCP. Taken together, these results suggest that apoaequorin is selectively expressed in the mitochondria of rat neurons and that these organelles take up  $Ca^{2+}$  when  $[Ca^{2+}]_i$  is elevated by either influx or release from intracellular stores. Supported by the NIH and the NSF.

## 153.2

INHIBITORY ACTION OF NOOTROPIC NEFIRACETAM ON  $Ca^{2+}$  RELEASE FROM MITOCHONDRIA INDUCED BY Ro 5-4864 IN NG108-15 CELLS. M. Yoshii\*, S. Watabe<sup>1,2</sup>, T. Nukada<sup>3</sup>, T. Shiotani<sup>2</sup> and M. Tanaka<sup>2</sup>. <sup>1</sup>Dept. of Neurophysiology, <sup>2</sup>Dept. of Neurochemistry, Tokyo Institute of Psychiatry, Tokyo 156 and <sup>3</sup>Tokyo R & D Center, Daiichi Pharmaceutical Co., Ltd., Tokyo 134, Japan.

We have recently shown that nefiracetam, a nootropic agent, has an inhibitory action on bradykinin-induced  $Ca^{2+}$  mobilization in NG108-15 cells (Yoshii et al, *Soc. Neurosci. Abstr.* 20, 188, 1994). In the present study, we have further examined whether nefiracetam also exerts an inhibitory action on a  $Ca^{2+}$  release from mitochondria which might be induced by stimulation to the peripheral-type (or mitochondrial) benzodiazepine receptor (PBR or MBR). Cytosolic  $Ca^{2+}$  activities of NG108-15 cells were measured fluorometrically using fura-2/AM (5  $\mu$ M). Ro 5-4864 (25-50  $\mu$ M), a specific agonist for PBR, induced a sharp rise of  $Ca^{2+}$ . The  $Ca^{2+}$  response to Ro 5-4864 remained intact in a  $Ca^{2+}$ -free medium, even after repetitive stimulation by bradykinin (0.2-1  $\mu$ M) was applied to deplete stored  $Ca^{2+}$ . The  $Ca^{2+}$  rise in response to Ro 5-4864 was prevented in the presence of PK 11195 (20  $\mu$ M), a specific antagonist for PBR. Similarly, nefiracetam (50  $\mu$ M) inhibited  $Ca^{2+}$  response to Ro 5-4864. The results suggest that nefiracetam might interact with MBR thereby inhibiting  $Ca^{2+}$  release from mitochondria.

## 153.3

**PHARMACOLOGICAL CHARACTERIZATION OF A CLONED RAT EXTRACELLULAR CALCIUM SENSING RECEPTOR IN TRANSFECTED CHO CELL LINES.** M. Ruat\*, S. Ferry, B. Chatel, R. H. Dodd\*, A.M. Snowman and S.H. Snyder\* CNRS, UPR9040 and # ICSN, 91198 Gif sur Yvette, France and (\*) Dept. of Neuroscience, J.H.U. Sch. of Med., Baltimore, MD 21205.

The calcium sensing receptor (CaSR) belongs to the superfamily of G-protein coupled receptors and responds to extracellular calcium ions. In brain, immunohistochemistry revealed discrete punctate localizations reflecting nerve fibers and terminals (Ruat et al, 1995).

We have characterized a Chinese hamster ovary cell line (CHO(CaSR)) stably expressing rat CaSR (Ruat et al, 1996) and studied the transduction mechanisms and the pharmacology of rat CaSR. Western blot analysis of membrane preparations from these transfected cells using antibodies raised against a synthetic peptide based on the rat CaSR carboxyl domain, identified two highly glycosylated proteins with apparent molecular masses of 140 and 160 kDa. Stimulation of phosphatidylinositol (PI) hydrolysis and arachidonic acid (AA) release via phospholipases C and A2 respectively displayed highly cooperative responses to calcium and magnesium with a Hill coefficient of 4-5. These observations show that stimulation of the rat CaSR can trigger several major intracellular signals in response to extracellular calcium and magnesium.

In the presence of 1.5mM calcium, NPS 568, an organic compound, potently stimulated PI hydrolysis with an EC50 of 3  $\mu$ M. In the presence of lower concentrations of calcium, the dose response curve was shifted to the right suggesting that the potency of the drug was dependent upon the concentration of external calcium. Experiments are underway in order to further characterize CaSR transduction mechanisms and to investigate any link between CaSR and neurotransmitter release.

## 153.5

**INTERCELLULAR CALCIUM WAVES IN HIPPOCAMPAL SLICE EXPLANTS.** A.C. Charles<sup>1</sup>\*, S.A. Frautsch<sup>1,2,3</sup>, S.A. Zanotti<sup>1</sup> and M.E. Harris<sup>2,3</sup>. UCLA Departments of Neurology<sup>1</sup> and Medicine<sup>2</sup>, Los Angeles, CA 90095 and GRECC, VAMC Sepulveda<sup>3</sup>, Sepulveda, CA 91343.

Organotypic slice cultures provide an excellent system to study basic cellular physiology and cell-cell interactions. Hippocampal slice cultures have a well-preserved cellular organization and proper cell-cell contacts are maintained. We have utilized these slices, at 1 to 3 weeks *in vitro*, to examine calcium signaling activity. Spontaneous calcium waves occur in areas CA 1, 2 and 3. Intercellular calcium waves occur in at least 2 distinct patterns. Small, rapid calcium waves involving 5-20 cells and intracellular calcium concentrations of 100-200 nM occur in multiple areas of each slice region. Stimulation of the slices with NMDA or DNQX produces large intercellular waves involving in excess of 200 cells which often travel in spiral patterns. These large wave fronts travel at velocities ranging from 5 to 20  $\mu$ m/sec and intracellular calcium concentrations in these waves range from 200-400 nM. Simultaneous immunofluorescence labeling of neurons in these slices suggests that the majority of the intercellular waves are occurring in glial cells, although neurons may be capable of stimulating glial wave activity. These results indicate that glial cells in hippocampal slices are capable of extensive spontaneous and stimulus-evoked intercellular signaling. This work is supported by grants PO1-NS02808 (A.C.C.) and NS30195 (S.A.F.).

## 153.7

**SIGMA RECEPTOR LIGANDS MODULATE PROTEIN PHOSPHORYLATION AND INTRACELLULAR FREE CALCIUM LEVELS IN RAT FOREBRAIN SYNAPTOSOMES**

E.L. Brent, L. Herd, H. Saunders, A.T.R. Sim, B. Wamsley\* and P.R. Dunkley. The Neuroscience Group, University of Newcastle, NSW, Australia

We recently reported that sigma ( $\sigma$ ) ligands inhibit the depolarisation-dependent changes in phosphorylation of the key proteins synapsin I and dynamin which modulate neurotransmitter release and vesicle recycling respectively. These effects were not a result of a direct action on protein kinases or phosphatases I, IIA or IIB, but were dependent on extracellular calcium ( $\text{Ca}^{2+}$ ) and were inhibited by the  $\sigma$  receptor antagonist rimcazole. In the present study, intact synaptosomes (P2 fraction) isolated from rat forebrain were prelabelled with  $^{32}\text{P}$ , and preincubated with 1,3-di-O-tolylguanidine (DTG; 3-100  $\mu$ M). Aliquots were incubated for 10s in control (5 mM  $\text{K}^+$ ) or depolarising buffer (41 mM  $\text{K}^+$ ) and samples were run on polyacrylamide-SDS gel electrophoresis (PAGE). Phosphopeptides were digested with V8 protease and fractionated using PAGE. Protease digestion of protein bands for synapsin Ia and Ib demonstrated that DTG inhibited depolarisation-dependent phosphorylation of phosphopeptide fragments of synapsin I which are phosphorylated separately by PKA and CaMK-II, and of MARCKS protein, which is phosphorylated by PKC. In subsequent experiments, the effect of the  $\sigma$  ligands DTG, (+) and (-)pentazocine and BD1008 (1-100  $\mu$ M) on basal intracellular free  $\text{Ca}^{2+}$  levels ( $[\text{Ca}^{2+}]_i$ ) and the increase in  $[\text{Ca}^{2+}]_i$  produced by depolarisation with KCl (45 mM), veratridine (25  $\mu$ M) and 4-aminopyridine (4-AP, 1 mM) was investigated using a fura-2 assay. The  $\sigma$  ligands elicited concentration-dependent decreases in basal  $[\text{Ca}^{2+}]_i$ , and inhibited the rise in  $[\text{Ca}^{2+}]_i$  produced by all the depolarising agents. All  $\sigma$  ligands were more potent to inhibit the rise in  $[\text{Ca}^{2+}]_i$  after depolarisation with veratridine than with KCl and 4-AP. The effects on basal  $[\text{Ca}^{2+}]_i$  were blocked in the presence of 2 mM EGTA, indicating dependence on extracellular  $\text{Ca}^{2+}$ , and inhibited by preincubation with rimcazole (25  $\mu$ M) and the  $\text{Ca}^{2+}$ -channel antagonist,  $\omega$ -conotoxin MVIIC (200 nM; N-type), but not by nifedipine (5  $\mu$ M; L-type). The data suggests that activation of  $\sigma$  receptors leads to decreased entry of  $\text{Ca}^{2+}$  into synaptosomes resulting in changes to protein phosphorylation.

**LOW EXTRACELLULAR CALCIUM ACTIVATES PRODUCTION OF IP3 AND INTERCELLULAR CALCIUM WAVES IN GLIAL CELLS.** S.A. Zanotti, R.C. Collins\* and A.C. Charles. Dept. of Neurology, UCLA, Los Angeles, CA 90095

Changes in  $[\text{Ca}^{2+}]_i$  in primary mixed glial cultures from mouse cortex were measured using fluorescence videomicroscopy and fura2. Replacement of the normal extracellular medium with medium containing no added calcium induced an increase in  $[\text{Ca}^{2+}]_i$  in single cells which propagated as intercellular waves to groups of 10 to 100 cells. Intercellular calcium waves propagated at rates of 5-20  $\mu$ m/sec and were similar in their temporal and spatial characteristics to those induced by mechanical stimulation of a single cell. The low extracellular calcium ( $[\text{Ca}^{2+}]_o$ ) - induced calcium waves were abolished by pretreatment with 1  $\mu$ M thapsigargin and by the phospholipase C inhibitor U73122. The low  $[\text{Ca}^{2+}]_o$  - induced intercellular calcium waves did not occur when extracellular calcium was replaced by extracellular barium. Low  $[\text{Ca}^{2+}]_o$  - induced intercellular waves were unaffected by pretreatment of cells with pertussis toxin, or by replacement of  $[\text{Ca}^{2+}]_o$  with zinc. These studies provide evidence for coupling between  $[\text{Ca}^{2+}]_o$ , IP3, and  $[\text{Ca}^{2+}]_i$  in glial cells. This coupling may be involved in the regulation of glial intracellular calcium stores, as well as in regulation of the extracellular space by glia. Supported by NIH Grants R29-NS32283 and PO1-NS2554-05.

## 153.6

**LOCALIZED CALCIUM RELEASE "CA<sup>2+</sup> SPARKS" AND CALCIUM ACTION POTENTIALS RECORDED IN FLUO-3-LOADED CULTURES OF PITUITARY CORTICOTROPHS USING CONFOCAL SCANNING LASER MICROSCOPY.** J.F. Fiekers<sup>1</sup> and T.J. Heppner<sup>2</sup>, <sup>1</sup>Dept. of Anat. & Neurobiol., <sup>2</sup>Dept. Pharmacology, Univ. of Vermont Coll. of Med., Burlington, VT 05405.

Spontaneous calcium action potentials increase  $[\text{Ca}^{2+}]_i$  in a clonal pituitary cell line of corticotrophs, AtT-20/D16v cells. The present study was undertaken to determine the characteristics of these action potentials in single corticotrophs. Single cells were loaded with fluo-3/AM (2  $\mu$ M) and examined with a BIORAD MRC-1000 CLSM equipped with a krypton/argon laser. Single line scans were made through the cell body as well as cellular processes extending from the cell body. Action potentials were recorded as uniform waves of increasing  $[\text{Ca}^{2+}]_i$  which were initiated at random locations within the cell body. The duration of the waves of  $[\text{Ca}^{2+}]_i$  ranged from 1.5-2.5 sec. Examination of processes from single cells demonstrated that "sparks" of calcium, which represent locally released calcium, were present along cell processes and extended to the terminal ends. The time constant of decay of individual  $\text{Ca}^{2+}$  sparks ranged from 79-200 msec. These results demonstrate that cytosolic calcium can be increased within these cells by (1) global waves of calcium action potentials or (2) localized release of calcium within cytoplasmic domains in the form of  $\text{Ca}^{2+}$  sparks. Future studies will explore the role of these two calcium signals in both release and translocation mechanisms in these neuroendocrine cells.

## 153.8

**2,2'-DICHLOROBIPHENYL INCREASES  $[\text{Ca}^{2+}]_i$  IN CEREBELLAR GRANULE CELL CULTURES: TIME-COURSE, CONCENTRATION-RESPONSE, AND DEPENDENCE ON  $[\text{Ca}^{2+}]_o$ .** T.J. Shafer\*, W.R. Mundy and P.R.S. Kodavanti. Neurotoxicology Division, NHEERL, U.S. EPA, RTP, NC 27711.

Neuroactive polychlorinated biphenyls (PCBs) alter signal transduction processes in neurons. We have demonstrated previously that 2,2'-dichlorobiphenyl (DCB), a neuroactive PCB congener, increases intracellular free  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) in primary cultures of rat cerebellar granule cells as measured using the  $\text{Ca}^{2+}$ -sensitive dye, Fluo-3. In the present experiments, we examined the time-course, concentration-response and dependence on extracellular  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_o$ ) of DCB effects on  $[\text{Ca}^{2+}]_i$  in cerebellar granule cells using Fura-2. In buffer solution containing 2.5 mM  $\text{CaCl}_2$ , basal  $[\text{Ca}^{2+}]_i$  in cerebellar granule cells was  $43 \pm 8$  nM. Exposure of granule cells to 25, 50, and 100  $\mu$ M DCB for 15 min increased  $[\text{Ca}^{2+}]_i$  by approximately 1.5, 3.2 and 15 fold, respectively. During a 60 min exposure to 25 or 50  $\mu$ M DCB,  $[\text{Ca}^{2+}]_i$  increased by 4 and 11 fold, respectively. By contrast, exposure to 100  $\mu$ M DCB resulted in a biphasic response; in a typical experiment,  $[\text{Ca}^{2+}]_i$  increased to a peak of 1749 nM following 30 min of exposure and declined to 1014 nM after 60 min of DCB exposure. When  $[\text{Ca}^{2+}]_o = 0.75$  mM, a 30 min exposure to 50 and 100  $\mu$ M DCB increased  $[\text{Ca}^{2+}]_i$  from  $36 \pm 7$  nM to  $100 \pm 27$  and  $453 \pm 60$  nM, respectively. In buffers nominally free of  $[\text{Ca}^{2+}]_o$ , exposure to 50 or 100  $\mu$ M DCB resulted in a small, transient increase  $[\text{Ca}^{2+}]_i$  in cerebellar granule cells. However, when the buffer solution was returned to 2.5 mM  $\text{CaCl}_2$ ,  $[\text{Ca}^{2+}]_i$  increased to greater than 750 nM in 100  $\mu$ M DCB solutions and began a gradual increase in 50  $\mu$ M DCB solutions. These results confirm our previous observation that DCB alters intracellular  $\text{Ca}^{2+}$  homeostasis in cerebellar granule cells. Furthermore, they provide quantitative measurement of the concentration-response and time-course of DCB effects, and demonstrate that the DCB-induced increase in  $[\text{Ca}^{2+}]_i$  is largely dependent on extracellular  $\text{Ca}^{2+}$ .

## 153.9

**MOBILIZATION MECHANISM OF CALCIUM IN THE EARTHWORM MEDIAN GIANT FIBER.** K. Oka\* and H. Ogawa. Dep. of System Design Engin., Fac. of Sci. and Tech., Keio Univ., Yokohama 223, Japan and Kawachi millibioflight project, ERATO, JRDC, Tokyo 153, Japan

In the ventral nerve cord of the earthworm, *Eisenia foetida*, a median giant fiber (MGF) and a pair of lateral giant fibers (LGFs) are the most major and multifunctional interneurons mediating various behavior from contact reflex to escape response. In the MGF, we have reported  $\text{Ca}^{2+}$  wave propagation (Ogawa et al. 1994). We further investigated the spatio-temporal patterns of intracellular  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) change for elucidating  $\text{Ca}^{2+}$  mobilization mechanisms in the MGF by a confocal laser-scanning microscope and a fluorescent  $\text{Ca}^{2+}$  indicator, Indo-1. Depolarization by a high- $\text{K}^{+}$  saline induced localized elevation of  $[\text{Ca}^{2+}]_i$  in the MGF. Bath-application of high- $\text{K}^{+}$  saline containing 1 mM  $\text{Mn}^{2+}$  reduced the Indo-1 fluorescence, and the  $\text{Mn}^{2+}$ -quenching pattern was heterogeneous in the MGF. From these results, we suggested that voltage dependent  $\text{Ca}^{2+}$  channels (VDCCs) were heterogeneously located on the MGF. Caffeine, which evoked the  $\text{Ca}^{2+}$ -induced  $\text{Ca}^{2+}$ -release (CICR) from intracellular  $\text{Ca}^{2+}$  stores, continuously increased  $[\text{Ca}^{2+}]_i$  in all over the MGF even in a  $\text{Ca}^{2+}$  free saline. This result indicated that the CICR mechanism was homogeneously distributed over the MGF. From the results stated above, we speculate a model of the cellular mechanisms for  $\text{Ca}^{2+}$  wave propagation in the MGF. Electrical excitation of the MGF activates VDCCs heterogeneously located on the MGF. Then, influx of  $\text{Ca}^{2+}$  through VDCCs induces localized increase of  $[\text{Ca}^{2+}]_i$  around the areas of high VDCCs' density, and triggers  $\text{Ca}^{2+}$  release from homogeneously distributed CICR mechanism that propagates  $\text{Ca}^{2+}$  waves.

## 153.11

**DOPAMINE-MEDIATED PHOSPHORYLATION OF NMDA-R1 IN THE RAT NUCLEUS ACCUMBENS.** G. Snyder\*, A. Fienberg, I. Dulubova, A.C. Nairn, and P. Greengard. Lab of Molecular & Cell Neuroscience, The Rockefeller University, New York, NY 10021

There is considerable evidence to indicate that the neurotransmitters dopamine (DA) and glutamate interact to control the activity of medium spiny-type neurons of neostriatum and nucleus accumbens. The mechanism for this interaction involves the regulation of phosphorylation of receptors, ion channels, and membrane pumps. We have now obtained evidence for the regulation of glutamate receptor phosphorylation by dopamine.

Nucleus accumbens slices were prelabelled with  $\gamma^{32}\text{P}$ -phosphate. NR1 was immunoprecipitated and phosphate incorporation quantified by PhosphorImager analysis. Forskolin (1-50  $\mu\text{M}$ ) or DA (100  $\mu\text{M}$ ) increase phosphorylation of NR1, an effect which was mimicked by the D1-type receptor agonist, SKF-82526 (1  $\mu\text{M}$ ), but not the D2-type receptor agonist, quinpirole (1  $\mu\text{M}$ ). DA-induced phosphorylation of NR1 was blocked by an inhibitor of protein kinase A (H-89, 0.5  $\mu\text{M}$ ), but not by calphostin C, a protein kinase C inhibitor (1  $\mu\text{M}$ ). Moreover, the ability of DA to phosphorylate NR1 was strongly attenuated in mice lacking the gene for DARPP-32, a DA-activated inhibitor of protein phosphatase-1 (PP-1).

Taken together, these data provide evidence for the regulation of the glutamate receptor subunit NMDA-R1 by the D1/DARPP-32/PP-1 pathways in neurons of the basal ganglia. (Supported by USPHS Grant DA-10044 to PG and an APDA Research Grant to AF).

## 153.13

**THE NMDA RECEPTOR NR2A/B SUBUNITS BIND TO THE SH2-DOMAINS OF PLC $\gamma$ .** J.W. Gurd\*, N. Bisson and R. Wenthold. Division of Life Sciences, University of Toronto at Scarborough, West Hill, Ont. M1C 1A4 and Lab. Neuro-Otolaryngology, NIH, Bethesda, MD 20892.

Src-homology 2 (SH2) domains bind to phosphorylated tyrosine residues of proteins which are involved in intracellular signalling pathways. The NMDA receptor has recently been shown to be phosphorylated on tyrosine residues (Lau and Huganir, 1995, J Biol. Chem. 270 20036-41). In order to determine if tyrosine phosphorylation of the NMDA receptor might be involved in signal transduction in the postsynaptic cell we have investigated the interaction of the receptor with the SH2 domains of PLC $\gamma$ . Sequences corresponding to the N-proximal and C-proximal SH2 domains of PLC $\gamma$  were expressed as GST-SH2 fusion proteins and were bound to glutathione-agarose (PLC SH2-agarose). The binding of the postsynaptic glycoprotein, GP180, which corresponds to the NR2B subunit of the NMDA receptor (Moon et al., 1994. Proc. Natl. Acad. Sci. 91 3954-58), to SH2 domains was analysed by incubating the con A-binding glycoprotein fraction from rat synaptic junctions with PLC SH2-agarose. Bound glycoproteins were detected by immunoblotting with anti-tyr (P) antibodies. Tyr(P)-GP180 bound to both the N and C-proximal SH2 domains. Incubation of SJs with ATP increased the tyrosine phosphorylation of GP180 and enhanced its binding to SH2 domains. Analysis of immunoblots of SH2-bound proteins with antibodies specific for NR2A and B subunits confirmed that these receptor subunits bound to the SH2 domains and that binding was sensitive to phosphorylation levels; 0.45  $\pm$  0.05% and 6.1  $\pm$  2.0% of NR2A/B immunoreactivity being recovered in the SH2-binding fraction before and after incubation of SJs with ATP respectively. The results suggest that tyrosine phosphorylation may serve to link the NMDA receptor to signalling pathways which involve PLC $\gamma$ .

## 153.10

**MODULATION OF NMDA RECEPTOR FUNCTION IN RAT STRIATUM-INTERPLAY OF KINASES AND PHOSPHATASES.** T. Blank\*, J. Nijholt, H. Behrnsing and J. Spiess. Dept. Molecular Neuroendocrinology, Max Planck Institute Exp. Medicine, Hermann-Rein-Str. 3, 37075 Goettingen, Germany.

Ionotropic excitatory amino-acid receptors can be broadly classified as N-methyl-D aspartate (NMDA) or non-NMDA receptors. Recent studies demonstrated the critical, countervailing role of protein kinases and protein phosphatases in regulating receptor function.

The role of protein phosphorylation in modulating NMDA channels was explored in *Xenopus* oocytes injected with poly (A)<sup>+</sup> mRNA, which was isolated from rat striatal and hippocampal nervous tissue. Two electrode voltage clamp recordings showed that one minute incubation of oocytes with the PKC activator phorbol 12-myristate 13-acetate (PMA; 10 nM) caused comparable potentiation of striatal ( $264 \pm 33\%$ ; n=6) and hippocampal ( $244 \pm 32\%$ ; n=9) NMDA induced currents.

In contrast, incubation with the PKA activator forskolin (50  $\mu\text{M}$ ) for one minute potentiated NMDA-mediated responses only in the striatum ( $145 \pm 3\%$ ; n=4) whereas no effect could be observed with hippocampal NMDA-induced currents.

Interestingly, in rat striatum the PKA-mediated enhancement was inhibited when oocytes were preincubated with 500 nM calyculin A, a nonselective inhibitor of protein phosphatases 1 and 2A. On the other hand, the PKC-induced potentiation of NMDA-mediated responses was not affected by calyculin A injection. When 8-Bromo-cAMP (10  $\mu\text{M}$ ), the membrane-permeable analog of cAMP, was applied, responses were enhanced in a similar way as observed in the experiments using forskolin. Further incubation with PMA (10 nM) for one minute produced additional potentiation to  $413 \pm 60\%$  of control (n = 4). These results demonstrate that both PKA and PKC potentiate NMDA-mediated responses in the striatum, however, different mechanisms appear to be involved. (Supported by the Max Planck Society)

## 153.12

**ROLE OF DARPP-32 IN THE REGULATION OF  $\text{Na}^{+}$ - $\text{K}^{+}$ -ATPase ACTIVITY IN STRIATAL NEURONS.** A. Nishi<sup>1</sup>, G.L. Snyder<sup>1</sup>, A. Fienberg<sup>1</sup>, P. Allen<sup>1</sup>, G. Fisone<sup>1</sup>, A.C. Nairn<sup>1</sup>, A. Aperia<sup>2</sup> and P. Greengard<sup>1</sup>. <sup>1</sup>Lab. of Mol. and Cell. Neurosci., The Rockefeller Univ., NY, NY 10021; <sup>2</sup>Dept. of Woman and Child Health, Karolinska Institute, Stockholm, Sweden.

$\text{Na}^{+}$ - $\text{K}^{+}$ -ATPase (NKA) is a ubiquitous enzyme essential for the maintenance of electrolyte balance. In neurons, NKA maintains the ionic gradients of  $\text{Na}^{+}$  and  $\text{K}^{+}$  that underlie the resting and action potential. We have previously shown that dopamine inhibits NKA activity in striatal neurons. In this study, the regulatory mechanisms utilized by dopamine were investigated in acutely dissociated striatal neurons prepared from C57BL/6 mice. Dopamine (10  $\mu\text{M}$ ) and the D1 agonist SKF82526 (1  $\mu\text{M}$ ) each inhibited NKA activity by 20%. The inhibitory effect of SKF82526 was blocked by the D1 antagonist SCH23390 (1  $\mu\text{M}$ ). The fraction of NKA activity attributable to the  $\alpha 2$  and  $\alpha 3$  isoforms of the enzyme was significantly inhibited by SKF82526 whereas the activity of the  $\alpha 1$  isoform was unaltered. The inhibitory effect of SKF82526 was mimicked by the cyclic AMP analog, 8-Br-cAMP (1 mM), and was blocked by the cyclic AMP-dependent protein kinase (PKA) inhibitor, H89 (2  $\mu\text{M}$ ). In the same cell preparation, dopamine and SKF82526 were found to stimulate the phosphorylation of DARPP-32 (dopamine- and cAMP-regulated phosphoprotein-32kDa), an inhibitor of phosphatase-1 (PP-1). The effect of dopamine on NKA activity was examined in DARPP-32 knock-out mice. Dopamine inhibited NKA activity in striatal neurons from wild type but not DARPP-32 mutant mouse. In contrast, in mice deficient in inhibitor-1, a PP-1 inhibitor closely related to DARPP-32, NKA activity was inhibited by dopamine in both wild type and mutant. The phosphorylation of NKA was also examined using PKA phosphorylation-site specific Ab. The basal level of phosphorylation of NKA found in control condition was not modulated by PKA stimulants such as SKF82526 or forskolin. In conclusion, the inhibitory effect of dopamine is mediated by activation of the PKA pathway, and DARPP-32 plays an essential role in the regulation of NKA activity. (Supported by U.S.P.H.S. Grant MH-40899)

## 153.14

**IDENTIFICATION OF THE PRINCIPAL PHOSPHORYLATION SITE FOR  $\text{Ca}^{2+}$ /CALMODULIN-DEPENDENT PROTEIN KINASE II ON NMDA RECEPTOR SUBUNIT NR2B.** R.V. Omkumar, M.J. Kiely, and M.B. Kennedy<sup>\*</sup>. Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

The NMDA subtype of excitatory glutamate receptors is important for synaptic plasticity during development and in the mature nervous system. The receptor is a heteromultimer of a core subunit, NR1, and one or more regulatory subunits NR2A-D. Phosphorylation of the receptor has been shown to regulate its function in living neurons<sup>1-3</sup>. However, the full range of regulation by various kinases, and the sites on the receptor that govern various functions are still unknown. We have found that  $\text{Ca}^{2+}$ /calmodulin dependent protein kinase II (CaMKII) phosphorylates the NR2B subunit when the kinase is activated in the postsynaptic density fraction *in vitro*. To identify the site of phosphorylation, we used a recombinant fusion protein containing the C-terminal region of NR2B as a substrate for CaMKII *in vitro*. Compared to previously known substrates for CaMKII, the fusion protein showed very high affinity for the kinase as reflected in its  $K_m$ . We purified and sequenced phosphopeptides from the fusion protein, identifying a single principal phosphorylation site in the tail of NR2B. By comparison of phosphopeptide maps, we found that this site is also the principal site phosphorylated in the full length NR2B by CaMK II in the postsynaptic density fraction. Furthermore, this site is phosphorylated *in vivo* in organotypic hippocampal cultures.

## 154.1

Regulation of Mel 1a melatonin receptor expression in ovine pars tuberalis cells by protein kinase C. Perry Barrett\*, Gary Davidson, David Hazlerigg\*, Alison MacLean, Shaun Conway and Peter Morgan. Rowett Research Institute, Bucksburn, Aberdeen AB21 9SB, Scotland and \*Scottish Agricultural College, Aberdeen.

The long exposure of the melatonin receptor to the melatonin signal during extended periods of darkness (16h) in winter, presents a unique case in regulation of receptor function for a G-protein coupled receptor. Previous studies of ours have demonstrated that the mRNA for the ovine Mel 1a receptor is by cAMP through forskolin treatment of ovine PT cells. This elevation can be elevated reversed by melatonin. Furthermore there is a spontaneous increase in Mel 1a mRNA and protein levels in PT cells which can be inhibited by melatonin. This spontaneous increase is not due to a spontaneous increase in cAMP levels. We therefore sought to try and determine the mechanism of the spontaneous increase in Mel 1a mRNA and protein levels and its inhibition by melatonin. Here we present evidence that activation of isoforms of PKC by PMA in ovine PT cells can reverse the induction of the forskolin stimulated increase in Mel 1a mRNA levels. In addition this reversal occurs within the same time frame as the reversal by melatonin. Prolonged treatment of PT cells with PMA depletes several isoforms of PKC. In these depleted cells, melatonin can still reverse the forskolin elevated mRNA levels suggesting that melatonin does not act through the PMA responsive (depleted) isoforms of PKC. However, the involvement of another isoform of PKC is not ruled out, as the PKC inhibitor RO38220 has the same effect as PMA on forskolin elevated mRNA levels. Thus the expression and regulation of the melatonin receptor in ovine PT cells may be regulated by multiple pathways involving different isoforms of PKC. This work was funded by SOAEFD.

## 154.3

CALCIUM SIGNALING RESPONSIBLE FOR CHOLINERGIC ACTIVATION OF PHENYLETHANOLAMINE N-METHYLTRANSFERASE EXPRESSION. K. Morita\* and D.L. Wong, Dept. of Psych. & Beh. Sci., Stanford Univ. Sch. of Med., Stanford, CA 94305

Phenylethanolamine N-methyltransferase (PNMT) has been shown to be transcriptionally regulated through both neural and hormonal mechanisms. However, despite considerable evidence for the activation of PNMT mRNA expression by neural and hormonal factors in the adrenal chromaffin cell, the molecular mechanisms by which these factors regulate PNMT gene expression have not yet been completely elucidated. We have previously shown that a neural factor carbachol (CCh) activates the PNMT promoter as a consequence of stimulating Egr-1 expression, raising the possibility that Egr-1 is one intrinsic factors mediating the neural regulation of PNMT gene expression. To further investigate the mechanism of neural regulation, we examined the effects of various drugs affecting calcium mobilization on CCh-induced PNMT promoter activation in the RS1 cell using a transient transfection assay. The stimulatory action of CCh on the PNMT promoter was not inhibited by organic and inorganic calcium channel blockers, and was completely inhibited by pretreatment of the cells with an intracellular calcium chelator BAPTA/AM. Further studies showed that CCh action was inhibited by pretreatment of the cells with thapsigargin, but not ryanodine. These results suggest that CCh elevates the cytoplasmic concentration of calcium through the stimulation of calcium mobilization from inositol-1,4,5-triphosphate (InsP<sub>3</sub>)-sensitive calcium pools, resulting in the activation of PNMT promoter in the adrenal medullary cell.

## 154.5

ALDEHYDE DEHYDROGENASE (ALDH): LOW EXPRESSION IN RATS THAT OVEREAT FAT AND BECOME OBESE IN A NUTRIENT CHOICE CONDITION. C. Tang\*, P. Zheng, J. Ng, J. Wang and S.F. Leibowitz. The Rockefeller University, New York, N.Y. 10021

Studies in Sprague-Dawley rats, allowed to select from 3 macronutrient diets, have distinguished groups that spontaneously consume a high amount of fat (>40%; HFE) and gain weight, versus others that eat relatively little fat and stay lean (<20%; LFE). In order to identify the genes underlying this difference, mRNA differential display was used to screen high-fat (n=29) and low-fat (n=39) eaters. cDNA was made from the medial hypothalamus dissected from each group. One partial cDNA fragment, showing a 5-fold higher expression in the hypothalamus of a LFE, was isolated, cloned and confirmed with RNase protection assay. This fragment was used to screen a rat hypothalamus cDNA library, and a cDNA of 1.2 kb was identified and sequenced. The sequence had 80% homology with human aldehyde dehydrogenase (ALDH). To test the possible involvement of ALDH in fat metabolism, we analyzed the expression of ALDH in brain of the above two groups of rats, by using a rat ALDH cDNA fragment (from Dr. Pitot at the U. Wisconsin). By using RNA purified from both hypothalamus and midbrain, where ALDH-synthesizing neurons are concentrated, Northern blot showed lower mRNA level of ALDH in HFEs compared to LFEs. Using *in situ* hybridization, ALDH expression, while dense in the midbrain in the area of the substantia nigra (cell number/mm<sup>2</sup> of 257±21 for HFE vs 320±20 for LFE, p<0.05), was also dense in the ependymal layer surrounding the third ventricle of the hypothalamus and, once again, lower in HFEs. The function of this enzyme in the brain in relation to dietary fat is being explored.

## 154.2

MITOCHONDRIA MODULATE Ca<sup>2+</sup> WAVES IN OLIGODENDROCYTES. P.B. Simpson and J.T. Russell\* LCMN, NICHD, NIH.

Methacholine (MCh, 0.1mM) evoked Ca<sup>2+</sup> waves were investigated in cultured rat oligodendrocyte processes. Wave propagation was supported by several regions of enhanced Ca<sup>2+</sup> release kinetics (increased amplitude and rate of rise of response) along these processes. Using dyes that specifically stain mitochondria (JC-1 and DiOC<sub>6</sub>(3)), we observed that groups of 3 or more mitochondria were invariably found in the specialized Ca<sup>2+</sup> release sites along each process. Mitochondria were also found in dense clusters in the cell body. By staining the cell after stimulation with MCh, we found that in the processes, the presence of groups of mitochondria closely correlated with the sites of elevated Ca<sup>2+</sup> release kinetics. Mitochondria were absent in regions of the processes where elevated kinetics were not found. FCCP (1 µM, 2-5 min) inhibited (47/249 cells) or potentiated (97/249) Mch-evoked Ca<sup>2+</sup> signals in different cells within the same field and antimycin (2 µg/ml, 30 min), inhibited MCh responses in most (27/37) cells. A quantitative comparison of the presence of mitochondria with the sites of enhanced Ca<sup>2+</sup> release was carried out using cross-correlation analysis which showed significant positive correlation. Similar positive cross correlation was also found when the patterns of immunocytochemical staining with antibodies for inositol trisphosphate receptors, SERCA pumps and calreticulin were compared with local Ca<sup>2+</sup> release kinetics. It, therefore, appears that both the presence and the activity level of mitochondria may be important for MCh-evoked Ca<sup>2+</sup> waves in oligodendrocytes, and that the regions that support wave propagation can be identified by the presence of mitochondria, which may modulate the level of Ca<sup>2+</sup> near release sites, and by elevated levels of membrane proteins involved in Ca<sup>2+</sup> signaling.

## 154.4

MECHANISMS OF ELEVATED INTRACELLULAR Ca<sup>2+</sup> AND STIMULATION OF TYROSINE HYDROXYLASE GENE EXPRESSION. A. Menezes\*, H. Hiremagalur, R. Zeman\*, E.L. Sabhan, Depts of Biochem. and Molecular Biology and \*Cell Biol. and Anatom. New York Med. Coll., Valhalla, NY 10595.

Elevations of [Ca<sup>2+</sup>]<sub>i</sub> by different mechanisms can activate various calcium sensitive signalling pathways and regulate expression of several genes. We have been investigating the relationships between elevations of [Ca<sup>2+</sup>]<sub>i</sub> and increased tyrosine hydroxylase (TH) gene expression in PC12 cells. Blockers of various types of Ca<sup>2+</sup> channels were added to PC12 cells and their ability to inhibit the rise in [Ca<sup>2+</sup>]<sub>i</sub> and elevation of TH gene expression were monitored by ratioed Fura-2 fluorescence and by Northern blots. The nicotine (100 µM) mediated induction of TH gene expression was inhibited by the L-type channel blocker, nifedipine and was coupled to activation of adenylyl cyclase. Membrane depolarization with 50 mM K<sup>+</sup> elevated [Ca<sup>2+</sup>]<sub>i</sub> from about 50 to 120±8 nM. A N-type channel blocker w-conotoxin GVIA or L-type channel blocker calciseptine as well as dihydropyridine blockers reduced the rise in calcium by about 60%. The Q-type calcium channel blocker w-conotoxin MVIIC blocked almost 90% of the elevation of [Ca<sup>2+</sup>]<sub>i</sub>. In contrast to nicotine, L-type channel blocker did not prevent the rise in TH mRNA in response to 50 mM K<sup>+</sup>, while the Q type blocker inhibited the induction of TH mRNA. These results point to local actions of calcium in the vicinity of the respective channel.

Increased TH expression was also observed with released intracellular calcium stores by 300 nM thapsigargin, a Ca-ATPase inhibitor, which raised [Ca<sup>2+</sup>]<sub>i</sub> to 250-260 nM. Various concentrations of the chelator of intracellular Ca<sup>2+</sup>, BAPTA were loaded to gradually decrease, but not prevent rise in [Ca<sup>2+</sup>]<sub>i</sub>. The results indicate that in the range of 75-175 nM [Ca<sup>2+</sup>]<sub>i</sub>, the elevation of TH gene expression by thapsigargin is directly proportional to the rise in calcium (Grant 251 from Smokeless Tobacco Research Council and fellowship from NY Heart Assoc).

## 154.6

OVINE PLACENTAL SEROTONIN TRANSPORTER (oSERT): CLONING, AND EXPRESSION, J.F. Padbury\*, Y.T. Tseng, B. McGonnigal, K. Penado, M. Stephan and G. Rudnick, Dept. Pediatrics, Brown University, Providence, RI 02905 and Dept Pharmacology, Yale University, New Haven, CT 06510

The placenta is reported to express plasma membrane transporters for biogenic amines. We have demonstrated transporter-dependent placental catecholamine uptake *in vivo*. To confirm the molecular basis for this uptake, we screened an ovine placental cDNA library with human norepinephrine transporter (NET) cDNA. Several clones isolated and partially sequenced showed >87% homology to rat and human SERT. A 5.2 kb clone contained an 1893 bp open reading frame with >90% amino acid identity to human and rat SERT as well as 500 bp 5' untranslated sequence and ~3kb 3' sequence. Expression of this oSERT clone was carried out in transiently transfected HeLa cells. Transport assays using <sup>3</sup>H labeled substrates showed high affinity uptake of <sup>3</sup>H-5HT and little or no transport of <sup>3</sup>H-NE or <sup>3</sup>H-DA. The K<sub>m</sub> for competition with <sup>125</sup>I-βCIT binding in membrane vesicles prepared from transiently transfected HeLa cells is shown in the Table.

Transporter	Competitor	K <sub>m</sub>	Competitor	K <sub>m</sub>
ovine SERT	imipramine	6.6±1.6 nM	serotonin	1±0.2 µM
rat SERT	imipramine	47.8±7.3 nM	serotonin	0.9±0.1 µM

We conclude: The ovine placenta has abundant expression of the neuronal SERT gene which may play a unique role in fetal life and be important in the pathogenesis of the effects of drugs like cocaine which block neurotransmitter re-uptake.

**ROLE OF CREB IN CHRONIC MORPHINE-INDUCED ADAPTATIONS IN LOCUS COERULEUS NEURONS.** S.B. Lane, J. Pineda, V. A. Boundy, K.L. Widnell, G.K. Aghajanian\* and E.J. Nestler. Departments of Psychiatry and Pharmacology, Yale Univ School of Medicine, New Haven, CT.

Activation of locus coeruleus (LC) noradrenergic neurons mediates many of the signs and symptoms of physical opiate withdrawal. Previous work has shown that this activation is mediated in part by up-regulation of the cAMP pathway in the LC. Based on the finding that chronic morphine also increases expression of CREB (cAMP response element binding protein) in the LC (Widnell et al., *Proc Natl Acad Sci USA* 91, 10947, 1994), we have hypothesized a role for this transcription factor in the chronic morphine-induced up-regulation of the cAMP pathway in this brain region. In the present study, we investigated this possibility directly using a recently established CREB antisense oligonucleotide approach (Widnell et al., *J Pharmacol Exp Ther* 276, 306, 1996).

CREB antisense oligonucleotide was infused (20 µg/day) for 5 days via osmotic mini-pumps into the LC unilaterally. This treatment resulted in a partial reduction in CREB levels. This reduction was fully reversible upon cessation of oligonucleotide infusion, and was not seen upon infusion of CREB sense or scrambled oligonucleotide. CREB antisense oligonucleotide infusion decreased levels of certain cAMP pathway proteins in the LC. It also reduced the basal firing rates of LC neurons as well as their responses to 8-bromo-cAMP, consistent with a reduction in cAMP function. In addition, CREB antisense oligonucleotide infusion attenuated the ability of chronic morphine administration to upregulate certain cAMP pathway proteins in the LC as well as to increase basal firing rates of these neurons. However, the usual elevation in firing rates was restored upon application of 8-bromo-cAMP, suggesting an effect of CREB antisense oligonucleotide and morphine at a step proximal to cAMP formation. Together, these studies support a role for CREB in the maintenance of LC neuronal function and in the response of these neurons to chronic morphine administration. (Supported by DA08227.)

**CONVERGENCE OF CALCIUM AND GROWTH FACTOR SIGNALS ON CREB PROTEIN PHOSPHORYLATION IN GLIA.** M. Pende\* and V. Gallo. Lab. Cell. Mol. Neurophysiol., NICHD, NIH, Bethesda, MD 20892.

In rat cortical oligodendrocyte progenitor (O-2A) cells, activation of distinct receptors, such as glutamate-gated channels, G protein-coupled muscarinic receptors and growth factor receptors, lead to immediate early gene transcription initiation within 15 minutes (Pende and Gallo, *Soc. Neurosci. Abstr.* 1995, vol.21, Abstr. 521.5). We are now interested in defining the molecular mechanisms which account for such convergence of signals on gene expression. The selective agonists kainate and carbachol, and the combination of platelet-derived and basic fibroblast growth factors (PDGF and bFGF, respectively) induced phosphorylation of the transcription factor CREB (cAMP response element-binding protein) on Ser-133, as assessed by immunoblotting with a phospho-specific antiserum. The effects of kainate and carbachol on CREB were maximal 5 minutes after receptor stimulation, required calcium influx through the membrane and were inhibited by down regulation of protein kinase-C (PKC). Differently, the effects of PDGF+bFGF on CREB phosphorylation had a later onset, were long-lasting and were not affected by removal of extracellular calcium, or by down regulation of PKC. In transient transfection experiments, both calcium (kainate and carbachol) and tyrosine kinase (PDGF+bFGF) signals stimulated the activity of exogenous GAL4-CREB fusion protein, as measured by luciferase reporter gene expression driven by a promoter containing 5 GAL4 binding sites. Our findings suggest that CREB is a common nuclear target for distinct extracellular signals and is sufficient to induce receptor-mediated gene expression. Ongoing experiments are aimed at identifying the calcium- and growth factor-activated CREB kinases in O-2A cells. Supported by NIH.

## 154.11

**Na<sup>+</sup>/Ca<sup>2+</sup> EXCHANGER ISOFORM EXPRESSION IN DIFFERENT REGIONS OF RAT BRAIN.** L. Yu, L.C. Wince\* and R.A. Colvin. Program in Neurobiology, Ohio University College of Osteopathic Medicine, Athens, OH 45701.

The Na<sup>+</sup>/Ca<sup>2+</sup> exchanger (NCX) is a transmembrane protein that functions to maintain intracellular Ca<sup>2+</sup> homeostasis in neurons and glia. There are three distinct isoforms cloned from rat brain, named NCX1, NCX2, and NCX3. The present study has determined the regional isoform distribution of NCX by RT-PCR and Northern analysis. RT-PCR was performed to amplify the three isoforms from brain stem, cerebellum, frontal cortex, striatum/septum, and hippocampus. Digoxin-11-dUTP labeled probes specific to NCX1, NCX2, and NCX3 were made and each was used to probe a Northern blot consisting of poly(A)<sup>+</sup> RNA isolated from the five regions. RT-PCR showed that all three isoforms were present in each region studied. Northern analysis showed that NCX1 had two transcripts with the size of 15 and 6kb, the 6kb transcript was predominant in brain stem and cerebellum. The 4.8kb NCX2 transcript was most abundant among the three isoforms in all regions except in brain stem where NCX2 expression was lowest. The 6kb NCX3 transcript was also present in each region and the amount was much less than NCX2. It is concluded that all of three isoforms of Na<sup>+</sup>/Ca<sup>2+</sup> exchanger are expressed in brain stem, cerebellum, frontal cortex, striatum/septum, and hippocampus. NCX2 expression is much more abundant than NCX1 and NCX2 indicating this isoform might be responsible for most of the protein transport activity in rat brain. Supported by grants from the Alzheimer's Association.

## 154.8

**MOLECULAR MECHANISMS IN THE CELLULAR SPECIFICITY OF CREB EXPRESSION.** E.R. Covey, K.L. Widnell, J.S. Chen, W.H. Walker, V.F. Habener, and E.J. Nestler. Laboratory of Molecular Psychiatry, Yale Univ. Sch. Med., New Haven, CT; \*Harvard Med. Sch., MGH, Boston, MA.

CREB, cAMP Response Element Binding Protein, belongs to a family of leucine zipper transcription factors that share certain structural motifs and bind DNA as dimers. Perturbation of the cAMP pathway has been shown to regulate transcription of the CREB gene. Activation of the cAMP pathway in primary rat Sertoli cells results in up-regulation of CREB expression, an effect mediated via two CRE motifs found in the CREB promoter (Walker et al., 1995). Previously, we have demonstrated a transcriptionally mediated down-regulation of CREB expression by activation of the cAMP pathway in a locus coeruleus-like (CATH.a) cell line (Widnell et al., 1994, 1996).

In the current study, we examined the effect of stimulation of the cAMP pathway in rat C6 glioma cells. Brief treatment with isoproterenol and IBMX transiently down-regulates levels of CREB immunoreactivity and CRE-binding activity, whereas treatment for 6 to 24 hours significantly increases these levels. These effects are opposite to those observed in CATH.a cells. To determine whether these alterations could be accounted for by an activation of CREB promoter activity, CAT assays were performed in C6 cells transiently transfected with a CREB promoter-CAT fusion plasmid. Treatment for 24 h with isoproterenol and IBMX increases levels of CAT activity in C6 cells transiently transfected with plasmids containing progressive 5' deletions of a 1240 bp fragment of the CREB promoter. Mutations of the CRE or the Sp-1 DNA binding sites in the CREB promoter do not affect this regulation in C6 cells; likewise these mutations do not affect the forskolin-induced decrease in CAT activity observed in CATH.a cells. However, in both cell lines these sites play an important role in basal CREB promoter-driven CAT activity. These results show that regulation of CREB expression is transcriptionally mediated, exhibits an interesting cellular specificity, and may not be explained solely by recognized DNA-binding sites. (Supported by DA 08227.)

## 154.10

**EFFECTS OF AFTERDISCHARGE (AD) ON SYNTHESIS OF EGG-LAYING HORMONE (ELH) AND EXPRESSION OF PRO-ELH MRNA.** W. Lee\* and N.L. Wayne. Dept. of Physiology, UCLA Sch. Med., Los Angeles, CA 90095.

ELH of the marine mollusk, *Aplysia*, is a peptide cleaved from a larger prohormone, pro-ELH. It is synthesized by neuroendocrine bag cells and its secretion is triggered by an electrical AD. We hypothesize that AD stimulates ELH synthesis to replenish peptide loss through secretion and degradation. Previous work showed that depolarization of bag cells with high K<sup>+</sup> increased synthesis of ELH (Berry and Arch, 1981). To investigate whether AD has similar effects, pairs of bag cell clusters (n=3) were dissected from abdominal ganglia and separated from one another. One cluster was electrically stimulated; the other served as an unstimulated control. After initiation of AD, both clusters were incubated in medium containing 100 µCi/ml <sup>3</sup>H-leucine for 4 hr. Clusters were then homogenized and ELH peptide immunoprecipitated. Radioactivity of tritium was determined with a liquid scintillation counter. The result showed that AD stimulated a 2-fold increase in incorporation of <sup>3</sup>H-leucine into ELH. To determine whether this increase was due to increased expression of pro-ELH mRNA, bag cell clusters were dissected and electrically stimulated to AD; clusters from other animals were used as unstimulated controls. The clusters were homogenized 15, 30, 60, 120, and 240 min (n=3 each) after initiation of AD. Total RNA was isolated and subjected to Northern blotting analysis, using a <sup>32</sup>P-labeled ELH cDNA probe. The result showed that AD did not have a consistent effect on the level of pro-ELH mRNA at any of the time points compared to controls. These results indicate that AD stimulates ELH synthesis and this effect may occur mainly at the translational level. Supported by NIH-NS33548 (NLW).

## 154.12

**DISTRIBUTION OF mRNA FOR THE LIM-ONLY PROTEIN GENES *Lmo1*, *Lmo2*, *Lmo3* AND DIFFERENTIAL REGULATION IN THE MOUSE HIPPOCAMPUS FOLLOWING KAINATE-INDUCED SEIZURES.** G.L. Hinks\*, B. Shah, S. J. French, J. A. Poat and M. V. Sofroniew. Parke-Davis Neuroscience Research Centre and MRC Centre for Brain Repair, Cambridge University Forvie Site, Robinson Way, Cambridge, CB2 2QB, U.K.

LIM-only proteins contain cysteine-rich domains involved in protein-protein interactions. Studies suggest these interactions may be with transcription factors hence regulating transcriptional activity. In the present study we determined the expression pattern of the LIM-only protein genes *Lmo1*, *Lmo2* and *Lmo3* in the untreated adult mouse brain and following seizure activity, using radiolabelled oligonucleotide probes and a standard *in situ* hybridization protocol. *Lmo3* mRNA was found in many brain regions most notably throughout the hippocampus, striatum and cortex. *Lmo1* was expressed throughout the hippocampus and striatum, while *Lmo2* was predominately expressed in all regions of the hippocampus. Administration of the excitotoxin kainic acid (30 mg/kg i.p.) resulted in upregulation of *Lmo1* expression in the hippocampus. This was maximal 6 hours after injection returning to basal levels by 24 hours. In contrast, expression of *Lmo2* and *Lmo3* mRNA was reduced throughout the hippocampus with a similar timecourse. These studies suggest a role for lim-only proteins in the adult CNS, and that changes in *Lmo1*, *Lmo2* and *Lmo3* expression are triggered by the cascade of events following excitotoxicity. Supported by the Wellcome Trust, MRC and Parke-Davis & Co. Ltd.

## 154.13

**COMPUTER-ASSISTED IMAGE-AVERAGING STRATEGIES FOR THE TOPOGRAPHIC ANALYSIS OF *IN SITU* HYBRIDIZATION AUTORADIOGRAPHS.** W. Zhao\*, M.D. Ginsberg, J.T. Singer, O.F. Alonso, Y. Looor-Estades, W.D. Dietrich, M.Y.-T. Globus and R. Busto  
Cerebral Vascular Disease Research Center, Dept. of Neurology (D4-5), Univ. of Miami, Sch. of Med., Miami, FL, 33101.

*In situ* hybridization autoradiography is being increasingly applied to the topographic analysis of messenger RNA (mRNA) expression both in the normal brain and in brains of animals subjected to pathological insults. Conventional analysis of macroscopic (whole-section) autoradiographs typically involves densitometric region-of-interest measurements in individual brains; grand means may then be produced for multiple animals. We applied computer-assisted image-averaging strategies (Zhao et al. J Cereb Blood Flow Metab, 15:552-565) to the quantitative topographic analysis of whole-section *in situ* hybridization autoradiographs. The approach is based upon our recent development of a powerful method, termed "disparity analysis", for the alignment and mapping of sequential autoradiographic material. We mapped corresponding coronal sections from different animals into a preselected template to generate a "mean" section and a corresponding "S.D." (standard deviation) section. By setting a thresholding value, one can convert each section into a binary format. Mapping of these binary sections then yields a "frequency" map on which each pixel represents the number of animals affected. The application of these techniques to *in situ* hybridization autoradiographic analysis offers several advantages: a) quantitative mapping of group trends in a series of replicate animals by image-averaging; b) three-dimensional visualization of individual and averaged image data sets; c) quantitative topographic comparisons of mean trends in two or more series of replicate brains hybridized with the same probe but studied under differing physiological or pathological conditions; and d) feature-comparison of *in situ* autoradiographs derived from reaction of adjacent sections of the same brain with several different probes. This method has been applied to brain trauma study in our laboratory.

## 154.15

**REGIONAL DISTRIBUTION, AGE AND SPECIES DIFFERENCES OF BRAIN PHOSPHOLIPASES A<sub>2</sub>.** L. A. Horrocks\*, H.-C. Yang and A. A. Farooqui. Dept. Med. Biochem., The Ohio State Univ., Columbus, OH 43210.

Phospholipases A<sub>2</sub> (EC 3.1.1.4, PLA<sub>2</sub>) are involved in signal transduction and neurodegeneration. Cytosol fractions from bovine, horse, dog, pig, human and rat brains contain two different Ca<sup>2+</sup>-independent PLA<sub>2</sub> (PtdEtn-selective and PlsEtn-selective PLA<sub>2</sub>) that are separable on a Sephadex G-75 column. These enzymes are present in frontal, parietal, occipital, and temporal cortices and hippocampus. The occipital cortex from dog brain shows the highest activity of PtdEtn-selective and PlsEtn-selective PLA<sub>2</sub>. Activities of these enzymes increase rapidly in rat brain during development. Polyclonal antibodies against purified PlsEtn-selective PLA<sub>2</sub>, prepared in rabbits, do not cross-react with types I, II, or III, the 85 kDa cPLA<sub>2</sub> or the Ca<sup>2+</sup>-independent PLA<sub>2</sub> from P388D<sub>1</sub> macrophage-like cells. The PlsEtn-selective PLA<sub>2</sub> in rat is present only in brain and spinal cord. Western blotting experiments confirmed the presence of PlsEtn-selective PLA<sub>2</sub> immunoreactivity in cytosolic fractions, but not in membrane fractions, from horse, dog, pig, human and rat brains. The presence of these phospholipases A<sub>2</sub> in various mammalian brains suggests that they are involved in the regulation of arachidonate release and eicosanoid formation in the CNS.

Supported by NIH grants NS-10165 and NS-29441.

**THE ZINC FINGER PHOSPHOPROTEIN ETO AND THE RIBOSOMAL PHOSPHOPROTEIN P2 LOCALIZE TO RIBOSOMES PRIMARILY IN SPINE SYNAPSES IN THE ADULT RODENT BRAIN.** R. S. Lasher\* and P.F. Erickson†. Depts. of C & S Biology and Medicine†, Univ. Colorado Med. Sch., Denver, CO 80262.

The zinc finger phosphoprotein ETO is part of a fusion protein produced by the 8;21 translocation in acute myelogenous leukemia [Erickson et al., 1996. *BLOOD*, in press]. Relatively high levels of ETO are found in developing brain suggesting that it could be involved in the regulation of some aspect of neural development [Erickson et al., 1994. *Cancer Res.* 54:1782]. Using an affinity-purified polyclonal antibody to ETO we found by Western blotting that ETO is present in synaptic junctions. We then investigated the localization of this protein in adult rat brains by the ABC method. Immunohistochemically, ETO is seen in nuclei and as a fine punctate pattern in regions of neuropil. Preembedding immuno-electron microscopic analysis of ETO localization in the neuropil indicated that it is seen to be associated with 20 nm particles primarily in the postsynaptic elements of spine synapses in e.g., the cerebellum and cerebral cortex. These 20 nm particles were found in groups reminiscent of polyosomes and also were packed against and within the postsynaptic density. The size, distribution and morphology of the particles suggested that they might be ribosomes. Localization of ribosomal proteins was investigated in adult rat brain using two antibodies: a mouse monoclonal antibody to the ribosomal phosphoprotein P2 [Uchiyama et al., 1987. *J. Biol. Chem.* 265:89] and a polyclonal antibody to the ribosomal protein L7a [Ziemiński et al., 1990. *EMBO J* 9:191]. Preembedding immuno-electron microscopic analysis of the localization of these antibodies indicated that P2 and L7a are associated with 20 nm particles in synapses having the same distribution as seen for ETO. However, L7a was also highly concentrated in cytoplasmic rough ER, but ETO and P2 were not seen in this region. These data suggest a possible role for P2 and ETO in the regulation of synaptic protein synthesis. (Supported by NSF IBN-932 0823).

## 154.14

**HIGH LEVEL EXPRESSION OF THE HUMAN HISTAMINE1 RECEPTOR IN SF9 CELLS: PHARMACOLOGICAL AND FUNCTIONAL COMPARISON TO THE MAMMALIAN CHO SYSTEM.** K. Jossion, M. Ercken, G. Van Hecke, M. Jurzak, P. Lijnen, K. L. De Loore, W. H. M. L. Luyten and J. E. Leysen\*. Janssen Research Foundation, Department of Biochemical Pharmacology, 2340 Beerse, Belgium

The baculovirus expression system allows high levels of protein expression in insect cell lines. Functional coupling and/or posttranslational modifications for mammalian proteins, however, might be impaired. The coding region of the human histamine1 (H1) receptor was subcloned into the baculo expression vector pBacpak9. Expression levels in virus infected Sf9 cells were analyzed using [<sup>3</sup>H]pyrilamine binding. Bmax values increased with post-infection time up to 137 pmol/mg protein after 48-72 h; the K<sub>d</sub>-value of [<sup>3</sup>H]pyrilamine was 1.8 nM. Binding competition experiments using various H1-antagonists did not show significant pharmacological differences compared to the human H1 receptor expressed in CHO cells (Bmax values of 7 pmol/mg protein). Functional responses to histamine, however, were more marked in transfected CHO cells. In inositol phosphate measurements a 10-fold and 3-fold rise over basal levels were obtained with 100 μM histamine in CHO and Sf9 cells, respectively. Measurements of intracellular Ca<sup>2+</sup> ([Ca<sup>2+</sup>]<sub>i</sub>) in fura2 loaded cells revealed a 4-fold smaller peak of [Ca<sup>2+</sup>]<sub>i</sub> in the insect cells compared to the CHO cells. The most striking difference was found in measurements of [<sup>3</sup>H]arachidonic acid (AA) release. Histamine stimulated the AA release in CHO cells up to 20-fold, but AA release could be detected in Sf9 cells. Therefore, the insect cell system proved to be useful for binding experiments but suboptimal for functional studies.

## 154.16

**Expression of Elk-1 mRNA and protein in the central nervous system of the rat.** J. Caboche, P. Vanhoute, M. Rogard, C. Pagès, and M.-J. Besson\*. Lab. Neurochimie-Anatomie, IDN, UPMC, URA 1488, 9 Quai St Bernard, 75005 Paris.

The transcription factor Elk-1 plays an important role in the induction of *c-fos* by proliferative and CNS-specific signals that activate MAP kinase cascades. The activated MAP kinases translocate to the nucleus, where one of their major targets is Elk-1, which is part of the protein complex assembled on the *c-fos* SRE. The subsequent phosphorylation converts Elk-1 into a potent transactivator of transcription, thus Elk-1 is a key mediator of signal-directed gene activation.

We have analyzed the expression of Elk-1 in the rat central nervous system at both the mRNA and protein levels. Rat brain sections were probed with a <sup>33</sup>P-cRNA specific for the 3' region of mouse Elk-1. Elk-1 mRNA was highly expressed in neurons of the piriform cortex, the olfactory tubercles, the hippocampus and the cerebellum. Lower levels of Elk-1 hybridization were found in the cerebral cortex, the basal ganglia, and the amygdala. Elk-1 protein levels, revealed by immunocytochemistry using an antibody directed against the C-terminal region of the protein, showed a good correlation with the mRNA signals. One exception was the substantia nigra pars reticulata (SNr), where we detected strong immunoreactivity with the Elk-1 antibody in spite of low mRNA levels. Interestingly we observed immunolabelling in both nuclear and cytoplasmic compartments in all the regions investigated. Furthermore some dendrites also showed strong labeling. These results suggest that, in the central nervous system, Elk-1 might change its subcellular compartmentalization upon activation and/or may have other functions in addition to gene regulation. Intriguingly Western blot analyses using specific N-terminal or C-terminal Elk-1 antibodies reveal two isoforms of the protein in nervous tissues. One corresponds to the full length protein (52 kD) found in PC12, Cos7, or NIH3T3 cells, and the other appears to be a novel, smaller protein (45 kD) that is presently under investigation.

## 154.18

**EXPRESSION OF ARRESTIN, PHOSDUCIN AND OPSIN IN HIGHLY RESTRICTED SMALL NUMBERS OF CELLS IN THE MOUSE BRAIN.**

K. Sunayashiki-Kusuzaki\*, T. Kikuchi<sup>1</sup>, E. Wawrousek<sup>2</sup> and T. Shinohara<sup>3</sup>; <sup>1</sup>The Center for Ophthal. Res., Brigham and Women's Hospital, Harvard Medical School, 221 Longwood Ave. Boston, MA 02115. <sup>2</sup>Section on Molecular and Developmental Biology, NEI, NIH, Bethesda, MD 20892

Arrestin is expressed in the retinal photoreceptor rod cells and pinealocytes. To examine whether it is expressed in the brain tissue, we constructed a fusion gene which has well characterized a mouse or a bovine arrestin promoter and a Lac Z reporter gene, and generated three lines of transgenic mice having the fusion gene. (1) Serial sections of the brains were stained with X-Gal after fixation. The positive cells of β-galactosidase were found in the habenula commissura (chb), amygdala, ventral tegmental area (VTA) and superior colliculus in adult transgenic mice brain. (2) Immunohistochemistry on the brain sections with the antibody probes revealed that arrestin and phosducin were expressed at high levels and opsin was expressed at low level in the same brain regions. We found new cell types in brain which express arrestin, phosducin and opsin in these regions. Immunostaining for the 5-hydroxyindole-O-methyltransferase, an enzyme catalyzes a terminal step of melatonin synthesis, was also positive in the same cell types of chb and VTA. (3) The pattern of expression of these proteins is similar to that of pinealocytes but not that of retinal photoreceptor cells. These findings suggest that melatonin is synthesized and secreted from these cells. It is highly probable that a diurnal cycle of the brain cells is controlled by melatonin secreted from those cells. In contrast, melatonin from pineal gland regulates the cycle in the rest of the body through bloodstream.

## 155.1

PROTEIN INTERACTIONS ASSOCIATED WITH HOMEODOMAIN PROTEIN MEDIATED SECOND MESSENGER STIMULATION OF THE DOPAMINE  $\beta$ -HYDROXYLASE PROMOTER. D.J. Swanson\*, E. Zellmer, E.J. Lewis. Dept. Biochemistry and Mol. Biol., Oregon Health Sci. Univ., Portland OR, 97201

An enhancer element of the rat dopamine  $\beta$ -hydroxylase (DBH) gene that is necessary for tissue specific and second messenger mediated transcriptional activation contains two homeodomain (HD) core sites adjacent to two putative CRE-like domains. We have shown that Arix, an adrenergic-tissue specific homeobox protein which binds to this enhancer, is able to confer adrenergic-like regulation of the DBH promoter in non-adrenergic cells through a synergistic interaction with second messenger stimulation. This synergistic activation suggests an interaction of Arix with other nuclear proteins within the context of this DBH enhancer, termed the HD/CRE.

In an electrophoretic mobility shift assay (EMSA), four distinct protein-DNA complexes are formed using the HD/CRE probe and nuclear extracts from either unstimulated or cAMP/phorbol ester stimulated PC12 cells, suggesting that proteins binding to the enhancer region do so constitutively. Oligonucleotide competition indicate that HD and CRE-like sites contribute to distinct protein-DNA complexes independently and as compound sites. While competition with a consensus CRE indicated that CRE binding proteins contribute to some HD/CRE-protein complexes, antibody supershift analyses demonstrated that neither CREB nor c-fos are constituents of these complexes.

We have also co-purified five distinct proteins with molecular weights ranging from 65-300kD using an Arix affinity assay. To date Western blot and immunoprecipitation analyses have ruled out the second messenger-related transcriptional co-activators CBP and p300 as candidates for the highest molecular weight protein (MR 265-300kD). Further analyses are in progress to identify these candidate HD/CRE and Arix binding proteins as possible co-regulators of tissue-specific DBH transcription.

Supported by NIH Grant GM38696 (EJL).

## 155.3

ACTIVATION OF AP-1 TRANSCRIPTION FACTORS AFTER EXTRACELLULAR ATP TREATMENT IN PC12 CELLS. Y.-M. Chen and A.Y. Sun\*. Department of Pharmacology, University of Missouri, Columbia, MO 65212

Studies in our laboratory indicate that extracellular ATP may induce cell death by reactive oxygen insults. The ATP-induced cell death is  $P_{2X}$  receptor specific and is dependent on  $Ca^{++}$ . Lipid peroxidation of cell membranes occurred immediately after the addition of ATP. In addition a delayed cell death was observed. The purpose of this study was to examine how  $Ca^{++}$  causes transcription activation of the neuronal-death cascade. Results using a gel shift technique indicated that ATP treatment greatly increases AP-1 DNA binding in nuclear extracts from PC12 cells. Supershift assays using anti-Jun and anti-Fos antibodies demonstrated that Fos protein formed part of the AP-1 heterodimer, but not Jun protein. The changes from the normal Jun/Fos complex may alter the AP-1 DNA binding and transcriptional properties. The activation of AP-1 binding was  $P_2$  receptor specific since suramin blocked the activation. Both cyclohexamide and genistein also blocked the ATP activation of AP-1 binding activity indicating that the activation requires new protein synthesis and protein phosphorylation, especially by tyrosine kinase. This result indicates that the  $Ca^{++}$ -induced oxidative stress as elicited by ATP may lead to an activation of a specific AP-1 activity. (Supported in part by NIH Grant #AA02054)

TNF SIGNALING AND PROTECTION AGAINST  $A\beta$  TOXICITY: ROLES FOR NF $\kappa$ B AND MnSOD. G.H. Umberger\*, A.J. Bruce, S.W. Barger, F.W. Holtzberg, S.M. Steiner, and M.P. Mattson. Sanders-Brown Center on Aging, Dept. of Anatomy and Neurobiology, and Dept. of Biological Sciences, University of Kentucky, Lexington, KY 40536.

We previously reported that the cytokine tumor necrosis factor- $\alpha$  (TNF), which is released from active microglial cells and has been shown to be increased in Alzheimer's Disease (AD) brains, suppresses reactive oxygen species (ROS) formation and protects primary neurons from  $A\beta$  toxicity (PNAS 92:9328-9332). We now describe signaling pathways that mediate these neuroprotective actions of TNF. Exposure of cultured hippocampal and cortical neurons to TNF resulted in significant time-dependent increases in MnSOD activity and protein levels; TNF had little or no effect on other antioxidant enzymes, including Cu/Zn-SOD and catalase. One TNF signaling pathway involves ceramide release (from membrane-associated sphingomyelin) and activation of the transcription factor NF $\kappa$ B. We found that C2-ceramide mimics the effect of TNF on MnSOD activity. To determine if a specific increase in MnSOD protein and activity levels is sufficient to protect nerve cells from  $A\beta$  toxicity, we stably transfected pheochromocytoma (PC6) cells with human MnSOD. These cells exhibited a 2-3 fold increase in MnSOD protein and activity levels, and no changes in the levels of Cu/Zn-SOD or catalase.  $A\beta$  induced time-dependent increases in peroxide formation and subsequent cell death in control cells, while MnSOD over-expressing PC6 cells were protected from both manifestations of  $A\beta$ -induced injury. These results suggest that TNF decreases  $A\beta$ -induced oxidative stress in neurons through the induction of MnSOD by NF $\kappa$ B, and suggest that TNF associated with plaques could serve a neuroprotective function. (supported by the NIH).

## 155.2

SERUM RESPONSE ELEMENT (SRE)-MEDIATED INDUCTION OF zif268 GENE IN PC12D CELLS IS INHIBITED BY INCREASES IN INTRACELLULAR CALCIUM. T. Ebihara and D. Saffen\*. Institute for Brain Research, The University of Tokyo, Hongo 7-3-1, Tokyo 113, Japan.

We have previously reported that mRNA encoding the transcription factor Zif268 is rapidly induced following stimulation of m1 muscarinic acetylcholine receptors in PC12D cells, a subline of PC12 that undergoes accelerated neuronal differentiation in the presence of nerve growth factor (NGF). In the present study we examined the molecular mechanism of zif268 induction using expression vectors containing specific segments of the zif268 promoter linked to a luciferase reporter gene. As expected, a 0.5 kb proximal fragment of the zif268 promoter containing 6 SRE-like sequences was found to mediate the induction of the luciferase activity by NGF. Unexpectedly, however, this promoter fragment did not induce the reporter following exposure to carbachol, phorbol ester or calcium ionophore. Carbachol also failed to induce luciferase mRNA, but did rapidly increase levels of endogenous zif268 mRNA. These results are surprising, because NGF, carbachol, and the other agents are all effective in rapidly activating MAPK, the kinase thought to be required for SRE-dependent induction of the c-fos gene. Also unexpectedly, prior exposure to carbachol or calcium ionophore was found to reduce NGF-mediated induction of the luciferase reporter by 50%. A similar inhibition obtained with membrane-depolarizing concentrations of KCl, was specifically blocked by the L-type calcium channel blocker nifedipine. Taken together, these data indicate that increases in intracellular calcium antagonize NGF-mediated gene induction. This inhibition was not observed for a luciferase expression vector containing only a single SRE, suggesting that calcium does not block the SRE directly, but rather requires additional DNA sequences. (Supported by grants from the Ministry of Education, Science, and Culture of Japan)

## 155.4

GLUCOCORTICOIDS ATTENUATE AP-1 AND NF $\kappa$ B DNA BINDING ACTIVITIES IN RAT BRAIN: IMPLICATION OF GLUCOCORTICOIDS IN NEURONAL DEGENERATION. T. Unlap and R.S. Jope\*. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama at Birmingham, Birmingham, AL 35294-0017.

Neuronal degeneration occurs in various diseases including aging and Alzheimer's disease, in part due to oxidative stress, characterized by excess reactive oxygen intermediates. Neurons counteract oxidative stress by increasing antioxidants, DNA and protein repair enzymes, and free radical scavenging enzymes (FRSE). Two transcription factors, AP-1 (heterodimer of Jun/Fos) and NF $\kappa$ B (heterodimer of p50/p65), activate the FRSE system. Aging and Alzheimer's disease are characterized by high circulating glucocorticoid levels which can exacerbate neuronal degeneration. We have previously shown that this involves the attenuation of AP-1 DNA binding activity by glucocorticoids through a mechanism of protein-protein interaction between the glucocorticoid receptor (GR) and c-Jun. To study if this also involved the NF $\kappa$ B transcription factor, we examined NF $\kappa$ B DNA binding activity by gel mobility shift assay in rat cortex and hippocampus after 1, 3, 6 or 24 hr of dexamethasone (DEX; 2mg/kg) treatment. We found that DEX attenuated NF $\kappa$ B activity in both brain regions. It is unlikely that this effect of DEX is mediated through I $\kappa$ B since cytosolic I $\kappa$ B levels were significantly attenuated as well. With a p65 antibody, the GR and p65 coprecipitated. This may suggest that high circulating glucocorticoid levels, as found in aging and Alzheimer's disease, contribute to neuronal degeneration by compromising neurons' ability to counteract oxidative stress by attenuating AP-1 and NF $\kappa$ B DNA binding activities through a mechanism of protein-protein interaction between the GR and constituents of AP-1 and NF $\kappa$ B, and thus partially disabling the FRSE system.

## 155.6

OXIDATIVE STRESS IMPAIRS CHOLINERGIC SIGNALING. X. Li\*, L. Song, and R.S. Jope. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama at Birmingham, Birmingham, AL 35294-0017.

Oxidative stress appears to contribute to neuronal dysfunction in a number of neurodegenerative conditions, notably Alzheimer's disease in which cholinergic receptor-linked signal transduction activity is severely impaired. To test if oxidative stress could contribute to such deficits in cholinergic signaling, responses to carbachol were measured in human neuroblastoma SH-SY5Y cells exposed to  $H_2O_2$ . DNA binding activities of two transcription factors that are responsive to oxidative conditions, AP-1 and NF $\kappa$ B, were measured in nuclear extracts.  $H_2O_2$  and carbachol individually induced dose- and time-dependent increases in AP-1 and NF $\kappa$ B. In contrast, when given together  $H_2O_2$  concentration-dependently (30 to 300  $\mu$ M) inhibited the increase after carbachol in AP-1. Carbachol's stimulation of NF $\kappa$ B was not inhibited except with a high concentration (300  $\mu$ M) of  $H_2O_2$ , which was associated with impaired activation of protein kinase C. Lower concentrations of  $H_2O_2$  (30 to 300  $\mu$ M) inhibited carbachol-induced [ $^3H$ ]phosphoinositide (PI) hydrolysis and this inhibition correlated ( $r = 0.95$ ) with the  $H_2O_2$  concentration-dependent inhibition of carbachol-induced AP-1. Activation of [ $^3H$ ]PI hydrolysis by the calcium ionophore ionomycin was unaffected by  $H_2O_2$ , indicating that phospholipase C and phosphoinositides were impervious to this treatment. In contrast, activation with NaF of G-proteins coupled to phospholipase C was concentration-dependently inhibited by  $H_2O_2$ , indicating that G-protein function was impaired by  $H_2O_2$ . These effects of  $H_2O_2$  are similar to signaling impairments reported in Alzheimer's disease cortical membranes which involve deficits in receptor- and G-protein-stimulated PI hydrolysis, but not phospholipase C activity. Thus, these findings demonstrate that oxidative stress may contribute to impaired PI signaling in Alzheimer's disease and that oxidative stress can differentially influence transcription factors activated by cholinergic stimulation. Supported by NIH grant AG06569.

## 155.7

INTERACTIONS OF MEMBRANE LIPIDS AND OXIDATIVE STRESS ON AP-1 BINDING IN PC-12 CELLS. I. Cantuti-Castelvetri\*, W. Hassan<sup>1</sup>, E. Paulson<sup>1</sup>, N.A. Denisova and J.A. Joseph. USDA Human Nutrition Research Ctr. on Aging at Tufts Univ., <sup>1</sup>Department of Biochemistry, Tufts University, School of Medicine, Boston MA, 02111.

Research suggests that interactions between oxidative stress and altered brain membrane lipid composition in senescence (e.g., increased cholesterol/phospholipid ratios, sphingomyelin levels, etc.) may be responsible for the age-related deficits seen in  $Ca^{2+}$  activity. Studies from our labs have shown that exposure of PC-12 cells to non-lethal  $H_2O_2$  concentrations in growth media for 30 min. increased pre-K<sup>+</sup>-stim  $Ca^{2+}$  levels and post-stim recovery time ( $Ca^{2+}$  clearing), while decreasing the K<sup>+</sup>-stimulated  $Ca^{2+}$  depolarization levels.  $Ca^{2+}$  levels have been proposed to play important roles in AP-1 transcription factor regulation, and events such as long-term potentiation. Furthermore, AP-1 is highly responsive to oxidant stress stimuli. Therefore, we examined the binding and transcription regulation of AP-1 by  $H_2O_2$  and altered lipid composition. Cholesterol was shown to increase overall basal AP-1 binding compared to that of  $H_2O_2$  stimulated cells, but had no effect on  $H_2O_2$  induced AP-1 binding. Interestingly, sphingomyelin was shown to have no effect on basal AP-1, but dramatically increased AP-1 binding in response to  $H_2O_2$  treatment. These results demonstrate that membrane components can dramatically alter DNA-binding properties of the oxidative stress regulated AP-1 protein. (Supported by USDA intramural)

## 155.9

ANTISENSE RNA IDENTIFIES  $G_{\alpha 12}$  AS A MEDIATOR OF AGONIST INHIBITION OF M-CURRENT IN SYMPATHETIC NEURONES, P. Delmas, F. Abogadie, J. Haley, Y. Vallis, and N.J. Buckley and M.C. Caulfield\*. Wellcome Laboratory for Molecular Pharmacology, Dept. Pharmacology, University College London, U.K.

We have investigated the role of  $G_{\alpha 12}$  in mediation of agonist inhibition of the M-current ( $K^+_M$ ) in cultured superior cervical ganglia (SCG) neurones. G-protein immunostaining and in situ hybridization in SCGs showed that  $G_{\alpha 12}$  is expressed only in neurones whilst  $G_{\alpha 0}$  is expressed in both neurones and non-neurones. We used a PCR-cloning strategy to make expression plasmids in the pBK-CMV vector containing antisense sequences to the 3'untranslated region of  $G_{\alpha 12}$  and the coding region of rat  $G_{\alpha 0}$ .  $G_{\alpha 12}$ -antisense-injected SCGs show diminished immunostaining for  $G_{\alpha 12}$ , but not for  $G_{\alpha 0}$ . Conversely,  $G_{\alpha 0}$ -antisense-injected SCGs show diminished staining for  $G_{\alpha 0}$ , but not for  $G_{\alpha 12}$ . Intracellular injection of the  $G_{\alpha 12}$  antisense construct in rat SCG cells resulted in a reduction of muscarinic inhibition of the  $K^+_M$  48 hours later (300nM Oxo-M inhibition: control,  $30 \pm 7\%$ , n=3; injected,  $6 \pm 1\%$ , n=8). This inhibition was overcome by increasing the concentration of oxo-M 10 fold. Antisense constructs for  $G_{\alpha 0}$  did not alter  $K^+_M$  inhibition. Thus, muscarinic suppression of the  $K^+_M$  can be mediated via 2 different  $G_q$  subunits,  $G_{\alpha 12}$  and  $G_{\alpha q}$  (see accompanying abstract), belonging to 2 different classes of pertussis toxin insensitive G-proteins.

## 155.11

A NOVEL REGULATION OF EXPRESSION OF THE  $\alpha$ -SUBUNIT OF THE G STIMULATORY PROTEIN,  $G_{\alpha s}$ , BY DOPAMINE VIA D-1 DOPAMINE RECEPTORS. A. Sidhu\*, K. Kimura, Z-B. Tong, and D. Pilch Lab. Neurochem., Georgetown Univ. Med. Ctr., Washington D.C. 20007.

Chronic exposure of human neuroblastoma SK-N-MC cells, endogenously expressing D-1 dopamine receptors, to dopamine (DA) produces a progressive loss (upto 70%) of immuno-detectable membrane-bound levels of the  $\alpha$ -subunit of  $G_s$ . The loss in  $G_s$  protein was accompanied by a reduced ability (64.3) of NaF-mediated stimulation of adenylyl cyclase activity, after reconstitution of DA-treated  $G_s$  with cyc<sup>3</sup> membranes. This loss of functional  $G_s$  activity was independent of cAMP levels. The reduction in  $G_s$  protein was manifest at the transcriptional level and  $G_s$  mRNA levels were attenuated to  $56.5 \pm 10\%$  of control.  $G_s$  mRNA levels were also attenuated by the D-1 agonist SKF R-38393 and the attenuation by agonists was blocked by the D-1-selective antagonist, SCH 23390. Accumulated levels of cAMP did not modulate  $G_s$  mRNA levels. These results indicate that in SK-N-MC cells,  $G_s$  is subject to novel regulatory controls by DA, acting specifically via D-1 DA receptors.

Supported by grant NS 29685.

CYTOKINE INDUCES iNOS AND sPLA<sub>2</sub> IN ASTROCYTES. W. Li, J. Xia\*, M. Hannink and G.Y. Sun Biochem. Dept and Nutritional Sciences, Univ. Missouri, Columbia, MO 65212.

Astrocyte is known to have multifunctional roles in the brain including conferring various defense mechanisms against neuronal injury. Recent studies indicate the ability of astrocytes to respond to endotoxin (LPS) and pro-inflammatory cytokines such as tumor necrotic factor  $\alpha$  (TNF $\alpha$ ) and interleukin 1 $\beta$  (IL-1 $\beta$ ). This signaling system results in the dissociation of a RelA homodimer from its inhibitory kappa B protein (I $\kappa$ B) and subsequent binding of RelA to DNA (Diehl et al., J. Biol. Chem. 270: 2703, 1995). Cytokines are known to induce the increase in mRNA encoding the secretory phospholipase A<sub>2</sub> (sPLA<sub>2</sub>) and nitric oxide synthase (NOS). In this study, we examined the pattern of cytokine induction for sPLA<sub>2</sub> and NO in an immortalized astrocyte cell line (DITNC). Although TNF $\alpha$  was the weakest in stimulating sPLA<sub>2</sub> release into the culture medium, it could synergistically enhance sPLA<sub>2</sub> release when added in combination with IL-1 $\beta$  or LPS. Exposure of cells to staurosporine, a protein kinase C (PKC) inhibitor, abolished completely the cytokine induction of sPLA<sub>2</sub> mRNA, suggesting of an involvement of PKC. When these cells were tested for induction of NO, neither TNF $\alpha$ , IL-1 $\beta$  or LPS alone was able to stimulate NO release significantly as compared to interferon  $\gamma$  (IFN $\gamma$ ). In addition, IFN $\gamma$  together with TNF $\alpha$  and/or IL-1 $\beta$  greatly synergized NO release. Northern blot analysis showed the induction of iNOS mRNA in DITNC cells. Induction of iNOS mRNA could be inhibited by L-N<sup>G</sup>-(1-iminoethyl)lysine acetate (NIL), a specific iNOS inhibitor. Interestingly, cytokine induction of sPLA<sub>2</sub> mRNA was enhanced by NIL. These results indicate the presence of both commonalities and differences in cytokine induction of iNOS and sPLA<sub>2</sub> in astrocytes. (Supported by MU Res. Board & AA 06661 from NIH).

## 155.10

ANTISENSE RNA DISTINGUISHES BETWEEN  $G_{\alpha q}$  AND  $G_{\alpha 11}$  MEDIATED AGONIST INHIBITION OF M-CURRENT IN SYMPATHETIC NEURONES, F. Abogadie\*, P. Delmas, J. Haley, Y. Vallis, G. Milligan, M.C. Caulfield and N.J. Buckley. Wellcome Laboratory for Molecular Pharmacology, Dept. Pharmacology, University College London, U.K. §Dept. Biochemistry, University of Glasgow, Scotland.

We have used an antisense approach in order to determine the involvement of  $G_{\alpha q}$  or  $G_{\alpha 11}$  in the muscarinic inhibition of the M-current ( $K^+_M$ ) in cultured superior cervical ganglia (SCG) neurones. A PCR-cloning strategy was used to make pBK-CMV constructs containing antisense sequences to the coding region of rat  $G_{\alpha 0}$  and the 3'untranslated regions of rat  $G_{\alpha q}$  and  $G_{\alpha 11}$ . SCG neurones were injected with anti- $G_{\alpha q}$ , anti- $G_{\alpha 11}$  and anti- $G_{\alpha 0}$  (as controls) plasmid expression vectors (400  $\mu$ g/ml). The ability of Oxo-M (a muscarinic agonist) to inhibit  $K^+_M$  was checked 48 h after injection using the perforated patch method. In neurones injected with anti- $G_{\alpha q}$  expression vectors, the inhibition of  $K^+_M$  by 1 and 3  $\mu$ M Oxo-M was significantly ( $P < 0.01$ ) less (8% and 19%, respectively; n=9) than in either noninjected or anti- $G_{\alpha 0}$  injected neurones (56% and 75%, respectively), whereas in anti- $G_{\alpha 11}$  neurones (n=8) the extent of  $K^+_M$  inhibition was similar to that found either in non-injected or anti- $G_{\alpha 0}$  injected cells. However, a subpopulation (5/8) anti- $G_{\alpha 11}$  injected cells did show a diminished attenuation of  $K^+_M$ . G-protein immunostaining and in situ hybridization in SCGs showed that  $G_{\alpha q}$  is expressed in all neurones but not in glia.  $G_{\alpha 11}$  is expressed only in a subpopulation of neurones while  $G_{\alpha 0}$  is expressed in all cells.  $G_{\alpha q}$ -antisense-injected SCGs show diminished staining for  $G_{\alpha q}$ , but not  $G_{\alpha 0}$ . These data strongly suggest that the inhibition of  $K^+_M$  by muscarinic receptors is primarily mediated via a  $G_{\alpha q}$  protein.

## 155.12

INCREASED EXPRESSION OF PROGESTERONE RECEPTOR MRNA INDUCED BY A D<sub>1</sub> DOPAMINE RECEPTOR AGONIST IN BRAIN. C.M. Isbister\* and P.B. Reiner, Kinsmen Laboratory of Neurological Research, University of British Columbia, Vancouver, BC, V6T 1Z3.

Stimulation of the cAMP second messenger cascade has been shown to activate reporter gene transcription by the estrogen receptor in a "ligand-independent" fashion in various cell lines. Since estrogen receptors are known to induce progesterone receptor (PR) gene expression in many tissues including brain, we used PR gene expression as a reporter assay to test the hypothesis that such convergence occurs in the intact mouse brain. Ovariectomized adult female mice were injected (i.p.) once daily for 4 days with either control vehicle, 11  $\mu$ g of estradiol, or 30mg/kg of the D<sub>1</sub> receptor agonist SKF 38393. Semi-quantitative RT-PCR was used to measure expression of PR mRNA, normalized relative to expression of tubulin mRNA. Since both D<sub>1</sub> receptors and PR mRNA are found in high abundance in the prefrontal and cingulate cortex, we focused our investigations on regulation of cortical PR mRNA. As expected based upon previous receptor binding data, we found that estradiol markedly increased cortical PR mRNA. The D<sub>1</sub> agonist SKF 38393 also increased cortical PR mRNA; quantitative densitometry demonstrated that the increase evoked by SKF 38393 was 165% of that induced by estradiol. Our working hypothesis is that dopamine receptor activation results in ligand-independent activation of estrogen receptor transcriptional activity, ultimately resulting in up-regulation of PR gene expression in the brain.

## 155.13

**INDUCTION OF c-FOS mRNA BY LEAD IN PC 12 CELLS, K. Kim, T. Chakraborti, G.W. Goldstein and J.P. Bressler\*,** Depts. of Neurology, Pediatrics and Environmental Health Sciences, The Johns Hopkins University and The Kennedy Krieger Research Institute, Baltimore, MD 21205.

In children, subtle defects in behavior, psychomotor development, and learning are associated with exposure to low levels of lead ( $Pb^{2+}$ ). The mechanisms for these effects are unknown. It has been postulated that long-term neuronal changes such as those that occur during development or learning require the expression of specific genes. Thus,  $Pb^{2+}$  may affect neurodevelopment by interfering with the regulation of gene expression. Here, we demonstrate that  $Pb^{2+}$  induces expression of the immediate early response gene, c-fos. Induction of c-fos mRNA by  $Pb^{2+}$  was concentration- and time-dependent. In the presence of cycloheximide, the c-fos gene was superinduced by addition of  $Pb^{2+}$ . This ability of  $Pb^{2+}$  to induce c-fos mRNA was not duplicated by adding  $Cd^{2+}$  or  $Zn^{2+}$ . Induction by  $Pb^{2+}$  was inhibited by actinomycin D, a blocker of transcription. Also, c-fos mRNA was less stable than glyceraldehyde phosphate dehydrogenase mRNA in cells exposed to  $Pb^{2+}$ . Since the c-fos gene encodes a transcription factor, our data suggest that  $Pb^{2+}$  has the potential to regulate the expression of other genes.

**C-FOS GENE EXPRESSION IN GRANULE CELLS DURING CEREBELLAR DEVELOPMENT AND FOLLOWING KAINIC ACID INJECTION. S. Chen\* and D.E. Hillman,** Department of Otolaryngology and Physiology/Neuroscience, New York University Medical Center, New York, NY 10016.

Immediate early genes (IEG) couple short term external stimuli to long term cellular phenotypic changes by regulating late response target genes. The IEG, c-fos, maps to physiologically active neurons corresponding with 2-deoxyglucose. We examined c-fos expression in albino rats from birth to postnatal day 60 and after kainic acid administration into adults which normally have low baseline c-fos expression. We found that the c-fos gene is transiently expressed in granule and basket cells during postnatal development and in granule cells of adult animals following kainic acid administration.

Fos positive cells were found in the internal granular layer of ventral lobules at P5 and increased in all folia by P10. These reactive cells were distributed in clusters across the granular layer reaching their highest intensity at P12. Meanwhile, basket cells, which have reached their destination in the lower part of the molecular layer, also exhibited strong Fos protein staining. At P15, Fos protein labeling gradually declined and was no longer detectable by P21 and later. In adult rats, c-fos expression was induced in granular cells within 1 hour after a sub-seizure dosage of kainic acid (8mg/kg), peritoneously. The pattern of Fos protein distribution resembled developing granular cells.

Our results support the hypothesis that the c-fos gene plays a role in signaling transcription of target genes related to circuitry establishment as well as neuronal plasticity. Supported by NIH-NINDS NS-13742 and NIA AG-09480.

## 155.17

**FOSB "KNOCK-OUT" MICE: LOSS OF CHRONIC FRAS AND ABNORMALITIES IN COCAINE-REGULATED BEHAVIOR. N. Hiroi\*, J.R. Brown\*, C. Haile\*, M. E. Greenberg\*, E.J. Nestler\*,** 1 Div. of Mol. Psychiatry, Yale Univ. Sch. of Med., New Haven, CT 06508; 2 Children's Hospital, Harvard Med. Sch., Boston, MA 02115.

We have shown that chronic treatment with cocaine or electroconvulsive seizures (ECS) induces chronic FRAs in a region-specific manner in brain. Chronic FRAs are 35-37 kDa proteins recognized by an antiserum raised against a peptide sequence common to Fos family members. The chronic FRAs are immunochemically related to deltaFosB, a truncated splice variant of FosB, but their precise identity has remained elusive (*Mol. Pharmacol.* 48, 880, 1995). We have now used mutant mice, in which the fosB gene has been disrupted by homologous recombination, to further study the identity of the chronic FRAs as well as their physiological role in cocaine action.

Chronic FRAs, and their associated AP-1 DNA binding activity, were induced by chronic cocaine and chronic ECS treatments in specific brain regions of wild-type mice, as observed previously in rats. In contrast, induction of the chronic FRAs and the associated AP-1 binding activity was completely absent in fosB mutant mice. These findings clearly establish the chronic FRAs as products of the fosB gene, perhaps a variant of deltaFosB (see also Chen et al., this volume).

As a first step in assessing the functional role of the chronic FRAs, we studied cocaine-induced locomotor activity and sensitization in the wild-type and fosB mutant mice. The wild-type animals exhibited a gradual increase in cocaine-induced locomotor activity (i.e., sensitization) over a 6 day treatment. In contrast, the mutant animals showed a marked increase in locomotor activity in response to the first cocaine exposure, with no further increase seen after repeated exposures. The wild-type and mutant mice, however, exhibited equivalent levels of conditioned locomotor activity.

These findings show that the absence of fosB gene products, including the chronic FRAs, is associated with specific abnormal behavioral responses to cocaine and support an important role for these transcription factors in cocaine action. (Supported by DA07359 and DA08227).

## 155.14

**AMANTADINE INDUCES EXPRESSION OF C-FOS: COMPARISON WITH APOMORPHINE AND MK-801, M. S. Rappaport\* and D. P. Yells,** Department of Psychiatry, Univ. Nebraska Medical Center, Omaha, NE 68198

Amantadine (AMA) is used therapeutically to ameliorate conditions resulting from diminished dopaminergic neurotransmission (e.g., Parkinson's disease and extrapyramidal side effects of antipsychotics). Effects of AMA include enhanced release of dopamine (DA), inhibition of the reuptake of DA and weak, noncompetitive NMDA receptor antagonism, properties all consistent with its observed therapeutic effects. We recently found that AMA disrupts prepulse inhibition (PPI) of the acoustic startle reflex in rats. Haloperidol pretreatment prevented AMA disruption of PPI. In the same paradigm, MK-801 caused a disruption of PPI which was not prevented by haloperidol. The present study extends our effort to characterize the mechanism of AMA's therapeutic action. We examined the effect of AMA on the expression of immediate early gene product c-Fos in rat forebrain structures. Results were compared to the effects of DA receptor agonist apomorphine (APO) and noncompetitive NMDA receptor antagonist MK-801 on c-Fos induction. Male rats were injected ip with either AMA (20 mg/kg), APO (4.0 mg/kg), MK-801 (1.0 mg/kg) or 0.9% NaCl and were transcardially perfused with 4% paraformaldehyde 2 hr later. Fixed, frozen brains were sectioned coronally and a free floating, fluorescent immunohistochemical technique was used to visualize nuclear c-Fos. AMA induced c-fos in the striatum in a pattern grossly resembling that resulting from treatment with APO. MK-801 did not noticeably induce c-fos in the striatum. These results, along with our finding that haloperidol pretreatment prevents AMA and APO-induced disruption of PPI, but not MK-801-induced disruption of PPI are consistent with a DAergic mediation of AMA's therapeutic actions. Comparative studies of compartmental distributions of c-Fos induced by APO and AMA in rat striatum are in progress.

Funded by a grant from the Nebraska Psychiatric Foundation (MSR) and the Dept of Psychiatry, University of Nebraska Medical Center.

## 155.16

**IDENTITY OF THE CHRONIC FRAS INDUCED BY REPEATED COCAINE AND ELECTROCONVULSIVE SEIZURE (ECS) TREATMENTS. J.S. Chen\*, M.B. Kelz, B.T. Hope\*, Y. Nakabeppu\* and E.J. Nestler,** Laboratory of Molecular Psychiatry, Yale University School of Medicine, New Haven, CT; \*Molecular and Developmental Neuroscience, Massachusetts General Hospital, Charlestown, MA; \*Medical Institute of Bioregulation, Kyushu University, Fukuoka 812, Japan.

Previous studies have shown that repeated administration of cocaine, ECS, or other agents induces several long-lasting Fos-related antigens (Fra), named chronic FRas. These proteins are FosB-related, as indicated by Western blotting with specific anti-FosB antibodies and now confirmed in FosB knock-out mice (see Hiroi et al., this volume). However, the slow induction and persistent expression of the chronic FRas are not consistent with the rapid and transient induction of the mRNAs for FosB and its splice variant deltaFosB. In the present study, we transfected neuronal Cath.a. and C6 glioma cell lines with FosB or deltaFosB cDNAs, and compared FosB and deltaFosB proteins with the chronic FRas induced by repeated ECS treatment. Four proteins with apparent molecular weights of 29, 33, 35 and 37 kD were generated from the deltaFosB cDNA. Gel shift assays show that the AP-1 complex from the deltaFosB transfected cells migrated at the same position as the chronic AP-1 complex. In 2-D gel Western blotting, the 35 kD protein migrated to the same position as the 35 kD chronic Fra, which suggests that these two proteins are identical. Comparison of the stability of FosB and deltaFosB shows that deltaFosB is more stable than FosB. These results suggest that deltaFosB is an atypical immediate early gene: the mRNA of deltaFosB is induced rapidly and transiently, however, some of the protein products are stable and accumulate with repeated induction. The 37 kD protein from the deltaFosB transfected cells is not as abundant as that induced by chronic ECS or cocaine in brain, which suggests that posttranslational modification in the brain may be required for the accumulation of the 37 kD chronic Fra. We are currently using cell lines in which expression of FosB or deltaFosB can be induced to characterize the unique functional properties of the chronic FRAs. (Supported by DA07359.)

**JAK-STAT PATHWAYS IN NEURONAL CELL LINES.**

**K. Shimoda\*, H. Takahashi\*, J.W. Commissiona\*\*\*, T. Oshima\*, K. Inoue, D. Kaneto and T. Kitagawa,** Div. of Neurology, National Nishitottori Hospital, Tottori 68902, JAPAN. #Lab. Histochem., Mitsubishi-kasei, Inst. of Life Sci. Machida 163, JAPAN. #NTU, LMB, NINDS, NIH, Bethesda, MD 20892, USA.

In recent studies of the signal transducers and activators of transcription (STATs) of the cytokines in lymphoid cell lines, many STAT proteins were identified. We previously established an S1 cell line prepared by immortalization of cells from the fetal rat diencephalon, using the viral SV40 large T antigen. This S1 cell line expressed several protein tyrosine kinases, that were shown to be coupled to various receptors for neurotrophic factors and cytokines (Soc. for Neurosci. Abst. 446.1, 1994). We also identified the involvement of Janus kinases (Jak) in this cell line, in the signal transduction pathway (Soc. for Neurosci. Abst. 415.14, 1995). We have now identified a 100 kDa phosphorelated STAT 6, and are investigating the mechanisms of its activation in PC12 and F9 teratocarcinoma cell lines after exposure to differentiation factors. Understanding and clarifying the mechanisms of signal transduction and activation of transcription pathways would be an important step in our studies of differentiation and may provide clues to help to understand the mechanisms of neuronal degeneration.

## 155.19

GLUTAMATE ACTIVATES SAPK/JNK IN STRIATAL CULTURES. M.A. Schwarzschild\*, R.L. Cole and S.E. Hyman. Mass. Gen. Hosp., Boston, MA 02129.

Stress-activated protein kinase (SAPK) also known as Jun N-terminal kinase (JNK) activates the c-Jun component of the AP-1 transcription factor complex, and can mediate apoptosis and other "stress" responses in cell lines. To explore neurotransmitter regulation of AP-1 mediated gene expression in neurons, we examined the effects of glutamate and dopamine on SAPK/JNK and its targets in primary cultures of striatal neurons from E-18 rats. Glutamate but not dopamine rapidly increases SAPK/JNK activity measured *in vitro* by an immune-complex kinase assay. Pharmacologic analysis suggested primary involvement of an NMDA receptor, as the glutamatergic activation of SAPK/JNK was mimicked and blocked by NMDA agonists and antagonists, respectively. Moreover, the glutamate activation required the presence of glycine a necessary co-agonist with glutamate at the NMDA receptor. Glutamate was ineffective in glial cultures derived from the same striatal cell preparation, whereas hyperosmolar mannitol exposure led to similar SAPK/JNK activations in both the neuronal and glial cultures. Although the related kinase p38 is typically activated by cellular stresses in parallel with SAPK/JNK, hyperosmolar mannitol but not glutamate increased p38 activity. Western blot analysis demonstrated that glutamate also increases levels of phosphorylated c-Jun. Thus glutamate via NMDA receptors can rapidly and specifically activate SAP/JNK in cultured striatal neurons. The associated increase in phospho-c-Jun and AP-1 mediated gene expression may play a role in the physiologic and neurotoxic effects of glutamate.

Supported by PHS grants NS01729 and DA07134.

## 155.20

REGULATION OF AP-1 MEDIATED GENE TRANSCRIPTION BY GLUTAMATE, BUT NOT DOPAMINE, IN RAT PRIMARY STRIATAL CULTURES.

R.L. Cole\*, M.A. Schwarzschild, M.A. Meyers and S.E. Hyman. Laboratory of Molecular and Developmental Neuroscience, Massachusetts General Hospital, Charlestown, MA 02129.

Corticotriatal glutamatergic projections and mesostriatal dopaminergic projections are the predominant afferents innervating the medium spiny neurons of the striatum. AP-1 transcription complexes have been hypothesized to play an important role in drug-mediated plasticity within these neurons. Here we investigate the differential role of these two major neurotransmitters in the regulation of AP-1 mediated gene expression in primary cultures of rat striatal neurons. Glutamate stimulation of striatal neurons activates Jun kinase, induces c-fos and c-jun mRNA, increases AP-1 protein binding, and activates transcription of a transiently transfected 4X-AP-1-luciferase construct. All of these glutamate effects are blocked by pre-treatment with the non-competitive NMDA-receptor antagonist MK-801. In marked contrast, stimulation by dopamine and forskolin, an activator of cAMP pathways, induces c-fos mRNA and increases AP-1 binding, but fails to activate Jun kinase, induce c-jun mRNA or activate AP-1 mediated gene transcription. Therefore, although glutamate, dopamine and forskolin all increase AP-1 binding in gel mobility shift assays, the activation of c-Jun by glutamate may also be required for AP-1 mediated transcription in rat striatal neurons.

Supported by PHS grant DA07134

## NEUROENDOCRINE REGULATION: PARAVENTRICULAR HYPOTHALAMIC NUCLEUS

## 156.1

PROJECTIONS OF NPY NEURONS IN THE ARCuate NUCLEUS (ARC) TO THE PARAVENTRICULAR NUCLEUS (PVH): IS THERE REGIONAL SPECIFICITY WITHIN THE ARC? C. Li\*, P. Chen and M. S. Smith, Division of Neuroscience, Oregon Regional Primate Research Center; Dept. Physiol/Pharm., Oregon Health Sciences Univ., Beaverton, OR 97006.

We have identified a specific population of NPY neurons in the caudal portion of the ARC that is activated in response to the suckling stimulus or food deprivation. The present studies addressed two questions: 1) do NPY neurons from the caudal portion of the ARC project to the PVH, the site involved in regulation of food intake, and 2) are NPY projections to the PVH evenly distributed throughout the rostral to caudal extent of the ARC? The retrograde tracer, fluorogold (FG), was injected into the PVH (2% solution, iontophoresed by 5  $\mu$ A current, pulsed at 7 sec intervals for 20 min) on day 1 postpartum in animals suckling 8 pups. On day 11, the lactating animals were perfused with tissue fixative, and brain tissue (25  $\mu$ m sections) was subjected to immunocytochemistry to visualize FG, followed by *in situ* hybridization for NPY mRNA. The presence of FG-containing cells in the ventrolateral medulla, an area identified as projecting to the PVH, was used as a positive control for the retrograde labeling technique. FG-labeled NPY cells were identified throughout the rostral to caudal extent of the ARC; however, double-labeled cells were preferentially distributed in the caudal portion of the ARC (27  $\pm$  1% rostral versus 73  $\pm$  1% caudal,  $p < 0.001$ ). There was a similar rostral to caudal distribution of single-labeled NPY cells (as reflected by total NPY mRNA/section). Thus, the relative proportion of NPY neurons projecting to the PVH was similar in the rostral and caudal ARC. However, because the caudal ARC contains a larger number of NPY neurons, their influence on the activity of the PVH would predominate. Thus, the increase in NPY neuronal activity in the caudal portion of the ARC, in conditions such as lactation and food deprivation, would have the greatest effect on altering the activity of PVH neurons. (Support: NIH grants HD14643, RR00163).

## 156.2

SEQUENTIAL ESTRADIOL (E) AND PROGESTERONE (P) FOLLOWED BY P WITHDRAWAL DOES NOT ALTER THE PLASMA OXYTOCIN (OT) SECRETORY RESPONSE TO CHOLECYSTOKININ (CCK) IN OVARECTOMIZED (OVX) RATS. N. B. Kim\*, D. J. Hollingshead, A. Thomas and J. A. Amico. Div. of Endocrinology, Univ. of Pittsburgh Sch. of Med. and VA Med. Ctr., Pittsburgh, PA 15261.

The hormone OT is important for several pre- and post partum events, including uterine contractions at parturition, the induction of maternal behavior, and milk ejection during nursing. During late pregnancy OT mRNA is increased in the paraventricular nucleus (PVN) due to high E and declining P levels. Administration of sequential E and P to and withdrawal of P from an ovx rat also increases OT mRNA. However, pituitary OT peptide is not affected. In the present experiment, we determined if this steroid exposure alters peripheral OT secretion during a provocative stimulus to OT release, such as CCK. Adult ovx Sprague-Dawley rats were implanted on day 1 with either E or empty silastic capsules, on day 3 with P or empty capsules, and on day 14 P or empty capsules were removed. Forty-eight and 72 hrs after removal of the P capsules, plasma OT was measured before and after i.v. injection of 10  $\mu$ g/kg of CCK. At the completion of the study, pituitary glands were removed and OT peptide was measured. No significant differences were found between the sham and hormone-treated animals either in their basal or CCK-stimulated plasma OT levels nor their pituitary content of OT peptide. The hormonal pattern of sequential E and P with P withdrawal has no apparent effect on CCK mediated OT secretion or posterior pituitary OT content. This suggests that gonadal steroids can affect OT mRNA independent of pituitary OT peptide content or release.

Supported by Merit Review funds from the Dept. of Veterans Affairs and NIH Grant 5T32-DK-0752.

## 156.3

TIME COURSE OF INDUCTION OF OXYTOCIN MESSENGER RIBONUCLEIC ACID LEVELS IN GONADAL STEROID-TREATED RATS. B. J. Blyth, D. J. Hollingshead, N. B. Kim and J. A. Amico. Div. of Endocrinology, Univ. of Pittsburgh Sch. of Med. and VA Med. Ctr., Pittsburgh, PA 15261.

The nonapeptide oxytocin (OT) is important for uterine contractility at parturition, milk ejection during lactation, and the induction of maternal behavior. OT mRNA levels increase in the paraventricular nucleus (PVN) of late pregnant and lactating rats and are modulated by the steroid milieu that accompanies these states. Specifically, exposure to sequential estrogen (E) and progesterone (P) followed by P withdrawal 48 hrs prior to sacrifice increases PVN OT mRNA. To better define the time course of induction of OT mRNA levels following P withdrawal, ovariectomized Sprague-Dawley rats (6-10/group) were treated with empty or steroid-filled capsules. On day 1, animals received an E-filled or empty capsule, followed by P-filled or empty capsules on day 3. On day 14, P-filled or empty capsules were removed and animals were sacrificed 24, 36, or 48 hrs later. The hypothalamic PVN were analyzed for OT mRNA by *in situ* hybridization histochemistry. Significant differences in PVN OT mRNA were found among the groups ( $P < 0.0001$ , Kruskal-Wallis). Animals in the 48 hr ( $P = 0.007$ ) and 36 hr ( $P = 0.005$ ), but not the 24 hr, steroid-treated groups had significantly increased OT mRNA relative to their respective sham-treated cohorts (Mann-Whitney U test). The relative abundance of PVN OT mRNA differed among the steroid-treated groups (Kruskal-Wallis,  $P < 0.001$ ), with peak OT mRNA at 48 hr. We conclude that increases in PVN OT mRNA occur by 36 hrs, and peak at 48 hrs, after P withdrawal in the E-primed rat. Future studies will determine if the OT-mediated changes in behavior or physiology that surround parturition are related to these changes in OT mRNA.

Supported by Merit Review funds from the Dept. of Veterans Affairs.

## 156.4

STATIONARY ORGANOTYPIC CULTURES OF RODENT HYPOTHALAMIC OXYTOCIN AND VASOPRESSIN NEURONS. S.B. House, A. Thomas, K. Kusano\* and H. Gainer. Lab. of Neurochemistry, NIH, NINDS, Bethesda, MD 20892-4130.

In order to perform long-term studies of differentiated magnocellular oxytocin (OT) and vasopressin (VP) neurons *in vitro*, we previously developed an "organotypic" roller-culture system (Wray et al., *Peptides*, 9:1151-1175, 1988) in which many OT, but very few VP cells, survived. Recently, a "stationary" slice culture system has been reported to be very effective in maintaining "organotypic" suprachiasmatic nuclei *in vitro* (Belenky et al., *Neuroscience*, 70:127-143, 1995). In this study we describe the efficacy of this culture system in maintaining magnocellular OT and VP neurons from the mouse and rat hypothalamus. Hypothalamic slices (400  $\mu$ m) from postnatal (PN) day 7-9 rats or PN day 2-6 mice were cultured for 14-16 days on 30mm wide millicell-CM filters (Millipore, Corp.). Following this the cultured slices were fixed in 4% formalin in PBS and evaluated by immunocytochemistry using monoclonal and polyclonal antibodies to OT- or VP-neurophysin. Approximately 15% of the total population of magnocellular OT neurons originally present in the rat hypothalamic slices as well as substantial numbers of VP neurons survived in an "organotypic" fashion in these cultures. Similar results were obtained with mouse hypothalamic slices. Studies in progress which compare various media and procedures used in the slice preparation and culture stages (e.g., the use of serum-containing versus defined media), and the use of these cultures for gene expression (biolistics) and physiological studies will be described. This work is funded by the NINDS, NIH, Intramural Program.

## 156.5

QUANTITATIVE RT-PCR ANALYSIS OF OXYTOCIN, VASOPRESSIN AND SYNAPTOTAGMIN ISOFORMS IN RAT HYPOTHALAMUS AND PITUITARY. D. Xi, H. Chin, and H. Gainer. Lab. of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

Measurement of gene transcripts in small samples of cells or tissues by reverse transcription-polymerase chain reaction (RT-PCR) has become a standard technique due to its high sensitivity. We have developed competition-based RT-PCR methods with DNA or RNA mimics in order to quantify oxytocin (OT), vasopressin (VP) and synaptotagmin (SYT) isoform mRNA as well as other mRNAs present in individual samples of hypothalamus and pituitary during development and various forms of functional activity (e.g., during dehydration and lactation). We found that either mimic could be used to determine the relative changes for a given mRNA, but comparison of mRNA levels among different genes required an RNA mimic. Preliminary RT-PCR analysis shows that SYT isoforms I-IV are present in rat hypothalamus under various experimental conditions. The ratios of SYT I-IV to GAPDH (glyceraldehyde-3-phosphate dehydrogenase) was used as an internal control) mRNA appeared changed in postnatal day 7 and lactating female rat hypothalamus when compared to control rats. In addition, we found that the ratio of OT to GAPDH was increased about 5 fold in lactation. These results suggest that gene expression of SYT isoforms undergoes developmental and functional regulation. Further studies of the regulation of OT, VP and SYT isoform mRNA expression in hypothalamus and pituitary will be described. This work was supported by the NINDS, NIH, Intramural Program.

## 156.7

GONADAL STEROID-INDUCED INCREASES IN PARAVENTRICULAR NUCLEUS (PVN) OXYTOCIN (OT) MESSENGER RIBONUCLEIC ACID (MRNA) LEVELS: A POSSIBLE ROLE FOR A GAMMA-AMINOBUTYRIC ACID (GABA)- MEDIATED PROCESS. A. Thomas\*, N.B. Kim, J.A. Amico. Div. of Endocrinology, Univ. of Pittsburgh Sch. of Med. and VA Med. Ctr., Pittsburgh, PA 15261

Interactions between ovarian steroids and PVN OT neurons have been recognized for sometime but incompletely understood. Changing peripartum levels of ovarian steroids modulate PVN OT mRNA levels. Specifically sequential exposure to estrogen (E) and progesterone (P) followed by withdrawal of P increases OT mRNA in the PVN of the rat. Maintenance of P attenuates OT mRNA. Although gonadal steroids affect OT neurons, they contain few if any, E or P receptors. Within the CNS, P metabolites can bind to the GABA receptor complex. We questioned whether P may act upon OT mRNA via a GABA-mediated mechanism. In the presence of P, its metabolites would increase GABA tone and possibly inhibit OT expression. With removal of P, declining metabolites would lessen GABA tone and possibly increase OT expression. To test this hypothesis, ovariectomized (ovx) Sprague-Dawley rats were administered E-filled implants on day 1. P-filled implants on day 3, injected with either diazepam (1mg/100g body weight, a GABA agonist) or placebo on days 13-16, with removal of P implants on day 14 and sacrifice on day 16. Ovx rats that received no steroid treatment were used as controls. PVN OT mRNA levels were compared by *in situ* hybridization. Significant increases were found in OT mRNA levels in rats that received steroids and placebo injections (no diazepam) vs. sham hormone-treated or steroid-treated diazepam-injected animals ( $p < 0.04$ , Kruskal-Wallis). Diazepam administration attenuates steroid-induced increases in PVN OT mRNA. The data suggest that the effects of P upon OT mRNA in the E-primed rat may be mediated by GABA. Supported by Merit Review funds from the Dept. of Veteran's Affairs and NIH Grant 5732-DK-0752.

## 156.9

A PGE<sub>2</sub> RECEPTOR ANTAGONIST (SC19220) SELECTIVE FOR EP<sub>1</sub> DOES NOT ALTER THE RISE IN PLASMA OXYTOCIN (OT) AFTER L-NAME. V. Bui, S. Gestl, M. Kadekaro, J. Connor\* and J. Summy-Long. Dept. of Pharmacology, M.S. Hershey Medical Center, Pennsylvania State University, Hershey, PA 17033, \*Div. of Neurosurgery, Univ. Texas Medical Branch, Galveston, TX, 77555-0517.

Recent studies in our laboratory demonstrated that nitric oxide (NO) attenuates the excitatory effect of a prostaglandin(s) on OT release from the magnocellular system. To clarify which prostaglandin(s) stimulates OT release, conscious female rats were injected intracerebroventricularly (icv) with 10µl of vehicle (10% ethanol in CSF), PGE<sub>2</sub> (100 ng) or PGD<sub>2</sub> (20µg) and decapitated 5 min later. Plasma OT was quantified by RIA and differences determined by AOV and Newman-Keul's t. Compared with vehicle-treated animals, plasma OT (pg/ml, mean±SEM; n=7,8) increased ( $p < 0.01$ ) to a similar magnitude after both prostaglandins (vehicle < PGE<sub>2</sub> & PGD<sub>2</sub>;  $9 \pm 1 < 36 \pm 3$  &  $28 \pm 4$ ). In other female rats (n=36) we examined whether 40 min pretreatment (10µl, icv) with a selective antagonist of the EP<sub>1</sub> subtype of the PGE<sub>2</sub> receptor (SC19220; 500ng) could prevent the rise in plasma OT after L-NAME (250µg/5µl, icv) given 5 min before decapitation. Compared with vehicle (4% DMSO in CSF), SC19220 did not alter plasma OT in animals treated with either CSF ( $9 \pm 0.5$  vs  $9 \pm 0.7$ ) or L-NAME ( $34 \pm 4$  vs  $30 \pm 3$ ). Although PGE<sub>2</sub> stimulates release of OT, the EP<sub>1</sub> receptor does not mediate the stimulatory effect of prostaglandins that is attenuated by NO. Funded by RO1-25498 and 2RO1-23055.

## 156.6

CELL-SPECIFIC GENE EXPRESSION OF OXYTOCIN AND VASOPRESSIN IN HYPOTHALAMIC MAGNOCELLULAR NEURONS. S.W. Jeong<sup>1</sup>, D.M. Witt<sup>1</sup>, H. Chin<sup>1</sup>, H. Arnheiter<sup>2</sup> and H. Gainer<sup>1</sup>. Labs. of Neurochemistry<sup>1</sup> and Developmental Neurogenetics<sup>2</sup>, NINDS, NIH, Bethesda, MD 20892.

Regulatory elements for restricting expression of oxytocin (OT) and vasopressin (VP) genes to magnocellular neurons of hypothalamus have been hypothesized as being located in an intergenic region (IGR) between the two genes. The IGR of mouse is 3.5 kb in length and shows a 73% identity with a stretch of 3.5 kb found in the 9.9 kb IGR of rats. This stretch of homologous sequence contains several consensus elements for transcription factor binding (Ratty, Jeong et al., in press), suggesting that this region is involved in regulating the expression of the OT and VP genes. To test this hypothesis, we generated 6 OT and VP constructs that contain the mouse IGR and a LacZ reporter gene to be tested in transgenic mice and in mouse hypothalamic slice cultures transfected by gold particle-mediated gene transfer (Biolistics). Of these, two were tested. One was an 11 kb VP transgene construct consisting of 4 kb of 5' upstream region followed by the LacZ reporter and the 3.5 kb mouse IGR. The other was an 8 kb OT transgene construct consisting of 1 kb 5' upstream region, the mouse IGR and LacZ reporter. In transgenic mice, both expressed the LacZ gene throughout the brain of transgenic mice but this expression was not specifically confined to the hypothalamus. This suggested that the exon and/or intron sequences absent in these constructs might be necessary for the cell-specific expression of OT and VP genes. The 4 other OT and VP transgenes contain the exon and intron sequences with the LacZ reporter inserted in either the first or third exon, followed by the IGR. These constructs are presently being tested in transgenic mice and biolistic studies. This work is funded by the NINDS, NIH, Intramural Program.

## 156.8

PARTIAL COEXISTENCE OF NADPH-DIAPHORASE AND ACETYLCHOLINESTERASE IN THE HYPOTHALAMIC SECRETORY NUCLEI OF THE RAT. F. Sánchez<sup>1</sup>, C. Crespo<sup>2</sup>, R. Arévalo<sup>2</sup>, J. Carretero<sup>1</sup>, E. Saldaña<sup>2</sup>, J. Aijón<sup>2</sup>, and R. Vázquez<sup>1</sup>. <sup>1</sup>Dept. Human Anatomy and Histology. <sup>2</sup> Dept. Cell Biology and Pathology. Universidad de Salamanca. 37007 Salamanca Spain.

Colocalization of NADPH-diaphorase and acetylcholinesterase (AChE) was explored in the magnocellular secretory nuclei of the rat hypothalamus by means of combined double histochemical staining of the same sections. Partial coexistence was found in all the nuclei studied (supraoptic, paraventricular, fornicals, circular and the hypothalamic area situated between the supraoptic and paraventricular nuclei). All neuronal types considered in the present study (NADPH-diaphorase positive, AChE-positive and neurons expressing both markers), were preferentially located in the magnocellular populations whereas in the parvicellular subdivisions of the paraventricular nucleus only isolated neurons belonging to the same three groups were detected. This partial coexistence extends previous studies on the chemical nature of the neurons producing nitric oxide in the hypothalamic secretory nuclei and suggests that nitric oxide is probably not related to general mechanisms involving AChE but rather in specific functions shared by certain hypothalamic neuronal cell populations.

## 157.1

EFFECTS OF INSULAR LESIONS ON THE RAT BARORECEPTOR REFLEX  
N. Kulshreshtha, Z.H. Zhang and S.M. Oppenheimer. Laboratory of Neurocardiology  
Johns Hopkins University School of Medicine, Baltimore, MD 21287.

Clinical observations and animal experiments indicate that perturbation of the insular cortex's function can induce significant cardiovascular changes. We suggest that inactivation of different insular regions can affect the baroreflex. Pressor or depressor sites were identified by electrical stimulation in 18 male, urethane anesthetized Sprague-Dawley rats. Electrical lesions were made using a twisted stainless steel bipolar electrode with constant current (1 mA DC for 2 minutes). Lesion size ranged from 1.0 mm to 2.0 mm in anteroposterior extent within the insular cortex. Phenylephrine hydrochloride (PE) and sodium nitroprusside (SNP) dose-response curves assessed the baroreflex sensitivity before and after lesion placement. Right posterior insular lesions (n=8) significantly increased the PE dose-response curves ( $p=0.003$ ), while SNP dose-response curves were unaffected by the lesions. Lesions in other insular locations were without effect on the PE and SNP dose response curves. Inactivation of the right posterior insular cortex can reduce baroreflex sensitivity and resets the threshold of the baroreflex.

## 157.3

HYPOTENSIVE RESPONSES TO THE INJECTION OF ACETYLCHOLINE INTO THE PREFRONTAL CORTEX OF THE RAT. G.E. Crippa, E.M. Krieger, V.L. Peres-Polon and F.M.A. Corrêa. Dept. Pharmacology, FMRP; Unit of Hypertension INCOR-FM; Dept. Physiology, FORP, Univ. of São Paulo, 14040-900, SP, Brazil.

Dose-dependent hypotensive responses were observed after the injection of acetylcholine (ACh) into the prefrontal cortex of anesthetized or conscious rats. The responses were not associated to changes in cardiac or respiratory frequencies. The depressor response was blocked by the intracortical injection of atropine or 4-DAMP, but not pirenzepine, suggesting the involvement of  $M_2$  receptors. Hypotensive responses were observed after injection of ACh throughout the prefrontal cortex. The intensity of the responses were higher when ACh was injected in the lateral or medial prefrontal cortex. No changes in the sympathetic nerve activity (renal nerve) were recorded concomitant with the hypotensive response. Additionally no cardiac debit were simultaneously observed, suggesting that the hypotensive response to ACh does not involve an inhibition of the sympathetic output and is caused only by a fall in the peripheral resistance without a cardiac component. The depressor response to intracortical ACh is blocked by i.v. pretreatment with homatropine methylbromide, suggesting a mediation through a vasodilator peripheral cholinergic mechanism. The present report may be the first evidence of the existence of a centrally controlled cholinergic vasodilator system in the rat.

## 157.5

EFFECT OF OESTRADIOL ( $E_2$ ) ON CARDIOVASCULAR RESPONSES TO GLUTAMATE STIMULATION OF BED NUCLEUS OF THE STRIA TERMINALIS (BST). L. N. Gibbons\* and J. Ciriello. Department of Physiology, University of Western Ontario, London, Canada, N6A 5C1.

We have previously shown that circulating levels of  $E_2$  alter the magnitude of the heart rate (HR) response to glutamate (Glu) stimulation of BST. To determine whether  $E_2$  was acting directly at BST neurons to modify the HR response,  $E_2$  ( $0.5 \mu\text{M}$   $17\beta$ -oestradiol) was microinjected (40 nl) into cardiovascular responsive sites in BST and the sites were re-stimulated with Glu (1 M; 20 nl). The peripheral autonomic components mediating these cardiovascular responses were also investigated using autonomic receptor blockade. All experiments were done in Inactin anesthetized, paralyzed and artificially ventilated female Wistar rats previously ovariectomized and subcutaneously implanted with an empty or  $E_2$  containing silastic capsule that resulted in a constant circulating level of 30 pg/ml of  $E_2$ . Microinjection of  $E_2$  into BST resulted in the potentiation of the Glu mean arterial pressure (MAP;  $182 \pm 21\%$ ) and HR ( $189 \pm 38\%$ ) responses elicited from BST in animals containing circulating levels of  $E_2$  only. Injection of the vehicle (propylene glycol-saline) into BST did not effect the magnitude of the cardiovascular responses. Administration of the muscarinic receptor blocker atropine methyl bromide (1 mg/kg; iv) had no effect on the magnitude of the potentiated responses, whereas injection of the nicotinic receptor blocker hexamethonium bromide (20 mg/kg; iv) abolished the  $E_2$  induced potentiation of the MAP and HR responses to Glu stimulation of BST. Finally, microinjection of the protein synthesis inhibitor anisomycin (2.5-5 mg/ml; 40 nl) into BST 15 min prior to injection of  $E_2$  into the same site, prevented the potentiation of the cardiovascular responses to Glu stimulation of BST. These data suggest that  $E_2$  acts to alter the sensitivity of cardiovascular neurons in BST through a genomic mechanism and that this change in sensitivity results in an increased sympathoinhibition during BST stimulation. (Supported by Heart and Stroke Fdn. of Ontario).

## 157.2

CHARACTERIZATION, DISTRIBUTION AND LATERALISATION OF BARORECEPTOR-RELATED NEURONS IN THE RAT INSULAR CORTEX. Z.H. Zhang\* and S.M. Oppenheimer. Lab. of Neurocardiology, Johns Hopkins University School of Medicine, Baltimore, MD 21287.

There is controversy as to the lateralization and anteroposterior distribution of insular baroreceptor-related neurons. We recorded the response to baroreceptor challenge of 244 cells within and surrounding the right and left insulae in 34 urethane-anesthetized male Sprague-Dawley rats. Single unit activity (sampled at 20 Kz), blood pressure, ECG and respiration were digitized and recorded electronically using the BRAINWAVE system. Unit activity was analysed using DATAVIEWER. 1) 169/244 units responded to PE and/or SNP. 127/169 were located within the insula ( $p<0.0001$ ). Some clustering was seen in the right posterior insula ( $p=0.036$ ). 2) 60 units responded to both PE and SNP. 49/60 were classified as sympathoexcitatory (SE); 11 units were classified as sympathoinhibitory (SI). 43/49 SE cells were contained within the insula ( $p<0.0001$ ). These units were also clustered within the right posterior zone ( $P=0.0081$ ). SI cells showed no insular predominance or lateralisation. 3) 47 units responded only to PE; these cells were also situated mainly within the right posterior insula ( $p=0.004$ ). 4) 62 units responded only to SNP. There was no demonstrable clustering of these cells within the insula or any lateralisation. Baroreceptor units show a distinct distribution, being predominant in the insula, and particularly within the right posterior granular insular cortex. Responses to SNP baroreceptor challenge lacked insular specificity.

## 157.4

DETECTION OF VASOMOTOR AND RESPIRATORY RHYTHMS IN THE DISCHARGE OF SINGLE THALAMIC NEURONS IN CONSCIOUS CATS. N. Montano\*, T. Gnecci-Ruscone, M. Massimini, C. Cogliati, A. Porta, M. Mariotti, A. Malliani. Centro Ricerche Cardiovascolari, CNR, Medicina Int. II, Osp. L. Sacco & Fisiologia Umana II, University of Milan, Italy.

Spectral analysis of heart rate (HR) and systolic arterial pressure (SAP) variabilities in man as well as in experimental animals detects two major components: a low frequency (LF; 0.04-0.15 Hz) and a high frequency (HF; 0.25 Hz) components respectively related to vasomotor and respiratory activity. HF is considered a marker of vagal modulation while LF is a marker of sympathetic modulation. In a previous study (Montano et al, JANS, 57:116-122, 1996) spectral analysis in the range between 0 and 0.5 Hz, of single medullary neurons revealed a predominant LF oscillation, highly correlated with the LF detectable in SAP. The present study was undertaken to evaluate whether LF and HF oscillations could also be present in the discharge variability of single neurons within different thalamic nuclei. We analyzed, by means of autoregressive spectral analysis algorithms, RR interval (RR) and impulse activity of single units recorded extracellularly from different nuclei: reticular thalamic (RE;  $n=16$ ), mediodorsal (MD;  $n=16$ ) and ventral posterolateral (VPL;  $n=5$ ) in unanesthetized, conscious cats. Power spectra of single neuron discharges displayed both LF and HF oscillations, highly coherent ( $K2 = 0.6-0.8$ ) with the same rhythms detectable in RR variability spectrum.

In conclusion the presence of vasomotor and respiratory oscillations in the discharge variability of specific and non-specific thalamic nuclei neurons supports the existence of broad codes of information concerning the major variables of neurovegetative regulation.

## 157.6

NUCLEUS OF THE SOLITARY TRACT AND VENTROLATERAL MEDULLARY INPUTS TO NUCLEUS ACCUMBENS. G. J. Kirouac and J. Ciriello. \*Department of Physiology, University of Western Ontario, London, ON, Canada, N6A 5C1.

Nucleus accumbens (NA) is thought to be involved in behavioural and motivational responses. Recently, anatomical studies have shown that nucleus of the solitary tract (NTS) and ventrolateral medulla (VLM), cardiovascular brainstem regions, project directly to NA. Experiments were done in  $\alpha$ -chloralose anesthetized rats to investigate the effect of activation of cardiovascular responsive sites in NTS and VLM, and of arterial baroreceptors by the acute rise in arterial pressure to phenylephrine (10  $\mu\text{g/kg}$ , i.v.), on the discharge rate of neurons in NA. Extracellular single unit recordings were made from NA neurons. Electrical stimulation of depressor sites in NTS excited 41/77 (latency,  $44.4 \pm 4.5$  ms) or inhibited 7/77 (latency,  $34.8 \pm 7.9$  ms) of the NA units tested. Similarly, stimulation of the VLM region containing the A1 noradrenergic cell group excited 20/77 (latency,  $37.4 \pm 7.8$  ms) or inhibited 4/77 (latency,  $31.5 \pm 4.2$  ms) of the NA units tested. Fifteen units were found to be excited by stimulation of both NTS and VLM and the discharge rate of 6 of these neurons was also increased by baroreceptor activation. Responsive units in NA were found predominantly within the shell region of the nucleus. These data indicate that NA receives convergent information from sites in NTS and VLM that regulate arterial blood pressure and from arterial baroreceptors. These findings suggest that NA may require information regarding the current status of the cardiovascular system prior to evoking behavioural processes. (Supported by the Heart and Stroke Foundation of Ontario).

## 157.7

EFFECTS OF NMDA ANTAGONIST MK-801 ON CENTRAL ANGIOTENSIN II ELEVATED BLOOD PRESSURE AND FOS RESPONSES IN RAT FOREBRAIN. Z. Xu, R.L. Thunhorst and A.K. Johnson\* Departments of Psychology and Pharmacology and the Cardiovascular Center, University of Iowa, Iowa City, IA 52242-1407

Intracerebroventricular (ICV) administration of angiotensin II (ANG II) elevates arterial blood pressure in rats. The present study examined whether glutamatergic pathways and N-methyl-D-aspartate (NMDA) receptors are involved in mediating the pressor response to ICV ANG II and evaluated the central sites of actions of ANG II after pretreatment of NMDA antagonist, MK-801, by mapping FOS-immunoreactivity in the forebrain. ICV MK-801 (20 nmol for conscious rats, and 60 nmol for anesthetized rats) did not affect mean blood pressure and heart rate, but significantly suppressed ICV ANG II-induced pressor responses in both conscious and anesthetized rats. This suggests the involvement of glutamatergic mechanisms in mediating for the effects of ICV ANG II. FOS-immunoreactivity after ICV ANG II was significantly increased in the subfornical organ (SFO), organum vasculosum of the lamina terminalis (OVLT), median preoptic nuclei (MnPO), supraoptic nuclei (SON) and magnocellular paraventricular nuclei (PVN). Pretreatment with ICV MK-801 had no effects on FOS responses in the SFO, OVLT and magnocellular PVN, but quantitatively decreased FOS in the MnPO, SON and the magnocellular PVN. This suggests the central sites of glutamate system in the forebrain that may relate to ANG II-induced pressor responses. Supported by NHLBI HL 14388 and NASA NAGW-4358.

## 157.9

INJECTION OF MUSCIMOL INTO DORSOMEDIAL OR PARAVENTRICULAR HYPOTHALAMIC NUCLEUS: EFFECT ON STRESS-INDUCED INCREASES IN PLASMA RENIN ACTIVITY AND CARDIOVASCULAR FUNCTION IN RATS. T.W. Bailey, E.H. Stoltz-Potter, M.L. Blair and J.A. DiMicco\* Dept. Pharmacol. & Toxicol., Indiana Univ. Sch. of Med., Indpls, IN 46202, and Dept of Pharm. & Phys. Univ. of Rochester, Sch. of Med. and Dent., Rochester, NY 14642

Microinjection of muscimol (MUS), a GABA<sub>A</sub> receptor agonist, into the dorsomedial hypothalamus (DMH) reduces stress-induced increases in heart rate (HR), blood pressure (BP), and plasma ACTH, while similar treatment in the paraventricular hypothalamus (PVN) attenuates only increases in plasma ACTH. Here, we examined the effect of these treatments on stress-induced increases in plasma renin activity (PRA), another hallmark of the response to acute stress. Rats, with guide cannulae implanted at target coordinates corresponding to the region of the DMH or the PVN, and instrumented for monitoring HR and BP, were tested in either high stress (HS; 10 min air stress) or low stress (LS; associated with microinjection and baseline blood sampling) after bilateral injection of either vehicle (VEH; 100 nl saline) or MUS 80 pmol into the DMH (n=4, LS; n=5, HS) or the PVN (n=5, LS; n=4, HS). Injection of MUS into the DMH attenuated the increases in HR seen under HS (mean change from basal HR in beats/min  $\pm$  sem over 10 min period: VEH, +96 $\pm$ 18; MUS, +30 $\pm$ 11; p=0.015) and reduced HR below baseline under LS (VEH, +62 $\pm$ 23; MUS, -28 $\pm$ 7 beats/min; p=0.002), while injection of MUS into the PVN had no effect in either setting. Mean basal PRA for all rats was 4.0 $\pm$ 0.5 ngAngI/ml/hr. HS but not LS increased PRA by an average of 9.8 $\pm$ 2.1 (p=0.0008) in all treatment groups, and the increases were not affected by microinjection of MUS into the DMH or PVN. Thus, while the DMH is a key site for integration of cardiovascular and ACTH responses to stress, neural activity in this region may not play a role in stress-induced increases in PRA. ## 157.11

Effects of GABA-A Receptor Blockade on Inhibition of Autonomic Neurons in the Hypothalamic Paraventricular Nucleus (PVN) Evoked by Cardiopulmonary Vagal Inputs. G.M. Toney\* and S.W. Mifflin Department of Pharmacology, University of Texas, HSC, San Antonio, TX 78284-7764

Parvocellular PVN (pPVN) neurons influence autonomic activity through pontine, medullary and spinal projections. Evidence that lesions of pPVN neurons attenuate the renal vasodilation and sympathoinhibition that accompany saline infusions, implicates these neurons in the control of plasma volume. In this study, changes in pPVN cell discharge were recorded extracellularly following rapid (1-2 s), bolus (200  $\mu$ l) injections of saline or saline containing 5  $\mu$ g of phenylbiguanide (PBG) into the right cardiac atrium of chloralose/urethane anesthetized Sprague-Dawley rats. Spontaneously active cells (n=21) discharged either continuously (n=6) or with bursts of discharge (peak interspike intervals: 3-46 ms) (n=15). Eight cells responded to PBG - 6 inhibited, 2 excited. Inhibition reduced discharge 87  $\pm$  13 % (mean  $\pm$  SD) from 6.3  $\pm$  3.7 to 0.5  $\pm$  0.4 Hz. Saline injections alone (n=7) were without effect. Averages of renal sympathetic activity triggered from spontaneous spikes of PBG-inhibited cells showed a prominent peak at 162  $\pm$  36 ms. Similar averages from PBG-excited cells had reduced amplitude at a similar latency. Two cells inhibited by PBG were antidromically activated by spinal cord (T2-3) stimulation. Antidromic spike latencies (42 $\pm$ 76 ms) suggest unmyelinated axons. Iontophoresis of bicuculline methiodide (BMI)(10 mM, 1-2 min) did not change spontaneous discharge (baseline: 6.3  $\pm$  3.7 Hz, BMI: 6.6  $\pm$  1.8 Hz) and failed to prevent PBG-induced unit inhibition (n=6). The same "dose" of BMI (8.0  $\pm$  1.2 nA), however, reversed GABA (2 mM, ~12 nA)-mediated inhibition of unit activity. In 3 PBG-inhibited cells, vagus nerve stimulation (3 pulses-500 Hz, 500  $\mu$ A) inhibited cell firing for 140  $\pm$  34 ms, with a latency of 92  $\pm$  32 ms. Like PBG, vagal inhibition was BMI insensitive. Results indicate that autonomic pPVN neurons are inhibited by activation of unmyelinated vagal afferents-probably of cardiopulmonary origin. These inputs appear insensitive to rapid, atrial saline injections. Failure of somatic application of BMI to alter tonic activity or to attenuate evoked afferent inhibition, indicates that if inhibition is GABA-A receptor mediated, inhibitory synapses are likely to be located distant from the presumed somatic recording site. (support: HL36080)

## 157.8

NICOTINIC GANGLIONIC AND MUSCARINIC RECEPTOR INVOLVEMENT IN PRESSOR RESPONSE TO CARBACHOL MICROINJECTION INTO POSTERIOR HYPOTHALAMIC NUCLEUS. J.R. Martin\*, Dept. of Pharmacol. Kirksville Col. Osteo. Med., Kirksville, MO 63501.

The microinjection of the cholinergic agonist carbachol (CCh) into the posterior hypothalamic nucleus (PHN) of conscious rats evokes an increase in mean arterial pressure (MAP) which can be blocked by pretreatment with the combination of  $\alpha$ -adrenergic and V<sub>1</sub>-vasopressin receptor antagonists. The present study determined if the CCh induced pressor response could be inhibited by ganglionic and V<sub>1</sub>-vasopressin receptor blockade. Male Sprague-Dawley rats (280-300 g) were anesthetized (50 mg/kg of pentobarbital, i.p.) and instrumented with a guide cannula targeted to the left PHN, and catheters in the left femoral artery and vein for direct arterial pressure measurement and intravenous drug administration. Pretreatment with 10 mg/kg of the nicotinic ganglionic receptor antagonist pentolinium (PENT) attenuated the increase in MAP evoked by CCh (3.3 to 13.2 nmol in 50 nl). Adding 2 mg/kg of the muscarinic receptor antagonist methylatropine (MeATR) to PENT resulted in further inhibition of the CCh-evoked increase in MAP. Adding the V<sub>1</sub>-vasopressin receptor antagonist [d(CH<sub>2</sub>)<sub>5</sub>tyr(Me)]AVP (20  $\mu$ g/kg) to PENT and MeATR completely blocked the CCh-evoked increase in MAP. These results suggest that CCh microinjection into the PHN of conscious rats evokes an increase in MAP as a result of sympathoexcitation and increased plasma levels of AVP. The sympathoexcitation appears to involve ganglionic transmission via a nicotinic ganglionic and a muscarinic receptor. (Supported by NIH HL-44531 and Warner/Fermaturo Fund.)

## 157.10

EFFECT OF CHEMICAL STIMULATION OF THE DORSOMEDIAL HYPOTHALAMIC NUCLEUS ON BLOOD PLASMA GLUCOSE, TRIGLYCERIDES AND FREE FATTY ACIDS IN RATS. C.T.B.V. Zaia<sup>1</sup>, L.C.I. Gaziri<sup>1</sup>, D.A.M. Zaia<sup>2</sup>, M.S. Dolnikoff<sup>3</sup>, C. Timo-laria<sup>4</sup>. <sup>1</sup>Depto. de Ciências Fisiológicas and <sup>2</sup>Depto. de Química, Universidade Estadual de Londrina, Londrina, PR 86051-970; <sup>3</sup>Depto. de Fisiologia, EPM-UNIFESP; <sup>4</sup>Faculdade de Medicina, USP, São Paulo, SP, Brasil.

The effects of chemical stimulation of the dorsomedial hypothalamic nucleus (DMH) on blood plasma concentration of glucose, triglycerides, insulin and free fatty acids (FFA) were investigated in anesthetized adult Wistar rats. Microinjection of 12.5 nmol (0.5  $\mu$ l/min) of norepinephrine into the DMH increased blood plasma concentration of glucose (136.0  $\pm$  1.5 mg/dl) and FFA (104.5  $\pm$  6.2  $\mu$ moles/dl), decreased triglycerides (58.7  $\pm$  3.5 mg/dl), and did not change plasma insulin within 5 minutes compared with control group (113.2  $\pm$  1.2 mg/dl; 76.4  $\pm$  6.6  $\mu$ moles/dl e 86.9  $\pm$  6.6 mg/dl, respectively); after 20 minutes, blood glucose and FFA reached control values. Microinjection of epinephrine (12.5 nmol; 0.5  $\mu$ l/min) into the DMH also increased blood plasma glucose concentration (134.3  $\pm$  3.7 mg/dl) and decreased triglycerides (53.3  $\pm$  6.6 mg/dl) after 5 minutes. These effects are probably mediated by beta-adrenergic mechanisms, since they were prevented by beta-adrenergic antagonist propranolol, but not by alpha-adrenergic antagonist prazosin. Microinjection into the DMH of glutamate, dopamine, or acetylcholine failed to cause any change in those metabolic parameters, corroborating the hypothesis that the DMH is part of a beta-adrenergic pathway involved in short-term modulation of the availability of glucose and FFA.

## 157.12

HEMODYNAMIC RESPONSES TO HYPOTHALAMIC PARAVENTRICULAR NUCLEUS (PVN) INJECTIONS OF SPECIFIC OPIOID ANTAGONISTS IN CONSCIOUS RATS. André Lessard and Hélène Bachelard\*. Unité de Recherche sur l'Hypertension, Centre de Recherche du CHUL, Université Laval, Québec, G1V 4G2

The present study was designed to investigate the influence of the endogenous PVN opioid innervation on cardiovascular system. Therefore, the cardiovascular changes elicited by bilateral PVN injections (0.2  $\mu$ l) of naloxone (0.1-5.0 nmol), ICI-174,864 (0.1-1.0 nmol, a  $\delta$ -opioid antagonist), Nor-binaltorphimine (0.1-1.0 nmol, a  $\kappa$ -opioid antagonist), or  $\beta$ -funaltrexamine (0.05-0.5 nmol, a  $\mu$ -opioid antagonist) were characterized in conscious male Wistar rats. The rats were instrumented with intracerebral cannulae, intra-vascular catheters and pulsed Doppler flow probes implanted around specific arteries in a three step surgery. PVN injection of naloxone and  $\beta$ -funaltrexamine produced significant cardiovascular changes characterized by quick and transient increases in blood pressure, heart rate, and hindquarter vascular conductance and falls in renal and superior mesenteric vascular conductances. Thus, PVN injection of naloxone (5.0 nmol) produced increases in mean blood pressure (+12  $\pm$  2 mm Hg) and heart rate (+80  $\pm$  18 bpm), falls in renal (-17  $\pm$  5%) and mesenteric (-29  $\pm$  7%) vascular conductances and increases in hindquarter (+38  $\pm$  18%) vascular conductance. However, PVN injections of ICI-174,864 or Nor-binaltorphimine had no cardiovascular effects at the doses we used. Together these results suggest that the endogenous PVN opioid innervation exert a  $\mu$ -opioid receptor-mediated tonic inhibitory influence on the PVN neurons involved in cardiovascular regulation.

The work was supported by the FMCQ and the NSERC.

**HYPOTHALAMIC DISTRIBUTION OF FOS-LIKE IMMUNOREACTIVITY FOLLOWING HEMORRHAGE IN CYCLING AND PREGNANT FEMALE RATS.** R.L. Parman\*, M.L. Blair and D. Piekut. Univ. of Rochester Sch. of Medicine and Dentistry, Rochester, NY 14642.

In male rats, blood loss causes increased Fos expression in the supraoptic nucleus (SON), magnocellular paraventricular hypothalamic nucleus (PVH), and parvocellular PVH (*Clin. Exptl. Pharm. Phys.* 23:161, 1996). The goal of this study was to determine if hypothalamic neurons are similarly activated by decreased blood volume in cycling virgin females and pregnant females. Conscious unrestrained female Sprague-Dawley rats were subjected to a slow hemorrhage (HEM) on the morning of proestrus (n=3), metestrus (n=3) or mid-pregnancy (pregnancy day 11-13, n=3). HEM was performed by gradual withdrawal of 16 ml/kg blood over 24 min via an arterial catheter. The rats were anesthetized and perfused (4% paraformaldehyde) 100 min after initiation of HEM. Following HEM, blood pressure decreased similarly (to <55 mmHg) in cycling and pregnant female rats, in association with a significant bradycardia. Plasma renin activity (PRA) increased 4-fold in both cycling and pregnant rats. Immunocytochemical localization demonstrated numerous Fos-positive cell nuclei in the SON, magnocellular PVH, and parvocellular PVH, with no apparent difference in the distribution of Fos-immunoreactivity in females studied during proestrus, metestrus, or pregnancy. Non-hemorrhaged control rats (n=6 cycling, n=5 pregnant) showed few Fos-positive neurons within PVH or SON. In conclusion, HEM increases hypothalamic Fos expression in female rats in a pattern of distribution which is similar to that of males, and is not substantially altered by estrous cycle phase or mid-pregnancy. (*Sup. by American Heart Assoc. #9300794*)

## 157.15

**NEUROTRANSMITTERS IN THE LATERAL HYPOTHALAMIC AREA (LHA) MEDIATING CARDIOVASCULAR RESPONSES FROM THE INFRALIMBIC CORTEX (ILC).** M. Way and D.F. Cechetto\*. University of Western Ontario, London, Ontario, Canada, N6A 5K8.

Stimulation of the ILC elicits a number of autonomic responses and previous neuroanatomical studies have suggested that there is an efferent pathway from the ILC to the LHA. To determine the role of the LHA in mediating ILC cardio-vascular responses the ILC was stimulated before and after injection of a synaptic blocker or glutamate antagonists into the LHA. Male, Wistar rats (21) were anesthetized with inactin and prepared for monitoring mean arterial pressure (MAP), heart rate, and renal nerve activity (RNA). A five second train of electrical pulses (200-500  $\mu$ A, 80 Hz, 2 ms duration) administered to the ILC elicits a decrease in MAP of  $17.5 \pm 2.0$  mmHg. Injection of a general synaptic blocker (10 mM cobaltous chloride; 300 nl) into the LHA attenuates the depressor response to  $53.7 \pm 3.23$  % of the initial response (range 40 to 72.7 %). Injection of a general excitatory amino-acid antagonist (250 mM kynurenic acid; 240 nl) into the LHA attenuates the depressor response to  $56.3 \pm 12.18$  % of initial (range 0 to 79.2 %). Injection of a specific NMDA receptor antagonist (250  $\mu$ M AP-5; 240 nl) into the LHA attenuates the depressor response to  $53.7 \pm 4.52$  % of initial (range 43.5 to 61.7 %). Injection of Non-NMDA receptor antagonists (200  $\mu$ M GDE, 2 mM NBQX and 200  $\mu$ M NBQX; 240 nl) into the LHA attenuates the depressor response by  $39.8 \pm 10.46$  %,  $30.4 \pm 21.52$  % and  $38.2 \pm 6.49$  % respectively. These results suggest that there is a synapse in the LHA that mediates the cardiovascular responses from the ILC. In addition, glutamatergic synapses, primarily non-NMDA, in the LHA mediate these responses. (Supported by the Heart and Stroke Foundation of Ontario).

**BRAINSTEM PATHWAYS ACTIVATED BY THE SUCKLING STIMULUS: A COMPARISON OF NEURAL STIMULI DERIVED FROM SUCKLING VERSUS PUP EXPOSURE.** P. Chen, C. Li and M. S. Smith\*. Division of Neuroscience, Oregon Regional Primate Research Center; Dept. Physiol./Pharm., Oregon Health Sciences Univ., Beaverton, OR 97006.

We have identified a number of brainstem areas that are activated by the suckling stimulus. These studies in rats compare patterns of cFos expression induced by the suckling stimulus with those induced by sensory stimuli of pup exposure. The 8-pup litters were removed for 48 hrs, beginning on day 9 postpartum. On day 11, animals were divided into 3 groups: no resuckling (0 Pups), pup exposure for 90 min (PE), and resuckling 8 pups for 90 min (+8 Pups). Double-label immunocytochemistry was performed for cFos and tyrosine hydroxylase (TH) to identify catecholamine neurons. Data are reported for those areas with major projections to the hypothalamus. In the ventrolateral medulla [VLM/A1 (% cFos-positive TH cells): 0 Pups,  $0.5 \pm 0.4$ ; PE,  $1.4 \pm 0.7$ ; +8 Pups,  $37.4 \pm 4.1$ ], suckling caused a significant increase in cFos expression ( $p < 0.001$ ), whereas PE had no effect. There were no differences among the 3 groups in the VLM/C1 area. In the Nucleus of the Solitary Tract (NTS/A2), cFos expression (15-25% cFos-positive TH cells) was similar in the three groups. In the locus coeruleus [LC/A6 (% of cFos positive TH cells/section): 0 Pups,  $3 \pm 1$ ; PE,  $3 \pm 1$ ; +8 Pups,  $24 \pm 4$ ], PE had no effect, whereas suckling increased cFos expression ( $p < 0.001$ ). In non-catecholaminergic areas, such as the periaqueductal grey [PAG (% of cFos positive cells/section): 0 Pups,  $39 \pm 7$ ; PE,  $140 \pm 32$ ; +8 Pups,  $210 \pm 14$ ], PE increased cFos expression ( $p < 0.01$ ), and suckling caused an even greater level of cFos than did PE ( $p < 0.05$ ). Therefore, the neural impulses arising from the suckling stimulus, itself, result in activation of specific brainstem areas (VLM, LC, PAG), suggesting that projections from these areas may relay signals arising from suckling to the hypothalamus. (Support: NIH grants HD14643, RR00163).

## 157.14

**HYPOTHALAMIC DISTRIBUTION OF FOS-LIKE IMMUNOREACTIVITY AND NADPH-DIAPHORASE (NADPH-d) FOLLOWING GRADED HEMORRHAGE.** M.L. Blair\*, D. Mickelsen and D. Piekut. Univ. of Rochester Sch. of Medicine and Dentistry, Rochester, NY 14642.

The goal of this study was to determine if hypothalamic neurons containing nitric oxide synthase (NADPH-d) are selectively activated by decreased blood volume. A graded hemorrhage (HEM) was performed in conscious male Sprague-Dawley rats by gradual withdrawal of 9-16 ml/kg blood over 24 min via an arterial catheter. The rats were anesthetized and perfused (4% paraformaldehyde) at 85 min after initiation of HEM. Histochemical localization demonstrated intense NADPH-d staining in the median preoptic nucleus, dorsal supraoptic nucleus (SON), perifornical region, lateral hypothalamus, anterior paraventricular nucleus (PVH), ventrolateral parvocellular PVH, and posterior PVH. In rats subjected to a 14-16 ml/kg HEM which decreased blood pressure to <50 mmHg (n=6), immunocytochemical localization demonstrated numerous Fos-positive cell nuclei in ventral SON, magnocellular PVH, and ventrolateral parvocellular PVH. Only faint NADPH-d was seen in Fos-positive neurons in the SON and magnocellular PVH. However, >60% of NADPH-d-positive cells in the ventrolateral parvocellular PVH were also Fos-positive. A similar distribution of Fos-positive and double-labelled neurons was observed in rats subjected to a smaller HEM of 9-11 ml/kg which did not significantly decrease arterial pressure (n=4). Non-hemorrhaged control rats (n=6) showed few Fos-positive neurons within PVH or SON. In conclusion, NADPH-d-positive neurons within the parvocellular PVH are selectively activated by blood loss, even in the absence of hypotension. (*Sup. by Am. Heart Assoc. #9300794*)

## 157.16

**CARDIAC-RELATED PARASYMPATHETIC NEURONS IN THE CENTRAL NUCLEUS OF THE AMYGDALA IN GUANETHIDINE TREATED RATS.** A. Standish\* and J.S. Schwaber. E. I. DuPont Co., Neural Computation Group, The Experimental Station, Wilmington, DE 19880.

The distribution of labeled neurons in the central nucleus of the amygdala (CNA) following injection of pseudorabies virus (PRV) into the heart was investigated in guanethidine-treated rats. There is a large body of evidence to implicate the CNA in cardiac control. However, in our previous viral tracing studies from the heart, neurons in the amygdala regions were not or were only sparsely labeled. In an effort to solely study the parasympathetic cardiac circuit, rat pups were treated with guanethidine which resulted in permanent destruction of the peripheral sympathetic nervous system. Following a 5 week treatment period, we injected the rat heart with PRV. Since only the parasympathetic system was infected with PRV, these guanethidine treated rats lived significantly longer following PRV cardiac injection than non-treated rats. The additional survival time enabled PRV, which is transsynaptically transported in a temporal fashion, to infect neurons further along the hierarchical chain of synaptically linked neurons involved in cardiac control. We found a significant number of labeled neurons in the CNA in guanethidine treated rats sacrificed more than 100 hours after cardiac injection. The labeling of CNA was confined to neurons of the medial subdivision, a subdivision we have previously described as projecting to the vagal complex of the dorsal medulla. Thus, CNA neurons are presumed to be retrogradely labeled from neurons located in the cardiorespiratory (dorsal) nucleus of the tractus solitarius. These results suggest that neurons in the CNA are at least three perhaps four synapses from the vagal preganglionic cardiac motor neurons. Supported by grants from the ONR, NSF and by the E.I. DuPont Co.

## 157.18

**SYSTEMIC NITROGLYCERIN ACTIVATES PEPTIDERGIC AND CATECHOLAMINERGIC PATHWAYS IN RAT BRAIN**  
Cristina Tassorelli\*, Giuseppe Nappi<sup>1</sup> and Shirley A. Joseph<sup>2</sup>

<sup>1</sup> Division of Neurological Surgery, Strong Memorial Hospital Medical Center, Rochester, 14642 New York (USA) <sup>2</sup> Neurological Institute "C. Mondino", University of Pavia, 27100 Pavia (I).

Nitroglycerin (NTG) is a nitric oxide donor which induces sustained expression of Fos protein, a marker of neuronal activation, in specific neuronal groups in the central nervous system. The mechanisms which underlie nitroglycerin-induced neuronal activation are elusive at this moment. The aim of this study was to provide, by means of a dual immunohistochemical technique, a neurochemical characterization of the neurons which express Fos following systemic administration of nitroglycerin, in order to shed light on the pathways and neurotransmitters which are possibly involved in the central effect of the drug. Adult Sprague-Dawley rats were injected, subcutaneously, with NTG (10mg/kg b.w.). Animals were sacrificed and brain sections were processed for immunohistochemical detection of Fos using a rabbit polyclonal antiserum directed against an in vitro translated product of the *c-fos* gene; sections were subsequently processed according to an immunocytochemical staining protocol for the demonstration of two antigens with contrasting colors in the same tissue section, previously developed. In the brainstem, a significant percentage of activated neurons contained noradrenaline as a neurotransmitter, while only a few of them contained serotonin. In the paraventricular and supraoptic nuclei of the hypothalamus, numerous Fos-immunoreactive neurons were also positive for vasopressin, oxytocin and corticotropin releasing factor. Co-distribution with corticotropin releasing factor was also observed in the central nucleus of the amygdala. These data are consistent with and expand on those previously reported by our group; they provide a neurochemical map of the brain areas which respond to nitroglycerin administration, which include catecholaminergic, peptidergic and, to a lesser extent, serotonergic structures.

## 158.1

**NK<sub>1</sub> RECEPTOR IN SYMPATHETIC PREGANGLIONIC NEURONS (SPN): DIFFERENTIAL EXPRESSION AND ULTRASTRUCTURAL LOCALIZATION.** I.J. Llewellyn-Smith<sup>1</sup>\*, J.B. Minson<sup>1</sup>, P.M. Pilowsky<sup>1</sup>, L.F. Arnold<sup>1</sup>, A.I. Basbaum<sup>2</sup>, S.R. Vigna<sup>3</sup> and J.P. Chalmers<sup>1</sup>. <sup>1</sup>Dept of Medicine, Flinders University, Bedford Park, SA AUSTRALIA; <sup>2</sup>Keck Center for Integrative Neuroscience, UCSF, San Francisco, CA, and <sup>3</sup>Dept of Cell Biology, Duke University Medical Center, Durham, NC.

Substance P is involved in cardiovascular control at the spinal cord level, acting through neurokinin-1 receptors (NK<sub>1</sub>R). We used immunocytochemistry and retrograde tracing with cholera toxin B (CTB) to investigate the expression and ultrastructural localization of the NK<sub>1</sub> receptor in rat SPN that project to the superior cervical ganglion (SCG) or the adrenal medulla. NK<sub>1</sub>R-immunofluorescence outlined the somatic and dendritic surfaces of autonomic neurons in spinal cord segments T1-T12; immunofluorescence for CTB filled the retrogradely-labelled cells. There was a significant difference in the proportion of NK<sub>1</sub>R-positive SPN supplying the SCG and the adrenal medulla: 38% of SPN to the SCG contained NK<sub>1</sub>R vs. 70% of sympathoadrenal neurons. Of neurons projecting to the SCG, 15% were NK<sub>1</sub>R-immunoreactive in segment T1 vs. 45% in segments T2-6. Ultrastructurally, NK<sub>1</sub>R was localized mainly at the cell membrane, both at synaptic and non-synaptic sites. Label was also seen in rough endoplasmic reticulum and Golgi. When sections were double-stained for both substance P and NK<sub>1</sub>R, only 37% of substance P inputs were on NK<sub>1</sub>R-positive neurons. Thus, the expression of the NK<sub>1</sub> receptor by SPN is related to their target. Furthermore, SPN may be affected not only by substance P released from conventional synapses but also by substance P that diffuses from distant sites. Supported by National Health & Medical Research Council of Australia

## 158.3

**THE ACTIVITY OF A SEGMENTALLY-RESTRICTED POPULATION OF DORSAL HORN NEURONS IS CORRELATED WITH RENAL SYMPATHETIC NERVE DISCHARGES IN SPINALLY TRANSECTED RATS.** D. Chau and L.P. Schramm\*. Departments of Biomedical Engineering and Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

We used the spike-triggered averaging technique to identify dorsal horn interneurons whose spontaneous activities were synchronized with renal sympathetic nerve discharges. Experiments were conducted on 52 male, C1-transected, chloralose-anesthetized, paralyzed, artificially-respired, Sprague-Dawley rats. We recorded from renal nerves and from dorsal horn neurons at levels T2, T8, T10, T13, and L2 ipsilateral to the renal nerve recording and also from neurons at T10 contralateral to the renal nerve recording. Based on responses to noxious and innocuous stimuli, all neurons were classified as low-threshold (LT), high-threshold (HT), or wide-dynamic range (WDR). None of the T2 (0/22), T13 (0/25), or L2 (0/26) ipsilateral neurons, nor the T10 (0/26) contralateral neurons were correlated with RSA. Twenty percent (5/25) of T8, and 40.0% (14/35) of T10 ipsilateral neurons were correlated with RSA. Correlated T10 neurons were found only in laminae III-V. Uncorrelated neurons were located in laminae I, III-V. Correlated neurons were most likely to be WDR (of 13 tested: 12=WDR, 1=HT). Uncorrelated neurons, however, were heterogeneous with respect to modality (of 17 tested: 9=WDR, 6=HT, 2=LT). Action potentials of correlated T10 neurons preceded the major peak in the spike-triggered average by 50ms ( $\pm 10$ ms). This latency was consistent with the measured conduction time from the spinal cord to the recording electrodes. Excitatory and inhibitory somatic fields of correlated neurons overlapped somatic fields which, when stimulated, excited and inhibited RSA, respectively. Further, somatic stimulation evoked responses in dorsal horn neurons similar to those simultaneously elicited in RSA. We suggest that correlated dorsal horn neurons may mediate the generation of sympathetic tone and of somato-sympathetic reflexes in the spinally transected rat. (Supported by NIH grant HL16315).

## 158.5

**IMMEDIATE-EARLY GENE RESPONSES TO SPINAL CORD TRANSECTION.** D.A. Ruggiero<sup>1</sup>\*, A.L. Sica<sup>2</sup>, M. Anwar<sup>1</sup>, N. Gootman<sup>2</sup> and P.M. Gootman<sup>2</sup>. <sup>1</sup>Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., NY, NY 10021; <sup>2</sup>Dept. of Physiol., SUNY Health Sci. Ctr., Brooklyn, NY 11203.

Sympathetic nerve discharge (SND) is maintained and regulated at the spinal level after high spinal cord transection (SCT). The identities of the spinal circuits were explored by monitoring induction patterns of c-fos gene expression produced by high thoracic SCT (n=4). Isoflurane-anesthetized adult male rats were spinalized at T3. Spinal cords were exposed but not transected in four age-matched controls. After 2.5 hrs rats were perfused for immunocytochemistry. Dorsal root ganglia (DRG) and spinal segments C3-C5 and T1-L3 were cut at 35  $\mu$ m, incubated in sheep or rabbit anti-Fos and processed using the avidin-biotin immunoperoxidase technique. SCT induced neurons to express Fos in thoracolumbar laminae I, V<sub>ret</sub>, VII, X and the intermediolateral cell column. DRG and cervical segments revealed no evidence of c-fos gene induction. Neuronal responses to SCT were localized to laminae that contain sympathetic interneurons and preganglionic motoneurons identified by retrograde transneuronal transport of Pseudorabies virus Bartha (1x10<sup>8</sup> pfu/ml) from the superior cervical ganglion or adrenal medulla. Peripheral inputs processed by spinal-sympathetic reflex circuits may regulate SND in the absence of supraspinal drive. (Supported by NIH grants HL18974; NS28200 [DAR]; HL20864; HD28931 [PMG])

## 158.2

**DETECTION AND POSSIBLE FUNCTION OF PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE IN THE RAT SPINAL SYMPATHETIC NUCLEI.** H. H. Lin<sup>1</sup>, C. C. Lai, S. L. Dun and N. J. Dun. Dept. of Anatomy & Neurobiology, Medical College of Ohio, Toledo, OH 43614.

Pituitary adenylyl cyclase activating polypeptide (PACAP)-like immunoreactivity was detected by immunohistochemical methods in nerve fibers projecting to the intermediolateral cell column and other sympathetic nuclei of rat thoracolumbar spinal cords. In urethane-anesthetized rats, the right femoral artery and left femoral vein were cannulated for blood pressure recording and intravenous administration of drugs. Peptides and glutamate were administered intrathecally via an implanted cannula to the T2-T3 segments. Intrathecal injection of PACAP (0.1, 0.3 and 1 nmol) dose-dependently increased the mean arterial blood pressure and heart rate from minutes to over 1 hr. The pressor effect of PACAP (0.1 nmol) was small and not statistically significant as compared to saline control. Intrathecal injection of glutamate (1  $\mu$ mol) and substance P (5 nmol) caused a short- and long-lasting pressor response, whereas vasoactive intestinal polypeptide (1 nmol) had little or no significant pressor effect. In contrast to a pressor effect, intravenous injection of PACAP (0.3 nmol/kg) consistently lowered the blood pressure. The pressor effect of PACAP was not blocked by prior intrathecal injection of the type II PACAP receptor antagonist PACAP (6-38, 0.5 nmol). Intravenous injection of the  $\alpha$ -adrenergic receptor blocker phentolamine (1 mg/kg), which caused a fall in blood pressure, attenuated the pressor response of a second intrathecal injection of PACAP. The result shows that PACAP administered intravenously lowers and intrathecally increases blood pressure, respectively. The pressor effect caused by intrathecal injection of PACAP is probably exerted on spinal sympathetic preganglionic neurons. This study provides preliminary evidence of a novel peptidergic pathway to the intermediolateral cell column, the activation of which may increase spinal sympathetic outflow. (Supported by NS18710 & HL51314).

## 158.4

**LATERAL FUNICULUS AND LATERAL SPINAL NUCLEUS NEURONS PROJECT TO THE INTERMEIDIOLATERAL CELL COLUMN.** A.S.P. Jansen\* and A.D. Loewy. Dept. Anat. & Neurobiol., Wash. Univ. Sch. Med., St. Louis, MO 63110.

In two earlier studies (Brain Res., 616 (1993) 251; *ibid.* 683 (1995) 1), we found that neurons lying in the lateral spinal nucleus and lateral funiculus of the upper cervical spinal cord became transneurally labeled following pseudorabies virus injections into the kidney or stellate ganglion. In the present study, we have extended these findings and now report that similar results occur following pseudorabies virus injections into the superior cervical ganglion, celiac ganglion or adrenal gland. These findings were confirmed with an anterograde tracing method. Iontophoretic injections of the plant lectin *Phaseolus vulgaris* leuco-agglutinin were made in the lateral funiculus or lateral spinal nucleus of the C<sub>3</sub> spinal segment, resulting in bilateral axonal labeling in the intermediolateral cell column, laminae VII and X. Sparse axonal labeling was observed in the dorsal horn (lamina V) and ventral horn of the C<sub>5</sub>-C<sub>6</sub> segments as well as the thoracic spinal cord. A few labeled fibers were found in the lower lumbar or sacral spinal cord, but their termination sites were not identified.

In summary, this report provides the first evidence that two descending projection systems arise from neurons lying within the white matter of the cervical spinal cord and terminate in close apposition to sympathetic preganglionic neurons.

This research was supported by the National Institute of Heart, Lung, and Blood (HL-25449) of the NIH.

## 158.6

**THE PRESENCE OF SYMPATHETIC (SYMP) ACTIVITY FOLLOWING SPINAL CORD TRANSECTION (SCT) IN DEVELOPING SWINE.** A.L. Sica<sup>1</sup>, B.W. Hundley<sup>2</sup>, D.A. Ruggiero<sup>3</sup>, M. Anwar<sup>1</sup> and P.M. Gootman<sup>2</sup>. <sup>1</sup>Long Island Jewish Med. Ctr., New Hyde Park, NY 11040. <sup>2</sup>SUNY Hlth. Sci. Ctr. at Bklyn., NY 11203. <sup>3</sup>Cornell University College of Medicine, NY, NY 10021.

SYMP activity is not abolished by high spinal transection. It is possible that sensory inputs transmitted through dorsal root ganglia can retain activity via intraspinal reflex circuits. In Saffan anesthetized, vagotomized, paralyzed and artificially ventilated (100% O<sub>2</sub>) piglets, recordings were obtained from phrenic and lumbar SYMP nerves before and after SCT. Intact animals displayed modulation of SYMP activity by both baroreceptor and central respiratory-related inputs. Following SCT, modulation of SYMP activity related to lung inflation emerged; SYMP activity was maximum during inflation and at a minimum during deflation. The relationship of SYMP to lung inflation was quantified by autoper and coherence spectra. Prominent peaks (ca. 1 Hz), were highly correlated in coherence spectra (>0.1). These results suggest pulmonary afferent modulation of SYMP discharge may account for the observed vasomotor changes occurring in SCT mammals. C-fos gene expression was used to monitor functional responses of spinal cord neurons below SCT. Age-matched controls were subjected to identical surgical procedures but not to spinal cord injury. After 2.5-3 hrs, animals were prepared for immunocytochemistry. After SCT, larger numbers of intensely labeled nuclei were concentrated in C3-C5 (laminae V, VII and X) and thoracic spinal gray (laminae I, V, VII, X, including intermediolateral cell column). Neurons expressing Fos after SCT occupy laminae that harbor SYMP interneurons and motoneurons; interneurons may regulate SYMP in response to spinal cord injury. It appears that the activity present in efferent preganglionic discharge in developing animals is less dependent on supraspinal mechanisms, possibly because functional synaptic contacts with brain stem SYMP neurons are not yet fully expressed. (Supported by NIH grants HL-20864, HD-28931 [P.M.G., A.L.S.] and HL18974, NS-28200 [D.A.R.]).

## 158.7

POTENTIAL SUPERSENSITIVITY TO CATECHOLAMINES IN A CHRONIC RAT MODEL OF AUTONOMIC DYSREFLEXIA. L.M. Landrum, G.M. Thompson, and R.W. Blair\*. Dept Physiol, Univ OK Hlth Sci Ctr, Oklahoma City, OK, 73190.

Episodic hypertension, known as autonomic dysreflexia, can be induced by visceral and somatic stimuli following spinal cord injury above T6. Catecholamine supersensitivity was evaluated as a potential mechanism for autonomic dysreflexia by comparing dose-response curves to phenylephrine in chronic lesioned and intact control rats. Spinal cords were completely transected at T4 in two rats and partially transected in three rats. Thirty five days were allowed for the lesioned rats to recover. One day prior to the experiment, arterial and venous catheters were implanted in both lesioned and control rats to monitor blood pressure and infuse drugs, respectively. Dose-response functions were assessed on the next day in conscious lesioned or age- and weight-matched control rats. Pressor responses to phenylephrine were enhanced at all doses (0.25, 0.50, 0.75, 1.0, 2.0  $\mu\text{g/kg}$ ) in rats with complete transections compared to intact controls. Animals with incomplete lesions, as determined by presenting motor skills, reflected dose-response curves similar to intact controls. These results suggest that chronic lesioned rats with complete spinal cord transections are more sensitive to catecholamines than partially transected animals or intact controls. This study provides initial support for supersensitivity to catecholamines as a potential mechanism for autonomic dysreflexia. Supported by Provost Research Award.

#### CONTRIBUTION OF SPINAL CORD NMDA AND AMPA RECEPTORS TO EPISODIC HYPERTENSION IN CONSCIOUS SPINAL RATS.

D.N. Maierov\*, N.R. Krenz, A.V. Krassioukov and L.C. Weaver. Neurodegeneration Research Group, John P. Robarts Research Institute and Dept. of Physiology, University of Western Ontario, London, ON, Canada.

Spinal viscerosympathetic reflexes play a major role in the onset of episodic hypertension after spinal cord injury. The importance of glutamatergic transmission in mediating these spinal reflexes is not established. Therefore, we tested effects of intrathecally injected antagonists of the NMDA receptor (AP-5; 5 nmol) or the AMPA receptor (NBQX; 1.25 nmol) on the reflex hypertension caused by colon distension. Experiments were done using conscious rats 1-2 days (acute) or 14-15 days (chronic) after cord transection at the 5th thoracic segment. Before AP-5 injection, colon distension increased mean arterial pressure by  $25 \pm 2$  mmHg (from  $93 \pm 3$  mmHg) and by  $33 \pm 3$  mmHg (from  $122 \pm 5$  mmHg) in the acute (n=6) and chronic (n=6) groups, respectively. Intrathecal pretreatment with AP-5 attenuated the pressor responses by 45% and by 40% in the acute and chronic groups, respectively. Before NBQX injection, colon distension caused pressor responses of  $19 \pm 3$  mmHg (from  $104 \pm 5$  mmHg; n=4) and  $30 \pm 3$  mmHg from  $108 \pm 8$  mmHg; n=5) in the acute and chronic groups, respectively. Intrathecal pretreatment with NBQX attenuated the pressor responses by 39% and by 49% in the acute and chronic groups, respectively. At the doses used, AP-5 and NBQX blocked the pressor responses caused by intrathecal injection of NMDA (0.1 nmol) and AMPA (1 nmol), respectively. These data suggest that both NMDA and AMPA receptors contribute to spinal viscerosympathetic transmission and initiation of episodic hypertension in conscious spinal rats. #### RESPIRATORY MODULATION AND CHEMORECEPTOR REFLEX RESPONSES OF ADRENAL SYMPATHETIC PREGANGLIONIC NEURONS. S.F. Morrison\* Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL 60611.

Two populations of adrenal sympathetic preganglionic neurons (SPNs), putatively effecting selective control of the secretion from epinephrine- and norepinephrine-storing chromaffin cells in the adrenal medulla, have been differentiated by their responses to the blockade of cellular glucose utilization with 2-Deoxy-D-glucose and by their responses to activation of the RVLM. To examine how these SPNs are influenced by the central respiratory networks and by activation of the peripheral chemoreceptor reflex, the relationship of their spontaneous discharge to the phrenic nerve cycle was monitored and their responses to 10s periods of breathing 100%  $\text{N}_2$  were tested in urethane/chloralose-anesthetized, vagotomized, and artificially-ventilated rats. Adrenal SPNs potentially regulating norepinephrine release displayed a prominent respiratory modulation, usually with an increase in discharge probability during the late I-early E phase, and were also potentially excited during the period of increased respiratory frequency arising from chemoreceptor stimulation. The discharge probability of adrenal SPNs potentially regulating epinephrine release was not modulated over the phrenic nerve cycle and was changed little during chemoreceptor activation. These data suggest a further functional differentiation among sympathetic premotor neurons innervating SPNs regulating different target tissues. Supported by NIH HL47196.

## 158.8

#### CONFOCAL MICROSCOPY FOR MONITORING THE SURVIVAL OF SYMPATHETIC PREGANGLIONIC NEURONS IN LIVE EXPLANTS OF THE SPINAL CORD.

A. Krassioukov\*, S. McDonnell<sup>1</sup> & K. Rogers<sup>2</sup>. <sup>1</sup>John P. Robarts Research Inst. & Dept. of Physiol. Univ. of Western Ontario, & <sup>2</sup>Dept. of Anatomy and Cell Biology. Univ. of Western Ontario, London, Ont., Canada, N6A 5K8.

It is well documented that after spinal cord injury sympathetic preganglionic neurons (SPNs) caudal to the site of injury first atrophy, and then regenerate, forming new connections within the spinal cord. The purpose of this study was to develop an *in vitro* slice preparation of a neonate rat spinal cord as a model of spinal cord injury, and to study the responses of SPNs to various concentrations of ciliary neurotrophic factor (CNTF). CNTF has previously been shown to promote motor neuron survival *in vivo* following axotomy, and has known trophic effects on SPNs as well. In order to investigate the survival and morphology of SPNs *in vitro*, a retrograde tracer was injected into the adrenal glands of 7 day old rat pups three days before they were sacrificed, following which their spinal cord tissues were put into culture. Explants were maintained in culture for a period of 21 days in media containing 50 ng/ml CNTF. Samples were taken periodically for analysis using a confocal microscope: SPNs were identified and their integrity monitored at each time period. When compared to age-matched pups, their morphology appeared to be normal. Physiological integrity of SPNs was determined by examining for the presence of enzymes that are typically expressed in these neurons, such as acetylcholinesterase and NADPH diaphorase. SPNs in explants cultured without CNTF did not survive for a long period of time and showed signs of degeneration within 24h of culturing. (Supported by the Heart and Stroke Foundation of Canada).

## 158.10

#### EFFECT OF SPINAL CORD TRANSECTION ON THE 2-6 Hz COHERENT RHYTHMIC ACTIVITY IN DIFFERENT SYMPATHETIC (SY) NERVES.

B. Kocsis\* and K. Gyimesi-Pelczser. National Institute of Neurosurgery, Budapest, Hungary.

Periodically occurring slow waves between 2 and 6 Hz dominate basal discharge in all SY efferents. In the cat with an intact neuraxis, the 2-6 Hz rhythm is highly coherent between different nerves and also with similar oscillations in the population activity of brainstem SY networks. Although basal sympathetic nerve discharge (SND) is heavily dependent on the activity of these same networks, there is some evidence that some rhythmic synchronization is possible in the absence of rhythmic bulbospinal input. In order to examine the spinal SY oscillators and primarily the possibility of their coupling, we analyzed the SND simultaneously recorded in three nerves of 19 acute spinal cats after intrathecal injection of glutamate (i/t-GLU). We found that the response to i/t-GLU was highly variable but usually

included activation of rhythmically modulated SND (still with relatively high power above 6 Hz) which could indeed be correlated in different (even distant) nerves (see Figure), suggesting that they were generated by multiple oscillators capable of synchronization at low frequencies. (Supported by OTKA Grant T-020351)

#### CHARACTERISTICS OF THE RENAL SYMPATHETIC NERVE ACTIVITY RECORDED IN CONSCIOUS DAHL SALT-SENSITIVE RATS. K. Kato, T. Kunitake, T. Hanamori and H. Kannan\*. Dept. Physiol., Miyazaki Medical College, Miyazaki, Japan 889-16.

Dahl salt-sensitive (DS) rats develop hypertension when fed a high-salt diet, but remain normotensive on a low-salt diet. The mechanisms underlying salt-dependent hypertension are not entirely known, although several abnormalities in DS have been proposed to be of pathogenic importance: involvement of the kidneys, including abnormal renal excretory and humoral mechanisms, is one such suggested contributory factor. Renal sympathetic nerve activity (RSNA) has a direct effect on the control of renal blood flow, renin release and urinary sodium excretion. We have recorded RSNA in free-moving Dahl-rats on a low NaCl diet in order to characterize the RSNA discharge pattern and evaluate the RSNA response to intracerebroventricular (i.c.v.) administration of hypertonic sodium chloride. Under resting conditions, two types of discharge pattern were seen, a grouped cardiac-related discharge (GD) and a non-grouped irregular discharge (NGD). The GD was inhibited by i.v. administration of phenylephrine chloride, while the NGD was not. Both GD and NGD were seen in DS and Dahl-salt-resistant (DR) rats and both were completely abolished by i.v. administration of the ganglionic blocker, hexamethonium chloride, indicating postganglionic efferent nerve involvement. I.c.v. infusion of NaCl (0.3-1.0 M, 20 min, 1  $\mu\text{l/min}$ ) produced decreased RSNA in DS and DR rats, but more long-lasting decreased RSNA in DS rats was observed, compared to DR rats. The result does not support the hypothesis that salt-sensitive hypertension is due to a failure to suppress RSNA in response to salt loading. The experimental results also emphasize the importance of recording with a high signal-to-noise ratio to evaluate the true activity of the autonomic nervous system.

## THE INFLUENCE OF THE PARAVENTRICULAR NUCLEUS ON SYMPATHETIC ACTIVITY TO THE HEART AND KIDNEY: MEASUREMENT BY CLUSTER ANALYSIS

Jane Gardner\* and John H. Coote. Department of Physiology, University of Birmingham, Birmingham B15 2TT, U.K.

Following our previous studies (Gardner et al, 1995) a pattern of response in sympathetic nerve activity produced by stimulation in the paraventricular nucleus (PVN) was investigated using a computerised program of cluster analysis. Experiments were carried out on rabbits anaesthetised with urethane. Recordings were made from the left renal and cardiac sympathetic nerves whilst stimulating neuronal perikarya in PVN by microinjection of 200nl 0.2M D,L-homocysteine acid containing 1% Pontamine Sky Blue. Stimulation in PVN always produced an inhibition in renal nerve activity (RNA,  $32 \pm 7.1\%$ ), accompanied by an increase in cardiac nerve activity (CNA,  $41 \pm 8\%$ ), and an increase in mean arterial blood pressure ( $9 \pm 3.4\%$ ). There was no significant change in heart rate ( $p > 0.8$ ). The filtered and rectified nerve activity was subsequently analysed using a peak detection program, providing data on the peak to peak (p-p) intervals and peak heights. RNA showed a mean decrease in p-p interval of  $24.6 \pm 14\%$  whilst CNA increased by  $19.7 \pm 5.5\%$  suggesting a reduction in the number of active neurones in RNA and an increase of active neurones in CNA. Similarly the peak height, which is indicative of changes in firing frequency of the same neurones, was decreased in RNA ( $17 \pm 6.1\%$ ) and increased in CNA ( $9.7 \pm 2.4\%$ ). This analysis demonstrates that the PVN induced differential response involves an alteration in the number of active neurones and their firing rate, thus providing a more comprehensive understanding of the influence of PVN on the cardiovascular system.

