In vivo recovery of extracellular dopamine concentrations in the nucleus accumbens of female hamsters and rats have shown increases during mating. We tested the possibility that vagino-cervical stimulation is involved in the increase in accumbens dopamine during copulation in female Syrian hamsters. Using microdialysis we sampled accumbens dopamine during mating in females with vaginal masks which prevented penile insertion and in females receiving intromissions. Dopamine concentrations significantly increased during the first 30 min in copulation tests for the hormonally-primed females without vaginal masks, while no increases were seen in hormonally-primed females with vaginal masks or in oil-treated females not engaging in sexual activity. However, the total time spent in lordosis was not different between the two groups of hormonally-primed females. These results indicate that vagino-cervical stimulation is necessary to induce increases in extracellular dopamine in female hamsters during copulation and that neither the mere presence of the male nor the stimulation received during mounting of the male is sufficient to produce these changes.

MECHANISMS UNDERLYING THE EFFECTS OF DOPAMINE LOSS IN THE MEDIAL PREFRONTAL CORTEX ON THE ACTIVITY OF MESOLIMBIC DOPAMINE NEURONS. D. King\*, D.G. Harden, A.A. Grace, M.J. Zigmond & J.M. Finlay. Depts of Neuroscience & Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260.

We previously reported that dopamine (DA) loss in the medial prefrontal cortex (mPFC) potentiated the stress-induced increase in DA efflux in the nucleus accumbens (NAS) shell but not the NAS core. To determine whether this effect results from lesion-induced changes in the electrophysiological activity of DA neurons, we used extracellular recordings to examine the activity of DA neurons in the ventral tegmental area of control and lesioned rats (n=10/group). Depletion of DA in the mPFC decreased the firing rate (-24%) and the incidence of burst-firing (-23%) of these neurons (control rate = 4.7±0.2 Hz and bursts = 39±3%; n=113-148/group). Because the magnitude of evoked responses of DA cells is dependent upon basal activity, we propose that this decrease would result in larger stress-evoked responses. We also examined whether the differential effects of lesions on DA efflux in the NAS shell and core are paralleled by differences in the severity of DA loss between the mPFC subareas that preferentially innervate the NAS shell (ventral mPFC) and the core (dorsal mPFC). The distribution of DA terminals remaining in the ventral and dorsal mPFC after lesions was determined by examining tissue DA content and tyrosine hydroxylase immunoreactivity in control and lesioned rats (n=15/group). The absolute amount of DA remaining in the mPFC after lesions was greater in the ventral than in the dorsal area (0.04±0.00 vs 0.02±0.00 ng/mg tissue), although the percent loss was similar in the two areas (-74% vs -68%). In addition, more tyrosine hydroxylase immunoreactivity remained in the ventral mPFC. These data rule out the possibility that the selective effect of lesions on DA efflux in the NAS shell is due to greater DA loss in the ventral mPFC. Rather, we support the view that the selective effect of DA depletion in the mPFC on DA efflux in the NAS shell is due to the selective responsiveness of DA terminals in the ventral mPFC to stress [Supported by NARSAD, USPHS grants MH45156 & MH10773].

A HISTOLOGICAL METHOD FOR VERIFYING THE SOURCE OF ANALYTES RECOVERED IN MICRODIALYSIS STUDIES. R.L. Meisel\*, R.K. Rowe and J.G. Kohlert. Department of Psychological Sciences, Purdue University, West Lafayette, IN 47907.

Verification of probe placements in microdialysis studies typically rely on determination of the location of the probe in Nissl stained brain sections. Because the goal of microdialysis studies is to sample from a defined functional neurochemical system and because the distribution of terminal fields from such systems often defy conventional cytoarchitecture, we have begun developing a method to identify the cellular origins of the terminal field from which microdialysis samples are recovered. For our studies, we have been interested in the modulation of nucleus accumbens dopamine. Following a dialysis experiment, we flush the probes with fluorogold and then process the brains histochemically for tyrosine hydroxylase. Quantitative cell counts of midbrain neurons containing both fluorogold and tyrosine hydroxylase indicated that about 92% of the dopaminergic projection to the nucleus accumbens arose from the A10 ventral tegmental region. There were no quantitative differences between rostral and caudal accumbens probe placements, nor was the midbrain labeling of rostral bed nucleus of the stria terminalis placements distinguishable from the accumbens placements. The number of neurons labeled was positively related to the volume of the injection site, and basal dopamine levels were also positively correlated with the number of fluorogold-labeled cells. These results validate assumptions that dopamine recovered from the nucleus accumbens in microdialysis studies is primarily of A10 origin, and that basal dopamine levels reflect the size of the terminal field from which samples are recovered.

Supported by NSF grant IBN-9412543 (RLM).

## 69.12

ENDOGENOUS GLUTAMATE IN SUBSTANTIA NIGRA MEDIATES THE STRESS-INDUCED INCREASE IN STRIATAL EXTRACELLULAR DOPAMINE. S.L. Castro\* and M.J. Zigmond. Department of Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260.

We have shown that antagonists of excitatory amino acids (EAAs) infused into neostriatum attenuate the stress-induced increase in striatal DA synthesis, suggesting a role of endogenous glutamate in this process (Castro et al., 1996). However, we have failed to obtain any direct evidence for a role for endogenous EAAs acting within the striatum in regulating DA release (Keefe et al., 1992, 1993). EAA-containing terminals from cortex project to the cell bodies, as well as terminals, of the nigrostriatal DA neurons, and thus, may influence striatal DA release indirectly via these cell bodies. Several recent studies have suggested that such an interaction is possible, but that endogenous EAAs in the substantia nigra (SN) or ventral tegmental area do not alter basal DA release from striatum or nucleus accumbens. In this study we examined the influence of EAAs in SN on striatal DA release during stress. Microdialysis probes were directed to both the SN (1-mm probe; AP -5.2, ML -5.5, DV -9.6 angled 250 in the mediolateral plane) and the neostriatum (4-mm probe; AP +0.5, ML -2.5, DV -7.0) of adult male rats. Rats receiving vehicle infusion into SN showed a 46 ± 9% (n=3) increase in extracellular DA levels when exposed to 30 min of intermittent footshock. Intrastriatal infusion of the NMDA receptor antagonist APV (0.1 mM) into SN via reverse microdialysis, which did not significantly alter basal extracellular DA levels in ipsilateral neostriatum, significantly attenuated the footshock-induced increase (13 ± 4% above baseline, n=5). These data suggest that the stress-induced release of striatal DA may be mediated by an action of glutamate in SN. (Supported in part by USPHS grants MH29670 and MH45156.)

## 69.14

INTRA-ACCUMBENS INFUSION OF PREFERENTIAL D<sub>3</sub> RECEPTOR AGONISTS REDUCE SPONTANEOUS AND DOPAMINE INDUCED-LOCOMOTION IN THE RAT. A. Ouagazzal\* and I. Creese. Center for Molecular & Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

The objective of the present study was to test the hypothesis that D<sub>3</sub> dopamine (DA) receptors located within the nucleus accumbens exert an inhibitory influence on psychomotor functions. We first examined the effects of intra-accumbens infusion of the D<sub>3</sub>-preferring agonists, PD 128,907 and 7-OH-DPAT, on spontaneous locomotion. For comparison we also studied the preferential DA autoreceptor agonist, B-HT 920. Bilateral intra-accumbens infusion of PD 128,907 (1.5 and 3 µg/0.5 µl), induced a dose-dependent hypolocomotion, whereas its enantiomer, PD 128, 908 was inactive. Local infusion of 7-OH-DPAT and B-HT 920 also decreased spontaneous locomotion. In addition, both drugs induced yawning with the B-HT 920 producing the greatest effect. In a second experiment, the ability of these agonists to reduce the hyperactivity induced by bilateral intra-accumbens infusion of DA (10 µg/0.5 µl) was studied. Prior infusion of PD 128,907 or 7-OH-DPAT (3 µg) into the nucleus accumbens markedly reduced the locomotor hyperactivity induced by DA. However, local infusion of B-HT 920 (3 µg) failed to antagonize the locomotor effects of DA. These findings support the hypothesis that D<sub>3</sub> receptors exert an inhibitory influence on psychomotor functions and further suggest that these D<sub>3</sub> receptors may be located postsynaptically in the nucleus accumbens. Our data also indicate the involvement of dopamine autoreceptors, likely D<sub>2</sub> receptors, within the nucleus accumbens in the modulation of the yawning behavior in the rat. Supported by NIMH.

## 69.15

THE INVOLVEMENT OF NUCLEUS ACCUMBENS DOPAMINE IN LEVER PRESSING: A BEHAVIORAL AND NEUROCHEMICAL STUDY OF CORE AND SHELL REGIONS. J.D. Sokolowski\* and J.D. Salamone, Dept. of Psychology, University of Connecticut, Storrs, CT, 06269-1020.

A series of three experiments was undertaken to investigate the involvement of nucleus accumbens core and shell dopamine (DA) in lever pressing tasks. In the first experiment, rats were trained to lever press on a fixed-ratio 5 (FR5) operant schedule with lab chow concurrently available in the chamber. In the second experiment, rats were trained to lever press on the FR5 alone. In both experiments, rats were initially trained and then were injected with the neurotoxic agent 6-hydroxydopamine (6-OHDA) in either the nucleus accumbens core or shell. Injections of 6-OHDA into the core significantly decreased lever pressing and increased chow consumption in the first experiment. If lever pressing tests were conducted with no lab chow concurrently available (experiment 2), core injections of 6-OHDA produced a modest but significant decrease in lever pressing. Injections of 6-OHDA into the medial/dorsal region of shell produced much smaller behavioral effects, with only a slight reduction in lever pressing in both experiments. Although both core and shell injections produced similar DA depletions in the target region (about 90%), core injections produced larger depletions of total accumbens DA. In experiment 3, microdialysis probes were implanted in either the core or the shell following training on the FR5 schedule. There were increases in extracellular DA in both the core and shell during the lever pressing session, with a tendency towards a higher percentage increase in the shell. Thus, although DA release is increased in core and shell during lever pressing, the results of the DA depletion experiments indicate that rats with accumbens DA depletions in either core or shell remain directed towards the acquisition and consumption of food.

## DRUGS OF ABUSE: NICOTINE

## 70.1

NICOTINE SELF-ADMINISTRATION IN RATS HAVING UNLIMITED ACCESS TO THE DRUG. J.D. Valentine\*, J.S. Hokanson, S.G. Matta, and B.M. Sharp, Minneapolis Medical Research Foundation and Departments of Medicine, Hennepin County Medical Center and University of Minnesota, Minneapolis, MN 55404.

Identifying the neural substrates involved in chronic drug use will require the increased use of models in which animals choose to engage in patterns of drug-taking behavior similar to those of humans. We are currently using such a model to study the substrates affected by chronic nicotine self-administration. In this model, jugular-cannulated rats living in operant chambers are allowed 24-hour access to 2 levers; presses of one lever are programmed to deliver 0.03 mg/kg nicotine base in 50  $\mu$ l saline over 1.2 sec, with each injection being followed by a 1-min timeout; presses of the other lever have no programmed consequences. Initially, under these conditions, 24-hour self-administration rates can be quite erratic, but stabilize after approximately 1-3 weeks. Importantly, the vast majority of injections are self-administered during the active portion of the light/dark cycle. Changing the schedule of reinforcement from a FR1  $\rightarrow$  FR3  $\rightarrow$  FR5 leads to systematic increases in the number of presses on the active lever, without affecting on the number of presses on the inactive lever or the total number of injections administered per 24-hour session. Moreover, discontinuing the nicotine injections causes pressing of the active lever to extinguish. Thus, rats allowed unlimited access to nicotine self-administer the drug in a pattern comparable to humans, and the behavior is maintained by the reinforcing properties of the drug. We are currently using this model to investigate various types of neuronal plasticity that might underlie the chronic self-administration of nicotine. (Supported by DA03977 and T32-DA07234)

## 70.2

SELF-ADMINISTERED NICOTINE MAY PRODUCE DIFFERENT EFFECTS THAN YOKED NICOTINE, E. C. Donny, A. R. Caggiula, C. Rose, S. Knopf, C. G. McAllister, A. F. Sved, K. A. Perkins, University of Pittsburgh, Pittsburgh, PA. 15260

Injected nicotine results in activation of the hypothalamic-pituitary-adrenocortical (HPA) axis and sympathetic nervous system (SNS) and suppression of immune function. These findings form the basis of several hypotheses regarding the effects of nicotine on human smokers. However humans self-administer nicotine and other evidence indicates that self-administered drug produces different effects than experimenter-administered drug. This led us to ask whether the effects of experimenter-administered nicotine also result when rats self-administer the drug. Rats were trained to lever press for food and were implanted with IV catheters. One group self-administered nicotine while the other two groups received yoked infusions of either nicotine or saline. On the first day, self-administered and yoked nicotine significantly elevated plasma corticosterone (CORT) levels above a preinfusion baseline within 15 min after the first infusion (0.03 mg/kg) and showed partial tolerance by the end of the 1 hr session. In contrast yoked, but not self-administered nicotine elevated plasma epinephrine at 15 min and both epinephrine and norepinephrine at 1 hr. This experiment points to the importance of using self-administration as a model which more closely approximates human nicotine use. Supported by NIDA grants DA-07546 and DA-08505.

## 70.3

INTRAVENOUS NICOTINE SELF-ADMINISTRATION IN LABORATORY ANIMALS: CHASING THE ENIGMA. M.A. Bozarth\* & C.M. Pudiak, Addiction Research Unit, Department of Psychology, University at Buffalo, Buffalo, NY 14260.

Two standard intravenous self-administration procedures effective in demonstrating cocaine and heroin reinforcement were used to assess the reinforcing effect of nicotine — direct acquisition and cross-substitution procedures. The first experiment examined the ability of nicotine to establish self-administration behavior. Experimentally naive rats were tested using 10-hr sessions for a total of 20 days. Manipulations which enhance responding were not used, e.g., lever training, food deprivation. The second experiment examined the ability of nicotine to maintain responding in animals previously trained to intravenously self-administer cocaine (1 mg/kg/inf). Various nicotine doses were substituted for the reinforcing cocaine injections during 3-hr self-administration tests; each nicotine dose was tested for 5 consecutive days. Both studies used nicotine bitartrate (10, 30, or 100  $\mu$ g/kg/inf; dose expressed as free-base weight; solution pH adjusted to 7  $\pm$  0.2) infused in a 0.25 ml/500 g volume over 30 sec/500 g.

In the direct acquisition study, several rats showed periodic response levels suggesting nicotine self-administration during some days of testing. However, nicotine intake was erratic both across days and within sessions even for these subjects. When tested for cocaine self-administration after completion of the nicotine tests, all subjects showed reliable cocaine self-administration. In the cross-substitution study, response rates for 10 and 30  $\mu$ g/kg/inf nicotine unit-doses exceeded saline response rates. However, both nicotine doses produced nearly identical intake patterns decreasing across the 5-day tests. The 100  $\mu$ g/kg/inf nicotine dose failed to maintain responding above saline levels.

These data suggest that nicotine does not serve as an effective reinforcer when tested using standard procedures that readily demonstrate intravenous cocaine and heroin reinforcement. Unlike the self-administration of highly addictive drugs, nicotine self-administration appears enigmatic, requiring special testing conditions. This finding is consistent with other tests suggesting the reinforcing efficacy of nicotine is very low.

## 70.4

NICOTINE ABSTINENCE PRECIPITATED BY CENTRAL BUT NOT PERIPHERAL HEXAMETHONIUM. D.H. Malin, C.K. Schopen, J.W. Kirk, E.E. Sailer, B.A. Lawless, T.P. Upchurch, M. Shenoi, N. Rajan & J.R. Lake, Univ. of Houston-Clear Lake, Houston, TX 77058.

Nicotine dependence has been induced in the rat by 7 days s.c. infusion of 9 mg/kg/day nicotine tartrate via Alzet osmotic minipump. Abstinence syndrome has been precipitated by pump removal or by s.c. injection of the noncompetitive nicotinic antagonist mecamylamine, which freely crosses the blood-brain barrier (BBB). In contrast, the noncompetitive nicotinic antagonist hexamethonium crosses the BBB very poorly. Groups of 7 nicotine dependent rats were injected s.c. with 0.5 or 1 mg/kg hexamethonium dichloride (HEX) or saline alone and observed for 20 min. Few abstinence signs were observed in any group; one-way ANOVA revealed no significant drug effect. In a 2nd experiment, 18 rats were cannulated in the 3rd ventricle and rendered nicotine dependent. I.C.V. injection of 18 ng HEX precipitated an average of 42.8 signs in 20 min, 12 ng HEX precipitated 32.3 signs, and saline alone precipitated 9.2 signs. Both dose groups differed significantly from the saline group and there was a significant linear trend of signs as a function of dose. The higher dose had no significant effect in nondependent rats. It is concluded that HEX is at least 22 million times as potent by the central route, and there is a major CNS component in nicotine dependence. (NIDA DA08260)

## 70.5

NICOTINE ALTERS MET-ENKEPHALIN CONTENT AND PREPROENKEPHALIN mRNA IN THE STRIATUM OF MICE. M. Hadjiconstantinou\*, R. Isola, T.A. Wemlinger, G.A. Tejwani and N.H. Neff. Departments of Psychiatry and Pharmacology, The Ohio State University College of Medicine, Columbus, Ohio, 43210.

In mice, acute administration of nicotine increased the content of met-enkephalin (MET-ENK) in the accumbens, dorsal striatum and hypothalamus, but not in the hippocampus, frontal cortex and olfactory tubercle. The increase of the opioid in the striatum was prolonged and was accompanied by a rise of the mRNA for its precursor peptide preproenkephalin (PPE). Discontinuation of nicotine after chronic administration caused a withdrawal syndrome, that lasted longer than 72 hr. Early during the withdrawal, the content of MET-ENK in the accumbens and dorsal striatum fell, and remained low for more than 48 hr. In contrast, the abundance of PPE mRNA increased by 12 hr into withdrawal, and remained elevated for longer than 96 hr. Our results indicate that endogenous opioids might play a role in nicotine dependence/withdrawal.

## 70.7

LOCALLY APPLIED NICOTINE ENHANCES THE CLEARANCE OF EXOGENOUSLY ADMINISTERED DOPAMINE IN THE RAT NUCLEUS ACCUMBENS, N.A. Kisro\* and C. Ksir. Department of Psychology and Neuroscience Program, University of Wyoming, Laramie, WY 82071.

Many researchers believe that the mesolimbic system is one of the common biological pathways through which addictive drugs, including nicotine, exert their actions. Currently there is debate as to where in the mesolimbic system nicotine is exerting its actions: at the cell bodies located in the ventral tegmental area (VTA) or at the cell terminals located in the nucleus accumbens (NAc).

In vivo voltammetry was used to estimate changes in the clearance of exogenously applied dopamine after acute, local application of nicotine (0.003µM, 0.01µM nicotine, or 0.03µM nicotine) into the NAc of rats. The peak dopamine concentration was significantly lower after 0.03µM nicotine application when compared to those in the saline group, implying an increase in the reuptake of dopamine. This nicotine effect was partially blocked when mecamylamine (1 mg/kg) was administered systemically 20 minutes prior to nicotine application. In addition, peak dopamine concentrations were significantly higher after 0.10µM cocaine application. These results suggest that nicotine acts at dopamine terminals, perhaps causing an increase in the release of dopamine into the synapse. This could then lead to a facilitation of the dopamine reuptake process.

## 70.9

STIMULATION OF ENERGY METABOLISM AND DOPAMINE RELEASE IN THE ACCUMBAL SHELL BY NICOTINE. F.E. Pontieri\*, G. Tanda, E. Carmenini, F. Orzi and G. Di Chiara. Dept. Neuroscience, University 'La Sapienza', Rome; #Dept. Toxicology, University of Cagliari; \*INM 'Neuromed', Pozzilli (IS), Italy.

Intravenous administration of psychostimulants and opiates, at dosages corresponding to those that sustain self-administration, preferentially or selectively increases extracellular dopamine and energy metabolism in the shell of the rat nucleus accumbens. Then, enhanced energy metabolism and increased dopamine transmission in the shell represent distinctive neurobiological markers of the addictive potentials of drugs, independently from their specific mechanisms of action. This study was designed to investigate whether nicotine produces in the shell neurochemical effects which resemble those of typically addictive substances. Local rates of glucose utilization and extracellular dopamine were therefore measured in the shell and core of the nucleus accumbens following intravenous administration of nicotine (0.025-0.05 mg/kg, free base) in the rat, using the 2-deoxyglucose method and brain microdialysis, respectively. Nicotine produced dose-dependent increases of both glucose metabolism and dopamine output in the shell, without affecting values in the accumbal core. These results demonstrate that acute intravenous administration of nicotine in the rat selectively modifies dopamine transmission and functional activity in the accumbal shell. They, then, provide functional and neurochemical evidence for the existence of specific neurobiological commonalities between nicotine and typically addictive drugs.

Supported by grants from MURST and CNR, Italy.

## 70.6

EFFECT OF CHRONIC NICOTINE (NIC) ON RESPONSIVENESS OF TERMINAL REGIONS OF DOPAMINERGIC PATHWAYS TO A LOCAL NIC CHALLENGE. D.L. Marshall\*, P.H. Redfern and S. Wonnacott. Sch. Pharmacy & Pharmacol. and <sup>1</sup>Sch. Biol. & Biochem., Univ. Bath, Bath BA2 7AY, U.K.

Given that nerve terminal nAChRs are thought to play an important role in the central actions of NIC (McGehee *et al.*, 1995), we have compared the effect of two chronic NIC regimes on the responsiveness of nAChRs in the terminal regions of the 3 ascending dopaminergic pathways to a local application of NIC using *in vivo* microdialysis. Male Sprague-Dawley rats (250-350g) received NIC (0.4mg/kg/day s.c.) either by daily injection or osmotic pump for 7 days, after which dialysis probes were implanted into the striatum, accumbens or cortex. The following day the effect of a local application of NIC on dopamine (DA) levels was determined as previously described (Marshall *et al.*, 1996). Differences between chronic NIC and saline control were compared using two way ANOVA for repeated measures.

	Saline Inj	Nicotine Inj	Saline Pump	Nicotine Pump
Striatum	372±122%	1370±317%*	397±173%	264±73%
Accumbens	368±128%	663±199%	349±137%	351±151%
Cortex	173±32%	283±102%	211±47%	199±72%

Data shown are peak DA levels (expressed as % of basal, mean ± s.e.m.) after local nicotine challenge, n=3-8. \*p<0.05.

These data suggests that intermittent exposure to peak NIC levels sensitises nAChRs in the striatum whereas steady state, trough levels, produced by chronic infusion, do not.

McGehee, D.S., *et al.* (1995). *Science* 269: 1692-1696.

Marshall, D.L., *et al.* (1996) *Br. J. Pharmacol. Proceedings Suppl.* (in press).

## 70.8

CHANGES IN EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS AND IN THE PREFRONTAL CORTEX OF NICOTINE DEPENDENT RATS ARE DISSOCIATED FROM PHYSICAL ABSTINENCE SYNDROME. E. Carboni\*, C. Giua and G. Di Chiara. Dept. of Toxicology, Univ. of Cagliari. Viale Diaz 182, 09126 Cagliari, Italy

The nicotinic antagonist mecamylamine and the opioid antagonist naloxone are able to precipitate a physical abstinence syndrome in rats chronically exposed to nicotine. The aim of the present study was to investigate the relationship between the physical abstinence syndrome and changes of dopamine release in the n. accumbens and in the medial prefrontal cortex induced by mecamylamine and naloxone, in rats exposed chronically to nicotine delivered by osmotic minipumps. Male Sprague Dawley rats (260 g) were implanted with Alzet osmotic minipumps that deliver 9 mg/kg/day of nicotine tartrate. Nine days thereafter, rats were implanted with a dialysis probe in the nucleus accumbens or in the medial prefrontal cortex. 24 hour later dopamine was measured in the perfusate. Steady state dopamine output from the nucleus accumbens was increased by 44 % in rats implanted with nicotine minipumps. Mecamylamine at the dose of 1 mg/kg s.c. induced a physical abstinence syndrome and decreased by about 40 % dopamine release in rats implanted with nicotine minipumps but was ineffective in controls. Mecamylamine (1 mg/kg s.c.) increased dopamine output in the medial prefrontal cortex by about 40 % in nicotine dependent but not in control rats. Naloxone (2 mg/kg), failed to modify extracellular dopamine the n. accumbens and in the prefrontal cortex of control and of nicotine implanted rats. Blockade of nicotine receptors by mecamylamine causes a modification of dopamine output in the n. accumbens and in the prefrontal cortex that is associated with the abstinence syndrome. Naloxone, although able to precipitate the abstinence syndrome in nicotine dependent rats, did not modify dopamine output in both the accumbens and the prefrontal cortex, thus suggesting that the changes in dopamine output in the mesolimbic system of nicotine dependent rats are dissociated from the physical signs of abstinence.

## 70.10

NIMODIPINE BLOCKS NICOTINE-INDUCED LOCOMOTION BUT NOT LOCOMOTION INDUCED BY GBR-12909. C. Hart\*, N.A. Kisro, S.L. Robinson and C. Ksir. Department of Psychology and Neuroscience Program, University of Wyoming, Laramie, WY 82071

Several studies report an attenuation of psychostimulant-induced locomotion in rats when calcium channel blockers are administered beforehand. Nicotine and GBR-12909 are both potent inducers of locomotor activity in rats. However, the effects of pretreatment with calcium channel blockers on nicotine- and GBR-12909 induced locomotion have not been assessed.

The present study examined the effects of nimodipine, a dihydropyridine L-type calcium channel antagonist, on nicotine- and GBR-12909-induced locomotor activity in drug-naive rats. Nicotine (4 mg/kg IP) and GBR-12909 (10 mg/kg IP) both produced significant increases in locomotion following acute administration. However, when rats were given injections of nimodipine (10 mg/kg IP) one hour before test drugs, nicotine-induced locomotor activity was blocked. In contrast, pretreatment with nimodipine delayed the onset of, but did not block, GBR-12909-induced locomotor activity. These results suggest that nicotine and GBR-12909 induce increases in locomotor activity through different mechanisms: nicotine effects being calcium-dependent and GBR-12909 effects being calcium-independent.

## 70.11

EFFECTS OF LOW DOSE MECAMYLAMINE ON REGIONAL CEREBRAL GLUCOSE METABOLISM IN RATS RECEIVING CHRONICAL NICOTINE. M. Takagishi, A.S. Kimes\* and E.D. London, Brain Imaging Section, Intramural Research Program, NIDA, P.O. Box 5180, Baltimore, MD 21224

As a therapeutic strategy for smoking cessation, Rose *et al.* (1992) have proposed concurrent administration of nicotine (Nic), delivered transdermally along with orally administered mecamylamine (Mec), a noncompetitive antagonist of nicotinic cholinergic receptors. In the rationale for this treatment, Nic would provide adequate occupancy of receptors to prevent a withdrawal syndrome and Mec would attenuate the reinforcing effects of rapid dosing with nicotine self-administered by smoking. In human studies, low doses of Mec reduce the consumption of cigarettes without producing self-reports of withdrawal in smokers (Tennant *et al.*, 1984, Rose *et al.*, 1994). Although Nic/Mec treatment seems to have utility in clinical smoking cessation programs, and a theoretical basis for therapeutic success has been proposed, no data on the interaction of low dose Mec with chronic Nic (cNic) in the brain are available. To elucidate this interaction *in vivo*, we assayed regional cerebral metabolic rates for glucose (rCMRglc), using the 2-deoxy-D-[1-<sup>14</sup>C]glucose (2DG) technique in rats receiving cNic and given a challenge dose of Mec. Rats received an infusion of saline or 9 mg/kg Nic (as the base) per day in saline via osmotic pumps. After 7 days, rats were given Mec (0.3 mg/kg, s.c.) or saline 15 min before the 2DG injection. The dose of Mec was about one-third of what was used previously to precipitate Nic withdrawal (Malin *et al.*, 1994). In rats given cNic, rCMRglc was higher in some brain regions, including anteroventral and interanteromedial thalamic nuclei, and the interpeduncular nucleus, compared with control values. These 3 brain regions previously showed increased rCMRglc after acute Nic challenge (London *et al.*, 1988). Generally, Mec appeared to reverse rCMRglc increases in rats given cNic. The findings suggest that a low dose of Mec partially nullifies the effect of cNic on rCMRglc without producing a generalized withdrawal syndrome. These findings support the rationale of concurrent agonist-antagonist therapy in smoking cessation.

## 70.13

IBOGAINE AND KAPPA OPIOID AGONISTS HAVE A SELECTIVE INHIBITORY ACTION ON NICOTINIC RECEPTOR-MEDIATED CATECHOLAMINE RELEASE. A.S. Schneider\*, S.J. Mah, P.E. Liauw, Y.M. Tang and J.E. Nagel, Dept. Pharmacology & Neuroscience, Albany Medical College, Albany, NY 12208

We have tested the effects of ibogaine on catecholamine release from a model neuronal system, cultured bovine chromaffin cells, in an effort to determine sites and mechanisms of ibogaine action. Various modes of stimulating catecholamine release were used including nicotinic ACh receptor activation, membrane depolarization with elevated K<sup>+</sup> (70 mM) and Na<sup>+</sup> channel activation with veratridine (100 μM). In addition, because ibogaine has been reported to interact with kappa opioid receptors, we tested whether kappa receptor ligands either mimic or inhibit ibogaine's effects on catecholamine release. Ibogaine (< 10 μM) and the kappa agonists, cyclazocine (30 μM) and U50,488 (10 μM), were found to selectively inhibit nicotinic receptor mediated catecholamine release. The ibogaine and cyclazocine inhibitory actions were not prevented by the opioid antagonists, norBNI or naltrexone. At higher doses (100 μM) ibogaine also inhibited veratridine- and K<sup>+</sup>-evoked release. Ibogaine (100 μM) effects were not rapidly reversible and persisted for at least 19 hours following ibogaine washout. The results would be consistent with an action of ibogaine and cyclazocine at a site within the nicotinic receptor cation channel and may be relevant to claims of ibogaine interruption of nicotine addiction. Supported in part by PHS grant 5R01DA06787, Subcontract A101656.

IBOGAINE BLOCKS THE DOPAMINE RESPONSE TO NICOTINE. I.M. Maisonneuve\*, G.L. Mann and S.D. Glick, Department of Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208.

Ibogaine, an alkaloid found in *Tabernanthe iboga*, has been claimed to be effective in interrupting the nicotine dependence syndrome (Lotsof, 1991). Since there is increasing evidence that the rewarding effect of nicotine is mediated by the dopamine mesolimbic system, we investigated whether ibogaine could alter the acute dopamine response to two 5 minute i.v. infusions of nicotine (0.32 mg/kg/infusion), administered one hour apart. Experiments were conducted using *in vivo* microdialysis in awake and freely moving male Sprague-Dawley rats. Pretreatment with ibogaine (40 mg/kg, i.p.) 19 hours prior to the first nicotine infusion significantly attenuated the increase in extracellular dopamine levels induced by the nicotine infusions (treatment x time interaction,  $F_{(3,36)} = 5.39$ ,  $p < 0.004$ ). Ibogaine also attenuated nicotine-induced increases in dopamine metabolites (DOPAC and HVA). These results suggest that ibogaine may decrease the rewarding effect of nicotine. Further studies are warranted to explore possible mechanisms of this ibogaine-nicotine interaction as well as to determine the effects of ibogaine after chronic administration of nicotine. (Supported by DA03817).

## 70.14

EFFECTS OF SMOKING IN SCHIZOPHRENIC PATIENTS, MEASURED BY EVENT-RELATED POTENTIALS. E. Kodama, K. Morita\*, J. Nakamura, S. Kinoshita, N. Kawamura, A. Miyahira and H. Maeda, Department of Psychiatry, Kurume University School of Medicine, 67 Asahi-Machi, Kurume-City, 830, Japan

The present study examined the effects of acute nicotine administration following 18 hours of abstinence from cigarette smoking on event-related potentials (ERPs), using an auditory oddball paradigm in 11 male schizophrenic patients. Informed consents were obtained from all subjects at each test. The P300 component as reflected by cognition was analysed. The P300 peak amplitudes were negatively correlated with daily nicotine intake under daily-life condition ( $r = -0.65$ ). The peak amplitude and the area and latency of the P300 were not changed significantly during withdrawal following smoking abstinence. Significant decreases in both the peak amplitude and the area were observed after the resumption of smoking. No decrease in the peak P300 amplitude caused by the resumption of smoking was found with nicotine gum pretreatment. No reliable correlations were observed between these P300 values (the peak amplitude, the area and the latency) and psychotic scores (BPRS scores) or dosages of neuroleptics (CPZ equivalent dosages). The present data suggest that information processing as reflected by the P300 may be inhibited by both the chronic effects of smoking and the acute effects of the resumption of smoking following abstinence. The mechanisms involved in CNS sensitivity to schizophrenic patients to smoking may be different from that of healthy subjects.

ANANDAMIDE: IN VITRO REINFORCEMENT OF HIPPOCAMPAL BURSTING BY THE NATURAL LIGAND OF THE CANNABINOID RECEPTOR. L. Stein\*, B.G. Xue and J.D. Belluzzi, Department of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

Involvement of cannabinoid receptors in reward and addiction is suggested by widespread human use of marijuana, although animal tests of cannabinoid reinforcement have produced mixed results. Cannabinoid receptors are found in high density in rat hippocampus and other brain areas. Using the hippocampal-slice preparation, we attempted to demonstrate *in vitro* reinforcement of CA1 bursting with local micropressure applications of the endogenous cannabinoid ligand, anandamide. Approximately 60% of the CA1 neurons tested showed progressive increases in burst activity after a series of brief, burst-contingent applications of anandamide at pipette concentrations of 20-40 μM (Figure). Identical "free" microinjections of anandamide administered independently of cellular activity did not increase (and usually suppressed) hippocampal bursting, thus ruling out drug-induced stimulation of CA1 firing. We conclude that anandamide, like dopamine and dynorphin A, may serve as a natural reinforcement transmitter. (Supported by NIDA grant DA05107)

## 71.2

CORTICAL NEURONS PRODUCE *sn*-2 MONOARACHIDONOYLGLYCEROL, A PUTATIVE ENDOGENOUS CANNABINOID LIGAND. N. Stella\* and D. Piomelli, The Neurosciences Institute, 10640 John J. Hopkins Drive, San Diego CA 92121.

Endogenous cannabinoids constitute a family of lipid molecules that specifically activate cannabinoid (CB) receptors. The first member of this family to be characterized was anandamide, an ethanolamine derivative of arachidonic acid. Recently, another derivative of arachidonic acid, *sn*-2 monoarachidonoylglycerol (MAG) was shown to bind to and activate both CB1 and CB2 receptors with EC<sub>50</sub>s in the μM range.

We have addressed two questions relevant to the possible role of MAG as an endogenous cannabinoid. Is MAG produced by neurons? And if so, under what conditions? By using bidimensional thin layer chromatography and reversed-phase HPLC, we determined that rat cortical neurons in primary cultures contain MAG. We also found that the amount of MAG in these neurons is significantly enhanced by the Ca<sup>2+</sup> ionophore ionomycin in a concentration-dependent manner (0.3 μM - 3 μM). This effect of ionomycin is completely prevented when extracellular Ca<sup>2+</sup> was chelated with EGTA (1 mM). EGTA alone reduced the MAG levels by about 50% of basal. Depolarizing concentrations of KCl (40 mM) stimulates MAG formation. The effect of KCl is also dependent on extracellular Ca<sup>2+</sup> and is inhibited by Cd<sup>2+</sup> ions (30 μM), indicating the involvement of voltage-activated Ca<sup>2+</sup> channels. In several cell types, formation of 2-monoacylglycerols results from activation of diacylglycerol (DAG) lipase. We found that both the KCl- and ionomycin-induced formation of MAG were inhibited by the specific DAG lipase blocker, RHC 80267 (100 μM). Our results indicate that MAG is present in cultured neurons, and that its levels are controlled by Ca<sup>2+</sup> ions, probably acting through stimulation of DAG lipase activity. It remains to be determined whether mechanisms exist for the release and inactivation of MAG, as expected of an extracellular signaling molecule. Supported by Neurosciences Research Foundation

## 71.3

FORMATION OF AN ENDOGENOUS CANNABINOID PRECURSOR IN CULTURED NEURONS AND ITS CONTROL BY CALCIUM AND cAMP. P. Piomelli\*, H. Cadas, S. Gailllet\*, M. Beltramo, L. Venance. The Neurosciences Institute, 10640 John J. Hopkins Drive, San Diego, CA 92121; #Université Montpellier II, France; †Collège de France, 75321 Paris, France.

Anandamide, an endogenous lipid that activates cannabinoid CB1 receptors, and N-palmitoylethanolamine (which activates a CB2-like receptor in mast cells) are produced in an activity-dependent manner by primary cultures of rat cortical neurons. Formation of these compounds may occur through cleavage of a phospholipid precursor, N-acyl phosphatidylethanolamine (NAPE), catalyzed by a calcium-activated phosphodiesterase activity. We report here that NAPE in cultured cortical neurons is synthesized via a calcium-dependent reaction that is stimulated by neuronal activity (membrane depolarization) and potentiated by cAMP-dependent protein phosphorylation. We also show that extracts of cortical neurons contain a calcium-dependent enzyme activity that produces NAPE, by catalyzing the transfer of an acyl group from phosphatidylcholine to the amino group of phosphatidylethanolamine. We solubilized and characterized this N-acyl transferase (NAT) activity in a rat brain particulate fraction. We found that, in the presence of  $Ca^{2+}$ , brain NAT activity catalyzes the formation of NAPE (20:4), as well as NAPE (16:0), NAPE (18:0) and NAPE (18:1), from endogenous substrate. In the rat, NAT activity is most abundant in brain, testes and skeletal muscular tissues. Within the brain, NAT activity is greatest in thalamus and striatum, and lowest in hypothalamus and olfactory bulb.

Our results indicate that NAPE biosynthesis in neurons is controlled by  $Ca^{2+}$  and cAMP. Such regulatory effect may participate in maintaining a supply of cannabinomimetic N-acyl ethanolamines during synaptic activity, and prime target neurons for release of these bioactive lipids. Our results also show that NAPE, particularly the anandamide precursor NAPE (20:4), is produced in discrete regions of the brain by a  $Ca^{2+}$ -dependent NAT activity.

## 71.5

SUPPRESSIVE EFFECTS OF VARIOUS CANNABINOID AGONISTS ON INSTRUMENTAL LEVER PRESSING: A MICROANALYSIS OF THE BEHAVIORAL EFFECTS. J. Aberman\*, D. Carriero, S.-Y. Lin, A. Hill, A. Makrivannis, and J.D. Salamone. Depts. of Pharmaceutical Sciences and Psychology, U. of Connecticut, Storrs, CT 06269-1020.

In the present study, operant conditioning methods were used to characterize some of the motor effects of the cannabinoid agonists CP 55,940, AM 356 and delta 8 tetrahydrocannabinol (delta 8 THC). Behavioral output during lever pressing on a fixed ratio 5 schedule was recorded by a computerized system that measured response initiation time (time from offset of one response to onset of the next) and duration for each lever press. All three cannabinoid drugs substantially depressed lever pressing response rate. Cannabinoid-induced deficits in responding were largely due to substantial increases in the average response initiation time. Analysis of the distribution of response initiation times indicated that cannabinoid-treated rats made relatively few responses with fast initiation times (e.g. 0-125 msec). The cannabinoid drugs also increased the number of pauses in responding (i.e. response initiation times > 2.5 sec). In addition, there was an overall increase in average response duration among animals that received the higher doses of cannabinoids. The effects of cannabinoids on response initiation and duration were somewhat similar to those effects produced by other response-suppressing drugs, such as neuroleptics and cholinomimetics. The rank order of potency was CP 55,940 >> delta 8 THC > AM 356, with CP 55,940 being approximately 50 times more potent than the other drugs. Animals were ataxic and cataleptic at the higher doses of cannabinoids that produced an almost complete cessation of responding. The relative potencies of these behavioral effects are consistent with the affinities of these drugs for cannabinoid receptors, which suggests that suppression of lever pressing can be used as a behavioral test for the assessment of *in vivo* cannabinoid activity.

## 71.7

THE STIMULATORY EFFECTS OF  $\Delta^9$ -TETRAHYDROCANNABINOL ON ADRENOCORTICOTROPIN HORMONE AND CORTICOSTERONE SECRETION DURING DIFFERENT STAGES OF THE ESTROUS CYCLE IN FEMALE RATS. R. Cadena, L.L. Murphy, and R.W. Steger\*. Dept. of Physiology, SIU School of Medicine, Carbondale, IL 62901.

Our previous studies have shown that  $\Delta^9$ -tetrahydrocannabinol (THC), the major psychoactive component of marijuana, stimulates the hypothalamic-pituitary-adrenal axis in ovariectomized rats. The purpose of this study was to investigate the effects of THC on adrenocorticotropin hormone (ACTH) and corticosterone (CORT) release in intact, cycling female rats. Adult female Sprague-Dawley rats were subjected to daily vaginal lavage in order to determine the stages of the estrous cycle. Rats were implanted with indwelling jugular cannulae for THC administration and blood sampling. The rats were administered either THC (0.5 or 1.0 mg/kg b.w.) or its vehicle and blood was withdrawn every 30 minutes for 2 hours with the first sample obtained immediately prior to THC or vehicle administration. Plasma was collected for ACTH and CORT determinations. Results showed that there were significant dose-related increases in ACTH and CORT from 0 to 60 minutes following THC administration when compared to basal hormone levels ( $p < .05$ ). Even though basal levels of ACTH and CORT are elevated during estrus, it appears that the greatest percent increase in both ACTH and CORT following THC treatment occurs during proestrus. Therefore, THC stimulates both ACTH and CORT secretion in intact cycling rats. Furthermore, the finding that the greatest percent increase of ACTH and CORT occurred during proestrus suggests that the hormone milieu may affect the response of the hypothalamic-pituitary-adrenal axis to cannabinoids.

## 71.4

CLONING AND CHARACTERIZATION OF THE MOUSE CB1 CANNABINOID RECEPTOR GENE. Kara Ditto, Qing Tao and Mary E. Aboud\*. Dept of Pharmacology/Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond VA 23298.

The mechanisms underlying the development of tolerance to cannabinoids are not completely understood, but do not appear to result from pharmacokinetic changes; therefore biochemical and/or cellular changes are responsible for this adaptation. Studies in our laboratory have demonstrated reduced cannabinoid receptor (CB1) binding with a concomitant increase in receptor mRNA in cerebellar tissue isolated from mice chronically exposed to CP55,940. This suggests that tolerance to cannabinoids may be mediated, in part, by alteration of neuronal (CB1) cannabinoid receptor gene expression. In order to elucidate the role of transcriptional vs. post-transcriptional control during the development of tolerance, we have cloned the gene for the mouse CB1 receptor. The gene was isolated from a P1 genomic library. Sequence analysis of a 6 kb BamHI fragment of the mouse CB1 genomic clone indicates 95% nucleic acid identity between mouse and rat (100% amino acid identity) and 90% nucleic acid identity (97% amino acid identity) between mouse and human. The human and rat sequences diverge about 60 bp upstream of the translation initiation codon, suggesting the possibility of splice variants of the CB1 receptor as well as divergence of other regulatory sequences between these genes. Indeed, examination of the 5' untranslated sequence of the mouse CB1 genomic clone indicates a splice junction site approximately 60 bp upstream from the translation start site. In parallel studies, we are examining the effect of chronic exposure to  $\Delta^9$ -THC on CB1 gene expression in mouse N18TG2 neuroblastoma cells. We demonstrate specific CB1 binding sites on these cells using [ $^3$ H]SR141716A as a radioligand. Preliminary studies indicate the CB1 mRNA is altered in N18TG2 cells following 24 hours of  $\Delta^9$ -THC treatment. These results indicate that the N18TG2 neuroblastoma cell line may represent a model system with which we can examine transcriptional and post-transcriptional regulation of CB1 receptor gene expression. DA-05274.

## 71.6

CANNABINOID WITHDRAWAL AND CENTRAL AMYGDALA: A CORTICOTROPIN RELEASING FACTOR (CRF) *IN VIVO* MICRODIALYSIS AND A C-FOS IMMUNOHISTOCHEMISTRY STUDY IN RATS. F. Rodríguez de Fonseca\*, R.A. Carrera\*, M. Navarro\*, M. Wilson\*, G.F. Koob\* and F. Weiss\*. [1] Dpt. Psicobiología, Facultad de Psicología, Universidad Complutense, 28223-Madrid (SPAIN). [2] Dpt. Neuropharmacology, The Scripps Research Institute, La Jolla, CA (USA).

Previous research has suggested a role for CRF in the anxiogenic response to cannabinoids. The present study was designed to evaluate the effects of acute, chronic and withdrawal from cannabinoid treatment on CRF release from central amygdala in rats, monitored by *in vivo* microdialysis. A parallel study was conducted to assess the anatomical distribution of the early gene *c-fos* protein product using an immunohistochemistry approach. Acute exposure to the highly potent cannabinoid HU-210 (100  $\mu$ g/kg) resulted in both a reduction of extracellular CRF levels, starting 60 min. after the injection, and in a blockade of the 4-aminopyridine-induced release of CRF, when this  $K^+$ -channel blocker was added to the perfusion medium. Acute treatment with HU-210 resulted in a marked increase in *c-fos* expression in stress-related nuclei (including central amygdala, shell of nucleus accumbens, bed nucleus of the stria terminalis and paraventricular nucleus of the hypothalamus). Acute exposure to the novel cannabinoid receptor antagonist SR141716A (3mg/kg) did not alter CRF levels in naive animals but induced a sharp release of CRF from central amygdala in animals treated for 14 days with a daily dose of HU-210 (100  $\mu$ g/kg). The time course of SR141716A-induced CRF release paralleled the onset of behavioral indices of cannabinoid withdrawal. *c-fos* expression was found to be intense in withdrawal group but not in control animals treated with SR141716A. The present results support the hypothesis of a central amygdala involvement in the neuropharmacological effects of cannabinoids.

## 71.8

THE ROLE OF CANNABINOID RECEPTORS IN THE LUTEINIZING HORMONE (LH) AND ADRENOCORTICOTROPIN (ACTH) RESPONSE TO CANNABINOID. L.L. Murphy\* and B.C. Statham, Dept. of Physiol., So. IL Univ. School of Med., Carbondale, IL 62901.

The hypothesis that cannabinoid receptors mediate THC-induced inhibition of LH release and stimulation of ACTH secretion was investigated by using selective cannabinoid receptor agonists (CP 55,940 and WIN 55,212) and an antagonist selective for the brain cannabinoid receptor (SR141716A). Adult rats were ovariectomized and 4 weeks later implanted with polyethylene cannulae inserted into the jugular vein for drug administration and blood withdrawal. CP 55,940 (CP; 0.01, 0.05 or 0.1 mg/kg b.w.; Pfizer, Inc.), WIN 55,212-2 (WIN; 0.05, 0.1, or 0.5 mg/kg; RBI), THC (0.5, or 1.0 mg/kg) or their respective vehicles were administered at time 0 and sequential blood samples were taken for 2 hr for plasma LH and/or ACTH determinations. Plasma LH levels were significantly suppressed by CP, WIN and THC ( $p < .05$ ); THC > CP > WIN with respect to magnitude and duration of suppression. ACTH levels were significantly stimulated from 20 to 100 min in a similar dose-related manner after either THC or WIN administration when compared to vehicles ( $p < .05$ ). SR141716A (SR; 0.5 mg/kg b.w. ip; Sanofi Recherche) pretreatment blocked the inhibitory effects of WIN and THC on LH release but did not appear to block cannabinoid-induced ACTH release. In fact, SR itself produced a significant increase in basal ACTH levels 30 to 70 min after its administration relative to vehicle control ( $p < .05$ ). Whereas the results with the receptor agonists suggest that cannabinoid receptors mediate THC-induced alterations in LH and ACTH, the results using SR suggest that cannabinoids affect LH and ACTH release via different cannabinoid receptor-mediated pathways.

## 71.9

## EFFECTS OF DELTA-9-THC PERINATAL TREATMENT OF MOTHERS ON MORPHINE AND FOOD OPERANT REINFORCED BEHAVIORS IN THE ADULT OFFSPRING.

S. MARTIN, J.A. CRESPO, R. FERRADO, C. GARCIA-LECUMBERRI, L. GIL (#), J.A. RAMOS (#), J.J. FERNANDEZ-RUIZ (#), N. DIEZ, J. MANZANARES (#) AND E. AMBROSIO. Dept. Psicobiología, UNED, 28040 Madrid. (#)Dept. Bioquímica y Biología Molecular (Fac. Medicina) and (#)Dept. Farmacología (Fac. Farmacia), UCH, 28040 Madrid, Spain. Perinatal exposure to cannabinoids has been shown to alter the development and differentiation of central nervous system (CNS) and produce CNS impairment in rodents and other species. Different neurotransmitter and neuropeptidergic systems have been reported to be affected by perinatal administration of cannabinoids, including the dopaminergic and opioid systems. These changes can elicit long term neuroendocrine alterations and modifications in different behavioral patterns. The purpose of these experiments was to study the effect of perinatal treatment of delta-9-tetrahydrocannabinol (THC) of the mothers on operant morphine self-administration and food reinforced behavior in both sexes of adult offspring. Male and female age-matched adult offspring born from mothers Wistar rats perinatally exposed to THC (5mg/kg) or vehicle (VEH) from day 5 of gestation until day 24 after birth were tested on acquisition (6 days) of intravenous morphine self-administration or on food reinforced behavior under a Progressive Ratio schedule (3,5,7,9...775). Subjects were surgically prepared with an intravenous catheter in jugular vein and placed in operant chambers for morphine self-administration studies. Operant drug-reinforced behavior was examined in a 23h access paradigm in which each lever press resulted in 1 mg/kg morphine injection with a 30s timeout period (FR1: T0 30"). After morphine self-administration studies, operant reinforced behavior was examined in the same chambers daily during 3hr sessions in a separate group. Offspring of THC treated mothers showed a statistically significant increase in acquisition of morphine-reinforced behavior compared to the offspring of vehicle treated mothers. This increase was significantly greater in female than in male on the last days of acquisition period. On the contrary, there was not statistically significant differences between both mother pretreatment (THC or VEH) and sex in the offspring. These results suggest that the offspring of mothers treated with THC could be more vulnerable to morphine reinforcing effects. Moreover, this THC-induced susceptibility to morphine reinforcing effects may be differentially affected by sex. Supported by DGICYT PB93-0290.

## 71.11

AN IN VITRO MODEL OF PHENCYCLIDINE NEUROTOXICITY. M. Phillips, S. Alagarsamy, T.C. Pappas and K.M. Johnson. Dept. of Pharmacology, University of Texas Medical Branch, Galveston, TX 77555-1031.

Phencyclidine (PCP) and other NMDA antagonists have neurotoxic effects after acute administration in rats. This toxicity is largely confined to the cortex and related limbic areas. It is blunted by D1, muscarinic and kainate antagonists as well as by pentobarbital. To better understand this mechanism, we are attempting to model this in primary culture. Cortical cultures derived from rat fetuses (E16) were used for experiments on day 9-21 in vitro. Cultures were exposed to drugs in HEPES buffered saline lacking  $Mg^{2+}$  for 30 minutes followed by a 24h exposure to serum containing medium. Both the salt solution and the medium were assayed for lactate dehydrogenase (LDH) activity. The cultures were also visually examined using a LIVE/DEAD kit from Biomol. 100  $\mu M$  DA produced a profound increase in LDH release and ethidium homodimer staining indicating massive cell death. 10  $\mu M$  DA produced a smaller, but significant increase in LDH release. Addition of SOD/catalase slightly attenuated the death caused by 100  $\mu M$  DA and almost completely prevented that caused by 10  $\mu M$  DA. These data suggest that formation of  $OH^{\cdot}$  and  $O_2^{\cdot}$  may be responsible for DA-induced damage. However, there may also be an NMDA receptor mediated component since MK-801 reduced cell death by ~50%. Bicuculline (BIC) at 1mM produced substantial increases in LDH release, but 100  $\mu M$  produced a marginal increase in cell death. Carbachol at 1 mM also produced a marginal increase in LDH release, but in combination with BIC, this effect was potentiated. Finally, the combination of DA (10  $\mu M$ ), carbachol and BIC (100  $\mu M$ ) produced an additive effect on LDH release and apparent cell death. These data suggest that this approach may be useful in understanding the mechanisms underlying PCP-induced neurotoxicity. Supported by DA 02073 and T32 DA 07287.

## 71.13

STRUCTURE-ACTIVITY AND STRUCTURE-LIPOPHILICITY RELATIONSHIPS FOR 7-ARYLDENE AND 7-HETEROARYLDENE MORPHINAN-6-ONES. Hemendra N. Bhargava\*, Guo-Min Zhao, Jing-Tan Bian, Y. Nan, S.P. Upadhyaya, W. Xu, W.J. Dunn, III, and L. Bauer. Dept. Pharmaceutics/Pharmacodynamics and Dept. Med. Chem./Pharmacognosy, Univ. Ill., Chicago, IL 60612.

Five compounds related to 7-benzylidenenaltrexone (BNTX) were synthesized as potential selective and potent  $\delta$ -opioid receptor antagonists. The compounds were evaluated for their activity in vitro at the  $\mu$ -,  $\delta$ - and  $\kappa$ -opioid receptors using ligand binding assays, functional activity in mouse vas deferens (MVD) and guinea pig ileum (GPI) and in vivo (analgesic) activity against  $\mu$ -,  $\delta$ - and  $\kappa$ -opioid receptor agonists. In addition, the potential role of lipid solubility in the actions of these compounds was determined by measuring the partition coefficients between octanol/water. Most compounds showed greater selectivity towards  $\delta$  opioid receptors in comparison to  $\mu$  or  $\kappa$ -opioid receptors. All compounds showed opioid antagonistic activity in GPI and MVD preparations. BNTX and 4-pyridyl derivatives were equally effective against  $\delta_1$  and  $\delta_2$  agonist induced analgesia but BNTX was more potent. 3-Pyridyl and methylimidazolyl derivatives were more selective for  $\delta_2$  in comparison to  $\delta_1$  -opioid receptor. The 4-chlorophenyl and 4-fluorophenyl were twice as potent against  $\delta_2$  - than for  $\delta_1$  -opioid receptor. The apparent lipid solubility (CLOGP) values in decreasing order were: 4-chlorophenyl > 4-fluorophenyl > BNTX > 3-pyridyl > 4-pyridyl > methylimidazolyl. In general, BNTX and 4-pyridyl which had medium lipid solubility were equally effective against  $\delta_1$  and  $\delta_2$  receptors; 3-pyridyl and methylimidazolyl derivatives were more selective for  $\delta_2$  than  $\delta_1$  and had lower lipid solubility; 4-chlorophenyl and 4-fluorophenyl derivatives were the most lipid soluble and had intermediate activity (Supported by grants DA-08867 and a Research Scientist Development Award K-02-DA-00130 from the National Institute on Drug Abuse).

## 71.10

DEVELOPMENTAL PCP EXPOSURE PRODUCES DECREASED LOCOMOTOR RESPONSES TO PCP AND MK-801. F.M. Scalzo.\* Dept of Peds., Univ. Arkansas for Med. Sci., Little Rock, AR 72202.

Previous studies from our laboratory have shown that subchronic exposure to phencyclidine (PCP) on postnatal days (PNDs) 24-37 (but not PNDs 4-17) results in long-lasting (20 days) alterations in the behavioral response to a pharmacological challenge with PCP or the NMDA antagonist, MK-801. The present studies were designed to further define the critical period for obtaining these effects. Rats were dosed with saline or 7.5 mg/kg PCP on PNDs 1-9, 11-19, 21-29 or 31-39. Ten and 20 days post-dosing, locomotor activity and ataxia were measured for one hr following a challenge with either saline, 2.5 or 5.0 mg/kg PCP, 0.1 mg/kg MK-801 or 1.0 mg/kg d-amphetamine. Activity was measured via an automated system and ataxia was measured by observation. Subchronic PCP treatment after PND 11 resulted in decreased locomotor responses to both PCP and MK-801 challenges. These decreases were observed in the absence significant increases in ataxia in most instances. The locomotor response to a saline or d-amphetamine challenge was not affected by pretreatment with PCP. These results suggest that subchronic (9 days) exposure to PCP results in long-lasting decreases in the locomotor response to both PCP and MK-801. The mechanism(s) mediating this change in responsiveness are unclear but might involve alterations in NMDA systems or PCP treatment-induced alterations in PCP metabolism. Supported by NIDA.

## 71.12

RISPERIDONE THERAPY IN PHENCYCLIDINE (PCP) INTOXICATION. A. James Giannini\*, Gale L. Colapietro, Deirdre K. Cook. Ohio State University, Boardman, Ohio 44512.

PCP is a drug of abuse with agonist activity at both DA-2 (dopaminergic) and 5-HT-2 (serotonergic) activity. Heretofore, haloperidol, a mixed dopamine antagonist with predominant DA-2 activity, has been the standard treatment for PCP psychosis.

Risperidone is a novel neuroleptic which has both 5-HT-2 and DA-2 antagonist activity. Its efficacy was compared against that of haloperidol in sixteen consecutive male patients presenting with PCP psychosis. Eight patients were given haloperidol 5 mg. at three 30-minute intervals and the other 8, 3 doses of risperidone 3 mg. at similar intervals. Responses were measured using the BPRS by two blinded raters.

Results indicated that haloperidol was superior to risperidone at 30- (p < .02), 60-minute (p < .02) intervals. There was no difference at the 90 minute interval. Afterwards, risperidone gave superior responses at 120- (p < .02), 150- (p < .01) and 180-minutes (p < .01). It is hypothesized that haloperidol's initial superior response was due to increased rate of absorption, whereas the increased efficacy of risperidone was due to activity at both 5-HT-2 and DA-2 receptors.

PLASMA AND BRAIN PHARMACOKINETICS OF ENADOLINE AT NEUROPROTECTIVE DOSES IN HEALTHY NON-ANESTHETIZED RATS. J. P. Hinton\* and G. Hudson, Department of Pharmacokinetics and Drug Metabolism, Parke-Davis Pharmaceutical Research, Division of the Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48105.

A rat brain microdialysis study of enadoline (CI-977), a  $\kappa$ -opioid agonist, was conducted in non-anesthetized healthy rats to determine brain extracellular fluid (ecf) concentrations of enadoline associated with neuroprotective subcutaneous (SC) doses. Three groups of 3 to 4 non-anesthetized yet restrained Sprague-Dawley rats with jugular cannulas and implanted brain (striatum) microdialysis probes received single SC doses of 0.3, 1.0, or 3.0 mg/kg enadoline. Blood and microdialysate samples were collected over a 12 hour period. Enadoline equivalent concentrations were determined with a validated radioimmunoassay. Plasma and ecf pharmacokinetic parameters were calculated by standard non-compartmental methods. At each dose, brain ecf concentration-time profiles were nearly coincident with enadoline plasma free fraction concentration-time profiles. Furthermore at each dose the ratio of  $AUC_{ecf}/AUC_{plasma}$ , which represents the distribution of drug between plasma and brain, was determined to be unity within experimental error. These results suggest that unbound plasma concentrations may predict brain ecf concentrations of enadoline.

Research was supported by Parke-Davis Pharmaceutical Research.

## 71.15

ASPIRIN'S ABILITY TO ATTENUATE THE DEVELOPMENTAL DELAYS OF PRENATAL EXPOSURE TO 1,1,1-TRICHLOROETHANE. H.E. Jones, S.E. Bowen and R.L. Balster. Dept. Pharmacology and Toxicology, Medical College of Virginia-Virginia Commonwealth University, Richmond, VA 23298.

Many abused solvents share behavioral and pharmacological properties with established CNS depressant drugs like alcohol. Some infants exposed *in utero* to solvents have craniofacial anomalies similar to those associated with perinatal alcohol exposure (Pearson et al., Pediatrics, 93:211, 1994). Since fetal alcohol and solvent exposure share many phenotypic endpoints, perhaps similar cellular mechanisms govern their etiology. Although the exact mechanisms of the Fetal Alcohol Syndrome have yet to be elucidated, one possibility may be the overproduction of prostaglandins. In animals, aspirin, a cyclooxygenase inhibitor, attenuated the teratogenic effects of alcohol on fetal mortality and dysmorphology (Randall and Anton, Alcohol Clin Exp Res 8:513, 1984). Based on our previous observations showing that exposure to 1,1,1-trichloroethane (TCE) (8000 ppm; 60 min; 3 times/day) during gestation days 12-17 produced developmental and behavioral delays in mice, we attempted to attenuate these deficits by administering a s.c. injection of aspirin (300 mg/kg) 60 min prior to each exposure. Dams were assigned to one of four groups: 1) TCE 8000 ppm/vehicle injection, 2) sham exposure/saline injection 3) TCE 8000 ppm/aspirin injection or 4) sham exposure/aspirin injection. Upon parturition, dams exposed to TCE and aspirin had, on average, statistically smaller litter sizes (number of pups) relative to their sham counterparts. No other differences were observed in malformations, litter weight, sex ratio or length of gestation. Although we replicated our earlier findings of TCE-associated delays in weight gain, landmark development, righting reflex, rooting reflex, grip strength, negative geotaxis and the inverted screen task, aspirin did little to attenuate these effects. In fact, in some tasks, such as the rooting reflex, prenatal exposure to aspirin exacerbated the TCE-induced behavioral delays. Research Supported by NIDA grant DA03112 and predoctoral fellowship DA05665.

## 71.16

DISCRIMINATIVE STIMULUS EFFECTS OF ALKYL BENZENE SOLVENTS IN ETHANOL-TRAINED MICE. S.E. Bowen\*, H.E. Jones and R.L. Balster. Department of Pharmacology & Toxicology, Medical College of Virginia, Richmond, VA 23298-0613.

Drug discrimination procedures were used to compare the discriminative stimulus effects of ethanol (ETOH) and several volatile alkylbenzenes. Male albino mice were trained to discriminate between i.p. injections of ETOH (1.25 g/kg) and saline in a two-lever operant task in which responding was under the control of a fixed-ratio 20 (FR20) schedule of food presentation. Stimulus generalization was examined after 20-min inhalation exposures to toluene (1000-6000 ppm), ethylbenzene (500-4000 ppm) and propylbenzene (500-4000 ppm). Testing is in progress with benzene (500-4000 ppm), xylene (500-4000) and cumene (500-4000 ppm). Concentration-related increases in ETOH-lever responding were observed for all compounds tested to date. For toluene, maximal levels of > 85% ETOH-lever responding were obtained at 6000 ppm. For ethylbenzene and propylbenzene, the maximal mean percentages of ETOH-lever responding were lower, but 5 out of 10 mice showed full substitution at one or more concentrations. The shared discriminative properties of these compounds with ETOH suggest that these compounds may share some of ETOH's pharmacological properties. These data, in combination with previous research results, are beginning to suggest that alkylbenzenes produce a qualitatively similar profile of acute effects, differing only somewhat in potency. The increasing evidence for commonalities in the behavioral effects of solvents and ETOH may contribute to the understanding of the mechanisms underlying solvent abuse. In addition, this research may also provide a basis for selecting procedures for studying other homologous series. Supported by NIDA grant DA-03112 and NIDA fellowship DA-05670.

## DRUGS OF ABUSE: OPIOIDS I

## 72.1

CHRONIC TREATMENT WITH MORPHINE INCREASES PROTEIN KINASE C  $\beta$ 1 IMMUNOREACTIVITY IN RAT CEREBRAL CORTEX. M.M. Garcia\* and R.E. Harlan. Dept. Otolaryngol. and Anat., Tulane Med. Sch., New Orleans, LA 70112

The long-term consequences of chronic abuse of opiates are largely unknown. Although opiates are known to inhibit adenylate cyclase activity, several recent studies also have implicated protein kinase C (PKC) in the acute and long-term actions of opiates. To determine if chronic opiate exposure alters expression of specific isoforms of PKC, we implanted male rats with pellets containing 75 mg morphine sulfate or vehicle, daily for 5 days. On the sixth day, the rats were euthanized and perfused for immunocytochemical localization of the  $\beta$ 1 and  $\beta$ 2 isoforms of PKC. Produced by differential splicing of the same primary transcript, these two isoforms are expressed in markedly different populations of neurons throughout the rat brain. In the cerebral cortex, the  $\beta$ 1 isoform is found in scattered stellate neurons of layers 2 and 3, and in the neocortex and in stellate neurons of layer 4. Labeled neurons are nearly absent in layer 5, but numerous in layer 6, especially at the interface between layers 5 and 6. Immunoreactivity is found in somas, dendrites, axons and terminals. The  $\beta$ 2 isoform is found associated with the Golgi apparatus in numerous neurons of layers 2/3 and 6. Chronic treatment with morphine markedly increased the number of neurons containing PKC  $\beta$ 1, especially in layer 4, in the 5/6 interface and in deep layer 6. The intensity of neuropil staining in layer 4 was also greater following morphine. The effect was most obvious in the somatosensory cortex. No marked changes were noted in the number of labeled cells in the caudate-putamen, nor in the number of cortical neurons containing the  $\beta$ 2 isoform of PKC. These results suggest a region-specific up-regulation of PKC  $\beta$ 1 in neocortex following chronic morphine treatment. Supported by LEQSF RDA-029 to MMG.

## 72.3

DIFFERENTIAL FOS IMMUNOREACTIVITY AFTER HEROIN SELF-ADMINISTRATION IN DEPENDENT AND NON DEPENDENT RATS: M.R.A. Carrera\*, A.E. Ryabinin, M.C. Wilson and G.F. Koob. Dept. Neuropsychopharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Chronic drug-use produces adaptations in molecular or cellular processes which may oppose the pharmacological effects of the drug resulting in drug dependence. The current study sought to investigate the neural sites for the reinforcing actions of opiates and the motivational effects associated with opiate abstinence, and how these substrates change during the induction of dependence. Male Wistar rats were trained on heroin self-administration (HSA), implanted with morphine or placebo pellets and treated with naloxone (nlx) (0.00, 0.003 or 0.03 mg/kg). In this behavioral model, dependent (D) but not non-dependent (ND) rats present a shift to the left of the dose-effect function for nlx-induced increases in HSA. An analysis of Fos immunoreactivity (FI) in both groups (ND and D) following HSA show an overall activation of substrates associated with opiate actions including the pontine nuclei, central gray, ventral tegmental area (VTA) various hypothalamic and thalamic nuclei, basolateral amygdala (BLA) and nucleus accumbens (Acb). In the ND condition, nlx treatment produced virtually no change with the exception of small increases in the dorsomedial hypothalamus, ventral bed nucleus of the stria terminalis and central amygdala at the higher dose. In contrast, D subjects exhibited a heightened overall activation in addition to significant FI increases in hippocampus, lateral and ventromedial hypothalamus, centromedial thalamus, caudate putamen, globus pallidus, various septal subregions and accumbens core (AcbC). Whereas at the low nlx dose there was pronounced activation in VTA, ventromedial hypothalamus, rhomboid thalamic nucleus, and Acb, the high dose induced expression in the nucleus of the solitary tract, area postrema, locus coeruleus, paraventricular, supraoptic and lateral hypothalamus, central but not basolateral amygdala and core but not shell aspect of the Acb. These findings suggest that while the onset of opiate dependence yields higher neural activation of reward pathways, different brain regions are also recruited by this event.

## 72.2

MORPHINE-ALTERED CHANGES TRANSCRIPTION GENES IN RAT BRAIN. H. Ujike\*, X.B. Wang@, J.T. You@, G.R. Uhl#@. @Mol. Neurobiol. Br., IRP, NIDA, NIH; #Dept. Neurol. & Neurosci., JHUSM, Baltimore, MD 21224

Abuse of opiates induces long-lasting behavioral changes, including tolerance and dependence, that are likely to reflect adaptations in CNS function. To elucidate potential molecular mechanisms underlying these phenomena, we used subtracted differential display PCR to identify changes in the expression of 23 genes upregulated in brains of rats sacrificed 4h after 20mg/kg morphine. Sequence analyses showed that one was dihydropteridine reductase (DHPR), which promotes the NADPH-mediated reduction of dihydrobiopterin to tetrahydrobiopterin, a coenzyme for tyrosine hydroxylase. Northern analyses and quantitative RT-PCR confirmed that DHPR expression was increased in striatum and hippocampus after acute morphine treatments. Three different PCR products encoded a member of the K<sup>+</sup> channel gene family whose expression was increased in striatum and decreased in frontal cortex and thalamus in animals sacrificed following a morphine injection. The 21 other sequences, largely 3' untranslated regions, showed no Genbank sequence matches. Elucidation of the patterns of region-specific changes in transcription after acute morphine and identification of the effects of chronic morphine treatments will help to select genes that are candidates for involvement in mechanisms of opiate dependence.

## 72.4

ANDROGENIC-ANABOLIC STEROIDS MODULATE C-FOS INDUCTION BY MORPHINE OR COCAINE IN MALE RAT CAUDATE-PUTAMEN. H.E. Brown, M.M. Garcia, P.S. Guth\*, and R.E. Harlan. Depts. of Anatomy, Otolaryngology, and Pharmacology, Tulane U. Sch. Med., New Orleans, LA 70112.

Androgenic-anabolic steroids (AAS) have been reported to produce symptoms of abuse and dependence in human athletes. Induction of c-Fos antigen in the caudate-putamen (CPU), which may index the reinforcing properties of abused drugs, was used in the current studies to examine the view that AASs impact neural reward systems. Male rats were injected over 15 days with increasing dosages of testosterone cypionate (TC) plus nandrolone decanoate (ND), or oil. Initial and final TC + ND dosages were 0.5 + 0.25 mg/kg and 1.0 + 0.5 mg/kg body weight (BW). On Day 16, groups of rats received 1 or 10 mg/kg BW morphine sulfate, 1 or 10 mg/kg BW cocaine hydrochloride, or saline. Rats were euthanized 2 h later. c-Fos immunocytochemistry was done on coronally-sectioned CPU anteriorly from the decussation of the anterior commissure (d-ac). c-Fos immunoreactivity (IR) in 3 sections/brain was quantified by digital image analysis of dorsomedial CPU, a region in which we observed morphine- and cocaine-induced c-Fos IR overlap. AAS treatment alone did not affect c-Fos IR. The higher morphine dosage, and both cocaine dosages, significantly increased the number of cells exhibiting c-Fos IR. In each case, AAS pretreatment significantly decreased the number of IR cells. In morphine-treated rats, c-Fos IR was confined to the dorsomedial CPU, whereas c-Fos IR was widespread in cocaine-treated rats. In AAS- or oil-pretreated rats given 10 mg/kg cocaine, we therefore counted cells from the dorsal half of the CPU in brain sections at 240  $\mu$ m intervals anteriorly from the d-ac. In the anterior and posterior portions of this region, AAS pretreatment respectively decreased and increased c-Fos IR cell counts in rats challenged with 10 mg/kg BW cocaine. Although the precise loci of the AAS effects we report here are unclear, the data indicate that AAS actions in the brain are reflected by neostriatal neurons which might participate in the rewarding or reinforcing qualities of morphine and cocaine.

Supported by BIR-9203830, DA 05441, and DA 06194.

## 72.5

DEPOLARIZATION OF MYENTERIC NEURONS BY CHRONIC MORPHINE TREATMENT IS DUE TO A REDUCTION IN THE SODIUM PUMP. J.-Q. Kong, J. Meng, D.A. Taylor and W.W. Fleming\*. Dept. of Pharmacol. and Toxicol., R.C. Byrd Hlth. Sci. Ctr., West Virginia University, Morgantown, WV 26506-9223.

Chronic exposure to morphine leads to the development of heterologous subsensitivity of guinea pig myenteric plexus/longitudinal muscle to inhibitory agonists that is associated with a depolarization of myenteric 'S' neurons (MN). The mechanism underlying this depolarization was investigated by determining the effect of ouabain on MN from control and morphine treated (pellet implanted) guinea pigs. Intracellular electrophysiological recording from MN was accomplished using standard techniques. Morphine superfusion (1  $\mu$ M) led to a hyperpolarization of 'S' neurons which was not significantly different in magnitude between placebo ( $6 \pm 1$  mV) and tolerant ( $5.5 \pm 1.3$  mV) preparations. Ouabain superfusion (5  $\mu$ M) was performed in the absence or presence of TEA (0.5 mM) to eliminate the potential complicating interaction of ouabain with K channels in these neurons. Ouabain produced a depolarization of MN from placebo treated animals of  $17 \pm 3$  mV in the absence and  $14 \pm 2$  mV in the presence of TEA. However, in MN from animals implanted with morphine pellets, the same concentration of ouabain produced depolarizations of  $8 \pm 3$  mV in the absence and  $6 \pm 2$  mV in the presence of TEA. The magnitude of the depolarization produced by ouabain was significantly reduced in MN from morphine treated animals compared to controls either in the presence or absence of TEA. In addition, the resting membrane potential of MN from morphine treated animals ( $-45 \pm 2$  mV) was significantly reduced from that obtained in cells from placebo animals ( $-55 \pm 2$  mV) by 10 mV as previously observed in MN. These data suggest that the depolarization observed in MN following chronic treatment with morphine may be due to a reduction in electrogenic sodium pumping capacity of these neurons. Such an alteration in sodium pumping capacity could be responsible for the 10 mV reduction in membrane potential as well as the heterologous changes in sensitivity observed following chronic morphine treatment. A similar reduction in sodium pumping capacity has been implicated as a mechanism for adaptive sensitivity changes in a variety of other excitable tissues. Supported in part by NIH grant DA 03773.

## 72.7

ESTIMATION OF THE EXPRESSION OF MUSCARINIC m1 mRNA BY QUANTITATIVE PCR DURING AND AFTER SPONTANEOUS MORPHINE WITHDRAWAL. L. Zhang\* and J.J. Buccafusco. Department of Pharmacology and Toxicology, Medical College of Georgia, and Department of Veterans Affairs Medical Center, Augusta, GA, 30912.

Previous studies in this and other labs have demonstrated that central cholinergic neurons play an important role in the expression of morphine withdrawal symptoms. Also, selective muscarinic receptor antagonists exert marked antiwithdrawal activity. Rats were made dependent upon morphine using a chronic i.v. infusion schedule of increasing concentrations of morphine over 5 days. Spontaneous withdrawal was initiated by termination of the morphine infusion. Withdrawal-induced cardiovascular and behavioral symptoms were recorded and correlated with changes in the transcription of mRNA encoding the m1 muscarinic receptor in cerebral cortex and hippocampus. For the RT-PCR reaction, an internal standard was generated by using an Apo B gene fragment linked to the primers for the m1 muscarinic receptor. The forward composite primer included a linker sequence that allowed extension of the T7 RNA polymerase promoter sequence in a subsequent PCR reaction, and, using the T7 primer and the reverse primer of the target message. After the T7 promoter sequence was extended, cRNA was obtained using an *in vitro* transcription system. The molecular size of the m1 target and the internal standard PCR products were, respectively, 274 and 373 bp. PCR products were separated on electrophoretic gels and the bands stained and quantified by densitometry. Morphine infusion was shown to produce about a 50% increase in the level of mRNA encoding the m1 subtype of muscarinic receptors in the cortex. During withdrawal levels were reduced by 50%. At the completion of withdrawal m1 mRNA levels returned to the high levels observed prior to withdrawal. In contrast, m1 receptor mRNA expression was normal after morphine infusion in hippocampus, but levels were reduced by about 60% at the peak of withdrawal, and were reduced by 80% at the end of the withdrawal phase. Thus, in the hippocampus, these changes which occur after withdrawal may underlie the conditioned component of addiction. Supported by the VA Medical Research Service.

## 72.9

CHANGES IN THE DOPAMINERGIC SYSTEM OF THE ADULT RAT BRAIN AFTER ACUTE AND CHRONIC HEROIN EXPOSURE

A. Stadlin\*, H.L. Choi, B.N. Ladenheim\*, J.L. Cadet\* and S.F. Ali\* Department of Anatomy, Chinese University of Hong Kong, Shatin, N.T., Hong Kong; \*Molecular Neuropsychiatry Section, Addiction Research Center, NIDA/NIH, Baltimore, MD 21224 and \*Neurochemistry Lab, Division of Neurotoxicology, National Center for Toxicological Research, FDA, Jefferson, AR 72079, USA.

The dopaminergic system of the brain plays an important role in the acute and chronic effects of drugs of abuse. The present study investigates the effects of acute and chronic heroin exposure in this system. Male adult Sprague-Dawley rats received an acute dose of 20 mg/kg (s.c.) high-grade street heroin. The chronic group received 10 mg/kg/day for the first week (s.c.) followed by 20 mg/kg/day for the second week. Control animals received saline injections. Changes in the dopamine transporter (DAT), dopamine (DA), D1 and D2 receptors were studied in the striatum using receptor ligand binding assays and quantitative autoradiography. The DA and DOPAC levels were examined using HPLC/EC methods. Results showed that, after an acute dose of heroin, there is a 20% decrease in DAT, D1 and D2 binding with a concomitant increase in DOPAC levels in the striatum. Contrary to the acute heroin-exposed animals, chronic heroin-exposed animals showed a 36%, 22% and 48% increase in DAT, D1 and D2 receptor binding respectively. A corresponding increase in DA levels was also observed in these animals. The present results showed that acute and chronic exposure to heroin resulted in differential changes in the dopaminergic system. These results suggest that chronic administration of heroin may result in an overall upregulation of both presynaptic and postsynaptic elements of the dopaminergic system.

## 72.6

THE EFFECTS OF CHRONIC EXPOSURE TO MORPHINE ON MU OPIOID RECEPTOR CHARACTERISTICS IN C57 AND DBA MICE. R.L. Petrucci, T.N. Ferraro\* G.T. Golden, and W.H. Berrettini, Department of Psychiatry, Thomas Jefferson University, Philadelphia, Pennsylvania

Given a choice, C57 mice will self administer substantial quantities of morphine compared to DBA mice and much of this difference has been attributed to a genetic locus on chromosome 10 in the vicinity of the mu opioid receptor. To compare binding characteristics of mu opioid receptor populations between the two strains, mice were given single daily injections of morphine sulfate (0.1 mg/kg, sc) or saline for a period of seven days and sacrificed six hours after the last injection. Brains were removed and dissected into specific regions. Receptor binding studies were performed on frontal cortex, striatum, substantia nigra, and nucleus accumbens. Data were analyzed using Scatchard analysis, and  $K_d$  and  $B_{max}$  comparisons between strains and treatments were done by the Mann-Whitney U test. Results for nucleus accumbens and substantia nigra were inconclusive while frontal cortex results were not significant. Results in striatum show that before morphine injection, DBA mice have fewer opioid receptors than C57 mice ( $p=0.0080$ ); after injection, C57 mice have fewer receptors than DBA ( $p=0.0037$ ). In addition, C57 mice chronically exposed to morphine exhibit a decreased receptor density compared to C57 controls ( $p=0.0013$ ), a phenomenon not observed in DBA mice. No differences or changes in receptor affinity were indicated by  $K_d$  values. These results are consistent with the fact that C57 mice exhibit a significantly greater preference for oral and intravenous opioids compared to DBA mice. This work was supported by NIDA grant RO1-DA08041.

## 72.8

CHANGES IN QUANTITY AND PHOSPHORYLATION STATE OF L-TYPE CALCIUM CHANNEL  $\alpha_1$  SUBUNIT WITH ACUTE AND CHRONIC MORPHINE. M.A. Bernstein, D.R. Compton\* and S.P. Welch, Medical College of Virginia, Dept. of Pharmacology and Toxicology, Richmond, VA 23298.

The involvement of dihydropyridine-sensitive, or L-type, calcium channels in tolerance to morphine-induced antinociception has been implicated by *in vivo* studies showing cross-tolerance between parenterally administered morphine and intrathecal Bay K 8644. Such changes may be due to an increase in the number of L-type channel  $\alpha_1$  subunits, the pore-forming subunit of the channel, or may result from changes in cAMP-dependent protein kinase phosphorylation of the subunit, which has been shown to affect calcium gating. To quantitate  $\alpha_1$  channel subunit protein, Western immunoblot analysis was performed using membrane preparations from mice treated with morphine acutely or chronically. Changes were noted in  $\alpha_1$  subunit quantity in the spinal cord, suggesting channel sequestration following acute morphine treatment, and channel upregulation following chronic exposure. No changes were found in the brainstem. The phosphorylation state of the subunit is currently being assessed using a back-phosphorylation method followed by immunoprecipitation and SDS-PAGE separation.

Supported by NIDA grants DA07027, DA00186, DA06031.

## 72.10

EFFECTS OF CHRONIC ADMINISTRATION OF MORPHINE OR NALTREXONE ALONE OR IN COMBINATION ON THE ACTIVITY OF CENTRAL NITRIC OXIDE SYNTHASE (NOS) IN MICE. Shailendra Kumar, Robert V. House\* and Hemendra N. Bhargava, Dept. Pharmaceuticals/Pharmacodynamics, Univ. Ill., Chicago, IL 60612 and IIT Res. Inst., Chicago, IL 60616.

