University of Pittsburgh

# SOCIETY FOR NEUROSCIENCE POLICIES ON THE USE OF ANIMALS AND HUMANS IN NEUROSCIENCE RESEARCH

## POLICY ON THE USE OF ANIMALS IN NEUROSCIENCE RESEARCH

The Policy on the Use of Animals in Neuroscience Research affects a number of the Society's functions that involve making decisions about animal research conducted by individual members. These include the scheduling of scientific presentations at the Annual Meeting, the review and publication of original research papers in *The Journal of Neuroscience*, and the defense of members whose ethical use of animals in research is questioned by antivivisectionists. The responsibility for implementing the policy in each of these areas will rest with the relevant administrative body (Program Committee, Publications Committee, Editorial Board, and Committee on Animals in Research, respectively), in consultation with Council.

### INTRODUCTION

The Society for Neuroscience, as a professional society for basic and clinical researchers in neuroscience, endorses and supports the appropriate and responsible use of animals as experimental subjects. Knowledge generated by neuroscience research on animals has led to important advances in the understanding of diseases and disorders that affect the nervous system and in the development of better treatments that reduce suffering in humans and animals. This knowledge also makes a critical contribution to our understanding of ourselves, the complexities of our brains, and what makes us human. Continued progress in understanding how the brain works and further advances in treating and curing disorders of the nervous system require investigation of complex functions at all levels in the living nervous system. Because no adequate alternatives exist, much of this research must be done on animal subjects. The Society takes the position that neuroscientists have an obligation to contribute to this progress through responsible and humane research on animals.

Several functions of the Society are related to the use of animals in research. A number of these involve decisions about research conducted by individual members of the Society, including the scheduling of scientific presentations at the Annual Meeting, the review and publication of original research papers in *The Journal of Neuroscience*, and the defense of members whose ethical use of animals in research is questioned by antivivisectionists. Each of these functions, by establishing explicit support of the Society for the research of individual members, defines a relationship between the Society and its members. The purpose of this document is to outline the policy that guides that relationship. Compliance with the following policy will be an important factor in determining the suitability of research for presentation at the Annual Meeting or for publication in *The Journal of Neuroscience*, and in situations where the Society is asked to provide public and active support for a member whose use of animals in research has been questioned.

### GENERAL POLICY

Neuroscience research uses complicated, often invasive methods, each of which is associated with different problems, risks, and specific technical considerations. An experimental method that would be deemed

inappropriate for one kind of research may be the method of choice for another kind of research. It is therefore impossible for the Society to define specific policies and procedures for the care and use of all research animals and for the design and conduct of every neuroscience experiment.

The U.S. *Public Health Service Policy on Humane Care and Use of Laboratory Animals* (PHS Policy) and the *Guide for the Care and Use of Laboratory Animals* (the Guide) describe a set of general policies and procedures designed to ensure the humane and appropriate use of live vertebrate animals in all forms of biomedical research. The Society finds the policies and procedures set forth in the PHS Policy and the Guide to be both necessary and sufficient to ensure a high standard of animal care and use and adopts them as its official "Policy on the Use of Animals in Neuroscience Research" (Society Policy). All Society members are expected to conduct their animal research in compliance with the Society Policy and are required to verify that they have done so when submitting abstracts for presentation at the Annual Meeting or manuscripts for publication in *The Journal of Neuroscience*. Adherence to the Society Policy is also an important step toward receiving help from the Society in responding to questions about a member's use of animals in research. A complete description of the Society's policy and procedures for defending members whose research comes under attack is given in the Society's *Handbook for the Use of Animals in Neuroscience Research*.

### LOCAL COMMITTEE REVIEW

An important element of the Society Policy is the establishment of a local committee that is charged with reviewing and approving all proposed animal care and use procedures. In addition to scientists experienced in research involving animals and a veterinarian, the membership of this local committee should include an individual who is not affiliated with the member's institution in any other way. In reviewing a proposed use of animals, the committee should evaluate the adequacy of institutional policies, animal husbandry, veterinary care, and the physical plant. Specific attention should be paid to proposed procedures for animal procurement, quarantine and stabilization, separation by species, disease diagnosis and treatment, anesthesia and analgesia, surgery and postsurgical care, and euthanasia. The review committee also should ensure that procedures involving live vertebrate animals are designed and performed with due consideration of their relevance to human or animal health, the advancement of knowledge, or the good of society. This review and approval of a member's use of live vertebrate animals in research by a local committee is an essential component of the Society Policy. Assistance in developing appropriate animal care and use procedures and establishing a local review committee can be obtained from the documents listed below and from the Society.

### OTHER LAWS, REGULATIONS, AND POLICIES

In addition to complying with the policy described above, Regular Members (i.e., North American residents) of the Society must also adhere to all relevant national, state, or local laws and/or regulations that govern their use of animals in neuroscience research. Thus, U.S. members must observe the U.S. Animal Welfare Act (as amended in 1985) and its implementing regulations from the U.S. Department of

Agriculture. Canadian members must abide by the *Guide to the Care and Use of Experimental Animals*, and members in Mexico must comply with the *Reglamento de la Ley General de Salud en Materia de Investigacion para la Salud of the Secretaria de Salud* (published on Jan. 6, 1987). Similarly, in addition to complying with the laws and regulations of their home countries, Foreign Members of the Society should adhere to the official Society Policy outlined here.

*OPRR Public Health Service Policy on Humane Care and Use of Laboratory Animals* (revised Sept. 1986). Office for Protection from Research Risks, NIH, 6100 Executive Blvd., Suite 3B01-MSC 7507, Rockville, MD 20892-7507.

*Preparation and Maintenance of Higher Mammals During Neuroscience Experiments*. Report of a National Institutes of Health Workshop. NIH Publication No. 91-3207, March 1991. National Eye Institute, Bldg. 31, Rm. 6A47, Bethesda, MD 20892.

The following principles, based largely on the PHS *Policy on Humane Care and Use of Laboratory Animals*, can be a useful guide in the design and implementation of experimental procedures involving laboratory animals.

Animals selected for a procedure should be of an appropriate species and quality and the minimum number required to obtain valid results.

Proper use of animals, including the avoidance or minimization of discomfort, distress, and pain, when consistent with sound scientific practices, is imperative.

Procedures with animals that may cause more than momentary or slight pain or distress should be performed with appropriate sedation, analgesia, or anesthesia. Surgical or other painful procedures should not be performed on unanesthetized animals paralyzed by chemical agents.

Postoperative care of animals shall be such as to minimize discomfort and pain and, in any case, shall be equivalent to accepted practices in schools of veterinary medicine.

Animals that would otherwise suffer severe or chronic pain or distress that cannot be relieved should be painlessly killed at the end of the procedure or, if appropriate, during the procedure. If the study requires the death of the animal, the animal must be killed in a humane manner.

Living conditions should be appropriate for the species and contribute to the animals' health and comfort. Normally, the housing, feeding, and care of all animals used for biomedical purposes must be directed by a veterinarian or other scientist trained and experienced in the proper care, handling, and use of the species being maintained or studied. In any case, appropriate veterinary care shall be provided.

Exceptions to these principles require careful consideration and should only be made by an appropriate review group such as an institutional animal care and use committee.

## **POLICY ON THE USE OF HUMAN SUBJECTS IN NEUROSCIENCE RESEARCH**

Experimental procedures involving human subjects must have been conducted in conformance with the policies and principles contained in the Federal Policy for the Protection of Human Subjects (United States Office of Science and Technology Policy) and in the Declaration of Helsinki. When publishing a paper in *The Journal of Neuroscience* or submitting an abstract for presentation at the Annual Meeting, authors must sign a statement of compliance with this policy.

# POLICY ON ETHICS

It is expected that authors submitting papers or abstracts will have conducted their work in strict accordance with the following statement on ethics approved by the Society for Neuroscience in November 1989 and amended in November 1993.

The Society for Neuroscience believes that progress in understanding the nervous system materially benefits human welfare. It recognizes that such progress depends on the honest pursuit of scientific research and the truthful representation of findings. While recognizing that both scientific error and differences of interpretation are a natural part of the creative process, the Society affirms that misconduct, in the form of fabrication, falsification, or plagiarism, jeopardizes the success of the entire scientific endeavor. Members of the Society assume an obligation to maintain the highest level of integrity in all scientific activities.

The primary responsibility for considering and resolving allegations of scientific misconduct lies within the individual academic communities and institutions where scientific work is carried out. The Society for Neuroscience therefore supports the principle that academic institutions should develop and have in place procedures to deal with allegations of scientific misconduct. However, the Society has a special responsibility and interest surrounding those scientific activities for which it is directly responsible, e.g., publication of *The Journal of Neuroscience* and the presentations at the Annual Meeting.

Every author of articles or abstracts submitted for publication in *The Journal of Neuroscience* or the neuroscience *Abstracts* agrees to assume full responsibility, within the limits of his or her professional competence, for the accuracy of the report. In the case of multiple-authored papers, each author should have made a significant intellectual or practical contribution to the scientific work; "honorary authorship," i.e., the granting of authorship to persons who have made no substantive contribution to a scientific report, is not appropriate.

Scientists must have access to their original research results. The retention of accurately recorded and retrievable results is essential for the progress of scientific inquiry. Moreover, errors may be mistaken for misconduct when primary results are unavailable. Primary data should remain in the laboratory and should be preserved as long as there may be a reasonable need to refer to them.

Authors submitting articles or abstracts do so with the understanding that reports have not been submitted elsewhere. An abstract is a proper forum for rapid communication of work that will subsequently appear as a full-length article. However, submission of abstracts reporting already published work or publication of multiple similar manuscripts or abstracts, i.e., duplicate publication, is improper. When previously published data are presented as part of a new manuscript or abstract, as in a gradually developing longitudinal data set, or if a subject group or condition is included again for comparison purposes, citations to the previously published work should appear explicitly in the new report.

Scientific publication is an important part of the process by which priority is established for experimental work and ideas. Duplicating without citation of text previously published by others or expropriating the experimental findings of others without attribution, i.e., plagiarism, is unethical. When authors of articles or abstracts have prepublication access to related work of others, as in a review process, care must be taken to avoid the appearance that priority is being claimed for work already done by others.

It is the responsibility of the authors, therefore, and not of the Society or the Editorial Board of *The Journal of Neuroscience*, to ensure that relevant prior discoveries are appropriately acknowledged in manuscripts that are submitted to the *Journal* for publication.

Questions raised about the conduct of experiments or their presentation will be evaluated preliminarily by the Editor of *The Journal of Neuroscience* (in the case of an article in the *Journal*) or by the Chair of the Program Committee (in the case of an abstract), in consultation with the Chair of the Publications Committee and the Secretary of the Society. If possible, the matter may be resolved informally at this level. However, if deemed appropriate, the matter will be referred to the institution where the scientific work in question was done. There, it would be expected that the matter would be reviewed in accordance with institutional procedures for handling allegations of misconduct. At all stages, every effort should be made to ensure that the process is fair and just, both for those who are accused of misconduct and for those who have raised the issue of scientific misconduct.

Based on their own findings or those of the institution, the *Journal* Editor or the Chair of the Program Committee, in consultation with the Chair of the Publications Committee and the Secretary of the Society, may recommend action to the Publications Committee. The Publications Committee will then decide on appropriate action, including, for example, retracting a published report. The Council of the Society and the relevant institution will be informed of any action that is taken. Council retains the right to consider additional action. In accordance with the Bylaws, this action could include, for example, expulsion from the Society. If it is found that allegations were not made in good faith, or were maliciously motivated, action may be recommended for those responsible.

In the event that a published article or abstract is to be retracted, a statement of retraction will be published in *The Journal of Neuroscience* or in the *Abstracts* for the next Annual Meeting.

# CHRONOLOGICAL LIST OF SESSIONS

184. Neuropeptides and behavior I	464
185. Drugs of abuse: alcohol, barbiturates, and benzodiazepines I	467
186. Drugs of abuse: ethanol, barbiturates, and benzodiazepines I	470
187. Drugs of abuse: amphetamines I	473
188. Psychopharmacological agents: other	477
189. Psychopharmacological agents: antipsychotics II	480
190. Developmental disorders II	482
191. Degenerative disease: Alzheimer's-beta-amyloid— protein interactions I	486
97. History of neuroscience	242
98. Teaching of neuroscience: computers, World Wide Web, and multimedia	246
99. Teaching of neuroscience: curricular innovations	249
100. Teaching of neuroscience: laboratory exercises	253

Session Number & Title	Page
---------------------------	------

### Animals in Research Panel—5:30 p.m.

192. Everything You Ever Wanted to Know about the Revised  
*Guide* and Its Interpretation by Regulatory Agencies—  
Part II . . . . .No Abstract

### Presidential Symposium—8:00 p.m.

193. **Domains of Vision: Circuits, Models, and Maps**  
Neuronal Diversity and Parallel Processing in Macaque  
Visual System  
S.H. HENDRY . . . . .No Abstract  
More than Meets the Eye: Modulation of Visual  
Representation by Attention  
J.H.R. MAUNSELL . . . . .No Abstract  
The Anatomy of Conscious Vision  
S. ZEKI . . . . .No Abstract

## MONDAY, NOV. 18

### Symposia—8:00 a.m.

194. Central Nervous System Autoimmunity in Human Diseases  
*Chaired by:* P. DE CAMILLI . . . . .489  
195. Mitochondrial Involvement in Neuronal Degeneration  
*Chaired by:* J.M. DUBINSKY and I.J. REYNOLDS . . . . .489

### Special Lecture—10:00 a.m.

196. Using Words and Mazes to Probe Cognitive Function:  
Imaging and Lesion-Behavior Studies  
S. PETERSEN . . . . .No Abstract

### Special Lecture—11:15 a.m.

197. The Basal Ganglia and Action Planning  
A.M. GRAYBIEL . . . . .No Abstract

### Slide Sessions—8:00 a.m.

198. Visual cortex: striate II . . . . .489  
199. Retina and photoreceptors I . . . . .492  
200. Postsynaptic mechanisms: chemical excitability . . . . .494  
201. Hypothalamic-pituitary-adrenal regulation I . . . . .496  
202. Catecholamine receptors . . . . .498  
203. Cerebellum . . . . .500  
204. Degenerative disease: Alzheimer's-beta-amyloid—  
protein interactions II . . . . .502  
205. Cell lineage and determination II . . . . .504  
206. Presynaptic mechanisms II . . . . .506  
207. Transporters II . . . . .508  
208. Pain modulation . . . . .510  
209. Neurotrophic factors: biologic effects . . . . .512  
210. Long-term potentiation: physiology I . . . . .514

### Poster Sessions—8:00 a.m.

211. Developmental genetics I . . . . .516  
212. Developmental genetics II . . . . .518  
213. Genesis of neurons and glia: EGF and FGF effects . . . . .520  
214. Genesis of neurons and glia: mechanisms and kinetics . . . . .523  
215. Cell lineage and determination III . . . . .526

Session Number & Title	Page
216. Cell differentiation and migration IV	529
217. Cell differentiation and migration V	532
218. Process outgrowth, growth cones, and sprouting II	533
219. Formation and specificity of synapses III	534
220. Neurotransmitter systems and channels: development of intrinsic cellular properties—ionic currents and synaptogenesis	536
221. Neurotransmitter systems and channels: development of excitatory and inhibitory receptors	540
222. Neurotrophic factors: expression and regulation— physiologic and pathophysiologic mechanisms II	544
223. Neurotrophic factors: expression and regulation— physiologic and pathophysiologic mechanisms III	547
224. Neurotrophic factors: receptors and cellular mechanisms I	551
225. Neurotrophic factors: receptors and cellular mechanisms II	555
226. Hormones and development: sexual differentiation	558
227. Neuronal death: intracellular signals	561
228. Neuronal death: ICE—related responses	565
229. Neuronal death: p53 and Bcl family	568
230. Motor systems: development and regeneration I	571
231. Regeneration: altered gene expression—PNS	574
232. Transplantation: functional	577
233. Staining, tracing, and imaging techniques II	580
234. Neuroglia and myelin II	583
235. Gene structure and function: promoter analysis	585
236. Excitatory amino acid receptors: structure, function, and expression—functional properties	588
237. Excitatory amino acid receptors: structure, function, and expression—receptor assembly	592
238. Excitatory amino acid receptors: structure, function, and expression—regulation of expression	595
239. Excitatory amino acid receptors: physiology, pharmacology, and modulation—mGluR I	598
240. Catecholamines: norepinephrine	600
241. Serotonin: tryptophan hydroxylase	603
242. Serotonin: general	604
243. Serotonin: behavior	607
244. Serotonin: uptake and release	610
245. Serotonin transporters	613
246. Regional localization of receptors and transmitters I	616
247. Second messengers and phosphorylation IV	619
248. Thermal regulation	622
249. Osmotic regulation	624
250. Neuroendocrine regulation: supraoptic nucleus	627
251. Cardiovascular regulation: nucleus tractus solitarius	631
252. Subcortical visual pathways I	634
253. Subcortical visual pathways II	638
254. Visual cortex: striate III	640
255. Visual cortex: striate IV	643
256. Auditory systems: central physiology—brainstem	646
257. Olfactory receptors: cell physiology	650
258. Olfactory receptors: development and specificity	652
259. Motor systems and sensorimotor integration: invertebrate sensory and motor systems I	654

Session Number & Title	Page
260. Cortex: human studies I	656
261. Vestibular system: physiology and behavior	659
262. Oculomotor system: superior colliculus	662
263. Oculomotor system: brainstem	664
264. Control of posture and movement: motor units	666
265. Control of posture and movement: spinal cord	669
266. Limbic system and hypothalamus II	670
267. Comparative neuroanatomy: higher vertebrates	673
268. Brain metabolism and blood flow II	676
269. Learning and memory: systems and functions II	678
270. Learning and memory: systems and functions III	681
271. Motivation and emotion: brain stimulation	683
272. Biological rhythms and sleep: circadian rhythms and sleep	686
273. Biological rhythms and sleep: sleep III	688
274. Neuroethology: songbirds II	691
275. Invertebrate learning and behavior II	694
276. Hormonal control of reproductive behavior II	697
277. Drugs of abuse: ethanol, barbiturates, and benzodiazepines II	699
278. Drugs of abuse: cocaine—glutamatergic influences	702
279. Drugs of abuse: amphetamines II	705
<b>97. History of neuroscience</b>	<b>242</b>
<b>98. Teaching of neuroscience: computers, World Wide Web, and multimedia</b>	<b>246</b>
<b>99. Teaching of neuroscience: curricular innovations</b>	<b>249</b>
<b>100. Teaching of neuroscience: laboratory exercises</b>	<b>253</b>
<b>Symposia—1:00 p.m.</b>	
280. Modulation of Neuronal Excitability and Behavior <i>Chaired by: J.L. FELDMAN and R.M. HARRIS-WARRICK</i>	708
281. Cell Cycle Regulation and CNS Development: Is One Division Like Any Other? <i>Chaired by: M.E. ROSS</i>	708
<b>Special Lecture—1:00 p.m.</b>	
282. The Neurobiology of Suicide J.J. MANN	No Abstract
<b>Social Issues Roundtable—3:30 p.m.</b>	
283. What is the Impact of Today's Funding for Neuroscience in the 21st Century? Problems and Solutions	No Abstract
<b>Slide Sessions—1:00 p.m.</b>	
284. Neuronal death IV	708
285. Degenerative disease: other—molecular biology	710
286. Calcium channels: physiology, pharmacology, and modulation III	712
287. Ischemia: neuroprotection	714
288. Visual cortex: extrastriate—dorsal stream I	716
289. Learning and memory: systems and functions IV	718
290. Parkinson's disease	720
291. Cognition: language I	723
292. Excitatory amino acid receptors: structure, function, and expression I	725

Session Number & Title	Page
293. Alzheimer's disease: presenilin cell biology .....	727
294. Neuropsychiatric disorders: postmortem I .....	729
295. Transporters III .....	731
<b>Poster Sessions—1:00 p.m.</b>	
296. Process outgrowth, growth cones, and sprouting III .....	733
297. Process outgrowth, growth cones, and sprouting IV .....	736
298. Process outgrowth, growth cones, and sprouting V .....	739
299. Neurotrophic factors: biologic effects—novel or uncharacterized factors .....	741
300. Neurotrophic factors: biologic effects—NGF I .....	745
301. Neurotrophic factors: biologic effects—NGF II .....	751
302. Hormones and development: sex steroids .....	755
303. Sensory systems: somatosensory .....	758
304. Subcortical visual development .....	760
305. Regeneration II .....	763
306. Transplantation II .....	766
307. Aging processes: neuronal alterations .....	768
308. Blood-brain barrier II .....	771
309. Presynaptic mechanisms: neuromuscular junction .....	774
310. Mechanisms of neurotransmitter release I .....	777
311. Mechanisms of neurotransmitter release II .....	780
312. Postsynaptic mechanisms: morphological and molecular correlates .....	784
313. Postsynaptic mechanisms: Ach, ATP and peptide signal .....	786
314. Postsynaptic mechanisms: GABA signals .....	788
315. Postsynaptic mechanisms: dendritic functions .....	791
316. Postsynaptic mechanisms: Ca <sup>2+</sup> signalling .....	793
317. Postsynaptic mechanisms: glutamate signals .....	795
318. Excitatory amino acids: excitotoxicity I .....	798
319. Excitatory amino acids: excitotoxicity II .....	801
320. Excitatory amino acids: excitotoxicity III .....	803
321. Excitatory amino acids: excitotoxicity IV .....	805
322. Excitatory amino acid receptors: physiology, pharmacology, and modulation—mGluR II .....	807
323. GABA <sub>A</sub> receptors: native functions .....	810
324. GABA <sub>A</sub> receptors: native modulation studies .....	813
325. GABA <sub>A</sub> receptors: microanatomy .....	815
326. GABA <sub>A</sub> receptors: recombinant studies and molecular mapping .....	817
327. GABA <sub>A</sub> receptors: knock-outs and knock-downs .....	821
328. Opioid receptors II .....	822
329. Catecholamine receptors: localization and structure .....	825
330. Catecholamine receptors: molecular biology and receptor binding .....	828
331. Catecholamines: dopamine II .....	831
332. Transmitters in invertebrates: neuropeptides I .....	835
333. Transmitters in invertebrates: neuropeptides II .....	838
334. Serotonin/catecholamine interactions .....	841
335. Hypothalamic-pituitary-adrenal regulation II .....	843
336. Neural-immune interactions: cytokines I .....	847
337. Cardiovascular regulation: ventral medulla I .....	850
338. Cardiovascular regulation: blood pressure regulation .....	853
339. Sensory systems: spinal cord I .....	857
340. Sensory systems: spinal cord II .....	859

Session Number & Title	Page
341. Pain pathways: spinal cord and brainstem .....	861
342. Pain modulation: anatomy and physiology— neuropathic pain .....	864
343. Pain modulation: anatomy and physiology—spinal cord I .....	867
344. Pain modulation: anatomy and physiology—spinal cord II .....	870
345. Pain modulation: pharmacology—neuropeptides and capsaicin .....	874
346. Pain modulation: pharmacology—amines, purines, and cannabinoids .....	877
347. Retinal receptors and channels .....	880
348. Visual psychophysics and behavior II .....	883
349. Visual psychophysics and behavior III .....	886
350. Auditory systems: central physiology—midbrain .....	888
351. Cortex: human studies II .....	890
352. Basal ganglia: anatomy II .....	891
353. Basal ganglia: function II .....	894
354. Control of posture and movement: motor learning .....	897
355. Limbic system and hypothalamus III .....	900
356. Association cortex and thalamocortical relations .....	904
357. Brain metabolism and blood flow III .....	907
358. Learning and memory: physiology I .....	910
359. Learning and memory: physiology II .....	914
360. Hormonal control of reproductive behavior III .....	917
361. Drugs of abuse: cocaine—DA-5-HT interactions .....	920
362. Drugs of abuse: cocaine I .....	923
363. Drugs of abuse: cocaine II .....	926
364. Drugs of abuse: cocaine III .....	929
365. Drugs of abuse: cocaine IV .....	932
366. Ischemia: glutamate .....	935
367. Infectious diseases: HIV .....	939
368. Neuropsychiatric disorders: depression .....	942
369. Neuro-oncology: tumor biology .....	945
370. Neuro-oncology: treatment and diagnosis .....	947
<b>97. History of neuroscience .....</b>	<b>242</b>
<b>98. Teaching of neuroscience: computers,     World Wide Web, and multimedia .....</b>	<b>246</b>
<b>99. Teaching of neuroscience: curricular innovations .....</b>	<b>249</b>
<b>100. Teaching of neuroscience: laboratory exercises .....</b>	<b>253</b>

#### Grass Foundation Lecture—8:00 p.m.

371. The Molecular Biology of Smell R. AXEL .....	No Abstract
--	-------------

## TUESDAY, NOV. 19

#### Symposia—8:00 a.m.

372. The Synaptic Vesicle Neurotransmitter Transporters: Chemical Coding at Central and Peripheral Synapses Chaired by: L.E. EIDEN .....	950
373. Molecular Biology of Perception Chaired by: G.M. SHEPHERD .....	950

#### Special Lecture—10:00 a.m.

374. Calcium Channels: Elegant Molecular Transducers with a Multitude of Neuronal Effects R.W. TSIEN .....	No Abstract
--	-------------

Session Number & Title	Page
<b>Special Lecture—11:15 a.m.</b>	
375. Why Do Brain Cells Die So Readily After Hypoxic-Ischemia Insults? D.W. CHOI . . . . .	No Abstract
<b>Slide Sessions—8:00 a.m.</b>	
376. Visual cortex: striate V . . . . .	951
377. Cardiovascular regulation: ventral medulla II . . . . .	953
378. Gene structure and function II . . . . .	955
379. Hypothalamic-pituitary-gonadal regulation II . . . . .	957
380. Opioid receptors III . . . . .	959
381. Developmental genetics III . . . . .	961
382. Oculomotor system: pursuit, 3-D stimuli, head movements . . . . .	963
383. Pain pathways . . . . .	965
384. Cognition: memory I . . . . .	966
385. Serotonin receptors . . . . .	968
386. Axon guidance mechanisms and pathways I . . . . .	970
387. Postsynaptic mechanisms: electrical excitability and Ca <sup>2+</sup> signalling . . . . .	972
388. Alzheimer's disease: tau and ApoE . . . . .	974
389. Long-term potentiation: physiology II . . . . .	976
<b>Poster Sessions—8:00 a.m.</b>	
390. Genesis of neurons and glia: adult . . . . .	978
391. Genesis of neurons and glia: regulation . . . . .	981
392. Cell lineage and determination IV . . . . .	983
393. Cell differentiation and migration VI . . . . .	985
394. Cell differentiation and migration VII . . . . .	988
395. Morphogenesis . . . . .	989
396. Neurotrophic factors: biologic effects— BDNF and NT-4 I . . . . .	991
397. Neurotrophic factors: biologic effects— BDNF and NT-4 II . . . . .	994
398. Neurotrophic factors: biologic effects—NT-3 . . . . .	998
399. Neurotrophic factors: receptors and cellular mechanisms III . . . . .	1001
400. Neurotrophic factors: receptors and cellular mechanisms IV . . . . .	1005
401. Neurotrophic factors: receptors and cellular mechanisms V . . . . .	1007
402. Neurotrophic factors: receptors and cellular mechanisms VI . . . . .	1008
403. Cerebral cortex and limbic system . . . . .	1011
404. Development of visual cortex I . . . . .	1014
405. Regeneration: altered gene expression—CNS . . . . .	1017
406. Transplantation: mostly spinal cord . . . . .	1021
407. Neuroglia and myelin III . . . . .	1023
408. Other ion channels I . . . . .	1026
409. Other ion channels II . . . . .	1028
410. Acetylcholine: structure/function I . . . . .	1029
411. Acetylcholine receptors: nicotinic—regulation of gene expression . . . . .	1032
412. Excitatory amino acids: pharmacology— metabotropic receptors . . . . .	1035

Session Number & Title	Page
413. Excitatory amino acid receptors: structure, function, and expression—metabotropic glutamate receptor . . . . .	1037
414. Regional localization of receptors and transmitters II . . . . .	1040
415. Receptor modulation: up- and down-regulation II . . . . .	1043
416. Cardiovascular regulation: peripheral autonomic control . . . . .	1045
417. Gastrointestinal regulation: peripheral mechanism . . . . .	1049
418. Urogenital regulation: sexual organs . . . . .	1051
419. Somatosensory cortex and thalamocortical relationships V . . . . .	1054
420. Somatosensory cortex and thalamocortical relationships VI . . . . .	1057
421. Visual cortex: extrastriate—mapping . . . . .	1059
422. Visual cortex: extrastriate—functional organization II . . . . .	1060
423. Auditory, vestibular, and lateral line: hair cell properties . . . . .	1062
424. Auditory systems: central physiology—forebrain . . . . .	1065
425. Auditory systems: central anatomy—forebrain . . . . .	1069
426. Olfactory systems: olfactory bulb anatomy . . . . .	1072
427. Olfactory systems: invertebrates . . . . .	1074
428. Motor systems and sensorimotor integration: invertebrate sensory and motor systems II . . . . .	1077
429. Motor systems and sensorimotor integration: invertebrate sensory and motor systems III . . . . .	1080
430. Cortex: connectivity . . . . .	1083
431. Basal ganglia: function III . . . . .	1085
432. Basal ganglia: dopamine . . . . .	1088
433. Cerebellum: physiology, models . . . . .	1090
434. Vestibular system: behavioral studies . . . . .	1093
435. Reflex function: animal studies . . . . .	1096
436. Muscle . . . . .	1098
437. Brain metabolism and blood flow IV . . . . .	1102
438. Brain metabolism and blood flow V . . . . .	1105
439. Cognition: frontal/prefrontal . . . . .	1107
440. Cognition: language II . . . . .	1109
441. Cognition: memory II . . . . .	1111
442. Learning and memory: systems and functions V . . . . .	1115
443. Learning and memory: systems and functions VI . . . . .	1118
444. Learning and memory: systems and functions VII . . . . .	1122
445. Learning and memory: systems and functions VIII . . . . .	1124
446. Learning and memory: pharmacology VI . . . . .	1126
447. Learning and memory: pharmacology VII . . . . .	1129
448. Neural plasticity II . . . . .	1132
449. Motivation and emotion: drugs . . . . .	1135
450. Motivation and emotion: other . . . . .	1138
451. Biological rhythms and sleep: circadian rhythms II . . . . .	1139
452. Neuroethology: invertebrates . . . . .	1142
453. Stress II . . . . .	1146
454. Hormonal control of reproductive behavior IV . . . . .	1149
455. Neuropeptides and behavior II . . . . .	1152
456. Drugs of abuse: ethanol, barbiturates, and benzodiazepines III . . . . .	1155
457. Drugs of abuse: amphetamines III . . . . .	1158
458. Drugs of abuse: opioids IV . . . . .	1161
459. Aging: memory . . . . .	1164
460. Developmental disorders III . . . . .	1166

Session Number & Title	Page
461. Degenerative disease: Alzheimer's-beta-amyloid— accumulation and aggregation . . . . .	1168
462. Degenerative disease: Alzheimer's-beta-amyloid— neuropathology . . . . .	1172
463. Degenerative disease: Alzheimer's—cognitive function II . . . . .	1176
464. Ischemia: apoptosis . . . . .	1177
465. Trauma III . . . . .	1180
466. Trauma IV . . . . .	1184
467. Neuropsychiatric disorders: schizophrenia I . . . . .	1187
468. Neuropsychiatric disorders: imaging II . . . . .	1190
<b>97. History of neuroscience . . . . .</b>	<b>242</b>
<b>98. Teaching of neuroscience: computers, World Wide Web, and multimedia . . . . .</b>	<b>246</b>
<b>99. Teaching of neuroscience: curricular innovations . . . . .</b>	<b>249</b>
<b>100. Teaching of neuroscience: laboratory exercises . . . . .</b>	<b>253</b>

### Symposia—1:00 p.m.

469. The Neurobiology of OB Protein (Leptin): A Peripheral Signal Acting on Central Neural Networks to Regulate Body Energy Balance <i>Chaired by: L.A. CAMPFIELD . . . . .</i>	1193
470. Glutamatergic Transmission: A View from the Dendrite <i>Chaired by: R.J. WEINBERG and F. CONTI . . . . .</i>	1193

### History of Neuroscience Lecture—1:00 p.m.

471. The Primate Visual System and Consciousness F.H.C. Crick . . . . .	No Abstract
--	-------------

### Presidential Special Lecture—4:15 p.m.

472. Formation of the Neural Crest M. BONNER-FRASER . . . . .	No Abstract
--	-------------

### Slide Sessions—1:00 p.m.

473. Potassium channels: function and expression . . . . .	1194
474. Stress III . . . . .	1195
475. Visual cortex: extrastriate—attention . . . . .	1197
476. Cerebellum: basal ganglia . . . . .	1199
477. Visual system: development II . . . . .	1201
478. Excitatory amino acids: excitotoxicity V . . . . .	1203
479. Cell differentiation and migration VIII . . . . .	1205
480. Degenerative disease: Alzheimer's-beta-amyloid— pathogenesis . . . . .	1207
481. Transplantation III . . . . .	1209
482. Neurotrophic factors: receptors and cellular mechanisms VII . . . . .	1212
483. Sodium channels: synaptic transmission and disease . . . . .	1214
484. Patterning II . . . . .	1215

### Poster Sessions—1:00 p.m.

485. Formation and specificity of synapses IV . . . . .	1217
486. Hormones and development . . . . .	1219
487. Nutritional and prenatal factors: malnutrition . . . . .	1221
488. Glia and other non-neuronal cells II . . . . .	1223
489. Motor systems: development and regeneration II . . . . .	1226
490. Regeneration: influence of substrate . . . . .	1228

Session Number & Title	Page
491. Aging processes: hippocampus . . . . .	1232
492. Aging processes . . . . .	1234
493. Staining, tracing, and imaging techniques III . . . . .	1238
494. Presynaptic mechanisms: calcium and release . . . . .	1239
495. Calcium channel structure, function, and expression II . . . . .	1242
496. Potassium channels: structure and function . . . . .	1245
497. Potassium channels: modulation I . . . . .	1249
498. Potassium channels: modulation II . . . . .	1251
499. Acetylcholine: structure/function II . . . . .	1254
500. Acetylcholine receptors: muscarinic— structure/function I . . . . .	1256
501. Acetylcholine receptors: nicotinic—molecular biology and knock-out . . . . .	1259
502. Acetylcholine receptors: nicotinic—pharmacology I . . . . .	1262
503. Acetylcholine receptors: nicotinic—physiology . . . . .	1266
504. Acetylcholine receptors: nicotinic—binding . . . . .	1270
505. Excitatory amino acids: excitotoxicity VI . . . . .	1273
506. Excitatory amino acids: excitotoxicity VII . . . . .	1277
507. Excitatory amino acids: pharmacology—modulation . . . . .	1279
508. Excitatory amino acids: pharmacology— synaptic receptors . . . . .	1281
509. GABA <sub>A</sub> receptors: benzodiazepines . . . . .	1284
510. GABA <sub>A</sub> receptors: ethanol . . . . .	1286
511. GABA <sub>A</sub> receptors: anesthetics . . . . .	1287
512. GABA <sub>A</sub> receptors: steroids . . . . .	1291
513. GABA <sub>B</sub> and GABA <sub>C</sub> receptors . . . . .	1293
514. GABA: GAD, GAT and GABA studies . . . . .	1295
515. Peptide receptor structure and function I . . . . .	1297
516. Peptide receptor structure and function II . . . . .	1300
517. Peptide receptor structure and function III . . . . .	1303
518. Peptides: biosynthesis, metabolism, and biochemical characterization—opiates . . . . .	1305
519. Opioids: anatomy, physiology, and behavior—anatomy . . . . .	1306
520. Opioids: anatomy, physiology, and behavior— physiology . . . . .	1309
521. Opioids: anatomy, physiology, and behavior— behavior . . . . .	1312
522. Catecholamine receptors: second messenger signal transduction . . . . .	1315
523. Catecholamine receptors: knock-outs and behavior . . . . .	1318
524. Catecholamines: dopamine III . . . . .	1319
525. Serotonin receptors: electrophysiology . . . . .	1322
526. 5-HT <sub>1A</sub> receptors: binding . . . . .	1323
527. 5-HT <sub>1A</sub> receptors: pharmacology . . . . .	1326
528. 5-HT <sub>1B</sub> , 5-HT <sub>1D</sub> , 5-HT <sub>1F</sub> receptors . . . . .	1329
529. Transmitters in invertebrates . . . . .	1332
530. Behavioral pharmacology . . . . .	1334
531. Receptor modulation: up- and down-regulation III . . . . .	1338
532. Hypothalamic-pituitary-adrenal regulation III . . . . .	1340
533. Hypothalamic-pituitary-gonadal regulation III . . . . .	1343
534. Neuroendocrine regulation: growth hormone and somatostatin . . . . .	1346
535. Neuroendocrine regulation: prolactin . . . . .	1347
536. Neural-immune interactions: depression and stress . . . . .	1350
537. Neural-immune interactions: cytokines II . . . . .	1353

Session Number & Title	Page
538. Somatosensory cortex and thalamocortical relationships VII	1356
539. Pain modulation: pharmacology—GABA and NMDA receptors	1359
540. Pain modulation: pharmacology—opiates I	1362
541. Pain modulation: pharmacology—opiates II	1365
542. Pain modulation: pharmacology—amino acids, anesthetics, antidepressants	1368
543. Motor systems and sensorimotor integration: circuitry and pattern generation II	1372
544. Motor systems and sensorimotor integration: circuitry and pattern generation III	1375
545. Learning and memory: systems and functions IX	1378
546. Learning and memory: systems and functions X	1382
547. Learning and memory: systems and functions XI	1385
548. Learning and memory: physiology III	1388
549. Learning and memory: physiology IV	1391
550. Neural plasticity III	1394
551. Biological rhythms and sleep: circadian rhythms III	1397
552. Neuroethology: songbirds III	1401
553. Invertebrate learning and behavior III	1403
554. Invertebrate learning and behavior IV	1405
555. Ingestive behavior: forebrain mechanisms	1407
556. Ingestive behavior: hypothalamus and brainstem	1411
557. Hormonal control of reproductive behavior V	1414
558. Epilepsy: human studies and animal models—cellular mechanisms	1417
559. Alzheimer's disease: tau and neurofibrillary degeneration	1419
560. Ischemia: glia and edema	1423
561. Ischemia: glucose, pH and, temperature	1425
562. Ischemia: oxidative injury	1428
563. Ischemia: neurotransmitters	1431
97. History of neuroscience	242
98. Teaching of neuroscience: computers, World Wide Web, and multimedia	246
99. Teaching of neuroscience: curricular innovations	249
100. Teaching of neuroscience: laboratory exercises	253

## WEDNESDAY, NOV. 20

### Symposia—8:00 a.m.

564. Gene Transfer: Applications of Viral Vectors for the Study and Treatment of CNS Disorders <i>Chaired by:</i> L.S. BRADY and H.J. FEDEROFF	1434
565. Bird Song: Twenty Years of Progress <i>Chaired by:</i> E.A. BRENOWITZ	1434

### Special Lecture—10:00 a.m.

566. The Ia Fiber Projection of Motoneurons: Modifiability of Function at a Central Synapse L.M. MENDELL	No Abstract
---	-------------

### Presidential Special Lecture—11:15 a.m.

567. Notch Signaling—Gatekeeper of Cell Fate Decisions S. ARTAVANIS-TSAKONAS	No Abstract
---	-------------

Session Number & Title	Page
<b>Slide Sessions—8:00 a.m.</b>	
568. Alzheimer's disease: presenilin localization	1435
569. Motor systems and sensorimotor integration: circuitry and pattern generation IV	1437
570. Epilepsy: basic mechanisms—cellular and molecular studies	1439
571. Serotonin: pharmacology	1441
572. Potassium channels: physiology, pharmacology, and modulation	1442
573. Invertebrate learning and behavior V	1444
574. Subcortical visual pathways III	1446
575. Learning and memory: systems and functions XII	1448
576. Cortex: human studies III	1450
577. Glia and other non-neuronal cells III	1453
578. Neural-immune interactions: other	1455
579. Oculomotor system: saccades	1456
580. Long-term potentiation: physiology III	1458
581. Ischemia: mechanisms	1460

### Poster Sessions—8:00 a.m.

582. Cell differentiation and migration IX	1462
583. Process outgrowth, growth cones, and sprouting VI	1464
584. Axon guidance mechanisms and pathways: neurotrophins, netrins, and Eph family	1468
585. Axon guidance mechanisms and pathways: collapsins and semaphorins	1471
586. Formation and specificity of synapses V	1473
587. Neurotrophic factors: receptors and cellular mechanisms VIII	1476
588. Neuronal death: oxidative stress	1479
589. Neuronal death: excitotoxicity	1482
590. Neuronal death: calcium and potassium	1484
591. Regeneration: functional recovery	1487
592. Transplantation: Parkinson's disease—related	1491
593. Aging processes: toxicity, inflammation, and non-neuronal cells	1494
594. Neuroglia and myelin IV	1496
595. Presynaptic mechanisms: release and recycling	1500
596. Long-term potentiation: physiology IV	1503
597. Long-term potentiation: physiology V	1506
598. Long-term potentiation: physiology VI	1509
599. Long-term potentiation: physiology VII	1512
600. Long-term potentiation: physiology VIII	1516
601. Long-term potentiation: physiology IX	1519
602. Acetylcholine receptors: nicotinic—pharmacology II	1521
603. Acetylcholine receptors: nicotinic—recombinant	1524
604. Excitatory amino acids: pharmacology I	1528
605. Excitatory amino acids: pharmacology II	1531
606. Excitatory amino acid receptors: physiology, pharmacology, and modulation I	1534
607. Excitatory amino acid receptors: physiology, pharmacology, and modulation II	1537
608. Excitatory amino acid receptors: physiology, pharmacology, and modulation III	1541

Session Number & Title	Page
609. CRF receptors: structure and function	1544
610. NPY-like receptors	1547
611. Peptides: anatomy and physiology I	1550
612. Peptides: anatomy and physiology II	1552
613. Peptides: anatomy and physiology III	1555
614. Catecholamines: biosynthetic enzymes	1558
615. Other neurotransmitters	1561
616. Nitric oxide and other modulators	1564
617. Adenosine and ATP as neurotransmitters	1567
618. Glutamate transporters I	1570
619. Glutamate transporters II	1573
620. Dopamine transporters	1575
621. Regional localization of receptors and transmitters III	1578
622. Behavioral pharmacology: drugs of abuse	1582
623. Behavioral pharmacology: serotonin	1584
624. Hypothalamic-pituitary-gonadal regulation IV	1586
625. Neuroendocrine regulation: other	1590
626. Neuroendocrine regulation: estrogen	1593
627. Respiratory regulation: pattern generation and motoneuron	1595
628. Respiratory regulation: chemoreception and hypoxic responses	1597
629. Respiratory regulation: integrative mechanisms	1601
630. Retinal anatomy	1603
631. Subcortical visual pathways IV	1605
632. Visual cortex: striate VI	1608
633. Visual cortex: striate VII	1611
634. Visual cortex: extrastriate—ventral stream	1614
635. Visual cortex: extrastriate—dorsal stream II	1617
636. Auditory, vestibular, and lateral line: development and regeneration	1620
637. Auditory systems: central physiology— primate cortex	1622
638. Cerebellum: behavior and pharmacology	1626
639. Cerebellum: clinical, development, genetic models	1628
640. Cerebellum: anatomy	1629
641. Human posture	1632
642. Mechanics and dynamics	1635
643. Control of posture and movement: kinematics	1638
644. Motor systems and sensorimotor integration: circuitry and pattern generation V	1641
645. Learning and memory: systems and functions XIII	1643
646. Learning and memory: systems and functions XIV	1646
647. Genetic models: natural mutants	1648
648. Genetic models: transgenes	1652
649. Epilepsy: human studies and animal models— limbic seizures II	1655
650. Epilepsy: human studies and animal models— alterations in glutamate receptors	1657
651. Degenerative disease: Alzheimer's-beta-amyloid— therapeutic approaches I	1659
652. Alzheimer's disease: presenilin gene expression	1661
653. Alzheimer's disease: presenilin cell biology	1663
654. Ischemia: trophic factors, peptides, and hormones	1666
655. Ischemia: gene expression	1669
656. Ischemia: tolerance and stress proteins	1671

Session Number & Title	Page
657. Neuropsychiatric disorders: schizophrenia II	1674
658. Neuropsychiatric disorders: postmortem II	1677
97. History of neuroscience	242
98. Teaching of neuroscience: computers, World Wide Web, and multimedia	246
99. Teaching of neuroscience: curricular innovations	249
100. Teaching of neuroscience: laboratory exercises	253
<b>Symposia—1:00 p.m.</b>	
659. The Cellular Bases of Functional Brain Imaging <i>Chaired by: P.J. MAGISTRETTI</i>	1681
660. Neurotrophins and Synaptic Plasticity <i>Chaired by: B. LU</i>	1681
<b>Slide Sessions—1:00 p.m.</b>	
661. Peptide receptor molecular biology	1681
662. Drugs of abuse: other II	1683
663. Ingestive behavior: central mechanisms	1685
664. Oculomotor system: human studies	1687
665. Formation and specificity of synapses VI	1689
666. Visual cortex: extrastriate—dorsal stream III	1691
667. Ischemia: molecular biology	1693
668. Degenerative disease: Alzheimer's-beta-amyloid— ApoE	1695
669. Cognition: attention I	1697
670. Reaching and posture	1699
671. Excitatory amino acid receptors: physiology, pharmacology, and modulation IV	1701
672. Visual cortex: striate VIII	1703
673. Membrane composition	1705
<b>Poster Sessions—1:00 p.m.</b>	
674. Cell differentiation and migration X	1706
675. Process outgrowth, growth cones, and sprouting VII	1709
676. Axon guidance mechanisms and pathways: cell adhesion molecules	1711
677. Axon guidance mechanisms and pathways: outgrowth patterns	1714
678. Neuronal death: culture systems	1718
679. Neuronal death V	1719
680. Glia and other non-neuronal cells IV	1722
681. Retinal development I	1724
682. Development of visual cortex II	1727
683. Staining, tracing, and imaging techniques IV	1730
684. Neuroglia and myelin V	1732
685. Gene structure and function: expression	1735
686. Presynaptic mechanisms III	1739
687. Postsynaptic mechanisms: network activity and models	1741
688. Calcium channels: physiology, pharmacology, and modulation IV	1743
689. Calcium channels: physiology, pharmacology, and modulation V	1746
690. Calcium channels: physiology, pharmacology, and modulation VI	1749
691. Potassium channels: expression	1752

Session Number & Title	Page
692. Acetylcholine receptors: muscarinic— structure/function II . . . . .	1755
693. Excitatory amino acid receptors: physiology, pharmacology, and modulation—NMDA III . . . . .	1760
694. Peptides: biosynthesis, metabolism, and biochemical characterization I . . . . .	1763
695. Opioid receptors IV . . . . .	1765
696. Catecholamine receptors: pharmacology . . . . .	1768
697. Catecholamine receptors: anti-psychotic/nervous system disorders . . . . .	1771
698. Serotonin receptors: 5HT <sub>2</sub> —anatomy and behavior . . . . .	1774
699. Serotonin receptors: 5HT <sub>2</sub> I . . . . .	1776
700. Serotonin receptors: 5HT <sub>2</sub> II . . . . .	1780
701. Novel 5HT receptors: 5HT <sub>6</sub> , 5HT <sub>7</sub> , and others . . . . .	1781
702. Transporters IV . . . . .	1783
703. Transporters V . . . . .	1786
704. Hypothalamic-pituitary-gonadal regulation V . . . . .	1788
705. Neural-immune interactions: pathology . . . . .	1791
706. Neural-immune interactions: inflammation . . . . .	1794
707. Somatic and visceral afferents—visceral afferents I . . . . .	1798
708. Somatic and visceral afferents—visceral afferents II . . . . .	1800
709. Somatic and visceral afferents: nociceptors . . . . .	1802
710. Somatic and visceral afferents: mechanoreceptors . . . . .	1805
711. Pain modulation: anatomy and physiology—receptors and nerves . . . . .	1808
712. Pain modulation: pharmacology—inflammation and hyperalgesia . . . . .	1811
713. Retinal intracellular signalling . . . . .	1814
714. Subcortical visual pathways V . . . . .	1817
715. Auditory, vestibular, and lateral line: integration . . . . .	1819
716. Auditory systems: central physiology—hearing loss . . . . .	1820
717. Olfactory systems: olfactory responses . . . . .	1823
718. Gustatory sensation . . . . .	1825
719. Cortex: transformations . . . . .	1829
720. Vestibular system: anatomy and pharmacology . . . . .	1831
721. Oculomotor system: vestibulo-ocular and optokinetic systems . . . . .	1833
722. Spinal cord and brainstem: anatomic organization . . . . .	1835
723. Spinal cord and brainstem: plasticity and integrative mechanisms . . . . .	1839
724. Spinal cord and brainstem: responses to injury . . . . .	1842
725. Spinal cord and brainstem: properties of motoneurons and interneurons . . . . .	1844
726. Human locomotion . . . . .	1848
727. Effects of injury and disease I . . . . .	1850
728. Cognition: sensory . . . . .	1852
729. Cognition: attention II . . . . .	1855
730. Cognition: other . . . . .	1858
731. Learning and memory: systems and functions XV . . . . .	1862
732. Learning and memory: systems and functions XVI . . . . .	1864
733. Learning and memory: systems and functions XVII . . . . .	1867
734. Learning and memory: physiology V . . . . .	1870
735. Learning and memory: physiology VI . . . . .	1874
736. Neural plasticity IV . . . . .	1877
737. Drugs of abuse: cocaine V . . . . .	1880
738. Drugs of abuse: cocaine VI . . . . .	1883

Session Number & Title	Page
739. Drugs of abuse: cocaine—fetal and neonatal effects . . . . .	1885
740. Aging: other . . . . .	1889
741. Alzheimer's disease: cell biology . . . . .	1892
742. Ischemia: enzymes and metabolism . . . . .	1895
743. Trauma V . . . . .	1899
744. Trauma VI . . . . .	1902
745. Neurotoxicity: metabolic poisons . . . . .	1905
746. Neurotoxicity: glutamatergic agents . . . . .	1907
747. Neurotoxicity: environmental and therapeutic agents . . . . .	1910
748. Neurotoxicity: dopaminergic and sympathomimetic agents . . . . .	1912
749. Neurotoxicity: other . . . . .	1916
750. Neurotoxicity: oxidants . . . . .	1919
751. Neurotoxicity: metals . . . . .	1922
<b>97. History of neuroscience . . . . .</b>	<b>242</b>
<b>98. Teaching of neuroscience: computers, World Wide Web, and multimedia . . . . .</b>	<b>246</b>

<b>100. Teaching of neuroscience: laboratory exercises . . . . .</b>	<b>253</b>

## THURSDAY, NOV. 21

### Symposia—8:00 a.m.

752. Caught in the Act: Structural Changes Associated with Channel Gating <i>Chaired by:</i> S.A. SIEGELBAUM . . . . .	1925
753. Genes in Ischemia <i>Chaired by:</i> R.P. SIMON and R.S. ZUKIN . . . . .	1925

### Slide Sessions—8:00 a.m.

754. Peptides: biosynthesis, metabolism, and biochemical characterization II . . . . .	1925
755. Drugs of abuse: alcohol, barbiturates, and benzodiazepines II . . . . .	1926
756. Drugs of abuse: cocaine VII . . . . .	1928
757. Process outgrowth, growth cones, and sprouting VIII . . . . .	1930
758. Drugs of abuse: cocaine VIII . . . . .	1932
759. Learning and memory: physiology VII . . . . .	1934
760. Visual cortex: extrastriate—ventral stream/mapping . . . . .	1936
761. Ischemia: animal models . . . . .	1938
762. GABA <sub>A</sub> receptors: cellular and molecular studies . . . . .	1940
763. Neuromuscular diseases II . . . . .	1942
764. Degenerative disease: Alzheimer's-beta-amyloid— therapeutic approaches II . . . . .	1944

### Poster Sessions—8:00 a.m.

765. Axon guidance mechanisms and pathways II . . . . .	1945
766. Formation and specificity of synapses VII . . . . .	1948
767. Neurotrophic factors: biologic effects—GDNF . . . . .	1952
768. Neurotrophic factors: biologic effects—EGF, FGF, IGF, and TGF . . . . .	1956
769. Neurotrophic factors: biologic effects—CNTF, LIF, and interleukins . . . . .	1961
770. Neurotrophic factors: biologic effects— neurotransmitters . . . . .	1964
771. Nutritional and prenatal factors: dietary and environmental factors . . . . .	1966

Session Number & Title	Page	Session Number & Title	Page
772. Glia and other non-neuronal cells V . . . . .	1969	813. Drugs of abuse: ethanol, barbiturates, and benzodiazepines IV . . . . .	2071
773. Cerebral cortex and limbic system: molecular expression patterns . . . . .	1972	814. Drugs of abuse: ethanol, barbiturates, and benzodiazepines V . . . . .	2074
774. Cerebral cortex and limbic system: function . . . . .	1974	815. Drugs of abuse: amphetamine—neurotoxicity . . . . .	2076
775. Retinal development II . . . . .	1976	816. Genetic models . . . . .	2080
776. Neuroglia and myelin VI . . . . .	1979	817. Epilepsy: human studies and animal models . . . . .	2083
777. Cytoskeleton and membrane composition . . . . .	1981	818. Epilepsy: basic mechanisms—molecular studies . . . . .	2086
778. Cytoskeleton . . . . .	1984	819. Epilepsy: basic mechanisms—morphological studies . . . . .	2089
779. Presynaptic mechanisms IV . . . . .	1987	820. Epilepsy: basic mechanisms—other . . . . .	2091
780. Mechanisms of neurotransmitter release III . . . . .	1990	821. Epilepsy: basic mechanisms—transmitters and second messengers . . . . .	2092
781. Ligand-gated ion channels . . . . .	1993	822. Epilepsy: basic mechanisms—physiological studies I . . . . .	2096
782. Excitatory amino acid receptors: structure, function, and expression II . . . . .	1994	823. Epilepsy: basic mechanisms—physiological studies II . . . . .	2101
783. Peptides: anatomy and physiology IV . . . . .	1997	824. Epilepsy: anti-convulsant drugs—transmitter-related . . . . .	2104
784. Peptides: anatomy and physiology V . . . . .	1999	825. Epilepsy: anti-convulsant drugs—other . . . . .	2106
785. Peptides: anatomy and physiology VI . . . . .	2001	826. Degenerative disease: Alzheimer's-beta-amyloid— membrane interactions . . . . .	2109
786. Opioid receptors V . . . . .	2002	827. Degenerative disease: Alzheimer's-beta-amyloid— neurotoxicity . . . . .	2113
787. Opioid receptors: sigma receptors . . . . .	2005	828. Degenerative disease: Alzheimer's-beta-amyloid— apolipoproteins . . . . .	2116
788. Catecholamine receptors: regulation of gene expression . . . . .	2007	829. Degenerative disease: Alzheimer's— cognitive function III . . . . .	2118
789. Histamine . . . . .	2009	830. Degenerative disease: Alzheimer's— neuropharmacology and neurotransmitters III . . . . .	2121
790. Other peptide neurotransmitters . . . . .	2110	831. Alzheimer's disease: biochemistry . . . . .	2123
791. Hypothalamic-pituitary-adrenal regulation IV . . . . .	2012	832. Parkinson's disease: animal models I . . . . .	2126
792. Retina and photoreceptors II . . . . .	2016	833. Parkinson's disease: animal models II . . . . .	2129
793. Olfactory systems: olfactory bulb physiology . . . . .	2018	834. Degenerative disease: miscellaneous . . . . .	2132
794. Olfactory systems: olfactory bulb pharmacology . . . . .	2020	835. Degenerative disease: other—metabolic and inflammatory . . . . .	2134
795. Cortex: sensorimotor . . . . .	2022	836. Degenerative disease: other—ataxias and dementias . . . . .	2138
796. Cortex: premotor . . . . .	2024	837. Degenerative disease: other—ALS . . . . .	2141
797. Basal ganglia: function IV . . . . .	2026	838. Ischemia: inflammation and coagulation . . . . .	2143
798. Basal ganglia: models . . . . .	2028	839. Ischemia: behavioral, clinical, and imaging studies . . . . .	2145
799. Thalamus . . . . .	2029	840. Ischemia: models . . . . .	2147
800. Oculomotor system: behavioral studies, coordinate frames, and models . . . . .	2032	841. Ischemia: ionic mechanisms . . . . .	2151
801. Oculomotor system: accommodation, vergence, eye blink, and muscle . . . . .	2034	842. Trauma VII . . . . .	2153
802. Control of posture and movement: development . . . . .	2036	843. Trauma VIII . . . . .	2156
803. Effects of injury and disease II . . . . .	2038	844. Infectious diseases: other . . . . .	2159
804. Animal locomotion . . . . .	2042	<b>97. History of neuroscience . . . . .</b>	<b>242</b>
805. Motor systems and sensorimotor integration: circuitry and pattern generation VI . . . . .	2044	<b>98. Teaching of neuroscience: computers, World Wide Web, and multimedia . . . . .</b>	<b>246</b>
806. Limbic system and hypothalamus IV . . . . .	2047	<b>99. Teaching of neuroscience: curricular innovations . . . . .</b>	<b>249</b>
807. Biological rhythms and sleep: circadian rhythms IV . . . . .	2051	<b>100. Teaching of neuroscience: laboratory exercises . . . . .</b>	<b>253</b>
808. Biological rhythms and sleep: circadian rhythms V . . . . .	2054		
809. Stress IV . . . . .	2058		
810. Monoamines and behavior III . . . . .	2062		
811. Monoamines and behavior IV . . . . .	2065		
812. Neuropeptides and behavior III . . . . .	2068		

# THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions and symposia only.)

Session Number	Session Title	Type	Sun.	Day and Time Mon.	Tue.	Wed.	Thu.
<b>THEME A: DEVELOPMENT AND REGENERATION</b>							
492.	Aging processes . . . . .	Poster			Tue PM		
491.	Aging processes: hippocampus . . . . .	Poster			Tue PM		
307.	Aging processes: neuronal alterations . . . . .	Poster		Mon PM			
593.	Aging processes: toxicity, inflammation, and non-neuronal cells . . . . .	Poster				Wed AM	
386.	Axon guidance mechanisms and pathways I . . . . .	Slide			Tue AM		
765.	Axon guidance mechanisms and pathways II . . . . .	Poster					Thu AM
676.	Axon guidance mechanisms and pathways: cell adhesion molecules . . . . .	Poster				Wed PM	
585.	Axon guidance mechanisms and pathways: collapsins and semaphorins . . . . .	Poster				Wed AM	
584.	Axon guidance mechanisms and pathways: neurotrophins, netrins, and Eph family . . . . .	Poster				Wed AM	
677.	Axon guidance mechanisms and pathways: outgrowth patterns . . . . .	Poster				Wed PM	
281.	<b>Cell Cycle Regulation and CNS Development: Is One Division Like Any Other? . . . . .</b>	SYMP		Mon PM			
22.	Cell differentiation and migration I . . . . .	Poster	Sun AM				
119.	Cell differentiation and migration II . . . . .	Poster	Sun PM				
120.	Cell differentiation and migration III . . . . .	Poster	Sun PM				
216.	Cell differentiation and migration IV . . . . .	Poster		Mon AM			
217.	Cell differentiation and migration V . . . . .	Poster		Mon AM			
393.	Cell differentiation and migration VI . . . . .	Poster			Tue AM		
394.	Cell differentiation and migration VII . . . . .	Poster			Tue AM		
479.	Cell differentiation and migration VIII . . . . .	Slide			Tue PM		
582.	Cell differentiation and migration IX . . . . .	Poster				Wed AM	
674.	Cell differentiation and migration X . . . . .	Poster				Wed PM	
21.	Cell lineage and determination I . . . . .	Poster	Sun AM				
205.	Cell lineage and determination II . . . . .	Slide		Mon AM			
215.	Cell lineage and determination III . . . . .	Poster		Mon AM			
392.	Cell lineage and determination IV . . . . .	Poster			Tue AM		
403.	Cerebral cortex and limbic system . . . . .	Poster			Tue AM		
774.	Cerebral cortex and limbic system: function . . . . .	Poster					Thu AM
773.	Cerebral cortex and limbic system: molecular expression patterns . . . . .	Poster					Thu AM
404.	Development of visual cortex I . . . . .	Poster			Tue AM		
682.	Development of visual cortex II . . . . .	Poster				Wed PM	
211.	Developmental genetics I . . . . .	Poster		Mon AM			
212.	Developmental genetics II . . . . .	Poster		Mon AM			
381.	Developmental genetics III . . . . .	Slide			Tue AM		
25.	Formation and specificity of synapses I . . . . .	Poster	Sun AM				
122.	Formation and specificity of synapses II . . . . .	Poster	Sun PM				
219.	Formation and specificity of synapses III . . . . .	Poster		Mon AM			
485.	Formation and specificity of synapses IV . . . . .	Poster			Tue PM		
586.	Formation and specificity of synapses V . . . . .	Poster				Wed AM	
665.	Formation and specificity of synapses VI . . . . .	Slide				Wed PM	
766.	Formation and specificity of synapses VII . . . . .	Poster					Thu AM
118.	Genesis of neurons and glia . . . . .	Slide	Sun PM				
213.	Genesis of neurons and glia: EGF and FGF effects . . . . .	Poster		Mon AM			

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
390.	Genesis of neurons and glia: adult . . . . .	Poster	Sun PM	Mon AM	Tue AM	Wed AM Wed PM	Thu AM
214.	Genesis of neurons and glia: mechanisms and kinetics . . . . .	Poster			Tue AM		
391.	Genesis of neurons and glia: regulation . . . . .	Poster			Tue PM		
128.	Glia and other non-neuronal cells I . . . . .	Poster					
488.	Glia and other non-neuronal cells II . . . . .	Poster					
577.	Glia and other non-neuronal cells III . . . . .	Slide					
680.	Glia and other non-neuronal cells IV . . . . .	Poster					
772.	Glia and other non-neuronal cells V . . . . .	Poster					
486.	Hormones and development . . . . .	Poster					
302.	Hormones and development: sex steroids . . . . .	Poster					
226.	Hormones and development: sexual differentiation . . . . .	Poster	Sun AM Sun AM Sun PM	Mon PM Mon AM	Tue AM	Wed PM Wed AM Wed PM Wed AM	Thu AM
395.	Morphogenesis . . . . .	Poster		Mon AM	Tue PM		
230.	Motor systems: development and regeneration I . . . . .	Poster					
489.	Motor systems: development and regeneration II . . . . .	Poster					
26.	Neuronal death I . . . . .	Poster					
27.	Neuronal death II . . . . .	Poster					
127.	Neuronal death III . . . . .	Poster					
284.	Neuronal death IV . . . . .	Slide		Mon PM			
679.	Neuronal death V . . . . .	Poster					
228.	Neuronal death: ICE—related responses . . . . .	Poster		Mon AM			
590.	Neuronal death: calcium and potassium . . . . .	Poster	Sun PM	Mon AM	Tue AM Tue AM	Wed AM Wed PM Wed AM	Thu AM
678.	Neuronal death: culture systems . . . . .	Poster					
589.	Neuronal death: excitotoxicity . . . . .	Poster					
227.	Neuronal death: intracellular signals . . . . .	Poster					
126.	Neuronal death: lesions . . . . .	Poster					
588.	Neuronal death: oxidative stress . . . . .	Poster					
229.	Neuronal death: p53 and Bcl family . . . . .	Poster					
221.	Neurotransmitter systems and channels: development of excitatory and inhibitory receptors . . . . .	Poster					
220.	Neurotransmitter systems and channels: development of intrinsic cellular properties— ionic currents and synaptogenesis . . . . .	Poster					
209.	Neurotrophic factors: biologic effects . . . . .	Slide					
396.	Neurotrophic factors: biologic effects— BDNF and NT-4 I . . . . .	Poster	Sun PM	Mon AM	Tue AM	Wed AM Wed PM Wed AM	Thu AM
397.	Neurotrophic factors: biologic effects— BDNF and NT-4 II . . . . .	Poster			Tue AM		
769.	Neurotrophic factors: biologic effects— CNTF, LIF, and interleukins . . . . .	Poster					
768.	Neurotrophic factors: biologic effects— EGF, FGF, IGF, and TGF . . . . .	Poster					
767.	Neurotrophic factors: biologic effects—GDNF . . . . .	Poster					
300.	Neurotrophic factors: biologic effects—NGF I . . . . .	Poster					
301.	Neurotrophic factors: biologic effects—NGF II . . . . .	Poster					
398.	Neurotrophic factors: biologic effects—NT-3 . . . . .	Poster					
770.	Neurotrophic factors: biologic effects—neurotransmitters . . . . .	Poster					
299.	Neurotrophic factors: biologic effects— novel or uncharacterized factors . . . . .	Poster					
123.	Neurotrophic factors: expression and regulation— development and aging . . . . .	Poster	Sun PM	Mon PM	Tue AM	Wed AM Wed PM Wed AM	Thu AM
124.	Neurotrophic factors: expression and regulation— physiologic and pathophysiologic mechanisms I . . . . .	Poster					
222.	Neurotrophic factors: expression and regulation— physiologic and pathophysiologic mechanisms II . . . . .	Poster					
223.	Neurotrophic factors: expression and regulation— physiologic and pathophysiologic mechanisms III . . . . .	Poster	Sun PM	Mon AM			

Session Number	Session Title	Type	Sun.	Mon.	Tue.	Wed.	Thu.
125.	Neurotrophic factors: expression and regulation— synthesis, expression, and transport . . . . .	Poster	Sun PM				
224.	Neurotrophic factors: receptors and cellular mechanisms I . . . . .	Poster		Mon AM			
225.	Neurotrophic factors: receptors and cellular mechanisms II . . . . .	Poster		Mon AM			
399.	Neurotrophic factors: receptors and cellular mechanisms III . . . . .	Poster			Tue AM		
400.	Neurotrophic factors: receptors and cellular mechanisms IV . . . . .	Poster			Tue AM		
401.	Neurotrophic factors: receptors and cellular mechanisms V . . . . .	Poster			Tue AM		
402.	Neurotrophic factors: receptors and cellular mechanisms VI . . . . .	Poster			Tue AM		
482.	Neurotrophic factors: receptors and cellular mechanisms VII . . . . .	Slide			Tue PM		
587.	Neurotrophic factors: receptors and cellular mechanisms VIII . . . . .	Poster				Wed AM Wed PM	
<b>660.</b>	<b>Neurotrophins and Synaptic Plasticity . . . . .</b>	<b>SYMP</b>					
771.	Nutritional and prenatal factors: dietary and environmental factors . . . . .	Poster					Thu AM
487.	Nutritional and prenatal factors: malnutrition . . . . .	Poster			Tue PM		
290.	Parkinson's disease . . . . .	Slide		Mon PM			
23.	Patterning I . . . . .	Poster	Sun AM				
484.	Patterning II . . . . .	Slide			Tue PM		
121.	Patterning and gene expression . . . . .	Poster	Sun PM				
24.	Process outgrowth, growth cones, and sprouting I . . . . .	Poster	Sun AM				
218.	Process outgrowth, growth cones, and sprouting II . . . . .	Poster		Mon AM			
296.	Process outgrowth, growth cones, and sprouting III . . . . .	Poster		Mon PM			
297.	Process outgrowth, growth cones, and sprouting IV . . . . .	Poster		Mon PM			
298.	Process outgrowth, growth cones, and sprouting V . . . . .	Poster		Mon PM			
583.	Process outgrowth, growth cones, and sprouting VI . . . . .	Poster				Wed AM Wed PM	
675.	Process outgrowth, growth cones, and sprouting VII . . . . .	Poster					
757.	Process outgrowth, growth cones, and sprouting VIII . . . . .	Slide					Thu AM
108.	Regeneration I . . . . .	Slide	Sun PM				
305.	Regeneration II . . . . .	Poster		Mon PM			
130.	Regeneration and degeneration . . . . .	Poster	Sun PM				
405.	Regeneration: altered gene expression—CNS . . . . .	Poster			Tue AM		
231.	Regeneration: altered gene expression—PNS . . . . .	Poster		Mon AM			
591.	Regeneration: functional recovery . . . . .	Poster				Wed AM	
490.	Regeneration: influence of substrate . . . . .	Poster			Tue PM		
681.	Retinal development I . . . . .	Poster				Wed PM	
775.	Retinal development II . . . . .	Poster					Thu AM
129.	Sensory systems: auditory and olfactory . . . . .	Poster	Sun PM				
303.	Sensory systems: somatosensory . . . . .	Poster		Mon PM			
304.	Subcortical visual development . . . . .	Poster		Mon PM			
28.	Transplantation I . . . . .	Poster	Sun AM				
306.	Transplantation II . . . . .	Poster		Mon PM			
481.	Transplantation III . . . . .	Slide			Tue PM		
592.	Transplantation: Parkinson's disease—related . . . . .	Poster				Wed AM	
131.	Transplantation: Parkinson's disease—retina . . . . .	Poster	Sun PM				
232.	Transplantation: functional . . . . .	Poster		Mon AM			
406.	Transplantation: mostly spinal cord . . . . .	Poster			Tue AM		
114.	Visual system: development I . . . . .	Slide	Sun PM				
477.	Visual system: development II . . . . .	Slide			Tue PM		

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
THEME B: CELL BIOLOGY							
30.	Blood-brain barrier I . . . . .	Poster	Sun AM				
308.	Blood-brain barrier II . . . . .	Poster		Mon PM			
777.	Cytoskeleton and membrane composition . . . . .	Poster					Thu AM
778.	Cytoskeleton . . . . .	Poster					Thu AM
133.	Gene structure and function I . . . . .	Poster	Sun PM				
378.	Gene structure and function II . . . . .	Slide			Tue AM		
685.	Gene structure and function: expression . . . . .	Poster				Wed PM	
235.	Gene structure and function: promoter analysis . . . . .	Poster		Mon AM			
673.	Membrane composition . . . . .	Slide				Wed PM	
29.	Neuroglia and myelin I . . . . .	Poster	Sun AM				
234.	Neuroglia and myelin II . . . . .	Poster		Mon AM			
407.	Neuroglia and myelin III . . . . .	Poster			Tue AM		
594.	Neuroglia and myelin IV . . . . .	Poster				Wed AM	
684.	Neuroglia and myelin V . . . . .	Poster				Wed PM	
776.	Neuroglia and myelin VI . . . . .	Poster					Thu AM
132.	Staining, tracing, and imaging techniques I . . . . .	Poster	Sun PM				
233.	Staining, tracing, and imaging techniques II . . . . .	Poster		Mon AM			
493.	Staining, tracing, and imaging techniques III . . . . .	Poster			Tue PM		
683.	Staining, tracing, and imaging techniques IV . . . . .	Poster				Wed PM	
3.	Tyrosine Phosphorylation Pathways in Neuronal Signalling . . . . .	SYMP	Sun AM				
THEME C: EXCITABLE MEMBRANES AND SYNAPTIC TRANSMISSION							
9.	Calcium channel structure, function, and expression I . . . . .	Slide	Sun AM				
495.	Calcium channel structure, function, and expression II . . . . .	Poster			Tue PM		
139.	Calcium channels: physiology, pharmacology, and modulation I . . . . .	Poster	Sun PM				
140.	Calcium channels: physiology, pharmacology, and modulation II . . . . .	Poster	Sun PM				
286.	Calcium channels: physiology, pharmacology, and modulation III . . . . .	Slide		Mon PM			
688.	Calcium channels: physiology, pharmacology, and modulation IV . . . . .	Poster				Wed PM	
689.	Calcium channels: physiology, pharmacology, and modulation V . . . . .	Poster				Wed PM	
690.	Calcium channels: physiology, pharmacology, and modulation VI . . . . .	Poster				Wed PM	
752.	Caught in the Act: Structural Changes Associated with Channel Gating . . . . .	SYMP					Thu AM
781.	Ligand-gated ion channels . . . . .	Poster					Thu AM
138.	Ligand-gated ion channels: glutamate, GABA, and glycine receptors . . . . .	Poster	Sun PM				
137.	Ligand-gated ion channels: nicotinic acetylcholine and P2X receptors . . . . .	Poster	Sun PM				
135.	Long-term potentiation: pharmacology I . . . . .	Poster	Sun PM				
136.	Long-term potentiation: pharmacology II . . . . .	Poster	Sun PM				
210.	Long-term potentiation: physiology I . . . . .	Slide		Mon AM			
389.	Long-term potentiation: physiology II . . . . .	Slide			Tue AM		
580.	Long-term potentiation: physiology III . . . . .	Slide				Wed AM	
596.	Long-term potentiation: physiology IV . . . . .	Poster				Wed AM	
597.	Long-term potentiation: physiology V . . . . .	Poster				Wed AM	
598.	Long-term potentiation: physiology VI . . . . .	Poster				Wed AM	

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
599.	Long-term potentiation: physiology VII	Poster				Wed AM	
600.	Long-term potentiation: physiology VIII	Poster				Wed AM	
601.	Long-term potentiation: physiology IX	Poster				Wed AM	
310.	Mechanisms of neurotransmitter release I	Poster		Mon PM			
311.	Mechanisms of neurotransmitter release II	Poster		Mon PM			
780.	Mechanisms of neurotransmitter release III	Poster					Thu AM
408.	Other ion channels I	Poster			Tue AM		
409.	Other ion channels II	Poster			Tue AM		
313.	Postsynaptic mechanisms: Ach, ATP and peptide signal	Poster		Mon PM			
316.	Postsynaptic mechanisms: Ca <sup>2+</sup> signalling	Poster		Mon PM			
314.	Postsynaptic mechanisms: GABA signals	Poster		Mon PM			
200.	Postsynaptic mechanisms: chemical excitability	Slide		Mon AM			
315.	Postsynaptic mechanisms: dendritic functions	Poster		Mon PM			
387.	Postsynaptic mechanisms: electrical excitability and Ca <sup>2+</sup> signalling	Slide			Tue AM		
317.	Postsynaptic mechanisms: glutamate signals	Poster		Mon PM			
312.	Postsynaptic mechanisms: morphological and molecular correlates	Poster		Mon PM			
687.	Postsynaptic mechanisms: network activity and models	Poster				Wed PM	
691.	Potassium channels: expression	Poster				Wed PM	
473.	Potassium channels: function and expression	Slide			Tue PM		
497.	Potassium channels: modulation I	Poster			Tue PM		
498.	Potassium channels: modulation II	Poster			Tue PM		
142.	Potassium channels: pharmacology	Poster	Sun PM				
141.	Potassium channels: physiology	Poster	Sun PM				
572.	Potassium channels: physiology, pharmacology, and modulation	Slide				Wed AM	
496.	Potassium channels: structure and function	Poster			Tue PM		
31.	Presynaptic mechanisms I	Poster	Sun AM				
206.	Presynaptic mechanisms II	Slide		Mon AM			
686.	Presynaptic mechanisms III	Poster				Wed PM	
779.	Presynaptic mechanisms IV	Poster					Thu AM
494.	Presynaptic mechanisms: calcium and release	Poster			Tue PM		
134.	Presynaptic mechanisms: modulation—plasticity	Poster	Sun PM				
309.	Presynaptic mechanisms: neuromuscular junction	Poster		Mon PM			
595.	Presynaptic mechanisms: release and recycling	Poster				Wed AM	
32.	Sodium channels: expression and cloning	Poster	Sun AM				
33.	Sodium channels: pharmacology	Poster	Sun AM				
34.	Sodium channels: physiology, structure, and function	Poster	Sun AM				
483.	Sodium channels: synaptic transmission and disease	Slide			Tue PM		
<b>THEME D: NEUROTRANSMITTERS, MODULATORS, TRANSPORTERS, AND RECEPTORS</b>							
526.	5-HT <sub>1A</sub> receptors: binding	Poster			Tue PM		
527.	5-HT <sub>1A</sub> receptors: pharmacology	Poster			Tue PM		
528.	5-HT <sub>1B</sub> , 5-HT <sub>1D</sub> , 5-HT <sub>1F</sub> receptors	Poster			Tue PM		
500.	Acetylcholine receptors: muscarinic—structure/function I	Poster			Tue PM		
692.	Acetylcholine receptors: muscarinic—structure/function II	Poster				Wed PM	
110.	Acetylcholine receptors: nicotinic	Slide	Sun PM				
504.	Acetylcholine receptors: nicotinic—binding	Poster			Tue PM		
501.	Acetylcholine receptors: nicotinic—molecular biology and knock-out	Poster			Tue PM		

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
502.	Acetylcholine receptors: nicotinic—pharmacology I . . . . .	Poster			Tue PM		
602.	Acetylcholine receptors: nicotinic—pharmacology II . . . . .	Poster				Wed AM	
503.	Acetylcholine receptors: nicotinic—physiology . . . . .	Poster			Tue PM		
603.	Acetylcholine receptors: nicotinic—recombinant . . . . .	Poster				Wed AM	
411.	Acetylcholine receptors: nicotinic—regulation of gene expression . . . . .	Poster			Tue AM		
410.	Acetylcholine: structure/function I . . . . .	Poster			Tue AM		
499.	Acetylcholine: structure/function II . . . . .	Poster			Tue PM		
617.	Adenosine and ATP as neurotransmitters . . . . .	Poster				Wed AM	
530.	Behavioral pharmacology . . . . .	Poster			Tue PM		
622.	Behavioral pharmacology: drugs of abuse . . . . .	Poster				Wed AM	
623.	Behavioral pharmacology: serotonin . . . . .	Poster				Wed AM	
609.	CRF receptors: structure and function . . . . .	Poster				Wed AM	
202.	Catecholamine receptors . . . . .	Slide		Mon AM			
697.	Catecholamine receptors: anti-psychotic/nervous system disorders . . . . .	Poster				Wed PM	
523.	Catecholamine receptors: knock-outs and behavior . . . . .	Poster			Tue PM		
329.	Catecholamine receptors: localization and structure . . . . .	Poster		Mon PM			
330.	Catecholamine receptors: molecular biology and receptor binding . . . . .	Poster		Mon PM			
696.	Catecholamine receptors: pharmacology . . . . .	Poster				Wed PM	
788.	Catecholamine receptors: regulation of gene expression . . . . .	Poster					Thu AM
522.	Catecholamine receptors: second messenger signal transduction . . . . .	Poster			Tue PM		
614.	Catecholamines: biosynthetic enzymes . . . . .	Poster				Wed AM	
145.	Catecholamines: dopamine I . . . . .	Poster	Sun PM				
331.	Catecholamines: dopamine II . . . . .	Poster		Mon PM			
524.	Catecholamines: dopamine III . . . . .	Poster			Tue PM		
240.	Catecholamines: norepinephrine . . . . .	Poster		Mon AM			
620.	Dopamine transporters . . . . .	Poster				Wed AM	
35.	Excitatory amino acid receptors: physiology, pharmacology, and modulation—NMDA I . . . . .	Poster	Sun AM				
36.	Excitatory amino acid receptors: physiology, pharmacology, and modulation—NMDA II . . . . .	Poster	Sun AM				
693.	Excitatory amino acid receptors: physiology, pharmacology, and modulation—NMDA III . . . . .	Poster				Wed PM	
239.	Excitatory amino acid receptors: physiology, pharmacology, and modulation—mGluR I . . . . .	Poster		Mon AM			
322.	Excitatory amino acid receptors: physiology, pharmacology, and modulation—mGluR II . . . . .	Poster		Mon PM			
606.	Excitatory amino acid receptors: physiology, pharmacology, and modulation I . . . . .	Poster				Wed AM	
607.	Excitatory amino acid receptors: physiology, pharmacology, and modulation II . . . . .	Poster				Wed AM	
608.	Excitatory amino acid receptors: physiology, pharmacology, and modulation III . . . . .	Poster				Wed AM	
671.	Excitatory amino acid receptors: physiology, pharmacology, and modulation IV . . . . .	Slide				Wed PM	
236.	Excitatory amino acid receptors: structure, function, and expression—functional properties . . . . .	Poster		Mon AM			
413.	Excitatory amino acid receptors: structure, function, and expression—metabotropic glutamate receptor . . . . .	Poster			Tue AM		
237.	Excitatory amino acid receptors: structure, function, and expression—receptor assembly . . . . .	Poster		Mon AM			
238.	Excitatory amino acid receptors: structure, function, and expression—regulation of expression . . . . .	Poster		Mon AM			

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
292.	Excitatory amino acid receptors: structure, function, and expression I	Slide		Mon PM			
782.	Excitatory amino acid receptors: structure, function, and expression II	Poster					Thu AM
143.	Excitatory amino acids: anatomy and physiology I	Poster	Sun PM				
144.	Excitatory amino acids: anatomy and physiology II	Poster	Sun PM				
318.	Excitatory amino acids: excitotoxicity I	Poster		Mon PM			
319.	Excitatory amino acids: excitotoxicity II	Poster		Mon PM			
320.	Excitatory amino acids: excitotoxicity III	Poster		Mon PM			
321.	Excitatory amino acids: excitotoxicity IV	Poster		Mon PM			
478.	Excitatory amino acids: excitotoxicity V	Slide			Tue PM		
505.	Excitatory amino acids: excitotoxicity VI	Poster			Tue PM		
506.	Excitatory amino acids: excitotoxicity VII	Poster			Tue PM		
604.	Excitatory amino acids: pharmacology I	Poster				Wed AM	
605.	Excitatory amino acids: pharmacology II	Poster				Wed AM	
412.	Excitatory amino acids: pharmacology—metabotropic receptors	Poster			Tue AM		
507.	Excitatory amino acids: pharmacology—modulation	Poster			Tue PM		
508.	Excitatory amino acids: pharmacology—synaptic receptors	Poster			Tue PM		
514.	GABA: GAD, GAT and GABA studies	Poster			Tue PM		
511.	GABA <sub>A</sub> receptors: anesthetics	Poster			Tue PM		
509.	GABA <sub>A</sub> receptors: benzodiazepines	Poster			Tue PM		
762.	GABA <sub>A</sub> receptors: cellular and molecular studies	Slide					Thu AM
510.	GABA <sub>A</sub> receptors: ethanol	Poster			Tue PM		
327.	GABA <sub>A</sub> receptors: knock-outs and knock-downs	Poster		Mon PM			
325.	GABA <sub>A</sub> receptors: microanatomy	Poster		Mon PM			
323.	GABA <sub>A</sub> receptors: native functions	Poster		Mon PM			
324.	GABA <sub>A</sub> receptors: native modulation studies	Poster		Mon PM			
326.	GABA <sub>A</sub> receptors: recombinant studies and molecular mapping	Poster		Mon PM			
512.	GABA <sub>A</sub> receptors: steroids	Poster			Tue PM		
513.	GABA <sub>B</sub> and GABA <sub>C</sub> receptors	Poster			Tue PM		
618.	Glutamate transporters I	Poster				Wed AM	
619.	Glutamate transporters II	Poster				Wed AM	
470.	<b>Glutamatergic Transmission: A View from the Dendrite</b>	SYMP			Tue PM		
789.	Histamine	Poster					Thu AM
610.	NPY-like receptors	Poster				Wed AM	
38.	Neurotransmitter interactions I	Poster	Sun AM				
39.	Neurotransmitter interactions II	Poster	Sun AM				
40.	Neurotransmitter interactions III	Poster	Sun AM				
616.	Nitric oxide and other modulators	Poster				Wed AM	
701.	Novel 5HT receptors: 5HT <sub>6</sub> , 5HT <sub>7</sub> , and others	Poster				Wed PM	
37.	Opioid receptors I	Poster	Sun AM				
328.	Opioid receptors II	Poster		Mon PM			
380.	Opioid receptors III	Slide			Tue AM		
695.	Opioid receptors IV	Poster				Wed PM	
786.	Opioid receptors V	Poster					Thu AM
787.	Opioid receptors: sigma receptors	Poster					Thu AM
519.	Opioids: anatomy, physiology, and behavior— anatomy	Poster			Tue PM		
521.	Opioids: anatomy, physiology, and behavior— behavior	Poster			Tue PM		

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
520.	Opioids: anatomy, physiology, and behavior— physiology . . . . .	Poster			Tue PM		
615.	Other neurotransmitters . . . . .	Poster				Wed AM	
790.	Other peptide neurotransmitters . . . . .	Poster					Thu AM
661.	Peptide receptor molecular biology . . . . .	Slide				Wed PM	
515.	Peptide receptor structure and function I . . . . .	Poster			Tue PM		
516.	Peptide receptor structure and function II . . . . .	Poster			Tue PM		
517.	Peptide receptor structure and function III . . . . .	Poster			Tue PM		
611.	Peptides: anatomy and physiology I . . . . .	Poster				Wed AM	
612.	Peptides: anatomy and physiology II . . . . .	Poster				Wed AM	
613.	Peptides: anatomy and physiology III . . . . .	Poster				Wed AM	
783.	Peptides: anatomy and physiology IV . . . . .	Poster					Thu AM
784.	Peptides: anatomy and physiology V . . . . .	Poster					Thu AM
785.	Peptides: anatomy and physiology VI . . . . .	Poster					Thu AM
518.	Peptides: biosynthesis, metabolism, and biochemical characterization—opiates . . . . .	Poster			Tue PM		
694.	Peptides: biosynthesis, metabolism, and biochemical characterization I . . . . .	Poster				Wed PM	
754.	Peptides: biosynthesis, metabolism, and biochemical characterization II . . . . .	Slide					Thu AM
41.	Receptor modulation: up- and down-regulation I . . . . .	Poster	Sun AM				
415.	Receptor modulation: up- and down-regulation II . . . . .	Poster			Tue AM		
531.	Receptor modulation: up- and down-regulation III . . . . .	Poster			Tue PM		
246.	Regional localization of receptors and transmitters I . . . . .	Poster		Mon AM			
414.	Regional localization of receptors and transmitters II . . . . .	Poster			Tue AM		
621.	Regional localization of receptors and transmitters III . . . . .	Poster				Wed AM	
107.	Second messengers and phosphorylation I . . . . .	Slide	Sun PM				
152.	Second messengers and phosphorylation II . . . . .	Poster	Sun PM				
153.	Second messengers and phosphorylation III . . . . .	Poster	Sun PM				
247.	Second messengers and phosphorylation IV . . . . .	Poster		Mon AM			
151.	Second messengers: cAMP . . . . .	Poster	Sun PM				
150.	Second messengers: kinases . . . . .	Poster	Sun PM				
385.	Serotonin receptors . . . . .	Slide			Tue AM		
699.	Serotonin receptors: 5HT <sub>2</sub> I . . . . .	Poster				Wed PM	
700.	Serotonin receptors: 5HT <sub>2</sub> II . . . . .	Poster				Wed PM	
698.	Serotonin receptors: 5HT <sub>2</sub> —anatomy and behavior . . . . .	Poster				Wed PM	
525.	Serotonin receptors: electrophysiology . . . . .	Poster			Tue PM		
245.	Serotonin transporters . . . . .	Poster		Mon AM			
334.	Serotonin/catecholamine interactions . . . . .	Poster		Mon PM			
243.	Serotonin: behavior . . . . .	Poster		Mon AM			
242.	Serotonin: general . . . . .	Poster		Mon AM			
571.	Serotonin: pharmacology . . . . .	Slide				Wed AM	
241.	Serotonin: tryptophan hydroxylase . . . . .	Poster		Mon AM			
244.	Serotonin: uptake and release . . . . .	Poster		Mon AM			
154.	Signal transduction I . . . . .	Poster	Sun PM				
155.	Signal transduction II . . . . .	Poster	Sun PM				
372.	<b>The Synaptic Vesicle Neurotransmitter Transporters: Chemical Coding at Central and Peripheral Synapses . . . . .</b>	SYMP			Tue AM Tue PM		
529.	Transmitters in invertebrates . . . . .	Poster					
146.	Transmitters in invertebrates: monoamines . . . . .	Poster	Sun PM				
332.	Transmitters in invertebrates: neuropeptides I . . . . .	Poster		Mon PM			
333.	Transmitters in invertebrates: neuropeptides II . . . . .	Poster		Mon PM			
147.	Transmitters in invertebrates: nitric oxide . . . . .	Poster	Sun PM				
148.	Transporters I . . . . .	Poster	Sun PM				
207.	Transporters II . . . . .	Slide		Mon AM			
295.	Transporters III . . . . .	Slide		Mon PM			

Session Number		Session Title	Type	Sun.	Day and Time				Mon.	Tue.	Wed.	Thu.

THEME E: ENDOCRINE AND AUTONOMIC REGULATION												
338.	Cardiovascular regulation: blood pressure regulation	.....	Poster			Mon PM						
44.	Cardiovascular regulation: brainstem mechanisms	.....	Poster	Sun AM								
157.	Cardiovascular regulation: forebrain mechanisms	.....	Poster	Sun PM								
251.	Cardiovascular regulation: nucleus tractus solitarius	.....	Poster			Mon AM						
416.	Cardiovascular regulation: peripheral autonomic control	.....	Poster				Tue AM					
158.	Cardiovascular regulation: sympathetic preganglionic neurons	.....	Poster	Sun PM								
337.	Cardiovascular regulation: ventral medulla I	.....	Poster			Mon PM						
377.	Cardiovascular regulation: ventral medulla II	.....	Slide				Tue AM					
159.	Gastrointestinal regulation: CNS control	.....	Poster	Sun PM								
417.	Gastrointestinal regulation: peripheral mechanism	.....	Poster				Tue AM					
201.	Hypothalamic-pituitary-adrenal regulation I	.....	Slide			Mon AM						
335.	Hypothalamic-pituitary-adrenal regulation II	.....	Poster			Mon PM						
532.	Hypothalamic-pituitary-adrenal regulation III	.....	Poster				Tue PM					
791.	Hypothalamic-pituitary-adrenal regulation IV	.....	Poster								Thu AM	
42.	Hypothalamic-pituitary-gonadal regulation I	.....	Poster	Sun AM								
379.	Hypothalamic-pituitary-gonadal regulation II	.....	Slide				Tue AM					
533.	Hypothalamic-pituitary-gonadal regulation III	.....	Poster				Tue PM					
624.	Hypothalamic-pituitary-gonadal regulation IV	.....	Poster					Wed AM				
704.	Hypothalamic-pituitary-gonadal regulation V	.....	Poster					Wed PM				
43.	Neural-immune interactions: CNS mechanisms	.....	Poster	Sun AM								
336.	Neural-immune interactions: cytokines I	.....	Poster			Mon PM						
537.	Neural-immune interactions: cytokines II	.....	Poster				Tue PM					
536.	Neural-immune interactions: depression and stress	.....	Poster				Tue PM					
706.	Neural-immune interactions: inflammation	.....	Poster						Wed PM			
578.	Neural-immune interactions: other	.....	Slide						Wed AM			
705.	Neural-immune interactions: pathology	.....	Poster						Wed PM			
626.	Neuroendocrine regulation: estrogen	.....	Poster						Wed AM			
534.	Neuroendocrine regulation: growth hormone and somatostatin	.....	Poster				Tue PM					
625.	Neuroendocrine regulation: other	.....	Poster						Wed AM			
156.	Neuroendocrine regulation: paraventricular hypothalamic nucleus	.....	Poster	Sun PM								
535.	Neuroendocrine regulation: prolactin	.....	Poster				Tue PM					
250.	Neuroendocrine regulation: supraoptic nucleus	.....	Poster			Mon AM						
249.	Osmotic regulation	.....	Poster			Mon AM						
101.	Pain and the Cerebral Cortex	.....	SYMP	Sun PM								
628.	Respiratory regulation: chemoreception and hypoxic responses	.....	Poster							Wed AM		
629.	Respiratory regulation: integrative mechanisms	.....	Poster							Wed AM		
627.	Respiratory regulation: pattern generation and motoneuron	.....	Poster							Wed AM		
248.	Thermal regulation	.....	Poster			Mon AM						
45.	Urogenital regulation: bladder	.....	Poster	Sun AM								
418.	Urogenital regulation: sexual organs	.....	Poster				Tue AM					
THEME F: SENSORY SYSTEMS												
425.	Auditory systems: central anatomy—forebrain	.....	Poster				Tue AM					
57.	Auditory systems: central anatomy—hindbrain	.....	Poster	Sun AM								

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
161.	Auditory systems: central physiology—birds and bats . . . . .	Poster	Sun PM				
256.	Auditory systems: central physiology—brainstem . . . . .	Poster		Mon AM			
424.	Auditory systems: central physiology—forebrain . . . . .	Poster			Tue AM		
716.	Auditory systems: central physiology—hearing loss . . . . .	Poster				Wed PM	
350.	Auditory systems: central physiology—midbrain . . . . .	Poster		Mon PM			
637.	Auditory systems: central physiology—primate cortex . . . . .	Poster				Wed AM	
636.	Auditory, vestibular, and lateral line: development and regeneration . . . . .	Poster				Wed AM	
423.	Auditory, vestibular, and lateral line: hair cell properties . . . . .	Poster			Tue AM		
715.	Auditory, vestibular, and lateral line: integration . . . . .	Poster				Wed PM	
106.	Chemical senses . . . . .	Slide	Sun PM				
718.	Gustatory sensation . . . . .	Poster				Wed PM	
373.	<b>Molecular Biology of Perception</b> . . . . .	SYMP			Tue AM		
257.	Olfactory receptors: cell physiology . . . . .	Poster		Mon AM			
258.	Olfactory receptors: development and specificity . . . . .	Poster		Mon AM			
427.	Olfactory systems: invertebrates . . . . .	Poster			Tue AM		
426.	Olfactory systems: olfactory bulb anatomy . . . . .	Poster			Tue AM		
794.	Olfactory systems: olfactory bulb pharmacology . . . . .	Poster					Thu AM
793.	Olfactory systems: olfactory bulb physiology . . . . .	Poster					Thu AM
717.	Olfactory systems: olfactory responses . . . . .	Poster				Wed PM	
208.	Pain modulation . . . . .	Slide		Mon AM			
55.	Pain modulation: anatomy and physiology—behavior . . . . .	Poster	Sun AM				
53.	Pain modulation: anatomy and physiology—higher centers I . . . . .	Poster	Sun AM				
54.	Pain modulation: anatomy and physiology—higher centers II . . . . .	Poster	Sun AM				
342.	Pain modulation: anatomy and physiology—neuropathic pain . . . . .	Poster		Mon PM			
711.	Pain modulation: anatomy and physiology—receptors and nerves . . . . .	Poster				Wed PM	
343.	Pain modulation: anatomy and physiology—spinal cord I . . . . .	Poster		Mon PM			
344.	Pain modulation: anatomy and physiology—spinal cord II . . . . .	Poster		Mon PM			
539.	Pain modulation: pharmacology—GABA and NMDA receptors . . . . .	Poster			Tue PM		
346.	Pain modulation: pharmacology—amines, purines, cannabinoids . . . . .	Poster		Mon PM			
542.	Pain modulation: pharmacology—amino acids, anesthetics, antidepressants . . . . .	Poster			Tue PM		
712.	Pain modulation: pharmacology—inflammation and hyperalgesia . . . . .	Poster				Wed PM	
345.	Pain modulation: pharmacology—neuropeptides and capsaicin . . . . .	Poster		Mon PM			
540.	Pain modulation: pharmacology—opiates I . . . . .	Poster			Tue PM		
541.	Pain modulation: pharmacology—opiates II . . . . .	Poster			Tue PM		
383.	Pain pathways . . . . .	Slide			Tue AM		
52.	Pain pathways: behavior . . . . .	Poster	Sun AM				
51.	Pain pathways: higher centers . . . . .	Poster	Sun AM				
341.	Pain pathways: spinal cord and brainstem . . . . .	Poster		Mon PM			
199.	Retina and photoreceptors I . . . . .	Slide		Mon AM			
792.	Retina and photoreceptors II . . . . .	Poster					Thu AM
630.	Retinal anatomy . . . . .	Poster				Wed AM	
713.	Retinal intracellular signalling . . . . .	Poster				Wed PM	
56.	Retinal physiology . . . . .	Poster	Sun AM				
347.	Retinal receptors and channels . . . . .	Poster		Mon PM			

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
<b>4. Sensorimotor Integration in Superior Colliculus:</b>							
<b>What Does the Colliculus Control? .....</b>	<b>SYMP</b>		<b>Sun AM</b>				
339. Sensory systems: spinal cord I .....	Poster			Mon PM			
340. Sensory systems: spinal cord II .....	Poster			Mon PM			
707. Somatic and visceral afferents—visceral afferents I .....	Poster					Wed PM	
708. Somatic and visceral afferents—visceral afferents II .....	Poster					Wed PM	
710. Somatic and visceral afferents: mechanoreceptors .....	Poster					Wed PM	
709. Somatic and visceral afferents: nociceptors .....	Poster					Wed PM	
16. Somatosensory cortex and thalamocortical relationships I .....	Slide	Sun AM					
48. Somatosensory cortex and thalamocortical relationships II .....	Poster	Sun AM					
49. Somatosensory cortex and thalamocortical relationships III .....	Poster	Sun AM					
50. Somatosensory cortex and thalamocortical relationships IV .....	Poster	Sun AM					
419. Somatosensory cortex and thalamocortical relationships V .....	Poster				Tue AM		
420. Somatosensory cortex and thalamocortical relationships VI .....	Poster				Tue AM		
538. Somatosensory cortex and thalamocortical relationships VII .....	Poster				Tue PM		
46. Subcortical somatosensory pathways I .....	Poster	Sun AM					
47. Subcortical somatosensory pathways II .....	Poster	Sun AM					
252. Subcortical visual pathways I .....	Poster			Mon AM			
253. Subcortical visual pathways II .....	Poster			Mon AM			
574. Subcortical visual pathways III .....	Slide					Wed AM	
631. Subcortical visual pathways IV .....	Poster					Wed AM	
714. Subcortical visual pathways V .....	Poster					Wed PM	
475. Visual cortex: extrastriate—attention .....	Slide				Tue PM		
288. Visual cortex: extrastriate—dorsal stream I .....	Slide			Mon PM			
635. Visual cortex: extrastriate—dorsal stream II .....	Poster					Wed AM	
666. Visual cortex: extrastriate—dorsal stream III .....	Slide					Wed PM	
160. Visual cortex: extrastriate—functional organization I .....	Poster	Sun PM					
422. Visual cortex: extrastriate—functional organization II .....	Poster				Tue AM		
421. Visual cortex: extrastriate—mapping .....	Poster				Tue AM		
634. Visual cortex: extrastriate—ventral stream .....	Poster					Wed AM	
760. Visual cortex: extrastriate—ventral stream/mapping .....	Slide						Thu AM
117. Visual cortex: striate I .....	Slide	Sun PM					
198. Visual cortex: striate II .....	Slide			Mon AM			
254. Visual cortex: striate III .....	Poster			Mon AM			
255. Visual cortex: striate IV .....	Poster			Mon AM			
376. Visual cortex: striate V .....	Slide				Tue AM		
632. Visual cortex: striate VI .....	Poster					Wed AM	
633. Visual cortex: striate VII .....	Poster					Wed AM	
672. Visual cortex: striate VIII .....	Slide					Wed PM	
111. Visual psychophysics and behavior I .....	Slide	Sun PM					
348. Visual psychophysics and behavior II .....	Poster			Mon PM			
349. Visual psychophysics and behavior III .....	Poster			Mon PM			
<b>THEME G: MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION</b>							
804. Animal locomotion .....	Poster						Thu AM
164. Basal ganglia: anatomy I .....	Poster	Sun PM					
352. Basal ganglia: anatomy II .....	Poster			Mon PM			

**THEMATIC LIST OF SESSIONS**

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
432.	Basal ganglia: dopamine . . . . .	Poster	Sun PM	Mon PM	Tue AM		Thu AM Thu AM
165.	Basal ganglia: function I . . . . .	Poster					
353.	Basal ganglia: function II . . . . .	Poster					
431.	Basal ganglia: function III . . . . .	Poster			Tue AM		
797.	Basal ganglia: function IV . . . . .	Poster	Sun PM Sun PM			Wed PM	
798.	Basal ganglia: models . . . . .	Poster					
162.	Basal ganglia: striatum I . . . . .	Poster					
163.	Basal ganglia: striatum II . . . . .	Poster	Sun PM	Mon AM	Tue PM	Wed AM	Thu AM
<b>659.</b>	<b>The Cellular Bases of Functional Brain Imaging . . . . .</b>	<b>SYMP</b>					
203.	Cerebellum . . . . .	Slide					
640.	Cerebellum: anatomy . . . . .	Poster				Wed AM	
476.	Cerebellum: basal ganglia . . . . .	Slide	Sun PM	Mon PM Mon AM	Tue AM	Wed AM Wed AM	Thu AM
638.	Cerebellum: behavior and pharmacology . . . . .	Poster					
639.	Cerebellum: clinical, development, genetic models . . . . .	Poster					
433.	Cerebellum: physiology, models . . . . .	Poster					
802.	Control of posture and movement: development . . . . .	Poster	Sun PM	Mon AM	Tue AM	Wed AM	Thu AM
170.	Control of posture and movement: hand movement . . . . .	Poster					
643.	Control of posture and movement: kinematics . . . . .	Poster					
354.	Control of posture and movement: motor learning . . . . .	Poster					
264.	Control of posture and movement: motor units . . . . .	Poster	Sun PM	Mon AM	Tue AM	Wed AM	Thu AM
169.	Control of posture and movement: sensory control of reaching . . . . .	Poster					
265.	Control of posture and movement: spinal cord . . . . .	Poster					
13.	Cortex: animal studies . . . . .	Slide					
430.	Cortex: connectivity . . . . .	Poster	Sun AM	Mon AM Mon PM	Tue AM	Wed AM	Thu AM Thu AM
260.	Cortex: human studies I . . . . .	Poster					
351.	Cortex: human studies II . . . . .	Poster					
576.	Cortex: human studies III . . . . .	Slide					
796.	Cortex: premotor . . . . .	Poster	Sun AM	Mon AM	Tue AM	Wed AM	Thu AM Thu AM
795.	Cortex: sensorimotor . . . . .	Poster					
719.	Cortex: transformations . . . . .	Poster					
727.	Effects of injury and disease I . . . . .	Poster					
803.	Effects of injury and disease II . . . . .	Poster	Sun AM	Mon AM	Tue AM	Wed AM	Thu AM
58.	Exercise and therapy . . . . .	Poster					
726.	Human locomotion . . . . .	Poster					
641.	Human posture . . . . .	Poster					
642.	Mechanics and dynamics . . . . .	Poster	Sun AM	Mon AM	Tue AM	Wed AM	Thu AM
59.	Motor systems and sensorimotor integration: circuitry and pattern generation I . . . . .	Poster					
543.	Motor systems and sensorimotor integration: circuitry and pattern generation II . . . . .	Poster					
544.	Motor systems and sensorimotor integration: circuitry and pattern generations III . . . . .	Poster					
569.	Motor systems and sensorimotor integration: circuitry and pattern generation IV . . . . .	Slide	Sun AM	Mon AM	Tue AM	Wed AM	Thu AM
644.	Motor systems and sensorimotor integration: circuitry and pattern generation V . . . . .	Poster					
805.	Motor systems and sensorimotor integration: circuitry and pattern generation VI . . . . .	Poster					
259.	Motor systems and sensorimotor integration: invertebrate sensory and motor systems I . . . . .	Poster					
428.	Motor systems and sensorimotor integration: invertebrate sensory and motor systems II . . . . .	Poster	Sun AM	Mon AM	Tue AM	Wed AM	Thu AM
429.	Motor systems and sensorimotor integration: invertebrate sensory and motor systems III . . . . .	Poster					
436.	Muscle . . . . .	Poster					

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
801.	Oculomotor system: accommodation, vergence, eye blink, and muscle	Poster					Thu AM
800.	Oculomotor system: behavioral studies, coordinate frames, and models	Poster					Thu AM
263.	Oculomotor system: brainstem	Poster		Mon AM			
166.	Oculomotor system: cortex	Poster	Sun PM				
664.	Oculomotor system: human studies	Slide				Wed PM	
382.	Oculomotor system: pursuit, 3-D stimuli, head movements	Slide			Tue AM		
579.	Oculomotor system: saccades	Slide				Wed AM	
167.	Oculomotor system: smooth pursuit	Poster	Sun PM				
262.	Oculomotor system: superior colliculus	Poster		Mon AM			
721.	Oculomotor system: vestibulo-ocular and optokinetic systems	Poster				Wed PM	
670.	Reaching and posture	Slide				Wed PM	
435.	Reflex function: animal studies	Poster			Tue AM		
168.	Reflex function: human studies	Poster	Sun PM				
722.	Spinal cord and brainstem: anatomic organization	Poster				Wed PM	
723.	Spinal cord and brainstem: plasticity and integrative mechanisms	Poster				Wed PM	
725.	Spinal cord and brainstem: properties of motoneurons and interneurons	Poster				Wed PM	
724.	Spinal cord and brainstem: responses to injury	Poster				Wed PM	
799.	Thalamus	Poster					Thu AM
113.	Vestibular system	Slide	Sun PM				
720.	Vestibular system: anatomy and pharmacology	Poster				Wed PM	
434.	Vestibular system: behavioral studies	Poster			Tue AM		
261.	Vestibular system: physiology and behavior	Poster		Mon AM			
<b>THEME H: OTHER SYSTEMS OF THE CNS</b>							
356.	Association cortex and thalamocortical relations	Poster		Mon PM			
7.	Brain metabolism and blood flow I	Slide	Sun AM				
268.	Brain metabolism and blood flow II	Poster		Mon AM			
357.	Brain metabolism and blood flow III	Poster		Mon PM			
437.	Brain metabolism and blood flow IV	Poster			Tue AM		
438.	Brain metabolism and blood flow V	Poster			Tue AM		
267.	Comparative neuroanatomy: higher vertebrates	Poster		Mon AM			
60.	Comparative neuroanatomy: lower vertebrates	Poster	Sun AM				
564.	Gene Transfer: Applications of Viral Vectors for the Study and Treatment of CNS Disorders	SYMP				Wed AM	
171.	Limbic system and hypothalamus I	Poster	Sun PM				
266.	Limbic system and hypothalamus II	Poster		Mon AM			
355.	Limbic system and hypothalamus III	Poster		Mon PM			
806.	Limbic system and hypothalamus IV	Poster					Thu AM
<b>THEME I: NEURAL BASIS OF BEHAVIOR</b>							
77.	Aging behavior	Poster	Sun AM				
459.	Aging: memory	Poster			Tue AM		
740.	Aging: other	Poster				Wed PM	
65.	Biological rhythms and sleep: circadian rhythms I	Poster	Sun AM				
451.	Biological rhythms and sleep: circadian rhythms II	Poster			Tue AM		
551.	Biological rhythms and sleep: circadian rhythms III	Poster			Tue PM		
807.	Biological rhythms and sleep: circadian rhythms IV	Poster					Thu AM
808.	Biological rhythms and sleep: circadian rhythms V	Poster					Thu AM

Session Number	Session Title	Type	Day and Time				
			Sun.	Mon.	Tue.	Wed.	Thu.
272.	Biological rhythms and sleep: circadian rhythms and sleep . . . . .	Poster		Mon AM			
20.	Biological rhythms and sleep: sleep I . . . . .	Slide	Sun AM				
64.	Biological rhythms and sleep: sleep II . . . . .	Poster	Sun AM				
273.	Biological rhythms and sleep: sleep III . . . . .	Poster		Mon AM			
565.	<b>Bird Song: Twenty Years of Progress</b> . . . . .	SYMP				Wed AM	
669.	Cognition: attention I . . . . .	Slide				Wed PM	
729.	Cognition: attention II . . . . .	Poster				Wed PM	
172.	Cognition: disorders . . . . .	Poster	Sun PM				
439.	Cognition: frontal/prefrontal . . . . .	Poster			Tue AM		
10.	Cognition: functional neuroimaging . . . . .	Slide	Sun AM				
291.	Cognition: language I . . . . .	Slide		Mon PM			
440.	Cognition: language II . . . . .	Poster			Tue AM		
384.	Cognition: memory I . . . . .	Slide			Tue AM		
441.	Cognition: memory II . . . . .	Poster			Tue AM		
730.	Cognition: other . . . . .	Poster				Wed PM	
728.	Cognition: sensory . . . . .	Poster				Wed PM	
185.	Drugs of abuse: alcohol, barbiturates, and benzodiazepines I . . . . .	Poster	Sun PM				
755.	Drugs of abuse: alcohol, barbiturates, and benzodiazepines II . . . . .	Slide					Thu AM
815.	Drugs of abuse: amphetamine—neurotoxicity . . . . .	Poster					Thu AM
187.	Drugs of abuse: amphetamines I . . . . .	Poster	Sun PM				
279.	Drugs of abuse: amphetamines II . . . . .	Poster		Mon AM			
457.	Drugs of abuse: amphetamines III . . . . .	Poster			Tue AM		
362.	Drugs of abuse: cocaine I . . . . .	Poster		Mon PM			
363.	Drugs of abuse: cocaine II . . . . .	Poster		Mon PM			
364.	Drugs of abuse: cocaine III . . . . .	Poster		Mon PM			
365.	Drugs of abuse: cocaine IV . . . . .	Poster		Mon PM			
737.	Drugs of abuse: cocaine V . . . . .	Poster				Wed PM	
738.	Drugs of abuse: cocaine VI . . . . .	Poster				Wed PM	
756.	Drugs of abuse: cocaine VII . . . . .	Slide					Thu AM
758.	Drugs of abuse: cocaine VIII . . . . .	Slide					Thu AM
361.	Drugs of abuse: cocaine—DA-5-HT interactions . . . . .	Poster		Mon PM

**SYMPOSIUM. TYROSINE PHOSPHORYLATION PATHWAYS IN NEURONAL SIGNALLING.** J. M. Baraban, Johns Hopkins Univ. School of Medicine (Chairperson); D. Kaplan, Montreal Neurolog. Inst.; J. Schlessinger, New York Univ. School of Medicine; J. Settleman, Mass. Gen. Hosp. Cancer Ctr.; M.E. Greenberg, Harvard Medical School, and Children's Hosp.

Recent studies of tyrosine phosphorylation in the nervous system indicate that intracellular signalling pathways utilizing this uncommon form of protein phosphorylation exert pervasive, powerful influences in both developing and mature neurons. The presentations will highlight advances in understanding the organization and function of these signalling pathways in the nervous system. J. Baraban will present an overview of tyrosine phosphorylation pathways to orient neuroscientists unfamiliar with this area of research. D. Kaplan will discuss how multiple divergent signalling pathways are triggered by neurotrophin receptor activation. J. Schlessinger will report on recent developments in this rapidly advancing field. J. Settleman will present studies linking novel tyrosine phosphorylation pathways to neuronal development *in vivo*. M. Greenberg will review recent studies implicating a network of cytoplasmic tyrosine phosphorylation pathways as key regulators of neuronal survival and death.

4

**SENSORIMOTOR INTEGRATION IN SUPERIOR COLLICULUS: WHAT DOES THE COLLICULUS CONTROL?** R. H. Wurtz, NIH-NEI (Chairperson); D. P. Munoz, Queen's Univ., Kingston; E. L. Keller, Smith-Kettlewell Inst.; D. Guitton, Montreal Neurol. Inst.; D. L. Sparks, Univ. Pennsylvania.

The sensorimotor activity of the superior colliculus (SC) controls movement, but exactly what movement does the descending output of the colliculus control? The speakers will address two issues.

The first issue is whether the colliculus lies in a feedback loop and controls the dynamics of rapid eye movements. Munoz will describe the distribution of neural activity among the different populations of cells within the SC, show evidence for a shift in the spatial distribution of activity during a saccade, and consider a novel hypothesis to describe how the SC controls saccade dynamics. Keller will consider the difficulty in verifying this hypothesis because one needs to know the neural population activity over the entire area of the colliculus at each instant during a saccade, since the neural data exist as recordings from individual cells during many saccades.

The second issue is whether the SC controls gaze (eye and head) rather than just eye movement alone. Guitton will consider evidence from the cat which cannot deviate its eye in the orbit more than about 25 deg and so relies extensively on combined eye-head movements. Evidence from the discharge of SC output cells, microstimulation of the SC map, and activity of neural elements downstream of the SC indicates that the cat sends gaze related signals to brainstem eye and head motor circuits. In the primate, Sparks will show that the SC is involved in the coordination of eye and head movements during large gaze shifts. The most parsimonious explanation is that the SC generates a single functional signal of desired gaze displacement that is transmitted to separate eye and head controllers.

Work of the speakers was supported by the National Eye Institute, Medical Research Council of Canada, and the McKnight Endowment for Neuroscience.

## BRAIN METABOLISM AND BLOOD FLOW I

### 7.1

#### DOSE-DEPENDENT EFFECTS OF FLUOXETINE ON REGIONAL CEREBRAL GLUCOSE METABOLISM (rCMRglc) IN AWAKE RATS.

U. Freo, A. Merico, C. Ori<sup>1</sup>, P. Pietrini<sup>2</sup>, M. Dam G. Pizzolato and L. Battistin Neurology and Anesthesiology<sup>1</sup> Departments, 35100 Padova, ITALY and Psychiatry Department<sup>2</sup>, 56100 Pisa, ITALY.

Fluoxetine has a wide therapeutic spectrum (e.g. antidepressant, antiobsessional, antipanic and anorectic effects) which may not entirely depend on its serotonin (5-HT) reuptake blocking properties. The aim of this study was to assess the effects of graded doses of fluoxetine on rCMRglc, a putative index of neural function. Experiments were performed in male 3-month-old Fischer-344 rats (Charles River Italia, Como, Italy) according to the [<sup>14</sup>C]-2-Deoxy-D-glucose ([<sup>14</sup>C]DG) (Amersham International, Arlington Heights, IL, U.S.A.) autoradiographic technique. rCMRglc was determined in 56 brain regions 30 min after i.p. injection of saline or of 0.4, 4 or 40 mg/kg fluoxetine hydrochloride. rCMRglc values of each brain region were analyzed for statistical significance by Bonferroni multiple comparison test by comparing the mean of fluoxetine-treated groups to the saline-treated group. At a 0.4 mg/kg dose fluoxetine significantly ( $P < 0.05$ ) reduced rCMRglc in the hypothalamus and caudate nucleus only (3 brain regions, 5%); at 4 mg/kg dose fluoxetine reduced rCMRglc in the hypothalamus, caudate nucleus, prefrontal and frontal cortices, locus coeruleus and dorsal raphe (6 regions, 11%). At 40 mg/kg dose, fluoxetine produced widespread rCMRglc reductions (25 brain regions, 45%). Regional rCMRglc effects of fluoxetine may be related to fluoxetine anorectic (e.g. hypothalamus), antiobsessional (e.g. caudate) and antidepressant (e.g. frontal cortex) actions. The findings further suggest that fluoxetine exerts its pharmacological actions by modulating both 5-HT and adrenergic efferent outputs from the raphe and coeruleus nuclei to basal ganglia and cortical areas.

### 7.3

**7-NITROINDAZOLE ATTENUATES CORTICAL HYPEREMIA DURING RABBIT CORTICAL SPREADING DEPRESSION (CSD).** D.M. Colonna\*, D.D. Deal and D.W. Busija. Depts. of Anesthesia\* and Physiology & Pharmacology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157-1009.

CSD is a wave-like, temporary depolarization of excitable brain cells. Associated with the depolarization is a dilation of pial arterioles and an increase in cerebral blood flow (CBF). NO's role in promoting hyperemia during CSD remains controversial. Recent reports implicate constitutive brain NO synthase (bNOS) in promoting hypercapnic cerebrovasodilation<sup>(1)</sup>. We hypothesized that bNOS activity promotes CSD induced cortical hyperemia. New Zealand White rabbits were anesthetized with thiopental and urethane. They were instrumented for CBF determinations via colored microspheres. CSD was initiated by KCl microinjection. CBF (ml·100g<sup>-1</sup>·min<sup>-1</sup>) was measured at 4 timepoints: baseline (BL), during the first CSD (CSD1), 45min after 15mg/kg, 7-nitroindazole, i.p. (7-NI, a selective inhibitor of constitutive bNOS), (in corn oil), and after a second CSD (CSD2). 7-NI did not affect resting mean arterial blood pressure (MABP) or CBF, demonstrating its lack of endothelial NO (eNOS) inhibition, nor reduced resting CBF. \*7-NI

reduced CSD hyperemia (CSD1 vs CSD2, RM-ANOVA,  $p < 0.05$ ). 7-NI did not reduce resting cortical CBF (BL vs 7-NI), though at higher doses and in other species 7-NI decreased CBF up to 20-60%. The fact that CSD induced cerebral hyperemia was so robust after 7-NI suggests many possibilities: that bNOS was inadequately inhibited at this dose of 7-NI, that eNOS plays a significant role in this response, or that other substances (e.g., CGRP) promote cortical hyperemia during CSD. Reference: 1.) J. Cereb. Blood Flow Metab. 15:774, 1995

### 7.2

**PHARMACOKINETIC AND PHARMACODYNAMIC EFFECTS OF PHYSOSTIGMINE: IMPLICATIONS FOR BRAIN IMAGING STUDIES.** M.L. Furey\*, P. Pietrini, G.E. Alexander, M.J. Mentis, A. Dani, U. Shetty, S.I. Rapoport, M.B. Schapiro and U. Freo. Lab. Neurosci., National Institute on Aging (NIA), NIH, Bethesda MD 20892, USA

To identify the time during infusion at which the pharmacokinetic and pharmacodynamic effects of physostigmine (physo) become stable, we measured plasma drug levels, performance indices on a working memory (WM) task and regional cerebral blood flow (rCBF) using positron emission tomography and H<sub>2</sub><sup>15</sup>O during infusion to healthy subjects of saline (6F/3M; mean age=40yr) or physostigmine (3 F/9M; 45yr). Eight scans alternated between rest and a WM delayed (6 sec) match-to-sample face recognition task. After 2 control scans, the drug group received a 10 min loading dose of physo (1.93 mg/hr), followed by a maintenance drip (0.816 mg/hr) to study completion. After stereotaxic normalization of images, absolute rCBF was divided by the subject's global CBF and scaled to the group's mean baseline global CBF. Physo plasma levels increased slightly over time ( $p < 0.05$ ), and became stable by 30 min. Physo decreased reaction time (RT) ( $p < 0.05$ ), and this effect became generally stable by 20-40 min of infusion. During physo, CBF increased slightly in right inferior temporal cortex at rest, while CBF in right prefrontal cortex progressively decreased during task ( $p < 0.01$ ). These effects reached a plateau by 30-40 min. CBF and RT effects did not correlate with plasma drug levels, indicating that plasma levels do not reflect the central nervous system pharmacodynamic response. These results also show that pharmacokinetic and pharmacodynamic physo effects vary early during infusion, so that functional studies using physo require a 30-40 minute infusion period to obtain stable effects prior to initiating the study. Thus, in studying brain functions, identification of the time point at which the effects of infused drugs become stable is essential to separate the effects of experimental variables from the concomitant changes in drug effects over time. (Supported by NIA).

### 7.4

#### ANOXIC STRESS REDUCES OXYTOCIN-INDUCED PIAL ARTERIOLAR DILATION IN PIGLETS

R. Errico\*, F. Bari<sup>1,2</sup>, T. Louis<sup>3</sup>, and D. Busija<sup>1</sup>. Bowman Gray Sch. of Med., Winston-Salem, NC 27157, <sup>2</sup> Albert Szent-Györgyi Med. Univ., H-6720 Szeged, Hungary, and <sup>3</sup> East Carolina Univ. Sch. of Med., Greenville, NC 27858.

Current evidence indicates that oxytocin (OT) plays a role in regulating cerebral vascular tone in newborns. We compared the effects of hypoxia, global cerebral ischemia and asphyxia on pial arteriolar response to OT in anesthetized, newborn piglets. Pial arteriolar responses to 10<sup>-8</sup> and 10<sup>-6</sup> M of OT were evaluated before and 1 hr following either 10 min of hypoxia, 10 min of global cerebral ischemia or 5 min of asphyxia. Hypoxia was produced by inhalation of 7.5% O<sub>2</sub> - 92.5% N<sub>2</sub>. Global cerebral ischemia was achieved by increasing intracranial pressure and confirmed visually by cessation of cortical blood flow. Asphyxia was achieved by turning off the ventilator. In control conditions, OT dilated pial arterioles by 9±1% at 10<sup>-8</sup> M and by 16±1% at 10<sup>-6</sup> M ( $n=36$ ,  $P < 0.05$ ). For the time control animals, arteriolar dilation to OT did not change with repeated applications (9±1%, 15±1% vs. 10±1% and 13±2%,  $n=10$ ). One hour after hypoxia, dilatory effect of OT was diminished at either dose (2±2%, at 10<sup>-8</sup> and -3±2% at 10<sup>-6</sup>,  $n=8$ ). One hour after asphyxia, OT had no effect at 10<sup>-8</sup> M and conversely had a mild vasoconstrictor effect at 10<sup>-6</sup> M (-4±3%,  $n=9$ ). After ischemia, OT did not dilate arterioles at 10<sup>-8</sup> M and had vasoconstrictor activity at the 10<sup>-6</sup> M concentration (-6±4%,  $n=6$ ). Topical superoxide dismutase applied before during and after asphyxia failed to preserve vasodilation to OT ( $n=5$ ). We conclude that the absence of pial arteriolar dilation to OT after ischemia may be involved in the pathomechanism of perinatal brain injury. Supported by NIH grants: HL-30260, HL-46558 and HL-50587.

## 7.5

**FACTORS MODULATING N-METHYL-D-ASPARTATE (NMDA)-INDUCED DILATATION OF PIAL ARTERIOLES IN PIGLETS.**

F. Bari<sup>1,2</sup>, R. Errico<sup>1</sup>, T. Louis<sup>3</sup>, and D. W. Busija<sup>1</sup>. <sup>1</sup>Bowman Gray Sch. of Med., Winston-Salem, NC 27157, <sup>2</sup>Albert Szent-Györgyi Med. Univ., H-6720 Szeged, Hungary, and <sup>3</sup>East Carolina Univ. Sch. of Med., Greenville, NC 27858.

Anoxic/hypoxic stress transiently reduces NMDA-induced cerebral arteriolar dilation, but mechanisms are unclear. The purpose of this study was to examine the roles of oxygen radicals and extracellular adenosine as mediators of reduced vasodilation to NMDA. In anesthetized newborn piglets, we examined pial arteriolar responses using intravital microscopy. Topically applied NMDA resulted in dose-dependent dilatation of pial arterioles (9±1% and 28±5% above baseline to 10<sup>-5</sup> and 10<sup>-4</sup> M, respectively). Thirty minutes after 15 min hypoxia (inhalation of 7.5% O<sub>2</sub>-92.5% N<sub>2</sub>), arteriolar responses to NMDA were reduced to 3±3% at 10<sup>-5</sup> M and to 12±5% at 10<sup>-4</sup> M (P<0.05, n=6). In a separate group (n=6), topical application of superoxide dismutase (100 U/ml) 30 min before, during and after hypoxia preserved the arteriolar responses to NMDA. In other animals (n=6), we found that coadministration of a non-vasoactive level of adenosine (10<sup>-6</sup> M) with NMDA (10<sup>-4</sup> M) reduced pial arteriolar dilatation (31±6% to 20±4% with adenosine, P<0.05). We conclude that reduced responsiveness of cerebral blood vessels to NMDA caused by hypoxia appears to be due to oxygen radicals and elevation of extracellular adenosine concentration. Supported by NIH grants: HL 30260, HL 46558 and HL 50587.

## 7.7

**Ca<sup>++</sup>-SENSITIVE K<sup>+</sup> CHANNELS (K<sub>Ca</sub>) AND THE PERMISSIVE FUNCTION OF NITRIC OXIDE (NO) AND CYCLIC GMP IN HYPERCAPNIA-INDUCED PIAL ARTERIOLAR DILATION.** Q. Wang\* and D.A. Pelligrino. Dept. of Anesthesiology, Univ. of Illinois-Chicago, IL 60612.

Classically, NO-mediated cerebrovasodilation (CVD) is elicited by increased NO synthesis. That NO, in turn, diffuses to the vascular smooth muscle (vsm) cell, increasing cyclic GMP (cGMP) production. Recent findings have suggested that, in hypercapnia (HC) and other vasodilating conditions, NO synthase (NOS) inhibitors may act to suppress CVD by reducing basal NO and, subsequently, vsm cGMP levels below a critical threshold. Thus, cGMP functions in a "permissive" manner in promoting CVD. We sought to examine whether the permissive function of cGMP in the CVD elicited by HC relates to the capacity for cGMP to support activity of the hyperpolarizing K<sub>Ca</sub> channels in vsm. A closed cranial window technique was used to monitor pial arteriolar diameter changes in fentanyl/N<sub>2</sub>O-anesthetized, male S-D rats. Topical suffusions of the K<sub>ATP</sub> channel opener, levcromakalim (CR, 50 μM) and the K<sub>Ca</sub> channel opener, NS-1619 (NS, 50 μM), were sequentially applied, followed by exposure to HC (PaCO<sub>2</sub> = 60-65 mmHg). The neuronal NOS (nNOS) inhibitor, 7-nitroindazole (7-NI), was then injected ip (40 mg/kg). 30 min later, the following sequences were used: HC → HC + 8-bromo-cGMP (8-Br, 30 μM) → HC + 8-Br + iberiotoxin (IBX, 0.1 μM, the K<sub>Ca</sub> channel blocker) → IBX + NS + 8-Br → IBX + CR + 8-Br. Pial arteriolar CO<sub>2</sub> reactivity was attenuated by 7-NI, restored by 8-Br, and, upon addition of IBX, the restoration was reversed. The specificity of IBX was confirmed by its ability to reduce NS- but not CR-induced dilations. These results, not only confirmed that the NO-dependent portion of the cerebral arteriolar response to HC derives from nNOS, but also suggested that the NO acts in a permissive manner, via maintaining vascular smooth muscle cGMP levels. That apparent obligatory action of cGMP may be due to its capacity to support vsm K<sub>Ca</sub> channels, and implies that NOS inhibitors may reduce cerebrovascular responses to HC by affecting vsm membrane polarization.

## 7.9

**PRESERVED METABOLIC ACTIVATION TO SOMATOSENSORY STIMULATION DESPITE ABOLISHED BLOOD FLOW RESPONSE FOLLOWING NEURONAL NOS INHIBITION.** N. Cholet, J. Seylaz, G. Bonventito\*. Laboratoire de Recherches Cérébrovasculaires, CNRS UA 641, Université Paris 7, IFR 6, 75010 PARIS, France.

The mediators of the local cerebral blood flow (CBF) increases that occur during functional brain activation are not clearly defined. We have previously demonstrated that inhibition of neuronal NO synthase (nNOS) by 7-Nitroindazole (7-NI), abolished the vasodilatory response to whisker stimulation in the somatosensory cortex and ventral posteromedial nucleus of thalamus (VPM) but did not modify the vasodilation in the first order relay stations of the trigeminal pathway. In the present study, we sought to determine whether this differential cerebrovascular influence of nNOS could be ascribed to a specific action on cerebral metabolism. Rats were anesthetized (α-chloralose 40 mg/kg, sc) and ventilated without curarizing agent. Local cerebral glucose utilization (CGU) was measured using the quantitative [<sup>14</sup>C]-2-deoxyglucose autoradiographic method in control rats (n=8) and 25 min following 25 mg/kg ip 7-NI injection (n=9). CGU was determined bilaterally in six regions of the trigeminal pathway during mechanical stimulation (4 Hz) of the right C whiskers. In control rats, whiskers stimulation increased significantly CGU from 37-79% in the ipsilateral trigeminal nuclei and from 38-71% in the contralateral VPM and somatosensory cortex. Under 7-NI, CGU increases were not significantly different from control, ranging from 47-75 % and from 28-74% in the first and second order relay stations, respectively. These results show that nNOS does not affect the metabolic response to somatosensory stimulation and suggest that neurally-derived NO is an important mediator of the associated vasodilatory response.

## 7.6

**EFFECTS OF NMDA RECEPTOR ACTIVATION ON COLLATERAL CEREBRAL BLOOD FLOW.**

S.C. Robertson\*, C.A. Mazzocchi, C.M. Loftus. Div. of Neurosurgery, Univ. of Iowa College of Medicine, Iowa City, IA 52242

Recent evidence suggests that interruptions in the glutamate receptor excitotoxic pathway may confer neuronal protection in part by local alterations of rCBF by neuronal as well as endothelial forms of NO synthase. To our knowledge there is no work linking collateral cerebral flow to neuronal glutamate receptor agonism and antagonism. We studied the effects of NMDA on rCBF and specifically collateral blood flow following middle cerebral artery occlusion.

In seven dogs under 1% halothane anesthesia, a left sided craniectomy was performed. A branch of the MCA was cannulated and collateral-dependent tissue was identified by using the "shadow flow" technique. Regional cerebral blood flow (rCBF) was measured using radiolabeled microspheres. Cerebral vessel pressures in branches of the middle cerebral artery (MCA) were measured using a glass micropipette and servo-null system. After baseline and shadow flows and pressures were obtained, NMDA(300μM) in ACSF was perfused over the exposed brain and repeat flow and pressure measurements were obtained. After 30 min. the NMDA perfusion was stopped and recovery flow measurements was obtained at 30 and 60 min.

NMDA increased collateral and normal cerebral blood flow by 33.1% and 23.0% respectively, while causing a decrease in both small and large cerebral vascular resistance. Systemic and cerebral vascular pressures remained unchanged.

NMDA receptor activation, presumably through activation of endothelial and neuronal NO synthase, causes cerebral vasodilation and increased cerebral blood flow. This response is thought to increase blood flow to ischemic regions of the brain in an effort to minimize infarct. Proposed neuroprotective agents should be designed to maintain cerebral blood, while attenuating glutamate neurotoxicity.

**NITRIC OXIDE SYNTHASE ACTIVITY IN BRAIN AND ENDOTHELIUM: RELATION TO HYPERCAPNIC RISE OF CEREBRAL BLOOD FLOW IN RATS.** M. Lauritzen, M. Fabricius\*, I. Rubin, M. Bundgaard. Inst. of Medical Physiology & Biochemistry, University of Copenhagen, Dept. of Clinical Neurophysiology Rigshospitalet & Glostrup Hospital, DK-2200 Copenhagen, Denmark.

We examined whether attenuation of the hypercapnic increase of cerebral blood flow (CBF) associated with nitric oxide synthase (NOS) inhibition was related to local neuronal or aortic endothelial NOS activity, or local endothelial/neuronal NOS-dependent vasodilation. Halothane anaesthetized rats were ventilated, and CBF was measured by laser-Doppler flowmetry over the parietal and cerebellar cortex. I.v. N<sup>G</sup>-nitro-L-arginine (L-NNA) (30 mg/kg) inhibited brain and aortic NOS activity by 67-70%. Topical L-NNA (1mM) inhibited brain NOS activity by 91-94%, while aortic NOS activity remained constant. In contrast i.v. L-NNA attenuated the hypercapnic CBF rise much more efficiently than topical L-NNA. 7-nitroindazole, another NOS inhibitor, attenuated endothelial and neuronal NOS activity equally well, and inhibited the hypercapnic CBF increase as effectively as L-NNA. Topical L-NNA and 7-nitroindazole abolished local eNOS dependent vasodilation after 15 min, while hypercapnic CBF was only slightly reduced. L-NNA injected into the tissue abolished nNOS dependent vasodilation while hypercapnic CBF was unchanged. The findings suggest that local NOS activity, whether neuronal or endothelial, is unimportant for the hypercapnic rise of CBF.

**fMRI REVEALS GLUCOSE MODULATION OF HUMAN BRAIN RESPONSES TO VISUAL STIMULI** R.B. Barlow\*, E.A. Boudreau, D.C. Moore, S.C. Huckins, A.M. Lindstrom, and D.H.P. Streeten. SUNY Health Science Center and Syracuse University, Syracuse, NY 13210

Glucose, a major energy source for brain function, can modulate human visual sensitivity (Barlow et al, *Invest. Ophthalm. Vis. Sci.* 34 (4): 785, 1993.). We used fMRI to determine whether changes in blood glucose can also modulate cortical activity in response to visual stimuli (GE Signa, 1.5 Tesla, Advanced NMR Inc., gradient echo-echo planar sequence, TE 60ms, TR 3.5s). Subjects who had fasted overnight to induce mild hypoglycemia entered the imager and were instructed to view the center of a grid of alternating (5Hz) vertical and horizontal bars shown in 15sec on/off cycles during multislice scanning of the occipital pole. Remaining in the imager, the subjects ingested a 75gm glucose drink, waited 20-30min and were rescanned. We monitored blood glucose levels with a *One Touch* home kit and a standard laboratory assay throughout the experiment.

fMRI reveals increased activation at the posterior occipital pole and in some cases along the calcarine fissure after blood glucose levels increased an average of 61±13mg/dl (74±7 to 135±14mg/dl, n=6). This is equivalent to eating a substantial breakfast. We conclude that physiological changes in blood glucose levels can modulate cortical activity in response to visual stimuli. Whether blood glucose changes act pre- and/or post-synaptically in the cortex is not yet known.

## 7.11

**DECREASED FRONTAL LOBE GLUCOSE METABOLISM IN FEMALE COMPARED TO MALE ALCOHOLICS: A PET STUDY**  
 D. Hommer\*, W. Williams, R. Momenan, P. Ragan, U. Ruttimann, D. Rio, M. Eckardt. National Institute on Alcohol Abuse and Alcoholism, DICBR, Laboratory of Clinical Studies, Bethesda, MD 20892-1256

Previously we reported that female alcoholics have a significantly smaller corpus callosum than either male alcoholics or age matched female controls (Arch. Neurol. 53:354, 1996). We now report that alcoholic women have significantly lower cerebral metabolic rate for glucose (CMRglc) in the frontal lobes than alcoholic men. The reduction in frontal lobe CMRglc occurs despite a significantly higher overall brain glucose uptake among alcoholic women compared with alcoholic men. Data were collected from 8 alcoholic women and 31 alcoholic men using  $^{18}\text{F}$ -2-fluoro-2-deoxyglucose (FDG) positron emission tomography (PET). PET data were co-registered with MRI scans and tested for pixelwise group differences by a Gaussian random fields method. Analysis was performed using both absolute pixel CMRglc values as well as using mean-adjusted pixel values obtained by subtracting the overall mean brain CMRglc from each pixel CMRglc. Both mean-adjusted and absolute CMRglc produced similar results. In a smaller sample of normal subjects (10 males & 5 females) no significant differences in frontal lobe glucose utilization were seen.

**ACIDOSIS ALONE AND ACIDIC OXYGEN-SUBSTRATE DEPRIVATION INJURY OF PRIMARY ASTROCYTE CULTURES INVOLVE THE SODIUM/BICARBONATE COTRANSPORTER.** M.C. Papadopoulos, L.L. Haak, L. Hill, A.N. van den Pol, and R.G. Giffard. Depts. of Anesthesia and Biology, Stanford University, Stanford, CA 94305; Section of Neurosurgery, Yale University, Stamford, CT 06520.

Several studies show that animals subjected to cerebral ischemia with elevated blood sugars suffer more severe injury than control animals subjected to the same insult with normal blood sugars. This correlates with more severe lactic acidosis and glial cell death. We have previously shown that cortical astrocytes are more vulnerable to acidosis injury than are neurons in primary culture. We sought the mechanism of glial acid injury by exposing primary cultures of mouse astrocytes to acidosis under different ionic conditions. Cultures exposed to balanced salt solutions (BSS) at pH 7.4 were uninjured after 24 h; cultures kept at pH 6.8 in normal BSS containing sodium and bicarbonate suffered 70-95% death. When choline was used to replace the sodium or chloride replaced bicarbonate, injury at pH 6.8 was reduced more than 80%. We then asked whether ion substitution could prevent astrocyte injury by oxygen-substrate deprivation at pH 6.8. We found that removing sodium or bicarbonate was again able to reduce injury to near background levels. Intracellular calcium measured with fura-2, increased 350nM over baseline at pH 6.8 in conditions which led to injury, and was stable when sodium or bicarbonate was absent. This is the first data which implicates the sodium/bicarbonate cotransporter in glial cell injury.

**Nitric Oxide Dynamics as Monitored by Citrulline Immunoreactivity in Cerebral Ischemia**

M. J. L. Eliasson<sup>1</sup>, Z. Huang<sup>2</sup>, M. J. Schell<sup>3</sup>, M. A. Moskowitz<sup>2</sup>, and S. H. Snyder<sup>1,3\*</sup>. Dept. of Neuroscience<sup>3</sup>, and Pharmacology and Molecular Sciences<sup>1</sup>, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205. Stroke Research Laboratory<sup>2</sup>, Mass General Hospital, and Neurosurgical Service, Harvard Med. Sch., Charlestown, MA 02129.

Nitric oxide (NO) or its reactant products have been implicated as major mediators of tissue injury following focal cerebral ischemia. To localize the proposed synthesis of NO following MCA occlusion, we utilized the observation that endogenous citrulline in the brain appears to be formed solely by the enzyme nitric oxide synthase (NOS). Using an antibody highly specific for citrulline conjugated to glutaraldehyde we studied mice with unilateral occlusion of the middle cerebral artery (MCA) for 30, 60, 120, and 180 minutes, respectively.

We have observed a dramatic increase in citrulline immunoreactivity (IR) unilateral to the occlusion which is augmented with longer occlusion times. The IR is localized to neurons and the endothelium in the territory of the occluded vessel. Our findings support the notion of NO overproduction in cerebral ischemia and provide a tool to investigate the effect of stroke-protective agents on NOS.

## 8.2

**LACTATE, NOT GLUCOSE, IS THE ENERGY SUBSTRATE THAT FUELS RECOVERY OF NEURONAL FUNCTION AFTER HYPOXIA IN VITRO.**

A. Schurr\*, R.S. Payne, J.J. Miller\* and B.M. Rigor. Depts. of Anesthesiology and Pathology\*, University of Louisville, School of Medicine, Louisville, KY 40292.

Elevated glucose levels *in vitro* significantly increased the degree of recovery of neuronal function from hypoxia in hippocampal slices (*Brain Res.*, 421:135, 1987). This function can be supported by aerobic metabolism of lactate alone (*Science*, 240:1326, 1988). When given equicaloric amounts of either lactate or glucose, slices supplied with the former showed a higher degree of recovery of neuronal function from hypoxia than with the latter (*Soc. Neurosci. Abstr.*, 21:213, 1995). During ischemia/hypoxia the brain produces high levels of lactate. Thus, we studied here the role of endogenously-formed lactate in recovery of neuronal function after hypoxia.

Rat hippocampal slices were prepared and maintained as described elsewhere (*Brain Res.*, 614:10, 1993). Slices were perfused with standard artificial cerebrospinal fluid (10 mM glucose) under an atmosphere of 95% O<sub>2</sub>/5% CO<sub>2</sub>. A CA1 population spike, evoked by stimulation of the Schaffer collaterals, was used as a measurement of neuronal function. Hypoxia was produced by replacing O<sub>2</sub> with N<sub>2</sub> in the gas atmosphere. Tissue glucose and lactate levels were determined using standard assays.

When supplied with 20 mM instead of 10 mM glucose to increase anaerobic lactate production, all slices recovered their neuronal function upon reoxygenation from 23-min hypoxia. Of slices that were perfused with 20 mM 2-deoxyglucose (2DG) instead of glucose to inhibit glycolysis during the first 13 min of hypoxia, none recovered their neuronal function, although glucose was abundant (20 mM) during the last 10 min of hypoxia and during reoxygenation. In contrast, of slices that produced lactate for the first 10 min of hypoxia before the addition of 2DG for the last 13 min of hypoxia, 80% recovered their neuronal function upon reoxygenation. A similar degree of recovery was observed when glucose was absent during reoxygenation, however, it was short-lived due to the fast diminishing intracellular lactate pools.

We concluded that, upon reoxygenation after a long hypoxic insult, anaerobically accumulated lactate is an obligatory aerobic energy substrate that fuels the recovery of neuronal function.

This research was funded by the Department of Anesthesiology, University of Louisville.

## 8.4

**ANOXIA-TOLERANT CA1 NEURONS FROM RAT HIPPOCAMPUS: ANOXIA-EVOKED CALCIUM CHANGES AND NMDA RECEPTOR INACTIVATION.**  
 Philip Bickler\*, Anesthesia Dept. UCSF, San Francisco, CA 94143

Neurons from neonatal mammals survive hypoxia that kills mature neurons. I found that 5 min. anoxia/6 hr. recovery killed only 20% of CA1 neurons in post-natal day (PND) 3-7 hippocampal slices, compared to 66% in PND 18-22 slices (calcein-AM/ethidium stains). I tested the hypothesis that survival of hypoxia is associated with limited glutamate release, small intracellular calcium changes, and inactivation of NMDA receptor (NMDAR) function. Glutamate release was measured with the glutamate dehydrogenase assay, and anoxia and NMDAR-mediated calcium changes in CA1 were made with fura-2.

Hypoxia (PO<sub>2</sub> = 5 mm Hg, 10 min) increased calcium in PND 18-22 slice CA1 by 5 times basal; in PND 3-7 CA1 the changes were only twice basal (p<0.001). Despite the large difference in calcium changes, anoxia-evoked glutamate release only doubled between PND 3 and PND 22 (n=40, p<0.01), and 100 μM NMDA-evoked calcium changes decreased by 50% (n=60, p<0.01). This suggests NMDARs are hypoxia-inactivated in neonates to avoid large calcium changes. To test this, NMDAR-mediated calcium changes were measured after 5 min hypoxia (PO<sub>2</sub> 10 mmHg, no ATP loss). In PND <12 slices, hypoxia decreased NMDAR activity in CA1 by 52% (p<0.05), and in PND >16 slices by only 23% (NS). NMDAR blockade worsened hypoxia survival in PND 3-7 slices (57 vs. 80% cell survival), but enhanced it in 18-22 slices. I suggest NMDAR inactivation allows a limited and protective increase in cytosolic calcium in CA1 in neonates. In older slices, the greater calcium changes are lethal.

## 8.5

X-RAY MICROANALYSIS OF ANOXIC  $\text{Ca}^{2+}$  ENTRY MECHANISMS IN CNS AXONS. R.M.LoPachin<sup>1</sup> and P.K.Stys<sup>2</sup>. <sup>1</sup>Montefiore Medical Center, 111E. 210th St., Bronx, NY 10467. <sup>2</sup>Loeb Institute, University of Ottawa, Ottawa, Canada, K1Y 4E9.

Stys et al. (1992) have proposed that, in anoxic axons, reverse operation of  $\text{Na}^+$ - $\text{Ca}^{2+}$  exchanger mediates  $\text{Ca}^{2+}$  entry triggered by a presumed rise in  $\text{Na}^+$ . Here we used x-ray microanalysis and procedures that modify transaxolemmal  $\text{Na}^+$  and  $\text{Ca}^{2+}$  movements to specifically examine ionic influx routes and elemental changes in anoxic axons. Perfusion of rat optic nerve with zero- $\text{Na}^+$ /Li<sup>+</sup>-substituted medium or  $\text{Na}^+$  channel blockade by TTX (1  $\mu\text{M}$ ) prevented axonal increases in  $\text{Na}^+$  and  $\text{Ca}^{2+}$  normally associated with anoxia. Incubation with zero- $\text{Ca}^{2+}$ /EGTA perfusate impeded mitochondrial and axoplasmic  $\text{Ca}^{2+}$  accumulation during anoxia but did not affect  $\text{Na}^+$  increase or  $\text{K}^+$  loss. Inhibition of  $\text{Na}^+$ - $\text{Ca}^{2+}$  exchange with bepridil (30  $\mu\text{M}$ ) did not alter anoxia-induced changes in  $\text{Na}^+$  or  $\text{K}^+$  concentrations but did prevent increases in axonal  $\text{Ca}^{2+}$ . Neither nifedipine (5  $\mu\text{M}$ ) nor nimodipine (5  $\mu\text{M}$ ) influenced the effects of anoxia on intraaxonal  $\text{Na}^+$ ,  $\text{K}^+$  or  $\text{Ca}^{2+}$ . These findings suggest that during anoxia,  $\text{Na}^+$  enters axons primarily via voltage-gated  $\text{Na}^+$  channels and that subsequent increases in axoplasmic  $\text{Na}^+$  are functionally coupled to  $\text{Ca}^{2+}$  import. Intracellular  $\text{Na}^+$ -dependent,  $\text{Ca}^{2+}$  entry is consistent with reverse operation of the axolemmal  $\text{Na}^+$ - $\text{Ca}^{2+}$  exchanger. Additional studies with modified perfusates and conducted after 60 mins of reoxygenation indicated that ionic deregulation during anoxia is premonitory for severe ionic disruption associated with reoxygenation. We suggest that reverse  $\text{Na}^+$ - $\text{Ca}^{2+}$  exchange is a general route of  $\text{Ca}^{2+}$  entry during axon injury. Supported by grants NIEHS RO1-ES03038 and MRC MT-11595.

## 8.7

INHIBITION OF  $\text{Na,K-ATPase}$  INDUCES CELL DEATH IN SINGLE, ISOLATED MAMMALIAN CENTRAL NEURONS. Y.V.Senatorov\*, P.K.Stys and B.Hu, Loeb Medical Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada K1Y 4E9.

Inhibition of  $\text{Na}^+$ ,  $\text{K}^+$ -ATPase induces neuronal death, which may involve both direct cytotoxic effect due to  $\text{Na}^+$ / $\text{Ca}^{2+}$  accumulation and indirect excitotoxicity as a result of abnormal release/uptake of glutamate. Using imaging techniques, we assessed the direct cytotoxic mechanism of pump inhibition by isolating central neurons from their afferent nerve terminals and glial contact and exposing them to ouabain, a  $\text{Na}^+$ / $\text{K}^+$ -pump inhibitor.

Acutely dissociated rat thalamic neurons were plated and perfused with oxygenated Krebs solution at 32° C. Monensin, a  $\text{Na}^+$  ionophore was used to induce a homogenous enhancement of membrane permeability to  $\text{Na}^+$ . Cell survival was assessed using a membrane destruction assay based on calcein AM and ethidium homodimer.  $[\text{Na}^+]_i$  was monitored with the  $\text{Na}^+$  fluorophore Sodium Green<sup>TM</sup>. Combined application of ouabain (250  $\mu\text{M}$ ) and monensin (20  $\mu\text{g/ml}$ ) induced a sequence of neuronal responses, typically consisting of an initial rise of  $[\text{Na}^+]_i$ , cell swelling and membrane blebs, followed by membrane disintegration. Most cells (75%) died within 4 hrs after ouabain and monensin application while no cell death was observed within the same period in the control group. The percentage of cell death dropped significantly if monensin or ouabain was used alone. These data suggest that an enhanced  $\text{Na}^+$  membrane permeability coupled with cessation of ion pumping is sufficient to induce rapid membrane destruction in central neurons devoid of glutamatergic contacts. Supported by grants from MRC of Canada and Heart and Stroke Foundation of Ontario.

## 8.9

MECHANISMS OF DELAYED AMINO ACID EFFLUX DURING REPERFUSION AFTER FOCAL ISCHEMIA: A POSSIBLE ROLE FOR CARRIER DYSFUNCTION. K.Matsumoto\*, E.H.Lo, A.R.Pierce, T.Kano, C.Evans, R.Newcomb. Ctr for Imaging & Pharm Res, Harvard Med Sch, Boston, MA 02129; Neurex, Menlo Park, CA 94325; Neuropsychiatric Institute, UCLA, Los Angeles, CA 90024.

We have demonstrated a large delayed component to increases in extracellular amino acids after transient focal ischemia in rabbit cortex (Matsumoto et al, J Cereb Blood Flow Metab 16:114, 1996). Since this may underlie a process of secondary excitotoxicity in stroke, we have begun to explore the mechanisms involved. New Zealand White rabbits (n=15) were subjected to 2 h MCA occlusion and 4 h reperfusion. A chiral amino acid analysis procedure was used to determine concentrations of L-Asp, L-Glu, D-Ser, L-Ser, L-Gln, PEA, Gly, Tau, L-Ala, and GABA in brain microdialysates. The response of normal brain to depolarization was assessed with 10 min perfusion of 100 mM K<sup>+</sup> pre-ischemia. The transmitters L-Asp, L-Glu and GABA showed sharp transient efflux that rapidly renormalized. Gly showed a rapid but prolonged release. Tau and PEA showed delayed release and Gln showed a prolonged decrease. There were no changes in D-Ser, L-Ser or L-Ala. At 30 min post-reperfusion, K<sup>+</sup> depolarization efflux of GABA was increased 5-fold. After 2h reperfusion, K<sup>+</sup> efflux of L-Asp, L-Glu and GABA was elevated 3-10-fold. Delayed Ca<sup>2+</sup>-independent events (Gln, PEA, Tau) were either attenuated or abolished. Amplification of transmitter release and attenuation of delayed events suggest dysfunction of carrier systems in reperfusion injury after transient cerebral ischemia. Supported in part by NINDS NS32806 and Neurex.

## 8.6

INHIBITION OF THE  $\text{Na,K-PUMP}$  INDUCES A GIANT MEMBRANE DEPOLARIZATION IN MAMMALIAN CENTRAL NEURONS. B.Hu\*, D.M.Mooney, V.Senatorov and P.K.Stys, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, ON, Canada, K1Y 4E9.

Inhibition of the electrogenic  $\text{Na,K-pump}$  is thought to induce a significant membrane potential depolarization due to a breakdown of ionic gradients, although this phenomenon has not been clearly demonstrated in neurons. We examined this issue in rat thalamic neurons maintained *in vitro* in explants. In sharp-electrode intracellular recording mode, short (20s) applications of  $\text{Na,K-pump}$  inhibitor strophanthidin (<100  $\mu\text{M}$ ) induced two different types of membrane depolarizations: a small (<13 mV) electrogenic response and a large, prolonged membrane depolarization that could exceed 40 mV. Glutamate receptors blockers CNQX/APV did not prevent the large membrane response. Computer modeling suggests that if  $\text{Na}^+$  influx and  $\text{K}^+$  efflux are allowed to continue uncorrected following pump inhibition, they may lead to a significant decrease in transmembrane ionic gradients, thereby causing a giant membrane depolarization. This mechanism is especially prominent in a small neuron having a large dendritic area. In support of this prediction, in whole-cell recording mode where cell ionic gradients were maintained by equilibrium with the intra-pipette solution, strophanthidin failed to induce the large membrane depolarization. The small, electrogenic response remained, however, intact. The large membrane depolarization was also not observed in the medium containing  $\text{Na}^+$  channel blocker TTX. These data indicate that small central neurons may undergo sustained membrane depolarization as a result of breakdown of ionic gradients, such as that occurs in anoxia. Supported by grants from MRC and the Heart and Stroke Foundation of Ontario.

ANOXIA INDUCED POTASSIUM CHANNEL SUPPRESSION IN CA3 NEURONS OF THE RAT HIPPOCAMPUS. N.Hershkowitz\* and A.N.Katchman. Department of Neurology, Georgetown University School of Medicine, Washington, DC 20007.

There is little indication that a physiologically significant suppression of  $\text{K}^+$  channels occur in tissue preparations during anoxia. In this report we demonstrate a reduction in a potassium channel conductance in the *in vitro* slice preparation following anoxia which leads to increase cellular excitability. Whole cell patch recordings were made in CA3 pyramidal neurons in current clamp mode from rat hippocampal slices. Input resistance was monitored by hyperpolarizing current pulses. Anoxia was induced by switching perfusion and ambient gas of an interface chamber from a 95% $\text{O}_2$ /5% $\text{CO}_2$  to a 95% $\text{N}_2$ /5% $\text{CO}_2$  mixture. After the onset of anoxia, CA3 cells initially exhibited a small depolarization or hyperpolarization associated with a decrease in input resistance ( $53 \pm 3\%$  from preanoxic control; n=17). This was followed by a transient depolarization (the depolarizing nub) which was associated with a recovery of input resistance ( $85 \pm 3\%$  of preanoxic control). The nub evoked single as well as bursts of action potentials in the CA3 neurons. The possibility that the nub associated increase in resistance may result from a depolarization-induced turning off of an inwardly rectifying current was examined. Thus, during normoxia current injections which elicited depolarizations of a similar magnitude as the nub (+20 mV) resulted in only a  $1.0 \pm 3.0\%$  reduction in input resistance. This suggested that voltage induced alterations of an inward rectifier does not cause the observed alterations in conductance. Finally, no nub-like depolarization, or significant increases in resistance was observed in 7 cells recorded with an electrode containing the non specific potassium channel blocker, cesium. In conclusion, CA3 neurons recorded in whole cell patch current mode exhibited an excitatory depolarization which results from an anoxia-induced suppression of a potassium conductance. (Supported by NIH grant NS32426 and an Epilepsy Foundation of America Research Grant)

## 8.10

PRESYNAPTIC CONTROL OF GABA RELEASE AT INHIBITORY TERMINALS IS BLOCKED BY ANOXIA IN THE RAT HIPPOCAMPUS. M.Avoli\*, R.Köhling and M.Barbarosie. Montreal Neurological Institute and Dept. of Neurology & Neurosurgery, McGill University, Montreal, Quebec, H3A 2B4, Canada

Field-potential and  $[\text{K}^+]_o$  recordings were made in rat hippocampal slices to establish whether anoxia modifies the control of GABA release from inhibitory interneurons. Spontaneous, negative field potentials (ampl.=1.4 $\pm$ 0.6mV, mean $\pm$ SD; interval=40.9 $\pm$ 15.7s; n=10 slices) occurred in CA3 stratum radiatum in the presence of 4-aminopyridine (4AP, 50 $\mu\text{M}$ ) and ionotropic excitatory amino acid antagonists. These events were associated with  $[\text{K}^+]_o$  elevations (peak=5.3 $\pm$ 0.7mM; dur.=23.4 $\pm$ 3.5s; n=3) and were blocked by the GABA<sub>A</sub> receptor antagonist bicuculline methiodide (10 $\mu\text{M}$ ; n=5), the GABA<sub>B</sub> receptor agonist baclofen (100 $\mu\text{M}$ ; n=6) or the  $\mu$ -opioid receptor agonist (D-Ala2-N-Me-Phe,Gly-ol)enkephalin (DAGO, 10 $\mu\text{M}$ ; n=4). Hence, they represented monosynaptic, synchronous, inhibitory field postsynaptic potentials (IPSPs). Brief (4-5 min) anoxic episodes induced a slow elevation of the  $[\text{K}^+]_o$  baseline to 5.2 $\pm$ 0.3 mM (n=3) and an increase in the rate of occurrence of the field IPSPs. The depressant effects of baclofen (n=6) or DAGO (n=4) on these IPSPs disappeared during anoxia, and reappeared once oxygen supply was reconstituted. Our findings demonstrate that 4AP-induced monosynaptic IPSPs in the hippocampus are resistant to anoxia, thus supporting the view that GABA<sub>A</sub>-mediated post-synaptic responses are not influenced by oxygen deprivation. These results also reveal that anoxia blocks the presynaptic control of GABA release exerted by GABA<sub>B</sub> and  $\mu$ -opioid receptors at CA3 inhibitory interneuron terminals. Hence, G protein coupled mechanisms, modulating transmitter release in the hippocampus, may be impaired during oxygen arrest; such phenomenon may also occur at excitatory terminals thereby increasing excitotoxic damage. ## 8.11

Cerebral Injection of Antiinflammatory Cytokine IL-10 Increases the Size of Cerebral Infarcts in the Rat  
 Qi-Hui Zhai, Nancy Futrell\*, Fang-Jie Chen  
 Cerebrovascular Disease Laboratory, Medical College of Ohio

Inflammation following cerebral infarction may contribute to brain tissue damage. Interleukin-10 (IL-10) is an antiinflammatory cytokine. Systemically, it can inhibit the synthesis of proinflammatory cytokines, such as TNF- $\alpha$ , IL-1 $\beta$ , and IL-6, by deactivating macrophages. As mRNAs for IL-10, TNF- $\alpha$  and IL-1 $\beta$  are all present six hours after cerebral infarction, and as there is evidence that TNF- $\alpha$  and IL-1 $\beta$  worsen tissue damage, we studied the hypothesis that IL-10 would ameliorate tissue damage following cerebral infarction. Twelve male Fisher (8-9 weeks old) rats were studied. Six experimental rats received an intracerebral injection of 0.5  $\mu$ g recombinant murine IL-10 in 10  $\mu$ l of normal saline into the territory of the right middle cerebral artery (MCA), with a control group of six rats given a similar injection of 10  $\mu$ l of normal saline alone. Thirty minutes later, MCA occlusion was performed using a craniotomy and cauterization of the right MCA. Rats were sacrificed by transcardiac perfusion 24 hours later. Coronal sections were cut at 7  $\mu$ m thickness using a microtome and stained H&E. Infarct volume was measured by the MCID-M4 computerized image analysis system. The mean infarct volume was 102.83  $\pm$  25.12 mm<sup>3</sup> in the IL-10 group and 54.16  $\pm$  21.90 mm<sup>3</sup> in the control group (0.005 < P < 0.01, t-test). Larger infarcts following the injection of an anti-inflammatory cytokine contrast the results of smaller infarcts following administration of anti-ICAM antibodies, which also have an antiinflammatory effect. This suggests that the role of the inflammatory response in the propagation of ischemic cerebral injury may be complex, and the administration of anti-inflammatory therapeutic strategies may be not always beneficial. The precise roles of the multiple mediators and inflammatory cells need to be further studied before optimal modulation of this response following cerebral ischemia can be designed.

The study is supported by PHS-RO1-AG11759

## 8.12

THE ROLE OF STRESS-ACTIVATED PROTEIN KINASES (JNK/SAPK) IN ISCHEMIA AND REPERFUSION.

D.A. Shackelford\* and R.Y. Yeh  
 Dept. of Neurosciences, UCSD, La Jolla, CA 92093-0624

The MAP (mitogen-activated protein) kinase families, including ERK (extracellular signal regulated kinases), JNK/SAPK (cJUN amino terminal or stress-activated protein kinases), and p38, are instrumental in transducing extracellular signals to the nucleus. The effect of ischemia and reperfusion on JNK activity was investigated using the rabbit spinal cord ischemia model (RSCIM). Activity was determined in animals occluded for 15 min or 60 min and reperused for 2-30 min to determine the correlation with neurological outcome. The former animals will generally recover motor function upon reperfusion, whereas the latter will be permanently paraplegic. JNK activity decreased 45 % and 52 % after 15 min and 60 min of occlusion, respectively (p < 0.001). Upon reperfusion for 15 min, the activity increased to 99 % of control levels in animals occluded for 15 min, but was still significantly reduced (57 % of control level) in animals occluded for 60 min. Immunoblot analyses did not reveal a significant loss of JNK protein, however, there was a transient increase in JNK associated with the particulate fraction during reperfusion. These results indicate that JNK activity decreases during ischemia and then during reperfusion, JNK activity increases to essentially normal levels following short durations of ischemia (15 min) associated with recovery, but not after long durations (60 min) that result in permanent paraplegia. JNK phosphorylates the transcription factors, cJUN and ATF2, thereby increasing transcription of target genes that may be crucial for a regenerative response to ischemic/reperfusion injury. (Supported by grants from NIH and UCSD Academic Senate)

## CALCIUM CHANNELS: STRUCTURE, FUNCTION, AND EXPRESSION I

## 9.1

MOLECULAR CLONING OF CALCIUM CHANNEL SUBUNITS USING P-CHANNEL ANTIBODY. B.D. Cherksey\*, V.S. Sapirstein, M. Saito, M. Sugimori and R. Llinás Depts. of Physiology & Neuroscience and Psychiatry, NYU Medical Center, 550 First Ave., NY, NY 10016.

A polyclonal antibody was prepared against affinity purified P-channel protein from bovine cerebellum. Previous reports showed this antibody reacts with Purkinje cell mostly at the dendritic level (but that no reactivity was observed in this region prior to dendrogenesis.) Western blot analysis shows the antibody reacts with three molecular species of 38Kd, 46 Kd and 130-150Kd. This spectrum of reactivity was brain specific (Hillman et al., *Proc. Natl. Acad. Sci. USA*, 88:7076-7089, 1991) to include human cerebellum. The high molecular weight protein was also present in heart. We used this antibody to probe a human cerebellar lambda gt-11 cDNA library. Initial screening yielded 8 clones which were purified by successive screenings. Analysis of these cDNA showed that they represented three independent clones of 1.7kb, 3.4 kb and 3.7 kb. Each of these was subcloned into plasmids (BlueScript) and analyzed by nucleotide sequencing. Based on the position of the open reading frames it appears that at least two if not all three clones represent partial sequences. Comparison of the nucleotide sequences in the open reading frame of the 3.7 kb clone showed 55% matching with a known  $\alpha$ 2B calcium channel subunit. Preliminary results indicate the 3.4kb clone is similar to  $\beta$  channel subunits. The 1.7kb clone shows homology with different  $\alpha$ 1 calcium channel subunits. Its amino acid sequence predicts 5 transmembrane domains with three exhibiting clear helical structure. From the above we conclude that the antibody reacts with an  $\alpha$ 1  $\alpha$ 2 and  $\beta$  subunit indicating it recognizes a specific calcium channel. Support: NIA-AG09480, NS13742.

## 9.3

THE Ca CHANNEL  $\beta$ -SUBUNIT DOES NOT SIGNIFICANTLY AFFECT GATING OR MODULATION OF  $\alpha$ <sub>1B</sub> CURRENTS EXPRESSED IN OOCYTES. Diane Lipscombe\* & Zhixin Lin. Department of Neuroscience, Brown University, Providence, RI 02912.

It has been suggested that co-expression of Ca channel  $\beta$ -subunits with  $\alpha$ <sub>1B</sub> is required for normal N-type Ca channel function; including expression, channel gating and modulation by protein kinase C. We report that co-expression of the Ca channel  $\beta$  subunit with  $\alpha$ <sub>1B</sub> does not significantly affect N channel gating or PKC-mediated modulation, in *Xenopus* oocytes. Ca channel rscg $\alpha$ <sub>1B</sub> clones, constructed from our rat superior cervical ganglia cDNA libraries, were inserted in to the *Xenopus*  $\beta$ -globin expression vector (pBSTA, A. Goldin). N-type Ca channel expression was achieved in frog oocytes within 2-3 days, following injection of up to 23ng of rscg $\alpha$ <sub>1B</sub> cRNA. The main effect of co-expressing rscg $\alpha$ <sub>1B</sub> with the Ca channel  $\beta$  subunit (Campbell lab), was a significant enhancement in Ca channel current density. Ca channel current amplitudes were, on average, 0.5  $\pm$  0.4  $\mu$ A (n=24) for  $\alpha$ <sub>1B</sub> alone; and 2.92  $\pm$  0.7  $\mu$ A (n=25) when co-expressed in oocytes with  $\beta$ <sub>1</sub> (+10 mV; 5 mM Ba as charge carrier; oocytes were injected with 46 nl of 50 mM BAPTA prior to recording). Under these recording conditions, we observed little effect of  $\beta$ <sub>1</sub> on channel gating kinetics; the average time to reach peak current, following voltage steps to 0 mV, was 15  $\pm$  2 ms (n=11) in the absence of  $\beta$ <sub>1</sub>, and 22  $\pm$  1 ms (n=7) in its presence; the rate of current inactivation, was 317  $\pm$  30 ms (n=11) in the absence of  $\beta$ <sub>1</sub> and 363  $\pm$  33 ms (n=7) in its presence (480 ms depolarization; 0 mV). Finally, up-modulation of  $\alpha$ <sub>1B</sub> currents by PMA (phorbol-12-myristate 13-acetate) was also independent of the presence of  $\beta$ <sub>1</sub>, 100 nM PMA, but not 4- $\alpha$ -PMA, induced 2.3  $\pm$  0.3 fold (n=8) and 1.9  $\pm$  0.2 fold (n=14) increases in the peak of the N channel current in the absence and presence of  $\beta$ <sub>1</sub>, respectively. NIH NS29967.

## 9.2

A NEUROBLASTOMA T-TYPE CALCIUM CHANNEL IN THE ABSENCE OF ALPHA-1E mRNA. W. GOTTSCHALK\*, D.S. KIM\*, D. GILBERT\*, H. CHIN\*, E.F. STANLEY\*, SMS\*, LNC\*, ROSU\*, NINDS, NIH, Bethesda, MD 20892.

The T-type calcium channel plays an important role in the function of a large variety of cell types but relatively little is known about its molecular structure. It has been suggested that this channel is derived from the alpha-1E subunit of the calcium channel family (Soong et al., Science 260, 1993). We have tested this hypothesis for a T-type calcium channel observed in a neuroblastoma cell line.

The predominant calcium current in the 140-3 cell line, a hybrid derived from mouse neuroblastoma and rat glioma, is activated at about -40 mV and is inactivated at a holding potential of -50 mV. It has a unitary conductance of 7 pS in 110 mM Ba<sup>2+</sup>. This channel is blocked by high concentrations of nifedipine (10  $\mu$ M) and nickel (100  $\mu$ M), but is insensitive to a variety of other putative T-channel blockers.

Southern blot hybridization analysis demonstrated the presence of the alpha-1E gene in these cells but several approaches, including Northern blot hybridization analysis, RPA and RT-PCR failed to detect any alpha-1E mRNA. A set of specific PCR primers detected some alpha-1C message in these cells.

Our results essentially dissociate this variant of the T-type channel from the alpha-1E subunit and suggest that some heretofore unidentified protein forms the pore of this channel. This work is supported by the NINDS, NIH, Intramural Research Program.

## 9.4

REGULATION OF THE L-TYPE CALCIUM CHANNEL BY THE  $\alpha$ <sub>2</sub> $\delta$  SUBUNIT IN TRANSFECTED MAMMALIAN CELLS. Ricardo Felix\*, Christina A. Gumett and Kevin P. Campbell. Howard Hughes Medical Institute/Dept. of Physiology and Biophysics, University of Iowa College of Medicine, Iowa City, IA 52242.

The regulatory effects of the calcium channel  $\alpha$ <sub>2</sub> $\delta$  ancillary subunit on the L-type calcium channel were studied using a mammalian expression system. Cloned pore-forming  $\alpha$ <sub>1C</sub> subunit was transiently expressed in tsA201 cells alone or in combination (molar ratio 1:1) with the rat brain  $\alpha$ <sub>2</sub> $\delta$  subunit, and whole-cell barium currents were recorded using the patch-clamp technique. Transfection with  $\alpha$ <sub>1C</sub> subunit only resulted in the expression of voltage-gated currents that inactivated slightly during a 150-ms depolarizing pulse. Coexpression of the  $\alpha$ <sub>2</sub> $\delta$  subunit caused a 3-fold increase in macroscopic current amplitude, shifted the activation curve to more hyperpolarized potentials and altered markedly both activation and inactivation kinetics of the current. In addition, equilibrium radioligand binding experiments showed that the coexpression of  $\alpha$ <sub>2</sub> $\delta$  subunit with  $\alpha$ <sub>1C</sub> leads to an increase in the affinity for the dihydropyridine isradipine without affecting the total number of binding sites. These data suggest that the  $\alpha$ <sub>2</sub> $\delta$  subunit regulation of the cardiac L-type calcium channel activity in mammalian cells involves a modification in both gating and binding properties of the  $\alpha$ <sub>1C</sub> subunit.

**A DROSOPHILA MUTANT IDENTIFIES AN AMINO ACID AFFECTING CALCIUM CHANNEL ACTIVATION RATE AND PEAK CURRENT.** L.M. Hall\*, D. Ren, D.F. Eberl, H. Xu, and M. Chopra. Dept. of Biochemical Pharmacology, SUNY at Buffalo, Buffalo, NY 14260.

Null mutations in the gene *l(2)35Fa* cause recessive embryonic lethality. Deletion mapping, transformation rescue, and DNA sequencing of mutant alleles have shown that this gene encodes the calcium channel  $\alpha_1$  subunit Dmca1D. A missense mutation causing a C to Y change in a highly conserved region of domain ISI causes reduced viability in the organism. Expression in *Xenopus* oocytes of channels bearing this mutant change shows that channel activation rate and peak current are reduced. Additional *in vitro* mutagenesis shows that it is size and polarity of the amino acid at this position, rather than ability to form S-S bonds, which is important. Electrophysiological recordings from larval muscle show reduced current levels in mutant relative to wild-type. This mutant change persists in the presence of the T-type calcium channel blocker amiloride showing that the Dmca1D  $\alpha_1$  subunit is the amiloride-insensitive channel in muscle. This *Drosophila* mutant has identified the molecular component responsible for one pharmacologically distinct calcium channel expressed in *Drosophila* muscle and has identified an amino acid important for channel function in the organism and in heterologous expression systems. Supported by NIH grant HL39369.

## 9.7

**AUTORADIOGRAPHY OF L-TYPE AND N-TYPE CALCIUM CHANNELS IN AGED RAT BRAIN.** K.M. Kelly\*, A. Kume\*, R.L. Albin\* and R.L. Macdonald\*#. Depts. of Neurology\* and Physiology#, U. of Michigan, Ann Arbor, MI 48104-1687.

Brains from male (F344xBN)F1 rats aged 6, 17 and 32 mo were studied to determine whether there was age-dependent change in the number of L-type and N-type calcium channels in different brain regions. The L-type calcium channel antagonist PN200-110 and the N-type channel antagonist  $\omega$ -conotoxin GVIA were used to determine specific binding densities. Binding of the ligands was performed using methods described previously for the L-type channel (Cortes et al., J Neural Trans 1984;60:169) and the N-type channel (Filloux et al., Devel Brain Res 1994;78:131). The autoradiographic distribution of ligand binding from hippocampus (CA1, CA3, dentate gyrus), entorhinal cortex (laminae I-III, IV-VI) and neocortex (lamina I-III, IV-VI) was quantified with computer-assisted densitometry. Five to ten readings per area from each animal (n=4 at each age) were averaged. One-way ANOVA noted a significant variance in the mean value of binding density between different age groups only in neocortex laminae IV-VI for [<sup>3</sup>H]PN200-110 binding (p<0.05). Post-hoc testing indicated that the mean value of the 17 mo old group was significantly less than those of the 6 and 32 mo old groups (p<0.05). No other significant differences were found for either ligand within the different age groups for any other brain region.

These results indicate no age-dependent change in the number of binding sites for [<sup>3</sup>H]PN200-110 (except at 17 mo for neocortex laminae IV-VI) and [<sup>125</sup>I] $\omega$ -conotoxin GVIA suggesting no significant overall change in the number of L-type and N-type calcium channels in rat brains 6-32 mo of age.

## 9.6

**KINETIC DIFFERENCES IN THE INTERACTION OF  $\omega$ -CONOPEPTIDES WITH B-CLASS AND N-TYPE  $Ca^{2+}$  CHANNELS.** D. M. Rock<sup>1</sup>, S. J. Stoehr<sup>2</sup>, J. Offord<sup>2</sup> and A. Palma<sup>2</sup>. <sup>1</sup>Neuroscience Therapeutics and <sup>2</sup>Dept. of Biotechnology, Parke-Davis Pharmaceutical Research Division of Warner-Lambert Co., 2800 Plymouth Rd., Ann Arbor, MI 48105 and <sup>3</sup>Neurex Corp., Menlo Park, CA 94025.

Several peptides isolated from naturally occurring toxins have been useful in identifying voltage-gated  $Ca^{2+}$  channel subtypes in neuronal preparations. Molecular biological experiments have shown that differences in the  $\alpha_1$  subunits ( $\alpha_{1A}$ - $\alpha_{1E}$ ) code for different subtypes of  $Ca^{2+}$  channels, and the  $\alpha_1$  subunit contains sites for the interactions with toxins. Based mainly on sensitivity to the specific N-type  $Ca^{2+}$  channel blockers  $\omega$ -conopeptide GVIA and MVIIA, recombinant B-class  $Ca^{2+}$  ( $\alpha_{1B}$ ) channels have been classified as neuronal N-type  $Ca^{2+}$  channels.

Using whole-cell voltage clamp techniques, we compared the kinetics of  $\omega$ -conopeptide interactions with human neuronal B-class  $Ca^{2+}$  ( $\alpha_{1B}$ ) channels expressed in HEK-293 cells and N-type  $Ca^{2+}$  channels in rat superior cervical ganglion (SCG) neurons. All  $\omega$ -conopeptides tested (SNX-111 [MVIIA], SNX-230 [MVIIIC] and SNX-238 [MVIIID]) blocked  $Ca^{2+}$  channels in both B-class cell lines and SCG neurons, but there were differences in the kinetics and potencies of the block. On rates were slower in B-class compared to N-type channels for all conopeptides. SNX-230 produced a rapid, irreversible block of B-class channels but rapidly and reversibly blocked N-type channels. SNX-238 produced a rapid, incomplete and reversible block of both B-class and N-type  $Ca^{2+}$  channels, with a lower potency in SCG neurons. The kinetics of  $\omega$ -conopeptide interactions suggest that recombinant B-class and N-type  $Ca^{2+}$  channels are not identical. Potential explanations for these differences will be discussed. [Supported by Warner-Lambert Co. and Neurex Corp.]

## 9.8

**NONHOMOGENEOUS DISTRIBUTION OF DIFFERENT CALCIUM CHANNEL SUBTYPES ON PRESYNAPTIC TERMINALS IN THE HIPPOCAMPUS.**

C. A. Reid, J. D. Clements and J. M. Bekkers\*. Division of Neuroscience, John Curtin School of Medical Research, Australian National University, Canberra, Australia.

The N-type ( $\omega$ -Conotoxin GVIA-sensitive) and Q-type ( $\omega$ -Agatoxin GIVA-sensitive) presynaptic calcium channels have been shown to support the release of the neurotransmitter glutamate at excitatory synapses in the hippocampus. Several recent studies have proposed that a mixed population of calcium channels co-exist at a single release site and contribute jointly to the local calcium transient that triggers release. However, debate exists as to whether one calcium channel subtype alone can support release from a synaptic terminal. Whole-cell recordings were made from single cultured rat hippocampal neurons that form autaptic synapses. Probability of release (Pr) was measured by analysing the progressive block of the NMDA receptor-mediated synaptic current by the irreversible open channel blocker MK-801 (2  $\mu$ M). The time course of the progressive block could be fitted by the sum of two exponentials, consistent with there being at least two types of presynaptic terminals, one with a high Pr, the other with a low Pr. Although  $\omega$ -Conotoxin GVIA (1  $\mu$ M) blocked the EPSC by 41%  $\pm$  4.7 (Ave.  $\pm$  se) there was no significant change in either the fast ( $\tau_f$  control = 8.2  $\pm$  1.1 vs  $\tau_f$   $\omega$ -Ctx = 7.3  $\pm$  1.5) or slow ( $\tau_s$  control = 53.1  $\pm$  4.7 vs  $\tau_s$   $\omega$ -Ctx = 48.0  $\pm$  5.1) time constants of the MK-801 progressive block. A similar reduction in the EPSC by cadmium (a non-specific calcium channel blocker) significantly increased both the fast ( $\tau_f$  cadmium = 17.3  $\pm$  3.2) and slow ( $\tau_s$  cadmium = 81.0  $\pm$  8.3) time constants (p<0.01). These results suggest Pr is unchanged at a proportion of terminals following block of N-type calcium channels. Our conclusion is that functional N-type calcium channels are absent from some presynaptic terminals. (Supported by Australian Department of Health)

## COGNITION: FUNCTIONAL NEUROIMAGING

## 10.1

**RELATION OF TASK PERFORMANCE TO CEREBRAL BLOOD FLOW ACTIVATION PATTERNS DURING FACE PERCEPTION.** G.E. Alexander\*, M.J. Mentis, J.R. Moeller<sup>1</sup>, M.L. Furey, P. Pietrini, B. Horwitz, C.L. Grady. Laboratory of Neurosciences, NIA, NIH, Bethesda, MD 20892; <sup>1</sup>Dept. of Biological Psychiatry, NYSP, New York, NY 10032.

Face perception has been associated with cerebral activation of a ventral pathway including occipitotemporal and frontal brain regions. To investigate the interactions of regional cerebral blood flow (rCBF) during face perception in relation to task performance and age, we analyzed rCBF with high-resolution positron emission tomography and H<sub>2</sub><sup>15</sup>O in 9 healthy elderly (mean age = 67 $\pm$ 6 yrs) and 9 young, right-handed, adult males (mean age = 28 $\pm$ 4 yrs) using the Scaled Subprofile Model (SSM; Moeller, et al., 1987). SSM analysis of scan subtractions during face matching and sensorimotor control tasks in the young and old groups combined extracted a first principal component pattern whose expression was positively correlated with task accuracy (r=0.57, p<0.02) and did not differ between the two age groups. This pattern was predominantly characterized by higher activity in left lingual and fusiform gyri and bilateral inferior and middle frontal association regions with relatively lower activity in lateral inferior and middle occipitotemporal regions, bilaterally. Separate SSM analyses for the young and old groups each produced patterns which were correlated with the pattern from the combined groups analysis. These results suggest that individual differences in face matching performance are associated with the interaction of brain regions previously implicated in object perception and effortful information processing, and that this functional interaction occurs in both young and elderly subjects. This research was supported by the NIA Intramural Research Program.

## 10.2

**INVOLVEMENT OF THE SUPERIOR PARIETAL CORTEX IN MENTAL TRANSFORMATIONS OF THE BODY INDUCED BY TOUCH.**

E. Bonda\*, S. Frey and M. Petrides. Montreal Neurological Institute, McGill University, Montreal, Quebec, H3A 2B4, Canada.

The neural systems underlying body-space mental representation were studied by measuring changes in regional cerebral blood flow (CBF) with positron emission tomography (PET) in human subjects. The experimental paradigm involved identification of the left or the right hand of the experimenter that was presented in different orientations on the palm of the subject's right hand. The subjects were required to decide whether it was the left or the right hand that was presented. In order to perform this task, the subjects had to move mentally the position of their own arm to adopt that of the experimenter's arm. The control condition involved the same type of tactual stimulation without the requirement of mental transformations of the subject's body. The distribution of CBF was measured by means of the water bolus H<sub>2</sub><sup>15</sup>O methodology during the performance of these tasks. Comparison of the distribution of CBF between the experimental and the control tasks revealed significant increases in the caudal superior parietal cortex, including the intraparietal sulcus, and the adjacent medial parietal and cingulate cortex. The results indicate that there is a dorso-medial parietal system underlying the mental experience of the body in an interactive relation with space. These findings, taken together with earlier related findings obtained through the visual modality (Bonda et al., 1995, Proc. Natl. Acad. Sci.), establish that the involvement of this system in body-space interactions is amodal in nature.

## BRAIN AREAS INVOLVED IN THE EXECUTIVE CONTROL OF TASK SWITCHING AS REVEALED BY PET

J.E. Evans, E.J. Lauber\*, D.E. Meyer, J. Rubinstein, L. Gmeindl, L. Junck, R.A. Koeppe.  
Department of Psychology and Nuclear Medicine, University of Michigan, and Department of Psychology, University of Georgia.

The executive mental processes needed to switch between two simple tasks was examined using both behavioral and PET (O15 water) methodologies. Normal adult subjects were required to make perceptual judgments of color or shape, or to alternate between them, and respond with finger presses on a 3-button mouse. Subtraction of the activation images obtained in the average of the single-task conditions from the average of the dual-task conditions revealed peak activation foci in the left dorsolateral prefrontal cortex, left posterior parietal cortex, left premotor cortex, right cerebellum, and left anterior cingulate gyrus. These results are consistent with findings in the literature that implicate these brain areas in context updating or task designation (left prefrontal cortex), accuracy monitoring and response inhibition (anterior cingulate cortex), and movement preparation (premotor cortex).

## 10.5

## REGIONAL DIFFERENCES IN THE DEVELOPMENT OF WHITE MATTER DEMONSTRATED WITH MRI. M.A. Eckert\*, D.C. Wilson\*, O.F. Agee\*, T.H. Lucas\* &amp; C.M. Leonard\*. Depts. of Psychology\*, Mathematics\*, Radiology\*, Neuroscience\* Univ. of FL, Gainesville, FL, 32610.

The acquisition of myelin increases conduction speed and improves the temporal fidelity of neural processing. Postmortem studies show myelination to proceed in a regional order that correlates with the order of functional development. Sensory and motor areas reach mature levels of myelin within the first few years, while association areas continue to develop myelin into adulthood. Therefore, the state of myelination is assumed to represent the functional development of the brain. The cholesterol in myelin has been shown to produce high signal intensities on T1 weighted MR images. The percent of high signal intensity voxels can be quantified as an index of white matter development. The method used here to quantify voxels has replicated postmortem findings of regional differences in myelin development. Children ( $\times$  age = 8 yrs) demonstrated a significantly lower percentage of high signal voxels in the association cortex of the temporal lobe than adults ( $\times$  age = 34 yrs) in the right ( $F_{(1,38)}=83.14, p<.0001$ ) and left hemispheres ( $F_{(1,38)}=26.44, p<.001$ ). However, there was no difference in the visual cortex of the right ( $F_{(1,57)}=0.29, p>.05$ ) or left hemispheres ( $F_{(1,57)}=1.13, p>.05$ ). We plan to use this technique to investigate structural correlates for language development. Adult levels of myelination may reflect the attainment of mature levels of functioning and boundaries for sensitive periods of development. (Supported in part by MOD FY96-1021 and NIDCD2922.)

## SENSITIVITY OPTIMIZATION AND EXPERIMENTAL DESIGN IN FUNCTIONAL MAGNETIC RESONANCE IMAGING

TE Conturo, RC McKinsty, E Akbudak, AZ Snyder, T Yang, ME Raichle\*  
Depts of Radiology & Neurology, Washington U., St. Louis, MO 63110

**Introduction:** The fMRI signal responses are very small. The blood oxygenation level-dependent signal change (the BOLD signal) is ~2-4% for robust stimuli and even smaller for cognitive tasks. As sensitivity is very dependent on MRI acquisition parameters, these variables must be optimized.

**Methods:** Sensitivity to detect activation was modeled as the contrast-to-noise ratio (CNR) given by the time-averaged activated pixel intensity minus the time-averaged control relative to noise. Timing intervals TR and TE, tip angle  $\alpha$ , in-plane resolution, slice thickness, RF coil, number of time frames per run ( $N_{\text{frames}}$ ) and number of runs ( $N_{\text{runs}}$ ) were considered. Normal volunteers were studied with 8 Hz photic stimulation on a Siemens 1.5 T MR unit. Echo planar imaging was used with  $N_{\text{frames}} = 128$ ,  $N_{\text{runs}} = 1$  and 3 on/off blocks.

**Results:** For practical maximum  $N_{\text{frames}}$ , TR > 1 s and  $\alpha = 90^\circ$  are preferred. Optimally, TE = 90 ms but shorter TE can be chosen without severe penalty.  $N_{\text{runs}}$  should be maximized depending on subject tolerance. The measured sensitivity of surface coils was up to 4x that of a head coil. For 1.9x1.9x5 mm voxels with the head coil, CNR was only 3:1 but increased by a factor of 12 to 37:1 using 3.1x3.1x7 mm voxels with a surface coil. For large voxels there was uniform grey matter (GM) BOLD signal. For small voxels signal was inhomogeneous with higher signal in the sulci (suggesting vessels) and lower signal in GM. The measured GM CNR was approximately proportional to voxel volume as predicted. The low-resolution CNR was much larger than the sulcal high-resolution CNR, indicating that the large-voxel BOLD signal is dominated by GM signals with only minor effects from blurred sulcal signals. The CNR predictions may aid tailoring of experiments to anticipated BOLD responses. [Supported by NIH grant NS06833 and the Charles A. Dana Foundation]

## 10.4

## WITHIN SUBJECT NEUROACTIVATION MAPPING WITH WHOLE BRAIN ISOTROPIC EPI AND 3-D PET: A DIRECT COMPARISON. D.B. Weinerberger\*, A. Santha, A. Mattay, J. Frank, B. Kirkby, J. van Horn, G. Esposito, K.F. Berman. Clinical Brain Disorders Branch, NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032 and LDRR, Bethesda, Md. 20892

"BOLD" contrast fMRI is "in vogue" as a technique for in vivo human brain mapping, though its merits relative to state-of-the-art 3-D PET mapping are debatable. We have compared directly whole brain, multi-slice, isotropic (3.75mm) EPI and 3-D O-15 water PET (6.5 mm isotropic) in seven normal volunteers performing repetitive sequential finger movements. The fMRI protocol involved 18 "on-off" repetitions; the PET protocol involved twelve scans (i.e. six movement-rest pairs). The fMRI datasets were smoothed to the PET resolution and voxel density and then coregistered to each other. A rigorous T statistical analysis was applied with Bonferroni correction for the calculated number of "resels" unique to each method. Significantly activated voxels in primary sensorimotor cortex (SM) and in supplementary motor cortex were seen in every subjects with both techniques. Ipsilateral cerebellar activation was seen in every subject with fMRI, and in five subjects with PET. Only one study (PET) showed any activation of the contralateral basal ganglia region. Foci of activation were generally overlapping in SM, but less so in other motor regions. At these critical T thresholds, the number of activated voxels in SM and in other motor regions, especially cerebellum, were usually greater with the fMRI technique. These data show that the neuroactivation maps of this fMRI method and of 3-D PET, at least during motor function, are comparable.

## 10.6

## ADJUSTING FOR TEMPORAL AND SPATIAL CORRELATIONS IN ANALYSIS OF MEAN FMRI SIGNAL INTENSITY CHANGES.

J.J. Locascio\*, P.J. Jennings, and S. Corkin. Dept. of Brain and Cognitive Sciences and the Clinical Research Center, Mass. Institute of Technology, Cambridge, MA 02139.

Although functional magnetic resonance imaging (fMRI) methods yield a richness of temporal and spatial data for even a single subject, universally accepted data analysis techniques have not been developed yet that fully use all the potential information from fMRI of the brain. Specifically, temporal correlations and confounds are a problem in assessing change within pixels. Spatial correlations across pixels are a problem in determining regions of activation, and in correcting for multiple significance tests. We propose methods of addressing these issues in the analysis of mean fMRI signal intensity changes for individual subjects. Our approach to temporally based confounds within pixels is to employ autoregressive-integrated-moving average (ARIMA or "Box-Jenkins") time series analysis. To adjust for performing multiple significance tests across pixels, taking into account between-pixel correlations, we propose adjustment of p-values with computer intensive "resampling methods." Our objective is to produce 2- or 3- dimensional brain maps that provide, at each pixel in the map, an estimated p value with absolute meaning. That is, each p value approximates the probability of having obtained by chance the observed signal effect at that pixel, given that the null hypothesis is true. Time series analysis and resampling methods have been employed with success in fMRI analysis, but to our knowledge no one has tested their use in combination as we are proposing. Simulated and real data examples are provided.

## 10.8

## RELIABILITY AND CORTICAL UNFOLDING OF WITHIN-SUBJECT fMRI DATA FOR WORD-STEM COMPLETION. R.L. Buckner\*, A.M. Dale, R.B.H. Tootell, S.E. Petersen\*, M.E. Raichle\* and B.R. Rosen. MGH-NMR Center, Boston MA 02129. † Wash. Univ. Med. Sch., St. Louis, MO 63110.

Previous PET studies of word-stem completion have demonstrated a pathway of brain areas activated in averaged subject-groups (Buckner et al. *J. Neurosci.* 1995). The present study sought to determine if these areas (left inferior prefrontal, SMA, motor, and visual) could be reliably detected within-subject using fMRI. 8 subjects were imaged during 6 to 8 runs of word-stem completion (4 fixation and 3 word-stem completion blocks per run; each block 30 sec with 12 trials; whole brain fMRI using BOLD contrast, 1.5T GE scanner with ANMR EPI upgrade, 3x3x7mm voxels, 17 axial slices along the AC-PC plane). For each subject, data were divided into two sets. Reliability was assessed in two ways. (1) Regions were defined on activations in the first data sets and tested for replication in the second, independent, data sets using a KS test. (2) Correlations between KS maps in the first data sets (for a slice containing the left inferior prefrontal activation) and the second sets were determined on a voxel by voxel basis. Results showed high reliability within-subject: (1) 94% of the regions tested replicated ( $p<.05$ , 88% were  $p<.01$ ) and (2) the KS maps from the two separate data sets were highly correlated within-subject (mean  $r = .74$ , median  $r = .80$ ). For two of the subjects, the cortical surface was reconstructed from hi-resolution anatomic images and unfolded (Dale & Sereno *J. Cog. Neuro.* 1993). KS activation data were projected onto these unfolded cortical surfaces revealing similarly localized prefrontal activation for each subject. Moreover, significant and reliable left inferior prefrontal activation could be detected in all 8 subjects with a signal change magnitude of about 1%. Such high reliability within and between subjects serves as a foundation for detailed functional-anatomic exploration of cortical areas during cognitive tasks.

## 10.9

**fMRI IMPULSE RESPONSE CHARACTERISTICS FOR PREFRONTAL ACTIVATION DURING WORD-STEM COMPLETION** P.A. Bandettini\*, R.L. Buckner, K.M. O'Craven, R.L. Savoy and B.R. Rosen. MGH-NMR Center, Boston, MA 02129

Data presented in the companion abstract demonstrate within-subject reliability of prefrontal activation for a word-stem completion task. In the present study, we demonstrate that significant fMRI signal changes can be elicited in prefrontal areas using single trials for the same task. Use of single trial responses may be optimal for tasks that would benefit from mixed, rather than blocked, design.

Using a region defined on data from a block-designed word-stem completion task (see companion abstract for methods), fMRI time series data from 4 subjects were analyzed for separate runs containing spaced single word-stem completion trials (15 trials per run, 1 trial every 14 sec, 4 runs per subject). Shown below are signal averages for the left inferior prefrontal region for the first subject. (Shaded area represents approximate word-stem on time. Data are shown with standard error bars.) This ~1% signal change was reproducible across subjects.

These studies demonstrate that single trials can be used to map cognitive function. This cognitive "impulse response" approach may be optimal for cognitive tasks requiring stimulus or task randomization, or in cases where individual trials differ based on performance measures obtained from the subject.

## 10.11

**SUBORDINATE-LEVEL CATEGORIZATION IN HUMAN INFERIOR TEMPORAL CORTEX: CONVERGING EVIDENCE FROM NEUROPSYCHOLOGY AND BRAIN IMAGING.** J. Gauthier<sup>1</sup>, M. Behrmann<sup>2</sup>, M. J. Tarr<sup>3</sup>, A. W. Anderson<sup>4</sup>, J. Gore<sup>4</sup>, and J. L. McClelland<sup>2\*</sup>, Departments of Psychology<sup>1</sup> and Diagnostic Radiology<sup>4</sup>, Yale University, New Haven CT 06520; Department of Psychology<sup>2</sup>, Carnegie Mellon University, Pittsburgh, PA 15213 and Dept. of Cogn. & Ling. Sciences<sup>3</sup>, Brown University, Providence, RI 02912.

Several neuropsychological case studies of face-specific recognition deficits (prosopagnosia) and functional brain imaging studies appear to show that a portion of inferior temporal lobe -IT- (part of the fusiform and inferior temporal gyri) in humans is dedicated to face processing (Sergent et al., 1992; Haxby et al., 1994; Farah et al., 1995). However, face recognition can be considered a particular case of *subordinate-level recognition*, in which members of a visually homogeneous class must be distinguished. In several experiments using perceptual matching and match-to-sample tasks, we found that prosopagnosics are disproportionately sensitive to increasingly specific levels of categorization with both familiar and novel non-face objects. We also report an fMRI study in which the same region of IT associated with faces is engaged by the subordinate-level recognition of familiar non-face objects. Together, these results suggest that the level of visual categorization, not stimulus class membership *per se*, may be the mediating factor in dissociations generally found between face and object recognition in the human ventral pathway. At a minimum, such results provide more stringent controls for claims of face-specific mechanisms and neural substrates. (Support provided by ONR, Contract N000149303.)

## 10.10

**DETECTION OF CORTICAL AREAS WITH TRANSIENT BRAIN ACTIVITY USING ECHO-PLANAR MAGNETIC RESONANCE IMAGING.** S. Konishi, R. Yoneyama, H. Itagaki, I. Uchida, H. Kato, K. Nakajima, K. Okajima, H. Koizumi and Y. Miyashita\*. Department of Physiology, the University of Tokyo School of Medicine, Tokyo 113, Japan. Central Research Laboratory, Hitachi, Ltd., Tokyo 185, Japan.

With 'transient' regions of interest (ROIs), we identified transiently activated visual cortical areas using functional magnetic resonance imaging (fMRI) at 1.5 T in five human subjects. The validity of this method was confirmed by comparing them with conventionally determined continuously activated visual cortical areas. Ventral extrastriate cortices in the occipital lobe were activated by transient (0.2 or 2 s) or continuous (20 s) visual stimulation. The transient activation was assessed by estimating the pixel-wise statistical significance of signal increase at each of time points using a paired *t*-test to delineate transient ROIs, and the spatial distribution of the transient ROIs was compared with that of the conventionally determined ROIs derived from continuous activation. Ninety-five and 89 percent of the total areas of transient ROIs derived from 0.2 and 2 s activation, respectively, appeared at 5, 7 or 9 s after the onset of stimulus presentation. Eighty-nine and 76 percent, respectively, of them overlapped with conventional ROIs derived from 20 s activation. These results indicate that transient ROIs can be delineated by setting a time window for them of around 7 s after the transient brain activation and that few of them are false positive areas, and also suggest that the delineation of transient ROIs might be a powerful strategy for the exploration of cognitive functions with fMRI.

## 10.12

**CEREBELLAR CONTRIBUTIONS TO MOTOR REPRODUCTION OF TEMPORAL SEQUENCES** V.B. Penhune\*, R.J. Zatorre and A.C. Evans. Montréal Neurological Institute, McGill University, Montréal PQ H3A 2B4.

Motor reproduction of temporally complex auditory and visual sequences was investigated in a PET activation study (<sup>15</sup>O water bolus) in normal volunteers (N=12). Reproduction of the sequences in both modalities was expected to activate regions of the brain, particularly the cerebellum, required for processing the temporal content of the sequences and for executing the motor response. In the baseline conditions, subjects reproduced either auditory or visual isochronous sequences by tapping on a computer keyboard to imitate both the durations and the number of elements. In the activation conditions, subjects reproduced a series of temporally complex novel sequences in the same way. Paired image subtractions confirmed that sensory input and motor output were similar in the baseline and activation conditions, since no statistically significant ( $t > 3.5$ ) rCBF increases were observed in either sensory or motor cortical regions. In both modalities, significant increases were observed in anterior and posterior cerebellar vermis, left lateral cerebellar cortex, cingulate, and right insula. In the auditory condition, additional increases were observed in right lateral cerebellar cortex and the left insula. In the visual condition, additional increases were observed in the right dentate gyrus, as well as right orbito-frontal and posterior dorso-lateral frontal regions. These data provide partial support for the hypothesized cerebellar control of temporal processing, by revealing neural systems engaged in timed motor output, regardless of the modality of sensory input. However, they also indicate that additional, modality-specific neural systems may be involved. Supported by the NIH/NIMH and the Medical Research Council of Canada.

## NEUROTOXICITY: EXCITOTOXIC INJURY

## 11.1

**EFFECT OF MELATONIN ADMINISTRATION TO RATS ON KAINATE-INDUCED p53 IMMUNOREACTIVITY, DNA DAMAGE AND NEURONAL DEGENERATION IN THE BRAIN.** T. Uz\*, A. Kharlamov, J.-Y. Joo, D. Franceschini<sup>1</sup>, P. Giusti<sup>1</sup> and H. Manev, ASRI, Med. Coll. Pennsylvania and Hahnemann Univ., Pittsburgh, PA;<sup>1</sup> Dept. Pharmacol., Univ. Padova, Italy.

The pineal hormone melatonin has recently been shown to be capable of reducing neurotoxic action of the glutamate receptor agonist kainate both in neuronal cultures and in the rat brain in vivo. The mechanism of melatonin's neuroprotection does not appear to involve a direct blockade of kainate-sensitive glutamate receptors, and it may include the antioxidative properties of this hormone. An i.p. injection of 10 mg/kg kainate to male rats resulted in neuronal damage in the hippocampus (CA1, CA3, and CA4), the entorhinal cortex, and the amygdaloid complex that was accompanied by signs of both necrosis and apoptosis. We characterized in melatonin-treated rats (4 x 2.5 mg/kg, i.p.) and in corresponding controls the temporal pattern and the localization of kainate-triggered markers of apoptotic cell injury (i.e., by p53 immunoreactivity and the in situ TUNEL assay of DNA damage), and we assayed neuronal damage using Nissl and GFAP-specific (glial fibrillary acidic protein) stainings. In addition, we investigated the correlation between the behavioral response to kainate and kainate-induced brain injury. The TUNEL and Nissl assays revealed the occurrence of DNA damage and neuronal degeneration (Nissl loss) as early as 3 hr after kainate; both markers increased further by 24 hr and then remained stable for the next 2 days. The p53 immunostaining was positive 24 hr after kainate. At that time we also observed an increased number of GFAP-positive cells in the stratum radiatum of the CA1. Melatonin reduced the appearance of all the above-noted markers of injury. In addition, melatonin reduced the intensity of behavioral responses to kainate. However, we observed the neuroprotective action of melatonin in animals in which the behavioral responses to kainate were comparable. Thus, it appears that pharmacological doses of melatonin are capable of reducing excitotoxicity via a mechanism that does not directly involve glutamate receptors. Currently we are investigating whether similar effects are mediated by endogenous melatonin. (T. Uz: Fogarty Award F05 TW/NS5271-01).

## 11.2

**DECREASED LEVELS OF ENDOGENOUS MELATONIN POTENTIATE EXCITOTOXIC AND STROKE-INDUCED BRAIN DAMAGE.** H. Manev\*, T. Uz, A. Kharlamov and J.-Y. Joo, ASRI, Medical College of Pennsylvania and Hahnemann University, Allegheny Campus, Pittsburgh, PA, 15212.

Pharmacological administration of the pineal hormone melatonin to rats reduces kainate-triggered excitotoxic brain damage (Uz et al., this meeting). It is not clear yet whether endogenous melatonin would provide the same neuroprotective action and whether the pineal gland can be considered a part of endogenous neuroprotective systems which, if impaired, could put the brain at risk for neurodegenerative pathologies. We investigated the effect of endogenous melatonin on the response of the brain to excitotoxic (i.p. administration of 10 mg/kg kainate) and stroke (photothrombotic model with rose bengal and light)-triggered injury using two models of changed endogenous melatonin levels: a) diurnal rhythm, and b) pinealectomy. In addition, since it is believed that aging impairs pineal functioning, we characterized the effect of kainate in adult (2 months) and old (24 months) male rats. The extent of kainate-induced damage was assessed in brain slices using computer-assisted quantitative analysis of Nissl loss and in situ TUNEL labeling of DNA damage. The volume of stroke-triggered unilateral focal cortical lesions was also measured. An RIA assay (Alpco Ltd.) was used to measure the concentration of melatonin in the plasma. The extent of kainate-triggered DNA damage and the loss of Nissl staining were lower when kainate was injected at night (1:00 A.M.), i.e., in the presence of high endogenous levels of melatonin (5 times greater than levels at 12:30 P.M.). Fifteen days after pinealectomy, the daytime plasma level of melatonin could not be detected. Kainate injections into these animals resulted in greater damage than in the sham-pinealectomized rats. The volume of stroke-triggered lesion was also bigger in pinealectomized animals. In addition, kainate-triggered injury was greater in the brains, e.g., the CA3 of the hippocampus, of the old rats. Our results support the proposition that endogenous melatonin can influence the outcome of brain injury, and that this effect is not limited to kainate excitotoxicity only. Further studies are needed to evaluate the contribution the antioxidative action of melatonin makes to neuroprotection.

## 11.3

**LOSS OF P53 INDUCTION IS ASSOCIATED WITH INHIBITION OF APOPTOSIS.** D. Uberti, M. Belloni, C. Rizzini, L. Piccioni, F. Sinelli, F. Borsini\*, P.F. Spano and M. Memo Div. Pharmacol., Dep. Biomed. Sci. & Biotechnol., Brescia University, School of Medicine, 25123 Brescia, Italy

P53 is a tumor suppressor protein involved in controlling cell cycle checkpoint that is important for maintaining the integrity of the genome. The demonstration that p53 promotes apoptosis in abnormally proliferating cells may have important implications for the central nervous system (CNS), where cell death is observed normally during development, in response to injury and in neurodegenerative disorders. Recent findings suggest that p53 could be associated with induction of cell death consequent to some forms of cellular damage in the SNC. A possible role for p53-related modulation of neuronal viability is suggested by the finding that p53 expression is increased in damaged neurons in models of ischemia and epilepsy. Immunocytochemical studies using p53 antibody has performed during the cell development "in vitro". We found a significant increase of p53 immunoreactivity during the cell maturation. When the culture were exposed to kainic acid (60  $\mu$ M) for 24 h a significant increase of p53 immunoreactivity associated with a decrease of cell viability resulted. Time-course experiments revealed the increases of p53 expression to be maximal 2 h after the kainic acid treatment. P53 levels returned to basal values after 8 h. To investigate the relationship between p53 expression and Kainic acid induced neuronal damage neurons were preincubated with a specific p53 antisense oligonucleotide. This treatment resulted in an inhibition of the kainic acid induced increase of p53 immunoreactivity and prevented kainic acid induced apoptosis. However p53 antisense oligonucleotide treatment did not completely antagonize the kainic acid-induced cell death, suggesting that this excitatory amino acid triggers at least two separate cell death programs, only one of them strictly p53-dependent. This work is supported by C.N.R.

## 11.5

**USE OF RNA DIFFERENTIAL DISPLAY TO STUDY THE MECHANISM OF ACTION OF QUINOLINATE.** K.Dhanireddy<sup>1</sup>, R.Kori<sup>1</sup>, I.Rodriguez<sup>2</sup> and M.A.A.Namboodiri<sup>1\*</sup>. <sup>1</sup> Dept. Biol., Georgetown U., Washington, DC 20057, <sup>2</sup> Lab. Ret. Cell Mol. Biol. NEI, NIH, Bethesda, MD 20892.

Recent studies have shown that quinolinate (QUIN), an endogenous neurotoxin, is increased in the blood and CSF during a number of inflammatory neurological disorders, including neuroAIDS, and that QUIN may play a role in the neurotoxicity underlying these disorders. Based on the blocking of exogenous QUIN neurotoxicity by the NMDA receptor antagonist, MK801, QUIN is proposed to cause neurotoxicity via overexcitation of the NMDA receptor system. However, because of the relatively weak agonist nature of QUIN, it is not clear if QUIN is acting directly or indirectly on the NMDA receptor system. Presently, we have initiated studies on the mechanism of action of QUIN using the RNA differential display technique, a powerful tool for the study of differential gene expression.

A GnRH secreting neuronal cell line (GN cell line) was cultured in a custom synthesized medium in the presence of 5% fetal calf serum. At approximately 50% confluence, the cultures were exposed to QUIN acutely (100  $\mu$ M, 2h) or chronically (10  $\mu$ M, 24h). Total RNA was extracted using RNeasy B, DNA contamination was removed by DNase treatment and mRNA differential display was performed using the RNImage kit (GenHunter Corp., TN). A number of differentially expressed cDNA bands were detectable in both acute and chronic QUIN treated sample, some of which were common. Further studies involving TA cloning of these cDNA bands, sequencing and Northern blot analysis are in progress.

## 11.7

**NEUROPROTECTIVE ACTION OF NMDA RECEPTOR ANTAGONISTS IN A RAT GENETIC MODEL OF GLUTAMATE TOXICITY.** G. Müller, I. Bresink, H.H. Schneider\*, and L. Turski, Research Laboratories of Schering AG, Müllerstr. 178, D-13342 Berlin, Germany.

The mutant strain of Wistar rats spa/spa is characterised by decreased mRNA expression of the GluR2(B) receptor subunit in the brain and progressive degeneration of cerebellar and hippocampal cells. The first abnormal signs in these animals can be observed at the age of about 28 days - the rats become hyperactive and display tremor and ataxia. Subsequently, motor incoordination and muscle tone increase, and the animals die between 70-85 days of age. Since a decrease in the expression of GluR2(B) receptor subunit correlates with increased  $\text{Ca}^{2+}$  permeability of glutamate-activated channels and may contribute to the pathogenesis of neurodegeneration, we investigated whether chronic administration of the NMDA antagonist 3-( $\pm$ )-2-carboxypiperazin-4-yl)-propyl-1-phosphonate (CPP) may improve motor performance and prolong survival of mutant rats.

CPP (1 mg/kg/h) or vehicle were chronically administered i.p. by means of osmotic minipumps to rats at the age of 21-28 days and the motor coordination, locomotor activity and electromyographic activity were recorded. Treatment of mutant rats with the NMDA antagonist CPP did not improve the performance of the animals in tests of motor coordination and locomotor activity. Furthermore the onset of neurological symptoms and survival of mutant animals were not altered by the treatment. From these results it may be concluded that NMDA receptor antagonists may not be beneficial in the treatment of chronic neurodegeneration seen in spa/spa rats.

## 11.4

**NMDA-INDUCED c-fos and hsp70 mRNA EXPRESSION IN NEONATAL RAT CEREBROCORTICAL SLICES.** K. Hasegawa<sup>1</sup>, M.T. Espanol, L. Litt, F.R. Sharp, P.H. Chan, Depts. of Anesthesia, Neurology, Neurosurgery, The University of California, San Francisco, CA 94143

The temporal course of c-fos and hsp70 gene induction was studied during cell death induced by N-methyl-D-aspartate (NMDA), and during cell death blockade by MK801 (dizocilpine) pretreatment. In each of 3 experiments, forty 350  $\mu$ m thick cerebrocortical slices, obtained from ten 7-day old Sprague-Dawley rats, were studied during hyperoxic perfusion. A 30 min exposure to NMDA (100  $\mu$ M) or NMDA+MK801 (50  $\mu$ M) was followed by 8 hours of perfusion. In control experiments untreated slices were perfused for 11.5 hours. In situ hybridization of c-fos and hsp70 mRNA was done in 20  $\mu$ m adjacent sections of slices frozen just before treatment, and at 0, 1, 2, 4, 8 hrs after treatment, using <sup>35</sup>S-labeled oligonucleotide probes. Three hrs after decapitation, control slices showed moderate c-fos mRNA expression that plateaued for 2 additional hrs, and then decreased slowly. In control slices hsp70 mRNA was always barely detectable. NMDA treatment caused prolongation of c-fos mRNA expression, compared to control slices. Addition of MK801 attenuated the prolonged expression of c-fos mRNA. NMDA administration caused widespread edematous injury (Nissl stained sections) that was significantly reduced by MK801 administration. This suggests that c-fos involves stimulation of NMDA-type receptors and plays a role in neuronal cell death. MK801 did not reduce the intensity of hsp70 mRNA induction, which occurred weakly 2 hrs after NMDA treatment. This suggests that hsp70 induction was mediated by mechanisms unrelated to NMDA-type receptors. Supported by NIH GM34767, NS14543, NS25372.

## 11.6

**THE GP120-INDUCED RISE IN  $[\text{Ca}^{2+}]_i$  IN RAT HIPPOCAMPAL NEURONES IN CULTURE IS NOT MEDIATED BY NMDA RECEPTORS OR VOLTAGE-GATED CALCIUM CHANNELS.** I. Medina, S. Ghose, B.A. Esplina\* and Y. Ben-Ari, INSERM Unité 29, 123 bd Port-Royal, 75014 Paris; \*Pharmacology Dept., McGill University, Montréal, PQ H3G 1Y6, Canada.

The HIV-1 envelope protein gp-120 generates a rise in intracellular calcium concentration ( $[\text{Ca}^{2+}]_i$ ) in different types of rat brain cultures. The possible mechanisms of gp-120 action involve activation of the NMDA receptor-channels (Lipton et al., 1991), voltage-gated calcium channels (Dreyer et al., 1990) and change of glutamate uptake by astrocytes (Dreyer & Lipton, 1995). We have now studied the pathways involved in gp-120 induced rise of  $[\text{Ca}^{2+}]_i$  in 14-20 days-old culture of P2 rat hippocampal neurones. We used these as gp-120 does not induce a rise in  $[\text{Ca}^{2+}]_i$  in young cultures (<14 days) (see abstract Ghose et al.).  $[\text{Ca}^{2+}]_i$  was measured using confocal scanning microscopy with Fluo-3AM.

We found that gp-120 (200  $\mu$ M) increases  $[\text{Ca}^{2+}]_i$  in 90% of the neurones (n=51) with rise time (10 to 90%) from 30 to 100 s. This effect was mediated neither by NMDA, nor by voltage-gated calcium channels: it was observed in presence of  $\text{Mg}^{2+}$  (2 mM), APV (50  $\mu$ M), an antagonist of NMDA receptors and  $\text{Cd}^{2+}$  (100  $\mu$ M) or D600 (50  $\mu$ M), blockers of calcium channels. These results were confirmed by whole-cell patch-clamp recordings during which gp-120 induced no activation of NMDA or voltage-gated calcium channels or other change in membrane current (voltage clamp mode, -60 mV) or potential (current clamp mode) (n=24).

The rise of  $[\text{Ca}^{2+}]_i$  in neurones was prevented effectively by thapsigargin (10  $\mu$ M), (n=8 out of 9 studied neurones) suggesting an involvement of intracellular calcium stores in gp-120's action.

## 11.8

**ROLE FOR THE MITOCHONDRIAL GLUTAMINASE IN EXCITOTOXICITY IN VITRO.** R.Newcomb<sup>1</sup>\*, X.Sun<sup>2</sup>, L.Taylor<sup>3</sup>, N.Cuthbert<sup>3</sup>, and R. Giffard<sup>2</sup> <sup>1</sup>Neurex Corp. Menlo Park, CA, <sup>2</sup>Dept. Anesthesiology, Stanford Univ. Stanford CA, and <sup>3</sup>Dept. Biochemistry and Molecular Biology, Colorado State University, Fort Collins, CO.

We have been testing the hypothesis that neuronal death results in an exposed form of the mitochondrial glutaminase (Glnase), and that the enzyme subsequently produces significant amounts of glutamate (Glu). Healthy cultures of pure neurons did not generate significant amounts of extracellular Glu ( $\leq 0.025 \mu\text{M}/\text{min}$ ) during short term exposure to physiological concentrations of glutamine (Gln) (up to 2 hr at 2 mM). When damaged by 5 hr exposure to NMDA, or by 5-24hr exposure to Gln, the same cultures rapidly generated Glu (0.3-1.0  $\mu\text{M}/\text{min}$ ) from Gln, consistent with an earlier report (Glia 4 91). Glu generation by damaged neurons exposed to Gln was abolished by 30  $\mu\text{M}$  of the membrane impermeant Glnase inhibitor, p-chloromercuriphenylsulphonate (pCMPS). Since pCMPS does not inhibit the Glnase in intact mitochondria (Arch.Biochem.Biophys.242 1), an exposed form of the Glnase is implicated. Western blotting, as well as assay of Glnase activity, showed that the Glnase remained in fragments of neurons after damage. Can Gln neurotoxicity in hypoxic neuronal/glial cultures (Neurosci.Lett.94 57) be accounted for by this Glnase activity? Medium Glu is elevated from 0.3-0.8  $\mu\text{M}$  to 3-4  $\mu\text{M}$  by the combination of 2 mM Gln and 5 hr hypoxia. This amount of Glu is consistent with 1)The toxicity of Glu in pure neuronal cultures (IC50 2-10  $\mu\text{M}$ ) and 2)The neuronal death caused by 2 mM Gln in hypoxic mixed cultures (c.20%, or 2X the neuronal death with 0.05-0.1 mM Gln). The rate of Glu production by Glnase in damaged neurons, when compared with the rate of clearance of Glu from hypoxic mixed cultures, is consistent with this 3  $\mu\text{M}$  concentration of Glu. Finally, pCMPS protects neurons from damage caused by prolonged exposure to Gln. Funded by Neurex and grants from the NIH to N.C.(DK37124) and R.G. (GM49831)

**NEURONAL DEATH IN CYTOKINE-ACTIVATED PRIMARY HUMAN CNS CELL CULTURE: ROLE OF NITRIC OXIDE SYNTHASE 2, TNF $\alpha$  AND EXCITOTOXINS** M. Downen, T. Amaral and S.C. Lee. Dept. Pathology, Albert Einstein College of Medicine, Bronx, NY 10461.

Recent studies of rodent neurons and PC12 cells have demonstrated an important role for nitric oxide (NO) in neuronal toxicity. Currently debated issues include the role of different nitric oxide synthase (NOS) isoforms and the relationship of NO-mediated toxicity to that mediated by excitotoxins and superoxide radicals. In humans, the expression of NOS in CNS cells and its role in neuronal cytotoxicity have not been clearly defined. We examined mediators of neuronal death in primary mixed cell cultures prepared from human fetal cerebrum. In these cultures, astrocytes, but not microglia, selectively express inducible NOS (NOS2) after exposure to IL-1 $\beta$  and IFN $\gamma$ . Neuronal death is prevented by inhibitors of NO production (N<sup>G</sup>-monomethyl L-arginine or L-nitroarginine methyl ester), but not by glutamate receptor antagonists (2-APV, MK-801, or CNQX), or superoxide dismutase. An antibody to TNF $\alpha$  partially inhibits neuronal toxicity and production of NO in cultures treated with IL-1 $\beta$  and IFN $\gamma$ , while TNF $\alpha$  alone (1-100 ng/ml) has no effect. In combination with IL-1 $\beta$ , TNF $\alpha$  mediates neuronal toxicity via induction of NOS2 in astrocytes. These results clearly demonstrate that in primary human CNS cell cultures, NO released by activated astrocytes mediates neuronal toxicity through pathways that are independent of glutamate receptor stimulation or formation of peroxynitrite. Furthermore, TNF $\alpha$ 's role in neuronal toxicity in primary human neuroglial cultures is indirect and is mediated through production of NO. ## 11.10

**MAGNESIUM (Mg) PROTECTS AGAINST COCAINE-INDUCED HEMORRHAGIC STROKES IN A RAT MODEL: A <sup>31</sup>P-NMR IN-VIVO STUDY.** B.M. Altura, A. Gebrewold, B.T. Altura and R.K. Gupta. SUNY Health Sci. Ctr. at Bklyn, NY 11203 and Albert Einstein Col. Med., Bronx, NY 10461.

Cocaine (COC) abuse results in an increased incidence of aneurysmal subarachnoid hemorrhages, intracerebral hemorrhages, and occlusion-type strokes in humans. We have reported that COC administration to anesthetized rats can produce hemorrhagic strokes (HS), which are associated with loss of whole brain intracellular free Mg ions ([Mg<sup>2+</sup>]<sub>i</sub>), falls in intracellular pH (pHi), progressive falls in phosphocreatine (PCr) and elevation of inorganic phosphate (Pi) up until death. In-vivo <sup>31</sup>P-NMR studies were undertaken with anesthetized rats to determine whether systemic administration of MgCl<sub>2</sub> (10  $\mu$ mol/min for 45 min) could protect animals against COC-induced HS; and 2. A relationship exists between basal levels of brain [Mg<sup>2+</sup>]<sub>i</sub> and stroke risk. <sup>31</sup>P-NMR spectra were obtained at various intervals of time (3-120 min, or up until death) after COC (5, followed by 30 mg/kg at 2 hr). Ion selective electrodes were used to measure plasma Mg<sup>2+</sup>, K<sup>+</sup>, Na<sup>+</sup> and Ca<sup>2+</sup>. 40% of animals died in the absence of Mg<sup>2+</sup> infusion following COC. Only 18% died with Mg<sup>2+</sup> infusion ( $p < 0.05$ ). In the Mg<sup>2+</sup>-protected animals, neither [Mg<sup>2+</sup>]<sub>i</sub>, pHi, [PCr]/[ATP], nor [Pi]/[ATP] fell when toxic and lethal doses of COC were given. Low basal brain [Mg<sup>2+</sup>]<sub>i</sub> ( $275 \pm 24$  vs.  $466 \pm 75 \mu$ M) and low basal brain [PCr] ( $3.36 \pm 0.35$  vs.  $4.26 \pm 0.25$  mM) were found to result in a 2-fold increased incidence of stroke. A positive correlation ( $r = 0.31$ ,  $p < 0.03$ ) between brain [Mg<sup>2+</sup>]<sub>i</sub> and [PCr]/[ATP] was found. It is possible that basal brain [Mg<sup>2+</sup>]<sub>i</sub> and [PCr] may be useful as important predictors of susceptibility to COC HS. (Supported in part by NIAAA Grant AA-08674).

## INVERTEBRATE LEARNING AND BEHAVIOR I

## 12.1

**INDUCTION OF LTD OF CULTURED APLYSIA SENSORIMOTOR SYNAPSES IS BLOCKED BY POSTSYNAPTIC BAPTA AND BY NIFEDIPINE, BUT NOT BY D-APV OR BY OKADAIC ACID.** S. Chen, X. Y. Lin, and D. L. Glanzman\*. Dept. Physiol. Sci., UCLA, Los Angeles, CA 90024.

*Aplysia* sensorimotor synapses in cell culture exhibit long-term depression (LTD) following 2-Hz activation of presynaptic sensory neurons (Lin and Glanzman, *Soc. Neurosci. Abstr.* 21:1023, 1995). To determine whether this form of invertebrate LTD is mechanistically similar to hippocampal LTD, we tested the effect on LTD of sensorimotor synapses of several compounds reported to block the induction of LTD of CA1 hippocampal synapses (Mulkey and Malenka, 1992; Mulkey et al., 1993; Bolshakov and Siegelbaum, 1994). Injection of the Ca<sup>2+</sup> chelator BAPTA (200 mM in the recording electrode solution,  $n = 9$ ) into the postsynaptic motor neuron prior to 2-Hz presynaptic stimulation blocked the induction of LTD of sensorimotor synapses, as did postsynaptic injection of the L-type Ca<sup>2+</sup> channel blocker nifedipine (500  $\mu$ M in the electrode solution,  $n = 11$ ). By contrast, LTD of sensorimotor synapses was not blocked by the NMDA receptor antagonist D-APV (100  $\mu$ M in the perfusion medium,  $n = 8$ ), nor by the protein phosphatase inhibitor okadaic acid (500 nM in the perfusion medium,  $n = 7$ ). The lack of an effect of D-APV on LTD of sensorimotor synapses is particularly interesting, because this NMDA receptor antagonist does block the induction of long-term potentiation (LTP) of *Aplysia* sensorimotor synapses (Lin and Glanzman, 1994). We conclude that LTD of cultured *Aplysia* sensorimotor synapses requires Ca<sup>2+</sup> entry into the motor neuron through L-type channels, but does not require activation of NMDA-related receptors nor activation of protein phosphatases 1 and 2A. The cellular mechanisms underlying LTD of *Aplysia* sensorimotor synapses in culture appear to resemble those underlying LTD of synapses in the CA1 region of the neonatal mammalian hippocampus (Bolshakov and Siegelbaum, 1994).

## 12.2

**NONASSOCIATIVE ENHANCEMENT OF APLYSIA SENSORIMOTOR SYNAPSES IS NOT BLOCKED BY D-APV.** G. G. Murphy\* and D. L. Glanzman. Interdepartmental Program in Neuroscience, School of Medicine, and Department of Physiological Science, UCLA, Los Angeles, CA 90024.

Enhancement of sensorimotor synapses in the cellular analog of classical conditioning in *Aplysia* requires a postsynaptic rise in Ca<sup>2+</sup> (Murphy and Glanzman, *Soc. Neurosci. Abstr.* 20:1072, 1994). This essential rise in postsynaptic Ca<sup>2+</sup> appears to be mediated, in part, by training-induced activation of NMDA-related receptors, because the NMDA receptor antagonist D-APV significantly reduces the synaptic enhancement due to conditioning (Murphy and Glanzman, *Soc. Neurosci. Abstr.* 21:1023, 1995). An alternative explanation for this result, however, is that D-APV interfered with the activity, or efficacy, of facilitatory interneurons thought to mediate classical conditioning in *Aplysia*. To investigate this possibility, we tested whether D-APV disrupts nonassociative enhancement of sensorimotor synapses following unpaired presentations of the US and CS in the cellular analog of classical conditioning of *Aplysia*'s siphon withdrawal reflex (Hawkins et al., 1983). Both the preparation and experimental protocol were similar to those of our previous experiments (Murphy and Glanzman, 1995), except that the CS (brief activation of a siphon sensory neuron) and US (pedal nerve shock) were delivered in unpaired, rather than paired, fashion during training. Unpaired training resulted in nonassociative enhancement of the monosynaptic sensorimotor EPSP measured 60 min after the end of training (mean EPSP =  $136 \pm 17\%$  of the pretest EPSP,  $n = 3$ ). Unpaired training in the presence of the D-APV (100  $\mu$ M in the bathing medium) produced similar enhancement of the monosynaptic EPSP (mean EPSP =  $160 \pm 30\%$  of the pretest EPSP,  $n = 3$ ). Our results therefore suggest that D-APV's effect on associative synaptic enhancement in the conditioning analog is not due to disruption of the activity, or efficacy, of facilitatory interneurons recruited by the US.

Supported by funds from NSF, NIH, NIMH, and the State of California.

## 12.3

**DEGENERATION OF IDENTIFIED PEPTIDERGIC NEURONS IN THE BRAIN OF A MOLLUSC AND CESSATION OF EGG LAYING BEHAVIOUR.** C. Janse, M. van der Roest, E. J. G. Dubelaar (SPON: European Neuroscience Association). Graduate School of Neurosciences Amsterdam, Research Institute Neurosciences Vrije Universiteit, Faculty of Biology, Vrije Universiteit, De Boelelaan 1087, 1081 HV Amsterdam, The Netherlands.

In *Lymanaea stagnalis* caudodorsal cells (CDCs) selectively degenerate at the age of cessation of egg laying behaviour. The initial stages of degeneration consist of reduction of branching patterns of CDCs (Janse et al., *J. Neurobiol.* 29: 202, 1996). CDCs control egg laying behaviour and are located in the cerebral ganglia in two clusters totalling 100 electrically and chemically coupled cells. Preceding egg laying, CDCs become electrically active and release peptides at the cerebral commissure (CC) into the blood. CDCs have an ipsilateral axon that branches into the CC. Ventral CDCs are important for activation of the entire system; they have special synaptic input sites and have in addition to the ipsilateral axon an axon that crosses the CC and makes a contralateral loop (electrical and chemical contacts with CDCs) to branch again in the CC. Cessation of egg laying may be due to degeneration and electrical dysfunction of increasing number of CDCs of different types. Alternatively, ventral CDCs might deteriorate first. In the present study neurophysiological properties and gross morphology were studied of CDCs. Electrical and chemical coupling were studied with hyperpolarizing stimuli and by induction of depolarizing after potentials (DAP) respectively, into one CDC while recording another. DAPs and afterdischarges were induced with electrical stimuli (2 Hz). Subsequently one of the recorded CDCs was filled with LY. Reduced branching patterns especially occurred in ventral CDCs, other CDCs seemed to be less reduced. This indicates that ventral CDCs start to degenerate first. Reduced ventral cells still had an axon crossing the CC and still were electrically coupled to contralateral CDCs. Moreover, most cells produced a DAP and an afterdischarge which could be transmitted to other CDCs. Obviously, electrical and chemical transmission between CDCs stays present even during considerable morphological reduction of the ventral CDCs. Possibly, cessation of egg laying is due to the input sites of ventral CDCs being turned off. The latter may be part of the degeneration process in the CDCs.

## 12.4

**NONASSOCIATIVE SYNAPTIC PLASTICITY AT TYPE B TO A PHOTORECEPTOR CONNECTIONS IN HERMISSENDA.** L. M. Schultz\*, E. S. Lee, and G. A. Clark. Program in Neuroscience, Psychology Department, Princeton University, Princeton, NJ 08544.

The positive phototactic response of *Hermissenda* is suppressed following classical conditioning with a light conditioned stimulus (CS) and a rotation unconditioned stimulus (US). A lesser-understood, weaker suppression of phototaxis results from US- or CS-alone training. To determine possible neuronal mechanisms for these nonassociative effects, we investigated whether activation of the US or CS pathways would induce synaptic facilitation at the inhibitory type B to A cell connections. We found that activation of the US pathway by mechanical statocyst stimulation enhanced the inhibitory postsynaptic potentials (IPSPs) evoked in type A cells by intracellular stimulation of type B cells. This enhanced synaptic inhibition may represent a means by which US-alone training leads to suppression of phototaxis. We next examined the effects of activating the CS pathway by measuring changes in the synaptic strength of type B to A cell connections both during and after evoked type B cell activity. We found that during stimulus trains (interstimulus intervals of 0.3, 3, or 30 sec), there was a monotonic decrease in IPSP amplitude, with greater synaptic depression occurring at higher stimulation frequencies. In contrast, the IPSP amplitude was increased following high frequency activation of type B cells by either light or intracellular stimulation, which may represent a mechanism for CS-elicited suppression of phototaxis. Given that the type B to A photoreceptor synapse displays both depression and facilitation, this synapse may serve as an important control point in the neural circuitry for phototaxis.

## 12.5

NEURAL CORRELATES INTRINSIC TO PRE-SYNAPTIC AND POST-SYNAPTIC NEURONS IN THE CS PATHWAY OF CONDITIONED *HERMISSENDA*. R. J. Fryszak and T. Crow\*. Department of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77030

Identified type A photoreceptors of *Hermisenda* express differential effects of classical conditioning. Lateral type A photoreceptors exhibit an increase in excitability to both the conditioned stimulus (CS; light) and extrinsic current (Fryszak & Crow, 1993). In contrast, medial type A photoreceptors do not express enhanced excitability, but do show synaptic enhancement expressed by an increase in the amplitude of spike-elicited IPSPs following conditioning (Fryszak & Crow, 1994). Therefore, both enhanced excitability and changes in synaptic strength may contribute to long-term plasticity underlying classical conditioning. The activation of protein kinase C (PKC) has been implicated in the expression of enhanced excitability in B photoreceptors following classical conditioning. We have examined a possible role for PKC in the expression of enhanced excitability in lateral type A photoreceptors and synaptic enhancement in medial type A photoreceptors following classical conditioning. Spike frequency elicited by multiple extrinsic current steps in lateral type A photoreceptors of conditioned animals (N=10) was significantly reduced following intracellular injection of the PKC inhibitor peptide PKC(19-36) as compared to random controls (N=8) ( $p < .001$ ). Injection of the non-inhibitory analog peptide ([Glu<sup>27</sup>]PKC(19-36) did not affect excitability measured over multiple current steps (N=5). Conditioning resulted in an enhancement of IPSP amplitude recorded from the medial A cells as compared to the random controls (N=13) ( $p < .05$ ). However, injection of PKC(19-36) into the medial B cells did not significantly affect IPSP amplitude in conditioned animals or the random controls. We next examined the effects of PKC(19-36) on 5-HT induced facilitation, a PKC dependent phenomenon. 5-HT produced an enhancement of IPSP amplitude in the medial A ( $p < .05$ ). Enhancement was blocked in a group that received PKC(19-36) injections before 5-HT application. Thus, enhanced excitability in the lateral A photoreceptor of conditioned animals may involve a different mechanism from synaptic enhancement of the connection between the medial B and medial A photoreceptor detected after conditioning. Supported by a grant from NIMH.

## 12.7

TYROSINE KINASE INHIBITORS BLOCK CONDITIONING-PRODUCED CHANGES IN *Hermisenda* TYPE B CELLS. J. Jin\* and J. Farley, Program in Neural Science, Indiana University, Bloomington, IN 47405.

Bath-application of 100  $\mu$ M genistein, a protein tyrosine kinase (PTK)-inhibitor, reduced *in vitro*-conditioning (5 pairings of light and electrical stimulation of statocyst hair cells) produced cumulative depolarization of type B photoreceptors by 79%. Leakage of genistein or lavendustin A (another PTK inhibitor) from the recording electrode into B cells prior to conditioning reduced depolarization by 78% and 51%, respectively. To explore possible interactions between PTKs and PKC in B cells, the preceding experiments were repeated following exposure of B cells to specific activators or inhibitors of PKC. Exposure of the nervous system to the PKC activator, PMA, occluded B cell depolarization by ~50%. The remaining PMA-resistant depolarization was blocked by lavendustin A. Iontophoresis of the PKC pseudosubstrate inhibitor, PKC [19-31], into a type B cell reduced cumulative depolarization by 42%. Bath application of genistein completely prevented the development of PKC [19-31]-resistant depolarization. Voltage-clamp analysis of the effects of genistein upon the  $K^+$  currents of B cells (that are reduced by both conditioning and PKC-activation) revealed a selective increase in the A-type current of untrained specimens by ~25%. The delayed-currents ( $I_{K,V}$  and  $I_{K,Ca}$ ) were not affected. Our results suggest that PTK and PKC signal-transduction pathways both contribute to the occurrence of short-term, learning-produced changes in B cell excitability. Supported by grants from NIH.

## 12.9

GABA RECEPTOR STAINING IMPLIES FUNCTIONAL SUBDIVISION OF MUSHROOM BODIES. T.M. Brotz\* and A. Borst. Friedrich-Miescher-Laboratory of the Max-Planck-Society, Spemannstr. 37-39, D-72076 Tuebingen, Germany.

The mushroom bodies of dipteran and hymenopteran insects, a paired central brain region, are involved in olfactory learning. Until recently, the mushroom bodies have been thought to consist of a mainly isomorphic array of Kenyon cells. This view has been changed by recently published enhancer trap expression patterns in the mushroom bodies of *Drosophila* (Yang et al. 1995, Neuron, 15: 45) suggesting a subdivision of the Kenyon cell population. We have conducted antibody stainings against the Rdl-subunit of the insect GABA receptor in the blowfly *Calliphora erythrocephala*. Compared to all other neuropiles, immunoreactivity is by far strongest in the mushroom bodies. Furthermore, the regions of highest immunoreactivity are confined to the axonal part of the Kenyon cells. Cross sections of the pedunculus, the  $\alpha$ - and  $\beta$ -lobes show one or two (depending on the section plane) unstained core structures surrounded by strong concentric immunoreactivity. The posterior part of the pedunculus appears to be subdivided into discrete immunoreactive fascicles which segregate clearly before they project into the calices. Although the  $\gamma$ -lobes are also significantly labeled they do not show the concentric core-surround structure but a characteristic, complex subdivision into a number of compartments. This Rdl-immunoreactivity pattern has striking similarities with the enhancer trap lines mentioned above. Some of these lines, thus, could well be associated with GABA receptor expression. Additional staining against GABA revealed the presence of a number of GABA-immunoreactive neurons that are more or less homogeneously interspersed in the Kenyon cell array and that do not form such characteristic patterns as the Rdl-immunoreactive fibers. Taken together, these results reveal that (i) the population of Kenyon cell fibers is not homogeneous and (ii) inhibitory inputs onto Kenyon cell axons might play an important role for signal processing in mushroom bodies. This work was supported by the Max-Planck-Society.

## 12.6

MAY CYTOSOLIC FREE  $Ca^{2+}$  AFFECT NON ASSOCIATIVE LEARNING PROCESSES IN *H. MEDICINALIS*? M. Brunelli\*, R. Frandi, R. Mozzachiodi, R. Scuri and M. L. Zaccardi. Dip.to Fisiologia e Biochimica "G. Moruzzi", Università di Pisa, 56127 Pisa, Italy.

In the leech *H. medicinalis* it is possible to obtain short term habituation of swim induction by low rate application of electrical stimuli onto the body wall. In T sensory neurons (the first station of the neuronal swim network) the low rate intracellular stimulation elicits an increase of the after-hyperpolarization (AHP) amplitude: this AHP potentiation weakens the synaptic efficacy of the connection between T neuron and its followers.

Behavioral experiments have shown that Nifedipine, a L-type  $Ca^{2+}$  channel blocker, remarkably inhibits the habituation process. By using an electrophysiological approach we have observed that Nifedipine prevents the potentiation of AHP amplitude. These data suggest an important role of extracellular  $Ca^{2+}$  in this form of non associative learning.

In order to test whether also cytosolic free  $Ca^{2+}$  is involved in short term habituation, we have injected into the animals a blocker of  $Ca^{2+}$  release from intracellular stores, TMB-8 (100  $\mu$ M). We have observed a clear-cut reduction of the habituation process.

Preliminary electrophysiological data, at cellular level, show that TMB-8 affects the AHP amplitude. Investigations are in progress in order to clarify whether TMB-8 inhibits the AHP potentiation following low rate repetitive stimulation.

By using other specific antagonists and agonists of intracellular  $Ca^{2+}$  release we will further enlighten, at behavioral and electrophysiological level, the role of cytosolic  $Ca^{2+}$  in short term habituation.