## GENE TRANSFER INTO SYMPATHETIC PREGANGLIONIC NEURONS IN VIVO BY THYMIDINE KINASE DEFICIENT OR MULTIMUTANT HERPES SIMPLEX VIRUS TYPE 1. M.A. LeVatte, G.A. Dekaban and L.C. Weaver.

Neurodeq. Research Group, Robarts Research Institute, London, Ontario, N6A 5K8.

Long term improvements in faulty control of discrete functional groups of spinal sympathetic preganglionic neurones (SPNs) might be accomplished by introducing corrective genes into these cells using replication-defective herpes simplex virus type 1 (HSV-1). Thymidine kinase deficient HSV-1<sub>TK</sub> (TK-HSV-1) expressing the *E. coli*  $\beta$ -galactosidase ( $\beta$ -gal) from the HSV ICP6 promoter, was previously assessed as a transfer vehicle into SPNs *in vivo*. TK-HSV-1 ( $1-6 \times 10^6$  plaque forming units, PFU) infected many sympathoadrenal SPNs ( $353 \pm 97$ ;  $n=5$ ) 2 days post-inoculation into the left adrenal gland of hamsters. After 5 days, fewer SPNs ( $98 \pm 78$ ;  $n=7$ ) were detected and many showed abnormal morphology. Inflammatory infiltrates were abundant throughout the white and grey matter. TK-HSV-1 expresses all immediate early transcriptional activators, many of which are known to contribute to the cytotoxicity of HSV-1. Another recombinant HSV, 14HA3vhsZ, has mutations in the transactivator vp16, the immediate early transactivator ICP4 and virus host shutoff, expresses  $\beta$ -gal from a cytomegalovirus promoter and was noncytotoxic for cells in culture (Johnson *et al.*, *J. Virol.* 68: 6347, 1994). Three days after adrenal inoculation, 14HA3vhsZ ( $3-5 \times 10^6$  PFU) was retrogradely transported to many SPNs ( $212 \pm 97$ ;  $n=3$ ). These SPNs had normal morphology and elaborate dendritic processes. After 5 days,  $112 \pm 76$  ( $n=2$ ) SPNs were detected and fewer SPNs demonstrated abnormal morphology than had occurred after infection with TK-HSV-1. However, inflammatory infiltrates were also detected 5 days after inoculation with 14HA3vhsZ. 14HA3vhsZ was detected in few oligodendrocytes, microglia or astrocytes in contrast to the extensive extrasynaptic spread of TK-HSV-1 from infected SPNs. In conclusion, the multimutant 14HA3vhsZ is highly neurotropic *in vivo*, can be transported from the periphery to spinal neurons, appears to produce less neurocytotoxicity than TK-HSV-1 and may be a favorable gene transfer vehicle. Support: MRC Canada.

## 158.14

## CALCIUM-BINDING PROTEIN IMMUNOREACTIVITY MARKS SPECIFIC AUTONOMIC PATHWAYS IN THE RAT SUPERIOR CERVICAL AND STELLATE GANGLIA. C.R. Anderson\* and I. Grkovic. Department of Anatomy and Cell Biology, University of Melbourne, Parkville, 3052, Australia.

The superior cervical ganglion (SCG) and the stellate ganglion from Sprague Dawley rats were stained for the immunohistochemical demonstration of the calcium-binding proteins, calbindin and calretinin. Calbindin and calretinin were present separately, or in some cases in combination, in subpopulations of nerve terminals surrounding postganglionic nerve cell bodies. Calbindin, but not calretinin was also present in a subpopulation of postganglionic neurones in both ganglia. The postganglionic targets of some of the calbindin and calretinin terminals were determined in a series of retrograde tracing studies using Fast Blue or Fluorogold in combination with immunohistochemistry. Terminals containing calbindin but not calretinin were present around a subset of neurones projecting to the hairy skin. The vast majority of these neurones lacked NPY-immunoreactivity, suggesting they were pilomotor in function. Many large neurones lacking NPY-immunoreactivity, projecting to the submandibular salivary gland and predominantly in the SCG, were surrounded by terminals containing both calretinin and calbindin. Postganglionic neurones projecting to the skeletal muscle of the forelimb and iris were never surrounded by calbindin or calretinin terminals. Postganglionic neurones projecting to brown fat were not surrounded by calretinin or calbindin terminals but nearly all postganglionic neurones lacking NPY immunoreactivity were calbindin immunoreactive. Thus in the rat SCG and stellate ganglion, calbindin and calretinin are restricted to a range of functionally defined autonomic pathways.

This work was funded in part by the Australian National Heart Foundation.

## GASTROINTESTINAL REGULATION: CNS CONTROL

## 159.1

## PSEUDORABIES VIRUS (PRV) LABELING OF BOMBESIN-LI NEURONS IN THE PARAVENTRICULAR NUCLEUS (PVN) OF THE HYPOTHALAMUS CONTROLLING GASTRIC FUNCTION.

R.B. Lynn\*<sup>1</sup>, G.-Y. Cao<sup>1</sup>, M. Yang<sup>2</sup>, R.R. Miselis<sup>2</sup>. <sup>1</sup>Dept. of Med., Jefferson Medical College, Thomas Jefferson Univ., Phila. PA 19107; <sup>2</sup>Dept. of Animal Biol., Univ. of Penn., Phila. PA, 19104;

Bombesin injected centrally in rats inhibits gastric acid secretion and motility. Bombesin-like immunoreactive (LI) neurones in the PVN of the hypothalamus project to the dorsal vagal complex, consistent with a potential influence on vagal pathways. The aim of this study is to locate the bombesin-LI neurones that are synaptically connected to gastric pathways in rats. PRV, a neurotropic virus, was used as a retrograde transsynaptic tracer to label circuits of neurones in the brain that project to the stomach. PRV (6  $\mu$ l) was injected subserosally into the rat stomach. 60-65 hrs later, a time at which PRV has already reached PVN neurones, colchicine (50  $\mu$ g/100 gm body wt) was injected into the lateral ventricle. After an additional 28-34 hrs the animal was perfused and the entire brain was frozen sectioned. Bombesin was labeled with a primary antiserum raised in rabbits (Inestar) and a secondary antibody conjugated to Texas Red. PRV was labeled with a primary antibody raised in goat and a secondary antibody conjugated to FITC. Bombesin-LI neurones double labeled with PRV were mostly located in the medial parvocellular portion of the PVN of the hypothalamus. These neurones, labeled both for their phenotype and connectivity, likely play a role in the central inhibitory effect of bombesin on gastric function. This study provides further evidence that bombesin containing neurones in the brain synapse directly onto gastric vagal motoneurons since vagotomy eliminates most medial parvocellular PVN labeling. ## 159.2

## DORSAL MOTOR NUCLEUS CELL TYPES DISTINGUISHED WITH MULTIVARIATE ANALYSES. M.K. Jarvinen\*, T.L. Powley, Purdue U., West Lafayette, IN 47907.

A full classification of the neuronal cytoarchitecture of the dorsal motor nucleus of the vagus (dmnX) is still not available. Previous quantitative groupings of dmnX neurones, including univariate analyses of Lucifer Yellow-fill neurones projecting to the abdomen (Fox and Powley, 1992) and descriptions of HRP-filled neurones responsive to intestinal distension (Zhang et al. 1992) would not have detected interneurons or all preganglionics projecting to all targets, because of the sampling strategies employed. Golgi staining should randomly sample all subpopulations, but such material has not been analyzed by multivariate quantitative methods. To provide this analysis, male SD rats were perfused, and their brainstems stained *en bloc* with a Golgi-Cox protocol. Prior to perfusion, each animal received a Fluoro-gold injection (3mg i.p.) to label the dmnX. Separate stained blocks were sectioned at 170  $\mu$ m in horizontal, sagittal, and coronal planes. All darkly stained and non-truncated neurones were digitized (Eutectics Neuron Tracing System). Three-dimensional morphometric measures included dendritic length, number of total segments, spine density, number of primary dendrites, dendritic orientation, and soma form factor. Samples of 100+ neurones from a given plane of section were then subjected to cluster analysis (Ward's algorithm) and principle components analysis (PCA). Consistent with previous suggestions, neurones of the dmnX tended to be most elongated, i.e. to have their major axes running longitudinally. Cluster analyses identified four major categories of neurones in the horizontal sample and a similar set of homologous classes in the sagittal sample. PCA also identified a number of principle variables consistent with the defining characteristics of each cluster. As a further validity check on the cell categories identified in both horizontal and sagittal sections, a replicate sample of an additional 104 neurones from horizontal sections was analyzed. This replicate identified a similar set of four groupings. We are currently mapping the distributions of these four multivariate types within the dmnX, analyzing their dendritic branching outside of the nucleus, and relating them to previous descriptions of subsets of dmnX neurones. NIH DK27627 and NIMH MH01023.

## 159.3

**VAGAL AFFERENT AND EFFERENT INNERVATION OF THE GI TRACT COMPARED.** J. Kelly\*, F. B. Wang, E. A. Baronowsky, R. J. Phillips, and T. L. Powley. Purdue University, West Lafayette, IN 47907.

The number of axons and the ratio of sensory to motor fibers in the vagus nerve have been the basis for inferences about the innervation of the gut. Specifically, the number of axons in the abdominal vagus (~22000) has reinforced the assumption that the GI tract is sparsely innervated, and the disproportionate percentage of afferent fibers (e.g. 73%; Prechtl and Powley, '90) has generated the extrapolation that vagal innervation of the GI tract is largely sensory. These assumptions do not consider the divergence of the peripheral projections, hence we re-examined the issue by comparing terminal distributions. Male SD rats received unilateral injections of WGA-HRP in either the nodose ganglion or the dorsal motor nucleus of the vagus. Before injections, animals received unilateral intracranial vagal sensory rhizotomies (for efferent injections) or motor rhizotomies (for afferent injections) to eliminate inappropriate labeling. Control animals received WGA-HRP injections without prior rhizotomies or injections of Dil. The nodose ganglia, stomach, and the first 4 cm of duodenum were prepared as whole mounts and processed with TMB. Injections of either efferents or afferents caused heavily labeled vagal bundles and myenteric connectives, although, overall, motor label was denser than sensory label. This pattern was more pronounced as axons coursed from the connectives to targets: Efferent label delineated all myenteric ganglia, whereas afferent ganglionic label (i.e., intraganglionic laminar endings) was absent or barely detectable in many ganglia. In different gut locations, the relative densities of the motor and sensory terminal label (motor > sensory) were generally correlated, but in some regions this covariance was weak. In the antrum, for example, motor label was particularly dense whereas sensory label was relatively sparse. Conspicuous motor label is at odds with traditional expectations derived from counts of axons, but it is consistent with recent reconstructions of collateralization and termination in single efferent axons. More generally, these data indicate that axon counts—which do not consider divergence and terminal ramifications—are unreliable estimators of innervation densities. NIH DK27627 and NIMH MH01023.

## 159.5

**REINNERVATION OF THE STOMACH BY VAGAL AFFERENTS AFTER SELECTIVE VAGOTOMY: TERMINALS.** R. J. Phillips\*, E. A. Baronowsky, & T. L. Powley. Purdue University, West Lafayette, IN 47907.

The vagus has been shown to supply two distinct types of endings in the gastric muscle wall: intramuscular arrays (IMAs) and intraganglionic laminar endings (IGLEs). We have previously reported that after selective subdiaphragmatic vagotomy, the vagal bundles and axons normally innervating the stomach are able to undergo dramatic plasticity in response to the injury (Powley et al., this meeting). To further investigate the plasticity of vagal endings, inventories of terminals were taken in stomach specimens from male SD rats that had been given partial subdiaphragmatic vagotomies by cauterization, sparing only the hepatic branch. Animals were perfused 2 weeks (2wk; n=26), 6 weeks (6wk; n=12), and 18 weeks (18wk; n=21), post-vagotomy. Each rat received injections of Fluoro-gold (1-2 mg, i.p.) and WGA-HRP (3 µl, in the left nodose ganglion) 6 and 3 days before perfusion, respectively. The medulla was sectioned (56 µm) and used to verify the vagotomy (Fluoro-gold). The nodose ganglia and stomach were prepared (TMB) as whole mounts. Terminals in the stomach were counted and mapped with a sampling grid. At 2wk post-vagotomy, afferent endings (IGLEs and IMAs) were limited to the sparse terminal fields of the spared hepatic branch. At 6wk post-vagotomy, few new differentiated endings were present, although bundles and individual axons had entered the denervated regions of the stomach. By 18wk, both gastric walls were innervated by well developed endings. IGLEs were diffusely distributed throughout the stomach, whereas IMAs were found to be focused in the region of the fundus on both sides of the stomach. Although these restored distributions were similar overall to the spatial patterns of endings found in intact animals, some blurring and imperfections of the putative receptor maps occurred in the reorganized tissue. The formation of well developed IMAs and IGLEs by 18wk suggests that some afferent function(s) may be restored to the stomach. Additional analyses are required to determine the individual contributions of reorganization (of the hepatic branch) and regeneration (of the transected branches) to this plasticity. NIH DK27627 and NIMH MH01023.

## 159.7

**ACTIVATION OF RECEPTORS OF THE 5-HT<sub>1</sub> AND 5-HT<sub>2</sub> FAMILY AUGMENTS TRH ANALOG INDUCED GASTRIC ACID SECRETION AT THE DORSAL VAGAL COMPLEX.** S. Varanasi, J. Chi, R. L. Stephens, Jr., Dept. of Physiology, The Ohio State University, Columbus, OH 43210

Neurons from the caudal raphe (nucleus raphe obscurus and nucleus raphe pallidus) nuclei project to the dorsal vagal complex and contain colocalized thyrotrophin releasing hormone (TRH) and serotonin (5-HT). Previous work has established that 5-HT enhances TRH-induced stimulation of gastric acid secretion at the DVC and that receptors of the 5-HT<sub>1</sub> family mediate this augmented response. However in the present study, using more caudal co-ordinates for DVC injection, ketanserin or ritanserin pretreatment did not attenuate the 5-HT induced augmentation response. To investigate this discrepancy, 5-HT receptor selective agonists were co-injected with RX [12 pmole] into the DVC at a 5-HT agonist/RX molar ratio of 12. The selective agonists used were 5-CT (5-HT<sub>1</sub>), DOI (5-HT<sub>2</sub>) and 2-methyl-5-HT (5-HT<sub>2C</sub>). All injection volumes were 30 nl. The DVC co-ordinates were 0.2 mm anterior, 0.2 mm right, 0.6 mm ventral with respect to the calamus scriptorius. Acid responses (mean ± SEM, \* p < 0.05 compared with RX).

Cum. acid,	Saline	RX	5-CT/RX	DOI/RX	2-M-5HT/RX
µmole/90 min	(n=3)	(n=7)	(n=5)	(n=3)	(n=7)
± SEM	11 ± 4	42 ± 8	156 ± 23*	131 ± 37*	42 ± 12

The results suggest that 5-HT<sub>1</sub> and 5-HT<sub>2</sub>, but not 5-HT<sub>2C</sub> receptors are involved in the augmentation response. Examination of RX/5-HT agonist response in more rostral DVC confirms involvement of 5-HT<sub>1</sub> receptor in the augmentation response. The results reveal that receptors of both the 5-HT<sub>1</sub> and 5-HT<sub>2</sub> family mediate enhanced acid response to DVC TRH-analog. Supported by NIH-DK 730037.

**REINNERVATION OF THE STOMACH BY VAGAL AFFERENTS AFTER SELECTIVE VAGOTOMY: AXONS & BUNDLES.** T. L. Powley\*, E. A. Baronowsky, & R. J. Phillips. Purdue University, West Lafayette, IN 47907.

Vagotomies are used extensively to study GI function, but little attention is usually given to the possibility that the vagus might regenerate or reorganize after vagotomy. Extrapolations from robust remodeling of Vllth and IXth nerve innervation of the tongue after axotomy as well as clinical observations after palliative vagal surgery, however, suggest that the vagus might exhibit plasticity. To investigate such potential plasticity, we gave male SD rats partial subdiaphragmatic vagotomies by cauterization, sparing only the hepatic branch. Animals were perfused 2 weeks (2wk; n=26), 6 weeks (6wk; n=12), and 18 weeks (18wk; n=21), post-vagotomy. Each rat received injections of Fluoro-gold (1-2 mg, i.p.), and WGA-HRP (3 µl, in the left nodose ganglion) 6 and 3 days before sacrifice, respectively. The medulla was sectioned (56 µm) and used to verify the vagotomy (Fluoro-gold). The nodose ganglia and stomach were processed (TMB) as whole mounts. Vagal bundles (2 or more axons) and individual axons in the stomach were counted and mapped with a sampling grid. At 2wk post-vagotomy, vagal afferents were limited to the sparse projections of the hepatic branch: innervation of the ventral stomach consisted of 1-2 bundles which branched into relatively small terminal fields; the only fibers on the dorsal stomach were mainly distal axons that wrapped around from the ventral side. By 6wk post-vagotomy, both sides were innervated by several bundles and numerous axons. Most axons in these projections, however ended in growth cone profiles or free endings, not differentiated terminals. By 18wk, both sides of the stomach were densely (albeit incompletely) innervated by bundles and axons. At this later stage, afferent axons terminated in elaborate, differentiated types of endings (see Phillips et al., this meeting). Ingrowing vagal bundles and axons appeared to follow the normal organization of branches and connectives, although some axons separated from the bundles and followed tortuous, looping, or recurrent paths. The finding of vagal plasticity after damage to its peripheral axons, and the ability to quantify this phenomenon opens up a new arena in which to study regeneration and reorganization. NIH DK27627 and NIMH MH01023.

## 159.6

**RECIPROCAL CONTROL OF GASTRIC MOTILITY BY Y1 and Y2**

**RECEPTORS IN THE DVC.** CH. Chen,<sup>1</sup> IL. Taylor,<sup>2</sup> and RC Rogers<sup>2</sup>\*

<sup>1</sup>Ohio State Univ.: Department of Physiology, Columbus, OH 43221; <sup>2</sup>Medical Univ. of South Carolina: Department of Medicine, Charleston, SC 29425

The pancreatic polypeptide family of hormones and neurotransmitters including PP, PYY and NPY are emerging as potent central regulators of gastric function. There is, however, considerable debate concerning the mechanisms and even the direction of effects mediated by these peptides. Evidence shows that PYY is the "enterogastrone" released by the ileum into the circulation after feeding which acts on vagal reflex control circuits to reduce gastric motility [i.e. the "ileal brake"]. However, PYY and its close structural relative NPY may also act in the dorsal vagal complex (DVC) to increase gastric motility.

We hypothesize that the confounding observations are due to agonist effects on two different receptor types, Y1 and Y2. Both receptors are present in the DVC but may be accessed differentially by peripheral humoral [PYY] versus central [NPY] pathways. In our initial approach to this problem, we studied the effects of NPY, PYY, Y1 and Y2 agonists microinjected directly into the DVC on gastric motility in both basal and stimulated [by central TRH] conditions. Our results show that Y2 agonists applied to the DVC during conditions of TRH-stimulated gastric motility mimic the suppressive effects of PYY applied under the same conditions. Under basal conditions, Y2 agonists have no effect on motility. The DVC effects of the Y1 agonist are the opposite: Y1 agonist has no further effect to stimulate gastric motility in the TRH stimulated condition while Y1 agonist strongly stimulates motility in the basal condition. NPY effects depend upon the prevailing gastric motility. Under TRH stimulation [maximal motility] NPY in the DVC reduces, but does not completely suppress, gastric motility. In the basal state, NPY is a strong activator of motility. Our results are discussed in terms of the possible differential localization of Y1 versus Y2 receptors within the DVC and in terms of recent findings suggesting that PYY is rapidly converted to a Y2 agonist by a ubiquitous diamine peptidase [DAP IV]. Supported by grants from the NINDS and NIDDK

**DIRECT EVIDENCE THAT NEURONS IN THE DORSAL MOTOR NUCLEUS OF THE VAGUS (DMNV) ARE INHIBITED BY NEURONS IN THE NUCLEUS OF THE SOLITARY TRACT (NST).** X. Zhang\*, R. Fogel and W.E. Renshan. Div. Gastro., Henry Ford Hosp., Detroit, MI

It is known that mechanical or chemical stimulation of the gut activates a circuit that inhibits the activity of neurons in the DMNV. Though it is presumed that this reflex involves inhibitory neurons in the NST, direct evidence of such a relationship is lacking. The purpose of this study was to directly evaluate the effect of NST activation on DMNV neuronal activity. A multibarrel glass micropipette array was used to record from and label individual neurons in the NST and DMNV while releasing small volumes of 0.1 M glutamate or 0.9% NaCl in the vicinity of the recorded cell. A separate microsyringe filled with 0.1 M glutamate was lowered into the ipsilateral NST. The stomach and proximal small intestine were cannulated to allow delivery of distention and chemical stimuli to the gut. Ten neurons in the vagal complex were successfully characterized and labeled in this preliminary study. Each of the two NST neurons was excited by gastrointestinal stimulation, glutamate released from the multibarrel array, and glutamate injected into the NST via the separate microsyringe. The 8 DMNV neurons were either excited or inhibited by gastric and/or intestinal distension. Some of the DMNV neurons were also excited by injection of glutamate in the region of the recorded neuron, but all were inhibited by injection of glutamate into the NST. We suggest that these results provide direct evidence that gut-sensitive DMNV neurons are directly inhibited by neurons in the NST. Supported by NS 30083.

## 159.9

MODULATION OF NEURONAL ACTIVITY IN THE NUCLEUS OF THE SOLITARY TRACT BY THE PARABRACHIAL NUCLEI Z. Liu, R. Fogel\*, X. Zhang and W.E. Rhenan Division of Gastroenterology, Henry Ford Health Sciences Center, Detroit, MI 48202.

There is anatomical evidence that the parabrachial nuclei (PB) project to, and receive projections from, the nucleus of the solitary tract (NST). We know relatively little, however, about the role of the descending inputs from the PB to the NST. The principal aim of the present investigation was to evaluate the influence of the descending PB input on gut-sensitive neurons in the NST. Glass micropipettes filled with 2.0% Neurobiotin were used to record the response of individual NST neurons to an array of gastrointestinal stimuli (distention, 0.1 M HCl, 20% glucose and 3.2% NaCl) and electrical current stimulation of the ipsilateral PB. A total of 13 NST neurons were successfully characterized and labeled. Four of the 13 neurons were antidromically driven at 200 Hz by the PB electrode (presumably these four neurons projected to the PB). Each of the four neurons was excited by gastric and/or intestinal distention, with 2 of the 4 neurons responding to HCl as well. The remaining 9 NST neurons exhibited response properties that suggested the presence of descending modulatory inputs from the PB. The 9 NST neurons receiving PB input exhibited an increase ( $n = 4$ ) or a decrease ( $n = 5$ ) in activity during PB stimulation. These preliminary data suggest that the NST transmits information regarding a variety of mechanical and chemical gastrointestinal stimuli to the PB. In addition, the NST receive both excitatory and inhibitory inputs from the PB. Supported by NS 30083.

## 159.11

INTRACISTERNAL ANTISENSE OLIGONUCLEOTIDES TO TRH RECEPTOR ABOLISHES TRH-MEDIATED GASTRIC MOTOR EXCITATION IN RATS. D.V. Sivarao, Z.K. Krowicki and P.J. Hornby\*, Dept. Pharmacology, LSUMC, New Orleans, LA 70112.

TRH in the dorsal vagal complex (DVC) potentially stimulates gastric motor activity. The nucleus raphe obscurus (nROb) is a major source of TRH afferents to the DVC. Characterization of TRH reflex pathways controlling gastric function has been hampered by the lack of TRH receptor antagonists. Thus, we administered antisense oligonucleotides against the first 18 base pairs of TRH receptor mRNA intracisternally (100 µg per day for four days). The change in intragastric pressure (peak IGP and total AUC) after microinjection into the DVC of TRH (1 and 10 pmol;  $N=6$ ), L-glutamate (positive control) and saline was assessed. Controls received intracisternal mismatch oligonucleotide ( $N=4$ ) or saline ( $N=4$ ). Mean  $\pm$  SEM; \* $P < 0.05$  compared to saline.

Microinj.	Antisense	Mismatch	Saline			
agent	Peak IGP	AUC	Peak IGP	AUC	Peak IGP	AUC
Saline	-0.1 $\pm$ 0.1	0 $\pm$ 0	0.1 $\pm$ 0.1	0 $\pm$ 0	0.4 $\pm$ 0.2	0.3 $\pm$ 0.2
L-Glu	2.7 $\pm$ 0.8*	0.6 $\pm$ 0.1*	3.0 $\pm$ 1.0*	1.2 $\pm$ 0.4*	7.6 $\pm$ 1.7*	1.8 $\pm$ 0.2*
TRH 1	1.2 $\pm$ 0.9	0.6 $\pm$ 0.4	3.3 $\pm$ 1.0*	0.9 $\pm$ 0.2	4.7 $\pm$ 1.0*	2.5 $\pm$ 1.1*
TRH 10	1.9 $\pm$ 0.8	1.1 $\pm$ 0.6	5.2 $\pm$ 1.8*	1.4 $\pm$ 0.2	5.0 $\pm$ 0.9*	3.2 $\pm$ 0.6*

In the same animals, L-glutamate microinjected into the nROb to release endogenous TRH in the DVC resulted in much diminished increases in peak IGP and AUC in antisense-treated compared to saline- and mismatch-treated animals. This illustrates the utility of *in vivo* antisense oligonucleotides for characterization of central TRH pathways controlling gastric function. Support: DK42714 and Sloan Foundation.

## 159.13

THE NITRIC OXIDE SYNTHASE INHIBITORS N<sup>G</sup>-NITRO-L-ARGININE METHYL ESTER AND N<sup>G</sup>-NITRO-L-ARGININE ARE ANTIEMETIC IN FERRETS.

R.W. Dunn\*, R.L. Wynn and R.L. Gregory, NOS/CETS, Old Lyme, CT and University of Maryland, Baltimore, MD.

N<sup>G</sup>-nitro-L-arginine methyl ester (L-NAME) and N<sup>G</sup>-nitro-L-arginine (L-NOARG) inhibited cerebellar rat neuronal nitric oxide synthase (NOS) activity with IC<sub>50</sub> values of 0.90 and 0.48 µM, respectively. The effects of these NOS inhibitors were assessed in the morphine- and cisplatin-induced emesis models in ferrets. Non-fasted male ferrets (1-2 kg) were intravenously (iv) administered L-NAME or L-NOARG either 30 minutes prior to subcutaneous morphine (0.3 mg/kg) or 30 minutes after iv cisplatin (10 mg/kg). Animals were observed for emetic episodes (expulsion of solids or liquids) for either 30 or 180 minutes following morphine or cisplatin administration, respectively. Both L-NAME and L-NOARG dose-dependently antagonized the emetogenic effects of morphine (ED<sub>50</sub> values of 0.004 and 0.44 mg/kg, respectively) and cisplatin (ED<sub>50</sub> values of 0.019 and 0.008 mg/kg, respectively). For comparison, the ED<sub>50</sub> values for the 5-HT<sub>3</sub> antagonist ondansetron in the morphine and cisplatin assays were 2.58 and 0.41 mg/kg respectively. D-NAME (the stereoisomer of L-NAME which is devoid of NOS activity) had no protective effect in either the morphine or cisplatin models, suggesting that the antiemetic activity of L-NAME and L-NOARG was due to NOS inhibition. Therefore, NOS inhibitors may represent a novel class of antiemetic agents.

## 159.10

POSTNATAL DEVELOPMENT OF VAGAL-HYPOTHALAMIC CIRCUITS IN RATS. L. Rinaman\*, Dept. of Neurosci., Univ. of Pittsburgh, Pittsburgh, PA 15260.

In adult rats, ascending and descending connections between neurons in the dorsal vagal complex (DVC) and paraventricular nucleus of the hypothalamus (PVN) help integrate interoceptive stimuli and generate appropriate centrally-mediated autonomic, neuroendocrine, and behavioral responses. There is evidence suggesting that vagal-PVN connections are functionally immature in newborn rats. The present study was designed to further analyze the structural ontogeny of these connections. **Methods:** The anterograde and retrograde neural tracer cholera toxin (CTB; 100 nl, 0.25%; List) was microinjected into the DVC in anesthetized adults and pups at postnatal (P) days 1 to 6. Rats were anesthetized 24-48 hrs later and perfused transcardially with fixative. Fixed brains were sectioned coronally and treated for the immunocytochemical localization of tracer using goat anti-CTB (1:50K; List) and the Vectastain ABC immunoperoxidase procedure (Vector). **Results:** The membrane binding properties of CTB limited its diffusion from DVC injection sites. In adult rats, the PVN contained many retrogradely labeled neurons (491 $\pm$ 32;  $n=3$ ) and a network of anterogradely labeled fibers and terminals. In contrast to the adult labeling pattern, in neonates anterograde labeling in the PVN appeared sparse or absent through P6. Retrogradely labeled neurons were present in the PVN in pups injected with CTB as early as P1, but their number (205 $\pm$ 28;  $n=3$ ) was approximately half that observed at P6 (437 $\pm$ 41;  $n=2$ ). **Summary:** 1) Ascending projections from the DVC to the PVN appear sparse or absent during the first postnatal week. These data support an earlier report (*Dev. Brain Res.* 72:140) that PVN neurons are not activated by gastric vagal stimulation in newborn rats as they are in adults. 2) Descending projections from the PVN to the DVC may increase significantly during the first postnatal week. It remains to be determined whether retrogradely labeled PVN neurons form functional synapses within the DVC at these early ages. Ongoing work will further characterize the ontogeny of these and other CNS circuits that mediate homeostatic responses to interoceptive stimuli. Supported by NIH grant M1101208.

## 159.12

SYNAPTIC INPUTS IN NEURONS OF RAT DORSAL MOTOR NUCLEUS OF THE VAGUS REGULATING GASTROINTESTINAL ACTIVITY. M. Bertolino\*, R. Houghtling, S. Vicini\* and R. Gillis Department of Pharmacology, \*Department of Physiology and Biophysics Georgetown University School of Medicine, Washington DC 20007.

Evoked synaptic currents were studied in thin (200 µm) coronal slices of rat brainstem using the whole-cell configuration of the patch clamp technique. The synaptic currents were evoked by focal electrical stimulation either of the tractus solitarius (TS), or the commissural area of the nucleus TS (ComNTS). Stimulation evoked two types of synaptic currents in DMV neurons: an inward excitatory postsynaptic current (EPSC) at a holding potential (HP) of -70 mV blocked by 20 µM CPP and 5 µM NBQX (suggesting that the EPSC was elicited by glutamate receptors); and an outward inhibitory postsynaptic current (IPSC) at a HP of -40 mV blocked by 20 µM bicuculline (suggesting that the current was elicited by GABA<sub>A</sub> receptors). This dual innervation was recorded in neurons located either in the medial as well as in the lateral portion of the DMV. To investigate whether both types of ionotropic glutamate receptors were involved in the EPSCs evoked from the ComNTS, the decay phase of the EPSCs was studied with and without Mg<sup>2+</sup> in the perfusing solution. In both conditions the decay phase was fitted by a double exponential function showing the existence of a fast and a slow component. NBQX and CPP (in Mg<sup>2+</sup>-free solution containing 100 µM picrotoxin to block GABA<sub>A</sub> receptors) blocked the fast and slow component, respectively. These data suggest that GABA<sub>A</sub> and glutamate receptors may regulate the neurons controlling the GI tract function. Supported by NIH grant AM29975.

## 159.14

GASTRIC EXCITATORY MOTOR RESPONSES TO ENDOTHELIN-1 IN THE DORSAL VAGAL COMPLEX ARE MEDIATED THROUGH ET<sub>A</sub> RECEPTORS. Z.K. Krowicki\* and P.J. Hornby, Dept. of Pharmacology, Louisiana State University Medical Center, New Orleans, LA 70112.

Intracisternal administration of endothelin-1 (ET-1) and ET-3 in anesthetized rats evokes increases in gastric motor function (*Inflammopharmacology* 1996, in press). The aim of the present study was to investigate whether the dorsal vagal complex (DVC) is a medullary site for the gastric motor effects of ET and to identify the ET receptor subtype through which these effects are mediated. ET-1 (0.1-10 pmol per site) and ET-3 (1 and 100 pmol per site) were microinjected into the right DVC (30 nl) of  $\alpha$ -chloralose/xylazine anesthetized and artificially ventilated rats, while monitoring intragastric pressure and contractility of greater curvature longitudinal and pyloric circular smooth muscle. Endothelin-1 dose-dependently increased intragastric pressure and gastric contractility. The gastric excitatory motor effects of ET-1 (10 pmol) in the DVC were abolished by bilateral vagotomy. Since a 100-times higher dose of ET-3 (100 pmol) was required to produce changes in intragastric pressure of comparable magnitude to those elicited by ET-1 (1 pmol), we hypothesized that the gastric motor responses to ET in the DVC could be mediated via ET<sub>A</sub> receptors. This was supported by the observation that a specific ET<sub>A</sub> receptor antagonist, cyclo(-D-Trp-D-Asp-Pro-D-Val-Leu) (BQ-123; 400 pmol per site), microinjected into the DVC 15 min before ET-1 (10 pmol), completely blocked the gastric motor responses to ET-1. Therefore, we conclude that ET-1 acts in the brainstem at the level of the DVC to increase gastric tone and contractility via a vagally-mediated pathway and that these effects are mediated through ET<sub>A</sub> receptors. This may be important in mediating gastric motility alterations such as those occurring in diabetes, where the plasma levels of ET-1 are elevated. Supported by the LSU Neuroscience Center incentive grant (ZKK) and PHS grant DK42714 (PJH).

## 159.15

**GASTRIC ACID SECRETION (GAS) AND RESISTANCE OF THE MUCOSA TO ETHANOL INJURY IS MODULATED BY CENTRAL PYY THROUGH VAGAL CHOLINERGIC DEPENDENT PROSTAGLANDIN (PG) AND CALCITONIN GENE RELATED PEPTIDE (CGRP) MECHANISMS. H. Yang\* and Y. Taché. CURE-DDRC, VA Medical Center, Brain Research Institute and Dept. of Medicine, UCLA, Los Angeles, CA 90073, U.S.A.**

We previously reported that PYY injected into the dorsal motor nucleus of the vagus induced vagal stimulation of GAS (AJP 268:G943, 1995). There is evidence that central vagal activation induced PG and CGRP dependent modulation of gastric secretion and resistance of the mucosa to injury (J Gastro Hepatol 9:S29, 1994). We explored whether intracisternal (ic) PYY induces vagal mediated, PG/CGRP dependent changes in gastric function and resistance to ethanol lesions. Male rats weighing 250-310 g were fasted for 24 h and anesthetized with urethane, GAS was measured by flushing technique and gastric erosions were induced by intragastric administration of 45% ethanol. PYY 100, 200 or 500 ng (ic) did not influence basal GAS in vehicle-pretreated rats but increased GAS in indomethacin (5 mg/kg, -60 min, ip) pretreated rats by 18, 23 ( $P<0.05$ ) and 23 ( $P<0.05$ )  $\mu\text{mol}/90$  min respectively. This effect was completely prevented by cervical vagotomy. Gastric erosions induced by intragastric 45% ethanol, which covered  $22 \pm 3\%$  of the mucosa surface in 1 h, were significantly decreased by ic PYY 100, 200 and 500 ng (-30 min) by 37%, 62% ( $P<0.05$ ) and 58% ( $P<0.05$ ) respectively. Pretreatment with indomethacin (5 mg/kg, -60 min, ip), atropine (2 mg/kg, -30 min, sc) or CGRP antagonist, CGRP<sub>8-37</sub> (100  $\mu\text{g}/\text{kg}$ , -15 min, iv) did not significantly alter the erosion induced by 45% ethanol but reversed the cytoprotective effect of ic PYY (200 ng) by 66% (indomethacin) or completely (atropine and CGRP<sub>8-37</sub>). PYY (200 ng, ic) completely prevented the 133% increase of ethanol erosions induced by L-NAME (6 mg/kg, iv) pretreatment. These results suggest that ic PYY induced vagal dependent gastric PG release which inhibits GAS. In addition, central administered PYY increased the resistance of the gastric mucosa against ethanol injury through PG and CGRP mechanisms independent from nitric oxide.

## 159.17

**PITUITARY GALANIN (GAL) AND VASOPRESSIN (AVP) IN RELATION TO HIGH-FAT DIET IN FEMALE RATS. H.J. Yu, J. Wang, H.J. Chae, Z. Bedrin and S.F. Leibowitz\*, Rockefeller Univ, NY, NY 10021**

Previous biochemical and pharmacological studies have linked the peptide, GAL, in the hypothalamic paraventricular nucleus (PVN), to the overeating of fat. This relationship is further demonstrated by results, reported at this meeting (Wang et al.), showing higher GAL mRNA and peptide immunoreactivity (ir), in the anterior PVN (aPVN) and median eminence (ME), of animals on a high-fat diet. Since the anterior pituitary (AP) is also known to synthesize GAL and PVN projections pass through the ME to the posterior pituitary (PP), we examined whether this peptide in both pituitary lobes may be affected by a high-fat diet. We also studied AVP (n=4), which coexists with GAL in certain PVN neurons. Female rats, maintained for 2 weeks on either a single high-fat diet (60% fat + 10% carbohydrate, n=6) or high-carbohydrate diet (63% carbohydrate + 10% fat, n=6), were intracardially perfused and their pituitaries examined, using *in situ* hybridization with a digoxigenin labeled cRNA probe for GAL mRNA and immunocytochemistry for GAL peptide. Results show that, in rats on the high-fat diet, there was a significant ( $p<0.05$ ) increase in AP GAL mRNA ( $+413\%$ ,  $1725 \pm 71$  vs  $418 \pm 68$  cell density/cm<sup>2</sup>), and GAL peptide ( $+270\%$ ,  $409 \pm 68$  vs  $152 \pm 12$  cell density/cm<sup>2</sup>). This increase in GAL fiber density was also seen in the PP ( $+24\%$ ,  $p<0.05$ ). While GAL-ir was similarly increased in the aPVN ( $p<0.05$ ), no effect of high-fat diet on AYP fiber density was seen in the PVN ( $79 \pm 19$  vs  $116 \pm 77$  cell density/mm<sup>2</sup>) or PP ( $164 \pm 35$  vs  $169 \pm 23$  fiber density/mm<sup>2</sup>). These results show that AP cells synthesizing GAL are similar to PVN GAL neurons in their response to a high-fat diet, whereas PVN or PP AVP-ir shows little change.

## 159.19

**CHARACTERIZATION OF LEPTIN RECEPTOR. R.R.C. Huang, M. Tota, K. Mazina, C. Rosenblum, D. Cully, H. Chen, T. Smith, A. Yongs, S. Quershi, F. Chen, R. Smith, L.H.T. Van der Ploeg, and T.M. Fong\* Merck Research Laboratories, Rahway, NJ 07065**

The recently identified OB receptor (OBR) belongs to the cytokine receptor family, and the structure of the OB protein (leptin) is believed to resemble that of helical cytokines. Since many cytokine receptors consist of two or three subunits, it is important to determine what constitutes a functional leptin receptor. Two strategies will be discussed. One is to co-express the OBR with one of several common cytokine receptor subunits and measure the binding affinity of leptin. The common cytokine receptor subunits tested were gp130, KH97 and IL2R-gamma. The present study indicated that these subunits, when expressed in COS cells individually with OBR, did not lead to an increased leptin binding affinity for the OBR. The second strategy is to identify cell lines expressing endogenous OBR or responding to leptin with exogenous OBR transfection. Endogenous OBR has been detected in hypothalamic cell lines by RT-PCR, binding and intracellular activity. The availability of cell lines, recombinant leptin and novel functional assays will facilitate the characterization of the leptin receptor.

## 159.16

**MICROINJECTION OF BICUCULLINE METHIODIDE INTO DORSOMEDIAL HYPOTHALAMIC NUCLEUS STIMULATES GASTRIC ACID SECRETION IN RATS. S.L. Kendall-Eagleson\*, M.H. Bender, A.J. Monroe, and J.A. DiMicco. Department of Pharmacology and Toxicology, and Program in Medical Neurobiology, Indiana University School of Medicine, Indianapolis, IN 46202**  
Acute stress evokes characteristic increases in heart rate (HR) and blood pressure (BP), and stimulates both colonic motility and gastric acid secretion (GAS). We have shown that microinjection of the GABA<sub>A</sub> receptor antagonist bicuculline methiodide (BMI) into the dorsomedial hypothalamus (DMH) mimics the cardiovascular and colonic motor changes seen in stress, while inhibition of neurons in the same region suppresses stress-induced tachycardia. Here, we examined the effect of microinjection of BMI into the DMH on GAS. In 10 fasted urethane-anesthetized rats, a femoral artery was cannulated for continuous monitoring of HR and BP. The gastro-esophageal junction and pylorus were ligated and the stomach was cannulated. The gastric lumen was lavaged and then flushed with two 4 ml aliquots of 0.9% saline at 10 minute intervals. GAS was assessed by calculating  $[\text{H}^+]$  from pH of each pooled 10 minute sample. After attainment of a stable baseline, BMI 10  $\mu\text{mol}/50$  nl was microinjected into the DMH and GAS and cardiovascular function were monitored for an additional 50 minutes. All injection loci were verified by post-mortem histology. At  $t_0$ , the mean ( $\pm$ SE) baseline  $[\text{H}^+] \times 10^{-6}$  was  $62 \pm 17$ , and HR was  $390 \pm 12$  beats/min. In every rat, microinjection of BMI into the DMH was followed by increases in GAS (mean  $\pm$  SE at  $t_{50} = +52 \pm 14$ ; 222% with respect to original baseline) and HR ( $+60 \pm 7$  beats/min). In two additional rats in which BMI was injected in identical fashion into the ventromedial hypothalamic nucleus, no increases in GAS were seen and HR increased by 20 beats/min or less. Thus, blockade of inhibitory GABA<sub>A</sub> receptors in the DMH increases GAS in rats. In light of our previous findings, these results suggest that activation of the DMH may be responsible for stress-induced increases in GAS. (Supported by USPHS Grant NS 19883)

**INVOLVEMENT OF MEDULLARY CATECHOLAMINE CELLS IN NEUROENDOCRINE RESPONSES TO CHOLECYSTOKININ. K.M. Buller\* and T.A. Day, Dept. of Physiology & Pharmacology, University of Queensland, AUSTRALIA 4072.**

Systemic administration of cholecystokinin (CCK) stimulates neurosecretory oxytocin (OT) and tuberoinfundibular corticotrophin releasing factor (CRF) cells of the hypothalamus. Previous work suggests that A2 noradrenergic neurons of the dorsal medulla contribute to the OT cell response, but the role of other medullary catecholamine cells remains unclear. Using *c-fos* expression as a marker for cellular activity, we have found that CCK (100  $\mu\text{g}/\text{kg}$ , ip) activates overlapped noradrenergic and adrenergic cell populations in both the ventrolateral and dorsomedial medulla. In the ventrolateral medulla (VLM) there was a particularly prominent activation of C1 adrenergic neurons at the level of the obex. To directly test the contribution of VLM catecholamine cells to hypothalamic neuroendocrine cell responses to CCK, animals were prepared with unilateral VLM lesions corresponding to those areas that had displayed the most marked response to CCK. VLM lesioned animals treated with CCK displayed a significant although small reduction in paraventricular nucleus (PVN) OT cell *c-fos* expression ipsilateral to the lesion, but no change in the responses of supraoptic nucleus OT cells or in cells of the medial parvocellular PVN, many of which are CRF cells. These findings indicate that VLM catecholamine cells contribute little to hypothalamic neuroendocrine cell responses to CCK and thus serve to further highlight the role of dorsal medulla catecholamine cells. However, it is clear that in addition to A2 cells, CCK treatment also recruits C2 adrenergic cells of the dorsal medulla, many of which project to the PVN. (Supported by NHMRC and NHF.)

**THE INTERACTION OF TWO ORIXIGENIC PEPTIDES, NPY AND MCH (MELANIN CONCENTRATING HORMONE), AND LEPTIN IN DIFFERENT MODELS OF OBESITY. D. Ou, C. Mantzoros, R. Ahima, J. Elmquist, D. Vicent, D. Hoersch, J. S. Flier, C. Saper\*, E. Maratos-Flier. Joslin Diabetes Center and Beth Israel Hospital, Boston, MA, 02215**

The regulation of eating behavior results from a complex interaction of signals from the periphery and the central nervous system. NPY acts to stimulate eating behavior. We have found that MCH also stimulates eating behavior (Nature 380:243-247). In view of the potential importance of the fat hormone leptin in regulating eating behavior, we studied the interaction of leptin and MCH and NPY in different models of rodent obesity. *ob/ob* mice are absolutely leptin deficient and have increased hypothalamic mRNA levels of both MCH and NPY (both by at least two-fold). Despite high levels of expression, mRNA levels are increased further after fasting (as seen in normal controls). Two other models of rodent obesity demonstrate very high circulating leptin levels (100 fold higher than control animals) and are therefore leptin "resistant." Surprisingly, in brown adipose tissue deficient mice, NPY mRNA is low (50% of control) and the response to fasting is blunted. MCH mRNA levels appear to be unchanged. In the agouti mouse NPY and MCH mRNA levels are unchanged compared to control mice; however, neither peptide appears to respond to fasting. These data indicate that most models of rodent obesity are leptin resistant. We also examine the effect of leptin on NPY and MCH mRNA expression in response to fasting. Leptin treatment blunts the increase in NPY seen with fasting, but has no effect on MCH expression. Eating behavior is regulated by multiple peptides, understanding the mechanism of leptin action and resistance requires defining the multiple pathways regulated by leptin and other possible signals from the periphery. EDGE SELECTIVE CELLS CODE FIGURE-GROUND IN AREA V2 OF MONKEY VISUAL CORTEX. Hong Zhou\*, Howard Friedman, Rüdiger von der Heydt. Krieger Mind/Brain Inst. and Depts. of Neurosci. and Biomed. Eng., Johns Hopkins Univ., Baltimore, MD.

Visual perception organizes 2-D images into figure and ground, assigning the borders to the figure. We have studied the neural basis of this phenomenon.

We recorded from orientation selective cells of V1 and V2 in the awake, fixating monkey. A square (typically 4°) of uniform color or gray was displayed in an uniform surround field (11°) of different color or gray. The square was much larger than the response fields of the cells studied. Its orientation and color were optimized for each cell. In interleaved tests, we centered two opposite edges of the square in the RF, and also reversed the colors of square and surround. Flipping edges and colors produced pairs of displays with an identical edge in the response field, but the figure on opposite sides.

In V2 we found cells that were highly discriminative for the edge assignment, e.g., responding only to the left edge of a gray square with white surround, but not to the right edge of a white square with gray surround. In some cells, this discrimination was nearly independent of the figure size. The response could either be independent of local edge polarity (general edge assignment), or conditional on figure color (joint assignment of edge and color). We have observed direction-of-figure preference also in V1, but with smaller discrimination ratios.

In conclusion, figural edge assignment is part of early cortical processing.

Supported by NIH EY02966, HFSP RG-31, and Whitaker Foundation.

RESPONSE PROPERTIES OF AXIS-ORIENTATION SELECTIVE NEURONS OF THE PARIETAL ASSOCIATION CORTEX OF THE MONKEY STUDIED BY 3D COMPUTER GRAPHICS. M. Kusunoki\*, Y. Tanaka, E. Shikata, H. Nakamura<sup>1</sup>, and H. Sakata. Nihon University, School of Medicine and PRESTO, JRDC<sup>1</sup>, 30-1 Oyaguchi-kamicho, Itabashi, Tokyo 173, Japan.

Clinical studies of the patients with parietal cortex lesion showed deficit in the perception of line orientation as one of the symptoms of visuospatial disturbances. Recently we found a group of visual neurons in the monkey parietal cortex that were sensitive to the orientation of the axis of an elongated object in 3-dimensional space. Many of these neurons were binocular and their response to a bar of preferred orientation in binocular viewing condition was better than that in monocular viewing condition. However, in our previous study using real object as a stimulus, it was not clear what kinds of visual cues were effective to activate them. In the present experiment, we displayed visual stimuli on a stereoscopic display of 3D computer graphics and changed various parameters of the stimulus such as the length, thickness, distance and shape. Most of the axis-orientation selective (AOS) neurons preferred a longer and thinner stimulus to a shorter and thicker one. Thus the length response curve and thickness response curve were both monotonically decreasing function in most AOS neurons. However, we also found several AOS neurons which showed maximum response to the stimulus of intermediate thickness. Some of these neurons showed preference in the shape of the stimulus, preferring either cylinder or square column. Almost all the AOS neurons were strongly binocular and their response was much less to the monocular stimulus than to the binocular one. We also examined the orientation-selectivity of AOS neurons in both eyes to see the difference in preferred orientations between two eyes (orientation disparity) which is one of the important cues for the tilt in depth. A COMPARISON OF BIMODAL, VISUAL-TACTILE NEURONS IN PARIETAL AREA 7B AND VENTRAL PREMOTOR CORTEX OF THE MONKEY BRAIN. Michael S. A. Graziano\*, Charles G. Gross and Tom Fernandez. Department of Psychology, Princeton University, Princeton, NJ 08544.

Most neurons in the ventral premotor cortex (PMv) of the monkey brain respond to tactile stimuli and about 30% also respond to visual stimuli. These bimodal, visual-tactile cells have tactile receptive fields (RFs) on the face or limbs, and corresponding visual RFs, which extend outward from the tactile RFs into the space surrounding the body. For most cells with a tactile RF on the arm, the visual RF is anchored to the arm, moving as the arm is moved. These neurons appear to code the locations of visual stimuli with respect to the arm, in "arm centered" coordinates. (Graziano, Yap and Gross, *Science*, vol. 266, pp. 1054-1057, 1994).

PMv receives a strong projection from parietal area 7b, which also contains bimodal, visual-tactile neurons. We studied 349 neurons in area 7b of anesthetized monkeys and found that 33% were bimodal. Fifty-five bimodal neurons that had a tactile response on the arm were tested by placing the arm in different positions. In all cases, the visual RF did not move when the arm moved. Instead, the visual RF remained at the same location in space, independent of the position of the arm. In addition, for 23 neurons tested, the spontaneous activity and the magnitude of the visual response were unaffected by arm position. We could find no evidence that the static position of the arm had any effect on bimodal neurons in 7b. We conclude that area 7b may be an important source of visual and tactile information to PMv, but that the arm-position signal in PMv must come from a different source.

MODULAR ORGANIZATION OF AXONAL PROJECTIONS FROM FUNCTIONALLY IDENTIFIED V2 COMPARTMENTS TO V4 IN MACAQUES. Y. Xiao and D.J. Felleman\*. Dept. of Neurobiology and Anatomy, Univ. Texas Houston Medical School, Houston, TX 77225.

Area V4 receives a dense projection from V2 thin stripes and interstripes, but the degree to which their axonal terminations remain segregated from each other and contribute to the functional architecture of V4 remains unclear. In the current study, V2 functional compartments were first identified, *in vivo*, by optical recording of intrinsic cortical signals in response to different visual stimuli. Multiple distinguishable anterograde and retrograde tracers were then injected into specific V2 compartments. The patterns of axonal terminations were examined in horizontal and tangential sections. Axonal projections to V4 from V2 thin stripes and interstripes are characterized by both global segregation and locally, restricted integration. Terminals from V2 interstripe injections form multiple dense clusters (~500 µm) which aggregate to form a ~2.5x3 mm primary terminal field and provide weaker projections to smaller satellite foci. Terminals from thin stripe injections are distributed more diffusely to form ~2x2.5 mm primary terminal fields and smaller satellite foci. The thin stripe primary terminal field is separated from the interstripe primary terminal field. However, within each of these primary terminal fields, smaller satellite foci from the other V2 compartment are observed and thus provide a mechanism for functional integration between compartments. Optical recording in V4 reveals chromatically activated foci comparable in size to these thin stripe satellite foci. Finally, projections from the thin/interstripe border region is more diffusely distributed in V4 than those from either stripe compartment. Supported by NIH EY-08372, Texas ARP 011618-025, and by a grant-in-aid in honor of Bob Hope of the Fight For Sight research division of Prevent Blindness America.

CONNECTIONS OF VISUAL AREA VIP WITH SOMATOSENSORY AND MOTOR AREAS OF THE MACAQUE MONKEY. J. W. Lewis\*, D. C. Van Essen. Dept. Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

The intraparietal sulcus (IPS) of the macaque monkey contains multiple areas involved in motor control and in visual, somatosensory, or multimodal sensory processing. In this study, we examine the anatomical connections of area VIP (ventral intraparietal) with somatosensory, motor and premotor cortical regions, in an extension of our previous report on the connections of area VIP with other visual areas (*Soc. Neurosci. Abstr.* 20:324.11., 1994).

We pressure-injected retrograde tracers into the IPS using multibarreled glass electrodes that permitted simultaneous electrophysiological recording. Restricted injections of three different tracers were placed into a combination of cortical sites including area VIP. In several cases, we physiologically mapped the face and/or digit representations of areas 1 and 2. Areal borders were determined using a combination of Nissl, myelin, SMI-32 antibody and CAT-301 antibody stains. Labeled cells, section contours and architectonic boundaries were digitized and computationally reconstructed in 3D. These data were also computationally flattened to assist with quantitative analyses and to enhance the visualization of labeled field patterns across large expanses of cortex.

Area VIP received projections from the hand and/or face representations of several topographically organized somatosensory and motor areas. The strongest connections were from subdivisions of area 6 (mostly along the posterior bank of the arcuate sulcus), and moderate to light label from SMA, 7b, area 2, and primary motor cortex (area 4). We found consistently strong projections from STP, moderate to light projections from a ventral subdivision of area 5, S2 and surrounding cortex, AIP, area 23 and area 24. Projections from MDP (7m) were very strong in some cases, but weak in others. These results support the notion that area VIP contributes to the sensorimotor integration of eye-hand and mouth coordination. NIH EY02091.

OVERLAPPING AND NON-OVERLAPPING PREFRONTAL, POSTERIOR PARIETAL, AND SUPERIOR TEMPORAL PROJECTIONS TO CINGULATE AND PARAHIPPOCAMPAL CORTEX IN THE MONKEY. J. Padberg\*, C.G. Cusick, and B. Seltzer. Depts. of Psychiatry & Neurology and Anatomy, Tulane Univ. School of Medicine; V.A. Medical Center, New Orleans, LA 70112.

Networks of cortical areas, including dorsal prearcuate cortex, the caudal inferior parietal lobule (IPL), and the superior temporal gyrus (STG), have been implicated in attentional mechanisms. Other potential components of these networks include: superior temporal polysensory (STP) cortex, the cingulate gyrus, and parahippocampal gyrus (PHG). We have previously shown that cortical areas that are themselves interconnected send overlapping connections to the STP region whereas non-interconnected areas send spatially segregated projections to the target zone (Seltzer et al., 1996). To examine potential overlap in two other component areas of these networks, in three cases we combined in the same hemisphere a radioisotope injection into dorsal prearcuate cortex with WGA-HRP injections into the caudal IPL or STG, and then examined alternate or identical coronal sections for labelled terminals within the cingulate and PHG. Although many afferents from the two different sources were segregated, there were also columns within caudal area 23 where there was overlap between frontal and parietal and frontal and temporal fibers. Overlap was also found between frontal and parietal afferents within the presubiculum and areas TF and TL of the PHG. Supported by NIH grant EY08906, New Orleans VAMC, and Tulane University.

PATTERN OF THALAMIC STAINING WITH THE LECTIN WISTERIA FLORIBUNDA AGGLUTININ IN NON-HUMAN PRIMATES. C.G. Cusick\*, D. Gray, and T.M. Preuss. Dept. of Anat. and Neurosci. Training Program, Tulane Medical School, New Orleans, LA 70112 and Div. of Behav. Biology, Univ. of Southwestern Louisiana-New Iberia Research Center, New Iberia, LA 70560.

*Wisteria floribunda* agglutinin (WFA), like the monoclonal antibody Cat-301, binds to GalNac-containing proteoglycans concentrated in pericellular glial nets and neuropil. Using biotinylated WFA, we examined the dorsal thalamus of 3 macaques and 2 squirrel monkeys, and found a regionally specific pattern of staining similar to that reported for Cat-301 (Hendry et al., 1988, J. Neurosci. 8:518). In the anterior nuclei, WFA staining was very weak in AM and AV, while AD was more prominently stained. In MD, the parvocellular subnucleus (MDpc) was lightly stained, but laterally, patches of stained neuropil and large cells marked the multiform division (MDmf). The intralaminar paracentral (Pc) and central lateral (CL) nuclei were well stained, but the parafascicular (Pf) and centromedian (CM) nuclei were very light. In the motor thalamus, VA and dorsal VL were light, but the remainder of VL was well stained. In somatosensory nuclei, strong WFA staining overlapped cytochrome oxidase (CO) rich compartments in VPL and VPM and was found throughout VPS; the CO-poor zones in VPL and VPM were lightly stained, as were the VPI and anterior pulvinar (Pa) nuclei. In the LGN, the magnocellular layers were more darkly stained than parvocellular layers. Isolated patches of label were found in the lateral posterior nucleus (LP). The medial pulvinar was lightly stained, and label occupied specific subdivisions of the inferior pulvinar, as described in a separate abstract. Supported by NIH grant EY08906 and by USL-NIRC.

## 160.9

POSTERIOR PARIETAL, SUPERIOR TEMPORAL, AND PREFRONTAL PROJECTIONS TO HISTOCHEMICALLY DEFINED COMPARTMENTS OF THE DORSAL PULVINAR IN MACAQUE MONKEYS. C. Gutierrez\*, D. Gray, B. Seltzer, and C.G. Cusick. Dept. of Anat. and Neurosci. Training Prog., Tulane Univ., New Orleans, LA 70112.

The posterodorsal thalamus of macaques has traditionally included the medial and lateral pulvinar (PM and PL) and the lateral posterior nucleus (LP). PM has widespread connections with diverse functional regions of the cerebral cortex. To better understand the connective organization of the dorsal pulvinar complex, we placed separate injections of WGA-HRP and radiolabeled amino acids in 2 different cortical sites in the same hemisphere. The distribution of label was then compared with the neurochemical architecture of the dorsal pulvinar revealed by a variety of markers (parvalbumin, calbindin, AChE, Cat-301 and binding of the lectin *Wisteria floribunda* agglutinin (WFA)). A distinct parvalbumin- and AChE-dense, calbindin-poor wedge crossed the traditional dorsal PL and PM rostrally and was continuous with LP. This zone contained numerous neuronal profiles stained for Cat-301 and WFA. PM was generally light to moderate for AChE and parvalbumin, but contained an oval region ventromedially (PMvm) that stained more intensely than the surrounding region. Patchy neurochemical staining was also seen dorsal and lateral to PMvm. Injections in the inferior parietal lobule (IPL), superior temporal gyrus (STG), and prefrontal cortex labeled LP as well as the dorsal pulvinar between PMvm and LP. The oval PMvm was only labeled by STG injections; IPL and STG projections were found surrounding PMvm. Overlapping connections were found following IPL or STG and prefrontal injections in the same hemisphere but not after IPL and STG injections. The results suggest the neurochemical architecture of the dorsal pulvinar correlates with its connective heterogeneity. Supported by NIH grant EY08906.

## 160.11

DISTINCT REACTIVITY OF CORTICAL EVOKED RESPONSES AND RHYTHMS TO LUMINANCE AND PATTERN STIMULI. K. Portin\*, S. Salenius, R. Salmelin and R. Hari, Brain Research Unit, Low Temperature Lab., Helsinki Univ. Techn., FIN-02150 Espoo, Finland

We recorded neuromagnetic signals from 10 subjects with a Neuromag-122™ whole-scalp magnetometer to visual luminance and pattern stimuli, which were semicircles (Ø 16-17 deg), either white on a black background (luminance) or black-and-white 50'x50' checks on an equiluminant gray background (pattern). The stimuli were shown for 2 s once every 5 s, alternately to the right and left visual hemifield. Both stimuli evoked clear responses over the occipital lobes at 70-170 ms; luminance stimuli elicited additional strong signals over the parieto-occipital region at 180-350 ms. Cortical activation was modelled with a time-varying 3-dipole model, with 2 dipoles bilaterally in the occipital visual cortex and 1 in the medial parieto-occipital cortex. The occipital activation was contralaterally dominant both for pattern (contra/ipsi ratio 18) and luminance (ratio 2) stimuli. Parietal activation was 66% stronger for luminance than pattern stimuli. The posterior 10-Hz rhythm was suppressed more strongly by luminance than pattern stimuli, particularly in the parietal cortex. The contralateral dominance of the occipital suppression was stronger for pattern than luminance stimuli. Thus, the occipital activation is more lateralized for pattern than luminance stimuli, and the parietal cortex is predominantly responsive to luminance stimuli. This study was financially supported by The Academy of Finland, the Magnus Ehrnrooth foundation and the Sigrid Jusélius foundation.

## 160.8

INFERIOR PULVINAR SUBDIVISIONS IN SQUIRREL MONKEYS AND MACAQUES REVEALED BY AChE HISTOCHEMISTRY, CALBINDIN-D28k, CAT-301 IMMUNOSTAINING, AND WISTERIA FLORIBUNDA AGGLUTININ BINDING. D. Gray\*, C. Gutierrez, and C.G. Cusick. Dept. of Anat. and Neurosci. Training Prog., Tulane Univ., New Orleans, LA 70112.

The inferior pulvinar (PI) of macaque monkeys, defined as classical PI and ventral PL, contains multiple chemoarchitectonic subdivisions, medial (PI<sub>M</sub>), central (PI<sub>C</sub>), lateral (PI<sub>L</sub>), lateral-shell region (PI<sub>L-S</sub>) and posterior (PI<sub>P</sub>; Gutierrez et al., 1995, JCN 363:545). These subdivisions in macaques differed from those described in squirrel monkeys, in which the PI<sub>C</sub> division was relatively broader, and a lateral-shell zone was not described (Cusick et al., 1993, JCN 336:1). The present study reassessed the evidence for common patterns of PI subdivisions in monkeys. Similar results were obtained in squirrel and macaque monkeys using a variety of neurochemical markers. Acetylcholinesterase (AChE) staining was intense and patchy in PI<sub>M</sub>; intense in PI<sub>L</sub>; moderate in PI<sub>L-S</sub>; and light in PI<sub>C</sub> and PI<sub>P</sub>. Calbindin-D28k immunostaining was poor in PI<sub>M</sub>; intense in PI<sub>C</sub> and PI<sub>P</sub>; and moderate in PI<sub>L-S</sub>, which was characterized by a dispersed population of intensely stained cells. *Wisteria floribunda* agglutinin (WFA) binding, studied with biotinylated WFA, showed perineuronal nets and neuropil staining localized within PI<sub>M</sub> and throughout PI<sub>L-S</sub>, but little staining in PI<sub>P</sub> and PI<sub>C</sub>. In macaque monkeys, perineuronal nets immunostained for Cat-301 were also found around clusters of neurons in PI<sub>M</sub>, supporting the interpretation that PI<sub>M</sub> shares neurochemical features with magnocellular layers of the LGN. Scattered Cat-301 positive neurons were also found in PI<sub>L-S</sub> of macaques. The PI<sub>C</sub> subdivision in both species was narrow compared to PI<sub>L</sub>, and the lateral shell in squirrel monkeys appears to correspond to the previous PI<sub>L</sub> zone. The findings suggest similar PI subdivisions exist in New and Old World monkeys and thus probably in all primates. Supported by NIH grant EY08906.

## 160.10

MULTI-LEVEL SYNCHRONIZATION OF FAST (20-60 Hz) OSCILLATIONS IN A PROTOTYPICAL MODEL OF THE THALAMOCORTICAL SYSTEM. E. D. Lumer\*, G.M. Edelman, and G. Tononi. The Neurosciences Institute, 10640 John Jay Hopkins Drive, La Jolla, CA 92012

Neural activity in the mammalian thalamocortical system is often characterized by the presence of fast synchronized rhythms involving neurons distributed over multiple cortical and thalamic sites. What role do network mechanisms play in the generation of these widespread coherent oscillations? We investigated this question by using a large-scale computer model based on the anatomy and physiology of the cat thalamocortical visual system. The model consisted of 65,000 spiking neurons organized topographically to represent multi-layered sectors of a primary and secondary area of visual cortex, as well as two associated regions of the dorsal thalamus and of the reticular thalamic (RT) nucleus. A dense plexus of reciprocal intra- and interlaminar, interareal, corticothalamic, and thalamo-reticular connections was established. Simulations of the neural responses to visual input revealed sporadic epochs of fast rhythmic activity involving all levels of the model, similar to the fast rhythms recorded *in vivo*. Selective manipulations of structural and physiological parameters demonstrated that, in addition to the known oscillatory influences imposed by mutual inhibition in local circuits, high frequency oscillations could arise in population-averaged activities as an emergent property of the dynamics in polysynaptic loops. An interlaminar cortical loop provided a high-gain amplification mechanism that drove local cortical networks into an oscillatory regime, even in the absence of thalamic rhythmicity. In addition, a corticothalamic loop involving the RT complex induced synchronous oscillations at thalamic and cortical levels. Horizontal networks within each cortical layer, as well as forward and backward interareal projections, contributed to the coherence of these oscillations between different parts of the cortex. These results suggest that specific polysynaptic loops have distinct roles in organizing distributed, multi-level, activity patterns in thalamocortical systems. (Supported by Neurosciences Research Foundation)

HUMAN PATTERN ELECTRORETINOGRAMS AFTER COMPLETE CEREBRAL HEMISPHERECTOMY. P. Azzopardi, S.M. King & A. Cowey (SPON: European Brain and Behaviour Society), Dept. of Exptl. Psychology, University of Oxford, Oxford OX1 3UD, UK.

Subjects with damaged striate cortex can nevertheless detect and discriminate stimuli presented in their scotomas. Recently we showed that, unlike such subjects, hemidecorticate subjects have no detectable blindsight in their scotomas (King et al. 1996 *Vis. Neurosci.* 13, 1-13). Given that lesions restricted to striate cortex cause degeneration of 80% of Pp ganglion cells, and that degeneration following complete hemidecortication might be even greater, we assessed ganglion cell function in the retinae of a hemidecorticate subject by means of pattern electroretinography.

The subject, a 24 year old male, had had a complete right cerebral hemispherectomy 11 years previously. His visual acuity was 20/17. The stimuli, presented in 12°x10° fields at 6°-18° horizontal eccentricity, were 95% contrast vertical sinusoidal luminance gratings (mean 103 cd/m<sup>2</sup>) of 2.0 cpd and 12.0 cpd, and photometrically isoluminant chromatic (RG) gratings (mean 20.25 cd/m<sup>2</sup>) of 2.0 cpd, modulated temporally at 7.95 Hz. ERG signals were recorded using gold foil electrodes, amplified 20,000x. A 3-way ANOVA revealed significant differences in the amplitude of the second harmonic of the averaged signal with respect to eyes (p=0.012), intact and blind fields (p=0.048) and stimuli (p=0.031), but no significant interactions. Most importantly, the results showed that the pattern-evoked signals in the blind hemiretinae, though of slightly lower amplitude than the sighted hemiretinae, were otherwise indistinguishable from normal.

Our results suggest that the absence of residual vision in the scotomata of hemidecorticate subjects is not explicable in terms of degeneration of retinal ganglion cells. This lends support to our proposal that intact extrastriate cortex is required for mediating voluntary responses to visual stimuli in the scotoma.

Supported by grants from the MRC and The Royal Society.

**HERE'S NOT LOOKING AT YOU KID: AN ELECTROPHYSIOLOGICAL STUDY OF A REGION OF HUMAN EXTRASTRIATE CORTEX SENSITIVE TO HEAD AND EYE AVERSION.** T. Allison\*, D. Lieberman, and G. McCarthy. Neuropsychology Lab., VA Medical Center, West Haven CT 06516, and Dept. of Neurology and Section of Neurosurgery, Yale University School of Medicine, New Haven CT 06510.

In intracranial recordings faces evoke a field potential at about 200 msec (N200) in small regions of the fusiform and inferior temporal gyri (Allison et al J Neurophysiol 1994); eyes alone evoke a smaller potential. However, in scalp recordings in normal subjects a similar potential (N170), best recorded from left (T5) and right (T6) temporal scalp, is larger to eyes alone than to a full face, suggesting the operation of an "eye detector" (Bentin et al J Cog Neurosci in press). Here we tested the responsiveness of the putative eye detector while normal subjects viewed faces and eyes in varying orientations. The assumption that N170 would be largest when the eyes are looking at the viewer was incorrect for all manipulations of eye and head position. At T5 N170 was largest when the head was directed away from the viewer regardless of eye direction. At T6 N170 was largest when the eyes were directed away from the viewer regardless of head direction. These results suggest that regions of cortex, perhaps located in the occipitotemporal sulcus, are sensitive to head and eye aversion, similar to cells in monkey superior temporal sulcus that respond best to head and eye aversion (Hasselmo et al Exp Brain Res 1989; Perrett et al Int J Comp Psych 1990). Such cells may allow analysis of social interactions, specifically of the direction of attention and of threat and submission.

**HIGH SPATIAL RESOLUTION FUNCTIONAL MAGNETIC RESONANCE IMAGING OF THE HUMAN VISUAL SYSTEM** J.T. Voyvodic\*, G.X. Shen, S.Y. Chang and K.R. Thulborn, Magnetic Resonance Research Center, University of Pittsburgh Medical Center, Pittsburgh, PA 15213

Neuroimaging studies of the functional organization of specific brain regions requires optimization of the spatial resolution of the imaging technique. Although functional magnetic resonance imaging (fMRI) has the best spatial resolution of the human neuroimaging techniques, current approaches do not have adequate spatial resolution for detailed functional mapping of specific brain regions. We have developed methods for achieving higher resolution fMRI images of human brain activity using a combination of strategies, including: (1) optimized signal sensitivity by using a custom-designed 3 Tesla (GE Signa) scanner, (2) a custom-built 7" proton surface coil, (3) optimized pulse sequences sensitive to the microvasculature rather than the venous drainage, (4) a control system for accurate stimulus presentation and temporal synchronization of paradigm and image acquisition and (5) optimized statistical processing. The hardware combination provides improved signal stability (<1% over 30 minutes) and a 2-fold increase in signal to noise ratio (SNR) compared to a standard 1.5 T system. The increased SNR allows voxel size to be decreased by a factor of greater than 2 within reasonable acquisition times (15 minutes) with adequate signal sensitivity for near real-time generation of high resolution functional activation maps. This strategy has been used in the human visual system to explore aspects of within-region functional organization with enhanced spatial resolution.

**HUMAN CORTICAL REGION WHICH RESPONDS TO THE COLOR CHANGE.** Y. Kaneoke\*, S. Koyama, R. Kakigi. Dept. of Integrative Physiology, National Institute for Physiological Sciences, Myodaiji, Okazaki 444, Japan.

To investigate the precise region of human color center, we have developed the visual stimulus method by which one can observe the electrical response from the human cortical region which responds to the abrupt color change without the obvious response from the primary visual cortex. We studied the location of the human cortex which responds to this stimulus using 37 channels' BTi Neuromagnetometer. The subjects gazed the small light (0.2x0.2°) at the center of their visual field. The light was induced into the shielded room by fiberoptics from the two-color light emitting diode. The light changed its color from red to green or vice versa at 2 to 3 seconds' random interval. The subjective brightness of the two colors was adjusted to be identical by the flicker method. The responses from 200-225 repetitions of each color change were averaged to obtain the evoked magnetic fields. The latency of the first deflection and its dipole location was investigated with several normal subjects and compared with the results of motion visual stimulus. The onset latency of the first deflection evoked by the color change was about 130 ms and the peak latency was about 190 ms for the subject YK. Its electrical source was well estimated by the single dipole model (Correlation between the measured and estimated values >0.97) and determined to be in the temporo-occipital cortex. On the other hand, the onset and peak latency of the first deflection evoked by the motion stimulus for the same subject were about 110 ms and 155 ms, respectively. They were significantly faster than those for the wave form evoked by the color change. The electrical source was estimated to be different from that for the color change. The results indicate our method enables the precise localization of the individual color center and add the evidence of the functional segregation of the human visual system.

**ORIENTATION-SPECIFIC TRAINING EFFECT IN VISUAL ORIENTATION DISCRIMINATION, A PET STUDY.** C. Schiltz, J.M. Bodart, S. Dubois, S. Dejudin, C. Michel, G.A. Orban, M. Crommelinck and A. Roucoux\*. Lab. of Neurophysiology, U.C.L., Brussels; \*PET Unit, U.C.L., Louvain-la-Neuve; †Lab. of Neuro- en Psychofysiologie, KULeuven, Leuven, Belgium.

This study aims to assess changes in cerebral activity induced by training in visual orientation discrimination. In a previous experiment (Schiltz et al., 1995), we observed changes of activity in striate and extrastriate regions. The present study was designed to test which changes were specifically related to the orientation trained. Three tasks were tested: two orientation discriminations (using two different references) and a baseline task. During the orientation discrimination, subjects had to identify the orientation presented by pressing a button. During the baseline condition, subjects had to respond to the presentation of an uniform noise stimulus by alternative left/right button press. Six subjects were trained (10,000 trials) for the discrimination task at one reference only. rCBF was measured before and after training using <sup>15</sup>O-water PETscan (ECAT 961 HR). Statistical analysis on the rCBF brain images was performed by Statistical Parametric Mapping (Friston et al., 1995). Regions activated during orientation discrimination were located in left and right inferior occipital/fusiform gyrus (BA 18), in right posterior fusiform gyrus (BA 19), in left hippocampal gyrus (BA 27), in cerebellum (vermis and left nuclei) and in superior parietal lobule (BA 7). Orientation-specific training decreased activation of the right extrastriate regions (right posterior fusiform gyrus (BA 19) and cerebellar vermis. A tendency towards decrease existed in the right inferior occipital/fusiform gyrus (BA 18). Training decreased the deactivations situated on the left middle temporal/fusiform gyrus (BA 20, 37) and on left superior frontal gyrus (BA 8).

**ARE THERE SPECIFIC ANATOMICAL CORRELATES OF "BIOLOGICAL MOTION" PERCEPTION IN THE HUMAN VISUAL SYSTEM?** C.A. Racine<sup>1</sup>, L.M. Vaina<sup>1,2</sup>, J.M. Diaz<sup>1</sup>, A. Zamani<sup>2</sup> & C.G. Gross<sup>3</sup>\*, Dept. of Biomedical Eng. & Neurology, Boston University, Boston, MA<sup>1</sup>; Brigham & Women's Hospital, Boston, MA<sup>2</sup>; and Department of Psychology, Princeton University, N.J.<sup>3</sup>

"Biological motion" was defined by Johansson (1973) as the pattern of movement of a small number of lights attached to the major joints of a human performing simple actions. Normal observers watching such displays immediately recognize a person and their actions. In the present study we investigated the effect of focal brain lesions on the ability to recognize biological motion displays of varying complexity and how this ability relates to both the performance on psychophysical tasks which address different stages of motion analysis and to tasks of object and action recognition. We report results from 19 patients, 15 with unilateral brain lesions and 4 patients with bilateral lesions. The criterion for inclusion in the study was impaired performance on biological motion tasks. According to the anatomical locus of their lesion and the pattern of their spared and impaired visual abilities these patients were categorized into three groups: (1) patients with anterior temporal lobe lesions, similar to the cases reported by Vaina & LeMay (1992) and Vaina & Gross (1996), with normal performance on low level motion tasks but severe impairment on the recognition of objects and actions under conditions of limited information and inability to establish motion correspondence in texture-defined stimuli; (2) patients with occipital-parietal lesions whose visual deficits were consistent with "simultagnosia"; (3) patients with lesions involving the higher stages of the dorsal or ventral system, with intact early motion mechanisms but with deficits on tasks of motion integration or object recognition. We relate our results to the electrophysiological findings that neurons in the rostral part of the superior temporal lobe (area STP) respond selectively to biological motion and to the idea proposed by Boussaoud et al. (1990) and Gross (1995), that STP integrates the late stages of the dorsal and ventral cortical visual streams. Supported by NIH grant EY-2RO-1-07861-06

## 160.18

**BILATERAL FOCAL TRANSCRANIAL MAGNETIC STIMULATION (TMS) OF EXTRASTRIATE CORTEX DEGRADES THE EXTRACTION OF FORM FROM NOISE.** S. Anand\*, J. D. Olson, J. Hotson. Stanford Univ. Sch. of Med., Stanford, CA 94305; Calif. Inst. for Med. Res., San Jose, CA 95128.

Unilateral TMS of a large area encompassing human temporo-parieto-occipital cortex (TPO) degrades the perception of motion-defined form (MDF) in a time window that begins approximately 40 ms later than the effect of TMS of striate cortex (ARVO, 1995). We asked whether bilateral TMS of a discrete TPO region could selectively degrade the perception of MDF. Three subjects discriminated the orientation of a MDF and isoluminant color-defined form (CDF), both consisting of a random dot block letter C presented for 66 ms. The MDF was presented within dynamic noise and the CDF within static noise. Subjects correctly discriminated between four possible orientations of the MDF and CDF in 80-95% of control trials. Control trials were randomly intermixed with TMS trials. TPO was mapped in multiple locations in both hemispheres using 7x14 cm butterfly coils. In each subject, a TPO location was identified where bilateral focal TMS delivered 140 or 160 ms from the onset of the MDF degraded performance to 30% correct discriminations. TMS delivered 60-120 ms or 180-240 ms following stimulus onset had little effect on performance. TMS at the same TPO location degraded the perception of CDF in a similar time window. One of the subjects was also tested with a task in which he discriminated whether a uniformly colored square presented for 66 ms was reddish or greenish. The color difference between the reddish and greenish isoluminant stimuli was adjusted such that correct discriminations were made in 90% of control trials. Bilateral focal TMS delivered 120-180 ms from the onset of this color stimulus did not degrade performance. In sum, bilateral focal TMS of an extrastriate visual area degrades the extraction of form from noise in a discrete time window in which color discrimination may be spared. Supported by NIH EY03387.

**POSTERIOR CORTICAL AREAS ACTIVATED DURING VISUALLY-GUIDED GO/NO-GO TASK: A PET STUDY.** A. Mikami<sup>1,\*</sup>, I. Ando<sup>2</sup>, K. Kubota<sup>1</sup>, T. Sawaguchi<sup>1</sup>, E. Yoshikawa<sup>2</sup>, T. Kakiuchi<sup>2</sup>, K. Nakamura<sup>1</sup> and H. Tsukada<sup>2</sup>. <sup>1</sup>Dept. of Behavioral and Brain Sciences, Primate Res. Inst., Kyoto Univ., Inuyama, 484 JAPAN, <sup>2</sup>Central Research Lab., Hamamatsu Photonics K.K., Hamakita, 434 Japan

To determine the temporal and occipital areas working when the animal is choosing one of two behavioral conditions (GO or NO-GO), the regional cerebral blood flow (rCBF) was measured with <sup>15</sup>O-labeled H<sub>2</sub>O and positron emission tomography (PET) in two rhesus monkeys. In the GO/NO-GO task, with pressing a hold lever, a white square was presented for 1-3 s as a warning signal. Then a yellow or a blue square was presented surrounding the white square for 0.5 s as a cue to choose behavior. After the end of this period, the color of the central square was changed to red. When the color of the cue was blue, the monkey was required to release the lever within 0.8 s (GO trial). When the color of the cue was yellow, the monkey was required to hold the lever for 1.8 s (NO-GO trial). The monkey, with their upper head being surrounded by the gantry, looked down the 21 in. monitor display 69.6 cm away. The rCBF measurement was conducted for 120 s at 3 different task conditions: GO/NO-GO, GO only or NO-GO only. We found activation in the hippocampus, the superior temporal sulcus, the ventral V4 and the posterior cingulate during choice behavior (GO/NO-GO) compared with the non-choice condition (GO only or NO-GO only). Thus, these areas are involved to use the visual cues to select behavioral conditions.

## AUDITORY SYSTEMS: CENTRAL PHYSIOLOGY—BIRDS AND BATS

## 161.1

**VOLTAGE-GATED OUTWARD CURRENTS IN THE CHICK NUCLEUS MAGNOCELLULARIS (NM)** M.M. Rathouz\* & L.O. Trussell. Dept. of Neurophysiology, U. Wisconsin, Madison, 53706.

A combination of strong voltage-gated outward currents and fast-kinetic transmitter-gated channels allows neurons of the NM to phase-lock to high frequency acoustic stimuli. Previous studies (Reyes et al., 1994) showed that two K currents contribute to the firing properties in NM: a low threshold 4-AP-sensitive current, and a high threshold TEA-sensitive current. We have further explored the types of K currents in NM neurons by voltage clamping E17-19 cells in brain slices with the whole-cell patch technique. Currents were isolated by subtraction of records +/- hyperpolarizing pre-pulses or pharmacological blockers. In addition to an inward rectifying, "H"-like current, four different outward currents were apparent. Two were enhanced by strong (-100mV) prepulses and were resistant to 0.2-1 mM 4-AP. Of these, one had slow activation and deactivation kinetics and was sensitive to 1 mM TEA. Two additional currents were less sensitive to prepulse, had rapid (0.5-2 ms) deactivation kinetics and were blocked by 4-AP. Due to the large size of these currents (>20 nA), we explored ways to improve the voltage clamp. Reduction of internal [K] to 1/5 normal reduced peak outward currents by half and revealed stronger inactivation than was apparent in control [K]. Replacement of all [K] with Cs blocked the pre-pulse sensitive currents, leaving the 4-AP sensitive currents which were carried by Cs ions. Under these conditions, we have characterized the kinetics of activation and deactivation, and the relative permeabilities of these two currents. The mixture of inactivating and non-inactivating currents observed in NM may shape neuronal firing properties at different stimulus rates. Supported by NIH DC02004.

## 161.3

**IONIC CURRENTS IN NUCLEUS LAMINARIS NEURONS OF THE CHICK.** Larry Proctor\* & Gilles Laurent. Division of Biology, 139-74, California Institute of Technology, Pasadena, CA 91125.

In avian species, nucleus laminaris (NL) is the first site of binaural convergence in the time pathway of the auditory system and where interaural phase-difference tuning arises. When phase-locked inputs from each nucleus magnocellularis (NM) coincide at a particular neuron in NL, that neuron is driven maximally. Should the inputs from each NM arrive 180° out-of-phase, the activity of the NL neuron is less than when it is stimulated from one side alone. We have investigated the role of NL neurons' intrinsic membrane currents to assess their role in the formation of phase-difference tuning.

Neurons from NL were obtained in 250 µm thick coronal brainstem slices from E16 to E20 day chicks and voltage clamped on their soma with whole-cell patch-clamp electrodes. Neurons were recorded in a submersion chamber at 32-34°C. K<sup>+</sup> currents were isolated by adding 1 µM TTX and 1 µM Ω-conotoxin GVIA to the perfusion medium. Under these conditions, the outward currents were very large (60-80 nA at +10 mV) and consisted of a small rapidly inactivating component and a slowly inactivating component. The K<sup>+</sup> current activated at -60 to -50 mV, i.e. in a range of potentials very close to the resting potential of NL neurons. Na<sup>+</sup> currents were isolated by applying 20 mM TEA and 1 µM Ω-conotoxin GVIA to the perfusion medium and 10 mM TEA and 10 mM CsCl to the recording pipette. Inward currents under these conditions consisted of one component with a peak of -20 nA at -15 mV. Ca<sup>2+</sup> currents were isolated using the same solutions as for isolation of Na<sup>+</sup> currents but substituting 1 µM TTX for the Ω-conotoxin. The Ca<sup>2+</sup> current appeared to consist of at least two components; a rapidly activating and inactivating component and a slowly activating component. The maximum Ca<sup>2+</sup> current was approximately 5 nA. Supported by NIMH NRSA F32MH10783-01 to LP and NSF-PFF award and NIMH Center grant to GL.

**DIAZEPAM DECREASES PERFORMANCE IN A VISUAL LONG-TERM MEMORY TASK: A PET STUDY IN HUMANS.** A. Rosier<sup>1,2</sup>, L. Comette<sup>1,2</sup>, P. Dupont<sup>2</sup>, R. Vandenberghe<sup>1,2</sup>, L. Mortelmans<sup>2</sup> and G.A. Orban<sup>1</sup>. <sup>1</sup>Lab. Neuro- en Psychofysiologie, Medical School, KU Leuven, GHB. <sup>2</sup>PET Centre, Dept. of Nuclear Medicine, UZ, GHB, B-3000 Leuven, Belgium.

In this PET-rCBF (H<sub>2</sub><sup>15</sup>O) study, we compared activation patterns during delayed recognition of abstract visual shapes (Fourier) following a diazepam- or placebo-challenged acquisition. Twelve right-handed male subjects received placebo (n=6) or 15 mg diazepam (n=6) 1 hr before the acquisition of a list of visual shapes. In the PET-study for delayed recognition, performed 3 days later in diazepam-free conditions, the following tasks were scanned twice: (1) delayed recognition, (2) delayed recognition with a shortened stimulus presentation, and (3) fixation as control task. A diazepam-challenged acquisition resulted in a mean delayed recognition performance of 63%, compared to 84% as control value. Performance in the 'shortened' delayed recognition was 66% in placebo and 59% in the diazepam group. In both control and diazepam group, a significant increase in rCBF during delayed recognition as compared to fixation was observed bilaterally in fusiform gyrus, lateral occipital region, superior parietal cortex, precentral gyrus, and right cingulate and lateral cerebellum. When comparing the control with the diazepam group for [delayed recognition minus fixation], the left fusiform gyrus displayed a significant higher activation in controls, suggesting a role in recognition. The same fusiform region was significantly less activated in the recognition with shortened presentation than in the standard recognition, both in the placebo and diazepam group. This suggests that the left fusiform gyrus plays a role in the matching of incoming and stored visual information during recognition. (Supported by the IUAP grant nr. 22, and the NFWO, Belgium)

**ROLE OF PROTEIN KINASES A AND C IN ACTIVITY-DEPENDENT REGULATION OF [Ca<sup>2+</sup>]<sub>i</sub> IN AVIAN COCHLEAR NUCLEUS NEURONS.** L. Zirpel\* and E. W. Rubel, Virginia Merrill Bloedel Hearing Research Center, University of Washington School of Medicine, Seattle, WA 98195.

Neurons of the cochlear nucleus, nucleus magnocellularis (NM), of young chicks require excitatory afferent input from the eighth nerve for maintenance and survival. One of the earliest changes seen in NM neurons following deafferentation is an increase in intracellular calcium concentration ([Ca<sup>2+</sup>]<sub>i</sub>). This increase in [Ca<sup>2+</sup>]<sub>i</sub> is due to loss of activation of one or more subtypes of metabotropic glutamate receptors (mGluR) that activate second messenger cascades involved in [Ca<sup>2+</sup>]<sub>i</sub> regulation. It is prevented by orthodromic activation of NM neurons, or bath application of 1 mM ACPD, but not by antidromic stimulation. The goal of this study was to determine the direct roles of PKA and PKC activities in the regulation of NM neuron [Ca<sup>2+</sup>]<sub>i</sub> by eighth nerve stimulation.

Brain stem slices from E17 to E19 chicks were loaded with fura-2/AM. NM field potentials were monitored in all experiments in which the eighth nerve was stimulated to achieve orthodromic activation of NM. [Ca<sup>2+</sup>]<sub>i</sub> of individual NM neurons was monitored using ratiometric fluorescence imaging. Five Hz orthodromic stimulation maintained NM neuron [Ca<sup>2+</sup>]<sub>i</sub> at approximately 110 nM for 180 minutes. In the absence of stimulation, NM neuron [Ca<sup>2+</sup>]<sub>i</sub> increased steadily to 265 nM by 120 minutes. This increase was prevented by superfusion of either phorbol-12,13-myristate acetate (PMA; 100 nM), an activator of PKC, or by 1 mM 8-Br-cAMP, an activator of PKA. Inhibition of PKA (100 µM Rp-cAMPS) or PKC (50 nM bisindolylmaleimide) during continuous orthodromic stimulation resulted in an increase in NM neuron [Ca<sup>2+</sup>]<sub>i</sub> that reached 202 nM and 170 nM, respectively, by 120 minutes. These results suggest that eighth nerve activity maintains [Ca<sup>2+</sup>]<sub>i</sub> of NM neurons at physiologic levels via mGluR-mediated activation of PKA and PKC. (Supported by NIH grant DC00520.)

## 161.4

**FUNCTIONAL ORGANIZATION OF TIME-CODING CIRCUITRY IN THE NUCLEUS LAMINARIS OF BUDGERIGARS.** S. Amagi<sup>1,\*</sup>, M.F. Kubke<sup>2</sup>, C. Blanco<sup>2</sup>, E.A. Shelden<sup>3</sup>, R.J. Dooling<sup>1</sup> and C.E. Carr<sup>2</sup>. <sup>1</sup>Dept. of Psychology and <sup>2</sup>Dept. of Zoology, University of Maryland, College Park, MD 20742. <sup>3</sup>Dept. of Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109.

In the avian auditory brainstem, auditory nerve afferents synapse on the neurons of the nucleus magnocellularis (NM), which project bilaterally to the nucleus laminaris (NL), where they form maps of interaural time differences (ITDs). The organization of the ITD circuit differs among different species of birds. In the chicken, NL is composed of a monolayer of bipolar neurons forming a single map of ITDs in the medio-lateral direction. This is in contrast to the barn owl, where NL is hypertrophied to a multicellular structure with multiple ITD maps arranged in the dorso-ventral axis. We propose that this variation is correlated with time coding ability. Budgerigars can localize sound well, and recordings from NL show sharply tuned responses to ITDs. We investigated the level of organization of the budgerigar NL and the direction in which ITD maps are arranged.

We have used immunohistochemical and Golgi techniques to examine the morphology of NL in the budgerigar. Anti-calbindin staining reveals that, like in other birds, budgerigar NL neurons in the lateral-caudal low best frequency region have complex long dendritic arbors, while those in the medio-rostral high best frequency region have many shorter dendrites. In the high frequency region, NL forms a multilayered structure like the barn owl, but in the low frequency region, NL is more reminiscent of the chicken monolayer structure. The cell count of NL reveals that the budgerigar NL is more developed than the chicken and less so than the barn owl. Organizations of NM afferent delay-lines in NL is also under investigation both by small injections of biotinylated dextrans amine in NM and by physiological mapping of ITD sensitivity.

## 161.5

ELECTRICAL STIMULATION OF THE BARN OWL'S NUCLEUS LAMINARIS NEURONS IN VIVO. J.L. Peña, S. Viète and M. Konishi\*. Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

Nucleus laminaris neurons serve as coincidence detectors in the neural circuit that measures interaural time differences. The discharge rates of these neurons could be manipulated in vivo by current injection under "loose patch" recording conditions. Positive current excited the neurons and negative current reduced or extinguished their spontaneous and evoked discharge. The firing rate increased monotonically as a function of positive current. The neurons fired tonically to prolonged current steps, after an initial period of adaptation. Electrical stimulation could drive the neurons to maximal discharge rates much higher than the saturation levels reached by sound stimulation suggesting that gain control mechanisms operate during acoustic stimulation.

Injection of positive current during sound stimulation showed that the sensitivity for interaural time difference (ITD) could persist over a range of discharge rates which does not normally occur with sound stimulation. However, some of the neurons lost their ITD-tuning with large positive current. Negative current also had graded effects on sound evoked responses. ITD tuning persisted for all current levels used. In some of the neurons, stimulation with their least favorable ITD caused their discharge rates to decrease below the level maintained by current alone.

Supported by NIH grant R01 DC00134, and fellowships from the Pew Foundation (JLP) and the Deutsche Forschungsgemeinschaft (SV).

## 161.7

A SIMPLE BIOPHYSICAL MODEL FOR ANALYZING PHASE-LOCKING AND COINCIDENCE DETECTION IN AUDITORY CELLS. H. Agmon-Snir\*, C. E. Carr\* and J. Rinzel. Math Research Branch, NIH, Bethesda, MD 20892, \*Dept. Zoology, Univ. Maryland, College Park, MD 20742.

Using electrophysiological data gathered on cells in the auditory ITD (interaural time difference) pathway in birds, we developed a simple biophysical model for relay cells (in the N. magnocellularis) and coincidence detectors (in the N. laminaris). The simplest version of this Hodgkin-Huxley-like model assumes just two voltage-dependent currents, having just two dynamic variables and few parameters. The inward current produces the action potential's fast depolarization and the outward current repolarizes the cell back to rest. Input trains to the model mimic auditory nerve (AN) fiber activity for pure tone stimuli.

Our analysis shows that the Poissonian property of the AN input train lowers the cell's phase-locking ability: the phase of the output spike depends on the interspike interval that precedes this spike (due to the refractory period after the previous output spike). This reduction in phase-locking can be avoided by using very large synaptic inputs. We also find that convergence of a few AN fibers onto a single relay cell may improve the phase-locking of the output of this cell (see also Joris et al., 1994). This improvement is found regardless of synaptic input amplitude (sub- or suprathreshold), and can be explained using concepts from order statistics. The requirements for an improvement are analyzed and our results are compared to previous models (e.g., Rothman et al., J. Neurophysiol., 1993). Our model is also used for coincidence detection and several main results are shown.

Generally, the present model fails to phase-lock and perform coincidence detection at high frequencies (>3kHz). However, the model gives insights on the mechanisms of phase locking and coincidence detection in these cells and on the problems found in the high frequency domain.

This work was supported by HFSPO (H.A.-S.) and by NIHDC00436 (C.E.C.).

## 161.9

Anatomical basis for the adjustment of interaural time difference (ITD) tuning in the external nucleus of the inferior colliculus (ICX) of juvenile barn owls: selective pruning or synaptogenesis? DE Feldman\* and EI Knudsen. Neurobiology Dept., Stanford University Medical School, Stanford CA 94305.

Neural tuning for ITD in the barn owl's ICX is calibrated by visual experience during development. Normally, ICX neurons in adult owls are narrowly tuned to an ITD value systematically related to location in the ICX. In adult owls reared wearing laterally displacing prismatic spectacles, however, ICX neurons exhibit ITD tuning that is offset from the normal value by an amount corresponding to the prismatic displacement. Similarly, afferents providing the principal auditory input to the ICX from the central nucleus of the inferior colliculus (ICC) have a characteristic point-to-point topography in normal adults, but display an altered topography in prism-reared owls that corresponds to the shifted ITD tuning. How are these distinct physiological and anatomical adult states arrived at during development? Possibilities include differential sculpting of initially broad anatomical and physiological states, or the modification by prism rearing of an initial state that is already adult-like, perhaps by formation of novel synaptic connections. To distinguish these possibilities, we are assaying the initial state of the anatomy and physiology in juvenile owls before prism attachment.

Owls were reared with normal vision until 60 d of age, when the head has reached adult size. Preliminary data indicate that at this age, ICX neurons already have adult-like ITD tuning. After subsequent prism attachment, ICX neurons undergo robust ITD tuning modification, including the acquisition of responses to previously ineffective ITDs. Thus, prism rearing can cause the acquisition of novel auditory responses. We are currently determining the initial topography of the ICC-ICX projection in 60 d old owls to see how it, too, is modified by subsequent prism-rearing.

Supported by NIH R01 DC00155-16.

## 161.6

MAPPING OF ITD IN THE NUCLEUS LAMINARIS OF THE BARN OWL. C.E. Carr\* and M.E. Kubke. Univ. Maryland, Dept. of Zoology, College Park, MD 20742.

Barn owls use interaural time differences (ITDs) to localize sound in azimuth. ITDs are computed in the nucleus laminaris (NL) by a circuit composed of delay line inputs and coincidence detectors. A previous study (Sullivan and Konishi, 1986) had used multiunit recording of the tone-induced evoked potential, or neurophonic, to map NL, and had demonstrated an orderly map of ITD within NL, such that from dorsal to ventral, the best ITD shifts from the far contralateral hemifield through 0 ITD to the frontal ipsilateral hemifield (-130 to 50  $\mu$ s). Iso-ITD contours run along the mediolateral direction of NL, forming multiple maps of ITD within a single isofrequency slab.

The redundant nature of this representation has been questioned. Since the conclusions were reached after reconstruction of recordings not confined to an isofrequency slab or parallel to the delay line inputs, we repeated the experiments with a head angle of 70°, and recorded parallel to the delay line inputs. In 2 owls, we found essentially identical results to Sullivan and Konishi. A large neurophonic was encountered over a 700  $\mu$ m depth in the dorsal brainstem, corresponding to the position of NL. Recordings from 4.5-6.1 kHz regions showed steady changes in best ITD from -120/-90  $\mu$ s (dorsal) to +60  $\mu$ s (ventral), with 0 ITD represented about 500  $\mu$ m below the dorsal surface of NL. Multiple recordings along an isofrequency slab showed small variations in the position of 0 ITD; these changes did not appear to represent a systematic shift in iso-ITD along the mediolateral axis of NL.

Supported by NIH DCD00436 to CEC.

## 161.8

SPIKING PATTERNS IN THE OWL'S INFERIOR COLLICULUS PRESERVE TEMPORAL ACOUSTICAL STRUCTURE. T.T. Takahashi\* & C.H. Keller. Inst. of Neurosci., Univ. of Oregon, Eugene, OR 97403.

Neurons in the owl's inferior colliculus (IC) have well-defined spatial receptive fields. We recently observed that the temporal pattern of their spikes, elicited by the repeated presentation of a noise burst, was remarkably consistent from repetition to repetition. We report the results of two experiments suggesting that this pattern is related to the temporal structure of the stimulus noise. In one experiment, we recorded spike trains from isolated IC neurons (n=45) responding to a series of partially-correlated noise bursts (100-ms; 5 ms on & offsets). Correlation levels were controlled by adding to a reference noise, known proportions of an uncorrelated noise. PSTHs were constructed from spike trains obtained with each noise (20 reps/stimulus) and cross-correlated with the PSTH obtained with the reference noise alone. Typically, the cross-correlation coefficients for the PSTHs, when plotted as a function of the noise-bursts' correlation coefficients, showed a systematic relationship, suggesting that the spiking pattern changed in a manner related to the noise bursts' temporal structure. In the second experiment, a series of 100-ms noises were synthesized by inserting a 40-ms noise segment, N1, at successively later points along the time course of another noise burst, N2. PSTHs from IC neurons (n=44) were aligned with stimulus onsets and, in most neurons, found to have a consistent pattern of peaks and troughs whose positions changed in synchrony with the position of N1 within N2. These results suggest that neurons in IC, in addition to place-coding space, can also convey information about the temporal structure of complex stimuli. (Supported by NIH grant DC02050.)

## 161.10

Can Hebbian pairing of a binaural noise stimulus and electrical microstimulation alter binaural tuning in the inferior colliculus of barn owls? J.I. Gold\* and E.I. Knudsen. Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

The binaural tuning properties of neurons in the auditory space map of the optic tectum (OT) of barn owls adaptively adjust to changes in auditory and/or visual experience during development. A site of neuronal plasticity underlying such adjustments is the external nucleus of the inferior colliculus (ICX), in which tuning to interaural time difference (ITD) adaptively changes as a result of rearing with either prism-induced displacement of visual space or ear plug-induced, frequency-dependent displacement of auditory cue values. Although little is known about the cellular mechanisms of plasticity in either case, the existence of prism-induced changes in the auditory map suggests the presence of a vision-based "instructional signal" to guide changes in tuning. Such a signal could work via phasic excitation of ICX neurons by a structure containing visual information, causing potentiation of coincident auditory-driven input. To test this model, the effects of a Hebbian pairing of a binaural stimulus and direct electrical activation of ICX neurons were evaluated.

Juvenile owls were raised with either an ear plug-like device in one ear or optical displacing prisms. In these birds the deep layers of the OT, which receive input directly from neurons in the ICX, were surveyed for sites at which tuning to ITD differed significantly from normal (based on the site's visual receptive field) but responses to normal values remained. Microstimulation (150 Hz biphasic pulses of 50 - 200  $\mu$ A) at these sites, which antidromically activated ICX neurons, was paired with dichotically presented, broadband noise using the site's normal ITD. Responses to the microstimulation-paired ITD were evaluated relative to both pre-training and post-training, non-paired values and the time course of change, if any, determined. Preliminary results suggest that this manipulation increases neural responsiveness to the microstimulation-paired ITD values. Supported by NIH: R01 DC00155-16.

## 161.11

EFFECTS OF UNILATERAL COCHLEAR REMOVAL AND FREQUENCY-SPECIFIC LESIONS ON LOCALIZATION AND DISCRIMINATION OF SOUNDS BY THE BARN OWL (*Tyto alba*). R. Egnor\* Biology Division 216-76, California Institute of Technology, Pasadena, CA 91125

The barn owl is a nocturnal predator capable of using sound cues alone to localize prey. The anatomy, physiology and psychophysics of barn owl sound localization have been extensively studied. How barn owls process auditory information for sound recognition has not been studied, however. In order to investigate this capacity, three barn owls were trained to perform a sound localization task and a simple sound recognition task: frequency discrimination. Previous work has identified an anatomical segregation of the information from binaural cues used in auditory localization into two parallel pathways. Both bilateral pathways carry information about stimulus frequency. One pathway is specialized to preserve information about time and the other to preserve information about intensity. The effect of the removal of both of these pathways unilaterally (cochlear removal) and the complete removal of time information in a frequency band (local, frequency-specific inactivation of the time pathway) on frequency discrimination is discussed. In addition, although much is known about the processing of binaural cues for sound localization in the barn owl, the use of monaural cues has never been tested. Cochlear removal addresses whether owls can localize using only monaural cues.

## 161.13

A LATENCY MAP IN THE MUSTACHED BAT VENTRAL NUCLEUS OF THE LATERAL LEMNISCUS. W. E. O'Neill\*, Dept. of Neurobiology and Anatomy, Univ. of Rochester School of Medicine and Dentistry, Rochester, NY 14642

The ventral nucleus of the lateral lemniscus (VL) in echolocating bats is highly organized and differentiated into "multipolar" and "columnar" subdivisions. The columnar division (VLC) is composed of rows and columns of tightly-packed, glycinergic spherical cells. Excitatory inputs to VLC arise in the contralateral ventral cochlear nucleus and project in an orderly tonotopic fashion to the cell rows. VLC neurons in turn project tonotopically to the central nucleus of the inferior colliculus (IC). Presumably inhibitory inputs arise in the ipsilateral medial and lateral nuclei of the trapezoid body. VLC cells reliably fire only one or two spikes to the onset of best-frequency tone bursts. Latency variation is extraordinarily low (<40 to 250  $\mu$ s s.d.), and with level changes over 60 dB, latency shifts are less than 1 ms. These features are particularly useful for precise encoding of stimulus timing.

Afferents enter the VLC laterally and make their way across the nucleus, synapsing with cells lying in only one or two horizontal laminae. Therefore, lateral VLC cells should have the shortest latencies, and medial VLC cells should have the longest latencies. We reconstructed single-unit best frequencies (BF) and latencies from a series of parallel penetrations passing through the IC and crossing the columns of VLC cells diagonally in the dorsomedial to ventrolateral direction. In the VLC, a weak, dorsoventral, low-to-high frequency tonotopic gradient was found along cell columns, but not along cell rows. By contrast, a significant short-to-long latency gradient was found in the lateral-to-medial direction along cell rows, but not along cell columns. This latency gradient spanned a narrow range of latencies between 2 and 6 ms. However, the latency representation remained quite stable over wide changes in stimulus level, unlike that for an expanded latency gradient previously found in the IC. The level-tolerant representation in VLC can be considered a "map" for latency, although for what purpose such a map is intended is not yet clear.

## 161.15

A MIDBRAIN TEGMENTAL AUDITORY AREA (SAGULUM?) SPECIALIZED FOR PROCESSING FREQUENCY MODULATED SOUNDS IN THE MUSTACHED BAT. M. Gordon\*, W. E. O'Neill. Neuroscience Program and Dept. of Neurobiology and Anatomy, Univ. of Rochester Sch. of Med. and Dent., Rochester, NY 14642

Frequency modulations are an important component of the communication vocalizations of many species. For bats, they are also an important and often the only component of echolocation calls. In the mustached bat, we have found a region beneath the inferior colliculus and just lateral to the dorsal nucleus of the lateral lemniscus where every neuron so far recorded showed strong directional preference for linear and sinusoidal FM stimuli.

Units in this region responded with phasic discharge patterns to tone bursts and had best frequencies between 62 and 63 kHz (dominant biosonar component). In response to FM stimuli, these units were consistent in preferring upward sweeps over downward, by nearly 100% for certain FM rates ( $\Delta$ F/T). Upward preference was maximal at rapid FM rates (0.8-2.4 kHz/ms) for most units, and at slow rates (0.18-0.34 kHz/ms) for 1 unit. Evoked field potentials were also consistently larger to upward FM than to downward FM over multiple electrode penetrations through the area. Such consistency of the evoked field potential is a further indication of the uniformity of unit response type in this area. All units had inhibitory sidebands, some of which were temporally asymmetric. These sidebands have been previously implicated as a likely mechanism for creating FM selectivity (Gordon and O'Neill '96, Assoc. for Res. in Otolaryngology Abst. 19: 482).

HRP labeling of our recording site revealed it to be just beneath the anterolateral division of ICC in a region of small cells and light cytochrome oxidase staining. This is consistent with descriptions of the sagulum in cat (Henkel and Shneiderman '88, J. Comp. Neurol. 271:577-588).

## 161.12

HEAD-RELATED TRANSFER FUNCTIONS OF THE BARN OWL. Keller\*, C.H., K. Hartung, & T.T. Takahashi., Institute of Neuroscience., Univ. of Oregon, Eugene, OR 97403 USA & Lehrstuhl für allgemeine Elektrotechnik und Akustik. Ruhr-Universität Bochum D-44780 FRG.

In an effort to develop a headphone-based simulation of various complex acoustical environments, we have measured the head-related transfer function (HRTF) of the barn owl. HRTFs were computed from microphone recordings obtained in the ear canal of 4 freshly-euthanized adult barn owls. Stimuli were Gaussian enveloped broadband noise bursts (68 ms) broadcast from a speaker mounted on a vertical hoop. Samples were obtained in the frontal hemisphere with 5°-10° resolution on a double-pole co-ordinate system. Recordings were made with microphones (Knowles EM4046) placed in the ear canals with the ports facing outward at a distance 4 mm from the eardrum in 3 birds. In 1 bird, probe tubes (7mm x 1mm OD) attached to the microphone were inserted to within 2 mm of the eardrum. Microphone output was averaged over 100 stimulus repetitions at each location and digitized at 30,000 points/sec. Binaural phase and amplitude spectra, corrected for speaker and microphones, agreed well with earlier reports (Brainard et al. *J Acoust Soc Am* 91:1015 '92). At low frequencies (3-4kHz), binaural phase and amplitude differences co-varied with the source's azimuth but not its elevation. At higher frequencies (4-8kHz), the spatial axes along which the two cues changed were more orthogonal. Removal of the preaural flap decreased the magnitude of binaural differences at high frequencies, but had little effect on the directional dependency of these cues. By contrast, removal of the facial ruff affected the directional dependency and the magnitudes of the cues, particularly at higher frequencies, in agreement with earlier reports (Knudsen et al. *J Neurophysiol* '94). ## 161.14

THE INFLUENCE OF GABAERGIC INHIBITION ON THE RECOVERY CYCLES OF BAT INFERIOR COLLICULAR NEURONS. Y. Lu\*, Q.Y. Zheng and P. H.-S. Jen. Division of Biological Sciences, University of Missouri-Columbia, MO 65211

In echolocation, bats use the time lag between the outgoing orientation signal and the returning echo for measurement of the target distance. This echo ranging process depends heavily upon the recovery cycles of auditory neurons. To understand the dynamic aspect of the echo ranging, we examined the influence of GABAergic inhibition on the recovery cycles of inferior collicular neurons of the big brown bat, *Eptesicus fuscus*.

Recovery cycles of 64 inferior collicular neurons (in which 55 were phasic responders and 9 were tonic responders) were studied by means of two identical frequency-modulated (51 neurons) or best frequency pure tone (13 neurons) pulses. Their recovery cycles were classified into three types: (1) undelayed long inhibition (29 neurons, 45%) in which a neuron did not reach 50% recovery until the interpulse interval was more than 20ms; (2) short suppression (30 neurons, 47%) in which a neuron reached 50% recovery in 10 to 20ms; and (3) fast recovery (5 neurons, 8%) in which a neuron recovered to 50% within 10ms. The influence of GABAergic inhibition on the recovery cycles of 62 neurons was examined by ionophoretically injecting bicuculline methiodide (10mM, pH3.0, Sigma) into their recording sites. This application shortened the 50% recovery time of 47 (76%) neurons by more than 10% but it lengthened the 50% recovery time of 4 (6%) neurons by more than 10%. However, the 50% recovery time of the remaining 11 (18%) neurons was not affected by more than 10%. These data demonstrated that GABAergic inhibition contributes significantly to the recovery cycle of inferior collicular neurons. (work supported by NIH DC 247 to P Jen).

INHIBITION CREATES FILTERS FOR FREQUENCY MODULATED SOUNDS IN THE IC OF THE BIG BROWN BAT (*EPTESICUS FUSCUS*). U. Koch and B. Grothe\*, Zoologisches Inst., Univ. of Munich, 80333 Munich, Germany

Most natural occurring sounds are modulated in amplitude and frequency. Going from lower to higher auditory nuclei the range of modulation rates a neuron responds to becomes narrower and the optimal rate lower. This suggests active neuronal filtering. We have recently shown that binaural interaction influences the filter properties of neurons in the inferior colliculus (IC). Here, we investigated the role of GABAergic and glycinergic inhibition on the monaural and binaural filtering of frequency modulated sounds in the IC.

Action potentials were recorded from IC neurons while presenting sinusoidal frequency modulated sounds monaurally and binaurally (same intensity at each ear) via earphones. Neurons were tested at their best center frequency and best modulation depth with different modulation rates ranging from 10 Hz to 800 Hz. Based on spike counts the monaural and binaural modulation transfer function (MTF) for modulation rates was calculated and the upper and lower 50%-cut-off was determined. The same tests were repeated while ionophoretically applying the GABA<sub>A</sub>-receptor antagonist bicuculline or the glycine receptor antagonist strychnine.

Blocking GABAergic inhibition increased the upper 50%-cut-off in 50% of the neurons. Across the population of neurons this change was more pronounced for binaural than for monaural sound presentation. Bicuculline decreased the upper 50%-cut-off of some neurons. In 25% of the neurons the lower 50%-cut-off decreased after applying bicuculline for the monaural and binaural presentation. Strychnine had comparable effects. However, the difference of filter changes between monaural and binaural stimulation was less pronounced.

The results suggest that binaurally and monaurally induced GABAergic as well as glycinergic inhibition participate in creating filter properties for frequency modulated sounds of neurons in the IC.

COMBINATION-SENSITIVE NEURONS IN THE INFERIOR COLLICULUS OF THE MUSTACHED BAT: POSSIBLE ANALYSIS OF SOCIAL COMMUNICATION SIGNALS. S. A. Leroy\* and J. J. Wenstrup. Dept. of Neurobiology, Northeastern Ohio Univs. Coll. of Med., Rootstown, OH 44272

Neurons of the inferior colliculus (IC) were tested for responses to combinations of tone or noise bursts. We focused on neurons in two tonotopic regions: 1) the 24-31 kHz region, representing frequencies in the fundamental component of the biosonar signal, and 2) the 33-46 kHz region, representing frequencies outside the biosonar range, between the fundamental and second harmonic components of the biosonar signal. We examined whether single units in these parts of the IC are combination-sensitive, as are neurons in other IC regions.

It was difficult to record single units with best frequencies in the 24-31 kHz range. Penetrations through the anterolateral division of the IC often revealed a gap in this frequency range. Of the neurons tuned to 24-31 kHz, none showed additional sensitivity (whether alone or in combination) to frequencies in higher sonar harmonics, even when tested over a range of delays between the two stimuli. In contrast, about half of the neurons tuned in the 33-46 kHz range responded to the combination of two signals. These neurons, with best frequencies in the 37-46 kHz range, also responded to signals in 18-22 kHz range. Both facilitatory and inhibitory effects of the low frequency stimulus were observed, and these effects were strongest at or near 0 msec delay between the two components.

This latter group of neurons may encode information in social communication signals. Social vocalizations often include energy in both the 10-22 kHz and 33-46 kHz ranges (Kanwal et al., J. Acoust. Soc. Am. 96:1229-1254, 1994). These findings suggest that neurons at auditory levels as low as the IC may be specialized to respond to complex, multi-harmonic communication signals. (Supported by the National Institute on Deafness and other Communication Disorders.)

## 161.19

SPATIAL TRACKING OF MOVING TARGETS BY THE ECHOLOCATING BAT, *EPITESICUS FUSCUS*: PERCEPTUAL CONSEQUENCES OF VOCAL-MOTOR BEHAVIOR. C. F. Moss, R. Iannucci and W. W. Wilson\*. Department of Psychology, University of Maryland, College Park, MD 20742

Field data show that an echolocating bat modifies its outgoing sonar emissions, relying on incoming echo information to shape the characteristics of its subsequent sonar cries. In *Eptesicus fuscus*, a bat using FM vocalizations for echolocation, there are systematic changes in sound repetition rate, duration and bandwidth with closing target distance. We hypothesize that the temporal patterns of sound production during insect pursuit may provide the bat with acoustic information that is used in its perception of dynamic auditory scenes.

Here, we report on studies of insect capture by bats in a large laboratory flight room, where animals were trained to intercept tethered moving insects. The animal's flight behavior was recorded on video tape at high speed (500 frames/sec), and its sonar vocalizations were recorded on audio tape (30 inches/sec, Rascal Store 4D). Our video analyses show that the bat typically positions its head 3-4 cm above the tethered insect, locking its head-aim with an accuracy of approximately 5 deg. Our analysis of sonar sounds produced by the bat in this insect capture task reveals that the repetition rate during target pursuit does not change continuously over time. Rather, the repetition rate remains stable for fixed intervals before increasing. During the approach phase of insect capture, for example, the sound repetition rate may plateau at around 30 Hz for time periods as long as 150 ms. We hypothesize that the stable periods of sound repetition rate produced by *Eptesicus* may be used by the bat in the processing of spatial acoustic information about a dynamic environment. Thus, the bat's perception of dynamic auditory scenes may be shaped by its own vocal production patterns.

## 161.18

PERCEPTUAL ORGANIZATION OF SOUND FOR SPATIALLY-GUIDED BEHAVIOR IN THE ECHOLOCATING BAT. M. Morris and C.F. Moss\*, Departments of Psychology, Harvard University, Cambridge, MA 02138 and University of Maryland, College Park, MD 20742

Auditory perception involves the organization of sound, or the analysis of auditory scenes. Auditory scene analysis draws upon many dimensions of sound perception, including that of auditory space. Here we present data on the perceptual organization of sound in the echolocating bat, *Eptesicus fuscus*, an animal that emits brief FM range vocalizations and extracts spatial information about the environment from the features of returning echoes. The particular focus of our work is on the perceptual organization of sound along the axis of echo delay, the bat's cue for target distance. We have conducted a series of experiments on the bat's perception of sonar targets with changing echo delay to explore the extent to which the animal integrates and segregates spatial information from a dynamic auditory scene. In these experiments, the bat was trained in a 2-AFC task to discriminate between sets of echoes that differed in their patterns of delay-change over time. Targets were electronically simulated by digitizing, delaying and playing-back the bat's sonar emissions. Each stimulus set contained six different echo delays, and the bat received only one echo playback for each sonar emission. In one echo discrimination set, for example, the delays systematically increased or decreased (set A), and in the other echo set, the sequence of delays was random (set Z). The delay step-size of echoes in stimulus set A was unequal in some experiments to ensure that the bat was discriminating the direction of echo delay change, and not simply between variable and fixed delay-steps in echo sets A and Z. Our data show that the bat can integrate echo sequences along the dimension of delay, and these findings lay the foundation for behavioral experiments that explore the bat's segregation of echoes into separate streams along the range axis. Supported by an NSF Young Investigator Award to C.F.M.

## 161.20

CORTICOFUGAL CONTROL OF CENTRAL AUDITORY SENSITIVITY. P. H.-S. Jen\*, X. D. Sun and O. C. Chen. Division of Biological Sciences, University of Missouri-Columbia, Missouri 65211

During sensory signal processing, the brain has the built-in ability to edit and adjust the flow of information that reaches it. Our previous study on bats showed that electrical stimulation in the auditory cortex inhibited acoustically evoked responses of inferior collicular neurons (Sun et al., Brain Research 495:1-8, 1989). We have extended this study by examining the corticofugal control of rate-intensity function, auditory spatial sensitivity and sharpness of frequency tuning of inferior collicular neurons of the big brown bat, *Eptesicus fuscus*.

Electrical stimulation at 40 cortical sites (depths: 488-690  $\mu$ m) reduced acoustically evoked responses of 84 recorded inferior collicular neurons (depth: 270 and 1962  $\mu$ m). At the optimal interstimulus interval, electrical stimulation in the cortical site lowered the intensity-rate function, reduced the auditory spatial response area and narrowed the frequency tuning curve of recorded collicular neurons. Ionophoretic injection of Lidocaine into the cortical site significantly raised the intensity-rate function, expanded the auditory spatial response area and broadened the frequency tuning curve in these neurons. This suggests that the corticofugal pathway continuously suppresses acoustic signal processing in the central inferior colliculus. Ionophoretic application of bicuculline into the collicular recording sites greatly raised the intensity-rate function, expanded the auditory spatial response area and broadened the frequency tuning curves of these neurons. Application of GABA into the collicular recording sites produced the opposite effects. These findings suggest that corticofugal control of inferior collicular auditory sensitivity is likely mediated through GABAergic inhibition (work supported by NIH).

Developmental Expression of Plateau Potentials in Rat Striatal Neurons. E. Ghansah\*, T. DeFazio, P. Quan and J. P. Walsh. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089-0191.

Previous studies using microelectrode techniques have shown that an age-related decrease in the duration of calcium-mediated plateau potentials (PP) was correlated with a decrease in striatal neuron dendritic length. Our goal was to use development as a tool to further examine the relationship between dendrites and PPs. Whole-cell recording techniques were used on 400  $\mu$ m coronal sections obtained from P1 - P16 rats. All slices were perfused with oxygenated ACSF containing 30 mM TEA. Recordings were obtained using 4 - 8 M $\Omega$  patch electrodes filled with a K<sup>+</sup>-based internal containing biocytin. PPs were generated by 40, 80, 200 or 400 ms depolarizing current pulses, and biocytin-filled cells were examined for correlated morphology. In general, PP durations (PPD) increased with age while the threshold for evoking PPs decreased. P1 - P5 neurons showed increased action potential duration (APD), but no PPs even at supramaximal current injections. Long duration PPs were produced in neurons > P14, but removal of dendrites through acute isolation eliminated PP expression. Developmental differences could not be accounted for by changes in seal or input resistance. These data were supported by a dendritic compartment model developed through NEURON software. Our results suggest that developmental changes in dendritic length contribute to the expression of PPD. Supported by NIA grants AG09793 and AG00093.

## 162.2

Minimal stimulation of excitatory striatal afferents reveals age-dependent changes in quantal parameters. R. Nori and J. P. Walsh\*, Andrus Gerontology Center & Dept. of Biomedical Engineering, University of Southern California, Los Angeles, CA 90089-0191.

The present study determined whether quantal analysis of minimally evoked EPSPs would reveal age-dependent differences in quantal parameters. Each cell was tested for its "paired-pulse" response to activation of a large population of afferents (strong stimulation), and then the stimulation intensity was reduced to activate a small number or single afferent. Quantal content (m) was determined through the method of failures using a stimulation intensity set to produce failures  $\approx$  50% of the time. Release probability (p) was determined from the EPSP amplitude variance and m, and the number of release sites were determined from the binomial equation ( $m=np$ ). Paired, high intensity stimulation of the corpus callosum generally produced facilitation at a pairing interval of 50 msec in young rats. In the same cells, minimal stimulation revealed a pairing induced increase in m, p, and n. Pairing caused a reduction in failures and increased the likelihood of multiple release events. By contrast, aged cells generally responded to high intensity stimulation with paired-pulse depression and minimal stimulation revealed a pairing induced decrease in m and p. Pairing caused an increase in the number of failures and decreased the number of multiple release events in aged animals.

Addition of carbachol (1  $\mu$ M) reduced the amplitude of the EPSP produced in response to strong stimulation and changed paired-pulse depression into paired-pulse facilitation. By contrast, carbachol did not change the amplitude of the minimally evoked EPSP. These data indicate that aging affects the quantal characteristics of synapses and that carbachol sensitive and insensitive excitatory synapses exist in the striatum. Supported by NIA grant AG09793.

## 162.3

INTERACTION BETWEEN AGONISTS OF CHOLECYSTOKININ AND ACETYLCHOLINE AT NEOSTRIATAL NEURONS IN RATS. H. Davidowa, G. Vierig, K. Wetzel and D. Albrecht\* Institute of Physiology, Charité, Humboldt University Berlin, Tucholsky Str. 2, D - 10117 Berlin, Germany

Cholecystokinin (CCK) mainly excites striatal neurons via CCK-A or CCK-B receptors. Acetylcholine is the transmitter of one type of the interneurons within the neostriatum. Now we studied the interaction between iontophoretically administered agonists of CCK and acetylcholine (ACh) in rats anesthetized with urethane. Action potentials of single units were recorded extracellularly by means of glass micropipettes filled with trypan blue solution. A seven-barrel micropipette was affixed to the recording electrode. It contained one of the CCK-A agonists A-71623 (Boc-Trp-Lys-(N-methylphenylaminocarbonyl)-Asp-[NMe]-Phe-NH<sub>2</sub>, 0.25 mM, pH 7.8) or A-71378 (Des-amino-Tyr-Nle<sup>2</sup>-Nle<sup>5</sup>-NMe-Asp-CCK7, 0.25 mM, pH 7.8) the CCK-B agonist Suc-CCK4 (Suc-Trp-NMe-Nle-Asp-Phe-NH<sub>2</sub>, 0.25 mM, pH 7.8), Ki 1001 (Suc-Tyr(SE)-Met-Gly-Trp-Met-PEA, 0.25 mM, pH 7.8), a CCK-A antagonist (all synthesized by P. Henklein, Charité), PD 135,158 (N-methyl-D-glucamine salt, 0.25 mM, pH 7.8) (RBI). All these drugs were dissolved in solution of phosphate buffered saline (60mM). These substances were ejected with negative currents between 5 to 90 nA. Furthermore, acetylcholine chloride (0.7 M, pH 4) or atropine sulfate (0.1 M, pH 4.5) were administered with positive currents. Retention currents of opposite polarity (2-5 nA) were applied between the ejection periods. The agonists had mainly excitatory effects on neuronal discharge rates. These changed from  $1.75 \pm 2.4$  impulses/s (mean  $\pm$  STD; control, n = 45) to  $2.4 \pm 2.7$  imp./s during administration of the CCK-A agonists and to  $2.3 \pm 2.7$  imp./s during administration of the CCK-B agonist (Wilcoxon Signed Rank Test (Wt) p < 0.0001). Acetylcholine mainly reduced these effects or converted them to a suppression (Wt p < 0.001). During coadministration of ACh and one of the agonists the discharge rates of the neurons were  $1.8 \pm 2.6$  (CCK-A) and  $1.6 \pm 2.3$  (CCK-B). The coadministration of atropine did not significantly change the responses to the CCK receptor agonists and reduced the suppressive action of ACh. It can be concluded that cholinergic interneurons may reduce the activating action of the neuropeptide CCK within the neostriatum. Supported by the BMFT, F.R.G.

## 162.5

DIRECT AND INDIRECT EFFECTS OF SUBSTANCE P ON STRIATAL PRESYNAPTIC EXCITABILITY. P. Patino\*, S.J. Young, P.M. Groves and M. Garcia-Munoz. Dept. Psychiatry, Sch. of Medicine, UCSD, La Jolla, CA 92093-0603

Evidence suggests that striatal presynaptic Substance P (SP) heteroreceptors modulate neurotransmitter release from cortical-glutamate and nigral-dopamine (DA) afferents. We used the measurement of terminal excitability, an in vivo electrophysiological method, to study the activation of SP receptors on nigrostriatal and corticostriatal axons. Stimulating electrodes were placed in the dorsal striatum of urethane anesthetized male Sprague-Dawley rats to elicit antidromic action potentials recorded extracellularly from a substantia nigra pars compacta or medial prefrontal cortex neuron in different experiments. Drugs in saline were delivered (0.3  $\mu$ l over 5 min) via cannulae placed alongside the stimulating electrode. Excitability was assessed by determining the stimulating current required to elicit an antidromic response. Striatal administration of SP (2 nM) produced a significant increase in excitability ( $+11 \pm 0.6$  %) in nigrostriatal axons which was reversed ( $+2.2 \pm 0.6$  %) by intrastratial infusion of the specific SP antagonist Spantide II (10nM), confirming neurochemical reports that the SP-induced increase in DA release is due to a direct action of SP on DA axons. Infusion of SP (2 nM) significantly decreased corticostriatal excitability ( $-11 \pm 1.9$  %) in intact rats and in animals with kainic acid lesions (1.5  $\mu$ g/0.3 $\mu$ l) that eliminated most classes of intrinsic neurons ( $-19.6 \pm 2.1$  %). This suggests an indirect effect due to a SP-induced increase in DA and stimulation of corticostriatal DA receptors since, in animals pretreated with the DA antagonist sulpiride (10mg/kg, i.p.), SP significantly increased corticostriatal presynaptic excitability ( $+6.5 \pm 0.8$  %) in animals with kainate lesions) presumably by a direct effect on corticostriatal SP heteroreceptors. Experiments are underway to study the participation of glutamate and DA autoreceptors in these SP-induced changes in presynaptic excitability. These results provide electrophysiological evidence consistent with neurochemical studies that SP exerts a powerful presynaptic effect on DA release. Further, these studies suggest that direct and indirect activation of pre and postsynaptic receptors are important considerations in SP neurotransmission as well as in the interpretation of its effects following intracerebral administration. This research was supported in part by grant DA02864 from the National Institute on Drug Abuse and Research Scientist Award DA00079 to P.M.G.

## 162.7

GAP JUNCTION INACTIVATION IN THE STRIATUM PREVENTS ORAL STEREOTYPY INDUCED BY APOMORPHINE A.A. Grace\* and H. Moore. Depts. Neurosci. and Psychiatry, Univ. Pittsburgh, Pittsburgh, PA 15260

In the striatum, electrotonic coupling via gap junctions occurs between medium spiny projection neurons and is modulated by corticostriatal activity and dopamine (DA) receptor activation. In vivo intracellular studies have shown that systemic administration of apomorphine (APO) dramatically increases the extent of electrotonic coupling in the caudate-putamen (Omn & Grace, 1994). In the present study, we examined whether this dramatic increase in gap junction conductance mediates a subset of the effects of APO. To test this, we determined the effects of the gap junction inactivator, carbenoxolone, on APO-induced behaviors. The dose- and time-dependent behavioral responses to APO (0.2-2.0 mg/kg, i.p.) began with hyperlocomotion accompanied by stereotypical sniffing and progressed to spatially-confined stereotypical licking and biting. Carbenoxolone (35.0 mg/kg, i.p.) injected 30 min prior to APO blocked the oral stereotypy without affecting the increase in locomotion or sniffing. Similarly, infusion of carbenoxolone into the ventral caudate blocked oral stereotypy without affecting the locomotion and sniffing produced by systemic APO. These results suggest that the APO-induced increase in electrotonic coupling in the caudate may selectively mediate the oral stereotypy produced by this drug. One interpretation is that gap junctions between striatal medium spiny neurons mediate specific components of motor programs, and that the increase in gap junctions produced by APO may lead to oral stereotypy by allowing these components to be repeatedly initiated independent of stimuli that normally regulate the motor program. By contrast, the increased intensity of locomotion and sniffing is likely a result of DA receptor activation that is not dependent on gap junctions. Supported by USPHS MH 45159 and MH 42217 and an NRSA Fellowship to H.M.

## 162.4

PRESYNAPTIC STRIATAL INHIBITORY ACTION OF GABA. M. Garcia-Munoz\*, P. Patino, S.J. Young, and P.M. Groves. Dept. Psychiatry, Sch. of Medicine, UCSD, La Jolla, CA 92093-0603.

Published evidence supports the presence of presynaptic GABA-B receptors on cortical and dopaminergic axons. Increased stimulation of these receptors appears to attenuate cortical evoked postsynaptic responses and also to decrease the evoked striatal release of glutamate and dopamine. We used an in vivo electrophysiological technique, the measurement of electrical excitability, to examine presynaptic effects of GABA-B receptor activation on corticostriatal and nigrostriatal axons. Antidromic action potentials elicited by striatal stimulation were recorded extracellularly either from a substantia nigra pars compacta neuron or a medial prefrontal cortical cell in different experiments in urethane anesthetized, male Sprague-Dawley rats. Excitability was assessed in terms of the current required to elicit an antidromic response. Drugs in normal saline were delivered (0.3  $\mu$ l over 5 min) to the dorsal striatum via cannulae placed alongside the stimulating electrode. Striatal administration of the GABA-B receptor agonist baclophen (10 $\mu$ M) produced a significant decrease in nigral and cortical excitability relative to pre-drug levels ( $-17.2 \pm 3.5$  %;  $-16.1 \pm 2.1$  %, respectively) which was reversed by subsequent intrastratial infusion of the GABA-B receptor antagonist saclophen (100nM) ( $-1.7 \pm 2.7$  % for nigral and  $-4.1 \pm 0.8$  % for cortical afferents). Prior administration of saclophen (100nM) significantly increased nigral ( $+8.7 \pm 0.5$  %) and cortical ( $+10.8 \pm 0.9$  %) excitability, consistent with a tonic inhibitory action of GABA on these axons, and blocked the ability of baclophen to decrease nigral ( $+3.2 \pm 0.5$  %) and cortical ( $+3.6 \pm 0.8$  %) presynaptic excitability. These results are consistent with previous findings that GABA presynaptically inhibits nigral and cortical transmission. Evidence for a tonic action of GABA mediated by GABA-B heteroreceptors on nigral and cortical striatal afferents suggest that presynaptic interactions are a route through which GABA can influence striatal neurotransmission. This research was supported in part by DA02864 from the National Institute on Drug Abuse and Research Scientist Award DA00079 to P.M.G.

## 162.6

STRITIAL GLUTAMATE ANTAGONISM PRODUCES CONTRALATERAL NEGLECT J.J. Schuller\* and J.F. Marshall. Dept. of Psychobiology, University of California, Irvine, CA 92717

Unilateral ablation of the medial agranular cortex (AGm) in rats produces an initial impairment in behavioral orientation toward contralateral sensory stimuli, followed by recovery to control performance. Following this lesion, regions of the striatum that receive input from AGm show diminished glucose utilization, immediate-early gene expression, and glutamate receptor ligand binding. Because these striatal physiological changes are temporally correlated with the pattern of behavioral impairment and recovery after the AGm lesion, it is hypothesized that the loss of glutamatergic projections from AGm to the striatum may contribute to the subsequent deficit in responding to contralateral sensory stimuli. To test that hypothesis, we administered glutamate receptor antagonists into the left striatum of awake rats and quantified behavioral orientation to contralateral and ipsilateral stimuli of the visual, tactile, and auditory modalities. The AMPA-kainate antagonist DNQX (3.0  $\mu$ g/1  $\mu$ l) and the NMDA antagonist CPP (2.0  $\mu$ g/1  $\mu$ l) both induced a large asymmetry in responses, such that the rats oriented less to contralaterally-presented stimuli than to ipsilaterally-presented stimuli. These effects were significant for all sensory modalities tested. To determine the volume of tissue affected by the DNQX and CPP infusions, the ability of these antagonists to block kainate (10 mg/kg, i.p.)-induced Fos immunoreactivity was measured. DNQX blocked Fos through much of the anterior caudate-putamen, while not affecting cortical Fos. These data support the hypothesis that AGm lesion-induced neglect may be at least partially due to striatal glutamatergic denervation. Funded by NS 22698 and NS 33670.

## 162.8

DEPOLARIZATION ACTIVATED POTASSIUM CURRENTS IN CHOLINERGIC INTERNEURONS OF RAT NEOSTRIATUM. W.-J. Song\* and D.J. Surmeier. Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, TN 38163.

Cholinergic interneurons comprise only 1-2% of the total striatal neuronal population. Because of their scarcity, physiological study of these neurons has been difficult. In those recordings that have been made (e.g. Wilson et al., 1990), interneurons appear to reside at relatively depolarized potentials (ca. -60 mV) for long periods of time. In an attempt to understand the ionic mechanisms underlying this behavior, depolarization activated K<sup>+</sup> currents in acutely isolated cholinergic interneurons were characterized.

Large cholinergic interneurons were readily visualized after dissociation and their identification verified after recording by single cell RT-PCR detection of choline acetyltransferase mRNA. Depolarizing steps to -20 mV evoked outward currents that were dominated by a rapidly inactivating component. Depolarizing pre-pulses inactivated this transient, A-like component of the current, revealing a persistent, delayed rectifier-like current. This separation was confirmed by the observation that the transient component was blocked in a voltage-dependent manner by 4-aminopyridine whereas tetraethylammonium blocked most of the persistent current. While the voltage-dependence of A-current activation ( $V_{1/2} = 5.5$  mV, n=6) was similar to that reported in other neurons, the half inactivation voltage was considerably more depolarized than seen in many other cell types ( $V_{1/2} = -36$  mV, n=5).

Our results show that as a consequence of its inactivation voltage-dependence, the A current in cholinergic interneurons is capable of participating in spike repolarization and the regulation of repetitive activity at relatively depolarized resting potentials.

**SUBSTANCE P MODULATES  $Ca^{2+}$  CURRENTS IN CHOLINERGIC INTERNEURONS OF RAT NEOSTRIATUM.** D.J. Surmeier\*, J. Flores-Hernandez and W.-J. Song. Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, TN, 38163.

Neostriatal medium spiny neurons projecting to the substantia nigra co-release GABA and the neuropeptide substance P (SP). Within the neostriatum, SP released from axon collateral terminals appear to selectively target cholinergic interneurons. The functional consequences of SP on this clinically important set of interneurons are largely undefined, however.

In a variety of other cell types, SP has been shown to modulate voltage-dependent  $Ca^{2+}$  currents. To determine whether similar mechanisms were at work in the striatum, whole cell voltage clamp recordings of acutely-isolated cholinergic interneurons were obtained. Application of nanomolar concentrations of SP reduced peak  $Ca^{2+}$  currents. The  $NK_1$  receptor specific agonist SAR ([SAR<sup>1</sup>,Met(O<sub>2</sub>)<sup>11</sup>]-SP) reproduced the effects of SP with an  $IC_{50}$  of 20 nM, suggesting that  $NK_1$  receptors were responsible for the modulation. The  $NK_1$  antagonist WIN-51,708 also blocked the SP effect. Single cell RT-PCR experiments were performed to confirm  $NK_1$  receptor modulation.

The SP modulation was G protein mediated. Dialysis with GDP- $\beta$ -S blocked development of the modulation. However, unlike the M2 muscarinic modulation of  $Ca^{2+}$  currents, the SP effect was not blocked by exposure to NEM (50  $\mu$ M, 2 min), suggesting that a  $G_i/G_o$  class protein was not involved. In other cell types, SP couples to PLC $\beta$  through a  $G_q$ -class G protein. However, release of  $Ca^{2+}$  from intracellular stores did not appear to be involved as dialysis with 20 mM BAPTA did not block the SP modulation. Activation of protein kinase C also failed to mimic the modulation suggesting that an alternative signaling pathway was involved. This work was supported by USPHS grants NS 26473 and NS 34696.

## 162.11

**SELECTIVE SEQUESTRATION OF EXOGENOUS NEUROTENSIN IN LARGE DIAMETER STRIATAL NEURONS IN THE RAT.** M.A. Chapman\* and D.S. Zahm. Department of Anatomy and Neurobiology, St. Louis University School of Medicine, St. Louis, MO 63104.

Numerous studies have demonstrated that dopamine D-2 antagonists increase the number of neurotensin-immunoreactive (IR) neurons detected in the rat striatum. Increased synthesis, decreased release, and/or decreased degradation of the peptide may contribute to this effect. Another possibility is that striatal cells sequester neurotensin from the extracellular fluid following its release from nearby neurons. In order to test this hypothesis, neurotensin (.32nmol/400nl) was infused directly into the rat striatum and brains were processed for neurotensin-IR using standard immunoperoxidase methods. Although neurotensin-IR was rarely observed in striatal medium spiny neurons, which are evident following administration of dopamine D-2 antagonists, the cell bodies and dendrites of large diameter striatal neurons consistently exhibited neurotensin-IR at 10 minutes, but not 1 hour or 2 hours, post-infusion. These neurons probably correspond to striatal cholinergic cells. It is possible that neurotensin is sequestered in these cells via receptor-mediated endocytosis, as indirect evidence indicates that striatal cholinergic neurons possess neurotensin receptors (Lapchak et al., J. Neurochem. 56: 651-657, 1991). This observation raises questions regarding the possible sequestration of endogenous neurotensin under normal cellular conditions and its subsequent fate. Supported by NS-23805 and NS-07254.

## 162.13

**DISTRIBUTION OF NEUROTENSIN NEURONS AND FIBERS IN THE RAT BASAL GANGLIA FOLLOWING ADMINISTRATION OF d-AMPHETAMINE ALONE OR WITH HALOPERIDOL.** M.A. Welch, Y. Tan, J.S. Brog\* and D.S. Zahm. Department of Anatomy and Neurobiology, St. Louis University School of Medicine, St. Louis, MO, 63104.

Haloperidol (hal), an antagonist with preference for dopamine  $D_{2/2}$  receptors, and amphetamines elicit increases in striatal concentrations of neurotensin (NT), expression of striatal proNT mRNA and numbers of striatal NT immunoreactive (IR) neurons, suggesting that NT expression is suppressed by  $D_{2/2}$  receptor agonists and facilitated by agonists acting at  $D_{1/5}$  receptors. It is possible that striatal NT expression is co-regulated by  $D_{2/2}$  and  $D_{1/5}$  receptors, either co-localized or otherwise interacting. Here, the distributions of striatal NT-IR neurons and fibers, demonstrated with conventional immunoperoxidase methods, were compared following administrations of hal (0.25 mg/kg), d-amphetamine (amph, 4 mg/kg), hal&amph (same doses combined) and vehicle given thrice at 24, 8 and 4 hours before sacrifice. Numbers of NT-IR neurons were recorded in olfactory tubercle, nucleus accumbens core and shell and rostral, dorsomedial, dorsolateral, ventrolateral, central and caudal parts of the caudate-putamen. Patterns of immunostained fibers in the pallidum and substantia nigra were also evaluated. In most districts this sequence was observed: vehicle < amph < hal&amph < hal. The greatest production of NT-IR neurons, however, was in the olfactory tubercle following amph and was antagonized by hal. Amph and hal&amph elicited fiber staining in parts of substantia nigra reticulata and globus pallidus exceeding that seen after hal alone. The data suggest significant amph-hal interactions in the regulation of striatal perikaryal and fiber NT-IR. Supporting  $D_1$  antagonist (SCH-39166) co-administration data are planned, but unavailable at this writing. Support: NS-23805.

## 162.10

**POSTNATAL DEVELOPMENT OF POTASSIUM CURRENTS IN RAT STRIATAL NEURONS.** E.S. Nisenbaum\*. Department of Psychology, University of Connecticut, Storrs, CT 06269.

Adult striatal neurons possess at least three types of depolarization-activated potassium (K) currents. These include 4-aminopyridine (4-AP)-sensitive fast ( $I_{AF}$ ) and slowly ( $I_{AS}$ ) inactivating A-currents and a 4-AP-resistant, persistent K current ( $I_{Kp}$ ). These K currents are responsible for much of the outward rectification in the depolarizing voltage responses of striatal neurons. Indeed, in adult neurons, application of 10 mM 4-AP reveals a transient overshoot and subsequent polarizing sag in the depolarizing voltage transients near spike threshold, which reflects blockade of  $I_{AF}$  and the flow of  $I_{Kp}$ , respectively. A similar transient overshoot and polarizing sag is evident in the responses of neonatal striatal cells, but at more depolarized membrane potentials and in the absence of 4-AP. These results suggest that the voltage-dependence of  $I_{AF}$  and  $I_{Kp}$  may be more depolarized early in development. This hypothesis was tested using whole-cell voltage-clamp recording from acutely isolated striatal neurons at several developmental time points.

The whole-cell K current recorded from striatal cells taken from animals in the first postnatal week (P0-7) was composed of  $I_{AF}$  and  $I_{Kp}$ . Application of 10 mM 4-AP isolated  $I_{Kp}$  and also permitted isolation of  $I_{AF}$  by current subtraction. The voltage-dependence of activation of  $I_{AF}$  in P0-7 cells (half-activation voltage,  $V_h = 16.3$  mV; slope factor,  $V_e = 9.5$  mV) was more depolarized than in adult neurons ( $V_h = 4.1$  mV,  $V_e = 8.9$  mV). Similarly, the voltage-dependence of  $I_{Kp}$  in P0-7 neurons ( $V_h = 10.8$  mV,  $V_e = 11.3$  mV) was considerably more depolarized than in adult neurons ( $V_h = -12.8$  mV,  $V_e = 11.0$  mV). In P8-14 cells, the voltage-dependence of  $I_{Kp}$  ( $V_h = -1.2$  mV,  $V_e = 11.4$  mV) was intermediate to that observed for P1-7 and adult neurons.

These results demonstrate a hyperpolarizing shift in the voltage-dependence of  $I_{AF}$  and  $I_{Kp}$  during development. These data suggest that early in development, the capacity of  $I_{AF}$  to dampen the initial response to strong depolarizations is diminished, revealing a transient overshoot. Likewise, the depolarized shift in  $I_{Kp}$  accounts for the polarizing sag at more depolarized membrane potentials. Support: NS34254

## 162.12

**PRONEUROTENSIN mRNA EXPRESSION DISTINGUISHES SUBSETS OF RAT STRIATAL NEURONS FOLLOWING HALOPERIDOL ADMINISTRATION: TEMPORAL DISSOCIATION AND DESENSITIZATION.** D.S. Zahm\*, E.S. Williams, D. Poulad and J.E. Krause\*. Depts. of Anat. and Neurobiol., St. Louis Univ. & \*Washington Univ. Schs. of Med., St. Louis, MO, 63104 & \*63110.

The hypothesis that neurotensin (NT) acts as a functional antagonist of DA neurotransmission within the ventral mesencephalon and its mesolimbic dopaminergic (DA) projections (C.B. Nemeroff, *Biol. Psychiat.* 15:283-302, 1980) has intrigued basic scientists and clinicians. While it's clear that exogenous NT affects DA transmission, [1] whether endogenous NT does and, if so, [2] the neuroanatomical substrates and mechanisms responsible remain at issue. Here, subsets of striatal neurons that respond to blockade of dopamine receptors with altered expression of proneurotensin mRNA were examined. Injections of haloperidol (hal, 2 mg/kg, s.c.) were given at four or twenty-four hours and both twenty-four and four hours prior to sacrifice (3 rats/group). Hal rats were paired with age- and weight-matched controls injected with equivalent volumes of vehicle. Sections of striatum were processed non-isotopically with a cRNA probe against neurotensin/neuromedin N. As shown previously by others, massive numbers of neurons exhibited hybridization in the dorsolateral caudate at four hours. At twenty-four hours, hybrids were nearly absent dorsolaterally, but were more numerous in the dorsomedial and ventrolateral caudate than in controls. A second injection further enhanced the dorsomedial/ventrolateral response, but failed to elicit substantial numbers of dorsolateral hybrids, as are observed four hours after one injection. This resistance of NT expression to a second injection was selective for the dorsolateral quadrant and may reflect residual blockade by hal or altered DA receptors or second messengers. Support: NIH NS-23805 & 21937.

## 162.14

**MEASUREMENT BY SEMI-QUANTITATIVE RT-PCR OF C-FOS mRNA TRANSCRIPTS INDUCED BY DEXFENFLURAMINE IN RAT STRIATUM.** B. Guibert<sup>1</sup>, C. Jacquot<sup>1</sup>, H. Lebre<sup>2</sup> and A.M. Gardier<sup>1</sup>. <sup>1</sup>Lab. Neuropharmacol. JE MESR 92-372; <sup>2</sup>Lab. Toxicol. C.J.F. INSERM 9301, Fac. Pharmacie, Univ. Paris-Sud, F92296 Chateau-Malabry, FRANCE.

A single dexfenfluramine (d-fen) administration increases the extracellular serotonin (5-HT) levels in various brain regions as measured by *in vivo* microdialysis in rats. This presynaptic effect reflects the drug's ability to enhance central serotonergic transmission by both increasing the release of 5-HT and inhibiting its reuptake from nerve endings. However, little is known about the cascade of molecular events that follows d-fen's activation of postsynaptic receptors. Studies focusing on the expression of immediate early genes (IEGs) in nuclei of postsynaptic neurons might help to identify the selective neuroanatomical loci targeted by the drug. IEGs encode transcription factors that may be involved in the control of genomic events following neuronal stimulation. To better understand the rapid transcriptional activation of IEGs induced by d-fen, we studied the time course of *c-fos* induction by this drug in the caudoputamen (CPu) and whether this *c-fos* induction occurs in a dose-dependent manner. In a first experiment, rats were injected with a single dose of d-fen (10 mg/kg, i.p.) or saline (2 ml/kg). Then, we extracted total RNA from the CPu 0.5, 1, 2 and 6 hr after d-fen injection, converted extracted mRNA to cDNA by reverse-transcription and amplified cDNA by polymerase chain reaction (RT-PCR) for 30 cycles. Each level of *c-fos* mRNA is expressed as percentage of  $\beta$  actin mRNA expression. The time course study of *c-fos* mRNA induction demonstrated that d-fen induced a transient increase in *c-fos* mRNA that reached its maximum at 0.5-1 hr after d-fen injection and had returned to control levels after 6 hrs. In a second experiment, rats received a range of d-fen doses (0, 5, 10, 20, 40 mg/kg, i.p.) and RT-PCR analysis was performed on RNA isolated from the CPu 1 hour after the single drug injection. mRNA expression of *c-fos* and  $\beta$  actin was quantified by using successive fractions of cDNA. A dose-related *c-fos* gene expression induced by d-fen was observed in the CPu. These results confirm our previous immunohistochemical findings showing a dose-related increase in Fos protein levels in rat CPu 2 hrs after a single d-fen administration.

Epibatidine induces c-fos expression selectively in the limbic striatum. M. Cola and A. Jayaraman\*, Dept. of Neurology, LSU Sch. of Med. New Orleans, LA 70112.

Epibatidine is a powerful antinociceptive agent that mediates its analgesic properties through nicotinic acetylcholinergic receptors. Epibatidine is also a potent releaser of dopamine in striatal slices. To study the interactions between epibatidine and dopamine, we have studied the pattern of expression of Fos in the mesolimbic and mesostriatal systems. Acute injections of epibatidine resulted in the expression of Fos-like immunoreactivity in the nucleus accumbens and medial caudate nucleus and the prefrontal cortex. In the midbrain neurons with Fos-Li were noted in the medial and the lateral terminal nuclei of the accessory optic system, the superficial layers of the superior colliculus and the interpeduncular nucleus. Only very few neurons of the nucleus parabrachialis pigmentosus and caudal linear subdivisions of the ventral tegmental dopamine neurons were labeled with Fos-Li. Fos reactive cells were conspicuously absent in substantia nigra pars compacta. The pattern of expression of Fos-Li in the midbrain and the striatum shows significant similarities to the pattern of Fos-Li induced by acute injections of nicotine. Supported by the Dept. of Defense.

SUPPRESSION OF AMPHETAMINE-INDUCED c-fos AND ngfi-a EXPRESSION IN THE STRIATUM USING END-CAPPED ANTISENSE OLIGONUCLEOTIDES: FUNCTIONAL AND BEHAVIORAL ANALYSES M.O. Hebb\*, M. Hong and H.A. Robertson, Lab. Mol. Neurobiol., Dept. of Pharmacology, Dalhousie University, Halifax, N.S., Canada B3H 4H7.

We have studied the intrastriatal application of phosphothioate end-capped antisense oligonucleotides directed at c-fos or ngfi-a mRNA transcripts to determine if sulfur substitution solely at terminal nucleotides will be sufficient to produce nuclease-resistant oligonucleotides. Additionally, we wish to know if these antisense oligodeoxynucleotides are effective at both knocking down expression of the targeted protein and minimising toxicity. The end-capped oligonucleotides directed at c-fos and ngfi-a used in the present study were effective at reducing the expression of their targeted proteins for a maximal period of between 2-4 hours following infusion. Immunohistochemistry showed that while antisense oligonucleotides directed at c-fos mRNA had no effect on amphetamine-induced ngfi-a expression, those directed at ngfi-a transcripts reduced both the targeted protein as well as c-fos expression. Also, both oligonucleotides produced negligible toxicity. Unilateral administration of either antisense oligodeoxynucleotide produced an ipsiversive rotational bias when the animals were challenged with D-amphetamine. Infusions of random oligodeoxynucleotides or vehicle produced no decrease in c-fos or ngfi-a expression nor a significant rotational bias following amphetamine injection. These results suggest that while end-capped oligonucleotides may be degraded relatively rapidly, they are effective in suppressing expression of specific proteins for short time periods (2-4 hours). Also, the previously reported correlation between Fos protein knockdown and rotational bias is further supported and a possible link between ngfi-a and c-fos expression is suggested. [Supported by the MRC, SmithKline Beecham, and the Huntington Society of Canada.]

## 162.19

THE EFFECT OF CHRONIC HALOPERIDOL TREATMENT ON DENDRITIC SPINES IN THE RAT STRIATUM. J.J. Kelley, X.M. Gao, C.A. Tamminga, and R.C. Roberts\*, Maryland Psychiatric Research Center, Department of Psychiatry, University of Maryland School of Medicine, Baltimore, MD 21228.

Previous ultrastructural studies have shown that schizophrenics in comparison to controls have reduced spine density in the cortex and smaller spine size in the striatum. The current study in rat was conducted to determine whether such differences could result from neuroleptic treatment and whether they correlated with oral dyskinesias. Sprague-Dawley rats were administered 1.5 mg/kg/day of haloperidol (HA) (n=28) or water (n=10) for 6 months and tested for vacuuous chewing movements (VCMs). After 6 months, rats were divided into low (<10VCMs/5min, n=15) and high (>10VCMs/5min, n=13) VCM groups; all but 7 high VCM rats (withdrawn group) were sacrificed. These rats were withdrawn from HA for 4 weeks before sacrificing. Random electron micrographs of the striatum were analyzed for spine changes. Criteria for spine identification consisted of a dendritic protrusion or a solitary spine receiving a synapse. Spine size was not significantly effected by HA (0.193 vs 0.174 (control) nor correlated with oral dyskinesias (0.191 vs 0.196, low and high VCM groups). These results suggest that the difference in spine size seen in schizophrenic striatum may be correlated with the disease rather than caused by neuroleptic treatment. Spine density decreased in the HA treated group (32.7 ± 9.5) in comparison to controls (53.7 ± 7.3, p < .001) and remained low in the withdrawn group (35.0 ± 4.2, p < .04). Spine density decreased in both the low (37.3 ± 9.9, p < .01) and the high (28.0 ± 7.0, p < .000) VCM rats in comparison to controls; however there was no significant difference between high and low VCM rats. The observed decrease in spine density within the striatum of chronic HA treated rats suggests a drug effect; this may be correlated with the decreased synaptic density that we have previously observed. The results suggest that decreased spine density observed in schizophrenics may be a result of chronic neuroleptics. Supported by the Stanley Foundation.

## 162.16

COMPARISON OF NEURONAL GENE INDUCTION BY DIFFERENT DRUGS OF ADDICTION USING IMMUNOCYTOCHEMISTRY AND TWO-DIMENSIONAL PROTEIN ELECTROPHORESIS.

M.W. Soong, B. Bontempi, K. Baner, S. Massa, S. Sagar\* and F. Sharp, Dept. of Neurology, Veterans Administration Medical Center and University of California, San Francisco 94121.

Induction of immediate early genes has been shown to play an important role in the activation of neuronal pathways associated with addiction. Little is known about the genes targeted by the activation of these transcription factors and how they may differ between various drugs. The induction of c-fos in the rat striatum was studied immunocytochemically following systemic administration of morphine, cocaine, nicotine, and the caffeine analogue IBMX. While induction of Fos was common to morphine, cocaine and IBMX, each had its own specific regional pattern. Morphine induced Fos primarily in the dorsomedial striatum, while IBMX induced Fos mainly in the lateral striatum. Cocaine induced Fos over the entire striatum. Also, while nicotine has been shown to induce Fos expression in other brain regions, we were unable to demonstrate any such activity in the striatum. The implications of these different patterns of IEG induction were analysed by large format two-dimensional electrophoresis of proteins from primary cultured neurons treated with addictive drugs. The time course of gene induction in cerebellar granule neurons revealed a very similar pattern of IEG induction after short treatments, but vastly different patterns of protein expression after longer treatments with these drugs. These in vivo and in vitro models of the neuronal plasticity associated with adaptation to addictive drugs will help delineate the course of molecular events which underlie the transition from acute to chronic effects of these substances.

Supported by grants from the NIH and the VA.

INTRASTRIATAL CHOLINERGIC RECEPTORS MEDIATE AMPHETAMINE-INDUCED BEHAVIOR AND NEUROPEPTIDE GENE EXPRESSION. J. E. McGinty\* and J. Q. Wang, Dept. Anatomy & Cell Biology, East Carolina Univ. School of Medicine, Greenville, NC 27858-4354.

Systemic administration of the muscarinic receptor antagonist, scopolamine, augments, whereas the muscarinic receptor agonist, oxotremorine attenuates, stereotypical behaviors and striatonigral gene expression induced by amphetamine. In contrast, scopolamine blocks, and oxotremorine augments, amphetamine-induced preproenkephalin (PPE) mRNA induction in striatopallidal neurons (Wang & McGinty in press). We investigated the site of action of these effects by administering scopolamine and oxotremorine directly into the striatum. Three h. after a systemic saline or amphetamine (2.5 mg/kg, i.p.) injection, the rats were euthanized and the brains processed for quantitative in situ hybridization. Unilateral intrastriatal scopolamine augmented, whereas oxotremorine attenuated, amphetamine-induced behaviors. Intrastriatal infusion of 75, but not 7.5, mM scopolamine increased basal substance P (SP) and preprodynorphin (PPD) mRNA in the dorsal striatum. In addition, both 7.5 and 75 mM scopolamine significantly augmented amphetamine-induced SP and PPD mRNA levels. Intrastriatal infusion of 3 and 15 mM oxotremorine did not alter basal levels but both doses completely blocked amphetamine-induced SP and PPD mRNA. In contrast, a small but significant increase in PPE induced by amphetamine was completely blocked by 75, but not 7.5, mM scopolamine whereas both doses of oxotremorine slightly, but non-significantly, augmented basal and amphetamine-stimulated PPE mRNA levels in the dorsal striatum. These data indicate that cholinergic interneurons in the dorsal striatum exert a potent influence on amphetamine-induced stereotypies and striatal neuropeptide gene expression. Supported by DA03982.

## 163.1

**Regulation of dopamine fibre ingrowth into the striatum by metabotropic glutamate receptors.** B. Teng\*, D. Plenz and S.T. Kitai. Department of Anatomy and Neurobiology, University of Tennessee, College of Medicine, Memphis, TN 38163.

Glutamatergic inputs from the cortex and dopaminergic inputs from the substantia nigra converge in the striatum. We therefore studied the interaction of these two pathways during development using a triple culture preparation.

Cortical, striatal and nigral slices from rats at postnatal day 0 - 1 were cultured for 16 days *in vitro* (DIV) using a modified roller-tube technique. After 8 DIV glutamate receptor antagonists and/or agonist were added to the culture medium for 8 days, after which the cultures were fixed and processed for tyrosine hydroxylase (TH) immunoreactivity. The TH-fibre density was analyzed using confocal microscopy and correlated with total number of TH-positive neurons present in the nigral tissue.

The metabotropic glutamate receptor antagonist L-AP3 (100  $\mu$ M) decreased TH-fibre density by 70%, whereas the blockade of non-NMDA and NMDA neuronal transmission using 50  $\mu$ M DNQX and 50  $\mu$ M APV had no effect on striatal TH-fibre density, the morphology and numbers of TH-positive neurons. Furthermore, the addition of the metabotropic agonist 1S,3R-ACPD (100  $\mu$ M) increased the TH-fibre density in the striatum by 180% without affecting the total number of neurons in the mesencephalic tissue. This increase in TH-fibre density was antagonized by L-AP3.

These results indicate that metabotropic glutamate receptors activation increases the density of TH-positive fibres in the striatum during development. We propose that glutamatergic transmission in the striatum can regulate the development of the nigro-striatal pathway.

## 163.3

**NMDA RECEPTOR DEVELOPMENT IN NEOSTRIATUM: II. WHOLE-CELL VOLTAGE CLAMP ANALYSIS OF CURRENTS IN VISUALLY IDENTIFIED CELLS.** C. Cepeda\*, L. Shumate, C.S. Colwell, M.S. Levine. Mental Retardation Research Center, University of California, Los Angeles, CA 90024.

These experiments were designed to examine the development of NMDA-induced membrane currents and compare their maturation with that of currents induced by application of kainate (KA) in neostriatal (NS) cells. Whole-cell patch clamp recordings were obtained from visually identified NS neurons using infrared differential interference contrast videomicroscopy. Data were obtained from slices from rat pups of 4-18 postnatal days (PNDs). Induced currents were analyzed using two paradigms. In the first, NMDA and KA were applied iontophoretically 15-30  $\mu$ m from the recorded cell and inward currents were examined in standard artificial cerebrospinal fluid. In the second, NMDA or KA were bath-applied (10-30  $\mu$ M concentrations) and changes in currents induced by ramp voltage commands were analyzed also in standard artificial cerebrospinal fluid. At PNDs 4-7, NMDA-induced currents were small regardless of holding potential whereas KA-induced currents were typically larger. By PNDs 12-14, NMDA currents increased considerably. KA-induced currents also displayed further increases in amplitude over the first two postnatal weeks of age. At all ages examined, NMDA-induced currents were always smaller than KA-induced currents. The present findings indicate that NMDA- and KA-induced currents in NS neurons develop over the first two postnatal weeks in the rat.

Supported by USPHS Grant HD 05958.

## 163.5

**MODULATION OF NMDA-INDUCED CURRENTS BY METABOTROPIC GLUTAMATE RECEPTORS IN VISUALLY IDENTIFIED NEOSTRIATAL NEURONS.** C.S. Colwell\*, C. Cepeda, M.S. Levine. Mental Retardation Research Center, University of California, Los Angeles, CA 90024.

Previous data indicate that activation of metabotropic glutamate receptors (mGluRs) selectively inhibits NMDA-evoked responses in neostriatal (NS) slices. The present study was designed to examine mechanisms underlying this regulation. Whole cell patch clamp recordings were obtained from NS neurons visualized in slices using infrared differential interference contrast video microscopy. Iontophoretic application of NMDA and Kainate (KA) induced currents which were blocked by their appropriate antagonists AP5 and CNQX, respectively. NMDA currents were voltage-dependent and were enhanced in low magnesium. Bath or iontophoretic application of the mGluR agonist tACPD inhibited NMDA-induced currents but produced variable effects on KA-induced currents. mGluR inhibition of NMDA currents occurred at membrane potentials ranging between -70 and -40 mV and appeared to be mediated by regulation of voltage-sensitive calcium channels (VSCC). Inhibitory effects of tACPD were prevented by application of cadmium (50  $\mu$ M), a blocker of VSCCs. Furthermore, the addition of fluoride (125mM) into the internal solution of the electrode also prevented the tACPD-induced inhibition. Among other actions, fluoride blocks VSCCs. Together, these findings indicate that mGluRs postsynaptically regulate NS NMDA-induced currents via mechanisms involving calcium conductances.

## 163.2

**ROLE OF NMDA RECEPTORS OF THE STRIATUM IN THE INITIATION AND MAINTENANCE OF APPETITIVE ACTIONS.** M. Pisa\* and S. Shangardass. Dept. Biomed. Sci., McMaster Univ., Hamilton, Ont., Canada, L8N 3Z5.

In support of the hypothesis that NMDA receptors of the rat's dorsal striatum are involved in a response-selection mechanism, we previously reported that injections of the NMDA receptor blocker CPP into the lateral, "sensorimotor" subregion of the striatum increased a *consummatory*-type of oral movement, i.e. chewing *in vacuo*, while decreasing body grooming, a behavior that involves *appetitive*, i.e. reaching, movements of the mouth. Here, we extended these observations to examining the effects of CPP injections into the lateral striatum on appetitive movements required to feed on relatively large (2x3 cm) Purina Chow food pellets. Food-restricted rats with chronic intracerebral guide cannulae were examined for food consumption and feeding movements after injections of either vehicle or CPP (either 0.08 or 0.4 or 2 nmole in 0.2  $\mu$ l) into the lateral striatum, with dose as between-factor, N=8. Compared with vehicle, the effects of CPP were as follows: 1) food consumption significantly changed with increasing dose, with virtually no change at the 0.08 nmole dose and a decrease to 44% and 7% of control with 0.4 nmole and 2 nmole, respectively; 2) the 0.4 nmole dose increased the latencies to first contact with food and to first food bite, and also increased the duration of the intervals spent not eating between food-chewing bouts; 3) the 2 nmole dose virtually blocked the initiation of any feeding movements, including pellet picking, holding and biting, even though the number of snout approaches to the food pellets increased 4.5 times over baseline. The results indicate that activation of NMDA receptors of the lateral striatum is crucial for the initiation and maintenance of appetitive, contact-manipulatory actions, although not of actions reflecting motivational sensitivity (e.g. snout approach to food). Together with our previous results, they further support the hypothesis of a NMDA-receptor mediated mechanism in the striatum that controls the switching between appetitive and consummatory motor components of goal oriented actions. (Supported by NSERC).

## 163.4

**NMDA RECEPTOR DEVELOPMENT IN NEOSTRIATUM: I. CELL SWELLING AND RECEPTOR BINDING.** M.S. Levine\*, C.S. Colwell, C.A. Crawford, C. Cepeda. Mental Retardation Research Center, University of California, Los Angeles, CA 90024.

NMDA receptors serve many crucial functions in the maturing nervous system. The present studies were designed to examine functional development of NMDA receptors in the rat neostriatum (NS) using two experimental approaches. In the first approach, infrared differential interference contrast video microscopy was used to measure the development of cell swelling induced by NMDA and kainate (KA). This technique permits viewing live cells in brain slices without using dyes or stains. Swelling of single cells was assessed in response to bath application of NMDA or KA (1-1000  $\mu$ M). At postnatal day (PND) 3, there was no measurable response to NMDA while cells swelled in response to KA. By PND 7, NMDA caused swelling although responses were smaller than those found in older tissue. By PNDs 14-28, NMDA and KA produced concentration-dependent swelling which did not vary further with age. These results form the basis of a developmental time-course and suggest that NMDA receptor function develops later than KA receptor function in the NS.

The second approach examined the possibility that the developmental changes in NMDA responses may be due to age-related variation in receptor number. [<sup>3</sup>H] MK-801 was used in receptor binding assays with homogenates of NS tissue. The number of binding sites was significantly lower at PNDs 3-14 than at later ages. The affinity of the receptor for the ligand did not change over the age period examined. Thus, variation in receptor binding can only partially account for developmental changes in NMDA receptor function.

**EFFECTS OF NMDA RECEPTOR BLOCKADE ON DEVELOPMENT OF RAT CORTICOSTRIATAL SYNAPTIC INPUT** N.A. Sharpe\*, and J.M. Tepper. Aidekman Research Center, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ USA 07102.

Glutamate containing corticostriatal afferents form asymmetric synapses onto spine heads of medium spiny neurons. These synapses develop primarily during the 3rd postnatal week. Glutamate, and NMDA receptors, have been suggested to play a role in this development. To evaluate the role of NMDA receptors, MK-801 was administered once daily (0.25 mg/kg, i.p.) from P15 to P21. On P22, biocytin was iontophoretically injected into the frontal cortex. Rats were sacrificed 4-6 hours later and the striatum prepared for biocytin visualization and sequential light and electron microscopy.

Light microscopy revealed that the striatum of MK-801-treated rats appeared similar to controls based on the level of myelination. Biocytin labeled corticostriatal afferents were found to terminate almost exclusively on dendritic spines, as in control rats. No difference was noted in the distribution of asymmetric synapses with 87% of asymmetric synapses in MK-801 rats being axospinous compared to 83% in controls. In several cases, however, asymmetric synapses terminated on spine shafts near the base of the spine, which appeared unusually large. This type of synaptic contact was not seen in control rats. The mean number of vesicles per synapse, and mean active zone length for asymmetric axospinous synapses were similar for both MK-801 (33.1  $\pm$  5.1 ves/syn, 256  $\pm$  14 nm, respectively) and control (31.5  $\pm$  3.3 ves/syn, 256  $\pm$  18 nm, respectively) rats.

These data indicate that chronic blockade of NMDA synaptic input during the 3rd postnatal week had a minimal effect on corticostriatal asymmetric synapses. This may be because NMDA receptors have a minimal role in the development of corticostriatal synapses or because the NMDA blockade may need to be maintained longer or begun earlier in development. The latter appears more likely since following MK-801 treatment corticostriatal afferents are found to terminate more often at the base of large spines. This type of re-organization could give individual excitatory inputs a larger influence on the electrophysiological status of the spiny neuron. Additional MK-801 studies of longer duration are needed to conclusively determine the role of the NMDA receptor in corticostriatal synapse development. Supported by NS 30679.

## 163.7

## FLUOXETINE AND DOI REDUCE MRNA LEVELS OF NEUROPEPTIDES AND GLUTAMIC ACID DECARBOXYLASE IN THE STRIATUM OF THE RAT.

M.J. Mijster, T. van Haften\* and P. Voorn

Research Institute Neurosciences, Department of Anatomy, Vrije Universiteit, Amsterdam, the Netherlands.

In order to investigate serotonergic effects on striatal gene regulation, the serotonin reuptake blocker Fluoxetine (FLU, 10 mg/kg) and the serotonin 5-HT<sub>2</sub> agonist DOI (7 mg/kg) were administered daily i.p. for 5 and 9 days respectively. Quantitative *in situ* hybridization was used in the caudate-putamen to study changes in mRNA levels of preproenkephalin (ppEnk), preprodynorphin (ppDyn), preprotachykinin (ppT) and glutamic acid decarboxylases (GAD) 65 and 67. The indirect agonist FLU was found to reduce ppEnk mRNA levels with 14% over the entire rostro-caudal extent of the caudate-putamen, whereas DOI had no effect. Both the direct and the indirect agonist tended to reduce ppDyn (-16% and -6% respectively) and GAD 65 mRNA. In contrast, ppT and GAD 67 mRNA levels were not altered after FLU and only slightly increased after DOI administration. The preferential regulation of GAD 65 mRNA was unexpected in view that GAD67 and not GAD65 is thought to be regulated at the transcriptional level. Considering that two different striatal output-pathways exist, one marked by ppDyn/ppT/GAD65 and 67 and the other containing ppEnk/GAD65 and 67, we conclude that the activity in both output-pathways of the striatum appears to be inhibited by the indirect serotonin agonist FLU and that the serotonin 5-HT<sub>2</sub> agonist DOI reduces activity in the direct route. However, since GAD65 is produced in both routes, it cannot be excluded that DOI administration also affects the indirect route.

## 163.9

## SEROTONIN DEPLETION EXACERBATES STRIATAL GENE EXPRESSION CHANGES DURING THE NMDA RECEPTOR-MEDIATED EXCITOTOXIC CASCADE. T.J. Cummings\* &amp; P.D. Walker, Depts of Anatomy &amp; Cell Biology, Psychiatry &amp; Behavioral Neurosciences (Cellular &amp; Clinical Neurobiology Program), and Neurosurgery, Wayne State Univ. School of Medicine, Detroit, MI 48201.

Controversy exists as to whether serotonin (5-HT) plays a neuroprotective role when the brain is subjected to excitotoxic damage. We sought to test the hypothesis that neuronal loss in the striatum would be greater in the serotonin-depleted rat following induction of the excitotoxic cascade. Adult male SD rats (175-200g) received intraperitoneal injection of saline or p-chlorophenylalanine (pCPA, 300mg/kg) to block 5-HT synthesis. After 3 days, these rats received intrastriatal injection of saline or quinolinic acid (QA, 40µg in 1µl saline). All rats were sacrificed 6 or 48 hours later. Striatal tissue containing the saline or QA injection site was subjected to Northern mRNA analysis and HPLC-EC detection of monoamines. Contralateral uninjected striata served as intra-animal control tissue. Within all pCPA/saline or pCPA/QA groups, 5-HT levels were depleted greater than 90% as compared to saline/saline controls. At 48 hours post-QA injection, preproenkephalin (PPE) and preprotachykinin (PPT) mRNAs were markedly reduced within the striatal lesion site of saline/QA and pCPA/QA groups. In the pCPA/QA group, striatal PPE and PPT mRNA levels were further reduced as compared to the saline/QA group with PPE mRNAs reaching statistical significance at 95% (ANOVA with Fisher PLSD). Exacerbation of the excitotoxic lesion in the 5-HT-depleted rat was further exemplified by observations of a larger, prolonged zif/268 transcriptional response at 6 hours in the pCPA/QA compared to saline/QA groups. These results suggest that 5-HT depletion may adversely affect neuronal survival following intrastriatal excitotoxic damage. Supported by NIH NS 30550.

## 163.11

## NMDA AND AMPA GLUTAMATE RECEPTORS IN STRIATAL IMMEDIATE EARLY GENE INDUCTION BY DOPAMINE D2 RECEPTOR BLOCKADE. J.D. Wagstaff\* and C.R. Gerfen, Lab of Neurophysiology, NIMH, Bethesda, MD 20892.

In the striatum, removal of the tonic inhibitory influence of dopamine by blockade of D2 receptors results in the induction of immediate early genes in striatopallidal neurons. One possible mechanism responsible for such activation involves the unmasking of underlying glutamatergic excitatory input to these neurons. To examine this we used quantitative *in situ* hybridization histochemical localization of the mRNAs encoding the immediate early genes (IEGs) *c-fos* and *zif268* to mark changes in the function of striatopallidal neurons in response to D2 receptor blockade in the presence of NMDA or AMPA glutamate receptor antagonists. NBQX (20, 40 or 60 mg/kg) or MK 801 (1.0 mg/kg) was administered 15 minutes prior to treatment with the D2 antagonist eticlopride (1.0 mg/kg). Neither NMDA or AMPA antagonists alone affected the basal levels of immediate early gene expression in striatopallidal neurons. When combined with D2 receptor antagonist treatment (eticlopride, 1.0 mg/kg) the NMDA antagonist MK801 was without effect on the D2 antagonist induction of *c-fos* or *zif268*, whereas the AMPA antagonist NBQX resulted in a potentiation of this response. These results suggest that systemic administration of AMPA and NMDA antagonists do not significantly reduce the induction of immediate early genes in the striatum following D2 dopamine receptor blockade. Moreover, these data suggest that blockade of AMPA receptors reduces the activity of local inhibitory circuits resulting in further disinhibition of D2 expressing striatopallidal neurons. (supported by NIMH)

## 163.8

## REGULATION OF STRIATAL PREPROENKEPHALIN AND PREPROTACHYKININ mRNAs FOLLOWING SEROTONIN STIMULATION. J.M. Sall\*, T.J. Cummings &amp; P.D. Walker, Depts of Anatomy &amp; Cell Biology, Psychiatry &amp; Behavioral Neurosciences (Cellular &amp; Clinical Neurobiology Program), and Neurosurgery, Wayne State University School of Medicine, Detroit, MI 48201

Serotonin neurotransmission is hypothesized to provide a positive regulation of striatal tachykinin and enkephalin biosynthesis. In this study, we determined the effects of 5-HT<sub>2</sub> receptor stimulation on preproenkephalin (PPE) and preprotachykinin (PPT) mRNA levels within the rodent striatum. Adult male SD rats (175-200g) received single intraperitoneal injections of saline or the 5-HT<sub>2</sub> agonist RU24969 (5 mg/kg) followed by sacrifice 4 hours later. HPLC analysis with electrochemical detection revealed significant increases in tissue serotonin (5-HT) content accompanied by decreased levels of 5-hydroxyindoleacetic acid (5-HIAA) within the striatum as well as tissues containing the substantia nigra and midbrain raphe. The ratio of 5-HT to 5-HIAA was also significantly heightened in these tissues indicating that RU24969 causes increased storage of 5-HT in raphe neurons and terminal fields. Northern analysis revealed significant increases (>200%,  $p < 0.003$ ) in striatal PPE mRNA levels in the RU24969 group as compared to saline-injected controls. Striatal PPT mRNA amounts were only mildly raised in the RU24969 group. These results indicate that striatal enkephalinergic neurons may be more sensitive to 5-HT<sub>2</sub> receptor stimulation with RU24969 as compared to striatal tachykinin neurons. Additional *in situ* hybridization experiments will examine whether mRNA expression in specific striatal subregions is differentially sensitive to 5-HT<sub>2</sub> stimulation. Supported by NIH NS30550.

## 163.10

## REGULATION OF BASAL GANGLIA NEUROPEPTIDE mRNAs BY SEROTONIN: ROLE OF SEROTONIN-2 RECEPTOR. P.J. Gresch\*, T.J. Cummings, J.M. Sall &amp; P.D. Walker, Departments of Psychiatry &amp; Behavioral Neuroscience (Cellular and Clinical Neurobiology Program), Neurosurgery, and Anatomy &amp; Cell Biology, Wayne State University School of Medicine, Detroit, MI 48201

Decreased serotonin (5-HT) neurotransmission lowers preprotachykinin (PPT) and preproenkephalin (PPE) mRNA levels in the rat striatum (STR). In this study, we examined the effects of 5-HT<sub>2</sub> receptor stimulation on PPT and PPE mRNA levels in striatal subregions from control or 5,7-dihydroxytryptamine (5,7-DHT) lesioned rats. Adult male SD rats received 20µl icv injections of 5,7-DHT (10µg/µl) or vehicle (0.1% ascorbic acid). After 21 days, saline or the 5-HT<sub>2</sub> receptor agonist, DOI (1 mg/kg), was administered i.p. q.d. for 7 days. Whole STR or ventromedial (VM), ventrolateral (VL), and posterior (P) STR subregions were assayed for monoamines and metabolite levels by HPLC-EC and mRNA levels by Northern analysis. Striatal 5-HT levels were reduced >90% by 5,7-DHT as compared to controls. Striatal 5-HT levels were unchanged by DOI. Whole STR PPT and PPE mRNA levels were decreased in 5,7-DHT lesioned rats. DOI increased PPT and PPE mRNA levels to control levels in 5,7-DHT lesioned rats.

	5,7-DHT		DOI		5,7-DHT/DOI	
	PPT mRNA	PPE mRNA	PPT mRNA	PPE mRNA	PPT mRNA	PPE mRNA
VM-STR	118	105	162	137	133	106
VL-STR	48	37	89	72	83	76
P-STR	51*	38	156*	165*	132†	133

Expressed as % of veh/sal (n=3-5; \* $p < 0.05$  of veh/sal; † $p < 0.05$  of 5,7-DHT/sal). These results suggest that 5-HT<sub>2</sub> receptor stimulation reverses the reduction in striatal PPT and PPE mRNA expression in 5-HT-depleted animals. Supported by NIH NS 30550.

## 163.12

## DELTA AND MU OPIOID RECEPTOR REGULATION OF IMMEDIATE-EARLY GENE EXPRESSION IN STRIATOPALLIDAL NEURONS. H. Steiner\* and C.R. Gerfen, Dept. of Anatomy and Neurobiology, Univ. of Tennessee, College of Medicine, Memphis, TN 38163, and Laboratory of Neurophysiology, NIMH, Bethesda, MD 20892.

We have shown that, in the striatum, dynorphin, an endogenous kappa opioid receptor ligand, regulates D1 dopamine receptor responses in striatonigral neurons. Striatopallidal neurons contain D2 dopamine receptors and the opioid peptide enkephalin, an endogenous ligand of delta and mu opioid receptors. In the present study, we investigated effects of enkephalin receptor activation on striatopallidal neurons, using D2 receptor-mediated immediate-early gene (IEG) induction as a functional marker. Expression of IEGs (*c-fos*, *zif 268*) was measured with *in situ* hybridization histochemistry. Intrastriatal infusion of the delta receptor-preferring agonist DADLE blocked IEG induction by the D2 antagonist eticlopride and induced contravertive turning in a dose-dependent manner. Both DADLE-induced blockade of IEG induction and turning were inhibited by systemic and intrastriatal administration of the nonselective opioid receptor antagonist naloxone. Blockade of IEG induction was also produced by intrastriatal infusion of the more selective delta agonist deltorphin, or by the mu agonist DAMGO, but not by the kappa agonist U-50488. However, in contrast to delta agonist-induced turning, mu agonist-induced turning was inhibited by the D2 antagonist. These results show that, in the striatum, both enkephalin receptors (mu and delta), but not the dynorphin receptor (kappa), inhibit IEG expression in striatopallidal neurons. The different effects of the D2 antagonist on mu and delta agonist-induced turning indicate that other striatal functions are differentially affected by these two receptors. (Supported by NIMH/DIRP and USPHS Grants NS26473 and NS20702).