The time course of the effects of subcutaneous implantation of morphine (25 mg) or naltrexone (NTX) (10 mg) pellets alone or in combination on the NOS activity was investigated in male Swiss-Webster mice. Mice implanted with appropriate placebo pellets served as controls. NOS activity was determined in brain regions (cerebellum, cortex, midbrain, and remainder of the brain, and spinal cord) by the formation of [ $^3$ H]citrulline from [ $^3$ H]arginine. NOS activity decreased in all brain regions, but not in spinal cord, 24h after morphine pellet implantation. It was accompanied by high level of motor activity. NOS activity increased 48 and 72 h after pellet implantation in the cerebellum and cortex. Implantation of NTX pellets along with the morphine pellets completely antagonized the changes in central NOS activity induced by morphine. It is concluded that initial decrease in NOS activity may be related to the increased motor activity induced by morphine in the mouse. On the other hand, on subsequent days the induction of NOS in certain brain regions may be related to morphine tolerance-dependence process. Furthermore, the alteration in NOS activity by morphine involves opioid receptors since it is blocked by NTX (Supported by a Research Scientist Development Award, K02-DA-00130 from the National Institute on Drug Abuse).

## 72.11

EFFECTS OF MULTIPLE INTRACEREBROVENTRICULAR INJECTIONS OF  $\delta_1$ - or  $\delta_2$ - OPIOID RECEPTOR AGONISTS ON BRAIN  $\delta$  OPIOID RECEPTORS IN MICE. Guo-Min Zhao, Nicholas P. Plotnikoff\* and Hemendra N. Bhargava. Dept. Pharmaceutics/Pharmacodynamics, Univ. Ill., Chicago, IL 60612.

The effects of D-Pen<sup>2</sup>, D-Pen<sup>3</sup> enkephalin (DPDPE), and D-Ala<sup>2</sup>, Glu<sup>4</sup>  $\delta$ 1-receptorin II (deltorphin II), the selective agonists for  $\delta_1$ - and  $\delta_2$ -opioid receptors, injected i.c.v. for different duration on the brain  $\delta$ -opioid receptors were determined in male Swiss Webster mice. Twice daily injections of DPDPE (20  $\mu$ g/mouse) or deltorphin II (20  $\mu$ g/mouse) for 4 days resulted in the development of tolerance to their analgesic action. Under this condition, the binding constants ( $B_{max}$  and  $K_d$ ) for [<sup>3</sup>H]DPDPE in brain could not be determined, possibly due to destruction of binding sites. Twice daily injections of DPDPE (20  $\mu$ g/mouse) or deltorphin II (20  $\mu$ g/mouse) for two days also resulted in 45% and 56% decrease in their analgesic action compared to vehicle injected controls. Under this condition, DPDPE treatment decreased the  $B_{max}$  but had no effect on the  $K_d$  of binding of [<sup>3</sup>H]DPDPE. On the other hand, deltorphin II treatment decreased the  $B_{max}$  but increased the  $K_d$  of [<sup>3</sup>H]DPDPE in brain membranes. It is concluded that both DPDPE and deltorphin II in short term or long term treatment produce tolerance to their analgesic effects. The short term treatment of both drugs down regulates brain  $\delta$ -opioid receptors whereas long term treatment apparently results in neurotoxicity as seen by total loss of binding sites (Supported by grants DA-08867 and a Research Scientist Development Award, K02-DA-00130 from the National Institute on Drug Abuse).

## 72.13

A NEONATAL RAT MODEL OF OPIOID TOLERANCE AND DEPENDENCE. S. R. Thornton, F. L. Smith and L. S. Harris\*. Department of Pharmacology/Toxicology, MCV/VCU, Richmond, VA.

Human neonates and infants continuously infused with fentanyl or morphine become tolerant and dependent. Morphine has been shown to produce tolerance and dependence in neonatal animals, but there is no published data for fentanyl tolerance and dependence. We developed an animal model to investigate whether continuous fentanyl administration would render neonatal rats tolerant and physically dependent to fentanyl. Postnatal day 6 rat pups were anesthetized and then remained either naive or were surgically implanted with Alzet 1003D osmotic mini-pumps containing either saline (1  $\mu$ l/hr) or fentanyl (100  $\mu$ g/kg/hr) and challenged with fentanyl 72 hrs after implantation. The  $ED_{50}$  values for the naive and saline treated animals were not significantly different (20  $\mu$ g/kg for both groups). However, fentanyl treated animals demonstrated good tolerance when compared to the saline treated animals (90  $\mu$ g/kg vs. 20  $\mu$ g/kg, respectively). Fentanyl exposed animals injected with naloxone (0.1 mg/kg, s.c.) exhibited withdrawal signs, such as increased spontaneous activity, micturition, defecation and vocalization. Utilizing the osmotic mini-pump technology, fentanyl tolerance and dependence have been compared to the classical opioid, morphine. Future studies will assess the long-term cellular/molecular changes in rats neonatally exposed to fentanyl which may indicate a predisposition for juvenile and adult rats to self-administer more opioids than neonatal opioid naive rats. Research was supported by NIDA grant DA05274.

## 72.15

GESTATIONAL MORPHINE ALTERS THE DENSITY OF CATECHOLAMINE FIBERS IN THE HYPOTHALAMUS OF ADULT FEMALE RATS. I. Vathy\*, H.-J. He, M. Iodice and A. Rimanóczy<sup>1</sup>. Dept. Psych. and Neurosci., Albert Einstein Coll. Med., Bronx, NY. 10461. <sup>1</sup>Dept. Psych., A. Sz-Györgyi Med. Sch., Szeged, Hungary

The present study investigated the distribution of norepinephrine (NE) and dopamine (DA) fibers in different brain regions of adult female rats exposed to morphine in utero (10 mg/kg/twice daily on days 11-18 of gestation). Females were ovariectomized (OVX) at least one week prior to sacrifice, and some were injected with 3  $\mu$ g of estradiol benzoate 48 hours before sacrifice. Animals were perfused with 4% paraformaldehyde, brains were removed, post-fixed, saturated with sucrose, frozen and stored in -80°C. Coronal sections of 10  $\mu$ m were cut with a cryostat, and the distribution of tyrosine hydroxylase-immunoreactive (TH-IR) and DA  $\beta$ -hydroxylase (DBH)-IR fibers were identified in alternate sections. Prenatal morphine reduced the density of both TH- and DBH-IR fibers in several brain areas including the lateral hypothalamus of females. Estrogen treatment did not affect the density of TH or DBH-IR fibers in OVX females from either prenatal treatment group. The reduction in hypothalamic catecholamine fiber density may be related to the reduction in NE content and turnover rate observed in the hypothalamus of prenatally morphine-exposed females in previous studies (Vathy and Kátay, Dev. Brain Res., 68:125-134, 1992; Vathy et al., Brain Res., 662:209-215, 1994). The number of DA and NE cellbodies will also be investigated and analyzed later. Supported by DA 05833 awarded to IV.

## 72.12

EXPOSURE TO A DELTA OPIOID AGONIST DURING THE PREWEANING PERIOD ALTERS DOPAMINE RECEPTORS IN THE 28-DAY-OLD RAT BRAIN. D.E. Walters\*, G.-J. Shieh and C.C. Edge. Div. Pharmacology, School of Pharmacy, Auburn Univ. AL 36849.

To determine if exposure to a delta opioid receptor agonist during suckling could alter the development of brain dopamine (DA) receptors, on postnatal day 7 (PD7), 14-day osmotic pumps containing SNC 80, 37.5 mg/ml, or pH adjusted 0.9% saline vehicle were implanted into chloral hydrate anesthetized lactating rats. On PD21, the pups were weaned and on PD28, the striata of male offspring were dissected and assayed for DA D1 and D2 receptors.

There was a significant 24% increase in the density ( $B_{max}$ ) and a 44% decrease in the affinity ( $K_d$ ) of DA D1 receptors in the striatum of 28-day-old offspring exposed to SNC 80. However, SNC 80 had no significant effect on the  $B_{max}$  or  $K_d$  of DA D2 receptors in the striatum of 28-day-old offspring. Exposure to SNC 80 did not significantly alter the body weights at 28 days of age or the food consumption of offspring between weaning and sacrifice; nor was there a significant effect of SNC 80 on maternal food consumption during the nursing period. The results suggest that delta opioid mechanisms might be involved in the neurological changes observed in offspring of mothers addicted to opioids during nursing. The SNC 80 was provided by K. Rice. Supported by NIDA grant DA07968.

## 72.14

EFFECTS OF POSTNATAL NALOXONE EXPOSURE ON NEUROPEPTIDE mRNA EXPRESSION IN HYPOTHALAMIC NUCLEI OF NEONATAL RATS PRENATALLY EXPOSED TO METHADONE. J.W. Nemitz\*. Division of Structural Biology, WV School of Osteopathic Medicine (WVSOM), Lewisburg, WV 24901.

Pregnant Sprague-Dawley rats were made physically dependent to methadone (9mg/kg/day) using subcutaneous (sc) osmotic minipumps (Alza). The pregnancies were brought to term and the methadone exposed rat pups were injected with either naloxone (5mg/kg sc) or saline 24 hours postnatally. Both male and female rat pups were used in the study. Naloxone precipitated withdrawal signs, including, hyperactivity, increased oral behaviors and vocalizations, were observed for prenatally methadone exposed rat pups. Following an observation period of 1 hour the pups were sacrificed by decapitation. Frozen serial coronal sections (20  $\mu$ m), made at the level of the hypothalamus, were processed for *in situ* hybridization, using <sup>35</sup>S-oligonucleotide probes (DuPont), and emulsion autoradiography. Arginine-vasopressin (AVP) and oxytocin (OXY) mRNA levels were decreased in the supraoptic nucleus (SON) and paraventricular nucleus (PVN) of methadone exposed rat pups as compared to controls following a postnatal injection of saline. However, when methadone exposed rat pups were postnatally injected with naloxone, AVP and OXY mRNA levels in the SON and PVN were increased as compared to the neuropeptide mRNA levels observed in these nuclei of methadone exposed rat pups that were postnatally injected with saline. These data indicate that the decrease in AVP and OXY mRNA expression in the SON and PVN of neonatal rat pups prenatally exposed to methadone can be reversed by postnatal naloxone injection, thus providing evidence for an opioid mechanism of action. Supported by intramural WVSOM funds.

**DRD3 AND DRD4 GENE MARKER FREQUENCIES IN POLYSUBSTANCE ABUSERS AND CONTROLS<sup>1</sup>.** L.A. Rodriguez<sup>2</sup>, D.J. Vandenbergh<sup>2</sup>, E. Bendahhou<sup>2</sup>, and G.R. Uhl<sup>1,2</sup>. <sup>1</sup>Molecular Neurobiology Branch, National Institute on Drug Abuse, Intramural Research Program, Baltimore, MD 21224. <sup>2</sup>Departments of Neurology and Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Dopamine D<sub>3</sub> (Drd3) and D<sub>4</sub> (Drd4) receptor genes are implicated in substance abuse vulnerability due to their primary expression in limbic brain regions and recently reported links between measures of novelty seeking behaviors and specific Drd4 genotypes (Benjamin *et al.*, *Nat Genet* 12:81-84, 1996). Allelic association of Drd3 and Drd4 polymorphisms was sought in a sample of caucasian polysubstance abusers and controls largely ascertained through the Addiction Research Center in Baltimore, MD. Drd3 polymorphisms were identified in 111 drug abusers and 74 controls via an exonic A to G substitution producing a serine (A1 allele) to glycine (A2 allele) substitution at position 9 in the extracellular N-terminus. Drd4 polymorphisms were identified through exon III variants in 60 drug abusers and 66 controls via the presence of long (6 or more) or short (less than 6) repeats of a 48 bp sequence. No significant allelic associations were detected for either dopamine receptor gene (Drd3:  $\chi^2=0.04$ ; df=1,  $p=0.84$ ; Drd4:  $\chi^2=0.55$ ; df=1,  $p=0.31$ , one-tailed), suggesting that variants of the Drd3 and Drd4 genes in linkage disequilibrium with these markers may not play large roles in the genetic mediation of drug abuse risk.

## 73.3

**INCREASED SENSITIVITY TO THE STIMULANT ACTIONS OF MORPHINE AFTER INFECTION OF VTA WITH AN HSV VECTOR EXPRESSING GLUR1.** W.A. Carlezon Jr.<sup>1</sup>, V.A. Boundy, R.G. Kalb<sup>2</sup>, R. Neve<sup>3</sup>, and E.J. Nestler. Laboratory of Molecular Psychiatry and <sup>2</sup>Dept. Neurology, Yale University School of Medicine, New Haven CT, and <sup>3</sup>Molecular Genetics Laboratory, Harvard Medical School, Belmont MA.

Repeated administration of morphine upregulates expression of the AMPA receptor subunit GluR1 in the ventral tegmental area (VTA), the cell body region of the mesolimbic dopamine system. Increased GluR1 expression would be expected to alter the excitability of VTA dopamine cells, and could contribute to the neurobiological adaptations that accompany repeated morphine treatment. We now report that direct and specific upregulation of GluR1 in VTA—through the use of a recombinant defective Herpes Simplex Virus (HSV) vector expressing GluR1—increases sensitivity to the locomotor-stimulating actions of morphine. Sprague-Dawley rats were first screened for locomotor activity after morphine injection (1.0 mg/kg, SC). Rats (12 per group) then received either unilateral microinjections (2.0  $\mu$ l at  $2 \times 10^8$  pfu/ml) of pHSV-GluR1 or of pHSV-LacZ, or sham surgery (injection needle not lowered into brain). Rats were retested with morphine (1.0 mg/kg, SC) on day 3 and day 4 after surgery. The locomotor activity of rats given VTA microinjections of pHSV-GluR1 increased 70%, whereas 25% increases were seen after microinjections of pHSV-LacZ or after sham surgery. Immunohistochemical analysis 96 hr after infection revealed moderate numbers of highly GluR1-immunoreactive cells in VTA in the injected hemisphere of rats given pHSV-GluR1, whereas GluR1 immunoreactivity was at normal low basal levels in VTA on the non-injected side of the brains or on the injected side of the brains of rats given pHSV-LacZ. These studies suggest that altered expression of AMPA receptor subunits in VTA may underlie some behavioral adaptations to opiates. (Supported by DA08227)

**BLOCKADE OF TYPE II GLUCOCORTICOID RECEPTORS REDUCES BEHAVIORAL AND DOPAMINERGIC RESPONSES TO MORPHINE.**

M. Marinelli, B. Aouizerate, M. Barrot, M. Auriacombe, M. Le Moal and P.V. Piazza. SPON: European Brain and Behavior Society

INSERM U. 259, Université de Bordeaux II, 33077 Bordeaux Cedex, France.

Previous data show that glucocorticoid hormones facilitate the behavioral and dopaminergic effects of morphine. In this study we examined the role of glucocorticoid receptors on the behavioral and dopaminergic responses to morphine by selectively blocking glucocorticoid receptors via i.c.v. administration of receptor antagonists 2hr before the administration of morphine. In the first experiment we studied the effect of type I or type II receptor antagonists on the locomotor effects of morphine. Blockade of type II receptors by either RU 38486 (100 ng/6 $\mu$ L), or by the more selective RU 39305 (200 ng/6 $\mu$ L), which is void of antiprogesterone action, largely reduced the response to morphine whereas the type I antagonist spironolactone (100 ng/6 $\mu$ L) had no significant effect. In the second experiment we determined if the influence of type II glucocorticoid receptors on this drug-induced behavior was dopamine-dependent by injecting morphine directly in the VTA. Indeed, type II receptor blockade reduced the locomotor response to intra-VTA morphine. In a final experiment we examined how blockade of type II receptors could exert its effects on the dopaminergic system. To this end, we monitored extracellular concentrations of dopamine (DA) in the nucleus accumbens shell by means of microdialysis in freely moving rats. Blockade of type II receptors reduced both baseline values and morphine-induced DA release. In conclusion, these results show that type II glucocorticoid receptors modulate dopamine-dependent behavioral effects of morphine and that changes in the basal and drug-induced activity of DA neurons may, at least in part, account for these effects. Furthermore, these results also indicate that opioid effects may be decreased by acute pharmacological manipulations of glucocorticoid hormones.

## 73.2

**BIOCHEMICAL DIFFERENCES BETWEEN DARK AGOUTI AND FISCHER 344 RATS IN THE MESOLIMBIC DOPAMINE SYSTEM.** E.S. Brodtkin<sup>1</sup>, R.Z. Terwilliger, C.N. Halle, and E.J. Nestler. Laboratory of Molecular Psychiatry, Departments of Psychiatry and Pharmacology, Yale Univ Sch of Med, New Haven, CT.

Previous studies have found that Lewis (LEW) and Fischer 344 (F344) rats differ in levels of specific proteins in the mesolimbic dopamine system, in their behavioral and endocrine responses to stress and drugs of abuse, and in their susceptibility to autoimmune disease (LEW more autoimmune-prone). To determine whether these traits covary in other inbred strains, we studied another autoimmune-prone inbred strain, the Dark Agouti, relative to F344 rats under basal conditions. In the ventral tegmental area (VTA), we found by immunoblotting that Dark Agouti rats had significantly higher levels of GluR1 and glial fibrillary acidic protein and lower levels of neurofilament proteins than F344 rats. There also was a trend for Dark Agouti rats to have higher levels of tyrosine hydroxylase than F344 rats in the VTA. In contrast, in the nucleus accumbens (NAC), there was no difference in levels of protein kinase A, Gi1/2 $\alpha$ , or tyrosine hydroxylase, proteins that do differ in LEW rats. Thus, the VTA, but not the NAC, of the Dark Agouti is "LEW-like" as compared to F344 rats. Further studies will compare behavioral responses to drugs of abuse in Dark Agouti and F344 rats. With genetic maps now available, these phenotypic differences may be amenable to quantitative trait locus analysis. (Supported by DA08227.)

## 73.4

**ORAL INTAKE OF DRUGS OF ABUSE BY RATS BRED SELECTIVELY FOR OPIOID ACCEPTANCE.** K.R. Carlson<sup>1</sup> and L. Perez. Dept. of Pharmacology & Molecular Toxicology, U. Massachusetts Medical Center, Worcester, MA 01655-0126.

Lines which accept or reject solutions of the potent opioid etonitazene, and a randomly bred control line, have been established by selective breeding. In order to test the specificity of selective breeding, drug-naïve subjects from generation 8 were offered a continuous choice in their home cages between water and a 10% ethanol solution for 20 days. There was no difference between the accepting and rejecting lines in preference for one fluid or in dose of ethanol received. The same rats were then given a choice between water and increasing concentrations (0.08-0.64 mg/ml) of a cocaine solution, seven days at each concentration. There were no differences among the lines in preference for the drug, but the rejecting line ingested a higher dose than the accepting line. Finally, these animals were subjected to the same regimen as used in choosing rats for selective breeding: 2 days of 2.5  $\mu$ g/ml etonitazene alone, followed by 4 days of a water-etonitazene choice. In all measures the order of the lines was as expected: accepting > control > rejecting. Thus, selection has been rather specific and not for a generalized tendency to become intoxicated. Supported by NIH DA06539

## 73.6

**GLUCOCORTICOIDS SELECTIVELY MODULATE DOPAMINERGIC ACTIVITY IN THE NUCLEUS ACCUMBENS SHELL.**

M. Barrot, M. Marinelli, F. Rouge-Pont, N. Abrous<sup>1</sup>, M. Le Moal, P.V. Piazza. Psychobiologie des Comportements Adaptatifs, INSERM U259, Univ. de Bordeaux II, 33077 Bordeaux Cedex, France.

Previous investigations have shown that glucocorticoids can modify basal and drug-induced dopamine (DA) release. We studied the possible anatomical selectivity of these effects by means of microdialysis in freely-moving rats. DA levels were monitored at rest or after vehicle or morphine (2mg/kg, s.c.) injection in sham-operated (sham) and adrenalectomized (ADX) rats and in ADX rats with corticosterone replacement. Identical probes (CMA11/2mm) were used in the core and shell of the nucleus accumbens and in the dorso-lateral striatum. In sham animals, there were basal and morphine-induced differences in DA levels between the three regions, the shell being the most reactive. The shell was also the only region in which a s.c. vehicle injection increased DA levels. In the core and in the striatum, no significant difference was observed between sham and ADX rats. In contrast, ADX decreased basal DA levels by 66% in the nucleus accumbens shell; ADX also suppressed the response to vehicle injection, and the morphine-induced DA release in these rats just reached the basal levels of sham animals. The effects of ADX were reversed by restoring corticosterone circadian secretion. These differences between core, shell and striatum in sham rats and in the anatomic specificity of glucocorticoid action, point out that the three regions are physiologically different. This fact must be taken into account in dialysis studies of the nucleus accumbens, especially for phenomena in which glucocorticoids could be implicated. In conclusion glucocorticoids, which act on behavioral and motivational processes, selectively modulate dopaminergic activity in the shell, which is considered the limbic portion of the nucleus accumbens.

**NATURE OF STRESS INDUCED POTENTIATION OF MORPHINE'S REWARDING PROPERTIES.** M. J. Will\*, L. R. Watkins & S. F. Maier. Dept. of Psychology, University of Colorado, Boulder, CO 80309.

We have previously shown that inescapable tailshock (IS) potentiates the rewarding properties of morphine when measured by conditioned place preference. The physical nature of IS and the multiple pharmacological properties of morphine make interpretation of these data difficult. The present experiments were designed to address some of these interpretive issues. One approach involved attempting to produce the effects of IS with the benzodiazepine inverse agonist DMCM, a drug shown to mimic other IS induced behavioral effects. This approach would exclude external physical stress and possible injury. Initial preferences were measured over a 20 min trial in which rats explored 2 distinct environments separated by a neutral area. On day 2, the inverse agonist DMCM (.3mg/kg i.p.) or vehicle was administered and subjects then restrained for a period equal to the shock session. Conditioning occurred 24 and 48 hours after DMCM/restraint with 3mg/kg-mL s.c. morphine in one context & 4 hours later, 1ml/kg s.c. saline vehicle in the other context. Conditioning assignment was counter-balanced randomly. Testing of preference shift was conducted over a 20 min period approximately 24 hours following the last conditioning pairing. Difference in time spent in compartments before & after conditioning with drugs was determined. Significant potentiation of morphine conditioned place preference was observed in the DMCM treated groups compared to controls. Time course and stressor controllability effects were also investigated. Supported by Grant NIH MH50479.

**EFFECTS OF HALOPERIDOL ON THE RESPONSE-REINSTATING PROPERTIES OF DISCRIMINATIVE STIMULI IN AN OPERANT MODEL OF DRUG RELAPSE.** K. McFarland\* and A. Ettenberg. Behavioral Pharmacology Laboratory, University of California, Santa Barbara, CA 93106.

Olfactory stimuli (orange and almond food extract) served as discriminative cues about the availability (S+) or unavailability (S-) of heroin reinforcement (a single 0.1 mg/kg infusion) in the goal box of a straight arm runway. Following discrimination training, the running response was extinguished in the absence of the olfactory cues. On a single trial, the discriminative stimuli were tested for their ability to reinstate running behavior *prior* to presentation of any reinforcement. Subjects presented with the S+ on test day traversed the alley significantly more quickly than did those subjects presented with the S-. These results demonstrate, in an animal model of drug self-administration, that environmental discriminative cues possess the ability to reinstate drug seeking behavior following a period of abstinence. The response-reinstating properties of the S+ odor was unaltered by pretreatment with any of three doses of haloperidol (0.0, 0.15 or 0.3 mg/kg IP), suggesting that the motivating properties of heroin-predictive stimuli are independent of endogenous dopamine activity.

This research was funded by NIDA grant DA05041 awarded to Aaron Ettenberg and a NRSA (F31-DA05672-02) awarded to Krista McFarland.

## 73.11

**DELTA-OPIOID RECEPTOR BLOCKADE PREVENTS SENSITIZATION TO THE CONDITIONED REINFORCING EFFECTS OF MORPHINE**

A.C. Thompson\* & T.S. Shippenberg, Neuroimaging/Drug Action Section, NIDA-ARC, NIH, Baltimore, MD 21224

Opioid antagonists can block the reinforcing effects of cocaine as measured by the conditioned place preference (CPP) paradigm. The present study used an unbiased place preference conditioning procedure to examine the influence of selective  $\delta$ -opioid receptor antagonists on the development of, and sensitization to, the conditioned reinforcing effects of morphine. Male Sprague Dawley rats received once daily injections of morphine (5.0 mg/kg s.c.) or vehicle on days 1-5 either alone, or in combination with naltrindole or naltriben. Conditioning, consisting of 2 morphine and 2 saline sessions, was conducted on days 8-9 and rats were tested for place preference on day 10. Rats pretreated with morphine alone spent significantly more time on the drug-paired side than on the vehicle-paired side. Low doses of both naltrindole and naltriben (0.03-0.1mg/kg), when paired with morphine pretreatment, blocked the morphine-induced enhancement of CPP. In a second experiment without pretreatment, rats were conditioned for 3 days with morphine + naltrindole or naltrindole alone (3 drug and 3 saline sessions). Naltrindole was ineffective in blocking the development of CPP to morphine, and failed to produce conditioning when given alone. These data suggest that  $\delta$ -opioid receptors have an important role in modulating sensitization, but are not involved in the development of place preference to morphine. Furthermore, the effectiveness of naltriben, a selective  $\delta_2$  receptor antagonist, in blocking sensitization suggests the involvement of the  $\delta_2$  subtype in this effect.

## 73.8

**CORTICOSTERONE IS NOT INVOLVED IN STRESS- AND HEROIN-INDUCED RELAPSE TO HEROIN-SEEKING.**

Y. Shaham\*, D. Funk, S. Erb, T. Brown, C.-D. Walker, J. Stewart. Center for Studies in Behavioral Neurobiology, Concordia Univ., Montreal, and Addiction Research Foundation, Toronto, Canada.

We have found previously that brief exposure to footshock and to priming injections of heroin reinstate heroin-seeking behavior following prolonged extinction. Here we report on the role of the adrenocortical hormone, corticosterone, in stress- and heroin-induced relapse. Rats were trained to self-administer heroin (100  $\mu$ g/kg infusion, IV) during four 3-h sessions per day, over a 2-week period. Extinction sessions with saline were given for 4-6 days. Reinstatement of heroin-seeking was then studied after exposure to priming injections of saline and heroin (0.25 mg/kg, SC), and 15 min of intermittent footshock (0.5 mA). Neither adrenalectomy (performed at the end of the training phase), nor chronic exposure to a synthesis inhibitor of corticosterone, metyrapone (100 mg/kg, twice daily from day 1 of extinction), nor an acute injection of metyrapone, given 3 h before testing, altered reinstatement of heroin-seeking induced by either footshock or a priming injection of heroin. Surprisingly, acute exposure to metyrapone, alone, potentially reinstated extinguished heroin-seeking behavior. Thus the ability of footshock stress and priming injections to induce relapse to heroin-seeking would appear to be independent of the actions of corticosterone in the central nervous system. Supported by NIDA R01-09750

## 73.10

**CADMIUM EXPOSURE PREVENTS BEHAVIORAL SENSITIZATION TO MORPHINE.** D. Miller, C.L. Livermore and J.R. Nation\* Texas A&M University, College Station, TX 77843.

Adult male rats were exposed to diets containing 100 ppm cadmium chloride (Group Cadmium) or no added cadmium (Group Control) for 45 days prior to testing for the effects of acute and repeated ip morphine administration (10 mg/kg/daily session) on locomotor activity. Relative to saline injected animals, an initial (acute) challenge of morphine on Day 1 of testing decreased activity (total distance traveled) among control animals, but diminished responding was not exhibited by cadmium-exposed animals given morphine. With continued daily administration of morphine or saline for 14 days, the augmented locomotor stimulating effects of morphine (behavioral sensitization) apparent in controls were not evident in cadmium-exposed animals. These findings suggest that cadmium, which exists in high levels in all tobacco products, produces a hyposensitivity to morphine, and this effect may alter drug selection and use.

United States Public Health Grant DA07932

## 73.12

**CHRONIC EXPOSURE TO LEAD ALTERS THE INITIATION OF BEHAVIORAL SENSITIZATION TO MORPHINE.** C.L. Livermore, J.R. Nation, D.K. Miller, and M. W. Meagher.\* Texas A&M University, College Station, TX, 77843-4235.

To date, investigators have largely restricted their analyses of chemical co-treatment effects to naturally occurring or synthetic drugs that present known pharmacologic profiles. However, environmental pollutants may also influence drug sensitivity and therein disturb patterns of selection and use of drugs with substantial abuse potential. Continuing this line of research, the present investigation examined the effects of recurrent lead exposure on behavioral sensitization to morphine. Locomotor activity (total distance traveled) was monitored for control and lead-treated adult male rats (45 days exposure to 250 ppm lead acetate via *ad lib* food supply) across 14 daily one-hour test sessions. In each session, a daily i.p. injection of 10 mg/kg morphine or vehicle was administered for 14 successive days. Post-injection activity was then examined for 80 minutes. On Day 15, all of the animals received saline injections to test for effects due to conditioning components. A 10 mg/kg morphine challenge injection was given to all groups on Day 16 to compare acute and chronic administration of the drug. The findings show that lead exposure retards the initiation of sensitization, without any apparent contextual cueing. These data suggest that xenobiotic contamination may alter drug responsiveness and therein may influence patterns of drug selection and use.

## 73.13

FLUOXETINE BLOCKS THE EXPRESSION BUT NOT THE DEVELOPMENT OF MORPHINE-INDUCED SENSITIZATION OF ORAL STEREOTYPY IN THE RAT. H.K. Wennemer and C. Kornetsky\*. Departments of Pharmacology and Psychiatry, Boston University School of Medicine, Boston, MA 02118.

Repeated high doses of morphine sulfate (MS) administered to a rat causes an intense repetitive biting and gnawing behavior that can be reexpressed by a low dose of MS as long as 6 months after the initial morphine treatment (Pollock and Kornetsky, PB&B, 1996). The expression of this biting behavior has been found to be blocked by both D1 antagonists and the NMDA antagonist MK-801 (Livezey et al. Brain Res., 1995) with the latter also capable of blocking the development of the sensitization. The present experiment was designed to determine the role of serotonin in the acute expression and development of sensitization of morphine-induced stereotypy. Ten F-344 rats were administered four 10 mg/kg doses of MS (s.c.) in a 36 hour period. Half of these were administered 5.0 mg/kg (i.p.) of fluoxetine (FLX), a potent reuptake inhibitor of serotonin, while the rest received the vehicle injections 60 min prior to each of the four MS doses. Following each injection of MS, behavior was rated for 2 consecutive hours by an observer blind to the treatment history. By the final dose of MS the mean duration of stereotypic behavior was 40 min for the MS plus vehicle group and 4 min for the MS plus FLX group. At 1 and 3 weeks after the sensitizing treatment both groups were challenged with 4.0 mg/kg MS. Both groups of rats expressed approximately 75 min of biting with no significant difference between them. At 2 and 4 weeks both groups were challenged with 4.0 mg/kg of MS plus 10.0 mg/kg of FLX, little or no biting was seen in either group. The mean duration of biting in each group was approximately 3 min. These results indicate that although serotonin appears to play a role in the expression of MS-induced stereotypy, it is not involved in the development of sensitization. DIFFERENTIAL EFFECTS OF COMPETITIVE AND NON-COMPETITIVE ANTAGONISM ON INTRAVENOUS SELF-ADMINISTRATION IN DRUG-NAIVE MICE. Thøger Rasmussen\* and Michael D.B. Swedberg. Novo Nordisk A/S, Behavioral Pharmacology, Novo Nordisk Park, DK-2760 Måløv, Denmark.

Intravenous self-administration in drug-naive mice has the potential for rapidly assessing drug abuse liability. Typically, bell-shaped dose-dependent response curves are obtained with compounds possessing behaviorally reinforcing properties. With the aim of further characterizing the acute nose-poke self-administration model, we investigated the effects of morphine (0.025, 0.125, 0.225, 0.325 and 0.425 mg/kg/infusion) after prior treatment with the opiate antagonist naltrexone (3.0 mg/kg), and nicotine (0.025, 0.075, 0.125, 0.175 and 0.225 mg/kg/infusion) after prior treatment with the nicotine antagonist mecamylamine (0.1, 0.3 and 1.0 mg/kg). Whereas naltrexone shifted the morphine dose-response curve to the right, mecamylamine shifted the lower end of the nicotine dose-response curve to the right but as the dose of nicotine increased, the dose-response curves flattened out. These data support the idea that the mechanisms underlying self-administration in drug-naive mice are receptor mediated. The patterns of antagonism seen here fit the distinction between naltrexone as a competitive antagonist and mecamylamine as a non-competitive antagonist. Funded by Novo Nordisk A/S.

## 74.3

EFFECTS OF NALTREXONE ON HEROIN- AND COCAINE-MAINTAINED BEHAVIOR IN RHESUS MONKEYS RESPONDING UNDER A PROGRESSIVE-RATIO SCHEDULE. J.K. Rowlett\* and W.L. Woolverton. Dept. Psychiatry & Human Behav., U. Mississippi Med. Ctr., Jackson, MS 39216.

The opioid receptor antagonist naltrexone has been shown to block heroin-maintained behavior and either suppress or not alter cocaine-maintained behavior. This study assessed the effects of naltrexone on the reinforcing efficacy of heroin and cocaine using a progressive-ratio (PR) schedule. Four rhesus monkeys were prepared with intravenous catheters and trained to press a lever for cocaine injection. The PR schedule consisted of a 5-component daily session, each component with 4 trials at the same fixed ratio (FR). The FR sequence was 120, 240, 480, 960, 1920. Trials were separated by a 30 min time-out. A session ended when all injections were taken or 2 consecutive FRs were not completed (limited hold=15 min). Behavior was maintained on a single-alternation sequence in which drug (cocaine, 0.10 mg/kg/inj or heroin, 0.013 mg/kg/inj) and saline sessions alternated. When inj/session were stable (3 drug and 3 saline sessions with  $\leq 10\%$  variation and no upward or downward trends), test sessions were conducted according to the sequence: DSTSDT (D=drug, S=saline, T=test). Naltrexone (0.001-0.8 mg/kg, i.m.) or saline (0.1 ml/kg, i.m.) was given 10 min before the test session, in which heroin (0.0010-0.025 mg/kg/inj) or cocaine (0.013-0.10 mg/kg/inj) was available. Naltrexone dose-dependently decreased heroin-maintained behavior (0.013 mg/kg/inj) to saline levels. Naltrexone (0.006 mg/kg) produced a rightward shift in the heroin dose-response function, with a mean apparent  $pK_B$  value of 8.0 (range=7.7-8.3), consistent with  $\mu$ -opioid receptor antagonism. Naltrexone had no effect on cocaine-maintained behavior at doses over 100 times higher than those that antagonized heroin-maintained behavior. These results indicate that naltrexone reduced the reinforcing efficacy of heroin, but this reduction was surmounted by increasing the heroin dose (i.e., competitive antagonism). Naltrexone did not alter cocaine-maintained behavior, indicating no involvement of opioid receptors in the reinforcing effects of cocaine. Supported by NIDA DA-05625 from NIDA (JKR).

## 74.2

KAPPA-OPIOID RECEPTORS ANTAGONIZE HEROIN SELF-ADMINISTRATION AND DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS: AN IN VIVO FAST-CYCLIC VOLTAMMETRY STUDY. Z.-X. Xi, S.A. Fuller & E.A. Stein\*. Dept. of Psychiatry and Behav. Medicine, Medical College of Wisconsin, Milwaukee, WI 53226

Microdialysis and behavioral studies have demonstrated that  $\mu$  and  $\kappa$  opioid agonists exert different and/or opposite effects on basal mesolimbic dopamine (DA) release and rewarding/aversive stimulus properties. However, changes in DA release during heroin self-administration (SA), possible interactions between  $\mu$  and  $\kappa$  receptors in the mesolimbic DA system, and the relationship between mesolimbic DA transmission and heroin-induced reinforcing effects are still unclear. By monitoring extracellular DA changes in the nucleus accumbens (NAcc) with fast-cyclic voltammetry (Nafion-coated 8  $\mu$ m carbon fiber electrode) combined with heroin-SA (0.06, 0.1 & 0.2 mg/kg/inj), we observed: (1) dose-dependent monophasic increases in the DA-dependent electrochemical signal in NAcc during both heroin-SA and passive administration; (2) pre- or co-administration with U50,488H (a selective  $\kappa$  opioid agonist, 0.025-0.05 mg/kg/inj, iv) or pretreatment with dynorphin A (1-2  $\mu$ M/ $\mu$ l, icv) dose-dependently depressed heroin-induced DA release in the NAcc during heroin-SA; (3) pretreatment with Nor-BNI (a selective  $\kappa$  receptor antagonist, 1-2  $\mu$ M, icv) significantly potentiated heroin-evoked DA release; (4) 0.025 mg/kg/inj U50,488H or dynorphin A (2  $\mu$ M, icv) significantly increased heroin-SA, while 0.05 mg/kg/inj U50,488H co-administered reduced or completely blocked heroin-SA; (5) Nor-BNI (1-2  $\mu$ M, icv) also slightly increased heroin-SA. These findings that activation of central  $\kappa$  receptors can antagonize both heroin-induced DA release in the NAcc and heroin SA behavior suggest that  $\kappa$  receptors may play a role in modulating heroin reinforced behaviors. Supported by NIDA/INVEST Fellowship N01DA-3-0002.

## 74.4

THE EFFECTS OF DIETARY MACRONUTRIENT MANIPULATIONS ON INTRAVENOUS MORPHINE SELF-ADMINISTRATION.

B.A. Gosnell\*, D.D. Krahn, J.M. Yracheta and B. J. Harasha.

Department of Psychiatry, University of Wisconsin-Madison, Madison, WI 53719.

Manipulations of diet composition have been shown to influence opioid peptides, opioid receptors and the analgesic response to morphine. It is not known, however, whether changes in diet composition influence the self-administration of opiates. We therefore conducted an experiment to determine the effects of such manipulations on morphine self-administration. Jugular catheters were implanted in male rats (n=8). After recovery, morphine self-administration was measured in daily 18 hr sessions (FR 1 schedule, 0.1 mg/kg/infusion). During the session and during the 6 hr spent daily in the home cage, water and powdered lab chow were available. After self-administration stabilized, the lab chow was replaced with either a high-fat diet (FAT) (80% fat, 20% protein) or a high-carbohydrate diet (CARB) (80% carb., 20% protein). All rats were tested for 7 days on each diet, with a 7 day period of availability of only lab chow intervening between the test diet phases. Order of presentation of the diets was counter-balanced. Mean daily caloric intakes were  $71 \pm 3$ ,  $80 \pm 4$  and  $106 \pm 8$  kcal in the chow, CARB and FAT conditions, respectively; these represent increases over chow intake of 12% (CARB) and 49% (FAT). Maintenance on the CARB diet caused a slight but non-significant decrease in the number of infusions obtained; maintenance on the FAT diet had no detectable effect on the number of infusions. Mean numbers of infusions were  $86 \pm 10$ ,  $72 \pm 5$  and  $89 \pm 10$  for the chow, CARB and FAT conditions, respectively. These results indicate that imposed changes in the macronutrient composition of the maintenance diet have only minimal effects on concurrent morphine self-administration. This finding does not, however, rule out the possibility that baseline macronutrient preferences may be useful as predictors of morphine self-administration. Possible relationships between diet preferences and self-administration are currently under investigation. Supported by NIDA DA05471 and DA00210.

## 74.5

CAN THE REWARDING EFFECTS OF DIFFERENT DRUGS BE DETERMINED USING A PROGRESSIVE RATIO REINFORCEMENT SCHEDULE IN A DRUG SELF ADMINISTRATION MODEL? C.L. Duvauchoelle\*, T. Sapoznik and C. Kornetsky. Departments of Psychiatry and Pharmacology, Boston University School of Medicine, Boston, MA 02118.

In order to compare the relative reinforcement value of cocaine alone, heroin alone and their combination ("speedball"), a progressive ratio (PR) reinforcement schedule of the respective drugs was used to determine breakpoints. The initial training for all rats was on a combined dose of 18 µg/kg/inj of heroin (H) and 300 µg/kg/inj of cocaine (COC). Breakpoints for the training dose and individual component doses were determined for both half and double the training dose. Of the three doses of each treatment, only cocaine self-administration yielded the expected monotonic increase in breakpoint as a function of the self-administered dose. Also the breakpoint for COC was greater than for the combination of COC and H. Because these results suggested that H plus COC is less rewarding than is COC alone, we determined the doses for these three drug treatments that produced saline level responding. 1.2 H and 18.8 COC (µg/kg/inj) combined, and the same dose of COC alone produced breakpoints indistinguishable from saline. 4.5 µg/kg was the highest H dose resulting in a breakpoint no different than saline. However, a speedball combination of 2.3 µg/kg of H plus 37.5 µg/kg of COC, produced a breakpoint significantly higher than that for the COC component alone. These results suggest that a PR reinforcement schedule is not a reliable measure of relative rewarding value between drugs. In addition, because increased motor performance equals increased reward in this schedule, it is extraordinarily vulnerable to drug-induced influences on motor activity. ENSEMBLE NEURAL ACTIVITY IN THE NUCLEUS ACCUMBENS (NAc) AND PREFRONTAL CORTEX (PFC) OF THE AWAKE RAT DURING FOOD AND WATER REINFORCEMENT, AND HEROIN SELF-ADMINISTRATION. BY Subrahmanyam\*, JM Paris, J-Y Chang, DJ Woodward. Program in Neuroscience and Dept. of Physiology/Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

The purpose of this study was to analyze and compare the firing patterns elicited by different reinforcers in regions of the mesolimbic reward circuit. Adult male rats were surgically implanted with chronic multiwire recording electrodes into the NAc and PFC. Neural activity was examined while awake rats performed an operant task under a multiple FR5/FR1 schedule maintained by food and water. Neural activity was examined at specific nodes in the task sequence, including two conditioned stimuli (a light indicating lever activation and a tone signaling reinforcer delivery). A typical rat recorded over 5 sessions yielded a total of 36 NAc and 20 PFC neuron-sessions. Four patterns of neural activity were observed in both the NAc and PFC during food and water reinforcement: 1) increases in firing rate during lever-pressing; 2) increases prior to light presentation (anticipatory excitatory activity); 3) decreases prior to tone presentation (anticipatory inhibitory activity); and 4) decreases during tone presentation. The responses were relatively less robust in the same neurons during drinking segments. Increased activity during pellet consumption was also observed in both regions. Finally, increases and decreases in firing rate before lever-pressing (anticipatory activity) were observed in the NAc in a separate group of animals during heroin self-administration. This procedure allows a direct comparison of food- and heroin-reinforced neural patterns in the same animal under a multiple FR5/FR5 schedule. From these data, it appears that neural signals exist in the mesolimbic reward circuit that are specific to individual reinforcers as well as those which appear general across reinforcers. ## 74.9

AGONIST AND ANTAGONIST EFFECTS OF  $\mu$  OPIOIDS IN RATS TRAINED TO DISCRIMINATE A HIGH DOSE OF FENTANYL FROM SALINE. L. Zhang, M. Evola and A. M. Young\*. Department of Psychology, Wayne State University, Detroit, MI 48202.

We studied the discriminative stimulus effects of a high training dose of the high efficacy  $\mu$  agonist fentanyl. Male Sprague-Dawley rats (N=16) were trained to discriminate 0.04 mg/kg of fentanyl from saline under a fixed-ratio 15 schedule of food delivery. The higher efficacy  $\mu$  agonists etonitazene, fentanyl, methadone, and morphine evoked full fentanyl-lever responding and suppressed response rates in the same potency order (etonitazene > fentanyl > methadone > morphine). The lower efficacy  $\mu$  agonists nalbuphine and naltrexone evoked less than 50 percent fentanyl-lever responding. The  $\kappa$  agonist spiradoline and the nonopioids d-amphetamine and ketamine evoked saline-lever responding and suppressed rates. *In vivo* apparent pA<sub>2</sub> analysis showed that nalbuphine (3.2-32 mg/kg) and naltrexone (1.0-10 mg/kg) antagonized the stimulus effects of fentanyl with an apparent pA<sub>2</sub> of 5.4 for nalbuphine and 6.2 for naltrexone. Naltrexone (0.01-0.32 mg/kg) also antagonized stimulus and rate-altering effects of fentanyl with an apparent pA<sub>2</sub> of 7.7. In concert with previous findings from our laboratory that nalbuphine and naltrexone evoked full stimulus effects of 0.01 mg/kg fentanyl (Sutherland *et al.*, 1995, *Soc. Neurosci. Abstr.* 21: 727), these results suggest that the training dose of fentanyl can modulate the likelihood that certain  $\mu$  opioids (e.g., nalbuphine, naltrexone) will evoke or antagonize the stimulus effects of fentanyl. For nalbuphine and naltrexone, their observed antagonism of the stimulus effects of high-dose fentanyl is likely due to low efficacy  $\mu$  agonist actions. RESPONSES OF NUCLEUS ACCUMBENS AND VTA NON-DOPAMINE NEURONS TO HEROIN IN FREELY-MOVING RATS. R.-S. Lee\*, P. Griffin, S. C. Steffensen, S. Casalman, and S. J. Henriksen. The Scripps Research Institute, La Jolla, CA 92037.

The nucleus accumbens (NAcc) has been hypothesized to function as an integrator of motor and complex limbic information. Other evidence indicates that the NAcc and ventral tegmental area (VTA) may be critical sites for reward-seeking behaviors. To further investigate NAcc-related and VTA-related physiological correlates of drug-seeking behaviors, we have employed the following paradigm: Naive rats were allowed to explore freely in an operant chamber and to self-administer heroin intravenously (via an indwelling catheter) through nose-poking behavior (FR-1 schedule). Behaviorally related and drug dependent changes in neuronal activity of these regions were recorded using stainless steel microwires (62 µm) implanted into the NAcc and/or VTA under anesthesia. Our observations indicate that: 1) The acquisition of heroin self-administration (0.06 mg/kg/injection) is associated with specific changes in NAcc neuronal activity, beginning from as few as four 2 hour daily sessions of nose-poking behavior; 2) Presumptive VTA non-dopamine neurons (criteria: spike duration < 500 µs, and histological identification) also are inhibited during heroin self-administration behavior; 3) VTA non-dopamine neurons appear to be more sensitive than are NAcc to non-contingent heroin injection (0.2 mg/kg, i.v.); and 4) acute tolerance (desensitization) of NAcc neuron and presumptive VTA non-dopamine to heroin self-administration occurs during repeated, chronic heroin self-administration sessions. These data suggest that neuronal discharges in NAcc and in VTA are altered in a complex fashion during the acquisition and maintenance of heroin self-administration behavior. NMDA ANTAGONIST, MK-801, ANTAGONIZES THE DEVELOPMENT MORPHINE-INDUCED CONDITIONED PLACE PREFERENCE. M. C. Clavier, W. L. Nores, R. D. Olson & A. L. Vaccaro\*. Department of Psychology, University of New Orleans, LA 70148.

Several lines of evidence show a critical role of the N-methyl-D-aspartate (NMDA) receptor in the development of morphine-induced tolerance and analgesia. In the present study we examined the involvement of the NMDA receptor in the development of morphine-induced conditioned place preference (CPP). The CPP apparatus consisted of a grey start-box and two treatment compartments (white/wood chip floor and black/wire grid floor). On the day before conditioning, rats were placed in the start-box and allowed 15 min free access to both compartments to establish a baseline preference. Rats received 2 conditioning trials per day (6 h apart) on days 1, 3, 5, 7 and 9. On one conditioning trial rats were injected ip with MK-801 (0.1 mg/kg) + morphine (5 mg/kg), MK-801 + saline, saline + morphine, or saline + saline and were confined to the non-preferred side for 50 min. On the other conditioning trial rats received saline + saline and were confined to the other compartment for 50 min. The order of conditioning trials was counterbalanced. To examine the development of CPP rats were placed in a drug-free state in the start-box and allowed free access to both compartments for 15 min on days 2, 4, 6, 8 and 10. Morphine produced a significant CPP after one conditioning session (i.e., day 2), which increased after the second conditioning session (i.e., day 4), and then steadily decreased on subsequent trials. MK-801 did not affect morphine CPP on day 2, but MK-801 attenuated morphine CPP on subsequent days. MK-801 alone did not produce any changes. These results suggest that MK-801 disrupts the learning of the association between morphine and the environment, but does not affect morphine reward.

## 74.10

ASSESSMENT OF THE STIMULUS PROPERTIES OF MDA AND MDMA STEREOISOMERS IN A LSD-SALINE-AMPHETAMINE DISCRIMINATION. Michele M. Taylor and Lisa E. Baker. Department of Psychology, Western Michigan University, Kalamazoo MI 49008

The stereoisomers of 3,4-methylenedioxymphetamine (MDA) and 3,4-methylenedioxymethamphetamine (MDMA) have been demonstrated to differ in the extent to which they produce stimulus generalization in subjects trained to discriminate between either amphetamine or a hallucinogen and a vehicle. Inconsistencies among previous findings seem to indicate that the extent to which the discriminative stimulus effects of the optical isomers of both MDMA and MDA are amphetamine or hallucinogen-like depends on the training drug and the discrimination procedures utilized. The present study employed a three-choice discrimination procedure in order to further delineate the discriminative stimulus properties of the stereoisomers of MDA and MDMA. Eight male Sprague-Dawley rats were trained to discriminate amphetamine (1.0 mg/kg) and LSD (0.8 mg/kg) from saline in a three-lever, food reinforced (sweetened condensed milk) drug discrimination procedure. A fixed-ratio (FR) 20 schedule with a reset condition for incorrect responses was employed. When criteria (80% over 10 consecutive sessions) were met, (+)-MDA, (-)-MDA, (+)-MDMA (31-125 mg/kg) and (-)-MDMA (88-3.5 mg/kg) were tested for substitution. All of these compounds elicited a greater percentage of responding on the LSD lever than on the amphetamine lever. These results suggest that the discriminative stimulus properties of both MDMA and MDA isomers resemble those of LSD more closely than those of amphetamine. It is suggested that the use of a three-lever discrimination procedure affords a greater degree of precision in the assessment of the compound stimulus properties of these designer drugs.

**INDIVIDUAL DIFFERENCES IN THE EFFECTS OF COCAINE AND AMPHETAMINE IN SQUIRREL MONKEYS DISCRIMINATING MORPHINE.** Doreen M. Grech\* and Roger D. Spealman, Harvard Medical School, NERPRC, Southborough, MA 01772-9102.

The effects of cocaine and amphetamine were studied in squirrel monkeys trained to discriminate morphine from vehicle using a two-lever drug-discrimination procedure. In about half the subjects tested, both cocaine and amphetamine substituted for morphine in a dose-related manner and enhanced the discriminative stimulus effects of morphine when given as a pretreatment. In the remaining subjects, neither cocaine nor amphetamine substituted appreciably for morphine and typically attenuated the effects of morphine when given as a pretreatment. The former, but not the latter, subjects also showed full or partial substitution for morphine when tested with the dopamine transport inhibitor GBR 12909 and the delta opioid agonist BW 373U86. All subjects showed full substitution for morphine when tested with the mu opioid agonist fentanyl and none of the subjects showed consistent substitution for morphine when tested with the norepinephrine transport inhibitor talsupram, the serotonin transport inhibitor citalopram, or the kappa opioid agonist U50488H. The results suggest a role for both dopaminergic and delta opioid mechanisms in the morphine-like stimulus effects of cocaine and amphetamine in individual monkeys. **CONDITIONED TASTE AVERSION AND DRUGS OF ABUSE: A REINTERPRETATION.** P.S. Grigson\*, H. LL. K. Smith, P. Smith, P. Lyuboslavsky, and R. Norgren. Department of Behavioral Science, College of Medicine, The Penn State University, Hershey, PA 17033.

Rats treat morphine and cocaine as rewards. They will increase running speed, bar pressing, and preference for a compartment when associated with either drug. Paradoxically, however, the same drugs appear to function as aversive unconditioned stimuli (US) in a conditioned taste aversion (CTA) paradigm. The following data support a new hypothesis that potentially synthesizes these discrepant findings. That is, following saccharin-morphine pairings, for example, rats decrease intake of a saccharin CS, not because of the aversive properties of the drug, but because the reward value of the saccharin CS is outweighed by that of the morphine. Two experiments showed that morphine and cocaine selectively suppressed intake of a palatable CS (saccharin), but not of a more neutral CS (NaCl). In the same paradigm, a LiCl US reduced intake of both gustatory CSs. Two other experiments demonstrated that the suppressive effects of morphine, but not LiCl, increased as the concentration, and presumably the palatability, of the saccharin CS was increased. Together, the results support a reward comparison, rather than a CTA, account. Specifically, they show that the suppressive effects of the drugs of abuse on CS intake depend upon the well-established rewarding, rather than upon the hypothetical, aversive, properties of the US. Supported by NIH grants DC 02016, DC 00240, and MH 00653.

**OPIOID EFFECTS ON EXCITATORY AFFERENT-DRIVEN NEURONAL ACTIVITY IN THE MEDIAL PREFRONTAL CORTEX.** J.L. Giacchino\* and S.J. Henriksen. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The medial prefrontal cortex (mPFC) is a significant component of the reinforcement pathways which contribute to development and maintenance of opiate addiction. We previously reported that the spontaneous activity of mPFC neurons and their response to excitatory neurotransmitters are modified by both systemic and electrophoretic administration of mu-selective opioid agonists. We have now investigated the effects of these opioids on mPFC neuronal activity evoked by stimulation of major afferents including putative glutamatergic input from both mediodorsal thalamus (Gigg et al, 1992; Pirot et al, 1994) and CA1/subiculum (Jay et al, 1992; Gigg et al, 1994), as well as the basolateral amygdala (Pérez-Jaranay & Vives, 1991; Matsuda & Fujimara, 1995).

Extracellular recordings were made from neurons in the prelimbic subarea of the mPFC in halothane-anesthetized rats. Electrical stimulation of the mediodorsal thalamus, CA1/subiculum and the basolateral amygdala evoked short latency orthodromic single cell activity (3-8 msec, 6-14 msec, 8-15 msec, respectively). Systemic morphine (2.5mg/kg, sc) significantly decreased the response of mPFC neurons activated by stimulation of the thalamus and amygdala. This effect was reversed by naloxone (5mg/kg, sc). The effect of an electrophoretically-applied mu opioid agonist on driven mPFC neuronal firing was also investigated. Preliminary data indicates that local electrophoretic application of DAMGO (1 mM) does not affect the driven activity of mPFC neurons, although spontaneous activity may be altered. These data argue that the effect of systemic opiates on mPFC neuronal activity may be mediated through their effects on excitatory afferent inputs, although local effects at mPFC mu opioid receptors cannot be excluded. ## 74.12

**STIMULUS PROPERTIES OF A DEXTROMETHORPHAN-DIPHENHYDRAMINE COMBINATION IN RATS**

S.A. Vanecek<sup>1</sup>, D.V. Gauvin<sup>1</sup>, C.A. Sannerud<sup>2</sup>, K.D. Hutchinson<sup>2</sup>, R.L. Briscoe<sup>1</sup>, T.J. Baird<sup>1</sup>, M. Vallett<sup>1</sup>, K.L. Card<sup>1</sup>, & F.A. Holloway<sup>1</sup>; <sup>1</sup>Dept Psychiat & Behav Sci, O.U.H.S.C., Okla. City, OK 73190 & <sup>2</sup>Drug & Chem. Eval. Section, Drug Enforcement Admin., Washington, D.C. 20537

The stimulus properties of a combination of dextromethorphan and diphenhydramine (DEXTROMETH + DIPHEN) were evaluated using a two-choice discrimination task and a self-administration task in rats. Twelve male Sprague-Dawley rats were trained to discriminate between 10 mg/kg DEXTROMETH + 10 mg/kg DIPHEN versus saline in a food-motivated lever-press task. Once trained, each rat demonstrated a dose-dependent increase in drug-lever responding with increasing increments in the test combinations. Partial cross-generalization was engendered by both cocaine and *d*-amphetamine. Some rats demonstrated complete cross-generalization to low cocaine doses (1.0 - 3.2 mg/kg), while others cross-generalized to the higher doses (10-32 mg/kg). The drug discrimination data suggested that a "stimulant" dimensionality was produced by the DEXTROMETH+DIPHEN combination in rats.

Three-day substitution tests were conducted with various combinations of DEXTROMETH+DIPHEN in 4 rats trained to self-administer 0.5 mg/kg/inj. i.v. cocaine in daily 4 hr sessions. This combination failed to maintain avid self-administration. These data suggested that, while the combination of DEXTROMETH+DIPHEN could produce subjective effects that cross-generalized to those of cocaine and amphetamine test stimuli, the abuse potential assessed by self-administration appeared to be minimal. Therefore, the predicted abuse liability of these OTC combinations are, at best, equivocal.

## 74.14

**SHORT TERM MEMORY ABILITIES APPEAR TO BE DISRUPTED IN HUMANS WITH EXPOSURE TO METHADONE.** M.C. Fratzke\*,

T.L. Anderson, J.L. Perez, J.K. Shepherd, and H.L. Roitblat. University of Hawaii, Psychology Department, Honolulu, HI 96822

Present data suggest that methadone disrupts short term memory. Clearly, this may be detrimental to the effectiveness of substance abuse counseling, and possibly contributes to a poor prognosis. This study of short term memory demonstrates some of the possible consequences of methadone use on performance and cognitive functioning.

To provide a better understanding of the effects of chronic exposure to methadone, the study compares fifty-five volunteer subjects enrolled in a methadone maintenance program, all of whom have at least two weeks of methadone use as part of their treatment for opiate dependence, ninety-two subjects with no documented drug use and sixteen subjects enrolled in a "drug free" substance abuse treatment program. Subjects' short term memory was assessed with a modified form of the digit-span memory test (LETTSPAN). This instrument provides separate measures of the subjects' ability to recall items and to remember a given item's position in a sequence. Subjects who were administered methadone as part of their treatment scored significantly lower on the ability to recall the identity of items and to recall an item's position in a sequence, presented either successively or simultaneously. These results call for a reevaluation of the potentially disruptive effects of methadone on memory, effects which have not been fully delineated.

## 74.16

**PHARMACOLOGICAL CHARACTERIZATION OF OPIATE INTERACTIONS WITH NACC NEURONS IN VIVO.** J.R. Criado\*,

G.I. Berg, R.-S. Lee, S.-C. Dulawa and S.J. Henriksen. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037. Department of Neuroscience, U. California San Diego, La Jolla, CA 92093.

We previously reported electrophysiological data obtained in vivo suggesting that the effects of systemically administered opiates on NAcc neurons must occur through both the VTA dopaminergic projection to the NAcc, as well as directly within the NAcc (J. Neurosci., 9:3538). To characterize further the effects of heroin on limbic-NAcc inputs, we studied the effects of heroin and [D-Ala<sup>2</sup>, NMe-Phe<sup>4</sup>, Gly-o]-Enkephalin (DAMGO), a selective  $\mu$  agonist, on amygdala- and glutamate-activated NAcc neurons. Our results showed that while local application of DAMGO (1.0 mM) and systemic heroin (0.5 mg/kg, s.c.) suppressed only 25% of the recorded amygdala-activated NAcc neurons, these compounds markedly inhibited glutamate-activated NAcc neurons. Furthermore, MK-801 (0.5 mg/kg, i.p.), a selective non-competitive NMDA antagonist, or apomorphine (100  $\mu$ g/kg, i.p.), a mixed dopamine receptor agonist, had no effect on amygdala-activated NAcc neurons that were insensitive to heroin. In a subgroup of NAcc neurons that were characterized by stable spontaneous activity and a reliable excitatory response to amygdala stimulation, heroin markedly suppressed spontaneous activity, but it had no effect on amygdala-activated NAcc activity. In these neurons, heroin-induced suppression of spontaneous activity was clearly reversed by naloxone (5 mg/kg, i.p.). However, amygdala-activated NAcc neurons that were inhibited by heroin were not reversed by naloxone. These findings suggest that heroin-induced suppression of spontaneous activity in the NAcc is mediated primarily by  $\mu$  receptors, but opioid-induced effects on excitatory afferent inputs might be mediated indirectly via other as yet unidentified mechanisms (Supported in part by DA-08301 to S.J.H.).

## 75.1

RISPERIDONE INCREASES SEROTONIN RELEASE IN THE RAT FRONTAL CORTEX VIA  $\alpha_2$ -ADRENOCEPTOR ANTAGONISM IN THE NERVE TERMINAL REGION

P. Hertele\*, G.G. Nomikos, B. Schilström, L. Arborelius and T.H. Svensson. Dept. of Physiology and Pharmacology, Div. of Pharmacology, Karolinska Institutet, S-171 77 Stockholm, Sweden.

We have previously shown that risperidone (RISP), an antipsychotic drug with high affinity for 5-hydroxytryptamine (5-HT)<sub>2A</sub> and dopamine (DA)<sub>2</sub> receptors as well as for  $\alpha_1$  and  $\alpha_2$  adrenoceptors, enhances 5-HT metabolism selectively in the rat frontal cortex (FC). To further study the influence of RISP on central 5-HT systems, we compared its effects on 5-HT release in the FC with those obtained with other antipsychotic drugs, i.e. clozapine (CLOZ), haloperidol (HAL) and amperozide (AMP), as well as, with the selective  $\alpha_2$  or 5-HT<sub>2A</sub> receptor antagonists idazoxan (IDAZ) or MDL 100907 (MDL), respectively. The underlying mechanism for the stimulatory action of RISP on 5-HT release in the FC was also analyzed. RISP (0.2, 0.6 and 2.0 mg/kg, s.c.) dose-dependently increased 5-HT levels in the FC measured by microdialysis. This facilitatory effect was mimicked by AMP (10.0 mg/kg, s.c.) and, to some extent, by IDAZ (0.25 mg/kg, s.c.). In contrast, CLOZ (10.0 mg/kg, s.c.), HAL (2.0 mg/kg, s.c.) and MDL (1.0 mg/kg, s.c.) exerted only minor effects on 5-HT release in brain. Local administration of RISP or IDAZ (1-1000  $\mu$ M) in the FC dose-dependently increased 5-HT release in this area. Using single cell recording techniques, it was found that RISP (25-800  $\mu$ g/kg, i.v.) dose-dependently decreased the firing rate of 5-HT cells in the dorsal raphe nucleus (DRN), an effect that was largely antagonized by pretreatment with the selective 5-HT<sub>2A</sub> receptor antagonist WAY 100635 (5  $\mu$ g/kg, i.v.). These results indicate that the increased 5-HT release in the FC by RISP is related to its  $\alpha_2$  adrenoceptor antagonistic action, a property shared with both AMP and IDAZ, and seems to be executed at the nerve terminal level. The inhibition of 5-HT cell firing by RISP is probably secondary to increased 5-HT release, e.g. in the DRN, since it was antagonized by a 5-HT<sub>2A</sub> autoreceptor antagonist. The enhanced 5-HT release in the FC by RISP may be of particular relevance for the treatment of schizophrenia when associated with depression and in schizoaffective disorder. Supported by the Swedish Medical Research Council (4747), Karolinska Institutet and Janssen Pharmaceutica Ltd, Beerse.

## 75.3

## INDUCTION OF FOS PROTEIN IMMUNOREACTIVITY IN THE RAT FOREBRAIN BY THE DOPAMINE D3-SELECTIVE LIGAND NNC 00-3094

T.S. Ludvigsen<sup>1</sup>, P.J. Larsen<sup>2</sup>, N. Korsgaard<sup>1</sup>, R. Hohlweg<sup>1</sup>, M.A. Scheide-ler<sup>1</sup> and A. Fink-Jensen<sup>1</sup>. <sup>1</sup>Health Care Discovery, Novo Nordisk A/S, DK-2760 Måløv, Denmark and <sup>2</sup>Institute of Medical Anatomy, University of Copenhagen, Denmark.

The benzindole NNC 00-3094 has been identified as a dopamine D3 receptor selective ligand in radioreceptor binding experiments at the cloned dopamine receptor subtypes (Scheideler et al., Soc Neurosci Abstr, 252.13, 1995). In vivo, NNC 00-3094 exhibited a neuroleptic-like profile in several preclinical tests suggestive of antipsychotic activity without inducing the motoric side effects often associated with antipsychotic medication (Fink-Jensen et al., Soc Neurosci Abstr, 252.14, 1995). In the present study, we have used FOS protein immunohistochemistry as a functional index of the effect of NNC 00-3094. NNC 00-3094 (0.1, 1 and 10 mg/kg s.c.) induced a strong FOS protein immunoreactivity in the limbic medial prefrontal cortex and shell region of the nucleus accumbens and only a very weak effect in the non-limbic dorsolateral striatum at the highest dose (10 mg/kg). In contrast, the partial selective dopamine D3 agonist quinpirole (0.1 and 1 mg/kg s.c.) was without effect. The NNC 00-3094 induced specific pattern of FOS protein immunoreactivity in these forebrain areas resembles the effect of the "atypical" neuroleptic clozapine. The distribution is in concordance with the regional distribution of dopamine D3 receptors and with the pharmacological effects of NNC 00-3094. This research was supported by Novo Nordisk A/S.

## 75.5

## ELUCIDATION OF ANTIPSYCHOTIC MECHANISMS BASED ON ASSUMPTIONS OF BRAIN STATE: A MULTIVARIATE APPROACH

N. Waters\*, E.S. Holm, P. Martin, M.L. Carlsson, A. Carlsson and L. O. Hansson

Dept. of Pharmacology, Göteborg University, Medicinargatan 7, 413 90 Göteborg, Sweden

Due to the interconnectivity of brain structure, antipsychotic drugs must have effects on all neurons in the brain. They create a new, transient, equilibrium of brain state which is expressed behaviourally. Depending on the initial brain state antipsychotic drugs may have different global effects. To characterise drug effects, and accepting these assumptions one has to measure many variables at different locations in the brain, but also monitor drug effects at different initial brain states and use data evaluation methods that are capable of recognising systematic patterns in large data sets.

Our approach to the elucidation of drug action is based on the glutamate hypothesis of schizophrenia, some recent biochemical findings in post-mortem brain tissue of schizophrenics and effects of NMDA-receptor antagonists in the rat. Data are investigated by means of multivariate evaluation techniques. This approach offers a link between pathological biochemical aberrations in man and biochemical changes in rodents under experimental conditions along with a description of global effects of drugs in the normal and hypoglutamatergic brain state.

We find that NMDA receptor antagonists can induce a brain state resembling schizophrenia. Antipsychotics can partially normalise the hypoglutamatergic brain state via different mechanisms. Neuroleptics introduce other perturbations that counteract normalisation. Atypical antipsychotics interfere with a mechanism that is operative in the hypoglutamatergic, but not in the normal brain state. Neuroleptics block the utilisation of this mechanism.

The Stanley foundation is gratefully acknowledged for financial support.

## 75.2

## DIFFERENTIAL INDUCTION OF CHRONIC AP-1 BINDING ACTIVITY BY TYPICAL AND ATYPICAL ANTIPSYCHOTICS. P. Rogue\*, G. Vincendon, A. N. Malviya. UPR416-CNRS, Center for Neurochemistry, 5 rue Blaise Pascal, Strasbourg 67084 France.

Using gel-shift assays, we studied the effect of antipsychotics on AP-1 binding activity in the CNS. A single injection of haloperidol (2 mg/kg I.P.), which transiently induces *c-fos* and *jun B* expression in the striatum (Str) and nucleus accumbens (NAc) of the rat, produces a transient increase in AP-1 binding activity in these regions. Acute clozapine (20 mg/kg) raises *c-fos* mRNA and AP-1 activity in the NAc and in the prefrontal cortex (PFC). The therapeutic effects of antipsychotics are delayed, and the effects of chronic treatments were studied. After prolonged haloperidol administration (2 mg/kg for 15 days), though *c-fos* and *jun B* induction in the Str and NAc were desensitized, AP-1 binding activity remained elevated. Similar results were found in the NAc and PFC after prolonged clozapine treatment. *Jun D* expression was slightly but significantly increased in the Str by chronic haloperidol. Thus prolonged antipsychotic administration alters the composition of AP-1 transcription factor complex in a regionally specific manner.

## 75.4

THE ADENOSINE A<sub>2A</sub> RECEPTOR AGONIST CGS 21680 AS A POTENTIAL "ATYPICAL" ANTIPSYCHOTIC IN ANIMAL MODELS. R. Rimondini, S. Ferré\*, S. O. Ögren and K. Fuxe. Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden.

We have previously found experimental evidence for a predominant antagonistic interaction between adenosine A<sub>2A</sub> and dopamine D<sub>2</sub> receptors in the ventral compared to the dorsal striatum. It was therefore postulated that adenosine A<sub>2A</sub> agonists could have antipsychotic properties with an "atypical" profile (low extrapyramidal side effects liability), since the antipsychotic and extrapyramidal side effects of neuroleptics seem to be mediated, at least partially, by the blockade of dopamine D<sub>2</sub> receptors in the ventral and dorsal striatum, respectively. The systemic (i.p.) administration of CGS 21680 was found to dose-dependently antagonize spontaneous and amphetamine-induced (1 mg/kg i.p.) motor activity with a similar ED50 value (about 0.2 mg/kg). High doses of CGS 21680 were needed to induce mild catalepsy with the bar test and it never reached a significant effect with the grid test. The highest dose of CGS 21680 used, 10 mg/kg, produced much less catalepsy than haloperidol 1 mg/kg i.p. With that high dose the animals were clearly hypotonic and they had signs of pronounced peripheral side effects (tachycardia and diarrhoea). A high ratio between the ED50 value for induction of catalepsy and the ED50 value for antagonizing amphetamine-induced motor activity was therefore obtained (>20). It has been suggested that PCP-induced behavioural effects in animals represent an animal model of schizophrenia, since it reproduces both positive and negative symptoms of schizophrenia, while amphetamine only mimics positive symptoms. CGS 21680 induced a stronger depressant effect on the motor activity induced by PCP (2 mg/kg s.c.) than on the motor activity induced by an equipotent dose of amphetamine (1 mg/kg i.p.) (ED50 values of 0.03 versus 0.2 mg/kg, respectively). In conclusion, the present results show a clear "atypical" antipsychotic profile of the adenosine A<sub>2A</sub> agonist CGS 21680 in animal models. ## MULTIVARIATE MODELLING OF RELATIONS BETWEEN MONOAMINERGIC BRAIN BIOCHEMISTRY, THALAMIC GAD mRNA AND BEHAVIOUR: EFFECTS OF ANTIPSYCHOTICS.

ES Holm\*, N. Waters, A. Carlsson, P. Martin, LO Hansson and ML Carlsson.

Dept. of Pharmacology, Göteborg University, Medicinarg 7, S-413 90 Göteborg, Sweden.

The thalamus appears to have a crucial position in the cortico-subcortical feedback circuitry, regulating the incoming flow of information from the sense organs to protect the cortex from over exposure and to focus attention. The central thalamic nuclei are controlled by GABAergic projections from the thalamic reticular nucleus. The activity of these GABA neurons may be reflected in GAD mRNA levels, which have been found to change quickly in response to several psychoactive drugs. Thus GAD mRNA might be used as an indicator of influence on thalamic function.

To further explore the significance of thalamic GAD mRNA, the functional relationship between monoaminergic brain biochemistry, thalamic GAD mRNA and locomotor activity was evaluated using multivariate techniques. Studies were performed on rats receiving various antipsychotic drugs as well as on non-treated rats.

A robust relationship between locomotor activity and the biochemical variables measured could be established regardless of treatment. Common to all conditions is that GAD mRNA covaries strongly with the level of behavioural activity. In contrast, under the influence of various drugs, the interrelations between monoaminergic indices, GAD mRNA and behaviour are different, yet predictable.

These different relationships between biochemistry and behaviour can be thought of as the expression of different brain states, which all produce a particular behaviour. In all these brain states, thalamic GAD mRNA displays the same relation to motor activity. This may suggest that thalamic functioning is closely and constantly related to behavioural output. Such a constant relationship cannot be established between other brain regions and behaviour.

## 75.7

CHRONICAL HALOPERIDOL OR CLOZAPINE TREATMENT IN RATS: DIFFERENTIAL RNA DISPLAY ANALYSIS, BEHAVIORAL STUDIES AND PLASMA LEVEL DETERMINATION V. Fischer, U. Schmitt, B. v. Keller, S. Reuss, C. Hiemke\* and N. Dahmen, Departments of Psychiatry and Anatomy<sup>§</sup>, University of Mainz, 55131 Mainz, Germany.

Differential display, a method developed for the visual comparison of mRNA expression, is useful in the identification and cloning of specifically regulated genes. To study whether long-term administration of the typical neuroleptic haloperidol or the atypical neuroleptic clozapine changes neuronal gene expression, rats were treated orally for 21 days with 1.6 mg/kg haloperidol or 36 mg/kg clozapine per day. During the neuroleptic treatment the animal behavior was recorded in an open field. Compared with untreated controls, the total distance moved was reduced on day 5 by 22% under haloperidol and by 41% under clozapine. Blood samples were taken at the end of the experiment. Plasma analysis revealed mean concentrations of 22 ng/ml for haloperidol and 14 ng/ml for clozapine. RNA was isolated from each brain, without cerebellum, and subjected to differential RNA display. cDNAs were generated from mRNA using oligo-dT primers anchored to the beginning of the poly(A) tail and were then PCR amplified using the same 3' primer and a second 10 mere arbitrary 5' primer. Amplified products were analysed on a sequencing gel. Up to date we have analysed 22 out of 312 suggested primer combinations. Gene fragment patterns were highly reproducible between control and treated groups without revealing any consistent regulatory effect so far. However, preliminary data support the notion of gene fragments being regulated by chronic neuroleptic treatment.

Supported by the Deutsche Forschungsgemeinschaft (grant Da 370/1-1).

## 75.9

LEVELS OF EXTRACELLULAR DOPAMINE IN PREFRONTAL CORTEX AND NUCLEUS ACCUMBENS RESPOND DIFFERENTLY TO LOCAL ANTIPSYCHOTIC DRUG INFUSION. K.D. Youngren\*, E. A. Andrusiak, and R.H. Roth, Neuroscience Program, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

Previous studies in this laboratory have indicated that the atypical antipsychotic drug clozapine preferentially affects dopamine (DA) systems in the prefrontal cortex (PFC) of both the rat and the monkey. In order to examine this preferential effect of clozapine on the mesocortical DA system further, microdialysis was used to measure the extracellular levels of DA in both the PFC and the nucleus accumbens (NAS) of the rat. Clozapine (100  $\mu$ M) or haloperidol (100  $\mu$ M) was infused through the dialysis probe directly into the PFC and NAS. Infusion of clozapine into the PFC or the NAS produced significant increases in extracellular DA, although the increase in the PFC was of longer duration. Clozapine infusion into the PFC produced increases in extracellular DA levels that were significantly greater than in the NAS. Infusion of haloperidol into either the PFC or the NAS also produced significant increases, typically of short duration, in extracellular DA within the respective brain region. Infusion of lower concentrations of the two drugs is also being examined. The results indicate that differences within the terminal field regions of these two dopaminergic projections account for at least part of the differing responses of the two brain regions to antipsychotic drug treatment. Although the PFC and the NAS share a source of dopaminergic afferents in the A10 cell group, the two regions respond differently to local antipsychotic drug administration. The present results thus provide further evidence that the atypical antipsychotic drug clozapine preferentially affects dopaminergic transmission within the PFC. Supported in part by USPHS Award MH-14092.

## 75.11

CLOZAPINE-INDUCED ACh RELEASE IN THE PREFRONTAL CORTEX (PFC): NON-TOLERANCE AFTER CHRONIC TREATMENT. M.A. Parada\*, M. Puig de Parada, and L. Hernández, Department of Physiology, School of Medicine, Universidad de los Andes, Mérida 5101-A, Venezuela.

We have shown that acute ip clozapine increases ACh preferentially in the PFC by reference to the nucleus accumbens (NAC) and striatum (STR) (1). We postulated that a similar ACh release in the frontal cortex could be therapeutic for schizophrenic patients, but that proposition requires the demonstration of some pharmacological properties. This study focused on non-tolerance. Five male Wistar rats received a daily ip clozapine injection (20 mg/Kg) for 21 days. Simultaneous microdialysis was used to monitor in 25-min samples the effects of the first and last injections on the ACh outflow in the NAC, STR and PFC. Only values (pmol/20 $\mu$ l) for the last area are reported here. Removable probes were inserted at the beginning and at the end of the treatment period. Basal levels (0.83  $\pm$  0.16) increased to 2.16  $\pm$  0.23 (310  $\pm$  77.2 %) fifty min after the first injection [F(1/8): 22.9; p<0.002]. Basal levels during the last day (0.63  $\pm$  0.14) were slightly but not significantly lower than levels during the first day [F: 0.86; ns]. They increased to 1.9  $\pm$  0.3 (329.2  $\pm$  54.8 %) in the 2nd sample after the 21st injection (F: 13.7; p<0.01). There were no differences between the above-basal ACh release after the first (1.34  $\pm$  0.25) and the last (1.27  $\pm$  0.27) clozapine injection (F: 0.03; ns). These results show that the PFC clozapine-induced ACh release does not display tolerance, which fulfills one requirement for the suggestion that it could be an index of one of the therapeutic effects in human patients.

D-AMPHETAMINE REVERSAL AS A MODEL FOR ANTIPSYCHOTIC EFFICACY IN CEBUS APELLA MONKEY. C. L. Christoffersen\*, D. Johnston, F.W. Ninteman, L.T. Meltzer and T.G. Heffner, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105.

We report the modification of a d-amphetamine (AMP) antagonism test in cebus monkeys (Peacock and Gerlach, Eur. J. Pharmacol. 237:329, 1993) that was used to determine doses of antipsychotics that produce CNS effects presumably related to efficacy. This test allows a within species comparison of therapeutic doses with those that induce extrapyramidal side-effects (EPS) in haloperidol-sensitized cebus monkeys, a standard test for EPS liability. These data are compared with the therapeutic dose/EPS dose ratios derived from testing the inhibition of Sidman avoidance (SA) and EPS liability in squirrel monkeys. Five cebus apella monkeys were tested with various doses of AMP to determine the minimum dose required to reliably produce mild stereotypy and motor unrest. Monkeys were rated by an observer, blinded to the treatment condition, for the intensity of stereotypy and motor unrest present. With the dose of AMP(0.75 mg/kg IM) established, compounds were tested for their ability to block the effects of AMP. Compounds were given PO two hours before AMP and the monkeys were rated every 15 min. after AMP for 90 min. There was no separation between the minimal effective EPS dose and the anti-amphetamine(A-AMP) dose for haloperidol or SDZ 208-912. Clozapine had some A-AMP effects but did not produce EPS at the doses tested. The separation between the minimal EPS and the A-AMP dose in cebus monkeys is smaller than the separation between the SA ED50 and minimal EPS dose in squirrel monkey. However, the compounds tested remain in the same rank order for ratio of efficacy to side-effect in both species. (Supported by Warner-Lambert.)

## 75.10

PERSISTENT DOWNREGULATION OF TYROSINE HYDROXYLASE (TH) IN SUBSTANTIA NIGRA (SN) BUT NOT VENTRAL TEGMENTAL AREA (VTA) FOLLOWING WITHDRAWAL FROM HALOPERIDOL.

A. J. Levinson, S. Garside, P. I. Rosebush and M. F. Mazurek\*, Departments of Medicine (Neurology) and Psychiatry, McMaster University Medical Centre, Hamilton, ON L8N 3Z5.

The dopamine antagonist haloperidol (HAL) can cause tardive side effects that may persist after the drug is withdrawn. We studied the time course of changes in dopaminergic neurons of SN and VTA following withdrawal (WD) of HAL. Rats received daily intraperitoneal injections of saline (n=9) or HAL 2 mg/kg/day (n=21) for 8 weeks and were killed at 2, 4 or 12 weeks after the final injection. Sections of SN and VTA were processed for tyrosine hydroxylase (TH) and calbindin (CB) immunohistochemistry. In HAL-treated rats, TH-positive cell counts were normal in VTA but were decreased in SN by 34% at 2 weeks WD and by 52% at 4 weeks, with preferential loss in medial portions of SN; TH cell counts were almost fully recovered by 12 weeks WD. CB positive neurons were not spared, but rather showed the same pattern as TH positive cells. Using TH staining, the cross-sectional area of SN was reduced by 34% at 2 weeks WD and by 17% at 4 weeks, with full recovery by 12 weeks WD. Mean TH+ve cell size, by contrast, was essentially unchanged at 2 and 4 weeks WD, but significantly decreased in SN at 12 weeks WD. These results indicate that HAL can produce selective changes in midbrain dopamine neurons that persist long after discontinuation of the drug.

## 75.12

PCP-INDUCED DEFICITS IN SQUIRREL MONKEY SOCIAL BEHAVIOR ARE DIFFERENTIALLY AFFECTED BY CLOZAPINE AND HALOPERIDOL.

Rod J. Fishkin\*, Lily Zhou and James T. Winslow, Ph.D. Hoechst Marion Roussel, Inc., Neuroscience Therapeutic Domain, Bridgewater, New Jersey, 08807

Phencyclidine (PCP) and other glutamate channel blockers can induce a model psychosis in humans and precipitate psychotic symptoms in schizophrenic patients. This syndrome mimics both the positive and the more treatment resistant negative symptoms. The purpose of this study was to examine the pharmacological profiles of PCP and MK-801 on primate social interactions in small groups (2-3 males per group). Differential efficacies of clozapine and haloperidol in antagonizing these effects were also examined. PCP and MK-801 both produced significant and reliable decreases in the frequency and amount of time allocated to social initiatives expressed by treated squirrel monkeys (*Saimiri sciureus*). Changes in social behavior produced by MK-801 but not PCP were associated with marked decreases in all indices of motor activity at each of the doses tested. Clozapine reversed PCP-induced deficits at moderate doses and enhanced these decreases at higher doses where motor activity was also decreased. Haloperidol did not significantly affect PCP-induced deficits in social behavior at any dose tested. We are currently examining activities of both PCP and clozapine in an intruder challenge test associated with increased social interaction in the same animals. Initial findings suggest that PCP-induced deficits in the social behavior of squirrel monkeys may provide a discriminating test for antipsychotics against the treatment resistant social deficits associated with schizophrenia.