## 12.8

Receptor-Mediated Activation of Phospholipases and Arachidonic Acid Contribute Independently to Sensory Transduction and Activity-Dependent Neuronal Facilitation in *Hermisenda* Type B Photoreceptors. Andrew C. Talk\*, Isabel A. Muzzio, and Louis D. Matzel

Program in Biopsychology and Behavioral Neuroscience, Department of Psychology, Rutgers University, New Brunswick, New Jersey 08903

During contiguous pairings of light and rotation, B photoreceptors in the *Hermisenda* eye undergo an increase in excitability (e.g. input resistance and evoked spike rate) that requires a light-induced rise in intracellular  $Ca^{2+}$  in the photoreceptor concomitant with stimulation of G-protein coupled receptors as a result of presynaptic hair-cell activity. Here, we report that arachidonic acid (ArA) and its metabolites are involved in independent signal transduction pathways that underlie both receptor function and activity-dependent facilitation in the B photoreceptor. 4-Bromophenacyl bromide (BPPB), an inhibitor of phospholipases  $A_2$  ( $PLA_2$ ) and C (PLC), blocked the generation of light-induced depolarizing generator potentials, but had no effect on the inhibitory postsynaptic responses in the B cell in response to hair-cell stimulation. Quinacrine, which predominantly blocks  $PLA_2$  in neurons, had no effect on either the light response or the IPSP, but did block the increase in cell excitability (i.e. increased input resistance and spike rate) caused by pairings of light and presynaptic hair-cell stimulation. Neither nordihydroquaiaric acid (NDGA), which inhibits metabolism of ArA by cyclooxygenase, nor indomethacin, which inhibits lipoxigenase metabolism of ArA, had effects on the light response or IPSP, but both blocked the activity-dependent increase in excitability. In light of prior results indicating that ArA activates PKC in a synergistic fashion with  $Ca^{2+}$  and DAG in the B cell, the present experiments strengthen the possibility that  $PLA_2$  induced ArA release is a critical component of the signal convergence that produces associative learning in the system.

## 13.1

PRESERVATION OF MOTRICITY IN MACAQUE MONKEYS AFTER UNILATERAL NEONATAL LESION OF THE HAND AREA OF THE PRIMARY MOTOR CORTEX (M1). E.M. Rouiller<sup>(1)</sup>, V. Moret<sup>(1)</sup>, A. Tempini<sup>(1)</sup>, X.H. Yu<sup>(1)</sup> and M. Wiesendanger<sup>(2)\*</sup>. Dept. of Physiology, University of Fribourg, 1700 Fribourg<sup>(1)</sup>, Dept. of Neurology, University Hospital, 3010 Bern<sup>(2)</sup>, Switzerland.

Unilateral lesion of the hand representation of M1 in adult monkeys has devastating effects on the finely controlled motricity with digits of the opposite hand, such as the precision grip ability. However, following such a lesion at the neonatal stage, monkeys when adult exhibited a significant preservation of manual skill. The aim of the study was to investigate the plastic changes possibly underlying this preserved skill. Previous experiments in rats provided neuroanatomical evidence that the intact opposite hemisphere may contribute to the functional preservation of motricity, by re-directing some corticospinal (CS) axons to the denervated cervical cord. In monkeys, we found little evidence for axonal redirection from the intact hemisphere. First, as assessed by tracing experiments, the CS projection originating from the intact M1 hand representation was not significantly modified. Second, transient inactivation (by infusion of lidocaine) of the intact M1 did not change the behavioral score (precision grip task) of the hand partly deprived of its contralateral pyramidal input, while the performance of the "normal" hand (contralateral to the intact inactivated M1) was dramatically reduced. As assessed by transient inactivation, the supplementary motor area (SMA) on both sides did not contribute to the functional preservation of motricity. However, a comparison of the effects of IntraCortical MicroStimulations (ICMS) in the two hemispheres showed that the cortical territory adjacent to the lesioned M1 zone has been re-organized: in a zone normally representing proximal muscles, ICMS elicited clear movements of the fingers of the pyramidally deprived hand. The functional contribution of this peri-lesion territory was supported by the observation of a dramatic decrease of the behavioural score of the "affected" hand when this peri-lesion territory was transiently inactivated. In conclusion, structural cortical reorganization appears to contribute significantly to the partly maintained functional motricity after neonatal cortical lesion of the hand area of M1.

## 13.3

EVIDENCE FOR VISUO-MOTOR PROCESSING IN THE DIRECTIONAL FIRING OF MOTOR CORTICAL NEURONS. M.T.V. Johnson\*, J.D. Coltz, M.C. Hagen, T.J. Ebner. Depts. of Neurosurgery and Physiology, University of Minnesota, Minneapolis, MN 55455.

It is well known that both visual and movement information are combined in cortical regions surrounding the superior parietal sulcus. However, the degree to which motor cortical neuronal firing is influenced by visual information is less clear. To define the extent of visual processing in the primate motor cortex, a two-dimensional tracking paradigm requiring equal time for the observance and the tracking of a constant velocity target was used. A target appeared at the periphery of the workspace and moved to a central start box in which a cursor corresponding to the position of the animal's hand was waiting (Cue period). As the target moved away from the start box, the primate tracked so that the cursor remained within the target box (Tracking period). This task sequence was performed over 8 directions and 4 constant velocities.

The directionality of neuronal firing during the Cue and Tracking periods was evaluated using linear regression. A significant fit to a cosine function was found for 133/160 neurons (82 both in C and T, 15 in C, and 36 in T) in two monkeys. Neurons with significant directionality in both C and T periods had preferred directions which differed by a mean of 70°. Both C and T were then halved into early and late periods. Relative to the late Tracking period, the mean change in preferred direction was greatest for the early C (78°), less for the late C (46°), and least for the early T (22°) periods. The distributions differed significantly (Watson's F-test).

Individually and collectively, the preferred direction of neurons differed between the Cue and Tracking periods. The convergence of the "visual" preferred direction to that of the late tracking phase occurred gradually over the earlier periods. The large shifts in preferred direction between the Cue and Tracking periods suggest that substantial processing of visual target information takes place in the motor cortex. Supported by NIH grant NS07361.

## 13.5

DIGITAL VIDEO: A TOOL FOR CORRELATING ELECTROPHYSIOLOGY WITH BEHAVIOR. E.P. Gardner and J.Y. Ro. Department of Physiology and Neuroscience, NYU Medical Center, New York, NY 10016.

The ability to correlate motor behavior with neurophysiological activity has been limited by disparities in technologies used to monitor activity. We demonstrate how digital multimedia techniques allow simultaneous imaging of hand movements and spike trains recorded from the cerebral cortex while monkeys perform a prehension task. Monkeys are trained to grasp, lift and lower knobs (spheres, cylinders, and rectangular blocks) using visual cues. Hand movements are videotaped with two Hi8 cameras, digitally mixed and recorded on a Hi-8 computer video deck; spike trains are stored as an audio signal on the videotape. Hi-8 tapes are striped with RC time code, an electronic tag that numbers each frame, allowing precise synchronization of audio and video when they are digitized. QuickTime (QT) movies are made off-line using digital editing software; video and neuronal signals in 5 min clips are digitized simultaneously using a hardware video capture board interfaced to a Macintosh 840AV computer. Digital video provides a snapshot of the hand position every 33 ms, and precise calibration of the synchronously recorded spike waveforms digitized at 44 kHz. The spike train is displayed as a strip chart in a separate window. QT movies allow a frame-by-frame analysis of hand movements and the corresponding spike activity by matching the precise time codes in the video and the audio windows of the editing program. Subtle changes in hand position from frame to frame are evident in these pictures when they are placed in motion. We show that the kinematics of prehension and specific characteristics of the spike train are reproducible from trial-to-trial, and over several months of study. These imaging methods permit non-invasive, nontraumatic monitoring of behavior in experimental animals, and provide high quality records of synchronized neuronal spike trains. (Supported by Research Grant NS11862 from NINDS).

## 13.2

MOTOR CORTICAL ACTIVITY DURING TARGET MOTION IN THE PRESENCE AND ABSENCE OF MANUAL TARGET INTERCEPTION. N. Lindman Port\*, D. Lee, W. Kruse, & A. P. Georgopoulos. Brain Sciences Center, VAMC, Minneapolis, MN 55417

We investigated whether neurons in the motor cortex are involved in processing temporal properties of a target to be manually intercepted. The impulse activity of 202 cells was recorded in the arm area of the motor cortex of a monkey trained to use a 2D articulated manipulandum in both a "Go" and a "No-Go" task. On a computer screen, a target accelerated, decelerated or traveled at a constant velocity. For each motion type, targets traveled for 0.5, 1.0 and 1.5 s (target motion time). A target appeared randomly in either the right or the left lower corner of the screen, and traveled along a 45° path until it crossed the vertical meridian. In both tasks the monkey was required to maintain stable fixation. In the "Go" task, the monkey made an upward movement (12 cm) to intercept, within 130 ms, the moving target as it crossed the vertical meridian. In the "No-Go" task, the monkey was required to maintain fixation and hold the manipulandum steady, within a positional window.

In the "Go" task 57% and in the "No-Go" task 47% of the cells showed a significant difference in impulse frequency between the pre-target motion period and the target motion period (paired t-test,  $p < 0.05$ ). During the target motion period in the "Go" task there was a significant effect of target motion type, target motion time and direction of target motion on the frequency of discharge in 10%, 32% and 7% of cells, respectively (ANOVA,  $p < 0.05$ ). For the "No-Go" task these percentages were 8%, 30% and 8%, respectively. These results indicate that the motor cortex is involved in processing temporal characteristics of the moving target. ## 13.4

NEURAL CORRELATES OF STATIC AND DYNAMIC PROCESSES DURING ISOMETRIC FORCE OUTPUT IN THE MONKEY.

J. Bolino\*, J. Ashe, Brain Sciences Center, VAMC, and Departments of Physiology and Neurology, University of Minnesota, Minneapolis MN 55417

The activity of cells in the motor cortex has been shown to relate to both static and dynamic force output. However, there is no consensus as to the proportion of cells that relate exclusively to static or to dynamic force, or to both. We examined this issue in monkeys trained to use the arm to exert force on an isometric manipulandum in two different tasks. In the *dynamic* task the animal produced pure dynamic force pulses in eight different directions, while in the *static* task the animal maintained a steady force in the same eight directions. The tasks were carefully matched such that the direction and magnitude of force output was similar in each; they differed only to the extent that one task was purely dynamic and the other static. We recorded the activity from each of 299 neurons in the motor cortex of the monkey during the performance of both tasks. There were significant ( $p < 0.05$ ) changes in activity in 180 (60.2%) cells during both the static and dynamic tasks. Forty four (14.7%) cells changed activity exclusively during the dynamic task, while 34 (11.4%) cells were active only during the static task. These findings suggest the following: (1) within the motor cortex there are three functionally distinct groups of cells that relate to static and dynamic processes during isometric force output, (2) the proportion of cells that relate exclusively to static or dynamic force output is small relative to the total population of cells engaged during either process. (Supported by a Merit Review Grant from the Department of Veterans Affairs)

## 13.6

CUTANEOUS MECHANORECEPTORS IN HAIRY SKIN SIGNAL HAND KINESTHESIA. J.Y. Ro\*, S. Ghosh\* and E.P. Gardner. Dept. of Physiology & Neuroscience, NYU Medical Center, New York, NY 10016, and \*Dept. of Physiol. & Pharmacol., Univ. Queensland, St. Lucia, Brisbane, Australia.

To understand the role of active touch in hand motor function, we correlated firing patterns of S-I cortical neurons with the kinematics of hand movements during prehension. Three monkeys were trained to grasp, lift and lower knobs of different size and shape (spheres, cylinders, cubes and rectangular blocks) in response to visual cues. S-I cortical neurons with tactile receptive fields on the hand dorsum modulate their firing patterns during prehension even when no direct contact is made with the dorsal hairy skin. Most are tonically active, with steady firing rates proportional to the posture of the joints below the tactile fields. 24 of 27 cells respond to active hand and finger movements, whether or not the movement involves contact with an object. Neurons activated during hand movement (MA) fire most vigorously when the hand posture changes, as the grasp is initiated or released. Some also signal grip force during prehension. Movement inhibited (MI) neurons are silenced during sustained grasp and lift; they respond to steady hand posture when the hand rests quietly on the objects. The similarity of responses to tactile stimuli and to active movements suggests that skin stretch during prehension provides important postural and movement information about the hand kinematics when the fingers are used to perform skilled tasks. In contrast to glabrous skin receptors that signal the physical surface parameters of the object, the hairy skin receptors integrate information about the coordinated movements of the fingers that provides feedback to the motor areas of the brain, facilitating skilled manipulation of the environment with the hand. The principal function of tactile hairy units in the hand dorsum is postulated to be cutaneous kinesthesia, rather than tactile exploration. (Supported by Research Grant NS11862 from NINDS).

## 13.7

TEMPORAL COHERENCE PATTERNS BETWEEN SIMULTANEOUSLY RECORDED MOTOR CORTICAL NEURONS DURING PLANAR REACHING MOVEMENTS. Nicholas G. Hatsopoulos\*, Catherine L. Ojakangas, & John P. Donoghue. Box 1953, Dept. of Neuroscience, Brown University, Providence RI 02912.

A major problem in motor control is the manner in which muscles or motor primitives are combined to generate coordinated behavior. Correlation in the firing of motor cortical neurons may provide a way by which motor elements are bound together in a flexible manner. To examine this hypothesis, we recorded from up to 21 neurons simultaneously in motor cortex as a macaque monkey performed a radially-directed hand movement to one of eight possible peripheral targets. Using cross-correlations corrected using a shift predictor (CCR) and normalized joint peri-event time histograms (JPETH's), we found that the coherence between neurons modulates sharply around movement onset and could not be predicted by the firing rate alone. Moreover, both coherence measures (CCR and JPETH) appear to reflect interactions between neurons above those due to common firing modulation. We observed either phasic increases or decreases in coherence or tonic increases which continued to the end of the trial despite phasic modulation in firing rate of neurons. Of 112 neuron pairs examined, about 70 percent showed changes in correlation at around movement onset. The sign of these coherence changes seemed to depend partly on the tuning properties of the constituent neurons. Cells with opposite preferred directions exhibited a transient (100-250 ms) de- or anti-correlation at movement onset followed by a positive correlation. On the other hand, most cells with similar preferred directions showed a strong positive correlation around movement onset. These modulation in coherence may reflect the formation of flexible synergies among motor elements by motor cortical cell ensembles. Supported by NIMH MH19118 & NIH NS25074.

## 13.9

SYNCHRONIZATION BETWEEN FIELD POTENTIALS OF OLFACTORY BULB, SOMATOMOTOR, VISUAL, AUDITORY AND ENTORHINAL CORTICES OF AWAKE CATS

G. Gaál\*, P. German, S. Oshory, A. Smart and W. J. Freeman, University of California, Berkeley

Widespread intermittent synchrony in oscillations has been observed in neural and muscle activity in primates and cats. It has been debated whether it was related to attention (Kreiter & Singer, 1992; Murthy & Fetz, 1992; Gaál et al., 1992; Sanes & Donoghue, 1993; Roelfsema et al., 1995; Bressler & Nakamura, 1995; Menon et al., 1996). We have recorded EEGs from OB and surface epidural arrays over the SM, AI, VI and EC cortices from four awake cats, trained in a visuomotor or in an audiomotor task using CS+ /CS- stimuli. OB oscillations in the 50-60 Hz range were observed on the crests of the respiratory waves and in the 35-45 Hz range in the troughs of the slow waves both at rest and in the tasks. The OB bursts centered on 40 Hz in the task were often noted within 500 msec preceding the sensory stimuli (either CS+ or CS-) and before bar release (CR). They were regularly preceded or accompanied by bursts of similar frequency in SM and occasionally also in EC but rarely in AI or VI. Gamma bursts in AI became more apparent when the animals were retrained in the auditory task following visual discrimination. The spectra from AI, EC and VI showed an increase in beta but no change in the gamma range between task conditions and rest. The spectra from OB and SM did not change significantly in various behavioral conditions and across subjects. Jacobian matrices of nonlinear functions of EEG activity recorded simultaneously in the five brain areas (Gaál et al., 1995) revealed time segmentation of EEGs, relating to behavior, demarcated by valleys of low error. Supported by NIH R37 MH06686-31 and ONR-N00014-93-1-0938.

## 13.8

CHANGES IN SYNCHRONOUS ACTIVITY OF SIMULTANEOUSLY RECORDED NEURONS IN THE MOTOR CORTEX DURING EVOLVING MOVEMENTS. Catherine L. Ojakangas\*, Nicholas G. Hatsopoulos, and John P. Donoghue. Dept. of Neuroscience, Box 1953, Brown University, Providence, RI 02912 email: cojakang@brownvm.brown.edu

We have recently begun using a Utah multiple-electrode array to record synchronous activity of motor cortical (MI) populations in the monkey. As described in Hatsopoulos et al. (this meeting), during simple, targeted arm movements the activity of MI neurons becomes correlated, particularly around movement onset. These correlations may reflect binding of motor components into functional synergies. What happens to temporal correlations when movements are adapted over time? The activity of 21 MI neurons was recorded simultaneously while the monkey moved a cursor from a central hold zone to one of three targets. In an adaptation phase, one target was extinguished after movement initiation and a second target was illuminated, requiring the animal to redirect its movement. With the adaptation requirements held constant, movements changed gradually until they resembled direct movements to the second target. Cross correlations and joint peri-event histograms between 504 pairs of neurons revealed that activity was highly correlated before adaptation in 58% (294) beginning around movement onset. During adaptation, however, significantly correlated neuronal activity was weak or absent in 63% of these (186/294) and reduced in the majority of the remainder. With time, as the movements began to resemble the control movements, significant synchronous activity again emerged in 94% (175/186) of the neuronal pairs. This desynchronization and resynchronization of neuronal activity may reflect reorganization of motor cortical circuitry necessary to adapt new movement patterns to changing behavioral requirements. Supported by: NS25074.

## ALZHEIMER'S DISEASE: PATHOLOGICAL MECHANISMS

## 14.1

BRAIN  $\beta$ -SPECTRIN IS AN INTEGRAL COMPONENT OF AMYLOID PLAQUES IN ALZHEIMER'S DISEASE. R.K. Sihag\* and A.M. Cataldo. Mailman Research Center, McLean Hospital, Harvard Medical School, Belmont, MA 02178.

Spectrin, an  $\alpha\beta$  heterodimer, is a major constituent of the neuronal membrane skeleton. Increased proteolysis of spectrin has been identified as an early neurodegeneration marker following glutamate excitotoxicity, denervation, hypoxia and ischemia. In this study, we carried out immunohistochemical studies to examine whether or not spectrin was abnormally processed in Alzheimer's disease (AD). We raised antibodies to the N-terminal actin-binding region of  $\beta$ -spectrin<sub>N&G</sub>, C-terminal region of  $\beta$ -spectrin<sub>C</sub>, and  $\alpha$ -spectrin<sub>G</sub>. We report here that the  $\beta$ -subunit of spectrin is an integral component of  $\beta$ -amyloid plaques. When tissues from postmortem AD brains were immunostained with either the N-terminal or the C-terminal domain-specific affinity-purified  $\beta$ -spectrin antibodies,  $\beta$ -amyloid plaques were specifically stained in the cortical parenchyma in approximately one third of the cases. The immunostaining was unaffected by preadsorption of  $\beta$ -spectrin antibodies with A<sub>4</sub>/B<sub>1-40</sub> peptide. Pretreatment of the tissue sections from AD brains displaying  $\beta$ -spectrin negative amyloid plaques with formic acid for antigen retrieval did not show immunostaining with either the N-terminal or C-terminal domain-specific  $\beta$ -spectrin antibodies. The SDS-insoluble amyloid plaques were also stained by the  $\beta$ -spectrin antibodies. The anti- $\alpha$ -spectrin antibody stained neuronal processes, but not amyloid plaques. The presence of  $\beta$ -spectrin in the amyloid plaques in a subset of AD cases suggests that distinct biochemical pathways are involved in the formation or deposition of  $\beta$ -amyloid plaques and that an abnormality of  $\beta$ -spectrin structure or function may be involved in the formation or deposition of  $\beta$ -amyloid in plaques in a subset of AD cases. METABOLISM OF PRION PROTEIN IN THE AMBER CODON 145 MUTATION. N. Singh\*, G. Zanusso, P. Gambetti, R.B. Petersen. Division of Neuropathology, Case Western Reserve University, Cleveland, Ohio 44106.

Several mutations in the prion protein gene (PRNP) segregate with the phenotype of Gerstmann-Strausler-Scheinker disease (GSS): a chronic inherited prion disorder characterized by the presence of prominent amyloid plaques containing prion protein (PrP). One of the mutations associated with GSS phenotype is the substitution of a tyrosine (TAT) to a stop codon (TAG) at position 145 (Y145Amber) of PRNP leading to the production of a truncated PrP isoform. We have generated an *in vitro* model of the disease using human neuroblastoma cells transfected with normal or Y145Amber PRNP construct in order to study synthesis and processing of Y145Amber mutant PrP (PrP<sup>M</sup>). Our findings show that the PrP<sup>M</sup> is highly unstable and is rapidly degraded in an intracellular compartment. The degradative process is likely to take place in the endoplasmic reticulum (ER) or in an ER-associated compartment since it is maintained even at 15 °C, a temperature which blocks vesicular transport from the ER. However, PrP<sup>M</sup> degradation can be partially inhibited by ATP depletion or by inhibitors of ER proteases. Y145Amber provides the first example of PrP<sup>M</sup> that is completely degraded in the ER. This finding raises questions concerning the mechanism of PrP conversion in the Y145Amber human disease. Contrary to the accepted models of PrP conversion that presuppose the transit through the cell surface for the PrP to be converted, Y145Amber PrP<sup>M</sup> might convert into the amyloidogenic conformer inside the cell or in the extracellular space following secretion or release when with aging the ER degradation system becomes less effective. ## 14.3

**EXPRESSION OF INFLAMMATION RELATED CYTOKINES (CHEMOKINES) IN BRAINS OF ALZHEIMER'S DISEASE.** MO. Xia, SQ. Qin, M. McNamara, C. Mackay, O. Berezovskaya\* and B. T. Hyman. Mass General Hospital and LeukoSite, Inc, Boston, MA 02114.

Growing evidence suggests that brain may have the capacity of synthesizing its own repertoire of inflammatory cytokines. One class of cytokines, chemokines, have chemotactic activity for leukocytes. We examined the expression of a number of chemokines and their receptors in AD brain. Strong IL8RB immunoreactivity was present in neurons, dendrites, and axons in the normal hippocampal formation. In AD, IL8RB immunoreactivity was present in swollen dystrophic neurites surrounding plaques in the hippocampal formation and temporal neocortex. By confocal microscopy the IL8RB neurites did not colocalized with PHF-1 or AT8 (hyperphosphorylated tau) immunoreactive neurites. Gro  $\alpha$  (or Nap2), another IL8RB ligand, was detected in astrocytes. Other chemokines, IP-10 and MIP18, were present in both normal and (in elevated amounts) in AD astrocytes. Chemokine expression did not vary consistently with duration of illness. These data add to growing evidence that inflammatory cytokines are expressed in brain as well as in the periphery. The presence of IL8RB in neuritic plaques and the elevated expression of other chemokines in astrocytes of AD suggest that inflammatory related responses may be involved in the development of AD pathology. Supported by NIH grant 3P50AG05134

**PATHOLOGICAL OBSERVATIONS IN STRUCTURES ASSOCIATED WITH PUPILLARY FUNCTIONS: EDINGER-WESTPHAL NUCLEUS.** L.F.M. Scinto\*, C. K. Wu, D. Saroff, & C. Geula. Harvard Medical School, Boston, MA 02115

Studies have demonstrated that hypersensitive pupil dilation to dilute tropicamide might serve as a marker for Alzheimer's disease (AD). Neuropathological data from patients with AD and normal elderly individuals suggest a possible mechanism for the observed hypersensitivity. Analysis of the distribution of AD pathology in the brainstems of normal individuals revealed rare amyloid deposits and almost no Alz-50 or PHF1 positive dystrophic neurites and no tangles. The oculomotor complex (CN3), including the EW, was completely devoid of any pathology. In contrast, AD cases exhibited many amyloid plaques and Alz-50 and PHF1-positive dystrophic neurites and neuropil threads. The highest concentration of brainstem amyloid deposits occurred within the central gray (CG). Consistent with its location near the CG, the EW nucleus also contained numerous amyloid plaques. In contrast the somatic portion of CN3 was virtually devoid of any amyloid deposits. The EW also contained collections of Alz-50-positive dystrophic neurites indicative of neuritic abnormalities. Occasional tangles were seen in the EW nucleus. A surprising finding was that most neurons of CN3, including the EW nucleus, contained immunoreactivity for APP and 8-amyloid. The axons of these neurons were particularly intensely stained. This pattern of staining was present in both normal and AD cases. Changes in the amount of APP or  $\beta$ -amyloid within these neurons remain to be investigated. Such changes might contribute to pathology in CN3, and particularly the EW nucleus. Our observations suggest that the presence of AD pathology might be specific to the EW nucleus and not represent general pathology within CN3. Selective pathology in the EW nucleus might lead to neuronal loss and eventually upregulation of cholinergic receptors at the iris, thus accounting for the observed hypersensitivity of AD patients. *This work was supported by a grant from Johnson & Johnson.*

## 14.7

**OXIDATIVE INJURY PREFERENTIALLY AFFECTS PROJECTION NEURONS IN ALZHEIMER CORTEX.** Neil W. Kowall\*, Robert J. Ferrante, Robert H. Brown, Joseph S. Beckman, Ladislav Volicer, M. Flint Beal. GRECC, Bedford VA Medical Center, Bedford MA; Dept. Neurology and Pathology, Boston University School of Medicine and Massachusetts General Hospital, Boston MA.

Oxidative injury has been implicated in the pathogenesis of Alzheimer's disease (AD) and other neurodegenerative disorders. Recent evidence suggests that both beta amyloid neurotoxicity and NFT formation are mediated by oxidation reactions. Consistent with this theory, biochemical and/or histochemical studies of AD brain have shown increased amounts of 8-hydroxydeoxyguanosine (8-OHdG), a marker for DNA oxidation; malondialdehyde (MDA), a marker of lipid peroxidation; heme oxygenase-1 (HO), an antioxidant enzyme, and protein carbonyls, a marker of protein oxidation. We used specific antibodies that recognize 8-OHdG, MDA, HO, 3-nitrotyrosine (3NT), a marker of protein nitration mediated by peroxynitrite, and thiol-specific antioxidant protein (TSA), a ubiquitous free radical scavenger present in human brain, in order to determine the histochemical distribution of oxidative injury. Postmortem samples of hippocampus and neocortex from seven patients with AD and four control patients with other neurological diseases were studied. The general pattern of immunoreactivity seen with 8-OHdG, MDA, 3NT, and HO were highly concordant. Control brains showed little or no immunoreactivity. In all AD cases layers III and V projection neurons in the neocortex and pyramidal cells in the hippocampal formation were immunoreactive. Prominent vascular staining was also observed with HO and MDA antibodies. TSA was concentrated in nonpyramidal neurons in AD. Occasional astrocytes were seen with all antibodies. Senile plaque neurites were prominently stained with NT. Our results indicate that the selective pattern of neuronal degeneration and NFT formation in AD cortex may be a direct consequence of oxidation reactions that preferentially damage pyramidal projection neurons. Supported by grants from the Department of Veterans Affairs and the NIH.

## 14.4

**MICROGLIAL AND ASTROGLIAL ACTIVATION IN DIFFUSE AND NEURITIC PLAQUES IN ALZHEIMER'S DISEASE.** D. R. Thal<sup>1</sup>, R. Schober<sup>1</sup>, W. Härtig<sup>2</sup>. <sup>1</sup>Department of Neuropathology, University of Leipzig, 04103 Leipzig, Germany, <sup>2</sup>Department of Neurochemistry, Paul-Flechsig Institute for Brain Research, University of Leipzig, 04109 Leipzig, Germany.

Neuritic and diffuse plaques are hallmarks of Alzheimer's disease (AD). Diffuse plaques are known as amyloid deposits without a core and devoid of associated neuritic and neurofibrillary changes which are features of neuritic plaques. In both types of plaques microglial cells are found. Microglial cells in diffuse plaques are identified by IL-1 $\alpha$  expression (Griffin et al., J Neuropath Exp Neurol 54: 276-281; 1995) whereas microglial cells in neuritic plaques additionally show MHC class II- and IL-6-immunoreactivity. To further differentiate microglial and astrocyte activation, we studied diffuse and neuritic plaques in AD cases using double labeling with antibodies directed against  $\beta$ -amyloid peptides (A $\beta$ ), MHC class II complex (HLA-DR), IL-6, CD 68, GFAP, apolipoprotein E (polyclonal and monoclonal), APP-695 and hyperphosphorylated  $\tau$  (AT-8). Moreover, immunohistochemistry for such markers was combined with PAS and Gallyas counterstaining. Furthermore, plaques were screened electron microscopically for A $\beta$ , APP-695 and apolipoprotein E. In microglial cells located within APP-695-positive neuritic plaques large amounts of PAS-positive lipofuscin pigments were found. GFAP-immunoreactivity was present in activated glial cells of the outer part of these plaques and in astrocyte processes of their inner part. In diffuse plaques no accumulations of activated astrocytes or activated MHC class II and IL-6 positive microglial cells were observed. These results suggest that microglial activation is not primarily necessary for the formation of APP-positive diffuse plaques but plays an important role in classical plaques. Supported by BMBF 01 KS 9504, TP C1.

## 14.6

**HIERARCHICAL PATTERNS OF NEURONAL LOSS IN ALZHEIMER'S DISEASE.** T. Gómez-Isla, J.L. Price, D.W. McKeel, Jr., J.C. Morris, S. Greenberg\*, R.C. Petersen, J.E. Parisi, J.H. Growdon, and B.T. Hyman. Dept. of Neurology, Massachusetts General Hospital, Boston, MA, Depts. of Anatomy, Pathology and Neurology, Washington University, St. Louis, MO & Depts. of Neurology and Pathology, Mayo Clinic, Rochester, MN.

One of the most consistent alterations in the Alzheimer's disease (AD) brain is the development of neurofibrillary tangles (NFTs) in layers II and IV of entorhinal cortex (EC) early in the disease process, likely contributing to memory impairment. Later on, as the cognitive deficits become broader, NFTs are also found in increasing number in feedforward and feedback projection neurons in layers II, III and V in high order association cortices. We have applied stereological principles to determine whether neuronal loss in AD brains follows similar patterns of selective vulnerability. We studied 53 individuals who had been evaluated at Massachusetts General Hospital, Washington University or the Mayo Clinic. Of 53, 10 were cognitively normal at death, and 43 had a diagnosis of definite AD with different degrees of cognitive impairment at death. Stereologically based neuron counts were carried out in the EC and in a high order association cortex, the Superior Temporal Sulcus (STS). In the cognitively normal individuals, no significant neuronal loss in either of the regions studied was present across age. In the very mildly impaired group the number of neurons in layer II EC decreased by half, in layer IV by 40%, and in the entire EC by 25%. No significant neuronal loss in the STS was found in the same group compared to cognitively normal individuals. In the group with severe cognitive impairment the loss in layer II was about 90%, and about 60% in the entire EC. The number of neurons in the STS was reduced by 50% in this group compared to controls. Neuronal loss paralleled NFT formation, but was independent of A $\beta$  deposition. These results indicate that neuronal loss in AD brains does not occur in a random or widespread fashion but instead follows a hierarchical selective pattern of vulnerability. **ELECTROPHYSIOLOGICAL EVIDENCE INDICATES THAT SENILE DEMENTIA OF THE ALZHEIMER TYPE IS AN AGE-RELATED AGING-INDEPENDENT PROCESS.** A. L. Politoff\* and N. Monson. Neuropsychiatric Research Institute, Fargo VA Medical Center and Dep. Neurosc., Univ. of North Dakota School of Med., 1919 Elm Street, Fargo, N. D. 58102.

A crucial question regarding senile dementia of the Alzheimer type (SDAT) is whether it is the end result of the natural aging of the brain, as postulated by the serial, intrinsic or aging-related model, or the result of some other mechanism that runs in parallel to normal aging, as postulated by the parallel, extrinsic or age-related model. This question can be answered by comparing variables that measure biological aging (aging-dependent variables, ADVs) of normal individuals and of SDAT patients. If the serial model applies, the values of the ADVs of SDAT patients should be at the upper end of the normal ADV curves. If the parallel model applies, the values of the ADVs of SDAT patients might be incompatible with the normal ADVs values. When we analyzed the electrical power contained in the different bands of the electroencephalograms (EEG) of normal adult individuals (n = 44) between 19 and 78 years of age we found several ADVs. In normal control subjects the power of the alpha band in the 2 Hz flash stimulated EEG at the posterior head regions increased with age, while the power of the delta band in the resting EEG at the anterior head regions decreased with age. In SDAT patients (n = 16) the magnitudes of the ADVs were significantly different from normal and opposite to the trend of normal aging. The predicted ages of SDAT patients, as measured by their ADVs, ranged between 37 and 41 years of age while their chronological ages ranged between 58 and 94. The present observations support the parallel model and show that SDAT involves a pathogenic mechanism that is different from normal aging. Supported by a grant to ALP from the Neuropsychiatric Research Institute of Fargo.

## 14.9

A TEMPORALLY GRADED NEURAL STRESS-TEST DEMONSTRATES ABNORMAL VISUAL FUNCTION FROM STRIATE THROUGH FRONTAL CORTEX IN ALZHEIMER'S DISEASE (AD) DURING PET.

M.J. Mentis\*, G.E. Alexander, M.L. Furey, P. Pietrini, T. Strassburger, J. Krasuski, A. Dani, M.B. Schapiro, S.I. Rapoport, Lab. Neurosci., Natl. Inst. on Aging, NIH, Bethesda, MD 20892.

To determine the response to a temporally graded visual stress-test in AD, at all severity levels, we compared regional cerebral blood flow (rCBF) in 21 AD patients (71±9yr, MMS 15.6 range 0-28) and 19 controls (65±11yr) using PET. The visual stimulus was administered by goggles that flashed light alternately into each eye. All subjects had 5 scans, one at each of 0, 1, 4, 7, and 14 Hz frequencies. In controls, the stimulus evokes differential rCBF responses: biphasic in striate, monotonic increasing in posterior, and monotonic decreasing in frontal association areas. Compared to controls the AD group showed: smaller high frequency striate rCBF response, failure to activate V5 at 1 Hz, and smaller rCBF response in posterior and anterior association areas. rCBF response size was proportional to disease severity. Striate high frequency failure implied magnocellular greater than parvocellular failure at that level. Magnocellular failure was supported by AD inability to activate V5 (motion area with predominantly magnocellular input) in response to apparent motion at 1 Hz. As the percept changes were complex (form, luminance, motion, color), association area rCBF was interpreted as the integrated neural response to simultaneous visual processing of multiple visual modalities. Smaller responses in these areas in AD was interpreted as impairment of multi-modality visual processing. Funded by NIA intramural program.

## 14.11

ESTROGEN REPLACEMENT THERAPY AS A PROTECTIVE FACTOR FOR ALZHEIMER DISEASE: INTERACTIONS WITH OTHER RISK FACTORS. A.J. Lerner\*, E. Koss, S. Gilham, R. Cole, S. Debanne, C. Esteban-Santillan, G. J. Petot, D.Y. Rowland, K.A. Smyth, P.J. Whitehouse, R.P. Friedland, Alzheimer's Center and Laboratory of Neurogeriatrics, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

Estrogen Replacement therapy (ERT) has been proposed to be a protective risk factor for the development of Alzheimer's disease (AD). This effect may be mediated by estrogen receptors in brain regions important in AD, such as basal forebrain and hippocampus, and effects of estrogen on cholinergic neurotransmission, modulating levels of neurotrophic growth factors, and maintaining synaptic density. Previous clinical studies of ERT on AD risk have yielded conflicting results. We studied ERT as part of an epidemiologic study on AD risk factors, and assessed the interaction of ERT with cigarette smoking, also postulated to be a protective risk factor for AD. Our female study population consisted of 78 AD cases and 177 controls. AD patients were less likely to have received ERT during each two-decade surveyed. Comparing cases and controls, the odds ratio for ERT alone was 0.41 (95% confidence interval 0.12 - 0.69). When ERT and smoking were combined, the odds ratio was 0.18 (95% C.I. 0.13 - 0.23). These preliminary data suggest that estrogens interact with other risk factors, such as smoking, in a synergistic fashion to protect against the development of AD. Other risk factors such as Apolipoprotein E genotype need to be evaluated for their interaction in this regard. Supported by NIA, and Philip-Morris, U.S.A.

## 14.10

PICK'S DISEASE AND ALZHEIMER'S DISEASE HAVE DIFFERENT COGNITIVE PROFILES. G. Binetti\*<sup>1,2</sup>, J.J. Locascio<sup>1,2</sup>, S. Corkin<sup>2</sup>, and J.H. Growdon<sup>1,2</sup>. <sup>1</sup>Department of Neurology, Massachusetts General Hospital, Boston, MA 02114; <sup>2</sup>Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139.

Pick's disease (PcD) is a rare neurodegenerative disease characterized pathologically by focal cerebral atrophy, and clinically by progressive dementia. No agreement exists on the clinical diagnostic criteria for PcD; it is often confused with Alzheimer's disease (AD). The aim of this study was to describe the clinical presentation of PcD and to compare the cognitive deterioration in PcD with that in AD. The subjects were 33 PcD patients (21M/12F; mean age, 66.2; mean education, 14.2; 10 with autopsy confirmed diagnosis) and 121 AD (46M/75F; mean age, 70.7; mean education, 13.1; 8 with autopsy confirmed diagnosis) from the patient population assessed longitudinally between 1985 and 1996. All took a set of cognitive tests that assessed memory, language, visuospatial abilities, abstract reasoning, and executive functions. The tests were administered from 1 to 6 times to PcD patients, and from 2 to 8 times to AD patients. Analysis of the first cognitive assessment (mean time after symptom onset: PcD, 2.8 years; AD, 3.3) showed significantly better performance by the PcD group than by the AD group on NYU Story Recall ( $p < .001$ ) and the Luria Mental Rotation Test ( $p < .04$ ). In order to characterize the rate of progression of the cognitive decline, we performed a nonlinear regression analysis, corrected for age, education, and duration of disease. Over time, PcD patients declined significantly more than AD patients on the Boston Naming Test ( $p < .05$ ) and the Verbal Fluency Test ( $p < .001$ ). The groups did not differ significantly in rate of decline on the other cognitive tests ( $p < .1$ ). A relative preservation of episodic memory and visuospatial ability characterizes the early phase of PcD when compared to AD. The sharper decline of language abilities in PcD sharpens the clinical distinction from AD, and reflects the underlying frontal-lobe and temporal-lobe atrophy.

## 14.12

LEFT-HANDEDNESS AND THE RISK OF ALZHEIMER'S DISEASE. V.W. Henderson\*, W.A. Kukull, J.G. Buckwalter, E.B. Larson. Depts. of Epidemiology and Medicine, Univ. of Washington, Seattle, WA; Depts. of Neurology and Psychology and Sch. of Gerontology, Univ. of Southern California, Los Angeles, CA.

Left-handed persons are thought to differ from right-handers in terms of cerebral organization and environmental exposures. Conflicting contentions that left-handers may face an altered risk of Alzheimer's disease (AD) have not been previously evaluated in a defined population. We studied incident AD cases ( $n = 265$ , mean age of 79 years) and frequency matched non-demented controls ( $n = 331$ ), where all subjects were enrolled in a regional health maintenance organization. 13% of AD cases and 8% of controls were reported to be left-handed (a group that included ambidextrous subjects). In multivariate analyses that adjusted for age, education, and gender, cases were more likely to be left-handed (odds ratio = 1.8, 95% confidence interval = 1.0 - 3.0). For left- and right-handers, dementia severity was similar at the time of study enrollment, but left-handers were significantly younger when their dementia symptoms first appeared (74 versus 77 years). These data are consistent with a modestly increased risk of AD among left-handers. Supported in part by NIH grants AG06781, AG07584, AG05136, AG05142.

## INGESTIVE BEHAVIOR: REGULATORS OF INGESTION

## 15.1

FOURTH VENTRICULAR ADMINISTRATION OF GLUCAGON-LIKE PEPTIDE-1 (7-36) amide (GLP-1) INHIBITS FOOD INTAKE IN RATS. T.H. Moran\*, A. Wahn, G.J. Schwartz and E.E. Ladenheim. Department of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

To identify sites of action through which the brain/gut peptide GLP-1 inhibits food intake, we examined the effect of 4th ventricular infusions of GLP-1 on 30 min glucose (0.125 g/ml) intake in rats following a daytime six hour food deprivation. Rats equipped with a chronic 4th ventricular cannula were adapted to daily access to a glucose solution. Cannula placement was assessed by examining the ability of 4th ventricular bombesin to inhibit food intake. On test days, GLP-1 in doses of 0.1, 0.32, 1.0 and 3.2 nmoles/rat or saline vehicle were infused five minutes prior to glucose access in a volume of 3 µl and subsequent glucose consumption was measured. Beginning at the lowest dose (0.1 nmol), injections of GLP-1 significantly reduced intake relative to vehicle control. At a GLP-1 dose of 0.1 nmol, intake was reduced by 32%. The effect appears to be maximal at a GLP-1 dose of 1 nmol which resulted in a 60% suppression of glucose intake. The ability of 4th ventricular GLP-1 to inhibit intake, and the potency with which this occurs, suggests that the hindbrain is a site for GLP-1's actions in the control of food intake. (Supported by DK19302 and DK46448).

## 15.2

Cholecystokinin acts on the duodenum to reduce sucrose intake. J.E. Cox\*. Dept. Psychology, Univ. Alabama at Birmingham, Birmingham, AL 35294.

This experiment investigated the proposal that CCK-A receptors mediating cholecystokinin satiety are located within the duodenum. Adult, male Sprague-Dawley rats received bolus infusions of the CCK-A antagonist devazepide (20 µg/kg) into the jugular vein (IV group;  $N=6$ ) or superior pancreaticoduodenal artery (SPD group;  $N=6$ ). This artery supplies the proximal duodenum. Following 6 h food deprivation, rats received devazepide or vehicle followed immediately by intraperitoneal injections of CCK-8 (2 µg/kg) or saline. Intake of 30% sucrose was measured over the next 15 min. In the SPD group, devazepide significantly antagonized the actions of both exogenous and endogenous cholecystokinin: (1) When devazepide was infused, CCK-8 injections reduced sucrose intake less (36.5%) than they did when rats received vehicle infusions (71.8%;  $P < .01$ ); (2) On tests without CCK-8 administration, devazepide increased intake by 27.4% above baseline ( $P < .01$ ). By contrast, IV infusions of devazepide were ineffective in both respects ( $P > .25$ ). The enhanced potency of devazepide when administered into an artery perfusing the duodenum supports the hypothesis that endogenous cholecystokinin acts locally to reduce intake. Moreover, these results are consistent with exogenous cholecystokinin having the same mechanism of action.

## 15.3

LICK PATTERN AND INTAKE AS FUNCTIONS OF GLUCOSE CONCENTRATION AND LICK VOLUME. J.P. Baird, H.J. Grill, & J.M. Kaplan\*. Dept. Psychology, Univ. of Pennsylvania, Phila., PA, 19104.

We showed previously in rats ingesting 12.5% glucose from a drinking spout that meal size was actively defended despite explicit manipulation of the amount delivered per lick (drop size). For the current experiment we evaluated the generality of this finding by varying glucose concentration. Daily, rats were permitted 1 h to ingest one of five concentrations of glucose (0.0, 3.2, 6.25, 12.5 or 25%) at one of three drop sizes (2.5, 5.0 or 7.5  $\mu$ l), until all combinations were tested for each rat. A typical inverted-U concentration-intake function was obtained. There was no overall effect of drop size on amount consumed, however. The defense of intake against the drop size challenge was accomplished through broad adjustments in the licking pattern. Within each concentration, the number of licks varied over a 3-fold range. Meal duration generally increased with increasing concentration but decreased with increasing drop size. Initial (first minute) lick rates increased with concentration, as expected. Drop size also affected initial lick rates, with significantly lower values obtained with the largest relative to the two lower drop size conditions. There were considerable individual differences in the extent to which the increased number of licks with drop size increase was mediated by adjustments in burst number versus licks/burst. We conclude that rats exhibit considerable flexibility in the licking structure of their meals, apparently in order to preserve what may be reasonably regarded as an intake goal specified for each concentration. Supported by NIH DK42284.

## 15.5

POTENT SUPPRESSIVE EFFECTS OF THE PUTATIVE SATIETY AGENT GLP-1 ON SOCIAL-EMOTIONAL BEHAVIORS. J. Panksepp\*, M.Y.V. Bekkedal and M. Walter, Dept. of Psychology, Bowling Green State University, Bowling Green, OH 43403

With an ever increasing list of putative satiety peptides that are being postulated, new methods need to be developed to sift natural satiety mechanisms from the many nonspecific ways, such as emotional changes, that appetite can be temporarily suppressed. Glucagon-like peptide-1 (GLP-1) has recently been proposed to be a normal satiety factor (Turton, M.D. et al., *Nature*, 1996, 379, 69-72), and here we evaluated the effects of this peptide on various social behaviors including separation-induced distress vocalizations (DVs) in young chicks and rough-and-tumble play in juvenile rats, as well as the ability of this peptide to restore normal play behavior in food-deprived animals.

Intraventricular GLP-1 (1  $\mu$ g) in chicks not only reduced food intake but very markedly and dose-dependently reduced DVs. At 0.5-1.0  $\mu$ g DVs were eliminated for almost an hour, while at the 2.0  $\mu$ g the effect lasted almost 2 hrs. The effect was not naloxone reversible as it is with opioids. The 1  $\mu$ g dose reduced play (as monitored by dorsal contacts and pins) by about 50% in juvenile rats. A day of food deprivation also markedly reduced play which was returned to normal by a half hour meal. This satiety effect was not simulated by the administration of 1  $\mu$ g of GLP-1 to the food-deprived animals. Rather, play was even further reduced by the peptide. The data indicate powerful emotion modulating effects of GLP-1, with no clear indication that the peptide can produce play effects resembling normal satiation. Accordingly, our data do not support the idea that GLP-1 is a normal satiety factor of the body.

## 15.7

A REEXAMINATION OF THE ROLE OF THE GLUCOCORTICOIDS ON GLUCONEOGENESIS AND THEIR IMPACT ON FOOD INTAKE AND BODY WEIGHT. Ali Moshirfar, L. Terranella, O. Trocki, K. Kamara, and T.W. Castonguay\*. Department of Nutrition and Food Science, University of Maryland-College Park, MD 20742

The effects of adrenal steroids on several of the neural controls of food intake and body weight have been described. By contrast, little is known about how the glucocorticoids, via their control of hepatic gluconeogenesis, might also participate in the control of intake. In a series of studies, we have demonstrated that dietary factors (intragastric load of L-tryptophan (TRP)) can dramatically and quickly alter gluconeogenesis. TRP increased assayable phosphoenolpyruvate carboxykinase (PEPCK) activity, but in vivo catalysis was not observed. Further, we have demonstrated that either adrenalectomy (ADX) or RU 486 reduced PEPCK activity as well as food intake and body weight gains. Corticosterone replacement failed to restore PEPCK activity to control levels. Fructose 1,6 bis-phosphatase (FBP) activity was also reduced by ADX, TRP or RU 486. Corticosterone replacement following ADX prevented the decrease in FBPase activity as well as the decreases in food intake and body weight gain. These results suggest that normal control of food intake is achieved when glucose production remains unimpaired. However, if hepatic glucose production is attenuated (as in the case of ADX's simultaneous effects on both FBPase and PEPCK) then food intake and body weight gain is suppressed.

## 15.4

THE WEIGHT-REDUCING EFFECTS OF FLUVOXAMINE IN ZUCKER RATS ARE MEDIATED BY CORTICOTROPIN-RELEASING HORMONE (CRF). I. Wiczorek, C. Schulz, M. Grözinger\*, H. Lehnert. Dept. of Internal Medicine - Endocrinology, Otto-von-Guericke University, 39120 Magdeburg, Germany; \*Dept. of Psychiatry, University of Mainz, 55101 Mainz, Germany

Previous studies have demonstrated an inhibitory effect of i.p. injection of fluvoxamine, a selective serotonin reuptake inhibitor, on food intake and body weight in rats. The present study was designed to examine whether the effect of fluvoxamine on food intake is centrally mediated by CRF. A fused silica capillary (144  $\mu$ m od) was implanted under chloralhydrate anesthesia into the lateral ventricle of genetic obese Zucker rats fa/fa (12 weeks old) for i.c.v.-injections. The femoral artery was catheterized for blood sampling. On the first day post surgery, animals received an i.p. injection of fluvoxamine (25 mg/kg) and  $\alpha$ -CRF (25  $\mu$ g/kg) i.c.v., a CRF receptor antagonist. Blood samples were taken before and in 30 min intervals over a 2 hour period after injection. The i.p. and i.c.v. treatments were repeated on 7 consecutive days. In the control group, saline injections were administered i.p. and i.c.v., respectively. Body weight and food intake were monitored daily. During the experiment, animals treated with fluvoxamine i.p./saline i.c.v. exhibited a weight loss of 6-7 g/day, differing significantly from the control group (saline i.p./saline i.c.v.) with a daily weight gain of 5 g. A weight gain of 2 g/day was observed in the group treated with fluvoxamine i.p. and  $\alpha$ -helical CRF i.c.v.. Food intake was not affected by the different treatments. The results of our study very clearly demonstrate, that the inhibitory effects of fluvoxamine on weight gain are mediated by CRF and are independent of food intake. The apparent discrepancy between unaltered food intake and reduced weight gain can possibly be explained by stimulation of the autonomic nervous system and enhanced thermogenesis. This work was supported by Upjohn.

## 15.6

GLUCAGON-LIKE PEPTIDE-1 (7-36 AMIDE) ELICITS BEHAVIORAL SATIETY IN SHAM FEEDING RATS. L. Asarian, A.M. Cuomo, E. Corp, B. Hrupka, and N. Geary\*. Bourne Laboratory, Dept of Psychiatry, Cornell Medical College, White Plains, NY 10605.

Glucagon-like peptide-1 (7-36 amide) (GLP-1) and its receptors occur in several brain regions and may play a role in the physiological control of feeding behavior (Turton et al., *Nature* 379:69, 1996). To test whether GLP-1 is sufficient to inhibit feeding and elicit satiety in the absence of postgestive food stimuli, 10 rats were implanted with gastric sham-feeding cannulas and lateral ventricle infusion cannulas. Rats sham fed 0.8 M sucrose for 45 min beginning 5 min after icv injection of 2.5  $\mu$ l aCSF with 0-30  $\mu$ g GLP-1. Behaviors were measured each minute using a time sampling technique. Rats initiated sham feeding as rapidly after GLP-1 as after aCSF and sham fed similar amounts for 6 min, but subsequent sham feeding was potently inhibited by each GLP-1 dose (Table).

Sham intake	aCSF	3 $\mu$ g	10 $\mu$ g	30 $\mu$ g
1-3 min	3.7 $\pm$ 0.5	3.8 $\pm$ 0.9	3.5 $\pm$ 0.8	4.8 $\pm$ 0.5
4-6 min	4.5 $\pm$ 0.4	3.8 $\pm$ 0.4	3.0 $\pm$ 0.6	3.2 $\pm$ 0.4
7-9 min	5.1 $\pm$ 0.4	3.7 $\pm$ 0.5*	2.8 $\pm$ 0.7*	2.7 $\pm$ 0.5*
1-45 min	61.0 $\pm$ 4.3	40.1 $\pm$ 5.4**	29.5 $\pm$ 5.8**	31.6 $\pm$ 5.9**

Intakes are ml,  $m \pm$  sem; \*Less than aCSF,  $p < 0.05$ ; \*\*  $p < 0.001$ .

No abnormal behaviors were observed, and 30  $\mu$ g GLP-1 elicited resting, the terminal item in the behavioral sequence of postprandial satiety in real feeding rats (median latency to rest, 33 min vs. 46 min after aCSF,  $p < 0.02$ ). These data indicate that icv GLP-1 (i) does not affect rats' initial orosensory response to sucrose and (ii) is sufficient to inhibit feeding and induce satiety even in the absence of gastric and postgastric food stimuli. (NIH MH51135)

MERCAPTOACETATE ENHANCES INDEPENDENT INGESTION IN RAT PUPS. S.E. Swithers\*. Dept. of Psychological Sciences, Purdue University, West Lafayette, IN 47907-1364

In adult rats, administration of a blocker of fatty acid oxidation, mercaptoacetate (MA), increases ingestion (e.g. Langhans & Scharer, *J. Auton. Nerv. Sys.*, 18:13-18, 1987). Previous work has suggested MA does not enhance suckling intake in preweanling rats (Leshem, Flynn & Epstein, *Am. J. Physiol.*, 258:R365-R375, 1990). However, rat pups will also display ingestive behavior that is independent of the mother and suckling. The present study investigated the development of effects of MA on such independent ingestion. Rat pups were tested once at 6, 9, 12 or 15 days of age. Prior to testing, pups were injected i.p. with 100, 200, 400 or 800  $\mu$ mol/kg, (100  $\mu$ mol/ml) MA or 0.135 M saline. One hour following the injection, pups were placed into test containers lined with paper towels soaked with commercial half and half and allowed to ingest for 30 minutes. In 6- and 9-day-old rats, MA did not affect intake at any dose. However, in 12- and 15-day-old rats, doses of 100, 200 and 400  $\mu$ mol/kg MA enhanced intake, while a dose of 800  $\mu$ mol/kg suppressed intake. These results demonstrate that ingestive responsiveness to MA develops between 9 and 12 days of age in rats.

IDENTIFYING ROLES FOR INTESTINAL SIGNALS IN THE SATIATING EFFECTS OF FATS IN HUMAN ADULTS. D.A. Booth\*, L.A. Dibsall & N.W. Read. Food & Nutrition Lab., Sch. Psychology, Univ. Birmingham, Edgbaston B15 2TT, U.K.

Foods and their macronutrient contents have no inherent palatability or satiating efficacy. Suppression of food intake by fats depends on physical form as well as chemical structure, and on the timing of the meal's sensory and post-ingestional actions to coincide with access to foods. We hypothesized that fat which floats above aqueous contents of the stomach is delayed in its action on intestinal chemoreceptors that suppress appetite for food, while fat in aqueous emulsion begins to empty immediately and so may induce an early satiety. This was tested by a method for identifying post-oral control of intake: appetite ratings are corrected for effects on appetite the rat predicts after sensing the load menu and its immediate post-ingestional effects. The current-minus-expected amount of food wished for eating was -ve at 1 h after high-fat breakfasts with emulsified fat; it remains to be seen if this satiety effect of cream can be prompt and strong enough to condition down the size of meals on that menu, as rapidly digested carbohydrate does. In contrast, for about 2 h after a high-fat breakfast, cur.-exp. hunger-rating differences were +ve with (separating) spread fat. Yet, near lunchtime, post-oral satiety was just as strong after either form of fat as after the carbohydrate in high-starch or high-sugar breakfasts. [Supported by U.K. Government M.A.F.F.]

## 15.11

DUODENAL NUTRIENT EXPOSURE ELICITS ORGANIZED GASTROINTESTINAL MOTILITY AND GUT VAGAL AFFERENT SIGNALS IN RAT. G.J. Schwartz\* and T.H. Moran. Dept. of Psychiatry & Behav. Sci., Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205, USA

Upper gastrointestinal exposure to meal-related nutrient stimulation contributes to the negative feedback control of food intake in a variety of feeding paradigms, and a role for the afferent vagus in this negative feedback control has been demonstrated. We have been investigating the gastrointestinal and vagal afferent neural events arising from the upper gut in response to duodenal nutrient exposure in rats. Luminal stimulation of the upper 4 cm of the small intestine with 0.2 kcal/ml glucose, maltose or peptone, induces dramatic, short-latency alterations in the pattern of gastric and duodenal motility, compared to isotonic saline. This changed pattern of motility is characterized by an increase in the strength and duration of discrete gastric and duodenal contractile events. These organized changes in motility are paralleled by increases in the frequency and intensity of discrete bursts of activity in gastric and duodenal vagal mechanosensitive afferents. The motility and vagal afferent responses following peptone administration significantly outlasted those elicited by either equicaloric maltose or glucose. These data reveal nutrient chemosensitivity in the duodenal lumen, and demonstrate that neurophysiological activity in vagal afferent fibers supplying gastric and duodenal targets reflect the ability of the duodenum to discriminate its contents. Supported by the Whitehall Foundation and DK 47208.

## 15.10

CCK-33 INHIBITS FOOD INTAKE AFTER INTRAPORTAL AND INTRAVENOUS ADMINISTRATION. G.P. Smith\*, D. Dorré, and L. Melville. Bourne Lab, NY Hospital-Cornell Medical Center, White Plains, NY 10605.

When CCK-8 is administered to rats, its satiating potency depends on the route of administration: Intraperitoneal (ip) CCK-8 is much more potent than hepatic-portal (hp) or intravenous (iv) administration (Greenberg et al., 1987; Strubbe et al., 1989). We interpreted this differential potency to mean (1) that endogenous CCK-8 had a paracrine, not an endocrine, mode of action, and (2) that the reduced potency of CCK-8 after hp administration was due to hepatic uptake and degradation of peptides of less than 10 amino acids (Gores et al., 1986).

To test this interpretation, we administered CCK-33 ip, hp, and iv to male rats (n=5-9) given access to a high-carbohydrate liquid diet for 30 minutes after 16 hours of food deprivation. CCK-33 (6.6, 13.2, and 27.4 ug/kg) was injected ip 5 minutes before the test meal or infused hp or iv (0.39 ml/min for 12.8 min). Infusions began 5 minutes before the test meal and ended about half-way through the meal so that the total dose was delivered prior to the termination of the meal. The rank order of satiating potency of CCK-33 was ip>hp>iv. The fact that the satiating potency of CCK-33 was largest after ip administration suggests that CCK-33, like CCK-8, acts locally on CCK<sub>A</sub> receptors in the abdomen, presumably in the upper small intestine and pyloric sphincter. The larger potency of CCK-33 after hp infusion than after iv infusion is consistent with an additional site of action of CCK-33 in the liver and with CCK-33 being more resistant than CCK-8 to uptake and degradation by the liver.

Supported by NIH grant MH 40010.

## 15.12

EFFECTS OF TACHYKININS AND MAMMALIAN BOMBESIN-LIKE PEPTIDES ON SALT APPETITE: ROLE OF POST-ORAL FACTORS. M.E. SMITH\*, L. TANGEMAN AND F.W. FLYNN. Dept. of Psychology and Graduate Neuroscience Program, Univ. of Wyoming, Laramie, WY.

The tachykinins (TK) and the bombesin (BN)-like peptides have commonalities in both function and distribution. Both of these families of peptides are effective in suppressing need-free and sodium need-induced NaCl intake (salt appetite). The possibility that these neuropeptides have a common mechanism of action and suppress salt intake by potentiating post-oral signals was evaluated by testing the potency of TK and BN-like peptides in sodium deficient, sham drinking rats. The effects of lateral intraventricular injections of saline, or selective NK<sub>1</sub> receptor agonists (200 ng SENK, 200 ng MePhe<sup>7</sup> NKB, or 200 ng NH<sub>2</sub>-senktide) on salt intake (0.5 M NaCl) by sodium deficient rats in the gastric fistula open and closed conditions were tested. A second group of rats was tested in the identical manner except they were administered intraperitoneal injections of saline, 4, 8, and 16 µg/kg BN, gastrin releasing peptide (GRP), or neuromedin B (NMB). **RESULTS:** Intraventricular injections of SENK suppressed both sodium deficiency induced salt intake in both the fistula open and closed conditions. NH<sub>2</sub>-senktide suppressed intake in only the open condition, and MePhe<sup>7</sup> NKB had no effect in either fistula condition. Peripheral injections of BN and GRP were also potent in suppressing sham drinking of salt by sodium deficient rats. NMB had no effect on salt intake in either fistula condition. The results show that the effects of SENK, BN and GRP on salt intake are largely independent of ingestion-contingent feedback. (Supported by NIH NS24879 to F.W.F.)

## SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS I

## 16.1

NMDA RECEPTOR MEDIATED HORIZONTAL CONNECTIVITY IN LAYER IV OF MOUSE BARREL CORTEX. M.J. Gutnick\*, J.A. Fleidervish, A.M. Binshok, Zlotowski Center for Neuroscience and Faculty of Health Sciences, Ben-Gurion University of the Negev, Beersheva, Israel.

Although the coronal plane of section for neocortical slice experiments entails less damage to pyramidal cell dendrites and leaves intra-laminar circuitry intact, it disrupts much of the horizontal connections within a layer. We report a new neocortical brain slice preparation which is cut tangential to the pial surface; we apply it to the study of Layer IV stellate neurons in somatosensory cortex of juvenile (P18 - P22) mice.

Tangential slices (400 µm thick) were obtained by cutting in a plane parallel to the pial surface. In the one slice from each hemisphere that included layer IV, the typical barrel organization was readily visualized at low magnification. With higher magnification IR-DIC video microscopy, patch pipettes were directed to individual stellate neurons for whole cell recording. During the experiments, spiny and smooth neurons were tentatively distinguished on the basis of soma size; cells were filled with biocytin for subsequent morphological study. In current-clamp, 80% of neurons were regular spiking cells with varying degrees of spike adaptation, and the rest were fast-spiking; none were bursters, though we can identify intrinsic bursters in coronal slices using the same techniques. Bicuculline (10 µM) induced paroxysmal events that propagated from barrel to barrel. Although 2 mM Mg<sup>2+</sup> was present in the bath, the synchronous discharge was mediated by NMDA receptors, since it was insensitive to 10 µM CNQX, and reversibly blocked by 50 µM APV. In whole cell recordings, individual spiny stellate neurons showed two types of NMDAR-mediated evoked EPSC which were distinguished on the basis of different Mg<sup>2+</sup> sensitivities. The data suggest that long after the early critical period of development, Layer IV cells express more than one NMDAR subunit composition, and that a relatively voltage-insensitive receptor is prevalent in the local excitatory synaptic circuitry.

GABA<sub>A</sub>-DEPENDENT BURST-FIRING IN THALAMIC NEURONS: A DYNAMIC CLAMP STUDY. D. Ulrich\* and J. R. Huganard. Dept. of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford CA 94305.

Synchronized network responses in thalamus depend on phasic inhibition originating in the thalamic reticular nucleus (nRt), and mediated by the neurotransmitter γ-aminobutyric acid (GABA). The suggested role of intra-nRt connectivity in phasing its output remains controversial. Recently functional GABA<sub>A</sub> receptors were demonstrated on nRt cells and the slow time course of the GABA<sub>A</sub> synaptic response seems ideally suited to deactivate low threshold calcium channels. This would lead to burst firing, which is a characteristic feature of synchronized responses. In the present study we investigate GABA<sub>A</sub> mediated rebound burst firing in thalamic cells. Whole-cell current-clamp recordings were obtained from nRt cells and from thalamocortical (TC) relay cells of somatosensory thalamus in brain slices obtained from Sprague-Dawley rats at P11-13. An artificial hybrid computer-neuron synapse (dynamic clamp) was activated in each cell type. Dynamic clamp GABA<sub>A</sub> IPSPs triggered rebound low threshold calcium spikes in both nRt and TC cells, if the peak hyperpolarization of the IPSPs was greater than -92 mV. The threshold IPSP conductance for rebound burst generation was similar in the two cell types (nRt: 7 ± 1 nS (n=13); TC: 5 ± 1 nS (n=8); mean ± s.e.m.). However, burst onset in nRt cells (1 ± 0.07 s) was considerably delayed compared to relay cells (0.6 ± 0.08 s).

These results indicate that while GABA<sub>A</sub> IPSPs are capable of generating low threshold calcium spikes in both relay and nRt neurons, the resultant output frequency in TC cells would be in the range of 3 Hz but would be much slower in nRt cells. Furthermore, the minimal synaptic conductance required in nRt cells was much larger than the maximal GABA<sub>A</sub> conductance inferred from physiological measurements. Together, these findings suggest that intra-nRt GABA<sub>A</sub> mediated events contribute little to synchronization of the thalamic oscillations in the frequency range > 2 Hz. ## 16.3

**NORADRENERGIC AND CHOLINERGIC MODULATION OF AUGMENTING RESPONSES IN THALAMOCORTICAL PATHWAYS.** M.A. Castro-Alamancos\* and B.W. Connors. Department of Neuroscience, Brown University, Providence RI 02912.

The augmenting response is a form of short-term plasticity that is elicited in sensorimotor neocortex by applying two or more stimuli to the ventrolateral nucleus of the thalamus at a frequency of 7-14 Hz; the response to the second and subsequent stimuli in a train are enhanced, reaching a steady state by the third stimulus. Augmenting responses are very reliably generated during anesthesia, slow-wave sleep and awake immobility, but are inactivated during certain awake behavioral states, such as exploration of an open field and skilled motor performance.

In anesthetized rats, using 16-channel silicon probes with recording sites equally spaced (100  $\mu$ m) along the cortical depth, and a microdialysis probe to infuse drugs directly into the area of recording, we investigated the role of the noradrenergic and cholinergic systems in modulating the augmenting response. Application of nicotine enhanced similarly the response to the first pulse and the augmenting response. Application of muscarine depressed similarly both the response to the first pulse and the augmenting response. In contrast, application of norepinephrine produced a selective inactivation of the augmenting response with little effect on the response to the first pulse. The results suggest that a selective intracortical modulation by noradrenergic afferents may be responsible for the behavioral state-dependent inactivation of augmenting responses.

Supported by the NIH and ONR.

**CORTICAL SOMATOSENSORY OSCILLATORS AND THE DECODING OF VIBRISAL TOUCH** Ehud Ahissar\*, Gabriel Alkon, Miriam Zacksenhouse, Sebastian Haidarliu, Dept. of Neurobiology, The Weizmann Institute of Science, Rehovot 76100, Israel.

Many rodents utilize rhythmic vibrissal movements of 5-11 Hz to localize and identify objects. We suggest that vibrissal temporal information is decoded by thalamocortical phase-locked loops (PLLs). In the PLL model, cortical oscillators develop expectations concerning the timing of the next input, and thalamic cells compare these expectations with the actual input. PLL operation depends on the cortical oscillating frequencies (i) being in the range of peripheral frequencies, and (ii) being controllable by synaptic input. We characterized cortical oscillators in the somatosensory cortex of the guinea pig. Of 1119 units recorded from 11 anesthetized guinea pigs 546 (49%) showed signs of oscillations, and of them 189 (17%) were clearly oscillating. The oscillation frequencies were distributed in a tri-modal fashion with modes at ~1, 10 and 100 Hz. In many cases the 1 Hz oscillations appeared as synchronous activity of a group of cells, while those of 10 and 100 Hz were independent single-unit oscillations. Oscillating frequencies were increased, usually in a dose-dependent manner, by local applications of glutamate in 12/20 cases and were not affected in 7/20; one cell was inhibited. The locally-controllable oscillators in the 10 and 100 Hz fit the requirements of PLL circuits that decode object location and texture, respectively.

**MULTIPLE REPRESENTATIONS OF FERRET FOREPAW REVEALED BY CORTICAL EVOKED POTENTIALS: NORMAL AND REORGANIZED CORTEX.** D.F. McLaughlin\*, R.V. Sonty and S.L. Juliano, Department of Anatomy and Cell Biology, USUHS, Bethesda, MD 20814.

Our recent multi-unit data indicate that ferret somatosensory cortex contains multiple representations of forepaw and digits. To obtain a global view of the cortical representation of the forepaw, we recorded cortical surface potentials evoked by electrical stimulation of isolated ulnar and median nerves. We also recorded the receptive field of the individual nerves, and confirmed the peripheral cutaneous median and ulnar distribution. Topographic maps of the initial cortical negativity reveal that each nerve is represented multiple times in somatosensory cortex. In maps derived from stimulation of ulnar or median nerve, two foci consistently appear, and correspond to activity in areas 3a and 3b. In ulnar nerve maps, a third, less intense focus appears at the rostral crown of the coronal sulcus in area 1. Because much of the median nerve representation is deep within the coronal sulcus, surface recordings reflect both superficial generators for digit 3, and deep neural sources for digits 1 and 2. Deep activity appears at the surface as two foci, one caudal to the coronal sulcus and the other rostral to the sulcus. We also conducted experiments lesioning either the median or ulnar nerve when the animals were young (<15 days) or adults. These manipulations markedly alter the spatial distribution of the response. In experiments in which the ulnar nerve was lesioned in young (P5-7) animals (but the study conducted as an adult), median nerve stimulation evoked activity in regions normally occupied by ulnar nerve stimulation. Two clear peaks of evoked activity occurred within cytoarchitectonic area 3b, one corresponding to the normal site of median nerve activation, and the other extending into cortical territory normally activated by ulnar nerve. Further analyses of these data will characterize how adult reorganization is affected by interruption of afferent input at different ages of development. Supported by PHS RO1 NS24014.

**VB THALAMIC AFFERENTS HAVE LITTLE INFLUENCE ON LAYER-5 DESCENDING CORTICOFUGAL NEURONS OF RABBIT S1 BARREL CORTEX.** H.A. Swadlow\*, Dept. of Psychology, University of Connecticut, Storrs, CT 06269.

In previous work in the awake rabbit (Swadlow, J. Neurophysiol., 1995) three lines of evidence converged to indicate that VB thalamic barrel afferents exert a potent monosynaptic excitatory influence on suspected inhibitory interneurons (SINs) of the topographically corresponding barrel: (1) the great majority of SINs in layer 4, and some in layer 5 showed brief, significant peaks in shift-corrected cross-correlograms with VB afferents, (2) each of these SINs responded at very low thresholds to microstimulation of VB neurons (mean threshold = 4.9  $\mu$ A), (3) SINs in the vicinity of layers 4 and 5 were among the first cells in cortex to respond to peripheral stimulation, responding at a median latency of 6.6 ms, only 0.63 ms greater than the responses of VB axon terminals entering the cortex.

The present work extends this analysis to descending corticofugal neurons of layer 5 (CF-5 neurons). In contrast to the result for SINs, the same converging lines of evidence indicate that VB barrel afferents have little influence on CF-5 neurons of the corresponding barrel: (1) no significant peaks were seen in the shift-corrected cross-correlograms of VB barrel afferents and CF-5 neurons of the corresponding barrel (17 VB-CF-5 pairs tested), (2) None of 11 CF-5 neurons tested were synaptically activated by microstimulation of the corresponding barrel at intensities of < 10  $\mu$ A. At higher intensities some CF-5 neurons were activated, but at much longer latencies than was seen in SINs and (3) CF-5 neurons responded to peripheral stimulation at much longer latencies than was seen in SINs, and none responded at latencies of < 8 ms (Swadlow and Hicks, J. Neurophysiol., 1996).

Some of the SINs receiving monosynaptic VB input were clearly in layer 5, at the same depth or deeper than CF-5 neurons found in the same microelectrode penetrations. This result indicates that both cortical depth and cortical cell type are important factors determining the synaptic inputs to a cortical neuron. Previous work has documented that the corpus callosum provides a powerful excitatory synaptic input to CF-5 neurons of rabbit S-1 (Swadlow, J. Neurophysiol., 1990). This result, combined with the failure to observe a physiologically significant input from VB afferents suggests that CF-5 neurons may be selectively involved in the integration of corticocortical inputs. Supported by NS32021.

## 16.6

**SIMULTANEOUS NEURONAL ENSEMBLE RECORDINGS AT MULTIPLE TRIGEMINAL SYSTEM LEVELS: SELECTIVE CORTICAL RESPONSIVENESS TO ACTIVE DISCRIMINATIVE WHISKING.**

John K. Chapin\* (1), Ronald S. Markowitz (1) and Miguel A.L. Nicolelis (2), (1)Dept. of Neurobiol. & Anat., Med. College of PA & Hahnemann Univ., Phila., PA. (2)Dept. of Neurobiol., Duke Univ., Durham, NC

To investigate the mechanisms of somatosensory information processing during active tactile discrimination, ensembles of single neurons were simultaneously recorded through microelectrode arrays chronically implanted in up to 5 levels in the rat trigeminal somatosensory system, including the trigeminal ganglion (Vg), principal (PrV) and spinal (SpV) trigeminal nuclei, ventral posteromedial (VPM) thalamus, and primary somatosensory (SI) cortex. Blindfolded rats were trained to stand on a narrow platform and project their mystacial vibrissae across a wide gap to actively discriminate between a variety of randomly arranged tactile objects. The "correct" tactile object marked the position of a narrow slot through which the rat could jump and obtain a water reward. Active whisking movements were detected through videotaped records and EMG recordings in whisker protractor muscles. Marked differences were observed in the responses of neurons at lower vs. higher levels of this system during discriminative vs. non-discriminative whisking. Spontaneous non-discriminative whisker movements "through the air" produced robustly increased activity of neurons at lower levels of this system (e.g. Vg and PrV), but these responses were successively suppressed through higher levels of this system (VPM and SI). In contrast, neurons at the higher levels were generally more responsive than those at lower levels to discriminative whisker contact on the tactile objects, though the patterns of neuronal ensemble response varied widely across the range of objects. SI cortical neurons became particularly active when the correct tactile object was discriminated, but were then strongly suppressed as the rat began to jump across the gap and through the slot. To conclude, as tactile input from mystacial whiskers ascends to the cortex, neuronal responses to it become increasingly reflective of the sensorimotor and behavioral "significance" of the sensory information. ## 16.8

**LINEAR AND NON-LINEAR PROCESSING OF SPATIAL FORM IN AREA 3b OF THE AWAKE MONKEY.** J.A. Twombly, J.J. DiCarlo, K.O. Johnson, and S.S. Hsiao\*, Mind/Brain Institute, Johns Hopkins Univ., Baltimore, MD 21218

Single and multi-layer neural networks were used to model the spatiotemporal processing functions of 114 neurons in area 3b from five awake, behaving monkeys. The neural network architectures were loosely constrained to mimic the convergence of tactile information from the peripheral afferents to neurons in primary somatosensory cortex. The network input layer is an array of nodes analogous to the primary afferent population on the finger pad. The output layer is a single node analogous to a single neuron in SI cortex. The connectivity between the input and output is either direct (single layer models) or mediated through a layer of hidden units (multi-layer models). Models were trained using backpropagation with the average peripheral SAI response to embossed letter stimuli (8mm height, 500 $\mu$ m relief) as inputs and the cortical response to the same stimuli as the output.

Single layer models were used to determine the variance ( $r^2$ ) of each cortical response that could be accounted for by a linear processing function (including threshold rectification). The distribution of  $r^2$  values for the population of cortical responses is approximately normal (mean  $r^2$  = 0.58), indicating that no discrete sub-populations of "linear" and "non-linear" processing functions are present. The receptive fields (RFs) predicted from the single layer models are small, well defined regions of excitation and inhibition for models with high  $r^2$ , and larger, more complex regions of excitation and inhibition for models with low  $r^2$ . Multi-layer models typically explain 20% more variance than single layer models trained on the same data, and predict similar RF structures. These results show that both linear and non-linear processing contribute to the responses of cortical area 3b neurons, and that the predicted RFs vary from good to poor approximations of the true cortical processing functions in area 3b.

LAMINAR DIFFERENCES IN SPATIOTEMPORAL RECEPTIVE FIELD STRUCTURE OF NEURONS IN AREA 3b OF THE AWAKE MACAQUE. J.J. DiCarlo\*, J.A. Twombly, S.S. Hsiao, and K.O. Johnson. Krieger Mind/Brain Inst., Johns Hopkins Univ., Baltimore, MD 21218.

The spatiotemporal receptive field (RF) structure of 617 area 3b neurons was studied in three awake, behaving monkeys (*Macaca mulatta*). All RFs were centered on one of the distal finger pads. Stimuli consisted of a pattern of randomly-distributed (uniform, 10 dots/cm<sup>2</sup>) embossed dots (500  $\mu$ m dot diam., 400  $\mu$ m relief) and a pattern of embossed letters of the alphabet (8 mm height, 500  $\mu$ m relief). Stimuli were scanned over the neuron's RF at eight scanning directions (45 deg. increments) and three velocities (20, 40, 80 mm/sec). Single-unit recordings were made from neurons in all layers of area 3b and the laminar position of each neuron was histologically determined using a fluorescent marking method (1).

The linear spatiotemporal RF of each neuron was estimated by correlating the neural response to the random dot stimulus with the response of peripheral SAI afferents to the same dot stimulus. An RF estimate was also obtained from a neural network model trained to reproduce the neural response to the letter stimulus (2). For each neuron, both estimation methods produced similar spatiotemporal RF structure.

Results show a variety of RF structures. Neurons with RFs dominated by a single, small, excitatory region tend to be located in and around layer IV. Neurons with larger RFs containing spatially separate regions of excitation and inhibition tend to be found in the supra- and infragranular layers. These results demonstrate the existence of an isomorphic representation of spatial form in layer IV which is significantly transformed in the supra- and infragranular layers.

## 16.11

FMRI OF SOMATOSENSORY CORTEX: SOMATOTOPY AND LATERAL INHIBITION WITHIN THE POSTCENTRAL GYRUS. A. Gehi<sup>1</sup>, C. I. Moore<sup>1</sup>, S. Corkin<sup>1</sup>, B. R. Rosen<sup>2</sup> & C. E. Stern<sup>2</sup>. <sup>1</sup> Dept. of Brain & Cog. Sci., M.I.T., Cambridge, MA 02139; <sup>2</sup> MGH-NMR Center, Harvard, Charlestown, MA 02129.

Macro and microelectrode recordings have revealed detailed somatotopic maps in the mammalian postcentral gyrus (PCG). We used echo-planar fMRI to examine these representations within the PCG in 10 human subjects (age 20-25). Each subject received 6-8 4:00 min scans, with 10 7-mm slices aligned parallel to the PCG (1.5T; TR = 2500; TE = 70). Stimulation of the sole of the foot, the palm, or the volar forearm was alternated with periods of no stimulation. Stimulation consisted of 3-5 Hz contact with a 5.88(log 10, lmg) von Frey pressure aesthesiometer. Significant regions of activation were defined using a Kolmogorov-Smirnov statistic ( $p < 0.05$ ).

**Basic somatotopy.** In all subjects, we observed a somatotopic map in the PCG. In 4 subjects who received palm and sole stimulation, the PCG was activated in the appropriate regions (i.e., the foot representation was medial to the hand representation, and both stimulations activated regions of the PCG localized to the corresponding positions on the Penfield and Rasmussen homunculus (1950)). In 6 other subjects who received palm and forearm stimulation, we observed palm activation in the expected region of the PCG in 6/6, and forearm activation in 3/6. In all subjects, the superior bank of the insula, an area containing several somatosensory maps (e.g., SII), was successfully activated by tactile stimulation.

**Lateral inhibition within the PCG.** We observed inhibition of the fMRI signal in the hand representation during arm stimulation ( $n=6/6$ ; fig.). By contrast, inhibition following arm stimulation was not observed in the insula, suggesting that the different neural representations in the PCG and insula may be characterized by differential responses of the fMRI signal. *Support: SCRF-1416.*

## 16.13

CORTICAL REORGANIZATION IN ARM AMPUTEES: ALTERATIONS OF SOMATOSENSORY REPRESENTATION IN THE HEMISPHERE CONTRALATERAL TO THE INTACT SIDE. T. Elbert<sup>1</sup>, A. Stern<sup>1</sup>, H. Flor<sup>2</sup>, B. Rockstroh<sup>1</sup>, C. Pantev<sup>3</sup>, S. Knecht<sup>3</sup>, N. Birbaumer<sup>1</sup>, E. Taub<sup>4</sup>. Universities of Konstanz<sup>1</sup>, Berlin<sup>2</sup>, Münster<sup>3</sup>, and Alabama, Birmingham<sup>4</sup>; <sup>1</sup> 78464 Konstanz, Germany.

Magnetic source imaging has provided evidence that extensive cortical reorganization following somatosensory deafferentation in monkeys also occurs and persists in humans following upper extremity amputation. Here we demonstrate that the somatosensory map in amputees is altered also in the hemisphere contralateral to the intact side.

Six upper arm amputees and six controls served as subjects. Somatosensory stimulation was delivered separately to the first and the fifth digit of either hand and to the lower lip at the corners of the mouth. Within the range of 30-75 msec a first major peak was identified in each of the magnetically evoked waveforms and its generator was located using a single equivalent current dipole model. In amputees the cortical representations of D1 and D5 of the intact hand encompassed a greater area (Euclidean distance:  $12.4 \pm 5.5$  mm) than in controls ( $6.9 \pm 1.6$  mm;  $t = 2.4$ ,  $p < .05$ ). The average difference in inferior-superior direction was 5.5 mm larger in amputees than in controls ( $t = 3.2$ ,  $p < .01$ ). Compared to controls, only D1-representation had shifted: along the central sulcus in inferior (2.6 mm, n.s.) and lateral (7.7 mm,  $t = 2.1$ ,  $p < .1$ ) direction. However, the distance between the lip and D5-location was 5.5 mm greater in the amputees than in control subjects ( $p < .05$ ). There was no difference in the magnitude of the dipole moments of the digits. In amputees dipole moments were greater for the lip-stimulation on the amputated side than on the intact side.

The present comparison is the first evidence, that cortical reorganization after upper arm amputation occurs in both hemispheres. The alterations observed in the hemisphere contralateral to the intact side may be explained by the increased use of the remaining hand by amputees. The shift was greatest for D1, an observation that is consistent with the relative frequency of use of the different digits.

## 16.10

SOMATOSENSORY STIMULATION MAPPING IN RAT BRAIN: A FUNCTIONAL MRI STUDY. J.A. Marota, J.B. Mandeville, B.E. Kosofsky, J.B. Keltner, J. Berke, L. LaPonte, R. Weissleder, B. Rosen, R. Weisskoff, SE Hyman\*. Dept. Anaesthesia, Laboratory of Molecular and Developmental Neuroscience, and NMR Center, MGH, Harvard Medical School, Boston, MA 02114.

Because cerebral blood flow (CBF) is coupled to metabolism within the central nervous system (Ann Neurol. 22:289-297,1987), changes in local CBF can identify regions with altered neuronal activity. Since CBF is regulated by local cerebral vasodilatation, cerebral blood volume (CBV) also varies with regional metabolic activity. Using an electrical stimulation model in  $\alpha$ -chloralose anesthetized, paralyzed (pancuronium) rats, we have used MRI techniques to map brain regions activated by peripheral somatosensory stimulation. We employed high speed echo planar imaging with gradient and spin echo imaging sequences sensitive to the paramagnetic state of deoxygenated hemoglobin to quantitate 1) blood oxygen level dependent (BOLD) changes as a measure of local cerebral metabolism, and 2) CBV changes by use of a superparamagnetic iron oxide contrast agent. Electrical stimulation of the forepaw (3Hz, 5V, 0.5ms duration) resulted in an increase in BOLD signal in a discrete area of contralateral somatosensory cortex (SI). The signal took 30s to attain maximal change and required 30s to return to baseline after discontinuation of the stimulus. In the same volume of cortex, CBV increased with a time course which paralleled the BOLD signal change. Increases in both BOLD and CBV were also present in the ventral medial thalamus bilaterally, with a timecourse similar to that of SI neocortex. Although either right or left SI neocortex could be activated (depending upon paw stimulated), there was no change in either BOLD or CBV in SI neocortex ipsilateral to stimulation. In addition, both BOLD and CBV signal decreased in dorsal striatum bilaterally, with a timecourse similar to that of SI neocortex. These findings confirm and extend data previously obtained with other modalities correlating cerebrovascular changes and brain activation during peripheral somatosensory stimulation. ## 16.12

ACTIVATION OF HUMAN MESIAL CORTEX DURING SOMATOSENSORY ATTENTION TASK. N. Forss\*, I. Merlet, S. Vanni, M. Hämäläinen, F. Mauguière and R. Hari. Brain Research Unit, Low Temperature Laboratory, Helsinki University of Technology, 02150 Espoo, Finland, and Hôpital Neurologique, 59 Boulevard Pinel, 69003 Lyon, France.

We recorded somatosensory evoked fields (SEFs) from 10 healthy subjects with a whole-scalp neuromagnetometer to ulnar and median nerve stimuli, presented at random intervals of 2.4-21.6 s. The subjects either counted the stimuli or ignored them by reading a book. The stimuli activated in both conditions the contralateral SI cortex, the ipsi- and contralateral SII cortices, and the posterior parietal cortex, in line with earlier observations. In addition, a novel response was observed in nine subjects at 120-160 ms. It was clearly enhanced by attention and was originated in the mesial paracentral lobule, close to the end of the central sulcus. The observed signals may reflect attention-dependent activation which would be needed to prime the SMA in case a stimulus-related movement would be needed.

## 17.1

EVIDENCE OF APOPTOSIS IN AN ACUTE SPINAL CORD INJURY MODEL. T.K. Swoboda\*, Y. Li, R.P. Nockels, M. Chopp. Departments of Neurosurgery and Neurology, Henry Ford Hospital, Detroit, MI 48202.

Apoptosis differs from necrosis particularly in the manner of chromatin breakdown. Utilizing a commercial molecular histochemical marker (ApoTag kit; Oncor, Gaithersburg, MD) that labels the 3'-OH DNA ends generated by DNA fragmentation occurring during chromatin breakdown, apoptotic cells can be individually marked. To determine the extent of apoptosis in acute spinal cord injury, eight S.D. rats were anesthetized with pentobarbital and received laminectomies at the T<sub>10</sub> vertebral level. In four rats, a ten gram rod was dropped 25mm onto the exposed dura corresponding to the T<sub>12</sub>-T<sub>13</sub> spinal cord level utilizing the NYU contusion device. The wound was closed, and all rats were reanesthetized 24h after injury and perfused with heparinized saline and 10% buffered formalin solution. 5µm formalin-fixed paraffin-embedded cross-sections of spinal cord were cut from the T<sub>9</sub>-L<sub>1</sub> spinal levels. Sections were stained with the ApoTag kit and counterstained with hematoxylin. Adjacent spinal cord sections were stained with H&E to identify necrotic cells. 5µm serial coronal brain sections, with 2mm spacing, were also stained with H&E and the ApoTag kit for each animal. In the four lesioned animals, widespread necrosis and surrounding apoptosis were seen within the dorsal tracts at the lesion site from T<sub>11</sub>-L<sub>1</sub>. Apoptotic cells were noted in the dorsal region of lesioned spinal cords at the T<sub>9</sub>-T<sub>10</sub> and L<sub>2</sub> levels at numbers significantly higher than in the sham animals. No significant difference was found in the number of apoptotic corticospinal tract neurons in the cortices of lesioned and sham animals.

## 17.3

UPREGULATION OF CPP32 CYSTEINE PROTEASE ASSOCIATED WITH APOPTOSIS IN RAT CORTIX FOLLOWING TRAUMATIC BRAIN INJURY. A.G. Yakovlev\*, S.M. Knoblach, D. Rosenthal, M. Smulson, and A.I. Faden. Georgetown Institute for Cognitive and Computational Sciences and Dept. of Biochemistry, Georgetown Univ. Med. Ctr., Washington DC 20007.

This study delineated the apoptotic component in delayed neuronal death following traumatic brain injury (TBI) in rat cortex and determined the effect of such injury on the expression of the gene encoding ICE-like cysteine protease CPP32. An early biochemical event that accompanies apoptosis in many cell types is the proteolytic cleavage of poly(ADP-ribose) polymerase (PARP), a nuclear enzyme involved in DNA repair and protection of fragmented DNA. PARP is cleaved by a mammalian equivalent of ced-3, cysteine protease CPP32. Apoptosis was monitored by the analysis of associated internucleosomal DNA fragmentation in sham controls or cortex isolated after 1, 4, 12, 24 hrs and 3 days after moderate (2.0 atm) fluid-percussion induced TBI. DNA fragmentation was observed in injured but not in contralateral cortex starting from 4 hrs after trauma. The intensity of DNA "ladders" increased progressively and peaked at 3 days. To address the issue of CPP32 gene expression in traumatized brain we isolated the corresponding rat cDNA. Based on the obtained sequence we used RT-PCR technique for semi-quantitative analysis of this gene expression. Results showed that the levels of CPP32 mRNA were induced in the injured tissue at 4 hrs (4-fold increase) and peaked at 24 hrs (about 5 fold increase). Levels of CPP32 mRNA remained elevated up to 72 hrs after trauma. At the same time, these levels were not affected by trauma in rat cortex contralateral to injury site at any time point tested. The posttraumatic elevation of CPP32 mRNA was consistent with an increase of PARP-cleavage activity in cytosolic extracts of injured cortex, suggesting that TBI also leads to posttranslational activation of a PARP-cleaving protease, presumably CPP32. Taken together, these results suggest that programmed cell death contributes to secondary neuronal loss after fluid-percussion injury, and that early upregulation and activation of CPP32 may play an important role in the induction of apoptosis following TBI.

## 17.5

BCL-2 PROTEIN EXPRESSION AFTER SEVERE CONTUSIVE BRAIN INJURY IN RATS. R.S.B. Clark\*, P.M. Kochanek, S.C. Watkins, M. Chen, D.S. Turner, J. Chen, and S.H. Graham. Depts. of Anesth/CCM, Neurology, and Cell Biol. and Physiol., and the Safar Center for Resuscitation Research, U. Pittsburgh, PA 15213.

Delayed neuronal death occurs after traumatic brain injury (TBI). The exact mechanism is unknown but apoptosis may play a role. Bcl-2 is a highly conserved apoptosis-suppressor gene that is induced in brain after ischemic and kainate-induced injury<sup>1,2</sup>, and may serve to inhibit apoptotic delayed neuronal death. The purpose of this study was to determine if bcl-2 protein is also induced after severe TBI.

Anesthetized adult rats were subjected to severe controlled cortical impact injury to the left parietal cortex immediately followed by 30 min of hypoxia (PaO<sub>2</sub>=35-45 torr). Rats were killed at 8, 24, 72, or 168 h after trauma (n=3-5/group). Naive rats were used as controls. Brains were removed and Western analysis was performed using a mouse MoAb against human bcl-2 (Dako, Carpinteria, CA). Bcl-2 was induced at 8, 24, and 72 h in ipsilateral traumatized cortex and hippocampus. Minimal baseline bcl-2 was detected in control brains and in ipsilateral cortex distal to the contusion. By 7d bcl-2 expression decreased vs. earlier time points, but remained increased vs. controls. To determine what cell types expressed bcl-2 immunocytochemistry was performed on brain sections from separate rats 24 h after trauma (n=3). Immunocytochemistry was performed using fluorescent detection methods and the same primary antibody. Bcl-2 expression was seen in cells with the distinct morphologic appearance of neurons and endothelial cells. Other cells expressed bcl-2 and may have been leukocytes and/or glia. Bcl-2 expressing cells were seen only in the penumbra surrounding the contusion. Nonspecific staining was not seen in sections incubated without primary antibody.

Bcl-2 protein is expressed after severe TBI in cell-types that include neurons and endothelium. Because bcl-2 suppresses apoptosis, its induction in neurons in the penumbra surrounding the contusion may be an attempt to reduce delayed neuronal death. Supported by NIH/NINDS 2P50 NS30318-04A1. <sup>1</sup>Chen, et al, Neuroreport 1995;6:394-8, <sup>2</sup>Chen, et al, Soc Neurosci Abstr 1995;21:302

## 17.2

APOPTOSIS IN INJURED SPINAL CORD OF RAT. C. Yong, P. M. Arnold\*, M.N. Zoubine, B.A. Citron and B.W. Festoff. Neurobiology Research lab, VA Medical Center, Kansas City, MO 64128; Departments of Neurology and Surgery (Neurosurgery), University of Kansas Med. Center, Kansas City, KS 66160.

We studied neuronal cell death with Hoechst 33342 staining and the *in situ* TUNEL technique in the NYU weight-drop injured rat spinal cord. Functional deficit was assessed at day 1, 3, 7, 14 and 28 after injury by scores on a modified Tarlov scale and the inclined plane test. Rats were perfused with normal saline followed by 10 % formalin and then spinal cords were sectioned (7 µm) and stained with H&E or processed for *in situ* TUNEL with the TDT-mediated dUTP-biotin nick-end labeling method (ApoTag kit, Oncor, Gaithersburg, MD). For Hoechst 33342 staining, rats were perfused with normal saline followed by 4% paraformaldehyde/PBS prior to sectioning (20 µm). As early as one day after injury, multifocal petechiae appeared in all regions of the gray matter surrounding small capillaries, veins, and arterioles, and, to a lesser extent, the white matter. Both apoptosis and necrosis of neurons began 1 day after injury, where nuclei with condensed chromatin were mainly found in the dorsal funiculi, and less in dorsal and ventral horns. Selective stains identified apoptotic cells as both neurons and glia. By 3 days after injury, necrosis was prominent. Gliosis was evident on day 7 with glial like cells having small condensed chromatin nuclei on day 14. On day 28, the lesioned area was cystic with a wall made up of collagen, fibroblasts and astrocytes. This study suggests that apoptosis is evident early and up to 14 days after spinal cord injury. Which factors participate in apoptosis are subjects of current studies. Supported by Medical Research Service, DVA and ALS/Spinal Cord Research Fund.

## 17.4

DELAYED DEGENERATION OF DISTANT NEURONS FOLLOWING NEOCORTICAL BRAIN CONCUSSION IN INFANT RATS. C. Ikonomidou, M. Ishimaru\*, P. Bittigau, T. C. Der, Y. Q. Qin, and J. W. Olney. Depts. of Psychiatry and Pediatric Neurology, Washington University Medical School, St. Louis, MO 63110

Previously we described a method for inducing concussive head trauma in infant rats and described the acute lesion which evolves over a 6 hr period subjacent to the neocortical site of impact. We demonstrated that the acute lesion closely resembles the excitotoxic type of neuronal injury caused by glutamate and that NMDA glutamate receptor antagonists can prevent the acute lesion from expanding locally. We have now examined the brains of infant rats at more extended postconcussive time intervals and have found that cytopathological changes appear in a disseminated pattern at distant loci over a 6 to 24 hr period. The distant degenerative reaction was particularly conspicuous at all rostrocaudal levels of the ipsilateral cingulate and retrosplenial cortices, and foci of damage occurred ipsilaterally in the subiculum, dentate hippocampal gyrus, various thalamic nuclei and head of the caudate nucleus. In some cases, a circumscribed lesion was present in the contralateral medial geniculate nucleus. The distant lesions are being evaluated by light and electronmicroscopy in thin plastic sections, by de Olmos cupric silver staining and by the TUNEL staining method (for evaluating the possible involvement of an apoptosis mechanism). At 6 hrs post concussion these several methods show very little evidence of lesions anywhere except at the local site of impact, but in the ensuing 24 hrs the distant lesions become evident by all of these methods. Some of the degenerating neurons in the distant foci are robustly stained by the TUNEL method. It is not clear what this signifies regarding cell death mechanisms in that hypothalamic neurons killed by an excitotoxic mechanism (subcutaneous monosodium glutamate) also show TUNEL positivity while failing to meet other criteria for apoptosis. Supported by DA 05072, AG 11355 and RSA MH 38894 (JWO).

## 17.6

ROLE OF GROUP I METABOTROPIC GLUTAMATE RECEPTORS IN POSTTRAUMATIC NEURONAL INJURY. A.G. Mukhin\*, L. Fan and A.I. Faden. Georgetown Institute for Cognitive and Computational Sciences, Washington DC 20007

Increased glutamate release and activation of ionotropic glutamate receptors have been implicated in the pathophysiology of traumatic brain injury (TBI). The role of metabotropic glutamate receptors (mGluR) in posttraumatic central nervous system injury has been largely unexplored.

*In vitro* experiments were performed on 17-21 DIV rat cortical neuronal/glial cocultures, growing in 96-well plates. Traumatic injury to cells was delivered using a punch, that produces 28 parallel cuts 1.2 mm in length uniformly distributed throughout the cell layer at 0.5 mm intervals in each well. Cell death was detected 16 h after injury by measuring LDH release. For *in vivo* studies, male Sprague-Dawley rats were anesthetized with sodium pentobarbital (70 mg/kg, ip) and subjected to moderately severe (2.8 atm) lateral fluid percussion-induced TBI. Outcome variables included motor recovery and histology at 2 weeks after TBI.

(+)-MCPG (500µM) — an antagonist of both group I (phospholipase C-coupled metabotropic receptors subtypes mGluR<sub>1</sub> and mGluR<sub>5</sub>) and group II (subtypes negatively linked to adenylate cyclase activity) — reduced posttraumatic increases in phosphoinositide hydrolysis and neuronal cell death following mechanical trauma in mixed neuronal/glial cultures. (S)-4CPG (30µM), which is an antagonist at group I mGluR but an agonist at group II mGluR, showed a similar neuroprotective effect in tissue culture. In the *in vivo* studies, (RS)-MCPG administered either icv (0.5 µmol 15 min before, plus 0.5 µmol 60 min after, trauma) or iv (48 µmol 15 min after trauma) improved neurologic recovery and limited the cell loss in ipsilateral hippocampus following TBI. Administration of antisense oligodeoxynucleotides (2µM over 5 days) directed to mGluR<sub>1</sub>, but not those directed to mGluR<sub>5</sub>, reduced posttraumatic neuronal cell death in tissue culture.

Together, these findings suggest that activation of mGluR<sub>1</sub> contributes to posttraumatic neuronal injury, and that mGluR<sub>1</sub> antagonists may have therapeutic potential. Supported by NIH grant NS27849 and CDC grant CCR306634.

EVIDENCE FOR ULTRA-EARLY CYTOSKELETAL CHANGE AND ITS RELATION TO THE PATHOBIOLOGY OF TRAUMATIC AXONAL INJURY. J. MOROI<sup>1</sup>, J. TROJANOWSKI<sup>2</sup>, and J. POVLISHOCK<sup>1</sup>. <sup>1</sup>Depts. of Anatomy and Neurosurgery, Med. Col. of VA, VA Commonwealth Univ., Richmond, VA 23298, and the <sup>2</sup>Dept. of Neuropathology, Univ. of PA, Philadelphia, PA 19104.

Recently, we have suggested that the axonal injury associated with traumatic brain injury has two forms of genesis, one involving compaction of the neurofilaments (NF), with the loss of sidearms and the other involving NF misalignment (Pettus et al., J. Neurotrauma, 11(5), 1994). In the current investigation, we rigorously explore the genesis of these two different forms of reactive axonal change, using antibodies specific for each of these events. For this purpose, we used RMO 14 antibody, targeted to the rod domain which is only visualized once the associated NF sidearms are lost, together with antibodies targeting the 68 kD subunit, a marker for reactive axons showing NF misalignment. Anesthetized rats were subjected to severe impact acceleration insult, and at 15 min to 6 h postinjury were prepared for LM and EM visualization of both antibodies using double-labeling with immunogold and HRP-DAB. Antibodies targeting the rod domain readily identified damaged/reactive axons in various regions of the neuraxis. These sites were associated with NF compaction and side arm loss reminiscent of that previously described. Over time, these sites became more prominent, and the immunoreactivity was associated not only with sites of compaction, but also with the onset of reactive axonal swelling. In contrast, the 68 kD immunoreactivity was never associated with the site of NF compaction. Rather, it appeared to label an independent population of axons not showing overt NF compaction and sidearm loss. These double-label immunocytochemical findings clearly suggest that two distinct populations of reactive axons exist. It is posited that these distinct populations reflect differences in pathogenesis which may be linked to the severity of the insult sustained by individual axons. (Supported by NS 20193).

## 17.9

POST-TREATMENT WITH INTRAVENOUS BASIC FIBROBLAST GROWTH FACTOR REDUCES HISTOPATHOLOGICAL DAMAGE FOLLOWING FLUID-PERCUSION BRAIN INJURY. W.D. Dietrich<sup>1</sup>, O. Alonso, R. Busto, and S.P. Finklestein. Neurotrauma Res. Center, Dept. Neurology, Univ. Miami Sch. of Med., and the CNS Growth Factor Res. Lab., Dept. Neurology, Massachusetts General Hospital and Harvard Med. Sch., Boston.

We determined whether treatment with basic fibroblast growth factor (bFGF) would protect histopathologically in a rat model of traumatic brain injury (TBI). Fasted Sprague-Dawley rats were anesthetized with 70% nitrous oxide, 1% halothane and 30% oxygen. Under controlled physiological conditions and normothermic brain temperature (37-37.5°C), rats were injured with a parasagittal fluid-percussion pulse ranging from 1.6-1.9 atm. Rats were randomized into two groups where bFGF (45 ug/kg per hour) in vehicle (n = 7) or vehicle alone (n = 7) was infused intravenously for 3 hr, beginning 30 min after TBI. In vehicle-treated animals, necrotic neurons were observed throughout the lateral cerebral cortex remote from the impact site 3 days after TBI. An intracerebral contusion was present in all rats at the gray-white interface underlying the injured cortical areas. Post-traumatic administration of bFGF significantly reduced the numbers of damaged cortical neuron profiles at several coronal levels and reduced the total number of damaged neurons (696 ± 148 vs. 1,248 ± 198, means ± SEM, p < 0.05 ANOVA). In addition, contusion areas at several coronal levels and total contusion volume was significantly reduced (1.13 ± 0.39 mm<sup>3</sup> vs. 3.18 ± 0.81 mm<sup>3</sup>, p < 0.05). These data demonstrate neuroprotection with intravenous bFGF infusion in the post-traumatic setting.

## 17.11

DOUBLE LABELING STUDIES USING ANTIBODIES TARGETED TO THE NEUROFILAMENT ROD AND SIDEARM DOMAINS IN THE STUDY OF THE GENESIS OF TRAUMATICALLY INDUCED AXONAL INJURY. J. POVLISHOCK<sup>1</sup>, J. TROJANOWSKI<sup>2</sup>, AND J. MOROI<sup>1</sup>. <sup>1</sup>Depts. of Anatomy, Med. Col. VA, VA Commonwealth Univ., Richmond, VA 23298 and <sup>2</sup>Dept. of Neuropathology, Univ. of PA, Philadelphia, PA 19104.

We have recently emphasized the utility of antibodies targeted to the rod domain for recognizing the initiating steps in the pathobiology of axonal injury. It was posited that these antibodies were capable of recognizing the neurofilament (NF) rod domain segments whose sidearms had been altered by processes related to the traumatic insult. In this study, we attempt to confirm this suggestion through the use of double-labeling strategies targeting the NF rod and sidearm domains independently. Rats were subjected to impact acceleration traumatic brain injury and then, at 5 min to 6 h postinjury, were transcardially perfused and prepared for LM and EM visualization of antibodies targeting the NF rod (RMO14) and sidearm domains (RMO270, phosphorylation independent). The RMO14 antibody was visualized through the use of immunogold, whereas the RMO270 antibody visualized through the use of HRP-DAB. Consistent with previous reports, the RMO14 antibody served as an early marker of reactive axonal change, demonstrating sites of NF compaction which led to local cytoskeletal dysfunction, axonal swelling and detachment. When the antibody targeted to the NF sidearms was employed, it labeled all intact axons, and to our surprise, was also co-localized at the same sites showing RMO14 activity. This finding was contrary to our expectations, as we had posited that the unmasking of the NF rod domain was associated with the functional disruption of the NF sidearms. This suggests that these sidearms may be only partially cleaved by the traumatic insult. Alternatively, the constituent epitopes may not have been removed from the site of injury. This suggests that future studies directed at longer survival times may be necessary to fully reveal this NF sidearm alteration. (Supported by NS20193)

## 17.8

BONE MORPHOGENETIC PROTEINS AS MEDIATORS OF PLASTIC CHANGES FOLLOWING TRAUMATIC BRAIN INJURY. A. Lewén, S. Söderström, L. Hillered<sup>1</sup> and T. Ebendal<sup>2</sup> Departments of Neurosurgery, <sup>1</sup>Clinical Chemistry and Developmental Neuroscience, Uppsala University Hospital and Biomedical Centre, S-751 85 Uppsala, Sweden

Members of the transforming growth factor  $\beta$  superfamily act on the cell via induction of a heteromeric complex of type I and type II serine/threonine protein kinase receptors. Recently, a new type II receptor was identified as the human bone morphogenetic protein receptor II (BMPR-II). The expression of BMPR-II in the brain has until now not been studied. It is of interest to elucidate which receptors may act in concert *in vivo*, to mediate neurotrophic interactions, during brain development, during normal brain function and after brain injuries.

To investigate how serine/threonine protein kinase receptors are expressed in the brain after an acute brain injury, a focal cerebral contusion injury was produced over the right parietal cortex by the weight drop technique in artificially ventilated rats. The expression of BMPR-II-, ActR-IA-, ActR-IB-, ActR-IIA-, trkB- and *c-fos*-mRNA was studied by *in situ* hybridization 0.5 h, 2.0 h, 6.0 h and 18.0 h after injury. We found that, BMPR-II and ActR-IA were simultaneously upregulated in neurons in the dentate gyrus 6h after a mild cerebral contusion injury, a finding which seemed to be specific for these two receptors. This study suggests that type I and type II receptors act together in signal transduction *in vivo* and that BMPs may be involved in neuronal plasticity after traumatic brain injury.

## 17.10

INTERLEUKIN-6 (IL-6) AND INTERLEUKIN-10 (IL-10) IN CEREBROSPINAL FLUID (CSF) FOLLOWING SEVERE TRAUMATIC BRAIN INJURY (TBI) IN CHILDREN. M. Bell, P. D. Adelson<sup>1</sup>, L. Doughty, J. Carcillo, R. Clark, S. DeKosky and P. Kochanek. Safar Center for Resuscitation Research, Departments of Anesthesiology/CCM, Neurosurgery, Univ of Pittsburgh, Pittsburgh, PA 15213.

Inflammation may play an important role in the pathophysiology of TBI in children. IL-6 and IL-10 are markers of inflammation that are pro- and anti-inflammatory in nature, respectively, and have been measured in serum and CSF as an index of the degree of inflammation in diseases including sepsis and meningitis. We hypothesized that both IL-6 and IL-10 would be increased in the CSF of children after severe TBI. Eleven children who sustained severe TBI (GCS  $\leq 7$ ) were studied. Standard neurointensive care was provided. Ventricular CSF collected each of the first three days after TBI was analyzed for IL-6 and IL-10 concentrations (pg/ml) by ELISA. IL-6 was markedly increased on d 1 vs. d 2 and 3 (mean  $\pm$  SE, 2179.8  $\pm$  412.2 vs. 933.0  $\pm$  273.2 and 883.4  $\pm$  226.3, p = 0.004, repeated measures ANOVA). IL-10 concentrations tended to be increased on d 1 compared to d 2 and 3 but did not reach statistical significance (48.4  $\pm$  17.1 vs. 25.3  $\pm$  8.54 and 21.3  $\pm$  8.14). IL-6 and IL-10 concentrations were correlated on d 1 and 2 (r = 0.62 and 0.86, p < 0.05). IL-6 and IL-10 concentrations were not associated with initial GCS, age (< 4 y) or death. We conclude that CSF IL-6 was increased early after TBI in children. CSF IL-6 concentrations in children are comparable to those found in CSF of adults after TBI<sup>1</sup> and serum of children with septic shock<sup>2</sup>. The associated increase in serum IL-10 seen in sepsis, however, was not observed in CSF after TBI. This suggests that the balance between pro- and anti-inflammatory cytokines in brain after TBI is different than that observed in serum during sepsis. <sup>1</sup>McClain et al., J. Clin Med 1991, 118: 225-31. <sup>2</sup>Doughty et al., Crit Care Med 1996, 24:A33. ## 17.12

INCREASED IMMUNOREACTIVITY OF *c-JUN* AND *JUN-B* BUT NOT *JUN-D* IN DYING AND DEAD NEURONS AFTER PHYSICAL INJURY. R. Raghupathi<sup>1</sup>, L.J. Rosenberg<sup>2</sup>, T.K. McIntosh<sup>1</sup>, and J.H. Lucas<sup>2</sup>. Div. of Neurosurgery, Univ. of Pennsylvania, Philadelphia PA 19104 and Dept. of Physiology, Ohio State Univ., Columbus OH 43210.

To evaluate the immediate-early gene (IEG) response of CNS neurons to mechanical injury, cultured mouse spinal cord (SC) neurons were subjected to UV laser microbeam transection of a primary dendrite 100  $\mu$ m from the soma (n = 109 neurons in 14 cultures) and immunostained with *c-jun/AP-1*, a pan-*jun* antibody (AB). Unlesioned control neurons (n = 112) showed light AB staining of the somal cytoplasm and nucleus. Increased immunoreactivity in the cytoplasm and nucleus was observed in 19 of 27 cells at 30 min. Phase contrast microscope evaluations of viability at 2h revealed that 53% of lesioned neurons were either dead or dying; intense nuclear AB staining was observed in 52% of these cells. At 24h after lesioning, 15 of 39 lesioned neurons were still alive and stained similar to unlesioned cells. Among the dead cells at 24h, 30% were too deteriorated to stain (debris); however, 100% of the remaining dead cells exhibited intense nuclear staining. In separate studies, a similar pattern was revealed for *c-jun/p39* (specific for *c-jun*; 43 lesioned/39 control) and *junB* (51 lesioned/48 control) with increased somal staining in lesioned cells at 30 min and 2h, return to the control pattern in surviving cells at 24h, and intense nuclear staining in dead cells at 24h. Increased *junD* immunoreactivity was observed in 17 of 19 lesioned neurons 30 min after dendrotomy, but not in viable, dying or dead lesioned neurons at 2h or 24h (20 lesioned/20 control per time). *c-jun* has been implicated in neuronal death during development and after hypoxia/ischemia or seizures. These data suggest that *c-jun* and *junB* may play a role in neuronal death following physical (membrane disruption) injury of mammalian SC neurons. Supported by PHS grants 29683 to JHL at OSU and NINDS grants 26818 and 08803 to TKM at UPenn.

## 18.1

# BRAINSTEM CYSTS, CEREBRAL ANEURYSMS AND HYDROCEPHALUS IN A HIGHLY FUNCTIONING MALE: A POSSIBLE EXAMPLE OF DEVELOPMENTAL FIELD DEFECT.

B. W. Chopko\*, C. Ames, A. Brant, D. Barba. Division of Neurological Surgery, UCSD Medical Center, San Diego, CA 92103.

A 19 year old Caucasian male presented with new onset severe headaches and episodic bouts of unresponsiveness. Past medical history was noncontributory, including a normal prenatal, perinatal and developmental course. Physical exam was significant for gait ataxia; no other neurologic abnormalities were evident. Magnetic resonance imaging revealed obstructive hydrocephalus, multiple cysts of the midbrain, pons and cerebellum, and a left middle fossa mass lesion. Cysts were nonenhancing, without edema, contained fluid isodense with cerebrospinal fluid, and extensively involved the midbrain to the point of apparent total replacement. Cerebral angiography demonstrated a left internal carotid artery (ICA) giant (2.8 cm maximal dimension) paraophthalmic aneurysm, a second 8 mm left ICA paraophthalmic aneurysm, and fetal origin of the left posterior cerebral artery. Cysticercosis studies were negative. A midbrain biopsy revealed gray matter with mild diffuse microglial hyperplasia, scattered reactive lymphocytes, and a few chronic inflammatory cells. Neurons were of normal appearance, and no evidence of neoplastic or active infectious processes was observed. Hydrocephalus was treated with ventriculoperitoneal shunting, and the aneurysms were treated by carotid ligation. This case is an association of two unusual findings in a young, highly functioning male: ICA aneurysms and brainstem cysts of unknown etiology. The constellation of findings may represent a developmental field defect, with disruption of neighboring ectodermal and mesodermal derivatives culminating in vascular and parenchymal abnormalities.

Supported by University of California intramural funding.

## 18.3

# COGNITION AND LOCOMOTOR ACTIVITY IN THE DEVELOPING RAT: COMPARISONS OF HISTAMINE H<sub>3</sub> RECEPTOR ANTAGONISTS AND ADHD THERAPEUTICS C. E. Tedford\*, G. P. Pawlowski, M. A. Khan, J. G. Phillips, and S. L. Yates, Gliatech, Inc., 23420 Commerce Park Road, Cleveland, OH 44122

The localization and physiological role of the Histamine H<sub>3</sub> receptor subtype in the CNS has been recently described by several investigators. Ontogenetic studies have described independent and heterogeneous developmental patterns of histamine receptor subtypes (Ryu et al., 1995) and autoradiographic studies have identified unique CNS localization patterns for the H<sub>3</sub> receptor (Pollard et al., 1993). Behaviorally, arousal or vigilant properties of H<sub>3</sub> receptor agents have been indicated in EEG studies in several species. Additionally, modulation of learning and memory has been demonstrated with H<sub>3</sub> receptor subtype selective compounds.

The present studies characterized the behavioral development of cognitive and motor patterns in juvenile rat pups and evaluated the influence of histamine H<sub>3</sub> receptor blockade in both immature and adult rats. Comparisons with (methylphenidate, pemoline and d-amphetamine) were made for cognitive and motor effects. Immature rat pups up to postnatal days 15-16 displayed sustained locomotor activity profiles and acquisition deficits in a 10-trial passive avoidance response (PAR) paradigm. Improvements in the step-through latency were most prominent with either pre-treatment of methylphenidate (Ritalin) or the histamine H<sub>3</sub> receptor antagonists. Sustained SLA profiles were seen in the pups while habituation to novel environments developed with maturation. Psychostimulant as well as H<sub>3</sub> antagonist pre-treatment produced distinctly different SLA patterns in the immature rat pups versus the adult rats. These studies characterized cognitive and motor behavioral traits in immature rat pups and evaluated the use of this model for developmental disorders such as ADHD. Finally, the use of H<sub>3</sub> antagonists in cognitive and motor disorders is described. Funded in part by NINDS #1R43NS33808-1 and Gliatech, Inc.

# NEUROANATOMICAL ABNORMALITIES IN PEDIATRIC OBSESSIVE COMPULSIVE DISORDER: IMPLICATIONS FOR ABNORMAL DEVELOPMENTAL MATURATION OF FRONTO-STRIATAL CIRCUITRY. D. R. Rosenberg\*, M. Keshavan, K. O'Hearn, E. Dick, W. Bagwell, A. Seymour and B. Birmaher, Western Psychiatric Institute and Clinic, University of Pittsburgh Medical Center, Pittsburgh, PA 15213

Abnormalities in specific fronto-striatal circuits have been implicated in obsessive compulsive disorder (OCD). Although OCD commonly emerges during childhood or adolescence, few studies have examined fronto-striatal anatomy in psychotropic-naïve pediatric OCD patients near the onset of illness to study the possible role of atypical developmental processes in this disorder. Magnetic Resonance Imaging (MRI) scans from 20 psychotropic-naïve, non-depressed OCD patients aged 7.2-17.7 years, and 20 case-matched healthy comparison subjects were analyzed to determine the volumes of the following structures: prefrontal cortex, basal ganglia (caudate + putamen), lateral and third ventricles, and intracranial volume. OCD patients had significantly smaller basal ganglia volumes ( $F(1,33) = 9.33, p = .004$ ) than controls, but did not differ in prefrontal cortex, lateral and third ventricle or intracranial volume. Basal ganglia volumes were inversely correlated with OCD symptom severity (partial  $r = -.65, p = .004$ ) but not illness duration. Volumes of other structures were not significantly correlated with the duration or severity of OCD symptoms. Age was not correlated with basal ganglia volumes, but was inversely correlated with prefrontal cortical gray matter (partial  $r = -.53, p = .02$ ) and positively with lateral ventricular volumes (partial  $r = .52, p = .03$ ) in OCD patients but not controls. Our findings provide new evidence of pathology of the basal ganglia and frontal cortex in pediatric OCD. Moreover, our data suggest a possible abnormality in the developmental maturation of prefrontal cortical gray matter and lateral ventricular volumes in early-onset OCD patients compared to controls.

# DECREASED KAINATE RECEPTOR BINDING IN THE ARCuate NUCLEUS IN THE SUDDEN INFANT DEATH SYNDROME. A. Panigrahy\*, J. Filiano, L.A. Sleeper, F. Mandell, M. Valdes-Dapena, H. Krous, L.A. Rava, W.F. White, H.C. Kinney, Division of Neuroscience, Children's Hospital, Boston, MA 02115.

The sudden infant death syndrome (SIDS) is the leading cause of postneonatal mortality in the United States; its etiology is unknown. The arcuate nucleus (ARC), located on the ventral medullary surface (VMS), is postulated to be homologous to chemosensitive respiratory fields in the cat, leading to the hypothesis that a defect of the ARC in SIDS results in an impaired arousal response to hypercarbia or asphyxia during sleep and sudden death. Recently we reported a decrease in muscarinic receptor (mAChR) binding in the ARC in SIDS victims (Kinney et al, *Science* 269:1446-50; 1995). Glutamate via kainate (KA) receptors has been implicated in mediating the ventilatory response to carbon dioxide. KA binding is heavily localized in the human infant ARC (Panigrahy et al, *Neuroscience* 67:441-445; 1995). To test the specificity of the mAChR binding deficit in SIDS victims, we used the same database to test the hypothesis that KA binding is decreased in the ARC in SIDS victims. We assessed <sup>3</sup>H-KA binding with quantitative tissue receptor autoradiography in 17 brainstem nuclei. Cases were classified as SIDS, 47; acute control, 15, chronic control with oxygenation disorders, 17. The ARC was the only nucleus in which there was a significant difference in the age-adjusted mean KA binding between the SIDS group ( $37 \pm 2$  fmole/mg tissue) and both the acute controls ( $77 \pm 4$ ) ( $p < 0.0001$ ) and chronic group with oxygenation disorders ( $69 \pm 4$ ) ( $p < 0.0001$ ). There was a positive correlation between the density of mAChR and KA binding in the SIDS cases ( $R^2 = 0.212, p = 0.0025$ ). These data indicate that the putative neurochemical defect in the ARC in SIDS victims involves more than one neurotransmitter receptor, and that VMS binding deficits put infants at risk for SIDS. Supported by SIDS Alliance (HCK), HD-20991 (HCK), and a Howard Hughes Medical Student Research fellowship (AP).

## 18.4

# ALTERATIONS IN DOPAMINE AND GLUTAMATE RECEPTOR BINDING AFTER GESTATIONAL PROTEIN DEPRIVATION IN RATS: AN ANIMAL MODEL OF SCHIZOPHRENIA? P.D. Butler<sup>1,2,3\*</sup>, D.A. Klugewicz<sup>1,2</sup>, L. DeSanti<sup>1</sup>, J. Rotrosen<sup>1,2</sup>, J.M. Gorman<sup>1</sup>, and H.K. Kramer<sup>1</sup>, <sup>1</sup>Psychiatry Service, NYDVMC and Depts. Of Psychiatry, <sup>2</sup>NYU Medical Center and <sup>3</sup>New York State Psychiatric Institute.

Recent evidence indicates that prenatal nutritional deprivation is one early environmental exposure that may increase the risk of schizophrenia. Previous experiments in our laboratory have shown that female rats protein restricted throughout gestation had a significant increase in amphetamine-induced locomotion and apomorphine-induced stereotypy as adults, but not as adolescents. Because glutamate (GLU) modulates dopamine (DA) functioning, and abnormal DA/GLU interactions have been implicated in the pathophysiology of schizophrenia, we examined whether alterations in glutamatergic, dopaminergic and serotonergic receptor functioning may underlie the changes in DA-mediated behaviors previously found. In these rats at PND 85 we assessed the density of 5-HT (<sup>3</sup>H-paroxetine) and DA transporter sites (<sup>3</sup>H-GBR 12935), and D<sub>2</sub> and NMDA-type GLU receptors (<sup>3</sup>H-haloperidol and MK-801) in various brain regions. In the hippocampus of protein deprived female rats there was a 71% increase in the density of NMDA receptors, while the number of 5-HT uptake sites was unchanged from controls. In the striatum, significant increases in D<sub>2</sub> (43%) and NMDA (35%) receptors were observed while there was a 34% decrease in DA uptake sites. No significant changes were apparent in the cortex. Down-regulation of the DA transporter coupled with the up-regulation of D<sub>2</sub> receptor sites suggest less DA availability in the striatum. The elevated D<sub>2</sub> receptor density in the striatum may in part underlie our previously observed increase in DA-mediated behaviors. One potential mechanism of DA/GLU interaction in these animals could be that an increase in D<sub>2</sub> receptors on GLU terminals would decrease GLU release producing a functional NMDA receptor hypofunction, which could produce the compensatory increase in NMDA receptors seen here. The finding of alterations in NMDA and D<sub>2</sub> receptor binding provide further support for this as an animal model of schizophrenia.

## 18.6

# BRAIN SEROTONIN SYNTHESIS MEASURED WITH α[C-11]-METHYL-TRYPTOPHAN POSITRON EMISSION TOMOGRAPHY IN NORMAL AND AUTISTIC ADULTS D. C. Chugani\*, O. Muzik, P. Chakraborty, T. Mangner, H. T. Chugani, Dept. of Pediatrics, Neurology, and Radiology, Children's Hospital of Michigan, Wayne State Univ., Detroit, Michigan

Infantile autism is characterized by disturbances of social interaction, language, and stereotypic behaviors. Increased platelet serotonin is found in one-third of autistics; however, serotonin metabolites in cerebrospinal fluid have not demonstrated consistent abnormalities. Local cerebral serotonin synthesis rate was measured with α[C-11]-methyl-tryptophan ([C-11]AMT) in normal adult brain (n=10; 5 males, 5 females; mean age 28.3 years) and 4 autistic adults (n=4; 3 males, 1 female; mean age 26.5 years) using positron emission tomography (PET). Dynamic brain image data together with arterial plasma input function were used to perform Patlak analysis to determine the K-complex, a macro-parameter which is directly proportional to the serotonin synthesis rate. Values of K-complex for different brain regions corresponded well to the distribution of serotonergic terminals in the brain previously determined in vitro. Values in normal females were 10-20% higher ( $p < 0.05$ , MANOVA) than those measured in normal males. Comparisons made between male autistics and control male subjects showed that mean K-complex values were significantly higher for all brain regions in the autistic group ( $p < 0.05$ , MANOVA). In conclusion, we have shown gender differences in cerebral serotonin synthesis in normal subjects and increased serotonin synthesis in autistic men as compared to normal males.

Supported by the Mental Illness Research Association of Michigan.

## 18.7

**PET WITH [FLUORINE-18]FLUORODOPA IN AUTISM.** M. Ernst\*, A.J. Zametkin, J.A. Matochik, D. Pascualvaca, P.H. Jons, K. Hardy, R.M. Cohen. Laboratory of Cerebral Metabolism, NIMH, NIH, Bethesda, MD

Autism is a pervasive developmental disorder of early onset characterized by impairment in social interaction, verbal and nonverbal communication and a restricted range of interests. Dopamine function has been proposed to play a role in the etiology of this disorder. Using positron emission tomography, presynaptic accumulation of [Fluorine-18]Fluorodopa was measured in basal ganglia (caudate nucleus and putamen) ventral tegmental complex (substantia nigra and ventral tegmentum), and frontal and occipital cortices of 14 autistic children (age: 13.1±2.4 years; 8 males / 7 females), and 10 healthy controls (age: 14.9±2.0 years; 7 males / 3 females). Results were expressed as ratios of specific to nonspecific (occipital cortex) radioactive counts ([Fluorine-18]). [Fluorine-18] ratio was significantly lower in the medial frontal cortex of autistic subjects compared to controls ( $t=2.6$ ,  $p<0.02$ ,  $df=22$ ), and was similar in basal ganglia and ventral tegmental regions.

	Anterior medial Frontal Cortex	Basal Ganglia	Ventral Tegmental Complex
Control Ss (N=10)	1.15±0.47	3.18±0.98	1.10±0.63
Autistic Ss (N=14)	0.70±0.37	3.23±0.64	1.10±0.49

These findings support a dopaminergic deficit specific to the medial frontal cortex and are consistent with reports implicating the frontal cortex in the neuropathophysiology of autism.

**PROFILES OF DENDRITIC PROTEIN EXPRESSION IN RETT AND DOWN SYNDROMES.** W.E. Kaufmann\*, C.V. Taylor, J.J. Israel. Depts. of Pathology, Neurology, and Pediatrics, Johns Hopkins University and Kennedy Krieger Institute, Baltimore, Maryland.

Rett (RS) and Down (DS) syndromes, as most forms of mental retardation (MR), show a generalized reduction in dendritic arborizations in neocortex. In both disorders, there is temporal correlation between dendritic anomalies and cholinergic deficiency: early in RS and late-progressive in DS. We have studied patterns of dendritic protein expression as an approach to understand the pathogenesis of these dendritic abnormalities. In both RS and a murine model of early neocortical cholinergic denervation, we have demonstrated a selective reduction in microtubule-associated protein (MAP): 2 immunoreactivity. This investigation characterizes the expression of MAP-2 and other dendritic proteins in RS, contrasting them with DS, by quantitative immunoblotting after SDS/PAGE. Assays were performed on frontal cortical samples from 9 RS and 5 DS patients and 5 normal age-matched controls (NC), using monoclonal antibodies against MAP-2, MAP-5, and high and medium molecular weight (mw) neurofilaments (NFs), and the chemiluminescence method.

ANOVA and multiple regression analyses of optical density values, acquired using the NIH Image software, showed: a decrease in high mw MAP-2, which differentiated RS from NC and DS subjects ( $p=0.006$  and  $p=0.04$ , respectively); a relative increase in white matter low mw MAP-2 in RS ( $p<0.05$ ); and a reduction in the 68 kDa MAP-5 fragment in DS ( $p=0.016$ ); without significant changes in NF. These findings support the hypothesis that MAP-2 expression is selectively altered in RS. The relative increase in the immature (low mw) MAP-2 isoform, suggest a developmental arrest as the pathogenetic mechanism. MAP-5 reduction in DS may be related to the reported reduction in neuronal density in this condition. Similar studies in the murine model, currently undergoing, will provide information about the role of early cholinergic deficit in the differential protein profile found in RS and DS neocortex. Supported by HD01046 and HD24448 and the Research for Rett Syndrome Foundation.

**GENES WITH TRINUCLEOTIDE REPEATS: A ROLE IN NEURODEVELOPMENT.** R.L. Margolis\*, K.L. Chow\*, A.H. Sharp\*, M.R. Abraham\*, C.A. Ward\*, G. Schilling\*, O.C. Stine\*, C. Callahan\*, S.B. Gatchell\*, H.S. Yoon\*, M.G. McInnis\*, C.A. Ross\*. Lab. of Molecular Neurobiology, Dept. of Psychiatry, Johns Hopkins Univ., Balto., MD 21205; Dept. of Biology, Hong Kong Univ. of Sci. & Techn., Kowloon, Hong Kong.

In an effort to obtain candidate genes for neuropsychiatric disorders, we have used brain cDNA libraries to clone and characterize gene fragments containing trinucleotide repeats. We have recently reported that one of these, CAG1, contains a highly polymorphic (CAG) $n$  5' untranslated repeat that varies in length in the normal population from 6 to 31 triplets (Margolis et al, 1996). One individual with bipolar affective disorder type II and a movement disorder has an allele with 46 triplets. CAG1, located on chromosome 13q13, encodes an amino acid sequence homologous to the *C. elegans* cell-fate determining gene *mab-21*. We have used affinity purified polyclonal antibodies to examine mammalian CAG1 protein expression. CAG1 protein is expressed as a doublet migrating at about 40kDa on PAGE. Expression in several regions of the rat brain is developmentally regulated, with adult levels of expression not occurring until after the first postnatal week. The protein was found in both soluble and particulate fractions following subcellular fractionation. To further characterize the CAG1 protein, we coupled a CAG1 cDNA encoding the complete human protein to an inducible heat shock promoter. In both transient and integrating transformation of *mab-21* mutant nematode lines, induced expression of this construct partially reverses the mutant phenotype of sensory organ deficits. Taken together, these results suggest that CAG1 may play a role in the development of the mammalian nervous system. We are continuing to search for other cDNAs with polymorphic trinucleotide repeats and differential expression during development. (Supported, in part, by the NIMH, Stanley Foundation, and NARSAD Foundation.)

## 18.8

**QUANTITATION OF DOWN SYNDROME BRAIN METABOLITE CONCENTRATIONS USING IN VIVO <sup>1</sup>H MR SPECTROSCOPY.** W. Huang, E. Daly, J. Krasuski, L. Beason-Held\*, S. Rapoport, and M. Schapiro. Lab. of Neurosciences, Natl. Inst. on Aging, NIH, Bethesda, MD 20892

Our laboratory has reported elevated cerebrospinal fluid (CSF) myo-inositol (ml) concentration, as well as elevated CSF choline concentration, independent of dementia, in Down Syndrome (DS) adults between 22 and 63 years of age. In this study, *in vivo* <sup>1</sup>H MR spectroscopy (MRS) was employed to measure absolute brain concentrations of the following metabolites in 12 nondemented DS (6 young, 35 ± 4 yr; 6 old, 47 ± 3 yr) and 12 age-matched control (6 young, 31 ± 6 yr; 6 old, 48 ± 6 yr) subjects: N-acetylaspartate (NAA), total creatine (Cr), choline-containing compounds (Cho), and ml.

Using a 1.5 T GE Signa scanner, MRS data were collected from a volume ( $\approx$  8 cm<sup>3</sup>) in the occipital area, parietal area, and a bottle of standard solution (containing known concentrations of the four metabolites) which was placed next to the subject's head during scanning. Absolute concentrations (mmol/liter wet brain tissue) in the two brain regions were obtained following comparison of spectral signal intensities between standard and brain, and correction for CSF volume fractions.

Brain ml and Cho concentrations were found to be significantly increased (ml: 50-60%,  $p < 0.005$ ; Cho: 40-50%,  $p < 0.005$ ) in both locations of both DS age groups. Cr was increased (20-30%,  $p < .01$ ) in the old DS subjects in both brain regions, whereas NAA was decreased (10-20%,  $p < 0.05$ ) in the occipital region in both DS age groups.

The increase of brain ml in DS is consistent with the CSF ml studies and with a gene dose effect, as the gene for transporting ml is found on chromosome 21. The increase of brain Cho is consistent with the increase of CSF choline in young DS adults and may reflect increased membrane phosphatidylcholine turnover.

## 18.10

**In Vivo Imaging of Pre- and Postsynaptic Dopamine Receptors in Rett Syndrome** D.F. Wong\*, S. Naidu, F. Yokoi, G. Grunder, S. Szymanski, R.F. Dannals, H. Ravert, M. Kuhar, A. Gjedde, H. Moser. Johns Hopkins U., Baltimore, MD; Aarhus U., DK

Rett Syndrome (RS) is a disease of females associated with stereotypical movements, progressive rigidity, microcephaly and seizures. There is reduced melanin content and tyrosine hydroxylase in substantia nigra pars compacta (SNPC) with decreased tissue levels of dopamine. Post mortem decreases in D<sub>2</sub> dopamine receptors have also been observed.

We have carried out PET studies of both pre- and postsynaptic dopamine (DA) receptors. Twelve patients were studied for D<sub>2</sub> DA receptors using [<sup>11</sup>C]3-N-methylspiperone (NMSP) and two PET scans, each with high specific activity (HSA) [<sup>11</sup>C]NMSP, where one was preceded by haloperidol, to estimate B<sub>max</sub> (Wong et al., 1986). Another 12 pts were studied with a single HSA [<sup>11</sup>C]WIN 35,428 injection for dopamine transporter binding (DAT). For each scan, 50 frames and simultaneous plasma radioactivity via arterial sampling with HPLC metabolite correction was obtained over 90 min.

These studies have demonstrated low to low normal D<sub>2</sub> receptors compared to age-matched control values for the caudate. For the DAT, a simple tissue ratio method of total to nonspecific binding and a kinetic analysis measuring the binding potential were employed. The cerebellum (CB) K<sub>i</sub>/k<sub>d</sub> was assumed in the striatum in fitting k<sub>i</sub>/k<sub>d</sub> for the kinetic approach. When age matched (N=11) or age/gender matched (N=5) the kinetic method, for both the caudate (CA) and putamen (PU) yielded a significant reduction of up to 45% in the k<sub>i</sub>/k<sub>d</sub> ratio ( $p<0.01$ ). The CA/CB ratio and the PU/CB ratio were also significantly decreased with age/gender matching. In two subjects that had both pre- and postsynaptic measures, the DAT and D<sub>2</sub> receptors were either low or low-normal. These findings together with decreased DA levels postmortem suggest that there may be immature SNPC cells, neuronal loss and/or down-regulation of DAT with no compensatory D<sub>2</sub> up-regulation. Supported in part by HD 24448 and HD 24061.

**GENE THERAPY OF CANAVAN DISEASE.** M. Doring\*, Z. Zeng, R. Kaul, E. Sorigi, L. Huang, E. Mee, J. Wang, L. Maves, L. Ment, P. Leone. Auckland Hospital School, New Zealand; Yale University, New Haven, CT; Miami Children's Hospital, Florida; University of Pittsburgh, PA.

Canavan Disease (CD) is an autosomal recessive leukodystrophy associated with spongiform degeneration of the brain leading to death in the first decade of life. CD is characterized by mutations in the aspartoacylase (ASPA) gene resulting in loss of enzyme activity and elevated levels of N-acetyl-aspartate (NAA). We developed an *in vivo* gene transfer protocol for CD using a novel liposome-polymer-DNA (LPD) complex. LPD is a mixture of the neutral lipid DOPE with a cationic liposome, DC-Chol, together with poly-L-lysine to form unique virus-sized, i.e. 60-100 nm, non-aggregating particles. The expression plasmid consisted of a transcription unit (CMV promoter, human ASPA cDNA, SV40 polyA) flanked by AAV 145 bp ITR. Efficient transduction and enzyme activity was obtained *in vitro* using LPD-AAV. *In vivo* studies in rats (n=120) and primates (n=4) demonstrated safety and stability of gene transfer (to 6 months). Convection, blood-brain-barrier disruption and intraventricular approaches were evaluated for global brain delivery. Using a combination of intraventricular injections with mannitol, widespread expression extending into brain parenchyma was observed. Regulatory approval was given by local ethical and regulatory committees including the FDA for a Phase I safety study. Two children (aged 19 and 24 months) were operated on in early March 1996. No adverse effects occurred apart from a mild transient postoperative fever. At 6 weeks post-gene transfer, there were improvements in both psychometric testing and neurological function. NMR proton spectroscopy demonstrated NAA levels within or close to the normal range in several brain regions including frontal cortex, parietal white matter and the anterior occipital lobe. Levels of NAA remain high in posterior occipital cortex and basal ganglia. This preliminary data suggests that sufficient gene transfer was obtained to result in partial phenotypic correction. (8 month follow-up data will be presented). This study demonstrates that direct intraventricular gene transfer within the human brain can be safe. Moreover, our indirect data on gene expression provides real hope for clinical efficacy of neonatal genetic intervention in neurogenetic disorders.

## 19.1

**DIFFERENCES IN  $\beta$ -AMYLOID DEPOSITION IN TEN DOG BREEDS.** Marketta Bobik, M. J. Russell, R. G. White\*, Y. Hou, and J. W. Geddes<sup>1</sup>. Dept. of Anesthesiol., Univ. California, Davis, CA 95616. <sup>1</sup>Center on Aging, Univ. Kentucky, Lexington, KY 40536.

We previously reported differences in the incidence of  $\beta$ -amyloid (A $\beta$ ) plaques in beagles and St. Bernards. The occurrence of A $\beta$  in aged laboratory beagles is similar to that seen in Alzheimer's disease (AD), and the aged canine has been suggested as a model for the early stages of AD. Because comprehensive evaluations of dog breeds are limited, we have surveyed ten common breeds of dogs. Brain tissues from dogs that had been euthanized and archived for clinical reasons were evaluated. The breeds included: beagles, boxers, cocker spaniels, Dobermans, German shepherds, golden retrievers, Great Danes, Labrador retrievers, poodles and St. Bernards, the total of 314 dogs with a sample size of 13-103 in each group. The percentage of A $\beta$  positive dogs was found to be: 49, 65, 67, 56, 54, 67, 77, 65, 74, and 29, respectively for each breed. To determine the presence of A $\beta$  deposits, coronal half-brain sections from the parahippocampal region were stained with: a modified Bielschowsky, Congo Red, Thioflavine-S, and immunohistochemistry (10D5 antibody from Athena). Marked differences were observed in: 1) plaque incidence, 2) plaque type, 3) plaque distribution, 4) plaque density, and 5) the age of onset of plaque deposition. Taken together these data suggest a genetic component in canine  $\beta$ -amyloid deposition. Cerebral A $\beta$  angiopathy was independent of age and severity of amyloid plaques.

This work was supported by NIA grant RO AG11350.

## 19.3

**ANALYSIS OF MICE WITH TARGETED APLP2 AND APLP2/APP ALLELES.** C.S. von Koch<sup>1</sup>\*, F. Yu<sup>2,4</sup>, H. Zheng<sup>5</sup>, H. Chen<sup>5</sup>, M. Trumbauer<sup>5</sup>, L. van der Ploeg<sup>5</sup>, D.L. Price<sup>1,2</sup> and S.S. Sisodia<sup>1,2</sup>. Dept. of Neuroscience<sup>1</sup>, Pathology<sup>2</sup>, Johns Hopkins Univ. Sch. of Medicine, Baltimore, MD 21205; Schepens Eye Research Institute<sup>3</sup>, Harvard Medical School<sup>4</sup>, Boston, MA 02114 and Merck Research Labs<sup>5</sup>, Rahway, NJ 07065

APLP2 is a member of a larger gene family that includes APP and APLP1. In order to examine potential biological roles of APLP2 during development or aging, we have used gene targeting strategies to generate mice devoid of APLP2 expression. Homozygous APLP2 knockout (KO) mice are fertile and without overt abnormalities up to 14 months of age. Recently, *in situ* hybridization and immunocytochemistry analysis have shown that APLP2 is upregulated in migrating corneal epithelial cells following corneal wounding (Guo et al., submitted). To determine if APLP2 is required during corneal wound healing, we lesioned corneas of APLP2 KO and wild-type mice. Interestingly, we observed a ~1 day delay in wound closure compared with control mice. We are currently performing tissue culture experiments, using corneal explants, to more clearly define the role of APLP2 during wound healing.

Further, to study the function of APLP2 and other members of this gene family *in vivo*, we generated mice with targeted APLP2 and APP genes. Double KO mice are born at the expected frequency, but ~80% die within the first week after birth, suggesting a role for APLP2 and APP in early postnatal development. Surviving double KO mice are 20-30% reduced in weight compared with control mice and exhibit ataxia, weakness and spinning behavior.

## 19.5

**CORRELATIVE MEMORY DEFICITS, A $\beta$  ELEVATION AND AMYLOID PLAQUES IN TRANSGENIC MICE** K. Hsiao<sup>1\*</sup>, P. Chapman<sup>2</sup>, S. Nilsen<sup>1</sup>, C. Eckman<sup>3</sup>, S. Yonkin<sup>3</sup>, G. Cole<sup>4</sup>. <sup>1</sup>Department of Neurology, University of Minnesota, Minneapolis, MN 55455; <sup>2</sup>Physiology Unit, University of Wales, Cardiff CF1 3US; <sup>3</sup>Mayo Clinic Jacksonville, Jacksonville, FL 32224; <sup>4</sup>GRECC, Veterans Administration Medical Center, Sepulveda, CA 91343.

Transgenic mice overexpressing the 695-amino acid isoform of human K670N-M671L Alzheimer amyloid precursor protein (APP) driven by a prion protein cosmid vector have normal learning and memory in spatial reference and alternation tasks at three months of age but show impairment by nine to ten months of age. A five-fold increase in A $\beta$ (1-40) and 16-fold increase in A $\beta$ (1-42) accompanied the appearance of these behavioral deficits. Numerous congophilic A $\beta$  plaques were present in cortical and limbic structures in two mice with elevated A $\beta$  levels. The correlative appearance of behavioral, biochemical and pathological abnormalities reminiscent of Alzheimer's disease (AD) affords new opportunities for exploring the pathophysiology and neurobiology of AD in mice.

## 19.2

**OVEREXPRESSION OF PERLECAN AND BETA AMYLOID PROTEIN IN TRANSGENIC MICE.** K. Fukuchi<sup>1</sup>\*, T. Tokunaga<sup>1</sup>, J.R. Hassell<sup>2</sup>, and A.D. Snow<sup>3</sup>. <sup>1</sup>Dept. of Comparative Medicine, Univ. of Alabama at Birmingham, Birmingham, AL 35294; <sup>2</sup>Dept. of Ophthalmology, Univ. of Pittsburgh, Pittsburgh, PA 15213; <sup>3</sup>Dept. of Pathology, Univ. of Washington, Seattle, WA 98195.

Perlecan, a specific heparan sulfate proteoglycan, accumulates as part of the fibrillar amyloid deposits in neuritic plaques and cerebrovascular amyloid in Alzheimer's disease (AD). Several lines of evidence suggest that perlecan plays important roles in the pathogenesis of amyloidosis including AD. Perlecan also appears to be essential for consistent persistence of brain amyloid deposits in a rat infusion model for  $\beta$ -amyloidosis (Snow et al. 1994, *Neuron* 12:219). In order to study the roles of perlecan in AD amyloidosis and to possibly create a better animal model to study the neuropathology of AD, we have established transgenic mice that overexpress perlecan. A 12-kb cDNA coding for entire mouse perlecan under the control of a cytomegalovirus enhancer and  $\beta$ -actin promoter was injected into fertilized mouse eggs. Four founder lines of perlecan transgenic mice were identified by Southern blot analysis of DNA isolated from the emerging pups. These transgenic founders carried 1 to 10 copies of the transgene. Phenotypic consequences of overexpression of perlecan by the exogenous promoter will be presented. Perlecan transgenic mice will be mated with transgenic animals that overexpress human  $\beta$ -amyloid protein in order to establish new lines of transgenic mice that overproduce both perlecan and  $\beta$ -amyloid protein.

Supported by the National Institute of Health (AG12850-03 and AG12953-02).

## 19.4

**DEVELOPMENT OF  $\beta$ -AMYLOID PLAQUES IN HuAPP695.SWE TRANSGENIC MICE** G. M. Cole<sup>1</sup>\*, F. Yang<sup>1</sup>, S.A. Frautschy<sup>1</sup>, T. C. Saido<sup>2</sup> and K. Hsiao<sup>3</sup>. <sup>1</sup>Sepulveda VAMC, GRECC 11E, Sepulveda, CA. 91343 and Dept. Med., UCLA., <sup>2</sup>Dept. Mol. Biol., Tokyo Metropolitan Inst. Science, Tokyo 113 Japan and <sup>3</sup>Dept. Neurol., Univ. Minn., Minneapolis, MN 55455

High copy number Tg(HuAPP695.SWE)2576 transgenic mice bearing the "Swedish" NL double mutation (Tg2576) developed  $\beta$ -amyloid deposits with age which reacted with antibodies spanning the length of A $\beta$  from B1 to B42. Deposits were found in frontal, temporal and entorhinal cortex, presubiculum, subiculum, hippocampus, fimbria/fornix, corpus callosum and cerebellum. Deposits occurred between 9 and 12 months in the transgenic, but not in control mice. Dense deposits were thioflavin S positive and showed the amyloid characteristic apple green birefringence with Congo red. High magnification revealed the fibrillar character of thioflavin and Congo red positive amyloid. Deposits range from diffuse to classical. Gallyas silver stain identified abnormal neurites associated with deposits and the loss of fibers in areas with  $\beta$ -amyloid immunoreactive deposits. Selected plaques were associated with GFAP labeled reactive astrocytes. Microglia were found adjacent plaques and in areas of A $\beta$  deposition. Unlike sporadic AD brain, most deposits were immunoreactive for both A $\beta$ 40 and A $\beta$ 42 as might be expected with the "NL" mutation which dramatically increases both A $\beta$ 40 and 42. The areas around plaques showed abundant evidence of cell surface and process staining in the surrounding area where evidence of cellular and neuronal degeneration was evident. Additional punctate neuropil immunostaining was found with some A $\beta$  antibodies. Intense APP immunostaining could be found in neurons of the entorhinal cortex and hippocampus. Since this Tg2576 line of mice developed correlative age-related memory deficits and elevated A $\beta$  ELISA levels, it appears quite promising as a model for assessing the possible role of region-specific A $\beta$  deposits in age-related memory loss in an experimental model. Supported by NIH grants AG11125 (GMC), NS33249 (KH)

## 19.6

**THE PDAPP TRANSGENIC MOUSE DEPOSITS  $\beta$ -AMYLOID42 IN A REGION-SPECIFIC MANNER SIMILAR TO ALZHEIMER'S DISEASE** K. Johnson-Wood, M. Lee, R. Motter, K. Hu, G. Gordon, R. Barbour, M. Gordon, H. Tan, D. Games, J. Lieberburg, D. Schenk\*, P. Seubert, and L. McConlogue.

Athena Neurosciences, Inc., So. San Francisco, CA 94080

The PDAPP transgenic mouse, over-expressing the human amyloid precursor protein (APP717<sub>Val</sub>) has been shown to display amyloid deposition and neuropathology similar to that seen in Alzheimer's disease (AD). This animal provides a convenient system to study the mechanisms whereby different brain regions show selective vulnerability for  $\beta$ -amyloid (A $\beta$ ) deposition. Quantitative measures of APP metabolites and A $\beta$  were made in hippocampal, cortical, and cerebellar brain regions of heterozygote transgenic mice from 4 months up to 12 months of age. The APP-beta and APP-alpha/full-length levels within each respective brain region remain nearly constant at all ages, whereas total A $\beta$  levels in the hippocampal and cortical regions increase in an age-dependent manner that mirrors amyloid plaque deposition observed immunohistochemically. For example, hippocampal A $\beta$  levels in 12 month old mice were 106-fold higher than in 4 month old mice. In contrast, cerebellar A $\beta$  levels were comparatively low and remained unchanged with age. The A $\beta$ <sub>42</sub> peptide has recently been shown to be the predominant form of A $\beta$  in AD. In the 4 month old transgenic mice, it represents ~27% of the A $\beta$  present which increased to ~97% in 12 month old transgenes. The selective deposition of A $\beta$ <sub>42</sub> and the spatial distribution of the A $\beta$  deposits are further evidence that the pathological processes occurring in the PDAPP transgenic mouse parallel the human AD condition.

## 19.7

## DEVELOPMENT OF AGE- AND REGION- DEPENDENT PROGRESSION OF ALZHEIMER-TYPE NEUROPATHOLOGY IN PDAPP TRANSGENIC MICE.

D. Games\*, T. Guido, K. Khan, F. Soriano, A. Justice, M. Mallory, R. Motter, L. McConlogue, D. Schenk and E. Masliah#. Athena Neurosciences, 800 Gateway Blvd., South San Francisco, CA 94080. #University of California, San Diego, Department of Neurosciences, La Jolla, CA. 92093.

Transgenic mice overexpressing mutant beta-amyloid precursor protein 717<sub>V<sub>35</sub></sub> develop several pathological characteristics of Alzheimer's disease (AD), including the deposition of beta-amyloid protein (A $\beta$ ) into plaques, neurodegeneration and gliosis. In ongoing studies, we are documenting the age and region- dependent development of A $\beta$  deposits, A $\beta$  plaque-associated proteins, synaptic and dendritic loss, neuritic pathology and cytoskeletal abnormalities. Similar to AD, both diffuse and compacted plaques developed in the affected regions, with the first deposits occurring at approximately 4 months of age. A $\beta$ <sub>42</sub> constituted the majority of the plaques and was associated with the early deposits. A $\beta$ <sub>40</sub> deposition was less abundant than A $\beta$ <sub>42</sub> and was primarily associated with plaque cores and vascular amyloidosis. Plaque deposition initiated in the frontal and retrosplenial cortices and hippocampus, with later involvement of the amygdala, temporal and entorhinal cortex. A $\beta$  deposition was well-established by 9 months of age. Ongoing studies are examining the age-related progression of synaptic, dendritic and gliotic alterations. The time course of these changes and a comparison of homozygotic and heterozygotic mice will be presented.

## 19.9

## ANIMAL MODELS FOR ALZHEIMER'S DISEASE BASED ON GENETICS AND PATHOLOGY

B. Sommer\*, D. Abramowski, K. Bürki, K. Dixon\*, M. Duke, P. Kelly, B. Ledermann, P. Paganetti\*, A. Probst\*, C. Sturchler-Pierrat, K.-H. Wiederhold, M. Staufenbiel. Sandoz Pharma AG, Basle; \*Sandoz Research Institute, Berne; #Inst. of Pathology, Basle; Switzerland.

In an attempt to obtain features of Alzheimer's disease pathology we produced transgenic mice expressing human APP. Several expression constructs were engineered with cDNAs encoding mutated and wt APP<sub>751</sub> driven by various neuron specific promoters (Rhombotin, NSE, human Thy-1, mouse Thy-1, NF-L). In our hands, only the Thy-1 promoter gave rise to high expression levels of transgene mRNA. The highest levels obtained exceed the endogenous APP message by 1.5 to 5 fold. During aging of the animals, expression levels are maintained. In situ hybridization demonstrated the presence of APP transgene message throughout the brain with minor variations between different mouse lines. Expression studies have been extended to the protein level and confirm the in situ hybridization results. Biochemical analysis revealed considerably elevated levels of A $\beta$  peptide in the brains of mice expressing the double mutation 670/671. Histological analysis of these mice at the age of one year showed significant deposits of APP and A $\beta$  in cortex. These deposits were thioflavin S positive and showed Congo Red birefringence, significant features of senile plaques in AD pathology. The mice are currently undergoing behavioural assessment.

Furthermore, we used homologous recombination in embryonic stem cells to inactivate the APP gene as a strategy of assessing the natural function of the APP molecule and providing a mouse background lacking endogenous APP. A vector was designed to target the first exon of APP and electroporated into stem cells to generate chimeric mice. Homozygous APP k.o. mice have been generated and are currently under close investigation. (Supported by Sandoz Pharma AG)

## 19.11

LATERALITY IN THE HISTOLOGICAL EFFECTS OF BILATERAL AMYLOID- $\beta$  25-35 INJECTIONS *IN VIVO* INTO THE AMYGDALA OF YOUNG F344 RATS. E. M. Sigurdsson\*, J. M. Lee, X.-W. Dong, M. J. Heina, and S. A. Lorens. Depts. Pharmacology and Pathology, Loyola Univ. Chicago Medical Center, Maywood IL 60153.

The histopathological characteristics of Alzheimer's disease (AD) include amyloid deposition, reactive astrocytes, neurofibrillary tangles and neuronal cell loss in several brain regions. Previously, we have observed that single amyloid- $\beta$  25-35 (A $\beta$ ) injections (5.0 nmol) into the right amygdala (AMY) of rats produce progressive (8 vs. 32 d) cytoskeletal and astroglial reactions within the AMY, and at distant brain regions that project to the AMY (Neurobiol. Aging, in press). To examine the time course of these effects, and to determine if they are potentiated by bilateral injections of A $\beta$ , we injected A $\beta$  (5.0 nmol) into the right and left AMY of young male F344 rats. Control rats received vehicle infusions. Animals were sacrificed at 8, 32, 64, 96 and 128 d postoperatively (n = 16-29 per timepoint). A $\beta$  induced neuronal tau-2 staining and reactive astrogliosis (GFAP) within the AMY, as well as at distal sites such as the hippocampus and cortical regions. These histological changes were associated with neuronal shrinkage within the AMY and nearby cortical areas but not in the hippocampus. Surprisingly, these changes were predominantly observed within the right hemisphere with the left hemisphere significantly less affected ( $p < 0.05-0.001$ ). The effects of A $\beta$  peaked at 32 d postoperatively ( $p < 0.05-0.001$ ). These data support our previous findings within the right hemisphere at 8 and 32 d post-injection. They suggest, moreover, a laterality in the histopathological effects of A $\beta$ , and that the effects of single injections are in part transient. These findings also suggest a direct association between plaque and tangle formation in AD, and support the use of this rat model to screen drugs that may attenuate or enhance the initial pathological events associated with AD. [Supported in part by an unrestricted research grant from the Institut de Recherches Internationales Servier (France)].

## 19.8

## MOLECULAR AND ANATOMIC CORRELATES IN THE PDGF-hAPP V717F TRANSGENIC MOUSE. M.C. Irizarry\*, K. J. Page, F. Soriano, D. Schenk, D. Games, and B. T. Hyman. Neurology, Mass General Hospital, Boston, MA 02114; Athena Neurosciences, South San Francisco CA 94080.

The PDGF-hAPP V717F transgenic mouse displays many neuropathologic features of Alzheimer's disease, most prominently A $\beta$  deposition. Anti-A $\beta$  stained sections from 12 heterozygote transgenic mice consistently demonstrate initial A $\beta$  deposition at 8 months of age in the dentate gyrus, CA1 hippocampal subfield and cingulate. By 12 months of age, A $\beta$  deposits are present in entorhinal cortex, but not in subcortical structures or amygdala. In this study we utilized in situ hybridization to correlate these pathological features with mRNA expression of transgene products, synaptic proteins, and bioenergetic proteins. The transgene expresses the mRNAs for the major human APP (hAPP) isoforms hAPP695, hAPP751, and hAPP770. hAPP751 mRNA expression in 4 and 11 month animals (4 transgenic animals each age) displayed a regional gradient, with highest mRNA expression in the dentate gyrus and CA1, followed by the cingulate. There was minimal expression in the amygdala. There was a trend ( $p < 0.04$ ) to a small 8-23% increase in hAPP751 mRNA expression at 11 months compared to 4 months depending on brain region. Relative optical density of hAPP751 hybridization increased 39-74% in homozygote animals compared to heterozygotes. Regional mRNA distribution of synaptophysin and cytochrome oxidase IV did not differ among 4 heterozygote transgenic mice and 4 non-transgenic littermates at 4 months and 11 months of age. Thus, A $\beta$  deposition in these mice occurs with regional specificity that partially parallels expression of hAPP mRNA, and is not associated with significant alterations in synaptophysin or cytochrome oxidase IV mRNA in heterozygote animals at 4 and 11 months of age; further analysis of older animals is underway. Support: NIH AG05134-1S1.

## 19.10

FACTORS PROMOTING A $\beta$  DEPOSITION AND TOXICITY IN THE RAT. S.A. Frautschy\*, A. Li, M. E. Harris, F. Yang, G.M. Cole. (GRECC, Sepulveda VAMC, Dept. Med. & Neurol., UCLA)

Non-transgenic rodent models were developed to investigate factors that rapidly accelerate A $\beta$  deposition without increasing APP expression. Mini-osmotic pump infusion of soluble A $\beta$ 40 was co-infused into the lateral ventricle of 9 month old rats in the presence of factors that potentially modulate A $\beta$  deposition. Compared to A $\beta$ 40 infusion alone, co-injection of A $\beta$ 42 caused a 50% increase in the number of diffuse A $\beta$  deposits. Co-injection with A $\beta$ 40 with the immunostimulating peptide tuftsin (Thr-Lys-Pro-Arg) increased the number of diffuse plaques, without increasing toxicity at one month after infusion. Infusion of an immunoglobulin-derived tripeptide (Thr-Lys-Pro) that suppresses microglia activity did not increase the number of diffuse plaques. These deposits were frequently associated with lectin-GSA B4 positive ramified microglia, but not astrocytes. Except for the finding that A $\beta$ 42 infused rats had a diminution of hippocampal creatine kinase, biochemical analysis of brain homogenates did not suggest significant toxicity. We are currently developing more sensitive biochemical and histochemical methods to detect toxicity and whether the diffuse plaques eventually progress to become neuritic. Preliminary evidence suggests that the diffuse plaques are compacted with time by microglia. When apolipoprotein E related carriers were infused with A $\beta$ , gross neurotoxicity and enlargement of the ventricles relative to carrier alone was apparent by one month after infusion. These carrier-infused rats had diffuse A $\beta$  immunoreactive deposits but not amyloid plaques. These data suggest: (1) A $\beta$  neurotoxicity can occur independent of the development of amyloid plaques (2) microglia play an important role in plaque development (3) and A $\beta$  chaperones that increase delivery of A $\beta$  to the neuropil also increase toxicity. Supported by NS30195, AG10685

## 19.12

## B-AMYLOID-INDUCED NEUROTOXICITY AND TAU PHOSPHORYLATION IN THE AGED NON-HUMAN PRIMATE.

C. Geula\*, C.-K. Wu, D.M. Saroff, A. Lorenzo and B.A. Yankner. Harvard Medical School, New England Deaconess Hospital and The Children's Hospital, Boston, MA 02215

Neurotoxic effects of intracerebral injections of fibrillar and soluble  $\beta$ -amyloid protein (A $\beta$ <sub>1-40</sub>) dissolved in PBS were assessed in one young adult marmoset, three aged marmosets and two aged rhesus monkeys. Injections of vehicle caused a small area of gliosis confined to the needle tract. In contrast, injections of fibrillar A $\beta$  (200 pg) caused marked neuronal loss and gliosis. The loss of neurons extended as far as 0.5-1 mm away from the center of the injection. Soluble A $\beta$  produced much less toxicity. A $\beta$  injections caused more toxicity in the aged marmosets when compared to the young marmoset. Fibrillar A $\beta$  also markedly increased staining for phosphorylated tau epitopes (at Ser<sup>262</sup> and Ser<sup>396/404</sup>) in neurons, neurites and tangle-like structures. Some neurons were affected at quite a distance away from the center of the injection. Soluble A $\beta$  or vehicle, on the other hand, induced low levels of tau phosphorylation in a very small number of neurons. These results show that injection of A $\beta$  at a level similar to that in a single senile plaque is capable of causing significant neurotoxicity and inducing tau phosphorylation in the aged monkey cerebral cortex. This model more closely reproduces the pathological changes observed in AD as compared with the rat model, and can be used for screening agents which may alter the neurotoxic effects of A $\beta$  *in vivo*. (Supported by NINDS and Sandoz Pharma Ltd)

## 20.1

POTENTIAL BRAIN NEURONAL TARGETS FOR AMPHETAMINE, METHYLPHENIDATE AND MODAFINIL INDUCED WAKEFULNESS EVIDENCED BY C-FOS IMMUNOCYTOCHEMISTRY IN THE CAT  
J.S. Lin, Y. Hou, P.H. Luppi\* and M. Jouvet. Département de Médecine Expérimentale, INSERM U52, CNRS ERS 5645, Faculté de Médecine, Université Claude Bernard, 8 Avenue Rockefeller, 69373 Lyon, FRANCE

Many experimental and clinical data suggest that the pharmacological profile of modafinil, a newly discovered wake-improving substance, differs from that of amphetamine and methylphenidate, two classical psychostimulants. The brain targets on which modafinil acts to induce wakefulness, however, remain unknown. A double-blind study using the immediate-early gene *c-fos* as experimental marker in the cat was conducted, therefore, to identify the potential target neurons of modafinil and compare them with those for amphetamine and methylphenidate. Animals were sacrificed 90 and 120 minutes following a single oral administration of methylphenidate, amphetamine or modafinil at their equivalent doses for wake induction (2.5, 1, or 5 mg/kg respectively) and brain sections submitted to immunocytochemistry of *c-fos*. Both methylphenidate and amphetamine evoked a dense *c-fos* expression in a large number of neurons in the striatum and whole cortex, especially in the caudate nucleus and mediofrontal cortex known to be dopaminergic targets. In contrast, modafinil elicited no or few labelled cells in these striatal and cortical structures, but did induce marked *c-fos* labelling in neurons of the anterior hypothalamic nucleus and other localised areas such as pontine and periaqueductal gray. These results provide the first evidence for the potential brain targets of modafinil, which differ from those of amphetamine or methylphenidate, and further support the belief that modafinil induces wakefulness by mechanisms distinct from those of the two stimulants. In addition, in the light of these data and the fact that modafinil reduces cortical GABA outflow, we proposed an hypothesis of cortical disinhibition for the mode of action of modafinil in wake induction.

## 20.3

SYNCHRONIZATION AND DESYNCHRONIZATION OF THE EEG AND BEHAVIORAL EFFECTS AFTER CHOLINERGIC STIMULATION OF THE NUCLEUS RETICULARIS PONTIS CAUDALIS. M. Garzón, J. de Andrés\* and F. Reinoso-Suárez. Departamento de Morfología, Universidad Autónoma, Madrid, 28029, Spain

Local cholinergic stimulation of the ventral part of the nucleus reticularis pontis oralis (vRPO) produces EEG desynchronization with all polygraphic and behavioral signs of paradoxical sleep (PS). In the present study we have tried to precise the caudal extension of the PS producing area in the pontine tegmentum examining the polygraphic and behavioral effects of small volume carbachol microinjections (20 nl; 0.2M, 0.02M and 0.01M concentrations) delivered in different sectors of the nucleus reticularis pontis caudalis. Eight cats with electrodes for EEG, EOG, EMG and PGO chronic recordings were used. Carbachol microinjections in the rostral part of RPC at the level of the trigeminal motor nucleus (3 cats) resulted in sleep behavior associated with atonia and PGOs, but simultaneously there was a conspicuous synchronization in the cortical EEG. Synchronized EEG and PGOs but not atonia were obtained after RPC microinjections at the level of the abducens nucleus (2 cats). Behavioral and polygraphic wakefulness with desynchronized EEG occurred in the remaining 3 cats which had the most caudally RPC microinjections, situated at the level of the facial nucleus. EEG power spectra showed that the carbachol RPC-induced EEG synchronization after the highest carbachol dose (0.2M) was due to an enhancement of the 4-9 Hz band; while an increase of the 10-14 Hz band took place in EEG synchronization after the two remaining doses of carbachol (0.02M and 0.01M). In spite of the behavioral sleep of the animals which had EEG synchronization after RPC carbachol microinjections, a decrease of the 0.5-3 Hz band was observed. The present results indicate that the rostral RPC may be involved in the generation of some PS events such as PGO waves and atonia, but it seems not participate in PS desynchronization. EEG desynchronization after RPC cholinergic stimulation (in the caudal part) is associated with wakefulness. Supported by PB94-1545 DGI/CYT and CII\*-CT93-0002 EC Grants

## 20.5

MICRODIALYSIS PERFUSION OF AN ADENOSINE UPTAKE INHIBITOR IN THE BASAL FOREBRAIN INCREASES SLEEP. Robert E. Strecker\*, Tarja Porkka-Heiskanen\*, Mahesh Thakkar, Alvhild Alette Bjorkum, and Robert W. McCarley. Dept. of Psychiatry, Harvard Medical School, Brockton VA Med. Ctr., Brockton, MA 02401, and \*Institute of Biomedicine, University of Helsinki, Finland.

Increased levels of CNS adenosine (AD) are thought to promote the transition from wakefulness to sleep. Our lab has previously shown that AD inhibits mesopontine cholinergic (ACh) neurons involved in REM sleep regulation, and also that microdialysis perfusion of 300  $\mu$ M AD in the basal forebrain (BF) produces increased sleep in vivo. The present study tested whether increasing endogenous BF AD levels with an AD uptake inhibitor would also increase sleep. Microdialysis was performed in freely moving cats implanted with electrodes for the recording of behavioral state, and with cannula used to guide the probes to either the substantia innominata region of the BF (rich in ACh neurons), or the VA/VL of thalamus. Behavioral state and extracellular AD levels were simultaneously measured during a 3h control period, and during the subsequent addition of S-(4-nitrobenzyl)-6-thioinosine (NBTI; 1 $\mu$ M), a potent AD uptake inhibitor, to the artificial CSF perfusate. BF perfusion of NBTI (N=6) produced a significant decrease in the total proportion of time spent awake (from 50% to 31%), and a corresponding increase in slow wave sleep (from 40% to 52%). REM sleep increased also (11% to 17%), but not significantly ( $p < 0.1$ ). In contrast, NBTI perfusion in the VA/VL (N=4) did not produce a consistent change in behavioral state. NBTI produced a 2 fold increase in extracellular AD levels in 4 of 9 experiments. The finding that NBTI perfusion in BF, but not VA/VL, decreases wakefulness suggests that the AD effect on arousal may be specific to regions containing ACh neurons that are known to modulate CNS arousal. Supported by NIMH grant MH39683; Dept. Vet. Affairs; Fulbright Fellowship to AAB.

## 20.2

BILATERAL, PONTOMESENCEPHALIC LESIONS INCREASE MONOCULAR DEPRIVATION (MD)-INDUCED, PLASTIC CHANGES IN LATERAL GENICULATE NUCLEUS (LGN) CELLS. James P. Shaffery\*, Gerald A. Marks\*, Samuel G. Speciale\*, and Howard P. Roffwarg\*. Depts. of Psychiatry, \*Univ. of Mississippi Med. Center, Jackson, MS 39216, & \*Texas Southwestern Med. Center at Dallas, 75235.

Behavioral suppression of rapid eye-movement (REM) sleep in MD-kittens during the critical period of visual system development leads to augmentation of the morphological changes in LGN cells after MD alone. A cardinal electroencephalographic feature, which characterizes the activated nature of REM sleep, the ponto-geniculo-occipital (PGO)-wave, is eliminated with bilateral, pontomesencephalic lesions that sever the ascending pontine cholinergic fibers, thought to be responsible for producing PGO-waves. We predicted that because such lesions eliminate PGO-wave activity in LGN, while having no effect upon total sleep amounts, they would lead to morphological changes in LGN cell sizes in MD-kittens corresponding to what is observed after behavioral REM-sleep deprivation.

An opaque eye-patch was sutured beneath the right eyelid of 35 day old kittens and standard sleep-recording electrodes, including one in LGN, were implanted under IACUC approved conditions. After 6-7 days of recovery, a 24 hr baseline sleep-recording was obtained to detect PGO-waves. Kittens without PGO-waves (SHAM, N=7) were anesthetized (Ketamine and Xylazine) but no current was passed on electrodes implanted at initial surgery (P2, H-1 or either L2.5.3.5, or L1.0.2.0.3.0). Kittens exhibiting PGO-waves (LESION, N=7) received bilateral electrolytic lesions (5mA for 20s, or 30s). Changes in LGN cell sizes were indexed as a ratio of the mean of 100 A1-lamina cells in the LGN ipsilateral to the deprived eye to the mean of 100 A-lamina cells from the same LGN. During the seven day, post-lesion survival period only one LESION kitten still had PGO-waves. The other six LESION kittens, having a mean ratio (0.78, SE 0.05) significantly ( $p < 0.05$ ) smaller than SHAM kittens (0.90, SE 0.3), exhibited a combined effect of MD and PGO-wave suppression similar to that seen after MD and behavioral REM-sleep deprivation. These data lend additional support for our hypothesis that REM-sleep has a distinct role in CNS development. Research supported by NIH/NINDS grant NS31720 to HPR.

## 20.4

LONG-TERM ENHANCEMENT OF REM SLEEP BY MICROINJECTION OF VIP INTO THE ORAL PONTINE TEGMENTUM

P. Bourquin, C. Lebrand, M. Hamon and J. Adrien., (SPON: E.N.A.)

INSERM U288, CHU Pitié-Salpêtrière, 75013 Paris, FRANCE.

Rapid eye movement (REM) sleep can be elicited in the rat by microinjection of the cholinergic agonist carbachol into the oral pontine reticular nucleus. Intracerebroventricular administration of vasoactive intestinal peptide (VIP) during the light period enhances REM sleep in several species. Since this latter peptide is co-localized with acetylcholine in many neurons in the central nervous system, we hypothesized that the oral pontine tegmentum could be one target for VIP to induce REM sleep. After classical implantation of electrodes for sleep monitoring and of a guide tube for microinjections, we studied the effects on the sleep-wakefulness cycles of infusion into the oral pontine reticular nucleus of: 1- VIP (1 and 10 ng dissolved in 0.1  $\mu$ l saline), and: 2- fragments of VIP (VIP 1-12: 4.3 ng and VIP 10-28: 7 ng) in order to verify the specificity of the VIP effects.

When injected into the posterior part of the oral pontine reticular nucleus, the peptide (17 rats), but not its fragments (9 rats), produced an increase in the amounts of REM sleep. VIP at 1 (n=6) and 10 (n=17) ng induced a two-fold enhancement of REM sleep during 4 hours, at the expense of wakefulness. At the dose of 10 ng, these effects persisted during another 4 hours. Moreover, when the peptide was injected into the center of the positive zone (7 rats), REM sleep was enhanced during 3 to 8 consecutive days. These data provide the first evidence that REM sleep can be elicited at both short and long-term by a single intracerebral microinjection of VIP. Short-term effects would result from simple diffusion of the peptide up to the center zone. The results suggest that this peptidergic mechanisms within the caudal part of the oral pontine reticular nucleus may play a critical role in the long-term regulation of REM sleep. Further investigations will study the possible peptidergic-cholinergic interactions in this effect.

## 20.6

THE EXPRESSION OF C-FOS AND NGFI-A DURING SPONTANEOUS WAKEFULNESS IS DECREASED AFTER LESIONS OF THE LOCUS COERULEUS. G. Tononi\*, C. Cirelli, and M. Pompeiano. The Neurosciences Institute, San Diego, CA 92121

The expression of the immediate early genes (IEGs) *c-fos* and NGFI-A is higher after periods of waking (W) than after periods of sleep (S) in many brain regions. Systems with diffuse projections that fire at higher levels during W than during S, such as the noradrenergic locus coeruleus (LC), may coordinate such changes in gene expression. To determine whether LC activity is necessary for the induction of IEGs during W, WKY rats implanted for polysomnographic recordings were injected with 6-hydroxydopamine (6-OHDA, RBI) into the LC of one side (0.5-4  $\mu$ l; 2.5  $\mu$ g/ $\mu$ l). Animals were sacrificed after 2 weeks either during the light period after 3h of S, or in the dark period after 3h of W. As expected, in control rats immunocytochemistry for Fos (CRB) and NGFI-A (Zymed) showed no Fos and little NGFI-A protein expression after 3h of S (n=7) but a marked expression of Fos and NGFI-A in cerebral cortex and other brain areas after 3h of W (n=8). However, in rats who had been awake but in which the LC of one side had been lesioned (n=6), as indicated by the disappearance of dopamine B hydroxylase- (DBH, Eugene) and tyrosine hydroxylase- (TH, Boehringer) positive fibers in target cortical regions, Fos and NGFI-A expression was almost abolished on the lesioned side. On the intact side Fos and NGFI-A levels were high, comparable to those observed in normal rats after periods of W. To rule out circadian effects, other rats were kept awake for 3h during the light periods (n=9). As after spontaneous W, Fos and NGFI-A levels were high on the intact side but low or absent in areas depleted of TH-positive fibers. The levels of CREB phosphorylation (anti-P-CREB, UBI), which is involved in the transcriptional activation of both *c-fos* and NGFI-A, were reduced in correspondence with the disappearance of TH-positive fibers. There were no differences between the electrocorticogram on the intact and on the lesioned side, and power density spectra were comparable. To rule out volume conduction effects, a group of rats (n=5) was injected systemically with DSP-4 (RBI, 50mg/kg) to destroy LC terminals bilaterally. These animals exhibited a bilateral reduction of cortical TH staining associated with a corresponding reduction of Fos, NGFI-A, and P-CREB staining. However, the raw electrocorticogram and its power density spectrum were not significantly different before and after (5 to 8 days) the injection. These results suggest that LC activity during W is necessary for the induction of IEGs during W, while it is not necessary for the activation of the electrocorticogram. (Supported by Neurosciences Research Foundation).

## 20.7

**CAUSALITY ANALYSIS OF RHYTHMIC ACTIVITIES OF DESYNCHRONIZED SLEEP IN THE RAT.** <sup>1</sup>K. Sameshima\*, <sup>2</sup>L.A. Baccala, <sup>1,3</sup>G. Ballester, <sup>1,3</sup>A.C. Valle and <sup>1</sup>C. Timo-Iaria. Univ. São Paulo <sup>1</sup>School of Medicine and <sup>2</sup>Escola Politécnica; <sup>3</sup>Fed. Univ. São Paulo Medical School (EPM). 01246-903 São Paulo, SP, Brazil.

The degree of synchrony between two neural structures can be assessed through coherence of their electro-oscillograms. Alas, classical coherence proves useless in addressing the physiologically crucial question of causality between signals originating in two or more neural structures. One possible way to overcome this limitation resides in the study of *directed coherence* which allows one to determine the direction of information flow between structures by testing for the existence of signal feedback between them. Investigations of the theta rhythms during desynchronized sleep (employing electrocorticograms and subcortical field potentials recorded by bipolar electrodes) through this methodology revealed among other things that (i) direction of influences among structures exhibiting theta oscillations fluctuates along the desynchronized sleep, revealing the rat's dynamic state during the genesis of rhythmic electrical activity; (ii) information flow is essentially unidirectional from dentate gyrus to CA3, and to CA1 hippocampal fields in episodes of irregular oscillation, and the direction reverses or becomes bi-directional during oniric episodes when whiskers are observed to move vigorously; (iii) the usually high influence measured by directed coherence of cortical areas 3 and 17 onto hippocampal structures dies down during episodes of irregular oscillation; (iv) mutual influence between these areas may occur at different frequencies. These preliminary findings suggest that studies of the directed coherence can be useful in dynamically determining the functional as opposed to the anatomical relationships between neural structures.

## 20.9

**SLEEP-WAKE ACTIVITY AND THERMOSENSITIVITY OF NEURONS IN THE VENTRAL LATERAL PREOPTIC AREA OF RATS.** M.N. Alam, R. Szymusiak\*, T.L. Steininger and D. McGinty. Res. Service (151A3), V.A. Medical Center, Sepulveda, CA 91343 and Dept. Psychology, UCLA.

A subpopulation of warm-sensitive neurons in the medial preoptic/anterior hypothalamus of cats display increases in discharge rate at the onset of sleep (Alam et al., *Am J Physiol* 269:R1240, 1995). Warm-sensitive/sleep-active neurons are hypothesized to be a critical component of the rostral hypothalamic sleep regulatory mechanism. Enhanced c-fos expression during sleep has been recently described in a population of neurons located in the adjacent ventral-lateral preoptic area (VLPO) of rats (Sherin et al., *Science* 271:216, 1996). Sleep-wake discharge and thermosensitivity of VLPO neurons have not been characterized.

We examined sleep-waking discharge patterns of 47 cells in the VLPO region of rats, using chronic microwire technique. The majority of VLPO cells were slow-firing, with 30/47 exhibiting maximum discharge rates of <2 Hz and only 6/47 exhibiting peak rates >5 Hz. The most common cell type found were those displaying at least 20% higher discharge rates during nonREM sleep compared to waking (19/47). VLPO/sleep-active cells averaged a  $115 \pm 29\%$  increase in discharge rate during nonREM sleep compared to waking. Of the remaining cells, 17 exhibited higher discharge rates in waking compared to sleep, and 11 displayed similar rates during waking and sleep. Fifteen of 19 VLPO/sleep-active neurons were examined for responsiveness to local changes in temperature. A majority (10/15) were classified as warm-sensitive (>10% increase in discharge rate/°C); 2/15 were cold-sensitive and 3/15 were temperature insensitive.

These preliminary results demonstrate the presence of warm-sensitive/sleep-active neurons within the rat VLPO. Supported by the Veterans Administration.

**BILATERAL LESIONING OF THE FASCICULUS RETROFLEXUS DISRUPTS THE REM STAGE OF SLEEP IN RAT**

A. Valjakka<sup>1</sup>, M.M. Airaksinen<sup>1</sup>, J. Vartiainen<sup>2</sup>, J.T. Tuomisto<sup>3</sup>, H. Olkkonen<sup>4</sup> and L. Tuomisto<sup>1</sup>

<sup>1</sup>Dept. of Pharmacol. and Toxicol., University of Kuopio, <sup>2</sup>Nokia Research Center, Tampere, <sup>3</sup>National Public Health Institute, Kuopio, <sup>4</sup>Dept. of Applied Physics, University of Kuopio, Finland

The fasciculus retroflexus (FR) fiber bundle comprises the well delineated bidirectional axonal connection between the habenular nuclei complex of epithalamus and the interpeduncular nucleus (IPN) of limbic midbrain. According to the widespread anatomical connections of the IPN it may function as an essential signal communication crosspoint between the limbic forebrain and the limbic midbrain and the more caudal pontine structures which contain areas intimately involved in the control of sleep-waking stages. Hence, the present study addressed the influences of bilateral electrolytic lesioning of the FR on sleep-waking stages as assessed by six-hour day-time recordings of electroencephalogram (frontal cortex and hippocampus), electro-oculogram and body movement activity, in freely behaving rats. As compared to the control-operated rats, FR lesioning almost completely abolished the time spent in rapid-eye-movement sleep (REM) but had no significant effects on the durations of other types of synchronized sleep patterns (quiet, slow-wave or intermediate states of sleep) or active/quiet waking stages. REM sleep loss was attributable to the reduction of hippocampal theta activity and alterations of REM frequency without significant changes in frontal cortex EEG properties. Our results point to the dissociation of REM sleep control mechanisms comprising FR, IPN and basal forebrain-hippocampal parts of the limbic system from the thalamocortical arousal control.

## 20.8

**REM SLEEP SELECTIVELY ACTIVATES ANTERIOR PARALIMBIC GLUCOSE METABOLISM.** E.A. Nofzinger, R.Y. Moore, M.B. Wiseman, B. Gao\*, D.J. Kupfer, M.A. Mintun. Sleep and Chronobiology Center, PET Center, Center for Neuroscience, Univ. Of Pittsburgh, Pittsburgh, PA 15213.

Recent studies have elucidated brainstem mechanisms involved in REM sleep and it is well-known that this sleep state is associated with a general pattern of global cortical arousal similar to waking. Much less is known about other aspects of REM sleep and, particularly, about other forebrain mechanisms that would distinguish REM sleep from waking. This seems particularly important given the apparent importance of REM sleep in learning and memory and affective state regulation and the clear abnormalities of REM sleep associated with mental disorders. For these reasons, we sought to determine the differences between forebrain activity in REM sleep and waking in healthy control subjects using PET. Adult women (n=6) were screened by structured lifetime psychiatric interviews, medical history and examination, then underwent three nights of EEG sleep studies, magnetic resonance imaging scans of the head, and waking and REM sleep-related 18F-fluoro-deoxyglucose PET scans. PET images were spatially normalized using MR-based anatomical resolution and differences between the waking and REM sleep PET scans were determined by means of statistical parametric mapping (SPM, Friston, 1995). Regions showing increased relative glucose metabolism during REM sleep in comparison to waking included the orbital, parafactory, and medial prefrontal cortex, the anterior cingulate cortex and the insular cortex. These regions share several important features: 1) projections from midline thalamus; 2) reciprocal connections with the amygdala and other phylogenetically old cortical areas; 3) projections from dopaminergic and cholinergic cell groups. These structures are involved particularly in autonomic and endocrine control, motivated behavior and attention and form an important component of forebrain structures integrating homeostatic regulation with behavioral adaptation. REM sleep, therefore, in addition to activating neocortex, selectively activates an older forebrain network involved in integrating physiological regulatory mechanisms with behavioral adaptation.

## 20.10

**ACTIVITY OF REM-OFF CELLS DURING CATAPLEXY IN THE NARCOLEPTIC DOG.** M.-F. Wu\*, S. Gulyani, E. Mignot<sup>1</sup>, and J. M. Siegel. Neurobiol. Res. (151A3), Sepulveda VAMC, CA 92343, Dept. Psychiat., UCLA, CA 91020 and <sup>1</sup>Dept. Psychiat., Stanford Univ. Sch. Med., Palo Alto, CA 94305.

Cataplexy in narcoleptics has been hypothesized to be due to the release of REM sleep components into waking. We have previously reported on cells in the pons and the medulla of narcoleptic dogs that increase activity during cataplectic attacks and also during REM sleep (REMS), as well as cells that increased firing in REMS but not in cataplexy. Now we report on cells in the area of locus coeruleus (LC) that ceased firing in REMS and in cataplexy (CAT).

Cataplexy-off/REM-off cells (n=7) had a slow, regular, firing pattern in quiet waking, greatly reduced activity in non-REM sleep (NREMS), and were mostly silent in REM sleep and cataplexy (mean discharge rates in spikes/s: AW=1.37±0.15; QW=1.43±0.24; NREMS=0.28±0.05; CAT=0.31±0.18; REMS = 0.10±0.01). These cells were determined to be noradrenergic LC cells according to the criteria adapted from previous studies in the cat and rat. Clonidine (2 µg/kg, i.v. or 0.1 mg/kg, p.o.) reduced discharge rate by 50% in waking. Cells ceased firing in cataplexy and REMS after physostigmine (0.05 mg/kg, i.v.) and prazosin (0.5 mg/kg, p.o.), as in pre-drug conditions. Physostigmine, however, did not alter discharge in waking without cataplexy. On the other hand, prazosin reduced cell activity by an average of 56% in waking. While REM-off cells always ceased discharge during cataplexy, discharge cessation followed cataplexy onset and resumption of discharge preceded cataplexy offset, indicating that cessation of discharge in LC cells results from and may regulate cataplexy, but does not initiate the triggering of cataplexy. These studies suggest that cataplexy results from a disruption of REMS state organization, including an altered time course of activity change in REM-on and REM-off cells.

## 20.12

**A SUBPYROGENIC ENDOTOXIN CHALLENGE INCREASES SWS AND DELTA POWER IN HEALTHY MEN** J. Mullington\*, D. Hermann, C. Korth, F. Holsboer and T. Pollmächer. Max Planck Institute of Psychiatry, Clinical Institute, 80804 Munich, Germany

The current study was designed to examine nocturnal sleep following endotoxin challenge (*Salmonella abortus equi*) administered close to nocturnal sleep onset. A placebo controlled crossover design was used. Subjects were permitted to sleep ad libitum following injection of either .8 ng/kg (n=5), .4 ng/kg (n=5) or .2 ng/kg (n=7) body weight. Blood was sampled through an indwelling forearm catheter, processed for white blood cell counts or centrifuged and frozen for later assay of cytokines and cortisol. Rectal temperature (rT), EEG and EKG were measured continuously. Sleep was analyzed using standardized stage scoring as well as spectral analysis.

Significant (p<0.05) increases were found following each dose of endotoxin for TNF-alpha (174.3, 72.1, and 39.8 pg/ml for .8, .4 and .2 ng/kg respectively), IL-6 (235.9, 46.0, and 25.9 pg/ml), IL-1ra (35.1, 20.5, 3.0 ng/ml) and cortisol (192.8, 91.9, 26.2 µg/l). rT was increased following the .8 and .4 ng/kg doses (1.5°C and 0.5°C respectively, p<0.05), but not following the .2 ng/kg dose (0.1°C, n.s.). Sleep was transiently disrupted following the .8 and .4 ng/kg doses and REM sleep was suppressed, but following the .2 ng/kg dose, minutes of SWS were increased in every subject (42.9±5.7 vs 54.4±5.8 SEM, p<0.05). In addition, EEG delta power in SWS was increased 476.7±19.0 vs 537.7±24.7 SEM, p<0.01), particularly due to changes in the first 3 hours following the .2 ng/kg injection. These results demonstrate complex modulation of the human sleep-wake regulatory system by endotoxin host challenge. While endotoxin was sleep disruptive at 0.8 and 0.4 ng/kg, it led to enhanced sleep at subpyrogenic levels. Dose dependent sleep disruption and enhancement occurred when TNF-alpha and IL-6 were at peak levels, 2 h before the highest rT. Because subpyrogenic doses of endotoxin mimic a very early stage of host response, it seems possible that SWS plays an adaptive role particularly during the early stage of infection. -Supported by the Volkswagen-Stiftung, Hanover, Germany.

**SEQUENTIAL SEGREGATION OF TRUNK NEURAL CREST CELL FATES.** P. D. Henion, A. Novicki\* and J. A. Weston. Institute of Neuroscience, University of Oregon, Eugene, OR 97403

During embryonic development, trunk neural crest cells give rise to peripheral neurons, glial cells, and melanocytes. The process by which neural crest cells diversify, however, is unclear. We tested the prevailing hypothesis that neural crest cell precursors are specified in a stochastic manner from pluripotent precursors. We used *in vitro* clonal analysis to determine the differentiative behavior of individual neural crest cells at different times after segregation from the neural tube. We labelled individual cells of cultured quail neural crest populations with lineage dye, grew the cultures in a homogeneous, nutrient-rich medium, and subsequently determined the phenotype(s) of cells in the resulting clones using cell type-specific markers. We found that the initial population, 1-6h after cells had started to segregate from the neural tube, contains some fate-specified precursors, but is composed primarily of unrestricted or partially restricted precursors. One or possibly two cell divisions (4-7h) later however, we found no cells that gave rise to both neurons and melanocytes. Thus, soon after segregation from the neural tube, neurogenic and melanogenic fates had segregated. One day later, and two days before neuronal differentiation can first be detected, neuronal and glial fates had segregated. These results indicate that neural crest cell fates are specified soon after segregation from the neural tube in a sequential, non-random manner, even in a homogeneous *in vitro* environment. Supported by NS29438 and NS09031.

## 21.3

**ROLE OF MASH-1 IN THYROID C-CELL DIFFERENTIATION AND GENE EXPRESSION.** T. M. Lanigan<sup>1</sup> and A. F. Russo<sup>1,2</sup>  
<sup>1</sup>Mol. Biol. Program and <sup>2</sup>Dept. of Physiology and Biophysics Univ. of Iowa, Iowa City, IA 52242.

We have investigated the role of the developmentally-regulated transcription factor, MASH-1, in thyroid C-cell differentiation. A logical target for MASH-1 action is the calcitonin/calcitonin gene-related peptide (CT/CGRP) gene, since the phenotypic hallmark of C-cells is expression of the hormone calcitonin. We first showed that MASH-1 is present in juvenile rat C-cells. This is an unusual finding, since the only other example of MASH-1 expression in adult tissue is in the presumed neuroblasts of the olfactory epithelium. We have demonstrated that MASH-1 could transactivate the CT/CGRP cell-specific enhancer 3-4 fold in a heterologous cell line. Based on these findings, we predicted: 1) MASH-1 may regulate CT/CGRP gene expression *in vivo* and 2) MASH-1 may be required for thyroid C-cell differentiation. To test these predictions, we obtained homozygous mouse embryos containing a targeted mutation in MASH-1. Using a sensitive RT-PCR assay, we found calcitonin mRNA in the MASH-1 knockout mice. These preliminary data suggests that MASH-1 is not required for either C-cell differentiation or calcitonin expression. These results support the idea that C-cells are derived from a sympathoadrenal progenitor, and positions C-cells within a neuronal developmental pathway. This work was supported by National Institutes of Health (HD25969).

## 21.5

**ORIGIN OF INTERSTITIAL CELLS OF CAJAL IN THE MOUSE INTESTINE.** H.M. Young\*, D. Ciampoli, B.R. Southwell and D.F. Newgreen<sup>1</sup>. Department of Anatomy & Cell Biology, University of Melbourne, Parkville, 3052, VIC, Australia, and <sup>1</sup>The Murdoch Institute, Royal Children's Hospital, Parkville, 3052, VIC, Australia.

The interstitial cells of Cajal (ICC) are found in a number of different locations in the gastrointestinal tract, where they form close associations with both muscle cells and nerve terminals. They express receptors to a variety of different neurotransmitters and also the receptor tyrosine kinase, *c-kit*. In this study we examined the embryological origin of ICC in the mouse intestine to determine whether they arise from the neural crest or from the mesoderm of the intestinal wall. Segments of intestine were removed from embryos either before or after the arrival of neural crest cells (the precursors of enteric neurons and glial cells) and transplanted under the renal capsule of host (adult) mice and allowed to develop for 3 - 5 weeks. In the mouse intestine, antibodies to *c-kit* selectively label ICC at the level of the myenteric plexus and antibodies to the neurokinin receptor, NK1, selectively label ICC at the inner margin of the circular muscle. The presence of neurons in the explants was examined using antisera to neuron-specific enolase, nitric oxide synthase, substance P and calcitonin. In segments of gut explanted after the arrival of neural crest cells, immunoreactive neurons and *c-kit*- and NK1-immunoreactive ICC were present with a similar distribution to that seen in control tissue at a similar developmental age. In segments of gut explanted before the arrival of neural crest cells, neurons were not present, however immunoreactive ICC were present in these aneural explants, indicating that ICC do not arise from the neural crest. The source of ICC in mammals is therefore likely to be the mesenchyme of the gut. This work was supported by the NHMRC (Australia).

**CHICKEN EHAND AND DHAND INFLUENCE NEURAL CREST CELL DIFFERENTIATION.** M. J. Howard\* and P. Cserjesi. Medical College of Ohio, Toledo, OH 43699 and Columbia University NY, NY 10032.

Members of the basic helix-loop-helix (bHLH) family of DNA binding proteins have been implicated as having an important role in the development of subpopulations of peripheral neural crest-derived neurons. In rodents, the expression of MASH-1, an achaete-scute DNA binding protein homologue, has the temporal and spatial expression to indicate a role in peripheral neuron development. In animals that have a targeted null mutation of MASH-1, the development of neural crest-derived sympathetic and enteric serotonergic neurons is greatly reduced (Guillemot et al., 1993, Cell 75:463-476; Blaugrund et al., 1996, Development 122: 309-320). We have cloned the chicken homologues of dHAND (ckdHND) and eHAND (ckeHND), bHLH DNA binding proteins that have a similar but restricted expression pattern compared to MASH-1. Our whole-mount *in-situ* hybridization studies, using radiolabeled riboprobes synthesized from our cloned ckeHND and ckdHND cDNA's, suggest that ckeHND and ckdHND mRNA is present in heart, sympathetic and enteric neurons, beginning as early as two days in the heart and appearing between three and four days in peripheral neurons. No signal was detected in dorsal root ganglia or brain. In order to determine if neuronal differentiation would be affected by blocking expression of these gene products, antisense oligonucleotides (50  $\mu$ M) were applied *in-vitro*, to segments of quail neural tube from which neural crest cells were migrating. The differentiation of neurons was assessed by morphological criteria and the expression of either neurofilament proteins or the neurofilament associated protein, NAPA 73. Neither ckeHND or ckdHND antisense oligonucleotide applied individually blocked the differentiation of neural crest-derived neurons. However, if both antisense oligonucleotides were applied together (25 $\mu$ M each) over a period of 7 days, neural crest-derived neurons failed to develop even though the differentiation of neural tube-derived neurons was unaffected. These data suggest that chick HAND gene products can act in concert to influence the development of neural crest-derived neurons in culture. This work was supported by NIH-HD 28184 to MJH.

**TRANSCRIPTION FACTOR INVOLVEMENT IN CELL FATE DETERMINATION IN THE RAT PNS.** L.M. Donahue\* and A.J. Reinhart. Dept. of Cell Biology and Biochemistry, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

We are interested in the molecular mechanisms underlying the ability of multipotential neural crest stem cells to give rise to neurons and glia. We are using the rat PNS-derived cell line family called RT4 as a model of neuronal and glial differentiation. The RT4 stem cell (RT4-AC) converts spontaneously and reproducibly in culture to two neuronal derivatives (RT4-B, RT4-E) and one glial derivative (RT4-D). There is now a large body of evidence to suggest a role for transcription factors in the regulation of cell fate decisions during neural differentiation. We are examining the function(s) of candidate transcription factors expressed in the RT4 cell line family to assess their involvement in the conversion of the stem cell to the derivative cell types. We report here that four previously isolated POU domain-containing transcription factor genes (Oct-1, Oct-2, Brn-5 and SCIP), and REST, a repressor of mature neuronal gene transcription, are expressed in the RT4 family. REST, Oct-1, Oct-2 and Brn-5 are expressed in all of the RT4 cell lines, but SCIP is expressed only in the stem cell and glial derivative. Although Oct-2 is expressed in all of the RT4 cell types, it is preferentially expressed in the neuronal lineages. Work is currently underway to determine the role(s) of SCIP and Oct-2 in the conversion of the RT4 stem cell to the derivative cell types.

**Evidence for multiple cassettes of regulatory elements for Mash1 expression.** S. Verma\*, T. Savage, D. Smith, and J. E. Johnson. Cell Biology and Neuroscience, University of Texas Southwestern Medical Center, Dallas, TX 75235-9111

Mammalian achaete-scute homolog, *Mash1*, is a neural differentiation gene of the basic helix-loop-helix class whose expression is restricted to the developing nervous system. Gene knockout experiments have demonstrated that *Mash1* is required for the generation of olfactory neurons and neurons of the autonomic nervous system. As a means to identify genes that act upstream of *Mash1* to restrict its expression to the nervous system, we have characterized cis-regulatory elements using *lacZ* as a reporter gene in transgenic mice. We have obtained evidence for the presence of at least three lineage specific regulatory elements. We have tested a 36 kb sequence flanking the *Mash1* coding region. Transgenic mice containing this 36 kb region express the *Mash1/lacZ* transgene in the CNS and the PNS. Expression of the *Mash1/lacZ* transgene was never observed in the olfactory epithelium or retina suggesting that elements regulating expression in these lineages must lie outside of this (36 kb) region. Further dissection of the 36 kb sequence identified a 1.2 kb region upstream of the *Mash1* coding region that regulates CNS expression. Elements controlling PNS expression do not colocalize with the CNS elements and are found elsewhere in the 36 kb sequence. We are currently in the process of identifying proteins that bind these sequences to control *Mash1* expression. Supported by NIH RO1-NS32817-02.

## 21.7

**CHARACTERIZATION OF THE EARLY SA CELL LINEAGE IN THE MOUSE USING ANTIBODIES TO PHOX2 AND GAP43.** F. Deimling<sup>a</sup>, K. Krieglstein<sup>a</sup>, K. Unsicker<sup>a</sup>, C. Goridis<sup>b</sup>, & W.B. Huttner<sup>c</sup>. (a) Anatomy & Cell Biol./Neuroanatomy Univ. Heidelberg, (b) IBDM, F-13288 Marseille, and (c) Neurobiology Univ. Heidelberg, D-69120 Heidelberg, Germany.

Sympathetic neurons and endocrine chromaffin cells of the adrenal medulla and paraganglia are supposed to share a common precursor, the sympathoadrenal (SA) progenitor cell. Mice deficient for signals that have been considered to be essential for the development of the SA cell lineage (c-RET, MASH1, glucocorticoid, neurotrophins) have been generated, but require more detailed analysis of the lineage. We have employed a set of partially novel markers to immunohistochemically characterize and distinguish putative subsets of SA progenitor cells in wildtype mice. Several of the established rat SA lineage markers including SA1 and B2 could not be adapted to mouse. We find TH- and Phox2-immunoreactivities (ir) co-localized at E12.5 in migrating, MASH1<sup>+</sup> SA progenitors in the region of the urogenital crest and mesonephros tubules. Intensity of Phox2-ir in sympathetic paravertebral and preaortal ganglia is maintained between E13.5 and E18.5, while TH-ir declines and becomes undetectable in a large number of SA cells within the sympathetic sublineage. However, within the developing adrenal gland virtually all SA progenitors remain intensely TH- and Phox2-ir. GAP43, a proposed marker for postnatal noradrenergic chromaffin cells, was found from E13.5 to E18.5 in a subset of adrenal TH<sup>+</sup> cells, which comprised a substantial proportion of PNMT<sup>+</sup> cells. GAP43 is therefore unlikely to be a useful marker for presumptive noradrenergic chromaffin cells. PNA staining did not distinguish between subsets of chromaffin cells. We are now applying these and additional markers to an analysis of the SA cell lineage in glucocorticoid-receptor deficient mice. Supported by DFG (SFB 317/C8/D4)

## 21.9

**EARLY EXPOSURE TO DEPOLARIZING STIMULI LEADS TO LONG-TERM CHANGES IN TRANSMITTER REGULATION IN PRIMARY SENSORY NEURONS.** T. Brosenitsch, and D.M. Katz\*Case Western Reserve University, School of Medicine, Cleveland, OH 44106.

Mechanisms responsible for generating transmitter diversity in developing sensory neurons are not well defined. However, neuronal activity, and factors in the ganglionic microenvironment, may play a role in regulating expression of some traits. For example, depolarizing stimuli promote (Hertzberg, et al., 1995), and ganglionic non-neuronal cells inhibit (Fan & Katz, 1993) expression of catecholaminergic properties in sensory ganglion cells in culture. In the present study we asked whether responsiveness to depolarizing stimuli is developmentally regulated, and whether exposure to such stimuli early in development results in long-term changes in transmitter regulation. Dissociate cultures of embryonic rat petrosal ganglion (PG) sensory neurons were plated at various ages in the presence or absence of a depolarizing concentration of KCl (40mM) for 3 days and then stained for tyrosine hydroxylase (TH) and neurofilament protein. Neurons were most responsive to KCl treatment on embryonic day (E)16.5; at this age, nearly 100% of ganglion cells in treated cultures were TH<sup>+</sup>, compared to 10% in untreated controls. In contrast, KCl treatment induced TH expression in only 40-50% of E13.5 or postnatal day 1 ganglion cells. This peak in responsiveness on E16.5 corresponds to the stage at which TH normally appears in catecholaminergic ganglion cells in vivo (Katz & Erb, 1990), indicating that sensitivity to depolarizing influences and transmitter development may be linked. In addition, depolarization of fetal neurons had a long term effect on regulation of TH expression. Normally, TH levels in KCl-treated E16.5 PG cultures return to control values one week following removal of KCl. However, PG neurons exposed transiently to high KCl on E16.5 exhibited a 3.5-fold greater response to a second depolarizing stimulus ten days later compared to neurons with no prior history of stimulation [32% TH<sup>+</sup> (pretreated) vs 9% TH<sup>+</sup> (naive)]. These data indicate that early exposure to depolarizing stimuli may sensitize developing sensory neurons to subsequent activation. Supported by HL-25830 (Proj. 4;DMK) and T32NS07118.

**IN VITRO ISOLATED HUMAN CNS PRECURSOR CELL SHOW MULTILINEAGE CAPACITY.** X. Cui, P.M. Almqvist\*, A. Kjellgaard, U. Lendahl, A. Seiger, and L. Wahlberg. Dept. of Clinical Neuroscience, Section of Neurosurgery, Dept. of Gynecology and Obstetrics, Dept. of Cell and Molecular Biology, and Dept. of Clinical Neuroscience and Family Medicine, Section of Geriatric Medicine, Karolinska Institute, S-171 77 Stockholm, Sweden.

To address the question of lineage commitment of the differentiated progeny of human neural stem cells, embryonic neural tissues derived from elective first trimester abortions were used and precursor cells were isolated and expanded in culture and formed free-floating neurospheres in response to EGF and EGF/bFGF. Tissues from spinal cord, brainstem, and forebrain were collected. In the late developmental stage, the forebrain was further divided into cortex and subcortex. Neurospheres derived from either early (5-8 weeks of gestation) or late (9-11 weeks) first trimester tissue specimens were kept under permissive conditions for 1 - 4 weeks before transfer to a poly-D-lysine substrate and serum containing medium. Whole spheres of precursor cells were allowed to differentiate on the substrate for one week in culture followed by immunohistochemical analysis using cell-type specific markers. Neurospheres were isolated from all areas and were positive for the intermediate filament marker nestin and remained proliferative during the 1 - 4 weeks in free-floating culture conditions as indicated by BrdU uptake. After plating, the spheres differentiated rapidly into neuronal, astrocytic, and oligodendrocytic lineages. Precursor cells derived from the forebrain of early stage embryos differentiated mainly into NF positive neuronal cells (84%). The cortical tissue of the later gestational ages showed a predominance of GFAP positive astrocytes (80%). The subcortex differentiated into 50% NF positive cells and another 30% stained positive for GFAP. The spinal cord showed 55% NF positive neurons and 20% GFAP positive astrocytes.

In conclusion, we find that EGF responsive neural precursor cells can be isolated from all major divisions of the human first trimester CNS and remain proliferative for at least one month. Different regions and gestational ages appear to yield different proportions of the three major phenotypes. MFR grant # 13X-11570

## 27.8

**VISUALIZATION OF VESICULAR MONOAMINE AND ACETYLCHOLINE TRANSPORTERS IN DEVELOPING NEURONS AND NEUROENDOCRINE CELLS.** M.-K.H. Schäfer, B. Schütz, J.D. Erickson, L.E. Eiden and E. Weihe\*. Dept. Anatomy & Cell Biology, Philipps Univ., D-35033 Marburg, Germany; Sec. Molecular Neuroscience, Lab. of Cell Biology, NIMH, Bethesda, MD 20892.

The cholinergic and monoaminergic vesicular transporters VACHT and VMATs 1 and 2 have been visualized by immunohistochemistry in central and peripheral cholinergic and monoaminergic neurons and neuroendocrine cells during development using specific antibodies.

VMAT2, and not VMAT1, is expressed in neuroepithelial cells in the developing central nervous system at around embryonic day 12 (E12), and in monoaminergic nerve terminals beginning around E14. VMAT1 and VMAT2 are co-expressed during development in sympathoadrenal derivatives of neural crest cells (chromaffin, SIF and carotid body paracrine cells), with VMAT1 expression eventually predominating in endocrine and paracrine cells in the mature animal, and only VMAT2 expressed in peripheral neurons. In the gut, enterochromaffin cells express only VMAT1 throughout development, while enterochromaffin-like (ECL) cells of the stomach appear to express only VMAT2 throughout their development.

Cholinergic peripheral sympathetic innervation arises without the intermediacy of a monoaminergic phenotype as evidenced by parallel and exclusive innervation of developing sweat gland and sweat gland vasculature by VACHT- and VMAT2-positive terminals, respectively. In the CNS and PNS, VACHT-positive terminals are considerably more extensive than previously reported using the cholinergic marker ChAT, in primate as well as rat (J. Mol. Neurosci. 6:225, 1995; PNAS USA 93:3547 1996). Novel cholinergic systems have been identified in the rat hypothalamus and sensory mesencephalic trigeminal nucleus using the VACHT marker. An intrinsic neuronal system in cerebral cortex contains both VACHT mRNA and protein, and has been characterized according to its ontogeny and areal distribution. Supported by VW-Stiftung, DFG, and NIMH IRP.

## 21.10

**FUNCTIONAL ROLE OF N-MYC IN EARLY NEURONAL DIFFERENTIATION OF PC12 CELLS.** J. Bao\*, D.S. McGehee, D. Talmage\*\*, L. Role. Ctr for Neuro & Behav, \*\*Inst of Human Nutr, Columbia Univ, NY, NY 10032.

High expression of N-myc in embryonic neuronal tissue suggests a possible functional role of N-myc in early neuronal differentiation. The functional ability of N-myc in cellular proliferation and differentiation is believed to require dimerization with Max, a newly identified nuclear protein containing a basic helix-loop-helix region, and leucine zipper (bHLH-LZ), which permit dimerization and DNA binding. Despite these findings the neural-like cell line PC12, which undergoes neural differentiation in the presence of nerve growth factor (NGF) does not express Max. This raises the question as to whether N-myc is involved in neuronal differentiation of this cell line.

To address this question, we overexpressed a truncated form of Max that included only HLH-LZ domain as a dominant negative to block N-myc in PC12 cells. Transfected cells had no neurite outgrowth and no detectable voltage gated Ca<sup>2+</sup> influx even after 3-7 days of NGF treatment. In contrast, wild type PC12 cells sprout prodigious processes and manifest robust voltage-gated Ca<sup>2+</sup> influx. Our data suggest that N-myc, in the absence of its partner Max, can mediate early neuronal differentiation in PC12 cells perhaps in collaboration with another partner. We are using the yeast genetic screen to investigate the molecular basis of neural differentiation by N-myc (NS29071).

## 21.12

**CONDITIONAL IMMORTALIZATION OF HUMAN NEURONAL, GLIAL AND MULTI-POTENT CNS PROGENITOR CELLS.** D.W.Y. Sah<sup>1</sup>\*, J. Ray<sup>2</sup>, N. Richard<sup>1</sup>, J. Leisten<sup>1</sup> and F. Gage<sup>2</sup>. <sup>1</sup>Signal Pharmaceuticals, Inc., San Diego, CA 92121 and <sup>2</sup>Laboratory of Genetics, The Salk Institute, La Jolla, CA 92037.

CNS drug discovery would be facilitated by overcoming the difficulty of obtaining sufficient primary human CNS tissue for research and development, the limited lifespan of primary cultures and the paucity of human CNS lines. Presently, drug development is carried out with rodent cells or cloned human CNS channels and receptors; however, species differences, abnormal cellular environment and artificial subunit combinations are potential caveats. Human CNS lines containing functional native channels and receptors in their normal cellular environment offer significant advantages.

Here, we describe the establishment of conditionally-immortalized human CNS cell lines that can be differentiated in 1-2 weeks. We immortalized cultures of proliferating human CNS progenitor cells by retroviral infection with a tetracycline (tet)-responsive retroviral vector containing the v-myc oncogene and neo<sup>R</sup> (Hoshimaru et al., 1996); viable, proliferating cells that tolerated G418 were selected. In proliferative growth conditions, immortalized cells doubled every ~2 days and expressed the oncoprotein. In the presence of tet, the oncogene was suppressed rapidly and virtually completely; cell division stopped, neuronal (MAP2a/b) and glial (GFAP) cell-type specific markers were expressed, and voltage (sodium)- and ligand (NMDA, kainate, and GABA)-gated currents were present. Clonal cell lines could be differentiated rapidly into neurons only, astrocytes only, or both neurons and glia, establishing the existence of neuronal, astrocytic and multi-potent human CNS progenitor cells. Moreover, these cell lines provide powerful tools for drug discovery. [Supported by grant from NIA.]

## 21.13

MODULATION OF TYROSINE HYDROXYLASE (TH) EXPRESSION IN THE HUMAN CELL LINE N TERA-2 (NT2) R.S.Hartley\* and V.M.-Y. Lee Inst. of Neurol. Sci. and Dept. of Path & Lab. Med., Univ. of Penn. Sch. of Med., Phila, PA 19104

In our investigation of factors that affect the neurotransmitter phenotype of differentiated NT2 cells (NT2N), we find that TH immunoreactivity is dependent upon culture conditions. Specifically, mechanical and chemical purification procedures eliminate TH expression. Previously, we noted that purified cultures of NT2N cells did not express significant levels of TH *in vitro* or when implanted into the murine CNS, although untreated NT2 cells differentiated and expressed TH when implanted into the murine striatum. Additionally, TH expression levels increased slightly when NT2N cells were cultured with striatal extracts.

TH expression was monitored by immunofluorescence and western blotting with three different commercially available anti-TH antibodies. Using these techniques, we find that a majority of NT2N cells are strongly TH immunoreactive if the neuronal cells are not dissociated or purified. In these cultures, TH expression increases during the five week retinoic acid differentiation period along with the total number of neuronal cells. In contrast, TH immunoreactivity diminishes with increasing chemical and mechanical manipulation. Abundant presynaptic terminals containing large numbers of small clear vesicles and occasional large dense core vesicles are observed by electron microscopy (EM) in co-cultures of rat cortical astrocytes with NT2N. Future studies with these co-cultures will determine whether the dense core vesicles contain dopamine by immuno-EM and whether astrocytes cultured from different CNS areas can influence the expression of TH in NT2N cells. We are further investigating the NT2N catecholaminergic phenotype using HPLC. This system may be helpful for studying the differentiation of catecholaminergic cells and for therapeutic implantation in diseases such as Parkinson's Disease.

Supported by grants from the NIH.

## 21.14

RETINOIC ACID INDUCES THE EXPRESSION OF CHOLINERGIC MARKERS IN HUMAN NT2 NEURONS. M. Paterlini, A. Valerio\*, F. Baruzzi, M. Boifava, P. Liberini, M. Memo, P.F. Spano, Div. Pharmacol., Dept. Biomed. Sci. & Biotechnol., Brescia University School of Medicine, 25123 Brescia, Italy.

NT2era 2 clone D1 (NT2) cells acquire a neuronal phenotype after induction with retinoic acid (RA) yielding a highly purified population of human postmitotic neurons (hNT2 neurons). hNT2 neurons express cytoskeletal proteins typical of central nervous system (CNS) neurons and are being extensively used for studying neuronal development, degeneration and transplantation. The neurotransmitter(s) phenotype induced by RA treatment in NT2 cells *in vitro* has not been determined yet. RA treatment has been demonstrated to confer cholinergic properties to various types of cells in culture, also inducing the expression neurotrophin receptors. In the present study, we investigated on the neurotransmitter synthesized by hNT2 neurons by measuring the expression of choline acetyltransferase (ChAT), the enzyme responsible for acetylcholine production. *In vitro* maturation of hNT2 neurons was observed during 28 days *in vitro* (DIV) after RA treatment. The neuronal origin of differentiated cells was confirmed by immunoblotting with an anti-neuron-specific enolase monoclonal antibody (mAb) (DAKO). Mouse anti-ChAT (Chemicon) and anti-NGF receptor (p75) (Boehringer) mAbs were used to investigate on ChAT and p75 expression. ChAT immunostaining was undetectable in untreated NT2 cells. A significant ChAT immunoreactivity was found in purified hNT2 neurons starting from the third DIV and increased consistently over the following DIV. The specificity of this result was confirmed by immunoblotting showing the appearance of a 68 KDa ChAT band of increasing intensity from 7 DIV up to 28 DIV. p75 immunostaining and immunoblotting showed the appearance of a specific signal at later stages of development *in vitro* (significant levels at 21 DIV). Our data indicate that markers specific for cholinergic neurons appear during the terminal differentiation of hNT2 neurons, which represent therefore an useful model for the study of the pathophysiology of human CNS cholinergic systems. *This study was supported by funds from Telethon-Italy.*

## CELL DIFFERENTIATION AND MIGRATION I

## 22.1

ISOLATION AND CHARACTERIZATION OF A ZEBRAFISH HOMOLOGUE OF THE CELLULAR RETINOIC ACID-BINDING PROTEIN. A. A. Fluet\* and L. M. Roman, Department of Physiology, Johns Hopkins School of Medicine, Baltimore, MD, 21205.

Neural crest cells play an important role in the developing embryo, contributing to such diverse structures as the PNS and the outflow tract of the heart. Perhaps because of the precision in migration and cell interactions required for their proper development, the structures that neural crest cells contribute to are often sensitive to teratogens such as ethanol and retinoic acid (RA). Cellular Retinoic Acid-Binding Protein I (CRABPI) is involved in regulating retinoic acid (RA) availability within cells. CRABPI is expressed during early development in those cells which are sensitive to RA exposure, including a subset of migrating cephalic neural crest cells. The zebrafish (*Danio rerio*) provides many advantages for studying the effects of teratogens on the developing neural crest and related structures. As a potential marker for neural crest and/or RA sensitive cells, we have isolated a clone from a 9-16 h embryonic zebrafish cDNA library that encodes a CRABP. The predicted 137 amino acid protein includes two highly conserved arginine residues known to be involved in RA binding to both CRABPI and II. This protein is 82% and 83% identical to mouse and human CRABPI, respectively and 72% and 70% identical to CRABPII from these same species, suggesting it may be a CRABPI. Northern analysis of 9-10 h and 20 h zebrafish mRNA shows hybridization to a 1.96 kb and 0.85 kb transcript, respectively. Preliminary *in situ* hybridization experiments show the presence of transcripts in 10 h embryos. In 24 h embryos this expression is maintained in the hindbrain region. A more complete characterization of the expression pattern of this CRABP at the mRNA and protein level will provide insight into the role this binding protein plays during zebrafish development and provide a tool for studying the effects of teratogens on neural crest cells. Supported by a NIH NRSA (AA05443).

## 22.3

INITIAL CALCITONIN GENE RELATED PEPTIDE EXPRESSION IN RAT DRG NEURONS IN VIVO AND IN VITRO. X. Ai, C. P. Robertson, S. E. MacPhedran, and A. K. Hall\*, Dept. Neurosciences, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

The presence of the neuromodulator, calcitonin gene related peptide (CGRP) in some adult rat sensory neurons is correlated with connections to specific peripheral targets. How sensory neuropeptides are matched to targets during development is not known. Embryonic lumbar rat DRG neurons isolated at E14 before peripheral target connections are present *in vivo* develop appropriate CGRP expression in the presence of serum *in vitro* (C.P. Robertson and A.K. Hall, Soc. Neurosci. Abst. 21:569, 1995). Most DRG neurons at E14 are postmitotic, and lack CGRP mRNA as detected by RT-PCR. CGRP immunoreactive (IR) neurons can be detected after 4 days in culture, at a stage equivalent to E18, when CGRP protein and mRNA are detected *in vivo*. Thus, DRG neurons at E14 have the capacity to express CGRP around the period of target contact. By contrast, CGRP was not detected in DRG neurons isolated at E12 even after prolonged culture. Thus, E12 neurons do not appear competent to express CGRP. One factor that can elicit CGRP expression from E14 DRG in fully defined medium is high [KCl], suggesting that activity or calcium influx may affect initial CGRP expression. Although CGRP develops in isolated embryonic DRG, target tissues may also contribute to the regulation of this neuropeptide. The role of target tissues in the development of CGRP was evaluated by growing E14 DRG cells with rat skin, skeletal muscle, or smooth muscle primary cells or cell lines. Our data suggest that an event occurs *in vivo* between E12-E14 that confers to some sensory neurons the capacity to express CGRP at the equivalent of E18. A combination of this intrinsic program and environmental cues such as activity or target may contribute to the mature neuronal CGRP phenotype.

This work was supported by the National Institutes of Health NS 30842.

## 22.2

VSX-1, A RETINA SPECIFIC PAIRED-CLASS HOMEODOMAIN GENE IS EXPRESSED IN ZEBRAFISH EMBRYOS. M. Passini, A. Canger, E. Levine, N. Schechter, and A. Francis\*, Departments of Biochemistry, Cell Biology, and Psychiatry; SUNY at Stony Brook, Stony Brook, NY 11794.

We are studying the possible roles Vsx-1 has in eye development during zebrafish embryogenesis. Vsx-1 is a paired-class homeobox gene originally cloned from an adult goldfish cDNA library. Its expression is restricted to two regions of the retina: 1) in a subset of neurons occupying the inner nuclear layer (INL) of the mature retina; 2) in a subset of undifferentiated post-mitotic progenitor cells located at the retinal margin. This leads to a hypothesis that Vsx-1 is involved in directing the differentiation and maintenance of INL cells. To test this, we use zebrafish embryos because they are amenable to genetic and functional analysis.

Temporal and spatial analysis is a prerequisite to functional studies. RNase protection assays in temporal studies show low levels of Vsx-1 mRNA expression at 24hpf, but high levels at 48hpf and throughout embryogenesis. It is interesting to note that INL cells begin differentiating around 2 days post fertilization. The RNase protection assay in zebrafish embryos indicate that the expression of Vsx-1 may be restricted to the retina. *In situ* hybridization studies are now in progress to confirm this. Furthermore, in adult zebrafish Vsx-1 is exclusively expressed in the eye.

We have cloned full length goldfish Vsx-1 cDNA into pSP64T to generate full length Vsx-1 mRNA containing 5' and 3' UTR sequences from the Xenopus B-globin gene. The presence of these sequences extend the half-life of injected messages in both Xenopus and zebrafish. *In vitro* translation in rabbit reticulocytes demonstrate that Vsx-1 mRNA generated from this vector is being translated into the expected full length 38kd protein. Misexpression of Vsx-1 may disrupt the lamination of the retina by an overall increase in INL size in relation to the other layers, or a direct increase in a subset of INL cells that normally express Vsx-1. This phenotypic analysis is now in progress. (EY05212 to N.S.)

## 22.4

NGF AND NT-3 MEDIATE NEURITE OUTGROWTH FROM CHICK SENSORY GANGLIA WITHOUT RAISING THE Brn-3a mRNA LEVELS.

J. Lindeberg, A. Bäckström\* and T. Ebendal, Department of Developmental Neuroscience, Uppsala University, Biomedical Center, Box 587, S-751 23 Uppsala, Sweden.

We have isolated a member of the Brn-3 family of transcription factors from chicken. Based on sequence and expression pattern data it is homologous to the Brn-3a gene. In mouse, the Brn-3a gene is abundantly expressed in most peripheral and central sensory neurons. It shows gene activating properties and increased levels of expression under differentiation and neurite outgrowth in the ND7 neuronal cell line. In order to study the interactions between the Brn-3a gene and the neurotrophins and the Brn-3a effect on neurite growth we have established a quantitative PCR approach using fluorescent dUTP. This enabled us to measure the levels of chick Brn3a mRNA from small numbers of cells. Our results show that explanted E9 chick peripheral ganglia do not undergo any significant changes in Brn-3a mRNA levels when stimulated with NGF or NT-3. This correlate with earlier studies performed in cultured adult mouse DRG neurons but contrast with the studies done in the mouse ND7 cells since we in our experiments obtain neurite outgrowth without increase in Brn-3a mRNA. To investigate further the relations between Brn-3a and the neurotrophin system and to test whether Brn3a is necessary for neurite growth from sensory neurons *in vivo* we have isolated a genomic Brn-3a clone from 129SVJ mice. This has been used in a gene targeting experiment aiming at producing mice deficient in functional Brn-3a.

This work was supported by the Swedish Natural Science Research Council (B-BU 4024-317).

## 22.5

DEVELOPMENT OF INTERSTITIAL CELLS OF CAJAL (ICC) IN THE MOUSE GUT: REQUIREMENT FOR KIT LIGAND (KL) J. Wu, T.P. Rothman\*, & M.D. Gershon. Dept. of Anat. and Cell Biol. and Ctr. Neuro. & Beh., Columbia Univ., P&S New York, NY. 10032.

ICCs are small gastrointestinal cells, which act as pacemakers for smooth muscle and are closely associated with enteric neurons. All ICCs express Kit, and their numbers are decreased in W/W<sup>v</sup> mice, in which there is a *c-kit* mutation. The current study was carried out to determine the relationship of the development of ICCs to that of neurons. Kit immunoreactivity served as an ICC marker. Rare ICCs were detected in foregut as early as E12, but ICCs were abundant and present in networks throughout the bowel by E14. ICCs were found in the aganglionic colon of *Is/Is* mice in which the endothelin-3 gene (*edn3*) is mutated. ICCs also were also present in the entirely aganglionic bowel of *c-ret* <sup>-/-</sup> mice. ICC developed in organotypic cultures of gut explanted as early as E11; however, ICCs did not appear in dissociated cultures of bowel explanted at E11 - E16. Addition of EDN-3 to dissociated cultures (0.1-5  $\mu$ M) increased the numbers of both non-neuronal cells and neurons (PGP9.5-immunoreactive), but did not induce the appearance of ICCs. In contrast, when KL (100 ng/ml) was added to the medium, clusters of ICCs appeared. ICCs always grew on the surfaces of non-neuronal cells, which were smooth muscle actin-immunoreactive. There was no obvious relationship between Kit-expressing ICCs and neurons. These data support the idea that ICCs are mesodermal. Since KL must be supplied when the gut is dissociated, their development probably depends on cell surface KL. ICCs evidently develop independently of neurons and EDN3. Supported by NIH grants HD21032, NS12969, and NS15547.

## 22.7

SONIC HEDGEHOG IS INVOLVED WITH NEURONAL DEVELOPMENT OF MURINE SPINAL CORD PRECURSOR CELLS *IN VITRO*. R.Dutton, P.Bartlett\*, D.Bumcrot#, E.Marti#, R.Takada#, A.McMahon#, & M.Murphy. The Walter and Eliza Hall Institute, Parkville, Victoria, Australia, 3052, and #The Department of Molecular and Cellular Biology, Harvard University, MA, 02138.

Sonic hedgehog (shh) is a vertebrate homologue of the *Drosophila* gene family, hedgehog. Shh is expressed in many regions of the developing chick and mouse, including the ventral midline (Riddle et al., 1993 Cell 75:1401) and has been shown to induce floor plate cells and motor neurons in chick neural tube explant cultures (Roelink et al., 1995 Cell 81:445). The objectives of this study were to determine the effect of shh on the development of isolated murine spinal cord stem cells *in vitro*, to assess if shh may be acting directly on the cells to induce neuronal differentiation; specifically motor neuron differentiation. We found shh significantly increased the number of morphologically mature neurons compared to control cultures. The shh treated neurons also developed longer neurites compared to controls. Thus, under these conditions shh appeared to regulate neuronal differentiation, and may also have a role in neurite outgrowth. The increase in the number of morphological neurons observed with shh was transient, peaking at 18 hours, and therefore it does not appear to act as a survival factor for newly generated spinal cord neurons. However, there was no proportional increase in the number of cells expressing *is1-1* (a marker for early motor neurons) in shh treated cultures suggesting shh does not act directly on the precursor cell to induce motor neuron differentiation. Supported by NH&MRC, Australia.

## 22.9

NCAM 16, a Monoclonal Antibody Recognizing the Third Immunoglobulin-like Domain of the Neural Cell Adhesion Molecule N-CAM, is Chemotactic for Spinal Cord Neurons and for Neuronal Cell Lines R.L. Ackley, S.S. Roy, R. Madison, J.J. Hemperly\* Dept. of Molecular Biology, Becton Dickinson Research Center, P.O. Box 12016, Research Triangle Park, NC 27709 USA.

The proper and dynamic interactions between living cells involve both cell-cell and cell-substrate adhesion molecules. One of the best characterized of these is the neural cell adhesion molecule, N-CAM, which was originally isolated based on its ability to mediate direct cell adhesion among retinal neurons. N-CAM comprises a family of molecules which arise by alternative splicing of RNA derived from a single gene and are extremely well conserved among all species examined. It has more recently become clear that CAMs can not only mediate direct adhesion, but are also capable of cell signaling, perhaps using cellular kinase and phosphatase pathways. We have generated a number of monoclonal antibodies to human N-CAM, and shown that one of these antibodies, NCAM 16, a mouse IgG2b, is able to promote the migration of rat primary spinal cord neurons and a number of human neuronal cell lines. Both the whole antibody and Fab fragments exhibit this effect, suggesting that cross-linking at the cell surface may not be needed. In contrast, another antibody, NCAM 14, also a mouse IgG directed at an extracellular epitope of human N-CAM, is not chemotactic. We have mapped the epitope of NCAM 16 to the third Ig domain of N-CAM, a region shown by others in chickens, to be very important in the homophilic binding of N-CAM on one cell to N-CAM on another. Bacterial fusion proteins comprising this region of the molecule, however, do not stimulate migration of cultured medulloblastoma cells but can inhibit the effect of NCAM 16. Based on these observations, we also tested human brain N-CAM in these assays and demonstrated that it was also chemotactic for spinal motor neurons. Further studies will be required to evaluate the biochemical consequences of the binding of this antibody and how these effects parallel the effects of N-CAM itself *in vivo*.

## 22.6

DEVELOPMENT OF MIDBRAIN MOTOR NEURONS IN THE ABSENCE OF FLOOR PLATE AND NOTOCHORD.

G. S. Sohal\* and M.M. Ali. Dept. of Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA 30912.

The differentiation of motor neurons in the spinal cord is dependent on inductive signals from the floor plate and notochord. Whether the differentiation of motor neurons in the midbrain is similarly dependent was investigated. Almost all trochlear motor neurons are born on E5 & 6 and the nucleus first appears on E7 in normal duck embryos. Surprisingly, extirpation of the floor plate and notochord on E 2.5 (stage 9-10 duck embryos) did not prevent the formation of the trochlear motor neurons. Trochlear motor neurons failed to differentiate after extirpation of an area lateral to the floor plate, termed as the ventromedial region, on E 2.5, despite the presence of the floor plate and notochord. These results suggest that the floor plate/notochord may not be the only source of inductive signals for the differentiation of all motor neurons. The differentiation of midbrain motor neurons may depend on signals from elsewhere. Experiments are in progress to determine if cells associated with the ventromedial region can cause ectopic motor neuron formation. Supported by NIH grant HD 28601.

TARGET DEPENDENCY OF AUTONOMIC MOTOR NEURON DIFFERENTIATION. R. P. Barber\*, R. Wetts, and J. E. Vaughn. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010. USA.

In developing rat spinal cord, somatic and autonomic motor neurons (SMNs and AMNs) originate from the ventral ventricular zone, cease dividing at the same time, express choline acetyltransferase, and migrate together into a common primitive motor column. At this point, the fate of AMNs diverges: only they migrate dorsally into the lateral horn and express nitric oxide synthase as detected by NADPH diaphorase histochemical activity. In order to identify the cellular events that underlie this differential fate, we performed experiments on organotypic slice cultures of thoracic spinal cord. In control cultures, dorsal migration of AMNs and expression of diaphorase activity occurred as *in vivo*. If sympathetic ganglia were removed after the arrival of AMN axons at E14, dorsal migration and diaphorase expression occurred by 2 days *in vitro* (2 div). However, if target was removed prior to AMN axon arrival at E13, diaphorase expression in the AMNs did not occur by 2 div. Thus, diaphorase expression in AMNs seems to require target contact for its initiation, but apparently can continue autonomously thereafter. Current experiments seek to establish whether the dorsal migration, as well as other aspects of AMN differentiation, depend on target interaction as does the induction of diaphorase expression. Supported by NIH grant NS25784.

## 22.10

DIVERSITY OF NEURONAL STEM CELLS IN THE ADULT FISH RETINA. Andreas F. Mack\* PFI f. Brain Res. Universität Leipzig, Jahnallee 59, 04109 Leipzig, Germany.

The adult fish retina contains stem cells in two locations: dividing cells (called rod precursors) in the outer nuclear layer give rise exclusively to rod photoreceptors and cells in a peripheral germinal zone give rise to all retinal cell types.

I used a reaggregate culture method to test the developmental capacity of stem cells in the peripheral germinal zone and of rod progenitors in the center of the mature fish retina. Peripheral and central retinal areas of juvenile or adult cichlids (*Haplochromis burtoni*) were separated, dissociated, and allowed to reassociate on a rotary shaker. Dividing cells were labeled with bromodeoxyuridine either before or after dissociation. Rod precursors are the only proliferating cells in the central retinal areas. The aggregates were processed for immunocytochemistry.

In both central and peripheral cultures, cells reassociated readily. Cells derived from peripheral tissue formed sphere-like aggregates. Typically, pigmented cells are located in the center surrounded by opsin-positive cells. Cell processes positive for the glial marker protein vimentin showed radial and tangential orientation outlining the spherical arrangement of the aggregate. Cell proliferation continued in these aggregates during the entire culture period of about two weeks. In contrast, the aggregates derived from central retinal tissue showed little structural organization. Opsin-positive and vimentin-positive cells were present but did not reveal any particular arrangements. Continuous cell proliferation was observed only occasionally.

These results show that adult fish retinal tissue can regenerate retina-like structures. They indicate that rod precursors and central differentiated retinal cells are less capable of forming organized aggregates and maintain cell division.

EXPRESSION OF IODOPSIN MRNA IN LOW DENSITY CULTURES OF CHICK EMBRYO PHOTORECEPTOR CELLS GROWN IN LIGHT: DARK CYCLES. S.M. Argamaso-Herman<sup>1</sup>, E. Adler-Graschinsky<sup>2\*</sup> and R. Adler<sup>1</sup>, Wilmer Eye Institute, J. Hopkins Univ., Sch. Med., Baltimore, MD 21287<sup>1</sup>, ININFA, Buenos Aires, Argentina.<sup>2</sup>

Northern analysis has demonstrated that light regulates iodopsin expression in high density cultures of chick embryo retinal cells (Pierce et al, Neuron, 10:579-84, 1993). We are investigating this phenomenon in single cells using low density cultures in which chick embryo photoreceptors have been shown to react photomechanically to light (Stenkamp and Adler, PNAS 90:1982-86, 1993). Cultures grown in 12:12h light:dark cycles for 6 days were fixed at 4 hr intervals, processed for *in situ* hybridization with digoxigenin-labeled iodopsin probes, and analyzed quantitatively by an investigator unaware of sample identity. The overall frequency of iodopsin-positive photoreceptors remained unchanged at all time points, but there were clear differences in the relative intensity of hybridization signals. The strongest signals were recorded 2-6 hr after light offset, which is somewhat later than the peak of expression reported by Pierce et al (1993). The possibility that these changes in signal intensity may be correlated with photomechanical movements is currently under investigation using other agents that promote photoreceptor elongation, such as dopamine and cytochalasin D. Supported by NIH grants EY04859 and T32 EY07143

## 22.12

DO TYROSINE HYDROXYLASE- AND PEPTIDE-IMMUNOREACTIVE NEURONS COMPRISE OVERLAPPING CELL POPULATIONS IN THE CHICK SPINAL CORD? P.A. Gunulé, A.Y. Gonzales and J.A. Wallace\*, Dept. of Anatomy, Univ. of New Mexico Sch. of Med., Albuquerque, NM 87131.

Tyrosine hydroxylase-immunoreactive (TH-IR) cells occur in large numbers ventral to the central canal and along the outer border of the dorsal horn in the chick spinal cord near hatching. Although such TH-IR neurons in the spinal cord of lower vertebrates synthesize catecholamines, in contrast, comparable TH-IR cells in the chick do not (Wallace et al., '96). Of interest, though, are reports of various peptide-containing neurons that appear with remarkably similar distributions to both the ventral and dorsally located TH-IR cells in the chick embryonic spinal cord. Therefore, we have examined the potential of co-localization between several neuropeptides and TH within cells of the chick spinal cord near hatching. Using antisera against substance P (SP), somatostatin (SOM), VIP and M-ENK we first verified by nickel-intensified immunocytochemical staining the occurrence and position of cells containing these peptides, examined within the cervical and thoracic cord. Our results were similar to those described by Du and Dubois ('88) with the detection of SP-, SOM- and M-ENK-immunoreactive cells immediately ventral to the central canal and SP- and M-ENK-containing cells along the outer boundary of the dorsal horn. However, when dual-fluorescence immunocytochemistry was employed to visualize TH and individual peptides simultaneously, no TH-IR cells were found to possess any of the peptides studied, although their position and morphology were similar, and the cells were often situated immediately adjacent to one another. Therefore, at least near the age of hatching in the chick, it appears that TH-IR and peptide-containing cells in the spinal cord represent different neuronal populations. The possibility of co-existence of TH with peptides needs to be examined further with additional peptides and at different embryonic ages and cord levels. Supported by DHHS-GM08222 and RR08139.

## 23.1

MORPHOLOGICAL AND IMMUNOCYTOCHEMICAL CHARACTERIZATION OF TRANSIENT NEURONAL POPULATION OF THE INTERNAL CAPSULE IN THE DEVELOPING HUMAN CEREBRUM. K. Letinić and J. Kostović\*, Croatian Brain Research Institute, School of Medicine, University of Zagreb, Croatia.

Nissl, Golgi, AChE and immunocytochemical techniques were used to study pre- and postnatal development of the internal capsule neurons in postmortem brains of human fetuses ranging from 12 weeks of gestation to adult age. Surprisingly large population of cells lying among the fibers of the internal capsule is found during the fetal period. These cells resemble reticular thalamic neurons and are particularly frequent in areas of the internal capsule near the ventral parts of the reticular nucleus. Their frequency declines during early infancy and very few cells are apparent in the one year old infant as in adult. Internal capsule neurons are multipolar and polymorphous with well pronounced dendritic arborization and sometimes many spine-like protrusions covering their cell bodies and dendrites. Furthermore, they have properties typical of mature neurons showing intense immunoreactivity for MAP2 (microtubule associated protein 2), and they also contain one of neuropeptides, namely SRIF (somatostatin). Subpopulations of neurons are immunoreactive for calcium-binding protein calbindin-D<sub>28k</sub> and parvalbumin and some of them show AChE activity. Finally, low-affinity p75 NGF (nerve growth factor) receptor immunolabelled neuronal elements were observed within the internal capsule during the fetal period. A group of neurons described in this study corresponds to the perireticular thalamic nucleus found in certain mammalian species (Mitrofanis and Guillery, Trends Neurosci 16:240, 1993), hitherto unidentified in the primate brain. Recent study in the developing rat suggested that the perireticular cells send transient, "pioneer" projection to cortex appearing before thalamocortical projection (Adams and Baker, J Comp Neurol 359:613, 1995). The transient nature, distinct antigenic properties and early cortical projection of the perireticular nucleus suggest developmental roles comparable with those of the cortical subplate zone. By analogy with the subplate zone of the cortical anlage, the region lateral to the reticular thalamic nucleus can be regarded an essential compartment of the thalamic anlage and appropriately termed the "perithalamic zone". *Supp. Ministry of Science, Republic of Croatia.*

## 23.3

DEVELOPMENT OF DIFFERENTIAL LOCALIZATION OF MAP2 AND CaMKII mRNAs IN NEUROPILS OF THE RAT HIPPOCAMPAL FORMATION. M.A. Paradies\* and Q. Steward, Dept. of Neuroscience, University of Virginia School of Medicine, Charlottesville, VA 22908.

The presence of mRNA in dendrites is now well established. Moreover, different mRNAs are associated with different dendritic sub-domains. While the mRNAs for both microtubule associated protein 2 (MAP2) and the alpha subunit of calcium/calmodulin dependent protein kinase II (CaMKII) are present in the dendrites of hippocampal neurons, MAP2 mRNA is concentrated in proximal dendrites whereas CaMKII mRNA is distributed throughout the dendritic arbor. This pattern of mRNA distribution suggests a relationship with the laminar distribution of afferents. The present study uses *in situ* hybridization to evaluate the distribution of these two dendritic mRNAs during the period of afferent synaptogenesis, between postnatal day 1 (P1) and P28. MAP2 mRNA was present in cell body layers and proximal dendrites as early as P1. By P7, MAP2 mRNA extended into the proximal 1/2 of the neuropil of the dentate gyrus and hippocampus. In contrast, CaMKII mRNA was evident in cell body layers at P1 but was barely detectable in neuropil layers until P7. Levels of CaMKII mRNA increased substantially at P15 in both cell body and neuropil layers. By this time, CaMKII mRNA was visible throughout the proximo-distal extent of the neuropil. These observations reveal that the differential subcellular distribution of MAP2 and CaMKII mRNAs develops in concert with the growth of dendrites and the formation of synapses. Supported by NS12333. MAP is the recipient of NRSA NS09752.

## 23.2

A SOLUBLE OLIGODENDROCYTE-DERIVED SIGNAL INDUCES REGULARLY-SPACED SODIUM CHANNEL CLUSTERS ALONG CNS AXONS IN VITRO. M. R. Kaplan\*, A. Meyer-Franke, S. Lambert, V. Bennett, S. R. Levinson, B. A. Barres, Dept. of Neurobiology, Sherman Fairchild Science Building, Stanford Univ., Sch. of Med., Stanford, CA 94305-5401.