## 163.13

EFFECTS OF DIFFERENT CLASSES OF NMDA RECEPTOR ANTAGONISTS ON D1 DOPAMINE RECEPTOR-MEDIATED CHANGES IN STRIATAL NEURON FUNCTION. K.A. Keefe\* and A. Ganguly. Dept. of Pharmacology & Toxicology, Univ. of Utah, Salt Lake City, UT 84112.

Previous work has shown that intrastratial administration of the non-competitive NMDA receptor antagonist MK-801 potentiates immediate early gene expression in lateral striatum induced by D1 dopamine receptor stimulation, whereas the competitive antagonists CPP and APV do not. We therefore hypothesized that NMDA receptor antagonists interacting preferentially with different NMDA receptor subtypes exert different effects on striatal function. To test this hypothesis, we are examining the effects of different classes of NMDA receptor antagonists on immediate early gene expression induced by stimulation of D1 dopamine receptors. In intact rats, systemic administration of CPP (0.1-10 mg/kg, i.p.) attenuated *zif268* induction by the D1 dopamine receptor agonist SKF 82958, although this effect was not dose-dependent, and CPP alone at the highest dose attenuated basal *zif268* expression. Like CPP, the polyamine-site antagonist ifenprodil (5 mg/kg, i.p.) also attenuated basal *zif268* expression. However, ifenprodil (0.05-5 mg/kg, i.p.) potentiated *zif268* induction by SKF 82958. Like ifenprodil, MK-801 potentiated the effects of SKF 82958 at lower doses (0.01-0.1 mg/kg, i.p.). At higher doses (1-5 mg/kg, i.p.), however, regional differences in the effects of MK-801 were observed. *Zif268* expression in medial striatum was attenuated relative to that seen with SKF 82958 alone, whereas it was maintained in lateral striatum. These findings provide further evidence that different classes of NMDA receptor antagonists interact differently with D1 dopamine receptor-mediated processes in striatum. (Supported by University of Utah Health Sciences Center and College of Pharmacy)

## 163.15

CIRCUIT-LEVEL CHANGES IN bZip GENE EXPRESSION INDUCED IN THE STRIATUM DURING CHRONIC COCAINE TREATMENT AND WITHDRAWAL. R. Moratalla\*, B. Elibol, M. Vallejo\* and A.M. Graybiel. Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139; \*Reproductive Endocrine Unit, MGH, Harvard Medical School, Boston MA 02114

Repeated exposure to psychostimulants induces long-term changes in behavior characterized by addiction and sensitization. The neural mechanisms responsible for these long-term changes are not well understood, but pre- and postsynaptic changes in mesostriatal dopamine systems have been implicated. To examine the striatal changes, we administered cocaine to rats in a paradigm that produces behavioral sensitization and studied the changes in inducibility of Fos-, JunB- and Fra-like proteins in the striatum of rats treated with cocaine 25 mg/kg i.p., b.i.d. for 7 days and challenged with cocaine after 18 hrs or 3, 7 or 14 days of withdrawal. To detect changes during the chronic treatment, other rats were challenged after 4 days. After a week of chronic cocaine treatment, the numbers of neurons that expressed Fos 2 hr after cocaine challenge decreased 90% after 7 days, whereas JunB expression was reduced by half and Fra expression remained the same. Levels gradually returned to control values during withdrawal. A cluster of 35-37 kDa Fras with extended half-lives was detectable without challenge for up to 7 days of withdrawal by Western blot analysis. As we have previously shown, acute cocaine induced Fos/JunB proteins in both striosome and matrix compartments of the striatum. However, after the chronic cocaine treatment, the anatomical distributions of induced Fos/JunB expression shifted towards striosomal predominance in the anterolateral striatum. The pattern change was evident during the chronic treatment (day 5), persisted throughout the 2-week withdrawal period, and was observed for Fos and JunB as well as for persistently expressed Fras. This system-level change thus had a time course paralleling behavioral sensitization. Supported by NIDA 5R01 DA08037.

## 163.17

DEVELOPMENTAL CHANGES IN BASAL GANGLIA RESPONSIVENESS TO AMPHETAMINE AND COCAINE. E. Fusco\* and A.M. Graybiel. Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139

The induction of immediate-early genes (IEGs) provides a sensitive cellular assay to test functional responsiveness of neurons to stimulation. We have used an immunohistochemical IEG expression assay to test, in the rat, the functional maturation of striatal responsiveness to dopaminergic stimulation. We used polyclonal antisera against FOS, FRA and NGFI-A.

Cocaine (25mg/kg) and amphetamine (5mg/kg) both induced FOS expression predominantly in the striosomal compartment during the first postnatal week, confirming Johnson K. et al., 1991. Induction of FRA and NGFI-A also was confined to the striosomal compartment during this time. FOS induction was dependent on D1-class dopamine receptors, as pretreatment with the selective D1-class antagonist SCH23390 at doses of 0.2mg/kg blocked FOS expression. FRA and NGFI-A exhibited basal expression in striosomes but this was not completely blocked by pretreatment with SCH23390. Remarkably, although cocaine and amphetamine treatments led to a robust IEG induction in the striatum at P6/P7 and at P21, they did not at P15. Conversely, there was strong IEG induction in the globus pallidus (GP) at P15, but induction in GP was low at P6/P7 and P21. We tested whether the IEG induction in the GP required D1- or D2-class dopamine receptors by using pretreatments with SCH23390 or the D2-class antagonist, eticlopride (0.5mg/kg). Pretreatment with the D1 antagonist did not block the GP expression. The D2 antagonist suppressed the IEG induction in the GP and induced IEG expression in the striatum. By P21, the IEG induction acquired mature patterns of expression.

These results suggest that significant modifications occur in the effects of psychomotor stimulants on the basal ganglia through a prolonged period of postnatal development. We thank Drs. M. Iadarola and J. Milbrandt for antisera. Supported by NIDA grant 5R01 DA08037.

## 163.14

CORTICALLY-DRIVEN IMMEDIATE-EARLY GENE EXPRESSION IN STRIATAL NEURONS SHOWS SELECTIVITY FOR ENKEPHALINERGIC NEURONS OF THE RAT AND MONKEY STRIATUM. A.M. Graybiel, H.B. Parthasarathy, A.W. Flaherty\* and S. Berretta. Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139

The direct and indirect pathways of the basal ganglia have their primary origins in different populations of striatal projection neurons. Both cell types are GABAergic, but most indirect pathway neurons coexpress enkephalin, whereas most direct pathway neurons coexpress dynorphin and substance P. To examine activation of striatal projection neurons by the sensorimotor cortex, we electrically microstimulated physiologically identified sites in primary somatic sensory and motor cortex (SI, M1) in anesthetized squirrel monkeys (250 Hz, 40 msec pulses, Parthasarathy et al., Soc. Neurosci. Abstr. 20:987, 1994) and used epidural picrotoxin (0.3 mM) to stimulate sensorimotor cortex in freely moving rats (Berretta et al., Soc. Neurosci. Abstr. 1994). Both modes of cortical stimulation induced immunohistochemically detectable Fos- and JunB-like immediate-early gene proteins in the striatum within 2 hr after the start of stimulation. The induction followed known corticostriatal topography. In the monkey, the induced proteins were in cell clusters in the putamen that matched input fiber patches (matrisomes) labeled anterogradely from corresponding cortical sites. Dual antigen immunostaining demonstrated that most of the striatal neurons expressing Fos were enkephalin-positive (70-80%; rat; >70%, monkey). In rat, in which dynorphin immunostaining was possible, only 7% of the Fos-positive neurons were dynorphin-immunoreactive. Similar results were obtained in rat for JunB. These findings suggest that the sensorimotor cortex can selectively influence the indirect pathway of the basal ganglia and thus basal ganglia release functions. Supported by NIH Javits Award R01 NS25529.

## 163.16

EFFECTS OF CHRONIC COCAINE EXPOSURE ON CORTICOSTRIATAL TRANSMISSION IN THE RAT. V. Hillegaars\*, S. Berretta and A.M. Graybiel. Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139

A single shot of cocaine (25 mg/kg, i.p.) rapidly induces expression of Fos and Fos-family immediate-early gene proteins in striatal neurons. Repeated exposure to cocaine (25 mg/kg, b.i.d.) leads to a sharp decline in inducibility of Fos that is nearly complete after 7 days. In the present experiments we asked whether this depression of Fos inducibility would affect the capacity for cortical stimulation to induce Fos-like protein in the caudoputamen. The motor cortex of freely moving rats was stimulated with epidural local application with the GABA<sub>A</sub> receptor antagonist, picrotoxin (18 mg/100 ml). Evoked motor twitches were noted and the expression of nuclear Fos-like immunoreactivity (Fos-LI) in striatal neurons was monitored postmortem by immunohistochemistry (Berretta et al., Soc. Neurosci. Abstr. 20:987, 1994). The induction of Fos-LI was analyzed by counting Fos-positive nuclei with a quantitative computer-assisted method. Values were subjected to a log transformation and expressed as mean±S.D. (nuclei/striatal section). The levels of Fos induction were studied in four experimental groups: (1,2), rats pretreated for 7 days with cocaine (25 mg/kg i.p., b.i.d.) and given picrotoxin epidurally (1.90±0.40) or saline epidurally (0.82±0.44); (3) rats pretreated for 7 days with saline (i.p.) and given picrotoxin epidurally (2.28±0.44); (4) control rats pretreated for 7 days with cocaine (25 mg/kg i.p., b.i.d.) and given a final challenge of cocaine (25 mg/kg i.p.) (1.35±0.13). As predicted, chronic cocaine strongly down-regulated induction of Fos-LI by subsequent cocaine challenge. Two-tailed Student's *t*-tests between groups showed that in rats chronically treated with cocaine, cortical stimulation can still significantly increase Fos induction if compared to the down-regulation shown with cocaine challenge ( $t_{(18)}=3.46$  ( $p<0.01$ )). However, the Fos levels induced by cortical stimulation were significantly lower than those in rats pretreated with saline ( $t_{(23)}=2.24$ , ( $p<0.05$ )). We suggest that chronic exposure to cocaine induces network-level changes that affect the efficacy of corticostriatal transmission. Supported by NIDA 5R01 DA08037 and Swedish MRC K96-12P-11008-03A.

## 163.18

CHOLINERGIC PRESYNAPTIC MODULATION OF GLUTAMATERGIC AFFERENTS TO THE NEOSTRIATUM AS SEEN WITH PAIRED PULSE FACILITATION AND 4-AP-INDUCED RELEASE. E. Hernández, E. Galaraga and J. Bargas\*. Instituto de Fisiología Celular, UNAM, POBox: 70-253, México City DF 04510 México.

Both 4-AP-induced release of transmitters and paired pulse facilitation have been validated as a way to evaluate presynaptic modulation of transmitter release (e.g., Tibbs et al., J Neurochem 53: 1693; Dunwiddie and Haas, J Physiol 369: 365; Flores-Hernández et al., J Neurophysiol 72: 2246; Soc Neurosci Abs 1994: 563). Here we use both methods to evaluate cholinergic modulation of neostriatal afferents. In the presence of 10  $\mu$ M bicuculline, cholinergic agonists 1  $\mu$ M carbachol or 20 nM muscarine, significantly enhanced ( $\mu \pm$  SD:  $53 \pm 2$  and  $94 \pm 20$  %, respectively) the second synaptic potential of a pair of responses separated by 25-50 ms, evoked by field stimulation, and recorded intracellularly in a slice preparation. Facilitation of the second response with respect to the first one occurred in spite of a reduction in both responses by the cholinergic agonists. Paired pulse facilitation by cholinergic agents was blocked by 1  $\mu$ M atropine and 100 nM gallamine, but not by 500 nM pirenzepine, suggesting that cholinergic-muscarinic effects are not mediated by  $M_1$  or  $M_4$ -receptors. Cholinergic agonists decreased transmitter release induced by 100  $\mu$ M 4-AP in about 50% of experiments, suggesting that not all afferents may be modulated. This effect was reversed by atropine and occurred with no significant changes in synaptic potentials' mean amplitude or distribution. At the concentrations used, no cholinergic agent caused a change in postsynaptic input resistance, membrane potential or firing threshold. Financed by DGAPA-UNAM and CONACyT.

## 163.19

**ION MECHANISM FOR DOPAMINERGIC EXCITATION IN NEOSTRIATAL NEURONS.** S. Hernández, J. Vargas, A. Reyes and E. Galarraga\* Instituto de Fisiología Celular, UNAM, POBox: 70-253, México City DF 04510 México.

As reported previously (e.g., Hernández et al., 1995; Soc. Neurosci. 913), dopaminergic D<sub>1</sub>-receptor agonists inhibit firing in neostriatal neurons when stimulated at resting membrane potential (ca., -80 mV). Here we report that, at depolarized membrane potentials (> -60 mV), D<sub>1</sub>-agonists turn out to be excitatory on all neostriatal neurons tested. Thus, dopaminergic action is voltage-dependent. Slow maintained depolarizations were elicited in neostriatal neurons by brief intracellular current steps given at depolarized membrane potentials. Slow depolarizations could evoke firing after the stimulus (delayed firing), were facilitated by K<sup>+</sup>-blockers (2 mM TEA, 2 mM Ba) and dihydropyridines (e.g., 1  $\mu$ M BayK 8644), and were blocked by 50  $\mu$ M Cd<sup>2+</sup> or 200 nM calciseptine, which also blocked the dihydropyridines' agonist effects. This suggests that slow depolarizations are generated by the L-type of inward Ca<sup>2+</sup>-currents. Dopaminergic D<sub>1</sub>-, but not D<sub>2</sub>-receptor agonists, enhance the slow depolarizations and facilitate delayed firing (1  $\mu$ M CI-APB or 6-Cl-PB vs. 1-5  $\mu$ M quinpirole). Effects are blocked by 1  $\mu$ M SCH23390 but not by 5  $\mu$ M sulpiride. D<sub>1</sub>-actions were mimicked by cAMP analogs and occluded by dihydropyridines. Since the only inward current enhanced by D<sub>1</sub>-agonists (through the PKA pathway) is the one carried by L-channels (Surmeier et al., 1995, Neuron 14: 385), it is suggested that this current generates the D<sub>1</sub>-enhanced slow depolarizations and delayed firing. In conclusion, facilitation of Ca<sup>2+</sup>-mediated slow depolarizations and firing is the way dopamine uses to excite neostriatal neurons.

Financed by DGAPA-UNAM and CONACYT.

## BASAL GANGLIA: ANATOMY I

## 164.1

**EFFERENT PROJECTIONS OF DIFFERENT FUNCTIONAL TERRITORIES OF THE INTERNAL PALLIDIUM IN MONKEYS.** E. Shink\*, M. Sidibé\*, L.-E. Bouffard and Y. Smith. Centre Recherche Neurobiol., Univ. Laval, Québec, Canada.

The functional segregation imposed upon the striatum by the cortical afferents is maintained at the level of the output structures of the basal ganglia, hence in the internal pallidum (GPi), the dorsal third is related to associative functions, the caudo-ventro-lateral two-thirds process sensorimotor information and the rostromedial pole receives limbic-related inputs. The objective of this study was to verify whether this segregation is maintained in the targets of the GPi, namely the ventrolateral and intralaminar thalamic nuclear groups, the pedunculopontine nucleus (PPN) and the lateral habenular nucleus (LHb). This was achieved by using the anterograde transport of biotinylated-dextran amine (BDA) alone, or combined with the anterograde transport of *Phaseolus vulgaris*-Leucoagglutinin.

In a first series of experiments, we placed small injections of BDA in the different functional territories of the GPi. Following these injections, a common pattern disclosed in the different targets was the overlap of the field of anterogradely labelled terminals arising from the associative and limbic territories; which were largely segregated from the sensorimotor-related afferents. A second series of experiments is currently in progress to verify whether the overlap of terminal fields is reflected at the single cell level by the convergence of synaptic inputs. To do so, we use a double anterograde labelling method suitable with light and electron microscopic observations. So far, combined injections in the limbic and sensorimotor territories confirmed the segregation of afferents from those territories at the level of the thalamus, the LHb and the PPN. The possibility of convergence of synaptic inputs from associative and limbic territories is currently under investigation at the electron microscopic level.

In conclusion, these findings suggest that the cognitive and limbic information that remain segregated in the striatopallidal complex may be processed by common neurones in the different targets of the GPi. **LOCALIZATION OF METABOTROPIC GLUTAMATE RECEPTOR SUBUNITS IN THE BASAL GANGLIA OF MONKEYS.** Y. Smith\*, M. Paquet and L.-E. Bouffard. Centre Recherche Neurobiologie, Univ. Laval, Québec, Canada.

In order to further our knowledge on the role of metabotropic receptors in the basal ganglia (BG), we analysed the distribution of the mGluR1 $\alpha$  and mGluR2/3 subunits in the BG of squirrel monkeys by means of immunocytochemistry.

In the light microscope, the neuropil in the different structures of the BG displayed strong mGluR1 $\alpha$  immunoreactivity. The immunostaining was particularly dense along the membranes of dendrites and perikarya. No particular regionalization of labelling was found except in the caudate nucleus, where zones that probably correspond to the "patches or striosomes" were slightly less immunoreactive than the "matrix". At the electron microscopic level, a common feature was the association of dense reaction product with post-synaptic densities at the level of asymmetric synapses on dendrites, spines and perikarya. Occasionally, aggregates of reaction product were also found at non-synaptic sites along the dendrites. With the exception of the STR, thin glial processes were immunostained in the BG, but abounded particularly in the internal pallidal segment (GPi). In the subthalamic nucleus (STN) and the substantia nigra pars reticulata (SNr), a few terminals displayed immunoreactivity. Overall, the BG were devoid of mGluR2/3-immunoreactive neuronal elements except for lightly labelled perikarya in the STR and the STN. However, the neuropil in the different structures contained thin immunoreactive processes, presumably of glial nature. This needs to be confirmed in the electron microscope. In contrast, neurones in the nucleus basalis of Meynert displayed strong pericellular mGluR2/3 immunoreactivity.

In conclusion, our findings indicate that the mGluR1 $\alpha$  subunit of the metabotropic receptors may participate in the modulation of glutamatergic transmission in the BG in different ways including post- and pre-synaptic mechanisms as well as glial cell capture of neurotransmitter. Supported by MRC and FRSQ.

## 164.2

**SYNAPTIC INTERACTIONS BETWEEN THALAMIC AFFERENTS AND STRIATAL INTERNEURONES IN MONKEYS.** M. Sidibé\* and Y. Smith. Centre de Recherche en Neurobiologie, Univ. Laval, Québec, Canada.

Four major populations of interneurons are chemically characterized in the striatum, namely those immunoreactive for parvalbumin (PV), somatostatin (SS), calretinin (CR) and choline acetyltransferase (Chat). The objective of the present study was to analyse the synaptic relationships between the striatal interneurons and the thalamic afferents arising from the centre median (CM) nucleus in squirrel monkeys. This was achieved by combining the anterograde transport of biotinylated-dextran amine (BDA) with the immunostaining specific for the different populations of interneurons at the electron microscopic level.

BDA injections in the CM led to dense bands of anterograde labelling in the post-commissural region of the putamen. Double labelling at the light microscopic level showed that the thalamic fibres and interneurons largely overlapped in different regions. So far, analysis of those zones of overlap in the electron microscope revealed the existence of asymmetric synapses between BDA-containing terminals from the CM and the dendrites of PV and SS interneurons. In contrast, synapses between CR-positive elements and BDA-containing terminals were not found. The possibility of CM inputs to Chat-positive interneurons is currently under investigation. Double-labelled terminals for BDA and PV or CR were observed, which indicates that these calcium binding proteins may be used as neuromediators by thalamostriatal neurones. This was confirmed by the labelling of PV- and CR-immunoreactive neurones in the CM after injections of a retrograde marker in the putamen. In contrast, none of the BDA-containing terminals displayed immunoreactivity for SS and Chat. Some of the double-labelled terminals formed synapses with PV- or CR-positive dendrites.

In conclusion, our data indicate: (1) that striatal interneurons immunoreactive for PV or SS, but not those that contain CR, receive strong thalamic input from the CM and (2) that PV and CR are used as neuromediators by thalamostriatal neurones in monkeys. Supported by the Canadian MRC and the FRSQ.

## 164.4

**LOCALIZATION OF AMPA AND NMDA GLUTAMATE RECEPTOR SUBUNITS IN STRIATAL INTERNEURONES IN MONKEYS.** M. Paquet\* and Y. Smith. Centre Recherche Neurobiologie, Univ. Laval, Québec, Canada.

Four major populations of interneurons were chemically characterized in the striatum by their immunoreactivity for somatostatin (SS), parvalbumin (PV), calretinin (CR) and choline acetyltransferase (Chat). In order to understand better the nature and composition of the receptors that mediate the excitatory effects induced in these neurones by glutamatergic afferents, we compared the expression of NMDA (NMDAR1) and AMPA (GluR1, GluR2/3 and GluR4) receptor subunits between the different populations of interneurons. This was achieved by using a double immunohistochemical technique at the light microscopic level.

Although the intensity of immunostaining for GluR2/3 and NMDAR1 subunits was quite homogeneous throughout the striatum, such was not the case for the other subunits. The GluR1 immunoreactivity was light throughout the striatum except for the strong labelling associated with a sparse subpopulation of medium-sized neurones. Three populations of striatal neurones were distinguished on the basis of their GluR4 immunoreactivity; the majority were medium-sized and highly immunoreactive whereas subpopulations of medium- and large-sized perikarya were much strongly labelled. A common feature to the four populations of interneurons was the expression of the GluR2/3 subunits. The SS-positive neurones were lightly immunoreactive for GluR1 and GluR4 and displayed NMDAR1 immunoreactivity. On the other hand, the majority of PV- and CR-positive neurones were strongly labelled for GluR1 and GluR4. However, the PV-positive cells displayed NMDAR1 immunoreactivity whereas such was not the case for most of the CR-containing neurones. The Chat-immunoreactive neurones were lightly labelled for GluR1 but displayed strong GluR4 immunoreactivity and contained NMDAR1.

In conclusion, our findings indicate that AMPA and NMDA receptor subunits are differentially distributed in the subpopulations of striatal interneurons in monkeys. Supported by MRC and FRSQ.

## 164.5

DUAL REPRESENTATION OF STRIATUM IN THE SUBSTANTIA NIGRA PARS RETICULATA: RELATIONSHIP TO SACCADE ZONES IN SUPERIOR COLLICULUS. **AB Kelly** and **C.R. Gerfen**, Lab of Neurophysiology, NIMH, Bethesda, MD.

Processing of cortical information by the striatum is determined by several input-output organizational schemes. In one, striatal patch-matrix compartments provide parallel pathways for cortical neurons in different laminae to selectively target dopamine or GABA neurons in the substantia nigra. In another, different populations of striatal neurons provide either indirect, via the globus pallidus, or direct projections to the substantia nigra. In another scheme, individual striatopallidal (Chang *et al.*, 1981, Science 213:915) and striatonigral neurons provide inputs to two separate zones in each of the target nuclei. Thus there exist dual maps of the striatum in the globus pallidus and substantia nigra (Gerfen, 1985, J. Comp. Neurol., 236: 454). We examined the output organization to the superior colliculus (SC) of these dual striatal map zones of the substantia nigra, one located roughly dorsally, subjacent to the pars compacta and another located ventrally. The SC displays a map of eye movement saccades, from long saccades caudally to short saccades rostrally, ending in a rostral zone of the SC of active visual fixation (Munoz & Wurtz, 1992, J. Neurophysiol., 67:1000). Retrograde tracers, Fluoro-Gold and Fast Blue, were injected into rostral and caudal SC, respectively. Results showed that nigral neurons projecting to the caudal long-saccade zones of the SC are located in the ventral nigral map of the striatum, whereas those projecting to the anterior short-saccade zones of the SC are located in the dorsal nigral map of the striatum. Individual neurons do not appear to project to both zones of the SC. These results indicate that each of the dual striatal map zones of the substantia nigra provide inputs to different functional areas in the superior colliculus. (supported by NIMH)

## 164.7

ORGANIZATION OF TEMPORAL POLAR AND TEMPORAL OPERCULAR CORTICAL PROJECTIONS TO THE STRIATUM IN PRIMATES. **M. Chikama\*** and **S.N. Haber**, Department of Neurobiology & Anatomy, Univ. of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

On the basis of connections with cortices in primates, the striatum can be divided into the limbic-related ventral striatum and the sensorimotor-related dorsolateral striatum. Previously, we have shown that the cingulate, orbitofrontal and insular cortical projections to the striatum are topographically organized according to cytoarchitectonic cortical and functional striatal differentiations. For example, agranular cortical regions project primarily to the ventromedial striatum, while granular cortical regions project to the dorsolateral striatum.

Temporal pole and temporal opercular regions surrounding the piriform olfactory cortex, also contain consecutive cytoarchitectonic differentiations from agranular to granular cortex. We investigated the organization of projections from the different cytoarchitectonic temporal cortical inputs to the striatum. Agranular and dysgranular portions of the temporal polar cortex strongly project to the medial and ventral parts of the ventral striatum. In contrast, the dorsolateral striatum receives inputs primarily from the granular portion of the temporal opercular cortex.

According to cortical cytoarchitectonic differentiations, functionally segregated cortical areas project to a similar functional division of the striatum. (Supported by NS2251 and the Lucille Markey Charitable Trust)

## 164.9

THE RELATIONSHIP OF AMYGDALOID AND STRIATAL INPUTS TO THE VENTRAL MIDBRAIN: A RETROGRADE STUDY. **J.L. Fudge\*** and **S.N. Haber**, Department of Neurobiology and Anatomy, Univ. of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

The role of the amygdala in psychotic illness has not been well-studied. Nevertheless, evidence to date suggests that the amygdala is involved in the regulation of affect, and in the emotional "coloring" of environmental stimuli. Because dysregulation of dopamine is thought to play a role in psychotic syndromes, the connection of the amygdala to the ventral midbrain may be important. A previous study using anterograde tracing methods documented a projection from the central nucleus of the amygdala to the ventral tegmental area (VTA) and dorsal tier cells of the substantia nigra (SN) in primates (Price and Amaral, 1981). We analyzed the amygdalonigral projection in macaques by placing retrograde tracers in the SN and VTA at several dorsoventral and mediolateral levels. In addition, the projection was analyzed in relation to striatal inputs. An injection in the VTA and medial SN revealed cell bodies in the central and medial nuclei of the amygdala. Striatal inputs to this region of midbrain are predominantly from the rostral, pre-commissural striatum. Cell density was greatest in the ventromedial to central striatum, areas associated with limbic and association cortex input, respectively. An injection in the lateral SN also revealed a projection from the central and medial nuclei of the amygdala. The striatal innervation of this area arose primarily from the caudal limbic-related striatum. A central, ventral SN injection in the region of the reticulata and cell columns and densocellular area of the compacta failed to reveal cell bodies in the amygdala. Striatal cells innervating this area were broadly distributed rostrocaudally, with greatest cell density in central and dorsolateral regions. In summary, the amygdala projects to cells of the VTA and medial and lateral thirds of the SN. Striatal inputs to these areas arise from areas considered "limbic-related" on the basis of cortical innervation. The central, ventral SN, which did not have an amygdaloid innervation, had striatal input predominantly from association and sensorimotor regions. ## 164.6

INFEROTEMPORAL CORTEX IS THE TARGET OF BASAL GANGLIA OUTPUT. **E.A. Middleton\*** and **P.L. Strick\***, <sup>2</sup>Research Service, VA Medical Center and Departments of <sup>1</sup>Neurosurgery and <sup>2</sup>Physiology, SUNY Health Science Center, Syracuse, NY 13210.

The basal ganglia of primates are known to receive inputs from widespread regions of the cerebral cortex, such as the frontal, parietal, and temporal lobes. Of these cortical areas, only the frontal lobe is generally regarded as the target of output from the basal ganglia. One of the temporal lobe regions which is a source of input to the "visual" striatum is area TE, in inferotemporal cortex. This cortical region is thought to be critically involved in the recognition and discrimination of visual objects. We used retrograde transneuronal transport of the McIntyre-B strain of herpes simplex virus type 1 (HSV1) to examine whether TE is the target of basal ganglia output. Multiple small injections of HSV1 (0.05 - 0.1  $\mu$ l) were placed into area TE in Cebus monkeys (*Cebus apella*, n=3). Five days after these injections, HSV1 was detected in several thalamic nuclei that are known to project to TE, including the nucleus ventralis anterior pars magnocellularis (VAmc). In addition, neurons labeled by retrograde transneuronal transport of HSV1 were also found in the substantia nigra pars reticulata (SNpr). The region of SNpr that contained labeled neurons after TE injections lies within the region that receives input from the visual striatum. In addition, this region of SNpr was different from the regions labeled by HSV1 injections into motor and prefrontal areas of cortex. These results indicate that TE is not only a source of input to the basal ganglia, but also is the target of basal ganglia output via the thalamus. Thus, basal ganglia loops with the cerebral cortex appear to be involved in higher order aspects of visual processing, as well as motor and cognitive behavior. ## 164.8

THE THALAMOSTRIATAL PROJECTION AND ITS RELATION TO CORTICOSTRIATAL AND CORTICOTHALAMIC INPUTS. **N.R. McFarland\*** and **S.N. Haber**, Department of Neurobiology & Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

The thalamus plays a central role in basal ganglia circuitry. It receives output from the basal ganglia and relays this information to the cerebral cortex. The thalamus also provides a major source of input to striatum. Previously, we have demonstrated massive thalamostriatal projections from the midline, intralaminar and ventral thalamic nuclei. These thalamostriatal projections are topographically organized such that the medial thalamic nuclei project to the ventral 'limbic' striatum, while lateral nuclei (i.e. ventral anterior and ventral lateral nuclei) project to the dorsolateral 'sensorimotor' striatum. Retrograde tracer injections into discrete striatal regions show corticostriatal projections from areas which receive thalamic input from nuclei that also project to the striatum. These findings suggest that interconnected thalamic and cortical areas project to similar striatal regions. Our current study examines whether the thalamostriatal projection is influenced by cortical inputs to both its thalamic origin and its terminals in the striatum.

Anterograde tracer injections were placed into motor, prefrontal (area 9), and anterior and posterior cingulate cortices. Fiber and terminal labeling was examined using darkfield/light microscopy and charted with a drawing tube. After tracer injection into the medial motor cortex, corticothalamic fibers were observed primarily in the ventral lateral pars oralis, ventral posterior lateral par oralis, and dorsolateral centre median nuclei, while corticostriatal projections terminated in the dorsolateral putamen. Cortical projections from area 9 terminated in the ventral anterior and mediodorsal (MD) thalamic nuclei and in the rostral head of the caudate and central putamen. Anterior cingulate projections targeted mainly the ventral anterior, MD, and dorsal intralaminar thalamic nuclei and the rostral striatum and ventral body of the caudate. The posterior cingulate cortex projected to the ventral lateral pars caudalis, rhomboid and caudal MD nuclei.

These observations, when combined with our previous studies on the organization of thalamic projections to the striatum, support the idea that thalamostriatal projections may be influenced by cortical inputs to both the striatum and the thalamus. ## 164.10

ANATOMICAL AND FUNCTIONAL RELATIONSHIPS BETWEEN THE PREFRONTAL CORTEX AND THE BASAL GANGLIA IN THE RAT.

**A.M. Thierry\***, **N. Maurice**, **J.M. Deniau**, **A. Menetrey** and **J. Glowinski**, U114, Collège de France, URA1488, Université Paris VI, Paris, France.

Recently, we have described a prefrontal cortex-striato-thalamo-cortical circuit which involves the substantia nigra pars reticulata (SNr) (Montaron *et al.*, Neuroscience, 71,371-382,1996). This circuit originates from the ventral prefrontal (PL) and medial orbital (MO) areas of the prefrontal cortex and involves successively: a subterritory of the core of nucleus accumbens (NAcc), the dorsomedial part of the SNr and thalamic nuclei related to the prefrontal cortex. Since the ventral pallidum (VP) has been considered as a main output structure of the prefrontal cortex-basal ganglia circuits, instead of/or in addition to the SNr, the aim of the present study was to determine the position of the VP in the PL/MO-basal ganglia circuit. Following injection of biocytin into the close vicinity of NAcc neurons presenting an excitatory response to the stimulation of PL/MO areas, anterogradely labelled fibers were visualized in a delineated area of the VP. When biocytin injection was performed into this VP area, labelled fibers were observed in the medial part of SNr and in the medial region of subthalamic nucleus (STN) but not in thalamic nuclei. The existence of a functional link between these structures was further established using an electrophysiological approach. Electrical stimulation of the core of NAcc induced an inhibitory response ( $D=39.6\pm15.4$ ms) in 61% of the VP cells identified as projecting to the STN by the antidromic activation method and stimulation of the VP evoked an inhibition ( $D=19.8\pm7.3$ ms) in 55% of the STN neurons identified as projecting to the medial SNr. The present data show that the VP area involved in the PL/MO-basal ganglia circuit, cannot be considered as an output structure of the basal ganglia but participates with the STN to an indirect NAcc-SNr pathway. Thus, it can be proposed that the VP occupies in this prefrontal-basal ganglia circuit a position analogous to that of the external segment of the globus pallidus in the sensorimotor circuits of the basal ganglia. **SPECIFIC ANATOMICAL RELATIONSHIPS BETWEEN HIPPOCAMPAL AND BASAL AMYGDALOID AFFERENTS AND DIFFERENT POPULATIONS OF PROJECTION NEURONS IN THE NUCLEUS ACCUMBENS OF RATS.** A.V.J. Beijer and H.J. Groenewegen. (SPON: European Neuroscience Association). Dept. Anat. & Embryol., Vrije Univ. Amsterdam, The Netherlands.

The nucleus accumbens (Acb) is considered to be an interface between limbic structures and several effector regions in the diencephalon and mesencephalon. Within the Acb, afferents from the basal amygdaloid complex (BAC) and the subiculum of the hippocampus (Sub) as well as projection neurons, are inhomogeneously distributed. This raises the question whether these limbic structures specifically contact different populations of projection neurons within the Acb. To address this question, double anterograde tracer injections in parts of the BAC and the Sub were combined with a retrograde tracer injection in an Acb target. Double anterograde tracing revealed a complex pattern of overlap and segregation of afferents from different Sub and BAC subregions within the Acb. Combined anterograde/retrograde studies showed striking relationships between limbic inputs and specific populations of projection neurons. For example, ventral subicular efferents selectively innervate a neuronal population in the dorsomedial Acb that projects to the ventral tegmental area. This population is largely avoided by BAC efferents. Efferents from the dorsal Sub and the rostral BAC converge on a population of substantia nigra projecting cells in the rostromedial Acb. Strong relationships were also found between efferents from the BAC and Acb cells that project to different parts of the ventral pallidum. Different BAC subnuclei appear to selectively innervate or avoid subpopulations of VP projecting neurons. These results indicate that distinct populations of Acb projection neurons receive input from specific parts of BAC and/or Sub. It may thus be postulated that different amygdaloid and hippocampal subregions, via the Acb, exert differential influences on behavior.

## 164.13

**PRE- AND POSTNATAL DEVELOPMENT OF THE CORTICOSTRIATAL PATHWAY IN THE MOUSE.** L.K. Nisenbaum\* and J.J. LeTurco. Dept. of Physiology & Neurobiology, University of Connecticut, Storrs, CT 06269

The striatum receives excitatory glutamatergic input from the cerebral cortex. These cortical afferents are segregated into the functionally distinct patch and matrix regions of the striatum. Neurons from the prelimbic cortex, particularly those from the deeper layers, project predominantly to the striatal patch neurons whereas neurons from the somatosensory cortex project exclusively to the striatal matrix neurons. Although the corticostriatal innervation has been characterized in adults, the developmental timecourse and segregation of this pathway have not been investigated.

To determine the timecourse of corticostriatal innervation, the fluorescent dye, DiI, was injected into various regions of cortex in mice ranging in ages from embryonic day (E) 16 through postnatal day (P) 15. Injections into frontal cortex at E16 labeled corticofugal axons within the internal capsule fiber bundles. Relatively few collateral branches extended from the fiber bundles into the striatum at this age. In contrast, by E21 a plexus of labeled collateral branches extending from the internal capsule fibers into the striatum was clearly detectable. The density of corticostriatal axon collaterals continued to increase from P0 through P15. Whole-cell recordings from striatal neurons in corticostriatal slices were used to assess the functional innervation of the striatum during the first postnatal week. Stimulation of the corpus callosum produced a synaptic response that reversed at +10 mV, suggesting an excitatory glutamatergic innervation of the striatal neurons.

Injections into the prelimbic cortex of P1 and P9 mice revealed the initiation of cortical afferent segregation. At both ages, corticostriatal axon collaterals formed stripes and patches of apparent terminal fields within the medial aspects of the striatum. No such pattern formation was detected following injections into the frontal or occipital cortex in P1 and P9 mice. Together, these data suggest that cortical neurons innervate the striatum prenatally. In addition, corticostriatal afferent segregation may begin during late prenatal or early postnatal development.

**EVIDENCE OF MORPHOLOGICAL HETEROGENEITY IN THE CAT THALAMOSTRIATAL PROJECTIONS TO THE CAUDATE NUCLEUS.** S. de las Heras\*, E. Mengual, J.L. Velazco and J.M. Giménez-Amaya. Departamento de Morfología, Facultad de Medicina, U.A.M., 28029 Madrid, Spain.

The morphological heterogeneity of the cat thalamostriatal projections to the caudate nucleus (CN) and their relationships with the nigrothalamic connectivity were studied by means of retrograde and anterograde tracer techniques. In a first group of experiments, HRP-WGA, and fluorescent retrograde tracers such as Fast Blue and Diamidino Yellow were injected in different regions of CN, and then the distribution of single and double retrogradely labeled neurons in the thalamus was analyzed. Adjacent sections processed for acetylcholinesterase (AChE) were used as histochemical markers for the thalamic localization of labeled thalamostriatal neurons. In a second group of experiments, both fluorescent tracers Fast Blue and Diamidino Yellow were injected in different regions of CN whereas HRP-WGA was placed in the substantia nigra. The thalamic distribution of retrogradely labeled thalamostriatal neurons and anterogradely labeled nigrothalamic terminals was analyzed, in order to determine whether there are overlapping territories between the thalamostriatal and nigrothalamic projections. The main findings of this study were: (a) the thalamostriatal neurons displayed different patterns of organization depending on the thalamic group considered; (b) no double labeled neurons were observed when the two fluorescent tracers were injected in different dorsoventral and rostrocaudal sectors of the rostral CN whereas some double labeled cells were detected when larger injections in CN were localized far apart from each other in the rostrocaudal coordinate; (c) the thalamostriatal cells were heterogeneously distributed in reference to the thalamic distribution of AChE activity; and, (d) large overlapping thalamic territories between the thalamostriatal neurons projecting to CN and the nigrothalamic connections were observed in the rostral nuclei of the ventral thalamic group and, partially, in the rostral and caudal intralaminar nuclei. These results might help to understand the complex architecture of thalamic neurons projecting to CN in carnivores.

**BASAL AMYGDALOID RELATIONSHIPS WITH THE PREFRONTAL CORTEX AND THE VENTRAL STRIATUM IN RATS: CORTICAL LAMINATION AND STRIATAL COMPARTMENTATION.**

H.J. Groenewegen\* and C.I. Wright. Department of Anatomy and Embryology, Vrije Universiteit, 1081 BT Amsterdam, The Netherlands.

The basal amygdaloid complex (BAC) has specific anatomical relationships with both the prefrontal cortex (PFC) and the nucleus accumbens (Acb). In general, specific subnuclei of the BAC project to regions of the PFC and the Acb that are connected through corticostriatal projections. Recently, the relationships of the amygdalostriatal projections with the striatal compartments have been determined (Wright et al., 1996). For example, the mid-rostromedial BAC projects to the matrix of the core of the Acb and the adjacent ventral caudate-putamen, whereas the rostral and caudal parts of the BAC project to the patches of the same striatal region. It has previously been demonstrated that the superficial layers of the PFC project to the matrix whereas the deep layers reach the striatal patches (Gerfen, 1989). Amygdalocortical fibers terminate in a bilaminar pattern in both the deep and the superficial PFC layers. Our present aim was to determine whether and how this termination pattern relates to the amygdalostriatal compartmental organization. We used small injections of anterograde tracers in various BAC subnuclei. The results show that BAC subnuclei that target striatal patches have predominant terminations in the deep layers of the PFC, whereas those that project to the striatal matrix primarily project to the superficial layers. Therefore, these results indicate that amygdalocortical and amygdalostriatal projections both consists of subsystems and further stress the close anatomical association of the BAC with the prefrontal-ventral striatal system.

## 164.14

**SYNAPTOTOLOGY OF THE NIGROSTRIATAL PROJECTION IN RELATION TO THE COMPARTMENTAL ORGANISATION OF THE RAT NEOSTRIATUM.**

J.J. Hanley & J.P. Bolam. SPON: Brain Research Association. MRC Anatomical Neuropharmacology Unit, Mansfield Road, Oxford, OX1 3TH, U.K.

The heterogeneous organisation of the neostriatum, the patch (striosome)/matrix system, is defined on the basis of neurochemical heterogeneities and differential inputs and outputs. Sub-populations of midbrain dopamine neurons differentially innervate the patch and matrix compartments<sup>1,2</sup>. In view of these differences and the recognised structural differences between patch and matrix, the objective of the present study was to determine whether there are differences in the morphology and synaptology of dopaminergic axons innervating patch or matrix. Two approaches were used. 1) Rats received iontophoretic deposits of the anterograde tracer, biotinylated dextran amine (BDA) in different regions of the substantia nigra (SN). They were perfuse-fixed and sections of the neostriatum were processed to reveal the BDA and calbindin D28k, a marker for the patch/matrix system. 2) Perfuse-fixed sections of rat neostriatum were immunostained to reveal tyrosine hydroxylase (TH), a marker for dopaminergic structures, and calbindin D28k. The deposits of anterograde tracer in the SN led to two types of labelled afferents in the neostriatum. The anterogradely labelled fibres and the TH-positive fibres formed mainly symmetrical synapses in both the patch and matrix. Their synaptic targets were similar in both compartments and included spines, dendritic shafts and perikarya. The results so far demonstrate that deposits of BDA lead to the labelling of heterogeneous populations of fibres in the neostriatum, but that dopaminergic structures appear homogeneous. Although the nigrostriatal projection arises from sub-populations of dopaminergic neurons there appears to be no differences in their morphology and synaptology in relation to the patch and matrix. This implies that the dopaminergic input to the neostriatum modulates the flow of cortical information in a similar manner in the patch and matrix.

## 164.16

**THE NIGROSTRIATAL PROJECTIONS TO THE CAT CAUDATE NUCLEUS: A TOPOGRAPHICAL RE-EVALUATION WITH MULTIPLE RETROGRADE TRACERS.** B. Hontanilla, S. de las Heras and J.M. Giménez-Amaya\*. Departamento de Morfología, Facultad de Medicina, U.A.M., 28029 Madrid, Spain.

The anatomical organization of the cat nigrostriatal projections to the caudate nucleus (CN) was studied by retrograde tracers such as HRP-WGA, Fast Blue and Diamidino Yellow. These tracers were injected concomitantly in different regions of CN. The distribution of single and double retrogradely labeled neurons was analyzed in the substantia nigra (SN) compacta (SNC), substantia nigra lateralis (SNL), retrorubral area (RR) and ventral tegmental area (VTA). Adjacent sections processed for acetylcholinesterase were used as histochemical markers for the denocellular zone of SN. The main findings of this study are: 1) The rostral CN receives projections mainly from the caudal SN while the caudal CN receives projections from all rostrocaudal levels of SN. 2) SNL projects very specifically to the caudal CN. 3) The ventral RR close to the medial lemniscus projects to all rostrocaudal levels of CN. 4) The rostral CN receives projections mainly from the medial SN while more caudal sectors of CN receive projections from the medial and lateral SN. 5) A dorsoventral inversion of nigrostriatal projections from the medial SNC and VTA to CN was established. In contrast, we found zones within RR projecting both to the dorsal and ventral CN. 6) Distant injections of two different fluorescent tracers regarding both the dorsoventral and the rostrocaudal coordinates, yielded double-labeled neurons that were mainly located in the medial and caudal portions of SN and in the ventral RR. However the number of double-labeled neurons was higher after separate injections in the dorsoventral axis, suggesting that the collateralization to CN occurs mainly in the dorsoventral plane. 7) A clustering organization of nigrostriatal cells projecting to CN was detected mainly in the intermediate rostrocaudal part of SNC and in RR. The results of this comprehensive study on the cat nigrostriatal pathway to CN show novel findings on the anatomical organization of the nigrostriatal projections which might help to understand the complex architecture of nigral neurons projecting to CN in carnivores. EFFERENT CONNECTIONS OF THE STRIATUM AND THE NUCLEUS ACCUMBENS IN ANURAN AND URODELE AMPHIBIANS. W.J.A.J. Smeets<sup>a</sup>, O. Marin<sup>b</sup>, M. Muñoz<sup>b</sup>, H. Vara<sup>b</sup>, C. Sánchez-Camacho<sup>b</sup> and A. González<sup>a</sup>. <sup>a</sup>Graduate Sch. Neurosci., Dept. Anatomy & Embryology, Vrije Univ., Amsterdam, The Netherlands. <sup>b</sup>Dept. Cell Biology, Univ. Complutense, Madrid, Spain.

Recently it has been shown that, on the basis of position, chemoarchitecture and afferent connections, the basal forebrain of anuran and urodele amphibians can be subdivided into a nucleus accumbens and a striatum. As a further step in unraveling the organization of the basal ganglia of amphibians, we have studied the efferent connections of these basal forebrain subdivisions in the anurans *Rana perezi* and *Xenopus laevis*, and the urodele *Pleurodeles waltl*, using biotinylated or fluorescent dextran amines as anterograde tracers. A common pattern of efferent connections was observed in both groups of amphibians, but those in anurans were more elaborated. *Striatal efferent fibers* were found to reach the lateral and medial amygdala, the anterior and posterior entopeduncular nuclei, several thalamic nuclei, the dorsomedial posterior tubercle, the pretectum, the optic tectum, the torus semicircularis, the pontomesencephalic reticular formation and the caudal brainstem. *Efferent fibers of the nucleus accumbens* projected to the medial amygdala, the preoptic area, the ventral hypothalamic nucleus, the dorsomedial posterior tubercle, the medial tegmental area, the pontomesencephalic reticular formation and the raphe. In addition, the study has revealed the existence of intrinsic connections within the ventral telencephalic wall, suggesting a possible further compartmentalization of the amphibian basal forebrain. In conclusion, the results of the present study corroborate the notion that the basal ganglia of amphibians share many features with their presumed homologue in amniotes.

## BASAL GANGLIA: FUNCTION I

## 165.1

ROLE OF ANTERIOR STRIATUM IN MOTOR INITIATION AND POSTERIOR STRIATUM IN MOTOR EXECUTION IN HUMAN AND NON-HUMAN PRIMATES. B. Leis<sup>1</sup>, E. B. Montgomery<sup>1,2</sup> and W. C. Koller<sup>2</sup>. Human Motor Control Lab., Neurology, U. of Arizona<sup>1</sup>, Tucson, AZ 85724; Neurology, U. of Kansas Med. Center<sup>2</sup>.

We investigated motor initiation and execution using wrist flexion-extension movements in ten neurologically intact controls, ten patients with probable idiopathic Parkinson's disease (PDi), and four patients with Progressive Supranuclear Palsy (PSP). Patient groups were tested off medications. One monkey was studied before and after MPTP-induced Parkinsonism.

Montgomery et al. (1991) propose two separate physiologic mechanisms in the basal ganglia underlying motor initiation and execution, represented by reaction time (RT) and movement velocity (MV), respectively. The anterior striatum is advanced as programming motor initiation whereas the posterior striatum as programming motor execution. Parkinson's disease is characterized by greater dopamine loss in the putamen whereas in PSP and MPTP induced PD, more severe dopamine loss occurs in the caudate. We hypothesized lengthened RTs in PSP compared to PDi and equivalent MVs in PSP and PDi.

PSP RT exceeded PDi RT in pooled median RT across tasks, approaching statistical significance [Independent t-test,  $t(12)=2.0$ ,  $p=0.068$ ]. Median RT among groups were significantly different for the bounded flexion condition [One way analysis of variance (ANOVA),  $F(2,21)=13.6$ ;  $p<0.001$ ]. A Bonferroni t-test indicated the PSP RT (472ms) was significantly longer than the PDi RT (328ms). There were significantly prolonged median RTs in the monkey after MPTP using pooled RT between tasks [Mann-Whitney Rank Sum,  $p<0.01$ ]. No significant differences in median MV occurred among groups [Kruskal-Wallis one way ANOVA,  $p>0.05$ ] and no significant differences in MV occurred in the monkey before and after MPTP pooling MV between tasks, after Bonferroni correction [Independent t-test,  $t(40)=2.1$ ]. There was no association between RT and MV in the PSP or PDi patient groups [Spearman rank order correlation,  $p>0.05$ ]. Preliminary analysis suggests movement initiation is separate from execution and supports the role of the anterior striatum in motor initiation and the posterior striatum in execution. ## 165.3

COGNITIVE MODULATION OF HUMAN GLOBUS PALLIDUS (GP) NEURONS W.D. Hutchison<sup>a</sup>, A.M. Lozano<sup>a</sup>, E. Taub<sup>a</sup>, R.R. Tasker<sup>a</sup>, A.E. Lang<sup>a</sup>, J. Saint-Cyr<sup>a</sup>, J.O. Dostrovsky<sup>b</sup>. Departments of Surgery, Medicine, Psychology, Physiology, University of Toronto, Ontario, Canada M5S 1A8.

Recent studies have suggested that the GP is not only involved in the planning and execution of movements, but may also process cortical information subserving higher cognitive function (Middleton and Strick, *Science* 266: 458, 1994; Mushiake and Strick, *J. Neurophysiol.* 74: 2754, 1995). During 8 stereotactic pallidotomies for Parkinson's disease, the activity of single units in GP was studied during visually cued sequential pointing movements. Patients were requested to press a variable sequence of 3 of 5 buttons over 5 trials in each of 2 tasks: an internally cued task with a memorized sequence (MEM) and an externally cued task with the sequence given during the task performance (FOLLOW). EMG activity was measured in wrist flexors and extensors, biceps and shoulder, and hand movement was monitored with accelerometry. Average firing rate histograms of neurons were constructed for each task and aligned on the go cue, movement onset, and start of each button-press. Trajectories were reconstructed based on stereotactic co-ordinates and the location of the optic tract and internal capsule provided by visual or motor responses to microstimulation (1-100  $\mu$ A; 300 Hz, 0.2ms p.w.).

A total of 60 units was tested including 13 in GPe, 42 in GPi and 5 'Border cells'. Twelve of the 42 GPi cells (29%) showed MEM-specific inhibition or greater inhibition during MEM than FOLLOW, either during the entire sequence or at the end of one or more button press(es). The remaining 30 GPi cells did not respond to the task or showed no task-specificity. One of the 13 GPe cells showed excitatory MEM-specific activity. Two 'Border cells' were excited during the tasks but showed no specificity. Averaged EMG traces were the same on both tasks. MEM neurons were located in the dorsal portion of GPi in sagittal planes about 20 mm from the midline. The demonstration of cognitive modulation of neurons in dorsal GPi supports a role of basal ganglia in processing mnemonic function.

## 165.2

A PET STUDY OF THE EFFECTS OF THALAMIC AND GLOBUS PALLIDUS STIMULATION IN PARKINSON'S DISEASE. K.D. Davis<sup>1</sup>, E. Taub<sup>1</sup>, J.O. Dostrovsky<sup>2</sup>, S. Houle<sup>3</sup>, A.E. Lang<sup>3</sup>, R.R. Tasker<sup>1</sup> and A.M. Lozano<sup>1</sup>. <sup>1</sup>Dept of Surgery, <sup>2</sup>Physiology, <sup>3</sup>Neurology, and <sup>4</sup>The PET Centre, Clark Institute of Psychiatry, University of Toronto, Toronto, Ontario, Canada.

Chronic stimulation of the ventrointermediate (Vim) thalamus and internal segment of the globus pallidus (GPi) attenuates respectively, parkinsonian tremor and akinesia/rigidity. To better understand the neural mechanisms underlying these effects, we have obtained positron emission tomography (PET) images of the rCBF changes associated with Vim (n=6) and GPi stimulation (n=9) in patients with PD.

A Scanditronix GEMS-2048 scanner was used to image emissions from each i.v. injection of 40mCi  $H_2^{15}O$ . Six one minute scans were obtained for each patient: without stimulation (scans 1&4) and during stimulation at clinically ineffective (scans 2&5) or effective (scans 3&6) intensities. Scans consisted of 15, 6.5mm axial slices spanning the cerebrum and cerebellum. Right stimulation data were left-to-right flipped to pool with left stimulation data. Images were smoothed (15mm filter) and normalized to fit the Talairach and Tournoux atlas and analyzed with SPM software.

Vim stimulation at a clinically effective intensity increased rCBF bilaterally in frontal association areas and decreased rCBF ( $p<0.0001$ ) in the cerebellum, supplemental/cingulate motor cortex contralateral to Vim stimulation (ipsilateral to tremor). GPi stimulation at a clinically effective intensity increased rCBF ( $p<0.0001$ ) in the premotor cortex and post-commissural putamen/GPe region ipsilateral to GPi stimulation and decreased rCBF ( $p<0.001$ ) in the contralateral premotor and frontal association cortex.

These data suggest that Vim and GPi act differently through motor loops including the cerebellum, pallidum, thalamus, putamen and premotor cortical areas to alleviate parkinsonian symptoms. (Supported by Medtronic Corp.)

## 165.4

NEURONAL CORRELATIONS IN THE BASAL GANGLIA OF NORMAL AND MPTP-TREATED MONKEYS A. Feingold<sup>a</sup>, A. Nini<sup>a</sup>, A. Raz<sup>a</sup>, H. Slovín<sup>a</sup>, V. Zelenskaya<sup>a</sup>, E. Vaadia<sup>a</sup>, M. Abeles<sup>a</sup> and H. Bergman<sup>a</sup>. Dept. Physiol., Hebrew Univ.-Hadassah Med. Sch., Jerusalem, ISRAEL 91120.

To test whether information processing in the basal ganglia is carried by parallel or integrative circuits, we simultaneously recorded the activity of 4-10 single pallidal neurons or striatal TANs of two rhesus and two vervet monkeys before and after MPTP treatment.

The regular cross-correlation histograms of >93% of pallidal pairs were flat for most behavioral epochs. Even when the neuronal pairs were coactivated, the normalized correlograms were flat. Similar analysis of thalamic and cortical pairs showed significant correlated activity in more than 25% of the studied pairs, whereas 60% of TAN pairs demonstrated correlated activity.

Following MPTP treatment the monkeys developed typical parkinsonian symptoms. The rhesus monkeys developed infrequent short episodes of 7-11Hz tremor, whereas the vervet monkeys had many prolonged episodes of 5-7Hz tremor. Crosscorrelation of the pallidal and TAN pairs revealed significant synchronous oscillations, with bimodal distribution of oscillation frequencies (around 5 and 10-15Hz). All possible phase shifts were found in the oscillatory correlograms of the rhesus pallidal pairs.

The results support the view that in the normally-behaving monkeys pallidal neurons are engaged in "parallel processing," and a pathophysiological consequence of dopamine depletion in Parkinson's disease is increased oscillatory correlated neural activity in the basal ganglia.

## 165.5

COMPARISON OF THE EFFECTS OF EXPERIMENTAL PARKINSONISM ON NEURONAL DISCHARGE IN MOTOR AND NON-MOTOR PORTIONS OF THE BASAL GANGLIA OUTPUT NUCLEI IN PRIMATES. **T. Wichmann\*, H. Bergman, and M. R. DeLong.** Dept. Neurology, Emory Univ. Sch. of Med., Atlanta, GA 30322, and Dept. Physiol., Hadassah Med. Sch., Jerusalem, Israel.

These experiments tested the hypothesis that parkinsonian motor signs are primarily related to altered output from areas of the basal ganglia that are involved in "motor" rather than "non-motor" functions. Changes in neuronal discharge were compared between the predominantly "motor" internal pallidal segment (GPi), and the "non-motor" dorsal and central pars reticulata of the substantia nigra (SNr) in an African green monkey before and after treatment with MPTP. Neuronal discharge was evaluated with autocorrelograms and with a burst/inhibition detecting algorithm.

With MPTP-treatment, the discharge rate of neurons in GPi rose from  $41 \pm 18$  spikes/s ( $n = 20$ ; mean  $\pm$  SD) before, to  $49 \pm 27$  spikes/s ( $n = 59$ ;  $p < 0.05$ , t-test). The fraction of neurons discharging in bursts increased from 78% to 84%. Periodic bursts were virtually not seen before MPTP, but seen in 40% of cells thereafter. The contribution of increased phasic activity to the change in mean discharge rate was 79%. In the sampled regions of SNr, average neuronal discharge rates were unchanged:  $50 \pm 26$  spikes/s ( $n = 29$ ) before, and  $46 \pm 25$  spikes/s ( $n = 31$ ) after MPTP. Before MPTP, 48% of SNr cells discharged in bursts, and 44% thereafter (periodic bursts in 15%).

These findings support the notion that the non-motor areas of the basal ganglia output nuclei are not as severely involved in parkinsonism as are the motor areas. Moreover, much of the MPTP-induced change in average neuronal discharge in the motor portions of these structures appears to be due to increased phasic activity. Further experiments exploring the effects of MPTP in motor and non-motor areas of SNr are under way.

## 165.7

SLOWING OF WRIST MOVEMENT AND IMPAIRED ABILITY TO TURN OFF ACTIVE MUSCLES FOLLOWING INACTIVATION OF GLOBUS PALLIDUS PARS INTERNA (GPi): LOCALIZATION OF EFFECTIVE SITES. **J.W. Mink.\*** Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

It has been shown previously that injection of muscimol into GPi slows wrist movement to the greatest degree when the movement is made by relaxing a previously active muscle group (Mink and Thach, 1991). The purpose of the present study was to inject small volumes of muscimol into different GPi sites to determine 1) whether this effect is localized to a particular region of GPi and 2) whether inactivation of different sites in GPi affects aspects of the task differently (e.g. maintained position, flexion, extension, end-point position).

A rhesus monkey was trained to sit in a primate chair with its hand inserted into a wedge-shaped manipulandum. A visual target and cursor were displayed on an oscilloscope in front of the monkey. The monkey was trained to flex and extend the wrist to move the cursor and track the visual target in a hold-step-hold paradigm. The wrist movements were made with and without constant torque loads (0.15 Nm) opposing or assisting the movement. After the boundaries of GPi were mapped with single unit recording, muscimol (0.5  $\mu$ l of a 1  $\mu$ g/ $\mu$ l solution) was injected into sites in GPi. Injections were done once each week at sites 1 mm apart. Wrist position, velocity, force and EMG were recorded before and after injection of muscimol.

Wrist movement was slowed after injection into 9 of 10 sites studied to date in the posterior third of GPi. The impairment was qualitatively similar across sites, but the largest deficits were seen after injection into the more ventral and medial sites. The greatest impairment was seen in movements requiring relaxation ('turning off') the loaded flexors or extensors. There was a slight flexor positional bias. In the no-load condition extension was slow but flexion was near normal. After all GPi injections reaction time was normal.

These results confirm previous findings of relative inability to 'turn off' previously active muscles after GPi inactivation. (Supported by NIH grant K08 NS01808 and by the McDonnell Center for Higher Brain Function)

INTRACOLICULAR MICROINJECTIONS OF MUSCIMOL BLOCK MOTOR AND DEFENSIVE RESPONSES INDUCED BY KAINIC ACID LESIONS OF THE SUBTHALAMIC NUCLEUS IN THE RAT.

**M.A. Crumling, R.J.A. Banks, L. Naudon and M-F. Chesselet\*.** Dept. of Pharmacology, and Inst. Neurological Sciences, Univ. of Pennsylvania, Philadelphia, PA 19104.

Pharmacological manipulation of the subthalamic nucleus (STN) in rats elicits abnormal movements (Parry et al., 1994; Eberle-Wang et al., 1995, 1996). However, the behavioral effects of STN lesion are poorly understood. Unilateral lesions of the STN with kainic acid (KA; 200 ng/200 nl) in rats reliably induced transient locomotor activation, vacuous mouth movements, and a long lasting increase in defensive responses. These effects, however, were inconsistently observed after lesions induced by ibotenic acid. Although KA infusion into the STN induced a delayed neuronal loss in the reticular nucleus of the thalamus, all behaviors were observed prior to this secondary effect of the lesion. To identify the neuronal circuits involved in the behavioral effects of KA-induced lesions of the STN, anesthetized male Sprague-Dawley rats were stereotactically infused with 0.9% saline or KA into the STN and implanted with a unilateral guide cannula into the ventromedial superior colliculus on the side of the lesion. Intracolicular administration of the GABA agonist muscimol (100  $\mu$ g/500 nl) 1 hour prior to testing abolished the lesion-induced increase in locomotion, sniffing, and mouth movements observed 4 days post-surgery, as well as the lasting (up to 31 days) increase in vocalization to handling. Despite their different time-courses, the blockade by muscimol of both motor and defensive responses suggests the involvement of the subthalamo-nigro-collicular pathway in both types of behavioral effects of the KA-induced lesion. Supported by MH-44894 and MH-48125.

## 165.6

LOCAL BLOCKADE OF GABAERGIC INHIBITION IN THE PUTAMEN INDUCES BRIEF CHANGES IN PALLIDAL DISCHARGE AT RESTRICTED TIMES. **M.E. Anderson\*, M. Dubach, and J.A. Buford.** Depts of Rehab. Med. and Physiol. & Biophys. and Reg. Primate Res. Cntr, U. of Wash., Seattle, WA 98195.

Striatal projection neurons receive GABAergic inhibition both from recurrent axon collaterals and from striatal interneurons. What is the effect of intrastratial inhibition on the output of the striatum in awake, behaving animals?

We recorded from striatal target cells in internal (GPi) and external (GPe) globus pallidus while bicuculline was administered locally in the putamen. The drug was allowed to dialyze across a 6-7 mm extent of implanted permselective tubing in each experiment for a period of 0.5 to 1.5 hr. Pallidal cells were studied before and after placement of drug in the tubing while the monkey performed hand movements to visually-displayed or remembered sequences of target positions.

Within 15 min of bicuculline introduction, pallidal cells with either the regular discharge characteristic of GPi or the less regular activity characteristic of GPe showed brief, very high frequency bursts of activity. In some cells these bursts were preceded by abrupt pauses that lasted 35-70 msec. These unusual bursts or pause/bursts did not occur at random. Instead, they clustered at specific task-related epochs, e.g., around the initiation or termination of arm movement.

These data support the hypothesis that GABAergic inhibition is not the primary reason for the "resting" low discharge of striatal output cells. Instead, functional GABAergic inhibition is activated when input from extrastriatal sources excites both striatal output cells and GABAergic interneurons. Feedback or feedforward inhibition normally would act to limit the task-related activation of striatal output cells. When their discharge is not limited, pause-burst episodes in GPi cells could result from the interaction of striatal inhibition and intrinsic properties of target pallidal cells and/or by synaptic actions via the direct and indirect paths.

## 165.8

SUBTHALAMIC 5-HT<sub>2C</sub> RECEPTORS: BEHAVIORAL SUPERSENSITIVITY AND INCREASED EXPRESSION AFTER SEROTONIN DEPLETION. **K. Eberle-Wang\*, A. Mehta, R.J.A. Banks and M-F Chesselet.** Dept. of Pharmacology, U. Pennsylvania, Philadelphia, PA 19104.

Acute stimulation of 5-HT<sub>2C</sub> receptors within the subthalamic nucleus (STN) by peripheral or local administration of the 5-HT<sub>2C</sub> agonist m-cholophenyl-piperazine (m-CPP) produced abnormal orofacial movements in rats (Eberle-Wang et al., '95, '96). The present studies examined the regulation of this effect after serotonin depletion to determine whether removal of stimulation by endogenous serotonin affected the behavioral response and the 5-HT<sub>2C</sub> receptors. Rats received an intraventricular infusion of 5,7 dihydroxytryptamine (100mg/10ml) or vehicle after desimpramine (25 mg/kg, i.p.) pretreatment. Efficacy of serotonin depletion was confirmed by the presence of hyper reactive behaviors 3 days post-surgery and a decrease in serotonin uptake sites measured by autoradiography post-mortem. Repeated administration of m-CPP (1.0 mg/kg, i.p.) caused reproducible increases in orofacial movements throughout the 20 day testing period. In contrast, m-CPP-induced orofacial movements were markedly increased 4 (+91%) and 8 (77%) days post-surgery in the lesioned animals. In a separate group of rats, similar lesions induced a significant increase in both 5-HT<sub>2C</sub> receptor mRNA (+28%) and binding sites (+17%) in the STN 10 days post-surgery. The behavioral sensitivity and compensatory changes in receptor expression observed after serotonin depletion suggest that the subthalamic 5-HT<sub>2C</sub> receptors involved in the control of movements are normally stimulated by endogenous serotonin. Functional and molecular adaptation of 5-HT<sub>2C</sub> receptors in the STN may be involved in hyperkinetic disorders. Supp. by PHS grant MH-48125 and the Tourette Syndrome Association.

## 165.10

LESION OF THE SUBTHALAMIC NUCLEUS (STN) IMPAIRS COMPENSATION FOR MECHANICAL LOADS DUE TO INABILITY TO SUPPRESS ONGOING ANTAGONIST MUSCLE ACTIVITY. **D. Flament\*, I. Neyman, J.J. Nicholas, D.M. Corcos.** Dept. of Phys. Med. & Rehab., Rush Medical College, and School of Kinesiology, Univ. Illinois, Chicago, IL 60612.

Flexions of the wrist were studied in a patient who developed unilateral hemiballismus following a stroke localized to the STN. Three load conditions were tested: 1) a torque loading flexors (agonist), 2) a torque loading extensors (antagonist), and 3) a no torque condition. As it has been suggested that one function of the basal ganglia is to inhibit unwanted motor actions, these 3 loads were applied to test whether antagonist activity can be appropriately suppressed when initiating a movement. Movements of the affected limb were compared with those made by the contralateral limb.

Movements on the affected side were discontinuous, with multiple peaks in acceleration and deceleration. Extensor loads tended to produce discontinuities earlier in the movement, and were associated with an EMG pattern where agonist onset followed movement onset. This was found to be a consequence of the inability to rapidly inhibit tonic antagonist activity at movement onset when this muscle was loaded, and to simultaneously activate the agonist muscle.

The results suggest that the STN is necessary to compensate for mechanical loads and to suppress ongoing antagonist activity when a movement is initiated. The data support the hypothesis that one function of the basal ganglia is to enable selected motor programs and to inhibit potentially competing programs.

Supported by funds from Rush-Presbyterian-St. Luke's Medical Ctr. (DF), and NIH grants KO4-NS01508, RO1-NS28127 and RO1-AR33189 (DMC).

## 165.11

# LESIONS OF THE SUBTHALAMIC NUCLEUS DO NOT BLOCK REACTION TIME IMPAIRMENTS FOLLOWING SYSTEMIC ADMINISTRATION OF D1 OR D2 RECEPTOR ANTAGONISTS.

V.J. Brown and J.M. Phillips (SPON: Brain Research Association) School of Psychology, Univ. St. Andrews, St. Andrews KY16 9JU, Scotland, UK

Blockade of dopamine (DA) in the striatum results in impairments in reaction time performance of humans and animals. This akinesia appears to benefit from lesions, at the level of the pallidum or subthalamic nucleus (STN), of the overactive striatal outflow pathways via pallidum to thalamus and cortex. We examined the effects of systemic administration of the D1, SCH 23390 and the D2 receptor antagonist, Raclopride, on reaction time in rats with bilateral lesions of the STN.

We found a tendency for STN lesioned rats to show an increase in anticipatory responses, consistent with previous reports using this conditioned reaction time task (Baunez et al., 1995, *J. Neurosci.* 15:6531). However, employing a modified procedure in which error trials were repeated until successfully completed, we found that mean reaction time was not speeded following the lesion. Furthermore, the lengthened reaction time induced by systemic administration of either D1 (SCH23390 20, 40 and 80 µg/kg) or D2 (Raclopride 50, 100 and 200 µg/kg) receptor antagonists, was not blocked in the lesioned rats. However, both lesioned and control rats made few or no responses at the beginning of the drug sessions (particularly following higher drug doses) but the STN lesioned rats started responding earlier in the sessions than controls, indicating partial blockade of the effects of the drugs, particularly the D2 antagonist, Raclopride.

The lesions of the STN did not result in general hyperactivity, which might have accounted for the efficacy of this lesion in improving akinesic state induced by striatal dopamine depletion, but they were effective in reducing the cataleptic effects of DA antagonists. (The Wellcome Trust, Project Grant # 040551 z 94)

## 165.13

# EFFECT OF SUBTHALAMIC NUCLEUS (STN) STIMULATION ON MOTOR FUNCTION IN PARKINSON'S DISEASE (PD). I: CLINICAL AND PHYSIOLOGICAL MEASURES. P. Limousin, R. Brown, P. Brown, M. Jahanshahi, J. Rothwell\*. MRC Human Movement and Balance Unit, Institute of Neurology, Queen Square, London, WC1N3BG, UK

High frequency electrical stimulation of STN is an experimental neurosurgical treatment in disabling PD which is reversible when the stimulation is switched off. Five PD patients (mean age (± sem) 53 years ± 2 and mean duration of the disease 16 years ± 2) with bilateral STN stimulation (Grenoble University Hospital, Pr Benabid) were studied after an overnight withdrawal of medication. Motor function was compared with both stimulators turned either off or on in a randomized sequence. Strength and Bereitschaftspotential (BP) were assessed for the worst clinical side, stretch reflexes were assessed on both sides and the results averaged. The mean clinical evaluation score (motor UPDRS) decreased from 53 (108) ± 8 to 21 ± 4 (60%,  $p < 0.05$ ) when the stimulation was turned on. The upper limb akinesia subscore decreased from 8 (12) ± 1 to 3 ± 1 (63%,  $p < 0.005$ ), the rigidity item decreased from 3 (4) ± 0.3 to 1 ± 0.3 (76%,  $p < 0.0005$ ).

The maximal strength of the forearm extensors, during an isometric contraction against a strain gauge, was increased by a mean of 195% ± 29 in the stimulated condition. The BP, preceding self-initiated free direction joystick movement was slightly increased (peak amplitude at Cz: 4.78 µV ± 1.27 to 5.78 µV ± 0.88, NS), with the major effect being on the second (NS) component. The latency, the duration and the amplitude of the short and long latency component of the forearm flexor stretch reflex were not modified by the stimulation.

The increase in strength by STN stimulation and the increase in premovement BP may contribute to the decrease in bradykinesia. The effect of STN stimulation in rigidity does not seem to be related to a change in the stretch reflex, other mechanisms might be involved. (Funded by MRC UK, Wellcome Trust and EU)

## 165.15

# EXCITOTOXIC LESIONS OF THE SUBTHALAMIC NUCLEUS, BUT NOT THE PEDUNCULOPONTINE NUCLEUS, AMELIORATE ASYMMETRY INDUCED BY STRIATAL DOPAMINE DEPLETION J.M. Phillips, V.J. Brown, S.P. Gupta, M.P. Latimer and P. Winn (SPON: Brain Research Association) School of Psychology, Univ. St. Andrews, St. Andrews KY16 9JU, Scotland.

The motor symptoms of Parkinson's disease result from striatal dopamine (DA) depletion, which in turn leads to overactivity of striatal outflow pathways via globus pallidus to thalamus and cortex and to pontine nuclei. Lesions in these pathways, at the level of the globus pallidus or subthalamic nucleus (STN), have been shown to ameliorate some of the Parkinsonian motor deficits. It is possible that the restorative motor effects of the STN lesion are due to the induction of a hyperactive state rather than a genuine restoration of impaired function by reestablishing normal levels of activity in the outflow pathways. Thus, it is important to examine the effects of STN lesions on deficits following striatal DA depletion on a range of tasks, rather than focussing solely on motor functions. Unilateral striatal DA depletion results in sensorimotor asymmetry which is not due to an impairment in motor execution per se (Schallert et al. 1982, *Pharm. Bioch. Behav.* 16:455). We examined the effects of STN lesions and lesions of the striatopontine outflow pathway, at the level of the pedunculopontine nucleus (PPTg), on DA depletion-induced sensorimotor asymmetry. Whereas lesions of the STN restored symmetry following the striatal lesion, there was no effect (and, in particular, no evidence of hyperactivity) of the STN lesion on time to contact the patches. Lesions of the PPTg were without effect, failing to reduce the asymmetry induced by striatal lesion. These results suggest that specific deficits resulting from disordered basal ganglia function can be ameliorated by lesions of the STN and that the sensorimotor asymmetry following unilateral striatal DA depletion is due to "looped" thalamocortical striatal outflow, rather than striatopontine outflow. ## 165.12

# RESPONSES OF VENTRAL PALLIDAL NEURONS TO ELECTRICAL ACTIVATION OF THE SUBTHALAMIC NUCLEUS. M.S. Turner and T.C. Napier. Dept. of Pharmacol., Loyola Univ. Chicago, Sch. of Med., Maywood, IL 60153.

An efferent pathway from the subthalamic nucleus terminates in the ventral pallidum (VP). Neurons in the subthalamic nucleus use glutamate as a neurotransmitter, and the VP contains excitatory amino acid receptors. Microiontophoretic application of glutamate rapidly increases firing in the majority of VP neurons examined. These observations suggest that the VP may be under an excitatory amino acid control that originates in the subthalamic nucleus. The objective of this study was to characterize the response of VP neurons to electrical activation of the subthalamic nucleus and to determine the proportion of VP neurons that exhibit evoked responses to this stimulation. To do this, the subthalamic nucleus of chloral hydrate-anesthetized rats was electrically activated using a concentric bipolar stimulating electrode, and neuronal activity in the VP was monitored using extracellular electrophysiological recording techniques. Of the 67 neurons studied, 60 neurons (90%) demonstrated evoked responses to subthalamic nucleus stimulation. Of these, 39 exhibited an excitatory response (neuronal firing frequency increased to 249% above control) whose onset was 4.3±0.4ms following stimulation, with a duration of 14.5±1.9ms. Ongoing studies are evaluating the excitatory amino acid receptor-subtypes responsible for this response. Some sensitive neurons displayed other responses, including short latency (7.9±1.4ms; n=20) inhibitions, long latency (30.6±5.7ms; n=13) excitations and long latency (47.4±12.0ms; n=7) inhibitions. Complex responses occurred in 30% of sensitive neurons, with the most common (13% of sensitive neurons) being a short latency excitation followed by a long latency inhibition. Long latency evoked responses probably represent multisynaptic pathways and short latency responses are consistent with a monosynaptic pathway from the subthalamic nucleus to the VP. The large number of neurons responding to stimulation of the subthalamic nucleus indicates that the subthalamic nucleus has a significant influence on the VP. Thus, the response of the VP to the increased release of excitatory amino acid from the subthalamic nucleus that occurs in Parkinson's Disease could contribute to the symptoms of this neuropathology. # EFFECTS OF SUBTHALAMIC NUCLEUS (STN) STIMULATION ON MOTOR FUNCTION IN PARKINSON'S DISEASE (PD) II: BEHAVIOURAL MEASURES OF SIMPLE AND COMPLEX HAND-ARM MOVEMENT. R.G. Brown, M. Jahanshahi, P. Limousin, J.C. Rothwell, S. Channon\*. MRC HMBU, Institute of Neurology, Queen Square, London WC1N 3BG, UK.

The times taken to initiate and execute a variety of voluntary movements were assessed in 5 patients with PD, with and without STN stimulation in counter-balanced order. The tasks were: time to make a self-initiated 30° forearm flexion either alone (FLEX), or with a simultaneous 20 N 'squeeze' of the hand (FLEX+); the time to initiate (IT) and execute (MT) a multi-joint 15 cm movement in the sagittal plane in response to a visual reaction stimulus; the rate of repetitive finger tapping over a 30 s period (TAP), and the rate of picking up and placing pegs in a row of 3 mm holes over a 30 s period (PEG). Both right and left sides were assessed and the results averaged. Without stimulation, subjects showed marked slowing on all tasks. STN stimulation had a significant (1-tailed paired t-tests,  $p < 0.05$ ), positive effect on several measures. Most marked and consistent across subjects were the improvement in the speed of executing arm-hand movements. Simple FLEX time decreased by 154.3 ms±28.6 (39.2%), while FLEX+ improved by 213.6 ms±31.4 (45.8%). MT decreased by 283 ms±153 (mean±sem) (29.5%±9.9). The ability to perform the PEG task was also reliably improved, with an additional 2.3±0.87 pegs (24.9%±8.6). Smaller mean improvement, with greater between-subject variability, was seen in the other measures. IT improved by 101.8 ms±77.8 ( $p > 0.13$ ) (12.3%±9.5), while TAP increased by only 5.3 taps±10.1 over 30 s ( $p > 0.32$ ) (4.9%±12.3).

Thus stimulation of the STN in PD increases the speed of simple and complex movements indicating a direct facilitation of motor execution. In contrast, the effects on movement preparation (IT) and the ability to sustain repetitive movement seem less sensitive to the effects of STN stimulation. # BILATERAL 6-HYDROXYDOPAMINE LESIONS IN DOPAMINERGIC A8 CELL-GROUP PRODUCE LONG-LASTING DEFICITS IN MOTOR PROGRAMMING OF CATS. M.P.M. Arts, M.A. Gingras\* and A.R. Coops. Dept. of Psychoneuropharmacology, P.O. Box 9101, 6500HB, Nijmegen, The Netherlands.

The A8 cell-group (A8) have been suggested to play a role in the progressive degeneration of dopaminergic cells in Parkinson's disease (1). However, the contribution of the degeneration of A8 cells to parkinsonian symptoms is unknown. Still, the feline A8 has been suggested to contribute to at least one parkinsonian symptom, namely the mask-like expression of the face (2). For these reasons, we studied the effects of 6-OHDA lesions (10 µg/0.5 µL) in the A8 of cats (n=8) pretreated with 10 µg/0.5 µL desipramine. Behavioural deficits were studied with the help of a particular treadmill set-up that allows the assessment of subtle changes in motor programming (3). Effects were analyzed daily for 26 days (pre-lesion: 9 days; post-lesion: 17 days) and, thereafter, at increasing intervals for a minimum period of 7 weeks. The lesion being restricted to the A8 produced consistent and long-lasting deficits in all cats. The cats had a significantly reduced ability to switch arbitrarily motor patterns. The cats became fully bound to external stimuli provided by the apparatus and used these stimuli for switching their motor patterns. Moreover, the sequential patterning of their motor behaviour was fully changed. Finally, the kinetic melody of the movements was permanently changed. It is concluded that subtle lesions in the feline A8 produce long-lasting deficits in motor programming, implying that degeneration of dopaminergic cells in this brain region may also contribute to symptoms seen in Parkinson's disease. ## DEFICITS IN MOTOR MEMORY PRODUCED BY BILATERAL 6-OHDA CAUDATE LESIONS IN RAT.

X. Liu\*, R. Strecker, C. Geronimo and J. Brener. Depts. of Psychology and Psychiatry, SUNY, Stony Brook, NY 11794-2500.

Patients with Parkinson's disease are reported to have greater difficulty in executing sequential movements when external cues are not provided than when external cues are provided. The current experiment was designed to model this phenomenon in rats. Subjects were rewarded with sucrose for pressing three force-sensitive beams in one of two sequences. Each was signalled by a stimulus light. In one of the sequences, the order was: Left, Right, Center, whereas in the other sequence, the order was: Right, Left Center. Upon completion of the signalled sequence, a reward was delivered to a central food tray. For one group of rats, each of three sequential beam presses was signalled by a corresponding light, whereas for another group, only the first press was signalled, while the two following presses were not. Time intervals between consecutive responses as well as sequence errors were recorded.

Bilateral 6-OHDA injections into the caudate putamen resulted in 50% DA depletion in this structure. In both groups the lesion caused lengthening of reaction times to the first signal light and to the time intervals between the first and second beam presses in the sequence. These changes were found to be due to the increases in the numbers of response sequence errors. Furthermore, for the noncued rats, there was an additional lengthening in the interval between the second and the third presses that was not shown by the cued rats. The results suggest that DA plays an important role in controlling sequential motor behaviors, and in keeping movement elements in motor working memory. (Supported by HL-42366 to JB.)

## 165.19

## LEARNED MOTOR PERFORMANCE IN RATS: PRODUCTION OF TARGET RESPONSE FORCES.

J. Brener\*, X. Liu, S. M. Mitchell and S. Carnicom. Dept. of Psychology, SUNY, Stony Brook, NY 11794-2500 and Dept. of Psychology, University of New Hampshire, Durham, NH 03824-3567

Rats were rewarded with sucrose for pressing a force-sensitive beam with a criterion force. A concurrent feedback (CFB) group received auditory feedback as soon as their presses reached the criterion force whereas a terminal feedback group (TFB) only received auditory feedback on the termination of presses that met the force criterion. These contingencies permitted subjects in the CFB group, but not the TFB group to regulate force on the basis of external feedback. Fine-grain analyses of force-time trajectories under various conditions provided strong evidence that beam presses were composed of an initial ballistic phase followed by a controlled phase during which response force "horned in" on the force criterion under feedback control. The period of the feedback loop was found to be significantly longer in the CFB group (94.4 milliseconds between corrections) than in the TFB group (59.2 milliseconds between corrections). This difference is attributed to the use of exteroceptive feedback in force control by the CFB group in contrast to exclusive reliance on kinesthetic feedback by the TFB group.

Low doses of apomorphine and bilateral 6-OHDA SNpc lesions impaired force control under the TFB condition. The nature of the deficiencies suggest that under these conditions, the forebrain dopamine system was preferentially involved in the controlled phase of isometric beam presses: i.e. during the adjustment of response force on the basis of kinesthetic feedback. (Supported by HL-42366 to JB.)

## 165.18

LESIONS OF THE VENTRAL-MEDIAL STRIATUM AND DORSAL HIPPOCAMPAL FORMATION INDUCE OVERLAPPING BUT DISTINCT BEHAVIORAL ABNORMALITIES. M. Burke, A. Cousins, A. Perez, M. Peterson, N. Dumont, J. McLearn, S. Bhedda, S. Hye, S. King, M. Nislico, M. Allen-Racette, J. Losi, C. Engels, and J. P. Ryan.

Neurobehavioral Science Lab, Psychology Dept., State University of New York at Plattsburgh, Plattsburgh, New York 12901.

Disruption of the hippocampal system induces a variety of behavioral abnormalities that can be directly related to the hippocampus or to a disturbance in neural connections with other brain regions within the system such as the striatum. The present study attempted to delineate the aberrant behaviors of hippocampally lesioned animals in the T-maze, Activity Chamber, and Water Maze from the behaviors induced by lesions of the ventral-medial striatum. Using Long-Evans hooded rats, lesions of the dorsal hippocampus were induced with a total injection of 25 µg/µL of colchicine administered bilaterally. Lesions of the ventral-medial striatum were induced with a total injection of 30 µg/µL colchicine administered bilaterally. Preliminary results indicate that (1) marked deficits in Spontaneous Alternation Behavior are induced following both hippocampal and striatal lesions, (2) repetitive circumference swimming in the Water Maze is a unique characteristic of hippocampal lesions, and (3) increases in locomotion appear to be present in both lesioned groups with striatal lesioned animals demonstrating a unique pattern of activity in the T-maze.

## OCULOMOTOR SYSTEM: CORTEX

## 166.1

## MODULATORY ROLE OF D1-DOPAMINE RECEPTORS IN MNEMONIC CODING OF MONKEY PREFRONTAL CORTICAL NEURONS

T. Sawaguchi\* and K. Kubota. Dept. of Behavioral and Brain Sciences, Primate Res. Inst., Kyoto Univ., Inuyama, Aichi 484, Japan.

To examine the role of dopamine receptors in visuospatial mnemonic coding of neurons of the prefrontal cortex (PFC), dopamine antagonists (SCH23390 for a D1-antagonist and sulpiride for a D2-antagonist) were applied iontophoretically to PFC neurons of two rhesus monkeys which performed an oculomotor delayed-response (ODR) task. The ODR task was initiated by having the monkeys fixate on a central spot in a CRT; this was followed by an eye fixation (1 s), cue (one of four peripheral cues, 0.5 s, 15° in eccentricity), delay (fixation cue only, 4 s), and go periods (memory-guided saccade to the cued-target location). A total of 62 neurons, sampled from periprincipal sulcal areas, showed a delay period activity with a preferred direction, i.e., directional delay period activity, and this activity fit well with a cosine function with a proportion ( $r^2$ ) of mostly more than 0.8. Iontophoretic applications of SCH23390, but not sulpiride, with a 50 nA current decreased or increased the activities of most of the neurons with directional delay period activity ( $N=48/62$ ), and the effect was mostly decreasing ( $N=43/48$ ). For all of the neurons affected by SCH23390, their directional tuning, examined by the cosine curve fitting, was attenuated to become flatter during the application of SCH23390, whether the activity was increased or decreased by it. However, the preferred direction itself was not significantly altered during the application. These results suggest that the exciting and inhibiting activations of D1-dopamine receptors play modulatory roles in maintaining the directional or "mnemonic" coding of delay period activity of PFC neurons during ODR performance.

## 166.2

TRANSCRANIAL MAGNETIC STIMULATION OF THE PREFRONTAL CORTEX DELAYS CONTRALATERAL ENDOGENOUS SACCADDES, Tony Ro, Avishai Henik\*, Liana Machado and Robert D. Rafal. Dept. of Neurology and Center for Neuroscience, UC Davis and Dept. of Behavioral Sciences, Ben-Gurion Univ. of the Negev, Beer-Sheva, Israel

The contributions of the superior prefrontal cortex (SPFC) and the superior parietal lobule (SPL) in generating voluntary endogenous and reflexive visually guided saccades were investigated using transcranial magnetic stimulation (TMS). Subjects made horizontal choice saccades in response to a central arrowhead (endogenous signal) or a peripheral asterisk (exogenous signal) which were presented along with a single TMS pulse at varying intervals. When TMS was over the SPFC, saccade latencies in response to an endogenous go signal toward the hemifield contralateral to the TMS were delayed. No consistent effects were observed when the go signal was exogenous and TMS was over the SPFC or when TMS was over the SPL for either saccade type. The delayed contralateral endogenous saccades observed in this study are likely a consequence of disruption in the normal operations of the human frontal eye field.

## 166.3

**TRANSCRANIAL MAGNETIC STIMULATION (TMS) OF THE LEFT POSTERIOR PARIETAL AND PREFRONTAL CORTEX DURING MEMORY-GUIDED SACCADDES. IS THERE A HEMISPHERE ASYMMETRY IN SACCADDE CONTROL?** R.M. Müri<sup>1</sup>, B. Gaymard, S. Rivaud, A.J. Vermeersch, J.F. Cassarini, C.W. Hess<sup>2</sup>, C. Pierrot-Deseilligny.

INSERM 289, Hôp. de la Salpêtrière, 47 Bd de l'Hôpital, F-75651 Paris, France, and <sup>2</sup>Dep. of Neurology, University of Bern, Inselspital, CH-3010 Bern, Switzerland.

In a previous study (1) using transcranial magnetic stimulation (TMS), we have shown that the right posterior parietal cortex (PPC) and the right dorsolateral prefrontal cortex (PFC) play different roles in the control of contralateral memory-guided saccades. This study investigated TMS over the left homologous regions. In 6 normal subjects, temporal mapping was performed by stimulating 160 ms, 260 ms, 360 ms after the flashed target, during the mid-memorization period (700 - 1500 ms), and 100 ms after the go-signal, i.e. the extinguishing of the central fixation point (2100 ms). Horizontal component of saccades were recorded by DC-electrooculography. When comparing with the percentage of error in amplitude (PEA) without stimulation (median: 9%, range: 2-12%), a significant increase in the PEA was found for contralateral saccades with TMS applied over the PFC during the mid-memorization period (median: 16%, range: 6-28%, Mann-Whitney test,  $p < 0.01$ ). The PEA of ipsilateral saccades was not affected. Stimulation over the left PPC had no significant effect on PEA of contra- and ipsilateral saccades. The same was found in the control experiments with stimulation over the occipital cortex. These results show a difference between the previously reported effects of right TMS: for left stimulation, only prefrontal TMS (during the mid-memorization phase) had a significant effect on the right PEA. This suggests that 1) memory-guided saccades are mainly controlled by the contralateral PFC, and 2) an asymmetry between the right and left PPC exists concerning the control of these saccades.

**FRONTAL EYE FIELD VISUAL ACTIVITY PRECEDING SACCADDES TO MOVING TARGETS.** D. Shi\*, H. R. Friedman, and C. J. Bruce. Section of Neurobiology, Yale Univ. Sch. Med., New Haven, CT 06520-8001.

Saccades to moving targets are usually accurate even though saccades are executed ballistically and take 100-200 ms to program, implying a predictive mechanism. Previously, we studied presaccadic movement activity in the macaque monkey's FEF in conjunction with such predictive saccades and found that this movement activity showed significant compensation for target velocity. Here we examined visual activity of both the purely visual and visuomotor types of FEF cells. For each cell, the optimal receptive field (RF) vector was first estimated and then parametric step-ramp experiments were conducted wherein targets moved either 1) towards the cell's RF center along paths orthogonal to the cell's optimal vector, or 2) in radial paths along the optimal vector, both centrifugal and centripetal. For Exp. 1 we analyzed the neuronal data by adding a parameter (K) to quantify any compensation of the cell's best direction for target velocity to our Gaussian formula for the polar tuning of FEF response fields:  $R_i = B + R \cdot \exp(-0.5((\theta_i - (\theta_c - K \cdot d\theta_i)) / \sigma)^2)$  wherein  $R_i$  is the spike rate for trial  $i$  typically measured over the 50-200 ms interval after the step,  $\theta_i$  is the target's initial polar coordinate on trial  $i$ , and  $d\theta_i$  is its angular velocity. The remaining parameters are fit:  $\theta_c$  estimates the cell's optimal polar direction,  $\sigma$  the breadth of its directional tuning, and  $K$  estimates (in ms) the velocity compensation. Almost all FEF visual responses showed highly significant compensation, with most  $K$  values in the 100-200 ms range. Moreover, the degree of velocity compensation increased with time following the step, indicating that FEF visual responses to moving targets are continually updated. Analogous compensation was seen for radial motion (Exp. 2). These data suggest a mechanism for the velocity compensation of FEF movement activity. They also help explain why projections from visual motion areas in posterior cortex (e.g., MT, MST) are not confined to FEF's smooth pursuit representation in the depths of the arcuate sulcus, but terminate extensively in the saccadic FEF as well, where they could afford predictive motion compensation to the visual responses there. ## 166.7

**MACAQUE FRONTAL EYE FIELD INPUT TO SACCADDE-RELATED CELLS IN THE SUPERIOR COLLICULUS.** J.O. Holminski\* and M.A. Segraves. Dept. of Neurobiol. and Physiol., Inst. for Neuroscience, Northwestern Univ., Evanston, IL 60208.

Frontal eye field (FEF) neurons with movement-related or foveal visual activity project to the intermediate layers of the superior colliculus (SC) providing information concerning the maintenance and release of fixation and parameters of the impending saccade. The purpose of this preliminary investigation was to identify and characterize SC neurons receiving this FEF input. Extracellular recordings were made simultaneously in the saccade-related regions of the FEF and SC. Antidromic excitation was used to identify pairs of interconnected FEF and SC sites. Then, the FEF site was stimulated and evoked potentials were recorded every 100  $\mu$ m dorso-ventrally through the SC. Next, SC cells receiving short latency FEF input were identified with orthodromic stimulation and their activity characterized during visuomotor tasks.

Four pairs of interconnected FEF and SC sites in one monkey were identified with antidromic excitation. Field potentials were recorded and current source density was calculated, revealing FEF excitatory input concentrated at depths where cells with saccade-related activity were found. Nineteen superior collicular neurons receiving short latency, excitatory FEF input were identified and characterized in detail. An effective orthodromic stimulus was a pair of biphasic pulses (negative first, 0.02 ms total pulse width) with 3 ms separation between pulses applied 0.1-0.3 ms after the SC cell fired spontaneously. Current thresholds ranged from 100-800  $\mu$ A (mean 392  $\mu$ A); latencies from 2.0-5.8 ms (mean 3.9 ms). Every SC cell activated by FEF stimulation had movement-related activity. This activity was compared to a recent description of saccade-related activity in the SC (Munoz and Wurtz, 1995). Eighty-four percent of FEF-driven cells were classified as burst cells, discharging a burst of action potentials immediately before saccade onset. Sixteen percent were classified as buildup cells, discharging a long-lead buildup of activity between the signal for saccade initiation and saccade onset. There was no indication that the FEF contacts one of these cell types at earlier intervals than the other. Instead, it appears that the FEF makes short latency, presumably monosynaptic, contact with both buildup and burst cell types, allowing the FEF to directly influence all saccade-related activity in the SC.

**NEURAL CONTROL OF SACCADDE INITIATION STUDIED WITH THE COUNTERMANDING PARADIGM: FRONTAL EYE FIELD.** J.D. Schall<sup>1</sup> & D.P. Hanes. Vanderbilt University, Nashville TN 37240

A countermanding paradigm was employed to distinguish the functional role of neurons in macaque frontal eye field in generating saccades. On NO SIGNAL trials macaque monkeys shifted gaze to fixate a target that jumped to either side of the fixation spot which was removed. The target was positioned either in a neuron's movement field or in the opposite hemifield. On a fraction of trials the fixation spot reappeared at unpredictable intervals following the target jump. On these STOP SIGNAL trials monkeys were rewarded for countermanding the planned saccade and maintaining fixation. From a race model between independent GO and STOP processes, the time needed to inhibit the planned movement, STOP SIGNAL REACTION TIME (SSRT) was estimated (Hanes & Schall, 1995, Vis. Neurosci. 12:929). Based on the SSRT and the variation in saccade latency in NO SIGNAL trials the activity of individual neurons was compared between STOP SIGNAL trials when a saccade was inhibited and NO SIGNAL trials when a saccade was generated but would have been inhibited if the STOP SIGNAL had been given.

Two main populations of neurons were identified in frontal eye field. A population of cells with movement-related activity exhibited differential modulation before inhibited as compared to generated saccades. Because the difference in activity occurred before the SSRT had elapsed, these neurons can play a direct role in the voluntary control of movement. These neurons tended to be located deeper in the arcuate sulcus. A different population of visually responsive cells was recorded that did not exhibit differential activity before the SSRT had elapsed. These neurons tended to be located more superficially in the arcuate sulcus. These findings indicate the utility of the countermanding paradigm in distinguishing the functional role of neurons in movement production. (Supported by R01-MH55806 and F31-MH11178)

## 166.6

**SELECTIVE DISRUPTION OF MEMORY-GUIDED SACCADDES WITH INJECTION OF A CHOLINERGIC ANTAGONIST IN THE FRONTAL EYE FIELD OF MONKEY.** E. C. Dias\*, D. M. Compaan, M. M. Mesulam and M. A. Segraves. Institute for Neuroscience, Northwestern Univ., Chicago and Evanston, IL.

The frontal cortex receives a massive projection of cholinergic axons originating in the basal forebrain. There is a wealth of experimental results suggesting that the cholinergic muscarinic system plays a central role in learning and memory. For example, systemic injection of scopolamine, a cholinergic muscarinic antagonist, impairs memory in a variety of species, including primates. We tested the effect of local inactivation of the cholinergic system in the frontal eye field (FEF), a cortical region strongly involved in the generation of eye movements. Since many of the cells in the FEF have a memory component to their responses, we hypothesized that microinjections of scopolamine directly into the FEF might disrupt memory-guided saccades, but that visually-guided saccades would remain unchanged.

We made 6 microinjections (0.5-1.0  $\mu$ l) of scopolamine hydrochloride (10mg/ml) within the FEF. Injections were made through a cannula with an electrode protruding from its tip, allowing constant monitoring of cell activity. The main effect of the scopolamine injections was a decrease in accuracy of memory-guided saccades, which increased as the memory delay period was increased. At some sites, this deficit was mainly for saccades whose amplitude and direction were similar to the optimal saccade vector represented by that site, but in other sites the accuracy of saccades in all directions was reduced. There was also an increase in saccade latencies and frequently a reduction in saccade velocities. There were no observable effects of the injection on the visually-guided saccades. In addition to these saccade-related deficits, the monkey had difficulty maintaining fixation after the injection, and was easily distracted from the task. These findings are in contrast to FEF injections of muscimol, a GABA agonist, which disrupt both visual and memory-guided saccades. In addition, muscimol silences cell activity at the injection site, whereas the cells remained active after scopolamine injection.

These preliminary data suggest that the cholinergic afferent system is important for the memory component of the responses of FEF cells, and may also be involved in the control of fixation.

## 166.8

**INDIVIDUAL NEURONS IN THE VENTRAL ANTERIOR NUCLEUS OF THE THALAMUS OF CEBUS MONKEYS PROJECT TO BOTH THE SUPPLEMENTARY EYE FIELD AND THE FRONTAL EYE FIELD.**

J.C. Lynch<sup>1,2,3</sup>, J.-R. Tian<sup>4,5</sup>, and A.W. Chiemprabha<sup>1</sup>. Departments of Anatomy, Ophthalmology<sup>2</sup>, and Neurology<sup>3</sup>, University of Mississippi Medical Center, Jackson, MS 39216; and the Brain Research Institute<sup>4</sup> and Department of Neurobiology<sup>5</sup>, UCLA, Los Angeles, CA 90095.

Thalamocortical projections to the saccadic eye movement subregions of the supplementary eye field (SEFsac) and the frontal eye field (FEFsac) were studied in 3 *Cebus apella* monkeys. The SEFsac and FEFsac were localized using standard low-threshold electrical microstimulation. Retrogradely-transported fluorescent dyes were then injected into these areas. Neurons labeled by the SEFsac injections were found predominantly in area X of the VL complex and in the VA nucleus, with additional labeled neurons in the MD, VLo, VLc, and intralaminar nuclei. Neurons labeled by FEFsac injections were concentrated in the paralaminar MD nucleus, with additional labeled neurons in the VA nucleus, area X, VLc, VLo, and the intralaminar nuclei. In one monkey, the combination of tracers that was used permitted the detection of neurons labeled by both the SEFsac and FEFsac injections. Double-labeled neurons were observed only in the VA nucleus; 85.7% of these were in the magnocellular division (VAmc) and the rest were near the VAmc/VAPc border. Within VAmc, 12.2% of the neurons that were labeled by the FEF injection also sent collaterals to the SEF; 5.7% of the neurons that were labeled by the SEF injection also projected to the FEF. The VAmc is known to receive input from the substantia nigra and to relay neural information from the substantia nigra to the FEF. The present results demonstrate that some VAmc neurons are able to provide identical neural information to both the SEFsac and the FEFsac.

THE TRIPLE-STEP PARADIGM: AN ATTEMPT TO DISSOCIATE TARGET MAPPING FROM NEXT SACCADIC SELECTION. J.-R. Tian\*, J. Schlag, and M. Schlag-Rey. BRI and Dept. of Neurobiology, UCLA, Los Angeles, CA 90095-1763.

Quasi-visual cells (QV) are visual cells that discharge in the double-step paradigm when the subject (monkey) is ready to make a saccade toward a location where a target was flashed if - and only if - the initial saccade has brought this location in the cell receptive field. Such cells, first found in superior colliculus (Mays & Sparks, J.N. 1980, 43: 207) also exist in parietal cortex and frontal eye field (FEF). Their role can be interpreted in different ways: they can be elements of a dynamic map representing spatial relations between targets or they may signal the next, selected saccade.

To test these hypotheses, we designed a triple-step paradigm, consisting of one fixation point plus 3 targets, all flashed before the monkey had time to make the first saccade. The sites where targets were flashed were chosen so that only one of the last 2 target locations would be in the cell receptive field when the eyes had moved to the first target position. The "next saccade" hypothesis predicts QV cell activation at that position only if the next saccade is directed to the cell receptive field. In contrast, the "target mapping" hypothesis predicts cell activation even if the next saccade is directed away from the receptive field.

Unit recordings were made from visual FEF cells. Up to now, the majority of the QV cells tested were of the "target mapping" type. (Supported by USPHS grants EY02305 and 05879).

## 166.11

THE ROLE OF DORSOLATERAL PREFRONTAL CORTEX (DLPFC) IN THE EXECUTION OF SACCADIC TO REMEMBERED LOCATIONS. E.P. O'Sullivan<sup>1,2</sup>, S.C. Baker<sup>2</sup>, C.D. Frith<sup>3</sup>, L. Henderson<sup>1</sup>, D.J. Brooks<sup>2</sup>, C. Kennard<sup>1\*</sup>. <sup>1</sup>Dept of Clinical Neuroscience, Charing Cross & Westminster Med Sch, <sup>2</sup>MRC Cyclotron Unit, Hammersmith Hosp, <sup>3</sup>Wellcome Dept of Cognitive Neurology, Inst of Neurology, London, United Kingdom.

Electrophysiological studies of non-human primates executing saccades to remembered locations suggest that DLPFC is primarily concerned with working memory for locations in body-centred space. However, the requirement to delay saccades until a command given after target offset makes severe demands on attentional control processes, notably suppression of the tendency for target onset to attract an immediate saccade and such executive control of the saccadic system has been shown to be impaired in humans with prefrontal lesions. We therefore decided to compare regional brain activation during the execution of delayed saccades (DS), with and without a memory requirement.

The bolus  $H_2^{15}O$  PET technique was used to measure rCBF changes over a 30-40 second epoch. Eight normal volunteers were scanned while resting with eyes closed and during performance of a single trial in each of two DS tasks. In both a peripheral target was illuminated for 200 ms, and the saccade was summoned by a non-spatial cue after a delay of 45 seconds only, to exclude changes related to the motor component of the saccade. In the DS REM task target location had to be stored throughout the delay, whilst in the DS VIS task the target persisted until after the saccade. Four scans were obtained on each subject under each of these three conditions. Data were analysed with the statistical parametric mapping technique.

Comparison of either DS task to the baseline control revealed activation of DLPFC (right) but not the frontal eye field, whereas direct comparison of the DS tasks with and without the memory requirement failed to detect differential activations of DLPFC. This implies that activation relating to the motor component of the saccade was attenuated and that DLPFC was activated in relation to saccadic suppression, but not by the mnemonic component. (supported by The Wellcome Trust).

## OCULOMOTOR SYSTEM: SMOOTH PURSUIT

## 167.1

RESPONSE PROPERTIES OF SMALL-FIELD PRETECTAL NUCLEUS OF THE OPTIC TRACT (NOT) NEURONS DURING SMOOTH PURSUIT EYE MOVEMENTS. M.J. Mustari\*, A. Burrows, and C. Livingston. Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX. 77555.

The NOT comprises an essential part of the afferent limb for optokinetic response (OKR), elicited during coherent full-field visual motion. We reported previously<sup>1</sup> that the primate NOT contains units with large receptive fields (RFs) well suited to supporting the OKR. Here, we examine the potential role of parafoveal visual (PFV) neurons in the initiation and maintenance of smooth pursuit (SP). We recorded from 30 PFV NOT units in 2 monkeys (Macaca mulatta) during periodic and step-ramp SP tasks. Eye movements were measured by electromagnetic means, employing a scleral search coil. During SP, monkeys tended to have small tracking errors resulting in residual visual motion of  $\leq 1$  to  $10^\circ/s$  and modulation of PFV neuronal discharge. PFV units ceased their elevated discharge when the target spot was briefly extinguished during SP, despite maintained pursuit eye movements. PFV units respond preferentially for low velocity ( $<10^\circ/s$ ) stimuli, moving ipsiversively. For PFV neurons to play a role in SP initiation their response latency to the onset of ipsiversive visual motion should lead smooth pursuit initiation. During step-ramp target tracking, we found that PFV unit discharge always lead SP initiation; by 20 to 80 ms. In summary, the sensitivity of PFV neurons to visual slip could be useful in initiating SP, perhaps through direct projections to the medial vestibular nucleus and nucleus prepositus hypoglossi<sup>2</sup>. Potentially, PFV units could play a role in adjusting the gain of SP through climbing fiber associated pathways<sup>2</sup>.

## 166.10

SUPPLEMENTARY EYE FIELD (SEF) NEURONAL ACTIVITY IN MONKEYS CAN PREDICT THE SUCCESSFUL PERFORMANCE OF ANTISACCADIC TASKS. N. Amador, M. Schlag-Rey\* & J. Schlag. BRI & Dept of Neurobiology, UCLA, Los Angeles, Ca. 90095-1763.

We studied neuronal activity in the SEF of 2 monkeys performing interleaved antisaccades (AS) and prosaccades (PS) in directions chosen to coincide with each cell preferred or null direction. The instruction to make AS or PS was conveyed on each trial by a small square or a dot appearing as the initial fixation point. The saccade target (always a dot) was flashed during or after fixation of the instruction cue. The go signal was provided by the offset of the cue.

On correct trials, out of 39 units (located in the SEF region responsive to low threshold electrical stimulation), 72% had a significantly higher firing rate for AS than for PS at one or several phases of the task (initial fixation, target onset, movement onset) while the opposite was true for only 5%. Activity differentiating AS and PS was measured for identical stimulus locations when related to initial fixation or target, and for similar trajectories when related to movement. The tendency for the cells to favor AS in competition with reflexive PS programmed in the other hemisphere was even higher for presaccadic units, which may reflect a final decision (90% vs. 0%). The greater activity seen on those AS trials can begin with fixation of the instruction cue. In that case, we propose that this differential firing rate sets the brain to block a compelling PS whatever its direction. Consistent with this result, when an AS instruction was given but a PS was made, the firing rate was generally lower than that observed on interleaved correct AS trials. Our results suggest a neuronal mechanism for the purposeful inhibition of visual grasping reflexes which is known to be impaired by frontal lobe lesions. ## 167.2

ACTIVITY OF PURKINJE CELLS IN MONKEY CEREBELLUM DURING TRACKING OF TWO-DIMENSIONAL TRAJECTORIES. H.-C. Leung\* & R.E. Keizer. Institute for Neuroscience & Department of Physiology, Northwestern University Medical School, Chicago, IL 60611

Purkinje cells in flocculus/paraflocculus of the cerebellum were recorded during tracking of a laser spot moving along circular (0.6 Hz,  $5^\circ$ ), and sum-of-two-sines (0.6 Hz,  $5^\circ$ ; 0.9 Hz,  $3.3^\circ$ ) trajectories, as well as the component sinusoids used to create these trajectories. Saccadic and position sensitivity data were also obtained. Target position was computer controlled by horizontal and vertical mirror galvanometers. Eye position was monitored with a scleral search coil system. Juice reward was given for correct fixation and tracking. Pursuit directional sensitivity was determined from responses during tracking of a target moving sinusoidally in horizontal, vertical, and two diagonal ( $\pm 45^\circ$ ) directions. Most cells were maximally modulated during either horizontal or vertical pursuit, although some cells had oblique preferred directions.

To assess the linearity of each cell's response, circular and sum-of-two-sines period response histograms were compared with histograms created by summing responses from the sinusoidal components used to create these trajectories. For example, combined horizontal and vertical sinusoidal motions  $90^\circ$  out of phase produce circular trajectories. For a linear system, responses during circular pursuit should equal the summed responses during pursuit of the horizontal and vertical components. Diagonal sinusoids that combined to generate circular trajectories were also used to study the linearity of the system. In a related set of studies, average responses during sum-of-two-sines pursuit were compared to summed component responses. Results showed approximate linearity for some cells, while other cells exhibited responses that were non-linear. (Supported by NIMH grants MH 48185 and NIH training grant T32 DC00015-13)

## 167.3

**VECTOR AVERAGING FOR SMOOTH PURSUIT EYE MOVEMENTS INITIATED BY TWO MOVING TARGETS IN MONKEYS.** Stephen G. Lisberger\* and Vincent P. Ferrera, Department of Physiology and W.M. Keck Foundation Center for Integrative Neuroscience, UCSF, San Francisco, 94143.

When targets move across the visual field, the distributed representation of motion in the visual cortex must be transformed into commands for the correct direction and speed of pursuit eye movements. Possible transformations fall along a continuum between "winner-take-all", which posits that pursuit is guided exclusively by the preferred direction and speed of the units with the largest responses, and "vector averaging", which posits the pursuit is guided by an equally-weighted combination of the firing of all active units. We have probed this transformation by recording the initiation of pursuit when two targets moved simultaneously in different directions at the same speed for 150 ms. Thereafter, one of the targets disappeared and the other became the tracking target. We used 8 directions of motion along the cardinal axes and the 45° oblique axes and an 8x8 design so that each combination of two initial target motions and one final motion were equally likely. All target motion was toward the position of fixation from 3° eccentric. Unlike our earlier studies, in which pursuit used a winner-take-all rule when cued which target to track and only horizontal target motion was eligible for tracking, this approach revealed a role for vector averaging when there was no cue and all directions of motion were "eligible" for tracking. Average eye acceleration in the first 100 ms of pursuit was consistent with vector averaging of the motion of the two targets when the angle between the two targets was 45°. The overall response amplitude was lower than predicted by vector averaging when angle between the two targets was 90° or more. Analysis of the eye acceleration in individual trials failed to reveal evidence for a winner-take-all rule. We conclude that the pursuit system uses a nearly-equally-weighted average of the two target motions when there is no cue about which target to track. ## 167.5

**OFFSET RESPONSE OF THE HUMAN PURSUIT SYSTEM WHEN A TARGET JUMPS TO THE FOVEA: EFFECTS OF JUMP SIZE.** J. Pola\* and H. J. Wyatt, SUNY College of Optometry, New York, NY 10010.

Recently we showed (Soc. Neurosci. '94) that when a subject smoothly pursues a moving target and the target suddenly jumps to the fovea (and is stabilized there), smooth pursuit slows down with a time constant of about 0.5 sec. Here we explore effects that the target jump itself has on the dynamics of this pursuit offset. **Methods.** Subjects pursued a target moving horizontally at 15 deg/sec. When pursuit velocity became steady, the target jumped to the fovea with target velocity and feedback becoming 0 (target stabilized at the fovea). On 30% of the trials the target continued moving at 15 deg/sec with no jump. **Results.** The size of target jump varied from trial to trial due to variability of eye position relative to target position at the moment of the jump. (The jump was nearly always opposite to pursuit, since eye position trailed target position.) Pursuit offset following target jump had two components: an initial fast drop in velocity followed by a slow drop in velocity. As target jump increased, the fast component drop increased and the slow component drop decreased. However, as target jump varied from small to large, slow component deceleration remained roughly constant. **Conclusions.** Size of target jump had clear effects on pursuit offset. One possibility is that the target jump - a step change in target position - generated a "pulse" velocity signal opposed to the direction of ongoing pursuit, resulting in the fast component of pursuit offset preceding the slow component. However, the near constancy of the slow component deceleration suggests that the functional properties of the mechanism determining pursuit offset (e.g. parameters of an internal positive feedback loop) are not influenced by target jump. The fast component appears likely to be observed only in a laboratory environment; however, both components are suggestive of internal mechanism properties.

## 167.7

**ANTICIPATORY SMOOTH PURSUIT EYE MOVEMENTS IN RESPONSE TO REPETITIVE TARGET VELOCITY SEQUENCES** S.G. WELLS, G.R. BARNES, D.M. WOLPERT\* MRC HMBU, Inst of Neurology, Queen Sq, London WC1N 3BG

In response to an unexpected moving target there is a latency of ~100ms before smooth pursuit starts. However regular repetition of the same stimulus leads to the development of anticipatory smooth movements prior to target appearance. On average, anticipatory velocities increase with target velocity when only one velocity is used. This experiment tested the ability of 8 normal humans to control their anticipatory velocities when more than one target velocity was used in a repeated sequence of which they had full knowledge. Movements were recorded by infra-red oculography. Two velocities (Fast, 38°/s or Slow, 13°/s) of horizontal target motion were presented as  $n$  fast targets then  $n$  slow targets, repeated 12 times without a break. Three sequences ( $n=2, 3$  or 4) were used. The moving target was presented for 0.48s with 1.12s of darkness between presentations. In all 3 sequences, the response to the first slow target of each repetition was similar to the subsequent slow responses, but the first fast response was slower than subsequent fast responses for over 0.2s after target appearance. Anticipatory response magnitude was assessed by measuring smooth eye velocity ( $V_0$ ) at target onset, prior to visual feedback influence. Mean  $V_0$  decreased significantly ( $p<0.05$ ; t-test) from  $13.3 \pm 5.5^\circ/\text{s}$  to  $7.7 \pm 3.9^\circ/\text{s}$  (mean  $\pm$  stdev) between the last fast and first slow responses, but did not increase significantly between the last slow ( $6.6 \pm 2.8^\circ/\text{s}$ ) and first fast responses ( $8.3 \pm 4.2^\circ/\text{s}$ ), although the appropriate velocity was achieved for the second fast response. Thus subjects graded anticipatory velocity appropriately for a decrease, but not when an increase was needed, probably due to the effect of the preceding slow targets. Although significant differences were shown by averaging many sequence repetitions, subjects had quite high variability in  $V_0$ , so the differences may not hold for all repetitions. Thus anticipatory movements may just crudely estimate target velocity whilst awaiting visual feedback. (Funded by MRC UK).

## 167.4

**TOPOGRAPHIC ADAPTATION OF HUMAN SMOOTH-PURSUIT EYE MOVEMENTS REVEALED BY A STEP-RAMP-RAMP PARADIGM.** T. OGAWA\* and M. FUJITA, Neural Computation Sect., Communications Res. Lab., Koganei-shi, Tokyo 184, Japan

When a moving target appears in the peripheral visual field, saccade and pursuit eye movements are induced to acquire the target (Rashbass, 1961). Pursuit response is initiated immediately after the end of the saccade, and its velocity roughly matches to that of the target. Because pursuit has a latency of about 100 ms, this postsaccadic pursuit eye movement is probably generated based on information about the target moving in the peripheral visual field before the saccade (Newsome et al., 1985). The main purpose of the present study is to investigate the adaptive properties of these postsaccadic pursuit eye movements.

In adaptation trials, a target appeared in the peripheral visual field (2-10 deg) and moved away at a constant speed (10 deg/s). A subject was required to track it through eye movements, but the target speed was changed to a higher (20 deg/s) or lower (2 deg/s) constant speed at the termination of an initial saccade made to the target (step-ramp-ramp target motion). This adaptation paradigm induced adaptive modifications in postsaccadic pursuit responses and our results revealed the following properties in the pursuit adaptation system. **Topographic modification:** Modification of the initial pursuit velocities depends on the visual location of a moving target.

**Pursuit gain change:** Pursuit velocity is modified not by the addition of a constant bias to the pre-adaptation pursuit velocity, but by a change in the pursuit gain (pursuit velocity/target velocity). **Independence from saccade system:** Since pursuit adaptation did not change the amplitude and latency of saccades either to a moving target or to a stationary target, neuronal modifications for pursuit adaptation might occur at a level independent of the saccade system.

## 167.6

**THE VALIDITY OF DIRECTIONAL CUEING INFLUENCES SMOOTH PURSUIT LATENCY.** J.-L. Homg and M.J. Morrow\*, Dept. of Neurology, Olive View-UCLA Medical Center, Sylmar, CA 91342

Maximally predictable step-ramp stimuli elicit smooth pursuit initiation with latencies of about 25 msec less than responses to unpredictable step-ramps. Recent work in our laboratory has shown that step-ramp stimuli in which ramp direction alone is constant evoke pursuit with similar latencies to targets in which step amplitude and ramp speed, direction and timing are all constant. In order to further explore this finding, we tested 4 normal subjects, presenting centripetal step-ramps of unpredictable direction and timing but constant speed and step amplitude. These stimuli were preceded by a directional cue consisting of a briefly-illuminated arrow. The arrow usually (80% of trials) pointed in the same direction as the subsequent ramp motion, but occasionally (10% of trials each) pointed in the opposite direction ("invalid cue") or in both directions ("no cue"). We found that pursuit latency was significantly determined by cue validity, having values averaging 20 msec lower for valid directional cues than for invalid cues, and intermediate values for the "no cue" task. We assessed the contribution of "motor habit" by segregating pursuit responses according to the relative directions of the previous two ramp movements; our analysis revealed no consistent effect of this factor upon pursuit latency. We conclude that the mechanism that expedites smooth pursuit initiation for predictable targets is driven chiefly by a cognitive synthesis of the likely direction of target motion. Motor habit based upon the repetition of a recently-executed movement plays no significant role in this process.

## 167.8

**PREDICTIVE SMOOTH-PURSUIT EYE MOVEMENTS IN SCHIZOPHRENIA: REACTION TO SUDDEN PERTURBATIONS.** W. Heide, P. Trillenber, M. Blankenburg, K. Junghanns, V. Arolt, D. Kömpf, Depts. of Neurology and Psychiatry, Medical University, D-23538 Lübeck/Germany (SPON: European Brain and Behaviour Society).

A reduced gain of smooth-pursuit (SP) eye velocity has frequently been reported in schizophrenic patients. With respect to predictable stimuli, this could at least partly be due to a deficit in either generating an anticipatory component of SP or in modifying it according to unpredictable changes of the target trajectory. To test this we investigated the SP response to sudden perturbations of an otherwise sinusoidally moving visual target. Horizontal eye movements were recorded using infrared reflection oculography in 13 subacute schizophrenic patients and in 25 age-matched healthy adults, who were tracking a sinusoidally moving foveal target which after 5 cycles was suddenly stopped at one of the maxima of the position trace. Compared to the normal control group, the velocity gain of predictive SP was significantly ( $p<0.02$ ) lower in schizophrenics, but the phase lag was normal. After the unpredictable stop of target motion, the eye accelerated away from the target for ca. 180 ms in both groups, but the resulting velocity and position error into the direction of the previous predictive SP was above normal limits in schizophrenics. We conclude that schizophrenic patients like normal subjects are able to internally generate an anticipatory component of predictive SP. The enlargement of this component in schizophrenics might help to compensate for their lower velocity gain, but impairs their ability to adapt predictive SP to sudden perturbations of the external stimulus. (Supported by the DFG grant Ar 234/1-1)

## 168.1

**MODULATION OF THE H-REFLEX DURING HUMAN WALKING IS NOT CORRELATED WITH JOINT MOVEMENT.** B.A. Lavoie and C. Capaday. Centre de Recherche en Neurobiologie, Université Laval, Québec, (Qc) Canada, G1J 1Z4

It has been suggested that the soleus H-reflex modulation pattern during walking (Capaday and Stein, J. Neurosci. 6: 1308-1313) may be due to movement related afferent activity, especially from muscle afferents of the quadriceps muscle (Brooke et al. J. Neurophysiol. 73:102-111; Misiaszek et al. J. Neurophysiol. 73:2499-2506). Additionally, these authors have suggested that the reduction of the H-reflex during walking compared to standing is also due to movement related afferent activity. One implication of this hypothesis is that the modulation pattern observed during walking should be closely correlated to the joint kinematics. We have thus re-examined in detail the modulation pattern of the H-reflex during human walking and simultaneously measured the angular displacements of the ankle, knee and hip. The very strong inhibition of the H-reflex at heel contact occurs with little or no knee flexion at that time. This period of inhibition is best correlated with a very low level of activity in the soleus and a large burst of activity in the tibialis anterior (TA). The H-reflex reaches its maximum value late in the stance phase and begins to decrease abruptly, as does the soleus EMG, at least 100 ms before the onset of knee flexion. It reaches its minimum value of essentially zero just before the burst of activity in the tibialis anterior, at a time when knee flexion is just beginning, and well before full knee flexion. We have also studied one leg stepping (i.e. swing) initiated voluntarily after an auditory 'go' signal. In this task, the H-reflex attained its minimal value of near zero before the onset of EMG activity, or movement of any joint. We conclude that during walking the pattern of H-reflex modulation is strongly correlated with the motor activity, but not joint movements; and that the task dependent differences in the input-output characteristics of this reflex are centrally determined. (Supported by the MRC of Canada)

## 168.3

**A COMPARISON OF THE SOLEUS STRETCH AND H-REFLEX DURING WALKING IN HUMANS.** T. Sinkjaer\* and J.B. Andersen. Center for Sensory-Motor Interaction, Aalborg University, Fredrik Bajersvej 7D, DK-9220 Aalborg, Denmark.

The short latency reflex is highly modulated during walking. Assuming that the size of the stretch reflex probe central as well as peripheral factors and the H-reflex probe central factors only, a comparison between the two reflexes might elucidate how peripheral factors contribute to the short latency reflex modulation during walking.

In nine healthy subjects both types of stimuli were applied to the ankle extensors during walking on a treadmill. A step was divided into 10-segments where both H-reflex stimulations and stretches were applied in the same experiment. The stretch reflex in the soleus muscle was elicited by imposing a well defined dorsiflexion of 8° with a velocity of approximately 300°/s by a portable stretch device (Andersen & Sinkjaer 1995, TRE VOL. 3, NO. 4, p 299-306). The H-reflex was elicited by an electrical stimulation of the tibial nerve of the investigated leg through an electrode in the popliteal fossa.

Both the stretch reflex and the H-reflex were modulated throughout the step with a maximal amplitude in the stance phase, a complete suppression of the amplitude in the transition from stance to swing. In late swing both reflexes again increased. At 60% of the stance phase the amplitude of the stretch reflex started to decrease. At the same time the H-reflex and the background EMG were still high.

When the force builds up in the ankle extensors during the stance phase, the soleus muscle fibres start to shorten at 62.2±4.3% of the stance phase (Voigt et al. 1996, this meeting). It is therefore conceivable that the decrease in the stretch reflex in late stance phase is caused by an unloading of the muscle spindles which not is detectable in the H-reflex. This imply that changes in muscle length are overriding the effect of alpha-linked gamma action on the stretch reflex during human walking. Supported by the Danish National Research Foundation.

## 168.5

**Post-Exercise Facilitation of the Lateral Gastrocnemius H-reflex.** M.H. Trimble\* & S.S. Harp. Dept. of Physical Therapy, University of Florida, Gainesville, FL 32610-0154.

Following voluntary muscle activation, the amplitude of the soleus (S) H-reflex (HR) has been shown to be depressed for up to 10 s before returning to control values (Enoka, Hutton, & Eldred, 1980; Kukulka and Moore, 1991). We subjected 7 subjects to a vigorous bout of concentric-eccentric gastrocnemii exercise with the knee extended (8 bouts of 10 reps) using a modified Cybex II isokinetic dynamometer. Lateral gastrocnemius (LG) HRs were elicited before and after the exercise bout. Prior to the exercise, the test stimulus was set to produce a small M-wave and an HR with an amplitude of 10%-20% of the maximal M-wave. The small M-waves were used to monitor the stimulus amplitude pre and post exercise. All the subjects had an initial depression of the HR immediately post exercise. Some (5/7) but not all of the subjects demonstrated a large potentiation (30%-50%) of the HR over the control values following the initial period of inhibition. This potentiation often lasted 10 min. post exercise. The data suggest that at least 2 overlapping processes are occurring, an early inhibitory process of short duration, followed by or superimposed over a longer lasting facilitatory process. The facilitatory phase does not appear to be related to the background muscle activity since the LG or S RMS values did not change post exercise. A short term reduction of the tonic level of presynaptic inhibition of the Ia afferents may be responsible.

## 168.2

**MODULATION OF STRETCH REFLEX ACTIVITY AT THE HUMAN ANKLE DURING PASSIVE "WALKING" MOVEMENTS.** R.E. Kearney\*, R.B. Stein and M. Lortie. Department of Biomedical Engineering, Faculty of Medicine, McGill University, Montreal, Quebec, Canada, H3A 2B4.

The objective of this study was to assess the role of peripheral mechanisms in modulating stretch reflex gain throughout the walking cycle.

Ankle position was recorded while human subjects walked on a treadmill at 3 km/hr and ensemble averaged over 60 strides. Average ankle position was "replayed" to supine subjects through a hydraulic actuator attached to the ankle via a rigid boot. Subjects maintained a constant level of muscle activation aided by visual feedback of low-pass filtered EMG. Small amplitude pulse displacements lasting less than 50ms were superimposed on approximately 20% of the cycles. Pulses were applied at eight different points in the walking cycle. Position, torque and EMG were ensemble averaged for both control and perturbed cycles. Reflexively evoked EMGs and torques were isolated by subtracting the ensemble average of the control trial from those of the perturbed trials. The residual EMG records were characterized by a phasic burst of activity occurring with a latency of about 40 ms. Residual torque records comprised two components: a short-latency component associated with intrinsic mechanisms and a longer latency transient component due to reflex activation.

The amplitude of the reflex EMG and torque changed systematically throughout the walking cycle. Reflex EMG was near zero for several hundred milliseconds prior to heel strike. It then increased progressively for about 500 ms as the ankle was dorsiflexed, reaching a maximum near full dorsiflexion. Reflex EMG dropped rapidly to zero once the ankle began to plantarflex. Reflex torque was modulated similarly.

These results demonstrate that peripheral mechanisms, perhaps acting via pre-synaptic inhibition, are capable of producing the changes in reflex gain observed during walking. Supported by grants from the Canadian Medical Research Council

## 168.4

**DIFFERENCE BETWEEN ORIGIN-TO-INSERTION AND MUSCLE-SPINDLE LENGTH-CHANGE IN SOLEUS DURING HUMAN WALKING.** M. Voigt, T. Sinkjaer and R.J.H. Wilmink\*. Center for Sensory-Motor Interaction, Aalborg University, Denmark.

In a few animal studies it has been shown that the patterns of length-change of the muscle-spindles and the whole muscle-tendon unit are different especially when the muscle-tendon unit is loaded. This is an effect of the predominant compliance of the tendinous structures. However, in the majority of studies on humans the tendon compliance and the possible consequences for reflex control has been overlooked. The objective of the present study was to map possible discrepancies between the soleus muscle-spindle and origin-to-insertion (OI) length-change during human walking at different speeds.

Five normal healthy subjects participated in the study (2 female, 3 male). They performed over-ground walking at three different speeds: 2.5, 3.5 and 4.5 km/hr. The movement of the left leg was recorded 120 frames/s and ground reaction forces were measured under the left foot. EMG was recorded with surface electrodes from soleus and anterior tibial muscles. The OI length-change was calculated by an ankle joint to OI length-change transfer function and the muscle-spindle length-change was calculated using a tendon model with the ankle joint moment as input.

At all three walking speeds the OI-lengthening preceded the muscle-spindle lengthening by 4.5±0.8 % (mean±SD) of the ground contact time (GCT). The muscle-spindle shortening began 61.0±3.5 % GCT after the heel contact which was 3.1±2.1 % GCT earlier than the beginning of the OI-shortening. Additionally, both the peak muscle-spindle lengthening and shortening velocities were attenuated on average 36.9±10.3 % and 52.0±15.4%, respectively, in relation to the OI velocities, and the attenuation increased with increasing walking speed.

Therefore, it is likely that the reflex control scheme for soleus during human walking is significantly influenced by tendon compliance.

## 168.6

**INTRINSIC AND REFLEX CONTRIBUTIONS TO SPASTIC ANKLE STIFFNESS: MODULATION WITH ANKLE POSITION.** M.M. Mirbagheri\*, R.E. Kearney\*, H. Barbeau\*, and M. Ladouceur\*. Department of Biomedical Engineering<sup>1</sup>, and School of Physical and Occupational Therapy<sup>2</sup>, McGill University, Montreal, Canada H3A 2B4.

The objective of this study was to determine how the relative contributions of intrinsic and reflex mechanics to ankle mechanics varied with position in spinal cord injured (SCI) spastic subjects. Ankle stiffness dynamics were examined at different ankle positions in normal and SCI spastic subjects who maintained 10% MVC PF in the ankle extensors (gastrocnemius-soleus). Intrinsic and reflex contributions to the stiffness dynamics were separated using a new parallel-cascade identification method. Intrinsic stiffness dynamics were well modeled by a linear, second-order system relating intrinsic torque to joint position. Reflex dynamics were accurately described by a linear, third-order system between half-wave rectified velocity and reflex-torque.

In normal subjects, intrinsic and reflex stiffness gain increased as the ankle was progressively dorsiflexed. The relative contribution of reflex mechanics to ankle stiffness increased, nevertheless, the intrinsic torques were always dominant.

In SCI spastic patients, both intrinsic and reflex stiffness increased with ankle dorsiflexion. As for normal subjects, the relative contribution of intrinsic stiffness decreased and that of reflex stiffness increased as ankle was dorsiflexed. However, reflex stiffness gain was higher than in normal subjects, while intrinsic stiffness gain was similar. Consequently, the relative contribution of reflex mechanics to ankle stiffness was significantly greater in SCI spastic subjects than in normal subjects. Moreover, in contrast to normal subjects, the reflex torques were dominant in joint mechanics of the ankle as GS was stretched.

These results demonstrate that reflex mechanics are abnormal in spastic SCI patients and pathological muscle tone is due to enhanced reflex gain. (Supported by a grant from the Medical Research Council of Canada)

## 168.7

## RECIPROCAL INHIBITION BETWEEN QUADRICEPS AND HAMSTRING MUSCLES IN THE HUMAN

P. Evans and P.J. Harrison\* Department of Physiology, University College London, Gower St., London WC1E 6BT, U.K.

In the cat reciprocal inhibition is much stronger between knee extensors and flexors than between ankle extensors and flexors. Curiously, while reciprocal inhibition has been demonstrated between ankle extensors and flexors in man there are no reports of reciprocal inhibition in man between knee extensors and knee flexors. We have therefore investigated this.

Surface electrodes were used to record EMG activity in the hamstring muscles in awake human subjects. The subjects maintained a low level of isometric activity while sitting with the legs supported and electrical stimuli were applied to the femoral nerve. An inhibition of EMG activity was revealed which was sufficiently large to be visible in individual sweeps. The inhibition occurred at short latency (5-6ms) and at low intensity (0.8x motor threshold) indicating a short reflex inhibitory pathway mediated by large afferent Ia fibres.

This finding is in contrast to the relatively weak reciprocal inhibition observed between soleus and the anterior tibial muscles in humans (e.g. Tanaka 1974, *Exp Brain Res* 21:529-540) and indicates a similar quantitative distribution to that seen in the cat.

## 168.9

PROPRIOCEPTIVE CONTROL OF VOLUNTARILY ACTIVATED WRIST EXTENSOR MOTOR UNITS IN HUMAN: DEPENDENCE ON MOTOR UNIT TYPE AND INFLUENCE OF SUBJECTS' HANDEDNESS. J.-M. Aimonetti, D. Morin, A. Schmied, J.-P. Vedel\*, S. Pagni, CNRS-NBM, 13402 Marseille cedex 20, France.

The proprioceptive control of human motoneurone activity was investigated in relation to motor unit type and subject's handedness. The activity of 411 single motor units was recorded in the Extensor carpi radialis muscles of the right and left arms of 5 right-handers and 5 left-handers during voluntary isometric contractions, while percussions were applied to their tendon with a constant post-spike delay (80 ms). The tendon taps induced an increase in the probability of discharge of the motor units with a delay compatible with a monosynaptic pathway. The amplitude and the latency of the responses were studied in relation to the motor unit functional characteristics (discharge frequency, recruitment threshold, twitch contraction time, force and macro-potential). In agreement with the size-principle, motor units with lower recruitment thresholds, longer contraction time, larger contraction force and smaller macro-potential were found to display most commonly larger reflex activation and to respond with longer latency independently on the discharge frequency. The strength of the motoneurone proprioceptive control was found to depend on the subject's motor lateralization. Whatever their functional characteristics, the motor unit responses and the tendinous reflex were found to be larger in the right arm of right-handers, when no differences could be evidenced in both arms of the left-handers. In left-handers as in right-handers no differences was found in the H-reflex tested in both arms. These results indicate the existence of a spinal asymmetry, apparently restricted to the right-handers which favours the right side in the control exerted by the muscle spindles on the discharge of the wrist extensor motoneurons during a voluntary contraction, in superimposition to the gradient related to the motor unit characteristics. The lack of H-reflex lateralization favours differences in the muscle spindle sensitivity between right and left arms in the right-handers.

VARIATIONS IN PERCEPTION THRESHOLD DURING DIFFERENT MOTOR TASKS. C. Labrecque, J.P. Boucher, M. Bélanger\* Dép. de Kinanthropologie, Univ. du Québec à Montréal, Montréal, Canada, H3C 3P8

The perception threshold (Th) is used as the reference value for adjusting the cutaneous stimulation intensity in most of the withdrawal-reflex studies. However, only one study has examined the variability of the Th during locomotion (Duysens et al., 1995). The present study measured Th variations during four different conditions; 1) standing, 2) cycling, 3) 8 static pedal positions with the Tibialis Anterior and Soleus EMG levels matching those recorded during cycling 4) 8 static pedal positions without EMG activity. A modified cycle ergometer (the subject is seated behind the pedals) was used for data acquisition. The Th was measured 10 times with ascending and descending stimulation intensities for standing and for each of the 8 pedal positions of the last 3 conditions. The skin-electrode impedance was also measured after each series of Th measurements. Each condition and each position was randomly evaluated with a 10 ms train of 5-1 ms pulses applied to the skin area overlying the sural nerve as it passes behind the external malleolus. The results show that there is a difference between the tasks where the Th is 13% higher during cycling (active movement). In contrast, there is no difference within the tasks (no position effect on the Th). These results suggest to use caution when examining cutaneous reflex modulation between tasks, particularly when comparing static and dynamic conditions, and if the stimulation intensity is based on perception threshold. ## THE JENDRASSIK MANEUVER DOES NOT AFFECT PRESYNAPTIC INHIBITION OF THE H-REFLEX. E.P. Zehr\*

and R.B. Stein. Div. of Neuroscience, University of Alberta, Edmonton, Alberta, CANADA T6G 2S2.

Since its first description in 1883, the Jendrassik maneuver (JM) has been used in clinical neurological practice as an effective means of potentiating the tendon jerk stretch reflex in neurologically impaired patients. Subsequently, the JM potentiation of the electrical analogue of the stretch reflex, the Hoffman (H-) reflex has been studied. The purpose of the present study was to determine the mechanism of the reflex modulation, which has not been clearly established.

We studied soleus H-reflex modulation in neurologically intact subjects while at rest and during a mild plantarflexion contraction (EMG level equivalent to ~10 % MVC). The test H-reflex was elicited by stimulating the tibial nerve in the popliteal fossa with single pulses of 1 ms duration. Conditioning of the reflex was by either common peroneal (CP) nerve stimulation or JM, presented either alone or in combination. The JM was both by arm pulling and teeth clenching. As well, the conditioned reflex was elicited at 2 latencies after CP n. stimulation (10 and 100 ms; both of which are considered presynaptic effects) and JM (200 and 300 ms).

There was a significant ( $p < 0.05$ ) suppression of the H-reflex (50%  $H_{max}$ ) at both CP latencies, while JM values were significantly ( $p < 0.05$ ) facilitated as compared to CP n. conditioning. There was no difference ( $p > 0.05$ ) between CP + JM and CP n. at any latency, thus revealing no interaction between the two types of conditioning. We conclude that the JM acts independently of the presynaptic mechanisms that can inhibit the H-reflex.

EVIDENCE THAT LONG-LATENCY STRETCH REFLEXES IN THE HUMAN ANKLE DORSIFLEXORS MAY BE MEDIATED BY A TRANSCORTICAL PATHWAY. N. Petersen\*, J. Nielsen, H. Morita, and T. Sinkjaer, Department of Medical Physiology, University of Copenhagen, DK-2200, Denmark. \*Department of Physiology, Christian-Albrechts-University, Kiel, D-24098 Germany. †Center for Sensory-Motor Interaction, Ålborg University, DK-9100 Denmark.

Stretches applied to human ankle dorsiflexors muscles usually result in three distinct bursts of reflex activity (Toft et al., *Exp Brain Res* 74:213, 1989) labelled M1, M2 and M3. The latency of M1 and M2 is too short to be caused by a transcortical pathway, whereas M3 occurs at a latency of on average 97 ms, which would be just compatible with such a pathway. The present study was undertaken to investigate this possibility. With local ethics committee approval human subjects ( $n = 15$ ) were seated in an armchair with the left leg attached to a footplate which could be rotated by a strong motor. EMG activity was recorded by surface electrodes over the tibialis anterior (TA) muscle. During an isometric voluntary dorsiflexion a quick rotation of the footplate in plantar direction resulted in three distinct reflex bursts (M1, M2, M3) in the TA muscle. When a motor evoked potential (MEP), produced by transcranial magnetic stimulation (TMS) of the motor cortex, was superimposed on the late M3 stretch reflex a significant potentiation of the MEP was seen in all subjects. A similar potentiation was not seen when the MEP was superimposed on M1 or M2. In 18 single TA motor units from 7 subjects the monosynaptic peak in the post-stimulus time histogram (PSTH) following TMS was similarly increased when TMS was preceded by a stretch at the latency of M3. In none of 5 motor units was a similar increase of the monosynaptic peak observed when the magnetic stimulation was replaced by an electrical stimulation. Electrical brain stimulation is assumed to activate the axons of the corticospinal tract cells and is therefore, unlike the magnetic stimulation which activates the soma, not influenced by the excitability of the corticospinal cells (Edgley et al., *J Physiol* (Lond) 425:301, 1990). The present data thus demonstrate that the long-latency stretch reflex (M3) in the TA muscle is likely mediated by a transcortical reflex pathway. H-REFLEX EVOKED POTENTIAL (HEP) MONITORING DURING SURGERY: A SIMPLE SENSORY AND MOTOR EVALUATION OF PERIPHERAL NERVES AND SPINAL ROOTS

RD Rose,\* Department of Neurological Surgery and Center for Clinical Neurophysiology, University of Pittsburgh Medical Center, PUH B-400, Pgh PA 15213

Neurologic complications from some surgical procedures placing peripheral nerves at risk are substantial (e.g. sciatic nerve in total hip arthroplasty: 1% for primary to 5% for revision; Sherry 1995 *Sixth Int'l Symp on Spinal Cord Monitoring* NY p78 and acetabular fracture repair: >5%; Fassler et al 1993 *JBUS* 75-A:1157). The development of a direct analysis of motor function during surgical procedures involving risk to motor components of peripheral nerves should enhance nerve injury detection and prevention and thus reduce neurologic complications. The H-reflex involves both sensory and motor components; i.e. the monosynaptic stretch (myotatic) reflex of muscle spindle Ia afferents to  $\alpha$ -motoneurons to the homonymous muscle (continuing the sciatic example, HEPs from tibialis anterior provide the basis for a highly appropriate evaluation for the prevention of foot drop. Moreover, a concomitant SSEP can be recorded cervically or cortically (see Slomp et al 1996 *Spine* 21:99) in conjunction with the HEP as evoked activity continues rostrad. Because HEPs are observed as EMG responses, amplitudes are large. Additionally, novel HEPs are easily developed and adapted to particular situations as muscle innervation and nerve trajectories are well known.

## REFLEX INSTABILITY IN SPASTICITY: ORIGINS OF CLONUS.

Joseph M. Hilder, W. Zev Rymer, and Julius P.A. Dewald\*. Sensory-Motor Performance Program and Dept. of Biomedical Engineering, Northwestern University, Chicago, IL 60611.

Clonus is defined as an involuntary rhythmic muscle contraction which usually accompanies spasticity of ankle muscles, and occurs in people who have sustained lesions involving descending motor pathways such as stroke and spinal cord injury. We hypothesize that clonus arises when three conditions occur simultaneously: the reflex pathway contains a slow muscle actuator (i.e. soleus), there are long pathway delay times, and the excitability of the motoneurons is enhanced. We tested this hypothesis, in particular how motoneuron excitability, loop delay, and muscle type each influence reflex behavior, by developing a computer model representing the ankle reflex pathway. Simulations showed that as the motoneuron current threshold was reduced (reflecting increased excitability of spinal motoneurons), normal reflex responses became unstable and oscillations developed similar to those observed in clonus patients. Furthermore, sustained oscillations occurred when the loop delay time was set to that found in the human ankle reflex (50 msec), while reductions in this time delay forced the oscillations to damp out. This explains why clonus is largely restricted to the ankle, where conduction distances are greatest. Finally, when slow twitch muscle characteristics were replaced with those of fast twitch muscles, the effect was similar to reducing loop delay as the oscillations rapidly decayed. This illustrates why clonus is mediated by the soleus muscle which contains nearly all slow twitch muscle fibers. The findings in this study support the hypotheses that when the motoneuron excitability increases in a reflex pathway containing long latencies and a slow muscle actuator, unstable behavior such as the oscillations observed in clonus will occur. Furthermore, it is demonstrated that sustained oscillations can occur in a reflex pathway through self re-excitation, which contradicts the theory that a "spinal generator" must be involved in clonus. This work was supported by a T32 HD 07418 grant.

## SIMULATION STUDY OF INTERACTIONS BETWEEN SPINAL FEEDBACK LOOPS, M. G. Maltenfort\*, J. He and T.M. Hamm. Div. of Neurobiology, Barrow Neurological Inst., Phoenix, AZ 85013

The spinal circuitry for control of muscle length and tension is not uniform across motor nuclei or functional tasks. beta axons innervate 70% of muscle spindles in distal muscles but 40-47% in proximal muscles (Scott, *et al.*: *Neurosci. Lett.*, 190: 1-4, 1995); in comparison, motor nuclei innervating distal muscles receive less recurrent inhibition, and those innervating digits receive virtually none (Hörner *et al.*: *Neurosci. Lett.*, 122: 183-183, 1991; McCurdy and Hamm: *J. Neurophysiol.*, 67: 1359-66, 1992). What is the functional significance of this obvious discrepancy in feedback regulation of distal and proximal muscles from recurrent inhibition and stretch reflex?

To explore possible interactions between feedback loops, we have constructed a simulation of a single muscle with force- and length-dependent mechanics; feedback from muscle spindles and tendon organs; beta innervation of muscle spindles; and recurrent inhibition. The muscle acts against a viscoelastic load. Feedback gains are adjusted to match published measurements and observations of motor behavior.

Two questions will be addressed: how does the simulated system respond to stochastic input or load perturbations? and how do the beta innervation and recurrent inhibition interact with each other in a motor control task?

## CONTROL OF POSTURE AND MOVEMENT: SENSORY CONTROL OF REACHING

## 169.1

## THE EFFECTS OF ATTENTION ON MANUAL AIMING MOVEMENTS IN THE ELDERLY S.A. Morehouse and J.D. Fisk\*. Dalhousie University, Halifax, Nova Scotia, Canada.

This study examined the effect of premovement target location information on the planning and execution of visually directed pointing movements by healthy elderly subjects. Central visual cues (60% valid, 20% invalid, 20% neutral) indicated which of four positions the subjects would be required to point to. Experiment 1 allowed for endogenous covert orienting of attention (shift of attention to the target position) plus premovement planning. This was followed by exogenous overt orienting of attention (i.e. pointing to the target). Experiment 2 required endogenous overt orienting and allowed for premovement planning only since the target position was indicated at the point of central fixation. Subjects' 3-dimensional hand position was recorded optoelectronically (WATSMART). Valid cues reduced movement onset time in Experiment 1 but did not affect peak or average velocity, or accuracy. Cue validity had no effect in Experiment 2. The results suggest that probable target location information did not provide a movement initiation advantage unless subjects also covertly shifted attention to the probable target position. Peak and average velocity were higher in Experiment 1 but accuracy did not differ. This demonstrates a general advantage in movement planning and/or execution for movements directed to targets that elicit exogenous overt orienting of visual attention.

## 169.2

## ORIENTING THE ATTENTION AFFECTS AIMING MOVEMENTS.

M. Badan, N. Weideli and D. Corbetta\*. Faculty of Psychology and Educational Sciences, University of Geneva, Carouge, Switzerland, Department of HKLS, Purdue University, West Lafayette, IN, US.

To investigate visuo-spatial attention in right-handed adults, we used a paradigm in which the programming and execution of visuo-manual aiming movements were interfered with by visual distractors. The target was a dot displayed on a computer screen at one out of 6 different positions along a transversal axis (left-right). After the disappearing of a central cue that specified the hemisphere in which the next target would appear, the target was presented either alone, or with a left or a right distractor. Neutral, valid, and non-valid cues were given in the same proportion.

A pointer was mounted on a vertical handle placed in front of the screen in the midsagittal plane of the subject. When the target appeared, the subject had to orient the pointer to the target position as quickly and accurately as possible. The handle was connected to a potentiometer that recorded the spatio-temporal parameters of the manual responses (sampling rate: 200 Hz).

The results suggest that the type of cue, and the target position had an effect on movement programming time, whereas distractors did not affect this dependent variable. In contrast, the execution time of the movement was dependent on the presence of distractor but not on the type of cue. Execution time also varied as a function of target position. The results are interpreted in terms of the strategies developed by adults to allocate attention in the visual space prior and during aiming movements.

## 169.3

## CONTRIBUTIONS OF THE CENTRAL AND PERIPHERAL VISUAL FIELDS TO VISUAL INTERCEPTION. P.J. Bryden, F. Allard, &amp; M.P. Bryden\*. Departments of Kinesiology and Psychology, University of Waterloo, Waterloo, Ontario, N2L 3G1.

The relative contributions of both the central and peripheral visual fields to performance in a catching task was examined. Participants were asked to catch a ball attached to a pendulum, whose trajectory was close to the observer's head. The time of movement initiation, finger separation, and grasp were ascertained for each catch, and as well the total number of balls missed was determined. The first study examined the peripheral visual field and manipulated the observer's body and head alignment with respect to the oncoming ball. The peripheral visual field was found to be capable of mediating accurate catches, while no differences were found between the different body orientations investigated. The second study examined the central visual field. The acuity of the central field was manipulated by an optical defocus which reduced the acuity of the field to approximately that of the peripheral field. As well, a fixation control manipulation was introduced in order to restrain the participants from foveating the ball for its entire trajectory, and to equate the task demands between the two experiments. Catching performance was adversely affected by the defocusing of the central field when compared to performance under normal acuity. The manipulation of fixation also worsened catching performance. Equivalent conditions in the two experiments were compared statistically to evaluate the relative contributions of each field to catching performance. It was concluded that peripheral vision allows for more accurate interception of an oncoming ball than does central vision. It thus appears that the central field is dependent upon its superior acuity to perceive detailed information about the size and shape of the ball to mediate interception. Such detailed information appears to not be necessary for the peripheral field to mediate catching. The results seem to agree with recent research on the distinction between the two visual pathways (Goodale & Milner, 1995). Supported by the Department of Kinesiology, University of Waterloo.

## 2D-TRACKING HAND MOVEMENTS ARE INFLUENCED BY MOVING VISUAL BACKGROUND. W. Kruse\*, S. Dannenberg and K.-P. Hoffmann, Allgemeine Zoologie &amp; Neurobiologie, Ruhr-Universität Bochum, D - 44780 Bochum

The influence of linearly moving random dot patterns was studied during performance of visually guided circular tracking movements. Subjects used a 2-dimensional manipulandum to control a feedback cursor on a large video graphic display (43° x 52°). The vision of the limb was occluded during the task. Each tracking movement consisted of two consecutive cycles in clockwise direction, starting at the 12 o'clock position. The circular path of the visual target had a radius of 17.4°, corresponding to a tracking hand movement of 12.5 cm radius. After completion of the first target cycle (5 sec), the feedback cursor disappeared. Subjects were instructed to continue the tracking of the visual target for a second cycle („open loop“ cycle). During both cycles, a full field random dot pattern moved horizontally with constant velocity (19.4°/s), either to the left or to the right. Eight subjects performed the task using their preferred (right) hand. All subjects tended to draw an ellipse during the open loop cycle, which showed a prevalent pattern across all repetitions. In only 2 out of 8 subjects, the radial error at the end of the open loop cycle was significantly different between background movement from the left and from the right. At the end of the open loop cycle, in grand average, subjects were trailing the target by an angular error  $\Delta\alpha = \alpha_{\text{hand}} - \alpha_{\text{target}}$  of -13.7°, measured from the origin of the circular target trajectory. The main effect of the moving background was a modulation of this angular error. All subjects showed a clear increase in the angular lag when the background moved in the same direction as the target at the end of the open loop cycle (near to 12 o'clock position), compared to the background movement in opposite direction. These results indicate that 2-dimensional tracking movements are influenced by the visual background. The effect on the angular error is in accordance with previous results derived from 1D- manual tracking movements (Masson *et al.*, Vision Res. 35, (6): 837, 1994).

## 169.5

**THE ROLE OF VISION IN POINT-TO-POINT ARM MOVEMENTS.** L.E. Sergio\* & S.H. Scott CRSN, Dépt. Physiologie, Univ. de Montréal, Montréal, PQ, CANADA H3C 3J7

We wished to examine whether straight hand paths were an inherent property of goal-directed movements or an emergent property of visually-guided motor development. Comparisons were made between hand and joint paths produced during point-to-point arm movements by congenitally blind subjects and normally sighted subjects (with and without blindfolds). The planar horizontal movements covered many directions across the workspace.

Blindfolded sighted subjects produced hand paths with greater curvature compared to blind subjects in many movements. There was no systematic difference, however, between the paths produced by blind subjects and sighted subjects without blindfolds. These data suggest that visual input is not in itself essential for straight hand paths since blind subjects often produced straighter hand paths. Hand trajectories may be determined by constraints acting at a number of levels both perceptual and motoric in nature.

For some movements, sighted subjects made straighter paths in hand space with vision but straighter paths in joint space while blindfolded. The decrease in joint path curvature while blindfolded implies that the subjects may be linearizing the path in the perceptual space available to them. This may be a more general case of that seen by Flanagan & Rao (*J. Neurophys.* 74:2174-7, 1995), whose subjects produced straight paths in the space (hand or joint) displayed to them on a screen.

Supported by MRC Group Grant in Neurological Sciences, FCAR Post-Doctoral Fellowship (LES), & FRSQ Scholarship (SHS).

## 169.7

**DELAY INDUCED PATTERNS OF SINUSOIDAL TRACKING MOVEMENTS** H. Heftter\*, P. Tass, J. Salomon, K.R. Kessler, H.-J. Freund. Dept. of Neurology, H.-Heine-University, D-40225 Duesseldorf, F.R.G.

The overtrained matching between proprioceptive and visual feedback during sinusoidal forearm tracking movements was disrupted by introducing delays in the visual feedback loop.

During long term recordings (up to 15 mins) by making forearm flexion/extension movements, 10 normal subjects had to keep a thin response line in the middle of a sinusoidally moving target area on an oscilloscope screen. The movements of the forearm were displayed with different delays ranging from 0 to 100% of the target cycle duration. Target frequency was kept constant. Usually the most comfortable tracking rate was used. The Hilbert transformations of the target and response signal were determined to calculate the phase difference.

Analysis of the phase difference between the target and the response signal revealed four characteristic movement patterns: 1. A fixed point behavior for delays close to zero was found. 2. With increasing delays low-amplitude oscillations of the phase difference occurred. 3. A further increase of the delay led to cycle slipping, i.e. the subject preceded the target or fell behind, kept a fairly constant phase relation for a few cycles but then slipped into the next cycle again. 4. With delays around 50 % a drift behavior was seen, the subject being unable to keep a stable phase relation. Delaying the visual feedback beyond 50% of the cycle duration led to an improvement of the tracking performance in all subjects with many of them returning to a fixed point behavior or low-amplitude oscillation at delays close to 100%.

A nonlinear model was developed describing qualitatively the different movement patterns. Fitting the model to the experimental data will allow to quantify the visuo-sensorimotor interaction. Thus, detailed analysis of tracking with visual delay can be used as a clinical method to test the mutual interaction of the visual and the sensorimotor system.

## 169.9

**INTERACTION OF TREMOR AND MAGNIFICATION IN A MOTOR PERFORMANCE TASK WITH VISUAL FEEDBACK.** K. Vasilakos, P. Cordo\*, L. Glass, A. Beuter. Neurokinetics laboratory, UQAM, C.P. 8888, Station Centre-Ville, University of Quebec, Montreal, H3C 3P8, Canada.

This study investigates the interaction between increased gain in the visual feedback loop and motor control of the periphery. Subjects were asked to maintain a constant finger position while utilizing magnified visual feedback. The accuracy of each trial was quantified by taking the standard deviation (trial-error) of the finger position. Trials performed under magnification have lower trial-errors than trials without magnification. The change in trial-error between trials with and without magnification proves greater than the difference between trials at any two magnifications. In contrast, the differences between individual subjects is often greater than the difference between performances at individual magnifications. At higher magnifications performance seems to be limited by the tremor, the ratio of trial-error to tremor-intensity is constant. When applied to microsurgery these results are in accord with earlier research including results suggesting that the level of magnification used in microsurgery is not the most significant factor in achieving good results, and that tremor is the limiting factor in microsurgical tasks. Funded by FCAR (Québec) and NSERC (Canada).

## 169.6

**EFFECTS OF VISUAL FEEDBACK AND INITIAL START POSITION ON THE TEMPORAL COORDINATION OF BILATERAL WRIST MOVEMENTS.** E.L. Flansburg, P.B. Blank, S.H. Brown\*. Center for Human Motor Research, Division of Kinesiology, Univ. Michigan, Ann Arbor, MI. 48109-2214.

The degree of synchronization during bilateral arm movements depends upon such factors as movement direction, speed, and distance. In this study, we have examined the effects of initial start position and visual feedback on the temporal coupling of wrist movements. Six right-handed subjects (19-23 yrs) performed discrete flexion movements at the following initial start positions: self selected, matched extension of both wrists, and unmatched extension (extension/neutral wrist positions). For each position, movements were made without vision and with selective visual feedback of either the right or left hand. In the latter condition, subjects were required to point to a visual target with the displayed hand while simultaneously moving the non-displayed hand. Subjects were instructed to move both hands together at their own speed. Wrist displacement was recorded using electrogoniometry.

Differences in bilateral onset times were variable across subjects and were not significantly affected by selective visual feedback or start position. Mean onset difference was 13 +/- 30 ms across all conditions and subjects. In contrast, selective visual feedback had a marked effect on the matching of movement duration and amplitude in all subjects. Movement duration of the non-displayed hand was consistently greater than that of the displayed hand regardless of whether the dominant or non-dominant hand was displayed. Start position had no consistent effect on the degree of duration uncoupling. In some subjects, an increase in amplitude of the non-dominant hand was also observed which was independent of start position. These findings extend previous observations regarding the coordination of bilateral limb movements. It is also clear that visual information can exert a strong decoupling action, thus demonstrating the influence of sensory feedback in the control of bilateral motor tasks.

## 169.8

**TRANSFER OF GAIN ADAPTATION: EVIDENCE OF VECTORIAL CODING IN GOAL-DIRECTED MOVEMENTS.** P. Vindras, P. Viviani and D. Pelisson\*. Dept. of Psychobiology, FAPSE, Univ. of Geneva, 1227 Carouge, Switzerland.

It is still debated whether targets of goal-directed movements are coded by the coordinates with respect to the body, of vectorially, i.e. by the amplitude and direction of the vector from the starting to the final position. A key prediction of this second hypothesis is that any gain adaptation along one direction should transfer to any other arbitrary direction. Furthermore, between-arm transfer of adaptation is possible only according to the vector-coding scheme. In this study we tested both these predictions by altering movement gain through the use of non-veridical visual knowledge of the results (KR). In 3 separate sessions subjects pointed to 200 ms laser spot targets placed horizontally along 8 equally spaced (45°) directions at 6, 9 or 12 cm from a central starting position identified both visually and by a tactile landmark. Subjects, who could not see their arms, were instructed to point as precisely as possible. They received KR only in the case of right-hand movements to left or right 12 cm targets. KR was veridical during the first session. In the second and third session a biased KR was used to increase or decrease the gain by 15% along the left-right axis. Each session began and ended with 12 left-hand movements to 12 cm targets in the 4 cardinal directions. It also included 12 trials with KR, followed by 96 trials with one KR provided every 4 movements. For trials with KR, gain modulation was -13% and +8.4% with respect to the first session. About 2/3 of these modulations transferred to movements in other directions and amplitudes. The amplitude of left-hand movements at the end of the sessions also changed by -10.5% and +8.8% with respect to the initial left-hand movements. No systematic directional bias was observed. Our results suggest that hand-target distance is a relevant variable for reaching movements, and support the vectorial coding hypothesis. They are not compatible with the view that a transformation of target egocentric position into desired arm posture is the first stage of movement planning.

## 169.10

**PERCEPTION, APPLIED FORCE, AND MULTIPLE STRATEGIES IN A CONTINUOUS TRACING TASK.** C. Barczys\*, J. Boline, J. Ashe, and A.P. Georgopoulos. Brain Sciences Center, VAMC, Minneapolis, MN 55417.

To examine the relations between perception and applied force during movement, 4 subjects varying in motor-task experience traced a circle continuously at 1 Hz for 18 seconds, using a manipulandum that delivered combinations of spring (S), viscous (V), and inertial (I) torques. Subjects then rated the trial's difficulty from 1 to 100 (1 = easiest). Hand (H: left, right), movement direction (D: ccw, cw), and gravity (G: present, absent) were also varied in a randomized block design. There were 125 trials per session (S, V, and I varied), and 8 sessions per subject (G, D, and H varied). Using the last 6 seconds of each trial, a multiple linear regression model was applied to determine the effect of the following variables on each subject's perception of task difficulty: applied forces (S, V, I), task conditions (H, D, G), visual cues (RMS error of the trajectory from the template), motor performance (average velocity (Vavg) and standard deviation of Vavg), and output forces (subject force and net force). Regressions for all subjects were highly significant. The fit of the model and the relative importance of the different variables varied among subjects, with the more task-naïve subjects showing lower R<sup>2</sup> values, lesser dependence on the applied forces and heavier dependence on the visual and motor cues. Of the applied forces, V had the strongest effect followed by I for 3 subjects; for the fourth subject I was strongest. Of the task conditions, G and H showed the strongest effects. Force effects were largely restricted to the 2 experienced subjects. These results suggest that perception of difficulty in a motor task is a composite of several cues whose relative importance varies among subjects depending on the degree of motor-task experience: for task-experienced subjects the relationship between perception and applied forces is strong, whereas for task-naïve subjects that relationship is weaker and the dominant factors are visual and motor cues. (Supported by VA and NIH grants).

## 169.11

## PSYCHOMETRIC FUNCTION FOR MOVEMENTS OF THE ELBOW JOINT

L.A. Jones<sup>1</sup>, R.J. Irwin<sup>2</sup>, and I.W. Hunter<sup>1</sup>. Department of Mechanical Engineering, Massachusetts Institute of Technology, 77 Massachusetts Ave, Cambridge, MA 02139 USA<sup>1</sup> and Department of Psychology, University of Auckland, Auckland, New Zealand<sup>2</sup>.

The ability to detect the movement of a limb depends on the velocity of the movement and the joint moved, with lower thresholds being associated with faster movements (10–80°/s) and more proximal joints. In such experiments unidirectional movements have been imposed on the joint and so the threshold estimates obtained may not represent the optimal sensitivity of the joint.

The objective of the present experiment was to determine the psychometric function for movements imposed on the forearm. Subjects were seated in an experimental rig and with each hand held a rod protruding from an electromagnetic linear motor that was under computer control. On each trial two 5-s movement perturbations were delivered to the left and right arms. One stimulus was a 10 Hz signal embedded in a 5–15 Hz band of noise and the other a 5–15 Hz band of noise. Subjects indicated which perturbation included the signal by pulling against the appropriate motor at the end of the trial and were provided with feedback of the correct response. Eight different signal amplitudes were presented ranging from 1 to 4.5 times the rms amplitude of the background noise, and 100 trials were presented at each amplitude.

Over the amplitude range studied the psychometric function was steep for most subjects. The threshold (75%) for detecting the 10 Hz signal embedded in a 5–15 Hz band of noise ranged from 0.05 to 0.08 mm across subjects which corresponds to a movement of approximately 0.01°. This absolute threshold is larger than the differential threshold for elbow joint movements which is 5 µm (Jones et al., 1992).

## 169.13

## THE CODING OF SPATIAL LOCATIONS BY JOINT ANGLES

G. Baud-Bovy<sup>1</sup>, P. Viviani<sup>2</sup> and J. Requin<sup>3</sup>. Faculty of Psychology and Educational Sciences, University of Geneva, Carouge, Switzerland, <sup>2</sup>Department of Cognitive Science, Scientific Institute S. Raffaele, Milan, Italy, and <sup>3</sup>Center for Research in Cognitive Neuroscience, CNRS, Marseille, France

The pattern of errors in pointing to spatial targets (Flanders et al, 1992), and the recent demonstration that initial and final postures are not independent (Soechting et al, 1995) have rekindled the debate on the system of joint angles used by the CNS for coding posture and movement. We address this issue by separating the effects of the final posture from those of the target position. Targets located within the proximal part of the frontal space can be reached by either hand. However, outside the mid-sagittal plane, different sets of joint angles must be computed in the two cases. A robot arm guided the right (Condition 1), or the left hand (Condition 2) of blindfolded subjects to one of 27 targets arranged in a cubic array. After returning the arm to an invariable initial posture, the subject attempted to reach again the same position with the right hand. By measuring absolute and relative positions of all body segments involved in the task, we observed substantial systematic errors. Endpoints in the first condition were always shifted to the left in the first condition, and to the right in the second condition. Since pointings were performed by the same hand, starting from one posture, errors can be explained neither by biomechanical constraints, nor by factors related to movement execution *per se*. Instead, endpoint shifts must originate from the stage wherein the proprioceptive coding of the target is processed either to replicate the same set of joint angles (Condition 1), or to compute the new set of angles corresponding to the same final position as seen from the other arm (Condition 2). Mathematical analysis shows that the correspondence between joint angles that code for the same endpoint depends critically on the system of reference that the CNS is supposed to adopt. Our results suggest that this system may not be the Euler system that previous studies have favored.

## PROPRIOCEPTIVE INFLUENCES ON A STIMULUS-RESPONSE

## COMPATIBILITY REACTION TIME TASK. G.K. Kerr\* and C.J.

Worringham. School of Human Movement Studies, Queensland University of Technology, Brisbane, Q4059, Australia.; Department of Movement Science, The University of Michigan, Ann Arbor, MI 48109-2214.

This study examined how alterations in proprioceptive information induced by tendon vibration affected performance in a visual reaction time (RT) task. In the compatible instruction set group subjects responded with the finger that was on the same side as the visual stimulus. Whereas, in the incompatible instruction set group, subjects responded with the finger on the opposite side. For the present experiment subjects arms were passively moved to different positions by the experimenter such that subjects fingers were either crossed or uncrossed. These positions were chosen such that there were different amounts of separation between the fingers (2.4 to 12 cm). There was no contact between the limbs. On half of the trials subjects completed the task while the tendon of their right triceps brachii was vibrated (60 Hz).

RTs for the compatible group were significantly shorter than those for the incompatible group. For both groups there was an increase in RT as the amount of crossover of the finger tips increased. This systematic alteration in RT was correlated with subjects' perception as to whether their fingers were crossed or uncrossed at these positions. When vibration was applied RTs were longer than in the non-vibrated condition. RTs also demonstrated a systematic alteration as a function of the amount of finger crossover. This trend was consistent with subjects responding as if their fingers were in the "perceived" rather than their actual positions. That is, subjects behaved as if their limbs were crossed when they were not. These results demonstrate a strong proprioceptive influence on neural processes subserving stimulus response compatibility tasks.

## STOCHASTIC RESONANCE IN HUMAN MUSCLE SPINDLES.

S. Verschueren, P. Cordo, J. T. Inglis, J.J. Collins, D. Merfeld\* and F. Moss. R.S.Dow Neurological Sciences Institute, Portland, OR 97209

Noise—inherent to biological sensory systems—has traditionally been viewed as detrimental to signal detection and information transmission. Recently, however, it has been shown that noise can enhance the detection and transmission of weak signals in certain nonlinear systems via a mechanism known as "stochastic resonance." In the experiment reported here, we tested the hypothesis that the sensitivity of human muscle spindle receptors to a weak movement signal could be maximally enhanced by the presence of a particular, non-zero level of noise.

The firing activity of 8 single primary afferents from the finger and wrist extensors was recorded using microneurography in normal human subjects. The wrist was passively rotated with a sinusoidal waveform (0.5–0.8 Hz;  $\pm 1-3^\circ$ ), sufficient to excite the afferent weakly. A random noise signal (bandwidth 0–500 Hz; RMS amplitude 0–0.7 mm) was applied to the distal tendon of the parent muscle. The power spectrum of the spike train showed a peak at the wrist rotation frequency from which the output signal-to-noise ratio (SNR) was calculated as the area under the peak above the noise divided by the amplitude of the noise.

Six of 8 afferents showed stochastic resonance: the output SNR increased to a maximum and then decreased with increasing input noise intensity. Thus, low levels of noise improved the ability of muscle spindles to detect weak periodic movement signals. This positive effect of noise appears to be due to a direct effect on the spindle receptor rather than indirect (i.e., reflexive) fusimotor activation, as the same relation between input noise intensity and output SNR was found when the fusimotor system was inactivated by proximal block of the radial nerve.

## POINTING TO PROPRIOCEPTIVE TARGETS: THE DISSOCIATION OF MOVEMENT AND POSITION ENCODING. J. Paillard\* and G.E. Stelmach.

CNRS-Neurobiologie du Mouvement, Marseille (\*) and Motor Control Laboratory, Arizona State University.

Position sense under active and passive conditions was reexamined using the protocol first introduced by Paillard and Brouhon (1968), dissociating movement and position encoding. In a dynamic mode, subjects moved the target index finger to a location along a vertical track and immediately pointed at it with the left hand. In a stabilized position, subjects pointed at the stabilized finger, 15 seconds after reaching final position. In both modes, tactile or/and visual cues were added to the basic proprioceptive condition in separate blocs of trials. In the dynamic mode, the active was better than the passive condition. In the active trials, providing additional tactile or/and visual cues yielded no difference in pointing accuracy. However, under passive condition, tactile and visual cues both reduced pointing errors, with tactile cues showing the largest reduction. The combination of cues reduced the errors to the level of the tactile condition alone. In the stabilized mode, where the dynamic receptors were adapted, there was no more difference between active and passive pointing accuracy. Moreover, providing tactile cues had no impact on error reduction, whereas providing visual cues significantly reduced pointing errors. Providing both cues maintained errors at the level of the vision condition alone. The data suggest that proprioceptive cues lead to different location encodings according to the dynamic or stabilized modes. Proprioceptive encoding, following active positioning, clearly dominates tactile and visual cues, whereas visual encoding of target location dominates in a stabilized mode. Moreover tactile cues, which greatly improve pointing accuracy at passively positioned targets, do not influence the location encoding of passively or actively maintained limb.

## 169.16

## SOMATOSENSORY INPUT ENHANCES NEUROMUSCULAR ACTIVATION

## DURING MOVEMENTS PERFORMED WHILE FREE-FLOATING IN

MICROGRAVITY. C.S. Layne\*, A.P. Mulavara, P.V. McDonald, C.J. Pruett, J.J. Bloomberg. Neuroscience Movement and Coordination Laboratory, Space Biomedical Research Institute, NASA-Johnson Space Center, Houston, TX 77058.

Substantial evidence suggests that somatosensory input can modify neuromuscular activation characteristics (Burke, et al., 1991; McCloskey, 1995). What is not well understood is the integrated effects of somatosensory and other sensory input (e.g. visual, vestibular) on neuromuscular activation. This investigation utilized the microgravity environment of space flight to assess how foot pressure modifies neuromuscular activation in the absence of vision, a gravitational reference and a support surface. Four crewmembers performed two conditions of rapid, unilateral arm raises while free-floating during the course of two long duration missions (66 and 110 flight days) aboard the MIR space station. One condition consisted of arm movements without foot pressure. A second condition was performed with pressure being applied to the feet with the use of an inflatable insole encased in a specially constructed boot. All movements were performed with the eyes closed. Arm accelerations and surface electromyography from shoulder, trunk and lower limb muscles were obtained. Patterns of muscle activation were determined for each condition and then compared with ground-based patterns collected prior to flight. Results indicate that the temporal sequencing of muscle activation patterns associated with rapid arm raises performed while free-floating were very similar to those observed during ground-based performance. However, the addition of foot pressure enhanced the magnitude of activation relative to that observed during arm raises performed without foot pressure. These findings indicate that in the absence of vision, a gravitational reference, and the proprioceptive input resulting from the interaction of the performer and the support surface, the perceptual-motor system is able to generate neuromuscular activation patterns which support rapid arm movements. Importantly, the addition of somatosensory input from the feet can be used to enhance the magnitude of neuromuscular activation.

## 169.17

GENERALIZABILITY OF EVOKED POTENTIAL GAIN DURING PASSIVE MOVEMENT. J.D. Brooke\*, W.R. Staines, P.A. Angerilli and W.E. McIlroy<sup>1</sup>. Department of Human Biology and Nutritional Sciences, University of Guelph, Ontario, N1G 2W1, and <sup>1</sup>Sunnybrook Health Science Centre, Toronto, Ontario, M4N 3M5, Canada.

Somatosensory evoked potential (SEP) gain attenuates during passive movement. In the upper limb, this gating is restricted mainly to nerve stimulation supplying the moved limb segment. We hypothesized that movement-related gain attenuation in the lower limb would be generalizable from ipsi- to contralateral limb movement, but not to other sensory modalities. Evoked potentials were recorded in eight subjects from Cz, Cz' (2 cm posterior to Cz), O1, and O2 in response to stimulation of the tibial nerve at the popliteal fossa (SEPs), pattern reversal visual stimuli (VEPs), and binaural auditory stimuli (AEPs) during unilateral passive movement at 40 rpm of the leg ipsi- and contralateral to the stimulated limb. SEPs, referenced to Fpz, and soleus H reflexes were attenuated in both movement conditions compared to non-movement controls ( $p < 0.05$ ). VEPs (N75-P100), referenced to Fz, and short latency AEPs, referenced to the right earlobe, were not significantly altered by passive movement. Middle and long latency AEPs were inconsistent across subjects. We conclude that in contrast to sensory gating in the upper limb, gain attenuation in the lower limb is generalizable to passive movement contralateral to the stimulated limb. This gain attenuation is not generalized to other sensory modalities. Supported by NSERC (Canada).

## 169.19

REACHING MOVEMENTS DURING ILLUSORY SELF-ROTATION SHOW COMPENSATION FOR EXPECTED CORIOLIS FORCES. J.V. Cohn\*, P. DiZio and J.R. Lackner. Ashton Graybiel Spatial Orientation Laboratory and Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Subjects exposed to constant velocity, body rotation ( $60^\circ/\text{s}$ ) at the center of a fully enclosed rotating room feel stationary. When reaching to targets they show large trajectory deviations and endpoint errors in the direction of the transient Coriolis forces generated by their movements. By contrast, subjects who turn voluntarily ( $365^\circ/\text{s}$ , peak) reach accurately indicating that they compensate for their large self-generated Coriolis forces. We predicted that stationary subjects experiencing illusory self-rotation would make reaching errors because of "automatic" motor compensations for "expected" Coriolis forces.

We studied reaching movements of stationary Ss ( $N=10$ ) experiencing illusory self-rotation and displacement induced by full-field visual scene rotation ( $60^\circ/\text{s}$ ) in a LEEP Cyberface2 ( $140^\circ$  FOV) head mounted display. Ss experiencing illusory CCW self-rotation exhibited leftward trajectory deviations and endpoint errors in pointing to targets. These errors are mirror image to those generated during passive CCW body rotation in a rotating room. This means that Ss can compensate for anticipated Coriolis forces. These observations emphasize the importance of forward models in understanding human movement control and the necessity to take into account information about whole body orientation.

## 169.18

REACHING TRAJECTORY AND ENDPOINT ERRORS INDUCED BY CORIOLIS FORCE PERTURBATIONS IN LABYRINTHINE-DEFECTIVE SUBJECTS. P. DiZio\* and J.R. Lackner. Ashton Graybiel Spatial Orientation Laboratory and Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

We measured the effects of inertial Coriolis force perturbations on visually open-loop reaching movements in a fully enclosed rotating room. Five profoundly labyrinthine-defective (LD) individuals and five age-matched controls participated. The LD subjects do not experience self-rotation even during exposure to high levels of angular acceleration. Ss were tested at 10 rpm, constant velocity and all felt stationary during testing.

The normal Ss performed like Ss in our earlier experiments (Lackner & DiZio, 1994. *J. Neurophys.* 72:299-313), showing initial deviations of reaching trajectory and endpoint in the direction of transient Coriolis force perturbations, followed by complete adaptation to baseline within 40 reaches, and mirror-image aftereffects post-rotation. The LD Ss showed the same pattern of initial errors but fragmentary adaptation. They achieved 100% adaptation of trajectory but only 25% of endpoint after 40 per-rotation reaches, trajectory but not endpoint aftereffects were present post-rotation. Thus, 1) Coriolis forces and not vestibular stimulation are responsible for reaching errors in our paradigm during constant velocity rotation, 2) brachial proprioceptive feedback involved in adaptation depends on vestibular regulation, and 3) adaptation of posture (endpoint) and movement (trajectory) are separately controlled.

Supported by NASA grants NAG9-4374 and NAG9-4375.

## 169.20

TRANSLATING INSTRUCTIONS TO SPATIALLY-DIRECTED LIMB MOVEMENT: ELDERLY vs YOUNG. R.K. Parasher\*, A.M. Gentile, Z.M. Pine & P. Kringas. Teachers College, and College of Physicians & Surgeons, and Presbyterian Hosp., Columbia Univ. NYC, NY. 10027

Previously, spatially-directed limb movement was found to be initiated and executed faster following instructions using pictures (visuospatial - VS) than words (visuowritten - VW) (Parasher & Gentile, 1995). We proposed that VS instructions rapidly yield a visuospatial representation of the goal (associated with right hemisphere processing) and is used to guide movement organization. In contrast, VW (left hemisphere processing) necessitates interhemispheric transfer and recoding of input to derive the goal-representation. In the present study, an interaction of Age x Instruction was predicted: differences between VS and VW were hypothesized to be greater for elderly than young subjects as interhemispheric transfer of information may be disrupted. The task required reaching forward to grasp a dowel and placing its light or black end into one of 4 containers located left/right, near/far of the subject. Instructions specifying the goal were presented visually: VS - a line drawing depicted final dowel-placement; VW - 3 words described placement (e.g. BLACK FAR RIGHT). Right-handed females, 12 elderly (70-79 yrs) & 12 young (20-40 yrs), were tested under 8 conditions derived from right/left, near/far, black/light combinations of dowel-placements. Reaction time (RT) and movement times (MTs) were measured. Prior findings were replicated: RT & MTs were faster for VS than VW which appears due to simultaneous vs. serial processing. As predicted, differences between VS and VW were greater for elderly than young. The significant Age x Instruction interaction suggests a delay in interhemispheric transfer of information, which may be related to prior findings of structural changes in the corpus callosum with aging (cf. Doraiswamy, et al, 1991).

## CONTROL OF POSTURE AND MOVEMENT: HAND MOVEMENT

## 170.1

HUMAN INDIVIDUATED FINGER MOVEMENTS: HOW INDEPENDENT ARE THE DIGITS? R. Hayes and M. H. Schieber\*. Department of Neurology, University of Rochester, Rochester, NY, 14642.

Whereas nonhuman primates are capable of only relatively independent finger movements, the human fingers and thumb often are assumed capable of completely independent motion, except for some couplings produced by interconnections between tendons. In both unskilled tasks and skilled performances, however, humans typically make simultaneous movements of multiple digits. To quantify the degree to which human subjects move one finger without moving others, we used either a DataGlove or a video movement analysis system to record the movements of the thumb and fingers as subjects flexed and extended different digits in a verbally instructed pseudorandom rotation. Most human subjects made measurable movements of non-instructed digits, which were smaller than those previously reported for the individuated finger movements of rhesus monkeys, but showed generally similar characteristic patterns (Schieber, *J. Neurophys.* 65:1381-91, 1991). Consistent with common experience, thumb and index finger movements were highly independent, while movements of the middle, ring and little fingers were less so. Explicitly requesting that human subjects keep non-instructed digits still while moving the instructed digit failed to improve performance. We used the previously developed Individuation Index to quantify the degree to which non-instructed digits moved during each instructed movement, and the Stationarity Index to quantify the degree to which a digit remained stationary when it was a non-instructed digit. These indices confirm that human finger movements, though more highly individuated than those of Rhesus monkeys, are not completely independent. The causes may include tendons, multitendoned muscles, and descending control. Support: R01-NS-27686, P41-RR-0283.

## 170.2

COORDINATING THE MANY JOINTS OF THE HAND

J. F. Soechting and M. Flanders\*. Dept. Physiology, University of Minnesota, Minneapolis, MN 55455

The hand and fingers comprise an enormous number of kinematic degrees of freedom and the question arises: to what extent can each of them be controlled independently by the nervous system? We investigated this question by studying a well-practiced motor task involving the hand and fingers, namely typing, and by obtaining a fairly complete kinematic description of these movements. This description included 3 degrees of freedom at each of the fingers: flexion/extension at the metacarpophalangeal and proximal interphalangeal joints and abduction/adduction. It also included a 4 degree of freedom description of thumb motion and 2 more degrees of freedom at the wrist (pitch and yaw). We found principal component analysis and cluster analysis to be useful in providing a concise description of the experimental data. In particular, very few ( $<4$ ) principal components were needed to describe motion at all of the degrees of freedom for all of the keystrokes executed with the right hand. The data were found to be clustered, both for the patterns of motion for one degree of freedom as well as for the relations between degrees of freedom, but we did not find any obligatory coupling of motions of any of the fingers.