## 75.13

**THE NMDA-RECEPTOR ANTAGONIST MEMANTINE IS NOT PSYCHOTOMIMETIC IN YOUNG HEALTHY VOLUNTEERS** J. Kornhuber<sup>1</sup>, W. Retz<sup>2</sup>, L. Sitzmann<sup>3</sup>, A. Schmidtke<sup>3</sup>, M.K. Herbert<sup>1</sup>. <sup>1</sup>Dept. of Psychiatry, University of Göttingen, 37075 Göttingen; <sup>2</sup>Psychiatry and <sup>3</sup>Anesthesiology, University of Würzburg, 97080 Würzburg, Germany.

High-affinity uncompetitive antagonists at the N-methyl-D-aspartate (NMDA) type glutamate receptor, e.g. MK-801 or phencyclidine (PCP), share a high probability of inducing psychotomimetic side effects. Low-affinity NMDA receptor antagonists, like memantine and amantadine, are frequently used for the treatment of Parkinson's disease, dementia and spasticity. Their potential to cause psychotomimetic side effects, however, is still a matter of debate. In order to assess the psychotomimetic profile of memantine, we have conducted a monocentric, double-blind, two-arm, randomized study comparing one group of young male healthy students (n=20) receiving memantine 10 mg once daily for one week and 20 mg for a second week with another group (n=20) receiving placebo. Medication was given under supervision to ensure compliance. We have shown previously that this memantine dosage yields steady-state plasma and CSF concentrations significantly interacting with the NMDA receptor. Each volunteer was tested *before* and *during* (day 15) memantine/placebo treatment with (1) a self-rating scale for current subjective feeling ("Befindlichkeitsskala"), (2) a self-rating scale designed to detect dissociative symptoms, (3) the Brief Psychiatric Rating Scale, and (4) a concentration task ("d2-Test"). Test values *during* treatment were analyzed with the ANCOVA using test values *before* treatment as covariates. When looking at total test values, in none of the four test instruments significant effects of treatment were found ( $P > 0.05$ ). This study confirms our clinical observations that low-affinity NMDA receptor antagonists rarely induce significant psychotomimetic side effects during therapeutic use. Low affinity and associated fast voltage-dependent channel unblocking kinetics are likely to be responsible for the better tolerance of memantine and also of amantadine.

## 75.15

**PHARMACOKINETICS OF PHENCYCLIDINE AND COCAINE IN NEONATAL PIGLETS** S. Primozic<sup>1</sup>, A. Mrhar<sup>2</sup>, J. Valentine<sup>3</sup>, R. Karba<sup>4</sup>, J. Grabnar<sup>2</sup>, L. J. Burge<sup>1</sup>, T.M. Badger<sup>1\*</sup>, M.H. Creer<sup>2</sup>, C. Nehus<sup>2</sup> and F.M. Scalzo<sup>1</sup>. <sup>1</sup>Dept. of Peds., Univ. of Ark. for Med. Sci., and <sup>2</sup>Dept. of Tox., Veteran's Admin., Little Rock, AR and Faculty of <sup>3</sup>Pharmacy and <sup>4</sup>Elect. & Comp. Engin., Univ. of Ljubljana, Ljubljana, Slovenia.

The acute and residual motor and cardiovascular effects of developmental exposure to phencyclidine (PCP) and cocaine are poorly understood. Few animal models of human neonatal exposure to these compounds have been established. In order to determine the relationship between blood levels of cocaine and PCP and their acute behavioral and cardiovascular effects in neonates, a pharmacokinetic study was conducted to characterize the disposition of a single iv bolus of 6.0 mg/kg cocaine and 1.5 mg/kg PCP in piglets. For cocaine, mean maximal blood levels (34 mg/L) were observed 30 sec post-dosing. The mean volume of distribution was  $1.54 \pm 0.47$  L/kg. Systemic clearance was  $0.041 \pm 0.003$  L/min/kg with average distribution and elimination half-lives of  $0.3 \pm 0.1$  and  $58.0 \pm 18.0$  min, respectively. The volume of distribution ( $V_d$ ) was  $0.059$  L/kg. For PCP, a very rapid decline in concentrations was observed in the first 5 minutes post injection. Plasma concentrations of  $0.8 \pm 0.3$  mg/L and  $0.06 \pm 0.03$  mg/L were observed 5 min and 8 h post-dosing. Extensive distribution of PCP to tissues is reflected by a  $V_d$  of  $3.06 \pm 0.77$  L/kg. Systemic clearance was  $0.012 \pm 0.002$  L/min/kg. Average distribution and elimination half-lives were  $2.7 \pm 0.6$  min and  $2.5 \pm 0.8$  h, respectively;  $V_d$  was  $0.86$  L/kg. A comparison of the pharmacokinetic parameters for cocaine and PCP indicates that like in adults, the distribution of PCP is more extensive than cocaine and the elimination of PCP is prolonged compared to cocaine. The results also suggest that the blood pressure and heart rate increases following iv cocaine and PCP are related to high blood levels during the distribution phase of both compounds. ## 75.17

**REGULATION OF PKC ISOZYMES BY CHRONIC LITHIUM IN HUMANS** G. Chen, A. Jiang, M. E. Schmidt, R. Risinger, O. Kofman\*, W. Z. Potter AND H. K. Manji. Dept. of Psy. & Beh. Neuro., WSU School of Medicine, Detroit, MI 48201; NIMH, Bethesda, MD 28091 and Ben Gurion Univ., Israel

Lithium is a widely used, clinically effective antimanic and mood-stabilizing agent, but its therapeutic mechanisms of action remain to be elucidated. A growing body of evidence has indicated that upon chronic administration, lithium reduces the immunolabeling of Protein kinase C (PKC) isozymes in rat brain. The possibility that these biochemical effects may have therapeutic relevance is suggested by the fact that another clinically effective antimanic and mood-stabilizing agent, Valproate produces similar changes in PKC isozymes, and that manic patients have been reported to have elevated levels of platelet membrane associated PKC activity. In view of PKC's effects on neuronal excitability, neurotransmitter release, and regulation of gene expression, attenuation of PKC activity by lithium may play a role in its therapeutic effects, but have not yet been clearly established in humans. In the present study, healthy volunteers were administered therapeutic doses of lithium carbonate, and PKC isozymes were investigated after both 5 days and 5 weeks of treatment using both Western blotting and ELISA methodology; we used healthy volunteers in order to avoid the potentially confounding effects of alterations in mood-state dependent variables. We find that similar to the effects observed in rat brain, chronic but not acute lithium administration decreases the levels of PKC  $\alpha$ . Studies are underway to elucidate the role of PKC in the clinical efficacy of lithium.

## 75.14

**NEUROANATOMICAL LOCALIZATION OF DIZOCILPINE-INDUCED DEFICITS IN PREPULSE INHIBITION OF THE STARTLE RESPONSE** V.P. Bakshi\* and M.A. Geyer. Dept. of Neuroscience, UCSD, La Jolla, CA 92093.

Intense auditory or tactile stimuli elicit an involuntary startle response that is attenuated when a weak stimulus (a prepulse) is presented immediately prior to the startling stimulus. This phenomenon of "prepulse inhibition" (PPI) is thought to be an operational measure of sensorimotor gating. Because deficits in sensorimotor gating are characteristic of several disorders including schizophrenia, it is of interest to determine the neural substrates underlying deficient PPI. Systemic or intracerebroventricular administration of dizocilpine (DZ) and other non-competitive NMDA antagonists such as the psychotomimetic phencyclidine markedly disrupt PPI in rats. The purpose of the present investigation was to identify the specific brain regions that mediate these effects. Six regions were examined in separate groups of rats (male Sprague-Dawley): nucleus accumbens (NA), dorsomedial thalamus (DMT), ventral hippocampus (VH), amygdala (AM), medial prefrontal cortex (MPFC), and dentate gyrus (DG). In each study, rats received bilateral infusions of DZ (0, 0.25, 1.25 and 6.25  $\mu\text{g}/(0.5 \mu\text{l})$ ) in a counterbalanced order over 4 test days. Five min after drug administration, animals were tested in startle chambers. The test session consisted of presentations (in a counterbalanced order) of a 120 dB "pulse" (the primary startling stimulus) either alone or immediately preceded by non-startling "prepulses" that were 3, 6, or 12 dB above the background noise (65 dB). DZ markedly reduced PPI following administration into VH, AM, MPFC and DG, but not NA and DMT. These results indicate that the PPI-disruptive effects of DZ are mediated by multiple discrete brain regions.

**ALTERATIONS IN ZEBRA FINCH SONG PRODUCED BY BLOCKADE OF DOPAMINERGIC INPUTS** S. A. Helekar\*, N. Viswanath, D. B. Rosenfield and J. R. Nimerick. Stuttering Center Speech Motor Control Laboratory, Department of Neurology, Baylor College of Medicine, Houston, Texas 77030.

Analysis of the avian central nervous system has revealed dense catecholaminergic innervation of neural structures such as the higher vocal center and the robust nucleus of the archistriatum that control song production. As part of a program to study bird song as a model of human speech motor control, we have initiated a neuropharmacological study to investigate the functional contribution of the dopaminergic input in the production of song in zebra finches. We hypothesized that dopaminergic modulation of synaptic interactions within song-related structures is critical for the patterning of avian song output. We tested this hypothesis by blocking two predominant types of dopaminergic receptors, D1 and D2 with intramuscularly injected antagonist, haloperidol (0.2 - 10 mg/Kg body weight) in 8 adult zebra finches with well developed song. The female directed song in untreated birds although stereotypic showed 3 striking variations. These variations were as follows: 1) The numbers of introductory notes and motifs per song were highly variable. 2) The last syllable in a motif was frequently omitted (5/8 birds). 3) Repetitive sets of syllables were added to the end of a basic motif in >20% of motifs (3/8 birds). Haloperidol at lower doses (0.2 - 1 mg/Kg) significantly reduced the frequency of songs and the number of motifs per song. There was also an induction of the occurrence of abortive songs consisting only of a series of introductory notes in haloperidol treated birds (7/8). Strikingly, this blocker did not produce any significant alterations in the spectrographic characteristics of individual syllables within a song even at a dose (1mg/Kg) that produced a detectable impairment of the flight capability of birds. At high doses (2 - 10 mg/Kg), haloperidol produced a complete cessation of songs although occasional monosyllabic calls were still produced. These findings indicate that dopaminergic modulation within song structures influences only the duration of song output and exerts no intrinsic control over the neural microcircuitry that generates the complex acoustic patterns and timings of individual syllables within songs. This work was supported by Lowin Medical Research Foundation and M. R. Bauer Foundation.

## 76.1

MONOAMINERGIC DYNAMICS DURING CHRONIC FLUOXETINE ADMINISTRATION: *IN VIVO* MICRODIALYSIS IN AWAKE MONKEYS. J.D. Smith\*, R. Kuczenski, and S.L. Foote. Psychiatry Dept, UCSD, La Jolla, CA 92093

Fluoxetine (FLU) (Prozac), the latest drug to be widely prescribed for treatment of depression, is classified as a selective serotonin (5-HT) reuptake inhibitor. However, results from *in vivo* microdialysis studies in rodent brain suggest that dopamine (DA) and norepinephrine levels also may be affected by FLU. Although FLU blocks the reuptake of 5-HT in brain tissue within minutes, its antidepressant effect may not appear for weeks. Results from experiments in rodents examining mechanisms underlying this delay in therapeutic efficacy are equivocal. Therefore, we used newly developed *in vivo* microdialysis techniques in awake monkeys to compare extracellular 5-HT and DA in caudate (CD), hippocampus (HC) and frontal cortex (FCtx) prior to and during chronic (21 days) administration of FLU (10 mg/kg, p.o.). 5-HT and DA were assessed under basal conditions and during local infusion of either FLU to block reuptake or 120 mM K<sup>+</sup> to induce neuronal depolarization. Basal 5-HT levels were dramatically enhanced (3-6-fold) by 3-7 days of systemic FLU, but declined to double their original levels within 21 days in all brain regions. In contrast, basal CD and FCtx DA levels were reduced by half in 3-7 days of treatment and remained at this new lower level. Chronic systemic FLU progressively decreased, and finally abolished the ability of locally infused FLU to enhance extracellular 5-HT or cortical DA levels. In contrast, during the first week of systemic FLU, the striatal DA response was even more robust than in untreated monkeys. However, by day 14, DA levels in CD were no longer responsive. Chronic FLU administration also severely blunted the effects of locally infused 120 mM K<sup>+</sup> on 5-HT, and especially on striatal DA levels. These data indicate that, in non-human primates, chronic systemic FLU treatment differentially alters basal DA and 5-HT levels and reduces the enhancement of extracellular DA and 5-HT in response to locally-induced depolarization in terminal fields. Thus, diminished basal DA, as well as enhanced basal 5-HT levels may contribute to FLU's therapeutic efficacy. In addition, altered 5-HT and DA responses to acute challenges following chronic FLU suggest that changes in monoaminergic dynamics may also contribute to FLU's antidepressant effects. (Generously supported by DA08346)

A DOUBLE-BLIND STUDY OF SERTRALINE VERSUS PLACEBO IN THE TREATMENT OF POSTPARTUM DEPRESSION: PRELIMINARY FINDINGS. C.N. Epperson\*, D. Ward-O'Brien, L.H. Price, C.J. McDougle. Clinical Neuroscience Research Unit, Dept. of Psychiatry, Yale Univ. School of Med. 34 Park St., New Haven, CT 06519.

It remains a point of debate whether postpartum depression (PPD), which occurs in 10% of childbearing women, is the same as depression occurring at other times. To date, there has been no published report of a double-blind, placebo-controlled study of antidepressant treatment in PPD. The purpose of this ongoing study is to further our knowledge of the phenomenology, neurobiology and pharmacological treatment of PPD. **Methods:** Subjects were outpatients of the Yale Postpartum Mood Disorders Clinic and met DSM-IV criteria for major depression within 6 months of childbirth. After a 1-week placebo lead-in, women were randomized to sertraline (Zoloft) or placebo for 6 weeks. The main outcome measures for antidepressant response were the Hamilton Rating Scale for Depression and the Clinical Global Impression Scale. **Results:** To date, 6 of the 13 women enrolled have completed the study, while two are still in the double-blind phase. Four of the six completers were considered "responders"; 3 randomized to sertraline, one to placebo. Two women who were randomized to placebo were "nonresponders". After the placebo lead-in 3 were not randomized, one due to improvement, two due to decompensation. Finally, two women dropped out of the study. **Conclusions:** Preliminary findings from this ongoing study indicate that sertraline may be efficacious in the treatment of PPD. More women will need to be enrolled before making definitive conclusions regarding the role of biological and psychosocial stressors in PPD. **Funding Source:** NARSAD

## 76.5

*IN VITRO* BINDING PROFILE OF MODERN ANTIDEPRESSANTS AND THEIR METABOLITES: CORRELATION BETWEEN AFFINITIES AT VARIOUS RECEPTORS. D.L. Knight\*, W.N. Morgan, M.J. Owens and C.B. Nemeroff. Lab. of Neuropsychopharmacology, Dept. Psychiatry & Behavioral Sciences, Emory University School of Medicine, Atlanta GA 30322.

We have recently examined the affinity of a number of modern antidepressants at the rat and human serotonin (SERT) and norepinephrine (NET) transporters, rat 5-HT<sub>2A</sub>, 5-HT<sub>1A</sub>, muscarinic, guinea pig histamine<sub>1</sub> receptor, and human  $\alpha_1$  and  $\alpha_2$  receptors. The antidepressants studied included: nefazodone, hydroxynefazodone, mCPP, the desethyltrazodolone metabolite of nefazodone, trazodone, amitriptyline, desipramine, paroxetine, sertraline, citalopram, fluoxetine, fluvoxamine, venlafaxine, and O-desmethylvenlafaxine. Binding affinity (pK<sub>i</sub>) was highly correlated between the rat and human versions of the SERT or NET, but not between same species versions of the two transporters themselves. The affinity at the NET was positively correlated with muscarinic receptor binding. A less robust positive correlation was observed between SERT and muscarinic binding. Moreover, binding amongst the 5-HT<sub>2A</sub>, 5-HT<sub>1A</sub>,  $\alpha_1$ ,  $\alpha_2$ , and H<sub>1</sub> receptors were significantly positively correlated with each other in most instances. 5-HT<sub>2A</sub> binding correlated with 5-HT<sub>1A</sub>, H<sub>1</sub>,  $\alpha_1$ , and  $\alpha_2$  binding. 5-HT<sub>1A</sub> binding correlated with 5-HT<sub>2A</sub>,  $\alpha_1$ , and  $\alpha_2$  binding. H<sub>1</sub> binding correlated with 5-HT<sub>2A</sub> and  $\alpha_1$  binding.  $\alpha_1$  binding correlated with 5-HT<sub>2A</sub>, 5-HT<sub>1A</sub>,  $\alpha_2$ , and H<sub>1</sub> binding.  $\alpha_2$  binding correlated with 5-HT<sub>2A</sub>, 5-HT<sub>1A</sub>, and  $\alpha_1$  binding. These findings suggest that unique structural features of the individual compounds confer a certain degree (i.e., high, intermediate, or low) of potency/affinity at more than one type of receptor. Supported by a grant from Bristol Myers-Squibb and RISP MH51761.

## 76.2

ANTAGONISM OF AMPHETAMINE-INDUCED BEHAVIORAL CHANGES IN SELECTED MEMBERS OF A PRIMATE SOCIAL COLONY BY THE SELECTIVE 5-HT<sub>2A</sub> ANTAGONIST MDL 100,907. L.E. Shapiro, R.F. Schlemmer\*, J.E. Young, C.K. Fleming and J.M. Davis. University of Illinois at Chicago, Chicago, IL 60612.

Recent clinical evidence has suggested a potential role of serotonin (5-HT) in psychosis which has generated considerable interest in evaluating 5-HT antagonists as potential antipsychotics. The present study assessed the effect of the selective 5-HT<sub>2A</sub> antagonist MDL100,907 (*R*-(+)- $\alpha$ -(2,3-dimethoxy-phenyl)-1-[2-(4-fluorophenylethyl)]-4-piperidine-methanol (MDL) in an amphetamine (AMP)-induced screening model for antipsychotics in primates. During the study, 4 doses of MDL were tested alone and in combination with AMP. Four females from a stable social colony of 5 adult stump-tail macaques (*Macaca arctoides*) were assigned to 2 treatment groups. The male was not treated. After determining baseline behavior, each group received drug treatment for two days/week in a cross-over design. First, AMP was given alone, then one of 4 escalating doses of MDL, 0.1-5.0 mg/kg, was given each week. MDL was given nasogastrically in the AM and late afternoon on Day 1 and in the AM of Day 2. AMP, 1 mg/kg, was given i.m. 15 min before the second observation. Two 60 min behavioral observations were conducted daily by a "blind" observer, the first 35 min after administration of MDL and the next started 90 min later. MDL produced a dose-dependent antagonism of AMP-induced increased submissive gestures of treated monkeys. In addition, AMP-induced increased visual scanning (checking) and social withdrawal (increased distancing from cagemates) was antagonized at selected MDL doses. MDL failed to antagonize AMP stereotypy and did not induce movement disturbances. The results demonstrate that selective 5-HT<sub>2A</sub> antagonism reverses some behavioral changes induced by AMP in monkeys. Thus, selective 5-HT<sub>2A</sub> antagonists may have a potential role as antipsychotics.

## 76.4

THE PHARMACOKINETIC EFFECTS OF VENLAFAXINE ON IMPRAMINE METABOLISM. Albers LJ, Reist C\*, Vu R, Tang SW. VA Medical Center, Long Beach, CA, 90822, Department of Psychiatry, University of California - Irvine

Selective reuptake inhibitors have become important agents in the treatment of psychiatric illness. These drugs have a more benign side effect profile than tricyclic antidepressants and are less toxic in overdose. Important effects on cytochrome P450 enzymes, however, have emerged as relevant considerations in their clinical use. Venlafaxine (VF) is a new antidepressant which affects both serotonin and norepinephrine uptake. *In vitro* inhibition studies with human microsomes indicate minimal effects of VF on CYP2D6, CYP1A2, CYP3A4 and CYP2C9 isoenzyme function. This suggests that VF should have little interaction with drugs metabolized by these isoenzymes. To evaluate these findings *in vivo*, the metabolism of a single 100 mg dose of imipramine (IMI) was studied in 7 healthy volunteers before and after three days of treatment with 150 mg per day of VF. Serial blood samples were collected and assayed by HPLC for imipramine (IMI), desipramine (DMI), 2OH-IMI and 2OH-DMI levels to determine any pharmacokinetic changes in metabolism. Preliminary data indicate modest but significant elevations of C<sub>max</sub> and AUC for desipramine after venlafaxine treatment. No significant difference was seen in imipramine C<sub>max</sub> or AUC with venlafaxine.

## 76.6

EFFECT OF CHRONIC ANTIDEPRESSANT TREATMENT ON CRE- AND SP1-BINDING ACTIVITY IN RAT HIPPOCAMPUS AND FRONTAL CORTEX. D. Frechilla, A. Otano and J. Del Rio\*. Department of Pharmacology, School of Medicine, University of Navarra, Pamplona, Spain.

There is a lag time for the onset of clinical efficacy of antidepressant treatment and it has been suggested that the long-term adaptative changes induced by these drugs may also involve changes in gene expression. We have addressed this issue by studying the effect of chronic antidepressant administration on CRE- and SP1-binding activity in rat hippocampus and frontal cortex. Fluoxetine and desipramine (3 and 10 mg/kg/day respectively) were given daily to rats for 3 weeks and the animals were sacrificed 3 hours after the last injection. Nuclear extracts were prepared and the DNA-protein binding reaction was performed with consensus CRE and SP1 oligonucleotide probes. Gel-shift assays showed that CRE-binding activity was increased in both frontal cortex and hippocampus after chronic fluoxetine treatment. However, desipramine only enhanced CRE-binding activity in the frontal cortex. Opposite effects on SP1-binding activity were obtained after chronic antidepressants. This activity was reduced by fluoxetine in both brain regions and only in the frontal cortex by desipramine. The results show a differential and region-specific effect of the two antidepressants suggesting that these drugs may affect gene transcription by promoting changes in transcription factors. (Supported by CICYT, SAF94-1381).

## 76.7

POTENT BEHAVIORAL INTERACTIONS BETWEEN DESIPRAMINE AND THE NMDA RECEPTOR ANTAGONIST MK-801 IN RATS. K.A. Trujillo\*, J.M. Van Treijen, C. Lanning and A.B. Chinn, Psychology Program, California State University, San Marcos, CA 92096-0001.

There is increasing interest in the potential role of N-methyl-D-aspartate (NMDA) receptors in the effects of antidepressant drugs. While some investigators suggest that antidepressants may produce their therapeutic actions by direct effects on NMDA receptors, others suggest that NMDA receptors may have a more indirect role, mediating the adaptive changes thought to be critical to the therapeutic actions of antidepressants. The present study was undertaken to examine potential behavioral interactions between the tricyclic antidepressant drug desipramine (DES) and the non-competitive NMDA receptor antagonist MK-801.

Adult, male Sprague-Dawley rats were placed in a 16"x16" plexiglass open field chamber. After 30 minutes of habituation, animals received an injection of saline, DES (5.0 mg/kg), MK-801 (0.1 or 0.3 mg/kg) or a combination of DES plus MK-801. Activity was automatically recorded for 3 hours by computer-interfaced photocell arrays and MK-801-induced motor abnormalities were scored by experimenters.

As has been previously described, MK-801 produced a dose-dependent increase in activity -- while 0.1 mg/kg produced mild, non-significant increase in photocell counts, 0.3 mg/kg doubled activity relative to saline controls. Although DES produced no changes in activity alone, this drug potentially increased the response to the high dose of MK-801. These results suggest a potent interaction between DES and NMDA receptors, and are consistent with the idea that NMDA receptors may be involved in the therapeutic actions of antidepressants. Studies are currently underway examining chronic interactions between these drugs.

## 76.9

ANTIDEPRESSANTS PREVENT THE GLUCOCORTICOID STIMULATION OF TRH EXPRESSION IN CULTURED HYPOTHALAMIC NEURONS IVOR MD JACKSON\* AND LU-GUANG LUO Division of Endocrinology, Rhode Island Hospital, Brown University School of Medicine, Providence, RI 02903

This study used a well established fetal rat hypothalamic neuronal culture system to directly examine the effect of antidepressants on TRH expression. Glucocorticoids which are known to enhance TRH production *in vitro* were used in conjunction with each antidepressant. Cultured 17 day fetal hypothalamic neurons were treated with different concentrations of antidepressants for 7 days following which TRH content was measured by radioimmunoassay (RIA). The results showed that imipramine (IMIP), a tricyclic antidepressant, decreased the TRH content in a dose-dependent manner (from  $80.7 \pm 4.9$ , at  $10^{-9}$ M, to  $14.1 \pm 0.6$ , at  $10^{-5}$ M, fmol/well;  $p < 0.05$ ). Desipramine (DESIP), another tricyclic antidepressant, also decreased the TRH content (from  $63.6 \pm 2.5$ , at  $10^{-9}$ M, to  $12.6 \pm 0.4$ , at  $10^{-5}$ M, fmol/well;  $p < 0.05$ ) though the response was not dose-dependent. Sertraline (SERT) and fluoxetine (FLUO), serotonin selective reuptake inhibitors (SSRI), also decreased TRH content in a dose dependent manner (from  $83.9 \pm 7.9$ , at  $10^{-10}$ M, to  $7.6 \pm 0.4$ , at  $10^{-5}$ M, and from  $41.66 \pm 2.5$ , at  $10^{-8}$ M, to  $17.54 \pm 0.92$ , at  $10^{-6}$ M, fmol/well respectively; both  $p < 0.05$ ). However, tranlycypromine (TRAN), a monoamine oxidase inhibitor (MAOI), showed no effect on TRH expression. We then tested the effect of these antidepressants on the Dex stimulation of TRH content. IMIP, DESIP and FLUO at  $10^{-6}$ M reduced the TRH response to glucocorticoid stimulation ( $36.4 \pm 4.0$ ,  $56.6 \pm 2.4$ ,  $23.75 \pm 4.0$  respectively vs  $107 \pm 7.5$  fmol/well;  $p < 0.05$ ). These findings suggest that the enhanced thyroid function in depression, which we postulate may be secondary to glucocorticoid stimulation of TRH gene expression (Endocrinology 136:2793-4,1995), can be reversed by antidepressants through a direct effect on the TRH neuron.

## 76.11

ANTAGONISM BY WAY 100635, A 5-HT<sub>1A</sub> ANTAGONIST, OF THE EFFECTS OF FLUOXETINE AND BEFLOXATONE IN THE FORCED SWIM TEST. P.C. Moser\* and D.J. Sanger, CNS Pharmacology Group, Synthelabo Recherche, 10 rue des Carrières, 92500 Rueil-Malmaison, FRANCE.

Recent clinical data suggests that co-administration of pindolol with an antidepressant (AD), particularly the 5-HT reuptake inhibitor fluoxetine (FLX), can shorten the time to onset of clinical activity and increase the proportion of responders. It is hypothesized that pindolol blocks somatodendritic 5-HT<sub>1A</sub> receptors in the raphe nuclei, thereby mimicking the desensitisation of these receptors that occurs after chronic AD treatment and preventing the reduction in raphe cell activity that occurs after acute AD treatment. Although most animal tests use acute treatment to demonstrate AD activity, it remains possible that blockade of these 5-HT<sub>1A</sub> receptors may potentiate these effects. We examined this possibility using the selective 5-HT<sub>1A</sub> antagonist WAY 100635 (WAY) in combination with either FLX or the MAO-A inhibitor befloxtone using the forced swim test (FST) in rats. FLX (10-80 mg/kg po) and befloxtone (0.03-1 mg/kg po) dose-dependently reduced immobility time. WAY (0.01-0.1 mg/kg sc) was without effect itself. A combination of the ADs with WAY (0.1 mg/kg) demonstrated that rather than potentiate their effects, WAY significantly reduced their activity in this test. These results demonstrate that blockade of 5-HT<sub>1A</sub> receptors does not potentiate the effects of ADs in the FST. In contrast, they suggest that 5-HT<sub>1A</sub> receptors mediate, at least in part, the AD-like effects of FLX and befloxtone in the FST.

## 76.8

BLOCKADE OF 5-HT AND NE REUPTAKE BY VENLAFAXINE: *IN VIVO* ELECTROPHYSIOLOGICAL STUDIES IN THE RAT. J.C. Béteigue, C. de Montigny, P. Blier and G. Debonnel, Neurobiological Psychiatry Unit, McGill University, Montréal, Québec, Canada, H3A 1A1.

Venlafaxine (VLX) is an antidepressant agent which blocks *in vitro* the reuptake of both 5-HT and NE. The present *in vivo* electrophysiological studies were undertaken to assess the effect of VLX on the 5-HT and NE systems. Administered acutely, VLX prolonged dose-dependently the time required for a 50% recovery (RT<sub>50</sub>) of the firing activity of dorsal hippocampus CA<sub>3</sub> pyramidal neurons from the suppression induced by microiontophoretic application of 5-HT and NE. The RT<sub>50</sub> values for 5-HT were increased by 1 mg/kg i.v. of VLX, whereas 10 mg/kg i.v. were required for increasing the RT<sub>50</sub> values for NE. A two-day treatment with VLX (delivered s.c. by osmotic minipumps) also dose-dependently increased the RT<sub>50</sub> values for both 5-HT and NE applications: the RT<sub>50</sub> values for 5-HT were increased at a dose of 10 mg/kg/day, whereas those for NE were at 20 mg/kg/day. Acute i.v. administration of VLX suppressed the spontaneous firing activity of dorsal raphe 5-HT and locus coeruleus NE neurons with ED<sub>50</sub>s of 233 and 754 µg/kg, respectively. The selective 5-HT<sub>1A</sub> receptor antagonist WAY 100635 (100 µg/kg, i.v.) reversed this effect of VLX on 5-HT neurons and the α<sub>2</sub>-adrenoceptor antagonist piperoxane (1 mg/kg, i.v.) reversed that on NE neurons. Taken together, these results indicate that, *in vivo*, VLX blocks both reuptake processes, its potency being greater for the 5-HT than for the NE reuptake process. This differential potency of VLX might constitute the biological substratum of the positive dose-response relationship of the efficacy of VLX in major depression.

## 76.10

EFFECT OF CHRONIC COADMINISTRATION OF SERTRALINE AND PINDOLOL ON THE OPEN FIELD ACTIVITY OF OLFATORY BULBECTOMIZED RATS. R.I. Thielken & A. Frazer, Dept. of Pharmacol., UTHSCSA and Audie L. Murphy Memorial Veterans Hospital, San Antonio, TX 78284.

There is current interest in whether adjunctive treatments, such as the 5-HT<sub>1A</sub> receptor/β adrenoceptor antagonist pindolol, increase the rate of development of antidepressant (AD) efficacy. To study this phenomenon mechanistically, a test system in animals in which ADs alone exert results only after chronic treatment would be useful. Olfactory bulbectomized (OBX) rats show a number of behavioral deficits, some of which are reversed only by chronic AD treatment. The purpose of the present study was to examine whether coadministration of sertraline (5 mg/kg, ip) with pindolol (2 mg/kg, sc) would reduce the time necessary to see an AD-like effect in OBX rats. Rats were anesthetized, two holes were drilled into the skull 2 mm anterior to bregma, and the olfactory bulbs were removed by aspiration. Sham animals were treated identically, except the olfactory bulbs were not removed. After allowing two weeks for recovery, sham rats were treated with vehicle and OBX rats were treated with vehicle, pindolol-vehicle, vehicle-sertraline or pindolol-sertraline, twice daily for seven days. Rats were tested for open field activity for 5 min, 15 hr after the last drug administration. Sham and OBX rats did not show any differences at any time in total activity in the open field; however, OBX rats demonstrated a 2.5 fold increase in the number of crosses through the center of the open field during the last 3 min of the test compared to the sham rats. Pindolol alone had no effect on this increased center crosses; however, OBX rats treated either with sertraline alone or in combination with pindolol did not show an increase in center crosses compared with that of sham rats. These results demonstrate that seven day treatment with sertraline alone reverses some aspects of the open field behavioral alteration seen with OBX rats. Modification of this procedure should lead to a test able to detect changes in the onset of antidepressant activity.

## 76.12

ANTI-IMMOBILITY EFFECTS OF FLUOXETINE AND DESIPRAMINE IN RATS SELECTIVELY BRED FOR HIGH SENSITIVITY TO 8-OH-DPAT. D.S. Janowsky\* and D.H. Overstreet, Skipper Bowles Center for Alcohol Studies, University of North Carolina, Chapel Hill, NC 27599-7178.

Rats which were selectively bred for increased hypothermic responses (HDS) to the 5-HT<sub>1A</sub> receptor agonist, 8-OH-DPAT, were found to have innately higher immobility in the forced swim test compared to their parallel bred low sensitive group (LDS) or a randomly bred control (RDS). The present study compared the anti-immobility effects of chronic fluoxetine (10 mg/kg) treatment in the three lines and included a HDS group treated chronically with desipramine (5 mg/kg). Vehicle (isotonic saline), fluoxetine, or desipramine were injected intraperitoneally once daily between 08:00 and 10:00 for 14 days. Approximately 22 hr after the 10th injection, baseline temperatures were recorded and the rats were challenged with 8-OH-DPAT (0.5 mg/kg) and temperatures were recorded again 45 min later. Approximately 22-26 hr after the 14th injection, the rats were placed individually in the swim tank for a single 5-min recording. As found previously, the HDS rats were more hypothermic after 8-OH-DPAT and more immobile in the swim test. Fluoxetine both blunted the hypothermic response and reduced immobility in all groups. In the randomly bred RDS group, the correlation between the hypothermic response and immobility was 0.8 (n=8,  $p < 0.05$ ). The responses of HDS group to desipramine appeared to contradict this association, as there was a highly significant decrease in immobility, but no significant group change in the hypothermic response to 8-OH-DPAT. However, 5 of the 8 rats did in fact exhibit blunted responses and when a correlation was carried out between the hypothermic response and immobility in these rats, it was 0.90 (n=8,  $p < 0.01$ ). These findings support previous work implicating a relationship between 5-HT<sub>1A</sub> sensitivity and immobility and are consistent with the literature suggesting an involvement of 5-HT<sub>1A</sub> receptor function in affective disorders.

## 76.13

**PINDOLOL BOOSTS OR BLOCKS FLUOXETINE IN THE RAT FORCED SWIMMING TEST (FST) DEPENDING ON THE FLUOXETINE DOSE.**

**M. J. Detke\*, J. Ph. Reneric and I. Lucki.** Departments of Psychiatry, Pharmacology and Psychology, University of Pennsylvania, Philadelphia, PA 19104.

The combination of 5-HT<sub>1A</sub> receptor antagonists with selective serotonin reuptake inhibitors (SSRIs) has been shown to enhance the release of serotonin, presumably by blocking presynaptic autoreceptors in the midbrain raphe nuclei. Pindolol has also been shown to enhance the effects of SSRIs in the treatment of clinical depression in humans (Artigas et al., 1994; *Arch Gen Psychiatry*, 51:248-251). In the FST, an animal model of depression, SSRIs reduce immobility and increase swimming (Detke et al., 1995; *Psychopharmacology*, 121:66-72). This model was used to examine the effects of the combined treatment of pindolol with fluoxetine, an SSRI. Room-temperature water 30 cm deep was used to prevent the rats from supporting themselves with tails or hind limbs. After a 15-min pretest, drugs were administered 24, 5, and 1 hr prior to the 5-min swim test.

Fluoxetine at a dose of 20 mg/kg SC reduced immobility and increased swimming. Pindolol at doses of 0.06 - 2 mg/kg SC blocked the effects of fluoxetine in a dose-dependent manner. Fluoxetine, at a subthreshold dose of 3.2 mg/kg SC, did not produce statistically reliable behavior changes. In this case, pretreatment with pindolol at doses of 0.06 - 2 mg/kg SC enhanced the effects of fluoxetine, reducing immobility and increasing swimming behaviors. Pindolol administered alone at these doses did not produce significant changes in behavior.

These results confirm earlier findings showing that SSRIs produce antidepressant-like effects in the FST, and that these effects are behaviorally specific. The fact that low doses of pindolol enhance (sub-maximal) effects of fluoxetine may be mediated by pindolol's ability to block presynaptic 5-HT<sub>1A</sub> autoreceptors. Blockade of maximal fluoxetine effects by pindolol is presumed to be mediated by blockade of post-synaptic 5-HT<sub>1A</sub> receptors.

## 76.15

**THE EFFECT OF SELECTIVE SEROTONIN RELEASING AGENTS IN THE CHRONIC MILD STRESS MODEL OF DEPRESSION IN RATS.** **D. Marona-Lewicka\* and D. E. Nichols.** Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, Indiana 47907

Chronic exposure of rats to a sequence of mild unpredictable stressors causes an antidepressant-reversible decrease in responsiveness to reward (anhedonia) which can be monitored by a substantial decrease in the consumption of palatable weak (1%) sucrose solution. Stress-induced behavioral deficits may be maintained for a long time, however the chronic administration of clinically effective antidepressants can restore normal behavior. Usually this effect of antidepressants, in animals undergoing chronic mild stress, is observed following 3-4 weeks of drug treatment, whereas no effect is observed in non-stressed control rats. MMAI (5-methoxy-6-methyl-2-aminoinidan) and MTA (p-methylthioamphetamine) are non-neurotoxic, highly selective neuronal serotonin (5-HT) releasing agents. In drug discrimination substitution tests, MMAI fully mimicked citalopram and partially substituted in sertraline-trained rats, whereas partial substitution occurred with citalopram and sertraline in MMAI-trained rats. Citalopram and sertraline are selective 5-HT reuptake inhibitors (SSRI) and very clinically effective antidepressants. Chronic treatment with MMAI (5 mg/kg 2 x day i.p.; 4 weeks) reverses the deficit in rewarded behavior measured as a decrease in the consumption of 1% sucrose solution in a chronic mild stress model of depression in rats. The magnitude of this effect was comparable to that observed following administration of citalopram (10 mg/kg i.p.; 4 weeks), used as a standard antidepressant drug. These results indicate that MMAI has antidepressant activity in this animal model of depression. Studies in progress are also examining the effect of MTA in this chronic mild stress model of depression.

**REVERSAL OF FLUOXETINE-INDUCED SUPPRESSION OF SEROTONERGIC NEURONAL ACTIVITY BY WAY-100635: A DOSE-RESPONSE STUDY IN BEHAVING CATS.** **C. W. Metzler\*, C. A. Fornal, F. J. Martin and B. L. Jacobs.** Program in Neuroscience, Princeton University, Princeton, NJ 08544.

Recent evidence suggests that 5-HT<sub>1A</sub> autoreceptor antagonists may enhance the antidepressant efficacy of selective serotonin reuptake inhibitors (SSRIs) by blocking the negative neuronal feedback action of increased synaptic serotonin. We have previously shown that 5-HT<sub>1A</sub> autoreceptor antagonists such as WAY-100635 rapidly restore the firing of serotonergic neurons in the dorsal raphe nucleus (DRN) after acute treatment with the SSRI fluoxetine (Fornal et al., Soc. Neurosci. Abstr. 1995). In the present study, we examine the effects of increasing doses of WAY-100635 on the suppression of serotonergic DRN neuronal activity produced by fluoxetine in behaving cats. Serotonergic neurons were recorded and identified as described previously (Fornal et al., *JPET* 270: 1345, 1994). Drugs were injected remotely via a jugular catheter. WAY-100635 was administered in increasing doses at 6-min intervals starting 15 min after fluoxetine administration (5 mg/kg). Fluoxetine decreased the activity of serotonergic neurons to approximately 10% of baseline levels. Subsequent administration of WAY-100635 reversed the inhibitory action of fluoxetine in a dose-dependent manner. Whereas 0.005 mg/kg of WAY-100635 had no effect, a cumulative dose of 0.01 mg/kg restored neuronal activity to about 50% of pre-fluoxetine baseline values. Cumulative doses  $\geq 0.025$  mg/kg significantly increased (~60%) neuronal activity above baseline levels. The effect of WAY-100635 appeared to be maximal at 0.05 mg/kg, since cumulative doses up to 1 mg/kg produced little or no further increase in neuronal activity. These results indicate that WAY-100635 is a highly potent and effective 5-HT<sub>1A</sub> autoreceptor antagonist. Supported by grants from the AFOSR (F 49620-94-1-0128) and the NIMH (MH 23433).

## 76.14

**SEROTONERGIC AND NORADRENERGIC MECHANISMS INVOLVED IN THE EFFECTS OF ANTIDEPRESSANTS IN THE RAT FORCED SWIMMING TEST (FST).** **J. Ph. Reneric and I. Lucki\*.** Departments of Psychiatry and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Recent studies of the Porsolt behavioral despair test or FST using a time-sampling scoring technique have shown that serotonin reuptake inhibitors (SSRIs) decrease immobility while increasing swimming behavior, whereas norepinephrine (NE) reuptake inhibitors (NRIs) decrease immobility while increasing climbing. (Detke, et al., 1995; *Psychopharmacology*, 121:66-72). These different behaviors were used to examine the effects of combined treatment of an SSRI (fluoxetine) with a NRI (desipramine). In addition, the paradigm was used to assess the effects of three antidepressant compounds with mixed activity as serotonin-NE reuptake inhibitors (S-NRIs), venlafaxine, milnacipran and duloxetine. Room-temperature water was 30 cm deep to prevent the rats from supporting themselves with tails or limbs. After a 15-min pretest, drugs were administered 24, 5, and 1 hr prior to the 5-min swim test.

Desipramine and fluoxetine both reduced immobility, and these effects were additive. Desipramine increased only climbing behavior, whereas fluoxetine increased only swimming behavior. Desipramine administered with fluoxetine interacted to decrease high levels of swimming. The reduction in swimming was presumably secondary to spending more time climbing.

Compounds with mixed activity at inhibiting serotonin and NE uptake produced different behavioral patterns in the FST. Venlafaxine reduced immobility and increased swimming. These effects began at 10 mg/kg and were dose-dependent. Venlafaxine also increased climbing at the highest dose tested (80 mg/kg). These behaviors are consistent with venlafaxine being slightly more effective at inhibiting serotonin than NE reuptake. Milnacipran reduced immobility and increased climbing. These effects were dose-dependent and were statistically reliable at doses of 20 - 40 mg/kg. There was no effect on swimming. This is consistent with milnacipran's slight selectivity for NE reuptake blockade. Duloxetine dose-dependently reduced immobility at doses of 10 - 40 mg/kg. This appeared to be due to increased climbing rather than swimming behavior. Supported by MH 36262.

## 76.16

**CHRONIC ELECTROCONVULSIVE SEIZURE (ECS) INDUCES MOSSY FIBER SPROUTING.** **V. A. Vaidya\* and R. S. Duman.** Neuroscience Program, Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Recent work from our laboratory has shown that chronic ECS, as well as other antidepressant treatments, increases the expression of BDNF in the hippocampus. BDNF plays a role in neuronal survival, differentiation and growth raising the possibility that chronic ECS influences the morphology of hippocampal neurons. This is supported by recent work from our lab demonstrating that chronic ECS alters the phosphorylation state and amount of neurofilament subunits. To further study the influence of chronic ECS on hippocampal morphology we used the Timm method, which stains the mossy fiber pathway because of its high Zn<sup>2+</sup> content. Rats received 10 daily ECS treatments (50 mA, 0.3 sec) and were sacrificed 12 days after the last treatment. Chronic ECS treated animals showed a dramatically different pattern of staining with Timm granules present throughout the supragranular layer of the dentate gyrus, which is indicative of mossy fiber collateral sprouting. This prominent sprouting appears to arise in the absence of gross cell damage which has been associated with lesion induced sprouting. This synaptic reorganization is reversible since 35 days after the last ECS treatment there appears to be no difference between the groups. Further experiments are being conducted to study the time course of this sprouting at the light and ultrastructural level. Experiments are also being conducted to study the effect of BDNF infusions and other antidepressant treatments on the pattern of Timm staining. (Supported by MH45481)

## 76.18

**THE ABILITY OF WAY-100635 TO INCREASE SEROTONERGIC NEURONAL ACTIVITY AFTER ACUTE FLUOXETINE TREATMENT IS DEPENDENT ON BEHAVIORAL AROUSAL.** **B. L. Jacobs\*, C. A. Fornal, F. J. Martin and C. W. Metzler.** Program in Neuroscience, Princeton University, Princeton, NJ 08544.

The therapeutic efficacy of selective serotonin reuptake inhibitors (SSRIs) might be potentiated by agents which block the 5-HT<sub>1A</sub> autoreceptor and thereby prevent the negative feedback action of serotonin on serotonergic neuronal activity. In the present study, we examined the influence of behavioral state on the ability of WAY-100635 (0.1 mg/kg, i.v.) to increase the activity of serotonergic dorsal raphe neurons in behaving cats after acute treatment with the SSRI fluoxetine (5 mg/kg, i.v.). Serotonergic single-unit activity was recorded using methods described previously (Fornal et al., *JPET* 270: 1345-1358, 1994). The ability of WAY-100635 to reverse the effect of fluoxetine was highly influenced by the behavioral state of the animal. WAY-100635 maximally elevated neuronal activity when cats were behaviorally active, and was less effective or completely ineffective in increasing neuronal activity after fluoxetine treatment during periods of behavioral quiescence (e.g., drowsiness or sleep), when serotonergic neurons normally display little or no spontaneous activity. Since GABAergic mechanisms appear to mediate the state-dependent decrease in serotonergic neuronal activity, pharmacological blockade of 5-HT<sub>1A</sub> autoreceptors would not be expected to increase neuronal activity during sleep. These results suggest the potential utility of behavioral strategies (e.g., increasing general activity and/or sleep deprivation) in further augmenting the effects of combining a SSRI and a 5-HT<sub>1A</sub> antagonist. Supported by grants from the AFOSR (F 49620-94-1-0128) and the NIMH (MH 23433).

## 76.19

**CHRONIC ADMINISTRATION OF LITHIUM INCREASES THE EXPRESSION OF CREB AND BDNF IN RAT HIPPOCAMPUS.** M. Nibuya\*, A. Jung, E.J. Nestler, and R.S. Duman. Lab. of Molecular Psychiatry, Dept. of Psychiatry and Pharmacology, Yale Univ. Sch. Med., New Haven, CT, 06508

Chronic administration of lithium appears to upregulate the cAMP pathway in brain. For example, we have shown that expression of adenylyl cyclase in specific brain regions is increased by chronic lithium treatment. We have also found that chronic antidepressant treatments upregulate the cAMP pathway, including increased levels of PKA (cAMP-dependent protein kinase) and expression of CREB (cAMP response element binding protein). In the present study we demonstrate that chronic lithium administration also upregulates these intracellular components of the cAMP pathway. Chronic lithium treatment (28 d) increased soluble, but not particulate, levels of PKA enzyme activity and increased the expression of CREB mRNA in the hippocampus. Chronic lithium administration also increased levels of CRE binding, determined by gel shift analysis, indicating that the induction of CREB mRNA is accompanied by an increase in CREB function. Upregulation of CREB indicates that lithium may influence target genes of this transcription factor: we have found that increased expression of CREB in response to antidepressant treatments is accompanied by an increase in the expression of BDNF (brain derived neurotrophic factor). Here we find that chronic lithium treatment also increases levels of BDNF mRNA in hippocampus. Regulation of CREB and BDNF could enhance the function and survival of neurons in the hippocampus and thereby contribute to the therapeutic actions of lithium. (Supported by MH 51399).

## AGING BEHAVIOR

## 77.1

**OPEN FIELD ACTIVITY AND HUMAN INTERACTION VARY AS A FUNCTION OF AGE AND BREED IN DOGS.** J. Th. Rick\*, E. Head<sup>1</sup>, B.J. Cummings<sup>2</sup>, C.W. Cotman<sup>3</sup>, W.W. Ruehl<sup>4</sup>, B.A. Muggenberg<sup>5</sup> and N.W. Milgram

<sup>1</sup>University of Toronto, Scarborough College, Scarborough, Ontario, Canada, M1C 1A4, <sup>2</sup>Harvard Med. School, Boston, MA, <sup>3</sup>Institute for Brain Aging and Dementia, University of California, Irvine, CA, <sup>4</sup>Deprenyl Animal Health Inc., Overland Park, KS, <sup>5</sup>Inhalation Toxicology Research Institute, Albuquerque, NM.

Open field activity was studied in kennel reared purebred beagles from two separate colonies and in pound source mixed breed dogs. Animals ranged in age from 9 months to 13 years. Dogs were placed in an observation room for a 10 minute period and 8 behaviors were recorded: distance traveled, time spent inactive, urination, directed sniffing, grooming, rearing, vocalizing and jumping frequencies (Head & Milgram, 1992). A human interaction test was also conducted using identical procedures except for the presence of a familiar or unfamiliar person in the observation room.

Open field measures of exploratory and locomotor behavior decreased as a function of age in pound source dogs, but not in the human interaction test. Although young pound source dogs did not differ from young beagles with respect to the parameters measured, beagles from both colonies did not show evidence of age-dependent decreases in open field activity. Cognitive test scores obtained from the same group of dogs were not correlated with open field activity measures, indicating that cognitive dysfunction in aged dogs is unrelated to sensorimotor deficits. These findings raise the possibility of genetic factors affecting age-dependent changes in open field activity. However, rearing conditions and differential neuropathology may also contribute to the behavioral differences observed among breeds. Supported by NIA Grant (AG 12694) to CWC, BJC, BAM and NWM.

## 77.3

**REACTIVITY TO NOVELTY IN AGED, COGNITIVELY IMPAIRED RATS.** J. Rochford\*, E. Spreekmeester, M. Meaney, R. Quirion and W. Rowe. Douglas Hospital Research Center, Dept. Psychiatry, McGill University, Montreal, Quebec.

Two populations of aged, Long Evans, rats can be identified on the basis of performance in the Morris Water Maze Task. Aged (24 month) unimpaired (AU) rats perform similarly to young (Y, 6 month) animals. Aged impaired rats (AI) display latencies to find the submerged platform greater than two standard deviations from the mean of the Y animals. Whereas these data indicate that some aged animals are deficient in terms of their spatial learning and memory capacities, the mechanism underlying this deficit has yet to be identified. A hallmark of efficient cognitive processing is the ability to cope with environmental change. Consequently, the present studies were conducted to assess reactivity to repeated exposure to novel stimuli. Reactivity was assessed by examining the degree and duration of (1) neophobia exhibited towards a novel gustatory/olfactory stimulus (sweetened milk) (2) hypoalgesia induced by exposure to a novel hot-plate (48.5° C) apparatus and (3) exploratory behavior in an elevated plus maze. AI rats exhibited a greater initial degree of neophobia (lower consumption on day 1) and protracted reactivity (lower consumption over days 2-8) in comparison to AU and Y animals. AI rats were more reactive to novelty on the hot plate test (as indicated by longer paw lick latencies); this novelty-induced hypoalgesia did not habituate in AI rats following repeated plate exposures. The degree of exploratory behavior (total arm entries) exhibited during three exposures to the elevated plus maze was reduced in AI rats. This effect was not a consequence of deficient affective mechanisms as measures of anxiety (open/total arm entries, time in open arms) were not different among AI, AU and Y animals. These data suggest that AI rats are hyper-reactive to novelty, and that this sensitivity persists following repeated stimulus exposure. (Funded by MRC and NSERC).

## 77.2

**REPRODUCTIVE STATUS AND AGE EFFECTS ON LEVELS OF ACTIVITY AND TESTOSTERONE IN MALE DEER MICE.**

K.-P. Ossenkopp\*, T. S. Perrot-Sinal and M. Kavaliers. Neuroscience Program and Department of Psychology, University of Western Ontario, London, Ontario, Canada, N6A 5C2.

Deer mice are a long-lived species whose reproductive state is dependent on photoperiod. Locomotor activity was examined in a multivariate manner with an automated Digiscan monitoring system. Both level of activity and spatial distribution of activity (thigmotaxis) was quantified. Subsequently, plasma testosterone levels, testes and adrenal weights, and brain measures were obtained. Mice were grouped by age (old, 57 mo; middle aged, 38 mo; adult, 16 mo; young B, 3 mo) and kept under a long day photoperiod. An additional group of young mice (NB, 3.6 mo) was housed under a short day photoperiod. Old mice exhibited lower levels of activity for several measures as well as lower testosterone levels when compared to young B, but not young NB mice. The young B mice also had higher activity levels, but not testosterone values, than the adult and middle aged mice. The young NB mice had both lower activity and testosterone levels relative to young B mice. Only the young NB mice had lower corrected testes weights than the other groups. These findings indicate the need to consider reproductive status when examining age-related changes in behavior. (Supported by NSERC)

## 77.4

**RETENTION OF OPERANT BEHAVIOR BY YOUNG AND MATURE RATS.** K.S. Seybold\*, R.W. Brown, G. Fisher and R.L. Port. Dept. of Psychology, Slippery Rock University, Slippery Rock PA 16057.

Aged subjects relearn classical (Coffin & Woodruff-Pak, 1993) and instrumental (Port, Murphy & Magee, 1996) responses as quickly as younger animals, but were found to show a marked deficit when retention of a classically conditioned response was examined without reinforcement (Solomon, et al, 1995.) The present study examined retention of operant responses in the absence of reinforcement.

Eight young (3 mos) and 8 mature (15 mos) male rats were autoshaped to barpress for food reinforcement. After reaching a criterion of >100 responses on two consecutive days, they received no training for a two week period. Retention was tested in a twenty min nonreinforced session. Mature subjects took significantly longer to reach criterion and retention performance (number of responses) was deficient in comparison to the younger subjects. Thus, age-related retention deficits seem to be generally exacerbated by testing in the absence of reinforcement. Supported by SRU.

## 77.5

DECLINE IN LATERAL PINCH STRENGTH AND STEADINESS WITH AGE. A.A. Overton, K.H. Olson and J.J. Pellegrini\*. Departments of Biology and Occupational Therapy, College of St. Catherine, St. Paul, MN 55105.

This study quantitatively describes changes in hand motor function across the adult lifespan. We examined healthy female volunteers between 20 and 100 years of age with tests of strength, speed and steadiness. We assessed lateral pinch strength by having subjects apply maximum force to a pinch gauge. We measured speed of finely targeted movements by having subjects perform the Purdue pegboard test. We evaluated pinch steadiness by asking subjects to apply constant force to an isometric pinch gauge while they were provided with visual feedback of their force output on a computer screen; the target force was 2 N. Subjects used their dominant hand for all tasks. After finishing these tasks, subjects completed a self assessment questionnaire of manual dexterity.

## 77.7

ALTERED TIME PERCEPTION IN ELDERLY HUMANS RESULTS FROM THE SLOWING OF AN INTERNAL CLOCK. P. A. Mangan\*, P. K. Bolinsky, A. L. Rutherford, and C. D. Wolfe. Clinch Valley College of the University of Virginia, Wise, VA 24293.

Evidence suggests that the transformation of real time into psychological or subjective time involves the activity of an internal clock. Recent studies have shown that drugs that increase dopamine levels at the synapse, such as methamphetamine, accelerate this clock, and drugs that decrease dopamine levels, such as haloperidol, slow the clock. This evidence supports the position that dopamine plays an important role in the regulation of an internal clock.

While a general pattern of anatomical and physiological changes occur throughout the brain during normal aging, selective atrophy of the substantia nigra with a concurrent reduction in the production of dopamine and effectiveness of the dopamine system is a conspicuous characteristic of the aging brain. These findings lead to the hypothesis that the reduction in dopamine activity in the aging brain should alter the functioning of the internal clock, and that older adults should experience a slowing of their internal clock resulting in the underestimation of a duration of time.

A group of healthy active adults, 60-80 years of age, and a group of young adults, 18-22 years of age, performed two tasks; a simple counting task and a more complex visual comparison task. Each group was told to work on the task until they determined that 3 minutes had passed. The actual time spent on each task was recorded.

Comparison of the task performance showed that the older group underestimated the amount of time spent on both tasks, with the amount of time spent on the visual comparison task showing the most underestimation. The younger group underestimated the amount of time spent only on the visual comparison task, and their underestimation was significantly less than the older group. These findings are consistent with a selective decrease in the effectiveness of the dopamine system that results in the slowing of an internal clock during normal aging.

## 77.9

REGIONAL CEREBRAL BLOOD FLOW STUDIES OF MEMORY IN THE BALTIMORE LONGITUDINAL STUDY OF AGING. S. Golski\*, A. B. Zonderman, M. Kraut, R. N. Bryan, and S. M. Resnick. Lab. of Personality and Cognition, NIA, 4940 Eastern Ave., Baltimore, MD 21224.

Annual magnetic resonance imaging (MRI), positron emission tomography (PET), and neuropsychological assessments are being performed over 9 years in 180 BLSA participants, aged 60 and older, to assess the contribution of changes in brain structure and function to cognitive aging. PET-cerebral blood flow (CBF) scans are obtained using <sup>15</sup>Oxygen labelled water during a resting baseline and two activated conditions: performance of verbal and figural continuous recognition tasks. Accuracy in each task averaged 74%. Initial PET results for 107 right-handed individuals are reported. Activation patterns were examined separately for each of the 4 age X sex subgroups (35 men and 27 women aged 60-69; 27 men and 18 women aged 70-85) and for younger versus older subjects using statistical parametric mapping. Both recognition memory tasks elicited relative increases in CBF in the right frontal lobe, bilateral occipital lobes and posterior temporal and cerebellar region, and relative decreases in bilateral posterior cingulate gyrus. Comparisons between the verbal and figural tasks indicated relative left frontal-temporal activation for the verbal task and relative activation of right visual association areas for the figural task. Older women had less task-specific regional activations than younger women, but age groups were not significantly different for men. The relationship between individual performance and CBF activation is discussed. *NIH*

## 77.6

AGE EFFECTS ON SIX TEMPORAL FACTORS IN VISUAL PERCEPTION. R.S. Kennedy\*, Essex Corporation, Orlando, FL 32803; J.M. Ord, Neuroscience Research, Pittsford, NY 14534; and W.P. Dunlap, Tulane University, New Orleans, LA 70118.

There is a loss of both temporal and spatial discrimination in vision with normal aging. In human temporal visual tests, there is an apparent loss of temporal resolution of closely succeeding visual events that are recognized as separate by young adults. Although optical mechanisms are also involved in temporal and spatial resolution, interest has focused on possible differential, age-related changes in magnocellular and parvocellular pathways extending from the ganglion cells of the retina to LGN, and V1 of the striate cortex. These parallel pathways mediate information for motion, form, depth, and color. In this study, the effects of age were evaluated in a temporal visual factors (TVF) battery, administered on a PC, and comprising (1) Flicker, (2) Phi-Apparent Movement, (3) Masking, (4) Simultaneity, (5) Group/Element Movement, and (6) Saccadic Accuracy. Forty-five subjects, ranging from 35-75 years were tested, and correlations were performed between age and TVF scores. The correlations between age and Group/Element Movement showed the strongest relationship and was  $P < 0.001$ , followed by Saccadic Accuracy ( $P < .01$ ), Backward Masking ( $P < 0.01$ ), then Simultaneity ( $P < 0.05$ ). Phi-Apparent Movement and Flicker showed directionally consistent age effects, but they were not statistically significant. These findings indicated significant age effects on specific human temporal visual factors that appear to be critically involved in such dynamic psychomotor tasks as driving and flying.

## 77.8

VOCAL MANIFESTATIONS OF DEMENTIA IN NURSING HOME RESIDENTS. K. Hammerschmidt<sup>1</sup>, P. Werner<sup>2</sup>, J. D. Newman<sup>1\*</sup>, and J. Cohen-Mansfield<sup>2</sup>. <sup>1</sup>Lab. of Comparative Ethology, NICHD, NIH, Poolesville, MD 20837 and <sup>2</sup>Research Institute, Hebrew Home of Greater Washington, Rockville, MD 20852.

This study examined the vocal utterances of 25 vocally disruptive nursing home residents (20 female, 5 male, mean age 86.1 years), with the goal of identifying acoustic parameters associated with type and severity of dementia. Recordings were made during periods of spontaneous vocalization. Vocalizations were digitized at 12,500 samples/sec, using the RTS/SIGNAL sound analysis system (Engineering Design). A total of 419 utterances were saved as digital files. Dementia was rated as 'Alzheimer's', 'vascular', or 'unknown' by the attending physician. Statistical analyses were performed with SPSS. Eighty-five acoustic parameters were measured from each call, using LMA 5.0 (Hammerschmidt). These acoustic parameters were then used in a linear discriminant function analysis, with type of dementia as the grouping variable. Classification accuracy was 91.79%, well above chance, indicating the presence of acoustic differences in the vocalizations of the 3 groups. These findings indicate that acoustic analysis of vocalizations can be a useful tool in assessing cognitive impairment and degenerative disorders in aged humans.

Supported by NICHD (Hammerschmidt, Newman) and NIA (Werner, Cohen-Mansfield).

## 77.10

THE EFFECTS OF AGE ON THE NEURAL SUBSTRATE FOR VERBAL WORKING MEMORY. P.A. Reuter-Lorenz\*, J. Jonides<sup>1</sup>, E.E. Smith<sup>1</sup>, A.A. Hartley<sup>3</sup>, A. Cianciolo<sup>1</sup>, E. Awh<sup>1</sup>, C. Marshuetz<sup>1</sup> and R.A. Koeppel<sup>2</sup>. Dept. of Psych.<sup>1</sup>, Dept. of Nuclear Medicine<sup>2</sup>, Univ. of Michigan, Ann Arbor, MI, 48109; Dept. of Psych., Scripps College, Claremont, CA<sup>3</sup>.

Age-related impairments in cognition have been attributed in part to the decline of working memory with age. We used PET to investigate the neural substrates of verbal working memory in a group of young (mean age = 23 yrs.) and elderly adults (mean age = 70 yrs.). Performance on two different tasks was compared: An item-recognition task, in which on each trial subjects stored 4 letters in memory for 3 secs and then indicated whether an (opposite case) probe item was part of the memory set; A continuous performance task in which subjects viewed a sequence of letters and compared the current letter to the one 2-back in the sequence. Both tasks require the active maintenance/rehearsal of stored items; the 2-back task requires in addition maintenance, temporal coding and more continual updating of the stored contents. On the item recognition task older subjects were slower but as accurate as the younger group. The younger group showed activation in regions that previous research has identified with verbal storage and rehearsal. The older subjects showed a similar pattern of left hemisphere activations but there was additional activation of homologous right hemisphere sites, suggesting recruitment. On the 2-back task, analyses revealed bilateral activation in frontal and parietal sites and cerebellar activation in both groups. A comparison of high- and low-accuracy older subjects revealed that the low-accuracy subgroup had greater frontal and parietal activation whereas the high-accuracy subgroup showed higher cerebellar activation. The contribution of gender and differences in global activation levels to these differences are considered. These results suggest a change in working memory mechanisms with age.

PRELIMINARY RESULTS OF MULTI MODALITY PRESURGICAL EVALUATION FOR INTRACTABLE EPILEPSY D.J.Vincent<sup>1</sup>, A.E.Bryant<sup>2</sup>, D.R.Roberts<sup>1</sup>, J.J.Halford<sup>1</sup>, V.C.Worthington<sup>2</sup>, C.L.Vera<sup>1</sup>, M.S.George<sup>1</sup>.

<sup>1</sup> Radiology, Med. Univ. of South Carolina, Charleston, SC 29425 and

<sup>2</sup> Epilepsy Unit, Roper Hospital, Charleston, SC 29401.

Numerous techniques for mapping behavior onto brain regions are now available. It is unclear which of the available methods (fMRI, WADA testing, surface EEGs, ERPs, depth and subcortical electrodes or cortical grids) are best for presurgical determination of behaviors. These techniques have varying effectiveness, invasiveness, safety and cost. As a first step in the process of ascertaining the optimal techniques and to guide future research as to when and how noninvasive methods may replace the invasive, we have begun by using all methods and cross comparing results.

To date we have studied 7 patients with intractable epilepsy, using varying combinations of structural MRI, functional MRI, WADA testing, angiography, EEGs, ERPs, depth and subdural electrodes, cortical grids and surgery. All fMRI studies used the FAS verbal fluency language task. All WADAs tested language and memory.

In 3 out of 4 the fMRI and WADA were in agreement as to the hemisphere of language dominance. While, in one, the WADA showed bilateral language and the fMRI was lateralized.

This correlation between the WADA and fMRI is promising. Future work is necessary to determine the proper methods for presurgical determination of eloquent cortex.

## 78.3

ABSENCE OF CORRELATION BETWEEN AMOBARBITAL DISTRIBUTION, ASSESSED WITH SPECT BRAIN PERFUSION IMAGING, AND BEHAVIORAL MANIFESTATIONS DURING THE INTRACAROTID AMOBARBITAL PROCEDURE (IAP). J.P.Soucy\*, I.Rouleau, J.Robidoux and K.Laflamme, Hôpital Notre-Dame, Université de Montréal and UQAM, Montréal, Qc, Canada, H2L 4M1.

Direct intracarotid injection of Technetium-99m hexamethyl propylene amine oxime (<sup>99m</sup>Tc-HMPAO) combined with SPECT has been used as a mean to assess the cerebral territories perfused by coinjecting amobarbital during IAP in presurgical epileptic patients. However, the few available studies reporting memory testing results have been limited to the potentially functionally abnormal side ipsilateral to the determined epileptogenic focus. We have obtained right and left perfusion data in 9 patients, and unilateral injection (contralateral to the focus) in 1 patient, with well defined unilateral temporal lobe foci. Vigilance and memory were scored using a standardized procedure. Moderate to severe vigilance impairment was observed following 5 of the injections, without any correlation with either the distribution or number of territories perfused or the presence of contralateral crossover. As expected, significant memory deficits were observed after injection contralateral to the focus; however, performance varied from patient to patient and was in no way related to the perfusion pattern. Indeed, the patient with the best score was the only one with any (injected side) hippocampal visualization; the rarity of hippocampal perfusion during the IAP has previously been reported.

In conclusion, behavioural manifestations are determined not only by the directly perfused territories but also by the resulting deafferentation of structures not exposed to amobarbital.

TIME-FREQUENCY ANALYSIS OF MESIAL TEMPORAL LOBE SEIZURES USING THE MATCHING PURSUIT ALGORITHM

Piotr J. Franaszczuk,<sup>1,3,4</sup> Gregory K. Bergey,<sup>1,2,3</sup> P.J. Durka<sup>4</sup>

Departments of <sup>1</sup>Neurology and <sup>2</sup>Physiology, <sup>3</sup>Maryland Epilepsy Center University of Maryland School of Medicine, Baltimore, Maryland and <sup>4</sup>Laboratory of Medical Physics, Warsaw University, Warsaw, Poland

The onset and propagation of partial or focal epileptic seizures is frequently an evolving and nonstationary process. Yet the ability to analyse seizure activity is often limited by methods that require stationary or quasistationary epochs of data. Time-frequency transform analysis offers the ability to analyze relatively long continuous segments of seizure activity even when the dynamics are rapidly changing. We report our early experience with the application of the time-frequency transform using the matching pursuit (MP) algorithm. Up to 80 seconds of continuous seizure activity was analyzed from selected channels obtained from recordings in patients made with simultaneous subdural grid (lateral temporal neocortical) and depth electrode arrays (mesial temporal) as part of their evaluation prior to seizure surgery. The MP approach permitted decomposition of the seizure epochs which were then displayed using Wigner plots. This permits identification of the predominant contributing frequencies for any given time period. Two patterns of seizure activity have been observed. In one pattern the predominant frequency of seizure activity has a gradual but relatively continuous change over time. In the other, many more contributing frequencies are seen with no clear pattern of change. These patterns of changes of seizure frequency may reflect different characteristics of the neuronal generators of rhythmic seizure activity.

## 78.2

DELINEATION OF SEIZURE ONSET, SEIZURE SPREAD, AND NORMAL BRAIN ACTIVITY BY FUNCTIONAL MAGNETIC RESONANCE IMAGING (fMRI). J.Hirsch<sup>1,2</sup>, K.Kim<sup>1,2</sup>, J.D.Victor<sup>2</sup>, N.Relkin<sup>2</sup>, K.M.Lee<sup>1,2</sup>, D.R.Moreno<sup>2</sup>. Dept. of Neurology<sup>1</sup>, MSKCC; Dept. of Neurology and Neuroscience, Cornell U Med Coll<sup>2</sup>, NY, NY 10021.

A 16 year old right handed female with a congenital malformation in the right posterior frontal lobe and a seizure disorder participated in a functional imaging study to identify sensorimotor areas. One of the patients' typical sensory seizures occurred during one of the runs. This enabled us to localize fMRI signals associated with the onset of a spontaneous seizure, its progression, and the relationship to normally activated motor cortex. Images were acquired on a 1.5-tesla scanner (GE) equipped for echo planar imaging with an in plane resolution of 1.56 X 1.56 mm. 16 contiguous slices were acquired each 4.7 mm thick. The fMRI signals associated with the seizure were first observed in an area adjacent to the normal motor activity. There was minimal movement artifact which was further reduced by alignment of the images prior to a voxel-by-voxel statistical analysis. MR signal amplitudes exceeded the normal functional activity by as much as a factor of 5. A sequential time analysis (6 sec intervals) revealed both local spreading of the onset focus and the emergence of subsequent foci first in the ipsilateral prefrontal areas, and the mesial surface areas. These were followed by activity in the homologous regions of the opposite hemisphere suggesting that the generalization followed a specific pattern of functional connectivity. These findings are the first to co-localize eloquent motor activity and seizure activity, and to quantify the onset, progression pattern, time course, and relative MR amplitudes of the seizure event.

## 78.4

AN APPLICATION OF CORRELATION DIMENSION FOR PRE-PROCESS OF EPILEPTIC EEG SIGNALS. Xiaoyu Liu, Qiang Shen, Guoqing Chang\*, Dazong Jiang. Biomedical Engineering Research Institute, Xi'an Jiaotong University, Xi'an 710049, P.R. China; \*Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Epilepsy is a common disease in clinics. When the epileptogenic focus appears in the brain, it discharges periodically and results in epileptiforms in EEG recorded from patients. Therefore, epilepsy can be diagnosed by detecting characteristic epileptiforms such as spikes and sharp waveforms in recorded EEG signals. However, it is usually difficult and tedious for the technician to find these characteristic epileptiforms in clinical practice because there are many normal waveforms and various artifacts in such epileptic EEG signals. Thus, it is necessary to pre-process the epileptic EEG signals to select the segments which may have characteristic epileptiforms. On the other hand, normal brain is a chaotic system. When epilepsy occurs, brain chaos status and the value of correlation dimension, one of chaos's parameters, will be reduced. Accordingly, in the present experiment, we chose the value of correlation dimension as an indicator to pre-process epileptic EEG signals and select the segments which may have characteristic epileptiforms. A moving window (width: 48000 points) was used to calculate the correlation dimensions of EEG data recorded from 6 patients, including the pre-evoked, evoked and after-evoked recordings. The threshold for correlation dimensions was set at 3.0. Any segment with lower correlation dimension was automatically selected. Results show that our method can be used to obtain epileptiforms from epileptic EEG data in a very short period. Therefore, this method might be very useful to pre-process epileptic EEG data and for EEG Holter monitoring in clinics.

## 78.6

LANDAU-KLEFFNER SYNDROME: MODALITY INDEPENDENCE OF LINGUISTIC COMPETENCE J.Kegl<sup>1</sup>\*, K.Baynes<sup>2</sup>, D.Brentari<sup>3</sup>, H.Poizner<sup>1</sup>. Cntr. for Molec. and Behav. Neuroscience, Rutgers Univ., Newark, NJ 07102<sup>1</sup>, Cntr. for Neuroscience<sup>2</sup> and Linguistics Dept.<sup>3</sup>, Univ. of California, Davis, CA 95616

Landau-Kleffner syndrome (LKS) has been described as "acquired aphasia of childhood," and occurs secondary to epileptic activity. Symptoms include abnormal EEG, auditory agnosia, and bilateral, temporal lobe seizures, resolving at or before puberty. Our research strives to delineate the linguistic extent of the deficits associated with LKS. We present a case study of a 26 year old, right-handed female with LKS, who was a full-term birth, with mildly delayed speech milestones until age 4, when her speech deteriorated to babble. An EEG done in 1974 was severely abnormal bilaterally. Current EEG, MRI, and neurological exam are normal, but a PET scan demonstrates bilateral temporal lobe hypometabolism. This subject tests within the normal range on all tests of intelligence not requiring verbal mediation (WAIS-R (PIQ=110); RCPM; WMS-R; Wisconsin Card Sort; Trail Making Test A, B, etc.). In contrast, standard tests of language and vocabulary skills (WAIS-R) revealed severe impairment. Auditory agnosia severely compromises her spoken language production (Assessment of Phonological Properties-Revised-severely impaired) and reception (discrimination of 172 phoneme pairs (at chance for "different" pairs)), but performance on parallel tasks using Signed English was unimpaired. Auditory processing deficits seriously impacted vocabulary development (Boston Naming Test: Spoken English (28/60=impaired), Signed English (30/60=impaired); WAIS-R (vocabulary (2)), but syntactic competence, as measured by grammaticality judgment tasks (Linebarger, et al., 1993) and argument structure distribution profile (Kegl, 1995) in Signed English, as well as written and spoken English is surprisingly spared. We conclude that LKS is characterized by a severe deficit in processing speech and speech-like auditory input, but does not have consequences for higher level linguistic processes or production and comprehension of language in non-auditory modalities. Funding: NIH/NIDCD #DC01656 & DC01664 (to Rutgers U.).

## LOCALIZATION OF AN ICTAL ONSET ZONE USING A REALISTIC 4-SHELL HEAD MODEL OF SCALP, SKULL, LIQUOR AND BRAIN.

H. Nishijo<sup>\*1</sup>, H. Ikeda<sup>2</sup>, K. Miyamoto<sup>3</sup>, S. Endo<sup>2</sup>, T. Ono<sup>1</sup>. Depts. <sup>1</sup>Physiol. and <sup>2</sup>Neurosurg., Toyama Med. & Pharmaceu. Univ., Toyama 930-01; <sup>3</sup>Chuo Electronics Co., Ltd, Tokyo 192, Japan.

We developed stereotaxic dipole localization (dipole tracing, DT) by a boundary element method using a realistic 4-shell head model of scalp, skull, liquor and brain (SSLB) with conductivity ratios of 1:1/80:3:1. The SSLB/DT can correct attenuation of potentials due to high resistance of a skull, and current-shunt effects of cerebrospinal fluid. To localize ictal onset zone, the SSLB/DT was applied to ictal electroencephalograms (EEGs) of a 9-month-old baby with hemimegalencephaly who had an enlarged subdural liquor space due to prior right occipital lobectomy and right parietal cortical resection. Generators of ictal EEGs were also estimated by DT using a realistic 3-shell head model of scalp, skull and brain (SSB). Estimated dipoles were superimposed on the three-dimensional magnetic resonance imaging (3-D MRI) of the patient's brain. The DT with SSLB model localized dipoles in the surface of the right parietal lobe, while the SSB/DT localized dipoles in the enlarged subdural liquor space. The electrocorticograms (ECoGs) during the second operation confirmed that ictal ECoGs ( $\delta$  wave) propagated from the location of the dipoles estimated with SSLB model. The results suggest that the DT with SSLB model could accurately localize dipoles even when a subject has an enlarged subdural liquor space due to neurosurgical operation or brain atrophy.

## CORTICAL SPIKE-WAVE COMPLEX RESPONSES TO HUMAN THALAMIC CENTROMEDIAN (CM) STIMULATION. F. Velasco, \* M. Velasco, A.L. Velasco, F. Jimenez and B. Rojas. Functional Neurosurgery, General Hospital and Neurophysiology National Medical Center IMSS, México City.

Low frequency (3/s), high intensity (30=2400uA) combined stimulation of left CM and right Non-specific Mesencephalic Pathways elicited a reliable response similar to the 3/sec spike-wave EEG discharges and symptoms and "irresponsiveness" of the typical Absence Attacks, spontaneously observed in patients with genuine Primary Generalized Epilepsy. The Electrocortical features of the this response included: S1, S2, PT and W components of individual spike-wave complexes, generalized spike-wave discharges with sleep spindle afterdischarges. These were accompanied by clinical motionless stare, 3/sec eye blinking, lip smacking and fail in responsiveness to simple visual stimuli of patients under a simple responding task. Comparable stimulation of right lemniscal + left CM failed to produce such a response. This work was performed on patients with intractable seizures and CM electrodes for treatment.

## MATCHING PURSUIT ANALYSIS OF EPILEPTIC EEG

TRANSIENTS B. Shen\*, R. Zappulla, H.W. Harper. New Jersey Neuroscience Institute at JFK Medical Center, 65 James Str., NJ 08818

Epileptic EEG transients contain essential information about the seizure mechanism. The initial location of epileptic EEG transients suggests the epileptogenic focus; the spread of epileptic activities mainly reflects synaptic propagation along conducting pathways (Jasper 1969); the termination of seizure has been considered as a result of an active inhibition, possibly by cortical norepinephrine (Efron 1961, Levy and O'Leary, 1965, Chauvel et al., 1982). Traditional analytic techniques that are heuristic or based on the assumption of stationary processes (e.g., Fourier analysis) fail to provide objective, precise time-frequency characterization of the EEGs and are thus sub-optimal for either clinical applications or studies of epilepsy. A recently developed technique, matching pursuit, offers adaptive decompositions of non-stationary signals (Mallat and Zhang, 1993) and has been shown to be effective in hippocampal EEG analysis (Shen, et al., 1995) and event-related-potential studies (Allen, et al., 1995). In this study, we applied matching pursuit analysis to multi-channel EEGs recorded from epileptic patients. The Wigner distribution, the energy distribution of the decomposed signal in the time-frequency domain, revealed a fast transient of frequency increase from 2-4 HZ to 6-8 HZ at the beginning of a seizure, followed by a slow transient of frequency decrease from 6-8 HZ to 3-5 HZ. The spatial distribution of energy at different frequencies provided an intensity map of epileptic activities at any instance; a movie of it offered a clear picture of the onset, the propagation and the termination of a seizure event.

## CORTICAL INCREMENTAL AND DESYNCHRONIZING RESPONSES TO HUMAN THALAMIC CENTROMEDIAN (CM) STIMULATION. M. Velasco, \*

F. Velasco, A.L. Velasco, F. Brito and I. Marquez. Functional Neurosurgery, General Hospital, Neurophysiology, National Medical Center IMSS, México City.

Low frequency (6/s) threshold (320-640uA) stimulation of the basal, central and antero-basal portions of CM produced incremental recruiting, augmenting and primary responses, respectively. Recruiting and augmenting like responses showed a bilateral regional scalp distribution with emphasis at the ipsilateral frontal (recruiting) and central (augmenting) regions; while primary like responses showed a focal distribution at the ipsilateral parietal region. High frequency (60/s) suprathreshold (640-800uA) stimulation of the basal and central, but not the antero-basal CM regions, produced EEG desynchronization and a slow negative shift of the EEG baseline with same scalp distribution to that showed by recruiting and augmenting like responses. These data obtained from patients with intractable seizures and CM electrodes for treatment indicate that synchronizing/desynchronizing CM influences share the same regional pathways possible related to thalamo-cortical modulation of sensory information.

## 78.10

## CORTICAL SPIKE-WAVE COMPLEX RESPONSES TO HUMAN HIPPOCAMPAL HIGH INTENSITY STIMULATION. A.L. Velasco, \* M. Velasco, F. Velasco, I. Marquez and B. Rojas.

Unilateral 3/sec, 1.0msec and 50-60v (5-6mA) stimulation of the anteromedial portions of either Hippocampal Formation or Parahippocampal Gyrus elicited some feature of the Typical Absence Attacks in patients with Temporal lobe seizures where either depth or subdural electrodes were implanted for the topographic diagnosis of the epileptic foci and/or eloquent cerebral areas. The absence attack features included: S and W components of the individual spike-wave pattern, generalized discharges with no sleep spindle after discharges, 3/sec eye blinking and a partial "irresponsiveness" consisting of delayed reaction time and repetitive responses to visual stimuli of patients under a simple response situation. The fact that Hippocampal stimulation produced typical absence attacks only when large stimulation intensities are used suggests that such "Hippocampal Response" is due to the indirect volume conduction activation of the Thalamic and Reticular Ascending Pathways closely located to the mesial hippocampal area. Although a primary hippocampal response can not be ruled out.

## INTERICTAL PERCEPTUAL IMPAIRMENT IN THE ABSENCE OF EPILEPTIFORM SURFACE EEG ACTIVITY

S. Knecht, L. Osinska, B. Diehl, S. Stodieck, C. Weiller\*, H. Henningsen. Depts. of Neurology, Univ. of Münster and Jena, 48129 Münster, 07740 Jena, Germany

Conscious perception is held to depend on the induction of highly coordinated activity in extended cortical cell assemblies. Conversely, in epilepsy there is neuronal dysfunction spreading from a focus. We tested whether neural function remote from an epileptic focus can be disturbed in the absence of clinical or EEG evidence of epileptic activity. Bilateral psychometric forced-choice assessment of somesthetic thresholds in parallel to continuous surface EEG recording was performed in 12 patients with focal lateralized epilepsy but without structural lesions of the somatosensory cortex. Lateralization was evaluated by seizure semiology.

In 7 pts., somesthetic perception on the side with clinical involvement during focal seizures was impaired relative to the unaffected side, as well as to 32 normal controls. In the remaining pts., no side-to-side difference was found.