Saltatory conduction depends on the formation of regularly-spaced clusters of sodium channels at nodes of Ranvier. In the CNS, these clusters occur at axonal intervals of about 100 times the axon diameter. It is not known whether the regular spacing of nodes results from regularly-spaced glial contacts or is instead intrinsically specified by the axonal cytoskeleton. In the PNS, Schwann cell contact induces sodium channel clustering along the axons of DRG neurons in vitro and in vivo. Similarly, it has been suggested that astrocyte contact induces sodium channel clustering along CNS axons.

In this study, we have used an antibody specific to sodium channels to determine their distribution in purified rat retinal ganglion cells cultured either in the absence or presence of purified glial cell types. Using this system we have found that the induction, but not the maintenance, of sodium channel clustering depends on a soluble oligodendrocyte-derived signal. Surprisingly, the glial-induced clusters are regularly spaced at the predicted interval in the absence of glial-axonal contact. Thus, whereas oligodendrocytes produce soluble signals that are necessary to induce sodium channel clustering in vitro, the spacing of these clusters appears to be dictated by the axon.

## 23.4

INTRACORTICAL AND THALAMOCORTICAL PROJECTIONS IN ADULT RATS THAT SUSTAINED NEONATAL FORELIMB REMOVAL. D.L. Howell, A. Stoic, R.D. Lane\* and R.W. Rhoades, Dept. of Anatomy and Neurobiology, Medical College of Ohio, Toledo, OH 43699.

Neonatal forelimb removal results in innervation of the cuneate nucleus by sciatic nerve primary afferents and development of cuneothalamic neurons with receptive fields that include both the hindlimb and the forelimb stump (Proc. Natl. Acad. Sci. 92:4264-4268, 1995). However, this brainstem reorganization is almost completely unexpressed in the primary somatosensory cortex (S-I). Blockade of cortical GABAergic inhibition by bicuculline and phaclofen produced a large increase in hindlimb-responsive sites (44.2% versus 6.2% prior to blockade) in the cortical stump representation of neonatally manipulated rats. GABA blockade produces significantly ( $p < 0.01$ ) fewer (11.7% versus 2.7% prior to blockade) hindlimb-responsive sites in the forelimb representation of normal rats. The present study asked whether hindlimb information reached the stump representation via altered intracortical connections from the hindlimb representation in S-I or via thalamocortical innervation from the hindlimb representation in the thalamus. Anterograde and retrograde tracing with biotinylated dextran amine and *Phaseolus vulgaris* leucoagglutinin demonstrated no significant effect of neonatal forelimb removal on projections between the hindlimb and stump/forelimb representations in granular S-I. Retrograde labeling of the stump and hindlimb thalamocortical neurons with true blue and diamidino-yellow resulted in normal segregation of these two neuron populations. These results suggest that hindlimb information may reach the cortical stump representation of the amputated rats via thalamocortical neurons that respond to stimulation of both the stump and the hindlimb. Supported by NS 28888 and DE 07734.

## 23.5

**MORPHOLOGY OF TRIGEMINAL PRIMARY AFFERENT AXONS AFTER BLOCKADE OF AXOPLASMIC TRANSPORT DURING POSTNATAL DEVELOPMENT.** S. Zhang\*, F.P. Goldstein, N.L. Chiaia, and R.W. Rhoades. Dept. Of Anatomy and Neurobiology, Medical College of Ohio, Toledo, OH 43699

We previously reported that attenuation of axoplasmic transport in the developing infraorbital nerve (ION) with vinblastine does not abolish the normal vibrissae-related patterning of the ION primary afferents that supply the vibrissae follicles, but does result in a loss of all other central vibrissae-related patterns of cells and fibers. The present study was undertaken to determine the effects of this manipulation on the morphology of single trigeminal primary afferents that terminated within the vibrissae representation of subnucleus interpolaris (Spl). Vinblastine-impregnated implants were placed over the ION on the day of birth (P-0). On P-6, rats were anesthetized and the trigeminal ganglion was exposed by aspirating the overlying cerebrum and diencephalon. Neurobiotin was then injected into the trigeminal ganglion and animals survived for 8-12 hours. The tracer was demonstrated histochemically and labelled fibers within Spl were reconstructed using a computer-microscope system. Reconstruction of 35 axons from normal rats aged P-6 and 50 fibers from rats whose IONs were exposed to vinblastine demonstrated no significant between-group differences in morphological characteristics including total fiber length, arbor area, arbor volume, number of branch points, and number of boutons. These results, like those from our previous study, indicate that a relatively normal primary afferent pattern is insufficient for maintenance of vibrissae-related patterns by brainstem, thalamic, and cortical neurons. Supported by DE 07734, DE 08971, NS 28888.

## 23.7

**PRENATAL EXPOSURE TO COCAINE ALTERS SEROTONIN LEVELS AND THE REPRESENTATION OF THE VIBRISSAE FOLLICLES IN THE RAT'S PRIMARY SOMATOSENSORY CORTEX.** C.A. Bennett-Clarke\*, J. Garcia, N.L. Chiaia, and R.W. Rhoades. Dept. Of Anatomy and Neurobiology, Medical College of Ohio, Toledo, OH 43699

Previous studies have shown that prenatal cocaine exposure reduces the density of high-affinity serotonin (5-HT) uptake sites in the cerebral cortex and that altered levels of 5-HT can change primary somatosensory cortical development. The present study was undertaken to determine the effects of prenatal cocaine exposure on 5-HT levels in the primary somatosensory cortex and the organization of the patches of thalamocortical afferents representing the vibrissae follicles in this region. Fetal rats were exposed to cocaine between E-13 and birth by implantation of osmotic minipumps that delivered 15.5 mg/day of cocaine to the internal carotid artery of pregnant dams. Pups were delivered by cesarean section, cross-fostered until P-6 and then used in either anatomical or neurochemical experiments. Levels of 5-HT in cortex were measured by HPLC. The average value for 25 normal rats was 133.8 pg/mg and that for 48 cocaine-treated animals was 194.4 pg/mg ( $p < 0.05$ ). Measurements of the areas of the AChE-stained patches of thalamocortical afferents corresponding to the three most caudal vibrissae in rows A, C and D indicated an increase in average patch size of 7% ( $p < 0.0001$ ). Increases ranged between 5% (D-3 and A-1 patches) and 9% (A-2 and D-2 patches) for individual clusters of thalamocortical axons. These changes in the vibrissae representation were not associated with significant alterations in either brain or cortical weight. These results thus indicate that brief prenatal exposure to cocaine significantly influences both 5-HT and thalamocortical development. Supported by EY 08861 and DE 07734.

## 23.9

**LOCALIZATION OF APLP2 AND APP AT THE TECTAL MIDLINE IN DEVELOPING HAMSTERS.** A.M. Confaloni\*, K.L. Moya, A.W. Lyckman, and S. Jhaveri. Ist. Sup. Sanità, 00161 Rome, Italy; CNRS URA 2210 and INSERM U334, S.H.F.J., C.E.A., 91401 Orsay, France; Dept. Brain & Cognit. Sci., M.I.T., Cambridge, MA 02139, U.S.A.

Radial glial cells present along the midline of the developing tectum are thought to be involved in retaining the laterality of the retinotectal projection (Jhaveri, Persp. Dev. Neurobiol., 1994). Retinal axons cross the midline abnormally if the integrity of these raphe glia is compromised during early postnatal life (Schneider, Br. Behav. & Evol. 1973). Sulfated proteoglycans, expressed along the tectal midline, may mediate the barrier function of the tectal glia (Hoffman-Kim et al., Neuropsci. Abst., 1995). Since APP and APLP2 found in glial cells reportedly are CSPG core proteins (Pangalos et al., J. Neurochem. 65: 762, 1995), it was of interest to determine whether they are present at the tectal midline.

Postnatal hamster pups, were anesthetized, perfused with 4% paraformaldehyde, and their brains processed for immunostaining with MAb 22C11 (which targets epitopes on both APP and APLP2), CT-15 (which is directed against the cytoplasmic C-terminal of APP) and D2-II (which specifically recognizes APLP2). All three Abs stain the midline glia, but do so differentially. In P0 and P2 animals, CT-15 is localized near the ventricular surface only, whereas D2-II gives immunostaining along the apical processes of the radial glia. In contrast, immunoreactivity with MAb 22C11 is present along the full length of the glia from the ventricular surface to end feet at the pial surface. This is the first report of spatial segregation of specific (putative) PGs in different cellular compartments of the tectal glia.

We thank G. Thinakaran and S. Sisodia for CT-15 and D2-II. Supported by: CEE, CEA, INSERM, CNRS and NIH grant EY00504.

## 23.6

**EFFECTS OF ABNORMAL ACTIVITY ON DEVELOPMENT OF THALAMOCORTICAL AND INTRACORTICAL PROJECTIONS IN THE RAT'S PRIMARY SOMATOSENSORY CORTEX.** N.L. Chiaia\*, C.A. Bennett-Clarke, and R.W. Rhoades. Dept. Of Anatomy and Neurobiology, Medical College of Ohio, Toledo, OH 43699

Reduction of cortical activity during early postnatal development by blockade of voltage-dependent sodium channels with tetrodotoxin (TTX) has no significant effect on the patterning of either thalamocortical projections to the vibrissae representation in the primary somatosensory cortex or intracortical projections in lamina IV of this region. The present study asked whether inducing abnormal patterns of cortical activity during development by placement of penicillin-impregnated implants could alter either thalamocortical or intracortical projections. Implants were placed over the SI cortex on the day of birth (P-0) and resulted in abnormal bursting cortical activity in recordings made on P-5-9. Assessment of thalamocortical projections by staining for AChE in animals killed on P-6 indicated no change in the patterning of these fibers. Rows of dense patches corresponding to the vibrissae follicles remained visible in the treated cortices. Assessment of intracortical connections in layer IV on P-40-60 using anterograde and retrograde transport of biotinylated dextran amine also failed to reveal any changes from normal organization. A fenestrated pattern complementary to the vibrissae-related patches of thalamocortical afferents was present in both the normal and treated animals. These results, like those from the experiments in which activity was blocked with TTX, indicate that the postnatal development and maintenance of thalamocortical and intracortical projections in rat's primary somatosensory cortex are not influenced by marked changes in activity levels in this region. Supported by NS 28888, DE 08971, DE 07734.

**Searching for Tenascin-C receptors with a library of recombinant domains**

A. Scholze<sup>1</sup>, A. Niehaus<sup>\*1</sup>, U. Rauch<sup>2</sup>, H. Zimmermann<sup>3</sup>, and A. Faissner<sup>1</sup>

<sup>1</sup> Department of Neurobiology, INF 364, University of Heidelberg, D-69120 Heidelberg; <sup>2</sup> MPI for Biochemistry, Protein Chemistry, Am Klopferspitz 18a, D-82152 Martinsried; <sup>3</sup> Biocenter of J. W. Goethe-University, Zoological Institute, Neurochemistry, Marie-Curie-Str. 9, D-60439 Frankfurt am Main; Germany

Tenascin-C (TN-C) glycoproteins are transiently expressed by astrocytes and distributed in discrete patterns in some areas of developing neural tissues. TN-C mediates neuron-glia interactions and contributes to the control of neuron migration and neurite outgrowth and to the formation of transient boundaries. The glycoprotein is composed of a serial arrangement of EGF-like and Fibronectin type III repeats, and a carboxyterminal region homologous to fibrinogen  $\beta$  and  $\gamma$ . Several lines of evidence suggest that the different functions are encoded by distinct domains, which implies the existence of separate neural receptor systems. In order to characterize these further, an approach based on affinity chromatography with a library of recombinant domains encompassing the FNIII repeats of TN-C was designed. Affinity columns were constructed by coupling recombinant proteins to sepharose and loaded with detergent extracts of membrane preparations or physiological saline extracts from postnatal day 6 to 14 mouse brains. Subsequently, the columns were washed and eluted at different stringencies. The resulting eluates were analysed by SDS-page, ligand blots with appropriate recombinant TN-C domains and ELISA or Western blot approaches using defined antibodies to known components. Thereby, NCAM, 5' nucleotidase and neurocan could be identified as potential ligands. Currently, these hypothesized interactions are being tested with binding assays using the purified molecules.

**CO-CULTURES OF TECTAL ASTROCYTES AND RETINAL NEURONS: AN IN VITRO MODEL SYSTEM FOR STUDYING AXON-GLIA INTERACTION.** A. Sower\*, M.J. Young, and S. Jhaveri. Dept. Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Studies from our lab indicate that a group of radial glia located at the tectal midline is involved in retaining the laterality of the retinotectal projection; these cells begin to differentiate just prior to the arrival of retinal axons in the superior colliculus. Intertectally-projecting fibers, on the other hand, are able to successfully cross the tectal midline, but they do so before the midline glia have differentiated (S. Jhaveri, Persp. Dev. Neurobiol., 1: 237-243, 1993). As a prelude to examining the interactions of individual retinal axons and intertectal fibers with the raphe glia, we have developed a co-culture preparation in which astroglia are harvested from the dorsal midbrain of hamsters at different ages (E13-P0), grown in culture for varying amounts of time, and seeded with dissociated retinal cells. Cultures were immunostained with antibodies directed against neuron-specific enolase and GFAP to characterize the cell populations and quantify retinal neurite outgrowth.

Excellent neurite outgrowth is obtained from retinal cells plated on tectal glia: this growth is vulnerable to the effects of age of the donor astrocytes, and also to the time the glia have been in culture before retinal neurons are plated onto them, with greater extension obtained on younger astrocytes. We are presently investigating whether lateral vs. midline tectal astrocytes have differential effects on supporting retinal neurite outgrowth. These studies will provide new information on whether the age of the neurons or the maturity of the glial substrate determines the growth potential of afferent systems.

Supported by: NIH grant EYO5504.

## 23.11

## REGIONAL DIFFERENCES IN TECTAL CHONDROITIN SULFATE EXPRESSION REFLECT DIFFERENTIAL RATES OF GLYCOSAMINOGLYCAN BIOSYNTHESIS

Diane Hoffman-Kim<sup>1</sup>\*, Arthur D. Lander<sup>2</sup>, and Sonal Jhaveri<sup>1</sup>.<sup>1</sup>Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA; <sup>2</sup>Dept. of Developmental and Cell Biology, University of California, Irvine, Irvine, CA.

Chondroitin sulfate proteoglycans (CSPGs) are expressed throughout the developing brain, both in regions where axons preferentially grow and in areas that axons distinctly avoid. *In vitro* experiments also suggest that some CSPGs enhance while others inhibit neurite outgrowth. The expression of CS along the midline of the developing tectum and the inhibition of retinal axon growth *in vitro* by CS substrates have given rise to the hypothesis that midline CSPG(s) act as barrier molecules, preventing retinal axons from crossing the tectal midline. Earlier biochemical analysis of PGs in homogenates from midline and lateral tectum revealed that the concentration of CS at the midline does not reflect increased expression or any particular PG core protein. In the present study, we address the possibility that overall CS synthesis may be increased at the midline. Briefly, coronal tectal slices of 300  $\mu$ m thickness were labeled, either for one hour or overnight, with <sup>35</sup>S-sodium sulfate +/- <sup>3</sup>H-leucine. Sulfate incorporation specifically into glycosaminoglycans was quantified for midline and lateral regions. After overnight labeling, midline cells incorporated approximately 1.5 times the sulfate (normalized to protein) that lateral cells did, approximately 70% of which could be accounted for, in both regions, by CS and heparan sulfate. In contrast, midline cells did not incorporate significantly more <sup>3</sup>H-leucine than lateral cells, indicating that midline cells are not simply more metabolically active. Experiments in which metabolic labeling was limited to one hour also showed increased <sup>35</sup>S-sodium sulfate incorporation by midline (vs. lateral) cells, comparable to that seen with overnight labeling. These data suggest that high level expression of CS at the tectal midline is the result of an increased rate of CS biosynthesis by tectal midline cells.

## 23.13

## PURKINJE CELL PATTERNING IN THE EMBRYONIC CEREBELLUM OF MICE EXPRESSING AN OLFACTORY MARKER PROTEIN-LacZ TRANSGENE. M.G.Nunzi\* and E.Mugnaini. Institute of Neuroscience, Northwestern Univ., Chicago, IL 60611.

The cerebellar cortex is a unique system to study neuronal patterning in the CNS, as it is organized into compartments defined by the distribution of Purkinje cells (PCs) and afferent projections into a series of parasagittal domains. While it is known that PC compartmentalization occurs in embryonic development, the cellular events underlying segregation of different PC phenotypes and topographic matching are still obscure. In a previous study, we have shown that in a mouse line (HpY-1) carrying a *lacZ* transgene containing a 0.3kb of upstream and 0.35kb of downstream sequence from an olfactory marker protein (OMP) gene, the *lacZ* reporter is expressed by PCs arranged within parasagittal bands spanning the posterior lobe. We suggested that regulatory elements near the transgene integration site could be involved in specification of PC rostrocaudal compartments. To investigate early histogenetic events involved in segregation of *lacZ*-expressing PCs, embryonic cerebella were analyzed with X-gal staining and immunocytochemistry to PC - specific antigens. *LacZ* expression was first detected by E13 in a cluster of cells outlining the ventricular neuroepithelium. By E15, *lacZ* defined subsets of PCs settled in the cortical region. These observations suggest that PC heterogeneity occurs in or near the ventricular neuroepithelium and that segregation into on-off clusters very likely involves migrating PCs. Studies in progress may reveal whether the *lacZ*-expressing cells in the subventricular zone are mitotically active or represent a subpopulation of newly differentiated PCs. (Supported in part by NIH Grant NS 09904).

## 23.15

## 3-D RECONSTRUCTIONS OF FIBER PARTITIONING AND LOBULATION IN THE CEREBELLAR VERMIS AND HEMISPHERE. S. A. Bayer\*, and J. Altman. Department of Biology, Indiana University, Purdue University in Indianapolis, Indianapolis IN 46202-5132.

The developing cerebellum was reconstructed in rats from embryonic day (E) 15 to postnatal day (P) 20. Up to E20, the cerebellar cortex has no fissures. By E21, four fissures appear that separate five lobes. The anterobasal (vermal lobules I-III) and the anterodorsal (vermal lobules IV-V) lobes have little or no extensions into the hemisphere. The central lobe contains nearly all hemispheric lobules and vermal lobules VI, VII and VIII. The posterior lobe (paraflocculus and vermal lobule IX) and inferior lobe (flocculus and vermal lobule X) are pulled apart and the cortex is fragmented between P1 and P20. The medullary layer was separately reconstructed in the central lobe and lobulation in the vermis and hemisphere was linked to partitioning of its fiber panels. Boundaries between lobules are more distinct in the hemisphere than in the vermis on both P1 and P5. By P20, systematic branching of just two fiber panels in the medullary layer expand to service the majority of the hemispheric lobules. It is postulated that specific subsets of Purkinje neurons link up with tagged incoming fibers during migration to produce the characteristic lobules in the vermis and hemisphere. (supported by CRC Press, J. Altman, and S. A. Bayer)

## 23.12

SPINOCEREBELLAR MOSSY FIBER AFFERENTS FORM SEGREGATED COLUMNS IN JUVENILE *STAGGERER* MUTANTS. Z. Ji, Q. Jin, and M. W. Vogel\*. MPRC, Univ. MD Med. School., Baltimore, MD 21228.

Cerebellar afferents form segregated longitudinal terminal fields within individual cerebellar lobules, and Purkinje cells are hypothesized to be critical organizing elements for the connectivity patterns. In support of this hypothesis, a previous study has shown that mossy fiber projections are diffuse in P25 *staggerer* (*sg/sg*) mutants (Arsénio Nunes 1988 J. Comp. Neurol. 273: 120-136). *Staggerer* mutants have severe Purkinje cell deficits, but at P25 granule cells are also depleted. To test the hypothesis that mossy fiber distribution is disrupted because virtually all granule cells die after three weeks of development we have analyzed the distribution of WGA-HRP labeled spinocerebellar mossy fiber terminals in *sg/sg* mutants towards the end of the period of granule cell genesis (P12-P13) and before massive granule cell death (P16). The distribution of HRP labeled mossy fiber terminals was analyzed in 8 homozygous *sg/sg* mutants (P12-P16) and 5 controls (+/*sg* and +/+) following the injection of 2% WGA-HRP into the lower thoracic/upper lumbar region of the spinal cord. Spinocerebellar mossy fibers distribute in segregated terminal fields in the anterior vermal lobules of P12 to P16 *sg/sg* mutants. Although the pattern of labeled terminals is different from controls, the results indicate that topographic cues are expressed in the early postnatal *sg/sg* cerebellum (perhaps by *sg/sg* Purkinje cells) and mossy fiber terminals may become disorganized or retract as granule cells die in the older *sg/sg* mutant. The results suggest that granule cells play a role in stabilizing the pattern of mossy fiber projections. Supported by NIH grant NS29277 to MWV.

## 23.14

## REGIONAL VARIATION IN THE DEVELOPMENT OF THE DEEP CEREBELLAR NUCLEI: A TALE OF TWO MUTANTS

B. Kuemerle, S.M. Maricich and K. Herrup\*. Alzheimer Research Laboratory, Case Western Reserve University, Cleveland, Ohio 44106

Neurons of the deep cerebellar nuclei (DCN) are the major targets of the Purkinje cells of the cerebellar cortex. In the mouse, the DCN are organized into three clusters located in the cerebellar white matter, just above the fourth ventricle. Whereas many neurological mutations have profound effects on cerebellar cortical cell number, there is only one reported instance of change in the number of DCN neurons. As part of our ongoing study of two cerebellar mouse mutations, *Engrailed-2* (*En-2*) and *weaver* (*wv*), we have found that both suffer a 30% loss of neurons in the DCN. Interestingly, this loss is non-uniform; specific mediolateral subdivisions of the DCN are uniquely targeted. In the *Engrailed-2* mutant, the cells of the nucleus medialis are preferentially reduced, while in *wv/wv* mice, it is the nucleus interpositus that suffers the greatest loss. In both cases, the relationship between the cortical defect and the DCN loss suggests intriguing new facets of the phenotypes of the two mutations and the provide insight into the processes of cerebellar compartmentation.

## 24.1

**METALLOPROTEINASES ARE EXPRESSED BY SENSORY NEURONS.** T. Ferguson, D. Neubauer, and D. Muir\* Depts. of Neuroscience & Pediatric Neurology, University of Florida College of Medicine, Gainesville, FL 32610

Matrix metalloproteinases (MMPs) are implicated in wound healing, tumor metastasis, and other matrix remodeling events. We find that neurite outgrowth in 3D extracellular matrix gels is MMP-dependent and that induction of MMP-2 (type IV collagenase) by cultured dorsal root ganglia (DRG) neurons occurs in response to NGF (Muir, 1994 Exp. Cell Res. 210:243). To further examine the roles of MMPs in axonal outgrowth, we examined the immunocytochemical distribution of several MMPs within the rat nervous system. We find MMP-1, MMP-2 and MMP-3 are expressed by normal DRG neurons. In subsequent studies we focused on MMP-2 expression by DRG neurons during active axonal growth. All neurons within embryonic day 11 DRG immunolabeled for MMP-2. In contrast, only 50% of the neurons in adult DRG showed punctate, cytoplasmic and axonal MMP-2 staining. The majority of MMP-2-positive soma were 700-1300  $\mu\text{m}^2$  in area. However, seven days after sciatic nerve crush, the staining of cognate neurons (L4/L5 DRG) increased to over 75% largely due to de novo expression of MMP-2 by regenerating small DRG neurons. In spinal cord, dorsal horns were more intensely stained than surrounding gray matter, suggesting the presence of MMP-2 associated with centrally projecting DRG processes. MMP-2 expression appears unique to peripheral neurons since spinal cord neurons were not immunolabeled, including motor neurons which project axons along side DRG axons. In cultured DRG neurons, activated MMP-2 was shown to be transported to the growth cone and activated enzyme was enriched in a membrane fraction. Together, these findings suggest MMPs may play a role in peripheral nervous system matrix remodeling during axonal outgrowth. Presently, we are exploring whether MMPs are differentially expressed during neuronal development and regeneration. Supported by NIH/NINDS.

**CONTINUOUS RENEWAL OF THE AXONAL PATHWAY SENSOR APPARATUS BY INSERTION OF NEW SENSOR MOLECULES INTO THE GROWTH CONE MEMBRANE** L. Vogt, U. Ziegler, R. J. Giger, B. Kunz, P. Streit\*<sup>1</sup> and P. Sonderegger. Institute of Biochemistry and <sup>1</sup>Brain Research Institute, University of Zurich, CH-8057 Zurich, Switzerland

Growth cones are capable of probing their environment for local growth stimulating or inhibiting cues during neurite outgrowth. Guidance information residing in the molecular terrain of cell surfaces is thought to be recognized by cell adhesion molecules of the growth cone membrane. Using adenoviral vectors we heterologously expressed two functionally active chicken cell adhesion molecules, axonin-1 and Ng-CAM, in rat dorsal root ganglia (DRG) neurons, in order to determine whether cell adhesion molecules are inserted either into the membrane of the growth cone, the axolemma of the axon shaft, or the neuronal cell body. We found that axonin-1 and Ng-CAM are exclusively inserted at the growth cone. Interestingly, neither the glycosylphosphatidylinositol-anchored protein axonin-1 nor the transmembrane protein Ng-CAM exhibited evidence for retrograde diffusion along the axonal shaft. Therefore we concluded that these molecules are immobilized in the axon by interaction with other proteins with which they form the sensor apparatus of the growth cone. (Supported by the Swiss National Science-Foundation and the Théodore Ott Foundation).

## 24.5

**CHARACTERISATION OF MAP1B PHOSPHORYLATION AT A SITE RECOGNISED BY MONOCLONAL ANTIBODY SMI-31.** M. Johnstone, R. G. Goold, I. Fischer\* and P. R. Gordon-Weeks\*. D.B.R.C., King's College London, 26-29 Drury Lane, London WC2B 5RL, U.K. <sup>†</sup>Dept. Neurobiol. & Anatomy, Med. College of PA and Hahnemann University, 3200 Henry Ave., Philadelphia, PA 19129, U.S.A.

MAP1B is a microtubule-associated protein that is expressed early in neurons and plays a role in axonal outgrowth. MAP1B has at least two types of phospho-isoforms, one of which is developmentally down-regulated following neuronal maturation and one of which persists into adulthood. Since phosphorylation is likely to regulate MAP1B activity we characterised the different sites of phosphorylation using a series of recombinant GST-fusion proteins. These have been phosphorylated in an *in vitro* kinase assay in which the recombinant proteins were incubated with a high speed supernatant from neonatal rat brain in the presence of ATP. Phosphorylation of recombinant fusion proteins was detected on Western blots using a panel of phosphorylation-dependent mAb. The analysis showed that mAb SMI-31, which recognises a developmentally-regulated phospho-isoform of MAP 1B, recognises a recombinant protein equivalent to residues 1110-1361 of rat MAP1B after *in vitro* phosphorylation. This phosphorylation site has also been characterised by inclusion into the *in vitro* kinase assay pharmacological agents, peptides and antibodies based on candidate regions of the MAP1B sequence. We aim to use tools identified in these studies to probe the function of MAP1B in cultured neurons.

**ISOLATION OF NERVE GROWTH CONE PROTEINS AND CHARACTERIZATION WITH PEPTIDE ANTIBODIES.** R. Kuwano\*, H. Tanaka, H. Saitoh, and K.T. Abe. Research Laboratory for Molecular Genetics, Niigata University, 1 Asahimachi, Niigata 951, Japan

The nerve growth cone plays an important role in pathfinding and recognition of the axon for synapse formation. To elucidate molecular mechanisms of neural network formation and maintaining neuronal functions we analyzed proteins on the growth cone isolated from early postnatal mouse brain. We prepared growth cone particle-enriched (fraction A, the interface between 0.32M and 0.75M) and -non-enriched (fraction C, the interface between 1.0 M and 2.66M) fractions by sucrose density gradient centrifugation. Membrane proteins of the fractions A and C were analyzed by lectin-affinity chromatography, ion exchange chromatography, 2-dimensional gel electrophoresis and SDS-PAGE. Partial amino acid sequences of several proteins concentrated in the fraction A were obtained and compared with those in the protein and nucleotide sequence databases.

We identified GAP-43, NAP-22, gp93, MARCKS and M6 in the fraction A which were reported previously to present on the growth cone. In addition we found several proteins with unique sequences in the fraction A. We synthesized peptides corresponding to the partial amino acid sequences and inoculated rabbits for the peptides conjugated with KLH. Antibodies against some of these proteins are used for characterization of these proteins by western blotting and for determination their intracellular localization in differentiated murine neural precursor cells that were isolated from 10.5 days fetus head and cultured for several days.

## 24.4

**THE GOLGI IS LOCALIZED TO THE BASE OF THE INITIAL UNIPOLAR PROCESS IN CEREBELLAR GRANULE CELLS IN VITRO.** J. F. Zmuda and R. J. Rivas\*, Dept. of Zoology, U. of Maryland, College Park, MD 20742.

Cerebellar granule neurons differentiating *in situ* pass through unipolar and bipolar axonal stages before glial-guided neuronal migration and subsequent dendrite extension. The migrating granule cell is highly polarized in the direction of migration, positioning the nucleus to the cell posterior and localizing membranous organelles such as the Golgi to a rostral juxtanuclear area (Rivas and Hatten, 1995. *J. Neurosci.* 15: 981-989). To determine whether Golgi positioning plays a role in specifying the sites of initial unipolar and bipolar axon extension, purified P4-P6 mouse granule cells were cultured for 1-5 days *in vitro* (DIV). To mark the position of the Golgi at various times after plating, granule cells were labeled with the fluorescent lipid analog, BODIPY-ceramide (C<sub>5</sub>-DMB-Ceramide; Pagano et al., 1991. *J. Cell Biol.* 113: 1267-1279), which preferentially accumulates at the Golgi. At 1-2 DIV, most granule cells extended a single neurite; in 97% (287/296) of these unipolar cells, the Golgi was localized to a juxtanuclear area at the base of the unipolar process. By 2-3 DIV, many unipolar cells began to extend a second process from the opposite pole of the cell. In these cells, the Golgi was localized to the base of the newly emerging neurite in 89% (62/70) of cells observed, suggesting that the Golgi may have re-oriented from the initial position at the base of the first process. By 3-4 DIV, nearly all the cells had adopted bipolar or more complex multipolar morphologies. In bipolar cells, two well established neurites extended from opposite poles of the cell; the Golgi was observed to be positioned randomly between the two processes in 66% (40/61) of observed cells and toward one process or the other in the remaining cells. Since the Golgi is critically involved in the modification and targeting of newly synthesized proteins and lipids, these results suggest that the Golgi may re-orient to facilitate the emergence of newly forming neuronal processes at specific sites on the plasma membrane. Supported by American Paralysis Association RB1-9501.

## 24.6

**TAXOL INHIBITS PAF-INDUCED SHAPE CHANGE IN NEURITES.** R.S. McNeil, J.W. Swann and Gary D. Clark\*. Cain Foundation Laboratories, Baylor College of Medicine, Houston, TX 77030.

Platelet-activating factor (PAF) is a potent phospholipid that has been implicated in the human brain malformation disorder Miller-Dieker Lissencephaly. We have previously shown that activation of the neuronal, G-protein linked PAF receptor by nanomolar concentrations of PAF and of a nonhydrolyzable PAF, methyl carbamyl PAF (mc-PAF), lead to the collapse of neuronal growth cones and to neurite withdrawal in rat hippocampal culture. Associated with this withdrawal, PAF produced morphological changes in neurites, which led to the formation of bead-like structures. In these studies, we have examined the effects of culturing hippocampal neurons in media containing 1  $\mu\text{M}$  taxol, which has been shown to favor tubulin polymerization and stabilize microtubules, prior to PAF agonist application. The withdrawal of neurites associated with 1  $\mu\text{M}$  mc-PAF was  $-17.1 \pm 6.3$  (Mean  $\pm$  SE, N=5) in naive cultures and  $.27 \pm .58$  length units (N=5) in cultures treated with taxol. The bead-like morphologic changes induced by mc-PAF in nontreated neurites were not seen in taxol treated neurites. We conclude that pre-incubation with taxol significantly inhibits the neurite shape changes produced by PAF receptor activation, thus suggesting that microtubule depolymerization is a component of PAF-induced morphological changes in neurites.

## 24.7

EFFECTS OF MICROTUBULE AGENTS ON GROWTH CONE FILOPODIA. G. Gallo\* and E. D. Pollack. Dept. of Biological Sci., University of Illinois at Chicago, Chicago, IL 60607.

Microtubule polymerization and transport underlie nerve fiber elongation and have been shown to be involved in the regulation of growth cone lamellar remodeling (Gallo and Pollack, 1995, Mol. Biol. Cell, Suppl. 103a). The response of growth cones of spinal nerve fibers, growing from lumbosacral spinal cord explants from larval *Rana pipiens*, to microtubule agents were studied using video-microscopy. During microtubule agent induced growth cone collapse (50nM - 1 mM vinblastine and 0.1 mg/ml nocodazole, n=29), some but not all filopodia were observed to reach lengths up to 75% greater than the maximal lengths attained by filopodia in control growth cones. Also, filopodia were noted to give rise to small transient lamellae along their shafts. We have previously shown that 20 nM vinblastine affects the remodeling of growth cone lamellae without affecting nerve fiber integrity, microtubule arrays or the size of growth cones. Following a 24 hr exposure to 20 nM vinblastine, filopodial length was increased but filopodial number was not affected. The increase in filopodial length was not due to the elongation of filopodia to abnormal lengths, but resulted from a greater percentage of filopodia reaching greater lengths. These data show that microtubules are involved in the regulation of filopodia as well as lamellae at the neuronal growth cone. (Supported by the UIC Campus Research Board)

## 24.9

DIFFERENTIAL DISTRIBUTION OF CAMs ON EMBRYONIC AND ADULT MOUSE OPTIC AXONS *IN VITRO*. C.A. Bates\* and R.L. Meyer. Dev. and Cell Biology, Univ. Calif. Irvine, Irvine, CA, 92717.

Embryonic axons grow through the adult CNS, while injured adult axons can not. Since cell adhesion molecules (CAMs) can regulate axonal growth, the differential expression of CAMs may underlie regenerative failure. In this study, we compared embryonic and adult optic axons growing *in vitro* for the presence of CAMs involved in axon outgrowth.

Embryonic (E15 or later) and adult mouse retinas were removed and placed on a laminin substrate under serum free conditions where they extended optic axons within 2 days. Antibodies to the CAMs, L1, Thy-1, N-cadherin, NCAM and polysialylated NCAM (PS-NCAM), were used.

We found that embryonic optic axons were positive for L1, normally found on developing axons, while adult axons were negative. Similarly, N-cadherin was present in embryonic neurons, but was not detectable in adults. Thus, adult regenerating optic axons are not able to re-express the early CAMs, L1 and N-cadherin. Conversely, embryonic axons had no detectable Thy-1, while adult optic axons were Thy-1 positive. In this case, growing adult axons persisted in the expression of the mature CAM, Thy-1. NCAM, as expected, was present in both embryonic and adult optic axons. Unexpectedly, PS-NCAM, normally found only in embryonic axons, was also detectable in adult axons although possibly at lower levels. With the exception of NCAM, regenerating adult axons express different CAMs than embryonic axons.

Supported by NS 26750 to RLM.

## 24.11

ASSOCIATION OF MAP2C WITH ACTIN IN NEURONS. M. Morishima-Kawashima\* and K. S. Kosik. Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115.

MAPs were originally found as microtubule-associated proteins. There are many reports which showed that some MAPs interact with actin *in vitro*. This observation suggests additional functions for MAPs *in vivo*. We examined the interaction between actin and MAPs in cultured rat cerebrocortical neurons. Immunoprecipitation experiments showed the association of actin with MAP2C, but neither with HMW MAP2 nor tau. This association was detected during the first week in culture while neurites developed; thereafter the association decreased. MAP2C and actin co-immunoprecipitated from detergent-resistant cytoskeletal fractions, which indicates that MAP2C is not associated with free actin but with actin filaments. Treatment of cultures with cytochalasin D and colchicine shifted a part of the association to the cytosolic fraction. When cortical neurons were treated with neurotrophin-3 which enhanced neurite extension and branching, the association of MAP2C with actin increased. These results raise the possibility that one function of MAP2C is to interact with actin as well as microtubules during process formation. (supported by NIH grants.)

## 24.8

GROWTH CONE CYTOSKELETAL DYNAMICS. M. Steketeer and K.W. Tosney\*. Neuroscience Program and Biology Department, The University of Michigan, Ann Arbor, MI 48109.

We are examining how guidance alters cytoskeletal dynamics by studying an invariant response to contact with a physiologically relevant guidance cue. Sensory growth cones from the DRG normally encounter and always avoid posterior sclerotome (PS) in the embryo. In culture, filopodial contact always inhibits veil protrusion along contacting but not non-contacting filopodia. Since the response is invariant, we are using it to assess the dynamic cytoskeletal changes that mediate the avoidance response.

We see reproducible changes in the state of filamentous actin (f-actin) polymerization that correlate with the response to contact. The growth cone cytoskeleton is composed of f-actin in dynamic equilibrium with free globular actin (g-actin). Filopodial contact with PS inhibits f-actin polymerization locally while non-contacting filopodia support polymerization. The contacting, quiescent regions contain high [g-actin] and low [f-actin] while active protrusions contain high [f-actin] and low [g-actin]. Therefore, veil protrusion can be directed by guidance cues that locally promote or inhibit f-actin polymerization. We are also evaluating the roles of several actin binding proteins and second messenger systems in veil protrusion. For example, tyrosine phosphorylation increases at the leading edge of actively protruding veils. To determine if tyrosine phosphorylation is a prerequisite for f-actin polymerization, we are using inhibitors of tyrosine phosphorylation. These data support the hypothesis that environmental cues guide neurites to their targets by modulating the cytoskeletal dynamics of the growth cones. Supported by NIH #NS21308.

## 24.10

RETINAL GROWTH CONE MOTILITY CONTROLLED BY MYOSIN LIGHT CHAIN KINASE. John T. Schmidt\*, and Xiaoying Jian. Dept. Biol. Sci., SUNY Albany NY 12222

Actin-myosin interactions in non-skeletal muscle cells are regulated by the  $Ca^{2+}$ -calmodulin-dependent myosin light chain kinase (MLCK), which phosphorylates and activates myosin II. We previously showed that pharmacological inhibitors of MLCK block motility in retinal growth cones (Jian et al., 1994, *J. Neurobiol.* 25:1310), and that MLCK mRNA is both expressed in neurons and is upregulated during axon outgrowth in goldfish retinal ganglion cells (Jian et al., 1995 *Neurosci. Abstr.* 21: 1773). Here we have taken a peptide from the autoinhibitory domain of MLCK (aa743-758, KKYILRRKWKQTGHAV-NH<sub>2</sub>) and coupled it to stearate at its N-terminal to allow it to cross the plasma membrane, a technique shown to work with PKC inhibitors. The homologous 16aa sequence from chicken gizzard MLCK has an IC50 of 0.4μM and inhibits MLCK independent of calmodulin (Foster et al., 1990, *Arch. Biochem. & Biophys.* 280:397). Application of this peptide at 10μM to retinal growth cones first blocked motility and then collapsed the lamellipodia and filopodia just as the pharmacological inhibitors did. These structures are actin based and we previously showed that inhibiting MLCK eliminated F-actin staining by rhodamine-phalloidin. The time to effect is concentration dependent, and at low concentrations the effect is a reversible inhibition of motility. Control application of stearate alone is without effect. These results verify the conclusion from pharmacological inhibitors that MLCK controls growth cone motility via regulation of its actin cytoskeleton. We have also generated a polyclonal antibody against an MLCK peptide from the C-terminal domain that stains bands on western blots at 135kDa and 190kDa (MLCK isoforms) and at 35kDa (smaller kinase related protein-telokin), consistent with findings in chick and rat. It also stains cultured retinal neurons and their processes. Supported by NIH grant EY-03736.

## 24.12

LOCALIZED PHOTOLYSIS OF CAGED CALCIUM INDUCES ACCUMULATION OF F-ACTIN, AND TRANSIENT PROTRUSION OF FILOPODIA FROM NASCENT NEURONS *IN SITU*. P.M. Lau, R.S. Zucker and D. Bentley\*. Dept. of Molecular and Cell Biology, Univ. Calif., Berkeley, CA 94720.

A key element in growth cone steering is control of F-actin in filopodia. To regulate cytoskeletal changes within growth cones following contact with extracellular guidance cues, intracellular signaling cascades are activated. In many systems, calcium has been implicated as a critical intermediate in these cascades. To isolate effects of calcium ion concentration from upstream signaling elements, we injected caged calcium compounds, nitr-5 and nitrophenyl-EGTA, into grasshopper pioneer neurons *in situ*. Using brief (100 ms) flashes of UV through a 20-30 μm diaphragm, selected regions of the growth cone and/or nascent axon were illuminated. Within 1-2 min after illumination, filopodia emerged from the selected region. Following a single flash, filopodia reached a maximum length (5-30 μm) in about 10 min. Multiple flashes increased the persistence of filopodia, and initiated protrusion of additional filopodia. Using *in vitro* cultures of afferent (femoral chordotonal organ) neurons loaded with caged calcium and Calcium Green, elevation of calcium ion concentration within a few seconds of a flash was confirmed. Neurons *in situ* were co-injected with caged calcium and rhodamine-conjugated phalloidin. Within 20 seconds of illumination, bright spots of rhodamine appeared in the selected region. These spots dispersed in about 15 min. These results indicate that direct, local elevation of calcium ion concentration can initiate localized foci of actin polymerization, and subsequent protrusion of filopodia. Supported by NIH NS09074.

## 24.13

EXPRESSION OF A TRUNCATED NEUROFILAMENT PROTEIN DISRUPTS INTERMEDIATE FILAMENTS AND ALTERS EARLY PERIPHERAL NERVOUS SYSTEM DEVELOPMENT IN *XENOPUS LAEVIS*. B.G. Szaro\* and W. Lin. Department of Biological Sciences, University at Albany, SUNY, Albany, NY 12222.

Intermediate filament protein expression is both tissue-specific and developmentally regulated. This property has implicated intermediate filaments, a principal component of the cytoskeleton, in modulating cell structure during development. To explore the role of intermediate filaments in neural development, we injected RNA encoding a truncated form of the *Xenopus laevis* middle molecular weight neurofilament protein (NF-M) into embryonic frog blastomeres at the 2-cell stage. Similar truncated forms of mammalian NF-M disrupt both neurofilaments and vimentin intermediate filaments in transfected fibroblasts. Thus, expression of truncated NF-M in frog embryos should interfere with the organization of their intermediate filaments. In cultures made from dissociated neural tubes and their adjacent myotomes, expression of truncated NF-M disrupted neurofilaments in neurons and desmin filaments in muscle cells. In intact embryos, peripheral nerves were severely stunted as late as stage 37/38. Also, in these embryos, neurons appeared ectopically along the flank. Whereas the stunted peripheral nerves were identical to those seen previously with injected neurofilament antibodies, the ectopic neurons were novel. This suggested that the latter resulted from disruption of intermediate filaments other than the neurofilaments. Thus, these experiments suggest that intermediate filaments serve multiple functions important for normal neural development.

This work was supported by NIH grant NS-30682.

## 24.15

MEMBRANE PHOSPHOLIPID AND NEURITE OUTGROWTH: EVIDENCE THAT PHOSPHOLIPID SYNTHESIS INCREASES IN GROWING NEURONS. W. Araki\*, J. Breu and R. J. Wurtman. Dept. of Brain and Cog. Sci., Mass. Inst. of Technol., Cambridge, MA 02139.

Phospholipids are major constituents of cell membranes and are required to sustain neuronal growth. However, their regulation in growing neurons is not well understood. We are examining phospholipid synthesis and metabolism in growing neurons, using PC12 cells in which neurite outgrowth is induced by treatment with nerve growth factor (NGF). When PC12 cells are plated on collagen-coated dishes and cultured with or without 50 ng/ml NGF for 4 days, total phospholipid levels in the NGF-treated cells, normalized for DNA content, increase by 30% and 120% on the 2nd and 4th day respectively, as compared with untreated control cells. Analysis of individual phospholipids showed that the increases in phosphatidylcholine (PtdCho), phosphatidylethanolamine and sphingomyelin were more pronounced than those in phosphatidylserine and phosphatidylinositol. [<sup>14</sup>C]Choline incorporation into PtdCho was examined in cells labelled for 2 hr with [methyl-<sup>14</sup>C]choline. The amounts of radiolabelled PtdCho per DNA in NGF-treated cells were about 5-fold and 14-fold greater than in control cells, on the 2nd and 4th days respectively. These results indicate that (i) phospholipid synthesis in PC12 cells is enhanced by induction of neurite outgrowth with NGF; (ii) it continues to increase during induced neuronal growth; and, (iii) the enhancement involves the CDP-choline pathway (Kennedy cycle). The activities of particular enzymes in the CDP-choline pathway are being examined to identify the loci at which neuronal phospholipid synthesis is regulated. (Supported by NIMH 28783 and The Center for Brain Sciences & Metabolism Charitable Trust.)

## 24.17

DIGITAL ELECTRON MICROSCOPIC ANALYSIS OF REGENERATING AXON CLUSTERS IN HUMAN SURAL NERVE BIOPSIES. K.A. Sullivan\*, J.H. Lillie<sup>1</sup> and D.A. Greene. Dept. of Int. Med. and Anat. & Cell Biol.<sup>1</sup>, Univ. of Michigan, Ann Arbor MI 48109.

Diabetic neuropathy is characterized by distinct morphological features including thickening of basement membranes, axon degeneration and regeneration. Axon sprouting leads to an increased number of regenerative axon clusters; however, as the disease progresses there is an overall loss of axons. We have employed the most current digital imaging techniques in order to examine the number of regenerating axon clusters in whole nerve fascicles. Human sural nerve biopsies were assessed for EM suitability based on the degree of fixation, absence of mechanical artifacts and size (100,000 - 425,000  $\mu\text{m}^2$ ). Based on these criteria, the largest fascicle was selected. Thin sections were collected onto formvar coated slot grids and coated with a layer of carbon. The sections were then viewed on a Phillips CM100 transmission electron microscope equipped with a CompuStage. Digital images were captured with a Kodak digital Megaplug 1.6 camera and stored as individual tiff files. A montage of the entire fascicle was constructed and the resulting virtual image was viewed by trained EM readers. Computer assisted analysis included confirming the identification of individual axons and labeling regenerating axon clusters. A regenerating cluster was defined as two or more myelinated axons within a continuous basement membrane. Quality control was maintained by randomly assigning a sample to different readers and comparing the results. The EM readers were consistent in their analysis of the samples. It is now possible to acquire an accurate count of the total number of axons within an entire nerve fascicle and to further classify those axons into discrete populations based on relevant criteria.

NITRIC OXIDE SYNTHASE IN REGENERATING AXONS IS CONCENTRATED IN GROWTH CONES. D.B. Wayne\* and J.H.P. Skene. Department of Neurobiology, Duke University, Durham, N.C. 27710.

Nitric oxide synthase (NOS) is expressed in dorsal root ganglion (DRG) cell bodies during development and regeneration (Verge et al., PNAS 89: 11617, 1992). Inhibition of NOS with N<sup>G</sup>-methyl-L-arginine does not affect basal rates of neurite extension in vitro, but does attenuate calcium-induced inhibition of neurite extension. To better understand the role of NOS in neuronal responses to calcium, we determined the cellular distribution of the calcium-sensitive neuronal isoform of NOS (nNOS) in acutely isolated DRG neurons. Cells were primed with a nerve crush 4-14 days prior to dissociation, and stained after one day in vitro with an antibody specific for nNOS (generously provided by Piers Emson). nNOS is present in many but not all regenerating DRG neurons. In those cells that have NOS, the enzyme is present in all processes and particularly concentrated in growth cones. The presence of NOS in regenerating growth cones, as well as its ability to alter cellular responses to a calcium influx, suggest that NO may modulate neuronal growth as an intracellular signal molecule. [Supported by NIH grant EY11475]

## 24.16

MEMBRANE DOCOSAHEXAENOIC ACID CONTENT INFLUENCES A-TYPE PHOSPHOLIPASE ACTIVITY IN PC12 CELL NERVE GROWTH CONES. Rex E. Martin\* and J. Quyen Wickham. Anatomical Sciences, Univ. Oklahoma College of Medicine, Oklahoma City, OK 73106.

As the murine central nervous system develops, the essential fatty acid metabolite, docosahexaenoic acid (DHA) accumulates in membranes of nerve growth cones (NGC). At maturity, the brain's synapses retain high levels of DHA. Especially during development, specificity of function for DHA is indicated because visual impairment and cognitive deficits are noted when diets are deficient in DHA or its precursors. Testing the hypothesis that DHA decreases the activity of phospholipase A<sub>2</sub> (PLA<sub>2</sub>), we incubated nerve growth factor-differentiated PC12 cells with 33nM DHA for 4 days. DHA incorporation in NGC membranes was confirmed in parallel incubations with 33nM [<sup>3</sup>H]DHA. Control and DHA-enriched NGC particles were isolated and incubated with exogenous L- $\alpha$ -1-stearoyl-2-[<sup>14</sup>C]arachidonyl-phosphatidyl-inositol ([<sup>14</sup>C]AA-PI). Immediate incorporation of [<sup>3</sup>H]DHA into phospholipids including phosphatidylinositol was noted and the 4-day supplementation of PC12 cells with DHA clearly induced changes in the phospholipase activity of NGC. No radiolabeled phosphatidic acid was formed during the assays indicating limited PI-specific phospholipase D activity. [<sup>14</sup>C]arachidonyl-diacylglycerol formation indicated C-type phospholipases could be present, but they were not apparently DHA-sensitive. The A-type phospholipases were active in the PC12 NGC as radiolabeled free arachidonic acid and lyso-phosphatidylinositol were formed immediately. One or more of these enzymes was apparently sensitive to DHA because 40% less [<sup>14</sup>C]AA-PI was hydrolyzed by NGC extracts from DHA supplemented cells. Perhaps DHA's role in the nerve ending is to mediate activity of the A-type phospholipases. (OUHSC Alumni Assn. grant to REM and OCAST HN4-018).

CELLULAR MECHANISMS GOVERNING RETROGRADE SIGNAL TRANSDUCTION AT IDENTIFIED NEUROMUSCULAR CONTACTS IN CELL CULTURE. J. C. Poyer\* and M. J. Zoran. Department of Biology, Texas A&M University, College Station, TX 77843.

*Helisoma* motoneuron B19 undergoes significant presynaptic changes *in vitro* following target contact and these changes are restricted to neuritic sites of muscle contact. The percentage of B19-muscle preparations with excitation-secretion (E-S) coupling, detected by acetylcholine sensitive reporter cells, has been shown to be significantly increased in cocultures of appropriate partners as compared to inappropriate pairs. E-S coupling is never detected in neurites without target contact. In addition, the induction of secretory competence requires transsynaptic activity. Together, these results suggest that B19 acquires functional secretory properties through activity-dependent interactions with specific muscle targets.

In the present studies, acquisition of functional secretion was blocked in muscle-contacted neurons (n=14) following incubation in medium containing 10 mM suramin. Spontaneous transmitter release rates were similar in control neurons with (n=11) and without (n=18) muscle contact and in suramin-treated neurons with (n=14) and without (n=8) muscle contact. Suramin disruption of E-S coupling suggests that the induction of presynaptic changes in B19 might be regulated by a receptor/ligand interaction. Muscle cells that were stripped of extrinsic proteins by a 1 hr digestion in 100 ng/ml trypsin failed to induce E-S coupling when cocultured in contact with neurons (n=13) for 48 hr. Similarly, neurons (n=9) that were cultured in medium conditioned by sustained muscle incubation, but lacked direct appropriate muscle contact failed, to acquire functional secretion. Furthermore, muscle cells digested with phosphatidylinositol-specific phospholipase C (5 mU/ml) for 1 hr lost the ability to induce E-S in B19 (n=27). Collectively, these data indicate that retrograde signal transduction governing presynaptic modifications in B19 involves cell-surface associated proteins. Whether activity-dependent release of diffusible cues are also involved remains unclear. This research was supported by NSF Grant IBS-9421372.

## 25.3

*unc-55*, A NUCLEAR HORMONE RECEPTOR, PLAYS A ROLE IN THE DIFFERENTIATION OF THE VD MOTOR NEURONS IN *C. ELEGANS*. M. H. Zhou, W. W. Walthall\*. Biology Dept, Georgia State University, Atlanta, GA 30303

Six DD and 13 VD motor neurons (mns), collectively called the D mns, form a cross-inhibitory network and are involved in the forward and backward movement of the nematode *C. elegans*. The D mns share many features related to their structure, function and neurochemistry. However, they differ in their synaptic patterns. Mutations in the gene *unc-55* (uncoordinated) cause VD mns to adopt the same synaptic pattern as DD mns resulting in a reduction of ventral inhibition, an enhancement of dorsal inhibition, these two changes sum to create a ventral asymmetric locomotory pattern. Genomic sequence analysis suggested that *unc-55* encodes a nuclear hormone receptor that shares high sequence similarity with members of the COUP gene family. Both a P box and a D box, critical domains in this family, have been identified in *unc-55* genomic sequence. Mutations in five alleles are closely associated with the P Box, the DNA binding domain. To confirm the role of *unc-55* in the regulation of the VD mn synaptic choice we are attempting to: (1) Isolate *unc-55* cDNAs through library screening; (2) Characterize the mutated sites in *unc-55* alleles; and (3) Construct an *unc-55-lacZ* fusion to determine its expression pattern.

## 25.5

SYNAPSE-SPECIFIC ELECTRICAL COUPLING BETWEEN IDENTIFIED NEURONS REFORMS IN CELL CULTURE. T.M. Szabo\* and M.J. Zoran. Department of Biology, Texas A&M University, College Station, TX 77843.

Electrical synapses are crucial to the functioning of complex nervous systems and have been shown to play an important and integrative role. Electrical connections between identified motoneurons in the buccal ganglia of the snail, *Helisoma*, have been characterized based on electrophysiological analysis of motor patterns and image analysis of cellular morphology. In the present studies, we have investigated the nature of electrical coupling between phase and anti-phase components of the snail's feeding neural circuit. These neurons are active at different stages in the feeding cycle and receive antagonistic inhibitory and excitatory inputs from the central pattern generator. In dual electrophysiological recordings, neurons were penetrated by intracellular electrodes and assayed for electrical coupling under isopotential conditions. In reduced muscle-ganglion preparations, neuron B19 was electrically coupled to phase neurons, contralateral B19 and motoneuron B18, and possessed average coupling coefficients (cc) of 0.22 (n=30) and 0.16 (n=19), respectively. In contrast, B19 was coupled weakly, if at all, to anti-phase neurons VB10 and VBx, with an average cc less than 0.02.

To test whether phase and anti-phase neurons are competent to couple electrically, we examined them in cell culture. Isolated B19s plated into pairs for 6 days formed neuritic contacts and had a cc of 0.36 (n=32), which was significantly greater than the cc of 0.19 (n=38) measured between B19-VB10 pairs (p<0.001). In addition, B19-VBx cell pairs had a cc of 0.01 (n=6). Neurons forming electrical connections with inappropriate targets may selectively eliminate these connections as development proceeds. Preliminary results indicate that inappropriate connections in culture decrease in coupling strength during sustained periods of cell-cell contact.

## 25.2

TARGET-DEPENDENT INDUCTION OF NEURONAL SECRETION INVOLVES NEW PROTEIN SYNTHESIS. M.B. Turner\* and M.J. Zoran. Department of Biology, Texas A&M University, College Station, TX 77843

Synapse formation between *Helisoma* neuron B19 and muscle targets in culture involves a target-dependent induction of secretory properties. This induction requires many hours of B19-muscle contact. Neuron B5, however, forms functional synapses in minutes. These different latencies in formation of functional transmission suggests that B5 possesses secretory function prior to target contact, while B19 acquires target derived signals that upregulate secretory function. These intrinsic differences lead us to test whether target-dependent induction of B19 secretion involves new gene expression and protein synthesis.

Neurons were treated with a 1h pulse of either a transcriptional inhibitor, actinomycin D or  $\alpha$ -amanitin, or a translational inhibitor, anisomycin or cycloheximide. After removal of the inhibitor, muscle targets were cocultured with B19 for 2 days prior to electrophysiological recording. These inhibitors significantly decreased secretory efficacy of B19, but had no effect on B5. To insure that B19 was able to recover from the translational inhibitors,  $^3$ H-leucine uptake was monitored using autoradiography. Within hours of treatment, B19 showed uptake of radioactive leucine comparable to untreated neurons. In addition, treatment with anisomycin had no longterm detrimental effects on the initiation or rate of neuritic outgrowth. In further studies, B19 was treated with anisomycin 2 days prior to muscle contact. In this paradigm, upregulation of secretory function was not inhibited.

These results indicate establishment of functional synaptic transmission in B19, but not B5, requires new gene expression and protein synthesis. The finding that the disruption of secretion upregulation in B19 occurs only when protein synthesis inhibition is imposed at the earliest stages of neuron-muscle contact suggests that a critical period of new gene expression may exist for target-induced acquisition of functional secretory properties by B19. This work was supported by NSF Grant IBN-9421372.

## 25.4

*SHAKING-B (NEURAL)* IS ESSENTIAL FOR FUNCTIONAL GAP-JUNCTIONS IN A SUBSET OF *DROSOPHILA* SOMATIC MUSCLES. Jonathan P. Bacon\*, Richard A. Baines, Martin G. Todman, Lucy A. Stebbings and Jane A. Davies. Sussex Centre for Neuroscience, University of Sussex, Brighton, BN1 9QG, UK.

The *shaking-B* locus of *Drosophila* encodes at least two, highly homologous, membrane-spanning proteins, *shakB(neural)* and *shakB(lethal)*. Our previous work has shown that *shakB(neural)* is essential for electrical synapse formation in the Giant Fibre System (Phelan et al (1996) J Neurosci 16:1101-1113). *In situ* hybridisation shows that, in addition to CNS expression, *shakB* transcripts are present in some embryonic muscles. We compared membrane properties of first instar somatic muscle in larvae carrying mutations that disrupt the function of *shakB* proteins. The ventral obliques (muscles 15-17) that stain with the *in situ* probe and the ventral longitudinals (muscles 6 and 7) that do not, were investigated by whole-cell voltage clamp in a calcium free saline. Under these conditions, only two voltage-activated potassium currents are visible - a fast ( $I_A$ ) and a delayed rectifier ( $I_K$ ) current. These currents are significantly reduced in magnitude in muscles 15 and 16 of *shakB(neural)* mutant larvae compared to either their Oregon-R or *shakB(lethal)* mutant counterparts. The same currents are, however, normal in muscles 6 and 7 of *shakB(neural)* mutant larvae. This apparent increase in input resistance in muscles 15 and 16 of *shakB(neural)* mutant larvae could, hypothetically, be explainable by an absence of functional gap-junctions that serve to dye-couple these muscles to their neighbors during embryogenesis. This was tested: carboxyfluorescein injected into muscle 6 in Oregon-R stage 16 embryos spreads to adjacent muscles including muscles 15 and 16. In *shakB(neural)* mutant embryos, dye fails to invade muscles 15 and 16 indicative of a loss of functional gap-junctions in these muscles. Expression of a UAS-*shakB(neural)* construct using a muscle enhancer-GAL4 line (24B) in *shakB(neural)* mutants fully rescues both the dye-coupling and magnitude of whole-cell currents of the ventral obliques (15 and 16). These observations provide support for the hypothesis that *shakB(neural)* is essential for the normal functioning of some gap-junctions. Supported by the BBSRC, UK.

Adult pattern and embryonic development of synaptic connections between three identified neurons in the leech. F. James Eisenhart\* and William B. Kristan, Jr.\*<sup>1,2</sup> Group in Neurosciences<sup>1</sup> and Department of Biology<sup>2</sup>, UCSD.

A central question in neurobiology is, how do neurons find the right synaptic partners during development? We are addressing this question by studying the development of the synaptic connections between three identified neurons in the leech: cells 1, 102, and 3. These cells are motor neurons found in each segmental ganglion. Cells 1 and 102 inhibit the dorsal longitudinal muscles and also inhibit cell 3 centrally through graded synapses that are distributed across multiple synaptic sites. Previous work showed that cell 1 makes its entire connection on either the first (in 70% of ganglia) or second (30%) major branch of cell 3, suggesting that there may be competition between either pre- or postsynaptic processes within the neuropil.

To investigate this possibility, we used photoablation to isolate the site of the cell 102's connection onto cell 3 and determine its relationship to the cell 1 connection. We filled cell 3 with a fluorescent dye and photoablated successive postsynaptic branches while monitoring the size of IPSPs from cells 1 and 102. Our results suggest that cell 102 also makes its entire connection on a single major branch of cell 3 and that it occupies the same branch as cell 1. One interpretation of this result is that the postsynaptic cell 3 branches compete for the right to synapse with the two presynaptic inhibitors, who may then compete for space on the winning branch. To test this hypothesis, we are studying the development of these connections directly. As a first step, we filled cell 3 with a fluorescent dye in embryos from E9 to E13. We found that cell 3 initially produces many fine central branches from its main axon. Most of these are lost, and the survivors grow thicker and generate secondary branches. This oversprouting and retraction is consistent with the idea that the postsynaptic branches of cell 3 compete among themselves for presynaptic connections.

## 25.7

TIMING OF NEURITE OUTGROWTH AND SYNAPSE FORMATION BETWEEN IDENTIFIED NEURONS IN THE EMBRYONIC LEECH CNS.

D. Reese\* and P. Drapeau, Center for Research in Neuroscience, McGill University and Montreal General Hospital, Montreal, PQ, Canada, H3G 1A4.

We are interested in the physiological events leading to the formation of synapses between central neurons during embryonic development. Because of the accessibility of identified neurons in segmental ganglia of the leech (*Hirudo medicinalis*) embryo, we have been able to combine morphological and physiological techniques in order to correlate neurite extension and contact with synapse formation. In particular, we have examined the presynaptic Retzius (R) neurons and their targets the pressure-sensitive (P) neurons. In embryos at different stages of development, R neurons were injected with Lucifer Yellow and P neurons with Rhodamine-dextran. The embryos were fixed and examined by confocal microscopy in order to determine the timing of neurite outgrowth and contact between the neurons in the central neuropil. Neurites came into contact by embryonic day 12 (40% of development), at which stage whole-cell patch clamp recording first detected spontaneous synaptic activity in the P neurons. We have also been able to record simultaneously from both the R and P neurons in order to determine the timing of evoked release and changes in transmitter (serotonin) sensitivity.

## 25.9

DEVELOPMENT AND PLASTICITY OF REGENERATING APLYSIA SENSORIMOTOR SYNAPSES IN CELL CULTURE. R.L. Coulson and M. Klein\*. Lab. of Neurobiology & Behavior, Clin. Res. Inst. of Montreal, Montreal, Quebec, Canada H2W 1R7.

We used soma-to-soma preparations of Aplysia mechanoreceptor sensory neurons and LFS motor neurons in culture in order to investigate the time course of synapse formation and of 3 forms of short-term synaptic plasticity associated with simple forms of learning. The soma-to-soma configuration allowed us to examine synaptogenesis independently of the processes of neurite outgrowth and pathfinding.

We found that 25% of correct pairs had detectable synaptic connections at 1 h after pairing, and that this percentage increased to an asymptotic value of 82% by 20 h. The amplitude of the EPSPs increased from an average of  $2.36 \pm 0.52$  (SEM) mV at 2 h to  $11.01 \pm 1.62$  mV at 16-35 h. In some cases no EPSP was detected until after application of the facilitatory transmitter serotonin (5HT). If these pairs are taken into account, then the percentage of connections was 50% at 1 h, while there was no change in the maximal percentage.

Homosynaptic depression had similar kinetics in pairs at early (1-10 h), intermediate (17-35 h) and late (>40 h) times after pairing. Furthermore, synaptic augmentation induced by 5HT after 2 test stimuli and synaptic restoration induced by 5HT after 15-17 stimuli were not statistically different among the 3 groups.

We conclude that regenerating synapses form rapidly upon cell contact and that the plastic capabilities of the newly-formed synapses are similar to those of mature synapses. Our results suggest that recruitment of new functional synapses may not be limited to long-term forms of learning or other long-term phenomena, but could play a role in the induction of intermediate-term and perhaps even short-term forms of plasticity.

Supported by NIMH and NSERC.

INNERVATION OF FOREIGN CENTRAL TARGETS BY 1A AFFERENTS IN THE EMBRYONIC CHICK SPINAL CORD. A. M. Ritter\* and E. Frank. Dept. Neurobiology, U of Pittsburgh Sch. of Med., Pittsburgh PA 15261

Sensory neurons innervating muscle spindles (1a afferents) use cues derived from their peripheral target muscles to form connections with the correct motoneuron pools in the spinal cord (Wenner and Frank 1995). Here we ask whether the target muscles of motoneurons play a similar role in specifying which inputs motoneurons receive from 1a afferents, by looking at 1a inputs onto thoracic motoneurons which have been forced to innervate hindlimb muscles. Neural tube from segments LS1-3 in St 17-18 chick embryos was removed and replaced with thoracic neural tube from donor embryos St 16-17; embryos were then allowed to develop until St 39-40 for electrophysiological experiments. The transplanted motoneurons innervate hindlimb targets but still maintain features characteristic of their thoracic origin (Yin and Oppenheim 1992). In contrast to the weak 1a synaptic input that thoracic motoneurons normally receive, both ventral root and intracellular recordings revealed that hindlimb 1a afferents had established short latency, fatigue-resistant connections with the transplanted motoneurons. Further experiments will reveal whether the pattern of 1a inputs is appropriate for the novel peripheral targets of these thoracic motoneurons. Supported by NINDS to EF

## 25.8

SYNAPTIC PLASTICITY IN THE CEREBRAL GANGLION OF APLYSIA HAS A DEVELOPMENTAL ONSET. S.M. Fredman\*. Dept. of Physiology, Meharry Medical College, Nashville, TN 37208.

The monosynaptic connection between the A and B neurons in the cerebral ganglion of *Aplysia* exhibits two prominent forms of activity-dependent synaptic plasticity. We now report that they have a different developmental onset. In adult *Aplysia*, stimulation of individual presynaptic A neurons at <0.01 Hz results in low frequency synaptic depression (LFSD), a progressive reduction in the amplitude of EPSPs evoked in postsynaptic B neurons. Brief high frequency stimulation (2 sec @ 20 Hz) produces slow developing potentiation (SDP), an ~250 % increase in EPSP amplitude with slow kinetics. SDP reaches a peak 5 min after the tetanizing train and lasts ~30 min. Both forms of plasticity appear to be due to changes in transmitter release by the A neurons and are mediated by distinct second messenger/ signal transduction pathways. These forms of plasticity appear at different times during development, with LFSD being present before SDP.

In juvenile *Aplysia*, 155 days after hatching and weighing ~7.5 g, A-B neuron synapses exhibit LFSD but not SDP. LFSD also appears to be more pronounced in juveniles than in adults, with EPSPs decaying more rapidly. As development progresses, two changes take place. First, a weak form of SDP appears, but only in <50 % of the A neurons. Following the tetanizing train, EPSP amplitudes increase, but rarely exceed the initial amplitude, and decay back to control levels in <10 min. Second, more A neurons begin to display SDP. In slightly older and/or larger *Aplysia* (165-175 days, 12-14g) the potentiation is greater in amplitude, reaching ~150 % of the initial amplitude, and has a longer duration, ~15 min. By the time animals reach an age of ~200 days and a weight of ~18g, SDP is indistinguishable from that seen in the adult. We are presently trying to determine the cellular mechanisms underlying this developmental plasticity. ## 25.10

A MEMBRANE STRIPE ASSAY FOR DETERMINING NEUROMUSCULAR POSITIONAL SELECTIVITY. A.S. Norton<sup>1</sup>, R.L. Graves<sup>1</sup>, H. Wang<sup>1</sup>, J.G. Cloud<sup>2</sup>, W.R. Trumble<sup>1</sup>, L. Ziskind-Conhaim<sup>3</sup>, and M.B. Laskowski<sup>1</sup>. WAMI Medical Program<sup>1</sup> and Dept. of Biological Sciences<sup>2</sup>, Univ. of Idaho, Moscow, ID 83843 and Dept. Physiology<sup>3</sup>, Univ. Wisconsin Medical School, Madison, WI 53706.

Previous studies from our laboratory have shown that spinal cord motoneuron pools map onto the surface of the rat diaphragm and serratus anterior muscles, and that this map is partly reestablished after denervation. In an effort to define the mechanisms whereby developing and regenerating neurites seek out and synapse upon positionally matched muscle cell partners, we have developed an in vitro stripe assay system modelled after Bonhoeffer et al (Devel. 101:685, 1987). Rostral or caudal muscle groups were isolated including axial and proximal limb musculature of E-18 embryonic rats. Crude membrane fractions of muscles were prepared using sucrose gradient density centrifugation. Laminin-coated nitrocellulose filters were placed on a lane-forming matrix yielding alternating stripes of rostral and caudal membranes. Cervical and lumbosacral spinal cord (SC) slices (300 µm) of E-15 embryos were positioned on the nitrocellulose filters with the ventral regions facing the lanes, and the co-cultures were incubated at 37°C in Costar<sup>R</sup> dishes. Preliminary results show that after 4 days in culture, growth cones of neurites from cervical SC slices were positioned with equal frequency over rostral or caudal membranes. Similarly growth cones from lumbosacral SC were distributed with equal probability over both lanes. Although no gross differences were observed in rostral or caudal selectivity, this assay provides a novel method to identify more subtle growth patterns of developing SC neurites in our search for neuromuscular positional cues.

## 25.12

INNERVATION SPECIFICITY OF ENTORHINAL PROJECTION NEURONS CANNOT BE OVERRIDDEN BY ALTERING TARGET TISSUES IN 1 WEEK OLD POSTNATAL RAT SLICE CO-CULTURE.

P.M. Field, D. Li and G. Raisman.\*

The Norman and Sadie Lee Research Centre, Laboratory of Neurobiology, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA, UK

The entorhinal cortex *in situ* forms a projection from layers II and III to the subiculum, a projection exclusively from layer II to the dentate gyrus, and a projection from layer IV to the adjacent perirhinal cortex. We have carried out organotypic slice co-culture experiments to present postnatal day 7 (P7) rat entorhinal cortex with different types of P7 target tissue. (1) When entorhinal slices were co-cultured with target tissues that contained only the subiculum and adjacent part of the hippocampal field CA1, but not dentate gyrus, extracellular uptake of biotin dextran from crystals placed on the target slice retrogradely labelled cells in both layer II and layer III of the entorhinal cortex. (2) When entorhinal slices were co-cultured with target slices containing only dentate gyrus, the cells of the entorhinal layer II were retrogradely labelled, but those of layer III were not. (3) When entorhinal slices were co-cultured with target slices containing perirhinal area, only the cells of entorhinal layer IV were labelled. Thus the exclusive relationship of the layer II cells to the dentate gyrus target tissue has already been established by 1 week of age, and is maintained by the regenerating entorhinal axons. Layer III entorhinal cells cannot be induced to project to the dentate gyrus even when deprived of their own target, and layer IV cells are specified to project only to the perirhinal area. Deprivation of the normal target tissue and presentation of an incorrect target tissue is not sufficient to override the specificity of the entorhinal projection neurons.

## 25.13

**An Analysis Of The Synaptic Input From The Parafascicular Thalamic Nucleus Onto Parvalbumin Striatal Interneurons In The Normal Adult Rat And The Effect Of Neonatal Decortication Upon Its Organization.** T. Rudkin\* and A.F. Sadikot. Montreal Neurological Institute, McGill University, Montreal, Canada.

We use the rat striatum as a model system to address the question of how striatal afferents acquire their ordered synaptic relationship. Both the motor cortex and the lateral segment of the parafascicular thalamic nucleus (*Pf*) in the rat send massive, glutamergic input to the dorsolateral striatal area. Distributed within this striatal area is a population of interneurons which are identified by their immunoreactivity for the calcium binding protein parvalbumin (PV). PV-dendrites are the postsynaptic target of cortical terminals (Lapper et al '92). Our preliminary evidence suggests that thalamic boutons do not form synapses with PV immunoreactive elements in the normal, adult rat brain. To test whether competition between cortical and thalamic terminals during development contributes to the sparse thalamic innervation onto PV- interneurons, we performed anterograde tracing experiments on bilaterally decorticated P3 neonatal rats. The rats were allowed to survive into adulthood and were stereotactically injected into the *Pf* with the anterograde tracer biotinylated dextranamine. Double-labeling immunohistochemistry revealed overlapping thalamic fibres and PV-immunoreactive elements. If competitive mechanisms do indeed participate in the formation of the normal striatal synaptic organization, we would expect that unlike normal adult rats, thalamic terminals of neonatally decorticated rats will allow *Pf* to form synapses with PV-interneurons. Although more analysis is required, preliminary observations of electron micrographs have yet to demonstrate thalamic innervation of PV-immunoreactive elements. This suggests that mechanisms other than competition between afferents underlie the establishment of stable synaptic connections between cortical terminals and PV interneurons within the rat neostriatum. (Supported by the Canadian MRC and a studentship to T.R. from FCAR.)

## 25.15

**Disruption of nitric oxide synthesis and signalling prevents the establishment of proper retinal connections in the optic lobe of *Drosophila melanogaster*.** S. M. Gibbs and J.W. Truman\*. Dept. of Zoology, University of Washington, Seattle, WA 98195.

During the first half of metamorphosis in *Drosophila*, the photoreceptors express a soluble guanylate cyclase (sGC), the activity of which can be visualized through stimulation with exogenous nitric oxide (NO) and immunodetection with a cyclic GMP antibody. This period of NO sensitivity directly precedes the appearance of functional synapses within the optic lobe and ceases after 50% of pupal development. The laminar and medullar layers of the optic lobes display diaphorase activity during this time, indicating the possible presence of nitric oxide synthase (NOS). Using an *in vitro* brain-eye disc culture system, we have pharmacologically manipulated components of the NO/cGMP pathway during the period of NO sensitivity and observed the effects on retinal patterning in the medulla. The application of the NOS inhibitor L-NAME or the NO scavenger hemoglobin resulted in overall disruption of the retinal projection pattern and the failure of individual PR axons to terminate growth in the medulla; similar concentrations of D-NAME or methemoglobin had no effect. When low levels of methylene blue were added to inhibit the sGC, disruption was observed only in the posterior projections, those having grown into the medulla after the start of inhibitor treatment. Finally, flies mutant for sGC show an increased sensitivity to blocking NO synthesis with L-NAME, displaying posterior but not anterior disruption with lower concentrations having no effect on wild type flies. Together these experiments suggest strongly that NO and cGMP may be important components of a system used to maintain contacts between the retinal axons and their postsynaptic targets in *Drosophila*. Supported by NS Grant#13079.

## 25.14

**PLASTICITY IN THE RETINOTECTAL PATHWAYS: NITRIC OXIDE SYNTHASE BLOCKADE ENHANCES REORGANIZATION OF THE UNCROSSED AXONS FOLLOWING RETINAL LESIONS.** C.A. Scrlan\*, P. Campello-Costa & R. Pass de Carvalho. Departamento de Neurobiologia, Universidade Federal Fluminense, Niteroi, Brasil. 24001-970.

Nitric Oxide is a free radical that has been implicated in synaptic plasticity in the hippocampus, neocortex and cerebellum. We studied the ontogeny of tectal nitric oxide synthase and the effect of systemic blockade of NO-synthase on the rearrangement of the uncrossed retinotectal axons following retinal lesions. Homogenates from the superior colliculus of pigmented rats ranging from postnatal day 5 (P5) to P42 were prepared for the assay of NADPH-diaphorase activity or <sup>1</sup>(H) citrulline formation. Another group received a temporal retinal lesion which induces rearrangements in the uncrossed pathway of the intact eye. Unoperated animals were used as controls. Experimental and control groups were treated either with L-Nitro-Arginine (NARG, 50mg/kg) or vehicle. IP, during 2-7 days. Retinotectal projections were traced with intraocular injections of Horseradish Peroxidase (HRP). NO-synthase activity was detected at P5, peaked at P21 and declined at P42 in either diaphorase or <sup>1</sup>(H) citrulline assays. The systemic blockade with NARG revealed a conspicuous effect on the reorganization of retinotectal axons which invaded the visual layers of the superior colliculus in both normal and lesioned P10-P21 rats. In the later group (lesion/P21), an enhanced expansion of the uncrossed axons were observed towards the surface of stratum griseum superficiale (SGS) after NARG treatment. P5 rats did not show any significant effect on the axonal distribution after NARG injections and P42 rats showed only a slight expansion of retinal axons in the tectal neuropil. Both the time course of NO-synthase expression and the effects of systemic blockade suggest that NO plays a role on the stabilization of the retinotectal synapses after the period of topographic refinement, indicating a critical period of plasticity, dependent on retrograde messengers around the second and third post natal week. **INTIMATE CONTACT BETWEEN NEURONS AND GLIA DURING CARBOHYDRATE MEDIATED TARGETING.** M.-H. Tai\*, D.M. Autio, M. B. Rheuben and B. Zipser. Depts. Physiol. and Anat., Michigan State University, E. Lansing, MI 48824.

On embryonic day (E) 9-10, the initial defasciculation and dispersal of leech sensory afferents into the neuropil of CNS ganglia is mediated by a surface carbohydrate, the constitutive marker CE0. At E11-12, subsets of sensory afferents are distinguished by their subset markers CE1, CE2 and CE3, which now mediate the consolidation of sensory afferent subsets into unique target regions. Using HRP-labeled antibodies to these markers, we examined their function at the ultrastructural level. Sensory afferents project through roots and connectives in cohesive bundles in intimate association with glial processes. In the neuropil, dispersed sensory afferents are associated with both glial cells and central axons. Sensory afferents express CE0 over the entire surface. Contacted neurons and glial cells only express CE0 on membrane surfaces in the immediate vicinity of the sensory afferent. Possibilities include: (1) CE0 is expressed by central neurons and glial cells in a locally restricted way, or (2) CE0 is secreted or transferred after intimate contact from the sensory afferent to the cell that it contacts. Synapse formation coincides with the expression of subset markers in which sensory afferents can be presynaptic on small central profiles or postsynaptic to spine evaginations from large axons. NIH NS25117

## NEURONAL DEATH I

## 26.1

**TIMING OF GRANULE CELL DEATH IN THE CEREBELLA OF STAGGERER AND WILD-TYPE MICE.** J. M. Soha\* and K. Sunter-Mann. Dept of Surgery, Yale Medical School, New Haven, CT 06520.

Numerous studies have documented an episode of cell death among cerebellar granule cells in the mouse that occurs postnatally and depends on the size of the target Purkinje cell population. In the staggerer mutant, virtually all granule cells die owing to developmental failure of their target. We have undertaken an autoradiographic study to determine if significant granule cell death occurs before the majority of parallel fiber growth, and if the timing of death depends on the level of target support.

Groups of mouse pups, both staggerer and wild-type, were injected with <sup>3</sup>H-thymidine to label newly generated granule cells at one of three ages spanning the interval of granule cell genesis: P5, P9 and P13. Animals in each group were killed at a series of subsequent ages and their cerebella sectioned and processed for autoradiography. Pycnotic cells, including a fraction labeled with <sup>3</sup>H-thymidine, were identified and counted in the internal granular layer. The frequency of pycnotic cells is analyzed by age for each group, and by date of injection for given ages.

In staggerer, granule cell death is first observed but is rare at 3-4 days after injection. Labeled pycnotic cells are common in the IGL by 5 days post-injection. Granule cell death peaks at 5-10 days post-injection and is virtually complete by 15 days post-injection. Comparison with DiI labeling experiments suggests that granule cells axons (parallel fibers) attain nearly their mature length before the cell death decision occurs. Preliminary data supports a similar timing in wild-type, suggesting that the timing of granule cell death does not depend upon the level of trophic support.

## 26.2

**CELL PROLIFERATION AND APOPTOSIS IN THE POST-NATAL HUMAN CEREBELLAR CORTEX.** L.Lossi\*, S.Ghiella, M.A.Greco, D.Zagzag, G.C.Panzica\* and A.Merighi. Dept. 'Morfofisiologia Veterinaria and 'Anatomia e Fisiologia Umana, University of Turin, I-10126 Turin, Italy and 'Dept. of Pathology, New York University Medical Center, New York, NY 10016, USA.

*In situ* techniques for the detection of DNA fragmentation reveal the existence of a number of apoptotic cells in the post-natal cerebellum of rodents (Wood et al., Neuron, 11:621, 1993; Kruger et al., J.Neurosci., 15:3366, 1995). However, the nature of these apoptotic cells is controversial. In the mouse they have been considered to be granule cells, while in the rat they were identified as astrocytes. We have studied here cell proliferation and apoptosis in the human cerebellum from birth up to 400 days post-natally. Proliferating cells were immunocytochemically labeled using antibodies against the proliferating cell nuclear antigen (PCNA) and the Ki-67 nuclear antigen. Apoptotic cells were identified by the TUNEL and T7 DNA polymerase methods. Finally, we detected the *bcl-2* protein and type-III  $\beta$  tubulin by immunocytochemistry to further analyze the mechanism of molecular control and the nature of apoptotic cells.

PCNA/Ki-67 positive nuclei were observed from birth up to 4 months and were most concentrated in the external granular layer (EGL). Nuclei with fragmented DNA were visible from P1 to P90. During the first month they were mainly detected in the EGL, while at later stages tended to accumulate in the inner granular layer (IGL). Expression of the *bcl-2* protein was spatially and developmentally regulated in parallel with the presence of apoptotic cells. *Bcl-2* immunoreactivity was highest immediately after birth and localized to the external proliferative layer of the EGL and outer part of the IGL. The intensity of the reaction progressively decreased and was completely abolished by P120. Certain type-III  $\beta$  tubulin positive cells contained an apoptotic nucleus, thus they likely corresponded to neuroblasts and/or postmitotic granule cells.

## 26.3

**DEVELOPMENTAL NEURONAL DEATH IN THE SUBSTANTIA NIGRA PARS COMPACTA OF THE MOUSE.** Vernice Jackson-Lewis\*, Vladimir Kostic, and Serge Przedborski, Dept. Neurology, Columbia University, New York, NY 10032.

Neuronal death with the morphology of apoptosis occurs during development of the central nervous system. Recently, apoptosis was described in the substantia nigra pars compacta (SNpc) during development in rats. To examine the possibility that a similar phenomenon occurs in mice, we quantified the number of apoptotic SNpc neurons in developing mice. Counts were performed through the entire extent of the SNpc using Nissl and tyrosine hydroxylase stained sections from postnatal day 2 to postnatal day 28. We found that apoptosis does occur in the developing mouse SNpc. The vast majority of the apoptotic neurons, retained their tyrosine hydroxylase phenotype, indicating their dopaminergic nature. The number of apoptotic neurons decreased with age. However, a significant number of apoptotic neurons were still evident as late as postnatal day 28. This study demonstrates that development neuronal death in SNpc occurs in mice as in rats and thus strengthens the belief that development apoptosis is a phenomenon common among mammalian species.

## 26.5

**CHARACTERIZATION OF DOPAMINERGIC MIDBRAIN NEURONS IN A DBH:BDNF TRANSGENIC MOUSE.** Alonso-Vanegas M.A.\*, Sadikot A.F., Causing C., Miller F., Cone, Laboratory for Neurosurgical Research and Centre for Neuronal Survival, Montreal Neurological Institute, McGill University, Montreal, PQ, Canada.

Neurotrophic factors including BDNF have been implicated in neuronal survival, differentiation, and plasticity in the developing and adult nervous system. Dopaminergic (DA) neurons of the mouse midbrain develop according to a strict neurogenetic timetable, with birth of neurons between E10-13 (Bayer et al. '95) and adult spatial configuration largely achieved by the early postnatal period. BDNF displays neurotrophic actions on DA neurons in cell culture (Hyman et al. '91). As a model system for determining the role of BDNF in mid-brain development, we utilize a transgenic mouse that overexpresses brain-derived neurotrophic factor (BDNF) in adrenergic and noradrenergic neurons from the dopamine- $\beta$ -hydroxylase (DBH) promoter (DBH:BDNF) (Causing et al. '95). We have performed a quantitative analysis of dopaminergic neurons at the mid-substantia nigra level comparing heterozygote DBH:BDNF animals to wildtype control mice. Our preliminary results based on 4 transgenic animals and 4 controls indicate an increase in mean cell number of 63% in transgenic animals. This data suggests that BDNF protects dopaminergic neurons from developmental cell death. Such protection may be mediated by anterograde transport and release of neurotrophins by locus coeruleus. The precise subpopulations of dopaminergic midbrain neurons that are the target of this trophic effect remain to be determined. (Supported by the MRC of Canada and the Network of Centres for Excellence).

## 26.7

**CEP-1347 PROTECTS NIGROSTRIATAL DOPAMINERGIC NEURONS FROM DEGENERATION AFTER MPTP-INDUCED LESIONS IN VIVO.** M.S. Saporito\*, E.R. Brown, C. Murakata, M. Miller and S. Carswell, Cephalon Inc. 145 Brandywine Parkway, West Chester, PA 19380, \*Kyowa-Hakko Kogyo, Tokyo, Japan.

We have identified a class of small organic compounds that protect CNS neurons from degeneration. These compounds are represented by CEP-1347, a structurally novel indolocarbazole that lacks protein kinase C and Trk-inhibitory activities, yet, enhances the survival of cultured basal forebrain and spinal cord cholinergic neurons. Moreover, CEP-1347 promotes the survival of neurons in *in vivo* models of motoneuron and basal forebrain cholinergic degeneration. For example, systemic administration of CEP-1347 to rats subjected to an excitotoxic lesion of the nucleus basalis prevents the loss of cortically-projecting cholinergic neurons, suggesting that this compound may be useful in the treatment of diseases involving cholinergic degeneration. In the present studies, it was of interest to determine whether CEP-1347 prevents the degeneration of other neuronal types that reflect the pathology of additional CNS neurodegenerative disorders. In that regard, CEP-1347 was assessed in the MPTP mouse model, an *in vivo* model of Parkinson's disease. MPTP administration (20 mg/kg; s.c.) produced an approximate 50% loss of striatal tyrosine hydroxylase (TH) activity that was maximal 3 days post-injection. Administration of CEP-1347, at daily doses ranging from 0.01 to 10 mg/kg (s.c.), to MPTP-treated mice reduced the loss of striatal TH activity to approximately 25%. CEP-1347 did not inhibit monoamine oxidase B or block uptake of catecholamines into synaptosomes, indicating that this compound does not prevent the metabolic conversion of MPTP to MPP<sup>+</sup> or inhibit the active uptake of MPP<sup>+</sup> into dopaminergic neurons. These studies demonstrate that CEP-1347 protects dopaminergic terminals from the neurotoxic effects of MPTP and suggest that Parkinson's disease may be an additional therapeutic target for this class of indolocarbazoles.

## 26.4

**TIME COURSE OF DEVELOPMENTAL CELL DEATH IN PHENOTYPICALLY-DEFINED DOPAMINERGIC NEURONS OF THE SUBSTANTIA NIGRA.** T.F. Oo and R.E. Burke\*, Department of Neurology, Columbia University, New York, NY 10032.

We have previously shown that natural cell death, with the morphology of apoptosis, occurs within the cytoarchitectonic boundaries of the substantia nigra pars compacta (SNpc) postnatally in the rat (Mol Cell Neurosci, 1993). However, the occurrence of natural cell death within phenotypically-defined dopaminergic neurons of the SN has not previously been identified, nor has its time course been defined in pre- as well as postnatal development. To achieve these goals, we prepared complete sets of sections through the SN in prenatal (E19, 20, 21) and postnatal (P2 through P28) rats for tyrosine-hydroxylase (TH) immunostaining, to identify the dopaminergic phenotype, and for Nissl counterstain, to identify characteristic intranuclear apoptotic chromatin clumps. Sections were analyzed at 600x. We quantified the number of TH-positive cells with apoptotic chromatin clumps (i.e., TH-positive by cellular criteria) and the number of apoptotic profiles that were TH-negative, but within 15 microns of 2 TH-positive neurons (i.e., within the dopaminergic cell group by regional criteria). The counts of apoptotic profiles identified by cellular and regional criteria were analyzed separately, but were highly correlated ( $r = 0.939$ ). Both sets of data revealed two peaks of natural cell death within the SN, a major, broad peak occurring from E21 to P6, and a second minor peak at P14. These two peaks were apparent in data expressed as apoptotic cells/section or as apoptotic cells/SN. We conclude that natural cell death occurs within defined dopaminergic neurons of the SN, with a biphasic time course. The basis of the biphasic time course is unknown, but it is notable that P14 is a period of marked synaptogenesis within the target, striatum, so the P14 peak may represent a period of competition for target-derived trophic support. NS26836, PDF.

## 26.6

**STRIATAL INJECTION OF 6-HYDROXYDOPAMINE INDUCES APOPTOTIC CELL DEATH OF NIGRAL DOPAMINERGIC NEURONS IN NEONATAL RATS.** M.J. Marti\*, C.J. James, T.F. Oo, W.J. Kelly, R.E. Burke, Department of Neurology, Columbia University, New York, NY 10032.

Experimental manipulations that diminish target-derived support often result in an augmented regressive event in developing neurons. There is evidence that such support is also important for the development of substantia nigra (SN) dopaminergic system. We hypothesized that if developing dopaminergic neurons depend on target-derived trophic factors for their viability, then destruction of their intrastriatal terminals with 6-OHDA could lead to programmed death of these neurons. An intrastriatal injection of 6-OHDA (15  $\mu$ g/ $\mu$ l) was made at postnatal day (PND)7. Rats were sacrificed at different post lesion days (PLDs): 0 to 10. Sections were processed for silver staining and for tyrosine hydroxylase (TH) immunostaining with Nissl counterstain to identify and quantify cell death in SN and for *In situ* end labeling (ISEL). Intrastriatal 6-OHDA injection in PND7 rats resulted in augmented cell death in SN and the morphology of degenerating cells was apoptotic. Apoptosis was identified by the characteristic formation of rounded, distinctly bounded chromatin clumps on both Nissl and silver stain, and by ISEL. TH stain demonstrated that the apoptotic cells were dopaminergic. The induced apoptosis became apparent at PLD3 ( $E = 2.8 \pm 0.6$ ,  $C = 0.5 \pm 0.2$ ), was maximal at PLD6 ( $E = 7.2 \pm 1.0$ ,  $C = 0.3 \pm 0.1$ ) and was almost complete by PLD10. In conclusion, destruction of intrastriatal dopaminergic terminals is associated with augmented apoptotic cell death in the SN of immature rat brains. This result support the hypothesis that developing dopaminergic neurons are dependent on target-derived supports. (NS26836) (PDF) (HCP).

## 26.8

**SYSTEMIC 3-NP PRODUCES STRIATAL APOPTOSIS IN RATS BUT NOT BALB/C BYJ MICE.** T. Alexi\*, P.E. Hughes, H.Y. Kim, B. Knusel and A.J. Tobin, Dept. Physiological Sciences, UCLA and Andrus Gerontology Ctr, Univ. of Southern Calif., Los Angeles, CA.

Metabolic compromise of Sprague Dawley rat striatum with 3-nitropropionic acid (3-NP) results in its preferential degeneration, thus mimicking the pathology of Huntington's disease. We now show a surprising species difference in the susceptibility to systemic 3-NP, with BALB/c BYJ mice being resistant to striatal neurotoxicity. Both rats and BALB/c BYJ mice showed comparable levels of depletion of succinate dehydrogenase activity, the target of 3-NP inhibition. However, only rats developed striatal lesions, as revealed by TUNEL staining of chromatin condensation and apoptotic bodies. TUNEL-positive nuclei were widespread throughout the striatum in rats at 1-7 days after 3-NP injection. While mice did not show any striatal lesions, they did show CA1 hippocampal damage, at 3-7 days post-injection. Treated rats with striatal lesions also showed similar CA1 lesions.

Our results show an unexpected species difference in striatal neurotoxicity to systemic 3-NP despite equivalent levels of metabolic inhibition. In addition, systemic 3-NP in rats produces widespread striatal apoptosis. These results suggest that the link between the selective vulnerability of striatal cells to energy compromise is not as straightforward as previously believed.

## 26.9

LOSS OF CHOLINERGIC CELLS IN THE DEVELOPING SEPTOHIPPOCAMPAL SYSTEM OF RATS EXPOSED TO LOW LEVELS OF LEAD. N.A. Bourjeily\* and J.B. Suszkiw. Dept. of Molecular and Cellular Physiology, Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267-0576.

We previously reported a decrease in cholineacetyltransferase (ChAT) activity and HC-3 binding sites in the developing septohippocampal system of rats exposed to low levels of Pb. The similar reduction in ChAT and HC-3 binding sites suggests that Pb either compromises functional development of septal cholinergic neurons or causes their death. In this study, we sought to determine whether the Pb-induced cholinergic deficit is a result of partial loss of septal cholinergic neurons and whether this cell loss leads to a reduced cholinergic innervation of hippocampus. Timed-pregnant Sprague-Dawley rats received 0.2% lead acetate in drinking water starting one week before parturition and continuing until pups were 21 days old (P21). Brains from control and Pb-exposed pups were sectioned through the extent of MS/DB and dorsal one-third of hippocampus. Septal sections were stained immunocytochemically using a polyclonal anti-ChAT antibody and number of ChAT-immunoreactive (ChAT-IR) cells was determined. Hippocampal sections were stained using an AChE-histochemical method and density of AChE-positive fibers was assessed. In Pb-exposed P7 and P21 rats, there was a 24% decrease in number of ChAT-IR cells in MS/DB. In addition, density of AChE-positive fibers was reduced (14-18%) in four regions of hippocampus known to be innervated by cholinergic cells in MS/DB. Three months after termination of Pb exposure, density of AChE-positive fibers in the four hippocampal regions returned to normal. We conclude that perinatal low level Pb exposure results in death of cholinergic cells in the developing septohippocampal system and reduction in cholinergic innervation of hippocampus. The latter effect is evident as early as P7 and is followed by a delayed period of compensatory cholinergic fiber sprouting after termination of Pb exposure. The findings of this study implicate the involvement of the cholinergic septohippocampal pathway in the cognitive and learning impairments associated with developmental Pb exposure. (Supported by NIH grant ES06365).

## 26.11

DISTRIBUTION OF *GIRK2* RNA IN THE MIDBRAIN, CEREBELLUM, AND OLFACTORY BULB OF POSTNATAL MICE. J.C. Niu\*, S.M.W. Harrison, Y. Xu, D.D. Hunter and S.K. Roffler-Tarlov. Dept. of Neuroscience, Tufts Univ. Sch. of Med., Boston, MA 02111.

*Weaver* (gene symbol *wv*) is a murine autosomal recessive mutation that affects the postnatal development and viability of several types of cells. The effects of *weaver* on dopamine-containing neurons in the substantia nigra in the midbrain and the granule and Purkinje cells in the cerebellum can be seen during the first postnatal week. There is now compelling evidence to show that a point mutation in the *Girk2* gene, which encodes a G protein-coupled inwardly rectifying K<sup>+</sup> channel, is *weaver* (Patil et al. 1995, Nature Genetics 11:126).

Using *in situ* hybridization, we have begun to examine the expression of *Girk2* transcripts in the developing brain of wild-type mice, paying special attention to sites where cell death occurs in weavers. Specific digoxigenin-labeled RNA probes directed to the 3' UTR of *Girk2* RNA revealed wide distribution of *Girk2* on postnatal days (P) 7 and 24. In the ventral midbrain, several groups of nuclei express *Girk2*. Neurons in the substantia nigra, vulnerable to cell death in weavers, express *Girk2*, as do several cell groups that are retained in the weaver's midbrain. Granule cell death in weaver is most prominent in the postmitotic region of the external germinal layer in the vermis; however, in the P7 cerebellum, *Girk2* is expressed throughout the external germinal layer and in the internal granular layer. *Girk2* expression in Purkinje cells showed regional differences with expression high in the vermis and low in the cerebellar hemispheres. The olfactory bulb, not thought to be a target of the *weaver* mutation, shows strong *Girk2* expression in the mitral/tufted cells and in some periglomerular cells. Our data suggest that the *Girk2* mutation is a necessary but not sufficient cause of cell death in weaver mice. NIH NS 20181 and NS 31673.

## 26.13

MK-801-INDUCED EXPRESSION OF BCL-2, FOS AND HSP72 PROTEINS IN THE RAT CEREBRAL CORTEX.

X. Zhang, X. Fan, P.H. Yu\* and A.A. Boulton\*

Neuropsychiatry Research Unit, Department of Psychiatry, University of Saskatchewan, Saskatoon, Canada S7N 5E4.

The NMDA receptor antagonist (+)MK-801 (Dizocilpine) (5 mg/kg, sc) has been shown to induce a rapid and long-lasting (2 hr to 2 weeks) reduction in the expression of *bcl-2* proteins in the retrosplenial granular cortex (RSG), and layers IV and VI of the somatosensory cortex (SS), although dying neurons were only identified in the RSG. An induction of Fos and/or Fos-related antigens (Fra) was observed in the RSG and layers II, III, V and VI in SS adjacent sections from 1 hr to 1 week post-injection of (+)MK-801. The majority of HSP72-immunoreactive neurons in RSG were also Fra-immunoreactive. Western blot analysis revealed a rapid, transient and substantial expression of 69 kDa Fra as well as a rapid, prolonged and moderate expression of 46 kDa and 35 kDa Fra in the RSG. Such (+)MK-801-induced responses are quite unique. It has been reported that glucose utilization was significantly decreased in layer IV of SS and increased in RSG. Our results are consistent with the hypothesis that psychomimetic (+)MK-801 causes a functional disconnectivity in the SS (i.e. external signals cannot be properly perceived, while inter- and intra-cortical communications as well as self-defined outputs are increased). In addition the reduction in *bcl-2* expression is not necessarily related only to neuronal apoptosis. (Supported by Saskatchewan Health and HSURC)

## 26.10

DISTRIBUTION OF *GIRK2* mRNA IN THE TESTIS AND HYPOTHALAMUS OF THE NORMAL MOUSE: IMPLICATIONS FOR THE WEAVER MOUSE. S.M.W. Harrison<sup>1,\*</sup>, M.J. Hilderbrand<sup>2</sup>, J.C. Niu<sup>3</sup>, D.D. Hunter<sup>1,3</sup>, and S.K. Roffler-Tarlov<sup>1,2,3</sup>. <sup>1</sup>Dept. of Anatomy and Cell Biology, <sup>2</sup>Program in Genetics, <sup>3</sup>Dept. of Neuroscience, Tufts Univ. Sch. of Med., Boston, MA 02111.

A point mutation has recently been identified in the *Girk2* gene of the weaver mutant mouse (Patil et al. 1995, Nature Genetics 11:126) suggesting that mutated *Girk2* may lead to the neurological and fertility deficits found in the weaver mouse. We have begun to investigate the possible role of mutant *Girk2* in weaver male sterility by defining the distribution of *Girk2* mRNA in normal mouse testis and hypothalamus. We have used *in situ* hybridization (ISH) and RT-PCR to determine the spatial and temporal pattern of *Girk2* gene expression in these tissues.

Weaver male germ cells complete meiosis but are arrested and die during differentiation in mid-spermiogenesis. This pathology appears in the first spermatogenic cycle, after postnatal-day (P) 21. It is not known whether germ cells or another hypothalamic-pituitary-testicular axis cell type are the primary target of the mutation. We have studied *Girk2* expression in pubertal wild-type testis and hypothalamus with respect to the development of the weaver's male-sterile phenotype.

We were unable to detect *Girk2* expression in P7 wild-type testis. In the P7 wild-type hypothalamus, RT-PCR did not identify *Girk2* mRNA, however, a few cells in the arcuate nucleus were *Girk2* positive by ISH. At all other ages studied, *Girk2* message was present in testis and in several hypothalamic cell populations, including in a limited number of cells of the arcuate nucleus. The first testicular expression of *Girk2*, between P7 and P14, is coincident with the onset of meiosis in the first spermatogenic cycle. ISH revealed *Girk2* message specifically in mid-meiotic germ cells at P14, as well as in early post-meiotic germ cells in older mice. *Girk2* expression, therefore, precedes the weaver's testicular pathology by at least one week. These patterns of *Girk2* expression suggest that male germ cells may be a direct target of weaver, but do not eliminate involvement of the hypothalamus. NS20181, NS31673.

## 26.12

COORDINATED EXPRESSION OF FAS/APO (APOPTOSIS)-1, RIP (RECEPTOR INTERACTING PROTEIN), AND FAS-L (FAS LIGAND) IN THE DEVELOPING RAT EMBRYONIC AND POSTNATAL CEREBRAL CORTEX. W.C. Conner, J.S. Wieters, Z.F. Cheema, and R.C. Miranda\*, Department of Human Anatomy and Medical Neurobiology, Texas A&M University, College of Medicine, College Station, TX 77843

Cells within the developing rat cerebral cortex undergo apoptotic cell death within the first postnatal week. Our previous research demonstrated that the Fas/Apo-1 receptor is transiently expressed during this period of cell-suicide. The Fas receptor is activated by a transmembrane ligand, Fas-L. Additionally, Fas itself associates and interacts with other transmembrane proteins, RIP and FADD. In this study, we examined the spatio-temporal coordination of the expression of RIP and Fas-L with the Fas receptor. We used double *in situ* hybridization to examine the colocalization of RIP mRNA to Fas mRNA-expressing cells. Cells expressing both types of mRNA colocalized within the ventricular zone and cortical plate. In addition, combined immunohistochemistry was used to examine the relationship between Fas and Fas-L-immunoreactive cells. Fas-L-immunoreactive cells appeared to be localized proximate to Fas-immunoreactive cells, suggesting that cell-cell interactions may activate the Fas pathway. Our current research is focused on an examination of the interaction between these elements of the Fas cell-suicide signaling pathway. Supported by funds from Texas A&M University.

## 27.1

MUTATIONS IN *BENCHWARMER*, A NOVEL MEMBER OF A TRANSPORTER-LIKE PROTEIN FAMILY, INDICATE THAT A SMALL SUBSET OF GLIA PREVENT NEURONAL APOPTOSIS IN THE *DROSOPHILA* BRAIN. A. Kania, J.T. Littleton, J.D. Sweatt\* and H.J. Bellen. Howard Hughes Medical Institute and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Programmed cell death (apoptosis) is a fundamental feature of animal development and is under the control of similar effector molecules in evolutionarily divergent species. Apoptosis has been proposed to be the default pathway when vertebrate cells are deprived of necessary growth signals. The role of glia in neuronal survival and as a source of growth factors in vertebrates has been well documented. Glia are known to provide fully developed neurons with survival factors that prevent them from undergoing cell death. However, the role of glial derived signals in promoting survival of immature neurons and the ability of immature neurons to undergo programmed cell death is still being studied. We have screened for P-element enhancer detector mutations that affect nervous system development in *Drosophila* and have identified an essential gene which we have termed *benchwarmer*. *Benchwarmer* is the first member of a novel family of transporter-like proteins that includes a human homolog and that is expressed in a small subpopulation of glia throughout development. Mutations in *benchwarmer* cause pupal lethality with rare adult escapees. Mutant flies display behavioral and locomotor defects, and exhibit abnormal neuronal communication. These defects are accompanied by a severe loss of neurons in the adult brain. This loss of neurons results from extensive abnormal apoptotic cell death in early pupal development, suggesting lack of an essential non-cell autonomous signal from *benchwarmer* expressing glia. Furthermore, this apoptotic death indicates that newly born neurons have the capability for undergoing programmed cell death early in their life. These results, combined with previous studies, suggest that the default developmental pathway for neurons in the absence of glial derived survival signals is apoptosis. H.J.B. is an Associate Investigator of the Howard Hughes Medical Institute.

## 27.3

A TEMPORAL RELATIONSHIP BETWEEN MOTONEURON BIRTHDATE AND ONSET OF PROGRAMMED CELL DEATH. M.J. Burek\*, D. Prevette, and R.W. Oppenheim, Dept. Neurobiol. and Anat., Bowman Gray School of Medicine, Winston-Salem, NC 27157

We are interested in whether there is a fixed temporal interval between the genesis of developing neurons and when they undergo programmed cell death [PCD] (Galli-Resta and Ensini, 1996). One excellent model system to experimentally address this issue is the large-scale death of lumbar motoneurons (MNs) of the chick embryo spinal cord. MNs are born between embryonic days (E)2 and 4.5 and compete for access to target muscle-derived trophic factors between E6 and E11. This culminates in the death of approximately one-half of the original cell population. Since the earliest born MNs are the first to die *in vitro* in the absence of target muscle-derived trophic factors (Metzling et al., 1995), we hypothesized that a similar correlation between motoneuron birthdate and onset of cell death occurs *in vivo*. To test this we injected bromodeoxyuridine (BRDU) *in ovo* to label MNs born both early and late in the proliferative period and determined when, during the cell death period, these two neuronal cohorts undergo PCD. We report here that at E5.5 when motoneuron PCD commences, the latest-born MNs (E4-E4.5) (labeled by BRDU injections on E4) are not yet in the lateral motor column. Interestingly though, the absolute number of BRDU-labeled MNs increases between E5.5 and E8.5, but then declines by 50% coincident with a dramatic increase in the number of pyknotic BRDU-labeled cells. Since MNs born after E4 die only after E8 it suggests these cells have a fixed 4 day interval between their birth and onset of target dependence. We are currently testing whether, conversely, the earliest-born MNs are the first to die *in vivo*, and if MNs require cellular interactions with their target muscles to establish target dependence. Finally, we will determine a fixed temporal interval between cell birth and cell death is evident among other neuronal populations that undergo PCD in the developing chick embryo. Supported by NIH grants NS 20402 (R.W.O.) and NS 09838 (M.J.B.).

## 27.5

DIFFERENTIAL LEVELS OF APOPTOSIS IN DEVELOPING RAT SOMATIC AND AUTONOMIC MOTOR NEURONS. R. Wetts\* and J. E. Vaughn. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010. USA.

In contrast to numerous studies of apoptosis in developing chick CNS, few details are known about this process in mammalian species. To label apoptotic motor neurons in rat thoracic spinal cord, we used terminal transferase-dUTP nick end labeling (TUNEL). Among somatic motor neurons (SMNs), peak levels of TUNEL-positive cells (1.2 - 1.6 SMNs/section) during the E14 - E18 period were much higher than baseline levels (0.0 - 0.4 SMNs/section) from E20 - P15. However, TUNEL-labeled autonomic motor neurons (AMNs) were present only at baseline levels (0.0 - 0.4 AMNs/section) over the entire period studied (E15 - P15). In order to determine whether apoptosis of motor neurons was target dependent, we conducted experiments on cultured slices of E15 specimens. SMNs survived in control cultures, but disappeared within 4 days after removal of their peripheral target. AMNs, on the other hand, survived for 8 days without their target.

Considering the developmental and phenotypic similarities between SMNs and AMNs, it is surprising that SMNs undergo apoptosis to a much higher degree than AMNs. The phenotypic trait(s) that underlies this developmental difference might also be critical in amyotrophic lateral sclerosis, in which SMNs degenerate and AMNs do not. Supported by NIH grant NS25784.

## 27.2

MOLECULAR MECHANISMS OF DEVELOPMENTAL NEURON DEATH. J. Saltis and P.G. Noakes\*, School of Anatomy, University of New South Wales, Sydney 2052 NSW, Australia.

Neuron death is a normal developmental phenomenon that coincides with the formation of peripheral synapses. Peripheral tissues are thought to provide trophic factors to innervating neurons. A limited supply or access to these factors results in neuron death (1). Our aim was to investigate whether aberrant synapse formation affects motor and sensory neuron survival. Deletion of rapsyn, a specific post-synaptic membrane molecule, was achieved by gene knockout in mice (2). Rapsyn colocalises with acetylcholine receptor (AChR) clusters during the formation of the neuromuscular synapse. In its absence, AChRs and cytoskeletal elements associated with the postsynaptic membrane fail to concentrate beneath the motor nerve terminal. By measuring neuron numbers in these mutant mice, we hope to reveal whether a viable neuromuscular synapse is required for neuronal survival. We examined the number of motor, sensory and sympathetic neurons in rapsyn-deficient and wild type mice at birth. Animals were overexposed with 100% CO<sub>2</sub>. 10µm thionin stained paraffin sections were examined by light microscope. We found a significant reduction in both motor (p<0.03, t-test; n=3) and sensory (p<0.002; n=3) neuron number at the brachial level of mutant mice compared to wild type. There was no effect on sympathetic neuron number. Motor neuron number was reduced from 3055 ± 334 to 1873 ± 455 and sensory neuron number from 7155 ± 733 to 3483 ± 73. Sympathetic neuron number remained at around 13,700. These results indicate that a deficiency in rapsyn leading to an aberrant synapse interferes with the survival of motor and sensory neurons. The possibility remains that the disruption of the synapse may either reduce neurotrophic factor production or hamper the accessing of target-derived trophic factor.

## 27.4

A NOVEL TYPE OF PROGRAMMED NEURONAL DEATH IN THE CERVICAL SPINAL CORD OF THE CHICK EMBRYO. H.

Yaginuma\*<sup>1</sup>, M. Tomita<sup>1</sup>, N. Takashita<sup>1</sup>, S.E. McKay<sup>2</sup>, C. Cardwell<sup>2</sup>, Q.

W. Yin<sup>2</sup> and R. W. Oppenheim<sup>2</sup> <sup>1</sup>Inst. of Basic Medical Sci., Univ. of Tsukuba, Tsukuba, 305 Japan. <sup>2</sup>Dept. of Neurobiol. and Anat., and Neurosci. Prog., Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC27157

We examined the massive early cell death that occurs in the ventral horn of the cervical spinal cord of the chick embryo between embryonic day (E) 4 and E5. Studies with immunohistochemistry, *in situ* hybridization and retrograde tracing methods revealed that many of dying cells expressed Islet proteins and *Lim-3* mRNA (motoneuron markers) and send their axons to the somatic region of the embryo before cell death. These data strongly suggest that the dying cells are somatic motoneurons. Counts of motoneuron number between E3.5 and E10 revealed that, in addition to cell death between E4 and E5, motoneuron death also occurs between E6 and E10 in the cervical cord. Studies with <sup>3</sup>H-thymidine autoradiography revealed that the cells dying between E4 and E5 become post-mitotic before E3.5, whereas genesis of motoneurons is still ongoing between E4 and E5. Increasing the size of peripheral targets, treatment with neuromuscular blockade and treatment with partially purified muscle or brain extracts, and defined neurotrophic agents, such as NGF, BDNF, NT-3, CNTF, bFGF, PDGF, S100-β, activin, CDF/LIF, BMP-2, IGF-1, IL-6 and TGF-β1 were all ineffective in rescuing motoneurons dying between E4 and E5. Early cell death also occurs in a notochord-induced ectopic supernumerary motoneuron column in the cervical cord. Transplantation of cervical neural tube to other segmental regions failed to alter the early death of motoneurons. These results suggest that the mechanisms that regulate motoneuron death in the cervical spinal cord between E4 and E5 are independent of interactions with targets. Rather this novel type of cell death seems to be determined by signals that are either cell autonomous or that are derived from other cells within the cervical neural tube.

## 27.6

ETHANOL EFFECTS ON MOTONEURONS OF THE CHICK EMBRYO SPINAL CORD. D.M. Bradley\*, F. Beaman, D.B. Moore, and M.B. Heaton. Dept. of Neuroscience, Univ. of Florida Coll. of Med., Gainesville, FL 32610.

Ethanol is known to exert a variety of teratogenic effects in the developing central nervous system. The current studies are a continuation of earlier work in this laboratory which found embryonic chick motoneurons to be significantly reduced in number following chronic ethanol treatment (CET) from embryonic day 4 (E4) to E11. We hypothesized that ethanol could be exacerbating naturally-occurring cell death (NOCD), which is from E6 to E9 in the chick spinal cord, or exhibiting direct toxicity to this population. Further studies revealed that neuromuscular blockade by curare in conjunction with CET results in motoneuron numbers similar to control embryos and significantly lower than curare only embryos. Since NOCD is suspended in the presence of curare, we theorized that cell death resulted from directly toxic effects of ethanol. In an additional experiment, we wished to determine whether ethanol was toxic to spinal cord motoneurons during a later developmental period in which cell numbers were relatively stable. The time period of E10 to E15 was chosen because it follows the period for NOCD and motoneuron number is somewhat stable. For this study, chick embryos were divided into ethanol and control groups, and the lumbar section of the lateral motor column was counted on E16. Additional studies will explore whether exogenous neurotrophic factors can modulate the toxic effects of ethanol *in vivo* in a manner similar to previous *in vitro* experiments performed in this laboratory.

## 27.7

THE RESCUE OF AVIAN MOTONEURONS BY ACTIVITY BLOCKADE AT THE NEUROMUSCULAR JUNCTION. R.W. Oppenheim\*, D. Prevette and S.W. Wang. Dept. Neurobiology and Anatomy, Bowman Gray Sch. of Med., Winston-Salem, NC 27157.

Blockade of neuromuscular (NM) transmission rescues developing avian motoneurons (MNs) from programmed cell death. Prevention of cell death has been attributed to increased axonal branching and synapse formation elicited by activity blockade. However, according to a recent study, neither activity blockade nor increased axonal branching are necessary for the ability of NM blocking agents (e.g. curare) to prevent MN death (Hory-Lee and Frank 1995 *J. Neurosci.*). These investigators also report that curare potentiates the effects of muscle extract (MEX) in promoting MN survival *in vitro*. They conclude that NM blocking agents are more likely to rescue MNs by acting centrally at neuronal nicotinic receptors rather than by blocking peripheral NM activity. Although we have been able to repeat their *in vitro* results, our *in vivo* studies, by contrast, indicate that: (1) Curare rescues MN in a dose-dependent manner; (2) NM activity is similarly reduced by curare in a dose-dependent fashion; (3) Doses of curare that fail to affect NM activity also fail to rescue MNs; and (4) Blockade of neuronal nicotinic receptors with methyllycaconitine fails to alter MN survival. Studies are in progress to examine axonal branching following treatment with different doses of curare. Supported by NIH grants NS20402 and NS31380

## 27.9

REGULATION OF SCHWANN CELL DEATH IN DEVELOPING SPINAL CORD NERVE ROOTS. J. Calderó\*<sup>1</sup>, D. Cuiat<sup>1</sup>, R.W. Oppenheim\*, J. Ribera<sup>1</sup>, A. Casanovas<sup>1</sup>, O. Tarabal<sup>1</sup>, J. Lladó<sup>1</sup> and J. E. Esquerda<sup>2</sup>. <sup>1</sup>Dept. C. M. B. Facultat de Medicina, Universitat de Lleida, Av. Rovira Roure 44, 25198 Lleida, Catalonia, Spain. <sup>2</sup>Dept. of Neurobiology and Anatomy, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

In the chick embryo, Schwann cells (SCs) die by apoptosis both during normal development and following axonal degeneration induced with neurotoxins (Cuiat et al. 1996). Chronic blockade of neuromuscular activity during development with pharmacological agents such as (+)-tubocurarine (Tc) in the chick embryo rescues motoneurons from naturally occurring cell death. Treatment of chick embryos with Tc from E3 results in a reduction of SC apoptosis on E9-E10, but not in earlier stages. By contrast, limb-bud ablation performed on E2, which leads to degeneration and death of up to 90% of motoneurons, determines an important increase in SC apoptosis coincident with the period of maximal motoneuron loss. Sciatic nerve transection on neonatal rats also induces massive apoptotic cell death on SCs in distal nerve stump. These results suggest that the survival of SCs during development is transiently dependent on axonal derived trophic signals. Whether or not the massive SC death accounts for motoneuron death after neonatal axotomy is currently investigated. (Supported by Ministerio de Educación y Ciencia, PB93-0642, Ajuntament de Lleida and NIH, NS 20402 [RWO], grants).

## 27.11

CELL DEATH IN THE AVIAN CILIARY GANGLION IN VIVO IS MODULATED BY CILIARY NEUROTROPHIC FACTOR. T.P. Finn and R. Nishi\*. Department of Cell and Developmental Biology, Oregon Health Sciences University, Portland, Oregon 97201.

Chicken CNTF (chCNTF), also known as growth promoting activity (GPA), is a potent neurotrophic factor *in vitro* and a strong candidate for a true target derived neurotrophic factor *in vivo* for ciliary ganglion (CG) neurons. ChCNTF and chCNTF receptor messages are present during the time window of development when CG neurons are dependent on their targets in the eye for survival and chCNTF-like immunoreactivity is present in the target cells the neurons innervate. To establish whether chCNTF is a true target derived neurotrophic factor for CG neurons we altered chCNTF levels *in vivo*. Recombinant chCNTF (rchCNTF) injected into the eye socket did not, however, rescue any additional neurons over that normally seen, although it was able to rescue the majority of neurons which apparently died as a consequence of a lesion generated inadvertently from multiple injections. Multiple injections of rchCNTF into the vitreous of the eye under non-lesion conditions also did not result in a significant rescue of additional neurons. As a better means of making exogenous chCNTF available to CG neurons we infected E2.75 or E4 chick embryos with a replication competent retrovirus (RCAS) expressing full length chCNTF. *In vitro*, fibroblasts or choroid smooth muscle cells infected with the RCAS-chCNTF construct expressed high levels of chCNTF immunoreactivity and greater than a 1000 fold increase in chCNTF-like biological activity was present in choroid conditioned medium compared to controls. Western blots of cell extracts verified the full length protein was being made. *In vivo*, viral gag protein as well as ectopic chCNTF-like immunoreactivity could be detected throughout the two targets in the eye and extracts of infected eyes had at least 20 fold more chCNTF-like biological activity than control eyes. 21 - 93% of the neurons which would otherwise have died were rescued from cell death in RCAS-chCNTF infected embryos compared to embryos infected with vector alone. We are also infecting chick embryos with a RCAS construct expressing a reverse orientation (anti-sense) chCNTF construct as a means of blocking endogenous CNTF. The rescue of CG neurons in chCNTF overexpressing embryos strongly suggest that chCNTF is a neurotrophic factor for CG neurons *in vivo* and is a limiting factor in determining the size of the surviving neuronal population.

## 27.8

EFFECTS OF NEUREGULINS ON DEVELOPING NEURONAL AND NON-NEURONAL CELL POPULATIONS IN THE CHICK EMBRYO. V.L. Turgeon\*, D.M. Prevette, J. Calderó, J. Esquerda, S. Wang, J. Hong, L.J. Houenou and R.W. Oppenheim. Department of Neurobiology & Anatomy, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157, USA.

The neuregulin (NG) gene gives rise to a number of alternatively spliced transcripts [heregulin (HG), glial growth factors (GGF) and acetylcholine receptor inducing activity (ARIA)] whose protein products are expressed in various neuronal and non-neuronal cells during development. NG is a member of the EGF gene family and receptors for NG (ErbB) are also members of the EGF receptor gene family. Treatment of chick embryos *in vivo* during the period of programmed cell death (PCD) with HG had no effect on the survival of spinal sensory or motor neurons, but did increase the growth (cell size) of motor neurons, while there was no effect on cell size of sensory neurons. Addition of HG to purified populations of chick motoneuron cultures reduced their survival 48 hours after plating; whereas HG had little if any effect on the survival of cultured spinal sensory neurons. Experiments are in progress to examine the effects of HG on Schwann cell and trigeminal ganglion cell survival *in vivo*, and to examine GGF's effects on the survival of sensory and motor neurons and Schwann cells *in vitro* and *in vivo*. (We thank Genentech for the generous gift of rHG and Cambridge Neuroscience for GGF. Supported by NIH grant NS20402.)

## 27.10

THE EFFECTS OF ADENOSINE AND 2-DEOXYADENOSINE ON CHICK EMBRYO SYMPATHETIC GANGLION CELLS IN VIVO. W.J. Crossland\*, J. Kulkarni and A.R. Wakade. Departments of Anatomy and Pharmacology, Wayne State Univ. Sch. Med., Detroit, MI 48201.

Nucleosides, such as adenosine and 2-deoxyadenosine, are known to produce cell death in cultured neurons. We wanted to know if these nucleosides also have toxic effects *in vivo*.

Fertile chicken eggs were opened and 300 µl aliquots of adenosine, 2-deoxyadenosine (both containing the adenosine deaminase inhibitor 2-deoxycofomycin) or saline were pipetted onto the chorioallantoic membrane or yolk, the eggs resealed, replaced in the incubator until sacrifice. Sympathetic ganglia were dissociated and counts of ganglion cells carried out.

When injected on embryonic day (E) 3 both nucleosides were lethal to the embryos but by E6/7 only the 2-deoxyadenosine was toxic. Following sublethal doses of 2-deoxyadenosine injected at E7 and observed at E9, the normal development of the sympathetic chain ganglia at the lumbosacral level was grossly reduced in size compared to that of saline controls. Furthermore, the number of sympathetic neurons/ml was reduced from a control value of 198 X 10<sup>3</sup> to 23 X 10<sup>3</sup> and average wet weights of whole spinal cords decreased from 23.6 mg to 15.0 mg. These results demonstrate that the nucleosides are capable of inducing abnormalities in the nervous system *in vivo* and provide a substantiation of the effects of adenosine and 2-deoxyadenosine seen *in vitro*.

## 27.12

NATURALLY-OCCURRING AND DEAFFERENTATION-INDUCED CELL DEATH DURING POSTNATAL DEVELOPMENT OF THE VENTRAL COCHLEAR NUCLEUS. T.S. Tierney\*, F.A. Russell and D.R. Moore. University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, UK.

Ever since Hamburger and Levi-Montalcini (1949), most studies of naturally-occurring cell death (NCD) have emphasized the role of target tissue in governing neuron number. These studies have established the "neurotrophin hypothesis", in which competition for target-derived growth factor is thought to be the major regulator of neuron number. However, the role of afferents has received significantly less attention. In this study, we compared the critical period for deafferentation-induced cell death (DCD) to the time course of NCD in the developing gerbil cochlear nucleus. To investigate DCD, unilateral cochlear removals were performed on gerbils at two day intervals from postnatal day (P)3 to P11, and the brains were examined at 3 months. To investigate NCD, normal gerbil brains were examined between P0-P15 or at 3 months. In Nissl stained sections, stereological methods were used for estimating neuron number. From P5 on, the boundary of the cochlear nucleus was clearly circumscribed, and neuronal somata were relatively large, mononucleate and distinct from other non-neural elements. From P10-P140, NCD significantly reduced neuron number by 28% (Student's t-test,  $t_4=3.18$ ,  $p=0.003$ ). However, cell death was markedly increased (to >50%) following deafferentation during (but NOT after) the first postnatal week, clearly showing that an abrupt transition in the ability of cochlear nucleus neurons to survive in the absence of afferent input occurs before the period of NCD is complete. While afferent input is an important factor regulating neuron survival during early postnatal development, the critical period for DCD is not concomitant with NCD.

## 27.13

DEAFFERENTATION-INDUCED NEURONAL CELL DEATH IN CHICK COCHLEAR NUCLEUS INVOLVES MITOCHONDRIAL UNCOUPLING D. Durham\* and L. Crenshaw. Dept. of Otolaryngology and the Smith MRR, Univ of Kansas Med Center, Kansas City, KS 66160

Cochlea removal results in death of 30% of neurons in chick cochlear nucleus (n. magnocellularis, NM) within several days. Prior to death, NM neurons show a dramatic proliferation of mitochondria. Blockade of this mitochondrial upregulation with chloramphenicol (CAP) increases the number of dying NM neurons, suggesting that increased oxidative capacity enhances neuronal survival. We evaluated the role of mitochondrial dysfunction in the death of NM neurons using a histochemical stain for a Mg<sup>2+</sup>-stimulated ATPase whose activity increases with mitochondrial uncoupling (Meijer and Vloedman, 1980, *Histochem* 69:217).

Hatchling broiler chicks were anesthetized and one cochlea was removed. Birds were sacrificed 6 hr (n=8), 15 hr (n=10) or 3 days (n=6) after surgery. An additional set of animals received hourly injections of CAP (50 mg/kg, n=12) or saline (n=6) after cochlear ablation and were sacrificed at 15 hr. For all birds, frozen sections through NM were stained for ATPase activity. Optical density measurements of individual NM neurons were used to estimate ATPase activity, comparing neurons ipsilateral (deafferented) and contralateral (control) to cochlea removal in each bird.

In normal animals, all NM neurons show a low level of ATPase staining. At 6 hr after cochlea removal, all deafferented NM neurons show increased ATPase staining. By 15 hr, a subset of deafferented neurons showed markedly increased staining intensity. The number of these darkly staining neurons doubled in animals receiving CAP. No darkly staining neurons were evident 3 days after cochlea removal.

The percentage of neurons displaying great increases in ATPase staining matches the number of neurons that die after cochlea removal. Thus we conclude that mitochondrial uncoupling is involved in neuronal cell death in NM.

## 27.15

PERIODIC BLOCKADE OF AMPA/KAINATE RECEPTORS BEFORE THE ONSET OF SYNAPTIC TRANSMISSION ENHANCES NEURONAL SURVIVAL IN THE CHICK BRAINSTEM AUDITORY SYSTEM. D. Solum, D. Hughes and T. N. Parks\*. Dept. of Neurobiology & Anatomy, University of Utah School of Medicine, Salt Lake City, UT 84132.

*In ovo* administration of CNQX (a competitive antagonist of AMPA and kainate receptors) to chick embryos between embryonic days (E)8 and 15 significantly reduces normal neuronal death in nucleus laminaris (NL) and prevents the deafferentation-induced death of neurons in nucleus magnocellularis (NM) caused by unilateral otocyst removal on E3. Because similar effects are produced by the AMPA/kainate receptor antagonist GAMS, but not by the NMDA receptor antagonist CPP, non-NMDA receptors appear responsible for these effects. White Leghorn embryos (with or without unilateral otocyst removal at E3) were given daily 200  $\mu$ l injections of saline, or saline containing 200  $\mu$ g CNQX, onto the CA membrane on E8, E9 and E10. At E17, neurons in NL of unoperated animals were counted in thionin-stained paraffin sections. The CNQX-treated group had 2798 $\pm$ 122 (mean $\pm$ S.E.M., n=4) neurons in NL and the saline-treated control group had 2410 $\pm$ 49 (n=7); this 16% difference was statistically reliable. Treatment with CNQX from E8-10 also appears to prevent the 33% cell loss in NM that follows otocyst removal. Thirteen normal E10 embryos were given single injections of CNQX or saline and the number of spontaneous movements counted at 0.5, 1, 2, 4, 8 and 24 hrs after the injection. CNQX significantly suppressed spontaneous motility from 0.5-4 hrs but motility returned to control levels by 8 hrs. Therefore, CNQX administered on E10 should no longer be effective in blocking non-NMDA receptors by E11, when electrical stimulation of afferents can first elicit postsynaptic field potentials in NM and NL. We conclude that brief periods of non-NMDA receptor blockade prior to the onset of synaptic transmission can increase neuronal survival in central auditory neurons, both during normal development and following early deafening.

Supported by NIDCD grant 5 R01 DC00144-17 to TNP.

## 27.14

ACTIVITY-DEPENDENT REGULATION OF AVIAN COCHLEAR NUCLEUS NEURONS: ROLE OF METABOTROPIC GLUTAMATE RECEPTORS. R. L. Hyson\*. Program in Neuroscience, Florida State University, Tallahassee, FL 32306.

Elimination of auditory nerve activity results in atrophy and death of neurons in the cochlear nucleus, n. magnocellularis (NM), of the chick. One of the early events believed to lead toward cell atrophy and death is a disruption of ribosomes in the postsynaptic NM neurons. Rapid activity-dependent changes in ribosomes can be visualized by immunolabeling using an antibody, called Y10B, that recognizes ribosomal RNA. The signal by which auditory nerve activity maintains ribosomal integrity in NM neurons is unknown. One possibility is that the important trophic signal is the neurotransmitter, glutamate. This experiment examines the role of glutamate receptors in activity-dependent regulation of ribosomes.

Brain slices containing the auditory nerve and NM on both sides were obtained from 7-10 day old chickens. The auditory nerve on one side of the slice was stimulated for 1 hr. Slices were maintained in medium containing either ionotropic glutamate receptor antagonists (20  $\mu$ M CNQX and 50  $\mu$ M APV) or a metabotropic receptor antagonist (250  $\mu$ M MCPG). Ionotropic antagonists eliminated EPSPs evoked by auditory nerve stimulation, but NM neurons on the stimulated side of the slice still showed greater Y10B labeling than the neurons on the unstimulated side. The metabotropic antagonist did not block EPSPs but did block the activity-dependent difference in Y10B labeling. These data suggest that glutamate may play a trophic role in the young auditory system through activation of metabotropic glutamate receptors.

POTENTIAL CONTRIBUTIONS TO NEURAL TRANSPLANT SURVIVAL BY REACTIVE HOST ASTROCYTES. J.M. Krum\* and J.M. Rosenstein. The George Washington University Medical Center, Washington, DC 20037.

Neural transplants consisting of solid pieces of fetal neocortex placed within host neocortex or striatum are potential models for fetal hypoxia/ischemia, as transplants do not receive a regulated blood flow for 3 - 10 days. Since relatively short periods of hypoxia/ischemia *in vivo* result in destruction of neuronal elements in neonatal rat brain, a mechanism must exist which allows transplanted neurons to survive the initial post-operative (p.o.) period. The reactive gliosis that occurs adjacent to transplants may enhance the grafts' survival, since astrocytes *in vitro* can increase their levels of anaerobic glycolysis and use their glycogen stores to produce lactate which can be exported for use as a neuronal energy substrate. Astrocytes also metabolize glutamate via glutamine synthetase (GS) to form glutamine, another neuronal energy substrate. The spatial and temporal patterns of glycogen content (GLY), glutamate transporter (GLT 1), and GS expression in astrocytes associated with neocortical transplants were qualitatively determined and compared to GFAP expression. E19 neocortex was placed within the parietal cortex of adult hosts and allowed to survive from 3 days to 4 months. Serial sections from each transplant were processed for either GLY histochemistry, GLT 1, GS or GFAP immunohistochemistry. In the first week, a strong GFAP + astrocytic reaction was localized around the transplants which also exhibited intense GLT 1 and GS immunoreactivity and dense accumulations of GLY. Within the transplant, GLT 1 and GS immunoreactivity was negligible, but GLY + astrocytic processes were present throughout the grafts. Both GS expression and GLY content in the surrounding host tissue gradually decreased after 3 weeks. By 4 months p.o., GS and GLY were no longer distinguishable within the gliotic area. GLT 1 and GS immunoreactivity within the transplants began to increase during the second week p.o., while GLY remained prominent around the vasculature. From the third week on, transplant GS expression increased and was comparable to that of normal cortex by 4 weeks p.o., while GLY content diminished. The temporal and spatial patterns of GLT 1, GS and glycogen suggest that astroglia have the potential to support transplant survival at early postoperative times. Supported by NS-17468.

## 28.2

GRAFTING OF GENETICALLY TRANSDUCED ASTROCYTES INTO ADULT RAT BRAINS: THE HOST RESPONSE TO TRANSPLANTATION S. Ausim Azizi\*, Movement Disorders Center, Dept Neurology, Med College of Pennsylvania and Hahnemann Univ, Philadelphia, PA 19129

Astrocytes, because of their natural properties of migration, integration into the Central Nervous System (CNS), elaboration of trophic factors as well as availability may serve as ideal vehicles for gene transfer into the CNS. Using conventional culture techniques and gentle proteolytic enzymes, Dispase and Collagenase, we obtained primary cultures of astrocytes from adult rats. Astrocyte cultures were transduced using viral and non-viral vectors containing a reporter gene beta-galactosidase. The transduced astrocytes were grafted into the brains of adult rats. *Lac-Z* positive cells could be found in the brains for several weeks after transplantation. Currently, we are in the process of cataloguing the *in vivo* patterns of migration, integration and long term survival of the transduced grafted astrocytes. The host response to grafting in the brain is different from that elsewhere in the body, delineated by a phase of graft success followed by rejection. Our studies suggest that the initial reaction to grafting in the brain is marshaled by the glia; indeed the host astrocytes surround and 'wall-off' the graft in the first 24 hours post-transplantation. This 'gliosis' may have a protective role for the host and the graft, isolating one from the other. This process may initially protect the graft from detection and destruction by the peripheral immune system. We believe that this model has great overall promise for the study of autologous transplantation, the host CNS immune reaction and for *ex vivo* gene therapy. (Supported by The Dept of Neurology, MCPHU)

## 28.3

EFFECT OF NEOCORTICAL TRANSPLANTATION AND ENVIRONMENTAL ENRICHMENT ON HOST BRAIN DEVELOPMENT. J. Jones and A.J. Castro\*  
Department of Cell Biology, Neurobiology and Anatomy, Loyola University Stritch School of Medicine, Maywood, IL 60153.

Plates of presumptive sensorimotor (homotopic) or occipital (heterotopic) neocortex obtained from fetal rats 14-16 days of gestation were grafted into large lesion cavities made immediately prior to grafting in the right sensorimotor cortex of newborn rats. Unoperated normal and lesion only littermates served as controls. Postoperatively, half the litters were raised in standard (Std) home cage conditions and the remaining litters were raised in enriched (Enr) conditions until 5-6 months of age. Body weight, pinna detachment and eye opening were evaluated during rearing to ensure that there were no group differences in general somatic growth. Animals were sacrificed by anesthetic overdose and perfused with 4.0% paraformaldehyde solution. Brains were weighed, post-fixed, frozen and stored at -70°C until serial sectioning at 30µ using a cryostat. Adjacent Nissl and acetylcholinesterase sections were used to measure brain length and cortical thickness. Statistical analyses were made on the brains of Std versus analogous Enr animals using ANOVA and Fisher post-hoc analysis ( $p < 0.05$ ). A statistically significant enrichment induced increase in brain weight was observed in normal animals ( $1.976g \pm 0.034$ ) as well as in animals with homotopic transplants ( $1.927g \pm 0.031$ ) when compared to normal ( $1.834g \pm 0.030$ ) and homotopic ( $1.816 \pm 0.031$ ) Std animals. Brain length, measured by counting the number of sections between the initial crossing of the corpus callosum rostrally and the posterior commissure caudally was also found to be increased in normal and homotopic Enr animals. Dorsal and lateral cerebral cortical thickness, measured bilaterally using NIH Image Software at three levels: rostral to the corpus callosum, at the level of the anterior commissure and at the level of the posterior commissure, showed increases at all levels in normal and homotopic Enr animals. These results indicate that environmental enrichment can promote the growth of host brains receiving homotopic neocortical transplants. Such an effect was not observed in animals with heterotopic transplants. Comparisons of subcortical thalamic area are currently in progress.

Supported by a grant from the American Physical Therapy Association

## 28.5

AGE OF THE TARGET TISSUE INFLUENCES NORADRENERGIC INNERVATION. N. Srivastava\*<sup>1</sup>, G.A. Gerhardt<sup>2,3</sup> and A.C. Granholm<sup>1,3</sup>  
Departments of Basic Science<sup>1</sup>, Psychiatry<sup>2</sup> and Pharmacology<sup>3</sup>, University of Colorado Health Sciences Center, Denver, CO 80262.

The dependency on the age of the target tissue for the regenerative ability of central noradrenergic neurons (NE) was investigated using intraocular double transplants of fetal brainstem tissue together with young (3 weeks) or aged (16 months) iris tissue. Pieces of fetal brainstem tissue (E17), containing locus coeruleus (LC) neurons, and old or young irides from Fischer 344 (F344) rats were transplanted adjacent to each other in the anterior chamber of the eye of 5-6 week old F344 host rats. The double transplants were allowed to mature for 5 weeks, after which the intraocular grafts and the host irides were dissected out and were either frozen for HPLC measurements of NE, or stretch prepared for Falck-Hillarp monoamine histochemistry. All iris transplants from young donors received a dense innervation of noradrenergic fibers from the LC transplant, arranged as single varicose fibers or thick axon bundles. However, a mossy and sparse innervation pattern with few, if any, axon bundles could be seen in the aged iris transplants, as compared to the young. Preliminary studies with HPLC also suggest that NE levels were reduced in aged transplanted irides. These data indicate that the age of the target tissue can influence the fiber outgrowth from young LC neurons supporting, at least in part, the hypothesis that extrinsic factors in the target tissue can influence age-related changes in NE innervation. Supported by USPHS grants MH49661 and AG06434.

INFLUENCE OF CNS ENVIRONMENT ON C-JUN RESPONSE AND MIGRATION OF SCHWANN CELLS. E. Vaudano\*<sup>1</sup>, B. Finsen<sup>2</sup> and A. Björklund<sup>1</sup> Wallenberg Neurocenter, S-22362, Lund, Sweden and <sup>2</sup>Dept. Anatomy, Odense University, 5000 Odense C, Denmark.

Schwann cells (SCs) transplanted into the brain promote regeneration of CNS axons, although this regeneration is always limited when compared with PNS regeneration. SCs "activated" following denervation, or grown in vitro, express high levels of the transcription factor c-jun, while c-jun is rapidly downregulated in SCs implanted into the intact brain. This might be due either to the presence in the CNS of an active inhibitor of c-jun expression, or to the lack of factors necessary to maintain the c-jun response. After PNS injury there is a massive invasion of the lesioned nerve by macrophages which secrete interleukin 1 which induces c-jun expression. The lesion inflicted on the CNS by the transplantation of SCs is followed by a much more limited macrophage reaction, which in itself may be inadequate to maintain c-jun expression. The intensity of the reaction of brain macrophages can be enhanced by lesioning the target brain area prior to grafting. We implanted standard primary SCs, or SCs labelled by retroviral infection with the Lac-Z gene, either into the intact adult rat striatum, or into the striatum previously lesioned either with a) the excitotoxin quinolinic acid or b) with 6OHDA. We found maintenance of c-jun expression in SCs implanted into the excitotoxin lesioned striatum, which also displayed an intense brain macrophage and glial reaction, compared with a very limited c-jun response in the SCs implanted into the intact, or 6OHDA lesioned striatum (where the microglial responses were much weaker). We also found extensive migration (and possibly proliferation) of SCs transplanted in the excitotoxin lesioned striatum, compared to a limited migration in the intact, or 6OHDA lesioned striatum. Thus glial cell reactions, and the brain macrophage reaction in particular, may play a critical role in regulating the c-jun response as well as the migration (and possibly survival and/or proliferation) of SCs implanted into the brain. This work was supported by the Wellcome Trust.

INTEGRATION OF MOUSE POSTNATAL HIPPOCAMPAL PROGENITOR CELLS GRAFTED ONTO ORGANOTYPIC HIPPOCAMPAL SLICES. K. Bulsara\*, M.T. Austin, A.K. Shetty, Y.D. Phillips and D.A. Turner. Neurosurgery, Neurobiology, Duke Univ. Med. Ctr., VAMC, Durham, NC 27710.

We hypothesize that uncommitted neuronal progenitor cells will show enhanced migration and neuronal differentiation when grafted into an *in vitro* host after a lesion. We grafted EGF-derived progenitor neurospheres cultured from neonatal mouse hippocampi into normal and kainic acid (KA)-treated rat organotypic hippocampal slice cultures. We assessed migration daily using Dil labeling to measure cell outgrowth (confirmed using M6 anti-mouse antibody) and differentiation using MAP-2 antibody.

Neonatal mouse hippocampus was cultured in EGF using methods described by Svendsen et al. (1995). Following 7 days *in vitro* and 7 days post-passaging, numerous free-floating neurospheres were obtained. Organotypic hippocampal slices from postnatal rats (P10) were prepared (Stoppini et al, 1991), with preservation of principal hippocampal cell layers. Slice cultures exposed to 3 µM KA for 14 hr demonstrated selective loss of the CA3 pyramidal cell layer. Hippocampal neurospheres were explanted onto the surface of the hippocampal slice in the CA3 st. radiatum region. These explants onto both normal and KA-treated hippocampal slices demonstrated good cell survival. Migration was measured as the surface area of the graft (assessed by phase contrast, Dil and M6). The neurosphere grafts (n=5 in each group) showed initially a small area (control =  $0.045 \pm 0.008$  mm<sup>2</sup>; KA-treated =  $0.032 \pm 0.006$  mm<sup>2</sup>; NS) but enlargement by day 4 (control =  $0.7 \pm 0.22$  mm<sup>2</sup>; KA-treated =  $0.49 \pm 0.13$  mm<sup>2</sup>; NS), occupying most of the CA3 region of the slice cultures. Only a few MAP-2 positive cells were noted in the neurosphere grafts in control or KA-treated slices.

These initial results suggest that the KA lesion *in vitro* does not lead to enhanced dispersion or differentiation of progenitor cells beyond that already provided by the control slice culture environment. Thus, additional undefined factors may be critical to achieve enhanced neuronal differentiation. Supported by NIA AG13165, VAMC.

CONDITIONALLY IMMORTALIZED NEURAL PROGENITOR CELLS GRAFTED TO THE STRIATUM EXHIBIT SITE-SPECIFIC NEURONAL DIFFERENTIATION AND ESTABLISH CONNECTIONS WITH THE HOST GLOBUS PALLIDUS. C. Lundberg\*, C. Winkler, S.R. Whittlemore and A. Björklund.

Wallenberg Neuroscience Center, Dept. Physiol. and Neurosci., University of Lund, Sölvegatan 17, 223 62 Lund, Sweden# The Miami Project and Dept of Neurological Surgery, University of Miami School of Medicine, Miami FL 33136

The cell line RN33B has been reported to differentiate into neurons in a site-specific manner when grafted to the cortex and hippocampus of adult rats (Onifer et al, 1993, Exp.Neurol. 22:130, Shihabuddin et al, 1995, J. Neurosci. 15:6666). To investigate the fate of RN33B cells in a sub-cortical structure, we grafted RN33B cells into the intact or excitotoxically lesioned striatum of adult or neonatal rats. The total number and phenotypic characteristics of the <sup>3</sup>H-thy labeled grafted cells were analysed, by combined autoradiography and immunohistochemistry, at different time-points after transplantation. Transplanted RN33B cells were found to survive, integrate and differentiate into both neurons and astrocytes, and a significant proportion of the cells (approx. 10%) were found to differentiate into cells with morphological and phenotypic characteristics of medium-sized striatal projection neurons, as defined by their expression of the striatum-specific proteins DARPP-32 and STEP. Retrograde tracing, using Fluoro-Gold, showed that at least some of the graft-derived neurons were capable of establishing connections with one of the primary striatal targets, the globus pallidus. These findings demonstrate a remarkable capacity of the RN33B cells for site-specific neuronal differentiation in both the adult and developing striatum and suggest that the same differentiating factors that are operating during normal neurogenesis in brain development are retained, at least to some extent, also in the adult CNS. ## 28.8

INTEGRATION AND DIFFERENTIATION OF EGF-RESPONSIVE NEURAL PROGENITOR CELLS AFTER TRANSPLANTATION INTO THE DEVELOPING RAT BRAIN IS INDEPENDENT OF CELLULAR ORIGIN. C. Winkler\*, R.A. Fricker and A. Björklund. Lund University, Wallenberg Neuroscience Center, Sölvegatan 17, S-223 62 Lund, Sweden.

In this study the pattern of migration and differentiation of neural progenitor cells after transplantation into the neonatal or embryonic rat brain was determined. Cells derived from striatum, cortex and ventral mesencephalon (VM) of E14 mice were cultured in serum free medium containing EGF. The arising spheres of progenitor cells were triturated to single cell suspensions and re-seeded every week for 4 weeks. Small spheres derived from striatum, cortex or VM were transplanted into the ventricle of E15 rats. Cells derived from both striatum and VM were transplanted into striatum and midbrain of neonatal rats. Four weeks post-transplantation donor cells were visualized by mouse specific glial and neuronal antibodies and by *in situ* hybridization to mouse satellite DNA.

Following embryonic transplantation cells from either origin showed a similar pattern of integration and differentiation with many glial cells and neurons in midbrain, hippocampus and thalamus, fewer in cortex, hypothalamus and olfactory bulb and no integration in striatum or septum.

Following neonatal transplantation cells derived from striatum or VM behaved in a similar way. Thus, after intrastriatal transplantation cells migrated in the striatum and differentiated into glial and neuronal cells, partially expressing striatal phenotype and appropriate connections, while after transplantation into the midbrain cells from either origin were almost exclusively observed in the substantia nigra. We conclude that EGF-responsive progenitor cells behave as multipotent neural progenitors after transplantation to the developing brain, expressing features that appear to depend on local environmental cues rather than the subregion of the brain from which the cells are derived.

## 28.9

**EGF-RESPONSIVE NEURAL PRECURSOR CELLS ENGRAFT AND DIFFERENTIATE IN LESIONED ADULT BRAIN.** P. Zlomanczuk, L.D. Recht, P.J. Quesenberry, W.J. Schwartz\*. Dept. Neurol. & Cancer Center, Univ. Mass. Med. Sch., Worcester, MA 01655

Several laboratories have implanted neural progenitor or stem-like cells into brain, mostly in regions still undergoing neurogenesis. Recently, Svendsen et al. (Exp. Neurol. 137: 376) reported engraftment of EGF-responsive stem-like cells into lesioned adult rat striatum. However, further analysis was confounded by difficulties in labeling the donor cells, and no colocalization data could be obtained.

We have been using EGF-responsive cells derived from striatal/subventricular zone of embryonic mice bearing a promoter trap insertion of a  $\beta$ -galactosidase reporter gene (Rosa 26). Cells were propagated in serum-free DMEM/F12 medium with 20ng/ml EGF, and 2 $\mu$ l of single cell suspension (80,000-100,000 cells/ $\mu$ l) were implanted into electrolytic lesions of adult mouse hypothalamus. Brains were processed for X-gal histochemistry and immunocytochemistry 4 or 30 days after implantation. Initially, cells formed grape-like clusters at the injection site. By 30 days transplanted cells had developed into morphologically distinct structures, either as thin layers surrounding the lesion cavity, dense cellular nodules or multicellular filaments bridging the lumen of lesion cavity. Immunoreactivity for S-100 and GFAP was clearly colocalized to X-gal positive cells at 30 days, but no colocalization was observed at 4 days. Control injections of Rosa 26 hematopoietic stem cells or EGF-responsive neural stem cells without  $\beta$ -galactosidase reporter gene did not yield X-gal positivity. Abundant macrophages in the lesion cavity showed no X-gal reaction product in any of the implantations.

Our results show that transplanted cells differentiate in adult host brain, primarily into glia. Rosa 26 transgenic mice are a source for reliably-marked donor cells for neural transplantation. (Supported by UMass Cancer Center, Worcester, MA).

## 28.11

**PROGENY OF LONG-TERM MOUSE AND HUMAN CNS STEM CELL CULTURES SURVIVE TRANSPLANTATION AND DIFFERENTIATE INTO NEURONS AND GLIA.** Laurie L. Borg, Angelo L. Vescovi, Karen Blöte, Ann L. Kyle, Paula Hettiaratchi, Brent A. Reynolds, Lori A. Mudrick-Donnon\*, NeuroSpheres Ltd., 3330 Hospital Dr. N.W., Calgary, AB, T2N 4N1 CANADA.

CNS stem cells maintained *in vitro* will continue to divide indefinitely under appropriate conditions and, therefore, may provide an attractive cell source for transplantation therapy. In the present study CNS stem cells were isolated from embryonic mouse and human subependyma and put into primary culture. Cells proliferated to produce clusters of cells or "neurospheres" that were passaged every 7-10 days, 3-4 times (mouse) or 11-35 times (human) prior to transplantation. BrdU was added to the media 16 hr (mouse) or 10 days (human) prior to transplantation and incorporated into the DNA of cells undergoing cell division. For transplantation, cells were washed, dissociated, and resuspended to a final density of 10-50 X 10<sup>6</sup> cells/ml. Aliquots (1-3 ml) of suspension were injected into various CNS regions of nonlesioned adult mouse or rat hosts or to the striatum of Parkinsonian and Huntingtonian rat hosts. After a survival time of 1 week to 12 months anatomical analyses were undertaken to assess survival, differentiation, and migration of the stem cell progeny. Cell survival was estimated from the total number of BrdU-immunoreactive cells and ranged from 2-10% (mouse) and 10-35% (human). With time, transplanted cells moved away from the injection tract in a radial fashion and extended 0.5-1.5 mm mediolaterally and rostrocaudally. Double immunostaining techniques using antibodies to BrdU and antibodies toNSE or Human Neurofilament (proteins found in neurons), or GFAP (an astrocytic protein) demonstrated that the transplanted stem cell progeny underwent migration and differentiated into both neurons and astrocytes. The specific phenotype of the differentiated neurons is now under investigation.

## 28.13

**LONG TERM CULTURE AND CHARACTERIZATION OF NORMAL HUMAN FETAL SPINAL CORD CELLS.** E.A. Zompa\*, M.P. Moyer, L. Cain and C.E. Hulsebosch. Anat. & Neurosci., Univ. of Texas Med. Br., Galveston, TX 77555 and Cell & Gene Therapy Inst., UTHSC, San Antonio, TX 78258

The use of cultured fetal cells as a source for replacement neurons, growth factors, and glial cells to restore function after spinal cord injury is promising; however, maintaining normal cells in culture for any length of time is difficult. We report the long term culture and phenotypic analysis of normal human fetal spinal cord cells cultured in M3:5 medium (InCell Corp., San Antonio, TX) for longer than 2 years. No other media we have tested has permitted this long term propagation. The cells have been categorized with respect to morphology, neuronal and glial specific markers, transmitters and receptors. Preliminary results indicate that a population of precursor or stem cells is maintained, with the ability to differentiate into neuronal cells or proliferate for the duration of the period in culture. A minimum of five different morphological types are present. These have continued to replicate after 75 or more passages. Many of the neuronal-like cells extend processes as long as 3cm to target cells and form intricate networks in culture. The cells survive enzymatic treatment with trypsin upon subculture, often reforming aggregates of neuronal-like cells which then extend numerous and long processes. The cells have been characterized for the expression of embryonic markers Vimentin and Chromogranin A, neuronal markers NF68, NF200, NSE, transmitters GABA and acetylcholine, glutamate receptor subunits GluR 2/3, NMDAR subunits R1 and R2 and glial markers GFAP, and GalC in the cultured cells. Preliminary data indicate that subpopulations of the cells differentiate into these various lineages, but perhaps more importantly a stable population of precursor cells is maintained. (Supported by Kent Waldrep National Paralysis Foundation and NS 11255.)

## 28.10

**EXPRESSION OF TH-IMMUNOREACTIVITY IN LONG-TERM NON-PASSAGE EGF-RESPONSIVE NEUROSPHERES** Y.H. Chiang\* and F.C. Zhou, Program of Medical Neurobiology and Department of Anatomy, Indiana Univ. Sch. Med., Indiana, IN 46202

The epidermal growth factor (EGF)-responsive neurospheres procured from rat fetal brain tissue are able to differentiate into neurons and glia in the absence of EGF. The differentiation fate of these cell can be affected by exogenous factors (Chiang, Silani and Zhou, 1996). However, there is little available data about the differentiation of dopamine neurons. Here, we present the expression of tyrosine hydroxylase immunoreactivity (TH-im) among long-term nonpassage neurosphere cells *in vitro* and *in vivo*.

Mesencephalon of gestational day 14 (E-14) rat or mouse fetuses were collected and dissociated into single cells. The single cells were cultured in DMEM/F12 containing N2 supplement and EGF (20 ng/ml). After 3 to 9 months in culture, rat neurospheres were subplated onto 16-well chamber slides with Neurobasal medium and 2% fetal calf serum and were given 14 days to differentiate. Exogenous factors including bFGF (20 ng/ml), GDNF (1 ng/ml & 10 ng/ml), retinol (10  $\mu$ M), ibotenic acid primed striatal soup and fetal brain tissue extracts were tested to increase TH-im expression, respectively. Another group of neurospheres obtained from either E-14 rat or mouse fetal mesencephalon were collected and transplanted into either the 6-OHDA lesioned striatum of adult rats or normal striatum of adult mouse. Animals were sacrificed 2 months after transplant and the striatum was sectioned. The cultured cells and tissue sections were examined by TH immunocytochemistry.

The frequency of neurospheres that gave rise to TH-im positive neurons was about 6% (72/1200 neurospheres). Of these neurospheres, the TH-im neurons were about 504 cells/mm<sup>2</sup> (24% of total cells) in the area surrounding the neurosphere (about 1 mm wide) which had a higher population of neurons and other cells. However, the exogenous factors failed to increase the frequency of neurospheres giving rise to the TH-im cells. A low population of TH-im cells was identified outside of grafts among neurospheres transplanted into either 6-OHDA adult rat striatum or the normal mouse striatum. These cells had TH-im soma as well as TH-im neurites. Taken together, these results suggest that neurons derived from long-term nonpassage neurospheres are capable of receiving signals and differentiating into TH-im neurons. (PIRC 22-821-0)

## 28.12

**ULTRASTRUCTURE OF GRAFT- OR HOST-DERIVED 5-HT INNERVATIONS IN VENTRAL MESENCEPHALIC GRAFTS IMPLANTED INTO THE ADULT OR NEWBORN RAT STRIATUM.** H. Moukhles\*, M. Geffard and G. Doucet. Département de pathologie and Centre de recherche en sci. neurol., Université de Montréal, Montréal, Qc, Canada.

The majority of serotonin (5-HT) neurons innervating the substantia nigra also send collaterals to the neostriatum (Van der Kooy and Hattori, Brain Res 186: 1, 1980). Nevertheless, the 5-HT innervation is entirely synaptic in the substantia nigra pars reticulata (Moukhles et al, Submitted) while almost asynaptic in the neostriatum (Soghomonian et al, Brain Res 481: 67, 1989), suggesting an influence of the cellular environment on the formation of 5-HT synapses. To test the possibility of an epigenetic control on 5-HT synaptology, we prepared intrastriatal grafts of ventral mesencephalic tissue, either devoid of 5-HT neurons in newborn rats or containing small numbers of 5-HT neurons in adult rats. The former grafts are innervated by 5-HT neurons of the host whereas the latter are innervated only by the co-grafted 5-HT neurons (Mounir et al, Eur J Neurosci 6: 1307, 1994). Ultrastructural analyses were performed 6-8 months later on single ultrathin sections, following pre-embedding immunolabeling using a monoclonal antibody against a 5-HT-glutaraldehyde-protein conjugate. The morphometric data show that 5-HT varicosities are highly comparable in the two types of grafts to those of the host neostriatum and that only few established synaptic specializations. These results demonstrate that the synaptic incidence of the 5-HT innervation of the grafts is much lower (8-30%) than the one determined in the normal substantia nigra and plead against an epigenetic control of 5-HT synaptogenesis. Alternatively, the ventral mesencephalic grafts might not provide the "factors" normally promoting the formation of 5-HT synapses in the substantia nigra. Supported by MRC grant MT10982, an MRC fellowship to H.M. and FRSQ scholarship to G.D.

## 28.14

**THY-1 ALLELIC DIFFERENCES: A POWERFUL TOOL FOR REVEALING RECIPROCAL FIBER PENETRATION AND NEURON MIGRATION IN NEURAL TRANSPLANTATION.** K.R. Hendricks\*, R.C. Wilson, J.N. Kott and L.E. Westrum, Dept. of Neuro. Surgery, U. of Washington, Seattle, WA 98195.

The functional significance of neural transplants is directly related to their ability to integrate with host brain. Thus, the ability to identify and delineate neurons and processes as to host versus donor origin is essential. The membrane glycoprotein Thy-1 is an ideal marker since it is present at high density on almost all neurons (except olfactory nerve) and it exists in two immunologically distinct forms in mice. In this experiment, neonatal, Thy-1.1 mouse pups have had one olfactory bulb ablated and immediately replaced with a Thy-1.2, fetal, donor olfactory bulb. Results from the present experiment show: 1) inter-strain transplants are viable; 2) host olfactory nerve (via olfactory marker protein labeling) penetrates into donor tissue, entering glomerulus-like structures that are also penetrated by donor processes; 3) donor fibers are able to penetrate appropriate (olfactory peduncle and olfactory cortex) and novel (subependymal cell layer and rostral frontal cortex) areas of brain; 4) host fibers from the forebrain penetrate into the transplant and 5) host neurons can migrate into transplant tissue and remain viable. Our previous reports using traditional tract-tracing methods have demonstrated donor-host fiber integration in rats but only of selected fiber pathways. This experiment shows the robustness of host and donor fiber integration along with demonstrating, for the first time, that host neurons are able to migrate into donor olfactory bulbs.

## 29.1

CULTURED CELLS FROM THE CLEARNOSE SKATE, RAJA EGLANTERIA, R. M. Gould\* and C. A. Luger, N.Y.S. Inst. For Basic Res., Staten Island, NY and Mote Marine Lab, Sarasota, FL

The nervous systems of all gnathostomes, from cartilaginous fishes to humans have their origins in a common ancestor, all are well myelinated by oligodendrocytes in the CNS and Schwann cells in the PNS. Though highly similar at the structural and ultrastructural level, CNS myelin of fishes is biochemically different from mammals. The major protein in fishes is related to P<sub>0</sub>, the dominant protein in mammalian PNS myelin, and not proteolipid protein, the major protein in mammalian CNS myelin. Other biochemical differences have been noted. Whereas mammalian oligodendrocytes in culture differentiation from highly motile, proliferating O-2A progenitors (A2B5+) to cells that extend multiple processes and elaborate membrane sheets (they express myelin lipids and proteins), neural cells present in skate and spiny dogfish (Glia (1995) 15:401) cultures, which grow in standard mammalian medium supplemented to 1000 mOsm with urea, glucose, sodium chloride sucrose and HEPES, remain as A2B5+, HNK-1+ progenitors. Currently we are growing cells from 4, 5 and 6 week skate embryos in three different media supplemented with fetal calf or horse serum (2-10%). To see if these cells will differentiate in culture, we plan to grow these cells in chemically defined medium, to purify O-2A cells using the shake-off procedure of McCarthy and DeVellis (J. Cell Biol (1980) 85:890), and add gangliosides and forskolin to the medium. Markers that will be used to characterize possible differentiation stages in culture have been characterized using frozen sections of skate embryo spinal cord. These studies will hopefully resolve the issue whether or not the ability to differentiate in culture is another difference between fish and mammalian oligodendrocytes.

## 29.3

**Perisynaptic Glia at Frog Neuromuscular Synapses Express Schwann Cell Marker Protein Zero (P<sub>0</sub>), but Not Myelin Proteins.** J. Georgiou\*, and M.P. Charlton. Department of Physiology, University of Toronto, Toronto, Canada, M5S 1A8.

Neuromuscular synapses are enveloped by perisynaptic Schwann cells (PSCs) which do not make myelin wrappings. These specialized glial cells have properties similar to astrocytes in the CNS. For instance, they express neurotransmitter receptors and respond to nerve-evoked activity with changes in [Ca<sup>2+</sup>]<sub>i</sub>. Since the physiology of PSCs differs from myelinating Schwann cells (MSCs) surrounding motor nerves, we wondered whether these two cell types have similar origins.

Using immunocytochemistry and monoclonal antibodies to galactocerebroside and myelin-associated glycoprotein, we found that MSCs expressed both of these myelin proteins, but PSCs had neither.

We next used monoclonal antibody 1E8 to ask whether PSCs expressed the glycoprotein P<sub>0</sub>, which is expressed on all Schwann cell types, including non-myelinating Schwann cells, MSCs, and Schwann cell precursors (Bhattacharya et al., 1991; Neuron 7, 831). We detected 1E8 immunoreactivity on both MSCs and PSCs.

We conclude that PSCs belong to the Schwann cell lineage, but their lack of myelin protein expression indicates they are biochemically similar to non-myelinating Schwann cells. We speculate that factors released by the nerve terminal may block expression of the myelinating phenotype.

Supported by grants to M.P.C. from NeuroScience Network and MRC of Canada, and a NeuroScience Network scholarship to J.G.

## 29.5

**EXPRESSION OF PROTEOLIPID PROTEIN AND A PLP-LacZ TRANSGENE IN MOUSE SCIATIC NERVE.** C.S. Duchala\*, H. Jiang\*, M. Shy\*, S. Scherer\* and W.B. Macklin\*. \* Dept. Neurosciences, The Cleveland Clinic Foundation, Cleveland, OH 44195. \* Dept. Neurology, Wayne State Univ., Detroit, MI 48201. \* Dept. Neurology, Univ. Of Penn., Philadelphia, PA 19104.

Proteolipid protein (PLP) is the major myelin protein in the central nervous system and is also expressed by Schwann cells (SC) in the peripheral nervous system (PNS). PNS PLP is not thought to be incorporated into compact myelin and its expression has not appeared to be regulated like other myelin specific genes. We examined PLP expression in the PNS using a PLP-LacZ transgenic mouse (Wight et al., J. Cell Biol., 1993). X-gal histochemistry of adult sciatic nerves revealed  $\beta$ -gal expression predominantly in myelinating SC. When sciatic nerves were transected, with resultant degeneration of their axons and myelin sheath (Wallerian degeneration) PLP and  $\beta$ -gal decreased dramatically when analyzed by Western blot, X-gal staining and Northern blot. When the nerves were crushed, to permit axonal regeneration following axonal degeneration, regenerating axons re-induced  $\beta$ -gal expression in previously denervated SC. Finally, developing sciatic nerves demonstrated increasing PLP and  $\beta$ -gal expression between postnatal days 7 (the earliest day examined) and 21. Taken together, these results suggest that, contrary to our previous beliefs, PLP expression in the PNS is being regulated by axons as part of a coordinated program of myelin gene expression that includes myelin proteins P<sub>0</sub>, MBP and PMP-22. Ultrastructural studies to more precisely localize PLP with respect to PNS myelin, are currently underway. Supported by NS25304.

## 29.2

The myelin gene P<sub>0</sub> is expressed in a subgroup of neural crest cells, and is respectively down- and up-regulated during the development of non-myelin and myelin-forming Schwann cells. M.-J. Lee, A. Brennan, A. Tabernero, A. Blanchard, G. Zoidl, J. S. Altman\*, K. R. Jessen and R. Mistry. Department of Anatomy and Developmental Biology, University College London, Gower Street, London WC1E 6BT

The expression of the myelin protein P<sub>0</sub> was examined in the rat Schwann cell lineage using in situ hybridisation and immunohistochemical methods adjusted to higher sensitivity than needed to detect the exceptionally high levels of P<sub>0</sub> in myelinating cells in vivo. This reveals unambiguous P<sub>0</sub> mRNA expression in migrating neural crest cells, Schwann cell precursors from embryo day 14 (E14) nerves, and embryonic Schwann cells. Although 95% of cells in this nerve remain non-myelin-forming in the adult, the Schwann cells in the E18 sympathetic trunk are P<sub>0</sub> positive using this adjusted method, and the level is much the same as most pre-myelinating Schwann cells in E18 satic nerves. Transecting the sciatic nerve at birth does not alter this basal P<sub>0</sub> expression in nerves observed two days later (postnatal day 2). In contrast, it abolishes the strikingly high P<sub>0</sub> mRNA and protein seen in cells forming myelin sheaths in the contralateral control nerves. Furthermore, non-myelin-forming cells in adult nerves fail to show the basal P<sub>0</sub> levels, indicating P<sub>0</sub> expression has been suppressed in these cells. In this case, nerve transection results in up-regulation of P<sub>0</sub> mRNA expression in the denervated non-myelin-forming cells.

We conclude that the postnatal diversification of immature Schwann cells to form myelin-forming and non-myelin-forming cells involves axon-dependent amplification and suppression, respectively, of myelin-independent P<sub>0</sub> expression. In the Schwann cell lineage, this basal expression is an early phenotype that is likely to appear as one of the first signals of glial lineage choice in neural crest development.

## 29.4

**TOPOLOGY AND RELATIONSHIP BETWEEN CELLULAR LOCALIZATION AND FUNCTION OF THE PERIPHERAL MYELIN PROTEIN 22.** D. D'Urso\* and H.W. Müller. Molecular Neurobiology Lab., Dept. of Neurology, University of Düsseldorf, 40225, Germany

It has been suggested that the peripheral myelin protein PMP22 plays a role in the formation and maintenance of myelin in the PNS and in the regulation of cell growth. Immunohistochemistry and in situ hybridization studies have shown that PMP22 is largely synthesized by Schwann cells and mainly localized in compact myelin. Based on the amino acid sequence and computer analysis, the predicted disposition of PMP22 with respect to the membrane bilayer postulates the existence of three distinct hydrophilic loops and four transmembrane domains. Different mutations in the coding region of the PMP22 gene are associated with common inherited peripheral neuropathies in mice (Trembler and Trembler J) and humans (CMT1a, HNPP, DS). Whether the mutant proteins, which are probably misfolded, are correctly transported and targeted to the plasmamembrane is unknown, and it remains to be determined what cellular mechanisms affect myelination. We investigated the folding and sorting of wild type and mutant forms of PMP22 as well as its membrane topology. We inserted an octapeptide tag sequence at the N-terminus or the C-terminus of the PMP22 open reading frame and generated different chimeric constructs which were then transfected into HeLa or rat Schwann cells. The expression of the tagged PMP22 proteins was analyzed using antibodies directed against specific PMP22 epitope and the tag sequence. Cellular localization and membrane topology was examined by immunofluorescence and confocal microscopy. PMP22 interactions with other peripheral myelin proteins, using the same experimental paradigm will be also discussed. Supported by DFG (Mu 630 5-3).

## 29.6

**IN VITRO CHARACTERISATION OF HUMAN SCHWANN CELLS FROM CHARCOT MARIE TOOTH PATIENTS.** C. Rosenbaum, S. Kupfer, S. Wosch, C.O. Hanemann\*, H.W. Müller. Mol. Neurobiology Lab., Dept. of Neurology, University of Düsseldorf, 40225 Düsseldorf, Germany

Charcot Marie Tooth neuropathy is a frequent (1/2500) hereditary demyelinating neuropathy. The vast majority of patients (CMT1A) shows a PMP22 gene duplication, whereas in a few cases PMP22 point mutations have been described. PMP22 is a myelin protein produced in Schwann cells and is homologous to the growth arrest specific gene gas3. PMP22 expression levels seem to be increased in the disease and might be responsible for abnormal Schwann cell growth in CMT1A. We analysed the Schwann cell phenotype in different stages of CMT1A neuropathy and found a pathological expression of LING-R and NCAM in early and late stages (onion bulbs) of the disease. These results suggest that abnormal PMP22 expression alters the differentiation status of Schwann cells.

To elucidate if the altered Schwann cell phenotype is primarily due to PMP22 gene duplication or is secondarily changed during the disease process we established a modified method for culturing human Schwann cells isolated from sural nerve preparations of CMT1A patients and control nerves from multiorgan donors. We are able to grow Schwann cells up to the 7th passage with high proliferation rates and decreased numbers of fibroblasts (around 2%). Schwann cells from CMT1A patients show a significantly lower proliferation rate than control Schwann cells. Currently, we investigate the expression of PMP22 in cultured human Schwann cells from CMT1A and control nerves. In addition, we performed an extensive study on the expression of several Schwann cells markers under different growth conditions in order to compare the CMT1A Schwann cell phenotype to control cells in culture.

**PROCESSING AND RAPID DEGRADATION OF PERIPHERAL MYELIN PROTEIN-22.** S. Pareek<sup>1</sup>, L. Notterpek<sup>2</sup>, G. J. Snipes<sup>3</sup>, R. Naef<sup>4</sup>, W. Sossin<sup>1</sup>, J. Laliberté<sup>5</sup>, S. Iacampo<sup>1</sup>, U. Suter<sup>6</sup>, E. M. Shooter<sup>7</sup>, and R. A. Murphy<sup>1</sup>.  
<sup>1</sup>Montreal Neurol. Inst., McGill Univ., Montreal, Quebec, Canada, <sup>2</sup>Dept. of Neurobiol., Stanford Univ. School of Medicine, Stanford, California, and <sup>3</sup>Inst. of Cell Biol., Swiss Federal Inst. of Tech., ETH-Hönggerberg, Zürich, Switzerland.

We have studied the biosynthesis of peripheral myelin protein-22 (PMP22) in cultured Schwann cells, myelinating co-cultures of Schwann cells and neurons, and in sciatic nerve explants. Metabolic labelling and pulse chase studies indicate that most of the newly synthesized PMP22 is rapidly turned-over within the cell and does not become translocated to the cell membrane. A small fraction of PMP22 is complex glycosylated and is localized within the Golgi compartment. Similarly, in myelinating co-cultures of Schwann cells and neurons and in sciatic nerve explants *ex-vivo*, most of the newly synthesized PMP22, as measured by short term radiolabelling, is rapidly degraded. Long-term labelling studies show an accumulation of endoglycosidase H resistant PMP22 in Schwann cells alone or when combined with neurons. Furthermore, in long term myelinating co-cultures, PMP22 is localized in the Schwann cell membrane and in myelin. Taken together, the data suggest that most of the PMP22 produced by Schwann cells in culture, in the presence or absence of neurons, and in *ex vivo* sciatic nerve explants is rapidly degraded within the cell. In myelinating co-cultures, only a small fraction of the newly synthesized protein is transferred to the cell membrane where it is incorporated into myelin. These results suggest that during myelination, signals from neurons promote the trafficking, insertion, or stability of PMP22 in myelin, but do not alter the rapid rate of PMP22 turnover within Schwann cells.

**INITIAL SHEATH LENGTHS ALONG DEVELOPING RAT PNS AND CNS AXONS** C. Bjartmar\* and C. Hildebrand, Dept of Cell Biology, Faculty of Health Sciences, University of Linköping, Sweden.

In myelinated axons, nodal spacing, i.e. sheath length, is a parameter of functional importance. One of the determinants of nodal spacing is the initial sheath length at onset of myelination. The present study examines the lengths of newly formed sheaths along prospective myelinated rat PNS and CNS axons. Developing axons in the ventral root L5, the spinal cord ventral funiculus and the corpus callosum were subjected to serial section EM analysis. On the average, uncompacted Schwann cell sheaths were about 50 µm long, while partly compacted sheaths were some 70 µm long. The corresponding adult sheaths are 1250 µm long. Thus, these Schwann cell sheaths exhibit a developmental elongation of 17 times. The roots elongate 11 times only. This necessitates a myelin sheath remodelling. In developing white matter, many uncompacted sheaths were < 10 µm long. In the spinal cord, the average uncompacted and partly compacted sheath was 21 and 102 µm long respectively. The corresponding callosal lengths were 33 and 69 µm. Since the unmyelinated/ensheathed axon length ratio is too low to accommodate the calculated developmental sheath elongation, early white matter sheaths must undergo a remodelling. Finally, we found that the individual early myelinating PNS or CNS axon present is myelinated at some levels but unmyelinated at other levels. These data show that initial sheath length is markedly different in the PNS and the CNS, and that both sheath types undergo an early remodelling. Supported by SMRC grant 3761.

**VITRONECTIN IS ASSOCIATED WITH MYELIN SHEATHS IN THE ADULT RAT BRAIN.** S. Einheber<sup>1</sup>, T. A. Milner<sup>2</sup>, K.T. Preissner<sup>3</sup> and J. L. Salzer<sup>1,2</sup>. Depts. of <sup>1</sup>Cell Biology and <sup>2</sup>Neurology, New York Univ. School of Med., New York, NY 10016, <sup>3</sup>Dept. of Neurology and Neuroscience, Cornell Univ. Med. Coll., New York, NY 10021. <sup>4</sup>Haemostasis Research Unit, Kerckhoff-Klinik, Max-Planck-Inst., Bad Nauheim, Germany.

Oligodendrocytes ensheath and myelinate axons in the absence of a surrounding basal lamina. However, *in vitro* studies suggest that extracellular matrix (ECM) components, such as fibronectin and vitronectin (Vn) promote oligodendrocyte adhesion (Cardwell and Rome, J. Cell Biol. 107:1541-1549, 1988). Recently, integrin receptors for Vn were identified in cultured oligodendrocytes, further implicating this ECM protein in oligodendrocyte function (Milner and French-Constant, Development. 120:3497-3506, 1994). Vn is a multifunctional protein that promotes cell spreading and migration, modulates pericellular proteolysis and inhibits complement mediated cell lysis. In this study, we demonstrate that Vn is closely associated with myelin-forming oligodendrocytes *in vivo*. Vn immunoreactivity was localized in acrolein-fixed sections from adult rat brain using an affinity-purified polyclonal antibody against mouse Vn. By light microscopy, moderate Vn immunoreactivity was observed in bundles of myelinated axons in several fiber tracts, including the corpus callosum, internal capsule and ventral hippocampal commissure. At the ultrastructural level, Vn immunoreactivity was associated with the outer surfaces of myelinated axons as well as some unmyelinated axons. In addition, intracellular immunoreactivity was commonly observed in glial cells adjacent to immunolabeled myelin sheaths. The identity of these cells and their possible role in secreting Vn in the fiber tracts is currently under investigation. These results provide further evidence that Vn may influence oligodendrocyte function *in vivo* and provide a foundation for future studies focused on potential interactions between myelin-associated Vn and the immune system. ## 29.8

**INSULIN-LIKE GROWTH FACTOR-I (IGF-I) PROMOTES MYELINATION IN NEURONS.** J.W. Russell\*, H.-L. Cheng and E.L. Feldman. Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor, MI 48109.

IGF-I is an important neuronal mitogen and is able to promote the formation of adult, myelin forming oligodendrocytes in the central nervous system. Although IGF-I is produced by Schwann cells, the effect of IGF-I on peripheral neuronal myelination has not been previously established. E15 dissociated rat dorsal root ganglion neurons (DRG) were cultured in serum free defined medium (SFD) containing selenium, transferrin, hydrocortisone,  $\beta$ -Estradiol, glutamate, ascorbic acid, glucose, and 10 ng/ml 2.5S NGF to promote neuronal growth. DRG neuronal myelination was measured in SFD alone or with one of the following additions: 5% calf serum, 5-10 nM IGF-I, IGF-I + 1 mM 8-bromo cAMP, forskolin, or dibutyryl cAMP. Differentiating Schwann cells were photographed during development. At 21 d the cultures were fixed and stained with 2% osmium and Sudan black and the number of fully myelinated fibers/ $\mu\text{m}^2$  was measured in each sample by a blinded observer using a random order measuring system. Within 72 h, both cAMP and IGF-I promoted Schwann cell differentiation into mature forms which lined up and then formed a sheath along the growing axon. Neuronal survival at 21 days was increased in the following order IGF-I > serum treated > cAMP > SFD. IGF-I promoted myelination of the DRG neurons, however, the number of myelinated fibres was reduced by 32% compared to serum treated neurons ( $p < 0.01$ ). Myelination did not occur in DRG cultures treated with cAMP or in surviving neurons treated with SFD. These results imply that 1) cAMP and IGF-I promote differentiation of Schwann cells 2) IGF-I is an important promoter of survival and myelination in sensory neurons, and 3) An additional permissive factor present in serum is required to induce optimum myelin production.

## 29.10

**POST-MITOTIC OLIGODENDROCYTES ARE INCAPABLE OF REMYELINATION IN VIVO.** H.S. Keirstead\* and W.F. Blakemore. Department of Clinical Veterinary Medicine and MRC Cambridge Centre for Brain Repair, University of Cambridge, Robinson Way, Cambridge U.K., CB2 2PY.

In order to investigate the remyelinating potential of mature, post-mitotic oligodendrocytes *in vivo*, we have developed a model of demyelination in the adult rat spinal cord in which not all myelin bearing oligodendrocytes are killed by the demyelinating process. A single intraspinal injection of serum complement proteins plus antibodies to galactocerebroside (the major sphingolipid in myelin) results in demyelination which is rapidly followed by oligodendrocyte remyelination. This remyelination was not seen when the spinal cord was exposed to 40 Grays of x-irradiation prior to demyelination to prohibit a contribution by dividing cells. Histological, immunohistochemical and electron microscopic examination of the lesion at early and late time points following x-irradiation and intraspinal injection indicate that a proportion of oligodendrocytes in the area of demyelination survive. With time these cells extend processes which engage axons, and on occasions form compact myelin. These studies demonstrate that oligodendrocytes which survive within a region of demyelination in the adult rat spinal cord are not induced to divide by the presence of demyelinated axons. Furthermore, the radiation resistance of such cells indicates that differentiated oligodendrocytes are post mitotic and thus cannot be considered to make a significant contribution to remyelination in the CNS. Supported by the Medical Research Council of Great Britain and Northern Ireland.

## 29.12

**OLIGODENDROCYTES DO NOT MYELINATE AXONS BY DEFAULT.** A. Meyer-Franke\* and B. A. Barres. Stanford University School of Medicine, Department of Neurobiology, Stanford, CA 94305.

Myelination is a sequential, multistep process in which the process of an oligodendrocyte adheres to an axon, ensheathes and wraps it. The timing, rate and amount of myelination are controlled by signals from neurons, astrocytes, and some endocrine cells. The recent finding that signals from the same cell types promote the survival of oligodendrocytes has raised the following question: Is myelination primarily regulated by permissive signals, which promote oligodendrocyte survival, or does myelination also require instructive signals, which regulate specific steps of the myelination program independently of survival? Because surviving oligodendrocytes synthesize myelin proteins in the absence of other cell types, we hypothesized that myelination is a default program, which progresses inexorably forward in surviving oligodendrocytes.

The recent development of procedures to purify and culture defined types of postnatal CNS neurons and glial cells in serum-free medium (Barres et al., Cell 70:31-46, 1992; Meyer-Franke et al., Neuron 15:805-819, 1995) has allowed us to test this hypothesis. We purified and cultured oligodendrocytes from the rat optic nerve in the presence of saturating concentrations of oligodendrocyte survival signals and asked whether they would myelinate the axons of purified retinal ganglion cells in culture. Although axons freely grew over the oligodendrocytes in culture, the axons did not become ensheathed or myelinated. In contrast, when the co-cultures were treated with conditioned medium from purified optic nerve astrocytes, the oligodendrocytes dramatically altered their morphology, aligning their processes parallel to the axons. Immunostaining with antibodies to myelin proteins and neurofilaments showed that the axons were ensheathed by the oligodendrocyte processes. Electron microscopic studies are in progress. These findings demonstrate that surviving oligodendrocytes do not myelinate by default, but that other cell-cell interactions are required.

SERUM-INDUCED DEMYELINATION IN ORGAN CULTURES OF MATURE MOUSE SCIATIC NERVE. C. Lobato\*, J.M. Spies, and J.W. Griffin, Johns Hopkins University School of Medicine, Baltimore, MD 21287

We have established a system in which we can monitor and manipulate the cellular events that take place during demyelination *in vitro*. A number of immune-mediated disorders exist in which peripheral nerves undergo demyelination. In many of these disorders, antibody may play a role, but the cellular mechanisms of antibody-induced demyelination are uncertain. To examine the requirements for antibody-induced demyelination, organ cultures of whole mature C57/BL6/Wld<sup>+</sup> mouse sciatic nerves are maintained; the fibers survive for several days before Wallerian-like degeneration ensues. We have used this system to examine the effect of serum from rabbits with experimental allergic neuritis (EAN) induced by immunization with whole myelin. Demyelination of sciatic nerves occurred when nerves were cultured with immunoglobulin purified from EAN serum. Some demyelination took place in the absence of added complement. Circulating macrophages were not required for the initiation of vesicular demyelination. These results indicate that serum factors in EAN are sufficient to induce vesicular demyelination in mature nerves *in vitro*.

SHAKER-TYPE POTASSIUM CHANNEL (Kv1.1) CLUSTERING IN REMYELINATING RAT AXONS. M. N. Rasband, T. L. Schwarz, M. H. Ellisman, M. Schachner, S. D. Novakovic\*, and P. Shrager. Dept. of Biophysics, University of Rochester, Rochester NY, 14642.

Kv1.1 has been localized to the juxtaparanode in normal rat axons (J. Neurosci. 15, 3761-3774). We have induced demyelination by intraneural injection of lysolecithin into the sciatic nerve of Lewis rats. The distribution of Kv1.1 has now been investigated during subsequent remyelination using immunofluorescence applied to teased axon preparations. 6 days after lysolecithin injection, demyelinated axons showed broad diffuse labeling with elevated fluorescence at the edges of newly associated, MAG (myelin associated glycoprotein) negative, Schwann cells. 10 days after injection, Schwann cells had extended processes along the axon, had begun to elaborate myelin, and were MAG positive. No Kv1.1 labeling was seen at newly forming nodes. This is in contrast to our earlier report of sodium channel clustering at the edges of Schwann cell bodies as early as 8 days after injection. Kv1.1 perinuclear labeling of Schwann cell bodies, however, was pronounced and persisted in all stages of remyelination. 12 to 16 days following injection, Kv1.1 labeling appeared in the vicinity of nodes. Although it has not been definitively shown, Kv1.1 label appeared to be axonal and extended through the nodal gap between apposing Schwann cells. In comparison, sodium channel clusters are well formed by this stage of remyelination. Our findings indicate Kv1.1 clustering follows MAG expression. At 16 days, Kv1.1 began localizing to paranodes, indicating either active clustering or possibly exclusion from the center of the node. Labeling was clearly paranodal by 32 days, with a gap between adjacent paranodal clusters. The location of Kv1.1 remained paranodal even at periods of remyelination as long as 62 days. The time course of clustering and final distribution of Kv1.1 potassium channels differs from that of sodium channel clustering. This implies the mechanisms of clustering are likely different. The functional significance of sodium channel distribution is well understood, but remains unknown for Kv1.1 potassium channels. Supported by NIH and NMSS.

## 29.14

EXPRESSION OF PLATELET-DERIVED GROWTH FACTOR  $\alpha$  RECEPTOR AND LIGAND DURING CNS REMYELINATION. J.M. Redwine\* and R.C. Armstrong, Uniformed Services University of the Health Sciences, Bethesda, MD 20814, USA.

Oligodendrocyte precursors from neonatal rodent CNS express PDGF $\alpha$ R, and PDGF-AA ligand increases *in vitro* proliferation, migration, and survival of these cells. During remyelination following demyelination and oligodendrocyte loss, surviving oligodendrocytes or oligodendrocyte precursors must proliferate, migrate into the lesion area, and form new myelin. To determine the role of PDGF during remyelination, we first compared the expression of PDGF $\alpha$ R and PDGF-AA in normal versus remyelinating spinal cord. We used C57/BL6 mice experimentally demyelinated by intracranial injection with murine hepatitis virus strain A59, which produced motor dysfunction due to focal areas of demyelination throughout the spinal cord. In this model, widespread remyelination is achieved followed by functional recovery. Immunocytochemical markers demonstrated areas of astrocytic gliosis and myelin loss. Immunoreactivity for PDGF $\alpha$ R was increased in these lesion sites and immunoreactive cells included those with the morphology of oligodendrocytes or precursors. Immunoreactivity for PDGF-AA was present in neurons and axons of both control and lesioned tissues, and in reactive astrocytes in lesioned areas. Supported by National Multiple Sclerosis Society and National Institutes of Health.

## BLOOD-BRAIN BARRIER I

## 30.1

UPREGULATORY CIS-ELEMENT WITHIN THE 3'-UNTRANSLATED REGION OF GLUT1 GLUCOSE TRANSPORTER mRNA. H. Tsukamoto, R.J. Boado and W.M. Pardridge\*, Dept. of Medicine, UCLA School of Medicine, Los Angeles, CA 90095

The principal glucose transporter at the blood-brain barrier is GLUT1, and this gene expression may be regulated posttranscriptionally by specific interactions of cytosolic trans-acting factors and regulatory cis-elements within the untranslated regions (UTRs) of the GLUT1 mRNA. Our recent studies demonstrate that C6 rat glioma cytosol contains at least two proteins that react with specific sequences within the GLUT1 3'UTR and form two RNA/protein complexes with molecular masses of 88 and 44 kDa in ultraviolet crosslinking (UVCL) studies. The putative role of the GLUT1 3'UTR cis-acting element was studied using the luciferase expression vector pGL2. Transfection of C6 cells with pGL2 containing nucleotides 2,100-2,300 of the bovine GLUT1 3'UTR, encompassing the binding site of C6 proteins that form the 88 kDa complex, inserted at the PflMI site within the luciferase 3'UTR resulted in a fivefold increase in luciferase gene expression in C6 cells ( $484 \pm 33$  pg/35 mm dish), compared to levels with control pGL2 ( $95 \pm 19$  pg/dish). Deletion of 10 nucleotides (2,181-2,190) of bovine GLUT1 3'UTR, the binding site of the proteins forming the 88 kDa complex, was performed by site-directed mutagenesis. Luciferase expression in C6 cells transfected with this mutagenized plasmid was markedly reduced to levels obtained with control pGL2. UVCL study showed that the transcript of pGL2 containing the intact fragment of bovine GLUT1 3'UTR formed the 88 kDa complex with C6 proteins. The present study provides evidence suggesting that the interaction of the cis-regulatory sequence, nucleotides 2,181-2,190 of bovine GLUT1 3'UTR, and the cytosolic proteins that form the 88 kDa complex in C6 cells, may serve to upregulate GLUT1 gene expression.

## 30.2

IMMUNOHISTOCHEMICAL LOCALIZATION OF INTRANEURONAL TRANSFERRIN RECEPTOR IMMUNOREACTIVITY IN THE ADULT MOUSE CENTRAL NERVOUS SYSTEM. T. Moos\*, Inst. Med. Anat, sect A, Panum Inst., Univ. Copenhagen, Denmark

Iron is an essential determinant for a variety of intracellular functions. Accordingly, the transfer of iron from blood to brain is vital for normal brain function. In the CNS, the receptor for iron-transferrin is generally accepted to be located in endothelial cells, whereas its occurrence in other cell types is less well established. I have investigated the distribution of the transferrin receptor in the adult mouse central nervous system by immunohistochemistry using a monoclonal antibody raised against the transferrin receptor protein. Immunoreactive cell types comprised brain capillary endothelial cells, excluding those of circumventricular organs, and choroid plexus epithelial cells. Moreover, transferrin receptor immunoreactivity was detected intraneuronally in several brain regions without access to peripheral blood. The immunoreactive cell bodies were mainly confined to the cerebral cortex, hippocampus, habenular nucleus, red nucleus, substantia nigra, pontine nuclei, reticular formation, several cranial nerve nuclei, deep cerebellar nuclei, and cerebellar cortex. Transferrin receptor immunoreactivity was not ascertained in astrocytes, oligodendrocytes or microglial cells. The occurrence of transferrin receptors at brain-barrier sites, i.e. brain endothelium and choroid plexus epithelium, and the presence of the receptors intraneuronally are in accordance with the generally held belief that iron is released from liver transferrin and transported through capillaries and the choroid plexus into the brain interstitium. Subsequently, iron may be linked to brain transferrin synthesized within oligodendrocytes and choroid plexus epithelial cells followed by a concomitant uptake of iron-transferrin in neurons expressing transferrin receptors. Additional analyses of iron-transport within the brain are presented.

## 30.3

## OXOPROLINE REGULATES AMINO ACID TRANSPORT ACROSS THE BLOOD-BRAIN BARRIER

W.-J. Lee<sup>1</sup>, J. R. Viña<sup>2</sup>, D. R. Peterson<sup>1</sup> and R. A. Hawkins<sup>1\*</sup>,  
<sup>1</sup>Department of Physiology and Biophysics, Finch University of Health Sciences/The Chicago Medical School, North Chicago, IL 60064.  
<sup>2</sup>Department of Biochemistry and Molecular Biology, University of Valencia, Valencia-46010, SPAIN.

Regulation of neutral amino acid transport was studied using isolated plasma membrane vesicles derived from the bovine blood-brain barrier. Neutral amino acids cross the blood-brain barrier by facilitative transport system L1, which may allow both desirable and undesirable amino acids to enter the brain. The Na-dependent amino acid systems A and B<sup>+</sup> are located exclusively on abluminal membranes, in a position to pump undesirable amino acids out. Gamma-glutamyl transpeptidase, the first enzyme of the gamma-glutamyl cycle, is an integral protein of the luminal membrane of the blood-brain barrier. We demonstrate that oxoproline, an intracellular product of the gamma-glutamyl cycle, stimulates the rates of the Na-dependent systems A and B<sup>+</sup> by 70% and 20% respectively. Study of system A showed that 2 mM oxoproline increased the affinity for its specific substrate methyl-amino isobutyric acid by 50%. This relationship between the activity of the gamma-glutamyl cycle and system A transport may provide a short-term regulatory mechanism by which the entry of potentially deleterious amino acids (i.e. neurotransmitters or their precursors) may be retarded and their removal from brain accelerated.

Supported by NIH grant NS 31017, and FISS 94/1573 (Spain)

## 30.5

MORPHOLOGICAL PROPERTIES, ELECTRICAL RESISTANCE AND POTASSIUM TRANSPORT ACROSS AN "IN VITRO" BLOOD-BRAIN BARRIER, K.A. Stanness, L.A. Beck, L.E. Westrum, H.R. Winn, L.G. Costa, D. Janigro, Depts. Neurosurgery & Env. Health, Univ. of Washington, Seattle, WA

We have developed an *in vitro* model of the mammalian blood-brain barrier (DIV-BBB) by co-culturing endothelial cells (EC) with glia in a hollow fiber apparatus. Induction of BBB properties was characterized by a selective barrier to intraluminal potassium and glucose transport across the endothelial monolayer. We further characterized the BBB nature of our culture system by electron microscopic analysis of both intraluminal EC and extraluminal (ecs) glia. EC formed numerous tight junctions following co-incubation with glia; the latter did not develop any junctional specialization. During induction of BBB properties we monitored transendothelial electrical resistance (TER) by applying a voltage signal to the ecs while recording voltage changes in the lumen. The electrical resistance of the BBB was around 800 Mohms. "Osmotic openings" of the DIV-BBB were induced by intraluminal applications of high [KCl] and were characterized by a sudden and reversible decrease of TER (by approximately 25%). TER was also dramatically reduced by intraluminal perfusion with proteolytic enzymes but was not affected by exposure of the extraluminal glia to low pH, further suggesting the endothelial nature of the BBB. While the DIV-BBB effectively prevented intraluminal potassium movement to the ecs, potassium was actively transported from the ecs to the lumen in an ouabain-sensitive (100  $\mu$ M) fashion. Intraluminal furosemide application (2.5 mM) further decreased the potassium movement from the lumen to the ecs suggesting that a K/Cl/Na endothelial co-transporter is expressed in the DIV-BBB. Our results suggest that the DIV-BBB may be an useful tool for the study of brain ionic homeostasis and cellular development *in vitro*. Supported in part by Cellico Inc. (Germantown, MD) and NIH 51624 and NIEHS ES 07033.

## 30.7

POTASSIUM TRANSPORT SYSTEMS IN BRAIN CAPILLARY ENDOTHELIAL CELLS: RESPONSE TO ENDOTHELIN-1 AND HYPOXIA.

N. Kawai, R.M. McCarron, and M. Spatz\*

Stroke Branch, NINDS, NIH, Bethesda, MD 20892-4128

Endothelin-1 (ET-1), oxygen deprivation, or oligomycin treatment was shown to stimulate Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport in cultured rat brain capillary endothelial cells (RBEC), a constituent of blood-brain barrier (BBB). This report compares the effect of ET-1 and chemically induced hypoxia (by oligomycin, sodium azide, or antimycin A) on RBEC K<sup>+</sup> transport activity. <sup>86</sup>Rb<sup>+</sup> was used as a tracer for K<sup>+</sup>; bumetanide-sensitive K<sup>+</sup> uptake was defined as Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity. ET-1, phorbol myristate acetate (PMA), or thapsigargin increased Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity by 60, 150, and 200%, respectively. A protein kinase C (PKC) inhibitor, bisindolylmaleimide (BIS) inhibited PMA- and ET-1- (but not thapsigargin-) induced Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity. In contrast, the basal and induced (by all the above substances) Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity was reduced by intracellular Ca<sup>2+</sup> chelator, BAPTA/AM. Oligomycin, sodium azide, or antimycin A increased Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity by 80-200%; BAPTA/AM (but not BIS) reduced oligomycin-induced Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity. These data indicate that hypoxia stimulates Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity through Ca<sup>2+</sup>-dependent mechanisms, whereas ET-1 augmentation occurs through both Ca<sup>2+</sup>- and PKC-dependent pathways. ET-1 or oligomycin also increased K<sup>+</sup> efflux (50-120%) which was abolished by 300  $\mu$ M quinine, indicating involvement of Ca<sup>2+</sup>-activated K<sup>+</sup> channels in this response. Thus, the stimulation of K<sup>+</sup> uptake by ET-1 or hypoxia coincided with increased K<sup>+</sup> efflux through Ca<sup>2+</sup>-activated K<sup>+</sup> channels in RBEC. Similar mechanisms may be involved in altering the ion-transport activity at BBB and contribute to disturbances of water-electrolyte homeostasis reported in ischemic brain.

## 30.4

POLYAMINE MODIFICATION INCREASES THE PERMEABILITY OF PROTEINS AT THE BLOOD-NERVE AND BLOOD-BRAIN BARRIERS

Joseph F. Poduslo\* and Geoffrey L. Curran

Mayo Clinic and Mayo Foundation, Rochester, MN 55905 U.S.A.

The permeability of the BNB and BBB to superoxide dismutase (SOD), insulin, albumin, and IgG in normal adult rats was quantified by measuring the permeability coefficient-surface area product (PS) with the i.v. bolus injection technique before and after covalent protein modification with the naturally occurring polyamines - putrescine (PUT), spermidine (SPD), and spermine (SPM). The PS value of the BNB for PUT-SOD was 21.1-fold greater than the native SOD, and the PS values of the BBB for PUT-SOD ranged from 17.6-fold greater for the thalamus to 23.6-fold greater for the caudate-putamen compared to native SOD. Similarly, polyamine modified insulin showed a 1.7 to 2.0-fold increase in PS of the BNB and BBB compared to the high values of native insulin. Polyamine modified albumin showed a remarkable 54 to 165-fold increase in PS of the BNB and BBB compared to native albumin, while PUT-IgG resulted in an even higher increase in the PS that ranged from 111 to 349-fold for nerve and different brain regions compared to native IgG. Polyamine modification of proteins, therefore, can dramatically increase the permeability at the BNB and BBB of a variety of proteins with widely differing M<sub>r</sub> and function. Surprisingly, the PS values of the BNB and BBB decreased with the increasing number of positive charges of the protonated amino groups on the polyamines (PUT > SPD > SPM). While cationic proteins are known to interact with fixed anionic charges on the lumen of the microvascular endothelium, this observation of decreased permeability with increased positive charge distribution along the aliphatic carbon chain of the polyamines implies mechanisms other than simple electrostatic interaction involving charge density. Systemic administration of polyamine modified proteins might prove to be an efficient approach to deliver therapeutic agents into the CNS and PNS for the treatment of a variety of neurological diseases (Mayo Foundation).

## 30.6

AMMONIUM IONS IMPAIR POTASSIUM EFFLUX ACROSS THE BLOOD-BRAIN BARRIER OF THE RAT. K.A. Smart and M.B. Segal\*, Physiology Dept, UMDS, London, SE1 7EH, UK.

Ammonium ions (NH<sub>4</sub><sup>+</sup>) are believed to be the major toxin involved in the manifestation of the symptoms of Hepatic Encephalopathy (HE) (Schenker et al, 1974). Following acute liver failure, the plasma level of the NH<sub>4</sub><sup>+</sup> ion rises to in excess of three times the normal (39.9  $\pm$  3.7  $\mu$ M), and it has been proposed that the lipid insoluble NH<sub>4</sub><sup>+</sup> ion crosses the blood brain barrier (BBB) by competing with K<sup>+</sup>, leading to neuronal damage (Cooper and Plum, 1987). In this study we have loaded the brain with <sup>86</sup>Rb using the bilateral *in situ* brain perfusion technique (Preston et al 1995), then collected jugular vein effluent over a 30 minute period in the presence and absence of NH<sub>4</sub><sup>+</sup>. We have taken terminal CSF and brain tissue samples. Using dextran density capillary depletion analysis (Triguero et al 1990), we have been able to show an increase in the levels of <sup>86</sup>Rb remaining in the brain parenchyma and capillary endothelial cells, and loss of <sup>86</sup>Rb to CSF and blood. These data fit a 2 compartment efflux model as evident from the 2 different half-life (t<sub>1/2</sub>) values. (t<sub>1/2</sub> is a measure of the time taken for half of the contained activity to be lost). This suggests that there is a fast efflux component from the capillary endothelium, t<sub>1/2</sub>fast = 0.715  $\pm$  0.12 min, and a slower component from the brain parenchyma, t<sub>1/2</sub>slow = 20.125  $\pm$  1.2 min. NH<sub>4</sub><sup>+</sup> had no effect on t<sub>1/2</sub>fast, but increased t<sub>1/2</sub>slow to 28.8  $\pm$  0.1 min. NH<sub>4</sub><sup>+</sup> also decreased loss of <sup>86</sup>Rb to the blood and the amount remaining in the cerebral tissue. These results suggest that NH<sub>4</sub><sup>+</sup> inhibits efflux by acting on the brain side of the capillary endothelial cell.

THE PATTERN OF BLOOD-NERVE BARRIER BREAKDOWN AFTER DORSAL ROOT GANGLIONECTOMY. J.M. Spies, K.A. Sheikh, P. Kessins, T.W. Brushart, A.K. Asbury\*, J.W. Griffin, Johns Hopkins University School of Medicine, Baltimore, MD 21287

Increasing evidence suggests that humoral factors are important in the pathogenesis of a number of immune-mediated neuropathies. The blood-nerve barrier (BNB) has hindered efforts to establish animal models to investigate the role of these humoral factors. Nerves undergoing active Wallerian degeneration are known to have defective BNBs, and evidence suggests that restoration of the BNB depends on axonal regeneration. We investigated the pattern of BNB breakdown in the rat sciatic nerve after dorsal root ganglion (DRG) removal, a model in which axons are not expected to regenerate.

The left 5th lumbar DRG was removed from adult Lewis rats. Permeability of BNB to albumin at various times was assessed by quantitating endoneurial content of Evans blue dye in control and ganglionectomized nerves after intravenous injection. Permeability to immunoglobulin (Ig) M was assessed by immunostaining for rat IgM in the endoneurium.

Sciatic nerves on the side of ganglionectomy showed a significant increase in permeability to both albumin and IgM. This increased permeability was not seen diffusely throughout the nerve fascicles but was most marked in those parts of the fascicles where sensory axons were degenerating. Permeability was maximal at 3-5 weeks and thereafter returned towards baseline. By 6 months only minor increases in permeability were seen. These data suggest that, in the rat, the BNB can be restored in the absence of axonal regeneration.

## 30.9

**LEUKOCYTE-DEPENDENT BLOOD-BRAIN BARRIER BREAKDOWN FOLLOWING ASPHYXIA IN PIGS.** E.R. Gonzales, T.S. Park, J.W. Beetsch, A.R. Shah, R.G. Maceren, Y.-B. Lee, J.M. Gidday. Department of Neurosurgery, and St. Louis Children's Hospital, Washington University School of Medicine, St. Louis, MO 63110

Microvascular damage following ischemia contributes to brain edema and associated tissue injury, but the mechanisms responsible for disruption of the blood-brain barrier have yet to be conclusively identified. We tested the hypothesis that adherent leukocytes are involved in mediating post-ischemic edema. Newborn pigs were equipped with closed cranial windows for quantification by dual-filter videomicroscopy of the adherence of rhodamine 6G-stained leukocytes to pial venules, and the leakage of sodium fluorescein from these venules 20 min after its intravenous injection (1 ml/kg of a 1% solution). The latter was quantified by measurements of extravascular optical density on the videotape record using image analysis software. Three groups of animals (n=5 each) were studied: Non-asphyxial controls, animals rendered asphyxial for 9 min by discontinuing ventilation (which causes hypoxia, hypercapnia, hypotension, and acidosis), and asphyxial animals pretreated with a mouse anti-human monoclonal antibody against the leukocyte CD18 integrin (R15.7 from Boehringer Ingelheim; 2 mg/kg). Asphyxia induced a progressive and significant increase in adherent leukocytes during the initial 2 h of reperfusion, at which time a 103% increase in fluorescein leakage was measured. However, adherence and fluorescein leakage in the group treated with the CD18 antibody were reduced to levels equivalent to those measured in non-asphyxial controls. These findings indicate that adherent leukocytes are responsible for the increase in cerebrovascular permeability following asphyxia, and therefore may contribute to injury following ischemia. (NIH NINDS 21045 and 32568).

## 30.11

**A REPEATABLE TECHNIQUE FOR HYPEROSMOTIC BLOOD BRAIN BARRIER DISRUPTION IN THE DOG.** B. W. Culyer, K. R. Dyer, J. Jones, B. Jortner, R. Kroll. Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, VA 24061

Reversible hyperosmotic blood-brain barrier disruption (BBBD) enhances drug delivery across the blood brain barrier. A technique for repeatable BBBD in the canine has not been described. The purpose of this study was to develop a repeatable technique for BBBD in the dog and evaluate the effects of multiple BBBD.

Ten dogs were randomly assigned to treatment or control groups. A Norman catheter was introduced into the femoral artery and advanced under fluoroscopy into the internal carotid artery. Treatment dogs received intracarotid mannitol (2 - 2.3 ml/sec for 30 sec). Control dogs received saline at the same rate. Following BBBD, lohexal was administered prior to a CT scan. Dogs were allowed to recover after the first procedure and were monitored for clinical signs related to BBBD for 2 wk. A second, non survival procedure was performed as before with the addition of Evan's blue administration 15 min prior to BBBD. The degree of BBBD was estimated using CT densitometry values as well as Evan's blue staining graded (scale of 0-3).

All Treatment dogs had evidence of successful BBBD by CT and/or Evan's blue evaluation. None of the control dogs had CT densitometry values consistent with successful BBBD. Procedural complications consisted of: 1) hematoma of the internal carotid, 2) rupture of the femoral artery, and 3) self resolving, hematoma of the femoral artery catheter site. Side effects included: ipsilateral head tilt and circling, contralateral hemiparesis, and blindness. These side effects resolved in 12-48 hr. and while present in both groups, tended to be most pronounced in treatment dogs. Life threatening side effects were only seen in 2 treatment dogs and consisted of: CNS edema 12 hours post BBBD, and brain herniation immediately following BBBD.

This study describes a technique of repeatable BBBD in the dog using fluoroscopic guidance to place a percutaneous transfemoral catheter system into the internal carotid artery and open the way for further investigations of BBBD using the dog as a model.

Funding possible by a grant from The Virginia Veterinary Medical Association

## 30.13

**CHLOROQUINE/BLOOD-BRAIN BARRIER II. CHLOROQUINE MEDIATED DISRUPTION OF THE BLOOD-BRAIN BARRIER IN THE RAT.** M.P. Murphy\*, J. Mielke, S.C. Barsoum, and G.O. Ivy. University of Toronto, Scarborough College, 1265 Military Trail, Division of Life Sciences, Scarborough, Ontario, Canada M1C 1A4.

We have shown that chloroquine (CHL) has proconvulsant properties, possibly mediated by an interaction with the blood-brain barrier (BBB). Male Sprague-Dawley rats were implanted s.c. with an osmotic minipump (Alzet) containing either 0.9% saline (SAL; n=5) or 30 mg/ml CHL (n=13), delivered into the left lateral ventricle. One week later, rats were given kainic acid (KA; 12 mg/kg i.p.: 3 without pump, 3 SAL, 8 CHL) or 0.9% saline. CHL was administered orally (gavage) to another group of animals for 7 days [dosage/day, mg/kg (n=7-8/dose): 0, 7.5, 15, 22.5, 30, 45]; 2 hrs. after the final dose, half of the animals were injected with KA as above. CHL had a proconvulsant effect both i.c.v. and orally (45 mg/kg only). Animals were sacrificed with an overdose of sodium pentobarbital after 30 minutes of status epilepticus. Coronal sections (30 µm) were processed for immunocytochemical localization of extravasated IgG. CHL infusion caused massive IgG immunoreactivity, confined almost entirely to the treated side. Oral CHL caused a marked increase in IgG extravasation around blood vessels; this effect declined with increasing dose, probably reflecting CHL immunosuppression. For both methods, CHL and KA had an additive effect. Hence, CHL may damage the BBB, thereby allowing potentially toxic substances easier access to the CNS. Alternatively, CHL may have additional therapeutic use as a means to open the BBB to allow passage of beneficial compounds. Supported by NSERC, Canada.

## 30.10

**RELATIONSHIP BETWEEN DEMYELINATION (DM) AND BLOOD BRAIN BARRIER (BBB) DISRUPTION FOLLOWING RAPID CORRECTION OF HYPONATREMIA.** S. Adler, J.G. Verbalis, D. Williams and A.J. Martinez. U. Pittsburgh Sch. Med., and NMR Biomedical Research Center, CMU, Pittsburgh, PA 15261 and Georgetown Univ., Wash. D.C. 20007.

This study examines the hypothesis that the demyelination (DM) which may follow overly-rapid correction of hyponatremia (HN) is due to BBB disruption. Chronic (10d) HN was induced in rats by infusing dDAVP via osmotic minipump. HN was corrected by administering 1 M NaCl IP at 1.0 ml/100 g. At either 3 hours (n=23) or 16-24 hours (n=44) after initiating HN correction, BBB leakage was assessed by NMR imaging using IV gadolinium-DTPA. After 5-6 days, rats were sacrificed and brain DM determined histopathologically by luxol blue. Of the 67 rats studied, 45 showed BBB leakage; the table shows the relationship between leakage and DM.

	Number	Leakage (+)	Leakage (-)
DM (+)	35	31 (89%)	4 (11%)
DM (-)	32	14 (44%)	18 (56%)

The rate of (+) leakage and (-) DM was equal at both times. A separate study performed in 29 HN rats used a V<sub>2</sub> receptor antagonist to more slowly correct HN. BBB leakage and DM occurred in only two rats in this group. Data from all 96 rats reveals that DM occurred in 69% of rats with BBB leakage but in only 5% without a leak. These studies show that BBB disruption is closely associated with subsequent demyelination but that BBB disruption does not inevitably lead to DM. The results support the hypothesis that leakage of blood components, such as complement, into the brain could be in part responsible for the DM observed in this model.

## 30.12

**CHLOROQUINE/BLOOD-BRAIN BARRIER I. CHLOROQUINE ATTENUATES KAINATE-INDUCED IgG EXTRAVASATION IN MICE.** J. Maritz, M.P. Murphy, J.G. Mielke, K.M. Bengualid, and G.O. Ivy.\* University of Toronto, Scarborough College, 1265 Military Trail, Division of Life Sciences, Scarborough, Ontario, Canada M1C 1A4.

Kainic acid (KA) induced seizures damage the blood-brain barrier (BBB), as indicated by the presence of extravasated serum proteins, such as IgG. Since the commonly used anti-malarial drug chloroquine (CHL) has proconvulsant properties in both animals and humans, a BBB effect may exist similar to that of KA. BCF1 and BDF1 male and female mice were treated with either CHL (45 mg/kg, n=18) or vehicle (0.9% physiological saline, n=24), i.p., once/day for 6 consecutive days. On the day following the final dose, the subjects were given an i.p. injection of KA (12 mg/kg) or SAL (half of each group). Animals pretreated with CHL developed seizures an average of 45 minutes before controls [F(1,25)=3.81, p<0.06]. There were no strain or sex differences. Following 45 minutes of status epilepticus, the mice were sacrificed with an overdose of sodium pentobarbital and perfused transcardially with 4% paraformaldehyde. Coronal sections were taken (30 µm) from the septum through the hippocampus, and every 8th section processed for immunocytochemical localization of IgG. KA caused an increase in the number of IgG incursions in the brain [F(1,30)=8.56, p<0.0065], and CHL pretreatment attenuated this effect [F(1,17)=7.41, p<0.015]. These results suggest that CHL may exert its proconvulsant activity indirectly through an interaction with the BBB. **TRAFFICKING OF B AND T LYMPHOCYTES TO THE BRAIN FOLLOWING ANTIGEN INFUSION INTO CAUDATE-PUTAMEN OF PASSIVELY IMMUNIZED LEWIS RATS.** J. Szymdynger-Chodobska<sup>1,2\*</sup>, S.C. Nolan<sup>1</sup>, C.J. Harling-Berg<sup>1</sup> and P.M. Knopf<sup>1</sup>. <sup>1</sup>Div. Biol. Med., Brown Univ., Providence, RI 02906 and <sup>2</sup>Dept. Clin. Neurosci., Brown Univ./R.I. Hosp., Providence, RI 02903.

We have previously shown that in the absence of central nervous system disease, intrathecal antibody synthesis can occur within the brain following soluble antigen administration into CSF. In order to perform an immunohistochemical study of trafficking and retention of B and T lymphocytes to the site of antigen administration within the brain, we have developed a bilateral cannula model. A stainless steel cannula was implanted into each caudate-putamen of Lewis rats. One week later, these rats were passively immunized via i.v. injection of splenocytes (~10<sup>7</sup> cells) from ovalbumin (OVA)-primed syngeneic donors to increase the circulating pool of activated lymphocytes in the recipient. Sixteen hours prior to this cell transfer, recipient rats received OVA (45 µg/rat) infusion into one cannula and saline or an irrelevant antigen into the contralateral cannula. Brains were then evaluated at 4, 24, and 48 h after cell transfer. B and T cells were detected by immunofluorescence using mouse anti-rat IgG and CD4/CD8, respectively. In addition, OX6 antibody against class II MHC molecule (MHCII) was used. B and T lymphocytes were prominent in OVA-infused brain tissue 4 h following passive immunization, and diminished in quantity at 24 and 48 h. At all times cellular infiltration at the control site was significantly lower. The temporal profile of immunopositive staining for MHCII was similar to that of B and T cells, and may indicate presence of both macrophages/activated microglia and B lymphocytes. In conclusion, there is an early influx of B and T cells into the OVA-infusion site. Future studies will focus on antigen-specific retention of these cells. Supported by NIH Grant NS33070.

## EFFECTS OF UROKINASE &amp; VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) ON BRAIN VESSELS.

M. Kaya, L. Chang, A. Truong, M. Brightman\*. LN, N.I.H., Bethesda, Md. 20892-4062

Retinoic acid (RA) and phorbol myristate acetate (PMA), continuously infused into the cerebral cortex of rats for 28 days, create a cyst containing blood vessels. About 20-29 % of the vessels are converted from the continuous, barrier type to the permeable, fenestrated vessel (FV) type. It is now found that the conversion is reversed between 1-2 months after ending the infusion. By 1 month, very little circulating horseradish peroxidase enters brain and only 1-3% of the vessels are FV. At 2 months, no FV are found.

An activity common to both RA and PMA is to stimulate production of a proteinase that degrades extracellular matrix: urokinase. Because of its short half life, urokinase was infused into cortex intermittently: 1.5µg in 10µl for 1 h every 3rd day for 28 days. About 12% of cyst vessels became FV. VEGF, associated with FV of some organs, was also infused continuously at 500ng/ml for 28 days and produced vessels with short, 20nm thick segments, a few FV and, in addition, open endothelial junctions. It is inferred that urokinase, made by endothelial cells, may autocrinely mediate the action of RA and PMA, but not VEGF. (NIH Intramural funding).

## BRAIN AND SPINAL CORD DISTRIBUTION OF BIPHALIN, CORRELATION WITH OPIOID RECEPTOR DENSITY AND MECHANISM OF CNS ENTRY. T.J. Abbruscato\*, S.A. Williams, V.J. Hruby, T.P. Davis. Departments of Pharmacology and Chemistry, University of Arizona, Tucson, AZ 85724

Biphalin (Tyr-D-Ala-Gly-Phe-NH)<sub>2</sub> is a bivalent, opioid peptide containing two pharmacophores linked by a hydrazide bridge. When administered ICV, it has been shown to be more potent than morphine and etorphine at eliciting antinociception. Biphalin has also been shown to cross both the blood-brain and blood-CSF barriers (Abbruscato et al., 1996 JPET 276, 1049-1057). To understand the mechanism for biphalin potency, regional brain and spinal cord distribution studies with [<sup>125</sup>I-Tyr<sup>1</sup>]biphalin were performed after 5, 20 and 40 minute IV bolus injection. A statistically greater amount of [<sup>125</sup>I-Tyr<sup>1</sup>]biphalin was detected in the nucleus accumbens compared to other brain regions (P<0.05). This correlates with the high density of delta and mu opioid receptor mRNA and binding sites shown to be expressed in the nucleus accumbens (Mansour et al., 1995 TINS 18, 1995). Considerable amounts of [<sup>125</sup>I-Tyr<sup>1</sup>]biphalin were detected in spinal regions (cervical, thoracic, lumbar and cauda equina) in comparison to brain regions including frontal cortex, caudate-putamen, cerebellum and brain stem. Also, a statistically greater amount of [<sup>125</sup>I-Tyr<sup>1</sup>]biphalin was detected in two circumventricular organs, the choroid plexus and pituitary, when compared to other brain regions. These studies provide evidence that biphalin can not only reach brain sites that express mu and delta-opioid receptors, but it also can reach spinal sites to elicit antinociception. Additional *in situ* brain perfusion experiments identified a saturable component that contributes to CNS entry of [<sup>125</sup>I-Tyr<sup>1</sup>]biphalin. This work provides evidence that biphalin is a promising, potent analgesic that has a unique mechanism for reaching both spinal and supra-spinal opioid receptor sites. (supported by NIDA #DA-06284).

## 30.19

DEXAMETHASONE INCREASES ZO-1 AT THE JUNCTIONS OF BOVINE RETINAL ENDOTHELIAL CELLS. A.J. Barber\*<sup>1</sup>, G.E.W. Rutherford<sup>1</sup>, S. Khin<sup>1</sup>, E. Lieth<sup>2</sup>, and T. W. Gardner<sup>1</sup>.

<sup>1</sup>Ophthalmology, and <sup>2</sup>Neuroscience and Anatomy, Penn State University College Medicine, Hershey, PA 17033.

The steroid dexamethasone is known to decrease the transcellular permeability of cerebral endothelial cells, but the mechanism by which this occurs is not known. We tested the hypothesis that dexamethasone increases the accumulation of the tight junction protein ZO-1.

Endothelial cells isolated from bovine retina were purified and grown on fibronectin coated glass coverslips to a confluent monolayer. The cells were treated with 1µM or 100µM dexamethasone for 72 hrs. ZO-1 was detected by fluorescent immunocytochemistry using a monoclonal antibody (Chemicon).

ZO-1 immunoreactivity was clearly visible at the junctions between cells. Immunoreactivity was greater at the junctions of cells treated with 100µM dexamethasone, compared to both 1µM dexamethasone and untreated controls.

Dexamethasone increases the accumulation of ZO-1 at inter-endothelial cell junctions. The mechanism by which this occurs is not known but since dexamethasone has also been reported to upregulate enzymes associated with barrier function it may mimic an endogenous signal to cause expression of barrier properties in endothelial cells. We suggest that dexamethasone causes functional reinforcement of the blood-CNS barrier by increasing tight junction ZO-1.

## 30.16

## MATRIX METALLOPROTEINASE INHIBITION SELECTIVELY REGULATES BLOOD-BRAIN BARRIER OPENING IN LPS-INJECTED BRAIN. S. Mun-Bryce\*, G.A. Rosenberg. Dept. of Neurology, Univ. of New Mexico School of Medicine, Albuquerque, NM 87131.

The up-regulated production of inflammatory cytokines and matrix metalloproteinases (MMP) has been associated with several neuroinflammatory-related diseases such as ischemia and multiple sclerosis. An intracerebral injection of lipopolysaccharide (LPS) causes a significant rise in gelatinase B production, and increases blood-brain barrier permeability to sucrose (M.W. 340 Da) and dextran (M.W. 50-90 kD) molecules. These studies examined whether hydroxymate compound, BB-1101, regulates MMP production and blood-brain barrier breakdown in the inflammatory mediator-stimulated brain. Four hours after LPS-injection, treated animals received an i.p. injection of BB-1101. The zymogram lysis activity of 92 kD and 84 kD gelatinase B, and the 72 kD gelatinase A dropped significantly in treated animals, as compared to untreated animals, 12 hrs post-LPS injection. The MMP inhibitor markedly decreased blood-brain barrier permeability to <sup>14</sup>C-sucrose, but had no effect on the amount of <sup>14</sup>C-dextran uptake in brain tissue samples, 12 hr after LPS-injection. This data suggests that BB-1101 selectively inhibits blood-brain barrier opening to smaller sucrose-sized molecules in the LPS-injured brain.

## 30.18

IN VITRO BLOOD-BRAIN BARRIER PERMEABILITY AND STABILITY OF A SERIES OF [D-ALA<sup>2</sup>]DELTORPHIN I AND II ANALOGUES<sup>1</sup>. S. A. Williams, T. J. Abbruscato, V. Hau, T. J. Gillespie, J. Zsigo, V. J. Hruby and T. P. Davis\*. Departments of Pharmacology and Chemistry, The University of Arizona, Tucson, AZ 85724 USA.

[D-Ala<sup>2</sup>]Deltorphins are enzymatically stable, amphibian heptapeptides that have a higher affinity and selectivity for delta-opioid receptors than any other endogenous mammalian compound known. This study investigated the *in vitro* blood-brain barrier (BBB) permeability, using primary cultured bovine brain microvessel endothelial cells, and the resistance to enzymatic degradation, in 15% mouse brain homogenates and 100% plasma, of [D-Ala<sup>2</sup>]deltorphin I, [D-Ala<sup>2</sup>]deltorphin II and several analogues. Derivatives were designed with the addition of N-terminal neutral and basic amino acids or with alterations of the amino acids present within the deltorphin sequences. The results indicated that the N-terminal sequence and the amino acids in position 4 and 5 are critical to deltorphin analogue BBB permeability and biological stability i.e. T½ brain; 4.8 hr- [D-Ala<sup>2</sup>]deltorphin I; > 15 hr- [D-Ala<sup>2</sup>,Ser<sup>4</sup>,D-Ala<sup>5</sup>]deltorphin. Although, no analogue was found to increase the BBB permeability coefficient (PC; ×10<sup>-4</sup> cm/min) of the parent compounds ([D-Ala<sup>2</sup>]deltorphin II, PC=23.49±2.42), analogues were identified ([Arg<sup>0</sup>,D-Ala<sup>2</sup>]deltorphin II, PC=19.06±3.73; [Ala<sup>1</sup>,Pro<sup>0</sup>,D-Ala<sup>2</sup>]deltorphin II, PC=17.38±1.01) which had similar permeability coefficients, even though they had larger molecular weights and, in the case of the cationic pro-drug, a significantly lower lipophilicity. These results provide directions in the development of future pro-drugs for the treatment of pain and this study further clarifies the structure-activity relationship of the deltorphins. This work was supported by NIDA # DA-06284.

## 30.20

## POSSIBLE REGULATION BY DEXAMETHASONE OF THE HISTAMINERGIC SYSTEM IN CEREBRAL ENDOTHELIAL CELLS. K. Karlstedt, T. Sallmén, K.S. Eriksson\*, M. Lintunen, K. Wasowicz, H. Fukui, F. Joó and P. Panula. Dept. of Biology, Abo Akademi Univ., 20520 Abo/Turku, Finland, Dept. of Pharmacology II, Osaka Univ., Osaka, Japan and Lab. of Mol. Neurobiol., Inst. of Biophysics, Biological Research Center, 6701-Szeged, Hungary.

Histamine has powerful effects on brain endothelial cells through specific receptors. Previous studies have suggested that the endothelial cells can store histamine and transport it in both directions. The purpose of this study was to find out if endothelial cells possess the capacity to synthesize histamine, and if they express histamine receptors. We also studied the effect of dexamethasone *in vitro*. *In situ* hybridization experiments revealed expression of specific L-histidine decarboxylase (HDC) mRNA in tuberomammillary neurons but not in capillary endothelial cells in rat brain. Histamine immunofluorescence was detected in these neurons and thalamic mast cells, but not in capillary endothelium. RT-PCR amplification showed that an immortalized rat capillary endothelial cell line (RBE-4) does not express HDC indicating that these cells do not synthesize histamine. This was further verified by HPLC-measurements. Histamine could be detected neither in the cultured cells nor in the media. RT-PCR amplification results also indicated the presence of both H<sub>1</sub> and H<sub>2</sub> receptor mRNA in RBE-4 cells. They express H<sub>1</sub> and H<sub>2</sub> receptors and thereby possess the capability to react on histamine. Preliminary RT-PCR studies indicated that dexamethasone downregulates the expression of both H<sub>1</sub> and H<sub>2</sub> mRNA in cultured RBE-4 cells. This again suggests that glucocorticoid hormones may regulate the histaminergic system in the brain not only through HDC but also through specific histamine receptors. Supported by the MRC of the Academy of Finland.

## 31.1

**A CHANNEL FOR MONOAMINE EFFLUX IN SYNAPTIC VESICLES? RAPID EFFLUX OF 1-METHYL-4-PHENYL-PYRIDINIUM ION (MPP<sup>+</sup>).** E. Floor\* and A. Gaut. Div. of Biological Sciences, University of Kansas, Lawrence KS 66045

Dopamine (DA) storage in brain synaptic vesicles is highly dynamic and has rapid uptake and efflux components. Efflux by the uptake-independent pathway may involve passive diffusion through the membrane. To test this hypothesis, efflux of the dopamine neurotoxin, MPP<sup>+</sup>, a quaternary ammonium ion, was examined. MPP<sup>+</sup> is taken up by synaptic vesicles but, unlike DA, can not exist as a neutral, membrane permeant species. [<sup>3</sup>H]MPP<sup>+</sup> escaped from rat brain synaptic vesicles with a half-time ( $t_{1/2}$ ) of 2.1 min at 30°C after its uptake was blocked by tetrabenazine. Similarly, [<sup>3</sup>H]DA escaped with a  $t_{1/2}$  of 3.7 min. By contrast, efflux of [<sup>3</sup>H]MPP<sup>+</sup> ( $t_{1/2}$  = 51 h) or [<sup>3</sup>H]DA ( $t_{1/2}$  = 13 h) from 150 nm phosphatidylcholine/cholesterol liposomes was much slower. The identity of [<sup>3</sup>H]MPP<sup>+</sup> or [<sup>3</sup>H]DA in synaptic vesicles or liposomes was confirmed by chromatography. [<sup>3</sup>H]MPP<sup>+</sup> did not escape from synaptic vesicles at 0°C and was taken up by the same vesicles as DA as shown in competition experiments. These results suggest that a transmembrane channel mediates efflux of MPP<sup>+</sup> or DA from synaptic vesicles.

Supported by NIH grants NS24890 and AG10182.

## 31.3

**THE FUNCTIONAL COUPLING OF THE CELL BODY TO THE NERVE TERMINAL IS GATED BY AN I<sub>K</sub>-LIKE K<sup>+</sup> CONDUCTANCE IN THE AXON OF HIPPOCAMPAL PYRAMIDAL CELLS IN VITRO.**

D. Debanne\*, N.C. Guérineau, B.H. Gähwiler and S.M. Thompson. Brain Research Institute, University of Zurich, Switzerland

Pairs of monosynaptically coupled pyramidal cells were recorded with microelectrodes or with the whole-cell technique in hippocampal slice cultures. At the resting membrane potential, presynaptic action potentials (pAPs) evoked a postsynaptic response in all trials, i.e. there were no release failures. When the induction of the pAP was preceded by a brief hyperpolarization, no EPSP/C was elicited by the pAP. Such failures of transmission were associated with faster repolarization of the pAP. Functional coupling was also blocked when the pAP was preceded by an extracellularly evoked IPSP in the presynaptic cell, thus showing that this process is physiologically relevant. We suggest that activation of a voltage-dependent conductance impedes the conduction of the pAP to the axon terminal. Continuous hyperpolarization of the presynaptic cell to -70/-80 mV blocked pAP-EPSP coupling when pAPs were triggered  $\leq 15$  ms after the onset of a depolarizing step but not with longer delays, indicating that the conductance has a fast voltage-dependent inactivation. Recovery from inactivation was tested at hyperpolarized potentials with a depolarizing prepulse. Transmission recovered when the prepulse preceded the pAP by  $\leq 15$  ms, but not with longer intervals. Latencies of the monosynaptic EPSPs/Cs increased at the failure threshold, suggesting a local reduction of pAP conduction velocity due to shunting of the pAP (Segev 1990). Block of pAP-EPSP coupling was not observed with all postsynaptic partners of a single presynaptic cell, suggesting that pAP propagation fails at particular axonal branch points. We conclude that an axonal I<sub>K</sub>-like potassium conductance can shunt pAPs, and prevent their propagation to all axon terminals.

## 31.5

**RELEASE OF A SOLUBLE PROTEIN KINASE FROM BRAIN NEURONS TO THE EXTRACELLULAR SPACE CAN REGULATE INTERCELLULAR INTERACTIONS** H.-A. Yang, M.V. Hogan\* and Y.H. Ehrlich. CSI/IBR Ctr. Dev. Neurosc., Coll. Staten Island, Biol. Phd Prog., Grad. Sch. of the City Univ. of NY, NY 10314.

Extracellular protein phosphorylation that occurs on the surface of brain neurons serves as a target for factors that stimulate neurite outgrowth or can cause neurodegeneration, such as Alzheimer's  $\beta$ -amyloid peptides (Hogan et al., J. Neurochem. 65: 2022-2030, 1995). When primary neurons cultured from chick telencephalon were assayed for ecto-protein kinase (PK) activity, about 50% of the surface-radiolabeled 12/13kDa protein duplex phosphorylated as endogenous substrate was found to be released to the soluble fraction (100,000xg/90min) prepared from the extracellular medium. These released surface phosphoproteins may be related to the intermediates produced during the processing of amyloid precursor protein (APP) to  $\beta$ -amyloid peptides. When the same soluble fraction was prepared first from the medium, a prominent endogenous phosphorylation of a 17kDa protein was in evidence, and phosphorylation of the 12/13kDa substrates was not detected. We have obtained evidence that different protein kinases phosphorylate the 12/13kDa protein-duplex and the 17kDa protein: MBP (myelin basic protein) competes for the phosphorylation of the 12/13kDa substrates but not for the phosphorylation of the 17kDa protein. Antibody against the catalytic domain of PKC- $\delta$  inhibits the phosphorylation of the 12/13kDa, while stimulating the phosphorylation of the 17kDa protein (possibly by indirectly inhibiting its phosphatase). The PKC inhibitor bisindolylmaleimide has the same dual effect. We conclude that the 12/13kDa proteins are specific substrates of a membrane-bound ecto-protein kinase, and the 17kDa protein is a specific substrate of a soluble, exo-protein kinase that is released by neurons to the extracellular environment, and regulates interactions among cells and between the cell surface and components of the extracellular matrix. Supported by NIH grant HD28788 to YHE.

## 31.2

**EFFECT OF AMPHETAMINE ON SULPHYDRYL GROUPS IN MONOAMINERGIC SYNAPTIC VESICLES FROM RAT PINEAL NERVES.** A.Pellegrino de Iraldi\* and J.Pablo Corazza. Inst. de Biología Celular y Neurociencias Prof.E.de Robertis, Facultad de Medicina, U.B.A., Paraguay 2155, 1121 Buenos Aires, República Argentina.

Previous studies of our laboratory demonstrated that a mixture of zinc iodide-osmium tetroxide (ZIO) reacts intensely with sulphydryl groups giving an electron dense precipitate. It was also shown that this reaction was intensely positive in monoaminergic synaptic vesicles. In this work we studied the effect of d-amphetamine on the ZIO reaction in rat pineal nerves synaptic vesicles because it has been shown that amphetamine significantly reduces non-protein sulphydryl groups in mouse tissues. Male Wistar rats, 200-300 g body weight, were injected intraperitoneally with 10 mg/kg d-amphetamine and killed 5, 7, 10 and 15 min later. The pineal glands were extracted, trimmed in two blocks, treated with ZIO and studied at the electron microscope. The ZIO reaction was intensely positive in synaptic vesicles from control untreated animals but it decreased significantly in amphetamine injected rats. In some cases the sulphydryl group reaction was completely negative. Those results suggest that amphetamine may regulate dopamine- $\beta$  hydroxylase activity through sulphydryl compounds which are known to act as endogenous inhibitors of the enzyme.

**TRANSMISSION OF INFORMATION THROUGH EXCITATORY SYNAPSES.**

Budelli, R., Saa, R.E. and Segundo, J.P\*. Biomatemática, Facultad de Ciencias, Universidad de la República, Montevideo, Uruguay. Dept. of Neurobiology and Brain Research Institute, University of California, Los Angeles, Ca. 90095-1763 U.S.A.

The conceptual background for applying Communication Theory to the relation, or "coding," between spike trains across synapses was explained earlier (Segundo, Perkel and Moore, 1966, Kybernetik 3:67-82). The probability of a particular presynaptic spike triggering a postsynaptic spike depended on a bounded number of the former called "influential" and packed within a recent epoch called "integration period." Reasonable formulae were proposed for the entropies that measure uncertainties involving the individual trains, as well as for how much uncertainty is removed, —i.e., how much information is provided— by each train about the other. Stressed were the advantages of using the entire timings —i.e., jointly averages and patterns— of influential spikes rather than exclusively averages. Finally, called attention to was that physiological issues such as discharge statistics, PSP summation rules and refractoriness were strongly influential.

The present work models an excitatory synapse acting upon a spontaneously inactive neuron represented by a leaky integrator, and then measures precisely the uncertainties and informations present in this simple situation. Results illustrate the magnitudes to be expected. The differential information provided by rates and patterns over rates alone was evaluated for different sets of parameters. The dependence of the influential time and the number of influential presynaptic spikes as a function of the model parameters was determined.

## 31.6

**THE PARS INTERMEDIA OF THE AMPHIBIAN XENOPUS LAEVIS AS A MODEL FOR SYNAPSE PLASTICITY.** C.A.F.M. Berghs<sup>1</sup>, J.J.H. Hens<sup>2</sup>, G.W. Eagleson<sup>1\*</sup> and E.W. Roubos<sup>1</sup>. <sup>1</sup>Department of Cellular Animal Physiology, Nijmegen Institute for Neurosciences, University of Nijmegen, Toernooiveld, 6525 ED Nijmegen and <sup>2</sup>Department of Medical Pharmacology, Rudolf Magnus Institute for Neurosciences, University of Utrecht, The Netherlands.

The process of background adaptation of the clawed toad *Xenopus laevis* is regulated by the melanotrope cells in the pars intermedia of the pituitary gland, which produce and release the pro-opiomelanocortin (POMC)-peptide  $\alpha$ MSH. Suprachiasmatic neurons are responsible for the inhibitory control of the melanotropes. Immunoelectron microscopy, using freeze-substituted material, shows that their synapses in the pars intermedia contain GABA, NPY and dopamine. GABA is present in electron-lucent vesicles, whereas NPY and dopamine coexist in dense vesicles. Morphologically specialised synaptic contacts ("active zones") with melanotrope cells show clustering of exclusively lucent vesicles to the presynaptic membrane, indicating release of GABA. Ultrastructural morphometry reveals a strong plasticity of the synapses, in relation to background adaptation: transferring animals from a black to a white background leads to a significant increase in the number and size of the synapses and their active zones. This morphological plasticity of the synapses is reflected in a plasticity of the neurotransmitter contents: biochemical studies demonstrate effects of background on the storage and release of dopamine, GABA and NPY. These findings show that the pars intermedia is a valuable tool in the study of synapse plasticity. Studies of the underlying mechanisms of neurotransmitter release in *Xenopus* are currently in progress.

CHARACTERIZATION OF NEURONAL PROPERTIES OF HUMAN POSTMITOTIC NT2N CELLS. D.B. Hawver\*, A. Khaldi, A. Rashid, S. Doron, C.C. Chiueh, and W.Z. Potter. Section of Clinical Pharmacology, Experimental Therapeutics Branch, and Laboratory of Clinical Science, NIMH, Bethesda, MD 20892.

Cultures of NT2N cells were studied after 5 weeks of treatment with retinoic acid, 2 weeks with mitotic inhibitors, and 4-7 weeks of outgrowth on Matrigel-coated dishes. NT2N cells were able to transport 3H-GABA->3H-glutamate>3H-choline>3H-glycine, but not 3H-NE, 3H-DA, or 3H-5HT. Uptake of 3H-GABA, 3H-glutamate, and 3H-choline was substantially reduced in the presence of the specific transporter inhibitors NO-711, L-trans-pyrrolidine-2,4-dicarboxylic acid, and hemicholinium-3, respectively. Stimulation with 100 mM KCl evoked release of transmitter from cells preloaded with 3H-glutamate or 3H-choline, but not 3H-GABA or 3H-glycine. KCl-evoked release of transmitter was dependent on extracellular  $Ca^{++}$  and inhibited by verapamil. Fura-2 studies showed increases in intracellular  $Ca^{++}$  levels in NT2N cells exposed to KCl, glutamate, veratridine, 4-aminopyridine, or BAYK8644. Calcium responses to KCl were blocked by verapamil, nimodipine, and cobalt chloride. The response to veratridine was blocked by tetrodotoxin. Thus, depolarization of NT2N cells with KCl is able to evoke release of neurotransmitters by increasing intracellular calcium through activation of calcium channels with L-type pharmacology. In summary, our results demonstrate that NT2N cells exhibit many properties of CNS neurons, and therefore provide a valuable system for the study of multiple aspects of CNS neuronal function. ## 31.9

A MIXED GIANT SYNAPSE BETWEEN THE MEDIAL AND MOTOR GIANT FIBERS IN THE ABDOMINAL NERVE CORD OF *PENAEUS ORIENTALIS*. K. XU and X.Q. Shu\*. Shanghai Institute of Physiology, Chinese Academy of Sciences, Shanghai 200031, China.