**AUTOMATIC GRASP FORCE ADJUSTMENT IN A FES HAND NEURO-PROSTHESIS FOR TETRAPLEGIC PATIENTS.** A. Lickel, M. Haugland\*, Center for Sensory-Motor Interaction, Aalborg University, Fredrik Bajersvej 7D 9220 Aalborg, Denmark

When normal humans are grasping and holding an object between two fingers, the cutaneous mechanoreceptors are used for estimation of the precise force necessary to hold the object in a secure grasp without using excessive force. We have investigated the possibility of implementing such a mechanism in a system for re-establishing lateral handgrasp in a tetraplegic patient by functional electrical stimulation, by means of signals from a cuff electrode placed on a cutaneous nerve in the hand. A 26 yr male C5 tetraplegic volunteer subject was instrumented with 8 percutaneous stimulation electrodes implanted into four finger muscles (FPL, AdP, EPL and FDS) and a tripolar cuff electrode implanted around the palmar digital nerve to the radial side of the index finger. A scheme for detecting slips across the index finger was developed and used as a trigger for increasing the stimulation intensity, so that slips were stopped before the object being held was dropped. In a controlled setup, where the arm of the subject was stabilized in a vacuum cast, the object held in a key grip between the thumb and index finger and being pulled out of the grip horizontally, the performance of the tetraplegic subject using the FES system was compared to the performance of normal subjects in the same situation. The necessary stimulation intensity to hold a given load could be probed by slowly decreasing the intensity until a slip occurred. Using this scheme it was possible to automatically adjust the stimulation intensity and hold a constant load with the same or lower average grasp force than normal subjects would usually do. It was also shown that for sudden increases in load, the average slip length for the FES system was the same as for the normal subjects.

## 170.5

**INTERDIGITAL CONTROL OF ISOMETRIC FINGER FORCES** H. Henningsen\*, S. Knecht, M. Deppe, M. Fischer, B. Ende-Henningsen, A. M. Gordon, Dept. of Neurology, Univ. of Münster, 48129 Münster, Germany; Dept. of Movement Sciences, Teachers College, Columbia Univ., New York, NY 10027, USA.

Previously we have demonstrated asymmetries in the ability to match the finger forces exerted with the right and left hands which depend on the handedness of the subject. It can be hypothesized that functional asymmetries may exist in the ability to match the finger forces exerted within each hand as well. In the present study we investigated the ability to match the forces between adjacent and non-adjacent fingers of the same hand. Subjects were trained to produce an isometric flexion force of  $200 \pm 50$  g separately with each of two fingers of the right hand at a time. During the experiment, they were instructed to match the forces of these two fingers simultaneously within the trained force range. The training and testing were repeated for all possible two-finger-combinations of the index, middle, ring and little finger of the right hand in a randomized order. The results showed that the ability to match the force of two fingers depended on the specific fingers involved. Subjects were fairly accurate at matching forces of adjacent fingers, but performance progressively decreased as the number of digits between the two tested fingers increased. We suggest that the recently shown overlap of representation of the individual fingers within the primary motor cortex may facilitate the comparison of forces exerted by adjacent fingers.

## 170.7

**STRETCH REFLEXES ARE ATTENUATED IN HAND MUSCLES DURING HUMAN PRECISION GRIP.** D.F. Collins\* and A. Prochazka, Div. of Neuroscience, University of Alberta, Edmonton, Alberta, CANADA, T6G 2S2.

The aim of our study was to analyze the role of reflexes in hand muscles during grasping and lifting of weights. Stretch reflexes were reduced just prior to contact with the weights when compared to isometric contractions. Tasks involved the right hand only. Vision of the arm distal to the mid-forearm was prevented. Grip aperture and the full-wave rectified EMG activity of 4 muscles involved in the grip were monitored. The thumb and index finger were splinted to restrict interphalangeal joint movement. Step stretches (12 mm, 8 ms rise time) were applied using a servo-motor connected to a ring around the distal interphalangeal joint of the index finger during 2 grip tasks and one static hold task. Prior to each grip trial thumb and index finger positions were standardized. Task 1: grasp, lift and replace the  $1.5 \times 1.5 \times 3$  cm high, 750g weight using a precision grip between the index finger and thumb. Task 2: weight absent, move the index finger to contact the thumb. Task 3: constant isometric force between thumb and index finger. During each task reflexes were evoked at the same grip aperture, corresponding to just before finger contact with the weight in task 1 and 20 trials of perturbed and unperturbed trials were collected. During the static trials short latency (25-30 ms) and long latency (60-70 ms) excitatory responses were recorded. The amplitude of the short latency component was substantially reduced (as much as 90%) during tasks 1 and 2. The longer latency responses were depressed in some cases. The attenuation of these reflexes likely arises from central inhibition and possibly spindle unloading in the shortening muscles and suggests that this phase of human grip relies more on central than proprioceptive reflex control.

Supported by the MRC of Canada and the AHFMR.

## 170.4

**CONTROL OF 2-DIMENSIONAL FINGERTIP FORCE VECTORS DURING PRESSING: FORCE AND MUSCLE ACTIVATION PATTERNS.** K.J. Cole\* and W.G. Darling, Dept. Exercise Science, Univ. of Iowa, Iowa City, IA 52242.

Manipulating objects with the fingertips requires that we control the resultant fingertip force vector's direction and magnitude. It is not clear how this control occurs, given the complex geometry of the finger. For example, when pressing the distal, palmar surface of the index finger against a flat, rigid surface the long flexor muscles will produce the desired force normal to the surface and a tangential force directed towards the wrist. In the present experiment subjects pressed against a force plate with their index finger. They generated normal forces from 5% to 30% of their maximum pressing force (MPF). Only target force and normal force were displayed oscillographically to subjects in real time.

Tangential forces were minimal in all subjects; the resultant force vector was nearly normal to the force plate. In most subjects the vector was aimed no more than 3 degrees off the perpendicular, while in a few subjects the vector deviated up to 15 degrees. Thus, frictional forces were not exploited for stability (measured friction would permit 45 degree deviation from perpendicular). Intrinsic and extrinsic muscles coactivated during this pressing task, including extensor muscles. All scaled their activity with the size of the resultant fingertip force vector. The long flexors and lumbrical modulated most steeply, while the long extensors and dorsal interosseous modulated much less. Lumbrical was active at 20% of its maximal activity at 5% MPF, but was at 100% by 30% MPF. In contrast, the long flexors were between 25 and 50% of maximal activity at 30% maximal pressing force. Because of lumbrical's origin from the flexor digitorum profundus (FDP) tendon and insertion into the extensor expansion, it produces extensor torques at the distal interphalangeal joint, while removing flexor torque at this joint from FDP. This muscle may play a crucial role in directing the resultant fingertip force vector during dexterous manipulation.

## 170.6

**MUSCLE COORDINATION DURING MAXIMUM INDEX FINGER AD-ABDUCTION FORCES** F.J. Valero-Cuevas\*, C.G. Burgar\*, F.E. Zajac\*, V.R. Hentz\*, K.C. McGill\*, K.N. An\*

\*Rehab. R&D Ctr. and †Hand Ctr., VA PAHCS, Palo Alto, CA 94306; ‡Dept. Mech. Eng. Stanford U. and \*Dept. Funct. Rest. Stanford U. Med. Ctr. Stanford, CA 94305; †Orthop. Biom. Lab., Mayo Clinic, Rochester, MN 55905

The muscle excitation pattern (MEP) that produces index finger force in key pinch is relevant to the restoration of hand function as it may reveal surgical factors and principles that contribute to successful grasp outcomes. Due to the biomechanical complexity of the fingers, index finger force in key pinch may be produced by different MEPs. Our four degree-of-freedom (DOF) model of the index finger (flexion-extension at MCP, PIP and DIP joints, ad-abduction at MCP joint) included all seven finger muscles and predicted the unique MEP which produces maximum static force originating at the midpoint of the distal phalanx, in neutral MCP ad-abduction, in extended (10° flexion at all joints) and flexed (45° MCP and PIP, 10° DIP joint flexion) finger postures. For abduction force (analogous to force during key pinch), MEP predictions for the first dorsal (FDI) and palmar (FPI) interosseus agonist-antagonist pair consisted of maximum excitation of FDI and zero excitation of FPI, and viceversa for adduction force, invariant with posture.

We recorded intramuscular EMG from all seven muscles of the index finger during maximum voluntary static ad-abduction forces in eight adults in the extended and flexed postures. As predicted, we found no co-activation of the agonist-antagonist pair in the extended posture, but found unpredicted co-activation in the flexed posture ( $p < 0.05$ ).

We propose this co-activation of FDI and FPI may be evidence of active stabilization of proximal phalanx MCP torsion, a DOF generally omitted in finger models, which may be needed to produce key pinch force and control the MCP joint.

## 170.8

**ANTICIPATORY CONTROL OF PRECISION GRIP FORCE IN TOURETTE'S SYNDROME.** L.S. Jakobson\*, J.R. Flanagan and K.G. Munhall, Queen's Univ., Kingston, K7L 3N6, Canada.

When lifting or transporting an object held in a precision grasp, grip force normal to the sides is finely modulated in anticipation of changes in load force tangential to the surface such that the grip force tends to be just slightly greater than the minimum required to prevent slip. Such predictive control may be contrasted with reflex-mediated increases in grip force that follow an unexpected load force perturbation to the object. In this paper, we examine the control of grip forces in an individual with Tourette's Syndrome. A key issue is whether increases in load force associated with tics are anticipated by appropriate grip force adjustments or act as unexpected load perturbations requiring feedback based grip force modulation. Our results suggested that the subject employed a grip force safety margin that was greater than that used by control subjects. In addition, we observed a number of cases in which load forces due to tics were anticipated by an increase in grip force. These results suggest that "involuntary" tics are anticipated by the motor system in a manner similar to voluntary movements. The extent to which grip force adjustments were sensitive to the magnitude and/or direction of the load will be reported.

## 170.9

**MATCHING VISUALLY PERCEIVED OBJECT SIZES BY CONTROLLING FINGER SPAN.** M. Santello and J.F. Soechting\*. Department of Physiology, University of Minnesota, Minneapolis, MN 55455.

During the transport phase of grasping, finger span is found to be scaled to the object size. In order to study the accuracy of this scaling, we asked 5 subjects to match the size of cubes (ranging from 0.5 cm to 12.4 cm) by adjusting the finger span. The experiments were performed in a 'static' condition (*i.e.*, in absence of the transport phase) and without visual feedback of the hand. The experiments were designed to study the dependence of accuracy on (a) object size, (b) the finger coupled to the thumb, (c) shape of the object, (d) distance of the viewed object and (e) object orientation.

In all experimental conditions the error (underestimation of cube's size) tended to increase for larger sizes ( $p < 0.01$ ). A significant effect of finger was also found, the little finger being less accurate (larger underestimation of cube's size) than the rest of the fingers. A significant difference in the error was found when comparing the accuracy in estimating the same sizes of cubes and cylinders, but not when comparing cubes and rectangular prisms. No effect of viewing distance and object orientation was found.

The fact that the accuracy in reproducing a cube's size was not affected by changing the cube's retinal projection (experiments *c* and *d*) indicates that the subjects were able to infer the actual cube's size. Object's shape, on the other hand, altered the perception of size. The accuracy in the transformation from visual information to motor commands was found to be dependent on the finger used.

## 170.11

**SIGNIFICANT LEFT-RIGHT SYNCHRONIZATION OF PULSATILE MOTOR OUTPUT IN A HUMAN BIMANUAL FINGER MOVEMENT TASK.**

J. Wessberg\*. Dept. of Physiology, Göteborg University, Medicinargatan 11, S-413 90 Göteborg, Sweden.

Slow finger movements in humans are often characterized by velocity peaks or discontinuities recurring at 8-10 Hz, produced by a pulsatile modulation of the activity of agonist and often antagonist muscles as well (Vallbo & Wessberg, *J Physiol* 1993, 469, 673-691). It has been shown that the pulsatile modulation of muscle activity is not dependent on peripheral mechanisms, but generated within the central nervous system (Wessberg & Vallbo *J Physiol* 1995, 485, 271-282; *J Physiol* In press). The aim of this study was to analyze if the 8-10 Hz modulations of motor output to the left and right hand exhibit bilateral synchronization during a bimanual precision task. Movements were recorded in 5 healthy volunteers. The subjects were sitting with the hands resting on a table, and were asked to flex the two index fingers slowly and simultaneously towards a target object located mid way between the fingers. Movements were recorded with a video array tracking the location of a set of reflective patches.

Intermittent synchronization of the 8-10 Hz velocity peaks was observed during the movements. Statistical signal analysis in the time- and frequency-domains confirmed a significant synchronization in all subjects. Overall coherence of the joint angle acceleration for all movements in individual subjects peaked in the 9-10.3 Hz range, with values ranging from 0.023 to 0.071. Analysis of the coherence in relation to the instant of contact with the target object revealed that significant coherence was not limited to the onset of the movements.

The findings support the conjecture that the 8-10 Hz modulations of motor output are due to a modulation at similar frequency of the descending central command during slow finger movements.

## LIMBIC SYSTEM AND HYPOTHALAMUS I

## 171.1

**FUNCTIONAL SEGREGATION OF SYNAPTIC INPUTS TO CA3 USING MULTIELECTRODE PROBES.** C.Y. Perron\*, M.F. Yeckel and T.W. Berger. Dept. of Biomedical Engineering and Program in Neuroscience, University of Southern California, Los Angeles, CA 90089-1451.

The electrophysiological isolation of mossy fiber (mf) inputs to CA3 pyramidal cells by *in vivo* extracellular field potential recordings remains a challenge due to factors such as the spatial restriction of the mf pathway in *s. lucidum* and the proximity of other current sinks produced by CA3 collateral inputs and somatic spike generating processes. In this study, vertical multielectrode probes were lowered through CA3c to perform current-source density (CSD) analyses on halothane-anesthetized rabbits for different stimulation sites, which include the hilus of the dentate gyrus, the perforant path (pp) in the angular bundle and the Schaffer collaterals (Sch) in CA1 *s. radiatum*. Hilar stimulation was expected to produce a short latency, monosynaptic mf excitatory sink within 100  $\mu$ m of the CA3 population spike sink, as well as a longer latency, disynaptic sink higher in the dendrites due to activation of CA3 collaterals. The pp stimulation was expected to produce a monosynaptic sink in the apical dendrites of CA3 and a disynaptic mf sink if the stimulation intensity was high enough to activate granule cells. The purpose of Sch stimulation was to observe recurrent collateral sinks in the absence of mf inputs.

Recordings with the multielectrode probes revealed four main findings. (1) Hilar stimulation produced a short latency population spike, indicating that CA3 cells were monosynaptically activated by mf. (2) The expected short latency mf sink was weak. This may have been due to either the proximity of both the recurrent collateral sink and its associated source or to insufficient spatial resolution of the present probes. (3) The collateral sink in response to hilar stimulation was distinct both temporally and spatially from the population spike sink and occurred at the same location as the sink produced by Sch stimulation, although shifted in time. (4) Single pp stimulation did not produce a detectable disynaptic mf sink, but paired pulse or low frequency (10Hz) stimulation did. In summary, the present probes clearly identified some response components such as the recurrent collateral sink. Probes with higher spatial resolution may be required to accurately dissociate the mf sink from the recurrent collateral sink.

**DIGITAL INTERACTIONS IN THE CONTROL OF REACTIVE MOTOR RESPONSES IN BIMANUAL AND UNIMANUAL TASKS.** Y. Ohki\* and R. S. Johansson. Dept. of Physiology, Univ. of Umeå, S-901 87 Umeå, Sweden

When we manipulate objects the finger tip forces are controlled by digit-specific mechanisms for grasp stability, but higher level controllers account for aspects of inter-digital coordination. We addressed the relative importance of those control policies when subjects used two fingers to restrain a manipulandum with two horizontal grip plates. In a bimanual task they used the right and left index fingers, and in a unimanual task the index and middle fingers of the right hand. Trials of distally directed loads were unpredictably delivered to either one of the two grip plates or simultaneously to both. The probabilities of these three loading conditions were set differently among test series. Subjects prevented frictional slips by always responding to the load increase by rapidly increasing the normal force of a loaded finger. Although the very initial part of the dynamic response could be stronger in certain test series, simultaneous loading of the cooperating finger tended to attenuate the response in both grasp configurations, but most markedly in the unimanual task. Automatic responses also occurred in a finger that was not loaded. These were considerably smaller than those evoked while the same finger was loaded, but their sizes increased with the probability of loading of that particular finger in the test series. Such responses were essentially confined to a brief force rate pulse coinciding in time with the initial part of the dynamic response of the loaded finger. However, in the bimanual task the responses in a non-loaded finger lagged those of the loaded finger by some 20 ms. In conclusion, in both bi- and uni-manual grasp configurations digit-specific afferent inputs are necessary for eliciting a response strong enough to restrain an object. But the response is to some extent influenced by the loading of the cooperating finger, and its size depends on subjects' expectations of the behavior of the manipulandum. Finally, the features of the responses in loaded and non-loaded fingers indicate that these are in part mediated by fundamentally different neural processes both in bimanual and unimanual tasks. This work was supported by the Swedish MRC and the ONR, Arlington, VA.

**EONS: A MULTI-LEVEL MODELING SYSTEM.** I.-S. Liaw<sup>1</sup>\*, Y. Shu<sup>2</sup>, T.W. Berger.<sup>1</sup> <sup>1</sup>Dept. of Biomedical Engineering & Program in Neuroscience, <sup>2</sup>Dept. of Computer Science, Univ. of Southern California, Los Angeles, CA 90089

The capability of simulating neural systems at different levels of organization is essential for an understanding of brain function. We present EONS (Essential Objects for Neural Systems), a simulation system for developing neural models with different levels of analysis. Unlike traditional approaches of tightly coupling the user interfaces and the simulation systems, EONS tries to separate these two components to facilitate the reuse and portability of existing models so that scalability and extensibility of the simulation systems can be realized. In the approach presented here, object-oriented design methodology is used to form a hierarchy of neural models. Each model, *e.g.*, for a synapse or a neuron is self-contained. This provides the flexibility to compose complex system models from models of basic elements. Furthermore, by including a modularity which is independent of any user interface, EONS will facilitate collaboration among geographically distributed groups (*e.g.*, over the Internet).

As an example of this utility, we have used EONS to develop a neural network model for speech recognition that incorporates detailed synaptic mechanisms. In particular, short-term presynaptic plasticity such as facilitation, and feedback modulation are included. Due to presynaptic mechanisms, the synaptic strength changes dynamically, which we call the dynamic synapse. The probability of neurotransmitter release is determined by the temporal pattern of the spike train. That is, the dynamic synapses transform the temporal pattern of a spike train into a spatio-temporal pattern of discrete events of neurotransmitter release. As a result, the dynamic synapses provide an exponential increase in the computing capability of a neuron. We demonstrate the power of synaptic computation by performing speech recognition from unprocessed, noisy raw waveforms. Supported by ONR, NCRR, Human Frontiers Org., and NIMH.

**NONLINEAR SYSTEMS CHARACTERIZATION OF DENTATE GRANULE CELL EPSPs BY FULL WAVEFORM KERNEL MODELS.** S.S. Dalal\* and T.W. Berger. Dept. of Biomedical Engineering and Program in Neuroscience, University of Southern California, Los Angeles, CA 90089-1451.

The perforant pathway provides glutamatergic input to the granule cells of the dentate gyrus. Electrical stimulation of this pathway yields a granule cell EPSP comprised of both AMPA and NMDA receptor-mediated components, each of which is facilitated or depressed depending upon the pattern of prior stimulation. Hence, both components of the system are nonlinear with respect to interstimulus interval. We present here an experimentally based nonlinear characterization of this system through use of a Volterra functional power series.

Intracellular sharp microelectrode recordings of granule cell EPSPs were performed in the rabbit hippocampal slice preparation. The perforant pathway was stimulated by a random impulse train which consisted of 4064 pulses and had a mean frequency of 2 Hz. Recordings were conducted in both physiological and low magnesium concentrations (1.2 mM and 0.1 mM, respectively). Picrotoxin (20  $\mu$ M) was included in the perfusate to block GABAergic inhibition, and the AMPA and NMDA components were pharmacologically isolated by adding CNQX (10  $\mu$ M) and APV (50  $\mu$ M), respectively, to the medium.

First, second, and third order kernels for the full waveform of the EPSP response were computed. Results show that the measured, composite EPSP was not merely a linear superposition of the NMDA and AMPA components. Because of the different kinetic properties of the two receptor-channels, such as voltage-dependent blockade of the NMDA receptor, the nonlinearities exhibited by each channel type were different. Analysis of the full waveform was critical in that the nonlinearities expressed by each receptor subtype were observed to occur during both the initial and late phases of the composite EPSP. Supported by ONR, NCRR, and NIMH.

**COMPUTATIONAL MODEL OF A POPULATION OF DENTATE GRANULE CELLS BASED ON A NONLINEAR SYSTEMS ANALYTIC APPROACH.**

G.L. Wehrer\* and T.W. Berger. Department of Biomedical Engineering and Program in Neuroscience, University of Southern California, Los Angeles, CA 90089

We have shown previously that the response dynamics of dentate granule cells can be accurately modeled as the kernels of a functional power series. The kernel functions are determined on the basis of random impulse stimulation of the perforant path and represent higher order nonlinearities with respect to the inter-pulse interval of the stimulus. These experimentally determined kernel functions ( $h_n(\tau)$  in diagram below) were used as the basis of a computational model of a population of dentate granule cells. In addition, since the actual contribution of each synapse of a particular granule cell cannot be determined experimentally, it is necessary to estimate the distribution of the cell's dynamics over the estimated number of synapses in terms of a statistical description (a-d in diagram below).

The model utilizes the stochastic methods used in artificial neural networks to assign and modify individual weights to each of its processing units which correspond to each of the estimated pp-gc synapses. Each processing unit weight is modified in order to minimize the error between the network output and the experimental response. The optimum weight matrix represents the dynamics of the network which correspond to the dynamics of the cell. It is from this optimum weight matrix that the relative statistical distribution of pp-gc connectivity can be extrapolated.

**IDENTIFICATION OF HIGHER ORDER NONLINEARITIES OF HIPPOCAMPAL GRANULE CELLS BY FEEDFORWARD ARTIFICIAL NEURAL NETS** M.A. Saglam\*, V.Z. Marmarelis, and T.W. Berger. Dept. of Biomedical Engineering and Program in Neuroscience, Univ. of Southern California, Los Angeles, CA, 90089

A traditional approach to characterizing biological systems is the use of Volterra-Wiener (V-W) functional expansions and kernels. Nonlinear input/output properties of hippocampal dentate granule cells are characterized experimentally by stimulating perforant path input fibers with a Poisson process pulse-train and recording the evoked population spike amplitudes. Kernels express the response of the system to every pulse in the train as a function of the temporal pattern of the previously occurring pulses. However, the kernel-based model is practically limited in terms of the order of nonlinearity it can capture, and also requires long data sequences for its estimation. On the other hand, the nonlinear relation between the intervals and amplitudes can be easily modeled by feedforward Artificial Neural Networks (ANN). For example, the output of a second order system in response to an input pulse would be dependent only on the interval between the current pulse and the previous pulse and a three-layer perceptron with only one input unit would be able to model this second order relation. Higher order nonlinearities can be captured simply by including additional input units.

We compare the V-W and ANN models in terms of their prediction ability on test data. Results show two major advantages of the ANN approach: (1) a significant reduction in the required data length (by a factor of 10-20) and (2) an ability to model high-order nonlinearities. Since a net with 8-input units gave the minimum prediction error, we can conclude that nonlinearities up to 9th order may be present in the dentate granule cells, an order of nonlinearity that cannot be modeled with V-W kernels. This work was supported by ONR, NCRR, and NIMH.

## 171.4

**INTRACELLULAR EVIDENCE FOR GREATER PERFORANT PATH INPUT IN THE VENTRAL VS. DORSAL *in vitro* DENTATE GYRUS.** Choi Choi\* and T.W. Berger. Dept. of Biomedical Engineering and Program in Neuroscience, Univ. of Southern California, Los Angeles, CA 90089

Previously, we reported evidence from field EPSP recordings for greater perforant path excitatory input to dentate granule cells in slices prepared from the ventral vs. dorsal third of the hippocampus (with respect to the longitudinal axis). Input-output (I/O) curves for amplitudes of EPSPs elicited by twin pulse stimulation of the perforant path showed a steeper increase with increasing stimulus intensity and a larger maximum for ventral slices. In the present study, we examined intrinsic granule cell electrophysiology and intracellular EPSP I/O curves for 600  $\mu$ m thick transverse slices obtained from dorsal and ventral thirds of the hippocampus.

Sharp microelectrodes (impedance 100-180 M $\Omega$ ) filled with a 2 M KMeSO<sub>4</sub> salt solution, alone or combined with 50 mM QX-314, were used to impale and record (in current-clamp mode) from neurons in *s. granulosum*. Granule cells were identified by their location in the *s. granulosum* and by electrophysiological criteria (e.g. burst spike adaptation, action potential and/or EPSP to molecular layer stimulation). Orthodromic stimulation consisted of twin pulses (30 ms interval) delivered to the perforant path in the middle third of *s. moleculare*.

No dorsal-ventral differences were observed in granule cell resting membrane potential (RMP), input resistance ( $R_{in}$ ), threshold for action potential, or membrane time constant ( $\tau$ ). In the subthreshold portion of the intracellular EPSP I/O curve, a steeper increase in EPSP amplitude with increasing stimulus intensity was observed for ventral slices. The addition of QX-314 to the microelectrode solution depolarized the RMP 15 to 20 mV in all cells and eliminated the action potential in most cells for both groups of slices. In the cells where an action potential was not observed, the maximal EPSP was larger in ventral slices for both first and second responses. In addition, at maximal stimulus intensities, a greater proportion of cells from ventral slices continued to generate action potentials.

These results are consistent with previous extracellular results, and provide strong evidence for greater excitatory input to the dentate gyrus in slices from the ventral third of the hippocampus. Supported by ONR, NIH BMSR, NIMH.

## 171.6

**MIXED-SIGNAL VLSI IMPLEMENTATION OF A HIPPOCAMPAL MODEL.** T.W. Berger\*, B.J. Sheu, and R.H. Tsai. Depts. of Biomedical Engineering, Electrical Engineering, and Program in Neuroscience, Univ. of Southern California, Los Angeles, CA 90089.

We have demonstrated previously that a nonlinear systems analytic approach can be used to develop an experimentally-based model in the form of kernels of a functional power series of the dynamics of single neurons in the hippocampus. The kernels include the contribution of all possible sources of nonlinearities and represent the cell's response to the present input in the context of a "sliding window" of the input history. We used the kernel models of dentate granule cells and inhibitory interneurons to implement a hardware model of the dentate gyrus. In a previous design, a table-look-up approach was used that involved storage of discretized kernel values. Here we report a new design which utilizes a model-based approach in which extracted parameters are used to present the first and second order kernels in analog current-mode to save silicon area and maintain high accuracy. The model-based approach includes the following: i) the input is a series of impulses that can be conveniently specified, with effects from the history of input events accumulated in a set of capacitors; ii) the first order kernel function,  $h_1(\tau)$ , represented in analog, using capacitors charged to different voltage levels depending on the kernel value; the second order kernel,  $h_2(\tau, \Delta)$ , approximated by a characteristic curve of an analog circuit with parameter values that are externally programmable; iii) with each input event, output currents are generated from  $h_1(\tau)$  and  $h_2(\tau, \Delta)$ ; iv) summation of the currents from  $h_1(\tau)$ ,  $h_2(\tau, \Delta)$  determines the output of each silicon neuron. The above design has been incorporated into a 4x4-neuron prototype fabricated through MOSIS using 2- $\mu$ m technology. Supported by ONR, NCRR, NIMH.

## 171.8

**CHARACTERIZING UNOBSERVABLE NEURAL ELEMENTS IN THE HIPPOCAMPUS WITH NONLINEAR SYSTEMS ANALYSIS.** M.T. Chian\*, V.Z. Marmarelis, and T.W. Berger. Dept. of Biomed. Eng. & Prog. in Neurosci., Univ. of Southern California, Los Angeles, CA 90089

The hippocampal formation includes multiple feedback loops which are difficult to characterize through direct electrophysiological recording. However, the input/output properties (kernels of a functional power series) of these feedback connections may be quantified indirectly through nonlinear systems analysis. The input/output properties of the feedback system may be mathematically derived from those measured for the feedthrough and overall systems. Performing this calculation requires nonlinear algebraic system decomposition in the frequency domain. This method has been applied to characterization of the inhibitory effect of GABAergic basket cells on granule cells of the dentate gyrus. The granule cells of the dentate gyrus may be considered the feedthrough subsystem while the basket cells may represent an inhibitory feedback subsystem within an overall system. Since the feedthrough input/output properties may be isolated pharmacologically by blocking the feedback component, it is possible to mathematically deduce the feedback subsystem properties when the properties of the overall system and the feedthrough system are known.

Application of this method revealed that successful identification of unobservable subsystems depends primarily on accuracy of the initial estimates of observable system input/output properties and on the relative frequency bandwidths of the respective subsystems. Comparison of two input/output estimation methods showed that a new estimation method utilizing artificial neural networks allowed accurate recovery of the linear and nonlinear input/output properties of a given system. It also was discovered that in order to recover the nonlinear properties of the feedback element, the feedthrough element must have a larger frequency bandwidth than the feedback element. The influences of noise and different degrees of nonlinearities within each system were also studied. Supported by ONR, NCRR, and NIMH.

## 171.9

**ARE FEEDFORWARD AND FEEDBACK INHIBITION MEDIATED BY THE SAME OR DIFFERENT SETS OF INHIBITORY NEURONS?** *L.S. Fitzpatrick*<sup>1,2</sup>, *H.E. Scharfman*<sup>3</sup>, and *T.W. Berger*<sup>1,2</sup>. <sup>1</sup>Dept. of Biomedical Eng. and <sup>2</sup>Prog. in Neurosci., Univ. of Southern Calif., Los Angeles, CA 90089 and <sup>3</sup>NRC, Helen Hayes Hospital, and Columbia Univ. NY, NY.

Granule cell activity in the hippocampal dentate gyrus is subject to both feedforward and feedback inhibition. The present experiments were carried out to determine whether these two types of inhibition are mediated by two distinct sets of inhibitory neurons or by one common set of inhibitory neurons. Field recordings and sharp electrode intracellular recordings were made simultaneously from transverse rabbit hippocampal slices. Stimulating electrodes were placed in two locations: (1) the molecular layer (ML) to stimulate the perforant path, thereby activating (a) solely feedforward mechanisms if no granule cells generate action potentials or (b) both feedforward and feedback mechanisms if granule cells do generate action potentials; and (2) *s. lucidum* of area CA3c to stimulate mossy fibers (thereby activating feedback inhibition) and CA3 pyramidal cells (which could also activate feedback inhibition). We assume that stimulation at this second site did not activate feedforward inhibition. The extent to which feedforward and feedback inhibition originate from common or distinct sets of inhibitory neurons was assessed by comparing the IPSP resulting from simultaneous stimulation at both locations ("simultaneous IPSP") to the calculated sum of the two IPSPs produced by stimulation at the two locations individually ("calculated IPSP"). At maximal stimulation intensity, the results were mixed. Sometimes the "simultaneous IPSP" was identical to the "calculated IPSP," suggesting that the two stimulation locations activate distinct sets of inhibitory neurons. Other times the "simultaneous IPSP" was no larger than the IPSP elicited by ML stimulation, suggesting that feedforward and feedback inhibition are mediated by a common set of inhibitory neurons. At low or moderate stimulation intensities, the "simultaneous IPSP" was usually similar to the "calculated IPSP," indicating that sub-maximal stimulation at these locations activates distinct sets of inhibitory neurons. Supported by an NDSEG Fellowship to JSF; grants from ONR, NCR, and NIMH to TWB; and NINDS to HES.

## 171.11

**INTRACELLULAR  $Ca^{2+}$  CHANGES INDUCED BY TETANIC STIMULATION OF AFFERENTS IN RAT HIPPOCAMPAL INTERNEURONS.** *M. Ouardouz*<sup>1</sup>, *R. Robitaille*<sup>2</sup>, and *J.-C. Lacaille*<sup>1</sup>. Centre de Recherche en Sciences Neurologiques et Département de Physiologie, Université de Montréal, Montréal, Canada, H3C 3J7.

Hippocampal CA1 interneurons located in different layers show different  $Ca^{2+}$  responses to local application of glutamate. The aim of the present study was to characterize  $Ca^{2+}$  responses induced by synaptic activation of glutamate receptors in two types of interneurons in stratum oriens (OR) and lacunosum-moleculare (LM) in rat hippocampal slices. Interneurons were identified visually and whole cell recordings obtained with patch electrodes containing (in mM) 120 K-gluconate, 20 KCl, 2 MgCl<sub>2</sub>, 10 HEPES, 2 ATP-tris, 0.2 GTP-tris, as well as 0.1 calcium green-1 to measure intracellular  $Ca^{2+}$  changes. Changes in fluorescence were measured using a BioRad MRC-600 confocal microscope and expressed as percentage change from resting level. Synaptic responses were evoked using a monopolar electrode placed in the vicinity of the recorded cell. Tetanic stimulation (100 Hz, 1s) induced a larger  $Ca^{2+}$  increase in dendrites than soma ( $36.8 \pm 6.6\%$  and  $9.9 \pm 2.4\%$ , respectively,  $n=11$ ,  $p<0.01$  t-test). Dendritic  $Ca^{2+}$  responses were similar in LM and OR cells, and were of two types. First, transient responses in LM cells ( $n=18$ ) had an amplitude of  $43.3 \pm 7.0\%$ , a time to peak of  $1.4 \pm 0.2$ s and a recovery time of  $7.0 \pm 2.4$ s, versus an amplitude of  $34.2 \pm 8.6\%$ , a time to peak of  $1.0 \pm 0.2$ s and a recovery time of  $6.6 \pm 1.1$ s for OR cells ( $n=12$ ). Second, biphasic responses consisted of an initial  $Ca^{2+}$  peak ( $66.0 \pm 2.8\%$ ) followed by a secondary peak ( $n=3$  LM and 3 OR cells). Preliminary results indicate that  $Ca^{2+}$  responses were reduced by bath application of antagonists of ionotropic ( $20\mu M$  CNQX and  $50\mu M$  AP-5) or metabotropic ( $250\mu M$  MCPG) glutamate receptors. These results show that synaptically released glutamate can induce an elevation of intracellular  $Ca^{2+}$  in dendrites of both OR and LM interneurons. These  $Ca^{2+}$  responses may involve non NMDA, NMDA and metabotropic glutamate receptors.

## 171.13

**DISCORDANCE WITHIN ENSEMBLES OF CA1 AND CA3 CELLS IN CODING FOR SPATIAL RELATIONSHIPS.** *H. Tanila* (1)\*, *M.S. Shapiro* (2), *H.B. Eichenbaum* (3). <sup>1</sup>Dept. Neurology, Univ. Kuopio, Finland, <sup>2</sup>Dept. Psychology, McGill University, Montreal, Canada, <sup>3</sup>Cntr Behav. Neurosci, SUNY at Stony Brook, NY, USA.

Place fields of hippocampal pyramidal cells are controlled by salient local as well as distal environmental cues (Young et al., J Neurosci 14:6553, 1994). It is not known, however, whether all cells in an ensemble respond to a change in an environment in a concordant way. We recorded the activity of single hippocampal CA1 and CA3 cells in rats performing a win-shift task in a radial maze. Prominent distal visual stimuli were attached to the dark curtain surrounding the maze, and inserts with distinctive visual, tactile, and olfactory stimuli provided local cues on each maze arm. To test the influence of the different stimulus sets, the distal and local cues were rotated 90 degrees in opposite directions. In response to this manipulation, place fields could: maintain a fixed position to room coordinates, rotate with either the local or the distal cues, disappear, or new fields could appear. With one tetraode per animal we simultaneously recorded 2 to 10 complex spike cells with distinct place fields, providing a sample of 336 cells in 58 cell ensembles. On average 74% of cells within an ensemble responded in the same way (82% in 24-26 mo old rats who were impaired in spatial learning, 76% in aged learning-intact rats, and 68% in young rats.) Overall 31% of the ensembles were concordant (40% in aged learning-impaired, 33% in aged learning-intact, and 23% in young rats). Half of the discordant ensembles had place fields that rotated with one set of cues whereas the other fields disappeared or new fields appeared. In 19% of the discordant ensembles some cells had rotated fields whereas others maintained their fields in the original location. In 10% of the discordant ensembles there was one (but only one) cell with fields rotating in the direction opposite to that of the majority of cells. These findings suggest that hippocampal ensembles can simultaneously represent both the original and the altered environment and, in rare cases, conflicting orientations of cues within the same environment.

## 171.10

**CHARACTERIZATION OF  $Ca^{2+}$  RESPONSES INDUCED BY ACTIVATION OF mGluRs IN HIPPOCAMPAL INTERNEURONS USING CONFOCAL MICROSCOPY AND WHOLE CELL RECORDING.** *G. Woodhall*<sup>1</sup>, *R. Robitaille*<sup>2</sup>, and *J.-C. Lacaille*<sup>1</sup>. Centre for Research in Neurological Sciences, Department of Physiology, Univ. of Montreal, Montréal, Canada, H3C 3J7.

Hippocampal CA1 interneurons show diverse  $Ca^{2+}$  responses to excitatory amino acid receptor activation, including  $Ca^{2+}$  oscillations, fast transients and biphasic responses. Prolonged oscillations are associated with specific interneurons in the stratum oriens and alveus area (OA) and involve ionotropic and metabotropic glutamate receptors (mGluR). The aim of this project was to examine the response of interneurons in OA to mGluR activation using whole cell recording and confocal  $Ca^{2+}$  imaging in rat hippocampal slices. Interneurons in OA were visually identified and whole cell current clamp recordings obtained using patch electrodes (5-10MΩ) filled with (in mM) 120 K-gluconate, 20 KCl, 5 NaCl, 2 MgCl<sub>2</sub>, 10 HEPES, 2 ATP-tris, 0.2 GTP-tris. Biocytin (0.1%) was also included for morphological characterization of interneurons. The fluorescent  $Ca^{2+}$  indicator calcium green-1 (95μM) was included in the recording solution and responses monitored with a BioRad MRC-600 confocal microscope. The mGluR agonist 1S,3R-ACPD (250μM) was applied onto discrete regions of the cell (soma, dendrites) using pressure ejection (10-40 ms) from a patch pipette. OA cells responded to ACPD in two ways. Some cells showed an oscillatory  $Ca^{2+}$  response lasting 200-500ms and consisting of multiple rises in  $Ca^{2+}$  level ( $\geq 3$  peaks). Other OA cells responded with a gradual rise in  $Ca^{2+}$  level. The electrophysiological responses evoked by ACPD consisted of membrane depolarizations associated with either phasic discharges and occasional plateau potentials, or a more tonic firing pattern. These results suggest that activation of mGluRs produces two types of  $Ca^{2+}$  rise and electrophysiological response in OA cells.  $Ca^{2+}$ -mediated mGluR actions may thus be heterogeneous and selectively expressed in specific interneurons.

**INTRACELLULAR CORRELATES OF HIPPOCAMPAL DENTATE EEG SPIKES IN GRANULE CELLS, INTERNEURONS AND PYRAMIDAL CELLS IN VIVO.** *M. Penttonen*<sup>1</sup>, *A. Sik*, and *G. Buzsaki*. CMBN, Rutgers University, Newark, NJ 07102

Dentate spikes (DS) are large amplitude (1-4 mV), short duration (10-40 ms) field potentials that occur during behavioral immobility and slow wave sleep. DS are associated with burst discharge of putative hilar interneurons and suppressed firing of CA1-3 pyramidal cells. Here we recorded intracellularly from granule cells, CA3 and CA1 pyramidal cells and hilar interneurons during DS in urethane anesthetized rats. The neurons were anatomically identified. DS were associated with depolarization of granule cells and occasional action potentials. CA3 and CA1 pyramidal cells were hyperpolarized or not affected. A HICAP interneuron as well as a trilaminar interneuron with axon collaterals in CA3, CA1 and subiculum fired bursts during DS. Hilar interneurons with extradentate projections may be responsible for the DS-induced suppression of the CA3-CA1-subiculum circuitry.

## 171.14

**THE DORSO-VENTRAL DIFFERENCE IN THE DISTRIBUTION OF NON-PRINCIPAL CELLS IN THE RAT HIPPOCAMPUS.**

*TAKUO NOMURA*<sup>1</sup>, *TOSHIO KOSAKA*<sup>1</sup>, *MASAHICO SAKAGUCHI*<sup>2\*</sup>. <sup>1</sup>Dept. of Anat. and Neurobiol., Faculty of Med., Kyushu Univ. Fukuoka 812-82, Japan. <sup>2</sup>Dept. of Biol., Faculty of Educ., Shinshu Univ. Nishinagano, Nagano 380, Japan.

In the present study we examined major subpopulations of GABAergic nonprincipal neurons in the hippocampus, focusing on the dorsoventral differences in their distributions. The subpopulations analyzed are those immunoreactive for parvalbumin (PV), calretinin (CR), nitric oxide synthase (NOS), somatostatin (SOM), calbindin D28k (CB), vasoactive intestinal polypeptide (VIP) and cholecystokinin (CCK). Using a confocal laser scanning light microscope, we could confirm that the penetration of each immunostaining was complete throughout 50μm thick sections under our immunostaining conditions (except that of CB). So we counted the number of positive cells according to the detector principle and calculated the numerical densities (ND). Generally speaking, PV, CB, CCK and VIP neurons showed no significant dorsoventral differences in the NDs in any subdivisions of the hippocampus, whereas the NDs of CR, NOS and SOM neurons were significantly larger in the ventral than in the dorsal hippocampus. The ND of SOM neurons was significantly larger in the dentate gyrus. That of NOS neurons was significantly larger in the CA3 region as well as in the DG. The ND of CR neurons was larger in all hippocampal subdivisions. We concluded that the dorsal and ventral hippocampus differ from each other in the composition of GABAergic non-principal cells. RAPHE INFLUENCES ON GRANULE CELL EXCITABILITY: EFFECTS OF LOCAL ACTIVATION AND 5-HT ANTAGONISTS. K.Kao\* and E.J. Green. Dept. of Psychology, Univ. of Miami, Coral Gables, FL 33124

Prestimulation of the median raphe (MR) can markedly augment the flow of information through the hippocampus. Recent neurophysiological studies indicate that electrical activation of the MR increases granule cell excitability through inhibition of inhibitory interneurons (Kao, Sanders and Green, 1995), a finding consistent with anatomical evidence for MR-interneuron connections (Freund et al., 1990). The present experiments were designed to 1) assess whether local activation of MR cell bodies can support granule cell facilitation, and 2) determine whether facilitative MR prestimulation effects are mediated by 5-HT.

Anesthetized rats were prepared for stimulation of the perforant path (PP) and median raphe (MR), and recording of field potentials in the dentate gyrus. Prestimulation of the MR consistently produced substantial (>50%) facilitation of the perforant path-evoked population spike without affecting the evoked field EPSP. Microinjections of 0.1 M D,L-homocysteic acid (50-200 nL) into the MR over a period of 5-10 sec produced a dose-dependent facilitation of the population spike without altering EPSP slope. Mean  $\pm$  S.E. % spike facilitation for 50, 100, and 200 nL's were  $39.0 \pm 19.8$ ,  $71.7 \pm 25.6$ , and  $86.2 \pm 9.9$ , respectively, (all  $p < .05$ ). Facilitation started within 30 sec of injection, peaked in approximately two min and dissipated within four to five min. Preliminary results from separate experiments showed that electrically-induced MR facilitation was not attenuated by a 5-HT<sub>1A</sub> antagonist p-MPPI (10 mg/kg, i.p.).

The present study demonstrates that increases in granule cell excitability observed following electrical prestimulation of MR do not require activation of fibers of passage. While the systemic p-MPPI results suggest that 5-HT<sub>1A</sub> receptor activation is not necessary for the electrically-induced facilitation, it remains possible that activation of facilitative non-5-HT hippocampal afferents masked the effect. Alternatively, other 5-HT receptor subtypes might mediate the hippocampal disinhibition. Supported by BNS-9021632

DIVERGENT PROJECTIONS FROM THE PEDUNCULOPONTINE TEGMENTAL AREA CO-OPERATE IN GATING THETA RHYTHM N. R. Swain and N. McNaughton\*. Dept. Psychology and Centre for Neuroscience, University of Otago, POB 56, Dunedin, New Zealand

Hippocampal theta rhythm ( $\theta$ ) can be elicited from several 'synchronizing' pathways in the pons (Vertes, 1981, *J. Neurophysiol.* 46, 1140). One ascends from n. pontis oralis, relays in the supramammillary nucleus (SUM), and contributes to the frequency of  $\theta$ . A second ascends from the pedunculopontine tegmental nucleus (PPT), apparently diffusely through the reticular formation (Vertes, 1981). We used injections of procaine (20% w/v, 0.2 or 0.5  $\mu$ L) in urethane (1.5g/Kg) rats to map the course of the fibres originating in PPT. Using 100 Hz, 150  $\mu$ A, 0.1ms stimulation, two optimal synchronizing sites were found - in PPT and 1 mm dorsal to PPT. The same results were obtained with both sites. Injections of procaine into the ascending system eliminated  $\theta$  with latencies under six minutes and for durations of 30-60 minutes. In total contrast to procaine in the region of SUM, frequency of  $\theta$  was never changed and amplitude only showed small reductions. These data are consistent with a  $\theta$ -gating function for PPT and are similar to the effects of anti-cholinergic drugs. Effects were obtained throughout the ascending system as mapped by Vertes (1981) and also in two additional, distinct sites: in the region of the superior colliculus and the substantia nigra, respectively. All these areas are targets of the ascending cholinergic fibres originating in PPT. These results suggest 1) that output from PPT (possibly cholinergic) gates theta; 2) that this output relays in at least three distinct areas, two of which are in or near the superior colliculus and substantia nigra; and 3) that  $\theta$ -gating in the hippocampus can result from co-operation between subthreshold inputs from all three relays concurrently. CORTICOSTERONE MODULATES HIPPOCAMPAL CHOLINERGIC THETA ACTIVITY VIA MINERALOCORTICOID RECEPTORS. D. Murphy\*, B. Costall and J.W. Smythe. Dept. of Pharmacology, Univ. of Bradford, Bradford, U.K., BD7 1DP

Arousing stimuli elicit cholinergic theta activity in alert, immobile rats. Recently, we reported that intrahippocampal cholinergic blockade increased corticosterone (CORT) secretion induced by restraint stress. These data suggest that CORT modifies hippocampal cholinergic function and we examined the effects of blocking mineralocorticoid receptors (MR) on theta activity in urethane-anesthetized rats which exhibit only cholinergic theta. Adult male, Lister hooded rats ( $n=10$ ) were anesthetized with urethane and a theta recording electrode was positioned in the hippocampus. A bipolar stimulating electrode was placed in the dorso-medial posterior hypothalamus (DMPH) to activate theta. Baseline recordings of spontaneous and DMPH-stimulated activity (0.1-0.7 mA) were obtained. Rats were then administered the MR antagonist spironolactone (50 mg/kg IP) and basal and DMPH-stimulated activities were monitored for 60 min. Changes in theta frequency (Hz) were analyzed using ANOVA followed by a Bonferroni t-test, and by linear regression. ANOVA revealed a main effect of DMPH stimulation intensity on theta frequency ( $P<.001$ ). Theta frequencies increased in response to tail pinch ( $P<.01$ ) and with increasing stimulation intensities prior to drug administration. ANOVA also demonstrated a significant effect of time post-spironolactone ( $P<.03$ ). Spontaneous theta was absent by 5 min following spironolactone. Overall, maximal theta frequencies elicited by DMPH stimulation declined with the passage of time post-injection. A regression analysis on the 0.1 mA stimulation level looking at the time x frequency relationship revealed a significant negative correlation  $r = -0.64$  ( $P<.02$ ). Hippocampal cholinergic theta activity is modulated by CORT acting through MR. These data raise the possibility that hippocampal cholinergic systems and theta activity are involved in CORT-mediated negative-feedback control of the hypothalamic-pituitary-adrenal axis. CHANGES IN THE LEVEL OF GLUTAMATE (GLU) IN THE MEDIAN RAPHE NUCLEUS (MRN) ASSOCIATED WITH HIPPOCAMPAL THETA ACTIVITY IN THE ANESTHETIZED RAT. V.Varga, B.Kocsis, A.Kekesi, G.Juhász (SPON: European Brain and Behaviour Society) National Institute of Neurosurgery and Department of Comparative Physiology, Eotvos University, Budapest, Hungary

Serotonergic input from the median raphe nucleus (MRN) to the septum exerts a pronounced desynchronizing influence on hippocampal (Hipp) EEG. Long-lasting, uninterrupted theta elicited by antagonizing excitatory amino acid (EAA) transmission in the MRN (Kinney et al., Brain Res., 1994) suggested that, in turn, the activity of MRN serotonergic cells is under control of a tonically active EAAergic drive.

This study was designed to investigate the relationship between spontaneous changes of Hipp activity and the release of EAAs in the MRN, using the in vivo microdialysis technique. Dialysates were collected from the MRN during 2 to 6 sampling periods of equal length (20 min). The percentage of theta rhythmic pattern in Hipp recordings was calculated for each sampling period and the corresponding average GLU level was determined. The relationship between Hipp activity and GLU release in the MRN was characterized by comparison of GLU levels measured during consecutive sampling periods with different ratios of theta vs. non-theta segments in the Hipp EEG. We found high level of GLU in the MRN during periods dominated by desynchronized Hipp activity as compared with those mostly containing long or frequently occurring theta segments indicating that the desynchronizing serotonergic influence originating from the brainstem is maintained by strong tonic excitatory input to the MRN. During theta activity, due to suppression of this EAAergic activation, serotonergic neurons in the MRN become disfacilitated and the resulting decrease of their effect on the septum/Hipp serves to assist natural switching of the activity in the septum and Hipp from desynchronized to synchronized theta rhythmic pattern. (Supported by OTKA Grants T17778 and T16552)

## 171.18

HIPPOCAMPAL UNITS CHANGE PHASE RELATION TO LOCAL SLOW WAVE DURING RABBIT CLASSICAL CONDITIONING. R.L. Borgnis\*, M.A. Seager, & S.D. Berry. Center for Neuroscience, Miami Univ., Oxford, OH 45056.

Many years of previous research has established that hippocampal cells fire with a consistent phase relation to the local slow wave. However, recent evidence from Recce & O'Keefe (1991) and Brankack, Stewart, and Fox (1993), suggests that cells may change their preferred phase in special situations such as when a rat traverses a place field.

Analysis of multiple unit/slow wave cross-correlations in rabbit classical jaw movement conditioning (CJM) has shown that the pattern and timing of the correlation function differs from free-running activity to tone (CS) period, indicating a changing relationship between units and slow waves (Borgnis & Berry, 1996). To expand these findings, we undertook a single unit analysis of unit/slow wave relations during CJM.

Following recovery from surgery (to cement a capped metal cylinder over the left hemisphere), rabbits were trained to criterion in CJM. The next day, a microdrive unit was used to lower a single unit electrode (5-20  $\mu$ m tip) into dorsal hippocampus. Once a unit was isolated, a few minutes of spontaneous activity were recorded. The rabbit was then given up to three 9-trial blocks during which time-locked unit and slow wave responses were recorded.

EEG and unit activity were analyzed before and during the trial to note the preferred phase relation of the unit to the slow wave. Consistent with many reports, every unit had a consistent relation to the slow wave if theta was present. During the trial, however, this relation changed. To date, all conditioned responses include firing on the phase opposite to pre-trial preferred phase. These results suggest that, in rabbit CJM, as in rat place fields, as hippocampal neurons become engaged in task-specific processing, the change in synaptic inputs causes a shift in unit/slow wave phase relations.

## 171.20

THE EFFECTS OF SCOPOLAMINE, DELIVERED VIA INTRAHIPPOCAMPAL MICRODIALYSIS, ON THE FIRING OF LOCAL PLACE CELLS. S.E. Fox\*, N.Ludvig, J.L. Kubic, R.U. Muller, M. Stead and A. Fenton. Dept. of Physiology, SUNY Health Sci. Ctr., Brooklyn, NY 11203.

The hippocampus receives a dense cholinergic innervation from the septum that contributes to the EEG theta rhythm. The firing of hippocampal place cells within the place field is enhanced during theta rhythm, whereas the out-of-field firing is suppressed. This suggests that acetylcholine may modulate the firing of place cells. In previous studies using intracerebroventricular injections of scopolamine the in-field firing of place cells was dramatically reduced. With such injections it is not clear whether the effects are local to the hippocampus.

To test local drug applications, simultaneous microdialysis and single cell recording were performed in the CA1 region of freely moving rats. The electrode tips were in the stratum pyramidale, while the 1 mm microdialysis probe tip extended from stratum oriens to stratum lacunosum-moleculare, at a 400  $\mu$ m horizontal distance from the electrodes. The firing of place cells was recorded while the rat chased food pellets in a 70 cm dia. cylindrical chamber. Data collection periods of 10 to 60 min were used, separated by intervals when the rat was in a smaller "resting" box for at least one hour. Either artificial cerebrospinal fluid (ACSF) or a selected concentration of scopolamine (10-50 mM, dissolved in ACSF, applied for 15-20 min) was perfused through the microdialysis probe.

When ACSF was perfused, place cells displayed their normal location-specific firing. Adding scopolamine into the microdialysis fluid caused a concentration-dependent reversible suppression of the firing of recorded place cells. An initial, transient firing facilitation was also observed. The effects were not attributable to changes in the shapes or amplitudes of spike waveforms. These data support the notion that acetylcholine increases the sensitivity of CA1 place cells to the firing of afferents coding spatial information. Supported by NIH grant NS-17095.

## 172.1

AN ARTIFICIAL NEURAL NETWORK SIMULATING PERFORMANCE OF NORMAL SUBJECTS AND SCHIZOPHRENICS ON THE WISCONSIN CARD SORTING TEST. S. Berdia, J. T. Metz\*. University of Chicago, Chicago, IL 60637.

A major research challenge in psychiatry today is to relate the classic signs and symptoms of schizophrenia to underlying neurobiological processes. In addition, artificial neural networks are now offering clues about how biological events can accomplish cognitive tasks. By perturbing these neural models, one may better understand the biological basis for disordered cognition. Recently, a few researchers have developed neural network models that provide a framework for understanding some of the pathological processes in schizophrenia. However, the abilities to abstract and learn, which are some of the most appealing features of artificial neural networks, have not been incorporated into the models.

The Wisconsin Card Sorting Test (WCST) is a neuropsychological test considered sensitive to frontal lobe functions including abstracting and learning. The test requires subjects to match trial cards to target cards depending upon a sorting criterion. After subjects make ten consecutive correct matches, the sorting principle shifts without warning. We studied hospitalized psychiatric patients that met the DSM-III-R criteria for schizophrenia (N=28), and normal subjects with no psychiatric history (N=19). Performance on the WCST by schizophrenic patients was poorer than performance by normal subjects as estimated by various scoring measurements including perseverative errors.

We have modeled an artificial neural network, motivated in part by biological considerations, that provides a framework for understanding performance on the WCST. The network can be perturbed by inhibiting feedback and causing axonal instability so as to simulate different types of failure that occur in normals and schizophrenics. We expect this model to provide insight into the neurobiological pathology in schizophrenia.

## 172.3

ERP AND QUANTITATIVE EEG STUDY OF SCHIZOPHRENIC ABNORMALITY OF INFORMATION PROCESSING -FROM ASPECTS OF AUTOMATIC PROCESS AND CONTROLLED PROCESS- E. Kirino, M. Shinomiya, R. Inoue, Y. Minami, Y. Okada and H. Imai\*. Department of Psychiatry and Neurology Juntendo Univ. Sch. of Med., Tokyo 113

The present study examined the relationship between the automatic and controlled processes in schizophrenic disorder and changes of the relationship in various clinical course of the illness using ERPs. Thirty schizophrenic patients were classified into two groups according to ERP variations. Group-A consisted of schizophrenics who showed higher mismatch negativity (MMN) amplitudes and lower P300 amplitudes than group-B patients. On quantitative EEG, delta, theta and slow alpha activity of Group-B was higher than Group-A. After medication, Group-A showed decreased MMN amplitudes and increased P300 amplitudes and Group-B showed increased MMN amplitudes, but no significant changes in P300 amplitudes. In Group-A, theta activity decreased after medication. A negative correlation was obtained between MMN amplitudes and the left Sylvian fissure and the bilateral lateral ventricles on CT scans. It suggests that MMN might be a helpful marker of trait-dependent cerebral dysfunction in schizophrenic disorder. In information processing of schizophrenics, processing capacity is limited and automatic process and controlled process complement each other. Before treatment, that compensation are imbalanced but defensive to severe manifestation. In Group-A, higher MMN amplitudes suggested plasticity of processing, which responded well to psychopharmacological therapy. In Group-B, a lower MMN amplitudes and higher slow activity suggested more severe vulnerability, which responded to medication less favorably.

## 172.5

HUMAN BRAIN RHYTHMS AND ELECTROCONVULSIVE THERAPY. R. Salmelin\*, J.P. Mäkelä, P. Heikman, K. Kuoppasalmi, and R. Hari. Brain Research Unit, Low Temp. Lab., Helsinki Univ. of Technology, 02150 Espoo, and Dept. of Psychiatry, Univ. of Helsinki, 00180 Helsinki, Finland.

Electroconvulsive therapy (ECT), efficient in treatment of severe depression, is known to increase slow EEG rhythms. Where these rhythms originate and whether they have a beneficial or even an essential role in the patient's recovery have remained open questions.

We employed whole-head magnetoencephalography (MEG) to track the temporal and spatial modulation of spontaneous oscillations in five depressive patients (all females, 24-46 yrs). The patients were measured prior to the beginning of ECT, after the 4th and the last (8-13 in total) treatments, and one month after the end of ECT (4 patients). The normal human brain shows spontaneous magnetic rhythms with maximum signals typically around 10 and 20 Hz. Interestingly, ECT often resulted in a prominent increase of frequencies below 8 Hz. These anomalous slow oscillations largely disappeared within one month after the last treatment.

In 3 patients, relief of depression was accompanied by an increase of the 4-8 Hz oscillations by at least 50% after the first 4 treatments and up to 500% after 8 treatments, particularly over the temporal and rolandic areas. All frequency components were affected, most notably in the central and precentral areas, in the posterior temporal lobes, and around the temporo-parieto-occipital junctions. The signals also suggest a contribution from subcortical structures to the modulation of brain rhythms in response to ECT.

## 172.2

SINGLE TRIAL ANALYSIS OF EVENT RELATED POTENTIALS IN SCHIZOPHRENICS AND DEPRESSIVES.

J. Rösche\*, P. Wagner, K. Mann. Dept. of Psychiatry, University of Mainz, Germany

The aim of the present paper was to perform a single-trial analysis of event-related potentials in order to elucidate the mechanisms behind a reduced P300 amplitude occurring in unmedicated depressives (n = 11) and schizophrenics (n = 18). For this purpose, tools from linear system theory were applied to single trials in an oddball paradigm. This analysis provides estimates of the magnitude of the positive deflection occurring around the latency of P300 following target and nontarget stimuli. According to the density functions of these amplitude distributions, we operationally defined „false-negative“ (P300 amplitude lower than an individual threshold under target conditions) as well as „false-positive“ responses (P300 amplitude higher than the threshold following nontarget stimuli). Ford and coworkers recently published an article that schizophrenics have fewer and smaller single trial P300 amplitudes. Due to the different psychopathology and clinical signs of schizophrenia and depression we hypothesized that the mechanisms of reduced averaged P300 measurement might be of different nature in these two diagnostic groups. Therefore, we hypothesized that due to different psychopathology (a) schizophrenics manifest fewer single trial P300 and (b) depressives manifest attenuated single trial P300. Our investigations revealed a reduction of the single trial P300 amplitude in depression and a combination of amplitude reduction along with fewer elicited single trial P300 waves in schizophrenics.

## 172.4

PROCEDURAL AND STRATEGIC MEMORY IN SCHIZOPHRENIA. J. Singh\*, K. Gopal, D. Yohanna, A. De Wolfe, J. T. Metz, M. Mesulam. Department of Psychiatry and Behavioral Sciences, Northwestern University.

In the present study, we examined procedural and strategic memory in 10 patients with schizophrenia (SC, DSM-IV) and 10 age- and education-matched normal controls (NC). Procedural memory was examined with two widely used tests: pursuit rotor learning and mirror tracing (RP, MT). Subjects performed 3 blocks of the RP test, with each block consisting of 8 trials. In the MT test, the subjects traced a star by looking into a mirror for 5 consecutive trials in 2 blocks; the blocks were separated by a short time interval. Temporal Ordering and a modified version of Tower of Hanoi tasks were used to assess strategic memory. In the Temporal Ordering task, subjects are asked to reconstruct an original sequence of 10 words which are presented visually in a fixed sequential order during the study phase. A degree of correlation between the subject and test order was used as an index of the level of performance. In the Tower of Hanoi task, subjects were asked to move discs from one peg to another. Numbers of moves within each level (levels 1 through 7) were averaged and compared between the two groups.

The results of this study show that SC were unimpaired on both MT and RP tasks (NC vs SC, p > .05). However, they were markedly impaired on strategic memory tasks relative to their controls (Tower of Hanoi, < .001; Temporal Ordering, p < .001). These results suggest that SC have no difficulty in acquiring simple sensorimotor skills. However, they are unable successfully to complete tasks that make strategic memory demands and require complex cognitive processing. The strategic memory tasks used in the present study are known to be impaired in patients with frontal-lobe lesions. Impaired strategic memory in SC may indicate frontal lobe dysfunction in schizophrenia.

ANALYSIS OF PARTICULAR DOTTING PATTERN OF SDAT PATIENTS FROM THE VIEW POINT OF MEMORY. Havashi Mikio\*, Sakamoto Atuko, Kashiwamura Hiroko. Dep. of neuropsychiatry, Osaka Koseinenkin Hosp. Osaka, JAPAN

METHOD and OBJECT: 30 SDATs, 19 asymptomatic CVDs and healthy persons were tested 3 psychological tests (minimal dementia test, memory test (long and short memory), Benton's test) and CT/MRI and computerized test (hard and soft) which were developed by us, which is dotting 30 in the 12x20 grid at random, and programed variables were 19.

RESULTS: 1: multiple regression analysis was significant with 3 psychological tests in the inner samples. 2: transitional probability and number of transition was small in SDATs if compared with another objects. 3: dotting pattern of SDATs were classified 4. 4: particular dotting pattern is only dotting same point from the view of transition. This was thought as procedural memory. 5: this phenomena was relatively paralleled with deterioration. 6: SDATs lost firstly thematic memory and next lost procedural memory. 7: dotting pattern is expression, and expression was quantitatively analysed.

CONCLUSION: Dotting pattern of SDAT was analysed by our developed computerized system, and phenomena of particular dotting pattern of SDAT was explained from the view of memory.

## 172.7

MODULATION OF A STEADY-STATE VISUAL EVOKED POTENTIAL BY SHIFTS OF VISUAL SPATIAL ATTENTION IN NORMAL SUBJECTS AND IN PEOPLE WITH AUTISM. M.K. Belmonte\* <mkb4@Cornell.edu>  
http://www.cnf.salk.edu/~matthew/SSVEP/

Previous behavioural studies of autism have demonstrated a deficit in the rapid shifting of attention between sensory modalities, between object features, and between spatial locations. This study applied electroencephalographic measures to shifts in visual spatial attention in an effort to elucidate the time courses of such shifts both in normal subjects and in people with autism. A general-purpose software package for analysis of steady-state evoked potentials was constructed, and applied to quantify phase-locked and non-phase-locked EEG power levels during a behavioural task that required rapid, repetitive shifts in visual spatial attention. Background stimuli and occasional targets were flashed at 9Hz in both hemifields in order to drive a steady-state evoked potential. A target in the attended hemifield cued not only an overt behavioural response but also a covert shift of attention to the opposite hemifield. In normal subjects, attended targets produced a transient increase in phase-locked amplitude, in the interval 0 to 300ms post-stimulus, contralateral to the hemifield in which the target appeared. The latency of this increase varied with the length of time since the previous shift, attaining a minimum at shift intervals between 800ms and 1500ms. In addition, in the range 300ms to 600ms post-stimulus, phase-locked amplitude increased in the hemisphere contralateral to the newly attended visual hemifield and decreased in the ipsilateral hemisphere. Conversely, non-phase-locked amplitude decreased contralaterally to the newly attended visual hemifield and increased ipsilaterally. These modulations may reflect the sequential process of orienting to a target stimulus, reorienting to the opposite, cued location, and redistributing attention in anticipation of a subsequent shift back to the previous location. At the time of submission of this abstract, a comparison of this normal data to data from autistic subjects is underway. The previously documented behavioural impairment of people with autism in the rapid shifting of attention suggests that the reorienting component, which in normals manifests between 300ms and 600ms post-stimulus, may be delayed or diminished in autistic brains. Part of this work was funded by NIMH project 2-R01-MH36840-11A1.

## 172.9

LOCALIZED ABNORMALITIES OF rCBF AT REST IN CHILDHOOD AUTISM. M. Zilbovicius\*, B. Garreau, Ph. Remy, P. Belin, C. Barthélemy, A. Syrota, G. Lelord and Y. Samson. SHFJ, CEA, Orsay and INSERM U 316, CHU Bretonneau, Tours, France.

We previously failed to detect regional cerebral blood flow (rCBF) abnormalities at rest in autistic children older than five years. However, this negative result was obtained with a low spatial resolution SPECT camera, suggesting that well-localized rCBF abnormalities may have been overlooked. To test this hypothesis, we measured rCBF at rest with  $H_2^{15}O$  and a high resolution PET camera (31 slices, 5 mm resolution) in 11 children with primary autism (mean age  $\pm$  sd :  $8 \pm 3.1$  years) and six non-autistic control children ( $7 \pm 1.6$  years). All rCBF studies were performed under the same premedication, and the data were analyzed by comparing the regional pattern of rCBF in both groups using the SPM software. A significant ( $p < 0.01$ ) decrease in rCBF was found in the autistic group in four brain regions : superior cerebellar vermis (x: -14, y: -40, z: -12 mm in Talairach's coordinates), left insula/superior temporal gyrus (-42, -8, 0 mm), left insula/inferior frontal gyrus (-32, 12, 12 mm) and right anterior cingulate (6, 28, 20 mm). In contrast, we did not find any significant rCBF increase in the autistic group. These results indicate that rCBF abnormalities may be detected at rest in restricted but well defined brain regions using high resolution imaging techniques in autistic children. The cerebellar vermis hypoperfusion may be related to previous reports of MRI vermal hypoplasia. The left temporo-insular and left fronto-insular hypoperfusion may be related to an alteration of an auditory-verbal brain network. Finally, the anterior cingulate hypoperfusion is consistent with a limbic dysfunction in autism. Supported by INSERM network # 489001 and PHRC 95.

## 172.11

A MULTIDIMENSIONAL SCALING APPROACH TO CONTEXT-DEPENDENT FUNCTIONAL REPRESENTATIONS. K. C. Whang\*, D. A. Crowe, and A. P. Georgopoulos, Brain Sciences Center, VAMC, Minneapolis, MN 55417.

Functional deficits in constructional apraxias suggest that the internal representations used for a given set of objects or actions could differ considerably depending on specific task contexts. We present a psychophysical approach to characterizing such representations using standard parametric methods as well as Shepard-Kruskal multidimensional scaling (MDS).

Pairs of items from a set of 25 geometric fragments of a square were presented to healthy human subjects making two different judgments using two response methods for each judgment. The first judgment concerned similarity: in separate blocks, subjects either rated the similarity of items on a numerical scale or made a choice reaction time (RT) response depending on whether the two were the same or different. The second judgment concerned object completion: subjects made a numerical or choice RT response based on how well the two presented fragments fit together to form a complete square. Such a judgment might be expected to be an important component in object construction.

Analysis of choice RTs showed that the completion judgment took 100 msec longer on average than the similarity judgment. This is consistent with a first-order model of the completion task in terms of two additive component processes: one concerned with raw object identification and another specific to completion or construction. MDS configuration spaces derived from rating data suggest that the underlying representations used in the two judgments may be organized along qualitatively different dimensions. (Supported by USPHS grant NS17413)

## 172.8

BILATERAL OCCIPITAL-TEMPORAL DYSFUNCTION AND VISUAL AGNOSIA IN A CHILD: ROLE IN THE PATHOPHYSIOLOGY OF AUTISM. L. Carmant\* and L. Mottiron. \*Division of Neurology, Hôpital Ste-Justine and Department of Psychiatry, Hôpital Rivière des prairies, Université de Montréal, Montréal, Qc.

The purpose of studying this child is to understand the role of occipital-temporal structures in the pathophysiology of autism. We report neuropsychological, electrophysiological, neuroimaging, and clinical findings of a 5 year old boy with bilateral occipital and right temporal lobe lesions secondary to neonatal meningitis. Early investigations did not reveal significant abnormalities. At age three years, during an evaluation for developmental delay, autism was diagnosed with the Autism Diagnostic Interview. Repeated measures of his IQ showed subnormal results only on tests involving visual material. Neurology and ophthalmology evaluations confirmed the presence of severe prosopagnosia and visual agnosia. MRI showed extensive occipital-temporal encephalomalacia. Autism is a developmental disorder of neuronal organization. Abnormalities involve mainly the limbic system and cerebellum with growing evidence supporting disturbances of the associative cortex. This child's history suggests that a deficit in the construction of perceptive representation during development could play a role in the etiology of autism. We discuss these findings in view of the description by Jambaqué et al of autistic features in children with infantile spasms, a catastrophic epileptic syndrome often associated with posterior brain dysfunction.

## 172.10

DIFFERENTIAL PATTERN OF AMPLITUDE REDUCTION FOR ENDOGENOUS COMPONENTS WITH VARIOUS PROCESSING LOAD IN AUTISM, OBSESSIVE COMPULSIVE DISORDER AND NORMAL CONTROLS. K. T. Ciesielski, R. Elmasian, and A. Reeve\* Clinical Neuroscience Laboratory, Departments of Psychology and Psychiatry, University of New Mexico, Albuquerque, NM 87131.

We presented four stimuli, a green and red flash, a 903 Hz and 1923 Hz tone; each 50 msec duration and equally probable at random intervals that ranged between .5-3.5 secs. While stimuli were kept constant the processing load was varied only by changing task instructions. A designated target was the repetition of a stimulus in all conditions, except for the passive observation session. We hypothesized that subject would invest the most processing resources to target stimuli, less to non-targets in the same stimulus modality, less to passively observed stimuli and least to non-targets in the opposite modality. The results in 16 normal controls were in agreement with predictions. A parietal P3 at 330-390 msec and frontal brain negativity SNW at 470-530 msec systematically decreased with reduced processing resources to target and non-target stimuli, suggesting that background engenders similar processing although to a similar degree. The preliminary results in high functioning subjects with autism did not reveal significant modulation of the above components, although P3 and SNW were generally reduced in amplitude. A similar deficit in modulation of amplitudes was observed in the obsessive-compulsive group with significant amplitude enhancement. The role of frontal-parietal subsystem for selective inhibition mechanism is discussed in norm and disorders with frontal brain abnormalities.

## 172.12

HUMAN OSCILLATORY BRAIN ACTIVITY NEAR 40Hz: CORRELATION WITH COGNITIVE TEMPORAL BINDING AND ALTERATION DURING LONG TERM UNCONSCIOUSNESS.

Schiff, N.++, Ribary, U.++, Plum, F.++\*, and Llinas, R.++ +CNM, Dept. Physiology and Neuroscience, New York University Medical Center, ++Dept. Neurology and Neuroscience, Cornell Medical Center, New York, 10021.

A dual 37-channel MEG system (BTi) localized and monitored dynamic brain function from healthy controls and from a 49 year old woman continuously vegetative for 19 years who has shown no evidence of attention, recognition, or interaction. Atypically, she occasionally uttered single, understandable words with no accompanying expression or relevance to the environmental stimuli. MRI of the brain revealed no remaining right thalamus and only the anterolateral portion of left thalamus. Varying areas of cerebral cortex remained. Spontaneous and evoked magnetic activity in response to auditory clicks and tones, and somatosensory stimulation were used to evaluate global brain activity. Spontaneous oscillatory electrical activity at near 40 Hz in the human brain, and its reset to following sensory stimulation in normal subjects has been reported elsewhere, indicating that oscillatory activity near 40-Hz represents a neurophysiological correlate to the temporal cognitive binding of auditory stimuli.

In contrast to these normal findings, preliminary data in the unconscious patient indicate a loss of high frequency (gamma) activity especially in the right hemisphere, and a reduced correlation or even an anticorrelation of brain oscillatory activity between the two hemispheres. The data also suggest the existence of coherent and synchronized spontaneous oscillatory activity at around 40 Hz in the left hemisphere, including partial reset with incomplete synchronization in response to sensory stimulation. These findings suggest that the human cerebrum can express some gamma band activity, words, and an incomplete and disorganized coding of sensory stimuli in the absence of any behavioral evidence of the conscious state.

## 172.13

TWO MODES OF FUNCTIONAL REORGANIZATION FOLLOWING PARTIAL CALLOSOTOMY IN HUMANS. E. Zaidel<sup>1</sup>, N. Weekes<sup>1</sup>, M. Iacoboni<sup>1,2</sup>, J. Fried<sup>3</sup> and J. Bogen<sup>\*1</sup>. <sup>1</sup>Department of Psychology, UCLA; <sup>2</sup>Reed Neurological Institute, UCLA; <sup>3</sup>Division of Neurosurgery, UCLA

We measured callosal transfer through motor and auditory channels before and after anterior callosal section for intractable epilepsy in a 30 year old male. The surgery extended from the rostrum to the anterior splenium. Motor transfer was indexed by the Poffenberger paradigm, using unimanual simple reaction time to lateralized light flashes. Auditory transfer was indexed by the left ear score in dichotic listening to consonant-vowel syllables. This task is exclusively specialized in the left hemisphere (LH) and exhibits complete ipsilateral suppression, so that the left ear (LE) signal must relay from the RH to the LH through the corpus callosum.

Pre-surgically, the subject exhibited normal motor transfer, insensitive to visual parameters, in the Poffenberger paradigm. It changed to a visual channel, sensitive to eccentricity, within two days following surgery. This reflects immediate takeover by a parallel pre-existing but sub-dominant channel of the corpus callosum.

Pre-surgically, the patient exhibited a normal right ear advantage in divided attention in dichotic listening. It changed to a massive right ear advantage post-surgically. Over the next two years the patient gradually started reporting the LE in the divided, but not focused, attention condition. This reflects a slow shift of an attention-dependent auditory channel from the isthmus to the anterior splenium.

The results show radically different modes of functional reorganization of callosal channels for motor and auditory relay.

## 172.15

REVISED CHILDREN'S VERSION OF THE ALTERNATIVE IMPAIRMENT INDEX: A NEUROPSYCHOLOGICAL PILOT STUDY, A. M. Horton, Jr., \* Psych Associates, Towson, Maryland, 21204.

The Revised Children's Version of the Alternative Impairment Index is a new measure of neuropsychological impairment in older children derived from the Halstead-Reitan Neuropsychological Test Battery for Older Children. A sample of 16 normal and heterogeneously brain damaged children between the ages of 9 and 14, including the following conditions, normal controls (4), brain tumors (3), brain abscess (1), hemispherectomy (1), encephalitis (1), traumatic brain injury (4), learning disabled (3), behavior problems (1), was assessed. The hit rate obtained for agreement on level of severity for the Children's Version of the Alternative Impairment Index and the Older Children's Neuropsychological Deficit Score (i.e., 50% or 8/16 correct agreement) does not support further development of the Revised Children's Version of the Alternative Impairment Index.

CHANGES IN BRAIN METABOLISM INDUCED BY EEG-BIOFEEDBACK: AN FMRI-STUDY. N. Birbaumer\*, F. Pulvermüller, H. Preißl, C. Tempelmann, H. Scheich, H.-J. Heinze, B. Mohr & W. Lutzenberger Universities of Tübingen and Magdeburg, Germany

Metabolic changes in brain activity caused by EEG biofeedback were investigated using a 3 Tesla functional magnetic resonance imaging (fMRI) scanner. EEG biofeedback makes it possible to control the vertex potential, that is, to voluntarily shift it in the negative or positive direction. After 24 sessions of successful feedback training, fMRI experiments were carried out determining brain regions activated and deactivated by feedback. In the condition where negativity of vertex potentials was to be produced, pronounced and consistent feedback-induced enhancement of activity was seen in thalamus, putamen, and in medial prefrontal and temporo-occipital cortex. When vertex positivities were induced, relative reduction of activity was seen at these sites, but activity enhancement in lateral prefrontal and inferior occipital areas. Clinical implications of these results on biofeedback therapy of epilepsy are discussed.

Supported by the DFG (SFB 307/B1, Pu 97/5).

## 172.16

THE EFFECTS OF HYPOBARIC HYPOXIA ON COGNITIVE FUNCTIONING AND EEG. C.R. Swain<sup>1</sup>, C. Kourtidou<sup>2</sup>, G.F. Wilson<sup>3</sup>  
<sup>1</sup>Logicon Technical Services, Inc., Dayton, OH 45437-7258  
<sup>2</sup>Department of Aerospace Medicine, WSU, Dayton, OH 45401-0927  
<sup>3</sup>Armstrong Laboratory, USAF, Wright-Patterson AFB, OH 45433-7022

Cognitive impairment at high altitudes is of vital interest to those working in aviation and aerospace medicine. Despite the need, there is a paucity of research examining the relationship between complex task performance and brain electrical activity at altitudes greater than 20000 feet. In this study, 10 USAF personnel served as subjects in a repeated measures within subject investigation of cognitive performance at hypobaric simulated high altitude. EEGs were recorded from 19 sites (positioned in accordance with the 10-20 system) as subjects performed a three minute computer generated multitask flight simulation (MATB) during three conditions (hypobaric normoxia, hypobaric hypoxia, and recovery) at five altitudes (5000, 10000, 15000, 20000 and 25000 ft). Respiration, heart rate and  $P_{aCO_2}$  were monitored throughout. FFTs were calculated based on 2 minute samples of EEG at each condition and altitude and the absolute and relative power of five frequency bands (delta, theta, alpha, beta1 and beta2) were assessed. While all bands yielded significant hypoxia related changes at specific scalp sites, most notable were the widespread increases in absolute delta and alpha power at 25000 ft and increases in absolute theta, alpha, beta1 and beta2 at 20000 ft that were significantly correlated with decreases in continuous tracking task performance. At lower altitudes, decreases in monitoring task performance were significantly associated with increases in delta, theta and beta2 powers.

ENHANCED DELAYED RESPONSE ACCURACY IN RATS ADMINISTERED THE CHOLINERGIC CHANNEL ACTIVATOR, ABT-418. A.V. Terry, Jr.<sup>1,2\*</sup>, J.J. Buccafusco<sup>2</sup> and M.W. Decker<sup>1</sup>. <sup>1</sup>The University of Georgia Clinical Pharmacy Program and <sup>2</sup>Department of Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912, <sup>3</sup>Neuroscience Research, Abbott Laboratories, Abbott Park, IL 60064-3500

The purpose of this study was to evaluate the effects of ABT-418, a recently developed isoxazole bioisostere of nicotine, in rats trained to perform a delayed response task, the Delayed Stimulus Discrimination Task (DSDT). ABT-418 has recently been described as a selective nicotinic-acetylcholine receptor (nAChR) agonist and cholinergic channel activator (ChCA), which possesses memory enhancing properties (in animal models) while exhibiting a reduced side effect profile when compared to nicotine.

In a previous study, improved DSDT accuracy was observed in rats after nicotine and lobeline administration, but was diminished after mecamylamine administration, indicating a sensitivity of the task to nicotinic-cholinergic manipulation. The goal of these experiments was to assess the potential mnemonic effects of ABT-418 with this task and to compare the results to the previously characterized alkaloids, nicotine and lobeline. ABT-418 improved DSDT accuracy, exhibiting a significant dose-effect relationship in the  $\mu\text{g/kg}$  range of doses, and produced significant treatment and treatment x delay effects after optimal dose readministration. Post-hoc analyses revealed that the predominant improvements in DSDT performance were rendered at the shorter delay intervals. Surprisingly, mecamylamine (1.0 mg/kg) when combined with ABT-418 failed to prevent improvements in accuracy of the task (as it had with nicotine), although the delay-dependent pattern of improvement was altered. These data confirm the findings of previous rodent and non-human primate studies, which indicate that the nicotinic ligand ABT-418 has the potential to improve memory. In addition the lack of sensitivity to mecamylamine blockade by ABT-418 and lobeline (in this task) may reflect a difference in nicotinic receptor subtype mediated effects produced by these compounds when compared to nicotine.

## 173.2

LOBELINE AND ANALOGS EXHIBIT DIFFERENTIAL AGONIST ACTIVITY AND SENSITIVITY TO ANTAGONIST BLOCKADE WHEN COMPARED TO NICOTINE. G.F. Carl<sup>1</sup>, R. Williamson<sup>2</sup>, J.W. Beach<sup>3</sup>, C.R. McCurdy<sup>3</sup>, J.R. Pauly<sup>4</sup>, J.A. Sparks<sup>4</sup>, and A.V. Terry, Jr.<sup>1,2,3</sup> <sup>1</sup>Departments of Neurology and <sup>2</sup>Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912, <sup>3</sup>College of Pharmacy, University of Georgia, Athens GA, 30602 <sup>4</sup>College of Pharmacy, University of Kentucky, Lexington KY, 40536

Significant preclinical evidence supports the potential role of nicotine (nic) in the therapeutics of a number of CNS disorders. Nic associated dependence and cardiovascular side effects provide the impetus to evaluate other existing agonists (and develop novel compounds) which possess the desirable properties of nic without the adverse effects. Lobeline (lob) is one such compound which is currently being evaluated pharmacologically for this purpose. Lob shares some properties with nic in animals including a high affinity for nicotinic receptors, the ability to improve memory and decrease anxiety. However, lob is less potent in stimulating dopamine release, does not upregulate nicotinic receptors or substitute for nic in drug discrimination experiments and at least some of its effects are not reversed by nicotinic antagonists.

In the present study, lob and two structurally simplified analogs, CRM 1-13-1 and CRM 1-32-1 were compared to nic in ligand binding studies and rubidium ( $\text{Rb}^+$ ) efflux experiments to elucidate the agonist pharmacophore and compare agonist activity. Nic and lob displaced [ $^3\text{H}$ ]-cytisine from rat cortical synaptosomes with  $K_i$  values in the nM range, while each lob analog exhibited  $K_i$  values in the  $\mu\text{M}$  range. Nic over a range of 1.0 to 20  $\mu\text{M}$  stimulated efflux of  $\text{Rb}^+$  from rat striatal synaptosomes above baseline levels in a dose dependent manner and 10  $\mu\text{M}$  mecamylamine (mec) reversed these effects. Lob in contrast, appeared to produce a completely different concentration-effect relationship with 1.0 to 10  $\mu\text{M}$  slightly increasing  $\text{Rb}^+$  efflux over baseline levels, while 50 and 100  $\mu\text{M}$  reduced efflux significantly below baseline levels. In addition none of the effects of lobeline were reversed with mec (10  $\mu\text{M}$ ). Although less potent, the two lob analogs exhibited a similar pattern of activity. These data may suggest that lob and structurally similar compounds bind with different subtype selectivity than nic or to a mec insensitive receptor. (Supported by UGA Research Foundation).

## 173.3

PROTRACTED IMPAIRMENT OF WORKING MEMORY IN RATS, BUT NOT REFERENCE MEMORY IN MONKEYS EXPOSED TO LOW-LEVELS OF DFP. B.D. Goldstein\*, M.A. Frenderast, A.V. Terry Jr., and J.J. Buccafusco. Medical College of Georgia, Alzheimer's Research Center, Dept. Pharm. Tox., and Dept. Veterans Affairs Medical Center, Augusta, GA 30912, Univ. Georgia Clin. Pharm., Augusta, GA.

Chronic, low-level exposure to cholinesterase inhibitor organophosphate (OP) insecticides or chemical warfare agents produces marked abnormalities in CNS acetylcholine (ACh) function and may impair cognitive abilities. However, the duration of cognitive impairment following this exposure is unclear. In the present study, adult rats were administered the OP diisopropyl fluorophosphate (DFP; 50, 250, or 500 µg/kg) daily for 14 days. Spatial learning ability was assessed 3 or 16 days after completion of drug injections. Spontaneous locomotor activity and olfactory reactivity were suppressed beginning on Day 4 by the two higher doses. With the 250 µg/kg dose, behavioral tolerance was observed in that the frequency of these behaviors returned to baseline levels by Day 7. Spatial learning was impaired by the 250 µg/kg dose (to 65-70% of control levels) on Days 3-6 following the end of drug administration. On Days 16-19 after the end of DFP administration, learning was still impaired (to 60-80% of control levels). Acetylcholinesterase (AChE) levels in frontal cortex, cerebellum, medulla, and hippocampus were suppressed to 41%, 65%, 18% and 50%, respectively, of control levels at the end of the 14 day DFP treatment regimen. By the end of the first time-point of cognitive testing (Day 6) cortical AChE levels had recovered to 90% of control levels. In 3 rhesus monkeys well trained in the performance of a delayed response task, chronic daily exposure to 10-20 µg/kg of DFP produced severe toxicity and task impairment after 8 weeks of treatment. However, task performance was at near control levels by 6-10 days after DFP withdrawal. Withdrawal from chronic exposure to low levels of DFP may compromise working memory or learning of a new task, but fails to inhibit the performance of a well learned task if no toxicity is present. Supported by DAMD17-95-1-5036.

## 173.5

WITHIN-SUBJECT, WITHIN-SESSION ANALYSIS OF SCOPOLAMINE'S EFFECT ON SPATIAL ALTERNATION AND VISUAL DISCRIMINATION IN THE RAT. W. J. Wilson\*, G. S. Lyons, M. L. Griffith, T. Vanhorn, & J. D. Dillman. Psychological Sciences, Indiana-Purdue University, Fort Wayne, IN 46805 USA.

Eight female adult Sprague-Dawley rats learned a combined spatial alternation-visual discrimination task in a phi-maze, then were tested 15 min after i.p. injection of scopolamine or methylecopolamine. Performance of both tasks was impaired by centrally-acting scopolamine, but the spatial alternation task was more disrupted (see Figure), suggesting a greater effect of scopolamine on working memory than on reference memory. The same subjects were retested with delays of 5 or 20 s imposed between trials. Scopolamine (.1 & .2 mg/kg) impaired delayed alternation more than it did the other tasks. In a second experiment, scopolamine (.3 mg/kg) impaired choice performance in a visual discrimination task.

These results suggest that scopolamine's effects are not limited to working memory, but that perhaps working memory is more sensitive to muscarinic blockade than is reference memory. Research supported by IPFW Neuroscience Underground & Psychological Sciences.

## 173.7

LOW DOSES OF ATROPINE SULFATE ATTENUATE SPATIAL LEARNING IMPAIRMENTS PRODUCED BY NPC 17742 IN RATS IN THE WATER MAZE TASK. G. Tirado-Santiago\*, I.C. Katsarkas and M.L. Shapiro. Department of Psychology, McGill University, Montreal, Quebec H3A 1B1 Canada.

The effects of the combined administration of an NMDA and a muscarinic antagonist on spatial and cued learning in rats (male Long Evans, 3 months old) were assessed in the Morris water maze. Although the administration of either type of drug alone impairs spatial learning in rats in the water maze, the possibility of a synergistic effect between the cholinergic and glutamatergic systems on spatial learning has not been adequately explored. To test this possibility, a competitive NMDA antagonist, NPC 17742 (3 mg/kg, given i.p. 60 min before training), and a sub-threshold dose of a muscarinic antagonist, atropine sulfate (3 mg/kg, given i.p. 20 min before training), were administered separately or in combination during water maze training. Rats were given four 30 sec trials / day with a 10 sec rest period between trials. Cue training to find a visible platform was given for 4 days, which was followed by place training to find a hidden platform for 8 days. Escape latency measured performance. Rats given atropine sulfate alone (n=8) learned both the cued and spatial tasks as well as rats given either physiological saline (n=4) or distilled water (n=4). NPC 17742 (n=8) impaired learning in the place task (ANOVA,  $F(1,14) = 11.43$ ,  $p < 0.005$ ), but not the cue task. Rats given both NPC 17742 and atropine (n=8) learned both tasks normally. Thus, atropine sulfate given at low doses attenuates the effects of NMDA antagonists on spatial learning, perhaps by increasing cholinergic activity through muscarinic autoreceptors. ## 173.4

REACTIVATED MEMORIES ARE IMMUNE TO THE AMNESTIC EFFECT OF CHOLINERGIC ANTAGONISM IN DEVELOPING RAT PUPS. N. J. Sandstrom\* and H. M. Arnold. Department of Psychology: Experimental, Duke University, Durham, NC 27708.

The cholinergic system of the rat has been shown to undergo rapid physiological and behavioral maturation during the third and fourth postnatal weeks. In order to learn more about the role of the developing cholinergic system in memory, we examined the effects of scopolamine on performance of an odor preference task following odor aversion conditioning in rat pups. Twelve-day-old rat pups received mild footshock (1.0 mV) explicitly paired or unpaired with the presentation of a novel odor. Pups were then tested in an odor preference chamber either 2 or 48 hours after conditioning. When tested after a 2 hour retention interval, pups injected with saline or scopolamine hydrobromide (0.2 or 0.5 mg/kg) both showed significant aversion to the odor previously paired with shock relative to unpaired controls. After a 48 hour retention interval, pups injected with scopolamine 30 minutes prior to testing showed no evidence of an aversion while pups injected with saline continued to show an aversion to the conditioned odor. This amnesic effect of scopolamine was prevented by a reactivation treatment involving the administration of the US used during training (footshock) in the absence of any odor 90 minutes prior to injection. These data indicate that the memory for the odor aversion remains active and immune to the amnesic effect of scopolamine for at least 2 hours after conditioning. But after a long retention interval, the cholinergic system does appear to be necessary for expression of the memory. However, even at the long retention interval, expression of a recently reactivated memory is not affected by cholinergic antagonism. (Supported by HD17458 & AG09525)

## 173.6

ENHANCING AND IMPAIRING LEARNING AND SPATIAL MEMORY THROUGH MANIPULATING THE CHOLINERGIC SYSTEM. R.L. Galli<sup>\*,a,c</sup>, B.C. Thorpe<sup>b</sup>, R.E. Fine<sup>a,c</sup>, & H.R. Lieberman<sup>b</sup>. <sup>a</sup>Military Performance & Neuroscience and <sup>b</sup>Military Nutrition Divisions, United States Army Research Institute of Environmental Medicine, Natick, MA 01760, <sup>c</sup>Brain, Behavior & Cognition Program, Psychology Department, Boston University, <sup>d</sup>Departments of Biochemistry & Neurology, Boston University School of Medicine and <sup>e</sup>Geriatric Research, Education & Clinical Center, Bedford V.A. Hospital.

Decrements in cognitive abilities associated with normal aging and with age-related disorders such as Alzheimer's disease have been associated with decreases in cholinergic neurotransmission. A number of treatments to reverse these impairments have been evaluated in attempts to increase brain acetylcholine levels. In general, these strategies have met with only limited success. The experiments described here employed a pharmacological and a molecular manipulation to affect cognitive performance in rats by modulating cholinergic neurotransmission.

Behavior was tested using a two day version of the Morris water maze. On day 1, both the start position and the hidden platform location remained constant. On day 2, trials 1-7, the start position was varied in a semi-random manner and for trials 9-12 the platform location was moved 180°. Day 1, trial 10 and day 2, trial 8 were probe trials during which the platform was removed from the pool. It was determined that 0.2 mg/kg scopolamine significantly impaired performance on several measures of learning and spatial memory. The molecular treatment, previously tested in cell culture, significantly reversed two of the three scopolamine-induced decrements.

Supported by Department of Defense intramural funding.

## 173.8

ATTENUATION OF SCOPOLAMINE INDUCED MEMORY DISRUPTION IN A WATER MAZE TASK BY AN ANGIOTENSIN IV ANALOG. E.S. Pederson\*, K.E. Foley, R.E. Nielson, J.W. Harding and J.W. Wright. Prog. In Neuroscience, Wa. State Univ., Pullman, WA 99164

Recently, the Angiotensin II(3-8) (AngIV) hexapeptide receptor (AT<sub>4</sub>) has been localized in the hippocampus, suggesting its possible role in learning and memory. An analog of AngIV, norleucine<sup>-</sup>AngIV (Nle<sup>-</sup>AngIV) was synthesized by our laboratory and was shown to possess added resistance to degradation and binds to AT<sub>4</sub> receptors with high affinity. The present study examined the effects of scopolamine (SCOP), a cholinergic antagonist, previously demonstrated to disrupt spatial learning, and Nle<sup>-</sup>AngIV on learning hidden platform locations from various entry points in a circular water maze task. Twenty-four female Sprague-Dawley rats were intracerebroventricularly (ICV) pretreated with either SCOP or artificial cerebrospinal fluid (aCSF) 30 minutes prior to behavioral testing. Five minutes before testing, either Nle<sup>-</sup>AngIV or aCSF was delivered ICV. The rats were then tested for 8 consecutive days (5 trials per day) and latency to locate the platform (in seconds) and path distance (in meters) were measured. A sixth trial on day eight was run with the platform removed. Latencies in the target quadrant and number of annulus crossings were compared. The results indicate that animals treated with SCOP/Nle<sup>-</sup>AngIV had shorter latencies and distances as compared with SCOP/aCSF treated animals. Furthermore, SCOP/Nle<sup>-</sup>AngIV treated rats attained the low latencies and distances achieved by controls. Thus, these results suggest that Nle<sup>-</sup>AngIV compensates for the disruption of spatial learning induced by SCOP.

## 173.9

EFFECTS OF NICOTINE ON ACTIVE AVOIDANCE LEARNING: GENDER DIFFERENCES. O. Yilmaz, L. Kanit, B. Erdem, S. Demirezen\* S. Pogun Center for Brain Res. and Dept. of Physiology, Ege Univ. Sch. of Medicine Bornova 35100 Izmir Turkey

Nicotine, an addictive pharmacological agent, is reported to have an improving effect on cognitive functions and this cognition enhancing property may play an important role in nicotine's addictive potential. Recent work from our laboratory has revealed gender differences in central nicotinic receptor binding and response to chronic nicotine treatment in rats. The aim of the present study is to see the effect of nicotine on active avoidance learning with emphasis on gender differences.

Three-months-old Sprague Dawley rats received varying doses (0.2, 0.4, 0.6, 0.8 mg/kg) of nicotine or saline s.c. either before or after active avoidance learning trials which were done daily and consisted of 15 trials each for a period of 5 days. Behavioral testing was continued after the termination of nicotine treatment once a week for 4 or 12 weeks. Effects of nicotine on motor performance was tested using an inclined plane. Possible effects of stress arising from injections were also assessed. Female rats were significantly better than males in active avoidance learning as expected, and nicotine improved cognitive function during the acquisition phase of active avoidance learning trials in a dose dependent manner. Male rats benefited from nicotine at all doses tested whereas in females, at a dose of 0.6 mg/kg, learning performance deteriorated. In conclusion, nicotine pre-treatment affects active avoidance learning in a sexually dimorphic and dose dependent pattern and this outcome is not secondary to effects of stress or motor performance.

## 173.11

LEARNING IMPAIRMENT BY CHOLINERGIC DEAFFERENTATION AFTER CORTICAL NGF DEPRIVATION H. Gutiérrez, M.J. Miranda, A. Uribe and F. Bermúdez-Rattoni\* Depto. de Neurociencias, Instituto de Fisiología Celular, UNAM, México, D.F. 04510. México.

Cholinergic basal forebrain neurons (CBF) have been shown to respond *in vivo* to exogenous administration of nerve growth factor. Although neurotrophins and their receptor are widely expressed in the central nervous system, little data exists for the physiological significance of endogenous neurotrophin signaling in CNS neurons. In order to test directly whether cortically derived NGF is functionally required for the cholinergic functions mediated by the cerebral cortex, repeated injections of anti-NGF monoclonal antibodies were locally applied into the insular cortex (IC). Our results showed a dramatic decrease in the local extracellular levels of acetylcholine as determined by the *in vivo* microdialysis technique. Furthermore by using small injections of fluorogold, we have found a corresponding disruption in the connectivity between the IC and CBF. Behavioral experiments showed that the NGF antibodies into the IC produced a significant impairment in the acquisition of conditioned taste aversion and inhibitory avoidance learning. However, the same animals were able to recall the taste aversion when the conditioning trial was established before the blockade procedure. Given these results it seems that cholinergic activity from CBF is no longer necessary for recalling an aversive stimulus, but is necessary for the acquisition of aversively motivated conditionings. Supported by DGAPA-UNAM IN201893.

## 173.13

INTERACTIONS BETWEEN THE EFFECTS OF AGE AND CHOLINERGIC LESIONS ON CORTICAL ACETYLCHOLINE RELEASE. J. Fadel\*, M. Sarter and J.P. Bruno Department of Psychology and Neuroscience Program, Ohio State University, Columbus, OH 43210.

Investigations of the effects of normal aging on the cortical acetylcholine (ACh) system in aged rodents have led to inconsistent and heterogeneous results. The use of age as an interacting, rather than independent variable in assessing susceptibility of animals to cholinergic lesions and manipulations may represent a more productive approach to understanding age-related cholinergic deficits. Using *in vivo* microdialysis, we have previously demonstrated that young adult rats which received cortical infusions of the cholinergic immunotoxin 192 IgG-saporin showed significant decreases in cortical ACh efflux concomitant with a decrease in cholinergic (acetylcholinesterase-positive) fiber density. However, the ability of a benzodiazepine receptor (BZR) partial inverse agonist alone or weak inverse agonist in combination with an activating conditioned stimulus (darkness plus palatable food) to increase cortical ACh efflux was unaffected in these animals. Here, we extend these findings to aged (24-26 mos.) rats. Basal ACh efflux values did not differ between aged and young rats. Cortical infusions of 192 IgG-saporin (5 ng/0.5µL/infusion site; 3 infusion sites/hemisphere) resulted in significant (40-50%) decreases in basal cortical ACh efflux, relative to age-matched controls, a lesion magnitude similar to that seen in young rats following administration of the same dose of toxin. These animals also demonstrated the capacity for increased cortical ACh efflux in response to the aforementioned complex behavioral stimulus. The ability of the BZR weak inverse agonist ZK 93426 to potentiate this effect and of the BZR partial inverse agonist FG 7142 to increase basal efflux will also be discussed. (Funding: NIA 10173 to M.S. and J.P.B.)

## 173.10

STRAIN-DEPENDENT DIFFERENCES FOR THE ROLE PLAYED BY DOPAMINE-ACETYLCHOLINE INTERACTION IN MEMORY CONSOLIDATION IN THE MOUSE. A. Zocchi\*, S. Cabib, S. Puglisi-Allegra Dept. Psychology, University "La Sapienza", and Inst. Psychobiology and Psychopharmacology C.N.R., Italy

A number of studies indicates that an interaction between dopamine and acetylcholine systems is involved in the modulation of memory processes. Such a regulation appears to be genotype-dependent, as direct and indirect dopamine agonists improve memory consolidation in the C57BL/6 strain of mouse and impair it in the mice of DBA/2 strain. The opposite effect is obtained with DA antagonists. The observed difference might be correlated with a different susceptibility of the cholinergic system in the hippocampus to dopaminergic manipulation. In fact, microdialysis experiments have shown a strain-dependent response of the hippocampal extracellular acetylcholine levels after administration of DA agonists.

These data suggest that dopaminergic projections from VTA interact in a genotype-dependent manner with the hippocampal cholinergic pathway. This interaction might result in a different modulation of hippocampal acetylcholine release with a different effect on memory consolidation.

## 173.12

CORTICAL ACETYLCHOLINE EFFLUX AND OPERANT PERFORMANCE: ROLE OF ATTENTIONAL AND NON-ATTENTIONAL COMPONENTS. A.M. Himmelheber\*, N.M. Katovic, M. Sarter and J.P. Bruno Department of Psychology and Neuroscience Program, Ohio State University, Columbus, OH 43210.

Converging evidence in animals strongly supports the existence of a critical relationship between cortical acetylcholine (ACh) efflux and performance in a vigilance task (Sarter et al., *Cog. Brain Res.* in press). This relationship was assessed directly using microdialysis techniques to measure cortical ACh efflux while animals performed in the vigilance task. The presence of a distractor (flashing houselight, 0.5 Hz) impaired vigilance performance and concurrently increased medial prefrontal cortical ACh efflux (Sarter et al.). To aid in interpreting these results more thoroughly, a series of control experiments was designed to assess the effects on cortical ACh efflux of non-attentional aspects of operant performance such as sensory stimulation, motor activity, and reward loss. Animals were trained either to perform in a simple visual discrimination task or to respond on a variable interval schedule of reinforcement. In general, performance in these tasks did not correlate with medial prefrontal ACh efflux. Additionally, the presence of the flashing houselight did not affect either discrimination accuracy or cortical ACh efflux. The failure of these non-attentional variables to systematically affect cortical ACh efflux provides a framework within which the effects of environmental and pharmacological manipulations on cortical ACh efflux and operant vigilance performance can be assessed and interpreted.

## 173.14

CHANGES IN CENTRAL ACETYLCHOLINE RELEASE RELATED TO HABITUATION LEARNING R.K.W. Schwarting\*, C.M. Thiel & J.P. Huston Inst Physiol Psychol. and Biologisch-Medizinisches Forschungszentrum, Univ of Düsseldorf, 40225 Düsseldorf, Germany

The septo-hippocampal input and the striatal interneurons (nucleus accumbens, neostriatum) constitute major cholinergic systems in the brain. Functionally, these have been related to mechanisms of learning and memory, behavioral activity, arousal and, more recently, to motivational aspects of behavior. With respect to the study of learning and memory, one of the most elementary behavioral paradigms is that of habituation learning in the open field, where the decrease of exploration during repeated exposure to the same environment is taken as an index of memory. We monitored extracellular acetylcholine (ACh) in the hippocampus and nucleus accumbens during performance in this paradigm. Male Wistar rats were placed singly into a home cage next to the testing environment (open field). On the next day, the animal was taken from the home cage and exposed to the open field under dim light for 10min and locomotion and rearing was measured. On the following day, the animal was re-exposed to the open field in the same way. Two control groups were used: "Handling" controls were treated like experimental animals, however, they were placed into their home cage instead of the testing environment. "Lighting" controls were exposed only to dim light for 10min in their home cage. Our results show that extracellular ACh levels in hippocampus and nucleus accumbens usually increased when behavioral activity increased. Furthermore, ACh levels increased during and after exposure to the open field or when animals were handled. Most importantly however, the cholinergic increase was even more prominent during re-exposure to the testing environment, to which the animals had been habituated. Since re-exposure was accompanied by a decrease in exploration (indicating habituation) and presumably in arousal, the ACh increase may be a concomitant of an active process of recognition of the environment which is the basis or prerequisite for the habituation response.

## 173.15

GENDER DIFFERENCES IN THE EFFECTS OF CARBARYL ON THE REPEATED ACQUISITION AND PERFORMANCE OF RESPONSE SEQUENCES IN RATS. J. Cohn\* and R. MacPhail. <sup>1</sup>Curriculum in Toxicology, UNC, Chapel Hill, NC and <sup>2</sup>Neurotoxicology Division, NHEERL, U.S. EPA, RTP, NC.

The cholinesterase-inhibiting pesticide carbaryl decreases in a dose-dependent manner the accuracy of response sequences emitted by male rats trained under a repeated acquisition (RA) and performance (P) task (Cohn and MacPhail, Soc. Neurosci. Abstr. 20(2):1563, 1994). Some evidence suggests female rats may be more sensitive than males to the effects of cholinesterase inhibitors. In the present experiment we examined whether carbaryl would differentially affect males and females repeatedly learning response sequences. 24 adult male Long-Evans rats, maintained at 300 g, and 20 adult females maintained at 250 g, performed under a multiple schedule of RA and P. The RA component required rats to learn a new 3-member sequence of responses during each session (e.g., Center Right Left, RLC, etc.); the correct sequence of responses for the P component remained constant (CLR). Components alternated twice during a session. Rats were administered 0, 12.5, 25.0, 37.5 or 50.0 mg/kg carbaryl in corn oil by oral gavage. No significant gender differences were obtained under baseline conditions. Carbaryl produced dose-related decreases in both RA and P response accuracy and rate, regardless of gender. Females were, however, significantly more affected by carbaryl than were male rats. These data indicate an important gender difference in the behavioral effects of a carbamate pesticide.

## LEARNING AND MEMORY: PHARMACOLOGY V

SPATIAL MEMORY DEFICITS FOLLOWING QUISQUALATE ACID-INDUCED LESIONS OF THE NUCLEUS BASALIS MAGNOCELLULARIS: EFFECT OF NICOTINE. N.R. Katz\*, J. Rochford, S.A. Weiner. Douglas Hospital Research Center, Dept. Neurology & Neurosurgery, McGill University, Montreal, Quebec, CANADA.

Previous studies have shown that rats with ibotenic acid lesions of the nucleus basalis magnocellularis (NBM) display deficits in spatial memory (Hodges et al., 1991). This finding has been taken as indirect support for the hypothesis that basal cholinergic forebrain systems mediate spatial memory. Ibotenic acid, however, is not particularly selective for cholinergic neurons. Quisqualic acid has been demonstrated to cause less non-selective damage to non-cholinergic systems, and typically leads to a greater reduction in cortical choline acetyltransferase (ChAT) activity. Therefore, we examined the effects of NBM quisqualic acid lesions on spatial memory. To provide further evidence that this deficit may be the result of cholinergic neuronal destruction, we assessed the effect of the nicotinic receptor agonist nicotine. Two groups of rats were lesioned with quisqualic acid, and two groups served as controls. Following recovery, one group within each set received an injection of nicotine fifteen minutes prior to each testing session. Spatial memory was assessed using the eight arm radial arm maze. Food was placed at the end of each arm and errors were recorded for each re-visited arm. NBM-lesioned animals displayed a marked deficit in the acquisition of radial arm maze performance in comparison to non-lesioned animals. Performance of lesioned animals administered nicotine did not differ from controls, indicating that nicotine was able to reverse the deficit provoked by NBM-lesions. Nicotine did not influence performance in non-lesioned animals. These results add further to the evidence implicating basal forebrain cholinergic neurons in the mediation of spatial memory (Supported by the Medical Research Council of Canada).

## 174.3

SELECTIVE LESIONING OF DISCRETE REGIONS OF THE BASAL FOREBRIN USING INTRAPARENCHYMAL INJECTIONS OF 192IgG-SAPORIN. G.A. Ramirez\*, J. Winkler\*, D.P. Pizzo\* and L.J. Thal\*. <sup>+</sup>Dept. of Neurosciences, UCSD, and <sup>\*</sup>VAMC, San Diego, CA 92161.

Intracerebroventricular (ICV) infusions of the immunotoxin 192IgG-saporin result in a decrease in choline acetyltransferase (ChAT) activity in the projection areas of the basal forebrain system and in loss of cerebellar Purkinje cells. We used intraparenchymal injections to lesion the nucleus basalis (NBM) and/or medial septum (MS) using a broad range of concentrations of 192IgG-saporin (18.75 ng to 300 ng) to develop selective lesions, sparing Purkinje cells. Immunotoxin was infused into a single site at a rate of 0.05  $\mu$ l/min in a volume of 0.5  $\mu$ l. Dose response curves for ChAT activity were established to maximize depletion in the projection fields of the lesioned structure. The optimal dose for lesions of the NBM was 75 ng/site which resulted in an extensive depletion of ChAT activity in the frontal (>75%), cingulate (>60%), parietal (>55%), and occipital (>35%) cortex, and olfactory bulb (>75%) whereas hippocampal activity was reduced less than 20%. Optimal lesions of the MS were obtained with 37.5 ng/site and resulted in a depletion of ChAT activity in hippocampus (>90%), cingulate cortex (>80%), occipital cortex and olfactory bulb (>60%), whereas ChAT activity of the frontal and parietal cortex were least affected (<30%). This study defined the parameters for selective and topographically restricted lesions of components of the basal forebrain. Supported by VA Medical Research Service.

## 173.16

EFFECTS OF CHOLINERGIC AND ADRENERGIC DRUGS ON VISUAL SIGNAL DETECTION ("VIGILANCE") IN RATS. P.J. Bushnell\*, W.M. Oshiro and B.K. Padnos. Neurotoxicology Division, NHEERL, U.S. EPA, Research Triangle Park, NC 27711.

Both the adrenergic and cholinergic neurotransmitter systems have been implicated in the control of attention. Drug challenges were used to evaluate the effects of cholinergic and adrenergic agonists and antagonists on sustained attention ("vigilance") in rats, using a visual signal detection task. Daily 60-min test sessions consisted of 3 100-trial blocks. Signal detection analysis provided estimates of sensitivity (SI) and bias (RI) in each block; response time (RT) for each correct signal detection was also recorded. The role of muscarinic cholinergic receptors was tested with pilocarpine (0, 1.0, 1.8, and 3.0 mg/kg sc, 10 min prior to testing) and scopolamine (0, 0.03, 0.01, and 0.30 mg/kg ip, 15 min prior to testing); that of nicotinic cholinergic receptors with nicotine (0, 0.083, 0.25, and 0.75 mg/kg sc, 15 min prior to testing) and mecamylamine (0, 1.8, 3.0, and 5.6 mg/kg ip, 15 min prior to testing); that of  $\alpha$ -adrenergic receptors with clonidine (0, 0.003, 0.010, 0.030 mg/kg sc, 15 min prior to testing) and idazoxan (0, 1.0, 3.0, and 10.0 mg/kg sc, 30 min prior to testing). SI was decreased, and RT was increased by pilocarpine in Block 1; both measures of performance returned to normal in Blocks 2 and 3. RI was not affected. Scopolamine reduced SI and increased RT during the entire test session, without affecting RI. Nicotine at 0.75 mg/kg decreased SI in Block 1; both 0.75 and 0.25 mg/kg improved SI in Block 3. Nicotine did not affect RT. Mecamylamine reduced SI and increased RT across the whole session without affecting RI. Clonidine reduced SI and RI and increased RT in all blocks. Idazoxan reduced SI and increased RT across the whole session; RI was reduced in Block 1 only. Thus all drugs except nicotine reduced SI, and most slowed responding. Nicotine facilitated target detection in the last block of trials.

## 174.2

DIFFERENTIAL EFFECTS OF IgG-192 SAPORIN ON PERFORMANCE OF TWO MEMORY TASKS: REVERSAL OF DEFICITS BY CDD-0097. A.A. El-Assadi\*, M.A. Shepherd and W.S. Messer, Jr.. Department of Medicinal & Biological Chemistry, Center for Drug Design & Development, College of Pharmacy, The University of Toledo, Toledo, OH 43606.

Selective muscarinic agonists might be useful in the treatment of Alzheimer's disease. Previous studies identified CDD-0097 as a selective and efficacious m1 agonist with a low side-effect profile. The cognition-enhancing properties of CDD-0097 were examined using two paradigms to assess memory function and IgG-192 saporin to deplete acetylcholine levels.

In rats, injections of IgG-192 saporin (0.20  $\mu$ g total) into the diagonal band produced impairments of performance on a paired-run, delayed alternation paradigm in a T-maze ( $78 \pm 2.8\%$ ). Vehicle-injected controls were unimpaired ( $100 \pm 0.0\%$ ). Comparable IgG-192 saporin injections did not affect performance ( $94.8 \pm 4.0\%$ ) on a spatial discrimination task in a water maze relative to controls ( $97.9 \pm 2.4\%$ ).

CDD-097 (1.0 mg/kg) completely reversed the memory deficits induced by IgG-192 saporin in the T-maze task, and did not impair performance of control animals in either task. Taken together, the data implicate the basal forebrain cholinergic system in some, but not all forms of spatial memory function. Furthermore, the beneficial effects of CDD-0097 on memory function warrant further examination of the compound as a selective M<sub>1</sub> agonist for the treatment of Alzheimer's disease.

## 174.4

BEHAVIORAL EFFECTS AFTER INTRAPARENCHYMAL INJECTIONS OF 192IgG-SAPORIN INTO DISCRETE REGIONS OF THE BASAL FOREBRIN. D.P. Pizzo\*, J. Winkler\*, and L.J. Thal\*. <sup>+</sup>Dept. of Neurosciences, UCSD, and <sup>\*</sup>VAMC San Diego, CA 92161.

Cholinergic lesions using intracerebroventricular (ICV) administration of the immunotoxin 192IgG-saporin result in a broad range of behavioral impairments including deficits in learning and retention. However, Purkinje cells are destroyed at doses required to obtain behavioral impairments. At present it is unclear to what extent the destruction of cerebellar structures contributes to the behavioral impairment. We therefore selectively lesioned cholinergic neurons in the medial septum (MS) and/or the nucleus basalis (NBM) using intraparenchymal injections of 192IgG-saporin at a dose of 75ng/MS or 75ng/NBM in 0.5 $\mu$ l phosphate-buffered saline (PBS). These intraparenchymally-lesioned animals were behaviorally compared with ICV-lesioned, intraparenchymally-injected PBS controls, and non-lesioned animals. ICV-lesioned animals showed significant impairments in acquisition and spatial probe in the water maze, but retention was unaffected. In comparison, combined intraparenchymal-induced lesions of the NBM/MS resulted in a deficit in acquisition, retention and spatial probe. Single lesions of the MS or the NBM did not result in any behavioral impairment. These data indicate that single lesions of MS or NBM are not sufficient to induce behavioral impairments in the water maze. Supported by VA Medical Research Service.

## 174.5

**ATTENTIONAL AND MEMORY DEFICIT FOLLOWING INJECTION OF 192-IGG-SAPORIN INTO THE RAT NUCLEUS BASALIS MAGNOCELLULARIS (NBM).** P. Curzon\*, A.W. Bannan and M.W. Decker. Neuroscience Research, D-47W, AP-9A, Pharmaceutical Products Div., Abbott Labs, 100 Abbott Park Rd., Abbott Park, IL 60064-3500

192-IgG saporin (SAP) selectively destroys cholinergic neurons when injected into the NBM, reducing cortical acetylcholine (ACh) levels. Disruptive effects of NBM SAP lesions on attention have been reported but effects on performance of spatial and other memory tasks have been inconsistent. We used a rapidly acquired, operant, Go/No-go task (Winocur, Behav. Brain Res., 1985, 16:135) that involves both attention and short-term memory. The ratio of latency to press the lever during alternating rewarded and non-rewarded trials separated by delays of 5, 20, and 40 s is used as an index of performance. Injections of either 21 or 10.5 µg of 192-IgG saporin in 0.5 µl or vehicle were made into the NBM (-0.6 mm, ±2.8 mm lat. from Bregma and -7.5 mm from skull surface). Male Long-Evans rats (group sizes of 10-11) were lesioned either before or after training in the Go/No-go task to assess effects on acquisition and performance. For acquisition, a dose dependent SAP lesion effect was observed on the 3rd week of training ( $p=0.01$ ). The high dose SAP lesioned rats were significantly impaired ( $p=0.015$ ) at the 20 s delay and there was a marginal effect ( $p=0.066$ ) at the 5 s delay. In the group lesioned after training, there was an overall lesion effect ( $p=0.02$ ). The high dose of SAP impaired performance at the 5 s delay during the 1st but not during the 2nd week. Similarly, there was a marginal impairment during the 1st ( $p=0.06$ ) but not the 2nd week at a 20 s delay. In contrast, high dose SAP significantly impaired performance at a 40 s delay during both weeks post lesion. This somewhat more persistent impairment at the longest delay suggests that impaired memory plays a role in the disruptive effects of reduced cortical ACh on Go/No-go performance. However, impairments at the shortest delay suggest that impaired memory may not completely account for the lesion-induced deficit and that impaired attention may also be important. [Supported by Abbott Laboratories]

## 174.7

**THE ACTIONS OF GALANIN AND M40 ON DELAYED NON-MATCHING TO POSITION IN 192IGG-SAPORIN-LESIONED RATS.** M. P. McDonald<sup>1</sup>\*, G. L. Wenk<sup>2</sup>, & J. N. Crawley<sup>1</sup>. <sup>1</sup>Section on Behavioral Neuropharmacology, ETB, NIMH, Bethesda, MD 20892, and <sup>2</sup>Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Galanin is a 29-amino acid neuropeptide that coexists with acetylcholine (ACh) in the medial septum/diagonal band in the rat and inhibits acetylcholine release in the septohippocampal pathway. Galanin is overexpressed in the basal forebrain in Alzheimer's disease (AD). Galanin impairs performance on several rodent learning and memory tasks, including delayed non-matching to position (DNMTP). M40 (galanin[1-12]-Pro<sup>3</sup>-(Ala-Leu)<sub>2</sub>-Ala-NH<sub>2</sub>), a peptidergic galanin receptor ligand, has previously been shown to antagonize galanin-induced impairment on DNMTP. The current experiments used a lesion model of AD to evaluate the actions of galanin and M40 on DNMTP when cholinergic transmission was reduced. Rats were injected with 192IgG-saporin, an immunotoxin that selectively lesions cholinergic cells in the basal forebrain and produced a 54% reduction in hippocampal choline acetyltransferase in the present study. After recovery, rats were injected with galanin in the lateral ventricle and with M40 in the lateral ventricle or the ventral hippocampus. Galanin treatment significantly reduced choice accuracy in both the lesioned and sham groups. M40 alone did not affect choice accuracy. These results suggest that blocking endogenous galanin is not sufficient alone to improve performance in lesioned rats, indicating the potential need for a combined cholinergic-galaninergic treatment strategy.

## 174.9

**NEUROCHEMICAL PROFILE OF MHP-133, A NOVEL MIXED CHOLINERGIC AGONIST DEVELOPED FOR THE TREATMENT OF ALZHEIMER'S DISEASE AND RELATED DISORDERS.** J.J. Buccafusco\*, J.C. Powers, K.M. Starks, and M. Gattu. Alzheimer's Research Center, and Dept. Pharmacol. & Tox., Medical College of Georgia, and the VA Medical Center, Augusta, GA 30912, and the School of Chem. & Biochem., Georgia Institute of Technology, Atlanta, GA.

MHP-133 (3-(N,N-Dimethylcarbamoyl)hydroxy-1-methyl-2-[[N-phenylaminocarbonyl]hydrazono]methyl]pyridinium chloride) was one of a series of oxime, semicarbazone, and acyl hydrazone derivatives of 2-formyl-1-methylpyridinium chloride and 2-formyl-3 or 5-hydroxy-1-methylpyridinium chloride originally designed as potential pretreatment antidotes against poisoning by irreversible organophosphorus acetylcholinesterase (AChE) inhibitors. MHP-133 was demonstrated to be an effective protectant, and a moderate post-poisoning antidote in mice intoxicated with organophosphorus AChE inhibitors. Unlike many of the other compounds of the series, the effectiveness of MHP-133 as a protectant against organophosphorus poisoning could not be correlated with reversible inhibition of AChE. In fact, MHP-133 was shown to have weak affinity for the enzyme ( $K_i < 100 \mu M$ ) and was extremely slow in its ability to carbamylate the enzyme's active site ( $k_{obs}/[I] \sim 2.5 M^{-1} sec^{-1}$ ). Nevertheless, the drug was chosen for further study, because it was shown to be effective by the oral route of administration. Also, MHP-133 combined high effectiveness as a protective agent with the highest margin of safety ( $LD_{50}/Maximal \text{ effective dose} \sim 300$  for both i.m. and oral administration). The quaternary nature of this compound also may impart some ability to directly bind to neuronal nicotinic receptors. In this regard it is about 600 fold less potent than nicotine and about 30 fold less potent than carbachol. Despite its charged nature, however, the drug has actions on the central nervous system. Since both inhibition of brain AChE and stimulation of nicotinic receptors have been demonstrated to improve cognitive performance in animal models and in humans, MHP-133 was examined for potential memory enhancing ability in two animal models (see accompanying poster). Supported by a GIT/MCG grant and the Dept. of Veterans Affairs Medical Center.

## 174.6

**192IGG SAPORIN POSTNATAL DAY (PND) 7 LESIONS DO, BUT PND 1 LESIONS DO NOT, PRODUCE SIGNIFICANT BEHAVIORAL IMPAIRMENTS AND REDUCED CHOLINERGIC MARKERS IN YOUNG MALE RATS.** L. Ricceri<sup>1</sup>, G. Calamandrei<sup>1</sup>, and J. Berger-Sweeney<sup>2</sup>\*, <sup>1</sup>Comparative Psychology Section, Lab. Fisiopatologia, Istituto Superiore di Sanita, I-00161 Rome (ITALY) and <sup>2</sup>Dept. Biological Sciences, Wellesley College, Wellesley, MA 02181.

We have shown previously that 192 IgG-saporin, a p75 (NGF receptor)-specific antibody linked to a ribosomal inactivator produces cholinergic losses and behavioral impairments in adult rats (*J. Neurosci.* 14:4507-4519). The purpose of the current experiment was to examine the developmental role of the cholinergic system in behavior. Rats were injected with the neurotoxin into the 3rd ventricle on either PND1 or PND7; vehicle injected pups served as controls. Passive avoidance acquisition was assessed on PND15 and open field behaviors (locomotor activity, wall rearing and grooming) were assessed on PND 19. All rats were sacrificed on PND20 and choline acetyltransferase (ChAT) activity in hippocampus and cortex was determined. Passive avoidance acquisition was impaired in the PND7 lesioned group, but not in the PND1 lesioned group. Open field locomotor activity was not altered in either neurotoxin treated group. The PND7 group, however, exhibited significantly reduced wall rearing in an open field, while the PND1 group exhibited increased grooming in an open field. The PND1 group showed 14% and 17% reductions in hippocampal and cortical ChAT activity, respectively, as compared to controls. The PND7 group showed 78% and 65% reductions in hippocampal and cortical ChAT activity, respectively. It is clear that the more significant reduction in ChAT activity in the PND7 group was associated with impaired acquisition performance. The PND1 group results could indicate either that the toxin was not effective at that age, or that there was significant recovery of the cholinergic system by the time of testing such that a behavioral deficit was not detected. ## 174.8

**MODERATE LOSS OF CORTICAL CHOLINERGIC INPUTS AS A MODEL OF AGE-RELATED IMPAIRMENTS IN ATTENTION AND EFFECTS OF PUTATIVE THERAPEUTIC DRUGS.** J. McLaughy\* and M. Sarter. Department of Psychology and Neuroscience Program, The Ohio State University, Columbus, Ohio 43210.

Previously, we demonstrated that cortical cholinergic deafferentation by intra-basalis infusions of 192 IgG-saporin produced severe, prolonged deficits on behavioral vigilance. The lesion-induced impairments were not attenuated by the administration of either physostigmine, a cholinesterase inhibitor, or FG 7142, a benzodiazepine receptor partial inverse agonist (*Behav Neurosci* 110:247-265). These results did suggest, however, that FG 7142 was more efficacious in attenuating the behavioral deficits in animals with less severe depletions. In the current study, the effects of moderate cholinergic depletions were produced by diffuse intra-cortical infusions of the immunotoxin 192 IgG-saporin. Such depletions represent a more valid model of the extensive, but incomplete loss of cortical cholinergic inputs observed in aged and demented humans. As predicted, intracortical infusions of the toxin produced decreases in cortical AChE-positive fibers and attentional impairments that were less severe than those previously found following intrabasalis infusions of the immunotoxin. The efficacy of physostigmine and FG 7142 in ameliorating these more moderate deficits, and the implications of these results for the development of novel treatment strategies will be discussed.

## 174.10

**MHP-133-INDUCED ENHANCED PERFORMANCE OF MEMORY-RELATED TASKS IN RATS AND MONKEYS** M.A. Prendergast\*, J.J. Buccafusco and J.C. Powers. Alzheimer's Research Center, and Dept. Pharmacol. & Tox., Medical College of Georgia, and the VA Med. Ctr., Augusta, GA 30912, and School of Chem. & Biochem., Georgia Institute of Technology, Atlanta, GA.

In the Morris Water Maze task involving a stationary slightly submerged platform, i.p. pretreatment with MHP-133 to adult Wistar rats significantly improved the learning curve over 4 consecutive trials. Of 3 doses tested, 50, 100 and 200 µg/kg, the two lower doses were associated with significant improvement in task performance. A group of 12 macaques were well-trained in the performance of an automated delayed matching-to-sample (DMTS) task. The monkeys were represented by individuals from 3 species, both genders and two age groups, mature and aged. All, but 1 animal exhibited marked improvement in DMTS performance at 1 or more doses. Virtually all of the improvement was obtained for trials involving the longest delay intervals imposed between stimulus presentation and choice presentation. At the most effective dose (30 - 100 µg/kg i.m.), performance at long delay trials increased on average by 32.2% over baseline performance for the entire group. Thus, MHP-133 improves short-term memory ability in animals, including aged monkeys. MHP-133 was also examined for its ability to displace muscarinic receptor and neuronal nicotinic receptor ligands from rat cortical membranes using standard ligand binding techniques. The drug completely displaced the [<sup>3</sup>H]labeled receptor ligands, methylscopolamine and cytisine, with  $IC_{50}$  values in the µM range. Finally, MHP-133 was compared with physostigmine for the ability to increase blood pressure in conscious rats, and to produce other signs of acetylcholinesterase (AChE) inhibitor toxicity in rats. Over i.v. doses ranging from 25 - 750 nmol/kg physostigmine produced a dose-dependent increase in blood pressure up to about 70 mmHg. Over the same range, MHP-133 evoked no significant change in resting blood pressure. MHP-133 may improve the performance of memory-related tasks through a combined mechanism including weak AChE inhibition and nicotinic receptor stimulation. Supported by a GIT/MCG grant, & Dept. VA Med. Ctr.

## 174.11

COMPARATIVE STUDIES OF HUPERZINE A AND TACRINE ON SCOPOLAMINE-INDUCED AMNESIA OF SHUTTLE-BOX ACTIVE AVOIDANCE IN ADULT AND AGED RATS. Z.J. Dong, Y.L. Lo, K.Y. Chan and Y.F. Han. (SPON: The Hong Kong Society of Neuroscience). Department of Biochemistry, The Hong Kong University of Science and Technology, Hong Kong

Huperzine A (Hup A), isolated from a Chinese medicinal herb *Huperzia serrata*, has been well established as a potent and reversible cholinesterase inhibitor. In this study Hup A was compared with tacrine in both improving the learning process of normal rats and in reversing scopolamine-induced amnesia. Sprague-Dawley rats were trained to have active avoidance response to foot shock in the shuttle-box. Hup A effectively increased the learning process of adult and aged rats at the dose range of 0.2-0.4 mg/kg and 0.1-0.3 mg/kg (IP, immediately after training), respectively (all  $p < 0.05$ ). A similar effect of tacrine was observed at the dose range of 6-12 mg/kg (IP). In addition, Hup A (0.3 and 0.4 mg/kg, IP) significantly ameliorated the consolidation impairment in active avoidance responses induced by scopolamine (1 mg/kg, SC,  $p < 0.05$ ). These results suggest that Hup A, which is much more potent than tacrine, can potentially improve the learning process through a central cholinergic mechanism in both adult and aged animals. [Supported by Hong Kong RGC Direct Allocation Grant (94/95.SC11)]

## 174.13

NEFIRACETAM REVERSES MUSCARINIC AND NICOTINIC ANTAGONISTS IN EYEBLINK CONDITIONING IN RABBITS. D.S. Woodruff-Pak\* & R.M. Hinchliffe. Psychology Dept., Temple Univ., Philadelphia, PA 19122.

The septo-hippocampal cholinergic system plays a modulatory role in eyeblink classical conditioning (EBCC), and this provides a point of contact with Alzheimer's disease (AD). The focus of the role of the cholinergic system in EBCC has been on the muscarinic cholinergic receptors. Our research was the first to demonstrate a role for nicotinic cholinergic receptors in EBCC. However, we are not aware of research on the effect of nefiracetam on nicotinic cholinergic receptors. Given that nicotinic cholinergic receptors as well as muscarinic cholinergic receptors are involved in the modulation of learning of EBCC, experiments were carried out to examine reversal of cholinergic antagonists to nicotinic (mecamylamine) and muscarinic (scopolamine) receptors in young rabbits with nefiracetam. Two experiments were completed by a total of 88 young SPF female New Zealand white rabbits tested for 15 days in the 750 ms delay paradigm. Both paired and explicitly unpaired conditions were tested with drugs and vehicle. Nefiracetam at a dose of 10 or 15 mg/kg reversed the effects of both mecamylamine and scopolamine. The vehicle alone and nefiracetam alone groups performed similarly to the groups treated with mecamylamine and nefiracetam or scopolamine and nefiracetam. An interesting outcome in this experiment was that nefiracetam alone did not facilitate acquisition of EBCC in young rabbits over the rate of vehicle-treated young rabbits. Young rabbits were apparently performing at close to ceiling levels. In summary, nefiracetam acted to reverse the effects of both a nicotinic and a muscarinic cholinergic antagonist in young rabbits trained in the 750 ms delay EBCC paradigm. Our research has indicated that it is the disruption of the hippocampal cholinergic system that impairs EBCC in AD. Thus, the reversal of nicotinic and muscarinic cholinergic antagonists by nefiracetam suggests that nefiracetam has the potential to ameliorate impaired cognition in AD. Supported by Daiichi Pharmaceutical Co., Ltd., Tokyo, Japan.

## 174.12

REVERSAL EFFECTS OF HUPERZINE A AND TACRINE ON MEMORY DEFICITS IN BILATERAL NBM LESIONED RATS. O.Y. Yeung and Y.F. Han. (Spon: The Hong Kong Society of Neuroscience). Department of Biochemistry, The Hong Kong University of Science and Technology, Hong Kong.

Huperzine A (Hup A), a novel selective acetylcholinesterase inhibitor, was first isolated from a Chinese medicinal herb *Huperzia serrata*. The specific aim of this study was to evaluate the efficacy between Hup A and tacrine on nucleus basalis of magnocellularis (NBM) lesion-induced spatial memory deficits. Male Sprague-Dawley rats were trained to achieve the criterion level of performance in the radial maze in which eight arms were baited with reinforcement. Bilateral NBM lesion with ibotenic acid (6 µg/µl, per side) caused significant impairment in rats' ability to perform this working memory task as demonstrated by fewer correct choices before the first error, more total errors to complete the task and lower the percent efficiency. The behavior impairment was correlated to about 40% decrease of choline acetyltransferase activity in neocortex. Hup A (0.3-0.6 mg/kg, IP, 30 minutes before task) significantly reversed this memory deficits induced by NBM lesion. Tacrine (3-6 mg/kg) also ameliorated the memory impairment. The results suggest that the integrity of NBM lesion is critical for spatial memory processing, and the working memory impairment induced by NBM lesion can be more effectively reduced by Hup A than tacrine. Acknowledgment: To Prof. X.C. Tang and Mr. Z.Q. Xiong for their helps during the course of the experiment. [Supported by HK RGC DAG (94/95.SC11)].

INFLUENCE OF NEFIRACETAM ON NGF-INDUCED NEURITOGENESIS AND NEURAL CELL ADHESION MOLECULE POLYSIALIC ACID EXPRESSION: IN VIVO AND IN VITRO COMPARISONS. T. Shiotani, S. Watabe\*, O. Odumeru, K.I. Murphy, A.W. O'Connell and C. M. Regan. Dept. Pharmacology, University College Dublin, Ireland and Daiichi Pharmaceutical Co. Ltd, Tokyo, Japan.

Co-administration of nefiracetam (DM-9384) during acquisition of an avoidance response prevents attenuation of learning-associated polysialylation of dentate neurons in scopolamine-induced amnesia at a 12h post-training period. We now provide *in vitro* evidence for these enduring effects. Exposure of primed PC-12 cells to nefiracetam for an 8-12h period and subsequently to NGF alone for 36h augmented neurite growth and polysialylation in a dose-dependent manner and increased significantly the percentage of cells with neurites in excess of 30µm. In all cases the maximal effect was observed at the lowest dose evaluated (0.1µM). A 48h co-exposure of NGF and nefiracetam to naive PC-12 cells resulted in a 2-fold increase in PSA expression which could not be attributed to increased NCAM polypeptide prevalence. Chronic *in vivo* exposure of nefiracetam (3mg/kg; 40days), a dose known to reverse scopolamine-induced amnesia, failed to significantly prevent the basal expression of dentate polysialylated neurons suggesting the action of nefiracetam to be stimulus-dependent as provided by NGF *in vitro* and by the learning event *in vivo*. In contrast, higher doses of nefiracetam (≥9mg/kg) prevented age-dependent decline of dentate polysialylated neurons following chronic administration. This suggests that doses higher than those required to ameliorate scopolamine-induced amnesia may increase neuroplastic potential and account for the neuroprotective actions attributed to nefiracetam. Supported by Daiichi, EU Biotechnology Programme and Health Research Board of Ireland.

## NEURAL PLASTICITY I

## 175.1

INCREASED DENDRITIC ARBORIZATION OF CEREBELLAR STELLATE NEURONS FOLLOWING MOTOR SKILL LEARNING IN THE RAT. W.T. Greenough\*, J.A. Kleim, R.A. Swain, C. M. Czerlanis, J. Kelly & M. A. Pipitone. Depts. Psych., Cell & Struct. Biol., Neurosci. Prog. and Beckman Inst., Univ. Illinois, Urbana, IL 61801.

Following complex motor skill acquisition, increases in the number of parallel fiber to Purkinje cell synapses have been observed in the cerebellar cortex. In this study we examined whether motor skill learning affects the morphology of the stellate interneurons within the cerebellar cortex. Female rats were randomly assigned to either an Acrobatic condition (AC) or a Motor control condition (MC). The AC animals were trained to traverse a complex obstacle course which required a significant amount of motor coordination to complete. Each AC animal was pair matched with an MC animal which was forced to travel down a flat, obstacle free runway equal in length to the acrobatic course. Following ten days of training, the animals were sacrificed and neurons within the cerebellum were visualized using Golgi impregnation. Approximately ten stellate cells from both the upper and lower half of the molecular layer of the paramedian lobule were traced using camera lucida. Concentric ring analysis revealed the AC animals to have significantly more dendritic material than their MC littermates. In addition, cells in the lower half of the molecular layer had significantly more dendritic material than those in the upper half irrespective of condition. These results indicate that the inhibitory interneurons within the cerebellar cortex undergo dendritic remodelling in association with motor skill learning. Supported by AG 10154, NSF BNS 88 21219 and NSERC Scholarships.

## 175.2

AN EXAMINATION OF LATERAL CEREBELLAR NUCLEUS MORPHOLOGY FOLLOWING COMPLEX MOTOR LEARNING IN THE RAT. J.A. Kleim\*, M. A. Pipitone, J. Kelly, J. Drew, C. M. Czerlanis, & W.T. Greenough. Depts. Psych., Cell & Struct. Biol., Neurosci. Prog. and Beckman Inst., Univ. Illinois, Urbana, IL 61801.

The cerebellar cortex has been observed to undergo profound structural remodelling in association with motor skill learning but not with motor activity. In this experiment we examine how motor skill learning affects the morphology of the lateral cerebellar nucleus (LCN), one of the primary targets of cortical output. Female rats were randomly assigned to either an Acrobatic condition (AC), Motor control condition (MC) or an Inactive condition (IC). AC animals were trained to traverse a complex obstacle course which required a substantial amount of motor skill to complete. Each AC animal was pair matched with an MC animal which was forced to traverse a flat, obstacle free runway equal in length to the acrobatic course. IC animals received no motor training or activity but were handled daily. Following 14 days of training, the animals were sacrificed and serial 100µm sections were taken in the horizontal plane through one hemisphere of the cerebellum. The LCN was dissected from two of these sections and prepared for electron microscopy. Unbiased stereological techniques were then used to obtain estimates of LCN volume and neuron density from the remaining sections. Preliminary results indicate no significant effect of CONDITION on either LCN volume or neuron density. Ultrastructural analysis of synapse number is currently in progress. Supported by AG 10154, NSF BNS 88 21219 and NSERC Scholarships.

## 175.3

**CHANGES IN EXPRESSION OF bZIP PROTEINS AND DNA BINDING ACTIVITY IN MOUSE BRAINSTEM DURING TASTE AVERSION LEARNING.** D.S. Kotchmar<sup>1</sup>, K.R. Pennypacker<sup>2</sup> and M.W. Swank<sup>1</sup>. Dept. Psychology, Furman U., Greenville, SC 29613<sup>1</sup>, Dept. Pharmacology, U. South Florida, Tampa, FL 33612<sup>2</sup>

Previous immunohistochemical studies from this lab<sup>1</sup> have demonstrated CS- and US-specific patterns of bZIP expression in rodent brainstem during taste aversion learning. Using a micro-punch technique, we demonstrate the feasibility of performing Western blots and gel-shift assays with tissue collected from the intermediate NTS. Preliminary Western blot analysis using polyclonal antibodies for detection (Santa Cruz Biotechnology) reveals that a LiCl US produces an up-regulation of a number of bZIP proteins, including c-Fos, FosB, JunD, and a Fos-related antigen. Gel-shift analysis reveals increases in both AP-1 and CRE binding activity following US LiCl or CS saccharin. Treatment with both CS saccharin and US LiCl produces a pattern of AP-1 and CRE binding activity which resembles neither that of the CS nor US alone, suggesting an associativity of these two stimuli which is not merely additive. In light of the known different affinities and binding specificities of various bZIP heterodimeric combinations, present studies are directed at identifying the specific heterodimers formed as a result of the different behavioral treatments involved in taste aversion learning.

**ELECTROPHYSIOLOGICAL CORRELATES OF THE ESCAPE BEHAVIOR, IN THE ABDOMINAL MUSCLES, OF JUVENILE AND ADULT AMERICAN LOBSTERS, OVER THE MOLT CYCLE.** S.L. Cromarty<sup>\*1</sup> and G. Kass-Simon<sup>2</sup>. <sup>1</sup>Department of Biology, Georgia State University, Atlanta, GA 30302. <sup>2</sup>Biological Sciences Department, University of Rhode Island, Kingston, RI 02881.

Neuromuscular plasticity over the molt cycle has been well documented in the claw-opener musculature of the American lobster (Schwanke et al., 1990). Here we present evidence that similar molt-related differences occur in the flexor muscles effecting escape swimming.

We compared excitatory junction potentials (EJPs) in juvenile and adult lobsters in each of four molt stages (A, B, C, D) and analyzed the results with respect to the following parameters: EJP amplitude, EJP area, EJP rise and decay time, and facilitation and/or failure rates.

Our results show that increasing the frequencies from 1 to 6 Hz differentially affected the production of EJPs in the different molt stages among juvenile lobsters: EJPs of hard-shelled (C and D) juvenile lobsters failed at 4 and 5 Hz, while soft-shelled (A and B) juveniles continued to produce EJPs beyond 6 Hz. Among adult lobsters however, EJPs of soft-shelled lobsters, failed at 4 and 5 Hz, while hard-shelled lobsters continued to produce EJPs to 5 and 6 Hz. Soft-shelled adult (Stage A) lobsters produced the largest EJPs, indicating that there is a tendency for A lobsters to respond to a stimulus with a maximal transmitter release which is then not replenished at the higher frequencies resulting in EJP failure.

Our results therefore indicate that changes in the neuromuscular synapse occur not only as a function of relative weight and/or developmental period (small juveniles, large adults), but also as a function of molt-related physical condition. The differences in escape swimming (Cromarty, et al., 1991) among juvenile and adult lobsters in different molt stages can be in part accounted for by correlated differences in the electrical activity at the abdominal neuromuscular junction.

## 175.7

**SIGNS OF MAP-2 DEGRADATION IN THE HIPPOCAMPUS WITH CONTEXTUAL MEMORY** N.J. Woolf\*, M.D. Zinnerman and G.V.W. Johnson, Dept. of Psychology, UCLA, Los Angeles, CA 90095-1563 and Depts. of Psychiatry and Behavioral Neurobiology, University of Alabama, Birmingham, AL 35294-0017

We have previously found signs of MAP-2 degradation with Pavlovian conditioning to tone. In our previous studies, MAP-2 degradation in the auditory cortex correlated with conditional responses to tone. These changes were detected the day after the last training session, and, at that time, there was no sign that MAP-2 was degraded in hippocampus.

With Pavlovian conditioning to tone, rats also develop a memory of the context in which they are conditioned. Consolidation of a configuration, like the training context, is more complex and takes longer than the learning of elemental stimulus like a tone. For these reasons, we decided to look at longer intervals after training for signs of degradative changes in the hippocampus.

Sprague-Dawley rats were trained with a 2 KHz tone and a 1 mAmp grid shock in a novel chamber. Two weeks later, the rats were sacrificed for immunohistochemical studies or immunoblot analyses. Immunohistochemistry for MAP-2 was increased in CA1 of the hippocampus of conditioned animals as compared to controls ( $p < 0.01$ ). This suggested the possibility of increased breakdown products. Immunoblots confirmed that more trained animals exhibited a 90 kD breakdown product in the hippocampus than did the controls.

Previous studies have shown a 90 kD breakdown product when purified MAP-2 is exposed to calpain. Thus, calpain-mediated breakdown of MAP-2 in the hippocampus may underlie contextual memory.

## 175.4

**MEASUREMENT OF PRIMED BURST POTENTIATION DURATION VARIES ACROSS THE POPULATION SPIKE INPUT/OUTPUT FUNCTION IN THE DENTATE GYRUS OF FREELY BEHAVING RATS.** E.L. Hargreaves\* & M.L. Shapiro. Psychology, McGill University, Montreal, CANADA

Primed Burst Potentiation (PBP) is a form of neural plasticity that is similar to long-term potentiation (LTP), but of brief duration. Because PBP is repeatable, it may be a more useful tool for studying memory mechanisms in behaving animals than LTP. Here, we measured the duration of PBP across the population-spike (PS) input/output (I/O) curve.

I/O functions were recorded from the perforant-path/dentate-gyrus circuit of behaving Long-evans male rats (350-400g). Diphasic test pulses (0.1 ms/phase) were used to generate I/O functions and PBP. I/O functions consisted of 9 levels ranging from 50µA above PS threshold to maximal responses tailored for each animal. All I/O test pulses were delivered at a frequency of 0.1Hz. I/O functions were recorded continuously during PBP sessions. PBP was induced using 1000 uA stimuli: 1 priming pulse followed 170 msec later by a 200Hz pulse burst.

As in LTP, greater PS potentiation was measured at lower I/O test pulse intensities than at more maximal I/O test pulse intensities. Although greater potentiation was recorded at the lower test pulse intensities, the measured duration of this potentiation was shorter than that of the smaller potentiation recorded at the more maximal test pulse intensities. Potentiation at the more maximal test pulse intensities could be detected up to 2.7 hours after PBP was induced, whereas potentiation measured at the lower test pulse intensities could return to baseline levels within 30 min.

Thus, measurement of the degree and duration of PS enhancements, following PBP, are not uniform across the I/O curve. Lower test pulse intensities exhibit greater potentiation, but return to baseline faster than test pulse intensities evoked near or at maximal responses. Supported by NSERC and MRC of Canada.

## 175.6

**MEG AND FMRI INVESTIGATIONS OF CROSS-MODAL PLASTICITY IN A CONGENITALLY DEAF SUBJECT** Gregory Hickok†\*, David Poeppel‡, Kevin Clark†, Richard Buxton#, Howard A. Rowley‡, and Tim P.L. Roberts‡. †Salk Institute-UCN, 10010 N. Torrey Pines, La Jolla, CA 92037, #UCSD, and ‡UCSF, 513 Parnassus Ave, San Francisco, CA 94143.

It has been proposed that auditory cortex of deaf subjects may provide an example of cross-modal compensatory plasticity. This study investigated whether visual or somatosensory stimulation could elicit responses from primary auditory areas of a congenitally deaf subject. Neuromagnetic fields were recorded using a 37-channel biomagnetometer (Magnes, Biomagnetic Technologies, Inc., San Diego, CA) under conditions of (i) visual stimulation, (ii) somatosensory stimulation, and (iii) a simple motor task. Visual items were a reversing checkerboard and single spots of light, presented in various portions of the visual field and at different rates; somatosensory stimuli were pneumatic taps delivered to one digit-segment at a time; the motor task was self-paced finger tapping. In addition, functional magnetic resonance imaging was performed with a full-field checkerboard stimulus. Results: no obvious responses to passively presented visual or somatosensory stimuli were observed in auditory cortex. In contrast, somatosensory, motor, and visual cortices reveal evoked responses comparable to hearing control subjects, indicating canonical physiological organization in these areas. These data are consistent with previous ERP and fMRI data, as well as with analogous MEG studies of congenitally blind subjects, and suggest that primary projection areas do not reveal obvious plastic effects. Rather, compensatory plasticity effects emerge only in non-primary areas of cortex and only under attentionally demanding conditions. NIH R01 DC00201

## 175.8

**SYNAPTIC CORRELATES OF SPATIAL LEARNING IN DENTATE GYRUS AND AREA CA1 OF THE RAT HIPPOCAMPUS.** M.G. Stewart, D.A. Rusakov, H.A. Davies, E. Harrison, G. Diana and T.V.P. Bliss. (SPON: Brain Research Association). Dept. of Biology, The Open University, Milton Keynes MK7 6AA, UK; Istituto Superiore di Sanita', 00161 Roma, Italy; National Institute for Medical Research, London NW7 1AA, UK.

Structural correlates of a hippocampal-dependent learning task, water maze escape in the rat, were investigated at the level of synapses from dentate gyrus (granule cells) and CA1 (apical dendrites of pyramidal cells) of hippocampus. Nine rats were trained in 13 sessions to locate an invisible escape platform. Eight control rats were similarly trained but using a visible platform. Five days after the last session, rats were perfused and hippocampi dissected and processed for electron microscopy. Synaptic densities were estimated using disector routines. Sizes of synaptic active zones, and planar co-ordinates of synapses in sampling windows were recorded.

Each data set 'session vs. escape latency' showed an exponential regression, and we considered its time constant as an individual 'performance index'. Preliminary morphometric data show no significant changes in the spatial density, or active zone sizes, of synapses located either on dendritic spines, or the shaft, in either of the hippocampal areas, after training. However, a negative correlation was indicated between the 'performance index' and the density of shaft synapses in dentate gyrus (both groups) and CA1 (control group). In both areas, inter-synapse distances showed a significant trend towards lower values (in the range from 0 to 1.5 µm) after the task.

The results indicate that memory processing for the water maze task may involve subtle re-arrangement of synapses, including a switch between shaft and spine contacts, rather than dramatic changes in synaptic numbers.

PERFORMANCE IN A FREE SWIM TEST WITH VISUAL CUES IN ADULT MICE WITH BRAIN LESIONS INDUCED BY PRENATAL X-IRRADIATION R.W.F. Vitral (1,2), G. Campos (1), G. Faiva (1) and S.L. Schmidt\* (1), (1)Dept. Ciências Fisiológicas, Inst. Biol., UERJ, (2)Inst. Biof. Carlos Chagas Filho, UFRJ, Rio de Janeiro, 20551030, BRAZIL.

Exposure of pregnant mice to ionizing radiation on the sixteenth gestational day (E16) with doses greater than 2 Gy produces extensive depletion of neocortical superficial layers (II-IV) and callosal agenesis in the progeny. In this investigation, mice were exposed to X-rays at E16 receiving a total dose of 3 Gy. At adulthood, 49 irradiated (28 female and 21 male) and 61 non-irradiated (32 female and 29 male) animals were tested in a white free-swimming box. In one side there was a 11 cm high escape platform painted black. The platform was always visible to the animals because the water level was kept at a height of 10 cm. Each mouse was placed in the opposite side to the escape platform, facing the wall. They were submitted to two testing blocks that consisted of five consecutive trials each. The time interval between the two blocks was 24 hours. The trials were recorded with a video camera. From the recorded images, a microcomputer calculated the mean speed of each animal. In the first trial of the first block there was no significant difference between the velocity of the irradiated ( $v = 20.6$  cm/s) and non-irradiated ( $v = 24.5$  cm/s) animals. However, in the fifth trial of the first block there was a significant difference between irradiated ( $v = 21.9$  cm/s) and non-irradiated ( $v = 30.1$  cm/s) animals. This pattern was maintained in all trials of the second block. We concluded that, for both sexes, the irradiated mice do not improve their performance with repeated testing. This might be the result of a visuomotor integration deficiency of the irradiated mice. Supported by CNPq and UERJ.

## 175.11

ALTERATIONS OF SPONTANEOUS UNIT DISCHARGES IN THE DENTATE GYRUS FOLLOWING LTP INDUCTION. Akihisa Kimura\*<sup>1</sup> and Constantine Pavlides\*<sup>2</sup>. <sup>1</sup>Wakayama Medical College, Wakayama, Japan; <sup>2</sup>The Rockefeller University, New York, NY.

Long-term potentiation (LTP) is a use-dependent modification of synaptic plasticity following high-frequency stimulation (HFS) to a set of afferents. Typically, field potentials or intracellular recordings are made to assess changes in synaptic plasticity. In the present experiment we were interested in determining changes in spontaneous neuronal activity in relation to induction of LTP in the dentate gyrus (DG) following HFS of the perforant pathway. Experiments were performed in rats under chloral hydrate anesthesia. Field potentials and unit recordings were obtained alternatively from the same recording electrode.

Following baseline recordings of both field potentials and unit firing, HFS (400Hz, 20-50 pulses, 5 times, 10 sec apart) was applied and recordings of field potentials and spontaneous single or multi-unit discharges were continued. Experiments, in which LTP of field potentials was induced, were analyzed. In a quarter of cases, the enhancements of the field potentials were accompanied with an increase of unit discharges. A subgroup of cells, however, decreased their firing following enhancements of field potentials. In a subset of experiments, 30-40 min following induction of LTP, low frequency stimulation (1Hz, 10 min) was applied to the perforant pathway. This depotentiated the field potentials. Similar to the findings with LTP, depotentiation was accompanied with either enhancements or decrements in unit discharges. These results suggest that there exists a dynamic modification of unit activity in the DG, following LTP induction.

Supported by the grants from Wakayama Medical College and the Whitehall Foundation.

## 175.13

HIPPOCAMPAL LTP DECAYS MORE RAPIDLY IN RATS EXPOSED DEVELOPMENTALLY TO LEAD. M.E. Gilbert<sup>1,2</sup>, C.M. Mack<sup>2</sup>, and S.M. Lasley<sup>1</sup>, National Research Council, US EPA, RTP, NC 27711, and U.Ill. Coll. Medicine, Peoria, IL 61656.

Childhood lead (Pb) exposure has been associated with impaired cognitive function. We have previously shown an increase in the threshold for LTP induction in the urethane-anesthetized rat developmentally exposed to low levels of Pb. The present study examined the time course of decay of LTP in the dentate gyrus of the conscious rat chronically exposed to Pb. Pregnant female rats received 0.2% Pb-acetate in the drinking water and male offspring were maintained on this solution. As adults, animals were prepared with chronic stimulating/recording electrodes in the hippocampus. Following recovery from surgery and the establishment of stable field potentials evoked by single pulse stimulation (0.1 ms) of the perforant path, a pretrain input/output (I/O) function was collected. Saturable levels of LTP were induced by delivering 20 train pairs (4 pulses/pair at 400 Hz), 200 ms apart, at an intensity of 1000  $\mu$ A. Post-train I/O functions were collected 1 hr and 1, 2, 4, 7, 14, 21, 28 days after LTP induction to monitor the time course of its decay. Preliminary analysis comparing maximal levels of LTP measured 1 hr after tetanization with later time points indicated faster declines in Pb-exposed animals within the first week. These data indicate that in addition to threshold shifts, mechanisms supporting the maintenance phase of LTP are also impacted by developmental Pb exposure. (Supported by <sup>1</sup>NIH ES06253, <sup>2</sup>NRC, and <sup>3</sup>US EPA).

## 175.10

NEURAL CHANGES IN FORELIMB CORTEX AND THE BEHAVIOURAL DEVELOPMENT OF REACHING AND BIMANUAL COORDINATION IN THE RAT. B.L. K. Coles\* and I. O. Whishaw. Dept. of Psychology, University of Lethbridge, Lethbridge, AB, Canada, T1K 3M4.

Neural changes in the forelimb cortex were studied at Postnatal (P) 10, 15, 20, 25, 30, and 100 days. Three biological markers of brain development, glial fibrillary acidic protein (GFAP), c-Fos, and Acetylcholinesterase (AChE), as well as the morphology of motor cortex cells obtained from Golgi-Cox prepared tissue, were correlated with the behavioural development of reaching and bimanual coordination during feeding behaviors. Behaviors were filmed from P10 until P30 and then also in adults. For both behaviors there was a gradual development of the skilled patterns of paw and digit use seen in adults. The development of the adult patterns of movement were correlated with the morphological changes in the cortex. The results suggest that the maturation of skilled movement depends upon morphological maturation of the neocortex as well as upon experience.

This research was funded by NSERC.

## 175.12

DIFFERENTIAL SYNAPTIC LOCALIZATION OF AMPA AND NMDAR1 RECEPTOR SUBUNITS IN THE RAT HIPPOCAMPAL DENTATE GYRUS. N. L. Desmond<sup>1</sup> and R. J. Weinberg<sup>2</sup>. <sup>1</sup>Dept. of Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908 and <sup>2</sup>Dept. of Cell Biology & Anatomy, Univ. of North Carolina, Chapel Hill, NC 27599.

We are interested in the localization of glutamate receptor subunits at synapses in the adult hippocampal dentate gyrus (DG) and changes therein with synaptic modification. Toward this end, we used postembedding immunogold labeling for three glutamate receptor subunits (GluR1, GluR2/3, and NMDAR1) to characterize axospinous synapses in the middle third of the normal, adult DG molecular layer. These synapses are predominantly entorhinal-DG contacts. Synapses with gold particles within  $\pm 25$  nm of the postsynaptic density (PSD) trace length were evaluated. Axospinous synapses were substantially more likely to be NMDAR immunopositive than GluR1 or GluR2/3 immunopositive. If we compare immunopositive axospinous synapses as a function of their PSD form, another picture emerges. Axospinous synapses with either perforated or nonperforated PSDs are about equally likely to be NMDAR immunopositive. On the other hand, the probability of axospinous synapses with perforated PSDs being AMPAR (GluR1 or GluR2/3) immunopositive is about twice that of axospinous synapses with nonperforated PSDs. Given that perforated PSDs are hypothesized to be potentiated synapses, these data suggest that LTP leads to the insertion of AMPA receptors at the PSD.

## 175.14

CORRELATES OF LONG-TERM SENSITIZATION IN MOTOR NEURONS AND INTERNEURONS OF *APLYSIA*. W.L. Lee, L.J. Cleary<sup>\*</sup> and J.H. Byrne, Dept. of Neurobiology and Anatomy, Univ. Texas Houston Medical School, Houston, TX 77225.

Long-term sensitization is an important form of learning exhibited by the tail-siphon withdrawal reflex. Previous work demonstrated that long-term sensitization was lateralized, and was correlated with changes in the membrane properties of tail sensory neurons (Scholz and Byrne, 1987; Lee et al. 1995). In this study, we extended these observations to include tail motor neurons and interneurons.

Animals were trained as described previously (Scholz and Byrne, 1987). Enhancement of siphon withdrawal elicited by weak tail shock was greater on the sensitized side of the animal than on the contralateral control side. The median was increased from 102% (41 Interquartile Range (IR)) to 186% (95 IR) [ $P < 0.0001$ ]. In these same animals, two properties of motor neurons were affected. Resting membrane potential was increased from a median of -59 mV (9 IR) to -63 mV (6 IR) [ $P < 0.05$ ]. In addition, the threshold membrane potential for generation of an action potential was decreased from a median of -44 mV (9 IR) to -46 mV (7 IR). [ $P < 0.05$ ]. Two other biophysical properties of tail motor neurons were unaffected by long-term sensitization: input resistance at -80 mV and excitability. LPI17 is an excitatory interneuron that provides long-lasting synaptic input to motor neurons in pedal and abdominal ganglia (Cleary and Byrne, 1993). LPI17 was not affected by training, nor was the strength of the synaptic connection between LPI17 and tail motor neurons.

To our knowledge, this is the first report that long-term sensitization in *Aplysia* affects biophysical properties of motor neurons. Hyperpolarization may serve to bias the motor neuron to respond to strong stimuli. The reduced spike threshold would compensate in part for the increased membrane potential. Although LPI17 was unaffected by training, other elements of the circuit mediating tail-induced withdrawal reflexes have not yet been examined, and they may be important sites of plasticity.

Supported by NIH grant NS 19895.

## 175.15

REGULATION OF THE GLYCOLYTIC ENZYME, PHOSPHOGLYCERATE KINASE, BY TREATMENTS PRODUCING LONG-TERM FACILITATION IN *APLYSIA* NEURONS. **H. West\*, R. Homayouni, J. H. Byrne\*, and A. Eskin.** Dept. of Biochem. and Biophysical Sci., Univ. of Houston, Houston, TX 77204. \*Dept. of Neurobiology and Anatomy, Univ. of Texas Med. School, Houston, TX 77225.

Serotonin-induced long-term facilitation (LTF) of pleural sensory neurons requires protein and mRNA synthesis. Previously, using *in vitro* translation of mRNA and two-dimensional polyacrylamide gel electrophoresis (2D-PAGE), we found 4 proteins whose mRNA was altered by treatments with 5-HT (Zwartjes et al., 1992). Microsequencing revealed one protein to be 88% identical to human 3-phosphoglycerate kinase II (PGK II). To obtain *Aplysia* PGK (apPGK), we used human PGK II as a probe to screen a  $\lambda$  Zap *Aplysia* head ganglia cDNA library. A 2.9kb cDNA clone containing the 45 amino acid peptide obtained by microsequencing was isolated and partially sequenced. Complete sequencing of this cDNA is underway.

To confirm the changes in the mRNA of apPGK observed previously, ribonuclease protection assays were employed. The level of apPGK mRNA in pleural sensory neurons was increased 33±10% (n=9) after treatment of ganglia with 5-HT (5µM) for 1.5hr. However, similar treatments produced no change in the level of mRNA for another glycolytic enzyme, aldolase. These data confirm our previous findings and suggest that 5-HT might affect glycolysis through a specific effect on PGK. Perhaps treatments that induce LTF alter glycolysis to fulfill an increased energy demand during LTF. In other studies, we have shown that 5-HT treatments increase the rate of glycolysis in sensory neuron clusters (Homayouni, et al, 1994). Supported by NS28426.

## 175.17

REDUCTIONS IN SYNAPTIC TRANSMISSION (LONG-TERM DEPRESSION AND PAIRED-PULSE DEPRESSION) UPON REPEATED STIMULATION IN THE RAT PERIRHINAL CORTICAL SLICE. **M.W. Brown, Z. Ziakopoulos and Z.I. Bashir** (SPON: Brain Research Association). Anatomy Department, Bristol University, Bristol BS8 1TD, UK.

The results of recording, c-fos, and ablation experiments indicate the importance of perirhinal cortex to the judgement of the prior occurrence of individual visual stimuli in both rats and monkeys, such judgement being central to recognition memory. Neuronal responses in perirhinal cortex typically show long-lasting reductions with stimulus repetition. Two processes may be involved in these reductions as the relative familiarity and recency of occurrence of individual stimuli are separately encoded by different sets of neurons. In preliminary investigations using perirhinal cortical slices we are seeking changes in synaptic transmission that might provide potential neural substrates for these memory processes.

Standard techniques were used to record field excitatory postsynaptic potentials (epSPs) from the superficial layers of slices of adult rat perirhinal cortex maintained *in vitro*. Test stimuli were delivered alternately (at 0.033 Hz) to each of two stimulating electrodes placed in the same layer to either side of the recording electrode. When two consecutive stimuli were delivered to the same pathway, significant paired-pulse depression (PPD) was observed (n = 5 slices; P < 0.005). PPD was found at intervals of 10, 100, 200, 500 and 1000 ms, the depression being greatest at 200 ms. Low frequency stimulation (1 Hz, 900 stimuli) delivered to one pathway resulted in significant homosynaptic long-term depression (LTD) lasting for ≥ 30 min (n = 10; P < 0.005). Preliminary findings indicate that the magnitude and duration of the LTD is reduced in the presence of the NMDA receptor antagonist D-AP5. Thus both PPD and LTD can be induced in the adult rat perirhinal cortex. The mechanisms responsible for these synaptic changes *in vitro* could be those that underlie memory for the prior occurrence of stimuli *in vivo*.

LONG-TERM SYNAPTIC PLASTICITY IN THE BEE BRAIN. **S. Oleskevich\*, J. D. Clements and M. Srinivasan.** Visual Sciences, Research School of Biological Sciences, Australian National University, P.O. Box 475, Canberra, A.C.T., Australia 2601.

Synaptic plasticity such as long-term potentiation (LTP) has been hypothesized as the basis for learning and memory. The honeybee, with a highly developed learning capacity and relatively simple central nervous system, provides a good model to study the basic mechanisms of memory formation. The mushroom body in the bee brain contains  $4 \times 10^5$  neurons and, like the vertebrate hippocampus, is an important site for memory consolidation. Focal stimulation of a major afferent input to the mushroom body evoked an extracellular field response which consisted of a presynaptic afferent fibre volley followed by a postsynaptic potential and a superimposed population spike. Continuous low frequency stimulation (0.02 - 0.1 Hz for 10 min) induced a long lasting potentiation of the population spike (100-400%; > 3.5 hrs). The potentiation was input specific, reached saturation, and was maintained in the absence of stimulation. The potentiation was also stimulus frequency dependent (170% increase at 0.02 Hz stimulation and insignificant at 1 Hz). This is the first demonstration of long-term synaptic plasticity in the insect brain. (S.O. supported by Ramaciotti Foundations).

## 175.16

AGE-RELATED IMPAIRMENT OF LTP RETENTION IS ASSOCIATED WITH A DEFICIENCY IN SYNAPSE RESTRUCTURING TYPICAL OF THE MAINTENANCE PHASE OF LTP. **Y. Geinisman\*, L. deToledo-Morrell, F. Morrell, J. S. Persina and E. A. Van der Zee.** Dept. of CM Biol., Northwestern Univ. Med. Sch. and Dept. of Neurol. Sci., Rush Med. Coll., Chicago, IL 60611.

Old animals are known to be impaired in LTP retention since they loose potentiated synaptic responses more rapidly than young adults (Barnes, *J. Comp. Physiol. Psychol.*, 1979, 93:74; deToledo-Morrell et al., *Neurobiol. Aging*, 1988, 9:581). The aim of the present study was to determine whether the rapid decay of LTP in old animals has its structural synaptic substrate. LTP was induced in aged (28 months old) rats by high frequency stimulation of the medial perforant path carried out on four consecutive days. The animals were examined morphologically 13 days after the fourth stimulation when synaptic responses decayed and were no longer significantly enhanced relative to baseline. Stimulated but not potentiated rats served as controls. Synapses were quantified in the middle molecular layer of the dentate gyrus. Estimates of the number of synapses per postsynaptic granule cell were differentially obtained for various synaptic types with the aid of the double disector method. The results show that aged rats, which were potentiated and examined 13 days after LTP induction, do not significantly differ from control ones with respect to the number of synapses. In marked contrast, young potentiated animals were found to exhibit a selective increase in the number of axodendritic asymmetrical synapses during LTP maintenance over a period of 13 days (Geinisman et al., *Soc. Neurosci. Abstr.*, 1995, 21:444). Thus, the data presented here indicate that a deficiency in synapse restructuring characteristic of the maintenance phase of LTP is associated with and may be responsible for a rapid decay of LTP in aged animals.

## 175.18

DEVELOPMENT OF ENVIRONMENTAL MODIFICATION OF HIPPOCAMPAL LONG-TERM POTENTIATION (LTP). **Nicholas S. Waters\* and Thomas C. Foster.** Department of Psychology, University of Virginia, Charlottesville, VA 22903.

Juvenile rats are unable to perform a number of learning and memory tasks, which, in adults, appear to require an intact hippocampus. This inability appears despite competent sensory-motor systems, and the ability to perform other learning tasks. In adults, hippocampal long-term potentiation is reduced following a number of environmental manipulations, including the presentation of novel or stressful stimuli. To assess the maturity of hippocampal function, the induction of LTP was studied following behavioral testing at the ages during which hippocampally dependent learning emerges. At post-natal day 16 (P16; birth=P0), P23, and P30, subjects were tested for 5 min in a water motivated alternation (Y-maze) task, placed into a novel environment for 55 min, then sacrificed for *in vitro* electrophysiology in the hippocampal slice. Controls were sacrificed immediately after removal from the home cage. Paired pulses were delivered with a bipolar stimulating electrode in the Schaffer collaterals, and extracellular field potentials were recorded from s. radiatum in area CA1. LTP was induced with tetanic stimulation (two 1 sec bursts at 100Hz, 10 sec between bursts), and changes in the EPSP slope were measured as percent of baseline. The behavioral manipulation resulted in a decreased expression of LTP (compared to Controls) only in P30 subjects, the same age at which alternation behavior emerged. These results suggest that the emergence of the mechanisms which underlie hippocampal responsiveness to the environment coincides with the emergence of hippocampally dependent behavior.

This work was supported, in part, by NIH Grants NS31830 to TCF, and HD07323.

AUDITORY-SOMATOSENSORY CONDITIONING PRODUCES LONG-LASTING CHANGES IN THE RESPONSE PROPERTIES OF SINGLE NEURONS IN THE VIBRISAE REGION OF THE RAT SOMATOSENSORY CORTEX. **A.E. Butt\*, A.A. Myasnikov, & R.W. Dykes.** Département de Physiologie, Université de Montréal, Québec, Canada H3C 3J7.

We hypothesized that repeatedly pairing an auditory stimulus with the vibratory stimulation of an individual vibrissa would produce a conditioned response to the auditory stimulus in single neurons in the somatosensory cortex of awake rats. Rats were surgically implanted with a light-weight frame attached to the skull and, upon recovery, were habituated to partial restraint in a chamber with their heads immobilized. Five days later, rats were anesthetized again prior to receiving bilateral craniotomies over the vibrissae representation of the somatosensory cortex. To prevent spontaneous whisker movement during electrophysiological recording, rats also received bilateral transections of the facial nerves innervating the vibrissal pad. On the following two days, awake rats were restrained, a small opening was made in the dura, and a tungsten-in-glass electrode was lowered into the vibrissae region of the somatosensory cortex. Upon isolation of a single neuron that responded to whisker stimulation, the whisker driving that neuron was attached to an electromechanical stimulator. Rats then received 20 consecutive tone (750 ms, 2000 Hz) presentations, followed by 20 consecutive whisker stimulations (750 ms, 33 Hz), each at an average inter-stimulus interval (ISI) of 8 s. Next, rats received 100 tone-whisker stimulation pairings (300 ms ISI, avg 8 s inter-trial interval). Finally, rats received another 20 presentations of each stimulus alone. Controls underwent identical procedures except that the 100 tone and whisker stimulations were explicitly unpaired. Results showed that 2 of 5 cells developed a conditioned response to the tone following the tone-whisker stimulation pairings, compared to 0 of 3 cells in the control condition. These data show that cross-modal associative conditioning can produce long-lasting changes in the response properties of single neurons in the rat somatosensory cortex. (Supported by the Programme Québécois de Bourse D'Excellence and by the MRC).

## 176.1

RECOGNITION OF EMOTIONAL FACIAL EXPRESSIONS IN PARKINSON'S DISEASE. R. Schul, R. Adolphs, H. Damasio\* and A.R. Damasio, Dept. Neurology, Division of Cognitive Neuroscience, University of Iowa, Iowa City, IA 52242.

The role of the basal ganglia in processing emotion in humans is unclear. Damage to parts of the basal ganglia as a consequence of Parkinson's Disease (PD) results in impaired ability to express facial emotion, and it has been suggested that the recognition of emotions might also be impaired (Jacobs et al., 1995). In order to clarify this issue, we examined PD patients (n=18) and normal controls (n=13) on a task of recognition of multiple emotions within a single facial expression. No patient was demented, and none had impairment in basic visuo-perceptual function. The control subjects were matched to the PD group in age, education and verbal IQ. Both groups were asked to rate the facial expressions of six basic emotions (from Ekman and Friesen), happiness, sadness, disgust, surprise, fear and anger, by using appropriate verbal labels. The ratings were correlated with the mean ratings given by normal controls, as described previously (Adolphs, et al., 1994). A Group x Emotion (2x6) ANOVA revealed no significant difference between the PD patients and the normal controls on this task ( $F=0.16$ ,  $P>0.05$ , no interaction). Our results suggest that the basal ganglia components affected in PD do not play a critical role in the recognition of emotional facial expressions.

## 176.3

AMYGDALA ACTIVATION WITH EMOTIONALLY VALENCE AND NEUTRAL FACES: AN FMRI STUDY. N. Etcoff, H. Breiter\*, P. Whalen, W. Kennedy, S. Rauch, S. Hyman, B. Rosen MGH NMR Center & Dept. of Psychiatry, Charlestown, MA 02129

Humans with bilateral amygdala lesions can have selectively severe impairments for visual recognition of fear. We sought to extend these observations using functional MRI (fMRI) to characterize amygdala involvement with visual recognition of fearful, angry, happy, and neutral faces in normal subjects. Whole brain imaging was performed on nine healthy right-handed males with an asymmetric spin-echo sequence. The experiment employed an A-B-C-B-C-B design with blocks of 72 to 120 tachistoscopic presentations of faces from Ekman and Friesen's Standardized Pictures of Facial Affect. In A, subjects saw 36 presentations of a fixation point (0.3 seconds) followed by a blank screen (0.2 seconds). In B, subjects saw neutral expressions (0.2 seconds) followed by a fixation point (0.3 seconds). In C, subjects saw faces with one emotion presented with the same timing parameters as in B. Subjects were scanned twice per emotion (6 total runs in fixed order), with 4 minutes rest between scans. Time-course data were motion-corrected, Talairach transformed, averaged, and mapped using Kolmogorov-Smirnov (KS) statistics. At the Bonferroni level (KS  $p<10\exp-7$ ), bilateral signal increases were noted in the amygdala for fearful vs neutral faces. Right-sided amygdala activation ( $p<10\exp-5$ ) was noted for angry vs neutral faces. No amygdala signal change was noted for happy vs neutral runs. Surprisingly, the first neutral face block had higher signal than subsequent neutral face blocks, suggesting a novelty effect or assessment of threat effect. Post-scan, all subjects recognized the target emotions; some reported low-level experience of emotion congruent with the valence of the emotional faces which declined with time. Heart rate changes were not noted for anyone between experimental blocks. In summary, the amygdala was differentially active for faces valenced with fear and anger. The amygdala was not similarly active during visual recognition of happiness. These findings suggest a potential focus for the amygdala on the registration of threat-related stimuli. ## 176.5

NEUROANATOMICAL CORRELATES OF POSITIVE AND NEGATIVE EMOTION, R.D. Lane\*, E.M. Reiman, M.M. Bradley, P.J. Lang, G.L. Ahern, B.J. Davidson and G.E. Schwartz. U. of Arizona, Tucson, AZ; U. of Florida, Gainesville, FL; U. of Wisconsin, Madison, WI and The Samaritan PET Center, Phoenix, AZ.

Positron emission tomography (PET) and the International Affective Picture System (IAPS) were used to investigate the brain regions that participate in picture-generated positive and negative emotions. The ECAT 951/31 system, 40 mCi intravenous bolus injections of  $^{15}\text{O}$ -water, 60-sec scans, and a 10-15 min between-scan interval were used to acquire three images of regional cerebral blood flow (CBF) in each of four conditions. Twelve healthy female subjects viewed counterbalanced sets of 20 pictures previously demonstrated to elicit: 1) positive, pleasant emotions; 2) negative, aversive emotions; and 3) neutral emotion. Subjects also viewed 4) a central cross-hair.

Positive and negative emotion conditions were each distinguished from neutral emotion conditions by significantly increased CBF in the vicinity of medial prefrontal cortex (BA 9), thalamus, hypothalamus and midbrain ( $p<.005$ ) and by significantly decreased CBF in the vicinity of middle and superior temporal (BA 21,22,42), inferior parietal (BA 40), and lateral prefrontal (BA 10) and frontal (BA 44) areas ( $p<.005$ ). Negative emotion was distinguished from neutral and positive emotion conditions by significantly increased CBF in the vicinity of occipitotemporal cortex (BA 18,19,37), cerebellum, amygdala, and left parahippocampal gyrus (BA 28) ( $p<.005$ ). Negative emotion conditions were also distinguished from positive emotion conditions by significantly greater CBF decreases in the vicinity of anterior cingulate cortex (BA 24,32), superior and middle temporal gyri (BA 22,42) and inferior parietal cortex (BA 40). This study provides new information about the brain regions that participate in the perception of and reaction to emotional pictures and their relationship to emotional valence.

## 176.2

AN FMRI STUDY OF EMOTION PROCESSING: VALENCE-DEPENDENT HEMISPHERIC LATERALIZATION. T. Canli\*, I. Desmond<sup>1,2</sup>, G. Glover<sup>1</sup>, L. Gross<sup>1</sup>, I. D.E. Gabrieli<sup>1</sup>. Departments of Psychology<sup>1</sup> and Radiology<sup>2</sup>, Stanford University, Stanford, CA 94305.

There are at least two views on hemispheric specialization of emotion processing: one argues for a general dominance of the right hemisphere for all emotions, while the other holds that positive and negative emotions are processed by the left and right hemisphere, respectively. These two views were tested in the present study using functional magnetic resonance imaging (fMRI) in seven right-handed healthy female volunteers (age 18-32).

Subjects viewed alternating sets of emotionally positive or negative pictures that were selected from Lang's standardized stimuli set [Lang et al., IAPS Reports 1A-1C, Univ. of Florida, Gainesville]. Coronal slices of 6 mm or horizontal slices of 9 mm thickness were acquired, using a T2\* sensitive gradient echo spiral sequence (TR = 720 ms, TE = 40 ms, flip angle = 65°) in a 1.5 T GE Signa MR imager, and analyzed using the cross-correlation methods described by Friston et al. [Human Brain Mapping, 1994].

Viewing negative, compared to positive, pictures activated predominantly the right hemisphere, with significant ( $p<.025$ ) activation most frequently seen in the inferior and middle frontal gyrus and middle temporal gyrus. Significant activation of the right amygdala was also observed in some subjects. Viewing positive pictures, compared to negative ones, was predominantly associated with significant ( $p<.025$ ) left hemisphere activation, most frequently the superior, middle, and inferior frontal gyrus, and middle and superior temporal gyrus. The left amygdala was significantly activated in some subjects, as well. These data add to earlier evidence from EEG and other studies in favor of valence-dependent hemispheric lateralization of emotion processing. Supported NIH MH53673.

## 176.4

D2 and D4 DOPAMINE RECEPTOR POLYMORPHISMS AND TEMPERAMENT. E.P. Noble, T. Ozkaragoz, T. Ritchie, X. Zhang. Department of Psychiatry and Biobehavioral Sciences and the Brain Research Institute, University of California, Los Angeles, CA 90024.

Personality characteristics, using the Tridimensional Personality Questionnaire (TPQ), and polymorphisms of the D2 dopamine receptor (DRD2) and D4 dopamine receptor (DRD4) genes were determined in 119 healthy Caucasian (non-Hispanic) boys ( $12.1 \pm 1.2$  yrs). Novelty Seeking (NS) score was significantly higher in subjects who carried the A1 allele ( $P=.032$ ) or the B1 allele (.039) but not the 1 allele of intron 6 ( $P=.085$ ) of the DRD2 gene compared to those who did not carry these alleles, respectively. Reward Dependence (RD) score was higher, but not significantly different, in subjects who carried the A1 allele ( $P=.248$ ) or the B1 allele ( $P=.051$ ) but were significantly higher ( $P=.037$ ) in the 1 allele subjects when compared to those who did not carry these alleles, respectively. No significant differences were observed when these comparisons were made for the Harm Avoidance (HA) score. When the repeat alleles of exon 3 of the DRD4 gene were studied, NS score was significantly higher ( $P=.049$ ) in subjects who carried the 7 repeat (7R) allele than those without this allele. However, no significant differences were found among the DRD4 alleles in RD ( $P=.089$ ) or HA scores ( $P=.539$ ).

The relationship of TPQ scores and haplotypes of the DRD2 polymorphisms in individual combinations with DRD4 polymorphisms showed a stronger effect. Subjects with A1 and/or 7R alleles (A<sup>1</sup>), B1 and/or 7R alleles (B<sup>1</sup>) and 1 and/or 7R alleles (C<sup>1</sup>) had significantly higher NS scores ( $P=.009$ ) than the respective groups without these alleles (A<sup>2</sup>, B<sup>2</sup>, C<sup>2</sup>). RD scores were also significantly higher in A<sup>1</sup> compared to A<sup>2</sup> ( $P=.014$ ), B<sup>1</sup> compared to B<sup>2</sup> ( $P=.004$ ) and C<sup>1</sup> compared to C<sup>2</sup> ( $P=.004$ ). However, in none of these comparative groups were there significant differences in the HA scores.