We suggest that epilepsy-related mechanisms, e.g. continuous covert spiking or enhanced inhibition, can impair remote cortical function even when there is no clinical or surface-EEG evidence of epileptic activity.

**HIPPOCAMPAL DAMAGE IN INTRACTABLE FOCAL EPILEPSY OF CHILDHOOD.** J.H. Cross<sup>1</sup>, A. Connelly<sup>2</sup>, G.D. Jackson<sup>1</sup>, C.L. Johnson<sup>3</sup>, B.G.R. Neville<sup>1</sup> and D.G. Gadian<sup>2</sup>. <sup>1</sup>Neurosciences and <sup>2</sup>Radiology and Physics Units, Institute of Child Health, and <sup>3</sup>Great Ormond Street Hospital for Children, London WC1N 1EH, UK. (SPON: European Brain and Behaviour Society)

Patients with epilepsy commonly show hippocampal pathology, but debate continues as to the causes of this damage and its relationship to early febrile seizures. Hippocampal pathology can be investigated non-invasively using quantitative MRI techniques, including T2 relaxometry. Thirty-eight children (age range 3-17 years) underwent MRI on a 1.5 Tesla clinical imaging system, using a protocol that included T2 maps through the hippocampi. Based on clinical and/or EEG data, 28 had temporal lobe epilepsy (TLE) and 10 had extratemporal epilepsy. The children with TLE were divided into two subgroups: those with no tumour (n=19), and those with temporal lobe tumour on MRI (n=9). Abnormal hippocampal T2 values were seen in 14 of the 19 TLE cases with no tumour (unilaterally in 9 cases, bilaterally in 5), in 7 of the 9 TLE tumour cases (unilaterally in 2, bilaterally in 5), and in 6 of the 10 extratemporal cases (unilaterally in 3, bilaterally in 3). In the tumour and extratemporal cases, the damage tended to be less severe and less lateralizing than in the nontumour TLE group. These results demonstrate a high rate of hippocampal abnormality, not only in TLE, but also in extratemporal epilepsy where the hippocampus is assumed not to be primarily involved in seizure onset. In the latter cases, and in the tumour cases, the hippocampal damage may therefore be secondary rather than primary, resulting from seizures originating elsewhere in the brain. Such secondary damage could contribute to the cognitive impairments often seen in these children.

**GABA TRANSPORT IS REDUCED IN PATIENTS WITH MEDIAL TEMPORAL LOBE SCLEROSIS.** Anne Williamson\* and Dennis D. Spencer

Section of Neurosurgery, Yale University School of Medicine, New Haven, CT  
The dentate gyrus of epileptic patients with medial temporal sclerosis (MTLE) exhibit a number of anatomical and physiological changes that are not seen in the hippocampi of patients with extrahippocampal masses (MaTLE). Using intracellular recording techniques in dentate granule cells maintained in slices, we have previously shown that the responses to exogenously applied GABA are prolonged in MTLE tissue relative to those seen in MaTLE. This prolongation appeared to be due to an impairment in the GABA transport system. In the present study, we have used nipepic acid (NPA) to test further the function of the GABA transport system in MTLE. Brief applications of NPA can induce heterotransport of GABA and can thus be used to assess transporter function.

We compared the effects of GABA and NPA directly by using double barreled drug application pipettes. We found that NPA produced robust depolarizing responses in the MaTLE tissue which were indistinguishable from the responses to GABA in the same cells. The reversal potential for these responses was  $-54.8 \pm 6.0$  mV for GABA and  $-51.6 \pm 4.6$  mV for NPA,  $n = 3$ . By contrast, in the MTLE tissue, the response to NPA was greatly attenuated relative to the GABA responses. The reversal for the NPA response was  $-58.0 \pm 6.2$  mV,  $n = 7$ . We hypothesize that these depolarizing GABA responses are due to bicarbonate conductance through the GABA<sub>A</sub> channels. These effects of NPA were mediated by GABA heteroexchange since they could be blocked by either bicuculline or the GABA transporter type 1 (GAT-1) specific antagonist NO-711 in both types of tissue. These data provide further support for the hypothesis that there is an impairment in the GABA transport system in the dentate gyri of patients with MTLE.

## 78.17

**THE SERUM CONTENT OF AUTOANTIBODIES TO FRAGMENTS OF GLUTAMATE RECEPTORS INCREASES IN CHILDREN WITH EPILEPSY.** O.V. Globa, E.G. Sorokina, L.G. Gromova, O.I. Maslova, V.G. Pinelis\* Dpts of Neurological Diseases and membranology, Inst. of Pediatrics, RAMS, Moscow, 117963, Russia.

Neurotoxicity of glutamate (GLU) is responsible for neuronal damage that results from epilepsy. There are indications that damage of central glutamatergic neurons results in the appearance of autoantibodies (aAb) to fragments of GLU receptors (FGR) which can be detected in serum (S.A. Dambinova, 1989). The objective of the present work was to estimate the serum content of aAb in children with epilepsy using the paroxysmal activity test (Pat) elaborated by Inst. of Human Brain, RAS (St. Petersburg, Russia). We examined 85 children from 0.2 to 15 years of age with epilepsy. Control group consisted of 20 patients with different diseases of non neurological nature. The principal findings of present study are as follows: (1) The content of aAb to FGR was increased in 80% of patients with epilepsy and was in about two times higher than in control group ( $1.44 \pm 0.05$  ng/ml in patients 0.2-1 years and  $2.6 \pm 0.4$  ng/ml in children 1-15 years,  $0.7 \pm 0.4403$  ng/ml and  $1.4 \pm 0.1$  ng/ml in control group accordingly,  $p < 0.05$ ). (2) The level of serum aAb depended on the frequency and type of seizures. (3) There is direct correlation between aAb content and epileptic activity in EEG. (4) Even first episode of seizures accompanied by increase of serum aAb level. (5) In treated patients with positive effect of anticonvulsant drugs the content of aAb to FGR in serum decreased. The results obtained point to high sensitivity of Pat and this test can be used in diagnostic of epilepsy and in the estimation of therapy efficiency. (Supported by RFFI).

## 78.14

**ASTROCYTIC CHANGES IN HUMAN EPILEPSY: NITRIC OXIDE SYNTHASE-LIKE IMMUNOREACTIVITY.** B. Quinn, S. Sharma\*, W. Doyle, & L.S. Conklin, Div. Neuropathology, NYU Medical Center, New York, NY 10016.

Although some cases of human epilepsy are attributed to low-grade neoplasms, trauma, cortical maldevelopment, or other lesions, many cases of adult epilepsy are unexplained even after pathologic examination of tissue removed at surgery. Traditionally, 'gliosis', including a subpial form called Chaslin's gliosis, has been one histopathologic change noted. However, increasing understanding of neural-glial interactions and the important role of astrocytes in glutamate uptake and metabolism make more detailed studies of astrocytic involvement important in human epilepsy. Immunohistochemical studies of surgical tissues can provide qualitative data for protein induction in astrocytes, and suggest areas of study for *in vitro* systems such as human astrocyte cultures. To date, we studied 15 adult temporal lobe resections and several control cases from autopsy tissue. We found marked induction of nitric oxide-synthase (NOS)-like immunoreactivity in neocortical astrocytes using a polyclonal antibody to NOS Type III (endothelial NOS: Transduction Labs N30030), but not with a battery of other antibodies to Type I and Type II NOS (neuronal and inducible/macrophage NOS, respectively) from several sources. Best immunohistochemical results were obtained in alcohol-fixed tissues in floating sections after PEG embedment. The results contrast with animal studies reporting NOS II induction (iNOS) after epilepsy. It would seem unlikely that this NOS III antibody is cross-reacting with iNOS, since iNOS antibodies did not label the same cells in our hands. The immunoreactivity did not resemble CD44, GFAP, or S100 astrocyte staining. Additional studies with NOS III *in situ* probes and with additional NOS monoclonal antibodies are indicated. If the strong immunoreactivity does not reflect a NOS isotype, it may represent an inducible astrocytic protein different than GFAP or S100. **MODULATION OF NEURONAL EXCITABILITY IN DEVELOPING HUMAN CORTICAL NEURONS** K.L. Altemus\*, C. Cepeda, H.C. Cromwell, Z. Li, W. Peacock, N.A. Buchwald, M.S. Levine, Mental Retardation Research Center, Division of Neurosurgery, University of California, Los Angeles, CA 90024.

Our laboratory has examined dopamine (DA) modulation of excitability of developing human neocortical neurons obtained from patients undergoing cortical resection as treatment for catastrophic childhood epilepsy. We have shown that DA enhanced responses mediated by activation of NMDA receptors but attenuated responses induced by glutamate. The present studies had two aims: 1) to assess the role of different DA receptor subtypes in DA-induced modulation, and 2) to determine if human cortical neurons expressed persistent Na<sup>+</sup> currents. Intracellular recordings were obtained from cortical neurons in tissue slices using standard techniques. Subsequent identification of recorded cells revealed that most cells were pyramidal neurons. DA and D<sub>1</sub>, D<sub>2</sub> and D<sub>3</sub> receptor agonists produced small decreases in excitatory postsynaptic responses when slices were bathed in standard artificial cerebrospinal fluid. When response components mediated by NMDA receptors were isolated pharmacologically, DA and SKF 38393 (D<sub>1</sub> agonist) enhanced responses. Quinpirole, a D<sub>2</sub> agonist and 7-OH-DPAT, a D<sub>3</sub> agonist, produced more variable effects. Thus, the modulatory actions of DA in human cortex will depend upon the subtypes of both excitatory amino acid receptors and DA receptors activated. To examine expression of persistent Na<sup>+</sup> currents, whole-cell patch clamp recordings were obtained from visually identified pyramidal neurons using infrared videomicroscopy. The majority of cells displayed a tetrodotoxin-sensitive inward current probably corresponding to the persistent Na<sup>+</sup> current. These currents are important because they are potential targets for antiepileptic drugs. Supported by USPHS NS 28383.

## 79.1

## LONG TERM REDUCTION OF INHIBITION IN THE DENTATE GYRUS OF KINDLED RATS

**P. Rutecki\*, Ü. Sayin, T. Sutula.** Dept. of Neuro., Neurosurg., and Neuroscience Training Program, Wm. S. Middleton VA Hosp., Univ. of Wisconsin, Madison, WI 53792

Previous studies have shown that electrical stimulation of limbic pathways that kindled seizures increased inhibition in the dentate gyrus as assessed by paired pulse stimulation of the perforant path *in vivo* (Spiller & Racine, *Brain Res.* 635: 139, 1993), and also increased the frequency of spontaneous miniature IPSC's in granule cells of the dentate gyrus (Buhl et al., *Science* 271: 369, 1996). To investigate changes in inhibition during the different stages of kindling, inhibition was assessed by paired pulse stimulation of the perforant path and recording the response in the dentate gyrus of rat hippocampal slices. The second evoked population spike was expressed as a percentage of the amplitude of the initial response. Paired pulse inhibition (PPI) was investigated after 3 class (cl) V seizures (n=7 rats, 12 slices), 1 week after 30-35 cl V seizures (n=8 rats, 16 slices), 2.5-3 months after 90-120 cl V seizures (n=5 rats, 10 slices), and was compared to age-matched controls. PPI at a 15 ms interpulse interval was increased significantly after 3 cl V seizures (33.1±9.2% vs 73.4±4.5%) and at 1 week after 30-35 cl V seizures (38.8±4.5% vs 71.6±4.8%). A significant loss of PPI occurred at 2.5-3 months after 90-120 cl V seizures (120±6.6% vs 49.9±3.5%). In the early stages of kindling, epileptogenesis was associated with increased PPI. After kindling-induced neuronal loss and mossy fibre sprouting, there was an eventual loss of inhibition in the dentate gyrus which may contribute to a permanent susceptibility for evoked and spontaneous seizures.

## 79.3

## BEHAVIORAL AND ELECTROGRAPHIC CHARACTERISTICS OF EPILEPTIC KAINATE-TREATED RATS: SIMILARITIES WITH HUMAN TEMPORAL-LOBE EPILEPSY

**P.R. Patrylo\*, J.L. Bloomquist, P.S. Buckmaster, and F.E. Dudek**

Dept. of Anat. and Neurobiol., Colorado State University, Fort Collins, CO 80523

Tissue resected from patients with temporal-lobe epilepsy and the kainate-treated rat model show a qualitatively similar pattern of cell loss in the CA3 area of the hippocampus and the hilus and both show mossy fiber sprouting. We examined whether the kainate model has other characteristics of temporal-lobe epilepsy (e.g., a delay of seizure onset following an initial injury, permanence, and focal hippocampal seizures with secondary generalization). Adult male rats (175-360 g; n=33) were given multiple injections of kainate (IP; 5 mg/kg) for 5-10 hr, and class IV/V seizures were elicited in all rats for  $\geq 3\frac{1}{2}$  hr (approximately 12% mortality). The behavior of 28 rats was then monitored for an average of 6 hr/wk from 1 day after treatment until euthanasia. Chronic *in vivo* recordings with surface EEG and electrodes in the dentate gyrus were obtained from freely behaving epileptic rats (n=2) to determine whether electrographic seizure activity occurs in the dentate gyrus without overt behavioral manifestations (i.e., complex-partial seizures). All kainate-treated rats had recurrent, spontaneous, generalized seizures (i.e., either class III/IV/V) that were first observed after a delay of  $69.9 \pm 31.8$  days. Furthermore, 8 of 10 rats, which were monitored for  $\geq 200$  days post-treatment, continued to have generalized seizures until euthanasia, suggesting a permanent epileptic state. The chronic *in vivo* recordings showed that epileptic kainate-treated rats (n=2/2) can have electrographic seizures in the dentate gyrus with or without any overt behavioral manifestations (i.e., generalized and complex-partial seizures, respectively). Although further experiments are necessary, these data suggest that kainate-treated rats, like human temporal-lobe epileptics, show a delay of seizure onset, permanence, and focal limbic seizures.

## 79.5

The redox site of NMDAR controls the synaptic plasticity expressed by isolated NMDAR-mediated EPSPs. **J.C. Hirsch\*, C. Bernard, H. Gozlan & Y. Ben-Ari.** INSERM U29, 123 Bld de Port-Royal, Paris, France.

NMDAR are sensitive to S-H and S-S reagents and in the presence of the oxidizing reagent DTNB, pharmacologically isolated NMDAR-mediated field responses recorded in low magnesium (0.1  $\mu$ M) were decreased by 50% (GOZLAN & al., 1995, *Neurobiol.* 26:360-369). Despite this decrease, both LTP or LTD of NMDA-dependent AMPA-mediated field responses could be induced indicating that the redox site of the NMDAR was not involved (id.; BERNARD & al., 1995, *Neurosci. Lett.* 193:197-200).

We have examined in the CA1 area of the rat hippocampal slices if synaptic plasticity expressed by NMDAR-mediated responses depended upon the redox state of the receptor. In 1.3 mM extracellular magnesium, intracellular recordings showed that DTNB (200  $\mu$ M) irreversibly decreased (63  $\pm$  14%; N=15) the pharmacologically isolated NMDAR-mediated EPSPs (CNQX: 15  $\mu$ M; bicuculline: 20  $\mu$ M; glycine: 10  $\mu$ M) evoked by stimulation of the Schaffer-commissural pathway. The full response could only be restored by addition of a reducing drug such as TCEP (200  $\mu$ M). In control slices, LTP (197  $\pm$  35% increase, N=8) or LTD (77  $\pm$  4% decrease, N=9) of the isolated NMDAR-mediated EPSPs were induced. In contrast, when the isolated NMDAR EPSPs were mediated by fully oxidized NMDAR (i.e. in the presence of DTNB) neither LTP nor LTD could be obtained. However, returning the NMDAR to a reduced state by addition of TCEP readily restored the ability of inducing LTP or LTD (N=3 & 3, respectively).

In conclusion, the redox site controls synaptic plasticity expressed by NMDAR in non physiological conditions. This property could be useful in pathological states such as epilepsy in which NMDAR are overexpressed (see companion poster, Quesada & al.).

## 79.2

## PARTIAL RECOVERY OF PERFORANT-PATH-EVOKED HYPEREXCITABILITY IN THE DENTATE GYRUS OF FREELY-BEHAVING RATS DURING THE FIRST WEEK AFTER KAINATE TREATMENT

**J.L. Bloomquist<sup>1</sup>, P.R. Patrylo<sup>1</sup>, P. Dou<sup>2</sup>, G.M. Rose<sup>2</sup>, and F.E. Dudek<sup>1</sup>**

<sup>1</sup>Dept. of Anat. and Neurobiol., Colorado State University, Fort Collins, CO 80523 and <sup>2</sup>Dept. of Pharmacology, UCHSC and VAMC, Denver, CO 80220

The kainate-treated rat is an animal model of temporal-lobe epilepsy. After kainate treatment, perforant-path stimulation initially evokes enhanced responses. We tested the hypothesis that perforant-path responses recovered to normal levels after 1 week. Chronic *in vivo* recordings were performed during a 3-day period before and 1, 4, and 7-8 days after kainate treatment. Rats were given either multiple kainate injections (IP; 5 mg/kg per hr; n=6) for 5-10 hr, with class IV/V seizures elicited for  $\geq 3\frac{1}{2}$  hr, or multiple saline injections (n=3). Prior to kainate treatment, maximal stimulation of the perforant-path evoked a positive field-potential PSP that lasted for 5-13 ms (at  $\frac{1}{2}$  maximum amplitude) with 1-2 population spikes (n=6). One day after kainate treatment, however, single stimuli evoked prolonged field PSPs (duration 16-52 ms; n=6/6) with 3-5 population spikes (n=4/6), suggesting that inhibition was depressed. By 4-8 days, the duration of the field PSP and the number of population spikes were decreased in 4 of 6 kainate-treated rats, relative to 1 day after treatment. Five kainate-treated rats that were allowed to survive became epileptic months after treatment. Although further experiments are necessary, these results suggest that there can be a significant restoration of inhibition within 1 week after kainate treatment in rats that will eventually become epileptic.

## 79.4

## NMDA DEPENDANT SYNAPTIC CURRENTS DO NOT CONTRIBUTE TO PERMANENT SEIZURE SUSCEPTIBILITY AFTER KINDLING

**Ü. Sayin, P. A. Rutecki, T. P. Sutula\*** Depts. of Neuro., Neurosurg., and Neuroscience Training Program, Wm. S. Middleton VA Hosp., Univ. of Wisconsin, Madison, WI 53792.

Kindling is a phenomenon of brain plasticity in which repeated activation of neuronal pathways induces permanent susceptibility to evoked seizures and epilepsy. The NMDA receptor is critical for the induction of kindled seizures. To investigate whether long-term increases in NMDA-dependant synaptic neurotransmission contribute to permanent seizure susceptibility in kindled rats, NMDA-dependant synaptic currents were studied in granule neurons of hippocampal slices using single-electrode voltage-clamp techniques. Kindled rats were sacrificed after 3 class (cl) V seizures (n=5 cells, 5 rats), 1 week after 30-35 cl V seizures (n=6 cells, 6 rats), 2.5-3 months after the last of 90-120 cl V seizures (n=6 cells, 5 rats), and were compared to age matched controls. The charge carried by NMDA receptor activation was calculated as the difference in percent total charge before and after APV (50  $\mu$ M). Significant increases in the NMDA-dependant component of synaptic transmission were observed after 3 cl V kindled seizures (100%) and 1 week after 30-35 cl V kindled seizures (62%), but no increase was found 2.5-3 months after the last evoked seizure. The NMDA receptor plays a role in the induction of kindling, but does not account for permanent increases in seizure susceptibility in kindled rats.

## 79.6

The redox site of NMDAR controls the epileptiform activity in the kainic lesioned rat hippocampus *in vitro*. **O. Quesada, C. Bernard, J.C. Hirsch, J.P. Tenaux\* & Y. Ben-Ari.** INSERM U29, 123 Bld de Port-Royal, Paris, FRANCE.

In the presence of oxidizing drugs pharmacologically isolated NMDAR-mediated EPSPs are irreversibly decreased by 50%; the full response can only be restored by a reducing agent (see companion poster Hirsch & al.). Because epileptiform discharges (ED) result from an overactivation of NMDAR we have investigated whether drugs that selectively act at the redox site of NMDAR could control their expression. Evoked EDs were recorded in the pyramidal cell layer of the CA1 area a week after intracerebroventricular injection of kainate. In this model, CA3 pyramidal cells degenerate and stimulation of the surviving fibres in the stratum radiatum produced multiple population spikes in extracellular recordings and a burst of action potentials in intracellularly recorded pyramidal cells (Turner & Wheal, 1991, *J. Neurosci.* 11:2786-94). In seven cells which showed graded bursting activity in relation to the intensity of the stimulus, the oxidizing reagent DTNB (200  $\mu$ M) decreased to one the number of action potentials overriding the depolarisation. The bursting activity never recovered even following extensive washing (> 60 min) but was readily restored by addition of the reducing agent TCEP (200  $\mu$ M). APV (40  $\mu$ M) blocked the late part of the burst leaving a single AMPAR-mediated action potential. When NMDAR-mediated EPSPs were pharmacologically isolated, synaptic stimulation still evoked graded EDs. At sub-threshold intensity for action potential generation, DTNB decreased the NMDAR response to 56  $\pm$  10% of control (N=6) and TCEP reinstated the response to control levels (101  $\pm$  9%).

Thus manipulation of the redox sites of NMDAR may provide a novel epileptic treatment which does not share the disadvantages resulting from the complete blockade of NMDAR.

## 79.7

Interneurons are not so dormant after all in various models of temporal lobe epilepsy. C. Bernard, J.C. Hirsch, R. Khazipov, M. Esclapez, B. Zivkovic\* & Y. Ben-Ari. INSERM U29, 123 Bld de Port-Royal, Paris, FRANCE.

One week following intracerebroventricular injection of kainate, or two months following intraperitoneal injection of pilocarpine, stimulation of the surviving fibres in the stratum radiatum produced multiple population spikes in extracellular recordings, bursts of action potentials in pyramidal cells (intracellularly recorded) and surviving interneurons (recorded in the cell attached and whole cell configuration) in the CA1 and CA3 areas. Neurons were injected with biocytin and morphologically identified *a posteriori*. Bursts occurred simultaneously in interneurons and pyramidal cells. This evoked epileptiform activity was blocked by NMDA or AMPA receptor antagonists, suggesting that epileptiform activity was glutamatergic, or high concentration of divalent cations, suggesting the involvement of polysynaptic pathway. In CA1 pyramidal cells, fast and slow GABAergic IPSPs could be evoked after perfusion of CNQX and D-APV to block AMPA and NMDA receptor-mediated responses. When CNQX was applied alone, NMDA receptor-mediated EPSPs could be evoked in physiological concentration of Mg<sup>2+</sup> (1.3 mM) at resting membrane potential, despite the presence of underlying fast and slow IPSPs. NMDA receptor-mediated graded bursting activity could also be evoked. Together, these results suggest 1) that interneurons are not dormant since they are not disconnected from their glutamatergic afferences, 2) that inhibition is still present in CA1 pyramidal cells but 3) that its ratio with excitation has been modified since NMDA receptor-mediated responses can be measured in contrast to control tissue.

## 79.9

HILAR CELL LOSS AND MOSSY FIBER SPROUTING DUE TO BILATERAL KAINIC ACID LESIONS IN THE CA3 REGION OF RAT HIPPOCAMPUS. D.N. Chakravarty\*, T.L. Babb, C.K. Chung and R.M. Bushey. Depts. of Neurosciences and Neurosurgery, The Cleveland Clinic Foundation, Cleveland, OH 44195.

Unilateral kainic acid (KA) induced CA3 hippocampal damage in rats and ensuing hilar cell loss results in aberrant mossy fiber sprouting onto granule cell dendrites of the inner molecular layer. The aim of this study was to evaluate mossy fiber sprouting after 0.4 µg/0.2 µl unilateral injections of KA in the CA3 compared to bilateral injections of lower doses of KA. Adult male Sprague-Dawley rats were divided into 3 groups and anesthetized with ketamine/xylazine (85 mg/kg i.p.). Normal saline or KA was stereotactically infused into the CA3 region of the hippocampus using coordinates from Sherwood and Timiras (1970, 2.5 mm anterior to lambda, 4.5 mm lateral, 5.0 mm ventral from brain surface). Group 1 received unilateral right-sided KA (0.4 µg/0.2 µl) and the same volume of saline in the contralateral CA3. Group 2 received 0.2 µg/0.2 µl of KA in right CA3 and 0.1 µg/0.2 µl in the left. Group 3 received 0.3 µg/0.2 µl of KA in the right CA3 and 0.1 µg/0.2 µl in the left. One month following KA lesions, animals were perfused with 0.9% saline, 0.1% sodium sulphide and 3% glutaraldehyde, brains were removed and sectioned. Timm's and Cresyl violet staining were done. Hilar cell loss and mossy fiber sprouting were observed in all three groups. Mossy fiber sprouting was graded according to an ordinal scale 0-3, where 0 = no staining and 3 = most intense staining. In group 1, sprouting was observed only unilaterally (KA side) with a score of 2. In groups 2 and 3, hilar cell loss and mossy fiber sprouting were bilateral. In group 2, sprouting had a score of 2 on the right side and 1 on the left. In group 3, the sprouting had a score of 3 in right hippocampus and 2 in the left. This indicates that bilateral KA induced CA3 lesions, even at lower doses of KA will induce mossy fiber sprouting that is at least comparable to unilateral lesions induced by a higher dose of KA. This may be attributed to commissural deafferentation caused by even smaller KA hilar lesions.

## 79.11

PROTRACTED EXPOSURE OF PIRIFORM/PERIRHINAL CORTEX SLICES TO 0 Mg<sup>2+</sup> INDUCES DIFFERENTIAL PATHOLOGY IN NORMAL VS KINDLED TISSUE. M.E. Kelly\*, D.P. Nocent and D.C. McIntyre. Psychology Dept., Carleton Univ., Ottawa, Ont., Canada, K1S 5B6.

Partially relieving the Mg<sup>2+</sup> blockade from neurons in many kinds of *in vitro* slice preparations facilitates induction of self-sustaining, recurrent, epileptiform discharges. Recently, sustained seizure activity electrically triggered in low Mg<sup>2+</sup> has been suggested as an *in vitro* model of status epilepticus (SE) (Rafiq, et al., J. Neurophysiol., 1995).

In the present report, after many hours of exposure to 0 Mg<sup>2+</sup>, we examined amygdala-kindled and control tissue to determine whether a protracted seizure experience *in vitro* would induce a pattern of brain damage that was similar to *in vivo* models of SE. Coronal slices of the amygdala/piriform/perirhinal area from either normal or amygdala-kindled rats were exposed to 0 Mg<sup>2+</sup> or normal perfusate for 6 or 10 hours. At the appropriate time, slices were removed from the chamber and immersion fixed. Each 400 µm slice was resectioned at 40 µm and examined for argyrophilic neurons using two modifications of the Gallyas silver method. Tissues from control rats protractedly exposed to 0 Mg<sup>2+</sup> showed extensive damage throughout layers 2B and 3 of the piriform cortex similar to SE in *in vivo* models. By contrast, the kindled tissue in the piriform cortex was relatively little damaged. This result is similar to our previous *in vivo* demonstration of kindling-based neuroprotection against kainic acid SE. On the other hand, damage to the perirhinal cortex was laminarily more complicated, but again more extensive in control compared to kindled tissues. Tissue exposed to normal medium did not exhibit damage similar to 0 Mg<sup>2+</sup>.

GRANULE CELL AXON REORGANIZATION AND INTERNEURON LOSS IN THE DENTATE GYRUS OF EPILEPTIC KAINATE-TREATED RATS: A QUANTITATIVE STEREOLOGICAL STUDY. P.S. Buckmaster\* and F.E. Dudek. Dept. of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

We sought to describe quantitatively the morphological changes that occur in the dentate gyrus with temporal lobe epilepsy. Adult rats were treated systemically with kainate and months later, after displaying spontaneous recurrent seizures, were perfused for immunocytochemistry and Timm's staining. The optical fractionator and Cavalieri methods were used to estimate the numbers of parvalbumin-, CCK-, and somatostatin-immunoreactive neurons in the dentate gyrus and the volume of Timm's-positive regions in the granule cell layer and molecular layer. Age-matched vehicle-treated controls had averages of 3034 parvalbumin-, 1808 CCK-, and 8537 somatostatin-immunoreactive neurons/dentate. Some epileptic rats showed loss of parvalbumin- and CCK-positive neurons, and many showed loss of somatostatin-positive cells (means: 2343, 1311, and 4315 cells/dentate, respectively). The largest difference between epileptic and control rats was in the extent of Timm's staining in the granule cell layer and molecular layer. The volume of the granule cell layer and molecular layer that was Timm's-positive was less than 10% in almost all controls and greater than 10% in all epileptic rats (means: 5% vs. 30%). Axon reorganization and interneuron loss were most severe in the temporal pole -- an area homologous to the part of the hippocampus that is resected to treat patients with temporal lobe epilepsy. Supported by NIH grants NS16683 and NS01778.

MK-801 PRETREATMENT PREVENTS THE DEVELOPMENT OF SPONTANEOUS RECURRENT SEIZURES IN THE PILOCARPINE MODEL OF LIMBIC EPILEPSY. R.J. DeLorenzo\*, A.C. Rice, M.D. Shumate, and S.B. Churn. Department of Neurology, Medical College of Virginia, Richmond, VA 23298.

Ca<sup>2+</sup> entering neurons through N-methyl D-aspartate (NMDA) channels has been associated with many specific responses such as long-term potentiation, delayed neuronal cell death and hyperexcitability. Here we are assessing the ability of the NMDA channel blocker, MK-801, to affect the development of spontaneous recurrent seizures (SRSs) in the pilocarpine model of limbic epilepsy in rats. EEG monitoring of the animals indicated both the MK-801 pretreated (MP) and pilocarpine alone (PILO) rats exhibited comparable status epilepticus (SE). Diazepam abruptly terminated the SE in the MP rats, whereas the PILO rats exhibited SE for at least 3.6 ± 1 hr. Therefore, the MP animals were not administered DZ until 4 hrs post pilocarpine (MP-4). No SRSs were observed in the MP-4 group of animals compared to pilocarpine alone rats in which 78 % of the animals exhibited SRSs. Animals were video monitored for the occurrence of SRSs beginning 2 wks post pilocarpine injection and continuing for 6 wks or until a seizure was observed. In conclusion, MK-801 administered prior to pilocarpine-induced SE blocked the normal development of SRSs observed in this model of epilepsy. Supported by NIH grants RO1-NS23350 and T32-NS07288.

## 79.12

PARTIAL NEUROPROTECTIVE EFFECT ON THE HOST CA3/4 SUBFIELDS BY HIPPOCAMPAL FETAL GRAFTS FOLLOWING SEIZURES IN RATS.

H. Keyoung<sup>1</sup>, E.F. Sperber<sup>2</sup> and M.T. Romero\*<sup>1</sup>. <sup>1</sup>Department of Psychology, State University of New York at Binghamton, Binghamton, NY 13902; <sup>2</sup>Albert Einstein College of Medicine, NYC, NY 10461.

Systemic administration of kainic acid (KA) to adult rats produces status epilepticus and subsequent neural degeneration of the CA3/4 pyramidal cell layer of the hippocampus. However, the immature hippocampus (up to 3-4 weeks of age) is protected against neural degeneration.

We used fetal transplantation to explore whether the immature or adult hippocampus, devoid of its main inputs and outputs, was still resistant to neuronal degeneration and whether the presence of the grafted hippocampus in an adult host would have a neuroprotective effect on the host's hippocampus. Embryonic day 22 hippocampal tissue was implanted in the lateral ventricle of adult female rats.

Fifteen or 31-61 days following grafting the implanted hosts were injected with KA (15mg/kg, IP). Seizure activity was monitored for at least 2 hrs following the injection and status epilepticus was reduced with sodium pentobarbital a minimum of 3 hrs after KA administration. Five days later the animals were perfused and their brains processed for Timm staining and cresyl violet to visualize the mossy fiber pathway, determine the location of CA3/4 cell group in the grafted tissue, and assess the extent of neural degeneration produced in the host and graft.

Preliminary data indicate that following KA administration the percentage of hosts with complete degeneration of the CA3/4 subfields (40%) is significantly reduced as compared to nongrafted controls (100%). Sixty percent of the hosts showed either unilateral or no damage. There was no apparent degeneration in the graft regardless of age, indicating that input pathways are mediating seizure-induced damage. Further studies are underway to determine whether the protective effect is specific to hippocampal grafts.

## 80.1

APP AND APLP2 ARE FOUND IN DIFFERENT INTRACELLULAR COMPARTMENTS IN NTERA2 CELLS. E. Campbell<sup>1</sup>, S.M. Bowes<sup>1</sup>, R.C.A. Pearson<sup>2</sup>, D. Parkinson<sup>1</sup>, P. Francis<sup>3</sup>, M.T. Webster<sup>2</sup>. <sup>1</sup>Dept. of Biomedical Sci., Sheffield Hallam University, UK. <sup>2</sup>Dept. of Biomedical Sci., University of Sheffield, UK. <sup>3</sup>UMDS, London, UK.

Altered processing of the amyloid precursor protein (APP) is implicated in the pathogenesis of Alzheimer's disease. APP is very alike in structure to the amyloid precursor-like protein 2 (APLP2). It is therefore likely that they perform similar cellular functions and it was expected that they may follow the same route of subcellular trafficking. NTERA2 cells, a human cell line, were selected for this study because of their ability to differentiate into a neuronal phenotype upon treatment with retinoic acid, thus providing a model of APP and APLP2 processing in neurons in the brain.

Indirect immunocytochemistry was performed on NTERA2 cells in order to study the relative distributions of APP and APLP2 within the cell, using monoclonal and polyclonal antibodies. APLP2 is concentrated in large vesicles clustered close to the nucleus which appeared to be lysosomes. APP is localized in smaller perinuclear vesicles with a reticular appearance characteristic of the Golgi apparatus. These results suggest that APP and APLP2 have different subcellular distributions and therefore may be adapted to perform similar functions in different compartments. Supported by the Wellcome Trust.

## 80.3

EFFECTS OF PRESENILIN 1 AND ITS MUTATIONS ON THE PROCESSING OF AMYLOID PRECURSOR PROTEIN. X. m. Xu<sup>1</sup>, X. Wu, P. E. Fraser<sup>1</sup>, J. M. Rommens<sup>2</sup>, P. H. St George-Hyslop<sup>1</sup> and P. Gambetti. Division of Neuropathology, Case Western Reserve University, Cleveland, OH 44106 and <sup>2</sup>Centre for Research into Neurodegenerative Disease, Departments of Medicine and Medical biophysics, University of Toronto, and Division of Neurology, Department of Medicine, The Toronto Hospital, Toronto, Ontario M5S 1A8, Canada.

The majority of the cases with early-onset familial Alzheimer's disease are associated with mutations in presenilin 1 (PS-1) gene. This gene is postulated to encode a seven-transmembrane protein of unknown function. To determine whether PS-1 gene is involved in the processing of the amyloid precursor protein (APP), we have developed an efficient expressing systems of wild type and mutant forms of APP and PS-1 in human neuroblastoma cells. We found that secretion of the soluble form APP (APP<sub>s</sub>) by cells co-transfected with wild type APP (APP<sub>w</sub>) and wild type PS-1 is slightly reduced compared to that by cells transfected with the APP<sub>w</sub> construct and pcDNA3 vector used for PS-1 expression construct. Secretion of APP<sub>s</sub> is further reduced in cells co-transfected with the Swedish mutant APP (APP<sub>Sw</sub>) and the PS-1 gene. These results are consistent with the hypothesis that the PS-1 gene has a regulatory effect on APP metabolism. The effect of PS-1 on amyloid  $\beta$ -protein (A $\beta$ ) production is under investigation. Supported by NIA grants AG1812, AGNS08155, AG08992 and the Britton Fund.

## 80.5

DIFFERENTIAL EFFECTS OF ALZHEIMER'S DISEASE-CAUSING PRESENILIN MUTATIONS ON REGULATED APP PROCESSING. U. Langer<sup>1</sup>, M. Mayhaus<sup>1</sup>, P.H. St. George-Hyslop<sup>2</sup>, J.H. Growdon<sup>3</sup> and R.M. Nitsch<sup>1,3\*</sup>. <sup>1</sup>Center for Molecular Neurobiology, University of Hamburg, 20246 Hamburg, Germany; <sup>2</sup>University of Toronto, Toronto, Ontario, Canada; and <sup>3</sup>Department of Neurology, Massachusetts General Hospital, Boston.

Several forms of familial Alzheimer's disease are caused by missense mutations of the presenilin (PS) genes S182 (PS1) or STM2 (PS2). PS1 and PS2 are ubiquitously expressed, homolog genes of unknown function. In order to study whether disease-causing PS mutations interact with regulated APP processing pathways, we stably overexpressed both wild type and mutated PS1 in 293 cells, stimulated endogenous protein kinase C (PKC) activity with phorbol myristate acetate (PMA), and estimated the concentrations of APPs in the conditioned media by dot blotting and densitometry. In cells stably overexpressing the wild-type form of PS1, APPs secretion induced by PMA (10nM) was ~3.5-fold higher than in the untransfected parent cell line, or in control-transfected (pcDNA3) cells. The PS1 mutant L286V within the TM6-TM7 loop (presuming a 7-TMD structure) completely abolished increased APPs secretion. Dose-response curves revealed ~10-fold higher EC<sub>50</sub> values in the L286V mutants, as well as reductions of the maximal secretory response by approximately 50%. In contrast, mutations in other PS1 domains including A246E between TMD5 and TMD6, H163R within the TM2-TM3 loop and M146L within the second TMD failed to change PMA-induced secretion. Neither wild-type PS1 nor the disease-causing mutants changed the rates of unstimulated, constitutive APPs secretion. These data indicate a role for PS1 in regulated, but not constitutive, APPs secretion, and they suggest that structural integrity of the TM6-TM7 loop domain is important for this function.

## 80.2

SUBCELLULAR DISTRIBUTION OF PRESENILIN-1 (PS-1) IN HUMAN AND RAT CEREBRAL CORTEX. M.J. Walsh<sup>1</sup>, J.M. Murray<sup>1</sup>, J. Shioi<sup>2</sup>, N. Tezapsidis<sup>2</sup>, N.K. Robakis<sup>2</sup>, W. Byne<sup>2</sup> and G.M. Pasinetti<sup>1,2</sup>. <sup>1</sup>Department of Neurology, <sup>2</sup>Psychiatry and <sup>3</sup>Brookdale Center for Molecular Biology, Mount Sinai Medical Center, New York, NY 10029, USA

The distribution of proteins in subcellular fractions as assessed by immunoblotting is often a good indication of their subcellular localization *in vivo*. In this study we explored the sub-cellular distribution of Presenilin 1 (PS-1) and  $\beta$ -amyloid precursor protein ( $\beta$ APP) in cerebral cortex of human and rat brain. Post-mortem cerebral cortices were fractionated by density gradient centrifugation; immunodistribution was quantified by immunoblotting with polyclonal antibodies against PS-1 or  $\beta$ APP. PS-1 affinity purified antibodies were raised against a synthetic peptide of the predicted AA sequence of human PS-1 and characterized against a glutathione S-transferase bacterial fusion protein. Polyclonal  $\beta$ APP antibody cross-reacts with both the human and rat  $\beta$ APP. Immunoblots of total human and rat cortical homogenates reacted with PS-1 antibodies revealed a major immunolabelled protein band of approximately 55 kDa and a faint band of 110 kDa consistent with PS-1 homodimerization. Moreover, there was 3 fold enrichment for PS-1 in the nuclear and synaptosomal fractions compared with the signal from the total homogenate in both human and rat samples. Immunohistochemistry examined the cell type expression in human cortex and revealed an apparent neuronal PS-1 distribution of signal, as shown in rat cortex (Pasinetti et al., 1996). The same fractions used for PS-1 studies were also examined in parallel immunoblots probed with a polyclonal antibody against  $\beta$ APP. Unlike PS-1,  $\beta$ APP was found to distribute in all subcellular fractions without dramatic enrichment in any fraction examined and consistent with the widespread distribution of  $\beta$ APP throughout the CNS and many cell types. Thus, comparative immunoblot analysis is not indicative of any consistent co-localization of PS-1 and  $\beta$ APP *in vivo*. Supported by NIA grant AG13618 to GMP and AG08200 to NKR.

## 80.4

CO-EXPRESSION OF WILD TYPE AND FAMILIAL ALZHEIMER'S DISEASE (FAD) LINKED MUTANT PRESENILINS AND THE AMYLOID PROTEIN PRECURSOR (APP) IN A HUMAN NEURONAL CELL SYSTEM. T. E. Golde<sup>1</sup>, D. G. Cook<sup>1</sup>, M. Forman<sup>1</sup>, P. A. Holloway<sup>1</sup>, V. M.-Y. Lee<sup>1</sup>, J. Q. Trojanowski<sup>2</sup> and R. W. Doms. Dept. of Pathology and Laboratory Medicine, Univ. of Pennsylvania, Philadelphia, PA 19104-4283

Mutations in the presenilin (PS) genes result in FAD that, except for variation in age of onset, is virtually indistinguishable from FAD caused by mutations in the APP gene. Therefore, mutations in PS may alter APP processing or amyloid  $\beta$  peptide (A $\beta$ ) metabolism in a manner that leads to amyloid deposition. To explore the possible interaction between PS protein expression and APP processing in neurons, a Semliki Forest Virus expression system was used to transiently co-express PS and APP in a human neuronal teratocarcinoma cell line (NT2) that can be terminally differentiated with retinoic acid into post-mitotic fully polarized human neurons (NT2N). This system enables high level expression of APP and PS in the same cell, and proteolytic processing of both PS and APP is observed. Using this system multiple aspects of APP processing can be monitored including production of intracellular and secreted A $\beta$  which are detected using a sensitive sandwich ELISA capable of distinguishing A $\beta$ 40 from A $\beta$ 42. High endogenous APP levels in the NT2N cells make it possible to study the effect of PS expression on A $\beta$  production without co-expressing APP. To reproducibly measure intracellular A $\beta$ , however, co-expression of Semliki Forest virus transduced APP is necessary. The results of a systematic evaluation of the effects of expression of wild-type and mutant PSs on both intracellular and extracellular A $\beta$  production as well as other aspects of APP and PS processing in NT2N cells will be presented. ## 80.6

EXPRESSION OF A ~10-KD AMYLOIDOGENIC FRAGMENT OF  $\beta$ APP USING A VACCINIA VIRUS T7-EMC COUPLED TRANSCRIPTION-TRANSLATION SYSTEM. J. Daly, D.K. Lahiri<sup>1\*</sup> and G.J. Kotwal. Department of Microbiology and Immunology, Univ. of Louisville, KY-40292; <sup>2</sup>Department of Psychiatry, Indiana Univ. School of Medicine, Indianapolis, IN-46202

The amyloid  $\beta$ -peptide (A $\beta$ ) that aggregates to form the core of senile plaques in Alzheimer's disease, is generated proteolytically from a family of large integral membrane glycoproteins,  $\beta$ -amyloid precursor proteins ( $\beta$ APP). The cleavage of  $\beta$ APP by 'a-secretase' at amino acid Lys<sup>16</sup> of A $\beta$  prevents the formation of amyloidogenic fragments. Cleavages of  $\beta$ APP occurring at amino- and carboxyl-termini of the A $\beta$  sequence by 'B-' and 'c-secretase', respectively, generate an intact  $\beta$ -peptide which is potentially amyloidogenic. To understand the biosynthesis and cytoplasmic transport of  $\beta$ APP, we utilized the novel expression system of the vaccinia virus. DNA encoding A $\beta$  and the carboxyl-end of  $\beta$ APP was amplified by PCR from  $\beta$ APP cDNA. The 1.1 kb amplified DNA was cloned into the multiple cloning site of a vector containing the thymidine kinase gene of the vaccinia virus. The truncated  $\beta$ APP gene is placed under the control of a bacteriophage T7 promoter and a leader sequence from the encephalomyocarditis virus (EMC) that enables the cap-independent translation of the mRNA. Correct insertion of the DNA was confirmed by Southern blot analysis. The chimeric plasmid was then used to generate a stable recombinant virus containing the truncated  $\beta$ APP gene and was used as a template in an *in vitro* coupled transcription-translation reticulocyte lysate system in the presence of labeled methionine. Analysis of the translation products by SDS-PAGE revealed the presence of ~10 kDa protein equal in size to that predicted from the inserted cDNA. On 2D analysis, two spots of the expected size were observed. Also noted were spots of a higher size, suggestive of aggregation of the expressed protein. This expression system is being used to study the intracellular processing occurring in neuronal cells. Supported by the Humana and Graduate Research Council funds (GJK) and NIH-R01 grant (DKL).

## 80.7

## IS APP IN CULTURED CELLS AND PLATELETS PROCESSED IN MULTIPLE PATHWAYS?

R. Fukatsu<sup>1,4</sup>, K. Tsuzuki<sup>2</sup>, Y. Takamaru<sup>3</sup>, Y. Hayashi<sup>1</sup>, N. Sasaki<sup>1</sup>, T. Yoshida<sup>1</sup>, N. Fujii<sup>2</sup> and N. Takahata<sup>1</sup>. Depts. of <sup>1</sup>Neuropsychiatry, and <sup>2</sup>Microbiology, Sapporo Medical University, School of Medicine, South 1, West 16, Sapporo 060, Japan. <sup>3</sup>Dept. of Neuropsychiatry, Sapporo City General Hospital, Sapporo 062, Japan

The extracellular deposition of about 40 amino acids peptides, amyloid  $\beta$  protein ( $A\beta$ ) is invariable pathological feature in Alzheimer's disease brain.  $A\beta$  is derived from large cell surface protein, amyloid precursor protein (APP) by the proteolysis. It remains central issue to identify the subcellular compartment, or a pathway in which  $A\beta$  is generated from APP. In this study, we have examined processing of APP in cultured cells under lysosomotropic agents, and that in platelets before and after thrombin stimulation.

We characterized APP fragments, both potentially amyloidogenic and non-amyloidogenic in cultured U937, and HUT78 cell lines under leupeptin, chloroquine using polyclonal and monoclonal antibodies against synthetic peptides homologous to amino acid sequence of APP regions. APP fragments of 50, and 20 kDa containing full-length  $A\beta$  were increased in cultured cells under leupeptin and chloroquine. Subcellular fractionation of these cells showed that these 50 and 20 kDa fragments were produced in compartment closely related to endosomal/lysosomal pathway. 5-6 kDa amyloidogenic fragments were also detected in the same fractions, but these fragments did not apparently increase under lysosomotropic agents. These 50 and 20 kDa fragments were present in platelet lysate and insoluble membrane fractions after thrombin stimulation. 5-6 kDa fragments were also detectable in the same fractions but not in the platelet thrombin releasate.

Our data imply that compartments related to endosomal/lysosomal pathways may be involved in processing and generations of  $A\beta$ , and that there may be multiple pathways in which APP could be processed to generate  $A\beta$ . Amino acid sequencing of 5-6 kDa fragments are now under way.

## 80.9

Subcellular localization of Alzheimer Amyloid Precursor  $\gamma$ -secretase cleavage products by electron microscopy

Tobias Hartmann<sup>1</sup>, Sophie Bieger<sup>2,3</sup>, Pentti J. Tienari<sup>1,4</sup>, Nobuo Ida<sup>1,5</sup>, Colin L. Masters<sup>1</sup>, Carlos Dotti<sup>1</sup>, Klaus Unsicker<sup>1</sup> and Konrad Beyreuther<sup>1</sup>. <sup>1</sup>ZMBH Univ. Heidelberg, Germany; <sup>2</sup>Dept. Anatomy & Neurobiol., Dalhousie Univ., Halifax, N.S., Canada; <sup>3</sup>Dept. Neurol. Univ. Helsinki, Helsinki, Finland; <sup>4</sup>Toray Industries, Inc. Sonoyama Otsu Shiga, Japan; <sup>5</sup>EMBL, Heidelberg, Germany; <sup>6</sup>Dept. Anatomy & Cell Biol. Univ. Heidelberg, Germany; <sup>7</sup>Pathology, Univ. Melbourne, Australia.

The Alzheimer Amyloid Precursor Protein (APP) can be cleaved by different proteolytic activities which release the Alzheimer's disease-associated  $A\beta$ 4 or related peptides. Although the cleavage sites are well-characterized, none of the proteases involved have thus far been identified. APP  $\gamma$ -secretase is responsible for the final processing of APP that leads to the secretion of the Alzheimer's disease-related  $A\beta$ 4 peptides. The major activity of APP  $\gamma$ -secretase releases  $A\beta$ 4 peptides ending at Val<sub>40</sub> ( $A\beta$ 4 numbering) and Ala<sub>42</sub>. In order to better characterize this protease, we have investigated its subcellular localization by immuno-electron microscopy using our newly developed monoclonal antibodies directed against the free carboxy-terminal end of  $A\beta$ 4 1-40 (mAb G210) and 1-42 (mAb G24). Since these antibodies do not react with full-length APP, only  $A\beta$ 4 peptides should be recognized. Our studies with non-transfected and stably transfected COS-7 cells as well as with primary hippocampal neurons have revealed that  $A\beta$ 4 immunoreactivity is restricted to specific cellular localizations. Cell labeling could be blocked almost completely by pretreatment of the cells with APP  $\gamma$ -secretase inhibitors, while the immunoreactivities for the uncleaved APP and the precursor peptides A4CT and p3CT were not reduced. These results further support a direct correlation between the observed immunoreactivity with our  $A\beta$ 4 1-40 or 1-42 specific antibodies and the generation of  $A\beta$ 4 peptides. The subcellular localization of  $A\beta$ 4 provide insights into the mechanisms by which it is produced.

## 80.11

RU486 REGULATES  $\beta$ APP PROCESSING. F. Lam\* and P.B. Reiner. Kinsmen Laboratory of Neurological Research, University of British Columbia, Vancouver, BC, V6T 1Z3

Regulation of  $\beta$  amyloid precursor protein ( $\beta$ APP) is believed to be an important factor in the pathogenesis of Alzheimer's Disease.  $\beta$ APP cleavage is regulated by various signal transduction cascades in cells. In the course of studying this phenomenon, we observed that the glucocorticoid and progesterone receptor antagonist RU486 potentially increased APP, secretion from rat PC12 cells.

The effects of RU486 are clearly dose-dependent, with an EC<sub>50</sub> of about 3.0 nM. RU486 is potent: at the EC<sub>50</sub>, the increase in APP, secretion in PC12 cells is ~2.5 fold higher than when treated with 50 ng/mL nerve growth factor. RU486 is known to block transcriptional activation via steroid hormone receptors. However, the ability of RU486 to stimulate APP, secretion was manifest within 15 minutes of application, suggesting that this effect is not due to an alteration in gene transcription. Several intracellular second messenger cascades converge upon the enzyme MAP kinase; following 15 minutes of exposure to RU486, MAP kinase activity was unchanged, suggesting that RU486 was not altering APP, secretion via activation of this pathway. Current efforts are directed towards understanding the mechanisms underlying this phenomenon.

Reversed-Phase HPLC Separations of the  $\beta$ -Amyloid Peptides.

B. E. Boyes<sup>1</sup>, D. G. Walker<sup>2</sup>. <sup>1</sup>Rockland Technologies Inc., Newport, DE 19804, USA., <sup>2</sup> Div. of Neurological Sciences, Dept. of Psychiatry, Univ. of British Columbia, 2255 Wesbrook Mall, Vancouver, B.C. V6T 1W5 Canada.

In the Alzheimer Disease (AD) brain, amyloid precursor polypeptides (APPs) are processed in a fashion which ultimately leads to the deposition of extracellular amyloid plaques. The major peptidic components of the plaques are the  $\beta$ -amyloid peptides ( $\beta$ APs), which extend to the C-terminal 40-43 residue positions. Little is currently known of the N-terminal heterogeneity of the peptides. Chromatographic separations of the amyloid peptides would aid in detailing the heterogeneity of peptides present in tissue, but have been problematic, exhibiting poor resolution and recovery under standard gradient reversed-phase HPLC conditions. Conditions are described which permit highly-efficient HPLC separations of the  $\beta$ APs, allowing baseline resolution and high mass recovery. This procedure was applied to examine the *in vitro* proteolysis of synthetic  $\beta$ AP 1-40, 1-42, and 1-43 peptides by human cathepsins. Cleavage sites were established for the peptides by mass spectral and compositional analysis. Although the sites of cleavage did not differ, the rates of digestion were slower for the longer peptides. This separation has also been applied to measure the levels of resolved  $\beta$ AP peptides in AD brain tissue, using off-line immunoassays. Limited amounts of peptides extending to the N-terminal aspartate have been observed, raising the possibility that the peptides may be deposited as N-terminal truncated species, or may undergo processing after formation of the plaque.

This research was supported by Rockland Technologies, Inc. (BEB), and by the Alzheimer Society of B.C. (DGW).

## 80.10

## PROTEOLYTIC PROCESSING AND TURNOVER OF THE TRANSMEMBRANE DOMAIN OF THE AMYLOID PRECURSOR PROTEIN (APP). W. L. Bunnell\* and C. G. Glabe. Dept. of Mol. Biol. and Bioch., Univ. of Calif., Irvine, CA. 92717.

The generation of  $A\beta$  from APP requires proteolytic cleavage within the transmembrane domain (TMD) of APP by  $\gamma$ -secretase. This intramembrane cleavage as well as degradative proteolytic processes acting upon TMDs are not well characterized. To examine the processing and turnover of the TMD of APP, a 55 residue probe was constructed containing a signal sequence and the APP TMD flanked on each side by unique epitope tags. *In vitro* translation in the presence of pancreatic microsomes indicates that the probe is efficiently inserted into the membrane in the proper orientation. Pulse-chase experiments with stably-transfected 293 cells indicate that the probe turns over with a half life of ~0.5 hr, similar to the half life of the carboxyl-terminal fragments of APP. Although the cells secrete a 3 kDa P3-like protein in the media, no fragments or degradation intermediates are detected in the cell lysate with antibodies to either epitope. This suggests that the degradation process is highly processive and once a protein is selected for turn-over, it is rapidly degraded. A wide variety of protease inhibitors were tested without success in stabilizing any intermediates. A cysteine protease inhibitor causes a robust increase in the steady-state level of the probe and results in increased secretion of the 3 kDa fragment. 3-methyladenine, an inhibitor of autophagy, has similar effects. Treatment of transfected cells with Brefeldin A blocks secretion of the 3 kDa fragment, while having no effect on the steady-state levels of the probe. These results suggest that TMD degradation and  $\gamma$ -secretase processing are separate processes and that TMD degradation may occur in the RER. Leupeptin, E64 and chloroquine have no effect on the steady-state levels of the probe or on the secretion of the 3 kDa fragment, suggesting that lysosomal hydrolases may not play a critical role in TMD turnover. Supported by NS31230 and AG00538.

## 80.12

## ON THE MEK OF APP, REGULATION J. Mills\*†, D.L. Charest†, S.L. Pelech† and P.B. Reiner†. †Kinsmen Laboratory of Neurological Research, ‡Dept. of Medicine, University of British Columbia and Kinetek Biotechnology, Vancouver, B.C., Canada

Secretory processing of  $\beta$ -amyloid precursor protein ( $\beta$ APP) is subject to regulatory control involving both PKC-dependent and PKC-independent mechanisms as well as activation of a protein-tyrosine kinase. One such signal transduction pathway may involve the sequential activation of MAP kinase kinase (MEK) and mitogen-activated protein kinase (MAP kinase). To test the hypothesis that the MAP kinase cascade is involved in regulation of  $\beta$ APP processing, MEK was pharmacologically inhibited using the novel synthetic inhibitor PD98059. Western blot analyses demonstrated that PD98059 inhibits both NGF stimulation of APP, secretion and MAP kinase activation in PC12 cells. Moreover, PD98059 inhibits both phorbol ester stimulation of APP, secretion and activation of MAP kinase in HEK 293 cell lines. Our data indicate that activation of MAP kinase may be critically implicated in regulation of APP, secretion.

## 80.13

SECRETION OF MUTATED FORMS OF AMYLOID PRECURSOR PROTEINS. T. Utsuki, W.C. Wallace, J.W. Kusiak and B. Zhao. Drug Design & Development, Lab. of Cellular & Molecular Biology, and Molecular Neurobiology Unit, Lab. of Biological Chem., GRC/NIA/NIH, Baltimore, MD 21224

Cerebral amyloid- $\beta$  protein (A $\beta$ ) deposits, in the form of senile plaques, are a major pathological feature of Alzheimer's disease (AD). A $\beta$  derives from a glycosylated integral membrane protein,  $\beta$ -amyloid precursor protein (APP), which is expressed in most tissues. A $\beta$  and other components of APP have been reported to possess both neurotoxic and neurotrophic actions depending on factors such as their dose, mode of delivery, the cell type and state and exposure time. We have previously described the use of PC12 cells stably transfected with constructs harboring mutated forms of the APP (mAPP; A692G, E693Q and V717F) to elucidate the role of APP and its processing in AD neuropathology. The presence of these mAPPs elicited apoptosis in the cell culture. In order to determine whether the apoptosis was caused by processing of the mAPP or by the properties of the secreted mAPP, we have characterized their secretion. APP levels were measured in conditioned media by immunoblot analysis using antibody 22C11, which recognizes the amino terminal. Secreted APP levels in wild type, APPA692G, APPE693Q or APPV717F transfected cells were higher than levels in vector transfected cell; 2.2-, 1.6-, 1.8- and 5.5-fold by densitometric analysis, respectively. The secreted APP exhibited a single species of similar molecular weight (about 110 kDa) for each mAPP. We are currently purifying the mAPPs from conditioned media to determine whether the normal biological functions of APP were disrupted by the mutations.

IS CATHEPSIN D THE RATE LIMITING ENZYME IN BETA AMYLOID PRECURSOR PROCESSING? E. M. Johnstone\*, E. P. Dixon, K. Hui, S. P. Little. Central Nervous System Research Division, Lilly Research Labs. Eli Lilly and Company, Indianapolis, IN 46285

Aspartyl proteases are thought to cause the gamma secretase or carboxyl terminal (C-terminal) cleavage of the beta amyloid precursor protein (APP) to release the beta peptide. The implication of Cathepsin D as a gamma secretase candidate comes largely from studies using synthetic substrates or purified full length APP whereby Cathepsin D cleaves a region of APP which is physiologically predicted to be transmembrane or membrane proximal (Landor, et al, 1994, J.B.C.269:18422, Evin et al, 1995, Biochemistry 54, 14185). We have transfected 293 cells transiently with either wild type or Swedish mutant APP and Cathepsin D cDNAs and shown that under physiological conditions, Cathepsin D generates an APP C-terminal fragment that is larger than the predicted C-terminal fragment if Cathepsin D was gamma secretase. Second, we have treated cells transfected with the Swedish mutant APP with a Z-phe-ala-FMK, a cysteine protease inhibitor, that prevents the maturation of Cathepsin D to the mature active form of the enzyme and the level of amyloid peptide increased. Z-phe-ala-FMK, as well as cell-penetrating HIV protease inhibitors (aspartyl protease inhibitors) cause accumulation of APP C-terminal fragments in transfected cells. We conclude that Cathepsin D is involved with processing of APP under physiological conditions but not in beta peptide production.

## 80.17

GLUTAMATE METABOTROPIC RECEPTOR REGULATION OF AMYLOID PRECURSOR PROTEIN SECRETION IN HUMAN NTERA 2 NEURONS (NT2N CELLS). Y.C. Jolly\*, V.M.-Y. Lee and B.A. Wolf. Dept. Pathol., Univ. Penn. Sch. Med., Philadelphia, PA 19104.

Amyloid precursor protein (APP) can be cleaved by secretases to generate a beta amyloid (A $\beta$ ) peptide implicated in the pathogenesis of Alzheimer's disease. This study examines the signaling pathway of APP secretion in human neurons.

Metabotropic glutamate receptor subtypes 1 $\alpha/\beta$  and 5 $\alpha$  were identified in the NT2N cells by reverse-transcription-polymerase chain reaction (RT-PCR). Stimulation of these phosphatidylinositol (PI)-linked receptors with glutamate or specific receptor agonists resulted in a dose- and time-dependent increase in APP-s secretion, measured by the immunoprecipitation of APP-s from the media of [<sup>35</sup>S]methionine-labeled NT2N cells. Glutamate-induced APP-s secretion was maximum at 30 min. However, glutamate caused a decrease in APP synthesis, measured by pulse-chase, suggesting that glutamate regulated the secretion of stored APP rather than newly synthesized APP. Glutamate-induced APP-s secretion required activation of phospholipase C (PLC), which resulted in inositol 1,4,5-trisphosphate (IP<sub>3</sub>) and diacylglycerol (DAG) production, as shown by the rapid glutamate-induced accumulation of IP<sub>3</sub>. The protein kinase C activator phorbol 12-myristate 13-acetate (PMA), a phorbol ester, as well as 1-oleoyl-2-acetyl-3-glycerol (OAG), a cell-permeable DAG analog, also stimulated APP-s secretion. These findings suggest that APP-s secretion from NT2N cells can be regulated by activation of the PI-linked metabotropic glutamate receptor signaling pathway.

Supported by NIH AG11542 and KO4 DK02217.

## 80.14

EFFECTS OF WORTMANNIN AND BFA ON PROCESSING OF THE AMYLOID PRECURSOR PROTEIN. Suzana Petanceska, I\* Gopal Thinakaran, Sam Sisodia, Paul Greengard and Sam Gandy<sup>1,2</sup>. <sup>1</sup>Lab. of Mol. and Cell. Neurosci., Rockefeller University, 1230 York Avenue; <sup>2</sup>Cornell Univ. Med. Coll., Dept. of Neurol. and Neurosci., 1300 York Avenue, New York, NY 10021, <sup>3</sup>Dept. of Pathol. and the Neuropathol. Lab., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

Brefeldin A (BFA) is a fungal metabolite known to have pleiotropic effects on cellular trafficking, due to action on various cellular compartments from ER to lysosomes; hence BFA can not only prevent proper maturation of various cargo molecules but it can also cause their misrouting. Wortmannin is a relatively specific phosphoinositide 3-kinase inhibitor; recently this fungal product was shown to cause misrouting of newly synthesized lysosomal enzymes, and to interfere with early stages of endocytosis. We studied the effects of wortmannin and BFA on the formation of processed derivatives of the amyloid precursor protein (APP), in PC12 cells and N2a cells transfected with wild type or Swedish mutant variant of human APP. In our experimental paradigm, wortmannin caused a modest decrease of both sAPP $\alpha$  and amyloid  $\beta$  peptide in the media, and an increase in the levels of these APP derivatives within the cell, raising the possibility that it acts either by causing prolonged covisculation of full length APP with secretases or by inhibiting fusion of sAPP $\alpha$  and/or A $\beta$  transport vesicles with the plasma membrane. BFA caused retention of full length APP (wt and Sw) within the cell accompanied by a dramatic decrease in secretion of sAPP $\alpha$  and amyloid  $\beta$  peptide. The effects of both drugs can be partially reversed by including phorbol ester (PDBu) in the treatments. The implications of these results for localizing the cellular compartments where  $\alpha$ ,  $\beta$  and  $\gamma$  secretase cleavages occur are under investigation.

Prevalence of  $\gamma$ -Secretase Cleavage of  $\beta$ PP in Cultured Smooth Muscle Cells

T. Haske<sup>a</sup>, H.M. Wisniewski<sup>b</sup>, J. Frackowiak<sup>b</sup>, B. Mazur-Kolecka<sup>b</sup>, K.S. Kim<sup>b</sup>, P. Mehta<sup>b</sup>, M.R. Emmerling<sup>a</sup> and H. LeVine III<sup>a\*</sup>. <sup>a</sup>The Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor, Michigan 48105 and <sup>b</sup>New York State Institute for Basic Research in Developmental Disability, Department of Pathological Neurobiology, 1050 Forest Hill Road, Staten Island, NY 10314

$\beta$ -amyloid (A $\beta$ ) angiopathy in the brains of aged dogs is similar to that found in human brain. A $\beta$  deposition is also seen in culture in smooth muscle cells (SMC) obtained from leptomeningeal blood vessels of aged dogs. We used SMC from leptomeningeal vessels to study the possible processing pathways that lead to cleavage of  $\beta$ -amyloid precursor protein (BPP). SMC were isolated from the leptomeningeal vessels by enzymatic digestion and grown in DMEM (low glucose) supplemented with 10% heat-inactivated fetal calf serum. Cultures used for the study contained at least 95% myocytes, as determined by immunostaining with antibodies to smooth muscle-specific  $\alpha$ -actin and desmin.  $\beta$ -protein deposits were detected with monoclonal antibodies (mAb) 4G8 and 6E10, respectively. BPP was detected with mAb 22C11 (N-terminus) and mAb R57 (C-terminus). We show that dog vascular SMC secrete A $\beta$  as determined by ELISA. BPP and its C-terminal fragments from both formic acid-soluble fractions and cell media were characterized by western blotting using various monoclonal and polyclonal antibodies. Our results provide evidence for the existence of extensive proteolytic processing of BPP, a minor  $\beta$ -secretase pathway, an unusual  $\alpha'$ -secretase pathway and a major  $\gamma$ -secretase pathway. The prevalence of  $\gamma$ -secretase processing may be related to the accumulation of A $\beta$ -immunoreactive material. Supported by Warner-Lambert.

POST-TRANSLATIONAL PROCESSING OF AMYLOID PRECURSOR PROTEIN IN NTERA2 CELLS S.M. Bowes<sup>1</sup>, R.C.A. Pearson<sup>2</sup>, D. Parkinson<sup>1</sup>

<sup>1</sup>Div. Biomedical Sci., Sheffield Hallam University, S1 1WB, UK and <sup>2</sup>Dept. of Biomedical Sci., The University of Sheffield, S10 2TN, UK

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterised by the presence of neurofibrillary tangles and senile plaques (SP) in the brains of patients. The principle component of SPs is  $\beta$ -amyloid ( $\beta$ A4), a 40-42 amino acid peptide, cleaved from amyloid precursor protein. Several lines of evidence indicate that the production of  $\beta$ A4 is central to AD pathogenesis.  $\beta$ A4 is found in the CSF of control patients indicating that APP undergoes both amyloidogenic and non-amyloidogenic processing in normal brain. One of the possible steps leading to the deposition of  $\beta$ A4 in AD is that the proportion of APP undergoing amyloidogenic cleavage is increased.

The cell line Ntera2 (NT2) is a human testicular carcinoma cell line which can be induced to differentiate into a neuronal phenotype (NT2N cells). It has been shown that NT2N cells are a good model for studying APP expression and processing. Methods to study the processing of APP in NT2 and NT2N cells have been developed.

To study APP processing monoclonal antibodies were developed to specific epitopes in APP and used to recover secreted APP from the media of NT2 cells by immunoprecipitation. Any APP containing  $\beta$ A4 was removed by serial immunoprecipitation with an antibody recognising an epitope in the first 12 amino acids of  $\beta$ A4, then the remaining APP was recovered by an antibody recognising an epitope immediately N-terminal to  $\beta$ A4. The samples were then analysed by SDS-PAGE and Western blotting. Our results indicate that APP is processed by both amyloidogenic and non-amyloidogenic pathways in NT2 cells.

Supported by the Wellcome Trust.

REGULATION OF AMYLOID PRECURSOR PROTEIN METABOLISM IN HUMAN PRIMARY NEURONAL CULTURES. A.C. LeBlanc\*, C.G. Goodyer. Depts. Neurol. and Pediatrics, McGill U. and Lady Davis Inst. for Medical Research, Sir Mortimer B. Davis, JGH. Montréal, PQ. H3T 1E2

The amyloid  $\beta$  peptide ( $A\beta$ ) is proposed to play a major role in the pathogenesis of Alzheimer's disease. In order to determine if the production of amyloidogenic peptides is cell and/or species-specific, we have been investigating human and rodent amyloid precursor protein (APP) metabolism in primary cultures of the major cerebral cell types associated with the senile plaques of Alzheimer's disease (AD). In the present study, we find that metabolism of APP through amyloidogenic pathways is enhanced in human neurons and astrocytes compared to our previous study of rat APP metabolism [LeBlanc et al., J. Neurochem. 66(6), 1996]. Human neurons and astrocytes generate abundant 4 kDa  $A\beta$  and five C-terminal fragments. Astrocytes produce an additional C-terminal fragment of 14 kDa. In contrast, microglia produce low levels of C-terminal fragments and undetectable  $A\beta$ . Since decreasing the levels of  $A\beta$  is a likely therapeutic target of AD, we are presently investigating the regulation of APP metabolism in the human primary neuronal cultures. Supported by NIH RO1 NS31700 to ALB.

## DEGENERATIVE DISEASE: ALZHEIMER'S-BETA-AMYLOID-GLIAL INTERACTIONS

## 81.1

IS  $\beta$ -AMYLOID A CHEMOTACTIC PEPTIDE IN ALZHEIMER'S DISEASE? D. Lorton\* and J. Schaller. Sun Health Research Institute, Sun City, AZ 85372.

We propose that  $A\beta$  induces microglial functional changes by interacting with formyl chemotactic receptors. Formyl chemotactic peptides have been reported to promote chemotaxis and induce VLA expression and release of cytokines. It appears that  $A\beta$  promotes similar functions in cells of monocytic origin. Previous reports demonstrate that  $A\beta$  is chemotactic for microglia and macrophages (Davis et al., 1992) and induces the release of IL-1 $\beta$  from a monocyte cell line, THP-1 (Lorton et al., 1996). To test our hypothesis, we used THP-1 cells, to examine the effects of chemotactic peptides on  $A\beta$ -induced IL-1 $\beta$  release and determine whether  $A\beta$  can induce adhesion of these cells to VCAM, the ligand for VLA.

THP-1 cells were incubated with 125 ng/ml lipopolysaccharide (LPS) and  $A\beta$  1-42 (5  $\mu$ M) with and without the formyl chemotactic peptide inhibitor *in vitro*. Conditioned media were assayed for levels of IL-1 $\beta$  using an ELISA. Treatment of activated monocytes with  $A\beta$  1-42 resulted in an elevation of IL-1 $\beta$  into the media compared to untreated activated monocytes confirming previous studies. Treatment of activated human monocytes with  $A\beta$  1-42 and either chemotactic peptide blocked the release of IL-1 $\beta$  into the media.

To examine the ability of  $A\beta$  1-42 to induce adhesion of THP-1 monocytes to VCAM, eight chambered coverglass wells were coated with VCAM, the wells washed, and blocked with 3% BSA in phosphate buffered saline. THP-1 cells ( $4 \times 10^5$  cells) were added to the wells and incubated with 500 nM  $A\beta$  1-42 or FMLP in the presence and absence of chemotactic peptide inhibitor (500 nM). Control wells contained only untreated THP-1 monocytes. The media was removed and the wells washed. Cells attached to the coverslip were fixed with paraformaldehyde, stained, and counted. Treatment with either  $A\beta$  1-42 or FMLP significantly increased the number of cells bound to VCAM coated coverslips compared to untreated cells. This effect was blocked by addition of chemotactic peptide inhibitor. Together these data provide evidence that  $A\beta$  may act via formyl chemotactic receptors to induce functional changes in microglia of Alzheimer's disease.

## 81.3

ENDOCYTOSIS OF AMYLOID-BETA PROTEIN BY CULTURED HUMAN MONOCYTES. March D. Ard\* and Alan R. Salkind\*. Depts. of \*Anatomy and \*Medicine, Univ. of Mississippi Med. Ctr., Jackson, MS 39216.

Microglia cultured from adult rat CNS accumulate exogenous amyloid  $\beta$ -protein ( $A\beta$ ) from the medium, as shown by our previous studies. Depending on the composition of the medium,  $A\beta$  may accumulate at the cell surface or, with the addition of high density lipoprotein (HDL), in peripheral cytoplasmic vacuoles. HDL contains apolipoproteins E and J, as does CSF lipoprotein; so its ability to facilitate microglial endocytosis of  $A\beta$  suggests that lipoprotein may be an important determinant of  $A\beta$  clearance in brain.

In the present experiments we have used human peripheral blood monocytes as a model for microglia, to test the effects of HDL on endocytosis of  $A\beta$  (amino acids 1-42) by human cells. In culture, the monocytes become active macrophages. They accumulate  $A\beta$  both at their surface and intracellularly. Using immunogold labeling and electron microscopy, we find nonfibrillar  $A\beta$  accumulated in endosomes with heterogeneous contents. Fibrillar  $A\beta$  is phagocytosed into large vacuoles which appear to contain only  $A\beta$  fibrils plus fluid. Degradation or possible exocytosis of the fibrils over time remains to be studied.

Electron microscopic evidence shows that, unlike adult rat microglia, human monocytes endocytose  $A\beta$  in the presence or absence of added HDL. Monocytes appear to be in a state of activation in culture, having ruffled borders and numerous lipid droplets and endosomes, which are not typical of microglia. Activation may enhance their endocytosis of  $A\beta$  directly, or it may cause monocytes to secrete high levels of endogenous lipoproteins. Alternatively, the difference in results may be due to differences in receptors and transport mechanisms between the two cell types.

Supported by University of Mississippi Medical Center.

## 81.2

MICROGLIAL CELLS BIND AND INTERNALIZE AGGREGATES OF THE ALZHEIMER'S DISEASE AMYLOID  $\beta$ -PROTEIN BY A SCAVENGER RECEPTOR. D. M. Paresce<sup>1</sup>, R. K. H. Liem<sup>1,\*</sup> and F. R. Maxfield<sup>3</sup>.

<sup>1</sup> Pathology Dept., and <sup>2</sup> Biology Dept., Columbia University, New York, NY 10032. <sup>3</sup> Biochemistry Dept., Cornell University Medical College, New York, NY 10021.

Microglia are immune-system cells associated with senile plaques containing  $\beta$ -amyloid ( $A\beta$ ) in brain tissue from patients with Alzheimer's disease (AD). Although increased  $A\beta$  plaque density is one of the hallmarks of AD, whether this is mainly due to increased production or decreased clearance of plaque proteins is unclear. We found that although murine microglia could rapidly bind and internalize microaggregates of  $A\beta$  peptide (1-42), degradation of the  $A\beta$  microaggregates was slow. When microglia were pulsed briefly with fluorescent  $A\beta$  microaggregates, then chased in  $A\beta$ -free medium,  $A\beta$  fluorescence was increasingly concentrated in lysosomes with time. However, even after a one week chase, a large proportion of  $A\beta$  fluorescence persisted in the microglial lysosomes whereas fluorescently labeled  $\alpha_2$ Macroglobulin was degraded within 3 hours. Fluorescent  $A\beta$  microaggregate uptake was reduced by excess unlabeled  $A\beta$  indicating that binding was saturable. Binding was reduced by co-incubation with excess acetyl-low density lipoprotein. and DiI labeled acetyl-LDL uptake by microglia was blocked by excess  $A\beta$  suggesting that  $A\beta$  and Ac-LDL bind to the same receptor. Other type A scavenger receptor ligands (fucoidan and dextran sulfate) reduced  $A\beta$  binding to microglia. These results show that a type A scavenger receptor plays a significant role in saturable uptake of  $A\beta$  peptide aggregates by microglia. Using this receptor, microglia may play a role in the clearance and phagocytosis of  $A\beta$  plaques from the brain. Supported by NIH grants DK27083 and NS34761 to FRM.

## 81.4

NITRIC OXIDE ALTERS BETA-AMYLOID PRECURSOR PROTEIN LEVELS IN BV-2 MICROGLIA. R.T. Carroll\*, B. Hardt, C. Helmer, C. Parker, J. Grimm and B.D. Shivers. Neuroscience Therapeutics, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert, Co., 2800 Plymouth Road, Ann Arbor, MI 48106-1047.

Activated microglia are intimately associated with senile plaques in the brains of individuals with Alzheimer's disease (AD). Upon activation, microglia can induce of nitric oxide synthase (NOS) leading to the production of large quantities of nitric oxide (NO). NO has been shown to be a highly reactive compound with neurotoxic properties and affects the enzymatic activity of a number of proteins. Because of the profound effect of NO on cellular activity, we sought to determine if NO could alter beta-amyloid precursor protein (APP) expression/processing in activated microglia. For this experiment we used BV-2 mouse microglia which were activated with 4  $\mu$ g/mL of lipopolysaccharide (LPS) for 18 hrs. Activation of the BV-2 cells caused an increase in APP secretion into the media and a decrease in intracellular APP levels. NOS was also induced and nitrite, a breakdown product of NO, could be detected in abundance ( $>100 \mu$ M) 18 hrs after activation. When NOS activity was inhibited with N-methylarginine, an additional 4-fold increase in secreted APP was observed. This increase corresponded to an equivalent increase in detectable cell-associated APP. These data suggest that NO may be either inhibiting APP synthesis or accelerating its intracellular degradation through proteolysis. Either mechanism could influence beta-amyloid production derived from APP and, hence have profound on the pathogenesis of AD.

## 81.5

**AB<sup>+</sup>-INDUCED SUPEROXIDE ANION PRODUCTION BY CULTURED MICROGLIA.** C.Colton\*, O. Chernyshev, J. Snell, M. Vitek and D. Gilbert. Georgetown Med. Sch., Washington DC 20007; BNP, NINDS, NIH, Bethesda, MD 20892 and Dept. Neurol., Duke Med. Cntr., Durham, NC 27710

Microglia, the CNS macrophage, have been implicated in the formation of amyloid deposits associated with Alzheimer's disease. Although their exact role is unknown, microglia may serve as a source of reactive oxygen species and thus, alter the redox status of the surrounding environment. We have examined the effect of the amyloidogenic fragment of amyloid precursor protein A $\beta$  (1-40) on superoxide anion production in cultured neonatal hamster microglia and human monocyte-derived macrophages. Treatment with 1 to 25  $\mu$ M of A $\beta$  (1-40) for 24 hours produced a significant dose dependent increase in non-stimulated superoxide anion production but no change in phorbol ester-stimulated superoxide production. This effect was indistinguishable from the reverse peptide, A $\beta$  (40-1), or A $\beta$  (1-28), a peptide fragment which forms fibrils but is not directly toxic to neurons. The microtubule inhibitor, colchicine, reduced the level of superoxide produced in each case. Treatment with nitroblue tetrazolium demonstrated the deposition of formazan granules within vesicles of microglia treated with each of the 3 peptides. This data suggest that superoxide anion production is enhanced during phagocytosis of these peptides. In addition, the increased superoxide anion production is not associated with an increase in nitric oxide (NO) production since NO was not detected in the macrophage supernatants treated for up to 5 days with each peptide.

## 81.7

**AMYLOID  $\beta$  PEPTIDE AND OTHER INFLAMMATORY MEDIATORS ENHANCE PRODUCTION OF L-GLUTAMATE BY MACROPHAGES.**

A. Klegeris, D.G. Walker, E.G. McGeer\* and P.L. McGeer. Kinsmen Laboratory of Neurological Research, Department of Psychiatry, University of British Columbia, Vancouver, B.C., Canada, V6T 1Z3.

Immunological mechanisms, including stimulation of brain microglia and activation of complement, as well as NMDA receptor-mediated excitotoxicity have been implicated in the pathogenesis of Alzheimer's disease, while accumulation of amyloid  $\beta$  peptide (A $\beta$ ) is one of its main pathological features. We previously reported that activation of macrophages by amyloid  $\beta$  peptide and/or its subfragment (25-35) can be readily detected in several assays including monitoring of the respiratory burst, cell aggregation, NO production and TNF- $\alpha$  secretion. In this study the effect of A $\beta$  and various other substances on rat peritoneal macrophages was studied by their effect on L-glutamate secretion by the cells.

As previously reported by others, it was confirmed that macrophages spontaneously produced significant amounts of L-glutamate (100  $\mu$ M range) and that this secretion was further enhanced by serum-opsonized zymosan, lipopolysaccharide and phorbol myristate acetate. Human IFN- $\gamma$ , IL-1 $\beta$  and TNF- $\alpha$  did not have any significant effects. Application of A $\beta$  (1-40) also enhanced the production of glutamate, while A $\beta$  (25-35) did not. The effect of A $\beta$  (1-40) on macrophages was not altered by 'aging' of this peptide in PBS for 4 days at 37  $^{\circ}$ C.

The data presented support the hypothesis that inflammatory mediators, by acting upon microglia, could increase the concentration of L-glutamate in brain tissue. It is also suggested that A $\beta$  could directly stimulate glutamate secretion by microglia, placing glutamate-sensitive neurons surrounding amyloid plaques at high risk. Both these mechanisms could play important roles in the pathogenesis of neurodegenerative disorders, including Alzheimer's disease.

Supported by a grant from the Jack Brown and Family AD research fund.

## 81.9

**IMMUNOLocalization OF PERLECAN TO MICROGLIA IN VITRO AND IN VIVO.** J.D. Miller\*, J.A. Cummings, C. Ngo, K. Kimata, T.N. Wight, and A.D. Snow. Dept. of Pathology, Neuropathology Labs Box 356480, University of Washington, Seattle, WA 98195-6480 and Institute for Molecular Medicine, Aichi Medical University, Aichi, Nagakute, Japan 480-11.