The preparations of the chemical giant synapse of loligo and the electrical giant synapse of crayfish have been successfully used for analysing the mechanism of the two kinds of synapses accordingly. In our experiments the giant synapse between the medial and motor giant fibers was identified as not only an electrical one by demonstrating the dye (lucifer yellow) coupling in it, but also a chemical one by finding the densely populated transparent synaptic vesicles in diameter of about 50 nm in its presynaptic side. The identification of the transmitter of the mixed giant synapse is going on.

## 31.8

CALCIUM-SECRETION RELATIONSHIPS OBSERVED IN BOVINE CHROMAFFIN CELLS IN RESPONSE TO PULSE TRAINS. N.I. Chernetskaya\*, K.L. Engisch, & M.C. Nowicky. Dept. Neurobiol. & Anat., Med. Coll. Penn., Philadelphia PA, 19129.

We have examined  $Ca^{2+}$ -secretion coupling in individual bovine adrenal chromaffin cells, using the capacitance detection technique to monitor exocytosis ( $\Delta C_m$ ). Recordings were made in the perforated patch mode and cells were stimulated with trains of 5, 40, or 80 ms duration pulses (200 ms interval,  $V_H = -90$  mV,  $V_T = +10$  mV, 10-40 pulses).  $\Delta C_m$  was plotted against the cumulative integral of the  $Ca^{2+}$  current during a train. At the beginning of a train, the slope of the  $\Delta C_m$ - $Ca^{2+}$  load relationship was similar for the 3 different pulse durations. However, significant deviations occurred later in the train. Many (57%) of the 5 ms pulse trains exhibited an increased sensitivity to  $Ca^{2+}$  entry later in the train, while the majority (90%) of 40 and 80 ms pulse trains showed either a decreased responsiveness or maintained the initial relationship. These findings are strikingly different from results obtained in whole cell recordings (J. Neurosci. 16; 553, 1996). To determine the role of intracellular  $Ca^{2+}$  ( $[Ca^{2+}]_i$ ) on differences in  $Ca^{2+}$ -secretion-coupling, we loaded cells with fura-red AM and monitored  $[Ca^{2+}]_i$  as changes in dye fluorescence with a Gen-3 video camera. During trains,  $[Ca^{2+}]_i$  quickly reached a plateau (within 1-3 pulses of 40 or 80 ms duration and ~10-15 pulses of 5 ms duration) which did not change for the remainder of the train, again unlike the whole cell configuration. Thus, changes in  $[Ca^{2+}]_i$  levels alone cannot account for the different  $Ca^{2+}$ -secretion relationships. Supported by NS22281 and Muscular Dystrophy Association.

## SODIUM CHANNELS: EXPRESSION AND CLONING

## 32.1

ANALYSIS OF VOLTAGE-SENSITIVE  $Na^+$  CHANNEL  $\beta 1$  SUBUNIT GENE EXPRESSION USING QUANTITATIVE RT-PCR. Youngsuk Oh\*. Department of Medicine, Division of Nephrology, and Neurobiology Research Center, University of Alabama, Birmingham, AL 35294.

Two isoforms ( $\beta_{1.1}$  and  $\beta_{1.2}$ ) of the  $Na^+$  channel  $\beta 1$  subunit ( $Na\beta 1$ ) mRNAs have been found in certain glial cells as well as in neurons. The coding regions of the  $\beta_{1.1}$  and the  $\beta_{1.2}$  mRNAs are nearly identical, but the  $\beta_{1.2}$  mRNA contains an additional 86-nucleotide insert (which is an intron) in 3' noncoding regions. In the present study, I have constructed a competitive  $Na\beta 1$  DNA template that is cloned into pCR II vector and can be readily discriminated from the  $\beta_{1.1}$  and the  $\beta_{1.2}$  because of its different nucleotide size. The same primers were used to co-amplify the  $\beta_{1.1}$  (974 bp), the  $\beta_{1.2}$  (1060 bp), and the competitor (880 bp). For the application of the  $Na\beta 1$  competitor, two different methods were evaluated by determining basal levels of  $Na\beta 1$  mRNAs in cultured cortical or spinal cord astrocytes derived from postnatal day 0-5 Sprague-Dawley rats. First, a dilution series of the competitor DNA was added into a constant amount of astrocyte cDNA during PCR reaction. Second, a dilution series of the synthesized competitor cRNA was added into a constant amount of astrocyte RNA during RT reaction. The PCR products were resolved by gel electrophoresis, and quantitated by analyzing a digitalized image of the ethidium bromide stained gel. The results indicate that both DNA and RNA competitors are suitable for analyzing  $Na\beta 1$  gene expression by quantitative RT-PCR. This quantitative competitive RT-PCR will be useful to study  $Na\beta 1$  gene expression in response to various stimuli, such as cAMP treatment. [Supported by NS 34877]

## 32.2

IDENTIFICATION OF SODIUM CHANNELS IN HUMAN DORSAL ROOT GANGLIA. D.K. Rabert\*, M.J. Ilnicka and L. Sangameswaran. Institute of Pharmacology, Roche Bioscience, Palo Alto, CA 94303.

RT-PCR was used to amplify voltage-gated sodium channel  $\alpha$ -subunits that are expressed in human dorsal root ganglia (DRG). Nested, degenerate primer sets were designed to amplify either one of the major domains (I-IV) or one of the interdomain regions. Two known human  $\alpha$ -subunits were detected: 1) human brain HBA, 100% identity for the amino acid sequence between IIIS5 and IVS1, and 2) human neuroendocrine, 100% identity for the amino acid sequence between IVS1 and IVS6. The human neuroendocrine sodium channel was previously detected in the thyroid and adrenal gland (EMBO J., 14:1084, 1995). This study suggests that the neuroendocrine channel is a homologue of the rat PN1 channel based on the expression of the neuroendocrine channel in the DRG and the 93% identity of the amino acid sequence that is shared between the two channels. Tissue distribution of the PN1-like channel will be discussed.

## 32.3

SPINAL SENSORY NEURONS EXPRESS MULTIPLE SODIUM CHANNEL ALPHA SUBUNIT MRNAs. J.A. Black<sup>1</sup>, S. Dib-Hajj<sup>1</sup>, K. McNabola<sup>1</sup>, S. Jeste<sup>1</sup>, M.A. Rizzo<sup>1</sup>, J.D. Kocsis<sup>1</sup> and S.G. Waxman. Dept. of Neurology, Yale Univ. Sch. of Med., New Haven, CT and Neuroscience Res. Ctr., VA Medical Center, West Haven, CT 06516

Spinal sensory (dorsal root ganglion [DRG]) neurons constitute a heterogeneous population of cells, and multiple, distinct voltage-gated Na currents have been described in these cells. Neural Na channels are trimeric complexes composed of  $\alpha$ -,  $\beta$ 1- and  $\beta$ 2-subunits. The  $\alpha$ -subunits belong to a multigene family, with at least eight distinct isoforms being described in neural tissue. The molecular correlates underlying Na current diversity in DRG neurons has not been established. In the present study, we use *in situ* hybridization and RT-PCR to examine the expression of Na channel mRNAs in DRG neurons *in vitro* and *in vivo* from adult rats.

Riboprobes specific for Na channel mRNAs I, II/III, III, NaG, Na6, hNE-Na, SNS, mNav2.3,  $\beta$ 1 and  $\beta$ 2 were constructed, and DRG neurons *in vitro* and *in vivo* processed for *in situ* hybridization, as previously described (Black et al. 1994a,b). RT-PCR was performed on total cellular RNA extracted from brain and L4/5 DRG with primers designed against sequences in domains 1 and 4, and also against 3' untranslated sequences as previously described (Dib-Hajj and Waxman 1995).

The results demonstrate that multiple Na channel  $\alpha$ -subunit mRNAs, in addition to  $\beta$ 1- and  $\beta$ 2-subunit mRNAs, are expressed in DRG neurons *in vitro*, with high levels of expression for mRNAs I, NaG, Na6, hNE-Na, SNS,  $\beta$ 1 and  $\beta$ 2. Moreover, the pattern of expression of Na channel mRNAs in DRG neurons *in vitro* at 1 day in culture is similar to that observed in DRG neurons *in vivo*. ## 32.5

NA<sup>+</sup> CHANNEL  $\beta$ 1-A: AN AUXILIARY SUBUNIT EXPRESSED IN EMBRYONIC BRAIN AND NEUROENDOCRINE TISSUES. L.L. Isom<sup>\*</sup> and K. Kazen-Gillespie. Department of Pharmacology, The University of Michigan Medical School, Ann Arbor, MI. 48109-0632.

Voltage-gated Na<sup>+</sup> channels are composed of a central, pore-forming  $\alpha$  subunit and one or two auxiliary  $\beta$  subunits. The  $\beta$  subunits have been shown to be important modulators of channel kinetics and plasma membrane expression levels. Na<sup>+</sup> channel  $\beta$ 1 subunits cloned from brain have been shown to be expressed only after birth, whereas  $\beta$ 2 subunits have been shown to be expressed early on in embryonic development and have been postulated to play a role in neurogenesis and synaptogenesis. Both  $\beta$ 1 and  $\beta$ 2 contain immunoglobulin (Ig)-like domains with homology to neural cell adhesion molecules. Thus,  $\beta$  subunits may also function in Na<sup>+</sup> channel localization during brain development. We now describe the cloning of a  $\beta$ 1 subunit isoform that is significantly different from that originally reported. This new isoform,  $\beta$ 1-A, was isolated from a rat adrenal cDNA library.  $\beta$ 1-A contains a central region of identity to  $\beta$ 1 and two regions of non-identity, but retaining structural homology, at the 5' and 3' ends. Interestingly, the central region of identity includes most of the putative Ig domain found in  $\beta$ 1. The domains of non-identity retain structural homology to the remainder of the Ig domain. Outside of the putative Ig loop, however, the amino acid sequence of  $\beta$ 1-A contains little or no homology to  $\beta$ 1 or  $\beta$ 2. Thus,  $\beta$ 1-A is a new member of the Ig superfamily, homologous to members of the superfamily that are termed V-like, including the neural cell adhesion molecules. Investigation of the tissue-specific expression of  $\beta$ 1-A mRNA by Northern blot analysis revealed two positive hybridization signals at 1.4 and 4 kb. The mRNA migrating at 4 kb is expressed in embryonic brain, adult adrenal, and PC12 cell line cells. The signal in embryonic brain diminishes as development progresses and is not detected after birth. The lower band is more widely expressed, showing positive signals in embryonic and adult brain, heart, skeletal muscle, and adrenal. *In situ* hybridization analysis indicated that  $\beta$ 1-A is expressed in adrenal medulla but not in adrenal cortex, consistent with the hypothesis that  $\beta$ 1-A may be an auxiliary subunit of adrenal chromaffin cell Na<sup>+</sup> channels. Supported by the Michigan Diabetes Research and Training Center 5-P60-DK20572-19.

## 32.7

CLONING AND DISTRIBUTION OF THE MECHANOSENSORY- LIKE GENE EXPRESSED IN THE RAT NERVOUS SYSTEM.

Y. Minami<sup>1,2</sup>, S. Shimada<sup>1\*</sup>, K. Inoue<sup>1</sup>, H. Morimura<sup>1</sup>, T. Matsunaga<sup>2</sup> and M. Tohyama<sup>1</sup>. <sup>1</sup>Dept. of Anatomy & Neurosci., Osaka Univ. Medical School, 565 Japan. <sup>2</sup>Dept. of Otolaryngol., Nara Medical Univ., Nara, 634 Japan.

*Mec* (mechanosensory) genes are involved in the transduction of touch sensory in the nematode *C. elegans*. Especially mutation of degnerin gene family (*mec-4*, *mec-10*, *mec-6*, *deg-1*) cause neuronal degeneration. On the other hand, the amiloride-sensitive sodium channel was identified from rat colon, kidney and lung, and the subunit sequences of this channel showed significant identity with degnerin gene family. Recently, peptide-gated sodium channel was identified from *Helix* nervous tissue, it is suggested that these genes constitute a new gene family which is associated with mechanotransduction or the maintenance of the cellular volume or neurotransmission. We isolated a novel gene belong to these gene family from rat brain, and examined the distribution of this mechanosensory-like gene expression by *in situ* hybridization. Hybridization signal was seen in the almost all neuronal cells in the brain and retina. It is suggested that this gene may be involved in the osmosensor or the unknown peptide-gated ion channel in the rat nervous system.

## 32.4

STRUCTURE, FUNCTION AND CHROMOSOME MAPPING OF A NOVEL VOLTAGE-GATED, TETRODOTOXIN-RESISTANT SODIUM CHANNEL SPECIFIC TO SENSORY NEURONS. L. Sangameswaran<sup>1</sup>, S. G. Delgado<sup>1</sup>, L. M. Fish<sup>1</sup>, B. D. Koch<sup>1</sup>, C. Kozak<sup>1</sup>, L. B. Jakeman<sup>1</sup>, G. R. Stewart<sup>1</sup>, P. Sze<sup>1</sup>, J. C. Hunter<sup>1</sup>, R. M. Eglen<sup>1</sup> and R. C. Herman<sup>1</sup>. Institute of Pharmacology, Neurobiology Unit, Roche Bioscience, Palo Alto, CA 94304. <sup>1</sup>Laboratory of Molecular Microbiology, NIAID, NIH, Bethesda, MD 20892.

Small neurons of the dorsal root ganglia (DRG) play a significant role in nociception. These neurons express two types of sodium current, which differ in their inactivation kinetics and sensitivity to tetrodotoxin (TTX). We have cloned the  $\alpha$ -subunit of a novel voltage-gated sodium channel, PN3 (Peripheral sodium channel 3) from rat DRG. In *Xenopus* oocytes PN3 exhibited slow inactivation kinetics and little or no activation at -10mV, whereas most cloned sodium channels begin to activate between -60 and -30mV in this system. PN3 sodium current is resistant to TTX ( $IC_{50} \geq 100 \mu M$ ). PN3 mRNA was expressed at high levels only in DRG and nodose ganglia. It was not detected in brain, spinal cord, superior cervical ganglia, heart and skeletal muscle. *In situ* hybridization to rat DRG indicated that PN3 expressed primarily in small sensory neurons of the peripheral nervous system. Using a specific DNA probe for PN3, we have mapped the location of the PN3 gene (*SCN10a*) to mouse chromosome 9, close to the TTX-insensitive cardiac sodium channel, *SCN5a*.

## 32.6

LOCALIZATION OF SODIUM CHANNEL ALPHA SUB-UNIT NaG mRNA IN THE ADULT RAT. P.A. Felts<sup>\*</sup>, J.A. Black<sup>1</sup>, S. Dib-Hajj<sup>1</sup> and S.G. Waxman. Department of Neurology, Yale Univ. School of Medicine, New Haven, CT 06512.

The rat sodium channel alpha subunit NaG was originally cloned from a cultured cortical astrocyte cDNA library. NaG mRNA has been shown by RNase protection assay and Northern blot to be expressed at only very low levels within the adult rat brain, but at substantially greater levels within the dorsal root ganglion (DRG) (Gautron et al., *PNAS*, 89:7272). Previous studies in our laboratory (Waxman and Black, *Neurochem. Res.*, in press), utilizing non-radioactive *in situ* hybridization with an antisense riboprobe against a coding region of NaG (436 bp; GeneBank numbering 872-1308), demonstrated a lack of labeling in the adult CNS, but showed that NaG mRNA was present in adult rat DRG neurons. As DRG neurons are: 1) primary afferents and 2) derived from neural crest, we have used this technique, in some cases in conjunction with RT-PCR, to examine expression of NaG mRNA in several related tissues to determine if the expression of this transcript is correlated with one or both of these properties.

Hybridization signal with the NaG antisense riboprobe was observed in the primary afferents of the trigeminal ganglion, and the mesencephalic nucleus of cranial nerve V (the only primary afferent neuronal somata located within the CNS). However, labeling was absent from neurons within the spiral ganglion, vestibular ganglion, olfactory epithelium and retina. Of the non-afferent, neural crest derived tissues examined, light labeling was present in the chromaffin cells of the adrenal medulla (with scattered cells exhibiting dense label); neurons of the superior cervical ganglion were unlabeled, although satellite cells surrounding these neurons did exhibit moderate labeling. RT-PCR confirmed the lack of NaG mRNA in the retina, and demonstrated the presence of NaG mRNA within the trigeminal ganglion, and in agreement with the findings by Gautron et al., within the adrenal gland.

Our findings demonstrate that NaG, or a closely related alpha subunit, is expressed in some, but not all, primary afferent neurons, and in some, but not all, neurons derived from the neural crest. [Supported by the VA and NMSS]

## 32.8

CHARACTERIZATION OF VOLTAGE-DEPENDENT ION CHANNELS IN HUMAN BREAST CANCER CELLS. C.E. Davis, T.J. O'Shaughnessy, L.S. Gray, H.R. Brashear<sup>\*</sup>, and Y.I. Kim. Departments of Biomedical Engineering, Neurology, and Pathology, University of Virginia School of Medicine, Charlottesville, VA 22908.

Paraneoplastic neurological syndromes (PNS) are "remote effects" of cancer on nervous structures. They are believed to be autoimmune in nature, with disease symptoms brought about by autoantibodies against tumor antigens cross-reacting with the pathological target. In this study, we tested the possibility that human breast cancer cells may express voltage-dependent ion channels acting as potential antigens for PNS. Using the whole-cell patch-clamp technique, we initially characterized the types of ionic currents present in the tumor cells.

Of six breast cancer cell lines studied, five showed expression of at least one type of voltage-dependent ion channel. Cell line DU4475 was found to express a TTX-sensitive sodium current with a mean peak amplitude of 74 pA (n=88 cells), as well as a 90 pA (n=20) potassium current in 87% of the cells tested. In addition, preliminary data suggest that a calcium current (10-50 pA) may be present in these cells. Cell line MDA-MB-157 expressed  $I_{Na}$  (52 pA, n=7) in 35% of the cells and a 28 pA current in 30% of the cells tested (n=6), which had biophysical properties characteristic of  $I_{Ca}$ . Cell line MCF-7 was found to contain a 375 pA (n=12) whole-cell  $I_K$  in 57% of the cells. In 27% of these cells, only a rapidly inactivating  $I_K$  was seen (169 pA, n=7). Cell lines MDA-MB-468 and BT-549 also expressed  $I_K$  in the majority of cells tested.

These results provide experimental evidence for the presence of voltage-dependent ion channels in human breast cancer cells. Possible cross-reactivity of autoantibodies in PNS with these ion channels remains to be determined. (Supported by grants from NIH and MDA)

## 32.9

STRUCTURAL AND FUNCTIONAL FEATURES OF VOLTAGE-GATED SODIUM CHANNELS IN A HYDROZOAN JELLYFISH. J.D. Spafford\*, N. Grigoriev, A.N. Spencer and W.J. Gallin. Department of Biological Sciences, University of Alberta, Edmonton, Alberta, Canada T6G 2E9.

Whereas most animals' Na<sup>+</sup> currents are blocked by nanomolar concentrations of TTX, all known cnidarians' currents are insensitive to concentrations in excess of 100  $\mu$ M. In fact, no common Na<sup>+</sup> channel-specific drugs effective on mammalian currents alter the TTX-insensitive Na<sup>+</sup> current in swimming motor neurons ("SMNs") of the hydrozoan jellyfish, *Polyorchis penicillatus*. The Na<sup>+</sup> current in SMNs differs in its activation and inactivation curves, which are displaced 35 to 45 mV in the depolarizing direction relative to most Na<sup>+</sup> currents. In other regards, the current is typical, with multiple modes of inactivation gating and steeply voltage-dependent rates of activation and steady-state inactivation. The current also exhibits a channel permeability to monovalent cations and sensitivity to block by di-(tri)valent cations in rank orders that are typical of mammalian Na<sup>+</sup> channels. The Na<sup>+</sup> current in SMNs is one of three which have been identified in primary culture of jellyfish cell networks in whole cell patch clamp recording.

We have identified a single 6 kb Na<sup>+</sup> channel transcript in a Northern blot with probes made from fragments of a 13.5 genomic clone. Sequences from cloned regions of the genomic clone have an amino-acid similarity of ~70% to cDNA clones of mammalian and *Drosophila* Na<sup>+</sup> channels and 85% similarity with a Scyphozoan jellyfish clone. We are currently isolating a full-length cDNA clone of the 6 kb transcript. Data from the full-length expressed clone will help our understanding of the structural and functional features that make the subclass of Na<sup>+</sup> currents in jellyfish unique among those in the voltage-gated Na<sup>+</sup> channel family.

This research was supported by grants from the Natural Sciences and Engineering Research Council.

## 32.11

DIFFERENTIAL REGULATION OF SODIUM CHANNEL  $\alpha$ - AND  $\beta$ -SUBUNIT mRNAs BY PROTEIN KINASE C ACTIVATION IN ADRENAL CHROMAFFIN CELLS. T. Yanagita, H. Kobayashi, K. Masumoto, R. Yamamoto, T. Yuhi, H. Yokoo and A. Wada\*. Dept of Pharmacology, Miyazaki Medical College, Miyazaki 889-16, Japan.

Our previous [<sup>3</sup>H]saxitoxin binding and <sup>22</sup>Na<sup>+</sup> influx studies have shown that an activation of protein kinase C (PKC)  $\alpha$ - and/or  $\epsilon$ -isoforms by 12-O-tetradecanoylphorbol-13-acetate (TPA) down-regulates the number of functional Na<sup>+</sup> channels at plasma membranes with IC<sub>50</sub> 19 nM and t<sub>1/2</sub> 4.5 h, and it is mediated via the de novo synthesis of protein(s) (J. Neurochem. 66:1249-1253, 1996).

Present northern blot analysis with cDNA probes for human neuroendocrine type Na<sup>+</sup> channel (hNE-Na)  $\alpha$ -subunit and rat brain  $\beta$ 1-subunit was undertaken to examine the effects of TPA on the level of Na<sup>+</sup> channel subunit mRNAs. Treatment of cultured bovine adrenal chromaffin cells with 100 nM TPA decreased  $\alpha$ -subunit mRNA within 1 h, the reduction being maximal (by 58%) at 6 h, and restoring toward control level within 24-48 h, while TPA raised  $\beta$ -subunit mRNA by 130% at 24 h with an initial small decrease at 6 h. These results suggest that  $\alpha$ - and  $\beta$ -subunits of Na<sup>+</sup> channels in adrenal chromaffin cells are structurally related to those of hNE-Na and rat brain, and that PKC reduces the abundance of transcript of  $\alpha$ - (but not  $\beta$ -) subunit, culminating in the down-regulation of cell surface expression of Na<sup>+</sup> channels.

(Supported in part by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture, Japan.)

## 32.13

TRANSCRIPTIONAL REGULATION OF HUMAN BRAIN SODIUM CHANNEL GENES: CLONING AND CHARACTERIZATION OF THE  $\beta$ 1 SUBUNIT 5'-FLANKING REGION. M.L. Beckman\* and G.B. Brown. Psychiatry and Behavioral Neurobiology and The Department of Biochemistry and Molecular Genetics, Univ. of Alabama at Birmingham, Birmingham, AL 35294

Voltage-dependent sodium channels from central neurons are composed of a heterotrimeric complex of  $\alpha$ ,  $\beta$ 1 and  $\beta$ 2 subunits in a 1:1:1 stoichiometry. Several alpha subunit cDNAs as well as cDNAs for the  $\beta$ 1 and  $\beta$ 2 subunits have been obtained in rat, and with the exception of  $\beta$ 2, in human as well. Coexpression of the  $\beta$ 1 subunit with  $\alpha$  modifies the electrophysiological properties of the expressed  $\alpha$  subunit by accelerating inactivation, shifting the voltage-dependence of inactivation to more negative membrane potentials and increasing the peak amplitude of sodium current (W.A. Catterall, *Annu.Rev.Biochem.* 64:493-531, 1995).

Toward gaining an understanding of the transcriptional regulation of the  $\beta$ 1 subunit we have undertaken to clone and characterize the 5'-flanking region. A digoxigenin-labeled 416 base pair probe was generated by the polymerase chain reaction and used to screen a human genomic library in  $\lambda$  phage MG14 (Rotwein, et al. *JBC*. 261:4828-4832, 1986). Initial first round positive clones were taken through two additional rounds of screening and phage were then purified from a liquid lysate. A clone was obtained and the restriction map determined for a number of enzymes. Subsequently, the clone was confirmed to be a  $\beta$ 1 subunit by the polymerase chain reaction using  $\beta$ 1 specific primers.

Further characterization will include sequencing, subcloning into luciferase reporter vectors and functional studies of the promoter activity of segments of the 5'-flanking region. These studies will make use of the human neuroblastoma cell line LA-N-5 which has been shown to express the  $\beta$ 1 subunit (Beckman and Brown, *Soc.Neurosci.Abs.* 21(3) 714.6). DOPAMINE MODULATES SODIUM CURRENT VIA PKA ACTIVATION IN RAT HIPPOCAMPAL NEURONS. A.R. Cantrell\*, T. Scheuer, and W.A. Catterall, Department of Pharmacology, University of Washington, Seattle, WA 98195.

Voltage-gated sodium channels play an important role in neuronal excitability in the hippocampus but are infrequently recognized as targets for neuromodulation. As previously reported by our laboratory, phosphorylation of brain sodium channels by protein kinase A (PKA) decreases peak current. D1-like dopamine receptors on hippocampal neurons activate PKA. Therefore, we have tested whether sodium channels can be modulated by activation of D1-like receptors in acutely-isolated adult (3-5 wks postnatal) hippocampal neurons using whole-cell voltage clamp recording.

Application of the D1 agonist, 6CIPB (5 $\mu$ M), reduced peak sodium current an average of 25.3  $\pm$  1.5%. No changes in the voltage dependence of activation or inactivation were detected. These effects were mediated via PKA as they were eliminated when a specific PKA inhibitor peptide (PKAi<sub>1-9</sub>) was included in the pipette solution and mimicked by the extracellular application of the PKA activator, DClcBIMPS.

These results demonstrate that activation of endogenous D1-like dopamine receptors on hippocampal neurons strongly modulates sodium channel activity by activation of PKA. Such modulation is expected to have profound effects on overall neuronal activity. This work was supported by NIH grant NS15751 to W.A.C. and a postdoctoral fellowship from NIDA training grant DA07278 to A.R.C.

## 32.12

INDUCTION OF PERSISTENT Na<sup>+</sup> CURRENT BY OVEREXPRESSION OF G-PROTEIN  $\beta$  SUBUNITS. J.Y. Ma\*, W.A. Catterall and T. Scheuer. Dept. of Pharmacol., Box 357280, Univ. of Washington, Seattle, WA 98195.

We have shown that rat brain Na<sup>+</sup> currents are modulated by activation of G proteins. To determine the effects of particular G-protein subunits on brain Na<sup>+</sup> channels, we transiently overexpressed them in combination with rat brain type IIa Na<sup>+</sup> channel  $\alpha$  subunits in tsA201 cells. Overexpression of G-protein subunits modulated the presence of a TTX-sensitive, slowly and incompletely inactivating fraction of Na<sup>+</sup> current in whole cell voltage clamp recordings from these cells. In the absence of exogenous G-protein subunits, a small component of Na<sup>+</sup> current persisted after 2 ms of depolarization to +20 mV (8%). Overexpression of G $\beta$ 2y3 increased the component of current not inactivated at 2 ms 2.5-fold to 30%, with individual cells having >50% non-inactivated current. Conversely, overexpression of G $\alpha$ o or G $\alpha$ i resulted in a rapidly inactivating current (13% not inactivated at 2 ms), even in the presence of overexpressed G $\beta$ 2y3. These results suggest that G $\beta$ 2y3 subunits induce the slowly inactivating component of Na<sup>+</sup> current, and G $\alpha$  subunits inhibit the effect by binding and sequestering G $\beta$ y subunits. The slowly inactivating current inactivated at more positive potentials than the rapidly inactivating current. Inactivation curves in cells expressing G $\beta$ 2y3 showed two well-defined Boltzmann components with the positive component corresponding to the slowly inactivating current and shifted >30 mV positive to the negative component. We used prepulses to -25 mV to isolate the slowly inactivating component of current. Its voltage-dependence of activation was similar to that of the rapidly inactivating current but inactivation was slowed and incomplete at all test pulse potentials. Such slowly inactivating and persistent Na<sup>+</sup> currents are characteristic of a variety of central neuronal cell types and are thought to be important modulators of cell function. These persistent Na<sup>+</sup> currents may result from modulation of a single Na<sup>+</sup> channel subtype by G protein  $\beta$  subunits. Supported by NIH training grant NS09797 to J.Y.M.

## 32.14

TRANSCRIPTIONAL REGULATION OF HUMAN BRAIN SODIUM CHANNEL GENES: IDENTIFYING THE TRANSCRIPTIONAL START SITE OF THE SUBTYPE II GENE. S.D. Schade\*, C.-M. Lu, J.S. Eichelberger, M.L. Beckman, and G.B. Brown. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama at Birmingham, Birmingham, AL 35294

Voltage-gated sodium channels are responsible for the rising phase of the action potential in excitable cells. Human neuronal sodium channel subtype-specific mRNAs are differentially distributed regionally (Lu et al., *FEBS Lett.* 303(1):53-58, 1992), suggesting differential transcriptional regulation. Previously we described cloning, sequencing, and putative transcriptional start sites by primer extension and 5' RACE (rapid amplification of cDNA ends) for the subtype II gene (Eichelberger et al., *Soc. Neurosci. Abs.* 20(1), 33.14, 1994). Here we describe additional studies to identify the transcriptional start site and promoter region of this gene.

Two genomic subclones upstream of the translational start site identified by Ahmed et al. (*PNAS* 89: 8220-8224, 1992) were constructed to investigate potential promoter and regulatory elements in the immediate 5'-flanking region. The 2.7kb subclone overlaps and extends 5' to the translational start site. The 1.9kb subclone abuts the 2.7kb subclone further upstream. The 1.9kb subclone has been cloned into the promoterless and basic luciferase vectors for transient transfection into the human neuroblastoma cell line, SH-SY5Y. Luciferase assays show the 1.9kb subclone does not drive luciferase expression and thus does not contain the promoter region. Concordantly, ribonuclease protection assays (RPA) showed the 1.9kb clone does not contain the transcriptional start site. Within the 2.7kb subclone, primer extension and 5' RACE products map potential transcriptional start sites to 261 and 318 nucleotides upstream of the 5' end of a 1.7kb intron within the 2.7kb subclone, but preliminary RPA experiments suggest the transcriptional start site is 70 nucleotides further upstream.

Supported by USPHS grant DA 07237.

## 32.15

THE REGULATION OF SODIUM CHANNEL SUBUNITS IN THE HEK293 MAMMALIAN CELL LINE. S.L. Stewart, S.J. Wieland, and J.E. Fletcher. Dept. of Anesthesiology, Med. Col. of PA and Hahnemann Univ., Phila., PA 19102

The human skeletal muscle Na<sup>+</sup> channel consists of one of two  $\alpha$  subunits (adult and embryonic forms), which are the functional subunits of the channel, and a modulatory  $\beta$  subunit. In *Xenopus* oocytes injected with mRNA for the adult  $\alpha$  subunit alone, Na<sup>+</sup> channels are expressed which exhibit slow inactivation kinetics, however, co-injection with mRNA for the  $\beta$  subunit restores normal rapid inactivation kinetics. In contrast, plasmids containing  $\alpha$  subunits alone expressed in mammalian cells produce channels which exhibit normal rapid inactivation kinetics. In the present study, human embryonic kidney (HEK293) cells, with very low or no expression of Na<sup>+</sup> current, were transfected with a plasmid containing either the adult skeletal muscle sodium channel  $\alpha$  subunit (SkM1), or the embryonic skeletal muscle  $\alpha$  subunit (SkM2). Poly A<sup>+</sup> mRNA was reverse transcribed and the cDNA was amplified by PCR using primers to the Na<sup>+</sup> channel subunits. Transfection with either SkM1 or SkM2 induced transcription of the  $\beta$  subunit. These findings suggest that  $\alpha$  subunit expression induces  $\beta$  subunit transcription, and that the normal rapid inactivation kinetics exhibited by mammalian cultures transfected with Na<sup>+</sup> channel  $\alpha$  subunits may reflect the interaction between the  $\alpha$  and  $\beta$  subunits.

## 32.16

Temporal regulation of changes in the expression of specific Na channel  $\alpha$  subunits in adult rat DRG neurons following axotomy. S.D. Dib-Hajj, P. Felts, A. Kenney, J.A. Black and S.G. Waxman. Department of Neurology, Yale University School of Medicine, New Haven, CT. and Neuroscience & Regeneration Research Center, VA Medical Center, West Haven, CT. 06516.

Our group has previously demonstrated that, following axotomy, there is an increase in the amplitude of Na currents and the expression of the previously silent  $\alpha$  III subunit mRNA in adult rat DRG neurons. More recently, we also demonstrated that there is an enhancement of the fast, TTX-sensitive current and a decline in the slow, TTX-resistant current in identified medium size cutaneous afferent DRG neurons. We used RT-PCR to investigate the changes in the  $\alpha$  subunit expression profile in adult rat DRG neurons following axotomy at 1, 3, 5, 7, 14, 21 and 210 days post ligation (dpl).

Preliminary results show that the previously silent  $\alpha$  III subunit is expressed, as previously reported, and the expression level of the slow, TTX-resistant  $\alpha$  NS is reduced in the DRG neurons of the Ipsilateral (lesioned) side compared to the contralateral (control) side. Transcripts of  $\alpha$  III were detectable at 5 dpl but were undetectable by 21 dpl. Restriction enzyme polymorphism analysis shows only the adult form of  $\alpha$  III. Therefore, the expression of this subunit may not be a recapitulation of a developmental program, or axotomy does not restore factor(s) responsible for the embryonic-specific alternative splicing of this transcript.

Transcripts of  $\alpha$  NS appear to first increase at 1 and 3 dpl, then decrease between 5-14 dpl and partially recover by 21 dpl. No detectable difference from control is seen at 210 dpl.

This work is supported in part by the Medical Research Service, VA and NMSS.

## SODIUM CHANNELS: PHARMACOLOGY

## 33.1

INHIBITION OF VOLTAGE-DEPENDENT SODIUM CHANNELS BY HALOTHANE IN RAT CORTICAL SYNAPTOSOMES. L. Ratnakumari and H.C. Hemmings, Jr.\* Departments of Anesthesiology and Pharmacology, Cornell University Medical College, New York, NY 10021, USA

Although voltage-gated ion channels have been claimed to be insensitive to the action of general anesthetics, recent studies have shown that the volatile anesthetic halothane reduces Na<sup>+</sup> currents through Na<sup>+</sup> channels.<sup>1</sup> Volatile anesthetics inhibit synaptic glutamate release, probably through an effect on Na<sup>+</sup> channels.<sup>2</sup> In the present study, the effects of halothane on Na<sup>+</sup> channel function and ligand binding were examined by measuring changes in <sup>22</sup>Na<sup>+</sup> influx, free intracellular sodium levels ([Na<sup>+</sup>]) and binding of [<sup>3</sup>H]saxitoxin ([<sup>3</sup>H]STX), [<sup>3</sup>H]batrachotoxin-A 20- $\alpha$ -benzoate ([<sup>3</sup>H]BTX) and [<sup>3</sup>H]brevotoxin-3 ([<sup>3</sup>H]Pbtx-3) in rat cortical synaptosomes. Synaptosomes were isolated from cerebral cortex of adult Sprague-Dawley rats by the Percoll gradient method. [Na<sup>+</sup>] was measured by ion-specific spectrophotometry using SBFI-AM as Na<sup>+</sup>-sensitive fluorophore. Halothane inhibited veratridine-evoked <sup>22</sup>Na<sup>+</sup> influx and changes in [Na<sup>+</sup>], dose-dependently with IC<sub>50</sub> values of 1.1 and 0.96 mM (MAC=0.3 mM), respectively, without affecting basal levels. [<sup>3</sup>H]BTX binding to receptor site 2 of the Na<sup>+</sup> channel was also significantly reduced in the presence of halothane with 50% inhibition at 0.5 mM; [<sup>3</sup>H]STX binding to receptor site 1 was unaffected. [<sup>3</sup>H]Pbtx-3 binding at site 5 of Na<sup>+</sup> channel was increased marginally (10%, p<0.05) by halothane. These results provide biochemical evidence that halothane inhibits Na<sup>+</sup> channels at clinically relevant concentrations and support a role for Na<sup>+</sup> channels as

a molecular target of action for anesthetics. (<sup>1</sup>Anesthesiology, 75:716, 1991; <sup>2</sup>Anesthesiology, 82:1406, 1995; Supported by NIH grant # GM 52441 and Cornell Scholar Award).

## 33.3

VOLTAGE-DEPENDENT INHIBITION OF TETRODOTOXIN-RESISTANT NA<sup>+</sup> CURRENTS IN RAT SENSORY NEURONS BY LAMOTRIGINE. X.M. Xie, T.J. Dale and D.J. Trezise. Neurosciences Unit, GlaxoWellcome Medicines Research Centre, Stevenage, Hertfordshire SG1 2NY, U.K.

The antiepileptic, Na<sup>+</sup> channel blocking drug, lamotrigine (LTG, Lamictal), exhibits analgesic effects both in a variety of animal models and in man (*Pain* 63:33, 1995; *Br. J. Clin. Pharmacol.* 39:549P, 1995). However, the cellular and molecular mechanisms underlying these effects are poorly understood. In the present study, we have used whole cell voltage-clamp recording techniques to examine the actions of LTG on voltage-gated Na<sup>+</sup> currents in rat dorsal root ganglion (DRG) neurons. We have focused on tetrodotoxin-resistant Na<sup>+</sup> currents (TTX-R) in these cells, which are believed to be sensory neuron specific (*Nature* 379: 257, 1996).

Na<sup>+</sup> currents were recorded from acutely dissociated, neonatal rat (1-3 days old) DRG neurons (15-25  $\mu$ m) in the presence of 500nM TTX. Pilot studies demonstrated that 100nM TTX was sufficient to abolish fast TTX-sensitive Na<sup>+</sup> currents. TTX-R currents were activated by membrane depolarisation from a holding potential (V<sub>h</sub>) of -90mV (voltage for 50% activation, V<sub>0.5</sub>, was -17mV) and reached maximum at 0 to +10mV. The V<sub>0.5</sub> for fast inactivation was -18mV. At the peak current, the mean time constants for activation and inactivation (decay) were 0.6ms and 3.9ms, respectively. Bath application of LTG caused a reversible inhibition of TTX-R, in a concentration-dependent and voltage-dependent manner. The mean IC<sub>50</sub> obtained at a V<sub>h</sub> of -90 mV was 550  $\mu$ M, whereas an IC<sub>50</sub> of 260  $\mu$ M was obtained at a V<sub>h</sub> of -60 mV. No pronounced effects of LTG (50  $\mu$ M) on either activation/ fast inactivation kinetics, or the voltage dependence of these parameters were observed.

Our preliminary data demonstrate that LTG is capable of inhibiting TTX-R Na<sup>+</sup> currents in sensory neurones in a voltage-dependent manner. Further mechanistic studies on this drug action are underway. This inhibitory effect of LTG on TTX-R Na<sup>+</sup> channels may, in part, underlie the analgesic effects of this compound *in vivo*.

## 33.2

THE NMDA RECEPTOR ANTAGONISTS IFENPRODIL AND ELIPRODIL BLOCKED VOLTAGE-GATED NA<sup>+</sup> CHANNELS. S. J. Stoehr, G. W. Campbell and D. M. Rock. Neuroscience Therapeutics, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., 2800 Plymouth Rd., Ann Arbor, MI 48105.

The *in vivo* anticonvulsant and neuroprotective actions of ifenprodil and eliprodil have generally been associated with blockade of NMDA receptor channels. While both compounds have been shown to block voltage-gated Ca<sup>2+</sup> channels, contributions from Ca<sup>2+</sup> channel blockade to anticonvulsant properties or neuroprotection are not clear. There is a more direct link between blockade of voltage-gated Na<sup>+</sup> channels and the neuroprotective action of anticonvulsant drugs such as phenytoin and lamotrigine.

We investigated the effects of ifenprodil and eliprodil on voltage-gated Na<sup>+</sup> channels in acutely isolated rat superior cervical ganglion (SCG) neurons using whole-cell voltage-clamp techniques. Both ifenprodil and eliprodil blocked voltage-gated Na<sup>+</sup> channels in SCG neurons in a concentration- and voltage-dependent manner. The IC<sub>50</sub> for block of Na<sup>+</sup> channel currents with ifenprodil was approximately 30  $\mu$ M when neurons were voltage-clamped at a holding potential of -90 mV. However, the same concentration of ifenprodil (10  $\mu$ M) blocked 70% of the Na<sup>+</sup> currents when neurons were held at -60 mV, a holding potential at which approximately 50% of the Na<sup>+</sup> channels were inactivated. Eliprodil also blocked Na<sup>+</sup> channel currents in SCG neurons with similar potency.

This potent, voltage-dependent blockade of Na<sup>+</sup> channels may be involved in the neuroprotective and anticonvulsant actions of ifenprodil and eliprodil. Mechanisms that may account for the voltage-dependent block of Na<sup>+</sup> channels by ifenprodil and eliprodil will be discussed.

## 33.4

EFFECTS OF HALOPERIDOL ON TRANSIENT SODIUM CURRENT IN THE RETINAL GANGLION CELL OF YOUNG RATS. K. ITO<sup>1,2</sup>, Y. NISHIMURA<sup>1</sup>, Y. UJI<sup>2</sup>, K. NAKANO<sup>3</sup>, T. YAMAMOTO<sup>1</sup>. Dept. of Physiology<sup>1</sup>, Ophthalmology<sup>2</sup> and

Anatomy<sup>3</sup>, Mie University, School of Medicine, Tsu, 514, Japan

Some neuroleptic compounds are reported to suppress the transient sodium current (I<sub>Na,t</sub>) in central neurons and peripheral nerves. We have examined the effects of one of them, haloperidol on I<sub>Na,t</sub> of retinal ganglion cells in young rats. We used a whole-cell patch-clamp technique in the acutely dissociated cells by enzymatic treatment and gentle trituration. Ganglion cells were identified by retrograde labeling of Fast-Blue injected into the superior colliculus in advance. I<sub>Na,t</sub> was recorded in the perfusate containing tetraethylammonium, CsCl and CoCl<sub>2</sub> with a pipette filled with CsF- and EGTA- containing solution. I<sub>Na,t</sub> was voltage-dependent and reversibly blocked by tetrodotoxin (1  $\mu$ M). Application of haloperidol in the perfusate reversibly reduced the peak amplitude of I<sub>Na,t</sub> in a dose-dependent manner. The dose of half inhibition was 3-4  $\times 10^{-5}$  M and was intermediate between the doses reported in central neurons and peripheral nerves. Furthermore, we investigated the changes of the threshold, the reversal potential and the kinetics of I<sub>Na,t</sub>. We discuss the ionic mechanism underlying the pharmacological effects of the neuroleptic agent on the retina. This study was supported by Ministry of Education, Science and Culture of Japan.

## 33.5

**$\mu$ -CONOTOXIN PIIIA: A NEW LIGAND FOR SODIUM CHANNELS.** D. Yoshikami<sup>1</sup>, K. Shon<sup>3</sup>, B. M. Olivera<sup>1</sup>, J. S. Imperial<sup>1\*</sup>, B. Harris<sup>1</sup>, M. Marsh<sup>2</sup>, D. Hillyard<sup>2</sup>, H. Terlau<sup>4</sup> and W. R. Gray<sup>1</sup>. Depts. of Biology<sup>1</sup> and Pathology<sup>2</sup>, Univ. of Utah, Salt Lake City, UT, 84112; Dept. of Physiology and Biophysics<sup>3</sup>, Case Western Reserve Univ., Cleveland, OH, 44106; Molekulare Biologie Neuroenergetik<sup>4</sup>, Max-Planck-Inst. für Exp. Medizin, D-37075, Göttingen, Germany.

The  $\mu$ -conotoxins are a family of peptides that target Na channels; a well studied example is  $\mu$ -CTx GIIIA. We have recently identified a new peptide ( $\mu$ -CTx PIIIA) from *Conus purpurascens* venom which belongs to this family. PIIIA irreversibly blocks action potentials in frog skeletal muscle without blocking synaptic potentials. Biochemical assays reveal that PIIIA blocks <sup>3</sup>H-saxitoxin binding to electroplax membrane. In these respects PIIIA behaves like other  $\mu$ -CTxs, such as GIIIA, except that it acts essentially irreversibly in frog preparations. Thus, this new  $\mu$ -conotoxin provides a simple and permanent means to pharmacologically 'isolate' synaptic transmission from interfering action potentials and consequent muscle contractions.

PIIA was also tested on voltage-gated  $I_{Na}$  in neurons and *Xenopus* oocytes injected with cloned mRNA for Na channels. PIIIA is of exceptional interest because, together with GIIIA, it resolves TTX-sensitive sodium channels in mammalian CNS neurons into 3 classes: sensitive to both toxins, sensitive to PIIIA but not to GIIIA, and sensitive to neither conotoxin. Thus,  $\mu$ -CTx PIIIA provides a promising tool to discriminate among different Na channel subtypes in the CNS. (Supported by GM PO1 48677.)

## 33.7

**EFFECTS OF RILUZOLE ON TETRODOTOXIN-SENSITIVE AND TETRODOTOXIN-RESISTANT SODIUM CHANNELS IN RAT DORSAL ROOT GANGLION NEURONS.** J.-H. Song\*, K. Nagata, J. Z. Yeh and T. Narahashi. Dept. of Mol. Pharmacol. & Biol. Chem., Northwestern Univ. Med. Sch., Chicago, IL 60611.

The effects of riluzole, a neuroprotective drug, on tetrodotoxin-sensitive (TTX-S) and tetrodotoxin-resistant (TTX-R) Na channels in rat dorsal root ganglion neurons were studied using the patch clamp technique. When the membrane potential was held near the resting level, riluzole preferentially blocked the TTX-S Na channels, whereas at more negative potentials, it blocked both types of Na channels equally. The apparent dissociation constants for riluzole to block TTX-S and TTX-R Na channels in their resting state were estimated to be 90 and 143  $\mu$ M, respectively. Riluzole accelerated the time course of the inactivation of TTX-R Na currents, whereas it had little or no effect on that of TTX-S Na currents. Riluzole shifted the voltage dependence of activation in the depolarizing direction more efficaciously in TTX-R than in TTX-S Na channels. The voltage dependence of the inactivation was shifted in the hyperpolarizing direction in a dose-dependent manner, indicating that riluzole has a high affinity for the inactivated channels. From the concentration-dependent shift in the inactivation curve, the dissociation constants for riluzole to bind to the inactivated channels were estimated to be 2 and 3  $\mu$ M, respectively, for the TTX-S and TTX-R Na channels. Thus, riluzole has a similar affinity for both types of Na channels at either resting or inactivated state. Since the TTX-S Na channel has its mid-point of inactivation at a more negative potential than the TTX-R channel, more channels are inactivated at the resting membrane potential to which riluzole can avidly bind. Therefore, riluzole appears more potent to block the TTX-S than TTX-R Na channel. Supported by NIH grant NS14144.

## 33.9

**MODULATION OF SODIUM CHANNELS IN THE NEURONAL CELL LINE B50 BY BREVETOXIN-3 AND ITS DERIVATIVES.** S.L. Purkerson\*, L.A. Fieber, K. S. Rein, and D.G. Baden. NIEHS Marine and Freshwater Biomedical Sciences Center, RSMAS, University of Miami, Miami, FL 33149.

Among neurotoxins that affect Na<sup>+</sup> channel activity are those associated with Neurotoxic Shellfish Poisoning, called brevetoxins. These are multi-ring polyether toxins produced by marine dinoflagellates. The effects on voltage-gated sodium channels of brevetoxin-3 (PbTx-3) and PbTx-3 derivatives synthesized in our laboratory were studied in the stable cell line B50. The B50 cell line was derived from the rat central nervous system and expresses type I/II sodium channel mRNA (Schubert et al., Nature, 1974, 239:224-227; Baines et al., Mol Br Res, 1992, 16:330-338). Unitary Na<sup>+</sup> currents were studied using the cell-attached patch configuration of the patch clamp technique in a bath solution that contained (in mM) 140 NaCl, 3 KCl, 1 CaCl<sub>2</sub>, 0.6 MgCl<sub>2</sub>, 7.7 glucose, and 10 HEPES, pH 7.4. K<sup>+</sup> and Ca<sup>2+</sup> currents were blocked with the inclusion of TEA, Ba<sup>2+</sup> and Cd<sup>2+</sup> in the pipette. Na<sup>+</sup> channels activated with depolarizing steps to approximately -50 to -30 mV. 75% of membrane patches contained active sodium channels. When Na<sup>+</sup> channel modifier was present, the channels inactivated within ~20 ms during a sustained (50 ms) depolarization. When cells were bathed in 30 nM PbTx-3 or certain derivatives of PbTx-3 prior to an experiment, the open time was increased and the activation curve was shifted to more hyperpolarized potentials. When 100 nM TTX was present in the pipette, Na<sup>+</sup> currents were not observed (n=10). B50 cells provide a good model for the study of Na<sup>+</sup> channels before and after modification of the channels by brevetoxins. Supported by R01 ES05853, P30 ES05705.

## 33.6

**INTERACTION OF THE LOCAL ANESTHETICS LIDOCAINE AND PRILOCAINE.** J. M. Sidie\* and A. J. Mishizen, Ursinus College, Collegeville, PA 19426.

Lidocaine and prilocaine are amide-linked local anesthetics both with a pKa of 7.9. Utilizing the weakly electric fish *Eigenmannia* as a bioassay, we investigated the effects of these compounds on the electric organ discharge (EOD) frequency. The EOD frequency is driven by the medullary pacemaker nucleus and is very stable. At a concentration of 5x10<sup>-5</sup>M/pH9, lidocaine alone depresses the EOD frequency 25-30%, while under the same conditions prilocaine gives 10-15% depression. At this pH (9.0) these compounds are 93% in the uncharged (lipid-soluble) form. When the two drugs are given sequentially (first prilocaine then lidocaine or vice versa) the final EOD depression (15% vs 30%) is a function of the second drug delivered. The two drugs given simultaneously produce an intermediate effect. When the drug is removed, EOD frequency recovery is rapid and nearly complete (90-95%). The data support the view that there is one local anesthetic binding site, the two compounds exert different potencies at this site and under conditions investigated one drug displaces the other equally well regardless of which drug is bound first. The recovery data indicate that both compounds are rapidly metabolized.

Supported in part by HHMI.

## 33.8

**EFFECTS OF QX-314 ON THE TETRODOTOXIN-RESISTANT SODIUM CURRENT IN RAT DORSAL ROOT GANGLION NEURONS.** J.G. McGivern\*, Roche Bioscience, 3401 Hillview Avenue, Palo Alto, CA 94304.

The permanently charged quaternary amine derivative of lidocaine, QX-314, binds to the local anesthetic site and rapidly blocks rat neuronal tetrodotoxin-sensitive (TTX<sub>s</sub>) sodium channels only when applied to the intracellular side of the membrane (Strichartz, 1973, *J. Gen. Physiol.*, 62, 37-57). In contrast, QX-314 rapidly blocks TTX-insensitive (TTX<sub>r</sub>) sodium channels in rat heart when applied to either side of the membrane (Alpert et al., 1989, *Am. J. Physiol.*, 257, H79-H84). The present experiments were designed to investigate whether the TTX-resistant (TTX<sub>r</sub>) sodium current in small (<30  $\mu$ m diameter) acutely isolated adult rat (200 g) dorsal root ganglion (DRG) neurons is susceptible to inhibition by extracellular QX-314. The whole-cell patch-clamp technique was used to record sodium currents from single enzymatically dissociated DRG neurons in the presence of 1  $\mu$ M TTX. Extracellular application of QX-314 (30  $\mu$ M to 1 mM for 10 minutes) failed to rapidly inhibit the TTX<sub>r</sub> sodium current in 12 neurons. Increasing the rate of depolarization from 0.1 to 3.3 Hz caused the TTX<sub>r</sub> sodium current to rundown by 15% in the absence of drug. In the presence of 1 mM extracellular QX-314, the rundown was similar to control. In contrast, intracellular application of QX-314 (10 to 300  $\mu$ M) caused a reduction in the amplitude of the TTX<sub>r</sub> sodium current in 12 neurons, with an IC<sub>50</sub> of approximately 100  $\mu$ M at a depolarization rate of 0.1 Hz. Increasing the rate of depolarization from 0.1 to 3.3 Hz induced additional reversible block of the current. The present results provide evidence that, in contrast to rat heart, QX-314 cannot directly access the local anesthetic site on TTX<sub>r</sub> sodium channels in rat DRG neurons from the extracellular side of the membrane.

## 33.10

**LIDOCAINE EFFECTS ON A MUTANT NA<sup>+</sup> CHANNEL LACKING FAST INACTIVATION.** K.J. Gingrich\* and L. Wagner II. Anesthesiology, U. of Rochester, School of Medicine, Rochester, NY 14642

Local anesthetics (LA) block voltage dependent Na<sup>+</sup> channels. Fast inactivation is eliminated when hydrophobic amino acids on the intracellular linker between domains III and IV are mutated to polar residues. Bennett et al (1995) reported that such mutated cardiac channels do not exhibit long-term LA block and concluded that fast inactivation is required for use-dependence. We became interested in confirming these observations in skeletal muscle. Therefore, we studied the effects of lidocaine (LDCN) on a mutant form of the rat skeletal muscle  $\alpha$ -subunit ( $\mu$ 1) Na<sup>+</sup> channel (rskm1) that lacks fast inactivation. Rskm1 was mutated to the QQQ genotype (Q1303, Q1304, Q1305). *Xenopus* oocytes were injected with RNA and Na<sup>+</sup> currents were measured using a two-electrode voltage clamp 2-3 days after injection.

QQQ manifested slow biexponential inactivation ( $\tau_{SLOW1} = 0.33s$ ,  $\tau_{SLOW2} = 1.2s$ , -10mV) with biexponential recovery ( $\tau_{RECI} = 0.12s$ ,  $\tau_{RECI2} = 5.7s$ , -100mV). LDCN (0.5mM) induced a new rapid component ( $\tau_{FAST} = .004s$ ) in apparent inactivation that likely represents open channel blockade but also accelerated slow inactivation by nearly 2-fold ( $\tau_{SLOW1} = 0.12s$ ,  $\tau_{SLOW2} = 0.7s$ ). Slow inactivation enhancement was confirmed by a doubling of channels in the faster ( $\tau_{SLOW1}$ ) inactivated state.

These data indicate that LAs enhance slow inactivation. Further, these states are sufficiently long-lived (tenths of seconds) to provide for use-dependent block. Therefore fast inactivation may not be essential for use-dependent block in muscle, in contradistinction to heart. These results suggest genuine differences between skeletal and cardiac Na<sup>+</sup> channel isoforms that may be exploited to reveal the mechanistic details underlying long-lived LA blockade.

EFFECT OF VERATRIDINE ON CNaIIA-1 CELLS. L.D. Margolin\*, F.R. Wason, & S. Connaughton Cambridge Neuroscience, Inc., Cambridge, MA 02139.

Veratridine-induced [ $^{14}$ C]-guanine flux in a Chinese hamster ovary cell line that stably expresses the  $\alpha$ -1 subunit of the mammalian type IIA neuronal sodium channel (CNaIIA-1) is a useful high throughput screen for compounds with putative Na<sup>+</sup> channel blocking activity (Connaughton *et al.*, 1995). To better define the role of veratridine in the [ $^{14}$ C]-guanine flux assay, electrophysiological studies were performed in order to characterize its effect on the activity of known Na<sup>+</sup> channel blockers and on the resting membrane potential (RMP) of CNaIIA-1 cells.

Experiments were conducted by either voltage clamping cells in the whole cell configuration (Hamill *et al.*, 1981) for the Na<sup>+</sup> channel blockers or by using whole cell current clamp for the resting membrane potential studies. Cells used for voltage-clamp experiments were held at -90mV and stepped to test potentials that evoked maximal inward Na<sup>+</sup> currents. Cells used for current-clamp experiments were clamped at their RMP. All drugs were applied by bath perfusion (2ml/min).

When corrected for veratridine's ability to reduce transient inward Na<sup>+</sup> current, blockade of Na<sup>+</sup> channels by the local anaesthetic lidocaine and the anti-convulsant lamotrigine was not affected by treatment with 200 $\mu$ M veratridine. The resting membrane potential of CNaIIA-1 cells ranged from -10mV to +20mV. Current-clamp experiments were inconclusive; application of 200 $\mu$ M veratridine did not produce the expected depolarization of the RMP. In contrast similar experiments using N1E-115 cells (which contain K<sup>+</sup> and Ca<sup>2+</sup>, as well as Na<sup>+</sup> channels) exhibited a rapid depolarization of RMP to +20mV. The voltage-clamp results suggest that veratridine activity does not interfere with the action of Na<sup>+</sup> channel blockers. Additional current-clamp experiments are planned.

## 33.13

COUMAROYL SPERMIDINE, A PHENOLIC POLYAMINE, INDUCES HYPEREXCITABILITY IN CRAYFISH AXONS. S. R. Kelly, S. Jenkins, J. K. Atkinson and A. J. Mercier\*, Dept. of Biol. Sci. and Dept. of Chemistry, Brock University, St. Catharines, Ont., L2S 3A1.

Recent work investigating pest resistance in plants has led to the identification of several phenolic polyamines, which are structurally similar to acylpolyamines of spider and wasp venoms. This study investigated the effects of coumaroyl spermidine (CS), a synthetic polyamine, on giant axons in the ventral nerve cord of the crayfish *Procambarus clarkii*.

CS, at concentrations of 100-500  $\mu$ M, caused the appearance of multiple action potentials in response to brief (0.2 ms), single electrical stimuli. The action potentials typically occurred at frequencies of up to 400 Hz. The amplitude and time course of the first action potential in each train were not substantially different from those of impulses recorded in the absence of CS. CS did not alter the resting potential of the axon, and its effects on excitability reversed within 1 minute of washing with physiological saline. The effects CS were neither mimicked by 500  $\mu$ M spermidine (which had no effect) nor by reducing extracellular calcium concentration. Application of tetrodotoxin initially reduced the number of multiple action potentials induced in the presence of CS and eventually blocked impulses altogether. This suggests that CS may modulate gating of sodium channels.

STRUCTURE-ACTIVITY RELATIONSHIP OF DELTAMETHRIN ANALOGS ON SODIUM CHANNELS EXPRESSED IN *XENOPUS* OOCYTES. Timothy J. Smith\* and David M. Soderlund, Field of Environmental Toxicology and Dept. of Entomology, New York State Agric. Expt. Station, Cornell Univ., Geneva, NY 14456.

Pyrethroids make up a large class of potent neurotoxic insecticides whose principal target is the voltage-gated sodium channel. In this series of insecticides the R configuration at chiral carbon 1 or 3 of the cyclopropanecarboxylate moiety and the S configuration at the  $\alpha$ -cyano carbon of the phenoxybenzyl alcohol moiety are essential for toxicity. To further explore the stereospecific basis of pyrethroid action on sodium channels we expressed the rat brain IIa sodium channel  $\alpha$  subunit plus the rat  $\beta$ 1 subunit in *Xenopus* oocytes and determined the effects of pyrethroids on sodium currents measured by two electrode voltage clamp. Deltamethrin, (S)- $\alpha$ -cyano-3-phenoxybenzyl-(1R)-cis-3-(2,2-dibromovinyl)-2,2-dimethylcyclopropanecarboxylate, prolonged the time course of sodium channel inactivation and produced tail currents following repolarization that were qualitatively similar to the effects produced on sodium channels in intact nerves. The only other structurally related compound to produce tail currents was NRDC 158B, the 1R,trans, $\alpha$ S isomer of deltamethrin, which varies from deltamethrin in the absolute configuration only at carbon 3 of the cyclopropane ring. Other stereoisomers of deltamethrin that lack the preferred configuration for high neurotoxicity did not modify sodium currents. None of the compounds significantly modified the voltage dependence of activation or inactivation. The stereospecific action of pyrethroids on sodium channels are consistent with the high degree of stereospecificity observed in the neurotoxic actions of these compounds.

## 33.12

WHOLE-CELL PATCH-CLAMP ASSESSMENT OF VOLTAGE-DEPENDENT SODIUM CURRENT IN ACUTELY DISSOCIATED RAT HIPPOCAMPAL CA1 NEURONS DURING CHRONIC COCAINE INTOXICATION. J. Zhai\*, S.J. Wieland and F.M. Sessler, Dept. Of Neurobiology & Anatomy, Med. Col. Of Pennsylvania & Hahnemann University, Philadelphia, PA 19102.

The development of increased susceptibility to cocaine-induced seizures is not well characterized. High doses of cocaine reaching local anesthetic levels are known to produce these effects. These high doses become pharmacologically relevant when drug users increase their cocaine dose to recapture peak euphoric effects. In this study we began an assessment of potential cocaine-induced changes in excitability in the hippocampus. For this we used CA1 neurons from control and drug-treated rats were isolated from hippocampal slices using enzyme and trituration methods. Voltage-dependent sodium channels were activated by a series of depolarizing pulses under whole-cell patch-clamp recording. Steady-state inactivation was characterized with 100 ms prepulses in the range of -140 mV to -45 mV. Preliminary data show that the steady-state inactivation of sodium channel in cocaine-treated rats was substantially shifted in depolarizing direction. This could make a larger number of sodium channels available for activation and increase excitability. Considering the low threshold for seizure activities in the hippocampal formation, these changes may participate in the development of seizure sensitization and/or may be related to compensatory mechanisms in response to drug treatment. ## 33.14

ALTERED BIOPHYSICAL AND PHARMACOLOGICAL PROFILES OF SODIUM CHANNELS IN PYRETHROID-RESISTANT INSECTS. D. Lee\*<sup>1</sup>, T.M. Brown<sup>2</sup>, and M.E. Adams<sup>1</sup>, <sup>1</sup>Dept. of Entomology, University of California, Riverside, CA 92521 and <sup>2</sup>Dept. of Entomology, Clemson University, Clemson, SC 29634.

Heavy selection pressure on insect populations brought about by chronic use of neurotoxic insecticides has resulted in many forms of genetic resistance. A significant factor contributing to pyrethroid insecticide resistance is nervous system insensitivity. Since pyrethroids target voltage-dependent sodium channels, we compared the biophysical and pharmacological characteristics of sodium channels in central neurons of susceptible and pyrethroid-resistant tobacco budworm, *Heliothis virescens* using the whole-cell patch clamp technique. The synthetic pyrethroid permethrin causes a dramatic prolongation of tail currents following test depolarizations due to an extreme slowing of sodium channel deactivation. Steady-state [s-s] tail currents were plotted as a function of permethrin concentration to obtain dose-response curves. Low nanomolar concentrations of permethrin were sufficient to prolong tail currents in neurons from susceptible insects whereas neurons from resistant insects were ~20-fold less sensitive. Resistant currents showed a ~15 mV shift in the voltage-dependent activation curve to more positive potentials as compared to susceptible currents. Resistant currents also differed in their steady-state inactivation, with the  $\infty$  curve shifted about 7 mV more positive. Interestingly, resistant currents were ~2 times more sensitive to the scorpion toxin Lqh $\alpha$ IT, but showed no change in sensitivity to TTX. We conclude that neuronal sodium channels in resistant insects have altered gating properties, decreased sensitivity to pyrethroids, and enhanced sensitivity to Lqh $\alpha$ IT, all of which are consistent with the hypothesis that an alteration in channel structure contributes to neuronal insensitivity to pyrethroids.

## MODELS OF ACTIVITY-DEPENDENT CHANGES IN THE BACK-PROPAGATED ACTION POTENTIALS OF CA1 NEURONS.

M. Migliore\*, Inst. for Interdisciplinary Applications of Physics - Natl. Res. Council, 90123 Palermo, Italy.

Recent experimental advances using simultaneous somatic and dendritic recordings from hippocampal CA1 neurons (Spruston et al., *Science* 268:297-300, 1995) have shown that the active properties of dendrites can change the amplitude of the action potentials in the dendrites in an activity-dependent manner. Experiments, however, have not been paralleled by the development of a clear model of the mechanisms that could be involved with this effect. I modeled two different mechanisms, a shunting conductance and a slow sodium inactivation, to test if they could modulate the active propagation of a train of action potentials in a dendritic tree. Computer simulations, using a compartmental model of a pyramidal neuron, suggest that each of these two mechanisms could account for the activity-dependent attenuation and failure of the action potentials in the dendrites during the train. Each mechanism is shown to be in good qualitative agreement with experimental findings on somatic or dendritic stimulation and on the effects of hyperpolarization. The conditions under which branch point failures can be observed, and a few experimentally testable predictions, are presented and discussed. (Supported by C.N.R.)

## 34.3

DIFFERENCES IN CHARACTERISTICS OF IONIC CURRENTS IN BAG CELLS FROM SEXUALLY IMMATURE ADULT *APLYSIA*.

L. A. Fieber\*, Division of Marine Biology and Fisheries, Univ. Miami Rosenstiel School, Miami, FL 33149.

Experiments to assess whole cell ionic currents were executed with the whole cell variation of the patch clamp technique on bag cells 10-30  $\mu$ m in diameter from sexually immature adult *Aplysia* maintained in short term tissue culture.  $\text{Na}^+$  and  $\text{Ca}^{2+}$  currents were recorded in an intracellular solution of (mM): 450 CsCl, 2.9  $\text{CaCl}_2$ , 2.5  $\text{MgCl}_2$ , 10 EGTA, 5  $\text{Na}_2\text{ATP}$ , 300  $\mu\text{M}$  GTP, and 40 HEPES-CsOH, pH 7.4. For recording  $\text{K}^+$  and  $\text{Na}^+$  currents, the bath contained (mM): 417 NaCl, 55  $\text{MgCl}_2$ , 10  $\text{CaCl}_2$ , 10 KCl, 10 HEPES-KOH, pH 7.6. For recording  $\text{Ca}^{2+}$  currents the bath contained (mM): 460 tetraethylammonium Cl (TEACl), 10.4 CsCl, and 11  $\text{Ba}^{2+}$ , 55  $\text{MgCl}_2$ , and 10 HEPES-CsOH, pH 7.6. In addition to  $\text{K}^+$  currents, less than 50% of cells also had inward currents for  $\text{Na}^+$ ,  $\text{Ca}^{2+}$  or both.  $\text{Na}^{2+}$  currents were recorded in 10 of 33 cells and  $\text{Ca}^{2+}$  currents in 14 of 33.  $\text{Na}^+$  currents in immature bag cells were similar in many respects to those in mature bag cells (Fieber 1995, J. exp. Biol., 198:2237-47), with one important difference that might influence excitability. Time constants for recovery from inactivation using a double pulse protocol were 2.7 ms at  $V_h = -70$  mV, similar to the adult value of 2.9 ms, and 13 ms at  $V_h = -30$  mV, which is twice the adult value of 6.8 ms.  $\text{Ca}^{2+}$  currents were short-lived (<10 min) and were smaller than  $\text{Ca}^{2+}$  currents in mature bag cells. These data suggest that immature bag cell  $\text{Na}^+$  and  $\text{Ca}^{2+}$  currents have some characteristics that make them less likely than currents from mature animals to contribute to repetitive action potential firing. Supported by NSF IBN-9508705 and NIH RR-10294.

## 34.5

PRESENCE OF CARDIAC-LIKE  $\text{Zn}^{2+}$ -SENSITIVE  $\text{Na}^+$  CHANNELS IN LIMBIC REGIONS OF RAT BRAIN. H.A. Hartmann\*, L.V. Colom\*, M.L. Biophysics\* and Neurology\*, Baylor College of Medicine, Houston, TX 77030.

$\text{Zn}^{2+}$ -sensitivity is a property of the  $\text{Na}^+$  currents expressed from the cardiac tissue isoform, however classical brain  $\text{Na}^+$  channels are  $\text{Zn}^{2+}$ -resistant. Recently  $\text{Zn}^{2+}$ -sensitive  $\text{Na}^+$  currents have been described in neurons from the rat medial entorhinal cortex (White et al., *Neuron*: 11, 1037-47, 1993). We used *in situ* hybridization of mRNA to localize the expression of the cardiac  $\text{Zn}^{2+}$ -sensitive isoform in the rat brain. Two antisense oligonucleotide probes (P1 and P2) were designed to the rat heart  $\text{Na}^+$  channel cDNA nucleotides 1914 to 1958 for P1, and 6301 to 6350 for P2. The 45-mer for P1 corresponded to amino acids 638 to 652 of the intracellular linker between repeats I and II, and the 50-mer for P2 corresponded to a 3'-untranslated region. The 3' end-labelled oligos with [ $^{35}\text{S}$ ]dATP were hybridized to adult rat brain slices. Two sets of control probes were used: antisense probes were hybridized in the presence of 50-fold excess of unlabelled oligo, and sense probes were also used. Both P1 and P2 gave an identical, highly specific localization, labeling the pyriform cortex, septal area, dorsal and medial hypothalamus, mamillary nuclei, stria terminalis, and amygdaloid complex. Whole-cell patch recordings from enzymatically-isolated rat septal neurons demonstrated the presence of a  $\text{Zn}^{2+}$ -sensitive  $\text{Na}^+$  current. In 50% of neurons tested, 1, 10, and 100  $\mu\text{M}$   $\text{Zn}^{2+}$  blocked 10, 19, and 21% of the  $\text{Na}^+$  current, respectively. These results demonstrate the mRNA expression of a heart-like  $\text{Na}^+$  channel in limbic system structures and the functional expression of this channel in septal neurons of the rat brain. Since  $\text{Na}^+$  currents contribute to pacemaker and subthreshold potentials, this  $\text{Zn}^{2+}$ -sensitive  $\text{Na}^+$  current may play a critical role modulating excitability in these networks. Supported by Hankamer Foundation (HAH), Methodist Foundation (LVC), and NS29709 (JLN).

## 34.2

PROPERTIES OF THE PERSISTENT  $\text{Na}^+$  CURRENT GENERATING SUBTHRESHOLD OSCILLATIONS IN ENTORHINAL CORTEX (EC) LAYER II NEURONS. A. Galvez\* and A. Alonso. Dept. Neurol. & Neurosurg, MNI and McGill University, Montreal, Canada.

Neurons in EC layer II display subthreshold membrane potential oscillations that according to current-clamp and SEVC data in the slice are driven by a persistent TTX-sensitive  $\text{Na}^+$  current ( $I_{\text{NaP}}$ ). It is possible that  $I_{\text{NaP}}$  represents a window current resulting from the overlap of the  $m_{\infty}$  and  $h_{\infty}$  curves of the fast transient  $\text{Na}^+$  current ( $I_{\text{Na}}$ ) or that it is generated by a distinct  $\text{Na}^+$  conductance. To address this issue, the properties of different  $\text{Na}^+$ -current components were studied in acutely isolated neurons from EC layer II with the use of the whole cell configuration of the patch-clamp technique. A TTX-sensitive (100nM), persistent  $\text{Na}^+$  current but no transient current was seen in response to depolarizations of up to 20 mV from a H.P. of -80mV. Depolarizations positive to -50 mV elicited both a persistent and a transient component. The steady state I/V relation of  $I_{\text{NaP}}$  could be studied in isolation either by applying long depolarizing voltage steps or slow (<0.1mV/ms) ramp depolarizations.  $I_{\text{NaP}}$  reached a peak amplitude of -50 to -500pA at -35 mV, reversed at +40mV and the potential for half-maximum conductance was -55 to -60mV. In EC layer II neurons the transient  $I_{\text{Na}}$  displays a TTX sensitive and a TTX resistant component whose voltage dependent and kinetic properties are indistinguishable (White et al., *Neuron*, 1993). This allowed us to estimate the  $m_{\infty}$  curve for  $I_{\text{NaP}}$  and, following block of  $I_{\text{NaP}}$  with 100nM TTX, the  $m_{\infty}$  and  $h_{\infty}$  curves of  $I_{\text{Na}}$  which displayed minimal overlap. The data demonstrated that in EC layer II neurons the persistent  $\text{Na}^+$  current activated negative to -50mV and which provides the drive for the generation of subthreshold oscillations is mainly due to a distinct persistent  $\text{Na}^+$  current and not to a "window" current. Funded by the MRC and FRSQ.

## 34.4

## POST-NATAL DEVELOPMENTAL INCREASE IN THE DENSITY OF SODIUM CURRENTS IN MURINE MOTONEURONS. K.D. García\*, L.K. Sprunger\*, M. Meisler\* and K.G. Beam\*. Dept. Anat. Neurobiol. Colo. St. Univ. Ft. Collins CO 80525 and Dept. Human Genetics Univ. Mich. Ann Arbor MI 48109

At birth, mice display weak and uncoordinated motor activity, but during the first postnatal week acquire substantial motor skills. Because propagated action potentials in motor axons are required for coordinated motor activity, we have investigated whether changes in expression of motoneuronal sodium currents accompany the acquisition of motor ability. The whole-cell variant of the patch clamp technique was applied to motoneurons from neonatal mice ages P0-P8. Motoneuronal cell bodies, labelled by injection of dil into fore- and hind-limbs of anesthetized mice, were isolated by enzymatic dissociation and cultured 12-24 hours. Cultures were made from either whole spinal cords or spinal cords divided into cranial and caudal portions. Labelled cells were held at a potential of -80 mV and sodium currents (35 mM extracellular sodium) were elicited by test potentials ranging from -50 to +50 mV. In motoneurons obtained from whole spinal cords, the sodium current density (peak current divided by linear cell capacitance) was  $46.8 \pm 8.3$  pA/pF (mean  $\pm$  sem) for P0 mice and  $154 \pm 31.7$  for P8 mice. Sodium current densities for cranial and caudal cells, respectively, were  $48.4 \pm 14.0$  and  $48.7 \pm 9.2$  pA/pF at P0,  $77.0 \pm 26.0$  and  $49.8 \pm 20.4$  pA/pF at P1,  $100.6 \pm 6.7$  and  $70.9 \pm 16.5$  pA/pF at P2,  $127.0 \pm 16.3$  and  $90.3 \pm 21.6$  at P4. These results suggest that significant up-regulation of motoneuronal sodium currents occurs postnatally, proceeds rostrally to caudally, and may contribute to maturation of motor function. Ongoing studies are examining sodium current expression in motoneurons from mice with motor endplate disease (*med*), which have a null mutation in the sodium channel gene *Scn8a*. Supported by NIH grants NS26416, NS24444 and NS34509.

## 34.6

## PROPERTIES OF HODGKIN-HUXLEY TYPE POTASSIUM AND SODIUM CHANNELS IN SUBTHRESHOLD SIGNAL BOOSTING. M. Kauranen, K. Djupsund\* and M. Weckström. Department of Physiology, University of Oulu, Finland

Many neurons especially in peripheral sensory systems do not generate action potentials. However, they do express voltage-activated ion channels. Recent experimental evidence shows that many non-spiking cells show boosting, or resonance-like behaviour. How could nonspiking graded potentials be boosted in some frequency band in nerve membrane? The boosting could occur when membrane ion-channels are suitably activated in this frequency band so that electrochemical gradients of these ions could be used in signal boosting. We tested simulated models of sodium and potassium ion-channels with nonlinear differential equations of Hodgkin and Huxley type. Single channel frequency response under voltage clamp either with sinusoidal or white noise stimulus was simulated in several holding potentials. In addition, a membrane model with sodium or potassium channels with "co-expressed" leak channels and membrane capacitance was simulated under current clamp conditions. The results show that the  $\text{Na}^+$  channels are able to amplify the graded changes in membrane potential with holding potentials between -60 to -30 mV, while the resonance is between 500-1000 Hz. The +3 dB level is reached already near 100 Hz with sinusoidal stimulation. The amplification is most prominent when r.p. is between -50 to -35 mV. The amplification takes place also with very small stimulus amplitudes. With white noise stimulation the resonance is generally smaller, but the small-signal sensitivity is better. In a cell model the membrane capacitance shifts the resonance to smaller frequencies. The low-passing properties of the  $\text{K}^+$ -channels cause an increase in membrane impedance at high (50-500 Hz) frequencies. The voltage-gated ion channels are thus able to produce the required boosting effect, although the exact matching of real neuronal membranes' responses with simulation needs adjustment of the kinetic parameters of the channels.

## 34.7

OPTIMAL WAVEFORM POLARITY AND SEQUENCE FOR NEUROMAGNETIC EXCITATION OF PERIPHERAL NERVE: IN-VITRO AND SIMULATION STUDY. P.J. Maccabee\*, S.S. Nagarajan, V.E. Amassian, D.M. Durand, L.P. Eberle, R.O. Cracco and K.S. Lai. Department of Neurology, SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203.

Neuromagnetic excitation of mammalian phrenic nerve in a trough filled with saline was studied at the negative-going first spatial derivative of the induced electric field along a straight nerve, and at low threshold sites such as at a bend and at a cut nerve ending. With identical first phases, polyphasic (70  $\mu$ s, then 140  $\mu$ s, etc. durations) and predominantly monophasic (70  $\mu$ s duration) stimuli were induced by the MC. Experiments were also simulated using the identical waveforms.

In-vitro, at all excitation sites, largest amplitude responses were elicited by an induced polyphasic hyperpolarizing-depolarizing pulse; smaller responses by a monophasic depolarizing pulse; smallest responses by a polyphasic depolarizing-hyperpolarizing pulse. The simulation studies confirmed the in-vitro findings and further delineated the mechanism. 7% of the increased efficacy of the hyperpolarizing-depolarizing pulse sequence reflects the greater integrated depolarizing charge transfer afforded by the 140  $\mu$ s vs 70  $\mu$ s cycle. The remaining 3% of the increased efficacy of the hyperpolarizing-depolarizing pulse sequence represents reversal of Na inactivation by the initial hyperpolarization resulting in an increased fraction of open Na channels available to the subsequent depolarization.

## 34.9

CURRENT CLAMP SIMULATIONS OF A MODEL CELL USING A MICROSOFT EXCEL™ SPREADSHEET. A.M. Brown\*. Department of Pharmacology, Neuroscience Institute, University of Dundee, Ninewells Hospital, Dundee, DD1 9SY, U.K.

A method has been devised whereby a model cell containing multiple voltage gated ion channels can be modelled under current clamp conditions using a Microsoft Excel™ spreadsheet. This method does not require any programming or macro language knowledge. The features of spreadsheets which allow this are firstly, 'drag and drop to fill a range', secondly, the ability to insert formulae into cells allowing new columns of data to be generated based on existing columns, and thirdly, the instant charting of data.

In the example described the squid giant axon with  $I_{Na}$ ,  $I_K$  and  $I_{leak}$  was modelled. Ionic currents calculations were based on the Hodgkin & Huxley (HH) series of equations where the currents are described in the fashion:

$$I_{Na} = m^3 h g_{Na} (E - E_{Na})$$

In these types of simulation an initial potential is set and the voltage- and time-dependent parameters are calculated for this potential. The spreadsheet is set up so that each voltage dependent parameter ( $\alpha_m$ ,  $\beta_m$ ,  $\alpha_h$ ,  $\beta_h$ ,  $\alpha_n$ ,  $\beta_n$ ,  $g_{Na}$ ,  $g_K$ ,  $E_{leak}$ ,  $I_{Na}$ ,  $I_K$ ,  $I_{leak}$ ) occupies a separate column.  $\delta t$  is set at 20  $\mu$ s and each row increments the value of that particular variable and its change in value according to the change in voltage. The HH parameters are calculated by Euler integration and the membrane potential is calculated by integrating the total ionic current transfer ( $I_{Na} + I_K + I_{leak}$ ) across the membrane for the time interval  $\delta t$ . The specific membrane capacitance is assumed to be 1  $\mu$ F  $cm^{-2}$ . Resting membrane potential, action potential generation and repetitive firing are intrinsic properties of the model.

## 34.11

S(357)F confers tetrodotoxin sensitivity on the sensory neuron specific sodium channel SNS.

K. Okuse, L. Sivilotti\*, S. Moss, A.N. Akopian and J.N. Wood. Departments of Anatomy and Developmental Biology, and Pharmacology, University College, London WC1E 6BT, UK.

Small diameter sensory neurons, many of which are nociceptors, express an unusual voltage-gated sodium channel (SNS or PN3) that is resistant to tetrodotoxin ( $IC_{50}=60\mu M$ ). SNS is 65% homologous to the tetrodotoxin-insensitive cardiac channel. A number of residues that line the channel atrium have been implicated in tetrodotoxin binding. SNS exhibits sequence identity to other tetrodotoxin-sensitive sodium channels in 7 out of 9 such residues (Urenjak J. and Obrenovitch T.P. Pharm Revs. 1996, 48, 21-67). One difference is a conservative substitution at D(905)E. Interestingly, a single residue (C-357) has been shown to play a critical role in tetrodotoxin binding to the cardiac channel. In SNS, a hydrophilic serine is found at this position. Using site-directed mutagenesis we have substituted phenylalanine for serine at position 357. The mutated SNS channel, when expressed in *Xenopus* oocytes produces voltage-gated sodium currents similar in amplitude and time-course to the native channel. However, sensitivity to tetrodotoxin is restored to give an  $IC_{50}$  of 2.5 nM ( $\pm 0.4$  n=5), similar to other voltage-gated sodium channels that have aromatic residues at the equivalent position. These data are consistent with current models of tetrodotoxin binding to sodium channels, and provide further clues to the rational design of selective blockers of SNS.

## 34.8

ACTION POTENTIAL-LIKE RESPONSES IN B104 CELLS WITH LOW Na<sup>+</sup> AND K<sup>+</sup> CHANNEL DENSITIES. S.G. Waxman and X.Q. Gu\*. Department of Neurology, Yale School of Medicine, New Haven, CT 06510; and PVA/EPVA Neuroscience Research Center, VA Hospital, West Haven, CT 06516.

In order to study the generation of action potentials in cells with low densities of Na<sup>+</sup> channels, whole-cell patch-clamp methods were used to record Na<sup>+</sup> and K<sup>+</sup> currents, and responses to depolarization and hyperpolarization in B104 neuroblastoma cells *in vitro*. Action potential-like responses were elicited in 38 of 42 cells, with a threshold close to -55.4 mV for depolarizing stimuli, and -56.7 mV for anode-break stimuli. These responses were voltage-dependent, and were larger when cells were held at more negative prepulse potentials. Response amplitudes, plotted against prepulse potentials, were well fit by a Boltzmann distribution with a midpoint of  $\sim -75$  mV, close to the  $V_{1/2}$  for Na<sup>+</sup> current steady-state inactivation in these cells. Cells displaying action potential-like responses exhibited a peak Na<sup>+</sup> current density of  $133.0 \pm 0.1$  pA/pF (range, 10.2-196.2 pA/pF). Cells which did not support action potential-like responses displayed a peak Na<sup>+</sup> current density of  $30.3 \pm 0.1$  pA/pF. The  $g_K/g_{Na}$  ratio was  $0.0067 \pm 0.0023$  for cells which displayed action potential-like responses, and was  $0.1027 \pm 0.0296$  for cells which did not generate responses. Exposure to 0.1 mM Cd<sup>2+</sup> did not block the generation of action potential-like responses in B104 cells, while 1  $\mu$ M TTX abolished the responses in cells exposed to Cd<sup>2+</sup>. We conclude that low densities of Na<sup>+</sup> channels ( $<3\mu m^2$ , and  $<1\mu m^2$  in some cells) can support the generation of action potential-like responses in B104 cells. The low K<sup>+</sup> conductance of these cells may contribute to their ability to generate action potential-like responses. (Supported in part by the NMSS and Medical Research Service, Veterans Administration).

## 34.10

USING  $\mu$ -CONOTOXIN TO TEST A MODEL OF THE STRUCTURE OF THE VOLTAGE-GATED SODIUM CHANNEL OUTER VESTIBULE. N. S. Chang\*, S. Dudley, Jr., G. Lipkind, R. J. French, and H. Fozzard. Dept. of Pharmacological and Physiological Sciences, Univ. of Chicago, Chicago, IL 60637.

Data on sites critical for tetrodotoxin and saxitoxin binding to the voltage-gated sodium channel allowed our laboratory to develop a model of the pore outer vestibule. With this model, we predicted a binding configuration for  $\mu$ -conotoxin ( $\mu$ -CTX). We have demonstrated a specific interaction, as predicted, between E758 of the adult rat skeletal muscle Na<sup>+</sup> channel ( $\mu 1$ ) and R13 of  $\mu$ -CTX. We sought to examine binding of the toxin mutant R13D to the  $\mu 1$  mutant E758K. Wild-type and mutant  $\mu 1$  channels were heterologously expressed in *Xenopus* oocytes. IC<sub>50</sub>'s of mutant and wild-type  $\mu$ -CTX blockade of peak sodium current (shown below in  $\mu$ M  $\pm$  SEM) were determined under two-electrode voltage clamp. Although E758K has a 260-fold lower affinity for  $\mu$ -CTX than does wild-type  $\mu 1$ , R13D binds to E758K with slightly greater affinity than to wild-type  $\mu 1$ . This partial recovery of wild-type binding supports our hypothesis that there is at least one other critical interaction site for R13 which is most likely at the putative selectivity filter.

We also examined interaction of the  $\mu 1$  mutant E403Q with R13A, R13D and R13Q. The calculated coupling coefficients ( $\Omega$ ) are 7, 5, and 18, respectively. This implies some contribution of E403 to the binding of R13. However, consistent with our model, this contribution appears to be much smaller than that of E758, where coupling coefficients were 111, 54, and 56 for E758Q vs. R13A, R13D and R13Q.

STRUCTURE-FUNCTION SURVEY OF THE S4-5 LINKER OF THE SODIUM CHANNEL.

G.N. Filatov, S.D. Kraner and R.L. Barchi\*. Depts. of Neurology and Neuroscience and the Mahoney Inst. of Neurological Sciences, Univ. of Penn Sch. of Med., Philadelphia, PA 19104.

The S4-5 linker has been proposed to play a major role in sodium channel inactivation. Schiffer-Edmondson analysis of the S4-5 interhelical sequence suggests an amphipathic helical structure, in which a conserved region of small hydrophobic residues occupies one contiguous surface. This surface may interact with the other channel helices, while the opposite face which contains multiple charged and polar residues may help to form the cytoplasmic mouth of the pore. We hypothesize that the polar face of S4-5 forms a part of the docking surface for the ID3-4 inactivation gate after conformational changes during activation. We replaced 16 residues on the helix with substitutions which differed in charge, polarity, size and the presence of an aromatic ring. A total of 62 single amino acid substitutions were analyzed. The introduction of any charge into the hydrophobic surface resulted in failure of functional channel expression. All other mutations in this face produced channels with activation, inactivation, recovery from inactivation and steady-state inactivation kinetics similar to wild type. In the polar surface, charged mutations caused a pronounced slowing of inactivation, shifted voltage dependence of steady-state inactivation toward more depolarized potentials and decreased recovery from inactivation time constants. Noncharged substitutions usually showed the opposite effect. All mutations at P1473 (rat SKM1 numbering) resulted in nonfunctional channels and the effects of mutations beyond this proline differed from those at preceding residues. Charged mutations at hydrophobic residues caused a slowing in inactivation and produced different effects on recovery. An interpretation of our results in terms of channel function will be presented. Supported by NIH NS 18013.

## 34.13

EPITOPE-TAGGING OF THE RAT SKM1 SODIUM CHANNEL CORROBORATES AN EXTRACELLULAR LOCATION FOR THE S1-S2 INTERHELICAL LOOP. **S.D. Kraner\***, W.-J. Sun, G.N. Filatov, J. Lindstrom, R.L. Barchi, Depts. of Neuroscience and Neurology and Mahoney Inst. of Neuroscience, Univ. of Penn., Philadelphia, PA 19104.

The SKM1 channel was epitope-tagged at positions within and between the S1, S2, and S3 helices of domain 2 (584, 595, 599, 605, 619, 630, 651, and 654) by insertion of a sequence from the Torpedo AChR  $\alpha$  subunit. The epitope is found only in the Torpedo sequence and not in the mammalian AChR or sodium channel sequences, and a high-affinity monoclonal antibody (mAb 142) to it is available for our use. All insertional mutations were first screened for function by expression of the cRNA in *Xenopus* oocytes followed by two-electrode voltage clamp. Insertional mutants at positions 595, 599, 630, 651, and 654 all gave rise to large ( $>2 \mu A$ ) currents in oocytes, whereas those at positions 584, 605 and 619 failed to function. Functional mutants were transfected into primary muscle cells and analyzed for surface membrane staining following immunofluorescent labeling by confocal microscopy. Intracellular as opposed to extracellular availability of the epitope was determined by permeabilizing the cells with the detergent saponin. The mutant at position 599 gave rise to a clear pattern of membrane staining along the surface of the myotube, both before and after membrane permeabilization with saponin. In addition, internal staining, presumably of nascent proteins, is seen in saponin-treated cells. The mutants at positions 595, 630, 651, and 654 failed to yield a signal in the absence of saponin and gave rise only to internal staining in the presence of saponin. These results provide corroboration that the S1-S2 interhelical segment has an extracellular location, as predicted by models of tertiary structure. Supported by NIH NS 18083.

## 34.15

CELLULAR EXPRESSION AND FUNCTIONAL ANALYSIS OF WILD TYPE AND MUTANT FORMS OF EPITOPE-TAGGED NA CHANNEL  $\beta$ 1 SUBUNIT **R.M. Shah<sup>1</sup>, L.P. Henderson<sup>1,2</sup>, I.R. Jones<sup>1</sup>, G.J. Huang<sup>1</sup>, and R.A. Mauge<sup>1,2\*</sup>**

Depts. of <sup>1</sup>Biochem. and <sup>2</sup>Physiol., Dartmouth Medical School, Hanover, NH 03755. During assembly and expression of voltage-dependent Na channels, the noncovalent interaction between the  $\beta$ 1 and  $\alpha$  subunits has important functional implications. For example, in *Xenopus* oocytes co-expression of  $\beta$ 1 increases Na channel expression, speeds activation and inactivation kinetics, and causes a hyperpolarizing shift in the voltage-dependence of activation and inactivation. As an approach to understanding the molecular and cellular basis of  $\beta$ 1 actions in neurons and muscle cells, a  $\beta$ 1 cDNA was isolated from rat brain mRNA using RT-PCR, sequences encoding an epitope of the hemagglutinin protein (HA) were added by PCR, and then the cDNA encoding the HA-tagged  $\beta$ 1 subunit inserted into expression vectors. HA-tagged  $\beta$ 1 subunits were then expressed in *Xenopus* oocytes, Cos cells, and primary cultures of embryonic neurons. The tagged  $\beta$ 1 subunit could be detected in Western blots, with a commercially available HA antibody binding to a protein of the predicted molecular weight in lysates from transfected, but not mock transfected, cells. Immunofluorescent labelling and confocal microscopy of transiently transfected Cos cells and embryonic neurons suggested that the HA-tagged  $\beta$ 1 will facilitate analysis of Na channel expression and distribution in muscle cells and neurons, as the expression of the tagged  $\beta$ 1 subunit on the cell surface was nonuniform, and in primary neurons was detected in both cell bodies and neurites. *Xenopus* oocyte expression studies confirmed that the HA-tagged  $\beta$ 1 modified the functional properties of the SKM1 ( $\mu$ )  $\alpha$  subunit as expected, increasing Na current amplitude and speed of inactivation, and causing a hyperpolarizing shift in the voltage-dependence of steady state inactivation. Deletions and point mutations of the HA-tagged  $\beta$ 1 subunit had differential effects on Na channel function, and highlight the utility of this approach in determining structural elements necessary for the interaction with  $\alpha$  subunits and effects on Na channel function. ### EXCITATORY AMINO ACID RECEPTORS: PHYSIOLOGY, PHARMACOLOGY, AND MODULATION—NMDA I

## 35.1

BOTH *d*- and *l*-METHADONE BIND TO THE NMDA RECEPTOR. **A.L. Gorman\*, K.J. Elliott, C.E. Inturrisi**, Dept. of Pharmacology, Cornell University Medical College, NY, NY 10021.

Recently, Ebert et al. (1995), reported that racemic methadone (MET) binds to and inhibits the NMDA receptor. To characterize further this effect, competition binding studies were conducted to determine (1) stereoselectivity of MET's affinity for the NMDA receptor and (2) whether other opioids exhibit a similar binding profile. Well-washed rat forebrain synaptic membranes were incubated with 5 nM [<sup>3</sup>H]MK-801, vehicle or 200  $\mu$ M MK-801 (non-specific binding), 1  $\mu$ M Glycine, 30  $\mu$ M *l*-Glutamate, and 0 - 100  $\mu$ M concentrations of the competing drugs. The opioid agonists, *l*-morphine (MOR) and hydromorphone (HM), and the opioid antagonist naltrexone (NTX) exhibited negligible affinity for the NMDA receptor. However, both isomers of MET exhibited moderate affinity for the NMDA receptor (K<sub>i</sub> values: *l*-MET = 2.9  $\mu$ M; *d*-MET = 5.4  $\mu$ M), and produced inhibition curves similar to that of the NMDA receptor antagonist, dextromethorphan (DM: K<sub>i</sub> = 3.3  $\mu$ M). Therefore, MET, unlike the other opioids (MOR, HM, or NTX) has affinity for the NMDA receptor. Since previous studies (Elliott et al., 1994) have shown that NMDA receptor antagonists attenuate the development of MOR tolerance, NMDA receptor antagonism by the analgesically inactive *d*-MET and/or the active *l*-MET isomers may contribute to the incomplete analgesic cross-tolerance observed between MET and MOR *in vivo*. ## 34.14

MOLECULAR MOTION IN THE PORE OF THE SODIUM CHANNEL: EVIDENCE FOR FLEXIBILITY OF THE P LOOPS

Jean-Pierre Benitah, Maria Janecki, Ravi Ranjan, Gordon F. Tomaselli, Eduardo Marban\*. The Johns Hopkins University School of Medicine, Baltimore MD

Permeation through ion channels is generally conceptualized as ion passage through rigid structures that discriminate particles of varying size and charge. In contrast, molecular dynamics simulations reveal that proteins can undergo sizable thermal motions on a submillisecond time scale. We investigated the extent of motion in the pore-lining (P) loops of the rat skeletal muscle Na<sup>+</sup> channel by constructing double-cysteine mutants and quantifying their propensity to form disulfide bonds. Whole-cell Na<sup>+</sup> currents were measured in oocytes before, during and after exposure to the redox catalyst Cu(II)(1.10-phenanthroline)<sub>3</sub> (CuP, 0.1 mM). Disulfide bond formation was inferred by redox-sensitive occlusion of ion flux, and by concomitant changes in sensitivity to Cd<sup>2+</sup> and Zn<sup>2+</sup>. Only one of 14 double mutants (Y401C-E758C, bridging domains I & II) spontaneously formed a disulfide bond. Nevertheless, three other sites (W1239C in domain III, and G1530C & D1532C in domain IV) could form disulfide bonds with Y401C when the reaction was catalyzed by CuP. These reactions occurred over 1-5 minutes at 22° C and were partially reversed by dithiothreitol. The selectivity filter position K1237 (domain III) formed disulfides catalyzed by CuP with two P loop residues in domain IV (G1530 and W1531), but interestingly not with the other classical "selectivity filter" sites. We will present a structural model of the pore which depicts the minimal motions required to account for the salient results. We conclude that the pore of the Na<sup>+</sup> channel, rather than being rigid, exhibits considerable internal flexibility.

A TALE OF TWO VALINES: Na CHANNEL MUTATIONS IN NEUROMUSCULAR DISEASE. **D.S. Green<sup>1</sup>, L.J. Hayward<sup>1</sup>, A.L. George<sup>2</sup>, and S.C. Cannon<sup>1\*</sup>** (1) Dept. of Neurobiology Harvard Med. Sch. Boston, MA 02114; (2) Dept. of Pharmacology Vanderbilt Univ. Med. Center Nashville TN 37232

Mutations of the skeletal muscle  $\alpha$  subunit (hSkM1) cause hereditary forms of myotonia and periodic paralysis. We have tested the functional consequences of two previously uncharacterized mutations: V781I - at the extracellular end of IIS6 and associated with HyperPP + cardiac dysrhythmia; V1293I - at the -NH end of the III-IV linker and associated with a variant of paramyotonia congenita (PMC) without paralysis on exposure to cold. Na currents were recorded from HEK cells transfected with cDNAs coding the h $\beta$ 1 subunit and WT hSkM1 or either mutant  $\alpha$  subunit.

V1293I disrupted fast inactivation as evidenced by a 3-fold increase in the persistent Na current at 50 msec and a 2-fold increase in the rate of recovery from inactivation. The voltage-dependence of steady-state inactivation ( $h_{\infty}$ ) was not significantly altered, and the decay of  $I_{Na}$  ( $\tau_h$ ) was similar for WT and V1293I. The voltage-dependence of activation was identical for WT and V1293I. In contrast, the only feature of fast inactivation that was altered for V781I was a small shift, -3.5 mV, in the midpoint of  $h_{\infty}(V)$ . Furthermore, this shift was in the wrong direction to cause paralysis. We conclude that V781I is a benign polymorphism and not a disease-causing mutation. V781I does not occur in the general population, and has been found in only one individual with a HyperPP-like phenotype. The proband was adopted so molecular confirmation was not possible in affected relatives.

## 35.2

SYNTHETIC CONANTOKIN ANALOGS: NOVEL POLYAMINE ANTAGONISTS OF NMDA RECEPTORS. **L.-M. Zhou\*, G. I. Szendrei<sup>1</sup>, M.-L. Maccacchini<sup>2</sup>, L. Otvos, Jr.<sup>1</sup> and P. Skolnick**, Lab. of Neuroscience, NIDDK/NIH, Bethesda, MD 20892, <sup>1</sup>The Wistar Institute, Philadelphia, PA 19104, <sup>2</sup>Symphony Pharmaceuticals, Malvern, PA 19355.

Conantokin G (con-G) is a 17-amino acid peptide originally isolated from marine snails of the genus *Conus*. This peptide is a NMDA antagonist as evidenced by its ability to reduce glutamate-induced neurotoxicity and inhibit NMDA-stimulated cGMP formation in primary neuron cultures. The NMDA antagonist properties of con-G have been attributed to a specific, non-competitive inhibition of polyamine actions. Thus, con-G potentially inhibits spermine-enhanced [<sup>3</sup>H]MK-801 binding to NMDA receptors from rat brains at concentrations without significant effect on radioligands binding to glutamate or glycine sites. Structure-activity studies indicate that the  $\gamma$ -carboxyglutamate (Gla) residues at positions 7, 10, and 14 could be replaced individually without altering the NMDA antagonist properties of con-G. By contrast, Gla<sup>3</sup> and Gla<sup>4</sup> appear to be required for NMDA antagonism. Ala<sup>7</sup>con-G was found to be the most potent NMDA antagonist among con-G analogs with an IC<sub>50</sub> of 0.045  $\mu$ M in inhibiting spermine-enhanced [<sup>3</sup>H]MK-801 binding, 4-fold more potent than the parent peptide. We report here newly synthesized con-G analogs and their biological activities at NMDA receptors. Ala<sup>7,10,14</sup>con-G exhibited an IC<sub>50</sub> value of ~0.075  $\mu$ M, comparable to Ala<sup>7</sup>con-G. By contrast, the potency of Glu<sup>7,10,14</sup>con-G, was dramatically reduced (IC<sub>50</sub> ~4  $\mu$ M) while Glu<sup>4</sup>con-G was inactive at concentrations of up to 20  $\mu$ M. Several Tyr-substituted con-G analogs have been prepared in order to develop potential radioligands for the putative polyamine-sensitive con-G sites. Among these compounds, Ala<sup>7</sup>Tyr<sup>10</sup>con-G was as potent as con-G (IC<sub>50</sub> ~0.17  $\mu$ M). The present data are in agreement with and provided additional evidence to support previous SAR findings with derivatives of con-G.

## 35.3

REGIONAL DISTRIBUTION AND PROPERTIES OF [<sup>3</sup>H]MDL 105,519-LABELED NMDA GLYCINE SITES ASSESSED BY QUANTITATIVE RECEPTOR AUTORADIOGRAPHY. P.A. Chmielewski, B.W. Siegel\*, and B.M. Baron. Hoechst Marion Roussel, Cincinnati, OH 45215.

MDL 105,519 is a potent and selective competitive antagonist of glycine at the NMDA receptor. In membrane binding studies, the pharmacology of the site labeled by [<sup>3</sup>H]MDL 105,519 closely correlated with that of the recognition site labeled by [<sup>3</sup>H]glycine. These results suggested that [<sup>3</sup>H]MDL 105,519 could provide an improved tool to characterize anatomical variations in NMDA receptor pharmacology using quantitative autoradiographic techniques (QAR).

[<sup>3</sup>H]MDL 105,519 binding parameters were optimized for QAR using sagittal rat brain sections. Both the density ( $B_{max}$ ) and affinity ( $K_D$ ) of [<sup>3</sup>H]MDL 105,519 binding sites was heterogeneous in the seven brain regions examined. The  $B_{max}$  was highest in the hippocampal formation and cerebral cortex (20-25 fmol/mm<sup>2</sup>) and lowest in the cerebellum (6 fmol/mm<sup>2</sup>) an observation consistent with results obtained in membrane preparations. QAR  $K_D$  values ranged from 7 nM (striate cortex) to 21 nM (caudate). Competition binding experiments were used to determine  $K_i$  values for 4 unlabeled ligands. In the cerebral cortex, the rank order of potency was L-701,324 > ACEA1021 > glycine > D-serine. Regional variations in  $K_i$  were observed for these glycine site ligands in other areas of the rat brain.

## 35.5

ETHANOL INHIBITION OF NMDA CURRENTS IN ACUTELY DISSOCIATED RAT MEDIAL SEPTUM/N. DIAGONAL BAND (MS/DB) CELLS. C.A. Grover\*, A.S. Fincher, and G.D. Frye. Dept. of Med. Pharmacol. & Toxicol., Texas A&M Univ., College Station, TX 77843.

Ethanol inhibits NMDA currents in cultured hippocampal cells (Lovinger et al., *Sci.* 243:1721-1724; 1989), and acute tolerance to ethanol inhibition of NMDA-mediated EPSPs occurs in hippocampal slices (Grover & Frye, *Brain Res.* 642: 70-76; 1994). The present study examined the time dependency of ethanol (60 mM) inhibition of NMDA (100  $\mu$ M)-induced whole-cell currents in acutely isolated MS/DB cells from adult male Sprague-Dawley rats. Three baseline 3 s NMDA currents were obtained 30 s apart, followed by 3 NMDA responses 30 s apart either with ethanol applied only during 3 s applications of NMDA (Brief), or with ethanol applied continuously for 90 s (Continuous). Ethanol reversibly inhibited NMDA currents by 38, 31, and 39 % (n=7) with the 3 consecutive Brief tests. NMDA currents in each of these cells was inhibited by more than 20 % with the first Brief test, and none of these cells showed reduced inhibition by the third NMDA-ethanol application. Continuous ethanol inhibited NMDA currents by 34, 26, and 26 % (n=31) with the 3 consecutive Continuous tests. However, inhibition was less than 20% in 9 of the 31 cells, and while 17 of the remaining 22 cells showed consistent inhibition (40, 37, 40 %), 5 cells showed at least a 20% reduction of inhibition by the third response during continuous exposure to ethanol (68, 30, 27 %).

This suggests that acute tolerance to continuous ethanol inhibition of NMDA currents occurs in a subpopulation of MS/DB neurons. Supported by AA10067-02 (GDF).

## 35.7

CHRONIC ETHANOL INCREASES NMDA RECEPTOR SUBUNIT EXPRESSION IN CORTICAL NEURONS GROWN IN LOW BUT NOT HIGH GLUTAMINE. L. J. Chandler\* and D. Norwood. Department of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130.

The high concentration (2 mM) of glutamine commonly present in culture media has been reported to inhibit upregulation of NMDA receptors in response to chronic exposure to antagonist. We have previously shown that chronic ethanol can enhance NMDA receptor function in cortical neurons grown in high glutamine without an apparent increase in NMDA receptor density. The present study examined the effect of chronic ethanol exposure on the expression of NMDA receptor subunit proteins in cortical neurons grown in high (2 mM) versus low (100  $\mu$ M) glutamine. Since L-glutamine is relatively unstable in media, cells were grown in media containing dipeptide L-alanyl-L-glutamine, a stabilized form of L-glutamine. Exposure of low glutamine cultures to 100 mM ethanol for 4 days (starting at culture day 9) significantly enhanced expression of NR1, NR2A and NR2B subunit polypeptides as determined by immunoblot analysis using subunit selective antibodies. In contrast, and in agreement with our previous observations, chronic ethanol did not alter NR1, NR2A or NR2B subunit expression in the presence of high glutamine. Reducing the glutamine concentration did not alter the developmental expression of any of the receptor subunit proteins. These results 1) demonstrate the use of a stabilized form of L-glutamine in neuronal cultures; 2) confirm and extend previous observations that upregulation of NMDA receptor expression in response to chronic ethanol is enhanced in low glutamine media; and 3) suggest that other mechanisms in addition to increases in NMDA receptor density may contribute to upregulation of NMDA receptor function in response to chronic ethanol exposure. Supported by a grant from the Alcoholic Beverage Medical Research Foundation.

## 35.4

ZINC INHIBITION OF [<sup>3</sup>H]MK-801 BINDING IS DIFFERENT IN MOUSE BRAIN AND SPINAL CORD: EFFECT OF GLYCINE AND GLUTAMATE. K. J. Kovács and A. A. Larson\*. Dept. of Veterinary Pathobiology, University of Minnesota, St. Paul, MN 55108.

Zinc (Zn<sup>2+</sup>) inhibits N-methyl-D-aspartate (NMDA)-type excitatory amino acid activity by a non-competitive action. Based on regional differences in the CNS in binding characteristics of [<sup>3</sup>H](+)-5-methyl-10,11-dihydro-5H-dibenzo[a,d]cyclohepten-5,10-imine maleate ([<sup>3</sup>H]-MK-801) and other compounds used to label open channels in the receptor complex, we compared the inhibitory influence of Zn<sup>2+</sup> on [<sup>3</sup>H]MK-801 binding in whole mouse brain to that in spinal cord membranes. Radioligand binding techniques were used in the presence and absence of maximally effective concentrations of glycine and/or glutamate. Using extensively washed membranes without exogenous glycine and glutamate, Zn<sup>2+</sup> was found to be a weaker inhibitor of [<sup>3</sup>H]MK-801 labeled sites in the spinal cord ( $IC_{50} > 50 \mu$ M) than in the whole brain ( $IC_{50} = 9.8 \mu$ M). In contrast, addition of exogenous glycine and glutamate decreased the inhibitory effect of Zn<sup>2+</sup> in the brain ( $IC_{50} = 42.6 \mu$ M) but dramatically increased the inhibitory effect of Zn<sup>2+</sup> in the spinal cord ( $IC_{50} = 4.1 \mu$ M). Thus, Zn<sup>2+</sup> can inhibit NMDA activity over a wider range of concentrations in the spinal cord than in the brain. In addition, increases in NMDA activity appear to potentiate the inhibitory effect of zinc in the spinal cord but attenuate the inhibitory effect of zinc in brain. The different actions of Zn<sup>2+</sup> may be attributable to a differential distribution of NMDA NR2 receptor subunits in mouse brain and spinal cord. Zinc may play a role in sensory processing at the spinal cord level as the density of zinc is highest in the superficial layers of the dorsal horn. [NIDA04090 to AAL]

## 35.6

EFFECT OF CHRONIC ETHANOL EXPOSURE ON GLYCINE SITE OF THE NMDA RECEPTOR COMPLEX IN MAMMALIAN CORTICAL NEURONS. Xian-Jue Hu\* and M.K. Ticku. Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284-7764.

We have previously demonstrated that chronic ethanol (50 mM, 5 days) treatment upregulated the NMDA receptor function and binding in cultured cortical neurons, as measured by [<sup>45</sup>Ca<sup>2+</sup>], with Fura-2/AM and [<sup>3</sup>H]MK-801 binding (Hu and Ticku, *Mol. Br. Res.* 270:485, 1994). Furthermore, we have shown that it also selectively increased the NMDA receptor R2B subunit mRNA gene expression (Hu et al. *Mol. Br. Res.* 36:211, 1996). In the present study we further investigated the effect of chronic ethanol treatment on [<sup>3</sup>H]DCK (a glycine site ligand) binding and the potentiation of [<sup>3</sup>H]MK-801 binding by glycine in cortical neuronal membrane preparation. The results demonstrate that chronic ethanol treatment increased the specific [<sup>3</sup>H]DCK binding by ~60%, and the potentiation of [<sup>3</sup>H]MK-801 binding by glycine was also increased by ~90%. The increased binding and the potentiation were reversible following ethanol withdrawal for 72 hrs. These results suggest that glycine site may also play a role in the upregulation of the NMDA receptor function following chronic ethanol exposure. The potential mechanisms involved in the upregulation of the binding to the glycine site is under investigation.

## 35.8

USE OF TRYPSIN IN NEURONAL TISSUE DISSOCIATION ALTERS THE EFFECT OF ETHANOL ON NMDA-ACTIVATED WHOLE-CELL CURRENTS IN VITRO. D.W. Frederick and J.M. Wright\*. Howard Univ., Washington, D.C. 20059, and Lab. of Molecular & Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892-8205.

One of the problems in the study of alcohol effects on ligand-gated ion-channels has been the variation in response among and within various laboratories. We developed a non-enzymatic dissociation protocol with cell yield and % viable cells similar to that of enzymatic protocols. Neurons from E-16 mouse (NCI C57/BL6) hippocampus or cortex were plated on laminin-coated 35 mm dishes and cultured for 11 to 20 d. Cells dissociated by a non-enzymatic process exhibited a potentiation of the peak NMDA-activated current ( $254 \pm 54\%$ ; N = 15) when 1 mM ethanol was preapplied for 10 s. This potentiation was not observed in parallel cultures of neurons dissociated by treatment with trypsin (N = 4) and had not previously been observed over a 3 year period in cultures produced using trypsin in the dissociation protocol. The potentiation was transient with no effect seen after 3 min continuous exposure to 1 mM ethanol. Potentiation occurred both in whole-cell (N = 11) and permeabilized patch (N = 4) configurations. The results suggest that attention should be paid to the enzymes used in the tissue preparation protocol. This work was supported by NIMH grant #5T32MH19547 and NIAAA.

## 35.9

## BLOCK OF NMDA RECEPTOR BY A MILNACIPRAN ANALOG.

K. Yoshii, T. Noguchi, Y. Ohtsubo, H. Imoto, and E. Tanaka\*, Kyushu Inst. of Tech., Iizuka, 820 Japan, Dept. of Physiology, Kurume Univ. Sch. Med. Kurume, 830 Japan.

A milnacipran analog synthesized by Shuto and Matsuda (Hokkaido Univ. Sapporo, Japan) blocked NMDA receptors of cultured mouse hippocampus neurons and those produced by *Xenopus* oocytes injected with rat brain mRNA under voltage clamp conditions. The analog blocked NMDA responses to 30  $\mu$ M NMDA (+ 1 or 10  $\mu$ M Gly) with IC<sub>50</sub> of 1.7  $\mu$ M and decreased the maximum responses of concentration-response curves for NMDA (+ 10  $\mu$ M Gly) and those for Gly (+ 30  $\mu$ M NMDA) in uncompetitive manner. The blocking effect was use-dependent and potentiated on hyperpolarization. The time constants of block and recovery from the block were much shorter than those for MK-801. The analog hardly blocked the responses of non-NMDA, metabotropic Glu, 5HT<sub>1C</sub>, GABA<sub>A</sub>, and ACh<sub>M1</sub> receptors produced by the oocytes. These results indicate that this analog acts as a faster open channel blocker than MK-801.

This study was supported by The Ministry of Education, Japan.

## 35.11

## EFFECT OF NMDA ON HIPPOCAMPAL NEURONS FROM TS16 FETAL MICE.

R.J. Siarey, E. Coan, S.I. Rapoport, and Z. Galdzicki\*, LNS/NIA, NIH, Bethesda, MD 20892, USA.

The trisomy 16 mouse (Ts16) is regarded as a model of Down's syndrome. Voltage-dependent ion channels from fetal Ts16 hippocampal neurons have been shown to be abnormal (Galdzicki et al., Brain Res. 604, 69-78, 1993). The NMDA receptor ion current is voltage-dependent (Nowak et al., Nature 307, 462-465, 1984). In order to determine if there were similar defects in ligand-gated channels we examined NMDA responses on Ts16 neurons.

Hippocampal cultures were prepared from diploid and Ts16 mouse fetuses (E15-17) as previously described (Galdzicki, et al., 1993). The initial plating medium consisted of MEM, 1% glutamine, 10% fetal bovine and 5% horse serum (all v/v), after 24h the fetal bovine serum was omitted. Whole-cell patch clamp recordings were performed at culture days 16-29. Neurons were superfused with extracellular medium consisting of (in mM) NaCl, 140; KCl, 5; MgCl<sub>2</sub>, 2; CaCl<sub>2</sub>, 1; NaOH/HEPES, 10 and dextrose, 15 at pH 7.4, plus 1  $\mu$ M glycine, 1  $\mu$ M TTX and 50  $\mu$ M picrotoxin. The pipette solution contained (in mM) CsF 130, CaCl<sub>2</sub>, 1; BAPTA, 11; CsOH/HEPES, 10 and Mg-ATP, 2. Passive membrane properties of the neurons were not significantly different, resistance,  $\tau$  and capacitance values were 228 $\pm$ 50M $\Omega$ , 6.0 $\pm$ 0.8ms and 35.3 $\pm$ 4.8pF (n=17) for diploid and 181 $\pm$ 28M $\Omega$ , 7.0 $\pm$ 1.3ms and 36.3 $\pm$ 3.6pF (n=11) for Ts16 neurons. Whole-cell currents were evoked from an holding potential of -60 mV by four 30 mV steps, in the absence and presence of NMDA (10-80  $\mu$ M). I-V relationships for the NMDA-induced current were plotted and used to estimate the reversal potential and conductance, which was then normalized. The presence of NMDA evoked an inward current in both diploid and Ts16 neurons. There was no significant difference in the conductance at the concentrations applied or reversal potentials, -6.6 $\pm$ 3.6mV (n=20) and -9.9 $\pm$ 4.4mV (n=12) for diploid and Ts16 respectively.

Therefore, in contrast to our observations on voltage-dependent ion channels, these data suggest that the trisomic condition does not produce abnormal NMDA evoked ionic current in fetal hippocampal neurons.

## 35.13

SIGNAL TRANSDUCING MECHANISMS IN THE MODULATION OF NMDA-INDUCED INWARD CURRENT BY THE 5-HT<sub>2A/C</sub> RECEPTOR AGONIST DOB IN RAT CORTICAL CELLS. X.F. Liang, V.L. Arvanov, R. Roberts, J.Y. Zhang\* and R.Y. Wang, Dept. Psychiatry, SUNY/SB, Stony Brook, NY 11794-8790.

We have previously demonstrated that at low (0.01-1  $\mu$ M) and high (10-40  $\mu$ M) concentrations, DOB facilitated and inhibited, respectively, NMDA-evoked inward current in pyramidal cells of the medial prefrontal cortex slice preparations. The aim of the present study was to determine the cellular mechanisms by which DOB modulates NMDA-induced current. Using the techniques of intracellular recording and single electrode voltage clamp, we examined the effects of agents modifying cytosolic [Ca<sup>2+</sup>] as well as inhibitors of Ca<sup>2+</sup>-related protein kinases. We found that inclusion of Ca<sup>2+</sup>-chelator BAPTA (200 mM) in the recording micropipette had no effect on the facilitating effect but it eliminated the inhibitory action of DOB on NMDA's response, whereas bath application of membrane permeable BAPTA-AM (30  $\mu$ M) prevented both effects of DOB. Bath application of thapsigargin (1  $\mu$ M), a Ca<sup>2+</sup>-mobilizing agent, produced a time-dependent action: it facilitated NMDA-induced current 10 min after superfusion, mimicking the action of low concentrations of DOB, which disappeared after 30-40 min. Additionally, thapsigargin blocked both the facilitating and inhibitory action of DOB on NMDA's response. Chelerythrine (2  $\mu$ M), a selective PKC inhibitor, completely prevented the facilitating effect but did not affect the inhibitory action of DOB. In contrast, the calmodulin antagonist W-7 (10  $\mu$ M) had no effect on DOB's potentiating action, but prevented DOB-induced inhibition of NMDA's response. In conclusion, these results support our previous findings that the potentiating and inhibitory effects of DOB on NMDA-induced inward current are the results of its action on presynaptic glutamate terminals and postsynaptic pyramidal cells, respectively. Our results further suggest that the pre- and postsynaptic actions of DOB were mediated via the PKC and Ca<sup>2+</sup>-calmodulin transducing mechanisms, respectively (Supported by USPHS grants MH-41440 and DA-07193).

## 35.10

## WAGLERIN-1 MODULATES GLYCINE AFFINITY FOR NMDA RECEPTORS OF MURINE CNS NEURONS. J.H. Ye\* and J.J. McArdle. Depts Pharm &amp; Phys and Anesthesiology, NJ Med Sch (UMDNJ) Newark, NJ 07103-2714

In this study we explored the effect of Waglerin-1 (WTX), a lethal peptide purified from the venom of *Wagler's* pit viper (*Trimeresurus wagleri*), on the NMDA-activated current of freshly isolated murine hypothalamic neurons. Whole cell currents were recorded with the nystatin perforated patch technique. Current in response to NMDA and glycine increased when WTX was co-applied. This effect of WTX was not observed either in the absence of added glycine or when saturating glycine concentrations were co-applied. Evaluation of the dependence of NMDA current on glycine concentration revealed that WTX increased the affinity for glycine. For rat cortical membrane preparations, 10  $\mu$ M WTX caused a 20 fold enhancement of the affinity of the strychnine-resistant glycine binding site. WTX did not potentiate the response of hypothalamic neurons to kainate. These data suggest that WTX selectively potentiates the NMDA type of glutamate receptor through an action on the glycine modulatory site. (Funds supporting this work were derived from NIH grant NS31040 as well as the Department of Anesthesiology.)

## 35.12

## PRE- AND POSTSYNAPTIC ACTIONS OF HALLUCINOGENS ON NMDA-NEUROTRANSMISSION IN THE RAT MEDIAL PREFRONTAL CORTICAL (PFC) SLICES. V.I. Arvanov\*, P.G. Magro and R.Y. Wang, Dept. Psychiatry, SUNY/SB, Stony Brook, NY 11794.

Serotonin<sub>2A</sub> (5-HT<sub>2A</sub>) receptors are implicated in the action of hallucinogens and antipsychotic drugs. The aim of the present study was to examine the modulatory action of the hallucinogens DOB and LSD, which are 5-HT<sub>2A</sub> receptor agonists, on NMDA-induced effect in pyramidal cells. Application of NMDA evoked EPSPs and depolarizations. DOB exerted a concentration-dependent modulation of NMDA's responses: at low (0.01-1  $\mu$ M) and high (10-40  $\mu$ M) concentrations, DOB facilitated and inhibited, respectively, NMDA-evoked depolarization and EPSPs. LSD also produced a biphasic effect in the presence of the 5-HT<sub>2A</sub> antagonist WAY 100635: at 0.01-0.1  $\mu$ M, LSD facilitated and at 1-10  $\mu$ M, it inhibited NMDA response. In contrast, lisuride (a non-hallucinogenic congener of LSD) potentiated NMDA's response in a monophasic fashion. Without WAY 100635, LSD inhibited NMDA's response. These modulatory actions of DOB, LSD and lisuride were also observed in voltage-clamp mode, in the presence of TTX, glycine and bicuculline. The biphasic modulatory action of hallucinogens (but not the effect of lisuride) was blocked by the selective 5-HT<sub>2A</sub> receptor antagonists MDL 100907 and ketanserin but not by bicuculline or WAY 100635. Interestingly, a non-NMDA receptor antagonist CNQX (20  $\mu$ M) decreased NMDA's response. Moreover, it totally eliminated the potentiating action and unmasked the inhibitory action of hallucinogens at 100 nM on NMDA's response. Riluzole (30  $\mu$ M), an inhibitor of glutamate release from presynaptic terminals, produced similar results to those of CNQX. Combined, these results suggest that the hallucinogens DOB and LSD interact with 5-HT<sub>2A</sub> receptors on presynaptic glutamate terminals and postsynaptic pyramidal cells, respectively, to produce the potentiating and inhibitory effects. In addition, they suggest that the hallucinogenic effect of DOB and LSD is mediated by their postsynaptic action (Supported by MH-41440, DA-07193).

## 35.14

## THE POTENTIATION OF NMDA-INDUCED INWARD CURRENT BY ANTI-PSYCHOTICS IN CORTICAL CELLS. R.Y. Wang\* and V.L. Arvanov, Dept. Psychiatry, Sch. of Med., SUNY/SB, Stony Brook, NY 11794-8790

The glutamate hypothesis of schizophrenia proposes that N-methyl-D-aspartate (NMDA) receptor hypofunction may cause the behavioral deficits associated with schizophrenia. Accordingly, NMDA receptor agonists or compounds that facilitate NMDA-mediated neurotransmission might be potential antipsychotic drugs (APDs). Using the techniques of intracellular recording and single electrode voltage clamp, we examined the effects of typical and atypical APDs on NMDA-induced inward current and the role of 5-HT<sub>2A</sub> receptors and corresponding second messengers in the action of APDs in pyramidal cells of the medial prefrontal cortex in *in vitro* brain slice preparations. The following drugs ( $\mu$ M) were included in the superfusion solution: 1 glycine, 0.5 TTX and 5 bicuculline methiodide. Our preliminary results show that neither haloperidol nor clozapine altered membrane current and input resistance of pyramidal cells. However, both haloperidol (50 - 100 nM) and clozapine (50 - 100 nM), but not fluoxetine (50 - 100 nM), produce a marked 3-4 fold potentiation of NMDA-induced inward current. By comparison, responses evoked by AMPA in the same neuron were not affected by haloperidol but depressed 59-78% by clozapine. MDL 100907, a selective 5-HT<sub>2A</sub> receptor antagonist (K<sub>i</sub> = 0.5 nM) and a putative atypical APD, but not its less active enantiomer MDL 100009, also produced a striking potentiation of NMDA-induced inward current. As clozapine (K<sub>i</sub> = 10 nM) and haloperidol (K<sub>i</sub> = 50 nM) have a moderate affinity to 5-HT<sub>2A</sub> receptors *in vitro*, it is likely that the potentiating effect of putative APDs on NMDA-induced inward current is the result of their interactions with 5-HT<sub>2A</sub> receptors. (Supported by USPHS grants MH-41440 and DA-07193).

## 35.15

CP-101,606 ANTAGONIZES NMDA RECEPTORS BY INTERACTING WITH THE POLYAMINE MODULATORY SITE. David D. Mott\*, Sunan Zhang, Mark S. Washburn, Morris Fendley and Ray Dingleline. Dept. of Pharmacology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

CP-101,606, an ifenprodil analogue, is a potent and selective antagonist of NMDA receptors that protects cultured neurons from glutamate neurotoxicity. The mechanism by which CP-101,606 antagonizes NMDA receptors has not been clearly defined. To better understand its mechanism of action we examined the effect of CP-101,606 on heteromeric NMDA receptors expressed in *Xenopus* oocytes.

NR1a/2B receptors were reversibly inhibited by CP-101,606 in a non-competitive and voltage independent manner. Maximum inhibition was 78% at a concentration of 3  $\mu$ M. Interestingly, at drug concentrations below 100 nM, inhibition was initially large but then faded over 20-30 sec to a steady state value. Concentration response curves suggest that CP-101,606 inhibits NR1a/2B receptors through both high affinity (transient;  $IC_{50} < 10$  nM) and low affinity (steady state;  $IC_{50} = 200$  nM) mechanisms.

We initially examined the site of action of CP-101,606 by testing its effect on NMDA receptors with different subunit composition. CP-101,606 produced steady state ( $IC_{50} = 250$  nM), but no transient inhibition of NR1b/2B receptors, suggesting that the transient inhibition was suppressed by the presence of exon 5 in the NR1b subunit. In contrast, CP-101,606 had a markedly reduced effect on NR1a/2A receptors ( $IC_{50} = 540$  nM) with a maximum inhibition of only 30%, suggesting that the NR2B subunit contributed to the development of the steady state inhibition. Since the NR1b and NR2B subunits are both involved in the actions of spermine on the NMDA receptor, we examined the effect of spermine on the inhibition of NR1a/2B receptors produced by CP-101,606. Spermine (100  $\mu$ M) significantly inhibited both the peak and steady state inhibition produced by CP-101,606. These results suggest that CP-101,606 produces both a high and low affinity inhibition of NMDA receptors by interacting with the polyamine modulatory site. Supported by the Epilepsy Foundation and NS-27452.

## 35.17

MODULATION OF [<sup>3</sup>H]MDL 105,519 BINDING TO THE GLYCINE SITE OF THE NMDA RECEPTOR BY POLYAMINES. T.A. Constantine\* and L.J. Reynolds. Dept. of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Several studies have suggested that polyamines modulate the interaction of glycine with the NMDA receptor. We have further investigated the effects of polyamines using the glycine site antagonist [<sup>3</sup>H]MDL 105,519. [<sup>3</sup>H]MDL 105,519 binding assays were performed using well washed membranes prepared from frozen rat brains. Non-specific binding was determined by the addition of 1mM glycine. The polyamines spermine, spermidine, and 1,5-(diethylamino)piperidine (DEAP) increased the fraction of non-specific binding in the [<sup>3</sup>H]MDL 105,519 binding assay from 40% to 60% when spermidine or spermine concentration was increased from 1 to 100  $\mu$ M.

We investigated the characteristics of the polyamine induced increase in [<sup>3</sup>H]MDL 105,519 non-specific binding. We performed a 5,7-dichlorokynurenic acid (DCK) dose response curve in the presence of 300  $\mu$ M spermine and 1mM glycine. High concentrations of DCK (10-100  $\mu$ M) were necessary to displace the polyamine induced binding suggesting [<sup>3</sup>H]MDL 105,519 is binding to a site that is unrelated to the high-affinity glycine antagonist site. An arcaïne dose response curve was performed in the presence of 300  $\mu$ M spermine and 1mM glycine and a decrease in [<sup>3</sup>H]MDL 105,519 binding was observed only at high arcaïne concentrations ( $>100 \mu$ M). This suggests that polyamines are working on a different site than the "arcaïne-sensitive" site to cause the increase in non-specific [<sup>3</sup>H]MDL 105,519 binding.

Spermine, spermidine, and DEAP (30  $\mu$ M) do not appear to have a significant effect on the displacement of [<sup>3</sup>H]MDL 105,519 binding by glycine. Further studies of the effects of polyamines on [<sup>3</sup>H]MDL 105,519 binding are currently in progress in order to resolve the ambiguity of whether polyamines alter the affinity of both glycine agonists and glycine antagonists. Supported by NIH grant DA 07409

## 35.19

MODULATION OF NMDA RESPONSE BY LEUKOTRIENE B4 IN RAT HIPPOCAMPAL NEURONS. N. Horimoto\*, M. Abe, J. Nabekura and T. Ogawa. Dept. of Physiology, Akita Univ. Sch. of Med., Akita 010, Japan.

Leukotriene B4 (LTB4), one of the arachidonic acid metabolites, is produced in various tissues including brain. However, the influence of LTB4 on neurons is not well understood. In the present study, we investigated the effect of LTB4 on NMDA-receptor mediated currents in acutely dissociated rat hippocampal neurons using a patch recording under the voltage clamp. At a holding potential of -40 mV, 10<sup>-4</sup>M NMDA induced initial peak followed by a rapid decrease of inward current. Extracellular application of LTB4 (300 nM - 3  $\mu$ M) attenuated the peak NMDA-induced current in 10 of 25 neurons. The intracellular perfusion with LTB4 dissolved in a pipette solution prolonged the time constant of the decreasing phase from the peak to the steady state. These observations show that LTB4 could affect the NMDA response both extracellularly and intracellularly, suggesting that LTB4 has not only an effect related to inflammation but also plays a modulatory role in neuronal excitation in the hippocampus.

This study was supported by a Grant-in-Aid for Scientific Research (No.07670047, No. 07457390) from the Ministry of Education, Science and Culture, Japan, and also assisted by Ono Pharmaceut. Co. with LTB4 and related drugs.

S-3,5-Dihydroxyphenylglycine Potentiates the NMDA Response of Cortical Neurons H.J. Flavlin\* and N.W. Daw. Dept. Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, CT. 06520-2089.

Recent work demonstrated that the metabotropic glutamate receptor (mGluR) agonist (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (ACPD) potentiates the NMDA response in Layer V/VI neurons and in some Layer II/III visual cortical neurons (Wang, X.F. and Daw N.W., Investigative Ophthalmology & Visual Science 37(3); S486, 1996). In order to elucidate the specific mGluR subtype(s) responsible for this potentiation, the current study compared the effect of the Type I (mGluR 1,5) agonist S-3,5-dihydroxyphenylglycine (DHPG) and the Type II (mGluR 2,3) agonist (2S,3S,4S)-alpha-(carboxycyclopropyl)glycine (LCCGI) on the NMDA response of rat visual cortical neurons. Whole cell recordings were obtained for each cell with iontophoretic drug application. In Layers II/III and Layers V/VI, DHPG always potentiated the NMDA response. The mean ratio of the cell's response to NMDA + DHPG to the control NMDA response was 3.93 for Layer II/III (8 cells) and 1.97 for Layer V/VI cells (11 cells). Some cells in Layers II/III (observed in 4 of 8 cells) and Layers V/VI (4/11 cells) responded to LCCGI by potentiating the NMDA response while other cells responded by attenuating the NMDA response (4/8 cells in Layer II/III and 7/11 cells in Layers V/VI). These data suggest that mGluR 1 and/or 5 stimulation always enhances the NMDA response whereas mGluR 2 and/or 3 stimulation has at least two effects. Further work will establish whether these multiple effects are due to presynaptic versus postsynaptic localization of mGluR's. Supported by R01EY00053 and P32EY06591.

## 35.18

FREE INTRACELLULAR Mg<sup>2+</sup> CONCENTRATION AND BLOCK OF WHOLE-CELL NMDA-ACTIVATED CURRENT. Y. Li-Smerin\*, E.S. Levitan and J.W. Johnson. Depts. of Neuroscience and Pharmacology, University of Pittsburgh, Pittsburgh, PA 15260.

Free intracellular Mg<sup>2+</sup> (Mg<sup>2+</sup>) was found previously to inhibit NMDA-activated current flow in cell-free patches more effectively than in whole cells. To test whether this difference is due to cellular regulation of Mg<sup>2+</sup>, we measured [Mg<sup>2+</sup>]<sub>i</sub> in cultured cortical neurons using the fluorescent dye mag-indo-1. 50  $\mu$ M mag-indo-1 and various buffered Mg<sup>2+</sup> solutions were dialyzed into neurons from whole-cell pipettes. The ratio of the dye emission at 405 to that at 495 nm was converted to [Mg<sup>2+</sup>]<sub>i</sub> using a calibration curve constructed in cells (K<sub>eq</sub> of the dye = 10.6 mM). We then measured [Mg<sup>2+</sup>]<sub>i</sub> in cells dialyzed with pipette solutions which were previously used to test Mg<sup>2+</sup> block of NMDA-activated currents. Pipette solutions contained 10 mM EGTA with theoretically calculated free Mg<sup>2+</sup> of 1, 3, and 10 mM. Measured steady-state [Mg<sup>2+</sup>]<sub>i</sub> in these cells was (in mM) 1.3  $\pm$  0.2 (mean  $\pm$  sem) (n = 3), 2.2  $\pm$  0.08 (n = 3), and 6.2  $\pm$  1.6 (n = 5), respectively. Based on an independent calibration constructed in vitro (K<sub>eq</sub> = 7.5 mM), the free [Mg<sup>2+</sup>]<sub>i</sub> in the same three pipette solutions was (in mM) 0.8  $\pm$  0.05 (n = 5), 2.1  $\pm$  0.1 (n = 5), and 6.4  $\pm$  0.2 (n = 7), respectively. The cellular [Mg<sup>2+</sup>]<sub>i</sub> is not significantly different from the pipette [Mg<sup>2+</sup>]<sub>i</sub> for the intermediate and the high Mg<sup>2+</sup> solutions. Thus, cellular regulation of [Mg<sup>2+</sup>]<sub>i</sub> cannot explain the less effective inhibition by Mg<sup>2+</sup> of whole-cell NMDA-activated current. Based on these measurements of [Mg<sup>2+</sup>]<sub>i</sub> and previous measurements of fractional block, we determined that the K<sub>d</sub> of inhibition by Mg<sup>2+</sup> at +60 mV in cell-free patches is 1.8  $\pm$  0.1 mM, whereas the K<sub>d</sub> in whole cells is 5.0  $\pm$  0.9 mM. The two values of K<sub>d</sub> are significantly different (P < 0.05). Thus, the difference observed in the inhibition by Mg<sup>2+</sup> of NMDA-induced current flow through patches and whole cells appears to be due to a difference in the sensitivity of NMDA receptors to Mg<sup>2+</sup>. Supported by NIH.

CHRONIC TREATMENT WITH SIGMA LIGANDS PRODUCES FUNCTIONAL CHANGES IN NMDA RECEPTOR ION-CHANNEL: *in vivo* AND *in vitro* STUDIES. T. Yamamoto\*, S. Tanaka and H. Yamamoto. <sup>1</sup>Lab. of Mol. Recognition, Grad. Sch. of Integrated Sci., Yokohama City Univ., Yokohama 236; <sup>2</sup>Dept. of Psychopharmacol., Tokyo Inst. of Psychiatry, Tokyo 156, Japan.

Sigma binding sites have been implicated to be involved in the psychotomimetic effects for the certain benzomorphans and in the action for the antipsychotic drugs. Despite the accumulation of data, the function of the sigma sites remains somewhat unclear. Our previous studies demonstrated that sigma sites modulate the NMDA receptor ion-channel complex by using intact cell binding for primary culture cells from rat cerebrum. In the present study, we further characterized the interaction between sigma sites and NMDA receptor ion channel complex. The effects of chronic treatments of haloperidol or (+)-pentazocine on sigma sites and NMDA receptor in brain membrane were assessed using [<sup>3</sup>H]NE-100 and [<sup>3</sup>H]TCP (or [<sup>3</sup>H]MK-801) binding. Administration of haloperidol (2 mg/kg, i.p.) or (+)-pentazocine (5 and 10 mg/kg, i.p.) to rat for 7 days (twice a day) resulted in 37-48 % decreases or no significance in various regions of brain in the specific binding of [<sup>3</sup>H]NE-100 (for sigma-1 sites), respectively. Moreover, haloperidol or (+)-pentazocine produced 17 % increase or 13 % decrease the specific binding of [<sup>3</sup>H]MK-801 in the frontal cortex, respectively. These findings suggest that chronic haloperidol and (+)-pentazocine treatment inversely modulates [<sup>3</sup>H]MK-801 binding in frontal cortex.

## 35.21

**NOVEL ANTAGONISTS OF THE GLYCINE SITE OF THE NMDA RECEPTOR: IN VITRO CHARACTERIZATION AND REVERSIBILITY WITH GLYCINE** L. J. Robichaud\*, L. L. Coughenour, S. Borosky, G. W. Campbell, D. M. Rock, S. J. Hays, D. M. Retz, P. W. Yuen, C. F. Bigge, and P. A. Boxer. Neuroscience Therapeutics and Chemistry, Parke-Davis Pharm. Research, Div. Warner-Lambert Co., Ann Arbor, MI 48105.

Spontaneous epileptiform discharge (SED) frequency in the  $Mg^{2+}$ -free rat cortical wedge model is inhibited by various modulators of the NMDA-ion channel receptor complex (e.g. competitive and non-competitive antagonists, glycine-site antagonists) and ion channel blockers. Glycine, a co-agonist of the NMDA receptor, is present in excess in cortical wedges, since addition of glycine at concentrations up to 1 mM has no effect on SED frequency. Furthermore, inhibition of SEDs by known glycine antagonists (e.g., 7-chlorokynurenic acid) is reversed by additional glycine, in contrast to SED inhibition by other functional antagonists. Known and novel compounds representative of diverse chemical series (kynurenes, quinoxalines, 2-hydroxyquinoxaline-3-carboxylic acids, indole-2-carboxylic acids, and ester or sulfonamide derivatives) were evaluated in the following assays: [ $^3H$ ]glycine binding, inhibition of SEDs and reversal of this inhibition by addition of glycine, and glutamate-induced LDH release from cultured cortical neurons. There was a good correlation between the  $IC_{50}$ s in these assays across all classes and potencies of compounds. Reversal of SED inhibition was a good predictor of glycine receptor affinity and inhibition of LDH release, whereas compounds without glycine reversibility of SED inhibition (CPP, MK-801, ifenprodil, spermine, toxins) frequency did not show glycine receptor affinity although they could inhibit glutamate-induced neurotoxicity. Supported by Warner-Lambert Co.

## 35.22

**POTENTIATION OF NMDA RECEPTOR-MEDIATED RESPONSES BY DYNORPHIN AT LOW GLYCINE** U. Brauneis\*, R. W. Peoples, M. Oz, F. F. Weight, and Li Zhang. Laboratory of Molecular and Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892-8205

The effect of dynorphin on NMDA-activated currents in the presence of low glycine was investigated in oocytes expressing heteromeric NMDA receptors. While at 10  $\mu M$  glycine dyn 1-13 inhibited NMDA-activated currents, lowering glycine to 100 nM caused a dramatic potentiation of NMDA-activated currents by 10  $\mu M$  dyn 1-13:  $\epsilon 1/\zeta 1$ :  $3377 \pm 1416\%$  ( $n = 13$ );  $\epsilon 2/\zeta 1$ :  $1897 \pm 893\%$  ( $n = 5$ );  $\epsilon 3/\zeta 1$ :  $4356 \pm 846\%$  ( $n = 12$ );  $\epsilon 4/\zeta 1$ :  $1783 \pm 503\%$  ( $n = 14$ ). This potentiation was inhibited by the glycine antagonist kynurenic acid. Glycine concentration-response curves showed the shift of potentiation to inhibition to be between 1  $\mu M$  and 10  $\mu M$  glycine, depending on subunit combination of the NMDA receptor. Potentiation, like inhibition, of NMDA-activated currents by dyn 1-13 was not mediated by an opioid receptor. Dyn 2-13 and dyn 3-13, both of which have a glycine as the first amino acid, potentiated NMDA-activated current more strongly at low glycine than dyn 1-13. No potentiation was observed for dyn 4-13. In hippocampal neurons, dyn 1-13 and dyn 2-13 also potentiated NMDA-activated currents in the nominal absence of glycine. We investigated possible glycine contamination and concluded that the small amount of free glycine present in solutions, equipment and peptide preparations was insufficient to account for the observed potentiation of NMDA-activated current. This work was supported by NIAAA/NIH. U.B. was an NRC Fellow.

EXCITATORY AMINO ACID RECEPTORS: PHYSIOLOGY,  
PHARMACOLOGY, AND MODULATION—NMDA II

**DISSOCIATION BETWEEN NMDA RECEPTOR MEDIATED INTRACELLULAR CALCIUM SIGNALLING AND ION FLUX** KEG Richter\*, MJ Pagnozzi, JT Lazzaro, FS Menniti. Pfizer, Inc., Central Research Division, Groton, CT 06340.

NMDA receptors (NMDAR) are glutamate-gated cation channels that mediate depolarization, increases in cytoplasmic calcium concentration ( $[Ca^{2+}]_i$ ), and calcium accumulation in the cell. We examined the agonist properties of NMDA at its receptor in rat cortical neurons in culture. The EC50 of NMDA measured in whole cell recordings was 60  $\mu M$ , measured by  $45Ca^{2+}$  uptake was 100  $\mu M$ , but measured by changes in  $[Ca^{2+}]_i$  (using Fura-2) was only 5  $\mu M$ . This suggests that maximal changes in  $[Ca^{2+}]_i$  occur at levels of NMDAR activation well below those which mediate depolarizing transmembrane ion flux. CP-101,606, a noncompetitive NMDAR antagonist, potently ( $IC_{50} = 200$  nM) and efficaciously (extent of block 75%) inhibited NMDA-induced ion flux (measured in whole cell recordings) but very weakly inhibited the increase in  $[Ca^{2+}]_i$  (20% block @ 10  $\mu M$ ). However, CP-101,606 potently (EC50 30 nM) potentiated the ability of  $Mg^{2+}$  to block NMDA-induced increases in  $[Ca^{2+}]_i$ . Thus, by blocking depolarization, CP-101,606 potentiated the inhibitory effect of  $Mg^{2+}$ . In summary, these results suggest that the NMDAR regulates  $[Ca^{2+}]_i$  at a level of activation far below that required to cause depolarization and calcium accumulation. This has implications for our understanding of NMDAR mediated signalling and neurotoxicity. Supported by Pfizer Central Research, Groton, CT.

## 36.2

**ALKALINIZATION PROLONGS RECOVERY FROM GLUTAMATE-INDUCED INCREASES IN  $[Ca^{2+}]_i$**  Kari R. Hoyt\* and Ian J. Reynolds. Dept. Pharmacol. Univ. Pittsburgh, Pittsburgh, PA 15261.

Using indo-1-loaded cultured rat forebrain neurons, we found that increasing extracellular pH from 7.4 to 8.5 caused a dramatic increase in the time required to recover from a glutamate-induced (3  $\mu M$ , in the presence of 1  $\mu M$  glycine, for 15 s.) increase in  $[Ca^{2+}]_i$ . Recovery time to 3-fold basal  $[Ca^{2+}]_i$  levels, in pH 7.4 Hepes-buffered saline solution (HBSS) was  $62.9 \pm 23.6$  s. ( $n = 9$ ), while recovery in pH 8.5 HBSS required  $173.4 \pm 18.6$  s. ( $n = 22$ ). We tested whether this effect of alkalization resulted from an increased  $Ca^{2+}$  influx via a  $Ca^{2+}/H^{+}$  exchange function of the plasma membrane  $Ca^{2+}$  ATPase. This pH 8.5 effect was not due to increased influx of extracellular  $Ca^{2+}$  as removal of extracellular  $Ca^{2+}$  did not inhibit the prolongation caused by increasing pH ( $144.1 \pm 25.6$  s. ( $n = 15$ )). Cadmium (200  $\mu M$ ) which inhibits  $Ca^{2+}$  influx through calcium channels and/or the  $Na^{+}/Ca^{2+}$  exchanger, also did not completely block the effect of pH 8.5 HBSS ( $128.13 \pm 16.4$  s. ( $n = 8$ )). The addition of ketamine (100  $\mu M$ ) to the pH 8.5 HBSS did not block the prolongation ( $167.1 \pm 32.9$  s. ( $n = 13$ )), excluding a role for continued NMDA receptor activation as a mechanism for the effect of pH 8.5 HBSS. Exposure of BCECF-loaded neurons to pH 8.5 HBSS resulted in a rapid intracellular alkalization, thereby raising the possibility that the pH 8.5 HBSS may be exerting its effects on  $Ca^{2+}$  recovery by affecting intracellular  $Ca^{2+}$  buffering mechanisms, including mitochondrial  $Ca^{2+}$  uptake. The effect of pH 8.5 HBSS on  $Ca^{2+}$  recovery was similar to the mitochondrial uncoupler, FCCP (750 nM) in pH 7.4 HBSS ( $201.5 \pm 49.2$  s. ( $n = 6$ )), and combining pH 8.5 HBSS and FCCP did not have a substantially greater effect than either treatment alone ( $252.9 \pm 61.2$  s. ( $n = 7$ )). Removal of extracellular  $Na^{+}$  along with pH 8.5 HBSS resulted in a longer recovery time ( $553.7 \pm 75.9$  s. ( $n = 7$ )), that was also not potentiated by FCCP ( $591.8 \pm 48.2$  s. ( $n = 6$ )). For comparison,  $Na^{+}$  free-pH 7.4 HBSS resulted in a recovery time of  $315.5 \pm 68.0$  s. ( $n = 4$ ), while addition of FCCP to this  $Na^{+}$  free pH 7.4 HBSS resulted in a substantial additional prolongation of recovery time ( $777.4 \pm 164.7$  s. ( $n = 5$ )). In summary, these results suggest that the prolongation of  $[Ca^{2+}]_i$  recovery time by alkalization is not caused by an increase in  $Ca^{2+}$  influx (by a  $Ca^{2+}/H^{+}$  exchange function of the plasma membrane  $Ca^{2+}$  ATPase), but instead may reflect an effect on intracellular  $Ca^{2+}$  buffering mechanisms, with inhibition of mitochondrial  $Ca^{2+}$  uptake representing a possible target. ## 36.3

**HOW IMPORTANT ARE ENDOPLASMIC RETICULUM CALCIUM STORES TO GLUTAMATE-INDUCED CHANGES IN  $[Ca^{2+}]_i$ ?** L. J. Reynolds\*. Dept. of Pharmacology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Glutamate receptor activation results in increases in intracellular free  $Ca^{2+}$  ( $[Ca^{2+}]_i$ ) due to  $Ca^{2+}$  entry. Endoplasmic reticulum (ER)  $Ca^{2+}$  stores may influence the effects of glutamate on  $[Ca^{2+}]_i$ , either by contributing to the buffering of cytoplasmic  $Ca^{2+}$  or by amplifying the response subsequent to  $Ca^{2+}$ -induced  $Ca^{2+}$ -release. Previous studies have suggested that the latter effect makes a substantial contribution to the NMDA component of the glutamate response. The present study has investigated the contribution of ER stores to the effects of glutamate on  $[Ca^{2+}]_i$ .

Experiments were performed on cultured forebrain neurons from e17 rats maintained for 14-18 days *in vitro*.  $[Ca^{2+}]_i$  was usually measured with indo-1. Typically, two responses were obtained to glutamate in each cell, and the second, drug modified, response was compared to the first, as previously described (J. Neurosci. 15:1318, 1995). Drug effects were monitored in neurons stimulated with 0.3, 3.0 or 30  $\mu M$  glutamate.

Inhibition of the ER  $Ca^{2+}$  ATPase with thapsigargin (0.05-1.25  $\mu M$ ) or cyclopiazonic acid (0.25-12.5  $\mu M$ ) alone produced small increases in  $[Ca^{2+}]_i$  (<50 nM) in <20% of neurons tested. These drugs decreased subsequent glutamate responses by <40%. They did not measurably alter the rate of recovery of  $[Ca^{2+}]_i$  to baseline. Inhibition of  $Ca^{2+}$  release with dantrolene (30  $\mu M$ ) inhibited responses to a similar extent. Caffeine (10 mM,  $[Ca^{2+}]_i$  measured using fura-2) infrequently produced small increases in  $[Ca^{2+}]_i$ , and also decreased glutamate-induced responses by about 40%.

Thus, in these studies the release of  $Ca^{2+}$  from ER stores appear to make a smaller contribution to glutamate-induced  $[Ca^{2+}]_i$  changes than has previously been reported. Also, there is no evidence for a substantial contribution of ER  $Ca^{2+}$  ATPase to  $Ca^{2+}$  buffering following glutamate receptor activation.

## 36.4

**MITOCHONDRIA ACCUMULATE  $Ca^{2+}$  STORES FOLLOWING INTENSE GLUTAMATE STIMULATION IN CULTURED RAT FOREBRAIN NEURONS** R. J. White\* and L. J. Reynolds. Center for Neuroscience and Dept. of Pharmacology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

In cultures of rat forebrain neurons, mitochondria buffer the  $Ca^{2+}$  influx resulting from brief NMDA receptor activation by glutamate. Here, we have independently varied both the glutamate concentration and the duration of exposure to investigate the  $[Ca^{2+}]_i$  transients and cellular mechanisms recruited to buffer  $Ca^{2+}$  within different stimulation paradigms. For a 15 s. stimulus, the recovery time doubled as the glutamate concentration was raised from 3 to 300  $\mu M$ . Changing the duration of exposure from 15 s. to five minutes increased the recovery time tenfold even when the glutamate concentration was held at 3  $\mu M$ .

We then used a selective inhibitor of the mitochondrial  $Na^{+}/Ca^{2+}$ -exchange, CGP-37157, to explore the  $Ca^{2+}$  buffering role of mitochondria under these more intense stimulation paradigms. When applied immediately after a 15 s., 100  $\mu M$  glutamate challenge, CGP-37157 consistently caused a rapid fall in  $[Ca^{2+}]_i$ , followed by a slow rise after the drug was washed out. A similar pattern was seen with the 5 min., 3  $\mu M$  glutamate stimulus. Since this pattern was not seen following a 15 s., 3  $\mu M$  glutamate stimulation, we propose that the slow rise following CGP-37157 washout reflects the release of mitochondrial  $Ca^{2+}$  stores which would have otherwise been expelled while the mitochondrial  $Na^{+}/Ca^{2+}$ -exchanger was inhibited.

These studies suggest that mitochondria become progressively more important for buffering glutamate-induced  $Ca^{2+}$  loads as the stimulus intensity increases. Moreover, the recovery of  $[Ca^{2+}]_i$  to baseline following glutamate removal is critically regulated by the release of  $Ca^{2+}$  from mitochondrial stores via mitochondrial  $Na^{+}/Ca^{2+}$ -exchange; this highlights a previously under-appreciated role for  $[Na^{+}]_i$  in the regulation of  $[Ca^{2+}]_i$ .

## 36.5

GLUTAMATE-INDUCED  $[Mg^{2+}]$  CHANGES IN NUCLEAR AND NON-NUCLEAR AREAS IN CULTURED FOREBRAIN NEURONS USING CONFOCAL MICROSCOPY. C. Cheng\* and I.J. Reynolds. Dept. of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Previously in our laboratory, it has been shown that a glutamate stimulus that causes excitotoxicity in cultured rat forebrain neurons also causes millimolar increases of intracellular free magnesium ( $[Mg^{2+}]$ ) (Brocard *et al.*, *Neuron* 11: 751-757, 1992). This suggests that  $[Mg^{2+}]$  may be important in the mechanism(s) underlying glutamate's excitotoxic effect. Although magnesium is an abundant intracellular cation, and is essential for many cellular functions, little is known about how it is regulated within neurons. In order to gain a better understanding of magnesium buffering within cells and how glutamate perturbs this balance, we sought to identify the possible intracellular pools of magnesium affected by glutamate exposure. Cultured forebrain neurons were loaded with the fluorescent magnesium indicator, Mag-indo-1, and confocal microscopy of single cells was used to visualize a  $1\mu m$  section across the neuron.  $[Mg^{2+}]$  was monitored by measuring the ratio of fluorescence emission at 405 and 490nm. The nucleus was identified in the same samples using the fluorescent indicator, Hoechst 33342. Neurons loaded with Mag-indo-1 showed significantly higher levels of fluorescence in the nucleus compared to the cytoplasm; however, the 405/490 ratio was not different across the cell suggesting that the  $[Mg^{2+}]$  does not vary between the nucleus and cytoplasm. The addition of glutamate, in the presence of calcium or in  $Ca^{2+}$ -free buffer supplemented with 9.0mM  $Mg^{2+}$ , resulted in an increase in  $[Mg^{2+}]$  in both cytoplasm and nucleus of similar magnitude and duration. Thus, the impact of glutamate-induced changes in  $[Mg^{2+}]$  on neuronal function may not be limited to cytosolic effects.

## 36.7

TRH ATTENUATES GLUTAMATE-STIMULATED INCREASES IN INTRANEURONAL  $Ca^{2+}$  BY REDUCING THE INFLUX OF  $Ca^{2+}$  THROUGH NMDA, AMPA, AND VOLTAGE-GATED CHANNELS. M.L. Koenig\*, D.L. Yourick, and J.L. Meyerhoff. Div. of Neurosciences, Walter Reed Army Institute of Research, Washington, DC, 20307-5100.

TRH, a tripeptide with anticonvulsant properties which is widely distributed in the mammalian central nervous system, has been reported to reduce glutamate-induced excitation of cerebral cortical neurons (Science 205:1275, 1979). Further, we have found that the reduction in excitation can be attributed, at least in part, to an attenuation of glutamate-stimulated increases in intraneuronal  $Ca^{2+}$  ( $[Ca]_i$ ) (in primary neuronal cultures - Soc. Neurosci. Abstr. 20:278, 1994). To determine the mechanism by which TRH reduces glutamate-stimulated elevations in  $[Ca]_i$ , we loaded neurons (in primary culture) with the ratiometric  $Ca^{2+}$  indicator dye indo-1, and quantified changes in  $[Ca]_i$  induced by exposure to ionotropic and metabotropic glutamate receptor agonists and depolarizing concentrations of KCl in the absence and presence of the tripeptide. We have found that a 2 min pre-exposure of neurons to TRH significantly reduces  $Ca^{2+}$  influx through channels opened by AMPA and NMDA (by 49% and 28% respectively), but has no effect on influx mediated by kainate. Prior exposure of cultured neurons to the tripeptide also has no effect on increases in  $[Ca]_i$  generated by exposure to the Class I metabotropic receptor agonist *trans*-ACPD. Interestingly, TRH does seem to have an inhibitory effect on  $Ca^{2+}$  influx through voltage-gated  $Ca^{2+}$  channels. This is significant, because these channels are opened indirectly by glutamate, as the increased  $[Ca]_i$  effects a depolarization.

ANGIOTENSIN II TYPE-2 RECEPTOR ( $AT_2$ )-MEDIATED INHIBITION OF NMDA RECEPTOR SIGNALING IN NEURONAL CELLS. W.R. Schelman, J.L. Kurth, S.-W. Norby, B.C. Wheeler\* and J.A. Weyhenmeyer. Department of Cell and Structural Biology, University of Illinois, Urbana, Illinois, 61801.

N-methyl-D-aspartate (NMDA) type-1 receptor subunit (NR1) has a critical role in normal brain function and in neurologic disease. Here, we present immunohistochemical evidence for the expression of the NR1 receptor subunit in undifferentiated PC12W cells, which selectively expresses only the  $AT_2$  receptor subtype, and in undifferentiated NG108-15 (NG108) cells, a murine neuroblastoma/glioma hybrid. We have recently reported that NMDA stimulated PC12W cells produce nitric oxide (NO) as measured by *in vitro* spin-trapping combined with electron paramagnetic resonance (EPR) spectroscopy (Norby *et al.*, 1996). In the present studies, we show that the addition of angiotensin II (AngII) to the PC12W cells resulted in a  $27.8 \pm 5.1$  decrease in NMDA-induced NO formation. Pretreatment with the isoform specific  $AT_2$  antagonist, PD 123319, attenuated the inhibitory effect of AngII on NO production. Incubation with NMDA did not have an effect on cGMP accumulation in PC12W cells. Similar experiments were performed using undifferentiated NG108 cells since the binding and functional properties of the NMDA receptors expressed by these cells have been previously reported (Ohkuma *et al.*, 1994). NMDA induced a dose-dependent increase in the levels of cGMP, which was decreased in the presence of AngII. The effect of AngII on NMDA-mediated changes in cGMP levels was partially blocked by PD 123319, but was not significantly altered by the  $AT_1$  isoform specific antagonist, losartan. Further, AngII action in NG108 cells was completely inhibited by the addition of both the  $AT_1$  and  $AT_2$  antagonists. Taken together, these results suggest that AngII inhibits NMDA-mediated NO and cGMP production through a mechanism involving the  $AT_2$  receptor subtype. ## 36.6

SIMULTANEOUS MEASUREMENT OF INTRACELLULAR FREE CALCIUM AND INTRACELLULAR FREE MAGNESIUM CONCENTRATIONS IN NEURONS. A.K. Stout\* and I.J. Reynolds. Department of Pharmacology, University of Pittsburgh, Pittsburgh, PA 15261.

Previous fluorescence microscopy experiments using the magnesium-sensitive dye mag-fura-2 have demonstrated that glutamate can cause millimolar increases in intracellular free magnesium concentrations ( $[Mg^{2+}]$ ) in cultured rat forebrain neurons (Neuron, 11: 751-757, 1993). Since mag-fura-2 is also sensitive to micromolar increases in intracellular free calcium concentrations ( $[Ca^{2+}]$ ) and is frequently used as a low-affinity calcium probe, it is therefore important to demonstrate that mag-fura-2 is measuring increases in  $[Mg^{2+}]$ , rather than very large increases in  $[Ca^{2+}]$ , in our experimental paradigm. Since previous results from this lab have shown that the increases in  $[Ca^{2+}]$ , stimulated by glutamate (100  $\mu M$ ) plateau or decline over the course of a 5-minute stimulation while  $[Mg^{2+}]$  continue to increase over the course of the same stimulation, and since previous studies have also shown that glutamate-induced  $[Ca^{2+}]$  increases are not of a magnitude to result in significant binding to mag-fura-2 (Neurosci. Letters, 162: 149-152, 1993), these results suggest that mag-fura-2 is indeed measuring increases in  $[Mg^{2+}]$ . Using a monochromator-based imaging system, we are currently measuring glutamate-induced changes in  $[Mg^{2+}]$ , and  $[Ca^{2+}]$ , simultaneously in neurons loaded with both mag-fura-2 and either a high- or a low-affinity calcium-sensitive dye such as fluo-3 or calcium green-5N. The results of these studies will help to differentiate whether we are indeed measuring  $[Mg^{2+}]$ , changes with mag-fura-2 or whether the excitotoxic glutamate stimulations employed in these studies are causing large (*i.e.*, tens of micromolar) increases in  $[Ca^{2+}]$ . ## 36.8

HETEROMERIC NMDA RECEPTOR CALCIUM RESPONSES ARE SUBUNIT DEPENDENT IN TRANSFECTED HEK-293 CELLS. E.R. Grant\*, B.J. Bacskai, L. Kricka, D.E. Pleasure, and D.R. Lynch. Dept. of Pharmacology, Neurology, and Pathology, U. Pennsylvania and Children's Hosp. of Philadelphia, PA 19104

The NMDA receptor mediates increases in intracellular calcium levels. Previously we have shown that application of 100  $\mu M$  glutamate, 100  $\mu M$  glycine, and 2 mM  $Ca^{2+}$  to cells transfected with various NMDA receptors results in a subunit specific rise in intracellular calcium. Recently, using both the calcium sensitive bioluminescent protein aequorin, and the fluorescent calcium indicator fluo-3, we have quantitated peak rises for the NR 1a/2A combination as  $1.36 \pm 0.09 \mu M$  and  $1.14 \pm 0.19 \mu M$  measured with aequorin and fluo-3 respectively. The NR 1a/2B combination also elicited a significant intracellular calcium response ( $0.61 \pm 0.03 \mu M$ ) to agonists, as did the 5HT<sub>2A</sub> receptor to 10  $\mu M$  serotonin ( $0.78 \pm 0.06 \mu M$ ). However, no intracellular calcium responses to NMDA receptor agonists in cells transfected with the NR 1a/2C or NR 1a/2D subunit combinations were observed, even though differences in expression levels from NR 1a/2A were not found with <sup>3</sup>H-glutamate binding, <sup>3</sup>H-MK-801 binding, or western blotting. To determine the calcium source which mediates the rise in calcium for the NR 1a/2A combination, we found that substitution of the divalent cation barium for calcium in the extracellular buffer eliminated the NR 1a/2A calcium response to agonists. Transfection of the mutant NR1 (N598Q) with the 2A subunit decreased, but did not eliminate, intracellular calcium responses to agonists compared to wildtype NR 1a/2A.  $Ca^{45}$  influx studies revealed a  $2.0 \pm 0.2$  fold increase in  $Ca^{45}$  uptake upon agonist application compared to vehicle control in NR 1a/2A transfected cells, but not in NR 1a/2C transfected cells. NMDA receptor mediated changes in intracellular calcium are partly dependent on the receptor subunit composition and require extracellular calcium. (NIH-DA07130, NS01789)

NITRIC OXIDE MODULATES RESPONSIVENESS TO NMDA IN PARAVENTRICULAR NUCLEUS. 1) TYPE I NEURONS. J.S. Bains\* and A.V. Ferguson. Department of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Electrophysiological and anatomical evidence suggests that glutamate is the primary transmitter at fast, excitatory synapses in the paraventricular nucleus of the hypothalamus (PVN). Activation of glutamate receptors, and more specifically, the NMDA subtype, in other brain areas results in the subsequent synthesis and release of the diffusible messenger, nitric oxide (NO). The localization of NO synthase within PVN neurons led us to investigate the putative interactions between NO and NMDA receptor activation within this nucleus.

Whole cell recordings, using K-gluconate filled electrodes were obtained from PVN neurons in coronal brain slices (400  $\mu m$  thickness) of adult, male Sprague-Dawley rats. Cells were classified as type I (putative oxytocinergic or vasopressinergic) if they displayed prominent outward rectification when depolarized from negative potentials (Tasker and Dudek, J. Physiol. 434: 273-294). Bath application of NMDA (10 nM - 1  $\mu M$ ) elicited robust depolarizations in all cells tested ( $n=48$ ). At hyperpolarized potentials, NMDA application elicited profound oscillations of the membrane potential resulting in the emergence of burst like activity. Following bath application of the NO synthase inhibitor, N<sup>G</sup>-Nitro-L-arginine methyl ester (L-NAME), subsequent depolarizing responses to NMDA were potentiated by  $52 \pm 27\%$  ( $n=7$ ). NMDA application was also accompanied by inhibitory postsynaptic potentials (IPSPs) in 35% of the cells. These IPSPs were inhibited by bath application of the GABA<sub>A</sub> receptor antagonist, bicuculline methiodide ( $n=4$ ). IPSPs were also elicited by bath application of the NO donor, N-Acetyl-S-nitroso-D-penicillamine (SNAP) ( $n=4$ ). IPSPs activated by NMDA were completely abolished in the presence of 1 mM L-NAME ( $n=6$ ). These results support the hypothesis that NO regulates the excitability of Type I neurons in PVN by increasing GABA<sub>A</sub>ergic input to these cells.

## 36.11

NITRIC OXIDE MODULATES RESPONSIVENESS TO NMDA IN PARAVENTRICULAR NUCLEUS. 2) TYPE II NEURONS. A.V. Ferguson\* and J.S. Bains. Department of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Electrophysiological and anatomical evidence suggests that glutamate is the primary transmitter released at fast, excitatory synapses in the paraventricular nucleus of the hypothalamus (PVN). Activation of glutamate receptors, and more specifically, the NMDA subtype, in other brain areas results in the subsequent synthesis and release of the diffusible messenger, nitric oxide (NO). The localization of NO synthase within PVN neurons led us to investigate the putative interactions between NO and NMDA receptor activation. We have previously reported that NO depolarizes the majority of type II cells in PVN (Bains and Ferguson, Soc. For Neurosci., 1995, 450.16).

Whole cell recordings, using K-gluconate filled electrodes were obtained from PVN neurons in coronal brain slices (400 µm thickness) of adult, male Sprague-Dawley rats. Cells were classified as type II if they displayed inward rectification at hyperpolarized potentials and a prominent low-threshold calcium spike. Bath application of NMDA (10 nM - 1 µM) elicited robust depolarizations in all cells tested (n=43). At hyperpolarized potentials, NMDA application elicited profound oscillations of the membrane potential resulting in the emergence of burst like activity. Following bath application of the NO synthase inhibitor, N<sup>G</sup>-Nitro L-arginine methyl ester (L-NAME), subsequent depolarizing responses to NMDA were inhibited by 39 ± 18 % (n=4). Inhibitory postsynaptic potentials (IPSPs) were also inhibited by application of NO (n=4). The IPSPs were also blocked by 1 mM bicuculline methiodide (BMI), confirming their identity as GABA<sub>A</sub> mediated events. These results support the hypothesis that NO regulates NMDA receptor activity on Type II neurons by decreasing GABA<sub>A</sub>ergic input to these cells.

## 36.13

MODULATION OF NMDAR CHANNELS BY Ca<sup>2+</sup>-CALMODULIN IN RAT CEREBELLAR GRANULE CELLS. N. Filippova, K. Hattar\* & P. Bregestovskii. Koltzov Inst. Develop. Biology, Moscow, INSERM, U-29 & U-261, Paris.

Transient inactivation of NMDA receptor (NMDAR) channels by cytoplasmic calcium ([Ca<sup>2+</sup>]<sub>i</sub>) was described in neurons and transfected HEK-293 cells. According to Medina et al. (J. Physiol., in press) the ability of [Ca<sup>2+</sup>]<sub>i</sub> to inhibit NMDAR channels decreases with time during whole-cell recording and disappears shortly after excision of inside-out patches. This suggests that Ca<sup>2+</sup> actions on NMDAR may be mediated by a putative diffusible factor. From the study of Ehlers et al. (Cell, 84:745-755, 1996), the Ca<sup>2+</sup>-dependent protein, calmodulin (CaM), is a likely candidate. These authors demonstrated that NMDAR function can be regulated by direct binding of CaM to the NR1 subunit.

Using patch-clamp techniques we studied the effect of CaM on NMDAR channels in rat cerebellar granule neurons in culture. During whole-cell recording, to increase [Ca<sup>2+</sup>]<sub>i</sub>, long (5 s) conditioning pulses of 100 µM NMDA (2 mM [Ca<sup>2+</sup>]<sub>o</sub>) were applied to neurons. For a quantitative estimation of Ca<sup>2+</sup>-induced inactivation, the amplitude of brief (100 ms) NMDA test-currents was analyzed before and after conditioning applications. With 4 mM Mg-ATP in the pipette solution, in cells that did not show rundown, the Ca<sup>2+</sup>-induced inactivation decreased continuously during the recording: 28 ± 7 % and 6 ± 5 % on 3-rd and 22-rd min respectively (n=15). Addition of 200 nM CaM to the internal solution did not prevent this continuous decrease of [Ca<sup>2+</sup>]<sub>i</sub> action: inactivation of NMDA test-currents was 47 ± 14 % on 3-rd and 8 ± 4 % (n=6) on 23-rd min of recording.

In inside-out patches (5 µM NMDA, 10 µM glycine in the pipette), direct application of 10 µM Ca<sup>2+</sup> to the cytoplasmic side of the membrane resulted in a reversible decrease in the open probability (P<sub>o</sub>) of single NMDAR channels (50 ± 20 %, n=5). However, 3-5 min after obtaining the inside-out patches, NMDAR channels became Ca<sup>2+</sup> insensitive (0.1-1 mM Ca<sup>2+</sup> was ineffective). Application at this time of 10 µM Ca<sup>2+</sup> with 200 nM CaM induced 71 ± 19 % reversible decreases in P<sub>o</sub> (n=5). Our data indicate that in cerebellar granule neurons direct application of Ca<sup>2+</sup> + CaM to excised inside-out patches causes inhibition of NMDAR channels, however, during whole-cell recording intracellular dialysis leads to the loss of NMDAR channel sensitivity to [Ca<sup>2+</sup>]<sub>i</sub> independently of CaM.

## 36.15

1-AMINOCYCLOPROPANECARBOXYLIC ACID (ACPC) PROTECTS AGAINST NMDA RECEPTOR-MEDIATED INJURY TO CULTURED SPINAL CORD NEURONS BOTH ACUTELY AND THROUGH DESENSITIZATION. Y. Lin\* and J.B. Long. Div. of Neurosciences, Walter Reed Army Inst. of Res., Wash., D.C. 20307.

ACPC is a high affinity partial agonist for the glycine binding site within the NMDA receptor complex. This compound has been shown to protect against ischemic brain and spinal cord injury in vivo and to block NMDA receptor-mediated neurotoxicity in vitro. Chronic treatment with ACPC in vivo also appears to reversibly desensitize the NMDA receptor complex, prompting suggestions that it might provide an effective means of ameliorating degenerative mechanisms mediated through this ligand-gated ion channel. In these experiments, cultured rat spinal cord neurons were used to further examine the effects of acute and sustained ACPC exposures on NMDA-induced neurotoxicity and changes in [Ca<sup>2+</sup>]<sub>i</sub>. Cell damage was quantitatively assessed using a tetrazolium salt colorimetric assay, and changes in [Ca<sup>2+</sup>]<sub>i</sub> were measured in single identified neurons preloaded with the Ca<sup>2+</sup>-sensitive dye Fluo-3. With incubation, 1 mM ACPC significantly reduced the neuronal cell damage caused by 30 min exposure to 25 or 50 µM concentrations of NMDA, but failed to alter the cell injury induced by 100 µM NMDA. The protective effects of ACPC were competitively abolished by co-addition of glycine (1-1000 µM), verifying that they were mediated through glycine binding sites. Sustained 20 hr exposure to 1 mM ACPC (which was removed 30 min before addition of 25 µM NMDA) also caused cells to be significantly less responsive to the neurotoxic effects of NMDA than were vehicle-pretreated control cells. Pre-exposure to ACPC for shorter intervals (< 1 hr) failed to alter subsequent NMDA toxicity. Acute or sustained exposures to ACPC alone did not affect cell viability or [Ca<sup>2+</sup>]<sub>i</sub>. Also, paradoxically, ACPC did not alter the NMDA-triggered elevations in [Ca<sup>2+</sup>]<sub>i</sub>. These results support earlier indications that: 1) ACPC provides an effective means of antagonizing excitotoxic phenomena, and 2) sustained exposure to ACPC desensitizes the NMDA receptor complex.

Research funded by the U.S. Army Medical Research and Materiel Command.

## 36.12

INTERACTION BETWEEN PERMEANT CATIONS AND CHANNEL BLOCKERS WITHIN THE PORE OF THE NMDA RECEPTOR. S.M. Antonov, V.E. Gmitro and J.W. Johnson. Dept. of Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15260; \*Institute of Experimental Medicine RAMS, St.Petersburg, A-22, Russia.

Single-channel currents through native NMDA receptors were recorded in outside-out patches excised from cultured rat cortical neurons. The mechanism of open-channel block of the NMDA receptor pore by IEM-1857 and IEM-1754 applied in the external solution revealed considerable deviations from conventional models of channel block. (i) The voltage dependence of the rate constant of binding (k<sub>b</sub>) for either blocker was not single-exponential: the voltage dependence was over two times weaker at membrane voltages (V<sub>m</sub>s) from -90 to -140 mV than at V<sub>m</sub>s from -20 to -90 mV. (ii) External and internal permeant cations affected the k<sub>b</sub> of the IEM drugs. The effect of a reduction of [Cs<sup>+</sup>]<sub>o</sub> was voltage-dependent. When [Cs<sup>+</sup>]<sub>o</sub> was reduced from 130 to 20 mM the values of k<sub>b</sub> were increased, but only at voltages more positive than -90 mV. The magnitude of the increase of k<sub>b</sub> became progressively greater as V<sub>m</sub> was depolarized. A reduction of [Na<sup>+</sup>]<sub>int</sub> from 140 to 70 mM caused an increase of approximately three-fold of the values of k<sub>b</sub> over the entire V<sub>m</sub> range tested. (iii) The reduction of [Cs<sup>+</sup>]<sub>o</sub> decreased the values of the rate constant of unbinding (k<sub>u</sub>) of IEM-1754 at V<sub>m</sub>s from -60 to -140 mV. (iv) Finally, the reduction of [Na<sup>+</sup>]<sub>int</sub> caused a voltage-independent increase in the values of k<sub>u</sub> of IEM-1857 and IEM-1754.

The data show that experimentally measurable rate constants of channel block by the IEM drugs applied externally are influenced by permeant cations. A model which is consistent with our data suggests the existence of permeant cation binding sites in the external and internal vestibules of the NMDA receptor pore. These binding sites appear to be located outside the region of the pore where the drop of the membrane electric field occurs. Supported by NIMH.

## 36.14

NMDA RECEPTOR SUBUNIT COMPOSITION EFFECTS THE KINETICS OF DESENSITIZATION AND RECOVERY FROM DESENSITIZATION. T. Priestley, P. Laughton and R.G. Hill\*. Merck Sharp & Dohme Research Laboratories, Terlings Park, Harlow, Essex, CM20 2QR, UK.

A characteristic feature of NMDA receptors is that they desensitize during prolonged agonist exposure and the desensitization has both glycine- and calcium-dependent components. Molecular cloning has revealed that these ligand-gated ion channels are hetero-oligomeric assemblies of subunit proteins. We have examined the macroscopic kinetics of glycine-independent desensitization and recovery from desensitization in L(tk-) cells permanently transfected with human NR1a/NR2A and NR1a/NR2B subunit combinations.

Whole-cell currents were recorded from cells following rapid steps into glutamate (30 µM) in the presence of a saturating concentration of glycine and 2 mM external calcium. NR1a/NR2B receptor desensitization proceeded with a monophasic exponential time course and relatively slow kinetics (τ<sub>d</sub> = 5.5 s, n = 16); recovery from desensitization was slow (τ<sub>rec</sub> = 21 s) and monophasic. Recombinant NR1a/NR2A receptors showed biphasic desensitization kinetics comprising fast (τ<sub>fast</sub> = 0.4 ± 0.04) and slow (τ<sub>slow</sub> = 3.5 ± 0.7 s, n = 5) components together with biphasic, time-dependent recovery (τ<sub>rec</sub> = 1.6 s and 49 s). The influence of the slow component of desensitization of NR1a/NR2A receptors declined with time during prolonged whole-cell recordings. This had two consequences: NR1a/NR2A receptors desensitized more quickly but also recovered from the desensitized state more quickly at the end of a 30 min recording period compared to time zero. Thus, the macroscopic kinetics of desensitization and recovery from desensitization are also affected by changes in receptor state brought about by protracted whole-cell recording. These time-dependent changes appear to be due to an altered phosphorylation state of receptor proteins which also appears to be dependent upon subunit composition.

Funded entirely by Merck Sharp & Dohme Research Laboratories.

## 36.16

FREQUENCY-DEPENDENT MODULATION OF NMDA RECEPTOR DESENSITIZATION IS MEDIATED BY RECEPTOR MECHANOSENSITIVITY AND GLYCINE. L.A. Raymond\* and R.L. Huganir\*. \*Div. Neurosci., Dept. Psych., U. of British Columbia, Vancouver, B.C. and \*HHMI, Dept. Neurosci., Johns Hopkins Med. Inst., Baltimore, MD.

N-methyl-D-aspartate (NMDA) receptors play a critical role in synaptic plasticity, and studies have shown that synaptic stimulation of these receptors can result in their desensitization. In whole-cell patch clamp recordings from human embryonic kidney 293 cells transfected with NR1/NR2A, we have found that the extent of desensitization of agonist-evoked current can be modulated by changes in hydrostatic pressure and glycine concentration. Desensitization of current evoked by 0.5-1 s applications of glutamate or NMDA is <20% under conditions of constant hydrostatic pressure, independent of glycine concentration. However, when transfected cells are subjected to intermittent pulses of increased hydrostatic pressure, the extent of desensitization is inversely related to the fraction of time exposed to higher pressures. Therefore, high frequency pressure pulses result in high steady-state to peak current ratios (I<sub>ss</sub>/I<sub>p</sub>) while low I<sub>ss</sub>/I<sub>p</sub> result from low frequency pressure pulses. Switches between low and high I<sub>ss</sub>/I<sub>p</sub> states begin after a delay of a few pressure pulses at the new frequency, and occur gradually over several pulses, thus exhibiting "memory" for the previous pulse frequency protocol. Modulation of I<sub>ss</sub>/I<sub>p</sub> by pressure pulses is due to a change in receptor affinity for glycine and can be overcome by >10 µM glycine. Pressure-induced modulation of NMDA receptor desensitization may represent a novel mechanism for short-term NMDA receptor-mediated synaptic plasticity. (Supported by MRC of Canada (LAR); HHMI (RLH)).

PROTONS INCREASE DESENSITIZATION OF *N*-METHYL-D-ASPARTATE RECEPTORS EXPRESSED IN *XENOPUS* OOCYTES. Y. Liu\*, R. H. Hill, G. von Euler and P. Århem. Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden.

It has been reported that protons inhibit *N*-methyl-D-aspartate (NMDA)-activated currents in cultured hippocampal and cerebellar neurons. The results indicated the presence of a proton binding site, which is located at the extracellular surface of the membrane.

In the present study we have investigated the effects of pH on NMDA receptors expressed in *Xenopus* oocytes. Oocytes were injected with *in vitro*-synthesized mRNA of the NMDA receptor subunits NR1 and NR2A. The results showed that the inward current induced by 100  $\mu$ M NMDA and 100  $\mu$ M glycine was reduced by decreasing the pH levels stepwise from 9.0 to 6.0, and that the current reduction is voltage-independent. The ratio of steady state (corresponding to a desensitized state) current to peak current varied at different pH levels. At pH 8.5, NMDA and glycine induced a large current with little or no desensitization. However, at pH 7.4, NMDA and glycine induced a rapidly rising current followed by a pronounced desensitization. At pH 6.5, agonist application lead to a small steady state current without a clear peak current. When the agonists were applied at the same time as pH was changed from 7.4 to 6.5, a clear but small peak current was observed, followed by a strong desensitization. This can be explained by an onset of desensitization when the pH was quickly lowered.

In conclusion, our results suggest that protons inhibit the inward current induced by glutamate and glycine, at least partly, by enhancing the desensitization of NMDA receptors. The mechanism of the proton-dependent desensitization appears to be different from the glycine-sensitive and the calcium-dependent desensitization. This work was supported by the Swedish MRC (04X-06552 and 14X-10377).

## 36.18

GLYCINE: ITS ROLE IN MODULATING THE NMDA RECEPTOR RESPONSE AND REGULATING DESENSITIZATION. G. A. Worrell, B. N. Christensen and M. Phillips\*. Department of Physiology and Biophysics and Department of Pharmacology, University of Texas Medical Branch, Galveston, TX, 77555.

The response from acutely dissociated catfish (*Ictalurus punctatus*) horizontal cells (CFHC) to *N*-methyl-D-aspartic acid (NMDA) and glycine were recorded using the whole-cell recording technique. A system that provided rapid concentration clamp for the agonist, of the order ~20 msec, over the entire neuron surface was used to study the modulation of the NMDA response by glycine. The glycine concentration was determined for each experiment using HPLC. Nominal glycine was routinely < 10 nM. The best fit of the Hill equation to the glycine concentration-response data yields an apparent dissociation constant ( $K_d$ ) of 195.0 nM and a Hill coefficient ( $N$ ) of 1.1. The current response in the complete absence of glycine ( $I_0$ ) was also used as a fitting parameter and was found to be 74% of the response measured at a saturating glycine concentration. This result indicates that most of the response to NMDA can be produced in the complete absence of glycine.

Cells that were pretreated with 5.0  $\mu$ M glycine and then concentration clamped with NMDA and a nominal glycine concentration, demonstrated rapid desensitization. Desensitization was eliminated if the agonist solution contained a saturating concentration of glycine. The rate constant of the rapid phase of desensitization is approximately a linear function of the NMDA concentration with slope of 15.1 (mSec-M)<sup>-1</sup> and an intercept of 0.85 sec<sup>-1</sup>. The intercept provides an estimate of the dissociation rate of glycine from the receptor in the absence of NMDA. This result indicates that desensitization in these cells is a result of unbinding of glycine from its receptor site. The rate of unbinding increases as the concentration of NMDA is increased. Supported by grant NEI-01897 from the NIH.

## OPIOID RECEPTORS I

## 37.1

LOCUS COERULEUS-LIKE CATH.a CELLS EXPRESS DELTA OPIOID RECEPTOR WHICH ARE FUNCTIONALLY COUPLED TO INHIBITION OF ADENYLYL CYCLASE ACTIVITY.

M. Leid\*, V.J. Peterson, B.D. Hettinger-Smith, K. Soderstrom, T.F. Murray and C. Bouvier. College of Pharmacy, Oregon State University, Corvallis, OR 97331.

CATH.a cells are a locus coeruleus (LC)-like cell line which exhibit a strongly catecholaminergic phenotype. We have carried out a pharmacological characterization of CATH.a cells to define the opioid receptor complement expressed by these cells. Three lines of evidence strongly suggest that CATH.a cells express predominantly  $\delta$  opioid receptor (DOR): (1) the rank order of potency with which a series of prototype, subtype-selective opioid receptor agonists inhibited [<sup>3</sup>H]Diprenorphine binding in CATH.a cell membranes was identical to that carried out using membranes derived from CHO cells stably expressing recombinant DOR: (DPDPE >>> DAMGO > U50488).

(2) CATH.a cell membrane preparations were directly labeled with high affinity using the DOR-selective radioligand [<sup>3</sup>H]DPDPE and the number of receptors labeled with this agonist radioligand corresponded to fraction of [<sup>3</sup>H]Diprenorphine binding sites exhibiting high affinity for agonists in competition experiments, and (3) DPDPE potently ( $IC_{50}$  = 1.86 nM) and robustly (~40% inhibition) inhibited forskolin-stimulated, CATH.a cell adenylyl cyclase activity in a naloxone-reversible manner. These findings demonstrate that CATH.a cells express DOR and that at least one of the opioid signaling pathways (inhibition of adenylyl cyclase) is operant in this cell line. This cell line may be of use in the characterization of DOR-mediated events without the confounding variable of expression of other opioid receptor subtypes. We thank D. Chikaraishi and D. Grandy for CATH.a cells and CHO cells stably transfected with recombinant DOR, respectively.

## 37.2

EFFECTS OF ESTRADIOL ON cAMP IN OPIOID-RESPONSIVE SK-N-SH CELLS AFTER CHRONIC MORPHINE TREATMENT.

Anna Ratka\* and Val McKinley. Department of Pharmaceutical Sciences, College of Pharmacy, Idaho State University, Pocatello, ID 83209.

The SK-N-SH human neuroblastoma cells express opioid receptors. Cyclic AMP responses to morphine (M), attributed to the activation of opioid receptors, are well defined in these cells. The inhibitory effect of an acute M on cAMP is significantly reduced after chronic pretreatment with M.

Differentiated and undifferentiated SK-N-SH cells were exposed to M (10  $\mu$ M) for 6 days. Treatment with 5 nM estradiol (E) was for 1 hr, 1 day and 6 days. Changes in cAMP level, measured by radioimmunoassay, induced by an acute 10  $\mu$ M dose of M, served as a marker of opioid receptor function. E had a time-dependent attenuating effect on M-induced inhibition of prostaglandin E<sub>1</sub>(PGE<sub>1</sub>)-stimulated accumulation of cAMP in differentiated SK-N-SH cells. The degree of M inhibition declined from 63, 42, 28 to 26 % in M-naive cells, and from 34, 31, 20 to 15% in M-treated cells, after no E, 1 hr, 1 day and 6 days of E treatment, respectively. Moreover, 1 and 6 day treatment with E significantly potentiated the PGE<sub>1</sub>-induced cAMP accumulation in M-treated cells, from 616.9 $\pm$ 18.0 to 1405.9 $\pm$ 62.0 and 1142.2 $\pm$ 250.0 pMol/mg protein, respectively. We conclude that in opioid-responsive differentiated SK-N-SH neuroblastoma cells, E has a profound attenuating effect on the function of both M-naive and M-treated opioid receptors.

## 37.3

$\mu$  RECEPTOR ACTIVATION IN SH-SY5Y HUMAN NEUROBLASTOMA AND CHO-MOR CELLS IS BLOCKED BY G-PROTEIN  $\alpha$  SUBUNIT ANTISENSE DNA. K.M. Standifer\*<sup>1</sup>, G.P. Brown<sup>2</sup> and G.W. Pasternak<sup>2</sup>. <sup>1</sup>Dept. Pharmacological and Pharmaceutical Sciences, University of Houston, Houston, TX and <sup>2</sup>Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center, NY, NY.

A cultured cell line stably expressing the cloned  $\mu$  receptor allows for examination of interactions between second messenger systems and a molecularly defined receptor, an advantage over a natively expressing cell line such as SH-SY5Y. One disadvantage is that the receptor is expressed in an environment which may not accurately reflect native conditions. Thus, when utilizing these different model systems, it is important to understand differences in receptor activation and signalling between the systems. One approach is to determine which G-proteins are responsible for transducing agonist-mediated effects in each cell line by down-regulating  $\alpha$  subunit expression with administration of antisense DNA. SH-SY5Y and CHO-MOR cells were treated for 42-48 hr with antisense DNA (1.2  $\mu$ M) directed against G $\alpha$ 1, G $\alpha$ 2, G $\alpha$ 3 or G $\alpha$ , and the ability of DAMGO to inhibit forskolin-stimulated cAMP accumulation was determined. Treatment with G $\alpha$  antisense significantly reduced the EC<sub>50</sub> value in both cell lines, while G $\alpha$ 2 and G $\alpha$ 3 antisense treatment was effective in SH-SY5Y and CHO-MOR, respectively. G $\alpha$ 1 antisense was without effect. This suggests that different G-proteins are responsible for  $\mu$  receptor-mediated cAMP inhibition in the two cell lines. This work was supported by NIDA and the Wendy Will Case Cancer Fund.

## 37.4

EFFECT OF KINASE SITE MUTATION ON  $\mu$  OPIOID RECEPTOR FUNCTION. L. S. Bye and L. Yu\*. Dept. of Med. and Mol. Genetics, Indiana Univ. Sch. of Med., Indianapolis, IN 46202

The  $\mu$  opioid receptor is the site of a number of clinically used opioids for analgesia and anesthesia. Prolonged use of  $\mu$  receptor agonists, however, often results in tolerance to these drugs. The cellular mechanism of the development of tolerance is unknown.

Using the cloned  $\mu$  opioid receptor we established a model to study desensitization at the cellular level. Using *Xenopus laevis* oocytes as an expression system, the  $\mu$  opioid receptor was coexpressed with an inwardly rectifying K<sup>+</sup> channel (GIRK1). Activation of the  $\mu$  opioid receptor results in an increase in the K<sup>+</sup> current. We previously showed that desensitization of this receptor-mediated K<sup>+</sup> current is modulated by cAMP-dependent protein kinase (PKA). To further study the molecular mechanism of PKA-mediated modulation, a mutant was generated using oligonucleotide-mediated, site-directed mutagenesis in which the putative PKA phosphorylation site threonine was changed to alanine. The mutant receptor, when expressed in *Xenopus* oocytes, can be activated to elicit the K<sup>+</sup> current. Compared with the wildtype  $\mu$  receptor-mediated K<sup>+</sup> current, however, the mutant receptor-mediated current displayed altered kinetics upon agonist washout, with a significantly larger decay time constant. This suggests that the capability to be phosphorylated by PKA plays an important role in  $\mu$  opioid receptor function. (Supported in part by NIDA and NINDS.)

## 37.5

**INHIBITION OF cAMP ACCUMULATION AND STIMULATION OF GTP $\gamma$ S BINDING CORRESPOND CLOSELY TO RECEPTOR NUMBER IN  $\mu$  RECEPTOR-CONTAINING CHO CELLS.** Lawrence Toll\* and Willma E. Polgar. SRI International 333 Ravenswood Ave. Menlo Park, CA 94025.

$\mu$ -Receptor-containing CHO cells were subcloned and individual clones tested for binding parameters using [ $^3$ H]bremazocine, inhibition of forskolin-stimulated cAMP accumulation, and opiate-stimulated [ $^{35}$ S]GTP $\gamma$ S binding. In four individual clones, receptor levels varied from 0.1 to 1.5 pmol/mg protein, without any changes in affinity of bremazocine, approximately 0.15 nM in each clone. For both inhibition of cAMP accumulation and [ $^{35}$ S]GTP $\gamma$ S binding, maximal activity correlated closely with receptor number. The clone with the lowest receptor number was essentially devoid of activity in either functional assay. The clones with intermediate receptor number produced intermediate levels of opiate-induced inhibition of cAMP accumulation and stimulation of [ $^{35}$ S]GTP $\gamma$ S binding. In the clone with the highest receptor number DAMGO produced 75% inhibition of cAMP accumulation, and 250% stimulation of [ $^{35}$ S]GTP $\gamma$ S binding. The potency of the selective  $\mu$  agonist DAMGO was also tested in the [ $^{35}$ S]GTP $\gamma$ S binding assay, and found to be independent of receptor number in this assay. In each clone the EC $_{50}$  for DAMGO was found to be approximately 5 nM. This indicates that there is no receptor reserve with respect to the [ $^{35}$ S]GTP $\gamma$ S binding assay, and activity is directly related to the receptor number and efficacy of the agonist tested.

Supported by NIDA grant DA06682.

## 37.7

**EXPRESSION OF THE G PROTEIN-COUPLED RECEPTOR KINASES 2 AND 3 DOES NOT AFFECT THE COUPLING OF THE  $\mu$  OPIOID RECEPTOR TO THE G PROTEIN-GATED INWARDLY RECTIFYING POTASSIUM CHANNEL COMPLEX IN *XENOPUS* OOCYTES** A. Kovoor, D. Henry\*, C. Chavkin, Dept. of Pharmacology, Univ. of Washington, Seattle, WA

Chronic morphine exposure leads to an uncoupling of the  $\mu$  opioid receptor from downstream G proteins. Previously, agonist-dependent phosphorylation of the  $\mu$  opioid receptor has been reported in cell lines and homologous desensitization of  $\mu$  opioid receptor-effector coupling has been reported in the brain. We used the *Xenopus* oocyte system to test the hypothesis that the above events were a result of phosphorylation of the  $\mu$  opioid receptor by G protein-coupled receptor kinases (GRKs) leading to a functional uncoupling to the effector. The application of  $\mu$  opioid agonists evoke an increase in K $^+$  conductance in *Xenopus* oocytes expressing the rat  $\mu$  receptor and the G protein-coupled, inwardly rectifying K $^+$  channel subunits, GIRK and CIR. GRK2 and GRK3 were separately coexpressed with the  $\mu$  receptor and the inwardly rectifying channel complex (Kir) and overexpression of either kinase failed to alter the coupling of the receptor to the channel. Neither the peak response nor the rate of desensitization of the response to the  $\mu$  opioid agonist DAMGO was altered. Subsequent coexpression of either arrestin 2 or arrestin 3 with GRKs 2 and 3 also failed to alter the coupling of the  $\mu$  receptor to the Kir. Functional expression of the GRK and arrestin proteins was tested by verifying their ability to inhibit the  $\beta$ 2-adrenergic receptor stimulation of CFTR mediated Cl $^-$  currents in oocytes exogenously expressing these proteins. Supported by DA04213.

## 37.9

**OPIOID-INDUCED CURRENTS IN ACUTELY DISSOCIATED LOCUS COERULEUS NEURONS.** S. L. Ingram\* and J. T. Williams. Vollum Institute, Oregon Health Sciences University, Portland OR 97201.

Whole-cell recordings from acutely dissociated locus coeruleus neurons were made to further study activation of the G-protein coupled inward rectifying potassium channels by opioids. Opioid-induced inward currents were recorded in a high potassium external solution (30 mM K $^+$ ). Agonists were applied with a fast flow system (exchange < 100 ms). One second applications of saturating concentrations of [Met] $^5$  enkephalin (ME) elicited inward currents ranging from 100 pA to 1 nA at -60 mV. The time course of decay ranged from 1.3 to 4.1 s. One second applications of a saturating concentration of the selective  $\mu$ -receptor agonist DAMGO produced inward currents ranging from 100 pA to 500 pA at -60 mV and time to decay ranged from 0.88 to 1.5 s. Therefore, DAMGO currents seem to recover to baseline faster than ME currents. The latency of response (36 to 306 ms) and time to peak (1.2 to 1.5 s) were similar for both agonists. These results show that the opioid responses were substantially slower than solution exchange. There was no evidence for desensitization for applications of agonists up to 20 s. Interestingly, saturating concentrations of morphine did not produce inward currents but reversed the DAMGO current in all cells tested. Naloxone (1  $\mu$ M) also reversed the inward current produced by ME and DAMGO. Under these conditions, morphine appears to act as an antagonist, suggesting that the efficiency of coupling may be compromised during the dissociation procedure. Supported by NIDA grant DA08163.

## 37.6

**$\mu$ -SPECIFIC OPIOID COMPOUNDS AFFECT SECRETION FROM PEPTIDERGIC NERVE TERMINALS WITHOUT ALTERING THEIR ELECTROPHYSIOLOGICAL PROPERTIES.** V.J. Coccia, G. Wang, G. Davaniti\*, and J.R. Lemos\*, Worcester Foundation for Biomedical Research, Shrewsbury, MA 01545 and  $\dagger$ CNRS, University of Montpellier II, France 34095

Peptidergic nerve terminals in the neurohypophysis (NH) secrete either oxytocin (OT) or vasopressin (AVP) in response to depolarization. We investigated the effects of  $\mu$ -specific opioids on both the electrophysiological and secretory responses of these terminals to depolarization.  $\mu$ -specific opioid compounds have profound effects on the secretion of both OT and AVP from isolated NH terminals. We treated NH terminals with either DAMGO ( $\mu$ -agonist) or naloxonazine ( $\mu$ -antagonist) and examined the change in the amount of either OT or AVP secreted by high K $^+$ . Increasing the dose of DAMGO decreased the amount of both AVP and OT secreted; OT secretion was reduced 76% by 100 nM DAMGO. 100 nM DAMGO reduced AVP secretion by 20%. Treatment with naloxonazine potentiated release of OT and AVP from isolated terminals; OT secretion was increased 52% after treatment with 1  $\mu$ M naloxonazine. AVP secretion was increased 10% by the identical treatment. The mechanism of the  $\mu$ -opioid compound's effect on peptide secretion in the NH is not clear, since DAMGO has been shown to have no effect on calcium currents in isolated terminals (Rusin et al., 1995, *Neurosci. Abs.* 21: 1092). We, therefore, examined action potentials and their underlying sodium-, A- and Ca $^{2+}$ -activated K $^+$ -currents from isolated NH terminals using the perforated, "whole-cell" patch-clamp configuration. Treatment with up to 13  $\mu$ M DAMGO or naloxonazine did not alter either the amplitude or duration of the action potential of electrically stimulated terminals. Consistent with this, alterations in the underlying currents were not statistically significant from control currents. These results challenge the notion that modulation of the ion channels in the terminal are solely responsible for changes in peptide secretion from the terminal. (Supported by NIH grants NS07366 & NS29470).

## 37.8

**THE PHOSPHORYLATION STATE OF THE KAPPA OPIOID RECEPTOR IS INCREASED IN GUINEA PIG BRAINS FOLLOWING AN ACUTE INJECTION OF U50,488H, BUT DECREASED IN GUINEA PIGS TOLERANT TO U50,488H.** S.M. Appleyard, W. Jin, T.A. Patterson and C. Chavkin\*, Dept. of Pharmacology, University of Washington, Seattle, WA 98195.

Phosphorylation has been shown to modulate opioid receptor function. In this study we used antibodies generated against the kappa opioid receptor to examine whether the phosphorylation state of the kappa receptor is altered in the brains of guinea pigs following acute or chronic exposure to U50,488H. Guinea pigs were given a single injection of U50,488H (25 mg/kg, sc), sacrificed an hour later, and then brain membranes were solubilized in the presence of phosphatase inhibitors. The kappa opioid receptor was immunoprecipitated, then phosphorylated *in vitro* with  $^{32}$ P-ATP and PKC. The amount of protein immunoprecipitated was quantified by immunoblot and the  $^{32}$ P incorporation was measured by phosphorimager analysis. The  $^{32}$ P incorporated into the kappa receptor was decreased by 23 $\pm$ 7.5% (n=3) following acute U50,488H compared to saline injected controls. In contrast, for guinea pigs made tolerant to the effects of U50,488H by repeated injections of increasing doses of U50,488H, the  $^{32}$ P incorporation was increased 187 $\pm$ 37% (n=3) compared to saline treated controls (=100%). These results suggest that an acute injection of U50,488H leads to a small increase in the phosphorylation of the kappa opioid receptor, but that following chronic exposure to U50,488H the phosphorylation state of the receptor is reduced. Supported by DA04123.

## 37.10

**DIFFERENTIAL EFFECTS OF  $\omega$ -CONOTOXIN, NIMODIPINE, CALMIDAZOLIUM, AND KN-62 INJECTED SPINALLY ON ANALGESIA INDUCED BY  $\beta$ -ENDORPHIN AND MORPHINE ADMINISTERED SUPRASPINALLY.** H. W. Suh, D. K. Song\*, S. R. Choi, and Y. H. Kim, Department of Pharmacology, Institute of Natural Medicine, College of Medicine, Hallym University, Chunchon, Kangwon-Do, 200-702, S. Korea.

Several lines of evidence have demonstrated that  $\beta$ -endorphin and morphine administered supraspinally produce the antinociception by activating different descending pain inhibitory systems. In the present study, the effects of nimodipine (a L-type calcium channel blocker),  $\omega$ -conotoxin (a N-type calcium channel blocker), calmidazolium (a calmodulin antagonist), or KN-62 (a calcium/calmodulin-dependent protein kinase II inhibitor) injected intrathecally (i.t.) on the antinociception induced by morphine, DAMGO, or  $\beta$ -endorphin administered intracerebroventricularly (i.c.v.) were examined in the present study. Antinociception was assessed by the tail-flick test. The i.t. injection of nimodipine,  $\omega$ -conotoxin, calmidazolium, or KN-62 at the doses from 0.01 to 1 ng alone did not affect the basal tail-flick latencies. The pretreatment of mice i.t. with nimodipine,  $\omega$ -conotoxin, calmidazolium, or KN-62 dose dependently attenuated the inhibition of the tail-flick response induced by  $\beta$ -endorphin administered i.c.v. However, the inhibition of the tail-flick response induced by morphine or DAMGO administered i.c.v. was not changed by i.t. pretreatment with nimodipine,  $\omega$ -conotoxin, calmidazolium, or KN-62. The results suggest that spinally located L- and N-type calcium channels, calmodulin, and calcium/calmodulin-dependent protein kinase II may be involved in the modulation of antinociceptive action induced by  $\beta$ -endorphin, but not morphine and DAMGO, administered supraspinally (supported by grant 941-0700-009-2 from KOSEF).

## 37.11

ACUTE AND CHRONIC DRUG EFFECTS ON OPIOID AND CANNABINOID RECEPTOR ACTIVATED G-PROTEINS IN RAT BRAIN. S.R. Childers\*, L. Sim, R. Xiao, & D. Selley. Dept. Physiol./Pharmacol., Bowman Gray Sch. Med., Winston-Salem, NC 27157.

Receptor-activated G-proteins can be measured by agonist stimulation of [<sup>35</sup>S]GTPγS binding in membranes or brain sections in the presence of excess GDP. In membranes from thalamus or CHO cells transfected with mu opioid receptors, different mu agonists stimulated [<sup>35</sup>S]GTPγS binding with different efficacies; these differences were determined by the concentration of GDP, with higher [GDP] increasing efficacy differences between agonists. Chronic morphine treatment of rats (7 days) produced specific decreases in mu-stimulated [<sup>35</sup>S]GTPγS binding in certain brainstem nuclei, including parabrachial nucleus, locus coeruleus, and dorsal raphe nucleus, but no changes in other brainstem nuclei or in any region in the forebrain. In these same sections, no changes were observed in stimulation of [<sup>35</sup>S]GTPγS binding by either delta agonists or ORL1 peptide, thus suggesting a homologous-type desensitization in these areas after chronic morphine treatment. In contrast, chronic THC treatment of rats (20 days) produced widespread desensitization of cannabinoid (WIN-55212-2)-stimulated [<sup>35</sup>S]GTPγS binding (decreasing agonist activation by 50-70%) in every region that contained appreciable WIN-stimulated [<sup>35</sup>S]GTPγS binding. These data suggest that different mechanisms of desensitization predominate for these two drugs of abuse.

Supported by NIDA (DA02904, DA06784, DA06634 and DA07246).

## 37.13

IN VIVO ETHANOL CONSUMPTION INCREASES OPIOID INHIBITION OF cAMP PRODUCTION IN MOUSE STRIATUM WITHOUT AFFECTING δ-OPIOID RECEPTOR DENSITY OR mRNA. K. Chan, F. Sehba, A. Duttaroy, S. Shah, J. Philippe, T. Monderson, B. Chen, J. Carroll and B.C. Yoburn\*. College of Pharmacy, St. John's University, Queens, NY 11439.

Interactions between systems that mediate the effects of opioids and ethanol have been suggested. *In vivo* ethanol consumption decreases the analgesic potency of μ and δ opioid agonists in mice without affecting the density or affinity of brain or spinal cord opioid receptors (FASEB J., 1996, 10, A451). This effect was unrelated to changes in access of opioids to the CNS. In this study, the effect of *in vivo* ethanol consumption on cAMP in striatum and opioid inhibition of forskolin stimulated cAMP production was determined. Effects on striatal δ-opioid receptor (DOR) density, affinity, and mRNA were also examined. Mice had unlimited access to 7% ethanol alone or water for 7 days and were then sacrificed, and striata removed for analysis. There was no difference in basal cAMP between controls and ethanol-treated striata, respectively (98, 106 pmole/min/mg protein). Forskolin (10 μM) stimulated cAMP production equally in both groups (3.4-3.6-fold). However, there was a significant effect of ethanol treatment on the inhibitory effect of DADLE on forskolin-stimulated cAMP formation (p<0.01). The mean DADLE IC<sub>50</sub> for controls (0.61±0.36 μM) did not differ (p>0.05) from the ethanol treated IC<sub>50</sub> (0.66±0.50 μM); whereas maximal inhibition was significantly less (p<0.02) for controls (13.7%±0.65) compared to ethanol treated (17.6%±1.36). Saturation binding studies ([<sup>3</sup>H] dextropropionolone II) indicated no differences in B<sub>max</sub> or K<sub>d</sub> between controls and ethanol treated mice, respectively (B<sub>max</sub>: 257, 274 fmole/mg protein; K<sub>d</sub>: 0.53, 0.54 nM). No difference between control and ethanol-treated striata was observed in DOR mRNA using a 550 NT riboprobe in a solution hybridization assay, respectively (14.4±1.0; 13.6±1.8 pg DOR transcripts/μg RNA). These data indicate that ethanol consumption can alter the effect of DADLE on striatal mechanisms that regulate cAMP. However, this effect is not related to changes in any δ-opioid receptor parameters that were examined. (supported by DA 04185)

## 37.15

THE MU-OPIOID RECEPTOR (μOR) IS LOCATED ON THE PLASMA MEMBRANE OF DENDRITES WHICH RECEIVE ASYMMETRIC SYNAPSES FROM AXON TERMINALS CONTAINING LEUCINE-ENKEPHALIN (L-ENK) IN THE RAT LOCUS COERULEUS (LC) E.E.O. Colago\*, E.J. Van Bockstaele, A. Moriwaki#, G. Uhl#, Dept. of Neurol. and Neurosci., Cornell Univ. Med. Coll., NY, NY, 10021; #NIDA Intramural Research Program, Baltimore, MD, 21224.

We have recently shown using immunoelectron microscopy that the μOR is prominently distributed within noradrenergic perikarya and dendrites many of which receive excitatory-type (i.e. asymmetric) synapses from unlabeled axon terminals in the LC (Van Bockstaele et al., J. Neurosci. in press). To further characterize the neurotransmitter present in these terminals, we examined the ultrastructural localization of μOR in sections which were also dually labeled for the opioid peptide, L-ENK. Gold-silver labeling for μOR was localized to para- and extra-synaptic portions of the plasma membranes of perikarya and dendrites. The μOR-labeled dendrites were usually postsynaptic to axon terminals containing heterogeneous types of vesicles and forming asymmetric specializations characteristic of excitatory-type synapses. The majority of these were immunolabeled for L-ENK. Some μOR-labeled dendrites received synaptic contacts from unlabeled terminals in fields containing L-ENK. In such cases, the μOR-labeled dendrites were in proximity to L-ENK terminals which contained intense peroxidase labeling within large dense core vesicles along the perimeter of the axoplasm suggesting that L-ENK may be released by exocytosis from dense core vesicles and diffuse within the extracellular space to reach μOR sites on the postsynaptic dendrite or dendrites of other neighboring neurons. Unlabeled terminals apposed to μOR-labeled dendrites may also contain other opioid peptides such as methionine-ENK. These data demonstrate several sites whereby opioid peptides may interact with μOR receptive sites in the LC and may provide an anatomical substrate for the LC's involvement in mechanisms of opiate withdrawal. CLONED μ- AND δ-OPIOID RECEPTORS INHIBIT PROLACTIN SECRETION FROM TRANSFECTED GH3 CELLS. E. T. Pirots\*, C. E. Marounian, T. G. Hales, & C. J. Evans. Departments of Anesthesiology & Psychiatry, UCLA, Los Angeles, CA, 90095.

Endogenous opioids modulate pain pathways and endocrine functions by inhibiting neurotransmitter and hormone release. Vesicular release can be inhibited by hyperpolarization or reduced Ca<sup>2+</sup> entry into the cell, as well as by direct interference with the secretory mechanism (e.g. phosphorylation-dephosphorylation of proteins involved in release). Opioid receptors activate K<sup>+</sup> channels and inhibit Ca<sup>2+</sup> channel and adenyl cyclase activity. The contribution of these actions to the inhibition of vesicular release is unclear. We have used the prolactin (PRL) secreting GH3 cell line, stably transfected with μ- (GH3MOR), and both μ- and δ-receptors (GH3MORDOR), to investigate the mechanisms by which these receptors modulate PRL release. Previously we have shown that μ-receptors inhibit L-type Ca<sup>2+</sup> channels and cAMP accumulation in GH3MOR cells (Pirots et al., Mol. Pharmacol. 47:1041, 1995), while δ-receptors have similar inhibitory actions only in GH3MORDOR cells.

The μ-selective ligand DAMGO (1 μM) inhibits PRL release, measured by a competitive ELISA, by 32.2 ± 4.7% and 49.1 ± 6.8% in GH3MOR and GH3MORDOR cells, respectively. In GH3MOR cells, expressing μ-receptors only, the δ-agonist DPDPE was without an effect. However, DPDPE inhibited PRL release dose-dependently (IC<sub>50</sub> = 3.8 nM) in GH3MORDOR cells. The inhibitory actions of DAMGO and DPDPE were attenuated by pertussis toxin pretreatment. We are currently investigating whether μ- and δ-opioids inhibit PRL release through modulation of adenyl cyclase, K<sup>+</sup> or Ca<sup>2+</sup> channels in GH3 cells.

## 37.14

ULTRASTRUCTURAL LOCALIZATION OF μ OPIOID RECEPTORS IN DENDRITIC TARGETS OF DOPAMINE TERMINALS IN RAT NEOSTRIATUM. H. Wang\*, A. Moriwaki#, J.B. Wang#, G.R. Uhl#, and V.M. Pickel. Dept. of Neurol. & Neurosci., Cornell Univ. Medical College, New York, NY 10021. \*Mol. Neurobiol. Branch, IRP, NIDA, NIH & Johns Hopkins Univ. School of Medicine, Baltimore, MD 21224.

Many motor effects of opiates acting at μ opioid receptors (MOR) are thought to reflect functional interactions with dopamine released from nigrostriatal afferents to the neostriatum. Since dopamine is the major catecholamine identified by the presence of the tyrosine hydroxylase (TH) in this region, we examined the cellular and subcellular basis for this interaction in the striatal patch region by dual immunocytochemical labeling for MOR and TH. MOR-like immunoreactivity (MOR-IR), labeled by immunogold particles, was mainly seen in medium-sized spiny neurons, while immunoperoxidase labeling for TH was exclusively located in axon and axon terminals devoid of detectable MOR-IR. Many MOR and TH immunolabeled profiles were in close apposition to each other, although most lacked well-defined synaptic junctions. From 639 noted appositions, over 90% were between MOR-labeled dendrites and/or dendritic spines and TH-containing terminals. The dendritic spines also often received the asymmetric synapses characteristic of excitatory inputs from unlabeled terminals. Endogenous opioids acting at MOR in the striatal patch region are well positioned to preferentially modulate the output of spiny neurons at sites having most access to released dopamine.

## 37.16

ULTRASTRUCTURAL LOCALIZATION OF MU OPIOID RECEPTOR IMMUNOREACTIVITY TO GABAergic NEURONS IN RAT DENTATE GYRUS. C.T. Drake\* and T.A. Milner. Dept. Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021

Physiological studies have determined that mu opioid receptor agonists (e.g. morphine, enkephalin) exert their effects in the dentate gyrus by inhibiting GABAergic neurotransmission. The objective of the present study was to determine the morphological correlate of these effects by analyzing the light and electron microscopic distribution of mu opioid receptor immunoreactivity (MOR-I) in the dentate gyrus, using an antiserum to the predicted C-terminus of the MOR (Incstar). Some sections were dually labeled for MOR- and GABA-immunoreactivity. By light microscopy, MOR-I was present in scattered perikarya and processes in all lamina of the dentate gyrus. Labeled neurons were most common in the granule cell layer and the subgranular region of the hilus. In sections dually-labeled for MOR- and GABA-I, MOR-I was present in a subset of GABA-I neurons. By electron microscopy, perikarya with MOR-I exhibited the infolded nuclei characteristic of interneurons, and most MOR-I perikarya also contained GABA-I. Additionally, in all subfields MOR-I was present in dendrites, axons, and axon terminals, most of which also contained GABA-I. Most dendrites with MOR-I were aspiny, and received numerous asymmetric synapses on their shafts. Most axons with MOR-I were unmyelinated. MOR-labeled terminals formed exclusively symmetric synapses with dendrites and somata of granule cells, as well as with unidentified dendrites. In experiments where gold particles were used to visualize MOR-I, labeling in perikarya, dendrites, and terminals was predominantly associated with the plasmalemma and to a lesser extent with the membranes of cytoplasmic organelles. We conclude that the MOR in dentate gyrus is positioned to effect both pre-synaptic modulation of GABA release and post-synaptic modulation of GABAergic neurons. Supported by DA08259 and an Aaron Diamond Postdoctoral Fellowship.

**OPIATE-PICROTOXIN INTERACTIONS: EFFECT OF NATRINDOLE ON PICROTOXIN-INDUCED SEIZURES.** J. Thomas\* and W.L. Nores. Dept. of Psychology, University of New Orleans, New Orleans, LA 70148.

The effects of natrindole (NTI), an opiate antagonist selective for delta receptors, on picrotoxin-induced seizures and sensitivity to morphine was investigated. For seizure testing, female rats were injected IP with NTI (.5 mg/kg) or saline 30 min prior to seizure testing with picrotoxin (1.5 mg/kg, SC). On the first day they received this treatment, animals were observed for 45 minutes for the latencies to myoclonic jerks and focal seizures. To induce morphine sensitivity, animals received the respective pretreatments followed by an injection of picrotoxin on two additional occasions at one week intervals. Four days after the last treatment, tailflick latencies were tested after pretreatment with morphine. NTI increased the latencies to myoclonic and fully developed focal seizures during the acute phase of the experiment. Pretreatment with NTI also enhanced the development of the sensitivity to morphine that results from repeated seizure episodes. The findings support the thesis of opiate receptor involvement in picrotoxin seizures. However, the mechanisms involved in seizure-induced alteration of opiate receptor sensitivity are still not known.

## 37.18

**KAPPA OPIOID RECEPTOR EXPRESSION ON CELLS OF THE IMMUNE SYSTEM.** Tracey A. Ignatowski\* and Jean M. Bidlack. Department of Pharmacology and Physiology, University of Rochester, Rochester, NY 14642-8711.

A sensitive method for receptor detection has recently been implemented to determine the presence of  $\kappa$  opioid receptors on cells of the immune system. Indirect immunofluorescence using a fluorescein-conjugated arylacetamide (FITC-AA), a  $\kappa$ -selective opioid, in conjunction with an amplification procedure and flow cytometric analysis was employed. Thymocytes, isolated from 6-8 week old C57BL/6ByJ mice, were incubated with FITC-AA, followed by biotinylated anti-fluorescein IgG and extravidin-R-phycoerythrin, in order to demonstrate labeling of the receptor. Specific labeling was greater than 50% above background as determined by inclusion of the  $\kappa$ -selective antagonist nor-binaltorphimine. Phenotypic characterization using monoclonal antibodies directed against the cell surface markers CD3, CD4, and CD8, combined with labeling of the  $\kappa$  opioid receptor, revealed that the majority of thymocytes express the receptor, and 82% were double-positive (CD4<sup>+</sup>/CD8<sup>+</sup>). Similarly, nylon-wool purified splenocytes demonstrated greater than 50% specific labeling of the  $\kappa$  opioid receptor. Additional data will be presented identifying specific immune cell subpopulations which express this receptor. Thus, these studies characterize distinct populations of immune cells involved in opioid responsiveness. (Supported by USPHS grants DA04355 and DA09676).

**SIGMA<sub>1</sub> RECEPTOR REGULATION OF N-METHYL-D-ASPARTATE (NMDA) STIMULATED [<sup>3</sup>H]DOPAMINE RELEASE IN GUINEA PIG STRIATUM.** G. M. Gonzalez-Alvarez\* and L. L. Werling. Dept. of Pharmacology, The George Washington University Medical Ctr., Washington, D.C. 20037.

We have previously reported inhibition of NMDA-stimulated [<sup>3</sup>H]dopamine release from rat striatal slices by sigma receptor agonists (+)pentazocine and BD737. We have now investigated the effects of these sigma agonists on NMDA-stimulated [<sup>3</sup>H]dopamine release from guinea pig striatal slices.

Striata were dissected, chopped, and washed in Mg<sup>2+</sup>-free modified Krebs-HEPES buffer, then incubated with 15 nM [<sup>3</sup>H]dopamine for 30 min. Slices were loaded into a superfusion apparatus and superfused with buffer to establish a low, stable baseline release. Tissue was stimulated to release [<sup>3</sup>H]dopamine by a 2 min exposure to 50  $\mu$ M NMDA. Inflow was returned to non-stimulating buffer, with or without potential inhibitor of release for 10 min. Tissue was then stimulated a second time (S2) with NMDA for 2 min in the presence or absence of an inhibitor.

(+)Pentazocine inhibited NMDA-stimulated [<sup>3</sup>H]dopamine release in a concentration dependent, monophasic manner. Additionally, the sigma<sub>1</sub> agonist BD737 was also found to inhibit NMDA-stimulated [<sup>3</sup>H]dopamine release from guinea pig striatal slices. Both (+)pentazocine and BD737 inhibited NMDA-stimulated [<sup>3</sup>H]dopamine release in a naloxone-insensitive manner. Furthermore, the sigma<sub>2</sub> antagonist DuP 734 and BD1008, a non-selective sigma antagonist, completely reversed the inhibition of release. Neither DuP 734 nor BD1008 had any effect on NMDA-stimulated [<sup>3</sup>H]dopamine release in the absence of a sigma agonist. These data suggest that sigma<sub>1</sub> receptors are involved in the regulation of dopamine release in guinea pig striatum. **DIFFERENTIAL REGULATION OF NON-NMDA SUBUNIT mRNA BY ANTIPSYCHOTICS IN RAT.** D.J. Healy\*, R.E. King, K.A. Bovenkerk, S.P. Damask, J.H. Meador-Woodruff. Mental Health Research Institute and Department of Psychiatry, University of Michigan, Ann Arbor MI 48109.

Dopamine is the neurotransmitter most often implicated in the pathogenesis of schizophrenia. However, glutamatergic antagonists cause both negative and positive psychotic symptoms in otherwise normal humans, and exacerbate these symptoms in schizophrenics. These findings have led investigators to attempt to synthesize these data, resulting in a model of dopamine-glutamate interactions in limbic cortex and striatum as a potential substrate for symptom production in schizophrenia. We are interested in exploring this model, and in this study have examined the effects of chronic antipsychotic treatment on the expression of some glutamate receptors within discrete neuroanatomical regions in this model. Glutamate receptors are divided into four subtypes, two of which are ionotropic receptors recognized by their relative affinity for AMPA and kainate, respectively. These receptors are composed of five subunits with potentially varying stoichiometries. Some of the variability in subunit stoichiometry is due to the fact that these subunits are encoded by separate genes, referred to as *gluR1-gluR7*, and *KA1-KA2*. We examined the regulation of gene expression of the AMPA (*gluR1-gluR4*), low affinity kainate (*gluR5-gluR7*), and high affinity kainate (*KA1-KA2*) receptor subunits by clozapine (20 mg/kg/day) and haloperidol (2 mg/kg/day) treatment for two weeks. Both clozapine and haloperidol caused region-specific alterations in the mRNA levels of these subunits, but in dissimilar patterns. This dissimilarity may represent an interesting mechanism for some of the differential therapeutic or toxic effects of clozapine and haloperidol, and also may be relevant to our understanding of dopamine-glutamate interactions as a potential substrate of schizophrenia. **CHRONIC TREATMENT WITH L-DOPA DECREASES LIGAND BINDING TO STRIATAL NMDA AND NON-NMDA GLUTAMATE RECEPTORS IN RATS WITH NIGROSTRIATAL INJURY.** S.J. O'Dell\* and J.F. Marshall. Department of Psychobiology, University of California, Irvine, Irvine, CA 92717.

Changes in the activity of CNS dopamine (DA) systems modulate corticostriatal neurotransmission, suggesting that DA-influenced changes in striatal GLU receptors may play an important role in neurodegenerative disorders such as Parkinson's disease. To investigate the influence of dopaminergic modulation on striatal GLU receptors, rats were given unilateral nigrostriatal damage via intracerebral 6-OHDA injection. One month later, these lesioned rats and unlesioned control rats were given 2 daily injections of Sinemet (100 mg L-dopa + 25 mg carbidopa/kg, ip) or vehicle for 21 days. Three days after the last injection, their brains were processed for *in vitro* autoradiography, quantifying DA uptake sites and the AMPA, kainate (KA) and NMDA subtypes of GLU receptor in the caudate-putamen (CPu), nucleus accumbens (NAc) and cingulate cortex (Cing). Nigrostriatal 6-OHDA injections alone reduced ipsilateral striatal DA uptake sites by 83-99%, but had little effect on radioligand binding to striatal AMPA, KA, or NMDA receptors. In contrast, chronic Sinemet treatment of 6-OHDA-injected rats produced significant decreases in AMPA, KA, and NMDA receptors in the striatum and cortex. In 6-OHDA-injected rats, Sinemet produced the greatest reductions in KA and NMDA receptors (30-40%) in the denervated CPu, with moderate declines (18-25%) observed in the CPu, NAc and Cing of the intact hemisphere. In contrast, Sinemet produced moderate (15%), uniform decreases in AMPA receptors in the CPu, NAc and Cing of both the intact and lesioned hemispheres. Additionally, Sinemet administration produced prolonged, vigorous rotation in rats with unilateral nigrostriatal damage, but not in neurologically intact rats. Taken together, these results suggest that after nigrostriatal injury prolonged treatment with Sinemet differentially influences corticostriatal glutamatergic transmission mediated by AMPA, KA and NMDA receptors. Funded by NS 22698.

## 38.4

**STRESS INCREASES EXTRACELLULAR GLUTAMATE AND DOPAMINE IN THE VENTRAL TEGMENTAL AREA.** Z.L. Rossetti\* and R.A. Wise. CSBN, Concordia University, Montreal, Quebec, Canada H3G 1M8 and Dept. of Neuroscience, University of Cagliari, 09124 Cagliari, Italy.

Stress is known to activate DA neurons and to increase neurotransmitter release from dopaminergic terminals. Stress also activates glutamatergic neurons causing increased extracellular glutamate (GLU) in cortical and subcortical structures. Since VTA DA neurons receive major excitatory innervation and express GLU receptors, we determined whether stress was associated with increased GLU input to the VTA by measuring GLU and DA levels in microdialysis samples. DA, released in the VTA by dendrites as a correlate of impulse flow, was measured as means of estimating dopaminergic activation by GLU. DA and GLU were measured by HPLC in split 20-min samples (0.6  $\mu$ l/min), starting 24 h after probe implantation, with fluorescence and electrochemical detection, respectively. Baseline GLU and DA concentrations were  $7.65 \pm 0.71$   $\mu$ M and  $0.43 \pm 0.06$  nM, respectively. Tail pinch stress was delivered for 10 min. In the first sample after stress, extracellular GLU increased to  $4.51 \pm 0.58$  % of baseline, remaining elevated for at least 1 h. An increase in extracellular DA (to  $176 \pm 23$  % of baseline) was time-locked to GLU elevation. Thus glutamatergic input to the VTA is increased by stress and this effect is associated with neuronal activation of DA neurons. Given the increasing evidence for the regulation of subcortical DA function by glutamatergic afferents to DA cell bodies, we suggest that GLU release in VTA may be a primary mechanism for the response of mesolimbic DA neurons to stress.

## 38.5

## GLUTAMATERGIC MODULATION OF FEEDING EVOKED DOPAMINE RELEASE IN THE RAT NUCLEUS ACCUMBENS.

M.T. Taber\*, L. Crookall, and H.C. Fibiger. Division of Neurological Sciences, Dept. of Psychiatry, University of British Columbia, Vancouver, BC, V6T 1Z3, Canada.

Glutamatergic projections synapse in both the cell body region (ventral tegmental area: VTA) and the terminal region (nucleus accumbens: NAc) of the mesolimbic dopamine (DA) system. Glutamatergic mechanisms in both areas have been proposed to modulate DA neurotransmission in the NAc. The present study used *in vivo* microdialysis to determine the contribution of glutamatergic receptors in these two areas to the modulation of DA release in the NAc that has been shown to occur during feeding. Feeding in 18 hour food-deprived rats increased DA release by approximately 50 percent, an effect which lasted for about 90 minutes, while food was still present. Local application in the NAc of the ionotropic glutamate receptor antagonist kynurenic acid (1 mM) through the microdialysis probe potentiated the effect of feeding on DA release by about 80%. To investigate the possibility that ionotropic glutamate receptors in the ventral tegmental area mediate the effect of feeding, a combination of antagonists, CNQX (50  $\mu$ M) and AP5 (200  $\mu$ M), was applied in this region while recording accumbal DA concentrations during feeding. The antagonists produced a small (20%) decrease in basal DA release and reduced the effect of feeding by 70%. Neither of these treatments affected the amount of food eaten over the two hour feeding period or the latency to begin eating. These results demonstrate that glutamate receptors in the ventral tegmental area mediate feeding-induced increases in DA release whereas glutamate receptors in the NAc have an inhibitory influence.

## 38.7

THE ROLE OF GLUTAMATE IN DOPAMINE-MEDIATED GENE EXPRESSION IN THE RAT STRIATUM. J.C. Leveque and C. Konradi\*. Neuroscience Center, Mass. General Hospital East, Charlestown, MA 02129.

Dopamine activates the expression of target genes in the striatum in a  $D_1$  as well as  $D_2$  receptor-dependent manner. Treating rats with amphetamine induces the immediate early gene *c-fos* and the *prodynorphin* gene, through the stimulation of  $D_1$  receptors. The neuroleptic haloperidol stimulates *c-fos* as well as *proenkephalin* gene expression in a  $D_2$ -dependent manner. Interestingly, the NMDA antagonist MK-801 is able to inhibit this dopamine-mediated gene expression. Experiments in rat primary striatal culture demonstrate that this inhibition is due to an intra- rather than inter-neuronal mechanism. Results in primary striatal culture indicate that the influx of calcium through NMDA receptors, rather than calcium channels, is necessary for dopamine-mediated gene expression. Moreover, low levels of glutamate lead to a superinduction of dopamine-mediated gene expression. While dopamine-induced cAMP levels are unperturbed by MK-801, the dopamine-mediated phosphorylation of the transcription factor CREB is blocked by MK-801. We will present data that further elucidates the interaction between dopamine and glutamate in the expression of the *proenkephalin* gene and the immediate early gene *c-fos* and characterizes the second messenger pathways of both transmitters.

## 38.9

GLUTAMATERGIC REGULATION OF GABA RELEASE IN THE PREFRONTAL CORTEX DURING BASAL AND STRESS-ACTIVATED CONDITIONS. Bita Moghaddam\*, James Bagley, and Herman Bruins. Department of Psychiatry, Yale University School of Medicine, VA Medical Center 116A/2, West Haven, CT 06516

Intracerebral microdialysis in awake rats was used to study the glutamatergic regulation of GABA release in the prefrontal cortex. Glutamatergic neurotransmission was increased by local application of exogenous ionotropic agonists, and by stress, which has been shown to increase glutamate neurotransmission in the prefrontal cortex. Local perfusion of NMDA at 100  $\mu$ M and 500  $\mu$ M, through the microdialysis probe, produced a dose-dependent increase in GABA efflux. Kainate did not affect these levels at 10  $\mu$ M, but produced a small increase at the relatively high concentration of 50  $\mu$ M. AMPA, at 20  $\mu$ M and 100  $\mu$ M, produced a small increase of about 25% in GABA levels. Exposure to stress (20 min tail pinch) increased GABA efflux by about 50% in the PFC. To examine whether an increase in endogenous glutamate in response to stress alters GABA release in the prefrontal cortex, the effect of locally applied AMPA/kainate receptor antagonist, CNQX, and NMDA receptor antagonist, AP5, during the stress procedure was examined. Infusion of CNQX did not alter the basal or stress-activated GABA levels. In contrast, AP5 produced a trend toward a decrease in basal GABA efflux and it blocked stress-induced GABA release. These studies demonstrate that glutamatergic regulation of GABA release in the prefrontal cortex occurs primarily via the NMDA receptors. Supported in part by USPHS awards MH-48404 and MH-44866 the Scottish Rite Foundation, and West Haven VA Center for Schizophrenia.

IMPAIRED LEARNING OF A SHORT-TERM MEMORY TASK AND DECREASED NMDA-RECEPTOR-MEDIATED REGULATION OF IN VIVO PREFRONTAL CORTEX DOPAMINE RELEASE IN ADULT RATS NEONATALLY EXPOSED TO THE NMDA-ANTAGONIST MK-801. M. Feenstra\*, M. McLean, L. Ogle, M. Botterblom, R. Joosten, J. de Bruin. Neth Inst Brain Res, Grad Sch Neurosci A'dam, 1105AZ Amsterdam ZO, The Netherlands.

We recently showed that neonatal blockade of NMDA-receptors affects adult spatial learning and DA metabolism (Gorter et al: Brain Res 580(1992)176, Neurosci Lett 137(1992)97). As the mesocortical dopaminergic (DA) projection and NMDA-receptors are both important for the involvement of the prefrontal cortex (PFC) in short-term learning and memory, we studied these parameters in adult male rats that were treated as pups with the noncompetitive NMDA-antagonist (+) MK-801 (0.05 mg/kg, twice daily, postnatal day 5-15).

Acquisition of a Delayed-Matching-To-Position task was assessed in Skinner-boxes and was delay-dependently impaired in the MK-801-exposed rats. For 15 and 30 sec delays the level of controls was reached only after 14 days of testing. In vivo DA overflow was measured in the PFC using microdialysis. Basal levels and novelty-induced increases were not altered, but the increase in DA overflow induced by 0.3 mM D-AP-5 was significantly less in neonatally MK-801-exposed rats compared with saline controls.

Neonatal blockade of NMDA-receptors led to a severe deficit in adult short-term learning and memory. The decreased response to D-AP-5 indicates a reduction of tonic NMDA-receptor dependent inhibition of DA release. The increased DA metabolism in the ventromedial PFC, the most densely DA-innervated PFC area, found in tissue measurements, points in the same direction. (no external funding).

## 38.8

MODULATION OF EXTRACELLULAR DOPAMINE LEVELS IN THE STRIATUM BY A METABOTROPIC GLUTAMATE RECEPTOR AGONIST: A MICRODIALYSIS STUDY. Anita Verma\* and Bita Moghaddam. Department of Psychiatry, Yale University School of Medicine, VA Medical Center 116A/2, West Haven, CT 06511

In vivo microdialysis was used to assess the effect of the metabotropic agonist, trans-(±)-1-amino-1,3-cyclopentanedicarboxylic acid (ACPD) on the extracellular levels of dopamine in the rat striatum. ACPD increased dopamine release in a concentration range of 50 to 500  $\mu$ M. The lower dose of ACPD (50  $\mu$ M) failed to elicit a significant effect on extracellular dopamine levels. The higher doses of 100  $\mu$ M and 500  $\mu$ M produced a significant increase in extracellular levels of dopamine. The ACPD-induced increases in dopamine levels were decreased by local perfusion of tetrodotoxin, indicating that activation of dopamine release by ACPD is impulse flow dependent. Further, ACPD attenuated the increased dopamine release in response to 30mM KCl. These data suggest that during basal conditions metabotropic glutamate receptors activate striatal dopamine release; however, under stimulated conditions, they attenuate these levels. Thus, during conditions of hyperstimulation, activation of metabotropic receptors, in contrast to ionotropic receptors, may act to reduce the excess dopamine release.

This work was supported in part by USPHS awards, MH-48404, MH-44866 and The Scottish Rite Foundation.

## 38.10

ROLE OF GLUTAMATE RECEPTOR SUBTYPES IN REGULATING AMPHETAMINE-INDUCED ALTERATIONS OF STRIATAL ACETYLCHOLINE EFFLUX. Elizabeth D. Abercrombie\* & Michael J. Bickerdike. Center for Molecular & Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Striatal ACh efflux is modulated by opposing dopaminergic influences: striatal  $D_2$  receptors directly inhibit ACh release, whereas extrastriatal  $D_1$  receptors indirectly potentiate ACh efflux. Previous studies have demonstrated that  $D_1$ -mediated increases in ACh efflux are dependent on glutamate.<sup>1</sup> The current study employed microdialysis to investigate the effect of locally administered NMDA antagonists (MK801 and AP-5) and an AMPA antagonist (CNQX) on the response of striatal ACh to a systemic amphetamine (AMPH) challenge. Male rats received local CNQX (10 $\mu$ M), MK801 (10 $\mu$ M), AP-5 (100 $\mu$ M), or CSF, then were given 4mg/kg AMPH i.p. 105 min later. Local administration of the antagonists had varying effects on striatal ACh: the AMPA antagonist CNQX produced a brief 23% increase in striatal ACh; MK801 likewise produced a transient increase in ACh (17%) which then settled 15% below baseline; and AP-5 produced a significant reduction in basal ACh (35%). By itself, AMPH produced a mild, slowly developing increase in striatal ACh efflux (30% after 2 hr). However, in the presence of CNQX, AMPH challenge induced a significant decrease in ACh efflux (40%). In the presence of MK801, AMPH produced a significant, prolonged, increase in ACh (79%), while AP-5 did not significantly affect the ACh response to AMPH (17% increase). These results suggest a clear differentiation of function between AMPA and NMDA receptors in their influence on striatal ACh release. The decrease in ACh produced by AMPH in rats given CNQX likely results from indirect blockade of the positive  $D_1$ -mediated effects produced by AMPH. Striatal perfusion with the NMDA receptor antagonists MK801 and AP-5 did not result in a similar decrease. It therefore follows that  $D_1$  receptor-mediated increases in striatal ACh are ultimately driven by AMPA rather than NMDA receptor activation<sup>1</sup>. Moreover, the increase in ACh observed after AMPH in MK801-treated rats suggests that NMDA receptors mediate a strong inhibitory effect on striatal ACh perhaps via activation of striatal GABAergic processes. (Supported by NIDA 08086)

REGULATIONS OF NMDA-EVOKED RELEASE OF ACETYLCHOLINE IN STRIOSOME- AND MATRIX-ENRICHED AREAS OF THE RAT STRIATUM. M.L. Kemel, F. Blanchet, S. Perez, M. Desban, J. Glowinski and C. Gauchy. INSERM U114, Collège De France, 11pl M. Berthelot, 75005 Paris France.

Using local microsuperfusions of sagittal striatal slices, in the absence of  $Mg^{2+}$ , NMDA (50  $\mu M$ ) was shown to enhance the release of  $^3H$ -ACh previously formed from  $^3H$ -choline in striosome- and matrix-enriched areas. D-serine (10  $\mu M$ ) potentiated the response induced by 10  $\mu M$  NMDA but surprisingly it reduced those evoked by 50  $\mu M$  or 1 mM NMDA suggesting, in these cases, the intervention of released inhibitory transmitters such as dopamine (DA) or GABA.

...Confirming the inhibitory role of released DA, the NMDA (1 mM + D-serine)-evoked release of  $^3H$ -ACh was enhanced under the complete blockade of DA transmission with (-)-sulpiride (1  $\mu M$ ) and SCH23390 (1  $\mu M$ ) (D1 and D2 antagonists respectively), this effect being more important in striosomes (X4) than in the matrix (X1.6). In contrast, the blockade of GABA transmission with the GABA A antagonist (bicuculline, 5  $\mu M$ ) was without effect on the NMDA response in the striosomes but reduced this response in the matrix. Moreover, the presence of the GABA A antagonist did not prevent the desinhibitory effects of the combined application of the D1 and D2 antagonists on  $^3H$ -ACh release in both compartments suggesting that the reduced NMDA response induced by bicuculline alone in the matrix results from a blockade of the inhibitory effect of GABA on the release of DA. Additional experiments performed with the D2 or D1 antagonist alone in the presence of bicuculline indicated that D2 receptors play a prominent role in the inhibitory effect of DA on NMDA-evoked responses in both compartments and that D1 receptors are involved in an excitatory effect of DA on NMDA-evoked ACh release in the matrix compartment.