In conclusion, polymorphisms of both the DRD2 and DRD4 gene are associated with certain characteristics of temperament suggesting a genetic basis for some aspects of personality. (Supported by Smithers Foundation)

## 176.6

Depression and cardiovascular regulation in Multiple Sclerosis, B.J. Diamond, J. DeLuca, H. Kim, S. Kelley, R. Engel, K. Fontaine, D. Cordero, Kessler Institute, Pleasant Valley Way, West Orange, NJ 07052.

Individuals with Multiple Sclerosis (MS) can exhibit dysregulation in Heart Rate Variability (HRV) and depression (i.e. Beck Depression Scale(BDI)). Because linkages between HRV and depression are not well understood the goal of this study was to examine this relationship. Subjects consisted of 18 clinically definite MS and 20 matched controls. The major findings showed that the MS group was significantly more depressed (total score:  $z=2.85$ ,  $p=.004$ ), exhibiting higher mean somatic subscores on the BDI ( $z=-3.7$ ,  $p=.001$ ); and a trend towards higher scores on the vegetative ( $z=-1.7$ ,  $p=.07$ ) and self-reproach ( $z=-1.6$ ,  $p=.10$ ) subscores. Higher self-reproach and somatic subscores were correlated with slower heart rates ( $\rho=.67$ ,  $p=.006$  and  $\rho=.55$ ,  $p=.02$ ), respectively. Relatedly, higher self-reproach scores correlated with increased HRV ( $\rho=.73$ ,  $p=.008$ ). In contrast, high versus low somatic score groups exhibited lower HRV during paced breathing ( $H=7.2$ ,  $p=.02$ ). Overall, during unpaced breathing, higher somatic and self-reproach scores were associated with a diminished sympathetic response. In contrast, during paced breathing, the level of entrainment of respiration and heart rate in the high somatic score group was diminished and manifested as lower HRV and reduced parasympathetic control. Mechanisms mediating patterns of physiological reactivity may, therefore, be differentially associated with certain types of depression.

HOSTILITY and IRRITABILITY PREDICT PARIETAL P300 EVOKED POTENTIAL AMPLITUDE. Mallery D. Gilbert\* and Jim H. Patton. Neuroscience Program, Baylor University, Waco, TX 76798-7334.

Twelve college females were selected from a larger group based on their total scores on the 75-item Buss-Durkee Hostility Inventory (BDHI). Six subjects had scores in the lowest quartile (below 27) and six had scores in the highest quartile (above 45) of the larger sample. Evoked potentials were recorded from a 24-lead Neurodata system running on a Macintosh Power Mac 7100 while subjects performed an auditory P300 oddball task. Subjects with the highest hostility scores had the lowest P300 peak amplitudes. While there was a trend toward significance over the entire parietal region (PZ, P3, P4) the effects were statistically reliable in the central (PZ:  $t = 2.715$ ;  $p < 0.035$ ) and left (P3:  $t = 2.649$ ;  $p < 0.027$ ) parietal areas. When female subjects were classified by BDHI Irritability subscale scores the P300 amplitude was again reduced over parietal areas, but the statistically reliable effect was limited to the left parietal lobe (P3:  $t = 2.587$ ;  $p < 0.0181$ ). Interestingly, female subjects who scored at the extremes on the BDHI, either total or Irritability, also scored reliably different on the Barratt Impulsivity Scale (BIS-11) total score and all three subscale scores. These results support the thesis that there may be a relationship between predictors of violence and aggression such as hostility, irritability and impulsivity and left parietal lobe function.

## 176.9

CONDITIONED PATTERN PREFERENCE WITHOUT AWARENESS IN HUMANS. I.S. Johnsrude\*, Y. W. Zhao, A.M. Owen, and N.M. White. Cog. Neuroscience Unit, Montreal Neurol. Inst., McGill Univ., Montreal, QC, Canada H3A 2B4.

Conditioned preferences for places or visual cues have been demonstrated previously in rats and in other non-human species. In this study, a conditioned pattern preference was induced in neurologically normal human participants without their explicit knowledge using a novel computerized touchscreen procedure. Three abstract monochrome patterns, presented incidentally over 180 trials in the context of a cognitive estimation task, were randomly assigned to one of three reinforcement contingencies. One pattern was paired with positive visual and auditory feedback together with food reward on 90% of the trials in which it was presented, and with negative visual and auditory feedback together with no food reward on the other 10% of trials. The other patterns were similarly reinforced, but at ratios of 50%:50% and 10%:90% with positive and negative feedback respectively. Subsequently, participants preferred the 'positive' pattern (the pattern paired most often with positive reinforcement), to the 'negative' pattern (the pattern paired least often with positive reinforcement). Importantly however, the participants were not able to relate their preference explicitly to the conditioning procedure. In a subsequent study, we tested a group of patients who had undergone unilateral temporal-lobe resection, a procedure that includes removal of the amygdaloid region. Preliminary results suggest attenuation of the conditioned preference in these patients. Thus, conditioned preferences similar to those demonstrated previously in non-human species may be induced in humans in the absence of conscious awareness, and, as in non-human species, may depend on circuits involving the amygdaloid region.

## 176.8

TICKLISH RELATIONSHIPS: AN ENIGMA RESOLVED. R. R. Provine\*, B. Fischer and K. Taylor. Dept. of Psychology, UMBC, Baltimore, MD 21228.

Tickle is an ancient and elusive behavior associated with laughter that has not yielded its secrets to anatomists and physiologists. The present questionnaire study ( $N = 215$ ) of who tickles who and what they think about it reveals the essential social nature of tickle, a critical variable missing in most laboratory studies of cutaneous sensation. Tickle is the product of a social interaction between a "tickler," the person administering the stimulus, and the "ticklee," the person being stimulated. There is no sensation of tickle without the complicity of the tickler. Solo tickle is even emptier than solo sex. This insight is consistent with one of the few points of agreement about tickle, that you can't tickle yourself. (False alarms from self-stimulation are prevented by an efferent process that also enhances the detection of non-self animate objects on the skin surface.) The social nature of tickle is emphasized further by patterns of who tickles who. People both tickle and are tickled, and desire to tickle and be tickled, by members of the opposite sex, especially those with whom they have a close or romantic relationship, a pattern consistent with the report of tickle as an expression of affection. Tickle often brings pleasure and laughter to both ticklee and tickler. Tickle is a central component of the intimate and emotionally charged medium of touch (e.g., caress, stroke, hug, fondle, grope) that is important in establishing and maintaining social bonds between mother and infant, relatives, friends, and especially lovers. Tickle is present in chimpanzees and is a principal stimulus for what may be the most ancient form of laughter (Am. Sci., 84 (1996) p. 38). Tickle is a reminder that we must consider the social and emotional contexts of neurobehavioral evolution and function.

## 176.10

CONTRIBUTION OF CORTICAL AND SUBCORTICAL BRAIN STRUCTURES TO AFFECTIVE PROCESSING. C. Breitenstein, J. Daum, H. Ackermann and W. Larbig\*. Institute of Medical Psychology, University of Tuebingen, 72074 Tuebingen, Germany.

Deficits in the processing of facial and prosodic expressions were studied in four groups of patients with cortical lesions ( $n=32$ ), in two groups of patients with subcortical dysfunctions (Parkinson's disease=PD;  $n=14$ ) as well as in healthy control subjects ( $n=12$ ). A standardized test battery for measuring emotional perception and production was administered to all subjects. The results show that both patients with damage to the frontal right hemisphere and patients in advanced stages of Parkinson's disease were significantly impaired in affect recognition in both modalities (facial expression, prosody). Affective prosodic expression, as measured by three acoustic parameters, was reduced in the PD group only. The findings imply the involvement of the fronto-striatal circuitry in emotional processing.

## MOTIVATION AND EMOTION: LESIONS

## 177.1

EXCITOTOXIC LESIONS OF THE PEDUNCULOPONTINE AND LATERODORSAL TEGMENTAL NUCLEI IN RATS: II. EFFECTS ON CONDITIONED PLACE PREFERENCE. G.L. Keating\* and P. Winn. School of Psychology, Univ. St Andrews, Fife, KY16 9JU, Scotland.

The pedunculopontine and laterodorsal tegmental nuclei (PPTg, LDTg) both contain heterogeneous neuronal populations and are organized in parallel. In a series of lesion studies, we and others have shown that PPTg loss does not impair basic activities such as feeding, drinking or locomotion but does impair various reward-related behaviors, including acquisition of conditioned place preferences. We have argued that this disruption is a consequence of interference with striatal outflow (see Inglis WL and Winn P (1995) Prog. Neurobiol. 47: 1). However, PPTg and LDTg also affect striatal input: PPTg innervates A9 dopamine neurons while LDTg neurons project to A10. Since A10 rather than A9 dopamine neurons have been associated with reward, the LDTg, by virtue of its direct excitatory connections to these, might be expected to influence reward-related behavior. Having shown that LDTg lesions do not alter daily food or water intake, or locomotion, we investigated the acquisition of place preferences. We made bilateral ibotenate lesions in the LDTg and, in a separate group of rats, the PPTg. Control rats received phosphate buffer injections. Following surgery we habituated rats to a standard place preference apparatus after which systematic side pairings were run: one side of the apparatus had food present, the other side had no food. Different groups of rats were tested in food-deprived and non-deprived states. Unlike sham lesioned control rats, neither PPTg nor LDTg lesioned rats acquired normal place preferences. This confirms that the PPTg is important in regulating reward-related behavior, and shows for the first time that, as might be expected from their anatomical connections with mesolimbic dopamine neurons, LDTg lesions also interfere with reward-related behavior.

## 177.2

LESIONS OF THE CAUDAL PERIAQUEDUCTAL GREY DO NOT ATTENUATE RATS' DEFENSIVE AVOIDANCE OF A PREDATOR. B. M. De Oca\* and M. S. Fanselow. Dept. of Psychology, University of California, Los Angeles, CA 90095-1563.

The midbrain periaqueductal grey (PAG) is a structure implicated in fear and defense-related behaviors. Lesion studies suggest that the caudal region ventral to the aqueduct (vPAG) is critical for the defensive behavior of freezing while the region dorsal and lateral to the aqueduct (dIPAG) is implicated in circa-strike defensive behavior. Studies using chemical stimulation of the PAG suggest that avoidance behaviors are also mediated by the PAG, particularly the dIPAG. However, these studies did not examine responses to a natural predator. In order to determine whether the PAG is necessary for both freezing and avoidance behaviors, rats with lesions of either the dIPAG, vPAG or sham lesions were presented with a cat in a long runway apparatus. Significant levels of freezing, and avoidance were observed in response to the cat but not a stuffed animal used as a control stimulus. Lesions of the vPAG or dIPAG did not alter the pattern of avoidance demonstrated by rats in response to a cat. However, lesions of the vPAG did attenuate freezing. Thus, while the vPAG is necessary for freezing, neither the vPAG nor the dIPAG are necessary for defensive avoidance. In contrast to the specificity shown by lesions of the PAG, lesions of the amygdala have been reported to attenuate both the autonomic and behavioral components of defensive responses in a variety of measures. As the PAG is an efferent of the amygdala, the possibility that different defensive behaviors are mediated by different efferents of the amygdala was examined. Supported by MH 39786 to MSF.

## 177.3

**EXCITOTOXIC LESIONS OF THE PEDUNCULOPONTINE AND LATERODORSAL TEGMENTAL NUCLEI IN RATS: I. EFFECTS ON INTAKE AND DAILY PATTERN OF LOCOMOTION.** P. Winn, M.P. Latimer, A.J. Brewin and C. O'Nions. School of Psychology, Univ. St Andrews, Fife, KY16 9JU, Scotland.

The pedunculopontine and laterodorsal tegmental nuclei (PPTg, LDTg) both contain heterogeneous neuronal populations and are organized in parallel. In order to understand better PPTg functions we have undertaken a series of lesion experiments (Inglis WL and Winn P (1995) *Prog. Neurobiol.* 47, 1-29) and shown in acute tests that neither drug-induced nor spontaneous locomotion is affected by PPTg lesion. Feeding and drinking are also unaffected by PPTg lesions, though reward-related responding is altered. The LDTg has not been closely examined to determine its psychological functions. Before doing so it is necessary to consider what effect LDTg lesions have on basic processes such as feeding, drinking, and locomotion. In these experiments we measured, for the first time in LDTg lesioned rats, intake and locomotion over 24h: daily locomotion has not previously been measured in PPTg lesioned rats. We made bilateral ibotenate lesions in LDTg and, in a separate group, PPTg. Control rats received phosphate buffer injections. Following surgery we measured feeding and drinking in the home cage, followed by measurement of locomotor activity over 24h in cages equipped with photocell beams to which the rats had been habituated for 4 days. Neither lesion affected food or water intake, total locomotion over 24h or the amount of locomotion in the different phases of the light-dark cycle. PPTg lesioned rats showed fewer, longer bouts of locomotion than either LDTg or sham lesioned rats. These data show that neither PPTg nor LDTg lesions affect basic activities such as feeding, drinking or amount of locomotion, but PPTg, not LDTg, lesions did affect the pattern of locomotion.

## 177.5

**LESIONS OF THE NUCLEUS BASALIS MAGNOCELLULARIS ENHANCE CONDITIONED APPROACH RESPONSES TO STIMULI PREDICTIVE OF FOOD.** M.C. Olmstead\*, T.W. Robbins and B.J. Everitt. Dept. of Experimental Psychology, Univ. of Cambridge, Downing St., Cambridge, CB2 3EB, UK.

The nucleus basalis magnocellularis (NBM) receives efferents from the ventral striatum (VS) and projects to neural structures implicated in reward including the basolateral amygdala and prefrontal cortex. NBM neurons are in turn influenced by dopamine signals from the VS and respond to reward and stimuli associated with reward. These findings suggest that the NBM may be part of the neural systems that mediate incentive motivation. The present study examined this hypothesis by investigating the effects of NBM lesions on locomotor responses to appetitive stimuli and the acquisition of responding with conditioned reinforcement (CR). Male Lister-Hooded rats received bilateral lesions of the NBM induced by infusions of 1ul (0.5 ul per side) of a 0.01M solution of the excitotoxic amino acid AMPA, which relatively selectively destroys magnocellular cholinergic neurons but not surrounding pallidal areas. Brain sections were processed immunohistochemically to reveal neurons immunoreactive for nerve growth factor and cholinergic cell loss was quantified by image analysis. NBM lesions enhanced the locomotor response to a novel environment and increased the magnitude of hyperactivity conditioned to the presentation of food, but had no effect on the unconditioned locomotor stimulating effects of d-amphetamine (0.5, 1.5 and 5.0 mg/kg i.p.). During CR training animals underwent Pavlovian conditioning in which the presentation of a CS (5 s illumination of a tray light) preceded a US (5 s elevation of a sucrose filled dipper). The ratio of responding during the CS compared to the pre-CS period increased across trials in both groups of animals, but to a lesser extent in rats with NBM lesions. In contrast, NBM lesions did not disrupt the acquisition of responding with CR and appeared to enhance its potentiation by systemic amphetamine (0.2, 0.4, 0.8 mg/kg i.p.). The effects of quinolinic acid lesions of the basal forebrain, which preferentially destroy non-cholinergic pallidal neurons but relatively spare cholinergic NBM neurons, on the two behavioural tasks are currently being investigated.

## 177.7

**FIMBRIA-FORNIX LESIONS AND MODULATION OF PROGRESSIVE RATIO RESPONDING FOR FOOD IN THE RAT.** A. M. Bratt\*, J. P. Knowles and G. Mittleman. Dept. of Psychology, University of Memphis, Memphis, TN 38152.

Our laboratory has reported on the role of the hippocampus in rewarded responding (Schmelz & Mittleman, 1996). In a progressive-ratio (PR) operant task, bilateral neurotoxic lesions of the total hippocampus resulted in enduring increases in breakpoint (BP), an indicator of the amount of effort an animal will exert to obtain a reinforcer. The current experiments aimed to investigate PR responding in rats with electrolytic lesions of the fimbria-fornix (FIFO).

Twenty young adult male rats (350-380g), food deprived to 85% free-feeding weight, were trained to lever press for a food reward (Noyes, 45mg grain-based pellet) in operant chambers, initially on a fixed ratio (FR) schedule (10 trials), progressing on to a PR10 schedule. Efficient PR responding required the rat to exert progressively more effort to obtain successive reinforcement, until breakpoint was reached. Upon attaining a stable baseline response, 12 of the subjects received electrolytic FIFO lesions (1mA, 40s, anodal current, coordinates: AP: -1.3, -1.5mm; L: ±1.5, ±0.5mm; DV: -3.6, -3.3mm) and PR responding was monitored immediately thereafter for 50 post-operative trials. Significant increases in breakpoint were observed in FIFO rats, as compared to controls, over the initial 25 trials, however, this effect was lost in subsequent trials, with control rats increasing responding with training. Prefeeding both groups of rats with 50, 100, 150 & 200 grain pellets prior to PR testing decreased breakpoint for both groups, however FIFO rats showed no performance effects indicative of differential satiety levels. These data suggest that partial deafferentation of the hippocampal formation following destruction of the FIFO pathway does not mimic the effects on rewarded responding obtained with total hippocampal loss. This may indicate the role of more specific intrinsic hippocampal circuitry in addition to input/output FIFO pathways in rewarded responding. \*A. Bratt holds a Wellcome Trust post-doctoral travel grant.

## 177.4

**ANXIETY-RELATED BEHAVIOR OF THE MAS KNOCK-OUT MOUSE** J.-P. Voigt\*, M. Bader\*, Th. Walther\* and H. Fink. Institute of Pharmacology and Toxicology, Medical Faculty (Charité) of the Humboldt University at Berlin, D-10098 Berlin, \*MDC, D-13125 Berlin-Buch, Germany.

The *mas* proto-oncogene is expressed in brain regions (hippocampus, cerebral cortex) and is developmentally regulated. Since the product of the *mas* gene may be involved in the development of the brain, behavioral consequences are likely to occur following a knock-out of the gene. The present study was performed to detect effects of the knock-out on anxiety related behavior. For this purpose, *mas*<sup>0/0</sup> mice, *mas*<sup>+/0</sup> and their wild-type controls were subjected to the murine Plus-maze. Each animal underwent a test of 10 min duration. The behavior was recorded and videotaped. Two indices of anxiety were obtained in the present experiment: the number of entries into open arms expressed as percentage of the total number of arm entries, and the amount of time spent on the open arms as percentage of total time. In addition, the total number of entries into both open and closed arms was counted as a measure of locomotor activity. Homozygous knock-out mice entered less often the open arms of the maze and spent less time on this section. Heterozygous mice showed an intermediate behavior, but they were not significantly different from either the homozygous or the wild-type control. However, no significant overall group differences were found in total entries. The lack of overall statistical significance on this parameter suggests specificity of the anxiety measure. Upon a second exposure to the maze the behavioral profile remained the same, except that locomotor activity was reduced in all groups. The latter suggests memorization of the first exposure in all experimental groups. In conclusion, the behavioral data obtained from the Plus-maze experiment suggest a significantly higher level of anxiety in the *mas*<sup>0/0</sup> mice compared to wild-type control mice. ## 177.6

**DYNAMIC CHANGES IN CYTOCHROME OXIDASE ACTIVITY IN AMYGDALOID AREAS AFTER LESION OF REWARDING LATERAL HYPOTHALAMIC SITES.** R. Shiao\*, and C. Bielajew. School of Psychology, University of Ottawa, ON K1N 6N5, Canada.

There are limited amygdaloid areas, such as the central and cortical nuclei, that receive direct projections from the lateral hypothalamic sites. Here we report the changes in cytochrome oxidase activity (COA) induced by electrolytic lesion of lateral hypothalamus that support self-stimulation, using histochemical and photometric semi-quantitation techniques. Sixteen adult rats with unilaterally implanted electrodes aimed at the lateral hypothalamus that give rise to vigorous bar-press behaviour were perfused to examine the changes in COA following different periods after lesion. Overall we observed a discrete reduction of oxidative metabolism in the cortical nucleus of the amygdala compared with the contralateral side. These effects were seen two to four weeks after lesion, and there was some recovery in COA 8 weeks after lesion. A lesser decrease in COA in the neighbouring piriform cortex was also observed. No similar changes were found in the basolateral, central, and medial nuclei of the amygdala. One characteristic of the COA activity is that it occurred in specific areas of cortical nucleus, namely, the frontal-middle region. The functional significance of these alterations in cytochrome oxidase activity in discrete amygdaloid areas to rewarding lateral hypothalamus is under investigation. Project supported by an NSERC grant to CB.

**ELECTROLYTIC LESIONS OF THE VENTRAL TEGMENTAL AREA ATTENUATE HYPERACTIVITY ELICITED BY INFUSING LOW DOSES OF KAINIC ACID INTO THE LATERAL HYPOTHALAMUS IN THE RAT.** M.R. Pitzer\* and D. Wirtshafter. Dept. of Psychology, University of Illinois at Chicago, Chicago, IL. 60612.

Previously we have reported that low doses of the L-glutamate analog kainic acid (KA) elicit dose-dependent increases in locomotor activity when injected into three separate rostro-caudal levels of the lateral hypothalamus (LH). These results suggest that the activation of cells throughout the LH region, without the recruitment of fibers of passage, is capable of eliciting hyperactivity. One theory to account for these results is that the relevant LH fibers either pass through or terminate in the ventral tegmental area (VTA). In order to investigate this possibility, intra-LH KA-elicited hyperactivity was measured following unilateral electrolytic VTA lesions. In rats implanted with bilateral cannulae directed toward the LH, intra-LH KA (10ng/0.25ul) elicited hyperactivity was significantly attenuated when injections were made into the ipsilateral LH. In contrast, lesions had less of an effect when injections were made into the contralateral LH. These results suggest that the relevant LH fibers may pass through the region of the VTA or that, perhaps, VTA cells are involved in LH-elicited hyperactivity. To explore these possibilities, experiments are currently being conducted to assess intra-LH KA elicited hyperactivity following excitotoxic lesions of VTA neurons. Research supported by NS33992.

## 177.9

**REACTION TIME PERFORMANCE IN RATS FOLLOWING OCCLUSION OF THE ANTERIOR CEREBRAL ARTERY**

N.M. Ward\*, J. Sharkey and V.J. Brown. Sch. of Psychology, Univ. St. Andrews, St. Andrews KY16 9JU, and Fujisawa Institute of Neuroscience, Dept. of Pharmacology, Univ. Edinburgh, Edinburgh EH8 9JZ, Scotland.

Occlusion of the anterior cerebral artery (effected by stereotaxic application of the vasoconstrictor, endothelin-1, at the artery anterior to the Circle of Willis) results in widespread ischemic damage to cingulate and infralimbic cortex and medial septum. The cortical areas compromised by the lesion have been thought to be involved in limbic functions, whereby motivational information can influence motor output. Therefore, to assess the behavioral consequences of this lesion, rats were tested on a reaction time task in which motivation is manipulated from trial to trial by the provision of visual cues indicating the proximity of reward.

Rats were trained to maintain a sustained nose-poke into a response hole until a temporally unpredictable tone sounded, whereupon they withdrew the snout from the hole and turned to press a panel covering a food hopper. Visual cues (a progressive change in brightness of peripheral lights) indicated the availability of reward, which was either on the current trial or after two or three correct responses (a cued multiple-ratio schedule of reinforcement).

As fewer trials intervened before reward, reaction times were faster and there were fewer errors. Following the lesion, there was no behavioral impairment: the rats were still able to interpret the meaning of the cues which continued to be reflected in both speed and accuracy of performance. Furthermore, when the meaning of the cue lights was reversed, the lesioned rats were able to learn the new relationship as rapidly as unlesioned control rats.

**SOCIOEMOTIONAL BEHAVIOR IN ADULT RHESUS MONKEYS AFTER EARLY VERSUS LATE LESIONS OF THE HIPPOCAMPAL FORMATION. J.H. Chaudhuri, L. Malkova, J. Bachevalier<sup>2</sup>, S.J. Suomi<sup>1</sup>, and M. Mishkin<sup>1</sup>. Lab. of Neuropsychology, NIMH, 1 Lab. of Comparative Ethology, NICHD, NIH, Bethesda, MD 20892, 2 University of Texas, Houston, TX 77030, USA**

Our earlier studies in rhesus monkeys demonstrated that early damage to the hippocampal formation yielded only subtle changes in socioemotional behavior at 2 months of age and these changes became even less evident by 6 months of age. When the same monkeys were observed as adults in dyads with their normal peers, the amount of time they spent in social contact was markedly less than that in normal dyads, and they exhibited more locomotor stereotypies than normal controls (Beauregard et al., *NeuroReport* 6:2521-2526, 1995). To determine whether this degree of behavioral abnormality would follow the same damage to the mature brain, we prepared adult monkeys with bilateral removals of the hippocampal formation and the underlying cortex (H) and compared their behavior with that of i) normal adult monkeys and ii) adult monkeys with the same lesions sustained early in infancy from our previous study. Dyads consisting of either one operated monkey and its normal control (2 pairs, each including a monkey operated in adulthood, H+N; 5 pairs, each including an adult monkey operated in infancy, neoH+N), or two normal monkeys (7 pairs, N+N) were examined in a large enclosure and their behavior videorecorded for two 5-minute intervals (10 AM and 4 PM) on each of five consecutive days. The average amount of social interaction per observation in the H+N dyads (196 sec) was less than that in N+N dyads (281 sec) but more than in the neoH+N dyads (66 sec). In addition, the monkeys operated in adulthood did not exhibit any locomotor stereotypies. These results indicate that early damage to the hippocampal formation yields more profound socioemotional effects than the same damage in adulthood, a pattern that is similar to that we reported for combined lesions of the amygdala and hippocampus (Malkova et al., *Soc. Neurosci. Abstr.* 20:368, 1994). Interestingly, the hippocampal lesions alone appear to produce a decrease in social contact comparable to that of combined amygdalohippocampal removals. ## 177.10

**LESIONS OF THE RAT VENTRAL STRIATUM CHANGE PERFORMANCE IN A PROGRESSIVE FIXED-RATIO SCHEDULE OF REINFORCEMENT WITHOUT AFFECTING REACTION TIMES WHEN VISUAL CUES INDICATE REWARD COST E.M. Bowman\* and V.J. Brown. School of Psychology, Univ. St. Andrews, St. Andrews KY16 9JU, Scotland.**

This study examined the possibility that lesions of the nucleus accumbens in rats impair the perception of the "cost of reward", as defined by the number of operant responses to obtain it. In the first experiment, visual cues indicated the cost of reward, which was either available on the current trial or after two or three correct responses (a multiple-ratio schedule of reinforcement). Reaction time was faster and performance more accurate as fewer trials intervened before reward. Following lesions centred on the core of the nucleus accumbens, this pattern was preserved, demonstrating that the integrity of the nucleus accumbens is not required for the interpretation of visual cues carrying motivational information or for the translation of this motivational signal to response vigor. In a second experiment, the cost of reward in terms of the number of lever presses required for each reward incremented with each trial (i.e., a progressive ratio schedule of reinforcement). In this task, there were no external cues to signal the increasing cost: only the internalized knowledge of the position in the schedule gave indication of the current cost of reward. Following lesions of the nucleus accumbens, rats showed a pattern of behaviour indicating an impairment in the ability to monitor position within the schedule of reinforcement. Specifically, "breaking points" were higher and latency to resume responding with each increment in the schedule was lower. The results are considered in terms of the traditional idea of the nucleus accumbens as a "limbic-motor interface". We suggest that the nucleus accumbens serves functions which might be regarded as those of an interface between the limbic and motor systems in only limited contexts. ## 177.12

**EARLY CENTRAL SEROTONIN DAMAGE INCREASES "ANXIOUS" BEHAVIORS IN JUVENILE RATS. B. Knutson\*, J. Panksepp, T.K. Narayanan, and J. Rossi III. Department of Psychology, Bowling Green Univ., Bowling Green, OH 43402.**

Although the "serotonin-anxiety" hypothesis postulates that enhanced serotonergic tone can increase anxiety, recent clinical trials suggest that serotonin-enhancing compounds (e.g., SSRIs) can effectively remediate some anxiety disorders in humans (e.g., social phobia). Comparative studies on the effects of serotonergic manipulations on anxious behavior have yielded mixed results (Johnston & File (1986), Pharm., Biochem., & Behav., 1467-70). As a strong test of the yet ambiguous role of serotonin in anxiety behaviors, we lesioned the central serotonergic systems of 35 young rats with 5,7-dihydroxytryptamine and observed the effects on behavioral tests of anxiety, relative to 35 sham-lesioned controls. In Experiment 1, subjects were placed in an open field for 5 minutes, and line crosses, rears, locomotion away from the wall, and fecal boli were recorded. In Experiment 2, subjects were placed in an elevated plus maze and the number and duration of entries into closed and open arms was recorded, as well as "risk assessments." Finally, in Experiment 3, subjects were placed in a habituated shuttlebox and their locomotor activity was recorded. In both Experiments 1 and 2, 5HT-lesioned subjects showed increased "anxious" behavior compared to sham-lesioned subjects, but also decreased locomotion. However, in Experiment 3, there was no difference in the locomotor activity of 5HT-lesioned versus sham-lesioned subjects. HPLC analyses were conducted on brain amines and their metabolites in these subjects and correlated with indices of anxious behavior. The behavioral results suggest that the serotonin system is not necessary for the expression of anxious behavior. Further, as a whole, brain serotonin may play more of an inhibitory than a facilitative role in behavior linked to this negative emotional state. ## NEUROETHOLOGY: OTHER SYSTEMS

## 178.1

**STRIKE BEHAVIOR IN THE MUSKELLUNGE, *ESOX MASQUINONGY*: RELATIVE CONTRIBUTIONS OF LATERAL LINE AND VISUAL SENSORY SYSTEMS.**

L. Alborg, S. Coombs and J.G. New\*. Dept. of Biology and Parmlly Hearing Institute, Loyola University Chicago, Chicago, IL 60626

The muskellunge, *Esox masquinongy*, possesses both well-developed visual and lateral line systems. They are voracious predators, displaying robust feeding behavior in captivity. The purpose of this study is to analyze the strike feeding behavior of the muskellunge and to determine the role played by the visual and lateral line senses in organizing the strike.

Juvenile muskies in a test arena were presented with live fathead minnows (*Pimephales promelas*) and their strikes and feeding behavior was videotaped and analyzed. Muskies were tested under three conditions: (1) control animals, (2) animals with the lateral line suppressed via immersion in 0.1 mmol CoCl<sub>2</sub>, and (3) animals blinded via bilateral optic nerve transection. Quantitative measures (distances, angles and times) were obtained for two positions during discrete phases of the attack, and compared across the three groups.

Muskies initiate their approach to prey with a slow, directed stalk using fin sculling but little body trunk movement to decrease angle and distance to the prey. This phase is followed by an explosive C- or S-start strike directed at the target. Additionally, muskies employ different strategies in striking at near or far prey. Our data indicate that both lateral line and vision play important roles in directing the strike behavior: muskies with suppressed lateral line systems align themselves with prey but hesitate or have difficulty in initiating the rapid strike. Blinded muskies will strike at minnows, but the apparent detection range of prey is greatly decreased.

## 178.2

**SEXUALLY DIMORPHIC SWIMBLADDER MUSCLES IN AN ELECTRIC FISH. X. Huang, J. Kozlowski, & J.D. Crawford.\* Dept of Psychology, University of Pennsylvania, Philadelphia, PA 19104.**

In the African fish *Pollimyrus* (Mormyridae), males produce acoustic signals when courting females. While it is not known how these sounds are produced, these fish have a swim bladder, and other teleost fishes are known to generate sounds by coupling rapid muscle contractions to a bladder. We have recently discovered that *Pollimyrus* has a pair of extrinsic muscles enveloping the posterior end of the swim bladder. These muscles are clearly distinguished from the adjacent trunk muscles by their orientation orthogonal to the trunk muscles (ie the swim bladder muscles are aligned in the dorso-ventral plane). Just like the acoustic behavior of breeding adults, there is a conspicuous sexual difference in these muscles: the muscles are 5-fold larger in males than in females ( $P < 0.02$ , 5 df, t-test). In behavioral tests males became temporarily mute when this muscle was injected with local anesthetic, but not when anesthetic was injected into the trunk muscles, nor when saline was injected into the swim bladder muscles. We suspect that these muscles are involved in male sound production. The mechanisms of sound production in these fish are of interest since their sonic repertoire is unusually complex and because analysis of the sounds indicates that the sonic muscles may normally contract at high rates (340 Hz at 28°C), exceeding rates known for other sonic muscles. ## 178.3

## TIME CODING IN THE AUDITORY MEDULLA OF A SONIC FISH.

James Kozloski\*, John D. Crawford. Institute of Neurological Sciences & Dept. of Psychology, Univ. of Pennsylvania, Philadelphia, PA 19104.

We are examining temporal coding in the auditory medulla of the mormyrid fish *Pollimyrus*. The auditory periphery of this vertebrate is simple and shows little specialization for mechanical frequency analysis. *Pollimyrus* uses a repertoire of temporally structured sonic communication signals in its courtship behavior, and cells in the midbrain show selectivity for temporal features of sounds. We have identified two types of neurons in the medulla which appear to represent critical steps in the processing of temporal information. The first type shows broad tone-frequency selectivity in the 100 to 900 Hz band, has shallow, non-saturating rate level functions, and fires small bursts of spikes synchronized to each stimulus cycle. Intracellular dye fills indicate that these are primary afferents recorded as they course through the medulla. The second type shows similar broad tuning, but has steep, saturating rate-level functions, and generates a single spike per stimulus cycle over a wide range of frequencies; these cells show exceptionally strong phase-locking. Intracellular fills indicate that these cells are second-order auditory neurons in the descending nucleus of the medulla. These cells thus transform intensity-dependent afferent input into a relatively intensity-invariant output of a single spike synchronized to each stimulus cycle. We conclude that this part of the ascending auditory pathway functions to isolate temporal information from intensity information for further analysis in the midbrain. ## VOCAL PATHWAYS IN CATFISH: COMPARISON WITH OTHER VOCAL TELEOSTS.

F. Ladich\* and A.H. Bass. Section of Neurobiology and Behavior, Cornell Univ., Ithaca, NY 14853; Institute of Zoology, Univ. Vienna, Althanstraße 14, 1090, Vienna, Austria.

The diversity of sonic/vocal organs, and central pathways delineated by retrograde transport of biotin compounds, was analyzed in four families of catfish (order Siluriformes) and compared to representative families of two distantly related orders, the Scorpaeniformes (families Cottidae and Triglidae) and the Batrachoidiformes (family Batrachoididae). In all groups, sonic motoneurons (SMNs) are located in the medulla oblongata and rostral spinal cord and exit the CNS via occipital or occipital and spinal nerves. Some catfish have two sonic mechanisms - pectoral spine stridulation and swimbladder (SB) vibration established by "drumming muscles". The latter differ between catfish families in origin and insertion and in motoneuron supply. Paired motor nuclei are located on the midline between the fourth ventricle or central canal and the medial longitudinal fasciculus (MLF) (Doradidae, Mochokidae), lateral to the MLF (Ariidae) or at both locations (Pimelodidae). Pectoral spine-associated motoneurons, however, are always located within the ventrolateral motor column (VMC), lateral to the ventral fasciculus. Contrary to catfishes, the diversity of sonic mechanisms in scorpaeniforms is not correlated with different SMN positions. Cottids lack a SB although sonic muscles originate at the occipital cranium and insert at the pectoral girdle (PG); SMNs are in the VMC. Triglids also have VMC-positioned SMNs but "intrinsic" muscles directly attached to the SB only; ontogenetic data however report a transitory attachment of SB muscles to the PG (Rauther, 1945; Zool. Jb. Anat. 69:159). Batrachoidids possess intrinsic SB muscles that are never attached to the PG and always supplied by midline SMNs positioned as in doradid and mochokid catfish. We propose that a VMC vs. non-VMC position for SMNs is coupled to respectively PG vs. non-PG associated sonic muscles. ## 178.7

## TEMPORAL COMPUTATION OF THE DIFFERENCE FREQUENCY OF CONCURRENT ACOUSTIC SIGNALS IN THE CENTRAL AUDITORY SYSTEM OF A VOCAL FISH. D.A. Bodnar\*, J.R. McKibben and A.H. Bass.

Neurobiology & Behavior, Cornell Univ., Ithaca, NY 14853.

Male midshipman, *Porichthys notatus*, generate long duration, sinusoidal-like advertisement calls ("hums") with a fundamental frequency (F0) of 90-100 Hz. Males often cluster and hum simultaneously. The summation of two hums generates a beat-like waveform characterized by amplitude and phase modulations at the difference frequencies (dF). To identify and localize individual vocalizations, the auditory system must segregate the concurrent signals of the beat waveform. Responses to beat stimuli with varying dFs (F0A = 90 Hz; F0B = 90 ± 10 Hz in 2 Hz increments) were recorded from auditory VIIIth nerve afferents and midbrain neurons. Synchronization to the individual components is significantly higher for afferents than midbrain units. In contrast, the maximum vector strength (VS) of synchronization to dF is significantly higher for midbrain units. Afferent VS vs. dF profiles are generally V-shaped; synchronization is lowest for dF = ±2 Hz and highest for dFs ≥ 10 Hz. Auditory midbrain VS vs. dF profiles reflect both untuned and tuned response types for beat stimuli. Untuned units exhibit moderate synchronization to all dFs between ±10 Hz, but no significant changes in their VSdF. DF tuned units exhibit significant changes in their VSdF (ANOVA, effect of dF, p < 0.05) with distinct peaks at a particular dF. Among the dF tuned units, a subset of units exhibit different responses to positive and negative dFs (asymmetric units). Thus, there is a transformation from an afferent periodicity code of the individual components of low frequency beats to a midbrain periodicity code of their dF. This indicates that in midshipman, a temporal computation of the dF of concurrent signals occurs centrally, suggesting that dF information is utilized in the segregation of concurrent vocal signals. Support from NIH, NSF & Cornell Univ.

## 178.4

CHARACTERISTICS OF DIRECTIONAL AUDITORY AFFERENTS IN THE TOADFISH (*OPSANUS TAU*). P.L. Edds-Walton, S.M. Highstein, and R.R. Fay\*.

Marine Biological Laboratory, Woods Hole, MA 02543

The sensory hair cells on the saccule of fishes are arranged in different orientation patterns that may be important for encoding the direction of acoustic particle motion for directional hearing analyses in the CNS. We have been working with the toadfish saccule because directional responses to sound have been reported for this species, and the saccule is an auditory organ in toadfish. A particle motion stimulus was produced by sinusoidal oscillations (nm displacements) of a rigid, water-filled dish in which the fish was firmly held by the head. The fish was stimulated along six axes (0, 30, 60, 90, 120, 150°) in both horizontal and midsagittal planes. Initially, we recorded extracellularly from over 200 afferents to characterize directional response from the rostral, middle, and caudal regions of the saccule. Most afferents were highly directional with wide-ranging "best directions." We are currently recording intracellularly from saccular afferents. Once characterized, the cell is filled with neurobiotin (Vector) to compare the dendritic arbors and central projections of cells with different response properties. Axon diameters (1.7-8.8 µm), minimum number of terminal endings (7-114), and arbor lengths, widths, and areas have been determined for directional fibers from different regions of the saccule. Dendritic arbor drawings will be presented along with the response properties of each (threshold, best direction, spontaneous activity). (Funded by Program Project Grant 1P01DC018737 from NIH, NIDCD).

## 178.6

## AUDITORY PATHWAYS IN A VOCAL FISH: INPUTS TO A MIDBRAIN NUCLEUS ENCODING ACOUSTIC BEATS. A.H. Bass\*, D.A. Bodnar and M. Marchaterre.

Neurobiology & Behavior, Cornell Univ., Ithaca, NY 14853.

Male midshipman fish, *Porichthys notatus*, generate long duration (minutes to > 1 h) vocalizations known as "hums" that attract females to nest sites. Males often vocalize simultaneously which results in beat-like waveforms with envelope modulations at the difference frequencies (dF) between hums. Recordings with indium and 5% neurobiotin-filled electrodes revealed neurons in the midbrain's nucleus centralis (NC) that synchronize their spike outputs to the dF of synthetic beats. (NC is a division of the torus semicircularis, homologue of the mammalian inferior colliculus.) The locations of dF-encoding neurons were identified in a far medial region of NC following iontophoretic injections of neurobiotin. Retrograde transport distinguished multiple sources of input to NC (survival times, 1-6h). The majority of labelled neurons were clustered throughout various divisions of a secondary octaval nucleus (SO) comparable in location to that of other teleosts (McCormick & Hernandez, Brain Behav. Evol. 47:113, 1996). However, a SO appears more expansive in midshipman, extending ventrolaterally to far rostral levels of the lateral division of the trigeminal motor nucleus (see Bass et al., J. Neurosci. 14:4025, 1994). The SO identified here includes the positions of neurons previously shown to receive input from VIIIth nerve-recipient hindbrain nuclei (Bass et al. 1994). Though less abundant, neurobiotin-filled cells afferent to NC were also located in the descending octaval nucleus (an VIIIth nerve recipient nucleus), hindbrain paraventricular groups, a pretoral dorsal tegmental nucleus, and just dorsolateral to nucleus glomerulosus. To conclude, the majority of inputs to midbrain, dF-encoding neurons arise from secondary rather than primary octaval-targets in the rostromedial medulla. This study now delineates the circuitry underlying central computation of dF in the auditory system of midshipman fish. (NIH, NSF & Cornell Univ.)

## 178.8

## PERIPHERAL ENCODING OF BEHAVIORALLY RELEVANT ACOUSTIC SIGNALS IN A VOCAL FISH. J.R. McKibben\* and A.H. Bass.

Section of Neurobiology & Behavior, Cornell Univ., Ithaca NY 14853.

The midshipman fish, *Porichthys notatus*, produces simple, constant frequency (F0 90-100 Hz) harmonic sounds by vibrating intrinsic swimbladder muscles. Different vocalizations are used in agonistic and courtship behaviors (Brantley & Bass, Ethology 96:213) and playbacks of signals resembling the long duration "hum" of nesting males elicit phonotaxis by gravid females. We recorded from individual VIIIth nerve afferents innervating the sacculus, the major inner ear end organ, while presenting computer synthesized sounds via an underwater loudspeaker (UW-30 beneath the fish in a 35 cm diameter tank). Auditory afferents (n=200) responded best from 60 to 200 Hz, encompassing the frequency range of midshipman vocalizations. Iso-intensity plots ranged from "low-pass" (highest spike rate at 60-70Hz), to "band pass" (highest spike rates at 140-180Hz) to more complex, multi-peaked curves. Synchronization to pure tones was very high, resulting in more sensitive and less ambiguous encoding of frequency than given by changes in average spike rate. Spike rate increases encoded stimulus level over a 10 to 50 dB range. The ability to maintain firing rates to long duration (5-10 s) stimuli varied with frequency and among units. However, synchronization remained strong at all stimulus durations. Two-tone harmonic stimuli were presented in order to examine the effects of higher harmonics on the encoding of an individual hum; units synchronized to both F0 and F2. Two tones at slightly different frequencies were added to generate stimuli with phase and amplitude variations, or beats, at the difference frequency (dF). This stimulus corresponds to the natural listening task, where the receiver's ear must process the overlapping calls of nearby fish. At most dFs, cells synchronized best to one of the two tones, usually the lower frequency. Generally, synchronization to the dF was much lower than to either of the component tones. In conclusion, the peripheral auditory system of midshipman precisely encodes the temporal waveforms of species-typical signals. (NSF, NIH, NIMH & Cornell Univ.)

## 178.9

THE ROLE OF DORSAL TORUS LONGITUDINALIS IN PROCESSING LUMINANCE INFORMATION IN THE GOLDFISH VISUAL SYSTEM. M.A. Gibbs<sup>\*1</sup> and D.P.M. Northmore<sup>2</sup>. Depts. of Biology<sup>1</sup> and Psychology<sup>2</sup>, University of Delaware, Newark, DE 19716.

The torus longitudinalis (TL) is a unique actinopterygian structure situated along the medial borders of optic tectum, from which dorsal TL receives a topographic visual input. Based on electrophysiological recordings in goldfish TL, which revealed a sustained neural discharge inversely related to luminance (Northmore, 1984), we hypothesize that TL is a specialized luminance processor acting in parallel with the optic tectum that is more involved in color vision. Behavioral and electrophysiological experiments were conducted to determine the role of TL in processing luminance information and whether it is part of a parallel processing visual system. Bilateral ablation of TL resulted in a 66% reduction in the dorsal light reflex, which involves comparison of luminance levels by the two eyes, indicating a significant role for TL as a luminance processor. Additionally, an examination of the dorsal light reflex in TL-ablated fish revealed a loss of gain in the luminance-response function. Multiunit recordings from TL revealed relatively flat, broad-band action spectra that matched behaviorally derived luminance spectra. However, recordings in tectum yielded a variety of spectra, many with pronounced peaks and troughs indicative of chromatic opponent processing. The tectal action spectra averaged about 1 log unit less sensitive than TL spectra. It appears, therefore, that tectum processes chromatic information, but also elaborates a broad-band luminance signal that is relayed to TL without the chromatic information. Together, the results provide evidence for parallel processing of chromatic and luminance processing in the goldfish.

## 178.11

PREY CAPTURE EFFICIENCY IN NORMAL AND MONOCULAR FROGS. P. Patton<sup>\*</sup> and A. Weerasuriya. Mercer University School of Medicine, Division of Basic Sciences, Macon, GA 31207.

Anurans capture small prey by means of a ballistic snap, involving a lunge and tongue flip. Capture efficiency was studied with 6 frogs (*Rana pipiens*) between 7 and 9 cm in snout/vent length presented with mealworm targets at distances between 2 and 11 cm. During each presentation, animals were videotaped at 30 frames per second using a camera held vertically above the frog. The images were analysed to determine the location of the tip of the frog's tongue, at greatest extension, with respect to the prey. A total of 193 snaps were observed, of which 91% resulted in successful capture, with success rates ranging from 81-97% for individual frogs. 67% of all misses were due to errors of distance, usually undershooting, with the remainder due to errors in elevation (22%) or azimuth (11%). 85% of snaps directed at targets placed frontally within 30° of the midsagittal plane were successful, whereas a 95% success rate was observed for prey placed more laterally. This tendency to respond inappropriately to frontally placed targets was especially pronounced in frogs rendered monocular by occlusion of one eye by a plastic eyepatch. Only 64% of the 55 frontal snaps observed for such animals resulted in successful capture. This deficit was quite pronounced for two of the tested animals, but was less evident, or absent, in 3 others. Frogs and toads rendered monocular by enucleation or optic nerve transection have not been reported to exhibit such a deficit (Ingle Psychon. Sci. 29(1): 37-38; Collett et al. Exp. Brain Res. 66:35-40; Grobstein et al. J. Comp. Physiol. A 156:775-785). These results suggest that some readjustment of visual distance discrimination occurs following destruction of the optic nerve, which does not occur so readily when an eye is simply occluded (Supported by NSF IBN-9420525).

## 178.13

FORAGING STRATEGY AND SPATIAL MEMORY IN LIZARDS. L. B. Day<sup>\*</sup>, W. Wilczynski and D. Crews. Institute for Neuroscience, Univ. of Texas, Austin, TX 78712.

Mental capacities for spatial memory and ecological demands for these abilities appear to be integrally related in several species of birds and mammals. We explored whether a similar relationship exists between spatial ability and foraging strategy in lizards. *Acanthodactylus boskianus* (n=6), an active forager that collects clumped, immobile prey, was expected to perform better than *A. scutellatus* (n=9), a sit-and-wait predator that collects distributed, mobile prey, on a spatial memory task. No species difference was expected for a similar visually cued task that did not require use of spatial memory. In the spatial memory task, lizards were placed in the center of a circular arena (1.5m D) in a cold (23°C) room where they could escape to a insulated hot rock (40°C) that was identical to 7 other unheated rocks placed along the perimeter of the arena. There were no local cues and we controlled for olfactory detection. The lizard had to use distal cues to locate the hot rock. For visually cued trials a small red light was moved randomly each day to a different heated brick. We ran 3 trials a day for 12 days for both spatially and visually cued trials. Latencies to the goal declined across trials for both species, but contrary to expectations, there were no species differences on latency to the goal in the spatial cued task (p>.05). There may, however, be species differences in distance traveled to reach the goal. These data are currently being analyzed. Unexpectedly, when the goal was visually cued we found a species difference. The sit-and-wait predator was significantly faster than the active forager at locating the goal (F = 5.13, p<.04). Sit-and-wait predators are more likely to detect prey using vision and thus species differences in ability to attend to or form associations with visual cues might explain this difference. HOW DO FROGLETS RESPOND WHEN THEY SEE A BUG FOR THE FIRST TIME? N. Licata and A. Weerasuriya<sup>\*</sup>. Mercer University School of Medicine, Division of Basic Sciences, Macon, GA 31207.

Herbivorous tadpoles metamorphose into carnivorous frogs. This entails drastic changes in their gut as well as in their behavior. The objective of this study was to characterize the emergence of prey catching behavior in newly metamorphosed froglets (*Rana pipiens*). Two to three week old tadpoles were maintained in pond water at room temperature. Development was monitored and staged according to Gosner (1960). Emergence of air breathing was noted, and upon reaching stage 46 their prey catching behavior was examined. Prey was either mutant wingless fruit flies (*Drosophila* sp.), small (4-8 mm) wood lice (*Armadillidium* sp.), or newly emerged (<8 mm) mealworm larvae (*Tenebrio* sp.). For each trial, a froglet was placed in a testing arena and presented with one or more of the above prey. The behavior of the froglets was recorded with a high resolution video camera at 30 frames per second. In 10 froglets, prey catching behavior was observed for up to 4 weeks after reaching stage 46. The froglets became air breathers 3 to 9 days before reaching stage 46. The first prey-elicited snap was observed 4 to 12 days (6 ± 1 (S.E.)) after reaching stage 46. All responses were directed at prey and a fully protracted tongue contacted the prey. Eight of the ten snaps were successful in retrieving the prey into the mouth. From the third day after the first snap, seven froglets were presented with 30 mm mealworm larvae; these prey were too big for the froglets to ingest. Nevertheless, all 7 froglets responded to these larvae with targeted prey catching behavior. Therefore, in *Rana pipiens*, within a few days of completing metamorphosis, an unlearned, fully functional and efficient prey catching motor program emerges. On the other hand, visual discrimination of prey objects is less than optimal in froglets. (Supported by NSF IBN-9420525).

THE EVOLUTION OF BIASES IN MATE CHOICE: MODELING CALL RECOGNITION IN THE TUNGARA FROG WITH NEURAL NETWORKS. S.M. Phelps, M.J. Ryan and W. Wilczynski<sup>\*</sup>. Departments of Zoology and Psychology, Univ. of Texas, Austin, TX 78712.

The origins of female preferences for male traits are a pivotal concern in current sexual selection theory. Recent data from neural network models suggest that significant biases in mate choice may arise as by-products of selection for mate recognition. To date these models have used simple abstractions of visual stimuli to represent traits, such as tail length and symmetry, that are preferred by females of some species. We asked whether artificial neural networks could evolve to recognize an actual acoustic signal used in mate choice, the call of the tungara frog, *Physalaemus pustulosus*. We chose a simple recurrent network architecture and evolved weights using Goldberg's simple genetic algorithm and "roulette-wheel selection." Networks were selected for their ability to discriminate call spectrograms from noise presented in the same amplitude envelope. We found that these networks can learn to recognize calls, and that they generalize to calls they have not been selected to recognize. Recent field studies exploring the ability of *P. pustulosus* females to generalize to the calls of other species demonstrate that phylogenetic relatedness is a better predictor of call recognition than call similarity--suggesting biases may be the result of the evolutionary history of the female sensory apparatus. We are currently investigating whether the artificial neural networks have biases that correspond to those of real females, and whether the evolutionary history of the networks shapes these biases. ## 178.14

DISSOCIATION BETWEEN MK-801- AND CAPTIVITY-INDUCED STEREOTYPES IN BANK VOLES (*Clethrionomys glareolus*). L. Vandebroek, R. Meusen<sup>\*</sup> and F.O. Odberg. Dep. of Animal Nutrition, Genetics, Production and Ethology, Univ. of Ghent, Heidestraat 19, B - 9820 Merelbeke, Belgium.

Pharmacologically-induced stereotypes (PHIS) following amphetamine and, more recently, the non-competitive NMDA-antagonist MK-801, are used to study human psychopathology and for screening potential neuroleptic drugs. On the other hand, it is also possible to elicit stereotypes by captivity, for example in barren environments. In this study, the relationship between PHIS and captivity-induced stereotypes (CIS) was investigated by repeated administration of MK-801 (RBI, Natick, MA, 0.3 mg/kg) to bank voles that had respectively developed a typical jumping stereotypy in captivity (ST) or not (NST). ST and NST received saline for 9 days followed by 9 daily sc injections with MK-801, with a 48 h break between both treatments. Their behaviour was subsequently recorded during 2 min every 5 min for a total of 112 min with a pocket computer loaded with the Observer 3.0 software (Noldus Information Technology, Wageningen, The Netherlands) on days 1, 5, 9, 11, 15 and 19. According to our results, jumping was not evoked in NST voles, nor increased in ST. Instead, other stereotypes such as intensive sniffing, followed by locomotor stereotypy characterized as running in unidirectional circles, were elicited by the drug. Furthermore, differences between both groups were encountered with repeated injections. ST showed a progressive increase in levels of locomotor stereotypy (one-way ANOVA for repeated measures: F = 5.71; p = 0.015) and no change in levels of sniffing, while in NST intensive sniffing was progressively enhanced (F = 5.64; p = 0.016) and levels of locomotor stereotypy did not vary significantly. These results seem to point, at least in part, to a different regulation of the neurobiochemical background of CIS and PHIS. This research was supported by a specialization grant of the Belgian IWT.

## 178.15

GERBILS REGULARLY RETURN TO THEIR ENTRY POINT WHEN EXPLORING A NOVEL ENVIRONMENT. D.S. Touretzky\*, S. J. C. Gaulin†, A. D. Redish. Computer Science Dept. and Center for the Neural Basis of Cognition, Carnegie Mellon Univ., Pittsburgh PA 15213. \*Dept. of Anthropology, University of Pittsburgh, Pittsburgh PA 15261

Recent theories of rodent navigation have suggested that rodents associate visual cues with path integrator coordinates as they explore a novel environment. Because path integration is subject to cumulative error, these theories predict that rodents must periodically return to places where the association has already been made, in order to correct for drift. One likely reference point is the location where the animal first entered the environment. Informal observations of rodents exploring a novel environment suggest that they return to their entry points at regular intervals. We quantify this in two ways: by measuring the distance from the entry point as the animal explores, and by counting the number of times the animal returns to a small circle around this point. Eight gerbils (four male and four female) were individually released into an open, 3-meter diameter arena and allowed to explore for 10 minutes while their position was tracked at 18.2 frames per second. The gerbils explored a

large portion of the arena during this period. The graph at left shows distance from entry point (in cm) vs. time for one animal. Each time the value drops to zero, the animal has returned to its entry point (14 times for this trial). This plot differs significantly from that produced by a random walk.

## 178.17

VESTIBULAR INFORMATION DEFINES A DIRECTIONAL REFERENCE NECESSARY TO ELABORATE A SPATIAL REPRESENTATION. P. Lavenex (1), V.M. Bajo-Lorenzana (2)\*, L.F. Jacobs (1). 1-Dept of Psychology, University of California, Berkeley, CA 94720. 2-Inst of Physiology, University of Lausanne, CH-1005 Lausanne

The aim of this study was to investigate the importance of vestibular information in the definition of a directional reference necessary to elaborate a spatial representation of the environment. The caching and retrieval behavior of kangaroo rats was analysed in a visually controlled environment. The experiment took place in a square arena surrounded by curtains, which prevented the access to distant visuospatial information. This apparatus constituted a symmetrical world, where internal spatial coordinates could be disambiguated only with the help of a directional reference. K-rats were transported in their home-cage from the housing room to a fixed position in the experimental room. They were then transferred in an opaque plastic transport box from their home-cage into the arena and allowed to cache seeds. During the caching trials, k-rats were always introduced into the arena from the same entrance (SW). Three different types of retrieval trials were conducted. (1) The k-rat was given access to the arena from the same entrance (SW) as in the caching session. (2) The k-rat was not transported directly from its home-cage to the experimental arena. Instead, the animal, in the plastic transportation box, was placed on a rotating platform for one minute with a rotation speed of 16 turns/min. It was then introduced to the arena from the opposite entrance (NE). This attempted to control for the integration of vestibular information and prevent the animal from maintaining an internal direction of reference. (3) The k-rat was introduced to the arena from the opposite entrance (NE), but was transported in the plastic box directly from its home-cage into the experimental arena. Animals should be able to integrate the vestibular information and maintain a correct directional reference. In (1), k-rats found the seeds that they had previously cached in the arena. In (2), they searched for their caches in positions exactly symmetrically opposite to their original caches. In (3), k-rats searched at the correct locations and at symmetrical positions in the arena. These results show that the integration of vestibular information enables the maintenance of an internal directional reference necessary to elaborate a spatial representation of the environment. If this integration is disrupted, the animals reset the integration of the vestibular information at the entrance of the arena. They consider this point to be the new point of reference (i.e. the origin), from which to calculate their position using vestibular and kinesthetic information. Supported by the Swiss National Science Foundation and the University of California, Berkeley.

## 178.16

GABA<sub>A</sub> RECEPTORS OF AMYGDALA ARE INVOLVED IN THE MODULATION OF DORSAL IMMOBILITY. W. I. C. Albuquerque-Araújo\*, M. R. Brentegani and A. Hoffmann. Lab. of Neurophysiology, University of São Paulo, Ribeirão Preto, SP 14049-900 Brazil.

Dorsal immobility (DI) is an inhibitory behavioral response that occur in the prey-predator relationship and in fight between conspecifics. It is elicited by grasping the animal by the dorsal skin at the nape of the neck and lifting it off its feet. In the rat, the animal immediately exhibits a stereotypical immobility posture that persists for a period of time until the animal suddenly emits escape-like behaviors. Extensive evidence indicates that the amygdala plays a crucial role in fear and anxiety. Many of the amygdaloid projection areas are critically involved in specific signs (changes in autonomic activity, simple reflexes) that are used to measure fear and anxiety. Electrical stimulation of the amygdala elicits a pattern of behaviors that mimic natural or conditioned states of fear. Local infusion of drugs (opiate agonists, benzodiazepines) have anxiolytic effects in several behavioral tests. In view of the above considerations the purpose of the present study was to investigate if the amygdala and the GABAergic system, acting through GABA<sub>A</sub> receptors, are involved in the modulation of dorsal immobility. The changes in the duration of dorsal immobility in seconds, were determined before (control 26.8 ± 2.55) and after microinjections of saline (25.2 ± 2.87; 0.2µl), muscimol (22.47 ± 4.26; 0.1µg/0.2µl), muscimol (25.6 ± 3.85; 0.3µg/0.2µl), muscimol (20.03 ± 3.21; 0.6µg/0.2µl), bicuculline (11.94 ± 0.98; 0.1µg/0.2µl), bicuculline + muscimol (22.8 ± 2.95; 0.6µg/0.2µl) and midazolam (48.6 ± 5.81; 20nmol/0.2µl) in the amygdala of adult Wistar rats (± 250g) chronically implanted with stainless steel guide cannulae. The results show: 1) muscimol alone don't interfere in the duration of DI, but blocks the inhibitory effect of bicuculline; 2) the anxiolytic action of benzodiazepines (injected in the amygdala) potentiate the duration of DI. THE DEVELOPMENT OF ROTATORY MOVEMENTS AROUND THE LONGITUDINAL AXIS DURING CONTACT-RIGHTING: SEX DIFFERENCES IN THE ORGANIZATION OF ROTATORY MOVEMENTS D. J. Martens, E. F. Field, V. C. Pellis\* & S. M. Pellis. Dept. of Psychology, University of Lethbridge, Lethbridge AB Canada T1K 3M4

Sex differences in the development of righting on the ground, from supine to prone, were studied. Righting, from the prone position, is initiated by a rotation of the head and shoulders to supine. Rotation then progresses cephalocaudally and is complete when the pelvis has also rotated to a supine position. Males take less time to rotate their pelvis, following rotation of their head and shoulders to prone, than do females. Males and females also use different combinations of axial rotation and limb movements to rotate from supine to prone. These differences appear to be due to differences in the way males and females integrate their fore- and hindquarter movements. These results suggest that males and females have different developmental patterns of movement organization in the rotatory plane. This research was supported by NSERC.

## NEUROETHOLOGY: ELECTRORECEPTION

## 179.1

PULSE TRAIN CHARACTERISTICS OF THE ELECTRIC ORGAN DISCHARGE (EOD) DURING THE COMMUNICATIVE BEHAVIOUR OF TWO SKATE SPECIES (*RAJA OCELLATA* AND *R. ERINACEA*). L. D. Hayes, B. Bratton. Dept. of Biology, Bates College, Lewiston ME 04240 & Oberlin College, Oberlin OH 44074.

The electric organ of marine skates (Chondrichthyes: Rajidae) produces weak electric organ discharges (EODs) that may occur within the detectable range of the ampullae of Lorenzini. Although it is believed that the electric organ is employed during social communication, the precise function of the EOD during behaviour has yet to be determined. This study examined the characteristics of the EOD pulse trains of grouped Winter skates (*Raja ocellata*) and Little skates (*R. erinacea*) observed in 4-11 day periods. EOD activity produced during intra-specific interactions were quantified into five defined behaviour types. Qualitative observations of EOD activity were also examined. Skates produced an average number of EODs per train that differed between the five behaviour types. Similar differences in the average EOD pulse train duration and frequency were not found. The EOD pulse train of *R. ocellata* was lower in frequency than that produced by *R. erinacea*. Two *R. ocellata* individuals developed a constant EOD pulse train of 0.4-0.6 pulses per second (pps) that occurred during behavioural interactions with other skates and in isolation. *R. erinacea* did not produce a constant EOD pulse train. Although distinct EOD pulse train patterns were not observed during specific behaviours, the occurrence of high frequency responses (>1.0 pps) to certain behavioural encounters suggests that the electric organ is used as a communicative signal. Differences between the EOD pulse trains produced by *R. ocellata* and *R. erinacea* provide evidence that the electric organ is used as an intra-specific signaler, possibly during reproductive and antagonistic behaviour.

## 179.2

LOCATING THE SITE OF ADAPTIVE REAFFERENCE SUPPRESSION: EVIDENCE FOR A ROLE OF PARALLEL FIBERS. D. Bodznick\*, M.R. Carey and B.W. Larner. Dept. Biol., Wesleyan Univ., Middletown, CT 06459.

Second order electrosensory neurons (AENs) in the skate medulla selectively suppress sensory inputs associated with the fish's ventilatory movements. This reafference suppression is based in part on an additive adaptive filter mechanism in which internal reference signals (central motor commands and sensory feedback) provide a cancellation signal input to each AEN that is the negative of the expected reafference in that cell. The cancellation signal is adaptive. Coupling electric field stimuli to the fish's ventilatory movements leads, within minutes, to a suppression of the AEN response to the stimulus. Immediately after the coupling, the modified cancellation signal is apparent as a negative image of the expected reafference in the neuron's firing pattern during ventilation. We report here the results of two experiments to determine the site of the plasticity and the source of the cancellation signal. First, we maintained stable intracellular recordings of AENs in freely-ventilating animals for periods up to 1 hr. and coupled intracellular current pulses with the fish's ventilatory movements. This pairing resulted in changes in the cancellation signal to the AEN (evidenced by the negative image after the coupling) similar to those seen following the coupling of sensory stimuli to ventilation. This indicates that the plasticity is due to changes in the strength of synapses onto the AEN itself. Second, we tested the hypothesis that the parallel fiber projection, which supplies central motor command and sensory feedback information to the AENs, is the source of the cancellation signal. Large extirpation lesions to DGR, the granule source of the parallel fiber projection, resulted in a significant decrease in the proportion of AENs exhibiting cancellation signals in response to coupling. This suggests that parallel fiber input to the AEN plays an important role in the plasticity mechanism. Plasticity in some AENs after lesioning may be due to incomplete lesions or may indicate an additional source of cancellation signal inputs.

## 179.3

BEHAVIORAL SIGNIFICANCE OF MULTIPLE SENSORY MAPS IN THE ELECTROSENSORY LATERAL LINE LOBE (ELL) OF THE ELECTRIC FISH, *EIGENMANNIA*. W. Metzner\* (1), J. Juranek (2) (1) Dept. of Biology, UCR, Riverside, CA 92521-0427, (2) Program in Neuroscience, Dept. Psychology, UCR, Riverside, CA 92521-0426.

Multiple representations of the environment are a common component of vertebrate sensory systems. For instance, four electrosensory maps are found in the hindbrain of weakly electric gymnotiform fish. Each of the four segments of the ELL contains a topographic map of electroreceptive input from the body surface. The medial segment receives information from low-frequency (ampullary) receptors and the three remaining maps (centromedial, centrolateral, and lateral) receive information from high-frequency (tuberosus) receptors. Differences in the neuronal activity between the three tuberosus maps indicate highest temporal resolution of neurons in the lateral and highest spatial resolution of neurons in the centromedial map. The behavioral significance of these differences, however, is purely speculative and suggests that the lateral map may be involved mainly in communication behavior and the centromedial map in the detection of jamming signals caused by neighboring conspecifics (jamming avoidance response; JAR) and possibly during electrolocation. We use pharmacological lesions (kainic and ibotenic acid) of various ELL maps in combination with a, in this context, new stimulation technique to determine the effects on the JAR: The fish is positioned in a chamber with multiple, electrically isolated compartments. This allows us to apply external electric fields only those body surface areas projecting to that particular portion of the ELL map where the multiple barrel electrode used for simultaneous recording and lesioning is located. Thus, compensatory effects of highly convergent input from different receptor afferents is minimized. Results indicate a strong separation of the behavioral significance of the maps, and even suggest that the ampullary map may be involved in the JAR.

## 179.5

CELLULAR EFFECTS OF DIFFERENT PREMOTOR CIRCUITRY ON THE PACEMAKER NUCLEUS IN TWO SPECIES OF ELECTRIC FISH. J. Juranek\* (1) and W. Metzner (2). (1) Program in Neuroscience, Dept. Psychology, UCR, Riverside, CA 92521; (2) Dept. Biology, UCR, Riverside, CA 92521.

*Eigenmannia* raises and lowers its electric organ discharge (EOD) frequency in response to jamming signals from neighboring conspecifics. The premotor control of this jamming avoidance response (JAR) is mediated by two anatomically distinct, antagonistically acting inputs to two cell types, pacemaker cells and relay cells of the medullary pacemaker nucleus (Pn). Input from a dienecephalic prepacemaker (PPnG/CP) terminates mainly on pacemaker cells and is normally inactive but can be activated to raise the EOD frequency above the resting level. An input from a sublemniscal prepacemaker (SPPn) terminates mainly on relay cells and is normally active but can be reduced to lower the EOD frequency below resting level (Metzner, 1993). In contrast, the closely related *Apteronotus* is unable to lower its EOD frequency below the resting level during a JAR. Although both inputs to the Pn and its cellular components exist, only the SPPn mediates EOD frequency changes during a JAR (Heiligenberg et al., 1996). The SPPn is normally inhibited and only when this inhibition is released, the EOD frequency raises above the resting level during a JAR. The aim of this study is to characterize the effects of this different premotor circuitry on pacemaker and relay cells in the two species. Thus, intracellular recordings from these cells were performed during iontophoretic stimulation of PPnG/CP (with L-Glutamate) and of SPPn (with GABA in *Eig.* and with L-Glutamate in *Apt.*) as well as during a JAR elicited by externally applied jamming signals. In both species, pacemaker cells are only affected by PPnG/CP input whereas relay cells respond only to SPPn input. Baseline voltage, spike amplitude, and rising and falling phases of action potentials revealed drastic differences between pacemaker and relay cells in the two species.

## 179.7

NATURAL AND EVOKED SEXUAL DIMORPHISM IN THE WEAKLY ELECTRIC FISH *HYPOPOMUS* SP. A. Silva, A. Caputi, M. Galeano, P. Errandonea, G. Eiris and R. Budelli\*. Labs. de Neurofisiología y Neuroanatomía Comparada, IIBCE-Fac. de Ciencias, 11600 Montevideo, Uruguay.

The Río de la Plata is the southern boundary of the geodistribution of Gymnotiforms in South America. Hundreds of freshwater sources within Uruguay were explored in order to determine the existence of native species and characterize their habitats. *Gymnotus carapo* is the more ubiquitous one, whereas *Hypopomus* sp. is restricted to the northeast region, and *Eigenmannia virescens* to the northern region of the country.

*Hypopomus* sp. showed natural morphological and electrophysiological sexual dimorphism during the breeding season in late spring and summer (November to February). On the other hand, 20 non differentiated individuals under captivity were intramuscularly injected with 20-50 µg/gr of testosterone ciclopentil propionate (Dispart).

Since the electric organ discharge (EOD) depends on complex spatio-temporal patterns, we used the multiple air-gap technique (Caputi et al., J. Comp. Physiol. A, 1993, 173:227-232) to record independently and simultaneously the contribution of different portions of the electric organ (EO) in the generation of the EOD.

We found a strong correlation between natural and evoked sexual EOD changes. The discharge generated by the intermediate portion was more affected. We observed an increase in the amplitude and duration (mainly of the negative component) of the electromotive force generated by this portion in the natural differentiated male and after hormonal treatment.

Data suggest that: a) testosterone is responsible for male changes as reported elsewhere, b) testosterone evokes an increase in the efficiency of action potential invasion of electrocyte rostral faces, c) this effect is not homogeneous along the EO. Partially supported by CSIC. Proj. N. 052 and CEC. Proj. N. C11\*-CT92-0085

## 179.4

ROLES OF ADAPTATION, PASSIVE ELECTRICAL FILTERING AND VOLTAGE-DEPENDENT CONDUCTANCES IN THE TEMPORAL SELECTIVITIES OF TONAL NEURONS, G.J. Rose\* and E.S. Fortune. Dept. Biology, Univ. Utah, Salt Lake City, UT 84112.

In its jamming avoidance response (JAR), the weakly electric fish *Eigenmannia* changes its frequency of electric organ discharges (EODs) to increase the frequency difference between its EODs and those of a neighbor. Frequency differences (beat rates) of approximately 3-8 Hz elicit largest JARs. A neural correlate of this behavior is that spiny neurons in the torus semicircularis respond best to beat rates in this range and the magnitude of EPSPs declines for higher rates. Processes that might contribute to this temporal selectivity include 1) passive electrical properties of the neuron 2) voltage-dependent conductances 3) adaptation. The contribution of each process to the temporal selectivity of tonal neurons was determined by recording intracellularly (whole-cell patch method) at several levels of negative current clamp while 1) varying the frequency of sinusoidal current injected 2) varying the electrosensory stimulus frequency or beat rate and 3) presenting AM or sine-wave bursts as electrosensory stimuli. Results indicate that all three processes can contribute to the temporal filtering properties of tonal neurons. The importance of each process varies across neurons. Supported by NSF grant IBN-9421039.

## 179.6

COMPLEX ELECTRIC SIGNAL STRUCTURE IN REPRODUCING GYMNOTIFORM ELECTRIC FISH. P.K. STODDARD\*, M.D. KILBURN, K.H. PATTERSON. Dept. Biological Sciences, Florida International Univ., Miami FL 33199.

Infrared video & DC-coupled electric field recordings of 7 pairs of the gymnotiform electric fish *Brachyhypopomus pinnaudatus* revealed 3 behavioral stages to reproduction: female approach, male courtship of female, and spawning. Each stage was associated with unique electric signaling patterns. (1) The male discharged at a steady rate until the female approached. (2) The male courted the female by giving rapid EOD accelerations as he prodded her with his snout. This rapid EOD acceleration interacts with the monophasic region of the male's local electric field to generate a large, head-positive pulse in the frequency range of the female's ampullary electroreceptor system. (3) Spawning occurred when the male and female were parallel. The male alternated his steady discharge rate with repeated periods of high frequency, low amplitude, EOD oscillation, each of which produced a low frequency pulse. Our data suggest the sexually dimorphic, biphasic, EOD waveform of the male acts as the mate attraction signal, and that courtship and spawning signals consist of more complex interactions of local electric field structure, EOD rate, and EOD amplitude modulation. Sexual advertisement appears to involve only the high-frequency tuberosus electroreceptive pathway, whereas courtship and spawning signals stimulate both this pathway and the evolutionarily older low-frequency ampullary electroreceptive pathway. Funding was provided by the FIU Foundation and NIGMS/NIH grant GM08205 to P. Stoddard.

## 179.8

ACCURACY OF PHASE-LOCKED NEURONS, ELECTRIC ORGAN DISCHARGES AND THE JAMMING AVOIDANCE RESPONSE OF THE AFRICAN WAVE-TYPE ELECTRIC FISH, *Gymnarchus niloticus*. Y.X. Guo and M. Kawasaki\*. Department of Biology, University of Virginia, Charlottesville, VA 22903.

A behavioral study on the jamming avoidance response (JAR) of the African wave-type electric fish, *Gymnarchus niloticus* (Kawasaki 1993 J. Comp. Physiol. 173:9-22), indicated that the JAR requires timing comparison in the order of microseconds between electrosensory signals from different body surfaces. In this study, accuracy of phase-locking neurons in the electrosensory lateral line lobe (ELL) and behavioral threshold for phase differences were measured.

The S-type primary afferent fibers, which fire an action potential in response to each cycle of electric organ discharges (EODs), project to the somata of giant neurons and to the inner cell layer (ICL) of the medial zone of the ELL. The giant neurons also fire in the phase-locked fashion and terminates also on the ICL. Thus the phase information is represented by action potentials of these phase-locking neurons at the differential-phase-sensitive neurons in the ICL (Kawasaki and Guo 1996 J. Neurosci. 16:380-391). Mean of standard deviations of jitter of these phase-locking neurons over several seconds were 5.6 µsec. Of 134 neurons tested, the most and least accurate neurons showed standard deviations of 1.3 µsec and 18.4 µsec, respectively.

The JAR could be induced when available phase differences were only a few hundred nanoseconds.

Although jitter of EODs was less than one microsecond on average, artificially induced jitter of an EOD replacement signal (up to 60 µsec) did not have any significant effects on the JAR even when phase differences of submicroseconds were available to curarized fish.

These results indicate that the differential-phase-sensitive neurons in the ELL receive phase information with accuracy of single-digit microseconds and further phase processing yields an approximately ten times higher behavioral acuity.

## 179.9

GLUTAMATERGIC INPUT TO PACEMAKER NUCLEUS FROM MAUTHNER CELL NETWORKS IN *GYMNOTUS CARAPO*. A. Falconi, M. Borde, S. Curti and F.R. Morales\*. Departamento de Fisiología, Facultad de Medicina- Facultad de Ciencias Montevideo 11800-Uruguay.

Activation of Mauthner cells (M-cells) in *G. carapo*, results in an abrupt increase in the rate of discharge of its electric organ (Mauthner cell initiated Abrupt Increase in Rate, M-AIR). This response is mediated by an excitatory input to the medullary pacemaker-cells (PM-cells). In the present work we explored, utilizing pharmacological tools, the nature of the neurotransmitter released by synapses responsible for this excitatory input. In addition we investigated the subtypes of postsynaptic receptors activated by this neurotransmitter. The experiments were conducted *in vivo* as described previously (Falconi et al. 1993, J. Comp. Physiol.). Glutamate and its agonists, as well as blockers for different receptor subtypes, were applied to the PMn by pressure injection.

Glutamate (1 to 10 mM), NMDA (500  $\mu$ M), Kainate (1 to 5 mM) and AMPA (500  $\mu$ M) injections induced abrupt and relatively short lasting acceleration of the electric organ discharge (EOD). *Trans*-ACPD (5 mM) induced a long lasting (about 60 s) biphasic increase in EOD rate. None of this agonist-induced responses were accompanied by any variation in EOD waveform. M-AIR was reversibly blocked (up to 80%) by AP5 (500  $\mu$ M), MCPG (5 to 10 mM) reduced both its amplitude and duration. CNQX (1 to 10 mM) either had no effects or slightly affected the onset of some M-AIR responses. All these data taken together indicate that the excitatory input to the PM-cells responsible for M-AIR responses appears to involve mainly NMDA and metabotropic subtype glutamate receptors. To our knowledge this is the first demonstration of the involvement of metabotropic glutamatergic actions in a specific behavior.

Supported by CSIC, Universidad de la República and CONICYT-Uruguay.

## 179.11

SENSORY EVOKED RESPONSES IN THE PALLIUM OF THE WEAKLY ELECTRIC FISH, *GNATHONEMUS PETERSII*. T.H. Bullock\*, J.C. Precht, G. von der Emde<sup>1</sup>, C.J.H. Wong, G.N. Akozov<sup>2</sup>, G.N. Andrianov<sup>2</sup>. Neurobiology Unit, Scripps Inst Oceanography, UCSD, La Jolla, CA 92093; <sup>1</sup>Zool Inst, Univ Bonn, 53115 Bonn, Germany; <sup>2</sup>Pavlov Inst Physiol, Russian Acad Sciences, 199034 St. Petersburg, Russia.

Little is known about the physiology and functional organization of the teleost forebrain. The everted pallium, well developed in this mormyrid species, was examined for structure and distribution of evoked responses (local field potentials, LFP and multiunit activity, MUA) in the dorsal medial nucleus and immediately ventral area in locally anesthetized, curarized fish. In each of 211 tracks, responses to 4 stimulus modalities were sampled from ca. 30 depths, in ca. 50  $\mu$ m steps, with 1-4 semi-microelectrodes, at 22-23°C. Stimuli were water displacement (adequate for lateral line receptors), light flash, electric field and acoustic tone pip, with intervals of  $>7$  s between them.

Results are described from single sweeps. 1) Sharp, usually negative LFPs with MUA are designated DEP, VEP, EEP & AEP (according to the 4 modalities), and are usually very local. Loci as little as 100  $\mu$ m from one with a good EP may show no hint of an EP to the same stimulus or quite a different wave form or latency (e.g. 25 vs 40 ms). Some high frequency LFPs with MUA have only a small amplitude slow component. 2) EPs often include induced rhythms between 40 & 80 Hz. 3) AEPs are usually obtained without concomitant EEPs but most EEP loci also yield some AEP activity. Some EEP loci are purely EEP. Loci with the large sharp DEPs show no EEP or AEP overlap activity. 4) AEPs do not follow at rates greater than 1 Hz. 5) AEPs and EEPs are almost always in the upper 600  $\mu$ m, begin ca. 300  $\mu$ m below the surface and span ca. 200  $\mu$ m. DEPs are deeper, ca. 600-800  $\mu$ m and caudal to the best AEP loci. 6) AEP onset latencies average 35ms, principal peak N20-100 ms (mean 64 ms). EEPs were similar, principal peak is N45-80 ms. DEPs have longer latencies (N105-130 ms). 7) VEPs are seen very locally  $>1,000$   $\mu$ m deep. Supported by NINDS.

FEATURE EXTRACTION IN THE ELECTROSENSORY LATERAL LINE LOBE (ELL) OF WEAKLY ELECTRIC FISH.

F. Gabbiani<sup>1,2</sup>, W. Metzner<sup>2</sup>, R. Wessel<sup>3</sup> and C. Koch<sup>1</sup>. <sup>1</sup>Div. of Biol., Caltech 139-74, Pasadena, CA 91125, <sup>2</sup>Dept. of Biol., UCR, Riverside, CA 92521-0427 and <sup>3</sup>Dept. of Biol., UCSD, La Jolla, CA 92093-0357.

The ELL in the hindbrain of weakly electric fish is the first CNS nucleus of the electrosensory pathway. P-receptor afferents encode electric field amplitude modulations (AMs) and transmit this information to pyramidal cells in the ELL. Two functional groups of pyramidal cells are distinguished: E-cells respond to increases in amplitude of an externally applied electric signal and I-cells respond oppositely. The aim of this study was to characterize the temporal information processing of ELL pyramidal cells in *Eigenmannia* and relate it to the information carried by P-receptor afferents. The responses of P-receptor afferents and pyramidal cells were quantified by an estimation method (Wessel et al., J. Neurophys. 1996) characterizing to what extent the neuronal response encodes the detailed time course of random AMs and a signal-detection method developed to identify features encoded in spike trains. Extracellular recordings from P-afferents revealed that they encode reliably the detailed time course of random AMs up to 40 Hz cut-off frequencies while specific features are not well encoded. In contrast, intracellular recordings from E- and I-cells revealed that, while the detailed stimulus time course is poorly encoded, up- and downstrokes of random AMs are reliably encoded. Up- and downstrokes were found to be encoded more reliably by short bursts rather than by isolated spikes. The results suggest that these features are extracted by the ELL circuitry from the detailed time-varying information provided by P-afferents. Analysis of the intracellular membrane voltage of pyramidal cells in response to the stimulus suggests that the feature extraction is most likely to occur in the dendrites of pyramidal cells. Support: NSF, ERC and UCR.

## 179.10

PACEMAKER REGULARITY: INTER-SPECIES COMPARISON OF ELECTRIC ORGAN DISCHARGE FREQUENCY. K.T. Moortgat<sup>1</sup>, T.H. Bullock<sup>2</sup>, and T.J. Sejnowski<sup>3</sup>. <sup>1</sup>Physics and <sup>2</sup>Neuroscience Depts., University of California, San Diego, 92093; <sup>3</sup>Computational Neurobiology Lab, Salk Institute, La Jolla, CA 92037.

Certain species of weakly electric fish produce pulses, commanded by a central pacemaker, orders of magnitude more regular than other known biological oscillations. Here we investigate the inter-species differences in electric organ discharge (EOD) timing regularity among some South American wave-type fish, *Sternopygus macrurus*, *Eigenmannia virescens*, and three species of *Apteronotus*, as well as *Microsternarchus* sp. Measurements were made during day and in physical isolation. The natural EOD of these species ranges from 20 to 1300 Hz.

We show that EODs of all three *Apteronotus* species (*leptorhynchus*, 650 Hz; *albifrons*, 980 Hz; sp., 1300 Hz) are regular to sub-microsecond resolution (standard deviation (sd) as low as 0.2  $\mu$ sec; coefficient of variation (sd/mean), cv = 0.00014) over thousands of EOD cycles. In contrast, the low frequency (20 Hz) *Microsternarchus* is much less regular (ca. 0.2 msec; cv = 0.00403). A 500 Hz *Eigenmannia* EOD was very stable (0.4  $\mu$ sec; cv = 0.00019) while *Sternopygus* (100 Hz) had less timing regularity (2.1  $\mu$ sec; cv = 0.0002). The regularity appears to be species-specific but independent of mean frequency.

The cv will remain constant over thousands of cycles but can vary by a factor of ten on longer time scales (hours). One hypothesis under study is that regularity is adjusted by the individual, depending on its behavioral state. The ability of a species to maintain regular EODs largely depends on the medullary pacemaker nucleus, which varies in cell number, degree and type of coupling, and ratio of cell types among species. We are studying which of these features is most important in attaining the observed EOD regularity. Support: NIMH fellowship to KTM; NINDS, NIH to W. Heiligenberg (deceased), and HHMI to TJS.

## 179.12

TISSUE PRINTED CELLS FROM THE ELECTROSENSORY LATERAL LINE LOBE (ELL) OF A WEAKLY ELECTRIC FISH. Suhas A. Kotecha, Douglas W. Eley, and Ray W. Turner\*. Dept. Anatomy, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

Several techniques have been used to isolate vertebrate CNS neurons for electrophysiological recordings and cell culture. B.A. Barres (1990) first used a procedure termed "tissue printing" to isolate and record from rat optic nerve glial cells. We now report a modification of this procedure to print vertebrate CNS tissue slices and obtain an organotypic distribution of identifiable, isolated cells without exogenous enzyme treatment.

Transverse 200  $\mu$ m ELL slices were placed in cold, oxygenated sucrose-NaCl substituted aCSF. Slices were placed in a petri dish with 2ml L-15 medium and maintained overnight at 4°C. Slices were warmed to 23°C for 60 min, attached to nitrocellulose paper, and inverted onto a glass coverslip pre-coated with Concanavalin A, poly-L-lysine and laminin. Slices were surrounded by a low level of HEPES-buffered medium in which Na<sup>+</sup> was substituted with sucrose and Na Gluconate, KCl and KH<sub>2</sub>PO<sub>4</sub> with K Gluconate, 0.1 mg/ml Kyn. acid, 10  $\mu$ M picrotoxin, 1 mM Na Pyruvate, 0.1 mM CaCl<sub>2</sub> and 4.5 mM MgCl<sub>2</sub>. Slices were centrifuged at 450 X g for 5 min, the slice removed from the coverslip and the dish filled with L-15 medium.

Isolated cells were distributed as an organotypic monolayer, with the boundaries of the slice and major cell laminae clearly delineated. Small diameter cells (ie glia, cerebellar granule cells) and axonal processes were isolated most often, followed by larger diameter somata and dendritic processes. In many cases, an excellent preservation of cell structure was obtained, with identifiable somata and attached dendrites up to 500  $\mu$ m in length. All ELL cell classes have been identified, including pyramidal, polymorphic, granule and spherical cells. Tissue prints are prolific in culture, given the high density and organotypic distribution of isolated glial cells. This work was supported by the AHFMR and Canada MRC.

## 180.1

TASTE AND OTHER ORAL RESPONSIVITY TO A HIGH-FAT SWEETENED CHOCOLATE PRELOAD. P.J. Geiselman\*, C.F. Smith, D.A. Williamson, R.A. Plum, N. Baker, C. Champagne, & D.H. Ryan. Pennington Biomedical Research Center and Dept. Psychol., Louisiana State University, Baton Rouge, LA 70808.

Our recent research has found that a high-fat, sweetened preload can provoke overeating in women. The present study was conducted to determine how the magnitude of overeating was associated with taste and other oral responsivity in women scoring high and low on disinhibition (tendency to lose control of food intake). We used the Three-Factor Eating Questionnaire to categorize women as high or low on the disinhibition scale. Women were randomly assigned to the preload or control condition. Subjects in the preload condition tasted and rated scales for intensity perception and hedonic responses to four chocolate puddings varying in sweetness (high and low) and fat (high and low) content. Preload subjects were then given a 350-kcal high-sugar/high-fat chocolate pudding to eat, following which they were presented with a pasta meal and told they could eat as much or as little as they wished. Subjects in the control condition were given only the pasta. Regardless of disinhibition level, subjects in the preload condition ate significantly more calories than did subjects in the control condition. Data will be presented showing how taste and other oral responsivity to the chocolate puddings are associated with overeating in each of the disinhibition groups.

## 180.3

THE EFFECTS OF LOW GI FOODS AND FREQUENT EATING ON HUNGER, SATIETY AND FATTENING,

A. Alvezos\* and K. Ageli.

IB program, Costeas - Gironas School, Pallini, Athens, Greece

The pattern of blood glucose changes reflects insulin levels and determines satiety and the overall degree of fattness. Depending on the composition of meal and frequency of eating, 3 different blood glucose curves can be obtained.

Curve A, maintains hunger and promotes fattening.

Curve B, promotes satiety and fat reduction.

Curve C promotes extreme hunger.

Curve B, is obtained by using combinations of low glycemic index foods and frequent eating (every 2.5 - 3 hours)

## 180.5

EFFECT OF DIETARY SATURATED FATTY ACID CHAIN LENGTH ON INSULIN, GLUCOSE TOLERANCE, AND MACRONUTRIENT SELECTION. R.J. Kaplan, G.H. Anderson\* and C.E. Greenwood. Dept. of Nutritional Sciences, Univ. of Toronto, Toronto, Ontario, Canada M5S 3E2.

Dietary saturated fatty acid (SFA) content has been shown to mediate macronutrient selection and cognition. This study examined the influence of SFAs of varying chain length on macronutrient selection and the role of insulin sensitivity in mediating this behaviour. Groups of rats were fed, *ad libitum*, one of 4 single diets, adequate in essential fatty acids, differing only in fat source (40% energy from fat) for a 14-day stabilization period. The fat source was high in: 1) long-chain SFAs ( $C_{16}$  and above; fully hydrogenated soybean oil (HSB)), 2) intermediate-chain SFAs ( $C_{12}$  and  $C_{14}$ ; hydrogenated coconut oil (HCO)), 3) medium-chain SFAs ( $C_8$  and  $C_{10}$ ; medium-chain triglyceride oil (MCT) or 4) polyunsaturated fatty acids (soybean oil (SBO)). The HSB, HCO and MCT diets contained similar concentrations of total SFAs. Each group selected for an additional 14 days between a high protein and a high carbohydrate (CHO) diet, each containing the identical fatty acid composition as the stabilization diets and dietary selection behaviour was monitored. Oral glucose tolerance and fasting insulin were determined 4 days after rats were returned to stabilization diets. While total energy did not differ, MCT rats consumed more energy as protein and less as CHO than rats in the other 3 groups. HSB rats did not select similarly to other, previously reported, long-chain SFA-fed rats. It appears, however, that HSB was not fully absorbed. Although group means did not differ with respect to plasma glucose or insulin levels, fasting insulin and the fasting glucose to insulin ratio significantly correlated with both percent of energy selected as protein and as CHO. These results suggest that SFA chain length mediates macronutrient selection, and a decrease in insulin sensitivity leads to an increase in protein and a decrease in CHO intake. HSB may be an anomalous fat source that acts more like a fibre or noncaloric substance than a normal dietary fat. (NSERC).

## 180.2

FLAVOR-CUED ANTICIPATED SATIETY: CROSS-NUTRIENT COMPARISONS. Z.S. Warwick\*, K. Jarkowicz, L.K. Grabill III, Dept. Psychology, Univ. of Maryland Baltimore County, Baltimore, MD 21228.

When trained with equal volumes of distinctively-flavored sucrose solutions differing in caloric density (and thus in total kcal), rats trained with relatively weak solutions (e.g. 1% and 5% wt/vol) preferentially consume in two-bottle tests (both flavors in identical solutions) the high-calorie-paired flavor. This "conditioned flavor preference" (CFP) is interpreted as reflecting the greater reinforcement previously provided by the more caloric solution. However, rats trained with concentrated solutions (5%, 30%) consume less of the high-calorie-paired flavor, presumably reflecting suppression of intake based on anticipated satiety. Since nutrients differ in their ability to reinforce a CFP (e.g. *Appetite* 14:29-44;1990, *Physiol. Behav.* 50:815-24;1991), the present studies investigated whether the magnitude of anticipated satiety was also nutrient-dependent. Rats were trained with distinctively-flavored solutions at 0.2 kcal/ml and 1.6 kcal/ml (one-bottle, overnight, 6 trials/solution), with nutrient type varied across groups. Nutrients tested thus far include the carbohydrates (CHOs) glucose, sucrose, and maltodextrin; and corn oil emulsion (FAT). Two-bottle tests (both flavors in 0.9 kcal/ml) assessed flavor-cued anticipated satiety. Anticipated satiety was evident in rats trained with CHOs: percent intake of the high-calorie-paired flavor averaged approximately 25% of total two-bottle intake for all CHOs. In contrast, FAT-trained rats consumed equal amounts of the high- and low-calorie paired flavors, indicating no anticipated satiety. Studies assessing anticipated satiety conditioned by other nutrients are in progress.

## 180.4

FEEDING DYNAMICS: WHY RATS EAT IN MEALS AND WHAT THIS MEANS FOR FORAGING. B.S. Zanotto<sup>1,2</sup>, J.E.R. Staddon<sup>1</sup>, S. Schiffman<sup>1</sup>. Department of Psychology: Experimental, Duke University, Durham, NC 27708, USA. <sup>2</sup>Facultad de Ingeniería, Paseo Colón 850, 1063 Buenos Aires, Argentina.

Feeding behavior in rats and other animals depends on both regulatory (homeostatic) processes and learning. In recent years, more and more aspects of feeding have been attributed to learning. We describe a very simple, real-time purely homeostatic model that can explain many aspects of feeding dynamics, including many hitherto attributed to learning. The model has two parts: a threshold, which is subject to stochastic fluctuations, and a satiation signal which is a delayed after-effect of eating. The output signal of a series of integrators simulates the temporal properties of the satiation signal, which is subtracted from the threshold to drive eating tendency. We consider that a meal is complete after the animal stops eating for a fixed amount of time. The predictions of this model, with a fixed set of parameters, are: i) animals eat in meals and, under free-feeding conditions, there is a significant correlation between meal size and the duration of the post-meal interval, but no correlation between the preprandial interval and meal size. When feeding is interrupted there is a positive correlation between the time of deprivation and the following meal size, up to a ceiling value at about 24-hours of deprivation. ii) Daily intake is regulated independently of the interpellet delay (smaller than 64 seconds). iii) In Collier-type procedures, with increasing prices for procurement or consumption of pellets, the frequency of eating is a decreasing function of the price, while the meal duration is an increasing function. The overall daily intake is a slightly decreasing function of the price. iv) When the price of access to food is alternated daily between low and high values (with a fixed low consumption price) animals eat much more at the low value. However, after a transient, animals eat almost the same amount of pellets at each price when the alternation is after two or more days. All these properties fit experimental data on feeding in rats. We conclude that most properties of feeding and foraging dynamics reflect regulatory rather than associative processes.

## 180.6

OBESITY PRONE RATS HAVE REDUCED SENSITIVITY TO THE SATIATING EFFECTS OF INTESTINAL FAT INFUSIONS COMPARED TO OBESITY RESISTANT RATS. D. Greenberg\*, J. McCaffery, M.D. Fisch, G.A. Bray and D. York. Dept. of Psychiatry Cornell Univ. Med. College, White Plains, NY 10605 and Pennington Biomedical Research Center, Baton Rouge LA 70808.

The Osborne-Mendel (OM) rat strain shows elevated fat intake and is particularly susceptible to diet-induced obesity while the SSB/PL (SSB) rat specifically avoids fat intake and is highly resistant to diet-induced obesity (Schemmel et al 1970). We wished to determine if this difference in fat intake reflects an alteration in the satiating potency of fats in these rat strains. We tested the ability of duodenal infusions of Intralipid (IL) or linoleic acid to elicit satiety in sham feeding OM and SSB rats.

Male OM (n=9) and SSB (n=8) were fitted with gastric cannulas and duodenal catheters to allow intestinal infusions during sham feeding. Rats were overnight food deprived and sham fed liquid food (40% v/v L10007; Res. Diets Inc.). Intestinal infusion of IL (5kcal/10ml), linoleic acid (0.65 kcal/10 ml) or 0.15M NaCl (10ml; rate=0.44ml/min) began 12 min after food presentation. Intakes were measured every 5 min for 90 min. Intestinal infusions of IL and linoleic acid suppressed sham fed intakes in both rat strains but to a significantly greater extent in SSB than in OM rats (see table).

Infusate	OM	SSB	t
0.15M NaCl	58.1 ± 4.2	56.9 ± 6.8	
IL (5%)	24.5 ± 3.2	12.8 ± 1.7	3.2 p<.01
Linoleic acid (0.65)	26.0 ± 3.4	13.0 ± 3.7	2.5 p<.03

These results suggest that duodenally infused fats have elevated satiating potency in SSB rats and reduced satiating potency in OM rats which may underlie the altered fat intakes in these strains.

## 180.7

CHANGES IN DIETARY SODIUM INFLUENCE DRINKING IN THE BILE DUCT LIGATED RAT. J. R. Lane\*, E. M. Starbuck, & D. A. Fitts. Dept. of Psychology, University of Washington, Seattle, WA 98195.

We have recently reported an increase in ad libitum water drinking at least two weeks following a ligation of the common bile duct (BDL) in rats maintained on a standard chow. In a separate group of BDL rats it was shown that the elevated water intake was accompanied by a reduced mean arterial pressure which generally results in increased renin secretion and high plasma levels of the dipsogenic hormone angiotensin II. In the present experiment, rats were given access to water and .3 M saline and maintained on a standard chow for approximately 6 days prior to a BDL or sham ligation and 11 days after the ligation. On day 12 post-ligation, all rats were given access to 5 pellets of sodium deficient diet in addition to their regular chow for approximately 9 days to habituate the rats to the diet. Rats were then given complete access to the sodium deficient diet for 3 more days. Rats receiving a BDL increased their consumption of water 7 days after the surgical manipulation compared to sham controls and this difference persisted throughout the remainder of the experiment. Reducing the sodium in the diet led to a reduction in water intake in BDL rats but less so in sham controls. Similarly, BDL rats with complete access to the low sodium diet drank less water than BDL rats with access to 5 pellets and standard chow or standard chow alone. The results suggest that the elevation in water intake following BDL is due partially to high dietary sodium intake. Supported by NS22274 and AA05390.

## 180.9

THE INFLUENCE OF THE ESTROUS CYCLE ON TASTE REACTIVITY RESPONSES IN RATS. S.N.D.A. Clarke\* and K.-P. Ossenkopp. Neuroscience Program, University of Western Ontario, London, Ontario, Canada, N6A 5C2.

Hormones (e.g., estradiol) ostensibly modulate taste and palatability, in both humans and animals. This hypothesis is supported by documented changes in food intake during the reproductive cycle, which are in part predicated on changes in the gustatory system. Traditional investigations of changes in the taste system during the reproductive cycle have relied on level of intake as an indirect measure of taste and palatability. The present study adopted a direct measure, the taste reactivity test (TRT), to assess the influence of the estrous cycle on taste responsivity in rats. Male and female rats were fitted with intraoral cannulae which permitted the direct infusion of solutions into the mouth. Subjects then received a brief (1 min) infusion (0.78 ml/min) of one of three tastants: sucrose (0.3 M), quinine (0.0003 M) and a sucrose-quinine mixture. The frequency of ingestive responses (e.g., tongue protrusions) and aversive responses (e.g., chin rubs) elicited by exposure to these tastants was then analyzed to assess the influence of the estrous cycle on taste responsivity. Preliminary analyses revealed that both sex and stage of estrous had an effect on the frequency of taste reactivity responses elicited by the tastants. Thus, the TRT was able to identify sexual dimorphism in taste responsivity which appears to be modulated by the estrous cycle of the female rat. (Supported by NSERC of Canada).

## 180.11

LITTER SIZE AND ITS EFFECTS ON DAM MACRONUTRIENT SELF-SELECTION DURING LACTATION. S.H. Heil\* and C.P. Cramer. Psychology Department, Dartmouth College, Hanover, NH 03755.

The existing literature on feeding during lactation suggest that there is a close positive correlation between a dam's food intake during this period and the number of pups she is nursing, i.e., dams with larger litters will consume more chow when compared to dams with smaller litters (Ota and Yokoyama, 1967; Isler et al., 1984). We have attempted to extend this finding by examining the effect of litter size on dam intake using a macronutrient self-selection paradigm.

On the day of birth, litters were culled to either six or fourteen pups (N = 6 litters/group). Throughout lactation, each dam's daily intake of isocaloric protein, carbohydrate, and fat diets, as well as dam bodyweight and cumulative litter bodyweight, were monitored. Contrary to previous findings, results indicate that dam bodyweight and total intake did not differ significantly between groups, although the litters of both groups grew at rates comparable to those reported in the literature. This may be a result of allowing the dams to self-select their diets, as the groups did differ significantly in their macronutrient intake over time. Specifically, dams with six pups had a higher protein:carbohydrate ratio when compared to dams with fourteen pups. Fat intake was comparable between groups. We are currently analyzing videotape recordings of these litters to determine whether different patterns of nursing (for example, bout duration or frequency) and/or different general activity levels may account for the distinct macronutrient patterns chosen by each group.

## 180.8

ION SPECIFICITY OF NEURAL TASTE RESPONSES TO ELECTROLYTES IN THE HAMSTER: RELATION TO TASTE QUALITY CODING. M.E. Frank\*, B.I. MacKinnon, B.K. Formaker and T.P. Hettinger. Dept. BioStructure & Function, University of Connecticut Health Center, Farmington, CT 06030

Nerve fibers of the Chorda tympani nerve of the golden hamster (*Mesocricetus auratus*) respond to a variety of acids, salts and sugars applied to the tongue. Responses to electrolytes are found in N and H fibers, which show different sensitivities to cations and anions. N fibers are selective for sodium salts, are inhibited by amiloride and show small anion effects. H fibers are less selective for cations, are not affected by amiloride, and show greatly reduced responses to salts containing large anions such as D-gluconate. The average neural response of 6 H fibers to 0.1 M NaCl or NaBr was significantly larger than responses to 0.1 M Na acetate, Na benzoate or Na D-gluconate ( $F(4,20)=5.41$ ,  $p<0.005$ ). Hamsters show an innate aversion to sodium chloride that is partially blocked by amiloride (Hettinger and Frank, 1990). Behavioral responses of hamsters to anions are difficult to interpret because some anions, such as m-nitrobenzenesulfonate appear to be similar to sucrose in conditioned taste aversion experiments (Herness and Pfaffmann, 1986). N fibers presumably are involved in regulation of sodium intake in hamsters, as in rats (Bernstein and Hennessy, 1987). Human perception of saltiness (van der Klaauw and Smith, 1995) is not selective for sodium salts and parallels H-fiber more than N-fiber sensitivity.

## 180.10

SEX DIFFERENCES IN ASSOCIATIVE AND NONASSOCIATIVE AVOIDANCE OF A NOVEL TASTE IN RATS. M. Fox<sup>1</sup>, S. Maren<sup>2</sup> and D. Mitchell<sup>3</sup>. <sup>1</sup>Dept. of Psychology, Loyola Marymount University, Los Angeles, CA 90045, <sup>2</sup>Dept. of Psychology, University of Michigan, Ann Arbor, MI 48109, <sup>3</sup>Dept. of Psychology, University of Southern California, Los Angeles, CA 90089.

Sexual dimorphism is commonly reported in tasks in which rats are offered a choice between novel and familiar alternatives, including taste neophobia and conditioned taste aversions (CTAs). Given theoretical assertions that delayed CTAs are mediated by nonassociative processes (Mitchell, Scott & Mitchell, 1977), and recent findings that basolateral amygdala lesions that disrupt taste neophobia also disrupt CTAs, we reasoned that both taste neophobia and delayed CTAs would also show significant sex differences. Accordingly, fluid deprived (30 min/day) male and female rats were compared in four different treatment conditions. Saccharin Poison Immediate (SPI) animals of both sexes were presented with a novel saccharin solution and made ill with lithium chloride (LiCl) injections administered immediately upon completion of the fluid session. Saccharin Poison Delay (SPD) animals were treated exactly as in condition SPI, except that LiCl administration was delayed 4 hrs after saccharin consumption. Water Poison Immediate (WPI) animals were also treated the same as SPI, except they were presented with familiar tap water immediately prior to LiCl administration. Water No Treatment (WNT) animals were presented with tap water and administered a needle poke immediately following the fluid session. Subsequent two bottle preference tests for the next 20 days revealed significant differences between the sexes in all treatment conditions. These results suggest that sex differences in CTAs are mediated by a common nonassociative learning process involved in both taste neophobia and delayed CTAs.

SERUM HORMONE LEVELS AND BODY WEIGHT GAIN IN NORMAL MALES DURING ONE-MONTH SULPIRIDE ADMINISTRATION. L. Tenenud\*, T. Alastre, O. Contreras, J.L. Martinez, E. Araujo de Baptista, L. Hernández, and T. Baptista. Department of Physiology, Medical School, Universidad de los Andes, POB 109, Mérida, 5101-A, VENEZUELA.

Obesity is an undesirable side effect of neuroleptics, afflicting up to 50% of patients under a regimen on chronic administration. Two mechanisms have been proposed to explain the increased appetite and weight gain by neuroleptic drugs: a) direct stimulation of brain feeding-related areas; b) metabolic and endocrine abnormalities secondary to hyperprolactinemia. Few studies have correlated weight gain with the endocrine status in neuroleptic treated subjects. In the present study we administered Sulpiride (200 mg daily for 30 days, n = 7) or placebo (n = 7) to healthy men, and correlated body weight gain with the serum levels of prolactin, luteinizing hormone, follicle-stimulating hormone, estradiol, free testosterone, thyrotropic hormone, free tetraiodothyroxine, cortisol, dehydroepiandrosterone sulphate (DHEA-S) and the ratios estradiol/testosterone and testosterone/DHEA-S. Body weight gain was significantly increased by Sulpiride ( $p = 0.05$ ). The serum levels of prolactin and tetraiodothyroxine were significantly increased by Sulpiride ( $p = 0.05$ ). A significant positive correlation was observed between prolactin levels and body weight gain in the Sulpiride group ( $p = 0.01$ ). The results show that in healthy male subjects, body weight can be increased in the short term by neuroleptic administration. This effect can be related to hyperprolactinemia, independently from the usual changes in gonadal steroids observed in men with simple obesity.

## 180.13

COMPARISON OF THE EFFECTS OF MIDAZOLAM AND MORPHINE ON THE MICROSTRUCTURE OF LICKING FOR INTRA-LIPID. Cooper, S.J. \*, and Higgs, S. Department of Psychology, University of Durham, Science Laboratories, South Road, Durham, DH1 3LE, U.K.

There are many parallels between the effects of benzodiazepines and opioids on ingestive behavior. The benzodiazepine receptor agonist midazolam and the opioid receptor agonist morphine induce hyperphagia, enhance taste preferences and increase hedonic reactions to tastants in taste reactivity tests. The aim of the present studies was to use a microstructural approach to compare the effects of these compounds on the patterns of licking for a fat emulsion. The emulsion used was Intra-lipid (Pharmacia Ltd, Milton Keynes, UK) at concentrations of 1, 3 and 10%. A brief contact test was employed in which rats had 60s access to each concentration of Intra-lipid in a random order. The effect of pretreatment with either midazolam (0.3-3 mg/kg i.p.) or morphine (0.3-3 mg/kg s.c.) on licking behavior was then examined. Both midazolam and morphine increased the total number of licks for Intra-lipid, but did so in different ways. Midazolam increased the number of licks by increasing bout duration, whereas morphine had a selective effect on bout number. The results indicate that the effects of benzodiazepines and opioids on ingestive behaviour can be differentiated using microstructural analysis of licking behaviour. They also indicate that these drugs affect ingestive responses for fat consumption.

## 180.15

ADVERSE EFFECTS OF CHRONIC CAFFEINE EXPOSURE ON ANIMALS SUBJECTED TO EXERCISE STRESS & MALNUTRITION: IMPLICATIONS FOR ANOREXIA NERVOSA (AN). C-T Hsu, T. Coon, S.R. Shenoy, J. McCormick, M-T Maa, & P.F. Aravich, Eastern Virginia Med. School, Norfolk, VA 23501; VAMC, Hampton, VA 23667; Governor's School for Sci. & Tech., Hampton, VA 23666; Christopher Newport Univ., Newport News, VA 23606.

Caffeine is the most widely used psychoactive substance. It can promote panic attacks & is abused by 15% of anorexics. AN is a devastating eating disorder associated with hyperactivity. Caffeine promotes brain serotonin (5HT), which may benefit AN. Thus, caffeine may be a way to self-medicate 5HT. However, it also promotes weight loss with sympathomimetics & has mixed effects on immunity. Hence, it might exacerbate weight loss & immunosuppression in compromised, sympathetically activated anorexics. Animal modeling is needed to resolve these possibilities. We determined the effects of chronic caffeine on the weight-loss syndrome produced by exercise-stress in moderately food-deprived rats. Numerous authors have stressed the syndrome's relevancy to AN. Doses were used that produce plasma caffeine levels obtainable in humans (0, 10 & 40 mg/kg, ip, daily). The rats (female Sprague-Dawley, n/group: ≥10) were injected for a period that produces tolerance to several actions of caffeine (7 days) & then subjected to the syndrome. No food or body weight effects occurred during tolerance. However, chronic caffeine increased syndrome weight loss, worsened the stress triad (adrenal hypertrophy, immune organ atrophy) & worsened activity-stress ulcers. Posterior pituitary weight was also decreased. There were no differences in food intake or running on the terminal day of the experiment (i.e., syndrome maximum). It is proposed that the weight-loss effect is due to sympathetically mediated energy expenditure & the stress triad effect to excess glucocorticoids. These data raise concerns about the body weight & immunological effects of caffeine abuse in disorders related to exercise & malnutrition such as AN.

FOOD INTAKE, BROWN FAT & PHYSICAL ACTIVITY ABNORMALITIES IN FAWN-HOODED RATS WITH CONGENITAL SEROTONIN ABNORMALITIES. M-T Maa, J. McCormick, T. Coon, S.R. Shenoy, C-T Hsu, B. Woytowicz, D.C. Meyer, & P.F. Aravich, Eastern Virginia Med. School, Norfolk, VA 23501; VAMC, Hampton, VA 23667; Governor's School for Sci. & Tech., Hampton, VA 23666; Christopher Newport Univ., Newport News, VA 23606.

Fawn-Hooded (FH) rats are an animal model of depression & alcoholism and are characterized by, e.g., serotonin & glucocorticoid abnormalities. While both of these systems interact with ingestive behaviors, circadian rhythms & physical activity, little information is available on these parameters in FH rats under basal conditions. We evaluated these variables in female FH rats (5-mo old, n=6) & weight-matched Wistar controls (n=5) (0600:1800 LD cycle) (t-tests at p<.05). FH rats had decreased daily food intake under both resting & wheel-running conditions and increased brown adipose tissue weight relative to body weight, which suggests metabolic inefficiency. They ran less than Wistar controls but ate a normal amount of food per wheel revolution, indicating appropriate compensation for activity. FH rats had normal circadian distributions of food & water intakes that peaked between midnight & 0600 as well as a normal distribution of wheel running. They had decreased relative thymus weight, which is consistent with increased glucocorticoid secretion. Relative ovary, spleen and lung weights were normal. Daily water intake was normal but the water-to-food intake ratio & urinary output were elevated while relative posterior pituitary & kidney weights were decreased; these data are consistent with the presence of early kidney disease. It is concluded that 5-mo. old FH rats have food intake, metabolic & spontaneous wheel running abnormalities. They also have water balance abnormalities that are not shown by simple water intake measures. Finally, they have normal circadian distributions of ingestion & wheel running.

HYPERPHAGIA OF GENETICALLY OBESE ZUCKER RATS IS DEPENDENT UPON FORM OF DIET. A.J. Strohmayr\* and D. Greenberg, Departments of Neurology and Psychiatry, Cornell Univ. Medical College, New York, NY 10021.

The meal patterns of genetically obese Zucker rats show increased daily food intake, increased meal size and decreased meal frequency when they are fed rat chow, Noyes pellets, or milk diet. This suggests a deficit in meal size regulation and satiety in obese Zucker rats. We wished to examine if meal patterns of Zucker rats are altered by the caloric density of the diet.

Male lean and obese Zucker rats (n=4/genotype) were tested in a meal pattern apparatus. Continuous recording was made of the intake of either solid lab chow (4.3 kcal/gm) or liquid (BioServ; 1 kcal/gm) diets. Body weights of both genotypes were maintained on both diets. With this apparatus we determined meal size (MS), daily food intake, intermeal intervals (IMI), and meal frequencies. Minimum IMI was 10 min.

Obese Zucker rats consumed more food per day, larger and less frequent meals compared to lean rats when feeding lab chow. When the less calorically dense liquid food was fed meal patterns of obese and lean rats did not differ.

Genotype	Diet	Daily Intake	MS	Meal Frequency	IMI
Obese	chow	134 ± 8.9	12.3 ± 0.9	10.9 ± 0.7	98 ± 6.4
Lean	chow	103 ± 2.4	8.4 ± 0.5	12.3 ± 0.9	89 ± 5.3
Obese	liquid	112 ± 3.7	5.2 ± 0.2	21.7 ± 1.4	55 ± 2.3
Lean	liquid	115 ± 2.9	7.3 ± 0.3	15.8 ± 1.1	76 ± 3.2

These findings could reflect differences in the gastric emptying rates of the two diets in lean and obese rats. The more rapid emptying of the liquid diet terminates meals sooner in the obese rats. The higher caloric density and slower gastric emptying of the chow may result in insufficient stimuli for satiation in the obese Zucker rat.

OPIOID RECEPTOR SUBTYPE AGONIST ENHANCEMENTS OF SUCROSE INTAKE ARE DEPENDENT UPON SUCROSE CONCENTRATION. H. Ruegg\*, W.-Z. Yu, R. Fein and R.J. Bodnar, Dept. of Psychol. and Neuropsych. Doc. Prog., Queens Col., CUNY, Flushing, NY 11367.

Mu, delta and kappa agonists mediate palatable intake with enhancements typically occurring at higher concentrations of saccharin. Delta (delta<sub>1</sub>, delta<sub>2</sub>) and kappa (kappa<sub>1</sub>, kappa<sub>2</sub>) receptor subtypes have been described. The present study examined the pattern of enhancements of sucrose intake induced by central administration of selective mu ([D-Ala<sup>2</sup>, MePhe<sup>4</sup>, Gly-ol<sup>5</sup>]-enkephalin, DAMGO), delta, ([D-Pen<sup>2</sup>, D-Pen<sup>5</sup>]-enkephalin, DPDPE), delta, ([D-Ala<sup>2</sup>, Glu<sup>3</sup>]-deltorphin, Delt II), kappa<sub>1</sub> (U50488H) or kappa<sub>2</sub> (naloxone benzoylhydrazone, NBzOH) agonists as a function of sucrose concentration (0.5, 2.5, 10%) in nondeprived rats. Sucrose intake following vehicle increased over 60 min as a function of concentration: 10%: 17.3 ml; 2.5%: 13.9 ml; 0.5%: 7.8 ml. DAMGO (500 ng: 17-66%) and DPDPE (1-20 ug: 17-46%) increased sucrose intake at 2.5% and 10%, but not 0.5%, concentrations. Delt II (1-20 ug, 27-50%) increased sucrose intake at 0.5% and 2.5%, but not 10%, concentrations. U50488H (1-20 ug) respectively increased (29%) and decreased (78%) sucrose intake at 10% and 0.5% concentrations. NBzOH (1-20 ug) sporadically increased (23-28%) sucrose intake across doses and concentrations. These data suggest that opioid receptor subtype agonists differentially enhance sucrose intake as a function of sucrose concentration. (Supported by NIDA 04194)

## 181.2

GENETICALLY-OBESE ZUCKER RATS DISPLAY DECREASED SENSITIVITY TO CENTRAL OPIOID RECEPTOR SUBTYPE ANTAGONIST WEIGHT REDUCTIONS. J.L. Cole\*, N. Berman, W.D. Bowen, G.W. Pasternak and R.J. Bodnar, Dept. of Psychol. and Neuropsych. Doc. Prog., Queens Col., CUNY, Flushing, NY 11367.

Chronic antagonism of opioid receptor subtypes (mu, mu<sub>1</sub>, kappa<sub>1</sub>, delta<sub>1</sub>, delta<sub>2</sub>) significantly reduce weight and intake in rats. Genetically-obese Zucker rats (fa/fa) show enhanced sensitivity to naloxone's reductions of spontaneous and deprivation-induced intake relative to heterozygous lean litter mates (Fa/fa). The present study examined whether chronic (7 days) central microinjections of selective, long-acting mu (beta-funaltrexamine, 20 ug), mu<sub>1</sub> (naloxonazine, 50 ug), kappa<sub>1</sub> (norbinaltorphamine, 20 ug), delta<sub>1</sub> ([D-Ala<sup>2</sup>, Leu<sup>5</sup>]-enkephalin, 40 ug) or delta<sub>2</sub> (naltrindole isothiocyanate, 20 ug) antagonists differentially altered weight and intake in Zucker and lean rats relative to vehicle. Zucker rats displayed significantly greater basal weight and intake than lean rats. Opioid antagonism significantly reduced body weight after 7 days to a greater degree in lean (mu: 11.4%; mu<sub>1</sub>: 18.9%; kappa<sub>1</sub>: 8.0%; delta<sub>1</sub>: 11.9%; delta<sub>2</sub>: 9.3%) than in Zucker (mu: 8.9%; mu<sub>1</sub>: 7.1%; kappa<sub>1</sub>: 2.4%; delta<sub>1</sub>: 4.1%; delta<sub>2</sub>: 5.6%) rats. The reduced weight loss was noted over the 7 day paradigm, and occurred despite greater magnitudes of intake reductions in Zucker rats following mu, mu<sub>1</sub> and delta<sub>2</sub> antagonism. Thus, Zucker rats defend weight better than lean littermates following chronic opioid receptor subtype antagonist treatment. (Supported by DA04194)

## 181.3

MODIFICATION OF DEPRIVATION, GLUCOPRIVIC AND PALATABLE INTAKE FOLLOWING OPIOID RECEPTOR SUBTYPE ANTAGONISTS IN THE VENTRAL TEGMENTAL AREA OF RATS. A. Ragnauth\*, H. Ruegg and R.J. Bodnar. Dept. of Psychol. and Neuropsych. Doc. Prog., Queens Col., CUNY, Flushing, NY 11367.

Selective mu, delta and kappa agonists in the ventral tegmental area (VTA) stimulate feeding. General and mu antagonism reduce deprivation, glucoprivic and palatable intake in either the hypothalamic paraventricular nucleus (PVN) or nucleus accumbens (NAcc). Kappa antagonism reduces all forms of intake in the PVN, and deprivation and glucoprivic intake in the NAcc. The present study examined whether general (naltrexone, 10-50ug), mu (beta-funaltrexamine, 1-4ug), kappa, (nor-binaltorphamine, 4ug), delta, ([D-Ala<sup>2</sup>, Leu<sup>5</sup>, Cys<sup>6</sup>]-enkephalin, 4-8 ug) or delta, (naltrindole isothiocyanate, 1-4ug) opioid antagonists in the VTA alter intake under either deprivation (24h), glucoprivic (2DG: 500 mg/kg) or palatable (10% sucrose) conditions. Deprivation intake was significantly reduced by general (23%, 2-4 h) and delta<sub>2</sub> (28%, 2 h) VTA antagonism. Glucoprivic intake was significantly reduced by delta<sub>2</sub> (39-69%, 0.5-4 h) and kappa, (33-54%, 0.5-4 h) VTA antagonism, and transiently reduced by general (1 h) and mu (1-2 h) VTA antagonism. Sucrose intake was significantly reduced by general (35-46%, 10-60 min) and delta, (19-44%, 5-60 min) VTA antagonism. Opioid antagonism in the VTA appears most effective for glucoprivic intake, and less effective for deprivation and palatable intake. (Supported by DA 04194)

CENTRAL INJECTION OF THE ORL-1 LIGAND, ORPHANIN FQ INCREASES FEEDING IN RATS. A.S. Levine\*, J.D. Pomonis, and C.J. Billington. Graduate Program in Neuroscience, Univ. of Minnesota and VA Medical Center, Minneapolis, MN 55417

It has long been known that opioids play a role in feeding behavior and that opioid antagonists decrease feeding induced by a variety of factors. Recently, orphanin fq (nociceptin), the presumed ligand for ORL-1, the orphan opioid receptor, has been purified and has been shown to have structural similarities with dynorphin A. It has also been shown to have very little activity at the classic opioid receptors. Similarly, the classic opioid peptides show very low levels of activity at ORL-1. In this experiment, we tested whether central administration of orphanin fq had any effects on feeding. Six male, Sprague-Dawley rats were fitted with cannulas into the lateral ventricle and were injected with either saline, 1 nmol, or 10 nmol orphanin fq, and food intake was measured for the two hours following injection. Injection of orphanin significantly increased food intake in both the low and the high doses when compared to saline administration [ $F(2,10)=5.019$ ,  $p=0.0309$ ]. Administration of 3mg/kg naloxone 20 minutes prior to ICV administration of 10 nMol orphanin fq, blocked the orphanin fq-induced increase in food intake [ $F(3,12)=4.515$ ,  $p=0.0243$ ]. These data suggest that orphanin fq shares at least one functional aspect with the classical opioid peptides, that being the ability to increase food intake. (Supported by NIH DA03999)

## 181.7

MULTIPLE INJECTIONS OF CHOLECYSTOKININ FAIL TO INDUCE A CONDITIONED, AVERSIVE SHIFT IN TASTE REACTIVITY RESPONSES IN RATS. L.A. Eckel\* and K.-P. Ossenkopp. Neuroscience Program, University of Western Ontario, London, Ontario, Canada, N6A 5C2.

The present study examined whether prolonging the pharmacological action of cholecystokinin (CCK) would promote aversive responses in rats exposed to a rapid gustatory conditioning paradigm. Over a 60 min test session, taste reactivity responses to 5 brief (30 s) oral infusions of a 0.30 M sucrose solution were monitored in rats following a single injection of lithium chloride (LiCl, 127 mg/kg, ip), or 5 injections of CCK (each 8 µg/kg, ip) or vehicle administered at 15 min intervals. Two days later, rats were tested for the development of a conditioned taste aversion (CTA). A conditioned, aversive shift in taste reactivity responses was observed in LiCl treated rats. In contrast, CCK treated rats showed an immediate, unconditioned decrease in ingestive responses that was not accompanied by an increase in aversive responses. Only the LiCl group showed evidence of a CTA. These results demonstrate that multiple injections of a moderate dose of CCK fail to produce the type of aversive internal cues responsible for conditioning a shift in taste reactivity responses and the subsequent production of a CTA. We conclude that these results are consistent with a satiety effect of CCK. (Supported by NSERC and MRC).

## 181.4

ANTISENSE OLIGODEOXYNUCLEOTIDES TARGETED AGAINST THE MOR-1 CLONE REDUCE HYPERPHAGIA INDUCED BY MU OPIOID AGONISTS IN RATS. L. Leventhal\*, G.W. Pasternak, G.C. Rossi and R.J. Bodnar. Dept. of Psychol. and Neuropsych. Doc. Prog., Queens Col., CUNY, Flushing, NY 11367.

Antisense oligodeoxynucleotides (AS ODN) targeted against the MOR-1 clone selectively reduce analgesia elicited by mu opioid agonists. MOR-1 AS ODNs also significantly reduce body weight and spontaneous food intake. The present study evaluated whether central pre-treatment over 5 days (Days 1, 3, 5) of AS ODNs (10 µg) directed against the 5' untranslated region of exon 1 of the MOR-1 clone altered hyperphagia induced by the selective mu opioid agonist, [D-Ala<sup>2</sup>, Me-Phe<sup>4</sup>, Gly-ol<sup>5</sup>]-enkephalin (DAMGO: 0.5-5 µg) administered 24 h after the last AS treatment (Day 6). All DAMGO doses significantly increased food intake after 2 and 4 h. MOR-1 AS ODNs significantly reduced the magnitude of DAMGO-induced hyperphagia following 0.5 and 1 µg doses after 2 (71-82%) and 4 (87-100%) h, but failed to alter hyperphagia following a 5 µg dose. The specificity of these actions was confirmed using the selective mu antagonist, beta-funaltrexamine to eliminate DAMGO (0.5-1 µg)-induced hyperphagia. These data extend MOR-1 AS ODN effects upon mu-mediated opioid agonist actions to ingestive behaviors, and further validate the use of antisense approaches as pharmacological and molecular tools in specifying functional effects. (Supported by DA 04194)

## 181.6

EFFECT OF U50488, A HIGHLY SELECTIVE KAPPA-OPIOID AGONIST ON BAR PRESSING FOR A SUCROSE REWARD. C. Barton\*, K. Stokes, S. Bilveu, and A. Armstrong. Department of Psychology, Tennessee Technological University, Box 5031, Cookeville, TN 38505.

Previous studies have suggested that selective opioid agonists and antagonists may act to modulate dietary macronutrient selection in rats. Specifically, it has been demonstrated that the kappa-opioid agonist U50488 stimulates consumption of meals high in fat, while the kappa-opioid antagonist nor-Binaltorphimine produces the inverse effect. The objective of this study was to investigate if U50488, a highly selective kappa-opioid agonist would stimulate bar pressing behavior rewarded by sucrose pellets in sucrose-sated rats. Cannulae were implanted into the lateral ventricle of 7 female Sprague-Dawley rats trained to bar press for 45 mg sucrose pellet rewards. Animals were injected with either U50488 (215, 21.5, or 2.15 nmoles/5 µl) or saline vehicle (0.9% w/v) using a randomized block, within subject design. Prior to testing animals were allowed unrestricted access to lab chow and were permitted to bar press for a 1 hr period prior to testing on a CRF schedule to receive sucrose pellets. Rats were then withdrawn from operant chambers, centrally injected, replaced into operant chambers, and bar pressing behavior as well as consumption of sucrose pellets were recorded for a period of 1 hr. The two highest doses of U50488 (215 & 21.5 nmoles) produced a significant increase in bar presses to obtain and consume sucrose pellets, as compared to saline controls. These findings suggest that the kappa-opioid receptor may not be specifically responsible for modulation of dietary fat macronutrient, but instead this receptor site may respond to agonists by stimulating rewarded behavior(s). This research was supported by funds from Tennessee Technological University.

## 181.8

A 35 AMINO ACID FRAGMENT OF LEPTIN INHIBITS FOOD INTAKE. W.K. Samson\*, T.C. Murphy, D. Robison, T. Vargas, E. Tau and J.-K. Chang. Physiology, UND School of Medicine, Grand Forks, ND 58202 and Phoenix Pharmaceuticals, Mt. View, CA 94043.

The 167 amino acid obesity gene related peptide, leptin, reverses hyperphagia in genetically obese animals and circumscribes feeding in normal animals. We attempted to identify the bioactive portion of the leptin molecule in feeding studies. Synthetic peptide fragments were injected either ip or icv into rats habituated to metabolic cages, after minimally three days of baseline data collection. Administration ip, once per day for two days, of the 116-167 fragment of leptin (15 µg) resulted in a slight but significant reduction in food intake at 24 and 48 hr. Central administration (3 µg) once per day for two days decreased food intake only after the second day of treatment. No receptor binding could be detected in CNS using I-125 labelled OBGRP 116-167. No significant effect on food intake was observed following injection of the 57-92 amino acid fragment of OBGRP. Similarly, injection of antiserum directed against the 57-92 aa fragment did not alter feeding suggesting that neither this fragment, nor a peptide fragment containing the 57-92 aa segment was bioactive. Finally we tested more N-terminally located fragments and observed significant, dose-related inhibition of food intake with the 22-56 aa fragment of OBGRP. A 25% decrease in intake was observed after icv 500 ng OBGRP 22-56 and a 45% decrease following 1000 ng. These data suggest that a small, readily synthesized fragment of the 167 aa peptide leptin can exert physiologically relevant satiety effects in brain.\*Funding

## 181.9

**CTAP REDUCES NPY- AND DEPRIVATION-INDUCED FEEDING AND THE ANTINOCICEPTIVE EFFECTS OF MU-OPIOIDS IN RATS.** D.C. Jewett\*, D.L. Totzkay, A.L. Shabazz, P. Sacchetti, R.R. Witte II and A.M. Young. Dept. of Psychol., Wayne State Univ., Detroit, MI 48202.

Opioid antagonists reduce deprivation- and NPY-induced feeding in a variety of species. Yet, the role of opioid receptor types in feeding regulation is unclear. The effects of CTAP, a peptidic antagonist selective for mu-opioid receptors, were studied in rats following 24-hr food deprivation [DEP] or intraventricular (i.c.v.) injection of NPY. DEP produced a 5-fold increase in food intake. CTAP (1-10 µg; administered 15 min prior to food access) dose-dependently reduced DEP-induced feeding. In non-restricted rats, NPY (5 µg) produced a 6-fold increase in food intake. CTAP also dose-dependently reduced NPY-induced feeding. The findings that CTAP is equipotent in reducing NPY- and DEP-induced feeding in rats is consistent with findings in other species (Jewett & Woods, 1995), and support further a role for mu-opioid receptors in NPY- and DEP-induced feeding. The ability of CTAP to antagonize the antinociceptive effects of mu-opioid agonists (morphine [MS] and DAMGO) was also assessed in the warm-water, tail withdrawal assay. Both MS and DAMGO dose-dependently increased tail-withdrawal latencies. The antinociceptive effects of fully effective dose of MS (10 mg/kg) or DAMGO (1 µg, i.c.v.) were reversed by CTAP (1 µg, i.c.v.). When administered as a pretreatment, CTAP (1 µg) reduced the potency of both morphine and DAMGO by 10- to 32-fold. Taken together, these studies demonstrate that CTAP is a very effective mu-opioid antagonist in rats. [Supported by USPHS Grants DA03796, K02 DA00132 and GM08167]

## 181.11

**GLUCAGON-LIKE PEPTIDE-1 (7-36) AMIDE (GLP-1) ACTIVATES THE HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) AXIS OF RATS.** T. Wang\*, G.L. Edwards and C.A. Baile. Grad. Stud. Res. Ctr., The Univ. of Georgia, Athens, GA 30602.

GLP-1 was reported to reduce food intake (FI) of rats following injections into the 3rd cerebral ventricle (Nature 379:69-72, 1996). The objective of the present study was to investigate whether the same dose of GLP-1 that reduced FI influenced the HPA axis. Eighteen rats were surgically prepared with guide cannula into the 3rd ventricle. All rats responded by drinking at least 1.5 ml of water in 30 min following an injection of 100 ng angiotensin II in 5 µl artificial cerebrospinal fluid. In the first part of the study, FI and water intake were measured after 10 µg GLP-1 in 5 µl saline or 5 µl saline was injected into the 3rd ventricle at the beginning of the 12 hr dark phase. Cumulative FI of the GLP-1 treated rats (n=9), compared to that of the saline treated rats (n=9), was reduced from 1.0 g to 0.9 g (p=0.85), 2.2 g to 1.1 g (p=0.05), 4.3 g to 1.9 g (p<0.001), 5.9 g to 2.2 g (p<0.001), 22.4 g to 18.1 g (p<0.02), 28.4 g to 23.0 g (p<0.01) at 0.5, 1, 2, 3, 16 and 24 hr, respectively. Cumulative water intake was also decreased by GLP-1 treatment compared to saline treatment from 0.5 ml to 0.1 ml (p=0.23), 0.9 ml to 0.1 ml (p=0.16), 2.2 ml to 0.2 ml (p=0.04), 3.6 ml to 0.3 ml (p=0.01), 28.3 ml to 18.8 ml (p=0.04), 29.4 ml to 23.7 ml (p=0.23), respectively. In the second part of the study, the effect of GLP-1 on HPA axis activity was examined without food present. GLP-1 (10 µg in 5 µl saline), injected into the 3rd ventricle at the onset of the dark phase, increased plasma corticosterone concentration at 30 min post injection compared to saline treatment (347.5 ng/ml [GLP-1, n=7] vs. 247.6 ng/ml [saline, n=9] (p=0.05)). We conclude that GLP-1 decreases food intake and water intake and increases the activity of the HPA axis in rats. GLP-1 may have a role in control of ingestive behavior and regulation of the HPA axis. (Supported by The University of Georgia).

## 181.13

**CENTRAL INFUSION OF NEUROMEDIN B & GASTRIN-RELEASING PEPTIDE RECEPTOR ANTISENSE OLIGONUCLEOTIDES REDUCE ANXIETY, BOMBESIN (BN) BINDING, & BN-ELICITED BEHAVIORS.** H. Plamondon\*, T.W. Moody<sup>2</sup> and Z. Merali<sup>1,3</sup>

<sup>1</sup>Psychology & <sup>3</sup>Pharmacology, University of Ottawa, Ont. Canada K1N 6N5. <sup>2</sup>Biomarkers & prevention research branch, NCI, Rockville, MD 20850.

Central BN administration induces satiety and elicits intense grooming that can partially be reversed by gastrin-releasing peptide (GRP) receptor blockade. Furthermore, recent findings in our laboratory suggest a potential role of BN-like peptides in stress and anxiety. In the current study, antisense oligonucleotides to mRNA for GRP and neuromedin B (NMB) receptor subtypes were used to determine the physiological role of BN-like peptides. NMB and GRP antisense oligonucleotides were infused over 2 days into the 3rd ventricle via cannula attached to an osmotic pump, at the rate of 0.94 µg/0.5 µl/h. Spontaneous food intake was monitored as was their response to an acute BN challenge (0.25 µg; i.c.v.) on palatable food intake and grooming response. Rats were also tested on an elevated plus maze and trough-tunnel oval maze, to assess their anxiety level. In both the mazes, the rats treated with the antisense oligonucleotides spent significantly more time on the open or exposed (anxiogenic) fields, reflecting an anxiolytic effect of the treatment, as compared to saline or scrambled antisense-exposed animals. The controls responded to acute BN challenge with a marked increase in scratching response and a suppression of the test meal consumption. In rats exposed to the oligonucleotides, acute BN failed to suppress food intake or to elicit scratching. In vitro receptor autoradiography revealed that antisense oligonucleotide treatment resulted in a reduction (15-35%) of BN binding site density in various brain regions. These results implicate physiological participation of BN-like peptides in the control of appetite and anxiety. Supported by Medical Research Council of Canada.

## 181.10

**EFFECTS OF A NPY ANTAGONIST ON FEEDING IN RATS AND MICE.** J.N. Wiley\*, L.M. Georgic, J.L. Wright, R.G. MacKenzie, and T.G. Heffner. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105.

Because brain neuropeptide Y (NPY) may exert important influences on the regulation of feeding, we examined the effects of a putative NPY-Y<sub>1</sub> antagonist, (R)-BIBP 3226 (Karl Thomae Co.), on food intake in rodents. (R)-BIBP 3226 was found to have high affinity for displacing [125I]-PYY from NPY Y<sub>1</sub> receptors expressed natively in SK-N-MC cells (K<sub>i</sub> = 7.6 nM). When given IP at the start of the 12 h dark cycle, (R)-BIBP 3226 caused dose-related inhibition of food intake in non-deprived male Zucker obese rats. Doses of 3, 10, and 30 mg/kg IP reduced 2 h food consumption by 27, 57 and 88%, respectively, relative to vehicle-treated controls. The effect had diminished by 8 hours after dosing and was absent at 24 h. (R)-BIBP 3226 was also effective but less potent when given to normal male Sprague-Dawley rats: doses of 3, 10, and 30 mg/kg IP reduced feeding by 0, 41, and 73%, respectively at 2 h post dose. Only the 30 mg/kg dose continued to have an effect for 8 h. (R)-BIBP 3226 given ICV reduced feeding in CD-1 albino mice: total doses of 10 and 30 µg ICV inhibited consumption by 63 and 94%, respectively, at 2 h post dose, effects that diminished by 6 h. In an attempt to further link the effects on feeding to NPY receptors, the (S)-enantiomer of BIBP 3226, which lacks affinity for NPY Y<sub>1</sub> receptors (K<sub>i</sub> >1,300 nM), was also tested. (S)-BIBP 3226 (30 mg/kg IP) reduced feeding in Zucker obese rats by 100% at 2 h, by 76% at 8 h, and by 83% at 24 h post dose. These data suggest that effects other than those on NPY receptors may account for the effects of the enantiomers of BIBP 3226 on feeding. (Supported by Warner-Lambert.)

## 181.12

**THE INHIBITORY EFFECT OF GLUCAGON-LIKE PEPTIDE-1 (GLP-1)(7-36) AMIDE ON FOOD AND WATER INTAKE IN RATS IS ABOLISHED AFTER NEONATAL TREATMENT WITH MONO-SODIUM GLUTAMATE (MSG).** M TANG-CHRISTENSEN<sup>1</sup>, S SHEIKH<sup>2</sup> and P.J. LARSEN<sup>1</sup> Medical Anatomy, section B and <sup>2</sup>Clinical Biochemistry, University of Copenhagen, Blegdamsvej 3, 2200 Copenhagen, Denmark.

Central administration of the gastrointestinal hormone Glucagon-Like-Peptide 1 (GLP-1) (7-36) amide inhibits food and water intake in hungry rats and the inhibitory effect upon water intake is also elicited by peripherally (ip) administered GLP-1. Furthermore GLP-1 inhibits angiotensin II (AII)(icv) induced drinking, both after ip and icv administration. By use of receptor autoradiography we have found wide distribution of central binding sites for [125]-GLP-1 including the subfornical organ (SFO) and the arcuate nucleus. These nuclei are involved in drinking and feeding behaviour in the rat. By far the majority of the SFO possesses no bloodbrain barrier, leaving this area accessible for hu-moral stimulation via the vascular system. It is our hypothesis that the SFO is involved in the GLP-1 induced inhibition of drinking elicited by thirst or AII whereas the arcuate nucleus (ARN) is involved in GLP-1 induced inhibition of food intake in hungry rats. To test this hypothesis we subjected neonatal wistar pups to excessive doses of subcutaneously administered mono-sodium-glutamate (MSG). Neonatal MSG-treatment infers profound lesions of the circumventricular organ, including part of the SFO and the ARN. The inhibitory effect of GLP-1 upon feeding was completely abolished in MSG-rats. Furthermore we found that the AII induced drinking response was preserved in MSG rats. However, only icv injection of GLP-1 abolished AII induced drinking while peripheral administration (ip) of GLP-1 did not inhibit AII induced drinking behaviour. Thus, it is evident that GLP-1 can modulate feeding and drinking behaviour. Further, that the ARN could be responsible for the GLP-1 inhibition of food intake and the SFO is a possible site of action for the inhibitory effect of the drinking response.

## 181.14

**MEAL-CONTINGENT INFUSION OF GASTRIN-RELEASING PEPTIDE 1-27 REDUCES MEAL SIZE AND INTERMEAL INTERVAL AND INCREASES THE SATIETY RATIO IN SPONTANEOUSLY FEEDING RATS.** P. A. Rushing\*, R. Henderson, and J. Gibbs. Bourn Laboratory, New York Hospital-Cornell Medical Center, White Plains, NY 10605 and Psychology Department, The Florida State University, Tallahassee, FL 32306-1051

We have recently reported that brief, meal contingent infusion of gastrin-releasing peptide, 1-27 (GRP) reduces spontaneous feeding in rats. However, only one dose (5 nmol/kg) was investigated. The present study explored the effects of a range of doses of GRP using a new system designed to examine spontaneous feeding in rats consuming a liquid diet. Undisturbed, *ad lib*-fed (milk) male rats (n = 4) with chronic inferior vena caval catheters were infused with saline and each of 3 doses (5, 10, and 20 nmol/kg) of GRP in counterbalanced order. Infusions were activated at the onset of the first nocturnal meal and continued for 2 min (60 µl/min), with delivery of peptide during the first minute. Infusions and recording of meal data (licks) were fully automated and computer-controlled.

	0†	5	10	20
Meal Size (licks)	1337 ± 254	534 ± 174*	479 ± 150*	284 ± 66*
Meal Duration (min)	285 ± 27	107 ± 30*	105 ± 33*	58 ± 8*
Intermeal Interval (min)	72 ± 5	53 ± 7*	40 ± 4*	40 ± 5*
Satiety Ratio (min/licks)	.06 ± .01	.13 ± .04	.10 ± .03	.16 ± .02*

† nmol/kg GRP. \* Significantly different from 0 nmol/kg, p < .05.

All doses of GRP significantly reduced the size and duration of the first nocturnal meal and shortened the interval from the end of the first meal to the onset of the next. Despite this, the satiety ratio (interval/meal size) tended to increase after GRP and was significantly increased by the highest dose. These results show that brief, meal-contingent intravenous infusion of GRP potently inhibits spontaneous feeding in undisturbed rats. Supported by USPHS grants MH18390 (PAR), DK33248 (JG).

## 181.15

PREGASTRIC AND GASTRIC STIMULI OF PREFEEDING ARE SUFFICIENT TO ENHANCE THE SATIATING EFFECT OF GASTRIN-RELEASING PEPTIDE<sub>1-27</sub>. J.M.Frennier, P.A.Rushing, C.Shamoian,\* and J.Gibbs. Bourne Laboratory, Dept. of Psychiatry, Cornell Medical Center, White Plains, NY 10605.

Prefeeding enhances suppression of food intake by peripherally administered gastrin-releasing peptide<sub>1-27</sub> (GRP; Kirkham et al, 1995). To identify the site(s) for this effect, we used an inflatable pyloric cuff to block gastric emptying and postgastric sites. Five male Sprague-Dawley rats implanted with cuffs were maintained on *ad lib* powdered chow and water. Rats received a 30-min test meal of high-carbohydrate liquid food under either Prefeed or No Prefeed conditions. In the Prefeed condition, the chow was removed, the cuffs were inflated, and rats were given a 3-min prefeed of a high carbohydrate diet (intake=7.45±0.5 ml). Fifteen minutes after the 3-min prefeed, rats received a 30-min test meal of the same liquid food. The No Prefeed condition was similar, but the 3-min prefeed was omitted. Five minutes prior to the 30-min test, in both conditions, animals were injected IP with saline vehicle, 14 µg/kg, or 21 µg/kg GRP.

	Saline	14 µg/kg GRP	21 µg/kg GRP
No Prefeed			
30-min intake (ml ± SEM)	24.2 ± 2.3	24.4 ± 3.0	20.6 ± 1.4
% Suppression		-1.3 ± 4.4	14.7 ± 4.1
Prefeed			
30-min intake (ml ± SEM)	13.7 ± 1.2	6.2 ± 1.3*	7.0 ± 1.8*
% Suppression		43.6 ± 12.1†	52.8 ± 15.9†

\* Significantly less than saline, † Significantly greater than No Prefeed

The enhanced suppression of intake produced by GRP after prefeeding with the cuff closed demonstrates that pregastric and gastric stimuli are sufficient to increase the satiating effect of GRP. [Supported by USPHS Training Grant MH18390 (PAR), and Research Grant DK33248 (JG)].

## 181.17

ANGIOTENSIN RECEPTOR BINDING IN RELATION TO SODIUM APPETITE. A.Morien\* and N.E.Rowland. Psychology Dept., University of Florida, Gainesville, FL 32611

Sodium appetite can be produced in rats by several procedures, including chronic low Na diet and administration of ANG I CEI (eg, enalapril, ENAL). These paradigms are known to produce changes in peripheral and central ANG II production. The purpose of the present study was to examine changes in ANG receptors in rat brain during these treatments. A second objective was to examine time-of-day effects. ANG II receptor binding was examined at four times: 2 & 8 hr after lights on and 2 & 8 hr after lights off. Three groups of male SD rats underwent two week treatment with (a) a mini-pump infusion of ENAL (3 mg/kg/day), or (b) a low Na diet (DIET, 0.03-0.05% Na), or (c) a normal diet (CONTROL, > 0.2% Na). Brains were sectioned, incubated with [<sup>125</sup>I]-SI-AII; alternate sections were blocked with losartan or ANG II. In the anterior circumventricular organs, ENAL increased binding and DIET tended to decrease binding, in relation to CONTROL. This may be related to the respective decrease and increase in plasma ANG II in these paradigms. Results from regions "downstream" of these organs showed greater binding in DIET and less binding in ENAL. A significant effect of TIME was evident in some regions. Grant: NIH-NRSA

## 181.19

THE HYPOPHAGIC EFFECT OF CCK-8S DEPENDS ON THE FEEDING CONDITIONS AND DIFFERS IN ADULT AND AGED RATS. M.Voits\*, J.P.Voigt, J.P.Huston\*, H.Fink. Institute of Pharmacology and Toxicology, Charité, Humboldt University, D-10098 Berlin, Germany; \*Institute of Physiological Psychology I, Heinrich-Heine University of Düsseldorf, Universitätsstr. 1 D-40225 Düsseldorf, Germany.

The sulphated cholecystokinin octapeptide (CCK-8S) regulates food intake in many species including humans by peripheral and central mechanisms. The majority of studies reported a hypophagic action of exogenous CCK-8S, but the results of the effect of CCK on food intake in humans are inconsistent. Besides the hypophagic action, CCK was shown to be involved in several other behavioral processes e.g., analgesia, anxiety and memory.

This study was performed to investigate the effect of CCK-8S on food intake under a fixed feeding condition in comparison to a test meal taken after 16h food deprivation in young (8 weeks old) and aged (23 months old) male Wistar rats. In the fixed feeding condition rats were adapted to a 4h feeding schedule for 4 days.

CCK-8S (8 and 40 µg/kg, i.p.) reduced the size of a test meal following 16h food deprivation significantly. This effect was independent of the age of the rats. However, under fixed feeding conditions neither of the doses used reduced food intake in the young adult rats, whereas the highest dose of 40 µg/kg did so in the aged rats. These results suggest that the hypophagic effect of exogenous CCK-8S depends on experimental conditions, being effective after a period of food deprivation but not under a fixed feeding regimen in adult rats. Furthermore, the data suggest that age is a factor contributing to the complex behavioral actions of CCK, since only old animals were more susceptible to the hypophagic action of CCK-8S. This may be explained by an interaction of other behavioral effects of CCK with its satiating action under the fixed feeding schedule. Supported by DFG (INK 231/A1-1).

## 181.16

BEHAVIORALLY SPECIFIC ENHANCEMENT OF THE SATIATING POTENCY OF GASTRIN-RELEASING PEPTIDE<sub>1-27</sub> BY ESTRADIOL. A.M.Cuomo, P.A.Rushing, J.Gibbs\*, and N.Geary. Bourne Laboratory, Dept. of Psychiatry, Cornell Medical Center, White Plains, NY, 10605.

Estrogen may cause the decrease in meal size during estrus by enhancing the actions of satiating peptides. To test this, 26 bilaterally ovariectomized, Sprague Dawley rats received either 0.1 ml 10 µg β-estradiol benzoate (EB) or the sesame oil vehicle subcutaneously at 0930h each Tues and Wed. The satiating potency of gastrin-releasing peptide<sub>1-27</sub> (GRP) vs saline (IP) was tested in crossover designs on consecutive Fridays. Test meals were 0.4M sucrose, and the prefeeding procedure of Kirkham et al. (Physiol Behav 58:1175, 1995) was used to maximize GRP's satiating potency.

Meal Size (ml)	Saline	5µg/kg	10µg/kg	21µg/kg
Oil	8.7 ± .09	6.8 ± 0.7*	5.8 ± 0.9	5.7 ± 1.2*
EB	8.4 ± .02	6.6 ± 1.3*	3.8 ± 0.8**	3.9 ± 0.6*
% Inhibition				
Oil	-	14 ± 16*	3 ± 20	46 ± 8*
EB	-	25 ± 14*	52 ± 10**	54 ± 8*

Values are mean ± SEM. \* compared to saline, \*\* compared to oil-treated, p<0.05.

In the 30 min between the prefeed and the test meal, EB-treated rats groomed significantly more (39 vs 25%; p<0.02) and rested significantly less (2 vs 18%; p<0.02) than oil-treated rats. GRP injection reduced meal size (Table), and 10 µg/kg GRP reduced meal size more in EB-treated than oil-treated rats. All rats displayed the full behavioral sequence of satiety after test meals. These data indicate that exogenous GRP has a specific satiating action on meal size in ovariectomized rats and that EB can increase the potency of this action. Increased satiating potency of GRP may be one mechanism mediating the effect of EB on meal size.

## 181.18

EFFECT OF ANGIOTENSIN (AT<sub>1</sub> AND AT<sub>2</sub>) ANTISENSE OLIGONUCLEOTIDES ON WATER DEPRIVATION INDUCED DRINKING. H.-B. Meng, E.-K. Yang, S.M. Galli, D.W. Walker\* and M.I. Phillips. Dept. of Physiology, Neuroscience, College of Medicine, University of Florida, Gainesville, FL 32610-0274 and Department of Physiology, Kyungpook National University, South Korea.

Water deprivation induced drinking is partially regulated by Ang II. There are conflicting data on the roles played by AT<sub>1</sub> and AT<sub>2</sub> receptor subtypes in water deprivation induced drinking by using different AT<sub>1</sub> and AT<sub>2</sub> antagonists. To resolve this issue we tested 15 mer length antisense oligonucleotides (AS-ODNs) designed against AT<sub>1</sub> and AT<sub>2</sub> receptor mRNA. Male Sprague-Dawley (SD) rats were cannulated in the lateral ventricle one day before the treatment. After i.c.v. injection of 50 µg/2 µl of AS-ODN or SC-ODN, rats were returned to cages and subjected to a 24 hrs period water deprivation. Then water bottles became available and the drinking response was monitored for 14 hrs (overnight). The control level of water intake was 51.3 ± 12.2 ml of water. The AS-ODN against AT<sub>1</sub> receptor significantly decreased the drinking response (21.925 ± 6.37 ml, P<0.01). The AS-ODN for AT<sub>2</sub> decreased the drinking response, but not significantly (43.3 ± 16.4 ml). The SC-ODN injected group showed no difference compared to saline control. In a receptor binding assay for rat brain tissue, both AS-ODNs specifically decreased the corresponding receptor subtype. The data show that AT<sub>1</sub> but not AT<sub>2</sub> is important in the drinking to water deprivation. We conclude that AS-ODN are useful in discriminating the role of two Ang II receptor subtypes as an alternative to pharmacological antagonists. (Supported by NIH HL27334).

ENDOGENOUS CHOLECYSTOKININ IN GASTRIC EMPTYING OF PEPTONE IN THE RAT. W. White, G.J. Schwartz, P.R. McHugh\* and T.H. Moran. Dept. of Psychiatry, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

The role of the brain/gut peptide cholecystokinin (CCK) in the control of gastric emptying of peptone solutions was studied. Awake male Sprague-Dawley rats were given intraperitoneal injections of 0, 10, 32, 100, 320, or 1000 µg/kg of the CCK A receptor antagonist L-364,718 (devazepide). Thirty minutes later they received, via gavage, a 5.0 ml intragastric infusion of 5.0% peptone solution, 12.5% peptone solution, or equimolar NaCl solutions. Ten minutes after infusion, stomach contents were withdrawn, and the volume of the remaining infused solution was measured. 5.0% peptone always emptied more quickly than 12.5% peptone. As the dose of the CCK A antagonist increased, the rate of emptying of both peptone concentrations appeared to increase in parallel and asymptotized at 100 µg/kg. A 0.9% saline solution emptied more quickly than either peptone concentration at any dose. Thus devazepide only partially reversed the slowed gastric emptying produced by peptone loads. Increasing the concentration (and so the osmolality) of the NaCl solution also slowed gastric emptying, but solutions of saline emptied substantially more quickly than equimolar solutions of peptone, and devazepide had no effect on emptying of NaCl solutions. Peptone appears to delay gastric emptying via at least two mechanisms, a CCK-dependent mechanism that is sensitive to protein content, and a CCK-independent mechanism that is sensitive to osmotic concentration. HUMAN OB PROTEIN INHIBITS NEUROPEPTIDE Y INDUCED FEEDING. F.J. Smith\*, L.A. Campfield, M. Renzetti, J. Yu, Dept of Metabolic Diseases, Hoffmann-La Roche Inc., Nutley, N.J. 07110.

Administration of OB protein (or leptin), the obese gene product, caused a long-lasting reduction in food intake and body weight in obese *ob/ob* mice. A major role for neuropeptide Y (NPY), a potent central stimulator of feeding, as a mediator of OB protein actions has been suggested. NPY secretion in vitro and elevated arcuate nucleus NPY mRNA levels were reduced by OB protein injections in obese *ob/ob* mice. To test this hypothesis, the effects of sequential central administration of human OB protein and exogenous NPY on the feeding behavior of obese *ob/ob* mice were examined. Chronic lateral ventricle infusion cannulas were implanted and, following recovery, free-feeding mice received two ICV injections: recombinant human OB protein (0.001-1 µg/mouse) or CSF contained in a volume of 1 µl followed one hour later by single doses of NPY (0.1-5 µg/mouse) or CSF. Central administration of OB protein, in a dose-dependent manner, partially or completely inhibited the expected feeding induced by exogenous NPY administration. These results indicate that OB protein can functionally antagonize the actions of exogenous NPY by either modulating the binding of NPY to its receptors critical for feeding or/and inhibiting downstream signal transduction. These studies provide evidence that the post-synaptic, receptor-mediated actions of NPY on feeding are under the control of OB protein. These results also imply that mediators, other than NPY, may also be involved in the biological actions of OB protein. Supported by Hoffmann-La Roche Inc.

## INGESTIVE BEHAVIOR: OTHER MEDIATORS

## 182.1

EFFECT OF FOOD INGESTION ON HYPOTHALAMIC SEROTONIN RELEASE IN NORMAL AND OBESE RATS E.B. Ribeiro\*, R.C.T. Mori, R.B. Guimarães and C.M.O. Nascimento, Dept. of Physiology, São Paulo Federal Univ. (UNIFESP), São Paulo, SP 04023-900, Brazil.

Serotonin (5-HT) exerts an inhibitory effect on food ingestion and may participate of the central mechanisms controlling satiety. The present study was aimed at evaluating, in normal and obese rats, the hypothalamic serotonin response to the stimulus provided by food ingestion. Obesity was induced in newborn male Wistar rats by monosodium glutamate (MSG, 2 mg/g/day, days 2-10 of life, sc.). At 3-4 months of age Control (C, n=7) and MSG (n=8) rats were implanted with microdialysis probes in the lateral hypothalamus. On the next day, after an overnight fast, 20 min microdialysate samples were collected to establish basal extracellular 5-HT levels. These were (Means ± S.E.M.)  $3.11 \pm 0.88$  and  $4.81 \pm 1.24$  pg/50 µl for C and MSG, respectively,  $p > 0.05$ . Food (powdered chow + water, 1:2) was then introduced in the cage and six additional 20 min samples collected. During the two hours after the food was available C rats consumed  $15.8 \pm 3.8$  g, 70% of this total within the first 40 min, corresponding to the two initial microdialysate samples. MSG rats consumed only  $7.8 \pm 0.9$  g, 78% of which during the first 40 min. 5-HT levels in microdialysates were significantly elevated from basal levels in the first two samples in both groups. The increments were of 46 and 68% in group C and tended to be higher (80 and 85%,  $p > 0.05$  vs. C) in MSG rats. No significant alterations occurred in 5-HIAA levels. The data suggest a higher serotonergic responsiveness to food in MSG rats, as indicated by the trend to a higher increment in 5-HT levels elicited by consumption of a significantly lower amount of food. Additionally, these proportionally high levels may have contributed to the lower food ingestion during the subsequent periods. Supported by a grant from FAPESP (Brazil).

## 182.3

BEHAVIOURAL ANALYSIS OF THE HYPOPHAGIC EFFECT OF IVTH VENTRICULAR INFUSION OF THE 5-HT<sub>1B</sub> AGONIST CP-93,129. M. D. Lee\* and K. J. Simansky, Dept Pharmacology, Medical Col. Pennsylvania and Hahnemann Univ., Philadelphia, PA 19129.

Previously we have shown that systemic administration of the pyrrolopyridine CP-94,253, a selective 5-HT<sub>1B</sub> agonist, reduces food intake and hastens the termination of meals (Lee and Simansky 1995) which suggests a role for 5-HT<sub>1B</sub> receptors in the control of ingestion. The structurally related compound CP-93,129, has no effect given systemically, but its administration into the area of the hypothalamic PVN causes anorexia (Macor et al. 1990). Rats implanted with 26g cannulae aimed to terminate more caudally, dorsal to the roof of the IVth ventricle 2.2mm anterior to the occipital crest suture, were treated with CP-93,129 (3µl/1min) at doses of 25 and 50 nmol. Consumption of a 10% sucrose solution was decreased by 32 and 44% with respect to saline controls ( $p < 0.05$ ). Time-sampling analysis revealed that non-feeding activity was reduced and standing increased, but meal duration was not affected. Microstructural analysis showed that lick number but not the efficiency of licking was reduced after the 50 nmol dose. These results using CP-93,129 as a probe, suggest that deep brainstem 5-HT<sub>1B</sub> receptors are involved in the inhibitory control of food intake. Currently we are performing autoradiographic binding studies of these receptors using <sup>125</sup>I-iodocyanopindolol in the presence of 8-OH-DPAT and isoproterenol, in order to localise sites into which CP-93,129 can be delivered directly. Supported by MH41987 to KJS.

## 182.2

STZ-DIABETES DECREASES HYPOTHALAMIC ATROPINE-INDUCED ACETYLCHOLINE INCREASE IN FREELY MOVING RATS. E. Murzi\*, P. Rada, M. Puig de Parada, B. Valecillos and L. Hernandez, Laboratory of Behavioral Physiology, Medical School, Los Andes University, Mérida, Venezuela.

Behavioral diabetic abnormalities such as polyphagia have been related to dopamine alterations (1,2). But polydipsia could also be attributable to cholinergic alterations (3). Ip. injections of atropine block the dipsogenic effect of intrahypothalamic administration of acetylcholine (ACh) or carbachol in normal rats (4). We evaluated the effect of atropine-induced ACh release on lateral hypothalamus (perifornical area, pfa) of normal or STZ-diabetic rats. Extracellular levels of ACh were measured in the pfa using microdialysis in 20-min intervals after ip. atropine sulfate (0, 5, 15, 25 mg/Kg). Seven normal or diabetic rats were used in each dose. Neostigmine was used in the perfusate to improve ACh recovery. ACh was measured by a reverse phase, HPLC with electrochemical detection system.

Preliminary results show that atropine-induced ACh increase was significantly lower in diabetic than normal rats. ACh increase was linearly related to the dose of atropine, but the slope of the curve was greater in the normal than in the diabetic rats. This result could be an alternatively explanation for the polydipsia seen in diabetes.

## 182.4

ACUTE AND CHRONIC FLUOXETINE SELECTIVELY SUPPRESSES FAT INTAKE IN FEMALE RATS. L.K. Heisler and R.B. Kanarek\* Psychology Department, Tufts University, Medford, MA 02155.

Fluoxetine hydrochloride is one of the most frequently prescribed antidepressants and is taken by more women than men. Fluoxetine is associated with a reduction in food intake and body weight and is under investigation as a possible treatment for obesity. Fluoxetine acts by blocking the reuptake of serotonin into the presynaptic nerve terminal. It has been hypothesized that the increased availability of serotonin should lead to a selective suppression of carbohydrate consumption through a biobehavioral feedback mechanism. To examine the acute effect of fluoxetine on macronutrient selection, 14 female Long-Evans rats were provided with separate sources of fat, protein, and carbohydrate. After a 2-week acclimation period, animals were injected at the beginning of the dark cycle with 0.0, 5.0, 10.0, or 15.0 mg/kg fluoxetine (IP), and food and water intakes were recorded at 2, 4, 6, and 24 hours post-injection. Fluoxetine significantly suppressed fat intake in a dose-dependent manner at all time points. Protein and water intakes were also reduced in a dose-dependent manner (n.s.). The effect of fluoxetine on carbohydrate intake was minimal. To examine the chronic effect of fluoxetine, baseline macronutrient intakes were collected for 21 days, after which 12 rats were given 10.0 mg/kg fluoxetine and 7 rats were given distilled water (IP) daily at the beginning of the dark cycle for 28 days. Food and water intakes were recorded daily during baseline, drug, and a 28-day withdrawal period. Fluoxetine-treated animals significantly suppressed fat, protein, and water intake and gained significantly less weight than controls. Fluoxetine-treated animals actually increased carbohydrate intake, while control animals decreased carbohydrate intake during the drug and withdrawal phases, producing a significant interaction. Food intake was also suppressed when rats were in estrus; however, no interaction was found between cycle and fluoxetine treatment for macronutrient selection. The observed significant suppression of fat after acute and chronic fluoxetine questions the proposed selective effect of serotonergic drugs on carbohydrate intake.

## 182.5

ENDOCRINE EFFECTS OF NEUROLEPTICS AND BODY WEIGHT GAIN: A STUDY IN NORMAL FEMALE SUBJECTS. T. Baptista\*, J. Calanche, M. de Quijada, O. Contreras, J.L. Martinez, L. Tencud, and L. Hernández. Department of Physiology, Medical School, Universidad de los Andes, POB 109, Mérida, 5101-A, Venezuela.

Weight gain and obesity is an important side effects of neuroleptic agents afflicting up to 50% of patients under chronic treatment. Drug-induced hyperprolactinemia has been proposed as the triggering factor of weight gain, by decreasing estradiol serum levels, which in turn impairs the functioning of satiety-related neurons in the ventromedial-paraventricular hypothalamus. Testing this hypothesis in psychiatric patients has been hampered by preexisting endocrine abnormalities independent from drug treatments. We administered Sulpiride ( $n = 17$ ) or placebo ( $n = 13$ ) to healthy women after a menstrual cycle in which serum levels of pituitary gonadotropins, gonadal and adrenal steroids, prolactin, cortisol, thyroid hormones and insulin under the curve of glucose tolerance were assessed during the follicular and luteal phases. During treatments, hormones were reevaluated the same day as in the first cycle. Body weight gain and appetite were also controlled. During Sulpiride treatment, a significant decrease was observed in estradiol and progesterone levels in the late follicular and luteal phases; follicle-stimulating hormone was significantly increased during the early follicular phase; prolactin was significantly increased during all the cycle; glucose was significantly increased and insulin tended to decrease. Except a mild increase in prolactin, none of these changes were observed in the placebo group. A mild, non-significant increment in body weight and appetite was observed during Sulpiride administration. The results suggest that changes in gonadal steroids observed during neuroleptic administration, if prolonged, may explain the excessive weight gain and obesity. Supported by CDCHT, ULA, Venezuela, Grant M-493-94.

## 182.7

EFFECTS OF CHRONIC CARBAMAZEPINE ON BEHAVIOR AND LIPID METABOLISM IN RATS. B. Culver\*, D.C. Rule, and F.W. Flynn. Neurosci. Prog., Depts of Pharmacology, Animal Science, and Psychology, Univ. of Wyoming, Laramie, WY 82071.

Weight gain has been reported in patients following chronic use of carbamazepine (CBZ) and is a major cause of non-compliance. We evaluated behavioral and lipid metabolic effects of chronic administration of CBZ (100-200mg/kg, gavaged twice daily for up to 8 wks) to rats. Body weight was not significantly altered by CBZ. Locomotor activity of CBZ rats was reduced during the exploratory period but not during nocturnal or nonexploratory periods. Lipoprotein lipase activity in adipose tissue of CBZ-treated rats was  $259 \pm 77\%$  of controls ( $62 \pm 23$  vs  $24 \pm 3$  neq fatty acid released/ (g x min)). Glucose conversion to total triacylglycerols of CBZ-treated rats was  $145 \pm 12\%$  and  $152 \pm 34\%$  of controls in liver and adipose tissue, respectively. Lipolytic rate in adipose tissue was increased above basal by  $1 \mu\text{M}$  isoproterenol to a greater extent in the control ( $3.9 \pm 1.2$  mmol glycerol released/(g x hr)) than in CBZ-treated rats ( $2.2 \pm .5$ ). We conclude that CBZ treatment increases lipogenesis and may blunt the lipolytic response to catecholamine in adipose tissue.

## 182.9

HISTAMINERGIC ACTIVATION OF ENDOGENOUS ANGIOTENSIN II FAILS TO AFFECT ALCOHOL INTAKE IN RATS. E.S. Kraly\* and K.M. Jones. Dept. of Psychology, Colgate Univ., Hamilton, NY 13346.

Subcutaneous (SC) injection of angiotensin II (Ang II) has been demonstrated to inhibit ingestion of alcohol in rats having daily access to ethanol (Grupp & Harding, Pharmacol. Biochem. Behav. 47: 385-392, 1994). We investigated the involvement of endogenous Ang II for ingestion of alcohol in adult male Sprague-Dawley rats maintained with limited (45-min) daily access to 3% ethanol, made available at the mid-point of the dark phase of a 12:12 light/dark cycle. Activation of the renal renin-angiotensin system (RRA) was accomplished with SC injection of histamine diphosphate (H): 0.3 mg/kg (threshold dose for decreased latency to initiate drinking of water) and 1.25 mg/kg (threshold dose for increased water intake) H elevated ( $p < 0.01$ ) plasma renin activity (PRA) at the time that ingestion of water is initiated. Despite the ability of these doses of H to stimulate drinking of water and increase PRA, these doses of H failed to inhibit ( $p > 0.20$ ) ingestion of alcohol in one-bottle tests. A 10 mg/kg dose of H increased ( $p < 0.05$ ) alcohol intake in a one-bottle test, but this effect of H appeared to be secondary to the dipsogenic effects of H because in two-bottle tests 10 mg/kg H decreased ( $p < 0.05$ ) intake of alcohol while increasing ( $p < 0.001$ ) water intake. A 10 mg/kg SC dose of the AT1 receptor antagonist losartan, sufficient to abolish drinking elicited by SC Ang II, failed to affect alcohol intake in one- or two-bottle tests ( $p > 0.20$ ). These findings do not support a role for endogenous Ang II for ingestion of alcohol in rats for two reasons: First, histamine-induced pharmacological activation of RRA was not sufficient to inhibit ingestion of alcohol. Second, losartan-induced pharmacological blockade of AT1 receptors for Ang II was not sufficient to increase ingestion of alcohol. (Supported by NIH grant NS19133.)

CENTRAL UK-14,304 AND IMIDAZOLACETIC ACID AND HYDROSALINE INTAKE. T.T. Miguel, A. Renzi, J.V. Menani and L.A. De Luca Jr. Dept. of Physiological Sciences, School of Odontology - UNESP, Araraquara, São Paulo, Brazil.

Clonidine, an  $\alpha_2$ -adrenergic agonist that also binds to imidazolic receptors, inhibits salt and water intake when injected into the brain. In the present work we test the effect of intracerebroventricular (ICV) injection of UK-14,304, a specific agonist of  $\alpha_2$ -adrenergic receptors that does not bind to imidazolic receptors, and the ICV injection of imidazolacetic acid, which binds to only imidazolic receptors. UK-14,304 (5, 10, 20 and 40 nmol/ $\mu\text{l}$ ) or imidazolacetic acid (40 nmol) was injected into the 3rd cerebral ventricle of adult male rats ( $n = 6/\text{group}$ ) submitted to either sodium depletion (furosemide + 24-hour removal of ambient sodium) or 24 hour of water deprivation. Animals that received ICV vehicle (propyleneglycol) injection ingested  $7 \pm 1$  ml/120 min of 3% NaCl or  $16 \pm 2$  ml/120 min of water. UK-14,304 induced a dose-dependent inhibition (from 20 to 70%) of 3% NaCl and of water intake in sodium deplete and water deprived animals, respectively. Imidazolacetic acid did not alter 3% NaCl or water intake. The results are consistent with an inhibitory role of  $\alpha_2$ -adrenergic receptors on hydromineral fluid intake and suggest that the inhibitory effect of clonidine is not through imidazolic receptors.

Reversal of fenfluramine and fluoxetine anorexia by 8-OH-DPAT is attenuated following raphe injection of 5,7-dihydroxytryptamine. P.J. Currie\*, D.V. Coscina, and P.J. Fletcher. Section of Biopsychology, Clarke Institute of Psychiatry, Toronto, ON, M5T 1R8 and Department of Psychology, Wayne State University, Detroit, MI, 48202

Injections of 5-HT, its agonists or uptake inhibitors have been shown to reduce food intake by directly or indirectly activating serotonergic receptors. In the present study we examined the effects of the 5-HT<sub>1A</sub> agonist 8-OH-DPAT on the feeding suppressant action of the indirect 5-HT agonists fenfluramine (FEN) and fluoxetine (FLU), as well as the 5-HT<sub>1B/2C</sub> agonist TFMPP. 8-OH-DPAT was administered 5 min prior to FEN, FLU or TFMPP, injected 30 before access to a palatable wet mash diet. While FEN (0.625-2.5 mg/kg), FLU (2.5-10 mg/kg) and TFMPP (0.5-2 mg/kg) dose-dependently reduced 2 hr food intake, 8-OH-DPAT (62.5-250  $\mu\text{g/kg}$ ) stimulated eating. Pretreatment with 8-OH-DPAT also reversed the anorectic action of FEN and FLU but not TFMPP. Separate groups of rats were then treated with 5,7-dihydroxytryptamine (5,7-DHT), administered into both the dorsal and medial raphe, resulting in extensive 5-HT depletion in hypothalamus (80%), striatum (90%) and hippocampus (90%). In both sham injected and 5,7-DHT (3  $\mu\text{g}$  free base) treated rats, FEN and FLU were found to suppress feeding. In 5,7-DHT treated rats, however, the ability of 8-OH-DPAT to either stimulate eating or block FEN and FLU induced anorexia was attenuated. These findings confirm that widespread depletion of brain 5-HT has little impact on the anorectic capacity of either FEN or FLU. In contrast, the reversal of FEN and FLU induced anorexia by 8-OH-DPAT is at least partially dependent on the integrity of brain 5-HT systems since their disruption compromises the ability of this 5-HT<sub>1A</sub> agonist to antagonize the feeding suppressant action of both compounds. (Supported by MRC and NSERC).

METABOLIC "MEMORIES": ENCODING BY THE RAT, SELECTIVE ACTIVATION BY LIPOPRIVATION, AND MEDIATION BY VAGAL AFFERENT FIBERS. T. L. Davidson, A. M. Altizer, E. K. Wallis\*, M.-C. Holst, S. C. Benoit, & T.L. Powley. Dept. of Psychological Sciences, Purdue Univ., West Lafayette, IN 47907.

Our research addressed three questions: (1) Can rats form distinct memorial representations of fats and carbohydrates? (2) Is activation of these metabolic "memories" selectively enhanced by lipoprivation or glucoprivation? (3) Does this selective enhancement involve vagal afferent pathways? In Experiment 1, rats ( $n = 8$ ) learned that one conditioned stimulus (CS) signaled delivery of peanut oil and another signaled delivery of sucrose pellets. The identity of the CSs (10 sec tones or lights) was counterbalanced for each unconditioned stimulus (US). Following CS training, the rats received additional trials in which only the USs were presented. Ingestion of one US (oil for half the rats and sucrose for half) was followed by toxicosis induced by LiCl. Ingestion of the other US was followed by saline injection. Next, US delivery was suspended and the capacity of each CS to promote conditioned responses (i.e., approach to the food cup) was assessed. Conditioned responding was abolished only for the CS that signaled the poisoned US. This result indicates that the rats formed distinct representations of each US. In Experiment 2, all rats ( $n=24$ ) were food sated following CS training. Then Group MA was injected with 400  $\mu\text{mol/kg}$  of the lipid anti-metabolite Na-2-mercaptoacetate (MA). Group 2-DG was injected with 350 mg/kg of the glucose anti-metabolite 2-deoxy-d-glucose. Group SAL received isotonic saline. During testing (without USs) Group MA showed reliably ( $p < .05$ ) more responding to the CS that previously signaled oil than to the CS that signaled sucrose. No differences between CSs were observed for either Group 2-DG or SAL. Experiment 3 found that this capacity of MA to augment responding to a CS that signaled oil was abolished for rats ( $n=8$ ) that received subdiaphragmatic vagal deafferentation but not for sham-lesioned controls ( $n=8$ ). Vagal deafferentation had no reliable effect on performance during CS training. These results suggest that vagal afferents mediate the capacity of lipoprivacy signals to selectively activate the memorial representations of fat USs. This research was funded by grants from the National Institutes of Health.

**aODN TO THE MBK1 GENE CODING FOR K<sup>+</sup> CHANNEL STIMULATES FOOD INTAKE IN MICE** A. Pecori Vettori, C. Ghelardini, N. Galeotti, S. Capaccioli, A. Quattrone and A. Bartolini Depts of Pharmacology and Pathology, University of Florence, Italy, SPON: Eur. Neurosci. Ass.

Ashford et al. (1989, 1990) and Boden et al. (1989) have reported that the enhancement of plasmatic levels of glucose induced a depolarization of rat hypothalamic neurones by modulation of ATP-sensitive K<sup>+</sup>-channels. To further investigate the role of K<sup>+</sup>-channels as an intracellular effector in the regulation of food intake, the effects produced by antisense-mediated switching off of the K<sup>+</sup>-channel expression were examined in mice. A specific aODN targeting the translation start region of the MBK1 K<sup>+</sup>-channel mRNA was designed. Mice were randomly assigned to an antisense, degenerated or vehicle group. Each group received a single i.c.v. injection on days 1, 4 and 7. The effect of the aODN treatment was evaluated 72 h and 7 days after the last i.c.v. injection by measuring the food assumption in mice. The aODN (1-3 nmol per injection) produced, at 72 h, an increase in food intake whereas the dose of 0.5 nmol per injection did not produce any effect. The orectic efficacy of aODN was comparable to those produced by aurothiogluconase (200 µg per mouse i.c.v.) and 2-deoxyglucose (200 µg per mouse i.c.v.) and greater than that induced by NPY (0.5 µg per mouse i.c.v.). The degenerated and vehicle treatments did not modify mouse feeding in comparison with naive and saline i.c.v. injected mice. A quantitative RT-PCR study demonstrated a reduction of mRNA levels only in the aODN treated group indicating the absence of an aspecific sequence-independent action on cerebral structures. Mice receiving the aODN treatment did not show any modification of spontaneous motility and inspection activity as revealed respectively by the Animex apparatus and the hole-board test. The integrity and functionality of the central K<sup>+</sup>-channels is, therefore, fundamental in the regulation of the mouse food intake.

This work was supported by grants from MURST.

## 182.13

**EARLY ENVIRONMENTAL MANIPULATIONS AND/OR CAPSAICIN TREATMENT PERMANENTLY ALTER ENDOCRINE AND INGESTIVE RESPONSES TO BOMBESIN.**

Z. Merali<sup>1,2</sup>, P. Kent<sup>1</sup>, D. Michaud<sup>1</sup>, & H. Anisman<sup>1</sup>

<sup>1</sup>School of Psychology & <sup>2</sup>Dept. of Pharmacology, University of Ottawa; <sup>3</sup>Institute of Neuroscience, Carleton University, Ottawa, Ontario, Canada.

Inasmuch as intra-individual variability exists in the ingestive patterns, and pharmacological responses to satiety peptides, this study was undertaken to elucidate whether neonatal handling and/or chemical deafferentation (using capsaicin) altered adult ingestive and endocrine responses to bombesin (BN). On day 2 of life, capsaicin (50 mg/kg; s.c.) was administered to rats (C) whereas the controls received vehicle (V). The groups were then subdivided into those that were handled (H) (for 1 min daily, for over 21 days) or those that were not handled (NH). The final group consisted of rats that were never injected, or handled (no treatment; NT). On day 40, the performance of rats on the elevated plus maze was assessed. The CH and VH groups spent significantly more time on the open arms, indicating that handled rats were less "anxious" than those that were not handled. Next, the rats were food deprived for 18 h, injected with BN (0, 4, and 8 µg/kg; i.p.) and their food intake monitored. BN dose-dependently suppressed food intake in NT group. The BN effect was slightly attenuated in VH and VNH groups. In the capsaicin treated rats, BN-elicited satiety was markedly blunted in the NH group and was completely blocked in handled rats. Handling also blunted BN-elicited ACTH increase and this effect was eliminated by capsaicin treatment. Finally, handled rats showed a potentiated corticosterone response to BN, which was attenuated in the CH group. It can be concluded that 1) both neonatal handling and capsaicin-treatment attenuate the satiety effects of BN, 2) these effects are additive, and 3) systemic BN mediates its effects neurally, through the capsaicin-sensitive myelinated A-δ and/or unmyelinated C-fibers of the primary afferent fibers. Supported by Medical Research Council of Canada.

**DIFFERENTIAL FEEDING-INHIBITORY EFFECTS OF PERIPHERAL AND CENTRAL CYTOKINE ADMINISTRATION IN ZUCKER OBESE (fa/fa) AND LEAN (Fa/Fa) RATS.**

J.R. Vasselli, C.R. Plata-Salamán, H.R. Kissileff\*, D. Casey, and G. Sonti. St. Luke's-Roosevelt Hosp., New York NY 10025 and Univ. of Delaware, Newark, DE 19716-2590.

The expression and release of TNF-α has recently been found in the adipose tissue of both rats and humans, and increases with increasing adipocyte size/mass. Also, central injections of this and other cytokines are known to potently inhibit feeding in normal rats. To test the feeding-inhibitory effects of cytokines in genetically obese rats, we injected rmTNF-α i.p. at the start of the dark cycle into 15-wk old male obese and lean rats at doses of 0 (saline), 50, 100, and 150 µg/kg body weight. Intake was monitored at 2, 4, 6, 8 and 24 hrs. Dose-dependent reductions of obese and lean intake were observed from hrs 6-24 (p < 0.01), with obese twice as responsive to the feeding-inhibitory effects of TNF-α as lean rats. We next tested the effects of intracerebroventricular infusions of IL-1 (1.0, 4.0, and 8.0 ng/rat), TNF-α (50, 100 and 500 ng/rat), and IL-1 (1.0 ng) + TNF (100 ng) in a similar feeding protocol. All doses of IL-1 and TNF-α, and their combination, inhibited feeding in obese and lean rats (p < 0.01), with IL-1 significantly more potent than TNF-α. Obese rats were twice as responsive to the feeding-inhibitory effects of IL-1, and to the combination of IL-1 + TNF-α (p < 0.01). We conclude that cytokines of peripheral origin may serve as feeding-inhibitory signals when elevated in association with the development and/or maintenance of the obese state. ## 182.12

**POSSIBLE INVOLVEMENT OF NITRIC OXIDE IN GLUCOPRIVIC FEEDING IN THE MOUSE.** D.A. Czech\* Department of Psychology, Marquette University, Milwaukee, WI 53201

Nitric oxide (NO) has been implicated in ingestive behaviors in several animal species. We recently observed that the NO synthase (NOS) inhibitor L-NG-nitro arginine (L-NOARG) reliably attenuated chlordiazepoxide-induced food intake in mice in a dose-related manner. The current study probes an effect of L-NOARG on a feeding stimulatory action of insulin (INS) and 2-deoxy-D-glucose (2-DG).