The origin of the specific heparan sulfate proteoglycan (PG), perlecan, in beta-amyloid protein (A $\beta$ )-containing amyloid deposits in Alzheimer's disease (AD) brain is not known. In the present study indirect immunofluorescence identified possible cell candidates of perlecan production in primary cell cultures and in a rodent model. Double and triple-labelled indirect immunofluorescence was performed on dissociated primary rat septal cultures using specific antibodies for identification of different cell types, and for perlecan core protein. In mixed cultures of both embryonic day 18 and post-natal day 2-3, microglia identified by labeling with OX-42 or anti-ED1 were the only cell type also double labeled with a polyclonal antibody against perlecan core protein. Similar immunolabeling of microglia with the anti-perlecan antibody was also observed in purified cultures of post-natal rat microglia. Western blot analyses of microglial cell layer PGs with the perlecan core protein antibody revealed a ~400 kDa core protein (suggestive of perlecan) following heparitinase digestion. Other lower  $M_r$  bands were also found implicating either degradation of the 400 kDa core protein or the presence of separate and distinct gene products immunologically related to perlecan. Following a 1-week continuous infusion of A $\beta$  (1-40) into rodent hippocampus, double and triple-labeled immunofluorescent studies revealed endogenous perlecan accumulation primarily localized to infiltrating microglia within the A $\beta$  infusion site. These studies suggest that microglia may represent one source of perlecan (or an immunologically related PG), which may be important for the ongoing accumulation of both perlecan and A $\beta$  in the amyloid deposits of AD. Partially supported by NIH AG12953-02 and AG05136.

## 81.6

**NEUROTOXICITY OF A $\beta$  PEPTIDE: CONFOCAL IMAGING OF CELLULAR CHANGES INDUCED BY  $\beta$ -AMYLOID IN RAT CNS *IN VIVO*.**

D.T. Wakdon, J.P. Cleary, W.P. Esler, J.R. Ghilardi, E. O'Hare, S.D. Rogers, S.O. Giraudo\*, J.E. Maggio, P.W. Mantyh. Behav Pharm and Mol Neurobiol Labs, VAMC and University of Minnesota, Minneapolis, MN 55417; Dept of Biol Chem and Mol Pharm, Harvard Medical School, Boston, MA 02115.

A key issue in Alzheimer's Disease (AD) is the relative contribution that soluble versus aggregated forms of A $\beta$  play in eliciting the reactive gliosis and neurotoxicity that are hallmarks of AD. To address this question, single 10  $\mu$ l injections of fibrillar A $\beta$ 1-40 aggregates ( $\approx$  2500 aggs/inj, av diam = 20  $\mu$ m), 10<sup>-4</sup> M soluble A $\beta$ 1-40 or saline were made into rat striatum or hippocampus. The cellular changes that occurred in response to these injections were then quantified using specific cell markers for microglia (OX-42), astrocytes (GFAP) and inducible nitric oxide synthase (iNOS) together with confocal microscopy, which allows single and intracellular resolution of cellular changes.

Injection of soluble A $\beta$  showed no significant increase in glial proliferation or activation beyond that induced by saline injection. In contrast, by 14 days, injections of A $\beta$  aggregates induced a significant increase in the number of OX-42+ microglia when compared to injections of soluble A $\beta$ , with microglia observed phagocytizing individual A $\beta$  aggregates. Similarly, by 30 days, injections of A $\beta$  aggregates induced a significant increase in GFAP+ astrocytes when compared to injections of soluble A $\beta$ , with astrocytes observed "walling off" the injection area. Expression of iNOS paralleled these trends and showed a marked increase over soluble A $\beta$  injections. These data demonstrate that injections of fibrillar A $\beta$  aggregates, but not soluble A $\beta$ , induce glial proliferation, activation and iNOS expression, which may mediate the neurotoxicity of A $\beta$  in the CNS. These data suggest that injection of aggregated A $\beta$  may prove an excellent model system for assessing A $\beta$  effects *in vivo* and for evaluating therapies for blocking A $\beta$  neurotoxicity. Supported by NIH (AG11852 & AG12853) and VA Merit Review.

## 81.8

**CHARACTERIZATION AND EVALUATION OF MMGT-16 CULTURE (A TRANSFORMED MURINE MICROGLIAL CELL LINE) AS A MODEL SYSTEM FOR STUDYING MICROGLIA AND EFFECTS OF POLYMERIZED A $\beta$  (1-40) ON THE VIABILITY OF MMGT-16 CULTURE**

F. Dean Miller<sup>1</sup>, Andre Van De Voorde<sup>2</sup>, Tony W. Briers<sup>2</sup>, Paul A. Hyslop<sup>1\*</sup>

Dept. CNS Research, Eli Lilly & Co., Lilly Corporate Center, Indianapolis, IN 46285. 2) Innogenetics, Industriepark Zwijnaarde 7, Box 4, B-9052 Gent, Belgium. Inflammation in the central nervous system (CNS) is thought to play a major role in the development and progression of chronic neurodegenerative diseases. It is also thought to be a major determinant in controlling the extent of neuronal cell damage following acute injury to the CNS. Activated microglia associated with the senile plaque in brains from Alzheimer's disease patients produce and secrete many known mediators of the inflammatory process. In order to further understand the role of microglial activation in the progression of Alzheimer's disease, we have further characterized the microglial cell line MMGT-16 [Briers, et al, J. Neuroimmunol., 52; 153, 1994]. We have confirmed that these cells secrete the appropriate cytokines (IL-1 $\beta$ , IL-1 $\alpha$ , TNF- $\alpha$ , and IL-6) when activated by LPS and also display the correct surface marker profile for microglia as measured by immunocytochemical methods. We have also shown that this cell line constitutively produces PGE<sub>2</sub> (2.8 ng/ml  $\pm$  0.25 ng/ml) during a 24 hr incubation and the mechanism of this production is under investigation. This cell line however does not secrete any of the above cytokines in the presence of 25 to 50  $\mu$ M A $\beta$  following 6 to 72 hr exposure. Furthermore, exposure of these cells to deposited fibrillar A $\beta$  also gave no enhancement of cytokine response. However, microglia exposed to the A $\beta$  fibrils maintain their viability following withdrawal of growth media for longer than control as measured by calcein fluorescence [3 day control 2900  $\pm$  81 RFUs, 3 day A $\beta$  treated 8490  $\pm$  885 RFUs]. This observation may indicate that microglia interacts with A $\beta$  and this mechanism of interaction is under investigation. (Funded by Eli Lilly and Company)

## 81.10

**MICROGLIAL RESPONSE TO ALZHEIMER  $\beta$ -AMYLOID PROTEIN.** B. Tate\*, J. Maguire, J. Newton and R. Majocha. Dept. Psychiatry and Human Behavior, Miriam Hosp. and Brown Univ., Providence, RI and McMaster Univ. and Hamilton Civic Hosp., Hamilton, ONT, Canada.

In Alzheimer's Disease, activated microglia are associated with dense  $\beta$ -amyloid deposits. *In vitro*,  $\beta$ -amyloid can stimulate microglia to become reactive. The *in vivo* microglial response to  $\beta$ -amyloid peptide 1-40 in mammalian brain was investigated. Rats were given intracranial ventricular (ICV) infusion of  $\beta$ -amyloid for 2-4 weeks. Light microscopic immunohistochemistry documented increased numbers of microglia including reactive glia surrounding amyloid deposits. Staining with antibodies to inducible nitric oxide synthase (iNOS) demonstrated iNOS expression in the area of amyloid deposition. At the ultrastructural level both diffuse and fibrillary amyloid were found within cells. Macrophages with intracellular amyloid were found surrounding blood vessels. The finding of intracellular fibrillary and diffuse amyloid suggests a role for cellular amyloid processing early in senile plaque formation and subsequent neuronal degeneration.

**BRAIN MICROGLIA CONTAIN FRAGMENTS OF AMYLOID  $\beta$ -PROTEIN IN ALZHEIMER'S DISEASE.** H. Akiyama<sup>1</sup>, H. Kondo<sup>1</sup>, H. Mori<sup>1</sup>, F. Kametani<sup>1</sup>, K. Ikeda<sup>1</sup>, C. Schwab<sup>2</sup>, E. G. McGeer<sup>2</sup> and P. L. McGeer<sup>2</sup>.  
<sup>1</sup>Tokyo Institute of Psychiatry, 2-1-8 Kamikitazawa, Setagaya-ku, Tokyo 156, Japan, and <sup>2</sup>Kinsmen Laboratory of Neurological Research, University of British Columbia, Vancouver, B.C., V6T 1W5, Canada

Microglia which contain granules that are immunopositive for C-terminal fragments of amyloid  $\beta$ -protein ( $A\beta$ ) appear around extracellular amyloid deposits in both aged control and Alzheimer's disease (AD) subjects. Brain macrophages in some AD patients with cortical ischemic lesions, also contain such granules. Granule containing cells are absent in control brains lacking  $A\beta$  deposits. The granules themselves are not recognized by antibodies specific for the N-terminal sequences of  $A\beta$ . These include  $A\beta$ 1 (specific for N-terminal Asp<sup>1</sup>), R17 ( $A\beta$ 8-17) and 6F/3D ( $A\beta$ 8-17). As far as the C-terminal regions are concerned, the vast majority are recognized by an antibody specific for the Ala<sup>42</sup>-Thr<sup>43</sup> region of  $A\beta$  but negative for the Val<sup>40</sup> region. This might be attributable to the relative paucity of  $A\beta$  fragments ending at Val<sup>40</sup> in extracellular  $A\beta$  deposits. Two antibodies 4G8 and 2F recognize N-terminally located epitopes of  $A\beta$  (17-24) peptide. Both 4G8 and 2F stain the majority of granules, although a small number which are negative for 4G8 and 2F are positive for E50 ( $A\beta$ 17-31) and  $\beta$ mid ( $A\beta$ 25-35). These data suggest that the granules are fragments of  $A\beta$  which have been cleaved between residues 17 and 24, with the N-terminal regions being degraded. We propose that  $A\beta$  is phagocytosed and processed by brain microglia and macrophages, and that the C-terminal fragments are more resistant to proteolysis than the N-terminal fragments.

**RAGE IN ALZHEIMER'S DISEASE: A RECEPTOR MEDIATING AMYLOID-BETA PEPTIDE-INDUCED ACTIVATION OF MICROGLIA.** Shi-Du Yan, Xi Chen, Jin Fu, Ming Chen, Huajie Zhu, Lei Zhao, Mariko Nagashima, John Morser, Alex Rohrer\*, David Stern, Ann Marie Schmidt. Columbia University, New York, NY 10032; Sun Health Res. Inst., Sun City, AZ 85372.

The immunoglobulin superfamily molecule RAGE has been previously characterized as a Receptor for Advanced Glycation Endproducts (RAGE) expressed by macrophages. Microglial expression of RAGE is enhanced in affected Alzheimer's brain, by immunostaining for RAGE and the microglial marker CD68. Transfection of COS-1 cells with the RAGE cDNA resulted in specific binding of amyloid-beta ( $A\beta$ ) peptide, Kd = 25 nM, compared with absence of such binding on mock-transfected controls. Primary cultures of rat microglia and the transformed microglial line of BV-2 cells expressed RAGE; binding of [<sup>125</sup>I]- $A\beta$  (1-40) to these cells was dose-dependent (Kd 50 nM), and was prevented by blocking RAGE with anti-RAGE IgG or by adding excess soluble RAGE (extracellular domain). Chemotaxis of BV-2 cells occurred in the presence of an increasing concentration gradient of soluble  $A\beta$  (1-40 or 25-35); this was prevented by blocking RAGE.  $A\beta$  adsorbed to the upper surface of the chemotaxis membrane prevented the migration of microglia in response to another stimulus, such as formyl-met-leu-phe. This was due to microglial RAGE engagement of the immobilized  $A\beta$ , as blocking RAGE allowed the cells to pass through the membranes as in controls coated with albumin or irrelevant peptides.  $A\beta$ -induced activation of microglia, assessed by activation of NF- $\kappa$ B and induction of tumor necrosis factor- $\alpha$  (TNF; the latter at the mRNA and protein level) were both blocked by anti-RAGE IgG. We propose that in Alzheimer's microglia migrate down a concentration gradient of soluble  $A\beta$ , their motility is arrested when they encounter immobilized  $A\beta$ , and they undergo sustained activation, due at least in part, to RAGE interaction with  $A\beta$ . **INDUCTION OF IMMEDIATE EARLY GENES BY  $\beta$ -AMYLOID PEPTIDE IN CULTURED GLIAL CELLS.** A. Copani<sup>1</sup>\*, A. Calogero<sup>2</sup> and F. Nicoletti<sup>2,3</sup>. Institute of Pharmacology, <sup>1</sup>School of Medicine or <sup>3</sup>Pharmacy, Catania University, Italy; <sup>2</sup>I.M.N. "Neuromed", Pozzilli, Italy.

$\beta$ -Amyloid peptide ( $\beta$ AP) induces apoptosis in cultured neurons, and its action is accompanied by a persistent increase in c-jun and an occasional and transient increase in c-fos expression (Anderson et al., J. Neurochem., 1995). Knowing that  $\beta$ AP induces morphological changes without apparent toxicity in astrocytes, we have studied the expression of immediate early genes (IEGs) in primary cultures of cortical glial cells exposed to  $\beta$ AP.  $\beta$ AP induced a substantial expression of Fos and Egr-1 proteins, which peaked between 3 and 6 hours and was no longer visible after 24 hours. The immunostaining was restricted to cell nuclei. In cultures arrested in G<sub>0</sub> and then committed to proliferate,  $\beta$ AP induced a longer-lasting increase in Egr-1 expression, which was still present after 20 hours. Whether or not the induction of IEGs by  $\beta$ AP is cell-cycle dependent is under investigation.

## 81.12

**LN3 IMMUNOPOSITIVE MICROGLIA ARE PRESENT WITHIN ALL SUBTYPES OF SENILE PLAQUES IN ALZHEIMER'S DISEASE.** Brian J. Cummings<sup>1,2</sup>, Shari L. Weinstein<sup>2</sup>, Arman Afagh<sup>2</sup> and Carl W. Cotman<sup>2</sup>. <sup>1</sup>Lab for Molecular Neuroscience, McLean Hospital, Harvard Medical School, 115 Mill St., Belmont, MA 02178 and <sup>2</sup>Institute for Brain Aging and Dementia, Irvine, CA.

Senile plaques are the major neuropathological hallmark of Alzheimer's disease (AD), yet it is unclear what role, if any, microglia play in plaque formation and maturation. We have undertaken a series of studies to help elucidate the time-course and contribution of different cellular elements to the development and maturation of senile plaques. For example, APP laden neurons are present within diffuse plaques (Cummings et al., 1992), while GFAP-immunopositive astrocytes are associated predominantly with thioflavine-positive "primitive" and "neuritic" plaques and are rarely observed in thioflavine-negative "diffuse" plaques (Pike et al., 1994). In the present study, tissue sections from mild, moderate and severely demented AD cases were simultaneously triple-labeled for  $A\beta$  (anti- $A\beta$ 42 and Cy3 fluorochrome), activated microglia (anti-LN3 and DAB peroxidase) and thioflavine S counter-staining to evaluate the relative level of thioflavine/S-sheet assembly and extent of microglial association within each plaque. One hundred randomly picked plaques per case were selected via  $A\beta$  immunoreactivity and evaluated by two blind observers on a semi-quantitative scale for (i) thioflavine intensity and (ii) extent of LN3-positive microglia. Inter-rater reliability for scoring was strong (0.92). Nearly 50% of diffuse plaques contained elevated numbers of LN3-positive microglia relative to the surrounding neuropil. The percentage of plaques containing LN3 positive microglia increased with increasing thioflavine intensity. Chi-square analysis indicates this relation is highly significant ( $p < 0.0001$ ). These results suggest that, unlike GFAP-immunopositive astrocytes, a subset of activated microglia (e.g. LN3-positive) are present in the initial stages of plaque formation. Alternatively, plaques may form/mature by more than one pathway. (Supported by AG00538 to C.W.C.)

## 81.14

**REGULATION OF  $\beta$ -AMYLOID PRECURSOR PROTEIN (APP) ISOFORM mRNAs AND PROTEINS BY SENILE PLAQUE ASSOCIATED CYTOKINES IN CULTURED NEURAL CELLS.** A.J. Patel, A. Jen, C. Wickenden, L.S. Jen and H.A.R. de Silva (SPON: Brain Research Association). MRC Neurodegenerative Disorders Group, Neurological Sciences Research Division, Charing Cross & Westminster Medical School, London W6 8RF, U.K.

Recently we proposed that in Alzheimer's disease the normal balance of metabolic pathways regulating plaque associated cytokines is disrupted. Reduction in cytokines may result in neurons being deprived of neurotrophic factors while an excess may initiate a cascade of interactions between glial cells and APP metabolism thereby facilitating plaque formation. In support of the latter proposal, we show that these cytokines play an important role in the regulation of neural cell specific splicing of APP. More than 90% of APP mRNAs expressed in astrocytes and microglia were of Kunitz inhibitor domain (KPI)-containing APP751 and APP770 isoforms, while neurons expressed mainly the non-KPI-containing APP695 isoform. Purified IgGs against N-terminal (AP-1), KPI (AP-2),  $\beta$ -amyloid (AP-4) and C-terminal (AP-5) stained discrete bands on Western blots of homogenates of neural cells. Levels of KPI-containing proteins were much greater in cultured astrocytes than neurons. In fimbria-fornix lesioned rat hippocampus, labelling of KPI-containing APP proteins was specifically increased in glial fibrillary acidic protein-positive reactive astrocytes. Treatment of cultured neural cells with plaque associated cytokines, basic fibroblast growth factor, transforming growth factor- $\beta$ 1 and interleukin-1 $\beta$ , significantly elevated the expression of APP isoform mRNAs and proteins in age- and neural cell-specific manner. The changes in the regulation of alternative splicing of the APP gene with excess production of the exon 8 containing isoform and no production of the exon 15 containing isoform would modify the properties and tertiary structure of APP protein, which, in turn, may change the patterns of APP trafficking, proteolysis and the production of  $\beta$ -amyloid peptide in the Alzheimer's brain. (Supported by MRC Grant).

## 81.16

**$\beta$ -AMYLOID STIMULATES METALLOPROTEINASES, PLASMINOGEN ACTIVATORS, AND THE DEGRADATION OF EXTRACELLULAR MATRIX PROTEIN IN RAT ASTROCYTES.** S. Deb\*, B. Bing and P. E. Gottschall. University of South Florida, Department of Pharmacology and Therapeutics, Tampa, FL 33612-4799

Senile plaques of Alzheimer's disease (AD) are characterized by the presence of  $\beta$ -amyloid ( $A\beta$ ) at the core and are associated with activated astrocytes and microglia, and dystrophic neurites. Recent studies indicate that components of the extracellular matrix (ECM), especially laminin, fibronectin and heparan sulfate proteoglycan, as well as ECM degrading enzymes, the matrix metalloproteinases (MMPs), are localized in and around senile plaques in AD brain. We have shown that  $A\beta$  (1-40) induces MMP-9, MMP-2 and MMP-3 production in rat mixed hippocampal and astrocyte cultures. The aim of this study was to further elucidate whether  $A\beta$  induces the production of ECM-degrading enzymes and if this stimulation of enzyme influences the stability of ECM components.  $A\beta$  (1-42) was a potent inducer of gelatinase (Glase) activity in rat astrocyte cultures. Also, increased plasminogen activator-like activity (measured by plasminogen-casein zymography) was observed in conditioned medium obtained from  $A\beta$  (1-40)-treated astrocytes compared to untreated cells. Astrocyte  $A\beta$ -treated conditioned medium, when immunoblotted for fibronectin using polyclonal anti-rat fibronectin, showed several lower molecular weight products indicative of degradation of the protein. These products were observed to a significant lesser degree in control conditioned medium. The molecular weight of these products were 160, 100, 72, 56 and 47 kDa. Thus,  $A\beta$  peptides including  $A\beta$  (1-42) induce Glase and plasminogen activator-like activities in astrocyte cultures. In addition,  $A\beta$  appeared to stimulate the release of enzymes capable of degrading fibronectin. (supported by NIH AG12160)

**ACTIVATION OF CULTURED ASTROCYTES BY AMYLOID  $\beta$  PEPTIDE.** K.T. Akama\*, J. Hu, L.-M. Zhou, G.A. Krafft, and L.J. Van Eldik. Depts of Cell and Molecular Biology, and Mol Pharmacology and Biological Chemistry, Northwestern University Medical School, and Northwestern Univ. Institute for Neuroscience, Chicago, IL 60611.

One common feature of many neurodegenerative disorders, including Alzheimer's disease (AD), is the presence of large numbers of activated astrocytes and microglia. Glial activation involves morphological changes (enlargement of the cell soma, hypertrophy of nuclei, and process elaboration) and changes in expression of a variety of proteins. In AD, activated astrocytes surround the neuritic shell of the amyloid plaque, and activated microglia are near the center of the neuritic shell adjacent to the core of amyloid  $\beta$  protein (A $\beta$ ). There are a number of stimuli that lead to glial activation, but the relationship between glial activation and disease progression is not known. We evaluated the possibility that A $\beta$ , a primary constituent of plaques, contributes to glial activation by testing the effects of aggregated A $\beta$  peptides on cultures of rat cortical astrocytes. In contrast to its neurotoxic effects, A $\beta$  did not significantly decrease astrocyte viability. Instead, A $\beta$  induced astrocyte activation, as assessed by reactive morphological changes and upregulation of selective glial mRNA and proteins, such as the inflammatory cytokine IL-1 $\beta$ . A $\beta$  1-42, a major form of amyloid associated with neurotoxicity, activated astrocytes in a time- and dose-dependent manner, whereas A $\beta$  17-42 (the A $\beta$  form associated with diffuse plaques) had little or no effect. Our data suggest that part of the neurodegenerative cascade in AD involves effects of A $\beta$  on glial cells, perhaps contributing to the progression of toxicity by release of glial factors that exacerbate or attenuate A $\beta$  function (supported in part by NIH grant AG10481).

## DEGENERATIVE DISEASE: ALZHEIMER'S-BETA-AMYLOID-NEUROPROTECTION

## 82.1

**NEUROPROTECTIVE EFFECTS OF INSULIN-LIKE GROWTH FACTOR I AGAINST TOXICITY INDUCED BY INTERLEUKIN-15, HUMAN AMYLIN AND  $\beta$ -AMYLOID PEPTIDES IN CULTURED HIPPOCAMPAL NEURONS.** S. Doré\*, S. Bastianetto, F. Mennicken, S. Kar and R. Quirion. Douglas Hospital Research Centre, McGill University, Montréal, Québec, Canada, H4H 1R3.

Multiple evidence suggests the critical importance of the insulin-like growth factor I (IGF-I) in the maintenance of tissues integrity. IGF-I acts via specific receptors uniquely distributed throughout the brain, being especially concentrated in the hippocampal formation (eg. Quirion *et al.*, this meeting). We recently reported that IGF-I was able to protect against  $\beta$  amyloid-induced toxicity in primary hippocampal neuronal cultures (Doré *et al.* Soc. Neurosci. Abst 21, 475, 1995). Our objective was to evaluate if this neuroprotective action was unique to A $\beta$  toxicity (A $\beta$ <sub>25-35</sub>: 30 $\mu$ M; A $\beta$ <sub>1-42</sub>: 20 $\mu$ M) or applicable to other models such as toxicity induced by human amylin (30 $\mu$ M; rat amylin being ineffective) and interleukin-15 (IL-15: 50ng/ml; Mennicken *et al.*, this meeting). Rat hippocampi were dissected from E19 rat embryos and grown in DMEM for 6 days under serum-free conditions with B-27 as supplement. Neurons were treated with the various peptides for another 6 days in a Neurobasal medium with N-2 supplement with or without IGF-I. The neurotoxicity was determined using the MTT colorimetric assay which is an index of mitochondrial activity. Interestingly, IGF-I (10-100nM) was found to significantly protect the neurons against these various types of toxicity in a time and concentration-dependent manner. IGF-I is thus able to act as a rather global neuroprotective agent. Supported by the MRCC and the Alzheimer Society of Canada.

## 82.3

**REDUCTION OF BETA-AMYLOID NEURONAL TOXICITY BY HIGH DENSITY LIPOPROTEIN.** Z.S. Farhangrazi\*, L.M.T. Canzoniero<sup>1</sup>, S.L. Sensi<sup>1</sup>, G. Bu<sup>2</sup>, L.L. Dugan<sup>1</sup>, D. Holtzman<sup>1</sup>, D.W. Choi<sup>1</sup>. <sup>1</sup>Center for the Study of Nervous System Injury and Dept. of Neurology, and <sup>2</sup>Edward Mallinckrodt Department of Pediatrics and Molecular Biology and Pharmacology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Recently, a major genetic risk for Alzheimer's disease (AD) was identified to be the  $\epsilon$ 4 allele of apolipoprotein E (apoE). It is thus of interest to examine the ability of lipoproteins to influence the neurotoxicity of beta-amyloid (A $\beta$ ). In the CSF, both apoE and some A $\beta$  are found within high density lipoprotein (HDL) particles.

In this preliminary study, we examined the effect of adding HDL upon the toxicity of A $\beta$  (1-42) on cultured murine cortical neurons. Cultures exposed to 30  $\mu$ M A $\beta$  exhibited widespread neuronal degeneration without astrocyte degeneration 48 hr later. We found that inclusion of HDL purified from human serum in the exposure medium markedly reduced A $\beta$  toxicity, in a dose dependent manner, over the range 5-100  $\mu$ g/ml cholesterol. One possible mechanism for this protective effect is an ability of HDL to associate with A $\beta$  and perhaps reduce the A $\beta$  aggregation required for neurotoxicity. We also found that a significant amount of A $\beta$  associates with HDL using a column assay.

These results support the idea that lipoproteins within the brain may substantially influence the neurotoxic potential of A $\beta$ . Supported by NIH NINDS grant NS 32636 (DWC).

## 81.18

**Alpha-1-antichymotrypsin secretion from human astrocytoma cells induced by amyloid  $\beta$ .** B. D. Gitter\* and J. Hackett. Central Nervous System Research Division, Lilly Research Labs., Lilly Corp. Ctr., Indianapolis, IN 46285.

Neurodegenerative processes in Alzheimer's disease (AD) are thought to be driven in part by the deposition of amyloid  $\beta$  (A $\beta$ ), a 39-43 amino acid peptide product resulting from an alternative cleavage of amyloid precursor protein (APP). A $\beta$  may promote AD neuropathology directly through its neurotoxic effects or indirectly by activating immune/inflammatory pathways. In support of the latter hypothesis, we have recently shown that A $\beta$  potentiates inflammatory cytokine secretion from interleukin-1 (IL-1)-stimulated human astrocytoma cells (Proc. Natl. Acad. Sci., 92, 10738-10741, 1995).  $\alpha$ -1-antichymotrypsin (ACT), an acute phase reactant produced by astrocytes and found in close association with compact neuritic plaques, may also be secreted from A $\beta$ -stimulated cells. Here we report that A $\beta$  can activate human astrocytoma (U-373 MG) cells to secrete ACT. Freshly prepared A $\beta$  (2-50  $\mu$ M) or human IL-18 (0.01-10 ng/ml) dose-dependently induced an increase in ACT secretion from U-373 MG cells. At the highest concentrations tested, 100% (with A $\beta$ ) and 340% (with IL-18) increases in ACT secretion were observed (determined by Western blotting and densitometric scanning). The effects of combining these treatments (50  $\mu$ M A $\beta$  + 0.01-10 ng/ml IL-18) were additive. In addition, significant increases in ACT secretion were not detected from A $\beta$ (25-35)-treated U-373 MG cells. Since ACT may promote A $\beta$  fibrillogenesis and regulate APP processing, increased ACT secretion by A $\beta$ -stimulated astrocytes may exacerbate AD neuropathology. This study was fully funded by Lilly Research Laboratories, a division of Eli Lilly & Co.

## 82.2

**PROTECTIVE EFFECTS OF TRANSFORMING GROWTH FACTORS- $\beta$  AGAINST CYTOTOXICITY OF  $\beta$ -AMYLOID PEPTIDE IN HUMAN POSTMITOTIC NEURONS.** Renee F. Ren\*, Richard S. Kim and Kathleen C. Flanders. Laboratory of Chemoprevention, National Cancer Institute, NIH, Bethesda, MD 20892

In a previous study in rat hippocampal neurons, we observed that transforming growth factors- $\beta$  (TGFs- $\beta$ ) can protect cells from neuronal degeneration induced by  $\beta$ -amyloid peptide fragment 25-35 (BAP). This finding could be valuable for protection of neurons in Alzheimer's disease (AD) if this phenomenon also appears in human neurons. Here we report similar protective effects in human postmitotic neurons (hNT neurons). The hNT neurons were generated by treating the human teratocarcinoma cell line NT2/D1 with retinoic acid for 14 weeks, inducing the expression of markers of terminally differentiated neurons. Cells were treated with 10 ng/ml TGF- $\beta$ 1 for 24 h before being exposed to 10<sup>-5</sup> M BAP. After 24 h exposure to BAP, morphological examination following MTT incorporation showed that the TGF- $\beta$  treated cells had a significant increase in cell viability compared to cells not pretreated with TGF- $\beta$ . Studies using reverse transcription-polymerase chain reaction (RT-PCR) revealed endogenous expression of TGF- $\beta$ s in hNT cells. Semi-quantitative RT-PCR showed that treatment with BAP resulted in little change in mRNA levels of TGF- $\beta$ 1 and TGF- $\beta$ 3, while TGF- $\beta$ 2 mRNA increased approximately 4-fold. The mRNA level of amyloid precursor protein (hAPP 770, 751) was decreased approximately 2-fold. Interestingly, the protective effects of TGF- $\beta$ s were not found in NT2/D1 cells from which hNT neurons are derived. Our preliminary results show that TGF- $\beta$  type II receptor, that is expressed in hNT cells, is not detectable in NT2/D1 cells, suggesting the protective effects of TGF- $\beta$  are probably mediated by the TGF- $\beta$  Type II receptor.

## 82.4

**ZINC ATTENUATES AMYLOID  $\beta$  (A $\beta$ )1-40 NEUROTOXICITY.** K.S. Fuson\*, L.N. Boggs, and P.C. May. Lilly Research Laboratories, CNS Research Division, Eli Lilly and Company, Indianapolis, IN 46285.

Amyloid-beta peptide (A $\beta$ ) is a major component of senile plaques found in Alzheimer's disease (AD) brain regions important for cognition and memory. While both soluble A $\beta$  and zinc are found in cerebrospinal fluid (CSF), recent *in vitro* studies have stated that zinc binds to A $\beta$  and induces aggregation of the peptide. These *in vitro* A $\beta$ -zinc interactions have led some investigators to propose that an altered zinc metabolism in AD patients may contribute to A $\beta$  pathology. Using primary fetal rat hippocampal cultures, we examined the effect of zinc on the neurotoxic properties of multiple lots of synthetic A $\beta$  1-40 (Bachem). The co-addition of zinc with A $\beta$  caused a dose dependent attenuation of A $\beta$  neurotoxicity with 50  $\mu$ M zinc affording complete neuroprotection against 25 - 50  $\mu$ M A $\beta$ . Similar concentrations of zinc conferred no protection against kainate or hydrogen peroxide neurotoxicity, suggesting a specific zinc-A $\beta$  peptide interaction. Co-treatment of cultures with the metal chelator o-phenanthroline (o-P) could reverse most of the A $\beta$  neuroprotection afforded by zinc. However, the intrinsic neurotoxicity of o-P limited our testing capacity in these hippocampal cultures. Interestingly, the intrinsic neurotoxic properties of o-P could be blocked by co-treating cultures with zinc. May *et al* (accompanying abstract) show that zinc interfered with the cellular deposition of A $\beta$  (as measured by thioflavin S fluorescence) under the same conditions used to assess zinc neuroprotection. Thus, zinc may protect against A $\beta$  neurotoxicity by interfering with A $\beta$  deposition. [Eli Lilly & Co.]

## 82.5

**ZINC INTERFERES WITH A $\beta$ (1-40) DEPOSITION ONTO CULTURED NEURONS: CORRELATION WITH NEUROPROTECTION.** P.C. May<sup>1</sup>, L.N. Boggs, Z. Zhang, G.J. Drzewiecki, P.A. Hyslop and K.S. Fuson. CNS Div., Lilly Research Labs, Eli Lilly and Co., Indianapolis, IN 46285

Aggregation of A $\beta$  appears to be a critical determinant for neurotoxicity and recent studies suggest that Zn can modulate A $\beta$  aggregation in vitro. However, in the accompanying abstract (Fuson et al.) we demonstrate that Zn co-treatment affords dose-dependent neuroprotection against A $\beta$  toxicity. To explore the mechanism of Zn neuroprotection, we evaluated A $\beta$  deposition onto cultured rat hippocampal neurons in the presence and absence of zinc. Primary mixed hippocampal cultures were treated with 25  $\mu$ M A $\beta$  (Bachem ZM605) in N2/DMEM. At various times after treatment, conditioned media was removed for analysis of LDH. A $\beta$  remaining adherent to the cultures was quantified by addition of thioflavin-S (ThS) to 0.2% and the fluorescence shift measured in a cytofluorimeter. A significant fraction (> 50%) of aggregated A $\beta$  deposited in the culture by 24 hours and maximal deposition occurred at 48 hours. Interestingly, water-lysed wells containing only cell-derived extracellular matrix components, did not support the deposition of A $\beta$  at these time points, suggesting some requirement for intact cells. Co-treatment of cultures with 50  $\mu$ M zinc and 25  $\mu$ M A $\beta$  markedly interfered with the formation of adherent ThS-positive A $\beta$  deposits. Control experiments confirmed that Zn did not interfere with detection of pre-formed A $\beta$  deposits by ThS fluorescence. These data suggest that A $\beta$  deposition precedes overt neurotoxicity by 24-48 hours. Moreover, neuroprotection from A $\beta$  by zinc may result from interference with the deposition of ThS-positive A $\beta$  aggregates in vitro. [Eli Lilly & Co.]

## 82.7

**A SECRETED FORM OF THE AMYLOID PROTEIN PRECURSOR (APP<sub>751</sub>) ENHANCES MEMORY IN VISUAL DISCRIMINATION AND OPERANT TASKS IN NORMAL AND AMNESTIC MICE.** H. Meziane<sup>1</sup>, C. Mathis<sup>1</sup>, J. Clemens<sup>2</sup>, S. Little<sup>2</sup>, A. Ungerer<sup>1</sup> and S.M. Paul<sup>2</sup>. <sup>1</sup>Lab Ethol & Neurobiol, URA-CNRS 1295, ULP, Strasbourg, France; <sup>2</sup>Lilly Res Lab, Indianapolis, 46285, USA.

In some early-onset cases of Alzheimer disease, abnormal proteolytic processing of the amyloid protein precursor (APP) is believed to lead to  $\beta$ -amyloid peptide accumulation in extracellular neuritic plaques. However, the normal physiological function(s) of APP is/are unknown. Secreted forms of APP (APP<sub>751</sub> or APP<sub>695</sub>) have neuroprotective actions in a number of neurodegeneration models. The intracerebroventricular (i.c.v.) administration of anti-APPs antisera induces memory impairment in rats performing a passive avoidance task (Huber et al., 1993). In the present study, the possible memory-enhancing effects of APP<sub>751</sub> were studied following i.c.v. administration of APP<sub>751</sub> to mice either alone or following scopolamine administration using both a Go-No Go visual discrimination and operant learning tasks. Administration of scopolamine (3 mg/kg, s.c.) after the first session of training impairs learning during the second and third daily sessions in the visual discrimination task. Administration of APP<sub>751</sub> (0.05 - 5000 pg, i.c.v.) after the first session of training, dose-dependently blocks learning deficits induced by scopolamine, with the most potent effect at doses of 5 and 50 pg. In addition, APP<sub>751</sub> (0.5 and 5 pg i.c.v.) has a memory-enhancing effect when administered alone after the first training session. Post-training administration of APP<sub>751</sub> (5 pg i.c.v.) also reduces learning deficits induced by 3 mg/kg scopolamine in the operant bar-press task. In a traction reflex test, scopolamine (3 mg/kg s.c.) causes motor disturbances when administered 15 min before the first session. These deficits disappeared 24 h later and suggest that memory deficits induced by scopolamine are not related to its motor effects. Furthermore, APP<sub>751</sub> (5 pg i.c.v.) co-administered with scopolamine does not block these motor deficits, which suggest that APP<sub>751</sub> has a specific action on memory processes.

## 82.9

**THE ACETYL-L-CARNITINE DERIVATIVE ST857 PREVENTS  $\beta$  25-35 INDUCED-NEUROTOXICITY IN CEREBELLAR GRANULE CELLS.** S. A. Scorziello, S. O. Meucci, M. Calvani, and S. G. Schettini\*. <sup>\*</sup>Chair of Pharmacology, Department of Clinical and Experimental Oncology, University of Genoa, Unit of Neuroscience, Advanced Biotechnology Center (ABC), National Institute for Cancer Research (IST), <sup>†</sup>Department of Neuroscience, Section of Pharmacology, University of Naples "Federico II", <sup>‡</sup>Sigma-Tau Gathered Pharmaceutical Industries, ITALY.

We studied the effect of ST857 on  $\beta$  25-35-induced neurotoxicity in cerebellar granule cells and the intracellular mechanisms involved. Cells at different stages of maturation in vitro (1 or 6 DIV), were treated with  $\beta$  25-35 and ST857 in presence of 25 mM KCl in the culture medium, and neuronal viability was assessed by morphological criteria. The treatment for 3 days with the peptide slightly modified the survival of 1 DIV-treated cerebellar granule cells, which degenerate and die five days later  $\beta$ -amyloid matching. Similarly, a significant neurotoxic effect was observed on 6 DIV treated-cells after 5 days of treatment, while the death occurred within 8 days. Coincubation with  $\beta$  25-35 and ST857 was able to rescue neurons from  $\beta$  25-35-induced neurotoxicity.

We also studied the changes in calcium homeostasis following glutamate stimulation, in control and  $\beta$ -amyloid treated single cells, either in presence or in absence of ST857.  $\beta$  25-35 did not affect basal  $[Ca^{2+}]_i$ , while modified glutamate-induced  $[Ca^{2+}]_i$  increase, causing a sustained plateau phase of  $[Ca^{2+}]_i$ , that persisted after the removal of the agonist. ST857 pretreatment completely reverted this effect suggesting that, in cerebellar granule cells chronically treated with  $\beta$  25-35, ST857 could protect the cells by neurotoxic insults of the peptide likely interfering with the intracellular mechanisms involved in the control of calcium homeostasis.

## 82.6

**Reduction of A $\beta$  Fibril Formation and Neurotoxicity by Native or Activated  $\alpha_2$ -Macroglobulin**

Y. Du<sup>1\*</sup>, B. Ni<sup>1</sup>, M. Glinn<sup>1</sup>, J. W. Hom<sup>2</sup>, E. Hamilton-Byrd<sup>1</sup>, X. Wu<sup>1</sup>, K. Bales<sup>1</sup>, X. Liu<sup>1</sup>, S. P. Little<sup>1</sup> and S. M. Paul<sup>1,3</sup>. <sup>1</sup>Division of CNS, Research, <sup>2</sup>Toxicology, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285 and <sup>3</sup>Departments of Pharmacology and Toxicology and Psychiatry, IU School of Medicine, Indianapolis, IN 46285

The amyloid  $\beta$  (A $\beta$ ) peptide is a normal proteolytic processing product of the amyloid precursor protein (APP). For reasons which are still unclear, the A $\beta$  peptide is deposited in an aggregated fibrillar form in both diffuse and senile plaques in the brains of patients with Alzheimer's disease (AD). The factors responsible for aggregation and fibril formation of soluble A $\beta$  present in biological fluids or tissues are poorly understood. We now report that  $\alpha_2$ -macroglobulin ( $\alpha_2$ M) and  $\alpha_1$ -antitrypsin ( $\alpha_1$ T) regulate A $\beta$  fibril formation and toxicity. The addition of aged A $\beta$ 1-40 (25  $\mu$ M) to cultured fetal rat cortical neurons results in significant cell death following 2-3 days of exposure. However, the addition of native  $\alpha_2$ M ( $\geq$  50  $\mu$ g/ml) significantly reduces A $\beta$  toxicity of these neurons compared to parallel cultures exposed to A $\beta$  alone. ACT (100  $\mu$ g/ml) enhances A $\beta$  neurotoxicity and  $\alpha_2$ M attenuates the toxicity of neurons exposed to A $\beta$  and ACT. Fibrils formed by insoluble A $\beta$  were examined by electron microscopy and thioflavin-T fluorescence. Incubation of A $\beta$ 1-40 alone for 3 d at 37°C in PBS resulted in the formation of 8 nm filaments and increasing thioflavin-T fluorescence. When A $\beta$ 1-40 was coincubated with ACT, more fibril formation was observed. Incubation of  $\alpha_2$ M with A $\beta$ 1-40 led to the formation of fewer fibrils than A $\beta$ 1-40 only at 3 d. No protease activity was detected in native  $\alpha_2$ M (500  $\mu$ g/ml). Moreover, trypsin (also expressed in AD brain)-activated  $\alpha_2$ M ( $\alpha_2$ T) is able to degrade A $\beta$ , preventing formation and toxicity. ACT appears to inhibit  $\alpha_2$ T-mediated degradation of A $\beta$  possibly by decreasing binding of A $\beta$  to  $\alpha_2$ T. We postulate that  $\alpha_2$ M inhibits A $\beta$  fibril formation by binding to A $\beta$  and that protease-activated  $\alpha_2$ M may represent a clearance mechanisms for A $\beta$ .

## 82.8

**THE NONPSYCHOTROPIC CANNABINOID HU-211 RESCUES HIPPOCAMPAL NEURONES FROM  $\beta$ -AMYLOID PEPTIDE INDUCED TOXICITY.** Striem S., Lavie V.\* and Biegon A.

Pharmos Ltd., Kiryat Weizman, Rehovot 76326, Israel.

The synthetic cannabinoid HU-211 that lacks psychotropic effects, has been shown to act as a noncompetitive NMDA-receptor antagonist in vivo and in vitro. In vitro studies revealed that HU-211 possesses an overall broader spectrum of neuron protective activities and mechanisms as compared to other NMDA-receptor antagonists, such as: (a) preventing lipid peroxidation triggered by peroxyl radicals, (b) inhibiting protein oxidation, (c) acting as a reducing agent and (d) protecting neurons from sodium nitroprusside-induced toxicity. In the present study we further characterize its neuroprotective effects and mechanism of action. Primary hippocampal cultures, derived from 18-day old rat embryos, were exposed for 24 hours to various concentrations of the synthetic  $\beta$ -amyloid peptide,  $\beta$ -22-35 ( $\beta$ APP), either alone or in concert with 3 - 5  $\mu$ M HU-211. "Aged" (incubated for five days at 37°C)  $\beta$ APP at concentrations of 5 - 30  $\mu$ M was toxic to the neurones in a dose-dependent manner (42.1% - 100% toxicity). HU-211 present with all the  $\beta$ APP concentrations was significantly protective against this toxicity:  $\beta$ APP at 20  $\mu$ M was 100% toxic while HU-211 at 5  $\mu$ M showed 79.7  $\pm$  6.3% rescue. These results are consistent with previous works that suggested that the  $\beta$ -amyloid peptide toxicity is mediated by destabilization of calcium homeostasis. HU-211 may attenuate this toxic effect by blocking the influx of calcium ions into the neurones, although other mechanisms of action are not excluded.  $\beta$ -amyloid protein deposition in the core of the senile plaques is a hallmark of Alzheimer's disease. The present work suggests possible therapeutic implications of HU-211 in Alzheimer's disease.

## 82.10

**PROTECTIVE EFFECT OF CATECHIN AGAINST  $\beta$ -AMYLOID TOXICITY IN HIPPOCAMPAL NEURONS AND PC12 CELLS**

K. Shin-ya\*, T. Kunigami and H. Seo. Institute of Molecular and Cellular Biosciences, The University of Tokyo, Bunkyo-ku, Tokyo 113, Japan

Alzheimer's disease is associated with accumulation of  $\beta$ -amyloid peptide and disappearance of specific neurons.  $\beta$ -Amyloid has been shown to induce neuronal cell death in vitro.

In the course of our screening for substances to inhibit the toxicity of  $\beta$ -amyloid peptide, we isolated catechin from a traditional medicinal plant, guarana. To estimate the protective effects of catechin against  $\beta$ -amyloid toxicity, we have employed the system reported by Behl et al. (Cell, 77, 817-827 (1994)). Vitamin E which was reported to show the protective effect against  $\beta$ -amyloid toxicity, was used as a positive control. Catechin and vitamin E protected hippocampal neurons from the  $\beta$ -amyloid toxicity at concentrations of 50  $\mu$ M and 100  $\mu$ M, respectively.  $\beta$ -Amyloid peptide decreased MTT reduction in PC12 cells. In this system, catechin completely recovered the MTT reduction rate at a concentration of 50  $\mu$ M, whereas the effect of vitamin E to the same system was partial.

Since the toxicity of  $\beta$ -amyloid is considered to involve oxygen radicals, we assessed the intracellular oxygen radicals. In hippocampal neurons  $\beta$ -amyloid peptide significantly increased intracellular oxygen radicals, which were suppressed by the addition of catechin and vitamin E. In contrast,  $\beta$ -amyloid did not affect the intracellular oxygen radical level in PC12 cells. Other antioxidants, which were known to scavenge directly intracellular oxygen radicals, did not show protective effects against the  $\beta$ -amyloid toxicity in both hippocampal neurons and PC12 cells.

We next evaluated the function of mitochondria, which acts as the main source of MTT reduction.  $\beta$ -Amyloid markedly suppressed the mitochondrial function in hippocampal neurons. On the other hand it had no effect on the mitochondrial function in PC12 cells, even though it decreased MTT reduction. In addition, catechin and vitamin E did not recover the mitochondrial function in hippocampal neurons. These results indicate that  $\beta$ -amyloid peptide acts on hippocampal neurons and PC12 cells through different mechanisms.

## 82.11

BETA-AMYLOID TOXICITY IN CULTURED NEURONS IS NOT BLOCKED BY STANDARD ANTIOXIDANTS. B.J. Hamilton\*, D.D. McKinley, J.S. Althaus and D.B. Carter. CNS Research, Pharmacia & Upjohn, Inc., Kalamazoo, MI 49001.

Beta-amyloid peptide (A $\beta$ ), a primary component of senile plaques, is a predominant neuropathological feature of Alzheimer's disease. Several studies have suggested a direct neurotoxic effect by A $\beta$ . One possible mechanism of action for A $\beta$  toxicity is through the generation of free radicals. To investigate this hypothesis, we utilized an *in vitro* tissue culture cell model system. Using both continuous cell culture and primary cell lines, we demonstrate a cytotoxic response to A $\beta$  (25-35) by the inhibition of cellular redox activity as measured by MTT reduction. This inhibitory response occurred at concentrations of peptide at which no decrease in cell viability was observed, suggesting that this assay is an early indicator of cell damage. The pyrrolopyrimidine, U-104067, shows a weak protective effect against A $\beta$  toxicity in this assay. In contrast to numerous published reports, no other antioxidants, including Vitamin E, acetyl cysteine and other low oxidation potential pyrrolopyrimidines have shown a significant protective effect. The lack of robust efficacy of antioxidant pyrrolopyrimidine compounds in addition to the lack of efficacy of some standard antioxidants in this assay indicates that processes other than those associated with oxidative damage may be involved in beta amyloid toxicity on cultured cells.

## 82.13

A PRODUCT(S) FROM A MONOCYTE CELL LINE (RAW 264.7) PROTECTS CULTURED CHOLINERGIC NEURONS FROM  $\beta$ -AMYLOID NEUROTOXICITY. G. M. Jonakait, Y. Wan, G. E. Ringheim, and L. Ni\*. Dept. of Biological Sciences, Rutgers University, Newark, NJ 07102 and Hoechst Marion Roussel, Bridgewater, NJ 08807.

In cultures of embryonic septal nuclei with adjacent basal forebrain (SN/BF), treatment with  $\beta$ -amyloid (250  $\mu$ g/ml) results in a  $67.6 \pm 5.1\%$  loss of choline acetyltransferase (ChAT) activity, one measure of cholinergic neuronal survival. In previous studies, we have identified a soluble factor(s), obtained from media conditioned by either activated microglia or by a murine macrophage/monocyte cell line RAW 264.7 (RAW-CM), that promotes cholinergic differentiation of undifferentiated precursors (Jonakait et al., *Dev. Biol.*, in press). When included with  $\beta$ -amyloid, RAW-CM restores ChAT activity to control or above-control levels. Neurotrophins (NGF, BDNF, NT3, and NT4) had no such protective effect. Basic FGF (10 ng/ml) was as effective as RAW-CM in restoring ChAT levels.

Anti-oxidants were also tested for their ability to protect against  $\beta$ -amyloid neurotoxicity. Both  $\beta$ -mercaptoethanol (0.0003%) and N-acetylcysteine (1.5 mM) -- even in the presence of neurotoxic concentrations of  $\beta$ -amyloid -- elevated ChAT 2.5-5-fold, suggesting that they, too, protected against  $\beta$ -amyloid neurotoxicity in this population.

## 82.15

A $\beta$ 1-42 NEUROTOXICITY AND THE INFLUENCE OF NMDA RECEPTOR ANTAGONISTS. G.K. Rieke\* and K. Jacobson. Dept. of Anat. & Cell Biol., Sch. of Med. & Health Sci., Univ. of North Dakota, Grand Forks, ND 58202.

The neurotoxicity of the beta amyloid protein fragment A $\beta$ 1-42 is an issue of intense interest with respect to the neuropathology of Alzheimer's Disease. Neurons in the hippocampus/dentate gyrus (HP/DG) die in response to chronic challenge with A $\beta$ 1-42. Does the NMDA receptor which is present at high density on HP/DG neurons, participate in the expression of A $\beta$ 1-42 neurotoxicity? Male Sprague Dawley rats anesthetized with pentobarbital had cannulas implanted, under sterile conditions, into the dorsal HP/DG. Test substances (A $\beta$ 1-42 [0.22 nmol/ $\mu$ L], AP-5 [0.22 nmol/ $\mu$ L, pH 7.4]) were delivered through guide cannulas or cannulas coupled to Alzet (2004) pumps. Co-injection of AP-5 with A $\beta$ 1-42 attenuated the toxicity of the peptide. The calculated volume of the A $\beta$ 1-42 lesion was five times larger than the A $\beta$ 1-42/AP-5 lesion. A $\beta$ 1-42/AP-5 resulted in a limited localized reduction of HP pyramidal cells, while A $\beta$ 1-42 alone destroyed HP pyramidal cells and induced apoptosis in many DG granule cells. Other NMDA receptor antagonists (MgCl, AP-7, CGS 19755) are being tested to determine if they have can ameliorate the toxicity of A $\beta$ 1-42 similar to AP-5.

Supported by UND SOM Grant to G.K. Rieke.

## 82.12

CYTOTOXICITY OF  $\beta$ -AMYLOID PEPTIDE 25-35 ON A CULTURED VASCULAR SMOOTH MUSCLE CELL MONOLAYER AND ATTENUATION BY VITAMIN E AND GARLIC. E. T. Gwebu\*, M. Selassie, J. Williams, B. Webb, J. Warden. Department of Chemistry, Oakwood College, Huntsville, Alabama 35896.

A hallmark feature of Alzheimer disease is the presence of insoluble deposits of  $\beta$ -Amyloid peptide (A $\beta$ ) on vascular walls and other tissues. Cultured vascular smooth muscle cells accumulate A $\beta$ , (J. Frackowiak et al. Brain Res. 676: 225; '96) and the  $\beta$ -Amyloid protein precursor is bound to the media of blood vessels (M. Kawai et al. Brain Res. 623: 142; '93). Neuronal death induced by the A $\beta$  peptide is prevented by vitamin E (C. Behl et al. Biochem. Biophys. Res. Commun. 186: 944; '92). The A $\beta$  is toxic to vascular endothelial cells (E. Blanc et al. FASEB J. 10: Abstract #3911, '96).

The purpose of this study was to determine the extent to which A $\beta$  is cytotoxic to vascular smooth muscle cells (VSMC) and possible attenuation of this toxicity by vitamin E and garlic. A primary culture of vascular smooth muscle cells was prepared and experiments performed at passage 3-4 using "aged" A $\beta$ . The methylthiothiazolium (MTT) assay was used to determine cell death. In this report, we show that A $\beta$  is toxic to VSMC. This A $\beta$  toxicity is attenuated by the antioxidant, vitamin E and garlic.

Funded by NIGMS/NIH MBRS Grant # S14-GM 48439-03

## 82.14

DOMINANT NEUROPROTECTIVE EFFICACY OF  $\alpha$ -SECRETASE DERIVED SECRETED-APP MEDIATED BY HEPARIN-BINDING DOMAIN OF A $\beta$ . K. Furukawa\*, B. L. Sopher, R.E. Rydel, G.M. Martin, M. Fox, and M.P. Mattson. Sanders-Brown Research Center on Aging, Univ. Kentucky, Lexington KY 40536. Dept. of Pathology, Univ. of Washington, Seattle, WA 98195. Athena Neurosciences, Inc., South San Francisco, CA 94080.

$\beta$ -amyloid precursor protein (BAPP) is known to be a source of amyloid  $\beta$  peptide (A $\beta$ ) and secreted forms of BAPP (sAPP). We have reported that A $\beta$  kills neurons by destabilizing cellular calcium homeostasis (*J. Neurosci.* 12: 376-89) and increasing reactive oxygen species (*J. Neurosci.* 15: 6239-49), and that sAPPs protect neurons by activating K $^{+}$  channels and stabilizing cellular calcium homeostasis (*Nature* 379: 74-78). Different sAPPs (sAPP $\alpha$  and sAPP $\beta$ ) are liberated from BAPP by  $\alpha$ - and  $\beta$ -secretases, respectively; BAPP mutations linked to Alzheimer's disease may decrease levels of sAPP $\alpha$ . We now report that sAPP $\alpha$  is 100-fold more potent than sAPP $\beta$  in protecting cultured rat hippocampal neurons against excitotoxicity, A $\beta$  toxicity and glucose deprivation. Patch-clamp recording and calcium imaging using fura-2 showed that sAPP $\alpha$ s were also more effective than sAPP $\beta$ s in activating K $^{+}$  channels and attenuating Ca $^{2+}$  increases by glutamate. Structure-activity studies using recombinant sAPP $\alpha$  and sAPP $\beta$  fragments and synthetic APP peptides showed that a C-terminal region of sAPP mediates neuroprotection, and that a heparin-binding domain specific for sAPP $\alpha$  is responsible for the increased efficacy of sAPP $\alpha$ . Physiological and pathological conditions that affect BAPP processing are likely to greatly affect the biological activities of the resultant sAPP products (supported by the NIH and the Alzheimer's Association).

## 82.16

POTASSIUM-INDUCED DEPOLARIZATION PROTECTS CULTURED NEURONS FROM  $\beta$ -AMYLOID TOXICITY. C.J. Pike\*, R. Balázs and C.W. Cotman. Institute for Brain Aging & Dementia, Univ. of California, Irvine, CA 92717 USA.

$\beta$ -Amyloid protein (A $\beta$ ) is implicated as a primary contributor to neurodegeneration associated with Alzheimer's disease (AD). In cultured neurons, fibrillar aggregates of A $\beta$  induce apoptotic cell death. Apoptosis is also observed in vulnerable regions of AD brain. To investigate potential protective strategies, we examined the ability of high [K $^{+}$ ] $_{o}$  to attenuate A $\beta$ -induced neurotoxicity *in vitro*. Previous *in vitro* studies have characterized a Ca $^{2+}$ -dependent pathway by which KCl-mediated depolarization inhibits development-related apoptosis. In 12-16 DIV cultures of rat hippocampal neurons, increasing [K $^{+}$ ] $_{o}$  from the normal 5 mM to a depolarizing 30 mM resulted in a significant attenuation of cell death induced by both  $\beta$ 1-42 and its active fragment  $\beta$ 25-35. Interestingly, membrane depolarization induced by high [K $^{+}$ ] $_{o}$  offered protection against A $\beta$  peptides only following a several hour pretreatment; increasing [K $^{+}$ ] $_{o}$  immediately prior to A $\beta$  addition did not significantly affect A $\beta$ -induced cell death. Consistent with observations in developmental paradigms of apoptosis, the elevated [K $^{+}$ ] $_{o}$  protective pathway was mimicked by a Ca $^{2+}$  channel agonist [S(-)-Bay K 8644] and attenuated by a blocker of voltage-dependent Ca $^{2+}$  channels [R(+)-Bay K 8644] as well as by an inhibitor of Ca $^{2+}$ /calmodulin-dependent protein kinase II (KN-62). These data suggest that depolarizing doses of KCl can prevent A $\beta$ -induced neuronal apoptosis by a cellular pathway involving Ca $^{2+}$  influx through voltage-sensitive channels followed by stimulation of Ca $^{2+}$ /calmodulin-dependent protein kinase activity and perhaps new protein synthesis. Extrapolation of these concepts to the *in vivo* condition would suggest a novel form of use-dependent plasticity whereby depolarization resulting from neural activity may provide neurons with a significant margin of protection against apoptotic insults associated with AD and other age-related neurodegenerative diseases. (Supported by NIH grant #AG12663).

## 82.17

**$\beta$ -AMYLOID ACTIVATES PROTEIN SERINE/THREONINE KINASE CASCADE WITH THE INVOLVEMENT OF PROTEIN KINASE C $\alpha$ .** Y. Luo\*, D. B. Hawver, T. Sunderland, K. Iwasaki, and B. Wolozin. Section on Geriatric Psychiatry, NIMH, Bethesda, MD 20892-1264.

Alzheimer's  $\beta$ -amyloid peptide (A $\beta$ ) is normally present at subnanomolar concentrations in body fluids and in the medium of cultured cells. In vitro experiments have shown that A $\beta$  has neurotrophic effects and can promote neuronal adhesion and elongation of axon-like processes. We have recently found that nanomolar doses of A $\beta$  can stimulate tyrosine phosphorylation and activate phosphatidylinositol-3-kinase in neuronal cells. [Luo, et al., *Brain Res.* 681:65-74 (1995); *J. Neurochem.* in press (1996)]. Here we show evidence that A $\beta$  activates a protein kinase C (PKC) involved in the serine/threonine kinase cascade in PC12 cells. A $\beta$ -stimulated kinase activities can be detected by anti-phosphothreonine immunoblotting and *in vitro* phosphorylation of S6 peptide. Depletion of PKC by pretreatment of PC12 cells with PMA (1  $\mu$ M) for 24 hr prevented the increase of *in vitro* S6 phosphorylation by A $\beta$ . Additional immunoblotting experiments showed that A $\beta$  decreased the cytosolic 80 KDa PKC $\alpha$  and increased translocation of PKC $\alpha$  to the particulate fraction of cell lysates. A $\beta$  also increased immunoreactivity to a particulate fraction 50 KDa protein, a presumed proteolytic fragment of PKC $\alpha$ . This A $\beta$ -induced translocation of PKC $\alpha$  was enhanced by ionomycin, a calcium ionophore, and blocked by calcium-dependent protease inhibitors, calpain I and II inhibitors (1  $\mu$ M and 2  $\mu$ M respectively). These data suggest that A $\beta$  may regulate the protein serine/threonine kinase cascade through calcium-dependent PKC pathway.

## 82.19

**ALZHEIMER'S BETA AMYLOID PRECURSOR PROTEIN ( $\beta$ APP) AND PROLINE-RICH LIGANDS BIND TO PTB AND WW DOMAINS OF THE FE65 ADAPTOR AND FORM TRI-PARTITE PROTEIN COMPLEXES.**

K. Ermekova, N. Zambrano\*, T. Russo\* and M. Sudol\*. Dept. of Biochem. Mt Sinai School of Med., New York, NY 10029; # Dept. of Biochem. and Med Biotech. Univ. of Naples, Naples 80131, Italy.

FE65 is a new adaptor protein expressed preferentially in the brain. Its structure is modular and contains one WW and two PTB domains. The PTB domains of FE65 bind  $\beta$ APP [1]. Using expression cloning, we isolated binders to the WW domain of FE65, which may encode activities involved in normal function of the  $\beta$ APP. From among the potential binders, we selected those that form a complex with FE65 protein both *in vitro* and in cell lysates. Similarly to SH2, SH3, PH and PTB, the WW domain mediates protein-protein interaction and is present in various signaling molecules in yeast, nematode and mammals [2,3]. The name WW stands for 2 tryptophans (W) present among 4 conserved aromatics in the consensus sequence spaced 20 amino acids (aa) apart. The WW domain is 38 aa long and forms a compact structure composed of a 3 stranded beta-sheet. The structure is distinct from that of the SH3 domain [4]. A cognate ligand (WBP1 protein) for the WW domain of human YAP was isolated and its binding site was mapped to the PPPPY motif with the consensus XPPXY being critical for binding [5]. Recent studies (review [6]) have implicated the WW domain-ligand link in several genetic disorders and biological processes including Liddle's syndrome, muscular dystrophy, limb and kidney development, and retroviral budding. 1. Fiore, F., et al., (1995) *J. Biol. Chem.* 270; 30853-56; 2. Bork, P., & Sudol, M. (1994) *TIBS* 19, 531-33; 3. Sudol, M., et al., (1995) *J. Biol. Chem.* 270, 14733-41; 4. ## DEGENERATIVE DISEASE: ALZHEIMER'S-COGNITIVE FUNCTION I

## 83.1

**CORTICAL DEMENTIA OF ALZHEIMER'S DISEASE IS ASSOCIATED WITH DIFFUSE AND CORTICAL ATROPHY AND THE PRESENCE OF AT LEAST ONE APOE4 ALLELE.** P.R. Mouton<sup>1,2</sup>, M.E. Calhoun<sup>3</sup>, N. Bakhos<sup>2</sup>, and J.D. Glass<sup>2</sup>. Departments of Pathology<sup>1</sup> and Neurology<sup>2</sup>, and the Neuropathology Laboratory<sup>3</sup>, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

The presence of apoE4 alleles is associated with clinical-pathological findings characteristic of Alzheimer's disease (AD). This prospective study was designed to determine whether a specific pattern of cortical atrophy combined with psychometric testing and apoE genotyping are useful criteria for the diagnosis of AD. Stereology was used to quantify total cortical volumes ( $V_{\text{ctx}}$ ) of formalin-fixed brains from 100 autopsied cases that received longitudinal neuropsychological testing and comprehensive neuropathological studies. Final diagnoses of young and aged controls and cases of definite AD, possible AD, Lewy body variant of AD (AD-LB), Parkinson's disease (PD), Huntington's Disease (HD), and AIDS were made on the basis of clinical and pathological findings. No age-related  $V_{\text{ctx}}$  loss was seen in controls ranging in age from 45-91 years. ANOVA revealed severe, diffuse reduction in  $V_{\text{ctx}}$  from frontal to occipital poles in cases of definite AD (25%), HD (24%), and PD (20%) compared to age-matched controls, whereas  $V_{\text{ctx}}$  for AD-LB and possible AD were not different from controls. Ninety percent of cases with AD and cortical atrophy ( $V_{\text{ctx}} \leq$  median) have at least one apoE4 allele; cases with normal cognitive function did not show the combination of cortical atrophy and apoE4 allele. Cortical atrophy in AIDS is mild as compared to AD and not associated closely with dementia. These findings support the view that severe, diffuse cortical atrophy provides an important adjunct to the antemortem diagnosis of AD and a logically compelling basis to understand the pathophysiology of cortical dementia. This work was supported by a grant from the NIH (NS 26643).

## 82.18

**sAPP'S NEUROTROPHIC ACTIVITY INVOLVES TWO DISTINCT SIGNALING PATHWAYS** I. Mook-Jung, M.W. Jung\* & T. Saitoh. Dept of Neurosci, School of Medicine, UCSD, La Jolla, CA, 92093-0624. \*Neurosci Lab, Institute for Medical Sciences, Ajou University, Suwon, Korea, 442-749.

Secreted form of amyloid precursor protein (sAPP) functions as a trophic factor for neuronal and non-neuronal cells. Little is known, however, about the intracellular signals that mediate these effects. We previously suggested that sAPP function is mediated through tyrosine phosphorylation. To determine which domain of sAPP induces tyrosine phosphorylation, we tested effects of sAPP and a RERMS domain peptide (APP319-335) known to have neurotrophic activity. Western blot analyses using an antibody against phosphotyrosine showed that 125kD band was increased in a dose-dependent manner by sAPP. The RERMS domain peptide induced tyrosine phosphorylation more strongly than sAPP. Consistent with this result, A $\beta$ 1-15 inhibited tyrosine phosphorylation. Thus, A $\beta$ 1-15 domain might play an important role in regulating the action of sAPP. Heparin or a heparitinase treatment attenuated the neurotrophic effect as well as tyrosine phosphorylation induced by sAPP. Since A $\beta$ 1-15 region contains a consensus heparin binding domain, these results suggest that the A $\beta$ 1-15 domain is essential for sAPP action. The present results suggest that sAPP induces tyrosine phosphorylation, and the RERMS domain and A $\beta$ 1-15 domain in sAPP activate separate signal transduction pathways. The balance between activities of the two regions might be important for regulation of biological functions of sAPP. Supported by NIH and Alzheimer's Assoc.

## 83.2

**ISOFORM-SPECIFIC NEUROTOXICITY OF APOLIPOPROTEIN E: POSSIBLE ROLE OF THE 22 KDA FRAGMENT.** M.A. Marques\*, M. Tolar and K.A. Crutcher. Department of Neurosurgery, University of Cincinnati College of Medicine, Cincinnati, OH 45267-015.

In vitro toxicity assays demonstrate that the 22 kDa thrombin-cleavage fragment of apolipoprotein E (apoE) is toxic to embryonic chick sympathetic neurons in culture (Crutcher et al, *Neurobiol. Aging*, in press). Since a similar fragment is present in postmortem human brain tissue (Marques et al., *Soc. Neurosci.*, 21: 1485, '95) and apoE is susceptible to proteolytic degradation by different cell types in vitro, the present study was undertaken to examine the potential toxicity of apoE when added to primary neurons in culture.

ApoE was isolated from concentrated media of HEK cells transfected with either the E3 or E4 human apoE gene (kindly provided by Dr. M.J. LaDu). ApoE was purified by an affinity heparin column followed by gel filtration chromatography. Addition of either apoE isoform to embryonic chick sympathetic neurons resulted in significant neurotoxicity. In all cases the greatest toxicity was associated with the E4 isoform. An immunoblot of the media exposed to neurons showed the presence of a 22 kDa apoE fragment. Furthermore, an immunoblot of fresh cerebrospinal fluid from both Alzheimer's disease (AD) and control cases demonstrated the presence of a 22 kDa apoE fragment, indicating its normal production *in vivo*.

These results, demonstrating a potent isoform-specific neurotoxicity of apoE, suggest that the generation of the 22 kDa fragment may be the means by which apoE causes neuronal degeneration. These findings implicate apoE as a candidate for playing a direct role in AD pathogenesis and provide a biological basis for the apoE isoform-specific risk for developing the disease. (Supported by NIH NS31410.)

## 83.3

LOSS OF THE PRESYNAPTIC VESICLE PROTEIN SYNAPTOPHYSIN IN HIPPOCAMPUS CORRELATES WITH EARLY COGNITIVE DECLINE IN AGED HUMANS. C.-I. Sze<sup>1,4</sup>, J.C. Troncoso<sup>1,2,4</sup>, C.H. Kwas<sup>2</sup>, P.R. Mouton<sup>1,4</sup>, D.L. Price<sup>1,4</sup>, and L.J. Martin<sup>1,3,4</sup>. Departments of Pathology<sup>1</sup>, Neurology<sup>2</sup>, and Neuroscience<sup>3</sup>, and the Neuropathology Laboratory<sup>4</sup>, The Johns Hopkins University School of Medicine, Baltimore, Maryland, USA.

We tested the hypothesis that regionally specific defects in the levels of the presynaptic vesicle protein synaptophysin (p38) occur in the brains of aged humans with recent onset memory decline and in demented individuals with Alzheimer's disease (AD). Controls with normal and stable cognition, cognitively normal subjects with senile plaque densities diagnostic for possible AD (p-AD), and individuals with a clinical and neuropathological diagnosis of AD were studied. By immunoblotting, p38 and  $\beta$ -tubulin levels were quantified in synaptic membranes of hippocampus, entorhinal cortex, caudate nucleus, and occipital cortex. Average p38 levels were reduced significantly in hippocampus when comparing AD to control (55%,  $p < 0.0001$ ), p-AD to control (25%,  $p < 0.005$ ), and AD to p-AD (30%,  $p < 0.05$ ). When comparing either AD or p-AD to controls, p38 levels in entorhinal cortex, occipital cortex, and caudate nucleus were either unchanged or less significantly altered than in hippocampus. Regional  $\beta$ -tubulin levels were similar in all groups. By univariate analysis of all cases, p38 levels in hippocampus strongly correlated with Mini-Mental State Examination scores ( $r = 0.83$ ,  $p < 0.0001$ , Spearman correlation = 0.77) and Blessed scores ( $r = 0.74$ ,  $p < 0.001$ , Spearman correlation = -0.58). We conclude that synaptic abnormalities in hippocampus correlate significantly with the severity of age-related cognitive/memory deficit and that defects in presynaptic functioning in hippocampus occur as an early abnormality in the progression of memory impairments in AD. ## 83.5

PATHOLOGY OF THE INSULAR CORTEX IN ALZHEIMER'S DISEASE. D.J. Bonthuis<sup>\*</sup>, A. Solodkin and G.W. Van Hoesen. Departments of Anatomy, Neurology and Pediatrics, University of Iowa, Iowa City, IA 52242.

The insular cortex plays important roles in a variety of regulatory mechanisms ranging from visceral control and sensation to covert judgments about inner well being. The dementia of Alzheimer's Disease (AD) often includes behavioral dyscontrol not observed in other diseases that affect cognition. This could be related to a loss of the sense of self, and the insula may play an essential role. The pattern of pathology in the insula of 16 patients with AD was examined, and the severity of pathology in the insula was compared with that of the entorhinal cortex (EC), a region known to be involved early in AD and to have reciprocal connections with the insula. Thioflavin S staining revealed that neurofibrillary tangles (NFTs) of the insula are largely confined to layers V and VI, while neuritic plaques (NPs) are distributed throughout the cellular layers and subcortical white matter. In the insula, the density of NFTs, but not of NPs, was highly correlated with the degree of pathology in the EC. However, NFTs were not seen in the insula until pathologic changes in the EC reached a relatively advanced level, with NFTs necessarily present in EC layers II and IV. In the insula, the density of NFTs, but not of NPs, was also highly correlated with years of clinical dementia. No anterior-posterior differences in NFT or NP density were observed. Immunohistochemical staining with Alz-50 revealed labelling of cell bodies in all of the cell layers of the insula, but most densely in layers III and V. The density of Alz-50-labelled cells in the insula was correlated with degree of pathology in the EC. The results demonstrate that the insula is often involved in AD and suggest that some of the behavioral abnormalities in AD may reflect insular pathology. ## 83.7

THE APOLOPROTEIN CI A ALLELE SERVES AS A RISK FACTOR FOR ALZHEIMER'S DISEASE. S.E. Podusko<sup>\*</sup>, M. Neal, K. Herring, S. Shelly. Texas Tech University Health Sciences Center, Department of Neurology, Lubbock, Texas, 79430

Alzheimer's disease is a degenerative disorder characterized by loss of memory and cognition. The disease is genetically heterogeneous in that genes on chromosomes 21 and 14 have been associated with early onset disease, a gene on chromosome 1 in Volga German kindreds, and a gene on chromosome 19 with late onset disease. The E4 allele of the APOE gene on chromosome 19 is a significant risk factor for Alzheimer's disease (Saunders et al, 1993). Downstream from the gene for APOE is the gene for APOCI, both of which are located within a 45 kb cluster of apolipoprotein genes. The presence of a restriction site in the 5' end of APOCI is present at increased frequency in Alzheimer's patients. It can also be considered to be a risk factor for the disease. The APOCI A allele and the APOE 4 allele are in linkage disequilibrium. The frequency for the APOCI A allele is increased in both early and late onset Alzheimer's patients as well as in familial and sporadic cases. No differences in frequencies were found between male and female patients or in the average age of onset of the disease in the patients with AA or AB phenotypes. However, we did find that males with a higher frequency of the APOCI A allele tend to have an earlier age of onset than females. The odds ratio indicates that the risk of developing the disease is 6x greater for those homozygous for the APOCI AA genotype. Haplotype frequencies indicate a strong association between the two markers and the disease, but there appears to be a more significant association with APOE.

This research was supported by funds from the state of Texas for the DNA bank of Alzheimer's families for genetic research.

## 83.4

COMPARTMENTAL PERIAQUEDUCTAL GRAY PATHOLOGY IN ALZHEIMER'S DISEASE. G.F. Wu<sup>1</sup>, A. Solodkin<sup>2</sup>, and G.W. Van Hoesen<sup>2</sup>. Program in Neuroscience<sup>1</sup> and Departments of Anatomy and Neurology<sup>2</sup>, University of Iowa, Iowa City, IA 52242.

Recent studies have suggested a discrete functional organization in the midbrain periaqueductal gray (PAG). Although the brainstem has been analyzed in Alzheimer's Disease (AD), data on the PAG is sparse and mentioned usually in the context of dorsal raphe pathology. Since the PAG has close anatomical connections with limbic areas, we evaluated AD pathology in the PAG and correlated it with entorhinal pathology in 30 brains. Fifty micron sections were stained with Thioflavin-S and immunohistochemically labeled with the Alzheimer's-related antibodies Alz-50 and 10D5. Pathology in the PAG was clearly segregated both rostro-caudally and dorso-ventrally. Neuritic plaque (NP) distribution was most concentrated in the dorsolateral, lateral, and ventrolateral areas at rostral and intermediate levels, whereas neurofibrillary tangles (NFTs) were situated preferentially in the caudal ventrolateral and ventral areas. Dorsomedial pathology was consistently low. Furthermore, a significantly high correlation between midbrain and entorhinal cortex density of NFTs, as well as NFT density and the number of years with clinical dementia, was found. The density of NPs did not have the same correlation. These results suggest the existence of a compartmental organization in the human PAG similar to that reported in other species. Also, these data indicate a delayed but parallel development of pathology in the PAG in relation to other limbic areas. The pathological changes in the PAG may contribute significantly to some of the later behavioral changes seen in AD and must be viewed as an adjunct correlate to those previously attributed only to cortical destruction. Supported by NS 14944 and 19632.

## 83.6

ELEVATED  $\alpha_1$ -ANTICHYMOTRYPsin, BUT NOT  $\alpha_2$ -MACROGLOBULIN, IS ASSOCIATED WITH COGNITIVE IMPAIRMENT IN A PROSPECTIVE STUDY OF THE VERY OLD. S.M. Gabriel<sup>\*</sup>, D.B. Marin, P.S. Aisen, M. Lantz, L.D. Altstiel, K. L. Davis, R.C. Mohs. Departments of Psychiatry, Mount Sinai School of Medicine, New York, NY 10029 and Bronx VA Hospital, Bronx, NY 10468.

Considerable research suggests an immunological component to Alzheimer's Disease (AD), the primary neurodegenerative illness of aging. The present prospective study determined the levels of the acute phase proteins,  $\alpha_1$ -antichymotrypsin (ACT) and  $\alpha_2$ -macroglobulin (MAC), in sera from 94 medically stable, elderly nursing home residents. Protein concentrations were determined by antibody capture enzyme-linked immunosorption assay. There was a negative correlation between mini mental state examination (MMSE) score and ACT ( $r = -0.39$ ,  $p < 0.0001$ ), and a positive correlation between clinical dementia rating (CDR) score and ACT ( $r = 0.37$ ,  $p < 0.001$ ). There was no significant relationship between MAC and these cognitive measures. These data extend previous reports that patients with AD have increased concentrations of ACT in their blood by demonstrating in a diagnostically diverse nursing home population a relationship between serum ACT and cognitive status. Further, increased serum ACT in AD and in patients with compromised mental status may reflect a cerebral acute phase response.

ANGIOTENSIN CONVERTING ENZYME INHIBITORS AND COGNITION IN AN ALZHEIMER'S POPULATION. A. Kashani<sup>\*</sup>, C.F. Phelix<sup>1</sup>, M.F. Weiner<sup>2</sup>. <sup>1</sup>Univ. of TX. at San Antonio, Division of Life Sciences, 6900 North Loop 1604 West, San Antonio, TX 78249-0662; <sup>2</sup>Univ. of TX Southwestern Med. Sch., 5323 Harry Hines Blvd., Dallas, TX 75235-9070.

Alzheimer's disease (AD), the most common dementing illness of older adults, is characterized by decreased cholinergic activity in brain. Choline acetyltransferase activity is reduced substantially in neocortex, certain forebrain nuclei, and the hippocampal region of AD patients. The reduction of brain cholinergic activity parallels the cognitive decline seen in these patients. By contrast, there is increased activity of angiotensin converting enzyme (ACE) in the brains of these patients suggesting increased synthesis of angiotensin II (AII). Because AII inhibits presynaptic acetylcholine release in rats and humans, AII might aggravate the cholinergic deficit in AD and contribute to the impairment of cognition. For this reason, ACE inhibitors have been considered for use as cognitive enhancers in humans. Short-term studies of ACE inhibitors have shown no effect on cognition in AD. We reviewed the records of 458 AD patients in the database of the Alzheimer's Disease Center at the University of Texas Southwestern Medical Center. Of these 56 patients were hypertensive, 39 patients were on ACE inhibitors and 17 were on other antihypertensive medications. The remaining 402 patients were on no antihypertensive medication. There was a trend toward lower scores on the Blessed Dementia Rating Scale ( $4.8 \pm 2.56$ ) in the ACE group as compared to the non-ACE group ( $5.81 \pm 2.82$ ) and the normotensive group ( $5.76 \pm 3.37$ ) - with no significant difference ( $p = 0.24$ ). There was also a trend for the ACE group to have higher Mini-mental State scores ( $18.31 \pm 5.79$ ) than did the non-ACE group ( $16.65 \pm 7.06$ ) or the normotensive group ( $16.14 \pm 6.51$ ) -  $p = 0.14$ . Both findings suggest the possibility that ACE inhibitors might slow the progress of AD, but to demonstrate an effect, a long-term prospective study would be needed. **SHORT-TERM TREATMENT WITH CEP-1347 PRODUCES CHRONIC IMPROVEMENT IN DELAYED ALTERNATION PERFORMANCE BY RATS WITH NUCLEUS BASALIS LESIONS.** A. DiCamillo, N. Neff\*, S. Carswell, C. Murakata\*, M. Miller and F. Haun. Cephalon Inc., West Chester, PA, 19380, and \*Kyowa-Hakko Kogyo Co., Tokyo, Japan.

The structurally novel indolocarbazole CEP-1347 prevents the death of neurons in nucleus basalis magnocellularis (nbm) following ibotenic acid lesions in adult rats, as well as increasing markers of cholinergic function in these animals. This study examined whether CEP-1347 also improves a behavior sensitive to nbm lesions. Adult Sprague-Dawley rats were first trained to alternate responses in a T-maze to an 88% correct criterion (discrete trial procedure, 1 min delay between runs). The animals then received bilateral ibotenate lesions of the nbm followed 18 h later by administration of CEP-1347 (s.c. 0.1 mg/kg, Q.O.D.) for 12 days. Retention of delayed alternation learning was first tested 24 h following the last injection of CEP-1347. Lesioned rats receiving vehicle-only injections committed 4 times as many errors before reaching pre-operative criterion as did sham operates ( $15.9 \pm 3.7$  vs.  $3.5 \pm 1.1$ ), while rats receiving CEP-1347 made significantly fewer errors ( $8.6 \pm 1.3$ ) than the vehicle controls. To test whether this behavioral improvement reflects a chronic change in cognitive ability, the same rats were re-tested 10-12 weeks after dosing was completed with no further behavioral training during the test-retest interval. Lesion/vehicle rats continued to make significantly more errors ( $11.1 \pm 3.7$ ) than did sham operates ( $4.6 \pm 0.7$ ), while the performance of CEP-1347 rats was identical to that of unlesioned untreated animals ( $2.75 \pm 0.8$  errors). To our knowledge this is the first demonstration of a long-term cognitive improvement following short-term delivery of a neurotrophic agent in a model of Alzheimer's disease. Initial analysis of the types of errors committed suggests that the nature of the cognitive improvement by CEP-1347 is attentional, rather than mnemonic.

## 83.11

**IDEBENONE PROTECTS AGAINST OXIDATIVE STRESS MEDIATED NEURONAL CELL DEATH BY COUPLING WITH THE MITOCHONDRIAL ELECTRON TRANSPORT SYSTEM.** K. Hirai, H. Hayako, K. Kato\* and M. Miyamoto. Pharmaceutical Research Laboratory I, Takeda Chemical Industries, Ltd., Osaka 532, Japan

We examined the effects of idebenone, a potent antioxidant, on two models of oxidative stress mediated neuronal cell death, glutamate-induced cell death in the N18-RE-105 cell line and amyloid  $\beta$ -peptide (A $\beta$ ) 1-40-induced cell death in rat hippocampal neurons. Glutamate-induced neurotoxicity in the N18-RE-105 cell line is mediated by an inhibition of cystine uptake from medium into the cell, which leads to a marked decrease in cellular glutathione levels, exposing the cells to the oxidative stress. The glutamate-induced cell death was partially protected by rotenone (complex I inhibitor) and antimycin A (complex III inhibitor) and enhanced by thenoyltrifluoroacetate (TTFA: complex II inhibitor). These results suggest that reactive oxygen species (ROS) generated in the mitochondrial electron transport system is important in the neurotoxicity. Idebenone protected against the glutamate-induced cytotoxicity in a concentration-dependent manner (0.1 to 10  $\mu$ M). The protective effect of idebenone was attenuated by rotenone and TTFA. Idebenone (0.1  $\mu$ M) protected against A $\beta$ 1-40-induced neuronal cell death after 4-5 days treatment. The protective effect of idebenone against the A $\beta$ 1-40-induced toxicity in hippocampal neurons also evaluated by immunostaining with anti-MAP-2 antibodies. After 4 days exposure to 10  $\mu$ M of A $\beta$ 1-40, the numbers of neurons were reduced and the survived neurons had apparently declined number of neurites. When idebenone was added to the culture medium with A $\beta$ , the numbers of survived neurons were significantly increased and neurites of survived neurons remained long as seen in the control culture. These results suggest that idebenone protects neurons against oxidative stress caused by glutamate and A $\beta$ 1-40 by coupling with the mitochondrial electron transport system.