## 38.13

ACUTE MK-801 ADMINISTRATION INDUCES EXPLOSIVE JUMPING BEHAVIOR AND AN INCREASE IN CENTRAL NICOTINIC RECEPTORS IN MICE. Y. Tizabi\*, C. H. Park and S. I. Deutsch. Dept. of Pharmacology, Col. of Med., Howard Univ. Washington, DC 20059, and Psychiatry Service, V. A. Medical Center, Washington, DC 20422.

Administration of MK-801 (dizolcipine) to rodents causes a complex series of behaviors including "popping," characterized by involuntary explosive jumping episodes, in an outbred strain of NIH Swiss mice. MK-801, an NMDA receptor antagonist also inhibits nicotinic cholinergic receptor channels. To investigate possible involvement of nicotinic receptors in MK-801-induced popping behavior, mice were injected with MK-801 (1.8 mg/kg, i.p.) and following a 30 min test period, low and high poppers were selected for measurements of nicotinic receptor binding. Mice were sacrificed either immediately following the test session or 24 h later. Nicotinic receptor densities were measured by [ $^3H$ ]cytisine binding in homogenates of specific brain regions. There was an increase in nicotinic receptor concentrations in the cortex, striatum and midbrain of both high and low poppers 30 min following the MK-801 injection. There were no changes in hippocampal and cerebellar nicotinic receptor concentrations. At 24 hour following MK-801 injection all nicotinic receptor changes were back to normal. The lack of correlation between nicotinic receptor densities and intensities of "popping" episodes does not support a direct involvement of nicotinic receptors in MK-801-induced popping. However, MK-801 induced increases in nicotinic receptor bindings in discrete brain regions suggests a possible involvement of nicotinic receptors in some aspects of MK-801 actions. Supported in part by a grant from the Department of Veterans Affairs.

ON-LINE MEASUREMENT OF SYNAPTICALLY RELEASED GLUTAMATE IN CULTURED RAT CORTICAL NEURONS USING ELECTROCHEMICAL DETECTION. K. Torimitsu\*, A. Kawana and O. Niwa, NTT Basic Research Laboratories, 3-1, Morinosato-Wakamiya, Atsugi-shi, Kanagawa, 243-01, Japan.

The measurement of synaptically released neurotransmitters is essential for understanding the synaptic transmission mechanism and functions of neural networks in the brain. Various methods have been used to measure the neurotransmitters released during synaptic transmission. Most researchers have used microdialysis-sampled liquid chromatography for *in vivo* experiments or labelled neurotransmitters for *in vitro* experiments, in order to estimate the transmitter concentration and movement. However, these methods are problematic as regards long term and real time measurements under stable conditions. Here we have developed a novel method of measuring the glutamate concentration in a medium on-line. E18 rat cortical neurons were cultured for 2 weeks in an MEM-based culture medium. Real time measurements of synaptically released glutamate were carried under serum-free conditions. The glutamate was measured by a glutamate oxidase immobilized glassy carbon detector connected to either a glass capillary or microdialysis tube to provide continuous suctioning of the medium at a rate of 4  $\mu l/min$ . Spontaneously released glutamate at a submicromolar level was observed. The addition of potassium induced a transient glutamate release. The mechanism which modulates glutamate release will be discussed at the meeting.

## 38.12

MUSCARINIC MODULATION OF NMDA RESPONSES REQUIRES A G-PROTEIN MEDIATED EVENT. V. B. Aramakis\*, A. E. Bandrowski, M. F. Bashir and J. H. Ashe. Departments of Neuroscience and Psychology, University of California, Riverside, CA 92521.

The muscarinic receptor agonist, acetyl- $\beta$ -methylcholine (MCh) facilitates both the NMDA-mediated late-EPSP and NMDA-induced membrane depolarizations (NMDA-DPs) in the *in vitro* rat auditory cortex (Aramakis et al, submitted). Here we present evidence that the facilitating actions of MCh are G-protein mediated. Whole-cell recordings (WCR) were obtained from layer II/III pyramidal neurons and iontophoretic application of either MCh (1M, 3-100 nA, 1-4 min) or NMDA (50 mM, 13-130 nA, 5 sec) was also applied to layer II/III.

Intracellular infusion of the GTP activator, GTP $\gamma$ S (100  $\mu M$ ) mimicked the facilitating actions of MCh. Facilitation of both the late-EPSP, generated by deep gray/white matter stimulation (n=6), and NMDA DPs (n=5) developed gradually with infusion of GTP $\gamma$ S into the cell, following establishment of the WCR configuration. Facilitation of the late-EPSP, elicited in isolation by blockade of AMPA/kainate receptors with CNQX, did not develop gradually, but could be induced by low current ejection of MCh (3-25 nA, n=6). In contrast, infusion of the competitive G-protein inhibitor, GDP $\beta$ S (200  $\mu M$ ), prevented the MCh-mediated facilitation of either the pharmacologically isolated late-EPSP (n=5) or the NMDA-DPs (n=7).

Our results suggest that ACh, acting at muscarinic receptors, produces a long-lasting enhancement of NMDA-mediated neurotransmission in auditory cortex, and that this modulatory effect is dependent upon a G-protein mediated event. Supported by NSF (IBN 9310582).

## 38.14

MK-801-INDUCED EXPLOSIVE JUMPING BEHAVIOR IN MICE IS INHIBITED BY NICOTINE PRETREATMENT. S. I. Deutsch\*, J. Mastropaulo, R. L. Riggs and Y. Tizabi. Psychiatry Service, V. A. Medical Center, Washington, DC 20422, and Dept. of Pharmacology, Col. of Med. Howard Univ. Washington, DC 20059.

MK-801 is a noncompetitive antagonist of the N-methyl-D-aspartate subclass of glutamate receptor that elicits hyperactivity, stereotypic behaviors, and "popping," an explosive jumping behavior, in mice. The mechanism(s) responsible for MK-801-induced popping is not known. MK-801 also inhibits nicotinic receptor channels. Previously we have observed an increase in central nicotinic receptors following acute administration of MK-801 (1.8 mg/kg i.p.). Since nicotine itself may interfere with MK-801 binding, this study was designed to determine whether pretreatment with nicotine may block MK-801-induced popping behavior. Nicotine administration by itself (0.56 - 1.8 mg/kg, i.p.) had no effect on popping behavior. However, nicotine pretreatment dose-dependently inhibited MK-801-induced popping. The mechanism responsible for this effect of nicotine is currently not known. These findings suggest important interactions between nicotine, MK-801 and each other's binding sites. Further elucidations of these interactions are necessary in pharmacotherapeutic considerations of these agents.

Supported in part by a grant from the Dept. of Veterans Affairs and Office of the Vice President for the Health Affairs, Howard Univ.

IN MICROCULTURE SINGLE MESENCEPHALIC DOPAMINE NEURONS MAKE TWO CHEMICALLY DISTINCT TYPES OF SYNAPSES. S. Rayport, L. Lin, T. Hattori\*. Depts. Psychiatry, Anatomy & Cell Biology, and Ctr. Neurobiology & Behavior, Columbia Univ.; Dept. Neuroscience, N.Y.S. Psychiatric Institute, NY 10032; Dept. Anatomy & Cell Biology, Univ. of Toronto, Ontario M5S 1A8.

In the intact brain, single nigrostriatal dopamine (DA) neurons appear to make DAergic and non-DAergic synapses (Hattori, Neurosci. Res. 1993). Previously we reported (Sulzer et al., Soc. Neurosci. Abstr. 1994; Rayport et al., 1995) that DA neurons grown in microculture form excitatory autapses and stain for glutamate (GLU). We have now double stained mesencephalic DA neurons in microcultures for the DA-synthetic enzyme tyrosine hydroxylase (TH) and for GLU. This reveals that single TH $^{+}$  neurons have TH $^{+}$ , GLU $^{+}$ , and TH $^{+}$ /GLU $^{+}$  varicosities. At the ultrastructural level, TH staining, which we visualized with DAB, shows a patchy somatic distribution; both TH $^{+}$  and intensely TH $^{+}$  processes arise from the soma and intermingle in the neuritic field. Within individual processes staining sometimes abruptly starts and stops. Synaptic specializations are mainly found near the cell body. Most presynaptic terminals are TH $^{+}$  and make asymmetric synapses. Rarely TH $^{+}$  presynaptic terminals make symmetric synapses. Thus single mesencephalic DA neurons can form symmetric DAergic and asymmetric GLUergic terminals; the functional roles of these two types of synapses and their potential impact on DA-dependent processes such as psychostimulant sensitization remain to be determined.

## 38.17

MODULATORY EFFECTS OF SCOPOLAMINE ON PAIRED PULSE DEPRESSION OF DENTATE GRANULE CELL FIELD POTENTIALS. **L.J. Burdette\***, Dept. Neurology, Graduate Hospital, Philadelphia, PA 19146

We previously have found that the NMDA antagonist, MK-801, potentiates late paired pulse depression of dentate granule cell field potentials. Evidence of cholinergic modulation of GABA-mediated inhibition suggested that the muscarinic antagonist, scopolamine (5 mg/kg, ip), may mimic the enhancement of late paired pulse depression seen with MK-801. Male Long Evans rats were prepared with chronic electrodes in the perforant path and dentate gyrus. Following post-operative recovery, stimulus intensity functions (0.1 ms, 50-1500  $\mu$ Amps) were obtained using single pulses and paired pulses delivered at 0.05 and 1 Hz under vehicle and drug conditions. In contrast to the effects of MK-801, scopolamine did not significantly alter late paired pulse depression (200 ms interpulse interval) or the 1 Hz depression of the population spike. However, scopolamine produced a significant increase (17.8%,  $p=0.016$ ) in early paired pulse depression (20 ms interpulse interval) at all stimulus intensities, resulting in a lower threshold for evoking early paired pulse depression (20% v. 40% of maximum stimulus intensity). No drug effects were detected in the stimulus intensity function for the population spike or the slope of the EPSP. The enhancement of early paired pulse depression by scopolamine is consistent with a block of the cholinergically-mediated depression of the fast IPSP observed in hippocampal pyramidal cells, and suggests a similar cholinergic modulation of GABA<sub>A</sub>-mediated inhibition in the dentate gyrus. MICRODIALYSIS STUDIES WITH INTRASTRIATAL NEUROTENSIN 1-13 AND NEUROTENSIN 8-13 ON STRIATAL GABA AND DOPAMINE RELEASE IN THE AWAKE RAT. EVIDENCE FOR NEUROTENSIN RECEPTOR HETEROGENEITY IN THE NEOSTRIATUM. **W.T. O'Connor<sup>1</sup>, L. Ferraro<sup>2</sup>, T. Antonelli<sup>2</sup>, U. Ungerschl<sup>3</sup>, K. Fuye<sup>4</sup> and S. Tanganelli<sup>1</sup>**. <sup>1</sup>Dept. of Physiology, University College, Dublin, Ireland; <sup>2</sup>Inst. of Pharmacology, University of Ferrara and <sup>3</sup>Dept. of Neuroscience, University of Cagliari, Italy; <sup>4</sup>Dept. of Pharmacology and Neuroscience, Karolinska Inst., Stockholm, Sweden.

In the present study we investigated (a) the effects of intrastriatal perfusion with the tridecapeptide neurotensin NT(1-13), and its active fragment NT(8-13) on striatal GABA and dopamine (DA) release and (b) the ability of intrastriatal NT(1-13) to influence D<sub>2</sub> receptor mediated inhibition of striatal GABA release.

Basal striatal GABA and DA levels were and  $20.3 \pm 1.6$  nM and  $4.11 \pm 0.34$  nM respectively. Both NT(1-13) (100 nM) and NT(8-13) (100 nM), increased striatal GABA release (+37  $\pm$  9% and +29 $\pm$ 3% respectively) and these effects were antagonised by intrastriatal perfusion with the non peptidergic NT receptor antagonist SR48692 (100 nM). However, while NT(1-13) (100 nM) was associated with a prolonged increase (+55  $\pm$  8%) in striatal DA release, NT(8-13) displayed only a slight and shortlasting effect even at the 1  $\mu$ M concentration.

Intrastriatal NT(1-13) (10 nM) counteracted the pergolide (500 and 1500 nM) induced inhibition of striatal GABA release and the inhibitory action of the D<sub>2</sub> agonist was restored when SR48692 (100 nM) was added to the perfusion medium.

The finding that NT(1-13) (100nM) increases striatal GABA and DA release while its active fragment NT(8-13) (100nM) increases GABA but not DA release indicates that NT receptors located on GABA neurons differ from those on DA terminals and provides *in vivo* evidence for functional NT receptor subtypes in the CNS. Furthermore, the ability of NT (1-13) to counteract the pergolide induced inhibition of striatal GABA release strengthens the evidence for an antagonistic receptor-receptor interaction between striatal NT and D<sub>2</sub> receptors located on GABA neurons.

## 39.3

EFFECTS OF INTRACEREBROVENTRICULAR ADMINISTRATION OF ETHYLCHOLINE AZIRIDIUM ON DOPAMINERGIC NERVOUS SYSTEMS. **D.K. Lim\*, Y. Ma and E.Y. Yi** College of Pharmacy, Chonnam National University, Kwang-Ju, 500-757, Korea

Changes in dopaminergic activities were investigated after the intracerebro-ventricular (icv) administration of ethylcholine aziridium (AF64A) in rats. The levels of dopamine (DA) and metabolites, the activities of tyrosine hydroxylase (TH) and monoamine oxidase (MAO), and the specific bindings of dopamine receptors in striata, hippocampus, and frontal cortex were assessed 6 days after the AF64A treatment with 3 nmol/each ventricle. The levels of DA and metabolites, TH and MAO activities, the specific binding sites of dopamine receptors were measured using HPLC-ECD, enzyme assays, and ligand binding assay, respectively. In frontal cortex, the levels of DA and metabolites were significantly decreased in the AF64A-treated group. However, the ratios of metabolites and DA were significantly decreased in striatum and hippocampus in the AF64A-treatment. The activity of TH in frontal cortex was significantly decreased without changes in the other areas. Although the activity of MAO-A was not changed in the brain regions studied, the activity of MAO-B in striatum was significantly increased. The specific bindings of dopamine D1 and D2 receptors were increased in frontal cortex after AF64A-treatment. However, those were not changed in striatum and hippocampus except the small decrease of dopamine D1 receptor in striatum. These results indicate that the dopaminergic activity was altered in AF64A treatment. Furthermore, it suggests that the dopaminergic activities in each brain regions may be differently affected by AF64A treatment.

## 39.2

PRELIMINARY EVIDENCE OF SUBSTANCE P-INDUCED INHIBITION OF STRIATAL DOPAMINE EFFLUX IN THE AWAKE RAT. **R.N. Iyer\*, A.B. Giordani and M.D. Davis**. Departments of Chemistry and Neuropharmacology, Parke-Davis Pharmaceutical Research, Division of Warner Lambert Co., Ann Arbor, MI 48105.

The observation of a striatonigral pathway containing the undecapeptide substance P (SP) has elicited substantial interest in potential interactions between this neurotransmitter and dopamine (DA). The elucidation of this potential interaction has, however, been complicated by reports of the ability of SP and various SP fragments to both inhibit and facilitate DAergic function *in vitro* and *in vivo* (in anaesthetised animals). In light of the potential importance of such an interaction and due to the contradictory observations reported in the literature, we have examined the effect of the peptide SP, when locally infused through a microdialysis probe for 20 minutes, on striatal extracellular DA levels in conscious, freely-moving Sprague-Dawley rats.

Basal dialysate levels of DA were found to be  $3.9 \pm 1.0$  fmol/ $\mu$ L,  $n=9$ . Preliminary data indicate that while the inclusion of 10  $\mu$ M SP in the perfusate appears to have no significant impact ( $n=3$ ), infusion of 10 nM SP produces an approximately two-fold attenuation of basal extracellular DA ( $n=3$ ), consistent with the increase in striatal DA release observed *in vivo* by Gygi et al. (1993) following local application of the NK<sub>1</sub> receptor blocker CP-96345. Lower perfusate concentrations of the peptide (1 nM) were not found to affect basal DA efflux ( $n=3$ ).

The data suggest that the neuroactive peptide SP may function, in part, to inhibit striatal DA release *in vivo*.

## 39.4

MUSCARINIC ENHANCEMENT OF NMDA-INDUCED ADENOSINE RELEASE IN RAT CORTICAL SLICES IN VITRO. **K. Semba\* and T.D. White**. Depts. of Anat. & Neurobiol. and Pharmacol., Dalhousie Univ., Halifax, N.S. B3H 4H7 Canada.

Acetylcholine (ACh) facilitates neuronal responses to sensory stimulation in the cortex, and is thought to be important in cortical EEG activation. Adenosine is a neuromodulator released in response to increased metabolism and may have sleep-promoting functions by providing inhibitory tone to neurons with a role in behavioural state regulation. In this study we examined the effects of carbachol on NMDA-induced adenosine release in adult rat cortical slices *in vitro*. Carbachol (up to 300  $\mu$ M) alone did not affect basal release of adenosine. Carbachol (100  $\mu$ M), however, induced a  $253 \pm 47\%$  increase in NMDA (20  $\mu$ M)-induced adenosine release in the presence of  $Mg^{2+}$ . In the absence of  $Mg^{2+}$  carbachol induced less of an increase ( $60 \pm 18\%$ ). Atropine (1.5  $\mu$ M) reduced, by  $59 \pm 4\%$ , the facilitatory effects of carbachol on NMDA-evoked adenosine release. Similarly, 4-DAMP (1  $\mu$ M) and pirenzepine (1  $\mu$ M) reduced the carbachol effects by  $69 \pm 7\%$  and  $47 \pm 7\%$ , respectively. An M1-selective dose of pirenzepine (50 nM) did not appear to block carbachol's action on NMDA-evoked adenosine release. Carbachol did not affect AMPA-induced adenosine release. These results suggest that ACh does not affect basal adenosine release but enhances NMDA receptor-mediated evoked adenosine release through M3 and, possibly, M1 receptors in the cortex. The facilitatory effects of ACh on evoked adenosine release may have a role in regulating the response of cortical neurons to stimulation. Supported by the MRC of Canada and The Scottish Rite Charitable Foundation.

## 39.5

**DIFFERENTIAL EFFECT OF HALOPERIDOL ON RELEASE OF NEUROTENSIN IN EXTRAPYRAMIDAL AND LIMBIC SYSTEM.** W. Huang, G. R. Hanson\*. Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT 84112.

The effect of the antipsychotic drug haloperidol on extracellular neurotensin-like immunoreactivity (NTLI) was investigated by microdialysis and compared with the time-dependent response of tissue NTLI content in brain structures containing dopamine nerve cell bodies and terminals. Acute administration of haloperidol (1 mg/Kg) increased the extracellular NTLI levels in nucleus accumbens, but decreased it in the striatum. The same treatment increased the tissue content of NTLI in both the nucleus accumbens core and striatum within 24 hours after the injection. Interestingly, although the NTLI concentration in the substantia nigra was not altered by the haloperidol treatment, NTLI levels did decrease significantly in ventral tegmental area. These findings suggest that neurotensin systems associated with nigrostriatal and mesolimbic dopamine pathways do not respond homogeneously to haloperidol. In addition, changes in the release of neurotensin may contribute to altered striatal and accumbens NTLI contents induced by haloperidol treatment, but other factors, such as variation in synthesis also likely influence these changes. Differential effects of haloperidol on neurotensin release might be due to regional differences in dopamine receptor subtypes expressed by the neurotensin-containing neurons. (Supported by NIDA grant # DA 09407).

## 39.7

**IN VIVO MODULATION OF STRIATAL AND NIGRAL GABA EFFLUX BY D1 AND GLUTAMATE RECEPTOR LIGANDS.** A.M. Reilly\*, L.M. Byrnes, & J.P. Bruno. Dept. of Psychology and Neuroscience Program, Ohio State University, Columbus, OH 43210

The modulation of striatonigral GABA efflux via D1 and glutamate receptor ligands was examined using *in vivo* microdialysis in awake rats. Intrastriatal administration of the glutamate agonists AMPA (100  $\mu$ M) and kainate (100  $\mu$ M) both increased striatal GABA efflux (60-90% and 200-250%, respectively); however, only intrastriatal kainate administration led to a concomitant increase in GABA efflux in the substantia nigra. Intrastriatal administration of the full D1 agonist SKF 81297 yielded a dose-dependent bidirectional effect; 10  $\mu$ M decreased striatal GABA efflux (25-50%), while 100  $\mu$ M increased striatal GABA levels (100-275%). Both of these effects were blocked by local perfusion of the D1 antagonist SCH 23390 (10  $\mu$ M). Like AMPA, intrastriatal administration of either dose of SKF 81297 had no systematic effect on GABA efflux in nigra. On the other hand, intranigral administration of either kainate (100  $\mu$ M) or SKF 81297 (100  $\mu$ M) increased GABA efflux in nigra. These results illustrate the complex modulation of striatonigral GABA release *in vivo*, and suggest a possible dissociation between the regulation of GABA release in the striatum and in the substantia nigra.

We will also present data on the D1- and glutamate-receptor modulation of striatal and nigral GABA efflux in animals depleted of striatal DA at various stages of development.

## 39.9

**GABA AUGMENTS BASAL AND ELECTRICALLY-STIMULATED <sup>3</sup>H-NOREPINEPHRINE RELEASE IN HYPOTHALAMIC, PREOPTIC AND CORTICAL SLICES OF FEMALE RATS.** J.M. Fiber\* and A.M. Etgen. Dept. Neurosci., Albert Einstein Coll. Med., Bronx, NY 10461.

The anatomical delineations of the preoptic area (POA) and hypothalamus (HYP) have been well established; however, the neurochemical circuitry of these regions has been less studied. Using superfusion of 350  $\mu$ m brain slices of ovariectomized female rats, we have shown that 100  $\mu$ M GABA enhances the basal release of <sup>3</sup>H-norepinephrine (NE) in the POA, HYP and frontal cortex (n=9-10, p < .01). This effect is partially Ca<sup>++</sup> dependent. Females treated with estrogen and progesterone in doses known to induce sexual receptivity show greater GABA-enhanced NE release in the HYP than vehicle-treated controls (n=5, p < .05).

GABA also augments evoked <sup>3</sup>H-NE release when HYP, MPOA and cortex slices are stimulated with 72 pulses of 3Hz, 18mA. Slices were stimulated once (S1), then superfused with vehicle or 100  $\mu$ M GABA and simultaneously stimulated a second time (S2). S2/S1 ratios were greater in slices superfused with GABA (n=7-14, p < .001). The duration of <sup>3</sup>H-NE release during S2 was also greater in GABA-treated slices (p < .01). GABA augmentation of electrically-stimulated <sup>3</sup>H-NE release in the POA and HYP is mediated through GABA<sub>A</sub> receptors as evidenced by its blockade by 10  $\mu$ M bicuculline, but not by 200  $\mu$ M 2-OH-saclofen (n=5-10, p < .05). GABAergic influence on noradrenergic transmission within the POA and HYP may play a role in the regulation of gonadotropin release and reproductive behavior.

## 39.6

**EFFECT OF DOPAMINERGIC AGONISTS ON LOCOMOTOR ACTIVITY AND STRIATAL GABA RELEASE: IN VIVO MICRODIALYSIS IN FREELY MOVING RATS.** I. Shim\*, D. Wirtshafter and J.I. Javald. Department of Psychiatry and Psychology, University of Illinois at Chicago, Chicago, IL 60612.

The majority of neurons in the striatum use gamma-aminobutyric acid (GABA), the major inhibitory transmitter in the mammalian brain. Several studies indicate that dopamine containing terminals within the striatum contact GABAergic neurons, and thus striatal GABA release is likely to be under dopaminergic control. These dopamine-GABA interactions seem to be important for the control of striatal-related motor behaviors. In the present studies, we examined the effect of dopaminergic drugs on locomotor activity and extracellular concentrations of GABA using *in vivo* microdialysis in the striatum of freely moving rats. When high potassium (100 mM) was included in the perfusion CSF, extracellular GABA levels were increased 300% over basal GABA levels. Injecting rats with D<sub>1</sub> agonists, quinpirole and bromocriptine, decreased striatal GABA release and increased activity. Pretreatment with raclopride blocked quinpirole-induced locomotor activity and decreases in striatal GABA output. These results suggest that stimulation of D<sub>1</sub> receptors inhibits GABAergic transmission in the striatum, and appears to be important in mediating locomotor activity.

## 39.8

**SHORT-TERM AND LONG-TERM EFFECTS OF 6-HYDROXYDOPAMINE ON DOPAMINERGIC INHIBITION OF GABA RELEASE IN NEOSTRIATUM.** L. G. Harsing, Jr.\* and M. J. Zigmond. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Previous studies have indicated that severe loss of striatal dopamine (DA) is needed to detect deficits in neostriatal functions and that restoration of impaired dopaminergic influences develops even after large lesions. Since GABAergic neurons are known to be the major targets for DA in neostriatum, we examined the changes in dopaminergic inhibition of striatal GABA release after lesions produced by 6-hydroxydopamine (6-OHDA). Rats were injected with 6-OHDA (25-100  $\mu$ g, icv.) and striatal slices were prepared 3 days or 3 weeks later. The slices were loaded with [<sup>3</sup>H]GABA and superfused with Krebs buffer containing aminooxyacetic acid and nipecotic acid. [<sup>3</sup>H]GABA overflow was then measured during electrical field stimulation (8 Hz, 3 min). Tissue levels of DA, assessed by HPLC-EC, provided a measure of dopaminergic innervation. In nonlesioned striatum, a 2-fold increase was observed in [<sup>3</sup>H]GABA overflow in response to the D<sub>2</sub> receptor antagonist sulpiride (10  $\mu$ M), an index of the inhibitory influence of endogenous DA. Three days after 6-OHDA, this effect of sulpiride remained at control levels as long as the loss of DA terminals did not exceed 60%. Three weeks after 6-OHDA injection, the effect of sulpiride on [<sup>3</sup>H]GABA overflow had returned to control even in slices with a 90% loss of DA terminals. These results suggest the existence of compensatory mechanisms which maintain dopaminergic control over GABA transmission even after extensive destruction of DA terminals. (Supported by USPHS grant NS19608 and a Fogarty International Center fellowship NS05270).

## 39.10

**CHOLECYSTOKININ REDUCES EVOKED DOPAMINE OVERFLOW IN THE STRIATUM: AN IN VIVO VOLTAMMETRIC STUDY**

T. Reum\*, R. Morgenstern, A. Marburger and D. Schönfuß. Inst. of Pharmacology and Toxicology, Medical Faculty (Charité), Humboldt-University at Berlin, D-10098 Berlin, Germany

Cholecystokinin (CCK) is capable of modulating the dopaminergic transmission in the striatum. It has been shown that CCK decreases the electrically evoked striatal release of dopamine (DA) *in vitro* (Rakovska, Neurosci. Lett. 195: 151-154). In order to investigate the influence of CCK under *in vivo* conditions an electrical stimulus (2 mA, 200  $\mu$ sec, 100 pulses, 100 Hz) was applied to the medial forebrain bundle (MFB) every five minutes and 100 nl CCK-8s solution (10<sup>-3</sup> M-10<sup>-6</sup> M) was ejected once into the striatum 250  $\mu$ m away from a calibrated carbon fibre microelectrode. Using amperometry (AMU 130, Tacussel) a potential of +400 mV was applied vs. Ag/AgCl and the oxidation current was recorded continuously. The evoked responses after MFB stimulation, reflecting changes of extracellular DA, were recorded before and up to 120 min after CCK ejection and were analyzed for the maximum overflow and for the rate of DA elimination.

CCK diminished the maximum DA overflow dose dependently with a 50% decrease after 10<sup>-3</sup> M and a 15% reduction after 10<sup>-6</sup> M vs. the vehicle-treated control group. This effect was observed immediately after CCK application and remained stable for the whole time of recording. The rate of extracellular DA elimination was not influenced by either concentration of CCK.

These findings indicate that CCK modulates the DA release in the striatum, which is triggered by electrical stimulation of DAergic fibres. Due to the unchanged elimination rate an altered function of the presynaptic DA transporter by CCK seems to be improbable.

**DISTINCT PHARMACOLOGICAL PROFILES OF TWO CCK-B AGONISTS: FURTHER EVIDENCE OF RAT CCK-B RECEPTOR SUBSITES.** L. Léna, Y. Dauge, B.P. Roques and C. Durieux. Département de Pharmacochimie Moléculaire et Structurale, U266 INSERM - URA D1500 CNRS, UFR des Sciences Pharmaceutiques et Biologiques, 75270 Paris Cedex 06.

Previous binding studies have suggested the existence of two affinity states for rat CCK-B receptor. One study, using BC 197 and BC 264, two highly selective CCK-B agonists, has shown that BC 197 is selective for one subsite, B<sub>1</sub> and that BC 264 has the same affinity for the two subsites, B<sub>1</sub> and B<sub>2</sub>. Therefore, the possible involvement of CCK-B subsites in the modulation of endogenous dopamine (DA) release from slices of the anterior part of nucleus accumbens was investigated with these two agonists in order to associate a functional response with activation of each subsite. The selective B<sub>1</sub> agonist BC 197 produced a dose-dependent increase (48%) of 35 mM K<sup>+</sup>-stimulated DA release. In contrast, at a low concentration (20 nM), BC 264 inhibited the potassium-evoked DA release (29%), whereas at a higher concentration (1 μM), it stimulated the DA release (43%). These two opposing effects were suppressed by the CCK-B antagonist PD-134,308 but not by the CCK-A antagonist L-364,718 and were not prevented by tetrodotoxin, a sodium channel blocker. Moreover, BC 264 at 20 nM, in the presence of PD-134,308 at a concentration which would block the B<sub>2</sub> subsites (0.1 nM), increased the evoked DA release (53%). Furthermore, after stereotaxic injection in the anterior nucleus accumbens, BC 264 and BC 197 induced distinct behavioral responses in the Y maze test. All together, these results support further the existence of distinct CCK-B subsites and suggest that, in the anterior nucleus accumbens, their stimulation mediates different effects.

## 39.13

**SYNERGISTIC INTERACTION BETWEEN AN ADENOSINE ANTAGONIST AND A D1 DOPAMINE AGONIST ON ROTATIONAL BEHAVIOR AND STRIATAL FOS INDUCTION IN 6-HYDROXYDOPAMINE LESIONED RATS.** A.E. Pollack\* and J.S. Fink. Molecular Neurobiology Laboratory, Mass. General Hospital and Dept. of Neurology, Harvard Medical School, Boston, MA 02114; \*Dept. of Psychology, Brown University, Providence, RI 02912

In rats depleted of forebrain dopamine coadministration of D1 and D2 dopamine (DA) agonists synergistically increases motor behavior and induces Fos-like immunoreactivity (Fos-Li) in the dorsolateral striatum. Motor activation produced by a D1 DA agonist in DA-depleted rats is also enhanced by adenosine antagonists, but the anatomical basis of adenosine-D1 DA interaction has not been clearly demonstrated. In this study, we sought to (1) determine whether administration of an adenosine antagonist, like a D2 DA agonist, would enhance Fos-Li activation following treatment with a D1 DA agonist, and (2) use the regional pattern of striatal Fos-Li activation to gain insight into the anatomical basis of adenosine antagonist-D1 DA agonist interactions. In rats with unilateral 6-hydroxydopamine (6-OHDA) lesions coadministration of the adenosine antagonist 3,7-dimethyl-1-propargylxanthine (DMPX) (10 mg/kg) and the D1 DA agonist SKF38393 (0.5 mg/kg) synergistically enhanced contralateral rotation and induced Fos-Li expression in the ipsilateral striatum compared to 6-OHDA treated with either drug alone. However, the pattern of striatal Fos-Li activation following treatment of 6-OHDA rats with SKF38393 + DMPX was different from that produced following coadministration of D1 and D2 DA agonists (SKF38393: 0.5 mg/kg + quinpirole: 0.05 mg/kg). These data are consistent with a functional interaction between D1 dopaminergic and adenosinergic receptors in the striatum. However, these data suggest that activation of different subsets of striatal neurons appears to underlie the behavioral synergy observed following adenosine antagonist-D1 DA agonist and D1-D2 DA agonist treatment. ## 39.15

**D-AMPHETAMINE AND RESERPINE MODULATE KYNURENIC ACID LEVELS IN THE RAT BRAIN IN VIVO.** A. Rassoulpour, H.-Q. Wu, B. Poeggeler\* and R. Schwarcz. Maryland Psychiatric Research Center, Baltimore, MD 21228.

Interactions between excitatory amino acids and monoamines play important roles in brain physiology and pathology. We have therefore explored the effects of two classic monoaminergic agents, D-amphetamine (Amph) and reserpine (Res) on the levels of the cerebral metabolite and broad spectrum excitatory amino acid receptor antagonist kynurenic acid (KYNA) in the rat brain. The first set of studies was designed to examine Amph and Res effects on extracellular KYNA levels using hippocampal microdialysis in unanesthetized rats. I.p. Amph caused a dose-dependent decrease in KYNA levels, reaching a nadir of 70% of control values 1 h after application of 5 mg/kg of the drug. In contrast, Res (10 mg/kg, i.p.) caused a substantial increase in extracellular KYNA levels, reaching approximately 300% of baseline values by 6 h and remaining elevated for at least another 12 h. Ex vivo experiments confirmed the results from the microdialysis studies. Thus, 5 mg/kg Amph (i.p.) caused a  $27.0 \pm 3.9\%$  (SEM) decrease in hippocampal KYNA levels after 1 h ( $N=14$ ;  $P < 0.05$ ) whereas 10 mg/kg Res (i.p.) resulted in a  $87.4 \pm 8.6\%$  KYNA increase by 6 h ( $N=10$ ;  $P < 0.05$ ). No changes in the levels of KYNA's bioprecursor kynurenine were found in these tissue specimens. Quantitatively very similar drug-induced changes were observed in several brain regions but not in the liver. These data suggest that endogenous monoamines modulate KYNA production in the brain.

## 39.12

**ELECTRICAL STIMULATION OF THE AMYGDALA EVOKES FREQUENCY-DEPENDENT CHANGES IN DOPAMINE EFFLUX IN THE RAT NUCLEUS ACCUMBENS.** C.D. Blaha\*, S.B. Floresco, C.R. Yang and A.G. Phillips. Departments of Psychology and Psychiatry, University of British Columbia, Vancouver, B.C., V6T 1Z4.

Interactions between the basolateral nucleus of the amygdala (BLA) and ventral striatal dopamine (DA) neurons have been implicated in both rewarding and fear-mediated behaviors. The present study assessed the role of BLA modulation of DA efflux in the nucleus accumbens (NAc) of urethane-anesthetized rats using *in vivo* chronoamperometry (30s sample rate) with searate-graphite paste electrodes. A concentric bipolar stimulating electrode positioned in the BLA was used to deliver monophasic square-pulse electrical stimulation (800 μA, 300 single pulses). Low frequency stimulation of the BLA (3Hz, 100 s duration), stimulating firing patterns observed during fear conditioning paradigms, increased the DA basal signal in the NAc by 25% (0.5 s after stim.), followed by a decrease of 30% (3 min after stim.), with recovery to baseline levels within 5 min. Higher frequency single-pulse stimulation, stimulating reward sensitive BLA firing patterns (e.g. 20 Hz, 15 s duration), resulted in an initial increase (35%, 0.5 s after stim.), then a decrease (30%, 3 min after stim.), followed by a prolonged increase ( $>100\%$ , 15 min after stim.) in the DA signal. Burst stimulation (100 Hz burst, 5 pulses/burst, 1 s inter-burst interval, 60 s duration) resulted in a pattern of DA efflux similar to 20 Hz stimulation but without exhibiting the prolonged increase component. Co-infusions of the AMPA and NMDA glutamate receptor antagonists DNQX (1 μg) and APV (1 μg), respectively, into the NAc, but not the VTA, abolished the increase in DA efflux following burst-stimulation of the BLA. Additional experiments examining the role that metabotropic glutamate receptors play in mediating these stimulation-evoked effects in NAc DA efflux will be presented. Supported by MRC, Canada.

## 39.14

**NALTREXONE ATTENUATES ACUTE AMPHETAMINE-INDUCED REARING AND BLOCKS ITS SENSITIZATION BY REPEATED AMPHETAMINE.** M. Balcells-Olivero\* and P. Vezina. Department of Pharmacological/Physiological Sciences and Department of Psychiatry, The University of Chicago, Chicago, IL 60637.

The effect of opiate receptor blockade on the horizontal locomotion and rearing produced by acute and repeated injections of amphetamine was investigated. Rats in different groups were preexposed to seven injections (one injection every other day) of amphetamine (1.5 mg/kg, i.p.) or saline each preceded by an injection of naltrexone (0, 1 or 5 mg/kg, i.p.). Soon (early withdrawal) and again long (late withdrawal) after the last preexposure injection, all animals were injected with amphetamine (0.75 mg/kg, i.p.) in the absence of naltrexone (test for sensitization). Naltrexone, at doses producing no behavioral effects of their own, acutely reduced the increased rearing produced by amphetamine but had no effect on the increased horizontal locomotion produced by this drug. Animals that received naltrexone prior to amphetamine during preexposure showed no evidence of sensitized rearing on either the early or late withdrawal tests, indicating that naltrexone blocked sensitization of this response to amphetamine. These animals showed sensitized horizontal locomotor responding on the early withdrawal test but less so on the late withdrawal test. These results suggest an important role for dopamine-opioid interactions not only in the production of acute locomotor responding to psychomotor stimulants but also in the sensitization of these responses when these drugs are administered repeatedly. Supported by a grant to P.V. from The Brain Research Foundation.

## 39.16

**DIFFERENTIAL REGULATION OF GLUTAMATE AND NORADRENALINE RELEASE IN THE BED NUCLEUS OF STRIA TERMINALIS: IN VIVO MICRODIALYSIS STUDIES.** K. Gysling\*, M.I. Forray and G. Bustos. Lab. Biochemical Pharmacology, Dept of Cell and Molecular Biology, Faculty of Biological Sciences, Catholic University of Chile, Santiago, CHILE.

The purpose of this work was to study the regulation of noradrenaline (NA) and glutamate (L-GLU) release in the ventral bed nucleus of stria terminalis (vBNST), the area of the brain with the highest concentration of NA nerve terminals. There is evidence indicating that L-GLU afferent projections to the vBNST originate in part from the subiculum. Microdialysis probes were stereotactically implanted in the vBNST of anesthetized rats and perfused at a rate of 2 μl/min with artificial CSF. NA and L-GLU levels in each sample were measured by HPLC-EC and HPLC coupled to fluorometric detection respectively.

Basal and K<sup>+</sup> evoked release of NA and L-GLU were studied, under the same conditions, and several differences were observed. First, NA was released with lower K<sup>+</sup> concentration than L-GLU. Second, NA levels increased rapidly with K<sup>+</sup> stimulation, but decreased to basal levels even though high K<sup>+</sup> was still present. Instead, L-GLU release is maintained throughout the stimulation period. Third, NA but not L-GLU basal levels were decreased with perfusion with TTX (10-50 μM).

These results indicate that NA but not L-GLU release in the vBNST is under tonic control. They also support a differential regulation of NA and L-GLU extracellular levels in vBNST. (Supported by grants FONDECYT N° 2950010 to M.I.F., N° 1930686 and N° 1960482 to K.G.)

## 39.17

SYNAPTIC INTERACTION BETWEEN CRF-IMMUNOREACTIVE NEURONS AND FIBER TERMINALS WITH VIP AND PACAP IMMUNOREACTIVITY IN THE LATERAL DIVISION OF THE BED NUCLEUS OF STRIA TERMINALS. T. KOZICZ<sup>1</sup>, A. ARIMURA<sup>1</sup>, A. GERRALL<sup>2</sup>\*, <sup>1</sup>U.S.-Japan Biomed. Res. Labs., Tulane University Hebert Center, Belle Chasse, LA 70037; <sup>2</sup>Psychology Dept., Tulane Univ., New Orleans, LA, 70118.

The limbic-hypothalamic-pituitary-adrenal system plays an important role in regulation of stress responses. The BNSTL was suggested as a relay nucleus between amygdala (sensory input to BNSTL) and paraventricular, parabrachial, and dorsal vagal nuclei. There are many corticotropin releasing factor (CRF) immunoreactive (ir) neurons in the BNSTL. These cells might be involved in a central response to stress which affects hypothalamic and brain stem neuronal activities. The BNSTL also receives a dense vasoactive intestinal polypeptide (VIP) and pituitary-adenylate-cyclase-activating-polypeptide (PACAP) innervation, probably from amygdala through stria terminalis.

Based on our light microscopic findings, we hypothesized synaptic connections between CRF structures and the fiber terminals of VIP and PACAP neurons. To prove the hypothesis, we performed double-label immunocytochemical study with an electron-microscope. We found synaptic connections between CRF ir cell bodies and VIP and PACAP ir terminals. We also found synapses between VIP or PACAP ir fibers and CRF ir dendrites.

The VIP and PACAP afferents onto CRF neurons in BNSTL could modulate the activity of CRF neurons during stress in animals depending on different sensory stimuli. Further electrophysiological studies will be needed to clearly understand the functional aspects of these synaptic interactions.

## NEUROTRANSMITTER INTERACTIONS III

## 40.1

MODULATION OF EXCITATORY SYNAPSES BY ENDOGENOUS ADENOSINE RELEASED FROM SINGLE HIPPOCAMPAL PYRAMIDAL NEURONS. J.M. Brundage<sup>\*</sup> and T.V. Dunwiddie, Dept. of Pharmacology, Univ of Colorado Health Sci Center, and Veterans Admin Medical Research Service, Denver, CO 80262.

Adenosine is a potent neuromodulator in the central nervous system, but the mechanisms that regulate the concentration of extracellular adenosine remain unclear. To determine whether neurons can modulate their synaptic inputs through the release of adenosine, we increased the intracellular concentration of adenosine in individual CA1 pyramidal neurons in rat hippocampal slices. We recorded excitatory postsynaptic currents (EPSCs) from pyramidal neurons using the whole-cell voltage-clamp technique, and "loaded" the neurons with adenosine by including adenosine in the electrode filling solution. Loading cells with adenosine inhibited EPSCs by increasing the extracellular adenosine concentration at presynaptic A1 receptors on the excitatory nerve terminals. In order to determine whether a nucleoside transporter was responsible for the adenosine release, we included both adenosine and uridine in the electrode filling solution. Uridine blocked the inhibition of the EPSCs, suggesting that adenosine is released by a saturable nucleoside transport system for which uridine is a competitive substrate. In order to determine whether the cell could produce enough adenosine on its own to modulate synaptic activity, we loaded neurons with the adenosine kinase inhibitor 5'-iodotubercidin. 5'-iodotubercidin increased the adenosine-mediated inhibition of EPSCs in a manner similar to adenosine. These results suggest that individual CA1 pyramidal neurons are capable of forming and releasing enough adenosine to modulate their own excitatory inputs. Supported by NS29173 and the VA Medical Research Service.

## 40.3

Protein kinase A-mediated enhancement of glycine response by alpha2-adrenoceptor activation in rat sacral dorsal commissural neuron. J. Nabekura<sup>\*</sup>, T. Xu and N. Akaike, Dept. Physiol., Kyushu Univ. Fac. Med., Fukuoka 812-82, Japan

The effect of noradrenaline (NA) on glycine response was investigated in neurons acutely dissociated from rat sacral dorsal commissural nucleus (SDCN) using nystatin perforated patch recording under voltage-clamp. NA potentiated the glycine-induced  $Cl^-$  current ( $I_{Gly}$ ) in a concentration-dependent manner ( $>10^{-9}M$ ) without changing the reversal potential of  $I_{Gly}$  nor affected the affinity of Gly to its receptor. Clonidine mimicked and yohimbine blocked NA action on  $I_{Gly}$ , indicating the  $\alpha_2$ -adrenoceptor mediated enhancement. Forskolin and IBMX + dibutyl cAMP suppressed the  $I_{Gly}$ . H-89 mimicked the effect of NA on  $I_{Gly}$ . However, NA failed to affect the  $I_{Gly}$  in the presence of these cAMP and PKA modulators, suggesting that cAMP and PKA were involved in the pathway. Phorbol potentiated  $I_{Gly}$ . NA further enhanced the  $I_{Gly}$  in the presence of the phorbol and chelerythrine, indicating that PKC is not involved in NA facilitatory action. Pertussis toxin (IAP) treatment for 8 hr blocked the NA facilitatory effect on  $I_{Gly}$ . In conclusion, the activation of  $\alpha_2$  adrenoceptors coupled with IAP-sensitive G protein inhibits adenylyl cyclase activity. The reduction of cAMP production decreases PKA activity, resulting in the potentiation of  $I_{Gly}$  in the SDCN neurons.

## 40.2

GLYCINE AND GABA AS INHIBITORY NEUROTRANSMITTERS IN RAT TRIGEMINAL MOTOR NUCLEUS. H.W. Yang, M.Y. Min, K. Appenteng and T.F.C. Batten (SPON: European Neuroscience Association), Dept. of Physiology and Cardiovascular Research, University of Leeds, Leeds LS2 9NQ, U.K.

The immunogold labelling and whole cell patch recording techniques were employed to investigate the different roles and possible interaction between GABA and glycine in rat trigeminal motor nucleus. In the morphological study, serial untrathin sections were cut, and the alternate sections incubated with antibodies to GABA, glycine and glutamate. Boutons immunoreactive (ir) for GABA, glycine and glutamate formed axo-somatic and axo-dendrites contacts onto motoneurons identified by retrograde transport of HRP following intramuscular injection into the masseter muscles. For 19 out of 34 GABA-ir boutons, their alternate serial sections incubated with anti-glycine also showed glycine-ir. Similarly 22 out of 32 glycine-ir boutons were also GABA-ir. In contrast boutons immunopositive for glutamate were not immunopositive for GABA nor glycine. Some glutamate-ir boutons received axo-axonic contacts with the presynaptic element being found to be GABA-ir but not glycine immunopositive.

In the electrophysiological study, bath application of CGP35348 or strychnine both resulted in an increase of mean amplitude of EPSPs (abolished by CNQX) evoked by stimulation of interneurons caudal to the motor nucleus. The increase in mean EPSP amplitude with CGP35348 was accompanied by an increase in the ratio of square of mean amplitude and its variance ( $M^2/\sigma^2$ ). No change of  $M^2/\sigma^2$  was seen, though there was an increase of the mean amplitude of EPSPs after application of strychnine. Furthermore, CGP35348 or baclofen, but not strychnine, could alter the failure rate of synaptic transmission. Taken together the results suggest 1) GABA and glycine act as inhibitory transmitters and they may colocalize within same boutons, 2) a presynaptic inhibition that is mediated by GABA via GABA<sub>B</sub> receptors but not glycine, in this system. (supported by the MRC)

## 40.4

MODULATION OF ACETYLCHOLINE RELEASE IN THALAMUS AND PONTINE RETICULAR FORMATION BY SEROTONIN IN THE RAT. D.D. Rasmussen<sup>\*</sup> and K. Semba, Departments of Physiology & Biophysics and Anatomy & Neurobiology, Dalhousie U., Halifax, N.S. Canada, B3H 4H7

Presynaptic inhibition of acetylcholine (ACh) release by serotonin (5-HT) could account for the activation of neurons in the pontine reticular formation (PRF) during REM sleep but not during wakefulness. To test this, ACh was collected simultaneously from the thalamus and the PRF using microdialysis probes. After 60 min stabilization period, ten 20 minute samples were collected and analyzed for ACh content. 5-HT ( $10 \mu M$ ) was delivered to either the thalamus or PRF by adding it to the perfusion solution beginning with the 5th sample.

Delivery of 5-HT to the PRF produced only a 28% increase in ACh release from the PRF (n=8). Delivery of 5-HT to the thalamus, on the other hand, produced an immediate large (150%) increase in ACh release from the thalamus (n=9). This increase was blocked when TTX ( $1 \mu M$ ) was applied with 5-HT (n=4). Administration of 5-HT to the thalamus also produced a delayed increase in high frequency cortical EEG activity.

These data suggest that, contrary to expectations, 5-HT does not block ACh release in either the PRF or thalamus and in fact facilitates ACh release in the thalamus. The receptor specificity responsible for these effects is yet to be determined.

Supported by MRC and the Scottish Rite Charitable Foundation of Canada.

## 40.5

NEUROPEPTIDE Y POTENTIATES  $\alpha_2$  - ADRENERGIC RECEPTOR-MEDIATED INHIBITION OF cAMP LEVELS IN A CATECHOLAMINERGIC CELL LINE. A. Lee, A. E. Wissekerke, and K. B. Lynch.<sup>\*</sup> Neuroscience Graduate Program and Dept. of Pharmacology, University of Virginia, Charlottesville, VA 22908.

Neuropeptide Y (NPY) is colocalized with norepinephrine in a subpopulation of central noradrenergic neurons. Although the functional significance of this colocalization remains unclear, NPY has been shown to modulate noradrenergic signaling mediated by  $\alpha_2$  - adrenergic receptors ( $\alpha_2$  - ARs). In this study, we determined whether such interactions between NPY and  $\alpha_2$  - ARs occurred in CATH.a cells, a catecholaminergic cell line. CATH.a cells were found to express high levels of NPY and its mRNA by immunocytochemistry and northern blot.  $\alpha_2$  - AR expression was confirmed by saturable, high affinity binding of the  $\alpha_2$  - AR-selective radioligand [<sup>3</sup>H]RX821002 ( $B_{max}$  =  $35 \pm 2.9$  fmol/mg,  $K_d$  =  $0.46 \pm 0.06$  nM,  $n=4$ ). In addition, mRNAs encoding the A and C-subtypes of  $\alpha_2$  - AR were detected in CATH.a cell extracts by northern blot. The  $\alpha_2$  - AR agonist UK14304 inhibited forskolin-stimulated cAMP production, an effect prevented by the  $\alpha_2$  - AR antagonist yohimbine. NPY (100 nM) alone had no effect on cAMP levels, but enhanced significantly the inhibition of cAMP levels mediated by  $\alpha_2$  - ARs ( $p<0.05$ ,  $n=5$ ). NPY (100 nM) administered with UK14304 (1  $\mu$ M) produced a  $50 \pm 4.3\%$  inhibition of forskolin-stimulated cAMP production as compared to  $29.4 \pm 2.7\%$  inhibition by UK14304 alone. NPY may act, in part, through the Y1 receptor subtype since the Y1 but not the Y2 receptor transcript was detected in northern blots of CATH.a cell mRNA. These results suggest that CATH.a cells may provide a useful system in which to study the neuromodulatory functions of NPY in relation to  $\alpha_2$  - AR signaling. (Supported by NIH grant F31 MH11074-01 and AHA grant 95011200).

## 40.7

FUNCTIONAL UNCOUPLING OF LINKED NEUROTRANSMITTER EFFECTS BY COMBINATORIAL CONVERGENCE. V. Brezina, I.V. Orekhova and K.R. Weiss.<sup>\*</sup> Dept. Physiol. & Biophys., Mt. Sinai School of Medicine, New York, NY.

In this work we consider some basic consequences of the structure of physiological signaling pathways. These pathways characteristically both diverge and converge: a single neurotransmitter has multiple effects in the same target cell, and multiple transmitters have the same effects. Divergence couples the effects of a transmitter so that they are produced together in a relatively fixed ratio. Different physiological circumstances may require a different ratio, however: the coupling must be made modifiable. How may this be achieved? We suggest that an elegant, general mechanism is provided by convergence. If two transmitters couple the effects in a different ratio, then combinations of the transmitters give the effects in all possible intermediate ratios. The coupled effects become functionally uncoupled. Moreover, each transmitter may become tuned to produce mainly just one of the effects.

We have analyzed how this mechanism operates in a well-understood simple invertebrate neuromuscular circuit. The ARC muscle of *Aplysia* is innervated by two motoneurons, B15 and B16, which release ACh to contract the muscle, but also different peptide cotransmitters that modulate the ACh-induced contractions. B15 releases the small cardioactive peptides (SCPs) and B16 the myomodulins (MMs). Both SCPs and MMs have three distinct effects on the muscle: they potentiate contractions by enhancing the Ca current, they depress contractions by activating a K current (these two effects together determine net contraction amplitude), and they accelerate relaxation of the contractions. The SCPs and MMs act equally in all these respects except on the K current: the MMs activate much larger K currents, and so are much stronger depressors, than the SCPs. By virtue of this single inequality in their convergence, the MMs and SCPs produce very different ratios of the ultimate functional effects on contraction amplitude and relaxation rate. However, these are still fixed ratios. Through modeling as well as experimentally, we show how SCP-MM combinations give all otherwise unobtainable intermediate ratios. Furthermore, in the presence of a low, fixed concentration of one modulator, one of the effects of the other modulator becomes particularly emphasized. These phenomena are likely to have direct behavioral significance in this system, as B15 and B16 fire differentially in different behaviors, exposing the muscle to different, and apparently appropriate, SCP-MM combinations. Supported by NIMH and the Whitehall Foundation.

## 40.6

TWO DIFFERENT SOMATOSTATIN RECEPTOR SUBTYPES MEDIATE OPPOSITE MODULATION OF AMPA-KA RESPONSES IN HYPOTHALAMIC NEURONS: PHARMACOLOGICAL AND MOLECULAR IDENTIFICATION.

C. Lanneau, A. Faivre-Bauman, C. Loudes, J. Rivier, C. Kordon, J. Epelbaum, and R. Gardette.<sup>\*</sup> INSERM U159, 75014 Paris and <sup>\*</sup>Salk Institute, San Diego

AMPA-KA mediated glutamate (Glu) responses in mouse fetal hypothalamic neurons in culture can either be increased or decreased by somatostatin (Gardette et al., Dev. Brain Res., 1995). In order to investigate whether this differential modulation depends upon activation of different somatostatin receptor subtypes, we have compared the effects of octreotide (OCT), a selective sst2 agonist, 24127515 compound (241), a selective sst1 agonist, and SRIF14 (SRIF), an agonist common to all subtypes, on AMPA-KA mediated Glu sensitivity, and characterized, by single cell RT-PCR, somatostatin receptors borne by these neurons.

Glu peak response was either decreased (64% of cells (18/28),  $-37 \pm 4\%$ ) or increased (25% of cells (7/28),  $+31 \pm 6\%$ ) by SRIF. It was constantly decreased by OCT (48% of cells (12/25),  $-19 \pm 3\%$ ) and increased by 241 (35% of cells (6/17),  $+47.8 \pm 17\%$ ). No significant difference was found between inhibitory responses to SRIF and OCT or between stimulatory responses to SRIF and 241, both in terms of cell percentage or Glu peak amplitude variations. Preliminary results obtained from 5 neurons processed for single cell RT-PCR analysis after whole cell clamp recordings show that both subtypes were expressed in 3 cells whereas one neuron expressed only sst1 and the last one only sst2.

These data strongly suggest that inhibitory and excitatory effects of SRIF on glutamate responses are respectively mediated by sst2 and sst1 receptor subtypes. Moreover, RT-PCR results support the hypothesis that a differential distribution of somatostatin receptor subtypes within hypothalamic neurons could account for the differential modulation by the neuropeptide.

## 40.8

EFFECT OF SULPIRIDE ON AMPHETAMINE-INDUCED CHANGES IN STRIATAL DOPAMINE AND BEHAVIOR.

J.N. Jaworski\*, J.S. Randall, D. Crippens, R.A. Gonzales, and P.K. Randall.<sup>\*</sup> Division of Pharmacology, University of Texas, Austin, TX, 78712.

Amphetamine (AMPH) administered to rats induces a complex range of stereotypical behaviors. AMPH also produces increases in extracellular dopamine (DA). While these stereotypic behaviors have been shown to be associated with the increased DAergic activity, the precise relationship between the two is unclear. Classical DA antagonists, e.g. haloperidol, block the behavioral response to AMPH, while other antagonists are weakly effective or enhance stereotypy. This study examined the effect of D2 antagonist sulpiride (SULP) (50 mg/kg sc) pretreatment on the biochemical and behavioral response to AMPH (0.5, 2.0, or 8.0 mg/kg ip) in male Sprague-Dawley rats. Extracellular DA in the striatum was monitored using *in vivo* microdialysis and HPLC-EC. Cage crossing and rearing were measured from videotapes, and stereotypic behavior was quantified using a rating scale technique. DAergic and behavioral time curves were analyzed using non-linear regression and residual F testing. AMPH enhanced extracellular DA and stereotypy scores in a dose dependent manner. SULP augmented the increase in DA induced by 0.5 and 2 mg/kg mainly by decreasing the rate of DA concentration fall off in the extracellular space ( $p<0.05$ ). Sulpiride also potentiated the amount of DA increased by 8 mg/kg AMPH, but did so by affecting the maximum concentration achieved (22 pg/ $\mu$ l vs. 8.5  $\mu$ l for vehicle,  $p<0.05$ ), not the onset or offset rates. In contrast, sulpiride enhanced the behavioral effect of AMPH at doses up to and including 2.0 mg/kg AMPH, but had no effect at higher doses. This work was supported by NIDA grant DA06201 and NIAAA grant AA08484.

## RECEPTOR MODULATION: UP- AND DOWN-REGULATION I

## 41.1

CHRONIC COCAINE ADMINISTRATION INCREASES MELANOCORTIN 4-RECEPTOR mRNA EXPRESSION IN RAT STRIATUM.

J.D. Alvaro<sup>1</sup>, M.L. Entwistle<sup>2</sup>, J.B. Tatoo<sup>2</sup>, and R.S. Duman<sup>1</sup>. <sup>1</sup>Laboratory of Molecular Psychiatry, Yale Univ. School of Med., New Haven, CT 06508, <sup>2</sup>Dept of Medicine, NEMC and Tufts Univ. School of Med., Boston, MA 02111.

Following our demonstration that exogenous opiates regulate central melanocortin 4-receptor (MC4-R) gene expression, we have examined the regulatory effects of cocaine. Whereas chronic morphine administration in rats down-regulates MC4-R mRNA expression in the neostriatum, chronic cocaine administration has the opposite effect. Rats were treated with either saline or 15 mg/kg cocaine (i.p) twice daily for 14 days, and levels of MC4-R mRNA were determined by RNase protection assay 3 hours following a final injection on day 15. We found that chronic cocaine administration increased levels of MC4-R mRNA in striatum more than 150% above control. This up-regulation did not persist 18 hrs following the final cocaine injection, nor was the regulation seen after 1, 3, or 7 days of drug administration. Preliminary results indicate that chronic cocaine significantly decreases hypothalamic levels of POMC, the precursor to the ACTH and MSH peptides that bind to and activate MC4-R. Examination of the effects of cocaine on MC4-R mRNA expression in other brain regions as well as on levels of melanocortin receptor binding are in progress. Altered MC4-R activation in the striatum may be one neuronal adaptation which contributes to the development of cocaine addiction. (Supported by DA08227 and MH44694.)

## 41.2

EFFECTS OF LONG-TERM METHAMPHETAMINE AND COCAINE TREATMENT ON NEUROKININ I (SUBSTANCE P) RECEPTORS AND PREPROTACHYKININ mRNA LEVELS IN THE STRIATUM AND NUCLEUS ACCUMBENS OF THE RAT BRAIN. M. Kraft\*, Y. Zhang, H. Mueller and J. A. Angulo. Hunter College and the Graduate School of the City University of New York, Department of Biological Sciences, NY NY 10021.

We have assessed the effect of chronic treatment with methamphetamine (METH) or cocaine on <sup>3</sup>H-substance P (SP) binding to neurokinin I (NK1) receptors. We also assessed preprotachykinin (PPT) mRNA expression from the same animals. Rats received either 4 mg/kg of methamphetamine or 15 mg/kg cocaine twice daily for 1, 3, 6 and 14 days. <sup>3</sup>H-SP binding levels decreased in the dorsomedial (10%) and ventralmedial (15%) aspects of the striatum at day 14. PPT mRNA levels increased gradually from days 1-14 in all areas of the neostriatum, with increases of up to two-fold at day 14. In contrast, <sup>3</sup>H-SP levels showed no changes in cocaine-treated animals although PPT mRNA levels increased significantly in the neostriatum (20-50%). The NMDA non-competitive receptor antagonist MK-801 attenuated the psychostimulant-induced increases in PPT mRNA levels but had no consistent effect on METH-induced decreases in NK1 receptor binding levels. Both methamphetamine and cocaine increase preprotachykinin mRNA levels but only methamphetamine modulates substance P receptor levels.

## 41.3

NEUROPEPTIDE Y Y1 AND Y2 RECEPTOR BINDING IN THE RAT BRAIN AFTER ANTISENSE OR MISSENSE OLIGODEOXYNUCLEOTIDE TREATMENT. R. T. F. Cheung\*, A. J. Stoessl, T. J. McDonald and D. F. Cechetto. Roberts Research Institute, University of Western Ontario, London Ontario, N6A 5K8 Canada.

The regional distribution of neuropeptide Y (NPY) Y1 and Y2 receptor binding in the brain was studied in untreated adult male Wistar rats and rats following treatment with an antisense oligodeoxynucleotide (D-oligo) specific for the NPY Y1 receptor gene or a missense D-oligo. The D-oligos were given into the left lateral ventricle (50 µg in 10 µl of saline every 12 h, 4 times) via an implanted 23-G guide cannula. The treated rats were decapitated 1-2 h after the last injection. Coronal brain sections (20 µm) at 0 and 3 mm Bregma levels were processed for *in situ* receptor binding autoradiography, using porcine [<sup>125</sup>I]-peptide YY (100 pM; 2200 Ci/mmol). Non-specific binding was determined in the presence of porcine NPY (1 µM), and Y2 sites were defined by occluding Y1 sites with porcine [Leu<sup>31</sup>,Pro<sup>34</sup>]-NPY (50 nM). A computer-assisted image analysis system was used to quantify the binding density in the frontoparietal cortex (PFC), caudate putamen, lateral septum, amygdaloid region, and dorsal hippocampus. The autoradiographic distribution of the binding in the untreated rats revealed predominantly Y1 binding in the PFC. The other areas had equal Y1 and Y2 binding or mainly Y2 binding. The antisense treatment significantly reduced the Y1 binding in the PFC but did not change the Y2 binding in any area. Missense treatment did not significantly affect Y1 or Y2 binding in any area. We conclude that the antisense D-oligo can selectively reduce receptors in areas of high regional density. (Supported by the Heart and Stroke Foundation of Ontario)

## 41.5

ETORPHINE-INDUCED CHANGES IN µ OPIOID RECEPTOR-IR IN THE CEREBRAL CORTEX. N.C. Brecha<sup>§</sup>\*, M. Melone<sup>°</sup>, A. Minelli<sup>°</sup>, C. Stermini<sup>§</sup>\*, B. Anton<sup>°</sup>, C. Evans<sup>°</sup>, and F. Conti<sup>°</sup>. Inst. Hum. Physiol<sup>°</sup>, Univ of Ancona, Ancona, Italy; Depts. of Neurobiol.<sup>§</sup> and Psych.<sup>°</sup>; UCLA, and CURE<sup>§</sup>, Los Angeles, CA, USA.

µ opioid receptors (MOR) are activated by alkaloids used for pain control and are involved in addiction and tolerance. We have studied MOR immunoreactivity (IR) in the first somatic sensory area (SI) of the rat neocortex and the effects of MOR agonists/antagonists using an antibody directed to the C-terminus of rat MOR. Adult rats received etorphine (0.1 mg/kg i.p.), an opioid receptor agonist, and euthanized 15, 30, and 60 min following drug injection. Other rats were injected with etorphine and naloxone, an opioid receptor antagonist, and sacrificed 30 min later.

In the SI cortex of non-treated animals, MOR-IR consisted of few lightly stained, nonpyramidal neurons in layers VI and II-III, and strong neuropilar staining in layers II-III and VI. In the SI cortex of etorphine-treated animals: i) at 15 min, MOR- immunoreactivity (IR) appeared slightly denser than in controls; ii) at 30 min, there was an increase in MOR-IR, both at cellular and neuropilar levels. MOR+ neurons were more numerous and more intensely stained than those from control animals. Their processes were shorter and were characterized by a pronounced "granular" appearance. MOR+ cells were all layers II-III and VI nonpyramidal neurons. At 60 min, changes were more pronounced than at 30 min, and the number of MOR+ cells was further increased. Cells were counted in the neocortex of the 4 groups of animals, and statistical analysis was performed using ANOVA and multiple comparisons test. The results show that the number of MOR+ neurons increases significantly as a function of time ( $p < 0.001$ ); and iii) naloxone abolished the effects of etorphine.

The present results demonstrate a rapid, agonist-induced, increase of the number and staining intensity of detectable MOR+ neurons and, given the rapid onset of the changes, they suggest that these effects may be due to MOR internalization. (Funded by EY, MURST, VA, DK, DA, and NATO)

## 41.7

RAPID BRADYKININ RECEPTOR UPREGULATION IN SKIN FIBROBLASTS IN ALZHEIMER'S DISEASE PROMPTED BY PROTEIN KINASE C (PKC) ACTIVATION. N.L. Baenziger\* and Y.-J.I. Jong. Department of Anatomy and Neurobiology, Washington University, St. Louis, MO 63110.

Hyperactivity of bradykinin (BK) receptor signal transduction pathways in Alzheimer's disease (AD) skin fibroblasts interfaces with a complex cast of molecular characters with primary pathophysiology in brain but aberrant behavior reflected at a systemic level.  $\tau$  protein Ser/Thr hyperphosphorylation lies downstream of BK receptor signal transduction; presenilin 1 and 2 (PS-1,2) cellular functions are still under study. In AD skin fibroblasts with PS-1 mutations A246E and L286V, PKC activation by phorbol ester (PMA) plus phosphoprotein phosphatase 2a inhibitor Calyculin A augmented, within 1 min, BK B<sub>2</sub> subtype receptors with K<sub>d</sub>'s 5 nM (intermediate) and 44 nM (L<sub>500</sub>) affinity, implicating Ser/Thr phosphorylation as the augmenting mechanism. Control fibroblasts did not show rapid augmentation. By immunoblotting after nonionic detergent solubilization and SDS-PAGE, AD B<sub>2</sub> receptors were a well-resolved doublet of M<sub>r</sub> 76-78 kDa and 80-82 kDa, also seen in human lung fibroblasts vulnerable to PKC-mediated upregulation but rarely observed in normal fibroblasts where an M<sub>r</sub> 76-78 kDa singlet was prevalent. Selective PKC-induced quantitative and qualitative changes in AD fibroblast BK B<sub>2</sub> receptors suggest the cellular role of presenilins may bear on not only intracellular trafficking functions postulated for these species but phosphorylation/dephosphorylation pathways which govern expression and activity of G-protein-coupled receptors over a very short time frame.

Supported by the Alzheimer's Association.

## 41.4

NEONATAL EXPOSURE TO ARGININE VASOPRESSIN ALTERS ADULT VASOPRESSIN V1a AND OXYTOCIN RECEPTOR mRNA EXPRESSION IN RAT BRAIN. C.S. Vaccari, Carter, C.S. and N.L. Ostrowski\*. NIMH, Bethesda, MD, 20892, and Dept. of Zool., Univ. MD, College Park, MD, 20742.

The possibility that neonatal exposure to vasopressin may play a role in regulating the expression of vasopressin (AVP) and/or oxytocin receptor (OTR) genes was investigated. Neonatal rats were treated for 7 days (1/day) with saline, arginine vasopressin, a selective V1a, or V2 receptor antagonist, or AVP in combination with the antagonists. AVP decreased rate of growth and neurological development during the seven days of treatment. Treated rats demonstrated perturbations in body weight indices as adults, confirming previous work (Boer et al., 1988). *In situ* hybridization experiments on brains of adult males demonstrated that neonatal treatments produced permanent changes in V1a and OTR messenger ribonucleic acid (mRNA) densities. In the lateral septum, the V1a receptor antagonist significantly increased V1a mRNA labeling, whereas AVP, alone, produced little change. Moreover, neonatal treatment with AVP decreased expression of OTR mRNA in the paraventricular nucleus (PVN) where both OT and AVP expressing neurons are located. These data demonstrate that 1) neonatal treatments that affect AVP receptors produce long-term changes in AVP and OTR receptor gene expression; 2) AVP may play a determining role in the regulation of V1a receptor mRNA levels in brain; and, 3) the PVN may be a possible site for interactions between the AVP and OT neuropeptide systems. Compounds were donated by Dr. M. Manning; plasmid DNA was prepared by Dr. S. Lolait; brains were sectioned by S. Leonard. Supported by NSF and NIMH.

## 41.6

INTRAVESICAL XYLENE CAUSES SUBSTANCE P RELEASE, UPREGULATION OF NK1 RECEPTORS AND INDUCTION OF NK1R mRNA IN RAT BLADDER. L. Kushner\*, M. Sherman, T. Singh, P.Y. Chiu, S. Tillem, S. Press, Y. Chen and R. Moldwin. Long Island Jewish Med. Cent., New Hyde Park, NY 11040

In order to explore the role of substance (SP) in bladder inflammation, we induced inflammation by intravesical instillation of xylene. Bladders of anesthetized adult female Sprague-Dawley rats were either catheterized (controls), instilled with 0.3 ml silicone oil (vehicle) or 0.3 ml 30% xylene in silicone oil (xylene) for 15 min. Evans Blue perfusion to determine plasma protein extravasation demonstrated significant differences for xylene-instilled (72.63 ± 12.37 ng Evans Blue/wet wt. tissue) compared to vehicle-instilled (27.39 ± 6.85,  $p < 0.01$ ) or control (14.43 ± 2.43,  $p < 0.001$ ) bladders. The SP content of xylene-treated bladders (1.57 ± 0.12 pg/mg protein) was reduced compared to control bladders (4.28 ± 0.89,  $p < 0.01$ ) as determined by RIA. Depletion of neuronal SP was confirmed immunohistochemically. High affinity, saturable, and monophasic specific binding of the NK1R selective agonist (9-sar,11-met(O<sub>2</sub>),[prolyl-3,4-H]-SP) to bladder membranes indicated an apparent single class of sites with a binding affinity (K<sub>d</sub>) of 0.20±0.05, 0.31±0.22 and 0.56±0.17 nM and a binding capacity (B<sub>max</sub>) of 29.55 ± 2.0, 23.5 ± 1.2 and 94.6 ± 3.9 fmol/mg protein for control, vehicle- and xylene-instilled bladders, respectively. Thus, NK1 receptors were three-fold higher in xylene-treated bladders. Transcripts encoding NK1R were transiently elevated by three-fold between 5 and 7 hrs following xylene instillation as determined by solution hybridization/nuclease protection normalized to the constitutive IB15 transcript. Intravesical xylene results in SP release from sensory neurons, plasma protein extravasation and upregulation of NK1 receptors as well as induction of NK1 receptor gene transcription, indicating a response to SP depletion consistent with neurogenic inflammation. (Supported by the Interstitial Cystitis Association and an LIJMC Faculty Research Award).

## 41.8

RAPID DESENSITIZATION OF SOMATOSTATIN INHIBITION OF CALCIUM CHANNEL CURRENT IN NG108-15 CELLS.

V. Beaumont, M. Hepworth, E.P. Kelly, J.L. Benovic & G. Henderson\*. Dept. of Pharmacology, University of Bristol, Bristol BS8 1TD, U.K. and Dept. of Pharmacology, Thomas Jefferson University, Philadelphia, PA 19107 USA.

Somatostatin inhibited the N-type calcium channel current in NG108-15 cells recorded using the whole cell or amphotericin-permeabilized patch techniques. However the inhibition of the calcium channel current was not sustained but decayed rapidly during continued exposure to the drug. For a supramaximal concentration of somatostatin (300nM) the inhibition desensitized by 53 ± 2% and was complete within 2.5min of drug application. In contrast the desensitization of the inhibition of the current by the δ-opioid agonist DPDPE (300nM) was much less (17 ± 7%) over the same time period. Both the rate of somatostatin desensitization and the degree of desensitization were concentration-dependent over the range 10 - 1000nM. The time course for recovery from desensitization was exponential with a t<sub>1/2</sub> of 2min.

The desensitization to somatostatin (300nM) was reduced by intracellular application of Zn (3-30µM) in a concentration-dependent manner. Zn has been proposed as a G-protein receptor kinase (GRK) inhibitor. In cells stably transfected with a dominant negative mutant of GRK2 the rate and degree of the rapid desensitization induced by somatostatin (300nM) was not reduced from that seen in wild type cells or in cells transfected with the plasmid alone. Supported by the MRC of the UK.

## 41.9

**MOLECULAR MECHANISMS OF THE DESENSITIZATION OF THE SOMATOSTATIN RECEPTOR SSTR2.** G. Singh and T. Reisine. Department of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

The somatostatin (SRIF) receptor SSTR2 mediates a number of the physiological actions of SRIF. A result of continuous stimulation of SSTR2 with agonist is desensitization. To investigate the mechanisms of SSTR2 desensitization, the splice variants of SSTR2, SSTR2A and SSTR2B, which differ only in their C-terminal amino acid sequences, and mutants of these receptors were expressed in CHO-K1 cells and tested for their coupling to adenylyl cyclase. Both SSTR2A and SSTR2B effectively mediated the inhibition of cAMP accumulation by SRIF. Pretreatment of CHO-K1 cells expressing the SSTR2 splice variants with SRIF (1  $\mu$ M) for 3 hr diminished the potency and effectiveness of SRIF to inhibit cAMP accumulation. A mutant of SSTR2B (SSTR2BT) truncated at amino acid 331, the point at which the splice variants diverge in amino acid sequence, coupled to adenylyl cyclase and desensitized following prolonged agonist pretreatment, indicating the region required for the desensitization of the receptor does not reside in the C-terminus of the receptor. Two serine residues in the third intracellular loop of SSTR2B were mutated individually to alanines to create the mutants (SSTR2B<sub>S244A</sub> and SSTR2B<sub>S245A</sub>). Both mutants coupled to adenylyl cyclase. Pretreatment of SSTR2B<sub>S244A</sub> with SRIF desensitized the receptor. In contrast, SSTR2B<sub>S245A</sub> was more resistant to desensitization. These findings suggest that phosphorylation of single amino acid in the third intracellular loop of SSTR2B may be critical for desensitization. Supported by MH45533 and MH48518.

## 41.11

**TESTOSTERONE INCREASES AMPA GluR 2/3 PROTEIN- AND GluR 2 mRNA LEVELS IN THE CA1 REGION OF THE HIPPOCAMPUS AND DECREASES NEURONAL DAMAGE DURING ISCHEMIA.** S. Diano, F. Naftolin\* and T.L. Horvath. Department of Ob/Gyn, Yale University, School of Medicine, New Haven CT, 06520.

We tested the hypothesis that the gonadal steroid-induced increase in GluR 2/3 protein levels in the hippocampus is induced by local action of testosterone and involves the regulation of GluR 2 mRNA. Furthermore, since glutamate-induced neuronal death of CA1 pyramidal cells during ischemia was associated with low levels of GluR 2 AMPA receptors, we hypothesized that testosterone upregulating GluR 2 in the CA1 region may increase the survival rate of pyramidal cells. **Experimental:** To verify the local effect of testosterone, male rats received testosterone-implants in the CA1 region of the hippocampus, and were sham-operated on the contralateral side. Seven days later, a group of animals were killed and the hippocampi were used for either immunocytochemical labeling of GluR 2/3 or Northern blot analysis for GluR 2 mRNA. Ischemia was induced in implanted animals by occlusions of the vertebral and carotid arteries. Immunocytochemical studies showed an increased intensity (120% as revealed by image analyzer) of GluR2/3 labeling in the CA1 pyramidal cells in particular in their dendrites in the vicinity of the testosterone implant but not around the sham implant. Northern blot analysis demonstrated that the increased receptor content corresponded with an increase (100%) in GluR2 mRNA levels in the CA1 region. Seven days after inducing ischemia, animals were killed, and the hippocampi were counterstained with cresyl violet. Ipsilateral to the testosterone implants, the number of surviving CA1 neurons were higher than that of the control, contralateral side. **Conclusions:** These results suggest that testosterone, acting locally, may decrease the vulnerability of CA1 pyramidal cells during ischemia, at least in part, by increasing the expression of the GluR 2 subunit of the AMPA receptors. (Supported by NIH grant HD 13587)

## 41.13

**REGULATION OF PITUITARY CORTICOTROPIN RELEASING HORMONE RECEPTOR mRNA BY GLUCOCORTICOID.** C. Rabadan-Diehl, A. Kiss and G. Aguilera\*. DEB, National Institute of Child Health and Human Development, NIH, Bethesda, MD 20892

The regulation of pituitary corticotropin releasing hormone receptors (CRH-R) by glucocorticoids was studied in the rat by CRH binding autoradiography and Northern blot and in situ hybridization of CRH-R mRNA after adrenalectomy (ADX) or glucocorticoid administration. CRH-R mRNA levels decreased by 48% of controls 18 hr after ADX but returned to basal levels by 4 and 6 days. Dexamethasone (DEX), 100  $\mu$ g, s.c. prevented the transient effect of ADX. In sham operated or intact rats, DEX increased CRH-R mRNA only after 6-day repeated injection, while decreasing POMC mRNA, POMC hnRNA and CRH binding. Daily injection of corticosterone (B), 2 mg, sc, to mimic stress levels, had no effect on POMC mRNA, POMC hnRNA, CRH-R mRNA or CRH binding. On the other hand, supraphysiological B doses (10 mg) for 6 days decreased POMC mRNA by 67%, POMC hnRNA by 58% and CRH binding by 35%, but had no effect on CRH-R mRNA levels. However, 2 to 4 hr after injection, DEX (10 to 100  $\mu$ g) or B (2 to 5 mg) decreased CRH-R mRNA by about 50%, indicating biphasic regulatory actions of glucocorticoids on CRH-R mRNA. The data indicates that regulation of pituitary CRH-R mRNA is complex, probably involving direct effects of glucocorticoids on mRNA transcription and stability, as well as indirect actions mediated by glucocorticoid dependent changes of hypothalamic regulators.

## 41.10

**DESENSITIZATION OF CANNABINOID-MEDIATED INHIBITION OF GLUTAMATERGIC SYNAPTIC TRANSMISSION BETWEEN CULTURED RAT HIPPOCAMPAL NEURONS.** M. Shen\*, S.A. Thayer. Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455.

We have shown previously that activation of cannabinoid receptors inhibits the presynaptic release of glutamate from cultured rat hippocampal neurons. Here we describe the effects of prolonged exposure to cannabimimetics on excitatory neurotransmission. Reducing the extracellular  $Mg^{2+}$  concentration to 0.1 mM elicited repetitive increases in intracellular  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$  spikes) that were recorded with indo-1-based microfluorimetry.  $[Ca^{2+}]_i$  spikes required glutamatergic synaptic transmission as indicated by pharmacological characterization. Win55212-2 (100 nM), a potent cannabinoid receptor agonist, completely blocked  $[Ca^{2+}]_i$  spiking. In the continued presence of Win55212-2,  $[Ca^{2+}]_i$  spiking resumed after approximately 1 hr, suggesting that the response had desensitized. The desensitization could be overcome by subsequent application of a high concentration (1  $\mu$ M) of the agonist. The selective cannabinoid receptor antagonist, SR141716 (300 nM), completely reversed the inhibition of  $[Ca^{2+}]_i$  spiking produced by 100 nM Win55212-2. In the neurons desensitized from a 2 hr exposure to 100 nM Win55212-2, 300 nM SR141716 precipitated a rebound increase in the frequency of  $[Ca^{2+}]_i$  spiking that exceeded control by 34%. The desensitization process should be considered in evaluating the abuse potential and the clinical utility of cannabimimetics. (Supported by the NIH and the NSF)

## 41.12

**NMDA receptor subtype 1a mRNA in the lumbar spinal cord of adult spinal rats in response to spinal transection and locomotor training** N.J.K. Tillakaratne\*, W.M. Walwyn, R.J. Monti, A.J. Tobin and V.R. Edgerton. Department of Physiological Science, UCLA, Los Angeles, CA 90095.

NMDA receptor activation induces alternating locomotor patterns in the spinal transected animal and plays an important role in spinal cord excitability following repeated conditioning stimuli. The NMDA receptor consists of several subunits, one of which is the NMDAR1, and this subunit exists in several isoforms. Little is known of the effect of spinal transection on the NMDAR1a isoform mRNA and how repeated locomotor patterns may alter the localization and level of this receptor RNA. We have evaluated the effect of transection of the spinal cord and of repeating specific motor patterns on the localization of the mRNA of NMDAR1a in the spinal cord. Adult female rats were transected at T6-8, allowed 7 days to recover and were then trained to step using a combination of modes of sensory stimulation to induce bipedal locomotion. The training protocol included alternating placement of the rear feet in plantarflexion, and light stimulation of the skin over the knee and hip joints, and was performed once daily for 10 min, 5 days a week for 10 weeks. Using non-radioactive in situ hybridization histochemistry we examined the changes in NMDAR1a mRNA in the lumbar spinal cord. Increased levels of mRNA were found in all laminae of the L4 segment of the lumbar spinal cord following spinal cord transection. This was further elevated following 10 weeks of step-training. Training did not alter NMDAR1a mRNA in age-matched intact rats. These results indicate that there is an activity dependent component of regulation of NMDAR1a mRNA in the lumbar spinal cord. Supported by grants to NKJT (NRSA, HD07416), AJT (NS 22256) and VRE (NS16333).

## 41.14

**GLUCOCORTICOIDS DOWN-REGULATE LEVELS OF CRF-R1 mRNA IN AtT-20 CELLS.** P.A. Iredale\* and R.S. Duman. Lab. of Molecular Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Glucocorticoids are known to be involved in a plethora of physiological responses via activation of discrete receptors which are translocated into the nucleus where they act as positive and negative transcriptional regulators. CRF receptors in the anterior pituitary represent one of the most extensively studied sites for negative feedback by adrenocortical glucocorticoid hormones, however the molecular mechanisms have yet to be elucidated. The present study examines the mechanism by which glucocorticoids regulate CRF-R1 expression in the pituitary cell line, AtT-20. Treatment of these cells with dexamethasone resulted in a concentration- and time-dependent inhibition of CRF-R1 mRNA that was significant by 1 hr and maximal after 4 hr. Levels of CRF-R1 mRNA then returned to control levels after 24 hr. Similar changes were observed when the cells were treated with corticosterone. The down-regulation of CRF-R1 mRNA was dependent on *de novo* protein synthesis as it was blocked by pre-treatment with cycloheximide. Furthermore, half-life studies with actinomycin D suggested that the observed decrease was not due to a change in CRF-R1 mRNA stability and therefore likely the result of a decrease in the rate of gene transcription. This hypothesis is currently being tested. POMC mRNA was also decreased following dexamethasone pre-treatment, however the time-course was much slower with a maximal decrease observed after 24 hr. These data suggest that glucocorticoid down-regulation of CRF-R1 mRNA is mediated by decreased gene transcription and that this effect involves the induction of a regulatory protein. (DA 08227 Program Project Grant).

## 41.15

**PHORBOL ESTERS DOWN-REGULATE  $\beta_1$ -ADRENERGIC RECEPTOR GENE TRANSCRIPTION IN RAT C6 GLIOMA CELLS.** Z. Li<sup>1</sup>, V. A. Vaidya<sup>1</sup>, L. R. Fitzgerald<sup>1</sup>, P. H. Fishman<sup>2</sup>, C. A. Machida<sup>3</sup>, R. S. Duman<sup>\*1</sup>. <sup>1</sup>Dept. Psychiatry, Yale Univ. Sch. Med., New Haven, CT 06508 and <sup>2</sup>Lab. Mol. Cel. Neurobiol., NINDS, NIH, Bethesda, MD 20892 and <sup>3</sup>Div. Neurosci., Oregon Regional Primate Res. Ctr., Beaverton, OR 97006

Protein kinase C (PKC) is known to have multiple effects on the  $\beta$ -AR-coupled cAMP system. We have investigated the mechanism by which PKC regulates the expression of  $\beta_1$ AR in rat C6 glioma cells. Treatment of cells with PMA, an activator of PKC, results in a down-regulation of both  $\beta_1$ AR binding sites and mRNA levels in a time- and concentration-dependent manner. Maximal loss (>50%) of  $\beta_1$ AR mRNA levels was observed after 2 h, preceding that of receptor binding sites which occurred by 24 h. An EC<sub>50</sub> of 15-20 nM PMA was observed for both processes. Pretreatment of the cells with exotoxin A, a protein synthesis inhibitor, had little effect on the PMA-mediated down-regulation of  $\beta_1$ AR mRNA, but slowed the loss of receptor binding sites. Exposure of the cells to PMA did not reduce the half life of  $\beta_1$ AR mRNA, which is ~1 h. In contrast, PMA treatment for 6 h significantly decreased the rate of  $\beta_1$ AR gene transcription as determined by reporter analysis. Treatment with PMA decreased reporter activity by 40-50% as observed with the promoter construct (-3351, -1) bp and with constructs shortened to (-348, -1), but no decrease was seen with constructs shorter than (-331, -1). Consistent with this observation, the construct (-484, -325), as well as mutant CRE or CCAAT reporter constructs which locate upstream of -348, are still responsive to PMA. Based on these results, we conclude that activation of PKC down-regulates  $\beta_1$ AR gene transcription via a small element in the promoter region located between -348 and -331. Studies are currently underway to identify this element. (Supported by DA 08227)

## 41.17

**ESTROUS CYCLICITY OF BRAIN ANGIOTENSIN II RECEPTORS** E.E. Nilsson and R.C. Speth\*. Dept. VCAPP Washington State Univ., Pullman, WA 99164-6520

Although angiotensin II (AII) is best known for its effects on blood pressure and fluid and electrolyte balance, it has also been shown to be a regulator of reproductive function (Phillips *et al.* Adv-Exp-Med-Biol. 1995, p. 357). To further explore the relationship between the brain renin-angiotensin system (RAS) and reproductive function, this study examined <sup>125</sup>I-sar<sup>1</sup>,ile<sup>8</sup> AII (<sup>125</sup>I-SI AII) binding in 24 different brain regions of the rat, at the 4 different stages of the estrous cycle. Mature, cycling Sprague-Dawley rats (n = 37) were sacrificed at 1600 hours on either proestrus (P), estrus (E), metestrus (M) or diestrus (D). The brains were frozen and coronally sectioned at 20 microns in a cryostat. The sections were incubated with 500 pM <sup>125</sup>I-SI AII, alone or in the presence of 10  $\mu$ M losartan, 10  $\mu$ M PD123177, or 3  $\mu$ M SI AII and subjected to autoradiography. Subsequent densitometric analysis of films then determined total, AT<sub>2</sub> receptor subtype, AT<sub>1</sub> receptor subtype, and nonspecific binding density respectively. Results of this study showed that in virtually all brain nuclei and the anterior pituitary, <sup>125</sup>I-SI AII binding to AT<sub>1</sub> and AT<sub>2</sub> receptors was lowest on the day of proestrus, indicating the lowest AII receptor density was on that day. <sup>125</sup>I-SI AII binding varied less on the remaining 3 days of the estrous cycle, however AT<sub>2</sub> receptor binding was lower on D than on E or P. These results suggest that female rat brain AII receptors undergo cyclic changes that correlate with the estrous cycle, confirming the linkage between the brain RAS and reproductive function.

## 41.19

**KNOCKDOWN OF THE ANGIOTENSIN TYPE-1 RECEPTOR BY ANTISENSE OLIGONUCLEOTIDES IN CELL CULTURE** T. Leshner, Y. Bao, D. Conklin, P. Hartig\* and S.P. Ho. CNS Diseases Research, DuPont Merck Research Laboratories, Wilmington, DE 19880.

Four phosphorothioate oligonucleotides targeted against the coding region of the angiotensin type-1 (AT<sub>1</sub>) receptor mRNA were tested in CHO cells stably transfected with the AT<sub>1</sub> receptor. Complexation with Lipofectin facilitated uptake of a fluorescein-labeled oligonucleotide by 400-fold over controls, (assayed by fluorescence activated cell sorting). The oligo was evenly distributed (fluorescence microscopy) in the cytoplasm but was most prominently visible in the nucleus. Knockdown of the AT<sub>1</sub> receptor was determined using a radioligand binding assay. Using oligonucleotide concentrations as low as 0.25  $\mu$ M, knockdown with the 4 sequences ranged from 55-75%. Sequences targeting the mRNA downstream of the start codon were more potent than the oligonucleotide at the ATG. Specificity of the antisense knockdown was demonstrated using mismatched sequences (3 mismatches) and reverse sequences.

2'-methoxyribonucleotide analogs of the above antisense sequences hybridize efficiently to the mRNA but do not promote RNase H mediated degradation of the RNA target. These analogs produced good knockdown when targeted at the ATG; however, the knockdown became progressively poorer when 2'-methoxyribonucleotide sequences were targeted against downstream coding regions. This data indicates that antisense knockdown through hybrid arrest is most effective when the oligonucleotide is targeted against the 5'-regions of the mRNA. These results also support the involvement of RNase H in antisense knockdown in this CHO cell line.

## 41.16

**MODULATION OF NEURONAL ANGIOTENSIN II TYPE 2 (AT<sub>2</sub>) RECEPTOR mRNA BY GROWTH FACTORS.** X.-C. Huang, U. Shenoy, C. Summers\*. Dept. of Physiology, Univ. of Florida, Gainesville, FL 32610.

The expression of neuronal AT<sub>2</sub> receptors demonstrates dramatic spatiotemporal changes before and after birth, suggesting a role for these sites in development. Our previous studies showed that stimulation of neuronal AT<sub>2</sub> receptors inhibited mitogen activated protein kinases, which are the key components of growth factor induced signal transduction pathways. Molecular cloning of the AT<sub>2</sub> receptor promoter region demonstrated the presence of potential growth factor regulatory sites, including AP-1 and IRS of PEPCK gene. The present study was undertaken to evaluate the effects of various growth factors on modulation of neuronal AT<sub>2</sub> receptor mRNA levels in neurons cultured from newborn rat hypothalamus and brainstem. Reverse transcriptase polymerase chain reaction (RT-PCR) analysis was employed to evaluate the changes in the mRNA level. The data indicate time-dependent modulation of AT<sub>2</sub> mRNA by growth factors. Incubation of neuronal cultures with nerve growth factor (50 ng/ml, 0 - 2h) increased steady state levels of AT<sub>2</sub> mRNA and this effect was mimicked by the phorbol ester, PMA(100 nM). However, incubation of cultured neurons with nerve growth factor (50 ng, 12-24h) or insulin (1670 nM, 0 - 24h) decreased AT<sub>2</sub> mRNA levels. Our results provide a link between changes in the growth factor milieu in the developing brain and AT<sub>2</sub> receptor levels. (Supported by NIH grant NS-19441)

**INHIBITION OF ANGIOTENSIN RECEPTOR (AT<sub>1</sub>) EXPRESSION IN NG108-15 CELLS TRANSFECTED WITH AT<sub>1</sub> RECEPTOR ANTISENSE IN AN ADENO-ASSOCIATED VIRAL VECTOR.** T. Zelles, D. Mohuczy and M.I. Phillips\*. Dept. of Physiology, Univ. of Florida, Gainesville, FL 32610.

We are using gene therapy for hypertension by inhibiting angiotensin II (AngII) receptor genes. The adeno-associated virus (AAV) is a potentially useful vector for non pathogenic delivery of genes into cells. Antisense inhibition is a specific and potentially therapeutic application of gene therapy.

We transfected NG108-15 cells with the AngII type 1 (AT<sub>1</sub>) receptor antisense vector pA9, constructed from pTR-UF, containing a recombinant AAV cassette. The cassette also contained a neomycin resistant gene and the transfected cells were selected by G418 in the medium. To investigate the effect of pA9 transfection on AngII receptor level we carried out <sup>125</sup>I-Sar<sup>1</sup>-Ile<sup>8</sup>AngII binding assay on the membranes of undifferentiated, 3 and 5 days differentiated (1.5 % DMSO/0.5 % FBS) NG108-15 cells. The numbers of AT<sub>1</sub> and AngII type 2 (AT<sub>2</sub>) receptors were determined using the AT<sub>1</sub> receptor selective antagonist losartan and the AT<sub>2</sub> receptor selective PD12319. Cell differentiation resulted in about a 70x increase in total AngII receptor number which was mainly due to the huge increase of the numbers of AT<sub>2</sub> receptors, reaching the plateau on day 5. AT<sub>1</sub> receptors reached their elevated level (7x) on day 3. Transfected cells had about a 40 % decrease in AT<sub>1</sub> receptor number in the undifferentiated, 3 and 5 days differentiated cells. Simultaneously, the AT<sub>2</sub> receptor number increased 2.5 times in the differentiated stages suggesting an interaction between the two AngII receptors during differentiation.

These results demonstrate that AT<sub>1</sub> receptor antisense DNA, transfected in an AAV cassette, significantly reduces AT<sub>1</sub> receptor binding through several cell passages. AngII receptor antisense delivery in AAV is useful to investigate the role of AngII receptors in neuronal differentiation and apoptosis. (NIH grant HL27334.)

## 41.20

**DISTRIBUTION OF BIOTIN-LABELED OLIGONUCLEOTIDES FOLLOWING LATERAL VENTRICLE AND INTRASTRIATAL INJECTIONS: A COMPARISON.** G. Dent, S.P. Ho, P. Hartig and R. Grzanna\*. The DuPont Merck Pharmaceutical Company, Wilmington, DE 19880-0400.

The successful application of the antisense technology in the CNS requires delivery of adequate amounts of antisense oligonucleotides (ON) to the appropriate target regions. This study was conducted to compare the extent of diffusion of biotinylated random ON delivered into the lateral ventricle (lcv) and striatum, respectively. ON were delivered stereotactically and rats were perfused 24 h later with 4% paraformaldehyde. Transverse sections were processed to visualize the spread of ON. Some sections were stained with cresyl violet to assess the extent of tissue damage.

Following lcv injections of 20 nmoles, ON were observed to penetrate up to 2.0 mm into the tissue surrounding the lateral, third and fourth ventricle. lcv injections of 2 nmoles caused the ON to spread approximately 0.8 mm into the tissue. No diffusion into brain tissue was observed when 0.2 nmoles of ON were injected. In sections counterstained with cresyl violet, no tissue damage was detectable in the zone of ON uptake.

Intrastriatal injections of 2 nmoles of ON resulted in a sphere of labeling with a radius of more than 2 mm. At 0.2 nmoles the spread was 0.8 mm; and at 0.02 nmoles the ON diffused approx. 0.4 mm from the center of the injection. This zone was characterized by severe tissue necrosis. With either route of delivery, ON had a granular distribution in the cytoplasm of neurons with no detectable labeling of neuronal nuclei.

The results show that the optimal choice for the route of ON delivery depends on the brain regions to be targeted. lcv injections of nanomolar amounts of ON are preferable when targeting brain regions lying close to the ventricular surface. Regions beyond this periventricular zone are best targeted by parenchymal injections. However, either route of administration will be of limited value in targeting large brain regions such as the cerebral cortex or the cerebellum.

## 42.1

EXTRACELLULAR MEMBRANE ASSOCIATION OF THE ENDOPEPTIDASE EC 3.4.24.15. T.J. Wu\*, P.J. Crack, M. Glucksmann, J.L. Roberts. Fishberg Research Center for Neurobiology, Mt Sinai School of Medicine, New York, NY 10029.

Endopeptidase EC 3.4.24.15 (EP24.15) is a soluble metalloenzyme abundant in the brain, pituitary and testes. Expression of EP24.15 is ubiquitous in the brain and in the pituitary, having a cellular localization (nuclear and/or cytoplasmic) in both neurons and glia. Our laboratory's interest in this enzyme involves the processing of GnRH released from the median eminence. For the extracellular metabolism of GnRH, the enzyme is expected to be associated in the same compartment, near or at the cell surface. The present biochemical and immunocytochemical study was conducted to ascertain the location of EP 24.15 on the extracellular surface of a pituitary-derived cell line (AT20). In order to visualize immunostaining on the cell surface in the absence of the cytoplasmic fraction, live AT20 cells were stained utilizing a specific antibody to EP24.15 and subsequently visualized with confocal laser microscopy. Our results indicate that EP24.15 is sparsely expressed on the surface of the AT20 cells and bore a punctate appearance with occasional floccular staining in regions with a higher cell density. Cells treated with 1  $\mu$ M A23187 for 30 min, a known stimulator of EP 24.15 "release" exhibited a decrease in extracellular staining. Biochemical analysis with a thiol-cleavable cross-linker, DTSSP, performed with subsequent western blot analysis of an isolated membrane preparation, also suggests membrane association. In a reduced state (cross-linker broken) a 77 kDa band corresponding to EP24.15 was resolved but in non-reducing conditions (cross-linker intact) this band was absent indicating a complex of membrane proteins and EP24.15 generated by DTSSP. These results suggest that EP24.15 is anatomically situated in a manner consistent with a physiological role in the degradation of GnRH. (Supported by NSF IBN-9512113)

## 42.3

PHOTOPERIODIC DIFFERENCES IN THE IMMUNOREACTIVE GONADOTROPIN-RELEASING HORMONE NEURONAL SYSTEM OF MALE SIBERIAN HAMSTERS D.J. Bernard\*, R. Nussbaum, T.H. Horton, and F.W. Turek. Dept. of Neurobiology & Physiology, Northwestern University, Evanston, IL 60208

Previous research on photoperiodic Siberian hamsters (*Phodopus sungorus*) has failed to detect differences in the gonadotropin-releasing hormone (GnRH) neuronal system between animals housed chronically on long and short days. Recent work in our laboratory, however, has identified a transient change in both GnRH mRNA and GnRH peptide content in the preoptic area and hypothalamus during the transition from inhibitory short days to stimulatory long days. We observe an increase in GnRH mRNA containing neurons and GnRH content on the morning of the second long day after transfer from short to long days, but not at time points examined before or after this time. These increases may reflect a transient increase in the number of neurons producing GnRH or an increase in the amount of GnRH produced by an otherwise stable population of GnRH neurons. In this study, we used immunocytochemical methods to help discriminate between these possibilities. Male Siberian hamsters born into long days (16L:8D) were weaned at post-natal day 18 and transferred to short days (6L:18D) or maintained on long days (Long Day Control). Four weeks later, half of the short day hamsters were transferred back to long days (Experimental) while the other half remained on short days (Short Day Control). Experimental animals were perfused two hours after light onset on the morning of the second long day. Age-matched control animals were perfused two hours after light onset on their respective light-dark cycles. Brains were sectioned and processed for GnRH immunoreactivity with the LR-1 antibody (gift of R. Benoit). The number of GnRH-immunoreactive (-ir) neurons was quantified using brightfield microscopy. There was no difference in the number of GnRH neurons between short day control and experimental animals (approx. 330 per brain). Contrary to previously published reports, long day control hamsters had significantly fewer GnRH-ir neurons than both of the other groups (approx. 230 per brain). Based on these data we hypothesize that during the transition from short to long days, male Siberian hamsters experience a transient increase in GnRH production in a stable population of neurons in anticipation of increased secretion on long days. When GnRH secretion increases there is a decrease in the peptide contained within neuronal cell bodies leading to a decrease in their detection with immunocytochemical methods. ## 42.5

PROGESTERONE - BLOCKADE OF SYNCHRONIZED PREOVULATORY LH SURGES ARE ASSOCIATED WITH LOW MEDIAN EMINENCE (ME) IN VIVO RELEASE OF LHRH, NPY, AND  $\delta$ -ENDORPHIN ( $\delta$ END). J. Klein, S. Goebbert, J. Babii, and J.P. Advis\*. Departments of Animal Sciences and Biological Sciences, Rutgers University, New Brunswick, NJ 08903.

We proposed a mechanism by which P4 inhibits synchronized preovulatory LH surges, based on a follicular model of sequential P4 removal and E2 silastic packets implantation into intact cycling ewes. Each animal served as both control (low P4 if P4 implants are removed at the end of a luteal phase, LH surge: 18  $\pm$  2 h after E2) and experimental ewe (high P4, in another estrous cycle, if P4 implants are not removed, no LH surge occurred). We have previously shown that synchronized LH surges are preceded by parallel increases in ME push-pull cannula (PPC) perfusate content of NPY and  $\delta$ END, while the LH surge itself is associated with highest LHRH and NPY but decreasing  $\delta$ END release. In follicular ewes, in vivo ME-LHRH release is increased by NPY and decreased by  $\delta$ END perfusion through the ME-PPC probe. Similarly, ME perfusion of NPY-antiserum stopped the ascending phase of an ongoing synchronized LH surge, while mid-follicular ME perfusion of naloxone ( $\delta$ END antagonist) advanced LH surge onset. On the other hand, if P4 is maintained high in another cycle of the same ewe, synchronized LH surges are absent and ME neuropeptide in vivo release is low ( $P < 0.01$ ). LH (mean  $\pm$  sem in ng/ml) and neuropeptide release (mean  $\pm$  sem in pg/100  $\mu$ l of ME-PPC perfusate) at the time of the expected synchronized LH surge in control vs experimental cycles in these ewes (n=6) are as follows, LH: 97  $\pm$  11 vs 0.6  $\pm$  0.1; LHRH 25  $\pm$  4 vs 1  $\pm$  0.5; NPY 331  $\pm$  44 vs 21  $\pm$  9;  $\delta$ END 71  $\pm$  18 vs 7  $\pm$  6. Therefore, P4 may prevent preovulatory in vivo release interactions of facilitatory NPY and inhibitory  $\delta$ END on in vivo LHRH release from ME neuronal terminals and thus block synchronized LH surges. ## 42.2

CHARACTERIZATION OF THE GONADOTROPIN-RELEASING HORMONE RECEPTORS IN THE PITUITARY GLAND OF THE DEVELOPING AMMOCOETE, JUVENILE, AND SEXUALLY MATURING ADULT LAMPREY. O.L.I. Materne and S.A. Sower\*. Dept. of Biochemistry and Molecular Biology, University of New Hampshire, Durham, NH 03824-3544.

In our previous study we have shown two classes of high affinity binding sites for gonadotropin-releasing hormone (GnRH) in the pituitary of the adult female sea lamprey, *Petromyzon marinus*. In the current studies, saturation binding assays were done to determine the concentration and affinity of both GnRH binding sites in the pituitaries of lamprey at different developmental stages. In addition, these studies were done in an effort to determine the presence of two GnRH receptors or one receptor having two binding sites, and to detect any cooperativity between the two binding sites. Pituitary sections of 20  $\mu$ m were incubated for 3 hrs at 4°C with ten serial dilutions (1.0  $\times$  10<sup>-8</sup>M to 1.95  $\times$  10<sup>-11</sup>M) of the GnRH agonist D-Ala<sup>6</sup>, Des Gly<sup>10</sup> mGnRH. Interestingly no specific-binding was detected in the pituitaries of larval (ammocoetes) and parasitic lamprey that were kept at 2°C water temperature. In comparison, non-parasitic adult lamprey, held at the same water temperature did demonstrate two classes of binding sites: Kd=1.03  $\times$  10<sup>-12</sup> M, Bmax=2.5  $\times$  10<sup>-15</sup> M, and Kd=2.06  $\times$  10<sup>-9</sup> M, Bmax=5.1  $\times$  10<sup>-14</sup> M. This work was supported by NSF: 9022834 & 9407767.

## 42.4

CIRCADIAN RHYTHMICITY OF GnRH GENE EXPRESSION IN THE RAT. Andrea C. Gore\* and James L. Roberts. Fishberg Research Center for Neurobiology, Mount Sinai Medical Center, Box 1065, NY, NY 10029.

The release of the decapeptide GnRH from neuroterminals in the median eminence undergoes afternoon increases in female rats during the proestrous LH surge and in chronically ovariectomized rats given estradiol. With respect to the biosynthetic events responsible for these rhythms, we have reported that increases in GnRH mRNA levels precede and may be causal to the afternoon proestrous GnRH/LH surge. In the present study, we examined whether male rats exhibit a circadian periodicity in GnRH mRNA levels, and are currently elucidating the mechanism for any such diurnal changes, across a 24-hour period. **Methods:** Male Sprague-Dawley rats (2-3 months of age) were maintained on a controlled light cycle (12:12 light:dark, lights on 0700 hours). They were sacrificed by decapitation at four hour intervals at 1000, 1400, 1800, 2200, 0200 and 0600 hours. The preoptic area-anterior hypothalamus was rapidly dissected out on ice and frozen in liquid Freon for subsequent analysis of GnRH mRNA levels by RNase protection assay using a rat GnRH cDNA clone. **Results:** GnRH mRNA levels exhibited significant variation with time of day. They increased two-fold between 1000 and 1400 hours; remained elevated at 1800 hours; and returned to baseline (1000 hour levels) at 2200 through 0600 hours. We are currently determining the mechanism for this circadian rhythm (transcriptional or post-transcriptional) since it is our hypothesis that "chronic" changes in inputs to the GnRH system (e.g. circadian rhythm, stage of estrous cycle) are transcriptionally regulated, while acute inputs (e.g. neurotransmitter stimulation) to the GnRH system appear to affect post-transcriptional mechanisms of regulation. We are also examining whether a circadian rhythm in GnRH gene expression occurs during puberty, when large nocturnal elevations in GnRH release are observed. (FRCN Devel. Grant)

## 42.6

COLOCALIZATION OF MU, DELTA AND KAPPA OPIATE RECEPTOR AND LHRH mRNAs IN THE PREOPTIC AREA OF THE RAT BRAIN. S.L. Petersen\* and M. Sannella. Biology Department, Neuroscience and Behavior Program, Univ. of Massachusetts, Amherst, MA 01003

Abundant evidence suggests that ovarian steroid regulation of LHRH and LH release is mediated by opiate peptides. The present studies were designed to test the hypothesis that opiates directly regulate LHRH neurons and to determine what opiate receptor(s) mediate this regulation. Female Sprague-Dawley rats were ovariectomized (OVX) and one week later (Day 0) implanted with Silastic capsules of estrogen. At 0900 on Day 2, some estrogen-treated animals were injected with 5 mg progesterone and all animals were sacrificed at 1530 on the same day. Brains were removed, frozen on dry ice and stored at -80°C until cryosectioned. Twelve-micron sections through the preoptic area of the brain were collected and used for dual-label *in situ* hybridization histochemistry. For these studies, we used a digoxigenin-labeled cRNA probe for LHRH mRNA and <sup>33</sup>P-labeled cRNA probes for mu, delta or kappa opiate receptor mRNAs. The digoxigenin-labeled probe was detected with antidigoxigenin conjugated to horseradish peroxidase and diaminobenzidine/hydrogen peroxide. The radiolabeled probes were detected by dipping the slides in NTB-3 emulsion. All three receptor mRNAs were expressed in cells of the preoptic region; however, regardless of steroid treatment, we found no LHRH neurons that expressed mu, delta or kappa opiate receptors. These results suggest that opiate modulation of LH release is not through a direct action on LHRH neurons. (Work supported by NIH grant HD27305 to SLP.)

## 42.7

POLYCYSTIC OVARY SYNDROME INDUCED BY ESTRADIOL VALERATE IS INDEPENDENT OF BETA-ENDORPHIN. J.L. Smart, C.C. Field, M.J. Low\*. Vollum Inst., Ore. Health Sci. Univ., Portland, OR 97201.

Female rats and mice chronically treated with estradiol valerate (EV) exhibit chronic anovulation, persistent vaginal cornification, and polycystic ovaries. EV-treated rats exhibit attenuated pituitary luteinizing hormone (LH) content, LH response to gonadotropin releasing hormone (GnRH), LH replenishment following GnRH-stimulated release, and mean plasma LH concentration. The mechanism that has been proposed to explain these effects is a supersensitivity of GnRH neurons in the medial preoptic area to hypothalamic  $\beta$ -endorphin (BE). Other researchers speculated that  $\mu$ -opioid receptor supersensitivity is induced by the EV mediated destruction of a subpopulation of arcuate BE neurons (Desjardins G.C., et al. Endocrinol. 132: 86-93, 1993).

To test this hypothesis, we utilized a strain of mice deficient in beta-endorphin produced by gene targeting techniques (Rubinstein M, et al. PNAS, USA 1996, in press). Normal control and BE deficient mice were treated with a single 1 mg dose of EV by i.m. injection. Both groups of mice developed persistent vaginal cornification indicative of anovulation and polycystic ovaries 8 weeks following EV injection. *In situ* hybridization for POMC message in the hypothalamic arcuate nucleus showed no reduction in POMC mRNA in EV treated wild-type or BE deficient mice. Normal and BE deficient mice given EV injection had a 4-5 fold decrease in follicle stimulating hormone beta subunit mRNA measured by an RNase protection assay compared to sesame oil treated controls. Daily injections of naltrexone, a stable opiate receptor antagonist, for 3 weeks starting 8 weeks after EV injections were unable to reinstate normal cyclicity in wild-type or BE deficient mice. From these data, we conclude that BE deficient mice have normal onset of puberty, and normal frequency and duration of estrous cycles. Furthermore, BE does not play an important role in the chronic estradiol induced HPG inhibition in mice. These studies were supported by HD30236.

## 42.9

CHARACTERIZATION OF THE MECHANISM THROUGH WHICH ESTROGEN REGULATES POMC GENE EXPRESSION IN THE RAT HYPOTHALAMUS. C.A. Priest\* and J.L. Roberts. Fishburg Research Center of Neurobiology, Mount Sinai School of Medicine, New York, NY 10029.

In the rat hypothalamus, estrogen has been shown to regulate proopiomelanocortin (POMC) gene expression in a temporally dependent manner. Gonadectomy produces an up-regulation of POMC mRNA levels that is reversible by chronic estrogen treatment, although acute transcriptional effects of estrogen have been difficult to interpret. Importantly, the promoter region of the rat POMC gene does not contain a consensus estrogen response element. However, as AP-1 activation constitutes a major regulatory pathway for POMC gene expression, we have proposed that estrogen may modulate POMC mRNA levels through a non-classical mechanism that involves AP-1 proteins. To investigate this regulatory pathway further, transient transfections of partial POMC promoter sequences which contain the exon 1 AP-1 site are being assessed *in vitro* for their ability to modulate transcription in the presence of estrogen. In addition, to establish whether an anatomical substrate exists in the rat hypothalamus for such an interaction, immunohistochemical double-labeling was used to examine neurons in the arcuate nucleus (ARC). Adult female rats were ovariectomized for two weeks and either received no experimental treatment, or were given an i.p. injection of ethanol vehicle or 50  $\mu$ g estradiol (E2) and were perfused 1, 2, 4, or 48 hrs later. ARC sections were processed for sequential immunohistochemistry using commercially available antisera directed against  $\beta$ -endorphin (BEND) or c-Fos. Cell populations which were immunoreactive (IR) for BEND, c-Fos or both proteins were quantified using an optical disector and unbiased stereological methods. Treatment with E2 gradually increased all three populations of cells, with statistically significantly higher numbers of c-Fos-IR, BEND-IR and doubly-labeled cells appearing after 4 hrs. By 48 hrs after E2, numbers of c-Fos-IR and doubly-labeled cells had declined, while the number of BEND-IR cells remained high, indicating population-specific effects of E2 on BEND neurons in the ARC. (Supported by: ADF/HRI-817-5332)

## 42.11

PARAVENTRICULAR NUCLEUS PLAYS A CRITICAL ROLE FOR FASTING-INDUCED SUPPRESSION OF PULSATILE LH RELEASE IN TESTOSTERONE-TREATED CASTRATED MALE RATS. H. Tsukamura\*, S. Yamada, N. Tamaya, M.A.C. Estacio, K.-I. Maeda. Lab. Animal Reproduction, Nagoya University, Nagoya 464-01, Japan.

We have previously revealed that 48-h fasting profoundly suppresses pulsatile LH secretion in female rats in an estrogen-dependent manner. The present study was aimed to determine whether fasting-induced suppression of pulsatile LH secretion in male rats is testosterone-dependent, and whether the paraventricular nucleus (PVN) is involved in the fasting-induced inhibition of pulsatile LH release. Wistar-Kimichi strain male rats were castrated, and some of them were implanted with various length of Silastic tubings filled with testosterone. Pulsatile LH secretion after 48-h fasting was suppressed only in the testosterone-implanted castrated males, but not in castrated animals without testosterone. Fos protein expression was also determined immunocytochemically in the several brain regions at various time after fasting in castrated males with or without testosterone treatment. Induction of Fos protein was shown in the PVN and supraoptic nucleus only in testosterone-treated animals at the beginning of dark period on the day of fasting, but not in unfasted controls with or without testosterone treatment or castrated animals at any time of the day. Furthermore, PVN lesion blocked the inhibitory effect of fasting on pulsatile LH release. These results clearly suggest that fasting suppresses pulsatile LH secretion in a testosterone-dependent manner, and that the PVN plays a critical role in mediating the fasting-induced suppression of pulsatile LH secretion in male rats.

## 42.8

MEDIAL PREOPTIC  $\mu$ -OPIOID RECEPTOR DENSITY INCREASES FOLLOWING THE LH SURGE. R. P. Hammer, Jr.\* and B. S. Rubin. Depts. of Psychiatry and Anatomy & Cellular Biology, Tufts University School of Medicine, Boston, MA 02111.

$\mu$ -Opioid receptors are gonadal steroid hormone-dependent in the medial preoptic area of female rats, wherein endogenous opioids regulate luteinizing hormone (LH) secretion. Therefore,  $\mu$ -receptor density was examined by quantitative *in vitro* receptor autoradiography following hormone treatment to induce an LH surge. Adult Sprague-Dawley female rats were housed in a controlled environment with a 14:10 h light cycle. Regularly cycling animals were ovariectomized and received estradiol (40  $\mu$ g/kg) followed by progesterone (8 mg/kg) 48 hr later at 1000 h. Rats were anesthetized and decapitated at 1000, 1400, 1800 or 2000 h, at which time trunk blood was collected for radioimmunoassay, and brains were removed, frozen and sectioned. Sections were incubated in a saturating concentration of [ $^3$ H]-D-Ala<sup>2</sup>, MePhe<sup>4</sup>, Gly-o<sup>15</sup>-enkephalin (10 nM) to selectively label  $\mu$ -receptors. Adjacent sections were hybridized with a digoxigenin-labeled 330 bp riboprobe to preproLHRH. Medial preoptic  $\mu$ -receptor density was significantly greater at 1800 and 2000 h than at 1000 or 1400 h, but was unaffected in the adjacent lateral preoptic area. LH levels increased at 1400 and 1800 h and declined by 2000 h, while the number of neurons expressing LHRH mRNA increased until 1400 h then declined at 1800 hr. A significant correlation ( $r = -0.65$ ,  $p \leq 0.005$ ) was present between  $\mu$ -receptor density and number of mRNA-expressing neurons across this period. Thus, the upregulation of medial preoptic  $\mu$ -receptors may provide a substrate for endogenous opioid termination of LHRH synthesis and/or secretion. Supported by USPHS Awards R01 DA06645, HD19174 and P30 HD28897.

## 42.10

REGULATION OF PRO-OPIMELANOCORTIN (POMC) GENE EXPRESSION IN THE HAMSTER ARCULATE NUCLEUS BY PHOTOPERIOD AND TESTOSTERONE. Eric L. Bittman\*, Catherine M. Hegarty, Maureen L. Tubbiola, and Gretchen Foltz. Dept. of Biology and Neuroscience and Behavior Program, University of Massachusetts, Amherst 01003.

In seasonal breeders including hamsters, daylength regulates reproduction by altering responsiveness to gonadal steroid hormones. Changes in the action of endogenous opiates which influence gonadotropin secretion and sexual behavior may participate in these effects of photoperiod. Testosterone (T) decreases hypothalamic  $\beta$ -endorphin content in rats and hamsters; effects on POMC mRNA abundance in rat arcuate are controversial. It is not known whether androgens or photoperiod influence POMC gene expression in hamsters. We quantified POMC gene expression in the arcuate of hamsters which were either left intact, castrated without androgen replacement, or castrated and implanted with T either immediately or after a 5-week delay. An additional group was pinealectomized in order to determine whether the pineal gland mediates effects of daylength on POMC expression. Half the animals in each group were moved to short days (SD: 5L:19D); the others remained on 14L:10D (LD). Ten weeks later, brain sections were processed for *in situ* hybridization to detect POMC mRNA using <sup>35</sup>S-labeled I13 cDNA probe. The numbers of POMC cells and grains per cell were measured in emulsion-dipped sections.

SD precipitated profound, pineal-dependent testicular regression. T suppressed serum LH more effectively in SD than in LD. ANOVA indicated overall effects of photoperiod and surgical treatments on POMC mRNA (grains/cell;  $p=0.01$ ). Pairwise comparisons (Tukey test) indicated that T significantly reduced POMC mRNA in SD, but not in LD, in the rostral and middle but not the caudal arcuate. T reduced POMC expression in the mid-arcuate whether it was given immediately or 5 weeks after castration, but delayed T replacement was not effective in rostral arcuate. Effects of photoperiod on T's influence on POMC expression may contribute to seasonal breeding. Supported by NIH MH44132, MH00914, and NSF IBN 9319653.

## 42.12

PARAVENTRICULAR NOREPINEPHRINE RELEASE MEDIATES GLUCOPRIVIC SUPPRESSION OF PULSATILE LH SECRETION IN OVARECTOMIZED RATS. S. Nagatani<sup>2</sup>, H. Tsukamura<sup>1</sup>, K. Murahashi<sup>1</sup>, D. C. Bucholtz<sup>2</sup>, D. Foster<sup>2</sup>, T. Matsushima<sup>1</sup>\* and K.-I. Maeda<sup>1</sup>. <sup>1</sup>Sch. of Agri. Sci., Nagoya Univ., Nagoya 464-01, Japan; <sup>2</sup>Reprod. Sci. Progr., Univ. Michigan, Ann Arbor MI 48109, USA.

Restriction of glucose availability by 2-deoxyglucose (2DG) suppresses pulsatile luteinizing hormone (LH) release. The purpose of the present study was to determine if norepinephrine (NE) release in the paraventricular nucleus (PVN) is involved in the glucoprivic suppression of LH secretion in ovariectomized rats. Twelve days after ovariectomy, animals were stereotactically implanted with a unilateral guide cannula for microdialysis in the PVN. Two days later, the PVN was perfused continuously with Ringer's solution or Ringer's solution containing a catecholamine synthesis inhibitor,  $\alpha$ -methyl-p-tyrosine ( $\alpha$ -MPT, 100  $\mu$ M) through a microdialysis probe inserted in the guide cannula two hours before the beginning of sampling which lasted 3 h. Blood samples were collected every 6 min through an atrial cannula and dialysates were collected every 20 min. One hour after the beginning of sampling, 2DG (400 mg/kg BW) was administered intravenously through the atrial cannula. Paraventricular NE levels significantly ( $P<0.05$ ) increased immediately after 2DG injection, and both mean LH concentrations and the frequency of LH pulses decreased. Administration of  $\alpha$ -MPT into the PVN blocked 2DG-induced increase in paraventricular NE release as well as decrease in plasma LH levels. These results suggest that the 2DG-induced suppression of LH pulses is mediated by the NE release in the PVN in ovariectomized rats.

## 42.13

**FASTING-INDUCED FOS EXPRESSION IN HYPOTHALAMIC NEUROPEPTIDE Y (NPY) NEURONS OF ADULT MALE RHESUS MONKEYS: A SEARCH FOR NEURAL SYSTEMS WHICH MAY MEDIATE FASTING-INDUCED SUPPRESSION OF LUTEINIZING HORMONE (LH) SECRETION.**

**Al. Caston-Balderrama, GE Hoffman, MS Smith and JL Cameron.** Depts. of Psychiatry, Cell Biol & Physiol, Neurobiol, and Neurosci, Univ. of Pittsburgh, PA 15213 and the Oregon Regional Primate Research Center, Beaverton, OR 97006

Short-term food restriction suppresses LH secretion in adult male rhesus monkeys (*Macaca mulatta*), with a slowing of LH pulse frequency apparent within the first 6 h after a single missed meal. Conversely, refeeding a normal meal after a brief period of fasting rapidly increases the secretion of LH. In this study, we examined Fos expression in hypothalamic NPY neurons, in response to fasting and refeeding, to determine whether NPY neurons are activated by changes in energy intake, and thus may be playing a role in mediating the fasting-induced suppression of pulsatile LH secretion. NPY neurons are likely candidates because they have been shown to respond to changes in energy availability and are known modulators of the reproductive axis. In this study, 3 monkeys were fasted for 2-3 days and sacrificed at 1000 h, prior to the normal feeding time in our colony (1100 h), to minimize extraneous neural stimulation that accompanies the daily meal (FASTED group). A second group of 3 monkeys was fasted for 2-3 days, a liquid meal was infused through an indwelling gastric cannula between 0630-0830 h, and then this group was sacrificed at 1000 h (REFED group). Intense Fos expression in NPY neurons was observed in the FASTED group along the ventral surface of the hypothalamus, with a 5-fold greater activation when compared to the REFED group. However, NPY neuronal activation in other regions was similar in the two groups. Therefore, only a select population of hypothalamic NPY neurons appear to be activated by short-term fasting, suggesting that these NPY neurons may play a causal role in mediating the fasting-induced suppression of LH secretion.

**THE COMBINED USE OF FOS IMMUNOCYTOCHEMISTRY AND LESIONS IN THE STUDY OF NEURAL PATHWAYS UNDERLYING METABOLIC CONTROL OF REPRODUCTION.** B.C. Finnerty, D. Jacobs, M. Szajna, J.M. Swann and J.E. Schneider\*. Department of Biological Sciences, Lehigh University, Bethlehem, P.A. 18015

Previous work supports the idea that signals generated by changes in glucose metabolism control reproduction in female Syrian hamsters. Estrous cycles are delayed when glucose utilization is blocked by cerebroventricular or systemic treatment with the glucose antimetabolite, 2-deoxy-D-glucose (2DG) in hamsters. We have examined the effects of anesthetic-inducing doses of systemic 2DG (1750 mg/kg) on FOS-like immunoreactivity in a variety of brain areas that have been implicated in metabolic control of food intake and reproduction in other species. These areas include, but are not restricted to the area postrema (AP), nucleus of the solitary tract (NTS), lateral and medial parabrachial nucleus (LPBN and MPBN respectively), central nucleus of the amygdala (CNA), and paraventricular nucleus (PVN). We have noted significantly increased FOS staining in the AP, NTS, LPBN and PVN in hamsters treated with 2DG (1750 mg/kg) compared to vehicle-treated controls ( $p < 0.05$ ). Additionally, we have noted a significant dose-response relationship between 2DG (doses ranging from 750-2000 mg/kg) and number of cells showing FOS-like immunoreactivity in the AP and NTS. A similar trend was apparent in the PVN. To examine whether these areas contain cell bodies or fibers that are important in mediating the effects of 2DG on estrous cycles, we have performed radiofrequency lesions or sham surgeries of these individual areas, treated the hamsters with 2DG or saline, and examined indices of estrous cyclicity. Preliminary results suggest that the effects of 2DG on estrous cyclicity require an intact AP and medial NTS, but not PVN or CNA. Supported by IBN9121056 from NSF, 1K02MH01096 from the NIMH, and HD28467 from NICHD.

## 42.17

**LEPTIN IS A METABOLIC SIGNAL TO THE REPRODUCTIVE SYSTEM.** I.A. Barash, C.C. Cheung, D.S. Weigle, P. Ren, J.M. Kramer, M. Fallon, E.B. Kabigting, J.L. Kujiper, D.K. Clifton, and R.A. Steiner\*. Departments of Ob-Gyn, Physiology and Biophysics, and Medicine, University of Washington and ZymoGenetics, Inc., Seattle, WA 98195

The activity of the reproductive system is gated by metabolic signals that reflect nutritional state; however, the identity of these signals remains unknown. Leptin, a newly discovered hormonal product of the *ob* gene, is expressed by adipocytes and thought to play a role in the regulation of food intake and metabolism. We postulated that, as a derivative of the body's nutritional state, leptin may also signal metabolic information to the reproductive axis. We tested this hypothesis by examining the effects of leptin on the reproductive endocrine system of the *ob/ob* mouse, which has a congenital deficiency in leptin and is thought to be infertile because of a neuroendocrine defect. We treated pair-fed, male and female *ob/ob* mice with leptin (50 µg twice daily, ip) or vehicle ( $n=10$ /group) for 14 days, after which the animals were bled and killed. We measured serum levels of LH and FSH, weighed the ovaries, testes, uteri, and seminal vesicles, and performed quantitative histology on all tissues sampled. In females, leptin-treated animals had elevated serum LH levels ( $p<0.001$ ), higher ovarian ( $p<0.01$ ) and uterine weights ( $p<0.001$ ), and increased morphological measures of ovarian and uterine histology ( $p<0.001$ ) compared to controls. In males, leptin-treated animals had elevated serum FSH levels ( $p<0.001$ ), higher testicular ( $p<0.05$ ) and seminal vesicle weights ( $p<0.02$ ), and increased morphological measures of seminal vesicle histology compared to controls. These results suggest that leptin stimulates the reproductive endocrine system in both sexes of the *ob/ob* mouse. **Conclusion:** In the normal animal, leptin may serve as a metabolic "green light" to the activity of the reproductive system. ## 42.14

**TIME COURSE OF THE SEXUALLY DIMORPHIC RESPONSE IN ESTROGEN RECEPTOR IMMUNOREACTIVITY IN UNDERFERED PREPUBERTAL MICE** JN Roemmich<sup>1</sup>, X Li<sup>2</sup>, AD Rogol<sup>1,3</sup>, and EF Rissman<sup>\*2</sup>. Dept. of Pediatrics<sup>1</sup> Biology<sup>2</sup>, and Pharmacology<sup>3</sup>, University of Virginia, Charlottesville, VA 22903.

The influence of sex steroids on GnRH release is mediated by the estrogen receptor (ER). We have shown that underfeeding prepubertal female mice for 7 d reduces ER-ir cells in the medial preoptic area (mPOA) and ventromedial nucleus (VMN) but not in the arcuate. Here, we investigated the time course of the reduction in ER-ir in representative sections of the mPOA and VMN. Weanling female (FW) and male (MW) mice were sacrificed at 16 days of age ( $n=8$  FW;  $n=7$  MW). Additional groups were underfed for 24 ( $n=6$  FUF-24;  $n=7$  MUF-24) or 48 ( $n=7$  FUF-48;  $n=7$  MUF-48) h. Brains were perfused, frozen and every fourth coronal section (30 µC) processed and incubated with a monoclonal antiserum for ER (H222, Abbott Laboratories). Using Mocha software one observer, blind to sex and condition of the animal, counted all ER-ir cells on one side of matched sections. Results [mean (SD)] from ANOVA are presented. Like letters ( $P<0.05$ ).

	FW	FUF-24	FUF-48	MW	MUF-24	MUF-48
mPOA ER-ir	717(163) <sup>ab</sup>	487(198) <sup>a</sup>	359(197) <sup>b</sup>	549(166)	538(148)	557(106)
VMN ER-ir	243(88) <sup>c</sup>	164(83) <sup>d</sup>	111(35) <sup>e</sup>	162(53)	129(34)	145(35)

Underfeeding female mice reduced the number of ER-ir in the mPOA within 24 h and VMN within 48 h. Underfeeding had little effect on ER-ir of male mice. Others have shown nutritional alterations modify GnRH pulse generator activity within 24 to 48 h. We have shown changes in ER-ir cell numbers within this same time frame. Thus, underfeeding may stall puberty by impairment of ER protein in brain areas important for modulating the effects of sex steroids on GnRH release.

**EFFECT OF AREA POSTREMA LESIONS ON ESTROGEN RECEPTOR IMMUNOREACTIVITY IN FOOD-DEPRIVED FEMALE SYRIAN HAMSTERS.** A.K. Panicker, J.D. Blaustein and G.N. Wade\*. Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

Female Syrian hamsters reduce their reproductive activity, including ovulation and estrous behavior, when they are food deprived. Previous studies from this lab showed that 48 hrs of food deprivation caused a decrease in estrogen receptor immunoreactivity (ERIR) in the ventromedial hypothalamus (VMH) and arcuate nucleus (ARC) and an increase in the medial preoptic area (MPOA) and posterior parvocellular paraventricular nucleus (pPVN). One way by which visceral sensory information, including peripheral metabolic status, is conveyed to the brain is believed to be through the area postrema (AP), which is a circumventricular organ in the hindbrain. In order to determine if the AP is involved in mediating metabolic effects on forebrain ERIR, female hamsters were subjected to AP lesions or sham lesions, and the effects of 48 hrs of food deprivation were determined. AP lesions blocked the effect of food deprivation on ERIR in VMH, but had no effect in the pPVN. Previous studies on ERIR in vagotomized animals given metabolic inhibitors like 2-deoxy-D-glucose and methyl palmoxirate showed that vagotomy did not block the decrease of ERIR in VMH, whereas it blocked the increase of ERIR in pPVN. Taken together, these results suggest that ERIR-containing cells in the VMH receive at least some metabolic information via AP, whereas PVN receives it via the vagus. In addition, these results indicate that ERIR cells in the VMH and PVN do not detect metabolic fuel availability directly. Analysis of ERIR in the MPOA and ARC are in progress. Supported by NS 10873, MH00321 and MH00850.

## 42.18

**EXPRESSION OF LEPTIN RECEPTOR MESSENGER RIBONUCLEIC ACID (mRNA) IN NEUROENDOCRINE AND ENDOCRINE TISSUES OF THE RAT.** P. L. Zamorano, V. B. Mahesh, L. P. Chorch, L.M. DeSevilla and D. W. Brann\*. Dept. of Physiology & Endocrinology, Medical College of Georgia, Augusta, GA, 30912.

The obese (*ob*) gene product, leptin, has recently been shown to be produced by adipocytes and function as a hormone to modulate appetite and metabolism. Intriguingly, the *ob/ob* mutant female mouse, which does not produce leptin, has been shown to be sterile. This sterility can be reversed by treatment with recombinant leptin, but not by diet restriction - suggesting that leptin is required for normal reproductive function. To determine whether endocrine and neuroendocrine tissues could be targets for leptin action and regulation, we examined whether these tissues express the leptin receptor mRNA transcript by using RT-PCR. The results revealed that the leptin receptor mRNA transcript is highly expressed in the female rat brain, hypothalamus, ovary and uterus, with moderate to low expression in the anterior pituitary and adrenal, respectively. In the male rat, high expression was observed in the brain and hypothalamus, with moderate expression in the anterior pituitary and testis, and low expression in the adrenal. Interestingly, modest expression of the leptin receptor was also observed in immortalized GnRH (GT1-7) neurons. Taken as a whole, the above findings raise the intriguing possibility that reproductive tissues are targets for leptin action, and that leptin may influence reproduction through direct effects on reproductive tissues. Supported by NIH Grant R29HD28964.

## 42.19

**INFERTILITY IN THE *fatfat* MOUSE IS ASSOCIATED WITH A DEFICIT IN PROCESSING THE LHRH PRECURSOR.** W.C. Wetsel<sup>1,\*</sup> and E.H. Leiter<sup>2</sup>.<sup>1</sup>Lab. of Cellular and Molecular Pharmacology, NIEHS, Research Triangle Park, NC 27709, and <sup>2</sup>The Jackson Laboratory, Bar Harbor, ME 04609.

Mice homozygous for the *fatfat* mutation are obese, diabetic, and infertile. These mice have a point mutation in carboxypeptidase E (CPE), an enzyme responsible for processing prohormone intermediates to bioactive peptides such as insulin. Recently, immortalized LHRH neurons have been shown to express CPE and this enzyme has been postulated to be involved in processing pro-LHRH intermediates. The purpose of the present study was to determine whether *fatfat* mice were deficient in processing the pro-LHRH to LHRH. Adult *fatfat* male and female mice weighed approximately 2-fold more, had elevated plasma insulin levels, and were hyperglycemic compared to their heterozygous littermates. Whole hypothalamic LHRH content was analyzed by RIA with two different antisera. One antiserum (A772) recognized the decapeptide and [Gln<sup>1</sup>]-LHRH; a second antiserum (B9) bound all of the different pro-LHRH intermediates including LHRH. Levels of LHRH-like immunoreactivity (IR), as determined with the A772 antiserum, were significantly reduced in hypothalami from male and female *fatfat* mice compared to those from heterozygotes. Despite this fact, analysis with the B9 antiserum revealed that hypothalami from all mice, regardless of genotype, contained comparable amounts of LHRH-like IR materials. HPLC analyses confirmed that male *fatfat* mouse hypothalamus was defective in processing the LHRH prohormone. Quantities of [Gln<sup>1</sup>]-LHRH-[Gly<sup>11</sup>,Lys<sup>12</sup>] and LHRH-[Gly<sup>11</sup>,Lys<sup>12</sup>,Arg<sup>13</sup>] were particularly elevated in hypothalami from these *fatfat* mice. Moreover, LHRH levels were reduced by approximately 4-fold in the mutant mice. These data indicate that CPE may be the prominent carboxypeptidase involved in processing pro-LHRH intermediates to LHRH. Because LHRH is the major regulator of reproduction in mammals, the mutation in CPE may contribute to infertility in the *fatfat* mouse. (Supported by the NIEHS Intramural program to WCW.)

## NEURAL-IMMUNE INTERACTIONS: CNS MECHANISMS

## 43.1

**AREA POSTREMA REMOVAL ABOLISHES STIMULATORY EFFECTS OF INTRAVENOUS INTERLEUKIN-1 $\beta$  ON HPA AXIS ACTIVITY AND *c-fos* mRNA IN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS.** H. Y. Lee and M. Herkenham<sup>\*</sup>. Section on Functional Neuroanatomy, Laboratory of Cell Biology, NIMH, Bethesda, MD 20892.

This study examined the role of the area postrema (AP) in transducing peripheral immune signals, represented by i.v. interleukin-1 (IL-1), into a neuroendocrine response, manifested by induction of *c-fos* mRNA in the hypothalamic paraventricular nucleus (PVN). The AP, a circumventricular organ with a leaky blood-brain barrier, lies adjacent to the nucleus of the solitary tract (NTS). The AP was removed by aspiration, and two weeks later, AP-lesioned or sham-lesioned rats were injected i.v. with 0.5  $\mu$ g/kg IL-1 $\beta$  or saline. After 30 min, brains were removed and analyzed for *c-fos* mRNA levels in structures implicated in the HPA axis response to peripheral cytokine challenge. The sham-lesioned animals responded to IL-1 with large elevations in ACTH and corticosterone in the plasma and *c-fos* mRNA in responsive structures. Prior AP removal abolished the IL-1-induced increases in plasma hormone levels and *c-fos* mRNA in the NTS and PVN. However, AP removal had no effect on IL-1-induced increases in *c-fos* mRNA levels in the other areas examined. The selective AP lesion effects suggest that the AP plays a pivotal role in transducing a circulating IL-1 signal into HPA axis activation by a pathway that may be comprised of known anatomical links between the AP, NTS, and corticotropin-releasing hormone (CRH) neurons of the PVN. (Support: NIMH Intramural Research Program)

## 43.3

**RAPID INDUCTION OF INTERLEUKIN-1 $\beta$  mRNA IN CIRCUMVENTRICULAR ORGANS AFTER PERIPHERAL ADMINISTRATION OF LIPOPOLYSACCHARIDE.**N. Quan<sup>\*</sup>, M. Whiteside, and M. Herkenham. Section on Functional Neuroanatomy, LCB, NIMH, Bethesda, MD 20892.

Peripheral LPS induces IL-1 bioactivity in brain tissue. To identify the neuroanatomical loci of these IL-1-producing cells, we investigated brain IL-1 $\beta$  mRNA expression by *in situ* hybridization histochemistry (ISH) using a 500 bp ribonucleotide probe on brain sections from rats injected intraperitoneally with 2.5 mg/kg LPS or saline. In control animals, IL-1 $\beta$  mRNA was not detectable by ISSH. In LPS-injected animals, cell labeling appeared at 0.5 h, peaked at 2 h, declined at 8 h and disappeared at 12–24 h. Labeled cells were concentrated in circumventricular organs (CVOs)—organum vasculosum of the lamina terminalis, subfornical organ, median eminence, and area postrema—and were sparsely scattered in blood vessels, choroid plexus, and meninges. Labeling was not observed in any neural structures. In the pituitary, LPS induced strong IL-1 $\beta$  mRNA expression first in the anterior lobe at 0.5 and 1 h, and then in the neural lobe beginning at 2 h, which subsided quickly thereafter. The results show that peripheral LPS induces IL-1 $\beta$  production at the blood brain barrier (BBB) and in CVOs where the BBB is leaky and suggest that these cells are the source of brain IL-1 activity after peripheral LPS injection. (Support: NIMH Intramural Research Program)

## 43.2

**INDUCIBLE CYCLOOXYGENASE mRNA EXPRESSION IN RAT BRAIN FOLLOWING PERIPHERAL ADMINISTRATION OF LIPOPOLYSACCHARIDE.**M. Whiteside, N. Quan, X. Wang<sup>\*</sup>, and M. Herkenham. Section on Functional Neuroanatomy, LCB, NIMH, Bethesda, MD 20892.

Inducible Cyclooxygenase (Cox-2) converts arachidonic acid to prostaglandin E2 (PGE2), which is thought to mediate various peripheral LPS-induced central effects, including generation of fever and activation of the HPA axis. To localize PGE2 production in the brain following peripheral LPS administration, *cox-2* mRNA expression was examined by *in situ* hybridization histochemistry in rats injected i.p. with 2.5 mg/kg LPS or saline. *Cox-2* mRNA levels were not altered in saline-injected animals as compared to non-injected controls. In LPS-injected animals, beginning at 0.5 h, *de novo* labeled cells appeared; their numbers increased to a peak at 2 h and subsided gradually to basal levels by 24 h. Initially, labeling was observed in cells comprising major, surface-lying blood vessels and meninges. Later, vascular and perivascular cells associated with smaller, penetrating blood vessels, and scattered, small non-vascular cells also became intensely labeled. Changes in *cox-2* mRNA expression were not observed in circumventricular organs. These results suggest that peripheral LPS induces a rapid global increase of PGE2 production, which could affect the activity of widespread brain regions. (Support: NIMH Intramural Research Program)

## 43.4

**CO-EXPRESSION OF ENKEPHALIN AND GABA IN NEURONS RESPONSIVE TO INTERLEUKIN-1 $\beta$  IN THE RAT CENTRAL NUCLEUS OF THE AMYGDALA.**Heidi E.W. Day<sup>\*</sup>, Eileen J. Curran, Stanley J. Watson and Huda Akil.

Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

One brain region which is particularly strongly activated following intraperitoneal (i.p.) administration of IL-1 $\beta$  is the central nucleus of the amygdala (CeA) [1]. The neurochemical nature of these activated neurons was assessed by a double *in situ* hybridization (ISH) technique described previously [2].

Male Sprague Dawley rats (300–350g) were treated with IL-1 $\beta$  (5 $\mu$ g/ml/kg i.p.) or 0.9% saline vehicle (n=5/group). After 30 minutes, animals were killed, the brains frozen and 10 $\mu$ m sections cut and processed for ISH for *c-fos* mRNA with one of the following markers: glutamic acid decarboxylase (GAD65/67 used concurrently as a marker for GABAergic neurons), preproenkephalin (ENK), neurotensin (NT) or corticotropin releasing hormone (CRH) mRNA.

In keeping with published results, relatively few cells within the CeA expressed *c-fos* mRNA following vehicle injection. In contrast, robust labeling for *c-fos* mRNA was observed in the CeA in IL-1 $\beta$  treated animals. The distribution of *c-fos* mRNA was mainly confined to the lateral subdivision of this nucleus (CeL), with most intense expression observed in ventrolateral regions. Within the CeL, although colocalization with each marker showed regional variations, in general, ~85% *c-fos* positive cells were also positive for GAD 65/67 mRNA. In addition, ~75% cells expressing *c-fos* mRNA expressed ENK mRNA. Fewer cells contained both *c-fos* and NT mRNA (~25%). In contrast to that observed for the paraventricular nucleus of the hypothalamus, very few cells labeled for both *c-fos* and CRH mRNA.

Further studies to determine the projection pathway(s) of these cells may help us to predict the functional significance of activation of the CeA by IL-1 $\beta$ .

## 43.5

**RESPONSES OF THE SPLENIC SYMPATHETIC NERVE ACTIVITY TO CENTRAL ADMINISTRATION OF PROSTANOIDS AND CORTICOTROPIN-RELEASING FACTOR IN RATS.** T. Katakuchi\*, T. Ichijo, T. Ando, S. Take, and T. Hori. Dept. of Physiology, Kyushu Univ., Fac. of Med., Fukuoka 812 Japan.

It has been reported that the suppression of cellular immunity induced by central administration of interleukin-1 $\beta$  (IL-1 $\beta$ ) and interferon  $\alpha$ , at least partly, mediated by an enhancement of the splenic sympathetic nerve activity (SSNA) and that the immunosuppression or the increase in the nerve activity are blocked by pretreatment with corticotropin-releasing factor (CRF)-antagonist and cyclooxygenase inhibitors.

In the present study, we confirmed that an infusion of CRF (0.1-5.0  $\mu$ g/10 $\mu$ l/rat) into the third cerebral ventricle (ICV) increased the SSNA in a dose-dependent manner in urethane +  $\alpha$ -chloralose anesthetized rats. The responses of the SSNA to CRF (1.0  $\mu$ g) were completely blocked by ICV pretreatment with  $\alpha$ -helical CRF<sub>41-47</sub> (20  $\mu$ g/20  $\mu$ l). No changes in the arterial blood pressure was observed after CRF injection. An enhancement of the SSNA induced by CRF (1  $\mu$ g) was not blocked by pretreatment with sodium salicylate (1  $\mu$ g) at a dose of 1000 times more than that for suppressing the IL-1 $\beta$ -induced activation of the SSNA. An ICV injection of prostaglandin E<sub>2</sub> (PGE<sub>2</sub>, 1 ng) also produced an increase in the SSNA through an activation of EP1 receptors. In contrast to CRF, the PGE<sub>2</sub>-induced enhancement of the SSNA was completely blocked by pretreatment with  $\alpha$ -helical CRF<sub>41-47</sub>. These findings indicate that there is a sequential relationship between actions of CRF and PGE<sub>2</sub>, with an activation of PGE<sub>2</sub> followed by that of CRF system. ## 43.7

**PROLONGED EFFECTS ON GENE REGULATION IN THE PARAVENTRICULAR NUCLEUS (PVN) FOLLOWING A SINGLE INJECTION OF INTERLEUKIN-1 $\beta$**

K. Van Koughnet, O. Smirnova, S.E. Hyman, D. Borsook\*, Molecular and Developmental Neurobiology Laboratory, Mass. Gen. Hospital, Boston MA 02114

The proinflammatory cytokine interleukin 1- $\beta$  (IL-1 $\beta$ ) has a number of physiological effects on the nervous system, including the paraventricular nucleus (PVN) of the hypothalamus. We have produced transgenic mice expressing an ENK  $\beta$ -Galactosidase fusion gene containing 3kb of 5' flanking sequences and 1kb of the 3' flanking sequences of the human preproenkephalin gene. The transgene is correctly expressed and physiologically regulated in the PVN. Administration of IL-1 $\beta$  either via i.p. (0.1  $\mu$ g - 5  $\mu$ g in 0.2ml NS) or i.c.v. (2.5-10 ng) injections produces a significant increase in transgene expression in the PVN. Following a single i.p. injection of IL-1 $\beta$  (5 $\mu$ g), there is inhibition of stress-induced transgene expression in the PVN and SON in mice receiving a 1.5M stressor 4 or 7 days later. This effect is also observed following a 1.5M saline stressor administered 7 days after mice received i.c.v. injections of IL-1 $\beta$  (10ng). The long-lived suppression is not due to the initial transgene induction nor due to "tolerance" of the system since a 1.5M stressor administered on day 1 in a separate group of mice did not have any effect on induction by 1.5M saline stressor on day 7. In preliminary experiments, a single i.p. injection of morphine (10mg/kg) had a similar, albeit smaller, effect on transgene induction compared with IL-1 $\beta$ . Induction of the transgene in the PVN correlated with c-Fos expression following i.p. injections. These results suggest that IL-1 $\beta$  stimulation may induce prolonged alterations in the response of genes such as the preproenkephalin gene to subsequent stressors.

## 43.9

**LOCALIZATION OF IMMUNE AND INFLAMMATORY MARKERS IN THE RAT VAGUS NERVE AND LIVER HILUS.** L.E. Goehler\*, R.P.A. Gaykema<sup>1</sup>, F.J.H. Tilders<sup>1</sup>, S.F. Maier, and L.R. Watkins.

Dept. Psych, Univ. Colorado, Boulder CO 80309, and <sup>1</sup>Res. Instit. Neurosci., Dept. Pharmacology, Vrije Universiteit Amsterdam, The Netherlands.

Recent evidence implicates the vagus nerve in immune to brain communication. The signal transduction pathways by which immune stimuli may activate the vagus, however, have not been identified. Potential immune/inflammatory mediators include interleukin-1 (IL-1), prostaglandin E<sub>2</sub>, nitric oxide, and serotonin (5HT). The aims of the present experiment were 1) to identify immune elements, such as macrophages, dendritic cells and mast cells, associated with the abdominal vagus nerve and liver hilus, and 2) to localize potential signalling substances within these cells. To identify immune elements within the vagus nerves, associated paranglia, and connective tissue, cryostat sections of ventral abdominal vagus nerve, including the hepatic branch and liver hilus, from i.p. endotoxin-treated rats were incubated with antisera raised against either complement receptor 3 (OX42), MHC class II antigen (OX6), or 5HT. In addition, sections were incubated with antisera raised against IL-1, cyclooxygenase 2 (COX2), and inducible nitric oxide synthase (iNOS). Dendritic cells (OX6 positive) extended processes along the nerves and within the paranglia, whereas macrophages (OX42, IL-1, COX2, & iNOS positive) were found in abundance around the nerve, and within nerve-associated lymphoid tissue. In addition, COX2 antiserum labeled endothelium in whole nerve and liver hilus. Anti-5HT antiserum labeled numerous mast cells throughout the tissue, as well as glomus cells in the paranglia. These results indicate that cells producing inflammatory mediators are located in close association with vagal nerve fibers and paranglia. As such they provide an anatomical basis for immune to brain communication via vagal afferents.

## 43.6

**BRAIN PROSTAGLANDIN E<sub>2</sub>-INDUCED FEVER AND CHANGES IN NOCICEPTION IN RATS ARE MEDIATED BY DIFFERENT TYPES OF EP RECEPTORS.** T. Hori\*, T. Oka, M. Hosoi, K. Oka and S. Aou. Dept. Physiol, Fac. Med., Kyushu Univ., Fukuoka 812-82, Japan.

To determine which EP receptors are involved in the PGE<sub>2</sub>-induced fever and changes in nociception, we observed the changes in colonic temperature (Tco), nociceptive behavior and the activities of nociceptive neurons in the trigeminal nucleus in the rat after intracerebral injection of PGE<sub>2</sub> and its agonists, i.e., 17-phenyl- $\omega$ -trior (17PT)-PGE<sub>2</sub>, butaprost and M&B28767 (EP1, EP2 and EP3 agonists, respectively). A microinjection of PGE<sub>2</sub> (0.1-10 nmol) and 17PT-PGE<sub>2</sub> (1-10 nmol) into the lateral cerebroventricle (LCV) produced a rapid and dose-related rise in Tco. Neither butaprost (0.1-100 nmol) nor M&B28767 (0.01-1 nmol) produced any significant changes in Tco. The PGE<sub>2</sub>-induced fever was blocked by the LCV pretreatment with SC19220 (EP1 antagonist). On the other hand, non-pyrogenic doses of PGE<sub>2</sub> (10 fmol-10 pmol, LCV) and M&B28767 (1-100 fmol, LCV) enhanced nociception as assessed by a hot-plate test, but 17PT-PGE<sub>2</sub> and butaprost had no effect on nociception. However, the LCV injection of PGE<sub>2</sub> at 1 nmol and 17PT-PGE<sub>2</sub> (50 nmol), but not the EP2 and EP3 agonists, induced a rapid and short-lasting hypoalgesia. Nociceptive responses of wide dynamic range neurons in the trigeminal nucleus in urethane-anesthetized rats were enhanced by M&B28767 (10 fmol, LCV) and attenuated by 17PT-PGE<sub>2</sub> (10 nmol, LCV). The results indicate (1) that the PGE<sub>2</sub>-induced fever is mediated by EP1 receptors and (2) that PGE<sub>2</sub> at low (non-pyrogenic) doses and high (pyrogenic) doses produces hyperalgesia and hypoalgesia by its actions on EP3 and EP1 receptors, respectively. [Supported by Grant No.06454153 (TH) from Monbusho, Japan]

**PERIPHERAL ENDOTOXIN SIGNALS HYPOTHALAMIC CRH NEURONS VIA VAGAL AFFERENTS: EVIDENCE FROM VAGOTOMY AND PVN LESIONS.** R.P.A. Gaykema\*, G.B. Makara, I. Dijkstra and F.J.H. Tilders. Res. Inst. Neurosciences Vrije Universiteit, Dept. Pharmacology, 1081 BT Amsterdam, The Netherlands, and Inst. Exp. Med. Hung. Acad. Sci., Budapest, Hungary.

Systemic bacterial endotoxin (LPS) as a inflammatory stimulus induces brain-generated illness responses such as fever and activation of the HPA axis. Macrophage-derived IL-1 $\beta$  is known to be involved, but signalling routes to the brain are not well understood. LPS and IL-1 $\beta$  induce c-fos in defined brain areas including the n. tractus solitarius (NTS), and the n. paraventricularis (PVN). The question emerged whether vagal afferents are involved in the activation of the HPA axis by LPS. Therefore, we assessed whether 1) vagal transection abrogates activation of an ascending pathway via NTS to PVN and 2) the activated substrate as revealed by c-fos expression is not part of a descending route from PVN to medulla oblongata. Rats received subdiaphragmatic vagotomies (VGX), PVN lesions, or were sham-operated. Two hours after LPS (20 or 250  $\mu$ g/kg i.p.) or saline, the rats were decapitated, brains and trunk blood were collected, ACTH and corticosterone levels in plasma, as well as Fos, CRH and TH immunoreactivity in brain sections were determined. VGX suppressed low dose ip LPS-induced Fos expression in NTS and in CRH neurons of the PVN, and suppressed ACTH responses. Responses following the high dose of LPS were much less affected by VGX, but also involved increased Fos expression in the area postrema. PVN lesions attenuated ACTH and cort responses to LPS, but did not influence Fos expression in the NTS. We conclude that low dose of ip LPS leads to activation of a sensitive pathway via vagal afferents that subsequently activate neurons in the NTS, which in turn stimulate neurosecretory CRH cells in the PVN. Additional pathways operating parallel to the vagal route, including the area postrema, may become important in the HPA responses to higher doses of LPS.

**RESPONSES TO INTRAVENOUS CYTOKINES (IL-1 $\beta$  & TNF- $\alpha$ ) ARE ATTENUATED BY SUBDIAPHRAGMATIC VAGOTOMY.** B. A. Schwartz\*, M. Flechner, M. McGorry, L. E. Goehler, D. Martin<sup>1</sup>, S. F. Maier, & L. R. Watkins. Dept Psychology, Univ Colorado at Boulder, Boulder, CO 80309 & <sup>1</sup>Amgen, Boulder, CO.

Sudiaphragmatic vagotomy blocks fever & corticosterone (CORT) responses produced by intraperitoneally (i.p.) administered IL-1 $\beta$  & TNF- $\alpha$ . There is some evidence that transection of the vagus does not block these responses if cytokines are administered intravenously (i.v.). Thus the present studies tested whether sudiaphragmatic vagotomy will block either fever or CORT responses to i.v. IL-1 $\beta$  & TNF- $\alpha$ . Dose response studies were conducted to match the levels of fever produced by i.p. IL-1 $\beta$ , as well as to match the CORT response produced by i.p. TNF- $\alpha$ . In Exp. 1, rats (8/grp) received either sudiaphragmatic vagotomy or sham surgery. Rats (4-6wks after surgery) were then implanted with thermistors i.p.. Three days after thermistor implantation, rats were injected i.v. with either 0 or 500ng IL-1 $\beta$ . Core body temperatures (CBT) were taken prior to injection (BL) and then each 30 min for 6 hrs. Complete sudiaphragmatic vagal transections were verified using fluorogold. Sudiaphragmatic vagotomy attenuated the elevation in CBT produced by i.v. IL-1 $\beta$ . In Exp. 2, rats (6/grp) received either sudiaphragmatic vagotomy or sham surgery. Rats (4-6wks after surgery) were injected i.v. with either 0 or 75 $\mu$ g TNF- $\alpha$ . Blood samples were taken at 0, 1, 2 & 4 hrs after injection & serum CORT levels measured by RIA. Complete sudiaphragmatic vagal transections were verified using fluorogold. Sudiaphragmatic vagotomy attenuated the TNF $\alpha$  induced increase in CORT. Thus the vagus is involved in mediating peripheral (both i.p. & i.v.) cytokine communication to the brain. Supported by NIH MH55283, NIH MH45045, & UROP.

## 43.11

**SUBDIAPHRAGMATIC VAGOTOMY SELECTIVELY BLOCKS TNF $\alpha$  EFFECTS ON CARRIER PROTEINS & SERUM CORTICOSTERONE.** M. Fleshner\*, L. Silbert, T. Deak, L.E. Goehler, D. Martin<sup>1</sup>, S.F. Maier, & L.R. Watkins. Dept Psych, U. Colorado, Boulder, CO 80309 & <sup>1</sup>Amgen, Boulder, CO.

We have previously reported that subdiaphragmatic vagotomy blocks corticosterone (CORT) elevation & hypothalamic NE depletion induced by peripheral IL-1 $\beta$  [Brain Res. Bull. 37 (1995): 605-610]. The present studies tested whether TNF $\alpha$ : 1) produces the same pattern of changes as that produced by IL-1 $\beta$ ; 2) signals the HPA response via the vagus; & 3) signals liver protein synthesis changes via the vagus. In Exp. 1, rats (8/grp) received 0, 250 (x2) or 500 (x2)  $\mu$ g i.p. TNF $\alpha$ . Blood samples were taken at 0.5, 1, 2 & 4 hrs later & serum CORT levels measured by RIA. After the final blood sample, hypothalami were removed. Tissue NE levels were assayed using HPLC. Both doses of TNF $\alpha$  produced an elevation in serum CORT at 1, 2 & 4 hrs after injection similar to that reported with IL-1 $\beta$ . In contrast, TNF $\alpha$  did not produce hypothalamic NE depletion. Exp. 2 examined the role of the vagus in TNF $\alpha$  mediated effects. Rats (6/grp) received subdiaphragmatic vagotomy or sham surgery. Rats (4-6wks after surgery) were injected with either 0 or 250 (x2)  $\mu$ g i.p. TNF $\alpha$ . Blood samples were taken at 0, 1, 2 & 4 hr after injection & serum CORT measured. In addition, liver protein synthesis was assessed by measuring total serum protein & corticosterone binding globulin (CBG; the CORT carrier protein). Subdiaphragmatic vagotomy blocked the TNF $\alpha$  induced increase in CORT but did not block the TNF $\alpha$  induced decrease in serum protein & CBG. Thus the vagus plays a selective role in TNF $\alpha$  mediated communication to the brain. Supported by NIH MH55283, NIH MH45045, & UROP.

## 43.12

**LEUKOCYTE TRAFFICKING INTO THE RAT CENTRAL NERVOUS SYSTEM AFTER VIRAL INFECTION OF VISUAL CIRCUITRY.**

S. Rassnick\*, L. W. Enquist<sup>1</sup>, A.F. Sved, and J. P. Card. Dept. of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260 and <sup>1</sup>Dept. of Molecular Biology, Princeton University, Princeton, NJ 08544.

The temporal characteristics of leukocyte infiltration into the rat CNS was studied using a well-characterized model of viral-induced neuropathogenesis. Rats received an intra-vitreous injection of a virulent neurotropic alpha herpesvirus (pseudorabies virus, PRV-Becker) to produce a productive infection of central visual circuitry that arises from transsynaptic passage of PRV from retinal ganglion cells. A powerful aspect of this model is that temporally separate stages of infection emerge: the onset of productive viral replication is evident in the dorsal geniculate nuclei and tectum approximately one day prior to that in retino-recipient regions of the circadian timing system (e.g., suprachiasmatic nucleus). Immunocytochemical procedures were used to identify infected sites 72 hrs post-inoculation using antibodies to virion proteins. Non-neuronal cells that were localized around these sites of infection were detected with antibodies that recognize the leukocyte common antigen (i.e., mononuclear leukocytes and microglia), a cytoplasmic antigen on monocytes and macrophages (ED-1+), or the  $\beta$  chain of CD8 antigen on cytotoxic T-lymphocytes. Viral infection and leukocyte recruitment first occurred in the dorsal geniculate and tectum, then in the suprachiasmatic nucleus. Localization of subclasses of cells with specific antibodies showed focal recruitment of reactive microglia, monocytes, and CD8+ lymphocytes to regions of viral infection. Quantitative analysis revealed that the magnitude of this recruitment correlated with the number of infected neurons and pathological changes in each retino-recipient area examined and that ED-1+ and CD8+ cells were most numerous in areas of advanced infection. Because the transport of PRV through the visual circuitry preceded leukocyte infiltration, these findings suggest that leukocyte trafficking is spatially and temporally-linked to the transsynaptic passage of virus and the severity of infection in the nervous system [Supported by RO1 MH53574 (JPC) and RO1 NINDS33506 (LWE)].

## CARDIOVASCULAR REGULATION: BRAINSTEM MECHANISMS

## 44.1

**PERIAQUEDUCTAL GRAY MATTER PROJECTIONS TO AUTONOMIC PREGANGLIONIC NEURONS.** E. Farkas, A. S. P. Jansen and A. D. Loewy\*. Dept. of Anatomy and Neurobiology, Washington University, School of Medicine, St. Louis, MO 63110

Stimulation of the periaqueductal gray (PAG) produces a variety of autonomic and somatomotor responses. In order to analyze the anatomical substrate of the visceral responses, we have used pseudorabies virus (PRV), a transneuronal retrograde marker and *Phaseolus vulgaris* leucoagglutinin (PHA-L), an anterograde axonal tracer to determine the specific PAG projections to autonomic preganglionic nuclei. Two sympathetic systems (adrenal gland and stellate ganglion) and two parasympathetic systems (trachea and pancreas) were studied with the PRV tracing method. After inoculating these targets with PRV, the lateral, ventrolateral and dorsomedial PAG subnuclei contained virally infected neurons. In a second experiment, specific subregions of the PAG were injected with PHA-L. The PAG projects to the dorsal vagal nucleus, the nucleus ambiguus and the salivatory nuclei. We suggest that the PAG coordinates autonomic output via direct pathways to autonomic preganglionic nuclei, in addition to known projections to pontine and medullary premotor areas.

**LOCUS COERULEUS ACTIVITY AND SYMPATHETIC NERVE DISCHARGE DURING CLONIDINE WITHDRAWAL.** M. Fisher\*, R.L. Stornetta and P. G. Guyenet. Pharmacology Dept., Univ. of Virginia, Charlottesville, VA 22908.

The present experiments sought to determine the discharge pattern of locus coeruleus (LC) neurons and a sympathetic nerve (SND, splanchnic) during antagonist precipitated clonidine (CLO) withdrawal. Rats were treated chronically with CLO via osmotic minipumps (200  $\mu$ g/kg/day, s.c.) or received sham operation.

After 7-13 days CLO-treated rats or sham rats were anesthetized with halothane, artificially respired, and instrumented for i.v. drug administration, arterial pressure (AP), SND measurement and LC unit recording. After baseline measurements were obtained the  $\alpha_2$ -adrenergic receptor antagonist atipamezole was administered (1.5 mg/kg, i.v.). Chronic treatment with CLO did not alter resting mean AP and heart rate (CLO: 103 $\pm$ 5mmHg, 359 $\pm$ 14bpm; sham: 106 $\pm$ 4mmHg, 338 $\pm$ 12bpm). In addition baseline LC unit firing was unaltered by chronic CLO treatment (CLO: 2.0 $\pm$ 0.1 spikes/s, n=82; sham: 1.6 $\pm$ 0.2, n=54). CLO withdrawal with atipamezole produced tachycardia (+86 $\pm$ 9bpm vs +3 $\pm$ 8bpm for shams, p<.001) but no change of mean AP (p<0.46). CLO withdrawal increased SND (163 $\pm$ 14%, p<0.001) and produced abrupt swings between 2 levels of activity (SND upswings of 30-120 s duration occurring every 1-4min). Administration of the  $\alpha_2$  antagonist to sham rats produced little effect on LC firing (1.7 $\pm$ 0.1 spikes/s after drug, n=51). In rats treated chronically with CLO atipamezole silenced LC units for several min (n=7). Then units fired selectively during the SND upswings (n=32). In conclusion, antagonist precipitated CLO withdrawal in halothane-anesthetized rats exhibits several features reported previously in awake spontaneously CLO withdrawing rats including tachycardia but little change in mean AP. Under anesthesia the syndrome included increased SND with periodic upswings synchronized with episodes of LC activity. These abrupt fluctuations may underlie the characteristic AP upswings present in awake rats that undergo spontaneous CLO withdrawal. Supported by NIH RO1 HL28785.

**PERIAQUEDUCTAL GRAY NEURONAL RESPONSES TO HINDLIMB MUSCLE CONTRACTION IN THE CAT.** J.M. Kramer\*, M.D. Jarboe and T.G. Waldrop. Depts. of Molecular and Integrative Physiology and Kinesiology, College of Medicine and the Neuroscience Program, University of Illinois at Urbana-Champaign, Urbana, IL 61801.

The cardiovascular and respiratory responses to muscle contraction have been well defined; however, the brain substrates responsible for these responses have not been completely mapped. Therefore, the goal of this study was to examine the possible involvement of the periaqueductal gray region of the midbrain (PAG), an area known to play a role in blood pressure and respiratory control, in exercise regulation. Static contractions of hindlimb muscles were evoked by stimulation (40Hz, 3X MT) of the peripheral, cut ends of the L7 and S1 ventral roots in anesthetized cats. The Achilles tendon was isolated and attached to a force transducer for force measurement. Single unit activity of PAG neurons was recorded with tungsten microelectrodes; signal averaging was performed to characterize basal rhythms of the neurons relative to the cardiac cycle, cervical sympathetic nerve and phrenic nerve activities. Static muscle contraction altered the discharge rate of 60% of the PAG neurons studied. Most (78%) neurons responded to contraction with an increase in firing rate; 22% neurons were inhibited by contraction. Neurons in more caudal regions of the PAG appeared to respond with a greater increase in firing rate than neurons in rostral regions. The basal discharge of most neurons stimulated by muscle contraction was related to cardiac, sympathetic or respiratory rhythms with cardiac rhythms being most prevalent. Thus, these findings indicate that PAG neurons receive input from skeletal muscle receptors responsive to muscular contraction. Since the basal discharge of these contraction-sensitive neurons have cardiovascular/respiratory related rhythms, the PAG may play a role in eliciting cardiorespiratory adjustments observed during exercise. ## 44.4

**Somatostatin Activates An Apamin-Sensitive Potassium Conductance in Parabrachial Neurons *In Vitro*.** Samuel B. Kombian<sup>1</sup>\*, Tarek M. Saleh<sup>1</sup>, Jeffrey A. Zidichouski<sup>1,2</sup>, and Quentin J. Pittman<sup>1</sup>. <sup>1</sup>Neuroscience Research Group, University of Calgary and <sup>2</sup>Ciba-Geigy Canada Ltd., Calgary, Alberta, Canada T2N 4N1

The peptide somatostatin 1-28 (SOM) has previously been shown to modulate the flow of visceral afferent information through the parabrachial nucleus (PBN) to the cortex in the rat *in vivo*. However, the cellular mechanism by which SOM produces this effect is not known. We therefore examined the effects of SOM on PBN cells and on synaptic transmission in this nucleus using a pontine slice preparation and the nystatin perforated-patch recording technique. Bath application of SOM over a wide concentration range, affected neither the CNQX-sensitive EPSC evoked by perinuclear stimulation nor the frequency of TTX resistant mEPSCs. However, SOM (10  $\mu$ M) attenuated the inward current induced by a brief bath application of AMPA. While in many neurons, SOM activates an M-current, we did not find evidence for the presence of this current in PBN cells. SOM reversibly induced an apamin-sensitive (charybotoxin-insensitive), calcium-activated potassium conductance leading to an outward current in these cells. It also blocked an outwardly rectifying conductance activated above -50 mV. These effects were mimicked by the SOM fragment 1-14 but not by the fragment 1-12. Furthermore, SOM did not affect the charybotoxin-sensitive AHP recorded in these cells. When slices were incubated overnight in pertussis toxin, the SOM-induced effects were abolished, suggesting that a pertussis toxin-sensitive G-protein couples the SOM receptor to its effectors in PBN cells. These results show that SOM modulates a potassium conductance in PBN cells. This postsynaptic effect of SOM may decrease the excitability of PBN cells and modulate their response to other inputs. (This work is supported by MRC, Alberta Heart and Stroke and AHFMR).

**Peptidergic modulation of synaptic transmission in the parabrachial nucleus *in vitro*: Importance of degradative enzymes in regulating synaptic efficacy.** TM. Saleh<sup>1</sup>\*, SB. Kombian<sup>1</sup>, JA. Zidichouski<sup>1,2</sup> and OJ. Pittman<sup>1</sup>

<sup>1</sup>NRG, University of Calgary and <sup>2</sup>Ciba-Geigy Canada Ltd., Calgary, Alberta, Canada

This study examined the effects of substance P (SP) and calcitonin gene-related peptide (CGRP) on synaptic transmission in a pontine slice preparation containing the parabrachial nucleus (PBN). Stimulation of the ventral, external lateral portion of the PBN elicited glutamate-mediated, excitatory postsynaptic currents (EPSC) in cells recorded using the nystatin perforated-patch recording technique in the external lateral, external medial and central lateral subnuclei of the PBN. Bath application of SP or CGRP dose-dependently and reversibly attenuated the evoked EPSC. The attenuation of the EPSC induced by both of these peptides was not accompanied by changes in input resistance of PBN cells over a wide voltage range, nor did these peptides alter the inward current induced by a brief bath application of AMPA. Both peptides did cause a decrease in the frequency on spontaneous, miniature-EPSCs. The combined application of subthreshold concentrations of these two peptides revealed a synergistic interaction in reducing the evoked EPSC. The substance P neurokinin-1 (NK-1) receptor antagonist, CGP49823, completely and reversibly blocked both the SP- and CGRP-induced attenuation of the EPSC. However, the rat-CGRP receptor antagonist, human-CGRP (HCGRP<sub>8-37</sub>) did not block the actions of CGRP or SP on the EPSC. Using a metabolically stable analogue of SP, SP (5-11), or an endopeptidase inhibitor, phosphoramidon, we were able to demonstrate that CGRP enhances the SP effect by inhibiting a SP endopeptidase. These results suggest that SP (and CGRP indirectly through an inhibition of the SP endopeptidase) acts on presynaptic, NK1-receptors to cause an inhibition of excitatory transmission in the PBN. These results indicate an important role of endopeptidases in regulating synaptic modulation by peptides. (This work is funded by the MRC and Alberta Heart and Stroke and AHFMR).

## 44.7

**MODULATION OF ARTERIAL CHEMORECEPTOR INPUTS IN THE RAT NTS BY ACTIVATION OF THE LATERAL PARABRACHIAL NUCLEUS (LPBN).** L.F. Hayward\*, and R.B. Felder. Dept. of Internal Med., University of Iowa College of Medicine, Iowa City, IA 52242

There is increasing evidence that the LPBN may be an important modulator of cardiorespiratory reflexes, including the arterial baroreflex and the arterial chemoreflex. Previous studies have demonstrated that descending projections from the LPBN to the nucleus tractus solitarius (NTS) are involved in LPBN attenuation of baroreflex function. The present study was undertaken to investigate whether interconnections between the LPBN and the NTS may also be involved in LPBN modulation of arterial chemoreflex function. Extracellular recordings were made from urethane anesthetized male Sprague Dawley rats (300-350 gm). Arterial chemoreceptors were stimulated by intracarotid injection of CO<sub>2</sub> saturated bicarbonate. LPBN neurons were activated with a monopolar stimulating electrode placed in the ipsilateral LPBN. Ten of 21 NTS neurons were responsive to arterial chemoreceptor stimulation, including 5 which were chemoreceptor excited (mean increase in discharge rate 40±17%; mean±SEM) and 5 which were chemoreceptor inhibited (mean decrease in discharge rate -47±10%). Electrical stimulation of the LPBN inhibited the spontaneous discharge of 6/10 chemoreceptor responsive NTS neurons (mean decrease in baseline activity 65±9%), including 3 chemoreceptor inhibited and 3 chemoreceptor excited neurons. These preliminary results demonstrate that activation of the LPBN may modulate central processing of chemoreceptor inputs at the level of the NTS, supporting previous work which implicates the LPBN in the central modulation of the arterial chemoreflex. Supported by AHA (LFH) and HL14388 (RBF).

## 44.9

**CHOLINERGIC BLOCKADE ELIMINATES THE HEART RATE PAUSES OF TONIC REM SLEEP.** R.T. Lau, U.T. Walloppillai, B.D. Nearing, J. Quattrochi\*, J.A. Hobson, and R.L. Verrier. Laboratory of Neurophysiology, Program in Neuroscience, Harvard Medical School; Institute for Prevention of Cardiovascular Disease, Deaconess Hospital, Boston, MA 02115 and Harvard College, Cambridge, MA 02138.

Abrupt changes in cardiac rhythm reflect the high degree of autonomic variability associated with REM sleep but the precise CNS and peripheral autonomic mechanisms mediating these changes are unclear. In order to investigate state-dependent changes in heart rate, respiration, and the autonomic mechanisms responsible for these events during REM sleep, cats were chronically implanted under surgical anesthesia with EEG, EMG, EOG, LGB, hippocampal CA1, diaphragmatic, and ECG electrodes.

Following control recordings, 0.3 mg/kg of the  $\beta_1$  adrenergic blocker atenolol and 0.1 mg/kg of the muscarinic blocker glycopyrrolate (neuroactive compounds with polar hydrophilic properties which do not cross the blood-brain barrier) were administered intravenously in freely moving, unanesthetized animals, both alone and in combination. R-R intervals were computer analyzed and correlated with pontine, cortical, hippocampal, and diaphragmatic activity.

Normal REM sleep was marked by distinct pauses in heart rate defined as decelerations in rate of  $\geq 20\%$  lasting 1.2 to 5 sec. Pauses occurred principally during tonic and low-level phasic REM sleep and were shown to be respiratory-independent as measured by diaphragmatic activity. Parasympathetic blockade with glycopyrrolate selectively eliminated pauses with or without concomitant autonomic blockade with atenolol.

These results suggest that cholinergic mechanisms play a major role in heart rate variability during REM sleep. Specifically, we conclude that: 1) tonic activity during REM is associated with pauses in heart rate; and 2) pauses are the result of vagal cholinergic influence as opposed to sympathetic withdrawal. Research supported by HL50078 and MH13923.

## 44.6

**Cholecystokinin Inhibits and Neurotensin Enhances Excitatory Synaptic Transmission in the Parabrachial Nucleus *In Vitro*.** JA. Zidichouski<sup>1,2</sup>\*, TM. Saleh<sup>1</sup>, SB. Kombian<sup>1</sup>, and OJ. Pittman<sup>1</sup>. Neuroscience Research Group, University of Calgary and <sup>2</sup>Ciba-Geigy Canada Ltd., Calgary, Alberta, Canada T2N 4N1

Cholecystokinin (CCK) and neurotensin (NT) are present in fibres innervating the parabrachial nucleus (PBN) and have previously been shown to modulate the flow of visceral afferent information through the PBN to the cortex in the rat. This study examined the effects of CCK and NT on synaptic transmission in the PBN using a pontine slice preparation and the nystatin perforated-patch recording technique. Stimulation of the ventral, external lateral portion of the PBN elicited glutamate-mediated, excitatory postsynaptic currents (EPSC) in cells recorded in the PBN. Bath application of NT dose-dependently and reversibly enhanced, while CCK attenuated, the evoked EPSC. In addition, the frequency of spontaneous, miniature-EPSCs recorded in PBN cells was significantly increased by NT and decreased by CCK application. Paired-pulse depression was also enhanced and decreased by NT and CCK, respectively. These synaptic changes induced by NT and CCK were not accompanied by changes in input resistance of PBN cells over a wide voltage range (although NT reduced an outwardly rectifying conductance at potentials positive to -20 mV), nor did these peptides alter the inward current induced by a brief bath application of the glutamate agonist, AMPA. The NT antagonist, SR48692 (100  $\mu$ M), completely and reversibly blocked the NT-induced enhancement of the EPSC. The non-selective CCK receptor antagonist, proglumide (100  $\mu$ M), completely and reversibly blocked the CCK-induced attenuation of the EPSC. In addition, the selective CCK-A receptor antagonist, L-364,718 (10  $\mu$ M), but not the selective CCK-B receptor antagonist, L-365,260 (100  $\mu$ M), blocked the effect of CCK on synaptic transmission. These results suggest that NT and CCK act at presynaptic NT and CCK-A receptors respectively to modulate excitatory synaptic transmission through this nucleus. (This work is supported by MRC, Alberta Heart and Stroke and AHFMR).

## 44.8

**SUBSTANCE P MAY EXCITE BARORECEPTIVE UNITS OF THE LATERAL PARABRACHIAL COMPLEX.** J.A. Lovell and S.L. Stuesse\*. Kent State University, Tuscarawas Campus, New Philadelphia, Ohio 44663 and Neurobiology Dept., NEOUOM, Rootstown, Ohio 44272.

Cardiovascular information ascends from the nucleus tractus solitarius of the medulla to the Lateral Parabrachial Complex (LPB). Substance P-containing fibers and cells are found throughout the rostrocaudal extent of the LPB. Although commonly associated with transmitting painful stimuli, substance P is found in brain regions not associated with processing information about pain. To explore whether substance P might play a role in the processing of baroreceptive information within the LPB, we identified areas of the LPB containing neurons that displayed blood pressure-dependent changes in activity and determined if exogenously applied substance P affected the activity of these neurons.

Substance P and norepinephrine were pressure ejected into the lateral parabrachial complex in areas that contained units responsive to acute changes in systemic blood pressure. The effects of these drugs on multiple unit activity was ascertained. Substance P (10 ng/ $\mu$ l and 100 ng/ $\mu$ l) increased multiple unit activity of blood pressure-sensitive units of the lateral parabrachial complex, while a lower dose of substance P (1 ng/ $\mu$ l) had no effect. Neither norepinephrine (1  $\mu$ g/ $\mu$ l) nor phosphate buffer changed the activity of blood pressure-sensitive neurons. Thus, substance P may play a role in processing of baroreceptive information in the lateral parabrachial complex.

## 44.10

**SYMPATHETIC BLOCKADE ELIMINATES THE HEART RATE SURGES OF PHASIC REM SLEEP.** J. Quattrochi, U.T. Walloppillai, R.T. Lau, B.D. Nearing, J.A. Hobson\*, and R.L. Verrier. Laboratory of Neurophysiology, Program in Neuroscience, Harvard Medical School; Institute for Prevention of Cardiovascular Disease, Deaconess Hospital, Boston, MA 02115 and Harvard College, Cambridge, MA 02138.

REM sleep is characterized by intense phasic central activation and surges in heart rate coupled with elevations in coronary blood flow reflecting marked variability in autonomic regulation. The neural mechanisms underlying these phasic alterations in CNS state and cardiac rhythm remain to be defined. In order to investigate state-dependent changes in heart rate, respiration, and the autonomic mechanisms responsible for these events during REM sleep, cats were chronically implanted under surgical anesthesia with EEG, EMG, EOG, LGB, hippocampal CA1, diaphragmatic, and ECG electrodes.

Normal REM sleep was marked by episodes of surges in heart rate lasting  $>3.5$  sec with a mean R-R interval  $<300$  msec. Surges were closely associated with phasic PGO activity and theta rhythm, but independent of respiratory diaphragmatic activity. Following a control series of recordings, atenolol ( $\beta_1$  adrenergic blocker, 0.6 mg/kg i.v.) and glycopyrrolate (muscarinic blocker, 0.1 mg/kg i.v.) were administered in freely moving, unanesthetized animals, both alone and in combination. R-R intervals were computer analyzed and correlated with pontine, cortical, hippocampal, and diaphragmatic activity. Sympathetic blockade with atenolol selectively eliminated surges.

These results suggest that an ascending degree of cholinergic phasic activity in the pontine tegmentum and hippocampal theta during REM sleep promotes an increase in sympathetic innervation of the heart leading to surges in heart rate. Research supported by HL50078 and MH13923.

DO LATERAL PARABRACHIAL NEURONES PROJECT TO THE INTERMEDIOLATERAL CELL COLUMN IN THE THORACIC SPINAL CORD?

John H. Coote†, Kamal Motawejit†, Susan Pynert†, Richard Ransont† and Maher Kamel†, †Department of Physiology, University of Birmingham, Birmingham B15 2TT UK and ‡Department of Anatomy, University of Minia, Minia, Egypt. SPON: Brain Research Association

The lateral subnuclei of the parabrachial complex [LPBN] located in the dorsolateral pons are considered to play an important role in modulating cardiorespiratory activity. Several studies have shown this region has the appropriate connections both to and from the medulla and higher brain regions, to carry out this role, but so far no direct projections to sympathetic nuclei in the spinal cord have been described. In an anterograde tracing study using biotin dextran amine injected into a highly discrete site in the external LPBN we have traced axons to the thoracic cord where terminal branches entered the intermediolateral cell column [IML] and central autonomic area. However, these branches did not make synaptic contact with sympatho-adrenal preganglionic neurones which had been pre-labelled with the retrograde tracer cholera B toxin HRP. Furthermore the density of terminals was greater in the upper thoracic segments T<sub>1</sub>-T<sub>8</sub> than in the lower thoracic segments. Therefore it is possible that the LPBN neurones project to the thoracic cord and their axon terminals synapse with interneurons in or close to IML or preferentially synapse with non adrenal medullary sympathetic neurones.

ROSTRAL PARA-AMBIGUOUS FIELD NEURONS HAVE ACTIVITY CORRELATED TO THE 8-13 HZ RHYTHM IN SYMPATHETIC NERVE DISCHARGE IN CAT. C. W. Dempsey\*, D. E. Richardson, C. J. Fontana, and J.-H. Song. Lab. of Neurosurgery, Tulane University School of Medicine, New Orleans, LA 70112.

The 8-13 Hz rhythm of the sympathetic nerve discharge (SND) has previously been reported (J. Neurophysiol. 72:106-120, 1994) to correlate to unit activity in the rostral caudal ventrolateral medulla (0-2.5 mm rostral to the obex, 4-4.25 mm lateral, and within 2 mm of the ventral surface) in cat, but not to any region more anterior. We have now shown that such correlation can be obtained for neurons in the rostral para-ambiguous field, extending 3.8 mm rostral to the obex and over a wider range of laterality (3.5 to 4.2 mm), and at similar depth. Twenty-one of 78 examined cells in baroreceptor-denervated, urethane-anesthetized cat correlated with a 9.3-12.2 Hz peak in the SND, while firing at an average rate of  $2.8 \pm 0.6$  spikes/sec. The power spectra of all neurons displayed a sizable peak corresponding to the correlating frequency. Several neurons had power spectra containing additional peaks that were comparable in size to the peak of the correlating frequency, but were not cardiac related or relevant to any known phenomena. Activation of the baroreflex (by aortic obstruction) in these baroreceptor-denervated animals regularly shifted the 8-13 Hz rhythm of the SND to the cardiac frequency, the higher frequency returning promptly when the blood pressure returned to normal. (Funding provided by the Tulane Department of Neurosurgery.)

DIFFERENTIAL RELATIONSHIPS AMONG RESPIRATORY-RELATED RHYTHMIC DISCHARGES OF SYMPATHETIC NERVES WITH DIFFERENT TARGETS. S.-Y. Zhou\*, G.L. Gebber, S. Zhong and S.M. Barman. Dept. Pharmacol./Toxicol., Michigan State Univ., E. Lansing, MI 48824

Partial coherence analysis was used to study the relationships among the respiratory-related rhythmic discharges of the left and right inferior cardiac nerves (CNs), left renal nerve (RN) and splenic nerve (SN) in vagotomized, baroreceptor-denervated cats anesthetized with pentobarbital. Whereas the ordinary coherence values (near 1.0) relating the respiratory-related discharges of pairs of these nerves were statistically indistinguishable, mathematical removal of the portion of the linear relationship between two signals common to a third (i.e., partialization) revealed that the relationships were differential. For example, the coherence value relating the respiratory-related discharges of the left CN and SN was reduced to a significantly greater extent by partialization using right CN activity than RN activity. Thus, the rhythmic discharges of the left CN and SN had more in common with right CN activity than RN activity. This might be explained by 1) episodes of selective gating of respiratory-related activity to the RN, 2) differential influences of the respiratory oscillator on circuits controlling the four sympathetic nerves, 3) differential crosstalk among circuits receiving inputs from a common rhythm generator or 4) nonuniform coupling of multiple rhythm generators, each controlling a different sympathetic nerve. The existence of multiple sympathetic rhythm generators is supported by instances when the rhythm in phrenic nerve activity became locked 1:2 to that in one sympathetic nerve and 1:1 to that in another. These observations suggest that the respiratory-related rhythmic discharges of sympathetic nerves with different targets are derived from separate although normally coupled oscillators which are themselves distinct from the respiratory oscillator. (Supported by NIH Grant HL13187).

## 44.12

PRESSOR RESPONSES ELICITED BY NATURAL STIMULATION OF VESTIBULAR RECEPTORS IN THE CAT. B.J. YATES\*, S.F. WOODRING and C.D. ROSSITER, Depts. of Otolaryngology and Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15213.

Considerable evidence suggests that the vestibular system has influences on the sympathetic nervous system and participates in compensating for posturally-related hypotension. Increases in sympathetic outflow are produced by nose-up vestibular stimulation in the cat to presumably offset a drop in blood pressure that could accompany movements that place the animal's long longitudinal axis against the force of gravity, such as vertical climbing. The purpose of the present study was to determine the characteristics of the pressor response elicited by natural vestibular stimulation.

Experiments were conducted on decerebrate, paralyzed, and artificially-ventilated cats. Selective vestibular stimulation was produced by trapezoidal movements of the head (with the body fixed) in animals whose C<sub>1</sub>-C<sub>3</sub> dorsal roots and IXth and Xth cranial nerves were transected. Nose-up trapezoidal rotations (50° amplitude, 2 sec rise time) routinely produced pressor responses in animals with systemic blood pressure > 100 mm Hg. The median amplitude of the response was ~20 mm Hg, and the latency from stimulus peak was ~1.4 sec. The responses disappeared when blood pressure dropped below 100 mm Hg, drugs that produced peripheral vasoconstriction were injected, or the VIIIth cranial nerves were cut. No changes in blood pressure were elicited by ear-down rotations.

These data demonstrate that vestibular receptors activated by nose-up tilt can elicit a large increase in blood pressure that is appropriate to offset orthostatic hypotension.

Supported by NIH grant R01 DC00693.

## 44.14

EFFECTS OF CO<sub>2</sub> DRIVE ON 10-HZ COHERENT RHYTHMS IN MULTIPLE SYMPATHETIC DISCHARGES AND ON HFOS IN PHRENIC DISCHARGE. Q.P. Yu\*, M.I. Cohen and W-X. Huang. Dept. of Physiol., Albert Einstein Col. Med., Bronx, NY 10461.

In 6 midcollicular decerebrate, vagotomized, baro-denervated, gallamine-paralyzed cats, recordings were taken from both phrenic nerves and from 3-4 sympathetic (symp.) nerves (cervical, splanchnic, inferior cardiac) at different levels of end-tidal CO<sub>2</sub>. Spectral coherences between both phrenic activities and between pairs of symp. activities were computed. During hypercapnia and normocapnia, all symp.-symp. coherences had distinct peaks around 10 Hz. In 5 cats, phrenic apnea (disappearance of respiratory rhythm) was produced at sufficiently low CO<sub>2</sub> (2-3%). As CO<sub>2</sub> level was lowered, the spectral frequency of the HFO peaks in phrenic discharge was reduced. However, during phrenic apnea distinct 10-Hz peaks were still present in symp.-symp. coherences, although they were reduced in both amplitude and frequency. The degree of reduction was variable between cats and also between signal pairs in the same cat. These results indicate that, although symp. rhythms are reduced with reduction of CO<sub>2</sub> drive, they are influenced less strongly than respiratory activity. (Supported by N.I.H. Grant HL-27300.)

## 44.16

COUPLED OSCILLATORS ACCOUNT FOR THE SLOW RHYTHMS IN SYMPATHETIC NERVE DISCHARGE (SND) AND PHRENIC NERVE ACTIVITY (PNA). S. Zhong\*, G.L. Gebber, S.-Y. Zhou, and S.M. Barman. Dept. Pharmacol./Toxicol., Michigan State Univ., E. Lansing, MI 48824.

Phase-locked slow rhythms in SND and PNA at the frequency of breathing in vagotomized animals are believed to arise from a common brain stem oscillator. The results obtained in vagotomized, baroreceptor-denervated cats anesthetized with pentobarbital do not support this view. First, whereas the coherence values relating PNA to either inferior cardiac or renal SND were close to 1.0 at the frequency of the respiratory cycle, the discharges of the two sympathetic nerves often remained significantly correlated at this frequency after partialization by using PNA. Partialization is equated to mathematical removal of the portion of the linear relationship between inferior cardiac and renal SND common to PNA. Thus, the residual coherence suggests that the slow rhythm in SND is dependent upon central mechanisms in addition to those responsible for rhythmic PNA. Second, during hypercapnia, the strong 1:1 relation between the slow rhythms in SND and PNA was disrupted. In such cases, the rhythms in SND and PNA became coupled in a 2:1 relation. Third, during hypocapnia, the slow rhythm often was maintained in SND when the phrenic nerve became quiescent. In other cases, the rhythms in SND and PNA became uncoupled (zero coherence). These observations suggest that the slow rhythms in SND and PNA arise from separate although normally coupled oscillators rather than from a common brain stem cardiorespiratory generator. (Supported by NIH grant HL13187).

## 44.17

INTERRELATIONS OF LUNG INFLATION AFFERENT ACTIVITY (LIA), PHRENIC NERVE ACTIVITY (PNA) AND SYMPATHETIC NERVE DISCHARGE (SND). G.L. Gebber\*, S. Zhong, S.-Y. Zhou and S.M. Barman. Dept. Pharmacol./Toxicol., Michigan State Univ., E. Lansing, MI 48824.

Partial coherence analysis was used to study the relationships among intratracheal pressure (ITP; index of LIA), PNA and inferior cardiac SND in normocapnic, artificially respired cats anesthetized with urethane or pentobarbital. This method mathematically removes the portion of the relationship between two signals common to a third signal. The three signals were related 1:1 at the frequency of artificial respiration, and the ordinary coherence values relating any two signals approached unity. Under urethane anesthesia, partialization of the ITP → SND relationship by using PNA reduced the coherence value from  $0.87 \pm 0.02$  to  $0.35 \pm 0.03$ . Since the partial coherence value was significantly different from zero, these data suggest that 1:1 locking of ITP and SND is dependent, in part, on a pathway from the lungs that bypasses the respiratory oscillator. The ITP → SND coherence value was reduced from  $0.87 \pm 0.01$  to  $0.15 \pm 0.01$  after partialization by using PNA under pentobarbital anesthesia. Thus, the "direct" pathway from the lungs to sympathetic networks was less important in pentobarbital-anesthetized cats. As expected, vagotomy eliminated the coherence of ITP to SND as well as PNA. Partialization of the PNA → SND relationship by using ITP (vagus intact) reduced the coherence value from  $0.85 \pm 0.02$  to  $0.23 \pm 0.04$  (urethane) and  $0.86 \pm 0.01$  to  $0.13 \pm 0.02$  (pentobarbital). These low partial coherence values suggest that either direct coupling of central respiratory and sympathetic networks was weak or ITP and PNA were almost mathematically equivalent. (Supported by NIH Grant HL13187).

## 44.19

ADRENAL NERVE RESPONSES TO ELECTRICAL VESTIBULAR STIMULATION. I.A. Kerman\* and B.J. Yates, Depts. of Otolaryngology and Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15213.

There is abundant evidence to suggest existence of vestibulo-sympathetic reflexes in the cat. These reflexes appear to counteract effects of postural changes on blood pressure to prevent orthostatic hypotension. Responses to natural and electrical vestibular stimuli have been observed in the abdominal splanchnic nerve (SN). Since SN carries some of the sympathetic preganglionic fibers innervating the adrenal gland, it is possible that adrenal function is influenced by the vestibular system. To investigate this hypothesis we recorded adrenal nerve (AN) responses to electrical stimulation of vestibular afferents.

Experiments were conducted in 4 decerebrate cats. A pair of stimulating ball electrodes was implanted in the labyrinth near vestibular afferents bilaterally. In 3 of the animals cerebellectomy was performed prior to start of recording. In the other animal recordings were performed with cerebellum first intact and then removed. ANs selected for recording were either terminal branches of SN or adrenal branches of surrounding ganglia. AN responses to stimulation of the vestibular nerve (1-5 shocks, 0.2 ms width, interpulse interval 3 ms, duty cycle 1 sec) were recorded using bipolar hook electrodes. In two animals bilateral AN dissection was performed, in the other animals only contralateral adrenal fibers were dissected. Modulating effects of electrical stimulation were observed in all animals. In three of the animals responses consisted of excitation, and in one animal the response was a combination of excitation and inhibition. Average response threshold (5-shock trains) was  $214 \pm 28$  (SEM) mA with the average latency from the effective shock of  $28 \pm 4$  (SEM) msec. Average duration of the response in all of the animals was  $54 \pm 5$  (SEM) msec. In three of the animals vestibular lesions were performed: bilateral VIIIth nerve resection, aspiration of vestibular nuclei, and kainate injection into vestibular nuclei, respectively. Each of these lesions abolished previously-recorded responses.

The present data suggest that vestibular inputs may influence adrenal medullary function and contribute to vestibulo-sympathetic reflexes. Supported by NIH grant DC00693.

## 44.18

THE DISCHARGE PATTERN IN RENAL SYMPATHETIC NERVE ACTIVITY RELATED TO FLUCTUATION OF BEAT TO BEAT BLOOD PRESSURE IN THE CONSCIOUS RAT. T. Kunitake, A. Shimokawa, Y. Ishizuka, K. Kato, M. Saita, Y. Ishida\*, T. Hanamori, H. Kannan Department of Physiology, Miyazaki Medical College, Miyazaki, 889-16, JAPAN

The periodicity in the sympathetic nerve activity has been discussed in many reports. We also have examined by using the spectral analysis the periodicity in renal sympathetic nerve activity (RSNA) in the conscious rat. The cardiac-related component had larger power than others. Therefore we have studied the temporal relationship between the cardiac-related activity in RSNA and the R wave of ECG in more detail. After detecting the peak in integrated RSNA by using the differential method, the peak to peak interval was measured. The time lag of each peak from the preceding R wave of electrocardiogram was also measured. The scatter diagram of peak to peak interval against time after R wave was made. On this diagram, four discrete areas that included almost all points were demonstrated. The result suggested that the discharge pattern (DP) could be subdivided into four classes depending on the number of bursting discharge during one cardiac cycle. (Kunitake, et al., Soc. Neurosci. Abstr., 21: 1399, 1995) In the present study, we examined the relationship between the DP in RSNA and the spontaneous fluctuations of blood pressure and its derivative (dP/dt). The cross correlation analysis indicated that beat to beat blood pressure (BBP) and dP/dt prior to two or three cardiac cycle have close relationship with DP. The differences of BBP or dP/dt among four classes of DP at second or third previous beat were larger than those at current beat, i.e., BBP and dP/dt in DP which showed two bursting discharges were significantly lower than those in other DPs which had no or one bursting discharge. Therefore, the DP could be simulated by the multiple regression with BBP, dP/dt and those previous values. The result suggests the RSNA at rest is regulated as the "beat to beat baroreflex".

## 44.20

ACETYLCHOLINE EXCITES VAGAL CARDIAC NEURONS IN THE NUCLEUS AMBIGUUS BY BOTH POST-SYNAPTIC AND PRE-SYNAPTIC NICOTINIC MECHANISMS. D. Mendelowitz\*, R.A. Neff and M. Mihalevich, Dept. Physiology and Biophysics, Univ. Tenn., Memphis, TN 38163.

Neurons in the Nucleus Ambiguus (NA) are known to receive dense cholinergic innervation. However the population of neurons in the NA that receive these synapses and the evoked responses are unknown. In this study we examined the direct post-synaptic responses, as well as changes in spontaneous synaptic events, that occur in identified vagal cardiac neurons in the NA in response to different cholinergic agonists.

The soma of these neurons were visualized in an in-vitro 250μ thick brainstem slice and identified by the presence of a fluorescent tracer that had been previously applied to their peripheral terminals surrounding the heart. DIC optics, infrared illumination and detection cameras were used to guide and position the patch pipette onto the surface of the identified neuron. Whole cell perforated patch clamp recordings were obtained by including nystatin in the patch pipette solution.

Both acetylcholine (ACh) and nicotine, but not bathanechol, evoked post-synaptic inward currents in identified vagal cardiac neurons (control:  $-186 \pm 42.2$  pA, bathanechol:  $-191 \pm 42$  pA, nicotine:  $-381 \pm 75.4$  pA, recovery:  $-164 \pm 42$  pA). The ACh and nicotinic responses reversed close to 0 mV and were accompanied by a decrease in membrane resistance. ACh and nicotine also elicited an increase in spontaneous glutamatergic synaptic events, presumably by a presynaptic mechanism. Surprisingly, the membrane resistance recovered to greater levels than during control. These results suggest that nicotine excites vagal cardiac neurons in the NA by activating post-synaptic receptors, and in addition, increases the spontaneous activity of glutamatergic synapses that innervate these vagal cardiac neurons.

SENSORY ASPECTS OF MICTURITION CONTROL IN THE HUMAN: A POSITRON EMISSION TOMOGRAPHY (PET) STUDY.

Bertil F. M. Blok\* and Gert Holstege, Department of Anatomy and Embryology, University of Groningen, The Netherlands.

Previously, we have shown using the PET-scanning method that certain cortical and brainstem areas of the human brain are specifically active during micturition and urine storage. The micturition related areas in the human brainstem are located in the same regions as those in the cat. The next step was to define the brain areas involved in bladder filling.

Cerebral blood flow was monitored in 18 right-handed male volunteers (22-51 years) using a CTI ECAT 951/31 whole body positron emission tomograph. Changes in regional cerebral blood flow (rCBF) were measured using the intravenous radioactively labeled water ( $H_2^{15}O$ ) bolus technique. An injection of  $1.85$  MBq  $H_2^{15}O$  was given for each run. Scanning was made during 4 successive conditions: 1) with a filled bladder, 2) during micturition, 3) and 4) with an empty bladder.

During the condition with a filled bladder (scan 1) in comparison to the other conditions (scan 2, 3 and 4), a significant increase ( $p < 0.001$ ) in rCBF was found in the medial cerebellum and the left and right temporal lobe. Significant decreases in rCBF were found on the left in the rostral striatum and dorsolateral prefrontal cortex and in the right anterior cingulate gyrus. No activation was found in the thalamus or periaqueductal gray (PAG). The results suggest that the suppression of the sense of a filled bladder is regulated at the sacral cord level, and not at the level of the PAG, thalamus or more rostrally. The involvement of the cerebellum and the striatum can be explained in terms of inhibition of movement to avoid the sense of a filled bladder. Understanding the central control of bladder filling in humans might help to understand the pathophysiology of sensory urge, an important problem in many women.

## 45.2

INNERVATION AND NERVE GROWTH FACTOR IN THE EARLY POST-NATAL RAT BLADDER. W.D. Steers\*, J.D. deHoll, J.M. Spitsbergen and J.B. Tuttle, Departments of Urology and Neuroscience, University of Virginia, Charlottesville, VA 22908.

The adult pattern of visceral innervation is often not present at birth and post-natal development of bladder innervation has not been thoroughly described. We examined the appearance of adrenergic bladder innervation and how this relates temporally to measures of bladder function and expression of nerve growth factor (NGF), upon which the development of many autonomic neurons depends. Adrenergic fibers, visualized by glyoxylic acid fluorescence, first appeared in the bladder just after birth and increased post-natally. Norepinephrine (NE) content was low at 1 wk but tripled between 2 and 3 post-natal wks. Bladder tissue NGF, assayed by ELISA, dropped significantly at 3 wks and remained low at 6 wks post-natal while NGF in the major pelvic ganglion rose from 3-6 wks, suggesting uptake by NGF-dependent neurons. Ganglionic cell counts showed no significant decline indicating a mild or absent cell death period. Levels of bladder NGF mRNA assayed by RT-PCR correlated with NGF protein. Immediately post-natal rat pups were unable to void spontaneously, requiring perineal stimulation, and had grossly abnormal cystometrogram. By 3 wks, animals voided spontaneously but retained some perineal responsiveness. Compliance improved from 1-6 wks when it showed a rise. The results suggest adrenergic innervation of the bladder develops post-natally during the period of shift from a primarily somato-visceral to viscerovisceral micturition reflex. NGF is implicated in regulating neural innervation. A recapitulation of this ontological process may accompany neuroplasticity following obstruction or denervation of the adult bladder. Supported by grants from NIDDK.

## 45.3

**ELECTROPHYSIOLOGICAL EVIDENCE FOR POTENTIAL SUB-GROUPS OF BLADDER PREGANGLIONIC NEURONS IN THE CAT.** C.W. Morgan\* Anatomy and Neurobiology and Urology, Eastern Virginia Medical School, Norfolk, VA 23501

Extracellular and intracellular recordings were obtained from 19 bladder preganglionic neurons (BPGN) in the S2 spinal cords of chloralose anesthetized female cats. BPGN were identified in the lateral lamina VII by responding antidromically to ventral root stimulation and by their response to bladder distension generated from filling or to reflex bladder contractions. These BPGN had thresholds of 0.4-0.7V, conduction velocities of 3.5-7 M/sec, and fired at bladder pressures of 10-20 cm water. Individual BPGN showed similar firing patterns (in terms of numbers of spikes and numbers of bursts) across successive contractions. No BPGN was observed to fire constantly over an entire contraction but bladder pressure rose steadily even when a neuron was silent (in between bursts). Comparison of different BPGN over the same bladder contractions indicated (1) different firing patterns across neurons during each contraction and (2) some neurons were firing during the time others were silent.

Though conduction velocities and thresholds were not discriminating, the firing pattern data suggest there may be separate and specific roles for PGN innervating the bladder. If this proves to be true it this would suggest sub groups of BPGN, each having specific functions in bladder contraction.

This research has been supported by the National Institute of Diabetes and Digestive and Kidney Diseases, R01-DK49480-02.

## 45.5

**ACUTE EFFECTS OF DIMETHYL SULFOXIDE ON C-FOS INDUCTION AND NITRIC OXIDE RELEASE IN SENSORY NEURONS.** M.A. Pezzone\*, A.J. Kanai, W.C. de Groat, and L.A. Birder. Departments of Pharmacology and Medicine, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261 and Department of Physiology, University of North Carolina, Chapel Hill, NC 27599.

Intravesical administration of dimethyl sulfoxide (DMSO) has been used to provide symptomatic relief in patients with interstitial cystitis, a chronic, painful disorder of the urinary bladder. To determine if DMSO directly affects sensory pathways, the induction of c-Fos immunoreactivity in the rat spinal cord was measured following intravesical administration of DMSO. In urethane-anesthetized, adult female, Wistar rats (150-200 g), intravesical instillation of a 50% solution of DMSO for 2 hours resulted in an up-regulation of c-Fos immunoreactivity in laminae I, II, and X, as well as, lamina VII near the sacral parasympathetic nucleus of the spinal cord. DMSO also induced firing on the pelvic nerve. These findings paralleled those produced by capsacin-sensitive bladder afferents activated by chemical irritation of the bladder.

Given that capsacin-sensitive afferent neurons in dorsal root ganglia (DRG) express neuronal nitric oxide synthase (nNOS), the release of nitric oxide (NO) from sensory neurons was also investigated following local administration of a 0.1% DMSO solution on individual, acutely-dissociated, lumbo-sacral DRG cells. A nifedipine-coated porphyrinic microsensor (tip dia, 0.5-1.5 µm; NO detection limit, 5 nM; response time, 1 msec) was placed directly on the surface of individual neurons to directly measure NO release. The calcium ionophore, A23187, elicited a transient release of NO from DRG cells, demonstrating the presence of a constitutive NOS in these neurons. DMSO elicited a smaller release of NO from individual DRG neurons (range 25-75 nM). These observations suggest that DMSO may release NO in DRG cells via increased  $[Ca^{2+}]_i$ . In conclusion, direct stimulation of sensory neurons and release of NO may be the initial event involved in the de-sensitization of pain pathways by DMSO. Supported by NIH grant NIDDK 49430.

## 45.7

**SUPRASPINAL AMPA AND NMDA GLUTAMATERGIC TRANSMISSION IN THE MICTURITION REFLEX IN THE RAT.** M. Yoshiyama\* & W.C. de Groat. Dept. Pharmacol., Univ. of Pittsburgh, Pgh., PA 15261.

Our previous studies revealed that glutamatergic transmission mediated by AMPA and NMDA receptors in the lumbosacral spinal cord plays an essential role in the micturition reflex pathway. In the present study, the effect of intracerebroventricular (i.c.v.) as well as intrathecal (i.t.) administration of LY215490 (LY), a competitive AMPA receptor antagonist and MK-801 (MK), a non-competitive NMDA receptor antagonist on the micturition reflex were evaluated in the urethane-anesthetized rat, to determine if glutamatergic mechanisms in the brain as well as the spinal cord are important for the control of micturition. Bladder activity was monitored during continuous infusion cystometrograms. I.c.v. or i.t. injection of LY215490 in small doses (0.01-0.03 µg) did not change bladder contraction amplitude (BCA) or external urethral sphincter (EUS) EMG activity. However, larger doses (0.1-0.3 µg) abolished BCA and rhythmic EUS EMG activity. In some rats, tonic EUS EMG activity persisted. MK administered i.c.v. in a dose of 0.6 µg had no effect, but 1.8 µg decreased BCA and EUS activity by 30-40% and 6 µg completely abolished these responses. I.t. injection of MK in similar doses (0.6-6 µg) did not change BCA or EUS EMG activity but a large dose (18 µg) totally suppressed bladder and EUS activity. In some rats, baseline bladder pressure markedly increased after i.c.v. injection of either drug. This was not as prominent after i.t. injections. Combined i.c.v. administration of doses of MK (0.6 µg) and LY (0.03 µg) which individually had no effect on BCA and EUS EMG activity completely suppressed these responses. Combined i.t. administration of MK (6 µg) and LY (0.03 µg) in doses which individually had no effect completely suppressed EUS EMG activity and decreased BCA by 30%. These data indicate that glutamatergic mechanisms in the brain as well as the spinal cord are essential for controlling micturition and that the interaction between AMPA and NMDA glutamatergic transmission is important at both sites. (Supported by NIH grant DK-49430)

## 45.4

**MUSCARINIC FACILITATION OF ACETYLCHOLINE (ACh) AND NOREPINEPHRINE (NE) RELEASE IN THE HUMAN URINARY BLADDER.** G.T. Somogyi\*, H.D. Flood, M.F. Bellinger and W.C. de Groat. Department of Pharmacology, Division of Urologic Surgery, University of Pittsburgh, Pittsburgh PA, 15261.

Previous studies revealed a facilitation of ACh and NE release in the rat bladder by M1 muscarinic receptors (Somogyi et al. J. Physiol. 480, 81, 1994). In this study presynaptic facilitation was examined in bladder specimens obtained from patients aged 4-8 years undergoing ureteral reimplantation. Strips weighing 10-15 mg were taken from the bladder body and were prelabeled with  $^3H$ -choline and  $^3H$ -NE. One period of electrical stimulation was used and the release was expressed as percent fraction of the tissue  $^3H$  or  $^3H$  content. The release of ACh and NE which was measured in the presence and absence of the choline uptake inhibitor hemicholinium-3 (HC-3) (10 µM) was dependent on the pattern of stimulation. Continuous stimulation (CS) with 20 Hz 200 shocks evoked a large release of ACh and NE (5.88±1.4% and 1.81±0.35%, respectively), in comparison to intermittent stimulation (IS) with the same number of shocks (10 trains every 5 sec), which produced a small release of 0.79±0.19% and 0.19±0.03%, respectively, (n=7). The non-specific muscarinic blocker, atropine (0.1 µM) significantly inhibited (p<0.05) the CS induced release of ACh and NE (0.56±0.15% and 0.65±0.2%, respectively, n=4). However, the M1 muscarinic blocker, pirenzepine (50-100 nM) inhibited the ACh and NE release (1.76±0.6% and 0.51±0.13%, respectively, n=7) only in the absence of HC-3. Interestingly, atropine was effective even in the presence of 10 µM HC-3. The cholinesterase inhibitor, eserine (5 µM) enhanced both the CS and IS induced release of ACh and NE (CS: 13.03±1.99% and 3.34±0.77%, respectively, n=3 IS: 5.63±2.1% and 1.4±0.32%, respectively). Our present results indicate that muscarinic M1 receptor mediated presynaptic facilitation is operating in the human urinary bladder. The fact that the specific M1 receptor blocker, pirenzepine, is ineffective in the presence of HC-3, but that the non-specific muscarinic blocker, atropine, is still effective raises the possibility of additional non-M1 muscarinic presynaptic facilitation in the human urinary bladder. (Supported by the NIH grant NIDDK DK-45741 and by a grant from the Interstitial Cystitis Association (ICA).

## 45.6

**FREQUENCY DEPENDENCE OF MUSCARINIC FACILITATION OF TRANSMITTER RELEASE IN URINARY BLADDER STRIPS FROM NEURALLY INTACT (NI) OR CHRONIC SPINAL CORD TRANSECTED (SCT) RATS.** G.V. Zernova, M. Yoshiyama, A.M. Booth\*, W.C. de Groat and G.T. Somogyi. Dep of Pharmacology, Univ of Pittsburgh, Pittsburgh PA, 15261.

Frequency dependent facilitation of  $^3H$ -acetylcholine (ACh) and  $^3H$  norepinephrine (NE) release was studied in the urinary bladder strips of NI and chronic (30 days) SCT rats. After prelabelling the strips with  $^3H$ -choline and  $^3H$ -NE, one period of electrical stimulation was applied (100 shocks at frequencies of 2, 5, 10 and 40 Hz), which increased the release of ACh and NE from nerve terminals in a frequency dependent manner (maximal facilitation: 7-10 fold). In SCT bladders the ACh frequency response curve was shifted to the left and reached a maximum at 10 Hz, whereas, in NI bladders 40 Hz produced the maximal release. In NI bladders the non-specific muscarinic blocker atropine (ATR) (0.1 µM) and the M1 muscarinic receptor blocker pirenzepine (PIR) (0.05 µM) were ineffective at 2 Hz but between 5-40 Hz significantly decreased ACh release by 35-80%. However, in SCT bladders PIR did not significantly decrease ACh release at any frequency except 2 Hz, whereas, ATR produced significant inhibition at all frequencies (p<0.05; 2 Hz: by 83%, 40 Hz: by 66%). In NI bladders ATR increased NE release at 5 Hz (by 113%) but decreased it at 40 Hz (by 45%), whereas, PIR was ineffective at 5 Hz and decreased NE release at 10 and 40 Hz (by 26% and 37%, respectively). In SCT bladders ATR decreased the release of NE at every frequency (2 Hz: 74% and 40 Hz: 60%). After ATR in both NI and SCT bladders, ACh and NE release was 2-8 times higher at 40 Hz than at 2 Hz indicating the existence of a non-muscarinic facilitatory mechanism. This was more prominent in SCT bladders. These results indicate that M1 muscarinic facilitation, which is the main facilitatory mechanism of ACh and NE release in NI bladders is down regulated in SCT rats, whereas, non-M1 muscarinic and non-muscarinic facilitatory mechanisms are upregulated. (Supported by the NIH grant NIDDK DK-45741 and by a grant from the Interstitial Cystitis Association (ICA).

## 45.8

**EFFECT OF INTRAVESICAL ADMINISTRATION OF ZD6169 ON THE MICTURITION REFLEX AND ON C-FOS EXPRESSION IN THE SPINAL CORD INDUCED BY NOXIOUS BLADDER STIMULATION IN THE RAT.** Y. B. YU\*, M. O. FRASER, W. C. de Groat. Department of Pharmacology, University of Pittsburgh, Pittsburgh, PA 15261.

The effects of ZD6169, an ATP-sensitive K<sup>+</sup> channel opener, on reflex urinary bladder (UB) activity and on spinal processing of afferent input from the UB were evaluated in urethane anesthetized female Wistar rats. Continuous transvesical cystometrograms (0.04 mL/min) were performed in untreated (U-T), capsacin-treated (C-T; 125 mg/kg, s.c.) and capsacin-vehicle-treated (V-T) rats. ZD6169 administered intravesically in concentrations of 2, 5, 10, and 100 ng/mL increased by 30% to 161% the intercontraction interval (ICI) in a concentration dependent manner in U-T and V-T rats but not in C-T rats. ZD6169 did not alter the ICI in C-T animals. The effects appeared within 30 min after administration. ZD6169 did not alter peak intravesical pressure during voiding. Pretreatment with ZD6169 (10 ng/mL) intravesically for 1 hr also suppressed C-fos gene expression in the L6-S1 spinal cord induced by a 2 hr infusion (0.04 mL/min) of 0.25% acetic acid (AA) into the urinary bladder. Irritation of the bladder with AA elicited a large increase in the numbers of Fos positive cells in the dorsal commissure (DCM), sacral parasympathetic nucleus (SPN) and dorsal horn (DH) in L6-S1 segments of spinal cord in AA-irritated rats. Capsacin pretreatment also markedly decreased the numbers of AA-induced Fos positive cells by 81% in DCM, 62% in DH and 49% in SPN. These results suggest that ZD6169 can influence bladder capacity by suppressing capsacin-sensitive, C-fiber afferent receptors in the bladder wall and thereby alter the afferent limb of the micturition reflex. ELECTRICAL STIMULATION OF THE MEDIAN PREOPTIC AREA OR THE LATERAL SEPTAL NUCLEUS INHIBITS BLADDER CONTRACTIONS IN ANESTHETIZED FEMALE RATS. **P.L. Vera\***, Dept of Neurosurgery, George Washington University, Washington DC 20037

The medial preoptic area (MPA) projects to the pontine micturition center in the rat (Nadelhaft et al., *Neurosci. Lett.*, 143:271-274). The purpose of this study was to determine the role of the MPA in micturition. Female Sprague-Dawley rats (n=6; 200-300 g) were anesthetized with halothane and then urethane (1.1 g/kg; iv) through the jugular vein. The carotid artery was cannulated for blood pressure recording. The bladder was exposed and cannulated either through the urethra or through the dome of the bladder. Cystometrograms were performed by infusing saline either through the urethra or the dome of the bladder. Following a craniotomy, electrical stimulation (50 Hz, 3 sec, 2 msec, 25-300 uAmps) of the MPA or the lateral septal nucleus (LSN) resulted in inhibition of bladder contractions and a small depressor response. Continuous stimulation (20 Hz; 5 min; 50 uAmp) completely abolished contractions in the case of transurethral CMG or resulted in high resting pressure and overflow incontinence in the case of transvesical CMG. This inhibition was present even after sectioning the hypogastric nerves bilaterally, and the sympathetic chains bilaterally, between the L4 and L5 ganglia. Stimulation during periods of bladder quiescence failed to elicit bladder contractions.

These results suggest that the MPA and LSN directly inhibit bladder contractions. This inhibition is not mediated by the sympathetic nervous system.

Supported by intramural funding from the Dept of Neurosurgery, GWU.

## 45.11

CENTRAL NERVOUS SYSTEM SITES LABELED FOLLOWING INJECTION OF PSEUDORABIES VIRUS (PRV) INTO THE DISTAL COLON OR BLADDER OF ADULT RATS. **W.C. de Groat\*, J.P. Card and M.A. Vizzard\***, Univ. of Pittsburgh, Depts. of Pharm. and Neurosci., Pittsburgh, PA 15261 and the Univ. of Vermont, Depts. of Neurol. and Anat. and Neurobiol., Burlington, VT 05405.

PRV ( $10^6$ - $10^8$  pfu/ml) was injected into the wall of the distal colon (n=14) or urinary bladder (n=15) and the distribution of PRV-infected neurons (PRV-IN) examined following survival times of 52-96 h. After colon injection, PRV-IN in L6-S1 spinal cord (SC) were mainly in S1 whereas after bladder injection, PRV-IN were in both segments. Following bladder injection, PRV-IN were present in supraspinal sites: pontine micturition center (PMC), raphe, A5, A7, periaqueductal gray (PAG), parabrachial nucleus (PBN), locus coeruleus (LC), subcoeruleus, red nucleus (RN), hypothalamus and cerebral cortex. Following colon injection, PRV labeling in supraspinal sites included those sites labeled following bladder injection as well as the vagal dorsal motor nucleus (DMV), N tractus solitarius (NTS), N ambiguus (NA) and area postrema (AP). To determine if labeling at these sites (DMV, NTS, NA and AP) was mediated by vagal pathways, PRV was injected into the colon of T8 SC transected (SCT) animals (n=5) and allowed to survive for 96 h (n=2) or 120 h (n=3). At 96 h in SCT animals, PRV-IN were present in the thoracolumbar and lumbosacral SC. A few PRV-IN were also present above the SC transection site in T7 in the intermediolateral cell column and dorsal horn. However, at 96 h, no PRV-IN were present in any supraspinal site. At 120 h in SCT animals, the most heavily PRV-infected supraspinal sites were the DMV, NTS, NA and AP. Few if any PRV-IN were present in the PMC, PAG or PBN. A few PRV-IN were present in A5 and A7 regions. In one animal with more extensive PRV labeling in the SC above the transection, PRV-IN were present in A5, A7, LC and RN. These results demonstrate that: (1) the PMC may have multiple functions; (2) PRV labeling in the DMV, NTS, AP and NA following colon injection is most likely mediated via vagal pathways; (3) PRV labeling in the PMC, PAG and PBN following either colon or bladder injection is most likely mediated via lumbosacral spinal pathways. ## 45.13

SUPRAMEDULLARY INNERVATION OF THE URETHRA

**B. Erokwu, W.M. Grill, and M.A. Haxhiu\***

Case Western Reserve University, Cleveland, Ohio, 44106

The supraspinal CNS cell groups that innervate spinal neurons controlling functions of the urethra were identified by the viral retrograde transneuronal labeling method. Pseudorabies virus (PRV) was injected into the wall of the pre-prostatic urethra of male Sprague-Dawley rats. After five to eight days survival, spinal cord and brain tissue sections from these animals were processed for immunohistochemical detection of PRV. Labeled cells were found in the parapyramidal area, lateral paragigantocellular and gigantocellular nuclei, and in the midline neurons. Within the dorsal aspect of the pons, labeling was found in Barrington's nucleus. A few labeled neurons were observed within the locus coeruleus and subcoeruleus nuclei, as well as Kolliker-Fuse nucleus. In the ventral aspect of the pons, labeled neurons were found within the nucleus raphe magnus, and in the A5 cell group. In the mesencephalon, PRV labeled cells were found in the ventrolateral part of the central gray matter. A few labeled cells were observed in the gigantocellular division of the red nucleus. In the diencephalon, PRV labeled cells were seen in the hypothalamus: lateral dorsal and paraventricular nuclei. A few cells were observed in retrochiasmatic region. At seven and eight days following PRV injection, intense labeling was seen in the medial nucleus of amygdala, less intense in central and lateral nuclei of amygdala complex. Labeling was observed in lateral septal nucleus, hippocampus, primary motor cortex, and in piriform cortices. The overall distribution of labeled neurons was similar to that observed following PRV injections into the wall of the bladder. These results indicate that the CNS neurons controlling the genitourinary system are found to be located within many of the same regions that are involved in autonomic and neuroendocrine functions.

## 45.10

ELECTRICAL STIMULATION OF THE SUBSTANTIA NIGRA OR VENTRAL TEGMENTAL AREA INHIBITS BLADDER CONTRACTIONS IN ANESTHETIZED FEMALE RATS. **D.R. Liskowsky\* & P.L. Vera\***, Universities Space Research Association, Washington, DC, 20024; Dept. of Neurosurgery, George Washington University, Washington, DC 20037.

The substantia nigra has been shown to inhibit bladder contractions in cats (Yoshimura et al., *Neurourology & Urodyn.*, 11:535-545). In contrast, systemic activation of dopaminergic receptors in rats results in bladder hyperreflexia (Kontani et al., *Jpn. J. Pharmacol.*, 54:482-486). The aim of this study was to determine the effect of electrical stimulation of the substantia nigra pars compacta (SNpc) and the ventral tegmental area (VTA) on micturition in the rat. Female Sprague-Dawley rats (n=8; 200-300 g) were anesthetized with halothane and then urethane (1.1 g/kg; iv) through the jugular vein. The carotid artery was cannulated for blood pressure recording. The bladder was exposed and cannulated either through the urethra or through the dome of the bladder. Cystometrograms were performed by infusing saline either through the urethra or through the dome of the bladder. Following a craniotomy, electrical stimulation (50 Hz, 3 sec, 2 msec, 25-300 uAmps) of the SNpc (n=8) or the VTA (n=1) resulted in bladder inhibition. This inhibition persisted even after bilateral sectioning of the hypogastric nerves and the sympathetic chains at the level of the L4 ganglia. In addition, haloperidol (2 mg/kg, i.v.) did not prevent the inhibition. These results suggest that stimulation of the SNpc or VTA inhibits bladder contractions. This inhibition is not mediated by sympathetic pathways or dopaminergic systems.

## 45.12

PSEUDORABIES VIRUS (PRV) DOES NOT ESCAPE TO THE NEUROPIIL FROM INFECTED NEURONS. DOUBLE LABELLING OF MAJOR PELVIC AND DORSAL ROOT GANGLION NEURONS FROM THE BLADDER AND COLON OF RAT, **L. Nadelhaft\*, G. Smith and S. C. Nuding\***, Research and Development Service, Veterans Administration Medical Center, Bay Pines, FL, 33504.

The use of pseudorabies virus (PRV) as a neuroanatomical tracer is based on its ability to be transported from the initial site of infection to a neuron, its subsequent replication within that neuron and, most importantly, its export from this neuron to other neurons only via the synapses they make with the infected neuron. To test this property, PRV was injected into either the urinary bladder or the distal colon of male rats and, at the same time, fast blue was injected into either the distal colon or the bladder. After a two to four day incubation, the animal was perfused and the major pelvic (MPG) and L1-L2 and L6-S1 dorsal root (DRG) ganglia examined for PRV-IR cells, dye labelled cells and double labelled cells. The number of double labelled neurons ranged between 2% and 10% of the number of PRV-labelled cells. This number is about the same as is found when two different dyes are used for injections into the colon and bladder [Keast et al., *Cell Tissue Res* 256:105(1989)]. Therefore, it appears that the pseudorabies virus is confined to the infected neurons and is not exported to the surrounding neuropil.

These results also suggest there are single neurons in the MPG as well as the DRG that send processes to both the bladder and the colon.

## 45.14

CHEMICAL CODING OF NEURONS IN THE HYPOGASTRIC (HG) AND MAJOR PELVIC GANGLION (MPG) OF ADULT MALE RATS. **R.W. Hamill\* and M.A. Vizzard\***, University of Vermont, College of Medicine, Departments of Neurology and Anatomy and Neurobiology, Burlington, VT 05405.

The MPG and HG of the rat pelvic plexus contain postganglionic neurons that innervate the urinary bladder, colon, reproductive organs (MPG) or reproductive organs primarily (vas deferens, prostate gland, seminal vesicles) (HG). To identify potential chemical coding in MPG and HG neurons, single and double fluorescence immunohistochemistry were employed to assay for putative neurotransmitters. MPG and HG were removed under sterile conditions from male Sprague-Dawley rats (n=20; 180-200 g) and incubated in culture medium for 48 h at 37 °C without colchicine prior to fixation. Cryostat sections (25 µm) of ganglia were mounted directly onto gelatinized slides. Immunoreactivities for enkephalin-endorphin (ENK-END), neuronal nitric oxide synthase (NOS), vasoactive intestinal peptide (VIP), neuropeptide Y (NPY) and tyrosine hydroxylase (TH) were demonstrated within the MPG and HG using standard techniques. In double-labeled preparations, many neurons in both the MPG and HG that exhibited TH-immunoreactivity (IR) also exhibited NPY-IR whereas many additional NPY-IR neurons did not contain TH-IR and may have been cholinergic. TH/NPY-IR neurons tended to be larger than NPY-IR only neurons and TH-IR only neurons tended to be among the largest cells in either ganglion. NPY-IR nerve fibers and pericellular baskets of varicosities were present throughout both ganglia whereas pericellular TH-IR varicosities were rare. In double-labeled preparations, many neurons in both the MPG and HG that exhibited NOS-IR also exhibited VIP-IR whereas many additional VIP-IR neurons did not contain NOS-IR. NOS-IR and VIP-IR neurons were among the smallest cells in either ganglion. Numerous NOS-IR and VIP-IR nerve fibers and pericellular varicosities were also present throughout each ganglion. In single-labeled preparations, pericellular ENK-END-IR varicosities were numerous and distributed throughout both the MPG and HG. Very few neurons contained detectable ENK-END-IR in either ganglion. These studies indicate substantial neurotransmitter heterogeneity of pelvic autonomic ganglia, probably reflecting functional diversity. ## 45.15

## PUTATIVE NEUROTRANSMITTER INPUTS TO RETROGRADELY LABELED NEURONS IN THE PONTINE MICTURITION CENTER OF THE RAT.

A. Nadel\* & P.L. Vera, Dept. of Neurosurgery, Washington, DC 20037.

The aim of this study was to describe the neurotransmitter content of projections to neurons in the pontine micturition center (PMC). Sprague-Dawley female rats (n=4; 200-250 gm) were anesthetized with sodium pentobarbital (50 mg/kg; IP) and a L1 laminectomy was performed to expose the L6/S1 spinal cord. Bilateral injections of Fluorogold (2%; 250 nl) were made in the spinal cord. The rats were allowed to recover for 1 week and then perfused transcardially with 4% paraformaldehyde fixative. 10 or 14  $\mu$ m thick sections through the PMC, containing retrogradely labeled neurons were exposed to the following antisera: leu-enkephalin (L-enk), met-enkephalin (m-enk), serotonin (5-HT), substance P (SP), tyrosine hydroxylase (TH) and calcitonin gene related peptide (CGRP). The primary antisera were visualized using a secondary antibody labeled with rhodamine or indocarbocyanine.

Immunoreactive processes containing these putative neurotransmitters were detected in the PMC, except for CGRP. Some of these terminals were also seen in close apposition to retrogradely labeled neurons in the PMC.

These results suggest that terminal processes containing putative neurotransmitters are present in the PMC and in close apposition with retrogradely labeled neurons. Thus, it is possible that these transmitter may modulate the output of PMC neurons to affect bladder function.

Supported by intramural funding from the Dept of Neurosurgery, GWU (PLV).

## 45.17

## OPTICAL IMAGING DEMONSTRATION OF THE SPONTANEOUS NEURONAL ACTIVITIES IN THE MALE RAT MAJOR PELVIC GANGLION (MPG) FOLLOWING PELVIC NERVE TRANSECTION.

M. Imaizumi and M. Kawatani\* Dept. of Physiology, Akita Univ. Sch. of Med., Akita, Japan 010.

Membrane potential changes were measured in the MPG by optical imaging system. The MPG was isolated from Nembutal anesthetized rats (40-50 mg/kg) and perfused with modified Tyrode's solution. After identified the MPG, 128  $\times$  128 photopixel-array-multi-channel system was used for detection of voltage-sensitive dye (RH-975). In normal ganglia (n=12), KCl (300 mM) and ACh (3.3  $\times$  10<sup>-7</sup> M) excite the ganglion cells dose dependently. Area distribution of the excited cells was different for these two drugs. The effect from the formal drug was 724% larger than the latter. No rhythmic excitation was observed. Following pelvic nerve transection (2-6 weeks period to the experiments) rhythmic voluntary excitation (CVE) was observed (14/21). The excitation occurred more than one spotted area and spreading out the ganglion cells. The frequency of excitation was 1.8-3.4 Hz. TTX (6.0  $\times$  10<sup>-7</sup> M) abolished the CVE. Following hypogastric nerve transection, CVE was not recorded (n=4). These data suggest that spontaneous neural finding was developed following pelvic nerve transection that could have major excitation for emptying the urinary bladder during pelvic nerve injury.

## 45.19

## PROJECTIONS OF THE PONTINE MICTURITION CENTER TO THE SACRAL PARASYMPATHETIC NUCLEUS IN THE RAT, S.C. Nuding\*, G. Smith and I. Nadelhaft, Research and Development Service, VA Medical Center, Bay Pines, FL 33504.

Experiments in our laboratory have previously established a connection between the sacral parasympathetic nucleus (SPN) of the intermediolateral region of the L6-S1 spinal cord segments and the pontine micturition center (PMC) [Neurosci. Abstr. 13: 734 (1987)]. After small (20 - 60 nL) unilateral injections into the SPN, retrograde transport of fluorescent microspheres labelled neurons in the PMC bilaterally, suggesting that individual PMC neurons might have projections to both SPNs. To test this hypothesis, a small injection of rhodamine labelled latex microspheres was made into the SPN on one side of the rat spinal cord; a similar injection of fluorescein tagged microspheres was made into the other. After several days, the animals were perfused. Inspection of 40  $\mu$ m cord sections confirmed that the placement of these injections was similar along the rostro-caudal axis of the cord and that neither of the tracers had spread across the midline. 30  $\mu$ m brain sections were examined for rhodamine (red) and/or fluorescein (green) labelled PMC neurons. Red, green and double labelled PMC neurons were found on both sides of the brain. We therefore conclude that there is a redundancy in the connections from the PMC to the spinal cord and that at least some PMC neurons send axons to parasympathetic preganglionic neurons in the SPN on both sides of the lumbosacral spinal cord.

## 45.16

## PELVIC NERVE STIMULATION INDUCES FIELD POTENTIALS IN PERIAQUEDUCTAL GRAY OF CAT. J.W. Downie\*, M. Duong, J.L. Martin and H.J. Du. Dept. Pharmacology, Dalhousie Univ. Halifax, Nova Scotia, Canada B3H 4H7.

Neuroanatomical studies have indicated that the periaqueductal gray (PAG) may be a target for projecting sacral cord neurons conveying afferent information from the urinary bladder. As a prelude to studies on these projecting cells, we have mapped the PAG for areas responding to electrical stimulation of bladder afferents in the pelvic nerve (PLN) of cat, and compared that map to ones obtained from stimulation of the pudendal (PDN) and superficial perineal (SPN) nerves. Under halothane anesthesia, electrodes were implanted on the PLN close to the bladder and PDN and SPN were dissected through a parasagittal incision near the base of the tail. Laminectomy was done to permit placement of a cord dorsum (CD) electrode. Field potentials in the PAG (A6-P2) were recorded under chloralose anesthesia using a monopolar tungsten electrode (9-12M $\Omega$ ). The area from A6-P2 (0=intraural line) was sampled. The cats were perfusion-fixed with cold 4% paraformaldehyde. Histological localization of lesion sites and tracks was carried out in 40  $\mu$ m sections stained with thionin. The data were obtained in 8 cats. PAG field potentials were multiphasic, with occasional single unit discharges observed on the early phase. Mean central conduction velocities (CD-PAG) for the beginning of the early phase were 33 (range: 16-45) m/s for the PLN evoked response, 32 (17-51) for PDN and 41 (32-51) for SPN. The sites of maximum PLN-evoked field potentials for each experiment lay between A3.5 and P1.5 and overlapped the rostrocaudal extent of PDN-evoked potentials. SPN maxima were found from A6-P0.2. In conclusion, the PAG may be involved in processing bladder afferent information for perception of fullness or reflex micturition. Supported by the Medical Research Council of Canada.

## 45.18

## THE ROLE OF GLUTAMINERGIC TRANSMISSION ON DETRUSOR-SPHINCTER DYSSYNERGIA IN UNANESTHETIZED RATS. T. Satoh, K. Sugaya, H. Noto\*, O. Nishizawa, M. Kawatani, Dept. Physiol. and Urol., Sch. Med., Univ. Akita, Japan. 110

Suprasacral spinal cord injury in human result in inappropriate contractions of the external urethral sphincter muscle during micturition (detrusor-sphincter dyssynergia: DSD). This study was undertaken to examine the role of glutaminergic neurotransmission on DSD in unanesthetized chronic spinal rats (CSR). Chronic spinal cord (Th 7-8) transection (under inhalation anesthesia) in female Wistar rats were used. MK-801 (0.03-100  $\mu$ g), a noncompetitive NMDA receptor antagonist and LY293558 (0.03-100  $\mu$ g), a competitive AMPA receptor antagonist were administered intrathecally. The effects of antagonists were also examined in acute capsaicin rats (ACR) (capsaicin was applied topically on the bladder dome) and chronic capsaicin rats (CCR) (capsaicin was administered subcutaneously 4 days before experiments). DSD developed in all CSR and the amplitude of urethral contraction (UC) was 6.8  $\pm$  1.1 cmH<sub>2</sub>O (mean  $\pm$  S.E., n=14). MK-801 and LY293558 slightly inhibited bladder activities and markedly reduced intraurethral pressure (IUP) during bladder contractions (DBC). 10  $\mu$ g of LY293558 moved IUP DBC below zero (-1.2  $\pm$  0.6 cmH<sub>2</sub>O, n=7) which synergistic pattern. Acute capsaicin treatment reduced UC. The antagonists did not alter UC in ACR. The antagonists reduced the UC in CCR, which is similar to the result from the CNTR. These data suggest that capsaicin-sensitive C-fiber afferents have role of both promoting and reducing DSD. Capsaicin sensitive A $\delta$ -afferents are essential for the development of DSD, and glutamate convey its transmission.

## 45.20

## VAGINAL RECEPTIVE FIELDS MODULATE THE BLADDER REFLEX. B.W. Tedeschi\* and C.W. Morgan. Anatomy and Neurobiology and Urology, Eastern Virginia Medical School, Norfolk, VA 23501

Experiments were done on 10 female cats anesthetized with  $\alpha$ -chloralose, a suprapubic tube installed to record bladder pressure, and a laminectomy done to allow recording from preganglionic neurons in the sacral spinal cord. Reflex bladder contractions were initiated by increasing inflow to the bladder from raising a reservoir 10-20 cm above the bladder. Under conditions of constant volume repeated slow, rhythmic contractions up to 45 cm water were observed on a chart recorder over 5-10 min periods. These detrusor contractions were inhibited by deep vaginal/cervix stimulation with a lubricated glass rod. The latency for the inhibition varied from 1-10 sec and the effect lasted for minutes. In contrast, stimulation in the vestibule region of the vagina, possibly involving the urethral meatus, elicited bladder contractions similar in amplitude and rhythm to a normal reflex. This reflex occurred from a baseline accommodation pressure of 5-7 cm water with a latency of 1-3 sec and continued for many seconds beyond the stimulus similar to a normal reflex.

The excitatory response may be part of a urethra to bladder reflex that facilitates detrusor contraction when urine enters the urethra. The detrusor inhibitory reflex may serve sexual function, working along with the sphincter muscles to maintain continence during copulation.

**REGIONAL AND SEX DIFFERENCES IN GUINEA PIG BLADDER NITRIC OXIDE SYNTHASE ACTIVITY.** M. Sales, A. Cowan\*, M. R. Ruggieri and M. A. Pontari. Temple University School of Medicine, Philadelphia, Pennsylvania.

Preliminary evidence indicates a possible alteration of nitric oxide synthase (NOS) in the bladder mucosa of patients with interstitial cystitis. The function and distribution of NOS in the bladder is unknown. The purpose of this study is to compare NOS levels in the mucosa and muscle of the bladder dome and base from male and female guinea pigs. Results of assays performed in triplicate are shown in the table below (mean  $\pm$  sem for  $n=3-6$ ). Both calcium dependent (CD) and independent (CI) NOS activity was measured by the conversion of  $^{14}\text{C}$ -L-arginine to  $^{14}\text{C}$ -L-citrulline in soluble fractions of bladder homogenates. Overall, levels of NOS were higher in the males than females. In the muscle, equal amounts of both CI and CD activity were found in the dome of both sexes, while in the base, levels of CI activity were roughly double that of CD activity. In the mucosa, CI NOS activity was greater than CD in the base of both sexes. In the mucosa of the dome, CI activity was greater than CD in the male but not in the female, where the CD NOS activity was greater. These data show greater amounts of CI than CD NOS activity throughout the bladder base in both sexes. These differences may give a structural basis for regional differences in bladder physiology.

NOS ACTIVITY: pM/min/mg protein		Males		Females	
		CD	CI	CD	CI
DOME	Mucosa	5.37 $\pm$ 0.01	12.5 $\pm$ 0.13	5.12 $\pm$ 0.01	1.07 $\pm$ 0.05

## SUBCORTICAL SOMATOSENSORY PATHWAYS I

## 46.1

**LIGHT AND ELECTRON MICROSCOPIC EXAMINATION OF PRIMATE TRIGEMINAL MESENCEPHALIC NEURONS.** N.F. Capra\*, D. Dessem\*, P. Luo† and P.J. May†. Dept. of Oral and Craniofacial Biological Sciences, U. of Maryland Dental School, Baltimore, MD 21201, Depts. of Anatomy, Ophthalmology and Neurology†, U. of Mississippi Med. Ctr., Jackson, MS 39216.