In expt.1, male ICR mice were injected s.c. with several doses of L-NOARG or 0.9% NaCl vehicle (Veh). Forty-five min later, 5 U/kg of INS or 500 mg/kg of 2-DG was administered i.p. Nine groups were thus formed: Veh/Veh (baseline intake control) and eight groups given doses of L-NOARG (0 [Veh], 10, 25 or 50 mg/kg) along with INS or 2-DG. Mice were then placed in a test cage containing a preweighed rodent chow pellet held in a wall-mounted "food clip;" tap water was available *ad lib*. Pellet was weighed at 30, 60, 120 & 240 min, and cumulative food intake at each measurement point was separately evaluated with randomized one-way ANOVAs, along with Dunnett's and Student's *t*-tests; alpha level was set at p < 0.05. A robust INS-induced hyperphagia was attenuated in a dose-related manner, reaching statistical significance at all doses of L-NOARG by 30 min. A marginal and transitory 2-DG feeding action was also attenuated.

In expt.2, mice were injected s.c. with 25 mg/kg of L-NOARG, along with 500 or 1000 mg/kg i.p. of the natural NOS substrate, L-arginine (L-arg), or 500 mg/kg of the inactive isomer, D-arginine (D-arg). INS (5 U/kg) was injected i.p. 45 min later. Food intake was monitored as in expt.1. Data were evaluated with Duncan's multiple range tests. L-arg partially, but significantly, reversed an L-NOARG attenuation of INS-induced hyperphagia; D-arg was without significant effect, reflecting a stereospecific action.

These data are consistent with and extend previous research reporting inhibitory action of L-NOARG on feeding behavior in several small animal models, and provide further support for some involvement of NO in feeding mechanisms.

## 182.14

**CAPSAICIN TREATMENT INCREASES STIMULATED FLUID INTAKE BY RATS.** K.S. Curtis<sup>1</sup>, J.G. Verbalis<sup>2</sup>, and E.M. Stricker<sup>1</sup>. Departments of <sup>1</sup>Neuroscience, Univ. Pittsburgh, Pittsburgh, PA 15260 and <sup>2</sup>Endocrinology, Georgetown Univ. School of Medicine, Washington D.C. 20007.

These studies examined stimulated fluid intake by rats in which vagally-mediated signals of gastric distension were eliminated by systemic treatment with the neurotoxin capsaicin, as verified by the loss of cholecystokinin-induced inhibition of food intake. Administration of hypertonic NaCl ip stimulated greater water intake by capsaicin-treated rats than by intact rats (13.1 ± 1.3 ml/3 h vs. 8.0 ± 1.0 ml/3 h; n = 17, 8). Capsaicin-treated rats also drank more water than did intact rats when isosmotic hypovolemia was induced by sc administration of a hyperoncotic colloidal solution (22.4 ± 1.9 ml/3 h vs. 12.4 ± 1.1 ml/3 h; n = 10, 7). Similarly, after overnight food deprivation, intake of a 10% sucrose solution by capsaicin-treated rats was greater than that by intact rats (38.6 ± 2.5 ml/30 min vs. 26.7 ± 2.5 ml/30 min; n = 11, 7). Finally, during chronic administration of the mineralocorticoid deoxycorticosterone acetate, capsaicin-treated rats consumed more of a concentrated NaCl solution than did intact rats (18.7 ± 1.7 ml/3 h vs. 12.1 ± 2.4 ml/3 h; n = 11, 8). In all tests, intakes by capsaicin-treated rats were significantly greater than those by intact rats within 5-15 min. These results suggest that early signals of gastric distension, such as those that occur during food, water, or NaCl intake, may modulate ongoing ingestion, and that in the absence of such general inhibitory signals ingestion continues until later postgastric signals are detected. (MH-25140)

## 182.16

**CYTOKINE-INDUCED ANOREXIA: 1) CYTOKINE-CYTOKINE INTERACTIONS; 2) CYTOKINE-NPY INTERACTIONS; 3) ANOREXIA INDUCED BY ACTIVATORS OF THE SIGNAL TRANSDUCER GP 130 (USED BY IL-6 FAMILY RECEPTOR MEMBERS) THAT SHARES HOMOLOGY WITH A LEPTIN RECEPTOR.** G. Sonti, S.E. Ilyin and C.R. Plata-Salamán\*, Sch. Life and Hlth. Sci., Univ. Delaware, Newark, DE 19716-2590, USA.

Cytokine-cytokine interactions were studied with the ICV infusion of individual or multiple combinations (8 dyads and 5 triads) of IL-1β, IL-8 and TNFα at doses that yield estimated pathophysiological concentrations in the CSF. Various cytokine combinations exhibited additive or synergistic activities inducing anorexia. Computerized analysis demonstrated that the most effective treatment (triad of 1.0 ng IL-1β plus 20 ng IL-8 plus 20 ng TNFα/rat, n=11) decreased nighttime meal size (MS) by 42% and feeding rate (MS/meal duration) by 26%, while increased the satiety ratio (postprandial intermeal intervals/MS) by 80%; meal duration and meal frequency were not significantly affected. Heat-inactivated triad had no effect. Additive or synergistic cytokine-induced feeding inhibition may participate in the anorexia associated with pathological processes.

NPY (5.0 µg) blocked the anorexic effect induced by 1.0 (n=8), 4.0 (n=7) or 8.0 ng (n=7) IL-1β when both compounds were infused (ICV) concomitantly. Central infusion of NPY also induced feeding in IL-1β-pretreated rats exhibiting marked anorexia (n=9).

Various activators of the glycoprotein 130 (gp 130), a common signal transducer among receptors for members of the IL-6 family (IL-6, IL-11, CNTF, LIF, OSM), induce anorexia. The data show that ICV IL-11 and LIF are the most effective at 1.0, 20 and 100 ng (8 rats/group). A leptin receptor is most related to gp 130. Thus, gp 130 and related molecules may represent an interface associated with feeding control in health and disease. Supported by Univ. Del. Research Grants.

## 183.1

STRESS-INDUCED CHANGES IN PERIPHERAL BLOOD FLOW AND BEHAVIOR: A POTENTIAL FACTOR CONTRIBUTING TO NON-FREEZING COLD INJURY. D. Shurtleff\*, C. L. Foreman, C.-M. Staschen, J.R. Thomas & J. Schrot. Naval Medical Research Institute, Bethesda, MD 20889-5607.

Non-freezing cold injury (NFCI) is a unique syndrome that results from damage to peripheral tissue, usually in the extremities, exposed to cold temperatures for prolonged periods of time. Although non-vascular components are involved in the development of NFCI, alteration in peripheral blood flow in cutaneous circulation is most often a salient feature. Previous research has shown that, in a rat tail model, brief exposure to cold water induces a protective pattern of blood flow -- vasoconstriction followed by vasodilation. This study determined whether exposure to a conditioned stressor disrupts peripheral blood flow. Rats' tail blood flow was measured with laser-Doppler flowmetry while they licked a tube for liquid. On separate days, rats experienced a CS+ condition (three 1-min long stimuli (tone (n=2) or light (n=2)) followed by a 1s foot shock) and a CSn condition (the alternate stimulus presented alone). Over sessions, the licking was suppressed in the presence of the CS+, an indication of a conditioned emotional response, but licking recovered following CS+ termination. Conditioned vaso-constriction also occurred during the CS+ but, unlike licking, continued long after CS+ cessation. The tone CS+ conditioned more vasoconstriction than light, suggesting that conditioned vasoconstriction, and not behavior, may be dependent on stimulus modality. CSn did not alter licking or blood flow. These data suggest that after cessation of a conditioned stressor, behavior recovers, while vasoconstriction continues. Therefore, conditioned stress could contribute to NFCI development by prolonging vaso-constriction, and potentially disrupting a cold-induced protective blood flow pattern. Supported by Naval Medical Research & Development 61153N.MR04101.007.1507.

## 183.3

DIFFERENTIAL EFFECTS OF PSYCHOLOGICAL (FERRET EXPOSURE) & PHYSICAL STRESSORS ON NEUROPEPTIDE & ENDOCRINE RESPONSES OF 'SLOW' VERSUS 'FAST' SEIZURE SUSCEPTIBLE RATS.

P. Kent\*, D. McIntyre, H. Anisman & Z. Merali<sup>1,2</sup>. <sup>1</sup>Sch. of Psychol. & <sup>2</sup>Dept. of Pharmacol., Univ. of Ottawa; <sup>3</sup>Institute of Neuroscience, Carleton Univ. Ont. Canada.

This study assessed the effects of psychological (predator (ferret) exposure) or physical (restraint) stressors (15 min. exposure) on plasma levels of ACTH and corticosterone (CORT) as well as regional levels of CRF and BN-like peptides in 'slow' and 'fast' seizure susceptible rats. Although these lines of rats were selectively bred for proneness to kindling effects, cursory observations suggested differential responsiveness to stress. Effects on CRF and BN were evaluated as they appear to play a role in mediation of stress response; administration of either peptide increases plasma ACTH and CORT levels. The results demonstrate that the strains differ in their CORT and ACTH responses to stressors; both strains showed a marked ACTH and CORT increase following restraint, however, 'slow' rats appeared to be more reactive to ferret exposure as reflected by a much larger ACTH and CORT response. In terms of basal peptide levels, the 'slow' rats had higher CRF levels at the hippocampus and lateral hypothalamus but lower BN levels at the cingulate cortex and nucleus of the solitary tract (NTS); basal peptide levels were comparable at all other regions examined. In the 'fast' rats, restraint increased levels of BN at the anterior hypothalamus, but decreased BN levels at the median eminence (ME) and CRF levels at the paraventricular nucleus (PVN). Exposure of 'fast' rats to ferret, decreased BN levels at the NTS, and both BN and CRF levels at the ME. In the 'slow' rats, restraint increased CRF levels at the PVN and ferret exposure decreased BN levels at the NTS. We can conclude that 1) Exposure of rat to a ferret represents a powerful psychological stressor, and 2) Inasmuch as marked inter-individual differences exist in response to stressors, these rat strains may provide useful animal models in the elucidation of mechanisms subserving such differences. Supported by NSERC.

STRESS-INDUCED DECREASE IN OUT OF NEST ACTIVITY IN THE MOUSE: A MODEL OF STRESS-INDUCED WITHDRAWN BEHAVIOR. Y. Zhang\*, E.A. Stone and D. Quartermain. Depts. Psychiatry & Neurology, New York University School of Medicine, New York, NY 10016

We have recently shown that various forms of stress reduce nocturnal out of nest activity in the mouse. The present experiments were undertaken to further characterize this behavioral change in terms of its probable cause and response to medication. Mice were housed singly in nest cages attached to outer cages in which nocturnal away from nest activity could be recorded by videotape. After baseline behavior was established the animals were subjected to daily aggression stress for 5 days during which time behavior was continuously recorded. It was found that the stress significantly reduced out of nest activity but did not affect food or saccharine consumption or risk assessment behavior in the nest. Plus maze behavior was unaltered. Plasma corticosterone levels were elevated immediately post stress, reduced at 5 hr post stress and no different at 24 hr post stress. Pretreatment with the antidepressant, DMI, attenuated the behavioral change whereas fluoxetine was ineffective. Acute treatment with librium on the night of the first stress exposure did not significantly affect the change. It is concluded that the reduction in out of nest behavior is a form of stress-induced withdrawn or avoidant behavior which does not appear to be prompted by an increase in anxiety but may be the result of a decreased motivation to leave the nest. Supported by NIH MH45265 and a Stanley Foundation Award.

## 183.2

EVIDENCE FOR LONG TERM BEHAVIORAL EFFECTS OF ACUTE DEFEAT. L.A. Lumley\*, M.A. Hebert, M.L. Sipos, and J.L. Meyerhoff. Division of Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

Acute defeat in male mice elicits prolonged avoidance of non-aggressive conspecifics but only transient decreased mobility in the forced swim test. Male DBA/2 mice received four 2 min trials of defeat, whereby the DBA mice were continuously attacked and consequently defeated by aggressive C57BL/6 mice. Unlike its reported effect in the Porsolt test, Fluoxetine (IP) administered immediately following defeat further decreased swim mobility 30 minutes after defeat. The altered physiological state of a defeated mouse, as well as different testing paradigms may account for these differences. Twenty-four hours after defeat, the mice avoided approaching a barrier separating them from a nonaggressive intruder placed within the home cage of the defeated mice. Previous fluoxetine administration had no observable effects on barrier avoidance. Without further defeat exposure, mice received daily injections of saline or fluoxetine and were tested in this modified resident-intruder paradigm four times over two weeks. In previous experiments, barrier avoidance persisted only for one week following acute defeat, indicating the effects of acute defeat on barrier avoidance are limited in duration. Two weeks following acute defeat, mice were placed in a novel cage with a filter paper floor and a barrier separating them from control DBA mice. Since urine fluoresces, urine marks were observed using a transparent grid and quantified under ultraviolet light. Previously defeated DBA mice failed to mark their territory, whereas many of the control DBA mice extensively marked their territory. These results from the urine marking test provide behavioral evidence of long term effects of acute defeat, lending further validation for a potential model of post-traumatic stress disorder. (Intramural research funded by U.S. Army Medical Research and Materiel Command.)

## 183.4

CHRONIC STRESS INDUCES AN EARLY BUT TRANSIENT DISRUPTION OF ESTROUS CYCLING IN RATS. S.M. Anderson\*, G.A. Saviolakis, R.A. Bauman, K.Y. Chu, S. Ghosh, and G.J. Kant. Division of Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

Female Sprague-Dawley rats were chronically stressed using a behavioral paradigm of an around-the-clock signalled intermittent footshock in which some rats could pull a chain to avoid/escape shock (stress) while another group of rats was yoked to the first group (yoked-stress) and did not have control over shock termination. Control rats were never shocked but all groups leverpressed for food pellets on an FR1 schedule (one pellet per leverpress). Daily vaginal samples were obtained for several weeks prior to stress onset and throughout the chronic stress period. After 14 days of stress, the experiment was terminated. Stress transiently decreased leverpressing for food pellets and body weights, but both measures returned to prestress levels by day 14 of stress. Vaginal smears indicated a disruption of the previous pattern of sequential stages of the estrous cycle in both controllable stress and yoked-stress rats during the first few days after introduction of the stress. However, apparent adaptation to the stress resulted in no significant differences among experimental groups in estrous cycle length when averaged over the entire 14 days of stress. (Intramural research funded by the U.S. Army Medical Research and Materiel Command)

## 183.6

CHRONIC SUBORDINATION STRESS ATTENUATES ACTIVE DEFENSES IN MALE SWISS WEBSTER MICE. M.A. Hebert\*, J.H. Dangler, J.A. Henrie, J.K. Shepherd, D.C. Blanchard & R.J. Blanchard<sup>2</sup>. <sup>1</sup>Bekesy Lab. of Neurobiology & <sup>2</sup>The Dept. of Psychology, Univ. of Hawaii, Honolulu, HI 96822.

The experience of social defeat in agonistic encounters with conspecifics is a potent naturalistic stressor that can have profound and lasting consequences. Even brief episodes of social defeat in mice have been shown to enhance anxiety-like behavior in such tests as the elevated plus maze. In a chronic model of social defeat in which male mice were defeated daily by aggressive counterparts, subordinate C57BL/6J mice developed depression-like behavior, such as increased immobility in the Porsolt swim test (Kudryavtseva et al. 1991). In the present study, pairs of male Swiss Webster mice (35-45 gm) were maintained in home cages that were divided into equal halves by a perforated partition that prevented animals from freely interacting but permitted non-tactile communication. On each of thirty consecutive days, the partition was removed to permit agonistic interactions between each pair. The encounters were terminated 4 min following the first attack or ten minutes, whichever came first. Dominance was quickly established, typically on the first encounter, and remained constant in almost every pair throughout the study. Single-housed males served as controls. During the final week, all mice were subjected to several behavioral tests of defensiveness ranging from the elevated "zero maze" (an improved variant of the elevated plus maze) to the Mouse Defense Test Battery (MDTB) in which the animals' reactions to a natural predator, the rat, were examined. Subordinate mice showed signs of reduced defensiveness in many of the tests: 1) they had significantly higher percent open "arc" times than dominants in the zero maze. 2) flight distance from the rat in the MDTB was significantly shorter in the subordinates relative to controls and dominants, 3) fewer subordinates displayed defensive attack (biting) toward the rat. The results appear to suggest that chronic subordination stress leads to shifts from active toward passive defensive strategies. Results are discussed with reference to the PAG. ## 183.7

BEHAVIORAL CONSEQUENCES OF SUBORDINATION IN THE VISIBLE BURROW SYSTEM (VBS). E.B. Yudko\*, D.C. Blanchard, M. Hebert, J.A. Henric, R.J. Blanchard. Dept. of Psychology, University of Hawaii, Honolulu, HI 96822.

Subordinate male rats of groups maintained in semi-natural visible burrowing situations have higher mortality rates and higher plasma corticosterone and lower plasma testosterone levels than dominants. They show enhanced defensive behavior, but reduced social, sexual, exploratory and aggressive activity, within the habitat, and altered patterns of risk assessment in the open field, plus maze, and cat-odor test. They exhibit increased food and water consumption outside of the VBS but continue to lose weight. These findings indicate that while subordination is typically associated with heightened defensiveness it may produce specific changes in particular components of an animals defensive profile.

The present study attempted to better understand the nature of these changes by examining the behaviors of dominant and subordinate rats compared to controls in a variety of tests of defensive behavior. The tests were chosen to analyze defensive behavior over a continuum of threatening stimuli from human contact, to a novel environment, to the presentation of an anesthetized conspecific, a cat-odor, or a cat. In response to human contact subordinates exhibited less locomotion, less exploration, and longer latencies to right themselves after being inverted. In the same tests, dominants made fewer escape attempts, and hid less than controls showing more investigation of the experimenter. In the open field test, subordinates showed less activity than controls during VBS housing but not 7 days later. All animals showed marked reduction of activity when exposed to the cat. These data suggest an impact of subordination on defensive behaviors that is more prominently expressed in response to relatively low level threat stimuli.

PLACE NAVIGATION ON THE OPEN FIELD IN MICE EXPOSED TO PRENATAL X-RAYS: REFERENCE AND SOUND STIMULI AS CONTRASTING AGENTS, D.M. Abramov (1), R.T. Vital (1), R.W.F. Vitral\* (1,2) and S.L. Schmidt (1). (1)Depto. Ciências Fisiológicas, UERJ, (2)IBCCF, UFRJ, Rio de Janeiro, 20551030, BRAZIL.

Previous studies suggest that mineralocorticoid receptors in the hippocampus may be related to the animal's tendency to move toward the center of the open-field when a stimulus is present in this region. Here we studied place navigation in irradiated mice on the open field with different backgrounds, since it has been shown that prenatal ionizing irradiation on sixteenth gestational day (E16) with 3 Gy changes hippocampal lamination. Pregnant female mice were exposed to a source of X-rays at E16 receiving a total body dose of 3 Gy. At adulthood, 34 irradiated and 38 non-irradiated male mice were tested in an elevated open field (24 x 24 cm) with no walls divided into 8 rows and 8 columns. The open field was also divided in center and periphery (two more external rows/columns). The reference stimulus was a squared prism (4.25 x 4.25 cm), which was placed on its center. The sound stimulus had a frequency of 3500 Hz. For the behavioral testing, the animals were subdivided in four subgroups: ① without reference stimulus/without sound (10 irradiated and 10 non-irradiated), ② without reference stimulus/with sound (10 irradiated and 10 non-irradiated), ③ with reference stimulus/without sound (7 irradiated and 8 non-irradiated) and ④ with reference stimulus/with sound (7 irradiated and 10 non-irradiated). The animals were placed for 10 minutes in the open field where their movements were recorded with a video camera. The analysis of the place navigation showed that the irradiated and non-irradiated mice moved to the center in the presence of the reference stimulus. This was more pronounced in the non-irradiated group. The presence of the sound stimulus abolished the differences between the two groups. We suggest that the differences seen in relation to the two background stimuli on the open field may be due to different mechanisms of behavioral reaction associated with the possible effects induced by the radiation upon the hippocampus.

EFFECTS OF POSTNATAL HANDLING IN SPRAGUE-DAWLEY, ROMAN HIGH AVOIDANCE/VERH AND ROMAN LOW AVOIDANCE/VERH RATS.

A. Tobena<sup>1</sup>, T. Steimer<sup>2</sup>, R.M. Escorihuela<sup>1</sup>, J.F. Núñez<sup>1</sup>, P. Ferré<sup>1</sup>, P. Driscoll<sup>3</sup>, A. Fernández-Teruel<sup>1</sup>. <sup>1</sup>Med Psychol Unit, Medicine School, Autonomous Univ Barcelona, Barcelona, Spain; <sup>2</sup>Psychopharmacology, IUPG, Chene-Bourg/GE, Switzerland; <sup>3</sup>ETH-Zentrum, Animal Science Inst, Zurich, Switzerland.

The present studies were devoted to evaluate postnatal handling (PH; during the first 21 days of life) effects on tests specifically measuring anxiety (i.e. tests involving conflict or conditioned fear) both in randomly bred Sprague-Dawley (SD) rats as well as in Roman high- and low-avoidance (RHA/Verh and RLA/Verh) rats. The Roman lines, which have been selected for rapid vs non acquisition of two-way active (shuttlebox) avoidance, present differential emotionality, as well as HPA-axis reactivity and prolactin response to stress (low in RHA/Verh and high in the RLA/Verh). A second objective was to evaluate whether those genetically-related differences could be enduringly affected by PH. The results show that both spontaneous and conditioned emotionality/fear were enduringly reduced in all PH-treated rats (as compared to control animals) in several situations. PH significantly decreased HPA-axis (ACTH and corticosterone) and prolactin responses to open field exposure in adult SD and RLA/Verh rats. Remarkably, PH eliminated the differences among the Roman/verh lines in most parameters, including self-grooming, defecation under fear-conditioning and prolactin response to open field exposure in RLA/Verh rats. (Supported by FISS 95/1779).

## 183.8

STRESS-RELATED ALTERATIONS IN AGGRESSION IN MICE SELECTIVELY BRED FOR HIGH AND LOW STRESS-INDUCED ANALGESIA. W.F. Sternberg, C. Geneve, D. Goldstein, J.S. Mogil, Department of Psychology, Haverford College, Haverford, PA 19041.

The effects of stress on aggressive behavior were assessed in mice selectively bred for high and low analgesic (HA and LA, respectively) responses to stress. The selection procedure, based on analgesic responsiveness to a 3-min swim stress, resulted in large and reliable differences in opioid-mediated analgesic processes in succeeding generations; HA's display higher magnitudes of morphine, stimulation-produced, and stress-induced analgesia, and an increased density of brain opiate receptors compared to LA's. It is unknown, however, if HA's diverge from LA's with respect to other behaviors influenced by opioids, such as aggression. Opiate agonists decrease several forms of aggressive behavior; opiate antagonists increase aggression. HA and LA mice provide an interesting model in which to assess the effects of stress-induced opiate activation on aggression, since they exhibit such varied opiate responses to swim stress. Adult male mice of each line (n=8) participated as the residents in a territorial aggression procedure. Each subject established residence in the testing chamber for 24 hours, then was exposed to the swim stressor. Following recovery from the stress, number of intruder-directed aggressive attacks, latency to first attack and number of attacks per minute (APM) were recorded for the resident. Each animal also participated in a territorial aggression encounter under non-stressed conditions. Half of the subjects in each line received an injection of naloxone (10 mg/kg, i.p.) or saline before testing on each day. Analysis of variance revealed a significant inhibitory effect of stress on aggression. There was also a significant strain x drug interaction, with naloxone increasing APM in the HA's, but not in the LA's. A significant 3 way interaction indicated that in the baseline condition, naloxone decreased aggressive behavior in LA's, but increased APM in HA's. The results suggest that the profound stress-induced decrease in aggressive behavior is not opioid-mediated, however, naloxone increases the aggressive behavior seen in HA's under baseline conditions. ## 183.10

SOCIAL ROLES, TERRITORIAL AGGRESSION AND CENTRAL MONOAMINES IN WILD *Sceloporus jarrovi*.

Patrick J. Ronan, John M. Matter, S. Waller\* and Cliff H. Summers. Dept. of Biology, University of South Dakota, Vermillion, SD 57069.

Central monoamines were quantified from wild mountain spiny lizards (*Sceloporus jarrovi*) during the breeding season by electrochemical HPLC. Monoamine profiles from territorial males, adult females, satellite males, young males and young females, as well as males following aggressive defense of territory, revealed significant differences in content and turnover between lizards from different social classes. Socially subordinate satellite males exhibited significantly higher telencephalic 5HIAA and 5-HIAA/5-HT, as well as enhanced diencephalic 5-HIAA/5-HT. Adult females had higher telencephalic 5-HTP and 5-HT. Additionally, immediately following a heightened agonistic interaction territorial males exhibited very rapid elevation of 5-HTP, 5-HIAA and 5-HIAA/5-HT. Following aggressive defense of territories, males exhibited higher elevated telencephalic and diencephalic DOPAC, telencephalic DOPAC/DA, and brainstem MHPG/NE compared to noncombative territorial males. Social stresses, experienced by satellites as they exist at the interstices of territories, and by males defending territories, activate serotonergic systems. Aggressive interaction, while stimulating serotonergic systems, also activates noradrenergic and dopaminergic systems in dominant males. Supported by NSF grant OSR-9108773.

## 183.12

MAINTAINING PREGNANT RATS ON A STANDARD VS. REVERSED LIGHT/DARK CYCLE: IMPLICATIONS FOR GESTATIONAL STRESS. A. E. McCrea\* and M. T. Williams. Tobacco and Health Res. Inst., Lexington, KY 40506.

Stressing pregnant rats during the third trimester can produce offspring that themselves demonstrate an attenuated response to stress. There are, however, inconsistent results in the literature, which may be attributable to methodological variations, such as stressing females during the light or the dark phase of the light/dark cycle. The present study addresses this issue. Pregnant females were randomly assigned to a colony room maintained on a standard (STAND) or reverse (REV) light/dark cycle and further to a gestationally-stressed (GS) or nonstressed (NS) condition. Offspring weights and anogenital distances (AGD) were measured on PN-1 and PN-20. On PN-21, one male and female from each litter was either isolated for 1 hour in a novel environment (ISOL) or sampled immediately upon removal from the home cage (BASE) during the dark phase of the cycle. Trunk blood was assayed for corticosterone (CORT), aldosterone (ALDO), ACTH, and in males, testosterone (T). The weights of GS offspring were reduced on all days. Furthermore, GS males had shorter AGDs than NS males; no effect was observed among females. As expected, CORT, ALDO and ACTH were elevated in ISOL pups. However, the elevations over basal levels for CORT and ALDO were smaller in STAND pups. Furthermore, plasma ALDO and CORT were greater in females, although CORT only approached significance. BASE and ISOL titers of ACTH were lower for GS vs. NS pups. Elevations in T levels over basal levels were greater in REV than in STAND males. ACTH was the only hormone observed to be affected by GS, however, the attenuation in endocrine responses in the STAND room suggests that maintaining rats under standard animal husbandry procedures may itself be an external source of stress. This work was supported by THRI grant #5-41078

## 183.13

CORTISOL LEVELS AND SOCIAL COMPETITION IN THE MARMOSET (*CALLITHRIX JACCHUS*). Woodall K.L., Domenev A.M., Kelly M.E. Postgraduate Studies in Pharmacology, University of Bradford, Bradford, W.Yorks. BD7 1DP. <sup>1</sup>Battelle Europe, 7 Route de Drize, CH 1227 Carouge, Geneva.

Studies of dominant-subordinate relationships in terms of competition for palatable substances have been studied in rodents and non-human primates (Syme, 1974, *Anim. Behav.*, 22: 931-940). Hierarchical relationships have been proposed as being relatively more stressful for the subordinate animal and this has implications in the development of psychological disorders such as anxiety. The purpose of the present study was to determine if there were differences in plasma cortisol levels between dominant and subordinate marmosets during basal conditions and following social competition.

During a 5 min test period, pairs of marmosets (n=4) were given access to milk and the dominant-subordinate animal in each pair differentiated according to the time spent at the drinking spout; the dominant animal spending the most time. Blood samples (0.5 ml) were taken via the femoral vein, centrifuged and the plasma cortisol measured by radioimmunoassay. Data were analysed using two factor ANOVA followed by Dunnett's t-test.

Results from this study show that there was no difference in basal cortisol concentrations between subordinate and dominant marmosets,  $117.3 \pm 14.4 \mu\text{g/dL}$  and  $83.5 \pm 7.1 \mu\text{g/dL}$  respectively. Following 5 min competition for milk, the level of cortisol in the plasma of subordinate animals was significantly higher than in dominant animals,  $167.8 \pm 12.0 \mu\text{g/dL}$  compared to  $105.5 \pm 18.8 \mu\text{g/dL}$  ( $p < 0.05$ ).

These findings provide evidence that competition in pairs of marmosets induces a situation that is more stressful for the subordinate member of the social hierarchy.

## 183.15

DIFFERENTIAL EFFECTS OF BENZODIAZEPINE RECEPTOR AGONISTS AND INVERSE AGONISTS ON CARDIOVASCULAR AND SOMATIC DEFENSIVE AND STARTLE RESPONSES. S. Hart\*, G. Bernston, M. Sarter. Dept. Of Psychology & Neuroscience Program, The Ohio State Univ., Columbus, OH 43210

Previous work from our laboratory has demonstrated that systemic administration of the benzodiazepine receptor (BZR) partial inverse agonist  $\beta$ -carboline FG 7142 (FG) augments the cardiovascular defensive response to non-signal stimuli. This effect mimics the cardiovascular effects of a conditioned aversive stimulus, and was found to depend on the basal forebrain cholinergic system. More recently, however, we have found that FG decreases somatic and cardiovascular startle responses. This dissociation between defensive and startle responses raises an important question as to what specific reactions are potentiated by the putative anxiogenic agent FG 7142. The present studies were designed to further explore this issue. Rats were trained with either contingent or random relation pairs of the light CS and a 0.6 mA shock. Following training, subjects systemically received either FG, chlordiazepoxide or vehicle. Somatic and cardiovascular responses to the startle stimuli, and cardiovascular responses to a novel probe tone were measured in the presence or absence of the light CS. Consistent with previous findings, results suggest that FG enhances cardiovascular reactivity to non-signal stimuli and light CS, but attenuates somatic startle in the same experimental context. These findings suggest that BZR partial inverse agonists may selectively enhance defensive-like responses. Supported by NIH/National Heart, Lung, and Blood Grant # 1 RO1 HL54428

EFFECTS OF FLUMAZENIL ON RESPONSES TO YOHIMBINE IN HEALTHY HUMAN SUBJECTS.

M. Narayan, D.S. Charney, S.W. Woods\*, G.M. Banks, G.R. Heninger, A.W. Goddard. Dept of Psychiatry, Yale U. Sch. of Med, New Haven, CT 06519.

Flumazenil (FLU) has been found to be anxiogenic in patients with panic disorder (PD). Also a subgroup of patients with PD have evidence of noradrenergic overactivity. This study investigated the hypothesis that acute administration of a specific benzodiazepine (BDZ) antagonist (FLU) would result in the potentiation of behavioral, biochemical and cardiovascular effects of the  $\alpha_2$  adrenergic antagonist yohimbine (YOH). **METHODS:** Six healthy human subjects (4 males and 2 females; mean age  $\pm$  SD =  $25 \pm 3.7$  years) consented to participate in this protocol. FLU (2mg) IV and YOH (0.4 mg/kg) IV were administered to subjects in a randomized, placebo-controlled, cross-over fashion. Each subject received a combination test of either YOH/FLU, YOH/placebo, FLU/placebo, or placebo/placebo on 4 separate days, approximately 1 week apart. Within test measures included visual analog scale (VAS) (0-100 mm, self report) anxiety, nervousness, vital signs, plasma MHPG and cortisol. **RESULTS:** The mean peak change from baseline anxiety levels in subjects receiving a combination of YOH and FLU =  $26 \pm 27$  mm on the VAS, compared to the score =  $9 \pm 11$  mm on the YOH/placebo test (paired t-test,  $t=2.1$ ,  $df=5$ ,  $p=0.1$ ). The YOH/placebo test was more anxiogenic than placebo ( $t=2.1$ ,  $df=5$ ,  $p=0.1$ ). The combination test had no particular effects on either nervousness or blood pressure in comparison to controls. Additional physiological and neuroendocrine data will also be presented. **DISCUSSION:** The combination of FLU and YOH resulted in a trend towards increased anxiety in healthy human subjects. Interactions between the BDZ/  $\gamma$ -amino-butyric acid and noradrenergic systems may be involved in the mediation of human subjective anxiety.

## 183.14

NEONATAL HANDLING INCREASES BEHAVIORAL DESPAIR AND ACOUSTIC STARTLE RESPONSES. E.P. Zorrilla\*, E. Redei. Depts. of Psychology and Pharmacology, U. Pennsylvania, Philadelphia, PA 19104.

Previously, we found that neonatal handling, especially when administered during the second postnatal week, increased immobility during the Porsolt forced swim test (FST) in adulthood (Zorrilla et al. *Soc. Neurosci. Abstr.* 21:1686). To replicate and extend these findings, we subjected 16 litters derived from Sprague-Dawley dams mated in our colony to 1 of 2 postnatal conditions: cage-cleaning control (C; n=7) or twice daily handling during the 2nd postnatal week (H2; n=9). At 95 days of age, behavior in the FST was assessed at the unit of litter (1-3 offspring/litter mean). Both H2 males and females were more immobile early in the posttest; males climbed less and both males and females swam less. Additionally, males climbed less and were more immobile during the initial test. Irrespective of rearing, marked sex differences were observed; females were more immobile than males, as they swam and climbed less. These differences replicate our prior findings. At 125 days of age, offspring were tested for habituation/sensitization of acoustic startle responses (ASRs) or acoustic startle threshold and prepulse inhibition. H2 females, but not males, showed exaggerated ASRs to 120 dB stimuli. Greater ASRs were due, in part, to a failure to habituate, as H2 females showed an initial and delayed sensitization. H2 offspring did not differ in their acoustic startle threshold, suggesting that differences were not due to perceptual differences. Furthermore, H2 offspring showed normal prepulse inhibition and unstimulated motor activity. Coupled with the well-established finding that handled animals have increased HPA negative feedback efficacy, the present findings of increased 'behavioral despair' and altered regulation of startle responsiveness suggest that neonatal handling should be pursued as a potential animal model of post traumatic stress disorder.

## 183.16

THE ROLE OF CENTRAL NORADRENERGIC MECHANISMS AND FOS RESPONSES TO STRESS IN STRESS-INDUCED BEHAVIORAL DEPRESSION. E.A. Stone\*, Y. Zhang and D. Quartermain. Depts. Psychiatry & Neurology, New York University School of Medicine, New York, NY 10016

The noradrenergic system has long been thought to play a role in the genesis of depressed behavior. The fos response to stress, which is largely controlled by the noradrenergic system (Stone & Zhang, *Brain Res.* 694:279,1995) is also thought to contribute to the disorder or be an adaptation to stress. The present study investigated the role of these factors in depression evoked by stress. Mice were housed in specially designed cages that allowed recording of nocturnal activity. After behavior had stabilized the animals were subjected to restraint stress once daily for 2 days. Prior to receiving stress or control treatment the animals were administered saline, combined prazosin ( $\alpha_1$ -antagonist) and betaxolol ( $\beta_1$ -antagonist) or atipamezole ( $\alpha_2$ -antagonist). Blockade of  $\alpha_1$ - and  $\beta_1$ -receptors reduced the fos response to stress whereas blockade of  $\alpha_2$ -receptors augmented the response. Preliminary results indicated that by itself  $\alpha_1$ - and  $\beta_1$ -blockade produced a depression in nocturnal activity whereas  $\alpha_2$ -blockade produced a variable stimulation. The interactions of these treatments with stress is currently under investigation. Supported by NIH MH45265 and a Stanley Foundation Award.

## 183.18

EFFECTS OF BENZODIAZEPINE AGONIST/ANTAGONIST ON CONDITIONED FEAR STRESS IN RATS. T. Izumi\*, T. Inoue, T. Ohmori and T. Koyama. Dept. of Psychiatry, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

We investigated the effects of benzodiazepine omega 1 and omega 2 agonist, lorazepam and benzodiazepine omega 1 antagonist, flumazenil on conditioned fear stress (CFS) in rats, an animal model of anxiety. CFS (exposure to an environment paired previously with footshock) 24 hours after single footshock induced marked freezing behavior. Administration of lorazepam (0.001-0.003 mg/kg, s.c.) 30 min before CFS significantly reduced freezing, suggesting that lorazepam inhibited expression of conditioned fear. Administration of flumazenil 30 min before CFS significantly reduced freezing only at a high dose (10 mg/kg, s.c.). This result suggests two possibilities. One is that high dose of flumazenil exerted agonist activity, and another is that flumazenil antagonized endogenous ligands for benzodiazepine receptor, such as DBI, that act as a negative allosteric modulator of GABA.

## 183.19

**THE EFFECTS OF CAFFEINE IN THE DEFENSIVE WITHDRAWAL TEST.** D.A. White\* and D.L. Birkle. Department of Pharmacology & Toxicology, West Virginia University, Morgantown, WV 26506-9223.

The defensive withdrawal testing paradigm (DWT) is a behavioral test used to determine levels of anxiety, stress, and psychoactivity via the measurement of a number of behavioral parameters including: latency to the first exit, motor activity, rears per time in field, time in chamber, time in field, total exits, and time per visit in the chamber. Traditionally, increased latency, increased time per visit, and decreased rears per time in field have served as markers for anxious behavior. Corticotropin releasing factor (CRF) given i.c.v. and restraint stress have both been previously shown to cause changes in behavior in the DWT associated with increased levels of anxiety in rats. With this in mind, the effects of caffeine, a known anxiogenic agent, were tested in male Sprague-Dawley rats using the DWT. Caffeine at 0, 10, 20, and 40 mg/kg (i.p.) was given to rats, which were subsequently tested for 10 min. Their behavior was video taped for later analysis. It was found that there were no significant changes in the time per visit or latency at any dose of caffeine. However, there was a significant decrease in the rears per time in field at both the 20 and 40 mg/kg doses, which is similar to an effect observed after the administration of i.c.v. CRF. This suggests that CRF may be altering complex behavior via multiple pathways and that caffeine may exert at least some of its behavioral effects via a common pathway. This research was supported in part by NSF (IBN-9222263) and the WVU Foundation.

## 183.20

**EFFECTS OF CHRONIC SUBORDINATION STRESS ON BETA-ADRENOCEPTOR BINDING IN THE BRAIN.** G. Flügge\*, O. Ahrens and E. Fuchs. German Primate Center, D-37077 Göttingen, Germany.

Psychosocial stress (PSS) is known to affect the functioning of the central noradrenergic system. In the present study, the consequences of recurrent stressful experiences on  $\beta_1$ - and  $\beta_2$ -adrenoceptors (ARs) were analyzed in male tree shrews (*Tupaia belangeri*). The animals were submitted to subordination stress for 2, 10, 21, and 28 days, and  $\beta$ -adrenoceptors were quantified by in vitro autoradiography using <sup>125</sup>I-iodocyanopindolol.

$\beta_1$ -ARs were transiently down-regulated after 2 days of PSS in the prefrontal cortex and in the olfactory area, and were decreased after 28 days of PSS in the parietal cortex and the hippocampus. A transient up-regulation of  $\beta_1$ -ARs occurred in the pulvinar nucleus after 10 days of PSS.  $\beta_2$ -ARs were transiently down-regulated after 2 days of PSS in the prefrontal cortex, and up-regulated in the pulvinar nucleus after 28 days of PSS.

These data demonstrate that chronic PSS stress leads to time dependent changes in the central nervous  $\beta$ -AR system. The high regional variability in receptor regulation may be due to the complex mechanisms of intracellular  $\beta$ -AR sequestration which enables the individual to balance the central nervous adrenoceptor number. (Supported by German Science Foundation; SFB 406 to G. F.)

## NEUROPEPTIDES AND BEHAVIOR I

## 184.1

**CORTICOTROPIN-RELEASING FACTOR ANTAGONIST INFUSED INTO THE LOCUS COERULEUS ATTENUATES IMMOBILIZATION STRESS-INDUCED INCREASE OF NOREPINEPHRINE IN THE PREFRONTAL CORTEX IN RATS** G.N. Smagin\*, J. Zhou, R.B.S. Harris, D.H. Ryan. Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, LA 70808 USA

Substantial evidence indicates that CRF mediates stress-induced responses. Neuroanatomical, neurophysiological and behavioral studies also suggest that brain stem nucleus locus coeruleus (LC) plays an important role in this response. The present study was designed to clarify, whether infusion of CRF antagonist,  $\alpha$ CRF into the LC could attenuate or block stress-induced changes in norepinephrine (NE) concentrations in microdialysates collected from the medial prefrontal cortex (PFM), which receives noradrenergic input primary from the LC. Rats were implanted with a bilateral cannulae assembly aimed in the LC and a microdialysis probe (4 mm active membrane length) in the PFM. Ten minutes before the onset of 30 min immobilization stress animals received bilateral infusion of  $\alpha$ CRF (1  $\mu$ g per site) into the LC. Immobilization of animals significantly increased the concentration of NE in microdialysates from PFM to a maximum of  $170.8 \pm 12.8\%$  of the baseline ten minutes after the onset of stressor. Concentration of NE in dialysates remained significantly elevated for the next 40 minutes. Infusion of  $\alpha$ CRF into the LC significantly attenuated stress-induced increase in PFM NE concentration in samples collected at 10, 20, 30, 40 and 50 minutes after the onset of immobilization. Infusion of  $\alpha$ CRF alone (no immobilization) did not change NE concentrations at any time during sample collection.

These results are consistent with other studies and suggest that stress can facilitate NE release in the PFM through the activation of the CRF system in the brain.

## 184.2

**BEHAVIORAL ACTIVATING PROPERTIES OF CORTICOTROPIN-RELEASING FACTOR INFUSED INTO THE NUCLEUS ACCUMBENS SHELL.** Matthew R. Holahan, Ann E. Kelley, and Ned H. Kalin\*. Department of Psychiatry, University of Wisconsin Medical School, Madison, WI 53706

Corticotropin releasing factor (CRF) has long been recognized as a neuropeptide involved in the response to stress. Although the behavioral effects of intraventricular CRF have been well characterized, little is known about its possible functions in the ventral striatum. The posterior shell of the nucleus accumbens has moderate levels of CRF fibers and receptors. In the first experiment, the effects of CRF (125, 250 ng) were evaluated following infusion into the core and shell regions of accumbens. CRF elicited a significant, dose-dependent increase in spontaneous motor activity after infusion into the shell region, but not the core. In a second experiment, CRF (250, 500 ng) induced behavioral activation when infused into the shell, but not the ventricle. This activation appeared to consist of increased movements within a small area, rather than locomotor activity. A third experiment utilizing observational methods examined the precise behaviors affected by CRF (250, 500 ng) injected into the shell. Treated rats displayed increased levels of grooming, sniffing, and oral behavior, with much lower levels of "still" behavior. In a fourth study, CRF (250 ng) infused into the posterior shell via angled cannulae that avoided the ventricle elicited the same behavioral pattern. These results suggest that CRF within the posterior accumbens modulates behavior; however, its relationship to motivational state, stress, or reinforcement awaits further study. Supported by grant DA04788, NIDA.

## 184.3

**BEHAVIORAL AND PHYSIOLOGICAL EFFECTS OF LONG-TERM ADMINISTRATION OF CORTICOTROPIN-RELEASING FACTOR IN THE RAT BRAIN.** B. Buwalda\*, A.A. van Kalkeren, S.F. de Boer, J.M. Koolhaas. Dept. of Animal Physiology, University of Groningen, P.O.Box 14, 9750 AA Haren, The Netherlands.

In the present study we examined the effects of long-term, chronic and episodic administration of corticotropin-releasing factor (CRF) on a number of physiological and behavioral parameters. By implanting transmitters in male Wistar rats daily rhythms of body temperature and activity were biotelemetrically monitored in the home cages. CRF was administered for a period of 10 days intracerebroventricularly (icv) either chronically (5  $\mu$ g CRF/day) with the aid of osmotic minipumps or episodic (1  $\mu$ g/3  $\mu$ l saline as a bolus injection in the morning). For both groups controls were administered saline in a similar fashion. The chronic infusion of CRF increased both night and day temperature as compared to controls. However, the effect on temperature was strongest and most persistent (6 days) during the light, i.e. resting period. CRF reduced the daily amplitude in temperature for this period. The rats habituated to the end of the 10-day period. CRF, however, persistently reduced daily amplitudes of motor activity. In the episodic treatment design heart rate was also monitored. Immediately following CRF injection in the morning heart rate and temperature and motor activity increased. Compared to control treated rats the heart rate during the night period was reduced during the 10-day period. Temperature responses to the daily CRF injections gradually decreased. There was no habituation in heart rate and motor activity increases during daytime following administration of the peptide. Chronical and episodic CRF administration reduced weight gain during the treatment period. Organ weight of adrenals was increased and thymus weight reduced. Exposure to the elevated plus-maze 7 days after starting the chronic and episodic treatment showed an increased anxiety in the CRF treated rats in this test.

## 184.4

**NEUROTENSIN AND ITS ANTAGONIST, SR48692 DIFFERENTIALLY MODULATE EXPLORATORY BEHAVIOR IN THE ELEVATED PLUS MAZE: A POTENTIAL ROLE FOR CORTICOTROPIN-RELEASING HORMONE.**

W. Rowe<sup>1</sup>\*, J. Rochford<sup>1</sup>, D. Gully<sup>2</sup>, M. J. Meaney<sup>1</sup> and R. Quirion<sup>1</sup>. <sup>1</sup>Dept. of Psychiatry and Neurology/Neurosurgery, Douglas Hospital Research Center, McGill University, Montreal, Canada, H4H 1R3. <sup>2</sup>Sanofi Recherche, 31036 Toulouse Cedex, France.

The neuroendocrine actions of centrally administered neurotensin (NT) on the hypothalamic-pituitary-adrenal (HPA) axis are mediated via the activation of hypophysiotropic corticotropin releasing hormone (CRH) release (Rowe et al., *J. Neuroendo.*, 1995, 7:109-117). CRH, acting in its capacity as a hypothalamic releasing hormone, stimulates the release of adrenocorticotropin (ACTH) and corticosterone (B) following NT administration. However, CRH in the central nervous system also appears to enhance behavioral responses to stressors. These effects are believed to occur independently of the HPA axis and can be reversed by selective CRH antagonists. Further, the localization of CRH and its receptors in extrahypothalamic brain regions indicates that CRH may act as a neurotransmitter. Thus, we were interested in determining whether the NT-induced increases in the HPA activity were also accompanied by alterations in CRH and CRH-related behavior. Male Long-Evans rats were treated with chronic NT for 14 days (1 pmol/hr) via Alzet Miniosmotic pumps. Immunoreactive CRH levels were found to be significantly higher in the median eminence, consistent with its role in mediating hypophysiotropic HPA activity. Similarly, these animals also displayed significant decreases in latencies and entries into the open arms in the elevated plus maze. A significant decrease in mean locomotor activity was also noted in the chronically-treated NT animals following exposure to a novel environment. Conversely, when a separate group of animals were treated with the newly developed NT antagonist, SR48692, prior to testing on the elevated plus maze, these animals spent significantly more time on the open arms than controls. As one of the behavioral characteristics of CRH hyperactivity is an increase in anxiolytic behavior elicited by novelty (Stenzel-Poore et al., 1994, *J. Neuroscience*, 1994, 14: 2579-2584) it is likely that a NT-induced increase in HPA activity and central CRH levels may in part be related to the behavioral response to novelty seen in these animals. EFFECT OF CENTRAL ADMINISTRATION OF UROCORTIN, A NOVEL CRF-RELATED NEUROPEPTIDE, IN BEHAVIORAL STUDIES IN RATS. M. Spina, A.M. Basso, E. Merlo-Pich, B. Chan<sup>1</sup>, J. Rivier<sup>1</sup>, W. Vale<sup>1</sup> and G.F. Koob. The Scripps Research Institute, Dept. of Neuropharmacology, and <sup>1</sup>Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037.

Corticotropin-releasing factor (CRF) is known to be secreted by the hypothalamus in response to stress. Administration of CRF intracerebroventricularly (ICV) produces a "stress-like" reaction of the hypothalamic-adrenal-axis including an increase in sympathetic activity, a decrease in parasympathetic outflow and a decrease in feeding behavior. Recently a neuropeptide called urocortin (Ucn) has been identified in mammals which shares similar biological activities with rat/human CRF (45% homology) and fish urotensin (65% homology). As already found with other non-mammalian CRF-like peptides as urotensin, Ucn binds with better affinity to CRF<sub>2</sub> receptors as compared to CRF. The aim of this study was to compare the effects of Ucn, CRF and urotensin in a series of behavioral tests. ICV administration of doses as low as 0.1 µg of Ucn were effective in decreasing food-intake in food-deprived animals without producing "anxiogenic-like" effects on plus-maze, behavioral activation in locomotor activity and taste aversion. Thus, Ucn was significantly less potent than CRF in producing stress-like effects and activation but significantly more potent than CRF in suppressing food intake in fasted animals. This effect was attenuated or reversed by central administration of CRF antagonists. The results suggest that Ucn has a different central nervous system profile than CRF and may have an important role in controlling food-intake. (Supported by NIH DK 26741).

THE ROLE OF THE BED NUCLEUS OF THE STRIA TERMINALIS IN CRH-ENHANCED STARTLE: AN ANIMAL MODEL OF ANXIETY. Y. Lee\* & M. Davis, Dept. of Psychiatry & Psychology, Yale Univ., New Haven, CT 06508

CRH given i.c.v. produces a profound, dose-related increase in acoustic startle amplitude in rats (CRH-enhanced startle). However the primary receptor sites for CRH given i.c.v. have not been identified. Our laboratory showed that electrolytic, but not chemical, lesions of the septum blocked CRH-enhanced startle, suggesting that fibers passing through the septum (e.g., the fornix) are critically involved in CRH-enhanced startle. Because the ventral hippocampus (VH) projects to the bed nucleus of the stria terminalis (BNST) via the fimbria/fornix, and to the amygdala via the BNST, the role of these structures in CRH-enhanced startle was investigated.

Chemical lesions of the VH or the BNST, or knife cut of the fimbria/fornix blocked CRH-enhanced startle, whereas chemical lesions of the amygdala did not. However, infusion of CRH into the VH did not mimic i.c.v. CRH, whereas CRH given to the BNST enhanced startle in a dose-dependent manner. Moreover, a CRH antagonist infused into the BNST blocked CRH-enhanced startle, suggesting the BNST may be a primary receptor site for i.c.v. CRH.

A functional double dissociation between the BNST and the amygdala was also found. Thus, chemical lesions of the BNST, but not the amygdala blocked CRH-enhanced startle, whereas lesions of the amygdala but not the BNST blocked fear-potentiated startle. A CRH antagonist infused into the amygdala did not block the expression of fear-potentiated startle, and there was perfect additivity between fear-potentiated and CRH-enhanced startle measured in the same animal.

The present studies strongly suggest that CRH in the CSF can activate the BNST via mechanisms different from those involved in conditioned fear. Currently we are using *c-fos* to assess whether the constellation of neural effects produced by i.c.v. CRH will be blocked by lesions of the BNST. ## 184.9

ELECTROPHYSIOLOGICAL AND BEHAVIORAL STUDIES ASK: IS THERE AN NPY<sub>1</sub>-LIKE RECEPTOR INVOLVED IN FEEDING? T.A. Piller\*, D.G. Harden, J.V. Cassella, S.H. Lang, M.M. Bennett, P.Z. Gallipoli, and C.A. Blum, Neurogen Corporation, Branford, CT, 06405.

NPY is one of the most potent stimulators of feeding behavior in laboratory animals, and at least four subtypes of the NPY receptor exist. Various fragments of the NPY peptide differentially bind to these receptor subtypes. Use of the NPY<sub>1-36</sub> and NPY<sub>2-36</sub> fragments has led to some confusion regarding the involvement of the NPY<sub>1</sub> receptor or an NPY<sub>1</sub>-like receptor subtype in feeding behavior. We investigated the effects of both human(H)- and porcine(P)-derived 1-36 and 2-36 fragments, as well as the potent and selective NPY<sub>1</sub> receptor antagonist, BIBP3226 ((R)-N<sup>2</sup>-(diphenylacetyl)-N-[(4-hydroxyphenyl)methyl]-argininamide), in two functional assays. In *Xenopus* oocytes, peptide effects were assessed electrophysiologically by coexpressing the NPY<sub>1</sub> receptor with a G-protein activated inward rectifying K<sup>+</sup> channel (GIRK1). Despite large differences in potency reported in the literature, in oocytes NPY<sub>1-36</sub> was only three to ten fold more potent than NPY<sub>2-36</sub>, and P and H forms of the peptides were equipotent. Currents induced by NPY fragments at the NPY<sub>1</sub> receptor were antagonized by BIBP3226 (IC<sub>50</sub> ~1.5 nM). In behavioral studies, ICV infusion of H- or P-derived forms of both NPY fragments (2.5 and 10 µg) in rats housed in metabolic cages elicited robust and equipotent feeding responses while BIBP3226 significantly attenuated feeding elicited by H-NPY<sub>1-36</sub>. Thus, using these fragments, electrophysiological studies on the NPY<sub>1</sub> receptor and behavioral studies are concordant supporting the involvement of the NPY<sub>1</sub> receptor in feeding behavior. ## 184.6

APPETITE-SUPPRESSING EFFECTS OF UROCORTIN, A NOVEL CRF-RELATED NEUROPEPTIDE, IN FREE FEEDING RATS. A.M. Basso, M. Spina, E. Merlo-Pich, P. Griffin, J. Rivier<sup>1</sup>, W. Vale<sup>1</sup> and G.F. Koob\*. The Scripps Research Institute, Dept. of Neuropharmacology, and <sup>1</sup>Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037.

Corticotropin-releasing factor (CRF) has been implicated in modulating behavioral and physiological responses to stress. Central administration of CRF increases arousal and produces "anxiogenic-like" and anorectic effects. These effects are independent of the pituitary-adrenal-axis activation, suggesting a direct action on brain CRF receptors. Until recently only endogenous CRF-like neuropeptide had been isolated from mammalian brain and had been implicated in stress-induced behavioral changes, including anorexia. Urocortin (Ucn), a novel 40 amino acid neuropeptide related to CRF which binds to CRF<sub>2</sub> receptor, has been shown to be less potent than CRF in inducing anxiogenic-like effects and behavioral activation, but more potent than CRF in suppressing food intake in meal deprived animals. The aim of this study was to evaluate the appetite-suppressing effect of Ucn in animals not submitted to food deprivation. Male Wistar rats were allowed to obtain 45mg pellets and 100 ul of water ad-libitum during the dark phase of the light/dark cycle using a nose-poke response. Ucn at doses as low as 0.1 µg administered intracerebroventricularly (ICV) produced a significant decrease in food and water intake for up to 12h. At doses of 0.01 - 1.0 µg Ucn ICV decreased significantly the meal size and at 1.0 µg Ucn decreased the number of meals. These results indicate that Ucn has a different profile than CRF showing a powerful anorectic effect without aversive or anxiogenic-like effects, suggesting that Ucn may be an endogenous CRF-like factor responsible for controlling appetite. (Supported by NIH DK 26741).

## 184.8

REGIONAL AND DEVELOPMENTAL DIFFERENCES IN ALTERATION OF CRF CONTENT IN BRAIN OF PRENATALLY STRESSED RATS. D.L. Birkle\* and D.A. White. Department of Pharmacology & Toxicology, West Virginia University, Morgantown, WV 26506-9223.

The effects of prenatal stress were studied in offspring of pregnant rats subjected to daily 0.9% NaCl injection (0.1 ml, s.c.) from gestational day 14 to 21 (G14-G21). In adulthood, these prenatally stressed (PNS) offspring exhibit increased fearfulness, elevated content of CRF in amygdala, increased density of CRF-immunopositive neurons in amygdala and hypothalamus, adrenal hypertrophy, and elevated plasma corticosterone levels. In the present study the content of CRF was measured by RIA in brain regions from PNS rats perinatally. There was an age dependent increase in CRF content in all regions, but with varying time courses. In hypothalamus from PNS rats, elevated CRF content was detectable at all ages, including at embryonic day 18 (E18). In control offspring, CRF levels were stable in the hypothalamus over the stress-hyporesponsive period (129 pg/mg protein at P3 and P13), while in PNS rats, CRF increased markedly during this period (148 pg/mg protein at P3 increasing to 284 pg/mg protein at P13). This may explain elevated ACTH and corticosterone responses observed previously in preweaning PNS rats. In amygdala, PNS-induced increases in CRF content were not evident until P13 (21 pg/mg protein in control; 57 pg/mg protein in PNS). This suggests a possible role for post-natal factors in the manifestation of the effects of prenatal stress in amygdala. In anterior telencephalon (frontal cortex, striatum, hippocampus) and in brain stem (pons, medulla, midbrain), there were substantial age dependent increases in CRF from E18 to P13 but no effects of PNS at any age. Supported in part by NSF IBN922263 and the WVU Foundation.

HYPOTHALAMIC cAMP RESPONSIVE ELEMENT BINDING PROTEIN, CREB, MEDIATES NPY-INDUCED FEEDING IN RATS. S. Sheriff, W. T. Chance\*, J. E. Fischer and A. Balasubramaniam. Department of Surgery, University of Cincinnati and VA Medical Centers, Cincinnati, OH 45267

We have previously shown that NPY-induced feeding is mediated by a pertussis toxin sensitive G protein in rats [Peptides 10:1283-1286, 1989]. NPY receptors are coupled to cAMP and/or Ca<sup>2+</sup>. Since these second messengers are known to activate cAMP responsive element (CRE) binding proteins, CREB, CREM or ATF-1, we investigated whether these transcription factors mediate NPY-induced feeding in rats. As compared to control injections of CSF (1 µl), intrahypothalamic (iht) administration of NPY (1 µg) increased CRE binding to rat hypothalamic nuclear extracts in a time-dependent manner, as detected by an electrophoretic mobility shift assay. In contrast, iht-administration of the anorectic neuropeptide, PACAP (2 µg) strongly inhibited the CRE binding. Food deprivation for 48 hrs also increased CRE binding, while 8 hrs of refeeding normalized CRE activity. Preincubation of the hypothalamic nuclear extracts of NPY-treated and fasted rats with antibody specific to CREB blocked CRE binding, while preincubation with phospho-CREB antibody supershifted the CRE-CREB complex indicating that phospho CREB is involved in this process. Iht-NPY also increased hypothalamic CaM kinase II activity. These results suggest that CaM kinase induced phosphorylation of CREB regulates the feeding behavior induced by NPY, hunger and satiety in rats.

## 184.11

**INCREASED PROGRESSIVE RATIO RESPONDING AFTER INTRAHYPOTHALAMIC NEUROPEPTIDE Y IS NOT MEDIATED BY DOPAMINE.** C.M. Brown<sup>1</sup>, P.J. Fletcher<sup>1</sup>, and D.V. Coscina<sup>1,2</sup>. Section of Biopsychology, Clarke Institute of Psychiatry, Toronto, ON M5T 1R8<sup>1</sup> and Dept. of Psychology, Wayne State Univ., Detroit, MI 48202<sup>2</sup>.

Neuropeptide Y (NPY) is a 36 amino acid pancreatic peptide that is distributed throughout the central and peripheral nervous systems. One of its best known behavioural effects is to induce feeding in previously satiated animals after injection into the hypothalamus, especially the perifornical region (PFH). NPY also appears to have rewarding properties of its own, as evidenced by its ability to produce a conditioned place preference following injection into the nucleus accumbens. This effect is seemingly mediated by dopamine (DA) since  $\alpha$ -flupenthixol (FLU), a DA antagonist, blocks this effect. Another paradigm that has been used to assess reward is the progressive ratio (PR) operant schedule. To determine if intra-PFH NPY increases PR responding for sucrose and if DA might mediate this effect, four different experiments were conducted. In the first, PR output for sucrose reward was determined by injecting NPY (0, 78, 156, and 235 pmol) into the PFH of male rats. In the second study, FLU (0, 0.05, 0.1, 0.2 mg/kg, s.c.) was given 2 h prior to intra-PFH NPY (156 pmol) and PR responding was recorded. The third study tested FLU's effects alone on PR responding. The last experiment examined FLU's capacity to block intra-PFH NPY (156 pmol)-induced free-feeding. Although NPY reliably increased PR responding and FLU attenuated it, FLU had no greater inhibitory effect on NPY-stimulated output compared to drug-free output and also did not affect NPY-induced free-feeding. Collectively, the results suggest that distinct reward mechanisms are activated during NPY-induced feeding vs. PR responding since FLU disrupted the latter but not the former.

Supported by funds from NSERC of Canada.

**IN-VITRO SECRETION AND IN-SITU EXPRESSION OF HYPOTHALAMIC NEUROPEPTIDE Y DURING ZINC DEFICIENCY** C. Tovar-Palacio, A. Cole, H. Mangian, and N. Shay\*. Division of Nutritional Sciences; Department of Food Sci. & Human Nutrition; University of Illinois, Urbana, IL 61801.

Zinc deficient (Zn-) rats show marked anorexia and growth retardation compared to rats consuming a Zn-adequate (Zn+) diet. The mechanism causing this anorexia is not well understood. We have been investigating the changes in neuropeptide metabolism in the hypothalamus during zinc deficiency. Herein, we report findings from two studies: I - In vitro secretion of Neuropeptide Y (NPY) from microdissected sections of the paraventricular nucleus (PVN); and II - In-situ immunohistological assays of NPY in the PVN. Male Sprague-Dawley rats were provided either a Zn+ or Zn- diet for 21 d. In study II, groups of Zn- rats were also repleted with Zn after the development of zinc deficiency. All rats were killed at the onset of the dark cycle and tissues were either microdissected for secretion studies or fixed in buffered formalin for embedding and sectioning. In study I, tissue was incubated in neurobasal medium (GIBCO) for two 30 min periods, followed by a third 30 min incubation in high K<sup>+</sup> to verify tissue viability. Secreted NPY in media was measured by ELISA. NPY was secreted at a higher rate from Zn- rats (0.41 vs. 0.22 ng/mL,  $p < 0.05$ ). In study II, immunohistochemical staining was assessed through both blind ranking of immunostaining in photographs and by computer-based quantitation of immunostaining using image capture and "NIH Image" software. We found that NPY was present in the PVN at higher levels in the Zn-group. Data from studies I and II are consistent with data from our own lab indicating elevated NPY peptide and mRNA content in the PVN and ARC of Zn- rats. We conclude that although Zn- rats are anorexic, NPY content and secretion is higher, paralleling results observed in food-restricted rats, which eat reduced amounts of diet, but in contrast have a desire to consume greater amounts of diet.

## 184.15

**NEUROTOXIN-INDUCED TRANSIENT HYPERPHAGIA IS NEGATIVELY CORRELATED WITH HYPOTHALAMIC NEUROPEPTIDE Y** M.G. Dube, B. Xu, S.P. Kalra and P.S. Kalra\*, Depts. of Physiology and Neuroscience, Univ. Fla. Col. Med., Gainesville, FL 32610

The ventromedial hypothalamus (VMH) is known to play a role in the hypothalamic control of hyperphagia and obesity, however, its relationship with hypothalamic NPY, a neuropeptide involved in stimulation of feeding, remains to be ascertained. We employed colchicine (COL), a neurotoxin that interrupts axonal flow, to examine the relationship between food intake and NPY levels and gene expression. Microinjection of COL (4  $\mu$ g/0.5  $\mu$ l saline) bilaterally into the VMH of male rats produced a transient and robust hyperphagia; 24-hour food intake for the first 3 days was 2-3-fold higher than in saline injected control rats. COL-injected rats displayed marked body weight gain and weighed 50 g more than the controls by day 4. Thereafter, both food intake and rate of weight gain stabilized and were similar to controls. On days 1, 2 and 4 post-injection, we measured NPY levels in the paraventricular nucleus (PVN) and preproNPY mRNA levels in the arcuate region by RIA and RNase protection assay, respectively. Surprisingly, a negative relationship between hypothalamic NPY and hyperphagia was detected in COL-injected rats; On days 2 and 4, NPY gene expression was decreased by 75% and NPY levels in the PVN were reduced to 50%. These results show that a temporary inhibition of information flow from the VMH results in a marked decrease in NPY activity. Thus, the transient hyperphagia may be due either to increased release of NPY and/or to increased NPY receptor activation in the PVN target sites. (Supported by NIH NS32727).

## 184.12

**ANXIOLYTIC EFFECTS OF NEUROPEPTIDE Y IN RATS WITH LESIONS OF THE LATERAL SEPTUM.** E. Thomas\* and J. Snellman. Dept. of Psychology, Bryn Mawr College, Bryn Mawr, PA 19010

The role of the lateral septum in the mediation of the anxiolytic properties of neuropeptide Y (NPY) was assessed using the elevated plus-maze. The design of the experiment was a 2x2 factorial with half of the animals receiving a bilateral electrolytic lesion of the lateral septum and the other half receiving a sham lesion. Half of each these groups received NPY (1 nmol) administered intracerebroventricularly. The other half received vehicle alone. Thirty minutes later animals were placed in the plus-maze for a 5 minute session. Number of entries into the open arms and time in the open arms were measured.

Both the drug and the lesions were found to significantly increase the percentage of entries and the amount of time spent on the open arms. The effects of the lesion and the drug were additive with the greatest effect seen in the animals receiving both lesion and NPY.

The data suggest that the septum is not the primary site of action of the anxiolytic properties of NPY despite being relatively high in NPY receptor density. The results were interpreted as reflecting a combination of an anxiolytic effect of NPY with an impairment of a fear-relief mechanism normally provided by the septum.

## 184.14

**THE EFFECTS OF INTRACEREBROVENTRICULAR INJECTIONS OF NPY, PYY, AND PP ON ACUTE FEEDING BEHAVIOR AND LOCOMOTOR ACTIVITY IN THE MOUSE.** M.E. Judge\*. Dept. of Behavioral Pharmacology, Novo Nordisk A/S, DK-2760, Måløv, Denmark.

Neuropeptide Y (NPY) is known to be involved in the central regulation of feeding. Central injections of NPY and the related peptides PYY and PP via indwelling cannulae in the rat have been shown to enhance feeding (PYY>NPY>PP), but the need for surgical pretreatment places severe limits on study designs. In this study, mice were given injections of the neuropeptides directly into the lateral ventricle utilizing a freehand technique requiring neither anaesthesia nor pre-implanted guide cannulae. This permitted the testing of relatively large groups of animals, allowing full dose response curves to be generated. Thirty minutes after ICV injection of .02-10 micrograms ( $\mu$ g) of human NPY, PYY, or PP, separate groups of 6 mice were given one of two tests, each lasting ten minutes. Infrared photocell activity chambers were used to record spontaneous locomotor activity. All three peptides depressed activity at high doses, but for NPY and PP the maximum effect was only marginal ( $p < 0.1$ ), while 5  $\mu$ g of PYY suppressed activity by 77% ( $p < 0.01$ ). NPY increased activity at low doses, with a maximum increase of 109% over controls at 0.5  $\mu$ g ( $p < 0.001$ ). No increases in activity were seen with PP or PYY. Effects on feeding were tested by measuring the total time spent consuming an infant milk formula during a 600sec test. In terms of the maximum response measured, PP gave the least enhancement of feeding (107sec / 5  $\mu$ g), NPY gave a somewhat greater response (127sec / 5  $\mu$ g), and the greatest response was obtained with PYY (311sec / 2  $\mu$ g), a 4 fold increase over controls. These data are similar to those obtained in rats, demonstrating intra-species similarities, some of the differences between the peptides, and the utility of the technique.

## 185.1

THE ANTICIPATORY EFFECTS OF ETHANOL ON DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS OF P AND WISTAR RATS. S.N. Katner\* and F. Weiss, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

It has been argued that alcohol-associated environmental cues can activate reinforcement substrates, thereby initiating ethanol-seeking behavior and maintaining ethanol intake until the direct reinforcing actions of the drug take effect. To test this hypothesis independent groups of alcohol-preferring (P) and Wistar rats were trained to orally self-administer either 10% (w/v) ethanol or saccharin (0.05%). Accumbal dopamine (DA) efflux was then monitored via microdialysis during self-administration of either substance. Self-administration of saccharin failed to elevate extracellular DA in both strains. However, when ethanol-trained P rats were tested by substituting saccharin for ethanol, the sweetener produced a significant elevation (150% of baseline within the first 15 minutes) in extracellular DA. In contrast, when ethanol-trained Wistar rats were tested by substituting saccharin for ethanol, no change in extracellular DA was observed. These results indicate that in P, but not Wistar rats, the expectation of ethanol promotes some DA release during the self-administration of a substance that is not normally associated with increased DA efflux. It is possible the "expectation-induced" stimulation of DA release in the P rat plays a role in the maintenance of ethanol-seeking behavior and that incentive stimuli enhance the neurochemical effects of the primary reinforcer in this line of rats. ## 185.3

ACCUMBAL DOPAMINE-OVERFLOW AFTER ETHANOL; LOCALIZATION OF MECAMYLAMINE'S ANTAGONIZING EFFECT.

M. Ericson\*, O. Blomqvist, J.A. Engel and B. Söderpalm, Inst. of Physiology and Pharmacology, Dept. of Pharmacology, Göteborg University, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

Ethanol, as well as several other drugs of abuse can activate the mesocorticolimbic dopamine system, which is regarded as an important neuroanatomical substrate for drug dependence. It appears that ethanol's activation of this system involves central nicotinic acetylcholine receptors (nAChR). Thus, we have previously shown that mecamylamine (1 mg/kg i.p.), a blood brain barrier penetrating antagonist at the nAChR, completely blocks ethanol-induced (2.5 g/kg i.p.) dopamine overflow in the nucleus accumbens in Wistar rats, as measured by *in vivo* microdialysis, while hexamethonium (10 mg/kg i.p.), a quaternary nAChR antagonist, does not.

In the present study, two microdialysis probes were placed in each rat for simultaneous perfusion in the ventral tegmental area (VTA) and the ipsilateral nucleus accumbens. When mecamylamine was perfused in the VTA, but not in the nucleus accumbens, ethanol-induced (2.5 g/kg i.p.) accumbal dopamine overflow; 30% above baseline levels, was completely blocked. Mecamylamine by itself produced no statistically significant effect neither in the nucleus accumbens nor in the VTA. Since mecamylamine, given systemically, previously was demonstrated to decrease voluntary ethanol-intake in high-preferring rats, we hypothesize that ethanol's dopamine-releasing effect, which may be of importance for its reinforcing effect, is mediated via activation of central nAChR preferably in the VTA.

In ongoing studies we examine whether high-preferring rats decrease their voluntary ethanol-intake when perfused with mecamylamine in the VTA.

This study was supported by Swedish MRC (no 11583 and no 4247)

## 185.5

ETHANOL ALTERS ACTION POTENTIAL SHAPE IN DOPAMINERGIC NEURONS OF THE VENTRAL TEGMENTAL AREA. M.S. Brodie\* and S.A. Shefner, Dept. Physiology & Biophysics, Univ. Illinois at Chicago, College of Medicine, Chicago, IL 60612-7342.

The reinforcing effects of ethanol may be mediated by dopaminergic (DA) neurons of the ventral tegmental area (VTA). Intracellular recordings were made from VTA neurons in brain slices from male rats (Fischer 344 and Sprague-Dawley). All cells were identified as DA based on electrophysiological criteria. Ethanol (40 - 160 mM) excited 60% of 35 spontaneously active VTA neurons studied. Most cells (57%) were depolarized by ethanol. Mixed cationic, time-dependent inward rectification appeared to be increased by ethanol (40 - 160 mM) in 65% of cells tested (n = 26).

For cells excited by ethanol, action potential data were collected and analyzed with pClamp software. Measurements of spike shape were made on averaged spontaneous action potentials in the presence and absence of ethanol and compared by paired t-test. Spike amplitude was reduced by 80 mM ethanol from  $59 \pm 2.3$  mV to  $55 \pm 2.4$  mV (n = 11,  $P < 0.01$ ), and by 160 mM ethanol from  $66 \pm 1.4$  mV to  $60 \pm 1.7$  mV (n = 12,  $P < 0.001$ ). Spike duration at 1/2 amplitude was not significantly altered by either concentration of ethanol. The peak amplitude of the afterhyperpolarization was reduced by 80 mM ethanol from  $-15.7 \pm 1.3$  mV to  $-14.7 \pm 1.3$  mV (n = 11,  $P < 0.05$ ), and by 160 mM ethanol from  $-16.4 \pm 0.7$  mV to  $-14.4 \pm 0.9$  mV (n = 12,  $P < 0.001$ ). Of cells excited by ethanol, 80 mM ethanol caused a mean membrane potential change from  $-50 \pm 1.9$  mV to  $-49 \pm 1.7$  mV (n = 11,  $P < 0.05$ ); 82% of these cells were depolarized by 80 mM ethanol (from  $< 1$  mV to 4 mV). Ethanol (160 mM) also depolarized most cells tested (75%, from  $< 1$  mV to 4.5 mV), but produced a non-significant change in mean membrane potential from  $-54 \pm 1.6$  mV to  $-53 \pm 1.8$  mV (n = 12, n.s.,  $P > 0.05$ ). These effects may underlie the ethanol-induced excitation of VTA neurons which is associated with the rewarding effects of alcohol.

## 185.2

THE EFFECT OF NEFAZODONE ON ETHANOL-INDUCED ACCUMBAL DOPAMINE RELEASE, ETHANOL PREFERENCE AND INTAKE IN RATS. P. Olsson\*, M. Ericson, A. Petersson, A. Kosowski, J.A. Engel and B. Söderpalm, Inst. of Physiology and Pharmacology, Dept. of Pharmacology, Göteborg University, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

Most drugs of abuse, including ethanol, activate the mesocorticolimbic dopamine (DA) system, an effect considered to be involved in mediating drug reward. Evidence indicates that serotonin (5-HT) may influence rewarding mechanisms via modulation of mesocorticolimbic DA activity. The present study evaluated the effects of the antidepressant nefazodone, a combined 5-HT<sub>2</sub> receptor antagonist and 5-HT reuptake inhibitor, on ethanol reward mechanisms in the rat.

In microdialysis experiments in male Wistar rats, ethanol (2.5 g/kg i.p.) and nefazodone (50 mg/kg s.c.) both induced DA release, 40% and 30% respectively, above baseline in the nucleus accumbens (N Acc). Interestingly, nefazodone (50 mg/kg s.c.) injected 40 min before the administration of ethanol strongly attenuated ethanol-induced DA release (30% decrease compared to ethanol alone) in the N Acc. Nefazodone (25 mg/kg i.p.) did not affect the DA release *per se* and did not significantly alter the ethanol-induced DA release in the N Acc.

The effect of nefazodone (50 mg/kg s.c.) on voluntary ethanol preference and intake in high- ( $\geq 60\%$  ethanol) and low-preferring ( $\leq 20\%$  ethanol) Wistar rats was also evaluated. In high-preferring rats administration of nefazodone significantly decreased both ethanol preference (20%) and intake (50%), while the intake of water was unaffected. However, in low-preferring rats the water intake was significantly lowered but the ethanol preference and intake were not altered, probably due to the low baseline ethanol intake.

The present results show that nefazodone attenuates ethanol-induced DA release in the N Acc and suggest that this neurochemical effect may be of functional significance in terms of ethanol reward in high-preferring rats.

This study was supported by Bristol Myers Squibb, Scandinavia and by the Swedish MRC (grants no 4247 and 11583).

## 185.4

SINGLE UNIT RESPONSES RECORDED IN THE NUCLEUS ACCUMBENS OF RATS DURING ETHANOL SELF-ADMINISTRATION ARE RELATED TO BOTH OPERANT RESPONDING AND REINFORCER DELIVERY. P.H. Janak\* and D.J. Woodward, Dept. of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Medical Center Blvd., Winston-Salem NC 27157.

A variety of studies, including single-unit recording studies, suggest that the nucleus accumbens (Nac) may be part of a neural circuit that regulates behavioral responding for drugs and other reinforcers. In the present study, we recorded neural activity within the Nac during ethanol self-administration to determine if neural activity in this region also is associated with ethanol reinforcement. Male Long-Evans rats were trained to bar press on a continuous reinforcement schedule for drops (.1 cc) of 10% ethanol, or 10% ethanol/2% sucrose, solutions. A tone preceded delivery of the reinforcer. Following training, rats were chronically implanted with one or two square arrays of 16 microwires each into the Nac. After surgical and behavioral recovery, simultaneous recordings of the extracellular spike activity of 6-30 single units per subject were made during ethanol-reinforced operant behavior. Neurons showed phasic changes in firing related to the operant response and to the delivery of the reinforcer. In addition, a small number of units showed either excitation or inhibition in relation to the tone stimulus that preceded reinforcer delivery. These data suggest that neural activity within the Nac may serve to integrate sensory stimuli and motor activity preformed to obtain ethanol, and support the hypothesis that the Nac is a component of a response initiating system that associates conditioned stimuli and reinforcers with operant behavior. VOLTAGE-DEPENDENT ETHANOL EFFECT ON NMDA RECEPTOR-MEDIATED EXCITATORY SYNAPTIC TRANSMISSION IN BASOLATERAL AMYGDALA. J.L. Calton, S.D. Moore\*, and W.A. Wilson, Duke University Medical Center and VAMC, Durham, NC 27705.

We are currently using the whole-cell recording technique to investigate the effects of ethanol on NMDA transmission in the cells of the basolateral amygdala, a brain region which may mediate anxiolytic effects of ethanol.

Coronal brain sections were prepared from rats (21-28 days old) and whole-cell current-clamp and voltage-clamp recordings were made of pyramidal neurons in basolateral amygdala, using a Cs<sup>+</sup> based internal solution. Bicuculline (20  $\mu$ M) and DNQX (20  $\mu$ M) were added to the bath. Stimulation near the cell produced large (15-45 mV) depolarizing events that were eliminated by bath application of APV (50  $\mu$ M). Application of ethanol to the bath in anxiolytic concentrations (22-88 mM) resulted in a dose-dependent attenuation of these NMDA receptor-mediated events. We determined this effect to be voltage-dependent, with increased attenuation of the evoked responses at more hyperpolarized membrane potentials. The average attenuation at an ethanol concentration of 44 mM was 12.2% at 0 mV, 13.1% at -20 mV, and 23.1% at -40 mV. This voltage-dependent relationship was seen at all ethanol concentrations tested. Washout of the ethanol effect could be observed after 20 minutes.

We feel that a voltage-dependent ethanol effect will have significant consequences for overall functioning of the amygdala network. Supported by grants from the NIH and the VA.

## 185.7

**Effects of Chronic Ethanol Treatment on Glutamate Receptor Subunits in Rat Brain Regions.** R.P. Yasuda<sup>1,2\*</sup>, A.W. Dunah<sup>1,2</sup>, J. Luo<sup>1</sup>, Y.-H. Wang<sup>1</sup>, J.G. Rudolph<sup>3</sup>, and F.T. Crews<sup>2</sup>. <sup>1</sup>Department of Pharmacology, and <sup>2</sup>Interdisciplinary Program in Neuroscience, Georgetown University School of Medicine, Washington, D.C. 20007, and <sup>3</sup>Center for Alcohol Studies, University of North Carolina, Chapel Hill, N.C. 27599.

Chronic ethanol treatments lead to changes in glutamate receptor function and receptor densities. The glutamate ionotropic receptors are complexes of several different subunits. Therefore, chronic ethanol treatments could alter the function or the number of receptors by changes in one or all of the subunits of the ion channel. Recently, Trevisan *et al.* (J. Neurochem. 62:1635-1638, 1994) observed a 65% increase in the NMDA R1 receptor subunits in the rat hippocampus after 30 days of chronic ethanol treatment. This study investigates whether other NMDA and AMPA receptor subunits change after 2 weeks of an ethanol diet. Rats were pair-fed a liquid ethanol diet and rats consumed 4-5 grams of ethanol a day for two weeks. The rat frontal cortex and hippocampus were examined with antibodies that have been previously characterized as being selective for a given NMDA or AMPA receptor subunit. Preliminary studies have demonstrated a 19% increase in the NMDA 2D receptor subunit in the hippocampus but not the frontal cortex. The NMDA R1, NMDA 2A, NMDA 2B, GluR1, and GluR4 receptor subunit number were not different from control rats in either the hippocampus or frontal cortex. Other rat brain regions will be examined. NMDA receptors containing the NMDA 2D receptor subunit form a channel with a prolonged decay time and a decrease in the ability of magnesium to block the channel. Since the NMDA receptors in the hippocampus have been implicated in long-term potentiation, an increase in the expression of this receptor subunit may alter the normal function of the NMDA receptor complex in learning and memory.

**HIPPOCAMPAL SUPERSENSITIVITY FOLLOWING CHRONIC ETHANOL EXPOSURE.** L. P. Gonzalez\* and M. Wu. Univ of Oklahoma HSC, Dept of Psychiatry & Behavioral Sci., P.O. Box 26901, Oklahoma City, OK 73190.

The studies reported here were conducted to determine if chronic ethanol alters the responsiveness of hippocampal neurons to locally-applied acetylcholine. Extracellular single-unit activity was recorded with one barrel of a multibarrel glass micropipette containing 4M NaCl; additional barrels contained acetylcholine chloride (ACh), glutamate and vehicle control solutions. Brief applications of ACh (0.05-5.0 mM) or of glutamate (0.01-1.0 mM) were administered by micropressure-ejection. Acetylcholine application resulted in increases in single-unit activity in the hippocampal CA<sub>3</sub> field, but only slight changes in the CA<sub>1</sub> field. Glutamate increased single-unit activity in both the CA<sub>1</sub> and CA<sub>3</sub> fields. Chronic exposure to ethanol by vapor inhalation, followed by withdrawal from ethanol for ten to 24 hrs resulted in significant increases in the response to ACh in the hippocampal CA<sub>3</sub> field, but not in the CA<sub>1</sub> field. Responding in the CA<sub>3</sub> field returned to control levels within 48 hrs after ethanol withdrawal. Responses to glutamate did not differ in either area after chronic ethanol exposure and withdrawal. These data suggest a significant increase in the cholinergic responsiveness of hippocampal CA<sub>3</sub> pyramidal cells after chronic ethanol exposure, and show that this effect is unique to this region of the hippocampus.

**CHRONIC ETHANOL ADMINISTRATION INCREASES TYROSINE HYDROXYLASE MRNA, BUT NOT NOREPINEPHRINE TRANSPORTER MRNA IN THE LOCUS COERULEUS** Patricia Szoj<sup>1</sup>, Sylvia S. White, Richard C. Veith and Dennis Rasmussen, Depts. Psy. Beh. Sci. and Med., Univ. Washington and VA Puget Sound Health Care System, GRECC, Seattle, WA 98108.

Noradrenergic neurons have been implicated in the development of dependence and tolerance to ethanol's effects. Chronic ethanol (ETOH) consumption increases the rate of NE synthesis and turnover with no change in norepinephrine transporter (NET) sites. The following study was performed to determine the effects of chronic ethanol administration on two indices of noradrenergic function: the mRNA expressions of the rate limiting enzyme tyrosine hydroxylase (TH) and NET in the locus coeruleus (LC). Adult male Sprague-Dawley rats were given ETOH 6% in a liquid diet for 5 weeks, followed by a slow withdrawal over the next week. To adjust for altered food consumption during chronic ETOH administration, both pair-fed (PF) and ad lib fed control groups were added. After 5 weeks of ETOH and 1, 3 and 7 days following 0% ETOH administration, animals were sacrificed by decapitation and the brains were rapidly removed and frozen. TH mRNA expression in the LC was significantly elevated compared to ad-lib and PF only in animals exposed to ETOH for 5 weeks (pixels over LC in ad-lib=824.6±69.8, PF=964.5±48.8 and ETOH=1423.8±132.3). The increase in TH mRNA expression could be attributed to a significant increase in the number of cells in the LC expressing TH mRNA (number in ad-lib=110±10.7, PF=111±4.3 and ETOH=140±6.6). TH mRNA expression in the LC was not significantly different following ETOH withdrawal. NET mRNA expression in the LC was not significantly different in the ETOH animals or withdrawn animals compared to ad-lib or PF. These data indicate that TH mRNA expression is elevated following a chronic 5 week administration of ETOH, while the expression of the neurotransmitter mRNA is unchanged. The increase in TH mRNA in the LC may be responsible for the enhanced rate of NE synthesis observed with chronic ETOH. ## 185.8

**WITHDRAWAL FROM CHRONIC ETHANOL EXPOSURE IN HIPPOCAMPAL EXPLANT SLICE CULTURES: EPILEPTIFORM EVENTS CORRELATE WITH ENHANCEMENT OF THE NMDAR COMPONENT OF SYNAPTIC TRANSMISSION.** MP Thomas\* and RA Morrisett. Dept. of Pharmacol., Univ. Nebraska Med. Ctr., Omaha, NE, 68198-6260.

Much evidence suggests an involvement of voltage-gated calcium channels in the induction and expression of ethanol withdrawal hyperexcitability (Whittington *et al.*, 1993). A good deal of correlative evidence also implicates NMDA receptors in this alcohol-related disorder. We utilized the hippocampal slice explant preparation to simultaneously assess alterations in NMDAR-mediated synaptic responses and neural hyperexcitability following withdrawal.

Slice cultures were prepared from 9-10 day old rat pups and exposed to 35 or 75 mM ethanol for 6-11 days. Field potentials evoked by Schaffer collateral stimulation were recorded from the CA1 cell layer. Recordings were initially made in ethanol and for 7 hours following acute *in vitro* withdrawal; control slices were recorded in standard solution over the same time period.

Withdrawal from chronic exposure was associated with an enhancement of the slow, NMDAR-mediated synaptic potential (D-APV-sensitive) and the induction of epileptiform events. The NMDAR component increased by 74% and 132% in the 35 and 75 mM explant groups respectively over the entire 7hr WD period compared to pre-WD levels. Prolonged electrographic seizure events (>90 sec) occurred following ethanol withdrawal in 10 of 14 slices from both treatment groups. Bath application of the NMDAR antagonist, D-APV (25-50 μM) selectively inhibited the enhanced NMDAR synaptic responses and completely abolished epileptiform activity.

These data demonstrate a dose-dependent enhancement of NMDAR function following chronic ethanol exposure and suggest a direct correlation with the expression of seizure activity during withdrawal. (R29 9230 to RAM).

## 185.10

**ETHANOL IMPAIRS DISCRIMINATION PERFORMANCE: RELATION TO HIPPOCAMPAL NEUROPHYSIOLOGY** B. Givens\* and D. Kent. Department of Psychology, The Ohio State University, Columbus, OH, 43210.

The disruption of hippocampal circuitry by ethanol may underlie ethanol-induced memory impairments. Rats were trained on a two tone auditory discrimination task, and then implanted with electrodes in the dentate gyrus, the perforant path and the medial septal area. Ethanol (0.0, 0.5, 0.75, and 1.0 g/kg i.p.) dose-dependently impaired performance on the discrimination task, and simultaneously affected hippocampal physiology. The slope and amplitude of the dentate evoked responses elicited by perforant path stimulation were dose-dependently suppressed by ethanol. In addition, the magnitude of paired-pulse inhibition was reduced by ethanol. In contrast to previous results in a working memory task, the auditory stimuli did not produce a resetting of theta activity. However, theta activity during the 2 sec period following tone onset was significantly greater for the relevant (rewarded) tone than for the irrelevant tone. Ethanol dose-dependently reduced this difference by selectively suppressing theta activity following the relevant tone. The data indicate that disruption of hippocampal neurophysiology correlates with decrements in discrimination performance following ethanol. Supported by PHS-AA09484.

## 185.12

**ENDOGENOUS CATECHOLAMINES REGULATE ETHANOL SENSITIVITY ON CEREBELLAR PURKINJE NEURONS.** Michael R. Palmer\*, Ronald K. Freund, and Yun Wang. Dept. of Pharmacology, Univ. of Colorado Health Sci. Ctr., Denver, CO 80262 and National Defense Medical School, Taipei, Taiwan, R.O.C.

We and others previously reported that ethanol (EtOH) will potentiate the β-adrenergic modulation of GABA-induced depressions of cerebellar Purkinje neurons, and we have published evidence that isoproterenol, a β-adrenergic agonist, potentiates the depressant effects of EtOH on these neurons. During that study, we also found that on 20% of Purkinje neurons in Sprague Dawley rats A) the depressant EtOH effects can be decreased by timolol, a β-adrenergic antagonist, and B) the EtOH potentiation of unmodulated GABA responses can be blocked by timolol, suggesting that endogenous catecholamine transmission might interact with these EtOH actions in that population of neurons. We tested that possibility in the present investigation. 1) We found that a catecholamine reuptake antagonist, DMI, potentiated the depressant effects of EtOH on those cells. 2) We also observed that naloxone withdrawal from chronic morphine, which activates catecholamine circuits, caused EtOH-induced depressions to become larger. 3) Finally, we found that stimulation of the catecholamine input to the cerebellum by stimulation of the locus coeruleus facilitated the inhibitory actions of EtOH on spontaneous firing. We concluded that endogenous catecholamine input to the cerebellum can regulate the responsiveness of cerebellar Purkinje neurons to the depressant effects of EtOH.

**ABERRANT MEMBRANE AND SYNAPTIC PROPERTIES OF INFERIOR COLLICULUS DORSAL CORTEX NEURONS DURING WITHDRAWAL IN ETHANOL DEPENDENT RATS.** Y. Li\* and C.L. Faingold. Department of Pharmacology, Southern Illinois Univ. Sch. Med., Springfield, IL 62794-1222.

Ethanol withdrawal (ETX) after continued administration results in neuronal hyperexcitability. Previous *in vivo* results have shown that the inferior colliculus (IC) is critically involved in the network for audiogenic seizure (AGS), which is one of the most severe ETX signs. The present study investigated firing patterns, membrane properties and synaptic responses in IC dorsal cortex (ICd) during ETX. Intracellular recordings *in vitro* were made from IC slices during ETX in rats that were made dependent by ethanol administration three times daily for 4 days (9-15 g/kg/day). The data from ETX were compared with data from normal rats. In normal ICd, spontaneous action potentials (APs) were never observed (0 of 31). However, tonic or phasic spontaneous APs were recorded in ETX (5 of 16). Bath applications of an AMPA receptor antagonist DNQX (20  $\mu$ M) and an NMDA receptor antagonist, AP-5 (50  $\mu$ M), blocked spontaneous APs. Synaptic stimulation of the IC commissure can normally induce two IPSPs with different time courses in ICd neurons. These IPSPs may be mediated by GABA<sub>A</sub> receptors, since bicuculline (20  $\mu$ M), a GABA<sub>A</sub> antagonist, can block them. During ETX as the intensity of the stimulus was increased the EPSP occurred between the IPSPs became more dominant and often developed into an AP (3 of 3), which was not seen in normals (0 of 4). This EPSP could be blocked completely in the presence of AP-5 and DNQX. Synaptically-evoked paired pulse facilitation was seen in ICd neurons during ETX (3 of 3), whereas paired pulse inhibition was observed in most normal ICd neurons (6 of 8). Epileptiform activity can be induced by electrical stimulation of the IC commissure during ETX in ICd neurons (4 of 10), but could not be evoked in normal ICd neurons (0 of 15) unless the slice was first perfused with bicuculline or NMDA. Thus, ICd neurons during ETX show aberrant firing patterns, hyperexcitable membrane properties and abnormal synaptic responses, which are likely to contribute importantly to AGS susceptibility during ETX. (Supported by NIAAA AA08591)

**EFFECTS OF ETHANOL ON SPONTANEOUS SYNAPTIC CURRENTS IN CULTURED CORTICAL NEURONS** W. Marszalec\* and T. Narahashi. Dept. of Mol. Pharmacol. & Biol. Chem., Northwestern Univ. Med. Sch., Chicago, IL 60611.

Neurons dissociated from embryonic rat frontal cortex generate spontaneous synaptic currents after a week in culture. With the membrane potential held near -40 mV these currents could be differentiated into outward excitatory and inward inhibitory postsynaptic currents (EPSCs and IPSCs) by replacing some of the chloride in the pipette solution with the impermeant gluconate anion. IPSCs were inhibited by the GABA<sub>A</sub> receptor antagonist bicuculline, whereas EPSCs were blocked by the glutamate antagonist CNQX. No spontaneous activity occurred in the presence of tetrodotoxin or 10 mM MgCl<sub>2</sub>.

The bath application of 100 mM ethanol dramatically inhibited the occurrence of spontaneous EPSCs in all cells tested. Concomitant with this effect was a small enhancement of IPSC amplitude. IPSC frequency in most experiments was also reduced. The reversal of these effects upon washout of ethanol was sometimes accompanied by a rebound enhancement of EPSC amplitude. Ethanol, at 30 mM, produced similar effects in some, but not all cells. Ethanol at 30-100 mM decreased the currents evoked by 3  $\mu$ M glutamate by approximately 25%, whereas currents evoked by 3  $\mu$ M GABA were unaffected. The data suggests that the depression of spontaneous synaptic currents in these neurons by ethanol cannot be explained by an effect on postsynaptic glutamate or GABA receptor channels alone. Supported by NIH Grant AA07836.

## 185.17

**FYN TYROSINE KINASE AND ETHANOL SENSITIVITY: RELATION TO NMDA RECEPTOR FUNCTION.**

T. MIYAKAWA<sup>1</sup>\*, H. KITAZAWA<sup>2</sup>, N. KAWAI<sup>2</sup>, T. YAGI<sup>3</sup>, M. YASUDA<sup>3</sup> and H. NIKI<sup>1</sup>. <sup>1</sup>Dept. of Psychol., Fac. of Lett., University of Tokyo, Tokyo, 113, Japan, <sup>2</sup>Dept. of Physiol., Jichi Medical Sch., Tochigi, 329-04, Japan, <sup>3</sup>Dept. of Neurobiol. Behav. Genet., National Inst. of Physiol. Sci., Okazaki, 444, Japan.

The aim of the present study was to examine possible roles of Fyn in ethanol sensitivity. We produced Fyn-deficient mice by inserting the *lacZ* into the *fyn* gene. Fyn-deficient mice were found to be more sensitive to ethanol when we measured the duration of loss of righting reflex. Western blot analysis revealed enhanced tyrosine phosphorylation of the NMDA receptor in the hippocampus after administration of ethanol while such up-regulation was not seen in the Fyn-deficient mice. Extracellular recording of field EPSPs in the CA1 field of the hippocampal slices showed that acute tolerance to ethanol inhibition of NMDA-mediated EPSPs developed in the heterozygous Fyn-deficient mice while it did not in the homozygous Fyn-deficient mice. These results suggest a role of Fyn in the recovery process from the inhibition of the NMDA receptor function after application of ethanol. Supported by Grant-in-Aid for Scientific Research 07451018.

## 185.14

**PARTIAL CHARACTERIZATION OF Ca<sup>2+</sup> CHANNELS WHICH MEDIATE MUSCIMOL-INDUCED INCREASE IN CYTOSOLIC [Ca<sup>2+</sup>] IN GT1-7 NEURONS: EFFECTS OF ETHANOL.** M.A. Javors\*, T.S. King, and X. Chang. Departments of Psychiatry, Pharmacology, and CS&B, University of Texas HSC, San Antonio, Texas 78284.

GT1-7 hypothalamic neurons, which synthesize and secrete GnRH (gonadotrophin releasing hormone), were immortalized from transgenic mice and have been shown to express functional GABA<sub>A</sub> receptors. Our previous experiments showed that stimulation of these receptors with muscimol produced an efflux of <sup>36</sup>chloride, an increase of cytosolic [Ca<sup>2+</sup>], and the release of GnRH. Ethanol enhanced GABA<sub>A</sub>-mediated increase in cytosolic [Ca<sup>2+</sup>], but not <sup>36</sup>chloride efflux, suggesting that the ethanol effect did not occur at the GABA<sub>A</sub> receptor. This previous work supports the hypothesis that the GABA<sub>A</sub>  $\gamma$  subunit, which is not expressed in GT1-7 neurons, may be required for low dose ethanol effects. The purpose of this study was to further characterize the calcium channels that mediate muscimol-induced increase in cytosolic [Ca<sup>2+</sup>] (M-ΔCa) and to test the effects of ethanol. GT1-7 neurons were grown to confluence on plastic coverslips and cytosolic [Ca<sup>2+</sup>] was measured using the fura-2 method and a Deltascan fluorometer. Our results indicate that nimodipine, an L-type Ca<sup>2+</sup> channel inhibitor, inhibited M-ΔCa by approximately 70% with an IC50 of 1  $\mu$ M. Conotoxin and agatoxin had minimal effects on M-ΔCa. (+/-)BayK8644 enhanced M-ΔCa with an ED50 of 0.05  $\mu$ M. This enhancement was inhibited by ethanol. (-)BayK8644, an activator of L-type Ca<sup>2+</sup> channels, enhanced M-ΔCa and its effect was inhibited by ethanol. (+)BayK8644, an inhibitor of L-type Ca<sup>2+</sup> channels, inhibited M-ΔCa. Pentobarbital enhanced M-ΔCa, probably through an effect at the GABA<sub>A</sub> receptor. These results support the notion that L-type Ca<sup>2+</sup> channels mediate a significant percentage of muscimol-induced, GABA<sub>A</sub> mediated increase in cytosolic [Ca<sup>2+</sup>] in GT1-7 neurons and that ethanol may interact with these channels. (Supported by NIAAA grant number 10112.)

## 185.16

**MODULATION BY ADENOSINE (ADO) OF ETHANOL-INDUCED MOTOR IMPAIRMENT (EIMI) IN THE RAT MOTOR CORTEX: POSSIBLE ROLE OF CYCLIC AMP.** V. S. Barwick and M. S. Dar\*. Department of Pharmacology, School of Medicine, East Carolina University, Greenville, NC 27858.

Earlier work from our lab showed that, when given systemically, ADO antagonists lessen and uptake-blockers enhance EIMI. Subsequently, we have shown that ADO agonists and antagonists accentuate and attenuate, respectively, EIMI when microinfused into the ventricles, striatum and the cerebellum of rats. Since then, we have shown that, via the ADO A<sub>1</sub> receptor, ADO agonists enhance and antagonists diminish EIMI when microinfused into the motor cortex. Participation of the motor cortex in the mediation of EIMI was established by the benzodiazepine partial agonist, Ro15-4513. Microinfused bilaterally into the motor cortex, Ro15-4513 significantly attenuated EIMI in a dose related manner. The dispersion patterns of a microinfused [<sup>3</sup>H]-labelled ADO agonist and antagonist, followed by systemic injection of ethanol (EtOH, 1.5 g/kg) or saline, were similar. The dispersion was confined to a circumscribed area of the motor cortex and was not affected by EtOH or saline. It is well known that the A<sub>1</sub> receptor is coupled to the pertussis toxin (PT)-sensitive G<sub>i</sub>/G<sub>o</sub>-protein. Pretreatment of the motor cortex with PT significantly attenuated the enhancement of EIMI by ADO agonists. There was also an attenuation of EIMI which approached significance at 45 min post-EtOH (p<0.07). These data suggested a role for the PT-sensitive G<sub>i</sub>/G<sub>o</sub> protein in the modulation of EIMI by ADO. A significant decrease in motor cortical cAMP in response to EtOH as measured by RIA suggested the possible involvement of the AC/cAMP system and provided further insight into the signal transduction pathway in the modulatory role of ADO in EIMI. Further, behavioral data has indicated that forskolin, which stimulates AC, significantly lessens EIMI when microinfused into the motor cortex. We propose that the elements involved in the mediation of EIMI, and perhaps modulation by ADO, in the rat motor cortex include the G<sub>i</sub>/G<sub>o</sub> protein and the AC/cAMP system.

**THE EFFECTS OF ETHANOL ON THE EXPRESSION OF BRAIN METALLOTHIONEIN AND CYTOCHROME P4502E1.** G. Helal, M.L. Heidrick, F.M. Hamada, M.P. Leuschen, J. Hofert, J.F. Rodriguez-Sierra, P.L. Iversen and M. Ebadi. Depts. of Pharmacology, Biochemistry and Molecular Biology, and Cell Biology and Anatomy, Univ. of Neb. Coll. of Med., Omaha, NE 68198-6260.

Microsomal ethanol-oxidizing system (MEOS), a nonalcohol dehydrogenase (ADH) pathway of ethanol oxidation, plays a significant role in ethanol metabolism, and its activity increases after chronic consumption of ethanol. This system is dependent on cytochrome P450, and the ethanol-inducible form has been designated as cytochrome P4502E1 (CYP2E1), which exhibits no difference in its gene frequency in healthy subjects when compared to alcoholics. Ethanol induces single DNA breaks in brain cells, inhibits neurite extension by increasing N-myc and C-myc protein expression, and increases oxygen derived free radical generation, through reaction of CYP2E1. In view of the fact that: 1) zinc is a cofactor for alcohol dehydrogenase; 2) ethanol causes a zinc deficiency state; and, because 3) zinc is able to prevent the deleterious effects of ethanol, the association among metallothionein (MT), a low molecular weight zinc binding protein capable of averting oxidative stress, and CYP2E1 was studied in the liver and various brain regions of ethanol treated rats. Acute administration of ethanol dramatically induced the synthesis of MT in the liver but not in the brain. On the other hand, the chronic consumption of ethanol modestly and nonuniformly enhanced both the levels of MT and CYP2E1 in various regions of the brain. However, no direct or causal association among the effects of ethanol on the levels of MT and CYP2E1 were observed. (Supported in part by a grant from USPHS NS34566.)

## 185.19

CONDITIONED TOLERANCE TO ETHANOL-INDUCED C-FOS EXPRESSION IN THE RAT BRAIN. M. F. Roitman, T. E. Thiele, G. E. Schafe, D. S. Ramsay\*, and I. L. Bernstein. Dept. of Psychology, U. of Washington, Seattle, WA 98195.

Learned tolerance refers to the observation that environmental cues that have been repeatedly associated with delivery of a drug, such as ethanol, can, through conditioning, come to trigger responses which contribute significantly to the development of drug tolerance. Effects of ethanol which show clear development of tolerance are hypothermia and the induction of cFos expression in a number of brain regions including the paraventricular nucleus of the hypothalamus (PVN) and locus coeruleus (LC). To assess the contribution of conditioning to the development of tolerance to ethanol-induced cFos expression rats were tested to determine the extent to which tolerance development relies on exposure to an ethanol-paired-environment. Over a series of trials, rats received 12 ethanol injections (2.0g/kg) in the presence of one set of environmental cues and 12 saline injections in the presence of a different set of cues. Other rats received saline injections in both environments. On the test day, alcohol pretreated animals received ethanol injection either in the ethanol environment (Same) or in the saline environment (Different). Saline pretreated animals were given their first ethanol injection at that time. Relative to those receiving ethanol for the first time, cFos expression in PVN and LC was substantially lower. Although the Same and Different groups had received the same number, dose and spacing of prior ethanol treatments, tolerance was significantly greater in the Same group, tested in the ethanol-paired environment; much less tolerance was seen in the Different group, tested in the saline-paired environment. A similar pattern of results was seen for ethanol-induced hypothermia. These results support a significant role that conditioning plays in the development of tolerance to ethanol-induced cFos expression in PVN and LC.

## 185.20

EFFECTS OF ACUTE ADMINISTRATION OF ETHANOL ON DOPAMINE, SEROTONIN, GLUTAMATE AND GABA IN THE MESOCORTICOLIMBIC PATHWAY. Q. S. Yan\*, M. E. A. Reith, M. Y. Li, P. C. Jobe and J. W. Dailey. Department of Biomedical and Therapeutic Sciences, University of Illinois College of Medicine, Peoria, IL 61656

The time course of the effects of acute administration of ethanol on the extracellular levels of dopamine (DA), serotonin (5-HT), glutamate (GLU), and  $\gamma$ -amino butyric acid (GABA) within the nucleus accumbens (NACC) and prefrontal cortex (PFC) of freely-moving Sprague-Dawley rats was analyzed using microdialysis in conjunction with HPLC and electrochemical detection. Local infusion of ethanol (0.5, 1, 2%, v/v) through a microdialysis probe produced a significant reduction of GLU and increment of DA and 5-HT in dialysate output from the NACC, both in a dose-dependent fashion. No significant change of GABA in dialysate output from the NACC was observed. Perfusion with 0.5% of ethanol caused larger increases in extracellular DA but smaller increases in extracellular 5-HT in the NACC than it did in the PFC, suggesting that focal administration of ethanol preferentially affects DA transmission in the NACC and 5-HT transmission in the PFC, respectively. In a separate group of rats with two-probe implantation, systemic administration of ethanol (0.5 g/kg, i.p.) resulted in larger increases in extracellular DA in the NACC than in the ventral tegmental area (VTA) in the same animal suggesting the involvement of additional brain circuitries in the effects of systemic as opposed to focal ethanol. Local application of sulpiride (20  $\mu$ M) into the NACC or VTA did not affect significantly the effects on DA transmission produced by systemic administration of ethanol in either the NACC or the VTA, consonant with our previous findings of a lack of dependence of the focal ethanol effects on impulse activity.

## 186.1

ETHANOL DECREASES SYNAPTIC TRANSMISSION IN THE RAT SPINAL CORD. G. Cheng\*, B.-X. Gao, H. Xie, and L. Ziskind-Conhaim. Dept. of Physiology and Ctr. for Neuroscience, University of Wisconsin, Madison, WI 53706.

Effects of acute ethanol exposure on synaptic transmission, repetitive firing, and voltage-gated  $Ca^{2+}$  channels were studied in spinal cords of 1-3-day postnatal rats. Dorsal root-evoked synaptic potentials were recorded intracellularly in motoneurons in the hemisectioned spinal cord. Bath-applied ethanol (70 mM) significantly reduced the amplitude of dorsal root-evoked synaptic potentials. The effect was reversible, and the amplitude of evoked synaptic potentials returned to its control level within minutes after ethanol washout. To study the action of ethanol on neuronal excitability, whole-cell current clamp recording were carried out in motoneurons in thick spinal cord slices. In control postnatal motoneurons, long-lasting intracellular current injection generated a sustained train of action potentials, and exposure to ethanol effectively reduced the number of action potentials. To test the possibility that ethanol-induced decrease in both synaptic transmission and motoneuron excitability resulted from a reduction in voltage-gated  $Ca^{2+}$  currents, the effect of ethanol on high-threshold  $Ca^{2+}$  channels was examined. Whole-cell voltage clamp recordings illustrated that the amplitude of inward  $Ca^{2+}$  currents, generated by a voltage step of 50 mV (from -50 mV to 0 mV), was significantly reduced by ethanol. These findings implied that ethanol-induced decrease in synaptic transmission and neuronal excitability might be related to its effect on voltage-gated  $Ca^{2+}$  currents. Supported by NIH grant NS23808 to L.Z.-C.

## 186.3

THE EFFECTS OF PRENATAL ETHANOL ON BARREL FIELD CORTEX PLASTICITY ARE EXACERBATED BY POSTNATAL SENSORY DEPRIVATION. V. Rema\* and F. E. Ebner. Institute for Developmental Neuroscience, John F. Kennedy Center, Vanderbilt University, Nashville, TN 37203.

Exposure of the fetal brain to ethanol throughout gestation results in long-term down regulation of NMDA receptor subunits in the adult rat brain (Rema and Ebner, NS abst, 1995). We have been testing the hypothesis that the long term effects of prenatal ethanol exposure and of sensory deprivation alone may have additive effects on cortical function impairment. Further, that these effects will be detectable by a test of cortical plasticity induced in the adult rat cortex by a non-invasive bias in sensory activity from the whiskers called "whisker-pairing" (WP) plasticity. WP is induced in S1 cortex by trimming all but two whiskers on one side of the face; e.g., D1 and D2 whiskers are left intact and the other whiskers are trimmed for 1 to 30 days at any age. In normal cortex when whiskers D1 and D2 are left intact, the neurons in the D2 barrel column develop a significant bias in their response to the paired D1 and the cut D3 whisker (D1 response up, D3 down) after <3 days (Armstrong-James, et al., J. Neurosci., 1994). Sensory deprivation by itself, produced by trimming all of the whiskers from P-0 to P-30, delays the bias significantly past 3 days of WP in P-90 animals (Huang and Ebner, NS abst, 1995). Here we show that prenatal ethanol exposure alone delays the onset of bias for longer than 3 days of WP, although after 7 days of WP some animals do show significant changes. In contrast, none of the alcohol exposed, sensory deprived animals show any bias after whisker-pairing for more than 7 days. The results show that both the prenatal toxin and the deprivation alone produce long term modest, but significant, slowing in the rate of activity-dependent cortical synaptic modification. The important implication of the results is that the depressed postnatal activity levels in sensory systems significantly exacerbate the negative impact of prenatal alcohol on cortical synaptic plasticity mechanisms throughout life. ## 186.2

NMDA RECEPTOR SUBUNIT COMPOSITION AND ETOH SENSITIVITY IN PRIMARY NEURONAL CULTURES. R. L. Popp\*, R. L. Lickteig, M. D. Browning, and D. M. Lovinger. Dept. Mol. Physiol. Biophys., Vanderbilt Univ. Sch. Med., Nashville, TN, 37232.

We are studying how ethanol (EtOH) sensitivity relates to N-methyl-D-aspartate receptor (NMDAR) subunit composition using different primary neuronal cultures. We have characterized NMDAR responses from striatal (S) and cerebellar granule cell (CGC) cultures using ifenprodil, a selective antagonist to NR2B-containing complexes and potentiation induced by spermine, which results when NR2B is complexed with the NR1-1a splice variants. Whole-cell patch-clamp electrophysiological recordings were performed and the effects of ifenprodil, spermine or 10, 25, 50, 100 and 200 mM EtOH in the presence of 100  $\mu$ M NMDA and 10  $\mu$ M glycine were examined. Values presented are the means  $\pm$  s.e.m. Western blots using antibodies directed against the C-terminus of the NR2A, NR2B or the N-terminus of the NR2C subunits were also performed. CGC were grown in high  $K^{+}$  (25 mM KCL) for 3-5 wk. In CGC cultures, 7 out of 8 cells were insensitive to 10  $\mu$ M ifenprodil (% inhibition =  $1.6 \pm 4.4$ ). The one cell showed 60% inhibition of NMDA-induced current. In all cells steady state (ss) current was inhibited by 100  $\mu$ M spermine at -25 mV (% inhibition =  $35.03 \pm 2.9$ ). Western blot analysis revealed the presence of NR2A but not NR2B in these cultures. Preliminary EtOH data suggested low EtOH sensitivity in that inhibition was less than 20% at 50 and 100 mM EtOH concentrations (8 out of 11 cells). In contrast, S cells exhibited a decrease in ifenprodil inhibition (58%, n=1) to a complete loss of inhibition (n=3) in 2-3 wk-old cultures (total n=8). This correlated well with the appearance of the NR2A subunit. Unlike CGC cultures, after 10 d in culture a population of S cells showed a potentiation (>10%) of ss current by 100  $\mu$ M spermine at -25 mV (10 d: 2 of 5; 2 wk: 6 of 7; 3 wk: 3 of 4 cells). Preliminary EtOH data indicated an inhibition threshold between 10 and 25 mM and a mean inhibition for 100 mM of  $-31.88 \pm 2.1$ . We will continue to examine the relationship between potentiation by spermine and EtOH sensitivity. Supported by NS30470, AA08986, AA09675 and AA03257.

## 186.4

TIMING AND DOSE EFFECTS OF FETAL ALCOHOL EXPOSURE ON CORPUS CALLOSUM DEVELOPMENT IN RATS. A. J. Elberger\*, S. E. Maier and J. R. West. Depts. of Anatomy and Neurobiology, The University of Tennessee, Memphis TN 38163 and Texas A&M University, College Station, TX 77843.

Humans with fetal alcohol exposure show abnormalities of the corpus callosum (CC), and we have previously found that rats exposed to alcohol *in utero* also show CC abnormalities. The goal of this study is to evaluate independently the effects of different doses and different time periods of fetal alcohol exposure on the rat CC.

Pregnant rats were given alcohol (EtOH), or an isocaloric equivalent of maltose dextrin (PF/INT) as a control, by intragastric intubation. A third group of pregnant rats served as normal controls (CHOW). Different doses of EtOH during gestation day (G) 1-20 caused peak EtOH blood alcohol concentrations (BACs) ranging from 81-497 mg/dl. Different timing of EtOH during G1-10, G11-20 or postnatal day (P) 4-7 in a narrow dose range caused peak BACs of 192-325 mg/dl. All pups were transcardially perfused with 4% paraformaldehyde at P10. Brains were sagittally bisected and crystals of Dil were applied to the anteroposterior extent of the midsagittal CC bundle. Tissue was stored in the dark at 37° C during Dil diffusion.

Sections 100  $\mu$ m thick were examined with a confocal laser scanning microscope. CC connections were identical in CHOW and PF/INT controls. However, CC connections were differentially abnormal in each EtOH dose and timing group. CC abnormalities included reduction in number of somata, laminar displacement of somata, tight clustering of somata, overextension of apical and basilar dendrites to one side, and misorientation of apical dendrites. These results suggest that the timing of alcohol exposure may be a significant factor in abnormal human CC development. Supported by UT Medical Group Research Grants Program (AJE) and NIAAA 10090 (JRW).

## 186.5

EFFECTS OF PRENATAL ETHANOL EXPOSURE ON THE DEVELOPMENT OF DENDRITIC SPINES IN CULTURE. T. Wu\*, S. Antonios, M.J. Maguire, E.F. Ebner. Institute for Developmental Neuroscience, John F. Kennedy Center, Vanderbilt University, Nashville, TN 37203

Prenatal ethanol exposure has been shown by others to affect the development of the density and morphology dendritic spines *in vivo*. We have investigated whether prenatal ethanol interferes with dendritic spine formation *in vitro* through its direct influence on neurons, or indirectly through its influence on glial cells. Pregnant rats were given a liquid diet containing 6.5% ethanol between day 1 and day 19 of gestation. At birth, the rat somatosensory cortex was removed to either harvest neurons which were then grown on normal glial cells, or to produce monolayers of ethanol-exposed glial cells on which normal neurons could be plated at a later time. Thus, three combinations of cells were examined in the present experiment: (1), normal neurons on normal glial cells (controls); (2), ethanol-exposed neurons on normal glial cells; (3), normal neurons on ethanol-exposed glial cells. After 28 days *in vitro*, neurons were injected with Lucifer yellow and dendritic spines of labeled neurons were imaged with a confocal microscope. The spine densities (#/100  $\mu$ m dendrite) and spine lengths for mushroom, stubby, thin and irregular-shaped spines were analyzed. We found that dendritic spine densities on the ethanol-exposed neurons on normal glia showed significant reductions in thin and stubby types of spines, but an increase in irregular-shaped spines which resemble the appearance of small growth cones. Spine lengths were significantly longer except for mushroom spines. Spine densities on the neurons plated on ethanol-exposed glial cells were not significantly different from those of control neurons. However, spine lengths were significantly shorter than those of control neurons, except for stubby spines. These results suggest that prenatal ethanol exposure interferes with spine formation through its direct influence on neurons. Ethanol-exposed glial cells may result in impairing mechanisms that adjust the efficacy of spines through modifying spine length. (supported in part by NS-13031 and HD-15052).

DELAY-DEPENDENT MEMORY DEFICITS IN FETAL ALCOHOL EXPOSED RATS: RELATIONSHIP TO D1 AND D2 DOPAMINE RECEPTOR BINDING IN THE BRAIN. J.A. Dowd, R.J. Handa, and A.H. Nagahara\*. Department of Cell Biology, Neurobiology, and Anatomy, Loyola Medical Center, Maywood, IL 60153.

Previous results in our laboratory have shown that fetal alcohol exposed (FAE) rats show a reduced induction of c-fos, jun-b, and zif268 mRNA in the prefrontal cortex and caudate following testing in a T-maze alternation task. These rats demonstrated a delay-dependent memory deficit in this task, suggesting that changes in the prefrontal cortex or caudate of FAE rats may contribute to this memory deficit. Since the dopaminergic system is prominent in these regions, we investigated the relationship between alternation performance and D1 and D2 receptor binding in these brain regions of FAE rats. Subjects were female offspring of Sprague-Dawley dams fed either a 35% ethanol derived-calories diet, pair-fed with sucrose, or control-fed with lab chow. Rats (104 days old) were food-deprived prior to training and trained in the T-maze for food reward. Rats were then tested at 0-s, 30-s, 60-s, and 180-s delays. On the day of sacrifice, rats were tested at the 60-s delay for 12 trials and were sacrificed 30 min after testing. Dopamine binding was examined by receptor autoradiography using [<sup>3</sup>H]-SCH23390 (D1) and [<sup>3</sup>H]-YM-09151-2 (D2). FAE rats showed a memory deficit at both the 60-s and 180-s delays, but not at the 0-s or 30-s delays. However, no differences in D1 and D2 receptor binding were observed in the prefrontal cortex, caudate, and other regions of the FAE rats compared to the control groups. These findings suggest that delay-dependent memory deficits observed in these FAE rats are not due to changes in D1 or D2 receptor binding in these brain regions. Alcohol Exposure During the Brain Growth Spurt Period in Rats Altered the Responsiveness of Neurotransmitter Systems to Acute Cocaine Challenge. W.-J.A. Chen\* & J.R. West, Human Anatomy and Medical Neurobiology, Texas A&M University HSC, College Station, Texas 77843

Alcohol exposure during the brain growth spurt (BGS) induces various detrimental effects on brain development. This study examined the influences of alcohol exposure during the BGS period on specific neurotransmitter levels following acute cocaine challenge. Two distinct brain regions, cerebellum (CB) and nucleus accumbens (NAc), were selected due to the CB's vulnerability to alcohol insults during BGS and NAc's sensitivity to acute cocaine challenge. Sprague-Dawley rat pups were reared artificially from postnatal day (PD) 4 to 10. Alcohol was administered at doses of either 3.3 or 4.5 g/kg from PD 4 to 9; appropriate controls also were included. On PD 10, animals were sacrificed 20 min after acute cocaine challenge (i.p.). The results were summarized as follows. (1) Alcohol exposure during the BGS period altered the basal content of dopamine (DA) in NAc of the 4.5 g/kg group, but not in the 3.3 g/kg group. (2) Acute cocaine administration significantly elevated the levels of DA, dihydroxyphenylacetic acid (DOPAC), serotonin (5-HT) and 5-hydroxyindoleacetic acid (5-HIAA) among control animals in NAc, but not in CB. (3) The treatment of 4.5 g/kg alcohol significantly retarded the elevation of DA, DOPAC, 5-HT and 5-HIAA, however, 3.3 g/kg alcohol treatment only inhibited the elevation of DA and DOPAC. Taken together, these data suggest that alcohol exposure during the BGS period significantly altered the responsiveness of various neurotransmitter systems, and these alterations appeared to be brain region and neurotransmitter system specific. (Funded in part by NIAAA grant AA05523)

## 186.6

"BINGE" ETHANOL-INDUCED BRAIN DAMAGE IN RATS: PROTECTION BY FUROSEMIDE. E.J. Neasey\*, J.Y. Zou, and M.A. Collins. Neuroscience Program and Depts. of Cell Biology, Neurobiology & Anatomy; and Molecular and Cellular Biochemistry, Loyola Univ. Med. Cntr., Maywood, IL 60153.

Modifying our severe (3xdaily) binge ethanol model (Collins et al., 1996), ethanol administered *once* daily to male adult rats for 6-10 days produces obvious neuronal degeneration (de Olmos cupric silver stain) in the entorhinal cortex (EC), dentate gyrus (DG), and olfactory bulb (OB). The effective dose is about 5g/kg in 0.9% saline, yielding a blood ethanol level (BEL) of approx. 250mg/dl at 2h. Since cytotoxic edema has been linked to other forms of brain damage, we examined whether it was involved by administering furosemide, a loop diuretic, (10-15mg/kg, IP) at 1h and 8h after each of the 10 daily ethanol doses (EF rats); a second group (E) received ethanol alone. Mean daily blood ethanol levels were similar in both groups. Brain damage was measured by cell counts ( $\pm$ SEM) of degenerating, argyrophilic neurons in EC or DG on 6-10 horizontal brain sections from each animal at levels 6-8mm below bregma; OB damage was measured as the percentage of glomeruli containing degeneration.

Grp(n)	Mn BEL (mg/dl)	%EC degen.	Entorhinal Cx		Dentate Gyrus		OB % Degen.
			Max	Mean	Max	Mean	
E(9)	252 $\pm$ 8	100	29.4 $\pm$ 10	9.2 $\pm$ 3	16.8 $\pm$ 4	5.9 $\pm$ 2	19.3 $\pm$ 6
EF(12)	253 $\pm$ 8	58	*4.3 $\pm$ 2	*1.4 $\pm$ 1	*5.3 $\pm$ 2	*1.5 $\pm$ 1	20.9 $\pm$ 6

Furosemide significantly reduced ( $p < .005$ , Mann-Whitney U) the mean and maximum counts/region/section of degenerating neurons in both EC (-84%) and DG (-74%) and completely prevented degeneration in the EC in 5/12 (42%) of the rats. The results support brain cell swelling as an essential step in ethanol-induced cortical neurodegeneration. Disturbed vasopressin secretion could be involved. Interestingly, brain overhydration has been hypothesized to underlie brain damage in alcoholics (Lambie, *Med. Hypoth.*, 1985). (LUMC NSAI)

## 186.8

Prenatal Exposure to Alcohol Decreases BDNF mRNA and Granule Cell Number in the Main Olfactory Bulb in Rats. S.E. Maier\*, J.A. Miller, J.R. West & F. Sohrabji. Human Anatomy and Neurobiology, Texas A&M University, College Station, Texas, 77843.

Developing forebrain structures such as the neocortex, hippocampus and olfactory bulb are significantly affected by prenatal exposure to alcohol. Since many forebrain neurons are sensitive to the neurotrophin family of growth factors, we hypothesized that alcohol-induced developmental anomalies may result from decreased availability of neurotrophins. In the present study, we examined the expression of the brain derived neurotrophin factor (BDNF) mRNA in the olfactory bulb following prenatal exposure to alcohol. Timed pregnant rats were intubated daily with alcohol from embryonic day 1 (E1) to E20 (mean BAC = 365 mg/dl). Paired controls received isocaloric maltose dextrin solution, chow controls were fed *ad libitum*. Olfactory bulbs from E21 fetuses were rapidly dissected and harvested for RNA. BDNF mRNA was analyzed by quantitative RT-PCR. Alcohol exposure significantly reduced total mRNA yields. Analysis of equivalent amounts of total RNA indicated that BDNF mRNA was significantly reduced compared to paired controls. To test whether the same prenatal alcohol paradigm would result in concomitant decreases in olfactory bulb neurons, brains from offspring at postnatal day 10 were processed for histological analyses. Serial sections through the olfactory bulbs were used to count granule and mitral cells using stereological methods. The prenatal alcohol treatment resulted in a significant decrease in the number of granule cells, but not mitral cells. These data suggest that a decrease in granule cell number may be related to alcohol-induced decreases in BDNF availability. Ongoing research will investigate the effect of alcohol-induced decreases in BDNF mRNA and granule cell number target size. (Supported by NIAAA 10090 to JRW).

SURVIVAL AND DEVELOPMENT OF ETHANOL-TREATED RAT CORTICAL NEURONS GROWN IN TISSUE CULTURE. L.M. Mudd\*, J. Katz and T. F. Lopez. School of Natural and Health Sciences, Barry University, Miami Shores, FL 33161.

Prenatal exposure to ethanol leads to a variety of effects known collectively as fetal alcohol syndrome. A number of toxic effects occur in the central nervous system, involving the decrease in survival or development of multiple subpopulations of neurons. We undertook a study to determine which aspects of neurite development might be affected by ethanol at the same concentration as effects on neuronal survival. Cortical neurons from embryonic day 16 rats were grown in defined medium with a glial plane at a distance of 1mm from the neurons. More than 96% of the cells in the neuronal layer were immunostained for neurofibrillary protein, while more than 97% of the cells in the glial plane were immunostained with an antibody to glial fibrillary acidic protein. Ethanol was administered on day *in vitro* 1 (DIV 1) and every 48 h, thereafter. Ethanol concentrations diminished rapidly, being less than one-tenth of the initial concentration at the 100mM dose after 24 h. In control cultures 70 $\pm$ 6% (mean $\pm$ SEM) of neurons were alive at DIV 4 while 53 $\pm$ 8.1 and 35 $\pm$ 7.4% were present at concentrations of 10 and 100mM ethanol, respectively. While treatment with 10mM or 100mM ethanol caused no significant effect on the numbers of primary neurites after 6 DIV, there were significant decreases in the numbers of secondary neurites and the ratio of secondary to primary neurites at both ethanol concentrations and there were significant decreases in the length of the longest neurite and the total neurite length in the 100mM ethanol group. THE EFFECTS OF PRENATAL ETHANOL TREATMENT ON REPRODUCTIVE BEHAVIOR AND NEURONAL EXPRESSION OF C-FOS. R.E. Leipheimer\* and R. Vivo. Dept. Biological Sciences, Youngstown State University, Youngstown, OH 44555

These experiments were designed to examine the effects of ETOH exposure *in utero* on the reproductive behavior and neuronal expression of c-fos in adult male rats. Pregnant rats were divided into three groups and given diets of either 35% ETOH, pair-fed liquid control diets, or solid food. Offspring from the ETOH-treated females had higher mortality rates and shorter body lengths at birth. When mature, the offspring were tested for sexual behavior and for neuronal expression of c-fos in separate experiments. 1. Naive males from each treatment group were tested with stimulus females for sexual behavior in three separate test sessions. Results demonstrated no significant differences between groups for mount latency, intromission latency or ejaculation latency. Thus, it appears that ETOH treatment had no significant effects on the sexual learning of the offspring. 2. Males were exposed to soiled bedding gathered from either estrous or ovariectomized females prior to immunocytochemical localization of fos. An increase in fos was found in the nucleus accumbens, diagonal band of Broca and corpus striatum in ETOH-treated rats suggesting that prenatal exposure to ETOH increases the expression of fos in response to stimulation.

MOTOR SKILL TRAINING ALTERS RAT CEREBELLAR MORPHOLOGY FOLLOWING POSTNATAL ALCOHOL EXPOSURE. A. Klintsova\*, J. Matthews, C. Goodlett<sup>1</sup>, R. Napper<sup>2</sup> and W. Greenough. Depts. of Psych. and Cell & Struct. Biol., Neurosci. Prog. and Beckman Inst. Univ. of IL, Urbana IL 61801, <sup>1</sup>Dept. of Psych., IUPUI, Indianapolis, IN 46202 and <sup>2</sup>Univ. Otago, Dunedin, New Zealand.

Developmental exposure to alcohol can produce permanent behavioral deficits and morphological damage in the CNS. The cerebellum is particularly sensitive to the effects of alcohol during the period of the "brain growth spurt" (West, *Alcohol Drug Res.*, 1987). The permanent loss of Purkinje cells (PC) and granule cells was shown to correlate with performance deficits on motor tasks (e.g. Goodlett et al., *Neurotox. Teratol.*, 1991). This study examined whether motor skill training, that has been demonstrated to increase synapse number, vasculature and glial cell processes in the cerebellar cortex, can compensate for the effect of alcohol exposure. Rats were assigned to one of the following treatments on days P4-P9: alcohol exposure (AE) of 4.5g/kg/day (using artificial rearing); an artificially reared control (GC); or suckle control (SC). At the age of 6 months, half of the rats from each group underwent the 10-day motor training; the other half stayed in individual cages. Although the three groups did not differ in the time to complete the obstacle course at the end of the training period, the acquisition time for the task was significantly higher in GC and AE animals on days 2, 5 and 6 ( $p < 0.05$ ) in female rats and on days 1, 2 and 3 ( $p < 0.05$ ) in males. The number of PC in the paramedian lobule (PML) and the number of parallel fiber synapses in the molecular layer of the PML were estimated using the physical disector. There was a significant loss of PC in the AE female ( $F_{2,24} = 4.19$ ,  $p < 0.03$ ) and male ( $F_{2,22} = 5.37$ ,  $p < 0.01$ ) rats. The number of synapses per PC in the PML was significantly higher in the AE animals trained on the motor skill tasks than in non-trained AE, GC and SC rats.

EFFECTS OF ETHANOL (EtOH) ON DIFFERENT LAYERS AND SUBTYPES OF NEURONS IN THE SOMATOSENSORY CORTEX. T.N. Felder, F.-C. Hsu, J. Zhai, R.C.-S. Lin, A.E.K. Kosobud, S.J. Wieland, M.C. Kennedy\* and F.M. Sessler. Dept. of Anat. and Neurobiol., Med. Col. of Pennsylvania and Hahnemann Univ., Philadelphia, PA 19102, and Dept. of Psychol., Indiana Univ. IN 47405

In this study, we characterized the effects of EtOH on postsynaptic potentials (PSPs) and membrane properties of somatosensory neurons. The hypothesis tested was that EtOH exerts differential effects on cortical layers and cell types within somatosensory circuits. Two selection schemes were formed to test the impact of EtOH: 1) A comparison of EtOH effects on layer II-III vs. Layer V and 2) A comparison of EtOH effects on 4 characterized subtypes of neurons. Intracellular recording of neurons in slices of rat somatosensory cortex revealed a concentration dependent (EtOH 10-100mM) suppression of PSPs and a decrease in cell excitability which were both stronger in L5 cells. In most of the adapting regular spiking cells, EtOH 10mM decreased input resistance (IR) and increased rheobase (Rh) resulting in a reduction of cell excitability. Similar observations were made in non-adapting regular spiking cells with the exception of a small group which was facilitated by EtOH. In both, intrinsic bursting and doublet spiking neurons, EtOH also produced changes in excitability. Other parameters are under examination. These preliminary observations support the hypothesis of a differential impact of EtOH on layers and cell components of the somatosensory cortex. In addition, it is suggested that mechanisms involved in EtOH depression of cell excitability may be distinct from those disrupting synaptic transmission. (Supported by NIDA DA08405 and Allegheny-Singer Research Institute Award to FMS).

THE EFFECTS OF BUTHIONINE SULFOXIMINE ON THE OUTCOME OF THE *IN UTERO* ADMINISTRATION OF ALCOHOL ON FETAL DEVELOPMENT. E. Reyes\*, G. Marquez, J. C. de Baca, and S. Ott. Dept. of Pharmacology, UNM, Sch. of Med., Albuquerque, NM 87131

Fetal Alcohol Syndrome (FAS) is characterized by pre and postnatal growth retardation, mental retardation, behavioral deficits and facial deformities. In spite of numerous animal studies, the biochemical mechanism(s) by which alcohol produces teratogenic effects on the developing fetus are not well understood. Several studies have shown that administration of alcohol to adult rats produces a decrease in hepatic levels of glutathione (GSH). The *in utero* administration of alcohol has also been shown to produce a decrease in GSH levels as well as prenatal growth retardation and intrauterine death. In an effort to determine if GSH may have a vital role in protecting the fetus against the teratogenic effects of alcohol, buthionine sulfoximine (BSO) was utilized to deplete GSH levels in the mother and fetus. Timed pregnant Sprague-Dawley rats were placed on a liquid BioServ diet containing either 0%, 11%, 23%, 29%, 31%, 33%, or 35% Ethanol Derived Calories (EDC), with or without BSO (888 mg/Kg/24h), starting on day one of pregnancy. The mothers were maintained on the diet until gestation day 21 when they were anesthetized with sodium pentobarbital and the pups delivered by Cesarean Section. The offspring were counted, weighed, sacrificed and the brain and liver weighed. The effects of BSO on the alcohol dose response curves (body weights, brain weights and litter number) were then determined in order to ascertain if a depletion in GSH potentiated the effects of alcohol. The *in utero* administration of BSO, aside from the depletion of GSH in liver and brain in the developing fetus, produced a shift to the left in the alcohol dose response curve. INCREASED p53 AND TUNEL STAINING IN ETHANOL INDUCED APOPTOTIC CELL DEATH IN SCHWANN CELLS. J.M. Collier and M.J. Johnson\*. Dept. of Pediatr., Steele Mem. Childr. Res. Cntr., Univ. of Arizona, Tucson, AZ 85724-5073.

Fetal alcohol exposure may result in CNS dysfunction and microcephaly, possibly with reduced numbers of neurons and glia known to be secondary to increased cell death in the CNS of developing mice. Studies in our laboratory have shown that ethanol increases axonal elongation but decreases the total number and percent dividing rat Schwann cells with concentrations as low as 2-3 mM and exposure of less than 24 hours. Studies using SEM and TEM show that dying cells have multiple cytoplasmic vacuoles and pseudopodia with chromatin condensation, which are characteristic of cell death via apoptosis. In these experiments, we use the TUNEL method of detecting nicked DNA as well as MAB staining to apoptosis-associated proteins. Rat sympathetic ganglia explants were cultured for 5 days *in vitro* and treated for 22-24 hours with ethanol prior to fixation, followed by TUNEL and p53 staining. The results show a dose-related increase of apoptotic cells with ethanol, especially with concentrations over 150 mg% and distances in excess of 1.0 mm from the explant edge. In one experiment the percent of total Schwann cells that were TUNEL positive at 1.5 mm was  $12.4 \pm 5.1$  for controls, and  $20.7 \pm 5.6$ ,  $25.6 \pm 11.4$ ,  $31.2 \pm 11.1$ ,  $30.3 \pm 7.0$  and  $32.0 \pm 6.5$  for 50, 100, 150, 300 and 750 mg% ethanol respectively (mean  $\pm$  SEM;  $p < .04$  for both 300 and 750 mg%). TUNEL positive cells stain positively for p53, with staining observed in both the cytoplasm and nucleus. In summary, dying Schwann cells in culture have the characteristics of apoptosis, the percentage of cells with TUNEL positive staining is dose related and TUNEL positive cells show p53 staining. ETHANOL DECREASES DENDRITE NUMBER AND TOTAL LENGTH IN DEVELOPING RAT HIPPOCAMPAL PYRAMIDAL NEURONS *IN VITRO*. P.A. Clamp<sup>1</sup> and T.L. Fletcher<sup>1,2\*</sup>. Depts. of Pharmacology & Neuroscience<sup>1</sup>, and Psychiatry<sup>2</sup>, Albany Medical College, Albany, NY 12208

Some of the neuropathological effects of prenatal alcohol exposure may result from disruption of normal neuronal development. Rat hippocampal pyramidal neurons in low density culture (Goslin and Banker, 1991), which develop axons and dendrites in a stereotypical sequence of events, can be used to assess the effects of ethanol on the establishment of neuronal polarity. We recently reported that ethanol accelerates the rate at which hippocampal neurons develop axons. The current study focuses on the effects of ethanol on dendritic outgrowth. Hippocampi from E18 Sprague-Dawley rats were dissociated and plated onto poly-L-lysine coated glass coverslips in serum-containing medium. After 3 hours, coverslips were transferred into dishes containing a monolayer of astroglial cells in defined medium with or without the addition of ethanol (300mg/dL or 800mg/dL). Cultures were maintained in modular incubator chambers saturated with water or ethanol (300mg/dL or 800 mg/dL) to prevent evaporation of ethanol from the medium. Neurons were fixed after 7 days *in vitro*, and somata and dendrites were stained by immunofluorescent cytochemistry using an antibody against MAP2. Stained cells were randomly selected and photographed. Dendrite length was measured using a digitizing pad and Jandel SigmaScan software. Ethanol treatment decreased both the number of dendrites per cell and total dendrite length per cell in a dose-dependent fashion ( $p < .001$ ). These findings suggest that ethanol may disrupt the mechanisms by which neurons establish distinct axonal and dendritic processes. Such altered molecular compartmentation may contribute to the neuropathologies observed in Fetal Alcohol Syndrome. Supported by NIH R03AA09624

CHANGES IN BRAIN CYTOSKELETAL PROTEINS FOLLOWING CHRONIC ETHANOL TREATMENT E. Fikova<sup>a</sup>, H. Eason, A. McReynolds, J. Poch. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309.

Ethanol-sensitive LS/IBG mice were treated with ethanol for 15 days and compared to control mice. Triton solubilized brain homogenates were fractionated under microtubule-stabilizing conditions (Black et al., Brain Res., 295:255, 1984), which yielded polymerized cytoskeletal components in the pellet (P1). After resuspension of P1 in a Ca buffer at 4 °C, subsequent centrifugation yielded a Ca/cold-insoluble cytoskeletal component in the pellet (P2). The amounts of  $\alpha$ -tubulin and actin were assessed with quantitative immunoblotting (Black et al., J. Neurosci., 9:358, 1989). Fifteen days of ethanol treatment resulted in a significant increase of  $\alpha$ -tubulin in P2 without any changes in the actin pool. Comparison of these results with those of 4 months on ethanol show that the initial increase of  $\alpha$ -tubulin in P2 is followed by a decrease in P1. Such a bifasic response suggests activation of compensatory mechanisms to the initial insult which breaks down after a prolonged exposure to the noxious stimulus. No bifasic response was observed in actin which was reduced in P1 after 4 months of ethanol. Changes in both  $\alpha$ -tubulin and actin could be caused by acetaldehyde which may be produced in the brain by at least two alcohol metabolizing enzymes: the alcohol-induced cytochrome P450 II E1 (Anandatheerthavarada et al., Brain Res., 601:279, 1993) and peroxide-dependent catalase (Gill et al., Alcoholism, 16:910, 1992). Acetaldehyde by forming stable adducts with both  $\alpha$ -tubulin (Tuma et al., Ann. NY Acad. Sci. 625:786, 1991) and G-actin (Xu et al., Alcohol & Alcoholism 24:281, 1989) will remove these proteins from the functional pool. The loss of  $\alpha$ -tubulin and G-actin results in a loss of microtubules and in a rigid actin network, respectively. Loss of microtubules will impair transport mechanisms of the neuron and a rigid actin network will reduce plastic properties of synaptic contacts. Supported by AA06196 and AA00130.

SECOND GENERATION EFFECTS OF MATERNAL ALCOHOL CONSUMPTION DURING PREGNANCY IN RATS. J. Homewood, M.K.-P. Lam, and E.J. Mazurski\* School of Behavioural Sciences, Macquarie University, Sydney, NSW, Australia, 2109.

Twenty four pregnant Hooded Wistars (FO) consumed either a nutritionally complete liquid diet containing 5% (v/v) ethanol or sucrose, or standard rat chow. The male and female offspring (F1) were subsequently bred with drug-free partners. The next generation (F2, total n=122), was assessed for neuromotor development and spatial learning ability. Weight and latency to right following placement on the dorsal surface were recorded on postnatal days 1, 5, and 7. Lower weights were recorded, particularly in males, whose dams were exposed to alcohol in utero (maternal line). Latency to right differences were seen on day 5. Pups descended from the alcohol-consuming group through the maternal line were the slowest to right. Rats did not differ on activity levels at 30 days of age. The spatial task measured alternation in a water-filled T-maze with a 1 min delay between trials. The number of errors (incorrect arm choice) decreased across the four days in all groups. Fewer errors were seen in the rats derived from alcohol-treated animals. These data demonstrate cross generational effects of in utero exposure to alcohol, which appear to be mediated by line of descent and sex of subject. Funded by Macquarie University Research Grant to JH.

## 186.18

EFFECT OF ETHANOL EXPOSURE DURING GESTATION ON SPATIAL MEMORY IN ADULT/JUVENILE RATS. P.J. Best, D.B. Matthews, P.E. Simson. Miami Univ., Cen. for Neuro. Res. & Dept. of Psy., Oxford OH, 45056.

Exposure to ethanol during gestation causes damage to several brain sites, including the hippocampus. Damage to the hippocampus includes decreased number of CA1 pyramidal neurons (Barnes & Walker, 1981), aberrant mossy fiber projections from the dentate gyrus to the CA3 region (West, Hodges & Black, 1981) and decreases in dendritic spines and branches (Ferrer, Galofre, Lopez-Tejero & Llobera, 1988). However, many of these changes, such as decreases in dendritic spines and branches, may not be permanent (Ferrer et al., 1988).

Exposure to ethanol during gestation also impairs cognitive processing that is dependent on the hippocampus. For example, both juvenile and adult rats prenatally exposed to ethanol show impaired learning on spatial tasks (Blanchard, Riley & Hannigan, 1987; Gianoulakis, 1990).

In the present study, prenatal exposure to ethanol produced deficits in adult rats' use of spatial memory. However, these deficits were only observed after a long (3 day), but not a short (1 day) time delay between training and testing. Additional studies are underway to determine if similar results are obtained in juvenile rats prenatally exposed to ethanol.

Supported in part with a Pre-doctoral grant to D.B.M. from NIAAA (AA-05414) a FIRST award to P.E.S. from NIAAA (AA-09079) and a grant to P.E.S. from the Alcoholic Beverage Medical Research Foundation.

## 186.20

RADIAL ARM MAZE PERFORMANCE IS ENHANCED IN ADULT RATS CHRONICALLY, BUT NOT ACUTELY EXPOSED TO ETHANOL. E.S. Steigerwald, and M.W. Miller\* Departments of Psychiatry and Pharmacology, University of Iowa College of Medicine, Iowa City IA 52242 and Research Service, Veterans Affairs Medical Center, Iowa City IA 52246.

The effect of ethanol exposure on learning and memory was assessed in adult rats. Adult male rats were required to learn versions of a radial arm maze task that depended upon extramaze cues (visual and somatosensory spatial) or intramaze cues (various odors). Rats were fed *ad libitum* on a liquid diet containing ethanol, pair-fed an isocaloric/isonutritious diet, or fed chow and water *ad libitum*. These diets were provided for 0, 14, 20, or 28 wk prior to maze testing. Each rat was tested twice daily for 26 d while being maintained on the diet. The latency required to successfully navigate the maze and the number of reference and working memory errors were recorded. Rats maintained on the ethanol diet performed significantly better on the reference memory task in the odor condition of the maze task. This enhancement was transient (observed only after 14 or 20 wk of ethanol exposure). The performance of the ethanol-fed rats in the spatial task was similar to that for the two control groups. Thus, after an extended period (e.g., 28 wk), alcohol had no effect on learning and memory. On the other hand, under certain conditions, alcohol can transiently (14 or 20 wk) enhance memory.

Funded by the Department of Veterans Affairs and NIH grants DE 07734, AA 06916, and AA 07568.

## DRUGS OF ABUSE: AMPHETAMINES I

## 187.1

THE EFFECT OF 2,3-DIHYDROXY-6-NITRO-7-SULFAMOYL-BENZO(F)QUINOXALINE ON METHAMPHETAMINE- AND COCAINE-INDUCED BEHAVIORAL SENSITIZATION, K. Akiyama<sup>a,b</sup>, H. Ujike<sup>b</sup>, K. Sakai<sup>3</sup>, T. Ishihara<sup>b</sup>, Y. Shimizu<sup>b</sup> and S. Kuroda<sup>b</sup>, Departments of Neuropsychiatry<sup>a</sup> and Neurology<sup>b</sup>, Okayama University Medical School, Okayama 700, Japan.

The present study investigated the effect of pretreatment with 2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo(f)quinoxaline (NBQX), a novel antagonist of  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor antagonist of quinoxalinedione derivative on methamphetamine- and cocaine-induced behavioral sensitization, respectively. 7-week-old male Sprague Dawley rats were randomly assigned to four groups which received daily either NBQX 20 mg/kg + methamphetamine 3 mg/kg, NBQX 40 mg/kg + methamphetamine 3 mg/kg, methamphetamine 3 mg/kg, or saline during the 10-day pretreatment session. In the other experiment, methamphetamine was replaced by cocaine 15 mg/kg. NBQX (20, 40 mg/kg) inhibited both acute methamphetamine- and acute cocaine-induced rearing and locomotion, but not activity/stereotypy score. Pretreatment with NBQX (20, 40 mg/kg) did not affect augmentation of activity/stereotypy scores by repeated administration of methamphetamine or cocaine for 10 days. There was no significant difference in the activity/stereotypy scores following a challenge injection with methamphetamine (2 mg/kg) or cocaine (15 mg/kg) alone among all treatment groups 7 days after the last dose of repeated pretreatment session, although rearing induced by this challenge was significantly inhibited in rats which had been pretreated with NBQX 40 mg/kg prior to each methamphetamine or cocaine injection. Blockade of AMPA receptors inhibits some behaviors induced by acute psychostimulants, but AMPA receptors are unlikely to be involved in formation of behavioral sensitization induced by repeated administration of methamphetamine and cocaine. Supported by the research grant (5A-7) for Nervous and Mental Disorders from the Japanese Ministry of Health and Welfare.

## 187.2

SENSITIZATION TO LOCOMOTOR EFFECTS OF AMPHETAMINE IS INFLUENCED BY THE TIME OF ADMINISTRATION O. Gaytan, A. Swann, and N. Dafny\* Dept. of Neurobiology and the Dept. of Psychiatry, UT Medical School at Houston, P.O. Box 20708, Houston, TX 77225

Chronic administration of stimulants like amphetamine (Amp) have been reported to produce behavioral sensitization to its effects on locomotor and stereotypic activity. This phenomena may be related to the pathophysiology of recurrent psychiatric disorders. Disturbances in various physiologic circadian rhythms are found in many psychiatric disorders. This study was designed to investigate the effect of repeated treatment with a low dose of Amp on the circadian pattern of locomotor activity, and whether the development of sensitization differs if Amp is given at different times of the light/dark cycle. 96 male Sprague-Dawley rats were housed in activity monitoring system test cages after 7 days of acclimation to a 12:12 light/dark cycle (lights on at 07:00) and continuous recording for 16 days was begun as follows: Baseline (Day 1-2), Saline Injection (Day 3), Amp Challenge Doses (Day 4) - either 0.3, 0.6, or 1.2 mg/kg s.c., followed by Maintenance dose of 0.6 mg/kg Amp for five days (Day 5-9), Withdrawal (Days 10-14), and rats were Re-Challenged on Day 15 with the same Amp doses as day 4. This regimen was run at 4 times (0800, 1400, 2000, 0200). In general, sensitization occurred at all the time points with the largest augmentation in effect occurring with the lower doses (0.3 and 0.6 mg/kg). The index of total distance (cm) was more affected than horizontal activity. There were slight differences between the time points with the 08:00 displaying the weakest sensitization. There were no significant changes in the levels of diurnal activity with repeated administration. In conclusion, the development of sensitization to the locomotor effect of Amp is not greatly affected by the time of drug administration.

## 187.3

**ONTOGENY OF METHYLPHENIDATE-INDUCED SENSITIZATION AND PROTEIN KINASE A ACTIVITY.** T.L. Meier, R. Collins, S.A. McDougall, J. B. Watson<sup>1</sup>, M. S. Levine<sup>1</sup>, C. A. Crawford<sup>1\*</sup>. Department of Psychology, CSUSB, San Bernardino, CA 92407. <sup>2</sup>Department of Psychiatry, UCLA, Los Angeles, CA 90024.

Repeated exposure to the psychostimulant amphetamine, produces augmented behavioral responses (i.e., behavioral sensitization) accompanied by dopamine receptor mediated changes in signal transduction. However, it is unclear if repeated treatment with the widely used psychostimulant, methylphenidate (MPH) or Ritalin, produces sensitization. Moreover, it is not known to what extent development plays in these behavioral or neurochemical changes. To test this hypothesis, 16- and 90-day-old rats were given 5 daily injections of saline or MPH (5, 10, or 20 mg/kg, ip). After a 2 day washout period, behavior was recorded for 40 min., rats were sacrificed, and cAMP-dependent protein kinase A (PKA) activity was measured. Results showed that repeated MPH treatment (10 & 20 mg/kg) enhanced the sniffing of young and adult rats while the same doses of MPH depressed the locomotor activity and rearing of both age groups (relative to controls). Interestingly, acute treatment with MPH produced a dose-dependent increase in the PKA activity of adult rats, whereas repeated treatment with MPH produced a dose-dependent decline. PKA activity of young rats showed a very different response, in which neither repeated nor acute treatment with MPH (10 & 20 mg/kg) affected the low baseline levels of PKA activity. We concluded from these results that MPH will induce behavioral sensitization in both young and adult rats, but that the downstream regulation mediated via PKA signalling pathways may vary according to age.

## 187.5

**COMPONENTS OF BOTH THE ACUTE AND SENSITIZED BEHAVIORAL RESPONSE TO AMPHETAMINE ARE DIFFERENTIALLY BLOCKED BY HALOPERIDOL.** L.H. Conti<sup>1</sup>, D.S. Segal and R. Kuczenski. Dept. of Psychiatry, Univ. California, San Diego, La Jolla, CA 92093

Following amphetamine (AMPH) administration, extracellular concentrations of dopamine (DA) decline from peak levels while behavioral stereotypy continues to be maintained. Thus, the initial extracellular DA peak may act as a "trigger" for both the induction and maintenance of stereotypy. To address this hypothesis, saline or haloperidol (HAL; 0.1 mg/kg, ip) was administered either prior to AMPH (4.0 mg/kg, sc), or after the induction of stereotypy. Expression of stereotypy was precluded by prior HAL treatment, and was interrupted by HAL administration during the stereotypy response. Instead of stereotypy, a large-magnitude locomotor response was displayed under both conditions. These results suggest that DA does not simply act as a "trigger" for the expression of stereotypy, and indicate that the response remains sensitive to DA receptor blockade even when extracellular DA levels are declining. The fact that a locomotor response was displayed in place of stereotypy indicates that not all acute effects of AMPH are equally sensitive to HAL. With repeated AMPH administration, sensitization of both the stereotypy and locomotor components of the response develops. To test the hypothesis that the development of sensitization of both responses is also differentially dependent on stimulation of HAL-sensitive DA receptors, responses to AMPH challenge were assessed in rats that had received either saline or HAL prior to each daily injection of AMPH. HAL/AMPH-treated rats did not display stereotypy during repeated treatment, and showed no evidence of sensitization of stereotypy during AMPH challenge in the absence of HAL. Instead, locomotion was exclusively displayed during the repeated treatment phase and, this response was sensitized. Thus, sensitization failed to develop only for the aspects of the AMPH response which were acutely sensitive to HAL. [Supported by NIDA]

## 187.7

**NORMAL PSYCHOSTIMULANT SENSITIZATION IN LTP-IMPAIRED *FYN* MUTANT MICE.** Bryan K. Tolliver, Seth G.N. Grant, and S. Paul Berger\*. Department of Psychiatry, Univ. of Calif. San Francisco and SFVAMC, San Francisco, California and Center for Genome Research, Univ. of Edinburgh, Edinburgh UK

Mice with a null mutation in the nonreceptor tyrosine kinase gene *fyn* are known to be significantly impaired in their development of long-term potentiation (LTP) and some forms of spatial learning. Because the augmented behavioral response which develops with repeated stimulant treatment shares several common features with LTP, we hypothesized that *fyn* mutant mice may be deficient in the development of behavioral sensitization and conditioned place preference (CPP), a process known to require contextual learning. No differences in baseline locomotion or in the acute locomotor response to d-amphetamine (3 mg/kg i.p.) were observed between homozygous mutant, heterozygous, and wild-type (C57BL/6J-129/SV hybrid) mice. The locomotor response to amphetamine challenge was significantly enhanced relative to the initial response in all three groups of mice after 7 daily amphetamine injections, with the greatest sensitization found in homozygous mutants. *Fyn* mutants treated daily with amphetamine for one week were significantly more responsive to amphetamine challenge than mutants administered daily saline. When given a choice between two chambers previously paired with saline or amphetamine, mice of all three *fyn* genotypes preferred the drug-paired chamber. These results indicate that the *fyn* gene is not required in the development of stimulant sensitization or place preference conditioning, suggesting that not all of the mechanisms necessary for the induction of LTP are involved in behavioral sensitization. (Supported by USPHS Award DA-07376)

## 187.4

**THE EFFECTS OF CCK<sub>A</sub> AND CCK<sub>B</sub> RECEPTOR BLOCKADE ON THE ACQUISITION AND EXPRESSION OF BEHAVIORAL SENSITIZATION TO AMPHETAMINE.** G.R. Wunderlich<sup>1</sup>, N.J. DeSousa<sup>1</sup>, and F.J. Vaccarino<sup>1,2</sup>. <sup>1</sup>Dept. of Psych., Univ. of Toronto, Toronto, Canada, M5S 1A1; and <sup>2</sup>Clarke Inst. Psychiatry, Toronto, Canada, M5T 1R8.

Numerous studies implicate the mesolimbic dopamine (DA) system in both the acquisition and expression of behavioral sensitization to psychostimulants. The neuropeptide, cholecystokinin (CCK), is co-localized with DA in a significant subpopulation of mesolimbic DA neurons and modulates DA neurotransmission. These experiments investigated the possibility that endogenous CCK modulates the acquisition and/or expression of locomotor sensitization to amphetamine (AMPH). In exp. 1, rats were treated in their home cage with AMPH (0, 1.5 mg/kg i.p.) once daily for seven days (acquisition phase). Following a 10 day withdrawal period, animals were injected with AMPH (0, 0.75 mg/kg i.p.) and placed in a test environment and their locomotor activity was recorded (expression phase). Exp. 2 followed a similar protocol except that AMPH-treatment was preceded by i.p. injection of either a CCK<sub>A</sub> antagonist (devazepide; 0, 1, 10 and 100 µg/kg i.p.) or a CCK<sub>B</sub> antagonist (L-365,260; 0, 1, 10 and 100 µg/kg i.p.) during the 7 day acquisition phase. In exp. 3, rats were pretreated with either devazepide or L-365,260 (0, 1, 10 and 100 µg/kg i.p.) prior to AMPH challenge during the expression phase. Results from exp. 1 showed that prior exposure to AMPH resulted in a sensitized AMPH-induced locomotor response. Results from exp. 2 replicated these findings and further showed that treatment with devazepide and L-365, 260 attenuated the acquisition of this effect. Results from exp. 3 also replicated those in exp. 1, and showed that devazepide, but not L-365,260, attenuated the expression of the sensitized response to AMPH. These results suggest that endogenous CCK modulates both the acquisition and expression of behavioral sensitization to AMPH. (Funded by a Medical Research Council of Canada grant to FJV).

## 187.6

**cAMP IN THE NUCLEUS ACCUMBENS IS INVOLVED IN THE ENHANCED LOCOMOTOR RESPONSE TO AMPHETAMINE IN A PERTUSSIS TOXIN MODEL OF SENSITIZATION.** S. Narayanan<sup>1</sup>, A. Dalia, J. Battisti, L.J. Wallace and N.J. Uretsky. Division of Pharmacology, College of Pharmacy, The Ohio State University, Columbus, OH 43210.

The administration of pertussis toxin (PTX) into the ventral tegmental area (VTA) mimics some of the salient features of sensitization seen after repeated administration of psychostimulant drugs. This model of sensitization is characterized by a markedly enhanced responsiveness to activation of dopaminergic D<sub>1</sub> agonists in the nucleus accumbens (N.Ac). The purpose of the present study was to determine whether altered responsiveness of second messenger systems regulated by D<sub>1</sub> receptors exists in this sensitized state. Ten to 14 days after treatment with PTX in the VTA, rats were challenged with amphetamine either in the presence or in the absence of SQ22536 (0.2 µg/side), an adenylate cyclase inhibitor, administered directly into the N.Ac. SQ22536 inhibited amphetamine induced activity in PTX-pretreated animals but not in controls. In addition, administration of 8-Br-cAMP (2 µg/side), a membrane permeable analog of cAMP, into the N.Ac produced an enhanced locomotor response in PTX-treated but not control animals. These observations suggest that the administration of PTX into the VTA results in a sensitization of the adenylate cyclase-protein kinase system in the N.Ac. Amphetamine induction of c-fos, an event thought to be mediated by D<sub>1</sub> receptor stimulated increases in protein kinase A activity, was also augmented in PTX-treated animals. Taken together, these results suggest that the injection of PTX into the VTA results in postsynaptic changes in the N.Ac., involving the D<sub>1</sub> receptor and cAMP. (NIH grants DA 06776 and DA 7722)

## 187.8

**ELECTROLYTIC LESIONS OF THE NUCLEUS ACCUMBENS IN RATS ENHANCE LOCOMOTOR SENSITIZATION TO 0.4 MG/KG NICOTINE.** J. E. Kelsey\* and E. P. Johnson. Dept. Psychology, Bates College, Lewiston, ME 04240.

To examine the hypothesis that the locomotor activating and sensitizing effects of nicotine are mediated by activation of the mesolimbic DA pathway, we examined the effects of electrolytic lesions of the n. accumbens on locomotor responses to nicotine. In two experiments using different lesion placements, 60 male Long Evans rats were placed in 58- x 58- x 45-cm activity chambers immediately after an i.p. injection of isotonic saline or 0.4 mg/kg nicotine (base weight) for 7 1-hr sessions on alternate days. Distance travelled was measured by a video tracking system. The lesions tended to increase locomotion. Nicotine had no overall effect on the sham-operated animals, either on the first session or across sessions. Although nicotine also had no overall effect on the lesioned animals on the first session, repeated injections increased locomotion across sessions, producing locomotor sensitization. Moreover, a subsequent challenge dose of 0.1 mg/kg nicotine increased activity only in the previously sensitized lesioned rats. There was no evidence of conditioned sensitization. Subsequent amphetamine injections (1.0 mg/kg) increased activity equally in all four groups. Thus, in contrast to the prediction of the mesolimbic DA hypothesis, electrolytic lesions of the n. accumbens enhanced, rather than retarded, locomotor sensitization to nicotine. These data indicate that the n. accumbens contains neurons that act to inhibit locomotor sensitization produced by nicotine. (Support was provided by Bates College.)

## 187.9

**METHAMPHETAMINE-INDUCED REVERSE TOLERANCE PHENOMENON IN STEREOTYPY AND IMPAIRED CLIFF AVOIDANCE REACTION IN THREE STRAINS OF RATS.** S. Yoshida\*, Y. Numachi#, H. Matsuoka, Y. Fuse and M. Sato. Dept. Psychiatry, Tohoku Univ. School of Med., Sendai, 980-77 Japan. #Mol. Neurobiol. Br., NIH/NIDA/IRP, Baltimore, MD 21224, U.S.A.

To elaborate an index behavior reflecting the late-onset methamphetamine (MAP) psychosis, MAP-induced reverse tolerance (MAP-RT) in the behavioral stereotypy was compared with impairment of cliff avoidance reaction (CAR). Three strains of rats (Fischer 344: F, Lewis: L, and Sprague-Dawley: SD) were received daily MAP administrations (4 mg/kg/day, i.p.) for 30 days. MAP-RT developed within 10, 14 and 21 days in L, SD and F, respectively. On the other hand, incidence of impaired CAR was unchanged during daily MAP administrations for 4 weeks in L, while it was increased significantly after 14 and 21 days in F and SD, respectively. Thus, MAP-RT developed earliest in L without accompanying any late-onset impairment of CAR even after 4 weeks of MAP administration. Contrary, F showed slowest development of MAP-RT with earliest impairment of CAR. As 4mg/kg of MAP did not affect motor function including ataxia, impaired CAR might reflect a cognitive dysfunction. It is suggested that after increase in CAR impairment, rather than MAP-RT, appeared during chronic MAP administrations may be a new model for the late-onset MAP psychosis (ICD-10). Supported in part by grant-in-Aid for Scientific Research (C) (#07671045).

## 187.11

**ALTERED ENERGY METABOLISM ASSOCIATED WITH BEHAVIORAL SENSITIZATION INDUCED BY QUINPIROLE.** D.V. Coscina\*, P.J. Currie, J.W. Chambers and H. Szechtman. Dept. of Psychol., Wayne State Univ., Detroit, MI 48202; Sect. of Biopsychol., Clarke Inst. Psychiat., Toronto, ON M5T 1R8; and Dept. of Biomed. Sci., McMaster Univ., Hamilton, ON L8N 3Z5

Repeated exposure to drugs classed as psychostimulants can produce behavioral sensitization, defined as augmented motor responses to fixed doses of such compounds. For example, chronic treatment of rats with the D2/D3 dopamine agonist, quinpirole (QUIN), can increase motor activity up to several times normal levels. To determine if such enhanced locomotor output is associated with changes in nutrient utilization, one group of rats received 10 injections of QUIN (0.5 mg/kg every 2nd day) while a second received equal numbers of saline (both  $n = 16$ ). Immediately after each injection, rats were placed in one of eight closed plastic chambers the size of their home cages in which  $O_2$  consumption,  $CO_2$  output and motor activity were measured every 5 min for the next 2 hr. Locomotor responses to QUIN doubled during the course of this treatment even in such a relatively confined space, thus confirming the establishment of behavioral sensitization. The magnitude of energy metabolism and motor activity were closely coupled in control rats but not in QUIN-treated rats. Of particular interest, QUIN reliably reduced rats' Respiratory Quotient ( $CO_2/O_2$ ), suggesting that the substrate for overall energy utilization had shifted towards the use of lipids for metabolic needs. The capacity to utilize such fuel may represent a physiological adaptation that causes or sustains the dramatic increases in locomotion and exploration normally seen in rats tested in more spacious environments after QUIN-induced behavioral sensitization.

Supported by NSERC and MRC of Canada and OMHF of Ontario

## 187.13

**Chronic quinpirole treatment induces a switch from locomotor inhibition to excitement in the drug-paired environment.** Karen K. Szumlanski, James R. Blackburn\* and Henry Szechtman. Dept Biomedical Sciences, McMaster University, 1200 Main St. West, Hamilton, Ontario, CANADA L8N 3Z5

The repeated administration of the D2/D3 receptor agonist, quinpirole (QNP), results in a progressive augmentation in the behavioural response to subsequent injections (behavioural sensitization). However, the relationship between QNP dose and locomotor behaviour in the chronically treated animal remains undescribed. Such a description is provided by this study. To induce behavioural sensitization, animals received either 19 injections of QNP (0.5 mg/kg, s.c., twice weekly) or saline, followed by dose-response tests for the expression of behavioural sensitization (0, 0.01, 0.04, 0.05, 0.06, 0.07, 0.08, 0.2 and 1.0 mg/kg). Chronic QNP-treated animals displayed a robust behavioural sensitization as indicated by an approximately 10-fold increase in locomotor behaviour across injections. Compared to the acute dose-response curve, chronic QNP treatment increased the efficacy and potency of QNP. In addition, some doses which produce behavioural inhibition in the acute QNP animals induced maximal locomotor activation in animals repeatedly treated with the drug. The results demonstrate that chronic QNP treatment not only enhances sensitivity to this drug but also alters the drug's biphasic profile. (HS is a Research Associate of the OMHF. Supported by MRC).

## 187.10

**CORRELATION OF DOPAMINE TRANSPORTER AND D<sub>2</sub> RECEPTOR BINDING WITH BEHAVIORAL AMPHETAMINE SENSITIZATION** J.-C. Chen\*, H.-J. Su, L.-Y. Huang and M.-C. Hsieh. Dept. Pharmacology, Chang-Gung College of Medicine & Technology, Tao-Yuan, Taiwan, R.O.C.

Repeated intermittent administration of amphetamine (AMPH) HCl (5 mg/kg/d, i.p. for 14 days) in male SD rats produce behavioral sensitization. The AMPH-induced stereotypy behaviors, such as sniffing, licking or head nodding appeared earlier and thus suppressed the subsequent affected locomotor activity. In order to understand the subcellular changes of DA neuron underlying behavioral AMPH sensitization, we examined the dopamine transporter (DAT) and DA D<sub>2</sub> receptor binding in both dorsal and ventral striatum at AMPH withdrawal periods. Using [<sup>3</sup>H]BUTCP to label DAT binding site, we found there was an approximate 2-fold increase in K<sub>d</sub>s in the ventral striatum at withdrawal day 7. The binding affinity to [<sup>3</sup>H]BUTCP in the dorsal striatum as well as B<sub>max</sub> values in both dorsal and ventral striata did not change up to withdrawal day 10. On the other hand, the binding of DA D<sub>2</sub> receptors, defined by [<sup>3</sup>H]raclopride, exhibited a progressive decrease in B<sub>max</sub> values in both dorsal and ventral striata after withdrawal day 7. The binding affinity of DA D<sub>2</sub> receptors in both striata remained unchanged up to withdrawal day 10. We further tested the behavioral activity to D<sub>2</sub> receptor agonist, bromocriptine (5 mg/kg, i.p.) in both saline- or AMPH-withdrawal animals. The result showed that AMPH-sensitized animals had robust locomotion response than controls during first 2 hrs, whereas all the animals reached the plateau level at 5-hr recording period. It appears that behavioral D<sub>2</sub> up-regulation was in contrast to the D<sub>2</sub> receptor binding in the striatum during AMPH sensitization. It is possible that there is a differential regulation on pre- vs. post-synaptic D<sub>2</sub> receptor during the development of AMPH sensitization, the issues are currently under investigation. (NSC85-2331-B-182)

## 187.12

**Influence of practice and environment-drug pairing on the expression of sensitization induced by the dopamine agonist quinpirole.** Haim Einat\* and Henry Szechtman. Dept Biomedical Sciences, McMaster University, 1200 Main St. West, Hamilton, Ontario, CANADA L8N 3Z5

The relative influence of the behavior practised during chronic drug treatment on the expression of sensitization to quinpirole was compared to the influence of environment-drug pairing. Four groups of rats received 10 injections of quinpirole (0.5 mg/kg) and saline, according to a two factor design. One factor was the presence or absence of cage bedding (to increase the likelihood of mouthing and locomotion respectively). The other factor was the explicit pairing or unpairing of quinpirole with the test environment. All groups were tested for the expression of sensitization in a common environment that permitted the display of both locomotion and mouthing. Results showed that locomotor sensitization to quinpirole is greater in rats pretrained in the cages without bedding than with bedding. Mouthing showed tolerance but it was retarded by the presence of bedding. The effect of environment-drug pairing on the locomotor or mouthing response to chronic quinpirole was not statistically significant. It is suggested that the behavior practised during chronic drug treatment is a non-associational mechanism influencing locomotor sensitization and tolerance of mouthing, and that the role of this mechanism at the 0.5 mg/kg dose of quinpirole is relatively greater than that of an associational process due to environment-drug pairing. (HS is a Research Associate of the OMHF. Supported by MRC).

## 187.14

**DOPAMINE TRANSPORTER MRNA IS UP-REGULATED IN THE VENTRAL TEGMENTAL AREA OF BEHAVIORALLY SENSITIZED RATS AFTER ONE WEEK WITHDRAWAL FROM AMPHETAMINE TREATMENT.** P.D. Shilling\*, J.R. Kekoe, D.S. Segal. Dept of Psychiatry and Neurosciences Program, Univ. Calif., San Diego, CA 92093.

Converging evidence supports a significant role for dopamine in the development of behavioral sensitization. There have been several reports of changes in dopamine transporter (DAT) mRNA in behaviorally sensitized rats (Xia et al. J Neurochem. 59:1179;1992, Cerruti et al. Mol. Brain Res. 22:132;1994). To determine if changes in DAT mRNA are long lasting and parallel the time course of amphetamine-induced behavioral sensitization we performed the following experiment. Four groups of adult Sprague Dawley rats were used. Two groups were given daily injections of saline (SAL) for 5 days and two groups were treated with AMPH (2.5mg/kg). After a 1 week withdrawal period, one SAL pretreated group was challenged with SAL and the second SAL pretreated group was challenged with AMPH (2.5mg/kg). The two AMPH pretreatment groups were also challenged with either AMPH or SAL. Locomotor activity was measured for 4 hours after AMPH challenge. All animals were sacrificed 6 hours after the last treatment and *in situ* hybridization was performed with a DAT antisense probe. Message was detected by film autoradiography. Quantification of mRNA was accomplished by computer analysis of digitized images of the ventral tegmental (VTA) area using Image 1.42. Rats pretreated with AMPH and challenged with AMPH exhibited robust behavioral sensitization. In addition, rats pretreated with AMPH and challenged with SAL exhibited a significant up-regulation of DAT mRNA in the VTA compared to the baseline group (SAL/SAL) ( $p < .05$ ). These data support a role for DAT in the expression of amphetamine-induced behavioral sensitization. [Supported by PHS grants DA-01568 (DSS), 5 T32 MH19934-02 (PDS) and RSA MH-70183 (DSS)]

## 187.15

**LONG-LASTING SENSITIZATION TO THE ACCELERATING EFFECTS OF AMPHETAMINE ON THE SPEED OF A BIOLOGICAL "STOPWATCH."** A. Badiani<sup>\*</sup> and J. Stewart<sup>2</sup>.  
<sup>1</sup>Biopsychology, The University of Michigan, Ann Arbor, MI 48109;  
<sup>2</sup>Center for Studies in Behavioral Neurobiology, Concordia University, Montréal, PQ, Canada H3G 1M8.

Drinking in the rat occurs in bursts of rapid licking (mean within-burst inter-lick interval, ILI, of about 150 ms) driven by a neural pacemaker, or "stopwatch," located in the brain stem. This neural "stopwatch" is thought to be similar to those that control more complex psychological processes such as time discrimination and time estimation. There is some evidence that the speed of neural "stopwatches" can be modulated by drugs acting on dopaminergic transmission. Since long-lasting sensitization of central dopaminergic systems has been observed in animals repeatedly exposed to amphetamines, we speculated that enduring changes in the activity of a neural "stopwatch" could be induced by repeated amphetamine. We studied the effect of repeated i.p. injections of 3.0 mg/kg of *D*-amphetamine on licking behavior in the rat. Amphetamine reduced the mean ILI on the first day of treatment and this effect increased progressively over test sessions (i.e., sensitized). This sensitization was long-lasting, being clearly evident when amphetamine was re-administered after almost two weeks of withdrawal. The reduction in the mean ILI was accompanied by a shift to the left in the frequency distribution of the ILIs. The present findings might be of importance for an understanding of the psychotropic effects of amphetamine, and possibly even for its addictive properties. (MRC#MT6678)

## 187.17

**REPEATED ADMINISTRATION OF AMPHETAMINE INDUCES SENSITIZATION OF ACOUSTIC STARTLE IN RATS.** D.-Y. Chen, S. Hsiao<sup>\*</sup>, & K. C. Liang. Dept. of Psychology, Natl. Taiwan Univ., Taipei, Taiwan, 10764, R.O.C.

Repeated administration of amphetamine (AMPH) renders its effects sensitized to later AMPH challenge. This sensitization seems to involve conditioning to the testing environment. AMPH given systemically enhances acoustic startle. Evidence shows that this enhancement is further augmented by repeated AMPH injections in mice. In view of these findings, this study addressed the role of conditioning in development of AMPH sensitization of acoustic startle in male Sprague-Dawley rats.

Startle was elicited by a noise burst (115 dB, 40 ms) under a background noise of 55 dB. Each session consisted of 180 trials with 30 s inter-trial intervals. After the 60th trial, AMPH was injected (i.p.). Differences between pre- and post-AMPH scores were used to evaluate the enhancement. Consistent with previous findings, 5.0 mg/kg AMPH enhanced startle but 1.0 or 3.0 mg/kg did not. This effect was not abolished by adrenalectomy and intra-cerebroventricular infusion of 50 µg AMPH produced similar potentiation, suggesting that the effect is central. Sensitization was developed by daily injections of 5.0 mg/kg AMPH consecutively for 7 days. One or two days later, rats were challenged with 3.0 mg/kg AMPH which was previously ineffective. Rats receiving chronic AMPH in their home cages did not show sensitization. Rats receiving chronic AMPH in the startle chamber but without being tested daily developed small and marginally significant sensitization. Rats receiving chronic AMPH in the testing chamber and being tested daily for startle under AMPH influences developed robust sensitization. When rats were tested daily and then given AMPH afterwards, sensitization was barely discernible. These findings, taken together, suggest that repeated elicitation of the target response under the influence of AMPH in the specific context may be crucial for rapid development of amphetamine sensitization.

## 187.19

**SENSITIZATION AND TOLERANCE TO DIFFERENT EFFECTS OF AMPHETAMINE ON SEXUAL BEHAVIOR IN THE MALE RAT.** M.F. Wilkins<sup>\*</sup> and J.G. Pfaus. CSBN, Department of Psychology, Concordia University, Montréal, QC, Canada H3G 1M8.

The present study was conducted to examine whether sensitization or tolerance to amphetamine's disruptive effects on male rat sexual behavior is dependent upon attempting sexual activity during drug intoxication. *D*-amphetamine sulfate (2.5 or 5 mg/kg) was injected either 30 minutes prior to (drug-before) or immediately following (drug-after) tests of sexual behavior conducted every 4 days in bilevel chambers. Males in all groups received 8 drug trials. On the final drug trial, all rats were injected prior to the test. Results obtained in the drug-before group replicated previous findings, with a dose-dependent decrease in the proportion of rats that mounted, intromitted, and ejaculated. Conditioned level-changing was also disrupted, secondarily to the induction of stereotypy. In rats that continued to copulate, latencies to initiate mounts and intromissions increased whereas the number of intromissions and the latency to ejaculate decreased. In contrast, all males in the drug-after groups copulated to ejaculation and latencies to mount and intromit declined. Anticipatory level changing was not affected. However, as with the drug-before rats, both the number of intromissions and the latency to ejaculate declined. On trial 8, drug-after rats showed greater increases in mount and intromission latencies and a larger decrease in ejaculation latencies compared to the drug-before group, indicating the development of tolerance in drug-before rats. Thus, although sensitization develops to some of amphetamine's effects on sexual behavior, tolerance can accrue contingently to those effects. Supported by NSERC of Canada (OGP-0138878).

## 187.16

**CLONAZEPAM PREVENTS THE DEVELOPMENT OF SENSITIZATION TO METHAMPHETAMINE.**

K. Ito<sup>\*</sup>, T. Ohmori, and T. Koyama. Department of Psychiatry, Hokkaido Univ. Sch. of Med., Sapporo 060 Japan.

The GABA-benzodiazepine neurotransmission has been implicated in various forms of plasticity such as kindling and learning. The present study examined the effects of clonazepam, a GABA-benzodiazepine agent, on the development of behavioral sensitization to methamphetamine (MA). Rats (Male Wistar-King rats) treated with MA (1 mg/kg, sc.) for 10 days /showed significantly enhanced motor activity compared to those treated with saline when tested with MA (1 mg/kg) after a 7-8 day withdrawal, indicating the development of behavioral sensitization. Pretreatment with clonazepam (0.5mg/kg) prior to MA administration prevented the development of the phenomenon. Rats treated with clonazepam alone showed no difference in the motor activity compared to those treated with saline. These results suggest that stimulation of GABA-benzodiazepine receptors plays a role in the development of behavioral sensitization. This study was supported in part by Grant-in-Aid No 05670796 and No 07671042 for Scientific Research from Ministry of Education, Science and Culture, Japan.

## 187.18

**SEX DIFFERENCES IN BEHAVIORAL SENSITIZATION TO AMPHETAMINE.** R.H. Mills<sup>1\*</sup>, T. Slade<sup>1</sup>, J. Meiners<sup>1</sup>, J.W. Johnson<sup>1</sup>, G.R. Hanson<sup>2</sup>, G.J. Bloch<sup>1</sup>. <sup>1</sup>Dept. of Psychology, BYU, Provo, UT 84602 and <sup>2</sup>Dept. of Pharmacology & Toxicology, University of Utah, SLC, UT 84112

Camp & Robinson ('88) have shown that intact male rats show less sensitization to *D*-amphetamine (*D*-AMPH) than intact females, adult-Gx males, and adult-Gx females; adult-Gx male and female rats, however, were not significantly different from each other. Forgie & Stewart ('93), however, reported that adult-Gx male rats showed less sensitization to *D*-AMPH than adult-Gx females. To further study this issue, males and females were Gx or sham-Gx at 6-30 hr after birth; all rats that remained gonadally intact were Gx at 75-80 days of age. Animals were acclimated to the activity chambers on days 5 & 6 after adult-Gx. On days 7-10, animals were acclimated, then injected i.p. with 1.0 mg/kg *D*-AMPH. Locomotor behavior was analyzed by recording both ambulatory and stereotyped behavior for 35 min. In addition, each animal was given a behavioral sensitization rank based on the combined ambulatory and stereotyped behavior scores (Kohler & Bloch, '94). Adult-Gx males showed significantly less behavioral sensitization than the other groups ( $p < 0.04$ , ANOVA;  $p < 0.001$ , Kruskal-Wallis). No significant difference was detected in striatal *D*-AMPH concentrations following the first or after the 4 daily injections of *D*-AMPH, indicating that differences in brain metabolism of *D*-AMPH cannot explain the sex difference. These results suggest that testosterone acts after the neonatal period to decrease the behavioral sensitization response to *D*-AMPH. Since this response was observed in the adult-Gx male, this effect on neural structures may be an organizational one. Supported by HD27334

## 188.1

**ACTIONS OF LITHIUM AND VALPROATE ON GENE EXPRESSION.** H. K. Manji, P. X. Yuan, W. Z. Zeng, J. Granneman\*, and G. Chen. Dept. of Psychiatry & Behavioral Neurosciences, Wayne State Univ. School of Medicine, Detroit, MI 48201

Lithium (Li) and Valproic acid (VPA) are widely used, clinically effective antimanic and mood-stabilizing agents, but despite extensive research, their molecular mechanism(s) remain to be elucidated. Interestingly, the therapeutic effects of Li and VPA are only observed after chronic (days to weeks) treatment; such delayed effects suggest that the therapeutic effects may be modulated by the long-term modulation of gene expression. We have examined the effects of lithium and VPA on gene expression since both Li and VPA have marked effects on protein kinase C (PKC) isozymes, and since PKC is known to play a major role in the regulation of many transcription factors. Our initial studies have shown that VPA increases AP-1 DNA binding activity *in vitro* and *ex vivo*. The ability of both drugs to turn on gene expression has been further demonstrated in C6 glioma and neuroblastoma cells which were either transiently or stably transfected with a reporter (luciferase) gene driven by SV40 or MMTV-LTP promoter/enhancers. Both Li and VPA increased luciferase gene expression in a time and concentration dependent manner. Using mRNA differential display methodologies, we have identified a gene which is markedly turned on by both Li and VPA treatment in rat brain. Taken together, the evidence indicates that both lithium and VPA modulate of gene expression in brain; these effects may play a major role in the long term therapeutic effects of these agents.