## 83.13

**CORRELATION OF COGNITIVE STATUS WITH  $\alpha$ -TOCOPHEROL LEVELS IN PATIENTS WITH ALZHEIMER'S DISEASE.** M. Grundman\*, M. Sano\*, R. G. Thomas\*, C. Ernesto\*, D. Galasko\*, and L. J. Thal\*. \*Dept. of Neurosciences, University of California, San Diego, La Jolla, CA 92093-0949; \*Dept. of Neurology, Columbia University, NY, NY, 10032.

Free radicals may be important in the pathogenesis of Alzheimer's Disease (AD). Vitamin E is an antioxidant and might therefore slow cognitive decline in AD. We explored the relationship of cognition to vitamin E levels ( $\alpha$ -tocopherol and  $\gamma$ -tocopherol) in Alzheimer's patients with respect to age, gender, body weight and other variables.

Prior to the initiation of a clinical trial, 295 recruited subjects were tested using the Alzheimer's Disease Assessment Scale - Cognitive (ADASCOG) and had serum assayed for  $\alpha$ -tocopherol and  $\gamma$ -tocopherol. The subjects consisted of 190 women and 105 men. The mean age of the subjects was  $72.9 \pm 7.8$ . The mean score on the ADASCOG was  $34.1 \pm 9.8$ . The mean  $\alpha$ -tocopherol level was  $1.36 \pm 0.45$ . The mean  $\gamma$ -tocopherol level was  $0.19 \pm 0.11$ . The ADASCOG score had a modest but significant correlation with  $\alpha$ -tocopherol levels ( $p = -.125$ ,  $p = .032$ ) but not with  $\gamma$ -tocopherol levels ( $p = -.008$ ,  $p = .89$ ). Analysis of the results by gender revealed higher  $\alpha$ -tocopherol levels in women than men (mean  $1.40 \pm .48$  vs.  $1.29 \pm .38$ ,  $p = .04$ ).  $\alpha$ -tocopherol levels significantly correlated with the ADASCOG in women ( $p = -.170$ ,  $p = .019$ ) but not in men ( $p = -.028$ ,  $p = .78$ ). The correlation remained significant in women after adjusting for age, duration of illness and body weight.

Higher  $\alpha$ -tocopherol levels were associated with better scores on the ADASCOG in AD subjects recruited to participate in a clinical trial. The significant correlation in women may be related to their higher  $\alpha$ -tocopherol levels. The results suggest a positive relationship between vitamin E intake and cognition in AD patients. (Supported by AGO-10483)

## 83.10

**LONG-TERM ADMINISTRATION OF IDEBENONE AMELIORATES AGE-RELATED BEHAVIORAL DEFICITS AND PROLONGS LIFE SPAN IN RATS.** M. Miyamoto\*, M. Ohkura, T. Nakayama and Y. Nagai. Pharmaceutical Res. Lab. I, Takeda Chem. Industries, Ltd., Osaka 532, Japan

Major involvement of oxidative stress in pathogenesis of Alzheimer's disease (AD) and in normal aging has been demonstrated. In the present study, the effects of idebenone, a centrally active antioxidant, on age-related behavioral deficits and life span in rats were examined. Also, effects of idebenone on reduced local cerebral glucose utilization (LCGU) were studied. Fischer 344 aged rats were fed laboratory chows containing idebenone (67 or 200 ppm) commencing at 24 months of age. Young adult rats and aged control rats were given laboratory chows containing no drug. Aged rats showed a marked impairment in the Morris water maze task at 27 months of age as compared with young rats. Long-term administration of idebenone ameliorated the impairment in a dose-dependent manner; the high dose group (5.6 mg/kg/day) had a significantly decreased latency to find the hidden platform and exhibited a significant increase in the number of the platform area in the spatial probe test. Idebenone also attenuated abnormality of circadian rhythm of spontaneous motor activity and drinking behavior, in which both of the low (2.1 mg/kg/day) and high dose groups reversed the reduction in circadian amplitude. Furthermore, the long-term treatment with idebenone prolonged life span. However, food consumption and body weight in idebenone-treated groups did not differ from those of the control group, suggesting that the prolongation of life span is not attributable to the caloric restriction. Also, repeated administration of idebenone (30 mg/kg/day) over 30 days significantly recovered the rate of LCGU, especially in the temporal cortex and hippocampus which play a key role in learning and memory. These effects of idebenone are considered to be closely related to its protective action against oxidative stress and enhancement of cerebral energy metabolism, and strongly suggest that idebenone is useful for the treatment of AD.

## 83.12

**TRANS-DERMAL ESTROGEN IMPROVES MEMORY IN WOMEN WITH ALZHEIMER'S DISEASE.** S. Asthana\*, S. Craft, L. D. Baker, M. A. Raskind, E. Avery, C. Lofgreen, C. W. Wilkinson, S. Falzgraf, R. C. Veith, S. R. Plymate. Geriatric Res., Educ. & Clinical Center (GRECC) & Extended Care, VA Puget Sound Health Care System, American Lake Div., and Univ. of Washington, Seattle, WA 98195.

Estrogen has well documented neuromodulatory, neurotrophic and organizational effects in developing, mature, and aging rodent brain. Recent research findings suggest that estrogen replacement therapy in women with Alzheimer's disease (AD) might reduce their risk of developing AD, and enhance cognition. However, no controlled clinical study has evaluated the potential role of estrogen in augmenting cognition in AD. We report results of a randomized, placebo-controlled, double-blind, parallel group design study that characterizes the effects of transdermal estrogen on cognitive functions of postmenopausal women with AD. Ten subjects with probable AD were randomized into one of two treatment groups. Each group received an 8 week therapy of either 50  $\mu$ g/day of 17- $\beta$  estradiol (n=5) via a transdermal patch (Estraderm™, Ciba-Geigy) or a placebo patch (n=5). Following termination of therapy, subjects were followed for another 5 weeks to study the effects of estrogen withdrawal on cognition. An extensive battery of neuropsychological tests was administered during both estradiol treatment and withdrawal phases to evaluate effects on cognition. Verbal memory as measured by the Buschke Delayed Recall (F(1, 4)=16,  $p < 0.02$ ) and Paragraph Recall (F(1, 4)=8.12,  $p < 0.05$ ) significantly improved above baseline with estradiol treatment. The improvement in Buschke test scores was seen within 1 week of starting estradiol and persisted for up to 2 weeks after the treatment was terminated. The improvement in Paragraph Recall test scores was seen in week 5 of treatment. In the placebo group, no significant change ( $p > 0.15$ ) above baseline in performance was observed on either test.

The results of this prospective, controlled clinical study demonstrate that treatment with transdermal 17- $\beta$  estradiol significantly enhances verbal memory in postmenopausal women with AD. Supported by a grant from the Alzheimer's Association/The National Catholic Soc. of Foresters and by Ciba-Geigy Corporation.

**HIPPOCAMPAL VOLUME PREDICTS VERBAL AND SPATIAL MEMORY PERFORMANCE IN THE BUSCHKE "CONTROLLED LEARNING" TASK.** Leyla de Toledo-Morrell\*, B. Dickerson, M.P. Sullivan, C. Spanovic, F. Morrell and D.A. Bennett. Department of Neurological Sciences and the Rush Alzheimer's Disease Center, Rush Medical College, Chicago, IL 60612

Quantitative magnetic resonance imaging (MRI) techniques provide a unique tool for studying brain-behavior relationships *in vivo*. Atrophy of the hippocampal formation, a region important for the acquisition of new declarative knowledge, has been well documented in Alzheimer's disease (AD) and in individuals with mild cognitive impairment. In the present study, we examined the relation between extent of hippocampal atrophy and memory performance in the "Controlled Learning" task developed by Buschke and his colleagues (Buschke & Grober, *Dev. Neuropsychol.*, 1986, 19:287-307). This task has been shown to identify "genuine" memory deficits in aged individuals and in the early stages of AD. 28 subjects were studied with a high resolution MRI protocol as well as the verbal and spatial versions of the Buschke controlled learning task. They consisted of patients with a clinical diagnosis of probable AD (N=14) and those who presented at the clinic with a memory complaint, but did not meet criteria for dementia (N=14). An interactive 3-D reconstruction program was used to compute hippocampal and, as a control, temporal neocortical volume from gapless, 5mm coronal slices taken perpendicular to the long axis of the hippocampus. To correct for individual differences in brain size, volumes of regions of interest were divided by total intracranial volume computed from gapless sagittal slices spanning the entire brain. Separate stepwise regression analyses with age, normalized temporal lobe, right, left and total hippocampal volume as the independent variables showed that total hippocampal volume was the best predictor of free recall and delayed free recall of verbal information ( $p < 0.002$  and  $p < 0.0001$  respectively). Recall of the spatial location of verbal items was best predicted by right hippocampal volume ( $p < 0.001$ ). Temporal lobe volume did not significantly enter the model in either case. These anatomical/behavioral dissociations strongly suggest that the results reported here cannot be attributed to generalized atrophy. Supported by NIA grants PO AG9466 & P30 AG10161.

## 84.1

IMMUNOHISTOCHEMICAL LOCALIZATION OF PARVALBUMIN AND CALBINDIN D28k IN THE HIPPOCAMPAL FORMATION OF AGED BRAIN WITH ALZHEIMER RELATED NEUROPATHOLOGY. D.M. Armstrong\*, K. Mizukami, M.D. Ikonomic, R. Sheffield and K.G. Baimbridge. Neuroscience Research Center, Medical College of Pennsylvania and Hahnemann University, Pittsburgh PA 15212.

It is our hypothesis that neuronal vulnerability in Alzheimer's disease (AD) is defined, in part, by a balance of excitatory and inhibitory stimulation. Together with our studies of selected glutamate and GABA<sub>A</sub> receptor subunits in the AD hippocampus we sought to determine the localization and cytological features of the calcium-binding proteins, parvalbumin (PV) and calbindin D28k (CaBP). Both proteins identify subpopulations of GABAergic neurons thus allowing us to investigate the organization of the inhibitory circuitry in the AD hippocampus. These investigations were performed on hippocampi obtained from 18 subjects presenting a broad range of neuropathology (i.e., Braak stages I-VI). For each subregion of the hippocampus the density (i.e., number per unit area) of immunolabeled neurons was determined. PV-labeled neurons were reduced in polymorphic subregion of the dentate gyrus as well as the CA4, CA1 subfields and subiculum of pathologically severe cases (Braak stages V & VI) compared to mild (I & II) and moderate (III & IV) cases. Moreover, in severe cases the dendrites of remaining PV-positive neurons often appeared shrunken. In contrast, no significant differences were observed in the density of CaBP-labeled cells, in part, because of the marked variability of the severe group. In addition, in many subjects displaying severe AD pathology (stages V & VI) CaBP-positive neurons were characterized by thickened dendrites extending for considerable distances from the soma. In summary, our data support: (1) a differential response for PV- and CaBP-labeled neurons in the hippocampus; (2) the maintenance of at least one subpopulation of GABAergic interneurons even in subjects with severe AD pathology. This work supported by NIH grant AG08206.

## 84.3

TEMPORAL ORDER AND REGIONAL DISTRIBUTION OF NEUROPATHOLOGIC CHANGES IN AD HIPPOCAMPUS: AN IMMUNOCYTOCHEMICAL STUDY USING MAP2, MC1 AND GLUR2/3 ANTIBODIES. M.D. Ikonomic\*, K. Mizukami, R. Sheffield, P. Davies and D.M. Armstrong. Neuroscience Research Center, Medical College of Pennsylvania and Hahnemann University, Pittsburgh, PA 15212.

The results of our previous studies of the hippocampal formation suggested a temporal, if not causal, relationship between the loss and/or reduction of GluR2/3 immunolabeling and the development of neurofibrillary pathology. To confirm these data, we employed double-labeling immunocytochemical techniques and examined the hippocampus of nineteen elderly subjects including controls and those displaying a broad range of Alzheimer's disease pathology (i.e., Braak stages I-VI). Each hippocampus was immunolabeled using antibodies against the AMPA receptor subunit GluR2/3 together with MAP2 (eg. a marker of normal cytoskeleton) or MC1 (eg. a marker of early cytoskeletal alterations involving changes in the conformation of the tau molecule).

In the hippocampus of normal controls and mildly affected AD cases the vast majority of pyramidal neurons within the CA fields display both GluR2/3 and MAP2 immunolabeling. In pathologically more advanced cases the number of GluR2/3-positive neurons are reduced particularly within the CA1 subfield and subiculum. Concomitant with the reduction in GluR2/3 protein is the increase in MC1 immunolabeling. Despite the fact that both proteins are localized within hippocampal pyramidal neurons, in no instance, was there co-localization of GluR2/3 and MC1. These data suggest that the reduction in GluR2/3 immunolabeling precedes the appearance of MC1-positive elements. Moreover, we hypothesize that reduction in GluR2/3 protein contributes to the development of neurofibrillary pathology via a mechanism involving the destabilization of intracellular calcium homeostasis. This work is supported by NIH Grant AG08206.

## 84.5

A NOVEL ANIMAL MODEL OF ALZHEIMER'S DISEASE: CHOLINERGIC CYTOTOXICITY INDUCED BY INFLAMMATORY CYTOKINES. G.L. Wen\*, D. Roice and L.M. Baker. Division of Neural Systems, Memory & Aging, University of Arizona, Tucson, AZ 85724.

Chronic inflammatory processes may play a role in the neural mechanisms that underlie basal forebrain (BF) cell loss or dysfunction associated with aging and Alzheimer's Disease (AD). One potential cascade of biochemical steps that might lead to BF cell death is: IL-1 → Prostaglandins → [Glutamate]<sub>out</sub> → NMDA<sub>rec</sub> → Nitric Oxide. The cytokine interleukin-1 (IL-1) induces the release of prostaglandins that elevates extracellular glutamate, that activates NMDA receptors to induce the release of the cytotoxic nitric oxide. We investigated whether inflammatory processes are involved in BF cellular dysfunction and death. Lipopolysaccharide (LPS) can induce IL-1 release. In the present study, young (3 mo) and old (24 mo) rats were given single unilateral BF injections. BF injections of IL-1 (0.5 µg), tumor necrosis factor (1.0 µg), LPS (2.0, 20 or 40 µg) or NMDA (1.0 µg), significantly decreased cortical ChAT activity, as compared to the unlesioned side. The effects of LPS were dose-dependent. The combination of 2.0 µg LPS with 1.0 µg NMDA produced a decline in BFC cell number that was greater than the sum of either agent given alone. Immunocytochemical analysis for ChAT-positive cells found that all of the cytokines produced a significant decrease in cholinergic cell number in both young and old rats. These results demonstrate that cytokines, even when administered acutely, are cytotoxic to cholinergic BF cells. The actions of neuroprotectants and chronic exposure will also be presented. Supported by NIH AG10546 and the Alzheimer's Association, IIRG-95-004.

## 84.2

IMMUNOHISTOCHEMICAL LOCALIZATION OF GABA<sub>A</sub> RECEPTOR B2/3 SUBUNITS IN THE HIPPOCAMPAL FORMATION IN AGED BRAIN WITH ALZHEIMER-RELATED NEUROPATHOLOGY. K. Mizukami\*, M.D. Ikonomic, R. Sheffield, R.T. Rubin, D. Grayson, R. Hamilton, D. Ward, and D.M. Armstrong. Neuroscience Research Center, Medical College of Pennsylvania and Hahnemann University, Pittsburgh PA. 15212.

Our work on the role of glutamate in Alzheimer's disease (AD) neuronal degeneration and death provided significant insights into the importance of the GABAergic neurotransmitter system in counteracting the pathologic consequences of excessive glutamate receptor stimulation. It is our hypothesis that neuronal vulnerability is defined, in part, by a delicate balance of excitatory and inhibitory stimulation. As part of our initial investigations into the GABAergic neurotransmitter system in AD we employed immunohistochemical techniques and examined the expression and anatomical distribution of the GABA<sub>A</sub> receptor subunits B2/3 in the hippocampus of nineteen elderly subjects (average age: 81.6 years) presenting a broad range of pathologic severity (i.e., Braak Stage I-VI). Quantitative analysis of eight regions of the hippocampus revealed the highest density of B2/3 receptor subunits in the inner molecular layer of the dentate gyrus > CA1 > CA2 while the lowest levels were observed in the granular layer of the dentate gyrus ≤ CA4 < CA3 subfields. Despite these regional variations in the density of immunolabeling no significant differences in the density of B2/3 subunit immunoreactivity was observed among the pathologically mild (Stage I & II), moderate (Stage III & IV), or severe (V & VI) groups, despite significant Nissl-stained cell loss in the CA2 and CA1 subfields as well as the subiculum of severe cases. These data suggest: (1) that within this latter group B2/3 subunits may be localized to cells not affected by AD pathology (i.e., interneurons); (2) remaining pyramidal neurons may be overexpressing this protein possibly as the result of diminished GABAergic stimulation; (3) a critical role for GABA<sub>A</sub> receptor subunits in hippocampal plasticity and in maintaining hippocampal functioning. This work is supported by NIH Grant AG08206.

APP INDUCTION VIA MUSCARINIC RECEPTOR BLOCKADE. L.D. Acevedo\*, V. Haroutunian, and W.C. Wallace. Lab of Cell & Mol Biol, GRC, NIA, Baltimore, MD 21224. Bronx VA, Bronx, NY 10468.

Lesions of the nucleus basalis of Meynert in rats cause a marked and persistent elevation in APP secretion into the CSF from cortical target regions. This increased secretion is signaled by elevated APP mRNA synthesis in the cortex. The loss of cholinergic innervation to cortical projection areas which leads to enhanced APP secretion is mimicked by subcutaneous infusion of scopolamine, a muscarinic receptor antagonist. Muscarinic receptor blockade, in the absence of nbM lesions, is therefore sufficient to elevate cortical APP secretion.

We hypothesize that increased APP synthesis *in vivo* is a postsynaptic response to reduced receptor occupancy. We have established *in vitro* cultures of various neuronal cell lines to investigate the mechanism by which APP mRNA induction follows this loss of receptor function. Untransfected SH-SY5Y neuroblastoma and rat PC12 cell cultures produce and secrete APP constitutively into the culture medium, as measured on immunoblot using the 22C11 antibody. Preliminary results suggest that differentiated PC12 cells exposed to nanomolar concentrations of scopolamine exhibit enhanced APP secretion, in a dose-dependent manner. Undifferentiated PC12 cells are not as sensitive to added scopolamine.

These observations may reflect either pre- or post-synaptic responses to disrupted receptor function. To distinguish between these two alternatives, we will administer scopolamine to cells previously exposed to acetylcholine, which more faithfully represents *in vivo* conditions during the nbM lesioning paradigm.

## 84.6

DISTRIBUTION OF BUTYRYLCHOLINESTERASE IN THE HUMAN FOREBRAIN. S. Darvesh, D. Grantham and D.A. Hopkins\*. Depts. of Medicine and Anatomy and Neurobiology, Dalhousie University, Halifax, NS B3H 4H7.

Butyrylcholinesterase (BuChE) is an enzyme closely related to acetylcholinesterase (AChE). In cholinergic neurotransmission, AChE terminates the action of acetylcholine and it has been hypothesized that BuChE plays a similar role. The levels of AChE and BuChE are altered in Alzheimer's disease. Therefore, to obtain baseline data, we compared the distribution of neuronal BuChE and AChE in normal brain using a modified Karnovsky-Roots method.

In the basal forebrain BuChE-positive multipolar neurons were scattered throughout the nucleus basalis of Meynert. There were numerous fusiform neurons in both segments of the globus pallidus. The putamen and ventral striatum had multipolar cells with elaborately-branched processes. In the hippocampal formation there were BuChE-positive granule cells in the dentate gyrus, pyramidal cells in the zona pyramidalis and small interneurons in the zona oriens. In the amygdala small multipolar BuChE-positive neurons were found in all the subnuclei of the amygdala. The majority of thalamic nuclei contained numerous BuChE-positive neurons.

The human brain contains populations of BuChE-positive neurons that are distinct from those with AChE. The distribution of BuChE in forebrain structures suggests that it may play a role in neural mechanisms of cognition.

**DIFFERENTIAL REGULATION OF ADENYL CYCLASE ACTIVITY IN SKIN FIBROBLASTS FROM SPORADIC AND FAMILIAL ALZHEIMER'S DISEASE CASES WITH PRESENILIN-1 AND SWEDISH APP670/671 MUTATIONS.** M. Vestling\*, A. Adem, M. Racchi\*, S. Govoni\*, L. Lannfelt, G. Gibson\* and R. F. Cowburn, Karolinska Institute, Div. of Geriatric Medicine, S-141 86 Huddinge, Sweden, 1 Alzheimer's Dept., FBF Hospital, Brescia, Italy, 2 Cornell Univ. Med. Coll. at Burke Medical Res. Inst., White Plains, NY 10605, USA.

B-adrenoceptor-stimulated adenylyl cyclase has been shown to be altered in fibroblast cell lines from sporadic Alzheimer's disease patients. From a pathophysiological and diagnostic point of view, it is important to elucidate whether disrupted adenylyl cyclase occurs in different (familial and non-familial) subgroups of Alzheimer's disease patients.

In the present study, we compared basal, isoprenaline- and forskolin-stimulated adenylyl cyclase activities in fibroblast cell lines established from sporadic Alzheimer's disease cases (n=7) and age-matched controls (n=7), individuals from a Swedish family carrying the Presenilin-1 163 mutation (n=8), a Swedish/Finnish family carrying the Presenilin-1 146 mutation (n=6) and a Swedish family carrying the APP 670/671 double-mutation (n=14).

Our data showed a decreased B-adrenoceptor-stimulated adenylyl cyclase activity in fibroblasts from sporadic Alzheimer's disease cases when compared to age-matched controls (p<0.05). This result is in agreement with that of a previous report (Huang and Gibson, J. Biol. Chem. 268, 14616-14621, 1993).

In contrast, both B-adrenoceptor- and forskolin-stimulated adenylyl cyclase activities were significantly increased in the Presenilin-1 mutation-carrying fibroblasts compared to fibroblasts without the mutation (p<0.05, Student's unpaired t-test for the comparison of cell lines from both Presenilin-1 mutation families). No differences were seen between cell lines with and without the Swedish APP 670/671 mutation.

This study suggests that various Alzheimer's disease gene mutations have different consequences for the regulation of adenylyl cyclase mediated signal transduction in this disorder. (Supported by Stiftelsen för Gamla Tjänarinnor and Åke Wibergs Stiftelse, Sweden).

## 84.9

**SENSITIVITY TO MK-801 NEUROTOXICITY IS INCREASED IN AGED MALE RATS.** D. F. Wozniak\*, N. B. Farber, A. Nardi, G. Taylor and J. W. Olney, Dept. Psychiat., Washington Univ. Sch. Med., St. Louis, MO 63110 and Dept. Psychol., Univ. MO-St. Louis, St. Louis, MO 63121.

Blockade of NMDA glutamate receptors by MK-801 or other NMDA antagonists causes vacuolar injury of neurons in the rat posterior cingulate/retrosplenial (PC/RS) cortex. Putatively, the mechanism of this neurotoxic effect may have relevance to Alzheimer's disease. Age and sex are important determinants of sensitivity to this neurotoxic effect in that immature rats prior to puberty are totally insensitive, and during early adulthood, females are more sensitive than males. In the present study, we investigated whether sensitivity of adult rats of either sex changes with increasing age. Male or female adult rats at various ages were treated with 0.5 mg/kg MK-801 and sacrificed 4 hrs later for histological evaluation of the number of vacuolated PC/RS neurons. In the first experiment, Sprague Dawley male rats 24 mos old had significantly larger numbers of injured PC/RS neurons than 4 or 8 month old males. This result was replicated in a second experiment where 20-month old Sprague Dawley male rats had significantly greater numbers of vacuolated PC/RS neurons than 4-month old males. In a third experiment, using female Long Evans rats that were 4, 9, or 24 mos old, the vacuolated neuron counts were not significantly different among groups (all groups showed high sensitivity, an apparent ceiling effect). To rule out strain differences as the basis for absence of an age-related effect in females, we studied 6- and 24-month old Long Evans males and found that the 24-month old males were significantly more sensitive. The results suggest that adult male rats become more sensitive to MK-801 neurotoxicity with increasing age. Whether female rats also become more sensitive with age is not clear from these data because the dose of MK-801 employed produced a likely ceiling effect in females at all ages. Supported by AG11355, DA05072, SDAC DA00290 (NBF), and RSA MH 38894 (JWO).

## 84.11

**m2 Immunoreactive Neurons Are Not Reduced In The Basal Forebrain of Patients with Alzheimer's Disease.** E. J. Mufson\*, S. Jaffar, J. H. Kordower and A. J. Levey, Research Center For Brain Repair and Dept. of Neurological Sci., Rush Medical Ctr., Chicago, IL 60612 and Dept. of Neurology, Emory Univ., Atlanta, GA 30322.

Some studies suggest that basal forebrain (BF) cholinergic neurons are a source of presynaptic muscarinic receptors in cortical terminal fields. The present study determined the correspondence between neurons containing the m2 muscarinic receptor subtype and cholinergic cell bodies within the aged human BF and evaluated pathologic changes seen in Alzheimer's disease (AD). Tissue immunostained with an antibody against the m2 receptor revealed small and large multipolar neurons scattered within the cholinergic BF continuum. Similar observations were also seen in the cynomolgus monkey BF. To determine whether m2 neurons codistributed with cholinergic BF neurons, adjacent sections were stained with an antibody against the low affinity p75NTR-receptor, an established marker for these neurons. Neuron counts revealed 10 times as many p75NTR than m2 immunoreactive BF neurons. Co-localization studies indicate that some m2 neurons are cholinergic. Quantitative evaluation of the number of m2 neurons within the BF between normal aged and AD cases failed to reveal a significant difference between groups (F[1,7]<1). These observations indicate m2 containing neurons within the primate basal forebrain are primarily non-cholinergic. Further, the lack of a decrease in m2 neurons in AD, suggests that the reduction in cortical "M2"-receptors in this disease are not due to degeneration of cortical afferents emanating from cholinergic BF neurons. Supported by AG10668, AG10161, AG09466, AG10130 and NS30454.

## 84.8

**INDIVIDUAL RESPONSES OF ALZHEIMER PATIENTS DURING TREATMENT WITH THE CHOLINERGIC DRUGS ARECOLINE AND PHYSOSTIGMINE: KINETIC, PHYSIOLOGICAL, AND COGNITIVE MEASURES.** K. C. Raffaele\*, S. Asthana, A. Berardi, N. H. Greig, M. B. Schapiro, J. V. Haxby, and T. T. Soncrant, LCNB/LNS, National Institute on Aging, Bethesda, MD 20892.

Cholinergic function is consistently decreased in Alzheimer's disease (AD). However, responses of individual AD patients to treatment with cholinergic agents has varied. To determine whether individuals responding to one class of cholinergic agent were more likely to respond to a different class of cholinergic agent, and to evaluate whether positive responses to treatment were associated with specific kinetic profiles or with changes in physiological variables, patients received (during separate inpatient stays) long-term intravenous infusions of escalating doses of physostigmine (a cholinesterase inhibitor; 2, 6, 12, 18, and 25 mg/day) and arecoline (a muscarinic agonist; 1, 4, 16, 28, and 40 mg/day). Before, during, and after drug treatment, plasma drug levels, changes in physiological variables (blood pressure, respiratory rate, temperature, and pulse), and changes in neuropsychological performance (including visuo-spatial construction, verbal fluency, attention, and verbal memory) were measured. Responses for all types of measures varied among patients. Cognitive responses to treatment varied among different cognitive measures and among patients; visuo-spatial performance and verbal memory were most consistently improved for both drugs but not all patients showed improvement, and the dose at which improvement was seen varied. For physiological responses, an increase in pulse was the most consistent change for both drugs and was also most likely to predict an improvement in cognitive performance. Plasma drug levels varied across administered doses and across patients, but given the same administered dose, the plasma level of physostigmine varied more than did that of arecoline. Measurement of multiple parameters in the same individuals will improve our understanding of the interaction of those parameters in determining responses to drug treatment. Funded by NIA (intramural funding).

## 84.10

**Glutamate Transport Deficiency is Associated with Synaptic Pathology in Alzheimer's Disease.** Shi Li#, Michael Alford, M. Mallory#, Arnold Miller# and E. Masliah#. Depts. of Neurosciences# and Pathology\$, University of California, San Diego, La Jolla, California 92093.

While the mechanisms of synaptic damage in Alzheimer's disease (AD) are not fully understood, the decreased functioning of glutamate transporters might be involved in neurodegeneration by failing to uptake excess glutamate in the synaptic cleft. When the levels of D- and L-[<sup>3</sup>H]aspartate binding in midfrontal cortex were correlated with synaptophysin, brain spectrin degradation products and clinical and pathological indicators, AD cases showed a 30-50% decrease in D-[<sup>3</sup>H]aspartate binding, L-[<sup>3</sup>H]aspartate binding, and synaptophysin immunoreactivity compared to controls. The decreased aspartate binding activity and synaptophysin immunoreactivity correlated with increased levels of brain spectrin degradation products. Moreover, L-[<sup>3</sup>H]aspartate binding activity correlated with synaptophysin immunoreactivity. To further understand the molecular mechanisms of decreased glutamate transport activity in AD, we performed RNase protection assays and Western assays in midfrontal cortex of AD and control cases. The preliminary data indicated that the EAAC1 and GLT-1 subtypes expression might be affected in AD. These results suggest that the abnormal functioning of glutamate transport might be involved in the AD synaptic pathogenesis.

**DETERMINING REGIONAL VARIANCES IN GLUTAMATE TRANSPORTER PROTEIN SITES IN ALZHEIMER DISEASE: BINDING VS UPTAKE.** H. L. Scott, R. I. Westphalen\* and P. R. Dodd, Clinical Research Centre, Royal Brisbane Hospital Research Foundation, Brisbane, Q 4029, AUSTRALIA.

Alzheimer disease (AD) is characterised by area specific neuropathology. Based on the neurotoxic process of excitotoxicity, the present study investigated whether the glutamate uptake system is altered in "affected" areas of AD brain using two methods of transporter analyses: membrane binding and synaptosomal uptake. Other studies have described several forms of the glutamate transporter protein, a variant of which may be inefficient at removing the potential excitotoxicant, glutamate, from the synaptic cleft. Previously, we used a range of glutamate transport inhibitors to displace Na<sup>+</sup>-dependent, high-affinity D-[<sup>3</sup>H]aspartate binding to the glutamate uptake site in control and Alzheimer disease cortical tissue<sup>1</sup>. The binding profiles of these inhibitors were found to be significantly different within cortical regions of AD cases, but not in controls. High-affinity synaptosomal uptake inhibition profiles were found to be significantly different within cortical areas of controls but not in AD cases. Comparing rat cortex and cerebellum tissue, a significant difference was found in the binding displacement profile (p < 0.001) and uptake inhibition profile (p < 0.001), suggesting a variance in glutamate transporter sites between these regions. However, a significant difference was also found between displacement and inhibition profiles within rat brain regions. The differing profiles of binding displacement and uptake inhibition may represent regional variations in glutamate removal systems, depending on the method of glutamate transporter analysis used.

REPEATED ADMINISTRATION OF METRIFONATE, A CHOLINESTERASE INHIBITOR, INCREASES LOCAL CEREBRAL GLUCOSE UTILIZATION IN YOUNG AND AGED RATS. M.H. Bassant\*, F. Poindessous, Y. Lamour. INSERM U 161, 2, rue d'Alésia, 75014, Paris, France

Inhibitors of acetylcholinesterase (AChE) improve cognitive deficits in some Alzheimer's disease patients. This effect may be related to an increase in local cerebral glucose utilization (LCGU). We have shown previously that metrifonate (MFT, 80mg/kg i.p., single dose), a slow-release AChE inhibitor, increases significantly LCGU in a number of cerebral regions in young and aged rats. In the present experiment, the drug was given repeatedly (oral administration of 120mg/kg, twice daily) over a period of 3 weeks, in order to mimic more closely the clinical situation in the human patient. LCGU was measured in 3 and 28-month-old MFT-treated and vehicle-treated rats, using Sokoloff's autoradiographic 2-deoxyglucose method. Virtually no side effects were observed. In young rats, MFT increased significantly LCGU in 23 of the 54 regions studied. In these regions, the average MFT-induced increase in LCGU was 31% above control. The whole brain mean LCGU increased by 17% ( $p < 0.001$ ). Dramatic effects were observed in the limbic system (cingulate, retrosplenial cortices, medial septum, diagonal band of Broca, dorsal and ventral hippocampus, subiculum, basolateral amygdala), in the thalamus and the substantia nigra. The effects were extremely similar in aged rats. As compared to acute administration, both the number of regions affected and the amplitude of the metabolic activation were larger after chronic treatment. Our results show that the durable inhibition of AChE induced by MFT increases LCGU in young as well as in aged rats in a number of brain regions, including regions involved in learning and memory. ## 84.15

NITROTYROSINE RESIDUES COLOCALIZE TO NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASE AND ALS/PDC OF GUAM. P.F. Good\*, P. Werner, A. Hsu, D.P. Perl, and C.W. Olanow. Division of Neuropathology, Mount Sinai School of Medicine, New York, NY 10029

The possibility that oxidative stress produces cellular damage in Alzheimer's disease has received wide attention. Speculations have focused on the coupling of excitotoxic mechanisms initiated by glutamate receptor agonists to the production of reactive oxygen species. While there have been a number of reports demonstrating such phenomena *in vitro* and in animal models, data on human disease is still in the early stage. Employing antibodies that specifically recognize nitrated tyrosine residues we have demonstrated the presence of nitrated tyrosine colocalized to neurofibrillary tangles in Alzheimer's disease (AD) and in amyotrophic lateral sclerosis/parkinsonism dementia complex (ALS/PDC) of Guam. The nitrated tyrosine residues are colocalized to neurofibrillary tangles occurring in the hippocampus of AD of ALS/PDC, as well as the neurofibrillary tangles within dopaminergic neurons of the substantia nigra in ALS/PDC. Immunolabeling was abolished by preabsorption with antigen and by reduction of tissue sections with sodium dithionite. Nitrated tyrosine residues have been shown to be the product of peroxynitrite attack on tyrosine (Beckman, et al. 1992, Arch. Biochem. Biophys. 298, 438-445). Peroxynitrite is formed in the diffusion rate limited reaction of superoxide ( $O_2^-$ ) with nitric oxide ( $NO$ ), derived from either calcium-activated neuronal nitric oxide synthase, (nNOS) or from inducible NOS (iNOS). Nitration of tyrosine residues is readily catalysed by iron which has also been localized to neurofibrillary tangles. Evidence that excess superoxide and nitric oxide play a direct role in neuropathological changes in AD provides a potential link of excitotoxicity with oxidative stress in the production of neurofibrillary tangles in AD and ALS/PDC. Supported by grants AG-5138 and AG-2210 from the National Institutes of Health and the Lowenstein Foundation

## 84.17

SELECTIVE, AGE-RELATED LOSS OF CALBINDIN-D<sub>28K</sub> FROM BASAL FOREBRAIN CHOLINERGIC NEURONS IN THE MARMOSET. C.-K. Wu\* and C. Geula. Harvard Medical School, Boston, MA 02215.

We have reported previously an age-related loss of calbindin-D<sub>28K</sub> (CB) immunoreactivity from the cholinergic neurons of the human basal forebrain (BFCN). The loss of CB from the BFCN is a potential mechanism for the selective degeneration of these neurons in neurodegenerative diseases of the elderly, particularly Alzheimer's disease. Since the presence of CB is a specific feature of the primate BFCN, we used a primate model for the study of age-related changes in this protein. Two young (2 years) and three old marmosets (8, 9, and 15 years) were processed for CB, choline acetyltransferase (ChAT), high affinity (Trk A) and low-affinity ( $p75^{LNGFR}$ ) nerve growth factor receptor immunohistochemistry in adjacent sections of the basal forebrain. Quantitative assessment revealed loss of CB immunoreactivity from 21% to 41% of BFCN in the old marmosets. ChAT, Trk A and  $p75^{LNGFR}$  immunoreactivity, which are co-localized with CB in these cholinergic neurons, displayed no similar age-related loss. Furthermore no age-related loss was observed in CB immunoreactivity within other CB-positive neurons in the forebrain. The similarity between the age-related loss of CB from the BFCN of the human and marmoset indicates that the latter represents an appropriate animal model for investigations of the role of CB in the vulnerability of BFCN to degeneration. (Supported by NIA grant AG10282)

## 84.14

TRK RECEPTOR ALTERATIONS IN ALZHEIMER'S DISEASE.

B. Connor\*, D. Young, P. Lawlor, R.L.M. Faul and M. Dragunov. Depts. of Pharmacology and Anatomy, University of Auckland, Auckland, New Zealand.

Recently it has been proposed that neurodegeneration associated with Alzheimer's disease may be due to impaired retrograde transport of nerve growth factor due to deficits in production and/or utilisation of the trkA receptor. The expression of trk receptors in post mortem normal, Huntington's disease and Alzheimer's disease human brains was investigated using immunohistochemistry and *in situ* hybridisation. Hippocampal and temporal lobe sections (50µm) from normal, Huntington's disease and Alzheimer's disease brains were incubated with primary polyclonal antibodies to trkA, trkB (full-length) and trkB (truncated) and the immunostaining visualised using the Extravidin/HRP-diaminobenzidine method. Alzheimer's disease hippocampi displayed an increase in trkA receptor-immunopositive levels in astrocytes around the CA1 region, some of which were associated with  $\beta$ -amyloid-positive plaques. In addition, truncated trkB receptors were found in high levels in senile plaques, while the full-length trkB receptor was expressed in glial-like cells in the hippocampus of Alzheimer's disease brains. Using an oligoprobe directed against trkA, hippocampal and temporal lobe sections (16µm) were processed for *in situ* hybridisation. Results indicated that trkA receptor mRNA levels were also elevated in the Alzheimer's disease hippocampus. The alteration in trkA and trkB receptors in the hippocampus and temporal lobe of the Alzheimer's disease brain and their association with astrocytes and plaques suggests that they may play a functional role in promoting the synthesis of  $\beta$ -amyloid and plaque formation.

B. Connor is the recipient of a Health Research Council of New Zealand Postgraduate Scholarship. This work was supported by grants from the New Zealand Neurological Foundation, the New Zealand Health Research Council, Auckland University Research Committee and the New Zealand Lotteries Board.

MAO INHIBITORS POTENTIATE ACETYLCHOLINESTERASE INHIBITOR EFFECTS ON PASSIVE AVOIDANCE LEARNING IN THE RAT. F. Camacho, R.W. Dunn, F.P. Huger, J.T. Winslow\*, Hoechst Marion Roussel, Neuroscience Therapeutic Area, Bridgewater, N.J., 08807

Cholinomimetic agents have had limited efficacy in treating dementia associated with Alzheimer's Disease. Monoaminergic systems including noradrenergic, dopaminergic and serotonergic substrates have also been implicated in cognitive processes and are significantly affected in Alzheimer's Disease. This study reports the effects of increased monoaminergic and cholinergic neurotransmitter activity produced by drugs which interfere with enzymatic degradation. These effects were examined in a passive avoidance paradigm designed to detect enhanced memory retention in rodents. The acetylcholinesterase inhibitor heptylphosphostigmine significantly enhanced retention latencies of a passive avoidance response at moderate doses (1.25-2.5 mg/kg, IP). The non-selective MAO inhibitor tranylcypromine (2.5-20 mg/kg, IP) and the MAOA inhibitor moclobemide (5.0-40.0 mg/kg, IP) did not affect passive avoidance in this paradigm, while a high dose of the MAOB inhibitor deprenyl (40 mg/kg IP) did enhance performance 24 hrs after administration and training. When a sub-threshold dose of heptylphosphostigmine (0.625 mg/kg, IP) was co-administered with ineffective doses of moclobemide (5, 10 mg/kg), tranylcypromine (5, 10 mg/kg) or deprenyl (10, 20 mg/kg) the combination of drugs also enhanced retention of the passive avoidance response. These data indicate that cholinergic and monoaminergic substrates may interact in the formation of a long-term memory trace. The specific monoamines associated with this action are not clear from these findings since MAOI's of both the A and B types potentiated heptylphosphostigmine. Over all, these results indicate that chemotherapy targeted at multiple neurotransmitter systems may be an efficacious alternative for the treatment of AD.

## 84.18

BUTYRYLCHOLINESTERASE: IS IT IMPORTANT FOR CORTICAL ACETYLCHOLINE REGULATION? E. Giacobini\*, PL. Griffini, T. Maggi, G. Mascellani, and R. Mandelli. Research Dept, Mediolanum Farm, Milan, Italy and <sup>1</sup>Dept. of Geriatrics, University Hospitals of Geneva, CH-1226 Thonex-Geneva, Switzerland.

The mammalian brain has been shown to contain two major forms of cholinesterases (ChE), acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE). Using specific substrates and selective inhibitors it has been demonstrated that in rat brain, 80% of the ChE activity is AChE and 20 % BuChE (Giacobini and Holmstedt, 1958) and that AChE and BuChE are mainly localized in neurones and glia respectively (Giacobini, 1959). In the cortex of patients suffering by Alzheimer disease (A.D.), AChE activity is decreased to 10-15 % of normal values while BuChE is unchanged or slightly increased (Perry et al., 1978, Davies, 1979, Attack et al., 1987, Giacobini, 1989, Arendt et al., 1992). Since AChE is inhibited by high concentrations of acetylcholine (ACh), while BuChE remains unaffected, it may well be that BuChE may play an important role in the *in vivo* regulation of synaptic concentrations of ACh in the brain of A.D. patients. This hypothesis may gain support if it were possible to demonstrate that a selective inhibitor of BuChE brings about an increase in extracellular ACh and that this effect can be potentiated by the association with a selective AChE inhibitor. For this purpose we have utilized a sensitive microdialysis method with low femtomole sensitivity without a second ChE inhibitor in the probe using the BuChE selective phenylcarbamate derivative MF 8622 (IC<sub>50</sub>=6.5 nM). Our results show that MF 8622 (15µM and 50 µM) was able to significantly increase the level of extracellular ACh in a dose dependent manner when infused directly into the cortex via the dialysis probe. The maximal observed extracellular concentration of ACh was 25 nM (from 5 nM base line).

## 84.19

**INCREASED AMYLOID PRECURSOR PROTEIN (APP) SYNTHESIS IN RAT CORTICAL ASTROCYTES BY ADRENERGIC RECEPTORS COUPLED TO CAMP FORMATION.** Richard J. Wurtman\*, Robert K. K. Lee, Wataru Araki, Youjeong Kim and U. Ingrid Richardson. Dept. Brain & Cognitive Sci., MIT, Cambridge, MA 02139.

We have shown that APP metabolism is accelerated by neurotransmitters and second messengers that activate protein kinase C. We now present evidence that APP synthesis (i.e., mRNA and holoprotein) can be increased by neurotransmitter receptors coupled to a different messenger, cAMP formation. Confluent primary astrocytes treated with serum-free medium containing 50, 100 or 250  $\mu$ M respectively of 8-Bromo-cAMP (8Br-cAMP) for 24h showed a dose-dependent increase in APP mRNA on Northern blots (120%, 150% and 180% of untreated cells). In comparison,  $\beta$ -actin mRNA was decreased to 50% of untreated cells by 8Br-cAMP (250  $\mu$ M). Both L-norepinephrine (NE, 50 or 100  $\mu$ M) and the  $\beta$ -adrenergic agonist isoproterenol (50  $\mu$ M) increased APP mRNA to 180% of untreated cells. The  $\beta$ -adrenergic antagonist propranolol (50  $\mu$ M) reduced the NE-stimulated increase in APP mRNA to baseline levels. N- and C-terminal APP antibodies 22C11 and R37 (from Dr. F. Kametani, Tokyo Inst. Psychiatry) respectively showed that 8Br-cAMP or NE also increased APP holoprotein in cell lysates to 200% of that seen in untreated cells. Both drugs also increased process formation and glial fibrillary acidic protein immunoreactivity in astrocytes. Thus, activation of  $\beta$ -adrenergic receptors coupled to cAMP formation increases both APP mRNA and holoprotein in reactive astrocytes.

The APP gene promoter contains a consensus sequence for a cAMP response element (CRE). The immunosuppressant cyclosporin A (CycA, 10  $\mu$ M), which is known to inhibit CRE-mediated transcription, blocked the increase in APP protein caused by 8Br-cAMP. This suggests that CycA may be used to prevent increases in APP and, possibly, amyloid formation in Alzheimer's disease.

## 84.20

**N-Acetylaspartylglutamate, N-acetylaspartate and N-acetylated alpha-linked acidic dipeptidase in human brain and their alterations in Huntington's and Alzheimer's disease.** L. A. Passani\*, J.-P. G. Vonsattel\*, R. E. Carter\* and J. T. Coyle\*. Lab. Molec. & Develop. Neurosci. and Lab. Molec. Neuropathol. \*Harvard Medical School / MGH, Charlestown, MA 02129.

The dipeptide N-acetylaspartylglutamate (NAAG) may be involved in the process of glutamatergic signaling by both serving as an endogenous receptor ligand and a glutamate transporter. NAAG levels and the activity of N-acetylated alpha-linked acidic dipeptidase (NAALADase), an enzyme which hydrolyses NAAG to glutamate and N-acetylaspartate (NAA), are altered in nervous system disorders associated with the dysregulation of glutamatergic neurotransmission such as schizophrenia, seizure disorders, and amyotrophic lateral sclerosis. The processes leading to these alterations are not well understood. In the present investigation, we have extended the study of NAAG and its hydrolytic enzyme to Alzheimer's disease (AD) and Huntington's disease (HD). Since NAAG is localized to neurons especially vulnerable to the degenerative process in AD and HD, we investigated alterations in neuronal and glial density as a possible factor impacting levels and activity. The levels of NAAG, NAA and several amino acids and the activity of NAALADase were determined in eight different brain regions of control, AD and HD brain. Cell density was determined by counting the number of neurons, oligodendrocytes and astrocytes in defined samples of each brain region. The cell density counts were correlated to the NAAG levels and NAALADase activity determined in corresponding samples. Significant reductions in both NAAG levels and enzyme activity were found in AD amygdala, hippocampus, frontal cortex, cerebellar cortex and putamen as well as in HD caudate nucleus, putamen, frontal and temporal cortex and cerebellar cortex. Reductions in neuronal density in brain regions affected by these disorders correlated significant in most regions with the reductions in NAAG, NAA and NAALADase, whereas there were no correlations between NAAG, NAA, NAALADase and glial density. The parallel reductions of NAAG levels and NAALADase activity in these two neurodegenerative disorders suggest a close spatial and/or functional relationship between the two neurochemical parameters in the affected neurons. Therefore, we hypothesize that NAAG and NAALADase may be involved in the pathological processes of HD and AD. This work was supported by NIH Grant MH-572901.

## DEGENERATIVE DISEASE: ALZHEIMER'S—NEUROPHARMACOLOGY AND NEUROTRANSMITTERS II

## 85.1

**AN  $\alpha_1$ -ADRENOCEPTOR AGONIST, ST 587, AND A PARTIAL GLYCINE-B BINDING SITE AGONIST, D-CYCLOSERINE, STIMULATE SPATIAL BEHAVIOR IN AGED RATS.** M. Riekkinen\* and P. Riekkinen Jr. Department of Neurology, University of Kuopio, P.O.Box 1627, FIN-70211 Kuopio, Finland.

The present study was designed to investigate the efficacy of single and combined stimulation of  $\alpha_1$ -adrenoceptors and glycine-B binding sites to alleviate age-related water maze (WM) reference (fixed location of the platform) and working (reversal of the platform location) memory defect. We found that in aged rats daily intraperitoneal (i.p.) pretreating treatment with ST 587, an  $\alpha_1$ -adrenoceptor agonist, at 3000  $\mu$ g/kg, but not at 1000  $\mu$ g/kg, facilitated reference memory in WM task. However, ST 587 at 3000  $\mu$ g/kg i.p. did not stimulate working memory. A partial glycine binding site agonist, D-cycloserine (DCS; i.p.), at 10 000  $\mu$ g/kg facilitated WM reference memory performance in aged rats. The subthreshold doses of DCS 1000 or 3000  $\mu$ g/kg did not increase the therapeutic effect of ST 587 1000 or 3000  $\mu$ g/kg. Further, a subthreshold dose of ST 587 1000  $\mu$ g/kg did not enhance the therapeutic effect of DCS 10 000  $\mu$ g/kg. The present results indicate that activation of  $\alpha_1$ -adrenoceptors and glycine-B binding sites may to some extent alleviate age-related defect of spatial navigation.

**$^{125}$ I-HUMAN-GALANIN BINDING SITES IN ALZHEIMER'S DISEASE: INCREASES IN HIPPOCAMPAL SUBFIELDS AND A DECREASE IN THE CAUDATE NUCLEUS.**

Rodríguez-Puertas Rafael, Nilsson Siv, Pascual Julio\*, Pazos Angel, Hökfelt Tomas. Dept. of Neurosci., Karolinska Inst., Stockholm, Sweden. and Dept. of Physiol. and Pharmacol., Univ. of Cantabria, Santander, Spain

Using iodinated human galanin and autoradiography, galanin binding sites were studied in cortical and hippocampal areas and in some brainstem nuclei of 8 patients with senile dementia of the Alzheimer type (SDAT) and of 9 matched control cases. The pattern of distribution showed the highest density in the substantia nigra with a less intense labelling in the hippocampus and cortical regions. In the SDAT cases a significant increase in galanin binding sites was found in some hippocampal areas, a decrease in the caudate nucleus and no significant changes in frontal and entorhinal cortices. These findings suggest that some central galanin systems may be deranged in SDAT.

## 85.3

**NEUROPEPTIDES, PHOSPHORYLATED TAU AND NEUROPATHOLOGY IN ALZHEIMERS DISEASE** G. Bissette\*, W. Smith, B. Crain and C. B. Nemeroff. Depts. of Psychiatry and Pathology, Duke Univ. Med. Ctr., Durham, N.C. 27710

In cortical post-mortem brain tissue from Alzheimer's disease (AD) patients, the concentrations of the neuropeptide neurotransmitters, corticotropin-releasing factor (CRF) and somatostatin (somatostatin-release inhibiting factor, SRIF), are decreased relative to non-AD control patients. In contrast, the hyperphosphorylated form of the microtubule associated tau protein which is detected by the ALZ-50 antibody and forms the paired helical filaments of the neurofibrillary tangles is increased in the cortex of AD patients. Using punched samples of the frontal (Brodman's area 10) and temporal (Brodman's area 21) cortex from patients with neuropathologically confirmed AD (n=91) and non-AD controls with (n=19) and without (n=8) dementia, the concentration of CRF, SRIF and the ALZ-50 reactive tau were measured and correlated with numbers of senile plaques and neurofibrillary tangles as well as the demographic variables of age, sex, duration of disease, post-mortem delay and freezer residence time. Both CRF and SRIF were significantly reduced while the ALZ-50 reactive tau concentrations were increased in AD in both cortical regions relative to the controls. Demented controls had reduced concentrations of both peptides relative to non-demented controls also, but were not significantly different in ALZ-50 reactive tau levels. As expected, the concentration of the ALZ-50 reactive tau was highly correlated with the numbers of neurofibrillary tangles in both regions. Significant correlations were also obtained between CRF and SRIF in both regions in AD and control patients, with SRIF and the tau protein in the controls and for both peptides and plaque counts in the AD patients. These data support the hypothesis that the neuropeptide changes in AD are more associated with the presence of dementia than with the presence of the specific pathogenic structures used to diagnose AD. Supported by NIH grants MH-40524 and AG-05128.

## 85.4

**AUTORADIOGRAPHIC STUDY OF GALANIN BINDING IN THE NORMAL AND ALZHEIMER'S DISEASE BRAIN: EVIDENCE FOR INCREASED RECEPTOR OCCUPANCY IN ALZHEIMER'S DISEASE.** J.B. Leverenz\*, M.A. Raskind, and M.A. Miller. Depts. Neurology and Psych & Behav. Sci., Univ. of Washington, Seattle, WA 98195

Excess galanin (GAL) may play a role in the memory dysfunction observed in patients with Alzheimer's disease (AD). Previous studies have observed a reduction in the number of GAL receptors in the parahippocampal gyrus (PHG) but not in the basal forebrain (BF) with AD. Since occupancy of these receptors by endogenous GAL may result in an underestimation of total receptor number, GTP pretreatment can be used to induce dissociation of endogenous GAL from its receptor prior to incubation with radio-labeled ligand. We have used this method to evaluate the alterations in total GAL receptor number and receptor occupancy by endogenous GAL with AD. Fresh frozen coronal sections (20  $\mu$ m) from normal (n=6) and AD (n=6) brains were sampled at the level of the superior frontal gyrus (SFG), BF, hippocampus, PHG, and lateral hypothalamus (LH). Sections were pretreated with or without GTP ( $10^{-4}$  M) and then incubated in 0.25 nM  $^{125}$ I-GAL. Non-specific binding was assessed by the addition of excess unlabeled GAL. We observed that the ability of GTP pretreatment to enhance  $^{125}$ I-GAL binding site density was greater in the SFG, hippocampus CA-1, and LH ( $p < .05$ ) of the AD versus normal brain indicating enhanced occupancy of GAL receptors in these regions. Consistent with previous reports, we observed a significant decline in GAL receptor density in the PHG ( $p < .05$ ) which was not reversed by GTP pretreatment. In contrast, GAL receptor number was not reduced in the SFG, BF, LH and hippocampus with AD. Our observation of regionally specific increases in GAL receptor occupancy provides further evidence for excess GAL release in AD. Since the number of GAL receptors in most regions are preserved in AD, this excess in GAL release may contribute to the cognitive deficits observed in this disease. ## 85.5

**ALTERATION IN MUSCARINIC ACETYLCHOLINE RECEPTOR SUBTYPES IN DIFFUSE LEWY BODY DISEASE AND ALZHEIMER'S DISEASE** K. Shiozaki\* and Y. Watanabe, Department of Pharmacology, National Defense Medical College, 3-2 Namiki, Tokorozawa, 359 Japan.

Dementia accompanied by Lewy bodies in the brain stem and cortex has been termed diffuse Lewy body disease (DLBD). Recently, it is reported that DLBD is the second most common cause of dementia in the elderly, after Alzheimer's disease (AD). Severe decrease in choline acetyltransferase activity and increase in muscarinic acetylcholine receptor (mAChR) binding were reported in DLBD cortices. We have generated subtype specific antibodies against mAChR subtypes (m1-m4) and examined their distributions in postmortem brain. Membrane fractions were prepared from postmortem brains which were histopathologically diagnosed as physiological aging (n=3), DLBD (n=7) and AD (n=5). mAChRs were prelabeled with [<sup>3</sup>H]QNB, then solubilized with 1% digitonin and 0.1% cholate and immunoprecipitated with antisera. The proportions of specifically precipitated mAChR subtypes were estimated as the differences in the amounts of bound [<sup>3</sup>H]QNB precipitated with specific antibody and those precipitated with non immune serum. Marked changes were observed in preparations of temporal cortex and hippocampus. In these areas, [<sup>3</sup>H]QNB binding sites in DLBD were found to be significantly decreased. The level of immunoprecipitated m1 receptor was found to be significantly decreased in AD compared to physiological aging. The level of m2 was lower in DLBD compared with physiological aging and AD. The level of m4 was also diminished in DLBD.

## 85.7

**BIIP 20 XX IS A POTENT AND SELECTIVE ANTAGONIST OF ADENOSINE A<sub>1</sub> RECEPTORS *IN VIVO* AS DEMONSTRATED BY BEHAVIOURAL, EEG AND MICRODIALYSIS STUDIES.** A. J. Carter\*, W. T. O'Connor, M. J. Carter, W. Gaida, E. Lehr, U. Küfner-Mühl and U. Ungerstedt. Departments of Biological Research and Medicinal Chemistry, Boehringer Ingelheim KG, D-55216 Ingelheim, Germany and Department of Physiology and Pharmacology, Karolinska Institute, S-17177 Stockholm, Sweden.

BIIP 20 XX is a purine derivative which potently and selectively antagonizes adenosine A<sub>1</sub> receptors *in vitro*. In this study, we have investigated the ability of BIIP 20 XX to antagonize adenosine A<sub>1</sub> receptors *in vivo*. Oral administration of BIIP 20 XX failed to influence locomotor activity in mice. However, it antagonized the inhibition of locomotor activity induced by administration of the selective A<sub>1</sub> agonists cyclopentyladenosine (CPA) and dihydroxypropyladenosine (DHPA). Furthermore, oral administration of BIIP 20 XX dose-dependently increased the extracellular levels of acetylcholine in the hippocampus of awake, freely moving rats as measured by microdialysis. These effects were completely blocked when the microdialysis probe was perfused with a Na<sup>+</sup>-channel blocker, tetrodotoxin, and strongly attenuated when a Ca<sup>2+</sup>-free perfusate was used. Furthermore, the effects of BIIP 20 XX were concentration-dependently counteracted by local perfusion of CPA but not by a selective A<sub>2</sub> agonist, CGS 21680. Although BIIP 20 XX had no intrinsic effect on EEG patterns of conscious rabbits, it dose-dependently antagonized the sedative effects of DHPA and attenuated the anticholinergic effects of scopolamine. Finally, BIIP 20 XX produced vigilance-enhancing effects as measured by polysomnography in chronically implanted, freely moving cats. In summary, these results demonstrate that BIIP 20 XX is a potent and selective antagonist of adenosine A<sub>1</sub> receptors *in vivo*. The effects of BIIP 20 XX on central cholinergic transmission demonstrated in this study suggest that this agent may be a novel and powerful approach for the treatment of reduced cholinergic function such as that observed in Alzheimer's disease.

**ADRENERGIC RECEPTORS IN ALZHEIMER'S DISEASE: INCREASES IN THE CEREBELLA OF AGGRESSIVE OVER NON-AGGRESSIVE PATIENTS.** A. Russo-Neustadt\* and C.W. Cotman, Institute for Brain Aging and Dementia, University California, Irvine, CA 92697

Behavioral aggression is an important problem in a significant subpopulation of patients with Alzheimer's Disease (AD). Much evidence exists that norepinephrine is important in mediating and modulating aggressive behaviors in limbic regions of the brain. The distribution and concentration of  $\alpha_2$ ,  $\beta_1$  and  $\beta_2$  adrenergic receptors was examined through receptor autoradiography in three brain regions of a group of AD patients who were aggressive and agitated during their disease course. These receptor levels were compared to those in the brains of AD patients without these behavioral complications. Tissue from two regions of frontal cortex (dorsolateral prefrontal cortex and orbitofrontal cortex), hypothalamus (dorsomedial, ventromedial, lateral and posterior nuclei) and cerebellum (cortex from the hemisphere) from 24 patients was processed for receptor autoradiography with [<sup>125</sup>I]iodopindolol for  $\beta$ -adrenergic receptors (in conjunction with the subtype-selective antagonists ICI-118,551 and ICI-89,406 to visualize  $\beta_1$  and  $\beta_2$  subtypes, respectively), and [<sup>3</sup>H]bromoxidine ([<sup>3</sup>H]UK-14,304) for  $\alpha_2$  receptors. Results showed no significant differences in  $\alpha_2$  or  $\beta$ -adrenergic receptor distribution or density between these groups of AD patients in the frontal cortical areas or hypothalamic nuclei examined. In contrast, the cerebellar cortices of agitated demented patients showed significant increases in adrenergic receptor concentrations over the non-aggressive group, with the most striking differences found in  $\alpha_2$ . Cerebellar  $\beta_1$  and  $\beta_2$  receptors within the granule cell layer and cortical white matter of the aggressive patients were increased in density approximately 30% over the non-aggressive AD patients. Cerebellar  $\alpha_2$  receptors in the molecular and granule cell layers were increased approximately 80% in agitated AD patients over the non-agitated subgroup. These results support clinical evidence that adrenergic agents may be helpful in the management of aggression, and also suggest a cerebellar contribution to the modulation of behavior.

## 85.6

**BIIP 20 XX: A POTENT AND SELECTIVE A<sub>1</sub> ADENOSINE RECEPTOR ANTAGONIST FOR THE TREATMENT OF COGNITIVE DEFICITS.** H.A. Ensinger, W.D. Bechtel, W. Gaida, J. Mierau, U. Küfner-Mühl and M. Wiennicht\*, Dept. Biological Research and Dept. Chemical Research, Boehringer Ingelheim KG, 55216 Ingelheim, Germany

Alzheimer's patients suffer from extensive neuronal cell loss coherent with reduced synaptic transmission. Antagonism of A<sub>1</sub> adenosine receptors constitutes one possible strategy to activate central neurotransmission.

BIIP 20 XX demonstrates high and selective affinity for the A<sub>1</sub> adenosine receptor subtype in receptor preparations from rat (r), monkey (m) and human receptors expressed in CHO-cells (h). The following affinities could be determined: A<sub>1</sub>: K<sub>i</sub>=3.0nM (r), K<sub>i</sub>=8.2nM (m) and K<sub>i</sub>=7.3nM (h). A<sub>2</sub>: K<sub>i</sub>=2640nM (r), K<sub>i</sub>=1418nM (m) and K<sub>i</sub>=440nM (h). A<sub>3</sub>: K<sub>i</sub>=2856nM (h).

In functional assays *in vitro* such as electrically stimulated acetylcholine release from rat hippocampal slices a pA<sub>2</sub> value of 8.7 could be determined. BIIP 20 XX also reversed the inhibition of the noradrenaline and serotonin release by CPA (cyclopentyladenosine). In hippocampal slices, the suppression of electrically evoked synaptic transmission by the A<sub>1</sub> adenosine receptor agonist CPA was concentration-dependently antagonized by BIIP 20 XX (pA<sub>2</sub>=8.5). Additionally, the activation of human A<sub>1</sub> receptors expressed in CHO cells was measured by the stimulated proton efflux using the cytosensor technology. BIIP 20 XX blocked the agonist CPA effectively (pA<sub>2</sub>=8.6). Caffeine, theophylline and DPCPX (dipropylcyclopentylxanthine) were investigated as reference antagonists.

In conclusion, BIIP 20 XX has a high selectivity for the A<sub>1</sub> adenosine receptor from rats, monkey and man. Furthermore, BIIP 20 XX displays a consistently high potency as A<sub>1</sub> antagonist in the rat hippocampal slice preparation and the cytosensor assay using CHO hA<sub>1</sub>-cells.

## 85.8

**DECREASED EXPRESSION OF mRNA ENCODING NR1 SUBUNIT OF THE NMDA RECEPTOR IN SELECT REGIONS OF ALZHEIMER BRAIN.** I. Ulas\* and C.W. Cotman, Institute for Brain Aging and Dementia, University of California, Irvine, CA 92717, USA.

The aim of this study was to assess whether reduced binding to specific sites of the NMDA receptor complex observed in the hippocampus (HP) and parahippocampal gyrus of patients with Alzheimer's disease (AD, Ulas et al., 1992) is attributable to the altered expression of the gene encoding the obligatory NR1 subunit of the NMDA receptor. Accordingly, we examined the distribution of NR1 mRNA in the HP and adjacent cortical areas of seven AD patients and seven normal, elderly individuals. Densitometric analysis of *in situ* hybridization autoradiograms revealed a 34% ( $P < 0.05$ ) decrease in NR1 mRNA levels in layer III of the entorhinal cortex (EC) in AD brains. Similar deficits were observed in other layers of EC and in dentate gyrus granule cells. Reduced levels of NR1 mRNA were also found in layers II-VI of the perirhinal cortex (40-50% decrease,  $P < 0.02$ ). There were no significant changes in NR1 mRNA expression in the CA1, hilus, or subiculum. However, there was a slight decrease in the number of silver grains overlying individual neurons in the CA1, EC and dentate gyrus granule cell layer. These data suggest that the reduction in the NR1 transcript may reflect either cell loss, occur indirectly in response to abnormalities in glutamatergic input to the HP, or represent alterations in the HP and subicular output. When followed by changes at the NR1 protein level, an aberrant expression of the NR1 gene in AD brain may result in the formation of NMDA receptors with new properties, thus contributing to altered binding to certain receptor recognition sites, abnormal vulnerability of select neuronal populations to excitotoxic cell death, and/or learning and memory deficits.

## 85.10

**1-[(3-Fluoro-4-pyridinyl)amino]-3-methyl-1(H)-indol-5-ylmethyl carbamate (P10358): Pharmacological activity and safety profile of a novel, orally-active acetylcholinesterase inhibitor for Alzheimer's Disease (AD).** C. P. Smith\*, G. M. Bores, W. Petko, M. Li, D. Selk, D. Rush, J. Winslow, F. Camacho, R. Fishkin, D. Cunningham, H. Hartman, K. Brooks, L. Davis and H. M. Vargas, Hoechst Marion Roussel, Neuroscience Therapeutic Domain, Bridgewater, N.J. 08807. P10358 is a potent, reversible acetylcholinesterase inhibitor (AChEI) with central biochemical and behavioral activity after oral or parenteral administration. *Ex vivo* studies showed that P10358 produced significant and dose-dependent inhibition of brain AChE over a range from 0.2 - 20 mg/kg, p.o. At 10 and 20 mg/kg, this compound produced long-lasting hypothermia in mice, another *in vivo* measure of brain cholinomimetic activity. This compound reversed scopolamine-induced passive avoidance deficit in mice (0.03-0.1 mg/kg) and scopolamine-induced deficits in the Morris water maze in rats (1.25 and 2.5 mg/kg, p.o.). It also enhanced performance in rats in both a step-down passive avoidance task (0.62 and 1.25 mg/kg, p.o.) and in a social recognition paradigm (0.32, 0.64, and 1.25 mg/kg). A higher dose (20 mg/kg, p.o.) enhanced striatal homovanillic acid (HVA) levels in rats, an effect consistent with cholinomimetic activity. Hemodynamic studies in the conscious rat showed that there was a 16-fold separation between behaviorally-active doses (1.25 mg/kg) and those which elevated arterial pressure (20 mg/kg). Chemically, P10358 is an N-aminoindole and may not have the hepatotoxic liability associated with aminoacridine structure of THA. Lethality in rats after oral administration did not occur until a dose of 80 mg/kg. P10358 had weak affinity for a variety of other receptors or uptake carriers, and had a pharmacological profile consistent with a single mechanism of action. Based on these studies, P10358 may be a promising therapeutic for the symptomatic treatment of AD. Research funded by HMR, Inc.

**COMPARISON OF THE EFFECTS OF TWO SELECTIVE CHOLINERGIC NEUROTOXINS (AF64A and 192-IgG Saporin) ON SPATIAL LEARNING IN THE MALE RAT.** W.A. Dorman, M. Easterday, T. Folkers, L. Hickman, J. Johns, M. Kern, J. Litwiler, S. Russell, G. Tinkler. Dept. of Psychology, Illinois Wesleyan University, Bloomington, IL 61702.

Alzheimer's Disease (AD) is caused by a gradual degeneration in specific areas of the brain, most notably the hippocampus and cerebral cortex. Despite this knowledge, however, presently no animal model exists that reliably mimics the profound pathological and behavioral changes that characterize the disease. Moreover, while a considerable amount of evidence has implicated the loss of cholinergic basal forebrain (CBF) input to the hippocampus and cortex as being one of the major neuropathological components characteristic of AD, the exact role the CBF plays in the cognitive deficits observed in AD is still uncertain. One factor that has contributed to this ambiguity is that until recently the lack of a specific cholinergic neurotoxin has hindered attempts to selectively destroy the cholinergic input to the cortex and hippocampus. As a result, there is considerable excitement regarding the introduction of the new cholinergic toxin, 192 IgG saporin as a potential new tool in generating an animal model that mimics the profound memory impairment that characterizes AD. In this study, we compared the effects of multiple injections of 192-IgG saporin into the CBF to intraventricular injections of AF64A on performance of the Morris water maze (MWM) and the radial arm maze (RAM) task in male rats. Our results revealed a dose-dependent effect of AF64A on three components of the MWM compared to controls. Intraventricular injections of AF64A significantly affected the performance of a non-cued test, a reversal test, and a discrimination test using the MWM when compared to controls. Multiple injections of 192 IgG saporin into the CBF, however, failed to appreciably effect the retention or acquisition of spatial learning in the RAM or the MWM. These data provide further support for the use of AF64A but not 192 IgG saporin as a viable approach to study the neurochemical mechanisms that underlie the cognitive deficits of AD.

## 85.13

**EFFECTS OF A CHOLINE DEFICIENT DIET ON THE GLUTAMINE SYNTHETASE ACTIVITY IN THE BRAINS OF MALE AND FEMALE SWISS-WEBSTER MICE.** V.G. Carson\*, B.A. LaDuca, H.B. Lee, and T.K. Tran. Chapman University, Orange, CA 92666

Cholinergic neurons are impaired in Alzheimer's Disease (AD). In order to acquire animal models similar to Alzheimer's patients, male and female Swiss-Webster mice were put on a choline deficient diet by substituting N-aminodeanol (NAde) for choline. Some were reversed to a normal diet after six months. It was hypothesized that a choline deficient diet would affect astrocytes, which are the major source of the brain's glutamine synthetase (GS). This enzyme has been shown by Carney et al. (Annals N. Y. Acad. Sci. 738:44-53, 1994) to be depressed in the frontal lobe of AD autopsy material. After behavioral tests were performed on the mice, they were sacrificed at 12 months of age and their brains extracted and stored at -80° C. Distilled water homogenates of tissue samples were analyzed for GS activity per mg protein. The brain homogenates from experimental animals had significantly less GS than those from control or diet reversed mice. This study indicates that there may be a linkage between choline deficiency and the GS enzyme. In addition, this finding strengthens the proposal of Russell et al. (Pharmacol. Biochem. Behav. 37:811-20, 1990) that the syndrome generated by NAde replacement of choline represents an experimental model of progressive degenerative dementia. (Supported by U. S. Public Health Service Grant MH-17691 to D. J. Jenden and R. W. Russell and Chapman University's Summer Research Grant.)

## 85.15

**ASSESSMENT OF CHOLINERGIC NEURONS IN TRANSGENIC MICE OVEREXPRESSION ALZHEIMER AMYLOID PRECURSOR PROTEINS.** M. A. Westerman\*, L. L. Pundi, S. B. Love, K. K. Hsiao, W. C. Low. Departments of Neurosurgery and Neurology, Grad. Prog. in Neuroscience, Univ. of Minnesota, Mpls., MN 55455.

Transgenic (Tg) mice which overexpress human or mouse Alzheimer amyloid precursor protein (APP) have been shown to die early and manifest behavioral abnormalities which include neophobia and impaired spatial alternation in a Y maze. In one form of clinical Alzheimer's disease there is a reduction of cholinergic neurons in the brain. In the present study, we examined the number of cholinergic cells in the medial septal nucleus (MS) and the horizontal limb of the diagonal band of Broca of Tg mice (HDB). Male Tg positive (n=3) and Tg negative (n=3) mice ranging from three-six months of age were assayed. Anatomically matched sections (20µm) evenly distributed throughout MS and HDB (120µm apart) were stained with an antibody for choline acetyltransferase (ChAT). ChAT positive cells were quantified and assessed for morphological differences. No significant differences were found in the number of ChAT positive cells between Tg positive and Tg negative mice in either MS or HDB. A blinded analysis of morphological differences between groups suggested the presence of densely stained dystrophic processes in Tg positive ChAT neurons. Arbitrary values were assigned to animals based on specific morphological characteristics of MS ChAT neurons. A value of 2 was given to animals which contained an increased intensity of staining in neuronal fibers and dystrophic processes. Animals with fine, lightly stained neuronal processes were assigned a value of 1. Tg positive mice received an average score of 2.0, while Tg negative mice received an average score of 1.2 (p<0.001). The abnormal morphology may be attributable to inefficient transport of molecules along axons to target areas such as the hippocampus. Although the number of cholinergic neurons is not affected by the overexpression of APP, the functional expression of these neurons may be compromised. Supported by PHS grants RO1-NS-24464 and RO1-NS-33249.

## 85.12

**CORTICAL ASTROCYTES CONTAIN LESS GLUTAMINE SYNTHETASE IN ALZHEIMER'S DISEASE.** S.R. Robinson<sup>1</sup>, J. Kri<sup>2</sup>, G.M. Halliday<sup>3\*</sup> & D. Noone<sup>1</sup>.

<sup>1</sup>Vision, Touch & Hearing Research Centre, University of Queensland, St. Lucia, QLD, 4072, Australia; <sup>2</sup>Dept. Pathology, University of Sydney, NSW, Australia, 2006; <sup>3</sup>Prince of Wales Medical Research Institute, NSW, Australia, 2031.

Extracellular glutamate concentrations are elevated in Alzheimer's disease (AD; Pomara et al., 1992, *Am. J. Psychiatr.*, 149: 251-254), suggesting that glutamate may have an excitotoxic role in this disease. Homogenates of AD brain tissue show reduced activity for glutamine synthetase (GS; Le Prince et al., 1995, *Neurochem. Res.*, 20: 859-862). Since this glial enzyme converts glutamate to glutamine, a reduced expression of GS may underlie the etiology of AD. The present study uses immunohistochemistry to compare the cellular localisation of GS in the entorhinal cortices of normal, non-demented donors (aged 58-84 years), and in individuals who had died with advanced AD (aged 66-76 years). The tissue was fixed in formalin, then cut coronally at 50µm. Sections were incubated with antisera directed against GS (1:500; Chemicon), GFAP (1:2500; Dako) or  $\beta$ -amyloid (1:100; Dako), then processed with streptavidin-HRP-DAB.

Immunolabelling for GS revealed numerous well-labelled cells homogeneously distributed through layers 2-6 of the cortex, but they were less frequent in layer 1 and were absent from the white matter. Their dendrites extended to the walls of blood vessels, where they terminated as endfeet. A small proportion of the cells were large and closely resembled GFAP-labelled fibrous astrocytes, but the majority were smaller and had dendrites that were finer, more numerous and more convoluted in their course. They may be protoplasmic astrocytes or grey matter oligodendrocytes. In AD, the frequency of labelled cells was reduced, they had fewer contacts onto blood vessels and the intensity of their immunolabelling was considerably lower. Unlike GFAP-labelled astrocytes, GS-labelled glia showed no reactivity to amyloid plaques. GS is extremely sensitive to inactivation by free radicals (Schor, 1988, *Brain Res.*, 456: 17-21), so we speculate that the substantially reduced intracellular levels of GS may be due to the elevated levels of free iron present in AD (see Robinson et al., *Alzheimer's Res.*, 1: 191-196).

Supported by grants to SRR from the ARC and Utah Foundation.

## 85.14

**CONSEQUENCES OF OXIDATIVE STRESS ON THE LEVELS OF APOLIPOPROTEIN E AND J RELEASED BY CULTURED ASTROCYTES.**

C. Ramassamy\*, S. Bastianetto, D. Dea, A. Schoofs<sup>a</sup>, Y. Christen<sup>b</sup>, R. Ouirion and J. Poirier. Douglas Hospital Research Centre 6875 Blvd Lasalle H4H 1R3 Montreal, Quebec. a: Centre Europeen de Bioprospective 24 bis rue Jacques Boutrolle BP24 76131 Mont Saint-Aignan Cedex France. b: Institut IPSEN 24 Rue Erlanger Paris. France

Apolipoprotein E (apoE) genotype and aging are risk factors associated with late onset and sporadic Alzheimer's disease (AD). Age-related oxidative challenges may also be important factors in AD since several indices of oxidative damage, such as lipoperoxidation, were increased in relevant brain regions of AD patients. We have investigated the effects of oxidative stress, induced by hydrogen peroxide (H2O2), on the release of apoE and apolipoprotein J (ApoJ) by cultured cortical astrocytes and hippocampal astrocytes cocultured with neurons from rats. Cells were treated by H2O2 (3mM) for 3 hours in DMEM/F12 medium. The levels of ApoE and ApoJ, measured in culture medium 24h after the end of the treatment by Western blotting, were markedly reduced. In the same conditions, the levels of these apolipoproteins were partially decreased (~50%) when hippocampal astrocytes were cocultured with neurons. The pretreatment by a Ginkgo biloba extract (Egb 761), at 10µg/ml, prevented the neurotoxic effect of H2O2 evaluated by the increase of lactate in the culture medium. In these conditions, the neurosteroid dehydroepiandrosterone sulfate (DHEAs) was partially effective. After 3 h exposure to 3mM H2O2 cell viability, as assessed by MTT colorimetric assay, was reduced by 70%. Our results suggest a potential link between processes involved in aging (oxidative stress) and critical proteins involved in the pathogenesis of AD. Furthermore, Egb 761 and DHEAs may be potent agents to protect astrocytes from oxidative injury. (Supported by Centre Europeen de Bioprospective and IPSEN Foundation).

**CHOLINERGIC SYSTEMS IN APOLOPOPROTEIN E KNOCKOUT MICE**

P. Krzyzowski, F. Momoli, J. Rochford, S. Gauthier\* and J. Poirier.

Douglas Hospital Research Centre, Department of Psychiatry and Centre for Studies in Aging, McGill University, Montréal, Québec, Canada, H4H 1R3.

Apolipoprotein E (apoE) is a glycoprotein implicated in lipid metabolism. Over the last few years, one of apoE isoforms, apoE4 was shown to be a major risk factor for sporadic and familial Alzheimer's disease (AD). The precise role of apoE in the etiology of AD is currently unknown. In view of the selective vulnerability of the cholinergic system in AD (which could be due to its dependence on phospholipids), we decided to study the effect of the absence of apoE on cholinergic activity in apoE knockout mice. Control C57 and apoE knockout mice (2 month-old) were tested behaviorally using the Morris swim maze task. Knockout mice showed a marked deficit in this task. Autoradiographic analysis of cholinergic receptors revealed little or no change in the pirenzepine-M1 binding sites in the medial septal area, the hippocampus or the cortex. In contrast, a decrease in the AF DX 384-M2 binding sites was observed at the middle level of the hippocampus (in the CA1/2 and CA3 fields) and a mild, although non significant, decrease of binding was observed in septal and cortical areas. Furthermore, a significant increase in cytosine-nicotinic binding sites occurred in cortex but not in septal and hippocampal areas. Measurement of choline acetyltransferase (ChAT) activity showed a slight but significant decrease in the striatum of the knockout mice, but not in the hippocampus, entorhinal, frontal or parietal cortices nor cerebellum. Studies are currently underway to examine the same parameters in 10 month-old knockout animals.

Taken together, these data show behavioral deficits in apoE knockout mice as early as 2 months of age. These are accompanied by subtle but specific changes in the cholinergic receptors. Although the mechanism underlying these deficits is poorly understood, there may be a close relationship between apoE neurobiology and cholinergic integrity in the CNS. This could very well explain the apoE genotype-dependent alteration of cholinergic function reported in apoE4 AD subjects.

This work was supported by fellowships from Specia/FNG (France), INSERM/FRSQ (France and Quebec, Canada) and the Alzheimer's society of Canada.

## 85.17

ENHANCED VASODILATORY EFFECT OF TACRINE IN THE CORTEX OF BASAL FOREBRAIN LESIONED RATS. P. Peruzzi, J. Seylaz and P. Lacombe. Laboratoire de Recherches Cérébrovasculaires, CNRS UA 641, Université Paris 7, IFR 6, Faculté Lariboisière-Saint Louis, 10, avenue de Verdun, 75010 PARIS, France.

The cholinesterase inhibitor, tacrine, is presently the most widely used agent for treating Alzheimer disease. The finding in the rat of the remarkable, age-dependent cerebrovasodilatory function of the nucleus basalis of Meynert/substantia innominata (SI) potentiated by cholinesterase inhibitors, is in support of the "cholinergic hypothesis" and substitutive therapy. Since these data suggest that cerebrovascular investigations offer a valuable experimental approach to test this hypothesis, the present study was designed to determine whether tacrine is able to reflect a cerebral circulatory deficit originating in the basal forebrain. Cerebral blood flow (CBF) measurement was performed 1-2 weeks following SI lesion with ibotenic acid, using the tissue sampling [ $^{14}$ C]iodoantipyrine technique, in two groups of lesioned rats infused intravenously either with tacrine at 8mg/kg/h or saline. SI lesion resulted in moderate, significant blood flow decreases in the parietal, frontal and occipital cortical areas. In most of the cortical and subcortical regions investigated tacrine induced significant increases in CBF, ranging from 21% (hypothalamus) to 101% (parietal cortex) in the intact hemisphere compared to the control group. The increases in the lesioned hemisphere were 1.9 and 1.5 times greater in the frontal and parietal cortex, respectively, than in the intact hemisphere. This result indicates that tacrine selectively favors the circulation in the cortex, soon after its deafferentation from the SI.