The trigeminal mesencephalic nucleus (Mes V) supplies critical information on the state of the masticatory muscles to the brainstem nuclei controlling jaw movements. Despite this important role, the morphological features of these primary sensory neurons are not well described in primates. In macaque monkeys, a number of neurons were retrogradely labeled following injections of 10-15  $\mu\text{l}$  of WGA/HRP into the masseter or pterygoid muscles. Large spherical neurons were found among small clusters of neurons along the mesencephalic tract in the pons, and along the margins of the periaqueductal gray in the midbrain. The subsequent experiments sampled only this latter region for labeled neurons. Injections of 0.1-0.2  $\mu\text{l}$  of biotinylated dextran amine (BDA) placed in the exiting trigeminal nerve produced homogeneous staining of presumptive Mes V neurons. These cells generally had large, round somata that ranged up to 40  $\mu\text{m}$  in diameter. Although many showed no dendritic processes, numerous short processes, which extended up to 50  $\mu\text{m}$  and sometimes branched, emerged from other labeled somata. EM examination of labeled and unlabeled presumptive Mes V neurons revealed somata with pale nuclei and copious cytoplasm containing numerous mitochondria and scattered stacks of rER. Their plasma membranes were largely bare of synapses, but showed numerous protrusions, and small processes that sometimes enclosed nearby neuronal elements. A few small terminals contacted these neurons. They contained clear pleomorphic vesicles, although clear and dense-cored spherical vesicles were also present. Many of these features have been reported in non-primate species. However, the number and complexity of dendritic processes on BDA labeled macaque Mes V neurons is striking. Furthermore, ultrastructural confirmation of synaptic input suggests that central modulation of primate trigeminal mesencephalic neurons occurs. ## 46.3

**A COMPARISON OF THE TERMINATION PATTERN OF THE CERVICO-THALAMIC TRACT AND THE DISTRIBUTION OF CAT301-IMMUNOREACTIVITY.** J. Broman\* and M. Zhang. Department of Cell Biology, Faculty of Health Sciences, Linköping University, S-581 85 Linköping, Sweden.

The distribution of cervicothalamic tract (CTT) terminations, labeled with anterogradely transported tracers (WGA-HRP or biotinylated dextran) injected into the lateral cervical nucleus of cats, was compared with the distribution of immunoreactivity for a cell-surface antigen detected with the monoclonal antibody Cat301 (kindly provided by Dr Susan Hockfield) in the same or adjacent sections.

The most abundant CTT termination was detected in the ventroposterior nucleus (VP), mainly in its lateral part (VPL) and sparsely in its medial part (VPM) and in the ventral periphery of VP. In the VPL, CTT terminations were seen in a peripheral rim of the nucleus and in between its lateral and medial subdivisions (VPLl and VPLm). A larger field of termination was evident in the dorsal part of VPLl and dorsolateral part of VPLm rostral to the caudal pole of VPLl. The regions of the VPL receiving CTT terminations were characterized by sparse occurrence of Cat301 immunoreactivity (Cat301-ir). In the central parts of the VPL containing dense Cat301-ir, anterograde labeling had mainly the appearance of fibers of passage. Dorsal to the VP, scattered CTT terminations were seen in the medial division of the posterior complex, which was virtually devoid of Cat301-ir. Dense focussed CTT termination was detected in the medial extension of the magnocellular medial geniculate nucleus (MGmc) but absent from its main lateral part. The termination was centered upon clusters of cells in MGmc displaying dense Cat301-ir.

Our present observations demonstrate that the CTT terminates in a compartment of the VPL characterized by sparse occurrence of the antigen recognized by the Cat301 antibody. Thus, the CTT is related to a chemically defined compartment of the VPL that may be the origin of specific thalamocortical channels, the organization of which remains to be elucidated. In contrast, anterograde labeling in the medial MGmc is associated with clusters of Cat301 immunolabeled cells. The significance of this difference between CTT recipient cells in the VPL and MGmc is unclear. (Supported by the Magnus Bergvall Foundation.)

**FUNCTIONAL CLASSIFICATION OF MUSCARINIC RECEPTOR SUBTYPES IN THE RAT URINARY BLADDER.** A. S. Braverman, I. J. Kohn, and M. R. Ruggieri\*. Temple University School of Medicine, Philadelphia, Pennsylvania.

Muscarinic agonists (e.g. bethanecol) and antagonists (e.g. oxybutinin) have been used clinically to treat a variety of voiding disorders, although the muscarinic control of bladder function remains incompletely understood. We investigated the effects of subtype selective muscarinic antagonists on both carbachol induced (direct muscle stimulation) and electrically stimulated (nerve evoked) contractile responses of rat bladder body strips *in-vitro*. Two electric field stimulation paradigms were performed after purinergic desensitization. In the first paradigm, the tissue was stimulated with 100 shocks at each frequency. In the second paradigm, the tissue was stimulated at each frequency until maximum tension was achieved. Both paradigms yielded similar results. The affinity of a series of muscarinic antagonists derived from analysis of cumulative carbachol dose response curves indicates M3 mediated bladder contraction. Quite different affinities were observed with inhibition of electrically stimulated contractions. The M2 selective antagonist methoctramine (10 nM, 30 nM) increased nerve evoked contractions by 10% (p,0.05) whereas the M1 selective antagonist pirenzepine (10 nM) inhibited contractions by 15% (p,0.05). These doses of antagonists had no effect on carbachol induced contractions. These findings indicate presynaptic M1 facilitory and M2 inhibitory receptors and post-synaptic M3 receptors mediating bladder smooth muscle contraction.

Unlike M2 and M3 receptors, the presence of m1 receptors in the rat bladder body could not be demonstrated by immunological methods nor could the presence of m1 receptor mRNA be demonstrated by Northern blot analysis. RT-PCR utilizing subtype specific primers confirmed the presence of the m1, m2, m3, and m4 receptor mRNA. No m5 mRNA was detected. The function of the M4 receptor is unknown. RT *in-situ* PCR localized m1 receptor mRNA in what appeared to be nerve fibers surrounding blood vessels and bladder smooth muscle, particularly adjacent to the serosal surface. ## 46.2

**SOMATICALLY-EVOKED RESPONSES IN THE PONS DETECTED MAGNETICALLY OUTSIDE THE BRAIN OF THE JUVENILE SWINE.** Y. C. Okada\*, N. S. Papuashvili†, and C. Xu. Depts. Neurol. & Physiol., Univ. New Mexico Sch. Med., Albuquerque, NM 87131. †Depts. Neurosurg. & Pathophysiol., Inst. Clin. & Exp. Neurol., Tbilisi 380092, Georgia.

Subcortical activities generated by stimulation of the snout can be detected magnetically above intact brain in the juvenile swine (Hashimoto et al., Neurosci. Lett., 1996). The generator for the somatic evoked field (SEF) was identified here. Based on our earlier study, we hypothesized that the generator was located in a region inferior to the thalamus, possibly in the midbrain or brainstem. Thus, these regions in the brain of the swine (3-5 weeks old, 5-12 kg) were exposed laterally under anesthesia (ketamine 9.0 mg/kg/hr i.v. and xylazine 3.6 mg/kg/hr i.v.) by removing the facial muscles and the mandibular bone. The location in the snout near the dorsal portion of a nostril was stimulated with a bipolar needle electrode (5-6 mA, 300  $\mu\text{s}$ , 2 sec/stim). Somatic evoked potentials (SEPs) recorded on the surface of the pons consisted of a spike having the same morphology and latency as the spike recorded simultaneously within the cortex and thalamus. The polarity reversed along the rostral-caudal direction with the reversal occurring about 1 cm posterior to the trigeminal nerve root in the pons. The polarity was positive rostrally as in the responses in the cortex and thalamus. The SEF recorded laterally over the pons was stronger (as much as 20 pT) than that recorded above the decorticated brain surface (about 5 pT). It consisted of a spike having the same latency as the simultaneously recorded SEPs. Its generator was in the pons close to the reversal point for the SEP and its underlying current was directed rostrally, consistent with the SEP polarity. Neuronal currents in the pons, possibly from the spinal trigeminal complex, seem to be capable of generating SEFs that are strong enough to be detected even above the vertex of the intact brain. Supported by NIH grant RO1-NS30968.

## 46.4

**ANATOMY AND PHYSIOLOGY OF CORTICO-TECTAL PROJECTIONS FROM THE SOMATOSENSORY NEOCORTEX OF THE RAT: GOLGI-LIKE RETROGRADE LABELING USING DEXTRANAMINE.** R. M. Brown\*, G. Paschall, M. Burton, D. Geron, B. Clancy and L. J. Caulier. GR 41, Cognition and Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083-0688.

Pressure injections of biotinylated or rhodamine dextranamine (10kMW) into deep layers of the superior colliculus (SC) produced retrograde Golgi-like filling of the dendrites of layer Vb pyramidal neurons in rat neocortex including: primary and secondary somatosensory areas (SI and SII); medial areas including FR2 and cingulate cortex; and lateral areas including polysensory and perirhinal cortex. Only cells in layer Vb characteristic of intrinsically bursting neurons were labeled. And all labeled dendrites involved profuse apical tufts extending to layer I. Therefore the cortico-ectal neurons are of the morphological type that is very sensitive to "backward" corticocortical projections (Caulier and Connors, 1994, *J. Neurosci.* 14:751) indicating top-down cortical influences are extended to superior colliculus. Injections of dextranamine into SI or SII anterogradely labeled fibers terminating in the deep layers of superior colliculus. Accordingly, electrical stimulation of SI or SII evoked peak-negative field potentials in deep layers of the superior colliculus and positive potentials in upper layers. Antidromic activation of the collaterals of these layer Vb neurons by stimulation in superior colliculus evoked widespread cortical activation which may represent the general function of the layer Vb pyramidal neurons. This fluorescent dendrite technique also offers the unique opportunity to locate and analyze the apical dendrites of layer Vb neurons *in vivo*.

Supported by a grant from the Whitehall Foundation.

## 46.5

GABA-MEDIATED INHIBITION SHAPES PHASIC RESPONSES IN THE RAT'S THALAMIC VENTROBASAL COMPLEX (VB). C. Vahle-Hinz<sup>1</sup> and T.P. Hicks<sup>2</sup>, <sup>1</sup>Physiol. Inst., UK Eppendorf, D-20246 Hamburg, Germany, & <sup>2</sup>Inst. Biol. Sci., Natl. Res. Council, Ottawa, Canada.

The role of GABAergic inhibition in thalamic processing of information from whisker mechanoreceptors was studied in urethane-anesthetized rats. VB neurones were activated by trapezoidally shaped mechanical displacements of whiskers in the presence of GABA receptor subtype-selective agonists and antagonists. Apart from an increase in discharge rate, phasic neuronal responses remained phasic in the presence of levels of bicuculline (BIC) sufficient to block muscimol- but not (-)baclofen-induced suppressions of firing. However, in phasic neurones responding solely with on/off discharges to the transitional phases of trapezoidal stimuli, BIC induced temporally increased responses which lasted for the entire duration of the dynamic portions of the whisker displacement, thereby inducing responses where previously none had occurred. Higher levels of BIC (or activation by the amino acid excitant, AMPA) that resulted in ongoing activity outside of the stimulus period, revealed a BIC-resistant phase of suppression lasting for several hundred milliseconds during the statically maintained, plateau phase of the stimulus. There was no reliable action of 2-hydroxysaclofen consistent with a contribution of GABA<sub>B</sub> receptors. The results show that GABA<sub>A</sub> receptors do contribute significantly to the form of dynamic aspects of the responses of phasic VB neurones. Other events appear to contribute further to the modification of responses in VB and are mediated through neither GABA<sub>A</sub> nor GABA<sub>B</sub> receptors. Supported by DAAD.

## 46.7

Single channel properties of neuronal GABA<sub>A</sub> receptors in rat nucleus reticularis thalami (nRt) and ventrobasal relay complex (VB). J. Kang, J.R. Huguenard\*, D.A. Prince. Dept. Neurol. & Neurol. Sci., Stanford Univ. School of Medicine, Stanford University, CA 94305.

Synaptic inhibition within the thalamus plays a critical role in sensory processing and in generating thalamocortical rhythms, such as those occurring during sleep and generalized absence epilepsy. We have previously demonstrated differences in inhibitory post-synaptic currents (IPSCs) recorded in thalamic relay vs nRt neurones - IPSC duration in nRt cells was approximately 3 times longer than in relay cells. These functional differences, in conjunction with the known heterogeneity in GABA<sub>A</sub> receptor subunits in various thalamic nuclei, led to the hypothesis that single channel properties would be diverse. GABA<sub>A</sub> channels in nRt, where there appears to be a predominance of  $\alpha 3$  and modest levels of  $\gamma 2$  subunits, would have single channel properties distinct from those in relay neurones, where  $\delta$ ,  $\beta 2$ ,  $\alpha 4$ , and  $\alpha 1$  levels are high, with low amounts of  $\gamma 2$ .

Single channel recordings were made in rat thalamic slices from nRt and VB neurones. With cell-attached patches, 2  $\mu$ M GABA activated single or multiple channel events with similar unitary conductances ( $\gamma$ ) in both cell types (nRt: 16.0  $\pm$  0.5 pS; VB: 17  $\pm$  1.7 pS). Channel activity was clustered into bursts in patches from both cell types, but single channel open times were much longer in nRt cells (biexponentially distributed;  $\tau_{1/2}$  = 1.5 & 14 ms) compared to VB cells (monoexponentially distributed;  $\tau_{1/2}$  = 1.9 ms). Similar results were obtained with inside-out patches under symmetrical [Cl<sup>-</sup>] conditions ( $\gamma$  = 27 pS). Further, bath application of 100  $\mu$ M Zn<sup>2+</sup> preferentially depressed the activity in patches from nRt (84  $\pm$  2% suppressed; n = 6), but had much less effect on VB channels (24  $\pm$  4% suppressed, n = 4).

These data further support the proposal that functional differences in GABA<sub>A</sub> receptor-mediated inhibition in the thalamus are the result of diverse heteromultimeric receptor combinations. Thus GABA modulatory compounds might have relatively selective actions in a subset of thalamic nuclei. Supported by NIH grants NS06477 and NS07280.

## 46.9

NMDA RECEPTOR SUBTYPE 1 IS LOCALIZED TO A SUBPOPULATION OF LOCAL CIRCUIT NEURONS IN THE CAT VB COMPLEX. X. Meng\* and H. J. Ralston III. Department of Anatomy, W.M. Keck Foundation Center for Integrative Neuroscience, University of California, San Francisco, CA 94143-0452.

Previous studies have indicated that GABAergic local circuit neurons (LCNs) modulate glutamate mediated excitatory activity in the ventrobasal thalamus (VB). Nitric oxide synthase (NOS) resides within a sub-population of GABA-immunoreactive (GABA-ir) LCNs in the cat VB. The purpose of the present study was to explore the distribution of n-methyl-D-aspartate receptor subtype 1 (NR1) on GABA-ir and NOS LCN neuronal profiles in the cat VB.

Deeply anesthetized adult cats were euthanized by an intracardiac perfusion with mixed aldehydes. Serial vibratome sections of the thalamus were cut in the coronal plane. Fluorescence-labeled antibodies were used to study the distributions of GABA, NOS and NR1 with a confocal laser scanning microscope. Many GABA-ir and NOS positive LCNs were also immunoreactive for NR1, as were the non-GABA-ir projection neurons. Immunoelectron microscopic studies in which a pre-embedding NR1 immunoreactive technique was combined with a post-embedding GABA-immunogold method, indicated that many thalamic somata and postsynaptic dendrites exhibited NR1 immunoreactivity, some of which also contained immunogold labeling for GABA. In the LCN presynaptic dendrites, GABA labeling was occasionally colocalized with NR1. NR1 immunopositivity was rarely detected in axons, although GABA-immunogold was frequently seen in many axon terminals and numerous dendrites. These data provide additional evidence that glutamate acting through NR1, such as occurs at the terminals of medial lemniscal axons, may alter responsiveness of thalamic relay neurons through nitric oxide facilitatory and/or GABA inhibitory mechanisms. Furthermore, these organizations could provide a circuitry wherever excitatory afferent activities mediated by NR1 can influence the GABAergic LCN appendages in VB, resulting in feed-forward GABAergic inhibition of thalamic relay neurons. Supported by NIH grant NS 23347.

## 46.6

FAST AND TIME-DEPENDENT ANOMALOUS RECTIFICATION IN THALAMOCORTICAL NEURONES. S.R. Williams and V. Crunelli\*, Physiology Unit, School of Molecular and Medical Biosciences, University of Wales Cardiff, Cardiff, CF1 3US, UK.

Thalamocortical (TC) neurones are known to express a Na<sup>+</sup>/K<sup>+</sup> hyperpolarisation-activated current, I<sub>h</sub>, that is thought to exclusively mediate anomalous rectification of the voltage-current (V/I) relationship. We report that anomalous rectification properties of TC neurones are more complex, and are a product of three different ionic mechanisms. Intracellular recordings were made from TC neurones of the cat ventrobasal complex under current- and discontinuous voltage-clamp. Under control conditions V/I relationship were non-linear when measured at peak and steady-state, similarly under voltage-clamp current-voltage relationship were non-linear (n=13). ZD 7288 (100-300  $\mu$ M) (n=24) irreversibly abolished time-dependent rectification mediated by I<sub>h</sub>, whilst sparing fast rectification. In some neurones in the presence of ZD 7288 voltage responses demonstrated a time-dependent increase in input resistance, that was apparent from potentials negative to -80 mV and was reflected as a fading inward current under voltage-clamp (n=6). Ba<sup>2+</sup> (0.1-2 mM) reversibly abolished fast rectification (n=9) and this time-dependent increase in input resistance. Ba<sup>2+</sup> however, revealed a non-inactivating inward current with very slow activation kinetics, first apparent at potentials negative to -90 mV: this current was sensitive to Cs<sup>+</sup> (5 mM) (n=4) and had a reversal potential between -60 and -50 mV, indicative of a mixed cationic current. These data indicate that TC neurones express I<sub>h</sub>, an inwardly rectifying K<sup>+</sup> current, I<sub>KIR</sub> and a slow form of I<sub>h</sub> termed I<sub>hslow</sub>. SRW is a Wellcome Prize Student.

## 46.8

Functionally diverse inhibitory innervation of ventrobasal thalamus by thalamic reticular neurones. C.L. Cox\*, J.R. Huguenard and D.A. Prince. Dept. Neurol. & Neurolog. Sci., Stanford Univ. Sch. Med., Stanford, CA.

The thalamic reticular nucleus (nRt) provides the primary source of inhibition in rodent ventrobasal thalamus (VB), influences receptive fields of VB cells, and has an essential role in generating intrathalamic rhythms. We previously showed that nRt axonal arborizations in VB range from dense clusters to diffuse projections (J.Comp. Neurol., 366:416). In the present experiments we tested the hypothesis that these arborization types mediate different inhibitory influences on VB neurones.

Dual intracellular recordings were obtained from pairs of synaptically-connected nRt and VB neurones using whole cell patch techniques with biocytin-filled electrodes. Single action potentials (APs) from nRt neurones evoked inhibitory postsynaptic currents (IPSCs) without failure in 4 of 6 VB neurones (>100 trials/cell). In the remaining pairs, single APs failed to evoke IPSCs in 44% and 74% of trials.

Amplitude distributions of IPSCs in 2 neurones with failures consisted of a single peak averaging 18.5  $\pm$  8.8 and 20.6  $\pm$  9.6 pA, whereas IPSCs were larger and more variable (mean range: 28-514 pA) in the remaining pairs. To estimate the number of release sites required to account for the evoked IPSCs, we recorded miniature IPSCs (mIPSCs) in VB neurones. The mIPSCs amplitude distributions consisted of a single, slightly skewed peak which was fit by a single gaussian (6/8 cells), and the remaining distributions were best fit by two gaussians. Mean mIPSC peak amplitude was 12.2  $\pm$  1.3 pA, suggesting that 1-3 release sites could account for IPSCs in neurones with failures, whereas ~2-70 release sites would be required to produce IPSCs in the non-failure neurones. Burst discharge (3-7 APs) specifically augmented IPSCs in non-failure neurones.

Following axonal reconstruction, nRt neurones that produced no postsynaptic failures had cluster arborizations (n=2), whereas a nRt neuron that produced failures had a diffuse arbor with few branches. Our data suggest that nRt neurones produce at least two types of inhibitory influence in VB: large IPSCs result from discharge of neurones with focal arbors and many synaptic contacts, while less potent IPSCs are evoked by nRt cells with diffuse projections and fewer release sites. Supported by NIH grants NS06477 and NS07280, and the Pimley Training Fund.

## 46.10

CHARACTERIZATION OF THALAMIC TERMINAL ARBORS FROM THE PRIMATE TRIGEMINAL PRINCIPAL SENSORY NUCLEUS.

D.L. Andrew\*<sup>1,2</sup>, P.J. May<sup>1,3</sup> and S. Warren<sup>1</sup>. Depts. of Anatomy<sup>1</sup>, Occupational Therapy<sup>2</sup> and Ophthalmology<sup>3</sup>, Univ. of Mississippi Med. Ctr., Jackson, MS 39216

Previous studies of the trigeminal system have focused on the barreloids in the rat thalamus. However, there is limited information describing the trigeminothalamic projections in primates. Using biotinylated dextran amine (BDA), we previously demonstrated the pattern of the terminal arbors arising from the spinal trigeminal nucleus in macaques. The present experiments used BDA injections in *M. fascicularis* monkeys to characterize the trigeminal principal nuclear projections to the ventral posterior medial (VPM) nucleus. Labelled trigeminothalamic terminal arbors are located throughout the rostral-caudal axis of VPM. The contralateral label extends dorsal-ventrally, adjacent to the arcuate lamina. The ipsilateral label is located more medially within the nucleus. Terminal fields in VPM are arranged in a honeycomb pattern. Axons of different sizes intermingle and contribute terminal arbors to this complex. The terminal arbor characteristics of thin and thick fibers appear to differ. Thinner fibers predominate in the dorsally located terminal fields. They are studied with *en passant* boutons that have a variety of shapes. These long, undulating fibers lack a consistent relationship to the somata. This suggests the VPM neuropil is the primary target of the thin arbors. Thicker fibers are more numerous in the core of the nucleus. They appear fragmented, lack clear branches and display fewer conventional boutons. These thick fibers form a complex, three-dimensional cluster near cell bodies. This arrangement suggests that the proximal dendrites receive a dense termination from the thick arbors. EM analysis reveals irregularly shaped labelled profiles with clear spherical vesicles that make asymmetric synaptic contacts on dendritic profiles. In general, the principal nuclear projections are more centrally located than those arising from the spinal trigeminal nucleus. These variations in terminal field organization may provide a morphological substrate for differential processing of trigeminal signals within the primate VPM. Supported by NIH Grants: NS27996 (SW); EY09762 (PJM)

## 46.11

THE ORGANIZATION OF SPINAL AND CORTICAL PROJECTIONS TO THE INTRALAMINAR CENTRALIS LATERALIS (CL) OF THE PRIMATE THALAMUS. Henry J. Ralston III\*, Antonia M. Milroy and Diane Daly Ralston. Department of Anatomy and the W.M. Keck Foundation Center for Integrative Neuroscience, University of California, San Francisco, CA, 94143-0452.

The somatosensory zone of CL in the non-human primate receives afferents from the dorsal horn of the spinal cord (STT) for processing nociceptive information. It also receives projections from the primary somatosensory cortex. Four adult male *M. fascicularis* monkeys were used in this study, three for spinal projections and one for cortical projections. Wheatgerm agglutinin conjugated to horseradish peroxidase (WGA-HRP) was injected into the dorsal horn of the spinal cord in the cervical enlargement or into the primary somatosensory cortex, area 3 in the hand representation. After 2 days survival the reanesthetized monkeys were euthanized by intracardiac perfusion with mixed aldehydes. Vibratome sections of thalamus were reacted with TMB and labeled regions of CL were prepared for electron microscopy using post-embedding GABA immuno-gold methods.

STT terminals were large, with rounded synaptic vesicles (RL) and formed asymmetric contacts with dendrites of thalamic neurons. Only occasionally did these terminals contact vesicle-filled profiles that were GABA immunoreactive (GABA-ir). Cortical projections also end as RL profiles as well as smaller terminals with rounded synaptic vesicles (RS). Both types of cortical terminals contact GABA-ir presynaptic dendrites as well as non-GABA-ir dendritic shafts.

We conclude that: 1- the spinal projections to macaque CL are similar to the projections to VPL in that few spinal terminals contact GABA-ir neurons. This is in contrast to STT projections to VPL and CL in the cat which commonly contact GABA-ir neurons; 2- the macaque CL has properties of the two classes of thalamic nuclei, "First order" and "Higher order" (Guillery, J. Anat. 187: 583, 1995), in that it exhibits features of both sensory relay and of association types of thalamic nuclei. Supported by NIH/NS 23347.

## 46.13

THE INFLUENCE OF ELECTROMAGNETIC WAVES OF MILLIMETER-RANGE ON SOMATOSENSORY EVOKED POTENTIALS PARAMETERS IN RESIDUAL SPASTIC CEREBRAL PALSY. S.Nikitin\*, P.Sokolov (1), V.Desnizza (2), Lab. of Neurophysiol., Inst. of Neurol., Volokolamskoe sch., 80, Moscow, Russia(1); Pain Res.Gr., Langestr.40-2, 76530 Baden-Ba'en, Germany(2).

The influence of electromagnetic wave (EMW) of millimeter-range (7,1 mm) on somatosensory evoked potentials parameters (SSEP) - the duration of N0+P1 - was analysed in 21 patients (23,0±4,5 years old, 13 male, 8 female), with residual spastic cerebral palsy (RSCP) before/after the treatment. SSEP were registered after the stimulation of left:right n. ulnar. With standart physiotherapeutic protocol patients were treated at cervical, thoracic and low back paravertebral projection levels with EMW-radiator (IAV-1) for 10 min from the distance of 1 cm. There were no side effect of the treatment, in 14(66%) cases the spasticity decreased subjectively and objectively, but there were no correlation with the SSEP changes. There were no statistical difference between left:right sides for N0+P1 duration. The N0+P1 duration was increased in all patients - 12,9±3,9; 12,6±3,3 / 16,9±4,6; 16,1±3,8 ms (p<0,05). The results reflect the dispersion because of the desynchronization of sensory afferents functional activity in RSCP. The latencies of the analysed components were normal. EMW may have an influence on the sensory afferent axon ionic channels. Supported by the Inst. of Neurology, Moscow, Russia.

## 46.12

DEAFFERENTATION AND LOCAL DAMAGE GIVE RISE TO BURSTING ACTIVITY IN THALAMUS OF AWAKE PATIENTS. J.Tsoukatos\*, K.D. Davis, R.R. Tasker, A.M. Lozano, and J.O. Dostrovsky. Departments of Physiology and Surgery, University of Toronto, Toronto, Ontario, Canada, M5S 1A8.

Thalamocortical relay neurons fire in a bursting pattern mediated by a low threshold calcium current during sleep but not during wakefulness. However, a number of studies have reported the existence of bursting activity in thalamus of awake chronic pain patients and have hypothesized that this activity might be related to their pain. In order to examine this hypothesis we have analysed the incidence of bursting neurons in motor and sensory thalamus of 63 movement-disorder, 8 multiple sclerosis, and 55 pain patients during microelectrode recordings performed to assist in localizing the target for a lesion or implantation of a stimulating electrode. The average incidence of bursting cells per track (bursting index-BI) was higher in multiple sclerosis and pain patients (BIs: 1.7 and 3.5 respectively) than in Parkinson disease (PD), essential tremor, and cerebellar tremor patients who had no deafferentation (BIs: 0.6, 0.6 and 0.7 respectively). In a subgroup of PD patients who had previously undergone thalamotomy many bursting cells were encountered when the electrode traversed the borders of the previously lesioned region (BI: 1.6 for subgroup). In a phantom limb pain patient (BI: 7.7) we identified regions which contained bursting cells with no receptive fields and where electrical stimulation evoked pain or paraesthesia in the phantom. In a dystonia patient with a traumatic lesion to the thalamus (BI: 2.5) we encountered bursting cells near the borders of damaged regions. In many cases the intra-burst firing pattern was analysed and was consistent with an underlying calcium spike. These findings suggest that neurons in damaged and/or deafferented regions of motor and sensory thalamus switch to a bursting firing pattern and this activity is not necessarily related to pain. However, if such bursting were to occur in thalamic pain relay sites following deafferentation, it might cause chronic pain. (Supported by Canadian MRC, Parkinson Foundation of Canada, NIH)

## SUBCORTICAL SOMATOSENSORY PATHWAYS II

## 47.1

INNERVATION DENSITIES ON THE CAT HINDLIMB. J. Culbertson\*, R. Millecchia, and P. Brown. Depts. of Anatomy and Physiology, West Va. Univ., Morgantown, WV 26506.

In order to examine the relationship between innervation density and other physiological and psychophysical variables as a function of position on the hindlimb, we have devised a method for visualizing cutaneous innervation density (ID) using data accumulated from several animals.

In anesthetized cats, low threshold mechanoreceptive innervation fields (IFs) of cutaneous nerves were mapped electrophysiologically; the nerves' myelinated axons were counted in histological sections. Each nerve's IF was digitized from a standard leg drawing and all points on a 1 mm grid within an unfolded skin representation of the IF were assigned a value equal to the nerve's ID (axons/IF area). Combining data across all nerves in all animals, the average ID was computed for each grid point. Exponential smoothing was applied across the grid. IDs were plotted in pseudo-color on an unfolded skin view and three standard leg views. The highest innervation density is on the plantar foot, rather than on the toes. These data will be correlated with map scale estimates to determine whether there are regional departures from constant convergence/divergence ratios.

Supported by NIH grants 1 R01 NS30725 and 1 R01 NS29997.

## 47.2

A MODEL OF LAMINA III - IV CELL RECEPTIVE FIELDS. P. Brown\*, R. Millecchia, J. Lawson, J. Culbertson, and S. Stephens. Depts. of Physiol. and Anat., W. Va. Univ., Morgantown, WV 26506.

Low threshold mechanoreceptive fields (RFs) of 500 dorsal horn neurons recorded in anesthetized cats were drawn on standard views of the leg. Recording sites were marked with microlesions. The recording locations were shifted rostrocaudally to compensate for interanimal variation in pre- and postfixation of the somatotopic map. RF outlines were characterized by RF center in cylindrical coordinates; area; length/width ratio; and orientation of long axis. Exponentially smoothed mean and variance surfaces were estimated for these five variables, on a grid of 40 points mediolaterally (ML) by 20/segment rostrocaudally (RC). Number of cells per grid point was estimated by exponential smoothing of cell counts in laminae III and IV.

Elliptical RFs were simulated for 100,000 cells, using the mean and variance data. When RFs were simulated at the locations of the original 500 cells, the RFs of real and simulated cells overlapped by approximately 80% (cross-correlation of real and simulated RF points on a grid on the skin with 0.5-mm spacing).

The density of cell representation of skin points on the hindlimb was represented as contour plots on dorsal view maps and dermatomes were similarly plotted on the standard views of the leg. Overlap of modeled and real data was at the 80% level.

Supported by NIH grants 1 R01 NS30725 and 1 R01 NS29997.

## 47.3

VISUALIZATION OF SIGNIFICANT DIFFERENCES OF CELL PROPERTIES IN SOMATOTOPIC MAPS. J. V. Odom\*, R. Millecchia, and P. Brown. Depts. of Ophthalmol. and Physiol., W. Va. Univ., Morgantown, WV 26506

In order to test for differences between two populations of cells as a function of location in a somatotopic map, we must compare data sets in which sampled cells are randomly scattered throughout the map. We describe cell properties as exponentially smoothed surfaces fitted to data in the plane of the map. All data contribute to the computation of the value of each grid point, but each datum is weighted with a coefficient which declines exponentially with distance from the grid point. Both means and variances are represented using standard computations, substituting the sum of weights for the number of data at each point. Student's *t* values are computed at all grid points, keeping in mind the fact that grid points' *t* values are not independent of each other. Values of *p* are then derived, and significant difference surfaces are equal to differences of means where differences are statistically significant (e.g.,  $p < 0.01$ ) and zero where differences are not significant. We used Monte Carlo simulation methods to test this approach using two populations of 100,000 values at 4,000 grid locations. Correlations between calculated population and sample surfaces were 0.96 (mean1); 0.97 (mean2); 0.91 (variance1); 0.91 (variance2); 0.99 (difference); 0.97 (*r*); 0.78 (*p*), and 0.70 (significant difference).

Supported by NIH grants 1 R01 NS30725 and 1 R01 NS29997.

## 47.5

ROSTROCAUDAL DISTRIBUTIONS OF CORD DORSUM POTENTIALS AND OBSERVED AND MODELED SINGLE-UNIT RESPONSES. Stephens, S., Millecchia, R., Culbertson, J., Lawson, J., Gladfelter, W.\*, and Brown, P. Depts. of Anatomy and Physiology, West. Va. Univ., Morgantown, WV 26505.

Previous studies showed rostral-caudal (RC) distributions of cord dorsum potentials (CDPs) evoked by intra-axonal stimulation reflect the RC distributions of the axons' boutons. This study compared RC distributions of CDPs and responding dorsal horn cells.

Single tactile afferents were stimulated at thirty-two standard sites (SSs) on legs of anesthetized cats while signal averaging from 15 sites spanning the RC extent of the hindlimb representation. CDP data for each stimulation site were combined across animals by exponential smoothing. The RC distributions of CDPs were compared to the distributions of responding cells, determined by overlap of each SS and the RFs of 500 recorded neurons and 100,000 simulated neurons. Correlations were highest for the model population: mean  $\pm$  SD  $0.76 \pm 0.18$ , and there was no difference of distribution centers. Standard deviations of CDP RC distributions (a measure of RC spread) were significantly greater than the SDs of responding cell RC distributions:  $1.07 \pm 0.21$  vs  $0.88 \pm 0.42$ , respectively,  $t = 3.64$ ,  $p < 0.001$ .

Supported by NIH grants 1 R01 NS30725 and 1 R01 NS29997.

## 47.7

PLASTICITY IN THE SPINAL DORSAL HORN FOLLOWING PERIPHERAL NERVE REGENERATION. H.R. Koerber\* and K. Mimics. Dept. of Neurobiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Adult cats were anesthetized with  $\alpha$ -chloralose 5-12 months following transection and self union of the left tibial and sural nerves. In each experiment a regenerated fiber was impaled in the dorsal columns with electrodes containing 5% Neurobiotin (NB) in 1M K-acetate. The impaled fiber's adequate stimulus was determined and the fiber activated by passing brief (200  $\mu$ s) current pulses through the microelectrode. The resulting cord dorsum potentials (CDPs) were recorded at 8 sites in response to shocks delivered every 56ms and to pairs of shocks (50ms ISI) delivered every 2s, and the fiber injected with NB. In the same preparations electrodes containing 3 M K-acetate were used to penetrate dorsal horn cells. The impaled cells' receptive fields (RFs) were mapped taking note of areas of skin from which the most vigorous responses were elicited. Needle electrodes inserted into these cutaneous "hot spots" were used to electrically activate individual or small numbers of regenerated fibers while simultaneously recording the resulting CDPs and intracellular EPSPs (if any). This allowed the determination of the incidence of connectivity between regenerated fibers and dorsal horn cells with overlapping RFs. At the completion of the recording experiments the animals were perfused, the cord removed and processed to recover the injected fiber. In agreement with findings in intact animals, NB revealed many long-ranging collaterals which were not seen using intracellularly injected HRP. Although there was no qualitative difference in their morphology compared to those seen in controls, the correlation between spatial distribution of boutons and amplitudes of the monosynaptic CDPs revealed significant shifts in the functional efficacy of the central connections. Transcutaneous stimulation revealed a significantly higher incidence of connectivity between regenerated fibers and cells with overlapping RFs with time after regeneration (5-6 mo. 20%; 9 mo. 67%; 12 mo. 86%). Qualitatively, there was no obvious anatomical reorganization in the nucleus proprius, however, functional changes observed with time following transection suggest the formation new somatotopically appropriate central connections. NS23725 (HRK).

CORRELATION OF DORSAL ROOTLET RFs AND DORSAL HORN CELL RFs AT THE LEVEL OF ENTRY OF DORSAL ROOTLETS. J. Lawson\*, R. Millecchia, J. Culbertson, S. Stephens, C. Holbert and P. Brown. Depts. of Physiology and Anatomy, West Va. Univ., Morgantown, WV 26505

We have proposed that spinal dorsal horn cells assemble their prototype receptive fields (RFs) during development by receiving input from primary afferent fibers entering the cord at their rostral-caudal levels, and that these initial RFs are subsequently modified by activity dependent mechanisms. If this is the case, then the combined RFs of adult dorsal horn cells at any rostral-caudal level should closely match the aggregate RFs of primary afferents entering at the same level.

In anesthetized adult cats, RFs of dorsal horn cells confined to a band as wide as an adjacent dorsal rootlet were determined. Individual rootlet primary afferent RFs were obtained by teasing apart the rootlet with fine forceps, and then suspending small fascicles on a hook electrode. Rootlets rostral and caudal to the cell band were also recorded. Aggregate dorsal horn cell RFs and rootlet RFs were correlated using degree of overlap on the skin. The correlation between rootlets and the cell band declined with rostral-caudal separation. While this suggests that cell band and adjacent rootlet RFs are highly correlated, undersampling of rootlet RFs made analyses difficult.

NEURAL CORRELATES OF SPATIAL DISCRIMINATIONS IN THE DORSAL HORN. R. Millecchia\* and P. Brown. Physiol. Dept., W. Va. Univ., Morgantown, WV 26506.

Variations of two-point discrimination and localization thresholds on the skin have been attributed to variations of CNS receptive field (RF) size and map scale. Variation of two-point discrimination with orientation has been attributed to longitudinal elongation of RFs. These hypothesized correlations were tested with a model of the 100,000 neurons in the cat dorsal horn laminae III-IV representation of the hindlimb. Stimuli were simulated as single or paired skin contacts, 2mm x 2mm. Each stimulus was tested for overlap with the RF of each of the 100,000 neurons, and responding cell density was depicted on dorsal view grids. For each discrimination, responses to a reference and a comparison stimulus were compared by cross-correlation of the distributions of responding cells. As comparison and test stimuli were varied from identical to more and more different, the correlations declined monotonically from 1.0 toward 0. Correlation criteria were used as discrimination thresholds; as criteria were decreased from 1.0 toward 0, difference limens (DLs) increased. Two point discrimination and localization DLs varied with position on the skin in parallel with map scale and dorsal horn cell RF size. Two point discrimination was also better for transverse than for longitudinal stimulus orientation.

## 47.8

ULTRASTRUCTURE OF LESION-INDUCED CHANGES IN SYNAPTIC ORGANIZATION IN TRIGEMINAL SUBNUCLEUS CAUDALIS: NEUROTRANSMITTERS AND RECEPTORS.

L. E. Westrum\*, N. L. Anderson, P. A. Irish, and M. A. Henry. Dept. of Neuro. Surgery, U. of Washington, Seattle, WA 98195.

Synaptic reorganization following primary deafferentation of trigeminal nucleus might be associated with remodeling of the neurotransmitter patterns and their receptors. We are using lesions of the trigeminal nerve in conjunction with pre- and postembedding electron microscopy immunolocalization protocols to study resultant synaptic reorganization emphasizing patterns of immunoreactivity for glycine (Gly), GABA and the NMDA subtype of glutamate receptor. Normally primary afferents are glutamatergic, form type I contacts onto dendrites and receive type II contacts from GLY positive and GABA positive axons. Following lesions, primary afferent terminals degenerate but retain contacts by Gly and GABA positive terminals. The postsynaptic type I specializations persist. Some of these type I postsynaptic sites, vacated by the degenerated terminals are reoccupied by Gly positive terminals in addition to the previously reported GABA positive terminals. These "reinnervated" type I postsynaptic sites are being studied to determine if they retain or have lost their NMDA receptor reactivity. Thus deafferentation of excitatory postsynaptic sites results in reoccupation by inhibitory axons which could affect the receptor characteristics of these postsynaptic sites.

**QUANTITATIVE ELECTRON MICROSCOPIC STUDY OF GLUTAMATE AND GABA IN DEVELOPING FELINE SPINAL TRIGEMINAL NUCLEUS.** P.S. Irish, A.L. Marquardson, L.E. Westrum, M.A. Henry\*. Dept of Neurological Surgery, Univ. of WA, Seattle, Washington 98195.

Information on the amino acid neurotransmitters involved in nociception is important for understanding the specific roles of excitatory and inhibitory neurotransmitters in modulation of pain. We examined tissue from kittens of 3 and 17 days, when the trigeminal system shows major periods of increase in axo-axonic synapses. Double-labeling with different sized colloidal gold particles was used for the excitatory neurotransmitter glutamate (GLU) and the inhibitory neurotransmitter gamma aminobutyric acid (GABA). Synaptic vesicle-containing terminal profiles were identified in electron micrographs of ultrathin sections from trigeminal subnucleus caudalis, lamina II. A total of 252  $\mu\text{m}^2$  was analyzed per age. Results comparing 3 day to 17 day show: 1) the number of small terminal profiles ( $<1\mu\text{m}^2$ ) decreases (91%-88%), while the number of large terminal profiles ( $>3\mu\text{m}^2$ ) increases (0.9%-4%), approximately 4-fold; 2) the increase in the terminal profiles size is not correlated with increase in number of synaptic vesicles; 3) the number of terminal profiles with high GLU and GABA- immunoreactivity increases approximately 2-fold. These data suggest that the increase in amino acid immunoreactivity reflects the developmental role of GLU and GABA during synaptogenesis and in pain modulation.

## 47.11

**DEVELOPMENTAL CHANGES IN MEMBRANE PROPERTIES OF BRAINSTEM TRIGEMINAL NEURONS DURING PATTERN (BARRELETTE) FORMATION.** E. Gunhan-Agar\*, R.S. Erzurumlu & W. Guido. Anatomy & Neuroscience Center, LSU Medical Center New Orleans, LA 70112.

Little is known about the electrophysiological properties of brainstem trigeminal neurons during development and refinement of connections in the rat trigeminal pathway. For example, the functional state of first-order central relay neurons in brainstem trigeminal nuclei (BSTC) during whisker-specific pattern (barrelette) formation has yet to be explored. Using intracellular recordings in a brainstem slice preparation, we examined the membrane properties of BSTC cells from rats during PND 0-21. At all ages tested, neurons were capable of generating trains of action potentials in response to intracellular injection of depolarizing current pulses. Increasing the amplitude of the depolarizing current also reduced the latency of the first spike and increased firing frequency. During times when barrelettes develop (PND 0-5), spikes were shorter and longer and showed frequency accommodation; the latter was due to the activation of a large two component after-hyperpolarization (AHP). After the consolidation of barrelettes (PND 5), several voltage-dependent conductances emerged which greatly altered signal transmission. These included a large low threshold (LT)  $\text{Ca}^{2+}$  conductance which led to  $\text{Ca}^{2+}$  spikes and burst firing, a transient  $\text{K}^{+}$  conductance ( $I_h$ ) which delayed the onset of spike firing, and a mixed cation conductance ( $I_m$ ) which prevented strong hyperpolarization and contributed to the establishment of intrinsic burst activity. Cells from earlier ages (PND 0-5) lacked  $I_h$  and  $I_m$ , and had a weak LT  $\text{Ca}^{2+}$  conductance that gave rise to small  $\text{Ca}^{2+}$  spikes devoid of bursts. Taken together, these results suggest that the electrophysiological properties of BSTC neurons play a significant role in pattern formation by minimizing signal distortion and insuring that excitatory responses from sensory periphery are accurately received and transmitted according to stimulus strength. ## 47.13

**BRAINSTEM TRANSNEURONAL LABELING AFTER HSV-1 INJECTION INTO THE ETHMOIDAL NERVE OF THE MUSKRAT.** W.M. Panneton\* and P.E. McCulloch. Dept. of Anatomy and Neurobiology, Saint Louis University, St. Louis MO, 63104

When the nasal cavity of muskrats is stimulated with either ammonia vapors or water there are dramatic cardiorespiratory responses similar to those of diving. To define the brainstem circuitry of the diving response, we inoculated the ethmoidal nerve of muskrats with Herpes Simplex Virus 1 (HSV-1), strain 129, and waited for the anterograde transneuronal transport to occur. As a transneuronal tracer, HSV-1 crosses synapses and therefore can label secondary and tertiary neurons in a circuit. The ethmoidal nerve, which innervates the nasal mucosa, was injected with 1  $\mu\text{l}$  of virus ( $1 \times 10^8$  PFU) and the animals survived 3 to 6 days. The animals were then perfused, their brains harvested and processed immunohistochemically using a commercial antibody against HSV-1. After short survival times only sparse label was found in the superficial medullary dorsal horn (MDH) ipsilaterally and the ventrolateral medulla. Longer survival times showed increased label in the ventrolateral parts of the superficial MDH, in lamina V, as well as in the ventral paratrigeminal n. Neurons were found in the rostral and caudal ventrolateral medulla, the dorsal reticular formation (RF), and the dorsolateral n. tractus solitarius (NTS). The area around the A5 group and the locus coeruleus were well labeled bilaterally. The ventrolateral part of the parabrachial nucleus and the Kolliker-Fuse n. contained neurons mostly ipsilaterally. The median raphe also contained label. With longest survival times there was increased label in the MDH, and all parts of the NTS, raphe, RF and dorsolateral pons. The anterograde transport of HSV-1 shows promise as a method for defining the brainstem circuitry of the diving response. Research supported by N.I.H. grant HL-38471 awarded to W.M.P.

## 47.10

**NATURE OF SYNAPTIC TRANSMISSION IN THE COCULTURED RAT TRIGEMINAL SYSTEM.** W. Guido\*, F.S. Lo & R. S. Erzurumlu. Dept of Anatomy and Neuroscience Center, LSU Medical Center, New Orleans, LA, 70112.

In explant cocultures of embryonic rat trigeminal ganglion (TG) with same age whisker pad and early postnatal brainstem slices (containing brainstem trigeminal nuclei, BSTC), TG axons grow and arborize in both targets. Furthermore, central TG axon arbors form functional connections with brainstem target neurons in BSTC. Here, we examined various aspects of synaptic transmission in this *in vitro* sensory system. Excitatory postsynaptic potentials (EPSPs) in BSTC cells were reliably evoked by electrical stimulation of the ganglion explant. EPSPs had short latencies (0.9-3 msec) and variable durations (20-80 ms), and were occasionally followed by an IPSP (EPSP/IPSP pairs). Recordings of postsynaptic activity over a wide range of membrane potentials revealed several important features about these responses. At depolarized levels, EPSPs triggered action potentials, while at hyperpolarized levels they evoked low threshold  $\text{Ca}^{2+}$  spikes. The amplitude of EPSPs peaked early and declined with membrane depolarization, a pattern consistent with glutamatergic nonNMDA receptor activation. The IPSP component of the EPSP/IPSP pair was short (40 ms) and reversed polarity at -70 mV, a pattern consistent with the activation of a GABA<sub>A</sub> mediated  $\text{Cl}^{-}$  conductance. Bath application of the GABA<sub>A</sub> antagonist, bicuculline produced two changes. First, spontaneous EPSP activity became prevalent. In some cells, synchronous barrages of spontaneous EPSP activity led to periodic waves of depolarization and high frequency firing in BSTC cells. Second, the duration of EPSPs became longer (200-800 msec). EPSP duration increased with membrane depolarization, a pattern consistent with NMDA receptor activation. Taken together, these results indicate that developing BSTC cells in coculture form both excitatory and inhibitory connections and the latter may play a role in regulating the pattern and nature of excitatory postsynaptic activity. ## 47.12

**POSSIBLE FEATURE DETECTION IN THE SOMATOSENSORY BRAINSTEM** D. W. Doherty\* and H. P. Killackey. Department of Psychobiology, University of California, Irvine, 92717

Rat trigeminal ganglion neuron responses are tuned to the direction of vibrissa deflection. Recent data demonstrate that directional tuning is also prominent in nucleus principalis neurons. Directionally tuned response profiles may reflect a deflection direction response probability profile. The structure of the particular surface sampled by the rat results in vibrissa deflections that correspond to a unique probability profile. Probability profiles built up over several small vibrissa movements, or "tremors," can result in signals ideally suited for discriminating textures or detecting surface orientation and contour. Specifically, signals utilized for texture discrimination could result from responses to small vibrissa deflections, between approximately  $0.3^{\circ}$  and  $0.6^{\circ}$ . Small deflections usually result in single vibrissa receptive fields and relatively tight directional tuning in nucleus principalis neurons. In contrast, signals leading to surface orientation and contour detection could result from relatively large vibrissa deflections, between  $1.2^{\circ}$  and  $2.3^{\circ}$ . Large deflections usually result in multi-vibrissa receptive fields and broader directional tuning. Our hypothesis predicts that signals in brainstem neurons, specifically neurons in nucleus principalis, could play a role in feature detection in the somatosensory system. ## 47.14

**FOS-DETERMINED NEURONAL ACTIVATION WITHIN THE BRAINSTEM OF THE MUSKRAT AFTER NASAL STIMULATION.** P.E. McCulloch, W.M. Panneton and P.A. Young\*. Dept. of Anatomy and Neurobiology, Saint Louis University, St. Louis MO, 63104

The immunohistological detection of FOS, the protein product of *c-fos*, was used as a marker of neuronal activation within the brainstem of muskrats after repeated stimulation of the nasal passages with either ammonia vapors or retrogradely-flowing water. Both methods of nasal stimulation produced the same cardiorespiratory events (an immediate 62% decrease in heart rate, 29% increase in mean arterial blood pressure, and sustained expiratory apnea). After ammonia stimulation of the nasal passages, increased FOS label was detected within the spinal trigeminal nucleus (ventral laminae 1 and 2 of the medullary dorsal horn (MDH), ventral paratrigeminal nuclei, and spinal trigeminal nucleus interpolaris), an area just ventromedial to MDH, the caudal dorsal reticular formation and the area of the A5 catecholamine group compared to control animals. Water stimulation of the nasal passages produced increased FOS label only in the A5 catecholamine group. There was increased FOS label in the ammonia group in the ventral laminae 1 and 2 of MDH and the ventral paratrigeminal nuclei compared with the water group. We conclude that ammonia stimulation of the nasal passages produces a different pattern of neuronal activation within the brainstem compared with water stimulation. In addition, we found that FOS immunohistochemistry did not detect significant changes in neuronal activation within known cardiorespiratory control centers, even though stimulation of the nasal passages produces both apnea and changes in heart rate and blood pressure.

**CHRONIC CHANGES IN S100B CONCENTRATION WITHIN THE RAT TRIGEMINAL BRAINSTEM FOLLOWING ADULT INFRAORBITAL NERVE TRANSECTION.** B.G. Klein\*, and D. Jones. Dept. of Biomedical Sciences and Pathobiology, College of Veterinary Medicine, Virginia Polytechnic Institute and State University, Blacksburg, VA 24061.

We have previously demonstrated increases in serotonin (5-HT) content and immunoreactivity within rat trigeminal subnucleus interpolaris (SpVi) correlated with somatosensory alterations following adult infraorbital nerve (ION) transection. No such lesion-induced increases in 5-HT afference were observed within subnucleus caudalis (SpVc). We have also demonstrated that ION transection is not associated with a chronic change in the density of SpVi cells immunoreactive for S100B, a 5-HT growth regulator. This does not preclude that lesion-induced changes in S100B content or release in those S100B immunoreactive cells might influence alterations of 5-HT afference following nerve transection. Here, we investigated whether ION transection was associated with a change in S100B concentration within the trigeminal brainstem. Eleven adult male rats were decapitated approximately one year after ION transection and brains were rapidly removed and frozen on dry ice. Nine normal rats were subjected to a similar procedure. Transverse sections were then made through SpVi and SpVc and samples from each section were taken according to previously described methods. S100B content was then analyzed by an enzyme-linked immunosorbent assay (Griffin et al., 1993). Concentrations of S100B were calculated following protein assay of the brain samples. Within SpVi, no significant differences in S100B concentration were found between the medians of the lesioned and intact sides of the lesioned rats nor between the intact side and normal rats. However, in SpVc, median S100B concentration on the lesioned side (0.11 ng/mg) was significantly less ( $p < .005$ ) than on the intact side of lesioned rats (0.94 ng/mg), while the intact side did not significantly differ from normal. ## 47.17

**POSTSYNAPTIC EFFECTS PRODUCED BY MOTOR CORTEX AND PRIMARY AFFERENT FIBRES IN THE CUNEATE NUCLEUS OF THE CAT.** L. Martinez\*, J. Marino and A. Canedo. Dep of Physiol. Fac of Med. Univ of Santiago de Comp. 15705, Santiago, SPAIN.

The experiments were carried out in anaesthetized ( $\alpha$ -chloralose) and paralyzed (pavulon) cats. The records were restricted to the medial cuneate nucleus (0-4 mm caudal to the obex) by using the whole-cell patch recording technique. Cuneothalamic neurons (CTNs) were identified by stimulating the contralateral medial lemniscus (ML) at A2. In addition, stimulating electrodes were placed in the ipsilateral dorsal columns (DC) at C2; in the forearm representation area of the motor cortex (MCx); and, once determined, in the center of the cutaneous receptive field (RF) for each neuron. Both MCx and afferent stimuli at DC or RF evoked postsynaptic inhibition or excitation on cuneate cells (CNs). Electrical stimulation of the RF elicited doublets of spikes (mean latency 6.2, range 5.6-7.2), doublets or bursts of discharges (mean latency 6.4, range 4.8-9.8) in CTNs and interneurons respectively, and also evoked inhibitory postsynaptic effects lasting 20-120 ms (IPSPs, mean latency 6.7 ms, range 5-9 ms) in CNs. MCx stimulation elicited excitatory postsynaptic effects (EPSPs) in all the cuneate interneurons tested ( $n=30$ ; mean latency 5.4, range 2-10 ms), and IPSPs of 60-120 ms duration in all the tested CTNs ( $n=31$ ; mean latency 9 ms, range 7.3-15 ms). The EPSPs seemed to be generated at the dendritic arbor distant from the soma, since they were not affected by the polarization of the membrane; and the IPSPs appeared to be generated at somatic level for they reversed polarity with injections of negative current. Responses evoked by stimulation of the RF, DC and MCx were also found at hyperpolarized membrane potentials, suggesting activation of a low threshold calcium conductance in analogy with other places (e.g. thalamus). Presumed calcium dendritic spikes were also recorded following RF and MCx stimuli. Protocols specifically conducted to reveal presynaptic inhibition gave negative results. Thus, trains of long duration (up to 750 ms) applied to the DC at several frequencies (from 10 up to 500 Hz) were consistently followed in a one-to-one manner by the CTNs, but the interneurons failed at stimulus frequencies of 100 Hz or higher. The frequency-following failure of the interneurons was not due to the amplitude decrease of the EPSPs, indicating that the release of neurotransmitter was normally produced. Instead, the spike generating mechanism was disrupted probably due to the inactivation of the postsynaptic sodium channels. Finally, paired pulses (stimulating DC as conditioning and RF as test, at different intervals) did not reveal presynaptic processes over CNs. It is concluded that, in our experimental conditions, both MCx and primary afferent stimuli evoked postsynaptic effects on cuneate neurons without evidence of presynaptic influences.

**SIZE RELATIONSHIPS OF THE HAND AND CUNEATE NUCLEUS IN HUMANS AND NONHUMAN PRIMATES.** X-F Wu\*, J. Nguyen, M.J. Forgues, and J.T. Wall. Department of Neurobiology & Anatomy, Medical College of Ohio, Toledo, OH 43699.

Recent studies in monkeys describe size relationships of the hand and the main cuneate nucleus (CN), the brainstem nucleus receiving cutaneous inputs from the hand. Extrapolation of these relationships to humans presumes similarities across species; however, given the large differences in body and brain sizes of humans and monkeys, this presumption may not be valid. To evaluate size relationships of the hand and CN in human and nonhuman primates, this study compared peripheral volumes of the hand skin, and central volumes of the CN, in adult humans and squirrel monkeys. Hand skin thickness and area were measured from hand dissections to determine hand skin volume. CN volumes were determined from three dimensional reconstructions of cytochrome oxidase stained sections that spanned the CN. In humans, the hand skin occupied a mean volume of 62,569 mm<sup>3</sup> (range = 58,647-66,143). The CN in humans occupied a mean volume of 57 mm<sup>3</sup> (range = 52-65). In contrast, the hand skin in monkeys occupied a smaller mean volume of 1,852 mm<sup>3</sup> (range = 1,438-2,379). Likewise, the CN in monkeys occupied a smaller mean volume of 2.3 mm<sup>3</sup> (range = 2.1-2.5). From these findings, it is clear that CN volumes are much smaller than hand skin volumes in both humans and monkeys. To quantify this scaling, compression factors were calculated from the ratio: hand skin volume (mm<sup>3</sup>) / CN volume (mm<sup>3</sup>). Compression factors were similar in humans (mean = 1,098; range = 902-1,272) and monkeys (mean = 805; range = 575-1,132). Thus, as would be expected, hand skin and CN volumes are larger in absolute size in humans. This difference aside, the compression factors indicate that scaling of the relative sizes of the hand and CN is similar in humans and monkeys. Supported by NIH Grant NS21105.

## 47.16

**ANODALLY-FOCUSSED POLARIZATION ALLOWS DIFFERENTIATION OF LARGE AND SMALL PRIMARY AFFERENT INPUT TO CAUDAL BRAINSTEM.** J.C. Petruska\*, C.H. Hubscher, and R.D. Johnson. Depts. of Neurosci. and Physiol. Sciences, University of Florida, Gainesville, FL, 32610.

Various techniques are currently used to study the processing of nociceptive information conveyed centrally by small diameter afferent fibers (SDAF; thinly myelinated A $\delta$  and unmyelinated C). These fibers are activated by noxious stimuli (mechanical, thermal, chemical, electrical) applied directly to the nerves or their somatic or visceral territories. These stimulation methods are confounded by (i) damage to the tissue, receptors, or peripheral nerves and (ii) large diameter afferent fiber (LDAF; A $\beta$  and large A $\delta$ ) activation (i.e., LD+SDAF stimulation). Alternatively, application of anodally-focused polarization to a peripheral nerve blocks activity of LDAF and thus allows selective propagation of strictly SDAF action potentials (Petruska and Johnson, Soc. Neurosci. Abst., 1994) without these confounding problems. In the present study, the applicability of this technique for accurately differentiating between large and small peripheral fiber input to neurons in the CNS was assessed using electrophysiological techniques. Electrical stimuli were applied to the tibial and caudal cutaneous sural (CCS) nerves in urethane-anesthetized rats. Polarization electrodes were placed on the sciatic nerve at the hip. Recordings were made from neurons in the nucleus gracilis (NG) and nucleus reticularis gigantocellularis (Gi) having receptive fields innervated by the tibial or CCS nerves. Responses of these single NG and Gi neurons were tested in response to both LDAF and LD+SDAF stimulation, with and without polarization. As expected, most NG neurons responded preferentially to LDAF stimulation alone, although preliminary data suggest SDAF mediated effects on some neurons in NG. Neurons in Gi responded to LD+SDAF stimulation. Polarization blocked LDAF mediated but not SDAF mediated neuronal responses in both nuclei. Thus, this technique allows for the identification of small versus large afferent fiber mediated input to CNS neurons. Supported by UF DSR and NIH Center MH15737 grants.

## 47.18

**RAPID CHANGES IN PRIMATE CUNEATE NUCLEUS MAPS AFTER HAND NERVE INJURY.** J. Xu\* and J.T. Wall. Department of Neurobiology & Anatomy, Medical College of Ohio, Toledo, OH 43699.

Cortical maps of the hand begin reorganizing within minutes-hours after injury of hand nerves. The main cuneate nucleus (CN) contains a map of the hand that is the origin of lemniscal projections to cortical hand maps. To assess potential CN contributions to cortical reorganization, this study mapped the CN of monkeys during the first minutes-hours after distal forearm transection of the ulnar and median nerves. Functional organization in CN regions that normally represent the hand was clearly altered following this injury. Cutaneous fields of neurons at some recording sites underwent rapid shifts from, for example, glabrous hand locations innervated by the sectioned nerves, to hairy hand or forearm locations innervated by the intact radial nerve. Due to these changes, normal discontinuous and small representations of hairy hand skin innervated by the radial nerve became more continuous and larger (normal mean = 16% [ $\pm$ 3] versus postinjury mean = 28% [ $\pm$ 4] of CN transverse area;  $t[11] = 5.70$ ;  $p < 0.001$ ). Within these postinjury representations, inputs from proximo-radial to more disto-ulnar locations on the hairy hand were represented at ventral to dorsal locations in the CN. Neurons at other CN locations lost cutaneous responsiveness, and became either unresponsive or only responsive to tap stimuli (normal mean = 3% [ $\pm$ 2] versus postinjury mean = 18% [ $\pm$ 5] of CN transverse area;  $t[11] = 7.21$ ;  $p < 0.001$ ). Overall, normal CN organization patterns characterized by a continuous representation of the glabrous hand and discontinuous, small representations of the hairy hand, were transformed into abnormal patterns characterized by no representation of the glabrous hand, larger continuous representations of the hairy hand, and large cutaneously unresponsive regions. These transformations resemble previously reported cortical map transformations seen during the first minutes-hours after this injury. Thus, initial central reorganization after this injury entails CN and cortical changes that are similar in nature and that appear with a similar rapid time course. Supported by NIH Grant NS21105.

**"REAL-TIME" MONITORING OF WHISKING KINEMATICS IN THE HEAD-FIXED RAT.** R. Bermejo\*, D. Houben and H. P. Zeigler. Biopsychology Program, Hunter College, City University of New York, New York, NY.

Neurobehavioral studies of the rat's vibrissa system require isolation of individual vibrissae, experimental control of vibrissa movements, and measurement of the kinematics of these movements. We have previously described a head-fixed preparation for isolation and experimental control of individual vibrissa movements. To increase the utility of this preparation we have developed an inexpensive system for the "real-time" monitoring of individual vibrissa movements with high spatial and temporal resolution (13 $\mu$ ; 1 msec). The system utilizes an optical sensor composed of an array of 2048 light-sensitive elements (CCDs). The sensor is mounted below the whisker pad and aligned with the axis of the body. Illumination of the array by a collimated light source generates a constant baseline voltage in each element. Interruption of the light by an object generates a voltage shift in a subset of elements. Movement of the whisker with respect to the sensor produces successive displacements in the position of that voltage shift which are linearly related to the whisker position. The entire CCD array is repeatedly scanned to read the voltage at each of its elements. A comparator circuit identifies the successive positions of voltages above a preset threshold and outputs the data to a microprocessor for computation of the whisker movement trajectory. The system may be used to monitor the kinematics of a single vibrissa movement with all other whiskers clipped, or the relative detectability of a selected single whisker may be differentially increased. Because amplitude and velocity measurements are made "on-line", preselected output values of these kinematic variables may be used to trigger differential reinforcement in conditioning paradigms. The system should facilitate behavioral, electrophysiological and functional mapping studies of the rodent's whisking behavior.

(Supported by Research Scientist Award MH-00320 to H. P. Z.).

## 48.1

ACTIVITY ASSOCIATED EXPRESSION OF ZIF268 IN THE RAT WHISKER BARREL FIELD. L. Rioux<sup>1</sup>, J. Nissanov<sup>2</sup>, A. Chaudhuri<sup>3</sup><sup>1</sup>Dept. Pharmacology, Univ. Pennsylvania, Philadelphia, PA 19104.<sup>2</sup>Biomed. Eng. & Sci. Inst., Drexel Univ., Philadelphia, PA 19104.<sup>3</sup>Dept. Psychology, McGill Univ., Montreal, PQ H3A 1B1, Canada

Activity dependent expression of the immediate early genes (IEG) has been widely utilized for functional brain mapping. Due to the punctate characteristic of labeling, a consequence of the nuclear compartmentalization of these proteins, immunodetection of these gene products can support visualization of neuronal activity at spatial resolution of individual neurons. We exploited this feature to examine the relation between sensory stimulation of the whiskers and expression of Zif268 in the somatosensory cortex. Previous studies (Melzer and Steiner, 1994, Neurosci Abst 20:566.9; Steiner & Gerfen, 1994, J. Comp. Neurol. 344:297-304), utilized *in situ* hybridization to demonstrate that an increased level of expression of the *zif268* mRNA is observed in response to whisker stimulation. Is this due to increased level of expression by individual cells only or is there an increase in the number of *zif268* expressing cells? We evaluated this by comparing the contralateral and ipsilateral somatosensory cortex following first clipping of the whiskers on one side and then three hours of light brushing of the whiskers on the intact side. Whisker barrel fields were visualized using cytochrome oxidase and the number of Zif268 labeled cells within the barrel field counted on adjacent sections. A 50% to 100% greater number of labeled cells was observed on the side contralateral to the stimulated whiskers over the ipsilateral side. The increase in Zif268 immunopositive neurons suggests that the increase in *zif268* mRNA abundance is also due in part to increase in the number of expressing cells. INTRACORTICAL MICROSTIMULATION INDUCES LONG-TERM DEPRESSION OF FIELD POTENTIALS IN THE RAT SOMATOSENSORY CORTEX *IN VITRO*. G. Boehmer\*, P. Heuser, H.R. Dinse. Dept. of Physiology and Pathophysiology, Johannes Gutenberg University, 55099 Mainz, Germany.

Intracortical microstimulation (ICMS), i.e. repetitive electrical pulse trains delivered to the somatosensory cortex of the rat *in vivo*, results in cortical reorganization of skin field representation. The present *in vitro* study aimed at examining mechanisms underlying this type of cortical plasticity. Experiments were performed on brain slices (500  $\mu$ m) including the rat somatosensory cortex. Brain slices were superfused with carbogen-saturated artificial cerebro-spinal fluid (ACSF) at 36 °C. Field potentials (FP) were evoked by electrical stimulation in cortical layer IV/V using steel-needle electrodes. FP were recorded from cortical layer II/III using ACSF-filled glass-microelectrodes. ICMS was delivered to cortical layer IV/V by a steel-needle electrode. For ICMS pulse trains of 40 ms duration (13 pulses of 100  $\mu$ s and 400  $\mu$ A to 1 mA at 300/second) were repetitively delivered at a rate of 1.5/second. Duration of ICMS was 100-150 minutes. FP were composed of an antidromic component (neither blocked by APV, NBQX, or low-calcium ACSF) and several synaptic components (S1-Sn). S1 mainly depended on activation of AMPA receptors (blocked by NBQX), while the contribution of NMDA receptors (blocked by APV) was small. Contribution of NMDA receptor activation increased with increasing order number of the synaptic component. ICMS induced a reduction of the amplitude of the synaptic components as well as an increase of the synaptic delay. After cessation of ICMS a transient strong effect was observed during the first minutes reaching a lower but significant level of depression outlasting the observation period of 90 minutes. When ICMS was delivered during continuous superfusion of the brain slice with ACSF containing bicuculline methochloride (1  $\mu$ M) the reduction of S1 amplitude and the increase of S1 latency was strongly enhanced. Effects of ICMS were interpreted in terms of the induction of long-term depression (LTD) of synaptic efficacy. Results suggest an involvement of LTD in ICMS-induced reorganization of representational maps of the somatosensory cortex.

ENVIRONMENTAL ENRICHMENT COUNTERACTS DECLINE OF SENSORIMOTOR PERFORMANCE AND DETERIORATION OF CORTICAL ORGANIZATION IN AGED RATS. L. Churs, F. Spengler, M. Jürgens, H.R. Dinse\*. Inst. Neuroinformatik, Ruhr-Univ. RUB, Bochum, Germany

We have shown that aging results in severe deterioration of a number of parameters reflecting cortical organization such as receptive field (RF) size, RF overlap, temporal integration (TI) properties and response latencies of somatosensory cortex (SI) in old rats. Here we report that an enriched environment has a beneficial effect on the development of age-related cortical deterioration.

Starting at 26 months, FBNF1 rats were housed under enriched environmental conditions (EC) for 6-8 months. Age-matched controls were kept under social but input deprived conditions (SC). Sensorimotor performance was scored based on a pole-running test and on analysis of footprints and video recordings during walking. We recorded single- and multiple unit activity in layer IV of the fore- and hindpaw representations of SI of urethane anesthetized EC and SC animals (31-35 months) and in normal adult, SC housed animals (3-7 months). RF size, response strength and latencies and TI properties were analyzed. Behavioral tests revealed significant improvements of sensorimotor performance and coordination in all enriched animals including prolonged pole-running, increased step length and decreased step width. The maintenance of behavioral fitness was paralleled by profound effects on cortical organization. In comparison to SC controls which showed the typical age-related enlargement of RF size, RFs in the EC-group were significantly smaller by about 50 %, thereby reaching an intermediate state between old SC and normal adult animals. The typical decline of TI properties in old animals due to a decreased ability to follow high frequency stimulation was not observed in old EC animals. Response latencies were lengthened with chronological age in both SC and EC animals.

The results demonstrate that enforced stimulation and exercise based on unspecific and multifactorial cues as provided by an enriched environment has a profound effect on cortical organization in old rats, thereby supporting the concept of "use it or lose it". The age-related lengthening of latencies in both EC and SC animals indicates that this parameters seem not to be involved in plastic reorganizational processes during aging (cf. the effects of a CA<sup>2+</sup> blocker in old animals, this meeting).

ACTIVITY DEPENDENT CHANGES IN THE DISTRIBUTION OF CORTICO-CORTICAL AFFERENTS TO SI IN ADULT MONKEY. M. Coscia\*, A. Nuñez, J.A. Gandia and E. Rausell. Dept. of Morphology, School of Medicine, Autónoma University, 28029 Madrid, Spain.

The modifications that occur in the extent of partial body SI representations under activity dependent conditions can be explained on the basis of sprouting of cortico-cortical axons from other somatosensory areas. We have explored the possibility of this being one of the underlying mechanisms for the extension of the representation of digit 2 (D2) into the representation of digit 1 (D1) after peripheral selective denervation of D1.

The lateral border of D2 representation in area 3b was identified by means of single unit extracellular recording in normal adult anesthetized monkeys (Macaca Fascicularis), and in monkeys that had been subjected to peripheral selective cutaneous denervation of the first digit fifteen days earlier. Small paired injections of Fast Blue (FB) and Diamidino Yellow (DY), or fluorescent Texas Red and Fluorescein labeled dextran (Molecular Probes) were made at each side of this border. Retrogradely single and double labeled cortico-cortical cells were localized in areas 2, 1 and SII, then plotted and counted, using the Neurolucida system and software. 3-D reconstructions of the "clouds" of labeled cortico-cortical cells were made at each cortical area.

In normal monkeys, pairs of fluorescent injections separated about 100  $\mu$ m resulted in less than 10% neurons retrogradely labeled with both dyes in areas 1.2 and SII. In denervated monkeys, pairs of fluorescent dyes separated 150-250  $\mu$ m, resulted in a range of 15-20% neurons retrogradely labeled with both dyes, particularly in areas 1 and 2. We analyzed the degree of overlapping between the two sets by calculating the "segregation" and "probability" indices (cf. Agmon et al., J. Neurosci., 15: 549-561, 1995), in each case. We then calculated the degree of correlation between significant variations in those indices and the experimental denervation, to explore the presence of pre-existing collaterals or the occurrence of sprouting of new cortico-cortical terminals.

Our results suggest that sprouting of cortico-cortical terminals might have occurred in the deafferented cortical region, and could be considered as an additional mechanism underlying the plastic changes observed in the SI cortical representation under activity dependent conditions.

## 48.4

TRAINING IMPROVES SOMATOSENSORY DURATION DISCRIMINATION IN HUMANS S.S. Nagarajan\*, D.T. Blake, B.A. Wright and M.M. Merzenich. Keck Center, UCSF, CA 94143-0732.

The purpose of this study was to determine whether or not and how specifically normal adult humans learn to improve somatosensory duration discrimination with practice. In a two-alternative forced choice paradigm, subjects were presented with one pair of vibratory pulses separated by a base duration (BD) and another pair by a target duration (TD). Subjects indicated which pair was the TD which was always greater than the BD by a variable amount and was adjusted adaptively over 60 trials to determine discrimination thresholds expressed as Weber fractions [(TD<sub>threshold</sub> - BD)/BD]. The flutter-vibration pulses were sinusoidal displacements (100 $\mu$ m, 25ms, 40Hz) delivered with a probe (1.5mm diameter with a rigid surround) either to the thenar eminences (n=4) or the distal segment of the ring finger (n=6). Each subject was trained for 900 trials/day with a BD of 100ms for 10-15 days. Significant improvements (mean change from 0.35 to 0.17) were observed between mean Weber fractions measured before and after training ( $F_{1,9}=37.04$ ,  $p<0.0005$ ). Before and after training, Weber fractions were also measured for different BDs, skin-sites and pulse frequencies. Observed improvements at the trained BD transferred to adjacent digits ( $F_{1,4}=39.5$ ,  $p<0.005$ ) and to the same skin-site in the contralateral hand ( $F_{1,4}=6.28$ ,  $p<0.05$ ). By contrast, when the pulse frequency was changed to 200Hz there was no significant learning at the trained duration ( $F_{1,3}=0.01$ ,  $p>0.9$ ). Interestingly, improvements transferred to BDs of 50 ms ( $F_{1,9}=10.4$ ,  $p<0.01$ ) but not to BDs of 200ms ( $F_{1,9}=3$ ,  $p>0.1$ ) or 500ms ( $F_{1,9}=7$ ,  $p>0.05$ ). Control subjects tested over comparable periods without training showed no significant changes on any condition ( $F_{1,4}=0.231$ ,  $p>0.65$ ), indicating that training accounted for all observed changes. These results indicate that (1) somatosensory duration discrimination improves with training and (2) this learning generalizes widely across skin-sites, even to the untrained hand and that it also generalizes to a shorter (50ms) duration, but not across stimulus frequencies and to durations longer than 100ms. This data suggests channel and duration specificity in learning somatosensory durations. [Supported by the Charles A. Dana Foundation and NIH Grant NS-10414]

## 48.6

EFFECTS OF REPETITIVE SENSORY STIMULATION ON HUMAN CORTICAL RHYTHMS L. Narici\*, K. Portin\*, R. Salmelin\* and R. Hari\*. <sup>1</sup>Brain Research Unit, Low Temperature Laboratory, Helsinki University of Technology, 02150 Espoo - Finland; <sup>2</sup>Department of Physics, University of Rome "Tor Vergata", 00133 Roma - Italy

The effect of short trains of somatosensory, visual, and auditory stimuli on the human cortical rhythms was studied by recording MEG signals from 9 healthy subjects with a 122-channel Neuromag-122™ whole-scalp neuromagnetometer. Electric 0.3-ms pulses to the median nerve at intensity above motor threshold, 30-ms light pulses with red 1 mm-diameter LEDs covering 1 cm<sup>2</sup> at an eccentricity of 7 deg in the left hemifield, and 15-ms monaural noise bursts were delivered in separate sessions in trains of 15 stimuli, interleaved with 1.6-s pauses. The stimulus repetition rates within the trains varied randomly from 6 to 14 Hz. Two different phenomena were observed in cortical signals in the 5 to 25 Hz frequency band: driving of rhythms during the stimulus trains and global suppression of all cortical spontaneous signals after the stimulus trains. Driving was seen as a clear enhancement of cortical activity at the stimulus frequency in the sensory-specific cortex of the stimulated modality. After stimulus trains, spontaneous activity was suppressed below resting level for a few tens of seconds. At least three stimuli in a train were needed to induce the post-stimulus suppression. The suppression did not depend on the stimulated modality, nor did it show lateralization. Our results indicate that repetitive stimuli may alter the functional state of human cerebral cortex for relatively long periods.

## 48.7

**SPATIOTEMPORAL REPRESENTATION OF MULTI-WHISKER STIMULI IN THE THALAMOCORTICAL LOOP.** A. A. Ghazanfar\*, L.M.O. Oliveira, V.S. Votaw, and M.A.L. Nicolelis. Dept. Neurobiology, Box 3209, Duke University Medical Center, Durham, NC 27710.

Although rats use rhythmic movements of most of their whiskers to discriminate surfaces, few studies have applied multiple whisker stimulation to characterize neuronal responses in the VPM and SI cortex. Since distributed representations have been observed at both levels for single whisker stimuli, we hypothesized that neuronal ensembles in these structures should be optimally organized to process object attributes based on patterns of multiwhisker stimulation. To explore this possibility, we have combined ensemble recordings in the VPM and layer V of SI cortex with stimulation of whisker rows and columns at 1-10 Hz. We recorded from 263 SI cortical neurons and 177 VPM neurons in 12 different animals under pentobarbital anesthesia while stimulating sets of three whiskers, either in rows or columns. A large proportion of SI and VPM neurons showed a summated response following multiwhisker stimulation that was greater than the arithmetic sum of the individual whisker responses. Furthermore, some neurons only responded to multiwhisker stimuli. In cortex, the amount of non-linear facilitation covaried with the receptive field of the neuron: summation was greatest for rows in the surround receptive field and neurons with RF centers in caudal whiskers showed greater summation for rostral than caudal whisker columns. In some instances, multiwhisker stimuli recruited more cortical tissue faster, and the responses lasted longer, than those obtained for single whisker stimuli. Some of these cortical properties were altered by neonatal facial nerve section which disrupted whisker movements. Thus, we suggest that, during active exploration, patterns of multiwhisker contact continuously shape representations in the thalamocortical loop and that this process is computationally useful. ## 48.9

**DEPTH PROFILES OF THE RECIPROCAL CORTICOCORTICAL AND THALAMOCORTICAL RESPONSES IN SI AND SII NEOCORTEX OF RATS.** K. Paul, P. Hamilton, and L.J. Cauler\*. GR 41, Cognition and Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083.

This study employed depth profiles (0.1 mm increments) of evoked field potentials, multiple unit activity (MUA) and current source density to examine the cortical responses to somatosensory, thalamocortical or corticocortical inputs recorded in the forepaw areas of the primary (SI) and secondary (SII) somatosensory areas of anesthetized rats. The SI response profile evoked by VPI thalamic stimulation was similar to the profile evoked by forepaw stimulation: peak-negative field potentials, MUA and current sinks beginning in layer IV followed by current sinks and unit activity ascending to supragranular layers. In addition, VPI stimulation evoked a short latency layer VI response. The response profile evoked in SII by stimulation of SI resembled the somatosensory or thalamocortical SI response consistent with the characteristic termination of "forward" cortical projections from SI to layers III/IV of SII. In contrast, the SI response to stimulation of SII involved superficial peak-negative field potentials and current sinks with MUA distributed through deeper layers consistent with the characteristic termination of "backward" cortical projections from SII to layer I/II of SI. Similarly, the response of SI and SII to stimulation of the VM thalamus involved a more superficial activation consistent with the superficial termination of the VM thalamocortical projections. In sum, these electrophysiological profiles in anesthetized rats correspond to the established laminar patterns of thalamocortical and reciprocal corticocortical projections between areas of the somatosensory cortex (Clancy, et al. 1995, *Soc. Neurosci. Abstr.*; Mitchell and Cauler *ibid*). Supported by a grant from the Whitehall Foundation.

## 48.11

**LAMINAR ANALYSIS OF SOMATOSENSORY ACTIVITY IN AREAS SII, 5, and 7b OF THE AWAKE MONKEY: II. CONTRIBUTION TO LONG-LATENCY SURFACE SEPs.** J.C. Arezzo\* and M.C. Lee. Departments of Neuroscience and Neurology, Albert Einstein College of Medicine, Bronx, NY 10461.

The epidural somatosensory evoked potential (SEP) recorded over the dorsolateral convexity in primates is characterized by early components occurring at 12, 20, and 45, and by compound late responses peaking at approximately 110 and 160 ms. Previous studies isolated the generators of the initial components to the anterior and posterior banks of the central sulcus, and the crown of the postcentral gyrus. The present study was designed to investigate the contribution of the non-primary areas SII, 5, and 7b, whose activity is described in the accompanying study, to the later components of the scalp-recorded responses.

Contralateral, ipsilateral, and bilateral SEPs and multiunit activity (MUA) were recorded in three awake male monkeys (*M. fascicularis*), as described in the previous abstract. Laminar profiles in the contralateral non-primary cortical areas sampled are characterized by complex patterns of polarity inversions and associated regional transmembrane current flow (one-dimensional CSD), with prominent activity ranging from 50 to 200 ms post-stimulation. In contrast, stimulus driven increases or decreases in MUA are completed by 100 ms. Ipsilateral and bilateral response profiles are similarly characterized by long-latency, long-duration SEP and CSD activity. In most sites, the magnitude of transmembrane current flow and associated long-latency activity exceeds that of the initial responses. Analysis of both the intracortical and volume conducted signals confirms the presence of several "open-field" generator configurations with potentials traceable from the epidural surface to their deep intracortical dipole sources (e.g. banks of the intraparietal and lateral sulci).

These findings suggest that SII, 5, and 7b contribute to the late components of the epidural SEP, and further, that the surface response also represents activity in select ipsilateral cortical regions. Long-latency SEP responses in humans may thus provide an index of the functional integrity of bilateral non-primary cortical somatosensory areas. Supported by MH06723.

## 48.8

**IMMEDIATE AND SIMULTANEOUS REORGANIZATION IN THE BRAINSTEM, THALAMUS, AND CORTEX INDUCED BY PERIPHERAL DEPRIVATION.** B.M. Faggin\*, K.T. Nguyen and M.A.L. Nicolelis. Dept. Neurobiology, Duke University, Durham, NC 27710.

Previously (Nicolelis et al, 1993), we have demonstrated that small injections of local anesthetics in the rat face induce an immediate reorganization in the ventral posterior medial nucleus of the thalamus (VPM). Since these changes involved both short and long-latency components of neuronal responses, we suggested that both ascending and descending pathways should contribute to this reorganization. Here, we tested this hypothesis by recording the simultaneous activity of up to 100 neurons, located in the principal (PrV) and spinal (SpV) subnuclei of the trigeminal brainstem complex, the VPM, and the infragranular layers of the primary somatosensory cortex (SI). The same set of neurons were recorded before and after lidocaine (1%, 0.01-0.04 ml) was injected around the whisker pad. Stimulation of at least 15 single whiskers were used to quantify changes in receptive fields (RF) induced by the facial anesthesia in 12 Long-Evans rats. Simultaneous reorganization of the whisker representation in the PrV/SpV, VPM, and SI cortex was observed a few minutes after the lidocaine injection. This global reorganization was characterized by changes in both the spatial and temporal domains of RFs. In each structure, we identified a silent area, where most responses were abolished; a transition area, where responses either increased or decreased; and an unmasking area, where new sensory responses emerged. In this latter region, we observed unmasking of both short-latency (SpV = 0-5 ms, VPM = 4-8 ms, SI = 8-15 ms) and long-latency components (SpV = 5-10 ms, VPM = 15-25 ms, and SI cortex = 15-40 ms). These results support the hypothesis that plastic reorganization observed at each level of somatosensory system depends on changes occurring at other levels of the pathway. Supported by NIH/DE-11121-01.

## 48.10

**LAMINAR ANALYSIS OF SOMATOSENSORY ACTIVITY IN AREAS SII, 5, and 7b OF THE AWAKE MONKEY: I. EVIDENCE FOR PARALLEL THALAMO- AND SERIAL CORTICO-CORTICAL INPUT.** M.C. Lee\* and J.C. Arezzo. Departments of Neuroscience and Neurology, Albert Einstein College of Medicine, Bronx, NY 10461.

Recent studies have suggested an evolutionary transition from parallel to serial modes of somatosensory processing in lower to higher mammals. The present study was designed to investigate the issue of hierarchical versus parallel models of cortical organization in primates. Contralateral somatosensory evoked potentials (SEPs) and multiunit activity (MUA) were recorded intracortically from neuronal ensembles with a linear array, multicontact (15 channels, 200  $\mu$  intercontact spacing), low-impedance electrode (300-500 kOhm at 1 kHz) in three male monkeys (*M. fascicularis*). One-dimensional current source density (CSD) profiles were calculated and used to determine the sequence of activity onset: i) across laminae within each cortical "column" sampled, and ii) across equivalent laminae from discrete cortical areas.

Initial activity, determined by earliest onset cortical sinks and MUA, indicates that the granular laminae of these areas are activated about 2 ms within that of SI. This latency difference is not consistent with feedforward input from SI, given that the separation of initial activity in layer IV versus that in layers I/III of SI itself is on the order of 4 ms. Later activity in SII and portions of 5 and 7b, determined by longer latency cortical sinks, are usually associated in time with long-latency, long-duration MUA. This activity is localized in the supragranular laminae and may reflect intrinsic feedforward or feedback cortical processing or continuous afferent input.

The timing and laminar pattern of activity apparent in these data provide evidence to support both early, parallel, thalamic input and later, serial, cortical input to the non-primary somatosensory areas SII, 5, and 7b. In addition, the present results suggest that the previously anatomically defined thalamic afferents to these areas are indeed activated by passive stimulation. Finally, the demonstration of multiple, independent, temporally overlapping generators precipitates the question of what is the contribution of these nonprimary elements of the somatosensory network to the surface response? Supported by MH06723.

## 48.12

**THE PROPERTIES OF THALAMOCORTICAL AND INTRACORTICAL SYNAPTIC TRANSMISSIONS IN THALAMOCORTICAL SLICES OF THE RAT BARREL CORTEX STUDIED BY OPTICAL RECORDING.** H. INOKAWA\*, S. HIGASHI, T. KUROTANI, E. AKASE, & K. TOYAMA. Department of Physiology, Kyoto Prefectural University of Medicine, Kyoto 602, Japan

Our previous optical recording study of rat thalamocortical slices revealed patchy excitation occurring in layer 4, which corresponded to morphologically identified barrels, after electrical stimulation of ventrobasal nucleus (VB) of the thalamus. In the present study, we analyzed laminar differences in the responses evoked by VB stimulation and the receptors contributing to thalamocortical and intracortical synaptic transmissions. VB stimulation produced steeply rising responses (fast responses) in layers 4 and 6 (latency 4.8 ms  $\pm$  0.66) followed by slow responses appearing in layers 2/3 and 5 (latency 7.8 ms  $\pm$  0.76 and 6.7 ms  $\pm$  0.70, respectively) as well as in layers 4 and 6. The differences in the latency between the fast and slow responses suggests that the former represents monosynaptic excitation, while the latter represents the polysynaptic excitation transmitted via layers 4 or 6. Consistent with this supposition, high divalent cations (6 mM  $Ca^{2+}$  and 6 mM  $Mg^{2+}$  in Krebs), which reduce polysynaptically activated responses, selectively reduced the slow responses in all layers. The NMDA receptor antagonist APV (50  $\mu$ M) only slightly reduced the slow responses in all of the layers without affecting the fast responses in layers 4 and 6 when bath applied, while the AMPA receptor antagonist DNQX (40  $\mu$ M) almost completely abolished both the fast and slow responses in all of the layers. In addition, when intracortical inhibition was blocked by the GABA<sub>A</sub> receptor antagonist bicuculline (20  $\mu$ M) preferentially enhanced the slow responses. These results suggest that fast and slow responses are mediated by thalamocortical and intracortical connections, respectively, that the AMPA receptors dominate over the NMDA receptors in the thalamocortical as well as the intracortical transmission, and that the intracortical transmission is under strong control of GABA inhibition.

## 48.13

## LOCAL INHIBITORY RESPONSES IN THALAMOCORTICAL RELAY NEURONS: COMPARISON OF RAT AND GUINEA PIG IN VITRO

C.-Q. Kao\*, D.A. Coulter, Department of Neurology, Medical College of Virginia, Richmond, Va 23298

GABAergic inhibition originating from nucleus reticularis thalami (NRT) synchronizes thalamocortical rhythms. However, the role of thalamic interneurons in generating rhythms is unknown. This is complicated by use of rodents in many of thalamocortical rhythm-generation studies. Rodents differ from primates and carnivores in that many of the thalamic nuclei lack GABAergic interneurons. We have begun to characterize local thalamic stimulation-evoked IPSPs within the ventrobasal complex (VB), comparing properties between rats and guinea pigs. These two species differ in that rats lack interneurons within VB, while guinea pig VB contains 15-20% interneurons, which synapse with relay neurons in the typical synaptic triad arrangement (Spreafico et al. *Neuroscience* 59: 961, 1994).

Whole cell patch recordings of VB neurons in thalamocortical slices were employed to characterize responses evoked in the presence of D,L APV (50  $\mu$ M) and CNQX (10  $\mu$ M). Local stimuli activated IPSPs in VB neurons at a lower threshold in guinea pig than in rat, presumably due to the lower threshold activation of interneuron cell bodies compared to NRT-originating fibers. These low-threshold IPSPs had two components: an early, bicuculline-sensitive component, and a later, 2-hydroxysaclofen-sensitive component, with a reversal potential of approximately -110 mV. Further differential quantitative and pharmacological comparison of GABAergic inputs to VB neurons in these species could provide useful information clarifying the role of local circuit interneurons in generation of thalamocortical rhythms.

Supported by NIH grant NS-31000.

## 48.15

## REGIONALLY SELECTIVE BLOCKADE OF GABAergic INHIBITION BY ZINC IN THE THALAMOCORTICAL SYSTEM: FUNCTIONAL SIGNIFICANCE.

John W. Gibbs, III\*, Yun-Fu Zhang\*, Melissa D. Shumate\*, and Douglas A. Coulter<sup>1,2,3</sup> Depts. of Neurology<sup>1</sup>, Physiology<sup>2</sup>, and Anatomy<sup>3</sup>, Medical College of Virginia, Richmond, Va. 23298.

GABAergic inhibition originating in the thalamic reticular nucleus (NRT) directed onto the thalamus serves to synchronize and drive thalamocortical (TC) rhythms. Timm's stain of coronal sections of rat brain demonstrated zinc-containing terminals in the cortex, thalamus, and particularly in NRT. To explore the role of endogenous zinc in modulation of rhythms generated within the TC system, we have begun to functionally characterize zinc effects on GABA<sub>A</sub>-mediated currents in the thalamus, NRT, and the cortex. Effects of zinc were also investigated on TC rhythms in TC slices.

GABA<sub>A</sub>-evoked chloride currents were recorded using whole-cell voltage clamp techniques in acutely isolated adult (>p60) rat NRT, thalamic, and cortical neurons. Zinc blocked GABA<sub>A</sub>-mediated responses noncompetitively. Zinc concentration/response curves showed zinc effects to be strongest in thalamic, intermediate in NRT, and weakest in cortical neurons. Bath application of zinc 300  $\mu$ M had differential effects on distinct types of TC rhythms. Zinc exacerbated rhythms resembling spike wave discharges, while it blocked rhythms resembling generalized tonic-clonic seizure discharges. The differential effects of zinc on TC rhythms suggests distinct neuromodulatory roles on differing seizure types supported by the TC system. Supported by NIH-NINDS Grant NS 31000.

## 48.14

## THALAMOCORTICAL RHYTHMS IN VITRO: CELLULAR CONTRIBUTIONS OF CORTICAL, THALAMIC, AND THALAMIC RETICULAR NEURONS.

Coulter, D.A.\* and Zhang, Y.-F. Department of Neurology, Medical College of Virginia, Richmond, VA 23298-0599

The thalamocortical (TC) system supports phasic oscillations as one of two main states of function. We have developed a TC slice which supports spontaneous TC oscillations when exposed to a medium containing no added Mg<sup>2+</sup>. In the present study, we examine cellular contributions of thalamic, cortical, and thalamic reticular (NRT) neurons to TC rhythms.

Single patch recording techniques were employed to assess cellular contributions to ongoing rhythms, recorded by an extracellular electrode located in cortex or thalamus. Extracellular stimulation was via an electrode located in NRT. Some neurons (20%) did not exhibit activity correlated with ongoing TC rhythms. These neurons were not considered further. All of the "participating" cortical neurons recorded exhibited strong excitation during TC rhythms (58/58 cells). Both NRT and thalamic neurons evidenced two populations which contributed to TC rhythms in contrasting ways. For NRT neurons, 58/86 recorded neurons were strongly excited during ongoing rhythms, with little evidence for inhibition contributing to activity. In these neurons, lateral stimulation within NRT rarely evoked IPSPs. In a second group of NRT neurons (28/86 cells), large IPSPs were evident during ongoing activity, often triggering rebound bursts. Lateral NRT stimulation usually evoked large IPSPs in these neurons. In thalamus, similar groups were seen, with 42 cells strongly excited, and 40 cells strongly inhibited (with rebound bursting) during ongoing rhythms. These data suggest that there are populations of NRT and thalamic neurons which contribute to TC rhythm generation in distinct ways. Support by NIH grant NS-31000.

## CHARACTERISTICS OF CONDITIONS FOR PROPAGATING NEURONAL ACTIVITY IN NEOCORTEX. D. Golomb\* and Y. Amitai. Zlotowski Center for Neuroscience and Dept. of Physiology, Ben-Gurion University, Beer-Sheva 84105, Israel.

In neocortex, evoked neuronal population discharges propagate over long distances when GABA<sub>A</sub> inhibition is blocked. Using field potential recordings and pharmacological manipulations in slices, together with a computational model, we have examined how the duration, shape and velocity of these discharges depend on the strength of excitatory conductances  $g_{AMPA}$  and  $g_{NMDA}$ . Complete blockade of NMDA receptors by APV (25-50  $\mu$ M) reduced the velocity, but did not abolish propagation. Increasing the concentration of the AMPA blocker CNQX was followed by a parallel decrease in propagation velocity, until it ceased altogether. In the computational model, pyramidal cells were coupled via AMPA and NMDA synapses with a one-dimensional, spatially-decaying connectivity pattern. Brief local stimulus evoked traveling activity if  $g_{AMPA}$  was above a threshold  $g_{AMPA,c}$ . Activity was terminated by a slow outward current and by synaptic depression. Away from the stimulus, the activity profile maintained its shape and propagated at a constant velocity. Each cell fired  $n$  spikes during the discharge. The number  $n$  and the system's parameter set uniquely determined the discharge shape. Larger- $n$  discharges were associated with a stronger initial stimulus. The model predicts: 1. For  $g_{AMPA} \gg g_{AMPA,c}$ , propagation velocity is linearly dependent on  $g_{AMPA}$  and is independent of  $n$ . 2. For  $g_{AMPA} \gtrsim g_{AMPA,c}$ , multiple discharge shapes with different  $n$  occur, depending on the stimulus strength. Propagation is faster for a larger  $n$ .

## MODULATION OF EVOKED SOMATOSENSORY ACTIVITY IN RAT BARREL CORTEX BY REMOTE NOCICEPTIVE STIMULI. R.T. Stevens\*, W.W. Chuang and C.J. Hodge, Dept. Neurosurgery, SUNY Health Sci. Center, Syracuse, N.Y. 13210

Using intrinsic cortical optical imaging (COI), the rat barrel cortex was studied to determine whether the cortical response to low threshold inputs (whisker movement) would be altered when competitive stimuli are introduced at a remote cutaneous site. Optical images were obtained following single whisker movement and compared when the same whisker is activated coincident with stimulation of tail or hindlimb.

Using either thinned skull or partial craniotomy preparations, anesthetized rats were fixed in a stereotactic apparatus and skin was tied back to form a saline well over the barrel cortex. COI was done using a 850nm reflected light. Pairs of data files were collected and compared between whisker stimulation alone (W-alone) and whisker stimulation combined with a competitive stimulus applied to tail or hindlimb, i.e., vibration (W-v), warming (W-w), heat (W-h), or pinch (W-p).

When no competitive stimuli are introduced, the resulting paired W-alone images are similar in size and location. When a non nociceptive competitive stimulus was applied (W-v or W-w) the resulting COIs were not discernibly different from W-alone COIs. Painful heat (>60°C) applied to the tail or hindlimb produced some decrease in the whisker COI when compared to its paired W-alone COI although this effect was variable. A 3 second noxious pinch of tail, hindlimb or forelimb, however, dramatically decreased the whisker barrel COI. These results demonstrate a modulation of cortical response to peripheral inputs by remote noxious stimuli which is reminiscent of the process of Diffuse Noxious Inhibitory Controls previously described at the spinal cord level.

## THE CONNEXION BETWEEN MEDIAL THALAMUS AND ANTERIOR CINGULATE CORTEX: AN ELECTROPHYSIOLOGICAL STUDY. M.-M. Hsu\* and B.-C. Shyu\*. Graduate Inst. of Life Sci., National Defense Medical Center and Inst. of Biomedical Sci., Academia Sinica, Taipei, Taiwan, R. O.C.

We attempted in the present study to characterize the neuronal properties of anterior cingulate cortex (ACC) evoked by electrical stimulation of medial thalamus (MT) and to verify the synaptic connection between these two structures.

Male Sprague Dawley rats (body weight 250 to 350g) were maintained in general anesthesia by  $\alpha$ -Chloralose (50mg/kg, i.v.). Tungsten microelectrodes were used for electric stimulation in the MT (CL & Pf nuclei) and for recording in the ACC. The field potentials, multiple or single units activities in the ACC were evoked by electric stimulation of MT where the nociceptive responses were identified.

An evoked negative potential with 24 ms latency was recorded by MT stimulation on the surface of ACC. An early negative potential (15 ms latency) could be recorded between 0.5 and 1.0 mm from the surface. The polarity of the surface negative potential was reversed between 1.0 and 1.5 mm in the depth of the ACC. The evoked multiple units activities were occurred at about the latency of 15 ms or 24 ms at the depth between 1.0 mm to 2.0 mm of the ACC. A total of 68 units was identified histologically in the ACC. The mean amplitude of the action potentials was  $0.8 \pm 0.1$  mV (Mean  $\pm$  S.E.). All of the responsive neurons were discharged spontaneously and about 32.3% (21/68) of them were firing in a burst pattern. The majority (93.7%, 63/68) of MT-evoked ACC units were activated trans-synaptically at the Cg1, Cg3, IL areas of ACC. The mean latency of response was  $20.1 \pm 1.4$  ms. About 7.3% (5/68) of units were activated antidromically at the Cg1 area and their mean latency was  $9.6 \pm 1.1$  ms.

The electrophysiological findings in the present study have confirmed the neuroanatomical connection between MT and ACC. The nociceptive information in the MT is transmitted to ACC and may be modulated reciprocally by the activities from ACC. (Supported by grant from the National Science Council, ROC)

## 49.3

**RAT SOMATOSENSORY CORTEX: AN ANATOMICAL SUBSTRATE FOR BILATERAL INTEGRATION** Victor Pegado, David Froc, Emily Spironello & Kathryn M. Murphy\*, Departments of Psychology, Neural Organization & Plasticity Laboratory, McMaster University, Hamilton ON Canada L8S 4K1

Primary sensory areas demonstrate physiological, metabolic and cellular compartmentalization that reflects their division into function modules. Within the rat somatosensory cortex inputs from the contralateral vibrissae form the barrel field which is comprised of dense thalamic inputs representing individual vibrissae and a surrounding lattice-work called the septa. The septa regions does not receive direct thalamic input and instead is involved in cortico-cortical connectivity, including callosal connections. Therefore, the septa region is where sensory information from the vibrissae on both sides of the snout is integrated. We have investigated the features of the septa that could provide a substrate for those neurons to integrate bilateral somatic stimulation. Using immunohistochemical techniques the distribution of large pyramidal neurons (SMI-32) and the NMDAR1 subunit of the voltage-gated NMDA receptor was examined in tangential sections through the rat primary sensory cortex. In supragranular layers, both large pyramidal cells and the NMDAR1 receptor subunit were found to be most dense in the septa region. Previous studies have demonstrated that large pyramidal cells have *active dendrites*, these processes respond in a non-linear fashion and can act as coincidence detectors or temporal integrators. In addition, the NMDA receptor is involved in the transmission of correlated activity. Thus, large pyramidal neurons with apical dendrites that extend up through the barrel and septa, and that have active dendrites and NMDA receptors, are ideally suited to integrate bilateral behaviourally relevant sensory information. Based on our findings, we propose that these features of the septa in rat barrel field provides the substrate for bilateral integration of somatic information that could be involved in certain orienting behaviours.

**DYNAMIC POPULATION CODING IN RAT SOMATOSENSORY CORTEX.** T. Kall, A.C. Akhavan\*, D. Jancke, and H.R. Dinse, Institut für Neuroinformatik, Theoret. Biol. Ruhr-Univ. Bochum RUB, Bochum, Germany

We present an analysis of the neural population behavior recorded in rat primary somatosensory cortex following tactile stimulation based on the population coding approach. The activity of single neurons was recorded extracellularly in urethane anesthetized rats. Single or paired stimuli were applied to a number of fixed locations along the distal-proximal extension of the hindpaw. Two-point stimulation at two loci was applied either simultaneously or with time-delays between 35 to 70 ms. The population representations of activity were constructed in the parametric (stimulus) space of the hindpaw skin area with each neuron contributing at the location of its RF.

When single tactile stimuli were used, their location could be reconstructed by the population with high precision. When composite stimuli were presented, we found distance-dependent global nonlinear behavior of the entire neural population with respect to the amplitude and to the location of the population representation. The amplitudes of the representations were reduced compared to the linear superposition indicating distant-dependent inhibitory interactions. The shift of the population representation compared to the calculated linear superposition can be interpreted as an attraction of one stimulus towards the other. Generally, this effect was specific and asymmetric, resulting in an attraction of activity towards the tip of the digits. Both effects may be considered as correlates of psychophysical phenomena.

In order to resolve the dynamic aspects of the population responses, population representations were calculated for separate time-slices of 3 ms duration. The resulting sequences of representations provided a coherent and continuous image of the emergence and fading of neuronal activity over time. Interaction effects as outlined before resulted in latency shifts and changes of inhibitory and excitatory components.

The results indicate that the population coding approach allows accurate reconstruction of tactile stimuli and the time-resolved analysis of global, nonlinear interactions due to two-point stimulation of entire neural populations.

## 49.7

**DIFFERENTIAL CHANGES OF AFFERENT SENSORY TRANSMISSION TO THE SI CORTEX DURING TRANSIENT LOWERING OF BODY TEMPERATURE BETWEEN RAT AND HAMSTER** C.K. Won<sup>1</sup>, B.K. Kim<sup>1</sup>, N.-P. Jung<sup>2</sup>, Y.K. Oh<sup>3</sup>, I.H. Choi<sup>3</sup>, H.W. Park<sup>2</sup>, H.K. Jeon<sup>2</sup> & H.C. Shin\*<sup>2</sup>, Dept. of Physiology<sup>1</sup>, Coll. Med., Hallym Univ., Dept. of Biology<sup>2</sup>, Yonsei Univ., Wonju, Dept. of Biology<sup>3</sup>, Yonsei Univ. Seoul, Korea

We have compared the effects of acute lowering of BT on the afferent sensory transmission to the primary somatosensory (SI) cortex between hamster and rat. Quantitative determination of the effect of hypothermia on the afferent sensory transmission was carried out by generating poststimulus time histograms of single unit responses to the subcutaneous electrical stimulation of the receptive field located in the whisker area of the face. Rats showed no change of afferent sensory transmission until BT 27°C, but dramatic suppression of sensory transmission from 26°C to 22°C, reaching 100% inhibition at BT 21°C, while hamster exhibited gradual suppression of sensory transmission from 34°C till 18°C, reaching 95% of inhibition. Differential effects were also observed while elevating BT up to 37°C. Rats began to show steep disinhibition from BT 26°C, while hamster exhibited immediate, but gradual recovery from BT 19°C. Response latencies of evoked unit responses were also differentially affected during hypothermic condition. Significant delay of the latencies was observed from 29°C in rat, but from 22°C in hamster. These results suggest the presence of inherently different neural mechanisms to process somatosensory information during transient lowering of body temperature between hibernator and non-hibernator. ## 49.4

**CONNECTIONS FROM CINGULATE, POSTERIOR PARIETAL AND MOTOR CORTEX TO ANTERIOR PARIETAL CORTEX (APC) IN MACAQUES** K.A. Findlay, M.M. Glasier, E.R. Ergenzinger, V.J. O'Boyle Jr. and T.P. Pons\*, Department of Neurosurgery, Bowman Gray School of Medicine, Winston-Salem, NC 27157-1029.

Topographic representations of the body surface are located in APC of macaques. APC receives inputs from multiple cortical and subcortical regions. In this study, we examined the pattern of projections from cortical areas other than the secondary somatosensory cortex and insula. Microelectrodes were used to delineate the representation of various body parts in APC. The retrograde tracers fast blue (FB), diamidino yellow (DY), and fluororuby (FR) were then injected into electrophysiologically defined representations of the hand, face and occiput/shoulder/neck regions in APC. Analysis of areas 5 and 7b of posterior parietal cortex revealed neurons projecting to the occiput/shoulder/neck representation. Neurons labeled from each of the separate injection sites were found in the same general region of primary motor cortex though none was double or triple labeled. This pattern of label is interpreted as indicating a lack of topographic projections from this region to APC. In cingulate cortex, neurons projecting to the occiput/shoulder/neck representation were found in both banks of the cingulate sulcus in layers V and VI. Neurons projecting to the face and hand representations in APC were found in layers V and VI immediately lateral to the cingulate sulcus. These findings suggest a topographical pattern of connections from the cingulate region to APC.

T. P. Pons was an Alfred P. Sloan Fellow (Supported by NIMH grant RO1 MH53369-02)

## 49.6

**SPATIAL ANALYSIS CAN INFORM ON THE SOCIOLOGY OF CELL POPULATIONS: A STUDY OF EXTRA-RELAY AFFERENTS TO PRIMARY SENSORY AREAS.** A. Granato\* and D. Minciaccchi, Inst. of Anat., Catholic Univ., Rome, ‡Dept. of Neurol. and Psychiat. Sci., Univ. of Florence, Italy.

The informational flow through the cortical mantle starts from the primary sensory cortices, whose computational frame is fed substantially via thalamo-cortical projections. The projection from the thalamic relay nucleus supplies the competent information and the extra-relay projections provide accessory information; the meaning of this latter input is largely unknown. We approached this issue by studying the distribution and the "social" interactions of extra-relay cell populations projecting upon single cortical representations. We analyzed, in the cat, the projections from the thalamic anterior intralaminar nuclei (AIN) and from the claustrum (Cl) to different representations of the primary somatosensory (S1) and visual (V1) cortices. After electrophysiological identification, fluorescent tracers were injected into discrete regions of S1 and V1. We already analyzed the fine topography of Cl and AIN projections (Minciaccchi et al., J. Comp. Neurol., 362: 46-70, 1995).

Here we use spatial analysis tools to gain further insights on the geometrical attributes of cell populations. Three-dimensional reconstructions and rotations revealed that cortical projections of AIN display a high level of complexity: our findings indicate that it is plausible to recognize at least two separate sets of input, originating from the medial AIN sector and from the central lateral nucleus. The use of spatial tessellation (Voronoi diagrams) further strengthens our result: in the lateral sector of AIN neurons projecting to a given representation (e.g. to V1 retinal periphery representation) are strongly aggregated into clusters, whereas in the medial sector this tendency is present for neurons projecting to the vertical meridian representation.

The use of spatial analysis has proven fruitful both for suggesting peculiar modes of thalamo-cortical communication, and for refining the taxonomic subdivision of thalamic entities.

## 49.8

**LEARNING INDUCED FORMATION OF CORTICAL POPULATIONS INVOLVED IN TACTILE OBJECT RECOGNITION.** E. Spengler\*, T. Hilger, X. Wang\* and M. M. Merzenich\*, Inst. für Neuroinformatik, Ruhr-Universität Bochum, 44780 Bochum, Germany; #Keck Center for Integrative Neuroscience, UCSF, San Francisco 94143, USA

We designed a behavioral training task for somatic discrimination to study reorganizational mechanisms involved in tactile object recognition in adult owl monkeys. The task was designed as a stimulation train of alternating and successive vibrations (75 Hz, 80 ms duration, 300 ms interstimulus interval) applied to the glabrous surface of the hand by two objects, spatially specified as bars. Object A touched the tips of finger 2-3-4 and object B touched all three segments of third finger. Monkeys were trained to hold the hand on the stimulation bars during the alternating background stimulation (A-B-A-B) and to retract the hand when two vibrations occurred successively at bar A or B within a distinct time window.

After the behavioral training, a detailed electrophysiological mapping procedure and quantitative data collection in the middle layers of the hand representation in the primary somatosensory cortex, Area 3b in the trained and control hemisphere was done in the anesthetized monkeys. In two monkeys the cortical hand representation contralateral to the trained hand revealed in striking contradiction to the ipsilateral control hemisphere two representational domains of reorganized receptive fields of simultaneously stimulated skin fields segregated by non-cutaneous or deep input representations. This results support the hypothesis of neuronal plasticity based on coincident input-dependent synaptic changes, which may be mediated mainly by hebbian mechanisms, and on an additional, possibly non-hebbian mechanism, which results in the spatial separation of sequentially perceived inputs. Both active input-driven network processes may provide the neuronal bases of the learned object recognition and discrimination.

## 49.9

**IMPORTANCE OF STIMULUS LOCATION ON THE TIME COURSE AND MAGNITUDE OF MOVEMENT-RELATED SUPPRESSION OF TACTILE DETECTION IN HUMANS.** Williams S.R., Shenasa J. and Chapman C.E\*. CRSN, Université de Montréal, Montréal, Québec, Canada, H3C 3J7

As part of an ongoing study of the effects of active movement on the perception of tactile stimuli, the spatial extent of the perceptual suppression caused by a simple active movement (abduction of the right index finger) was evaluated using data collected from 42 human subjects. Electrical stimuli were delivered to one of 10 stimulation sites (right index finger, dorsum of right hand, right digit 5, right dorsal forearm, right dorsal arm, right shoulder, right pectoral area, left shoulder, left index finger, right thigh) in separate blocks of trials. At each site, the intensity of stimulation was initially set at a level where 90% of the stimuli were detected at rest. The time course and amplitude of any movement-related suppression of tactile perception was examined at each stimulation site in relation to two peripheral events: the onset of movement and the onset of movement-related electromyographic (EMG) activity.

At all but the three most distant sites, a significant and sustained decrease in perceptual performance was observed during movement. The time course and the magnitude of the observed perceptual suppression were both found to depend on the site of stimulation. As distance between the stimulation site and the site of movement increased, the initial decrease in perceptual performance occurred later, occurring 70 ms prior to EMG onset when stimuli were applied to the moving digit and 50 ms after EMG onset when stimuli were applied to the chest. The maximal decrease in perceptual performance was smaller at more distant sites. These results indicate that a relatively constrained active movement can decrease tactile detection over a wide area of the skin, and that the timing and amplitude of these effects depend on the distance between the site of stimulation and the body part in motion. Supported by the MRC, FRSQ, GRSNC and Unimédia.

## 49.10

**DIFFERENTIAL TEXTURE SENSITIVITY IN SI AND MI CORTICAL AREAS OF MONKEYS DURING PASSIVE TACTILE DISCRIMINATION.** W. Jiang\* and C. E. Chapman. CRSN, Université de Montréal, Canada.

The present study compared the texture sensitivity of neurones in two cortical structures, the primary somatosensory (SI) and primary motor (MI) cortices, in two monkeys performing a passive tactile discrimination task. The animals were trained to discriminate a standard surface (raised dots, 2 mm spatial period (SP) over the entire length) from 3 other surfaces in which the SP was proportionally increased to 3, 4 or 5 mm over the second half of its length (surfaces physically continuous). Following the presentation of each surface to the 3rd and 4th digit tips (D3 and D4), the monkeys indicated the presence or absence of a change in texture by, respectively, pulling or pushing a lever with the opposite hand to obtain a juice reward (Task). The monkeys were also trained to maintain the same hand position without paying attention to the presentation of the surfaces (monkey not working, distracted with random drops of juice) (No-Task). Single unit recordings were made from both MI and SI of one monkey and MI of the other. 72 units with a cutaneous receptive field on D3 and/or D4 were tested in both conditions (34 MI; 38 SI). Graded texture-related responses were obtained for 28/38 (74%) SI neurones. Only 11/28 (39%) MI neurones showed graded responses to texture. All of the texture-related SI neurones encoded the roughness changes in both conditions, Task and No-Task. In contrast, only 2/11 MI neurones showed similar texture-related activity in both conditions. The remaining 9 MI neurones displayed texture-related discharge only in the No-Task condition. The results suggest that SI is more sensitive than MI to peripheral texture information. Moreover, the presence of texture-related discharge in MI, but not SI, neurones was dependent upon the experimental conditions, indicating the existence of powerful state-related controls over sensory transmission to motor cortex. Supported by the MRC and Université de Montréal.

## SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS IV

**THE DEVELOPMENT OF SYNAPSES IN MOUSE BARRELS, EMPHASIS ON BARREL D4.** E.L. White\*, D. Lev and E. Weinfeld Center for Brain Research, Faculty of Health Sci., Ben-Gurion Univ., Beer Sheva, ISRAEL.

This abstract reports on a continuing, comprehensive study of the development of synaptic patterns in mouse PMBSF barrels. One aspect of the study focuses on the distribution of synaptic profiles in the neuropil as assessed in EM montages taken of thin sections cut in the tangential plane through the entire extent of barrel D4 at the mid-layer IV level. To date, two samples of roughly 10,000µm<sup>2</sup> each have been analyzed at ages P6, P9, P11, P13 and at 65 days (P1=the first 24 hours after birth). Results show a steady increase with age in the number of axodendritic and axospinous, synapse profiles. In parallel, the development of synaptic input to cell bodies is being followed. Most somata received symmetrical synapses only and are presumed to be spiny stellate cells. At P6, nearly all these somata receive no synapses; from P7 on there is a steady growth in the numbers of synapses received by these somata with the mode of one synapse per cell body well established by P12 and the trend towards larger numbers of synapses per cell body becoming more pronounced subsequently. Distributions of axo-somatic synapses similar to the adult are observed by P15. Supported by Israel Acad. of Sciences 618/93 to E.L.W.

## 50.2

**SYNAPTIC ZINC IN THE DEVELOPING BARREL CORTEX OF THE MOUSE.** J. Skangiel-Kramska\* and A. Czupryn. Department of Neurophysiology, The Nencki Institute, 02-093 Warsaw, Poland.

It has been suggested that synaptic zinc may be involved in the processes that underlie developmental and functional plasticity. One of useful model systems to study cortical plasticity is the whisker-to-barrel system of the mouse. We sought to establish whether the distribution of synaptic zinc developmental pattern is correlated with the critical periods of morphogenetic and functional plasticity. In order to examine the distribution of zinc-containing terminals in the barrel cortex of the mouse during postnatal development, the selenite method of Dansher was used. Zinc staining during the first postnatal days was very low. Laminar variations in zinc staining in SI cortex emerged from PND 6. At PND 8 these variations were clearly visible. The intense zinc staining was found in layers I, II, III and V. Layers IV and VI demonstrated weaker staining. These pattern persisted in adulthood. Section through layer IV from PND 6 revealed association between the cytoarchitectonically visible modular organization of barrels and the distribution of zinc-containing terminals due to higher zinc concentration in septa between barrels and surrounding cortex. Barrel sides showed the relative scarcity of zinc in comparison to the barrel hollows. The difference in zinc staining between barrel side and barrel hollow diminished with age but was still present in adult mouse (up to PND 70). Serial tangential sections through layer IV, obtained from animals at different ages, demonstrated that zinc staining within barrel hollow firstly appeared in the deep part of layer IV (PND 6). As the brain matured, the upper part of layer IV showed the presence of zinc-containing terminals.

Supported by the State Committee for Scientific Research grant 6P20301406.

## 50.3

**CHANGES IN THE DISTRIBUTION AND DENSITY OF NADPH-D POSITIVE CORTICAL NEURONS DURING THALAMOCORTICAL CONNECTIVITY.** R. Erzurumlu\* and E. Ulupinar. Department of Anatomy, Louisiana State University Medical Center, New Orleans, LA 70112.

Nitric oxide is a messenger molecule involved in activity-dependent refinement of synaptic connections during development and in some forms of learning. Nitric oxide synthase (NOS) is an essential enzyme in the synthesis of nitric oxide. We used NADPH-diaphorase histochemical staining to visualize NOS-positive cells in the mouse somatosensory cortex during the establishment of thalamocortical (TC) connectivity (as revealed by Dil labeling). We then quantified the distribution and density of stained cells in relation to developing TC projections using Magiscan Image Analyzer. Between the ages postnatal day 0 (PND0) to two weeks of age (PND14), the distribution and density of NOS-positive cells changed dramatically. On PND0, NOS-positive cells were found in the ventrolateral parts of the somatosensory cortex and in deep layers. The distribution of NOS-positive cells corresponded to the location of TC axons at this age. Gradually NOS-positive cells appeared in dorsomedial cortex and in more superficial layers. As TC axons developed arbors in layers VI and IV (between PND0 and 3), the number of NOS-positive cells almost doubled. Following the establishment of whisker-specific patterning of TC axon arbors and formation of barrels in layer IV, diffuse neuropil staining demarcated the barrel hollows. The density of NOS-positive cells also decreased and reached a plateau between PND7-14. These results suggest a role for nitric oxide in activity-dependent stabilization of patterned connectivity within the somatosensory thalamus and neocortex. Supported by NIH (NS32195)

## 50.4

**THE DEVELOPMENT OF GLUTAMIC ACID DECARBOXYLASES (GAD) IN RAT SOMATOSENSORY CORTEX WITH RESPECT TO BARREL FIELDS.** P.J. Kiser, N.G.F. Cooper and G.D. Mower\*. Department of Anatomical Sciences and Neurobiology, University of Louisville School of Medicine, Louisville, KY 40292.

The purpose of this study was to detect correlations between the development of barrel fields in rat somatosensory cortex (SI) and the development of the GABA synthetic enzymes GAD65 and GAD67. Developing barrel fields were identified in coronal sections (40µm) from 1, 3, 4, 5, 6, 9, 13, 19 and 31-day-old rats using cytochrome oxidase (CO) and acetylcholinesterase (AChE) staining methods. Adjacent sections were then immunoreacted with antibodies to GAD65 or GAD67. From day three onward, CO staining shows a darkly stained band in the lower cortical plate that corresponds to the barrels that are evident by days five to six in layer IV. At day one, a dark band of GAD67 stained cells and processes in the superficial subplate is the dominant characteristic. More cells and processes are present below this darker band than are present superficially. A second band is apparent on day six that overlaps the barrels in layer IV. The original band persists in layer V at this age approximately 100µm below layer IV. By day nine, the barrel septa are evident by their diminished immuno-staining clearly demarcating the barrels present in layer IV. The staining intensity of the lower band has diminished and cell staining is clear in all cortical layers. By day 13 the lower band is no longer detected and this pattern is maintained into adulthood.

These results show the presence of GAD67 in a defined layer of the subplate before the formation of barrels as evidenced by Nissl or CO staining (day's 1-3). These GAD67 elements (which are not evident after day 9-13) could represent an embryonic remnant GABA system which interacts with segregating thalamocortical afferents in the formation of mature barrels.

## 50.5

COMPLEXITIES IN THE THALAMOCORTICAL AND CORTICOTHALAMIC PATHWAYS. N.C. Adams<sup>†</sup>, D.A. Lozsádi<sup>†</sup> and R.W. Guillery<sup>†</sup>. <sup>†</sup>Department of Developmental Neurobiology, UMDS, Guy's Hospital, London, SE1 9RT, England; <sup>†</sup>Department of Human Anatomy, Oxford University, South Parks Road, Oxford, OX1 3QX, England.

The complex reorganization of fibres passing between the telencephalon and diencephalon early in development was previously demonstrated in the rat (Adams and Guillery (94) *Soc. Neurosci. Abs.*, 20, p1685). In the adult this latticework lies in the thalamic reticular nucleus, derived from the ventral thalamus, and lateral to that in the perireticular nucleus. We now report, in the developing chick and adult turtle, a comparable latticework in the fibres in the ventral thalamus.

We suggest that the fibre reorganization produced in this lattice is a fundamental requirement for linking topographically organized maps in the thalamus to the several corresponding cortical maps. Since one thalamic nucleus can connect to several cortical maps, and cortical maps are often mirror reversals of each other, complex crossings in the two way thalamocortical and corticothalamic connections are necessary. Two transient groups of cells, the perireticular nucleus (located in the internal capsule lateral to the reticular nucleus) and the cells of the cortical subplate, are prominent along the course of axons linking cortex and thalamus early in development. The functions of these two cell groups are not known. However, since complex patterns of reorganization, defasciculation and crossings occur in the regions of these cells, it is likely that they play a role in creating the latticework of the adult.

We suggest that the ubiquitous presence of such a zone of fibre reorganization is integral to the functioning of the thalamocortical pathways, and that the complexity of these pathways, with multiple cortical representations may have been central to the evolutionary success of the thalamotelencephalic system.

Supported by the Wellcome Trust and MRC.

## 50.7

THE TOPOGRAPHIC ORGANIZATION OF SOMATOSENSORY AREA 3A IN THE MARMOSET MONKEY (*CALLITHRIX JACCHUS*). K. J. Huffman\*, L. Krubitzer, J. Clarey and R. Tweedale. Center for Neuroscience and Department of Psychology, University of California, Davis, USA, and Vision, Touch and Hearing Research Centre, University of Queensland, Australia.

In four marmosets, the topographic organization of somatosensory area 3a, the area of cortex immediately rostral to the primary somatosensory area, S1 or 3b, was examined using electrophysiological recording techniques. Neural activity was recorded at a number of closely spaced recording sites; receptive fields for neurons at these sites were determined; and stimulus preferences for neurons were identified. In all cases, neurons in area 3a consistently responded to deep stimulation of the contralateral body surface. Most neurons responded exclusively to taps to a particular body part, but in some cases neurons also responded to cutaneous stimulation. Although receptive fields for neurons in area 3a were somewhat larger than for those in area 3b, the details of the digit and face representation could still be obtained. By examining sequences of receptive field progression and order in area 3a, maps of the body surface were constructed, and the internal organization of the field ascertained. Like area 3b, the mediolateral organization of area 3a progressed from the toes and foot, to the hindlimb, trunk and forelimb, and more laterally to the hand, digits and face representations. The representations of the hand and digits assumed the largest portion of area 3a. Area 3a was observed to form a mirror reversal of area 3b such that the ventral surface was represented caudally and the dorsal surface rostrally. When electrophysiological results were related to myeloarchitecture in cortex that was flattened and cut parallel to the cortical surface, it was found that the map in area 3a was coextensive with a 1 - 2 mm strip of lightly myelinated cortex just rostral to the darkly myelinated area 3b. These results represent the first complete description of area 3a in any primate, and indicate that somatosensory cortex is composed of a number of separate representations of the sensory epithelium.

## 50.9

BEHAVIORAL, CORTICAL, AND MECHANOSENSORY SPECIALIZATIONS IN THE STAR-NOSED MOLE (*CONDYLURA CRISTATA*) K.C. Catania\* and J. H. Kaas. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240

The nose of the star-nosed mole consists of 22 fleshy appendages (11 per side) covered with thousands of epidermal sensory organs called Eimer's organs. Each appendage is innervated by a single nerve branch and is represented in cortex by a stripe of tissue that can be visualized by flattening cortex, sectioning parallel to the pia, and processing the sections for cytochrome oxidase. In 4 moles, the number of Eimer's organs, the number of myelinated afferents, and the area of the cortical representation in primary somatosensory cortex was quantified for the 11 appendages from one half of the nose. These anatomical measurements were related to behavioral measurements (analysis of slow motion video), which revealed preferential use of specific nasal appendages.

Although the structure and form of the Eimer's organs is uniform across the different appendages, the preferentially used appendages have higher innervation densities. In addition, these appendages have greater cortical magnification per Eimer's organ, and larger cortical areas per afferent, compared to larger but less used appendages. Observations of newborn star-nosed moles suggest these appendages also develop earliest. The results indicate some of the ways in which peripheral receptors and central nervous structures may be specialized to enhance input and processing for behaviorally important areas in a sensory array.

## 50.6

WIDESPREAD PROJECTIONS FROM LAYER VII (VIB, MATURE SUBPLATE) NEURONS TO LAYER I IN ADULT RAT CORTEX REVEALED SELECTIVELY WITH FLUORESCENT TRACERS. B. Clancy\* and L.J. Cauller GR 41, Cognition and Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083.

Projections to cortical layer I originating from a tangential band of neurons (layer VII) at the interface of the cortex and the white matter were demonstrated with surface applications of retrograde fluorescent tracers, confirming the persistence of this circuit in the adult (100-550 g) rat cortex. Ten-minute surface applications of diamidino yellow (DY) or Fast Blue (FB) placed on primary sensory cortices (<1 mm<sup>2</sup>; application confined to layer I, i.e., no layer IV cells labeled) identified both local and widespread (>4 mm) ipsilateral projection neurons subjacent to cortical layer VIIb which send axons to the superficial layer. Applications of fluorescent retrograde tracer on the surface of primary somatosensory cortex (S1) labeled layer VII neurons directly below the application site, rostromedially above the forceps minor, and caudolaterally in a continuous band to secondary somatosensory cortex (S2). Application to layer I of M1 labeled layer VII neurons from the application site discontinuously as far as S2. Applications on layer I of the auditory cortex labeled layer VII neurons in auditory areas and in V1, while applications on V1 labeled layer VII neurons in auditory cortices as well as in V1 and V2. The entire sub-set of cortical layer VII neurons failed to label with local or interareal applications or injections of non-fluorescent conventional tracers (e.g., HRP, biocytin). The layer VII neurons, with dendrites in the white matter and in the corticocortical fiber system (deep cortical layers) demonstrate progenitive, morphological and immunopositive correspondence to interstitial neurons as well as to neurons of the claustrum. The persistence of the developmental projection pattern from NADPHd+ layer VII (adult subplate) neurons to cortical layer I in rat cortex provides anatomical evidence for their participation in mature cortical function.

Supported by a grant from the Whitehall Foundation.

THE SOMATOTOPIC ORGANIZATION OF THE PARIETAL MEDIAL AREA IN THE CALIFORNIA GROUND SQUIRREL (*SPERMOPHILUS BEECHYII*). D. Slutsky, P. Manger, K. J. Huffman, and L. Krubitzer\*. Center for Neuroscience & Department of Psychology, University of California, Davis, USA.

In the somatosensory cortex of rodents such as mice and rats, a primary somatosensory area, S1, and a second somatosensory area, SII, have been consistently identified. Studies of rodents from other major lineages including Sciuridae, have demonstrated that cortex in these rodents is more complexly organized, and contains multiple representations of the sensory epithelium. For instance, in the eastern gray squirrel, three complete representations, S1, SII, and the parietal ventral area, PV, have been identified. Connectional data indicate the presence of two additional fields, the parietal medial area, PM, and the parietal rhinal area, PR. The present investigation in which electrophysiological recording techniques were combined with analysis of cortical architecture demonstrates that PM contains a complete representation of the contralateral body surface. Multiple recording sites were made in the cortex of three squirrels; receptive fields were obtained and stimulus preferences ascertained for neurons at these sites. Recording results were related to architectonic distinctions in cortex that was flattened, cut parallel to the cortical surface, and stained for myelin. The mediolateral organization of the body surface was similar to that described for S1. The hindlimb was represented most medially, followed by the trunk, forelimb, hand, vibrissae, and the face representations most laterally. The hand and vibrissae representations occupied a relatively large portion of the entire field. Neurons in PM responded to stimulation of deep receptors and often habituated to the stimulus. When electrophysiological recording results were related to cortical myeloarchitecture, it was found that a 1 mm strip of lightly myelinated cortex was coextensive with PM. These results in rodents indicate that cortex caudal to S1 contains neurons which are responsive to somatosensory stimulation. This cortex corresponds to areas 1 and 2 in primates and SIII in cats. Thus, it is possible that a caudal field is part of a basic somatosensory processing network present in all or most mammals.

## 50.10

CORTICAL AND THALAMIC CONNECTIONS OF THE SECOND SOMATOSENSORY AREA, S2, IN THE PROSIMIAN PRIMATE, *GALAGO GARNETTI*. Wan-hsun Carolyn Wu\*, Pamela D. Beck and Jon H. Kaas. Department of Psychology, Vanderbilt University, Nashville, TN 37240

The present study was part of an effort to compare the organization of the somatosensory system in different primates. Injections of fluorochromes (DY, FB and FR) or WGA-HRP were placed into portions of S2 identified by microelectrode recordings. After 7 days survival, the perfused cortex was flattened and cut parallel to the surface. The thalamus was cut coronally. Alternative sections were mounted for fluorescence or reacted for TMB, CO, myelin or Nissl substance. The dense ipsilateral cortical connections were with S1 (3b), presumptive 3a, PV and cortex caudal to S1. The major callosal connections were with S2. Thalamic connections differed from those of S1 in that S2 injections revealed more label in the ventroposterior inferior nucleus and less in the ventroposterior nucleus. Labeled neurons were also in the presumptive posterior nucleus. These results are consistent with the distribution of label in simian primates. Taken together, they indicate that many of the major connections of S2 in simian and prosimian primates are similar. Supported by NIH grant NS 16446.

INDIVIDUAL DIFFERENCES IN THE SIZE OF THE HAND AND SOMATOSENSORY CORTICAL REPRESENTATION OF THE HAND. J.T. Wall\*, R.C. Kolarik, A.C. Silva, X-F Wu, and S.K. Rasey. Department of Neurobiology & Anatomy, Medical College of Ohio, Toledo, OH 43699.

Hands vary significantly in size. Longstanding views suggest that the size of the cortical representation of the hand is dictated by peripheral factors relating to size or innervation of the hand. Thus, individuals with large hands and large numbers of afferents might be expected to have large cortical representations of the hand. This study analyzed interindividual differences in skin areas of hands, and areas, lengths, and widths of the related area 3b somatosensory cortical representations of these hands, in 15 normal adult squirrel monkeys. Hand skin areas ranged from 1837 - 2449 mm<sup>2</sup>, a 33% difference between largest and smallest hands. Cortical hand representations ranged in area from 10.5-14.6 mm<sup>2</sup>, a 39% difference between largest and smallest representations. The hand representation was a much compressed representation which, in different individuals, ranged from 126-210 times smaller than its hand skin area. There was no significant correlation between hand skin area and cortical representation area ( $r = -0.22$ ;  $p = 0.42$ ). The length of the hand representation, defined by functional borders with the face and forelimb representations, and the width of the hand representation, defined by cytoarchitectonic borders of area 3b, varied independently. The area of the hand representation was significantly correlated with the length ( $r = 0.65$ ;  $p = 0.009$ ), but not width of the representation. These results suggest that individual differences in the size of the hand representation are more strongly correlated with variability in the functional, as opposed to cytoarchitectonic, borders of this representation. The results further indicate that cortical representation size is not directly related to hand size. This perspective differs from views that suggest cortical representation size is dictated by peripheral factors relating to size of the hand. Supported by NIH Grant 21105.

## 50.13

CORTICAL REPRESENTATION OF VISCERAL AND SOMATIC SENSATION IN HUMANS. A. Schnitzler\*, J. Volkmann, P. Enck, T. Frieeling, H.-J. Freund and O.W. Witte. Dept. of Neurology and Dept. of Gastroenterology, Heinrich-Heine-University, D-40225 Düsseldorf, Germany.

It is well established that somatic afferents project to the contralateral primary (SI) and bilateral secondary somatosensory cortex (SII). However, very little is known about cortical representation and localisation of consciously perceived visceral sensory stimuli. The aim of the present study was to delineate the spatiotemporal characteristics of cortical responses elicited by electrical stimulation of the human esophagus as compared to stimulation of somatic afferents. Cortical magnetic activity to electrical stimulation of the distal and proximal esophagus, the lips, and median nerves on both sides were recorded from six healthy, right-handed adults using a whole-head neuromagnetometer. The distributions of the responses were adequately explained by time-varying multi-dipole models, and the localisation of the current sources was determined by superposition on individual MRI scans. In contrast to responses evoked by stimulation of somatosensory afferents (median nerves, lips), no discernible signals could be detected in SI after esophageal stimulation. Well reproducible responses peaking at 90 to 130 ms after stimulation of esophageal afferents were obtained bilaterally in SII in close vicinity to SII sources evoked by median nerve and lip stimuli. Strengths of the esophageal SII sources increased with increasing interstimulus intervals (0.5s, 1s, 2s, 4s). Source activity was positively correlated with the psychophysical perception of distinct stimuli as determined on a subjective rating scale. At an ISI of 0.5s perceptible temporal discrimination of successive stimuli was poor and SII response amplitudes were small. Similarly, stimuli were perceived dull and spatially diffuse when shorter ISIs were used.

Our results suggest that visceral afferents from the esophagus project to SII probably bypassing SI. This may represent a neurophysiological basis for the relatively low temporal and spatial resolution of conscious visceral sensation.

## 50.12

LIMITS ON INTRACORTICAL CONNECTIVITY WITHIN THE SENSORY-MOTOR CORTEX OF MACAQUE MONKEYS. A. Munoz, T.M. Woods\*, P.R. Manger and E. G. Jones. Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Representational maps of the hand and foot have been electrophysiologically identified in the different cytoarchitectural areas of the macaque sensory-motor cortex, and correlated with its differential connectivity patterns. Connections within and between parts of the representation may form a basis for map plasticity but have not been thoroughly explored. In macaque monkeys (*Macaca mulatta* and *M. fasciata*) microelectrode multiunit mapping of neuronal responses to tactile stimulation identified the representations of individual fingers and toes in areas 3b and 1. Small extracellular iontophoretic injections of biocytin were made at single identified sites. Parasagittal or tangential sections were processed for biocytin histochemistry, electrode tracks were identified and Nissl staining matched cytoarchitectonic boundaries. Injections at D1 and D2 hand digit representations in area 3b showed a patched pattern of anteroposterior reciprocal connections with areas 3a and 1, and efferent projections to area 2, along a limited mediolateral band perpendicular to the central sulcus. Only limited connections were found between representations of adjacent digits and connections beyond the representations of the digits were sparse or absent. There was a sharp boundary corresponding to the face representation. Area 1 injections in D1 representation showed efferent projections to area 4 and reciprocal connections with areas 3a, 3b, 2 and 5, with a similar mediolateral restriction as in the case of area 3b injections. The present data suggest the presence of mediolaterally limited, but anteroposteriorly elongated connectivity patterns concentrated within the representations of individual digits at different cytoarchitectonic regions within the primate sensory-motor cortex. The degree of overlap into adjacent digit representations should limit activity-dependent plasticity. Supported by NIH NS21377 and HFSP

## 50.14

SYNAPTIC INACTIVITY INDUCES STRUCTURAL PLASTICITY IN AXOSPINOUS SYNAPSES OF CORTICAL DENDRITIC SPINES.

G. Benshalom\* and V. Glukhman. Dept. of Morphology, Fac. of Health Sciences, Ben-Gurion Univ. of the Negev, Beer-Sheva, Israel.

This study was aimed at determining if structural alterations are induced in cortical dendritic spines by synaptic inactivity of their axospinous synapses, as was previously hypothesized (Benshalom, 1989, Synapse 4: 210-222). Ultrastructural observation focused on a population of dendritic spines along dendrites of spiny stellate neurons in layer IV of the barrel region of mouse somatosensory cortex. Approximately 10-23% of all axospinous synapses on these neurons are thalamocortical. Sensory neural input conducted via the thalamus to each of the two cortical barrel regions originates in a set of vibrissae at the contralateral side of the face. Deprivation of thalamocortical synaptic activity in the barrel cortex of one hemisphere was accomplished by removal of vibrissae unilaterally. 1-3 days later, mice were intracardially perfused with aldehyde solution and the Golgi-gold toning technique applied for light and electron microscopic identification of spiny stellate neurons. Ultrastructural examination revealed that the mean frequency of dendritic spines along the identified spiny dendrites was the same for both hemispheres. The percentage of dendritic spines exhibiting flat contour of axospinous synapses was similar in both hemispheres, but the percentage of dendritic spines with "postsynaptic-concave" spine heads was 4.5X higher, and the percentage of spines with "postsynaptic-convex" spine heads was 0.84X lower in the activity-deprived cortical hemisphere than in the control hemisphere. These results support the hypothesis that neural activity-related structural plasticity is an ongoing process within the mature brain. Supported by The Israeli Academy of Sciences, BRF grant.

## PAIN PATHWAYS: HIGHER CENTERS

## 51.1

BRAIN NUCLEI AND TRANSMITTERS INVOLVED IN RESPONSE TO PROXIMAL COLON DISTENTION IN CONSCIOUS RAT. L. Wang\*, V. Martinez and Y. Taché. CURE/DDRC, Dept. of Med. and Brain Res. Inst., UCLA, Los Angeles, CA 90073

Colon distention activates neurons in the brain autonomic regulation centers, as demonstrated by *c-fos* expression. Oxytocin (OT) vasopressin (AVP) and corticotropin-releasing factor (CRF) are the major transmitters in the hypothalamic nuclei influencing visceral functions. Central catecholaminergic (CA) neurons have been identified for their role in stress related autonomic and neuroendocrine circuitry. The aim of this study was to determine the neural pathways and neurochemical coding related to proximal colon distention by detecting the co-existence of the *c-fos* gene protein (Fos) expression with OT, AVP, CRF and CA. Visceral stimulation was performed in conscious SD male rats by proximal colon distention (10 ml of air, 30 s on/off for 10 min, approximately 80 mmHg) through a balloon chronically implanted in the proximal colon. Dual immunohisto-chemical staining were performed one hour after the stimulation by processing immunohistochemistry first for Fos with ABC-nickel intensified DAB technique and then for OT, AVP, CRF and tyrosine hydroxylase (TH) with ABC-DAB. For CRF immunohistochemistry rats were pretreated with a low dose of colchicine (20 µg/rat). Fos expression induced by proximal colon distention in conscious rats was observed in the paraventricular nucleus (PVN), supraoptic nucleus (SON) and accessory neurosecretory nuclei of the hypothalamus, locus coeruleus (LC), Barrington's nucleus, nucleus tractus solitarius (NTS), A1/C1 and A5 areas. Double stained cells of Fos with OT or AVP were observed mostly in the magnocellular division of the PVN (81% of OT- and 18% of AVP-positive cells), in SON (36% of OT- and 16% of AVP-positive cells) and in accessory neurosecretory nuclei. The Fos expression after colon distention was lower in the rats treated with colchicine than those without colchicine. However, it was still increased when compared with sham distention, and the double stained neurons with Fos and CRF were located in the parvocellular part of the PVN. Most of the Fos-expressing neurons in the pons and medulla after the proximal colon distention were detected in TH-positive nuclei, such as A1/C1, NTS, LC and Barrington's nucleus. In A1/C1, 74% of TH-containing neurons and in the NTS 42% were Fos-expressing. The results indicate that stimulation of the proximal colon by repetitive distention in conscious rats activates CA-, OT-, VP- and CRF-producing neurons in the brain and that these transmitters may be involved in processing information related to noxious visceral mechanical stimulations and in modulating pain-related visceral reflexes.

## 51.2

THE NUCLEUS GRACILIS (NG): A CROSS ROAD FOR PELVIC VISCERAL AND CUTANEOUS INPUTS INTO THE THALAMUS. K. N. Westlund, E. D. Al-Chaer and W. D. Willis\*. Department of Anatomy and Neurosciences, University of Texas Medical Branch, Galveston, TX 77555-1069.

The role of the nucleus gracilis (NG) in processing viscerosensory information arising from pelvic visceral organs is a major concern of researchers investigating mechanisms of visceral pain. In an earlier report and in the accompanying abstract, we have shown that the dorsal column (DC) mediates colonic input into the ventral posterolateral (VPL) nucleus of the thalamus and that NG cells respond to colorectal distension (CRD) and colon inflammation induced by mustard oil. This study focuses on the role of the NG per se as the mediator or the main gate for pelvic visceral information to go into the VPL nucleus. Experiments were made on male Sprague Dawley rats anesthetized with pentobarbital (40 mg/kg ip; 5 mg/kg/h iv). In one group, recordings were made from single cells in the VPL nucleus in response to CRD and cutaneous stimuli before and after consecutive microlesions of the contralateral and sometimes of the ipsilateral NG. The results obtained indicate that lesion of the contralateral NG interrupts the majority and sometimes all of the colorectal input into the VPL; at the same time, it reduces dramatically the responses of VPL cells to cutaneous stimuli mainly of innocuous nature. Occasionally, new cutaneous receptive fields are unmasked that would activate the same VPL cell with different stimulation modalities. In group 2, recordings were made from postsynaptic dorsal column (PSDC) cells at L6-S1 spinal segments in response to CRD and cutaneous stimuli. The projections of these cells were followed into the NG by antidromic activation of their axons using microstimulation (< 40 µA). These inputs and outputs through the nucleus gracilis put it at a major cross-road of visceral and cutaneous information between the periphery and higher brain centers. (Supported by NS09743, NS32778, NS11255).

## 51.3

MODULATION OF VISCEROSOMATIC INTERACTIONS IN THE THALAMUS BY DORSAL COLUMN INPUT. E. D. Al-Chaer\*, K. N. Westlund and W. D. Willis. Department of Anatomy and Neurosciences, University of Texas Medical Branch, Galveston, TX 77555.

The role of the dorsal column (DC) in visceral pain processing is becoming more evident as recent studies have elucidated its importance over that of other spinal tracts in mediating nociceptive visceral input into the ventral posterolateral (VPL) nucleus of the thalamus (Al-Chaer et al. 1995; 96). On the other hand, increased responses of VPL nucleus, nucleus gracilis (NG) and postsynaptic dorsal column (PSDC) cells to graded colorectal distension after colon inflammation were also recently reported (Al-Chaer et al. 1996). This study focuses on the interactions between simultaneous visceral and cutaneous inputs before and after selective lesions of different spinal tracts. Experiments were done in anesthetized male Sprague Dawley rats. Responses of viscerosensitive cells in the VPL nucleus, the NG and of PSDC cells to cutaneous stimuli (Brush, Pressure and Pinch) and to graded colorectal distension (CRD) were obtained before and after colon inflammation induced by intracolonic injection of mustard oil (MO). The results obtained so far, indicate that colon inflammation with mustard oil, not only potentiates the responses of single cells to CRD but also modifies their responses to cutaneous stimuli. Similarly, cutaneous stimuli applied during inflammation alter the increased background activity of viscerosensitive cells observed following MO injection into the colon. These interactions between visceral and cutaneous inputs are differentially affected by various spinal lesions involving the DC or pathways in the ventrolateral columns. (Supported by NS09743, NS32778, NS11255.)

## 51.5

ORIGIN OF SPINOTHALAMIC INPUT TO VMpo IN THE MONKEY. E.-T. Zhang\* and A.D. (Bud) Craig. Div. of Neurobiology, Barrow Neurological Institute, Phoenix, Arizona 85013.

The posterior part of the ventral medial n. (VMpo) is a cyto- and chemo-architectonically distinct nucleus in monkey and human thalamus that receives dense, topographic lamina I spinothalamic (STT) input, contains a concentration of nociceptive- and thermoreceptive-specific neurons, and projects topographically to the dorsal anterior insular cortex (Nature 372:770, 1994). In this study, we have used cholera toxin subunit B (CTb) to retrogradely label cells that project to VMpo.

Recordings were used to localize VMpo. A single iontophoretic injection of de-salted 0.3% CTb (2  $\mu$ A, 20 min) or large hydraulic injections of 2% CTb were made (6-14  $\mu$ l). Animals survived 3-4 wks, and an immunohistochemical ABC/DAB reaction was performed. Thionin and calbindin staining verified injection placement. The entire brainstem and spinal cord was examined.

Injections that covered all of thalamus labeled cells contralaterally in lamina I (31-49%), laminae IV-VI (31-47%), and laminae VII-X (17-38%). In contrast, in cases with a single injection in VMpo, 85-90% of the labeled cells were in lamina I, 10-15% were in laminae IV-VI, and none were found in laminae VII-X.

The finding that STT input to VMpo originates almost exclusively from lamina I neurons confirms that VMpo is a lamina I spino-thalamo-cortical sensory relay nucleus. This is consistent with the fundamental concept that lamina I projections relate the sense of the physiological condition of the body, which includes the specific sensations of pain and temperature. (Supported by NS 25616)

## 51.7

RECEPTIVE FIELD EXPANSION AND FUNCTIONAL CHANGES OF VENTROBASAL THALAMUS (VB) NEURONS IN RATS WITH STRYCHNINE-INDUCED ALLODYNIA. S.E. Sherman\*, L. Luo and J.O. Dostrovsky. Department of Physiology, University of Toronto, Toronto, Ontario, Canada M5S 1A8

Spinal strychnine (STR; glycine receptor antagonist) produces allodynia, as evidenced by nociceptive behavioural and autonomic responses to otherwise innocuous tactile stimuli (e.g. touch, brush, air jet). The aim of the current study was to determine if spinal STR causes changes in thalamic somatosensory processing that might contribute to the production of allodynia. Extracellular, single-unit recordings were conducted in the VB of 19 urethane-anesthetized, male, Wistar rats (342  $\pm$  44 g). Receptive fields (RFs) and responses to noxious and innocuous cutaneous stimuli were determined for 19 units (1 per animal), prior to, and immediately following intrathecal (i.t.) STR (40  $\mu$ g). Eighteen animals, developed allodynia with a mean onset time of 5 ( $\pm$  3) minutes after i.t. STR, as evidenced by the ability of innocuous brush or air jet to evoke cardiovascular and/or motor reflexes. All (3) nociceptive specific (NS) units became responsive to brush stimulation within 4 minutes after the onset of allodynia, and 1 became sensitive to brushing over an expanded RF. RF expansion was also noted for all of the low threshold (LT; 14) and wide dynamic range (WDR) neurons (2), either concurrently with allodynia (1 NS; 5 LT; 2 WDR) or within 10 minutes after the onset of allodynia. These RF changes were substantial for the WDR neurons, whose small, contralateral RFs expanded to include extensive bilateral regions. Nine LT units displayed similar dramatic RF expansion, and 10 LT units with contralateral RFs, developed bilateral RFs after i.t. STR. One NS and 9 LT neurons had increased spontaneous firing rates. The present results demonstrate that the direct actions of STR on spinal processing of sensory information are reflected by changes in the receptive fields and response properties of nociceptive and nonnociceptive thalamic neurons, and infer that thalamocortical mechanisms may be operative in the expression of STR-induced allodynia. (Supported by the Gifford-Jones and W. Ward Awards)

## 51.4

ANATOMICAL EVIDENCE FOR CELLS OF ORIGIN OF A POSTSYNAPTIC DORSAL COLUMN VISCERAL PATHWAY: SACRAL SPINAL CORD CELLS INNERVATING THE MEDIAL NUCLEUS GRACILIS. M.D. Christensen\*, W.D. Willis and K.N. Westlund. Marine Biomedical Institute, Dept. Anatomy & Neurosciences, UTMB, Galveston, TX 77555-1069.

The goal of this anatomical study is to characterize the neurons of the lumbosacral spinal cord which project through the dorsal column to the medial portion of the medullary nucleus gracilis. The retrograde tracer, Fluoro-ruby, tetramethyl rhodamine conjugated dextran (10,000MW, Molecular Probes) was pressure-injected into the medial nucleus gracilis of male Sprague-Dawley rats (n=4). Eight to ten days later, colchicine (10 $\mu$ l, 10 $\mu$ g/1 saline) was injected subdurally at a laminectomy site over the lower lumbar enlargement. After 10-15h, the animals were transcardially perfused with 4% buffered paraformaldehyde. Cryosections of L6-S1 were processed immunocytochemically with substance P antibody (1:10,000; Incstar) and subsequently with fluorescein conjugated anti-rabbit IgG. Cells of origin of terminals innervating the medial nucleus gracilis were primarily localized medially in lamina III. Additional cells were localized medially in laminae X, VII and IV or more centrally in lamina III. Substance P co-localization will be examined. Midline dorsal column lesions will eliminate effective retrograde labeling. These data provide detailed anatomical descriptions of the localization of neurons in the sacral spinal cord which may be responsible for transmission of nociceptive visceral input through the dorsal column to the nucleus gracilis and ultimately to the ventrolateral nucleus of the thalamus observed in electrophysiological studies. (Supported by NIH grants NS11255, NS32778 and NS09743).

## 51.6

SPONTANEOUS ACTIVITY OF MEDIAL AND LATERAL THALAMIC NEURONS IN RATS. B.J. Haworth, V.M. Tronnier, D. Sterio\* and P.C. Rinaldi. Dept. of Neurosurgery, University of California, Irvine, CA 92717.

Hyperactivity and bursting have been studied in lateral thalamic nuclei in patients during stereotactic procedures for relief from pain and in animals, typically in response to stimuli or in relation to sleep. Less is known of spontaneous activity and bursting in the medial thalamic nuclei. The purpose of this study is to characterize spontaneous thalamic activity, focusing on bursting, from medial and lateral thalamic nuclear groups in somatosensory and pain related structures. In 23 chloral hydrate sedated male rats 115 neurons were isolated and analyzed from extracellular recordings from the medial (CM, DM, Pf, CI) and lateral (VPL, VPM) thalamus. Cells were classified in terms of fields and response to noxious and non-noxious stimuli, periodicity, interval histogram and burst analyses. In medial nuclei, 39% (16/41) and in lateral nuclei, 83% (39/47) of the cells responded to pain and/or touch. Spontaneous bursting was exhibited by 74% (39/53) of medial cells and 87% (41/47) of lateral cells. The cells from the medial nuclei exhibit a longer average interval duration and fewer spikes per burst than cells from lateral nuclei. Activity of lateral cells exhibits a tendency for spikes within a burst to organize in a pattern of shorter to longer successive intervals, while this relationship breaks down for medial cells. This study supports the concept that not only do the medial and lateral nuclei differ with respect to response to somatosensory stimulation, but that spontaneous activity appears specific to each region, again paralleling differences in function.

These findings also provide a framework for evaluating the hyperactivity and bursting which appear as modulation in the activity of the network of these nuclei following deafferentation.

## 51.8

ARE RESPONSES TO VISCERAL STIMULATION IN THE CAT'S LATERAL THALAMUS ORGAN SPECIFIC? A.C. Hom, J. Brüggemann\*, M. Petersen, C. Vahle-Hinz' and K.-D. Kniffki. Physiologisches Institut, Universität Würzburg, D-97070 Würzburg, and 'Physiologisches Institut, UK Eppendorf, D-20246 Hamburg, Germany.

In squirrel monkeys and macaques there exists a high degree of viscerovisceral convergence in the lateral thalamus (72% and 41%, respectively). We studied the representation of a thoracic (esophagus) and an abdominal visceral organ (distal colon) in the lateral thalamus of  $\alpha$ -chloralose-anesthetized cats. Distension of the viscera with pressure intensities of up to 80 mm Hg was effected via balloon catheters. In addition, somatic receptive fields (RFs) were determined with non-noxious and noxious mechanical stimuli. Location of recording sites were verified histologically. Visceroceptive neurons were located in the dorsal and lateral parts of the posterior complex (POd/I). Most (80%) of the neurons responded either to colon or to esophagus stimulation. These responses were nociceptive, and consisted about equally often of discharge increases and decreases. Both types of viscerceptive neurons, however, had similar low-threshold somatic RFs, located on the lower back, hindleg or foot. Somatic RFs of the viscerceptive neurons were equally often of hetero- or homo/perisegmental origin. Only one neuron was activated by noxious mechanical stimulation of the foot as well as both kinds of viscera. All neurons with viscerovisceral inputs had excitatory responses. The results indicate that a convergent representation of thoracic and abdominal viscera may be rare in the cat's POd/I, implying organ specific processing of visceral information.

Supported by DFG grant Kn 177/5-3.

## 51.9

DYNAMICS OF POPULATIONS OF NEIGHBORING NEURONS FOR INNOCUOUS AND NOXIOUS STIMULI IN THE VENTROPOSTERIOR LATERAL NUCLEUS. T. Shi\*, J. Brüggemann, L. R. Airapetian and A. V. Apkarian. Dept. of Neurosurgery at SUNY Health Science Center, Syracuse, NY 13210

With a multi-microelectrode recording technique, we examined the dynamics of population neurons in the ventroposterior lateral nucleus (VPL) of the monkey. Earlier we reported that with this technique the incidence of nociresponsive neurons was much higher than that recorded with single electrodes (10% vs 30%) and that the cross-correlations between neurons were different between the noci-sites (defined as some neurons responding to a noxious stimulus online) and the rest i.e., non noci-sites. In the present study the changes in the firing rate and in cross-correlation and relative locations of neurons were further analyzed.

Individual neuronal activity of multiple neurons were recorded from VPL of the halothane-anesthetized squirrel monkey with a matrix microelectrode. Four-channel neuronal signals were collected and then offline clustered with Datawave. Innocuous and noxious stimuli were applied. It was found that some of the recorded neurons repeatedly responded to a stimulus but others did not. Both excitatory and inhibitory cross-correlations were found in noci- and non noci-sites. Some neurons did not change their firing rates for a stimulus but their cross-correlations did. During noxious stimuli the number of excitatory cross-correlation pairs were increased compared to that during innocuous stimuli at both noci- and non-noci-sites even if there were much less nociceptive responses at non noci-sites. Pressure stimulus caused more inhibitory cross-correlation pairs than did the other innocuous stimuli at noci-sites. The averaged distance between recorded neurons at noci-sites was longer than that at non noci-sites. The results suggest that local neuronal networks in VPL constantly adjust to incoming signals by changes in firing rates and connectivities.

Funded by Department of Neurosurgery at SUNY HSC.

## 51.11

NEURAL CORRELATES OF STATIC MECHANICAL HYPERALGESIA IN VPM THALAMUS OF THE BEHAVING MONKEY. C.-C. Chen\*, R.C. Kupers, and M.C. Bushnell. Départ. Stomatologie et Centre de Recherche en Sciences Neurologiques, Université de Montréal, Montréal, Canada H3C 3J7.

Spinothalamic tract cells show changes in activity after tissue damage consistent with their involvement in hyperalgesia. Yet, little is known about thalamic processes underlying hyperalgesia and allodynia. We studied the role of VPM thalamic neurons in the production of mild mechanical hyperalgesia.

One rhesus monkey pressed a lever to escape a mechanical stimulus or to receive food reward for detecting a light. A plastic probe (tip diam.=0.5mm; displacement=2cm) was placed 1-cm from the facial skin. At 6-10s intervals, the mechanical stimulator was applied at a force of 25, 50, 75 or 150g for 5 sec or the light was illuminated for 1.5 sec. Single VPM neurons were isolated while the monkey performed the tasks. The neuronal and behavioral responses to mechanical stimulation were tested before and after 20 min topical application of capsaicin (0.02M, dissolved in 5.0ml 70% ethanol) to the receptive field.

The monkey escaped more mechanical stimuli after capsaicin application than before ( $p<0.05$ ), suggesting a mild mechanical hyperalgesia to punctate stimuli. Of four cells that responded maximally to noxious pressure (150g), three were more responsive to mechanical stimulation after capsaicin ( $p<0.05$ ). In all cases, the increased responsiveness was reversed by cold application to the receptive field ( $p<0.05$ ). Of four cells that responded maximally to innocuous mechanical stimuli, two showed decreased responsiveness to mechanical stimulation after capsaicin ( $p<0.05$ ), whereas two were unaffected.

These data indicate that activity in ventroposterior thalamus could subserve mechanical hyperalgesia. The increased excitability of cells that normally code noxious stimuli is similar to that found in STT neurons of anesthetized monkeys. The decreased excitability of some tactile thalamic neurons supports other reports of C fibre modulation of low threshold somatosensory transmission. Supported by the Canadian MRC and the Ministère de l'Éducation du Québec.

PHYSIOLOGICAL PROPERTIES OF VENTROLATERAL ORBITAL (VLO) CORTEX IN AWAKE RATS WITH THERMAL HYPERALGESIA. M-M Backonja\* and C. Levenick, Department of Neurology, Medical School, University of Wisconsin, Madison WI, 53792

It has been postulated, on the basis of anatomic and physiologic investigations that Ventrolateral Orbital (VLO) cortex of frontal lobe participates in pain related processes. This study was conducted for the purposes of further characterization of this cortical area in awake behaving rats. An array of 6 stainless steel electrodes was advanced according to stereotactic coordinates. There was continued monitoring of electrical activity at each electrode. Once an acceptable number of units was identified at the stereotactically determined depth, the electrodes were fixed with dental acrylic. Activity in at least two electrodes per rat remained stable for a period of several weeks. That allowed longitudinal recordings from the same group of units. Within this time period, recordings were performed before and after thermal hyperalgesia was induced by loose ligation of the sciatic nerve with chromic gut, as per Bennett and Xie (1988). Analysis of the recordings have revealed thus far that thermal stimuli produce an increase in neuronal activity, especially when stimuli are in the noxious range. VLO units responded to bilateral stimuli. The unit activity during the time when rats exhibited thermal hyperalgesia was not significantly different from the unit activity during the time prior to hyperalgesia state. This preliminary finding suggests the possibility that although VLO may be involved in pain perception, is unlikely that it is the cerebral region is involved in genesis or maintenance of neuropathic processes underlying thermal hyperalgesia.

## 51.10

A MECHANICAL STIMULATOR FOR PSYCHOPHYSICAL AND NEUROPHYSIOLOGICAL STUDIES OF PAIN AND TOUCH. L. TenBokum, R.C. Kupers, C.-C. Chen, G.H. Duncan, and M.C. Bushnell\*. Départ. Stomatol. & Cent. Rech. Sci. Neurol., Univ. Montréal, Montréal, Canada H3C 3J7.

Most commercially available mechanical stimulators lack the displacement and force characteristics to adequately stimulate the skin across a wide range of innocuous and noxious forces. We describe here a small, inexpensive stimulator which addresses these limitations; its application to human and monkey psychophysical and neurophysiological studies is reported.

The computer-controlled stimulator advances a mechanical probe against the skin until a target force is achieved and maintains that force until retracting the probe at the end of stimulation. A single load cell (resolution 1g; range 250g) monitors the probe force and provides feedback to a servo-controller which adjusts probe displacement (max 25mm), thus maintaining the target force in spite of variable skin compliance. Plastic tips differing in size and shape can be mounted on the probe; a conical tip with a 0.5mm spherical point was tested in human psychophysical and monkey behavioral and neurophysiological experiments.

A monotonic relationship was found between perceived stimulus intensity and probe force across a range of 5 to 200 grams applied to the maxillary face. Forces greater than approximately 100 grams were perceived as painful by the humans and were frequently escaped by the monkey. Single neurons in VPM thalamus of the monkey produced monotonic response functions when receptive fields were stimulated with the probe at different forces.

This small, inexpensive mechanical probe provides great versatility in its application to human and animal psychophysical, behavioral and neurophysiological studies. Reliable human psychophysical ratings, as well as monkey escape behavior and single-unit responses, demonstrate the usefulness of this apparatus for studies of pain and tactition.

Supported by the Canadian MRC and the Ministère de l'Éducation du Québec.

## 51.12

MICRO-INJECTIONS OF MUSCIMOL INTO LATERAL SUPERIOR COLLICULUS DISRUPT ORAL ORIENTATION TO THE SITE OF INJECTION IN THE FORMALIN MODEL OF PAIN. P. Redgrave\* and S. Wang. Dept. Psychology, University of Sheffield, Sheffield, S10 2TP, U.K.

Nociceptive neurones in the basal ganglia, cerebellum and related structures are probably involved in generating nocifensive behaviour. However, little is known of the circuits through which pain can affect movement. The present study used the comparatively well understood output projection from striatum to superior colliculus (SC) via substantia nigra pars reticulata, to study the mechanisms used by rats to locate a persistent source of pain. Our specific aim was to test whether interrupting basal ganglia output at the level of the SC, by local injections of the GABA agonist muscimol, is critical for directing oral behaviour to a region of the body injected with formalin. C-fos immunohistochemistry was used to determine the regional spread of the inhibitory effect of muscimol on neuronal activity.

Oral behaviour elicited by 50µl of 4% formalin injected into the hindpaw was suppressed in a dose-related manner by micro-injections of muscimol into the lateral-SC (12.5-50ng; 0.5µl/side); injections in medial SC had little effect. Bilateral inhibition of lateral-SC caused animals to re-orient their attention and activity from lower to upper regions of space. Unilateral injections of muscimol into lateral-SC elicited contralateral turning independent of which hindpaw was injected with formalin. Oral behaviour was suppressed when injections of muscimol and formalin were contralaterally opposed. However, when formalin was injected into the perioral region, micro-injections of muscimol into contralateral lateral-SC had no effect on the ability of animals to localise the injected area with either foot.

These findings suggest that basal ganglia output via the lateral SC is critical for nocifensive responses which entail the mouth moving to and acting on the foot, but not when the foot is the active agent applied to the mouth. The data also suggest that pain produces a general facilitation of units throughout collicular motor maps, which can be converted into a spatially inappropriate signal by locally suppressing parts of the map with muscimol. ## 51.14

MAPPING PAIN CIRCUITS: LIMBIC STRUCTURES AFTER NOXIOUS STIMULATION OF VISCERA. A. Solodkin<sup>1</sup>, GF Gebhart<sup>2</sup> and RJ Traub<sup>2</sup>. Departments of Anatomy & Neurology<sup>1</sup> and Pharmacology<sup>2</sup>. University of Iowa, Iowa City, IA 52242.

The perception of pain has been subdivided into a discriminative and an affective component. While the discriminative component of visceral pain is under much study, the latter is poorly understood. Since emotion and memory are important aspects in the perception of visceral pain, an understanding of the pathways involved is relevant. Hence, using c-Fos expression as a marker, we have studied the participation of limbic areas after noxious colorectal distention (CRD) in the rat.

Our observations showed that: i) In all cortical areas studied, layers III and V consistently had the largest density of Fos-labeled nuclei. In addition, some of these cells were identified as pyramidal by double labeling with SMI-32; ii) Within the cortical and subcortical areas studied, the distribution of Fos showed preferential localization to certain subregions and nuclei. Among the areas with the largest density of Fos-labeled nuclei were: Cingulate (Cg3), agranular insula and infralimbic cortices at the prefrontal cortex level; posterior retrosplenial and ventral perirhinal cortices, subicular complex, central nucleus of amygdala, anterior-dorsal and medio-dorsal nuclei in thalamus and ventral periaqueductal gray.

It is suggested that: 1) A subpopulation of neurons expressing Fos after noxious CRD are either cortico-subcortical projection neurons or cortico-cortical association neurons; 2) The variation in the density of Fos-labeled nuclei within and between areas provides an indication of the complexity and importance of events taking place in limbic structures during visceral pain. In addition, it provides a good model for the prediction and testing of the circuitry involved during higher cognitive functions such as emotion or memory. Supported by NS 30604 and NS 19912.

## 51.15

## ANATOMY OF A CORTICAL ANTINOCICEPTION TRIGGERING SITE (CATS-1) IN THE AGRANULAR INSULAR CORTEX OF THE RAT

*Adam R. Burkey\** and *Luc Jamin* Georgetown University Medical Center, Departments of Neurosurgery and Cell Biology, Washington, DC 20007

We have recently identified a cortical antinociception triggering site (CATS-1) in the agranular insular cortex of the rat which contributes to systemic morphine-induced antinociception in association with a descending inhibition of spinal nociceptive neurons. The anatomical connectivity of CATS-1 was determined using anterograde tracing with biotin dextran and retrograde tracing with Fluoro-Gold. Those connections with most relevance to nociception include reciprocal projections to and from the ventral lateral orbital cortex and infralimbic cortex; a bilateral projection to the nucleus accumbens; reciprocal connections with the ipsilateral basolateral amygdaloid nuclei; and reciprocal connections with the midline thalamic nuclei, lateral hypothalamus and medial parabrachial area. CATS-1 also receives afferents from the ventral tegmental area and substantia nigra. Direct injection of the CATS-1 efferent pathway through the ventral striatum filled CATS-1 neurons and their dendrites. The multipolar morphology of these cells, with somata 40  $\mu$ m and extended dendrites measurable to 600  $\mu$ m, strongly resembles that of the mu-opioid receptor bearing cells defined by mu-opioid receptor immunocytochemistry in CATS-1. This study suggests possible routes by which morphine acting within CATS-1 could result in descending inhibition of nociceptive neurons. This route appears to be through the rostral ventral medulla via the lateral hypothalamus, and through the periaqueductal gray via the infralimbic cortex. The connections of CATS-1 to the midline thalamus and limbic structures further imply that CATS-1 could modulate nociception through mechanisms other than descending inhibition. This work supported by a Howard Hughes Fellowship Training Grant.

## 51.17

PERSISTENT NOXIOUS INPUT VIA INFLAMMATION PREFERENTIALLY AFFECTS THE EVOKED RESPONSES OF NOCICEPTIVE SI NEURONS TO MECHANICAL STIMULI. *M. Sholas\** and *D.R. Kenshalo, Jr.* Neurobiology & Anesthesiology Branch, NIDR, NIH, Bethesda, MD. 20892, \* Program in Neuroscience, DMS, Harvard Medical School, Boston, MA. 02115.

Subcutaneous injection of 30 mg of carrageenan into the glabrous skin of the hand of a monkey produces a profound increase in volume ( $72 \pm 24\%$ ) lasting 24 to 48 hours. We examined the effects of inflammation on the population of SI neurons. Male rhesus monkeys were sedated with ketamine 24 hours prior to the recording session for the carrageenan injection. We recorded from nociceptive units in the hand representation of SI. Once a nociceptive neuron was isolated, the receptive field of each neuron 500  $\mu$ m above and below it were categorized as: low threshold mechanoreceptor (LTM), wide-dynamic range (WDR), nociceptive specific (NS), deep/joint receptor (DT), or as a hybrid between WDR and LTM (HB). The categorization was based on the responses of the neuron to a graded series of mechanical stimuli and an intradermal capsaicin injection (50  $\mu$ g).

Eighty neurons were studied in the inflamed state and compared to a control population of 88 neurons. The group after inflammation had similar proportions of cell types as the control group. The receptive field sizes were comparable as well. However, the evoked responses of nociceptive units to pressure and pinch stimuli in the group after inflammation were significantly (ANOVA,  $p < 0.05$ ) increased as compared to those in the control population. No differences were found in the evoked responses to brush stimuli, or in the background activity of the neurons. The hyperalgesia associated with inflammation reflect a central hyperexcitability of nociceptive units without global changes in the number of neurons responsive to noxious stimulation.

## 51.19

OVERLAP OF MEDIAL WALL fMRI ACTIVITY BETWEEN PAIN, MOTOR, AND VIBROTACTILE TASKS IN HUMANS. *P.A. Gelnar<sup>1</sup>, B.R. Krauss<sup>1\*</sup>, N.M. Szeverenyi<sup>2</sup>, A.V. Apkarian<sup>1</sup>*, Depts. Neurosurgery<sup>1</sup> and Radiology<sup>2</sup>, SUNY HSC, Syracuse, NY.

A recent comparison of medial wall activity in human PET studies to monkey data (Picard and Strick, 1996) revealed corresponding subdivisions in supplementary motor area (SMA and pre SMA), and rostral (anterior and posterior divisions; RCZa, RCZp) and caudal cingulate (Cing) zones (CCZ). The present study compares the medial wall functional magnetic resonance imaging (fMRI) pain activations to the above subdivisions. fMRI studies were done in which motor, vibratory, and painful stimuli were utilized in the same subject.

Multislice fMRI (echoplanar BOLD) was utilized to investigate cortical activity in 28 subjects. Eight slice locations were imaged beginning at either the anterior commissure (AC) and extending rostrally 45.5mm or 6.5mm posterior to the AC extending caudally 45.5mm. Significant medial wall clusters were identified and their slice locations and dorsoventral position noted.

For all three tasks activity was seen bilaterally in SMA and Cing. In the motor task contraSMA and contraCing were more active than ipsiSMA and ipsiCing. However in the pain task the ipsiSMA was more active than contraSMA. There was greater activity in contraSMA with the motor task as compared to noxious heat and vibratory stimuli ( $p < 0.005$ ). In the motor task, 2 subdivisions were found in SMA and 3 subdivisions in Cing, corresponding respectively to preSMA, SMA and RCZa, RCZp and CCZ. In the pain task, specific portions of contra-preSMA and contra-SMA were active, while Cing regions were more homogeneously activated bilaterally. The results show substantial overlap between tasks in the medial wall cortex. Although there may be specialized segregations within these subdivisions. This research was funded by the Department of Neurosurgery at SUNY HSC.

## 51.16

NOCICEPTIVE NEURONS IN PRIMATE INSULAR CORTEX. *J.O. Dostrovsky\** and *A.D. (Bud) Craig*, Dept. of Physiology, Univ. of Toronto, Ontario, Canada, and Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

Previous work indicates that a distinct region of the dorsal anterior insula, posterior to gustatory cortex, receives topographic input from the posterior part of the ventral medial n. (VMpo), a lamina I spinothalamic relay nucleus in monkey and human thalamus that contains a concentration of nociceptive- and thermoreceptive-specific neurons (Nature 372:770, 1994; SNA 21:1165, 1995). In this study, we examined the response properties of neurons in this cortical region.

Recordings were made with tungsten microelectrodes using a dorsal approach in pentobarbital-anesthetized cynomolgus monkeys. Histological reconstructions from Nissl sections verified penetrations through the appropriate region of the insula. In one animal anterograde dextran labeling from VMpo (injected one month prior to recording) confirmed the recording sites within the VMpo projection field. In such sites responses to noxious mechanical and in some cases also thermal stimuli could be evoked (22 background or multi-unit clusters and 19 single units in a total of 16 tracks). Most of these neurons responded tonically (or phasically) only to noxious stimulation. A somatotopic organization was found with face most anterior and arm posterior, consistent with anatomical findings. Interestingly, in one monkey a region in dorsal insula anterior to the VMpo projection field was found where noxious stimulation produced a profound inhibition of spontaneous firing.

This demonstration of a concentration of nociceptive neurons in primate anterior insula confirms that VMpo is a lamina I spino-thalamo-cortical sensory relay nucleus and establishes a solid basis for the EEG and PET activation of human insular cortex by noxious stimuli. This supports the fundamental concept that lamina I projections relate the sense of the physiological condition of the body, which includes the specific sensations of pain and temperature. (supported by DE 05404 and NS 25616)

## 51.18

ANTERIOR CINGULATE PROJECTION FROM MDvc (A LAMINA I SPINOTHALAMIC TARGET IN THE MEDIAL THALAMUS OF THE MONKEY). *A.D. (Bud) Craig\** and *E.-T. Zhang*, Div. of Neurobiology, Barrow Neurological Institute, Phoenix, Arizona 85013.

Earlier PHA-L results demonstrating topographic lamina I trigemino- and spinothalamic terminations in the ventral caudal part of the medial dorsal n. (MDvc), a distinguishable region in both monkey and human thalamus) suggest a primate medial pain pathway. We have examined the cortical projections of MDvc, which prior studies have not established.

Injections in MDvc of anterograde tracers (TRITC- and biotin-labeled dextrans, 7  $\mu$ A x 20 min, or 1-3  $\mu$ l; barbiturate-anesthetized cynomolgus monkeys; 3-4 wks survival) produce a discrete band of middle layer terminal labeling in the fundus and both banks of the anterior cingulate sulcus at the level of the genu of the corpus callosum (area 24c). Cortical injections (FB, DY and CTb) retrogradely label MDvc only from this sulcal area, confirming the anterograde finding. Detailed analyses of the neighborhood relationships of this area with regard to connections with other regions (VL/VA, AM, Csl, Cem; motor and insular cortex; spinal cord; amygdala) have begun.

This result identifies an anatomical substrate that could be the basis for the involvement of anterior cingulate cortex in pain (and itch) indicated by clinical and PET evidence. This lamina I spino-thalamo-cortical pathway could underlie the thermal grill pain illusion and central pain, consistent with a fundamental role in the integration of pain, temperature and homeostatic activity. (Supported by NS 25616)

## 52.1

## ADULT RATS SPINALIZED AT BIRTH EXHIBIT INAPPROPRIATE WITHDRAWAL REFLEXES.

J. Schouenborg, H. Holmberg\*, X.-L. Luo and A. Levinsson. Dept. of Physiology and Neuroscience, Lund University, Lund, Sweden.

**Aim:** In normal adult rats, single hindlimb muscles receive cutaneous excitatory input from well defined receptive fields whose distribution of sensitivity reflects the withdrawal action of the muscle. This spatial organization is attained through a postnatal tuning process. The underlying mechanisms are not known. To study the role of descending pathways in this context, withdrawal reflexes were studied in adult rats which had been spinalized at birth.

**Methods:** Electromyography was used to record CO<sub>2</sub>-laser evoked reflexes (20-30 sites were stimulated on the plantar surface of the right hindpaw) of peroneus longus, extensor digitorum longus and gastrocnemius muscles in adult decerebrated rats (n=5) which had been spinalized at the level of Th 8-10 at birth. In addition, compound hindlimb reflex responses evoked by CO<sub>2</sub>-laser stimulation were characterized in four awake rats (recorded on videotape).

**Results:** Hindlimb reflexes were typically highly excitable, being evoked even by light touch. Reflexes of gastrocnemius, which are abolished after spinalization in normal adult rats, were consistently evoked. The functionally adapted spatial organization of the withdrawal reflexes seen in normal rats was lacking.

**Conclusions:** Withdrawal reflexes in rats with chronic spinal transection do not become functionally adapted as in normal rats, indicating that the normal postnatal tuning of withdrawal reflex function depends on intact descending connections from the brain.

Supported by Swedish MRC proj. no. 1013 and No. 10569, and the Medical Faculty of Lund.

## 52.3

## NEONATAL RATS EXHIBIT AN EARLIER DEVELOPMENT OF PEAK RESPONSE TO PERIPHERAL INFLAMMATION AND HYPERALGESIA THAN ADULT RATS. R.X. Zhang\*, K. Malsnee and M.A. Ruda. NAB, NIDR, NIH, Bethesda, MD 20892.

Spinal nociceptive neural circuits undergo considerable postnatal (P) changes. Although peptide-containing primary afferents are present in the spinal cord at birth, their synaptic circuits continue to develop postnatally. This study examines neonatal rats' peripheral response to noxious stimulation and spinal neuronal gene induction in comparison to that of adult rats in a model of peripheral inflammation and hyperalgesia. Complete Freund's adjuvant (CFA) was injected unilaterally into the hindpaw of P1, P3, P9, P13, P21 and adult rats. Paw diameter and withdrawal latency to radiant heat were examined at 2hr, 1, 2, and 3 days after CFA injection and preprodynorphin (PPD) mRNA expression was measured at 4hr, 8hr, 1, 2, and 3 days. The extent of edema, based on difference scores between the ipsi and contra hindpaws, was different in each age group but all peaked at day 1 (0.16 cm at P1 and P3, 0.26 at P9 and P13, 0.3 at P21 and 0.45 for adult rats). In neonates thru P21 the withdrawal latency in the injected paws was shortest at 2hr and approached control latencies by day 3, except for P21 rats which continued to show significant hyperalgesia. Adult rats exhibited peak hyperalgesia at day 1, which was reduced at day 3 but still significant. Baseline withdrawal latency of neonates was 1 sec faster than adults. The constitutive expression of PPD was higher in neonatal than adult rats. At P9 there was significant induction of PPD in ipsilateral spinal cord, which was near peak levels by 8hrs after CFA and significantly reduced by day 3. In contrast, the PPD increase in adult rats reached peak levels at day 1 after CFA and persisted at high levels through day 3. Neonates and adult rats had the same peak percent increase in PPD mRNA expression. These data demonstrate a robust inflammation induced hyperalgesia in the neonates and a corresponding dramatic response in spinal nociceptive neuronal circuits that occurs faster than seen in the adult. The fact that in neonates the PPD mRNA induction occurs at the same percent increase as seen in adults stresses the importance of pain control in neonates to prevent alterations in spinal neural circuits due to excessive activity in pain pathways. Funded by IRP, NIDR, NIH.

## 52.5

## CHEMICAL LESIONS TO BRAINSTEM DOPAMINERGIC NEURONS FACILITATE NOCICEPTIVE REFLEXES (NR) AND ACCELERATE AUTOTOMY (AT) BEHAVIOR IN RATS. S.F. Atweh\*, S.J. Jabbur, N.B. Bahuth and N.E. Saadé. Fac. of Med., American Univ. of Beirut, Lebanon.

Previous work from our laboratory has shown that kainic acid lesions of striatal neurons inhibited NR and reduced AT in rats (Saadé et al. Soc. Neurosci. Abstr. 21:1166, 1995 and *Physiol. & Behav.*, in Press). In view of the important input to the striatum from the substantia nigra (SN), the aim of this study was to investigate the effects on NR and AT of selective chemical lesions to the dopaminergic supply to the striatum.

Various groups of rats were subjected to pain tests including paw pressure (PP), hot plate (HP) and tail flick (TF) latencies one week prior to injection of saline (sham group) or 5-hydroxydopamine (20µg in 3.3µl) either in the striatum or in the SN. After one week recovery, NR were tested for another 2 week period. Then the animals were subjected to a leg denervation contralateral to brain injection site.

Latencies of TF, HP and PP on the contralateral leg were significantly decreased (30%, 40% and 45%, respectively) while the AT of the denervated legs were significantly accelerated. We conclude that the dopaminergic nigrostriatal system plays a role in triggering central mechanisms involved in acute and chronic deafferentation pain.

## 52.2

## ADRENALECTOMY CAUSES EXAGGERATED PERIPHERAL AND NEURONAL RESPONSE TO NOXIOUS STIMULATION THAT IS REVERSED BY DEXAMETHASONE. M.A. Ruda\*, K. Malsnee and R.X. Zhang. NAB, NIDR, NIH, Bethesda, MD 20892.

Glucocorticoids (GC) function peripherally to suppress inflammation by acting on the inflammatory/immune response and centrally at neuronal steroid receptors to modify gene expression. GC receptors include subtypes with corticosterone (CORT) having a high affinity for type I and dexamethasone (DEX) having a high affinity for type II. This study examines the role of GC in a model of peripheral inflammation and hyperalgesia. Male Sprague-Dawley adrenalectomized (ADX) rats with, and without, GC replacement by CORT or DEX were compared to normal (N) and sham (SH) surgery rats. CORT or DEX was delivered by osmotic minipumps (10-20 µg/µl/hr) beginning 4 days prior to unilateral hindpaw injection of complete Freund's adjuvant (CFA) (4 weeks after ADX). Paw withdrawal latency to radiant heat was measured at 2 hr, 1, 2, and 3 days. The post-CFA withdrawal latency in ADX rats was significantly shorter than N and SH rats at 2 hr; ADX rats receiving CORT were similar to control rats, while DEX rats demonstrated significantly less hyperalgesia. Edema in ADX rats resulted in significantly larger paw diameters than N and SH rats; ADX rats receiving CORT were similar to control rats, while those receiving DEX had substantially reduced edema. Day 3 after CFA injection the spinal lumbar enlargement was removed, total RNA extracted, and RNA blots hybridized with a preprodynorphin (PPD) probe. ADX markedly increased the induction of PPD mRNA related to inflammation and hyperalgesia compared to that in N and SH rats. CORT reversed the PPD enhancement by ADX back to N and SH induced levels; DEX rats showed no PPD induction. These data demonstrate profound effects of GC on both the peripheral and central response to inflammation and hyperalgesia. Since DEX acts mainly at the type II GC receptor, these results suggest a major role for this receptor in the response to a noxious inflammatory agent. The substantial attenuation of PPD gene induction after DEX treatment suggests that DEX may be clinically useful to prevent excess neuronal activity in nociceptive neuronal circuits and prevent their alteration. Funded by IRP, NIDR, NIH.

## 52.4

## HORMONAL AND BEHAVIOURAL EFFECTS OF GONADECTOMY IN FORMALIN-TREATED MALE AND FEMALE RATS. A.M. Aloisi\* and C. Lupo. Istituto Fisiologia Umana, Univ. degli Studi di Siena, I-53100 Siena Italy

Sex hormones play a role in the hormonal and behavioural responses to pain. In the present experiment we evaluated the interaction between gonadectomy (gdx) and persistent pain induced by formalin in male and female rats. Twelve males and 12 females were anesthetized and then half were gonadectomized and half were sham-operated. Twenty days later they were s.c. injected with formalin (50 µl, 10%) and tested in the hole-board for 60 min. Rats were then anesthetized and blood was collected from the abdominal aorta. ACTH, corticosterone, testosterone and estradiol plasma levels were determined by RIA. Gdx increased paw-jerk frequency in males but decreased it in females. In addition gdx increased flexing duration in both sexes. Gdx did not affect ACTH and corticosterone, while it decreased testosterone and estradiol in both sexes. These data indicate that the gdx-induced effect on pain-evoked responses is not related to significant modifications in ACTH and corticosterone plasma levels.

## THE EFFECTS OF NMDA ANTAGONIST, AP5, INJECTED INTO THE DENTATE GYRUS AND PERIAQUEDUCTAL GREY ON FORMALIN-INDUCED PAIN IN RATS. J.E. Magnusson\*, K.L. Ruck, G.J. Mader, Jr., H.R. Clemmons &amp; A.L. Vaccarino. Department of Psychology, University of New Orleans, LA 70148.

Several lines of evidence show a critical role of the N-methyl-D-aspartate (NMDA) receptor in the development of formalin-induced pain. In the present study we examined the role of NMDA activity in the dentate gyrus and periaqueductal grey in the development of formalin-induced. Under sodium pentobarbital anesthesia rats were implanted unilaterally with a guide cannula aimed at the dentate gyrus or periaqueductal grey. Following a 7-14 day recovery period rats received an infusion of the NMDA antagonist, AP5 (5 µg/0.5 µl/min), or saline into the dentate gyrus or periaqueductal grey. Five min after the infusion of AP5 rats received a sc injection of 1% formalin into the plantar surface of the paw contralateral to the cannula. The rats were then observed for pain-related behaviours (paw elevation) for the subsequent 70 min. The results showed that AP5 had differential effects when injected into the dentate gyrus and periaqueductal grey. Supported by a Louisiana Education Quality Support Fund (LEQSF).

HUMAN A $\delta$  AND C-FIBER NOCICEPTOR RESPONSES TO LOW INTENSITY PAINFUL HEAT. R. H. Gracely and D. R. Kenshalo Jr.\* NAB, NIDR, NIH Bethesda MD 20892.

Peripheral pain suppression and central summation have been demonstrated with frequent (0.3 Hz), intense (51°C) heat pulse stimulation. This study used low intensity, infrequent heat stimuli applied to the volar forearm to evaluate temporal effects of A $\delta$  and C-fiber mediated pain sensations.

Forty-two subjects performed both pain rating and reaction time tasks to pain sensations evoked by trains of 8 3s-duration heat stimuli delivered at 15s intervals via a 0.8 cm diameter contact thermode. In random order, stimulus trains were delivered to each of two sites 3 cm apart (SAME), or to a new site for each stimulus in each of two trains (CHANGE). Stimulus temperatures in each train were 47, 47, 47, 47, 45, 45, 47, 47°C.

Responses to 47°C were stable in the CHANGE condition. In the SAME condition, responses (stimulus 1 rating=13.9, latency=1657 msec) were altered to the second stimulus (rating decrease to 10.3,  $P<.0001$ ; latency increase to 2738 msec,  $p<.0001$ ) and stable thereafter. Correcting for increased latencies observed with less intense sensations, the increased latency to stimulus 2 (0.4s) is consistent with a shift in conduction velocity from A $\delta$  to C-fibers. Stimulus control was demonstrated by increased latencies and decreased ratings to 45°C in each condition ( $p<0.0001$ ).

These results show that repetitive 47°C stimuli suppress A $\delta$  activity, isolating A $\delta$  and C-fiber nociceptor function.

## 52.8

EXTEROCEPTIVE SUPPRESSION OF MASSETER MUSCLE ACTIVITY EVOKED BY PAINFUL HEAT STIMULI IN HUMANS. J. Ellrich<sup>1</sup>, H.C. Hopf<sup>2</sup> and R.-D. Treede<sup>1</sup> (SPON: European Neuroscience Association). Johannes Gutenberg-University, <sup>1</sup>Institute of Physiology and Pathophysiology, Saarstr. 21, D-55099 Mainz, <sup>2</sup>Department of Neurology, Langenbeckstr. 1, D-55101 Mainz, Germany.

Electrical stimulation of the mental nerve evokes two suppression periods (SP) in masseter muscle activity. It is controversial whether these periods are evoked by activation of tactile (Crucchi et al., Exp. Brain Res., 77 (1989): 447-450) or nociceptive fibers (Miles et al., Exp. Brain Res., 65 (1987): 331-336).

We investigated 10 healthy volunteers (20 to 26 years) using an infrared laser, that selectively activates nociceptors in hairy skin. Perceptual and pain thresholds of mental nerve area were determined. While volunteers clenched their teeth at maximum strength 20 painful laser stimuli (600 mJ) were applied. Latencies of SP were measured from the rectified and averaged signal. A SP was defined as more than 50% suppression of the background EMG, measured in a 100 ms pretrigger interval. Latencies and durations of SP were measured at the point when EMG activity reached 80% of the background level. SP was also elicited by electrical pulses (200  $\mu$ s) with intensities twice the individual pain threshold.

With a mean pain threshold of  $366 \pm 68$  mJ the applied intensity was certainly painful in all volunteers. In 9 of 10 subjects the SP could bilaterally be evoked by painful laser stimuli. The onset latency was 46.9 ms, the duration 58.8 ms. In only one subject SP consisted of two separate periods. The electrical thresholds of detection were 1.3 mA, of early SP 9 mA, of late SP 4.7 mA, and of pain 11.6 mA. The onset latencies were 11.8 ms and 44.9 ms for electrically evoked SPs, respectively.

Comparing the latencies of laser and electrically evoked SP one has to consider the nociceptor activation time of about 40 ms. The adjusted latency of laser evoked SP agrees well with that of the electrically evoked early SP, but not late SP. The high electrical threshold of the early SP could point to a nociceptive origin as well. Supported by the Deutsche Forschungsgemeinschaft (Tr 236/6-1)

## PAIN MODULATION: ANATOMY AND PHYSIOLOGY—HIGHER CENTERS I

## 53.1

EFFECTS OF SEROTONIN RECEPTOR AGONISTS ON NEURAL ACTIVITY IN THE ROSTROVENTRAL MEDULLA (RVM). R. Vallabhapurapu, M. Dewberry, C.L. Thurston\*. Dept. Biomedical Sciences, Univ. South Alabama, Mobile, AL 36688.

I.v. administration of serotonin (5-HT) inhibits the tail flick (TF) reflex and produces triphasic effects on mean arterial pressure (MAP) and ON and OFF cell activity of the RVM. The current study compared the effects of i.v. administration of a 5-HT<sub>1</sub> receptor agonist (5-carboxyamidotryptamine maleate) and a 5-HT<sub>2</sub> receptor agonist (2 methyl 5-HT maleate) to the effects of 5-HT on TF latency, MAP, and ON and OFF cell activity in rats.

The 5-HT<sub>1</sub> receptor agonist produced a dose-dependent (0.1 - 40 nmole) decrease in MAP for 1-15 min that was tightly correlated to an increase in ON cell activity and a decrease in OFF cell activity. The greater doses produced a delayed increase in TF latency. The 5-HT<sub>2</sub> receptor agonist (10 - 720 nmole) produced a brief decrease in MAP (30-120 sec), a dose-dependent excitation of ON cells that lasted less than 30 sec, and inhibition of OFF cells that lasted up to 7 min at the greater doses. The 5-HT<sub>2</sub> receptor agonist also inhibited the TF reflex 10 sec after injection of the greater doses, similar to 5-HT. These data suggest that the inhibition of the TF reflex observed within 10 sec after 5-HT administration may involve activation of 5-HT<sub>2</sub> receptors. The 5-HT-induced decreases in MAP, excitation of ON cells, and/or inhibition of OFF cells may involve activation of 5-HT<sub>1</sub> and/or 5-HT<sub>2</sub> receptors. Further studies are underway to determine the effects of 5-HT<sub>2</sub> and 5-HT<sub>4</sub> receptor agonists on MAP and ON and OFF cell activity, and to determine the role of vagal afferents in any of the observed effects.

## 53.2

CHEMICAL STIMULATION OF THE ROSTRAL VENTROMEDIAL MEDULLA: ANALYSIS OF CONDITIONED PLACE AVOIDANCE AND STRESS HORMONE RELEASE. M.M. Morgan\*, P.K. Whitney, J.S. Boyer and A.M. Strack. Dept. of Psychology, Washington State University, Vancouver, WA 98686 and Dept. Physiology, UCSF, San Francisco, CA 94143, USA

Stimulation of the rostral ventromedial medulla (RVM) produces both antinociception and immobility. Because RVM stimulation reduces pain it is assumed to be rewarding. In contrast, because immobility is a defensive behavior it is assumed to be aversive. The objective of the present study was to determine if stimulation of the RVM is aversive by assessing conditioned place aversion and the release of stress hormones.

Male Sprague-Dawley rats were tested in one of two ways: 1) Conditioned Place Aversion—microinjection of kainic acid (40 pmol/0.2  $\mu$ l) and saline into the RVM were paired with different sides of a conditioning chamber over 4 days. On the fifth day, the rat was placed in the center of the conditioning box and the amount of time spent on each side was measured. 2) Stress Hormones—rats were decapitated 5 min after microinjection of kainic acid or saline into the RVM so that blood plasma could be collected and assayed for ACTH and corticosterone levels.

Following training, rats neither preferred nor avoided the side of the chamber paired with kainic acid microinjections. Likewise, there was no difference in ACTH (mean = 351 vs 362 pg/ml) or corticosterone levels (27 vs 31  $\mu$ g/dl) for rats receiving kainic acid and saline, respectively. As reported previously, locomotion was significantly reduced in rats receiving kainic acid compared to saline controls (mean of 6.6 vs 19.1 squares crossed in 30 s;  $t(42) = 5.62, p<.05$ ).

These data indicate that despite the production of immobility, activation of RVM neurons is not aversive. This is surprising given that the RVM and periaqueductal gray (PAG) are two parts of the same descending pathway, and stimulation of the dorsolateral PAG produces place aversion and an elevation in stress hormones. This investigation was supported in part by funds provided for medical and biological research by the State of Washington Initiative Measure No. 17.

## 53.3

IDENTIFICATION OF RAPHE MAGNUS NEURONS ACUTELY ISOLATED FROM DEVELOPING RAT MEDULLA. S. C. Nam, S. S. Cho, W. Lim and J. Kim. Dept. of Physiology, Chonnam University Medical School, Kwangju and Depts. of Anatomy and of Physiology & Biophysics, College of Medicine, Seoul National University, Seoul, Korea

The nucleus raphe magnus (NRM) is one of the major nuclei in the rostral medulla. It is known that neurons in the NRM are involved in the descending modulation of nociceptive processing from supraspinal levels. Cellular mechanisms in these neurons, however, are poorly understood. In this study, as a tool to study its cellular mechanism, we tried to identify NRM neurons acutely isolated from medial and ventral medulla at the level of facial nerve compared to those in postnatal rat medulla *in situ*. Immunohistochemical method using antibody against serotonin was used to identify NRM neurons because these neurons contain serotonin. Positively stained neurons with the antibody were observed *in situ* as well as in neurons isolated enzymatically and mechanically from medial and ventral medulla. A small number of neurons were immunostained and displayed either bipolar or multipolar neurites in both preparations. Viability of these neurons was also checked using electrophysiological method. High-threshold and low-threshold, voltage-activated calcium currents were recorded in the acutely isolated multipolar neurons. These results indicate that NRM neurons acutely isolated from postnatal rat medulla are intact and can be used for studying cellular mechanisms of their descending modulation of nociceptive processing.

## 53.4

INTRINSIC FIRING RHYTHM IN RAPHE MAGNUS. T.R. White and I.D. Hentall\*. University of Illinois College of Medicine, Rockford, IL 61107.

We explored the source and statistical structure of the roughly periodic activity found in nociceptively-inhibited raphe magnus cells. Techniques included cathodal excitation (artifact <1 ms) or anodal block via the extracellular recording microelectrode, and iontophoresis of clomipramine (a 5-HT re-uptake blocker). In pentobarbital-anesthetized rats (female, 250-300 g), spontaneous intervals ( $I$ ) were fitted to the standard gamma probability-density distribution,  $P(I) = \beta^{-\alpha} I^{\alpha-1} \exp(-I/\beta) / \Gamma(\alpha)$ .

Group means for estimates from 46 cells were 6.4 for unitless "delay" parameter  $\alpha$ , 31 ms for "rate" parameter  $\beta$ , 90 ms for the mode of  $I$  ( $= \alpha\beta$ ), and 147 ms for mean  $I$  ( $= \alpha\beta$ ). Correlation of adjacent intervals was weak but positive in most cells ( $p<0.05$ ); mean  $r$  was 0.072 in 15 cells with 4,000 spikes/cell.

Oscillation can be defined parametrically from the theoretical autocorrelation  $A(I)$  for gamma-distributed, serially uncorrelated, normalized ( $\beta=1$ ) intervals,  $A(I) = \exp(-I) \sum_{n=1}^{\infty} I^n / \Gamma(n)$

(summing over  $n = 1, 2, 3, \dots, \infty$ ). Multiple, evenly-spaced autocorrelogram peaks, to which intuitive definitions appeal, exist if  $\alpha > 2$ . A definition with acceptably conspicuous peaks is  $\alpha > 4$  (coefficient of variation  $= \alpha^{-0.5} < 0.5$ ).

Spike-triggered pulses at excitatory threshold (0.3 ms, -0.4 to -3.1  $\mu$ A), given about 50% out of firing phase, caused a mean wait until the next spike of 1.2 mean spontaneous intervals (13 cells). The comparable wait was 0.4 (6 cells) after anodal block timed to erase one expected spike (30-60 ms, 0.13 to 0.67  $\mu$ A). The post-block interval was fitted by a much lower  $\alpha$  (2.3, control 6.1), with  $\beta$  relatively unchanged (22 ms, control 27). Conversely, steady clomipramine (1 to 20 nA, 2 min, 7 cells) markedly altered  $\beta$  (376 ms, control 87), but not  $\alpha$  (4.6, control 4.9); buspirone (a 5-HT<sub>1A</sub> agonist) was similarly selective.

This resetting of the rhythm implies an "oscillator" intrinsic to the cell. We suggest that random excitatory input is low-pass filtered by dendritically released 5-HT, which inhibits the activated cell at its 5-HT<sub>1A</sub> autoreceptors.

## 53.5

INTERFERENCE WITH EXCITATORY AMINO ACID (EAA) TRANSMISSION WITHIN THE ROSTRAL VENTROMEDIAL MEDULLA (RVM): EFFECTS OF BLOCKING ON-CELL DISCHARGE. V. Tortorici\*, S. McGaraughty and M.M. Heinricher, Div. Neurosurgery, Oregon Health Sciences University, Portland, OR 97201.

Two classes of neurons with distinct responses to opioids have been identified in the RVM, a region with a well-documented role in nociceptive modulation. "Off-cells," activated by opioids, are likely to exert a net inhibitory effect on nociceptive processing. This activation is indirect, via disinhibition. "On-cells" are directly inhibited by opioids. This cell population thus provides a means through which opioids can gain access to the modulatory circuitry of the RVM, and it has been suggested that on-cells act as inhibitory interneurons within this region.

We have previously shown that EAA neurotransmission is crucial to the nociceptive reflex-related on-cell burst. The aim of the present study was to examine the consequences of blocking this input for neuronal interactions within RVM, and for nociceptive responsiveness, by infusing the non-selective EAA receptor antagonist kynurenate (1-2 nmol, 200-500 nl) into the RVM while recording activity of on-, off- and neutral cells in lightly anesthetized rats. Kynurenate infusions led to a significant decrease in on-cell firing, including suppression of the on-cell burst. Off-cells continued to pause. Tail flick latency was unaffected by kynurenate infusions.

That the on-cell burst is blocked without affecting the off-cell pause indicates that on-cells do not have an important role as inhibitory interneurons within the RVM. Moreover, under the conditions of these experiments, the role of this cell class in controlling ongoing nociceptive responses is not critical. Supported by grants from NIDA, the National Headache Foundation, and the Fogarty International Center (VT).

## 53.7

SPECTRAL ANALYSIS OF ARTERIAL BLOOD PRESSURE AND PONTOMEDULLARY RAPHE NEURONAL ACTIVITY IN THE ISOFLURANE-ANESTHETIZED RAT. C.G. Leung\* and P. Mason, Committee on Neurobiology and the Dept. of Pharmacological and Physiological Sciences, The University of Chicago, Chicago, IL 60637

In order to determine whether the discharge of neurons in the nucleus raphe magnus (RM) and adjacent nucleus reticularis magnocellularis (NRMC) reflects autonomic as well as nociceptive processes, spectral analyses were used to determine component frequencies common to both arterial blood pressure (abp) and the activity of RM/NRMC neurons in rats lightly anesthetized with isoflurane. The abp contained extremely low frequency (period length: 6.4-18.5 min) oscillations that have not previously been described in the rat. Oscillations of the same frequency were also found in the activity of several classes of RM/NRMC neurons. These oscillations corresponded to the alternating bursts of activity and periods of inactivity exhibited in the records of ON, OFF, and NEUTRAL cells or the rhythmic changes in REGULAR and SEROTONERGIC-LIKE cell activity. The discharge of all ON cells increased during periods of low abp, whereas the discharge of OFF cells and SEROTONERGIC-LIKE cells tended to increase during periods of high abp. In contrast, the discharge of NEUTRAL and REGULAR cells did not have a consistent relationship to abp. ON, OFF and SEROTONERGIC-LIKE cells may participate in the modulation of both autonomic and nociceptive processing. The role of NEUTRAL and REGULAR cells in both autonomic and nociceptive processing remains unclear. This research was supported by grants NS33984 & DA07861 (PM) & 1F31DA05698 (CGL).

## 53.9

EVIDENCE THAT THE ANTINOCCEPTION PRODUCED BY CARBACHOL IN THE NUCLEUS RAPHE MAGNUS IS MEDIATED BY NORADRENERGIC NEURONS IN THE A7 CATECHOLAMINE CELL GROUP. K. Nuseir\*, B.A. Heidenreich, and H.K. Proudfoot, Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60612.

Activation of neurons in the nucleus raphe magnus (NRM) produces antinociception that may be mediated in part by the activation of spinally-projecting noradrenergic neurons. Anatomical studies have demonstrated that neurons in the NRM project to noradrenergic neurons in the A7 catecholamine cell group that innervate the spinal cord dorsal horn, while pharmacological studies have demonstrated that stimulation of A7 neurons produces antinociception that can be reduced by intrathecal injection of  $\alpha$ -adrenoceptor antagonists. The present studies were designed to provide more direct evidence that activation of NRM neurons produces antinociception by activating noradrenergic neurons in the A7 cell group. NRM neurons were stimulated by microinjecting the cholinergic agonist carbachol (5  $\mu$ g) into sites in the ventromedial medulla of lightly anesthetized Sprague Dawley rats (Sasco). The antinociception produced by carbachol was assessed using the tail flick test. Microinjection of carbachol into sites in the NRM produced antinociception that lasted more than 60 min. However, the effects of carbachol were attenuated by microinjection of the local anesthetic tetracaine (10  $\mu$ g) into sites within the A7 cell group. Similar injections of tetracaine more than 500  $\mu$ m from A7 neurons, identified by tyrosine-hydroxylase immunoreactivity, did not alter the effect of carbachol. These results support the conclusion that the antinociception produced by activating neurons in the NRM is mediated by the subsequent activation of spinally-projecting noradrenergic neurons in the A7 cell group. Supported by PHS grant DA03980 from NIDA.

## 53.6

THE EFFECTS OF MORPHINE IN THE BASOLATERAL NUCLEUS OF THE AMYGDALA ON THE ON, OFF, AND NEUTRAL CELLS IN THE ROSTRAL VENTROMEDIAL MEDULLA OF ANESTHETIZED RATS. S. McGaraughty\* and M.M. Heinricher, Div. of Neurosurgery, Oregon Health Sciences University, Portland, OR, 97201.

The amygdala is implicated in fear-motivated defensive responses, one of which is hypoalgesia. Freezing and analgesia defensive responses require the periaqueductal grey (PAG), a site which has dense reciprocal connections with the amygdala. However, PAG-mediated antinociception occurs via the rostral ventromedial medulla (RVM), which has direct projections to the dorsal horn. Three classes of physiologically characterized neurons have been previously identified in the RVM. Morphine given systemically, in the PAG, or locally in the RVM activates OFF cells, inhibits ON cells and does not affect NEUTRAL cells. In order to show that hypoalgesia induced by intra-amygdaloid morphine involves RVM neurons, a microelectrode was placed in the RVM of lightly anesthetized rats to record the activity of ON, OFF, and NEUTRAL cells while morphine (10  $\mu$ g in 0.4  $\mu$ l) was infused bilaterally into the basolateral amygdala (BLA). Following the BLA morphine, tail flick latency increased significantly from baseline as did OFF cell activity; ON cell activity was depressed and NEUTRAL cells were unaffected. All effects were reversed by naloxone (0.4 mg/kg, iv). These results demonstrate that the infusion of morphine into the BLA causes hypoalgesia and recruits RVM ON and OFF cells in a similar manner to systemic, PAG, or locally administered opioids.

## 53.8

PHYSIOLOGICAL CHARACTERIZATION OF SEROTONERGIC CELLS IN THE PONTOMEDULLARY RAPHE AND RETICULAR FORMATION. Peggy Mason\*, Dept. of Pharmacological & Physiological Sciences and Committee on Neurobiology, University of Chicago, Chicago, IL 60637.

Although serotonin is an important neuromodulator of nociceptive, autonomic and motor processing in the spinal cord, little is known about the physiological characteristics of SEROTONERGIC neurons in the inferior raphe nuclei. After characterizing neurons by their responses to noxious stimulation and their unstimulated discharge pattern, 47 cells were intracellularly labeled with Neurobiotin in the lightly anesthetized rat; all labeled cells were tested for serotonin immunoreactivity. Labeled neurons were located in raphe magnus, pallidus and obscurus and in the adjacent ventral reticular nuclei. SEROTONERGIC cells discharged, without long pauses, at an average interspike interval of 738 ms with a range of 320 - 2039 ms. Most SEROTONERGIC cells were unaffected or slightly excited by pinch and unaffected by noxious heat. Non-serotonergic cells were physiologically heterogeneous and differed from SEROTONERGIC cells in that they 1) were consistently excited or inhibited by noxious heat; 2) had a "bursty" discharge pattern and/or 3) had a rapid discharge rate. A discriminant function was derived which allows for the identification of pontomedullary SEROTONERGIC neurons based solely on their unstimulated discharge characteristics. The physiological characteristics of pontomedullary SEROTONERGIC neurons suggest that these neurons 1) have state-dependent activity and 2) are not directly affected by opioid administration. This research was supported by grants DA07861 and NS33984 and the Brain Research Foundation.

## 53.10

RELATIONSHIP OF  $\mu$ -OPIOID RECEPTORS TO GABA-SYNTHESIZING NEURONS WITHIN THE PAG, RVM, AND SPINAL CORD. A. Kalyuzhny\* and M. Wessendorf, Dept Cell Biol & Neuroanat, Univ Minnesota, Minneapolis, MN 55455

In previous studies we have reported immunoreactivity for the cloned  $\mu$ -opioid receptor (MOR1) within the PAG, NRM, and spinal cord. Since activation of  $\mu$ -opioid receptors has been reported to affect the sizes of GABA-mediated synaptic potentials, we investigated the distribution of MOR1-staining in relation to neurons synthesizing GABA within these regions. To allow double-labeling immunocytochemistry, we combined MOR1 antiserum with monoclonal antibodies to either GABA or GAD. Secondary antibodies were donkey anti-rabbit IgG conjugated with cyanine 3.18 and donkey anti-mouse IgG conjugated with cyanine 5.18. In the midbrain, dense GAD-ir varicosities were observed in the caudal PAG. Both GABA-ir and MOR1-ir were observed in the area adjacent to the aqueduct, and the cells were intermingled. In the RVM and spinal cord dorsal horn, GAD-ir varicosities were found apposed MOR1-ir somata. In addition, MOR1-ir processes apposed many GABA-ir somata in the spinal cord. We conclude that  $\mu$ -opioid receptors have the potential to interact with GABAergic neurons at a number of sites relevant to the modulation of nociception.

Supported by NIDA grants DA 05466 and DA09642.

## 53.11

**ANALYSIS OF INTRINSIC RAT PERIAQUEDUCTAL GRAY NEURONS: MODULATION OF OPIOID PEPTIDE mRNA'S BY PERIPHERAL NEUROPATHY** E.G. Williams\* and A.J. Beitz  
Dept. of Pathobiology, University of Minnesota, 1988 Fitch Ave., St. Paul, MN 55108

Our previous studies in the rat periaqueductal gray (PAG) using an experimental model for neuropathic pain have demonstrated increases in the number of enkephalin-immunoreactive terminals, and increases in both cellular levels and frequencies of neurons expressing proenkephalin A mRNA. However, it was unknown whether the PAG neurons that respond to the nociceptive state have intrinsic connections, or whether they project outside the PAG. We previously demonstrated that local axon collaterals are rare, hence local circuit neurons can be identified to an acceptable probability by small, local injections of retrogradely-transported dyes. In the present study, we combined hybridization histochemistry of proenkephalin A mRNA with retrograde identification of intrinsic PAG neurons to learn how chronic nociception affected PAG-intrinsic neurons. Six days after loose ligation of the sciatic nerve with chromic gut suture, 30-50 nl of rhodamine-dextran was placed in the ventrolateral PAG. Ten days after ligation the animals were sacrificed and the brains were sectioned, fixed, alkylated and delipidated. 48-mer probes were end-labeled using biotin-16-dUTP and terminal transferase, hybridized using standard conditions, and then visualized using FITC avidin and epifluorescence microscopy. In the ventrolateral PAG, mononeuropathy increased by 63% per unit area the number of double-labeled neurons, i.e. local circuit neurons that contained proenkephalin A mRNA. This demonstrates that the "nociceptive-specific" region of the PAG contains enkephalinergic intrinsic neurons, and suggests that the intrinsic neurons are a significant source of the enkephalin participating in disinhibitory anti-nociceptive descending circuits. Supported by NIH grants NS 28016, DA 06687, and DE 06682.

## 53.13

**THE MEDIAL PREOPTIC NUCLEUS OF THE HYPOTHALAMUS (MPO) MODULATES ACTIVITY OF NITRIC OXIDE (NO) SENSITIVE NEURONS IN THE MIDBRAIN PERIAQUEDUCTAL GRAY (PAG)**  
Charles W. Hall, T.M. Da Costa Gomez, and M.M. Behbehani\*, Department of Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH 45267-0576.

Synaptic activities in the presence and absence of the NO donating compound sodium nitroprusside (SNP) were recorded in PAG slices using gramicidin perforated patch electrodes. SNP increased the number of synaptic events in 6 out of 9 cells. This response was attenuated in 4 of these 6 cells by glutamic acid receptor antagonists (CNQX and MK801). This experiment suggests that NO enhances the presynaptic release of glutamic acid in the PAG.

In chloral hydrate anesthetized rats, the characteristic depressor response elicited by MPO stimulation was attenuated by microinjection of the nitric oxide synthase (NOS) inhibitor *l*-*N*-nitro-*L*-arginine (NLA) into the dorsal PAG (2/2 rats). Furthermore, microinjection of NLA into the dorsal PAG independently produces increases in MAP (2/2 rats), while microinjection of SNP into the dorsal PAG produces a slight depressor response (1/1 rat). These experiments suggest that the depressor effect observed secondarily to MPO stimulation is due, at least in part, to NO-producing PAG neural circuits.

The effect of MPO stimulation on PAG neuronal firing activity was evaluated in the presence and absence of the NOS inhibitor 7-nitroindazole (7NI). Before the application of 7NI, 2 cells were inhibited, 1 cell was excited, and 1 cell did not respond to MPO stimulation. In the presence of 7NI however, MPO stimulation excited 1 cell that was previously inhibited, and the responses of the remaining cells to MPO stimulation were blocked. This final series of experiments confirms that the MPO alters the activity of NO responsive neurons in the PAG. (Supported by NIH grant # NS-20643).

## 53.15

**PARABRACHIAL AREA-INDUCED MODULATION OF CORNEAL-RESPONSIVE NEURONS IN TWO REGIONS OF THE SPINAL TRIGEMINAL NUCLEUS.** L.D. Meng\*, J.W. Hu, A.P. Benetti, and D.A. Bereiter, Depts. Neuroscience & Surgery, Brown Univ./RI Hospital, Providence, RI 02903 & Faculty of Dentistry, Univ. of Toronto, Ontario.

The aim of this study was to compare the inhibitory effects of PBA conditioning stimulation (CS) on electrically evoked A- and C-fiber input from characterized corneal-responsive neurons in two regions of the spinal trigeminal nucleus: the subnucleus interpolaris/caudalis transition region (Vi/Vc) and laminae I/II of the subnucleus caudalis/cervical cord transition region (Vc/C1). In chloralose anesthetized rats, Vi/Vc (40) and Vc/C1 (20) corneal-responsive neurons were functionally classified according to their cutaneous receptive field properties as either LTM, WDR, NS, deep (D) or cornea only (CO). At the Vi/Vc transition region, LTM (9), WDR (2), NS (1), D (3), and CO (25) neurons were studied, whereas at Vc/C1 all neurons were either WDR (11) or NS (9). Projections to PBA were determined, followed by testing the effect of PBA CS (20-40  $\mu$ A, 400 Hz, 0.1 ms pulse duration for 20 ms) delivered 50 ms prior to test stimulation (1.1-1.5 x T) of the cornea or cutaneous receptive field. No Vi/Vc and 15/20 Vc/C1 neurons projected to ipsi- or contralateral PBA (mean latency = 5.3 $\pm$ 5.7 ms). Inhibition of evoked responses (<75% of control) occurred in >70% of Vi/Vc and Vc/C1 neurons regardless of neuronal class. Facilitation was found in only 2 neurons. At the Vi/Vc transition region, no difference was found in the extent of A- and C-fiber inhibition (means of 16% and 18% of control, respectively). However, at the Vc/C1 transition region the A-fiber input was inhibited more than the C-fiber input (means of 32% and 65% of control, respectively;  $P < 0.05$ ). Also, PBA CS inhibited both A- and C-fiber evoked activity to Vi/Vc neurons more than to Vc/C1 neurons ( $P < 0.05$ ). Glutamate injections into PBA (500 nl, 200mM) inhibited both A- and C-fiber evoked responses, including those from Vc/C1 neurons in which electrical stimulation produced inhibition of only A-fiber responses. These results suggest unequal descending control of corneal input to Vi/Vc and laminae I/II of Vc/C1 by local excitation of PBA neurons. RIH funded.

## 53.12

**ACTIONS OF SEROTONIN ON IDENTIFIED NEURONES IN THE MIDBRAIN PERIAQUEDUCTAL GREY MATTER** V.V. Stezhka and T.A. Lovick (SPON: Brain Research Association)  
Dept. Physiology, Univ. Birmingham, Birmingham B15 2TT, U.K.

Recent evidence suggests that 5HT1A and 5HT2-mediated effects are involved in the antiaversive effect of serotonin in the periaqueductal grey matter (PAG) (Noguiera, R. and Graeff, F. Pharmacol. Biochem. Behav. 52 (1995) 1-6). We have therefore investigated the effects of serotonin and agonists at 5HT1A and 5HT2 receptors on neurones in the "defence area" of the PAG.

Whole cell patch recordings were made from 29 neurones in the dorsolateral PAG in coronal midbrain slices from 150-300g rats. In 14 cells (48%), close application of 5HT evoked depolarising responses of 4.3-17mV, mean duration 461.7 $\pm$ 46.9s, accompanied by a 8-109% increase in input resistance. These responses were mimicked by  $\alpha$ -methyl 5HT. In 10 cells (35%) hyperpolarising responses of 4.2-21mV, mean duration 250 $\pm$ 80.1s, were mimicked by 8-OH-DPAT. Five cells (17%) were unresponsive.

Morphological reconstructions of 9 cells filled with biocytin (7 depolarised by 5HT, 2 unresponsive) revealed round, triangular and fusiform-shaped somata, diameter 14-29 $\mu$ m with up to 5 varicose primary dendrites which arborised within the PAG. In 6 of the responsive cells, the axon coursed dorsally or dorsolaterally out of the PAG into the tegmentum or superior colliculus after giving off collaterals dorsally and ventrally in the PAG. The 2 unresponsive cells were bipolar fusiform cells with intrinsic axons.

These results suggest that 5HT can excite a population of projection neurones in the PAG via an action at 5HT2 receptors.

## 53.14

**SOMATIC AND VISCERAL INPUTS TO NEURONES IN THE ANTERIOR HYPOTHALAMUS WITH IDENTIFIED AFFERENT AND EFFERENT PROJECTIONS.** R.K. Snowball and B.M. Lumb, SPON: Brain Research Association. Dept. of Physiology, University of Bristol, Bristol, BS8 1TD, U.K.

Activation of neurones in the anterior hypothalamus (AH) can evoke antinociception and autonomic changes. Direct projections to the AH from nociceptive neurones in the spinal cord, and descending projections from AH neurones to the midbrain periaqueductal gray (PAG) and midline caudal medulla have been described. The aim of the present study was to determine whether descending systems originating in AH and relaying in the PAG and/or caudal medulla might be triggered by nociceptive inputs from the spinal cord.

Extracellular single unit recordings were made from neurones in the AH of 12  $\alpha$ -chloralose-anesthetised and paralysed rats. AH neurones were tested for their responses to noxious visceral and somatic stimuli. The central connections of the same AH neurones were determined by their responses to electrical stimulation in the spinal cord and in the PAG and midline caudal medulla, at physiologically-identified pressor and depressor sites. Of 36 AH neurones tested with the peripheral stimuli, 13 responded to visceral and/or somatic stimuli. Seven of these received excitatory inputs from the spinal cord and 5 of the 7 were driven orthodromically from the PAG and midline medulla. Of 9 AH neurones that were antidromically activated from the PAG and/or medulla, only 2 responded to peripheral stimuli and none responded to spinal cord stimulation.

These results do not support the idea of a simple 'loop system' since most of the AH neurones that responded to peripheral stimuli and spinal cord stimulation were driven orthodromically and not antidromically from the PAG and medulla. However, the data raise the possibility that the PAG and/or caudal medulla may act as relay sites in an ascending projection from the spinal cord to the AH.

Supported by the Wellcome Trust. RKS is a Medical Research Council scholar.

**ALTERATION IN OPIOID mRNA IN THE PARABRACHIAL NUCLEUS IN RESPONSE TO PERIPHERAL NOXIOUS INFLAMMATION.** L.L. Bellavance\*, F.G. Williams, M.F. Jacquin & A.J. Beitz, Neuroscience Program, University of Minnesota, St. Paul, MN 55108; Dept. of Neurology & the Center for the Study of Nervous System Injury, Washington University School of Medicine, St. Louis, MO 63110.

We have previously shown that Complete Freund's Adjuvant (CFA)-induced peripheral inflammation results in an increase in the number of cFos immunoreactive nuclei in the pontine parabrachial nucleus (PBN) of the rat. This increase in cFos-like immunoreactivity (cFos-LI) was restricted to the Kolliker-Fuse and lateral subdivisions of the PBN, regions associated with both nociception and antinociception. Further, we have also shown that the distributions of the endogenous opioid, enkephalin, and its two putative receptors, MOR and DOR, are localized in the same regions of the PBN that show an increase in cFos-LI in response to noxious peripheral inflammation. These data suggested to us that the PBN's involvement in noxious peripheral inflammation could include local and/or general opioid circuitry. As a result, it is possible that CFA-induced noxious inflammation may alter mRNA levels for opioids and their receptors in the PBN. We have recently started a study using *in situ* hybridization to help quantify mRNA levels for opioid ligands and receptors in the PBN in response to CFA-produced noxious peripheral inflammation. Preliminary data suggest that there is an alteration in mRNA levels for the endogenous opioid ligand, enkephalin, and its putative receptors, MOR and DOR, in specific subdivisions of the lateral PBN in response to noxious peripheral inflammation.

PHOSPHORYLATED CREB IN THE PARABRACHIAL NUCLEUS: RELATION TO PREPROENKEPHALIN mRNA EXPRESSION. O. Hermanson\* and A. Blomqvist, Dept Cell Biol., University of Linköping, S-581 85 Linköping, Sweden.

The rat parabrachial nucleus (PB) contains a very large number of preproenkephalin mRNA (ppENK)-expressing neurons. We have shown that the ppENK-expression in the Kölliker-Fuse subnucleus (K-F) increases after noxious stimulation. The promoter region of the ppENK gene contains an AP-1/CRE site named ENKCRE-2, which has been shown to be crucial for ppENK transcription. It has been suggested that FOS may interact with ppENK at ENKCRE-2, but the distribution of noxious-evoked FOS in PB is not coherent with the distribution of ppENK-expressing neurons (Hermanson & Blomqvist, J. Comp. Neurol., 1996). Recent studies have instead suggested that CREB may be the primary regulator of ppENK transcription at the ENKCRE-2 site. The transcriptional ability of CREB is dependent on phosphorylation at position Ser-133. We have investigated the immunoreactivity of phosphorylated CREB (pCREB) in PB after acute noxious stimulation.

Male Sprague-Dawley rats received a brief ether anesthesia, followed by an injection of 100 µl 5% formalin in one hindpaw. Thirty minutes after the injection, the rats were killed with an overdose of sodium pentobarbital, followed within three minutes by transcardial perfusion with 4% paraformaldehyde. The brain was cut at 20-40 µm on a freezing microtome. Brain stem sections were incubated in primary antibody (rabbit anti-pCREB, UBI, 1:1000) for 24 hours, and the immunoreactivity was visualized with standard PAP procedures.

Many neurons displayed pCREB immunoreactivity in PB. Large numbers of neurons were detected in the K-F, superior, central, internal, and ventral parabrachial subnuclei. Smaller numbers of labeled neurons were detected in the dorsal and external subnuclei. The present findings show that the distribution of pCREB-expressing neurons is largely coherent with the distribution of ppENK-neurons in PB. We are currently performing double-labeling with *in situ* hybridization for ppENK and immunohistochemical staining for pCREB or FOS after acute noxious stimulation.

## 53.19

MU OPIOIDS IN THE RVM CONTRIBUTE TO ANTINOCICEPTION FOLLOWING DAMGO STIMULATION OF THE AMYGDALA.

L. H. Poore\* & F. J. Helmstetter, Department of Psychology, University of Wisconsin-Milwaukee, Milwaukee, WI 53201

Hypoalgesia produced by environmental stressors involves a descending antinociceptive system that includes the amygdala, periaqueductal gray (PAG), and rostral ventromedial medulla (RVM). We have previously shown that injections of the *mu* opioid agonist DAMGO into the basolateral nucleus of the amygdala (BLA) will increase tail flick latency in rats and this effect can be blocked by injections of lidocaine in the PAG and RVM. Furthermore, we have been able to block the effects of DAMGO with injections of the *mu* opioid antagonist CTAP in the PAG. The purpose of the present study was to determine if CTAP injections in the RVM will prevent or reverse the effects of DAMGO injections in the BLA. Rats were anesthetized by constant i.v. infusion of a barbiturate anesthetic and steel guide cannulae were positioned over the BLA and RVM. Rats were also implanted with a femoral arterial catheter for measurement of blood pressure. Injections of CTAP (0.005 µg/4 µl) in the RVM made 10 minutes prior to the DAMGO (2 µg/µl - 25 µl/side) injection in the BLA attenuated the increase in tail flick latency. Moreover this effect was not reversed by RVM injections of the same dose of CTAP made 20 minutes after the DAMGO injection in BLA. Arterial pressure remained stable throughout the session. These results suggest that *mu* opioid receptors in the RVM are involved in hypoalgesia produced by amygdala *mu* opioid receptor stimulation. Supported by NIDA grant - DA09429.

## 53.18

FOREBRAIN ACTIVATION OF DESCENDING ANTINOCICEPTIVE SYSTEMS DEPENDS ON OPIOID AND NON - OPIOID MECHANISMS IN THE VENTRAL PERIAQUEDUCTAL GRAY. S. A. Tershner\* & F. J. Helmstetter, Department of Psychology, University of Wisconsin - Milwaukee, Milwaukee, WI 53201.

The presence of certain environmental stressors activates a descending antinociceptive system which includes the amygdala, periaqueductal gray (PAG) and rostral ventral medulla. We have previously shown that pretreatment with a *mu* opioid receptor antagonist into the ventral PAG attenuates tail flick (TF) inhibition produced by microinjection of a *mu* opioid agonist into the basolateral amygdala (BLA). Injections of an *epsilon* receptor antagonist into the ventral PAG was not effective. The purpose of this experiment was to further examine the role of opioid and non-opioid receptors in the ventral PAG in TF inhibition produced by *mu* receptor stimulation in the BLA. Rats maintained under constant barbiturate infusion were implanted with cannulae aimed at the BLA and ventrolateral PAG. Radiant heat TF latency was recorded at 2 minute intervals. As was previously shown, DAMGO (0.5 µg X 2) applied to the BLA produced a time dependent increase in TF latency. The administration of a *delta* opioid receptor antagonist, naltriben (12, 1.2, 4.0 µg), or a NMDA receptor antagonist, APV (0.3, .30, 3.0 µg), into the ventral PAG failed to block TF inhibition produced by amygdala stimulation. D-trp<sup>11</sup>-Neurotensin, at antagonist doses (4.0 and 16.0 pmol), attenuated TF inhibition when injected into the ventral PAG. These results suggest that forebrain modulation of nociceptive responses involves *mu* opioid and neurotensin receptors located in the ventral PAG.

## 53.20

ANTINOCICEPTIVE EFFECTS OF UNILATERAL INJECTIONS OF DAMGO IN THE RAT AMYGDALA. M.S. Shin\* & F.J. Helmstetter, Department of Psychology, University of Wisconsin-Milwaukee, Milwaukee, WI 53201

We have previously shown that activation of *mu* opioid receptors in the basolateral amygdala results in inhibition of the radiant heat tail flick (TF) reflex in barbiturate anesthetized rats [JPET 275:381]. While we have consistently found that the posterior part of the basolateral nucleus is the most effective region for antinociception produced by DAMGO, these studies typically use simultaneous bilateral injections and therefore a precise description of regional sensitivity within the amygdala has not been possible. Several recent studies have also suggested that the left versus right amygdala may not contribute equally to its various behavioral and physiological functions. In the present study rats were maintained under barbiturate anesthesia and prepared for microinjections and TF testing. After a series of baseline TF trials the *mu* agonist DAMGO (0.05 µg/0.25 µl) was infused into the right or left amygdala. TF testing continued at 2 min intervals for 40 min. While DAMGO significantly elevated TF latencies this effect was reliably larger when injections were made on the left side. In most cases, the largest effects were seen when injections were made in the posterior basolateral nucleus. These results replicate our previous mapping studies and indicate that the left and right amygdala may not be equally sensitive to DAMGO.

## PAIN MODULATION: ANATOMY AND PHYSIOLOGY—HIGHER CENTERS II

## 54.1

THE ELECTRIC STIMULATION OF THE CINGULUM BUNDLE ANTICIPATES THE ONSET OF AUTOTOMY INDUCED BY THE CHRONIC INFLAMMATION IN RAT. Pellicer, F.ª, López-Avila, A.ª Laboratorio de Neurofisiología, Instituto Mexicano de Psiquiatría, Facultad Mexicana de Medicina, Universidad La Salle. México D.F. Fax + 655 99 80

The evidence that the cingulum is related to emotional processing was established by Papez. Recently the cingulum cortex has been related to a neuronal network, "neuromatrix". The relevance of this concept has been focused on the possible mechanism of phantom limb and central pain. Experiments have achieved a delay or hindered autotomy, due to peripheral neuropathy or to a chronic inflammatory process. The purpose of this work was to reduce the autotomy behavior onset by electric stimulation of the cingulum bundle. Wistar rats were stereotactically implanted in the cingulum bundle for chronic stimulation. The experimental groups were: group 1 (n=5), implanted non-stimulated control; group 2 (n=4), implanted and stimulated 10 min. daily, for 7 days (100Hz for 1 s, every 5 s); group 3 (n=4), implanted and stimulated 2h daily, for 7 days (100Hz for 1 s, every 5 s). For the induction of inflammatory process carrageenan was injected in the paw (CAR. 250 µl at 1%), 2 or 3 days after the last stimulation day. The results show that autotomy behavior appeared 20% in group 1, after 5 days of injection of CAR; while 100% in groups 2 and 3, in the same period. Further in these two groups the autotomy was more severe. We concluded that is possible to facilitate the onset and intensity of the autotomy behavior by anterior cingulum bundle stimulation, previous to a noxious regional inflammatory process. IMP project 3230 for FP.

STIMULATION OF THE CINGULUM BUNDLE AND SURROUNDING CORTICAL TISSUE: EFFECT ON TONIC PAIN IN THE RAT. P.N. Fuchs\*, M. Balinsky and R. Melzack, McGill Univ., Dept. of Psychology, 1205 Dr. Penfield Ave., Montreal, PQ, Canada H3A 1B1.

Surgical lesions of the cingulum in humans decreases cancer pain and many forms of chronic pain. Similarly, a temporary block of the rat anterior cingulum bundle decreases formalin-pain and reduces autotomy following peripheral neurectomy. The present study examined changes in formalin-pain responses following stimulation of the cingulum bundle/surrounding cortical tissue (CB/CT) in the rat. Male Long-Evan rats were randomly assigned to one of four groups and the effect of stimulation the CB/CT 15-min prior to the formalin injection (Stimulation-15min, n=8; Surgery Control, n=10) and 20-min following the formalin injection (Stimulation+20min, n=10; Surgery Control, n=10) was explored. Stimulation consisted of 30 sec of 0.2 msec biphasic square-wave pulses separated by 0.2 msec delivered at a frequency of 50 Hz and a current level of 50 µA. The stimulation remained off for 30 sec and was then repeated, until five applications were delivered for a total of 2.5 min of brain stimulation over a 5-min period. Stimulation 15-min prior to the formalin injection significantly decreased pain responses during both the first (0-5 min) and second (20-60 min) period of the formalin test. Stimulation 20-min following formalin injection significantly decreased pain responses which persisted for the duration of the 35-min post-stimulation test period. The temporal pattern of analgesia following stimulation of the CB/CT is dramatically different from the short-duration analgesia following stimulation of other limbic and brainstem structures. Stimulation of the CB/CT may disrupt patterned activity in the limbic system, which is known to play an especially important role in the affective-motivational dimension of pain.

DORSAL HIPPOCAMPUS FIELD CA1 PYRAMIDAL CELL NOCICEPTIVE RESPONSES AND THEIR SEPTAL MODULATION. S. Khanna\*. Department of Physiology, National Uni. Singapore 119260.

Previously, we suggested that an acute noxious heat stimulus-induced depression of field CA1 pyramidal cell synaptic excitability is mediated via septal-hippocampal afferents. We have now recorded changes in field CA1 pyramidal cell neural activity to formalin injection, a model of persistent pain, and investigated the effect of medial septal region electrolytic lesion on CA1 nociceptive responses.

Extracellular recordings from field CA1 were made in urethane (1g/kg, i.p.) anaesthetized male rats. In comparison to an acute noxious heat stimulus, formalin (5%, 0.05ml sc) into right hind paw induced a persistent (a) increase in period of sinusoidal rhythmic theta field activity, (b) depression of pyramidal cell synaptic excitability, and (c) decrease in extracellular activity of majority of pyramidal cells (15/20) with only few excited (5/20). In medial septal region lesioned animals, a noxious stimulus failed to evoke a depression of pyramidal cell excitability or extracellular activity. Rather, noxious stimulation excited majority of pyramidal cells studied (8/10).

The evidence suggest that (a) formalin nociception evoke a selective excitation of a small proportion of CA1 pyramidal cell, and (b) septal-hippocampal afferents are involved in a noxious stimulus-induced field CA1 pyramidal cell suppression. (Supported by ARF research grant from NUS).

## 54.5

EFFECTS OF OSTEOPATHIC MANIPULATIVE TREATMENT (OMT) UPON PARASPINAL MUSCLES IN SUBJECTS WITH LOW BACK PAIN AND SOMATIC DYSFUNCTION (SD): A NEUROPHYSIOLOGICAL STUDY UTILIZING MAGNETICALLY INDUCED SOMATOSENSORY EVOKED POTENTIALS (SEPs) R.A. Sugerman,\*<sup>1</sup> Y. Zhu,<sup>2</sup> D.B. Hagie,<sup>3</sup> J.M. Jones,<sup>3</sup> A. Starr,<sup>2</sup> A. Cao,<sup>4</sup> Dept. of <sup>1</sup>Basic Sci. and <sup>3</sup>Osteop. Manipul. Med., COMP, Pomona, CA 91766 and <sup>2</sup>Dept. of Neurology, Univ. of CA-Irvine, Irvine, CA 92717, <sup>4</sup>California State Polytechnic University, Pomona, CA 91768.

We endeavored to determine whether SD in subjects with low back pain and muscle spasm is associated with abnormal muscle evoked potentials and whether OMT on these subjects can result in a quantifiable change in SEPs. Thirty-seven subjects were tested: 20 were classified as clinically abnormal, 12 normal, and 5 did not complete tests or were determined to be outside the physical criteria. A general health history was solicited with specific questions concerning their low back history and a pain location diagram. Subjects were examined osteopathically for positional asymmetry, low back Strain/Counter Strain tender points, level and degree of muscle spasm from which the level and degree of somatic dysfunction was determined. The specific lumbar vertebral level to be magnetically stimulated was chosen. These paraspinal muscles were stimulated at 30% of maximum output and at 3 Hz by a magnetic stimulator and SEPs were recorded by an EMG EP apparatus. Then, the subjects received OMT and were retested (within 30 minutes of the initial magnetic stimulation). Before OMT in abnormal subjects the early cortical components of their SEPs showed significantly prolonged latencies and decreased amplitudes. The principal effect of OMT on the cerebral potentials was to the latency and amplitude of the P30 parietal component. In these subjects, P30 cortical potentials were significantly decreased in their latencies and significantly increased in their amplitudes at  $P < 0.05$ . The latter components following the P30 were relatively less affected. Normal subjects showed no changes in SEPs. Therefore, OMT caused significant changes in SEPs in abnormal, but not normal, subjects. This work was supported by AOA Grant 93-01-375, COMP Intramural Grant 431-308, and Forty-First Medical Trustee Endowment.

## 54.7

HYPNOTIC INDUCTION AND SUGGESTION-RELATED CHANGES IN REGIONAL CEREBRAL BLOOD FLOW (rCBF) IN THE PRESENCE AND ABSENCE OF PAIN. G. H. Duncan\*, P. Rainville, D.D. Price, and M.C. Bushnell. Mont. Neurol. Instit. & Univ. Mont., Montreal, Canada H3C 3J7 and Med. Coll. Virginia, Richmond, VA 23298.

Numerous studies have demonstrated the effectiveness of hypnosis in producing analgesia. However, little is known about the cerebral mechanisms of this perceptual modulation. We report the effects of hypnotic induction and hypnotic suggestions of increased or decreased pain on rCBF.

Changes in rCBF were measured using bolus injections of  $H_2^{15}O$  and 3-D high-resolution PET. Four trained subjects received scans before and after hypnotic induction, with one hand immersed in 35°C (neutral) or 47°C (pain) water. Scans preceded by algic or analgesic suggestions were then taken in the pain condition. Global searches were conducted using statistical brain maps.

Hypnotic induction had no effect on subjects' ratings of pain intensity (Hypnosis: 70.0, Control: 67.5, n.s.) or unpleasantness (47.5 vs 50.0, n.s.). Significant hypnotic induction-related rCBF changes included bilateral increases in occipital cortices, and decreases along the medial wall of frontal and parietal cortices. This hypnotic induction effect was less pronounced in the painful (47°C) than in the neutral (35°C) condition. In contrast, both algic and analgesic suggestions produced significant increases in rCBF in medial and lateral frontal, and anterior insular cortices.

These findings show differential distribution of activation during hypnotic induction and suggestion. During induction, the large increases in occipital activation, reduced by pain, may reflect visualization strategies that were disrupted by the noxious stimulus. The strong frontal activation observed following hypnotic suggestions of both algia and analgesia could underlie increased attentional effort toward or away from the pain. This mechanism could regulate the observed modulation of the pain-related cerebral activation (Rainville et al, 1996). Supported by the Canadian MRC.

## 54.4

The Effects of Amitriptyline on Regional Cerebral Blood Flow in Rats With Painful Peripheral Mononeuropathy. Pamela E. Paulson,\* Thomas J. Morrow, Kenneth L. Casey. VAMC and Univ. of MI, Depts of Neurology, Ann Arbor, MI 48105.