## 188.3

**EFFECTS OF SEROTONIN-1A AGONISTS AND ANTAGONISTS ON ULTRASONIC VOCALIZATIONS IN ADULT RATS.** R. Lopez and A. Frazier. Univ. of Texas Health Sci. Ctr., Dept. of Pharmacology, and Audie L. Murphy Memorial Veterans Hospital, San Antonio, TX 78284.

Rats and other small rodents will emit ultrasonic sounds (20 to 40 kHz) when confronted with aversive stimuli, or when anticipating the occurrence of an aversive event (e.g., electric foot shock). These ultrasonic vocalizations may be a useful tool for studying neurochemical mechanisms underlying anxiety. We have developed a system that quantifies the duration of ultrasonic vocalizations on-line for any given period of time. The output of a condenser microphone is fed to a Pentium minicomputer outfitted with an analog-to-digital card. A software package developed by us monitors and analyzes (using Fast Fourier Transforms) the output of the analog-to-digital card to determine if there are ultrasonic vocalizations present and their durations. In the present experiments, male Wistar rats (100-200 g) were exposed to 20 foot shocks (0.3 mA, 2 sec duration, distributed across 20 min) once daily for 4 days. On Days 5 and 6, rats were exposed to 5 foot shocks over 42 sec and then immediately monitored for ultrasounds for 5 min. On subsequent days, rats were treated with drugs or vehicle, tested again for 5 min, and ultrasound durations were compared to the average duration of Days 5 and 6. Agonists at the serotonin-1A receptor (gepirone, 0 to 0.3 mg/kg, s.c.; 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT), 0 to 3 mg/kg, s.c.) caused dose-dependent reductions in ultrasonic vocalizations. Administration of the new serotonin-1A antagonist 4-(2-methoxyphenyl)-1-[2'-[N-(2'-pyridinyl)-p-iodobenzamido]ethyl]piperazine (p-MPPI 10 mg/kg, i.p.) 10 min prior to gepirone completely antagonized the effect of gepirone. These results suggest that this ultrasonic vocalization system is capable of detecting pharmacological manipulations affecting this measure of anxiety, in particular those involving the serotonin-1A receptor. **PHARMACOKINETICS (PK) AND PHARMACODYNAMICS (PD) OF BMS-180048 IN MIGRAINE.** N.R. Cutler (1)\*, J.E. Fulmor (2), D.E. Salazar (2), J.J. Sramek (1), N. Ford (2). (1) California Clinical Trials, Beverly Hills, CA; (2) Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ

BMS-180048 is a novel 5-HT<sub>1D</sub> receptor agonist currently in development for the treatment of migraine. This double-blind, placebo-controlled, randomized, parallel group study was designed to evaluate the PK, safety, and preliminary efficacy of BMS-180048 in migraine patients during migrainous and pain-free states. Patients who participated met IHS criteria for migraine with or without aura, and suffered between one and six migraines per month for at least one year. Patients were randomized to receive BMS-180048 75 mg, 150 mg, 200 mg, or placebo. Blood samples were obtained just prior to and 0.25, 0.5, 0.75, 1, 1.5, 2, 2.5, 3, 4, 5, and 6 h after dosing. Headache intensity was rated prior to and up to 6 h after dosing. Seven to 30 days after completion of the in-clinic treatment, patients returned to the clinic in a pain-free state and were administered a repeat of the original study medication. All PK and safety measures were then repeated. Forty-eight patients (9 males, 39 females) were randomized and received BMS-180048 75mg (n=12), 150mg (n=12), 200mg (n=12), or placebo (n=12). Peak plasma concentrations of BMS-180048 were achieved 1 to 2 h following study drug administration in migraine and pain-free states for all doses. PK parameters of BMS-180048 were proportional to dose after administration during a migraine attack over the 75-200 mg dose range. The 150 mg and 200 mg doses of BMS-180048 demonstrated a greater decrease in headache intensity scores and a higher percentage of patients reporting "Any Relief" at 2 h post-dose. The most common adverse event was paresthesia. Thus, BMS-180048 was rapidly absorbed, well tolerated, and demonstrated preliminary efficacy in this population.

**COMPARISON OF VALPROIC ACID AND LITHIUM ON THE EXPRESSION OF THE PKC SUBSTRATE MARCKS IN IMMORTALIZED HIPPOCAMPAL CELLS.** D.G. Watson<sup>1</sup>\*, J.M. Watterson<sup>2</sup>, and R.H. Lenox<sup>1,2,3</sup>. Departments of Psychiatry<sup>1</sup>, Pharmacology<sup>2</sup>, and Neuroscience<sup>3</sup>, University of Florida, Gainesville, FL 32610.

While lithium has been the drug of choice for the acute treatment of mania and the prophylactic management of manic-depressive illness, the broad spectrum anticonvulsant valproic acid (VPA) has recently emerged as an efficacious alternative and adjunctive treatment for this disorder. Studies in our laboratory and others have provided evidence for a role of PKC in mediating the effects of chronic lithium in the brain. We previously reported that in both the rat hippocampus and in immortalized hippocampal cells in culture, chronic lithium down-regulates a major PKC substrate, MARCKS (Myristoylated Alanine-Rich C-Kinase Substrate), a protein known to be critical for normal CNS development, and found in regions of the brain which exhibit a high degree of plasticity. The lithium-induced regulation of MARCKS is modulated by inositol availability and receptor-mediated signaling through the IP<sub>3</sub>/DAG pathway. We present evidence that, like lithium, chronic exposure of HN33 cells to VPA, produces a dose- and time-dependent reduction in the expression of MARCKS protein. The reduction in MARCKS protein expression was observed following chronic, but not acute, exposure to VPA. Maximal reduction in MARCKS levels were observed following 3 days of VPA exposure at or above the therapeutic level (0.6-1.0 mM). The reduction of MARCKS produced by lithium or VPA was enhanced when the two drugs were combined. However, in contrast to lithium, where the reduction of MARCKS is both prevented and reversed by the addition of inositol, the down-regulation observed following VPA exposure was unaffected by the addition of *myo*-inositol (up to 1 mM) to the medium, suggesting an alternative mechanism for VPA's effect. These data suggest that regulation of the MARCKS protein may represent a pharmacological property shared by drugs with therapeutic efficacy in the prophylactic treatment of manic-depressive illness. (Supported in part by NIMH grant MH50105).

## 188.4

**DEXFENFLURAMINE ELEVATES C-FOS EXPRESSION IN HYPOTHALAMIC CRF AND OXYTOCIN NEURONS VIA A SEROTONINIC MECHANISM.** T.S. Gray\*, A. Javed, M. Kamrati, C. Bartholomew, and L.D. Van de Kar. Neuroscience Program and Dept. of CBNA, Loyola University Medical Center, Maywood, IL 60153

Dexfenfluramine (DFEN), a serotonin (5-HT) releaser, has been shown to have anorectic effects in both clinical and experimental studies. It is used as an appetite suppressant in Europe, and was recently approved for use in the United States. DFEN increases the expression of c-fos in discrete brain regions, including the hypothalamus and amygdala (Li and Rowland, 1993). In addition, it stimulates the secretion of corticotropin-releasing factor (CRF), oxytocin, and vasopressin (VP). The present study was conducted to test the hypothesis that DFEN increases c-fos expression in CRF, oxytocin, and VP neurons. The subjects of this study were male adult rats that were handled for twice daily to reduce background c-fos expression. DFEN was given i.p. at 5 mg/kg. Some rats received fluoxetine 10 mg/kg i.p. 12 hours prior to DFEN injection to competitively block the access of DFEN into the serotonin terminals. Two hours after DFEN administration, rats were deeply anesthetized and perfused. Brains were removed and processed according to standard immunohistochemical procedures. Sections from the hypothalamus were immunohistochemically stained for c-fos and then labeled for CRF, oxytocin, or VP. DFEN caused a significant increase in c-fos expression in the medial parvocellular division of the PVN and in other regions as previously described. Numerous CRF containing neurons were observed to contain c-fos. A small percentage of oxytocin cells also contained c-fos. No c-fos expression was observed in neurons expressing VP. Fluoxetine blocked c-fos expression in CRF and oxytocin cells, and overall in the medial parvocellular PVN. This study suggests that DFEN activates CRF and oxytocin cells in the hypothalamus through a serotonergic mechanism. Supported by NIH NS20041 and NS 34153.

## 188.6

**EFFECTS OF MILACEMIDE AND CGP 37,849 ON PUNISHED RESPONDING IN A MODIFIED GELLER-SEIFTER PROCEDURE IN RATS.** A.D. Compton\*, J.D. Holcomb\*, S.E. Strong\*, J.L. Wiley\*, J.H. Porter\*, and R.L. Balster\*. Dept. of Psychology, Univ. of Richmond<sup>1</sup>, Dept. of Psychology, VA Commonwealth Univ.<sup>2</sup>, and Dept. of Pharmacology & Toxicology, Medical College of VA<sup>3</sup>, Richmond, VA.

A number of NMDA antagonist compounds have produced promising results in animal models that assess anxiolytic potential. In the present study, 15 male, Sprague-Dawley rats were trained to barpress for food reward on a modified Geller-Seifter operant procedure (MULT FI 30 s, FR 10 + shock). Dose/response data were first collected with chlordiazepoxide (VEH, 1.25, 2.5, 5.0, 10.0, & 20.0 mg/kg), which produced modest and selective significant increases in punished responding at the 10 and 20 mg/kg doses. The pro-glycine compound, milacemide (VEH, 100, 200, & 400 mg/kg), significantly decreased response rates in the unpunished schedule component at the 200 mg/kg dose, and in both schedule components at the 400 mg/kg dose. The competitive NMDA antagonist, CGP 37,849 (VEH, 0.3, 1.0, 3.0, 5.6, & 10 mg/kg) increased punished responding to a similar degree as did CDP at the 1.0 mg/kg dose; however, the effect was not selective, as unpunished responding was also significantly elevated at this dose. CGP 37,849 produced a similar (but selective) increase in punished responding in a previous study that used the Vogel lick model, suggesting that the anxiolytic effects of NMDA antagonists may be task specific. Further, the present results suggest that milacemide would not share anxiolytic effects with NMDA antagonists. (Research supported by NIDA grant DA-01442.)

## 188.7

COMBINATION OF OPEN FIELD AND ELEVATED PLUS-MAZE: A SUITABLE TEST BATTERY TO ASSESS STRAIN AS WELL AS TREATMENT DIFFERENCES IN RAT BEHAVIOR. ULRICH SCHMITT, KLAUS MANN\* AND CHRISTOPH HIEMKE. Department of Psychiatry, University of Mainz, 55131 Mainz, Germany.

A test battery consisting of an standard open field, an enriched open field and elevated plus maze was used to study rat behavior. The first part of the study was aimed to evaluate interstrain differences with and without pre-test handling. The study included male rats of the strain PVG/OlaHsd (PVG) and Sprague-Dawley-Hsd (SPRD) (150-200g body wt). SPRD rats displayed higher motor activity levels in each of the tests, and also higher levels of exploratory behavior than the PVG rats. In contrast plus-maze activity indicated more anxiety of SPRD than PVG rats. One week pre-test handling increased the activity of both strains but it increased explorative behavior in the enriched open field only in SPRD rats. Moreover, the behavior in the elevated plus-maze was differentially affected by the handling procedure. The second part of the study based on the results of the first study in the way that male PVG rats (150-200g body wt) were used and was aimed to study rat behavior after acute treatment with diazepam or zolpidem. The behavioral pattern in the 3 different tests indicated a substantial anxiolytic effect of diazepam whereas zolpidem enhanced the explorative activity but had only minor anxiolytic properties. In conclusion, a test battery in contrast to a single test has been shown to be a necessary tool to evaluate differences in pharmacological activity and also displayed that strain differences in behavior of rats are not only determined genetically, it may also be the result of preceding handling procedures. Since the rat strains responded differentially to the pre-test handling, a well-defined handling procedure is recommended to establish the "spontaneous" behavior of control animals before start of treatments like psychopharmacological tests that require handling procedures.

## 188.9

THE MOUSE CHROMOSOME-4 *Bis1* GENE IS INVOLVED IN BOTH SEIZURE AND ANXIOTIC PROCESSES. B. Martin\*†, Y. Clément†, P. Venault† and G. Chapouthier†. (SPON: European Brain and Behaviour Society) †URA CNRS 1294 - CDTA, 3b rue de la Férolerie, 45071 Orléans Cedex 02- France. ‡URA CNRS 1957, 47 boulevard de l'Hôpital, 75651 Paris Cedex 13 - France.

Two genes were recently identified, *Bis1* on chromosome 4 and *Bis2* on chromosome 13, as specifically involved in  $\beta$ -CCM-induced seizures and not in pentylenetetrazol- (PTZ) or strychnine-induced seizures. The aim of the present work is to show whether *Bis1* is also involved in anxiogenic and/or mnemonic processes. To this end, we used JE/Le mice carrying the *je* marker very close to the *Bis1* locus; the *je/je* genotype predicting with a very strong probability the *Bis1/Bis1* genotype, and alternatively, the *je/+* genotype predicting the *Bis1/+* genotype. The preceding work on the JE/Le strain, had shown that *je/je* mice are sensitive to  $\beta$ -CCM-induced seizures whereas *je/+* mice are highly resistant to  $\beta$ -CCM-induced seizures, reflecting that *Bis1/Bis1* is a  $\beta$ -CCM-drug-sensitive genotype whereas *Bis1/+* is a  $\beta$ -CCM-drug-resistant genotype. We applied a T-maze learning task to *je/je* and *je/+* mice under saline,  $\beta$ -CCM or PTZ treatments, at anxiogenic doses. An increased learning performance is interpreted as a learning process whereas a decreased is interpreted as an anxiogenic process. The statistical analysis confirms the preceding hypotheses concerning the involvement of the *Bis1* locus in anxiogenic processes.

## 188.11

BRAIN GLUCOSE METABOLIC AND SYMPATHETIC RESPONSES TO ACUTE ALPHA-2 BLOCKADE BY ETHOXYIDAZOXAN IN MALE VOLUNTEERS B.J. Oshinsky\*, Mark E. Schmidt, Jennifer Schouten, Bradley Folley, William Z. Potter Section on Clinical Pharmacology, NIMH, Bethesda, MD, 20892.

Alpha-2 adrenoceptors in brain modulate the release of a number of neurotransmitters thought to influence arousal, attention, anxiety, and mood. Intravenous challenge with idazoxan (IDX), an  $\alpha_2$  antagonist, results in increased activity in primary visual cortex and decreased activity in right prefrontal cortex in healthy males. IDX also has affinity for imidazoline (I2) binding sites in brain. To determine whether previous findings can be accounted for solely by  $\alpha_2$  blockade, we measured the sympathetic and brain glucose metabolic (CMRglu) responses to ethoxyidazoxan (ETX), an IDX analogue with no affinity for I2 sites. Seven healthy male volunteers (20-38 y/o) underwent serial  $F^{18}$ -fluorodeoxyglucose (FDG) PET scans, before and after infusion with ETX, 9  $\mu$ g/kg. Brain metabolism images were analyzed by Statistical Parametric Mapping. A transient increase in systolic BP occurred after ETX, without a significant change in diastolic BP or heart rate. In brain, the post-ETX FDG scan revealed relative increases in CMRglu in the mesial occipital and left parietal-occipital cortices. Relative CMRglu decreased in right prefrontal cortex after ETX. These findings parallel those reported with IDX infusion, and lend credibility to the concept that IDX-mediated changes in CMRglu in these regions are mediated by  $\alpha_2$  receptor blockade.

## 188.8

EFFECTS OF KETOCONAZOLE ON BENZODIAZEPINE PHARMACOKINETICS, RECEPTOR BINDING AND FUNCTION. G.A. Pritchard\*, J.S. Pratt, J.M. Grassi and D.J. Greenblatt. Department of Pharmacol. and Exp. Ther., Tufts University Sch. of Med., Boston, MA 02111.

Ketoconazole (KET) is an antifungal agent which has been shown to inhibit benzodiazepine metabolism in humans. We have recently demonstrated this effect in a clinical study. Despite elevations in triazolam (TRZ) plasma levels, the degree of pharmacodynamic change (EEG effects) of KET plus TRZ was lower than TRZ alone despite equivalent plasma TRZ levels. The present study examines the effect of KET on TRZ pharmacokinetics and pharmacodynamics as well as its effect on benzodiazepine receptor binding in vitro in male CD-1 mice. TRZ alone inhibited [ $^3$ H]FNTZ binding with an IC50 of 0.85 nM and a Ki of 0.46 nM. In the presence of KET (1.3 or 9  $\mu$ M) the IC50 of TRZ was increased to 1.11 nM, 1.58 nM and 5.73 nM respectively while maximal binding was reduced by 36, 69 and 89%, respectively. This disruption of TRZ displacement of [ $^3$ H]FNTZ binding could be explained by KET ability to dose dependently antagonize [ $^3$ H]FNTZ binding in a competitive manner with an IC50 of 1.56  $\mu$ M and corresponding Ki of 0.98  $\mu$ M. Consistent with clinical findings, ketoconazole (50 mg/kg, i.p.) significantly elevated mouse serum, brain and liver TRZ levels versus TRZ alone. KET or vehicle (VEH, PEG400 100  $\mu$ l i.p. final volume) was administered to mice at time 0 and TRZ (0.05, 0.1, 0.2 and 0.3 mg/kg) or VEH (100  $\mu$ l i.p.) were administered 60 minutes later. Open-field activity was monitored for 50 min following TRZ or VEH injection and blood, brain and liver samples were collected to determine KET and TRZ levels. KET administration had no effect on open field activity (horizontal activity, rears and stereotypy) but significantly potentiated TRZ's ability to decrease open field activity on all three parameters analyzed. Preliminary evidence in a pentylenetetrazole (PTZ) seizure susceptibility assay indicates TRZ (0.1 mg/kg) had a significant protective effect versus VEH but was not significantly altered by KET (50 mg/kg) coadministration.

## 188.10

SYMPATHONEURONAL AND BRAIN GLUCOSE METABOLIC RESPONSES TO  $\alpha_2$  ADRENERGIC BLOCKADE DURING ELECTROCONVULSIVE TREATMENT OF DEPRESSION. Mark E. Schmidt\*, Michael Henry, Bradley Folley, John Matochik, Hyung-Gun Kim, William Z. Potter. Section on Clinical Pharmacology, NIMH, Bethesda, MD, 20892.

Convulsive treatments are highly effective for ameliorating severe mood episodes, although the mechanism of therapeutic effect is not known. Current theories of the mechanism of action include changes in central catecholamine receptors such as  $\alpha_2$  adrenoceptors. We compared sympathetic and brain metabolic responses to acute  $\alpha_2$  blockade by idazoxan (IDX) given before and after electroconvulsive therapy (ECT). 6 patients (2 men, 4 women) with a Major Depressive Episode underwent 6-12 ECT treatments. IDX (2.00  $\mu$ g/kg) challenge studies were conducted before and 1 week after the course of ECT. FDG PET scans were obtained before and after infusion of IDX; plasma norepinephrine (NE), epinephrine (EPI) and blood pressures were measured. Brain metabolism images were analyzed voxel by voxel following stereotactic normalization and adjustment for global rate (SPM). Systolic pressure (SBP), NE, and EPI increased after IDX. SBP, NE and EPI responses were slightly, but not significantly larger after ECT. In brain, IDX resulted in relative increases in metabolism in primary visual cortex. Relative metabolic rate decreased in left dorsolateral prefrontal cortex (PFC), only after ECT. While preliminary, our findings of slightly larger sympathetic responses and relative decreases in left PFC are consistent with greater sensitivity to  $\alpha_2$  blockade following ECT.

## 188.12

TREATMENT OF POSTOPERATIVE NAUSEA/VOMITING(PONV): OLD DRUGS, NEW USE, Y.F. Sung\*. The Emory Clinic and Emory Univ. Sch. Of Med., Atlanta, GA 30322

One of the most distressful syndromes that presents in post anesthesia care units (PACU) besides pain is PONV. As day care surgery gains in popularity, this syndrome must be prevented or treated to get the patient (Pt) home-ready, prevent hospital admission, and decrease medical cost.

The aim of this study was to compare the combination of ephedrine(E) and promethazine (P) with saline (S) placebo and with each drug individually in treating patients who had a previous history (Hx) of PONV or severe motion sickness.

One hundred sixteen female pts who had laparoscopic procedures participated in the study. All pts had similar anesthesia. Pts had intramuscular injection of one of 5 treatments 15 min prior to emergence in 1.5 mL volume: Group S; E (E25mg + 1mL S); EP1 (E25mg + P12.5mg + 0.5mL S); EP2 (E25mg + P25mg); P (P25mg + 0.5mL S).

Anesthesia times were similar among 5 groups (ANOVA - NS). Average PACU time range was from EP1, 122 min, to S, 144 min (ANOVA = NS). PONV in PACU among 5 groups were: S 14/21, E 11/23, EP1 7/26, EP2 5/24, P 12/22 (chi square test, P = 0.008). Individual treatment group compared with saline group (Fisher's exact test): EP1 vs. S (P=0.009), EP2 vs. S (P=0.003), E & P were NS. The Emory Clinic/Emory Univ. School of Medicine

## 188.13

DISSOCIATION OF NORADRENERGIC AND CHOLINERGIC EFFECTS ON ALERTING AND ATTENTIONAL ORIENTING IN RHESUS MONKEY.

M.C. Davidson\* E.B. Cutrell, and R.T. Marrocco

Institute of Neuroscience, University of Oregon, Eugene OR. 97403

This study combined a cued target detection (CTD) task with systemic drug treatments to explore the relationship between neurotransmitters and attentional behavior. Increases in cholinergic activity following low dose nicotine injections increased the size of the validity effect (invalid cue RTs - valid cue RTs) by decreasing the invalid cue trials relative to saline controls. The cholinergic antagonist scopolamine reduced the size of the validity effect by increasing valid cue RTs. In contrast, the  $\alpha$ -2 agonist clonidine reduced the size of the alerting effect (double cue RTs - no cue RTs) by increasing RTs in double cue trials relative to saline controls. These data are consistent with previous results using yohimbine, an  $\alpha$ -2 antagonist, which also altered the alerting effect. Neither adrenergic drug affected validity scores. Thus, our data suggest a dissociation between attention and alerting behaviors and the systems that presumably mediate these processes.

FUNCTIONAL MAGNETIC RESONANCE IMAGING (fMRI) OF NICOTINE EFFECTS ON BRAIN ACTIVATION IN HUMANS. E.A. Stein, A.S. Bloom\*, J. Pankiewicz, S.A. Fuller, H.H. Harsch, and J.-K. Cho. Departments of Psychiatry and Pharmacology, Medical College of Wisconsin, Milwaukee, WI 53226.

Nicotine is the most commonly abused psychoactive substance producing a high level of tolerance and physical dependence. However, the sites and mechanisms within the human CNS responsible for these properties are poorly understood. fMRI provides excellent spatial and temporal resolution able to resolve the anatomy and physiology of drug effects in the CNS. Whole brain imaging was obtained with single shot GE-EPI on a 1.5 T Signa scanner. Experienced smokers received IV saline and nicotine (0.75, 1.5 or 2.25 mg administered over 1 min) in a cumulative dosing paradigm every 30 min first in a hospital setting to test for drug safety and subsequently while fMRI data were acquired for 20 min (TR=6 sec; TE=40 msec; 8 mm slice thickness). Subjects all displayed consistent increases in heart rate, arterial blood pressure and generally reported positive subjective effects to the drug. Plasma drug levels peaked at 2 min and decreased to about 50% by 5 min. A waveform recognition algorithm was used to identify activated voxels. Areas of activation included dose-related increases in the inf., med. and sup. frontal gyrus, anterior and posterior cingulate, visual and insular cortex, cerebellum, colliculi and caudate n. Signal activation peak occurred between 2.5-3 min, and declined by 50% within 3.5 min; mean signal intensity was 2-3 % above baseline. These data suggest that nicotine produces a regionally selective, dose-related increase in brain activity consistent with the observed behavioral and physiological effects of the drug. Supported DA09465 to EAS.

## 188.17

THE EFFECTS OF NPA ON U50488-INDUCED BEHAVIORS AND Fos IR IN THE YOUNG RAT. M. Duke, T. Meier, C. Bolanos, C. Crawford\* & S. McDougall\*, Dept. of Psych., CSUSB, San Bernardino, CA 92407; \*NPI, UCLA, Los Angeles, CA 90024.

The ability of NPA, a NPI DA agonist, to modulate U50488-induced behaviors and Fos IR was assessed in young rats. In the first experiment, 17-day-old rats were given the  $\kappa$ -opioid agonist U50488 (5.0 mg/kg) followed, 30 min later, by NPA (0.001-1.0 mg/kg, IP). Activity and sniffing were assessed for 60 min. Rats were killed 1 h later for analysis of Fos IR. In a second experiment, the ability of U50488 to cross-sensitize (CS) with NPA was determined. To that end, 11-day-old rats were given NPA (1.0 mg/kg) for 5 days, with CS being tested 2 days later after an injection of U50488. The results showed that U50488 dramatically enhanced the activity of the rats, with NPA depressing this activity in a dose-dependent manner. Conversely, sniffing was increased by NPA, an effect blocked by U50488. Fos IR in the nucleus accumbens, olfactory tubercles, septal area, striatum, habenula, and preoptic area was also enhanced by U50488. NPA attenuated U50488-induced Fos in all regions except the habenula and preoptic area. Although NPA-induced sensitization was evident, there was no CS between NPA and U50488. When considered together, these results suggest that the  $\kappa$ -opioid agonist U50488 and the DA agonist NPA have a generally antagonistic relationship, with NPA depressing U50488-induced activity and Fos IR.

## 188.14

EFFECTS OF SMOKING ON EEG AND THE VEP ARE INDEPENDENT. M. S. John and F. R. Ervin\*. Dept. of Psychiatry, McGill Univ., Montreal, QC H3A-1A1.

Changes in the EEG after smoking were examined both at rest and under mental load as induced by playing the game TETRIS and a computer version of Reverse Mirror Drawing Task. Visual evoked potentials were also recorded both before and after smoking. Under mental load, approximately half the subjects produced frontal midline theta (FMT) as has been previously reported. In addition to FMT, mental load produced an increase in delta, most pronounced posteriorly. In half of the subjects, post-nicotine EEG was characterized by a 300 percent narrow band increase of beta2 power. The beta2 response started 2 minutes after termination of the smoking period, and lasted for 7 minutes. Overall, the peak frequency of delta, theta, and alpha was increased by nicotine, and the duration of the VEP P1-N2 response was decreased by nicotine. However, while a negative correlation (-.72) was found between the post-nicotine alpha rhythm amplitude and P1-N2 amplitude, no correlation was found between the latency of any VEP component and the increase in alpha rhythm peak frequency. Results suggest the posterior alpha rhythm and VEP are independently modulated by nicotine thereby contradicting the model proposed by Liberson.

BLOCKADE OF APOMORPHINE-INDUCED CONDITIONED TASTE AVERSIONS IN RATS BY THE NK<sub>1</sub> ANTAGONIST GR205171A. K.H.M. McAllister and J.A. Pratt. SPON: Brain Research Association. Dept. of Physiology and Pharmacology, University of Strathclyde, Glasgow, G1 1XW, U.K.

Neurokinin<sub>1</sub> (NK<sub>1</sub>) receptors have been implicated in nociception, migraine and emesis. The aim of this study was to determine if the NK<sub>1</sub> receptor is involved in the phenomena of conditioned taste aversion (CTA), which has been hypothesised to recruit similar neural systems to those involved in emesis. CTA responses to apomorphine (0.25 mg kg<sup>-1</sup>; sc) and the NK<sub>1</sub> antagonist GR205171A (0.1 - 1.0 mg kg<sup>-1</sup>; sc) were investigated in rats using a 2-trial conditioning procedure. Water deprived rats were presented with either a sodium saccharin (0.1%) or a sodium chloride solution (0.9%) and immediately afterwards injected subcutaneously with apomorphine or vehicle. During the conditioning trials pretreatment with GR205171A was given 15 minutes prior to flavour presentation. The drug-paired and the vehicle-paired solutions were then presented simultaneously in a two-stimulus test to assess CTA and the fluid intake recorded. Following treatment with apomorphine (0.25 mg kg<sup>-1</sup>) the percentage of the drug-paired fluid intake was 26.2 ± 1.1%. GR205171A (0.1 - 1.0 mg kg<sup>-1</sup>) blocked apomorphine-induced CTA in a dose dependent manner. At doses of GR205171A (0.3 & 1.0 mg kg<sup>-1</sup>) apomorphine induced CTA was blocked with drug-paired fluid intakes being 43.9 ± 1.0% and 44.8 ± 1.3% respectively. Conversely GR205171A alone (0.1 - 1.0 mg kg<sup>-1</sup>) did not evoke CTA. These data suggest an involvement of NK<sub>1</sub> receptors in the CTA phenomena. However it remains to be established whether this occurs through an action of GR205171A on NK<sub>1</sub> receptors located in brain stem emetic circuitry or in forebrain structures involved in aversion learning. We would like to thank S.H.E.R.T. and Glaxo Wellcome for supporting this work.

## 188.18

LIPID-MEDIATED GENE TRANSFER IN THE RAT BRAIN, A. Thorsell<sup>1</sup>, E. Fox<sup>2</sup>, M. Heilig<sup>1</sup>, Karolinska Institute, Department of Clinical Neuroscience, Section for Clinical Alcohol and Drug Research, Magnus Huss Clinic, Karolinska Hospital, S-171 76 Stockholm, Sweden, <sup>2</sup>Megabios Corp 863A Mitten Rd. Burlingame CA 94010

Gene transfer and expression in the central nervous system (CNS) has to date mainly employed viral vectors as carriers of genetic material. Disadvantages to the use of viral vectors, such as e.g. immune reactions, may limit the usefulness of this strategy. A novel, alternative strategy for gene transfer is based on cellular uptake of expression-vectors bound to cationic lipids. This approach has been developed and proven efficient in cell-culture systems, and its potential has previously been demonstrated *in vivo* outside of the CNS. Here, its potential in the CNS was examined.

In initial experiments, an expression construct encoding prepro-neuropeptide Y (NPY) cDNA complexed to lipofectin or lipofectamine was administered i.c.v. to rats. This resulted in low-level but long term (up to 1 month) expression of a vector-derived NPY-transcript detected with RT-PCR within most brain regions. To optimize expression levels, in order to yield them useful for functional studies, we turned to a proprietary biodegradable lipid, which can be administered repeatedly without apparent toxicity, and a reporter construct encoding chloramphenicol-acetyltransferase (CAT). Expression of a functional CAT-protein was obtained after i.c.v. administration of complexes. Expression levels were assayed after 2, 7, 28 and 56 days. In most brain regions, expression was found to increase over the first 4 weeks. By 8 weeks, expression remained at high levels in cortex, but started to decline in other brain regions. It was demonstrated that the lipid:DNA-ratio is a critical parameter for effective lipofection, since only one of three lipid:DNA ratios studied mediated a robust gene transfer and expression.

Long-term expression of transferred genetic material is presently being evaluated. Different means of delivering complexes to the lateral ventricles and to local structures are being examined, as are ways to increase expression levels.

These results have been obtained in the apparent absence of adverse effects. Thus, in summary, cationic lipid-mediated gene transfer appears to have a considerable potential as an efficient, safe and accessible experimental method for the study of genes and their products in the normal adult living brain.

## 189.1

**OLANZAPINE VS. CHLORPROMAZINE IN TREATMENT-RESISTANT SCHIZOPHRENIA.** R. R. Conley\*, C. A. Tamminga, W. Satterlee, and the Maryland Study Group. MD Psychiatric Research Center, Baltimore, MD 21228.

Since the demonstration of the superior effect of clozapine in treatment-resistant schizophrenia (Kane, 1988) there has been an ongoing search for other drugs with the same effect. Although there have been multiple hypotheses about the mechanism of clozapine's efficacy, none have yet clearly explained clozapine's differential effect. This is largely because there are no other antipsychotics that have shown clozapine's effect in a similarly designed trial. Olanzapine is an excellent candidate drug for study. It has a very similar binding profile to clozapine (e.g.,  $K_i$  @  $D_1$ -31 nM,  $D_2$ -11 nM,  $\alpha_1$ -119 nM,  $H_1$ -7 nM,  $5-HT_2$ -5 nM,  $M_1$ -1.9 nM), but has a higher dose potency. It has a high affinity at  $D_4$  receptors (Beasley, 1993) which may be a critical clozapine property (Lahti, 1992). Olanzapine is an effective antipsychotic (Satterlee, 1995). We have studied the effect of olanzapine vs. chlorpromazine in a ten-week, double-blind clinical trial. All subjects had a DSM-III-R diagnosis of schizophrenia and were classified as treatment-resistant by failing to have a 20% or greater response to at least two different neuroleptics, exclusive of haloperidol (at 1000 mg/day CPZ equivalents for six weeks each), been persistently ill with no periods of good functioning for at least five years, and had failed to show a 20% improvement in a six-week prospective trial of haloperidol. All subjects signed informed consent. Subjects had a two-week single-blind neuroleptic washout, followed by ten weeks of treatment either with 25 mg/day of olanzapine or 1200 mg/day of chlorpromazine in a fixed-dose design after a one week titration period. Subjects were rated weekly. To date, 81 subjects have entered the trial, 10% have responded. We will report unblinded data at the meeting. This is, to our knowledge, the first large trial of olanzapine in this population.

Supported by NIMH MH 47311, Lilly Pharmaceuticals provided olanzapine.

**RESTORATION OF PREPULSE INHIBITION IN SOCIALLY ISOLATED RATS BY SEROQUEL AND OLANZAPINE.** M.A. Geyer\*, V.P. Bakshi, D.L. Braff and N.R. Swerdlow. Depts. of Neuroscience and Psychiatry, UCSD, La Jolla CA 92093.

Intense auditory or tactile stimuli elicit involuntary startle responses that are attenuated when a weak stimulus (a prepulse) is presented immediately prior to the startling stimulus. This phenomenon of "prepulse inhibition" (PPI) is thought to be an operational measure of sensorimotor gating and is disrupted in schizophrenia (SZ) patients. The early developmental manipulation of rearing animals in social isolation results in a deficit in PPI that models the impairment seen in SZ. The present investigation evaluated the ability of two new putative atypical antipsychotics, seroquel and olanzapine, to reverse the deficit in PPI produced by isolation rearing. Upon weaning, all animals were assigned randomly to one of two housing conditions for the duration of the studies: isolation rearing (IR, singly housed) or social rearing (SR, housed in groups of 3). Eight weeks later, all animals were treated with either saline or seroquel (5.0 mg/kg) 30 min before being tested with 120 dB startling stimuli presented either alone or 100 msec after non-startling prepulses that were 3, 6, or 12 dB above the background noise (65 dB). Two weeks later, animals were treated with either saline or olanzapine (2.5 mg/kg) and tested for PPI 30 min later. IR animals exhibited markedly lower levels of PPI than did SR animals. Pretreatment with either seroquel or olanzapine significantly improved PPI in IR animals without affecting PPI in SR rats. These results indicate that IR-induced deficits in PPI are sensitive to atypical antipsychotics.

**GLUTAMATERGIC MECHANISMS OF ANTIPSYCHOTIC DRUG ACTION.** T.I. Lidsky\*, E. Yablonsky-Alter, L. Zuck, S.P. Banerjee, NYS Institute for Basic Research, Staten Island, NY 10314

Previous work from this laboratory indicated that some antipsychotic drugs (APs) possess unique action at NMDA receptors that could contribute to antipsychotic efficacy. Both functional neurochemistry and *in vitro* electrophysiology showed that APs, at concentrations similar to that found in schizophrenics' CSF, augment NMDA activity while, at higher concentrations, NMDA activity is suppressed. Using similar analysis, the present paper reports that this pattern of response, consistent with partial agonism, is shown by haloperidol, chlorpromazine, thioridazine, pimozide and clozapine. In contrast, sulpiride and metoclopramide, drugs with high affinity for  $D_2$  dopamine receptors but with weak or no antipsychotic efficacy, lack effects at the NMDA receptor. The present results indicate that  $D_2$  activity is neither necessary nor sufficient to achieve antipsychotic potency. Conversely, the drugs with clinical efficacy that were tested in the present study all share unique influence on NMDA receptors. Further work with other APs will be necessary to determine if partial agonism at NMDA receptors is the defining characteristic of antipsychotic effectiveness.

## 189.2

**MOOD STABILIZING ACTION OF SM-13496, A NOVEL ATYPICAL ANTIPSYCHOTIC AGENT, IN CONDITIONED FEAR STRESS-INDUCED FREEZING BEHAVIOR MODEL IN RATS.** Y. Ohno\*, K. Ishida-Tokuda, H. Sakamoto, T. Ishibashi, R. Tojima, J. Yasui, T. Morita and M. Nakamura. Research Center, Sumitomo Pharmaceuticals Co., Ltd., Konohana-ku, Osaka 554, Japan.

SM-13496 is a novel 5-HT<sub>2</sub> and dopamine D<sub>2</sub> receptor antagonist with negligible extrapyramidal and CNS depressive side effects. To evaluate the action of SM-13496 on the dysphoric mood disturbances in animals, we compared its effects on the conditioned fear stress (CFS)-induced freezing behavior in rats with those of other antipsychotics. Exposure of rats to the environment previously paired with the foot shock induced marked freezing behavior, which was reduced by the anxiolytic diazepam or the antidepressants, desipramine and imipramine. SM-13496 (0.3-6 mg/kg, p.o.) significantly attenuated the CFS-induced freezing behavior in a dose-dependent manner. Other serotonin-dopamine antagonists (SDA), clozapine and risperidone, also reduced the freezing behavior showing a U-shaped dose-response curve but the improvement rate was lower than that with SM-13496. By contrast, neither the conventional antipsychotic, haloperidol, chlorpromazine, thioridazine, mofenazine nor tiapride reduced the CFS-induced freezing behavior. In addition, the selective 5-HT<sub>2</sub> antagonists, ritanserin and ketanserin, also reduced the induction of the freezing behavior by CFS. These findings suggest that SM-13496, like other SDA-type antipsychotics, is effective for the treatment of mood disturbances (e.g., anxiety, tension and depression) associated with schizophrenia and have a broader efficacy profile as compared with the conventional antipsychotics. The 5-HT<sub>2</sub> blocking action of SM-13496 seems to be at least partly involved in its mood stabilizing action in the CFS-induced freezing model.

## 189.4

**EFFECTS OF TYPICAL AND ATYPICAL NEUROLEPTICS ON DOPAMINE REUPTAKE IN THE STRIATUM: AN ELECTROCHEMICAL STUDY.** D.S. Rothblatt\*, and J. S. Schneider. MCP and Hahnemann University, Department of Neurobiology and Anatomy, Philadelphia, PA 19102-1192.

Typical neuroleptics, such as Haloperidol (HAL), have high affinity for dopamine (DA) D<sub>2</sub> receptors, enhance DA release and have a high incidence of motor side effects while atypical neuroleptics, such as Clozapine (CLOZ), have low affinity for DA D<sub>2</sub> receptors, do not enhance DA release and have reduced likelihood of producing motor side effects. While DA D<sub>2</sub> receptor affinity may underlie some of the side-effect potential of neuroleptics, it is possible that these drugs may affect DA release and/or reuptake which could also influence production of motor side effects. The present study investigated neuroleptic effects on DA-reuptake in the dorsal and ventral striatum of urethane-anesthetized (1.25mg/kg) adult Sprague Dawley rats. High-speed chronoamperometry utilizing nafion-coated carbon fiber electrodes was used to measure DA reuptake in the striatum. Dopamine (200  $\mu$ M) was pressure ejected from a pipette (2-15 psi) attached to the recording electrode (100-300  $\mu$ m tip separation). Once a reproducible signal was achieved, CLOZ or HAL (10  $\mu$ M) was pressure ejected from a second pipette and effects on DA clearance were measured. Pressure and duration of DA ejections were varied to reproduce peak levels recorded prior to neuroleptic application. Reuptake rate ( $\mu$ M/sec) was reduced by 28% in the dorsal striatum and 46% in the ventral striatum after CLOZ application, while HAL reduced the reuptake rate by 55% in the dorsal and only 19% in the ventral striatum. Similar trends were also observed in animals that received systemic HAL (10mg/kg) or CLOZ (5mg/kg). These results suggest that while both typical and atypical neuroleptics can slow DA-reuptake, HAL's effect was much greater in the dorsal (sensorimotor) striatum. Increased extracellular DA levels, particularly in the dorsal striatum, could contribute to the generation of motor side effects by several mechanisms including augmentation of glutamatergic neurotransmission. Such mechanisms will be the focus of future studies. Supported by the F.M. Kirby Foundation.

## 189.6

**SEROTONIN AND DOPAMINE RECEPTOR AFFINITIES PREDICT ATYPICAL ANTIPSYCHOTIC DRUG (AAD) ACTIVITY.** H.Y. Meltzer\*, B. Roth, P. Thompson. \*Ctr for Psychobiology, Case Western Res Univ, Cleveland, OH 44106

Atypical antipsychotic drugs (AAD), e.g. clozapine, differ from typical antipsychotic drugs (TAD), e.g., haloperidol, in producing low extrapyramidal side effects (EPS) and have apparent advantages for improving some types of psychopathology. A hypothesis offered by us to explain the biological basis for the differences in these classes of drugs has been weak  $D_2$  relative to 5-HT<sub>2A</sub> receptor blockade. However, a discriminant function analysis (DFA), using only the affinities for these two receptors, classified 4 of 37 drugs incorrectly. We have now examined whether the inclusion of other receptor affinities can improve the classification. Affinities of 11 and 9 AAD and TAD, respectively, were determined for  $D_1$ ,  $D_2$ ,  $D_4$ , 5-HT<sub>2A</sub>, 5-HT<sub>2C</sub>, 5-HT<sub>7</sub>, and 5-HT<sub>1</sub> receptors, using cloned cell expression systems or brain membranes. With DFA, in order of importance,  $D_2$ , 5-HT<sub>2A</sub>, 5-HT<sub>2C</sub>, and 5-HT<sub>7</sub> receptor affinities correctly classified all compounds, including loxapine and amoxapine, which had been incorrectly classified previously. The squared canonical correlation was 0.77, indicating 77% of the variance in atypicality is explained by this model. The parameter estimates were: (1)  $D_2$ , 0.53,  $p=0.001$ ; (2) 5-HT<sub>2A</sub>, -0.41,  $p=0.01$ ; (3) 5-HT<sub>2C</sub>, 0.25,  $p=0.02$ ; and, (4) 5-HT<sub>7</sub>, -0.18,  $p=0.06$ , indicating AAD had weak  $D_2$  and 5-HT<sub>2C</sub> and potent 5-HT<sub>2A</sub> and 5-HT<sub>7</sub> affinities. These results suggest that multiple receptor affinities are important to the pharmacology of the APD and that compounds highly selective for the receptors studied here are unlikely to be of comparable value in the treatment of schizophrenia. The differences between serotonin-dopamine antagonists such as clozapine, risperidone, and olanzapine with regard to the affinities for these four receptors may account for some of the clinical differences between these compounds.

## 189.7

COMPARATIVE ANTIPSYCHOTIC PROFILES OF NEUROTENSIN AND A RELATED SYSTEMICALLY ACTIVE PEPTIDE AGONIST. S. Sarhan, J.M. Hitchcock, C.A. Grauffel, R.M. Pruss\* and J.G. Wettstein. Hoechst Marion Roussel, Department of Pharmacology, 16 rue d'Ankara, 67080 Strasbourg, France.

Several lines of evidence have shown that neurotensin can modulate dopamine neurotransmission. It has been suggested that neurotensin has potential antipsychotic activity because it reduces dopaminergic activity preferentially in the nucleus accumbens. In the present study, the effects of neurotensin and NT1 (N<sup>6</sup>MeArg-Lys-Pro-Trp-Tle-Leu or Eisai hexapeptide), a metabolically stable and systemically active neurotensin agonist, were examined in several models of antipsychotic activity and side effect liability in mice. Analgesic and hypothermic effects of both compounds also were determined. Even at high doses, neurotensin (5.0 and 10.0 µg, i.c.v.) and NT1 (10.0 and 20.0 mg/kg, i.p.) did not produce catalepsy. A much lower dose of neurotensin (0.03 µg, i.c.v.) significantly reduced amphetamine-stimulated locomotor activity; NT1 also diminished amphetamine- and phencyclidine-stimulated locomotion with ED<sub>50</sub> values of 0.3 and 0.4 mg/kg, i.p., respectively. In addition, neurotensin (0.01 - 0.3 µg, i.c.v.) and NT1 (0.1 - 1.0 mg/kg, s.c.) produced dose-dependent analgesia in the paw pressure test and decreased body temperature; these effects were insensitive to pretreatment with naloxone (10.0 mg/kg, i.p.). Together, the results support the hypothesis that neurotensin agonists have antipsychotic and analgesic activity. Moreover, use of such compounds may not produce extrapyramidal side effects.

## 189.9

PREVENTION OF DOI-INDUCED DISRUPTION OF LATENT INHIBITION BY MDL 100,907, CLOZAPINE, HALOPERIDOL AND RISPERIDONE. J.M. Hitchcock\*, S. Lister, T.R. Fischer and J.G. Wettstein. Hoechst Marion Roussel, Department of Pharmacology, 16 rue d'Ankara, 67080 Strasbourg, France.

Latent inhibition (LI), a measure of the ability to learn to ignore irrelevant stimuli, is disrupted in schizophrenics and in rats treated with amphetamine; antipsychotics prevent amphetamine-induced disruption of LI in rats. The 5-HT<sub>2</sub> agonist DOI [1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane HCl] has hallucinogenic properties in humans, and evidence suggests that 5-HT<sub>2</sub> antagonism is an important component of antipsychotic activity. In the present study, the ability of DOI to disrupt LI in rats was tested, and the effects of clinically-used and putative antipsychotics were assessed in this procedure. The method consisted of four phases. After *habituation* to the apparatus, thirsty rats underwent *pre-exposure* to a tone 24 hrs prior to two tone-shock *conditioning* trials. LI was demonstrated at *testing* (an additional 24 hrs later) by reduced lick suppression during tone presentation. When administered at both pre-exposure and conditioning phases, DOI disrupted lick suppression itself, obscuring measurement of LI. However, when administered at the pre-exposure phase only, DOI dose-dependently disrupted LI. Clozapine, haloperidol, risperidone and the selective 5-HT<sub>2A</sub> antagonist MDL 100,907 prevented DOI-induced disruption of LI. These results indicate that antagonism of DOI-disrupted LI has potential as a method for detection of antipsychotic activity and further support the involvement of 5-HT<sub>2A</sub> antagonism in antipsychotic activity.

## 189.11

CLOZAPINE BUT NOT HALOPERIDOL INDUCES C-FOS IN CERTAIN BRAIN REGIONS IMPLICATED IN SCHIZOPHRENIA. D. K. Rush\*, D. E. Bregna, S. E. Hanak, M. R. Szwedczak, and M. G. Cilio. Hoechst Marion Roussel, Inc., CNS Therapeutic Area, Bridgewater, NJ 08807-0800.

Much like the 2-deoxyglucose method for examining regional changes in metabolism induced by specific stimuli, induction of *c-fos* mRNA and protein has been utilized to examine regional changes in cellular activation induced by a variety of stimuli including drugs. In the current study, we examined the effect of haloperidol (1 mg/kg) and clozapine (30 mg/kg) on *c-fos* protein in a wide variety of forebrain regions. The drugs or vehicle (n=3-4, Sprague-Dawley rats) were administered ip 2 h prior to transcardial formaldehyde perfusion. *c-fos* was detected with a rabbit polyclonal antibody (Oncogene, PC05, 1:3000) with biotin-avidin amplification (Vector Elite) and DAB-nickel intensification in 30 µm cryostat sections taken every 150 µm from the beginning of the caudate-putamen to the posterior part of the hippocampus (+1.7 to -4.16 mm, Paxinos & Watson atlas).

A qualitative examination of all brain regions was followed by quantification of the number of *c-fos* positive cells in digitized video images using image analysis (MCID M4, Imaging Research Inc.). Haloperidol but not clozapine induced *c-fos* in the medial and lateral caudate-putamen. Both haloperidol and clozapine induced *c-fos* in the n. accumbens; clozapine increased *c-fos* in both shell and core, haloperidol was only effective in the core. Clozapine but not haloperidol induced *c-fos* in the lateral septum, thalamus, amygdala, hypothalamus and bed nucleus of the stria terminalis. Many of these latter areas, especially the thalamus, have been implicated in both the negative and positive symptoms of schizophrenia and may be sites of action of this atypical neuroleptic agent.

## 189.8

EFFECTS OF ANTIPSYCHOTIC DRUGS AND OTHER CNS-ACTIVE AGENTS ON THE BEHAVIORAL ACTIONS OF THE HALLUCINOGEN DOI (1-[2,5-DIMETHOXY-4-IODOPHENYL]-2-AMINOPROPANE). J.G. Wettstein\*, M. Host and J.M. Hitchcock. Hoechst Marion Roussel, Department of Pharmacology, 16 rue d'Ankara, 67080 Strasbourg, France.

It has been proposed that antagonists at 5-HT<sub>2</sub> receptors, in particular 5-HT<sub>2A</sub> sites, could have antipsychotic activity in humans. In an effort to understand the contribution of 5-HT<sub>2</sub> activity to the effects of antipsychotic drugs and to enhance screening for such compounds, a series of conventional, atypical and purported antipsychotics were assessed as antagonists of DOI in rats. DOI is an hallucinogen having high affinity and selectivity as an agonist at 5-HT<sub>2</sub> receptors. Over a 30-min period after injection, DOI (0.3 - 10.0 mg/kg; i.p.) produced dose-related behavioral effects including head-and-body shakes, forepaw tapping and skin-jerks. The effects of antipsychotics and other compounds (30 min pretreatment; i.p.) were examined against a fixed dose of DOI (3.0 mg/kg). In a dose-dependent manner, risperidone, haloperidol, clozapine, MDL 100,907, iloperidone, olanzapine, amperozide, ritanserin and the neurotensin agonist N<sup>6</sup>MeArg-Lys-Pro-Trp-Tle-Leu attenuated the behavioral effects of DOI. The following compounds had little or no effect on the DOI-induced behaviors: citalopram, CP 99994, diazepam, fluoxetine, ondansetron and SKF 97541. These data show that, as a drug class, antipsychotics block the effects of DOI and those with notable 5-HT<sub>2</sub> affinity (e.g., risperidone, MDL 100,907 and iloperidone) are quite potent in this regard; such effects are selective as a series of non-antipsychotic, centrally-acting drugs were inactive in the procedure.

## 189.10

LOCALIZING DRUG EFFECTS ON SENSORIMOTOR GATING IN A PREDICTIVE MODEL OF ANTIPSYCHOTIC POTENCY. S. Hart, M. Zreik, R. Carper and N.R. Swerdlow\*. UCSD Dept. of Psychiatry, La Jolla, CA 92093-0804

The degree to which a startle response to a loud noise is inhibited by a weak prestimulus is an operational measure of sensorimotor gating. "Prepulse inhibition" (PPI) can be measured across species, and is reduced or absent in schizophrenia patients, and in dopamine (DA)-activated rats. Preclinical and clinical data suggest that PPI is regulated by neural circuitry connecting prefrontal and limbic cortex with sub-cortical structures that innervate the pontine tegmentum. The loss of PPI in apomorphine (APO)-treated rats is reversed by DA antagonists; the ability of drugs to restore PPI in APO-treated rats correlates highly with their clinical antipsychotic potency.

We compared the ability of systemic- vs intracerebrally (ic)-administered haloperidol (HAL) to restore PPI in APO-treated rats. Consistent with previous studies, systemic (sc) administration of HAL completely restored PPI in rats treated with APO (0.5 mg/kg sc), with an ED<sub>50</sub> of approximately 0.05 mg/kg. In an otherwise identical paradigm, HAL failed to fully restore PPI after infusion into either the nucleus accumbens (NAC), caudate nucleus (CN), ventral subiculum (VS), dentate gyrus, medial prefrontal cortex, ventral tegmentum or dorsomedial thalamus. A subtotal, but statistically significant restoration of PPI was achieved after HAL infusion into the NAC, CN and VS. ED<sub>50</sub>'s for the effects of ic HAL tended to be approximately 5-fold lower than those detected after sc administration. Data from the effects of simultaneous multi-site HAL infusions will be presented. The results suggest that systemically-administered HAL may restore PPI in APO-treated rats via its action at multiple levels of PPI-regulatory circuitry.

## 189.12

EFFECTS OF CLOZAPINE IN SHR AND WKY RAT PUPS CHALLENGED WITH AMPHETAMINE: STEREOTYPY, CATALEPSY, AND ACTIVITY DATA. M.K. Murphy, P.M. Bettino, and A.C. Santucci. Dept. of Psychology, Manhattanville College, Purchase, NY 10577.

Previous studies have suggested the use of spontaneously hypertensive rats (SHR) as an animal model for Attention Deficit/Hyperactivity Disorder (ADHD). However, the literature is uncertain as to the cause of the hyperactivity seen in these animals. Therefore, in an attempt to better characterize this animal model, the present study examined the effects of dopamine blockade on measures of activity, stereotypy, and catalepsy. SHR and normotensive WKY controls (17-21-day-old pups) were injected with one of three doses of clozapine (0, 12.5, & 25 mg/kg), a putative selective D<sub>2</sub> limbic antagonist. All animals were then tested 30 min. later for open-field and wheel-running activity, stereotypy, and catalepsy in response to a d-amphetamine challenge (0 and 0.75 mg/kg). Results indicated that SHR animals were hyperactive as reflected in an increased number of square crosses, rears, and wheel turns (p < .05). When tested under amphetamine, a paradoxical reduction in activity was not observed in SHR animals (p < .05). In addition, SHR subjects took longer to initiate exploration in the open-field (p < .05). This suggests that these animals were hyper-reactive when placed in a novel environment. In general, activity in all clozapine-treated subjects was severely diminished. Interestingly, however, clozapine differentially increased measures of catalepsy and stereotypy in SHR subjects. These data suggest that SHR animals may be hypodopaminergic. In addition, this hypodopaminergia may be related to the behavioral profile displayed by SHR animals.

## 189.13

EFFECTS OF ATYPICAL AND TYPICAL NEUROLEPTICS ON SINGLE-UNIT RECORDINGS OF SUBSTANTIA NIGRA RETICULATA NEURONS. W. Timmerman\*, R. Bruggeman and B.H.C. Westerink. Department of Medicinal Chemistry, University Center for Pharmacy, 9713 AV, Groningen, The Netherlands.

Risperidone has proven to be effective as an antipsychotic drug and has fewer extrapyramidal side-effects than classical neuroleptics. Besides its D2 antagonistic properties, the antipsychotic agent is a potent serotonin-5HT2 antagonist. The atypical antipsychotic clozapine also possesses both, D2 and 5-HT2 receptor affinity next to affinities for other receptors. To gain insight in the consequences of treatment with these atypical neuroleptics vs typical neuroleptics for basal ganglia activity, effects of cumulative doses of risperidone, clozapine and haloperidol on substantia nigra reticulata (SNR) single-unit activity were studied in chloralhydrate anaesthetized male Wistar rats. Both, risperidone (0.05-3.2 mg/kg iv) and clozapine (0.1-6.4 mg/kg iv) dose-dependently decreased SNR activity maximally to 60% and 75% of basal activity, respectively. In contrast, haloperidol (0.012-0.8 mg/kg iv) induced a slight increase in SNR activity over time, which was identical to the SNR activity after saline treatment. Thus, these results indicate that typical and atypical neuroleptics differentially affect the output of the basal ganglia at the level of the SNR. The inhibition of SNR neuronal activity is hypothesized to be mediated via 5HT2 receptor blockade. [Supported by a grant from the Royal Dutch Academy of Sciences].

## 189.15

TYPICAL AND ATYPICAL ANTIPSYCHOTIC DRUGS UPREGULATE RAT CEREBROCORTICAL D<sub>2</sub> AND STRIATOLIMBIC D<sub>4</sub> DOPAMINE RECEPTORS. R.J. Baldessarini\*, F.L. Tarazi, S.K. Yeghiayan, and J.L. Neumeyer<sup>1</sup>. Psychiatry & Neuroscience Depts, Harvard Medical School; Mailman Research Center, Belmont, MA 02178, <sup>1</sup>Research Biochemicals International (RBI), Natick, MA 01760.

We examined changes in dopamine receptor binding following 21d treatment of rats with a typical neuroleptic, fluphenazine (FLU; 1.0 mg/kg/d), an atypical antipsychotic, clozapine (CLZ; 20 mg/kg, twice daily) and a novel potential antipsychotic agent, S(+)-N-n-propylnorapomorphine ([+]-NPA; 2.0 mg/kg, thrice daily) using *in vitro* quantitative receptor autoradiography. FLU treatment significantly increased binding of the D<sub>2</sub>-like (D<sub>2</sub>/D<sub>3</sub>/D<sub>4</sub>) ligand [<sup>3</sup>H]-nemonapride in medial prefrontal cortex (MPC; 46%), striatum (STR; 22%) and nucleus accumbens (ACC; 67%). In contrast, CLZ (59%) and [+]-NPA (48%) treatment increased D<sub>2</sub>-like receptor binding only in MPC. This pattern suggests that the MPC may be an important common site of action for typical and atypical antipsychotic drugs. D<sub>4</sub> receptors were quantified with [<sup>3</sup>H]-nemonapride plus excess S(-)-raclopride (300 nM) to occlude D<sub>2</sub>/D<sub>3</sub> receptors, as well as 100 nM pindolol and 500 nM 1,3-ditolyguanidine (DTG) to mask 5HT<sub>1A</sub> and sigma sites. FLU, CLZ and [+]-NPA treatments significantly increased D<sub>4</sub> receptor binding in ACC (124%, 71%, and 68% respectively) and STR (62%, 43%, and 48%) but not in the MPC. These results support the hypothesis that cerebrocortical D<sub>2</sub> and striatolimbic D<sub>4</sub> receptors may mediate the antipsychotic actions of both typical and atypical neuroleptic drugs, and encourage further consideration of [+]-NPA as a possible atypical antipsychotic agent.

## 189.14

A NOVEL SERIES OF 1-ARYLOXY-3-(4-ARYLOXYPIPERIDINYL)-2-PROPANOLS AS POTENT, SELECTIVE DOPAMINE D<sub>4</sub> RECEPTOR ANTAGONISTS. J.L. Wright, T.F. Gregory, T. G. Heffner, R.G. MacKenzie, T.A. Pugsley, S.J. Vander Meulen and L.D. Wise\*. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105

Both the antipsychotic efficacy and neurological side effects of dopamine (DA) antagonists have been correlated with their affinity for DA D<sub>2</sub> receptors which are widespread in limbic and striatal regions of the brain. These receptors now include D<sub>2</sub>, D<sub>3</sub> and D<sub>4</sub> subtypes. The D<sub>4</sub> subtype is expressed at relatively higher levels in limbic and cortical brain regions than in the basal ganglia. This suggests that a selective DA D<sub>4</sub> antagonist might provide antipsychotic efficacy without causing neurological side effects. High volume screening of our chemical library and subsequent studies have uncovered a novel series of 1-aryloxy-3-(4-aryloxy piperidinyl)-2-propanols with high affinity for cloned human DA D<sub>4</sub> receptors expressed in CHO-p-5 cells. For example, the analog in which both aryls were phenyl has a K<sub>i</sub> value of 4 nM at DA D<sub>4</sub> receptors with >100 fold less affinity at DA D<sub>2</sub> and D<sub>3</sub> receptors. Substituents on the aryl groups did not significantly improve affinity but the (R)-enantiomers had slightly higher DA D<sub>4</sub> affinity than the (S)-enantiomers. Several members of this series appeared to be antagonists; they showed no stimulation of mitogenesis in CHO-p-5 cells expressing D<sub>4</sub> receptors and blocked the stimulation of mitogenesis caused by the DA agonist quinpirole in such cells. These compounds modestly increased DA synthesis in rat hippocampus and striatum but, unlike traditional DA D<sub>2</sub> antagonists, did not alter locomotor activity in rodents. Such DA D<sub>4</sub> antagonists represent potential atypical antipsychotic agents. Supported by Warner-Lambert

## 189.16

EFFECT OF CHRONIC ANTIPSYCHOTIC DRUG TREATMENT ON CYTOCHROME OXIDASE ACTIVITY IN THE RAT BRAIN P.D. Lambert\*, T.D. Ely, R.E. Gross and C.D. Kilts. Dept. of Psychiatry and Behavioral Sciences, Emory Univ. Sch. of Med., Atlanta, GA 30322

The therapeutic effects of antipsychotic drugs are mediated by gradually developing, adaptive effects occurring as a consequence of long term receptor actions. An understanding of the relationship between such patterns of altered brain activity and the distinct clinical effects of different antipsychotics may provide neural system targets for novel drugs. Cytochrome oxidase (CO) is a mitochondrial enzyme that catalyzes the terminal transfer of electrons to molecular oxygen in cell respiration. CO mapping defines localized changes in energy demand resulting from sustained changes in neuronal activity and represents a powerful technique for identifying enduring patterns of altered brain function. We have used a histochemical assay of CO activity to map changes in neuronal functional activity following neuroleptic and atypical antipsychotic administration. Male Sprague-Dawley rats were dosed with clozapine (20 mg/kg i.p.), haloperidol (1mg/kg i.p.) or vehicle (tartaric acid 0.3%) once daily for 21 days. 18 hours following the final injection, brains were collected, sliced (30µm) and stained for CO using the methods of Gonzalez-Lima. The repeated administration of antipsychotic drugs was associated with significant alterations in CO activity in structures of the limbic, motor and prefrontal basal ganglia-thalamocortical circuits. These patterns were distinct for clozapine and haloperidol. Significant bilateral increases in CO activity compared to control were seen following 21d clozapine treatment in the central nucleus of the amygdala (R 31%, L 36%), globus pallidus (R 73%, L 49%), dorsolateral caudate (R 22%, L 30%), anteroventral thalamic nucleus (R 22%, L 26%) and mediodorsal thalamic nucleus (R 25%, L 22%). Thus, CO activity maps define patterns of changes in neuronal activity in response to antipsychotic drug administration and by pathway mapping may allow the neural system targets for individual antipsychotic drugs to be identified.

OLIGODENDROCYTE-RELATED ENZYMES IN HYDROCEPHALIC RAT BRAINS. M.R. Del Bigio\* and J.N. Kanfer, Departments of Pathology and Biochemistry, University of Manitoba, Winnipeg, MB Canada R3E 0W3

Hydrocephalus, a dilatation of the cerebral ventricles, can damage white matter. We induced hydrocephalus by injecting kaolin into the cisterna magna of 3 week old rats. After 1, 2, or 4 weeks, rats were killed or treated by shunting of CSF. Samples of corpus callosum/ supraventricular white matter, fimbria, and medulla were dissected from each brain. The myelin enzymes 2',3'-cyclic nucleotide 3'-phosphodiesterase (CNP) and p-nitrophenylphosphorylcholine phosphodiesterase (PNP), and the oligodendrocyte enzyme UDP-galactose: ceramide galactosyltransferase (CGaT) were assayed. In corpus callosum, CNP was reduced by 25% (p<.0001) and PNP was reduced by 47% (p<.0001), compared to controls. CGaT, which showed a maturation-related decline, was unaffected by hydrocephalus but showed a 43% increase (p=.0019) following early shunting. In the medulla, CGaT was reduced by 27% (p<.0001) in the 1 wk hydrocephalic rats. No changes were observed in the fimbria. Immunohistochemical labeling of myelin basic protein and O11 was unchanged in the corpus callosum, striatum, and fimbria. Labeling of oligodendrocytes in hydrocephalic brains by O4 resembled that of older control rats. The incidence of brain cell death, as determined by labeling of fragmented DNA, progressively increased from 1-3 weeks (p<.01). Summary: Damage to white matter by ventriculomegaly is reflected by reduced activity of myelin-related enzymes. Conclusion: Early reduction of ventricular size allows re-activation of oligodendrocytes, as indicated by CGaT activity in the corpus callosum. (Funded by the P.H.T. Thorlakson and Manitoba Medical Services Foundations.)

EFFECTS OF VALPROIC ACID ON THE EXPRESSION OF NEURAL CELL ADHESION MOLECULE DURING MOUSE NEURAL TUBE CLOSURE. K.K. Terry\*, S.L. Dial, R.D. Streck, and D.K. Hansen. Div. Reproductive & Developmental Toxicology; National Center for Toxicological Research, Jefferson, AR 72079.

During neurulation, neural cell adhesion molecule (N-CAM) plays an important role in neural tube closure. Valproic acid (VPA), an anticonvulsant drug, increases the incidence of neural tube defects in humans and elicits exencephaly in mice. This study examined quantitative changes in embryonic N-CAM expression following exposure to VPA. On gestation day (GD) 8, pregnant CD-1 mice were subcutaneously injected with saline or 600 mg VPA/kg. Embryos were examined for gross morphology on GD 9.25, and whole embryo heads were processed for Western blot analysis. Anterior neural tubes failed to close in 63 ± 8% (mean ± S.E.M.) of the VPA-treated conceptuses compared to 6 ± 5% of those exposed to saline. Preliminary Western blot analyses suggest that VPA induced no significant alterations in the overall amount of either 180 or 140 kD N-CAM isoforms in whole embryo heads. VPA may have effects on N-CAM expression in highly localized regions; therefore, concurrent *in situ* hybridization studies are underway to examine VPA-induced changes in the distribution of N-CAM transcripts within the closing neural tube. Supported by NCTR/FDA/DHHS.

## 190.3

CHRONOLOGICAL CHANGES OF CELL PROLIFERATION AND REGENERATION CAPACITY OF SURGICALLY INDUCED OPEN NEURAL TUBE DEFECTS IN CHICK EMBRYOS. K.C. Wang\*, M.S. Lee, Y.J. Lee, K.B. Sim, J.G. Chi and B.K. Cho Div Ped Neurosurg & Ped Path, Seoul Natl Univ Sch of Med, Seoul 110-744, Korea

To investigate the correlation between the regeneration capacity of surgically induced neural tube defect and its cell proliferation activity, The chronological changes of the size of the NTDs and proliferating cell nuclear antigen (PCNA) positivity in normal developing chick embryos were correlated. Neural tubes were incised at Hamburger & Hamilton stage 17-20 at the wing bud level. The incision was of 3- or 6-somite length. The healing was active in early postoperative days. It gradually became less active until the postoperative day 10, when the curves reached plateau. The chronological changes of healing of NTD correlated well with those of PCNA positivity in normal chick embryos. Though these data are not conclusive in the causal relationship, high possibility of correlation between the two processes is suggested.

A SINGLE EXPOSURE MODEL FOR ETHANOL-INDUCED TERATOGENESIS: CONVERGENT REGULATION OF MAPK? Margaret J. Davis\* and William Shain\*<sup>3</sup> University at Albany School of Public Health and <sup>2</sup>Wadsworth Center Albany, NY 12201.

Hippocampal damage can be caused by acute and chronic ethanol exposure during development. Wistar rat pups were given a single dose of ethanol (4.7 g/kg; 20% solution in normal saline) by intraperitoneal injection at 5 days of age (human third trimester equivalent) resulting in peak blood ethanol concentrations of 350 mg/dL 30 min after injection. One control group received isocaloric maltose and were isolated at 35°C for a period equivalent to the period of intoxication in experimental animals. A second control group remained with their dam. This exposure produced mild hyperactivity in males at 25 days of age. Ethanol can alter signal transduction through protein kinases and G proteins. Western blot was used to measure G protein levels. cAMP-dependent (PKA) and protein kinase C (PKC) activities were measured using kemptide and myelin-basic protein (4-14), respectively, as substrates. Mitogen-activated protein kinase phosphorylation state was detected by gel-shift. A single dose of ethanol produced biphasic changes in PKA activity. The initial increase peaked at 2 hours. Gas levels were also increased in experimental animals 2 hours after exposure. A steady decline in PKC activity was observed 0-6 hours after exposure. MAPK (p42) phosphorylation was decreased in ethanol-exposed animals and increased in injection control animals. Western blot analysis using phosphotyrosine and phosphothreonine antibodies indicates that this decrease in phosphorylation occurs on both tyrosine and threonine residues. This decrease in phosphorylation is correlated with an increase in PKA activity ( $r = -0.75$ ,  $p < 0.025$ ). These data indicate that binge-type exposure to ethanol may inhibit growth factor signaling through convergent regulation of MAPK by PKA and PKC. (Partially supported by RR-10957, AA-05381)

## 190.7

FEW NEUROBEHAVIORAL ALTERATIONS RESULT FROM EARLY POSTNATAL LEAD (Pb) TREATMENT IN RATS. S.A. Ferguson\*, R.J. Houston, P.H. Siitonen, R.A. Gazzara, R.R. Holson. National Center for Toxicological Research, Jefferson, AR 72079.

To investigate the neurobehavioral effects of low-level Pb treatment, Sprague-Dawley rats were treated with 300 ppm Pb or sodium acetate from birth to weaning via the dams' drinking water. Food and water intake were not altered by Pb treatment. Blood lead levels sampled from female offspring at weaning (postnatal {PND} 21) averaged 62 µg/dl for the Pb group. Offspring body weight through PND 120 was not affected by Pb treatment. At PND 21, whole brain weight was decreased ~4% in female Pb offspring. At PND 119, there were no differences in whole brain weight; however, frontal cortex was ~5% heavier in the Pb female offspring. Male offspring were assessed for play (PND 38 & 45), burrowing (PND 49-53), dominance (water competition test) (PND 58 & 65), activity (running wheel and Figure 8) (PND 68-82), maze (PND 83-94), and acoustic startle behavior (PND 98). There were no Pb-related differences on any behavior. Pb treatment may alter behaviors other than those assessed here, such as complex learning or attention/vigilance. Supported by DHHS/FDA/NCTR.

## 190.4

ISCHEMIA-INDUCED OLIGODENDROGLIAL DAMAGE IN THE ONE-WEEK-OLD RAT PUP S.E. Jelinski, J.Y. Yager\*, and B.H.J. Juurlink\*. Departments of Anatomy & Cell Biology, Pediatrics<sup>2</sup> and the Saskatchewan Stroke Research Centre, University of Saskatchewan, Saskatoon, SK, CANADA, S7N 5E5.

Periventricular leukomalacia, a predominant antecedent of cerebral palsy, is the most common hypoxic-ischemic (HI) lesion of developing white matter in premature infants. A suggested pathogenesis is that the glial cells in the periventricular region are undergoing active differentiation resulting in an intrinsic vulnerability to an HI injury (Volpe, 1989). In vitro work has shown that oligodendroglial precursors cells are more readily damaged by oxidative stress brought on by hypoxia than are astrocytes (Husain and Juurlink, 1995). To examine the effects of an HI lesion on oligodendroglia in vivo, 1-week-old rat pups, developmentally equivalent to premature infants born between 34 and 36 weeks of gestation, were subjected to a 10 min bilateral carotid ligation in the presence of 8% oxygen. Over the next 24 hr, during the reperfusion period, cells in the germinal zones and corpus callosum underwent pycnosis. Immunocytochemistry demonstrated that the affected cells bound O4 and/or BRD1 antibodies, thus demonstrating the oligodendroglial nature of the cells. We suggest that cell death may have been caused by an inability to cope with oxidative stress since it was coincident with both lipid peroxidation, as demonstrated by the TBAR reaction, and induction of hsp32. We also suggest that the increased vulnerability of oligodendroglial precursors following an HI insult may contribute to the pathogenesis of periventricular leukomalacia. Supported by the Heart and Stroke Foundation of Saskatchewan.

## 190.6

INCREASE OF POLISIALOGANGLIOSIDES BY NEUROTOXIC 2,4-DICHLOROPHENOXYACETIC ACID DURING CNS DEVELOPMENT. R.O. Duffard\*, S. Rosso and A.M. Evangelista de Duffard. Lab. Toxicologia Experimental. Fac. de Cs. Bioquímicas y Farmacéuticas. Universidad Nacional de Rosario. República Argentina.

Phenoxyacetic acid, its esters and salts are herbicides widely used in Argentina and in the world. In the last years maternal exposure to environmental chemicals has increased and fetuses as well as neonates may be at greater risk than adults. There is concern that exposure to phenoxyherbicides would imply toxicological risk, since teratogenic, embryotoxic and neurotoxic effects were observed. In order to determine whether the exposure to 2,4-Dichlorophenoxyacetic acid (2,4-D), during a specific period of the development, produce alterations in DNA, Protein content and Gangliosides pattern, a neurochemical study was performed. Pups rat exposed to 2,4-D at different doses and times were used. There were neither body weight nor Protein changes at any level of 2,4-D or different period of treatment. However, a decrease brain weight and an increase of DNA brain content were observed in all the treated groups. An increase of total gangliosides and GT1b, GD1a and GD1b in 2,4-D treated pups was observed. These increases were, doses and exposure time dependent and would be an expression of neuronal plasticity after a chemical injury.

INFANTILE POSTURAL ASYMMETRY IN RATS  $\gamma$ -IRRADIATED IN UTERO. A. Gisi, M. Mintz, S. Ben-Eliyahu, & M. Myslobodsky\*. Psychobiology Res. Unit, Dept. of Psychology, Tel-Aviv Univ., Ramat Aviv, 69978 Israel

Pregnant Sprague-Dawley rats were exposed on days 15, 17, and 19 of gestation (E15, E17, and E19) to a single dose of  $\gamma$ -radiation (dose - 1.5 Gy, a dose rate of 0.15 Gy/min; 6040 Ci <sup>60</sup>Co source). The present study is based on 603 pups, 369 exposed and 234 sham-irradiated controls. At Day 2, animals were tested for head-to-tail position using a procedure modeled after Ross et al. (Proc. Natl. Acad. Sci. USA, 78:1958-1961, 1981). In a sample of control and exposed pups (n = 603), axial asymmetry was encountered in 68.5% of cases ( $\chi^2 = 82.47$ ;  $df = 1$ ;  $p < 0.001$ ). This result was contributed by E17, and to a lesser extent by E19 pups, who manifested maximal rates of axial asymmetry (79% and 72%, respectively). By contrast, among E15, asymmetry was encountered in 63% ( $\chi^2 = 7.42$ ;  $df = 2$ ;  $p = 0.02$ ). Sham-irradiated pups showed axial imbalance in 66% which was not significant from the rate of exposed pups ( $\chi^2 = 1.27$ ;  $df = 1$ ;  $p < 0.26$ ). The role of gender was explored, but found not to play a statistically significant role. Likewise, no side "preference" appeared significant in either of the exposed or sham-irradiated groups. In summary, prenatal exposure caused no sharpening of the directionality of axial asymmetry. Only when all exposed and control asymmetry data were pooled, a slight (58.1%) and significant ( $\chi^2 = 10.87$ ;  $df = 1$ ;  $p = 0.02$ ) left-side imbalance emerged. \*Supported by Theodore and Vada Stanley Foundation Research Award

## 190.9

**STRESS AND IMMUNE MEASURES IN RATS GAMMA-IRRADIATED IN UTERO.** S. Ben-Eliyahu\*, A. Gigi, M. Mintz, E. Rosenne and M. Myslobodsky. Psychobiology Res. Unit, Dept. of Psychology, Tel-Aviv Univ., Ramat Aviv, 69978 Israel.

Pregnant Sprague-Dawley rats were exposed to a single dose of gamma-radiation (1.5 Gy, a dose rate of 0.15 Gy/min; 6040 Ci 60Co source) on days 15, 17, or 19 of gestation (E15, E17, and E19), or were sham irradiated. We assessed possible effects of irradiation on baseline and stress levels of two indices measured in the offspring: a) activity of the hypothalamus pituitary adrenal (HPA) axis, and b) resistance to the development of experimentally induced MADB106 tumor metastasis. This latter measure depends on natural killer (NK) cell activity and is markedly affected by activation of the sympathetic nervous system (SNS). The results indicated no differences in corticosterone levels at baseline and following 15 or 60 minutes of restraint stress in both 30 and 60 days old offspring. On the other hand, irradiation reduced the susceptibility to tumor metastasis in E15, but increased it in E17 and E19 in rats tested at the age of 2-3 month. Following 16 min of intermittent white-noise stress (3 burst/min, 40 msec/122 dB), control and all groups of irradiated adults displayed similar levels of significant increase in tumor metastasis. Compared to adults, prepubescent offspring (30 days old) demonstrated a 10-fold increase in tumor metastasis, but displayed no effects of irradiation or noise stress. This high tumor susceptibility of prepubescent rats may be related to low levels of NK activity found in our previous studies in such rats. The lack of effects of stress and irradiation in prepubescent rats may reflect delayed impact of irradiation, immature SNS, or a ceiling effect at this high level of tumor metastasis. Supported by Theodore and Vada Stanley Foundation Research Award.

## 190.11

**Neural Progenitor Transplantation into Newborn *Reeler* Cerebellum May Rescue Certain Aspects of Mutant Cytoarchitecture.** K.I. Augustine<sup>1</sup>, K. Nakajima<sup>2</sup>, T. Miyata<sup>2,3</sup>, M. Ogawa<sup>3</sup>, K. Mikoshiba<sup>2,4</sup>, & E.Y. Snyder<sup>1\*</sup>. <sup>1</sup>Depts. Neur. & Pediatr., Children's Hosp., Harvard Med. Sch., Boston, MA 02115, USA, <sup>2</sup>Mol. Neurobiol. Lab, RIKEN, 305 Ibaraki, <sup>3</sup>Dept. Physiol., Kochi Med. Sch., Kochi 783, <sup>4</sup>Dept. Mol. Neurobiol., IMSUT, Tokyo 108, JAPAN.

*Reeler*, a recessive mutation in mice, results in tremors, impaired motor coordination and ataxia. The *reeler* mouse displays cytoarchitectonic abnormalities in the cerebral and cerebellar cortices, as well as other laminated regions of the brain. The *reelin* gene has recently been cloned and its absence has been associated with the pathology and phenotype associated with the *reeler* mutation. However, it remains unproven whether the absence of *reelin* is sufficient to account for the *reeler* phenotype. Complementation studies would help resolve this question. By supplying the developing homozygote *reeler* cerebellum with an exogenous source of *reelin*, rescue of this phenotype might be possible if its absence alone accounted for the pathology. We sought to test this hypothesis through transplantation studies. The *reelin* protein is presumably expressed by wild-type cerebellar cells, in particular the multipotent neural progenitor C17-2 cell line, initially derived from the external granular layer (EGL) of normal newborn mouse cerebellum. Following transplantation of C17-2 cells into the EGL of the developing cerebellum of newborn *reeler* mutants, granule cell migration and layering as well as granule cell survival (of both host and donor cells) appeared to improve. Purkinje cell layering also seemed to be subtly improved. (The efficiency of *reelin* expression by C17-2 cells *in vitro* and *in vivo* is presently being assessed using the recently generated CR-50 monoclonal antibody, which was generated by immunizing *reeler* mice with normal embryonic brains and is likely to recognize a *reelin* protein itself.) These suggestions of successful complementation help support the role of *reelin* in promoting normal lamination and the sufficiency of *reelin*'s absence for engendering the *reeler* histogenetic phenotype. These findings may also suggest a strategy for the treatment of CNS diseases characterized by abnormal cellular migration, lamination and cytoarchitectural arrangement.

**DEVELOPMENTAL DYSLEXIA AND INCREASED CELL PACKING DENSITY IN LEFT TEMPORAL CORTEX: A CASE STUDY.** D.L. Kigar<sup>1</sup>, S.F. Witelson<sup>1</sup> and J.J. Glezar<sup>2</sup>. <sup>1</sup>Dept. of Psychiatry, McMaster Univ., Hamilton, ON, L8N 3Z5; <sup>2</sup>Dept. Cell Biol. Anat. Sci., CUNY Med. School, N.Y.C.

The brain specimen of a 62-year-old man with documented difficulty in learning to read and write from Grade 1 on was studied. In spite of years of remedial education, good intelligence and financial success, he never learned to read or write. He was consistently right-handed (CRH). Death was due to non-neurological cancer. Brain weight and overall morphology were well within normal limits. Study was focused on gross and microscopic aspects of the planum temporale (PT) in the posterior region of the superior temporal gyrus which, on the left side, is part of the posterior language region. Left and right PT areas were within normal limits for both horizontal and vertical components of PT compared to a control group of 13 CRH males (Witelson & Kigar, *Soc NSC Abstr*, 1991). Hand preference was controlled for because Sylvian fissure and consequently PT anatomy are different in CRH vs nonCRH men. The pattern and degree of asymmetry were also typical ( $L > R$ ). These results are similar to an MRI study of PT length in dyslexics (Leonard *et al.*, *Arch Neurol*, 1993), but different from a postmortem study of optically reconstructed PT areas (Galaburda *et al.*, *Ann Neurol*, 1985). Microscopic assessment revealed no evidence of ectopic cells or cytoarchitectonic dysplasia (cf Galaburda *et al.*). Numerical density of neurons ( $N_v$ ) was obtained for von Economo's cytoarchitectonic area T<sub>A1</sub> and compared to our sample of 4 CRH men with no reading difficulty (Witelson, Glezar & Kigar, *J NSC*, 1995). Mean cortical depth in each hemisphere was similar to that of the control group.  $N_v$  for the left hemisphere of the dyslexic case was more than 5 S.D. ( $p < .05$ ) greater than the controls (57,909 vs 42,299, respectively).  $N_v$  values for the right hemisphere were comparable to the control group. Since PT morphology and neuron number are established early in life, these results support a neurobiological factor in the etiology of developmental dyslexia. Supported in part by grants NS18954 and MRC (CA) MA-10610.

## 190.10

**CORRECTION OF NEUROCHEMICAL ABNORMALITIES IN THE ORNITHINE TRANSCARBAMYLASE (OTC) DEFICIENT SPARSE FUR (Spf/y) MOUSE GENE THERAPY.** C.S. Pabin, X. Ye, M.L. Batshaw\*, J.M. Wilson, and M.B. Robinson. Children's Seashore House, Depts. of Ped., Pharm., and Mol. and Cell Eng., Univ. of Penn., Philadelphia, PA 19104.

OTC deficiency is an X-linked disorder of urea synthesis which is associated with elevations in plasma ammonium ( $\text{NH}_4^+$ ) and resultant mental retardation. The neurodevelopmental disabilities are associated with increases in brain glutamine (Gln) and tryptophan (Trp). We have recently shown *in vivo* correction of the peripheral biochemical abnormalities in OTC deficient *spf/y* mice using gene transfer with an adenoviral vector containing the OTC cDNA and deleted in E1 with a ts125 mutation in E2a. To determine if this approach also corrects the neurochemical abnormalities, animals were injected by tail vein with the adenoviral vector ( $1 \times 10^{11}$  particles) and 14 days later brain tissue was harvested for analysis. Cortical Gln levels in untreated *Spf/y* mice were  $9.4 \pm 3.6$  compared to  $4.8 \pm 1.2$  (nmole/mg tissue) in control C3H mice. Gene transfer resulted in complete correction of this abnormality in the *Spf/y* mice ( $4.8 \pm 0.8$ ). Cortical Trp levels were partially corrected in OTC-treated mice ( $31.8 \pm 6.3$  pmoles/mg tissue) compared to C3H and *Spf/y* controls ( $21.8 \pm 6.5$  and  $43.2 \pm 8.3$  pmoles/mg tissue, respectively). These data suggest that gene therapy may have the potential to correct neurochemical as well as metabolic abnormalities. (HD32649)

## 190.12

**PURSUIT INITIATION IN DYSLEXIC CHILDREN** W.W. Ting\* & S.J. Heinen<sup>2</sup>. Northwestern University Medical School, Chicago, IL<sup>1</sup> and the Smith-Kettlewell Eye Research Institute, San Francisco, CA<sup>2</sup>.

Previous results concerning smooth pursuit eye movements of dyslexics have been mixed. We set out to determine if predictive smooth pursuit could provide a more sensitive indicator of dyslexia in children. Eye movements of two dyslexic and two normal children were measured using a dual-Purkinje-image eyetracker. The head was stabilized with a chin-rest and a head-rest. Ss first fixated, and then tracked a small bright spot that moved either left or right at 20°/s. The fixation period was either always 1000 ms (predictable), or random at 500 or 1000 ms (unpredictable). Saccades were removed from the velocity records using an acceleration criterion, and analyzed separately. Consistent with other studies, dyslexics exhibited more saccades during smooth pursuit in all conditions than did controls. However, dyslexics were more prone to make either smooth or saccadic eye movements *opposite* the direction of target motion at pursuit initiation. We defined reverse tracking intrusion (RTI) as a smooth or saccadic movement opposite target motion that occurred within  $\pm 50$  ms of when the eye started to follow the spot. RTI was evident in 33.3% and 35.3% of trials for each of the dyslexic children, compared to 7.5% and 9.5% for normals. In the 500/1000 ms condition, normal Ss (and adult normals also) were "primed" by the 500 ms condition, i.e., they show as good as or better anticipation for 1000 ms as in totally predictable trials. However, the dyslexics did not show this trend. Finally, early initial eye acceleration when target motion was totally predictable (10-50 ms after pursuit onset) was greater than later eye acceleration (70-110 ms after pursuit onset) in dyslexics but not in controls. The results suggest that dyslexic children are more uncertain about initiating smooth pursuit, and cannot rely as easily on internal signals that specify when predictable object motion will occur, rather they depend more on the visible motion of the target to accelerate the eyes.

**TACTILE PERCEPTION IN DEVELOPMENTAL DYSLEXIA** A. C. Grant\*, A. Zangaladze & K. Sathian

Dept. of Neurology, Emory Univ. Sch. Med., Atlanta, GA 30322.

Abnormal processing of visual and auditory stimuli has been reported in developmental dyslexia (e.g. *Ann. N.Y. Acad. Sci.*, vol. 682, 1993). It has also been suggested that similar abnormalities involve many other aspects of neural function, including the tactile system. We therefore investigated, psychophysically, tactile perception at the index fingerpad in individuals with developmental dyslexia. We used gratings of alternating ridges and grooves, which have proven useful in psychophysical and neurophysiological characterization of the tactile system (Sathian, *TINS*, 12:513-519, 1989).

We assessed discrimination thresholds, corresponding to 75% correct performance, in two-alternative, forced-choice paradigms. In one task, spatial acuity was measured as the groove width required to discriminate the orientation of gratings impressed statically into the immobilized fingerpad. Many but not all dyslexic subjects performed poorly on this task, compared to normals. Another task assessed subjects' ability to discriminate gratings differing in ridge width, that were scanned actively. Thresholds of dyslexic subjects were in the upper part of the normal range on this task. Thus, abnormal sensory processing in dyslexia may not be exclusively in the temporal domain. Supported in part by a grant from the Orton Dyslexia Society.

## 190.15

NEURONAL SIZE IS ALTERED IN THE VENTROBASAL COMPLEX OF NEWBORN MICE WITH CORTICAL ECTOPIAS. **A.R. Jenner\*, A.M. Galaburda, and G.F. Sherman.** Dyslexia Research Laboratory, Beth Israel Hospital; Harvard Medical School, Boston, MA 02215

Smaller cells in the LGN and MGN may play a role in the perceptual deficits seen in dyslexia. These thalamic changes may originate from neocortical layer I ectopias (Livingstone et al., *PNAS*, 88:7943, 1991; Galaburda et al., *PNAS*, 91:8010, 1994). Animal models have been used to test this correlation between thalamic changes and ectopias. For example, adult male New Zealand Black mice (NZB/BINJ) with barrel field ectopias have fewer small neurons and more large neurons in the ventrobasal complex (VB) than male mice without ectopias (Sherman et al., *Soc. Neurosci. Abstr.*, 21:1712, 1995). The present study examined neuronal size in VB of newborn NZB mice with and without ectopias to determine when thalamic changes are visible.

After immersion fixation in 4% paraformaldehyde and cryo-protection with sucrose, the brains of newborn (P0) NZB mice were cut coronally on a sliding freezing microtome at 30µm, mounted, dehydrated, and stained with thionin. Two sections (150µm apart) containing both VPM and VPL nuclei were selected from 14 ectopic and 16 non-ectopic mice. Cross sectional neuronal areas were measured in two fields of each nuclei in each hemisphere using a stereology-derived system (Williams and Rakic, *J. Comp. Neurol.*, 278:334, 1988). The cells were grouped into 10 consecutive bins increasing by approximately 7µm<sup>2</sup>. As in the adult, the cell size distributions at P0 differed between mice with and without ectopias. However, at P0 ectopic male mice had fewer large neurons and more small neurons in both VPM ( $\chi^2=122.78$ , df=9, p<0.001) and VPL ( $\chi^2=112.22$ , df=9, p<0.001). This difference was the most pronounced in the VPM nuclei ipsilateral to the ectopia ( $\chi^2=20.02$ , df=9, p<0.05). Unlike VPL this nucleus directly connects with the barrel field (Jenner et al., *Soc. Neurosci. Abstr.*, 21:1712, 1995). These findings show that the prenatal onset of ectopias in somatosensory cortex affects the organization of related thalamic nuclei early in development and further more indicates that this effect changes during development. (Supported by NICHD grant HD20806)

## 190.17

EFFERENT AND AFFERENT CONNECTIVITY OF INDUCED NEOCORTICAL MICROGYRIA. **G.D. Rosen\* and A.M. Galaburda.** Beth Israel Hospital and Harvard Medical School, Boston, MA 02215.

Cerebrocortical microgyria in humans is the result of injury during late neocortical neuronal migration, and microgyria can be induced in otherwise normal rodent neocortex by focal damage to the developing cortical plate (Humphreys et al., *J. Neuropath. Exp. Neurol.* 50:145, 1991). Disorders of late neuronal migration are seen in developmental dyslexia (Galaburda et al., *Ann Neurol* 18:222, 1985), and similar induced and spontaneous malformations in rats and mice are associated with a variety of behavioral alterations (e.g., Schrott et al., *Physiol Behav* 52:1085, 1992; Fitch et al., *Cereb Cortex* 4:260, 1994). It was hypothesized that these small focal malformations may cause connectional reorganization which might explain the widespread behavioral disturbances associated with them.

We induced microgyria in the somatosensory cortex (Par1) of the right hemisphere by placing a freezing probe on the skulls of rats on the first day of life for 10 s. For each lesioned animal, sham surgery was performed on another animal. In adulthood, some rats received biotinylated dextran amine (BDA) injections into the microgyria, while others were injected in the homologous region of the left hemisphere. Their matched shams received identically placed injections. The brains were subsequently processed for BDA visualization and the retrograde and anterograde labeling noted.

In comparison to controls, there was a decrease in efferent projections from the microgyric cortex to the left hemisphere. Par1 microgyria had abnormal efferent connections to secondary somatosensory cortex (Par2) of the left hemisphere. Although cortico-thalamic projections appeared normal, thalamo-cortical projections were markedly decreased. Injection of BDA into the homologous area of the left hemisphere highlighted aberrant projections into frontal and Par2 cortex of the affected hemisphere. The results support the hypothesis that early focal injury to the neocortex results in restructuring of connectivity. (Supported, in part, by HD20806).

## 190.19

RADIAL-ARM MAZE LEARNING IN BXSB MICE: EFFECTS OF NEOCORTICAL ECTOPIAS. **L.A. Hyde\*, G.F. Sherman and V.H. Denenberg.** Biobehavioral Sciences Graduate Degree Program, University of Connecticut, Storrs, CT 06269; Beth Israel Hospital and Harvard Medical School, Boston, MA 02215.

Learning behavior in the autoimmune BXSB mouse has been extensively studied in our laboratory. A major reason is that approximately 40-60% of these mice have neocortical ectopias, which are clusters of neurons abnormally located in layer I of cortex. Ectopias are formed prenatally, as early as E15, and are usually located in the prefrontal/motor region in the BXSB strain. This area of cortex has been shown to be important for working memory. One of our recent findings is that ectopic BXSB mice appear to be deficient in spatial working memory. However, we did not test the mice in a radial-arm maze, which is generally accepted as one of the better measures of working memory. We have recently developed a water version of the radial-arm maze and have tested a group of BXSB mice in the maze.

Mice were given one session per day for 11 days following 1 day of training. Ectopic mice exhibited more working memory errors in sessions 7-11 than non-ectopics, with the working memory errors of the non-ectopics dropping to low levels, while ectopics continued to make working memory errors through the end of testing. The two groups did not differ on the number of reference memory errors. These findings lend further support to our hypothesis that ectopic BXSB mice are impaired in working memory tasks. Supported in part by NIH grant H-20806.

## 190.16

CEREBROCORTICAL MICRODYSGENESIS IS ENHANCED IN C57BL/6J MICE EXPOSED IN UTERO TO ACETAZOLAMIDE. **G.F. Sherman\* and L.B. Holmes.** Dyslexia Research Laboratory, Beth Israel Hospital; Genetics and Teratology Unit, Massachusetts General Hospital; and Departments of Neurology and Pediatrics, Harvard Medical School, Boston, MA 02215.

C57BL/6J mice spontaneously develop collections of neurons in neocortical layer I (Sherman et al., *Acta Neuropathol.* 74:239-242, 1987) similar to the "ectopias" seen in 40-50% of NZB and BXSB autoimmune mice (Sherman et al., *Brain Res.* 532:25-33, 1990). In the autoimmune strains, ectopias are present before birth, probably occur because of a breach in the pial-glial membrane during neuronal migration, and is a recessively inherited trait (Sherman et al., *NeuroReport*, 5:721-724, 1994). The present study was designed to determine whether environmental factors can alter the expression of the ectopia trait. Because carbonic anhydrase may play a role in glial development, we prenatally exposed C57BL/6J mice to acetazolamide, a carbonic anhydrase-specific inhibitor and teratogen, to determine whether the prevalence or severity of ectopias is affected.

C57BL/6J time-mated mice were injected i.p. on embryonic day 9 (plug date=E0) with sodium acetazolamide (750 mg/kg maternal weight) and control mice were injected with water (0.2 ml). On day 30 the mice were transcardially perfused with 0.9% saline followed by 10% formalin. The brains of 105 acetazolamide-exposed and 89 control mice were embedded in celloidin, cut in 30µm coronal sections, and stained with cresyl violet. The presence and size (based on an estimate of the number of neurons in layer I) of ectopias were noted under a light microscope.

There was no difference in the overall prevalence of cerebrocortical ectopias between the acetazolamide and control groups: 34% of the acetazolamide and 28% of the control mice had ectopias. Most were present in the prefrontal, motor, or somatosensory areas. There was a striking difference between the control and acetazolamide group in ectopia shape and size: 69% of the ectopias were large in the acetazolamide group, whereas only 32% of the ectopias in controls were ( $\chi^2=6.89$ , df=1, p<0.01). Although most affected brains contained one ectopia, the acetazolamide group had more brains with multiple ectopias (36% vs 8%;  $\chi^2=4.86$ , df=1, p<0.05). Thus, there may be a genetic predisposition for developing ectopias in this strain, however, epigenetic factors such as prenatal acetazolamide-exposure, can affect the severity of the malformations. Supported by NIH grant HD 20806.

## 190.18

VISUALIZATION OF SMALL FOCAL DISORDERS OF LATE NEURONAL MIGRATION IN THE CEREBRAL CORTEX OF THE RAT BY MAGNETIC RESONANCE IMAGING (MRI). **A.M. Galaburda\*, D. Burstein, and G.D. Rosen.** Departments of Neurology and Radiology, Beth Israel Hospital and Harvard Medical School, Boston, MA 02215.

Disorders of late neuronal migration are associated with a wide variety of neurologic disorders. Magnetic resonance imaging (MRI) has proven useful in the visualization of some of the more severe anatomic disturbances (e.g., Kuzniecky, *Epilepsia* 35:S44, 1994), but has yet to be successfully used to visualize the more restricted anomalies, such as focal microgyria and molecular layer ectopias, that are seen in conjunction with certain types of epilepsy and developmental dyslexia. By exploiting an animal model for these neocortical malformations, the current experiment sought to determine if these lesions could be visualized with MRI.

We induced focal malformations unilaterally by placing a freezing probe on the skulls of rats on the first day of life (P1) for 5-10 seconds. In adulthood, these rats were anesthetized and placed in a 4.7 T 30 cm bore small animal MRI. A sagittal scout image was obtained in 30 seconds, from which a multislice coronal data set was set up with an in-plane resolution of 250 µm and a section thickness of 500 µm. After completion of the MRI studies, the location and extent of damage was assessed histologically.

Using a T2 weighted imaging sequence, we were able to detect a lesion in each animal imaged, ranging from a large porencephalic cyst to a relatively small region of microgyric cortex. The speed of image acquisition (<30 minutes) and the tight correlation with subsequent histology supports the use of MRI techniques for the visualization of minor focal neocortical malformations *in vivo*, permitting for the first time longitudinal assessment following interventions. Ongoing research is aimed at imaging smaller developmental neocortical malformation and extending these techniques to humans. (Supported, in part, by HD20806).

## 191.1

RESPONSES TO AMYLOID BETA PEPTIDES IN XENOPUS OOCYTES INJECTED WITH BRAIN RNA. R. Blitzer, T. Wong, M. Pangalos, N.K. Robakis, A.J. Serby, and E.M. Landau\*. Dept. of Psychiatry, Mt. Sinai School of Medicine and Bronx VAMC, New York NY 10029

To determine whether receptors for amyloid beta peptides ( $A\beta$ 's) might be present in brain, *Xenopus* oocytes were used to express whole-brain RNA derived from adult rats. Two membrane responses were studied, both of which are produced by receptors coupled to the phosphatidylinositol (PI) pathway and reflect intracellular  $Ca^{2+}$  release: (1) at  $V_H = -70$  mV, an inward, fluctuating  $Cl^-$  current, and (2) the enhancement of  $T_{out-2}$ , an outward  $Cl^-$  current evoked by a voltage step from -100 to 0 mV. Responses were observed using  $A\beta(1-40)$  and  $A\beta(1-42)$  in RNA-injected oocytes, but not in uninjected cells or RNA-injected cells exposed to either  $A\beta(25-35)$  or the reverse peptide  $A\beta(40-1)$ . The enhancement of  $T_{out-2}$  was the more sensitive response, with a  $K_D$  for  $A\beta(1-40)$  of 26 nM. Freshly-dissolved peptide was fully effective, indicating that expressed membrane receptors may recognize monomeric  $A\beta$  peptides. Both responses were intact in the presence of spantide and were therefore not mediated by substance P receptors, in contrast to earlier findings (*PNAS* 90, 7508-12, 1993).

These results suggest that specific  $A\beta$  receptors may be present in brain. The activation of the PI pathway by such receptors may play a role in neurotoxic and neuroprotective effects of  $A\beta$ 's via the  $IP_3$  and PKC pathways, respectively.

## 191.3

APPICAN, THE PROTEOGLYCAN FORM OF AMYLOID PRECURSOR PROTEIN, PROMOTES NEURAL CELL ADHESION TO THE EXTRACELLULAR MATRIX. A.Wu\*, M.N.Pangalos, S.Efthimiopoulos, J.Shioi, and N.K.Robakis. Department of Psychiatry and Fishberg Research Center for Neurobiology, Mount Sinai School of Medicine, New York, NY 10029-6574.

Appicans are secreted and cell-associated brain chondroitin sulfate proteoglycans produced by glia cells and containing Alzheimer's amyloid precursor (APP) as their core proteins. Rat C6 glioma cells transfected with appican displayed a dramatic change in their phenotypic appearance compared to control cells (non-transfected C6 cells or C6 cells transfected with APP). Appican-transfected cells lost the round shape of the control C6 cells, acquired a flat appearance, and elaborated more processes than control cells. Control cells were completely dissociated after 40 min of treatment with a cell-dissociation solution, while only 20% of the appican-transfected cells were detached. Extracellular matrix (ECM) prepared from appican-transfected cells contained high level of appican and was a significantly better substrate for the attachment of C6 cells than ECM prepared from control cells. Furthermore, cell adhesion to ECM was independent of the level of appican expression of the plated C6 cells. ECM prepared from appican-transfected C6 cultures stimulated adhesion of other neural cells including rat primary astrocytes, mouse N2a neuroblastoma and rat PC12 pheochromocytoma, but not fibroblast cells. Conditioned medium from appican-transfected C6 cells failed to promote cell adhesion. These results suggest that secreted appican incorporates into ECM and promotes adhesion of neural cells.

Supported by NIH grants AG08200 and AG05138.

## 191.5

INHIBITION OF NEURONAL CELL ADHESION TO FIBRONECTIN: A RAPID INDICATOR OF NEURONAL CELL INTERACTION WITH AMYLOID  $\beta$ -PEPTIDE. A.K. Barlow, W.S. Wade, H. Yu, G.A. Krafft\*, & W.L. Klein. Neurobiology & Physiology, Northwestern Univ., Evanston, IL 60208

Accumulating evidence implicates amyloid  $\beta$ -peptide ( $A\beta$ ) as an important neurotoxic factor in the development and progression of Alzheimer's disease (AD). Association of toxic forms of  $A\beta$  with the neuronal cell surface is likely to be involved in the initial stages of neurotoxicity and as such provides an early opportunity for therapeutic intervention. We have therefore focused on cell-surface interactions with  $A\beta$ . Several studies have shown that aggregated  $A\beta$  prevents cell adhesion and neurite extension;  $A\beta$  contains putative integrin recognition site and HSPG binding domain which may interact with cellular adhesion receptors. We have developed a quantitative cell adhesion assay to determine the effect of aged  $A\beta(1-42)$  on human SH-SY5Y and rat B103 cell adhesion to fibronectin (Fn). Both cell lines show reduced adhesion to Fn in the presence of  $A\beta(1-42)$ . The effect is dose-dependent and rapid; anti-adhesive effects are quantifiable within 2 h, establishing this as a rapid *in vitro* neuronal response to  $A\beta$ , well upstream of neurotoxicity. No anti-adhesive effect was observed when non-amyloid peptides or non-aggregating  $A\beta(1-42)$  variants were used. The anti-adhesive effect of  $A\beta(1-42)$  in both cell types was markedly reduced when polylysine was used as substrate, indicating specificity of the effect of  $A\beta(1-42)$ . Removal of putative HSPG and integrin binding sites from the  $A\beta(1-42)$  sequence did not prevent anti-adhesive effects, indicating that aged  $A\beta(1-42)$  does not impact directly on these cell surface receptors. We examined several compounds for their ability to protect against the anti-adhesive phenomenon: G-protein agonists Mas-7 and compound 48/80 increased SH-SY5Y cell adhesion in the absence of  $A\beta(1-42)$  and protected against  $A\beta(1-42)$  effects. Similar effects were obtained using pertussis toxin and cAMP or Forskolin. Compounds which impact cellular signaling molecules therefore can prevent the anti-adhesive effects of  $A\beta(1-42)$ , suggesting that disadhesion may result in part from  $A\beta(1-42)$  induced signaling. We have demonstrated that  $A\beta(1-42)$  is capable of inducing Fak tyrosine phosphorylation and paxillin translocation in B103 cells (Zhang 1994, 1996, Berg 1996). Anti-adhesion may be a rapid indicator of  $A\beta$ -induced signaling and as such allow for screening of compounds able to prevent  $A\beta$ -mediated impact on neuronal cells.

## 191.2

SOLUBLE  $A\beta$  FORMS STABLE DIMERS AT LOW CONCENTRATIONS. W. Garzon, M. Sepulveda, S. Milton, and C. G. Glabe, <sup>3\*</sup> Univ. Nacional Autonoma de Mexico, Facultad de Quimica, <sup>2</sup>Centro de Invest. Biomedica del Sur Xochitepec Mor IMSS, <sup>3</sup>Dept. of Mol. Biol and Biochem. Univ. of Calif. Irvine CA 92717.

Previously published data indicates that the smallest  $A\beta$ 1-40 species in aqueous solution elutes from a Superdex HR75 column with an apparent MW of a dimer. This data alone does not permit identification of this peak as a dimer because of uncertainties about the shape of  $A\beta$  in solution that can influence its elution behavior. We have utilized Fluorescence Resonance Energy Transfer (FRET) to study  $A\beta$  dimer formation in solution. We synthesized a series of fluorescent variants of  $A\beta$  to be used as a donors and acceptors in FRET experiments. We compared the aggregation of the fluorescent derivatives to wild type  $A\beta$  at pH 7.4, where  $A\beta$  is largely soluble and at pH 5.0 and pH 7.4 in the presence of 10 mM  $Zn^{2+}$ , where  $A\beta$  is largely aggregated. We chose fluorescent peptides that displayed the same aggregation behavior as wild type  $A\beta$ . Using several different donor-acceptor pairs, we confirmed that  $A\beta$  is well solvated and largely monomeric in DMSO. When donor and acceptor  $A\beta$  derivatives are mixed together in DMSO and then diluted into aqueous Tris buffer at pH 7.4 (10  $\mu$ M total  $A\beta$ ), efficient FRET is observed immediately, indicating that a donor-acceptor dimer exists in solution. The observed efficiency of the energy transfer varied from 0.17 to 0.1 depending on the nature and location of the dyes. Gel filtration confirms that the fluorescent peptide mixture elutes at the same dimeric position as wild type  $A\beta$ . Sub- $\mu$ M concentrations of  $^{14}C$ -labeled  $A\beta$ 1-40 also elute as a dimer. When homodimers of both donor and acceptor species are mixed at pH 7.4, no FRET is observed initially and after 24 hr incubation, indicating that the dimers are relatively stable once formed. Supported by NIH NS-31230.

## 191.4

FACSCAN ASSAY FOR  $A\beta$  RECEPTORS: SATURABLE BINDING TO CELL SURFACE PROTEINS. S. Bodovitz\*, M.P. Lambert, A.K. Barlow, J. Lin, G.A. Krafft, and W.L. Klein. Neurobiology & Physiology, Northwestern Univ., Evanston, IL 60208

$A\beta$  is a 39-43 amino acid peptide that accumulates as extracellular aggregates in Alzheimer's disease-afflicted brain tissue. Contact between synthetic aggregates and neurons is cytotoxic, although little is known about the nature of this interaction. We have investigated the binding of synthetic aggregates to the surface of intact CNS neuroblastoma cells using whole mount electron microscopy and flow cytometry. Electron microscopy revealed that aggregates bound to neurites and growth cones and were occasionally associated with actin stress fibers and/or local dystrophy. Binding to cells appeared to be predominately via cell surface fibrils and, even at high doses of aggregates, the cell surface was largely uncovered. Flow cytometry verified that binding to intact cells was saturable. Half maximal binding occurred at approximately 1-2  $\mu$ M and plateaued at approximately 5  $\mu$ M. Binding could be selectively inhibited by glycosaminoglycans, including heparan, heparin sulfate, and chondroitin sulfate, but not by general soluble proteins such as bovine serum albumin or fetal calf serum. Gentle trypsinization completely blocked binding. This demonstrates that binding is exclusively to cell surface proteins and, because trypsinization is a selective proteolysis, that aggregates bind to a subset of cell surface proteins. Following trypsinization of the cells, binding began to recover in 30 minutes and was completely recovered after 90 minutes. The recovery was not blocked by the protein synthesis inhibitor cycloheximide, indicating a reserve of binding proteins. Pre-treatment with cycloheximide, however, in order to measure turnover of binding proteins, resulted in a 40% decrease in binding after 24 hours. The long half-life plus rapid recovery suggested that there was a large pool of binding proteins. Nonetheless, binding could be blocked with relatively low doses of either secreted proteins or cell surface polypeptides released by trypsinization. Isolation and identification of these potent inhibitors is currently under investigation.

Supported by grants to W.L.K from N.I.H. and the Alzheimer's Association.

## 191.6

RAPID IMPACT OF THE ALZHEIMER'S  $A\beta$  PEPTIDE ON FOCAL ADHESION SIGNALING PROTEINS. M.M. Berg and W.L. Klein\*. Dept. Neurobiology and Physiology, Northwestern Univ., Evanston, IL 60208.

This laboratory has previously established that treatment of nerve cell lines with aggregates of the Alzheimer's  $A\beta$  peptide induces rapid membrane blebbing and disadhesion, followed by tyrosine phosphorylation of focal adhesion kinase (FAK), and cell death. Here we have further investigated the molecular mechanism(s) by which  $A\beta$  may exert its effects on cell adhesion, morphology and viability. In immunoblot experiments, aggregates of  $A\beta$  were found to induce the association of FAK, as well as the focal adhesion protein paxillin with the triton-insoluble cytoskeleton of B103 cells. Paxillin exhibited a 10-fold increase in cytoskeletal association after treatment with  $A\beta$ , while FAK association with the cytoskeletal fraction increased 2-10 fold. The paxillin and FAK responses were relatively rapid, nearly maximal at 1 hour. The response was also specific, as the focal adhesion protein vinculin showed no increase in cytoskeletal association after treatment with  $A\beta$ . In subsequent experiments, it was determined that only cytoskeletal-associated paxillin was phosphorylated on tyrosine. The rapid and specific effects of  $A\beta$  on focal adhesion signaling proteins illustrates a novel mechanism by which  $A\beta$  may impact processes linked to neuronal cytoskeletal architecture, synaptic plasticity, gene expression and cell viability.

Supported by grants from the NIH (to MMB and WLK), and the Alzheimer's Association and Boothroyd Foundation (to WLK)

## 191.7

MUSCARINIC M3 RECEPTOR-MEDIATED AMYLOID PRECURSOR PROTEIN (APP) PROCESSING IS CORRELATED WITH TYROSINE PHOSPHORYLATION OF PAXILLIN B.E. Slack\*, Dept. of Pathology and Laboratory Medicine, Boston Univ. School of Medicine, Boston MA 02118.

Secretory processing of APP was examined in human embryonic kidney (HEK) cells expressing m3 muscarinic receptors. Activation of these receptors by the muscarinic agonist carbachol stimulates release of soluble APP derivatives (APPs) into the medium (Nitsch et al., Science 258:304, 1992) via a mechanism that exhibits both protein kinase C- and tyrosine phosphorylation-dependent components (Slack et al., JBC 270:8337, 1995). In addition to stimulating APPs release, carbachol increased tyrosine phosphorylation of several proteins in HEK m3 cells. Two of these were identified as paxillin and focal adhesion kinase (FAK). Both proteins are components of focal adhesions (complexes of cytoskeletal-associated proteins that form at sites of attachment of cells to extracellular matrix) and both are known to exhibit increased tyrosine phosphorylation concomitant with focal adhesion formation. Tyrosine phosphorylation of paxillin reached maximal levels 5 to 10 minutes after exposure to carbachol, and remained elevated for at least 15 minutes. The increase in APPs release induced by carbachol was previously shown to exhibit a somewhat slower time-course, reaching a maximum within 30 minutes. Tyrosine kinase inhibitors caused concomitant reductions in APPs release and tyrosine phosphorylation of paxillin. In view of prior evidence that APPs release from adherent cells is greater than that from poorly-adherent cells (Mönnig et al., JBC 270:7104, 1995), a possible causal relationship between the formation of focal adhesions during cell attachment, and increased secretory processing of APP is proposed. (Supported by NIH grant NS-30791)

## 191.9

**ACTIVATION OF BOTH COMPLEMENT PATHWAYS BY THE ALZHEIMER'S DISEASE A $\beta$  PEPTIDE GENERATES ESTER-LINKED A $\beta$ -C3 COMPLEXES.** B.M. Bradt\*, T.S. Bixby, and N.B. Cooper. Department of Immunology, The Scripps Research Institute, La Jolla, CA 92037

Among the proteins associated with the A $\beta$  peptide in neuritic plaques (NP), there are markers of inflammation including many complement components and regulatory proteins. The complement system, consisting of more than 30 proteins, has the well recognized ability to damage cells and alter cellular functions. We earlier showed classical complement pathway (CCP) activation by the A $\beta$  peptide which is consistent with the presence of C1q, C2 and C4 which have been immunohistochemically localized to the area of NP in AD patients. Hitherto, alternative complement pathway (ACP) activation has been presumed not to be relevant to AD since ACP components (Factor B, properdin) have been immunohistochemically undetectable. Novel capture ELISAs demonstrate that aggregated A $\beta$  directly and independently activates both the CCP and the ACP, in the absence of antibody, leading to the formation of A $\beta$ -C3 complexes, a finding confirmed with purified complement component mixtures. The sensitivity of these ELISA assays for detection of complement activation by A $\beta$  is considerably greater than other assays and detects complement activation by nanomolar concentrations of A $\beta$ . Such activation generates covalent A $\beta$ -C3 complexes which are capable of being dissociated with alkaline hydroxylamine, and thus are ester-linked. The covalent A $\beta$ -C3dg complexes co-migrate on reduced SDS PAGE. Such complexes in NP could mediate chronic complement activation with associated tissue injury. Supported by NIH grant.

## 191.11

**ACTIVATION OF THE CLASSICAL COMPLEMENT CASCADE BY THE AMYLOID  $\beta$  PEPTIDE (A $\beta$ ) IS A FUNCTION OF THE AGGREGATION STATE OF A $\beta$ .** S. Webster\*, J. Rogers\*, B. Bradt\*, Todd Bixby\* & N. Cooper\*. <sup>1</sup>L.J. Roberts Alzheimer's Center, Sun Health Research Institute, Sun City, AZ 85372. <sup>2</sup>Department of Immunology, The Scripps Research Institute, La Jolla, CA 92037.

There have been a number of hypotheses put forth in recent years to explain the neuronal loss and neuritic dystrophy characteristic of Alzheimer's disease (AD) pathogenesis. Many of these have focused on A $\beta$ -mediated neurotoxicity, and although no single hypothesis has gained universal acceptance, recent evidence suggests that correlates of A $\beta$  aggregation are crucial to AD pathogenesis. Activation of the classical complement pathway has been widely investigated as a mechanism of neurodegeneration in AD. Previous studies have shown that in the diffuse plaques of the cerebellum complement activation does not go to completion, in contrast to aggregated neuritic plaques where full activation of the classical complement pathway occurs. In this report we demonstrate that although both forms of A $\beta$  bind complement subcomponent C1q equivalently, fibrillar A $\beta$  is a more potent activator of complement than is nonfibrillar A $\beta$ . This suggests that it is the regular spacing of A $\beta$  moieties in fibrillar A $\beta$  that leads to activation of complement component C1, as has been demonstrated for other nonimmune activators of complement. In contrast, nonfibrillar or amorphous A $\beta$  is not characterized by regular, repeating structure and is therefore expected to exhibit random arrangements of A $\beta$  moieties. This allows amorphous A $\beta$  to bind C1q in a fashion that does not lead to significant activation of C1. These results suggest that the classical complement cascade is a mechanism whereby neuronal degeneration occurs in the proximity of fibrillar but not diffuse A $\beta$  deposits in the AD brain. Supported by AGO-7387 (J.R.).

## 191.8

**NEURONAL LOCALIZATION OF COMPONENTS OF CLASSICAL COMPLEMENT CASCADE IN ALZHEIMER'S DISEASE BRAIN.** G. Bao<sup>1</sup>, R. Li<sup>1</sup>, P. McGeer<sup>2</sup>, and Y. Shen<sup>1</sup> <sup>1</sup>Departments of Psychiatry & Medicine, University of Louisville School of Medicine, Louisville, Kentucky 40292, USA. <sup>2</sup>Kinsmen Lab of Neurological Research, University of British Columbia, Vancouver, BC V6T 1W5, Canada.

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by neuronal loss and the presence of extracellular senile plaques and intracellular neurofibrillary tangles. Studies have shown that classical complement proteins and membrane attack complex (MAC) can be identified within senile plaques and dystrophic neurites of AD brain, suggesting complement-mediated cell lysis may be present in AD. We have recently reported that *in vitro*, neuronal cells can make all of the major complement components. Under deficiency of endogenous complement regulators (CD59), neuronal cells can assemble the components to form MAC. To examine if neurons in human brain express complement components *in vivo*, we used *in situ* hybridization histochemistry technique to localize the distribution of classical complement component mRNAs (C1q, C2, C3, C4, C5, C6, C7, C8 and C9) in AD brains. While these components were expressed in hippocampus, frontal cortex and temporal cortex, the expression of components in cerebellum was low. Furthermore, in AD brains, messages for these complement components were detectable in neuronal populations. Expression of C1q, C3, C6, C7, C8 and C9 has been found in higher percentage of neuronal population in hippocampus and frontal cortex compared to expression of C2, C4, and C5 in these areas. These results further support that neurons can synthesize all the complement components, indicating that the source of complement activation in AD may be, in part, derived from neuronal cells in the brain.

## 191.10

**THE ALZHEIMER'S DISEASE A $\beta$  PEPTIDE GENERATES C5a AND THE MEMBRANE ATTACK COMPLEX VIA ACTIVATION OF EITHER COMPLEMENT PATHWAY** N.B. Cooper\* and B.M. Bradt The Scripps Research Institute, Dept. of Immunology, La Jolla, CA 92037

Neuritic plaques (NP), a hallmark of the Alzheimer's Disease (AD) brain, have been shown to co-localize with various inflammatory markers, including complement components. Also closely associated with NP are abnormal neuronal processes and increased numbers of reactive astrocytes and microglia. Clearly, complement activation in the vicinity of NP could potentially be responsible for damaging neuronal membranes and for activating nearby glial cells. In this regard, we have recently shown that synthetic A $\beta$  peptides directly activate the alternative and classical complement pathways (ACP and CCP) in the absence of antibody (Ab) or A $\beta$  binding proteins, leading to the formation of ester linked A $\beta$ -C3 complexes. These findings provide a possible explanation for the presence of activation pathway components in NP from AD patients. In the present studies, we evaluated the ability of A $\beta$ -mediated complement activation to activate the terminal, biologically important portion of the complement system. A $\beta$ -mediated triggering of either the ACP or CCP generated C5a and led to assembly of the membrane attack complex. The ACP was far more efficient in this regard. ELISA analysis using multiple combinations of Abs to late complement components unequivocally showed that low nanomolar doses of A $\beta$  1-42 activated complement through the C9 step. These results provide a likely explanation for the association of the C5b-9 complex with damaged neuronal processes in the vicinity of NP from AD brains. They also suggest a possible mechanism for the accumulation of activated microglia and astrocytes around NP, since both of these cell types respond to C5a with activation and/or chemotaxis. Supported by NIH grant.

## 191.12

**STRUCTURAL FEATURES OF THE COMPLEMENT ACTIVATION DOMAIN OF  $\beta$ -AMYLOID.**

A.J. Tenner, P. Velazquez and D. H. Cribbs\*, Dept. Molecular Biology and Biochemistry and \*Dept. of Neurology, University of California, Irvine, California, 92717

$\beta$ -amyloid is a 39-43 amino acid peptide that accumulates in the brain of individuals afflicted with the neurodegenerative disorder Alzheimer's Disease (AD).  $\beta$ -amyloid has been implicated in the pathogenesis of AD via its toxicity to neurons and its ability to activate the classical complement (C') pathway. The ability to activate C' has been previously demonstrated to directly correlate with the ability of this peptide to form fibrils, and the interaction site on C1q, the recognition component of the classical C' pathway, mapped to the N-terminal region of the C1q A chain. A molecular model of this C1q region has now been constructed, and experiments designed to further define the structural elements of  $\beta$ -amyloid required for C' activation. Synthetic peptides that were either truncated or synthesized with altered amino acid sequences were evaluated for their ability to activate C'. Circular dichroism (CD) and electron microscopy (EM) were used to characterize the secondary and macromolecular structure assumed by these peptides. The results demonstrate that the region limited by amino acid residues 4 and 11 is essential for C' activation. Furthermore, the presentation of a negative charge at residue 7 was found to be critical, as substitution of asparagine for aspartic acid at residue 7 resulted in the complete abrogation of C' activating capacity. In addition, even more subtle changes such as the commonly detected isopropyl modification of this residue disrupted C' activation. This was not due to a lack of  $\beta$ -sheet structure as discerned by CD, or to the lack of fibrillar assembly as detected by EM. While additional  $\beta$ -peptide-C1 interactions may be critical in regulating the activation of C', these studies provide structural information which may be useful in the design of potentially therapeutic inhibitors of C' activation by  $\beta$ -amyloid. **BETA AMYLOID PEPTIDE (1-42) INHIBITS EVOKED ACETYLCHOLINE RELEASE VIA A MECHANISM INDEPENDENT OF EFFECTS ON NEURON VIABILITY, CHOLINE UPTAKE AND ACH SYNTHESIS.** N. Jacobsen, C. Cogswell and D. B. Gray\*. Department of Biology, Simmons College, 300 The Fenway, Boston, MA 02115.

Last year this lab presented evidence that ACh release from cultured avian ciliary ganglion (CG) neurons is significantly inhibited by exposure to 25  $\mu$ M 1-42 beta amyloid peptide (BAP). This peptide fragment is implicated in the pathogenesis of the neuritic plaques found in the brains of Alzheimer's patients. In this study, the beta amyloid peptide fragment 1-42 was 'aged' for at least 3 days at a concentration of 250  $\mu$ M before dilution ten-fold and addition to cultured stage 40 CG neurons for 24 hours. At this concentration, aged 1-42 peptide solution clearly contained insoluble crystals which decorated the neurons. After 24 hours in culture, potassium-evoked radiolabeled ACh release from CG cells is inhibited by 75-80 %. These neurons however, possess normal morphology and remain viable for at least 8 days, and labeled choline uptake is unaffected. Acetylcholine (ACh) synthesis rates in cells exposed to BAP 1-42 for 24 hrs were measured and were not significantly different from control levels. To determine if the peptide was affecting total ACh levels or loading of synaptic vesicles or exocytotic mechanisms, ACh release was next induced by adding 1  $\mu$ M calcium ionophore (A23187), causing inward  $Ca^{++}$  flux., bypassing endogenous calcium channels. 25  $\mu$ M BAP 1-42 was unable to inhibit ionophore-induced ACh release. These results support the hypothesis that the initial interaction between neurons and Alzheimer's associated  $\beta$ -amyloid peptides may cause a disruption of excitation-secretion coupling. ## 191.15

**CHARACTERIZATION OF A NUCLEAR FACTOR THAT BINDS TO THE APB $\beta$  ACTIVATOR DOMAIN IN THE AMYLOID  $\beta$ -PROTEIN PRECURSOR PROMOTER.**

A.A. Vostrov and W.W. Quitschke\*. Department of Psychiatry, State University of New York, Stony Brook, NY 11794-8101.

The promoter of the amyloid  $\beta$ -protein precursor [APP] gene directs high levels of cell-type specific transcription with 94 base pairs 5' to the main transcriptional start site. This region contains two nuclear factor binding domains designated APB $\alpha$  and APB $\beta$ . The factor that binds to the APB $\alpha$  sequence was identified as USF. However, the primary activator domain in the proximal APP promoter is APB $\beta$ , which contributes approximately 70-90% of the total transcriptional activity. The recognition sequence of the APB $\beta$  domain is contained within the sequence GCCGCTAGGGGT.

The protein factor that binds to the APB $\beta$  site was partially purified by ion exchange and affinity chromatography. Using UV crosslinking and SDS polyacrylamide gel electrophoresis, its molecular mass was determined to be approximately 150 kDa. By comparison, gel filtration of the native protein complex resulted in an estimate of the molecular mass of about 350 kDa. Thus, under native conditions the protein exists either as a dimer or in a complex with additional proteins. [supported by NS30994]

## 191.17

**A COMPARATIVE STUDY OF THE BAPP GENE PROMOTERS FROM PRIMATES AND RODENTS.** W. Song\* and D.K. Lahiri. Laboratory of Molecular Neurogenetics, Institute of Psychiatric Research, Program in Medical Neurobiology, Indiana University School of Medicine, Indianapolis, IN-46202

To study the transcriptional control of the gene encoding Alzheimer's beta-amyloid precursor protein (BAPP), we have cloned a 7.9 kb of the 5'-upstream regulatory region of the monkey BAPP gene. The proximal region of the promoter lacks both a TATA box and a CAAT box, has a high G+C content (65%) and contains multiple transcription start site (tss). Two copies of the GGGCGC sequence are present in the monkey promoter. It has a consensus sequence for binding of the AP-1 protein. A minimum region of 76 base pairs from tss was found to be sufficient to drive the basal promoter activity which has been tested by transfecting PC12 cells with different deletion promoter plasmids. Serial deletion analysis starting from -3.4 kb of the promoter reveals interesting transcriptional regulatory elements.

We compared sequences in the promoter region of the monkey with the human (LaFauci et al., 1989), mouse (Izumi et al., 1992) and rat (Chernak, 1993). On comparing the promoter sequence, up to ~1100 bp upstream from the tss, among human, monkey and mouse, we observed that the human promoter sequence is 82.4 % identical to the corresponding region of the monkey BAPP gene. On the contrary, the promoter sequences between the primate and rodent are only 26.1% identical. If we compare the promoter sequence of up to ~400 bp, we find a stronger identity (42.0%) between primates and rodents. Thus our results indicate that the basal level of promoter activity may be dependent on domains which lie within the first 400 bp of the promoter.

We thank NIH for supporting this research (PHS R01-AG10297).

## 191.14

**THE AMYLOID- $\beta$  PROTEIN REDUCES THE SYNTHESIS OF ACETYLCHOLINE IN A MURINE SEPTAL CELL LINE, SN56.** W.A. Pedersen, M.A. Kloczewiak, and J.K. Blusztajn\*. Department of Pathology, Boston Univ. School of Medicine, Boston, MA 02118.

We previously reported that A $\beta$  peptides reduce the intracellular levels of acetylcholine (ACh) in a murine cell line, SN56, derived from basal forebrain cholinergic neurons. After 48 hours of treatment, the ACh content of the cells was reduced up to 33% by A $\beta$  1-28 (50 pM), up to 43% by A $\beta$  1-42 (100 nM), and was unaltered by A $\beta$  1-16 (100 nM). None of these treatments caused toxicity to the cells nor altered their morphology in any way. We have further characterized the reductive effect of A $\beta$  on the levels of ACh in these cells. Treatment of the cells with A $\beta$  25-28 (100 nM; 48 hours) caused a statistically significant decrease in ACh content, suggesting that the sequence GSNK is responsible for the effect. The reduced levels of ACh caused by A $\beta$  1-42 and A $\beta$  1-28 were accompanied by proportional decreases in choline acetyltransferase activity. In contrast, acetylcholinesterase activity was unaltered, indicating that A $\beta$  specifically reduces the synthesis of ACh in SN56 cells. The ACh-reducing effect of A $\beta$  1-42 in SN56 cells could be prevented by cotreatment with all-*trans*-retinoic acid (10 nM) or with the tyrosine kinase inhibitor, genistein (75  $\mu$ M). These results demonstrate a non-toxic, suppressive effect of A $\beta$  on ACh synthesis, an action that may contribute to the cholinergic deficit in Alzheimer's disease basal forebrain. (Supported by AG09525)

## 191.16

**MICE TRANSGENIC FOR A HUMAN AMYLOID PRECURSOR PROTEIN PROMOTER-lacZ REPORTER CONSTRUCT.** K. Wright, M.N. Gordon, D.G. Morgan\*, C. Zehr, X. Yu, J. Salbaum and K. Duff. Depts. of Pharmacology & Therapeutics and Biochemistry & Molecular Biology, Univ. of South Florida College of Medicine, Tampa, FL 33612-4799.

To further explore factors regulating the expression of the amyloid precursor protein (APP) in vivo, transgenic mice carrying the human APP promoter were constructed. A construct consisting of human APP 5' sequence (from +104 to -2045) was fused to the coding region for the lacZ reporter gene. Transgenic mice were generated by pronuclear injection into FVB mice. Known promoter elements contained within the construct include consensus sequences for heat shock, AP1, AP4 and SP1 elements, as well as GC rich regions. Transgenic founder, F1 or F2 mice (identified by tail biopsy) were anesthetized with pentobarbital, and perfused with 0.9% saline, followed by 4% paraformaldehyde in 100 mM phosphate buffer. Brains were postfixed for 1h, then sectioned at 100  $\mu$ m in the horizontal plane using a vibratome. Sections were histochemically stained for  $\beta$ -galactosidase activity for 24h at 32°C. Many neurons were intensely stained throughout the hippocampus, cerebral cortex and thalamus in two independent transgenic lines. In the hippocampus, pyramidal cells were labeled, but granule cells and glial cells were not. Labeled cortical neurons were localized in deeper layers, and were most abundant in entorhinal cortex. These mice will be used to identify factors regulating APP expression, and their mechanisms of action. Supported by the Alzheimer's Association IIRG93-083 (DGM) and P01 AG13952 (DGM and KD).

## 191.18

**CHANGES IN AMYLOID PRECURSOR PROTEIN mRNA ISOFORMS DURING OLFACTORY NEURON TURNOVER.** N. Zaidi and B.R. Talamo\*. Dept. of Neuroscience, Tufts Medical School, Boston, MA 02111.

Amyloid precursor protein (APP) is the source of abnormal deposits of  $\beta$ -amyloid peptide in Alzheimer's disease. Although APP has been suggested to play a role in neuronal differentiation, neurite outgrowth and repair, its normal role is not understood. Evidence for the normal role of APP was examined by measuring expression of alternatively spliced mRNA transcripts during turnover of rat olfactory neurons. Quantitative RT-PCR was used for the three major isoforms, APP 695, 751 and 770, during experimentally accelerated olfactory neuron degeneration, neurogenesis and axon outgrowth at 3, 5, 7 and 14d following unilateral removal of the olfactory bulb, the synaptic target. Changes in GAP-43 and olfactory marker protein mRNA in the epithelium also were monitored as indicators of neurite outgrowth and mature, differentiated neurons, respectively. Initially, a 75% decrease was observed in the levels of all three APP mRNA isoforms, comparable to the loss in olfactory marker protein mRNA and consistent with our previous immunocytochemical and *in situ* data showing localization restricted to neurons. Recovery of levels of APP 695 lagged behind those of APP 751 and 770 during early stages of neuronal proliferation. By 7d, APP 695 had increased to pre-bullectomy levels, while APP 751 and 770 isoforms already surpassed levels in unperturbed epithelium. During the phase of active neurite outgrowth at 14d, amounts of all three isoforms were almost double those of the control steady-state epithelium, comparable to the increase and continued elevation of GAP-43 mRNA. These results are compatible with an early role for APP 751 and 770 in initial phases of proliferation and differentiation, while APP 695 may be involved in subsequent stages of neuronal differentiation and neurite outgrowth. Supported in part by R01-AG09200.

## 191.19

**EFFECTS OF SYSTEMIC MK-801 ADMINISTRATION ON THE EXPRESSION OF AMYLOID PRECURSOR PROTEIN (APP) mRNA.** T. Kakigi<sup>1</sup>\*, M. Yasuda<sup>2</sup>, Y. Yamamoto<sup>1</sup>, K. Maeda<sup>2</sup> and C. Tanaka<sup>2</sup>. <sup>1</sup>Dept. of Psychiatry and Neurology, Kobe Univ. School of Med., 7-5-2 Kusunoki-cho, Chuo-ku, Kobe 650, Japan and <sup>2</sup>Neuropharmacology Lab., Dept. of Neuroscience, Hyogo Institute for Aging Brain and Cognitive Disorders, 520 Saisho-ko, Himeji 670, Japan.

Glutamate is an excitatory amino acid involved in corticocortical association pathways, and the key change in Alzheimer's Disease (AD) has been considered to be shrinkage or loss of corticocortical pyramidal neurons, which use glutamate as a transmitter. The N-methyl-D-aspartate (NMDA) receptor is a marker for glutamate activity. There is evidence suggesting that these changes play a role in pathogenesis of AD: glutamatergic corticocortical neurons degenerate in the disorder, glutamatergic neurons are prominent in the hippocampus, which degenerates consistently in AD, and animal studies suggest that the NMDA receptor complex is involved in neuronal networks that underlie memory and behaviour.  $\beta$ -amyloid forms the core of senile plaques in AD brain and is broken down from much larger proteins, the amyloid precursor proteins (APPs). MK-801 is one of the dissociative anesthetics and acts on the ion channel as a potent noncompetitive antagonist of the NMDA receptor. In the present study, to investigate the effect of MK-801 on the expression of APP mRNA, we used *in situ* hybridization technique to determine the APP mRNA levels in rat brain. MK-801 (1.0mg/kg) was injected subcutaneously, at 5 time points (0 hour before injection and 1, 4, 10 and 24 hour after injection) rats were killed by decapitation. Oligodeoxynucleotide probes labeled by <sup>35</sup>S-dATP were used for *in situ* hybridization. Densities of the interested regions were measured by BAS2000 image analyzing system. Results were shown as % compared to the value of 0 time point and were analyzed by ANOVA. Results were as follows: at 1 hour after injection, the densities in the medial prefrontal cortex, sensorimotor cortex and hippocampus were significantly reduced, after 4 hours, the significant reduction was observed in the medial prefrontal cortex and the elevation in the anterior and posterior cingulate cortex. After 10 hours, the density was significantly reduced in the medial prefrontal cortex and was elevated in the posterior cingulate cortex, and at 24 hours following the MK-801 administration, the APP mRNA expression was significantly reduced in the parietal cortex, hippocampus and anterior and posterior cingulate cortex. Our results showed that noncompetitive NMDA receptor antagonist, MK-801, altered the expression of APP mRNA especially in the posterior cingulate cortex, where MK-801 produces reversible injury, vacuoles, throughout the cytoplasm. (Supported by Hyogo Institute for Aging Brain and Cognitive Disorders-HIABCD, Hyogo, Japan)

## MONDAY AM

## SYMPOSIA

## 194

**SYMPOSIUM. CENTRAL NERVOUS SYSTEM AUTOIMMUNITY IN HUMAN DISEASES.** P. De Camilli, Yale Univ./HHMI (Chairperson); L. Steinman, Weizmann Inst. and Stanford Univ.; J. Posner, Memorial Sloan-Kettering Cancer Cent.; M. Solimena, Yale Univ.; S. Rogers, Univ. of Utah.

The objective of the symposium is to review, for a broad audience of neuroscientists, our present knowledge about autoimmune disorders of the central nervous system (CNS). The initial speaker, L. Steinman will provide a general description of the mechanisms of immune surveillance in the brain and of how breakdown of tolerance to self-antigens of the nervous system may occur following microbial infections. Examples will be shown with microbial sequences that mimic myelin antigens and which may either induce demyelinating diseases or suppress ongoing inflammatory processes within the brain. The second speaker, J. Posner will illustrate the link between small cancers originating outside the CNS, the onset of brain paraneoplastic syndromes and the occurrence of autoantibodies against neuronal antigens. He will center his attention on the "onconeural" antigen HuD, which appears to be important in the development and maintenance of neuronal function. The third speaker, M. Solimena, will focus on autoimmunity against the presynaptic antigens glutamic acid decarboxylase and amphiphysin in Stiff-Man syndrome, a neurological disorder characterized by continuous rigidity of the body musculature that is often associated with autoimmune diabetes or, less frequently, with breast cancer. The last speaker, S. Rogers, will report on the recent discovery of autoantibodies directed against non-NMDA glutamate receptors in a variety of neurological disorders, including Rasmussen's encephalitis, paraneoplastic neurodegenerative syndrome and olivocerebellar atrophy, and provide insights into how these antibodies could interfere with the normal receptor activity.

## 195

**SYMPOSIUM. MITOCHONDRIAL INVOLVEMENT IN NEURONAL DEGENERATION.** J.M. Dubinsky, Univ. of Minnesota (chair), J.J. Reynolds, Univ. of Pittsburgh (cochair), A.N. Murphy, George Washington Univ., J.T. Greenamyre, Emory Univ.; M.F. Beal, Massachusetts General Hospital; S.M. Rothman, Childrens Hospital-Washington Univ. Sch. Med.

The contribution of mitochondrial function and dysfunction in neuronal death will be addressed in relationship to apoptosis, excitotoxicity, long term neurodegenerative diseases and mental retardation.

A.N. Murphy will discuss the consequences of  $Ca^{2+}$  sequestration upon mitochondrial respiration and free radical production. Overexpression of bcl-2, which protects neurons from ischemia/reperfusion injury, potentiates mitochondrial  $Ca^{2+}$  uptake and provides resistance to  $Ca^{2+}$ -induced respiratory inhibition. J.T. Greenamyre will discuss mitochondrial dysfunction in Parkinson's disease. *In vivo* and *in vitro* studies demonstrate that bioenergetic defects lead to secondary excitotoxicity, apparently by disrupting calcium homeostasis. M.F. Beal will review the bioenergetic defects and oxidative stress associated with Huntingtons and Alzheimers disease. Huntingtin binds to and inhibits glyceraldehyde-3-phosphate dehydrogenase. Lesions produced by mitochondrial toxins closely mimic Huntingtons disease. In AD there is evidence for mitochondrial defects encoding cytochrome oxidase. S.M. Rothman will discuss mutations of the mitochondrial genome resulting in hearing loss, blindness, epilepsy, myopathy, and neuronal degeneration. While ATP deficiency may be the primary explanation, there are alternatives, such as defective buffering of intracellular calcium. J.J. Reynolds will conclude by reviewing evidence from several laboratories regarding mitochondrial calcium changes associated with excitotoxicity.

## VISUAL CORTEX: STRIATE II

## 198.1

**THE MICROCIRCUITRY OF COMPLEX CELLS IN CAT STRIATE CORTEX.** José-Manuel Alonso\*, Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

According to the original model, complex cells are generated by the convergent input of simple cells with similar orientation preference (Hubel and Wiesel, *J Physiol* 160: 106, 1962). Alternatively, later studies have demonstrated that some complex cells receive direct input from the lateral geniculate nucleus (LGN) (Hoffman and Stone, *Brain Res* 32: 460, 1971). The aim of this study was to reconcile these two sets of findings and learn more about complex cell microcircuitry. Single unit activity from simple and complex cells, and multiunit activity from the LGN were recorded simultaneously, and their connectivity measured by cross-correlation analysis. Small reversible blockades were made in layer A of the LGN (pressure injections of GABA) to study the contribution of this input to complex receptive fields.

Preliminary results demonstrated, as expected, the existence of excitatory connections from layer IV simple cells to superficial complex cells with similar orientation preference. In addition, geniculate blockades were able to suppress the activity of both simple and complex cells. Among the complex cells affected, some appeared to receive excitatory connections from simple cells but not from layer A of the LGN. Other complex cells were less affected by the geniculate blockade (Malpeli, *J Neurophysiol* 49: 595, 1981) although some of them received direct geniculate input from layer A.

In summary, the mechanism of complex cell generation appear to be multifaceted. Some complex cells are apparently dominated by excitatory connections from simple cells. Other complex cells, however, might be generated by different mechanisms. (Supported by the C.H. Revson Foundation and NIH EY05253).

**COMPLEX CELLS IN LAYER 6 PROJECT TO THE SUPERFICIAL LAYERS IN THE CAT STRIATE CORTEX.** Judith A. Hirsch\*, José-Manuel Alonso, R. Clay Reid and Christine A. Gallagher, Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

Receptive field properties vary systematically across the different layers of the striate cortex. Understanding how these functional differences arise requires a precise description of the interlaminar connections. By making whole-cell recordings with dye-filled electrodes *in vivo*, we have been able to correlate the visual responses of cells in layer 6 with the pattern of their intracortical projections. The five complex cells we labeled projected to the superficial layers, a pathway not previously described in the cat. Two simple cells projected to layer 4, as first reported by Gilbert and Wiesel (*Nature* 280: 120, 1979).

We recorded from complex cells at different depths of layer 6. Patterns of dendritic branching ranged widely, apical arbors ended in layer 5, 2+3, or 1. The somas of two neurons lay near the white matter and sent axons to only the lower half of layer 2+3. The other cells were located in middle or upper layer 6 and extended collaterals that traveled the full extent of the superficial layers. The densest projections were in close vertical register with soma and sparser collaterals formed at least one nearby cluster. In addition to the terminal fields in the superficial layers, there were various degrees of arborization in the other laminae; all cells projected to the white matter, presumably to subcortical targets.

Our conclusion is that simple cells in layer 6 direct their output to simple cells in layer 4, while complex cells in layer 6 contact complex cells in layer 2+3. This parallel functional and anatomical division of layer 6 in the cat is reminiscent of patterns of connectivity in the primate striate cortex (Lund, *Ann Rev Neurosci* 11: 253, 1988). ## VISUAL ADAPTATION HYPERPOLARIZES CELLS OF THE CAT STRIATE CORTEX

M. Carandini\* and D. Ferster

Dept. of Neurobiology, Northwestern University, Evanston, IL 60208

Prolonged exposure to visual stimuli decreases the responsiveness of striate cortical cells, as measured by their spike rates (Maffei *et al.*, 1973).

To investigate the cellular basis of this phenomenon we recorded intracellularly from cells in the striate cortex of anesthetized cats using the whole cell patch technique. Visual stimuli were optimal drifting sinusoidal gratings. In "ramp" experiments, stimuli of increasing contrast were followed by stimuli of decreasing contrast (Bonds, 1991). In "top-up" experiments, the order of contrasts was randomized and adapting stimuli were presented before each test stimulus (Blakemore & Campbell, 1969).

The mean membrane potential of most cells increased with stimulus contrast. Adaptation to high contrasts antagonized this increase, reducing the mean membrane potential by 2-8 mV. The effect of adaptation on the spike responses was, as expected, a 2- to 5-fold reduction in contrast sensitivity (Ohzawa *et al.*, 1979). The strongest effects of adaptation on mean membrane potential, however, were not reflected in the spike responses since they occurred at low-contrast test stimuli that did not elicit spikes. In simple cells the increase in the mean of the membrane potential responses caused by increasing contrast was accompanied by a large increase in their first harmonic component. The first harmonic component, however, was not as much affected by adaptation as the mean. We conclude that the decrease in contrast sensitivity of the spike responses caused by adaptation is largely due to hyperpolarization, which increases the distance between membrane potential and spike threshold.

## 198.5

## THE CONTRIBUTION OF FEEDFORWARD PATHWAYS TO THE GAIN OF CORTICAL MICROCIRCUITS. J. G. Mancilla\* and P. S. Ulinski

Comm. Neurobiol. and Dept. Org. Biol. and Anat., U. Chicago, Chicago, IL 60637.

Current models of cortical microcircuitry (e.g. Douglas and Martin, 1991; Suarez *et al.*, 1995) suggest that relatively small thalamic inputs to the cortex are amplified by recurrent, excitatory pathways within the cortex. Since these models are based on experiments using electrical stimulation of the white matter, it seemed important to examine them using natural visual stimuli. Intensity-response functions were obtained from intracellular recordings of pyramidal cells in an *in vitro*, geniculocortical preparation of the turtle, *Pseudemys scripta*. One second, square light flashes of varying intensities produced ON responses composed of depolarizing potentials that increased in amplitude with increases in light intensity. The mean  $\pm$  SEM maximal amplitude of the responses was  $16 \pm 5$  mV ( $n = 5$ ). Action potentials were only produced at intensities corresponding to the maximal response and at higher intensities. The responses at intensities higher than that producing the maximal response demonstrated a clear decrement from the maximal. Sigmoid functions were fit to plots of response amplitude as a function of light intensity to obtain the slopes of the sigmoids at half maximal amplitude. The slopes yield a measure of the gain of the cortical responses ( $270 \pm 20$   $\mu$ V/photons- $\mu$ m<sup>-2</sup>·sec<sup>-1</sup>), which is significantly higher than the gain of single turtle cones ( $50$   $\mu$ V/photons- $\mu$ m<sup>-2</sup>·sec<sup>-1</sup>; Burkhardt, 1995). The absence of action potentials at the low light intensities used to obtain the gain measurements suggests that the gain at these intensities is solely a product of the feedforward pathways, while the production of action potentials at higher intensities indicate the involvement of feedback pathways. Thus, the data suggest that natural visual stimuli produce high gains in the feedforward components of cortical microcircuits, and that feedback pathways apparently function in controlling the gain of cortical circuits, rather than amplifying thalamic inputs. GABA<sub>B</sub> MEDIATED INHIBITION IN FEEDBACK CIRCUITS IS WEAKER THAN IN FORWARD CIRCUITS OF RAT VISUAL CORTEX. Z. Shao<sup>1</sup>, G.W. Harding<sup>2\*</sup> and A. Burkhalter<sup>1</sup>. <sup>1</sup>Dept. of Anatomy and Neurobiology, <sup>2</sup>Dept. Otolaryngology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Mechanistic models of cortical networks have shown that tuning of selective receptive field properties of cortical neurons requires amplification of monosynaptic inputs by local excitatory circuits (Douglas and Martin, 1991; Somers *et al.*, 1995). Evidence suggests that the gain of this amplification is controlled by inhibition of polysynaptic excitation which may be mediated by GABA<sub>B</sub> receptors (Morrisett *et al.*, 1991). To better understand excitatory gain control in different cortical circuits we have compared the mechanisms of GABAergic inhibition in forward and feedback circuits of rat visual cortex.

Intracellular recordings in slices of rat visual cortex showed that in most cells tested (10/13, 77%) forward input from area V1 to LM (V2) generated early EPSPs followed by early (latency to peak ~10ms) and late IPSPs (latency to peak ~160ms). Few cells responded with late, polysynaptic EPSPs. In contrast, at all strengths tested, feedback input from LM to V1 rarely elicited fast (Shao and Burkhalter, 1996) or slow IPSPs (1/12, 8%). However, most cells showed early and late EPSPs. In both pathways early IPSPs were blocked by the GABA<sub>A</sub> receptor antagonist bicuculline. Late IPSPs evoked by forward inputs were abolished by the GABA<sub>B</sub> receptor blocker saclophen. With GABA<sub>B</sub> receptors blocked forward inputs typically revealed late EPSPs.

These results suggest that in forward circuits the excitatory gain is regulated by GABA<sub>B</sub> receptor mediated inhibition, which may play a role in contrast invariant tuning. Because feedback circuits lack this late inhibition, amplification of feedback signals by local excitatory networks must rely on different mechanisms. Supported by NIH Grant EY05935.

## SPONTANEOUS FLUCTUATIONS IN MEMBRANE POTENTIAL OF COMPLEX CELLS IN VISUAL CORTEX

D. Ferster\* and M. Carandini

Dept. of Neurobiology, Northwestern Univ., Evanston, IL 60208.

Arieli *et al.* (J. Neurophysiol. 73:2072, 1995) have reported optically-recorded spontaneous waves of activity traveling across the cortical surface that compare in size to visually evoked responses. We have observed intracellularly recorded fluctuations in membrane potential that may underlie these optically-recorded signals.

Whole-cell patch intracellular recordings were obtained from the striate cortex of pentathol-anesthetized cats. In many complex cells and almost all simple cells, a moving bar evokes reproducible peaks of depolarization time-locked to the stimulus. In the absence of a stimulus in these cells, the membrane potential remains near rest with small spontaneous noise of a few mV in size. In the remaining complex cells, however, even in the absence of a stimulus the membrane potential rapidly and repeatedly rises by 10 to 20 mV and stays in this depolarized state for anywhere from 50 to 300 ms. These large depolarizing events occur with an average rate of 3-5 per second, but their timing seems largely random. Visually-evoked responses do not sum with the spontaneous events, since the size of these events is comparable to the size to the evoked response. Instead, visual stimuli increase the average time that the membrane remains depolarized. Nevertheless, the averaged responses of these complex cells still resemble those of complex cells that do not show spontaneous events.

The spontaneous fluctuations in membrane potential are well correlated with the extracellularly-recorded local field potential, as are the optically-recorded surface waves of activity of Arieli *et al.* This correlation and the similar dynamic properties of the fluctuations in membrane potential suggest that the intracellular and optical phenomena are related.

## 198.6

FEEDBACK CONNECTIONS FROM AREA V2 FAVOR ACTIVATION OF NMDA RECEPTORS IN NEURONS OF RAT PRIMARY VISUAL CORTEX. A. Burkhalter<sup>1</sup>, J. M. Nerbonne<sup>2\*</sup> and Z. Shao<sup>1</sup><sup>1</sup>Dept. of Anatomy and Neurobiology, <sup>2</sup>Dept. Molec. Biol. and Pharmacology, Washington Univ. Sch. of Med., St. Louis, Mo 63110.

Feedback inputs from V2 have been shown to facilitate visual responses in V1. Such gain changes might be due to a potentiation of excitatory inputs mediated by NMDA receptors. We have tested this hypothesis in slices of rat visual cortex by studying the effects of the selective NMDA receptor blocker, AP-5, on synaptic potentials (EPSPs) evoked by forward and feedback inputs.

The results show that in the presence of AP-5 the majority (5/8, 62.5%) of monosynaptic EPSPs evoked by feedback inputs were reduced in amplitude and exhibited an accelerated decay. In contrast, monosynaptic EPSPs elicited by forward inputs were affected only in 28.5% (2/7) of the cells tested. When inhibition was eliminated by intracellular blockade of Cl<sup>-</sup> channels or extracellular application of bicuculline, EPSPs of all cells tested in both pathways were sensitive to AP-5.

In the majority of cells, feedback input of any strength evoked polysynaptic EPSPs (13/15, 87%). In the forward pathway, in contrast, late EPSPs were seen only at lower stimulus strengths (5/6, 83%) and were infrequent at high stimulus strengths (1/12, 8%). The loss of the late EPSP was correlated with the appearance of a late IPSP that was evoked by stronger stimuli. Blockade of this late IPSP revealed late EPSPs that were blocked completely by AP-5.

These findings suggest that NMDA receptors play a more important role in feedback than in forward pathways and that this difference is determined in part by distinct inhibitory mechanisms present in each circuit (Johnson and Burkhalter, 1996).

## 198.8

## PAIRED-PULSE DEPRESSION OF UNITARY PYRAMID TO INTERNEURON EPSPs IN CAT VISUAL CORTEX IN VITRO.

E.H. Buhl\*, G. Tamas, T. Szilagyi, O. Paulsen and P. Somogyi. MRC Anatomical Neuropharmacology Unit, Oxford University, Oxford OX1 3TH, UK

Dynamic properties of unitary EPSPs were investigated using the paired-pulse paradigm in conjunction with dual intracellular recordings of synaptically coupled pyramidal to GABAergic cell pairs ( $n=4$ ; intervals 10 - 70 ms) in slices of the cat visual cortex. For each connection, we employed correlated light and electron microscopy to determine the numbers of all synaptic release sites ( $n = 1, 2, 2$  and 7, respectively) as well as their exact placement, ranging from very proximal to distal. On average, all unitary EPSPs showed a modest degree of paired-pulse depression, ranging between 2 and 31% (mean reduction = 16%) of the averaged conditioning 1st EPSP (mean amplitude 1st EPSP = 0.79 mV; 2nd EPSP = 0.66 mV), whereas the degree of amplitude fluctuation remained virtually the same (mean SD 1st EPSP = 0.38 mV; mean SD 2nd EPSP = 0.38 mV). Even for those preselected 2nd EPSPs which followed a small 1st response (<20% of averaged 1st EPSP) there was no significant increase of their amplitude above the level of the averaged conditioning 1st EPSP. Likewise, there was only a weak tendency of paired-pulse depression to be more pronounced at short interspike intervals. In conclusion, transmission at cat cortical pyramidal to interneuron connections (see also Paulsen, Stricker, Tamas, Szilagyi, Somogyi and Buhl, this meeting) is relatively robust, with unitary EPSPs showing only a modest degree of paired-pulse depression, which is relatively little affected by either amplitude of the conditioning event or the interspike interval.

PYRAMIDAL CELL MODULES AND DOUBLE-BOUQUET CELL AXONS IN MONKEY PRIMARY VISUAL CORTEX. **A. Peters\*** and **C. Sethares**. Dept. of Anatomy and Neurobiology, Boston Univ. Sch. of Med., Boston, MA 02118.

In earlier studies we showed that the apical dendrites of layer V pyramidal cells in rhesus monkey area 17 are clustered together into distinct and regularly spaced groups that have an average center-to-center spacing of 23  $\mu$ m, and it was proposed that these clusters of apical dendrites represent the axes of vertically oriented modules of pyramidal cells. It was subsequently shown that the myelinated axons that extend from the pyramidal cells to the white matter as discrete bundles have a similar center-to-center spacing. Since use of tracers shows that the axons of the pyramidal cells in the upper layers of the cortex enter these bundles, it was suggested that each module has its own individual output bundle of axons (Peters and Sethares, 1996).

Another vertical component of this cortex is the horse tails of axons that originate from double-bouquet cells with cell bodies in layer II/III. These horse tails, which can be visualized using antibodies to calbindin, extend as far as layer IVCx. The horse tails are most prominent in layer III, in which they are regularly spaced, and have an average center-to-center spacing of about 23  $\mu$ m, like that of the clusters and myelinated axon bundles. Indeed, in sections double-labelled with calbindin and MAP2 antibodies, it is evident that each horse tail of axons lies adjacent to an apical dendritic cluster. The relationship between these two vertically oriented entities is being more closely examined, but it is now apparent that not only pyramidal cells, but some nonpyramidal, inhibitory, neurons are regularly arranged and contribute to the vertical neuronal modules within cerebral cortex.

SPECIFICITY OF CONNECTIONS REVEALED BY LASER SCANNING PHOTOSTIMULATION IN RAT VISUAL CORTEX. **A. Sawatari\*** and **E.M. Callaway**. Molecular Neurobiology Laboratory, The Salk Institute for Biological Studies, La Jolla, CA 92037.

Do layer specific axonal projections form connections onto specific dendritic elements, or do they synapse indiscriminately onto any dendrite present in the layer? We addressed this question by examining the connectivity of neurons in the rat visual cortex, where both layer 2/3 and layer 5 pyramidal neurons have extensive dendritic arbors in layer 2/3. Axons of spiny stellate cells in layer 4 project to layer 2/3 but the specificity of these afferents is not known. Conceivably, layer 4 axons could form synapses selectively onto the dendritic branches of layer 2/3 cells or layer 5 cells, or make indiscriminate connections to both.

We determined the locations of neurons making functional connections with layer 2/3 and layer 5 cells using laser scanning photostimulation. Living sagittal brain slices from the visual cortex of Long-Evans rats were bathed in ACSF containing "caged" glutamate. Whole-cell, voltage-clamp recordings were made from individual layer 2/3 and layer 5 neurons while brief flashes of light (10 msec) from a UV laser, focused to a small spot by a microscope objective, were delivered to various locations in the slice to uncage the glutamate. The uncaged glutamate induces action potentials in nearby neurons. Monosynaptic excitatory post synaptic currents were recorded by stimulating cells in different layers in this manner. Neurons were also intracellularly labeled with biocytin to determine axonal and dendritic morphology along with laminar localization of the soma.

Our sample to date includes four layer 2/3 pyramidal cells and three layer 5 pyramidal cells. Layer 2/3 cells received input from layer 2/3 and layer 4 with moderate input from layer 5B. One layer 2/3 cell also received strong input from layers 5B and 6, suggesting diversity in layer 2/3 pyramids based on functional connectivity. In contrast, layer 5 cells received considerable input from layers 2/3, 5, and 6, but very little input from layer 4. Thus, our preliminary results suggest that layer 4 neurons connect preferentially to layer 2/3 neurons. These observations suggest that neurons can selectively target specific dendritic elements within a given layer. Further experiments will verify whether these trends are maintained in a larger sample.

This research is funded by NIH Grant #EY10742 and the Klingenstein Fund.

VISUAL CALLOSAL FIBERS LINK CORTICAL COLUMNS DOMINATED BY THE SAME EYE IN THE CAT. **Jaime F. Olavarria\***. Dept. of Psychology, Box 351525, Univ. of Washington, Seattle, WA 98195.

The development of callosal connections in cat areas 17 and 18 is thought to depend upon neuronal correlated activity between the hemispheres. A prevailing hypothesis is that correlated activity is generated from viewing the same object through both eyes. An alternative hypothesis (Olavarria & Li 95; Olavarria 96) proposes that interhemispheric correlated activity may be primarily monocular in origin. Afferents from temporal retina are relayed not only ipsilaterally, but also to the contralateral transition zone (TZ), an area of ipsilateral visual field representation located between areas 17 and 18. Active loci in temporal retina would thus induce synchronous activity in retinotopically corresponding loci in both hemispheres.

The binocular hypothesis predicts that callosal neurons should overlap both right and left eye ocular dominance columns (ODC). In contrast, the monocular hypothesis predicts that callosal neurons should overlap columns dominated by the same temporal retina, namely, ipsilateral ODC in regions outside the TZ, and contralateral ODC in regions within the TZ. These predictions assume that ODC influence callosal development, which is likely since ODC segregate long before callosal development is complete.

To test these predictions, callosal neurons were retrogradely labeled by injections of fluorescent tracers into areas 17, 18 and TZ of normal adult cats. The distribution of labeled cells was then correlated with the pattern of ODC labeled transneurally by intraocular injections of WGA-HRP.

Tracer injections into areas 17 and 18 outside the TZ labeled callosal cells in the opposite TZ, predominantly over columns dominated by the contralateral eye. On the other hand, injections into the TZ labeled cells outside the TZ in contralateral areas 17 and 18, and these cells were found preferentially over ipsilateral ODC. These data support the hypothesis that correlated activity of monocular origin plays an important role in stabilizing juvenile callosal linkages. Supported by NIH EY09343.

## 198.10

Do cortical cells integrate local inputs linearly? Short-range lateral interactions revealed by intrinsic signal and single-unit activity. **L. J. Toth\***, **D.-S. Kim**, **M. Sur**. Dept. of Brain and Cognitive Sciences, M.I.T. Cambridge, MA 02139.

In cat visual cortex, focal iontophoresis of the GABA<sub>A</sub> antagonist bicuculline within a column of known orientation preference shifts the optically imaged orientation preference of a region of cortex (~1.1mm radius) towards that orientation (Kim *et al.*, 1995, *SFN Abst.* 21:771). This effect is dose-dependent (responses become non-specific for orientation at higher doses), GABA<sub>A</sub> specific (saclofen, a GABA<sub>B</sub> antagonist does not cause this effect, whereas GABA causes the inverse effect), position dependent (moving the pipette tangentially through the cortex alters which orientation becomes overrepresented), and often anisotropic. We therefore believe that the imaged spread of activity reveals a range of local functional connectivity, inclusive of all orientations, from a given cortical point. Because up to 70% of the maximal intrinsic signal can result from subthreshold activity (Toth *et al.*, 1994, *SFN Abst.* 20:836), we investigated whether the change in orientation preference observed in optical maps was also reflected in neuronal spiking. Single-unit recordings between 0.2 and 1.0 mm from the site of bicuculline iontophoresis revealed only small changes (<10°) in a given cell's orientation preference, though such changes were consistently towards the preference at the site of iontophoresis. Other physiological characteristics, such as tuning width, direction selectivity, and spontaneous activity were also affected.

We are faced with the observation that although cells receive strong and functional lateral inputs, those inputs do not significantly alter the orientation preference of the postsynaptic neuron. These results indicate that local information non-linearly modulates cortical responses, rather than being linearly integrated within the cell. Supported by NIH EY07023.

## 198.12

ASYNCHRONOUS DEVELOPMENT OF RECEPTIVE FIELD PROPERTIES AND CLUSTERED HORIZONTAL CONNECTIONS IN MACAQUE STRIATE CORTEX. **J.B. Levitt\*** and **J.S. Lund**. Dept. of Visual Science, Inst. of Ophthalmology, University College London, Bath Street, London EC1V 9EL, UK.

A prominent feature of V1 cortical circuitry whose functional role remains enigmatic is the orderly intra-areal lattice of clustered pyramidal neuron projections spreading parallel to the cortical surface. We examined the anatomical organization of these circuits, together with a number of receptive field properties in infant rhesus monkeys. We sought to determine if there is a parallel relationship between the development of patchy horizontal connections and maturation of response characteristics in V1 neurons. We recorded unit response properties in all cortical layers from the parafoveal representation of V1 in 2 paralyzed, opiate-anesthetized infant macaques (4.5 and 9 weeks old), and compared neuronal responses to adult responses collected at similar eccentricities and under identical conditions. We then made small iontophoretic injections of biocytin or dil to examine horizontal connectivity in these same animals. The lattice system anatomy at 4-5 weeks of age appeared adultlike in all characteristics (terminal patch size, repeat distance, overall connective field coverage). Infant neurons were as orientation- and direction-selective as adult neurons, although they were somewhat less sensitive and responsive. Although infant V1 minimum response fields were the same size as in the adult, infant V1 largely lacked the neurons summing over distances greater than 5 deg found in the adult. Infant V1 also lacked strongly endstopped units. Furthermore, response modulation from regions surrounding the minimum response field was notably weak or absent in the infants, and did not exhibit the same strong stimulus selectivity of such effects as in the adult. While the lattice connectivity was apparently adultlike in the infants, the spatial characteristics of their V1 neurons were strikingly immature. Either lattice connections do not underlie these characteristics, or they have yet to mature their adult synaptic complement. Supported by NIH EY10021 & MRCG9408137.

## 199.1

**FUNCTIONAL ANALYSIS OF GANGLION-CELL RECEPTIVE FIELDS IN TURTLE.** J.R. Dearworth Jr. and A.M. Granda\*. Department of Biological Sciences, University of Delaware, Newark, DE 19716.

Retinal ganglion cells have receptive fields that are defined by the interaction of excitatory and inhibitory components. These components can be manipulated by colored adaptations and stimulations, and by the use of pharmacological agents. The interactions describe receptive-field organizations that are progressively complex: here, a representative symmetrical simple center-only organization, a double-opponent arrangement organized for polarity and for color, and a third arrangement that operates for directional selectivity.

Turtles (*Pseudemys scripta elegans*) were anaesthetized and their optic nerves exposed for extra-cellular recording. Eyes were focussed on a hemispherical surface onto which computer controlled targets of light were projected. Ganglion-cell action potentials were collected in time histograms and displayed in 3-D plots. Drugs were directly injected into the vitreous bodies of left eyes; the time courses of drug effects were tracked.

Colored-light adaptations of particular field regions lessen sensitivity from one region while enhancing sensitivity in another. Drugs that act at glutamate and GABA receptors also upset balances between excitatory and inhibitory regions. The simple center-only receptive-field organization can be described by a double integral of a Gaussian function. The center-surround, double-opponent field can be described by the addition of a Fourier transform to the double Gaussian function. The directional-selective receptive field that is asymmetric can be described by the above-mentioned functions implemented by a cardioid function.

**HOW ON-OFF AMACRINE CELLS WORK.** Robert F. Miller\* Toby Velte and Nathan Staff. Neuroscience Graduate Program and Department of Physiology, University of Minnesota, Minneapolis, MN 55455.

Electrophysiological studies of On-Off amacrine cells were carried out in the mupuppy retina. Both whole-cell and intracellular electrophysiological recordings were obtained from single amacrine cells in the superfused eyecup preparation; cells were stained intracellularly with either horse radish peroxidase or Neurobiotin. Confocal microscopy was used to evaluate the fine structure of amacrine dendrites and the morphologies of stained amacrine cells were entered into a computer through a commercial tracing program (Eutectic). Modeling studies were carried out on compartmental representations of the cell morphology to simulate the light-evoked synaptic conductance changes and the observed pattern of impulse activity. Simulations of impulse activity were based on 5 non-linear channels, identified in ganglion cells. Successful models of On-Off amacrine cells required impulse generating capabilities in both the dendrites and soma with approximately equal voltage-gated ion channel density. Supported by NIH grant EY03014 to RFM.

## 199.5

**MORPHOLOGY AND PHYSIOLOGY OF THE AII-AMACRINE CELL NETWORK IN THE MACAQUE MONKEY RETINA.** D.M. Dacey.\* Dept. of Biological Structure, Univ. of Washington, Seattle WA 98195

In mammalian retina, rod bipolar cells do not contact ganglion cell dendrites but instead direct output to a distinctive amacrine cell type, the AII cell. Synaptic output of the AII-amacrine is mainly to ON cone bipolar cells via gap junctions and to OFF cone bipolar cells via an inhibitory synapse; the AII cells thus provide a pathway by which rod signals can be transmitted to both ON and OFF ganglion cell populations. In primates, the AII cell has been previously identified anatomically (Wässle, et al., J. Comp. Neurol. 361:537 1995); here I report on the light response of the AII cell in the macaque monkey retina and on its gap junctional connections with ON cone bipolar cells. AII cells were identified in an in vitro retinal preparation by selective staining with DAPI (diamidino phenylindole), and targeted for intracellular recording under microscopic control. To photopic luminance-modulated stimuli the AII gave a sustained ON response (~5 mV amplitude); the receptive field showed a non-opponent, center-surround organization characterized by additive input from both long (L-) and middle (M-) wavelength sensitive cones. After 30 min dark adaptation, scotopic stimuli evoked a depolarizing response (~20 mV amplitude) with characteristic rod spectral and temporal sensitivity. Intracellular injection of Neurobiotin demonstrated the bistratified morphology and coupled network of AII cells. An array of ON cone bipolar cells were also tracer-coupled to the AII network. The spatial densities and morphologies of the coupled cone bipolar cells revealed that both ON-midget bipolar and multiple diffuse cone bipolar types are linked to the AII cells. Thus the AII-cone bipolar gap junctions must be the basis for the strong, cone-mediated center-surround receptive field of the macaque AII cell as well as serving as a channel for rod signals to both midget and non-midget ganglion cell visual pathways. Supported by PHS Grants EY 06678, EY11162 and RR00166.

## 199.2

**EXCITATORY INPUT THROUGH GAP JUNCTIONS TO ON-CONE BIPOLAR CELLS IN RAT RETINA.** E. Hartveit\* Dept. Neurophysiol., Univ. Oslo, Norway.

The glutamatergic photoreceptor input to rod bipolar cells and ON-cone bipolar cells seems to be mediated by an APB-sensitive metabotropic receptor, whereas the input to OFF-cone bipolar cells is mediated by an ionotropic receptor. It is important to determine whether the axon terminals of ON- and OFF-cone bipolar cells overlap in the inner plexiform layer (IPL) or whether they are segregated in separate ON- and OFF-sublaminae. With recent information on rat cone bipolar cell morphology (type CB1-CB9; Euler and Wässle 1995), this problem can be addressed by experiments combining physiological and morphological methods. Whole-cell voltage clamp recordings (int: cesium gluconate, TEA; ext: 2.5-5 mM  $\text{Co}^{2+}$ ) were obtained under visual control (IR-DIC videomicroscopy) from cone bipolar cells in vertical slices of the rat retina. Cells were identified and classified by filling with Lucifer yellow. Responses to glutamate agonists (kainate, AMPA) were obtained by pressure application from a multibarrel pipette. For CB1-CB4, every cell responded with a short-latency (~0.2 s) inward current at  $V_H = -70$  mV, suggesting they were OFF-cone bipolar cells. The current reversed ~0 mV, as expected for non-selective cation channels. In addition, there was evidence for long-latency, indirect GABAergic input to the axon terminals in the IPL ( $E_{rev} \sim E_{Cl}$ ; mediated by external  $\text{Ca}^{2+}$ -independent release; blocked by picrotoxin+3-APMPA). For CB5-CB8, some cells displayed only long-latency GABAergic responses ( $E_{rev} \sim E_{Cl}$ ), suggesting they were ON-cone bipolar cells. Surprisingly, others of the same type (CB5-8) displayed short-latency (~0.2 s) responses as well, raising the question whether each type encompasses both ON- and OFF-cone bipolar cells. When the short-latency current responses were studied in isolation, however,  $E_{rev}$  was +30 to +40 mV, or could not be reversed at all. This could be explained by assuming that the current was generated in AII amacrine cells, known from morphological investigations to be coupled via gap junctions to axon terminals of some cone bipolar cells. Whole-cell recording of a cone bipolar cell would not give adequate voltage-control of the AII cells. When kainate responses were recorded directly from AII cells,  $E_{rev}$  was ~0 mV. Current experiments aim at reversibly blocking the gap-junction input. NFR 101025/2-10 (NORWEGIAN RESEARCH COUNCIL)

## 199.4

**NICOTINIC ACETYLCHOLINE RECEPTORS ARE EXPRESSED BY SOME CHOLINERGIC AMACRINE CELLS IN THE RABBIT RETINA.** K.T. Keyser\*, M.A. MacNeil\*, J.M. Lindstrom\*, F. Wang\* and R.H. Masland\* Vision Science Research Center, University of Alabama, Birmingham, AL 35294\*, The Institute of Neurological Sciences, University of Pennsylvania, Philadelphia PA 19104\*, Howard Hughes Medical Institute, Mass. General Hospital, Boston MA 02114\*.

Acetylcholine (ACh) is a transmitter in the retina that affects the response properties of many ganglion cells, including those that display directional selectivity. Three structural ( $\beta$ ) and eight ligand binding ( $\alpha$ ) subunits of neuronal nicotinic acetylcholine receptors (nAChRs) have been purified and antibodies have been raised against many of them. As part of a continuing effort to understand the cholinergic circuitry in the retina, we used an acetylcholine receptor monoclonal antibody (mAb210) and an antiserum against choline acetyltransferase (ChAT), to determine whether or not cholinergic amacrine cells express nAChRs. nAChR immunoreactive cells in the Inner Nuclear Layer (INL) were 7-14  $\mu\text{m}$  in diameter and were restricted to the innermost one or two tiers of cells, although occasional cells were found in the outer half of the INL. nAChR containing cells in the Ganglion Cell Layer (GCL) were 7-16  $\mu\text{m}$ . ChAT immunoreactivity was found in amacrine cells in the INL and the GCL. In the INL, the 90-95% of the cholinergic cells did not express nAChR immunoreactivity while 5-10% did show colocalization. In the GCL, at least 57% of the ChAT-positive cells, all within the central retina, expressed nAChRs. The percentages represent the lowest estimate of colocalization; a larger proportion of the cholinergic cells may express the nAChR subtype recognized by mAb210 or other nAChR subtypes. Thus, our observations support earlier ultrastructural findings that some cholinergic cells synapse on one another. Supported by EY07845 (K.T.K.), HHMI (R.H.M.) and NS11323 (J.M.L.).

**ZINC PRESERVES ION-SELECTIVITY AND GATING OF OUTWARDLY RECTIFYING CURRENT IN RETINAL GANGLION CELLS.** T. Tabata and A.T. Ishida\*. Section of Neurobiology, Physiology & Behavior, University of California, Davis, CA 95616.

Voltage-gated  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Ca}^{2+}$ , and mixed-cation currents have been identified in retinal ganglion cells of various species. Using whole-cell patch-clamp methods, we have found outwardly rectifying current ( $I_{\text{out}}$ ) in goldfish retinal ganglion cell somata after the above currents were blocked with tetrodotoxin, tetraethylammonium,  $\text{Co}^{2+}$ , and  $\text{Cs}^+$ , respectively. In perforated-patch mode,  $I_{\text{out}}$  activated at membrane potentials more positive than -50 mV, and deactivated at membrane potentials more negative than -60 mV. The amplitude of  $I_{\text{out}}$  declined with extracellular  $\text{Cl}^-$  concentration, and was also reduced by furosemide and DIDS. This  $I_{\text{out}}$  thus appeared to be largely, if not entirely, anionic. However, after repeated depolarizations in ruptured-patch mode,  $I_{\text{out}}$  showed less selectivity for anions over cations, and its gating kinetics changed irreversibly. Both of these changes could be impeded by including as little as 3-30 nM free  $\text{Zn}^{2+}$  in the ruptured-patch pipet solution. Under these conditions, with  $E_{\text{Cl}}$  set either to 0 mV or to -50 mV, the voltage-sensitivity of  $I_{\text{out}}$  resembled that measured in perforated-patch mode. These results indicate that retinal ganglion cells possess voltage-gated  $\text{Cl}^-$  current whose relative contribution to  $I_{\text{out}}$  depends directly or indirectly on intracellular levels of  $\text{Zn}^{2+}$  or similar divalent cations. Supported by NIH grant EY08120.

## METABOTROPIC GABA RECEPTORS ACT AS DISCRIMINATORS.

J. Zhang, G. Haiduczk\* and M. M. Slaughter. Departments of Biophysical Sciences, Physiology, and Ophthalmology. School of Medicine, State University of New York, Buffalo, NY 14214, USA.

The electrogenic properties of the baclofen-sensitive metabotropic GABA receptor were examined in the retinal slice preparation of the salamander, *Ambystoma tigrinum*. Whole cell recordings were obtained from neurons in the ganglion cell layer. Baclofen application activated a conductance that had a reversal potential near that of potassium. This current was not calcium dependent. The conductance was small, but represented a significant fraction of the resting conductance of ganglion cells. Baclofen also reduced a high voltage activated calcium conductance that was sensitive to  $\omega$ -conotoxin-GVIA, a N-type channel blocker. By down regulating this calcium current, baclofen also produced a reduction of the outward potassium current. The net consequence of these three conductances was that baclofen produced a small inhibitory shunt around the resting membrane potential of the ganglion cell, but a potentiating inward current at more positive potentials. In combination, these conductances would serve to suppress weak depolarizing synaptic currents while enhancing stronger synaptic currents. This was tested by injecting currents of different amplitudes into ganglion cells under current clamp. As predicted, the voltage responses to 15pA currents were suppressed, but the responses to stronger currents (>30pA) were enhanced by baclofen. Therefore, baclofen-sensitive metabotropic GABA receptors function as discriminators, accentuating the differences between the responses to weak and strong synaptic inputs. In the retina, this serves to differentiate the large, phasic synaptic inputs from the smaller, tonic inputs to ganglion cells.

## SCANNING MICROINTERFEROMETRY DEMONSTRATES LONGITUDINAL REFRACTIVE INDEX GRADIENTS IN SUNFISH DOUBLE CONES M. P. Rowe, N. Engheta, S. S. Easter, Jr., J. M. Corless, and E. N. Pugh, Jr.\*

Cone inner segments/outer segments (CIS-COSs) were isolated from the retina of the green sunfish (*Lepomis cyanellus*). CIS-COSs were scanned with a microinterferometer capable of measuring optical path differences (OPD) with a precision of 6 nm. The scanning beam had a diameter of approximately 0.3  $\mu$ m, and moved in approximately 0.2  $\mu$ m steps between measurements. Cones were scanned perpendicular to the direction of in vivo light propagation. Such measurements have allowed us to characterize refractive index distributions in single cone CIS-COSs (Rowe, et al, JOA A, in press). The refractive indices of double cone CISs cannot be easily calculated from OPD measurements, because unlike single cone CISs they do not have circular cross-sections. Nevertheless, it is possible to make quantitative assessments of the variation in refractive index within a double cone CIS by comparing variations in OPD to variations in double cone size and shape as indicated by transmission electron microscope (TEM) images of tangentially sectioned sunfish retinas. Our analysis indicates that sunfish double cone CISs exhibit longitudinal refractive index gradients qualitatively similar to those measured in single cone CISs and inferred from examination of the electron density of double cones examined via TEM images of radially sectioned sunfish retinas. Double cone COSs can be measured much as those of single cone CIS-COSs (because they do have circular cross-sections), and are found to have refractive indices which are relatively constant (around 1.39) along their longitudinal axes. Our work shows that to accurately characterize waveguiding in real sunfish photoreceptors, future models will need to incorporate refractive index gradients.

## THE PRECISION OF RETINAL SPIKE TRAINS. Michael J. Berry\*, David K. Warland, and Markus Meister. MCB Department, Harvard University, Cambridge, MA 02138.

The reproducibility of retinal responses is a fundamental characteristic of the neural code that carries visual information from the eye to the brain. If retinal spike trains are highly deterministic, then a precise visual message can be attached to each spike. We have measured the reproducibility of ganglion cell spike trains, recorded extracellularly from isolated retinas using a multi-electrode array. The stimulus consisted of diffuse random flicker with intensity values chosen randomly every 30 msec from a Gaussian distribution of fixed mean (photopic range) and root-mean-square contrast (35%). The same 20 sec flicker sequence was repeated 100 times.

In both tiger salamander and rabbit retinas, ganglion cells fired action potentials only at sharply defined times. Both the timing and the number of spikes produced during such a firing event were highly reproducible: trial-to-trial timing jitter was as low as 2 msec, and the variance in the spike number up to 30 times smaller than the mean. As a result, the response of ganglion cells is not adequately described by a time-varying firing rate. At lower contrasts (2.3%) the firing events had high timing precision but poor precision of spike number. This suggests that the timing of individual action potentials conveys more information about the visual stimulus than the number of spikes. A calculation of information transmission rates confirms this conclusion.