## ALZHEIMER'S DISEASE: ApoE

## 86.1

EFFECTS OF APOLOPOPROTEIN E GENOTYPE ON BRAIN STRUCTURE AND FUNCTION IN ALZHEIMER'S DISEASE. J.L. Eberling\*, B.R. Reed, R.M. Krauss, A. Acharya, J. Leung, D.M. Mungas, W.J. Jagust, Lawrence Berkeley Laboratory, University of California, Berkeley, CA 94720, and University of California, Davis, CA 95616. The apolipoprotein E type 4 allele (APOE  $\epsilon$ 4) is a risk factor for both familial late-onset and sporadic Alzheimer's disease (AD). Positron emission tomography (PET) studies have revealed neocortical reductions in glucose metabolism in at-risk subjects with APOE  $\epsilon$ 4. We used PET and  $^{18}$ F-fluorodeoxyglucose (FDG) to compare cerebral glucose metabolism in AD patients with and without APOE  $\epsilon$ 4. Eighteen AD patients were studied with MR followed by 3-D PET during a continuous recognition memory task. Three of the patients were homozygous for the  $\epsilon$ 4 allele, 9 were heterozygous for  $\epsilon$ 4, and 6 did not have the  $\epsilon$ 4 allele. Patients were matched for age, education, gender and dementia severity. Three-dimensional volumes of interest (VOIs), drawn on MR data, were mapped onto the PET data. Atrophy corrected glucose metabolic rates for each VOI were calculated using previously determined rate constants and an operational equation and were normalized to the global metabolic rate for the entire brain. VOIs were grouped together according to structural complexity and differentiation, and included: heteromodal association cortex, unimodal association cortex, primary sensory cortex, and limbic/paralimbic cortex. RESULTS. A repeated measures ANOVA revealed a significant ( $p=0.01$ ) group effect for only the limbic/paralimbic regions. Follow-up one-way ANOVAs and Fisher post-hoc tests showed that the homozygous patients had significantly lower metabolic ratios than heterozygous patients ( $p<0.05$ ) and patients without  $\epsilon$ 4 ( $p=0.002$ ) in hippocampus and amygdala. Heterozygous patients had significantly ( $p<0.05$ ) lower metabolic ratios than patients without  $\epsilon$ 4 in hippocampus. In addition, homozygous patients had significantly smaller hippocampal volumes (normalized to intracranial volume) than patients without  $\epsilon$ 4. Hippocampal volumes for heterozygous patients were intermediate to homozygous patients and patients without  $\epsilon$ 4, but not significantly different from either group. These findings show a specific dose-dependent effect of APOE  $\epsilon$ 4 on hippocampal volume and glucose metabolism in AD patients. (Supported by NIH grants AG07793 and AG10129).

## 86.3

Effects of Aging on Glial and Neural Markers in Apolipoprotein E-Deficient Mice. C.A. Parker, M.J. Callahan, W.J. Lipinski\*, C.L. Bisgaier and L.C. Walker. Neurological and Neurodegenerative Diseases Group, Parke-Davis Pharmaceutical Research, Div. of Warner-Lambert Co., Ann Arbor, MI 48105.

Some neurodegenerative processes appear to be augmented in aged, ApoE deficient ("knockout") mice (Masliah et al., Exp. Neurol. 136, 107, 1995). Whereas age-related glial changes have been consistently observed, the degree to which neuronal markers are compromised in aged ApoE knockouts remains uncertain (Gandy et al., Soc. Neurosci. Abs. 21, 5, 1995). We analyzed neuronal and glial markers in ApoE knockout mice (Jackson Labs) ranging from 2 to 20 months of age. One hemisphere from each animal was characterized histochemically and the other by quantitative immunoblots and cholinergic enzyme analysis. Tissue sections and brain homogenate extracts were studied with antibodies against synaptophysin,  $\beta$ -amyloid precursor protein ( $\beta$ APP), glial fibrillary acidic protein (GFAP) and with probes for microglia. We also measured levels of choline acetyltransferase in whole-hemispheric homogenates. As expected, astrocytic and microglial markers, as well as the strain-specific emergence of clustered granules in the hippocampus, increased with age. Synaptophysin levels showed no consistent changes in aged ApoE knockouts, nor did choline acetyltransferase and  $\beta$ APP levels change significantly between 2 and 20 months of age. Further work is needed to determine whether neurodegenerative changes are robust enough to qualify ApoE knockouts as reliable models of Alzheimer-like pathological changes. Variability among murine strains and brain regions require particular attention. Supported by Warner-Lambert.

## 86.2

Neurodegeneration and cognitive impairment in apoE-deficient mice is ameliorated by infusion of recombinant apoE. E. Masliah\*, W. Samuel#, J. Veinberg#, M. Mallory#, M. Mante# and T. Saitoh#. Depts. of Neurosciences# and Pathology\$, University of California, San Diego, La Jolla, California 92093.

Recent studies suggest that apolipoprotein E (apoE) might play a neurotrophic function in the central nervous system and that altered functioning of this molecule could result in neurodegenerative disorders such as Alzheimer's disease. The main objective of this study was to determine if neurodegenerative and cognitive alterations in apoE-deficient mice are reversible by infusion of recombinant apoE into the lateral ventricles. ApoE-deficient mice treated with either apoE3 or apoE4 showed a significant improvement in their learning capacity in the Morris water maze compared to saline-infused apoE-deficient mice. While this improved performance was associated with restoration of neuronal structure, the poor learning ability of apoE-deficient mice treated with saline correlated with the disrupted synapto-dendritic structure. This study supports the contention that apoE might play a neurotrophic effect *in vivo* and suggests that apoE might have a potential therapeutic role.

This work was supported by NIH grants AG05131, AG10689 and with funding from the Alzheimers Disease and Related Disorders Association, and the Broad Foundation. This work was also partially supported by NIH grant RR04050.

## 86.4

APOE POLYMORPHISM IN ELDERLY EAST AFRICANS

J.G. Savi, D.R.D. Premkumar, N.B. Patel, A.S. Bhandari, S. Gatere, W.B. Matuja, R.P. Friedland, E. Koss and R.N. Kalaria (SPON: Society of Neuroscientists of Africa)

Departments of Neurology and Pathology, Case Western Reserve University, Cleveland, Ohio, USA; Neurology Unit, Muhimbili Medical Centre, Dar es Salaam, Tanzania; Department of Medical Physiology, University of Nairobi and Avenue Nursing Home, Nairobi, Kenya.

Recent studies have shown the apolipoprotein E (APOE)- $\epsilon$ 4 allele to be associated with late-onset familial and sporadic Alzheimer's disease (AD). The frequency of APOE- $\epsilon$ 4 allele in AD has been reported to be about three times greater than non-demented controls in Western populations. The link between APOE polymorphism and dementia remains unknown in developing countries. We examined APOE frequencies in non-demented and demented elderly East Africans. Blood samples were obtained from elderly African patients (age range 50-90 years) admitted at two clinical centres in East Africa. The DNA from samples was extracted in Cleveland for APOE genotyping. The first group consisted of 150 elderly Tanzanian Africans attending clinic for non-neurological complaints at Muhimbili in Dar es Salaam. APOE allele frequencies in this group were found to be 15.7% for  $\epsilon$ 2, 62.9% for  $\epsilon$ 3 and 21.3% for  $\epsilon$ 4. Assessment of APOE genotypes in another group of elderly Kenyan patients from Nairobi also revealed high frequencies of the  $\epsilon$ 4 allele. Our results suggest that elderly East Africans have relatively high APOE- $\epsilon$ 4 allele frequencies compared to normal aging subjects from Western countries and support the implication that the APOE- $\epsilon$ 4 allele may not necessarily be a risk factor in indigenous populations of Africa. Supported by WHO-NINDS fellowship and grants from NIH and ADRDA.

**Apolipoprotein E is induced by A $\beta$  accumulation in transgenic mice**  
 Y. Igeta\*, T. Kawarabayashi<sup>1</sup>, M. Sato<sup>2</sup>, E. Matsubara<sup>3</sup>, K. Ishiguro<sup>4</sup>, M. Kanai<sup>1</sup>, Y. Tomidokoro<sup>1</sup>, T. Kobayashi<sup>1</sup>, N. Tada<sup>1</sup>, K. Okamoto<sup>1</sup>, S. Hirai<sup>1</sup> and M. Shoji<sup>1</sup>  
<sup>1</sup>Department of Neurology, Gunma University Medical School, 3-39-15 Showamachi, Maebashi, Gunma 371, Japan, <sup>2</sup>Laboratory for Animal Center, Pharma Research and Development Division, Hoechst Japan Limited, 1-3-2, Minamidai, Kawagoe, Saitama 350-11, Japan, <sup>3</sup>Tokyo Metropolitan Hospital, 2-6-1, Musashidai, Fuchu, Tokyo 183, Japan

Apolipoprotein E (ApoE) is a significant risk factor for Alzheimer's disease (AD). The frequency of apoE4 allele is increased in sporadic and late onset familial AD. Gene dose effect of ApoE4 is also established to accelerate the onset of AD. In vitro study suggests ApoE may accelerate A $\beta$  aggregation and form stable A $\beta$ /ApoE complex. However, the precise role of ApoE in A $\beta$  amyloid formation in vivo is still unclear. Here we show the secondary induction of ApoE by A $\beta$  accumulation in the pancreas of transgenic mice expressing a signal peptide and 99 residues of carboxyl-terminal fragment of amyloid  $\beta$  protein precursor ( $\beta$ APP). These mice developed A $\beta$  amyloid fibrils in the pancreas. Immunocytochemically, these A $\beta$  amyloid fibrils were labeled anti-ApoE antibody. ApoE immunoreactivities were correlated with an age-dependent A $\beta$  accumulation. Western blotting showed that the amount of apoE was increased in the transgenic pancreas than that in controls. However, the amount of ApoE mRNA in the transgenic liver was not increased compared with controls. These findings suggest that ApoE was locally induced by A $\beta$  accumulation in the transgenic pancreas.

## 86.7

**ALPHA-1-ANTICHYMOTRYPSIN POLYMORPHISM MODULATES THE APOLIPOPROTEIN E ASSOCIATED RISK OF ALZHEIMER'S DISEASE.** A. Ueki, M. Otsuka and M. Watanabe\* Department of Neurology, Jichi Medical School, Omiya Medical Center, Omiya City, Japan 330

Apolipoprotein E-e4 allele (APOE\*4) is a major risk factor of Alzheimer's disease (AD). However, there are many cognitively normal elderly who carry APOE\*4. It is postulated there are other genetic or environmental factors preventing the effects of APOE\*4 for developing AD. Among these factors, alpha-1-antichymotrypsin (ACT) signal peptide gene polymorphism is interesting. Kamboh et al. have shown that APOE\*4 dosage effect associated with AD risk is significantly modulated by the ACT genotype. To test their hypothesis we examined ACT genotypes in AD and age matched controls, and compared their frequencies between APOE\*4 carriers and non-carriers. APOE and ACT were genotyped in 58 AD patients (mean age at onset, 73.7; range, 60-86) and 105 healthy controls (mean age, 72.6; range, 60-92). There are two ACT alleles (ACT\*A and ACT\*T) and three ACT genotypes (\*AA, \*AT, \*TT). The distribution of ACT genotypes in total patients with AD and controls did not differ significantly. The frequencies of \*AA, \*AT, \*TT were 0.179, 0.456, 0.366, in total AD, and 0.106, 0.469, 0.425 in total controls, respectively. However, the distribution of ACT genotypes differed significantly when compared between subgroups of AD and controls carrying APOE\*4. The frequencies of \*AA, \*AT, \*TT in APOE\*4 carriers of AD (n=38) were 0.198, 0.556, 0.246, and those in APOE\*4 carriers of controls (n=17) were 0.059, 0.397, 0.544, respectively. Allele frequency of ACT\*A in APOE\*4 carriers of controls was significantly lower than that in APOE\*4 carriers of AD (0.192 vs. 0.438,  $\chi^2=4.9$ ,  $p=0.03$ ). ACT genotypes between non-carrier subgroups of AD and controls did not differ. Although it is uncertain at present that ACT\*AA is a promoting factor or ACT\*TT is a preventing factor, ACT polymorphism modify the risk of APOE\*4 carriers for developing AD or not.

## 86.9

**EXPRESSION AND REGULATION OF THE LOW DENSITY LIPOPROTEIN RECEPTOR-2 AND ITS LIGAND APOLIPOPROTEIN J IN RAT BRAIN**

D. Michel<sup>1</sup>, G. Chatellain<sup>1</sup>, G. Brun<sup>1</sup>, W.S. Argyrakis<sup>2</sup> and G.M. Pasinetti<sup>3</sup> <sup>1</sup>Laboratoire de Biologie Moléculaire, Ecole Normale Supérieure, CNRS UMR 49, Lyon<sup>1</sup>, France; <sup>2</sup>Medical University of South Carolina, Department of Cell Biology, Charleston, SC 29425; <sup>3</sup>Department of Psychiatry and Brookdale Center for Molecular Biology of the Mount Sinai Medical School, NY, NY 10029;

This study explored the distribution and co-expression of the low density lipoprotein receptor-related protein-2/megalin/gp330 (LRP-2) and its ligand apolipoprotein J/clusterin (apoJ) in young adult rat brain. Experimental brain lesions known to induce apoJ expression were also used to identify the co-regulation of apoJ/LRP-2 mRNA expression in mechanisms of neuronal death/survival. Radiolabelled RT-PCR of total RNA from dissected brain regions was used to quantify LRP-2 and apoJ mRNA expression. Pairs of LRP-2 primers were designed from the coding region of the rat LRP-2 cDNA (nt 12462-12485 and nt 12714-12737); apoJ primers were previously described (Michel et al., 1995). In control rat, we found that regions previously found to express high level of apoJ mRNA such as ependyma/choroid plexus, retina and olfactory mucosa also express detectable levels of LRP-2 mRNA. However, no detectable LRP-2 signal was found in parietal cortex, hippocampus and striatum, which also are known to constitutively express apoJ mRNA (Pasinetti et al., 1994). In response to kainic acid (KA) excitotoxic lesions that model selective neuronal death, apoJ mRNA signal showed elevation in striatum and hippocampus but not in cerebral cortex. Contrary to apoJ mRNA, the KA mediated induction of LRP-2 mRNA in these brain regions was equivocal. Similarly, deafferentation of the olfactory mucosa that models apoptotic death in the olfactory neuroepithelium induced apoJ mRNA in the absence of evident LRP-2 mRNA elevation. This study indicates that apoJ expression may be regulated independently of its receptor LRP-2 supporting the idea that its role in neurodegeneration is independent of receptor binding. Supported by NIA grant AG13618 to GMP.

## 86.6

**NON-A $\beta$  COMPONENT OF ALZHEIMER'S DISEASE AMYLOID (NAC) BINDS ISOFORM SPECIFIC TO APOLIPOPROTEIN E. O.F.Olesen<sup>1</sup>, P.H.Jensen<sup>2</sup>, K. Frederiksen<sup>1</sup> and J.D.Mikkelsen<sup>1</sup>. <sup>1</sup>Dept. of Neurobiology, H. Lundbeck A/S, Ottilavej 9, DK-2500 Valby-Copenhagen, Denmark and <sup>2</sup>Dept. of Medical Biochemistry, University of Århus, DK-8000 Århus C, Denmark**

The non A $\beta$  component of Alzheimer's disease amyloid (NAC) is a newly discovered 35 amino acids peptide that is found closely linked to the beta-amyloid fibrils in senile plaques. NAC derives from a larger precursor protein, termed NACP or  $\alpha$ -synuclein, that consists of 140 amino acids and is associated with presynaptic vesicles. We report that NAC, as well as its precursor  $\alpha$ -synuclein, binds to A $\beta$  and induces its aggregation into amyloid plaques. We further found that NAC binds to apolipoprotein E (apoE), forming a complex that is resistant to reducing agents and separation by denaturing gel electrophoresis, whereas extreme acidic or basic pH strongly affected the binding. The complex was formed rapidly upon mixing the two molecules, reaching a maximum within the first hour of incubation. ApoE exists in different isoforms of which apoE3 is the most frequent, whereas apoE4 has been linked to late-onset Alzheimer's disease. We therefore examined the binding of NAC to individual isoforms of apoE and found that the complex between NAC and apoE was isoform-specific with respect to apoE. More than twice as much NAC was complexed with apoE4 as compared to apoE3. The isoform specific binding to NAC was maintained over a range of apoE concentrations, including those normally encountered in cerebrospinal fluid. The ability of NAC to interact with A $\beta$  and isoform-specific with apoE indicates that NAC and/or NACP may play an important role in the amyloidogenesis during Alzheimer's disease.

## 86.8

**NEUROTOXIC EFFECTS OF APOE-DERIVED SYNTHETIC PEPTIDES ARE RECEPTOR-MEDIATED.**

M.Tolar\*, J.A.K. Harmony and K.A. Crutcher. Dept. of Neurosurgery and Dept. of Pharmacology and Cell Biophysics, Univ. of Cincinnati, Cincinnati, OH 45267.

The E<sub>4</sub> isoform of apolipoprotein E (apoE) has been repeatedly shown to be associated with familial and sporadic Alzheimer's disease (AD). Synthetic apoE peptides corresponding to the receptor-binding region of apoE, as well as a 22 kDa thrombin-cleavage fragment of apoE, cause extensive degeneration in vitro when applied to dissociated cultures of chick sympathetic ganglia (Exp. Neurol. 130: 120-126; 1994). The E<sub>4</sub> isoform of the 22 kD fragment is significantly more toxic than the E<sub>3</sub> isoform, suggesting that naturally-occurring apoE fragments may directly contribute to the pathology found in AD. Since apoE can be internalized by the LDL receptor or the LDL receptor-related protein (LRP) acting in cooperation with cell-surface heparan sulfate proteoglycans (HSPGs), the role of these receptors in the toxicity of apoE peptides was evaluated.

Cultures of dissociated embryonic chick sympathetic neurons in 96-well microtiter plates were used to assess both the toxicity of the apoE peptides and the effects of various blocking agents. Peptides were applied at previously determined half-maximal effective concentrations and, after overnight incubation, cell viability was assessed with 5-carboxyfluorescein. The LRP-associated protein (RAP), which has been reported to block the binding of all known ligands to LRP, completely blocked toxicity at a concentration of 100 nM. Pretreatment of the cells with heparinase I, which degrades the glycosaminoglycan moiety of HSPG, as well as sodium chlorate, which prevents sulfation of glycosaminoglycans, were used to assess the role of proteoglycans in peptide neurotoxicity. Heparinase I (20 U/ml) or sodium chlorate (20 mM), or both together, provided partial blockade of toxicity. A polyclonal antibody raised against LRP (kindly provided by Dr. D. Strickland) completely blocked the toxicity, whereas a monoclonal anti-LDL receptor antibody showed no protection. Together with the previously reported blockade of apoE peptide-associated toxicity by heparin and heparan sulfate, these results suggest that the neurotoxic effects of apoE peptides are mediated through LRP in cooperation with cell-surface HSPGs. (Supported by a Research Challenge Grant and NIH grants NS31410 and HL27333.)

## 86.10

**EXPRESSION OF THE LOW DENSITY LIPOPROTEIN RECEPTOR-2 (LRP-2) IN THE ADULT RAT BRAIN FOLLOWING LESIONS.** J.T. Chun\*, J.E. Morgan<sup>1</sup>, G.M. Pasinetti<sup>2</sup> and C.E. Finch<sup>1</sup> <sup>1</sup>Andrus Gerontology Center and Dept. Biol. Sci., University of Southern California, Los Angeles, CA 90089; <sup>2</sup>Dept. Psychiatry, Mt. Sinai School of Medicine, New York, N.Y. 10029

LRP-2, also known as glycoprotein 330 and megalin, is a member of the LDL receptor family. Recent studies using mouse embryonal carcinoma F9 cells differentiated by treatment with retinoic acid and dibutyryl cAMP indicated that LRP-2 functions as an endocytotic receptor for clusterin, a protein present in aged and Alzheimer disease brains (Kounnas et al., 1995, J. Biol. Chem. 270:13070). In view of the fact that clusterin is a component of senile plaques and binds to amyloid  $\beta$  protein (A $\beta$ ), these observations raise the possibility that LRP-2 may play a role in neurodegenerative process involving clusterin and A $\beta$ . To address this issue in an animal model, we induced lesions to the rat hippocampus using kainate and perforant path transection and surveyed for LRP-2 mRNA in the rat brain. Toward this end, pairs of oligonucleotides were selected from both coding (nt 6,439-6,462; 6,942-6,921) and 3'-untranslated regions (nt 14,289-14,311; 14,449-14,425) of the rat LRP-2 mRNA sequence (GENBANK) and used as primers for RT-PCR analysis of the total RNA isolated from the intact and lesion-induced hippocampus. The efficacy of the primers was verified with RNA from kidney and liver, where LRP-2 is expressed at high and low levels, respectively. Using these primers, this ongoing study will examine whether the expression of LRP-2 mRNA is enhanced in the hippocampus following kainate-induced lesion and perforant path transection. (Supported by PHS grant AG13499 to C.E.F.)

## 86.11

SEQUENCE DETERMINATION OF THE LOW-DENSITY LIPOPROTEIN RECEPTOR GENE IN ALZHEIMER SUBJECTS. M. Danik, D. Dea and J. Poirier<sup>\*</sup>. Douglas Hospital Research Centre, Centre for Studies in Aging, McGill University, Montréal, Québec, Canada.

Apolipoprotein E (apoE) is a glycoprotein involved in lipid transport and metabolism throughout the body. It is a component of several lipoprotein complexes and serves as a ligand for specific cell surface receptors that mediate their intracellular uptake. ApoE is the only known lipoprotein ligand within the brain parenchyma. It is thus believed to play an important role in neuronal plasticity by delivering lipid precursors for the synthesis of cellular membranes and neurotransmitters such as acetylcholine. Moreover apoE-lipid complexes binding to the low-density lipoprotein receptor (LDLR) present on neurons increases during the early phase of brain reinnervation. The apoE4 allele frequency was shown to be significantly increased in both sporadic and familial late onset Alzheimer's disease (AD). Although apoE4 has been postulated to be involved in neurofibrillary tangles and plaque formation, as well as in lipid metabolism dysfunction, its exact role in AD remains to be established. However 30-40% of late-onset AD subjects are known not to carry the e4 allele. We hypothesized that in these subjects there may be an impairment in lipoprotein uptake due to a defect in the LDLR pathway. We have thus undertaken a screening process for the presence of mutations in each of the 18 exons coding for the human LDLR in several AD and control cases. The method is based on PCR amplification of individual exons followed by solid-phase sequencing using an automatic sequencer. No mutations have been found in either exon 18 or exon 5 which code for part of the internalization domain and apoE binding domain respectively. Data regarding other exons will also be presented and discussed.

(Supported by the Fonds de la Recherche en Santé du Québec and Pharmacia Biotech)

## 86.13

CO-EXPRESSION OF APOLIPOPROTEIN E AND AMYLOID PRECURSOR PROTEIN FOLLOWING BRAIN INJURY. J. Maquiere<sup>1</sup>, D.P. Binsack<sup>2</sup>, and C.A. Marotta<sup>2,3</sup>, Hamilton Civic Hospitals, McMaster University, Hamilton, Ontario<sup>1</sup>, and Departments of Psychiatry and Human Behavior<sup>2</sup> and Neuroscience<sup>3</sup>, Brown University, Providence, RI 02912.

We explored the relationship between APP and Apo E at the tissue level by means of a rat brain lesion paradigm. Immunohistochemistry techniques were used to assess the response of APP, Apo E, glial fibrillary acidic protein (GFAP), synaptophysin, and choline acetyl transferase (ChAT). Increased GFAP immunostaining was observed at 48 hours and well-established by 72 hours, while the ChAT activity was weak, and synaptophysin barely detectable, in the area of the wound. Immunoreactivity to APP was demonstrable by 48 hours within cell bodies surrounding the lesion. Apo E staining within cells was more robust than APP. These findings indicate that within the time frame examined, the experimental model revealed the co-expression of modest levels of APP and relatively high levels of Apo E in response to the lesion. The data support the view that APP and Apo E are components of an early and coordinated response to injury in brain.

## 86.15

DEPENDENCE OF CEREBROSPINAL FLUID TAU PROTEIN LEVELS ON APOLIPOPROTEIN E4 ALLELE FREQUENCY IN PATIENTS WITH ALZHEIMER'S DISEASE. S. Golombowski, F. Müller-Spahn, W. Naser, C. Hock<sup>\*</sup>. Dep. of Psychiatry, University of Basel, Switzerland and Boehringer Mannheim Research Lab., Tübingen, Germany.

We determined Apolipoprotein E (ApoE) genotypes in blood samples corresponding to cerebrospinal fluid (CSF) samples of patients with Alzheimer's disease (AD) that were previously assayed for Tau protein levels. CSF Tau was quantitated with an enzyme-linked immunosorbent assay (Innogenetics, Belgium). ApoE4 genotyping was performed with reverse hybridization applying the ApoE4 Genotyping Kit (Innogenetics, Belgium). CSF levels of Tau protein of patients with a diagnosis of probable AD (n=13, 7 male, 5 female, age 66.4 ± 9.8 years, MMS 19.1 ± 4.5) were increased compared with age-matched control subjects (elderly patients with depression, according to ICD10 (F32.0x/1x, F33.0x) and DMS-III-R (n=10, 2 male, 8 female, age 71.3 ± 9.8, MMS 27.7 ± 1.9) (65.5 ± 12.9 pg/ml (mean ± SEM) and 29 ± 6.3, respectively, p < 0.03). CSF Tau protein levels increased with increasing ApoE4 frequency. AD group (mean ± SEM): no Apo E4 allele: 32.5 ± 9.5, one Apo E4 allele: 56.5 ± 17.2, two Apo E4 alleles: 96.3 ± 24.3 pg/ml. Control group: no Apo E4 allele: 26.8 ± 6.8, one Apo E4 allele: 38.5 ± 20.5 pg/ml. Significance in the Spearman Rank Correlation, z=2.84, p=0.04 and Kruskal-Wallis Test p=0.01 was demonstrated for the group of AD patients and controls taken together. The AD group alone showed significance in the Spearman Rank Correlation z=2.05 and p=0.03. Our results suggest CSF Tau levels increase with increasing ApoE4 allele frequency. Our data may be in agreement with the hypothesis of a lesser binding of ApoE4 to Tau protein and a presumed less protective effect on microtubule stability.

## 86.12

DENTATE GRANULE CELLS IN APOE-KNOCKOUT MICE SHOW NO CHANGE IN SYNAPTO-DENDRITIC STRUCTURES. J.A. Varner<sup>1</sup>, M. Thomas, J. Gilbert, D. Schmechel, S. Zhang<sup>2</sup>, N. Maeda<sup>2</sup>, A.D. Roses, and G. Einstein. Depts. Neurobiology and Neurology, Ctr. for Aging, and Joseph and Kathleen Bryan ADRC, Duke University Medical Center, Durham, NC 27710; <sup>2</sup>Dept. Pathology, UNC, Chapel Hill, NC 27599.

Apolipoprotein E (apoE), a lipid carrier protein involved in the repair and maintenance of neurons, has been implicated in the risk of developing late-onset, sporadic and familial Alzheimer's disease. Its link to the disease process may involve a failure in its normal function. However at present, our understanding of the role apoE plays in maintaining neurons is equivocal; some strains of apoE-knockout mice (KO) show little to no neuropathology while others show changes to synapto-dendritic structures as early as 4 mo of age. In order to further explore these changes, or lack thereof, we studied the dendritic morphology and spine densities of an identified population of neurons (dentate granule cells) in a different strain of APOE KO mice. Tissue was prepared for electron microscopy or intracellular dye-injections. Qualitative examination of electron micrographs through the molecular layer of 15 mo old KO mice revealed no obvious changes to dendritic structure; qualitative analysis of dendritic structure of intracellularly filled dentate granule cells at 3, 6, 12, and 15 mo confirmed this. Quantitative analysis of spine density revealed no significant difference at 3, 6, or 12 mo from controls. These results suggest that apoE's effect on mouse neurons may be dependent on various background strains: In addition, certain cell types may exhibit differential susceptibility to the absence of apoE. Thus the stress of aging or damage may be required to reveal fully apoE's role in maintenance and repair. (Supported by AG05218-13, ADRA- IIRG-95136, AFAR, and AG00029.)

OXIDATION OF APOLIPOPROTEIN E BY MYELOPEROXIDASE, AN ENZYME PRESENT IN THE BRAIN. B. Leininger-Müller<sup>1</sup>, C. Jolival<sup>1</sup>, R. Drozd<sup>2</sup>, V. Shuvaev<sup>1</sup>, P. Bertrand<sup>1</sup>, Y. Christen<sup>1</sup>, and G. Sies<sup>1</sup> <sup>a</sup>, URA CNRS 597, Centre du Médicament, 30 rue Lionnois, 54 000 Nancy, F; <sup>b</sup>, Uniwersytet Jagiellonski, Collegium Medicum, Katedra Biochemii Klinicznej, 31-501 Krakow, P; <sup>c</sup>, IPSEN Foundation, 24 rue Erlanger, 75781 Paris, F.

Oxygen free radicals are increased in Alzheimer's disease patients. Among the proteins accumulating as amyloid deposits in the brain, the most studied at present are  $\beta$ -amyloid (A $\beta$ ) and apolipoprotein E (apo E) which is a polymorphic protein showing a strong affinity for A $\beta$  and it seems to be isoform dependent. Yet, if the relation with oxidative process has been investigated for  $\beta$ -amyloid, nothing is known about the oxidation of apo E.

We have already obtained preliminary data with *in vitro* chemical oxidation of recombinant apo E and here we show the consequences of the oxidation of recombinant apo E, in presence of free radicals produced by the action of neutrophils secreted myeloperoxidase (H<sub>2</sub>O<sub>2</sub> donor oxidoreductase). This heme enzyme takes place in inflammation and we demonstrate its presence in human brain. The *in vitro* incubation of free apo E with that enzymatic system leads to fragmentation of the protein for low concentrations of H<sub>2</sub>O<sub>2</sub> and polymerization for higher concentrations. As compared with bovine serum albumin used as a reference protein, apo E shows a higher susceptibility to oxidation in the same conditions of oxidation. Studies with discoidal complexes show that oxidation of apo E diminishes its ability to interact with phospholipids. Moreover, investigations of plasmonic resonance measures show that the affinity for A $\beta$  of oxidized apo E containing complexes is modified.

## 86.16

CELLULAR MODELS OF TAU ALZHEIMER-TYPE PHOSPHORYLATION: CHARACTERISATION OF TAU PROTEINS AND APOLIPOPROTEIN E IN VARIOUS HUMAN NEUROBLASTOMA CELL LINES. L. DUPONT, WALLOIS, C. SOULIÉ, A. DELACOURTE, P. VERMERSCH, M.C. CHARTIER-HARLIN, M.L. CAILLET-BOUDIN<sup>\*</sup> INSERM U422, PL. VERDUN, 59045 Lille, France. @@@@

Tau proteins are microtubule-associated proteins mainly found in axons of neurons. In human, six isoforms arise by alternative splicing of a primary transcript originating from a single gene. The fetal isoform is found in both fetal and adult brains. The five other isoforms only found in adult brain correspond to the fetal isoform modified by insertions corresponding to the expression of alternative exons. In Alzheimer's disease, these 6 isoforms are hyperphosphorylated in comparison to the normally phosphorylated Tau proteins and are the major constituents of the PHF (Paired Helical Filaments) present in neurodegenerating neurons. A recent hypothesis suggested that some Apo E alleles could have a preferential protector effect against the phosphorylation of Tau proteins.

The obtention of cellular model of Alzheimer-type Tau phosphorylation requires the endogenous expression and the characterisation of both Tau proteins and apo E expressed in the used cell lines. In this purpose, we studied three different human neuroblastoma cell lines. The endogenous expression, Tau transcript and Apo E allele identification were determined by RT-PCR and restriction analysis. Western blotting confirmed the intracellular presence of these two components and allows to study the Tau protein location and phosphorylation using phosphorylation-dependent immunoprobings.

These three cellular lines differed from each other by expressing different Tau isoforms or allele apo E. Although the interactions between Tau and apoE remain to be elucidated, our results show the presence simultaneous of fetal-type phosphorylated Tau proteins and Apo E in neuronal-type cell models.

Acknowledgement to Dr. J. C. Fruchart and H. Parra to apo E antibody. C. S. is a recipient of Servier grant.

**SENILE PLAQUES SHOW FIBROBLAST GROWTH FACTOR-9 IMMUNOREACTIVITY** S. Nakamura, T. Todo, M. Mizuguchi, K. Arima, S. Haga, T. Aizawa, Y. Namba, N. Otsuka, Y. Motoi, Y. Otsuka, A. Ueki, K. Ikeda\* Department of Ultrastructure and Histochemistry, Tokyo Institute of Psychiatry, Tokyo 156, Japan and Jichi Medical School, Omiya Medical Center, Omiya, Japan

FGF-9 is a newly identified member of FGF family including acidic FGF (FGF-1) and basic FGF (FGF-2). In the central nervous system FGF-9 is present in neurons (Seo and Noguchi, FEBS Lett, 370:231-235, 1995). Since senile plaques and neurofibrillary tangles of Alzheimer's disease (AD) brain are associated with FGF-2 immunoreactivity and since both FGF-1 and FGF-2 are implicated in the AD pathogenesis, we performed immunohistochemical studies of AD brain tissues by using antibodies to FGF-9.

Three antibodies, W, M and C, were raised in rabbits, respectively, against human recombinant FGF-9 and two synthetic peptides (corresponding to residues, 87-102 and 193-208). Hippocampal sections including occipitotemporal neocortex from 10 AD cases and 10 age-matched controls were cut from formalin-fixed, paraffin embedded blocks, pretreated with formic acid and subjected to immunohistochemistry.

In brain sections two antibodies (W and M) strongly stained dystrophic neurites of senile plaques. In contrast, antibody C mainly stained amyloid core. Neurofibrillary tangles were not immunostained by three antibodies. Studies of the fine localization of immunoreactivity are underway.

## 87.3

**TrkA, BUT NOT P75<sup>NTR</sup>, GENE EXPRESSION IS REDUCED WITHIN BASAL FOREBRAIN NEURONS IN ALZHEIMER'S DISEASE.** J.-M. Li\*, J. H. Kordower and E. J. Mufson. Research Center For Brain Repair And Department of Neurological Sciences, Rush Presbyterian-Luke's Medical Center, Chicago, IL 60612.

We have recently reported that nerve growth factor (NGF) is reduced within basal forebrain neurons and accumulates within the cortex in Alzheimer's disease (AD). These findings led to the hypothesis that basal forebrain degeneration in AD results, in part, from impaired binding and/or retrograde transport of this neurotrophin. The present study examined whether there is a defect in gene expression for the high (trkA) and low (p75<sup>NTR</sup>) affinity receptors in AD using *in situ* hybridization and RT-PCR. TrkA mRNA within individual nucleus basalis neurons was significantly reduced (66%) in AD cases (n=9) relative to age-matched controls (n=8; p<.01). RT-PCR quantitative analyses also demonstrated that trkA mRNA levels decreased markedly in AD. In contrast, p75<sup>NTR</sup> mRNA was not significantly different in AD and age-matched controls. These data indicate that there is a selective defect in trkA gene expression in patients with AD supporting the hypothesis that the diminished retrograde transport of NGF within AD basal forebrain neurons may be due to impaired synthesis of the trkA receptor. These data also suggest that impaired NGF trophic support at the level of the NGF/trkA complex plays a critical role in the degeneration of this important population of neurons in AD. ## 87.5

**SYNAPTIC NUMBERS IN THE ANTERIOR CINGULATE CORTEX (AREA 24) IN PATIENTS WITH ALZHEIMER'S DISEASE.** D.A. Price, D.L. Sparks\* and S.W. Scheff. Center on Aging Univ. Kentucky, Lexington, KY 40536-0230.

Clinical and experimental data clearly indicate that the anterior and posterior cingulate cortex are functionally distinct regions of the limbic system. The limbic system is known to be profoundly affected in Alzheimer's disease (AD). While the cingulate cortex was once thought to be a homogenous brain region, cytoarchitectonic studies have demonstrated that the anterior and posterior cingulate cortices receive distinct thalamic and cortical afferents. Several key cortical and limbic structures have previously demonstrated a significant decrement in connectivity resulting in a loss of synapses in AD as compared to age-matched controls. The posterior cingulate gyrus (area 23) is one of these areas manifesting a significant loss in AD. Because of the different afferent and efferent connections distinguishing the posterior and anterior cingulate areas, it is important to quantitatively assess the anterior cingulate for possible similarities and/or differences in synaptic numbers in AD.

Human brains were obtained at postmortem examination from 10 patients who met the NINDS-NIA criteria for AD and from 10 age-matched controls. These individuals were used previously to study the posterior cingulate. Both lamina III and V of area 24 were assessed and demonstrated a significant loss of synaptic contacts, similar to that found in the posterior cingulate. These results suggest that the mechanism(s) responsible for synaptic loss in AD may not follow strict morphological boundaries and connectivity. Supported by NIA AG 12138

## 87.2

**DECREASE OF TrkA mRNA LEVEL IN CHOLINERGIC NEURONS OF THE STRIATUM AND BASAL FOREBRAIN IN ALZHEIMER'S DISEASE.** E. Boissière, B. Faucheux, Y. Agid and E. C. Hirsch\*. INSERM U289, Hôpital de la Salpêtrière, 47 Bd de l'Hôpital, 75013 Paris, France.

Besides cortical pathology, one of the major characteristics of Alzheimer's disease (AD) is the selective degeneration of cholinergic neurons localized in the basal forebrain and the ventral striatum. However, cholinergic neurons located in the dorsal striatum (caudate nucleus and putamen) or in the mesencephalon are spared. A link between NGF sensitivity and the vulnerability of specific populations of cholinergic neurons has been suspected, since cholinergic neurons which degenerate are sensitive to this neurotrophin. Because level of NGF is not reduced in AD brains, we hypothesized that the lack of trophic support may be due to a deficiency of NGF receptors. Using *in situ* hybridization, we have analyzed the cellular content of TrkA mRNA, encoding for the high affinity NGF receptor, in immunohistochemistry identified cholinergic neurons of the striatum and of the nucleus basalis of Meynert of 6 patients with AD and of 9 control subjects. We have evidenced, in the brain of AD patients, a decreased TrkA mRNA expression in cholinergic neurons of the nucleus basalis of Meynert (-75%, P<0.001) and of the ventral striatum (-41%, P<0.01) where they degenerate, but also on those of the anterior (-43%, P<0.01) and posterior (-51%, P<0.01) parts of the putamen, where they are spared. These data, taken in conjunction with our previously published data showing a loss of high affinity NGF binding both in the ventral and in the dorsal striatum, indicate a loss of NGF receptors. Reduced choline acetyltransferase activity and presence of neurofibrillary tangles in remaining striatal cholinergic neurons suggest that the resulting decrease in trophic support may be a primary event leading to cholinergic neuronal loss observed in AD.

**GALANIN BASAL FOREBRAIN INTERACTIONS IN ALZHEIMER'S DISEASE: A CONFOCAL MICROSCOPIC ANALYSIS.** R. Bowser<sup>1</sup>\*, J.H. Kordower<sup>2</sup> and E.J. Mufson<sup>2</sup>. <sup>1</sup>Dept. of Pathology, Univ. of Pittsburgh, Pittsburgh, PA 15213 and <sup>2</sup>Dept. of Neurological Sciences, Rush Presbyterian Med. Ctr., Chicago, IL.

The galanin (GAL) containing fiber system that innervates cholinergic containing basal forebrain (CBF) neurons hypertrophies and hyperinnervates remaining CBF neurons in Alzheimer's disease (AD). It has also been suggested that GAL plays a critical role in the modulation of cholinergic neurotransmission in the normal human CBF. We and others have suggested that galanin may inhibit the production and release of acetylcholine from surviving CBF neurons in AD. To better understand the morphologic relationship/interactions of GAL hyperinnervation upon surviving CBF neurons in AD, we performed a double-label confocal microscopic analysis with antibodies to GAL and p75<sup>NTR</sup> receptor, an excellent marker of CBF neurons. Confocal microscopic evaluation revealed a hypertrophy of galaninergic fibers in the AD CBF in comparison to aged matched non-demented controls. Hypertrophic GAL positive fibers were seen in direct apposition to cholinergic neuron cell bodies, axons and dendrites. Galaninergic fibers wrapped around cholinergic cell bodies and neuritic processes. These findings support previous observations of an hyperexpression of GAL fibers in AD and provide evidence that galaninergic fibers make synaptic contact with remaining cholinergic neurons within the AD basal forebrain. Electron microscopic analysis is currently in progress to directly demonstrate the presence of synapses between GAL containing fibers and CBF neurons. Support by AG10668, AG10161 & AG09466.

## 87.6

**MORBUS ALZHEIMER: CORTICAL COLOCALIZATION PATTERN OF NICOTINIC RECEPTORS AND PATHOLOGICAL MARKERS.** A. Wevers<sup>1</sup>\*, L.M. Monteggia<sup>2</sup>, A. Maelicke<sup>3</sup>, E. Giacobini<sup>4</sup>, J.P. Sullivan<sup>2</sup>, S. Arneric<sup>2</sup>, and H. Schröder<sup>1</sup>. <sup>1</sup>Inst. II für Anatomie, Univ. zu Köln, 50931 Köln, FRG, <sup>2</sup>Abbott, Neurosci. Res., Abbott Park, IL, USA, <sup>3</sup>Inst. für Physiol. Chemie und Pathobiochemie, Univ. Mainz, 55128 Mainz, FRG, <sup>4</sup>Univ. Geneva, 1226 Thonex-Geneva, CH

The cholinergic dysfunction in Alzheimer's disease (AD) may be related to intra- and extracellular events impairing the expression of the nicotinic acetylcholine receptors (nAChR). To get more insights into the underlying mechanisms, the mRNA expression of the  $\alpha$ -bungarotoxin insensitive  $\alpha 4$ - and the  $\alpha$ -bungarotoxin sensitive  $\alpha 7$ -subunit of the nAChR and the correlation to accumulation of pathological proteins, e.g. hyperphosphorylated tau and  $\beta$ -amyloid has been investigated.

*In situ* hybridization was performed on autopsy superior frontal gyrus samples of AD and control brains. Hybridization of hapten-labeled riboprobes to nAChR subunits was visualized by an alkaline phosphatase coupled-digoxigenin antibody and incubation with BCIP/NBT. Colocalization of the pathological protein markers with  $\alpha 4$  and  $\alpha 7$  mRNA was achieved after hybridization by application of the corresponding monoclonal antibodies followed by an indirect immunoperoxidase technique.

The  $\alpha 4$  and  $\alpha 7$  transcripts were expressed in various neurons of all cortical layers, but the  $\alpha 4$  one was more abundant than the  $\alpha 7$  one as reported earlier already for control brains. The colocalization experiments revealed that in AD brains neurons in the vicinity of  $\beta$ -amyloid plaques bore both transcripts, whereas neurons heavily labeled for hyperphosphorylated tau expressed little to no  $\alpha 4$  and  $\alpha 7$  mRNA.

These results show, that in AD intracellular rather than extracellular changes could interfere with the  $\alpha 4$  and  $\alpha 7$  nAChR subunit expression. Ongoing investigations of the compartment-specific codistribution of both subunits on mRNA and protein level with hyperphosphorylated tau will provide further information on possible causes of the disturbed nicotinic binding in AD. PHARMACOKINETICS OF THE COMBINED CHOLINERGIC AND ADRENERGIC THERAPEUTIC CANDIDATE P11467 IN THE RAT AND DOG. E.M. DiLeo and D.J. Turk\*. Hoechst Marion Roussel, Neuroscience Therapeutic Domain, Bridgewater, New Jersey, 08807.

P11467, a combined acetylcholinesterase (AChE) inhibitor and  $\alpha_2$ -adrenoceptor antagonist, is undergoing evaluation as a potential therapeutic agent for Alzheimer's Disease. Pharmacokinetic parameters were determined for P11467 following administration in rat and dog. The samples obtained during a 24 hour period were extracted using a solid-phase extraction procedure and analyzed by a sensitive HPLC-UV method. The results indicated that P11467 was rapidly absorbed with estimated plasma half-lives for absorption on the order of 0.40 hours in both species and terminal phase elimination P11467 from the target brain tissue (rat) less than 3.1 hours. The P11467 brain profile also correlated well with the time course of AChE inhibition *ex-vivo* following oral administration in rats. The parent compound was shown to be the major circulating form with maximal levels ( $C_{max}$ ) in rat plasma of 482, 2728 and 5118 ng/mL and in rat brain of 170, 1100 and 1954 ng/g following 1, 5 and 10 mg/kg doses, respectively. The  $C_{max}$  levels in dog plasma were 327, 526, 1083 and 3081 ng/mL following 0.5, 1, 5 and 10 mg/kg doses, respectively. A comparison of the  $AUD_{0-24hr}$  values in both rat and dog following oral and intravenous administration indicated an absolute bioavailability on the order of 100% in both species. There was a linear increase in both the  $C_{max}$  and the  $AUD_{0-24hr}$  as the dose increased for rat (plasma and brain) and dog (plasma). In addition, the rat brain-to-plasma ratio remained constant at 0.4 across the dose range. The pharmacokinetic profile of this combined AChE inhibitor and  $\alpha_2$ -adrenoceptor antagonist indicated that P11467 was orally bioavailable, penetrated the target brain tissue and correlated well with biochemical activity.

Research Support: Hoechst Marion Roussel

CHARACTERISTICS OF ALZHEIMER'S DISEASE PATHOLOGIC CHANGES IN THE OLDEST-OLD. P. Giannakopoulos<sup>1</sup>, P.R. Hof<sup>2,3</sup>, E. Kovari<sup>1</sup>, P.G. Valleri<sup>1</sup>, D.P. Perl<sup>2,4</sup>, and C. Bouras<sup>1,2</sup>. <sup>1</sup>Dept of Psychiatry, Univ. of Geneva, HUG, Belle-Ide, 1225 Geneva, Switzerland, Depts of <sup>2</sup>Neurobiology, <sup>3</sup>Geriatrics, and <sup>4</sup>Pathology, Mount Sinai Sch. Med., New York, NY 10029.

Recent studies have revealed that in some very old people, certain neuronal subpopulations are consistently resistant to the degenerative process that occurs during aging and in Alzheimer's disease (AD). To explore further this issue, a quantitative stereological analysis of a large series of nonagenarians and centenarians was performed. Samples from the hippocampal formation and Brodmann's areas 9 and 20 were obtained from 24 non-demented (ND) patients and 19 AD patients, all older than 96 years of age (mean: 98.5  $\pm$  2.0 years; range: 96-105 years). The ND group had mean MMSE of 28.0  $\pm$  1.5 and extended CDR of 0.8  $\pm$  0.2, whereas these values were 20.5  $\pm$  1.5 and 3.0  $\pm$  0.5, respectively, in the AD group. Materials were stained with antibodies to tau and amyloid A $\beta$  proteins. Neuronal loss was estimated from Nissl-stained serial sections. Cases with AD had significantly higher NFT densities in the CA1 field of the hippocampus only compared to ND individuals. SP densities in areas 9 and 20, but not in the hippocampus, were higher in demented compared to ND centenarians. In contrast to younger cohorts; neuronal loss was observed in layer II of the entorhinal cortex and layers II-III and V-VI of areas 9 and 20, but not in the CA1 field, in centenarians with AD, and it was not correlated with the development of NFT in any of the areas studied. Moreover, there was a negative correlation between SP and neuron densities in entorhinal cortex and area 20 suggesting that SP formation may parallel neuronal depletion in certain neocortical areas in these cases. The present data reveal a distinct pattern of AD pathology in very old individuals and imply that brain aging patterns may change considerably in this particular age group. Supported by NIH AG05138 and FNRS.

OLFACTORY DISCRIMINATION AND REPEATED REVERSAL LEARNING IN YOUNG AND AGED DOGS. E. Head<sup>1\*</sup>, H. Callahan<sup>1</sup>, V. Balkissoon<sup>1</sup>, C. Thirwell<sup>1</sup>, G.E. Adam<sup>2</sup>, R.S. Astur<sup>3</sup>, F. Barrington<sup>4</sup>, A. Koerner<sup>5</sup>, M.P. Weisend<sup>6</sup>, R.J. Sutherland<sup>7</sup>, B.A. Muggenburg<sup>8</sup>, B.J. Cummings<sup>9</sup>, C.W. Cotman<sup>10</sup> and N.W. Milgram<sup>11</sup>. <sup>1</sup>University of Toronto, Scarborough, Ontario, Canada, M1C 1A4, <sup>2</sup>Dept. of Psychology, UNM, Alb., NM, <sup>3</sup>Inhalation Toxicology Research Institute, Alb., NM, <sup>4</sup>Harvard Med. School, Boston, M.A. and <sup>5</sup>Institute for Brain Aging and Dementia, UCI, Irvine, CA.

Olfactory discrimination, identification and memory deteriorate with age in humans and these deficits are exaggerated in early Alzheimer's Disease. We are unaware of parallel studies in olfaction using animal models of aging. We studied olfactory discrimination (OD) and reversal learning (OR) in pound source dogs of mixed breeds ranging in age from 2 to 12 years. We previously reported that dogs show age dependent cognitive deficits that are correlated with  $\beta$ -amyloid accumulation (Cummings et al., 1996).

We found marked differences between young and old dogs in OD learning, with aged dogs making more errors (mean=121.8 sd=80.3 n=5) than young dogs (mean=44.4 sd=28.4 n=5) in reaching criterion. Two of the 5 aged dogs could not solve the problem in 400 trials. Dogs reaching criterion on the OD task were subsequently tested for OR learning. Three young dogs and one aged dog required more training trials to learn the OR problem, whereas two young dogs and one aged dog learned the OR problem with fewer errors than OD. Two dogs (one aged, one young) were also tested with repeated reversals to measure development of a learning set. Both dogs eventually learned to reverse odors in two or fewer errors. The aged dog however, showed a slower decline in error scores than the young dog. Our results suggest that aged dogs are deficient on an olfactory discrimination task and on repeated reversals. Supported by NIA Grant (AG 12694) to CWC, BJC, BAM and NWM.

DOPAMINERGIC LOSS CORRELATES WITH HIPPOCAMPAL LEWY BODY DENSITY. A.Y. Wang, M.S. Mega, U. Tomiyasu, H.V. Vinters, A.W. Nakanishi, J.L. Cummings\*. Alzheimer's Disease Center, UCLA School of Medicine, Los Angeles, CA 90024.

**Objective:** To determine if dopaminergic (DA) cell loss in the ventral tegmental area (VTA) is correlated to Lewy body (LB) occurrence in the hippocampus.

**Background:** DA decline is observed across the spectrum of Lewy body disorders. The VTA is the DA source for the limbic forebrain and D2 autoreceptor immunolabeling shows a terminal distribution in the hippocampus that corresponds to the regional distribution of LBs. If degenerating end terminals of DA cells contribute to LB production in the hippocampus, then the number of hippocampal LBs will be inversely related to the number of DA cells in the VTA.

**Methods:** The study included 25 dementia patients with varying degrees of LBs and AD pathology. Melanin containing DA cell profiles in the VTA were counted on H&E sections of midbrain at the level of the red nucleus; LBs were counted on ubiquitin immuno-stained hippocampal sections. LB and DA cell density per mm<sup>2</sup> were derived from profile counts corrected using the method of Abercrombie. Linear correlations among hippocampal LBs and VTA regions were determined by the least square fit method.

**Results:** Total hippocampal LB density had a linear inverse correlation ( $R^2 = 0.52$ ) with total VTA DA cell density when the extreme counts in the VTA were removed. Regional analysis of LB counts into the three CA fields showed CA3 had the weakest ( $R^2 = 0.13$ ) inverse correlation, while CA1 had the strongest ( $R^2 = 0.68$ ) inverse correlation with VTA DA cell density.

**Conclusion:** The inverse correlation between hippocampal LBs and VTA DA cell density supports the involvement of DA degeneration in the formation of LBs. (This project was supported by a VA Neuroscience Fellowship and an NIA Alzheimer's Disease Center grant: P30, AG10123).

## 87.10

OVEREXPRESSION OF  $\beta$ -AMYLOID PRECURSOR PROTEIN ( $\beta$ -APP) IN CEREBELLUM AFTER LESIONING IN THE INFERIOR OLIVE. K. Ito, K. Schluterman, R.D. Skinner, W.S.T. Griffin, T. Walls\*. Neurosurgery, U. Ryukyus, Okinawa, Japan; Anatomy, Physiology, and Medicine, U. Ark. Med. Sci., Little Rock, AR 72205.

We have previously used unilateral, ventral electrolytic lesioning of the rat inferior olive to characterize local astrocytic activation (enlargement) responses as well as those in projection targets, e.g. in cerebellum. In Alzheimer's disease, such astrocytic activation correlates with growth of dystrophic neurites overexpressing  $\beta$ -APP (J Neuropathol Exp Neurol 55:273; 1996). We sought to identify changes in  $\beta$ -APP expression in cerebellum following lesion of the inferior olive. Lesions were confined to the right pyramid and inferior olive; these were surrounded by activated astrocytes. In the cerebellum of these rats, activated astrocytes were also numerous. Ten days post lesion, tissue  $\beta$ -APP levels were significantly increased ( $p < 0.05$ ) in cerebellum, as determined by Western analysis. This suggests that physiological responses to traumatic damage (perhaps in the form of overgrown dystrophic neurites or neuronal somatic  $\beta$ -APP overexpression) occur in projection sites distant from a trauma. These results support our hypothesis (Neurosci Letts 176:133;1994) that diffuse inflammatory responses following head trauma may be an important predisposing factor for the later development of Alzheimer's disease. Supported in part by AG10208 and AG12411.

A CANINE MODEL OF DEMENTIA: TESTS OF COGNITIVE FUNCTION IN THE BEAGLE. G.E. Adam<sup>1\*</sup>, R.J. Sutherland<sup>1</sup>, R.S. Astur<sup>2</sup>, F.M. Barrington<sup>3</sup>, A. Koerner<sup>4</sup>, D. Oakley<sup>5</sup>, J. Schlife<sup>6</sup>, M.P. Weisend<sup>7</sup>, C.W. Cotman<sup>8</sup>, E. Head<sup>9</sup>, N.W. Milgram<sup>10</sup> & B.A. Muggenburg<sup>11</sup>. <sup>1</sup>Univ. of New Mexico, Abq., NM; <sup>2</sup>UC, Irvine; <sup>3</sup>Univ. of Toronto, Scarborough; <sup>4</sup>Inhalation Toxicology Research Institute, Abq., NM

A key to understanding human dementia is the development of an animal model to closely tie behavior to brain abnormalities. The search for a model of dementia led to the discovery that certain dog breeds develop  $\beta$ -amyloid plaques. These plaques, often seen in and around hippocampus, are diffuse, and the canine brains are without neurofibrillary tangles (Cummings et al., 1993). Furthermore, we recently have obtained preliminary evidence of a significant correlation between plaque density and a global index of cognitive dysfunction (Cummings et al., 1995). We have now tested 17 colony-raised beagles (2 - 15 years old) in a version of the Morris water task which has been shown to be hippocampal-dependent in rodents. After 15 training trials (2 per day) and one hidden platform trial (all cues removed from within the pool), the animals were tested for their knowledge of the platform location during a 60 second swim with the platform and cues removed. The proportion of swim path in the correct quadrant declined as the animals' age progressed from very young (2-4 years) to moderately old (8-11 years), but increased for the very old dogs (12+ years). These same beagles are now being trained on an object recognition task (DNMS). Although we expect no age-related differences in acquisition, with increasing delays a pattern of performance decline similar to that seen in the Morris water task would further support our idea that the very oldest dogs are less susceptible to plaque formation and cognitive dysfunction. MRI scans and histological procedures will be conducted at the end of behavioral testing to assess plaques and other pathology. **HUMAN BRAIN TISSUE IN NEUROSCIENCE: A RESOURCE FOR ANALYSIS OF BRAIN-BEHAVIOR CORRELATIONS.** S.L. Weinstein\*, M. H. Oshita, A.J. Wasserman, B. Choi, R. Kim, M. B. Dick, W. R. Shankle, and C.W. Cotman. Institute for Brain Aging and Dementia, University of California, Irvine, CA 92717 USA

The Institute for Brain Aging and Dementia Tissue Repository provides human, canine and feline brain tissue, blood, and CSF for use by other investigators. Available human cases have short *post mortem* intervals (most <4 hours), and represent many variants of dementia: including Alzheimer's disease (AD), Vascular dementia, Down Syndrome, and Lewy Body disease. Cases are all neuropathologically defined, and available across a range of disease severities, allowing for investigation of the sequence and timecourse of neurodegenerative events. Additionally, neuropsychological and neurological assessments have been conducted, providing clinical data which can be used in conjunction with pathological and genetic information to identify relevant correlations. Furthermore, all cases are subjected to a standard battery of immunohistochemical stains. Using a computer-based image analysis program in combination with immunohistochemistry, we provide quantitative analysis of antibody staining. This type of quantitative data can be invaluable when used in conjunction with other variables (*i.e.* cognitive decline, genotyping, etc.). For example, we recently reported that increasing levels of  $\beta$ -amyloid deposition correlate with severity of cognitive impairment on the mini mental state exam ( $r=0.90$ ,  $p<0.001$ ; Cummings *et al.*, 1995). We also discovered a novel "neurofibrillary" plaque type whose presence appears to be independent of disease severity (Pike *et al.*, 1995). Additionally, the ApoE isotypes of most cases have been determined, allowing for careful examination of the role of the ApoE gene in AD and other forms of dementia. In conclusion, use of human brain and select animal tissues is a valuable and available resource for investigation of dementia and other brain-behavior correlations.

**VOLUMETRIC MRI ANALYSIS OF THE ENTORHINAL AND PERIRHINAL CORTEX IN ALZHEIMER'S DISEASE.** K. Juottonen<sup>2</sup>, R. Insausti<sup>1</sup>, A. Pitkanen<sup>4</sup>, K. Partanen<sup>3</sup>, P. Vainio<sup>3</sup>, and H. Soininen<sup>2</sup>. Dept. Anatomy, Univ. of Navarra, Pamplona, Spain<sup>1</sup>; Dept. Neurology<sup>2</sup>, Clin. Radiology<sup>3</sup> and A.I. Virtanen Institute<sup>4</sup> Univ. of Kuopio and Kuopio Univ. Hospital, Kuopio, Finland.

The entorhinal and perirhinal cortices are part of the medial temporal lobe memory system that is damaged at the early stages of the Alzheimer's disease. By using our own recently designed protocol, we measured the volumes of the entorhinal and perirhinal cortex on MR images in patients with Alzheimer's disease (AD)(n=10, all fulfilled the NINCDS-ADRDA criteria for probable AD) and in age- and sex-matched normal controls (n=10). MR was performed with a 1.5 Tesla Magnetom and a 3D-technique allowing the reconstruction of 2.0 mm thick contiguous slices perpendicular to the axis of anterior-posterior commissure. The volumes of the right entorhinal cortex (AD  $840 \pm 274$  mm<sup>3</sup>, controls  $1659 \pm 374$  mm<sup>3</sup>), left entorhinal cortex (AD  $703 \pm 281$  mm<sup>3</sup>, controls  $1395 \pm 382$  mm<sup>3</sup>) and left perirhinal cortex (AD  $4085 \pm 1312$  mm<sup>3</sup>, controls  $5464 \pm 672$  mm<sup>3</sup>) were smaller in AD patients than in controls ( $p<0.01$ ). There was significant asymmetries between the volumes of the left and right entorhinal and perirhinal cortices in controls but not in patients with Alzheimer's disease. Our volumetric MRI measurements reveal significant atrophy of the entorhinal and perirhinal cortex in patients with probable AD.

## 87.17

**MR VOLUMETRY OF FRONTAL LOBE REGIONS IN ALZHEIMER'S PATIENTS: AN EFFECT OF SEX?** J.A.Y. Hall\*, S.E. Black and S. Kohler, Sunnybrook Health Sci. Centre, Toronto, ON, Canada, M4N 3M5

Recent studies suggest that language functions may be more impaired in women than men with Alzheimer's Disease (AD). Using functional MRI, one report demonstrated sex-dependent variation in the activation of the inferior frontal gyrus (IFG) during phonological processing. Given that women demonstrate a pre-morbid advantage over men on some verbal tasks, the relative decline in women with AD is curious. We performed MR volumetry of frontal regions including: the superior frontal gyrus (SFG), middle frontal gyrus (MFG), IFG and inferior pre-central gyrus (PCG). Subjects were 9 males and 9 females who met NINCDS-ADRDA criteria for probable AD and an equal number of control subjects (NC) matched for sex, age and education.

Analysis was performed using ANALYZE software on images obtained from a 1.5 Tesla GE magnet. The volume of each gyrus was calculated by stereology (point counting) using serial 1.3 mm thick coronal sections on a T1 weighted 3D sequence. Data for each gyrus (right, left and total) were analyzed in 2-way ANOVAs (sex by group) using a total brain volume, age and duration of illness as covariates.

No significant effects or interactions were noted for the SFG, MFG or IFG. The total PCG was smaller in women than men [ $F(1,27)=5.34$ ,  $p<0.02$ ] and smaller in the AD than NC group [ $F(1,27)=6.45$ ,  $p<0.02$ ], but there was no interaction. The left PCG demonstrated the same effect of sex [ $F(1, 27)=5.10$ ,  $p<0.02$ ] and group [ $F(1,27)=6.50$ ,  $p<0.02$ ] with no interaction. The right PCG showed no main effects or interaction.

The PCG is known to mediate some degree of motor processing for the lips, tongue and facial musculature. Although the interaction did not reach significance, the general direction of the data may suggest that women have a PCG which is smaller and more efficient for processing verbal/language information than men. A relatively small insult to this area may lead to a disproportionate loss of function as is seen in AD women compared to AD men. We are expanding our sample size to test this hypothesis. This project was funded by the Ontario Mental Health Foundation.

## 87.14

**MRI-BASED QUANTITATIVE ASSESMENT OF THE HUMAN ENTORHINAL AND PERIRHINAL CORTEX.** R. Insausti<sup>1</sup>, K. Juottonen<sup>2</sup>, H. Soininen<sup>2</sup>, K. Partanen<sup>3</sup>, P. Vainio<sup>3</sup> and A. Pitkanen<sup>4</sup>. Dept. Anatomy, Univ. of Navarra, Pamplona, Spain<sup>1</sup>; Dept. Neurology<sup>2</sup>, Clin. Radiology<sup>3</sup> and A.I. Virtanen Institute<sup>4</sup> Univ. of Kuopio and Kuopio Univ. Hospital, Kuopio, Finland.

The entorhinal and perirhinal cortex are part of the medial temporal lobe neuronal circuitries involved in memory processing. To investigate the contribution of the entorhinal and perirhinal damage to the memory impairment in neurological diseases such as in Alzheimer's disease and temporal lobe epilepsy, we designed a protocol that can be used to determine the volumes of these cortical areas in coronal MRI images. Histological material for the analysis of the cytoarchitectonic boundaries of the cortical areas was available from 72 autopsies. MRI scans (1.5 T Magnetom, T1-weighted partitions, 2.0 mm thick contiguous slices perpendicular to the axis of anterior-posterior commissure) were performed for 20 normal volunteers (11 women and 9 men, age 21-79 years). In one histological case, a premortem MRI was available. Based on cytoarchitectonic criteria, we determined the location of the entorhinal and perirhinal cortex in the human brain according the sulci and gyri that would best indicate the boundaries of these cortical areas as determined from the histological sections. By using the sulcal and gyral pattern as well as the rostrocaudal level, the outline of the entorhinal and perirhinal cortex was drawn on successive MR images and the volume was calculated. The right entorhinal cortex ( $1636 \pm 313$  mm<sup>3</sup>) was larger than the left ( $1378 \pm 328$  mm<sup>3</sup>) ( $p<0.001$ ). The volume of the right perirhinal cortex ( $5293 \pm 697$  mm<sup>3</sup>) was smaller than that on the left ( $5572 \pm 644$  mm<sup>3</sup>) ( $p<0.042$ ). The normalized volumes of the entorhinal or perirhinal cortices did not correlate with age. The intraobserver variability was <8%.

## 87.16

**LONGITUDINAL EVALUATION OF BRAIN ASYMMETRIES IN RELATION TO DEVELOPMENT OF PRECLINICAL DEMENTIA.** S.M. Koger<sup>1</sup>\* and J.A. Kave<sup>2</sup>. <sup>1</sup>Willamette Univ., Salem, OR, 97301 and <sup>2</sup>Dept. of Neurology, Oregon Health Sciences Univ., Portland, OR 97201.

Alzheimer's disease (AD) is characterized by bilateral hippocampal volume loss. Loss of normal hippocampal asymmetry (right>left) may be related to age-associated memory impairment (Soininen, et al, *Neurology*, 1994) or preclinical dementia. Volumetric analysis of magnetic resonance imaging (MRI) assessed if asymmetrical degeneration of medial temporal and cortical structures predicts development of dementia. Annual MRIs collected on 29 healthy elderly subjects, who were cognitively intact at entry, were compared over time with 12 of the subjects who subsequently manifested cognitive impairment as defined by a Clinical Dementia Rating of  $\geq 0.5$ . Repeated measures ANOVA of hippocampal volume showed a nonsignificant ( $p=.07$ ) diagnostic group by side interaction, suggesting a trend toward less asymmetry in those who declined cognitively. Left parahippocampal volume exceeded right for both groups. Atrophy of temporal and frontal cortices in the cognitively impaired subjects did not develop asymmetrically. Supported by: Dept. Veterans Affairs, NIH AG 08017 and Alzheimer Research Alliance of OR

## 87.18

**CELLULAR DEATH IN NORMAL AGING AND ALZHEIMER'S BRAINS.** W.P.Li<sup>1</sup>, H.W.L.Lai<sup>2</sup>, M.C.Yu<sup>3</sup>, and D.T.Yew<sup>4</sup>; Dept. of Neurology, First Military Medical Univ., Guangzhou, China<sup>1</sup>; Dept. of Anatomy, Chinese Univ. of Hong Kong, Hong Kong<sup>2,4</sup>; and Dept. of Anatomy, Cell Biology & Injury Sciences, New Jersey Medical School, New Jersey 07103<sup>3</sup>.

Seven normal aged brains and four Alzheimer brains (average age: 83 and 88 years old, respectively), obtained at postmortem with consent of patients' families and approval of institutions, were processed for evaluation of apoptosis in different areas of the cortex, using the "TUNEL" hybridization technique. The frontal cortex and hippocampus from Alzheimer's patients showed a higher number of apoptotic cells, with the CA4 field of the hippocampus being the most pronounced region exhibiting this difference. To determine whether the apoptotic cells were neurons or glia, these cells were dually labeled with GFAP antisera specific for astrocytes. Quantitative analysis indicated that the dying astrocytes comprised of 13% of apoptotic cells, suggesting that the majority of apoptotic cells were neurons. The proportion of cholinergic to dopaminergic to GABAergic neurons in the cortex of normal aged and Alzheimer's brains, based on immunohistochemical localization with appropriate antisera, was found to be very similar in these subtypes of neurons in both groups. The results indicate that some degenerative mechanisms may not be unique to Alzheimer's disease.

## 87.19

**Quaternary Carbamates with Blood Brain Barrier Permeability as Potential Drugs for the Treatment of Central Cholinergic Deficiency.** E. Heldman, E. Rachaman, R. Adani, I. Rabinovitz, R. Brandeis and G. Amitai, IIBR, Ness Ziona 74100, Israel.

A series of quaternary-lipophilic carbamates were synthesized based on N-alkyl substituted pyridostigmine (PYR), and on conjugates of these compounds with glucosyl residues attached via hydrocarbon spacers. The incorporation of alkyl chains ( $C_6-C_{12}$ ) renders these quaternary compounds lipophilic resulting in blood-brain barrier permeability. The kinetic parameters for inhibition of purified FBS-AChE by these compounds are: dissociation constants,  $K_i = 1.2 \times 10^{-7} - 2.3 \times 10^{-3}$  M, reactivation rate constants,  $k_r = 0.006 - 0.059 \text{ min}^{-1}$  and bimolecular rate constant,  $k_2 = 1.5 \times 10^4 - 2.6 \times 10^6 \text{ M}^{-1} \text{ min}^{-1}$ . Despite of their similar inhibitory potency some of these carbamates are 16-18 fold less toxic than PYR in mice (im). Moreover, PO (PYR- $C_8$ ) is 46 fold less toxic ( $LD_{50} = 230 \text{ mg/kg, sc}$ ) than PYR ( $5 \text{ mg/kg, sc}$ ) in rats. In vivo blood ChE inhibition by PO and PD (PYR- $C_{10}$ ) reaches its peak level within 0.25-6 hours in rats (45% at 20 mg/kg, sc) and sustains at 17-33% even after 24 hours. Significant inhibition of AChE at several brain regions was observed even 24 hours after sc injection in rats. Central activity of PO (20 mg/kg, sc) was demonstrated by reversing scopolamine-induced impairment of memory retention in rats using the passive avoidance test. These lipophilic-quaternary carbamates are potential non-toxic long-acting drugs for diseases associated with central cholinergic deficiencies, such as Alzheimer's disease and stroke.

## ALZHEIMER'S DISEASE: IMMUNE MECHANISMS

## 88.1

**EXPRESSION OF CD43 IN HUMAN MICROGLIA AND ITS DOWN REGULATION IN ALZHEIMER DISEASE.**

A. Matsuo<sup>1, 2</sup>, K. Terai<sup>1</sup>, D. G. Walker<sup>1</sup>, S. C. Sung<sup>1\*</sup>, E. G. McGeer<sup>1</sup> and P. L. McGeer<sup>1</sup>. Kinsmen Lab. of Neurol. Res., Univ. of British Columbia, 2255 Wesbrook Mall, Vancouver, BC, V6T1Z3, CANADA<sup>1</sup>, and Dept. of Neurology, Kyoto Univ., Kyoto, JAPAN<sup>2</sup>. CD43, which is also known as leukosialin or sialophorin, is thought to play an important role in inhibiting leukocyte adhesion, although its exact functions are still uncertain. Prominent expression of CD43 has previously been detected on the surface of T lymphocytes, monocytes, neutrophils and some B lymphocytes. Since microglia are the brain representatives of the monocytic phagocytic system, we investigated whether microglia also express CD43. We also explored whether this expression changes when microglia are activated as in Alzheimer disease (AD). Abundant CD43-like immunoreactivity was detected in ramified microglia of normal brain. It was also seen in residual leukocytes in capillaries and was faintly detectable on the surface of some normal appearing neurons. In AD brains, the overall expression of CD43 on microglia was markedly lower than in control brains. This was opposite to the change in expression of HLA-DR, which was greatly upregulated due to the reactive state of the microglia. This is the first report of a microglial marker which is more highly expressed in the resting or ramified state compared with the reactive state. Such expression is consistent with theories that CD43 plays as anti-adhesion role, and cleavage occurs during cellular activation. Supported by grants from the Alzheimer Society of B.C. and Jack Brown and Family A.D. Research Fund.

## 88.3

**NEURITIC PLAQUE EVOLUTION IN ALZHEIMER'S DISEASE (AD) IS ACCOMPANIED BY MICROGLIAL TRANSITION FROM PRIMARY TO ACTIVATED TO PHAGOCYTIC FORMS.** J.G. Sheng,\* R.E. Mrak, and W.S.T. Griffin. DVAMC; Univ Arkansas Med Sci, Little Rock, AR 72205.

IL- $1\alpha^+$  microglia are important in neuritic plaque formation in AD as evidenced by their distribution among different plaque types (J Neuropathol Exp Neurol 1995;54:276). To further evaluate this role, we classified and counted plaque-associated and non-plaque-associated IL- $1\alpha^+$  microglia as primary (resting), activated (enlarged), and phagocytic (enlarged with heterogenous cytoplasmic contents), and we determined the distribution of the plaque-associated microglia among plaque types. Temporal tissue from 11 AD patients (58-88 y) and 7 controls (61-83) was immunoreacted for IL- $1\alpha$  and  $\beta$ -amyloid. In AD, the number of primary, activated, and phagocytic microglia were increased 2.3-, 4.4-, and 8-fold, respectively. Most (84%) primary microglia were not plaque-associated; 13% were in diffuse non-neuritic plaques (DnNP) and 3% in diffuse neuritic plaques (DNP). In contrast, most activated (55%) and phagocytic (91%) microglia were plaque-associated; activated forms were prominent in DNP (39%), with some (8%) in DnNP and dense core neuritic plaques (DCNP), while phagocytic forms were sparse in DnNP (5%) but prominent in DNP (56%) and DCNP (30%). This suggests that microglial transformation from primary, to activated, to phagocytic forms is important in plaque evolution. NIH AG10208, AG12411.

## 88.2

**TISSUE SECTION CULTURE STUDIES OF RAT MICROGLIA ON ALZHEIMER'S TISSUE.** S.N. Joshi\* and K.A. Crutcher, Department of Neurosurgery, University of Cincinnati, College of Medicine, Cincinnati, OH 45267-0515.

Senile plaques consist of a variety of protein and cellular components. Activated microglia and reactive astrocytes are invariably associated with neuritic senile plaques, suggesting that glial cells may play a role in the production of, or response to, the plaque. Furthermore, some studies have shown that synthetic amyloid peptides induce reactive gliosis and activate microglia. However, since senile plaques are composed of many other elements, the response of glial cells to plaques may involve factors other than amyloid. An alternative approach is to use tissue section culture to determine the response of glial cells to plaques. Tissue sections from AD, human control and rat brains were thaw-mounted onto round coverslips and placed in 4-well plates. The sections were seeded with partially purified microglial cells prepared from mixed cultures of neonatal (P0-P5) rat cortical tissue (separated at 4°C by rotation for 2 hours on an orbital shaker). Dil-labeled acetylated-LDL, which is taken up by scavenger receptors, was used to identify microglial cells on the sections after 4 to 5 days in culture. Initial observations suggest that there are greater numbers of rat microglia on AD tissue sections as compared with the number on human control and rat tissue sections. Co-visualization of plaques, carried out using thioflavin S, did not reveal preferential association of microglial cells with plaques. These preliminary results demonstrate the feasibility of culturing neonatal rat microglial cells on tissue sections of postmortem human brain and suggest that such an approach can be used to examine the interaction of microglial cells with plaques. (Supported by NIH NS31410.)

## 88.4

**ACTIVATED AND PHAGOCYTIC IL- $1\alpha^+$  MICROGLIA, BUT NOT PRIMARY IL- $1\alpha^+$  MICROGLIA, INCREASE WITH AGE IN NORMAL HUMAN BRAIN.** R.E. Mrak,\* J.G. Sheng and W.S.T. Griffin. DVAMC; Univ. Arkansas Med. Sci., Little Rock, AR 72205.

Microglia-mediated inflammatory responses have been implicated in the pathogenesis of neuritic plaques in Alzheimer's disease. The strong age association of Alzheimer's disease suggests that events in normal aging promote these responses. We used computerized image analysis to determine the number and immunoreactive cross sectional area of IL- $1\alpha^+$  microglia in temporal lobe of 20 neurologically normal patients, ages 2-83 yrs. IL- $1\alpha^+$  microglia were characterized as primary (resting), activated (enlarged), and phagocytic (enlarged with heterogenous cytoplasmic contents). The number of activated and phagocytic IL- $1\alpha^+$  microglia, but not primary IL- $1\alpha^+$  microglia, increased with age ( $r = 0.5$   $p = 0.02$ ,  $r = 0.5$   $p = 0.007$ ,  $r = 0.39$   $p = 0.09$ ; respectively). The total number and cross sectional area of IL- $1\alpha^+$  microglia also correlated with age ( $r = 0.5$   $p = 0.017$ ,  $r = 0.6$   $p = 0.006$ ; respectively). The number of activated and phagocytic IL- $1\alpha^+$  microglia in patients  $> 60$  yrs was greater than that in patients  $< 60$  yrs ( $p < 0.001$ ). These age-related changes in activated and phagocytic, but not in primary, IL- $1\alpha^+$  microglia suggest that activation of IL- $1\alpha^+$  microglia in the course of normal aging underlies the age-related risk for Alzheimer's disease. This work was supported in part by NIH AG10208 and AG12411.

## 88.5

**MICROGLIAL ACTIVATION BY PERIPHERAL AND CENTRAL LIPOPOLYSACCHARIDE IN RAT.** W.J. Lipinski, M.J. Callahan, C.A. Parker, C.A. Raby\*, K. Spiegel and L.C. Walker. Parke-Davis Pharm. Res., Div. of Warner-Lambert Co., Ann Arbor, MI 48105.

In response to injury or disease, microglia become activated and release factors that can be cytotoxic to neurons. In chronic neurodegenerative processes such as Alzheimer's disease, microglia may remain activated and chronically produce factors that have neurotoxic potential. In this study, lipopolysaccharide (LPS) was administered to rats centrally and peripherally, and microglial activation was assessed using parallel Western blot and immunohistochemical techniques. Histologically, acute intraperitoneal injection of LPS resulted in a 2-3 fold increase in lectin-stained microglia that peaked 24 hrs after injection, and was only slightly reduced after 48 hrs. Quantitative immunoblot using antibody OX-42 did not detect this increase in microglia. Chronic intracerebroventricular (ICV) infusion of LPS for either 7 or 14 days resulted in a large increase in activated microglia that was readily evident by lectin immunostaining and OX-42 immunoblot. Additionally, chronic central infusion of LPS caused a dose-dependent increase in the  $\beta$ -amyloid precursor protein and activation of complement in brain. No change in  $\beta$ APP or complement was seen following acute peripheral LPS administration. To the extent that activated microglia may play a pathogenic role in some neurodegenerative diseases, these findings suggest that LPS-treated rats are a useful model for studying chronic inflammation in the CNS. Supported by Warner-Lambert.

## 88.7

**ASTROCYTE INVOLVEMENT IN SENILE PLAQUE DEVELOPMENT: STUDIES IN NON-ALZHEIMER TISSUES.** L.S. Conklin and B. Quinn\* Division of Neuropathology, NYU Medical Center, New York, NY 10016.

Although amyloid plaques are a hallmark of Alzheimer's disease, their exact origin remains obscure, as are factors defining their exact topologic shape and spatial distribution. Amyloid deposits are seen not only scattered amongst neurons in the familiar neocortical pattern, but also in the glia limitans or outer part of Layer I, particularly in occipital cortex; in broad penumbrae around cortical vessels (in selected cases); and in diffuse broad areas, particularly in mesial temporal cortex (H.M. Wisniewski et al., *Acta Neuropathol* 78:337, 1989). Amyloid plaques contain many proteins such as heparan sulfate proteoglycans, perlecan, decoran, laminin, apolipoprotein E and others, which may be co-factors in amyloid fibril formation. Using astrocytic markers such as GFAP and CD44, we have noted "smudge-like" zones of staining in normal or epileptic cortex which intermingled with well-defined cellular astrocytic staining for these markers. The immunohistochemical patterns suggest that astrocytes, including protoplasmic astrocytes, can leave behind smudge- or 'plaque'-like zones of glial proteins in human neocortical neuropil. The size and topologic distribution of these zones was reminiscent of the pattern of amyloid plaque formation in Alzheimer's disease. Although speculative, the histochemical data suggests the hypothesis that astrocytes might leave behind zones of neuropil proteins which could provide seeding areas for a much later cascade of amyloid plaque development in individuals vulnerable to Alzheimer's disease. Postmortem Alzheimer neocortex was co-stained for CD44 and amyloid plaques using the sensitive Resusche technique. Silver-positive senile plaques almost always showed broad penumbrae or annuli of CD44 staining, and at least occasionally seemed to coincide with the location of large protoplasmic astrocytes. GFAP immunostaining was more likely to show fibrous astrocytes at the perimeter of plaques. Sponsored by the NYU Alzheimer Center and the Stanley Foundation.

## 88.9

**IL-1 $\beta$  ALTERS THE MORPHOLOGY OF S-100 IMMUNOPOSITIVE GLIA IN CULTURES OF ADULT HUMAN TEMPORAL LOBE.** D.L. Davies\* and F.A. Boop. Depts. of Anatomy and Neurosurgery, Univ. of Arkansas for Med. Sci., Little Rock, AR 72205.

Microglial derived IL-1 $\beta$  has been implicated in several neuropathologic conditions including head trauma, Alzheimer's disease and microbial infections. As part of an endeavor to assess the influence of microglial activation on glial-neuronal interactions, recombinant human IL-1 $\beta$  was administered to secondary cultures of either gray or white matter from surgically resected adult human temporal lobe. In these cultures, vimentin immunopositive epithelioid cells constitute the predominate cell population. However, a subpopulation of cells was immunopositive for GFAP and S-100 protein; generally, these cells had a complex arbor of processes some of which were long (ca. 600  $\mu$ m). Beginning at 6 days *in vitro*, cells were exposed to IL-1 $\beta$  (4.0, 0.8, 0.2 ng/ml) in the culture medium for 72 hrs. Exposure to 4.0 or 0.8 ng/ml of IL-1 $\beta$  increased the number of S-100 immunopositive cells. The majority of these cells were epithelioid and had numerous cytoplasmic vacuoles. Whereas S-100 immunopositive cells in the control cultures retained an extensive arbor of processes. Qualitative differences in GFAP immunopositive cells were not discerned and the responses of gray and white matter cultures were similar. Since neurotrophic and mitogenic activities have been attributed to S-100 protein (Marshak, 1990, *Prog. Brain Res.* 86:169), increased expression of S-100 protein may have a role in the pathogenesis of disease states associated with microglial activation. Supported by: UAMS Research Council and NIH PO1 AG12411.