Antidepressant drugs are commonly prescribed to relieve chronic pain in humans. Recently, amitriptyline has been shown to be effective in suppressing pain behaviors in an animal model of chronic pain. However, the mechanism by which amitriptyline reduces pain behaviors is unknown. We recently reported that rats exhibiting pain behaviors following chronic constriction injury to the sciatic nerve showed a significant increase in baseline (unstimulated) cerebral metabolic activation patterns compared to controls. The regions of greater activation were both somatosensory (hindlimb, somatosensory cortex and ventral posterior lateral thalamus) and limbic (anterior cingulate and retrosplenial cortices, anterior-dorsal thalamus, habenula, interpeduncular nucleus and the periventricular nucleus of the hypothalamus) regions of the brain. In the present experiment we measured amitriptyline-induced changes in baseline (unstimulated) regional cerebral blood flow in rats 12-15 days after unilateral ligation of the sciatic nerve. Regional cerebral blood flow was assessed thirty minutes after injection of amitriptyline (0.5 mg/kg, i.v.), using the technique recently developed in this lab. These experiments are in progress, results to be reported at the meeting.

This work is supported by grants from the Veteran's Administration.

## 54.6

SELECTIVE MODULATION OF PAIN UNPLEASANTNESS ALTERS ACTIVITY IN HUMAN CEREBRAL CORTEX. P. Rainville\*, G.H. Duncan, D.D. Price, and M.C. Bushnell. Montreal Neurological Institute and Univ. Montréal, Montreal, Canada H3C 3J7 and Med. Coll. Virginia, Richmond, VA 23298.

Painful stimuli activate a number of cortical regions in humans, including primary and secondary somatosensory cortices (SI, SII), anterior cingulate cortex (ACC), and insular cortex (IC). However, the role of each area in processing the sensory and affective dimensions of pain is unknown. This study examined activation within these cortical nociceptive pathways relative to a selective alteration of the affective dimension of pain by hypnotic suggestion.

Regional cerebral blood flow was measured with a 3-dimensional high-resolution PET scanner following bolus injections of  $H_2^{15}O$  in 4 subjects selected for their high hypnotic suggestibility. During each scan the subject's hand was immersed in either 47°C (pain) or 35°C (neutral) water. Data were collected with and without hypnotic induction, with and without suggestions of increased (↑UNP) or decreased unpleasantness (↓UNP). Statistical brain maps were derived, and directed searches were conducted of SI, SII, ACC and IC.

Subjects' ratings of unpleasantness varied according to the type of suggestion (↑UNP = 72.9, ↓UNP = 25.0,  $p < 0.001$ ), whereas their ratings of intensity were unaffected (69.6 vs 65.0, n.s.). When 47°C and 35°C scans were compared, significant activations were observed in contralateral SI, SII, ACC, and IC both with and without hypnotic induction. However, in all regions except SI cortex, rCBF increases were more significant during ↑UNP than during ↓UNP. A direct comparison of ↑UNP and ↓UNP suggestions during 47°C stimulation revealed greater activation in IC ( $p < 0.05$ ), with similar trends in all regions except SI.

These results suggest a differential role of various cortical regions in pain processing. Activation in insular cortex may be particularly important for generating emotional responses to pain, whereas that in SI may have the least direct relationship to unpleasantness.

Supported by the Canadian MRC.

## 54.8

CORTICAL AND SUBCORTICAL RESPONSES TO NOXIOUS HEAT DURING COUNTER-STIMULATION HYPOALGESIA IN HUMANS. K. L. Casey\*, S. Minoshima, P. Svensson, T. J. Morrow and K.A. Koepp. Neurology Research Lab., V.A. Med.Ctr., Ann Arbor, MI 48105; Div. Nuclear Medicine, Univ. Michigan, Ann Arbor, and Royal Dental College, Univ. Aarhus, Aarhus, Denmark.

A noxious somatic conditioning stimulus applied contralateral to a noxious test stimulus produces hypoalgesia of the test stimulus. To determine if this effect is mediated by brainstem suppression of spinothalamic transmission, we studied 13 right handed normal volunteers (1 female and 12 males; av. age 22 ± 2.6 yrs.) using positron emission tomography with  $H_2^{15}O$  to detect decreases in regional cerebral blood flow (rCBF). As expected, the perceived intensity of repetitive contact heat pain on the left hand was reduced from 82.6 to 71.2 (av. of 0-100 VAS, 70=pain threshold;  $p < 0.05$ ) when the right hand was placed in painfully cold (1°C), but not in neutral (31°C), water. Statistical image subtraction analysis and standardized stereotactic registration was used to identify structures activated during noxious (50°C), as compared to innocuous (40°C), stimulation during innocuous (31°C) contralateral conditioning. These volumes of interest were used for comparison with the rCBF responses during left hand heat pain conditioned by noxious (1°C) contralateral stimulation. Of the cortical regions responsive during heat pain with innocuous conditioning, the bilateral S2, right anterior cingulate, right insular, and left premotor cortices showed reduced heat pain rCBF responses during painful cold conditioning (64-30% relative decrease;  $p = 0.017-0.029$  by 2 tailed t-test, except insula:  $p = 0.10$ ). In contrast, the following subcortical structures showed increased heat pain rCBF responses during painful cold conditioning: left lenticular nucleus/lateral thalamus (49%,  $p = 0.05$ ), right VPL (24%, n.s.), and dorsal midbrain (22%, n.s.). These results suggest thalamic, rather than brainstem, gating of nociceptive cortical responses during counterirritant hypoalgesia in humans. Supported by a V.A. Merit Review Grant and D.O.E. Grant DE-FG02-87-ER60561.

## 55.1

**COLD PAIN SENSITIVITY IN ASYMPTOMATIC AND SYMPTOMATIC (NECK PAIN) FIGHTER PILOTS: DIFFERENT EFFECTS OF EXERCISE-INDUCED ANALGESIA.** P. Kemppainen\*<sup>1</sup>, O. Hämäläinen<sup>2</sup> and M. Könönen<sup>1</sup>. <sup>1</sup>Dept. of Prosthetic Dentistry, Univ. of Helsinki and <sup>2</sup>Air Force Academy, Kauhava, Finland.

The effect of physical exercise on cold pain sensitivity was studied in fighter pilots. The pilots were divided in two groups: one group consisted of asymptomatic pilots (n=6), and the other group consisted of pilots (n=4) suffering from acute in-flight neck pain attacks. Different levels of exercise (50-200 W) were produced by a cycle ergometer. Cold pain sensitivity was tested by using cold pressor test. The ratings of sensory intensity and unpleasantness during cold pressor tests were evaluated by visual analogue scales. In control conditions the average sensory and unpleasantness ratings did not show any differences between the two groups. Physical exercise increased pain thresholds in symptomatic ( $p < 0.001$ ; ANOVA, two-way) but not in asymptomatic pilot group. During exercise the sensory intensity and unpleasantness responses to suprathreshold stimulation were attenuated ( $p < 0.001$ ) in both of the pilot groups; this attenuation was more marked in symptomatic group ( $p < 0.05$ ). These results show that cold pain sensitivity between symptomatic and asymptomatic pilots was modified by physical exercise in a different manner. Our present findings suggest that there could be different pain modulatory mechanisms, or mechanisms act differentially, in healthy subjects than in subjects with various pain conditions.

## 55.3

**HYPERALGESIA TO HEAT AND MECHANICAL STIMULATION IN HUMAN SKIN INDUCED BY EXPERIMENTAL TISSUE ACIDOSIS.** K.H. Steen\*, U. Issberner & P.W. Reeh. Dept. Dermatology, Univ. Bonn, D-53105 Bonn; Dept. Physiology I, Univ. Erlangen - Nürnberg, D-91054 Erlangen, Germany.

Tissue acidosis of human skin due to intradermal pressure infusion of acidic phosphate buffer (pH 5.2) has been shown to induce sustained graded pain and sensitization to punctuate mechanical (von Frey) stimulation (Steen et al., 1993, Neurosci Lett 154: 113) which corresponds to pH-induced nociceptor excitation and sensitization in the rat skin nerve preparation, *in vitro* (Steen et al., 1992, J Neurosci 12: 86).

Thermal thresholds (heat pain, cold and warm sensation) were examined in the forearm (n=6) using the TSA 2001 (Medoc Ltd., Ramat Yishai, Israel) with a Peltier thermode (18 mm<sup>2</sup>). Touch and "pin prick" thresholds were determined with von Frey hairs. Infiltration of the skin with isotonic acidic phosphate buffer causing moderate pain (pH 5.2, duration: 1 h) produced reduction of heat pain thresholds by 3.5°C on average (46.3±0.9°C SEM resp. 42.8±1.8°C) significant after 15 min ( $p < 0.05$ , Wilcoxon test). This thermal hyperalgesia was still significant after 24 hrs ( $p < 0.03$ ). In comparison to the untreated forearm, heat pain thresholds became significantly lower after 45 min of continuous infiltration (46.7±0.8°C resp. 42.1°C±0.9°C,  $p < 0.05$ , U-test). As previously reported, the "pin prick" thresholds were significantly lowered after 30 min of low pH infusion (medians: 104.5 mN resp. 54.7 mN,  $p < 0.02$ ) and remained so for the rest of infusion period. Cold and warm threshold showed no significant differences in the pH-treated and untreated skin.

The results suggest that protons sensitize nociceptors as well for mechanical as for heat stimulation; the latter remains to be supported by primary afferent recordings. This work was supported by DFG grant Ste 593/1-3.

## 55.5

**SELECTIVE SUPPRESSION OF PAIN AND ITCH AFTER LOCAL STIMULATION OF CUTANEOUS C FIBRES**

Hans-Jörgen Nilsson, Anders Levinsson and Jens Schouenborg\*. Department of Physiology and Neuroscience, Lund University, Sölvegatan 19, S-223 62 Lund, Sweden.

**Aim:** The effect of local electrical stimulation on cutaneous C fibres, using a technique called Cutaneous Field Stimulation (CFS), on sensations of itch, cold, warmth and light touch, was analyzed in humans.

**Methods:** A silicon plate (60 cm<sup>2</sup>) containing multiple needle-like electrodes (n=16) was applied either to the right volar forearm or the dorsum of the right hand of healthy subjects. The electrodes were stimulated consecutively for 25 min. (each electrode 4 Hz, 1 ms, 0.8 mA). Transdermal iontophoresis of histamine dihydrochloride (1% in distilled water, 1 mA, 30 s) was performed to evoke itch lasting approx. 30 min. A CO<sub>2</sub>-laser was used to elicit heat pain. Von Frey monofilaments were used to determine thresholds for touch. Thermal sensations were elicited by applying a metal bar (cold: 22°C, warmth: 41°C) to the skin.

**Results:** CFS resulted in a pricking, slightly burning, sensation that faded rather quickly. In all subjects, a local flare reaction, lasting about 1 h, developed around the electrode sites, indicating an activation of nociceptive C fibres. Within the stimulated area, CFS induced a strong (usually complete) and long lasting (> 2 h) post-conditioning inhibition of itch (n=14). A selective block of A fibre transmission in the superficial radial nerve did not abolish this effect (n=3). The sensation of heat pain was depressed by CFS (n=3). By contrast, sensations of cold, warmth and light touch were only marginally affected by CFS (n=7).

**Conclusions:** CFS produces a selective and powerful inhibition of experimentally induced itch and pain. The results indicate that nociceptive C fibres have a crucial role in inducing this inhibition. Supported by Swedish MRC proj. no. 1013 and No. 10569, and the Medical Faculty of Lund.

## 55.2

**TOLERANCE TO ISCHEMIC PAIN IS REDUCED IN INDIVIDUALS WITH DEPRESSIVE SYMPTOMS.** L. Piñerua-Shuhaibar, H. Suarez-Roca, D. Prieto-Rincon, A. Ferrer, E. Bonilla\* and W. Maixner. INBIOMED and Inst. Invest. Clin. Univ. of Zulia, Maracaibo, POB 1151, Venezuela and Dental Res. Ctr., Univ. of North Carolina, Chapel Hill, NC 27599-7455.

Although there is an increased vulnerability to pain problems in patients with affective disorders, most experiments have paradoxically found a depressed patient to report reduced sensitivity (higher threshold) to brief phasic electrical and thermal noxious stimuli. In this study we have examined the responses to ischemic pain produced by a maximal effort tourniquet procedure, in 32 controls and 8 drug- and psychotherapy-free depressive individuals (Zung autoscale >49). Threshold was not altered in depressed patients ( $7.50 \pm 2.00$  min) vs. controls ( $7.48 \pm 0.76$  min). In contrast, tolerance was reduced in depressed patients ( $10.50 \pm 2.44$  min) vs. controls ( $16.63 \pm 1.09$  min). Sensory, affective and global verbal pain reports and cardiovascular responses during the experiments were similar for both groups. Depressed patients reported more intense post-ischemic paresthesias than controls. Anxiety levels were not related to ischemic measures of threshold and tolerance. This finding suggests that depressed patients are more sensitive to a sustained tonic painful stimulus. (Supported by FUNDACITE-Zulia)

**ALLOGENIC INTERACTIONS BETWEEN PROTONS AND BRADYKININ IN HUMAN SKIN.** U. Issberner\*, S. Haupts, P.W. Reeh & K.H. Steen. Dept. Dermatology, Univ. Bonn, D-53105 Bonn; Dept. Physiology I, Univ. Erlangen - Nürnberg, D-91054 Erlangen, Germany.

A combination of mediators mimicking the inflammatory exudate has previously been shown to potentiate the algogenic effect of low pH (Steen et al., 1996, Pain, in press). The present psychophysical studies focused on the interaction between bradykinin (BK;  $10^{-7}$ ,  $10^{-6}$  M) and low pH (pH 6.7 & 6.1), applying various protocols of intradermal injections at 10 min intervals (0.1 ml) into normal skin through previously placed canulas (27 G) in the palmar forearms of six volunteers. In another series of protocols, the injections were performed into skin which was continuously infiltrated with a phosphate buffered electrolyte solution using a motorized syringe pump that was adjusted so as to induce around 10 resp. 20% pain magnitude on a visual analog scale in case the solution was acidified (Steen & Reeh, 1993, Neurosci Lett 154: 113-16) and no pain when the solution was neutral (control). All experiments were done double-blind, cross-over and in randomized order.

We found no more than additive effects in respect to magnitude and duration of pain induced with both concentrations of BK and of hydrogen ions. An apparent though significant reduction in tachyphylaxis found with acidic BK solution can be explained by the perfect reproducibility of the dominant pH-contribution to the pain evoked. A prolongation of the BK effect observed in the acidic skin may be due to a pH-dependent block of degradation (block of kininase I).

BK alone does not seem responsible for the facilitation of pH-induced pain. However, BK effects are known to be amplified by PGs and by 5-HT. This provides further working hypotheses. DFG grant Ste 593/1-3

**A NON-SPECIFIC PAIN-RELIEVING REACTION AS A RESULT OF ADDITIONAL Na-IONS APPLICATION IN CHRONIC PAIN SYNDROMES.** V. Desnizze\*. Pain Research Group, Langestr. 40-42, 76530 Baden-Baden, Germany.

Modern medicine prefers to ignore that even minor injuries of different structures produce significant reactions in the extracellular matrix. Different "miracle" effects in routine and alternative medicine can be explained from the point of view of basic regulations theory (BRT) which helps to modify and use simple methods in chronic pain syndromes (CPS): usually the fact that 0.9% saline solution (SS) gives a pain-relieving effect (PRE) is ignored because the effect is short or is considered to be a placebo-effect (PE). The PRE duration is prolonged if 0.5 ml of SS is injected close to the nerve branches into the 24 paravertebral projecting points at C1-C7/L1-S1 levels 12 times. 115 patients with CPS: disc prolaps - 38, spondylosis - 29, rheumatoid arthritis - 48 were treated with SS and the results compared with 156 patients with natural history of the disease. Pain intensity (PI) was checked by Algometer (Somedic AB), Visual Analogue Scale and Pain Questionnaire. PI decreased in treated patients for 30-70% ( $p < 0.01$ ). PRE can't be attributed to PE, as it was seen in 50-60% of cases and lasted for 6-12 months ( $p < 0.05$ ). PI correlates with the decreased microcirculation (MC) checked by laser Doppler flowmeter ( $R = 0.4$ ;  $p < 0.05$ ). Restored MC with SS injections removes metabolic products that irritate nerves terminals and produce pain.

## 55.7

DEVELOPMENT OF BEHAVIORAL SIGNS OF NEUROPATHIC PAIN FOLLOWING INJURY TO DISTAL SCIATIC NERVE BRANCHES. B.H. Lee\*, E.J. Baik, E.J. Kim, S.H. Lee and C.H. Moon. Dept. of Physiology, School of Medicine, Ajou University, San 5, Wonchong-dong, Paldal-gu, Suwon 442-749, Korea.

Injury to a peripheral nerve may produce chronic pain syndrome. Recently we observed that selective injury of sciatic nerve branches can produce behavioral signs of neuropathic pain. This study was conducted to see changes in neuropathic pain syndrome after injury to the tibial and sural nerves. Male Sprague-Dawley rats were anesthetized with halothane. Neuropathic injury was induced by transecting the tibial and sural nerves, leaving the common peroneal nerve intact. Behavioral tests for mechanical and cold allodynia and spontaneous ongoing pain were performed on these rats for 20 weeks. All the rats showed severe behavioral signs of neuropathic pain. Mechanical and cold allodynia and spontaneous pain peaked at 2 weeks postoperatively and were gradually diminished over time after injury. At 20 weeks postoperatively, these rats still showed vivid cold allodynia and some rats showed mechanical allodynia and spontaneous pain. Autotomy was gradually developed on these rats. The results suggest that injury to the tibial and sural nerves induce severe neuropathic pain syndrome and this animal model may provide convenient and easy method to produce neuropathic pain. Sympathetic dependence of this model will be discussed. (Supported by KOSEF 961-0701-014-2).

## 55.9

THE RELATIONSHIP BETWEEN VAGINAL HYPERALGESIA AND VAGINAL TONE IN RATS. H.B. Bradshaw\* and K.J. Berkley. Program in Neuroscience, Florida State University, Tallahassee, FL 32306-1051.

Vaginal hyperalgesia (VAGH) in rats, as evidenced by increased escape responses to vaginal distension stimuli, occurs as a consequence of ovariectomy, natural reproductive senescence, and experimentally-induced endometriosis. This study tested the hypothesis that VAGH is associated with an increase in vaginal tone. Adult virgin rats ( $n = 9$ ) were trained to escape vaginal distension produced by inflation of latex balloons with water. The probabilities of escape responses evoked by different volumes of distension were then measured in different estrous stages before and after ovariectomy, natural reproductive senescence, or the induction of endometriosis (abdominal autotransplantation of small pieces of endometrium). Vaginal tone was calculated from the pressures produced by the different distension volumes. Although VAGH was evident in all three conditions, vaginal tone failed to increase beyond levels observed in normal, estrous-cycling rats. This dissociation between escape behavior and vaginal tone is similar to earlier findings showing that escape responses in normal cycling rats do not vary predictably with the estrous variations that occur in vaginal tone. Together, the results suggest that the neural mechanisms that regulate vaginal tone differ from those that regulate vaginal behavioral sensitivity. Supported by NIH-RO1 NS 11892.

## 55.11

Differential effects of intraoral sucrose and suckling on forepaw and hindpaw nociceptive responses in 10-day-old rats. K.Ren\*, O-q. Zhou, E.M. Blass\* and R. Dubner. Dept. OCBs, University of Maryland Dental School, Baltimore, MD 21201; \*Dept. Psychology, Cornell University, Ithaca, NY 14853.

Sucrose and suckling produce calming and antinociceptive effects in infant rats. This model system was adapted to study the development of endogenous pain-modulating systems. Litters of 10-day-old Sprague-Dawley rats were tested for paw withdrawal latencies (PWL) to a heated brass thermal probe (48°C) or a non-heated probe (30°C). Paw inflammation was induced by s.c. injection of 0.01 ml of complete Freund's adjuvant (CFA, 1:1). Compared to naive rats, there were significant decreases in PWLs to both 48°C and 30°C stimuli 4 h following the injection of CFA, suggesting the development of thermal hyperalgesia and mechanical allodynia. In rats that were allowed to suckle their mother and received intraoral sucrose infusion (7.5%, 0.06 ml/h) during behavioral testing, the PWLs of the forepaw to the 48°C probe were significantly increased from  $13.1 \pm 2.7$  to  $28.7 \pm 3.4$  sec ( $n=13$ , naive rats,  $P < 0.001$ ) and from  $4.8 \pm 1.7$  to  $21.5 \pm 3.8$  sec ( $n=8$ , forepaw inflamed,  $P < 0.001$ ); the PWLs of the forepaw to the 30°C probe were also increased significantly from  $27.9 \pm 4.3$  and  $12.8 \pm 4.0$  sec to  $54.8 \pm 8.7$  and  $28.5 \pm 7.6$  sec for naive ( $P < 0.01$ ) and forepaw inflamed ( $P < 0.05$ ) rats, respectively. In contrast, intraoral sucrose and suckling produced no significant effects on PWLs of the hindpaws in naive and hindpaw inflamed rats. Intraoral saline infusion did not produce significant changes in PWLs in limbs in naive 10-day-old rats. CFA-induced Fos-protein immunoreactivity, a marker of neuronal activation, was also significantly reduced in the spinal dorsal horn (C7-8) by infusion of sucrose and suckling in forepaw inflamed rats, suggesting that the antinociceptive effects of sucrose and suckling were mediated via descending effects at the spinal level. These results demonstrate the development of inflammatory pain and hyperalgesia in newborn rats, a differential maturation of descending control systems to forepaw and hindpaw in 10-day-old rats, and a spinal basis for suckling-induced antinociception. Supported by NIH grants DA10275 (R.D.), HD28245 (E.M.B.) and MH00524 (E.M.B.).

## 55.8

LOW DOSES OF THYMULIN INJECTION IN THE HINDPAW OF RATS CAUSES LOCALIZED HYPERALGESIA. B. Safieh-Garabedian\*, S.A. Kanaan, S.J. Jabbur, S.F. Atweh and N.E. Saade. Fac. of Arts and Sci. and Fac. of Med., American Univ. of Beirut, Lebanon.

We have recently demonstrated that localized inflammatory hyperalgesia induced by intraplantar injection of endotoxin in rats can be significantly reduced by intraperitoneal injection of thymulin, in high doses (Safieh-Garabedian et al., *Brain Res.* in Press). We now report that intraplantar injection of thymulin, in low doses, produces localized hyperalgesia in rats.

A group of rats were subjected to paw pressure (PP), hot plate (HP) and tail flick (TF) tests for 3 days before (to determine baseline values) and at 3h, 6h, 12h and 24h after intraplantar injection of thymulin (5ng/50µl of saline) in the left hindpaws. Another group of rats received the saline vehicle (50µl) injections as controls.

Following thymulin injection, a significant reduction in both PP and HP latencies appeared after 3h, peaked (40-50% reduction in nociceptive thresholds) after 6h and recovered completely after 24h. No significant effects were observed in the PP test of the opposite right paw or in the TF test and the effects of thymulin injection were antagonized by i.p. injections of either dexamethasone (0.2mg/kg) or indomethacin (4mg/kg). Saline injections had no effects.

We suggest that low doses of thymulin, known to activate immune inflammatory reactions, can produce hyperalgesia through cytokine or prostaglandin dependent mechanisms.

## 55.10

MEASURING SOCIAL INTERACTIONS TO ASSESS PAIN AND ILLNESS IN FEMALE RATS. K.J. Berkley\*, M.L. Torlone and H.B. Bradshaw. Program in Neuroscience, Florida State University, Tallahassee, FL 32306-1051.

Animal models for chronic pain conditions such as endometriosis, gastrointestinal disorders, headaches, backaches and so forth are needed. They are lacking in part because we do not have a way to measure pain under conditions in which the eliciting circumstances are not obvious (i.e., during conditions of endogenous pain). Currently, the main indicators that an animal has chronic pain include large changes in its usual daily behaviors such as eating, sleeping, weight, grooming and overall activity. Such changes are likely to occur, however, only when the pain conditions are extreme. Given that humans often change their social interactions when they have endogenous pains, one way to index such pains in animals might be to assess their social behaviors. Accordingly, we developed a procedure to quantify an experimental female rat's normal social behaviors and tested in a few pilot cases how those behaviors changed under various conditions. Making use of the fact that rats in their natural environment are huddling animals who spend much of their active phase touching and grooming each other, or, depending on the female's estrous stage, mating, the procedure we developed involves measuring the percent time during a standard daily test period an experimental rat spends (a) alone, (b) in close proximity with a ovariectomized female rat or (c) in close proximity with a vasectomized male rat. The percentage pattern (i.e., % time alone, with female or with male) varied with the experimental female's reproductive condition (estrous stage; senescence;  $n=4$ ), and changed under conditions of pathology ( $n=3$ ). These results suggest that this method might be of value for future studies on neural mechanisms of pain and other illness behaviors associated with various disease states. Supported by NIH-RO1 NS 11892 and the Earth Trust Foundation.

## 55.12

INTERLEUKIN-6 KNOCK-OUT (IL-6 KO) MICE EXHIBIT ENHANCED BASAL NOCICEPTION AND NEUROPATHIC PAIN-RELATED BEHAVIOR, BUT HAVE REDUCED INFLAMMATORY REACTION COMPARED TO WILD TYPE (WT) MICE. Z. Wiesenfeld-Hallin<sup>1</sup>\*, X.-J. Xu<sup>1</sup>, J.-X. Hao<sup>1</sup>, S. Andell-Jonsson<sup>2</sup>, V. Poli<sup>3</sup>, and T. Bartfai<sup>2</sup>, <sup>1</sup>Karolinska Institute, Dept. Clin. Neurophysiol., 141 86 Huddinge, <sup>2</sup>Stockholm Univ., Dept. Neurochem. Neurotoxicol., 106 91 Stockholm, Sweden, <sup>3</sup>Inst. Ricerche Biol. Molec., Rome, Italy

IL-6 is a multifunctional cytokine which is rapidly induced under certain pathological and inflammatory conditions. IL-6 has been implicated in nociceptive modulation in the periphery and the CNS in a complex and sometimes contradictory manner. Thus, it has been reported that peripheral administration of agents neutralizing the actions of IL-6 reduce inflammatory hyperalgesia. In contrast, it has also been suggested that local administration of IL-6 elicits antinociception and is an important mediator for the peripheral analgesic action of opioids.

We have assessed the nociceptive threshold to cutaneous mechanical and thermal stimulation, the effect of unilateral sciatic nerve section and the development of inflammation and hyperalgesia after subcutaneous carrageenan in IL-6 KO and WT mice. The IL-6 KO mice had lower response threshold to both mechanical and thermal stimulation. After nerve section female IL-6 KOs autotomized more than male IL-6 KOs and both male and female WT. In contrast, both IL-6 KO and WT mice developed hyperalgesia to mechanical and thermal stimulation after carrageenan, but the hyperalgesia was less in IL-6 KO than in WT. The IL-6 KO also exhibited less plasma extravasation after carrageenan than the WT. Thus, IL-6 deficiency has a complex effect, with increased basal nociceptive sensitivity, increased neuropathic pain probably involving the endocrine system and reduced peripheral inflammation.

**BEHAVIORAL RESPONSES TO NOCICEPTIVE AND NON-NOCICEPTIVE STIMULI IN GLUR2 KNOCK OUT MICE.** M.W. Salter\*, G.J. Keil II, Z. Jia, W. Abramow-Newerly, J. Roda. Div Neurosci, Hospital for Sick Children and Dept Physiol, Univ of Toronto, and Samuel Lunenfeld Research Inst, Mount Sinai Hospital, Toronto, Ontario.

Nociceptive (pain) and non-nociceptive neurotransmission is primarily mediated by glutamate actions at AMPA receptors. The majority of AMPA receptors are impermeant to  $Ca^{2+}$ , but channels lacking the GluR2 subunit have greatly increased  $Ca^{2+}$  permeability. Processes which involve actions of excitatory amino acids at AMPA receptors, therefore, might involve  $Ca^{2+}$ -permeable and -impermeable AMPA receptors. To investigate if GluR2 subunits might be involved in sensory neurotransmission, we have investigated the behavioral responses of mutant mice lacking the GluR2 subunit (Jia et al, *submitted*) to various peripheral stimuli. Behaviors of wild type (+/+) and heterozygous (+/-) (n=10) or homozygous (-/-) (n=9) mice were evaluated in nociceptive (cold: 4°C and hot: 55°C) and non-nociceptive (warm: 40°C) thermal (tail withdrawal), non-nociceptive mechanical (von Frey hair), and nociceptive chemical (intraplantar formalin) assays. Tail withdrawal latencies to all thermal stimuli were not significantly different for mutant mice. Behavioral responses to von Frey hairs presented in two different paradigms indicated mutant mice were significantly more sensitive to mechanical stimuli. In addition, a novel biting and scratching response was seen in mutant mice with von Frey hair strengths which did not induce any behavior in wild type mice. Lastly, mutant mice responded to intraplantar formalin (10µL, 1%) significantly different than wild type mice in terms of the number of paw shakes, and licking or lifting time. The present studies were conducted to investigate if behaviors to various peripheral stimuli are altered in mutant mice lacking the GluR2 subunit. Mutant mice responded to thermal stimuli similarly to wild type mice. The biting and scratching response in mutant mice to von Frey hair stimulation, similar to mechanical allodynia, indicates altered sensory perception or transmission of this type of peripheral stimuli. Additionally, altered responses to intraplantar formalin suggests the GluR2 subunit might be necessary for the normal development and/or expression of behavioral responses to certain types of sensory stimuli. ## 55.15

**Strain, Load and Frequency as Indices of Nociceptor Sensitization in the Temporomandibular Joint.** Cooper\*, B., Friedman, R.M. and B. Loughner, Dept. of OMFS, University of Florida, Gainesville, USA.

Recent studies have placed an increased emphasis on the contribution of the CNS to the development of allodynia and hyperalgesia. This trend has been reinforced by a failure to observe substantial sensitization of mechanical nociceptive afferents when quantified methods are used. However, minimal quantification of stimulus and response variables have made it difficult to accept these reports as definitive. In the present study, we used computer controlled joint translation and systematic evaluation of soft tissue biomechanics to examine the changes in reactivity produced by prostaglandins of the E series. Recordings were made from the trigeminal ganglion of sixteen nociceptors (10 group III, 6 group IV) that innervated the soft tissue of the temporomandibular joint (TM) of the goat. Prostaglandins (PGE<sub>1</sub>, PGE<sub>2</sub>) or vehicle (VEH) were introduced into the capsule (50 µl, 2.8 mM) and reactivity was reexamined at early and late post-injection intervals (5-10 and 30-60 minutes). TM nociceptors transduced jaw rotations well beyond the normal range of motion (mean transduction range: 10.5 (+/- 1.11) to 24.1 (+/- 0.69) deg). Either PGs or repeated testing of nociceptors with intense stimuli was sufficient to produce substantial (and significant) decreases in mean load and strain reactivity at the 30 minute post injection interval (-0.43 +/- 0.09 N vs -0.41 +/- 0.21 N and -8.63 +/- 1.97 % vs -6.58 +/- 1.76 % strain for PG and VEH, respectively). In contrast, PGs significantly increased the average rate of discharge over the same strain and load ranges relative to VEH treated cases (97.2 +/- 55.2 % PGE vs -1.6 +/- 15.6 % in VEH treated cases; U=3, n=7,4; p<.042). We conclude that substantial changes in response properties can be observed in mechanical nociceptors when the complete range of transduction is determined, quantified stimuli are used, and frequency rather than threshold is the index of sensitization. **THE NEURAL MECHANISMS OF AUTOTOMY FOLLOWING BRACHIAL PLEXUS TRANSECTION IN RATS.** S. D. Wang\*, C. H. Cheng, S. T. Ho and J. C. Liu. Depts. of Biology & Anatomy, and Anesthesiology, National Defense Medical Center, Taipei, Taiwan, ROC.

Peripheral neurectomy in the rat usually induces a self-mutilation behavior, named autotomy, directed against the denervated regions. The early reports described the autotomy and supported this behavior as an experience of parathesia and/or pain in animals akin to the deafferentation pain in humans. Deafferentation pain is a chronic pain condition which mechanisms are still unknown. However, the sensory afferent and sympathetic components have been suggested as the mechanisms of deafferentation pain. In this study, we examine the sensory afferent and sympathetic nerve system with relationship to the autotomy following brachial plexus transection (BPT) in rats. Sprague-Dawley rats were undergone BPT, and then with dorsal and /or ventral rhizotomy, or with stellate ganglionectomy (StG). The autotomy behavior was observed daily for 8 weeks postoperatively. In the BPT with dorsal and ventral rhizotomy animals, autotomy behavior was significantly reduced. In BPT with StG rats, however, there is no difference of the onset time, severity and the incidence of severe autotomy in comparison with the BPT only animals. Therefore, we suggest the sensory afferent may contribute to the development of autotomy but not the sympathetic nervous system following BPT in rats. (Supported by NSC-84-2331-B016-024, ROC)

## 55.14

**OPTIMAL WEIGHTINGS OF PAIN BEHAVIORS IN THE FORMALIN TEST IN RATS.** K. J. Sufka<sup>1,2\*</sup>, G. S. Watson<sup>1</sup>, & T. J. Coderre<sup>3</sup>. Depts. of Psychology<sup>1</sup> & Pharmacology<sup>2</sup>, The University of Mississippi, Oxford, MS 38677, Clinical Research Institute of Montreal<sup>3</sup>, Montreal PQ H2W 1R7, Canada.

Coderre and colleagues (*Pain*, 54 (1993) 43-50) demonstrated the validity of the weighted scores technique (WST) of the formalin test by assessing the ordinality of behavioral categories associated with specific category weights. The present study sought to extend these findings by providing optimal weightings for these behavioral categories. Formalin concentration and morphine dose data from Coderre's study were submitted to Discriminant Function Analyses (DFA) and Multiple Regression Analyses (MRA). These weightings are summarized below.

Study	Analyses	Category 1	Category 2	Category 3
Formalin	DFA	0.0	0.8	0.6
	MRA	0.0	0.3	0.6
Morphine	DFA	0.1	0.4	0.9
	MRA	0.0	0.3	0.6

DFA and MRA weights were used to calculate composite pain scores (CPS), which were correlated with CPS derived by the WST. Formalin concentration and morphine dose were correlated with DFA-, MRA-, and WST-derived CPS. CPS intercorrelations for formalin data ranged from 0.95 to 0.98, and concentration-CPS correlations ranged from 0.77 to 0.82. CPS intercorrelations for morphine data ranged from 0.98 to 0.99, and dose-CPS correlations ranged from -0.83 to -0.85. These results suggest that formalin CPS can be accurately derived from categories 2 and 3 with weightings of 0.3 and 0.6, respectively.

## 55.16

**SHOCK-INDUCED HYPERALGESIA IN RATS.** T.E. King\*, R.L. Joynes, M.W. Meagher, J.W. Grau. Dept. of Psychology, Texas A&M University, College Station, TX 77843.

Exposure to a few moderately intense (1 mA) tailshocks has opposite effects on two measures of pain reactivity in rats. Tail-withdrawal to radiant heat is inhibited (hypoalgesia) while vocalization thresholds are lowered (hyperalgesia) to both heat and shock (King et al., *J. Exp. Psychol.: Anim. Beh. Proc.*, 22, 1996). Prior work indicates that hyperalgesia represents an unconditioned response and enhances the acquisition of both conditioned freezing and an avoidance response to thermal pain. The present experiments further explore the behavioral properties of hyperalgesia and the underlying neural mechanisms.

We have shown that hypoalgesia is limited to the distal region of the tail (Prentice et al., *Behav. Neurosci.*, 110, 1996). Experiment 1 shows that rats exhibit hyperalgesia irrespective of where the test stimulus is applied. Experiment 2 examined the shock conditions needed to induce hypo- & hyperalgesia. Exposure to 0.3 mA, but not 0.1 mA, tailshocks elicited both behavioral effects. Evidence indicates that the hypoalgesia is eliminated by both pentobarbital anesthesia and decerebration. Experiments 3 and 4 show that these manipulations also eliminate shock-induced hyperalgesia. Administration of a benzodiazepine (chlordiazepoxide) also attenuated the hyperalgesia. Results from additional pharmacological/physiological manipulations will be reported. Supported by MH48994 to J.W.G.

**EFFECTS OF STIMULATION PARAMETERS ON THE PLASTICITY OF FLEXION WITHDRAWAL REFLEXES IN THE SPINALIZED RAT.**

C.L. Cleland\*, J. Minette-Foré and G.F. Gebhart. Departments of Physiology and Biophysics, and Pharmacology, Univ. of Iowa, Iowa City, IA 52242

Hyperalgesia arises from both peripheral mechanisms and central plasticity. Although contributions from peripheral mechanisms and central chemical mediators have been partially clarified, the location and nature of the central plasticity remains obscure. The goal of this study was to investigate the necessary and sufficient stimulus conditions for expression of hyperreflexia in a rat model of hyperalgesia.

Rats were anesthetized with pentobarbital (45 mg/kg), their spinal cords were transected at T8-T9 and an electrode was implanted around the sciatic nerve. The following day, flexion withdrawal reflexes were evoked by stimulation of the sciatic nerve at either C (2-10 mA) or Aβ (200-400 µA) strength and measured by percutaneously recorded EMG in the knee flexor muscles. Hyperreflexia was induced by brief trains of electrical stimulation delivered to the sciatic nerve at C-fiber strength (2-20 mA).

Repetitive stimulation of the sciatic nerve induced long-lasting (>9 hours) and pronounced (>300%) increases in the magnitude of the flexion withdrawal reflex. Reflexes evoked by Aβ and C fiber stimulation were both enhanced, although the size and duration of C-fiber evoked reflexes were greater than for Aβ-fiber evoked reflexes. Systematic variation in the frequency (0.1-4 Hz), duration (250 ms-160 s) and number of stimuli (1-160) revealed that increases in duration and number monotonically enhanced the magnitude and duration of reflex enhancement, without reaching a plateau. In contrast, changes in frequency (10 stimuli) revealed an optimum (1 Hz), with greater or lesser frequencies causing less reflex enhancement.

TEMPORAL EFFECTS OF PRIOR STIMULATION ON LATER BLOCKING OF SPINAL FIXATION IN RATS. M.M. Patterson\*, T. Knewson UHS College of Osteopathic Med., 2105 Independence Blvd., Kansas City, MO 64124-2395.

Stimulation of an anesthetized rat's hind leg for over 35 minutes with an electric stimulus can induce a long-term alteration in the spinal flexion reflex known as *spinal fixation*. The altered excitability has been shown to last for days, and is a central sensitization of the spinal reflex circuit. Recently, we reported an effect which seems contradictory to the fixation paradigm (Patterson, et al. SNS Abstracts, 1995). Rats given a fairly low level of stimulation on day 1, followed by a fixating stimulation on day 2 or 3 showed less fixation after the second session than if they had been given only the second session. This apparent blocking of the fixation effect by the first session was seen over several stimulus parameters, and intervals.

The present studies were designed to look at the effects of longer times between sessions and of spinalization on the blocking process. In the first study, animals were anesthetized and received 40 min. of 1.5 ma. stimulation to the right hind leg. The retained flexion averaged 8.1 g. after the first session. The animals were allowed to awaken and 4 days later reanesthetized, spinalized, and given 40 min. of 2.5 ma. stimulation. Retained flexion was 5.3 g. A second group received the same treatment but with 6 days between sessions. The retained flexion was 7.6 and 6.3 g respectively. These studies show less severe blocking with the spinalization, and less with the longer time between sessions, when compared with earlier studies. The blocking effect seems to decrease with time and to be affected by spinalization.

NOCIFENSIVE FOOT-LIFT RESPONSE TO RADIANT HEAT IN THE LAND SNAIL (*HELIX ADSPERSA*): EFFECTS OF INTER-TEST INTERVAL AND NALOXONE J.J. Quinn, R.A. Wheeler, R.J. Brennan, A.E. Baldwin, & J.T. Cannon\*. Department of Psychology and Neuroscience Program, University of Scranton, Scranton, PA 18510-4396.

The foot-lift response to contact heat and the tail-flick response to radiant heat are two of the most widely used indices of nociception in rodents. Recently, Kavaliers and colleagues demonstrated the utility of examining the nociceptive foot-lift response to contact heat in the land snail. We have sought to establish an analog to the rodent tail-flick test in which radiant heat can be repeatedly applied to elicit a reliable withdrawal response in the land snail (*Helix adpersa*). Here, we examined the effects of test interval and naloxone on this response.

Forty-eight snails were group housed, fed *ad libitum*, and tested under red light during the dark phase of a 12/12 hour light/dark cycle. Animals (8/group) were randomly assigned to 30 min of testing at either 2 or 10 min inter-test intervals and received either: no injection, 2µL of physiological molluscan saline, or 1.0µg of naloxone in 2µL of molluscan saline. Animals were hydrated for 15 min prior to testing and injections took place after 5 min of hydration.

For behavioral testing, snails were gently restrained by a vacuum applied to the dorsal shell. They were placed on a movable sheet of transparency film which allowed for relatively unrestricted locomotion. Heat was applied through a 1.6 mm diameter hole at three locations on the caudal half of the foot: 2 mm rostral to the tip, and bilaterally 2 mm medial to the lateral edges of the foot 1 cm from the tip. The heat source was adjusted to elicit lifts with latencies of 2.5-3.5 sec.

ANOVA revealed no significant differences between uninjected and saline animals and these data were collapsed for subsequent analyses. ANOVA revealed that animals tested at 10 min intervals exhibited significantly longer latencies than 2 min animals. Animals injected with naloxone had significantly shorter latencies and this difference tended to disappear by the end of the 30 min test interval. There were no other significant main effects or interactions.

Overall, these data suggest that the foot-lift response to radiant heat may be a useful index of nociception in the land snail.

A NITRIC OXIDE DONOR AFFECTS ON-COMPONENTS OF ERG FROM CAT INNER RETINA. S. Viswanathan, L.J. Frishman\* and J.G. Robson<sup>1</sup> College of Optometry, University of Houston, Houston, TX 77204-6052; <sup>1</sup>Physiological Lab, Cambridge CB2 3EG, UK.

This study examined the effect of the nitric oxide (NO) donor S-nitroso-N-acetylpenicillamine (SNAP) on the electroretinogram (ERG) of anesthetized cats. We were searching for a physiological correlate of the NO-facilitated cGMP-mediated gap junction closure that has been observed in the scotopic circuit of mammalian inner retina (Mills & Massey, 1995). ERGs were elicited by brief (< 5 msec) or 200 msec Ganzfeld flashes using LEDs, and were recorded with both vitreal and intraretinal electrodes under scotopic conditions (blue flashes from darkness) and, as a control, under photopic conditions (red flashes on a steady blue background to suppress the rods). SNAP was administered intravitreally (500 µM). Under scotopic conditions SNAP selectively attenuated (but did not eliminate) the negative scotopic threshold response (STR) to weak flashes without appreciably reducing the a- and b-waves elicited by stronger stimuli. This finding is consistent with an effect on the scotopic circuit because the STR, which can be eliminated by intravitreal NMDA (1.3-3.9 mM) and partially suppressed by TTX (3-4 µM), is known to originate from rod-driven amacrine and ganglion cells. However, the effect of SNAP was not confined to the scotopic circuit: under photopic conditions SNAP selectively attenuated a negative wave following the cone b-wave that was similar in time course to a wave from inner retina that can be blocked by NMDA. Inner retinal contributions to the ERG at light-offset were not affected by SNAP. These findings suggest that NO may be involved in modulating photopic as well as scotopic ON circuits. (Supported by NIH EY06671)

## 56.3

INHIBITION OF GLUTAMINE SYNTHETASE SUPPRESSES THE ELECTRORETINOGRAM B-WAVE IN THE RAT. N.L. Barnett<sup>1</sup>, D.V. Pow<sup>1</sup>, M.B. Plenderleith<sup>2</sup> and S.R. Robinson<sup>1</sup>. <sup>1</sup>Vision, Touch and Hearing Research Centre, Department of Physiology and Pharmacology, University of Queensland, Brisbane, Australia, 4072. <sup>2</sup>School of Life Science, Queensland University of Technology, Brisbane, Australia, 4001.

Inhibition of retinal glutamine synthetase (GS) by methionine sulfoximine (MSO) caused a time and dose dependent suppression of the rat scotopic electroretinogram (ERG) b-wave. A-wave amplitudes were unaffected in Wistar rats (250g) injected intraocularly with 2µl of MSO (11mM, 110mM or 1.1M). ERGs were monitored for 5 hours and significant ( $P < 0.05$ ) differences between MSO and saline-injected contralateral eyes were evident in the b-wave:a-wave ratios after 3 hours, 1.5 hours and 30 minutes respectively. The three concentrations of MSO almost totally abolished the b-wave and no recovery of the b-wave was evident even 12 hours after injection. Immunohistochemical analysis of retinas subjected to MSO (2µl, 110mM) revealed a total depletion of neuronal glutamate and an accumulation of the transmitter in the radial glial Müller cells within 1 hour. These changes in glutamate distribution following GS inhibition, an enzyme that is localised exclusively within Müller cells, arise as a consequence of the reduction of glutamine synthesis and shunting between Müller cells and neurones. The b-wave, which is thought to be generated by ON-bipolar cell depolarisation and Müller cell potassium fluxes, could be suppressed by four possible mechanisms: (i) depletion of photoreceptor glutamate suppresses tonic transmitter release in the dark, thus abolishing light stimulated changes; (ii) increased Müller cell glutamate content may reverse glutamate transport, cause glutamate efflux, elevation of extracellular glutamate and inhibition of ON-bipolar cell activation; (iii) GS inhibition and glutamate accumulation may directly compromise Müller cell function; (iv) build-up of extracellular ammonia may be toxic to bipolar cells.

## 56.2

CONE PII COMPONENT OF MURINE ERG ISOLATED BY FLASHED BACKGROUND. A. Lyubarsky<sup>1,2</sup>, A. Iannaccone<sup>2</sup>, J. Chen<sup>3</sup>, J. Xu<sup>2</sup> and E.N. Pugh, Jr.<sup>1</sup> <sup>1</sup>Department of Psychology and <sup>2</sup>Ophthalmology, University of Pennsylvania, Philadelphia, PA 19104, <sup>3</sup>University of California, Los Angeles, CA 90095.

Murine retinas contain few cones (<sup>1</sup>) and at least one type of them absorbs at about the same peak wavelength as rods (<sup>2</sup>). Thus, it is impossible to segregate rod- and cone-driven components of the ERG solely by varying the wavelength of stimulation. A cone-positive ERG component consisting mostly of b-wave and oscillatory potentials has been recorded in mouse when rod-driven components are suppressed by steady adapting lights (<sup>3</sup>); this signal has been attributed to cone origin. We isolated and characterized this cone b-wave component in mice with a two-flash paradigm: the first, conditioning flash photoisomerized ~1% of total rhodopsin, and saturated the rods for >3 s, as indicated by complete absence of the a-wave (<sup>4</sup>); a second variable intensity flash was used to test recovering cone function while rods remained in saturation. Arrestin knock-out transgenic mice, which have extremely long rod recovery times (several hours even after moderate intensity illumination) were used as functionally rodless control animals in order to obtain the parameters of the cone b-wave in conditions of complete cone dark adaptation. Cone b-waves begin to recover from saturation by 0.3 s after the conditioning flash, and reach complete recovery by 2-3 s. Work is under way characterizing the full time course of recovery of the cone PII.

## 56.4

COMPUTATIONAL MODELING OF ELECTRICAL STIMULATION OF THE VERTEBRATE RETINAL GANGLION CELL R.J. Greenberg<sup>1</sup>, T.J. Vette<sup>2</sup>, M.S. Humayun<sup>3</sup> and E. de Juan<sup>1</sup> Departments of Biomedical Engineering<sup>1</sup> and Ophthalmology<sup>2</sup>, Johns Hopkins Univ. School of Medicine, Baltimore, MD. Howard Hughes Medical Institute<sup>2</sup>, Harvard Medical School, Boston, MA.

We have previously shown that focal electrical stimulation of human retinas blind by Retinitis Pigmentosa and Age-Related Macular Degeneration is possible (Humayun, M.S. 1996). To better understand how the electrode avoids stimulating passing fibers from distant ganglion cells, we have developed a compartmental model for electric field stimulation of the retinal ganglion cell (RGC). This is the first model of a neuron stimulated by extracellular fields with active channels and non-schematized cell morphology. Mudpuppy RGCs were stained with intracellular injection of Neurobiotin, traced in three dimensions with the Eutectic Neuronal Tracing System, and imported into the NEURON simulation package (Hines, M., 1993). Three membrane models were applied: a linear passive model, a Hodgkin-Huxley model with passive dendrites (HH), and a completely active model (AA) with five non-linear ion channels distributed at varying densities. Stimulation was provided by an idealized monopolar point and disk electrodes located at various positions 30µm above the cells. For both HH and AA, the position of lowest cathodal threshold (propagating action potential) was over the soma. Cathodic stimuli were 58%(HH) to 73%(AA) more effective over the soma than over the axon. In the passive model, with threshold depolarization defined as 15mV, only 10% less cathodic current was required to depolarize the axon vs. the soma. Our active models demonstrate that it may be possible to electrically stimulate RGCs near their cell body at lower thresholds than at their axon, which is consistent with our clinical results. In addition, we have shown that compartmental models with active channels and realistic geometry from neuronal tracings can be achieved with reasonable computing power and should be considered in the study of extrinsically applied electrical fields.

## 56.5

GAIN CONTROL IN THE AII AMACRINE CELL OF CAT RETINA. R.G. Smith\* Dept. of Neuroscience, Univ. of PA, Phila PA 19104-6058.

At scotopic intensities, the AII cell is hypothesized to collect and amplify single-photon signals in a circuit that includes voltage-gated Na and K channels and gap junction coupling. Our simulations of the AII network suggest that it selectively amplifies single-photon signals in the presence of synaptic noise (Smith and Vardi, 1995). At low scotopic intensities, gap junction tracer coupling is modest, but at 1-2 log units above ganglion cell threshold, gap junction coupling extends to a radius of about 10 cells (Bloomfield, 1996). This raises the question of what operation the AII circuit might perform at higher intensities where photon fluctuation noise obscures single photon events. Measurements of gain at scotopic intensities show square root law behavior psychophysically and also in ganglion cells (Donner et al., 1990), which implies that noise from photon fluctuation controls gain in some manner.

To explore the consequences of AII coupling for gain control, we simulated the AII network and adjusted Na conductance to generate subthreshold "spike events" in response to 4 mV photon events. In the presence of randomly-timed photon events (20/sec), full action potentials were generated where 2 or more photon events coincided, but the amplitude of this response depended on coupling. When we modulated the gap junctions by a temporal low pass function (200-500 msec) of depolarization in the AII, action potentials were limited to a few noise peaks at the coincidence of several photon events. A faster photon arrival rate increased gap junction conductance and reduced the regenerative tendency. The result was a dynamic gain control where the number of action potentials was related to the photon fluctuation noise amplitude, suggesting square-root law behavior. Supported by MH48168.

## 56.7

INTERACTIONS BETWEEN ON AND OFF SYSTEMS AT OFF CENTRE GANGLION CELLS IN ISOLATED CAT RETINA.

D.C. West\*, E.A. Read and A.M. Sillito Department of Visual Science, Institute of Ophthalmology, Bath Street, London, EC1V 9EL, UK.

We have developed a system using an in vitro eye cup preparation of cat retina that enables precise visual stimulation and response analysis combined with rapid and controllable drug delivery. In this first preliminary work we have examined the influence of blockade of the "on" system with L-AP4 on the capacity of "off" ganglion cells to provide an output that reflects the characteristics of a spatially restricted patch of drifting sinusoidal grating overlying their receptive field centre. The contrast, temporal and spatial frequency of the grating were varied. Cells were classified as X or Y using conventional visual criteria. Drugs were applied either in the perfusate or via a micropipette located adjacent to the extracellular recording electrode. We have considered the possibility that a glycinergic inhibitory mechanism driven by the "on" system (Wassle, Schaffer-Trenkler, Voigt 1986 J.Neuroscience 6:594-604) may provide a significant contribution to the normal response to these stimuli in "off" centre ganglion cells.

Application of L-AP4 (1-10  $\mu$ M) abolished the responses of "on" centre retinal ganglion cells and modified that of "off" centre cells. The modulation depth of the response to sinusoidal gratings (0.1-0.6 cpd, 0.5-4.0Hz) was decreased and the ability to detect stimuli that weakly activated them lost. The results seem to best support the view that a push-pull mechanism utilising an inhibitory arm driven by the "on" system is necessary for the ability of "off" centre cells to follow the full dynamic range of the stimuli used here. Supported by the Wellcome Trust.

## 56.9

STATIC AND DYNAMIC MEMBRANE PROPERTIES OF MB1 BIPOLAR CELLS FROM GOLDFISH RETINA. S. Mennerick\* and G. Matthews. Dept. Neurobiology & Behavior, SUNY Stony Brook, Stony Brook, NY 11794.

To explore the electrotonic architecture of retinal bipolar cells and to extend recently employed time-resolved capacitance measurements of isolated synaptic terminals to intact cells, we developed a compartment model of isolated MB1 bipolar cells. In whole-cell recordings, current relaxations in response to 10 mV hyperpolarizing voltage steps decayed with a double-exponential time course. This suggests that the passive membrane properties of MB1 cells may be described by a two-compartment equivalent circuit with compartments corresponding to the somal/dendritic (6-10 pF) and synaptic terminal (2-4 pF) regions of the cell, linked by the axial resistance (30-60 M $\Omega$ ) of the axon. Four lines of evidence validate the equivalent circuit: 1) Similar estimates of somal/dendritic and terminal capacitance were obtained whether the patch pipette was attached to the soma or to the synaptic terminal. 2) Estimates of the capacitance of the two compartments in intact cells were similar to estimates from somata and terminals that were spontaneously or experimentally isolated from parent axons. 3) The model yielded estimates of capacitance similar to values entered into a more sophisticated computer simulation of bipolar cells. 4) The model accurately reflected increases in terminal capacitance thought to represent exocytosis of synaptic vesicles. In contrast to other cells to which a two-compartment model has been applied, our results suggest precise morphological correlates in retinal MB1 bipolar cells of the equivalent circuit compartments. Additionally, the work suggests that time-resolved capacitance measurements of synaptic transmitter release may be feasible in intact tissue. Supported by NIH grants NS07371 and EY03821.

## 56.6

SPATIAL EXTENT OF THE CONTRAST GAIN CONTROL SIGNAL IN CAT RETINAL GANGLION CELLS. M.H. Rowe\*, Neurobiology Program, Ohio University, Athens, OH 45701.

The existence of a contrast gain control mechanism is well established in cat retinal X- and Y-cells. Because of similarities in their properties, this mechanism has been associated with the rectifying subunits first described by Hochstein and Shapley (1976), and since the subunits extend well beyond the classical receptive field, it is sometimes assumed that the contrast gain control signal is generated over an equally extensive area. The present experiments were conducted in order to determine whether or not the contrast gain control mechanism has the same spatial extent as the subunits in cat retinal X- and Y-cells. The spatial extent of the contrast gain control mechanism was assessed by presenting a test stimulus, consisting of a drifting grating at optimal spatial and temporal frequency, within a circular aperture centered on the receptive field. The response of the cell as a function of contrast in the test stimulus was then measured both in the presence and absence of a high contrast "background" grating presented outside the aperture. When the aperture was relatively small, the background grating affected the amplitude and phase of the test responses in a manner consistent with the action of a contrast gain control. When the aperture was large enough to easily encompass the classical center/surround receptive field, the background grating had no little or no effect on either the amplitude or the phase of the test responses. Nevertheless, under these conditions, the background grating was able to elicit a vigorous subunit response in the form of a "periphery effect".

These results suggest that subunits located beyond the boundaries of the classical receptive field are not involved in contrast gain control, but rather some other aspect of Y-cell function, e.g., responses to global motion.

RED-SENSITIVE CONES OF THE CYPRINID *Danio aequipinnatus* ARE ACTIVE UNDER SCOTOPIC CONDITIONS. Peter van Rosessel, Adrian G. Palacios\*, and Timothy H. Goldsmith. Department of Biology, Yale University, New Haven, USA.

Electroretinography was used to assess the spectral sensitivity of a fresh-water cyprinid fish, *Danio aequipinnatus*. The spectral sensitivity of fully dark-adapted (>4 hours) fish was determined by measuring the magnitude of the b-wave of the electroretinogram in response dim flashes of monochromatic light of known quantal flux. The resulting scotopic spectral sensitivity curve is not consistent with rods acting alone. It could be modeled, however, using an additive combination of the spectral sensitivity curves for both rod cells and the danio's long wavelength cone (maximal sensitivity at 561 nm, Palacios et al., 1996). Changes in spectral sensitivity were observed following adaptation to increasing intensities of dim, far-red background (<1% at  $\lambda > 650$  nm). Initial changes through a dynamic range of approximately 2 log units of sensitivity could be well modeled by hypothesizing a relatively increased contribution of long-wavelength cones to the rod-dominated scotopic ERG response. Still further adaptation to a red background selectively depressed the sensitivity of the long-wavelength cones, leaving a function whose peak reflects the 480 nm cone. The finding that long wavelength cones contribute to the ERG of fully dark-adapted danios suggests a plausible mechanism for dichromatic color vision in freshwater cyprinids at conditions nearing complete darkness, and accords with behavioral findings that suggest dichromatic color vision under scotopic conditions, possibly mediated by rods and red cones (Powers & Easter, 1978). **NEURAL NETWORK ARCHITECTURE FOR SPATIO-TEMPORAL DYNAMICS AT THE OUTER PLEXIFORM LAYER OF THE VERTEBRATE RETINA.**

Xianyi Yang\* and Greg Maguire\* #Department of Electrical and Computer Engineering, University of Houston, Houston, TX 77204-4793; @Department of Physiology, Keio University School of Medicine, Tokyo, Japan.

In the outer plexiform layer (OPL) of the vertebrate retina, there are three major types of cells making synapses: photoreceptors, horizontal cells, and bipolar cells. The photoreceptors are the only cells in the vertebrate retina that are sensitive to the light and transduce the light energy into neural activity. The horizontal cells receive sign conserving signals over a wide receptive field, and play an antagonistic role at the photoreceptor to bipolar cell pathway. There are two types of bipolar cells, the on- and off-bipolar cells, which have opposite response characteristics. The off-bipolar cells receive sign conserving signals from photoreceptors and inhibitory signals from horizontal cells directly, or indirectly through the photoreceptor terminal. Based on the neurophysiological and anatomical data, we proposed a neural network architecture for the spatio-temporal dynamics of the outer plexiform layer in the vertebrate retina. This architecture consists of transmitter processes, Hodgkin and Huxley membrane modeling (shunting equation), and a gated dipole model. The dynamics of all the OPL cells in the model responding at light-on and -off are in agreement with the physiological data. Stimulation of the model with constant center illumination and various surround illuminations also results in responses with the spatial and temporal dynamics of the physiological responses of bipolar cells. We also model the means of GABA inhibition from horizontal cell to bipolar cell. Our simulations show that GABAergic input, both direct or indirect, through the photoreceptor terminal, are possible to form the response characteristics of the bipolar cell.

Supported by NIH EY09133(GM).

## 56.13

**NEURAL MECHANISMS TUNE THE LIMULUS EYE TO ITS VISUAL ENVIRONMENT**

E.A. Dodge\*, C.L. Passaglia, and R.B. Barlow

Marine Biology Laboratory, Woods Hole, MA. Syracuse University & SUNY Health Science Center, Syracuse, NY.

How are the integrative mechanisms of the *Limulus* eye adapted for encoding information about potential mates? We measured the spatial and temporal properties of the eye by drifting sinusoidal and squarewave gratings on a monitor viewed by an animal located in a glass-sided seawater tank.

We found that both the spatial and temporal transfer functions of the eye have bandpass characteristics which tune the eye for specific stimuli. Lateral inhibition attenuates retinal sensitivity to low spatial frequencies and the eye's optics cutoff sensitivity to high spatial frequencies yielding maximal sensitivity to crab-sized objects (30°) at the sighting distance measured behaviorally. Lateral inhibition also suppresses responses to large spatial changes in illumination as a crab orients. Regarding the eye's temporal response properties, self inhibition attenuates retinal responses to slow modulations of light intensity and the finite duration of quantal events reduces responses to high temporal frequencies yielding maximal retinal sensitivity in the range of 1-5Hz. This range includes the temporal components of animal motion (1-3Hz) and natural light fluctuations (2-5Hz) that highlight reflective crab-sized objects. In sum, the lateral eye is both spatially and temporally tuned for seeing moving crab-sized objects in a dynamic visual environment.

## 56.15

**RELATIONSHIPS BETWEEN FEEDING STRATEGY AND RETINA STRUCTURE AND PHYSIOLOGY IN SHOREBIRDS** L.M. Rojas, T. Cabana, P. Lachapelle\* and R. McNeil. Sc. Biologiques, Université de Montréal, C.P. 6128, Succ. Centre-Ville, Montréal, Canada H3C 3J7, and Ophthalmology, McGill University, Montréal, Canada H3H 1P3.

Depending on the sensory modality most often solicited in their food foraging, aquatic birds can be classified as tactile or visual. Visual birds are generally active during daytime, whereas tactile birds can combine both diurnal and nocturnal activity. Electoretinograms (ERGs) were recorded on shorebirds having different foraging behaviors: *Charadrius wilsonia* is recognized as being visual, *Limnodromus griseus* as tactile, *Catoptrophorus semipalmatus* as visual during daytime but tactile at night, and *Himantopus mexicanus* as visual and tactile during the day and visual under moonlight conditions. Their eyes were then prepared for histology. The luminance-response function under scotopic condition revealed that *H. mexicanus* and *C. wilsonia* have a higher retinal sensitivity than *C. semipalmatus* and *L. griseus*. For instance, at -2 Log-unit, the average amplitude in  $\mu V$  is  $322.9 \pm 44.0$ ;  $259.5 \pm 47.7$ ;  $160.4 \pm 28.3$ ;  $94.8 \pm 13.0$ , respectively, taking into account the size of the pupil relative to the eye. These results are in accordance with their cones to rods ratio: 1:1.12; 1:1.56; 1:0.75; 1:0.97, respectively. Thus, these findings suggest the existence of a correlation between the structure and function of the retina and the foraging behavior of these birds. However, under photopic condition no significant difference was found in the ERG response between the four species. We conclude that visual capability is one, but not the sole, factor influencing their feeding strategy. (Supported by NSERC of Canada and CONOCIT of Venezuela)

## 56.12

**PATCH CLAMP ANALYSIS OF INTRINSIC MEMBRANE PROPERTIES OF ALPHA AND BETA CELLS IN CAT RETINAL WHOLEMOUNTS.** D.W. Robinson\* and L.M. Chalupa. Section of Neurobiology, Physiology and Behavior, University of California at Davis, Davis, CA 95616.

We have assessed the intrinsic spiking patterns of morphologically identified RGCs in retinal wholemounts. Current-clamp recordings were obtained at 35°C from 15  $\alpha$  and 59  $\beta$ -RGCs anatomically identified by incorporating Lucifer yellow into the electrode solution. The intrinsic temporal properties of these neurons were assessed using a variety of sinusoidal and square wave stimuli. The resting membrane potential did not vary as a function of anatomical cell class (-55 mV) and in all cases regenerative firing was observed at rest. In response to maintained depolarizations both classes responded with maintained discharges and exhibited a linear relationship between spike output and the magnitude of injected current. Both cell classes also showed a linear relationship between the discharge rate and the amplitude of sinusoidal stimuli modulated below 10 Hz. Above 10 Hz only 1 spike per cycle was generated irrespective of the stimulus amplitude. The tuning curves of  $\alpha$  and  $\beta$ -RGCs did not differ in any systematic manner and exhibited a peak at around 15 Hz. In all cases, the peak spike rate obtained to temporal modulation was higher than that observed to maintained depolarizations at an equivalent amplitude. As the stimulus frequency was increased above 10 Hz, the ability of both cell classes to follow the stimulus decreased quite markedly. Nevertheless, even at the highest stimulus frequencies, the spikes were tightly time-locked to the phase of the stimulus cycle. Many of the temporal properties examined mirror those obtained from psychophysical experiments, suggesting that RGCs shape retinal output to a greater degree than was previously thought. Supported by NIH grant EY-03991 to LMC

## 56.14

**BLUE-SENSITIVE PHOTORECEPTORS THAT MEDIATE FEEDING BEHAVIOR IN MANDUCA ARE LOCATED IN THE VENTRAL RETINA OF THE COMPOUND EYE.** R.H. White\*, J. Stockslager and R. R. Bennett, Biology Department, University of Massachusetts/Boston, Boston, MA 02125-3393

The spectral sensitivity of flower visitation in the nocturnal sphingid moth *Manduca sexta* indicates that feeding behavior is mediated mainly by blue-sensitive receptors. Distribution across the retina of the 3 spectral classes of receptors (green, blue, UV) was mapped by measuring ERG spectral sensitivity in localized regions, and by the light-dependent ultrastructural responses of individual receptors. The contribution of the 3 receptor types to ERGs was estimated by matching sensitivity curves with the summed absorption spectra of the 3 corresponding rhodopsins. Blue-sensitive receptors, mixed with green and UV cells, were found only in the ventral half of the retina. The dorsal half contained only green and UV receptors. The ventral localization of blue receptors is appropriate for guiding a moth that hovers above flowers while feeding.

Supported by NSF IBN-9210933

## 56.16

**EFFECTS OF DEFOCUS-INDUCED MYOPIA AND HYPEROPIA ON SEROTONERGIC AMACRINE CELLS IN CHICK RETINA.** S.T.Wong\*, A.J.Bakelaar\*, A.K.Ball\*, J.S.Frank\*, J.G.Sivak\*, School of Optometry, University of Waterloo, Waterloo, Ont., Canada N2L 3G1; Department of Biomedical Sciences, McMaster University, Hamilton, Ont., Canada L8N 3Z5.2

Avian animal models are often used in vision research since the visual capabilities of birds are highly developed. Myopia and hyperopia can be readily produced in young chicks using goggles with rigid contact lenses. Previous studies in our laboratory have shown that concave lenses produce enlarged myopic eyes, while convex lenses produce hyperopic eyes with smaller dimensions (Irving 1992). Other studies suggest that abnormal myopic eye growth is mediated by local retinal control (Troilo et al. 1987, Wallman et al. 1987) and that amacrine cells are involved (Wallman 1991). We examined how serotonergic amacrine cells are affected in ametropias produced by defocusing lenses.

Newly-hatched broiler chicks were unilaterally exposed to visual defocus ranging from -20 to +15 diopters (D). Retinoscopy and ultrasonography determined refractive states and axial lengths. After sacrifice, retinal wholemounts were processed for serotonin fluorescent immunohistochemistry and viewed by confocal microscopy. Prior to treatment, there were no differences between both eyes. After 5-7 days, each treated eye showed a refractive error nearly equal to the sign and magnitude of the defocusing lens. Myopic and hyperopic eyes respectively showed significantly larger or smaller dimensions compared to control eyes. There were no significant differences in serotonergic cell densities for moderate hyperopia (+15D) and moderate myopia (-10D). At high myopia (-20D), there were significantly higher serotonergic cell densities in treated eyes compared to control eyes. These results indicate that serotonergic amacrine cells may play a role in ametropia and eye growth mechanisms.

## 56.17

RETINYL ESTER HYDROLYSIS IN THE EYE: SUBSTRATE SPECIFICITY. A.T.C. Tsing\*, J.A. Ray, N.L. Mata. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, Texas 78249.

Hydrolysis of 11-*cis* and all-*trans* retinyl esters in the eye is catalyzed by microsomal hydrolases in the retinal pigment epithelium (RPE). In the present study, we have examined the hydrolysis of 11-*cis* and all-*trans* retinyl esters with fatty acids of various acyl-chain lengths and degree of saturation (i.e., all-*trans* and 11-*cis* retinyl stearate, palmitate, myristate, oleate, and linoleate). All-*trans* and 11-*cis* retinyl palmitate (ArRP and 11cRP) were hydrolyzed at faster rates than all other retinyl esters. Of the 18-carbon species examined, unsaturated (vs. saturated) 11-*cis* retinyl ester were hydrolyzed at higher rates, whereas these differences were not observed in the hydrolysis of all-*trans* retinyl esters. Employing substrates of two different radiolabels (i.e. [<sup>3</sup>H]11cRP and [<sup>14</sup>C]ArRP, [<sup>14</sup>C]triolein, or [<sup>14</sup>C]cholesteryl oleate), we also obtained experimental evidence showing that the hydrolysis of [<sup>3</sup>H]11cRP was not affected by the presence of either all-*trans* RP or esterase substrates. However, similar competition experiments showed that the presence of cholesteryl oleate, triolein, or 11cRP significantly reduced the hydrolysis of ArRP. Based on results from these experiments, we suggest two catalytic sites for retinyl palmitate hydrolysis: a higher activity/high specificity site for the 11-*cis* isomer and a lower activity/non-specific site for the all-*trans* isomer. As the visual cycle in the RPE includes only the hydrolysis of 11-*cis* retinyl ester (but not the all-*trans* isomer), our finding that 11-*cis* retinyl ester hydrolysis is associated with high activity as well as high specificity is consistent with its role in the rapid supply of visual chromophore during bleaching and regeneration of visual pigments. Supported by grants from the NIH (NEI and MBRS) and The San Antonio Area Foundation.

## 56.19

THE 5' FLANKING REGION OF ZEBRAFISH INTERPHOTORECEPTOR RETINOID-BINDING PROTEIN (IRBP) DRIVES REPORTER GENE EXPRESSION IN PRIMARY CHICK RETINAL CELL CULTURES

L.L. Cunningham<sup>1,2</sup>, J.M. Nickerson<sup>3</sup>, F. Gonzalez-Fernandez<sup>1,2</sup>, J. Peoples<sup>3</sup>, J.H. Boatright<sup>1</sup>. Graduate Program in Neuroscience<sup>1</sup> and Department of Ophthalmology<sup>2</sup>, University of Virginia, Charlottesville, VA; The Emory Eye Center<sup>3</sup>, Atlanta, GA

Interphotoreceptor retinoid-binding protein (IRBP) is a vitamin-A binding protein that is thought to function in the visual cycle by transporting retinoids between retinal photoreceptors and the overlying retinal pigment epithelium. Expression of IRBP is restricted to retinal photoreceptors and cells of the pineal gland. Expression of IRBP mRNA is regulated in a light-dependent manner in zebrafish (Rajendran et al., submitted). In order to study the *cis* elements that contribute to the regulation of IRBP expression, we cloned IRBP as well as 3 kb of its 5' flanking sequence from zebrafish. 797 bp of 5' flanking sequence were cloned upstream of the gene encoding chloramphenicol acetyltransferase (CAT). This plasmid was used to transfect (via calcium phosphate precipitation) primary retinal cell cultures prepared from E8-E11 chicken embryos. Four days after transfection, cells were harvested and assayed for CAT activity, which was considered an index of promoter activity. Results indicate that the 5' flanking region of zebrafish IRBP can drive reporter gene expression in the chicken retinal cell culture system. This system will be useful in determining the *cis* elements contributing to the tissue-specific and light-dependent regulation of IRBP expression. Supported by NIH ST32GM08328-04, NIH RO1EY09378, NIHEY09412, Research to Prevent Blindness (Olga Keith Weiss Award to J.M.N.), and a grant-in-aid from Fight for Sight (J.H.B.)

LIPICALIN TYPE PROSTAGLANDIN D SYNTHASE IN RETINAL PIGMENT EPITHELIUM (RPE) IS SECRETED INTO INTERPHOTORECEPTOR MATRIX (IPM). Gordon W.C.<sup>1</sup>, Marchessell V.L.<sup>1</sup>, Beuckmann C.T.<sup>2</sup>, Urade Y.<sup>2</sup>, Hayaishi O.<sup>2</sup>, Bazan NG<sup>1</sup>. LSU Neuroscience Center and LSU Eye Center, New Orleans, LA<sup>1</sup>; Osaka Bioscience Institute, Osaka, Japan<sup>2</sup>.

PGDS, glutathione-independent prostaglandin D synthase, a 26 kDa glycoprotein, forms prostaglandin D2 in brain, and occurs in retina. It has been sequenced, cloned, and found to be identical to cerebrospinal fluid  $\beta$ -trace. Homology searches show PGDS to be a lipocalin (secretory hydrophobic transporter), but PGDS is the only member displaying enzymatic activity, suggesting dual function. This study determines retinal PGDS distribution. Enzymatic activity of PGDS was determined on retinal protein fractions. Northern and Western blots of RPE, IPM, and retina were run. Immunohistological PGDS localization in retina was determined. *Xenopus* and Sprague-Dawley (albino), Long Evans (pigmented), and Royal College of Surgeons (RCS) rats were used. PGDS activity for retina was  $4.4 \pm 0.6$  nmol/(min·mg protein); Northern blots were positive for PGDS expression; *in situ* hybridizations showed PGDS mRNA only in RPE; a strong immunopositive signal occurred in RPE, a weaker signal extended proximally to the outer limiting membrane. PGDS occurred in all retinas examined, but RCS rat RPE had less overall labeling and some dim cells. *Xenopus* PGDS expression was 3-fold greater in RPE than retina. IPM protein levels of PGDS were highest (>300-fold); PGDS is a soluble protein, secreted into IPM by RPE. COX-2 was used to show distribution of an intracellularly secreted enzyme; protein levels and distribution were compared with PGDS. COX-2 was a major RPE and retinal membrane component, but not in IPM. Strong PGDS activity was immunologically localized to RPE cells and IPM, but its mRNA occurred only in RPE. Thus, PGDS is synthesized in, and then secreted from, the RPE in high concentrations, suggesting a dual function, an RPE synthesizing enzyme and an IPM transporter molecule (lipocalin). This may be an example of the gene sharing concept introduced by J. Piatigorsky (1989). NIH/NEI EY05121

RESPONSES OF CAT SCN-PROJECTING GANGLION CELLS

M. Pu\* and P. Sterling. Department of Neuroscience, University of Pennsylvania, Philadelphia, PA 19104

Retinal ganglion cells projecting to suprachiasmatic nucleus exhibit several distinct dendritic morphologies, but the spontaneous and evoked firing patterns are unknown. We injected fluorescent beads into the SCN and two days later placed the retina *in vitro* where we recorded extracellularly from retrogradely labeled neurons. Spontaneous firing was vigorous (>20 spikes/s), highly regular over periods up to 5 hours. A spot centered on the dendritic field evoked a transient burst followed by steady, brisk firing that was sustained indefinitely. Spatial summation occurred to spots from 0.1-1.5 mm diameter. At stimulus off, the cell returned to spontaneous level. Cells responded over mesopic and photopic intensities. One cell whose spectral responses were plotted responded from 450 to 676 nm with a peak around 510 nm.

## AUDITORY SYSTEMS: CENTRAL ANATOMY—HINDBRAIN

## 57.1

A COMPARISON OF THE CROSSED AND UNCROSSED, GABA-IMMUNOREACTIVE PROJECTIONS OF THE CAT DORSAL NUCLEUS OF THE LATERAL LEMNISCUS A. Shneiderman\*, D.A. Stanforth, and R.L. Saint Marie. Neuroanatomy Dept., House Ear Institute, Los Angeles, CA 90057.

The dorsal nucleus of the lateral lemniscus (DNLL) provides separate crossed (60%) and uncrossed (40%) inhibitory (GABAergic) projections to the inferior colliculus (IC). Immunocytochemical studies have shown that DNLL neurons exhibit a range of somatic GABA concentrations. We examined the laterality of DNLL projections and compared this with their somatic GABA concentration, position within DNLL, and prevalence of GABA-immunoreactive (GABA-IR) perisomatic puncta. Laterality was determined by retrograde transport of HRP from large injections confined to one IC. GABA-IR was determined from 1.5  $\mu$ m plastic sections which contained retrogradely labeled neurons in the DNLL opposite to the injected IC. DNLL neurons with crossed and uncrossed projections differed in several ways. Those with crossed projections (47-59% of the total were retrogradely labeled) tended to be lightly-to-moderately GABA-IR, although some examples of negatively and darkly stained neurons were occasionally found. They were more prevalent in the lateral part of DNLL and in areas dense with GABA-IR neuropil. Their somata were frequently covered with GABA-IR perisomatic puncta. DNLL neurons which did not transport HRP from the contralateral IC (41-53% of the total) were presumed to contribute uncrossed projections to the uninjected IC. These tended to be moderately-to-strongly GABA-IR and were more often found medially in DNLL, predominantly among the lemniscal fiber fascicles in areas generally lacking GABA-IR neuropil. They had few GABA-IR perisomatic puncta. The results indicate that DNLL neurons differ in their somatic GABA concentrations, position within DNLL, and their afferent inputs, depending on the laterality of their efferent projections. This suggests that the two types of projections may contribute different kinds of information to the IC.

## 57.2

DEVELOPMENT OF GABAERGIC CIRCUITS IN THE AUDITORY BRAINSTEM OF THE FERRET. Craig K. Henkel<sup>1</sup> and Judy K. Brunso-Bechtold. Department of Neurobiology and Anatomy, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, North Carolina 27157-1010

Inhibitory actions of gamma-aminobutyric acid (GABA) at synapses in the central auditory system are supported by a variety of evidence for several levels of the adult brainstem and midbrain. It is of considerable interest then to determine whether GABA is differentially regulated among various nuclei, circuits or cell types during development. Thus, we undertook immunohistochemical studies with standard methods using antibodies to GABA (Wenthold et al., '87) to describe the distribution of GABAergic cells and axons in the ferret auditory brainstem. At birth and in the adult, GABAergic neurons and axons were found generally in comparable regions of the cochlear nuclei, superior olivary complex, nuclei of the lateral lemniscus, and inferior colliculus. There were no obvious transient populations of GABAergic neurons during postnatal development. However, some of the most immunopositive neurons in the auditory brainstem at birth circumscribed the medial half of the lateral superior olivary nucleus. While principal neurons in the lateral superior olivary nuclei in the adult material were only ever moderately immunopositive, their distribution was extended from medial to lateral and across the core of the nucleus by the time of onset of hearing at approximately 30 days of age. The ventral cochlear nucleus and central nucleus of the inferior colliculus also demonstrated a comparable gradient. Thus, results support the hypotheses that GABAergic neurons involved in a variety of ascending, descending and local circuits are not disparate in their temporal appearance, that GABAergic neurons in different hierarchical levels appear synchronously, and that inhibitory processes in tonotopically ordered nuclei develop in a topographic sequence. NIDCD grants DC00335 and DC00813

## 57.3

**EVIDENCE THAT DISTINCT POPULATIONS OF GABA NEURONS ARE EXPRESSED IN THE SUPERIOR OLIVARY COMPLEX.** *SA Jenkins and DD Simmons*, Dept. of Physiological Science, Program in Neuroscience, and Brain Research Institute, UCLA, Los Angeles, CA 90095-1527.

Efferent projections from the brainstem to the cochlea play an important role in the modulation of auditory nerve activity. The modulatory actions of cochlear efferent neurons are believed to be mediated, in part, by GABA neurons in the superior olivary complex (SOC). The purpose of this study is to define the expression of GABA neurons within the SOC of the adult hamster brainstem using immunocytochemical and in situ hybridization techniques.

Our results indicate that there may be distinct populations of cells containing GABA. A postembedding immunocytochemical technique was used to identify GABA containing neurons in 1.5  $\mu$ m plastic sections through the SOC. Three categories of labeling occurred: dark, moderate and unlabeled. Greater than 70% of darkly labeled cell bodies were in the lateral superior olive (LSO) and the superior paraolivary nucleus (SPN). The majority of moderately labeled cell bodies were in periolivary regions.

Preliminary investigations have been done on the expression of the two isoforms of glutamic acid decarboxylase (GAD), the synthetic enzyme of GABA. Within the SOC, the cRNA probe for GAD67 preferentially labels cells in the LSO while the probe for GAD65 preferentially labels cells in periolivary regions. Although less precise, immunoreactivity to the GAD67 protein mostly paralleled the GAD67 transcript expression.

Combined, these data raise the possibility of different functional roles for GABA within neurons of the SOC. It is possible that these distinctions relate to the projection of the neuron.

(Supported by grants from the NIDCD and the UCLA Academic Senate)

## 57.5

**CHANGES IN GEPHYRIN IMMUNOLABELING IN THE AUDITORY BRAIN STEM OF MICE WITH MUTATIONS IN GLYCINE RECEPTOR SUBUNITS.** *J.M. Bonneau and R.A. Altschuler*, Kresge Hearing Research Institute, University of Michigan, Ann Arbor 48109-0506

Two strains of mice have nonlethal mutations in genes coding for glycine receptor (GlyR) subunits:  $\alpha 1$  in the spasmodic (spd) and  $\beta$  in the spastic (spa). As glycine is an important inhibitory neurotransmitter it is useful to see the effects of these mutations on glycinergic synapses. Gephyrin is an essential element in the GlyR/cytoskeletal complex and binds to a specific 49 amino acid sequence of the  $\beta$  subunit. Its localization identifies and defines the extent of the GlyR complex. We therefore examined spd and spa mutants for changes in the immunolocalization of gephyrin in the auditory brain stem. All of the mice exhibited perisomatic labeling in numerous cell types in cochlear nucleus and superior olivary complex but the most dramatic observations in this study were the changes in the medial nucleus of the trapezoid body (MNTB) in the spa/spa and spa/+ mice. MNTB neurons of the spa mutants had a reduction in perisomatic placement of gephyrin and an increase in numbers and size of densely labeled gephyrin sequestering regions. The decrease in labeled postsynaptic GlyR complexes and the increase in intracellular gephyrin accumulation indicate that a mutation in the gene encoding the  $\beta$  subunit of the GlyR in mice alters the receptor complex in the auditory brain stem. The mutation in the  $\beta$  subunit having its most pronounced effect in the MNTB is particularly interesting in light of recent findings of elevated levels of expression of the  $\beta$  subunit of the GlyR in MNTB neurons over other neurons in SOC regions in normal rats.

(supported by NIH, NIDCD grant R01DC00383-09A2)

## 57.7

**AMINO ACIDS IN RAT COCHLEAR NUCLEUS SLICES.** *L. Zheng<sup>1</sup>, D. A. Godfrey<sup>2</sup>, T. G. Godfrey<sup>1</sup> and H. J. Waller<sup>2</sup>*, Depts. of <sup>1</sup>Otolaryngology and <sup>2</sup>Neurological Surgery, Medical College of Ohio, Toledo, OH

Using high performance liquid chromatography (HPLC), amino acids were measured in samples microdissected from freeze-dried sections of rat cochlear nucleus slices. Slices were cut with a tissue chopper or vibratome, then incubated in artificial cerebrospinal fluid (ACSF). Data are shown for the fusiform soma layer of the dorsal cochlear nucleus (DCN), for incubated chopped slices (Inc-Chop), incubated vibratome slices (Inc-Vib), and incubated vibratome slices exposed to 50 mM K<sup>+</sup> for 3 (3 min K<sup>+</sup>) or 10 min (10 min K<sup>+</sup>). These results are compared to those for chopped nonincubated slices and to in vivo data. Average concentrations (mmol/Kg dry wt) are presented for aspartate (Asp), glutamate (Glu), glutamine (Gln), glycine (Gly),  $\gamma$ -aminobutyrate (GABA), taurine (Tau), and serine (Ser).

	Asp	Glu	Gln	Gly	GABA	Tau	Ser
In Vivo	14	41	19	25	9	11	5
Noninc	11	28	11	17	5	5	5
Inc-Chop	6	12	4	23	3	3	6
Inc-Vib	4	15	6	18	3	4	3
3 min K <sup>+</sup>	5	17	9	21	4	5	4
10 min K <sup>+</sup>	6	20	12	24	5	6	5

Most amino acids had similar concentrations in sections from near the surface or near the middle of a slice and in sections from slices cut with the chopper or vibratome. Compared with the in vivo data, there was a large loss of Asp, Glu, Gln, GABA and Tau in incubated slices, which was independent of incubation time between 4 and 12 hr. The concentrations of these amino acids were decreased even without incubation, suggesting rapid loss from the cut slices. In slices exposed to 50 mM K<sup>+</sup> for 3 or 10 min, Gln increased by 100% or more in all 3 DCN layers, while Ser increased by more than 60%. (Supported by NIH grant DC00172).

## 57.4

**GLYCINE TRANSPORTER MOLECULES (GLYT1 AND GLYT2) IN THE DEVELOPING AUDITORY BRAINSTEM OF RATS.** *E. Friauf<sup>1</sup>, C. Aragón, C. Giménez and F. Zafra*, Zentrum der Physiologie, Universität Frankfurt, Germany; Centro de Biología Molecular, Universidad Autónoma Madrid, Spain.

The synaptic action of many neurotransmitters is terminated (and possibly modulated) by high-affinity transporters which remove the transmitter molecules from the synaptic cleft. Two different glycine transporters (GLYT1 and GLYT2) have been cloned as yet. Here we have used immunocytochemistry to analyze the spatial and temporal distribution of GLYT1 and GLYT2 in auditory brainstem nuclei of postnatal rats, which are particularly rich in glycinergic synapses.

In adult rats, GLYT2 and GLYT1 immunoreactivity (ir) are present in all auditory brainstem nuclei up to the level of the inferior colliculus. GLYT2-ir is more intense than GLYT1-ir, and neuronal somata within the cochlear nuclear complex (except for octopus cells) and the superior olivary complex are most intensely decorated with GLYT2-ir puncta. Neurons in the MNTB, known to be heavily glycinergic, form the only cell population displaying a cytoplasmic staining for GLYT2. As the labeling pattern is very reminiscent of that found for glycine receptor subunits, these results comply with a strict co-localization of GLYT2 (presynaptic) and the inhibitory glycine receptor (postsynaptic).

At postnatal day (P) 1, weak amounts of GLYT-ir can already be seen in most auditory brainstem nuclei, with the labeling for GLYT2 appearing earlier and being heavier at a given age than that for GLYT1. Signal intensity increases rapidly during the first postnatal week, and at P8, GLYT2-ir is already very intense in all auditory brainstem nuclei. Both transporter molecules appear to be expressed most heavily around P12, i.e. around hearing onset, and labeling declines until adult levels are reached around P21. Our results show that GLYT1 and GLYT2 are abundant in the developing auditory system before the onset of hearing, suggesting that they also play a role during early ontogeny, when synapse maturation occurs. Supported by a DFG grant (SFB 269/BS).

## 57.6

**ULTRASTRUCTURAL LOCALIZATION OF GLUTAMATE RECEPTOR SUBUNIT IMMUNOREACTIVITY IN THE GERBIL LATERAL SUPERIOR OLIVE (LSO)** *J.R. Schwartz<sup>1</sup> and P.R. Eager*, Dept. of Surgery/Otolaryngology, Yale Univ. Sch. of Med., New Haven, CT 06520

Vibratome sections of aldehyde fixed brains of young adults were incubated with antibodies (Ab) recognizing the glutamate receptor subunits GluR1, 2/3, or 4 (Chemicon), processed and sections of the LSO examined electron microscopically.

In accord with our light microscopic findings, GluR4 had the greatest concentration of immunoreactivity (IR) throughout the somatic and dendritic cytoplasm and at postsynaptic specializations. Very heavy patches of label were seen associated with some stacks of endoplasmic reticulum (ER). Asymmetric postsynaptic densities were heavily labeled over the entire length of the convex specialization. A second pattern of postsynaptic localization, less heavy than the first, was also seen at some terminals. Both patterns were observed in a single dendrite, the first associated with terminals containing large round synaptic vesicles, the second with a terminal with smaller pleomorphic synaptic vesicles. GluR1 IR was also found throughout the somatic and dendritic cytoplasm but usually in somewhat lesser amounts. It was concentrated in small patches again in association with smaller clusters of ER. Postsynaptic IR was sometimes similar to that seen with GluR4, but was usually thinner and more spread. GluR2/3 IR was generally sparse in the cytoplasm of LSO somata and dendrites, but was seen in association with ER. IR was found at postsynaptic regions, but differed from the GluR4 pattern. It usually occupied less than the entire synaptic apposition. It was often punctate and associated with a cluster of labeled ribosomes immediately beneath the labeled density. With all three Abs some presynaptic IR was observed, occasionally within or near the synaptic junction, but sometimes at the sides of the terminal away from the synapse. All three Abs also showed IR in glial processes. This was most prominent with GluR4 where fine glial processes around synaptic terminals were often IR.

While postembedding immunocytochemical analysis of serial sections will be required to prove the exact distribution of each GluR at individual synapses, the present results suggest that in some cases they are not coincident and thus that the receptors in LSO neurons, in a single dendrite or even at a single synaptic terminal, may have several different combinations of subunits.

Supported by USPHS grant DC00132 from NIDCD.

## 57.8

**DENSITOMETRIC EVALUATION OF MARKERS FOR CHOLINERGIC TRANSMISSION IN RAT SUPERIOR OLIVARY COMPLEX.** *W. Yao<sup>1</sup> and D.A. Godfrey*, Dept. of Otolaryngology, Medical College of Ohio, Toledo, Ohio 43699

The superior olivary complex (SOC) gives origin to the olivocochlear bundle (OCB), for which acetylcholine is a neurotransmitter. However, little else is known about cholinergic elements in the SOC. Using NIH image 1.59, labeling densities in the lateral superior olive (LSO, lateral, intermediate and medial limbs), ventral nucleus of the trapezoid body (VNTB), superior paraolivary nucleus (SPN), medial nucleus of the trapezoid body (MNTB), and a middle zone (MZ, including the medial superior olive) were measured for acetylcholinesterase (AChE) histochemistry, choline acetyltransferase (ChAT) immunohistochemistry, muscarinic receptor subtype 2 (m2) immunohistochemistry, general muscarinic receptor (M35) immunohistochemistry and N-methylscopolamine (NMS) muscarinic receptor binding. The mean densities (4 rats), after subtracting the spinal trigeminal tract density as a background, are expressed as percentages of an average for cochlear nucleus (SOC/CN)%:

	LSO-l	LSO-i	LSO-m	VNTB	MZ	SPN	MNTB	Mean
AChE	53	57	81	114	52	61	40	65
ChAT	96	80	99	136	47	61	93	88
m2	76	67	82	137	64	73	63	80
M35	29	16	24	93	22	19	57	37
NMS	28	28	36	74	31	47	31	39

In general, the markers of cholinergic transmission are less prominent in the SOC than in the CN. VNTB contained the highest densities for all markers, in some cases higher than in the CN, suggesting relatively more cholinergic mechanisms there. In the LSO, AChE showed more labeling in the medial limb than in the lateral and intermediate limbs. Across the SOC, there are high correlations between AChE and m2 ( $r=0.94$ ), m2 and NMS ( $r=0.92$ ), and AChE and NMS ( $r=0.87$ ). Other correlations among markers are moderate ( $r=0.59-0.80$ ). (NIH grant DC 00172)

## 57.9

NEUROTRANSMITTER CHEMISTRY IN THE COCHLEAR NUCLEUS OF THE MOUNTAIN BEAVER. D.A. Godfrey<sup>1</sup>, N.L. Mikesell<sup>1</sup>, T.G. Godfrey<sup>2</sup>, and J.A. Kaltenbach<sup>2</sup>, Departments of Otolaryngology of <sup>1</sup>Medical College of Ohio, Toledo, OH, and <sup>2</sup>Wayne State University, Detroit, MI

Amino acids and enzymes of acetylcholine metabolism were mapped in the mountain beaver cochlear nucleus (CN) using microdissection of freeze-dried tissue sections, high performance liquid chromatography (HPLC) assay of amino acid concentrations, and radiometric assays of choline acetyltransferase (ChAT) and acetylcholinesterase (AChE) activities. Averaged results for two animals, which had similar chemistries, are presented for the amino acids aspartate (Asp), glutamate (Glu), glutamine (Gln),  $\gamma$ -aminobutyrate (GABA), glycine (Gly), and taurine (Tau), all in mmol/kg dry wt, and for ChAT, in  $\mu$ mol/kg dry wt/min, and AChE, in mmol/kg dry wt/min, for granular (Gran), dorsal (DCN), posteroventral (PVCN), and anteroventral (AVCN) regions.

	Asp	Glu	Gln	GABA	Gly	Tau	ChAT	AChE
Gran	10.6	42.5	43.8	5.7	9.5	18.0	13.0	84.7
DCN	9.1	42.2	45.9	10.4	17.2	15.4	7.1	43.9
PVCN	9.1	19.0	22.2	4.7	7.4	5.0	35.4	24.3
AVCN	10.9	19.2	22.6	6.1	9.1	5.2	45.7	42.1

The magnitudes of most amino acid concentrations resemble those measured with the same methods in rat CN, but Gln is much higher and Gly much lower. Although AChE activities are mostly similar, ChAT activities are strikingly lower than in rat CN. The value in the granular region is about 5% of that in rat and 8% of that in cat. Unlike in rat and cat, but in accord with its rather homogeneous histological appearance, the DCN contained few superficial-to-deep chemical gradients. (Supported by NIH grant DC00172 and departmental funds.)

## 57.11

AN ORGANOTYPIC SLICE CULTURE OF DEVELOPING AUDITORY BRAINSTEM NUCLEI. C. Lohmann\* and E. Friauf, Zentrum der Physiologie, Universität Frankfurt, D-60590 Frankfurt, Germany.

Nuclei in the mammalian auditory brainstem provide a suitable model to investigate the development of topographically organized *excitatory* and *inhibitory* projections. Excitatory (glutamatergic) and inhibitory (glycinergic) inputs, originating from neurons in the cochlear nuclear complex (CN) and the medial nucleus of the trapezoid body (MNTB), respectively, converge on neurons in the lateral superior olive (LSO) in a precisely tuned fashion. We have established an organotypic slice culture of the LSO, MNTB, and CN to be able to perform critical experiments which are not feasible *in vivo*. Ventral brainstem slices from rats between postnatal day 1-6 were maintained in a CO<sub>2</sub> incubator on porous membranes with serum-containing medium (Stoppini et al. 1991, J Neurosci Meth 37:173-182) for up to one week. Interestingly, neuron survival in the LSO (in contrast to CN and MNTB) required an elevated extracellular K<sup>+</sup> concentration, indicating that a depolarized membrane potential is crucial for their health. Organotypicity could be demonstrated after one week in culture: 1) Nissl staining revealed a well-preserved cytoarchitecture of the above auditory nuclei. 2) The topography of the internuclear connections, as shown by biocytin labeling, was indistinguishable from that *in situ*: for example, neurons located in *lateral* aspects of the MNTB projected into *lateral* aspects of the LSO. 3) Principal neurons in the LSO could be easily identified by their typical somatodendritic morphology. Furthermore, axons of some CN neurons, which had been cut during the slicing procedure, regenerated in culture and terminated properly in the LSO. We conclude that auditory brainstem nuclei of neonatal rats can be kept in organotypic culture for at least one week provided that depolarization-induced processes can exert their positive influence on LSO neurons. Supported by the DFG (SFB 269/B5).

## 57.13

DISSOCIATED CELL CULTURES OF CHICK BRAIN STEM AUDITORY NUCLEI. N.J. Hack, K.M. Charters, T.N. Parks and S.B. Kater, Department of Neurobiology and Anatomy, University of Utah, Salt Lake City, UT 84132.

The nucleus magnocellularis (NM) and nucleus laminaris (NL) of the avian brainstem auditory system are each composed of a single type of large principal neuron with highly specialized shape. These neurons show distinct morphological transformations during development and substantial change following deafferentation. The mechanisms underlying these changes may be best understood by partitioning the complexity of the events seen *in vivo*. In the absence of previous reports of cell culture of these nuclei, we are now defining methods for maintaining these neurons *in vitro* in order to obtain an experimental system compatible with high-resolution analysis of changes in dendritic morphology, calcium homeostasis, and gene expression. Papain dissociation and mechanical trituration of brainstem slices containing the NM and NL from embryonic chicks yields a mixed population of cells in culture. Such neurons can survive and display outgrowth for at least 5 days *in vitro*. Calretinin (CR) staining provided firm evidence that both neurons from the NM and NL survive well *in vitro* and can display strikingly similar morphologies to those seen *in vivo*. The embryonic stage of the donor from which neurons were derived is an important determinant of the number and viability of CR positive cells surviving in culture. Directly after plating on poly-L-lysine coated glass, many large CR-positive cells retain significant architecture, exclude trypan blue, and maintain calcium homeostasis. With subsequent days *in vitro* an array of CR-positive neuronal morphologies are displayed. Our system allows us to follow individual neurons over several days in culture. Some neurons retract their processes while some generate new processes reminiscent of several stages of normal developmental dendritic remodeling *in vivo*. Supported by development funds from the University of Utah.

## 57.10

DEVELOPMENTAL EXPRESSION OF A HIGH THRESHOLD K<sup>+</sup> CHANNEL IN THE CENTRAL AUDITORY SYSTEM OF RATS

W. Li\*, Y.-H. Liu, T.M. Perney, CMBN, Rutgers, Newark, NJ 07102.

The Kv3.1 K<sup>+</sup> channel gene encodes for a delayed rectifier-like channel with an unusually high activation threshold and very rapid deactivation kinetics. Computer simulations have predicted that the presence of the Kv3.1 channel would enhance a neuron's ability to follow high frequency synaptic input. Kv3.1 channels are highly expressed in several auditory nuclei including the ventral cochlear nucleus (VCN), the medial nucleus of the trapezoid body (MNTB) and inferior colliculus (IC). These data suggest a role for Kv3.1 channels in auditory temporal processing.

We used *in situ* hybridization and immunohistochemistry to examine the temporal expression pattern of Kv3.1 expression in the developing auditory system. Our *in situ* results showed that up until PD7, there was very low levels of Kv3.1 mRNA in the VCN, MNTB and IC. Between PD10 and PD14, there was a considerable jump in expression levels in the VCN. Significant increments in Kv3.1 message in the MNTB and IC were not observed until PD12 and PD14, respectively. Developmental changes in Kv3.1 immuno-reactivity followed a similar time course as that of the Kv3.1 message. Interestingly, the pattern of neuropil versus somatic staining was somewhat different from that of adult and varied among VCN, MNTB and IC.

Our data suggests that changes in Kv3.1 expression levels may contribute to the developmental changes in temporal acuity observed in auditory neurons. In addition, the large increase in Kv3.1 expression near the time of hearing onset coupled with the serial maturation pattern suggests that neuronal activity may play a role in regulating Kv3.1 expression levels. (Supported by a Rutgers Research Council Grant and PHS R29 DC02728-01)

## 57.12

DYNORPHIN-LIKE IMMUNOREACTIVITY IN THE CHICK AUDITORY BRAIN STEM. R.A. Code\*, Dept. of Biology, Texas Woman's University, Denton, TX 76204-3799.

Dynorphin-like immunoreactivity (DYN-I) was studied in brain stem auditory nuclei of the domestic chick using an antiserum to dynorphin-B and standard immunohistochemical procedures. In the cochlear nucleus magnocellularis (NM) of young posthatch chicks, DYN-I can be localized to both nerve cell bodies and terminals. Although few in number, DYN-I cell bodies are usually found in medial regions of NM. Many non-DYN-I nerve cell bodies in NM, however, are ringed by DYN-I structures that are especially prominent in lateral regions of NM. These structures, presumably nerve terminals, have a distinct calyceal, rather than punctate morphology, reminiscent of auditory nerve terminals, the end-bulbs of Held. In the cochlear nucleus angularis (NA), there was little, if any, DYN-I. The dendritic fields of neurons in the nucleus laminaris (NL) contained DYN-I as did an occasional cell body in lateral NL. A few small DYN-I cell bodies were observed in the superior olivary nucleus (SO).

This is the first report of DYN-I in the avian auditory brain stem. The data suggest that dynorphin may be a neuromodulator within end-bulbs of Held and may be expressed in neurons of several auditory nuclei.

The DYN-B antiserum was kindly provided by Dr. Stanley Watson, University of Michigan's Mental Health Research Institute. This work was supported by research grant number 1 R29 DC02633 from the National Institute on Deafness and Other Communication Disorders, NIH.

## 57.14

SYNAPTIC REARRANGEMENT IN THE BARN OWL AUDITORY BRAINSTEM DURING THE SENSITIVE PERIOD. M.F. Kubke, L.L. Rigby, L. Basu, C.E. Carr and A. Moiseff\*, Univ. Maryland, Dept. Zool., College Park, MD 20742 and \*Univ. Connecticut, Dept. Physiol. & Neurobiol., Storrs, CT 06269.

Barn owls use interaural time differences (ITDs) as a cue for sound localization. The auditory nerve (AN) projects to the nucleus magnocellularis (NM) which in turn projects bilaterally to nucleus laminaris (NL) where ITDs are computed. In the first 2 months posthatch, the owl's head grows, increasing the interaural distance and thus the range of ITDs experienced. These changes are accompanied by changes in excitatory and inhibitory connections in the auditory brainstem and by changes in the auditory brainstem response (ABR).

Synapses were visualized with an antibody against synaptic vesicle protein SV2 (gift of K. Buckley), while GABAergic synapses with an antibody against GAD (GAD-1440). Neurons were also labeled with antibodies against calbindin and calretinin.

In very young birds, ABRs are highly variable and not well differentiated. SV2 and GAD, however, delineate connections in the auditory brainstem and calretinin labels the axons of the time coding pathway. At 2-3 weeks posthatch, the shape of the ABR becomes predictable. At this time, there are dramatic changes in the maturation of the synaptic structures in the auditory brainstem. AN terminals in NM are fairly mature, and by P21 are indistinguishable from the adult. In NL, there is a large increase in the density of GAD terminals that peaks at P14 and drops by P21. Similarly, calretinin appears in NL cell bodies by P21. These morphological changes are temporally correlated with the appearance of synchronous ABR's in the young barn owl.

Supported by NIH DCD000436 to CEC and NIH DCD00277 to AM.

## 57.15

SYNAPSES IN THE AUDITORY BRAINSTEM OF THE BARN OWL FORM DURING THE PERIOD OF EMBRYONIC CELL DEATH. D.P. Massoglia\*, M.F. Kubke, L.L. Rigby and C.E. Carr. University of Maryland, Dept. Zoology, College Park, MD 20742.

In the barn owl, the auditory nerve (AN) projects to the intensity coding nucleus angularis (NA), and to the phase coding nucleus magnocellularis (NM). NM projects bilaterally to nucleus laminaris (NL) where ITDs are computed. Synaptogenesis in these auditory brainstem nuclei was described at the light and electron microscopic level the period of cell death (E17-E25). Neurons and synapses were visualized with antibodies against MAP2 and synaptic vesicle protein (SV2; kindly provided by K. Buckley).

At the onset of cell death (E17), synapses are formed between AN and NA and between NM and NL, but not between AN and NM. The NM input to NL is confined to the distal dendrites of NL neurons, and forms a band of terminals on the edges of NL, appearing to recapitulate the pattern found in chickens. By E21, NM receives AN inputs, NL dendrites have begun to retract and NM terminals have moved further into NL. Thus synaptogenesis and reorganization of the inputs to NL overlaps with the period of cell death.

Early in the cell death period, NL neurons receive both their appropriate inputs from NM and reach the NL projection area in the inferior colliculus core. NL neurons do not, however, receive primary sensory (AN) input via NM until later in the cell death period. This appearance of sensory input coincides with the movement of NM terminals into NL.

MORPHOLOGY OF NEURONS CULTURED FROM SUBDIVISIONS OF THE COCHLEAR NUCLEUS. J.L. Fitzakerley\* and L. Schweitzer. Department of Anatomical Sciences and Neurobiology, University of Louisville School of Medicine, Louisville, KY, 40206.

In the adult animal, neurons of the cochlear nuclear complex (CN) have been classified on the basis of their morphology, and cells with particular characteristics have been localized to specific CN subdivisions. It is not clear, however, whether cultured CN neurons exhibit the variety of somato dendritic morphologies observed among CN cells *in vivo*. The objectives of this study were: 1) to describe the morphology of cultured CN neurons using standard anatomical techniques, and 2) to compare cultures obtained from different subdivisions of CN. Low density, primary cell cultures were prepared from the CN of 7 postnatal day C57B6 mice and maintained in serum-free media. Cultures were obtained from the anterior or posterior regions or from the whole nucleus by dividing some CN at the nerve root. Cultures were fixed after 4 days *in vitro*, and MAP2-positive cells were identified using immunohistochemical techniques. CN neurons were successfully cultured from all three regions, although fewer cells were consistently obtained from the anterior region. Soma size was similar among all 3 groups, however, neurons obtained from the posterior region tended to have nuclei that occupied less of the cytoplasm. When plated at the same density, fewer neurons cultured from the posterior CN extended processes as compared to whole CN preparations. Neurons cultured from the different CN regions also exhibited differences in dendritic structure that may be due to differences in the density of the surviving neurons. The goal of these experiments is to establish cultures of CN subdivisions that provide equivalent environments in which to study the differentiation of CN neurons. ## 57.19

BILATERAL DESCENDING INFERIOR COLICULUS PROJECTIONS TO THE VENTRAL NUCLEI OF THE TRAPEZOID BODY IN THE GERBIL.

N. Kuwabara\*<sup>1</sup>, M.A. Notestine<sup>2</sup> and J.M. Zook<sup>2</sup>. <sup>1</sup>Dept. of Anat. Sci. and Neurobiol., Univ. of Louisville Sch. of Med., Louisville, KY 40292. <sup>2</sup>Dept. of Biol. Sci. and OUCOM, Ohio Univ., Athens, OH 45701.

The ventral nucleus of the trapezoid body (VNTB) receives both ascending and descending afferent projections and contributes both ascending and descending efferent projections, suggesting that it is the major intersection of the ascending and descending auditory systems in the superior olivary complex (SOC). In this study descending projections of the inferior colliculus (IC) were studied with the objective of examining the relationship of the afferent and efferent projections of the VNTB. Intracellular and extracellular labelings with Biocytin and Neurobiotin were combined with HRP retrograde tract-tracing technique in gerbil brainstem preparations. Biocytin was injected in the IC either ipsilateral to or contralateral to the HRP-injected ventral cochlear nucleus (VCN). In some cases axons that project to the VNTB cells were intracellularly labeled with Neurobiotin in brainstem tissue slices taken from gerbils with HRP-injected CN.

A sizable projection from the IC to the contralateral VNTB was found as well as the traditional projection from the IC to the ipsilateral VNTB. The axon terminals of IC cells within the contralateral VNTB were associated with HRP-labeled cells that, in turn, project to the VCN ipsilateral to the VNTB (contralateral to the originating IC). In the case where both Biocytin and HRP were injected in the same side, a minor descending projection from the IC was seen only in the ipsilateral VNTB, where they were associated with HRP-labeled cells. These results show that a majority of IC descending information is relayed to the contralateral VCN by way of both the ipsilateral and contralateral VNTB's. ## 57.16

DEVELOPMENT OF BRAINSTEM AUDITORY NUCLEI IN AN ECHOLocATING BAT. R. Roatright and E. Covey\*, Dept. of Psychology, University of Washington, Seattle, WA 98195.

Echolocating bats are able to navigate and forage in complete darkness based on acoustic information from echoes of the ultrasonic pulses that they emit. Because many species of bats do not begin to echolocate until several weeks after birth, we might expect to see a correlation between the onset of echolocation behavior and the maturation of those nuclei that are important for the echolocation process. We investigated the pre- and postnatal development of auditory structures in the big brown bat, *Eptesicus fuscus*, in terms of gross cytoarchitectural changes and in terms of cell density and distribution. The results show that all brain structures undergo substantial growth between birth and adulthood; however, the growth rates for different nuclei are not uniform. For example, at birth the medial nucleus of the trapezoid body (MNTB) is 78% of its adult size, indicating a substantial amount of prenatal growth. Other nuclei that are relatively mature at birth (64-71% of adult size) are the lateral superior olive (LSO), the cochlear nucleus (CN) and the inferior colliculus (IC). Nuclei that double their size between birth and adulthood include the medial superior olive (MSO), the superior paraolivary nucleus (SPN) and the nuclei of the lateral lemniscus (NLL). The medial geniculate body (MGB) is the least developed auditory nucleus at birth, with only 31% of its growth occurring prenatally. Amount of growth in each nucleus is roughly correlated with changes in cell density. In the LSO, CN and MSO, density decreases by over 50% prenatally, but by 20% or less postnatally. In contrast, cell density in the MGB decreases by only 9% prenatally, but by 28% postnatally. If decreases in cell density are in part due to increased formation of neuropil and synaptic connections, it is possible that the delayed development of the MGB is associated with postnatal learning and establishment of echolocation behavior. Supported by research grant DC-00607, from the NIDCD, NIH.

AXONS FROM ANTEROVENTRAL COCHLEAR NUCLEUS (AVCN) THAT TERMINATE IN MEDIAL SUPERIOR OLIVE (MSO) OF CAT: OBSERVATIONS RELATED TO DELAY LINES. D.L. Oliver\* and G.E. Beckius, Department of Anatomy, University of Connecticut Health Center, Farmington, CT 06030-3405.

A delay line composed of axons was proposed as the mechanism for computation of interaural time difference (ITD) in MSO. We hypothesize rostrocaudal differences in MSO innervation may be related to a map of ITD. In two cats, anterior AVCN was injected with biotinylated dextran where neurons had BF's of 1.4-1.5 kHz. Complete 3-D reconstructions of axons were made in serial 100  $\mu$ m-thick sections. Axons were traced from the injection site, through the superior olive, and to the contralateral lateral lemniscus. Axons terminated in bilaterally symmetrical, single, horizontal laminae. Due to their similar injection sites, these axons may have overlapping response areas. In the contralateral MSO, rostral neurons always receive inputs from axons that travel in the rostral trapezoid body and take a short, direct path from the cochlear nucleus. Innervating middle MSO are axons that either follow a short path through the middle trapezoid body or take a longer path via the rostral MSO (the Jeffress-type delay line). In the caudal MSO, axons either follow a short path through the caudal trapezoid body, take a longer path via middle MSO, or take the longest path via rostral MSO. Thus on the contralateral side, rostral MSO neurons may receive well-synchronized, phase-locked inputs that follow a uniformly short path-length; successively more caudal neurons may receive less synchronized inputs because of more variable path-lengths. On the ipsilateral side of MSO, the path-lengths follow a different pattern. Axons that innervate the middle MSO follow the shortest path from the cochlear nucleus. Axons to the rostral MSO may follow a longer route (the Jeffress-type delay line). Neuron in the caudal MSO receive variable-length inputs and may be less synchronized. Thus, our results support the Jeffress model and suggest that differential path lengths may contribute to small ITDs in rostral MSO and larger ITDs caudally. It also appears that the combination of different path lengths to middle and caudal MSO may provide less synchronized inputs to those areas. Supported by NIH grant DC00189.

## 57.20

AXON TERMINALS ON OLIVOCOCHLEAR NEURONS.

J.C. Adams\* ENT Dept., Mass. Eye & Ear Infirmary Boston, MA 02114.

Olivocochlear (OC) neurons were retrogradely labeled by HRP injections of cat cochleas. The retrogradely labeled cells were made fluorescent using the transported HRP to biotinylate the tissue and then applying FITC-labeled streptavidin. Nerve endings apposed to the labeled cells were immunostained with antibodies to synaptophysin, GAD, or substance P. Immunoreactive sites were labeled with CY-5 labeled secondary antisera so the positive cells and terminals could be viewed in the same tissue. Few immunostained nerve terminals were found apposed to any olivocochlear cell body or dendrite. Medial and lateral OC cells were indistinguishable by their innervation pattern as seen by synaptophysin and GAD immunostaining. Substance P positive terminals were associated with only lateral OC cells. This suggests an innervation to lateral cells from the inferior colliculus which is not shared by medial cells. These results indicate that OC cells are sparsely innervated. This property may be partly responsible for the chopper sound-evoked discharge patterns that characterize medial OC cells, as well as other sparsely innervated cells of the cochlear nucleus.

## 57.21

AFFERENT AND INTRINSIC PROJECTIONS TO THE DORSAL NUCLEUS OF THE LATERAL LEMNISCUS. J.M. Zook\*, B. Schanbacher and N. Kuwabara, Biol. Sci., Coll. Osteo. Med., Ohio U., Athens, OH 45701.

Recent anatomical and physiological data suggest that the dorsal nucleus of the lateral lemniscus (DNLL) represents much more than a simple relay station passing ascending auditory information on to the inferior colliculus (IC). One striking anatomical feature is the ordering of DNLL cells and dendrites into a complex 3-D pattern of nested spheres: each spherical layer representing a part of the tonotopic projection of the DNLL to the IC (Willard & Ryugo, '83; Merchan et al., '94). In the gerbil, only the ventral DNLL shows such a spherical pattern; dorsally cells and dendrites show a simpler pattern, extended parallel or perpendicular to the surrounding lemniscal fibers.

We have been examining the pattern of ascending and intrinsic axon terminals within these two distinct areas using intra-axonal injections of Lucifer Yellow and biocytin in a tissue slice preparation of the gerbil brainstem. In the ventral, spherically organized DNLL terminal branches tend to follow restricted paths along a single curving cytodendritic layer. Multiple branches coming off a single main axon often ramify within separate regions of the same cytodendritic shell. Some intracellularly labeled cells in the ventral DNLL showed locally terminating, intrinsic axon branches limited to single cytodendritic layers, but more commonly, intrinsic axons ramified across many different layers. In the dorsal DNLL, the distribution of ascending and intrinsic axons is less clearly organized, with some tendency for axons to terminate in horizontal bands. At least in the ventral part of the gerbil DNLL, the distribution of afferent input appears to be dictated by this region's striking cytodendritic organization. (Supported by DC02397 and OUCOM).

THE INFLUENCE OF CONTRALATERAL AFFERENT STIMULATION ON QUADRICEPS FEMORIS (QF) MAXIMAL VOLUNTARY ISOMETRIC CONTRACTION (MVIC) - L.E. Tremblay\*, Chris Sulway and David Frake, Physiotherapy Program, Univ. of Ottawa, Canada.

Past research shows a decrease in muscular force generated during a bilateral lower extremity contraction. Our investigations have been to decide whether this is central, postural or mechanical in origin. This study was undertaken to examine whether a stimulus to the contralateral (contra) lower extremity has an influence on the ipsilateral (ipsi) QF MVIC, in the hope that the stimulus response would explain the decrease in force. Forty five volunteer subjects (male,  $27 \pm 5$  years) were obtained for the study. The following forms of contra stimulation were administered: MVIC, tetanizing electrical stimulation (TES), QF M-response, QF H-reflex, QF patellar reflex, vibratory (on the patellar tendon) and cutaneous stimulus. The stimulation was applied using standardized protocol to the femoral nerve, the inguinal skin surface or the patellar tendon. The ipsilateral QF MVIC was measured with a KIN-COM 550 H at  $0^\circ$  per sec. angular velocity, fixed at an angle of  $90^\circ$ , using standardized protocol. Furthermore an interpolated twitch technique (ITT) was used on the IPSI QF during bilateral contraction to evaluate motor unit activation. This technique aims to induce an M-response during MVIC. EMG recordings of both QF were monitored on a few subjects for subjective comparison. Among the healthy subjects, contra-stimulation produced the following ipsi inhibitory effects ( $P < 0.05$ ): MVIC -  $5 \pm 1.2\%$ , TES -  $12.2 \pm 1.8\%$ , QF H-reflex -  $11.6 \pm 2.6\%$ , QF patellar reflex -  $17.5 \pm 3.3\%$ , QF M-response, vibration and cutaneous stimulus - no significant effect. By using the ITT, we can exclude postural and mechanical sources as possible origins for the deficit. The inhibition can however be explained by peripheral afferents either within a spinal cord loop or a longer sensori-motor cortex loop. Further research is needed to decide the exact mechanism of the central inhibition.

## 58.3

NERVE CUFF RECORDED RESPONSES FROM CUTANEOUS NERVES IN MAN, EVOKED BY SLIPPAGE EVENTS ON THE SKIN. R. R. Riso\* and P.J. Slot, Center for Sensory-Motor Interaction, Aalborg Univ. Fredrik Bajersvej 7D, Aalborg, 9220-Denmark

We are studying means to extract control signals from mechanoreceptor afferents within the digital skin in spinal injured, individuals. Such signals are needed for closed-loop control in FES that can restore grasp function. It has been demonstrated that an artificial reflex can be set up for use with FES grasp: This entails detecting the afferent activity evoked by slippage of a grasped object and using this activity to increase the grip strength to arrest the slippage (Lickeal et al., IEEE Ann. Meeting, Amsterdam, 1996). To optimize the slippage based control strategy we wish to know the effect of friction of the grasped surface and the effect of the slip velocity. ENG was recorded using a tripolar nerve cuff implanted chronically around the digital nerve subserving the lateral border of the index finger in a C6 subject. A servo-controlled mechanical stimulator was used to move a contactor across the digital skin. The ENG was filtered (1k-5kHz), and sampled (12.8kHz). Vertical and lateral positions of the contactor, and the normal and shear forces were also recorded (400Hz). We studied 3 frictional surfaces: sandpaper, suede and silk, and investigated velocities of sliding from 2.5 to 25mm/s. Results showed that the ENG increased in a linear fashion with increasing velocity for each different surface. The effect of different frictional surfaces was that the ENG decreased for lower friction. Close examination of the sliding events revealed that the ENG sliding was mainly driven by skin stretch immediately before the onset of the sliding and then again immediately after in a cyclical slip-catch-slip sequence. The effect of the increase in ENG with increased sliding velocity is useful because it suggests that an adaptive FES controller could be developed so that increased sliding velocity would be detectable in the ENG.

## 58.2

ELECTRICAL ACTIVATION OF CUTANEOUS AFFERENTS FOR REDUCTION OF SPASTICITY: EFFECT OF STIMULUS FREQUENCY

Brian D. Schmit\*, Julius P.A. Dewald, Joseph D. Given and W. Zev Rymer, Sensory Motor Performance Program, Rehab. Institute of Chicago, and Dept. of Physical Medicine and Rehabilitation, Northwestern University Medical School, Chicago, Illinois 60611

Electrical activation of cutaneous afferents with a stimulus frequency in the range of 1-100 Hz reduces spasticity in stroke subjects. The results of the current study provide evidence for an expanded range of frequencies effective for spasticity reduction and follow from previous results demonstrating spasticity reduction by activation of cutaneous afferents at 20 Hz. The effects of a wider range of stimulus frequencies will be used to optimize the stimulus parameters for spasticity reduction.

Spasticity was quantified by examining the stretch reflex response to constant velocity ramp flexion and extension of the elbow joint. Elbow torque, position, and velocity were measured along with surface EMG's of the biceps, lateral head of the triceps and brachioradialis. Stimulus electrodes were placed on the skin over the biceps muscle. The EMG's were measured using a custom amplifier with an artifact suppression circuit to ascertain that the stimulus was below motor threshold at all elbow positions. Trials were initiated in the extension position and ramped to the flexion position held for 10 seconds and then ramped back to extension. Sixty seconds were allowed between trials. The angular velocity was selected to produce a stretch reflex. The experimental protocol consisted of 20 prestimulus ramp stretches followed by fifteen during stimulation and thirty post stimulus trials. A stimulus intensity between sensory and motor thresholds was applied at a frequency of 1, 20 or 100 Hz.

We observed reductions in spasticity during stimulation and throughout the 30 minutes following stimulation in the frequency range of 1-100 Hz. The efficacy of cutaneous afferent stimulation over a wide range of stimulus frequencies may provide additional information for identifying the physiologic mechanism responsible for the lasting effects of cutaneous stimulation. These data will be used to develop the framework for the use of electrical stimulation to reduce spasticity in stroke and spinal cord injury using surface skin electrodes.

## 58.4

MUSCLE AFFERENT ACTIVITY RECORDED DURING PASSIVE EXTENSION-FLEXION OF RABBIT'S FOOT. K. Mosallae\*, R. R. Riso and T. Sinkjaer, Aalborg Univ., Fredrik Bajersvej 7D., 9220, Aalborg, Denmark

Damage to the spinal cord such as traumatic injuries results in a permanent loss of motor function and sensation due to the disruption of communication at the lesion site. However, the peripheral motor and sensory nerves and muscles retain some functionality below the lesion. FES can be used to restore function in paralyzed patients, however, lack of feedback results in imprecise and inefficient movements. Natural sensors, which are already present in the body, may provide information for feedback control in an FES system. The objective of this study was to study muscle afferent activity during passive motion of the ankle joint. The nerve signals were recorded from peroneal and tibial nerve using cuff electrodes in a reduced rabbit model. The experimental apparatus consist of a computer controlled position servo system to rotate the animal's ankle in dorsi-flexion/plantar-flexion. Neural activity was recorded simultaneously from tibial and peroneal nerves during passive trapezoidal motion. Excursions of 10, 20 and 30 (deg) and rates of 5, 10, 20, and 30 (deg/sec) along with different starting positions were investigated. Descending branches of the tibial and peroneal nerves and the sural nerve were transected to eliminate cutaneous input. Also lidocaine was infused into the joint capsules of the ankle and knee which did not significantly diminish the responses. The evoked activity included a mixed components from both primary and secondary muscle afferent endings. Evoked activity from both nerves increased when the corresponding muscles were stretched. Nerve activity decreased abruptly when the muscles were shortened. However, the maximum peak was nearly independent of the rotation rate and was mostly dependent on the excursion magnitude. For either nerve, the activity increased with increasing velocity of rotation. We also observed silent periods, close to the neutral ankle position, where there was no significant neural activity from either of the extensor or flexor muscle afferents. We conclude that the evoked activity mainly originates from muscle afferents with both position and velocity sensitivities.

CONDITIONING HUMAN LONGER LATENCY REFLEX RESPONSES IN THE BICEPS BRACHII. S.L. WOLF\*, R.L. SEGAL, P.A. CATLIN, R.L. SLAVEN, J.K. TAFFS, H.C. TREES, E.F. VICKERS. Div. Phys. Ther., Emory Univ. Sch. of Med., Dept. Rehab. Med., Atlanta, GA 30322.

Conditioning of the biceps brachii spinal stretch reflex (SSR) produces concurrent changes of the same direction in longer latency reflex responses (LLRR, Wolf et al. 1995; Wolf and Segal, 1996). The purposes of this study were to determine if the magnitude of the biceps brachii LLRR in able-bodied subjects could be reduced with direct operant conditioning, and to examine the relationship of changes in the conditioned biceps brachii LLRR with changes in the biceps brachii SSR, and the LLRR and SSR of a synergist muscle, the brachioradialis. Fourteen subjects participated in six baseline sessions. Then, all subjects were randomly assigned to either control (n=6) or training groups (n=8). The control group received eight more baseline sessions, while the training group received eight sessions with feedback of the biceps brachii LLRR magnitude in an attempt to downtrain the response. The training group significantly reduced the magnitude of the LLRR compared to mean baseline values by 57% in the biceps brachii and by 68% in the nontargeted brachioradialis. The SSR of the biceps brachii and brachioradialis did not change significantly. Training effect specificity occurred since changes were only seen in the response targeted by operant conditioning. Because response specificity had not been observed previously when conditioning SSR responses, different sites within the nervous system may be altered for each training effect.

## 58.7

PROPRIOCEPTIVE COORDINATION OF AXIAL MOVEMENT. P. CORDO, V. GURFINKEL, S. VERSCHUEREN, T. SMITH and J. J. COLLINS\* R. S. Dow Neurological Sciences Institute, Portland, OR 97209

To understand how the CNS coordinates axial movement, sitting up from a supine position was examined in normal human subjects. Sitting up is a complex movement, because body mass distribution favors lifting of the legs rather than the trunk during activation of hip flexors. Due to the sequential nature of sitting up, proprioception might play an important role in the coordination of this movement.

Twelve subjects—lying on a large force plate—sat up from a supine position with the arms across the chest. Movement time was constrained to 2 s. Recordings were made of whole-body kinematics, support-surface forces and the EMG activity of neck, trunk and leg muscles. In addition to standard trials, subjects performed sit-ups with the legs strapped to the force plate (i.e., making sitting up easier), with the legs hanging off the end of the table (i.e., making sitting up more difficult), and during vibration of the thoracic back extensor muscles.

We found that sitting up is carried out in two distinct and sequential phases. In the first phase, the upper body curls in a sequence of neck, upper-trunk and lower-trunk flexions, thereby shifting the upper-body center of mass towards the hips. In the second phase, hip flexor activation rotates the pelvis towards the feet, thereby lifting the trunk into a sitting position. Strapping the legs to the force plate eliminates the sequential properties of sitting up, resulting in one synchronized movement of the neck and trunk. Hanging the legs from the force plate delays sitting up and adds a rapid knee extension to the sequence. Vibration of the thoracic paraspinalis muscles delays or can even prevent sitting up, thereby demonstrating proprioceptive coordination.

## 58.9

EFFECTS OF FATIGUE ON VOLUNTARY ELBOW FLEXION MOVEMENTS. H. JIANG, G. L. GOTTLICH, D. M. CORCOS\* University of Illinois at Chicago, Rush Medical Center and NeuroMuscular Research Center, Boston University,

Few studies have been conducted on how the control of limb movement is affected when muscles are fatigued. These studies suggest that fatigue leads to only small changes in movement kinematics which are accompanied by small increases in the duration of the agonist EMG. We hypothesized that one possible reason for observing only small changes in movement kinematics and EMG is that only small forces were generated in the particular movements studied. As such we designed an experiment which compared fatigued and unfatigued movements performed against an inertial load over two distances (20° and 60°). Considerably larger torques are generated for the longer distance.

Consistent with previous results, there were small changes in both EMG and kinematics for movements over the short distance in the fatigued condition. In contrast, for the long movement, peak movement velocity was reduced by 25% and peak inertial torque was reduced by 37%. This reduction in movement velocity and peak inertial torque was associated with a decrease in agonist EMG, a prolongation of the agonist burst and a delay in the activation of the antagonist muscles. The results suggest that even when muscles are fatigued to the point that they can only produce 50% of their maximum unfatigued voluntary contraction, when force requirements are low, movement is minimally affected by fatigue but when high force levels are required, movement may be significantly slowed. The muscle activation patterns are modified by fatigue in a manner that may represent a central adaptation to changes in peripheral, neuromuscular properties.

## 58.6

EFFECTS OF TWO TRAINING PROCEDURES ON PROPRIOCEPTIVE SENSITIVITY. D.K. Fry-Welch\* and C.J. Worringham. Physical Therapy Dept., University of Michigan-Flint, Flint, MI 48502.

Although many studies examine proprioception, very few studies have examined training-induced changes in proprioceptive sensitivity. Thirty subjects, age 19.5-40 years with no known upper extremity neurologic or orthopedic abnormalities, participated in pre- and post-treatment testing sessions. The proprioceptive comparison (PC) test required subjects to determine which elbow was more flexed without vision and the proprioceptive matching (PM) test required subjects to match the non-dominant elbow position with the dominant elbow position without vision. Ten subjects received training on distinguishing elbow angles similar to the PC test. Ten subjects received training on matching elbow positions similar to the PM test. Ten control subjects received no training.

The PM and PC trained groups both improved performance significantly on the post-test similar to their training ( $p=0.028$  and  $p=0.028$  respectively). The PM trained group also improved significantly on the PC test ( $p=0.020$ ). The control group did not improve on either test. The results suggest that proprioceptive sensitivity can be improved with training in normal adults. The finding that the PM trained group improved on both tests, whereas the PC trained group did not may be explained either by: 1) the error correction component in the feedback for the PM, but not PC, trained group; or 2) the graded motor output inherent in the PM but not the PC training.

SINGLE-LEG BALANCING FOLLOWING TREATMENT ON A BAPS<sub>®</sub> BOARD AND A THERASTEP<sub>®</sub> EXERCISER. B.R. JUNE\* and J.A. O'KROY. Human Performance and Health Sciences Department, Rice University, Houston, TX 77005.

A common treatment used for improving lower extremity proprioception is by exercising on a BAPS<sub>®</sub> board. A foam half-cylinder called Therastep<sub>®</sub> recently has been introduced to perform a similar function to the BAPS<sub>®</sub> board at considerably less cost. The purpose of this study was to compare the effects of exercise with each instrument on a single-leg balancing task. Thirty-one subjects (mean age=19.6, S.D.=8.5) participated. Each subject performed a block of three 20 sec trials by balancing on one leg on a force plate (AMTI) prior to any exercise. The subjects then exercised for one minute on one instrument followed by another block of trials on the force plate. After the second set of trials the subjects exercised on the other instrument for one minute before performing a third block of trials. The BAPS<sub>®</sub> board exercise was performed by rotating the ankle in circles. The Therastep<sub>®</sub> exercise was performed by balancing on one leg on the instrument. Approximately half the subjects exercised on the BAPS<sub>®</sub> board first and the others used the Therastep<sub>®</sub> first. The excursion of the Center of Pressure (COP) on the force plate was measured in the X (lateral) and Y (fore-aft) planes. The deviations were integrated for each trial and average force was normalized to body weight. The percent of COP time within a 2 cm radius was also calculated for each trial. The trials following the Therastep<sub>®</sub> had the least deviation in the X and Y directions (3.46 cm and 0.75 cm, respectively) compared with the trials following the BAPS<sub>®</sub> exercise (3.47 cm and 0.79 cm) and the pre-exercise trials (4.0 cm and 0.78 cm). Average percent of time of the COP within a 2 cm radius was greatest following the Therastep<sub>®</sub> exercise (87.0%) compared with the post-BAPS<sub>®</sub> board balancing (84.9%) and the pre-exercise means (81.2%). However, no significant differences were revealed for any of the variables between the pre-exercise, post-BAPS<sub>®</sub> and post-Therastep<sub>®</sub> balancing measures. It was concluded that if these exercise instruments improved proprioception it was not measured by a single-leg balancing task.

## 58.10

MYOELECTRIC CHANGES DURING MUSCLE FATIGUE AND RECOVERY. M. B. IYER\*<sup>1,2</sup>, J. F. ANDREWS<sup>1,3</sup> and T. W. FINDLEY<sup>1,2</sup>. <sup>1</sup>Dept. of Physical Medicine and Rehabilitation, UMDNJ-New Jersey Medical School, Newark, NJ; <sup>2</sup>Kessler Institute for Rehabilitation, Dept. of Research, West Orange, NJ; <sup>3</sup>Dept. of Elec. and Computer Engg., NJIT, Newark, NJ.

This study utilizes time- and frequency-domain analyses to examine the changes in myoelectric activity during fatigue and recovery following a sustained maximal isometric contraction. Muscle fiber conduction velocity (MFCV), power spectrum median frequency of the electromyogram (EMG), and the coherence function between EMG signals and force were studied in healthy human subjects. EMG signals were recorded from the abductor digiti minimi muscle. The experimental protocol was as follows: 1) the pre-fatigue phase consisting of brief isometric contractions in the range of 20% to 30% of maximal voluntary contraction (MVC); 2) the fatigue phase involving a sustained isometric contraction at 100% of MVC until the force output decreased to 50%; and 3) the recovery phase comprising a series of short contractions (range 20% to 30% of MVC) at brief intervals starting 30 seconds after termination of the fatigue phase. During the pre-fatigue and recovery phases, subjects produced either steady or nearly sinusoidal isometric contractions. The median frequency (MF) was computed from the auto-power spectrum of the EMG signal. The MFCV was computed by cross-correlation of surface EMG signals. Both MFCV and MF values decreased with fatigue. This study showed a rapid return to pre-fatigue values both in MFCV and MF. In contrast to the literature, no overshoot of these values was observed in the recovery phase. Studies are in progress to determine whether this finding is possibly due to the measurements being obtained during submaximal contractions under aerobic conditions.

Supported by NIDRR H133P40003 and NIH 5 T32 HD07417.

**CROSS-TRANSFER PHENOMENON: FACILITATED BY ELECTRICAL STIMULATION?** J.Lambert\*, T.Hortobagyi, K.Scott, J.Hill, C.Webb. Department of Physical Therapy and Biomechanics Laboratory. East Carolina University, Greenville, NC, 27858.

The purpose of the study is to determine if voluntary eccentric strength training elicits a greater cross-transfer of strength than passive electrically stimulated training. Sedentary females, matched according to maximum strength were randomly assigned to voluntary (VOL, n=8) or electromyostimulation (EMS, n=8) trained groups. Subjects of both groups trained 3-4 sessions/week for 6 weeks with a progressive training protocol of isokinetic eccentric contractions of the knee extensors. EMS-evoked contractions of the vastus lateralis and vastus medialis muscles were elicited at the maximum tolerable intensity. Matched subjects in the VOL and EMS groups trained at the same schedule with identical contractile intensities as determined by the maximal force that could be electrically evoked for the EMS subject. The contralateral leg was not exercised. The two trained groups and a control (CON, n=6) group, that did not receive training, were tested 3 times (2 times prior to training and 1 time following the 6 weeks of training). Pre to post training increases in volitional eccentric strength were observed for both legs of the VOL and EMS trained groups ( $p < .05$ ), but not the CON group. There was no significant difference between the VOL and EMS groups for increased strength of trained legs (VOL 54%, EMS 36%), or the untrained legs (VOL 23%, EMS 34%). These results indicate that the EMS-evoked eccentric training is equivalent to voluntary training in eliciting a cross-transfer of strength, suggesting that the responsible neural adaptations may not require volitional effort.

**AGING EFFECTS ON MOTOR SKILL LEARNING AS AN EARLY NEUROMUSCULAR ADAPTATION DURING CONCENTRIC AND ECCENTRIC DORSIFLEXOR STRENGTH TRAINING.** D. Connelly, H. Camahan, A.A. Vandervoort, and J.T. Inglis\*. Faculty of Kinesiology,

<sup>2</sup>Department of Physical Therapy, University of Western Ontario, London, Ontario, Canada.

<sup>3</sup>Department of Kinesiology, University of Waterloo, Waterloo, Ontario, Canada.

Torque values and integrated electromyography (iEMG) increase dramatically at the onset of resisted exercise and can be used to quantify neuromuscular adaptation. A 'learning effect' also contributes to this early increased force and iEMG production. The purposes of the study were: 1) to investigate the effects of age on motor learning during concentric and eccentric dorsiflexor (DF) isokinetic strength training and 2) to chart the time course of skill acquisition in older versus young subjects. Twenty women, 15 older ( $\bar{x} = 74.7 \pm 3.8$  years) and 5 young ( $\bar{x} = 24.2 \pm 1.6$  years), volunteered for a two-week, 3 days/week, strength training program. They were tested in a sitting position on a KinCom isokinetic dynamometer at 30, 90 and 180°/sec through 40° of DF movement. Criterion curves of lever arm angle patterns were cross-correlated against subject-generated angle patterns. Correlations for pre-test angle patterns for older and young women were significantly different ( $p < 0.01$ ). A significant difference was found between the pre- and post-test movement patterns for older ( $p < 0.01$ ) but not young subjects. Post-test DF movement patterns did not differ with age. The major training effect was observed at 180°/sec velocity, after several days of training ( $p < 0.05$ ). Only older subjects improved significantly in DF movement patterns over time. At the onset, young subjects performed at a higher level and maintained this level throughout the training. These results suggest that the 'learning effect' was gradual over the course of training. The decrease of several factors: muscle force production, control of muscle shortening and lengthening, and proprioceptive feedback may have contributed to the age differences. Supported by NSERC and PFC-RCL funding.

**HEAD AND TRUNK STABILIZATION DURING MULTIJOINT STANDING PULLS.** W.A. Lee<sup>1,2</sup> & J.W. Steege<sup>1</sup>. <sup>1</sup>Prog. Physical Therapy & <sup>2</sup>Inst. Neuroscience, Northwestern Univ., Chicago, IL, 60611.

It is often asserted that pitch plane head rotations are minimized during voluntary movements to facilitate sensory inputs for motor control, but little is known about how angular head stabilization (HS) changes as a novel, whole-body motor skill is learned. This study analyzed pitch plane HS and its relationship to angular and linear trunk movements during the learning of a multijoint pulling task. Ten healthy adults stood on a force platform, grasping a handle which was attached to a load cell. On each of 5 days, they made 120 abrupt pulls to target forces equal to 20, 40 and 80 percent of their theoretical maximum. They were told to keep their feet stationary, but could otherwise move their bodies freely. Kinetic, kinematic, and pulling force data were recorded.

Subjects adopted a general pattern of head rotations that persisted across force and practice levels; they rotated their heads forward during the Pulling phase (from the onset of the pulling force to the peak pulling force,  $F_{pk}$ ), reversed the direction of head rotation at  $F_{pk}$ , and then rotated their heads backward during the Release phase (from  $F_{pk}$  to the offset of pulling force). Angular trunk movement patterns were more variable. After practice, there was significantly less head rotation during the Pulling phase, indicating that overall HS had improved. Significant decreases in peak angular trunk velocity during both the Pulling and Release phases indicated that overall angular trunk stabilization also improved with practice. During 80% pulls, peak linear (AP) velocities of the neck also decreased with practice in 7 subjects, suggesting that these subjects may have learned to stabilize their heads via an avoidance mechanism in which they minimized both linear and angular trunk movements. During 40% pulls, in contrast, linear trunk perturbations of the head (peak AP neck velocities) increased with practice in 9 subjects; head movements nevertheless decreased in 5 of those subjects, suggesting that they may have improved HS by changing predictive control of their neck muscles. The results were inconclusive for 20% pulls: the magnitudes of head and trunk motion were small and showed no consistent practice effects. (Supported by NSF ISN9319601.)

**Adaptations in Human Motor Unit Discharge Behaviour to Strength Training.** C. Patten\*, G. Kamen. Motor Control Laboratory, Dept. of Exercise Science, University of Massachusetts, Amherst, MA 01003

Six young (mean: 23 yrs) and six older (mean: 76 yrs) adults performed a six week isometric strengthening program of non-dominant hand fifth finger abduction. To monitor for neural adaptations to strength training, motor unit (MU) signals were obtained from the abductor digiti minimi (ADM) muscle using a quadrifilar needle electrode. Force and MU signals were measured under maximal voluntary force conditions at baseline, 2, 14, and 42 days of training. To monitor for cross transfer effects, force and MU signals were also obtained from the untrained hand. MU signals were identified using custom written spike recognition software.

A transient increase in MU discharge rate (MUFR) accompanied significant increases in force (mean: 12%) following a single session of strength training. Overall, strength increases averaged 25% in all subjects. Notably, both groups demonstrated dissociation between MUFR and force levels, however, the pattern of adaptation in MU discharge behaviour differed markedly between young and older subjects.

**LEARNING TO COORDINATE CONTACT FORCE AND BALANCE GOALS IN MULTIJOINT, STANDING PULLS.** J.L. Patton\* & W.A. Lee<sup>2</sup>. Biomech. Phys. Ther. & Inst. Neurosci., Northwestern U., Chicago, IL 60611.

Subjects making 'bounce' pulls must learn to organize motion for two goals: produce a brief manual force and maintain balance. Skilled subjects could easily achieve the task's dual goals if their center of mass (CM) motion resembles a simple model of an inverted pendulum driven by constant ankle torque and a unidirectional, elastic spring. In contrast, they might learn a more complex organization and separately control each goal. We tested these contrasting hypotheses by comparing model predictions to subject data.

Ten standing subjects practiced (for 5 days) brief, bounce pulls in the horizontal direction to target forces (20-80% of maximum), while force plate, pulling force, and body kinematics were recorded. Subjects developed posterior momentum, then briefly pulled and reversed their motion, and finally they recovered their balance. An 8-segment link determined CM motion. We compared the effects of practice and pulling force on: the overall error of a regression model fit to CM motion, the difference between initial and final posture, the difference between pre-impact and rebound positions and speeds, and changes in ankle torque patterns. All should decrease with practice if subjects learn the model.

The regression model's error was small, varied with pulling force, and did not reduce with practice. Subjects CM at the end of movement was anterior to its initial position; this anterior shift was greater after practice. Rebound position was not significantly different than pre-impact position, and rebound speed was not significantly lower than pre-impact speed. These results suggested that practice effects occurred mostly in balance recovery, and that damping alone cannot explain the observed behavior. Ankle torque patterns were smoothly decreased during balance recovery, especially after practice. A modified model using these ankle torque profiles worked better than the original model for low and mid range force levels. However, it did not fully explain the anterior CM shift at high forces, suggesting that subjects also learn to capitalize on complex kinematics that the simple model neglects.

The differential effects of practice on CM motion during the force production and balance recovery phases suggest that subjects learn to control the dynamics of those phases independently. That is, the CNS learns a more complex organization after practice. A two-DF model with at least one varying parameter will be needed to fully model skill acquisition in this task. (Supported by NSF IBN-9319601)

## 58.16

**PHASING AND FUNCTION OF BIARTICULAR THIGH MUSCLES DURING BACKWARD PEDALING.** L.H. Ting<sup>1,2</sup>, S.A. Kautz<sup>1,3</sup>, D.A. Brown<sup>1,3</sup>, F.E. Zajac<sup>1,2,3</sup>. <sup>1</sup>Rehabilitation R&D Center, VA Palo Alto HCS (153), CA, 94304, <sup>2</sup>Departments of Mechanical Engineering and <sup>3</sup>Functional Restoration, Stanford University, CA, 94305.

Computer simulations of pedaling have shown that a simple control scheme using only three pairs of reciprocating functional muscle groups is sufficient to control pedaling. Predicted performance using this scheme closely matches maximum startup pedaling experimental data (Raasch et al., J. Biomech, in press). Furthermore, simulations of a variety of pedaling tasks were achieved. In smooth, steady-state forward pedaling, rectus femoris (RF) and hamstring muscles (HAM) can act as an alternating pair, with RF activity centered around top-dead-center (TDC), where the leg moves anteriorly, and with HAM activity centered through bottom-dead-center (BDC), where the leg moves posteriorly. In backward pedaling simulations, the phasing of this muscle pair was reversed to accommodate smooth movement through TDC and BDC, leading to the hypothesis that RF activity at BDC facilitates anterior leg movement and HAM activity at TDC facilitates posterior leg movement (Raasch, Ph.D. Thesis, 1995).

In this study, EMG data from subjects pedaling forwards and backwards smoothly at 60 rpm were compared to the model. RF was active through TDC during forward pedaling, and through BDC during backward pedaling. Similarly, HAM was active through BDC during forward pedaling, and through TDC during backward pedaling. This is consistent with the hypothesis that RF is used during anterior movement of the leg and HAM during posterior movement. However, RF and HAM activity extended beyond the predicted regions around TDC and BDC, and the phasing of these muscles was not strictly reversed between forward and backward pedaling. This suggests that there may be additional functionality of RF and HAM during pedaling which is not modeled. RF timing was closely correlated with extensor activity. Its function in both extension and anterior movements of the leg could account for the observed phase shifts. A modified model with dual function of RF is presented. ## 58.17

RECRUITMENT OF MOTONEURONES BY TRANSCRANIAL MAGNETIC STIMULATION IN SPINAL CORD INJURY. H.C. Smith<sup>1</sup>, N.J. Davey<sup>1</sup>, D.W. Maskill<sup>1</sup>, G. Savic<sup>2</sup>, P.H. Ellaway<sup>1</sup>. <sup>1</sup>Dept of Physiology, Charing Cross & Westminster Medical School, London, W6 8RF, UK. <sup>2</sup>National Spinal Injuries Centre, Stoke Mandeville Hospital, Aylesbury, HP21 8AL, UK.

The stimulus threshold for compound motor evoked potentials (cMEPs) in response to transcranial magnetic stimulation (TMS) is higher in patients with incomplete spinal cord injury (Davey *et al* 1995, *Abst Soc Neurosci* 21:172.7). We have now used the cMEP response as an index to investigate motoneurone recruitment.

Surface electromyographic responses in the tenar muscles to TMS were studied in 10 incomplete neck injury patients (ages 18-74 years, post-injury time 3-28 months) and 10 control subjects (ages 22-48 years) whilst maintaining a mean ( $\pm$  SE) isometric contraction force of  $15 \pm 1.6\%$  maximum voluntary contraction (MVC). The motor level of the injury in the patients (range C4-C7) was rostral to the level at which the nerves innervating the tenar muscles leave the spinal cord (C8/T1). Mean threshold stimulus strength (T) to TMS (round coil, centred over vertex), expressed as percentage of maximum stimulator output (%MSO), for evoking cMEPs in tenar muscles was  $46 \pm 3\%$ MSO in the patients and  $31 \pm 2\%$ MSO in the controls. Threshold for biceps brachii, a muscle innervated more rostrally, was no different in the patients ( $49 \pm 4\%$ MSO) from the controls ( $53 \pm 4\%$ MSO). Mean cMEP area at 1.5T, expressed as a percentage of the area at threshold, was greater in controls ( $2115 \pm 454\%$ ) than in patients ( $912 \pm 318\%$ ). However, the level of voluntary EMG produced at 50% MVC expressed relative to threshold cMEP area was equivalent in controls ( $917 \pm 195\%$ ) and patients ( $926 \pm 307\%$ ). We conclude that TMS at 1.5T recruits a smaller proportion of available motoneurons in the patients.

Our results suggest that the motoneurone recruitment curve to TMS is less steep in spinal cord injury and this may result from a rewiring of excitatory or inhibitory synaptic inputs in the cortex or spinal cord. *Supported by the Wellcome Trust.*

### MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: CIRCUITRY AND PATTERN GENERATION I

## 59.1

EXISTING STOMATOGASTRIC NEURON MODELS PREDICT SOME, BUT NOT ALL, RESPONSES TO RHYTHMIC INPUT. A.L. Weaver, R.A. DiCaprio<sup>\*</sup> & S.L. Hooper, Biol. Sci., Ohio Univ., Athens, OH 45701

Prior work has shown that when trains of hyperpolarizing current pulses are injected into Lateral Pyloric (LP) neurons isolated from the pyloric network, but still receiving inputs from anterior ganglia (i.e., the stomatogastric nerve is intact), the neuron's rebound delay depends strongly on pulse amplitude but relatively little on train frequency, and changes rapidly (in 3-5 sec) when pulse amplitude is altered. Alternatively, robust rebound activity of similarly isolated Pyloric (PY) neurons slowly develops (over ~10 sec) during a train, and depends strongly on train frequency and duty cycle.

We implemented the LP (Buchholz *et al.*) and PY (Harris-Warrick *et al.*) neuron models in GENESIS. The LP model reproduces our physiological data; rebound delay after single hyperpolarizing pulses decreases as pulse amplitude increases, and rebound delay decreases only slightly following later pulses. In the absence of  $I_h$ , rebound after single pulses or during pulse trains is extremely small both in amplitude and duration. The PY model, which lacks  $I_h$  or other currents with long time constants, was derived from conductance measurements of PY neurons isolated from anterior influences. This model requires injecting depolarizing current after the hyperpolarizing pulses to display rebound firing, and thus far we have been unable to mimic in it the slowly developing, robust PY neuron rebound activity observed physiologically with anterior inputs intact.

However, increasing  $I_h$  time constants in the LP model 3-fold results in the model exhibiting slowly developing PY neuron type rebound responses. These results thus suggest that anterior influences may induce functional expression of extremely slow conductances in PY neurons. [Research supported by OU, NSF, and HSFP.]

## 59.3

MOTOR PATTERN EXPRESSION OF A LATERAL PYLORIC CONSTRICTOR MUSCLE. T.A. Ellis, A.S. Donath, L.G. Morris, J.B. Thuma<sup>\*</sup> & S.L. Hooper, Biol. Sci., Ohio Univ., Athens, OH 45701

Pyloric constrictor muscle p1 of the lobster, *Panulirus interruptus*, is innervated by the lateral pyloric (LP) neuron, and is involved in the early phase of pyloric constriction. We are examining this muscle's response to physiologically relevant neural inputs to determine its contributions to pyloric movements. Stomachs were slit open mid-ventrally and pinned dorsal surface up. The p1 muscle was left attached to its ossicles, and surrounding muscles cut so only p1 muscle contractions were observed. A nerve containing the LP axon was stimulated using trains of trains (0.5-2 sec periods) that mimic LP neuron activity (60Hz, 20% duty cycle) observed *in vitro*. p1 muscle contractions (as revealed by ossicle movements) were recorded with a CCD camera and S-VHS VCR at 60 frames per second and analyzed using a digital video analysis system.

Preliminary experiments show that p1 contractions are small with little or no facilitation. They relax slowly and temporally summate; total contraction amplitude is thus a sum of phasic and tonic components. At a 2 sec period (400msec burst duration, 24 spikes), p1 contractions are 80% phasic with a total amplitude of 0.6 mm (8% of muscle length). At a 1 sec period (200msec, 12 spikes), p1 contractions are 37% phasic with a total amplitude of 0.35 mm; at a 0.5 sec period (100msec, 6 spikes) p1 contractions are only 20% phasic and 0.15 mm in total amplitude.

p1 contractions are thus similar to dorsal dilator muscle (cpv1b) contractions in that both these muscles show a graded transition between rhythmic (faithful follower) and tonic (sustained) contractions as cycle period changes. These data thus provide further evidence that pyloric movements may qualitatively change as pyloric network frequency changes, and that pyloric movement cannot be easily deduced from pyloric neural output. [Research supported by OU, NSF, and HSFP.]

## 58.18

FACILITATION OF CORTICOSPINAL PATHWAYS WITH INCREASING VOLUNTARY CONTRACTION IN SPINAL CORD INJURY. N.J. Davey<sup>\*</sup>, H.C. Smith<sup>1</sup>, D.W. Maskill<sup>1</sup>, G. Savic<sup>2</sup>, P.H. Ellaway<sup>1</sup>. <sup>1</sup>Dept of Physiology, Charing Cross & Westminster Medical School, London, W6 8RF, UK. <sup>2</sup>National Spinal Injuries Centre, Stoke Mandeville Hospital, Aylesbury, HP21 8AL, UK.

In incomplete spinal cord injury patients the stimulus threshold for compound motor evoked potentials (cMEPs), produced in response to transcranial magnetic stimulation (TMS), is higher than in controls (Davey *et al* 1995, *Abst Soc Neurosci* 21:172.7). We have now used the size of the cMEP response as an index of corticospinal excitability during a voluntary increase in isometric contraction force.

Surface electromyographic responses of the tenar muscles to threshold TMS were recorded in 10 incomplete neck injury patients (ages 18-74 years, post-injury time 3-28 months) and 10 control subjects (ages 22-48 years). The motor level of injury in the patients (range C4-C7) was rostral to the level at which the nerves innervating the tenar muscles leave the spinal cord (C8/T1). Mean ( $\pm$  SE) maximum voluntary contraction (MVC) was assessed as  $49 \pm 13\%$  in the patients and  $73 \pm 6\%$  in the controls. A ring attached to a force transducer was placed over the interphalangeal joint of the thumb and subjects were instructed to pull to a particular percentage of their MVC. Mean cMEP areas, expressed as a percentage of maximum, in patients were  $5 \pm 1\%$  in relaxed muscle,  $45 \pm 10\%$  at 10% MVC,  $56 \pm 7\%$  at 20% MVC,  $73 \pm 9\%$  at 50% MVC, and in controls  $6 \pm 3\%$  in relaxed muscle,  $73 \pm 5\%$  at 10% MVC,  $83 \pm 3\%$  at 20% MVC,  $82 \pm 6\%$  at 50% MVC. Evidently facilitation of the cMEP to TMS plateaus at a higher percentage of MVC in spinal cord injury.

Spinal cord trauma may indiscriminately have blocked axons of corticospinal neurons that could have been recruited at any level of voluntary effort. This could mean that an equivalent level of depolarisation of the motoneurone pool, or corticospinal neurons, is reached at a higher percentage of MVC in the patients than in the controls. *Supported by the Wellcome Trust.*

## 59.2

DUTY CYCLE, SPIKES/BURST, AND INTRABURST AND OVERALL SPIKE FREQUENCY AS PYLORIC CYCLE FREQUENCY CHANGES. S.L. Hooper<sup>\*</sup> & J.B. Thuma, Biol. Sci., Ohio Univ., Athens, OH 45701

We have been investigating the activity of the lobster (*Panulirus interruptus*) pyloric network as cycle frequency changes. We have shown that some pyloric pattern elements maintain phase considerably better than others, and have begun analyzing pyloric network duty cycle (burst length/period) and spike firing characteristics as cycle frequency changes.

The table shows pyloric neuron duty cycles at 1Hz cycle frequency, and the slope of the duty cycle vs. frequency line (positive: burst length changes too little to maintain duty cycle; negative: burst length changes too much). Intraburst spike frequency, spikes/burst, and overall spike frequency (5 spikes/burst x 2 bursts/sec = 10Hz overall spike frequency) were measured for the IC, LP, PD, and VD neurons. PD, LP, and IC neuron intraburst spike frequencies decreased as cycle frequency increased; VD intraburst spike frequency remained approximately constant. Spikes/burst decreased by ~2-fold for all neurons as cycle frequency doubled, and overall spike frequency remained roughly constant.

	IC	LP	PD	PY	VD
Duty Cycle	0.20 $\pm$ 0.06	0.22 $\pm$ 0.05	0.25 $\pm$ 0.04	0.38 $\pm$ 0.09	0.34 $\pm$ 0.09
Slope	-0.04 $\pm$ 0.04	0.00 $\pm$ 0.05	0.09 $\pm$ 0.03	-0.19 $\pm$ 0.06	-0.05 $\pm$ 0.06

Coupled with our results on pyloric muscle response to changing stimulus input, these data suggest that cycle frequency changes should induce dramatic changes in muscle contraction amplitude, particularly the phasic component. The relatively constant overall spike frequency observed here is interesting because two of these muscles have a summated contraction component that is likely sensitive to this parameter, and hence this component may be maintained as cycle frequency changes. [Research supported by OU, NSF, and HSFP.]

## 59.4

THE PYLORIC DILATOR MUSCLES SHOW VERY DIFFERENT CONTRACTION AMPLITUDE, FACILITATION, AND SUMMATION. L.G. Morris<sup>\*</sup> & S.L. Hooper, Biol. Sci., Ohio Univ., Athens, OH 45701

The dorsal (cpv1b) and ventral (cpv2b) dilator muscles of the lobster, *Panulirus interruptus*, are innervated by the Pyloric Dilator (PD) neurons and are thought to open the cardiopyloric valve of the stomach. We are examining the response of these muscles to physiologically relevant neural input to determine the movements of this region. Isotonic contractions were elicited by stimulating the nerve that contains the PD neuron axons using trains of trains that mimic *in vitro* PD neuron activity. Resulting contractions in these muscles were observed separately.

We have shown that cpv1b muscle contractions are small (0.2 mm maximum, 2% of muscle length), relax slowly, and hence show significant summation. Total contraction amplitude is therefore the sum of phasic and tonic components, and at 2Hz cycle frequency an average of 80% of cpv1b's total contraction amplitude is tonic. Total contraction amplitude of cpv1b shows relatively little facilitation (up to 3.5 fold).

Although initial contractions of muscle cpv2b are often undetectable, they show remarkable facilitation. In trains in which the initial contraction is measurable, 3,000-fold increases in contraction amplitude can be observed. Cpv2b contractions can become very large (2 mm maximum, 10% of muscle length) yet relax quickly and show little summation (at 2Hz, an average of 9.5% of total contraction amplitude is tonic).

The large (10-fold) difference in contraction amplitude of these two putative synergist muscles suggests they may play different functional roles in generating stomach movements. Furthermore, our results show that a single rhythmic neural input can simultaneously induce two qualitatively different activity patterns (one rhythmic contractions, the other a sustained contraction) in different muscles. [Research supported by OU, NSF, and HSFP.]

## 59.5

**COMPUTATION STYLES IN IDENTIFIED NEURONS FROM THE CRAB STOMATO-GASTRIC GANGLION.** D.K. Hartline\*, K. Graubard, A.E. Wilensky and G. Orr, U. of Hawaii, Honolulu, HI 96822 and U. of Washington, Seattle, WA 98195

Intermixture of input and output synapses along neurites, as occurs in stomatogastric neurons, opens a possibility for "local" integration of inputs in relative isolation from other functional regions of a cell. The rate of attenuation of electrical signals spreading from a synaptic input to more distant neurites is a key factor in this. VD and IC neurons present very different morphologies. We compared signal attenuation in passive compartmental models of VD and IC to assess potential differences in computational capabilities. Serial optical sections of Lucifer yellow filled cells were made with a confocal microscope for 3D reconstruction with imaging software. For current injected in distal neurites of either cell type, attenuation of voltage responses was five-fold in secondary neurites and distal neurites "down stream" of them. In VD but not IC, attenuation was less in neurites having a secondary neurite in common with the injection site, and still less in those having a post-secondary neurite in common. The results suggest that local computation, while possible in both types, may be more regionally limited in IC than in VD cells (Human Frontier Science Program; NIH NS15697).

## 59.7

### ANALYSIS OF THE STOMATO-GASTRIC PYLORIC NETWORK USING THE HYBRID NETWORK METHOD.

G.Le Masson\* and M. Moulins. Lab. de Neurobiologie et Physiol. Comp. URA CNRS 1126 and Université Bordeaux I, Arcachon 33120, FRANCE.

We use the "hybrid network" method to study systematically the individual impact of cellular and synaptic parameters on the overall activity of a simple neural network, the stomatogastric pyloric network of Crustacean. Multi-compartmental models of the three major types of interacting neurons (PD-LP-PY) were constructed, and used to replace their previously photo-inactivated biological equivalents in the pyloric circuit *in vitro*. We then examined the effect of linear changes in synaptic efficacy and in the maximal conductances of four intrinsic currents (ICa, IKCa, Ih and IA) expressed by each cell, on three major parameters of the pyloric pattern; pace makers cycle period, LP and PY bursts phases.

We have identified several combinations of cellular and synaptic parameters that provides the entire network with notable emergent properties such as a strong output pattern stability. We have also found target parameters that are crucial in the regulation of the pyloric period or for the maintenance of correct phasing within each cycle. The flexibility associated with these parameters has been compared to the target effects of known modulatory inputs to this network.

Finally we have studied the stability of the hybrid network in various modulatory environments. Our results suggest the existence of "stabilizing" modulatory influences, capable of constraining the network in highly stable functional configurations.

## 59.9

**STABILIZING CONTROL OF A MOTOR PATTERN GENERATING NETWORK VIA INTERACTING HIGHER ORDER MODULATORY INTERNEURONS.** S. Faumont, J. Simmers and P. Meyrand\*, Lab. de Neurobiol. et Physiol. Comp., Univ. Bordeaux I & CNRS, Place Peyneau, 33120 Arcachon, France.

Recent results have shown that neural networks are far from being fixed entities, but can be dynamically specified by modulatory neurons to satisfy particular behavioral demands (Meyrand et al. (1991), Nature 351, 60). While this lability is required for the initial configuration of a functional network from a pool of neurons, both short and long-lasting stability is necessary for its ensuing operation. How can such network stability be achieved? In the stomatogastric nervous system of the lobster, *Homarus gammarus*, bursting in an identified modulatory interneuron (PS) causes a massive restructuring of stomatogastric circuitry, followed immediately by a robust and long-lasting (for tens of minutes) activation of the gastric mill network when the interneuron falls silent. This delayed gastric activation is caused by PS itself, partly through a specific modulatory action on the gastric mill network, and partly via recruitment of another higher order interneuron (CG) also known to modulate the gastric network. PS not only elicits monosynaptic EPSPs in CG, but its repetitive burst firing is also able to induce a progressive build-up of slow plateau-like depolarizations that may eventually sustain elevated CG firing for several tens of seconds after a sequence of PS bursting. In parallel with this indirect excitatory action via CG, PS directly and longlastingly activates a gastric network element, Interneuron I, which in turn provides strong feedback inhibition to CG. Rebound from gastric-timed Int I inhibition triggers active membrane properties and intense firing in CG, thereby reinforcing the latter's excitatory drive back to the motor network. Our results suggest that through a combination of longlasting actions on the cellular properties of two coupled neurons, one a modulatory input and the other a component of the motor network itself, PS is able to prime the gastric network to express self-sustaining rhythmicity that far outlasts the interneuron's own discharge.

## 59.6

**SYNCHRONOUS BURSTING CAN ARISE FROM NON-OSCILLATORY CELLS CONNECTED WITH MUTUAL EXCITATION.** P.F. Rowat\* and A.I. Selverston. Biology Department, U.C. San Diego, La Jolla, CA 92093-0357

Mutual excitation between two neurons that are quiescent in isolation (do not burst), is not thought to cause bursting behavior: it merely raises the level of excitation. On the contrary, we show, by modelling, that two quiescent cells can be induced to burst in synchrony by mutual excitatory synaptic connections. The underlying dynamical mechanism is a combination of the escape and release mechanisms believed to underlie bursting when two quiescent cells are connected with reciprocal inhibition. The mechanism can be realized physiologically in two different ways: either the presynaptic threshold for graded synaptic transmission in each cell is at a different membrane potential, or the cells are identical but each has a different steady current either from experimentally injected currents or from different amounts of postsynaptic current from other cells. In either case, a characteristic feature of the mechanism is that bursts in one cell begin slightly before, and terminate slightly after, bursts in the other cell: one cell's bursts contain the other's.

We propose that this mechanism underlies oscillations in two small networks in the lobster. In *Homarus gammarus*, oscillations of the commissural pyloric oscillator in the stomatogastric nervous system of the lobster have been shown by Card and Nagy (1994) to be driven by two mutual excitatory cells, CP and LE; neither cell has been shown to be an endogenous oscillator, and the CP bursts contain the LE bursts. In *Homarus americanus*, the large and small cells in the cardiac ganglion are connected with reciprocal excitation and the large cell bursts contain the small cell bursts (Hartline 1979).

Finally, we note this mechanism could be present in cortex, since mutual excitation and synchronous oscillations are both widespread there.

Supported by Coast Mountain Intelligence.

## 59.8

**DYNAMIC INTERACTIONS BETWEEN MOTOR PATTERN GENERATING NETWORKS IN THE STOMATO-GASTRIC GANGLION OF INTACT LOBSTER.** S. Clemens (§), P. Meyrand and J. Simmers\*, Laboratoire de Neurobiologie et Physiologie Comparées, Univ. Bordeaux I & CNRS, 33120 Arcachon, France.

clemens@lncp.u-bordeaux.fr

Rhythmic movements of the gastric mill and pyloric regions of the crustacean foregut are controlled by two stomatogastric neuronal networks which have been intensively studied *in vitro*. By using EMG electrode recordings from the European lobster, *Homarus gammarus*, we have monitored simultaneously the motor activity of pyloric and gastric mill muscles for up to three months in intact and freely behaving animals. Both pyloric and gastric mill networks are almost continuously active *in vivo*, regardless of the presence of food. In an unfed animal, the pyloric network expresses the typical threephasic pattern seen *in vitro*, but at slower cycle periods of 2.5-3.5s (instead of ca. 1-1.5s). Gastric mill activity occurs at mean cycle periods of 20-50s but may suddenly stop for up to tens of minutes, then restart without any apparent behavioral reason. When conjointly active, the two networks express a strict coupling that involves a significant prolongation (up to 300%) of pyloric PY motoneuron bursts after onset of each gastric LG/MG burst. During feeding, this gastro-pyloric interaction disappears as the two networks now express accelerated rhythmic motor patterns (pyloric period: 1.2-1.5s; gastric period: 10-15s). The return to control levels of network activity occurs progressively over the following two to three days (depending on the type of food originally presented), and is associated with a gradual reappearance of the gastro-pyloric interaction. Our data suggest that this interaction appears only during a "free run" mode of foregut activity, and that it is not simply a consequence of activity-dependent changes from within the two networks, but rather is specified by extrinsic modulatory influences.

## 59.10

**MATHEMATICAL MODELS OF THE CRAYFISH SWIMMERET SYSTEM.** F.K. Skinner\* and B. Mulloney. Neurobiology, Physiology, and Behavior, Univ. Calif., Davis CA 95616-8755.

Swimmerets are paired, jointed limbs on many segments of the abdomen that can move rhythmically to propel the crayfish forward in the water. Locomotion in segmented animals requires well-coordinated movements of different limbs, but the neural basis of this coordination is not well-understood anywhere, and the swimmeret system poses problems of coordination clearly. Each swimmeret is driven by a modular neural circuit located in the segmental ganglion that innervates it. A separate coordinating circuit organizes the activity of these modules in different segments. Axons of coordinating interneurons project from each ganglion to both anterior and posterior neighbors, so this circuit is bidirectional.

From initial alternative hypotheses about the synaptic organization of this coordinating circuit, we developed alternative models of the crayfish swimmeret system. Each model includes a chain of modular local circuits of nonspiking interneurons that drive the motor neurons of each limb, linked to modules in neighboring segments by coordinating interneurons. Different patterns of connections made by these coordinating interneurons defined the different models. Local interneurons were described by Morris-Lecar equations that included graded currents from reciprocal inhibitory synapses. Coordinating interneurons were also driven by these local interneurons, "fired" when the presynaptic cell was depolarized, and caused synaptic currents in their target neurons. Comparing the performance of each model with experimental results suggests specific features of the real coordinating circuit needed to produce normal swimmeret coordination.

## 59.11

**'BUILDING BLOCKS' OF INSECT WALKING PATTERN GENERATION: IONIC BASIS OF CENTRAL RHYTHMIC SYNAPTIC DRIVE TO LEG MOTONEURONS.** A. Büschges\* and R. Haas. FB Biologie, Univ. of Kaiserslautern, 67653 Kaiserslautern, Germany.

During walking and searching movements of an insect leg, the activity of the leg motoneuron (MN) pools of each individual leg joint is generated by the interaction between signals from central rhythm generating (CRG) sources for each leg joint and peripheral signals as well as coordinating signals from other leg joints and legs (Bässler, 1993, Biol. Cybern. 69, 305). We recorded from leg MNs during walking and searching movements in a 'semi-intact' walking leg preparation of the stick insect middle leg. The recordings revealed that actual shaping of motoneuronal activity in the movement cycle is mediated by cyclic alterations of the motoneurons' membrane potential around its value at rest. As an example, in MNs driving the leg muscles of the femur-tibia (FT-) joint, e.g. extensor MNs, the activity was generated mainly by depolarizing synaptic signals during swing, i.e. the return stroke, and hyperpolarizing synaptic inputs during stance, i.e. the power stroke. The reverse was the case for flexor MNs.

We were interested in the nature of the synaptic drive from CRGs on the MN pools of the individual leg joints. We investigated this by pharmacologically activating CRGs in the isolated mesothoracic ganglion. Rhythmicity was induced by bath application of the muscarinic agonist pilocarpine with concentrations of  $1\text{-}3 \times 10^{-6}$  M. First, we focused on the MNs of the FT-joint, i.e. FETi, SETi and Flexor MNs. During rhythmicity MNs of both pools received slight tonic depolarization, but mainly rhythmic hyperpolarizing synaptic inputs, which appear in antiphase for both MN pools. DCC and SEVC recordings revealed the reversal potential of these inhibitory inputs between -80 to -85mV (FETi, n=10). After injection of TEA (4mM) through the intracellular electrode inhibition in FETi was significantly decreased by about 85% (n=3). Thus, it appears that potassium ions contribute to cyclic inhibition of motoneurons by CRGs during locomotor behavior. Currently we are investigating the ionic basis of central rhythmic synaptic drive for MNs supplying the other leg joints.

**PHASE-SENSITIVITY AND ENTRAINMENT IN BURSTING NEURONS: A SIMULATION STUDY** R. J. Butera, S. S. Demir, A. A. DeFranceschi, J. W. Clark\*, and J. H. Byrne†. Dept. of Elec. & Comp. Eng., Rice U., Houston, TX 77251 and †Dept. of Neurobiology & Anatomy, U. of Tex. Med. Sch., Houston, TX 77255.

Biological oscillators frequently exhibit a phasic dependency of the effect of perturbations. Although the parametric aspects of phase sensitivity and entrainment have been analyzed extensively, little is known about the underlying biophysical mechanisms. We used a model of neuron R15 in *Aplysia* to study the mechanisms determining the phase-response curve (PRC) of the cell in response to both extrinsic current pulses and modeled synaptic input. We also compared entrainment predictions from PRCs with those from actual simulations.

The PRCs of the model exhibited minimal dependence on stimulus amplitude, and a strong dependence on stimulus duration. Phase-plane analysis of the effect of transient current pulses provided several important insights into the relationship between the PRC and the underlying dynamics of the model. First, there was a strong correlation between pre-stimulus concentration of  $\text{Ca}^{2+}$  and the post-stimulus phase of the oscillation. Second, the existence of a stable fixed point in the presence of a hyperpolarizing stimulus was a sufficient criteria for the model to exhibit phase-independent resetting if the pulse was sufficiently long in duration. Third, the system nullclines of the two slow variables provided well-defined limits on the ability of a hyperpolarizing input to perturb the oscillation. These limits were related to the magnitude and duration of the input. Furthermore, the predictions of phase-locked 1:m entrainment from PRCs were valid, even when the duration of the periodically applied pulses were a significant portion of the control limit cycle.

These results demonstrate that experimentally applied hyperpolarizing current pulses are sufficient to determine the shape of the PRC in response to an inhibitory synaptic input, provided that the duration of the pulse is similar to that of the synaptic current. These findings also show that when utilizing hyperpolarizing stimuli, the PRCs alone are sufficient to predict the dynamic behavior of the model in response to transient and periodic input (see adjacent paper by Canavier et al.).

## 59.15

**A SPIKE TRAIN ANALYSIS FOR DETECTING THE DEPENDENCE OF SPIKE GENERATION OF ONE NEURON ON THE DOUBLET SPIKE FIRING OF ANOTHER.** D.C. Tam\*, Center for Network Neuroscience and Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.

A spike train analysis technique is introduced to determine how consecutive spike firings in one neuron contribute to the generation of spikes in another neuron (typical in temporal summation). In particular, we examine the dependence of spike firing in a given neuron with respect to the doublet firing in another neuron. We extended the analysis of conventional cross-correlation techniques to include the contribution of spike firing of more than a single preceding spike by computing the conditional probability of the next spike firing in a reference neuron given that the conditional neuron has fired two consecutive spikes (a doublet) prior to its firing. The conditional probability (or the joint probability) of spike firing is estimated by the statistics obtained from the conditional (or joint) distribution of the pre-interspike intervals (pre-ISIs) and post-cross intervals (post-CIs) relative to the reference spike. The characteristic features (such as peaks and valleys) revealed by the conditional probability density function provide information about the specific time intervals in which excitatory or inhibitory couplings between this neuron pair are correlated with the consecutive firing of a doublet in the conditional neuron. Thus, the contribution of spike firing from more than one spike can be revealed so that the temporal summation of consecutive spike firings can be deduced. The results of this analysis can lead to a better understanding of the influence of spike generation of one neuron on the burst-firing in another neuron. (Supported by ONR N00014-94-1-0686)

## 59.12

**TESTING THE CELLULAR REDUCTION HYPOTHESIS IN MODEL NEURAL CIRCUITS.** H.J. Chiel\* and R.D. Beer. Departments of Biology and Computer Engineering and Science, Case Western Reserve University, Cleveland, OH 44106.

A central hypothesis of cellular neurobiology, the cellular reduction hypothesis, is that one can explain the function of a neural circuit by analyzing the properties of its individual nerve cells and their interconnections. However, work on small, experimentally tractable nervous systems has shown that neural circuits have extensive recurrent connections, can functionally reorganize in response to neuromodulators, and have complex interactions with the periphery. These studies make it increasingly difficult to ascribe particular functions to individual neurons, and raise questions about the most useful way to decompose and understand neural circuits.

To address this question, we have begun to analyze model neural circuits capable of controlling locomotion that were generated using genetic algorithms, or hand-designed to be modular. Although these circuits are far simpler than those found in animals, they allow us to analyze highly recurrent circuits that are tractable to mathematical analysis without being limited by missing data, and that have many properties similar to those found in biological nervous systems. We have developed a set of tools that allow us to analyze these circuits as an experimentalist would do: we can examine their properties in isolation, their connectivity, and their function within the context of the circuit as a whole.

Our preliminary results indicate that (1) although one can readily distinguish motor neurons from interneurons in a modular circuit, all neurons play a role in pattern generation in a highly recurrent circuit, (2) in a recurrent circuit, motor neurons and interneurons play overlapping and time varying roles in producing the walking pattern, and (3) this dynamic redundancy provides recurrent circuits with a great deal of robustness in response to lesions of individual connections between neurons. We are also using the tools of dynamical systems analysis to complement the neurobiological analysis of these circuits.

Supported by Santa Fe Institute and ONR grant N00014-90-J-1545.

## 59.14

**ANIMATION OF A CENTRAL PATTERN GENERATION NETWORK: A NEW APPROACH FOR VISUALIZING NEURON ACTIVITY AND INTERACTIONS IN REALISTIC COMPUTATIONAL MODELS.** N. Koshiya\*, J.C. Smith, and W.B. Marks. Laboratory of Neural Control, NINDS, NIH, Bethesda, MD 20892.

We have developed methods for animating simulations from "realistic" computational models of CPGs which allow dynamic visualization of neuron activity and interactions in a computer-generated movie format. These methods were applied to animate simulations from our models of the mammalian brainstem respiratory network (Smith, J.C. *Soc. Neurosci. Abs.* 20, 1994) which consist of seven major types of interacting interneurons in the ventrolateral medulla. To generate the animations, we used *Mathematica* to construct a virtual elastic surface on which the different types of neurons were arrayed. Neuron activity is represented by upward surface motions described by a Gaussian-like function where the amplitude of the motion scales with the instantaneous neuronal spiking frequency. Functional synaptic interactions between neurons (excitatory or inhibitory) are represented as colors (red and blue, respectively) which flow in "synaptic traffic lanes" on the surface from presynaptic to postsynaptic neurons. The color intensities in these lanes change with the strength of synaptic activation allowing the activation patterns to be visualized dynamically. Changes in excitatory and inhibitory postsynaptic conductances are also separately color encoded, where the color intensity scales with the summated inhibitory or excitatory conductance. These conductance color changes are superimposed on the surface motions, providing a visual correlation of the regulation of neuron activity by synaptic inputs. Images are computed every 62.5 msec during the rhythmic respiratory cycle (2 - 3 sec period) and are compiled as a QuickTime movie/video including sound generated from the membrane potential of a selected model neuron. These animations are a tool for visualizing the complex dynamics of central pattern generation networks.

## 59.16

**A CROSS INTERVAL SPIKE TRAIN ANALYSIS TECHNIQUE (PRE-CI/ISID/POST-CI) FOR REVEALING THE COUPLING RELATIONSHIPS BETWEEN THE FIRING PATTERNS OF NEURON-PAIRS.** M. A. Fitzurka\*† and D. C. Tam.† †Dept. of Physics, Catholic University of America, Washington DC, 20064 and ‡Center for Network Neuroscience, Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.

A cross interval spike train analysis technique was developed to detect the correlation between pairs of simultaneously recorded spike trains. This new method, *pre-CI/ISID/post-CI analysis*, shows the relationship between trends in the firing of one neuron (the reference) and the firing in another (or compared) neuron. This trend, or ISID, is defined as the difference between consecutive ISIs in the reference spike train ( $\Delta\tau_n = \tau_n - \tau_{n-1}$ ). How this trend,  $\Delta\tau_n$ , is affected by the cross-interval preceding it (the *pre-CI*,  $\tau'_{n-2,1}$ ) is revealed by the distribution of points in a *pre-CI/ISID* phase plane. Additionally, how that trend,  $\Delta\tau_n$ , affects the next subsequent CI (the *post-CI*,  $\tau'_{n,1}$ ) is seen in the location of the points in an *ISID/post-CI* phase plane. In this way, the CIs (with respect to a compared neuron) leading to and from a given trend (in a reference neuron) can be compared. Whether or not these plots are symmetric reveals whether or not the couplings between the neurons preceding and succeeding a local trend are similar. This analysis was applied to simulated spike trains (where the processes generating firing patterns are known) to demonstrate its ability to detect correlation trends. Spike trains recorded experimentally from cultured neuronal networks were analyzed as well to reveal specific correlation trends found between pairs of interconnected neurons in biological networks. (Supported by ONR N00014-94-1-0686).

## 59.17

**CROSS-CORRELATION ANALYSIS OF SPONTANEOUS ACTIVITY IN THE HIPPOCAMPUS OF THE ANESTHETIZED RAT.** I. Espinosa\*, J. Quiza and A. Sierra. Lab. of Cybernetics, Physics Dept., Sch. of Sciences, Mexico National University, Mexico, DF 04510.

In urethane anesthetized rats we made a series of tungsten microelectrodes excursions across the hippocampus with the object of simultaneously recording spontaneous activity in small ensembles of neurons and later inferred functional connectivity using cross-correlation analysis. In eight experiments we recorded with one, two or four single microelectrodes that were guided towards pyramidal borders in CA1, CA3 and granular layer of DG and positioned the array where more than one unit could be discriminated per microelectrode. At the end of some of the experiments the microelectrode trajectory was verified by visual inspection of brain slices. The spikes were carefully sorted and a preliminary cross-correlation analysis shows signs of shared input and direct excitatory connections among the neurons recorded. Units in the same microelectrode have excitatory connections and units in different microelectrodes show histograms with shared input characteristics. Wiring diagrams have been obtained for some neuron ensembles. Partially supported by DGAPA UNAM IN100593.

**COMPUTATION OF HIGH SAFETY-FACTOR IMPULSE PROPAGATION AT AXONAL BRANCH POINTS.** M.D. Goldfinger\*. Dept. Physiology & Biophysics, Wright State University, Dayton, OH, 45435.

The purpose of this work was to reexamine the paradoxical theoretical result of low-safety factor impulse propagation at an axonal branch point (eg.1).

Differential equations were solved numerically using trapezoidal integration (2). For constant-current stimulation of finite-length single-diameter passive fibers, numerical solutions (using  $\Delta t = 50$  nanosec and  $\Delta x/\lambda = 0.0165$ ) reconstructed analytical solutions (3) with negligible errors ( $\leq 0.06\%$ ). Numerical solutions also reconstructed the speeding of voltage transients with increasing electrotonic length (3). Using the H&H equations (4), the computed membrane action potential ( $\partial V/\partial x = 0$ ) was compared with that computed with 8 other numerical methods (incl. explicit, implicit, predictor-corrector); all computed waveforms superimposed, differing by not more than 1.6mV. For branch point passive properties, computed solutions reconstructed constant-current-elicited voltage transients as well as the distribution of axial current at the branch point as recorded from an exact analog compartmental circuit (5).

Solutions were computed for a single impulse propagating from a 1- $\mu$ m-diameter axon into two daughter branches ( $\Delta t = 12.5$  nanosec and  $\Delta x = 0.0165 \cdot \lambda_{parent}$ ). Local conduction velocity -CV(x)- changed in the vicinity of the branch point; the eventual CV(x) in the daughters was predictable from parental the pre-branch local CV(x) and the daughter diameter. No impulse failure occurred despite daughter diameters as large as 10  $\mu$ m. These CV(x) patterns were reconstructed with 1- $\mu$ m-diameter daughters by proportionately reducing the daughters' axial resistivity.

Supported by NSF BCS-9315856 and Wright State University.

**EXPERIMENT AND THEORY OF THE ROLE OF SPONTANEOUS TRANSMITTER RELEASE IN CULTURED NEURAL NETWORKS** P.E. Latham\*, B.J. Richmond, and P.G. Nelson. Lab. of Developmental Neurobiology, NICHD, and Lab. of Neuropsychology, NIMH, Bethesda, MD 20892.

In long term (several hour) recordings from networks of cultured mouse spinal cord neurons, we have observed activity patterns that include random spiking, bursting, and transitions between these states. In an attempt to understand this behavior we have developed a reduced model which lumps neurons into two classes, excitatory and inhibitory, each of which can be described by its average firing rate. Comparison of our model with experiments indicates that: i) the rate of spontaneous transmitter release plays a crucial role in the observed state changes; and ii) the variety of behavior observed in experiments is explained by a relatively simple picture involving the interaction of excitatory and inhibitory cell populations. In addition, preliminary results indicate that network dynamics is extremely sensitive to system parameters (e.g., probability of transmitter release, pattern of connectivity), and small changes produce either epileptic activity or the complete absence of firing. This dependence is so sensitive that a long-term feedback mechanism regulating some of these system parameters is required to keep the network in the range of activity observed in experiments.

Support: IRP/NICHD and IRP/NIMH.

## COMPARATIVE NEUROANATOMY: LOWER VERTEBRATES

## 60.1

**ZEBRIN II EXPRESSION IN SEA LAMPREYS (*PETROMYZON MARINUS*).** M. J. Lannoo\* and R. Hawkes. Muncie Center for Medical Education, Indiana University School of Medicine, MB 209, Ball State University, Muncie, IN 47306 and The University of Calgary School of Medicine, Calgary, Alberta, CANADA T2N 4N1.

Zebrin II is a 36 kD polypeptide expressed by Purkinje cells in the cerebellum of elasmobranchs, teleosts, birds, and mammals, and by acousticolateralis pyramidal cells in developing teleosts. Cloning studies suggest that zebrin II is the respiratory isozyme aldolase C. In agnathans, Larsell described a cell type in the corpus cerebellum of adult lampreys that he termed the "primitive Purkinje cell". To determine whether these primitive Purkinje cells express zebrin II, ammocete larvae and adult sea lampreys were obtained and fixed by transcardial perfusion. Their brains were frozen sectioned and reacted with mab anti-zebrin II according to standard procedures. Four adults and two ammocetes were examined. No mab anti-zebrin II immunoreactivity was detected in adults. In ammocetes, however, acousticolateralis Purkinje cells consistently and robustly label. This zebrin II expression appears to be similar to that which we described previously for pyramidal cells in ostariophysan teleosts. Three possibilities exist for the lack of zebrin II expression in primitive Purkinje cells: 1) these cells are not Purkinje cells; 2) zebrin II<sup>+</sup> cells are present phylogenetically before zebrin II<sup>+</sup> cells; or 3) primitive Purkinje cells are equivalent to embryonic zebrin II<sup>+</sup> Purkinje cells but at a stage in their development that precedes the expression of zebrin II.

Supported by NIH grant NS30702-01 (MJL) and the Medical Research Council of Canada (RH.).

## 60.2

**THE DISTRIBUTION OF ZEBRIN II IMMUNOPOSITIVITY IN THE CEREBELLAR CORPUS OF STINGRAYS.** R.L. Puzdrowski\*, Dept. Anatomy and Neurosciences, Univ. Texas Med. Br., Galveston, TX 77550.

Anti-Zebrin II is an antibody directed against a 36kDa aldolase epitope expressed by Purkinje cells. Two patterns of Zebrin II labeling have been described in the cerebellar corpus of vertebrates. In the mammalian cerebellar corpus, the Zebrin II antibody labels longitudinal zones of Purkinje cells. In teleosts, all purkinje cells of the corpus are Zebrin II immunopositive. To determine which of these patterns represents the primitive condition for jawed vertebrates the distribution of Zebrin II immunopositivity was examined in two species of elasmobranch rays, *Dasyatis sabina* and *Dasyatis americana*. Rays were anesthetized with MS222 and transcardially perfused with elasmobranch Ringer's followed by 4% paraformaldehyde in 0.1M Phosphate buffer. The brains were removed and sectioned at 35 $\mu$ m. The sections were blocked in normal horse serum and incubated for 24-72hrs with monoclonal anti-zebrin II (culture fluid 1:50-1:1000). Sections were incubated in biotinylated anti-mouse IgG, followed by avidin-biotin-peroxidase complex, and reacted for HRP using DAB as the chromogen. In stingrays, anti-Zebrin II labels all Purkinje cells of the corpus. No banding pattern or compartmentation was observed. Purkinje cell projections to the deep cerebellar nucleus, and anterior, descending, and posterior octaval nuclei also were revealed. Western blot analysis demonstrates that the Zebrin II antibody recognizes a polypeptide antigen of the same molecular weight in stingrays, teleosts, and mammals. Based on these results it is concluded that a Zebrin II staining pattern, in which all Purkinje cells of the cerebellar corpus are immunopositive is the primitive condition for jawed vertebrates. Zebrin II antibodies were kindly provided by R. Hawkes. Supported by NSF IBN-9421393.

## 60.3

AFFERENT AND EFFERENT CONNECTIONS OF THE OPTIC TECTUM IN THE SENEGAL BICHIR *Polypterus senegalus* [Osteichthys: Cladistia] P. H. Holmes\* and R.G. Northcutt. Neurobiology Unit, Scripps Institution of Oceanography, and Dept. of Neuroscience, School of Medicine, University of Calif., San Diego, La Jolla, Ca 92093-0201.

Non-retinal afferents and efferent connections of the optic tectum were determined by injecting horseradish peroxidase or biotinylated dextrans into the optic tectum. Analysis of efferents also involved examination of degenerating fibers after tectal lesions. The tectum receives input from the ipsilateral caudal entopeduncular nucleus, the anterior, ventromedial, and possibly ventrolateral thalamic nuclei. Other sources of afferents include the central pretectal nucleus, ipsilateral nucleus supracommissuralis, ipsilateral torus semicircularis, bilateral lateral tegmental nucleus, and the ipsilateral locus coeruleus. Medullary afferents include all divisions of the reticular formation, contralateral dorsal and medial octavolateral nuclei, and the contralateral descending trigeminal nucleus. Ascending efferents project to the pretectum, the anterior, intermediate, ventromedial, ventrolateral, central posterior, and dorsal posterior thalamic nuclei. Efferents cross in the postoptic decussation to innervate the contralateral central pretectal nucleus, nucleus supracommissuralis, and nucleus anterior and intermedius of the thalamus. Descending efferents project to the ipsilateral torus lateralis, the contralateral torus semicircularis, ipsilateral tegmentum, and nuclei of the posterior tubercle. After crossing in the caudal mesencephalon, efferents descend and project bilaterally to the reticular formation. (Supported in part by a Markey Fellowship to P.H.H.)

## 60.5

IMMUNOCYTOCHEMICAL LOCALIZATION OF cGnRH-II and sGnRH in the Nervous System of Zebrafish, *Danio rerio*. S.P. Matz\* and R.G. Northcutt. Department of Neurosciences, U.C. San Diego, La Jolla, CA 92093

The distribution of gonadotropin-releasing hormone (GnRH) was examined in zebrafish using antisera to salmon GnRH (sGnRH) and chicken GnRH-II (cGnRH-II). sGnRH-immunoreactive (ir) cell bodies were localized in the olfactory bulb, ventral telencephalon, preoptic area and posterior tubercle. cGnRH-II-ir cell bodies were localized in posterior tubercle only.

GnRH-ir fibers are widely distributed in the CNS. Fibers immunoreactive to sGnRH are found in the olfactory bulb, telencephalon, diencephalon, optic tectum, midbrain and spinal cord. Furthermore, sGnRH-ir fibers are observed in the olfactory and optic nerves. Fibers in the optic nerve appear to be efferent fibers since terminal-like swellings are observed in the retina and no GnRH cell bodies are observed in the retina. We could not determine whether fibers in olfactory nerve were efferent axons or dendrites emanating from GnRH cells in the olfactory bulb. cGnRH-II-ir fibers were localized in the same areas as sGnRH the density of staining was much less, and the fibers were thinner.

The results of this study suggest that zebrafish are immunoreactive to sGnRH and cGnRH-II. Although there is overlap in the distribution of these two antibodies, the reactivity to sGnRH is much more widely distributed.

## 60.7

CONNECTIONS OF LATERAL LINE NEUROMASTS AND OTOLITHIC ENDORGANS OF THE INNER EAR IN A CLUPEID *C.A. McCormick\**. Dept. Biology, Oberlin College, Oberlin OH 44074

Connections of nerves associated with the inner ear and lateral line were studied in the gizzard shad, *Dorosoma cepedianum* using horseradish peroxidase. Labeling was carried out in exsanguinated specimens (see McCormick and Bradford, 1994). Additional specimens were used to determine the cytoarchitecture of the octavolateralis area, the relationship of the swimbladder to the inner ear, and the presence or absence of trunk neuromasts. As reported in other Clupeiformes, the utricle and cephalic lateral line canals are associated with the swimbladder, and the utricle contains three sensory maculae. The utricle has a major bilateral projection to the dorsomedial zone of the descending octaval nucleus; this zone is located medial to nuc. medialis and ventral to the cerebellar crest. Other utricular fibers terminate in ventral regions of the descending octaval nuc. Most saccular and lagenar fibers project ipsilaterally to a dorsal region of the descending octaval nuc. that is lateral, not medial as in other teleosts, to the utricular terminal zone. A few fibers also supply the dorsomedial zone, bilaterally in the case of the saccule. Other connections of the otolith endorgans include the anterior octaval nuc., nuc. magnocellularis, and the eminentia granularis. Most anterior and posterior lateral line fibers terminate in ventral and dorsal areas within nuc. medialis, respectively. Both head and trunk neuromasts provide light input to the dorsomedial zone of the descending nuc. and possibly also to the more lateral saccular/lagenar zone; connections to nuc. magnocellularis and the eminentia granularis are also present. The descending octaval nuc. in the shad therefore has an expansive dorsomedial zone like that of otophysans, but the input to this zone is dominated by utricular rather than saccular input. The results of this study will be presented in an evolutionary context. Supported by NSF IBN-9309977.

## 60.4

AFFERENT AND EFFERENT CONNECTIONS OF THE TELENCEPHALIC DORSOCENTRAL REGION IN A WEAK ELECTRIC FISH, *GYMNOTUS CARAPO*. S.A.L. Corrêa\*, K. Grant and A. Hoffmann. Lab. of Neurophysiology, University of São Paulo, Ribeirão Preto SP 14049-900 Brazil.

This is the first attempt to investigate possible connections between the dorsocentral (DC) area of the telencephalon and other regions of the central nervous system in *Gymnotus carapo*. To this end electrophoretic injections of biotinylated dextran amine (BDA) were applied to the different frontal planes of the DC. This resulted in retrograde labeling of the area ventralis pars centralis (Vc), pars dorsalis (Vd) and pars ventralis posterior, nucleus entopeduncularis, area dorsalis pars lateralis (DL) and pars lateralis (PGI), pars medialis (PGm) and pars rostralis (PGr) of the preglomerular complex. Anterograde labeling was detected in Vd, Vc, DL, PGI, PGm, pretectal nucleus, magnocellular tegmental nucleus, optic tectum (TeO) and dorsal torus semicircularis (TSd). We observed that the DC is heavily interconnected with the preglomerular complex, which is involved in the processing of multisensory information (auditory, gustatory, visual and electrosensory). The PGI receives electrosensory information via the TSd and the nucleus electrosensorius (nE) and projects toward caudal planes of the DC, while fibers from rostral and medial DC planes reach the PGI, TSd and TeO, structures that in gymnotiformes are related to the processing of electrosensory information. Thus, in gymnotiform fish, electrosensory information may be conducted from the nucleus electrosensorius to the dorsal telencephalon via the PGI.

This study was supported by the Brazilian agencies CNPq, CAPES, FAPESP and French CNRS.

## 60.6

EVOLUTION OF COGNITION IN TELEOSTS: CYTOARCHITECTURE OF THE HYPERTROPHIED DORSAL TELENCEPHALON OF SQUIRRELFISH, *L.S. Demski\** and J.A. Beaver. Division of Natural Sciences, New College, Univ. of South Florida, Sarasota, FL 34243

Squirrelfish are common coral reef fishes with enlarged eyes and visual pathways and highly sensitive hearing, a unique combination for teleosts. They are also unusual in having an exaggerated development of certain parts of the area dorsalis telencephali (Dc, pars centralis; Dd, pars dorsalis; Dl, pars lateralis); regions most likely related to the sensory enhancements. Toward a functional analysis of the areas, we describe their cellular components using Golgi, Nissl, and plastic preparations of *Holocentrus rufus*. The Dc is a spherical expansion (radius of ca. 1.2-1.4 mm) with a midline fusion; it contains scattered large multipolar neurons (ca. 22-25 µm, soma; 10-12.5 µm nucleus) with spiny dendrites extending spherically (at least up to 400 µm) to overlap those of many other similar cells as well as fibers of the lateral forebrain bundle. A thickened mantle (ca. 0.5 mm deep) or "cortex-like" zone, most likely related to Dd and/or Dl of other teleosts, overlies Dc and is separated from it by a capsule of myelinated fibers. The mantle zone has cords of small (ca. 7.5-10 µm, soma; 5 µm, nucleus) and medium (ca. 11-12.5 µm, soma; 7.5 µm, nucleus) sized cells separated by radially projecting axons and glial fibers. The larger cells have a denser cytoplasm. Both types have "lateral" dendrites (at least up to at least 125 µm in the larger and 75 µm in the smaller cells) that branch from spherical cell bodies and lie in a plane concentric with the outer pial surface and hence perpendicular to the radial fibers; other dendrites extend more ventrally in an elliptical pattern between the lateral ones. The largest dendrites are spiny and overlap those of cells in adjacent columns. The cells often occur in clusters of two or more with somal membranes in close apposition. Axons of all cell types originate from the soma or basal dendrites. Supported by grants from NSF and Florsheim Endowment to New College.

## 60.8

IDENTIFICATION AND LOCALIZATION OF NEUROHYPOPHYSICAL PEPTIDES IN THE BRAIN OF A CAECILIAN AMPHIBIAN. S.K. Boyd<sup>1</sup>, C. Hilscher-Conklin<sup>1</sup>, J.M. Conlon<sup>2</sup>.

<sup>1</sup>Biological Sci., Univ. of Notre Dame, Notre Dame, IN 46556; <sup>2</sup>Regulatory Peptide Center, Biomedical Sci., Creighton Univ. Sch. of Med., Omaha, NE 68178.

We used HPLC to isolate and purify brain and pituitary peptides from the caecilian *Typhlonectes natans* which belongs to the little-recognized amphibian order, Gymnophiona. Based on elution profiles, immunoreactivity and mass spectrometry, this caecilian possesses arginine vasotocin (AVT). Using immunocytochemistry, AVT cells were located in the preoptic area, hypothalamus, amygdala, ventral thalamus, trigeminal nucleus and spinal cord. AVT fiber distribution was extensive. Caecilian brains also contained a putative mesotocin, based on elution profile and immunoreactivity. MT-immunoreactive cells were present in the preoptic area, hypothalamus and amygdala only. Fiber distribution was more restricted than that of AVT. Neurohypophysial peptides of this caecilian species, therefore, are similar to those of anuran and urodele species, despite caecilians being evolutionarily separated by at least 200 million years from the other two orders.

Supported by NSF #IBN95-14305 and NIH #HD24653.

## 60.9

QUANTITATIVE THREE-DIMENSIONAL CHARACTERIZATION OF DENDRITIC TREES IN AMPHIBIAN FOREBRAIN. C. Mohr<sup>\*,a</sup>, S.K. Boyd<sup>a</sup>, S. Raghavachari<sup>b</sup> and J.A. Glazier<sup>c</sup>. University of Notre Dame, Departments of Biology<sup>a</sup> and Physics<sup>b</sup>, Notre Dame, Indiana 46556, USA.

Three-dimensional description of neuron anatomy is difficult. Current practices often depend on unrelated and subjective criteria (eg, shape of dendrite tree or soma, position of soma) to classify neurons. We have developed an unambiguous method for categorizing neurons, using a quantitative analysis of their dendrite structure. Golgi-stained neurons in the telencephalon of the South African clawed frog (*Xenopus laevis*) were drawn in their entirety using a computer-supported tracing system (NTS5, Eutectics) which automatically performs 3-D reconstruction. We quantified neuronal shapes using 1) the mean opening angle of the dendrites, 2) vector length (quantifies directionality of projection), and 3) neuronal asphericity (describes dendritic tree shape). Vector length is the vector sum of individual branch segment vectors and neuronal asphericity was calculated using the invariants of the inertia tensor. We then performed cluster analysis with the Ward's minimum variance statistic. We distinguished four non-overlapping groups of neurons with statistically significant separation. This method differs substantially from 2-D description of neurons. It describes a restricted set of neuron types in quantitative, objective fashion. General application of this method will allow comparison of neuron types both within and across species.

Supported by NSF#41941 (JAG), NSF#IBN14305 (SKB) and NIH#HD-24653 (SKB).

## 60.11

DEVELOPMENT OF AFFERENT CONNECTIONS TO THE STRIATUM AND THE NUCLEUS ACCUMBENS IN THE ANURAN AMPHIBIAN *Xenopus laevis* WITH EMPHASIS ON THE DOPAMINERGIC PROJECTIONS. Q. Marin<sup>\*,†</sup>, W.J.A.J. Smeets<sup>‡</sup>, M. Muñoz<sup>‡</sup>, A. Muñoz<sup>‡</sup>, C. Sánchez-Camacho<sup>‡</sup>, H. Varat<sup>‡</sup> and A. González<sup>‡</sup>. †Dept. Cell Biology, Univ. Complutense, Madrid, Spain. ‡Graduate Sch. Neurosci., Dept. Anatomy & Embryology, Vrije Univ., Amsterdam, The Netherlands.

Recently, we have presented data about the afferent connections of the basal forebrain of adult anuran and urodele amphibians. To broaden our insight into the organization of the basal ganglia (BG) of amphibians, we have now studied the development of the inputs to the striatum and the nucleus accumbens, using biotinylated or Texas Red-conjugated dextran amines as retrograde tracers. In double labeling experiments, antibodies against tyrosine hydroxylase were used as marker of catecholaminergic structures. Already at late embryonic stages, the basal telencephalon received inputs from cells located in the amygdala, the suprachiasmatic nucleus, the raphe nucleus and the rhombencephalic reticular formation. At these stages, the rostral part of the posterior tubercle seems to be the only source of the dopaminergic input to the basal forebrain. During *premetamorphosis* not only a differentiation between afferents to the striatum and the nucleus accumbens could be made, but also new sources of inputs were detected in the pontomesencephalic reticular formation and the nucleus of the solitary tract. During *prometamorphic stages* a gradually increase occurs in the number of cells that project to the basal telencephalon. At the beginning of the *metamorphic climax* the organization of the BG afferents resembles largely the pattern observed in juveniles and adults. Remarkably, during larval stages the cells that contribute to the dopaminergic innervation of the basal forebrain show a rostrocaudal gradient in time of appearance. Moreover, the dopaminergic fibers reach the striatum earlier than the nucleus accumbens, which is in agreement with the development of the telencephalon and the dopaminergic cell groups.

## 60.13

RHOMBOMERE IDENTIFICATION IN A DEVELOPING REPTILE. M.B. Pritz<sup>\*</sup>. Sect. of Neurol. Surg., Indiana U. Sch. of Med., Indianapolis, IN 46202-5124.

Subdivisions of the hindbrain were investigated in *Alligator mississippiensis* embryos. Embryos were examined between Ferguson stages 8 and 14.5 (8 to 17 days after egg laying). Brains were dissected free from non-neural tissue, divided at the isthmus, and examined with a dissecting microscope from both the internal (ependymal) and external surfaces. Afterwards, hindbrains were embedded in gelatin, sectioned on a sliding microtome, and stained with cresylviolet or with antibodies to acetylated tubulin or vimentin or processed for peanut agglutinin histochemistry. Rhombomeres were visible at the earliest stage available, stage 8, became less distinct by stage 12.5, and disappeared by stage 14. Whole mount, unstained hindbrains accurately identified the presence and absence of rhombomeres which were confirmed by light microscopic analysis of sectioned tissue stained with cresylviolet, with antibodies to vimentin and acetylated tubulin, and by peanut agglutinin histochemistry. These observations in *Alligator* identify rhombomeres whose morphology is similar to those neuroepithelial subdivisions described in other vertebrates. Taken together, these data suggest that transient hindbrain segmentation is a feature common to all developing vertebrate brains.

## 60.10

ORGANIZATION OF THE CAUDAL RHOMBENCEPHALIC ALAR PLATE IN THE URODELE AMPHIBIAN *PLEURODELES WALTLI*: PRESENCE OF DORSAL COLUMN AND LATERAL CERVICAL NUCLEI. A. González<sup>\*,†</sup>, A. Muñoz<sup>‡</sup>, M. Muñoz<sup>‡</sup>, Q. Marin<sup>‡</sup>, H. Varat<sup>‡</sup>, C. Sánchez-Camacho<sup>‡</sup> and †H.J. ten Donkelaar<sup>‡</sup>. Dept. Cell Biology, Univ. Complutense, Madrid, Spain, and †Dept. Anat. & Embryol., Univ. Nijmegen, The Netherlands.

The cytoarchitecture, chemoarchitecture, and fiber connections of the caudal rhombencephalic alar plate were studied in the ribbed newt, *Pleurodeles waltli*. A cytoarchitectonic analysis revealed that the caudal medullary alar plate consists of poorly segregated inner and outer cell layers in which different cell populations could be (immuno)histochemically distinguished. The inner cell layer is formed dorsomedially by the nucleus of the solitary tract, characterized by the presence of tyrosine hydroxylase and calbindin D-28k positive neurons, and ventrolaterally by the nucleus of the descending trigeminal tract, identified by the presence of calbindin, NADPH-diaphorase and nitric oxide synthase positive neurons with dorsolaterally directed dendrites intermingled with the fibers of the descending trigeminal tract. The outer cell layer at the obex level forms the dorsal column nucleus (DCN), whereas the ventrolateral part of this cell layer forms a lateral cervical nucleus (LCN). With anterograde and retrograde tracing the DCN and LCN were further delineated. Labeling of ascending dorsal root afferents showed that the dorsal column and the DCN are somatotopically arranged: lumbar primary afferents terminate on medial DCN neurons, whereas cervical primary afferents terminate on lateral DCN neurons. The LCN is densely innervated by the dorsolateral funiculus. Retrograde tracing showed extensive, predominantly contralateral, projections of both the DCN and LCN to the torus semicircularis and the ventral thalamus through the medial lemniscus. These data show that in urodeles, in addition to the direct ascending spinal projections, a dorsal column-medial lemniscal projection via the DCN as well as the spinocervicothalamic system via the LCN would be involved in the transmission of somatosensory information to various supraspinal centers.

## 60.12

OBSERVATIONS ON HABENULAR AFFERENTS IN RANID FROGS. T.J. Neary<sup>\*</sup>. Department of Biomedical Sciences, Creighton University School of Medicine, Omaha, NE 68178.

Following applications of wheat germ agglutinin-horseradish peroxidase in the habenula of bullfrogs, *R. catesbeiana*, intensely labelled cells were seen bilaterally, with a slight ipsilateral preponderance, in the magnocellular preoptic nucleus and in the superficial ventral thalamic nucleus (Vs, nomenclature of Neary and Northcutt [1983]). Levine [1980] and others have demonstrated that the Vs (rostral visual nucleus in his nomenclature) receives a strong input from the retina. Together, these findings suggest that one or both of the habenular nuclei in ranid frogs may be strongly influenced by visual stimuli. The Vs lies lateral to the magnocellular preoptic nucleus and labelled cells were present as a "bridge" between the two populations. This suggests that the Vs may be derived from the preoptic area and not from the ventral thalamus, as hypothesized by Neary and Northcutt [1983].

Self-supported.

## 60.14

ULTRASTRUCTURAL ORGANIZATION OF NUCLEUS ROTUNDUS IN A REPTILE. D. M. Schroeder<sup>\*</sup> and M. B. Pritz<sup>\*</sup>. Indiana University School of Medicine, Medical Sciences, Bloomington, IN 47405 and Section of Neurological Surgery, Indianapolis, IN 46202.

Nucleus rotundus is a prominent nucleus in the dorsal thalamus of reptiles. It receives retinal input via the optic tectum and projects to a well defined area of the telencephalon, the dorsal ventricular ridge. The present study examined nucleus rotundus in one species of reptiles, *Caiman crocodilus*, at the ultrastructural level.

Within the core area of nucleus rotundus, medium sized neurons are scattered among rich neuropil. A number of these neurons are clustered in groups and many are juxtaposed in such close proximity that their membranes appear to fuse. Within the neuropil there are many dendritic profiles densely surrounded with boutons and forming synaptic aggregations. This type of neuropil organization in *Caiman* is a distinguishing feature of dorsal thalamic nuclei of mammals. Most of these boutons contain spherical vesicles and only occasionally are boutons present with pleomorphic vesicles. As previously reported (Pritz, 1995), local circuit neurons are not present in nucleus rotundus of this species; thus the synaptic aggregations must consist primarily of the dendrites of the relay cells and the synaptic contacts from its afferents. Numerous unmyelinated axons are found throughout.

## 60.15

**DISTRIBUTION OF CRF IMMUNOREACTIVE STAINING IN THE BRAIN OF *Anolis carolinensis*.** Gary R. Ten Eyck\*, Amy-Lacy Adams, John M. Matter, Chris A. Lowry and Cliff H. Summers. Dept. of Biology, University of South Dakota, Vermillion, SD 57069. Immunoreactive staining to CRF was widely distributed in the CNS of the lizard *Anolis carolinensis*. Brains were frozen sectioned (-20°C) at 20 µm, then fixed with paraformaldehyde on slides. Polyclonal antibody against ovine CRF (Peninsula Laboratories), was applied (1:500) to the frozen sections and made visual by a reaction to an avidin-biotin 2° antibody with DAB. Staining was particularly heavy in medial (hippocampal) cortex and hypothalamus. Hypothalamic CRF was evident as two vertical bands, parallel to each other and to the third ventricle, spanning from the nucleus accumbens to the posterior hypothalamus. The strongest staining of these bands was in the paraventricular nucleus. Some diffuse CRF staining was evident in all hypothalamic nuclei. Extrahypothalamic CRF staining occurred in medial cortex, septum, paleostriatum (amygdala), anterior dorsal ventricular ridge, nucleus accumbens, optic tectum, cerebellum, periaqueductal grey, and raphe nuclei. Anoline central CRF distribution is similar to that seen in mammals. Hypothalamic, hippocampal, amygdalar, periaqueductal and raphe immunoreactivity for CRF is coincident with immune staining for serotonin and glucocorticoid receptors, suggesting a role in regulation of stress. Supported by NSF grant OSR-9108773.

## 60.17

**CO-LOCALIZATION OF VASOTOCIN AND GALANIN IN THE BRAIN OF THE TURTLE *Chrysemys picta*.** R. Goldberg\*, J. Haldar\*, and A.S. Powers\*. Depts. Of Psychol.<sup>1</sup> and Biol. Sci.<sup>2</sup>, St. John's University, Jamaica, NY 11439. Vasotocin (VT) is a peptide found in the brains of nonmammals. It shares a common structure with mammalian vasopressin (VP) but differs by one amino acid. Galanin (GAL) is a peptide found in both mammals and nonmammals. GAL and VP colocalize in the hypothalamus of many mammals. This study investigated the location of VT and GAL in the brain of the painted turtle *Chrysemys picta*. Preliminary experiments confirmed that our VP antibody stained the same cells as a VT antibody. Turtles were injected with colchicine (135µl in saline) and allowed to survive 3 days. They were perfused intracardially with saline followed by 4% formaldehyde. Brain sections (40µm) were incubated with an antibody against mammalian VP (made in guinea pig) and an antibody against human GAL (made in rabbit). They were washed and then incubated for 1 hr in a solution containing secondary antibodies, one against rabbit conjugated to rhodamine and the other against guinea pig conjugated to fluorescein. As has been shown before (e.g., Fernandez-Lebrez, et al., 1988; Smeets et al., 1990), VT-positive cells were found mainly in the supraoptic nucleus (SON), the paraventricular nucleus (PVN), and the bed nucleus of the stria terminalis. Also as has been shown before (Jimenez, et al., 1994), GAL-positive cells were found only in a few restricted locations within the hypothalamus, but GAL-positive fibers were widely distributed throughout hypothalamic and extrahypothalamic areas. Some but not all cells of the SON and PVN were positive for both VT and GAL. Dense fibers positive for both were seen in the hypophysis. These findings are important because they show conservation over evolution and suggest that those functions mediated by GAL may be the same in reptiles as they are in mammals. Supported by NIH grant # NS-31785 to ASP.

## 60.16

**NADPH-DIAPHORASE NEURONS IN THE SUBSTANTIA NIGRA IN TURTLES.** C. Kaeppler\*, W. Iaccino, and A. S. Powers. Dept. of Psychology, St. John's University, Jamaica, NY 11439. Neurons positive for NADPH-diaphorase (NADPH-d), a marker for nitric oxide, are seen in the midbrain tegmentum of turtles, in the region of substantia nigra. The substantia nigra of mammals, however, does not contain NADPH-d. The present study investigated whether the NADPH-d-positive cells in turtles are catecholaminergic and whether they project to the telencephalon. For immunohistochemistry, painted turtles (*Chrysemys picta*) were perfused intracardially with saline followed by 4% paraformaldehyde. Frozen sections (40µm) were incubated with an antibody against tyrosine hydroxylase (TH) and stained for immunofluorescence. TH-positive cells in the midbrain were photographed, and the tissue was subsequently stained for NADPH-d, using a standard histochemical technique. Again the tissue was photographed. Comparison of the two sets of photographs showed that virtually all of the TH-positive neurons in the substantia nigra contained NADPH-d. For tract tracing, Fluoro-Gold (FG) injections were made in the striatum of turtles. After 60 days survival, the animals were perfused with saline and 4% paraformaldehyde. The location of FG-positive cells in the midbrain was mapped and photographed. Then the tissue was stained for NADPH-d and re-photographed. Cells in the substantia nigra were double-labelled with FG and NADPH-d. These results show that the NADPH-d-positive cells of the midbrain tegmentum in turtles are the catecholamine-positive cells that project to the striatum, the equivalent of substantia nigra, pars compacta in mammals. Interestingly, this region contains NADPH-d in turtles but not in mammals. Interpretation of this finding awaits further study of the role of nitric oxide in the basal ganglia. Supported by NIH grant #NS-31785 to ASP.

## LEARNING AND MEMORY: PHARMACOLOGY I

## 61.1

**DIFFERENTIAL EFFECTS OF ACUTELY ADMINISTERED ETHANOL ON SPATIAL AND NON-SPATIAL COGNITIVE PROCESSING.** P.E. Simson, D.B. Matthews, & P.J. Best. Miami University, Center for Neuroscience Research and Dept. of Psychology, Oxford OH, 45056. Acute administration of ethanol selectively impairs spatial memory (Matthews, Simson & Best, 1995) and spatial learning (Vandergriff, Matthews, Simson & Best, 1995) in a dose-dependent manner. This impairment is remarkably similar to that found following lesions to the hippocampal system (O'Keefe & Nadel, 1978; Jarrard, 1986). Lesions to the hippocampal system also often facilitate learning/performance on non-spatial learning and memory tasks (M'Harzi, Jarrard, Willig, Palacios & Delacour, 1991; White & McDonald, 1993; Matthews & Best, 1995; White, Matthews & Best, 1995). However, it has yet to be determined if acute administration of ethanol can similarly facilitate non-spatial cognitive processing. In the first experiment, we investigated the effect of acutely administered ethanol on spatial memory in a task that does not require behavioral generalization by the animal during testing. In the second experiment, we investigated the effect of ethanol on non-spatial cognitive processing. Supported in part with a Pre-doctoral grant to D.B.M. from NIAAA (AA05414) a FIRST award to P.E.S. from NIAAA (AA-09079) and a grant to P.E.S. from the Alcoholic Beverage Medical Research Foundation.

## 61.2

**THE EFFECTS OF ETOH ON SPATIAL AND NON-SPATIAL WORKING MEMORY IN THE RAT.** A.M. White\*, P.E. Simson and P.J. Best. Dept. of Psychology and Center for Neuroscience Research, Miami Univ., Oxford, OH 45056. In rodents, the acute administration of ETOH leads to a pattern of learning and memory impairments similar to those that follow hippocampal system damage (Matthews et al., 1995). Jarrard et al. (1987) report that hippocampal lesions impair performance on a spatial, but not non-spatial, delayed match-to-sample task on a radial-arm maze. The purpose of the present experiments is to assess the effects of ETOH on a similar set of tasks. Subjects were trained on either a spatial or a non-spatial delayed match-to-sample task on a six-arm radial-arm maze. Ten trials were conducted during each day of training, the first of which was a forced trial. In the spatial task, subjects were required to remember the spatial location of the food reward received during the forced trial and to return to that location during nine subsequent free-choice trials. The spatial location of the food reward changed across days. In the non-spatial task, five of the six maze-arms contained salient intramaze cue inserts. Subjects were required to remember which cue insert was located on the maze-arm visited during the forced trial, and to enter the arm containing that cue during the nine subsequent free-choice trials. The spatial location of the cue changed across trials and the cue signalling the goal arm changed across days. Ethanol (0.0 g/kg, 0.75 g/kg, 1.5 g/kg & 2.0 g/kg) caused a dose dependent impairment in performance on the spatial task. (Supported in part by a FIRST award to P.E.S. from NIAAA (AA-09079) and a grant to P.E.S. from the Alcoholic Beverage Medical Research Foundation.)

## 61.3

**INHIBITION OF CHOLESTEROL SYNTHESIS BLOCKS ASSOCIATIVE LEARNING.** W.T.O'Brien<sup>\*1,3</sup>, G.Xu<sup>2,3</sup>, G.Salen<sup>2,3</sup> & R.J. Servatius<sup>1,3</sup>. <sup>1</sup> Depts. of Neuroscience (Graduate School of Biomedical Sciences), and <sup>2</sup> Medicine, New Jersey Medical School, Newark, New Jersey and <sup>3</sup> DVA Med. Cn. East Orange, N.J. 07018

Administration of BM15.766 (BM) blocks the last enzymatic step of cholesterol (CHOL) biosynthesis leading to a decrease in brain, liver and plasma CHOL and an increase in the immediate precursor, 7-dehydrocholesterol. This biochemical profile resembles that of children with Smith-Lemli-Opitz (SLO) syndrome, a congenital disorder associated with severe mental retardation. Using the classically conditioned eyeblink response (CCER) paradigm, we assessed new motor learning in just weaned rats fed BM (n=3) by gavage for 4 mos, rats given exogenous CHOL during the last two months of BM treatment (n=3), and non-treated controls (n=5). For conditioning, a 600 ms white noise conditioned stimulus coterminated with a 100 ms periorbital shock. The rats were given 300 trials. Treatment with BM or BM+CHOL did not alter either the spontaneous blink rate or sensory reactivity to the to-be-conditioned stimulus. The BM treated rats failed to learn the CCER after 300 trials. The BM+CHOL treated rats exhibited only a slight learning impairment, evident in the first 20 trials. Chronic treatment with a cholesterol synthesis inhibitor blocked acquisition of the CCER, while exogenous CHOL may be useful as a counter treatment. Just-weaned rats treated with CHOL-synthesis inhibitors may be appropriate for use as an animal model for Smith-Lemli-Opitz. Supported by GSBS-UMDNJ and DVA Med. Research Funds and PHS grants HL17818, HL18094, DK26756.

## 61.5

**DEVELOPMENTAL CHANGES IN HIPPOCAMPAL STAINING FOR ACETYLCHOLINESTERASE FOLLOWING PRENATAL CHOLINE TREATMENT.** R. Loy, D.D. Heyer and K. Maguire-Zeiss\*. Department of Neurology, University of Rochester, 435 E. Henrietta Road, Rochester, NY 14620.

Choline supplementation *in utero* results in a long-lasting facilitation of spatial memory and a variety of correlated brain changes, including enhanced hippocampal LTP, elevated levels of hippocampal NGF, an increase in the size of diagonal band neurons and their content of mRNA for low affinity neurotrophin receptor, and alterations in phospholipase D, choline acetyltransferase and acetylcholinesterase (AChE) activities. Behavioral improvement in memory capacity is apparent early postnatally, as are decreases in AChE activity. To determine if these changes could be localized anatomically, male rats were treated *in utero* from embryonic day 12-17 (300 mg/kg/day choline chloride, *p.o.* to the dam) with supplemental choline or control saccharine solution and raised to either postnatal day 16 or 90, then anesthetized and perfused with formalin. Frozen, coronal brain sections were stained histochemically for AChE. Staining in the hippocampus and dentate gyrus was significantly reduced in laminae corresponding to septal terminal fields in choline-treated rats compared to controls at postnatal day 16. There also appeared to be fewer AChE-positive interneurons, particularly in the temporal dentate hilus and CA3. By contrast, at postnatal day 90, there was no longer a significant difference between choline-treated and controls, either in the density or the pattern of staining. Thus, choline-induced changes in cholinergic activity may develop early but show compensation later in life. Supported by AG09525.

## 61.7

**PRENATAL AND PRE-POSTNATAL CHOLINE SUPPLEMENTATION REDUCES THE THRESHOLD TO INDUCE LONG-TERM POTENTIATION IN HIPPOCAMPAL SLICES FROM ADULT RATS.** J.P. Jones<sup>\*1</sup>, W.H. Meck<sup>1</sup>, C.L. Williams<sup>1</sup>, & H.S. Swartzwelder<sup>2,3</sup>. Departments of Psychology: Experimental<sup>1</sup>, and Psychiatry<sup>2</sup>, Duke University, Durham, NC 27708 and Veterans Administration Medical Center<sup>3</sup>, Durham, NC 27710.

Perinatal choline supplementation has been found to increase the capacity and precision of visuospatial memory throughout adulthood, and to reduce the detrimental effects of normal aging on memory. In this study we investigated possible changes in the induction of long-term potentiation (LTP) in hippocampal slices from adult male rats (6-8 mo) following a combination of both pre- and postnatal choline supplementation, choline deficiency, or control procedures (ED 9 - PD 30). Our data indicate that the threshold for initiation of LTP, as well as LTP magnitude following theta-burst stimulation trains in area CA1 were enhanced in hippocampal slices from choline supplemented rats compared to controls and deficient. We also investigated the effects of prenatal choline supplementation, choline deficiency, or control procedures (ED 12 - 17) in the initiation of LTP in older adult male rats (12 mo). These data also showed a significant reduction in the threshold for inducing LTP even with the reduced time period of treatment, coupled with possible age-related alterations in hippocampal LTP. Taken together, these electrophysiological data support the hypothesis that choline availability to the developing fetus during periods of neurogenesis and synaptogenesis enhances the subsequent initiation of hippocampal LTP. These alterations in synaptic plasticity may underlie the observed differences in memory capacity between control and perinatally choline-supplemented rats. (Supported by AG09525)

## 61.4

**APOPTOSIS IN RAT FETAL HIPPOCAMPUS AND PHEOCHROMOCYTOMA (PC 12) CELLS IS INDUCED BY CHOLINE DEFICIENCY.** M. Holmes-McNary, R. Loy\*, M.H. Mar, and S. Zeisel. Department of Nutrition, University of North Carolina, Chapel Hill, NC, 27599-7400 and \*Department of Neurology, University of Rochester, Rochester, NY, 14620.

Choline deficiency (CD) causes DNA damage, many biochemical changes and cell death in hepatocytes. We now know that cell death in these hepatocytes is due to an apoptotic process. In order to understand this process and the generality of the effects of CD, we investigated the effects of CD on the rat pheochromocytoma (PC12) neuronal cell line, which express neuronal-like properties, and in whole rat brain. PC12 cells were plated in choline-free DMEM/F12 supplemented with 15% serum for 2 days, then cultured in serum-free N2 media with 70µM choline chloride (N2-CS) or without choline chloride (N2-CD) for 2 days. Cell viability, by exclusion of trypan blue, was 86% for cells in N2-CS and 73% for cells in N2-CD. Cells maintained in N2-CD showed an increase in DNA strand breaks (TUNEL method). Classical apoptotic bodies were detected in N2-CD cultured cells (25%) compared to cells in N2-CS (10%). Cleavage of DNA into 200 bp internucleosomal fragment sizes in PC-12 cells was studied by gel electrophoresis. We used an *in-vivo* model to determine the dietary effects of CD on the neuronal cell types in fetal rat brain. Pregnant rats were fed a CS or a CD diet for 6 days and embryonic day 18 fetal brain slices were analyzed for DNA strand breaks (TUNEL method). In fetal rat hippocampus CD caused DNA strand breaks and apoptosis in neuronal-type cells like the response of PC-12 cells. These results suggest that CD induces apoptotic cell death in neuronal-like cells and fetal rat brain. (Supported by the NIA Grant #AG09525 and Carolina Post-Doctoral Fellowship #2-39941.)

## 61.6

**PRENATAL CHOLINE AVAILABILITY ALTERS THE POSTNATAL DEVELOPMENT OF ACETYLCHOLINESTERASE (AChE) AND CHOLINE ACETYLTRANSFERASE (ChAT) ACTIVITIES IN RAT HIPPOCAMPUS.** J.M. Cermak\*, T. Holler and J.K. Blusztajn. Boston Univ. Sch. of Med., Boston, MA 02118.

Choline supplementation during embryonic days (E) 12-17 permanently enhances performance on visuospatial memory tasks in rats. In order to characterize the neurochemical mechanisms that may mediate this effect, we investigated the development [postnatal days (P) 1, 3, 7, 17, 27, 35, 90] of ChAT and AChE activities in the rat hippocampus, cortex, and striatum as a function of prenatal choline availability. During E11 through E17 Sprague-Dawley pregnant rats received a choline-deficient, control, or choline-supplemented diet. The average choline intake was 0, 1.3, and 4.6 mmol/kg/day, respectively. Small, but significant changes in hippocampal ChAT activity were observed on P17 and P27 only. ChAT activity in hippocampal homogenates was higher in choline-deficient and lower in choline-supplemented male rats compared to controls ( $p < 0.05$ ). AChE activity in hippocampal homogenates was higher (by 10-30%) in choline-deficient and lower (by 10-15%) in choline-supplemented rats compared to controls on P7, 17, 27 and 35 ( $p < 0.001$ ). Prenatal choline availability had no effect on striatal and cortical AChE and ChAT activities. The reductions in hippocampal AChE activity in choline-supplemented rats are consistent with the notion that decreased degradation of hippocampal acetylcholine contributes to the enhanced memory performance in these animals. (Supported by AG09525)

## 61.8

**MODULATION OF LEARNING AND NEURONAL MEMBRANE COMPOSITION IN THE RAT BY ESSENTIAL FATTY ACID**

**PREPARATION: TIME COURSE ANALYSIS.** Shlomo Yehuda<sup>1</sup>, Sharon Rabinovitz<sup>1</sup> and David I. Mostofsky<sup>2</sup>. <sup>1</sup>Psychopharmacology Laboratory, Department of Psychology, Bar Ilan University, Ramat Gan, Israel 52900, and <sup>2</sup>Department of Psychology, Boston University, Boston, MA 02215, USA.

Previous studies have shown that chronic administration of SR-3 (a 1:4 mixture of  $\alpha$ -linolenic and linoleic acid) affects spatial learning, thermoregulation, pain threshold and protection from seizures. The mode of action is unknown. One possible explanation is that the preparation induces changes in the fatty acids profile and in the cholesterol level in the neuronal membrane.

This study used 15 independent groups of rats (n=12) which were given either saline, mineral oil (vehicle) or SR-3 (25 mg/kg) for 0, 1, 2, 3 or 4 weeks. The learning capacity was measured in the Morris Water tank and the fatty acids profile and the cholesterol level were examined by the GC method in synaptosomes obtained from the frontal cortex of the rats.

SR-3 improved the learning capacity and induced major changes in the neuronal membrane composition, such as an increase in the total level of fatty acids, an increase in the level of essential fatty acids and a decrease in the cholesterol level. Those changes occurred after 3 weeks of treatment. The biochemical variables can predict the behavioral variables but not vice versa. The changes in the neuronal membrane may result in a modification of the membrane fluidity, which may, in turn, enhance cognitive and neuropharmacological effects.

Supported by Ginzburg Chair and The Farber Center.

## 61.9

EFFECTS OF MAGNESIUM ON LEARNING AND MEMORY: A CELLULAR AND BEHAVIORAL STUDY, H. Lu\*, G. Wang\* and F. Wu. Lab. of Neurobiology, Nanjing Univ. Nanjing 210093, China, Biology Department, Nanjing Normal Univ.\* Nanjing 210024, China

Many works have revealed that magnesium to be involved in long-term potentiation(LTP) in the hippocampus, a form of synaptic plasticity which is believed to be involved in learning and memory. However, there is little direct evidence showing the effects of magnesium on learning and memory. Using Y-maze discrimination task and one trial step-through passive avoidance task respectively, we found the discrimination learning capability and the retention of passive avoidance behavior of mice were significantly attenuated after the treatment of MgCl<sub>2</sub> for two weeks. The plasma and hippocampal magnesium levels increased as a result of magnesium exposure. In parallel with this, the post-synaptic density (PSD) in both of the hippocampal CA3 area and cerebral sensorimotor cortex became significantly thinner and the length of synaptic active zone in the cerebral sensorimotor cortex was obviously shortened. Furthermore, the hippocampal synaptosome of mice with long term magnesium treatment showed greatly reduced uptake of <sup>45</sup>Ca<sup>2+</sup>. These findings suggest that high levels of magnesium induced learning and memory disorders which are associated with the changes in PSD and the length of synaptic active zone and decreased calcium influx into the hippocampal nerve terminals. (Supported by Excellent Young Teacher Project of Jiangsu Provincial Education Committee, China)

## LEARNING AND MEMORY: PHARMACOLOGY II

## 62.1

NITRIC OXIDE SYNTHASE INHIBITION IMPAIRS DELAYED RECALL IN MONKEYS, SPATIAL LEARNING IN RATS, AND INDUCES CONDITIONED TASTE AVERSION. W.J. Jackson\*, M.A. Prendergast, A.V. Terry Jr., and J.J. Buccafusco. Medical College of Georgia, Alzheimer's Research Center, Dept. Physiol. Endo., Dept. Pharm. Tox., and Dept. Veterans Affairs Med. Ctr., Augusta, GA 30912.

The free radical gas nitric oxide is synthesized by NO synthase (NOS) in brain regions associated with learning and the formation of memory and appears to function as a neuromodulator of these processes. We examined the effects of peripheral administration of the NOS inhibitor L-Name on delayed recall in 7 mature macaques, and on spatial navigation learning in adult rats. In monkeys, doses of L-Name including 1, 5, 25, and 50 mg/kg each produced impairment of delayed matching-to-sample accuracy. The task impairment produced by the 25 mg/kg dose of L-Name was blocked by concomitant administration of an equi-mol dose of L-arginine. For the 50 mg/kg dose only, task impairment occurred concomitantly with significant gastrointestinal disturbance and lethargy. In rats, L-Name (5, 20, and 50 mg/kg) impaired acquisition of cued spatial learning in the Morris water maze, although even in the presence of L-Name, the animals eventually learned the task. To examine the aversive properties of L-Name administration in rats, a two-bottle conditioned taste aversion (CTA) trial was employed with water-deprived rats. The low dose of L-Name (5mg/kg) did not induce a CTA to the novel 20% sucrose solution employed. Both the 20 mg/kg and 50 mg/kg did, however, induce CTA following an initial pairing of the sucrose taste and drug administration. Consumption in both groups was decreased by 50-60% during repeated exposures to the solution. Both the spatial learning deficits and CTA were blocked by co-administration of L-arginine. These data indicate that L-Name produces deficits in the cognitive performance of both monkeys and rats that are associated with attenuated biosynthesis of NO. At higher doses (>20-25mg/kg), however, inhibition of task performance may occur along with drug-induced malaise, possibly related to peristaltic dysregulation of gastrointestinal musculature. Supported by the VA Medical Research Service

## 62.3

INHIBITION OF NEURONAL NITRIC OXIDE SYNTHASE IMPAIRS LEARNING OF RATS IN A 14-UNIT T-MAZE. R.C. Meyer\*, E.L. Spangler, N. Patel, and D.K. Ingram. Gerontology Research Center, NIH/NIA, Baltimore, MD 21224.

Nitric oxide (NO), a putative retrograde messenger of glutamatergic synaptic transmission, has been suggested to play a role in establishing LTP (Schuman & Madison, Science, 254:1503, 1991). We have shown previously that the NO synthase (NOS) inhibitor N<sup>G</sup>-nitro-L-arginine (NARG) produces dose-dependent learning impairment in rats in a 14-unit T-maze, and that this impairment is attenuated by sodium nitroprusside (SNP), a NO generator (Ingram, Ann. NYAS, 717:16, 1994). However, it is possible that hypertension produced by NARG contributed to the impaired performance. In two new experiments, we have investigated 7-nitro-indazole (7-NI), a NOS inhibitor that is selective for neuronal NOS (nNOS) and does not produce hypertension (Moore et al. Brit. J. Pharmacol. 108:296, 1993). In addition, we tested the NO donor molsidomine (MOL) which is much longer acting than SNP (Vertesi et al. J. Cardio. Pharmacol. 17:3, 1991). Subjects were 3-4 mo old male Fischer-344 rats. Rats were trained to avoid a shock in a straight runway, and 24 hr later received training in the 14-unit T-maze. Experiment 1: 30 min prior to maze training, rats were given i.p. injections of either 7-NI (25, 50, or 65 mg/kg) or saline. The 7-NI produced significant learning impairment in a dose-dependent manner. Experiment 2: 30 min prior to maze training, rats were given i.p. injections of either 7-NI (70 mg/kg), 7-NI (70 mg/kg) plus MOL (2 or 4 mg/kg), or saline. Both doses of MOL significantly attenuated the learning deficit induced by 7-NI. These results suggest an involvement of NO in memory formation, and would support the hypothesis that NO acts as a retrograde messenger to enable synaptic strengthening during learning.

## 62.2

INVOLVEMENT OF THE NITRIC OXIDE/CYCLIC GMP SYSTEM IN OBJECT RECOGNITION MEMORY OF THE RAT. I. Prickaerts, J. de Vente, W. Raaijmakers, and H. W. M. Steinbusch\*. European Graduate School for Neuroscience in Brain and Behavior, University of Maastricht, P.O. Box 616, 6200 MD Maastricht, The Netherlands

Recently, several studies have suggested a possible role for the nitric oxide (NO)/cGMP system in memory processes. Thus, NO is a retrograde messenger which increases cGMP levels by activating soluble guanylyl cyclase. The effects of 7-nitro indazol (7-NI), a NO synthase inhibitor, and zaprinast (ZAP), a cGMP-selective phosphodiesterase inhibitor, were evaluated on recognition memory of rats in the object recognition task. This task is based on the differential exploration between a new and a familiar object. Two doses of 7-NI (10 and 30 mg/kg) and ZAP (3 and 10 mg/kg) were used. The substances were administered i.p. immediately after the exposure to two identical objects, i.e., at the start of the retention interval. After a retention interval of 1 h, saline-treated rats spent more time exploring the new object which demonstrates that they recognized the familiar one. Both doses of 7-NI impaired the discrimination between the two objects after the 1 h interval. After a 4 h interval, saline-treated rats did not discriminate between the objects. The highest dose of ZAP facilitated object recognition after the 4 h interval. Further, this dose of ZAP (10 mg/kg) reversed the recognition deficit of 7-NI (10 mg/kg) at the 1 h interval. Interference with the NO/cGMP system can also induce cardiovascular effects which may influence memory performance. The highest dose of 7-NI slightly increased mean arterial blood pressure (MAP) 1 h after its administration. Four hours after administration of ZAP (10 mg/kg), MAP was also slightly increased, yet not 1 hour after ZAP administration. However, these effects on blood pressure seem not to be related to or explain the differential effects on object recognition memory. These results therefore indicate that the NO/cGMP system is involved in memory processes of object recognition independently of its cardiovascular role.

## 62.4

INTRA-SEPTAL INFUSIONS OF GLUCOSE DO NOT REVERSE BUT POTENTIATE INHIBITORY AVOIDANCE DEFICITS WHEN CO-INFUSED WITH THE GABA AGONIST MUSCIMOL. M.B. Parent\* & P.E. Gold. Dept. of Psychology, University of Virginia, Charlottesville, VA 22903.

Systemic infusions of glucose, as well as direct brain injections into the medial septum, hippocampus, and amygdala enhance retention and reverse memory deficits produced by aging, neural pathologies, and some drugs. However, in examining interactions between glucose and the GABA agonist muscimol, we noted that intra-septal infusions of a high dose of glucose did not reverse and instead appeared to potentiate the memory-impairing effects of intra-septal muscimol infusions. Because hyperglycemia increases GABA release in some brain regions (e.g., substantia nigra, Amorosio, et al., 1990), we hypothesized that glucose may potentiate the impairing effects of muscimol by increasing endogenous GABA release in the medial septum. We predicted that a dose of muscimol that has no effect on memory should impair when co-infused with a high dose of glucose. Different groups of rats were given an intra-septal infusion of vehicle, glucose (33 nmol), muscimol (3 nmol), or glucose co-infused with muscimol 15 min prior to one trial inhibitory avoidance training (1 mA, 1 sec). On a retention test 24 hr later, the retention performance of rats given infusions of muscimol or glucose alone was not impaired. However, infusions of muscimol with glucose produced a robust deficit. Although glucose typically reverses memory deficits, these results indicate that glucose potentiates the memory-impairing effects of a GABA agonist, perhaps by increasing endogenous GABA levels. Supported by NIA (AG07648, AG05658) & NINDS (NS32914).

## 62.5

EFFECT OF GLUCOSE ON MEMORY IN HUMANS: DOSE-DEPENDENT FACILITATIVE ACTION ON LONG-TERM MEMORY. C. Messier\*, A. Desrochers and M. Gravel. School of Psychology, University of Ottawa, (Ont) Canada K1N 6N5.

The memory-improving effect of glucose has been demonstrated in rodents and humans. In rodents, this facilitative effect has been observed for two doses: 100 mg/kg and 3 g/kg. In the present experiment, we examined the effect of water, saccharin and 7 doses of glucose (10, 100, 300, 500, 800, 1000, 2000 mg/kg) on the performance of young women. The memory task consisted in the immediate recall of 8 lists of 20 words presented on a computer screen at a rate of one word/2 sec. The lists were presented randomly and were equivalent for imagery index, subjective and objective frequency, word length and syllable count. Subjects arrived fasted in the morning and their baseline memory performance was tested using the first two lists. They then ingested the solution and were tested using the remaining 6 lists. The word recall rate was computed for the first 5 words of each list (primacy effect), the last 5 words (recency effect) and the remaining 10 words in the middle of each list. The results showed that for the 2 pre-treatment lists, subjects better recalled the first 5 words and the last 5 words compared to the remaining 10 words. In the water and saccharin groups, the primacy effect gradually disappeared from list 3 to 8. The ingestion of glucose (100, 1000 and 2000 mg/kg) prevented this disappearance while the other doses of glucose did not. The results show that the same 2 optimal doses are effective in humans and that glucose appears to modulate long-term memory processes. Supported by a Natural Sciences and Engineering Research Council grant to C.M. and by the U. of Ottawa.