## PHOTOPIGMENTS IN REGENERATED RETINA

D.A. Cameron\*, M.C. Cornwall, and E.F. MacNichol, Jr. Department of Physiology, Boston University Medical School, Boston, MA 02118

Adult fish retinas can regenerate following injury. We have performed a microspectrophotometric analysis of rod and cone photoreceptors in normal and regenerated retinas of adult green sunfish (*Lepomis cyanellus*), in order to determine if the spectral characteristics of regenerated photoreceptors are similar to those of normal photoreceptors. In normal retinas all photopigments are apparently dehydrorretinal-based, with all members of double cones containing a long-wavelength pigment ( $\lambda_{max} = 620 \pm 1$  nm,  $n = 45$ ), all single cones containing a middle-wavelength pigment ( $\lambda_{max} = 532 \pm 1$  nm,  $n = 24$ ), and all rods containing a different middle-wavelength pigment ( $\lambda_{max} = 527 \pm 1$  nm,  $n = 21$ ), consistent with an earlier report (Dearry & Barlow, 1987, *J Gen Physiol* 89,745). Photoreceptors derived from patches of regenerated retina six weeks following injury have also been examined. The pigments in the regenerated photoreceptors were not significantly different from normal: double cone members,  $\lambda_{max} = 622 \pm 2$  nm ( $n = 9$ ); single cones,  $\lambda_{max} = 533 \pm 1$  nm ( $n = 8$ ); rods,  $\lambda_{max} = 526 \pm 2$  nm ( $n = 14$ ). There has been no evidence for any short-wavelength or ultraviolet photopigments in either normal or regenerated retina. These results are consistent with the hypothesis that the spectral, and perhaps physiological, characteristics of regenerated photoreceptors are similar to those of photoreceptors in normal retina.

## CODING VISUAL SCENES WITH ENSEMBLES OF RETINAL NEURONS

C.L. Passaglia\*, F.A. Dodge, and R.B. Barlow

Marine Biology Laboratory, Woods Hole, MA. Syracuse University and SUNY Health Science Center, Syracuse, NY 13210.

Many animals use their eyes to seek food, pursue mates, and avoid predators in a visually-rich environment. To survive they must process visual information efficiently. Using *Limulus* as a model processing system, we recorded the animal's visual world with a videocamera mounted next to the lateral eye and simultaneously monitored the activity of a single optic nerve fiber with an underwater microsection electrode. We then computed the eye's response to the underwater scenes by driving a cell-based computer model of the eye with digitized video frames. The model computes the spike rates of all optic nerve fibers and displays them as a sequence of grey-scale images. The pixel array of these "neural images" represents the retinal mosaic of neurons. We verified the model calculations with the response of the recorded single optic nerve fiber.

We found that behaviorally-important underwater objects, i.e. other horseshoe crabs, strongly modulate the computed optic nerve responses in the neural images. Important stimulus characteristics are object size, contrast, and motion as well as natural light fluctuations caused by overhead waves that highlight reflective crab-sized objects. Information about objects appears to be encoded in the coherent activity of a dynamic ensemble of neighboring retinal neurons.

## MECHANISMS OF CONCERTED FIRING AMONG RETINAL GANGLION CELLS.

I. H. Brivanlou, D. K. Warland\*, and M. Meister. MCB Dept., Harvard University, Cambridge, MA 02138.

Parallel observation of spike trains from many retinal ganglion cells has shown that nearby neurons often fire in near synchrony, as evidenced by a strong central peak in their cross-correlograms. We have investigated the circuit mechanisms underlying this concerted firing in the retina of the tiger salamander. During both spontaneous and light-driven activity, different ganglion cell pairs showed 3 types of peaks in the cross-correlogram: broad (100-200 ms width), medium (20-40 ms) and narrow (< 2 ms). When vesicular transmitter release was blocked with Cd<sup>2+</sup>, light responses were abolished. The broad correlations disappeared, but medium and narrow correlations persisted. Occasionally, waves of activity propagated across the retina at high speeds of 20 mm/s.

We propose that nearby ganglion cells share input from a slow neuron via chemical synapses (broad correlations), excitation from fast non-spiking neurons via electrical junctions (medium), and input from spiking neurons via electrical junctions (narrow). Electrical coupling among ganglion cells appears strong enough to sustain propagating bursts under Cd<sup>2+</sup>-block, which may normally be suppressed by a sustained inhibitory input.

SPIKE BURSTS IN VISUAL RESPONSES OF RETINAL GANGLION CELLS. S.M. Smirnakis<sup>1</sup>, D.K. Warland<sup>2</sup>, M.J. Berry<sup>2</sup>, and M. Meister<sup>2,1</sup> Physics Dept. and Medical School, Harvard University; <sup>2</sup>MCB Dept., Harvard University.

How much does the temporal fine structure within a spike train contribute to the neural code? We stimulated isolated tiger salamander retinae with diffuse flicker and recorded ganglion cell spike trains extracellularly with a multi-electrode array. The light intensity was chosen randomly every 30 ms from a Gaussian distribution with photopic mean intensity and 35% root-mean-square contrast. Ganglion cells tended to fire tight bursts with a variable number of spikes. Within a burst, action potentials were separated by a few milliseconds, little more than the cell's refractory period. By contrast, different bursts were separated by several hundred milliseconds. By correlating the stimulus with bursts of different sizes, we found that bursts had qualitatively different visual response properties from those of single spikes. Using a linear decoding algorithm (Bialek *et al.*, *Science* 252, 1854) we estimated and compared the information individual spike trains transmit about the stimulus, before and after identifying the bursts as distinct symbols. If higher visual centers could distinguish between bursts of different sizes rather than treating each spike equally, they could extract 5-50% more information per ganglion cell.

## 199.14

MULTINEURONAL FIRING PATTERNS AMONG RETINAL GANGLION CELLS CARRY DISTINCT VISUAL MESSAGES. M.J. Schnitzer<sup>1</sup>, and M. Meister<sup>2</sup> <sup>1</sup>Depts. of Physics and Molecular Biology, Princeton University, Princeton, NJ 08544, and <sup>2</sup>MCB Dept., Harvard University, Cambridge, MA 02138.

Large neuronal assemblies potentially make use of distributed coding schemes, in which neural messages are conveyed by the simultaneous activity of multiple neurons. In such codes, messages cannot be deciphered by examining the output of single neurons. To determine whether such a coding scheme prevails in the retina, we used a multielectrode array to record the simultaneous activity of 40-60 tiger salamander ganglion cells. Within this population, groups of up to seven cells fired patterns of synchronous spikes with <25 ms delay. This form of concerted activity comprised 30-45% of all spikes recorded in darkness or with a flickering checkerboard stimulus, and over 90% of the spikes from some individual cells. The visual receptive fields of the synchronous firing patterns could not be predicted from those of individual ganglion cells, suggesting that the visual messages conveyed by spike groups carried novel information. It is proposed that retinal ganglion cells use fine structure in their spike trains – on time scales shorter than the ~100 ms photoreceptor integration time – to transmit additional visual messages through the optic nerve bottleneck. Supported by grants to M.M. from ONR and HFSP.

## POSTSYNAPTIC MECHANISMS: CHEMICAL EXCITABILITY

## 200.1

SYNAPTIC INPUTS LIMIT THE PROPAGATION OF SOMATIC ACTION POTENTIALS (APs) INTO THE DENDRITES OF NEOCORTICAL PYRAMIDAL NEURONS IN VIVO. D. Paré<sup>\*</sup>, E. I. Lang and A. Destexhe. Dept. of Physiol., Sch. of Med., Laval Univ., Quebec, Canada G1K 7P4.

To determine if the back-propagation of APs in dendrites occurs *in vivo*, we performed intracellular recordings of layer V pyramidal neurons located within 2 mm of an electrode array that allowed the delivery of electrical stimuli at various depths. Recording pipettes contained K-ac or Cs-ac.

The shape of APs varied depending on whether they were triggered synaptically or by current injection. In comparison to current-evoked spikes, orthodromic APs elicited by intracortical stimuli were reduced in amplitude and duration. The magnitude of this reduction was correlated to the stimulation depth with superficial and deep cortical stimuli producing the smallest and largest decrements, respectively. For instance, in Cs-filled cells, spike amplitudes and duration could be reduced by as much as 30% and 90%, respectively. This phenomenon resulted from the fact that stimuli applied at different depths preferentially activated afferents ending at corresponding dendritic levels as demonstrated by shifts in IPSP reversals and related  $R_{IN}$  decreases as a function of the stimulation depth.

These results were replicated in a computational model based on recent data on the distribution of  $Na^+$  channels in the dendrites, soma and axon initial segment of layer V pyramidal cells. Simulated proximal IPSPs were the most effective in preventing the activation of dendritic  $Na^+$  channels by current-evoked spikes. Collectively, these findings suggest that the somatic spike amplitude is critically dependent on the participation of dendritic  $Na^+$  channels and that synaptic inputs impose significant limitations on the retrograde propagation of action potentials in the dendritic tree. Supported by MRC, FRSQ and NINDS.

## 200.3

PATCH CLAMP RECORDINGS OF SYNAPTIC CURRENTS FROM SYMPATHETIC NEURONS DURING NATURAL REFLEX ACTIVITY. V. I. Skok, G. Farrugia, L. G. Ermilov, S. M. Miller and J. H. Szurszewski<sup>\*</sup>. Department of Physiology and Biophysics, Mayo Clinic and Mayo Foundation, Rochester, MN, 55905, USA, and <sup>†</sup>Department of Autonomic Nervous System Physiology, Bogomoletz Institute of Physiology, Kiev 24, Ukraine.

Fast excitatory postsynaptic currents (e.p.s.c.s) elicited by distension of the colonic wall or by electrical stimulation of afferent nerve fibers from the colon were recorded from the neurons of mouse superior mesenteric ganglion (SMG) at 20°C with the whole cell patch clamp recording method. The e.p.s.c.s reversed at -3.5 mV and were abolished by 100  $\mu$ M hexamethonium in voltage-dependent fashion, indicating that they were mediated by nicotinic acetylcholine receptors (nAChRs). Analysis of the amplitudes and time courses of the e.p.s.c.s evoked by colonic wall distension suggests that at least 25 afferent nerve fibers converged on the same SMG neuron, that the e.p.s.c.s decay phase included two main kinetic components with mean exponentials of 7.8 and 14.5 msec, and, less commonly, longer exponentials ranging up to 70 msec, at -70 mV holding potential. These results provide the first recordings of whole cell currents of single sympathetic ganglion neurons during natural synaptic reflex activity. They indicate that different colonic mechanosensory afferent nerve fibers can activate nAChR channels with markedly different kinetic characteristics. Supported by NIH grant DK17632.

## 200.2

THE FUNCTION OF BACKGROUND SYNAPTIC INPUT IN CEREBELLAR PURKINJE CELLS EXPLORED WITH DYNAMIC CURRENT CLAMPING. D. Jaeger<sup>\*</sup> and J.M. Bower, Div. Biology 216-76, Caltech, Pasadena, CA 91125

Dual whole cell recordings of single Purkinje cell somata were obtained in rat slices and artificial synaptic input was injected using dynamic current clamping. The artificial synaptic conductances we employed consisted of mixed excitatory and inhibitory inputs that were obtained from simulations with a realistic Purkinje cell model. Synaptic conductances from all excitatory and inhibitory synapses in the model were summed and stored in a file. The large number of synapses impinging on a single Purkinje cell and the assumed background of random activity in each of these inputs resulted in a considerable level of continuous synaptic conductance. The appropriate current during whole cell recording resulting from these conductance waveforms was calculated with a refresh rate of 10 KHz using a reversal potential of 0 mV for excitation and -70 mV for inhibition. The use of a separate electrode for injecting current eliminated interference between transients in injected current and recorded membrane potential that is typical for single electrode configurations.

*In vitro* recordings using this type of artificial random background input resulted in a pattern of somatic spiking that was very similar to recordings obtained *in vivo*. Thus, emulating a background of synaptic input transformed the bursty spontaneous activity of Purkinje cells typically seen *in vitro* into an ongoing irregular spike pattern characteristic of *in vivo* recordings. The total injected current was negative during spiking, as predicted from a previous modeling study. This finding indicates that intrinsic Purkinje cell currents are sufficient to keep the cell depolarized and that synaptic input operates as a variable current sink. When the same input pattern was repeated multiple times, we found that a number of spikes was timed accurately within 1 ms for each stimulation, but that these spikes did not result from distinct excitatory inputs. These results suggest a complex input-output function for the cerebellar Purkinje cell. Supported by NIH ns-31378-04, HFSP and the Sloan Foundation

## 200.4

DOES ACTIVE UPTAKE LIMIT SPILL-OVER OF GLUTAMATE ONTO EXTRASYNAPTIC NMDA RECEPTORS IN THE HIPPOCAMPUS? Fredrik Asztely<sup>\*</sup>, Gül Erdemil & Dimitri M. Kullmann, Dept. Clinical Neurology, Institute of Neurology, Queen Square, London WC1N 3BG, United Kingdom

We have recently proposed that NMDA receptors on a CA1 pyramidal cell can sense glutamate released from terminals which are presynaptic to other cells (Kullmann & Asztely; Erdemil & Kullmann; Soc. Neurosci. Abs. 1996). This could explain why 'pure' NMDA receptor-mediated EPSCs can be elicited with minimal stimulation, and why there is a discrepancy between the amplitude variability of AMPA and NMDA components of population EPSCs: the statistic  $1/CV^2$  is larger for the NMDA component, implying a greater quantal content, because NMDA receptors sample more release sites than AMPA receptors. Does active uptake of glutamate limit the extent of activation of extrasynaptic NMDA receptors? Evidence for this includes the observation that the non-competitive uptake blocker dihydrokainate can increase the amplitude of NMDA receptor-mediated EPSCs (Hestrin *et al.*, Neuron 5: 247, 1990). Since the  $Q_{10}$  for glutamate uptake is greater than that for diffusion, there should be less spill-over at higher temperatures. We therefore measured  $1/CV^2$  for both AMPA and NMDA components in CA1 cells in guinea pig hippocampal slices at different temperatures, using methods described by Kullmann (1994, Neuron 12: 1111). The average ratio  $[1/CV^2 \text{ NMDA}] / [1/CV^2 \text{ AMPA}]$  was  $2.1 \pm 0.1$  (S.E.M.) at 20 - 24 °C ( $n = 42$ ) and  $1.4 \pm 0.1$  at 34 - 36 °C ( $n = 18$ ). This is compatible with a major role for glutamate uptake in limiting the spatial extent of NMDA receptor activation, and implies that spill-over may be much less prominent at physiological than at room temperatures. To control for other effects of temperature on glutamate release and receptors, we are currently comparing the relative frequency of transmission failures with minimal stimulation in cells held at negative and positive membrane potentials, at the different temperatures. (Supported by the MRC and the Wellcome Trust)

## 200.5

**EVIDENCE FOR AMPA RECEPTOR DESENSITIZATION AT A CENTRAL SYNAPSE.** T.S. Otis\* & L.O. Trussell. Dept. of Neurophysiology, University of Wisconsin Medical School, Madison WI 53706.

The AMPA subtype of glutamate receptor desensitizes within milliseconds upon exposure to glutamate (GLU). Even so, no direct evidence demonstrates that desensitization limits receptor availability during physiological synaptic activity. Using whole cell recordings from chick cochlear nucleus neurons (nucleus magnocellularis or NM) in brain slices, we show with 3 independent approaches a rapidly developing, slowly recovering ( $\tau > 30$  ms), postsynaptic depression following activation of single presynaptic inputs. 1) Quantal current size (peak mEPSC amplitude) is transiently reduced following evoked EPSCs in SrCl<sub>2</sub>. 2) GLU released during an EPSC "cross desensitizes" the steady state current activated by an exogenously-applied, non-desensitizing agonist. 3) Currents activated by UV photolysis of caged GLU are depressed following an EPSC. These three methods uncover ~50% postsynaptic depression at 10 ms after the EPSC and a time constant for recovery ranging from 50-100 ms. Furthermore, the resulting synaptic depression is synapse specific, as two neighboring synapses on the same cell body strongly depress themselves, but do not depress one another (intervals from 10-100 ms).

In outside-out patches, the recovery (in the absence of GLU) of the response to a second of a pair of rapidly-applied GLU pulses occurs with  $\tau = 16$  ms. We hypothesize that recovery from postsynaptic depression in NM is delayed by the previously described slow removal ( $\tau \sim 40$  ms) of tens of micromolar GLU from the calyceal synaptic cleft (*J. Neurosci.* 16:1634-1644). AMPA receptors cannot recover from desensitization until [GLU] is cleared below  $\mu$ M levels, accomplished in part by GLU transporters. Clearance is slowed with increasing quantal content, thus the magnitude and rate of recovery from synaptic depression will vary according to recent activity. Lastly, these results suggest a potential locus for modulation of short-term depression. Supported by Grants GM16300 (T.S.O.) and NS28901 (L.O.T.).

## 200.7

**Photostimulation using caged glutamate reveals differential distribution of glutamate receptors on rat neocortical neurons.**

H.-U. Dodt\*, A. Frick, T. Rütger and W. Zieglgänsberger. Max-Planck-Institute of Psychiatry, Clinical Institute, Clinical Neuropharmacology, 80804 München, FRG.

A combination of infrared videomicroscopy and photostimulation using caged glutamate was used to investigate the distribution of excitatory amino acid receptors on the soma and apical dendrite of neocortical layer V pyramidal neurons in brain slices. Both conventional and laser light sources were used for the localised stimulation of neocortical neurons visualized by infrared videomicroscopy. Responses resulting from L-glutamate released locally by photolysis, were recorded somatically with a patch pipette in the whole-cell current-clamp mode.

Neocortical slices were superfused with medium containing 1  $\mu$ M TTX and 1 mM caged glutamate. UV-irradiation, provided by a mercury burner, was used to release L-glutamate by photolysis locally ( $\sim 20$   $\mu$ m spot diameter) at the soma and along the apical dendrite. After the selective glutamate antagonists APV (25  $\mu$ M, n=10) or CNQX (2.5  $\mu$ M, n=8) were added to the perfusion medium, stimulation was repeated at the same sites. Blockade of the NMDA receptors by APV was most effective at somatic and proximal dendritic sites. At a distance of 350  $\mu$ m from the soma the decrease induced by APV was only 38% compared with the soma (=100%). Conversely, CNQX reduced glutamate-evoked responses at this dendritic site by 143%. This signifies a higher contribution of AMPA-mediated currents at remote dendritic regions.

By uncaging L-glutamate with a UV-Laser, we were able to stimulate areas in the 1  $\mu$ m range on the neuronal surface. Glutamate sensitivity was spatially not uniform along the dendrite. In fact, discrete "hot spots" of glutamate sensitivity could be demonstrated by laser photostimulation. Laser stimulation was also used to activate neighbouring pyramidal neurons. Synaptic connections originating from neurons as remote as 900  $\mu$ m were found. The data suggest that uncaging of excitatory amino acids by means of laser light allows, besides the detailed analysis of the distribution of neurotransmitter receptors, the characterization of neuronal circuits. Supported by a grant of the BMBF.

## 200.9

**MUSCARINIC LTP DEFICIENCY IN AGED RATS.** J. M. Auerbach, M. C.

Bundman\* and M. Segal. Neurobiology, The Weizmann Institute 76100 Israel.

We have previously shown two opposing, concentration-dependent effects of the muscarinic agonist carbachol (CCh) on reactivity to afferent stimulation in area CA1 of the hippocampal slice in young adult rats (Auerbach and Segal, *J. Physiol.* 492:479, 1996). CCh (0.5  $\mu$ M) induces muscarinic long-term potentiation (LTP<sub>m</sub>) whereas  $\geq 5.0$   $\mu$ M CCh causes a reversible depression of stratum radiatum EPSP slope. Aged animals are known to be slightly deficient in several cholinergic parameters, as well as in learning and memory. Here we compared slices from aged animals (24-27 months) to those from young animals (2 months), in their ability to express tetanic and muscarinic LTP.

In response to tetanic stimulation (100Hz, 1s), old slices showed post-tetanic potentiation (PTP) indistinguishable from that of young slices. A difference was seen, however, in the maintenance phase of LTP. Forty minutes after the tetanus, EPSP slopes recorded from young slices were stable at  $65.4 \pm 7.8\%$  above baseline whereas those from aged slices decayed to a level  $32 \pm 7.1\%$  above baseline. In addition, an age-dependent difference was found in the dose-response of the slices to CCh. While slices from aged animals displayed a depression of EPSP slope in response to high CCh concentrations similar to that of young animals, slices from these animals completely lacked LTP<sub>m</sub>.

Furthermore, we found that 0.0001% H<sub>2</sub>O<sub>2</sub> blocked LTP<sub>m</sub> in young slices, but had no effect either on baseline EPSP slope or on response to high CCh concentrations. We also found that the addition of catalase, which breaks down H<sub>2</sub>O<sub>2</sub> to water and oxygen, restored LTP<sub>m</sub> in slices from aged animals. These findings indicate that cognitive deficits in aged animals and humans, as well as dementias such as Alzheimer's Disease, may be based on an enzyme imbalance leading to accumulation of H<sub>2</sub>O<sub>2</sub> in the brain. The mechanisms associated with the action of H<sub>2</sub>O<sub>2</sub> are currently being investigated. Supported by a grant from the Minerva Foundation.

## 200.6

**TRANSPORTERS BUFFER SYNAPTICALLY RELEASED GLUTAMATE ON A MILLISECOND TIME SCALE.** J. S. Diamond\* and C. E. Jahr. Vollum Institute, Portland, OR 97201.

Recent studies suggest that synaptically released glutamate remains in the cleft only briefly ( $\tau \sim 1$  ms; Clements, et al., 1992); glutamate transporters have been proposed to assist in the rapid clearance of free transmitter by binding glutamate in the first ms following release (Tong and Jahr, 1994). Others suggest that a large fraction of glutamate is cleared via transport  $>15$  ms after release (Mennerick and Zorumski, 1995). We have estimated the effect of uptake blockers on the size and shape of the synaptic glutamate transient in cultured CA1 hippocampal synapses using the rapidly dissociating AMPA receptor competitive antagonist kynurenic acid (KYN) and a kinetic model of AMPA receptors. Because KYN is displaced from AMPA receptors by glutamate during a synaptic event, the block by KYN is very sensitive to glutamate concentration. The relatively fast kinetics of AMPA receptors and KYN dissociation ( $k_{off} \sim 5$  ms<sup>-1</sup>) allowed us to estimate the time course of glutamate in the cleft with greater temporal resolution than previous approaches using NMDA receptors (Clements, et al., 1992). A glutamate transient was chosen so that the model replicated the dose-inhibition of the AMPA receptor EPSC by KYN and also the slowing of the mEPSC rise time observed in 100  $\mu$ M KYN. A good fit to the data was obtained with a glutamate transient that decayed with an exponential time constant of 400  $\mu$ s from a peak concentration of 1.5 mM. In the continuous presence of 100  $\mu$ M KYN, blocking glutamate transporters with three- $\beta$ -hydroxyaspartic acid (300  $\mu$ M) further slowed the mEPSC rise time, suggesting that transporters help shape even the earliest components of the glutamate transient and that diffusion and transporters clear glutamate at similar rates. These results are also consistent with the idea that, independent of transporters, removal of glutamate from the cleft is slower than predicted by free diffusion alone (Eccles and Jaeger, 1958; Wahl, et al., 1996).

**PRE- AND POSTSYNAPTIC FACTORS DETERMINE SYNAPTIC INTEGRATION OF GLUTAMATE-MEDIATED EPSPS IN GABAergic INTERNEURONS OF THE HIPPOCAMPUS.** J.R.P. Geiger, J. Lübke, M. Frotscher, A. Roth and P. Jonas\*. Physiologisches Institut und Anatomisches Institut der Universität Freiburg, D-79104 Freiburg and Max-Planck-Institut für medizinische Forschung, D-69120 Heidelberg, Germany

To investigate excitatory synaptic transmission of glutamatergic principal neurons onto GABAergic interneurons, we performed whole cell patch clamp recordings from pairs of synaptically coupled granule cells (GCs) and basket cells (BCs) in the dentate gyrus of hippocampal slices (at 32 °C). At -70 mV, the GC-BC evoked EPSCs were blocked by 5  $\mu$ M CNQX, indicating that they were mediated by AMPA-type glutamate receptors. GC-BC EPSCs and EPSPs showed a rapid time-course. The EPSCs had a 20 - 80 % rise time of  $\approx 100$   $\mu$ s and a decay time constant of  $563 \pm 78$   $\mu$ s (range 200 - 940  $\mu$ s, n = 8). The EPSPs showed a rise time of  $\approx 500$   $\mu$ s and a decay time constant of  $3.3 \pm 1.0$  ms (n = 7). Hence, EPSCs and EPSPs in the BC were about 5-fold faster than those in hippocampal principal neurons. EPSCs and EPSPs showed a marked paired-pulse depression (PPD); the amplitude of the second EPSC was  $44 \pm 9\%$  of that of the first (20 ms interpulse interval). The number of failures in the second response was higher than that in the first, indicating that the PPD was of presynaptic origin. Light microscopical analysis of synaptically coupled pairs of neurons filled with biocytin indicated that 2-5 synaptic contacts on basal dendrites of BCs close to the soma ( $<100$   $\mu$ m, n = 6) underlie the GC-BC synaptic event. Simulations of EPSPs based on a detailed passive cable model of the BC show that the time course of the EPSP is determined by the kinetics of the postsynaptic conductance change. When the conductance decay time constant was between 250  $\mu$ s and 1.5 ms, the simulated EPSP decay time constant varied between 3.8 and 7.0 ms. Due to the marked PPD and the very rapid time course of the postsynaptic conductance change, EPSPs caused by single GC activity do not exhibit summation. This suggests that specific pre- and postsynaptic properties of the GC-BC synapse favor coincidence detection of excitatory synaptic events by BCs. Funded by the DFG (SFB 505/C5).

## 201.1

**POSITIVE REGULATION OF CRH-BINDING PROTEIN PROMOTER ACTIVITY BY CRH.** A.F. Seasholtz\* and D.N. Cortright, Department of Biological Chemistry and Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Corticotropin-releasing hormone (CRH) is the major hypothalamic releasing factor in the mammalian stress response. A 37 kD CRH-binding protein (CRH-BP) distinct from the CRH receptor has been shown to neutralize the ACTH-releasing activity of CRH *in vitro*. The CRH-BP has been localized to a variety of brain regions and to corticotroph cells in the anterior pituitary, suggesting a role for this binding protein as a modulator of the endocrine and synaptic activities of CRH. In an effort to further elucidate the physiological role of the CRH-BP, we have examined the regulation of CRH-BP gene promoter activity by cAMP and CRH. A 3.5 kb fragment of the rat CRH-BP gene containing 3.4 kb of 5' flanking DNA and 66 bp of the 5' untranslated sequences was fused to the chloramphenicol acetyltransferase (CAT) reporter gene and transiently transfected into COS-7 and  $\alpha$ -TSH cells. High basal levels of reporter activity were observed in both cell lines and 24 hour treatment with forskolin/IBMX (10  $\mu$ M/250  $\mu$ M) increased activity 11-fold in COS cells and greater than 300-fold in  $\alpha$ -TSH cells. Co-transfection of  $\alpha$ -TSH cells with the CRH-BP-reporter construct and an expression construct for the CRH receptor showed a time- and concentration-dependent positive regulation of CRH-BP-reporter activity in the presence of CRH. Twelve hours of treatment with 20 nM CRH alone increased reporter activity by 13-fold, while treatment with CRH/IBMX increased activity by greater than 350-fold. These results suggest that CRH-BP gene expression is positively regulated by CRH and cAMP. (NIH DK42730)

**Demonstration of a novel receptor mediating the stress effects of central Neuropeptide Y.**

Small, C.J., Meenan, K., Morgan, D.G.A., Heath, M.M., O'Shea, D\*, Gunn, L., Taylor, G.M., Choi, S.J., Smith, D.M., Ghatge, M.A., and Bloom, S.R.

Division of Endocrinology and Metabolic Medicine, Department of Medicine, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0NN, UK.

Hypothalamic neuropeptide Y (NPY) is clearly implicated in the regulation of feeding, the stress response, growth and sexual function. NPY modulates the stress response by stimulation of adrenocorticotrophic hormone (ACTH) secretion via hypothalamic corticotrophin releasing hormone (CRH). Of the four recognised NPY receptors (Y1-Y4), it is not known which, if any mediate the activation of the hypothalamic pituitary adrenal (HPA) axis. We administered Intracerebroventricular (ICV) NPY and analogues of NPY which have a reduced affinity for the Y1 and Y4 receptors (NPY(13-36)), the Y2 receptor ([Pro<sup>34</sup>]NPY) and the Y3 receptor (PYY) and measured plasma ACTH. All NPY fragments studied caused a significant rise in plasma ACTH compared to saline or a peptide control (random sequence of 31 amino acids) at a 0.72nmol dose (F(7,42)=3.7; p<0.005) and 7.2nmol dose (F(7,36)=5.4; p<0.001). In addition the novel NPY fragment [Pro<sup>34</sup>]NPY(13-36), which binds with low affinity to the Y1 & Y2 receptors, did not stimulate two hour food intake (NPY 2.4nmol 5.6  $\pm$  0.6g, [Pro<sup>34</sup>]NPY(13-36) 50nmol 0.7  $\pm$  0.3g, saline 0.8  $\pm$  0.2g) but was as effective as NPY at stimulating ACTH release. These studies demonstrate a novel NPY receptor mediating ACTH secretion and indicate that this receptor is functionally distinct from the previously recognised NPY receptors, and the NPY receptor which mediates feeding.

**ADRENAL SPLANCHNIC DENERVATION DECREASES PLASMA CORTICOSTERONE RESPONSES TO WATER DEPRIVATION IN RATS** W.C. Engeland\*, L.M. Rogers, D.A. Fitzgerald and J.T. Walworth Departments of Surgery and of Cell Biology / Neuroanatomy, University of Minnesota, Minneapolis MN 55455, USA

Chronic volume depletion produced by water deprivation (WD) increases sympathetic activity and plasma corticosterone (B). Studies were done to determine whether the plasma B response results from changes in plasma ACTH or in sympathetic input to the adrenal. To determine pituitary-adrenal responses to volume depletion, plasma ACTH and B were measured in rats at 24 or 48h after WD or ad lib water. Both plasma ACTH and B were increased after 24 and 48h of WD. To determine whether adrenal innervation was required for the response, rats were unilaterally adrenalectomized, allowed to recover and underwent thoracic splanchnicectomy (SPLNX) or sham SPLNX (INTACT). After 10 days, rats were WD or hydrated for 48h. Plasma ACTH and B increased after WD in SPLNX and INTACT rats; however, the B response was reduced in SPLNX vs INTACT rats. To determine the possible adrenal site affected by SPLNX, adrenals were examined for differences in steroidogenic enzyme mRNA using *in situ* hybridization. Adrenals sections were hybridized with <sup>35</sup>S-labeled oligonucleotide probes, exposed to film, and autorads were scanned and calibrated to a density scale. In response to WD, expression of cytochrome P450 11 $\beta$ -hydroxylase, but not 3 $\beta$ -hydroxysteroid dehydrogenase mRNA was increased; however, no differences were found between SPLNX and INTACT adrenals. These findings show that splanchnic nerves contribute to the plasma B response to WD, but the adrenocortical mechanism affected is unknown. Supported by NSF IBN-9319097.

## 201.2

**STEROID-INDEPENDENT REGULATION OF GLUCOCORTICOID RECEPTOR FUNCTION** C.M. Pariente\*, B.D. Pearce, T.L. Pisell, A.H. Miller, Emory Univ. Sch. of Med., Atlanta, GA 30322.

Data has indicated that glucocorticoid receptor (GR) expression and function can be regulated by a number of factors via steroid hormone-independent mechanisms. Interestingly, these pathways may be involved in the glucocorticoid receptor dysregulation believed to underlie the hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis found in several neuropsychiatric disorders. For example, in vivo and in vitro treatment with the pro-inflammatory cytokine, IL-1, can induce resistance to the effects of glucocorticoid hormones, while antidepressants have been shown to both upregulate GR expression in the brain and increase glucocorticoid-mediated negative feedback on the HPA axis. Our laboratory is currently examining the in vitro effects of these two modulators of the GR. Mouse fibroblasts (L929 cells) were pre-incubated with IL-1 $\alpha$  (1-1000 U/ml) or the antidepressant, desmethylimipramine (DMI), (0.1-10  $\mu$ M) for 24 hours. Cells were then exposed to the synthetic glucocorticoid hormone, dexamethasone (10 nM), for an additional 90 minutes. Translocation of the GR from the cytoplasm to the nucleus was evaluated using immunofluorescent staining of the GR and a cytosolic radioligand binding assay. In addition, GR-mediated gene transcription was measured by means of L929 cells transfected with a CAT reporter gene behind a glucocorticoid response element. IL-1 $\alpha$  (1000 U/ml) was found to significantly attenuate both dexamethasone-induced GR translocation and GR-mediated gene transcription without affecting cytosolic binding. In contrast, DMI (10  $\mu$ M) was found to facilitate GR translocation from the cytoplasm to the nucleus and to decrease cytosolic receptor binding. We suggest that HPA axis function and dysfunction during disorders involving the neuroendocrine and immune systems may be related to steroid-independent mechanisms of GR regulation. ## 201.4

**REGULATION OF GLUTAMIC ACID DECARBOXYLASE mRNA IN CENTRAL STRESS CIRCUITRY.** G.L. Bowers, W.E. Cullinan\* and J.P. Herman, Dept. of Anatomy and Neurobiology, Univ. of Kentucky Medical Center, Lexington, KY 40536-0084, and Dept. of Basic Health Sciences, Marquette Univ., Milwaukee, WI 53233.

$\gamma$ -amino butyric acid (GABA) plays a major inhibitory role in neuronal regulation of the hypothalamo-pituitary-adrenocortical (HPA) axis. Glutamic acid decarboxylase (GAD), the precursor enzyme for GABA, exists in two isoforms (GAD 65 and 67). Both are present in areas containing HPA-relevant GABAergic neurons. The present studies examined regulation of GAD 65 and 67 mRNA following exposure to acute restraint or a 14-day chronic variable-stressor paradigm. GAD mRNA was analyzed in HPA regulatory regions projecting to the paraventricular nucleus (PVN), including the bed nucleus of the stria terminalis (BST), preoptic area (POA), and hypothalamus, and in the hippocampal formation. Increased expression of both GAD 65 and 67 mRNA was observed in CA1 and dentate gyrus (DG) and in the anterior dorsal (AD) and anterior medial (AM) regions of the BST sixty minutes following stress. Up-regulation of GAD 67 mRNA also occurred in the arcuate (ARC) and dorsomedial (DMH) nuclei of the hypothalamus, and the medial POA. The 14-day chronic variable-stressor paradigm yielded increased GAD 65 and 67 mRNA expression in the AD and AM regions of the BST and medial POA. GAD 65 mRNA up-regulation was also observed in the anterior hypothalamic nucleus, DMH, and suprachiasmatic nucleus (SCN), while an increase in expression of GAD 67 mRNA also occurred in CA3 and DG. Significant changes were not observed in the caudate nucleus, reticular thalamic nucleus, or frontal cortex, indicating confinement of GAD up-regulation to stress-responsive regions of the CNS. Increased synthesis of GABA in these PVN-projecting regions following exposure to acute and chronic stress is consistent with involvement of these selected cell populations in modulation of HPA activity. The significance of differential up-regulation of GAD isoforms in observed brain regions remains unclear. Supported by MH49698.

## 201.6

**CORTICOSTEROID-DOPAMINERGIC INTERACTIONS IN MONKEYS TREATED WITH METYRAPONE** D. Lyons\*, O. Wang, S. Lindley and A. Schatzberg, Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine, MSLS P111, Stanford, CA 94305-5485.

Corticosteroid-dopaminergic interactions thought to occur during major depressive disorders in humans are examined during social separations in squirrel monkeys treated with metyrapone (an 11 $\beta$ -hydroxylase inhibitor that blocks cortisol biosynthesis). Beginning 1-hr before monkeys were separated from groups and housed alone, eight adult females received either 15 mg/kg metyrapone or the fruit drink vehicle administered at 4-hr intervals for 24 hr in a counterbalanced crossover design. Social separation-induced hypersecretion of cortisol was initially driven by hypersecretion of the adrenocorticotrophic hormone ACTH. From 1-25 hr post-separation, however, cortisol remained elevated above pre-separation controls while simultaneous measures of ACTH were reduced. This suggests that pituitary corticotrophs are stimulated by the ACTH-releasing hormone CRH, but this stimulatory effect is suppressed by high levels of cortisol. By removing cortisol feedback with the metyrapone blockade, these overdriven corticotrophs are revealed. In addition to producing a significant decrease (88%) in cortisol and a large increase (380%) in ACTH, metyrapone produced post-separation changes in plasma levels of the dopamine metabolite homovanillic acid (HVA). Although HVA levels were not significantly different from pre-separation controls at 1-hr post-separation, HVA was significantly higher (34%) than controls in metyrapone (but not vehicle) treated monkeys at 25-hr post-separation. These results are consistent with our clinical studies of humans and experimental studies of rats, which suggest that hypothalamic-pituitary-adrenal axis hyperactivity produces delayed changes in peripheral dopamine metabolites and central mesocortical dopamine utilization. This research was supported by NIMH grant MH47573.

## 201.7

DIFFERENTIAL REGULATION OF HYPOTHALAMIC CORTICOTROPIN-RELEASING HORMONE-mRNA BY CHRONIC AND ACUTE INTERMITTENT STRESS IN INFANT RATS. E.E. Gilles<sup>1,2</sup>, C. Guirguis<sup>2</sup>, L. Schultz<sup>2</sup>, S. R. Snodgrass<sup>3</sup> and T. Z. Baram<sup>2</sup>, Neurology/USC, Los Angeles, CA<sup>1</sup>; Pediatrics & Anatomy/Neurobiology, UCI, Irvine, CA<sup>2</sup>; Pediatrics, U Mississippi, Jackson, MI<sup>3</sup>.

Rationale: The modulation of the hypothalamic-pituitary-adrenal axis by chronic or acute intermittent stress in infancy has not been fully defined. We have created an infant rat model of continuous stress manifested by increased secretion of corticosterone (CORT) and downregulation of pituitary corticotropin-releasing hormone (CRH) receptors. The goal of the current study was to examine CRH-mRNA abundance in the hypothalamic paraventricular nucleus (PVN) in this model, in comparison to a single or intermittent acute cold stress. Methods: Rat pups (n=92) were assigned to 3 treatment groups during postnatal days (PND) 2-9: 1) no handling with limited bedding; 2) no handling; 3) routine bedding-handling. On PND 9, pups from groups 1 and 2 were sacrificed under stress-free conditions. Pups from group 3 were either exposed to maximally tolerated cold stress (Yi and Baram, 1994) 1 or 3 times (AM-PND 9, PM-PND 9 and AM-PND 10) and sacrificed 4 hours after the last cold stress, or were sacrificed under stress-free conditions. CRH-mRNA abundance in the PVN was determined using *in situ* hybridization and MCID image analysis. Results: CRH-mRNA levels of chronically stressed pups were 57% of nonhandled controls (p<0.005). CRH-mRNA levels of the group exposed to a single episode of acute cold stress were 191% of controls (p<0.01), while levels of the group exposed to multiple cold episodes were reduced to 49% of controls (p<0.01). Discussion: A single episode of acute cold stress results in increased CRH-mRNA levels while either repeated acute cold stress or severe chronic stress causes a reduction of CRH-mRNA levels. This "exhaustion" of the ability of pups to express CRH-mRNA may limit their ability to respond appropriately to subsequent acute stressors.

## 201.9

THE EFFECTS OF CHRONIC STRESS AND ANTIDEPRESSANT TREATMENT ON THE CORTICOSTERONE RESPONSE TO RESTRAINT STRESS. C.A. Zimmer, J.F. López, D.M.V. Vázquez\* and S.I. Watson, MHRI, University of Michigan, Ann Arbor, MI 48109.

There is evidence from both animal and clinical studies that the final products of the Hypothalamic-Pituitary-Adrenal axis (cortisol in humans, corticosterone in rats) have profound effects on mood and behavior (McEwen 1987; Murphy 1991). We have previously shown that in rats, Chronic Unpredictable Stress (CUS) results in elevated basal corticosterone (CS) levels and antidepressant administration can prevent this increase. In this study, we investigated the acute and long term effects of CUS and antidepressants on the stress response to restraint (RS). Rats were stressed daily for 4 weeks and received antidepressant treatment. Non stressed rats treated similarly served as controls. Six groups resulted: Saline (S), desipramine (D), zimelidine (Z), saline stress (SS), desipramine stress (DS) and zimelidine stress (ZS). Twenty four hours after the last CUS session animals were restrained for 30 minutes and blood samples were taken at 0, 15, 30, 60 and 120 min for CS determination. All animals were then allowed to rest for 4 weeks without stress or antidepressant treatment, at which time they were again exposed to a 30 min restraint. We found that after the first RS, the SS group and animals that received desipramine (D, DS), had lower CS levels at 120 min. After one month of rest, the CS response to RS were higher than on the first RS session for all groups, and all animals that received CUS or antidepressants had lower levels at 60 and 120 min when compared to the S group. We conclude that antidepressant treatment does not prevent the acute CS response to stress but has a long lasting effect, preventing prolonged exposure to elevated CS levels after a stressor. Supported by NARSAD Young Investigator Award (JFL) and NIDA (DMV).

## 201.11

LOW FREE CORTISOL RESPONSE TO PSYCHOLOGICAL STRESS IN CHILDREN WITH ATOPIC DISORDERS. A. Buske-Kirschbaum, S. Jobst, K. von Auer, W. Rauh, S. Weis, A. Wustmans, C. Kirschbaum and D. H. Hellhammer\*, Center for Psychobiology and Psychosomatic Research, University of Trier, 54286 Trier, Germany.

Atopic disorders are chronically relapsing inflammatory disorders which are often described as the results of an allergic response to various food or inhalant allergens. While most of the research has focused on the pathophysiological role of the immune system, the impact of endocrine signals in the pathology of atopic disorders has received only little attention. However, since the endocrine system is suggested to play an important regulatory role in immune functioning, it might be beneficial to study endocrine reactivity in atopic patients.

In a first study, children with AD (n=15) and age and sex matched healthy controls (n=15) were exposed to the "Trier Social Stress Test for Children" (TSST-C) which mainly consists of a free speech and mental arithmetic tasks in front of an audience. Salivary cortisol was measured in ten minutes intervals while heart rate was monitored continuously. Results showed that the TSST-C induced significant increases in cortisol and heart rate. However, AD children showed a significantly blunted cortisol response to the stressor compared to the control group. In order to investigate whether attenuated cortisol response might be a general phenomenon associated with allergic inflammation, a second study was designed investigating patients with AA. Children with allergic asthma (n=20) and healthy controls (n=20) were again exposed to the TSST-C. Salivary cortisol and heart rate were determined as previously described. It was found that again, the TSST-C resulted in significantly elevated cortisol response and heart rate. However, comparable to the previous findings, a significantly decreased cortisol response was found in AA children. These data suggest a hyporesponsive hypothalamus-pituitary-adrenal (HPA) axis in children suffering from atopic disorders.

## 201.8

PERSISTENT EFFECTS OF MATERNAL DEPRIVATION ON HPA ACTIVITY. - H.J.J. van Oers<sup>1,2</sup>, E.R. de Kloet<sup>2</sup> and S. Levine<sup>\*,1</sup>, <sup>1</sup> Dept. of Psychology, Univ. of Delaware, Newark, DE 19716-2577, U.S.A.; <sup>2</sup> Div. of Medical Pharmacology, LACDR, P.O. Box 9503, 2300 RA Leiden, The Netherlands.

Maternal deprivation of both male and female neonatal rats for 24 hours enhances the adrenocortical response to stress during the stress hyporesponsive period (SHRP). The current experiments test the hypothesis that such maternally deprived neonatal rats show altered hypothalamic-pituitary-adrenal (HPA) axis regulation not only immediately after deprivation but also at a later time. In addition, we looked at mRNA levels for corticosteroid receptors in the hippocampus.

Litters were deprived for 24 hours on postnatal day (pnd) 3 (DEP3-4), 7 (DEP7-8) or 11 (DEP11-12) and tested for their HPA responsiveness on pnd 20. Basal and stress-induced (saline injection) levels of both ACTH and CORT were determined using radioimmunoassays (RIA). Basal mRNA levels of corticotropin-releasing hormone (CRH), mineralocorticoid receptors (MRs) and glucocorticoid receptors (GRs) were measured in brain sections with *in situ* hybridization.

Compared with non-deprived (NDEP) rats: (i) DEP3-4 animals showed significantly higher ACTH levels after stress at pnd 20. MR mRNA levels in the CA3 and CA4 region of male hippocampi were elevated, while no changes were seen in the other parameters measured. (ii) DEP7-8 rats showed resembled a difference in hormone levels that did not read significantly. The expression of GR mRNA was decreased in all areas of the male hippocampi and in the dentate gyrus of the females. (iii) DEP11-12 animals had significantly lower ACTH values in response to stress. In this group deprivation resulted in a downregulation of GR mRNA in both sexes and MR mRNA in females. In contrast, all four experimental groups showed comparable values for CORT and CRH mRNA. Taken together, differential persistent effects of maternal deprivation are obtained dependent on the day of separation in the SHRP.

Supported by NIMH grant MH 45006 to S. Levine.

## 201.10

INVOLVEMENT OF THE LOCUS COERULEUS IN THE NEURONAL INTEGRATION OF STRESS. D.R. Ziegler\*, K. Bettenhausen, W.A. Cass, and J.P. Herman, Dept. Anatomy and Neurobiology, University of Kentucky, Lexington, KY 40536.

The locus coeruleus (LC) has been hypothesized to act as a central stress effector pathway. Numerous studies indicate that behavioral and perhaps neuroendocrine changes induced by stress are mediated by the LC. The present studies investigate the possibility that HPA-regulatory and effector roles of the LC occur in the context of acute and chronic stress. First, we hypothesized that lesions of the LC would impair HPA stress responsivity. Second, we predicted that the LC would show stress-induced changes in tyrosine hydroxylase (TH) and glucocorticoid receptor (GR) mRNA and, possibly, mRNA encoding the colocalized neuropeptides galanin and neuropeptide Y (NPY). Adult, male Sprague-Dawley rats with 6-OHDA lesions of the LC were subjected to a chronic variable stress regimen which, in sham animals, resulted in increased basal HPA activity (i.e., increased CRH mRNA expression, increased plasma ACTH and CORT levels, adrenal hypertrophy). LC lesions resulted in blunted plasma ACTH and corticosterone responses to acute restraint stress. However, recovery from acute stress and basal HPA activity were unaffected by LC lesion. A separate group of (unoperated) rats were also subjected to the chronic variable stress regimen to assess activation of LC gene expression. Relative to control (handled) subjects, the chronic stress group exhibited significantly elevated GR, galanin, and neuropeptide Y (NPY) mRNA expression (34%, 72%, 85%, respectively, p < 0.05). However, control and chronic stress groups did not show significantly different levels of TH mRNA. These results suggest that stress increases both co-transmitter expression and glucocorticoid receptivity in LC neurons. In conclusion, LC function seems to be required for a normal stress response; in addition, LC gene expression appears to be chronically enhanced by stress. How this activation of the LC impacts HPA function remains to be evaluated. Supported by MH 49698.

## 201.12

COMBINED LOW-DOSE PHYSOSTIGMINE AND AVP CHALLENGE IN MAJOR DEPRESSION. R.T. Rubin\*, L.K. Sekula, S.O'Toole, K. Czamel, Neurosciences Research Center, Medical College of Pennsylvania and Hahnemann University, Allegheny Campus, Pittsburgh, PA 15212.

Hyperactivity of the hypothalamo-pituitary-adrenal (HPA) axis occurs in 30-50% of patients with major depression. Central cholinergic neurotransmission stimulates CRH secretion, and increased CNS cholinergic activity relative to noradrenergic activity has been hypothesized as a neurochemical abnormality underlying major depression. This hypothesis has been supported by non-endocrine (sleep, pharmacological) studies. One study has shown that major depressives may have a greater HPA axis sensitivity to cholinergic stimulation than do controls, but at a dose of cholinergic agonist (physostigmine; PHYSO) that produces nausea and vomiting — noxious side-effects that themselves can activate the HPA axis.

We therefore designed a low-dose PHYSO/AVP challenge, uncomplicated by noxious side effects, that reliably stimulates the HPA axis in normal men and women. There are 4 test days, 4-7 days apart: saline/saline, PHYSO/saline, saline/AVP, and PHYSO/AVP. With this challenge we are testing moderate to severe major depressives and individually matched normal controls. Baseline serial blood sampling occurs from 1600 to 1800h; PHYSO or saline is given at 1800h; AVP or saline is given at 1900h; and sampling is continued until 2230h. Plasma is assayed for ACTH<sub>1-39</sub> and cortisol.

To date, eight female major depressives and eight female controls matched on age, race, and hormonal status have been studied. Average afternoon baseline ACTH<sub>1-39</sub> across the 4 test days was marginally lower in the patients, whereas baseline cortisol was higher. The patients had a clearly higher ACTH<sub>1-39</sub> response on the PHYSO-alone day. Patients and controls had similar ACTH<sub>1-39</sub> responses on the AVP-alone day. On the PHYSO/AVP day, the patients again had a clearly higher ACTH<sub>1-39</sub> response to PHYSO and a similar response to AVP. Cortisol responses paralleled the ACTH responses.

Our findings thus give further support to the hypothesis of increased CNS cholinergic activity in major depression. (Supported by NIH grants MH28380 and MH47363.)

## 202.1

RO 61-6270, A NEW HIGHLY SELECTIVE DOPAMINE D4 RECEPTOR ANTAGONIST, INDUCES C-FOS EXPRESSION IN MOUSE CORTEX. D.S. Hartman\*, R. Smeyne, M.-T. Zenner, C. Goepfert, E.-I. Schlaefer, F. Jenck, O. Civelli, T. Godel, and C. Riemer. Pharmaceutical Research, Preclinical Neurosciences, #Biotechnology, Hoffmann-La Roche, Basel, Switzerland.

The dopamine D4 receptor (D4R) has been implicated in affective and emotional disorders including schizophrenia. To identify novel potent and selective D4R antagonists, CHO cell membranes expressing the human D4R (Ashgari et al., 1995, J. Neurochem 65, 1157-1165) were used to screen over fifty thousand compounds. Optimization of one lead structure led to the synthesis of Ro 61-6270, a small molecule with high affinity and high selectivity for the human D4R. In competition binding assays Ro 61-6270 showed an inhibition constant (K<sub>i</sub>) of 5 nM at the human D4R, and over 1000-fold selectivity for D4 vs. D1, D2, D3, and D5 receptors as well as 40 additional receptor sites tested including adrenergic, serotonergic, muscarinic, and histamine receptor subtypes. Ro 61-6270 is a competitive D4R antagonist, inhibiting DA-induced GTPγS binding to CHO-D4 cell membranes with an IC<sub>50</sub> value of 175 nM. Intraperitoneal administration of Ro 61-6270 (30 mg/kg) to Sprague-Dawley rats resulted in efficient brain penetration measured 30 min after injection.

Transgenic lacZ/c-fos mice treated with Ro 61-6270 (10 mg/kg, i.p.) for 2 hr showed c-fos induction in frontal, cingulate, and piriform cortices, as well as in the paraventricular hypothalamic nucleus and in CA1/CA3 regions of hippocampus. Little or no induction in striatum or substantia nigra was seen. A time course of Ro 61-6270 induced c-fos expression should provide a map of brain areas potentially involved in D4R-mediated events, and will be compared to the pattern of <sup>3</sup>H-Ro-61-6270 binding in the brain and periphery. All funding provided by Hoffmann-La Roche, Basel, Switzerland.

## 202.3

D<sub>4</sub> DOPAMINE RECEPTOR INVOLVEMENT IN PHOSPHOLIPID METHYLATION AND ITS IMPLICATIONS FOR SCHIZOPHRENIA. R.C. Deth\*, P.F. Wick, M.L. Kramer, A. Sharma, D. Liu, C. DuRand, O.-B. Zhu, M. Nagata, Y. Gou, S. Chari. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115

Phospholipid methylation is thought to regulate the plasma membrane fluidity via a reaction in which S-adenosylmethionine (SAM) serves as a methyl donor for the enzyme phospholipid methyltransferase I. We now provide evidence that the D<sub>4</sub> dopamine receptor can also function as a donor of methyl groups, as a result of the adenosylation of MET313 at the cytoplasmic terminus of helix #6. This adenosylation is carried out by methionine adenosyltransferase, the same enzyme which adenosylates methionine, and requires the active R\* state of the receptor. Thus antagonists such as haloperidol and clozapine inhibit adenosylation and phospholipid methylation by shifting receptors to the inactive R state. Adenosylation of the receptor also causes the receptor to exhibit spontaneous activity with regard to the activation of G proteins. A deficiency in methionine metabolism has been well documented in schizophrenia. We therefore compared phospholipid methylation in lymphocytes from patients vs. controls and found a greater than two-thirds reduction in schizophrenic individuals. Based upon these results, a unified hypothesis can be developed which combines both the "dopamine hypothesis" and the "single carbon hypothesis", centered upon a reduced level of membrane phospholipid methylation and consequent alterations in membrane fluidity. This reduction results from the combined lower activities of at least three different enzymes which are critical for both the receptor-dependent and receptor-independent pathways of phospholipid methylation.

## 202.5

REGIONAL EFFECTS OF A D3-PREFERRING AGONIST ON CEREBRAL BLOOD FLOW. K. J. Black\*, T. O. Videen and J. S. Perlmutter. Depts. of Radiology, Psychiatry and Neurology, Washington University School of Medicine, St. Louis, MO 63110.

D3 receptors differ from other D2-like dopamine receptors in anatomic distribution as well as structure, pharmacology and second messenger function. We hypothesized that a D3-preferring agonist would alter neuronal activity in neuronal circuits that express D3 receptors. We performed 6 PET studies in 4 normal baboons. Each study included 3 baseline measurements of quantitative regional cerebral blood flow (rCBF), using PET and the H<sub>2</sub><sup>15</sup>O method, and then 3 rCBF scans after each successively higher intravenous dose of pramipexole (5, 50 and 500 µg/kg, i.e. "low," "medium" and "high"). PET scans were aligned with an MRI from each animal using a previously validated automated routine, and then transformed to stereotactic space using proportional measurements. We randomly selected about 1/3 of the scans at each condition to form a hypothesis-generating image in atlas space, and these scans were excluded from further analysis. Four areas of decreased rCBF (relative to global CBF) were identified at both medium and high doses, centered on medial orbitofrontal cortex, medial thalamus, right claustrum and posterior cingulate. An additional decrease (caudate head) and an increase (ventromedial pallidum) were identified at the high dose only. These areas were then tested using the remaining ("replication") scans. Preliminary analysis of the replication scans shows mean changes in rCBF in each of the first 4 regions, at both doses, of -8% to -15%. In the last 2 regions the rCBF change at the high dose was -3% and +4% respectively. Thus the change in each region was in the predicted direction, and even in this small sample uncorrected *p* values (*t*-test) for the first 4 regions at each dose ranged from 0.0035 to 0.09. We conclude that pramipexole may produce functional changes in ventral basal ganglia-thalamocortical circuits.

Supported by NIH grants AA-07466, NS-32318, and NS-31001, the Charles A. Dana Foundation [The Dana Clinical Hypotheses Research Program], and the Greater St. Louis chapter of the APDA. Pramipexole was a gift of the Upjohn Co.

## 202.2

SPlicing OF AN ATYPICAL ALTERNATIVE INTRON IN DOPAMINE D<sub>3</sub> RECEPTOR PRE-mRNA. C. Schmauss\*, B.V. Skryabin, and J. Haesik Yoon. Dept. Psychiatry & Brookdale Center for Molecular Biology, Mt. Sinai Sch. of Med., New York, NY 10029.

Dopamine D<sub>3</sub> receptor encoded pre-mRNA is processed alternatively to yield D<sub>3</sub> receptor mRNA and a truncated mRNA, named D<sub>3nf</sub>. In human brain both mRNAs are co-expressed and, interestingly, both are translated into protein. *In vitro* splicing of substrate D<sub>3</sub> pre-mRNA in HeLa nuclear extracts yields D<sub>3</sub> mRNA and, via additional removal of a short alternative spliceosomal intron, D<sub>3nf</sub> mRNA. The analysis of D<sub>3nf</sub>-specific splicing intermediates by primer extension shows that 3' cleavage of this intron occurs at a noncanonical sequence (GGA:GU) that deviates from the invariant 3' splice site sequence AG:N of the major class of introns. When mutant D<sub>3</sub> pre-mRNA in which the alternative 3' splice site is converted into the consensus sequence of the major-class introns (GAG:G) is spliced *in vitro*, 3' cleavage occurs one nucleotide upstream (GA:GG) of the wildtype cleavage site. Furthermore, D<sub>3nf</sub>-specific splicing is abolished in a mutant pre-mRNA that carries a single nucleotide mutation within the 3' GGA:G sequence, namely GUA:G. These results indicate that the sequence GA:N is essential for splicing of the D<sub>3nf</sub>-specific alternative intron. In addition, primer-extension experiments suggest that the branchpoint of this alternative intron is located within sequences that are also atypical for branchpoints of major-class introns. This suggests that the D<sub>3nf</sub>-specific intron represents a novel intron of the minor class. Interestingly, results from RNase protection experiments show that splicing of this intron is enhanced in brains of patients with chronic psychosis. (Supported by NARSAD and MH45212).

## 202.4

LONG TERM STABILITY OF DOPAMINE (D<sub>2</sub>) RECEPTOR ACTIVITY MEASURED WITH <sup>11</sup>C-RACLOPRIDE AND PET. R. Schloesser, J.D. Brodie, G.J. Wang, N. Volkow, J. Logan, D. Alexoff and S.L. Dewey, Dept of Psych, NYU Med Center, NY, NY 10016. Dept of Chem, BNL, Upton, NY, 11973-5000

This study evaluated the long term stability of dopamine (D<sub>2</sub>) receptor activity in normal human volunteers. Six healthy subjects (range: 24 - 75) were investigated twice with <sup>11</sup>C-raclopride under resting conditions with a mean time interval between scans of 14.7 months (range: 10-19). The methods used were similar to those published previously (Volkow et al., J. Nucl. Med. 34, 609-613, 1993). The ratio of the distribution volumes (DVs) of the basal ganglia (DV<sub>BG</sub>) to cerebellum (DV<sub>CB</sub>) revealed a mean absolute change of 6.0 % (range: -12.7 to 7.3) between study A and B. Mean change of DV<sub>BG</sub> was 3.1% (range: -4.2 to 4.3), mean DV<sub>CB</sub> change was 7.40 % (range: -10.7 to 11.3). The interindividual differences between both scans in our study were similar to the 24 hour interval test-retest data from Volkow et al. (repeated measures ANOVA with df = 9; F = 0.81; *p* = 0.389). Age and length of the time between scans did not significantly correlate with the binding parameters of <sup>11</sup>C-raclopride. Across subjects, the DV ratio index revealed a mean of 3.11 (range = 2.55 to 3.68, SD 0.44) in study A and of 3.07 (range 2.37 to 3.57, SD 0.45) in study B. These findings support the view that baseline dopamine (D<sub>2</sub>) receptor activity, in a given individual, and expressed by the DV ratio as an index of the binding potential, remains stable over many months. Furthermore, these results are consistent with previous findings of a substantial interindividual difference in D<sub>2</sub> receptor binding parameters. Future PET studies directed at measuring changes in dynamic properties (response to pharmacologic challenge) over time are necessary prior to beginning studies designed to investigate the effects of disease state or long term drug therapy on patients suffering from mental illness. MH47277, NS15638, RR00096 from the NIH, the DOE, DA06891 from NIDA, NARSAD and Schl 400/I-1 from the DFG.

## 202.6

EVALUATION OF EXTRASTRIATAL DOPAMINE RECEPTORS BY USING <sup>18</sup>F-FALLYPRIDE. J. Mukherjee\*, Z.-Y. Yang, T. Brown, J. Roemer and M. Cooper. Department of Radiology, The University of Chicago, Chicago, IL 60637.

Due to the increasing interest in evaluating the role of extrastriatal dopamine receptors in dopamine-related pathophysiology, we have attempted to identify the value of <sup>18</sup>F-fallypride ((S)-N-[(1-allyl-2-pyrrolidinyl)methyl]-5-(3-[<sup>18</sup>F]fluoropropyl)-2,3-dimethoxybenzamide), as an extrastriatal dopamine D-2 receptor radiotracer. Fallypride exhibits high affinities for D-2 and D-3 subtypes and low affinity for D-4 (<sup>3</sup>H-spiroperone IC<sub>50</sub>'s: D-2 = 0.60 ± 0.45 nM (rat striata), D-3 = 0.30 nM (SF9 cell lines, rat recombinant) and D-4 = 240 nM (CHO cell lines, human recombinant). *In vivo* rat biodistribution studies with <sup>18</sup>F-fallypride showed predominant binding in the striata followed by binding in thalamus, hypothalamus and frontal cortex. PET experiments with <sup>18</sup>F-fallypride in male rhesus monkeys were carried out in a PET VI scanner. In several PET experiments, apart from the specific binding seen in the striatum, specific binding of <sup>18</sup>F-fallypride was identified in the thalamus as well. Specific binding in the thalamus was significantly lower compared to that observed in the striata of the monkeys (thalamus/cerebellum = 2, striata/cerebellum = 10).

We have previously shown from PET studies that iv administration of *d*-amphetamine (AMPH) in rhesus monkeys alters binding of <sup>18</sup>F-fallypride in the striata. At high doses of AMPH (0.75 mg/kg and up) an immediate effect of increased dissociation rate *k*<sub>off</sub> (from <10<sup>-5</sup> min<sup>-1</sup> in controls to >10<sup>-3</sup> min<sup>-1</sup> in AMPH treatment) on specifically-bound <sup>18</sup>F-fallypride occurred resulting in a reduction of specifically-bound <sup>18</sup>F-fallypride in the striata. However, effect of AMPH on specifically-bound <sup>18</sup>F-fallypride in the thalamus was not evident in several experiments that were carried out at doses ranging between 0.25 mg/kg upto 1.0 mg/kg. Due to its high affinity, fallypride is possibly unable to measure very small changes in dopamine levels in the thalamus, which could account for the absence of a measurable AMPH effect. This result may also be indicative of significantly lower levels of endogenous dopamine in this extrastriatal region.

## 202.7

**DIFFERENTIAL REGULATION OF D3 DOPAMINE RECEPTORS BY ANTAGONISTS** K.D. Burris\*, S.M. Fausing, R.L. Bertekap Jr. and P.B. Molinoff. CNS Drug Discovery, Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492

We have previously reported an increase in the density of D3 dopamine receptors following exposure of transfected HEK-293 cells (HEK-D3 cells) to the agonists, 7-OH-DPAT and quinpirole, and the antagonist haloperidol (Soc. Neurosci. Abs. 20: 1066, 1994). These findings have been extended using antagonists from a variety of chemical classes in order to examine the pharmacological specificity of drug-induced increases in the density of D3 receptors. Exposure of HEK-D3 cells for 18 hours to haloperidol, a butyrophenone, resulted in an increase in the density of binding sites measured with the radiolabeled antagonist, [<sup>125</sup>I]-NCC-298. The maximum concentration of haloperidol examined, 1  $\mu$ M, stimulated a 2-fold increase in the density of receptors. Exposure of cells to the (+) and (-) enantiomers of butaclamol, a benzocycloheptapyridisoquinoline, revealed that (+)butaclamol was more potent than (-)butaclamol in stimulating an increase in the density of D3 receptors. This suggests that the increase in the density of receptors was mediated through specific interaction of the drugs with D3 receptors. In contrast to the effects of haloperidol and butaclamol, exposure of HEK-D3 cells to the benzamide, sulpiride, at concentrations up to 100  $\mu$ M, did not result in an increase in the density of D3 receptors. Sulpiride, however, blocked the increase in receptor density stimulated by haloperidol. Consistent with the affinity of D3 receptors for the enantiomers of sulpiride, (-)sulpiride was more potent than (+)sulpiride in blocking the effect of haloperidol. Euclopride, another benzamide, also blocked haloperidol-stimulated up-regulation of D3 receptors. The mechanism whereby haloperidol and butaclamol interacted with D3 receptors to stimulate an increase in the density of receptors is unknown. The mechanism appears to involve more than a simple occupancy-based decrease in the rate of receptor degradation since sulpiride and euclopride did not stimulate an increase in the density of receptors, though both antagonists interacted directly with D3 receptors to block the increase stimulated by haloperidol. The observation that haloperidol and butaclamol stimulated, whereas the benzamides blocked, an increase in the density of D3 receptors demonstrate that antagonists vary, perhaps through induction of different receptor conformations, in their ability to modulate D3 receptors.

## 202.9

**MAPPING AGONIST-INDUCED STRUCTURAL CHANGES IN A G PROTEIN COUPLED RECEPTOR BY SITE-SELECTIVE FLUORESCENT LABELING WITH A CONFORMATIONALLY SENSITIVE CYSTEINE REAGENT** S. Lin, U. Gether, P. Ghanouni, H.T. Schambye\* and B.K. Kobilka. Howard Hughes Medical Institute, Stanford University, Stanford, CA 94305.

To establish a system that would allow site-selective incorporation of biophysical probes in a purified G protein coupled receptor we have systematically mutated cysteines in the  $\beta_2$  adrenergic receptor and generated a series of mutants with only one, two or three remaining cysteines available for chemical derivatization. The mutant receptors were all expressed in SF-9 insect cells and purified. It was found that the mutants retained the agonist and antagonist binding properties of the wildtype receptor. Furthermore, their coupling to adenylate cyclase were indistinguishable from the wildtype. Previously, we have found that agonist-specific conformational changes in the  $\beta_2$  adrenergic receptor can be detected following labeling of the purified receptor with the sulfhydryl-reactive fluorophore, IANBD. The fluorescence from IANBD is highly sensitive to the polarity of its molecular environment making IANBD a sensitive molecular reporter of conformational changes. Site-selective labeling of the purified cysteine mutants with IANBD revealed that cysteines in transmembrane segments (TM) III and VI were responsible for the reversible and stereospecific decrease in fluorescence emission observed from the IANBD labeled receptor. This suggest that agonist binding causes a conformational change in the receptor that involves movement of TM III and VI. Site-selective incorporation of biophysical probes in G protein coupled receptors should prove a powerful tool for further characterization of the molecular events and structural changes that occur in the receptors during activation and transmission of signal across the membrane.

## 202.11

**ENHANCED QUINPIROLE-INDUCED ORAL ACTIVITY IN RATS LESIONED WITH 6-HYDROXYDOPAMINE DURING ONTOGENY AND WITH 5,7-DIHYDROXYTRYPTAMINE DURING ADULTHOOD** R.M. Kostrzewa<sup>1</sup>\*, R. Brus<sup>2</sup>, K.W. Perry<sup>3</sup> and R.W. Fuller<sup>3</sup>. <sup>1</sup>Dept. of Pharmacology, East Tennessee State Univ., Johnson City, TN; <sup>2</sup>Dept. of Pharmacology, Silesian Academy of Medicine, 41-808 Zabrze, Poland; <sup>3</sup>Eli Lilly Research Labs, Indianapolis, IN 46285.

To better understand the modulatory role of serotonin (5-HT) neurons on dopamine (DA) receptors, DA D<sub>1</sub> receptor supersensitivity was produced by lesioning DA neurons with 6-hydroxydopamine (6-OHDA, 134  $\mu$ g; bilateral icv injection with desipramine pretreatment, 3 days after birth). After observing enhanced oral activity responses to the DA D<sub>1</sub> agonist SKF 38393 and to the 5-HT<sub>1A</sub> agonist m-chlorophenylpiperazine (m-CPP) in these rats in adulthood, 5,7-dihydroxytryptamine (5,7-DHT; 3-30  $\mu$ g icv) was administered. In rats co-lesioned with 6-OHDA and 5,7-DHT, (a) m-CPP-induced oral activity was further enhanced, while (b) previously observed SKF 38393 enhancement of oral activity was absent, and (c) quinpirole-induced oral activity (D<sub>2</sub> agonist effect) became enhanced. In co-lesioned rats neostriatal DA content was reduced >98%, while 5-HT content was elevated vs. the saline control group and was slightly reduced (<15%) or unchanged vs. the 6-OHDA group. When 5,7-DHT (75  $\mu$ g) alone was administered to neonatal rats, quinpirole responses were likewise enhanced. In the group lesioned neonatally with both 6-OHDA and 5,7-DHT, however, neither SKF 38393 nor quinpirole responses were enhanced. The findings indicate that 5-HT neurons have a major regulatory influence on the sensitivity of both DA D<sub>1</sub> and D<sub>2</sub> receptors. (Supported by NS29505)

## 202.8

**STRUCTURAL INSTABILITY ASSOCIATED WITH CONSTITUTIVE ACTIVATION OF A G PROTEIN COUPLED RECEPTOR** U. Gether\*, E. Sanders-Bush and B.K. Kobilka. Howard Hughes Medical Institute, Stanford University, Stanford, CA 94305.

Discrete mutations in the carboxyterminal part of the third intracellular loop can cause constitutive activation of G protein coupled receptors (GPCR), but the structural and molecular basis for this agonist-independent activity is unknown. We have expressed the constitutively activated mutant (CAM) of the  $\beta_2$  adrenergic receptor in SF-9 insect cells and established a purification scheme that allowed the first structural analysis of a constitutively activated GPCR. Most strikingly, it was found that the solubilized, purified CAM was highly unstable as compared to the wildtype protein. Thus, incubation of CAM at 37°C for 1 hour completely abolished binding activity whereas the wildtype retained around 60% binding activity after 1 hour and around 20% after 4 hours. The loss of binding activity could be prevented by incubation with the inverse agonist ICI 118,551. Purified CAM was further analyzed after labeling with the environmentally sensitive, sulfhydryl-reactive fluorophore, IANBD, which we previously have used for monitoring of ligand-specific conformational changes in the wildtype receptor. The data showed that, after pretreatment with ICI 118,551, the agonist isoproterenol produced an approximately two-fold greater decrease in fluorescence intensity from CAM than from the wildtype receptor. This suggests that agonist occupancy can promote a more profound conformational change in the CAM receptor than in the wildtype protein. Summarized, our data support an activation mechanism for GPCR in which stabilizing conformational constraints keep the unliganded, non-constitutively activated receptor preferentially in an inactive state. In response to agonist binding or selective mutations these conformational constraints are disrupted enabling the receptor to assume an active conformation.

## 202.10

**Distribution of  $\alpha_{1A}$  Adrenergic Receptor mRNA in the Rat Brain Visualized by *In Situ* Hybridization** A.V. Domyancic and D.A. Morilak\*. Dept. of Pharmacology, University of Texas Health Science Center at San Antonio, 7703 Floyd Curl Dr., San Antonio, TX, 78284-7764.

Norepinephrine has been implicated in a number of physiological, behavioral and cellular modulatory processes in the brain. Many of these modulatory effects have been attributed to activation of post-synaptic  $\alpha_1$  adrenergic receptors. At least three  $\alpha_1$  receptor subtypes have been identified by molecular criteria, designated  $\alpha_{1A}$ ,  $\alpha_{1B}$  and  $\alpha_{1D}$ . In order to understand the specific functions of these different subtypes in the brain, it would be useful to specify their differential distributions. The distributions of  $\alpha_{1B}$  and  $\alpha_{1D}$  receptor mRNA expression in rat brain have been described previously, but the cDNA for the rat  $\alpha_{1A}$  receptor has only recently been cloned and characterized. In the present study, we describe the distribution of  $\alpha_{1A}$  message expression in the rat brain using a radiolabeled riboprobe derived from the rat  $\alpha_{1A}$  receptor cDNA (D. Perez, Cleveland Clinic). High levels of  $\alpha_{1A}$  receptor mRNA expression were seen in olfactory bulb, tenia tectae, diagonal band and preoptic area, zona incerta, ventromedial and lateral hypothalamus, lateral mammillary nuclei, ventral dentate gyrus, piriform cortex, medial and cortical amygdala, magnocellular red nuclei, pontine nuclei, lateral vestibular nuclei, brainstem reticular formation and several cranial nerve and spinal motor nuclei. More moderate hybridization signal was seen throughout the neocortex, and in the claustrum, diagonal band nucleus and lateral amygdala. This pattern of expression, when considered in comparison with that previously described for the other  $\alpha_1$  adrenergic receptor subtypes, may shed light on the different roles of the  $\alpha_1$  receptor subtypes in mediating the neuromodulatory effects of norepinephrine in processes such as arousal, neuroendocrine control, sensorimotor regulation and in the stress response. Support provided by research grants from the Whitehall Foundation and the American Heart Association, Texas Affiliate.

## 202.12

**ROLE OF  $\beta$ -ARRESTINS IN THE INTRACELLULAR TRAFFICKING OF G PROTEIN-COUPLED RECEPTORS** S.S.G. Ferguson\*, J. Zhang, K. Winkler, W.E. Downey III, L.S. Barak and M.G. Caron. HHMI Labs and Dept. of Cell Biology, Duke University Medical Center, Durham, North Carolina, 27710.

$\beta$ -arrestins and G protein-coupled receptor kinases (GRKs) are appropriately localized at neuronal synapses to play an important role in the desensitization of G protein-coupled receptors (GPCRs) involved in neurotransmission. However, little is known about the mechanisms contributing to the resensitization of GPCR responsiveness, except that agonist-promoted sequestration might be involved in this process. Recently we found, using a phosphorylation- and sequestration-defective  $\beta_2$ -adrenergic receptor ( $\beta_2$ AR) mutant, that GRK-mediated phosphorylation can facilitate  $\beta_2$ AR sequestration. In the present experiments, we find that  $\beta$ -arrestins, proteins which bind GRK-phosphorylated GPCRs, can promote  $\beta_2$ AR sequestration even in the absence of phosphorylation. In addition, wild-type  $\beta_2$ AR sequestration can be inhibited by a sequestration-specific  $\beta$ -arrestin dominant-negative mutant (V53D). In addition,  $\beta$ -arrestin1-V53D is co-immunoprecipitated in an agonist-dependent manner with the  $\beta_2$ AR following chemical cross-linking, indicating that this mutant is not impaired in its ability to interact with the receptor. Moreover,  $\beta_2$ AR sequestration is dependent upon functional dynamin, a protein required for the formation of clathrin-coated vesicles. However, the internalization of another GPCR, the angiotensin II Type 1A receptor (AT<sub>1</sub>AR), is not dynamin-dependent, indicating that alternate pathways for GPCR internalization exist. In addition, AT<sub>1</sub>AR internalization is not inhibited by the  $\beta$ -arrestin1-V53D mutant, but in contrast, the magnitude of AT<sub>1</sub>AR internalization is increased by overexpression of wild-type  $\beta$ -arrestin. As expected, this  $\beta$ -arrestin-induced increase in AT<sub>1</sub>AR internalization is dynamin-dependent. These findings suggest a dual role for  $\beta$ -arrestins in GPCR regulation:  $\beta$ -arrestins are not only involved in GPCR desensitization, they also function as trafficking molecules specifically directing GPCRs for clathrin-mediated endocytosis. Supported by NIH Grant NS19576.

## 202.13

DOPAMINE D2 RECEPTOR DEFICIENCY REVEALS COMPENSATORY LOCOMOTOR SYSTEMS, M.A. Kelly<sup>1</sup>, M. Rubinstein<sup>1</sup>, C. N. Lessov<sup>2,3</sup>, S. Burkhardt-Kasch<sup>2,3</sup>, J. R. Bunzow<sup>1\*</sup>, C. Saez<sup>1</sup>, T. J. Phillips<sup>2,3</sup>, D. K. Grandy<sup>1</sup>, M. J. Low<sup>1</sup>. <sup>1</sup>Vollum Inst., <sup>2</sup>Dept. Behav. Neurosci., Oregon Health Sci. Univ., <sup>3</sup>VA Med. Cent. Portland OR 97201

A role for the dopamine D2 receptor in locomotion was tested in mice homozygous for a targeted nonfunctional allele (KO). Open field activity of drug naive knockouts showed significantly decreased scores for initiation of movement and total horizontal distance, but normal speed and duration of movements compared to wild-type. KO mice showed no further change in activity when treated with the D2 antagonist haloperidol in marked contrast to significant decreases in initiation of movement and total horizontal distance in wild type and heterozygotes. These data suggest that compensatory mechanisms exist in the mutant mice to maintain locomotor activity at a level intermediate between drug naive and acutely D2 receptor antagonized wild-type mice. KO mice had normal increased locomotion in response to cocaine indicating intact D1 receptor function. The role of monoamines in modulating motor function in the D2 knockout mice was assessed by acute monoamine depletion with a combination of reserpine and AMPT. Akinesia was achieved in all mice and was slightly reversed by the D1-like agonist SKF 38393. The combination of SKF 38393 and the D2-like agonist Quinpirole had no additive effect in KO but increased distance scores in wildtypes. Surprisingly, heterozygotes demonstrated a return to pre-depletion distance scores at lower dosages than wild type siblings. Our studies suggest that the D2 receptor is important for the initiation of spontaneous movement (regulating the set-point) but not required for normal speed and duration of movements. Furthermore, the inability of combined D1 and D2 agonists to restore the basal locomotor activity of acutely monoamine depleted knockout mice implies that the compensatory mechanism(s) in these mice involves non-dopaminergic monoamine systems.

AN MRI ATLAS OF THE HUMAN CEREBELLUM IN TALAIRACH SPACE. J. D. Schmahmann\*, J. Doyon, C. Holmes, N. Makris, M. Petrides, D. Kennedy, A. C. Evans. Department of Neurology, Center for Morphometric Analysis, Massachusetts General Hospital, Boston, MA, 02114; McConnell Brain Imaging Center, Montreal Neurologic Institute, McGill University, Montreal, Quebec, Canada; ICBM Project.

The aim of this study was to develop a comprehensive atlas of the human cerebellum within Talairach space. The brain of a healthy young male was imaged using a 1.5 Tesla Philips MRI scanner. Twenty-seven T1 weighted images were obtained within Talairach coordinates (Holmes et al., 1996). Brain slices of 0.5mm thickness were co-registered in sagittal, axial and coronal planes. Using available published data, cerebellar fissures were identified on the midsagittal section and followed to their most lateral extent in the parasagittal plane. The location of the fissures was verified on coronal and axial sections as necessary.

The ability to change between planes of section was a major aid in the localization of the twelve major cerebellar fissures. The precentral, preculminate, intraculminate, primary, superior posterior, horizontal, ansoparamedian, prebiventer (prepyramidal), intrabiventer, secondary, and posterolateral fissures were all reliably marked on the three planes of section. Crus IA and crus IB of the ansoparamedian lobe were readily distinguishable from each other by a previously unnamed fissure which we called the "crus I internal fissure." The horizontal fissure was best seen in more lateral sections, the primary fissure optimally seen in the midsagittal plane. After defining the fissures, it was possible to identify the various cerebellar lobules, sublobules, and subfolia. The deep cerebellar nuclei were also identified.

We have developed a detailed atlas of the human cerebellum within Talairach coordinates using MRI. This will be valuable for the correlation of anatomy, function, and pathology, and for the development of probabilistic maps of the human cerebellum. (NSERC-GOPIN-012; Milton Fund of Harvard University).

## 203.3

PERCEPTION OF KINESTHETIC CUES REQUIRED FOR ASSESSING THE SHAPE OF TWO-DIMENSIONAL IRREGULAR PROFILES IS IMPAIRED IN CEREBELLAR PATIENTS. Yu. Shimansky\*, M. Saling\*, D.A. Wunderlich\*, V. Bracha\*, G.E. Stelmach\*, J.R. Bloedel\*. Neurobiology Div., Barrow Neurological Institute, Phoenix, AZ 85013; \*Motor Control Laboratory, ASU, Tempe, AZ 85287.

The purpose of this study was to determine the capability of cerebellar patients to acquire and use kinesthetic information in the absence of vision for perceiving the shape of two-dimensional unfamiliar profiles with closed irregular outlines. Patients with cerebellar lesions and age-matched healthy controls were tested on four tasks under two conditions that differed in the way information was acquired regarding the shape of these profiles. In the first condition (kinesthetic acquisition, KA), blindfolded subjects acquired information about the shape of a profile by tracing a grooved template three times. In the second condition (visual acquisition, VA), the subjects examined the profile visually. The first task consisted of four series. In each series the subjects were asked to trace a reference profile three times and memorize its shape. Then a sequence of five profiles was presented in a pseudo-random order. Two of five were the same as the reference profile and three were different. The subjects were required to trace each profile three times and indicate whether its shape was identical to the reference one. The number of errors was recorded. In the second task, a reference profile was presented to the subjects again, and then they were asked to draw it from memory five consecutive times while blindfolded. The third task was identical to the second one with the exception that the subjects drew the profile using vision. In the fourth task, the subjects were required to recognize the shape of the reference profile in a set of pictures. Analysis of errors (failure to recognize the reference profile or identification of a non-reference profile as the reference) showed that under the KA condition the number of errors was significantly increased in cerebellar patients. Furthermore, unlike the cerebellar patients, the control subjects significantly decreased the number of errors across the four series. No cerebellar patient was able to recognize the shape of the reference profile and they were unable to draw its characteristic features. No such deficits were observed in the VA condition. The results suggest that the perception of kinesthetic cues in patients with cerebellar dysfunction is considerably impaired. Consequently, the cerebellum plays an important role in processing this type of information. Supported by NIH grants R01NS21958 and P01NS30013 and Flinn Foundation.

## 203.2

THE INVOLVEMENT OF THE HUMAN CEREBELLUM IN NON ASSOCIATIVE- (STARTLE-) AND ASSOCIATIVE (LOWER LIMB FLEXION REFLEX) PROCESSES. ELECTROPHYSIOLOGICAL DATA SUPPORTED BY IMAGING TECHNIQUES.

F.P. Kolb\*, D. Timmann\*, C. Baier, C. Weiller\*, H.C. Diener\*, Inst. of Physiol. Univ. of Munich, 80336 Munich, \*Dept. of Neurol. Univ. Essen, 45122 Essen, Germany.

Beside the generally accepted participation of the cerebellum in motor control, information about the cerebellum's significant role in associative and non associative motor related processes has been accumulated. The aim of the current study was to compare responses in normal and cerebellar subjects during 1) classically conditioned limb flexion reflexes (associative process) and during 2) the habituation of the startle reflex (non associative process).

Current pulses were used as an unconditioned stimulus (US) and applied to the subjects medial plantar nerve eliciting an unconditioned flexion reflex (UR). Preceding the US by 450ms an auditory stimulus (CS) was applied via headphones. The acoustic startle reflex was evoked with a 95 dB 1 kHz pulse (50ms). The corresponding tibial- and sterno cleido mastoide muscle activity was recorded together with the accompanying cerebellar regional blood flow (rCBF), monitored by PET scan technique. The process of conditioning and that of habituation correlated significantly with the rCBF of the medial cerebellum. Cerebellar patients could be hardly conditioned and showed significant differences in temporal UR characteristics compared to control subjects. Our data strongly support the assumption of a medial cerebellar involvement in both, associative and non associative motor related processes. ## 203.4

MOTOR CORTEX ACTIVITY IS ABNORMAL PRIOR TO MOVEMENT IN CEREBELLAR DEGENERATION (CD) J. Liepert, E.M. Wassermann\*, A. Samii, L.G. Cohen, M. Hallett\*. Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892

Reaction time (RT) is prolonged in CD and Parkinson's disease (PD). Earlier studies showed that, in PD, motor cortex excitability build-up preceding a movement is abnormal presumably due to reduced thalamic drive. This study tested the hypothesis that patients with CD also have a deficit of pre-movement excitability build-up in motor cortex.

Ten patients with CD and no clinical involvement of basal ganglia or corticospinal tract and 10 age-matched normals performed a reaction time task making rapid wrist flexions in response to a visual go-signal. To test pre-movement motor cortex excitability, transcranial magnetic stimuli (TMS) below motor threshold were delivered at intervals (0-250 ms) after the go-signal. The number of motor evoked potentials occurring in each 20 ms time bin preceding EMG onset was determined, thus indicating the time-course of excitability prior to EMG onset. In 50% of trials, an additional TMS was given simultaneously with the go-signal to see if pre-activation of motor cortex changed the excitability build-up.

RT in CD was prolonged compared to controls (247 vs 200 ms, p=0.0015). Pre-movement excitability started 100 ms earlier in the patients than in the controls and showed a slower increase. With the additional TMS, the excitability build-up in the patients shortened and approached normal.

We postulate that the prolongation of RT in CD is mainly due to an abnormal excitability build-up in the motor cortex. The most likely cause is impairment of the cerebello-thalamo-cortical loop. Pre-activation of the motor cortex by TMS improves the excitability build-up in CD.

## 203.5

COMPARISON OF SHORT-LATENCY MAGNETIC EVOKED RESPONSES TO MEDIAN NERVE STIMULATION IN CEREBELLUM WITH INITIAL THALAMIC AND CORTICAL RESPONSES IN NORMAL HUMAN SUBJECTS. C. D. Tesche, Brain Research Unit, Low Temperature Laboratory, Helsinki University of Technology, FIN-02150 Espoo, Finland.

Synchronized post-synaptic current flow generated by a localized, spatially-ordered neuronal population is a primary source of magnetoencephalographic (MEG) signals. Simultaneous activation of multiple brain areas may be disentangled from MEG data if the topographies recorded by the sensors for each source are sufficiently distinct. In somatosensory afferent pathways, sites of synaptic activity include dorsal column nuclei, thalamus, vermis and paravermal area, and postcentral cortex. Magnetic evoked responses to unilateral median nerve stimulation at the wrist (Interstimulus interval 0.5 s, 0.3 ms duration, 15% random omission) were recorded from four adult subjects with a 122-channel MEG array placed over the scalp. Magnetic field patterns were computed for dipolar current flow in the neighborhood of the VPL nucleus, spinocerebellum and primary somatosensory cortex utilizing a realistic model for the conducting volume of the head. Signal-space projection (SSP) was used to identify evoked-response waveforms from the data. Although previously reported thalamic responses at 15–17.5 ms consistently preceded cortical activity by 1–2 ms (range 16–19 ms) (Tesche, in press), responses from the eight recordings were consistent with initial peak activation of cerebellar sources occurring over a wider range (13–19 ms) with no consistent sequential relationship with respect to the initial peak thalamic response. This pattern is consistent with parallel activation of these two structures. There are no previous reports of non-invasive detection of population dynamics in normal human cerebellum. This method provides a valuable new tool for functional studies of this important brain area. Support: NINDS 3 F33 NS09623-01S1

RELATIONSHIP OF CEREBELLAR PURKINJE CELL DISCHARGE TO MOVEMENT PARAMETERS DURING VISUOMOTOR ARM TRACKING. I. SIMPLE SPIKES. T.J. Ebner, M.T.V. Johnson & J.D. Coltz, Graduate Program in Neuroscience and Depts. of Neurosurgery and Physiology, University of Minnesota, Minneapolis, MN 55455.

In a previous electrophysiological study of cerebellar Purkinje cells in our laboratory (Coltz & Ebner, 1995), we attempted to determine the relationship between simple spike discharge and movement position, velocity, and acceleration in monkeys using two variants of a visuomotor arm tracking task. One task required the animal to track moving targets in two dimensions with a bell-shaped velocity profile, while the other specified a constant velocity. Movements were made at 4-5 peak or constant velocity levels (2-6 cm/s) to endpoints in 8 directions. A multiple linear regression model was used to fit the temporal profile of simple spike discharge to the temporal profiles of position, velocity, and acceleration. Analyses of 86 cells revealed that in both tasks, position, velocity, and acceleration all were important predictors of simple spike rate. On average, however, movement velocity was a better predictor of simple spike rate than position or acceleration (maximal mean  $R^2$  velocity=0.57,  $R^2$  position=0.46,  $R^2$  acceleration=0.36). An additional analysis evaluated the relationship between cell discharge and the kinematic parameters for each direction-velocity combination in the task. There was a tendency for single cells to correlate with position, velocity, and acceleration most strongly at different direction-velocity combinations. That is, for a given cell, a spatial parcellation of parameter encoding was found to exist. These findings demonstrate that Purkinje cell simple spike discharge correlates with kinematic parameters of movement and may do so using a spatial parcellation scheme. Supported by NIH grants NS 18338 and NS 31350.

## 203.9

SOMATOSENSORY PATHWAYS TO THE CEREBELLUM: SPATIAL ORGANIZATION OF CORTICOPONTINE TERMINAL FIBERS IN THE RAT.

K.A. Lyngstad<sup>1</sup>, J.H. Thompson<sup>\*2</sup>, J.M. Bower<sup>2</sup> and J.G. Bjaalie<sup>1</sup>, <sup>1</sup>Dept. of Anatomy, University of Oslo, 0317 Oslo, Norway. <sup>2</sup>Division of Biology 216-76, Caltech, Pasadena, CA, 91125. Information is transferred from the primary somatosensory cortex (SI) via the pontine nuclei (PN) to the cerebellar cortex. SI contains a continuous somatotopic map, whereas the cerebellar hemispheres contain 'fractured' somatotopic maps. We are investigating the somatotopic map at the intermediate level, the PN. Using high density micromapping, we have injected Phaseolus vulgaris - leucoagglutinin (Pha-I) into somatotopically defined regions of SI. The complete distribution of labeled fibers were displayed in computer 3D - reconstructions. With injections covering most parts of SI, labeled fibers were distributed in discontinuous zones located within a large lamella-shaped subspace of the PN, 'the pontine SI-lamella', with a thickness (from ventral to dorsal) of 300-450  $\mu$ m. Following injections covering most parts of the SI face representation, labeled fibers occupied a smaller lamella of roughly the same thickness. Within this 'pontine face-lamella', most of the fibers were located in two main zones: one large laterally located and one small medially located zone. These two main zones were connected with thin rims of labeled fibers. A single punctate injection in the SI upper lip (UL) representation gave rise to labeled fibers confined to a considerably thinner lamellar subspace. Labeled fibers within this 'pontine UL-lamella' was completely separated into two zones, corresponding to the lateral and medial zones within the face-lamella. This discontinuous labeling pattern may partly represent the basis for a fractured somatotopy in the further projection to the cerebellum. We are currently exploiting double anterograde tracing with Pha-I and biotinylated dextran amine to further elucidate the principles of the corticopontine somatotopic organization. ## 203.6

MYOCLONIC SEIZURE: NECESSITY OF THE INFERIOR OLIVE, TEMPORAL STRUCTURE, AND ALTERATIONS IN SEROTONIN FUNCTION. J.P. Welsh<sup>\*</sup>, M.E. Menaker, B. Chang and S.A. Aicher, Dept Physiology & Neuroscience, New York Univ Med Center, New York NY 10016 & Dept Neurology, Cornell Univ Med Col, New York, NY 10021.

Genetically Epilepsy Prone Rats (GEPR/3Hsd) were used to determine whether pathophysiological inferior olivary (IO) function was necessary for a myoclonic seizure. Seizures were induced by an ascending frequency ramp auditory stimulus. The seizures of 5 GEPR/3Hsd rats were measured non-invasively before and after lesion of the IO by i.p. administration of 3-acetylpyridine, harmaline and niacinamide. As previously described (Reigel et al., *Life Sci*, 1986), the seizure consisted of running, clonus, and dorsiflexion of the back. We further found that the clonus, which exhibited a frequency of 2-6 Hz, was always preceded by a 5-10 s period of profoundly exaggerated  $9.2 \pm 0.1$  Hz tremor. Electromyographic recordings obtained simultaneously from the left and right biceps brachii revealed the tremor to consist of 50 ms bursts of activity that were nearly perfectly synchronized across the midline. The neurotoxin abolished both the tremor and clonus in 4 of 5 rats. By 1 mo post-lesion, 2 rats regained the seizure, but 2 were seizure-free for 3 mos, at which time their brains were removed. A Nissl stain, immunostaining for NSE, and a retrograde tracer revealed a complete loss of IO neurons in the seizure-free rats, but some sparing in the caudal IO in the 2 that regained seizures. In a separate group of 4 GEPR/3Hsd rats, quantitative immunocytochemistry revealed a nearly complete absence of serotonin fibers within the IO. Further experiments revealed a reduced sensitivity of GEPR/3Hsd to the tremorogenic effect of harmaline. The data indicate that the IO, the origin of the cerebellar climbing fibers, may play an important role in the genesis of myoclonus and indicate a site where serotonergic drugs may have anti-myoclonic actions. (Supported by the Myoclonus Research Foundation & NINDS NS-31224)

## 203.8

RELATIONSHIP OF CEREBELLAR PURKINJE CELL DISCHARGE TO MOVEMENT PARAMETERS DURING VISUOMOTOR ARM TRACKING. II. COMPLEX SPIKES. J.D. Coltz<sup>\*</sup>, M.T.V. Johnson & T.J. Ebner, Graduate Program in Neuroscience and Depts. of Neurosurgery and Physiology, University of Minnesota, Minneapolis, MN 55455.

The relationship between cerebellar Purkinje cell complex spike discharge and limb movements remains poorly understood. In this study, we use a previously described visuomotor arm tracking task, coupled with novel analyses, in an attempt to evaluate this relationship. Purkinje cells were recorded in two monkeys during a 2-dimensional visuomotor task that required tracking of targets moving at 5 constant velocities (2-6 cm/s), reaching from a centrally located start position to endpoints in 8 different directions. The task comprised 2 periods: (1) a cue (nonmovement) period, during which the animal was provided information about the velocity and direction of the upcoming movement, and (2) a track (movement) period, during which the animal moved from start to endpoint. Single-trial analyses of 34 Purkinje cells utilized a multiple logistic regression model in which the complex spike data were related to movement velocity and direction in the cue and track periods. The strength of association between these parameters and cell discharge was quantified by calculating mean partial  $R^2$  values. Significant correlations with both velocity and direction were found; in addition, a temporal ordering of these correlations emerged. The maximal mean  $R^2$  for direction occurred during cue (0.22), dropping to a minimum of 0.06 during track. For velocity, correlations were stronger during track (maximal mean  $R^2$  = 0.23) than cue (0.05). These findings indicate that Purkinje cell complex spike discharge encodes information about both sensory and motor parameters during a visuomotor arm tracking task in primates. Supported by NIH grants NS 18338 and NS 31530.

## 203.10

SOMATOSENSORY INPUT TO THE MONKEY CEREBELLUM: DE-EMPHASIS OF DISTAL EXTREMITIES DEMONSTRATED IN COMPUTERIZED 3-D MAPS. K. Vassbo, G. Nicotra, M. Wiberg & J. G. Bjaalie<sup>\*</sup>, Dept. of Anatomy, University of Oslo, 0317 Oslo, Norway. <sup>§</sup>Dept. of Anatomy, University of Uppsala, 75123 Uppsala, Sweden.

The cerebellum receives somatosensory cortical information via the pontine nuclei. We have investigated the anatomic organisation of corticopontine neurons in the postcentral somatosensory areas 3a, 3b, 1 and 2 of the cynomolgus monkey. Large injections of wheat germ agglutinin - horseradish peroxidase were made in the pontine nuclei. Retrogradely labeled cells were found in cortical layer 5, and their distribution was quantitatively recorded. This distribution was analysed and visualised on a Silicon Graphics workstation running custom software. The software was developed for assembling section-based data into three-dimensional reconstructions for subsequent flattening. 3-D color-coded density graphs were used for visualizing the distribution of labeled cells. We found considerably higher average densities of labeled cells in areas 1, 2 and 3a as compared to area 3b. We also found marked and reproducible density gradients within areas. These gradients were compared with previously published somatotopic maps of the somatosensory cortex. Judging from this comparison, the density of corticopontine labeled cells was always higher in parts devoted to trunk and proximal limbs than in parts representing distal limbs. This suggests that impact from distal limbs on cerebellar movement control is quantitatively less important than hitherto assumed. Supported by The Research Council of Norway and The Jahre Foundation.

## 203.11

## CLASSIFICATION OF THE RAT CEREBELLAR BASKET AND STELLATE CELLS: EVIDENCE FOR A CONTINUOUS DISTRIBUTION OF TYPES THROUGH PRINCIPAL COMPONENT ANALYSIS

F. Sultan\* and J. Bower Div. of Biology, Caltech, Pasadena, CA 91101

The cerebellar inhibitory interneurons of the molecular layer (i.e., the basket and stellate cells) are probably the second most numerous inhibitory interneurons in the central nervous system. Unfortunately, their classification is still a matter of controversy. In this study we have compared the morphology of these neurons using a multivariate statistical analysis. Thirty six parameters extending over a variety of morphological features (geometrical, topological and metrical) were obtained from 3-dimensional reconstructions of twenty six rat rapid-golgi stained basket and stellate cells. The subsequent principal component (PC) analysis showed that the first PC was strongly correlated with the mean vertical (perpendicular to the pia) location of the axonal fiber swellings (SW), the number of basket collaterals, the vertical location of the soma in the molecular layer, the maximal distance of the dendritic tips from soma, and the dendritic thickness. The second PC was strongly correlated with parameters describing some of the axons' morphology: distal spread of the SW in the horizontal axis (in the parasagittal plane and tangential to the pia), the spread of the SW in the vertical axis and the ratio of the proximal vs. distal portion of the SW distribution. The principal plane showed no clustering of the data points, with respect to either the first PC, the second PC or both. First, this analysis suggests that inhibitory neurons in the molecular layer of the cerebellum represent a continuous distribution of morphological properties which vary dependent on the vertical position of the soma in the molecular layer. Thus, cells traditionally classified as either stellate or basket cells appear to be one cell type. Second, it may be possible to link the variations in neuronal morphology to specific features in the development or organization of the cerebellar cortex. For example, the first PC is most likely related to the time of the neurons birthdate. This was first proposed by P. Rakic for the dendritic morphology (J. Comp. Neurol.: 146, 1972). The second PC could be related to activity-dependent plasticity due to synaptic interactions with other neurons (inhibitory interneurons and/or Purkinje cells), and/or to differences in the spatial extent of the input to these cells, i.e., the different sizes of the fractured somatotopic patches of the granular layer (Shambes, G.M., Gibson, J.M., and Welker, W. Brain Behav. Evol.: 15, 1978).

## DEGENERATIVE DISEASE: ALZHEIMER'S-BETA-AMYLOID-PROTEIN INTERACTIONS II

## 204.1

AMYLOID BETA PROTEIN BINDS THE EUKARYOTIC 20S PROTEASOME. L. Gregori\*, J. F. Hainfeld\*, M. N. Simon\*, and D. Goldgaber. Department of Psychiatry and Behavioral Science, School of Medicine, State University of New York, Stony Brook, NY 11794. <sup>1</sup>Biology Department, Brookhaven National Laboratory, Upton, NY 11973.

Proteasomes are responsible for the ATP-dependent degradation of ubiquitinated proteins. In Alzheimer's disease (AD) and other age-related neurodegenerative disorders, ubiquitinated proteins are not removed and accumulate into intraneuronal structures. We previously found that amyloid beta protein (A $\beta$ ) inhibits ubiquitin/proteasome dependent conjugate degradation. Here we show that A $\beta$  directly binds the 20S eukaryotic proteasome and forms a stable proteasome-A $\beta$  complex which was detected by Western blot using anti-A $\beta$  antibodies. Using a 1.4 nm Nanogold labeled A $\beta$ , we visualized proteasome-A $\beta$  complexes by scanning transmission electron microscopy. Analysis of side and end views of proteasome-A $\beta$  complexes revealed mostly a single gold particle corresponding to one gold labeled A $\beta$  molecule inside the proteolytic structure, along the peptide channel. Direct interaction of A $\beta$  with the inner proteolytic compartment of the proteasome may explain the generation of ubiquitinated lesions observed in AD and other neurodegenerative disorders. In addition, the detection of Nanogold labeled peptide inside the 20S eukaryotic proteasome suggests that the informational requirements in peptide degradation by eukaryotic proteasomes are distinct from those of prokaryotic proteasomes. This study was supported by a Zenith award from Alzheimer's Association to D. G.

## 204.3

HUMAN FE65: IDENTIFICATION AND LOCALISATION OF A PROTEIN INTERACTING WITH THE INTRACELLULAR CARBOXY-TERMINUS OF THE AMYLOID PRECURSOR PROTEIN AND ITS EFFECT UPON PROCESSING OF THE AMYLOID PRECURSOR PROTEIN. D.M. McLoughlin and C.C.J. Miller\*. Depts. of Neurology and Neuroscience, Institute of Psychiatry, Denmark Hill, London SE5 8AF, UK

The yeast two-hybrid system was used to screen a human brain cDNA library for proteins that interact with the cytoplasmic domain (carboxy-terminal 47 amino acid residues) of APP. Four cDNA sequences coding for such proteins were isolated and identified. Two of these cDNA sequences encoded overlapping regions of the human homologue of a previously described rat neuronal protein, FE65. This has been shown to be developmentally regulated and contains a putative transcription activating domain. We have sequenced the entire cDNA encoding the human version of FE65 and have demonstrated that the amino-terminal approximate 80 amino acids are not required for binding to APP.

In order to study the subcellular localisation of FE65, a myc-epitope tagged version of FE65 was created and expressed in transfected CHO cells. Although previously considered to be a nuclear protein, it appears that human FE65 is localised to the cytoplasm. Wild-type human FE65 was co-transfected with APP 695 in order to investigate its effects upon the processing of APP.

This work was supported by grants from the Wellcome Trust and MRC to C.C.J.M. D.M.M. is a UK Alzheimer's Disease Society Research Fellow.

## 204.2

INTRACELLULAR DETECTION OF THE C-TERMINAL TAIL CONTAINING APP POLYPEPTIDES IN AD BRAIN TISSUE. G. J. Kotwal, J. Chan\*, M. Tseng\*, L. A. Carr\*, D. E. Justus, and J. Daly. Departments of Microbiology and Immunology, <sup>1</sup>Anatomical Sciences and Neurobiology and <sup>2</sup>Pharmacology, University of Louisville School of Medicine, Louisville KY 40292.

A major hallmark of Alzheimer's disease (AD) is the presence of extracellular amyloid plaques consisting primarily of beta peptide. The beta peptide is the product of processing of the amyloid precursor protein (APP). During the processing of APP, the cytoplasmic fragment has been suggested to remain within the cell. In order to investigate the fate of this fragment, we generated an antibody specific for a nine amino acid peptide, the sequence of which was derived from the carboxy-terminal putative cytoplasmic tail of APP. Computer analysis of the entire APP gene, searching for regions of greatest antigenicity, surface probability, hydrophilicity, and presence of beta turns, indicated that the cytoplasmic tail region is an immunodominant region of APP. The peptide coupled to keyhole limpet hemocyanin protein (KLH), produced a very high titer antibody (1:1X 10<sup>6</sup>). In order to further characterize the antibody, immunohistochemical staining of mouse neuroblastoma cells in cell culture (SN49MA) stably transformed with a full-length APP was done and the intense specific staining only in the SN49MA, but not in the controls was indicative of the specificity of the antibody for APP. EM analysis of rat brains subjected to reperfusion injury confirmed the intracellular localization of the antibody staining. The antibody was also able to specifically detect the accumulation of the stable C-terminal tail containing portion of APP in neurites of the amygdala and hippocampus of human Alzheimer brain tissue, but not in age-matched normal brain tissue. These findings are indicative of a likely role of the C-terminal tail of APP in the pathogenesis of AD. This work was supported by the Humana startup funds and the Graduate Research Council funds awarded to GJK.

## 204.4

NEURONAL PATHOBIOLOGY OF THE CARBOXYL-TERMINUS OF THE AMYLOID PRECURSOR PROTEIN. D.L. McPhie\*, K.J. Ivins, M.R. Kozlowski, R.L. Neve. Dept. Genetics, Harvard Medical School, McLean Hospital, Belmont, MA 02178; Geron Corp., Menlo Park, CA 94025.

We have shown previously that the carboxyl-terminal 100-amino acid fragment (C100) of the Alzheimer amyloid precursor protein (APP) is toxic to neurons, and that its expression in the brains of transgenic mice causes Alzheimer disease-like neuropathology and loss of cognitive functions. To begin to clarify the mechanism by which C100 kills neurons, we have sought cDNA clones encoding binding proteins for this fragment of APP. One of these cDNAs codes for a neural-specific P21-activated kinase (N-Pak) that binds both to C100 and to APP. The *n-pak* cDNA represents an ~11-kilobase mRNA with a 1632 base pair open reading frame encoding a 61 kilodalton serine/threonine kinase. RNA blot analyses and *in situ* hybridization histochemistry revealed that *n-pak* mRNA is nervous system-specific and is present at highest levels in regions of the adult brain that are severely affected in Alzheimer disease. Anti-APP immunoreactivity was specifically coprecipitated with N-Pak from neurons, and N-Pak immunoprecipitated from transfected cells demonstrated kinase activity in the presence of the activated p21 proteins rac1 and cdc42. The known involvement of these small G proteins in the machinery controlling axonal outgrowth suggests that disruption of this pathway by C100 or by familial Alzheimer disease APP mutants may play a part in the disassembly of the cytoskeleton that occurs in Alzheimer disease. Supported by AG12954 and Geron Corporation.

**$\beta$ -AMYLOID PEPTIDE INTERACTS WITH  $\alpha$ -TUBULIN ( $\alpha$ 1) IN VIVO.** S. R. Hughes<sup>1</sup>, T. Watanabe<sup>2</sup>, J. Cheetham<sup>2</sup>, J. Knaeblein<sup>1</sup>, J. D. Buxbaum<sup>2</sup>, P. Greengard<sup>2</sup>, N. G. Riedel<sup>1</sup>, and S. R. Sahasrabudhe<sup>1</sup>.  
<sup>1</sup>Hoechst Marion Roussel Inc., Neuroscience Therapeutic Area, P.O. Box 2500, Somerville, NJ 08876. <sup>2</sup>The Rockefeller University, Laboratory of Molecular and Cellular Neuroscience, New York, NY 10021.

Alzheimer's disease is characterized by the presence of neuritic plaques in the brain containing aggregates of  $\beta$ -amyloid ( $A\beta$ ) peptide, a 39-43 amino acid peptide derived post-translationally from a larger amyloid precursor protein (APP). We have used the yeast interaction trap or two-hybrid system to clone genes encoding proteins capable of interacting with  $A\beta$ . In this system, a LexA- $A\beta$  fusion protein (bait) occupies LexA binding sites in the upstream DNA region of LacZ and LEU2 reporter genes to inhibit their expression. Expression of an  $A\beta$ -interacting protein from a B42 fusion library with the bait allows the activation of the reporter genes by bringing the activator sequence B42 in close proximity to the LexA binding sites. In this study, we report the identification of the clone encoding human  $\alpha$ -tubulin ( $\alpha$ 1). This protein was capable of interacting with the  $A\beta$  peptide, but failed to interact with LexA-bicoid or LexA-C100 fusion proteins, indicating that the observed interaction with  $\alpha$ -tubulin was specific. When yeast cells expressing  $\alpha$ -tubulin were subjected to immunoprecipitation with anti-LexA antibody, the epitope of which is contained within the bands corresponding to the prey fusion protein, predictive of  $\alpha$ -tubulin-B42 complexes, were detected, indicating *in vivo* interaction between  $A\beta$  and  $\alpha$ -tubulin. Furthermore, purified preparations of tubulin were shown to bind the  $A\beta$  peptide. The presentation will discuss the implications of these findings.

## 204.7

**AMYLOID  $\beta$ -PEPTIDE MAY INDUCE EXTRACELLULAR  $Ca^{2+}$  ENTRY PATHWAYS INTO N1E-115 NEUROBLASTOMA CELLS.** L. Stejanko<sup>\*</sup> and R. M. Davidson. Neuroscience Graduate Program, University of Connecticut Health Ctr. Medical School, Farmington, CT 06030.

It has been well documented that the mechanism for amyloid  $\beta$ -peptide ( $A\beta$ ) induced neurotoxicity involves, in part, increased extracellular  $Ca^{2+}$  entry into cells, although, the ionic mechanism(s) to explain  $A\beta$  induced  $Ca^{2+}$  influx remains unclear. Based on our earlier findings with N1E-115 neuroblastoma (NB) cells (Davidson et al., 1994), we suggested that  $A\beta$  may be forming  $Ca^{2+}$  permeable channels *de novo* and/or causing a change in the activity of endogenous  $Ca^{2+}$  channels. To test our hypothesis, we have examined the effects of  $A\beta$  on the NB cell's dihydropyridine-sensitive ("L" type)  $Ca^{2+}$  channel single channel activity. In addition, we have studied its ability to form new channels using a synthetic, liposomal model of the NB cell membrane.

When cells were incubated with  $A\beta$  for 4-24 hrs, cell-attached recordings demonstrated a ~30% increase in  $P_{open}$  of the L-type  $Ca^{2+}$  channel ( $p < 0.05$ ). In addition, a statistically significant increase in  $P_{open}$  of the L-type channel was noted when  $A\beta$ 1-40 was added to the bath while recording channel activity in the cell-attached but not the excised-patch configuration. The control peptides  $A\beta$ 40-1,  $A\beta$ 25-35, human and rat amylin did not produce a statistically significant change in  $P_{open}$ . To confirm the electrophysiological finding, the viability tests performed at 48 hrs peptide treatment demonstrated that nimodipine (10nM) can attenuate the toxic effect of  $A\beta$ 1-40 (23 $\mu$ M) on NB cells. Furthermore,  $A\beta$ 1-40 (5 $\mu$ g/ml) incorporated into a synthetic NB membrane bilayer formed nimodipine-insensitive, non voltage-gated, low-conductance channels for both mono- and di-valent cations. The permeability sequence ( $P_{Ca^{2+}}$  as reference) estimated from the reversal potential of the channel current in asymmetrical solutions, was  $P_{Ca^{2+}} > P_{K^{+}} > P_{Na^{+}} > P_{Cl^{-}}$ . Furthermore,  $Ca^{2+}$  was able to impede monovalent ion conductance through the  $A\beta$  channels. Physiological levels of liposomal-membrane cholesterol attenuated calcium conductance and reduced the  $P_{open}$ . These data demonstrate that  $A\beta$ 1-40 may increase  $Ca^{2+}$  entry into neuronal cells by "exciting" endogenous  $Ca^{2+}$  channels and by forming  $Ca^{2+}$  channels *de novo* on the membrane surface. Understanding the mechanism further may help in designing appropriate pharmacological therapies for Alzheimer's Disease. Supported by NIH/NIDR grant # DE09662.

## 204.9

**PROGRESS IN UNDERSTANDING THE ACTIVITY-REGULATING AND NEUROPROTECTIVE SIGNAL TRANSDUCTION PATHWAY OF SECRETED APP.** M. P. Mattson<sup>\*</sup>, K. Furukawa, B. Sopher, R. J. Mark, and G. M. Martin. Sanders-Brown Center on Aging and Dept. of Anatomy & Neurobiology, Univ. of Kentucky, Lexington, KY 40536. Dept. of Pathology, Univ. of Washington, Seattle, WA 98195.

$\alpha$ -secretase cleavage of the  $\beta$ -amyloid precursor protein ( $\beta$ APP) liberates a secreted form of APP (sAPP $\alpha$ ) that may play important roles in regulating neuronal plasticity and survival. In embryonic rat hippocampal cell cultures sAPP $\alpha$  suppresses neuronal activity by activating  $K^{+}$  channels (Nature 379:74-78 (1996)). We have found that sAPP $\alpha$  also suppresses NMDA currents, but not AMPA or kainate currents. Cyclic GMP appears to mediate sAPP $\alpha$ -induced  $K^{+}$  activation, suppression of calcium responses to glutamate, and protection against excitotoxicity. Structure-activity studies revealed that the C-terminal portion of sAPP $\alpha$  mediates activation of the cGMP pathway, and that a heparin-binding domain therein greatly increases sAPP $\alpha$  activity relative to sAPP $\beta$  (see Furukawa et al., this meeting). These data suggest that APP mutations that increase  $\beta$ -secretase cleavage may promote neuronal degeneration in Alzheimer's disease by reducing levels of neuro-protective sAPP $\alpha$ . Most recently, we have initiated attempts to isolate a sAPP $\alpha$  receptor using two approaches. First, using a GST-sAPP444-612 affinity column we have isolated two sAPP $\alpha$ -binding proteins (approximately 80 and 50 kDa) and are in the process of obtaining amino acid sequence information. Second, based upon the possibility that the sAPP $\alpha$  receptor has intrinsic guanylate cyclase activity (Biochem. J. 311: 45-47 (1995)) we are determining whether "orphan" or novel receptor guanylate cyclases might be a receptor for sAPP $\alpha$ . (supported by the NIH and the Alzheimer's Association).

Neuroscience Interdepartmental Program, Brain Research Institute of UCLA Medical School, Los Angeles, CA 90024.

The formation of amyloid plaques has been implicated to play a role in the pathogenesis of Alzheimer's disease (AD). AD-related amyloid beta-peptide ( $A\beta$ ) and its active fragment  $A\beta$ 25-35 have been found to be neurotoxic, perhaps by dysregulation of intracellular  $Ca^{2+}$  levels. We have reported that  $A\beta$ 25-35 can form voltage dependent ion channels with multiconductive levels in planar lipid bilayers. The  $A\beta$ 25-35-containing membranes exhibit slight cation selectivity. The resulting ionic disturbance may lead to neuronal death. In this study, we have examined the channel forming activity of different variants of  $A\beta$ 25-35. Replacing the C-terminal Met with Cys, Ser, or Asp preserved both neurotoxicity and channel forming ability. Deleting the C-terminal Met caused a loss of both neurotoxicity and channel forming activity. Substitution of Asp for Asn at amino acid residue 27 eliminated  $A\beta$ 25-35 toxicity, and its channel forming activity.  $A\beta$ 25-35 with Gln at position 27 exhibited toxicity at high concentration (80 $\mu$ M), and formed ionic channels only at high concentration (80 $\mu$ M) as well. Deletion of two N-terminal amino acid residues (namely,  $A\beta$ 27-35) diminished toxicity and channel formation. Reversed  $A\beta$ 25-35 or amidated  $A\beta$ 25-35 did not have any toxic effect on neurons and could not form channels. Mutations at amino acid residue 35 did not alter properties of channels, whereas variations at amino acid residue 27 changed the voltage dependence. This indicates that residue 27 may play a role as voltage sensor of  $A\beta$ 25-35 ion channels. The results suggest that channel formation is necessary for neurotoxicity.

**CYTOSOLIC  $Ca^{2+}$  OSCILLATIONS IN DIFFERENTIATED HUMAN NEURONS: EFFECTS OF  $\beta$ -AMYLOID.** Z. Y. Gao<sup>1</sup>, H. W. Collins<sup>2</sup>, F. M. Matschinsky<sup>3</sup>, V. M. Y. Lee<sup>1</sup> and B. A. Wolf<sup>1</sup>. Depts. <sup>1</sup>Pathology & Lab Med., <sup>2</sup>Biochemistry & Biophysics, Univ. Penn. Sch. of Med., Philadelphia, PA 19104

Differentiated NT2N cells are a unique model of human neurons in culture. Measured by fura-2 technique, NT2N cells produced spontaneous  $Ca^{2+}$  oscillations, which were absent in undifferentiated Ntera2/C1.D1 (NT2) cells. The  $Ca^{2+}$  oscillations included  $Ca^{2+}$  wave, plateau and spike patterns. Glutamate induced a rapid and sustained cytosolic  $Ca^{2+}$  increase while acetylcholine only induced a transient increase. Addition of the glutamate receptor antagonists CNQX (10  $\mu$ M) + DAP5 (10  $\mu$ M) or atropine (20  $\mu$ M) did not block the spontaneous  $Ca^{2+}$  oscillations, thus glutamate receptor or muscarinic receptor activation is not required for the oscillations. Omission of extracellular  $Ca^{2+}$  completely abolished all types of  $Ca^{2+}$  oscillations and decreased the average  $Ca^{2+}$  level from  $106 \pm 14$  nM to  $59 \pm 8$  nM. Addition of the  $Ca^{2+}$  channel blocker nifedipine (L-type) or GVIA (N-type) significantly suppressed  $Ca^{2+}$  oscillations, while MVIIC (P- and Q-types) had no effect. Thapsigargin (endoplasmic reticulum  $Ca^{2+}$ -ATPase inhibitor) did not inhibit  $Ca^{2+}$  oscillations but induced a transient slight increase in the average cellular  $Ca^{2+}$  levels. Four day culture of NT2N cells with 40  $\mu$ M synthetic  $\beta$ -amyloid protein (A $\beta$ 42) abolished  $Ca^{2+}$  oscillations. 4  $\mu$ M A $\beta$ 42 caused minor inhibition while 0.4  $\mu$ M had no effect. In conclusion, NT2N cells generate spontaneous  $Ca^{2+}$  oscillations by  $Ca^{2+}$  influx through L- and N- type channels, which are inhibited by Alzheimer's A $\beta$ 42.

## 204.10

**SPECIFIC INTERACTIONS OF ALZHEIMER'S DISEASE MEMBRANE PROTEINS S182 AND STM2 WITH  $\beta$ -APP ON CELL SURFACES.** N. N. Dewji<sup>1</sup> and S. J. Singer<sup>2</sup>, University of California, San Diego, Departments of Medicine (1) and Biology (2), 0322, La Jolla, CA 92093.

Mutations in the genes for the  $\beta$ -amyloid precursor protein ( $\beta$ -APP), a type 1 single -membrane spanning integral protein, and the more recently identified closely homologous seven-membrane spanning integral proteins S182 and STM2, together account for all early-onset familial Alzheimer's disease. The normal functions of the three proteins are not known nor do we know how their functions are implicated in the disease.

We recently proposed (Science, 271, 159-160, 1996) based on precedents in other systems of an intercellular interaction crucial to development between single membrane spanning and seven membrane spanning integral proteins, that one or more forms of  $\beta$ -APP and S182 (or STM2) may normally be components of an intercellular signaling system.  $\beta$ -APP and S182 or STM2 on the surfaces of neighboring cells would bind to one another specifically through their extra-cellular domains protruding from the cell membranes,  $\beta$ -amyloid (A $\beta$ ) being a proteolytic by-product of this interaction. To test this proposal full-length cDNAs for S182 and STM2 were cloned by PCR and subcloned into pCDNA3.  $\beta$ -APP695 cDNA was also subcloned into pCDNA3 and the constructs were used to transiently transfect cultured cells. Polyclonal antibodies raised to peptide sequences of STM2 and S182 demonstrated the presence of the two proteins at the surface of transfected cells. In order to determine if STM2 or S182 on one cell interacts with  $\beta$ -APP on another, transfected cells expressing STM2 or S182 were mixed with cells expressing  $\beta$ -APP. Heterotypic cell aggregates were formed, as shown by double labeling with antibodies to  $\beta$ -APP and STM2 (or S182). Furthermore, this aggregation could be inhibited by excess soluble  $\beta$ -APP, indicating specificity of the interaction. Our work provides evidence for the direct physical interaction of  $\beta$ -APP with STM2 and S182, which may be crucial to the generation of A $\beta$  and the genesis of Alzheimer's disease.

## 205.1

**TF NEURO-E: A MOUSE NUCLEAR RECEPTOR INVOLVED IN THE CONTROL OF NEUROGENESIS.** A. Maelicke\*, U. Bauer, A. Maus, S. Schneider-Hirsch, S. Reinhardt, and M. Rentrop. Laboratory of Molecular Neurobiology, Institute of Physiological Chemistry and Pathobiochemistry, Johannes-Gutenberg Univ. Med. Sch., 55099 Mainz, Germany.

We have cloned the full length cDNA of a nuclear receptor, denoted TF neuro E, the transcription of which is induced early after cultured PCC7-Mz1 mouse embryonic carcinoma cells have been exposed to the morphogen retinoic acid (RA). TF-neuro-E expression was observed exclusively in the neuronal derivatives of Mz1 cells but not in glial or fibroblast derivatives. In the developing mouse brain, TF neuro-E was expressed in the early neuroepithelium and in zones of differentiating neurons. In the adult mouse brain, double labeling confirmed that TF neuro-E transcripts only occur in neurons. The coding sequence of TF neuro-E is 1482 bp. Using electrophoretic mobility shift assays, we have identified the direct repeat AGGTCA, without intervening nucleotide (DR0), as the hormone-responsive element of TF neuro-E. Because the E-domain of TF neuro-E does not contain an AF-2 subdomain, the transcription factor may act ligand-independent, either as homodimer, or as heterodimer with RXR. When transfected into PCC7-Mz1 stem cells that have not been exposed to RA, TF neuro-E induced within a day the expression of typical neuronal markers, suggesting that it acts as a determining or stabilizing factor of the neuronal cell lineage.

## 205.3

**TRANSCRIPTIONAL ACTIVITY OF MEF2 IS REQUIRED FOR NEURONAL DIFFERENTIATION OF P19 CELLS.** Shu-ichi Okamoto, Dimitri Krainc\*, Katerina Sherman, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital & Progr. in Neuroscience, Harvard Medical School, Boston, MA 02115.

MEF2A, B, C, and D are transcription factors that belong to the MADS (MCM1-agamous-deficiens-serum response factor) gene family. The expression of MEF2 proteins is highest in brain and skeletal muscle. Recent evidence suggests that MEF2 cooperates with basic helix-loop-helix proteins to induce myogenesis, whereas the function of MEF2 in brain remains unknown. In this work, we used P19 embryonal cells — a line of pluripotent cells that differentiate into the neuronal cell type when treated with retinoic acid (RA). Stable transfection of P19 cells with a dominant-negative form of MEF2 resulted in inhibition of RA-induced neurogenesis. We next examined the effects of ectopic expression of MEF2C on the developmental potential of P19 cells. In stable transfection experiments, most of the MEF2C-expressing cells were transformed into cells with bipolar morphology. The phenotypic characteristics of these cells are being examined in greater detail, but preliminary results suggest that some neuronal and muscle determinants are expressed. These results suggest that MEF2 may play an important role in cell fate determination of multipotential stem cells. This work was supported by NIH grant P01 HD29587.

## 205.5

**SONIC HEDGEHOG INDUCES PHOTORECEPTOR DIFFERENTIATION IN THE MAMMALIAN RETINA.**

E.M. Levine\*, J. Turner, H. Roelink, and T.A. Reh. Department of Biological Structure, University of Washington, Seattle, WA 98195.

Hedgehog is a diffusible protein that is important in many developmental patterning events in *Drosophila*. Several vertebrate hedgehog proteins have also been identified and one of them, sonic hedgehog (SHH) patterns the dorsal-ventral axis of the neural tube. In the *Drosophila* eye disc, hedgehog also controls the progression of photoreceptor differentiation in the morphogenetic furrow. We have identified two members of the hedgehog gene family that are expressed in the developing rat retina. In this study we investigated whether SHH is also active in promoting photoreceptor differentiation in the mammalian retina. An N-terminal recombinant SHH (SHH-N) was added to dissociated rat retinal cultures for 2-14 days and the number of retinal cells of various phenotypes was analyzed with immunohistochemistry. We found that the number of rod photoreceptors increased over 10-fold in the SHH-N treated cultures over the sister control cultures. By contrast, the number of retinal ganglion cells and amacrine cells was similar to those in control cultures. Thus, SHH-N specifically induces the generation of rod photoreceptors in rat retinal cultures. We propose that some of the molecular mechanisms for photoreceptor differentiation may be conserved in mammals and *Drosophila*.

This work was supported by funds from NINDS and NEI.

## 205.2

**P21 INVOLVEMENT IN NEURONAL DIFFERENTIATION.** F. Berger\*, P. Taupin, J. Ray, E. Gage. Laboratory of genetics, The Salk Institute, La Jolla. The process of terminal neuronal cell differentiation is intimately coupled to cell cycle arrest in G0. Molecules that inhibit cell cycle have been identified, among them p21 is an universal cell cycle associated kinase inhibitor. The investigation of p21 role in neuronal differentiation was motivated by: (i) its role in G1 restriction point which is essential for post-mitotic cells; (ii) its role in muscle cells differentiation; and (iii) its specific expression in adult neurons. Adult hippocampal neuronal progenitor cell line HC252, which contains a tetracycline regulatable v-myc oncogene, was used to investigate the role of p21 in neuronal differentiation. Two days after tetracycline addition, these committed cells stop dividing and terminally differentiate in 5 to 6 days. We also used adult hippocampal progenitors cultured in FGF-2 because of their pluripotential commitment to glial, neuronal and oligodendroglial lineages. HC252 cell differentiation is characterized by an early (day 3) p21 cytoplasmic immunodetection followed by a nuclear immunoreactivity of p21 by day 6 at which time the cells are terminally differentiated as demonstrated by tau expression. Adult unmodified progenitors with a neuronal morphology showed similar expression of p21. Immunocytochemistry data was confirmed by immunoblot and immunoprecipitation experiments. A functional study was also performed using antisense oligonucleotides targeting p21 expression. P21 antisense induced cell cycle reentry of differentiated HC252 cells. Retinoic acid differentiated progenitors decreased axono-dendritic formations and also reentered cell cycle when treated with antisense to p21. In both cell types sense and random controls did not induce any effect. In conclusion, p21 expression is correlated with neuronal differentiation both in adult progenitors and immortalized HC252 progenitor cells. Antisense experiments suggest an important role of p21 in maintenance of post-mitotic neuronal state. Transfection experiments using p21 inducible gene are currently underway to further analyze the inductive role of p21 in neuronal differentiation.

## 205.4

**STAGE-DEPENDENT RESTRICTIONS IN THE DEVELOPMENTAL POTENTIAL OF RETINAL PRECURSOR CELLS.** T. Belecky-Adams<sup>1</sup>, G. Teitelman<sup>2</sup> and R. Adler<sup>1</sup>. Wilmer Eye Instit., Johns Hopkins Univ. Sch. Med., Balto., MD 21287<sup>1</sup>, SUNY, Brooklyn, NY 11203<sup>2</sup>

Using the "window labeling" technique, that allows cell birth determination with a resolution of hours, we have shown that precursor cells born during embryonic day 5 (WL<sub>5</sub>) give rise predominantly to non-photoreceptor neurons when allowed to develop in vivo until embryonic day (ED) 18, or when they are isolated for low density culture after a 3 day exposure to the in vivo microenvironment. The same postmitotic cells, however, give rise predominantly to photoreceptors when isolated for culture 12 hr after terminal mitosis, suggesting that many WL<sub>5</sub> precursors remain plastic after cell birth. An equivalent comparison of the in vivo and in vitro fate of cells born on ED 6 or 7 (WL<sub>6</sub> and WL<sub>7</sub>) showed that many WL<sub>6</sub> precursors exhibit similar plasticity after terminal mitosis, whereas most WL<sub>7</sub> precursor cells give rise to non-photoreceptor neurons even when isolated immediately after terminal mitosis. Since there were no detectable differences in cell death between cultures, the data appear to indicate that the developmental potential of retinal precursor cells becomes restricted in a stage-dependent manner. Supported by NIH grant EY04859, NIH fellowship EYO6642, and Research to Prevent Blindness Inc.

## 205.6

**INVOLVEMENT OF DELTA-NOTCH SIGNALING IN THE CENTRAL TO PERIPHERAL ASPECTS OF GANGLION CELL DIFFERENTIATION IN THE RETINA.** C. Dooley, W.B. Thoreson\* and I. Ahmad. Dept. of Cell Biology and Anatomy, and Ophthalmology, University of Nebraska Medical Center, Omaha, NE 68198.

The Notch signaling regulates differentiation of immature cells through cell-cell interactions. We have shown previously that the expression of the Notch-1 receptor and the gene for its putative ligand delta-1 show a central to peripheral gradient during retinal development (Mech Dev. 53:73-85, 1995; ARVOAbstr.37: 200 1996). To test the hypothesis that Delta-Notch signaling is involved in the central to peripheral aspect of cell-fate determination in the retina we have studied the effect of antisense oligonucleotide corresponding to Delta-1 transcript on the expression of RA4 antigen, an early marker for retinal ganglion cell (RGC) differentiation. RA4 immunoreactivity shows central to peripheral gradient, being absent from the peripheral retina at stage 22. When the stage 22 retinal explant cultures were treated with 50µM of the Delta-1 antisense oligonucleotide RA4 immunoreactivity was more predominantly detected in the peripheral as compared to the central retina. Also, the number of RA4 positive cells was significantly decreased as compared to the controls treated with sense or missense Delta-1 oligonucleotides. Similar results were obtained with Notch-1 antisense oligonucleotide suggesting that the change in the spatial expression of RA4 was due to the attenuation in Delta-Notch signaling. These observations suggest that the attenuation in Delta-Notch signaling promotes cells in the peripheral retina to express RA4 during RGC differentiation. Supported by EY 10313.

## 205.7

LOSS OF CHICK ALAR PLATE MARKERS BY ABLATION OF DORSAL RHOMBENCEPHALON IS REVERSED BY BMP-4 *IN VIVO*. H. C. Eichevers\*, A. H. Monsoro-Burg and N. M. Le Douarin. Institut d'Embryologie, 94736 Nogent-sur-Marne, France.

In the light of recently published claims of neural crest respecification in chick after ablation of the rhombencephalic neural folds, we examined effects within the central nervous system. *In situ* hybridization of multiple markers of the dorsal neural tube and examination of dorsally located brainstem nuclei in more mature specimens were performed. Depending on the depth of the ablation, the nested domains of *Slug*, *Msx-2*, *Wnt-1*, *Msx-1* and *Pax-3* were deleted and not subsequently re-expressed. Substitutions of quail neural folds at the levels of the mesencephalon and rhombomere 7 demonstrated the capacity of the neural crest cells anterior and posterior to the ablation to compensate extensively and form normal crest derivatives for their new positions. On the other hand, embryos up to 11 days show dorsal but not ventral hindbrain disorganization. After implantation of fibroblasts expressing mouse BMP-4, we observed re-expression of *Msx-1*, *Msx-2* and *Pax-3* in the previously intermediate to ventral areas of the rhombencephalon, mimicking the *in vitro* or ectopic inductions of these markers by ectoderm seen by other authors. These results emphasize that regeneration in the early embryonic nervous system is more complex than previously implied. HCE is a HHMI Predoctoral Fellow. Supported by the CNRS and the Collège de France.

## 205.9

LASER ABLATION OF NERVE-ASSOCIATED LINEAGE PRECURSORS OF ADULT ABDOMINAL MUSCLES IN *DROSOPHILA*. E. R. Farrell\* and H. Keshishian. Biology Dept., Yale University, New Haven, CT 06520.

In *Drosophila*, two nerve-associated cells which express the mesoderm-specific transcription factor *Twist* serve as the lineage precursors of the lateral muscles of each adult abdominal hemisegment. These cells arise in the embryo and are located on nerve branches to muscle fiber 8. It has been hypothesized that each of these cells is a precursor for a group of 8-10 adult muscle fibers. The *Twist* expressing precursors proliferate during the second and third larval stages to produce two clusters of approx. 15 cells per hemisegment. During pupation their progeny migrate along the nerves to form the adult muscles. Treatment of larvae with an agent that disrupts cell proliferation has been shown to decrease the number of abdominal muscle fibers in the adult (Broadie and Bate, 1991, *Development* 113, 103-118). Here we directly examine whether laser ablation of the precursors during early stages of their proliferation has an effect on the number of lateral fibers in the adult. Trypan blue/*Twist* double labeling following *in vivo* ablation of single precursors confirmed that cell death is confined to the targeted cell. We next ablated cells in second instar larvae, when there are about 2-3 cells per cluster. Following ablation of one cell per cluster, we could find no significant change in the number of lateral fibers in the resulting adults ( $n = 32$  hemisegments in 16 animals). However, multiple cell ablation (two cells per cluster, on average) resulted in a 29-48% reduction in the number of lateral fibers ( $n = 7$  hemisegments in 5 animals). The remaining fibers are distributed equally over the lateral muscle region. In contrast, ventral and dorsal abdominal fibers in these hemisegments were not affected by the ablation. These results confirm the role of the *Twist* expressing cells in the adult muscle lineage, and indicate that the determinative events occur early in the lineage. Supported by NIH and NSF.

## 205.11

MULTIPOTENT NEURAL PRECURSORS TRANSPLANTED TO REGIONS OF TARGETED NEURONAL APOPTOSIS IN ADULT MOUSE SOMATOSENSORY CORTEX DIFFERENTIATE INTO NEURONS AND RE-FORM CALLOSAL PROJECTIONS. B.R. Leavitt\*, M. Canales, E.Y. Snyder and J.D. Macklis. Department of Neurology, and Program in Neuroscience, Harvard Medical School, and Division of Neuroscience, MRRCC, Children's Hospital, Boston, MA 02115.

In the neocortex, the effectiveness of potential transplantation therapy for diseases involving neuronal loss may depend upon whether donor cells can differentiate appropriately, reestablish precise long distance projections, and reconstruct complex functional circuitry. Previous studies demonstrated that embryonic neurons transplanted into neocortical regions undergoing photolytically targeted apoptotic neuronal degeneration in adult mice respond to reexpressed developmental signal molecules and selectively migrate to these regions, differentiate into pyramidal neurons, accept afferent synaptic input, and re-form specific long distance projections to the original targets of the replaced neurons. 15% of C17-2 multipotent neural precursors transplanted within lamina II/III of these regions also undergo directed neuronal differentiation in response to such signals, but only exhibit glial differentiation in intact or excitotoxically lesioned neocortex. The experiments presented here assess whether transplanted C17-2 cells further differentiate and send long distance axons to contralateral targets. C17-2 cells prelabeled with fluorescent microspheres and/or [<sup>3</sup>H]thymidine were transplanted into adult mouse primary somatosensory cortex (S1) undergoing apoptotic degeneration of callosal projection neurons ( $n=28$ ). Three to five months later the retrograde tracers Fluorogold, fluorescent microspheres, or DiI were injected into contralateral S1 cortex or ipsilateral thalamus. Many of the differentiated C17-2 cells in lamina II/III were retrogradely labeled from contralateral S1 cortex, the original target of host neurons undergoing degeneration, and most had a large pyramidal neuron phenotype. They expressed neuronal markers including NSE and NeuN but not the astrocyte marker GFAP. These data demonstrate that C17-2 neural precursors transplanted into adult neocortex undergoing synchronous apoptotic neuronal degeneration are capable of differentiating into pyramidal neurons and extending long distance projections that partially replace prior projections of degenerated callosal neurons. These results suggest that reconstruction of cortical circuitry by transplanted precursors may be possible in the mature neocortex, if appropriate donor cells are provided with the correct local and distant signals within a permissive host environment. ## 205.8

THE A-P IDENTITY OF DIENCEPHALIC AND TELECEPHALIC PRECURSORS IS DETERMINED G. Fishell\*, A. Langston, J.E. Johnson\*, S.O. Huh\*, E. Lai\* and C. Neyt. Developmental Genetics Program, The Skirball Institute and Dept. of Cell Biology, NYU Medical Center, 550 1st Ave, NY, NY, 10016; \*UT Southwestern, Cell Biology and Neuroscience, 5323 Harry Hines, Dallas, Tx, 75235-9111; †Sloan-Kettering Cancer Center, NY, NY, 10021

Previously we observed that telencephalic precursors from the LGE (lateral ganglionic eminence), the anlage of the striatum, when transplanted heterotopically to cortex adopt both cortical morphologies and cortical projections. In addition, we observed that these LGE cells integrated in a variety of areas as far posterior as the midbrain. Based on their neuronal morphology it was impossible to infer whether LGE cells which integrate into more posterior divisions of the CNS had maintained a telencephalic phenotype or adopted that of their host site. To resolve this issue, we used two lines of transgenic animals where LacZ expression was directed to either the telencephalon (using a line where LacZ was targeted to the Bf1 loci) or ventral diencephalon (expression driven by a MASH1 control elements), as endogenous markers of regional phenotype. Telencephalic cells from each of these lines that integrated into the diencephalon were Bf1 positive and MASH1 negative, respectively, suggesting that they maintain a telencephalic phenotype even when integrated into a diencephalic environment. In a set of complementary experiments, we transplanted ventral diencephalic cells into the forebrain. In these cases virtually no cells integrated in the telencephalon but large numbers were found homotopically integrated into the diencephalon. Together these results suggest that neural precursors in forebrain, while still able to change their phenotype within specific forebrain divisions, are not able to modify their A-P position and that cellular integration in itself is not sufficient to infer that the cells phenotype is altered. (supported by NIH grant RO132993-02).

## 205.10

PURIFICATION AND CHARACTERIZATION OF NEOCORTICAL CALLOSAL PROJECTION NEURONS IN CULTURE. M.W. Arnold, B.R. Leavitt, V.L. Sheen, M.J. Zylika, and J.D. Macklis\*. Dept. of Neurology & Prog. in Neuroscience, Harvard Medical School, Division of Neuroscience, Children's Hospital, Boston, MA 02115.

Reconstruction of complex neocortical circuitry may be possible via the transplantation of defined and controllable neuronal precursors under the guidance of developmentally relevant cellular and molecular control signals. In the neocortex, the effectiveness of potential transplantation therapy may depend critically on whether donor cells can undergo developmentally appropriate migration, differentiation, integration, and connectivity to restore function. Embryonic neurons and multipotent neural precursors transplanted into regions of neocortex undergoing photolytically induced apoptotic neuronal degeneration of pyramidal neurons can respond to reexpressed developmental signal molecules, selectively migrate into these regions, differentiate into pyramidal neurons, accept afferent synapses and re-form specific distant projections, although multipotent precursors do so with relatively low efficiency. The isolation of neuronal precursors with more restricted potential may provide more specific and efficient cellular reagents for reconstruction of neocortical circuitry. The present studies investigate whether relatively immature projection neurons from postnatal cortex can be purified to form such a restricted donor cell population, and begin to characterize their requirements for differentiation and survival. Callosal projection neurons were retrogradely labeled in P0 mice with fluorescent microspheres injected into contralateral projection fields. Labeled cortex was dissociated, and labeled projection neurons were isolated by fluorescence activated cell sorting (FACS) and plated onto poly-L-lysine coated plastic of glass. 85% to 95% pure projection neurons were cultured in conditioned or defined medium, or cocultured with glial cells. Immunocytochemical analysis confirmed that purified projection neurons were glutamatergic, and expressed NSE and mature neuronal markers including NeuN, but not the glial marker GFAP. When cocultured below a glial feeder layer, or in conditioned medium, they acquired mature, complex pyramidal neuron morphology and survived up to 4 weeks in culture. In contrast, purified projection neurons without medium conditioning underwent similar early differentiation, then died between 1 and 2 days *in vitro*. These results demonstrate that callosal projection neurons can be purified, survive, and undergo restricted differentiation retaining relatively homogeneous phenotype. Further characterization of these neurons may allow control over their differentiation and survival, and may suggest strategies to direct the development of less mature precursors toward the reconstruction of neocortical circuitry. Supported by HD28478, Alzheimer's Association IIRG-93-143, MRRCC HD18655, Leopold Schepp Fdn., and the Rita Allen Foundation.

## 205.12

TIMING AND LOCATION OF NON-RADIAL MIGRATION IN THE CHICK DIENCEPHALON J. A. Golden, J. C. Zitz, and C. L. Cepko\*. Dept. of Genetics, Harvard Medical School, Boston, MA 02115

Lineage analysis of the mature chick diencephalon using retroviral vectors has demonstrated that clones are widely dispersed in the medial-lateral, dorsal-ventral, and anterior-posterior planes. To define where and when sibling cells disperse in the chick diencephalon, embryos were infected at stage 10-11 (36 hours incubation) with a retroviral stock encoding a library of molecular tags. Embryos were harvested 4 to 8 days post injection and the brains fixed, serially sectioned and histochemically stained for alkaline phosphatase activity encoded by the retroviral vector. AP+ cells were mapped and clones determined based on the molecular tag in most cases. On embryonic day 4 (E4) all clones were organized in radial columns spanning the neuroepithelium. No migration was seen in the ventricular zone at any age. On E5 most clones remained radial, while a few clones had cells migrating perpendicular to the radial column. Clones dispersed in both the anterior-posterior and dorsal-ventral planes. Migration perpendicular to the radial column began at the limit of the ventricular zone. On E6 and E7 many clones had cells migrating perpendicular and sometimes orthogonal to the radial column that continued to define the clonal origin. By E8, clonally-related cells appeared to be migrating away from the radial column at multiple levels outside the ventricular zone. The proportion of clones showing migration in the anterior-posterior and dorsal-ventral directions was comparable to the percentage found to have dispersed in the mature diencephalon. These data indicate that migration independent of radial glia occurs in the chick diencephalon outside the ventricular zone, similar to non-radial migration in other areas of the central nervous system.

## 206.1

## CALCIUM CONTROL OF EXOCYTOSIS MEASURED BY FM1-43 FLUORESCENCE IN MAMMALIAN SYNAPTOSOMES.

M.A.M. Prado, M.A. Romano-Silva, P.S.L. Beirão, B. Collier<sup>1</sup>\*, M.V. Gomez and C. Guatimosim. Departamentos de Farmacologia, Bioquímica-Imunologia, (ICB-UFG) Belo Horizonte-MG 31270-901, Brasil and <sup>1</sup>Department of Pharmacology and Therapeutics, McGill University, Montréal H3G 1Y6, Canada.

In the present work, we investigated the exocytosis of synaptic vesicles from rat brain cortical synaptosomes using the styryl dye, FM1-43. The fluorescent labelling of synaptic vesicles from rat brain cortical synaptosomes occurred only if vesicles completed cycles of exo-endocytosis in the presence of dye. The decrease of fluorescence, due to dye release from synaptic vesicles, could be detected when synaptosomes were depolarized by high [KCl]<sub>o</sub> (25 or 60 mM) or influx of Na<sup>+</sup> through tetrodotoxin-sensitive channels. The curves for 60 mM KCl were fitted by a double exponential with ( $\tau$ s) of 10 $\pm$ 1 and 126 $\pm$ 18, and both components of FM1-43 destaining were dependent on calcium entry into the nerve terminals. The  $\omega$ -toxins, conotoxin MVIC and agatoxin IVA, blocked exocytosis induced by 25 mM KCl, but had no effect on the fluorescence drop due to 60 mM KCl depolarization. On the other hand, the  $\omega$ -conotoxin GVIA, a N-type calcium channel blocker, had only negligible effects on the decrease of fluorescence due to membrane depolarization. The above results suggest that destaining of FM1-43-labelled nerve terminals had several characteristics of the exocytosis of synaptic vesicles and occurred from two kinetically distinct pools. In addition, due to the sensitivity to low concentration of  $\omega$ -agatoxin IVA, it seems that the P type calcium channel contributed largely to the entry of calcium coupled to exocytosis induced by 25 mM KCl in mammalian nerve endings.

## QUANTAL VARIANCE REVEALED IN ELECTRON MICROSCOPICALLY IDENTIFIED EXCITATORY SYNAPSES OF THE CAT VISUAL CORTEX.

O. Paulsen\*, C. Stricker\*, G. Tamas, T. Szilagyi, P. Somogyi and E. H. Buhl. MRC Anatomical Neuropharmacology Unit, University Department of Pharmacology, Oxford OX1 3TH, U.K., and <sup>1</sup>Division of Neuroscience, John Curtin School of Medical Research, Australian National University, Canberra, ACT 0200, Australia.

In order to extract quantal parameters of excitatory synaptic transmission between layer II/III pyramidal cells and GABAergic interneurons in adult cat visual cortex, intracellular recordings were made with biocytin-filled sharp microelectrodes from pairs of neurons in standard slices. Unitary EPSPs in interneurons (means ranging between 316 and 1224  $\mu$ V), evoked at 1-2 Hz by action potentials of the pyramidal cell, were subjected to quantal analysis. Using stringent electron microscopic analysis, the numbers of synaptic release sites in each of five connections were determined to be one, two, two, five and seven (Buhl, Tamas, Szilagyi, Paulsen & Somogyi, this meeting).

The amplitude distributions of the EPSPs obtained during stable recording conditions (468-700 events in each cell pair) were fitted with three models based on noise deconvolution as in Stricker *et al.* (1994). The models were: a fully unconstrained mixture model, a quantal model with no quantal variance, and a quantal model with quantal variance. For each of the models, the minimum number of components was determined, for which addition of one more component failed to improve the fit significantly. For all five connections analysed, the first two models gave, excluding the failures, a minimum number of components, which exceeded the number of morphologically determined release sites. The third model, incorporating quantal variance, gave a minimum number of components compatible with the electron microscopically determined number of release sites. For all five EPSPs, a quantal model with quantal variance could be identified, which was compatible with the number of release sites, and which fitted the data as well as models incorporating additional components but no quantal variance. The quantal coefficient of variation (CV) for this best model varied between 0.33 and 0.46. The corresponding quantal sizes ranged between 260 and 657  $\mu$ V.

We conclude, that there is good agreement between the number of components in the model and the number of identified synaptic release sites. Therefore, a quantal release model can account for the transmission at this junction, but a significant amount of quantal variance has to be incorporated. These data demonstrate the importance of correlated anatomical information in the selection of the most pertinent model of synaptic transmission.

## CYCLIC NUCLEOTIDE-GATED CHANNELS IN SYNAPTIC TERMINALS OF RETINAL CONE PHOTORECEPTORS. A. Savchenko &amp; R.H. Kramer\* Dept of Molec. &amp; Cell. Pharm., Univ. of Miami Sch. of Med, Miami FL. 33136

Cyclic nucleotide-gated (CNG) channels are crucial for transducing changes in cGMP concentration into electrical signals during light responses in retinal photoreceptors. Here we show that CNG channels are highly concentrated not only in outer segments of rods and cones, but also in presynaptic terminals of cones, suggesting that they play an important functional role in synaptic transmission. These studies were done on enzymatically dissociated cones from lizard (*Anolis carolinensis*). In cones devoid of outer segments, application of pCPT-cGMP, a membrane-permeant CNG channel agonist, activated an inward current of 2-10 pA at -60 mV in 8 of 8 cones with terminals and 0 of 10 cones lacking terminals. Likewise, voltage-gated Ca<sup>2+</sup> current was detected in all cells containing terminals and none lacking terminals. Hence, aside from the outer segment, the terminals contain nearly all the CNG and voltage-gated Ca<sup>2+</sup> channels in the cell. Application of cGMP onto excised patches showed that CNG channels were present in 16% of terminal patches, 12% of inner segment patches, and 60% of outer segment patches. However, the CNG channel density in patches that responded to cGMP was much greater when the patch was taken from the outer segment (8-19 channels/patch) or the terminal (20-37 channels/patch) than when the patch was taken from the inner segment (2-5 channels/patch). These observations are consistent with a clustering of CNG channels in terminals, perhaps near sites of transmitter release. Fura-2 Ca<sup>2+</sup> imaging experiments demonstrate that both membrane depolarization and cGMP analogs trigger Ca<sup>2+</sup> influx into the terminal. Direct measurements with glutamate receptor "biosensors" are being performed to test if CNG channel activation can indeed trigger transmitter release. Supported by NIH grant NS30685 and AHA grant 9503002.

## FLUCTUATIONS OF EVOKED UNITARY SYNAPTIC RESPONSES IN CORTICAL PYRAMIDAL NEURONS. Shaul Hestrin\*, Dept. of Anatomy and Neurobiology, University of Tennessee, Memphis TN 38163.

Important parameters of local cortical circuits are the fluctuations in timing and amplitude of the postsynaptic responses induced by action potentials in a single presynaptic neuron.

Dual whole-cell recording were obtained from layer V pyramidal neurons in the rat visual cortex. The slices were kept at room temperature or at 34-36 °C. Pairs of neighboring pyramidal cells were selected using DIC optics. The average EPSP at different pairs was between 0.2 mV and 3.0 mV and the average EPSC was between 5.9 pA and 48.4 pA. The decay time constants of the EPSPs were between 25 ms and 93 ms whereas those of the EPSCs were between 2.5 ms and 11.3 ms.

In synaptically connected pairs of neurons, the average latencies between the presynaptic action potential and the initial phase of the EPSP(C) in different cell pairs were between 1-6 ms (n=14). However, for any given cell pair the trial to trial latencies fluctuated with standard deviations ranging from 120  $\mu$ s and 1.0 ms.

Variability of EPSP(C)s amplitudes often reflects previous presynaptic activity. In 13 out of 19 pairs the unitary EPSP(C)s exhibited paired-pulse depression. At intervals of 10 ms to 1 second the response ratio was 0.51  $\pm$  0.2. In most of these pairs (n=11) there was an increase in the rate of action potential failure to produce an EPSP(C). The failure rate increased from 7% in the first EPSP(C) to 29% in second EPSP(C). In two pairs exhibiting depression no failures were detected. These results suggest that paired-pulse depression reflects reduction in transmitter release.

## 206.4

## ARE SOME MINIS MULTIQUANTAL? M. Frerking, S. Borges, and M. Wilson\*. Section of Neurobiology, Physiology, and Behavior, University of California, Davis, CA 95616.

Amacrine cells from embryonic chick retinae form GABA<sub>A</sub>ergic autapses in culture. In the presence of external TTX, TEA, and internal Cs<sup>+</sup>, small depolarizations elicit Ca<sup>2+</sup>-influx-dependent, miniature IPSCs (minis) at low frequency. The amplitude distribution of these minis is positively skewed, as in other neurons. The origin of skew in the mini distribution is uncertain, but one recent model proposes that large minis represent multiquantal release synchronized by transient Ca<sup>2+</sup> influx sensed simultaneously at nearby but separate release sites (Edwards, 1995, *Physiol. Rev.* 75, 759-787).

A prediction of this model is that the skew and large coefficient of variation (CV) of the mini amplitude distribution are both contingent on transient Ca<sup>2+</sup> influxes. We therefore tested this model by examining minis evoked in the absence of external Ca<sup>2+</sup> either by internal perfusion of buffered Ca<sup>2+</sup>-containing solutions or by bath application of the Ca<sup>2+</sup>-independent secretagogue,  $\alpha$ -latrotoxin. Contrary to the predictions of the model, neither the CV nor the skew of the mini amplitude distributions evoked by these methods are resolvably different from the mini distributions evoked by Ca<sup>2+</sup> influx. We conclude that the mini amplitude distribution does not contain a significant number of Ca<sup>2+</sup> influx-evoked multiquantal minis. Supported by EY04112 (MW).

## 206.6

## DOPAMINERGIC MODULATION OF NUCLEUS ACCUMBENS GABA SYNAPSES. D. Geldwert, S. Rayport\*, Depts. Psychiatry, Anatomy &amp; Cell Biology, and Ctr. Neurobiology &amp; Behavior, Columbia Univ.; Dept. Neuroscience, N.Y.S. Psychiatric Institute, NY 10032.

In postnatal nucleus accumbens (nAcc) cultures medium-spiny neurons make inhibitory autapses blocked by the GABA<sub>A</sub> antagonist bicuculline (Shi and Rayport, *J. Neurosci.*, 1994), which we confirmed under voltage clamp (n=29). We now report that DA (1  $\mu$ M, n=29) produces presynaptic inhibition of autaptic IPSCs in 83% and facilitation in 10% of cells. The D1 agonist SKF38393 (1  $\mu$ M, n=12) and the D2 agonist quinpirole (1  $\mu$ M, n=14) each mimic DA action, but less strongly; the same is true when the two agonists are applied together (n=4). DA in the presence of the D1 receptor antagonist SCH23390 has a similar incidence and efficacy as quinpirole (n=10); similarly DA in the presence of the D2 antagonist sulpiride (1  $\mu$ M) resembles SKF38393 (n=10). However, sulpiride and SCH23390 applied together (n=4) do not block DA modulation. Overall, about 85% of cells show both D1- and D2-mediated modulation consistent with extensive colocalization of DA receptors on medium-spiny neuron presynaptic terminals. We also find that 5HT and NE, as well as the GABA<sub>A</sub> agonist baclofen (Shi and Rayport, 1994), mediate presynaptic inhibition, adding to the complexity of potential modulatory actions. These autapses model intrinsic GABA synapses in the nucleus accumbens (Shi and Rayport, 1994), and thus are likely to be a major target of DA action, indicating that further examination of these synapses will be important in discerning the signaling role of DA in the mesolimbic system.

## 206.7

PRESYNAPTIC  $\alpha$ -ADRENOCEPTORS UNDERLIE INDIRECT MODULATION OF EVOKED INHIBITORY EVENTS IN RAT SOMATOSENSORY CORTEX. **B.D. Bennett, J.R. Huguenard and D.A. Prince\***. Dept. Neurol. & Neurolog. Sci., Stanford Univ. Med. Ctr., Stanford CA 94305

Previous experiments have demonstrated that epinephrine (EPI) reduces the amplitude of monosynaptic, evoked inhibitory postsynaptic currents (eIPSCs) in the majority of neurons studied in P9-12 rat neocortical slices through a presynaptic mechanism. The depression of monosynaptic eIPSCs was always accompanied by a large increase in the frequency of spontaneous IPSCs (sIPSCs) resulting from activation of presynaptic  $\alpha$ -adrenoceptors (Bennett et al., Soc. Neurosci. Abst. 21: 431.9). In the present experiments, we tested the hypothesis that the attenuation of eIPSC amplitude might be due to an increase in sIPSCs that would elevate synaptic GABA levels and result in activation of presynaptic GABA<sub>A</sub> receptors. Whole-cell voltage-clamp recordings of IPSCs were obtained from layer V pyramidal neurons in slices of rat somatosensory cortex. Monosynaptic eIPSCs were obtained by layer V stimulation during perfusion of slices with ACSF containing 20  $\mu$ M DNQX and 50  $\mu$ M APV.

The presence of functional presynaptic GABA<sub>A</sub> receptors was confirmed in experiments where a profound reduction of eIPSC amplitude was produced by 5-10  $\mu$ M baclofen (16 $\pm$ 5% of control; n=5) and was antagonized by concurrent exposure to 0.5-1 mM CGP 35348 (91 $\pm$ 14% of control; n=4). EPI (10  $\mu$ M) applied in the presence or absence of 0.5-1  $\mu$ M CGP 35348 produced an enhancement (121 $\pm$ 13% of control; n=9) or depression (73 $\pm$ 8% of control; n=15) of eIPSC amplitude, respectively. The blockade of GABA<sub>A</sub> receptors did not prevent EPI-induced increases in sIPSC frequency which were observed in all neurons. These data indicate that the depression of eIPSC amplitude observed following EPI application is a consequence of indirect activation of presynaptic GABA<sub>A</sub> autoreceptors resulting from  $\alpha$ -adrenoceptor-mediated increases in sIPSC frequency. These studies were supported by NIH grant NS 12157 from the NINDS and a Pimley postdoctoral fellowship to BDB.

## 206.9

SELECTIVE ENHANCEMENT OF GLUTAMATE RELEASE BY INTERACTION OF PEROXYNITRITE AND A VOLTAGE-GATED CALCIUM CHANNEL SIGNAL. **M.J. Friedlander\* and C. Gancayco**. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294.

We evaluated the mechanism by which N-methyl-D-aspartate receptor (NMDAR) activation and nitric oxide (NO) production selectively modulate L-glutamate release in the cerebral cortex. Cortical synaptosomes were prepared from ether-anesthetized adult guinea-pigs (Montague et al., *Science*, 263:973, 1994). Release of endogenous glutamate was evaluated by a luminometric assay. The thirty-fold enhancement of glutamate release evoked by a single pulse of 100  $\mu$ M NMDA application was completely blocked by pre-treatment of the synaptosomes with either the nitric oxide synthase (NOS) inhibitor, L-nitro-arginine, (1  $\mu$ M LNA, n=64) or by application of the N-type voltage gated calcium channel (VGCC) blocker,  $\omega$ -conotoxin (0.5  $\mu$ M CTX, n=14). The application of exogenous NO (1-20  $\mu$ M NO gas) directly enhanced glutamate release by tenfold (n=20) but this action also was completely blocked by CTX (n=8). Since NO readily reacts with superoxide anion (O<sub>2</sub><sup>-</sup>) to form peroxynitrite (ONOO<sup>-</sup>), we evaluated whether this reaction plays a role in modulation of cortical glutamate release. Application of superoxide dismutase (5,000 units SOD) completely blocked the enhanced glutamate release evoked either by endogenous NO production subsequent to NMDAR activation (n=12) or by exogenous NO application (n=8). Moreover, direct application of ONOO<sup>-</sup> (1-20  $\mu$ M) was sufficient to elicit enhanced glutamate release (n=10), unless VGCCs were blocked (100nM CTX, n=6). SOD did not interfere with the ability of ONOO<sup>-</sup> to enhance glutamate release in the synaptosomes where VGCCs were not blocked (n=6). We conclude that NMDAR activation leads to NOS activation, NO production, and reaction with O<sub>2</sub><sup>-</sup> to form ONOO<sup>-</sup>. The ONOO<sup>-</sup> signal interacts either directly with VGCCs or with a calcium signal in active presynaptic terminals, selectively boosting glutamate release at active synapses in local volumes of cerebral cortex. Supported by NIH Grant EY-05116.

## 206.11

BIPHASIC CHANGES IN THE PHOSPHORYLATION STATE OF IDENTIFIED PRE- AND POSTSYNAPTIC PKC SUBSTRATES DURING LTD. **P.N.E. De Graan\*, G.M.J. Ramakers, I.H. Heinen, and W.H. Gispen** Rudolf Magnus Institute for Neurosciences, P.O. Box 80040, 3508 TA Utrecht, The Netherlands

LTP and LTD are two forms of activity-dependent long-lasting changes in synaptic efficacy. Activation of protein kinases is important in the process of LTP, whereas protein phosphatases have been implicated in LTD. B-50 (a.k.a. F1, GAP-43, neuromodulin) is a well characterized presynaptic PKC substrate. More recently RC3 (a.k.a. neurogranin, BICKS) has been identified as a postsynaptic, neuron-specific substrate for PKC. These two proteins share an 18 amino acid sequence, containing the unique PKC phosphorylation site and a calmodulin binding domain. Previously, we have shown that the phosphorylation of both B50 and RC3 is increased during narrow and partially overlapping time windows after the induction of LTP. In this study we investigated the effect of LTD induction on B-50 and RC3 phosphorylation. Hippocampal slices were prepared from young rats (60-80 g), and were labelled with <sup>32</sup>P<sub>i</sub>. After stable baseline recordings of dendritic field EPSPs (fEPSPs) in the CA1 field of the hippocampus, LTD was induced by a 15 min, 1 Hz stimulation at test intensity of the afferent fibres. This stimulation paradigm induced a 50 % reduction in the slope of the fEPSP, which could be blocked by the NMDA receptor antagonist AP5 (50  $\mu$ M). Control slices in the same chamber only received test stimulation. The in situ B-50 and RC3 phosphorylation state was determined in individual slices using quantitative immunoprecipitation and phosphorimaging at different time points after LTD induction. One hour after LTD induction we find a NMDA receptor-dependent increase in B-50 phosphorylation, but no change in RC3 phosphorylation. At shorter times after LTD induction, B-50 and RC3 phosphorylation was below control levels. Thus our data show biphasic changes in the in situ phosphorylation state of pre- and postsynaptic PKC substrates, and indicate that phosphatases and kinases may be activated in distinct time windows following LTD induction. (This work was supported by an ENP grant of the ESF)

## 206.8

MODULATION BY NEUROTRANSMITTERS OF NOREPINEPHRINE SECRETION FROM SYMPATHETIC GANGLION NEURONS DETECTED BY AMPEROMETRY. **D.-S. Koh and B. Hille\***. Dept. Physiol. & Biophys., Univ. Washington, Seattle, WA 98195.

Patch clamp studies of acutely isolated superior cervical ganglion (SCG) cells revealed inhibition of N-type Ca<sup>2+</sup> currents in the cell soma by many neuromodulators (TINS, 17:531). To test if the same neuromodulators can reduce release of norepinephrine (NE) at varicosities and terminals of SCG cells, we measured NE secretion using carbon-fiber amperometry at presumed sites of terminals in cultures of SCG neurons stimulated electrically. The pharmacological properties of NE release had many parallels to those of N-type Ca<sup>2+</sup> channels: Release was blocked by Cd<sup>2+</sup> or  $\omega$ -conotoxin GVIA. It was reduced 50 and 62% by 10  $\mu$ M NE or 2  $\mu$ M UK14,304, an  $\alpha_2$ -adrenergic agonist. It was reduced 63% by 10  $\mu$ M oxotremorine-M, a muscarinic agonist, which was antagonized by M<sub>2</sub> and M<sub>4</sub> receptor antagonists methoctramine and tropicamide. After overnight incubation with pertussis toxin (PTX), the inhibition by UK14,304 and oxotremorine-M was much reduced. Several other neuromodulators known to inhibit Ca<sup>2+</sup> channels in these cells, including adenosine, prostaglandin E<sub>2</sub>, somatostatin, and secretin, also depressed secretion 34-44%. In cultures treated with  $\omega$ -conotoxin, it was possible to evoke secretion dependent on L-type Ca<sup>2+</sup> channels with long KCl depolarizations. This secretion was not sensitive to UK14,304.

In conclusion, the neuromodulators that act on SCG somata also act on their secretory terminals. The depression of NE release at terminals parallels depression of N-type Ca<sup>2+</sup> currents in the soma.

## 206.10

PHOSPHORYLATION MODULATION OF THE INTERACTION BETWEEN N-TYPE CALCIUM CHANNELS AND SYNAPTIC CORE COMPLEXES. **C.T. Yokoyama, Z.H. Sheng, and W.A. Catterall\***. Department of Pharmacology and Graduate Program in Neurobiology and Behavior, University of Washington, Seattle, WA 98195.

N-type calcium channels contain a synaptic protein interaction (synprint) site in the cytoplasmic loop between homologous domains II and III which interacts with the synaptic core complex proteins syntaxin and SNAP-25 in a biphasic, calcium-dependent manner (Sheng et al. (1996) *Nature* 379:451-454). We report here the identification of second-messenger-activated protein kinases which phosphorylate the synprint and alter interactions with syntaxin and SNAP-25. Of a panel of protein kinases tested, only protein kinase C (PKC) and calcium/calmodulin-dependent protein kinase type II (Cam KII) phosphorylated a his-6-synprint fusion protein with a stoichiometry of at least 1:0. Two-dimensional tryptic phosphopeptide mapping correlated with the stoichiometry measurements and indicated that each kinase phosphorylated a distinct pattern of 2 or more sites within the synprint. Phosphorylation of the his-6-synprint with PKC or Cam KII strongly inhibited the ability of the synprint peptides to interact in a binding assay with immobilized GST-syntaxin or GST-SNAP-25, even at concentrations of free calcium which stimulate maximal binding. Binding assays with his-6 fusion proteins of smaller regions of the synprint indicate that disruption of binding is mediated by multiple phosphorylation sites. Furthermore, PKC and Cam KII phosphorylation of the his-6-synprint fusion protein inhibited interactions with native rat brain synaptic core complexes containing syntaxin and SNAP-25. These results suggest a candidate presynaptic mechanism whereby PKC and Cam KII phosphorylation of the synprint serves as a biochemical switch for interactions between N-type calcium channels and synaptic core complexes. Supported by NIH grants NS22625 and GM07108-21.

## 206.12

SYNAPTIC TRANSMISSION AND BEHAVIORAL ABNORMALITIES IN MUTANT MICE LACKING mGluR4. **A. Baskys\*, R. Gerlai, R. Pekkiletski, J. Roder and D. R. Hampson**. Dept. of Physiology and Fac. of Pharmacy, Univ. of Toronto, Mount Sinai Hosp., Toronto, Ont. M5S 1A8, Canada.

To understand the role of type 4 metabotropic glutamate receptor (mGluR4) in synaptic transmission we studied field EPSPs (fEPSPs) evoked in dentate gyrus neurons in vitro slices from mutant mGluR4-deficient (M) (n=27) and wildtype (W) mice (n=23). Paired pulse (interval=50 ms) stimulation of the lateral perforant pathway (LPP) revealed no significant difference in paired pulse facilitation or fEPSP/fibre volley ratio between the groups. In W mice, fEPSPs remained stable at the control stimulation rate of 0.1 Hz but decreased significantly following a five minute period of continuous stimulation at 0.5 Hz. Responses returned to control following a 10 min. pause in stimulation. Prolonged (10 min.) stimulation at 0.5 Hz produced only short-term depression (STD) and did not lead to long-term depression of the fEPSP slope. GABA<sub>A</sub> receptor/channel antagonist picrotoxin (50  $\mu$ M) or NMDA receptor antagonist D-APV (50  $\mu$ M) did not affect STD. There was no significant STD in slices from mGluR4-deficient mice. A putative agonist for mGluR4, L-AP4 (25 and 50  $\mu$ M), significantly (p<0.05) suppressed fEPSPs in M (n=9) and W (n=8) slices with no significant difference between the groups. Depression of fEPSPs by metabotropic agonist 1S, 3R-ACPD (25  $\mu$ M) was not different in W (n=5) and M (n=6) slices. In the Morris water maze paradigm both groups showed a similar decrease in escape latency over the course of 14 training sessions. Significantly shorter escape latencies were recorded in sessions 2 and 3 in M mice upon removal of the platform to a different quadrant but no significant difference was found in sessions 1, 4, 5 and 6. These results indicate that mGluR4 may be responsible for STD in LLP but is not responsible for L-AP4-induced depression. Improved learning of the new platform location by mGluR4-deficient mice may be related to diminished STD or to other processes influenced by this receptor. Supported by MRC.

## 206.13

**ENDOGENOUS ADENOSINE ON MEMBRANE PROPERTIES OF CA1 NEURONS DURING NORMOXIA AND ANOXIA.** P.J. Zhu\* and K. Krnjević, Anaesthesia Research and Physiology Depts., McGill Univ., Montréal, Québec H3G 1Y6, Canada

Ongoing effects of endogenous adenosine on CA1 neurons in hippocampal slices from Sprague-Dawley rats were studied by extra/intracellular and whole-cell recordings. The slices were submerged and kept at 33°C. During normoxia, an A1 antagonist (8-SPT), or adenosine deaminase potentiated both spontaneous (n=7) and evoked EPSPs (n=10), but not monosynaptic IPSP (n=6); and caused a minimal depolarization (by 1 mV) -- probably due to the enhanced synaptic activity -- but no significant change in input conductance (n=9). Hypoxia (4-5 min) induced an outward current and increase in input conductance. 8-SPT (10 µM) reversibly attenuated this effect (n=6). In the presence of Ba (1 mM), hypoxia produced no significant change in input conductance and the outward current was replaced by a small inward current. These data indicate that ongoing adenosine release tonically inhibits excitatory synaptic transmission; has no direct effect on inhibitory synaptic transmission; and contributes to hypoxic hyperpolarization.

## TRANSPORTERS II

## 207.1

**LOCALIZATION OF mRNA FOR VESICULAR MONOAMINE TRANSPORTERS, VMAT1 and VMAT2, IN THE DEVELOPING RAT EMBRYO.** Stefan R. Hansson\*, Eva Mezey\* and Beth J. Hoffman. Lab of Cell Biology, NIMH and @ Clinical Neurosciences Branch, NINDS, Bethesda, MD 20892

Monoaminergic neurons (dopamine, norepinephrine, epinephrine, serotonin, histamine) are physiologically functional prior to synapse formation. Catecholamines have been shown to induce morphogenesis such as closure of the neural folds, and to induce changes in the developing cortex. Following their synthesis, monoamines are packaged into synaptic vesicles or secretory granules by vesicular monoamine transporters (VMATs). The cDNA cloning of rat VMATs has revealed the existence of two highly homologous but distinct gene products. In the adult rat, VMAT1 is thought to be limited to the adrenal medulla. We have used *in situ* hybridization histochemistry with RNA probes to delineate gene expression of the two VMATs during rat development. VMAT2 was detected earlier and was more abundant than VMAT1 mRNA. In the central nervous system (CNS), VMAT2 mRNA was first detected in cells of the neural tube at embryonic day 11 (E11). By E13, VMAT2 mRNA was localized to monoamine cell body-containing regions in the brainstem and hypothalamus. In addition regions which receive monoaminergic innervation contain VMAT2 mRNA: rhinencephalon (E13), the pallidal neuroepithelium of the basal ganglia (E13), striatal part of the basal ganglia (E14), septum (E15), thalamus (E16), tegmentum (E17). VMAT1 mRNA was detected in pallidal neuroepithelium, striatal subventricular zone, cortex and hippocampus (E18) and the external germinal layer of the cerebellum (E18). The presence of VMAT1 mRNA in the subventricular zone (E18) and VMAT1 mRNA in the neural tube (E11) suggests a role for monoamines in differentiation. From early gestation, VMAT1 and VMAT2 mRNA have an overlapping distribution in sympathetic and autonomic ganglia, heart and adrenal medulla. In the gut VMAT1 mRNA was localized to the inner nerve plexus while VMAT2 mRNA was present in the outer enteric plexus. The presence of mRNA for VMATs implies possible regulated release, or a need for sequestration of monoamines before synapses are formed. mRNA for VMATs in non-monoaminergic cells of the limbic system as well as the basal ganglia suggest an unexpected role for these transporters.

## 207.2

**SYNAPTIC VESICULAR MONOAMINE TRANSPORTER GENE KNOCKOUTS.** N. Takahashi\*, J. Sora@, R. Revay@, D.M. Donovan@, H.F. Liu@, L.L. Miner@, G.R. Uhl@ @Molec. Neurobiol., NIDA-IRP, NIH; #Dept. Neurol. & Neurosci., JHUSM, Balto., MD 21224

The synaptic vesicular monoamine transporter (VMAT2) accumulates brain monoamines into synaptic vesicles. Amphetamine and its derivatives disturb dopamine storage in vesicles, resulting in dopamine release into cytoplasm where it could contribute to amphetamine toxicity. Overexpression of VMAT2 can suppress the toxicity of the Parkinsonism inducing toxin MPP+ *in vitro*. These observations imply that VMAT2 could protect dopamine neurons from toxicities of dopamine and MPP+. To study these effects, we have isolated genomic clones from a murine 129SvJ genomic library that contain the all exons of the VMAT2 gene and 5' flanking sequences. A VMAT2 gene targeting vector deleted the first three exons encoding the first two VMAT2 transmembrane domains and the large luminal loop, replacing them with a pgk neomycin resistance gene. Eight ABI embryonic stem cell lines harboring the desired homologous recombination were identified by Southern blot analysis, and several animals produced by blastocyst injection of two of these cell lines. The molecular, pharmacological and behavioral features of heterozygous and homozygous VMAT2 knockout phenotypes will advance our understanding of VMAT2 function.

## 207.3

**OVEREXPRESSION OF PUTATIVE VESICULAR ACETYLCHOLINE TRANSPORTER INCREASES QUANTAL TRANSMITTER PACKAGING IN DEVELOPING XENOPUS NEURONS:** H.-j. Song<sup>1</sup>, G.-l. Ming<sup>1</sup>, E. Fon<sup>2</sup>, B. Bellocchio<sup>2</sup>, R. H. Edwards<sup>2</sup>, and M.-m. Poo<sup>1</sup>. <sup>1</sup>Dept. Biol., UCSD, La Jolla, CA. 92093, <sup>2</sup>Depts. Neurol. and Physiol., UCSF, San Francisco, CA. 94143.

Putative vesicular acetylcholine transporter (VACHT) genes from several species have been cloned and both the mRNA and protein are localized in cholinergic neurons. However, the function of the putative transporter has not been clearly demonstrated. In this study, we tested the function of VACHT by overexpressing the protein in developing neurons when quantal transmitter secretion is not yet mature. Rat VACHT cDNA was injected into one of the early blastomeres of *Xenopus* embryos, together with a fluorescence marker FITC-dextran. Expression of VACHT was elevated in all cells derived from the injected blastomere, including spinal neurons. At the neuromuscular synapses made by these neurons, the spontaneous miniature endplate currents (MEPCs) showed a significant increase in the median amplitude (458.8±67.8 pA, SEM, n=30), as compared to that at control synapses (192.7±32.2 pA, SEM, n=26). Analysis of the amplitude distribution of MEPCs indicates a significant shift to higher amplitudes for neurons overexpressing VACHT. The increase in the quantal size is also accompanied by an increase in the MEPC frequency: 34.2±10.4 min<sup>-1</sup> (SEM, n=30) and 9.5±3.5 min<sup>-1</sup> (SEM, n=26), for the overexpressing and control neurons, respectively. These results supports the putative role of this protein in promoting ACh packaging into secretory vesicles. (Supported by NIH grant NS31923)

## 207.4

**TARGETED DISRUPTION OF THE MURINE SEROTONIN TRANSPORTER GENE.** D. Bengel<sup>1,2</sup>, D. L. Murphy<sup>1\*</sup>, D. Feltner<sup>3</sup>, M. Seemann<sup>2</sup>, A. Heils<sup>2</sup>, A. Grinberg<sup>3</sup>, H. Westphal<sup>3</sup>, and K.-P. Lesch<sup>2</sup>. <sup>1</sup>Lab. of Clinical Science, NIMH, NIH, Bethesda, MD 20892. <sup>2</sup>Dept. of Psychiatry, Univ. of Würzburg, 97080 Würzburg, Germany. <sup>3</sup>Lab. of Mammalian Genes & Development, NICHD, NIH, Bethesda, MD 20892.

The brain serotonin transporter (5-HTT) plays a central role in the modulation of serotonergic neurotransmission. It has been associated with mood disorders, anxiety and aggression and is the primary target for widely used serotonin uptake inhibiting antidepressant drugs such as fluoxetine. Interest in the mechanism of disease- and therapy-induced modification of 5-HTT function and its impact on early brain development and event-related synaptic plasticity is widespread and intensifying. To analyze the function of the 5-HTT, we have generated transgenic mice lacking the 5-HTT by means of homologous recombination in ES cells. The second exon was deleted, and homologous recombination was confirmed by Southern analysis in two embryonic stem cell clones. Four male chimeric mice, upon mating with wild-type mice, gave rise to germline transmission of the mutant allele. Homozygous mice were obtained by intercrossing of heterozygotes. Despite evidence that excess serotonin during embryonic development, including that produced by fluoxetine, may lead to severe craniofacial and cardiac malformations, no obvious developmental defects have been observed in mutant mice. Feeding behavior as well as weight gain are normal in the 5-HTT deficient mice. Further characterization of the molecular, pharmacological, and behavioral features of the homozygous mutant phenotype is underway.

**ACUTE REGULATION OF THE HUMAN NOREPINEPHRINE TRANSPORTER IN NATIVE AND HETEROLOGOUSLY TRANSFECTED CELL LINES.** S. Apparsundaram<sup>\*</sup>, and R.D. Blakely. Department of Pharmacology and Center for Molecular Neuroscience, Vanderbilt University Medical Center, Nashville, TN 37232-6600.

Active transport of norepinephrine (NE) into presynaptic nerve terminals via NE transporter (NET) is the primary means of modulating synaptic NE levels after release. Although many reports have demonstrated that NET activity can be both up- and down-regulated by hormones and neurotransmitters, the cellular mechanisms involved in acute regulation of NET activity remain to be defined. Activators of PKC ( $\beta$ -PMA and  $\beta$ -PDBu) produced a rapid and concentration-dependent inhibition of NE transport in human noradrenergic SK-N-SH, hNET stably transfected HEK 293 and transiently transfected COS cells. The inactive  $\alpha$ -isomers of these agents were ineffective. Kinetic analysis indicated that PKC activators produced a 40% decrease in  $V_{max}$  with little or no change in  $K_m$  of NE transport. Acute staurosporine treatment did not alter basal hNET activity but abolished  $\beta$ -PMA-induced inhibition of NE transport in hNET transfected cells. Since hNET contains multiple consensus Ser/Thr residues for phosphorylation in its putative cytoplasmic NH<sub>2</sub> and COOH domains, *in vitro* phosphorylation experiments were carried out using glutathione-S-transferase (GST) fusion proteins containing either NH<sub>2</sub> or COOH tails of hNET. Purified PKC, PKA and PKG phosphorylate both NH<sub>2</sub> and COOH tails with little or no phosphorylation of GST component. Cell-surface biotinylation and *in vivo* metabolic labeling are being used to determine whether PKC-mediated changes in NE transport involve surface redistribution, protein phosphorylation or both. **ACTIVATION OF PROTEIN KINASE C DOWNREGULATES SEROTONIN TRANSPORTERS VIA ALTERED CELL SURFACE DISTRIBUTION.** S. Ramamoorthy<sup>1</sup>, Y. Qian<sup>2</sup>, A. Galli<sup>1</sup>, Louis J. DeFelice<sup>1</sup> and R.D. Blakely<sup>1</sup>. <sup>1</sup>Dept. Pharmacol. and Ctr. for Mol. Neurosci., Vanderbilt Univ., Nashville, TN 37232; <sup>2</sup>Program in Neurosci., Emory Univ., Atlanta, GA 30322.

The plasma membrane serotonin (5HT) transporter (SERT) has been extensively investigated over the past decade as a mechanism for the clearance of synaptic and plasma 5HT, as a target of cocaine and antidepressants, and as a biological marker of mental illness. Multiple reports demonstrate a capacity of SERTs to be acutely regulated by second messenger-linked systems. Previously, we have shown that short term treatment of PMA causes a dose-dependent, stereospecific, and staurosporine-sensitive inhibition of 5HT uptake in HEK-293 cells that stably express human SERT (293-hSERT cells). The effect of PMA on 5HT uptake is mainly through a decrease of 5HT transport  $V_{max}$ , with little change in  $K_m$ . PMA treatment of 293-hSERT cells under voltage clamp also reveals a loss of SERT-mediated currents. In the present study, we labelled cell surface proteins using a nonpermeabilizing biotinylation agent, harvested the biotinylated proteins on streptavidin agarose beads and detected cell surface SERT protein by immunoblotting with a SERT-specific polyclonal antibody. In a paradigm of PMA treatment that causes a significant decrease in 5HT uptake, we observed in parallel a similar decrease of cell surface SERT protein. Total amount of SERT in the cell is not changed by PMA treatment. Consistent with the decrease of cell surface SERT, the nonbiotinylated SERT protein is also elevated in PMA treated cells. The effect of PMA on both 5HT uptake and cell surface SERT density is blocked by cotreatment with staurosporine. In conclusion, activation of PKC causes a decrease in 5HT uptake via decreasing cell surface SERT density, presumably by altered plasmalemmal translocation of SERT protein.