## 62.7

GLUCOSE VS. AMPA RECEPTOR MODULATORS: COMPARISONS BETWEEN FACILITATORY EFFECTS ON MEMORY AND LTP INDUCTION IN THE FREELY MOVING RAT. U. Staubli\*, F. Xu & J. Scafield. Center for Neural Science, New York University, 4 Washington Place, New York, NY 10003.

Considerable evidence from this and other laboratories indicates that a class of allosteric AMPA receptor modulators (AMPAKines), which cross the blood-brain barrier and facilitate glutamatergic transmission and hippocampal LTP induction, are highly effective at promoting the encoding and retention of memory when given before learning. This behavioral facilitation is dose-dependent and observed across a broad range of paradigms, with the threshold for synaptic facilitation corresponding to that for memory enhancement. A different strategy for memory modulation is suggested by the work of others indicating that systemic glucose injections, given before or shortly after training, are capable of enhancing some forms of learning. The objective of the present experiment was to (1) replicate the glucose-mediated memory enhancement, using paradigms identical to those in which memory is routinely facilitated by AMPAkin treatment, and (2) determine possible interactions between effective glucose dosages and LTP induction in area CA1 *in vivo*. Well trained animals (n=22) were tested on multiple days with each of three concentrations of glucose (100, 200 and 300 mg/kg) or saline, given 30 min before or 30 sec after the sample phase in spatial and olfactory working memory paradigms. Glucose given post-sampling failed to promote retention in either task, whereas pre-sampling glucose did produce an effect, but only in the spatial task: animals injected 30 min pre-sampling at 200 mg/kg, but not 100 or 300 mg/kg, made significantly more correct choices in an 8-arm radial maze before entering any of the 5 arms already sampled 3 hours earlier; the total # of re-entry errors to task completion was however not reduced by glucose. Despite its facilitatory action on correct choices before 1st error, glucose at 200 mg/kg given 30 min before LTP induction in awake rats failed to produce more or longer-lasting potentiation than saline injections.

## 62.9

SEXUAL STEROIDES HORMONES EFFECTS ON ALTERATION OF MEMORY CAUSED BY OZONE IN RATS. S.Rivas-Arancibia\*, S. Schneider-Rivas, A. Lechuga-Guerrero, G. Borgonio-Pérez and A. Fuentes. Departamento de Fisiología. Facultad de Medicina. Universidad Nacional Autónoma de México.

A free radicals hypothesis for neurodegeneration implicates that the oxidative stress as a contributing factor to aging alterations and the neurodegenerative diseases. The exposure to ozone increased production of free radicals which causes oxidative stress. The effect of the ozone concentration 0.3 ppm for 4 hours, causes long-term memory deterioration when the animals were submitted to passive avoidance conditioning. This work analyses the role of the sexual hormones and their effect on the alteration of memory in animals exposed to ozone. They were individually housed with free access to food and water and divided in six groups and each group received one of the following treatment: 1) without treatment (control), 2) ozone exposure; 3) Testosterone enanthate (20 mg, i.m) five minutes before the ozone exposure, 4) Testosterone (20 mg, i.m) five minutes after the ozone exposure, 5) estradiol valerate (0.8 mg, i.m) five minutes before the ozone exposure, 6) estradiol valerate (0.8 mg, i.m) five minutes after the ozone exposure. All group were submitted on a one-trial passive avoidance conditioning. Long-term-memory results indicate that the control group is significantly different from group exposed to ozone and estradiol. The testosterone groups didn't show statistically significant difference with control group and the ozone group is significantly different from the estradiol group. This results suggest that long-term memory deterioration caused by ozone exposure can be blocked by the use of testosterone applied before or after exposure to ozone. The estradiol increase the alteration of long term-memory provoked by ozone exposure.

## 62.6

INTRA-HIPPOCAMPAL PERFUSIONS OF GLUCOSE ENHANCE SPONTANEOUS ALTERNATION SCORES AND HIPPOCAMPAL ACETYLCHOLINE RELEASE. S.N.Pal, M.E.Ragozzino, K.E.Unick, A.C.Durham, M.R.Stefani & P.E.Gold\*. Department of Psychology, University of Virginia, Charlottesville, VA 22903.

Recent evidence indicates that hippocampal acetylcholine (ACh) output increases while rats are tested in a spontaneous alternation task. Systemic injections of glucose improve alternation scores and augment the accompanying increase in ACh output. The present experiment determined whether direct administration of glucose into the hippocampus would improve alternation scores and would, at the same time, augment the increase in ACh release in the hippocampus assessed during behavioral testing. Guide cannulae for microdialysis probes were implanted unilaterally in the hippocampus. At the time of testing, a microdialysis probe was inserted and 10 dialysate samples (20 µl in 12 min) were collected for analysis for ACh content by HPLC-EC detection. The first five samples provided baseline measurements. For glucose treatment, the dialyzing solution was changed from aCSF to 6.6 mM glucose in aCSF for two samples, beginning 12 min prior to spontaneous alternation testing in a plus maze. In the absence of administration of extra glucose, ACh output increased during spontaneous alternation testing. Unilateral delivery of glucose into the hippocampus through the microdialysis probe improved spontaneous alternation scores and also augmented the extent of increase in ACh output seen during behavioral testing. As observed before, administration of glucose did not result in changes in ACh output in control (resting) rats. Some rats were prepared with bilateral probes to determine whether the rise in ACh output after glucose administration was bilateral or only ipsilateral to the site of infusion. Importantly, unilateral glucose administration did not affect behavior-induced ACh release in the contralateral hippocampus. These findings suggest that increases in extracellular glucose availability augment ACh release in a manner correlated with regulation of memory processing. Supported by NIA (AG07648) and NINDS (NS32914).

## 62.8

DEFICITS IN SPONTANEOUS ALTERNATION PERFORMANCE FOLLOWING INFUSION OF MORPHINE INTO THE MEDIAL SEPTUM ARE REVERSED BY INFUSION OF GLUCOSE INTO THE AMYGDALA. E. C. McNay\* & P. E. Gold. Dept. of Psychology and Neuroscience Graduate Program, University of Virginia, Charlottesville, VA 22903.

The amygdala and the septohippocampal system appear to mediate functionally distinct memory systems. Previous work in our laboratory has shown that morphine infusions into the medial septal cause deficits in both spatial and aversive learning while morphine infusions into the amygdala cause a deficit in aversive learning but have no effect on spatial learning. In these cases, deficits caused by morphine can be reversed by co-infusion of glucose into the same brain area. In this study, we investigated whether deficits caused by infusion of morphine into one brain area could be reversed by infusion of glucose into a separate area. Three guide cannulae, aimed at the medial septum and bilateral amygdala, were implanted in rats at least one week prior to behavioral testing. Thirty minutes prior to test on a Y-maze spontaneous alternation task, the rats received an infusion into the medial septum of either morphine (4.0 nmol) or aCSF and simultaneous infusion of glucose (18.3 nmol) or aCSF bilaterally into the amygdala. In comparison with both unoperated and control animals, rats receiving septal morphine were impaired. This impairment was fully reversed by infusions of glucose into the amygdala. These results suggest that glucose injections into the amygdala can modulate spatial, as well as aversive, learning, demonstrating functional interactions between memory systems.

Supported by NIA (AG07648) and NINDS (NS32914).

## 62.10

DHEAS ENHANCES SPATIAL MEMORY AND HIPPOCAMPAL PRIMED BURST POTENTIATION. D.M. Diamond<sup>1,2\*</sup>, B.J. Branch<sup>1</sup>, K. Coleman-Mesch<sup>1</sup>, M.H. Mesches<sup>1</sup> and M. Fleshner<sup>1</sup>. Dept. of Pharmacology<sup>1</sup>, Univ. Colorado. Health Sci. Ctr. and VAMC<sup>2</sup>, Denver, Dept. of Psychology<sup>3</sup>, Univ. Colorado., Boulder

Dehydroepiandrosterone sulfate (DHEAS) serves a protective role in a broad range of physiological systems. Work in the past decade has shown that the brain synthesizes DHEAS *de novo*, with high levels of the steroid taken up by the hippocampus (*J Steroid Biochem Mol Biol*, 37:395, 1990). We recently reported that DHEAS enhanced primed burst (PB) potentiation, a form of LTP (*Neurosci Lett*, 202:204, 1996). The focus of this study was to test the hypothesis that DHEAS would enhance hippocampal-dependent spatial memory.

Male adult rats were administered DHEAS in their drinking water (range 50-400 µg/ml) for 5 days prior to, and during, water maze training (4 trials/day). Subjects receiving lower doses (50 & 100 µg/ml), but not the higher doses (200 & 400 µg/ml), exhibited a significant enhancement of memory. We then recorded PB potentiation in two of the groups of animals which were run in the water maze (50 & 400 µg/ml). Both groups developed significantly greater PB potentiation than the control group. These findings indicate that DHEAS can enhance cognitive and electrophysiological measures of hippocampal function.

## 62.11

**EFFECTS OF DHEAS ON HIPPOCAMPAL ELECTROPHYSIOLOGY IN VITRO.** M.H. Mesches<sup>1\*</sup>, C.J. Frazier<sup>1,2</sup>, G.M. Rose<sup>1,2,3</sup> and D.M. Diamond<sup>1,3</sup>. Dept. of Pharmacology<sup>1</sup> and Neurosci. Training Program<sup>2</sup>, Univ. Colorado Health Sci. Ctr. and VAMC<sup>3</sup>, Denver, CO

Dehydroepiandrosterone sulfate (DHEAS) is the most abundant adrenal steroid produced by people, is synthesized *de novo* in the brain and can improve memory. We recently reported that DHEAS produced an inverted-U enhancement of hippocampal primed-burst (PB) potentiation, a form of LTP, *in vivo* (Neurosci. Lett., 202:204-9, 1996). Here, we have begun to investigate the mechanisms by which DHEAS affects hippocampal electrophysiology, plasticity and memory.

We have studied the effects of DHEAS on CA1 in hippocampal slices from male rats. Preliminary findings indicate that DHEAS reduces both feedforward and feedback inhibition to increase the excitability of CA1, which may be related to the antagonism of GABA<sub>A</sub> receptors by this neurosteroid (Prog. Neurobiol., 38:379, 1992). A 10 min application of DHEAS (10-100  $\mu$ M) significantly increased the amplitude of the CA1 population spike for at least 30 minutes. We will present work designed to characterize the possible relationship between this effect and the DHEAS-induced enhancement of hippocampal PB potentiation and spatial memory described in the adjacent poster.

## 62.13

**ENHANCEMENT OF SPONTANEOUS ALTERNATION SCORES IN THE RAT BY INTRA-SEPTAL INJECTION OF THE K-ATP CHANNEL BLOCKER GLIBENCLAMIDE.** M.R. Stefani\*, G.M. Nicholson and P.E. Gold. Neurosci. Grad. Program & Dept. of Psych., U. of Virginia, Charlottesville, VA 22903.

Peripheral and central administration of D-glucose enhance memory on a variety of tasks and attenuate the memory-impairing effects of the opioid agonist morphine. The mechanism(s) by which glucose enhances memory is not known. One possible mechanism is via modulation of the ATP-sensitive potassium channel (K-ATP), a channel believed to contribute to the presynaptic regulation of neurotransmitter release by glucose and opiates. The present studies examined the ability of glibenclamide (GLIB), a K-ATP blocker, to increase spontaneous alternation (SA) scores and to attenuate a morphine-induced impairment in alternation scores. Morphine (4 nmol), injected into the rat medial septal area (MSA) 30 min prior to behavioral testing, produced a significant decrease in alternation scores assessed in a Y maze. Glibenclamide (10 nmol), administered concurrently with morphine, blocked the morphine-induced impairment. In a second experiment, rats were tested for SA performance in a plus maze following infusion of GLIB or glucose into the MSA. Both GLIB (10 nmol) and glucose (20 nmol) significantly enhanced SA scores. The results of these studies suggest that the K-ATP blocker glibenclamide is capable of producing effects on spontaneous alternation scores similar to those observed for glucose, including reversal of a morphine-induced decrease in SA scores on the Y maze and increase in SA scores on the plus maze, and suggest a mechanism by which glucose may modulate behavior. Supported by NIA (AG07648), NINDS (NS32914) and NIMH (MH11057).

## 62.15

**H<sub>3</sub> RECEPTOR LIGANDS MODULATE MEMORY PROCESSES IN MICE.** W.A. Stutts, E.L. Orr, H. Lai\*, and M.J. Forster. Dept. of Pharmacology, Dept. of Anatomy and Cell Biology, University of North Texas Health Science Center, Fort Worth, TX 76107

Previous investigations suggest that histamine (HA) is involved in modulation of memory of rats and mice for avoidance tasks. The current study examined this hypothesis by testing mice for memory: (1) following H<sub>3</sub> receptor ligands thought to modulate HA release presynaptically, or (2) following agents inhibiting HA biosynthesis or degradation. It was expected that an increase in neuronal HA would result in facilitation of memory processing whereas a decrease in HA release would disrupt memory processing. Each drug's dose effect on memory consolidation and memory retrieval was evaluated using one trial inhibitory (passive) avoidance training. A dose dependent facilitation of memory consolidation was obtained with the H<sub>3</sub> antagonist thioperamide whereas imetit, an H<sub>3</sub> agonist, produced a dose dependent disruption. On the other hand, the specific enzyme inhibiting compounds alpha-fluoromethylhistidine, a neuronal HA depleter and metoprine, a histamine-methyl transferase inhibitor showed no effect. This lack of effect of the enzyme inhibitors on memory processing suggests that an intact physiological signaling system via the H<sub>3</sub> autoreceptor is necessary for effective modulation of HA at levels appropriate for memory modulation.

## 62.12

**PREVENTION BY APAMIN AND CHARYBDOTOXIN OF AMNESIA INDUCED BY K<sup>+</sup>-CHANNEL OPENERS IN MICE.** A. Bartolini, C. Ghelardini, N. Galeotti, A. Quattrone and S. Capaccioli. Depts of Pharmacology and Pathology, I-50134 Florence, Italy, SPON: Eur. Neurosci. Association\*

Etcheberrigaray et al. (1993) reported that 113-pS tetraethylammonium (TEA)-sensitive K<sup>+</sup>-channel was functionally absent in fibroblasts from Alzheimer disease (AD) patients and in human fibroblasts treated with  $\beta$ -amyloid, the main constituent of neurite plaques in AD (Etcheberrigaray et al., 1994). More recently, Bartolini et al. (1995) observed that mice treated with the K<sup>+</sup>-channel openers, pinacidil (2.5-25  $\mu$ g per mouse i.c.v.) and minoxidil (10  $\mu$ g per mouse i.c.v.), injected immediately after the training session caused a reduction of memory retention of 31-66% and 68% respectively. K<sup>+</sup>-channel regulation appears, therefore, to be one of the critical steps in memory storage. The aim of the present study was to investigate the effects of two K<sup>+</sup>-channel blockers, apamin and charybdotoxin, on amnesia induced by K<sup>+</sup>-channel openers. The experimental procedure consisted of a mouse passive avoidance test in which a painless punishment (fall into cold water, 10°C) was used. In these experimental conditions, apamin and charybdotoxin, at the respective doses of 1 ng and 1  $\mu$ g per mouse i.c.v. administered 20 min before the test, completely prevented minoxidil and pinacidil induced amnesia without improving cognition in unamnesic mice. Doses of the two K<sup>+</sup>-channel blockers 10-time lower were not able to protect mice against minoxidil and pinacidil amnesia whereas doses 10 times higher produced convulsions and death. Apamin and charybdotoxin, at the dose active in the passive-avoidance test, did not modify the pain threshold, as revealed by the hot-plate and 0.6 % acetic acid writhing tests, and were devoid of behavioural side effects as shown by the animex and rota-rod tests. These data show that apamin and charybdotoxin are endowed with anti-amnesic properties in this animal model.

**REINFORCING PROPERTIES OF CHLORPHENIRAMINE IN GOLDFISH** R. Mattioli, C. A. Nelson, J.P. Huston\* and Spieler, R. Oceanographic Ctr, Nova Southeastern Univ., Dania, FL 33004, USA.

Many H<sub>1</sub> histamine receptor blockers, including chlorpheniramine (CPA), have been used to treat allergic reactions in humans. Recently, however, it was suggested that CPA can have a reinforcing effect in baboons. Moreover, evidence exists that the histaminergic tuberomammillary system plays an important role in reinforcing processes in rats. In teleost fish, histaminergic neuronal cell bodies occur only in the posterior part of the basal hypothalamus and it was suggested that these neurons are homologous to the tuberomammillary E groups in rats. The aim of the present study was to investigate whether CPA has a reinforcing effect in goldfish. For this purpose we used a conditioned place preference method that consisted of 1) establishing the less preferred of two compartments for each fish in a 10 min test; 2) confining each fish, 24 h later, in the less preferred compartment for 25 min, after it was injected i.p. either with CPA (1mg/kg, n=15) or with vehicle (V, n=14) and 3) reexamining behavioral preference, 24 h after injection and confinement.

In the first 10 min test, no differences between vehicle and CPA groups were obtained for either compartment. In the second test, the CPA group increased the time spent in the compartment in which they received the substance. They changed the compartment preference and spend more time in the previously less preferred compartment than did the V group (p=0.037, V X CPA, Mann-Whitney U test).

These results indicate that CPA has a reinforcing effect in goldfish. Considering that the only known histaminergic system in teleost fish is in the basal hypothalamus, and that this system appears to be homologous to the tuberomammillary system of mammals, we suggest that the tuberomammillary histaminergic system may be mediating the reinforcing effect of H<sub>1</sub> receptor blockers in other vertebrates as well.

**THE ROLE OF THE HISTAMINERGIC NEURON SYSTEM IN REWARD AND MEMORY PROCESSES.** J.P. Huston, Ch. Frisch, C. Privou, P.K. Zimmermann and R.U. Hasenöhrl. Inst. Physiol. Psychology, Univ. Düsseldorf, D-40225 Düsseldorf, Germany. (Spon: EBBS)

Experiments performed with lesions of the histamine (HA) neurons of the nucleus tuberomammillaris (TM) provided evidence for an involvement of this nucleus in reinforcement and memory. Uni- or bilateral DC- and excitotoxic lesions resulted in a lateralized increase in self-stimulation behavior and in a facilitation of mnemonic processes in adult and aged rats in diverse learning tasks. To investigate whether the observed effects are HA-mediated we performed a series of studies with systemic and intracranial injection of specific HA antagonists. First, we blocked HA transmission at H1 or H2 receptor sites with chlorpheniramine or ranitidine in brain structures known to be involved in reward and memory and assessed the effects with either an inhibitory avoidance task (up-hill test), a place-preference paradigm or intracranial self-stimulation. The intracranial injection of the H1 antagonist chlorpheniramine into the nucleus basalis mangelocellularis induced a conditioned place preference and facilitated inhibitory avoidance learning when administered post-trial. The H2 receptor antagonist ranitidine was not reinforcing in the place preference test. In a intracranial self-stimulation study the H1 receptor blockade in the nucleus pedunculo pontinus decreased lateral hypothalamic self-stimulation, whereas an enhancement in self-stimulation behavior followed the H1 receptor blockade in the nucleus accumbens. The chronic intraperitoneal administration of chlorpheniramine improved the performance of aged rats in the Morris water maze and in the step-through avoidance task. Supported by DFG.

## COGNITION ENHANCING EFFECTS OF S 17092, A POTENT AND LONG ACTING INHIBITOR OF POST-PROLINE CLEAVING ENZYME (PPCE)

J. Lepagnol, C. Lebrun, P. Morain\*, G. de Nanteuil, V. Heidet. Institut de Recherches Servier, 125 Chemin de Ronde, 78290 Croissy sur Seine, France.

S 17092 (1-[phenylcyclopropyl carbonyl]-2-[thiazolidinyl carbonyl]-octahydro-1-H-indole) is a selective inhibitor of PPCE, the main enzyme responsible for the catabolism of some peptides involved in cognitive function (substance P, vasopressin). S 17092 is a potent inhibitor of PPCE in the rat cerebral cortex *in vitro* (IC<sub>50</sub> = 1.3  $\mu$ M) and *in vivo* (ID<sub>50</sub> = 0.5 mg/kg i.p. and 10 mg/kg p.o.). The *in vivo* effect is of long duration (> 9 hours) and results from a high penetration of the compound in the brain. The inhibitory effects are similar after acute and chronic (2 weeks) treatments. *Via* reduced degradation of substance P, S 17092 inhibits the scopolamine-induced amnesia in the passive avoidance test in the rat (ED<sub>50</sub> = 0.3 mg/kg i.p. and 1 mg/kg p.o.). In the test of social memory in the rat (olfactive episodic memory), S 17092 (10 mg/kg p.o.) prevents the time-dependent spontaneous forgetting and this effect is similar to that of vasopressin. On the contrary, SP is devoid of any effect. Chronic treatment with S 17092 (10 mg/kg p.o., 2 weeks) antagonises the age-associated memory deficits in the test of spontaneous alternation in the mouse.

In view of these results, S 17092 seems to be a good candidate for treatment of cognitive deficit associated with cerebral aging and with neurodegenerative diseases in which deficits in SP and AVP levels have been described.

## LEARNING AND MEMORY: PHARMACOLOGY III

## 63.1

N-METHYL-D-ASPARTATE (NMDA) RECEPTOR BLOCKADE DIFFERENTIALLY MODULATES FETAL AND NEONATAL CONDITIONED TASTE AVERSIONS (CTA): BRAIN KETAMINE CONTENT. G.A. Mickley<sup>1</sup>, S.A. Balogh<sup>1</sup>, K. Neimanis<sup>1</sup>, P. Goullis<sup>1</sup>, J. Hug<sup>1</sup>, K. Sauchak<sup>1</sup> and B.K. Yamamoto<sup>2</sup>. <sup>1</sup>Departments of Psychology and Chemistry, Baldwin-Wallace College, Berea, OH 44017-2088. <sup>2</sup>Department of Psychiatry, Case Western Reserve University, Cleveland, OH 44016.

NMDA receptor blockade can either potentiate the formation of a CTA (in E18 rat fetuses) or impair CTA learning (in P0 rat pups) (Mickley et al. *Dev. Brain Res.* 85, 119-127, 1995; Mickley et al. *Soc Neurosci. Abstr.* 21/2, 1233, 1995). In these studies, ketamine was administered in different doses and routes of administration. Therefore, we attempted to see if brain levels of ketamine could offer a parsimonious explanation for the disparate results of the two experiments. We injected dams bearing E18 fetuses with 100 mg/kg ketamine, i.p. (the dose that produced CTA potentiation). Neonatal (P0) rats received 0.1, 1.0 or 10mg/kg doses of ketamine, i.p. (doses that produced CTA amnesia). Thirty minutes later, rats were decapitated and the cerebral hemispheres quickly dissected. Brains were analyzed for ketamine content using high pressure liquid chromatography (HPLC). Fetal brain tissue contained high levels of ketamine (14.4 $\pm$ 1.6 $\mu$ g/g) while significantly lower levels (<6 $\mu$ g/g) were detected in the neonatal brain. These data contrast with those from adult rats studies (Welzl et al., *Psychobiol.* 18, 43-47, 1990) suggesting that high doses of ketamine (e.g., 25mg/kg, i.p.) cause CTA amnesia while low doses (e.g., 6-12 mg/kg, i.p.) do not. NMDA receptor blockade may differentially modulate learning in the adult and developing rat.

## 63.2

## GABAERGIC AND CHOLINERGIC INTERACTIONS IN THE STRIATUM ON INHIBITORY AVOIDANCE. S. E. Cruz-Morales\* and R. A. Prado-Alcalá. Master in Psychology, ENEP-Iztacala and Fac. Med., UNAM. Tlalnepantla, Edo. Mex. 54030, México.

The systemic administration of cholinergic blocker scopolamine induces amnesia, which can be reversed by systemic injection of GABA antagonists. To evaluate whether similar effects can be obtained in the dorsal striatum, rats were trained in inhibitory avoidance with 1.0 mA and then injected into the striatum with scopolamine (30.0  $\mu$ g), picrotoxin (1.0  $\mu$ g), bicuculline (1.0  $\mu$ g), or the combination of scopolamine and picrotoxin (SCP+PX) or bicuculline (SCP+BI). Retention of the task was measured 24 hr later. The administration of SCP, PX and BI induced amnesia; and contrary to the effects of systemic treatment, SCP+PX and SCP+BI also produced amnesia. These results indicate that GABA antagonists exert their protective effects against SCP-induced amnesia in a cerebral region outside the dorsal striatum.

## 63.3

## ENHANCEMENT OF INTERMEDIATE-TERM MEMORY BY AN ALPHA-1 AGONIST (ST 587) AND A PARTIAL AGONIST AT THE GLYCINE SITE OF NMDA RECEPTOR (D-CYCLOSERINE) R. Pussinen and J. Sirviö\*, A.I. Virtanen Institute, University of Kuopio, P.O. Box 1627, FIN-70211 Kuopio, Finland

In order to study the role of norepinephrine in memory, the present study investigated whether the activation of alpha-1 adrenergic receptors and NMDA receptors can influence intermediate-term memory. Therefore, the effects of ST 587 (30 or 100  $\mu$ g/kg, s.c.), a putative alpha-1 agonist, and D-cycloserine (DCS, 1 or 10 mg/kg, s.c.), a partial agonist of the glycine site at the N-methyl-D-aspartate (NMDA) receptor on the retention of the radial arm task using the delayed non-matching to sample (baited arm) task was investigated in rats. The results indicated that ST 587 (100  $\mu$ g/kg) or DCS (10 mg/kg) when administered singly 45 minutes before a sampling phase increased the number of correct choices during a retention phase (4 hours after a sampling phase) (Figure). In addition, the combination of the subthreshold doses of the drugs (50  $\mu$ g/kg ST 587 + 5 mg/kg DCS) had a same kind of influence on the retention of this task (8 hours after a sampling phase). These data suggest that the activation of alpha-1 adrenoceptors and NMDA receptors both of which are known to be involved in the regulation of intracellular calcium levels facilitates synergistically hippocampus-dependent type of memory. This study was supported by the Academy of Finland.

## 63.4

## REVERSAL OF LEARNING IMPAIRMENT IN DBA/2 MICE BY COGNITIVE ENHANCERS AND GLUTAMATERGIC AGENTS. Ying Lu\* and Jeanne M. Wehner, Institute for Behavioral Genetics, University of Colorado, Boulder, CO 80309

Previous studies demonstrated that DBA/2J mice perform poorly on a contextual fear-conditioning task. The present study demonstrates that acute treatment with oxiracetam (10-1000 mg/kg) or aniracetam (10-100 mg/kg), administered prior to training and test sessions, reversed the contextual learning impairment in a dose-dependent manner without affecting auditory cue conditioning. These effects were inhibited by the AMPA receptor antagonists, NBQX and GYKI-52466, which did not alter the contextual and auditory freezing when administered alone. Performance in contextual but not auditory conditioning was also enhanced by the NMDA antagonists, (+)-MK-801 (0.1-0.3  $\mu$ g/kg), CPP (0.01-0.3 mg/kg), and (+)-HA-966 (0.1-3 mg/kg). The inactive stereoisomers, (-)-MK-801 and (-)-HA-966, were without effect. The combined administration of 30 mg/kg oxiracetam with 1  $\mu$ g/kg (+)-MK-801 produced an additive response. These results suggest that DBA/2 mice may be learning impaired due to altered function of both AMPA and NMDA receptors. (MH-48663 and AA-00141)

## 63.5

EFFECTS OF THE NMDA RECEPTOR ANTAGONIST MEMANTINE ON LEARNING AND MEMORY IN HUMANS. M.M. Schugens\*, R. Egerter, I. Daum, P.A. Löschmann and T. Klockgether. Institute of Medical Psychology and Behavioral Neurobiology and Department of Neurology, University of Tübingen, Germany

The effects of NMDA receptor antagonists on learning and memory have been widely examined in animals. The present study aimed to investigate the influence of the noncompetitive NMDA receptor antagonist Memantine on human learning and memory.

Sixteen healthy volunteers participated in a double-blind placebo controlled study. Subjects were randomly assigned to receive either 30 mg Memantine or placebo p.o. Four hours after drug intake a battery of neuropsychological tests was administered.

The two groups did not differ significantly on affect-arousal ratings or in performance on attention, fluency, or short-term memory tests. Apart from a slight impairment in immediate word list recall, the Memantine group did not show consistent memory deficits. Subjects receiving Memantine did, however, display a significant retardation in the acquisition of eyeblink conditioning and fewer CRs in total compared to the Placebo group. These effects may be related to the action of Memantine in the cerebellum.

Supported by the German Research Society (DFG, Da 259/4-1).

## 63.7

IMPAIRMENT OF ASSOCIATIVE PROCESSES BY EITHER AN NMDA AGONIST OR AN NMDA ANTAGONIST. H. Dai\*, J. Gui and R. J. Carey. Psychiatry, SUNY Health Science Center and Research and Development Service 151, VA Medical Center, Syracuse, NY 13210.

Habituation is a basic learning process. In rodents, habituation is reliably observed as a reduction in exploratory behavior in novel environment following a brief pre-exposure to the environment. In as much as NMDA receptors are known to be critically involved in learning processes, we examined the impact of pharmacological alteration of the NMDA receptors upon the habituation process. In a series of experiments, groups of rats were given pretreatments of either the NMDA antagonist dizocilpine (MK-801) or the NMDA agonist cycloserine before their first exposure to a novel environment. The animals were given a 10 min exposure to a novel open-field environment and subsequently re-tested in the same environment 1 or 3 days later to test for habituation. The animals which received the 10 min familiarization test reliably exhibited a decrease in exploratory locomotion on the second test as compared with their first test or with rats which were tested in the environment for the first time. Neither MK-801 (0.1 mg/kg) nor cycloserine (3.0 mg/kg) treated rats differed from saline treated animals in locomotor behavior in the familiarization test. In the test for habituation in which all animals were treated with saline, rats previously treated either with MK-801 or cycloserine failed to exhibit habituation. Thus, either antagonism or activation of the NMDA receptors effectively blocked habituation at dose levels which did not modify spontaneous exploratory behavior. This blockade of habituation was not a state dependency phenomenon in that MK-801 either given after the familiarization test or given before the habituation test to saline animals did not impair habituation. These findings argue against the conceptualization in drug development that if antagonism of a receptor impairs association then pharmacological activation of the same receptor can enhance learning. In the case of the NMDA receptor, it would appear that any pharmacological occupancy of the NMDA receptor may diminish the availability of the receptor to participate in association processes.

## 63.9

ATTENUATED MK801-INDUCED IMPAIRMENT OF RADIAL MAZE PERFORMANCE IN RATS: A POSSIBLE MODEL PREDICTING EFFICACY IN ALZHEIMER'S DISEASE. A. Bartolomeo, H. Morris, J. Moyer and C.A. Boast\*. Wyeth-Ayerst Research, Princeton, NJ 08543.

Glutamate has been implicated in learning and memory processes. In particular, blockade of NMDA receptors impairs memory in a variety of animal studies. The non-competitive NMDA antagonist, MK801, has been used for this purpose. Decreases in glutamate functioning have been reported in Alzheimer's Disease (AD) patients. Suggestions have been made that agents which can increase glutamate release, or balance the loss of excitatory input by reducing inhibitory input in key brain regions, may have utility in treating AD. Specifically, modulators of serotonin have been proposed as potential AD therapies, based on their ability to affect glutamate neurotransmission. We have studied a number of agents in rats (ritanserin, ondansetron, buspirone, WAY-100635, WAY-100802, arecoline) for their potential to attenuate a radial maze memory impairment caused by MK801 (0.1 mg/kg ip). Of these agents, the 5HT-1A antagonists, WAY-100635 and WAY-100802, significantly decreased the MK801 impairment. The 5HT-2 antagonist, ritanserin, the 5HT-3 antagonist, ondansetron, and the muscarinic agonist, arecoline, attenuated the MK801 impairment. The majority of animals treated with the 5HT-1A partial agonist, buspirone, in combination with MK801, were unable to complete the task. Since it has been demonstrated that 5HT-1A antagonists can increase glutamate release and also that they can block the inhibitory effects of serotonin in the hippocampus, we speculate that these mechanisms contribute to the beneficial effects observed in this model. The attenuation of the MK801-induced radial maze impairment may be a suitable model to evaluate potential drugs for the treatment of AD.

## 63.6

DISTAL CUES, BUT NOT THEIR SPATIAL ORGANIZATION OR ROOM GEOMETRY, ARE CRUCIAL FOR WORKING MEMORY PERFORMANCE IN THE RADIAL MAZE. M.L. Shapiro\*, G. Tirado-Santiago, N.Y. Zayas-Monce, L. Zozula. Dept. Psychology, McGill Univ., Montreal, Quebec, Canada.

Spatial learning but not working memory (WM) performance in the radial maze is impaired in rats given NMDA receptor antagonists at doses that also block primed-burst potentiation. The impairment is not due to procedural learning deficits, because pre-trained rats given NMDA antagonists perform the WM task normally in a familiar room but fail to learn the same task in an unfamiliar room. Because the same procedures and movements are required to solve the task in both rooms, learning about the stimuli in the new room must be impaired by the drug.

To identify the stimuli that are required for good WM performance in well-trained rats, an 8-arm radial maze was surrounded by black curtains that could be altered to change the shape of the room from square to circular. Rats were trained to perform the standard WM task while the curtains defined a square room, with each "wall" holding a prominent distal cue. After reaching criterion performance, the rats were given extensive additional training in this stable cue configuration and then were given probe tests with: (1) the same cues in a new configuration; (2) the same cue configuration in a circular room shape; (3) both a new room shape and a new cue configuration; (4) with the distal cues removed; (5) with an entirely new cue set in the room; and (6) in an unfamiliar room. For each probe test, the rats were brought to the testing room in an opaque container via a novel route. The probe tests were designed to resemble those that influence hippocampal place fields.

Altering the stimulus configuration, the room shape, or both slightly increased the time the rats needed to complete the task, but had no effect on WM performance. Removing or replacing the cues with new stimuli impaired WM performance slightly, whereas WM performance in the new room was profoundly impaired. The results suggest that: (1) good WM performance in the radial maze requires rats to encode the content of the environment, perhaps including its geometry, and (2) after this content is encoded, the spatial relationships among stimuli is not crucial for WM. ## 63.8

EFFECTS OF NEONATAL MK-801 TREATMENT ON NON-SPATIAL LEARNING.

G. Griesbach\* & A. Amsel. Dept. of Psychology & Inst. for Neuroscience, University of Texas, Austin, TX 78712.

Neural changes in the hippocampus, that result from NMDA receptor/channel intervention, are known to have a deleterious influence on learned behavior. Neonatal MK-801 treatment, over a critical period of development in laboratory rats, has been shown to cause a long-lasting learning impairment, particularly on the Morris Water Maze, the prototypical spatial learning apparatus. The present experiment studied the effects of neonatal treatment with MK-801, a non-competitive NMDA antagonist, on patterned single alternation (PSA), a form of non-spatial learning that has been related in several of our experiments to hippocampal function. In PSA, rewarded (R) and unrewarded (N) trials are alternated on a straight-runway apparatus, and learning depends on a discrimination based on carryover memorial cues from the preceding R and N trials. Neonatal rats were injected daily from postnatal days (PND) 7 through 19 with MK-801 and trained on PSA at PND 22. Training consisted of 10 sessions of 40 trials each, 3 sessions per day for 3 days and one session on the 4th day. The intertrial interval was 60s. Rats injected with MK-801 were significantly impaired in PSA when compared to rats injected with the saline vehicle. Because PSA is impaired in the MK-801-treated rats, the implication from this experiment, as in many others in our laboratory, is that NMDA receptor blockade during hippocampal development has deleterious consequences not only on spatial learning, but also on learning that is clearly non-spatial in nature. See, e.g., Amsel, 1993, *Hippocampus*, 3, 251-256. Supported by NIAAA grant AA07052.

## 63.10

EFFECTS OF MK-801 ON SPATIAL MEMORY IN HOMING AND NONHOMING PIGEON BREEDS. E. F. Meehan and A. Wieraszko\*. The College of Staten Island/CUNY, Staten Island, NY 10314.

Homing pigeon breeds, the product of artificial selection on the basis of navigational and spatial ability, differ from nonhoming breeds in hippocampal size and distribution of NMDA dependent receptors. The effects of dizocilpine maleate (MK-801, 0.1 mg/kg ip), a noncompetitive NMDA antagonist, on spatial reference memory (RM) were compared between the 2 breeds in a radial arm maze task. MK-801 disrupted the acquisition of RM in the nonhoming group, but not the homing group, which was equivalent to the 2 saline only control groups. In agreement with previous findings with mammals, working memory (WM) was not affected by MK-801. This behavioral dissociation, coupled with differences in NMDA dependent long-term potentiation (LTP) between breeds, suggests an exceptional opportunity to investigate the role and function of the dorsomedial telencephalon region in spatial RM, via anatomical, neurochemical, and behavioral comparisons between homing and nonhoming pigeon breeds.

## 63.11

## ROLE OF NUCLEUS ACCUMBENS IN MK-801 INDUCED IMPAIRMENT OF REACTIVITY TO SPATIAL AND NON SPATIAL CHANGE IN MICE.

A. Usiello, P. Rouillet, M. Ammassari-Teule, E. Passino and A. Mele<sup>\*</sup>. Dip. Genetica e Biologia Molecolare, Università di Roma "La Sapienza" and Ist. di Psicobiologia e Psicofarmacologia, C.N.R., Rome, Italy.

Nucleus accumbens is part of a larger limbic-striato-pallidal system mediating adaptive and learning strategies. Dopaminergic pathways from the ventral tegmental area and glutamatergic inputs from limbic structures like the amygdala and the hippocampus are the major afferents to this nucleus. We have recently shown, in mice, that systemic injections of MK-801, a specific non competitive antagonist of glutamatergic NMDA receptors, induced performance deficits in a non associative task specifically designed to test the encoding of spatial information. Basically, this task consists in placing the subjects in an open field containing five objects and examining their reactivity to the displacement (spatial change) or the substitution (non spatial change) of some of these objects. Purpose of the present study was to assess the role of the nucleus accumbens in mediating the MK-801 impairing effects on the response to spatial change. Two experiments were carried out. First, systemic injections of MK-801 were performed in mice with ibotenic lesions of the nucleus accumbens. Second, MK-801 was injected bilaterally into the nucleus accumbens. The results showed that ibotenic lesions of the nucleus accumbens, by itself, paradoxically improved the reactivity of mice to spatial change but did not block the impairing effect of systemic MK-801 injections. Intra-accumbens injections of MK-801, however, abolished the reactivity to spatial change in a dose-dependent fashion. No treatment nor the lesion affected the reactivity to non spatial change. Taken together these results suggest that the nucleus accumbens is involved in the response to spatial change but does not represent the only target site mediating the impairing effect of MK-801 systemic injections.

## 63.13

THE NON-COMPETITIVE NMDA RECEPTOR ANTAGONIST MK-801 POTENTIATES MORPHINE-INDUCED IMPAIRMENT OF MEMORY CONSOLIDATION IN MICE: INVOLVEMENT OF DOPAMINERGIC MECHANISMS. Y. Cestari<sup>\*</sup>, C. Rossi-Arnaud<sup>1</sup>, C. Castellano. Istituto di Psicobiologia e Psicofarmacologia (C.N.R.) Via Reno 1, 00198 Roma, Italy - <sup>1</sup>Facoltà di Psicologia, Università degli Studi di Roma "La Sapienza", Via dei Marsi 78, 00185 Roma, Italy.

Four sets of experiments were carried out with CD1 mice. The animals were posttraining injected intraperitoneally with the drugs used and tested in a one-trial inhibitory avoidance task. In a first series of experiments posttraining administration of morphine or of the non-competitive NMDA receptor antagonist MK-801 impaired memory consolidation. In the second set of experiments the memory consolidation impairment exerted by MK-801 was potentiated by the administration of the D1 dopamine (DA) receptor antagonist SCH 23390 or by that of the D2 DA receptor antagonist (-)-sulpiride. In the third set of experiments the administration of a per se non effective dose of MK-801 potentiated the memory impairment exerted by morphine. In the fourth series of experiments per se non effective doses of the D1 DA receptor agonist SKF 38393 or of the D2 DA receptor agonist LY 171555 antagonized the impairing effect on memory consolidation exerted by a combination of MK-801 and morphine, suggesting the involvement of dopaminergic mechanisms.

## 63.15

## MICROINJECTION OF GABA-A RECEPTOR AGONIST MUSCIMOL REVEALS FUNCTIONAL SPECIALIZATION WITHIN THE HIPPOCAMPUS OF RATS

J.B. Mao<sup>\*</sup> and J.K. Robinson. Dept. of Psychology, S.U.N.Y. at Stony Brook, Stony Brook, NY, 11794-2500.

Evidence from lesion studies has suggested that the dorsal extent of hippocampus may be especially critical to hippocampal involvement in spatial learning and memory, sensory-attentional processing, or both. This functional specialization is also predicted by distinct patterns of cortico-hippocampal connectivity. Inhibitory GABAergic interneurons are widespread throughout the hippocampus, and are likely to participate in hippocampal information processing. To evaluate the hypothesis that a functional specialization exists within the hippocampus, the present study compared the effects of muscimol microinjected into either dorsal (DH) or ventral (VH) regions of hippocampus on performance of an operant, spatial delayed nonmatching-to-position (DNMTP) task that simultaneously assessed visual stimulus detection and working memory parameters. Rats were extensively pretrained on DNMTP, then cannulated. Following retraining, muscimol (.003-0.2 µg/0.3 µL into DH; 0.2-1.0 µg/0.5 µL into VH) was administered. In VH, no reliable effects on nonmatching choice accuracy, stimulus detection, or procedural parameters were detected at any dose of muscimol. In contrast, a significant dose-dependent increase in errors of omission to sample-phase visual stimuli was observed following muscimol injection into DH. The smallest concentration of muscimol that was effective in DH was two hundred times weaker than the maximum administered into VH, suggesting a pronounced dissociation of sensitivity to GABA-receptor agonism between these two regions. These results indicate that the contribution of the hippocampus to sensory-attentional processing may vary along the septo-temporal axis. Supported by NIMH grant 1RO3MH5290-01

## 63.12

## MK-801 ATTENUATES THE MEMORY ENHANCING EFFECT OF INTRA-DORSAL STRIATAL INFUSIONS OF PLATELET-ACTIVATING FACTOR.

L.A. Teather<sup>1,2\*</sup>, M.G. Packard<sup>1</sup> & N.G. Bazan<sup>2</sup>. Department of Psychology, University of New Orleans and <sup>2</sup>LSUMC Neuroscience Center of Excellence, New Orleans, Louisiana

Recent evidence indicates that post-training injections of the bioactive lipid platelet-activating factor (PAF) enhances, and the PAF antagonist BN 52021 impairs, memory processes in the rodent hippocampus, entorhinal cortex, amygdala, and dorsal striatum (i.e. caudate-putamen). The mechanism by which PAF enhances memory is unknown. PAF increases glutamate release from presynaptic hippocampal terminals *in vitro*, and it has been proposed that PAF acts as a retrograde messenger in hippocampal long-term potentiation. The dorsal striatum receives sensory information via glutamatergic input from the cortex and thalamus, and the cortico-striatal pathway has been shown to exhibit various forms of use-dependent synaptic plasticity. In the present experiment we examined possible interactions between PAF and the glutamate NMDA receptor using the non-competitive receptor antagonist MK-801. Rats received an 8-trial training session in a striatal-dependent cued water maze task, in which a visible escape platform was located in a different quadrant of the maze on each trial. Following trial 8, rats were given an intra-dorsal striatal injection of a PAF agonist (mc-PAF; 1.0 µg/0.5 µl) or saline, in addition to a peripheral (IP) injection of MK-801 (0.025 mg/kg) or saline. Retention was tested 24 hours later, and latency to mount the escape platform was used as a measure of memory for the previous day's training. Rats given intra-striatal PAF had lower escape latencies on the retention test, indicating a memory enhancing effect of PAF. Concurrent IP injections of MK-801 blocked the memory enhancing effect of intra-striatal mc-PAF. Importantly, the 0.025 mg/kg dose of MK-801 did not affect retention when administered alone. The finding that a subeffective dose of MK-801 blocks the memory enhancing effect of dorsal striatal PAF infusions suggests that an interaction between PAF and glutamatergic systems may mediate the formation of striatal basal-memory processes. NS23002 (NGB)

## 63.14

THE INITIAL PHASE OF LEARNING OF CLASSICAL FEAR CONDITIONING IN GOLDFISH IS SELECTIVELY INHIBITED BY THE NMDA RECEPTOR ANTAGONIST MK-801. X.Xu<sup>\*</sup>. Department of Psychology, Grand Valley State University, Allendale, MI 49401.

Previous experiments showed that administration of intracranial MK-801 blocks learning of classical fear conditioning in goldfish. The impairment of learning was decreased when fish received limited pretraining, suggesting that only the early phase of conditioning may be sensitive to disruption by MK-801. The present studies investigated the possibility that classical conditioning in goldfish consists of two successive phases and only the initial phase is critically dependent on NMDA receptor function. A series of experiments showed that the anterograde amnesic effect of MK-801 is decreased when fish received pretraining consisting of six or more conditioning trials and eliminated when fish received 12 pretraining trials. MK-801-sensitive learning is inferred to be completed within 12 trials. The neural mechanism of the learning which occurs during the later trials is manifestly insensitive of MK-801. Furthermore, MK-801 impaired learning when fish received pretraining consisting of six pseudoconditioning trials, indicating that MK-801-sensitive learning is associative, or dependent upon the contiguity of the CS and US. The effects of MK-801 on classical fear conditioning in goldfish resemble the effects of atropine on maze learning in rats. The similarities suggest that learning in instrumental and classical conditioning tasks may consist of two successive phases which are mediated by different neural mechanisms. (Supported in part by GVSU research grant-in-aid)

## 63.16

## BACLOFEN INFUSED IN RAT HIPPOCAMPAL FORMATION IMPAIRS ACQUISITION AND RETENTION OF SPATIAL LEARNING.

M.P. Arolfo, H.F. Carrer<sup>\*</sup>, M.A. Zanudio and O.A. Ramirez. Depto. de Farmacología, Fac. Cs. Químicas, U.N.C., Córdoba, Argentina.

Recent studies show that baclofen (a selective GABA-B agonist), impairs different kinds of learning (McNamara and Skelton, Pharm. Biochem. Behav. 1996; Ramirez et al., unpublished results).

Neuroanatomically, GABA-B receptors can be subclassified according to their signal transduction mechanisms. GABA-B receptors are known to be located pre- and post-synaptically and can be identified electrophysiologically (Bowery, TIPS 1989; Dutar and Nicoll, Neuron, 1988). It has been demonstrated that baclofen modulates, in a biphasic manner, the mechanisms underlying the long term potentiation (LTP). The aim of the present study was to investigate a differential action of baclofen on spatial learning. Male Wistar rats (8-10 weeks of age) were implanted with cannulae aimed bilaterally to the hippocampal formation. Baclofen (20mM, 2mM) or sterilized saline, was microinfused, 1 h before each session (3 trials/session, 1 session/day) along 4 days. Our results show that baclofen 20mM and 2mM impaired the acquisition and retention of spatial information. Supported by grants from SECyT and CONICOR Argentina to O.A. Ramirez.

## 63.17

FAILURE OF SENSITIZATION IN GOLDFISH TREATED WITH GABA<sub>B</sub> AGONIST BACLOFEN. A. C. Kalya<sup>1</sup>, E. G. Antzoulatos<sup>1</sup>, P. Angelogianni<sup>2</sup> and M. M. Nikoletsas<sup>1</sup>. <sup>1</sup>Dept. of Psychol., Deree, The American College of Greece, A. Paraskevi, GR-15342; <sup>2</sup>Dept. of Experimental Physiol., Sch. Medicine, U of Athens, GR-11527, Greece.

A dramatic suppression of respiratory activity occurs when goldfish (*Carassius auratus*) is presented with novel stimuli. Muscle potentials from the opercular region show a decrease in amplitude and an increase in duration. This branchial suppression response (BSR) habituates, if the stimulus is weak, and is subject to heterosynaptic facilitation (is sensitized), if a strong stimulus is presented. In the present study two groups of fish of four subjects each were used in a sensitization experiment. The experimental group received baclofen (16 hrs in 25 mg/lit aqueous solution up to one hr before the experiment). The weak stimulus was a flashing light (2 s duration, approx  $19 \times 10^6$  lumens intensity, 6 Hz flashing rate). The sensitizing stimulus was a 5 ms duration constant current shock of 50 mA delivered subcutaneously through teflon coated silver electrodes. The BSR was recorded through a tungsten electrode inserted in the operculum and was displayed in a computer scope. Five minutes after the first presentation of the light stimulus, the shock stimulus was presented five times at 5 min intervals. The weak stimulus was presented again five min after the last shock. Results showed sensitization of the BSR in the undrugged group, as indexed by a wider, lower amplitude muscle potential ( $p < 0.05$ ). The baclofen group failed to show sensitization. Muscle potentials in the latter group remained narrow, and of high amplitude, indicating a diminished alarm reaction to the light stimulus. In general, baclofen treated animals showed low responsiveness to stimuli. The data are discussed in terms of the role of inhibitory systems in the development of sensitization. (Supported by Deree College funds)

## 63.19

SYSTEMIC AND NUCLEUS BASALIS INFUSIONS OF N-METHYL-D-ASPARTATE ENHANCE MEMORY IN A DOUBLE Y-MAZE. K. I. Mason<sup>\*</sup>, P. E. Mallet, K. Jhamandas, R. J. Boegman and R. J. Beninger. Departments of Psychiatry, Psychology, and Pharmacology & Toxicology. Queen's University, Kingston, Ontario, Canada.

N-methyl-D-aspartate (NMDA) receptors have long been implicated in learning and memory. There are many findings which demonstrate that the administration of NMDA receptor antagonists impairs memory. Few studies, however, have investigated the role of NMDA agonists in mnemonic function. Hence, the present study examined the effects of systemic and intra-nucleus basalis magnocellularis (nbm) injections of NMDA on memory. Wistar rats were trained in a two-component double Y-maze task consisting of a spatial discrimination and delayed alternation. In the first experiment, rats ( $n=12$ ) received saline (0.9%), NMDA (0.2, 2.0 and 10.0 mg/kg), physostigmine (0.1 mg/kg), or no injection, in a counterbalanced order. In the second experiment, rats ( $n=19$ ) were surgically implanted with bilateral cannulae in the nbm prior to maze training. Once trained, animals received bilateral intra-nbm injections (0.5  $\mu$ L) of saline (0.9%), NMDA (0.05, 0.075, and 0.10  $\mu$ g/side), the benzodiazepine receptor partial inverse agonist N-methyl- $\beta$ -carboline-3-carboxamide (FG 7142; 0.2  $\mu$ g/side), or no injection, in a counterbalanced order. During testing, delays of 0-, 30- and 60-seconds were introduced. Systemic physostigmine improved choice accuracy in both tasks; systemic NMDA, intra-nbm FG 7142, and intra-nbm NMDA produced an improvement in the delayed alternation task only. These results support the notion that NMDA receptors in general, and the nbm in particular, are involved in cognitive processes mediating memory (supported by OMHF).

MODULATION OF DIVIDED ATTENTION BY INFUSIONS OF BENZODIAZEPINE RECEPTOR AGONISTS AND INVERSE AGONISTS INTO THE BASAL FOREBRAIN. L.A. Holley Miner<sup>\*</sup>, A.J. Hanje and M. Sarter. Department of Psychology & Neuroscience Program, The Ohio State University, Columbus, OH 43210.

Infusions of benzodiazepine receptor (BZR) agonists or inverse agonists into the basal forebrain were previously demonstrated to produce dissociable effects on sustained attention (Psychopharmacol 120:99-108). The present experiment examined the effects of such infusions on divided attention. Divided attention was assessed by using a crossmodal divided attention paradigm developed for rats (Psychopharmacol 155:213-220). The effects of infusions of the BZR agonist chlordiazepoxide (CDP; 10 - 60  $\mu$ g/0.5  $\mu$ L/hemisphere) or the partial inverse agonist FG 7142 (0.2 - 6.0  $\mu$ g/0.5  $\mu$ L/hemisphere) into the basal forebrain were assessed. Infusions of CDP increased response latencies while decreasing response accuracy in the bimodal component of this task, suggesting the lack of a speed-accuracy tradeoff which was previously observed following systemic administration of CDP. Small doses of FG 7142 increased both accuracy and response latencies during the condition of modality uncertainty. These findings suggest that bidirectional modulation of basal forebrain GABAergic transmission mediates dissociable effects on divided attention.

GABA INFLUENCES ON THE CONDITIONED BRANCHIAL DEFENSIVE REFLEX IN THE GOLDFISH. E. G. Antzoulatos, A. C. Kalya and M. M. Nikoletsas<sup>\*</sup>. Dept. of Psychology, Deree, The American College of Greece, A. Paraskevi, GR-15342, Greece.

The branchial defensive reflex (BDR), characterized by muscle potentials of decreased amplitude and increased duration, is elicited when goldfish (*Carassius auratus*) are presented with novel stimuli. We report here the conditioning of BDR and the effects of baclofen, a GABA<sub>B</sub> agonist, on the conditioned BDR. An undrugged group (UG) and a baclofen-treated (BG) group (20hrs in a 25 mg/lit aqueous solution) were presented with the conditional stimulus (CS), a flashing light (5 Hz,  $5 \times 10^6$  lumens, 2 s) followed by the unconditional stimulus (UCS), a 50 mA DC, 5 ms shock with an interstimulus interval (ISI) of 8 s. The third group (PG) was presented with unpaired stimuli in random order to control for pseudoconditioning. The experiment consisted of 25 trials with 5 min intertrial interval. In the UG group a conditioned BDR developed in less than ten trials. CR latency gradually shortened and in CS alone test trials CR duration exceeded the 8 s ISI. In the PG group the original BDR was sensitized but remained weak compared to the UG group. Baclofen had an inhibitory effect on the development of the conditioned BDR; occasionally the CR showed increased amplitude and decreased duration of muscle potential. (Supported by American College of Greece funds).

SPATIAL LEARNING IN THE ABSENCE OF NMDA RECEPTOR-DEPENDENT LONG TERM POTENTIATION: REPLICATION WITH CGS19755. D.P. Cain<sup>\*</sup> and D. Säucier. Dept. Psychology and Graduate Program in Neuroscience, Univ. of Western Ontario, London, Ontario N6A 5C2 CANADA.

NMDA receptor-dependent LTP in the hippocampus is thought to be required for normal spatial learning in the water maze. We evaluated the ability of rats given CGS19755, a competitive antagonist of NMDA receptors, to acquire the water maze task. CGS19755 (4.0 mg/kg i.p.) completely blocked LTP in the dentate gyrus evoked by stimulation of the perforant path, measured at 1 and 24 hrs. Several days later the same rats received the same regimen of electrical stimulation in the absence of any treatment. Significant LTP of both the EPSP and population spike was measured at both 1 and 24 hrs. The same rats were then made familiar with the general task requirements by nonspatial pretraining using a standard protocol (3 trials/day, 4 days, curtains around pool, hidden platform moved after every trial; Morris, 1989). They were then given CGS19755 (4.0 mg/kg) and trained to find the hidden platform in the maze pool. Naive CGS rats were trained similarly, and had a severe deficit in finding the platform. The nonspatially pretrained CGS rats acquired the task as rapidly as controls as judged by measures of platform search time, platform quadrant dwell, and percent direct swims. These results replicate our earlier findings with the NMDA receptor antagonist NPC17742, and demonstrate that rapid spatial learning can occur in the absence of NMDA receptor-dependent LTP in the dentate gyrus. Supported by a grant from N.S.E.R.C.

## 63.22

BRETAZENIL DOES NOT IMPAIR SHORT-TERM MEMORY OF RATS AT DOSES EFFECTIVE AGAINST ETHANOL WITHDRAWAL. Y. Egilmez, C.J. Wallis, J. Grewal, H. Lal and M. Martin<sup>\*</sup>. Department of Pharmacology and SAINT, University of North Texas Health Science Center, Fort Worth, TX 76107.

Bretazenil is a partial benzodiazepine receptor agonist with potent anxiolytic and anticonvulsant effects. In the present experiments, we studied the effects of bretazenil on short-term memory and motor performance of rats at doses that are effective to alleviate ethanol-withdrawal symptoms. Male Long Evans rats were trained to find a hidden platform in a Morris Water Maze (1.8 m in diameter and 60 cm high, filled with opacified water and maintained at 24 °C). Following the acquisition, rats were given a nutritionally balanced liquid diet with or without (control) ethanol (4.5%) for 10 days. Twelve hours following the removal of the ethanol/control diet, rats were tested for their performance at the water maze on three consecutive test days. Each day, the platform was placed in a different location, and the effect of bretazenil (0.08, 0.32 and 1.25 mg/kg) was tested at 15, 30 and 60 min. following an information trial on measures of "latency to reach the platform", "path length" and "speed". There was no significant difference between ethanol and control groups in any of the measures used. Bretazenil did not significantly effect any of the performance in control group while decreasing speed in ethanol group at the lowest dose. These findings suggest that bretazenil does not impair short-term memory performance in rats at doses effective against withdrawal. (Supported by NIAAA #AA09567).

## 63.23

LEARNING DEFICITS INDUCED BY PONTINE TEGMENTUM LESIONS ARTIFACT OF ANXIETY? E.Leri\* and K.B.J. Franklin. Department of Psychology, McGill University, Montreal, Canada, H3A-1B1.

Normal animals were trained on a delayed non-matching to position task (DNMP) in a T-maze. Subsequent bilateral NMDA lesions to the pontine tegmentum (PTg), including the pedunculopontine nucleus, did not alter performance. During acquisition, the first trial was forced, however, when the first trial was made a free choice, the performance of the PTg group dropped, suggesting PTg lesions prevented generalization to a new condition. Naive animals with NMDA lesions of the PTg or sham lesions, were tested for their capacity to acquire DNMP with free sample choice. The sham lesioned subjects improved but, even after 15 days of training, PTg lesioned animals did not. We noted that PTg lesioned rats failed to eat the food reinforcement, and did not habituate to handling, suggesting that the failure to perform DNMP might be due to fear. DNMP performance of these PTg-lesioned animals significantly improved when they were injected with diazepam (1mg/kg) before testing. The performance of controls was not altered.

When naive animals were tested for acquisition of DNMP under diazepam, only the PTg group improved with training. Sham-lesioned rats acquired DNMP when diazepam was discontinued, but the performance of the PTg group deteriorated. These results suggest that PTg lesions did not directly affect learning or memory, but induced a state of high anxiety which influenced performance on the DNMP task. This conclusion is supported by the finding that bilateral NMDA lesions to the PTg produced high levels of anxiety as measured by performance on an elevated + maze. The anxiety scores were not reduced with 7 daily exposures to the apparatus, but were significantly attenuated by diazepam (1& 2 mg/kg).

## BIOLOGICAL RHYTHMS AND SLEEP: SLEEP II

## 64.1

SLEEP DEPRIVATION BY GENTLE HANDLING DOES NOT AFFECT GALANIN mRNA EXPRESSION IN THE RAT ANTERIOR HYPOTHALAMUS J.Toppila, L.Alanko, M.Asikainen, I.Tobler, D.Stenberg\* and T.Porkka-Heiskanen. Dept. of Physiology, Inst. of Biomedicine, FIN-00014, Univ. of Helsinki, Finland and Inst. of Pharmacology, Univ. of Zürich, Switzerland.

Galanin (GAL) is widely expressed in CNS and colocalized with neurotransmitters which take part in sleep regulation. Experimental lesions of the anterior hypothalamic area strongly inhibit sleep indicating a role of this brain area in the regulation of sleep. We found earlier that 24 h REM sleep deprivation (REMSD) with the platform method increased GAL mRNA in the periventricular nucleus (PeN) and medial preoptic area (MPA). We now studied the effect of total sleep deprivation (SD) on GAL mRNA expression in the same nuclei. SD was obtained by gentle handling i.e. by introducing or removing objects in the rat cage. Six hours of SD during the light phase is known to cause a strong rebound of EEG slow wave activity in the rat. Brains of male rats (kept in L:D 12:12, lights on at 0900 h) were collected immediately after 6 h SD (starting at lights on), or 12 h SD (dark phase). N=6 in each group. Unhandled animals (N=6+6) kept in their home cages served as controls. In situ hybridization was made from 20 µm cryosections through the anterior hypothalamus using <sup>35</sup>S-labelled 48-mer oligonucleotide probe for GAL. Slides were dipped in photographic emulsion, and developed after exposure. The number of cells expressing GAL mRNA counted under dark field photomicroscopy in corresponding sections did not change significantly after 6 or 12 h SD in PeN or MPA in contrast to 24 h of REMSD. 12 h of SD may be too short to induce GAL expression in the anterior hypothalamus. It is also possible that the loss of REM sleep in the prolonged REMSD causes the increase, and 12 h of SD does not enhance REM pressure enough to enhance galanin mRNA as after 24 h REMSD. ## 64.3

PROLONGED REM SLEEP DEPRIVATION ELEVATES TYROSINE HYDROXYLASE mRNA IN LOCUS COERULEUS. R.Basheer\*, M.Magner, K.Ryan, A.Segall, R.W.McCarley and P.Shirmani. Dept Psychiatry, Harvard Medical School- VA Medical Center, West Roxbury, MA 02132.

The rat LC consists of densely packed norepinephrine neurons. Electrophysiological studies have shown that LC neurons stop firing during REM sleep. With REM sleep deprivation these neurons should continue to discharge, resulting in an increased turnover and synthesis of the neurotransmitter and its synthesizing enzyme TH. To study this phenomenon, rats were deprived of REM sleep using the platform technique and the levels of TH mRNA were assessed by *in situ* hybridization. We also measured two of its known transcriptional activators, pCREB and c-fos, using immunohistochemistry. There was a significant increase in TH mRNA after 3- and 5- days on small platform (REM sleep deprived) whereas animals from 1 day (small or large platform) or 5 days (large platform) did not show any significant change relative to dry cage controls. c-Fos protein was not detected in LC in any of the above conditions whereas pCREB protein was detected in all rats.

## 64.2

CHANGES IN GLUTAMATE DECARBOXYLASE (GAD) mRNA LEVELS ASSOCIATED WITH THE PLATFORM TECHNIQUE OF REM SLEEP DEPRIVATION.

L.Ramanathan\*, R.W.McCarley and P.Shirmani. VA-Harvard Medical School, West Roxbury, MA 02132.

Emerging evidence shows that gamma-aminobutyric acid (GABA) plays an important role in sleep. In the hypothalamus, sleep-active cells are thought to be GABA and inhibitory on wake-active cells, while in the dorsal raphe, GABA cells show Fos expression with cholinergically-induced REM sleep. Increased GABA release has been found with REM sleep in the dorsal raphe and with non-REM sleep in the posterior hypothalamus. The present study investigated changes in the expression of GAD mRNA using the platform technique of REM sleep deprivation. Rats were placed on either large platforms (LP) or small platforms (SP) for 1 and 5 days, while control animals were kept in dry cages throughout the experimental period.

Total RNA was extracted from six different brain regions (cerebellum, cortex, striatum, hippocampus, pons and hypothalamus) electrophoresed on 0.8% agarose gels, transferred in 10X SSC by overnight capillary blotting to zeta probe membrane and probed with [<sup>32</sup>P]-UTP labelled GAD by *in vitro* transcription. Preliminary assessment of Northern blots indicate no changes in the levels of GAD mRNAs in any of the brain regions.

We and others have previously shown that sleep and REM-sleep deprivation induces differential expression of various messages including c-fos, preproenkephalin, tyrosine hydroxylase and IL-1. We have now extended these observations to include GABA.

## 64.4

HYPOTHALAMIC GHRH MRNA AND TNFα MRNA LEVELS ARE HIGHER DURING THE DAY THAN NIGHT. S. Bredow, F. Obál Jr., N. Guha-Thakurta, P. Taishi and J.M. Krueger\*. Dept. Physiol. & Biophys., Univ. Tennessee, Memphis, Memphis, TN 38163, USA.

Growth hormone releasing hormone (GHRH) and tumor necrosis factor α (TNFα) are involved in physiological sleep regulation (reviewed Krueger *et al.* 1995). Rats sleep about twice as much during daylight hours than nighttime hours. It is thus posited that levels of GHRH mRNA and TNFα mRNA are higher during the day than during the night in areas of the brain involved in sleep regulation. Male Sprague-Dawley rats (n=48, 320-350g) on a 12:12 light/dark cycle were sacrificed by decapitation at 4 hr intervals (8 animals/time point) starting 1 hr after light onset (08:00). The brains were quickly removed and dissected into cerebellum (CB), brain stem (BS), cortex (CT), hippocampus (HC) and hypothalamus (HT). Total RNA was extracted and analyzed for GHRH, TNFα and β-actin mRNAs by reverse transcriptase-polymerase chain reaction (RT-PCR). HT and CB levels of GHRH mRNA were higher during the light period than during the dark phase (P<0.05). The GHRH mRNA signal did not vary in the HC, CT or BS. HT β-actin levels did not vary significantly across the day. HT and HC TNFα mRNA levels were higher during the day than the night, but did not vary in the other brain areas examined. Since the HT is involved in sleep regulation, the data suggest that higher levels of GHRH and TNFα mRNAs in the HT could be associated with the greater amounts of sleep occurring during the day.

## 64.5

**THE TNF 55-KD RECEPTOR AND THE IL1 TYPE I RECEPTOR ARE INVOLVED IN PHYSIOLOGICAL SLEEP REGULATION.** J. Fang\*, L. Kapás, Y. Wang and J. M. Krueger. Dept. of Physiology & Biophysics, Univ. of Tennessee, Memphis, TN 38163.

Interleukin 1 (IL1) and tumor necrosis factor (TNF) are the best characterized sleep-promoting cytokines. Recently, we observed that the IL1 type I receptor and the TNF 55 kD receptor are involved in IL1 $\beta$  and TNF $\alpha$  induced sleep, respectively. However, it was unknown whether these receptors are involved in physiological sleep regulation. In the present experiment we determined the sleep patterns in TNF 55 kD receptor knockout (TNFR-KO), IL1 type I receptor knockout (IL1R-KO), and B6x129-F2 (F2) mice. Both types of knockout mice have a B6x129 background.

**Methods.** Three groups of mice (TNFR-KO, n=14; IL1R-KO, n=7; and B6x129-F2, n=13) were implanted with EEG and EMG electrodes. After surgery mice were kept in recording cages in a thermoneutral environmental chamber with ambient temperature at 30 $\pm$ 1 °C and with a 12:12 h light-dark cycle (light on at 5 a.m.) throughout the experiment. Food and water were freely available. Experiments started 10 days after surgery. Sleep was recorded for 1 to 3 days in different experiments. Sleep data were visually scored in 10 second epochs and analyzed with two way repeated ANOVA and Student-Newman-Keuls test (SNK).

**Results.** 1) TNFR-KO mice had significantly less non-rapid eye movement sleep (NREMS, [F(1,25)=6.69, p<0.02]) and rapid eye movement sleep (REMS, [F(1,25)=13.09, p<0.002]) compared to F2 controls, primarily due to the decrease in sleep during the light period in TNFR-KO mice. 2) IL1R-KO mice had significant decreases in NREMS during the dark period (SNK: q(2,11)=3.90, p<0.05) and significant increases in REMS during the light period (SNK: q(2,11)=3.79, p<0.05) compared to F2 controls.

**Discussion.** Both IL1 and TNF promote NREMS in several species. Current data showed that the absence of the IL1 type I receptor or the TNF 55kD receptor gene results in alterations of physiological sleep. These data support the idea that IL1 and TNF are involved in physiological sleep regulation and suggest that endogenous IL1 and TNF may promote sleep at different times of day.

## 64.7

**THE EFFECTS OF CCK-8NS AND CCK-4 ON SLEEP, SLOW WAVE ACTIVITY OF THE EEG AND BRAIN TEMPERATURE IN RATS.**

Hee-Yoon Chang and Levente Kapás\*. Department of Physiology and Biophysics, University of Tennessee, Memphis, TN 38163.

Systemic injection of 10-50  $\mu$ g/kg cholecystokinin-octapeptide sulfate ester (CCK-8SE) increases both non-rapid-eye-movement sleep (NREMS) and EEG slow wave activity (SWA) and causes hypothermia (1). In the present study we tested whether non-sulfated CCK-8 (CCK-8NS) and CCK-tetrapeptide (CCK-4) have sleep-promoting and hypothermic effects in rats. These two peptides have similar affinities to CCK-B receptors as CCK-8SE, but their affinity to CCK-A receptors is 600 and 50,000 times lower, respectively.

Male Sprague-Dawley rats (290-390 g), were implanted with chronic electrodes for cortical EEG, EMG and brain temperature (Tbr) recordings. After a habituation period of 7-14 days the animals were injected intraperitoneally at dark onset with isotonic NaCl on one (control) day and with CCK-8NS (10 or 50  $\mu$ g/kg, n = 7 for both) or CCK-4 (10 or 50  $\mu$ g/kg, n = 8 and n = 7, respectively) on another, test day.

After 50  $\mu$ g/kg CCK-8NS, there was a slight tendency towards an increase in NREMS in the first 2 h after the injection and later, both NREMS and rapid-eye-movement sleep (REMS) decreased in h 7-8. The increase and decrease in NREMS were accompanied with tendencies toward increased and decreased SWA, respectively. Tbr was not affected. 10  $\mu$ g/kg CCK-8NS caused similar but slighter effects than the high dose. The low dose of CCK-4 did not affect sleep, SWA, and Tbr; 50  $\mu$ g/kg CCK-4 did not affect NREMS and Tbr, but there was a slight tendency towards increased REMS and decreased SWA for 1-2 h after the injection. These results suggest that the activation of CCK-B receptors is not sufficient to elicit sleep and hypothermic responses.

## 64.9

**Pharmacological and EM-immunocytochemical evidence for recurrent axon collaterals mediating feedback inhibition to NOS+, cholinergic neurons of the laterodorsal tegmental (LDT) nucleus.** C.S. Leonard\*, J. Rhee, G.E. Stutzmann, and C. Aoki. Center for Neural Science, NYU, New York, 10003.

Increased activity among NOS+, cholinergic neurons of the LDT contributes to the induction of the EEG-desynchronized states of *waking* and *REM* sleep by releasing Ach and possibly nitric oxide in the thalamus, basal forebrain and reticular formation. Recent evidence suggests LDT activity is under inhibitory feedback control since LDT neurons have recurrent axon collaterals (Surkis et al. 1996, *Neurosci.*, In Press.) and are hyperpolarized by Ach. We now show that *endogenous* Ach hyperpolarizes LDT neurons and demonstrate by EM that local axon collaterals form synapses with NOS+ dendrites in the LDT. Intracellular recordings from a guinea pig brain slice indicated that eserine, a cholinesterase inhibitor, hyperpolarized and decreased  $R_{input}$  of LDT neurons like exogenous Ach. Atropine abolished the eserine effect and depolarized cells beyond their resting potential indicating significant baseline Ach release. Recorded neurons were then biocytin-injected, and studied by EM following NOS immunocytochemistry. Results indicate that NOS+ terminals from injected cells made symmetric type synaptic contacts with NOS+ and NOS- dendrites. Injected cells also received synaptic contact from both NOS+ and NOS- terminals. In addition, axonal terminals from injected cells were observed in direct apposition to unlabeled axonal terminals. These data support the hypothesis that the activity of LDT cholinergic neurons is under direct inhibitory feedback control. The presence of axo-axonic interactions raises the possibility that local release of Ach and NO may also have presynaptic actions upon synaptic afferents to the LDT. Supported by NIH NS27881 (C.S.L.) & NSF RCD 92-53750 (C.A.).

## 64.6

**NERVE GROWTH FACTOR ENHANCES SLEEP IN RABBITS.**

S. Takahashi\*, S. Gala, L. Kapás, and J. M. Krueger. Department of Physiology and Biophysics, University of Tennessee, Memphis, TN 38163

It is hypothesized that nerve growth factor (NGF) is involved in the regulation of sleep. NGF is a well-characterized neurotrophic factor that elicits rapid-eye-movement sleep (REMS) after 1  $\mu$ g microinjection into the pons in cats<sup>1</sup>. Further, a specific immunotoxin for NGF receptor-positive cholinergic basal forebrain neurons inhibits REMS, suppresses electroencephalogram (EEG) power and transiently impairs the circadian distribution of non-rapid-eye-movement sleep (NREMS) in rats<sup>2</sup>. The aim of the present study was to determine the effects of intracerebroventricular (icv) injection of NGF on sleep and brain temperature (Tbr) in rabbits. Male New Zealand White rabbits (3.5-5.5 kg) were implanted with EEG electrodes, a brain thermistor and an icv guide cannula. The animals were kept on a 12:12 h light-dark cycle (light on at 0600) at 21 $\pm$ 1 °C. Rabbits received recombinant human  $\beta$ -NGF (R&D Systems) icv [0.01  $\mu$ g (n=5), 0.1  $\mu$ g (n=6), 1.0  $\mu$ g (n=8) or 10  $\mu$ g (n=4)]. On a separate control day, the same rabbits were given 25  $\mu$ l pyrogen free saline icv. Injections were between 8:45 and 9:15 a.m. EEG and Tbr were recorded for 23 h after injections. Two-way ANOVA for repeated measure was used for statistical analyses.

The highest two doses of NGF significantly increased both NREMS and REMS across the 23-h recording period. REMS was enhanced dose-dependently, i.e. 16 % (0.01  $\mu$ g), 43 % (0.1  $\mu$ g), 56 % (1.0  $\mu$ g) or 65 % (10  $\mu$ g) increases above control. Tbr was not affected by any dose of NGF. These results suggest that NGF is involved in both REMS and NREMS regulation.

## 64.8

**REDUCTION OF NON-RAPID EYE-MOVEMENT SLEEP (NREMS) IN HUMAN GROWTH HORMONE (hGH) TRANSGENIC MICE.** J. Zhang, F. Obál, Jr., J. Fang, B. J. Collins\*, and J. M. Krueger. Dept. of Physiol. and Biophysics, Univ. of Tenn., Memphis, TN 38163; \*Sect. Endocrinol., Univ. of Illinois, Chicago, IL 60612.

Transgenic mice, bearing a 4.8 kilobase (kb) sequence of upstream rat tyrosine hydroxylase (TH) promoter sequences linked to an hGH reporter, exhibited a dwarf phenotype. Previous studies suggest that the expression of hGH at sites of TH synthesis in the brain exerts negative feedback on GH-releasing hormone (GHRH)-producing neurons of the hypothalamus. Hypothalamic GHRH has been shown to be involved in physiological sleep and to form part of the homeostatic sleep process. The present study was designed to determine whether the reduction of GHRH observed in the arcuate nucleus of THhGH transgenic mice would be reflected in altered sleep pattern.

Male hGH transgenic mice were selected from offsprings of two male hGH transgenic breeders by polymerase chain reaction (PCR) which targeted a 645 basepair (bp) fragment of the TH-hGH transgenic gene. Animals were implanted with electroencephalogram (EEG) recording electrodes over the frontal and parietal cortices and were allowed one week to recover from surgery. Sleep-wake activity was recorded for 3 consecutive days in both control (n = 9) and hGH transgenic (n = 9) mice which were maintained in a 12:12-hour light-dark cycle. The states of vigilance [NREMS, rapid eye-movement sleep (REMS), and wakefulness] were scored visually in 10 seconds intervals. The duration of states of vigilance was expressed as percent of recording time every two hours.

Two-way analysis of variance (ANOVA) for repeated measures revealed that the mean duration of NREMS for every two hours was significantly reduced in hGH transgenic mice over the 24 hour recording period (p < 0.01). But the mean duration of REMS in transgenic mice was not significantly different from that in control mice. Therefore, the ectopic expression of GH significantly suppressed the NREMS in transgenic mice possibly via the inhibition of endogenous GHRH secretion.

## 64.10

**REVERSAL OF GAMMA-HYDROXYBUTYRATE-INDUCED FACILITATION OF PARADOXICAL SLEEP BY NCS-382.**

V. Girodias, I. Beaulieu, H. H. Webster, M. Schmitt, J.J. Bourguignon, R. Godbout\*. Département de psychiatrie, Université de Montréal, Montréal (Québec) H4J 1C5.

Gamma-hydroxybutyrate (GHB) facilitates paradoxical sleep (PS) in the rat when administered in low doses at the beginning of the subjective night (*Soc. Neurosci. Abs.* 1995; 21: 450.). We analysed the effect of the newly synthesized GHB receptor antagonist NCS-382 in this model. GHB (10 or 160 mg/kg i.p.) or saline were given with or without NCS-382 co-treatment in six rats at 8:00 (lights on at 6:00 for 12h); EEG, EOG and EMG were recorded individually for four hours thereafter. Each rat was exposed in random order to each treatment level. GHB 10 mg/kg decreased PS latency (24.0  $\pm$  4.8 min. vs 53.5  $\pm$  10.2 min.; p < .02). Latency to slow wave sleep (SWS) and durations of SWS and PS were not affected by GHB at any dose. The co-administration of NCS-382 totally blocked the effect of GHB on PS latency. These results suggest that PS facilitation by low doses of GHB may be due to a selective activation of high affinity GHB receptors.

## 64.11

EFFECTS OF MICROINJECTIONS OF  $\alpha 1$  AND  $\alpha 2$  ADRENOCEPTOR AGONISTS INTO THE AMYGDALA ON SLEEP-WAKE STATES, L.D. Sanford\*, S.H. Fuchino, D.E. Tidikis, R.J. Ross and A.R. Morrison. Univ. of Penna. Sch. of Vet. Med. and Med. and Phila. VA Med. Center, Phila., PA 19104.

Noradrenaline, originating in the locus coeruleus (LC), has long been implicated in the regulation of sleep-wake states. LC projects to the amygdala, which has been demonstrated to have a role in modulating arousal and behavioral state. Virtually every region of the amygdala has a modest concentration of noradrenergic fibers, with the densest concentration of fibers being in the central nucleus of the amygdala. We examined the effect of microinjections into the amygdala of an  $\alpha 1$  adrenoceptor agonist, methoxamine, and an  $\alpha 2$  adrenoceptor agonist, clonidine, on sleep and wakefulness. Rats (90 day old, male, Sprague-Dawley) were implanted with electrodes for determining behavioral state and with guide cannulae for bilateral microinjections into the amygdala. Rats were injected during non-rapid eye movement sleep with methoxamine (1.0 - 10.0  $\mu$ g / 0.4  $\mu$ l normal saline; N=6) clonidine (0.01 - 0.05  $\mu$ g / 0.2  $\mu$ l normal saline; N=5) or multiple microinjections of normal saline alone (0.2  $\mu$ l; N=4). Each rat received 5 microinjections, normal saline or drug, with 7 day intervals between injections. Neither multiple normal saline microinjections nor clonidine, at the doses tested, significantly affected any sleep measure that we examined. Methoxamine (2.5 - 10  $\mu$ g) decreased time spent asleep during the first 3 hours post-injection ( $p < .05$ ). Moreover, time spent asleep remained suppressed one week following the last microinjection of methoxamine, suggesting the possibility of a prolonged alteration in sleep. The results indicate that an  $\alpha 1$  adrenergic mechanism in the amygdala can influence amygdaloid modulation of behavioral state. Support: MH42903, NS35281, Dept. of Vet. Affairs and Merck Summer Fellowship.

## 64.13

PERFUSION OF A 5-HT<sub>1A</sub> ANTAGONIST IN THE DORSAL RAPHE NUCLEUS (DRN) INCREASES SEROTONIN (5-HT) RELEASE IN DRN AND DECREASES REM SLEEP. Alvild Alette Bjorkum\*, Robert E. Strecker, Tarja Porkka-Heiskanen and Robert W. McCarley. Dept. of Psychiatry, Harvard Medical School, Brockton VA Med. Ctr., Brockton, MA 02401, USA, and \*Institute of Biomedicine, University of Helsinki, Finland.

The serotonergic system is involved in modulation of sleep and waking. Our laboratory has recently shown that microdialysis perfusion of the selective 5-HT<sub>1A</sub> receptor agonist 8-OH-DPAT in the DRN decreases 5-HT release and increases REM sleep in the freely moving cat. Conversely, we now demonstrate that DRN perfusion of antagonists at the 5-HT<sub>1A</sub> receptor produces an increase in extracellular 5-HT levels and a decrease in REM sleep. Microdialysis was performed in freely moving cats implanted with electrodes for the recording of behavioral state and with cannula used to guide the microdialysis probe to the DRN. Behavioral state and extracellular 5-HT levels were simultaneously assessed in a 3h control period, and during the subsequent addition of p-MPPI, a potent and selective 5-HT<sub>1A</sub> antagonist, to the artificial CSF perfusate. Perfusion of 5-HT<sub>1A</sub> antagonist in concentrations of 100 nM (n=3) and 300 nM (n=2) produced a 2 and 7 fold increase in extracellular 5-HT respectively. The highest dose of the antagonist also produced a 50% decrease in REM sleep. These effects are presumably caused by the blocking of 5-HT<sub>1A</sub> autoreceptor-mediated negative feedback, which consequently increases serotonergic neural activity. This 5-HT<sub>1A</sub> antagonist-induced increase in 5-HT neuronal activity presumably produces an increase in 5-HT release in brainstem target areas involved in the regulation of REM sleep, such as the cholinergic neurons of the LDT/PPT and the medial pontine reticular formation. MODEL OF HIPPOCAMPAL NEURONS INCORPORATING A CATIONIC NON-SELECTIVE CHANNEL AND A CELLULAR Ca<sup>2+</sup> STORE. Teresa Ree Chay\* and Young Seek Lee. Dept. Biol. Sci., Univ. Pittsburgh, Pittsburgh, PA 15260 USA and Dept. Biochem. Hanyang Univ., Ansan, Korea.

We have studied the origin of autorhythmicity in hippocampal neurons by constructing a minimal one-compartmental mathematical model. The plasma membrane of our model contains i) a cationic non-selective channel (NSC) which is activated by a depletion of luminal Ca<sup>2+</sup> in the intracellular Ca<sup>2+</sup> stores and ii) a Ca<sup>2+</sup> channel that is activated by voltage and inactivated by intracellular Ca<sup>2+</sup> ions. In addition, the plasma membrane contains iii) an AMPA-receptor and iv) an AMPA-sensitive Na<sup>+</sup> channel; v) a GABA-receptor and vi) a GABA-sensitive K<sup>+</sup> channel. Activity of a Ca<sup>2+</sup>-releasing channel (CRC) in the Ca<sup>2+</sup> store is gated by intracellular Ca<sup>2+</sup> ions. In this model, the luminal calcium concentration oscillates slowly, and this slow oscillation induces the electrical bursting via the NSC. The spikes are due to the Ca<sup>2+</sup> channel, which is controlled by compartmentalized Ca<sup>2+</sup> ions underneath the plasma membrane. Neurotransmitters such as ACh, NE, 5-HT, and carbachol can switch a silent cell to bursting and a bursting cell to spiking by raising the activity of the CRC (via the GTP-binding proteins). This model is incorporated into a network of neurons arranged in a ring structure. The network generates synchronized reentrant rhythms including chaos.

DIFFERENTIAL EFFECTS OF PARADOXICAL SLEEP DEPRIVATION ON  $\alpha$  AND  $\beta$  ADRENERGIC RECEPTORS IN RAT BRAIN. J.N. Nobrega\*, D.C. Hipólido, R. Raymond and S. Tufik. Clarke Institute of Psychiatry, 250 College St., Toronto, Canada, and Psychobiology Dept., Universidade Federal de São Paulo, Brazil.

Previous examinations of adrenergic receptors after paradoxical sleep deprivation (PSD) have produced conflicting results. In the present study comprehensive autoradiographic analyses were used to address the possibility that PSD induces differential regional effects on specific adrenergic receptor subtypes. Ten rats were sleep deprived for 96 hr using a multiple platform technique, and then sacrificed along with 10 home cage controls. Beta adrenergic receptors were labeled with 150 pM [<sup>125</sup>I]iodopindolol in the presence of 50 nM CGP-20712A to mask  $\beta_1$  sites, or 70 nM ICI-11855 to mask  $\beta_2$  sites. Non specific binding was defined in the presence of 200  $\mu$ M isoproterenol. Alpha<sub>2</sub> sites were labeled with 5 nM [<sup>3</sup>H]UK-14,304 in the presence or absence of 10  $\mu$ M phentolamine. Quantitative analyses indicated that  $\beta_1$  binding was significantly reduced in 12 of 69 brain regions examined;  $\beta_2$  binding was reduced in 25 of 75 regions examined. Increased [<sup>125</sup>I]iodopindolol binding was not observed in any brain region. In contrast to the widespread decreases in  $\beta$  adrenergic binding, [<sup>3</sup>H]UK-14,304 binding to  $\alpha_2$  sites was not altered in any of the 89 brain regions examined, including locus coeruleus. These results indicate that PSD induces different effects on  $\alpha$  and  $\beta$  adrenergic receptors. The observed effects on  $\beta$  receptors are consistent with the hypothesis that paradoxical sleep serves to counteract the downregulation of noradrenergic receptors which normally occurs during waking (Siegel and Rogawsky, *Brain Res.* 1988, 13, 213-233). ## 64.14

INTRACEREBRAL PERFUSION OF VITAMIN B12 AGGRAVATES CATAPLEXY IN NARCOLEPTIC CANINES. K. Honda<sup>1,2</sup>, S. Nishino<sup>1</sup>, D.M. Damm<sup>1</sup>, S. Inoue<sup>2</sup>, W.C. Dement<sup>1\*</sup> and E. Mignot<sup>1</sup> Stanford Sleep Research Center, Stanford University School of Medicine, CA, 2Tokyo Medical and Dental University, Tokyo.

Vitamin B12 supplementation (methylcobalamin, methyl-B12) is known to improve circadian rhythm sleep disorders in human patients (1). It has recently been reported that intracerebroventricular (ICV) infusion of methyl-B12 significantly increased rapid-eye-movement (REM) and non-REM sleep in rats (2). The mode of action of methyl-B12 on sleep/circadian rhythms is not known, but an enhancement of the synthesis of central acetylcholine by transmethylation may be involved (3). Furthermore, a significantly lower level of vitamin B12 in the CSF has been reported in Alzheimer's disease, a disorder characterized by degeneration of cholinergic neurons (4).

Cataplexy, an abnormal manifestation of REM sleep atonia, is one of the most disabling symptoms of narcolepsy. Experimental evidence in the canine model suggests that central cholinergic systems are critically involved in the regulation of cataplexy (5). In this study, we tested the effects of central administration of methyl-B12 in narcoleptic Dobermans, and found that ICV perfusion of methyl-B12, (10-5 - 10-2 M) using a microdialysis probe, dose-dependently aggravated cataplexy in narcoleptic dogs. In contrast, cyano-B12, an analog of vitamin B12 which does not have methyl donor ability, had little effect on cataplexy. The hypothesis that the transmethylation by methyl-B12 is involved in the effect on cataplexy is, however, not bolstered by the fact that S-adenosylmethionine (10-5 - 10-2 M), an endogenous methyl donor, induced only minor modifications of cataplexy. Although the mode of action of methyl-B12 should be further studied, our current results suggest that methyl-B12 may be an important modulator of normal and abnormal REM sleep. ## 64.16

Effects on the electroencephalogram induced by the changes in cerebrospinal-fluid Ca<sup>2+</sup>-concentration: cellular mechanisms. Alessandro Formenti\*, Elda Arrigoni, Mauro Mancía, Inst. of Human Physiol. II. Univ. of Milan, I-20133 Italy

It is well-known that in the pathological states accompanied by hypercalcemia, among neurological symptoms, a state ranging from drowsiness to lethargy accompanied by low frequency electroencephalographic (EEG) activity may be present. Sleep and wakefulness EEG rhythms are driven by the thalamo-cortical relay neurons that fire with single spikes during wakefulness (relay mode), and oscillate and synchronize their firing, producing bursts of action potentials, during slow-wave-sleep (oscillatory mode). The transition from the single spike to the rhythmic burst discharge is caused by a resting membrane hyperpolarization and low voltage-activated (LVA) calcium channels deactivation. On these bases it was hypothesized that the fluctuation of extracellular Ca<sup>2+</sup> concentration, especially in certain diseases, may represent a common mechanism that causes the modification of the sleep-wake cycles, changing the membrane potential and hence the discharge mode of the thalamic pacemaker and cortical neurons.

*In vivo* EEG recordings and *in vitro* whole-cell current and voltage-clamp were carried out using Wistar rats. A CaCl<sub>2</sub> solution (100 mM, 5 to 20  $\mu$ l) perfused into the third ventricle tripled the EEG amplitude and induced a decrease in the EEG frequency at all the doses tested. The neuronal discharge, induced by depolarizing current stimuli during current-clamp recordings on single cultured thalamic neurons, changed from the single spike mode to the burst mode, when the extracellular Ca<sup>2+</sup> concentration rose from 1 to 5 mM. Current-to-voltage relationship of LVA Ca<sup>2+</sup> channels, obtained from voltage-clamped thalamic neurons, showed an increase in the peak current amplitude and a shift of the current activation to positive voltage values at increasing extracellular Ca<sup>2+</sup> concentrations (0.5 to 5 mM).

In conclusion the increase in the extracellular Ca<sup>2+</sup> concentration induces a strong membrane hyperpolarization and a consequent recovery of LVA Ca<sup>2+</sup> channels from inactivation, favouring the transition of the neuronal firing from single spikes to burst mode. This condition is supposed to occur in many pathological states in which Ca<sup>2+</sup> metabolism is involved.

## 64.17

## NEUROTENSIN MICRO-INJECTIONS INTO THE BASAL FOREBRAIN PROMOTE CORTICAL ACTIVATION ASSOCIATED WITH THE STATES OF WAKE AND PS IN THE RAT.

E.G. Cape, A. Alonso, A. Beaudet and B.E. Jones\*. Montreal Neurol. Inst., McGill Univ., Montreal, Quebec H3A 2B4, Canada.

Neurotensin has been shown to be contained in afferent fibers and to bind through high affinity receptors to cholinergic neurons in the basal forebrain. In vitro application of Neurotensin has been shown to produce a slow depolarization and rhythmic bursting in these cells. To examine the effect of this modulation upon EEG and state of the animal, Neurotensin was injected into the region of cholinergic basal ganglia neurons using a remotely controlled microinjection device in chronically implanted, freely moving rats. As compared to Ringer, Neurotensin micro-injections (500 - 1500 pmoles) produced a decrease in delta activity (1-3 Hz) and an increase in both high frequency gamma activity (30-60 Hz) and rhythmic theta activity (4-8 Hz). This EEG pattern was associated with a behaviorally quiet, waking state that alternated with paradoxical sleep (PS). Preliminary results indicate that the effects of Neurotensin can be attenuated by peripheral administration of the neurotensin receptor antagonist, SR48692, or the muscarinic cholinergic antagonist, atropine. These results suggest that Neurotensin, which promotes rhythmic bursting in cholinergic neurons, can enhance gamma and theta cortical activity associated with the states of Wake and PS. ## VASOPRESSIN AND CIRCADIAN RHYTHMS IN SIMULATED SHIFT-WORK, C. H. Wideman\*, H. M. Murphy and G. R. Nadzam. Departments of Biology and Psychology, John Carroll University, Cleveland, OH 44118.

The role of vasopressin (VP) in circadian rhythms was examined using VP-containing, Long-Evans (LE) and VP-deficient, Brattleboro (DI) rats. Animals were maintained in individual cages while telemetered body temperature (BT), heart rate (HR), and activity (AC) data were collected. Subjects were exposed to a 12h/12h light/dark cycle (photocycle) and had one feeding period commencing at the second hour of the dark cycle (nonphotic zeitgeber). A simulation of shift-work was accomplished by introducing an 8h phase advancement (shift) to a component in the cycle when the rat is normally inactive for 5 days followed by a return to the original cycle (weekend) for 2 days. The alternation between shift-work and weekends was continued for 3 weeks. Feeding was shifted in synchrony with the light/dark cycle. When transferred from the habituation to the shift paradigm, both strains of animals evidenced a disruption of their circadian rhythm patterns. Immediately following the shift, the rats had an increase in BT, HR, and AC, which was followed by a precipitous drop in the three physiological variables in the "new active period". During the shift period, DI rats adapted more rapidly, readily, and completely than LE rats. When returned to the weekend schedule, DI rats adapted by the second day; whereas, LE rats had irregularities in rhythms of BT and HR. Results demonstrate that VP is significantly involved in circadian rhythm disruptions noted in a simulated shift-work paradigm. (Research supported by a Focused Giving Grant from Johnson & Johnson.)

## 64.18

CHANGES IN EXTRACELLULAR BASAL FOREBRAIN ADENOSINE LEVELS DURING SPONTANEOUS SLEEP-WAKING AND PROLONGED WAKEFULNESS. Taria Porkka-Heiskanen\*, Robert E. Strecker, Attilio Alette Björkum, and Robert W. McCarley. Dept. of Psychiatry, Harvard Medical School, Brockton VA Med. Ctr., Brockton, MA 02401, USA and <sup>1</sup>Institute of Biomedicine, University of Helsinki, Finland.

Adenosine (AD) is an inhibitory neuromodulator of the CNS that is thought to have a role in sleep regulation. Systemic treatment of AD and AD agonists produces increased sleep and decreased wakefulness, whereas AD antagonists, such as caffeine, induce arousal. However, it is not known whether AD levels undergo spontaneous changes during the sleep-wake cycle. Our development of a highly sensitive microbore high performance liquid chromatography (HPLC) assay for AD allowed detection of AD levels from in vivo brain microdialysis samples. Male cats were chronically prepared with electrodes to record EEG, EOG, EMG, and PGO spike activity. Guide cannulae were also implanted above the substantia innominata region of the basal forebrain, the VA/VL of the thalamus, and the cingulate cortex. Microdialysis probes were lowered through the guide cannula into the target areas and perfused with artificial CSF at a rate of 1.5 µl/min. Samples were analyzed by a microbore HPLC assay with UV detection (detection limit < 50 fmol/sample). In the basal forebrain, AD levels were higher during waking (100%) than sleep (82.5 ± 3.2%). No difference was found between waking and REM-sleep (95.3 ± 5.3%). Similar state-dependent changes were found in thalamus and the cortex. During 6h of sleep deprivation, produced by gentle handling, AD levels in BF stayed at the level of normal waking, or increased slightly. AD levels declined sharply during the rebound sleep that followed deprivation. These data show that AD levels change according to vigilance state, and support the hypothesis that high CNS levels of AD promote drowsiness and the transition from wakefulness to sleep. ## 64.20

## STIMULATION OF ADENOSINERGIC A1 RECEPTORS ENHANCE NONREM SLEEP SLOW WAVE ACTIVITY IN NEONATAL RATS.

<sup>1</sup>R. N. Morissette\*, <sup>2</sup>L. A. Yun, <sup>2</sup>D. L. Stevenson and <sup>2</sup>H. C. Heller. <sup>1</sup>Interdepartmental Program in Neurosciences, UCLA, Los Angeles, CA 90025; <sup>2</sup>Department of Biological Sciences, Stanford University, Stanford, CA 94305.

The non-rapid eye movement (nonREM) sleep electroencephalogram is characterized by high amplitude, low frequency slow wave activity (SWA). NonREM SWA is a measure of the intensity of slow waves (0.75-4.0 Hz), and serves as an indicator of sleep depth within nonREM sleep. In contrast to adult rats, where sleep deprivation promotes a compensatory increase in nonREM SWA, we have found that a compensatory increase in nonREM SWA following sleep deprivation is not present in neonatal rats until postnatal day 24 (P24). Therefore, in order to test whether rats younger than P24 have the ability to enhance nonREM SWA, we gave intraperitoneal (IP) injections of the adenosinergic A1 receptor agonist, *N*<sup>6</sup>-cyclopentyladenosine (CPA) to male Long-Evans rats aged P18 to P24. Systemic injections of CPA have been shown to increase nonREM SWA in adult rats.

CPA (1.0 mg/kg) significantly enhances nonREM SWA in rats as young as P18. This finding suggests that nonREM SWA can be enhanced in neonatal rats younger than P24 even though increased nonREM SWA is not seen in recovery from sleep deprivation.

This research is supported by an NICHD fellowship (5 F31 HD07895-02) and an NIH grant (5 P50 HD29732-04REV).

## BIOLOGICAL RHYTHMS AND SLEEP: CIRCADIAN RHYTHMS I

## 65.1

MELATONIN RECEPTORS IN CHICK ASTROCYTES *IN VIVO* AND *IN VITRO*. Vincent M. Cassone\*, Melissa G. Whitfield Rucker, Thomas Leath, Arjun Natesan, Laura Schneider and Evelyn Tiffany-Castiglioni. Departments of Biology and Veterinary Anatomy, Texas A&M University, College Station, TX 77843-3258.

Recently, we (Reppert et al., 1995, *Neuron* 15: 1003-1015) have successfully cloned messages encoding two melatonin receptors from a cDNA library derived from chick brain. *In situ* hybridization using radiolabeled riboprobes of these two receptor mRNAs reveals dramatically different distributions. One receptor, the Mella receptor, accurately reflects the distribution of most *in vitro* binding of the melatonin agonist 2-[<sup>125</sup>I]iodomelatonin (IMEL) in visual system centers of the avian brain. The other, the Melc receptor, is found primarily within non-neuronal elements of the chick nervous system. However, it was not possible to identify the cell-types expressing this hybridization definitively. We have employed two approaches to this question.

First, primary astrocytes from E17 chicks were isolated and cultured in DMEM with 10% FBS for 26 days at 38°C. Cells were harvested and frozen at -80°C until assay. Cell membranes were extracted, total protein was assayed, and equal aliquots of membrane were assayed for 2-[<sup>125</sup>I]iodomelatonin (IMEL) binding. Specific, reversible and high affinity IMEL binding was observed in these cell membranes. Second, employing digoxigenin-labeled riboprobes for the Mella and Melc melatonin receptors, we observe *in situ* hybridization for Mella receptor in neurons and Melc hybridization in astrocytes. The area of hybridization within astrocytes is greater during the day than during the night. These data are consistent with previous *in vivo* studies in our laboratory indicating a daily change in astrocytic fiber length such that fibers are longer during the day than during the night. Exogenous melatonin administration during the day, furthermore, decreases astrocytic fiber length to night-time values. The data are consistent with the hypothesis that melatonin affects astrocyte function via the Melc, but not the Mella, melatonin receptor. Supported by grants from the AFOSR to VMC.

## 65.2

## TRANSCRIPTIONAL REGULATION OF THE NOCTURNIN GENE BY A RETINAL CIRCADIAN CLOCK. C.B. Green, D.L. Osterbur and J.C. Besharse\*. Department of Anatomy &amp; Cell Biology, University of Kansas Medical Center, Kansas City, KS 66160.

We have recently identified a rhythmic retinal mRNA in *Xenopus laevis* that encodes a protein that we have named nocturnin. It contains a leucine zipper-like dimerization motif and sequence similarity to a yeast transcription factor named CCR4. It is expressed specifically in photoreceptor cells, the same cells that contain an endogenous circadian clock. We have identified sequences with high similarity in both human and mouse that are expressed in brain and retina.

Because the molecular mechanisms by which circadian clocks regulate gene transcription are unknown, we began an investigation of nocturnin gene regulation. Nuclear run-on analyses, performed on nuclei isolated from retinas at different times of day in both cyclic light and constant darkness verified that rhythmic nocturnin mRNA levels were the result of circadian control of transcription of this gene. Characterization of the nocturnin gene structure revealed that the gene was composed of 3 exons and 2 introns and spanned about 10 kilobases (kb). Differential polyadenylation of the primary transcript results in 2 nocturnin messages, both containing identical open reading frames. Both messages show identical time courses of expression; the mRNA levels are low (undetectable) during the day, rise sharply in early night, and return rapidly to undetectable levels by mid-night. The transcription start site was identified by both primer extension and by 5'-RACE and a consensus TATA box was observed 30 base pairs upstream of this start site. Characterization of the nocturnin promoter provides the means to identify promoter elements and trans-acting factors involved in circadian control of gene transcription. Funded by NIH grant EY02414 (JCB).

**Subjective Day Phase Shifts in the Mollusc *Aplysia californica*: The Role of a Transcription Factor?** D. Whitmore, R. Day and G.D. Block\*. Univ. of Virginia, Center for Biological Timing, Charlottesville, Va 22903.

Subjective day phase shifts are a common, but relatively unexplored feature of circadian pacemakers compared to light-induced phase shifts. Activity-dependent subjective day phase shifts can be produced in the rodent (Mrosovsky, 1988), and a number of treatments phase shift the pacemaker in mammalian SCN brain slice preparations (Gillette et al., 1988). Eskin and colleagues have described a subjective day phase shifting pathway in the mollusc *Aplysia* which is activated by the neurotransmitter serotonin (5HT). 5HT activates a cAMP-dependent signal transduction cascade in which increased cAMP leads to membrane hyperpolarization and a subsequent phase shift which requires protein synthesis. We examined levels of the *Aplysia* transcription factor CCAAT enhancer binding protein (ApC/EBP) in response to these subjective day phase shifting treatments. Using quantitative RT-PCR we show that 5HT, forskolin, hyperpolarization and low calcium all increase the amount of C/EBP mRNA in the retina. The pairing of light and 5HT in the late subjective night produces large phase shifts and superinduces C/EBP mRNA levels. A protein of predicted molecular weight and isoelectric point shows corresponding increases in response to these treatments on two-dimensional SDS protein gels. This correlational evidence argues for a role of ApC/EBP in 5HT mediated phase shifting in *Aplysia*. (NIH NS15264).

## 65.5

**NEUROPEPTIDE Y ADVANCES THE CIRCADIAN RHYTHM OF THE RAT SUPRACHIASMATIC NUCLEUS IN VITRO BY AN INTERACTION WITH A Y2 RECEPTOR.** V.K. Gribkoff<sup>1</sup>, R.L. Pieschl<sup>1</sup>, T.A. Wisialowski<sup>1</sup>, A.N. van den Pol<sup>2</sup> and F.D. Yocca<sup>1</sup>. <sup>1</sup>CNS Drug Discovery, Bristol-Myers Squibb Pharmaceutical Research Institute, 5 Research Parkway, Wallingford, CT 06492 and <sup>2</sup>Sect. Neurosurgery, Yale University, New Haven, CT 06510.

The mammalian hypothalamic suprachiasmatic nucleus (SCN) generates circadian neuronal discharge rhythms underlying some behavioral cycles. While cells within the SCN have an intrinsic circadian rhythmicity, the precise timing is susceptible to modulation by factors such as the timing of light-dark cycles. Several neuromodulators have been implicated in the mediation of this plasticity; these include melatonin, serotonin and neuropeptide Y (NPY). NPY originates in the retinoreceptive cells of the intergeniculate nucleus of the thalamus; these cells innervate the SCN via the geniculohypothalamic tract, where they may act as a link between visual cues and circadian rhythms. Previous evidence suggests that NPY microinjected into the SCN *in vivo* or *in vitro* can shift the phase of the SCN circadian rhythm. In the present experiments we have used the multi-unit recording technique to examine the effects of NPY and receptor-specific NPY analogs on circadian discharge rhythms in the rat SCN *in vitro*.

SCN slices were perfused on day 1 with 1.0  $\mu$ M NPY, 1.0  $\mu$ M [Leu<sup>1</sup>, Pro<sup>34</sup>]-NPY (a Y1 agonist), 1.0  $\mu$ M NPY fragment 13-36 (a Y2 agonist) or vehicle from circadian time (CT) 7.5-8.5. Electrical activity was recorded for 36-48 hr., and the peak of the discharge rhythm on day 2 was calculated. NPY and NPY fragment 13-36 significantly advanced the peak of the SCN rhythm relative to vehicle and [Leu<sup>1</sup>, Pro<sup>34</sup>]-NPY (ANOVA and Fisher's test,  $p < 0.05$ ). The time for the peak for each treatment in CT was 5.74 $\pm$ 0.22 vehicle; 5.56 $\pm$ 0.28 [Leu<sup>1</sup>, Pro<sup>34</sup>]-NPY; 4.62 $\pm$ 0.35 NPY; 4.59 $\pm$ 0.25 NPY fragment 13-36. These data demonstrate that NPY exerts its effects on the circadian electrical activity rhythm in the SCN by activation of the Y2 receptor, and further demonstrate the utility of the multi-unit recording method.

## 65.7

**PROMINENT ROLE OF SLOWLY INACTIVATING SODIUM CURRENT IN SPONTANEOUS FIRING AND MEMBRANE POTENTIAL OSCILLATIONS IN RAT SUPRACHIASMATIC NUCLEUS.** C.M.A. Pennartz\* and A.M.S. Geurtsen. Netherlands Inst. Brain Res., Grad. Sch. Neurosciences Amsterdam, Amsterdam, the Netherlands.

The biological clock is located in the suprachiasmatic nucleus (SCN). Neurons in this nucleus exhibit a circadian rhythm in spontaneous firing rate. To investigate the physiological basis of this rhythm, it is of paramount importance to unravel the ionic mechanisms governing spontaneous firing in SCN. Firing patterns were studied by whole-cell patch-clamp recording in transversal slices (250  $\mu$ m) using Kgluconate-filled pipettes with resistances of 4-8 M $\Omega$ . Biocytin staining of the recorded neurons revealed a diversity of morphology, including monopolar and bipolar cell types. In all cells, spontaneous or evoked action potentials were consistently preceded by depolarizing ramps (spike prepotentials). These ramps were shown to be Na<sup>+</sup> dependent and sensitive to tetrodotoxin (0.5-1  $\mu$ M). The Na<sup>+</sup> current underlying depolarizing ramps was activated well below firing threshold (-70 to -60 mV) and activated and inactivated more slowly than the fast Na<sup>+</sup> current. However, inactivation proceeded much more rapidly than has been observed for the persistent Na<sup>+</sup> current in neocortex. When fast action potentials were suppressed by lidocaine (0.5-1.0 mM), we observed damped oscillations in membrane potential. These autorhythmic oscillations were shown to involve the slowly inactivating Na<sup>+</sup> current and a TEA-sensitive K<sup>+</sup> current. Nimodipine (2-8  $\mu$ M) failed to affect the oscillations. Our observations strongly implicate the slowly inactivating Na<sup>+</sup> current in ionic mechanisms governing spontaneous firing in suprachiasmatic nucleus neurons. In addition, the Na<sup>+</sup> current mediating spontaneous firing in SCN presents novel kinetic characteristics and may be unique to neurons of the biological clock.

## 65.4

**REGULATION OF THE DROSOPHILA PROTEIN TIMELESS INDICATES A MECHANISM FOR RESETTING THE CIRCADIAN CLOCK BY LIGHT.** Melissa Hunter-Ensor, Andrea Ousley\*, Amita Sehgal. Dept. of Neuroscience and Ctr for Sleep and Respiratory Neurobiology, University of PA Medical School, Phila., PA 19104.

In *Drosophila melanogaster*, our understanding of the generation of circadian rhythms has until recently depended on the first circadian rhythm gene, *period* (*per*). With the identification of *timeless*, a new clock gene that disrupts locomotor as well as molecular rhythms, we are now fitting *tim* into what had previously been a *per*-based model of the clock. We recently raised an antibody against a bacterially expressed fragment of TIM, and examined the spatial and temporal regulation of TIM expression. Like *per*, *tim* mRNA cycles in a wild type background with peak levels observed early in the evening. TIM protein levels also cycle in nuclei, rising late at night while PER levels are also rising. Peak levels of TIM lag behind the *tim* mRNA peak by several hours. TIM is expressed in those cells that have been shown to express PER. TIM is not observed in the photoreceptor nuclei of *per<sup>0</sup>* flies, suggesting that PER is required for the nuclear localization of TIM. TIM staining is not observed in *tim<sup>0</sup>* flies. The phase of TIM cycling suggested that TIM levels were reduced at the end of the night, considerably earlier than the decrease in PER levels. We found that pulses of light at different times of day result in the lowering of TIM levels. This was assayed by immunocytochemistry as well as by western blot analysis. We suggest that the mechanism for TIM's response to light is post-transcriptional, as we observed no significant changes in *tim* or *per* RNA in response to light treatment. These findings suggest a mechanism for resetting the circadian clock by light.

**EVIDENCE THAT CIRCADIAN AND VISUAL SIGNALS FROM THE SCN AND THE LGN ARE INTEGRATED ON NEUROENDOCRINE DOPAMINE CELLS IN THE RAT HYPOTHALAMUS.** T.L. Horvath\*. Yale University, Dept. of Ob/Gyn, New Haven CT, 06520.

Prolactin has been implicated to play a major role in light- or time-shift-induced physiological alterations in activities of mammals including humans. The key role of hypothalamic dopamine and the circadian visual system (SCN and IGL) in the regulation of prolactin secretion have been recognized. However, the signaling pathway via circadian and visual signals reach the lactotrophs in the anterior pituitary is ill-defined. We hypothesized that direct connections may exist between the SCN or the intergeniculate leaflet (IGL) of the LGN and neuroendocrine dopamine cells of the hypothalamus. **Experimental:** The combination of anterograde (PHA-L) and retrograde (fluorogold) tracing techniques and immunocytochemistry employing ABC and PAP techniques and different color chromogens was used. PHA-L was injected into either the SCN or the IGL, in parallel with intraperitoneal administration of fluorogold to label neuroendocrine (median eminence-projective) cells. In the anteroventral periventricular nucleus, medial preoptic area, periventricular and arcuate nuclei, retrogradely labeled tyrosine hydroxylase-immunoreactive (putative dopaminergic) cells were frequently found to be targeted by PHA-L labeled SCN and IGL efferents. These cells also received a massive VIP and NPY innervation, neuropeptides that are characteristics of SCN and IGL efferents, respectively. Electron microscopic examination confirmed the putative connections to be synaptic. **Conclusion:** These experiments provided the first evidence that the SCN and IGL have direct efferents onto neuroendocrine dopamine cells which may underlie the time- and light-dependent activity of prolactin secretion. Furthermore, it is suggested that the IGL may not only subserve the SCN in supporting circadian activities, but, can also convey non-circadian visual signals directly to neuroendocrine cells. **INTERGENICULATE LEAFLET (IGL) AND VENTRAL LATERAL GENICULATE (VLG) PROJECTIONS IN THE RAT.** R.Y. Moore\*, M.M. Moga And R. Weis. Department of Psychiatry and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261.

The mammalian lateral geniculate nucleus has two subdivisions that derive from ventral thalamus, the IGL and VLG. The IGL is now recognized to be a component of the circadian timing system whereas the VLG has long been considered involved in visual reflex and oculomotor integration. In this study, we analyzed IGL and VLG projections in the rat using anterograde (PHA-L) and retrograde (HRP) transport.

The IGL and VLG have a pattern of partially separate and partially overlapping efferent projections. Both project along a dorsal pathway over the surface of the thalamus and a medial pathway to innervate the zona incerta, dorsal hypothalamic area and midline thalamus. IGL, but not VLG, axons terminate in the paraventricular thalamic nucleus. Both project through a caudal pathway to the lateral posterior nucleus, pretectal area, superior colliculus, periaqueductal gray and posterior hypothalamic area. The VLG projects selectively to the lateral tegmental field of the midbrain, interpeduncular nucleus, pontine gray, median raphe, parabrachial area, Kolliker-Fuse nucleus and inferior olivary complex. The IGL projects selectively through the geniculohypothalamic tract to the suprachiasmatic nucleus (SCN), retrochiasmatic area, subparaventricular zone, anterior hypothalamic area, medial preoptic area and organum vasculosum lamina terminalis. Thus, the IGL projects to the circadian pacemaker (SCN) and areas to which it projects whereas the VLG projects predominantly to visual and motor control areas. Supported by NS 16304.

A CIRCADIAN RHYTHM IN LUMINESCENCE IN SUPRACHIASMATIC NUCLEUS CULTURES FROM A *FOS/LUCIFERASE* TRANSGENIC MOUSE. Michael E. Geusz<sup>1</sup>, Steve A. Kay, Colin Fletcher, Gene D. Block, Neal G. Copeland, Nancy A. Jenkins, and Richard N. Day. NSF Center for Biological Timing, University of Virginia, Charlottesville, VA 22903 and Mammalian Genetics Laboratory, ABL-Basic Research Program, NCI-Frederick Cancer Research and Development Center 21702.

Entrainment of the circadian pacemaker in the suprachiasmatic nucleus (SCN) to light/dark cycles may involve the immediate-early gene *c-fos*. Light pulses applied during the subjective night phase shift the pacemaker and induce expression of *c-fos* in the SCN. To examine pacemaker control of *c-fos*, we generated a transgenic mouse expressing the human *c-fos* promoter coupled to the firefly luciferase gene. SCN sections from these mice were maintained in a Hepes-buffered medium with luciferin. Continuous luminescence recordings were made with either a luminometer or a photon-counting module. Sections containing the SCN, but not tissue from other regions, showed near-24 h luminescence rhythms lasting up to five cycles with an average period of  $22.9 \pm 0.76$  h (s. e. m.,  $n=6$ ) as analyzed by periodogram. In control experiments, SCN explants from a second transgenic mouse expressing the luciferase gene driven by the cytomegalovirus promoter demonstrated high-level luminescence that was not circadian. ( $n=5$ ). Brain slice cultures from the *fos/luciferase* mouse were also imaged to determine the distribution of the transgene's expression. Luminescence was detected in the supraoptic and paraventricular nuclei of the hypothalamus as well as in the SCN. These studies demonstrate that rhythmic expression of the *c-fos* gene promoter in the SCN can be monitored non-invasively in real time in living tissue. RESTORATION OF A DIURNAL CORTICOSTERONE RHYTHM IN CRH DEFICIENT MICE BY A CONSTANT INFUSION OF CRH. S. Weninger<sup>1,2</sup>, L. Muglia, L. Jacobson, D. S. Bae<sup>2</sup>, C. Luedke, and J. A. Majzoub<sup>1</sup>. Division of Endocrinology, Childrens Hospital, <sup>1</sup>Program in Neuroscience, Harvard Medical School, <sup>2</sup>Howard Hughes Medical Institute, Boston, MA 02115.

The hypothalamic-pituitary-adrenal (HPA) axis of most mammals exhibits circadian rhythmicity. The molecular basis of this rhythm is not known, although the hypothalamus and pituitary, but not the adrenal, are required for its generation. Recently, a line of CRH knockout (KO) mice has been generated in our laboratory. To determine the role of CRH in the circadian rhythm of the HPA axis, we have monitored morning (9AM) and evening (6PM) levels of corticosterone (cort) and ACTH in CRH KO and wild-type (WT) mice. Mice were maintained on a 12:12 light:dark cycle with lights on at 7AM. Although both genotypes have similar basal AM levels of cort ( $2\mu\text{g/dL}$ , vs.  $2.5\mu\text{g/dL}$  in WT and KO respectively), the CRH KO animals lack the PM rise in cort seen in WT mice ( $12\mu\text{g/dL}$ ). To determine if the rhythm in ACTH is also absent in CRH KO animals, ACTH levels were measured in adrenalectomized WT and CRH KO animals. Again, CRH KO animals had no detectable ACTH diurnal rhythm, whereas levels in WT animals rose 2-fold in PM vs. AM. To test the hypothesis that constant CRH replacement can restore the circadian cort rhythm, we chronically infused CRH using Alzet osmotic minipumps at doses of 0.1, 0.25, 0.5, or 1.0  $\mu\text{g/day}$ . All but the lowest dose tested were able to restore the diurnal rhythm, measured at 3 and 6 days following pump implantation ( $p < 0.02$  at 2 highest doses measured after 6 days). These data demonstrate that CRH is required for normal diurnal variation in ACTH and cort levels. Since CRH is believed to be necessary for ACTH synthesis, we postulate that tonic CRH may act to maintain corticotroph ACTH stores, and that other secretagogues, possibly such as vasopressin, actually drive the circadian rhythm in ACTH release. Supported by NIH, HHMI, NARSAD and Burroughs Wellcome.

## 65.10

INDIVIDUAL CELLS IN CULTURED MOUSE SCN EXPLANTS EXPRESS CIRCADIAN RHYTHMS IN FIRING RATE FOR WEEKS ON A MULTIMICROELECTRODE PLATE

Erik D. Herzog<sup>\*</sup>, Michael E. Geusz, Sat Bir S. Khalsa and Gene D. Block. NSF Center for Biological Timing, Univ. of Virginia, Charlottesville

Recent evidence strongly suggests that the mammalian suprachiasmatic nucleus (SCN) is comprised of multiple circadian oscillators. However, it is unknown which circadian properties are intrinsic to individual cells or to cellular interactions. As an initial step towards characterizing circadian properties in the SCN, we record extracellular spikes from cultured explants.

From neonatal C57BL mice (postnatal days 2-6), we grew 300  $\mu\text{m}$  sections of individual or paired SCN onto an array of 64, embedded microelectrodes. The multimicroelectrode plate (MMEP) offers a sterile and stable environment for long-term recording of extracellular action potentials. Over the next 2-3 weeks, the explants spread to cover approximately twice their area while retaining the gross appearance of the SCN *in vivo*. After as little as one week (earliest time tested) or as long as 7 weeks (latest time tested) in culture, SCN neurons exhibited spontaneous action potential activity on as many as all 64 electrodes. We discriminated the spikes on as many as 8 electrodes simultaneously and often saw synchronous bursting across several electrodes. In some, but not all cases, spike activity was rhythmic. In cases where we recorded from the same cell for at least 3 days, periods averaged 23.9 hours ( $\pm 0.7$  s.d.) and ranged from 22.4 to 25.0 h ( $n=13$  cells, 6 explants). The longest recording to date was terminated after 25 days while impulse activity continued. Supported by: NSF Center for Biological Timing

## 65.12

GENOTYPIC DIFFERENCES IN THE ONTOGENY OF CIRCADIAN RHYTHMICITY IN HONEY BEES. D. Moore<sup>1</sup>\*, T. Gray<sup>2</sup>, and G.E. Robinson<sup>2</sup>. <sup>1</sup>Dept. of Biological Sciences, East Tenn. State Univ., Box 70703, Johnson City, TN 37614. <sup>2</sup>Dept. of Entomology, Univ. of Illinois, Urbana, IL 61801.

A major factor contributing to the division of labor within the honey bee colony is age polyethism, in which the behavioral tasks performed by individual worker bees gradually change with age. Genotypic differences exist for the rates at which workers advance through this behavioral development which begins with a progression of in-hive duties and ends with the achievement of forager status. As a first step in assessing the possible role of circadian rhythmicity within the age-related development of behavior, we monitored locomotor activity in newly emerged, individually isolated worker bees under constant conditions (DD, 25°C). "Fast" and "slow" genotype bees were taken from different single-patrilines colonies in the field. Prior screening established that slow colony bees required significantly more days to become foragers than did fast colony bees.

All bees, regardless of genotype, were arrhythmic immediately after emergence. However, fast bees developed a circadian rhythm of locomotor activity significantly sooner than did the slow bees:  $5.6 \pm 0.6$  days vs.  $9.0 \pm 0.6$  days ( $p < 0.001$ ). The free-running period was significantly shorter ( $p < 0.01$ ) in the fast bees ( $23.3 \pm 0.3$  h,  $N = 22$ ) than in the slow bees ( $24.2 \pm 0.2$  h,  $N = 33$ ). The circadian period and the time to onset of rhythmicity (a once-in-a-lifetime event, occurring from 3 to 16 or more days post-emergence) were significantly correlated ( $p < 0.01$ ). Furthermore, a significant difference ( $p < 0.001$ ) between the two genotypes was also observed for yet another temporal pattern, hour-to-hour locomotor activity. Our results demonstrate: (a) the existence of an ontogeny of circadian rhythmicity in this species; (b) genotypic differences for the development of rhythmicity; and (c) three vastly different temporal processes that tend to vary with behavioral development time. ## NEUROETHOLOGY: SONGBIRDS I

## 66.1

A NEW SOURCE OF AUDITORY INPUT TO THE SONGBIRD ANTERIOR FOREBRAIN PATHWAY. G.E. Vates<sup>\*</sup>, D.S. Vicario, & F. Nottebohm. The Rockefeller University, New York, NY 10021.

Learned vocalizations in songbirds are produced by a specialized vocal control pathway in the forebrain that includes HVC and its projection to RA. HVC also projects to the anterior forebrain pathway, which is necessary for vocal learning during development but seems to play little role in adult vocal production. Song learning depends on auditory information both to memorize the tutor's song and to guide sensorimotor practice that leads to song imitation. Auditory input is thought to enter the vocal system at the level of HVC.

We have now recorded single and multi-unit activity in one anterior forebrain nucleus, LMAN, in response to auditory stimuli (bird's own song played forward and in reverse, conspecific songs, long calls, and synthetic sounds) in awake adult male zebra finches. Responses were seen to all stimuli, but were strongest for the bird's own song. Auditory responses showed a pattern of early bursts (latency 15-25ms) and tonic elevation of activity that long outlasted the stimulus. Because the response latency was the same or less than that seen in HVC, we tested HVC's contribution to these responses by lesioning HVC either reversibly with lidocaine or permanently by bilateral suction. Auditory responses were still seen in LMAN in the complete absence of HVC.

These results demonstrate the existence of a short-latency auditory input to LMAN that does not depend on HVC. We are now working to identify its anatomical basis. LMAN appears to be a convergence point where 3 different sources of information can be combined: 1) the HVC-X-DLM-LMAN pathway carrying auditory and/or motor signals; 2) the recently demonstrated RA-DLM-LMAN projection carrying an "efferent copy" of motor commands; and 3) an undescribed pathway carrying short-latency auditory input that has not been processed in the vocal motor pathway. ## 66.2

INTERHEMISPHERIC COORDINATION OF PREMOTOR NEURAL ACTIVITY DURING SINGING BY ZEBRA FINCHES. E. T. Vu<sup>1</sup>\*, M. F. Schmidt<sup>2</sup>, and M. E. Mazurek<sup>2</sup>. <sup>1</sup>Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013 & <sup>2</sup>Division of Biology, Caltech, Pasadena, CA 91125.

Unilaterally stimulating the forebrain nucleus HVC during singing alters the temporal pattern of the song of zebra finches, suggesting that neurons in HVC participate directly in specifying the song temporal structure (Vu et al., *J. Neurosci.* 14: 6924, 1994). Electrical stimulation of one HVC (on either side) would not have led directly to perturbation of neural activity in the contralateral HVC because each HVC does not project directly to the contralateral HVC. However, if the patterns of neural activity in both HVC's contribute to the song temporal pattern, then the rapidly altered song pattern following unilateral HVC stimulation suggests that the activity pattern in the contralateral HVC was also altered by the electrical stimulus.

To confirm this prediction, we implanted chronic microelectrodes in both HVC's of adult male zebra finches. We then recorded multi-unit neural activity in one HVC during singing and occasionally applied electrical stimuli to the contralateral HVC. In 4 out of 4 animals, the pattern of activity in HVC was altered every time the song pattern was altered by stimulation in the contralateral HVC. Following the brief stimulus, neural activity in the unstimulated HVC was first suppressed and then resumed in synchrony with the new song pattern. The neural suppression was not always immediate: elevated neural activity sometimes persisted for 10-70 ms after the end of the stimulus before being suppressed.

These results strongly suggest that the output of song premotor areas in the forebrain is continuously monitored and that an active mechanism exists for resynchronizing the outputs from the two hemispheres whenever a mismatch in their timing signals occurs. This would require feedback pathways to forebrain song control nuclei from lower stations of the motor pathway.

## 66.3

**BIRDS' EXPERIENCE OF THEIR OWN SONGS SHAPES THE AUDITORY SELECTIVITY IN THE ANTERIOR FOREBRAIN OF JUVENILE ZEBRA FINCHES** M.M.Solis\* and A.J.Doupe. Neuroscience Graduate Program, Departments of Physiology and Psychiatry, UCSF, San Francisco, CA 94143.

Auditory experience of both tutor and bird's own plastic song is crucial to song learning. The anterior forebrain pathway (AFP) may process this auditory information, since it is required for normal song acquisition, and contains auditory neurons throughout song development. AFP neurons also become selective for bird's own song during song learning, preferring it to conspecific song and to the reversed version of bird's own song (Doupe 1996). By an intermediate stage of learning (60d), many AFP neurons are already song and order selective, but often respond equally well to both the juvenile song and tutor song. These response properties could reflect experience of both of these stimuli, or might simply result from acoustic similarity between them.

In order to minimize the similarity that usually develops between a bird's own song and that of its tutor, juvenile male birds with highly abnormal song were produced by sectioning the tracheosyringeal (ts) nerve bilaterally before the onset of vocalization. At 60d, these birds sang temporally patterned series of harmonic stacks. Single units were recorded in two AFP nuclei, LMAN and X, of these 60d birds. The stimuli presented included the bird's ts cut plastic song (BOS), tutor, and conspecific songs. Some neurons were both song and order selective for BOS, responding more to it than to all other song stimuli. Despite obvious acoustic differences between BOS and tutor song, other neurons still responded equally to these two stimuli. Some of these neurons preferred tutor over conspecific song, yet lacked order selectivity for tutor song; others were untuned, having similar responses to all song stimuli.

The existence of song and order selectivity to the unnatural ts cut songs demonstrates that a bird's experience of its own vocalizations can shape the selectivity of neurons in the AFP, as is true for HVC (Volman 1993). Neurons tuned in this way could provide information to the bird about its developing vocalizations during sensorimotor learning. Responses to tutor song may reflect the broad selectivity of neurons in younger birds, residual similarity between BOS and tutor song, or the creation of selectivity in the AFP by both stimuli. ## 66.5

**METABOTROPIC GLUTAMATE RECEPTORS HYPERPOLARIZE NEURONS IN NUCLEUS HVC OF THE ADULT ZEBRA FINCH.** D. J. Perkel\* and M. E. Schmidt. <sup>1</sup>Dept. Neuroscience, University of Pennsylvania, Philadelphia, PA 19104 and <sup>2</sup>Division of Biology, Caltech, Pasadena, CA 91125.

In nucleus HVC of the songbird brain, glutamate excites neurons by activation of ionotropic glutamate receptors of the AMPA and NMDA types. We now report that activation of metabotropic glutamate receptors (mGluRs) has the unusual action of hyperpolarizing HVC neurons.

Intracellular recordings (pipettes filled with KAc) were obtained from HVC neurons in coronal or parasagittal brain slices (400  $\mu$ m thick) prepared from adult zebra finches and maintained *in vitro*. Bath application of the mGluR agonist 1S,3R-aminocyclopentane dicarboxylic acid (ACPD; 100  $\mu$ M) hyperpolarized most HVC neurons from resting potential by  $9.1 \pm 3.5$  mV ( $n = 10/12$ ). One cell showed no potential change and one cell was depolarized by 6 mV. The hyperpolarizing action persisted in the presence of a cocktail of tetrodotoxin (1  $\mu$ M) and glutamate and GABA receptor antagonists (CNQX, APV, bicuculline methiodide and picrotoxin), suggesting a direct action on the impaled cell and not an indirect effect of network activity. The mGluR antagonist MCPG (500  $\mu$ M) blocked the ACPD-induced hyperpolarization. An increase in conductance accompanied the hyperpolarization, likely reflecting opening of potassium channels.

The ACPD-induced hyperpolarization resembles the response to the GABA<sub>B</sub> receptor agonist baclofen, suggesting that both are mediated by increased K conductance. In most other neurons examined, mGluR activation depolarizes neurons by reducing K conductance or increasing nonspecific cation conductance. However, ACPD-induced hyperpolarization similar to that observed here, due to increased K conductance, has been observed in the mammalian amygdala. The response in zebra finch HVC could reflect an unusual inhibitory role of glutamate.

## 66.7

**LOCAL INHIBITORY NETWORKS IN THE ZEBRA FINCH RA REVEALED WITH DUAL INTRACELLULAR RECORDINGS AND PHOTOSTIMULATION.** J.E. Spiro\*, M.B. Dalva and R. Mooney. Dept. Neurobiology, Box 3209, Duke Univ. Med. Ctr. Durham, NC 27710.

Projection neurons (PNs) of the forebrain song control nucleus (SCN) RA are the vocal premotor neurons for learned song. They receive excitatory synaptic inputs from two other forebrain SCN, HVC and L-MAN, but less is known about the synaptic connections intrinsic to RA. To characterize how these intrinsic connections might influence RA's output during singing, we mapped them with intracellular recordings and scanning laser photostimulation techniques in brain slices made from male zebra finches.

Dual intracellular recordings made from both local and distant pairs of PNs (as confirmed by Neurobiotin (NB);  $n=18$  pairs) showed that although they spontaneously fired action potentials (APs), these APs were not synchronized, even though they were similar in frequency (ca. 20 Hz). Furthermore, synaptic coupling between these pairs of cells was not observed electrophysiologically ( $n=10$ ), nor did NB reveal dye-coupling. To map local inputs onto these cells, we used the focal uncaging of glutamate via a UV laser combined with whole cell recordings in voltage clamp conditions to detect evoked synaptic currents (PSCs). Strong inward PSCs ( $V_m = -60$  mV) could be elicited from PNs by photostimulation of cells in a ring-like zone around the soma ( $n=6$ ). These PSCs reversed between -50 and -30 mV; similar spontaneous PSCs in other PNs were blocked by picrotoxin (50  $\mu$ M), suggesting that they arose from GABAergic interneurons. Current clamp recordings coupled with focal puffer-pipette applications of glutamate within RA showed that evoking this inhibition could silence PNs' spontaneous APs for tens to hundreds of milliseconds. Since stimulating HVC efferents often produced a similar effect, RA's local inhibitory network might provide one way that RA's output is coordinated by HVC during singing.

## 66.4

**SPECTRAL AND TEMPORAL SENSITIVITY OF AUDITORY NEURONS OF NUCLEUS HVC IN THE ADULT MALE ZEBRA FINCH.** E.E. Theunissen\* and A.J.Doupe. Depts of Psychiatry and Physiology, UCSF, San Francisco, CA 94143.

Auditory neurons in nucleus HVC have been shown to respond selectively to the bird's own song (BOS) in contrast to other complex auditory stimuli such as conspecific songs or the BOS played in reverse. This selectivity emerges during development and song learning, and it has been postulated that these highly selective auditory neurons are part of the sensory feedback pathway required in the learning task. To begin to elucidate the potential role of these neurons in song recognition, we systematically investigated their tuning to the quality of the BOS along spectral and temporal dimensions.

To do so, we synthesized artificial versions of the BOS with different degrees of spectral and temporal degradation. We decomposed the waveform of the original song into a complete set of 120 band-passed signals (120 signals of 70 Hz bandwidth between 500 and 8000 Hz). Each band-passed signal was further described by a carrier frequency modulated by a low frequency amplitude envelope and an instantaneous phase. The spectral quality of the song was degraded by averaging the amplitude envelope across a larger and larger number of neighboring frequency bands. The temporal quality was degraded by randomizing the phase of the carrier frequency for all frequencies above a progressively lower cutoff.

HVC neurons showed a very high sensitivity to song degradation along these dimensions. In particular, the responses to synthesized song with correct amplitude envelopes but random phase were greatly reduced and often not significantly different from background; preliminary results indicate that the phase of the carrier must be preserved for frequencies below 4 KHz. These results suggest that the exact natural spectral and temporal qualities of a song are essential for the selectivity seen in HVC neurons in adult birds. Investigating neural responses to systematic song alterations along other parametric dimensions, such as those that may be used to distinguish between similar natural songs, will help in further characterizing the tuning of these neurons and their potential role in song discrimination.

## 66.6

**Neural Responses to Auditory Feedback During Singing in Field L of Adult Zebra Finches.** Marc F. Schmidt\*. Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

Birdsong is a highly stereotyped behavior that is learned by adjustment of vocal output to a memorized song template by way of auditory feedback. Because song learning involves the interaction of vocal motor output and auditory feedback, a characterization of the relationship between these two events is critical for understanding the neural bases of song learning. In this study, we have recorded from awake freely moving adult male zebra finches and characterized the temporal relationship between song pre-motor activity in nucleus HVC and neural responses to that vocalization in Field L. In addition, because it has been reported that auditory responses in nucleus HVC of adult song birds become inhibited during song and following vocalization (McCasland and Konishi, 1981), we also asked whether this inhibition is restricted to HVC or whether it occurs in auditory stations afferent to HVC. Our results indicate that neurons in all three subdivisions of Field L (L1, L2 and L3) have the capacity of responding to auditory feedback of the bird's own vocalization and neural responses in Field L typically occur 10-15 msec after vocal output. Pre-motor neural activity in nucleus HVC generally precedes the onset of vocalization by 35-40 msec implying that the time delay between the onset of syllabic pre-motor activity and auditory feedback of that same syllable in Field L ranges from 45 to 60 msec. These results demonstrate that higher auditory centers such as Field L are able to monitor the bird's own vocal output and suggest that vocalization-induced inhibition of auditory feedback in adult birds likely first occurs at the level of either Field L or HVC and not in more afferent auditory stations. Supported by NIH Grant NRSA-DC00125

## 66.8

**INTRINSIC AND SYNAPTIC PROPERTIES OF L-MAN NEURONS IN THE ADULT MALE ZEBRA FINCH** E. Livingston\* and R. Mooney. Department of Neurobiology, Box 3209, Duke University Medical Center, Durham, NC 27710.

The lateral part of the magnocellular nucleus of the anterior neostriatum (L-MAN) plays a pivotal role in the normal development of learned song in the zebra finch. As a first step towards a better understanding of its role in this process, we have used intracellular recording techniques both in acute brain slices and *in vivo* to study the electrophysiological and morphological properties of L-MAN neurons in the adult male zebra finch (>90 days posthatch).

L-MAN neurons have input resistances between 35-80 M $\Omega$ , with typical resting potentials between -70 and -85 mV, and fire trains of action potentials upon DC depolarization that show spike frequency adaptation over the course of several hundreds of milliseconds. Intracellular Neurobiotin staining revealed that many of these cells (27/98) have the morphological features of projection neurons, elaborating not only local axon collaterals but also projection axons that bifurcate, with one branch coursing ventral towards area X, and the other branch traveling caudal in the lamina hyperstriatica (LH), which is known to be the main route by which L-MAN axons travel to reach their synaptic targets in the robust nucleus of the archistriatum. L-MAN neurons are spontaneously active both *in vitro* and *in vivo*, displaying periodic bursts of synaptic activity. These synaptic bursts are present in the majority of cells that we have recorded from, and possess both excitatory and inhibitory components. Pharmacological studies suggest that these synaptic bursts are composed of inhibitory and excitatory components. In addition, electrical stimulation in areas ventral to L-MAN can drive both excitatory and inhibitory responses, as can antidromic activation via electrical stimulation of L-MAN projection axons in the LH.

## 66.9

INTRACELLULAR CHARACTERIZATION OF ELECTROPHYSIOLOGICAL PROPERTIES AND SYNAPTIC RESPONSES IN THE ZEBRA FINCH SONG NUCLEUS LMAN. C.A. Bostiger\* and A.J. Doupe. Neuroscience Graduate Program, Keck Center, Depts. of Psychiatry and Physiology, UCSF, San Francisco, CA 94143-0444.

In the zebra finch (*Taeniopygia guttata*), LMAN is thought to play a vital role in song learning. Lesions of this nucleus in juveniles severely disturb song learning. Furthermore, during learning, auditory LMAN neurons progress from being non-selective to a state of strong preference for the bird's own song. It is therefore of interest to investigate the nature of cellular changes occurring in LMAN during that period. As an initial step towards identifying these changes, we have used *in vitro* slice techniques to characterize the neurons in LMAN. Acute brain slices were prepared from zebra finches in the early stages of sensory learning (18-25d), when LMAN neurons are broadly responsive to auditory stimuli. Electrophysiological properties of LMAN neurons were assessed with intracellular recording techniques; the location of some neurons was verified by intracellular injection of biocytin. The cells were characterized by membrane resting potentials of  $62 \pm 5$  mV, input resistances of  $116 \pm 43$  M $\Omega$ , and membrane time constants of  $31 \pm 15$  msec ( $n=25$ ). Current-voltage and frequency-intensity relationships were examined by applying 500 msec square current pulses of variable amplitude. Cells displayed an approximately linear current-voltage relationship over the subthreshold range examined. During suprathreshold current pulses the frequency of firing adapted markedly; mean firing rates increased monotonically with suprathreshold current intensity. These input-output relationships resemble those of neocortical regular-spiking neurons.

Synaptic responses of LMAN neurons were also examined by activating intrinsic inputs and inputs from the thalamic nucleus DLM. Responses displayed both excitatory and inhibitory components. The excitatory components of both local and thalamic input activation were almost entirely abolished by bath application of the NMDA-type and non-NMDA-type glutamate receptor antagonists D,L-APV (100 $\mu$ M) and CNQX (10 $\mu$ M). Further studies will compare cellular and synaptic properties of LMAN neurons at various time points during song acquisition and development of song-selectivity in LMAN.

Supported by the Searle Scholars Program and a UCSF Opportunity Fellowship.

## 66.11

AN ASSOCIATIONAL MODEL FOR SENSORIMOTOR LEARNING OF BIRDSONG. T.W. Troyer\*, A.J. Doupe and K.D. Miller. Keck Center for Integrative Neuroscience, Univ. of California, San Francisco CA 94143

Two hypotheses in the field of songbird learning locate sequence generation in HVC and the sensory template in the Anterior Forebrain Pathway (AFP).

However, there is no direct anatomical connection between the AFP and HVC, and auditory feedback delay is likely to cause reinforcement signals to reach RA in the motor pathway during the subsequent burst of motor activity. An hypothesis of the sensorimotor phase of learning is outlined in which simple associational and reinforcement learning accomplish the task given known birdsong anatomy. Feedback delay is addressed by Hebbian association of song premotor activity in RA-projecting HVC neurons (HVC\_M) with the resulting sensory activity in the AFP-projecting (HVC\_S) neurons, hypothesized to receive most of the auditory feedback to HVC. This "efficiency copy map" or "forward model" within HVC is learned using direct auditory feedback without reference to the template. The AFP can then use this sensory prediction to reinforce the proper connections within RA without waiting for the auditory feedback signal. This first stage in the hypothesis is supported by a network model that learns template syllable representations, encoded as random activity patterns in RA. We further hypothesize that sequence generation results from reciprocal sensory->motor->sensory activity within HVC.

This framework constitutes a testable hypothesis concerning the interplay of motor and sensory information in the song system and makes specific anatomical and behavioral predictions. *McDonnell-Pew Prog. in Cognitive Neuroscience (TWT); Searles Scholars' Prog. and Lucille P. MECHANISMS UNDERLYING BINAURAL PHENOMENA IN BUDGERIGARS (*Melopsittacus undulatus*). M.L. Dent, O.N. Larsen\* & R.J. Dooling. Dept. of Psychology, University of Maryland, College Park, MD 20742.

The existence of an interaural pathway in birds has motivated a considerable amount of research on the mechanisms of avian hearing, particularly those related to sound localization. Poor high frequency hearing in birds and small interaural distances have implicated the interaural canal as a mechanism by which sound may propagate from one ear to the other. Inherently, this makes the ears directional pressure difference receivers. Changes in middle ear pressure have consequences for frequency responses of the eardrums and the directionality of the ears. The pressure changes may also affect the efficacy of masking noise and the susceptibility to damage from acoustic overexposure. In a series of experiments on 5 species of birds, only budgerigars show evidence of pressure changes in response to external sounds-evidence of a middle ear muscle reflex. The shape of this function is remarkably similar to the shape of the audibility function measured behaviorally in this species.

In spite of their small heads budgerigars show a significant binaural masking release, especially at low frequencies. These results suggest that budgerigars may use their interaural pathways to increase signal-to-noise ratios when signal and noise are spatially separated. Intercranial air pressure may play a more significant role in avian hearing than heretofore realized.

AVIAN INSPIRATORY PREMOTOR NEURONS: CONNECTIONS WITH RESPIRATORY AND VOCAL NUCLEI. H. Reinke and J.M. Wild\*, Dept. of Anatomy, Univ. of Auckland, Auckland, New Zealand.

To locate inspiratory motor and premotor neurons that are possibly involved in vocal control, Mm. scalenus, levatores costarum and intercostales externi were injected with either cholera toxin B-chain (CTB) or WGA-HRP in pigeons, finches and budgerigars. The motoneurons were located in medial lamina IX of lower brachial segments and at the tip of the ventral horn of upper thoracic segments. Their dendrites ramified in the lateral funiculus and near the central canal. Following injections of either CTB or WGA-HRP in the lateral and ventral funiculi in pigeons, labeled neurons in the medulla formed predominantly contralateral dorsomedial and ventrolateral clusters that extended from nucleus retroambiguus to about 0.8 mm rostral to the obex. Extracellular single unit recordings primarily from the ventrolateral tegmentum at levels straddling the obex in all species revealed inspiratory related activity, with almost all units being of the decrementing type. Following iontophoretic injections of biotinylated dextran amine at the recording sites, labeled axons were observed primarily in the contralateral lateral funiculus, and at lower brachial and upper thoracic levels they terminated in close proximity to the CTB-labeled dendrites of inspiratory motoneurons. There were also projections to the column of Terzi. The same injections also revealed projections to XIIIs, and to and from other nuclei involved in respiratory-vocal control, viz. retroambiguus, the rostroventrolateral nucleus of the medulla, the ventrolateral parabrachial nucleus, and the dorsomedial nucleus of the intercollicular complex. No afferents were noted from pulmonary-recipient regions of nTS. Supported by grants from Whitehall Foundation, Inc. to JMW and the DFG to HR.

## 66.12

SOME OF THE TEMPORAL COMPLEXITY OF BIRD SONG MAY ARISE FROM NONLINEAR DYNAMICS OF THE SYRINX. M.S. Fee\*, B. Pearson, P.P. Mitra and B.I. Shraiman. Bell Laboratories, Lucent Technologies, Murray Hill, NJ 07974.

Within a single zebra finch song note, there is complex spectral and temporal structure. We have observed that during frequency swept notes, the fundamental frequency may exhibit sudden transitions that occur in less than one period of the fundamental (<1 ms). In cases we have studied, the fundamental frequencies before and after such transitions are related by small integer ratios, characteristic of a phenomenon in nonlinear dynamics known as mode locking. Furthermore, we have observed notes exhibiting an abrupt offset of alternate spectral lines, indicative of another phenomenon known as period doubling.

Recent advances in chronic neural recording in singing birds have made it possible to study the neural organization of song production. It is therefore essential to understand which aspects of bird song are intrinsic to the vocal apparatus, and which are controlled by the brain. We find it unlikely that the rapid transitions observed could be controlled overtly by neural activity. In support of this view, we have developed a simple mathematical model in which the tympaniform membrane undergoes nonlinear relaxational oscillations driven by the Bernoulli effect. The model demonstrates how slow changes in a parameter controlling the resonant frequencies of the model membrane produce sudden transitions in the observed oscillation spectrum.

To further develop and test models of the syrinx, we are investigating excised zebra finch syrinxes, which are readily induced to oscillate *in vitro* and exhibit spectral characteristics similar to those found in zebra finch song.

STUDIES OF VOCAL PRODUCTION IN BUDGERIGARS USING FOOD REWARD. K. Manabe and R.J. Dooling\*. Dept. of Psychology, University of Maryland, College Park, MD 20742.

Song learning in birds has led to a number of insights into the neurobiology of learning. Generally much more is known about vocal production than about auditory perception, yet the interaction between hearing and vocalization is the critical issue in understanding vocal development and selective vocal learning in birds. We performed a number of experiments to examine which features of calls can be modified and whether these birds monitor their vocal production by hearing as humans do.

Budgerigars (parakeets) are small Australian parrots capable of vocal learning throughout adulthood. In the present experiments, birds were trained to produce or modify their species-specific call using food reward. Budgerigars were trained to modify the spectro-temporal pattern of their calls as well as the intensity. In producing call variants of their species-specific calls in order to match a stored template, birds made changes in the overall frequency range as well as the duration of their species-specific calls. Birds also performed better when the template to be matched was played to the bird immediately prior to call production. In other experiments, call intensity was shown to vary as a function of level of background noise in the spectral region of species-specific calls. These results suggest that all features of species-specific contact calls in budgerigars are under voluntary control.

More dramatic effects on hearing from exposure to intense noise or from administration of ototoxic drugs also affected vocal production. Both noise exposures and injections of kanamycin decreased call production accuracy usually for a period of days to weeks. In most cases, call accuracy was restored before the auditory papillae were repaired through hair cell regeneration and before auditory sensitivity returned to normal. These results suggest that budgerigars can maintain and recover their vocal production accuracy by relying on other cues such as tactile and proprioceptive feedback.

## 67.1

**SEX ON STEROIDS: TESTOSTERONE CYPIONATE, STANOZOLOL, AND OXYMETHOLONE EFFECTS ON THE SEXUAL BEHAVIOR OF MALE RATS.**

**A.S. Clark\*** and **E.V. Harrold**. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

We have previously described the effects of the anabolic-androgenic steroid (AAS) compounds 17 $\alpha$ -methyltestosterone, methandrostenolone, and nandrolone decanoate on the sexual behavior of male rats. In this report, we extend our analysis to include testosterone cypionate, stanozolol, and oxymetholone. Three doses of each AAS were administered daily to a) intact male rats for 12 weeks and b) castrated male rats for 6 weeks. Sexual behavior was quantified weekly.

Testosterone cypionate, as expected, induced no behavioral deficits in intact males and effectively maintained sexual behavior in castrated males. In contrast, stanozolol and oxymetholone, at the highest doses administered, interfered with the expression of sexual behavior in intact males. Serum testosterone levels were also suppressed in males which received the high doses of stanozolol and oxymetholone. In castrated males, neither stanozolol nor oxymetholone effectively sustained sexual behavior throughout the 6 week testing period. These results illustrate that the bioactivity of individual AAS compounds falls along a continuum. Furthermore, human AAS abusers may expose themselves to side effects and health consequences which vary as a function of the dose and type of AAS they consume. Supported by NIDA-08574 to ASC.

## 67.3

**NEURAL AND BEHAVIORAL EFFECTS OF TESTOSTERONE ON THE SEXUAL BEHAVIOR OF CASTRATED MALE RATS.** **S. Centeno\***, **A. Jacques**, & **J.G. Pfaus**. CSBN, Department of Psychology, Concordia University, Montréal, QC, Canada H3G 1M8.

The present study was conducted to examine Fos activation in different brain regions during the return of appetitive and consummatory sexual behaviors in castrated male rats given testosterone (T) replacement. Intact Long-Evans male rats (N=80) acquired baseline rates of sexual behavior with receptive females in bilevel chambers prior to surgical castration. Following recovery, males were tested for sexual behavior in bilevel chambers once every 4 days until all sexual activity ceased. Males were then assigned to one of two T dose conditions, 30 or 50  $\mu$ g/day, and tested for the reemergence of sexual behaviors with receptive females at 4-day intervals in bilevel chambers. A progressive increase in the proportion of males showing conditioned level changing, pursuits, mounts, intromissions, and finally ejaculations, was observed over a 24-day period (7 test sessions), with the higher dose group showing a faster return. On each test day, 4 males from each group were selected randomly, perfused, and their brains prepared for Fos immunocytochemistry. Males in both groups showed progressive and significant increases in the number of Fos-positive cells in the mPOA that were correlated with the reemergence of level changes, mounts, and intromissions with ejaculation, respectively. Fos expression in other brain areas (n. accumbens, striatum, hypothalamus, medial amygdala, and ventral tegmentum) is currently being examined and will be reported. These data show that the mPOA is activated by both appetitive and consummatory aspects of male sexual behavior. Supported by NSERC of Canada (OGP-0138878).

## 67.5

**MATING-INDUCED FOS EXPRESSION IN MALE AND FEMALE MUSK SHREWS** **C.J. Gill\***, **W.J. Cholbi** and **E.F. Rissman**. Dept. of Biology, University of Virginia, Charlottesville, VA 22903

Neuronal activity, as indicated by Fos protein immunoreactivity (ir), is increased in specific brain areas after mating in several mammalian species. We examined the induction of neural Fos in the musk shrew, a species in which both female sexual behavior and ovulation are induced by exposure to a receptive male. Sexually inexperienced, 54 to 58 day old males (n=6) and females (n=7) were paired with receptive opposite sex individuals until one ejaculation occurred. Matched control animals (n=7, each sex) were placed alone in a clean cage with no exposure to opposite sex cues for an equivalent time. Experimental animals and their matched controls were perfused one hour after the mating and their brains processed for Fos-ir (Cambridge Research Biochemicals). Mated animals had significantly greater numbers of Fos-ir cells in the bed nucleus of the stria terminalis (BNST), the medial preoptic nucleus (mPOA) and the preammillary nucleus, with the number in the mPOA in mated males significantly greater than in mated females. No significant differences have been observed in Fos-ir in the ventral medial nucleus (VMN) or the medial amygdala. These data show that, like rats, but unlike the female ferret, another induced ovulator, stimulation received during mating increases c-fos activity in the mPOA and BNST of both males and females. Increased Fos-ir is observed in the VMN of females but not males an hour after mating showing a sex difference in c-fos activation in this region. Additionally, in four brains in each group processed for GnRH-ir and Fos-ir, we only rarely found cells double labeled for Fos and GnRH. Since female musk shrews mate when estrogen levels are low, this supports the hypothesis that steroid activation is necessary for Fos induction in GnRH cells. This work was supported by NIH NRSA 1F31MH10570-01A1 and NSF grant IBN 94-12605.

## 67.2

**FOS IMMUNOREACTIVITY IN MALE RAT BRAIN FOLLOWING EXPOSURE TO CONDITIONED AND UNCONDITIONED SEX ODORS.** **T.E. Kippin\***, **C. Manitt**, **S. Talianakis**, & **J.G. Pfaus**. CSBN, Department of Psychology, Concordia University, Montréal, QC, Canada H3G 1M8.

Previous research has shown that pairing an artificial olfactory stimulus (almond odor) with copulation produces a mate-choice preference for females bearing that odor over females without it. However, the neural processes underlying this conditioned effect are unknown. Accordingly, the present study examined the induction of Fos immunoreactivity (IR) in response to conditioned and unconditioned sexual odors. Training procedures were identical to those used in previous experiments: 9 trials at 4-day intervals in which sexually-naïve male Long-Evans rats were exposed either to estrous females with almond extract applied to their backs and anogenital regions (A+E) or to estrous females with distilled water applied to their backs and anogenital regions (E-alone). Fos IR was assessed in the brains of males from both groups 2 hr after presentation of almond, estrous, or no odors in bedding. The almond odor increased Fos IR in the nucleus accumbens and piriform cortex of A+E-trained, but not E-alone-trained males. A more complete analysis of the Fos induction in other brain regions will be presented. These data indicate that an odor paired with copulation is capable of inducing Fos within different brain regions. Supported by NSERC of Canada (OGP-0138878).

## 67.4

**FLUOXYTINE INHIBITION OF MALE RAT SEXUAL BEHAVIOR: REVERSAL BY OXYTOCIN.** **J.M. Cantor<sup>1,2\*</sup>**, **Y. Binik<sup>1</sup>**, & **J.G. Pfaus<sup>2</sup>**. <sup>1</sup>Dept. Psychol., McGill Univ. & <sup>2</sup>CSBN, Dept. Psychol., Concordia Univ., Montréal, Québec H3G 1M8 Canada.

In the first phase of the experiment, 40 sexually experienced, male Long-Evans rats were assigned to four groups and tested for sexual behavior in bilevel chambers once every 4 days. Rats received daily injections of fluoxetine (0, 1, 5, or 10 mg/kg, ip) for 11 experimental sessions. Each test of sexual behavior lasted 35 min and was scored for frequency and latency of level changes, mounts, intromissions, and ejaculations. Consistent with the effects reported for clinical use of fluoxetine in human males, fluoxetine reduced sexual excitement and decreased ejaculations in male rats. In the second phase of the experiment, the same rats were maintained on daily fluoxetine treatment at the same doses and tested in the same manner. However, 60 min before tests of sexual behavior, the neuropeptide oxytocin (200 ng, ip) or vehicle was administered in an A-B-B-A design. Oxytocin treatments reversed the inhibitory effects of chronic fluoxetine on sexual behavior. These data are consistent with the hypothesis that serotonin reuptake inhibitors (SRIs) interfere with sexual behavior by inhibiting the release of oxytocin during sexual behavior. Co-administration of SRIs with oxytocin or oxytocin agonists may therefore provide antidepressant action without antisexual side-effects. Supported by NSERC of Canada to J.G.P. (OGP-0138878)

## 67.6

**SEX DIFFERENCE IN STRIATED PENILE MUSCLES AND INNERVATING MOTONEURONS IN THE MUSK SHREW** **L.M. Freeman\*** and **E.F. Rissman**. Dept. of Biology, University of Virginia, Charlottesville, VA 22903

The motoneurons (MNs) innervating the sexually dimorphic striated penile muscles are sexually dimorphic in either size or number in a variety of mammalian species, including rodents, carnivores and primates. We examined this neuromuscular system in an insectivore, the musk shrew *Suncus murinus*.

The bulbocavernosus (BC) and ischioavernosus (IC) muscles are present in male but not female musk shrews. Horseradish peroxidase (HRP) injections into either the BC or the IC labeled MNs in the L5 and S1 regions of the spinal cord. At these levels, four distinct MN pools are present. Based on their position and apparent homology to the rat lumbar spinal cord, we refer to these motor nuclei as retrolateral nucleus (RDLN), dorsolateral nucleus (DLN), ventrolateral nucleus (VLN) and ventromedial nucleus (VMN). HRP injections of the BC and IC muscles in males labeled a few MNs in the VMN, but the majority of filled cells were localized to the DLN. In both males and females, injections of a foot muscle, the flexor digitorum brevis, filled motoneurons in the RDLN.

To determine if there was a sex difference in these motor pools, MNs were identified and counted in alternate Nissl-stained sections (50 micron) of spinal cords from 11 males and 9 females. Raw counts are given  $\pm$  SEM.

	VMN	DLN	RDLN
MALE	139.3 $\pm$ 12.5	369.9 $\pm$ 12.5	253.7 $\pm$ 12.5
FEMALE	133.9 $\pm$ 13.9	229.1 $\pm$ 13.9*	245.3 $\pm$ 13.9

Two-way ANOVA showed main effects of both nucleus and sex and a significant interaction. Planned comparisons found a significant sex difference in MN number only in the DLN ( $p < .05$ ). We will examine these MNs to determine if they are sexually dimorphic in size and if early androgen treatments increase MN number in females. Supported by NIH T32-DK07646 and NSF IBN 94-12605.

## 67.7

CO-DISTRIBUTION OF ESTROGEN RECEPTOR AND AROMATASE IMMUNOREACTIVE NEURONS IN THE MALE MUSK SHREW. S.L. Veney\* and E.F. Rissman. Biology Department, University of Virginia, Charlottesville, VA 22903.

Aromatase enzyme catalyzes the conversion of testosterone (T) into estradiol (E<sub>2</sub>). There are several lines of evidence to suggest that this process is important for the activation of male and female sexual behavior. In this study we describe the distribution of neurons immunoreactive for estrogen receptors (ER-ir) and cells immunoreactive for aromatase enzyme (AROM-ir) using standard immunocytochemistry techniques. Adult male musk shrews were castrated and given a T implant (s.c., 10 mm). In addition, they received an aromatase inhibitor (vorozole; generously provided by Janssen Research Foundation). Previous studies have shown that injections of vorozole enhance the staining of AROM-ir neurons (Rissman et al., J. Neuroend., in press). After processing and sectioning the brain tissue, ER-ir was localized with H222 monoclonal antibody (generously provided by Abbott Labs) and AROM-ir cells were visualized with the polyclonal antibody R-8-1 (kindly supplied by Dr. Y. Osawa). We found an overlapping distribution of ER-ir and AROM-ir neurons in the VMN. In the POA however, two distinct populations of AROM-ir neurons are seen. In the mPOA a nucleus of AROM-ir neurons that does not contain estrogen receptors is present. In the lateral POA, there is a cell-zone that contains neurons with both ER-ir and AROM-ir. These data suggest that within the mPOA T is converted to E<sub>2</sub>, however, the E<sub>2</sub> may bind to cells in the lateral POA. This work is supported by NSF IBN 94-12605 (EFR).

## 67.9

DEFICITS IN NONCONTACT ERECTION AND COPULATION IN RATS AFTER LESIONS OF BED NUCLEUS OF STRIA TERMINALIS OR NUCLEUS ACCUMBENS. Y.-C. Liu\*, J.D. Salamone, and B.D. Sachs. Department of Psychology, University of Connecticut, Storrs, CT 06269-1020, U.S.A.

These studies continue our survey of brain areas mediating the rat's erectile response to inaccessible estrous female ("noncontact erection", NCE; Sachs et al., *Physiol. Behav.*, 1994). BST: We made radiofrequency (RF) lesions in the bed nucleus of the stria terminalis (BST), which has rich connections with the medial amygdala (MeA) and the medial preoptic area (MPOA). MeA lesions eliminate NCE (Kondo et al., *SNS Abstr.*, 1995). MPOA lesions cause a smaller deficit in NCE (Liu et al., *SNS Abstr.*, 1995), but eliminate copulation. NCE was displayed by 3/14 BSTx males vs. 9/10 Sham males ( $p < .01$ ) 10-12 days after surgery, and by 6/14 BSTx males vs. 10/10 Sham males ( $p < .01$ ) 16-18 days after surgery. In mating tests 1-2 days after the first NCE test, 8/14 BSTx males and 10/10 Sham males copulated to ejaculation ( $p < .03$ ); BSTx males had longer interintromission intervals ( $p < .01$ ) and ejaculation latencies ( $p < .01$ ); intromission ratios were unchanged. The results implicate projections from the MeA through the BST in mediating NCE. However, comparing the magnitude of lesion effects on NCE, MeAx > BSTx > MPOAx; hence, some MeA efferents may mediate NCE by a pathway not involving the BST and MPOA. NAcc: We also made RF or 6-OHDA lesions in the nucleus accumbens (NAcc). After 6-OHDA lesions, which caused a mean 78% reduction in NAcc dopamine, NCE was displayed by 5/11 NAccx males vs. 9/10 Sham males ( $p < .06$ ) one week after surgery, and by 2/11 NAccx males vs. 8/10 Sham males ( $p < .01$ ) two weeks after surgery. After RF lesions, there was not a reliable difference between groups in the incidence of NCE in Test 1 (3/10 NAccx, 5/10 Sham) or Test 2 (4/10 NAccx, 9/10 Sham,  $p < .06$ ); however, all Sham males responded in at least one post-lesion test vs. 5/10 NAccx males ( $p < .03$ ), and NAccx males had longer NCE latencies in Test 2 ( $p < .02$ ). All males copulated to ejaculation with no significant change in parameters. The modest effect of both types of lesion on NCE supports a hypothetical role for NAcc dopamine in sexual arousal, at least in response to remote cues from estrous females, if not during copulation. [UConn Research Foundation]

## 67.11

DOPAMINE AGONISTS INCREASE PARAVENTRICULAR NITRIC OXIDE PRODUCTION IN MALE RATS: CORRELATION WITH PENILE ERECTION AND YAWNING. A. Argiolas\*, S. Succu & M.R. Melis. Bernard. B. Brodie Dept. Neurosci., Cagliari Univ., 09124 Cagliari, Italy.

The effect of apomorphine (APO), a mixed D1/D2 agonist that induces penile erection (PE) and yawning (Y), on the concentration of NO<sub>2</sub><sup>-</sup> and NO<sub>3</sub><sup>-</sup> in the paraventricular nucleus of the hypothalamus (PVN), was studied in male rats by in vivo microdialysis. APO (80 µg/kg s.c.) increased the concentration of NO<sub>2</sub><sup>-</sup> from 1.12 ± 0.45 µM to 3.8 ± 0.75 µM and of NO<sub>3</sub><sup>-</sup> from 5.53 ± 0.82 to 11.25 ± 2.30 µM in the PVN dialysate. NO<sub>2</sub><sup>-</sup> was increased also by LY 171555 (50 µg/kg s.c.), a D2 agonist that induces PE and Y, but not by SKF 38393 (5 mg/kg s.c.), a D1 agonist ineffective on PE and Y. Conversely, APO effect on NO<sub>2</sub><sup>-</sup> was prevented by haloperidol (0.5 mg/kg i.p.), a mixed D1/D2 antagonist, and by L-sulpiride (25 mg/kg i.p.), a D2 antagonist, but not by SCH 23390 (50 µg/kg s.c.), a D1 antagonist, although all three compounds prevented PE and Y. The APO effect on NO<sub>2</sub><sup>-</sup>, PE and Y, was also prevented by the nitric oxide (NO) synthase inhibitor N<sup>G</sup>-nitro-L-arginine methyl ester (200 µg i.c.v.). The NO scavenger hemoglobin also (200 µg i.c.v.) prevented the NO<sub>2</sub><sup>-</sup> increase, but was ineffective on PE and Y. In contrast, the oxytocin antagonist d(CH<sub>2</sub>)<sub>5</sub>Tyr(Me)-Orn<sup>1</sup>-vasotocin (1 µg i.c.v.) and the guanylate cyclase inhibitor methylene blue (300 µg i.c.v.) were ineffective on the NO<sub>2</sub><sup>-</sup> increase, but prevented PE and Y. We infer that dopamine agonists induce PE and Y by acting on D2 receptors that increase NO synthase activity in the cell bodies of PVN oxytocinergic neurons projecting to extra-hypothalamic brain areas and mediating these behavioral responses.

## 67.8

LESIONS OF THE POSTERIOR MEDIAL NUCLEUS OF THE AMYGDALA DELAY SEXUAL SATIETY. DB Parfitt\*, LM Coolen\*, SW Newman\*, and RI Wood\*. Neuroscience Program<sup>a</sup> and Department of Anatomy and Cell Biology<sup>b</sup>, University of Michigan, Ann Arbor, MI 48109. Department of Obstetrics and Gynecology<sup>c</sup>, Yale University, New Haven, CT 06520.

In the male Syrian hamster, the anterior and posterior subdivisions of the medial amygdaloid nucleus (Me) have differential effects on mating behavior. Lesions of anterior Me (MeA) eliminate the behavior presumably by interrupting chemosensory signals, while posterior lesions of Me (MeP) alter the temporal sequencing of the behavior by interfering with somatosensory cues from the brainstem. Recent studies indicate that neurons in caudal MeP only express Fos protein in males mated to sexual satiety. This study tested the hypothesis that MeP facilitates the onset of sexual satiety, and thus elimination of MeP should enhance copulation. Mating behavior was observed in sexually-experienced adult male Syrian hamsters before and after lesions of MeP. All animals (n=27) were mated to sexual satiety for 3 consecutive days to establish a prelesion baseline. Following prelesion testing, 21 males received bilateral electrolytic lesions of MeP using Teflon coated stainless steel microelectrodes (0.5mA, 10 sec). The 6 remaining males served as sham operated controls. After a 1 week recovery, males were mated to sexual satiety for 3 consecutive days on 2 occasions one week apart. Males were then perfused with 4% paraformaldehyde and 40µm brain sections were processed to assess the location and extent of the lesion. Analysis revealed 10 animals with bilateral Me lesions, 5 in caudal MeP and 5 in mid-Me (MeA through rostral MeP); these 2 groups differed significantly in their postoperative behavior. The caudal MeP lesion group had a progressive increase in the number of ejaculations before satiety from 0.6±0.6 on prelesion day 3 to 2.6±0.2 and 3.8±0.6 on postlesion day 3 rounds 1 and 2 ( $p < .05$ ). Similar increases were not observed in either the sham operated controls or the mid-Me lesioned males. These results suggest that caudal MeP is important in terminating copulation at sexual satiety. (Supported by NIH HD-32669 and T-32-DC-00011)

## 67.10

CONVERSION OF TESTOSTERONE TO ESTROGEN IS NOT NECESSARY FOR THE EXPRESSION OF SEXUAL BEHAVIOR IN MALE SYRIAN HAMSTERS. T.T. Cooper\*, A.N. Clancy\*, & H.E. Albers\*. <sup>1</sup>Lab. of Neuroendocrinology & Behavior, Depts. of Biology and Psychology, Georgia State Univ., Atlanta, GA 30303, <sup>2</sup>Dept. Of Psychiatry and Behavioral Sciences, Emory Univ. Sch. Of Med., GMH, 1256 Briarcliff Rd, Atlanta, GA 30306, and Biology Dept., Georgia State Univ., Atlanta, GA 30303.

Male sexual behavior in some species is primarily controlled by androgens. In contrast, the sexual behavior of male rats is dependent on estradiol formed by the aromatization of testosterone to estradiol within the CNS. The present study examined the role of testosterone aromatization in controlling sexual behavior in male hamsters by determining whether systemic administration of the non-steroidal aromatase inhibitor, Fadrozole, decreases sexual behavior in hamsters. Hamsters were assigned randomly to one of two groups. Group 1 received 2.0mg/kg/day of Fadrozole administered s.c. by osmotic minipump for 8 weeks. Pilot data indicated that this dose of Fadrozole was effective at inhibiting aromatase activity in hamsters as revealed by anti-estrogen receptor immunocytochemical labeling in brain. Group 2 was implanted with empty minipumps. All animals were paired with a receptive female weekly for 8 weeks. Measures recorded included latency to mount, mounts, intromissions, and anogenital investigation. No significant decline in sexual behavior was observed in the Fadrozole treated hamsters. Furthermore, weekly comparisons revealed no significant differences between groups on any measure. These data suggest that aromatization of testosterone to estradiol is not necessary for the expression of male hamster sexual behavior.

## 67.12

OXYTOCIN INCREASES PARAVENTRICULAR NITRIC OXIDE PRODUCTION IN MALE RATS: CORRELATION WITH PENILE ERECTION AND YAWNING. M.R. Melis\*, S. Succu & A. Argiolas. Bernard. B. Brodie Dept. Neurosci., Cagliari Univ., 09124 Cagliari, Italy.

The effect of a dose of oxytocin, that induces penile erection (PE) and yawning (Y), on the production of NO<sub>2</sub><sup>-</sup> and NO<sub>3</sub><sup>-</sup> in the paraventricular nucleus of the hypothalamus (PVN), was studied in male rats by in vivo microdialysis. Oxytocin (50 ng i.c.v.) increased the concentration of NO<sub>2</sub><sup>-</sup> from 0.98 ± 0.29 µM to 4.2 ± 0.79 µM and of NO<sub>3</sub><sup>-</sup> from 5.6 ± 0.33 µM to 8.03 ± 0.99 µM in the PVN dialysate. NO<sub>2</sub><sup>-</sup> and NO<sub>3</sub><sup>-</sup> concentration increase was parallel with the increase in the number of PE and Y episodes. NO<sub>2</sub><sup>-</sup>, PE and Y were increased also by the oxytocin-related peptides [Thr<sup>4</sup>,Gly<sup>1</sup>]-oxytocin (100 ng i.c.v.) and oxytocin(1-8) (1 µg i.c.v.), which increased PE and Y, but not by oxytocin(1-6) (1 µg i.c.v.) or oxytocin(7-9) (1 µg i.c.v.), which were unable to induce PE and Y. The oxytocin effect on NO<sub>2</sub><sup>-</sup>, PE and Y were prevented either by the oxytocin receptor antagonist d(CH<sub>2</sub>)<sub>5</sub>Tyr(Me)-Orn<sup>1</sup>-vasotocin (1 µg i.c.v.), or by the nitric oxide (NO) synthase inhibitor N<sup>G</sup>-nitro-L-arginine methyl ester (200 µg i.c.v.). In contrast, the mixed dopamine D1/D2 receptor antagonist haloperidol (0.5 mg/kg i.p.) was unable to prevent either NO<sub>2</sub><sup>-</sup> increase or PE or Y. The NO scavenger hemoglobin (200 µg i.c.v.) prevented oxytocin-induced NO<sub>2</sub><sup>-</sup> increase, but was unable to prevent PE and Y. Methylene blue (300 µg i.c.v.), an inhibitor of guanylate cyclase, was ineffective on NO<sub>2</sub><sup>-</sup> increase, but prevented PE and Y. The results suggest that oxytocin induces PE and Y by acting on PVN oxytocin receptors that increase NO synthase activity in the cell bodies of paraventricular oxytocinergic neurons projecting to extra-hypothalamic brain areas and mediating these behavioral responses.

## 67.13

REGULATION OF REPRODUCTIVE BEHAVIORS AND BRAIN ANDROGEN RECEPTOR (AR) BY TESTOSTERONE IN PREPUBERTAL AND ADULT MALE GOLDEN HAMSTERS. R. D. Romeo, L. R. Meek, C. M. Novak, and C. L. Sisk, Dept. Psych., Neuroscience Program, Michigan State Univ., E. Lansing, MI 48824 and \*Dept. Psych., Univ. of Minnesota, Morris, MN 56267

Prepubertal males are less responsive than adults to the activation effects of testosterone (T) on reproductive behavior. This study examined whether the ability of T to increase AR immunoreactivity (AR-IR) in brain regions involved in reproductive behavior is also less in prepubertal males. Sexually naive male hamsters were castrated under anesthesia at 21 or 42 days of age, and implanted subcutaneously with either a 0, 2.5, or 5 mg T pellet. One week later, males were given a 20 min mating session with a receptive female. Animals were euthanized one hour after the behavioral test, and blood samples and brain tissue were collected. Plasma T levels were equivalent in prepubertal and adult males that had been administered the same dose of T. Despite similar T levels, adult males exhibited more mounts and intromissions compared with prepubertal males, demonstrating that prepubertal males are less responsive than adults to the behavioral actions of T. In both age groups, increased circulating levels of T were associated with increased density of AR-IR cells in several brain regions involved in steroid-dependent activation of male sexual behavior, including the medial preoptic area, medial amygdala, posteromedial bed nucleus of the stria terminalis and magnocellular preoptic nucleus. Surprisingly, T increased AR-IR cell density in the latter two regions to a greater extent in prepubertal males than in adults. Thus, prepubertal males are more responsive to the effects of T on AR-IR cell density in these regions. These results indicate that a testosterone-dependent pubertal increase in ARs may be necessary, but is not sufficient, for the pubertal increase in behavioral responsiveness to T. EFFECTS OF VARIATIONS IN REPRODUCTIVE ACTIVITY ON HYPOTHALAMIC, PITUITARY, ADRENAL, AND TESTICULAR HORMONES IN MALE RATS. M. T. Williams\*, A. E. McCrea, M. B. Hennessy and H. N. Davis, Dept. of Psychology, Wright State Univ., Dayton, OH 45435.

Male rats exhibit a stereo-typical pattern of sexual behavior in which a variable number of mounts (no vaginal penetration) and intromissions (mounts with vaginal penetration) precede each ejaculation, and as many as 8 to 12 ejaculations precede the onset of sexual satiety. At present, few data are available as to the cause of sexual satiety, although several studies suggest that various hormones, particularly those of the HPA axis, may be involved. The specific purpose of the present study was to systematically investigate the effects of variations in copulatory behavior on the production and release of hormones from hypothalamic, pituitary, adrenal or testicular origins. Male rats were either allowed to achieve 1 intromission (1-INTRO), 1 ejaculation (1-EJAC), or 5 ejaculations (5-EJAC), or were merely removed from their home cage (BASAL) and trunk blood, hypothalamia and testes were collected. Hypothalamic CRF levels tended to decline during sexual behavior, while plasma titers of ACTH were increased, as were the adrenal hormones corticosterone (CORT) and aldosterone (ALDO). Furthermore, 5-EJAC males had heightened serum testosterone titers. Testicular testosterone and CRF were also assayed. Testicular T increased during sexual activity, but was significantly elevated over BASAL males only after 5 ejaculations. Testicular CRF, however, was not affected by sexual activity. The decrement in hypothalamic CRF levels following sexual activity suggests a greater release as sexual activity continues and this is supported by the rise in ACTH titers. The present results clearly indicate that a variation in the amount of copulatory activity can significantly affect the production and release of a variety of hormones. Whether, and in what manner, these changes relate to sexual satiety remains to be determined.

PLASMA TESTOSTERONE AND TISSUE 17 $\alpha$ -HYDROXYLASE ACTIVITY IN CASTRATED AND FADROZOLE TREATED MALE ZEBRA FINCHES. N. Lane, W. Grisham, S. Brown\*, L. Thompson, A. Arnold and B. Schlinger, Dept. of Physiological Science and Lab of Neuroendocrinology of the BRI, UCLA, Los Angeles, CA 90095.

In songbirds, song and the neural circuits that control song, are highly sensitive to activation and organizational effects of estrogens (E). Nevertheless, manipulations of E physiology (gonadectomy, treatments with aromatase inhibitors or E-receptor antagonists) fail to block presumed E-dependent neural events and may fail to eliminate circulating E. Since E is derived from androgen (A), these data suggest that songbirds possess an important extragonadal site of A synthesis. To test this possibility, male zebra finches were castrated or left intact and were then injected daily with saline or with Fadrozole (Fad), a specific and effective aromatase inhibitor. 5 days later, birds were bled for measures of circulating testosterone (T) by RIA and sacrificed for measures of tissue P45017 $\alpha$ -hydroxylase/C17-C20 lyase (P450-17 $\alpha$ ) activity (measured by the conversion of <sup>3</sup>H-progesterin to <sup>3</sup>H-A). Castration significantly reduced circulating T levels whereas Fad increased T significantly in both castrates and intact birds. Though we have detected P450-17 $\alpha$  activity previously in adrenals, it was not detected in homogenates of adrenals or of brains in this experiment. P450-17 $\alpha$  was detected in testes. <sup>3</sup>H-A was formed in greater amounts by testes of males treated with Fad than with saline, perhaps contributing to the higher T levels found in these birds. Since we found no extragonadal P450-17 $\alpha$  activity, we do not know the site of synthesis of the T detected in castrated + Fad treated males. Supported by IBN-9120776 and DC0217.

## 67.14

ANDROGEN-RECEPTOR AND ESTROGEN-RECEPTOR CO-LOCALIZING NEURONS IN THE MEDIAL PREOPTIC AREA AND EXPRESSION OF MATING-INDUCED FOS IN MALE RATS. B. Greco<sup>1</sup>, D. A. Edwards<sup>1</sup> and A. N. Clancy<sup>1,2,3</sup>, <sup>1</sup>Psychology Dept., Emory Univ., Atlanta, GA 30322, <sup>2</sup>Biology Dept., GA St. Univ., Atlanta, GA 30303 and <sup>3</sup>Dept. of Psychiatry and Behavioral Sciences, Emory Univ. Sch. of Med., GMH, 1256 Briarcliff Rd., Atlanta, GA 30306.

Conversion of testosterone into estradiol is important for male rat mating behavior and both steroids probably contribute to mating. An overlap in the distributions of neurons containing androgen receptors (AR) and estrogen receptors (ER) has been documented, and many AR-immunoreactive (AR-ir) neurons express mating-induced Fos-immunoreactivity (Fos-ir). Because mating-induced Fos-ir in the male rat occurs mainly in AR-ir neurons and because both steroids are important for mating, we hypothesized that AR-ir and ER-ir are co-localized. We examined, in adjacent sections from the medial preoptic area, the co-localization of ER-ir in: i) AR-ir containing neurons, and ii) Fos-ir expressive neurons. PG21 anti-AR (G. Prins), anti-c-fos (Genosys), and H222 anti-ER (Abbott Lab) primary antibodies were visualized, respectively, with cyanine-conjugated, fluorescein or cyanine-conjugated, and fluorescein-conjugated secondary antibodies (Jackson Lab). Five days after subcutaneous implant of a minipump delivering 0.28 mg/kg/day of the aromatase inhibitor, Fadrozole (Ciba-Geigy Corp), male rats were killed 1 hour after ejaculating with a receptive female. Preliminary analysis of sections incubated with anti-ER and anti-AR primary antibodies showed that ER-ir labeling occurred predominantly in AR-ir expressive neurons but that not all AR-ir neurons were ER-ir positive. In sections incubated with anti-ER and anti-c-fos primary antibodies, ER-ir labeling occurred in cells expressing mating-induced Fos-ir but cells which were single-labeled with either ER-ir or Fos-ir were also present. Because in the male rat almost all mating-induced Fos-ir is found in AR-ir positive neurons, these new findings permit the tentative conclusion that two populations of neurons control mating in male rats, the first containing AR-ir only and the second co-localizing AR-ir and ER-ir. (Funded by NSF grant IBN-9421208 to DAE)

## 67.16

CELL-BODY LESIONS OF THE POSTERODORSAL PREOPTIC NUCLEUS (PdPN) AND THE POSTERODORSAL MEDIAL AMYGDALA (MeApd) DISRUPT SEX BEHAVIOR IN MALE GERBILS. M. M. Heeb\* and P. Yahr, Department of Psychobiology, University of California, Irvine, CA 92697.

The sexually dimorphic area (SDA) of the gerbil hypothalamus is essential for male sex behavior. Using c-Fos immunocytochemistry we previously determined that the SDA, and many areas connected to or near the SDA, are activated when males are exposed to a variety of sex-related stimuli. Two of these areas, the PdPN and the lateral part of the MeApd, are activated only when males copulate to ejaculation.

To test the hypothesis that these two areas affect sex behavior in sexually experienced male gerbils, we aimed cell-body lesions at either or both cell groups. Three groups of males were given N-methyl-D-aspartate (NMDA), a neuronal cytotoxin, via iontophoresis, bilaterally in either the MeApd, the PdPN or both cell groups. A fourth group was given N-methyl-L-aspartate, NMDA's inactive isomer, or water. Males were retested weekly for four weeks for male sex behavior with receptive females.

All eight control males intromitted in every test, and only one ever failed to ejaculate. Twelve of 13 males with lesions aimed at the PdPN also intromitted, but eight of them failed to ejaculate on at least one test. The last male never mounted. In contrast, only three of nine males with lesions aimed at the MeApd mounted in more than one test, and all three failed to ejaculate on at least one test that involved intromission.

These results suggest that the MeApd may be involved in the control of both mounting and ejaculation, but that the PdPN may be specifically involved in the control of ejaculation.

## 67.18

THE SYNERGISTIC ACTION OF TESTOSTERONE AND ESTROGEN IN THE RESTORATION OF MALE SEXUAL BEHAVIOR. M.E. Vagell\*, and M.Y. McGinnis, Department of Cell Biology & Anatomy, Mount Sinai School of Medicine, City University of New York, New York, NY 10029

This study assessed the role of aromatization in male reproductive behavior by testing the effects of the aromatase inhibitor, fadrozole, on the restoration of male sexual behavior and partner preference in testosterone-treated castrate rats. We measured nuclear estrogen receptor occupation to determine whether fadrozole blocked brain aromatase. In addition, nuclear androgen receptor assays were used to verify that fadrozole does not block androgen receptors. Mini-osmotic pumps fitted to brain infusion cannulas were used to deliver fadrozole (20  $\mu$ g/kg/day) into the right lateral ventricle. The majority of animals receiving fadrozole treatment with two, 10 mm testosterone filled Silastic capsules (T/F group) did not show any sexual behavior during the tests 7 and 14 days following implant surgery. However, animals receiving fadrozole treatment implanted with two, 10 mm testosterone capsules and one, 5 mm 1% estradiol capsule copulated normally, indicating that fadrozole's inhibition of male sex behavior was specifically due to blocking aromatase activity. Moreover, most of the animals which received only one, 5 mm 1% estradiol capsule (E group) also did not show any sexual behavior over this time course. Partner preference was measured in a three chambered apparatus as an index of sexual motivation. Repeated measures contrasts on the group x test interaction indicated that the T/F group was not significantly different from the T group. However, the E group did not show a preference for the receptive females and was significantly different from the T group. Fadrozole treatment resulted in a 59% decrease in brain nuclear estrogen receptor occupation relative to the T group. Fadrozole had no significant effect on brain or pituitary nuclear androgen receptor occupation. Our work suggests that both testosterone and estrogen are necessary for the restoration of male sexual behavior in rats. However, estrogen is neither necessary nor sufficient for the restoration of partner preference. This research was supported by NIH grant HD 27727.

SUICIDE TRANSPORT LESIONS OF STEROID-RESPONSIVE NEURONS IN THE MALE HAMSTER MATING BEHAVIOR CIRCUITRY. R.I. Wood\* and L.M. Coolen, Dept OB/GYN, Yale Univ Med School, Box 208063, New Haven, CT 06520.

Copulatory behavior in the male Syrian hamster is dependent on chemosensory and hormonal stimuli, and is prevented if either signal is interrupted. Lesions of brain regions that relay chemosensory signals abolish copulation. However, lesions of steroid-responsive regions fail to block behavior. We hypothesize that the steroid-responsive nuclei in the mating behavior circuit are redundant, for intracerebral implants of testosterone in medial amygdala or bed nucleus of the stria terminalis and medial preoptic area will facilitate behavior. If so, multiple lesions of these regions will be necessary to block mating behavior. This was tested in the present study using the suicide transport lectin, volkensin.

Volkensin is a toxic lectin from *Adenia volkensii* which lesions cells at the site of injection, and is taken up by terminals to lesion afferents to the injection site. Volkensin was injected (50 nl) unilaterally in the posteromedial subdivision of the bed nucleus of the stria terminalis (BNSTpm) via a glass micropipette. BNSTpm receives input from both posterior medial amygdala (MeP) and medial preoptic nucleus (MPN) and lesions centered in the BNSTpm fail to prevent copulation. One week after surgery, males were tested for mating behavior to determine the effects of the lesion. One hour after the mating test, males were perfused and brains were stained for Fos and androgen receptor immunoreactivity (AR-IR), and cresyl violet. AR-IR and Fos-IR were reduced unilaterally at the site of the injection and throughout MPN and MeP, indicating that volkensin lesioned BNSTpm and its afferents. With small unilateral lesions restricted to steroid-responsive brain regions, males continued to mate. However, when volkensin injection in BNSTpm was combined with contralateral bulbectomy mating was abolished.

These results demonstrate that volkensin is a useful tool to create multifocal lesions of steroid-responsive neurons and support the concept of functional redundancy within the hormone-sensitive portions of the circuitry for male sexual behavior. (Supported by NIH HD-32669).

VTA DOPAMINE BURST ACTIVITY IN RELATION TO SENSORY EVENTS, J.C. Horvitz\*, T. Stewart, B.L. Jacobs, Program in Neuroscience, Princeton University, Princeton, NJ 08544.

While DA neurons have previously been shown to exhibit single-spike activity with occasional bouts of burst firing (a train of 2-4 spikes with ISI's < 80 msec), the behavioral significance of these firing modes is unknown. In this study, single-unit activity of dopamine (DA) neurons in the ventral tegmental area (VTA) was recorded in freely-moving cats during the presentation of auditory and visual stimuli of 1 msec duration. The presentation of auditory and visual stimuli typically produced a 20-fold increase in the probability of burst firing, with the maximum probability occurring approximately 80 msec after stimulus presentation. The burst activity was followed by a 250 msec period during which burst activity had a near-zero probability of occurrence. NIMH (MH-10296)

## 68.2

PREPULSE INHIBITION OF THE ACOUSTIC STARTLE REFLEX IS RELATIVELY INSENSITIVE TO DISRUPTION BY INDIRECT DOPAMINE AGONISTS. J.P. Druhan\* and R.J. Valentino, Dept. of Psychiatry, Med Coll of PA and Hahnemann Univ, Phila., PA 19102.

Dopamine (DA) receptor agonists can interfere with the ability of moderate intensity prepulse stimuli to inhibit startle reflexes in rats. This influence of DA agonists on prepulse inhibition (PPI) suggests that mesotelencephalic DA neurons may modulate sensorimotor gating processes involved in regulating responses to salient environmental stimuli. However, studies examining the effects of amphetamine on sensorimotor gating have reported only moderate disruption of PPI by doses that are known to increase DA release. The present study examined this discrepancy further by comparing the effects of several direct and indirect agonists on PPI of the acoustic startle reflex in rats. Experiments with direct DA receptor agonists confirmed that PPI could be completely disrupted by low doses of the mixed D1/D2 DA receptor agonist, apomorphine (0.2 to 0.8 mg/kg) and by the selective D2 agonists, propylnorapomorphine (0.2 to 0.8 mg/kg) and quinpirole (0.2 to 0.8 mg/kg). In contrast, tests with indirect DA agonists failed to reveal significant effects of the monoamine reuptake inhibitor, cocaine (10.0 to 40.0 mg/kg), or the selective DA reuptake blocker, GBR 12909 (5.0 to 20.0 mg/kg). PPI was significantly disrupted by d-amphetamine, but only at the highest dose tested (4.0 mg/kg). These findings indicate that PPI is relatively insensitive to manipulations that increase extracellular DA, and they raise questions as to whether sensorimotor gating deficits in humans can be attributed to increased activity of mesolimbic DA neurons. (Supported by the Scottish Rite Benevolent Foundation Schizophrenia Research Program).

## 68.3

THE DAD2-LIKE AGONIST QUINPIROLE PRODUCES MONOTONIC REDUCTIONS IN MOTOR ACTIVITY OF C57 MICE. L.D. Middaugh\*, J.P. Halberda, and B.E. Gard, Dept. of Psychiatry, CDAP, Med. Univ. of SC, Charleston, SC 29425.

As reported for rats, the DAD1-like agonists SKF 38393 and SKF 82958 elevated or reduced the locomotion of C57 mice, the particular effect depending upon dose and testing conditions. Although DAD2-like agonists are also reported to have a biphasic action on locomotion of rats, quinpirole only reduced locomotion of C57 mice in this study. Reduced activity was observed whether the mice were male or female, were young or mid-aged adults, were naive or well habituated to the test environment, or were injected with very low or very high doses administered either IP or SC. Since the monotonic reduction in motor activity occurred over a wide range of testing conditions, it is unlikely that methodological variables can account for the apparent species differences in the effects of quinpirole. Thus, we conclude that the receptor systems mediating the effects of DAD1-like agonists on motor activity of C57 mice, and probably other strains, are similar to those of rats; however, that the systems mediating the effects of the DAD2-like agonist quinpirole are dissimilar for the two species. Possible reasons for the differences include species differences in DA sub-receptor numbers or affinity states, in their anatomical distribution including pre- and post-synaptic location, or in the interaction of D1, D2, and D3 subreceptor systems. (Funding source DA08034.)

## 68.4

D1 AND D2 DOPAMINE RECEPTOR INVOLVEMENT IN THE BEHAVIORAL EFFECTS OF MK-801 IN 6-OHDA LESIONED RATS. K.E. Asin\* and L. Bednarek, Neuroscience Research, Pharmaceutical Products Division, Abbott Laboratories, D-47U, Bldg AP9A, Abbott Park, IL 60064

In rats bearing unilateral 6-OHDA forebrain lesions, the NMDA receptor antagonist, MK-801, induces ipsilateral rotation, but interacts differentially with D1 and D2 dopamine (DA) receptors. Although both D1 and D2 receptor agonists produce contralateral rotation in these animals, co-treatment with MK-801 potentiates D1-agonist induced rotation but antagonizes the rotation produced by the D2/D3 receptor agonist, quinpirole. In a recent study, it appeared that repeated l-DOPA treatment subsequently interfered with MK-801's interactions with selective DA agonists (Engber et al 1994). Since repeated l-DOPA treatment differentially alters D1/D2 receptor sensitivity (Asin et al 1995), we investigated D1/D2 contributions to the effects of MK-801 in DA agonist treated, 6-OHDA lesioned rats.

In the first study, lesioned rats were treated with the D2 antagonist haloperidol (0.38 mg/kg, sc) 20 min prior to MK-801 (0 or 0.10 mg/kg, ip). Twenty min later rats were injected with the D1 DA receptor agonist, A-85653 (0.06 mg/kg, sc), and rotation was measured for 6h. Haloperidol dose-dependently blocked the potentiation of A-85653-induced rotation produced by MK-801. In a second study, rats were injected with MK-801 (0 or 0.10 mg/kg) 10 min prior to treatment with the D1 antagonist SCH 23390 (0-1 mg/kg, sc). Ten min later, rats were treated with quinpirole (0.15 mg/kg, sc) and rotation was measured for 3h. The reduction in quinpirole-induced contralateral rotation produced by MK-801 was dose-dependently blocked by SCH-23390. In a third study, rats were pretreated with either haloperidol or SCH 23390 prior to treatment with MK-801 alone (0.25mg/kg.sc) and rotation was recorded for 3 h. Both DA antagonists dose-dependently blocked the ipsilateral rotation produced by MK-801. The results of these studies indicate that the interactive effects of MK 801 with D1 and D2 agonists may rely on increases in DA tone and receptor synergism, perhaps in the intact striatum, resulting from NMDA receptor blockade. **DOPAMINE D<sub>1</sub> RECEPTOR AGONIST-INDUCED GROOMING IN RATS: AN EXAMINATION OF THE LINK TO ADENYLATE CYCLASE.** P.R. Rau, R.B. Mailman, D.E. Nichols, and C.P. Lawler. Neuroscience Center, Univ. of North Carolina, Chapel Hill, NC 27599, and <sup>1</sup>Purdue Univ., W. Lafayette, IN 47907.

Dihydroxidine (DHX) and the phosphodiesterase (PDE) inhibitor rolipram were used to assess the roles of adenylyl cyclase and the second messenger adenosine cyclic 3',5'-monophosphate (cAMP) in mediating the grooming induced by activation of D<sub>1</sub> dopamine (DA) receptors. Both drugs were evaluated for their ability to stimulate grooming in rats when administered alone, as well as when administered together. DHX (0.1, 1.0, and 3.0 mg/kg s.c.) produced the expected overall increases in total grooming time, whereas rolipram (7.5, 15 and 30 µg/kg s.c.) produced inconsistent effects on this measure. Most importantly, there was no interaction attributable to the combined effects of rolipram and DHX on total grooming time. An examination of grooming bout structure revealed striking differences between the actions of the two compounds. DHX produced moderate increases in both grooming frequency and bout duration. Rolipram produced larger increases in grooming bout duration, but these were offset by decreases in bout frequency. The ability of rolipram to depress grooming frequency was evident when it was coadministered with the two lowest doses of DHX (0.1 and 1.0 mg/kg), but not at the highest dose (3.0 mg/kg). In no case did rolipram produce a synergistic enhancement in any aspect of grooming behavior induced by DHX. This lack of synergism contrasts with a previous study in this laboratory in which a similar experimental strategy in a drug discrimination paradigm showed synergism. This inability of rolipram to enhance DHX-induced grooming adds support to the hypothesis that grooming induced through D<sub>1</sub> receptor activation is not mediated by the AC/cAMP system. ## 68.7

**DOPAMINE D-2 RECEPTORS MODULATE THE BEHAVIORAL RESPONSE TO ACTIVATION OF SEROTONIN 5-HT<sub>2A</sub> RECEPTORS IN THE RAT MEDIAL PREFRONTAL CORTEX.** David L. Willins\* and Herbert Y. Meltzer. Laboratory of Biological Psychiatry, Case Western Reserve University, Cleveland, Ohio 44106

The direct injection of serotonin<sub>2A</sub> (5-HT<sub>2A</sub>) agonists, (e.g. DOI, mCPP) into the medial prefrontal cortex (mPFC) of rats has been shown to elicit a head twitch response (HTR). This response is blocked by pretreatment with selective 5-HT<sub>2A</sub> receptor antagonists (e.g. ketanserin, MDL 100,907). In the present study the role of dopamine (DA) in the mPFC in the HTR to DOI was evaluated. The direct administration of the D-1 agonist, SKF38393 (3 µg/0.5 µl/site) bilaterally into the mPFC elicited a HTR. Co-injection of SKF38393 with DOI (3 µg/0.5 µl/site) produced a HTR which was not greater than additive with the effects of DOI. Systemic administration of a low dose (10 µg/kg) of SCH23390, a D-1 antagonist, inhibited the HTR to SKF38393 but did not block DOI-stimulated HTR. The direct injection of the D-2/D-3 agonist, quinpirole (3 µg/0.5 µl/site) into the mPFC produced a slight, but significant, increase in the HTR. However, co-administration of quinpirole with DOI inhibited the HTR produced by DOI. Co-injection of a low dose of the selective D-2 antagonist, sulpiride (1 µg) with DOI potentiated the effects of DOI. We have previously demonstrated that the systemic administration of DA receptor antagonists inhibits the HTR to intra-cortical DOI (Willins and Meltzer, Soc. Neurosci. Abstr., 809.9, 1995). This suggests that the behavioral effects of activating 5-HT<sub>2A</sub> receptors in the mPFC are suppressed by DA in the cortex and facilitated by DA in other brain regions. The present findings further indicate that DA elicits its effects on serotonin-mediated behavior in the mPFC through activation of postsynaptic D-2 receptors. (Supported by MHCR47808 and a NARSAD Young Investigator Award)

## 68.9

**DEVELOPMENTAL AND BEHAVIORAL DEFICITS OF DOPAMINE-DEFICIENT MICE.** Q.-Y. Zhou, M. Szczepka, J. E. Erickson, M. Fujanaga, H. Van Tol\*, and R. D. Palmiter. Clarke Institute of Psychiatry, University of Toronto, Toronto, ON M5T, 1R8, Canada and Howard Hughes Medical Institute, University of Washington, Seattle, WA 98195, USA.

A strain of DA-deficient mice was developed by combined gene knock-out and knock-in techniques. Dysregulated expression of neuronal genes in the striatum was observed in DA-deficient mice. However, general brain development appear normal in the absence of DA signaling including neurogenesis of both DA neurons and their major targets. DA-deficient mice exhibited a number of abnormal individual and social behaviors. All DA-deficient pups were severely hypoactive, failed to feed themselves and died within a few weeks of birth. Importantly, DA-deficient pups were rescued to adults by repeated administration of L-DOPA. Rescued adult DA-deficient mice also exhibited severe hypoactivity, adipsia and aphagia and performed poorly in rota-rod test in the absence of DA (8-12 hr after L-DOPA administration). The feeding and motor deficits were reversed by administration of L-DOPA. Preliminary work of intrastriatal delivery of L-DOPA indicated that the nigrostriatal pathway is responsible for both motor and feeding functions. Male DA-deficient mice displayed abnormal aggressive behavior towards intruders after L-DOPA administration whereas male TH heterozygous mice, which have reduced DA level, were less aggressive. Male DA-deficient mice also exhibited excessive and inappropriate sexual behavior towards females after L-DOPA administration. These results indicate that intact dopamine systems are essential for normal expression of a number behaviors of mice and the availability of reversible DA knock-out mice should help to study modulatory role of DA on target neurons including finding the target molecules of DA signaling. Supported by Howard Hughes Medical Institute and Clarke Foundation.

**THE EFFECT OF DOPAMINERGIC AGENTS ON REACTION TIME IN RHESUS MONKEYS** M.R. Weed\* and L.H. Gold. Department of Neuropsychopharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Measures of reaction time have been shown to be sensitive to CNS manipulations such as treatment with dopaminergic drugs or infection with viruses like HIV. Rhesus monkeys (4) performed a 5-choice reaction time procedure adapted from a human neuropsychological battery (CANTAB; Cambridge Neuropsychological Test Automated Battery; Paul Fray, Ltd., Cambridge, UK). Monkeys depressed a lever for a variable duration (0.75-2.5 s) until a stimulus flashed in 1 of 5 circles on a touch-sensitive computer monitor. Releasing the lever and touching the appropriate circle within 2 s from stimulus onset resulted in the delivery of two 190 mg food pellets. The behavior was shaped by hand until responding was reliable with stimuli of 0.6-0.1 s (16-26 sessions). One 30-trial training session was conducted Mon., Wed. and Thurs., and cumulative-dosing tests were conducted on Tues. and Fri. Stimuli were randomized by duration (1, 0.1 or 0.01 s) and circle position across each of four 30-trial test sessions. Baseline reaction times were established with 20 m saline pretreatments (i.m.) prior to each session. Saline injections had no effect upon either response latency or latency to release the lever, and there were no effects of the multiple tests (N=2). Amphetamine (1.0, 1.7 and 3.0 mg/kg, i.m., N=2) had little effect upon either measure until responding was suppressed (5.6 mg/kg, N=2). Selective dopamine receptor antagonists (D1) SCH 39166 (1.7-30 µg/kg, i.m., N=2) and (D2) raclopride (10-56 µg/kg, i.m., N=2) produced dose-dependent increases in both latency measures. The increases in latency with dopamine receptor antagonists verify that the current paradigm is sensitive to neuropsychological manipulation. Verification of the sensitivity of this task to CNS manipulations is critical prior to its use in the investigation of the CNS effects of immunodeficiency disease and/or drug-induced neurotoxicity in rhesus monkeys. **DIFFERENTIAL EFFECTS OF D1 AND D2 DOPAMINE RECEPTOR AGONISTS AND ANTAGONISTS ON APPETITIVE AND CONSUMMATORY ASPECTS OF MALE SEXUAL BEHAVIOR IN JAPANESE QUAIL.** J. Balthazart\*, C. Castagna, and G. F. Ball. Lab. Biochemistry, Univ. of Liège, B-4020, Belgium and Dept. of Psychology, Johns Hopkins Univ. Baltimore, MD 21218, USA.

Previous pharmacological studies in quail demonstrated that general dopaminergic agonists affect appetitive as well as consummatory aspects of male sexual behavior. Inhibition of both components of behavior were observed with the general agonist, apomorphine while the indirect dopamine agonists, nomifensin or amfonelic acid, enhanced certain aspects of these behaviors. These inhibitory effects of apomorphine in quail may reflect its predominant action at the level of D2-like dopaminergic receptors while the two other compounds primarily exert their effects through an interaction with D1 receptors. This was tested by studying the behavioral effects of specific D1 and D2 dopaminergic receptor agonists and antagonists in castrated male Japanese quail that were chronically treated with exogenous testosterone (subcutaneous Silastic implants). Appetitive male sexual behavior was measured by the time spent in front of, and looking through, a small window that provides a view of a female who is subsequently released into the cage to evaluate copulatory behavior per se. The effects of five compounds were tested: one D1 (SKF38393) and two D2 (PPHT or N-0434 and quinpirole or LY171555) agonists, and one D1 (SCH23390) and one D2 (Spiperone) antagonist. All compounds were tested at a low and a high dose (100 µg and 1 mg/kg respectively for all drugs except spiperone where the doses were 2 and 10 mg/kg). A consistent effect of all drugs on consummatory sexual behavior was observed: it was stimulated by the D1 agonist and the D2 antagonist but inhibited by the D1 antagonist and the D2 agonists. Far fewer effects of the treatments were detected on the two measures of appetitive behavior. The time spent in front of, and looking through the window was decreased by the two D2 agonists but not affected by the other treatments. These data therefore demonstrate that, as in rodents, male copulatory behavior in quail is stimulated by the action of dopamine at the level of its D1 receptors but inhibited by activation of the other receptor subtype (D2). The partial dissociation observed between the effects of the same treatments on appetitive and consummatory aspects of sexual behavior also suggests that these two behavioral systems may be controlled by the action of dopamine on different neuronal networks. ## 68.10

**ASSESSMENT OF BEHAVIORAL ORGANIZATION DIFFERENTIALLY CHARACTERIZES D2 AND D4 KNOCK OUT MICE.** M.P. Paulus\*, D. Grandy, M. Low, M. Kelly, S. C. Dulawa, and M.A. Geyer. UCSD Dept Psychiatry, La Jolla, CA 92093.

Targeting genes using homologous recombination that generates mouse strains with distinct mutations in their genome enables the investigation of gene-related behavioral organization. In this investigation, D2 and D4 knockout (KO) mice were tested in an unconditioned motor paradigm to assess overall levels of activity and the geometrical characterization of movements based on a scaling approach. Briefly, unconditioned motor activity was recorded with high temporal and spatial resolution from D2 or D4 KO male and female mice and wild type controls using a video-based system consisting of 41 x 41 x 38 cm white Plexiglas boxes. The amount of locomotor activity was assessed by measuring the number of micro-events, counts, within two 15-minute windows. In addition, the geometric characteristics of movement sequences was measured using the spatial scaling exponent, *d*, and the fluctuation spectrum of local spatial scaling exponents, *f(d)*. A mixed model ANOVA (*gender* x *genotype*) x (*within-session habituation*) was calculated for the D2 KO experiment. Neither the genotype (*F*(2, 23) = 0.36, n.s.) nor gender (*F*(1, 23) = 0.66, n.s.) factors had significant main effects on the amount of activity. There was a significant effect of time (*F*(1, 23) = 14.40, *p* < 0.001) but no interaction with genotype (*F*(2, 23) = 1.20, n.s.) or gender (*F*(1, 23) = 0.76, n.s.) on the counts measure. In contrast, there was a significant main effect of genotype on the geometrical patterns of movements (*F*(2, 23) = 13.89, *p* < 0.0001). While gender did not exert a main effect on geometrical patterns (*F*(1, 23) = 0.65, n.s.), there was a significant interaction between genotype and gender (*F*(2, 23) = 3.64, *p* < 0.05). Thus, D2 KO mice in general and female KO mice in particular are characterized by a significantly increased *d* suggesting an increased engagement in predominantly circumscribed movement sequences. Support provided by DA02925, MH01223, and NARSAD.

## 68.11

APOMORPHINE SUSCEPTIBILITY IN RATS IS DETERMINED BY BOTH GENETIC AND ENVIRONMENTAL FACTORS. B.A. Ellenbroek\* and A.R. Cools Dept. Psychoneuropharmacology P.O. Box 9101, 6500 HB Nijmegen, the Netherlands.

It is well known that animals show a large individual variability to the behavioural effects of dopaminergic drugs like apomorphine. It has been speculated that this susceptibility for apomorphine may be linked to the development of drug dependence and schizophrenia. The present study was designed to investigate the role of genetic and early postnatal environmental factors in determining apomorphine susceptibility. In order to investigate the role of genetic factors, the stereotyped gnawing response upon a challenging dose of apomorphine (1.5 mg/kg s.c.) was studied in a number of inbred strains of rats. The results show that the apomorphine response was highest in Sprague Dawley rats, and lowest in the ACI and Fischer rats. In order to investigate the role of early postnatal factors we separated the mother from her puppies at days 3, 6 or 9 after birth (day of birth is day 0). The puppies showed an enhanced stereotyped response to 1.5 mg/kg s.c. apomorphine at adult age. In a second series we studied the interaction between genetic and environmental factors by studying the effects of cross-fostering and maternal separation in rats bred selectively for apomorphine susceptibility (APO-SUS and APO-UNSUS). The results show that maternal separation enhanced apomorphine susceptibility in APO-UNSUS but not in APO-SUS, whereas cross-fostering reduced apomorphine susceptibility in APO-SUS but not APO-UNSUS. These data strongly suggest that the development of apomorphine susceptibility is determined by a complex interaction between genetic and environmental factors. Given the above mentioned relationship between apomorphine susceptibility and drug dependence and schizophrenia, these data may have important implications for the etiological theories regarding these mental illnesses.

## 68.13

PHASIC INCREASES IN EXTRACELLULAR DOPAMINE DURING A FREE-CHOICE NOVELTY TASK AS MEASURED BY FAST-SCAN VOLTAMMETRY. G.V. Rebec\*<sup>1</sup>, J.R.C. Christensen<sup>1</sup>, C. Guerra<sup>1</sup>, and M.T. Bardo<sup>2</sup>. <sup>1</sup>Program in Neural Science and Dept. Psychology, Indiana University, Bloomington, IN 47405; <sup>2</sup>Dept. Psychology, University of Kentucky, Lexington, KY 40506.

Response to novelty in rats is used as an analog of human sensation-seeking activity, which is associated with an increased risk for drug abuse. Previous research with slow-scan voltammetry has shown an increase in the catechol signal in the nucleus accumbens of rats allowed free-choice entry into a novel compartment (Rebec et al., Soc. Neurosci. Abstr. 20:826, 1994). To identify the catechol and to obtain a more precise time-course of the novelty-related increase, we repeated the novelty task using fast-scan cyclic voltammetry. Recordings were obtained at 100-ms intervals with carbon-fiber microelectrodes placed in either the shell or core region of the nucleus accumbens. In accumbal shell, we observed a pronounced increase in oxidation current (> 100% above baseline) that began immediately upon entry into novelty and terminated in < 10 s. Voltammetric analysis revealed that the increase in signal was due to dopamine. No novelty-related voltammetric changes were observed in accumbal core. Random motor activity either before or after entry into novelty had no effect in either accumbal region. Our results provide real-time evidence for mesolimbic dopamine release in novelty-seeking behavior, suggesting a common action with drugs of abuse. It also appears that phasic, rather than tonic, dopaminergic activation plays a critical role in free-choice novelty.

REGULATION OF DOPAMINE BY PROGESTERONE IN THE MEDIAL PREOPTIC AREA OF FEMALE RATS, L. Matuszewicz\*, D. S. Lorrain, & E. M. Hull. State University of New York at Buffalo, Buffalo, NY 14260.

Progesterone is frequently used to enhance the receptive and proceptive behaviors in estrogen-primed, ovariectomized female rats. One mechanism by which progesterone influences behavior may be through up or down regulation of the release of neurotransmitters in specific brain sites. The medial preoptic area (MPOA) contains progesterone receptors and plays a role in female rat sexual behavior. The present experiment explored the regulation of dopamine release by progesterone in the medial preoptic area. On the test day, microdialysis probes were inserted into the MPOA in 9 ovariectomized, estrogen primed female rats. Following a 2 hour stabilization period, samples were collected every 6 minutes for 36 minutes. A subcutaneous injection of either 500 ug progesterone or oil was then given to each subject. Three hours following the injection, 6 minute samples were again collected. All females that received progesterone showed a significant decrease in dopamine release compared to samples prior to injection. The oil treated females, however, did not show a decrease in dopamine activity. Dopamine's metabolites DOPAC & HVA also were significantly depressed in progesterone treated females compared to oil treated controls. Therefore, progesterone may influence female rat sexual behavior by decreasing dopamine activity in the MPOA.

## 68.12

THE EFFECTS OF TEMPORARY LESIONS OF THE INSULAR AND MEDIAL PREFRONTAL CORTEX ON FIXED-INTERVAL SCHEDULE-CONTROLLED BEHAVIOR IN THE RAT. S.B. Evans\*, and D.A. Cory-Slechta. Department of Neurobiology and Anatomy, University of Rochester School of Medicine and Dentistry, Rochester N.Y. 14642.

Sixteen food-deprived rats were trained to press a lever for food reinforcement on a one-minute-fixed-interval (FI) schedule. Previous work in this laboratory has shown that the rate of responding on this fixed-interval schedule of reinforcement is sensitive to dopamine (DA) neurotransmission in the nucleus accumbens (N.Acc.), such that temporarily inactivating D1 and D2 receptors with EEDQ, an irreversible DA antagonist, markedly decreases overall rate of responding. This decrease in rate can be prevented by protecting the D1 or D2 receptors with an antagonist during the EEDQ treatment. Therefore, if behavior on the FI schedule is sensitive to changes in the N.Acc. DA system, manipulations of other regions that regulate N.Acc. DA should have predictable effects on FI performance. It has been demonstrated by others that the rat prefrontal cortex (PFC) regulates DA neurotransmission in the N.Acc. Our FI-trained rats were therefore implanted with cannulae aimed at the medial PFC (n=8) or the Agranular Insular cortex (n=8). Lidocaine at varying concentrations was injected into these areas to observe the effect on subsequent FI behavior. Preliminary results from the temporary-lesion studies suggest that over an FI session, lidocaine into the PFC causes an initial decrease in run rate at the beginning of the session, followed by an increase in run rate at the end of the session. These changes were sometimes accompanied by decreased post reinforcement pause times. It is our hypothesis that the increase in run rate reflects an increase in DA release in the N.Acc. ## 68.14

ON THE ROLE OF DOPAMINE IN THE EFFECT OF NICOTINE ON THE EEG IN RATS B.Ferger and K.Kuschinsky\* Institute of Pharmacology and Toxicology, Faculty of Pharmacy, University of Marburg, D-35032 Marburg, Germany

In a previous study (Ferger and Kuschinsky, Naunyn-Schmiedeberg's Arch. Pharmacol 350: 346 (1994)), it was shown that a moderate dose of nicotine (0.2 mg/kg s.c.) produced desynchronization in the EEG of rats and a decrease of power which was not antagonized by blockade of D1-like dopamine receptors, although this EEG pattern seemed to be characteristic for activation of D1-like rather than D2-like receptors. This seemed surprising since nicotine is known to enhance dopaminergic neurotransmission in the basal ganglia. Due to a strong reciprocal connection between cortex and striatum, dopaminergic effects on the striatum should lead to alteration in the cortical EEG.

Therefore, the release of dopamine was studied in the striatum by microdialysis in awake rats and, in parallel studies, the cortical EEG was measured after administration of 0.4 mg/kg of nicotine s.c.. This dose produced a desynchronization in the EEG and a decrease of power in all of the frequency bands. There was very little increase of striatal extracellular dopamine (maximal increase: 28 % of baseline level).

We conclude that activation of striatal dopaminergic neurotransmission does not seem to be relevant for the EEG effects observed. Supported by VERUM Foundation

SEX DIFFERENCES IN POSTURAL COMPENSATION TO AN INCLINED PLANE DURING HALOPERIDOL CATALEPSY: THE ROLE OF NEONATAL ANDROGEN EXPOSURE S.M. Pellis\*, E.F. Field and I.O. Whishaw. Dept. of Psychology, University of Lethbridge, Lethbridge, AB Canada T1K 3M4.

Rats exhibiting haloperidol-induced cataleptic immobility can be induced to jump by placing them on a tilting inclined plane. Males and females injected with 5.0 mg/kg of haloperidol differ in their response to this. The angle of the incline plane was measured at the point where the rats jump. Females jump at a lower angle than do males. Males also shifted their body backwards and made backward adjusting steps. In contrast, females did not shift their body backwards and are more likely to step forward. This difference is modified by neonatal androgen manipulation. Females injected with testosterone propionate at birth were more male-like and males castrated at birth were more female-like. This suggests that sex differences in postural support mechanisms are partly determined by neonatal androgen exposure. This research was supported by NSERC.

## 68.17

SEX DIFFERENCES IN THE ORGANIZATION OF LATERAL MOVEMENTS ARE PRESERVED DURING APOMORPHINE INDUCED STEREOTYPY E. F. Field\*, S. M. Pellis and I. O. Whishaw. Dept. of Psychology, University of Lethbridge, Lethbridge AB Canada T1K 3M4.

Apomorphine is known to produce circling in rats. This circling involves modifications of the hindlimb stepping patterns commonly seen during turning in rats injected with saline. During turning behaviors by rats, sex differences in the lateral movement of the pelvis and associated hindlimb stepping patterns have also been reported. In this study the effects of apomorphine (1.1 mg/kg), on differences in turning patterns of male and female rats are compared. Males display more lateral movement of the pelvis, relative to the movement of the snout, during apomorphine-induced turning than do females. This difference reveals that while stepping patterns of male and female rats are modified by apomorphine treatment, the differences in lateral movement of the pelvis are not. This suggests that sex differences in lateral pelvic movement are independent of hindlimb stepping patterns. This research is supported by NSERC.

## 68.19

AMPHETAMINE AND THE ELICITATION AND INHIBITION OF THE STARTLE REFLEX IN ADULT AND AGED MICE. S. B. Schwarzkopf\*, V. Thai, P. Agrawal, E. Gutierrez, & J. R. Ison, Brain & Cognitive Sciences, University of Rochester, Rochester NY 14627.

Aged mice, like aged humans, show a diminished acoustic startle reflex (ASR), an effect too severe to be due to changes in auditory function. Here we tested the hypothesis that this decrement results from reduced arousal, which suggests that it may be partially remediated by a small dose of amphetamine (AMPH). We also examined prepulse inhibition for gaps in noise (1 to 15 ms long, 60 ms before the ASR) to see if gap thresholds were sensitive to AMPH. F1 offspring of CBA/Ca and C57Bl/6J mice were tested at 8 and 27 m (n = 18), first at AMPH levels of 0, .05, .1 and .5 mg/kg, and later, at 4 mg/kg vs 0. The old mice had lower ASRs, which were unaffected by low AMPH. There were no effects of age or low AMPH on relative PPI. With high AMPH ASRs were reduced to near activity values in old but not young mice. Thresholds were not affected even in old mice, as long as they had a response that could be measured. Rather than being engaged in interfering stereotyped acts, old mice seemed "behavioral inert" in the testing cage, but remained capable of processing small gaps in noise. These data suggest the testable hypothesis that normal dopamine release in mesolimbic regions was reduced in the aged mouse. Perhaps a primary effect of AMPH in old mice was to increase extracellular serotonin, which would be expected to diminish the ASR. Supported by NIH Grants AG09524 and EY01319, and by RICHSR

## 68.18

CHRONIC AMPHETAMINE TREATMENT INDUCES SENSITIZATION OF PREPULSE INHIBITION IN THE RAT. J. Zhang, J. A. Engel, B. Söderpalm and L. Svensson\* Department of Pharmacology, Göteborg University, Göteborg, Sweden.

Male Sprague-Dawley rats were repeatedly treated with amphetamine (AMP, 1 mg/kg, s.c.) at an interval of 3 days and tested for prepulse inhibition of acoustic startle after each treatment. This treatment regimen induced sensitization in the animals as evidenced by a progressive increase in the disrupting effect of AMP on prepulse inhibition. Persistent changes in brain function was indicated since an increase in sensitivity was observed in sensitized animals also after a 22 days long drug- and test-free period. The development of sensitization was blocked by pretreatment with haloperidol (0.1 mg/kg, s.c.), which suggests that sensitization of the disrupting effects of AMP was dependent on dopamine (DA) D<sub>2</sub> receptor activation. Furthermore, the development of sensitization was blocked by adrenalectomy, which suggests that sensitization was dependent also on circulating adrenal hormones. Increased DA-ergic activity has been implicated in the pathophysiology of schizophrenia and AMP-induced sensitization of the neuronal functions that modulate prepulse inhibition may be an experimental model to investigate this hypothesis.

This investigation was supported by grants from the Swedish Medical Research Council (4247).

## 68.20

R-(+)-HA-966, A GLYCINE-NMDA ANTAGONIST, ACTS IN THE VENTRAL TEGMENTAL AREA TO BLOCK CONDITIONED FEAR AND ASSOCIATED METABOLIC ACTIVATION OF MESOCORTICAL DOPAMINE NEURONS. J.D. Elsworth\*, B.A. Morrow, E.J.K. Lee and R.H. Roth, Depts. of Pharmacology and Psychiatry, Yale University School of Medicine, New Haven, CT 06520.

Systemic administration of the glycine-NMDA antagonist, R-(+)-HA-966, in the rat blocks the expression of conditioned fear behavior and the associated increase in mesocortical dopamine (DA) metabolism. In the present study, R-(+)-HA-966 was injected in the ventral tegmental area (VTA) to see whether the drug acted in the VTA to achieve its effects in the conditioned fear paradigm, an animal model of anxiety.

Rats underwent 3 sessions each lasting 30 min on 3 consecutive days: habituation (no tones, no footshocks), acquisition (10 tones paired with 0.4 mA x 0.5 sec footshocks), and extinction (10 tones, no footshocks). R-(+)-HA-966 (15 µg/0.5 µl) was administered into the VTA immediately before the session on either the acquisition day or the extinction day. Sacrifice was directly after the last session.

R-(+)-HA-966 given either on acquisition or extinction days prevented the conditioned fear-induced increase in DA metabolism in the medial prefrontal cortex, but not in the nucleus accumbens. On the acquisition day, exposure to R-(+)-HA-966 blunted the acquisition of fear, compared to saline controls, as measured by shock-induced immobility. On the extinction day, rats given R-(+)-HA-966 on the acquisition day displayed less immobility in response to the tone, compared to controls, both initially and throughout the test period. Rats treated with R-(+)-HA-966 on the extinction day had a greater rate of extinction than control rats. In another study, R-(+)-HA-966 (15 mg/kg i.p.) prevented the shock-induced increase in the number of tyrosine hydroxylase positive cells with Fos-LI in the VTA.

Thus antagonism at VTA glycine-NMDA sites blocks conditioned fear behavior and associated metabolic activation of mesocortical, but not mesoaccumbens DA neurons. Supported by US PHS MH-14092.

LOCAL APPLICATION OF GABA AGONISTS AND ANTAGONISTS FAILS TO MODULATE THE PREFRONTAL CORTICAL DOPAMINE STRESS RESPONSE. M. D. Doherty\* and Alain Gratton, McGill Univ., Douglas Hosp. Res. Ctr., Montreal, Canada, H4H 1R3.

Stress stimulates DA release in prefrontal cortex (PFC) and in nucleus accumbens (NAcc); increasing evidence suggests that meso-PFC DA projection modulates the meso-NAcc DA response to stress. We have recently shown that D1-, but not D2-, receptor blockade in PFC enhances (Doherty and Gratton, 1996), and that PFC GABA-B but not GABA-A receptor activation inhibits, stress-induced DA release in NAcc (Soc. for Neurosci., 1995). While it is clear from these studies that PFC DA and GABA both contribute to the regulation of NAcc DA transmission, the interaction between DA terminals and GABA neurons in PFC is not yet completely understood. While DA is known to influence GABA release, it is not clear if the PFC DA response is modulated locally by GABA. To investigate this, we used voltammetry to monitor the DA stress response in PFC following local injections (0.01, 0.10, and 1.00 nmole in 0.5 µl) of GABA-A and GABA-B agonists (baclofen and muscimol) and GABA-A and GABA-B antagonists (bicuculline and phaclofen). Neither the GABA-A or GABA-B agonists or antagonists altered the PFC DA stress response. We also report that intra-PFC injections of the D2/D3 DA agonist quinpirole inhibited, whereas local DA uptake blockade with GBR 12909 potentiated, the PFC DA stress response. These data indicate that the PFC DA response to stress is not modulated locally by GABA. It would appear therefore that the inhibitory effect of intra-PFC baclofen on the NAcc DA stress response is mediated by GABA-B receptors located on PFC interneurons or output neurons. Supported by the Medical Research Council of Canada.

## 69.2

MESOCORTICAL DOPAMINE RESPONSES TO PHYSICAL AND PSYCHOLOGICAL STRESS: RELATIONSHIP WITH LATERALITY AND PLASMA CORTICOSTERONE. R.M. Sullivan\* and A. Gratton, Douglas Hosp. Research Ctr., McGill University, Montréal, CANADA H4H 1R3.

Increasing evidence suggests that activation of the DA projection to the medial prefrontal cortex (mPFC) is asymmetric and functionally related to the ability to cope with stress. In the present study voltammetry was used to monitor changes in DA levels in the left and right mPFC of rats exposed to mild physical and psychological stress. These were 2 min. of tailpinch (TP), and 15 min. exposure to cat feces (CF), respectively. Fourteen male Long-Evans rats with bilateral mPFC carbon fibre recording electrodes were tested on four consecutive days, during which the electrochemical response to each stress was recorded in each mPFC in counterbalanced order. A week later, animals underwent a 20 min. restraint stress, with plasma taken at 0, 20 and 80 min. to determine corticosterone (CORT) levels. It was found that the DA response to TP was significantly longer-lasting in the left than in the right mPFC, while a trend in the opposite direction was noted for the DA response to CF. The peak increases in DA elicited by the two stressors were significantly correlated only in the right mPFC. The magnitude of stress-induced increases in plasma CORT was positively correlated to DA mPFC responses to both stressors, but significant only for TP. Finally, CORT responses were more pronounced and longer-lasting, when asymmetries in the DA response to CF favoured the right mPFC. The data suggest that asymmetric mesocortical DA activation depends on the type of stress, and that regulation of DA responses to both types of stress is most tightly coupled in the right mPFC. Also, while neuroendocrine and DAergic stress responses are positively linked, this relationship is only asymmetrical for the psychological stressor, which may reflect a specialized role for right mPFC mechanisms in the integration of emotional and physiological responses to stressful situations. (Supported by FRSC and MRC).

## 69.3

FLUCTUATIONS IN PREFRONTAL CORTICAL DOPAMINE DURING OPERANT RESPONDING FOR FOOD: AN IN VIVO ELECTROCHEMICAL STUDY IN RAT. N.R. Richardson\* and A. Gratton. McGill Univ., Douglas Hosp. Res. Ctr., Montreal, Canada, H4H 1R3.

Lesions to the prefrontal cortex (PFC) result in aphagia; feeding and food-related stimuli activate the meso-PFC dopamine (DA) system as does operant behavior rewarded by food. In the present study, we used voltammetry in combination with monoamine-selective probes to monitor DA levels in PFC of rats lever-pressing for a reward of condensed milk. Under standard conditions, each response was rewarded by 0.2 ml of milk delivered over 30 sec paired with a 30 sec light cue. Typically, lever-presses were immediately followed by small decreases in DA signal and these began increasing again once consumption of the milk reward was completed. The magnitude of signal decreases during milk consumption did not appear to change as a function of satiation or experience. Delaying milk delivery by 20 or 30 sec after each lever-press caused a corresponding decrease in DA signal accompanying milk consumption; these were preceded by increases time-locked to the duration of the delay. Decreases in signal preceded responses in the delay condition. Lever-presses rewarded with three times the usual volume of milk (0.6ml/30sec) were followed by more pronounced decreases while halving the expected reward (0.1ml/30sec) reduced the magnitude of signal decreases; withholding the milk reward altogether (0 ml) caused increases in DA signal. Orderly changes in DA signal were observed in response to increasing the response requirements to earn each reward (FR 3, FR 5, or FR 10). A decline in signal coincided with additional operant responding. The signal began to increase immediately after the rewarded lever-press before decreasing 12-20 sec into the period of milk delivery. The present data suggest that there are reward-related changes in PFC DA transmission. The magnitude of these changes is comparatively smaller and, in all but a few exceptions, opposite to those observed in nucleus accumbens (NACC) under the same conditions. These findings are also in agreement with the idea that meso-PFC DA indirectly modulates certain reward-related changes in NACC DA transmission. Supported by the MRC of Canada and McGill Graduate Scholarship program.

## 69.5

PREFRONTAL CORTEX DOPAMINE AND SEROTONIN: MICRODIALYSIS DURING AGGRESSION AND ALCOHOL SELF-ADMINISTRATION IN RATS A.M.M. van Erp\* and K.A. Miczek. Department of Psychology, Tufts University, Medford, MA 02155

Prefrontal cortex (PFC) dopamine (DA) has been shown to increase during exposure to stressors, including threat of attack, but little is known about PFC DA or serotonin (5-HT) in aggressive animals. Resident rats confronting an intruder were characterized neurochemically, using *in vivo* microdialysis of DA and 5-HT in PFC and n. accumbens (NAC). Male Long-Evans rats, housed with a female, attacked a smaller male intruder in their home cage during 5 min tests. After 2 encounters the residents were implanted with a guide cannula aimed at NAC or PFC. A microdialysis probe was inserted 18 hours before an intruder confrontation. Ten min samples were taken during 60 min baseline, 10 min intruder test and 120 min recovery. During the intruder test aggressive residents displayed up to 10 bites and threats, for a total duration of 110 seconds. In PFC, DA was increased to 160% after the intruder confrontation in aggressive animals, whereas 5-HT was decreased to 50% of baseline. These changes did not precede but followed the fight. In NAC, no such changes in DA or 5-HT were observed. In a second group of residents, intruder tests were combined with ethanol self-administration. During microdialysis an ethanol drinking solution was presented for 10 min, followed by a 10 min intruder confrontation, leading to increased DA levels in NAC; no such increase in DA was observed during intruder confrontations without ethanol. Effects of ethanol on PFC DA and 5-HT are under current investigation. The present results point to phasic changes in DA and 5-HT that are triggered by the display of aggressive behavior. (USPHS grant R37AA05122)

## 69.7

MESOLIMBIC DOPAMINERGIC NEURONS AND AFFECTIVE PERCEPTION: SPECIFICITY OF AMYGDALA- NUCLEUS ACCUMBENS INTERACTIONS. A. Louilot\* and C. Besson. CNRS UMR 5541 - Université de Bordeaux II - 146 rue Léo Saignat - 33076 Bordeaux Cedex - France.

We demonstrated previously that the responses of mesolimbic dopaminergic (DAergic) neurons to an affective stimulus are regionalized and lateralized in the nucleus accumbens (ACC). Furthermore, we showed that DA responses in the left core are directly dependent on the basolateral nucleus of the amygdala (BLA) if the stimulus is attractive and that other structures interact with the BLA if the stimulus presents an aversive value. In the present study, we investigated the involvement of the BLA-ACC interactions on the DA responses at the level of the left shell.

The DAergic reactivity was studied using the voltammetric measurements of DA in the ACC of freely moving male rats. Detection of DA was selectively obtained by the computed numerical analysis of the catechol signal. Experimental procedure was as following: animals were placed during one hour in the experimental cage; they were thus exposed for one hour to an appetitive olfactory stimulus (banana) and received consecutively either an injection of saline (NaCl 0.9%) (control group) or an injection of LiCl (0.15M) (experimental group) and stayed one more hour in the experimental cage; 72 h later animals were again exposed for one hour to the conditional olfactory stimulus (CS). Two hours before the second exposition to the CS animals received either a microinjection of phosphate buffered saline (PBS) or a microinjection of tetrodotoxin (TTX) in BLA.

The following results were obtained: during the 2nd presentation of the CS an increase of about 50±20% was observed in the control group+PBS whereas DA signal reached about 120±20% above the baseline in the experimental group+PBS; in the control group+TTX a maximal increase in DA release of about 160±20% was observed whereas in the experimental group+TTX the olfactory stimulus induced an increase of about 80±35% above the basal level. The present study strongly suggests that BLA is only involved in the perception of attractive stimulus in the shell part of ACC and that BLA interacts in this context with other forebrain structures.

## 69.4

PERINATAL ANOXIA FACILITATES DEVELOPMENT OF SENSITIZATION TO AMPHETAMINE IN ADULT RAT. W. Brake\*, P. Boksa, and A. Gratton. Dept. of Psychiatry, McGill Univ., Douglas Hosp Res Ctr, Montreal, Canada.

There is increasing evidence linking schizophrenia to obstetric complications (such as transient anoxia) at birth. We have found evidence in rat suggesting that anoxia at birth can later facilitate the development of sensitized dopamine (DA) transmission in nucleus accumbens (NACC). Animals as well as humans will sensitize to the behavioral stimulant effect of amphetamine. We examined the possibility that the locomotor stimulant action of amphetamine would sensitize to a greater extent in rats that had been subjected to an episode of perinatal anoxia. Dams were decapitated on the last day of gestation, the uterus was removed by Caesarian (C)-section and immersed in a 37°C saline bath for 15 min (C+15). Control groups comprised pups either delivered immediately after C-section (C+0) or born vaginally (VAG). Three months later, the spontaneous locomotor activity was monitored. Animals were then assigned to receive one of three pretreatment conditions: either 5 consecutive daily injections of D-amphetamine (2.0 mg/kg ip) or of equal volume of saline or no injection. One week later, all animals received a challenge injection of D-amphetamine (0.5 mg/kg ip). No differences were evident between the three birth groups that had received amphetamine pretreatment. However, of those animals that had been pretreated with saline, the C+15 group showed a significantly greater locomotor response to the amphetamine challenge than did the C+0 and VAG groups. There were no differences between birth groups in the no-pretreatment condition. It appears that the stress associated with repeated intraperitoneal injection of saline was sufficient to sensitize C+15 animals to the challenge of amphetamine. Stress will cross-sensitize with the behavioral effects of amphetamine. Stress also stimulates DA release in NACC and we have reported evidence that sensitization of this response is enhanced by perinatal anoxia. Together, these findings provide neurobiological evidence in support of the idea that obstetric complications involving anoxia may contribute to the pathophysiology of schizophrenia.

(+)-HA966 AND CLONIDINE, BUT NOT PROPRANOLOL, PREVENT FG7142- INDUCED INCREASES IN PREFRONTAL CORTICAL DOPAMINE TURNOVER AND AMELIORATE IMPAIRMENT OF SPATIAL WORKING MEMORY IN RATS AND MONKEYS. BL. Murphy\*, AFT. Amisen, JD. Jentsch, and RH. Roth. Department of Pharmacology and Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510.

The benzodiazepine inverse-agonist, FG7142, produces a selective increase in dopamine (DA) turnover in the rodent prefrontal cortex (PFC). Administration of FG7142 to rats and monkeys produces impairment of PFC-dependent, but not non-PFC-dependent, cognitive tasks. The level of FG7142-induced DA turnover in the rodent PFC correlates with the degree of the cognitive deficits, and the impairment can be blocked in rats and monkeys by DA-receptor antagonists (Murphy et al., 1994; 1996). The current study examines the effects of drugs which do not act at DA receptors, but rather alter the stress-induced increase in DA turnover, in order to determine their influence on the FG7142-induced impairment of spatial working memory. Systemic administration of clonidine, a noradrenergic agonist, and (+)HA966, a glycine/NMDA antagonist, prevented the FG7142-induced increase in DA turnover in the rodent PFC. In addition, a direct infusion of (+)HA966 into the ventral tegmental area also blocked the increase in rodent PFC DA turnover. (+)HA966 and clonidine treatment prevented the FG7142-associated PFC-dependent cognitive deficits in both rats and monkeys. (-)HA966, a GHB-like agent, also blocked the FG7142-induced increase in PFC DA turnover and attenuated the FG7142-associated cognitive deficits in the rat. Propranolol was ineffective at blocking FG7142-associated cognitive impairment in rats. These studies support our previous conclusion that excessive PFC DA turnover leads to impaired PFC-dependent cognition. Support for these studies came from NIH grants #MH14092, #AG0636 and from NSF #GER9253954 (BLM).

MICROINJECTION OF THE D1 ANTAGONIST SCH23390 INTO THE LEFT OR RIGHT MEDIAL PREFRONTAL CORTEX DIFFERENTIALLY ALTERS THE BEHAVIORAL AND NEUROCHEMICAL RESPONSES TO FOOTSHOCK STRESS. D.M. Nielsen\*, R.W. Keller, Jr. and S.D. Glick, J.N. Carlson. Dept. of Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208

Interactions between lateralized cortical, limbic, and striatal dopamine (DA) systems have been related to the response to stressors. During the stress response asymmetrical changes take place in these DA systems. The behavioral response to stressors may be modulated by lateralized DA systems in the medial prefrontal cortex (mPFC). One manifestation of endogenous lateralization of DA systems is rotation (or circling) behavior in normal unlesioned rats. In the present studies mPFC DA lateralization was augmented pharmacologically in male Long Evans rats of differing rotational biases. Animals were then placed in a shuttlebox and exposed to a footshock stressor. Escape behavior and resultant neurochemical responses were assessed. Intracerebral microinjections of the selective D1 antagonist SCH23390 into the left mPFC increased shuttlebox footshock escape latency, while right injections had no significant effect. Neurochemical differences were influenced by side of injection as well as by turning preference. DA, serotonin (5HT) and their metabolites were measured in the mPFC, nucleus accumbens (NAS) and striatum of both the left and right sides. Left drug injections had greater effects than right injections on DA and 5HT neurochemistry in the mPFC and striatum. Thus injections of the D1 antagonist SCH23390 into the left, but not right, mPFC altered both the behavioral and neurochemical responses to footshock stress.

EFFECTS OF D-AMPHETAMINE INJECTED INTO THE NUCLEUS ACCUMBENS OR VENTRAL PALLIDUM ON LOCOMOTION AND RESPONDING FOR A CONDITIONED REWARD. P.J. Fletcher\*, M.S. Sabian and N.J. De Sousa. Clarke Institute of Psychiatry<sup>1</sup>, Toronto, M5T 1R8 & Dept. of Psychology and Psychiatry<sup>1</sup>, University of Toronto, Toronto, Canada M5S 1A1.

Both the nucleus accumbens (NAcc) and ventral pallidum (VP) receive dopamine (DA) projections from the mesencephalon. Although DA inputs to the NAcc are implicated in both locomotion and reward processes, very little is known of the behavioural significance of DA in the VP. Therefore, these studies examined the effects of microinjections of d-amphetamine (AMPH; 0.1, 3 and 10 µg) into the NAcc or VP on locomotor activity and responding for a conditioned reward (CR). Male rats were prepared with cannulae aimed at either the NAcc or VP. In Experiment 1, AMPH injected into the NAcc dose dependently (1, 3 and 10 µg) increased locomotor activity measured as photobeam interruptions. Intra-VP microinjections of AMPH also increased activity (10 µg). In Experiment 2, food deprived rats were first trained to associate a light/tone stimulus (subsequently the CR) with food delivery. In the test phase, they were allowed access to a lever delivering the CR, and an inactive (NCR) lever. Responding on the CR lever was greater than responding on the NCR lever indicating that the light/tone stimulus functioned as a CR. Responding for the CR was selectively and dose-dependently potentiated by NAcc AMPH (3 & 10 µg). AMPH at 10 µg also enhanced CR responding when injected into the VP. However, the magnitude of this responding appeared to be lower than responding elicited from NAcc injections of AMPH. The results suggest that release of endogenous DA in the VP enhances locomotion and responding for a CR. However, these effects appear to be less intense than those resulting from DA release in the NAcc. (Funded by NSERC).