## 88.6

**ASSOCIATIONS OF IL-1 $\alpha$ <sup>+</sup> MICROGLIA AND S100 $\beta$ <sup>+</sup> ASTROCYTES WITH NEUROFIBRILLARY TANGLE (NFT)-BEARING NEURONS IN ALZHEIMER'S DISEASE (AD).** W.S.T. Griffin\*, J.G. Sheng, and R.E. Mrak. Dept. VA Med Ctr; Univ. Arkansas Med. Sci., Little Rock, AR 72205.

IL-1 $\alpha$ <sup>+</sup> microglia and S100 $\beta$ <sup>+</sup> astrocytes are important in the formation of NFT-bearing neurites in AD plaques (*J Neuropathol Exp Neurol* 1995;54:276 and 1996;55:273). To evaluate the role of these cells in the pathogenesis of neuronal NFT's, we used dual-label immunohistochemistry to quantify IL-1 $\alpha$ <sup>+</sup> microglia or S100 $\beta$ <sup>+</sup> astrocytes associated with four different stages of NFT formation. Using a monoclonal, phosphatase-independent Tau-2 antibody, neurons were classified as stage 0 (some, but only diffuse or finely granular, cytoplasmic Tau-2 immunoreactivity), stage 1 (early, delicate fibrillar or rod shaped Tau-2<sup>+</sup> tangles), stage 2 (mature Tau-2<sup>+</sup> tangles filling the neuronal soma, often with dislocation or pyknosis of the nucleus) or stage 3 (extracellular Tau-2<sup>+</sup> tangles--"ghost tangles"). The percentages of stage 0, 1, 2, and 3 neurons with associated IL-1 $\alpha$ <sup>+</sup> microglia were 48, 56, 67, and 92%, respectively; and the percentages with associated S100 $\beta$ <sup>+</sup> astrocytes were 21, 37, 55, and 92%, respectively. These results show that NFT formation in neurons is accompanied by early and progressive association with IL-1 $\alpha$ <sup>+</sup> microglia and S100 $\beta$ <sup>+</sup> astrocytes, and suggest a pathogenic role for IL-1 and S100 $\beta$  in NFT formation. Supported in part by NIH AG10208 and AG12411.

## 88.8

**A ROLE FOR INTERLEUKIN-18 IN IRON REGULATION OF ASTROCYTOMA CELLS.** J. Hu\* and J. Connor. Dept. of Neuroscience & Anatomy, M.S. Hershey Medical Center, Penn State University, Hershey PA, 17033

Previously, we have demonstrated that iron accumulates in Alzheimer's and Parkinson's diseased brains in those regions undergoing the most severe histopathological change. Ferritin, the iron storage protein, does not increase concomitantly with the increase in iron thereby increasing the possibility for iron induced oxidative damage. The goal of this research is to elucidate the mechanism by which iron can accumulate in brain tissue without inducing a ferritin increase. The iron regulatory protein (IRP) is responsible for the coordinate regulation of ferritin and the transferrin receptor. This protein acts on an iron responsive element (IRE) present on the transcripts of ferritin (5' UTR) and the transferrin receptor (3' UTR). Cytokines, as part of the inflammatory response, are known to stimulate iron uptake and ferritin synthesis in a number of cell types. In this study, the effect of IL-18 on the expression of the IRP in an astrocytoma (SW1088) cell line is determined. In the astrocytoma cells, IL-18 decreased IRP binding activity after 1 day of exposure, but after 2 days exposure IRP binding activity increased and remained elevated at 3 days post exposure. Ferritin protein levels initially increased and then decreased in a manner consistent with increased IRP binding activity. Treatment of cell lysates with a reducing agent revealed the amount of available IRP for binding after 1 day exposure to IL-18 was similar to control whereas the level of IRP appears increased by 2 days postexposure. These data suggest inflammatory agents known to be released in the brain in a number of neurodegenerative diseases may disrupt cellular iron homeostasis which would lead to decreased metabolic activity and increased susceptibility to oxidative damage.

## 88.10

**INTERLEUKIN-6 mRNA IS ELEVATED IN ALZHEIMER DISEASE BRAIN.** C.Zarow\*, K.E.Schlueter, Q.Zhang. Department of Neurology, University of Southern California, Rancho Los Amigos Medical Center, Downey, CA 90242. Interleukin-6 (IL-6) is a cytokine regulator of acute phase proteins produced by microglia and astrocytes under the influence of IL1 and TNF. Increased levels of IL-6 have been reported in Alzheimer disease (AD) brain, but it is not known whether regulation is at the transcriptional or translational level. Using polymerase chain reaction, the levels of mRNA for IL-6 were investigated in 8 AD and 7 non-AD cases. Non-AD cases included one normal control and cases with diffuse Lewy body disease, vascular dementia, PSP, cortical basal ganglionic degeneration, and Pick's disease, neurodegenerative diseases also associated with reactive astrocytes and microglia. Total RNA was extracted from tissue obtained at autopsy from two regions of the temporal lobe: superior temporal gyrus, Brodmann area 22, and the hippocampus. Post-mortem delays averaged 4.8  $\pm$  1.8 h. cDNA was prepared by reverse-transcription from total RNA using random hexamer primers. 20 ng of the resulting cDNA was amplified in a thermal cycler. Amplification products were resolved by electrophoresis in 2% high resolution 3:1 agarose gels. Bands were quantified from ethidium bromide stained gels using videodensitometry software (One-D Scan, Scanalytics). IL6 mRNA was detectable almost exclusively in AD (7 AD and 1 non-AD case in area 22 and 3 AD cases in the hippocampus) despite evidence of neurodegeneration in the non-AD cases. These data provide evidence that the reported elevation of IL6 protein in AD brains is specific for AD and is due to the regulation of IL6 at the level of transcription. (NIH AG-11126 and Alzheimer Association IIRG-94-048)

## 88.11

## CSF OLIGOCLONAL IMMUNOGLOBULIN SYNTHESIS IN A SUBSET OF PATIENTS WITH ALZHEIMER'S DISEASE.

H. Hampel<sup>1</sup>, H.U. Köster<sup>2</sup>, D.A. Körschenhausen<sup>1</sup>, and H.-J. Möller<sup>2</sup>.  
<sup>1</sup>National Institutes of Health, National Institute on Aging, Laboratory of Neurosciences, Bldg. 10/6C414, Bethesda, MD, USA; <sup>2</sup>Psychiatric Hospital, Ludwig-Maximilian University, Nussbaumstr. 7, 80336 Munich, Germany.

Oligoclonal bands (OCB) indicate the activation of the humoral immune response and can act as byproducts of CNS inflammation. To investigate whether humoral immunoreactivity is present in AD, we studied the frequency of OCB in serum and cerebrospinal fluid (CSF). 51 AD subjects [21 EO, 30 LO] were compared to patients with Vascular Dementia (VD; n=11), Major Depression (MD; n=29), Multiple Sclerosis (MS; n=38) and healthy age-matched controls. The presence of OCB was investigated by polyacrylamide Gel isoelectric focusing (IEF). For quantitative intrathecal IgG measurement the IgG-index was used. An elevated IgG-index was found in 82% of MS, 6% of AD, 9% in controls, and none in VD and MD patients. OCB could be traced in 97% of patients with MS, 20% in AD, and not in VD, MD and control subjects. The frequency was significantly elevated between MS and all other groups ( $p < 0.0001$ ) and in AD compared to MD ( $p < 0.03$ ) and VD ( $p < 0.05$ ) patients. There was no correlation with the age of dementia onset and the degree of cognitive impairment. Both the results of IEF and IgG-index seem to be influenced by the presence of blood-brain-barrier (BBB) dysfunction. Furthermore the combined use of quantitative and qualitative IgG detection methods increased the diagnostic sensitivity in AD but not in MS. In conclusion our findings indicate a possible humoral CNS immunoreactivity in a subset of patients with AD.

## 88.13

## LOCALIZATION OF COMPLEMENT C5b-9 (MEMBRANE ATTACK COMPLEX) IN DYSTROPHIC NEURITES IN ALZHEIMER'S DISEASE. W.C. Benzing\*, J.R. Wujek, N.F. Veloso and K.R. Brunden. Discovery Research Group, GliaTech Inc., Cleveland, OH 44122.

Production of the terminal complement complex, C5b-9 (membrane-attack complex), may play an important role in the neuropathology of Alzheimer's disease (AD). Clear demonstration of membrane-attack complex (MAC) within senile plaque dystrophic neurites (DN) would suggest complement activation may play an important role in neuritic damage in AD. The presence of MAC in DN, however, has been variably reported. One reason for these disparate findings could be due to fixation differences across studies. Thus, the present investigation assessed whether the immunohistochemical detection of MAC within DN was fixation-sensitive. Frozen samples of AD (n=7) and aged normal control (n=4) frontal cortex or amygdala were cut at 15µm on a cryostat and fixed on slides for 15 min in either 4% paraformaldehyde, acetone, methanol, Carnoy's fixative or Histochoice (Amresco). In addition, temporal pole samples from 3 other AD cases were immersion fixed in 4% paraformaldehyde for 48 hrs and cut at 40µm on a freezing sledge microtome. All tissue was then immunostained for MAC (Dako clone aE11 and Quidel A239), Aβ (4G8 and Sigma A8326), and PHF-tau (AT8, Innogenetics). Both the Dako and Quidel antisera revealed MAC within plaque DN when the tissue was fixed using acetone, methanol or Histochoice. In contrast, only the Quidel antibody revealed MAC immunostaining in the paraformaldehyde-fixed tissue. These results 1) suggest that the reported variability in detecting MAC within plaque DN may have been due to the choice of antisera and fixation conditions and 2) support the hypothesis that complement activation and consequent MAC formation may lead to the neuritic pathology that is characteristic of AD. Support: GliaTech Inc. and Janssen Pharmaceutica.

## 88.15

## OXIDATIVE DAMAGE IN AD LEUKOCYTES. P. Mecocci\*, A. Cherubini, R. Cecchetti, U. Senin. Dept. of Gerontology and Geriatrics, Perugia School of Medicine, Perugia (Italy).

Several studies have recently shown the usefulness of 8-hydroxy-2'-deoxyguanosine (8OHdG) as a marker of oxidative stress in DNA. Since the level of this molecule was found to be higher in nuclear and mitochondrial DNA of AD brain, the hypothesis that AD DNA is more sensitive to oxidative stress is conceivable. In this study we measured 8OHdG in leukocytes from 12 patients suffering from AD (mean age  $73.3 \pm 5.6$ ) and 12 normal subjects (mean age  $75.8 \pm 6.4$ ). After separation of leukocytes, DNA was extracted and digested to nucleoside level. Analysis was performed by means of HPLC with electrochemical and UV detection to reveal 8OHdG and deoxyguanosine (dG) respectively. Results, expressed as ratio of 8OHdG per  $10^5$  dG molecules, showed a statistically significant higher level in AD leukocytes compared to controls ( $4.6 \pm 1.4$  vs  $2.7 \pm 0.8$ ;  $p < 0.001$ ). Treatment of cells with increasing amount of  $H_2O_2$  slightly increased 8OHdG levels both in AD and control leukocytes but differences were not significant. From these results we may hypothesize that in AD leukocytes DNA is more sensitive to oxidative stress. The reason for this susceptibility is not clear but it could be related to a deficient repair or to a reduced activity of antioxidant systems.

## 88.12

CYCLOOXYGENASE-2 (COX-2) A DEVELOPMENTALLY REGULATED GENE THAT SHOWS REGIONAL INDUCTION TO EXCITOTOXIC LESIONS IN RAT BRAIN. A MODEL FOR ALZHEIMER'S DISEASE. G. Tocco<sup>1</sup>, J. Freire-Moar<sup>2</sup>, S. Schreiber<sup>1</sup>, M. Baudry<sup>1</sup>, P.S. Aisen<sup>1</sup> and G.M. Pasinetti<sup>1</sup>. Hedco Neuroscience Program, USC, Los Angeles, CA 90089; <sup>2</sup>Department of Inflammation Pharmacology, Roche Bioscience, Palo Alto, CA 94303; <sup>3</sup>Department of Psychiatry and Brookdale Center for Molecular Biology, The Mount Sinai School of Medicine, New York, NY, 10029-6574

There is evidence that cyclooxygenase (COX)-2, a key enzyme in prostaglandin biosynthesis, may also control mechanisms of apoptotic cell death in peripheral cells. In this study we explored the developmental expression and regulation of COX-2 mRNA in rat brain during responses to kainic acid (KA)-induced seizures that model select hippocampal neuron death/survival in Alzheimer's disease (AD). We found that COX-2 mRNA is developmentally regulated selectively in the same brain limbic structures where COX-2 is induced by KA-induced seizures. During response to KA-induced seizures in adult rat brain, COX-2 mRNA induction paralleled temporally and overlapped anatomically the appearance of cellular morphological features of apoptosis in subsets of cells of the pyramidal neuron layer of the hippocampal formation, amygdaloid complex and pyriform cortex. However, COX-2 mRNA also showed elevation in neurons of the granule cell layer of the dentate gyrus which are unaffected by KA treatment. Our study indicates that COX-2 is a marker of apoptosis in subsets of neurons of limbic pathways that show degeneration during AD. The involvement of COX-2 in apoptotic neurodegeneration may explain the putative neuroprotective effect of non steroidal anti-inflammatory drugs in AD. This work was supported by NIA grant AG13618 to GMP.

## 88.14

EXPRESSION OF LEUKEMIA INHIBITORY FACTOR (LIF) mRNA IN ALZHEIMER'S DISEASE BRAIN. R. Lemke<sup>1</sup>, R.A. Gadjani<sup>2</sup> and P.H. Patterson. Biology Division, Caltech, Pasadena, CA 91125 and <sup>2</sup>Paul-Flechsig Inst. for Brain Res., Univ. Leipzig, Germany.

The neurotrophic cytokine leukemia inhibitory factor (LIF) is a potent inflammatory mediator, and it is induced in injury models such as peripheral nerve transection and cortical stab wound. LIF may therefore play an important role in the neurodegenerative disorders that involve an inflammatory component e.g., Alzheimer's disease (AD). We studied LIF mRNA expression in AD and control brains by *in situ* hybridization, paying particular attention to the hippocampus and frontal (A9) and temporal (A22) cortices. In normal brain, LIF mRNA is predominantly expressed in neurons such as hippocampal hilar interneurons, pyramidal cells of hippocampus and cortex and granular cells of the dentate gyrus. Double-labeling with the neuronal markers MAP2 and NF200 confirm this identification. Neuronal LIF mRNA levels are reduced in AD brain as compared to controls. In addition, the staining intensity of MAP2 was strongly diminished in AD, reflecting a significant loss of neurons. A hypothesis currently under investigation is, whether activated glial cells, known to be important in CNS inflammation, may also express LIF mRNA.

## 88.16

C3a CONCENTRATIONS IN CSF FROM SUBJECTS WITH ALZHEIMER'S DISEASE, PARKINSON'S DISEASE, AND NORMAL CONTROLS. P.A. Lewitt<sup>1</sup>, D.A. Loeffler, C.M. Brickman, P.L. Juneau, M.F. Perry, and N. Pomara. Clin. Neurosci. Pgm., Sinai Hosp., Detroit, MI 48235, and Div. Geriatric Psych., Nathan S. Kline Inst. for Psychiatric Res., Orangeburg, NY 10962

Complement protein C3a concentrations were measured C3a in CSF from patients with probable AD (n = 19), Parkinson's disease (PD) (n = 5), normal aged controls (n = 9), and normal young controls (n = 10). AD and aged normal C3a concentrations (means  $\pm$  SE:  $365.93 \pm 40.47$  and  $427.57 \pm 92.28$  ng/ml, respectively) significantly increased vs. young controls ( $102.24 \pm 18.24$ ). C3a in PD CSF also increased two-fold vs. young controls ( $226.59 \pm 51.12$ ). These concentrations are similar to C3a levels in serum, in which C3a also increases with age. While C3a content in CSF may, in part, reflect serum levels (due to the low MW [9 kd] of C3a), similar C3a concentrations in CSF and blood suggest the possibility of significant local synthesis as well. Conclusion: CSF C3a appears to increase with age, but does not provide a marker for AD. (Supported by National Parkinson Foundation and Mental Illness Research Association)

## 88.17

A NF- $\kappa$ B/REL SITE IN THE APP GENE REGULATORY REGION IS RESPONSIVE TO INTERLEUKIN-1 AND GLUTAMATE. M. Grilli\*, F. Goffi, M. Memo & P.F. Spano. Div. Pharm., Dept. Biom. Sci. & Biotec., Un. of Brescia, Medical School, 25124 Brescia, Italy.

We originally reported that members of the family of transcription factors NF- $\kappa$ B/Rel can specifically recognize two identical sequences, referred to as APP $\kappa$ B sites, which are present in the 5' regulatory region of the APP gene (Grilli et al., JBC, 270, 26774-26777, 1995). Now we show that the APP $\kappa$ B sites interact specifically with a complex which contains one of the subunit of the family, the so called p50 protein, and that they behave as positive modulators of gene transcription in cells of neural origin. Additionally, the nuclear complex specifically binding to the APP $\kappa$ B sites is constitutively expressed in primary neurons from rat cerebellum and is upregulated in response to the inflammatory cytokine Interleukin-1 $\beta$  (IL-1 $\beta$ ) and the excitatory amino acid glutamate. We believe that these evidences are potentially relevant for understanding the neuropathology associated with Alzheimer's Disease (AD). Although distinct, two of the major pathogenetic pathways which are likely to contribute to the neuropathology associated with AD (inflammatory cytokines and excitatory amino acids), share a common step represented by the activation of a NF- $\kappa$ B/Rel activity.

The work was partially supported by grants from Regione Lombardia and Centro Nazionale delle Ricerche (CNR)

## PARKINSON'S DISEASE: PHARMACOLOGY AND THERAPY

## 89.1

COMPENSATORY EFFECTS OF GLUTAMATERGIC INPUTS TO THE SNC IN MPTP-TREATED MONKEYS C.E. Gross\*, E. Bezdud, T. Borau and B. Bioulac CNRS UMR 5543, Université de Bordeaux II, 33076 Bordeaux Cedex France.

It is well known that Parkinson's disease results from a progressive loss of dopaminergic neurons, but that initial symptoms are only slightly perceptible due to compensatory effects. The substantia nigra pars compacta (SNc) receives glutamatergic inputs from several structures. These inputs may play an important role in this compensation.

In order to test this hypothesis, we injected kynurenic acid (10  $\mu$ l at 5  $\mu$ l/min; broad spectrum glutamatergic antagonist) through an injection cannula into the SNc of two monkeys rendered parkinsonian by the daily injections of low doses of MPTP (i.v., 0.2 mg/kg/day) until the first clinical signs of the disease appeared. This method allowed us to obtain progressive SNc neuronal death (10-15 days). The effects of this temporary daily blockade of glutamatergic inputs were scored on a clinical rating scale.

Until the first appearance of irreversible clinical signs (1 < score < 5), the injections of kynurenic acid did not provoke any motor abnormalities. Between the first clinical signs and full parkinsonism (score > 20), however, this injections drastically increased parkinsonism.

These results would confirm the postulate that SNc afferent glutamatergic pathways play an essential role in compensation. What must now be elucidated is the relative influence of each glutamatergic input to the SNc.

## 89.3

REGULATION BY CHRONIC TREATMENT WITH THE LONG-ACTING DOPAMINE D2-LIKE AGONIST CABERGOLINE OF DOPAMINE D2 mRNA AND RECEPTOR LEVELS IN STRIATUM OF PARKINSONIAN DRUG-NAIVE MONKEYS. M. Morissette\*, M. Goulet<sup>1,2</sup>, R. Grondin\*, P. Falardeau<sup>1,3</sup>, D. Levesque<sup>2,4\*</sup>, P.J. Bédard<sup>4</sup> and T. Di Paolo<sup>1,2</sup>. <sup>1</sup>Sch. of Pharmacy, Laval Univ., and <sup>2</sup>Dept of Molecular Endocrinology CHUL, Québec, G1V 4G2, <sup>3</sup>Centre de recherche du CHUL, Québec, G1V 4G2, <sup>4</sup>Dept of Pharmacology, Faculty of Medicine, Laval Univ., Québec, G1K 7P4, and Neurobiology Res. Center, Enfant-Jésus Hospital; CANADA.

The effects of chronic continuous stimulation of D2-like receptor with the long-acting D2-like dopamine agonist, cabergoline, on D2 mRNA and receptor levels in the striatum were examined in drug-naïve MPTP parkinsonian monkeys. Cabergoline was administered s.c. at 0.25 mg/kg every 48 h during a month to 3 drug-naïve ovariectomized female *macaca fascicularis* monkeys rendered parkinsonian by MPTP. Untreated MPTP as well as naive control animals were also studied. The parkinsonian features in response to cabergoline were initially greatly improved, but decreased somewhat thereafter. However, a good relief of parkinsonian features was maintained until the end of the study. We also observed in the first days, transient dyskinesias in 2/3 monkeys. After a drug washout period of 3 days, the cabergoline-treated MPTP monkeys returned to their initial akinetic state. Density of D2 antagonist sites was examined by autoradiography of [<sup>3</sup>H]Spiperone and *in situ* hybridization histochemistry was performed using a human specific cDNA for D2 mRNA levels. A significant increase in D2 receptor density in the caudal putamen (+20%, p<0.05) was accompanied by an increase in D2 mRNA (+12% in medial caudal putamen, p<0.05) in MPTP-monkeys compared to control animals. Cabergoline treatment significantly decreased by half striatal D2 receptor density versus untreated MPTP monkeys. However, no change in D2 mRNA in middle and caudal striatum was observed, and only a slight tendency to decrease was measured in rostral striatum. The present results suggest that the cabergoline-induced D2 receptor decrease could occur via an increased receptor internalisation or degradation. Hence, the cabergoline-induced D2 receptor decrease may be implicated in behavioral partial tolerance, but our results do not support its decrease via alteration of D2 mRNA. (Parkinson Foundation)

## 89.2

IN SITU HYBRIDIZATION OF PREPRODYNORPHIN mRNA IN THE CAUDATE-PUTAMEN OF MPTP MONKEYS: EFFECT OF CHRONIC TREATMENT WITH L-DOPA AND WITH THE D2 AGONIST U91356A. M. Goulet<sup>1,2\*</sup>, M. Morissette<sup>4</sup>, P. Falardeau<sup>1,3</sup>, P.J. Bédard<sup>4</sup> and T. Di Paolo<sup>1,2</sup>. <sup>1</sup>Sch. of Pharmacy, Laval Univ., and <sup>2</sup>Dept of Mol. Endo. CHUL, Québec, G1V 4G2, <sup>3</sup>Centre de recherche du CHUL, Québec, G1V 4G2, <sup>4</sup>Dept of Pharmacology, Fac. of Medicine, Laval Univ., Québec, G1K 7P4, and Neurobiology Res. Center, Enfant-Jésus Hospital; CANADA.

Dopamine (DA) regulation of the relative levels of preprodynorphin (PPD) mRNA in the striatum of monkeys was analyzed by *in situ* hybridization histochemistry using a specific monkey cDNA. DA exerts its postsynaptic actions through interaction with two major populations of neurons, pallidal (GPe)- and nigral (GPi)-projecting neurons showing a segregation of peptide and receptor expression, in that the majority of the former express D2 receptor and enkephalin, whereas the majority of the latter express D1 receptor, dynorphin and substance P. Susceptibility to develop dyskinesias may be related to relative changes of pallidal- versus nigral-stimulation. *Macaca fascicularis* monkeys were rendered parkinsonian with administration of the toxin MPTP. Three of these animals received pulsatile administration of L-DOPA whereas U91356A was administered using a pulsatile (n=3) or continuous (n=3) schedule for one month. Untreated MPTP (n=4) as well as naive control (n=3) animals were also studied. Animals treated in a pulsatile mode with U91356A showed progressive sensitization and had dyskinesias whereas those receiving U91356A continuously developed behavioral tolerance and no dyskinesia. PPD mRNA was slightly increased by MPTP treatment when compared to control animals. L-DOPA treatment did not correct the MPTP induced increase PPD mRNA, whereas U91356A whether continuous or pulsatile corrected the lesion induced change. The failure of L-DOPA to alter levels of PPD mRNA compared to U91356A treatments reflects important D1 excitatory tone. The mode of chronic U91356A administration (continuous vs. pulsatile) did not affect differently PPD mRNA expression. Therefore, the different behavioral outcome observed in these animals is not directly related with different PPD mRNA expression. (Parkinson Foundation)

## 89.4

$\beta$ -CARBOLINE INDUCED NIGROSTRIATAL NEUROTOXICITY VIA N-METHYLATION IN C57BLACK MICE. K. Matsubara\*, Y. Kobayashi, T. Gonda, T. Idzu and K. Kimura. Neurosci. & Sense Organs, Shimane Med. Univ., Izumo 693, Japan

Several classes of heterocyclic molecules structurally related to MPTP have been advanced as possible natural toxins underlying the nigrostriatal degeneration. Indoleamine-related  $\beta$ -carbolines ( $\beta$ Cs) are structural analogs of MPTP. Simple- $\beta$ C, 2-methylated  $\beta$ C and 9-methylated  $\beta$ C were administered intraperitoneally twice per day for 7 days to C57/Black mice. Motor function was evaluated 48 h after the last injection. The mice were decapitated 72 h after the last injection, and catechol- and indole-amines were analyzed in various brain regions. Brain concentrations of  $\beta$ Cs were evaluated using *in vivo* microdialysis technique. Both sub-chronic treatments of simple- $\beta$ C and 2-methylated  $\beta$ C induced movement disorder and reduced dopamine content in the nigra and striatum regions. Although 2-methylated  $\beta$ C is a cationic form, a part of that administered penetrated blood-brain-barrier into brain possibly due to forming neutral base. 9-Methylated  $\beta$ C potentially induced movement dysfunction, but reduction of dopamine and its metabolites was not specific to nigrostriatal pathway. Also, 9-methyl  $\beta$ C reduced 5-HT and 5-HIAA in many regions. Since simple- and 2-methylated  $\beta$ Cs themselves are very weak toxins, 2,9-dimethylated  $\beta$ C formed in the brain would be an active neurotoxic metabolite of  $\beta$ Cs. The 2,9-dimethylated  $\beta$ C mirrors to MPP<sup>+</sup>, that is an active metabolite of MPTP. From the present results, simple- $\beta$ C would be a neurotoxin precursor undertaken methylation of 2[ $\beta$ ] and 9[indole] nitrogens of its structure sequentially. The 2,9-dimethylated  $\beta$ C lost selective toxicity to nigrostriatal neurons at relatively higher concentrations, however.

## 89.5

**$\beta$ -CARBOLINE-N-METHYLTRANSFERASE ACTIVITY IN HUMAN BRAIN TISSUE FROM CONTROL AND PARKINSON'S DISEASE (PD) SUBJECTS.** D.A. Gearhart\*, E.J. Neafsey, and M.A. Collins. Neuroscience Program and Departments of Cell Biology, Neurobiology & Anatomy; and Molecular and Cellular Biochemistry, Loyola University Medical Center, Maywood, IL 60153.

Brain N-methyltransferases catalyze the N-methylation of  $\beta$ -carbolines at the 2N- (pyrido) and 9N- (indole) nitrogens; resultant compounds are structural and functional analogs of the parkinsonian-producing neurotoxin, MPP<sup>+</sup>. We have hypothesized that N-methylated  $\beta$ -carbolinium compounds may contribute to the neuropathogenesis of PD. We measured human brain 2N- and 9N-methyltransferase activity (reported as mean pmoles/hr/mg protein  $\pm$  SEM) in the pellet and supernatant following centrifugation at 10,000g for 30 minutes.

Group (n)	SUBSTANTIA NIGRA			
	2-Methylation Activity		9-Methylation Activity	
	Pellet	Supernat.	Pellet	Supernat.
Control (5)	14.5 $\pm$ 10.1	34.4 $\pm$ 12.7	12.5 $\pm$ 8.3	19.0 $\pm$ 8.0
PD (6)	6.1 $\pm$ 2.8	39.7 $\pm$ 18.0	5.4 $\pm$ 2.4	15.1 $\pm$ 5.7
Group (n)	PUTAMEN			
	2-Methylation Activity		9-Methylation Activity	
	Pellet	Supernat.	Pellet	Supernat.
Control (7)	2.0 $\pm$ 0.8	16.1 $\pm$ 9.2	5.1 $\pm$ 1.7	14.9 $\pm$ 7.4
PD (7)	3.9 $\pm$ 1.2	15.4 $\pm$ 5.3	4.1 $\pm$ 1.6	14.2 $\pm$ 5.4
Group (n)	FRONTAL CORTEX			
	2-Methylation Activity		9-Methylation Activity	
	Pellet	Supernat.	Pellet	Supernat.
Control (8)	6.8 $\pm$ 1.8	13.8 $\pm$ 4.5	8.0 $\pm$ 1.4	12.5 $\pm$ 4.0
PD (7)	8.9 $\pm$ 1.2	17.4 $\pm$ 3.5	11.1 $\pm$ 1.0	*39.0 $\pm$ 7.9

The data confirm the presence in human brain of 2N-methylating activity and demonstrate for the first time indole 9N-methylating activity. Specific activity was generally higher in the supernatant, implying cytosolic localization. Levels were similar in Control and PD brains, except that 9N-methylation activity was significantly elevated in frontal cortex in PD (\*  $p < 0.02$ ). (NIH NS23891)

## 89.7

**LONG-TERM POTENTIATION OF THE DOPAMINE-INDUCED RESPONSES IN RAT MIDBRAIN DOPAMINERGIC CELLS.**

N. B. Mercuri\*, M. Scarponi, A. Bonci, and G. Bernardi. Clinica Neurologica, Università di Roma "Tor Vergata", 00173 Rome, Italy and IRCCS S. Lucia, 00179 Rome, Italy.

The inhibition of monoamine oxidase (MAO) A and B potentiated the depression of the firing rate and the hyperpolarization of the membrane potential caused by dopamine (DA) (10 - 30  $\mu$ M) on rat midbrain dopaminergic cells, intracellularly recorded *in vitro*. The inhibition of MAO enzymes was obtained by superfusing the slices with pargyline (10 - 100  $\mu$ M) for 20 - 120 min. The cellular responses to DA, which were due to the activation of somato-dendritic D2/3 autoreceptors, were prolonged and did not completely wash after the pharmacological blockade of both types (A and B) of MAO. On the contrary, the amphetamine-induced inhibition and hyperpolarization of the cells were slightly prolonged by MAO inhibition. The actions of amphetamine on the dopaminergic cells were due to an increased release of dopamine in the extracellular space. The present data suggest that the inhibition of MAO activity in the brain causes a long-term potentiation of the responses induced by exogenous DA but not of those induced by amphetamine-released DA. This increased DA action could suggest a therapeutic approach that use MAO inhibitors and DA precursors in DA-deficient psychiatric disorders and in Parkinson's disease.

## 89.9

**BRAIN [18F]6-FLUORO-L-M-TYROSINE METABOLISM STUDIED BY IN VIVO MICRODIALYSIS.** S. Jordan\*, J.L. Eberling, K. Bankiewicz, W.J. Jagust. Center for Functional Imaging, Lawrence Berkeley Laboratory, University of California, Berkeley, CA 94720; Somatix Therapy Corp. Alameda, CA 94501.

[18F]6-fluoro-L-m-tyrosine (FMT) is a Positron Emission Tomography (PET) tracer of central dopa decarboxylase activity. The FMT signal is preferentially retained in dopaminergic brain structures primarily in the form of its major metabolite [18F]6-fluoro-3-hydroxyphenylacetic acid (FPAC). The mechanism of intraneuronal FMT signal retention is currently uncertain. However, FPAC binds with high affinity to the vesicular amine transporter which suggests its possible uptake and capture inside presynaptic cytoplasmic vesicles. *In vivo* brain microdialysis was used to monitor striatal FPAC accumulation in control and reserpinized rats injected with FMT (25 mg/kg, i.v.) and then 120 min later with D-amphetamine (2.5 mg/kg, i.p.). Dialysate samples were collected every 20 min for two hours after FMT injection and for one hour after D-amphetamine injection and they were analyzed for their FPAC content by HPLC with electrochemical detection. In both control and reserpinized rats FPAC levels were highest during the first 20 min sampling period after which they remained almost stable prior to the D-amphetamine injection which produced a small but significant rise in striatal FPAC in the control animals only. This D-amphetamine stimulated release of FPAC from a reserpine sensitive pool suggests the FMT signal in PET is associated, at least in part, with presynaptic dopaminergic vesicles. Furthermore, these data support the recent hypothesis that D-amphetamine stimulates dopamine release by interacting with vesicular as well as cytoplasmic dopamine stores.

Supported by the Laboratory Technology Applications Division, Office of Energy Research, U.S. Department of Energy under a CRADA (Cooperative Research and Development Agreement) between Lawrence Berkeley National Laboratory and Somatix Therapy Corporation, Alameda, CA under US DOE Contract DE-AC03-76SF00098.

## 89.6

**RIBOZYME-MEDIATED DOWN REGULATION OF EXPRESSION OF TYROSINE HYDROXYLASE AND DOPAMINE TRANSPORTER GENES.** Leonidas A. Phylactou\*, Matthew JA Wood. Department of Human Anatomy, Oxford University, Oxford OX1 3QX, UK.

Hammerhead ribozymes are enzymes comprised of RNA that catalyze site-specific RNA cleavage in a base-specific way. They are at present being developed for gene therapy and protein function studies as inhibitors of gene expression. Tyrosine hydroxylase (TH) and dopamine transporter (DAT) are key molecules for the synthesis and regulation of neurotransmission of dopamine (DA). DA levels are found to be reduced in patients with Parkinson's disease (PD).

Hammerhead ribozymes have been designed and synthesised for the specific inhibition of production of tyrosine hydroxylase (TH) and dopamine transporter (DAT). The cleaving ability of ribozymes was tested in the presence of their targets *in vitro*. Both ribozymes were cloned into a plasmid containing a prokaryotic promoter. Similarly, inactive ribozymes, lacking catalytic activity were also constructed. Production of ribozymes was carried out by *in vitro* transcription using the T7 promoter. The target RNA was synthesised from total RNA extracted from rat brain followed by two rounds of amplification to introduce a T7 promoter. Each labelled RNA target was incubated with its specific ribozyme at both 50°C and 37°C in a neutral pH environment and in the presence of magnesium ions. Both ribozymes were shown to successfully cleave their targets. On the other hand, no cleavage products were detected with the inactive ribozymes. Adenoviruses will be the means of ribozyme delivery inside rat progenital adrenal cells and animals. Preliminary results show that adenoviruses can efficiently transport reporter genes into the substantia nigra when injected into the caudate nucleus of rat brains.

The above results suggest that hammerhead ribozymes can be used for the specific inhibition of TH and DAT production in the brain indicating their potential for therapeutic application in PD. (supported by MRC ROPA grant)

## 89.8

**THE NICOTINIC RECEPTOR AGONIST SIB-1508Y POTENTIATES L-DOPA RESPONSES IN PARKINSONIAN MONKEYS.** A. Pope-Coleman\*, G.

Kenneth Lloyd<sup>1</sup> and J.S. Schneider. Depts. of Anat. and Neurobiol. and Neurology, MCP and Hahnemann University, Philadelphia, PA 19102 and <sup>1</sup>SIBIA Neurosciences, Inc. La Jolla, CA 92037

Neuronal nicotinic acetylcholine receptor (NACHR) agonists may be useful for the treatment of Parkinson's disease (PD) and may protect nigrostriatal dopamine (DA) neurons from degeneration. There have been reports on the usefulness of nicotine as a therapeutic agent in PD patients; nicotine may effect PD symptoms by enhancing DA function in striatal and limbic areas and ACh function in the hippocampus, thalamus and frontal cortex. SIB-1508Y is a subtype-selective NACHR agonist which releases DA *in vitro* and *in vivo* and exhibits activity in rodent models of PD (Soc. Neurosci. Abstr., 1995; 21:11). In the present study, SIB-1508Y was evaluated on parkinsonian symptoms and L-DOPA responses in monkeys. Two cynomolgus monkeys, previously made parkinsonian by chronic administration of MPTP, were evaluated with a behavioral/motor rating scale and a timed motor test that involved retrieval of food pellets from 16 wells recessed in a Plexiglass board. SIB-1508Y, at doses of 8-12 mg/kg p.o., or at 2 mg/kg i.m. caused mild improvement in Parkinsonian symptoms in both monkeys. Both animals responded well to L-DOPA, beginning at doses of 15 mg/kg i.m. The combination of an ineffective dose of SIB-1508Y (1 mg/kg, i.m.) and L-DOPA caused a significant shift of the L-DOPA dose response curve. Significant anti-Parkinson effects were observed with L-DOPA doses as low as 5.0 mg/kg, when administered together with SIB-1508Y. There was no additional improvement in motor ratings, but enhanced reward retrieval performance when SIB 1508Y was added to maximally effective doses of L-DOPA. These data show the NACHR agonist SIB-1508Y to have mild anti-parkinsonian effects as monotherapy and to significantly potentiate the therapeutic responses to L-DOPA in Parkinsonian monkeys. Thus, NACHR agonists may play a significant role in the future therapy of PD. Supported by SIBIA Neurosciences, Inc.

**U95666A IS A HIGH INTRINSIC ACTIVITY AGONIST WITH SELECTIVITY FOR THE D2 DOPAMINE RECEPTOR.** M.E. Laiiness, C.L. Chio, P.J.K.D. Schreur\* and R.M. Huff. CNS Diseases Research, Pharmacia & Upjohn, Kalamazoo, MI 49001

Parkinson's Disease is characterized by progressive degeneration of dopaminergic neurons. Levodopa is currently the most effective therapy for controlling symptoms of the disease. However, long term treatment leads to loss of efficacy and serious side effects. Direct acting dopamine receptor agonists used in addition to or instead of L-DOPA cause a high incidence of psychiatric side effects and have limited efficacy compared to L-DOPA. The discoveries of three related but distinct members of the D2-like dopamine receptor family, (D<sub>2</sub>, D<sub>3</sub> and D<sub>4</sub>), provided an opportunity to develop dopamine agonists with selectivity for only one of the subtypes, which may enhance efficacy and lessen side effects. U95666A was found to have high selectivity for D<sub>2</sub> receptors over all other dopamine receptor subtypes. In several D<sub>2</sub> receptor expressing-CHO cell-based assays U95666A was a potent, highly efficacious agonist. U95666A does not activate D<sub>3</sub> or D<sub>4</sub> receptors, consistent with the selectivity determined in radioligand binding studies. The EC<sub>50</sub> values for U95666A stimulation of various second messengers range between 17 $\pm$ 4.8 nM in inhibition of forskolin-stimulated cAMP accumulation to 112 $\pm$ 34 nM in potentiation of arachidonic acid release. U95666A stimulated mitogenesis with an EC<sub>50</sub> of 32 $\pm$ 6.4 nM, and stimulated extracellular acidification with an EC<sub>50</sub> of 103 $\pm$ 8.7 nM. In all measurements, U95666A had a high level of intrinsic activity. These results indicate that U95666A is a high intrinsic activity agonist with selectivity for D<sub>2</sub> dopamine receptors. Acknowledgements to M.W. Smith, C.B.S., Pharmacia and Upjohn, for receptor binding data.

**A NOVEL THERAPY FOR PARKINSON'S DISEASE USING A GENETICALLY-MODIFIED HUMAN ASTROCYTE LINE.** Gal Yaidi<sup>1</sup>, Naomie Fitoussi, Eugene Major<sup>2</sup> and Carlo Tornatore<sup>2</sup>, Dept. of Life Science, Bar Ilan University ISRAEL and <sup>2</sup>Molecular Therapeutic section NINDS, USA.

Parkinson's disease is caused by degeneration of nigrostriatal dopaminergic neurons. A potential therapeutic approach for treating PD that utilizes a rat model for the disease and transplantation of a genetically-modified immortalized astrocyte cells (SVG-TH) that stably expresses tyrosine hydroxylase (TH) has been examined. SVG-TH cells were grafted into the striatum of 6-hydroxydopamine-lesioned (6OH-DA) rats and the *in situ* production of l-dopa, dopamine (DA) and its metabolites, dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA), determined by using a microdialysis technique coupled to a HPLC apparatus. Our result indicate that DA levels in extracellular space of 6OH-DA rats were only 3% of those observed in normal animals. Upon transplantation of the SVG-TH cells into the striatum of the parkinsonian rats, the levels of DA reached those of the normal rats. This recovery appear to correlate with a significant improvement of their behavioral deficit. The levels of DA metabolites in parkinsonian rats were low even after transplantation of the SVG-TH cells probably because of the damage to dopaminergic neurons integrity. No change in 5-hydroxyindolacetic acid (5-HIAA), the main serotonin metabolite, levels between all treatment groups indicate that we selectively lesioned the dopaminergic system. Application of NSD-1015 via the microdialysis probe enabled us to examine TH activity *in vivo*. Experiments using SVG-TH cells as a xenograft drug delivery system may evaluate the therapeutic potential for PD of this unique method for *in situ* supply of l-dopa on a behavioral, cellular, and molecular level.

**MESENCEPHALIC DOPAMINERGIC NEURONAL CELL LINES FROM TRANSGENIC MICE: NEUROTROPHIC REGULATION AND *IN VITRO* MODEL OF PARKINSON'S DISEASE.** J.H. SON<sup>1</sup>, S.H. CHO, B. CONTI, D.H. PARK, J.W. JAHNG, C. TINTI, C.H. PENG and T.H. JOH. Laboratory of Molecular Neurobiology, Cornell University Medical College at the W.M. Burke Medical Research Institute, White Plains, N.Y. 10605, U.S.A.

The potential implication of neurotrophic factors (NTF) in the etiology of Parkinson's disease (PD) has suggested their use as therapeutic agents in PD, where selective substantia nigra (SN) dopamine (DA) neuronal death occurs. Rational therapy requires detailed understanding of the functional role(s) of specific NTF in both the normal- and patho-physiology of the SN-DA cells. NTF has been tested primarily as to whether they can promote the survival and differentiation of DA neurons in mixed cultures of ventral mesencephalon derived from E15 - E16 rat embryos. The culture studies have often resulted in the confounding data primarily due to the paucity of DA cells in heterogeneous fetal mesencephalic cultures. In addition, the short survival rate and an inability of genetic manipulation have been major obstacles for the mechanistic study of the NTF. Therefore, we have developed *in vitro* model systems: A culture system of conditionally immortalized homogeneous DA neuronal cells lines produced from mesencephalic SN. Cell lines were established from transgenic mice expressing thermolabile SV40-TagsA58 in DA neurons using our central catecholamine neuron-specific 9 kb promoter region of the tyrosine hydroxylase (TH) gene (Mol. Brain Res. 27, 281 '94). Our SN-DA cell lines showed distinct DA phenotype: expression of TH and AADC enzymes for DA synthesis and target-specific neurite projection to striatum, but not to cortex in explant cultures. Moreover, NTF such as BDNF and GDNF retarded apoptotic SN-DA cell death during differentiation at nonpermissive temperature and enhanced cell survival after MPP<sup>+</sup> insult. (Supported in part by NIH grant MH24285)

## 89.15

**HIBERNATED MESENCEPHALIC NEURONS UNDERGO APOPTOSIS-INDUCED CELL DEATH; REVERSAL WITH TROPHIC FACTORS.** P.M. Carvey, P. Thajeb, Z.D. Ling and E.D. Potter. Neuropharmacology Research Laboratories, Rush Medical School, Chicago, IL 60612

We have previously demonstrated that harvested fetal rostral mesencephalic tegmentum (RMT) cells remain viable for up to 5 days *in vitro* in a high K<sup>+</sup> hibernation media (HM) and that the survival rate of tyrosine hydroxylase immunoreactive (THir) neurons can be enhanced by supplementing the HM with trophic factors. We have also shown that several factors including pH, storage density, temperature and method of dissociation dramatically influence survival. We now show that apoptosis-induced cell death initiated during hibernation is a major cause of reduced survival. E15 rat RMT was harvested and dissociated using mechanical trituration and stored at 4°C (pH 7.4) at a density of 1 million cells/ml HM. Using these optimal parameters, the number of apoptotic figures (Klenow technique) was determined 6, 24 and 48 hours following storage in HM alone, or HM supplemented with 8% human placental cord serum (HPCS), GDNF (10 ug/ml), or BDNF (10 ug/ml). Apoptotic cell counts were 33% in HM, 28% in BDNF, 19% in HPCS and 16% in GDNF supplemented media. Interestingly, the apoptotic rates were highest at 6 hours but did not change dramatically thereafter. Although HPCS and GDNF significantly reduced the apoptotic rate, all three trophic supplements yielded similar THir neuron survival rates when the hibernated cells were cultured for 72 hours. These results suggest that hibernation conditions dramatically influence cell survival. Moreover, it appears that apoptosis is initiated soon after the cells are harvested and can be prevented by supplementing the media with trophic factors. By reducing apoptosis during hibernation, the survival rate of transplanted DA neurons might be increased. (Supported by NINDS 1ROINS33174, GDNF supplied by AMGEN, Inc.)

## 89.12

**FUNCTIONAL AND ANATOMICAL RECOVERY OF THE NIGROSTRIATAL CIRCUITRY BY CONCURRENT INTRASTRIATAL AND INTRANIGRAL GRAFTS OF FETAL NIGRAL CELLS.** M. Hong<sup>1</sup> and I. Mendez. Neural Transplantation Laboratory, Department of Neurosurgery, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4H7

It is well known that grafts of fetal nigral tissue survive and grow in the dopamine (DA) depleted adult striatum. Although such grafts produce reversal of behavioural and biochemical deficits in the rat model of Parkinson's disease (PD), little is known about the restoration of the nigrostriatal circuitry following transplantation. To further study the functional and anatomical recovery produced by neural transplantation, we have employed a novel micrografting technique to stereotactically implant fetal (E14) nigral dopaminergic cell suspensions into both the striatum and substantia nigra of female Wistar rats (200-225 g) bearing unilateral 6-hydroxydopamine (6-OHDA) lesions of the nigrostriatal dopaminergic pathway. Analysis of functional recovery was carried out using a video activity monitor to assess animal locomotor activity and analysis of anatomical recovery was made using tyrosine hydroxylase (TH) immunohistochemistry. A pre-graft challenge with amphetamine (5 mg/kg i.p.) induced asymmetric turning behaviour towards the lesioned side: 566.2 ± 84.5 ipsiversive rotations vs 0.7 ± 0.4 contraversive rotations over a 60 minute observation period (mean ± SEM, n=6). In contrast, a post-graft challenge at 6 weeks with amphetamine failed to induce asymmetric turning behaviour. Immunohistochemical analysis using an antibody against TH revealed a large number of TH-positive cell bodies in the grafts both in the striatum and substantia nigra. A dense network of dopaminergic processes were also found within the grafts and a large number of axons projected from the nigral graft toward the striatal graft and viscera resulting in reconstruction of the nigrostriatal pathway. This study for the first time demonstrates both functional and anatomical restoration of the nigrostriatal pathway by concurrent fetal nigral grafts in the striatum and nigra in the 6-OHDA rat model of PD.

**SHORT-TERM SURVIVAL OF NEONATAL SUBVENTRICULAR ZONE PROGENITOR CELLS TRANSPLANTED INTO THE STRIATUM OF ADULT RATS.** R. Betarbet<sup>1,2</sup>, T. Zigova<sup>1</sup>, R.A.E. Bakay<sup>2</sup>, R.M. Lindsay<sup>3</sup>, S.J. Wiegand<sup>3</sup> and M.B. Luskin<sup>1</sup>. <sup>1</sup>Depts. of Anatomy and Cell Biol. & <sup>2</sup>Neurosurg., Emory Univ. Sch. of Med., Atlanta, GA 30322 and <sup>3</sup>Regeneron Pharmaceuticals, Inc. Tarrytown, NY 10591.

We have previously shown that the anterior part of the neonatal subventricular zone (SVZa) generates cells that migrate to the olfactory bulb and differentiate into GABAergic and dopaminergic neurons. The SVZa cells, when transplanted into the neonatal striatum, retain their neuronal phenotype as well as their ability to migrate (*Cell Transplantation* 5:165, 1996). In this study we examined the short-term behavior and phenotype of dissociated, BrdU-labeled SVZa cells transplanted stereotactically into the striatum of adult rats. Three days after transplantation most SVZa cells were immunoreactive for TuJ1, an antibody which recognizes neuron-specific class III  $\beta$ -tubulin. Within the adult striatum only the transplanted SVZa cells stained intensely for TuJ1. TuJ1(+) cells were also identified within 50 - 250  $\mu$ m of the transplant, suggesting that these cells had migrated from their site of implantation. Very few of the transplanted cells were GFAP(+). However, the transplant contained numerous GABA(+) cells, as well as a few tyrosine hydroxylase(+) cells. The ability of the SVZa cells to disperse and differentiate into neurons following transplantation into an adult striatum makes them potential candidates for cell replacement therapy in several neurodegenerative disorders. Supported by NIH, National Parkinson Foundation and Regeneron Pharmaceuticals, Inc.

**CYTOKINES INDUCE TRANSFORMATION OF MESENCEPHALIC PROGENITOR CELLS TO DA NEURONS** E.D. Potter<sup>\*</sup>, Z.D. Ling and P.M. Carvey. Neuropharmacology Res. Labs., Rush Med. School, Chicago, IL 60612

We previously demonstrated that progenitor cells isolated from fetal rostral mesencephalic tegmentum (RMT) can be maintained indefinitely in proliferation media with EGF and converted to DA neurons when co-cultured with freshly harvested RMT. The factor(s) required for this conversion remain unknown. Various cytokines have recently been shown to influence the development of neurons so we examined several different cytokines for their ability to convert progenitor cells to tyrosine hydroxylase immunoreactive (THir) cells. Interleukin-1 (IL-1)  $\alpha$  and  $\beta$  both induced the conversion of progenitor cells to the THir phenotype in a dose-dependent fashion whereas 13 other cytokines studied were without effect. This conversion only occurred when the progenitor cells were co-cultured with striatal cells suggesting that extracellular matrix proteins are required for the conversion process. The number of progenitor cells converted to THir cells could be further increased when a cocktail containing GDNF, leukemia inhibitory factor (LIF), interleukin 11 (IL-11) and IL-1 $\alpha$  were added. This cytokine cocktail not only yielded a progenitor cell transformation rate exceeding 20%, but also produced cells whose morphology was similar to typical DA neurons. Interestingly, the gp130 protein is involved in both IL-11 and LIF signaling while the intracellular domain of the IL-1 receptor is homologous with the gp130 protein suggesting the involvement of gp130 signal transduction cascade in the phenotypic conversion process. These results suggest that cytokines may be involved in the conversion of progenitor cells to DA neurons. Success in this regard would yield a DA enriched source of cells for laboratory study as well as in transplantation for Parkinson's disease. PRAMIPEXOLE INCREASES MESENCEPHALIC-DERIVED TROPHIC ACTIVITY IN TISSUE CULTURE AND IN VIVO. Z.D. Ling\* and P.M. Carvey. Rush Medical School, Chicago, IL 60612

We previously demonstrated that pramipexole (PPX) prevented the levodopa-induced loss of dopamine (DA) neurons in rostral mesencephalic tegmentum (RMT) cultures. In addition, defined media from PPX-treated RMT cultures enhanced the growth of freshly-harvested RMT while conditioned-media from parietal cultures incubated with PPX was without effect. We hypothesized that PPX's neuroprotectant effect against levodopa toxicity could be due to increased production of a RMT-derived trophic activity since the effect was heat-labile. We have now examined this phenomenon *in vivo*. Rats (8/group) were treated with 0.3 or 3.0 mg/kg PPX, 0.5 mg/kg pergolide (PERG) or vehicle, daily for 24 days. After 4 drug-free days the animals were sacrificed. The brains were mounted on a cryostat and 800  $\mu$  coronal sections were taken through the mesencephalon. The ventral mesencephalons (nigra and VTA) were dissected from the frozen sections, homogenized in HBSS and centrifuged at 100,000g. A section of the cerebellum was processed similarly. 100  $\mu$ L of the extracts were added to RMT cultures with defined media. After 72 hours, the cultures were fixed and stained and the number of tyrosine hydroxylase immunoreactive (THir) cells was assessed. Extracts from animals treated with PPX increased the number of THir neurons in a dose-dependent fashion ( $F=5.67$ ;  $p < 0.001$ ) while PERG was without effect. RMTs in cerebellar extracts were unaffected by drug treatment and exhibited reduced growth relative to RMTs incubated in mesencephalic extracts. These data suggest that a trophic activity capable of supporting the growth of DA neurons is normally present in the adult rat and that PPX increases its production. PPX may increase the production of this activity as a result of its full intrinsic activity at  $D_2$  receptors or as a result of its preferential affinity for  $D_3$  receptors. (Supported by Pharmacia & Upjohn)

## 89.19

DOPAMINE  $D_2$  AND  $D_3$  RECEPTOR SUBTYPES MEDIATE EXCITATORY AND INHIBITORY RESPONSES RESPECTIVELY IN RAT SNPR. W.E. Hoffmann and M.F. Piercey, Pharmacia & Upjohn, Kalamazoo, MI 49001.

Postsynaptic effects of dopamine (DA) agonists in caudate nucleus can be monitored in substantia nigra pars reticulata (SNPR), a major output for striatal efferent pathways. The effects of  $D_2$  and  $D_3$  agonists and antagonists were evaluated for effects on SNPR neuronal firing rates, using standard microelectrode techniques for extracellular recordings. The majority of SNPR cells responding to 0.3 to 3 mg/kg i.v. U-91356A, a  $D_2$ -preferring DA agonist (Piercey *et al.*, Clin. Neuropharmacol. 18(1):S34-S42, 1995), were stimulated (28 of 43 neurons). Haloperidol (0.1-0.3 mg/kg i.v.), a  $D_2$  antagonist (Sokoloff *et al.*, Nature 347:146, 1990), was able to completely reverse U-91356's stimulatory effects on SNPR neuronal firing rates ( $ED_{50}$  for antagonism = 183  $\mu$ g/kg). Conversely, 1-3 mg/kg i.v. U-99194A, a  $D_3$  antagonist (Waters *et al.*, J. Neural Transm. 94:11, 1993) tended to accentuate rather than antagonize cell firing stimulated by U-91356A. By itself, U-99194A did not affect SNPR firing rates. The predominant response to 1-10 mg/kg pramipexole, a  $D_3$ -preferring agonist (Piercey *et al.*, *ibid.*), was inhibition (31 of 63 neurons). U-99194A, 1-3 mg/kg, fully antagonized pramipexole-induced inhibitions in all cells tested. Haloperidol, in doses up to 0.3 mg/kg, was unable to significantly antagonize inhibitory responses after higher cumulative doses ( $\geq 3$  mg/kg) of pramipexole, and was only partially efficacious when given with high doses (0.3 mg/kg) in antagonizing lower doses of pramipexole. It is concluded that the stimulatory and inhibitory effects of DA agonists in SNPR are mediated through the DA  $D_2$  and  $D_3$  receptor subtypes, respectively.

## 89.18

THE DOPAMINE AGONIST PRAMIPEXOLE BLOCKS THE OXIDATIVE TOXICITY OF L-DOPA IN CULTURE. J.S. Althaus, G.J. Fici and P.F. VonVoigtlander\*. CNS Diseases Research, Pharmacia & Upjohn, Inc., Kalamazoo, MI 49001.

L-dopa is a standard treatment for Parkinson's disease (PD). Unfortunately, autooxidation of L-dopa has the potential to contribute to neuronal loss in PD. This raises questions about the long-term therapeutic benefits of L-dopa. Pramipexole (PPX) is a potent and selective dopamine  $D_2/D_3$  agonist recently submitted to the FDA as a treatment for PD. We found that PPX could oxidize within a biologically relevant range and may possibly act as an antioxidant as well as a dopamine agonist. We developed a cellular model of L-dopa toxicity and tested PPX's effects on this toxicity. L-dopa decreased cerebellar granule cell viability with a  $TC_{50}$  of approximately 50  $\mu$ M after 24 hrs. The mechanism of L-dopa toxicity appears to be based on the generation of superoxide and/or hydrogen peroxide because SOD and catalase were completely protective. PPX and its inactive receptor binding enantiomer blocked L-dopa toxicity equally with an  $EC_{50}$  of approximately 1  $\mu$ M and 70% protection at 10  $\mu$ M. PPX at 10  $\mu$ M also decreased the rate of cellular glutathione depletion observed with L-dopa incubation. PPX neuroprotection seen in this cellular model of oxidative stress seems to be independent of dopamine receptor binding and could be due to antioxidant properties of the drug.

## 89.20

ROLE OF ASTROGLIAL ENVIRONMENT IN SELECTIVITY OF DOPAMINERGIC LESION IN PARKINSON'S DISEASE. P. Damier<sup>1</sup>, Y. Agid<sup>1</sup>, A.M. Graybiel<sup>2</sup> and E.C. Hirsch<sup>1</sup>. <sup>1</sup>INSERM U289, Hôpital de la Salpêtrière, Paris, France Dept; <sup>2</sup>Brain & Cogn. Sci., MIT, Cambridge, MA 02139.

Parkinson's disease (PD) is characterized by a massive degeneration of dopaminergic neurons in the substantia nigra (SN). However, loss of dopaminergic is heterogeneous. We recently showed that patterns of calbindin  $D_{28k}$ -immunostaining can be used as a template to subdivide the SN. We defined the SN pars compacta (SNpc), a zone overlapped by calbindin-positive neuropile, and the SN pars dorsalis (SNpd), dorsal to that area. Moreover in the SNpc, we used the heterogeneity of calbindin-immunostaining to differentiate dopaminergic neurons included within calbindin-positive neuropile (named nigral matrix) and those located in five different calbindin-poorly stained pockets (named nigrosomes). We calculated degree of cell loss in these different groups in PD, and in particular, we found that loss of dopaminergic neurons was significantly higher in nigrosomes ( $95 \pm 5$ ) than in matrix ( $80 \pm 9$ ) and the SNpd ( $57 \pm 8$ ). To investigate reasons of such heterogeneity, we analyzed density of astroglial cells in the different groups of the SN.

Glial fibrillary acidic protein (GFAP) immunohistochemistry was performed at three transverse levels of a control human midbrain. To calculate density of astroglial cells in the different groups of the SN, we plotted GFAP-positive cells in 10 microscopic fields ( $150 \times 195 \mu$ m) randomly distributed by an image analysis system on each anatomical region.

Density of astroglial cells was different from one group to another. The density was lower in more affected groups in PD ( $101 \pm 19$  GFAP-positive cells/mm<sup>2</sup> in nigrosomes) than in less affected groups ( $265 \pm 35$  in the matrix and  $282 \pm 43$  in the SNpd).

Our results suggest that astroglial environment could play a main role in protection of dopaminergic neurons against PD degenerative process, and may explain lesion selectivity.

## PARKINSON'S DISEASE: NEUROTOXICITY

## 90.1

PATHOLOGICAL GLIAL-NEURONAL INTERACTION IN PARKINSON'S DISEASE. H.M. Schipper\*, L. Bernier and G. Bernatchez. Lady Davis Institute, Jewish Gen. Hosp. and Dept. of Neurology & Neurosurgery, McGill Univ., Montreal, Canada

The mechanisms responsible for the accumulation of redox-active brain iron in normal senescence and Parkinson's disease are poorly understood. In rat primary astrocyte cultures, we demonstrated that dopamine (0.1-1  $\mu$ M) rapidly induces heme oxygenase-1 (HO-1), followed by sequestration of non-transferrin bound, non-heme <sup>55</sup>Fe by the mitochondrial compartment. Conversely, dopamine appears to suppress mitochondrial trapping of transferrin-bound iron in these cells. Unlike dopamine, L-DOPA and norepinephrine had no effect on HO-1 expression and mitochondrial iron sequestration in cultured astroglia. In Parkinson's disease, dopamine released from dying nigrostriatal neurons may stimulate up-regulation of HO-1 in nearby astroglia which, in turn, results in the intracellular accumulation of heme-derived free ferrous iron and carbon monoxide. The latter are known mitochondrial toxins which may promote sequestration of redox-active iron within this subcellular compartment. Mitochondrial ferrous iron may promote non-enzymatic oxidation of dopamine or MPTP to neurotoxic semiquinones (Schipper *et al.* J Neurosci 11:2170, 1991) or MPP<sup>+</sup> (DiMonte *et al.* Glia 15:203, 1995), respectively, thereby establishing a vicious cycle of pathological glial-neuronal interactions in this disease.

CYTOSKELETAL CHANGES IN CULTURED EMBRYONIC MESENCEPHALIC NEURONS BEFORE CELL DEATH INDUCED BY QUISQUALIC ACID. D. Casper<sup>1</sup>, A. Pidel<sup>1</sup>, D.L. Gross<sup>2</sup>, S. Yung<sup>2</sup>, A. Prikhozhan<sup>2</sup>, B.M. Riederer<sup>3</sup>, I.M. Johnston<sup>1</sup>, and A.J. Berman<sup>1</sup>. <sup>1</sup>Department of Neurological Surgery, The Montefiore Medical Center, The Bronx, NY, 10467, <sup>2</sup>Fishberg Research Center for Neurobiology, The Mount Sinai School of Medicine, NY, 10028 and <sup>3</sup>Institut d'Anatomie, University of Lausanne, Switzerland.

We have previously demonstrated that dopaminergic neurons degenerate over several days in response to the non-NMDA glutamate agonist quisqualic acid (QA), and can serve as a model for slow neurotoxicity. In this report we have characterized this process at the cytoskeletal level. Cultures of dissociated embryonic rat mesencephalon were established in serum-containing or chemically defined medium. After several days in culture, the medium was replaced with defined medium  $\pm 5 \mu$ M QA and incubated for various times. Cultures were then fixed and double-label fluorescence immunocytochemistry was performed with antibodies to the neuronal cytoskeleton in conjunction with antibodies to tyrosine hydroxylase, which identified the dopaminergic neurons in these cultures. Results demonstrate that neurons in this culture system are heterogeneous with respect to the expression of various cytoskeletal epitopes, particularly in the neurofilament triplet. Treatment with QA produced morphological changes which at first resembled neuronal growth and differentiation, followed by degenerative changes. This was reflected in changes in the distribution of some of cytoskeletal epitopes, such as that defined by antibodies to the microtubule-associated protein tau. These observations lead to the suggestion that QA stimulation produces a trophic-like response which precedes cell death in culture.

## 90.3

SUBSTANTIA NIGRA DOPAMINE NEURONS FROM MICE HOMOZYGOUS FOR A TRANSGENIC KNOCKOUT OF THE P53 GENE RESIST MPTP NEUROTOXICITY. Patricia A. Trimmer\*, Trisha A. Smith, Anthony B. Jung, and James P. Bennett, Jr. Departments of Neurology, Psychiatry and Pharmacology, University of Virginia Health Sciences Center, Charlottesville, VA 22908.

The underlying mechanisms responsible for death of dopamine (DA) neurons in Parkinson's disease (PD) remain unclear. Systemic treatment with N-methyl, 4-phenyl, 1,2,3,6-tetrahydropyridine (MPTP) causes loss of DA neurons, and N-methylpyridinium (MPP+) induces programmed cell death (apoptosis) in DA neurons in culture. The p53 growth control gene is expressed in other systems during apoptosis, and may control the onset of cell death by decreasing the activity of the anti-apoptosis factors bcl-2 and bcl-x. In peripheral models p53 expression is necessary for apoptosis to occur. We tested the hypothesis that expression of the p53 gene is necessary for death of DA neurons in MPTP neurotoxicity.

Male black mice homozygous for a transgenic knockout of the p53 gene (p53<sup>-/-</sup>) and wild-type controls (wt) were obtained from Taconic Laboratories. Animals received MPTP at 24 mg/kg s.c. b.i.d. for 2 days (total MPTP dose=96 mg/kg). Animals were sacrificed at 2 or 3 weeks after starting MPTP or before receiving MPTP. Forebrains were frozen on dry ice and cut into 20 micron sections and incubated with <sup>3</sup>H-mazindol to measure dopamine transporter (DAT) density. Brainstems were fixed and stained for tyrosine hydroxylase (TH). Quantitative autoradiography and cell counting were used to measure total striatal DAT (<sup>3</sup>H-mazindol binding) and DA neuron number, respectively.

P53<sup>-/-</sup> and wt had similar baseline numbers of DA neurons and DAT density. MPTP treatment caused 30-35% loss of nigral DA neurons in wt but no loss in p53<sup>-/-</sup>. Striatal DAT density was reduced comparably in both groups. Expression of p53 appears to be necessary for subacute MPTP toxicity to nigral neurons. Since both MPTP and spontaneous PD are associated with loss of mitochondrial complex I activity, manipulation of growth control gene function may alter DA neuronal death in idiopathic PD.

## 90.5

LEVODOPA ACCUMULATION IN NONDOPAMINERGIC BRAIN REGIONS: POTENTIAL FOR OXIDATIVE STRESS DUE TO AUTOXIDATION? D.A. Loeffler\*, P.A. Lewitt, P.L. Juneau, D.M. Camp, and K. Hyland. Clin. Neurosci. Program, Sinai Hosp., Detroit, MI 48235 and Baylor Research Inst., Dallas, TX 75226.

Treatment of Parkinson's disease with levodopa (LD) may result in oxidant stress by deamination of dopamine (DA) or LD autoxidation. We studied LD distribution and DA metabolism in DAergic (striatum, ventral midbrain [VMB]) and non-DAergic (frontal cortex [FC], cerebellum) brain regions. Rats (n = 5/group) received i.p. carbidopa (2.5 mg/kg), 30 min later LD (100 mg/kg), then sacrifice 1 hr later. LD concentrations increased in all regions by > 60-fold vs. vehicle-treated controls. DA production (after subtraction of endogenous levels) was highest in striatum (DA/LD ratio = 1.51), moderate in VMB (0.88), and low in FC (0.10) and cerebellum (0.04). DA deamination increased > 10-fold vs. controls in all regions; DOPAC/DA ratios were: striatum 1.39, VMB 3.67, FC 3.46, and cerebellum 7.25. Conclusion: LD accumulation and DA deamination, potential sources of oxidative stress, increase in DAergic and non-DAergic brain regions after LD treatment. (Supported by National Parkinson Foundation)

## 90.7

NEUROPROTECTIVE EFFECTS OF THE NOVEL BRAIN-PENETRATING PYRROLOPYRIMIDINE ANTIOXIDANTS U-101033E AND U-104067F AGAINST POST-ISCHEMIC DEGENERATION OF NIGRO-STRIATAL NEURONS. P.K. Andrus\*, T.J. Fleck, J.A. Oostveen and E.D. Hall, Pharmacia & Upjohn, Inc., Kalamazoo, MI 49001

A 10-min period of bilateral carotid occlusion (BCO)-induced forebrain ischemia in gerbils triggers a delayed retrograde degeneration of 35-40% of dopaminergic nigrostriatal (NS) neurons. The mechanism involved in nigral cell death is as yet unknown, but evidence suggests that oxidative stress may play a key role. In the present study, we examined whether the novel brain-penetrating lipid antioxidant pyrrolopyrimidine U-101033E and its aromatized analog, U-104067F, could attenuate dopaminergic neurodegeneration in this model. Gerbils were dosed with U-101033E (1.5, 5 or 15 mg/kg p.o., b.i.d.) or U-104067F (5 or 15 mg/kg p.o. b.i.d.) for 27 days beginning on the day of the 10-min ischemic insult. Preservation of NS neurons was assessed by tyrosine hydroxylase immunohistochemistry at 28 days. In vehicle (40% hydroxypropyl-β-cyclodextrin)-treated animals, there was a 42% loss of NS neurons. In contrast, gerbils that received 5 or 15 mg/kg U-101033E had only a 23% or 28% loss of NS neurons, respectively (p<0.002 vs vehicle). U-104067F showed little effect at sparing neurons at the 10 mg/kg dose, but did significantly attenuate neuronal loss to only 20% at the 30 mg/kg dose level (p<0.01 vs vehicle). The results show that both pyrrolopyrimidines (U-101033E and U-104067F) significantly attenuate the post-ischemic loss of NS dopaminergic neurons, implicating a lipid peroxidative mechanism in this model.

## 90.4

EFFECT OF PROTEIN KINASE C (PKC) ACTIVATION ON MICROGLIA-MEDIATED CATECHOLAMINE NEUROTOXICITY. M.K. McMillan\*, P.J. Vainio, M. Tornwall and R.K. Tuominen. Department of Pharmacology and Toxicology, Inst. Biomedicine, University of Helsinki, Finland.

Microglia activation by lipopolysaccharide (LPS) in mixed neuronal/glia mesencephalic cultures selectively kills tyrosine hydroxylase-immunopositive (TH+) neurons and thus decreases [<sup>3</sup>H]dopamine (<sup>3</sup>H-DA) uptake. Oposonized zymosan A (OZ), a yeast protein which is phagocytosed by macrophages, reportedly activates microglia differently than LPS, and may produce a different type of neurotoxicity. In our studies, OZ always reduced <sup>3</sup>H-DA uptake more effectively than LPS. The OZ neurotoxicity requires microglial activation and persists for at least a week. OZ activates microglial and macrophage PKC and phospholipase D (PLD) while LPS does not. Treatment with the PKC activator phorbol myristate acetate (PMA, 10<sup>-6</sup>-10<sup>-4</sup>M) resulted in decreased TH+ neuron number and <sup>3</sup>H-DA uptake. PMA potentiated LPS-induced, but not OZ-induced neurotoxicity and production of the active toxin, nitric oxide. Massive PKC translocation and PLD activation responses to PMA were observed in enriched microglia. However, PMA was most effective at reducing <sup>3</sup>H-DA uptake early after plating neurons, and in enriched high-density neuronal cultures. PMA may stimulate differentiation and inhibit proliferation of the cultured TH+ neurons, in addition to activating microglia. OZ had no effect on <sup>3</sup>H-DA uptake in cortical neurons which become TH+ when co-cultured with blood vessels and membranes. Interestingly, bovine adrenal medullary (BAM) cells after PMA treatment became sensitive to the neurotoxic effect of OZ, presumably mediated via bovine macrophage activation. These PMA-treated BAM cells may provide a useful BIOCHEMICAL model for catecholamine neurotoxicity, since most BAM cells are catecholaminergic, in contrast to the small percent of mesencephalic neurons which are dopaminergic.

RAPID INDUCTION OF TRANSCRIPTION FACTORS NF-κB AND AP-1 IN BASAL GANGLIA FOLLOWING MPTP TREATMENT IN MICE. C. Fonck\*, Y. Rong and M. Baudry. Neurobiology Program, University of Southern California, Los Angeles, CA 90089-2520.

Damage to dopaminergic neurons in the nigrostriatal pathway caused by systemic injection of 1-methyl 1,4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) has been proposed as a model to study Parkinson's disease. It has been suggested that the deleterious effects of MPTP result from free radical formation within dopaminergic neurons of the substantia nigra. The present study examined changes in the activation of two transcription factors generally associated with oxidative stress, NF-κB and AP-1, in the substantia nigra and the striatum of adult male mice as a result of MPTP treatment. The levels of NF-κB and AP-1 were evaluated by means of a gel shift assay, at various time points after subcutaneous injection of MPTP (35 mg/kg). A significant induction of NF-κB was observed in the substantia nigra 6 hours after MPTP treatment. By 24 hours after MPTP injection, the level of NF-κB in substantia nigra was similar to that of the control group. AP-1 binding activity also doubled in the substantia nigra three hours after MPTP injection and returned to control levels 24 hours after drug treatment. Surprisingly, NF-κB and AP-1 activities showed a two and a four fold increase respectively in the striatum 3, 6 and 9 hours after MPTP treatment. Levels of NF-κB and AP-1 binding activity 24 hours after MPTP injection were still significantly higher than in the control group. Changes in the activation of NF-κB and AP-1 in the substantia nigra are consistent with the hypothesis that oxidative stress is involved in MPTP induced toxicity to dopaminergic neurons. The induction of AP-1 in the striatum also indicates that MPTP treatment might produce a significant activation of the nigro-striatal system. The activation of NF-κB in the striatum suggests that an oxidative stress response also takes place in this structure.

GLUTAMATE AND DOPAMINE TRANSPORT: SENSITIVITY TO REACTIVE OXYGEN SPECIES, DOPAMINE OXIDATION, AND SULFHYDRYL MODIFICATION. S.B. Berman\*, M.J. Zigmond, and T.G. Hastings. Departments of Neuroscience and Neurology, Pittsburgh, PA 15260

Dopamine (DA) oxidizes to form reactive oxygen species (ROS) and DA quinones. Both ROS and DA quinones can modify cysteinyl residues in proteins, and we have shown that DA oxidation products can affect the function of at least one cysteine-dependent protein, the DA transporter (Berman et al., 1996). We have now examined the effect of DA oxidation on glutamate transporters, which contain a conserved cysteinyl residue and demonstrate ROS-induced inhibition in astrocytes (Volterra et al., 1994). We compared the effects of ROS and DA oxidation on glutamate and DA transport in rat striatum by preincubating synaptosomes, washing, and then measuring uptake using <sup>3</sup>H-DA (250 nM) or <sup>3</sup>H-glutamate (10 μM). The SH-modifying reagent, N-ethylmaleimide (10-500 μM) inhibited the transport of DA (-55 to 100%) and glutamate (-20 to 70%), as did xanthine (500 μM) plus xanthine oxidase (25 mU/ml) (DA, -70%; glutamate, -86%). Preincubation with ascorbate (0.85 mM) under prooxidative conditions also inhibited both DA (-67%) and glutamate (-73%) uptake, whereas ascorbate plus the iron chelator DETAPAC (1 mM), which can prevent the prooxidant activity of ascorbate, had no effect. Preincubation with DA (100 μM) under conditions where 10% of the DA oxidized (as estimated by aminochrome formation) inhibited both DA uptake (-58%) and glutamate uptake (-24%). Finally, DA oxidation was enhanced by tyrosinase, which enzymatically forms DA quinone. Five min preincubation with DA (100 μM) plus increasing amounts of tyrosinase (to oxidize 0.2 to 90% of the DA) led to a concentration-dependent inhibition of both DA and glutamate uptake. We conclude that glutamate transport, like DA transport, can be modified by ROS and other DA oxidation products. This modification may play a role in several neurotoxic processes, including ischemia and methamphetamine exposure. (Supported in part by USPHS grants NS19608 and GM08208).

**EARLY INDICES OF OXIDATIVE STRESS: IMMEDIATE RESPONSE TO NEUROTOXIC LEVELS OF EXOGENOUS DOPAMINE.** A.D. Rabinovic, M.J. Zigmond, and T.G. Hastings\*. Departments of Neuroscience and Neurology, University of Pittsburgh, Pittsburgh, PA 15260.

Dopamine (DA) may contribute to the neurodegenerative process in Parkinson's disease, based upon the ability of DA to form reactive oxygen species and DA quinones. We have previously shown in rats that an intrastriatal injection of DA results in both biochemical evidence of DA oxidation at 24 h and selective damage to dopaminergic terminals at 7 d (Hastings et al., 1996). In this study, we examined early biochemical changes following intrastriatal DA (0.4  $\mu$ mol/2  $\mu$ l/20 min.). Using microdialysis, we observed that the peak DA concentration in the region of selective damage at 1-2 h following injection, was reduced  $10^2$ - $10^3$ -fold from the injected concentration to micromolar levels. DA levels returned to baseline levels within 6 h. Endogenous levels of GSH were decreased significantly in striatal tissue at 4 h (-24%) and 8 h (-11%) after injections, but had returned to control values by 24 h. Protein-bound cysteinyl-DA and cysteinyl-DOPAC levels were increased significantly above controls at 2 h (47-fold and 37-fold, respectively) and 24 h (21-fold and 16-fold, respectively). In an effort to measure DA-quinone formation in the extracellular fluid following intrastriatal DA, cysteine was utilized as a quinone trapping agent and perfused through a dialysis probe, a technique validated *in vitro* by incubation of DA with tyrosinase to form DA quinone and, subsequently, cysteinyl-DA. *In vivo* an intrastriatal injection of DA resulted in the formation of cysteinyl-DA which represent 0.2% of the peak DA level. These findings suggest that oxidative responses to exogenous DA occur immediately following DA administration. These studies may provide information as to the role of DA in the mechanism of neurodegeneration in Parkinson's disease. (Supported by USPHS grants NS 19608 and AG03705).

## 90.11

**PEROXYNITRITE-MEDIATED MODIFICATIONS OF TYROSINE HYDROXYLASE IN PC12 CELLS.** J. Ara, H. Ischiropoulos, J. Horvitz\*. Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129; Institute for Environmental Medicine, University of Pennsylvania, Philadelphia, PA 19104.

The pathology of neurodegenerative diseases is associated with excess production of reactive species. Nitric oxide and superoxide are free radicals that react at near-diffusion limited rate to form peroxynitrite, a relatively long-lived and highly reactive species. In previous studies, using PC12 cells, we showed that peroxynitrite decreased tyrosine hydroxylase (TH) activity. This suggested that the enzyme was a target for peroxynitrite-mediated modifications. Part of the toxic effect of peroxynitrite may be mediated by the nitration of tyrosine residues. In order to investigate this issue, homogenates of PC12 cells were treated with peroxynitrite. Nitrated proteins were precipitated with monoclonal antibodies to nitrotyrosine, separated by PAGE and blotted onto nitrocellulose. Western blots of these immunoprecipitates developed with polyclonal antibodies to nitrotyrosine revealed four prominent bands. These data indicate that peroxynitrite nitrates selected proteins. To learn if TH was nitrated, we immunoprecipitated with monoclonal antibodies specific for this enzyme, and analyzed the immunoprecipitate by western blotting. Development of the blot with polyclonal antibodies to nitrotyrosine revealed a band in peroxynitrite treated homogenates that was absent from controls. This band had an  $R_f$  corresponding to 60,000 kDa, the subunit molecular weight of TH. Parallel blots developed with polyclonal antibodies to TH revealed a prominent band in both control and peroxynitrite treated homogenates, indicating that TH had been precipitated. These data confirm that TH is nitrated by peroxynitrite. The precise role of nitration in determining the activity of the enzyme remains to be investigated (Supported by the Allegheny-Singer Health Education Foundation).

## 90.13

**ALTERED BCL-2 AND BAX EXPRESSION IN SUBSTANTIA NIGRA DOPAMINERGIC NEURONS FOLLOWING MPTP EXPOSURE.** D.W. Anderson<sup>1</sup>, J.C. Reed<sup>2</sup>, S. Krajewski<sup>2</sup>, and J.S. Schneider<sup>1</sup>. <sup>1</sup>MCP and Hahnemann Univ., Dept. Anatomy and Neurobiology, Philadelphia, PA 19102-1192, <sup>2</sup>La Jolla Cancer Res. Foundation, La Jolla, CA 92037.

Oxidative stress via inhibition of the mitochondrial complex I enzyme (NADH-dehydrogenase) by the dopamine neurotoxin MPP<sup>+</sup>, may initiate altered expression of oxidative response proteins associated with apoptosis. Apoptosis and decreased expression of the anti-apoptotic factor Bcl-2, a known anti-oxidant, has been shown to occur *in vitro* in several cell lines in the presence of MPP<sup>+</sup>. The present studies were conducted to elucidate any regulatory effects produced by MPP<sup>+</sup> with regard to apoptotic effector factors *in vivo*. The expression of Bcl-2 and its homologue the pro-apoptotic factor Bax, was assessed in the substantia nigra in young (7-8 weeks) and aged (12 months) C57Bl6 mice at both mRNA and protein levels using RT-PCR and immunohistochemical techniques, respectively. Some mice were administered MPTP at a dose that does not cause significant dopaminergic cell death (single injection at 30 mg/kg). In young MPTP-treated mice, there was a maximal up-regulation of both Bcl-2 and Bax at 12 hours post injection and a return to normal levels within 24 hours. A concomitant up-regulation of both Bcl-2 and Bax protein was detected immunohistochemically. The non-pathogenicity of the MPTP regime was identified via preservation of tyrosine hydroxylase immunohistochemical staining, which showed no identifiable loss of expression in nigral neurons. Comparable results have been obtained in the aged mice. Further characterization of the Bcl-2/Bax heterodimerization ratio, thought to be associated with control of apoptotic events, may indicate a potential pre-apoptotic regulatory event. These results are potentially indicative of an MPTP-induced oxidative stress response involving an apoptotic death mechanism which may also be involved in neuronal cell death associated with toxic concentrations of MPTP. The further characterization of MPTP-induced apoptotic cell death through end-labelling techniques and quantification of Bcl-2 and Bax regulation is presently being studied. Supported by NIH grant AG10280.

## 90.10

**METHAMPHETAMINE-INDUCED NEUROTOXICITY IS ASSOCIATED WITH THE FORMATION OF CYSTEINYL-DOPAMINE.** M.J. LaVoie\*, M.J. Zigmond, and T.G. Hastings. Depts. of Neuroscience and Neurology, Univ. of Pittsburgh, Pgh, PA, USA

Oxidative stress and free radical formation have been proposed to play a role in Parkinson's disease and the neurotoxicity associated with methamphetamine (METH) exposure. Under oxidative conditions, dopamine (DA) may contribute to these neurotoxic events by forming free radicals and reactive quinones. DA quinones bind covalently to cysteinyl residues in proteins, potentially inactivating critical protein functions. We have shown that exogenous DA injected into striatum causes a selective loss of DA terminals that is blocked by antioxidants and correlated with the level of cysteinyl-catechols (Hastings et al., 1996). In this study, we sought to determine whether neurotoxic doses of METH would result in oxidation of endogenous DA. METH (15 mg/kg, s.c.) or saline was administered to male Sprague-Dawley rats (325-375g) every 2 hours, for a total of 4 injections. Protein-bound cysteinyl-DA was increased by METH at 2 hr (+350%;  $0.7 \pm 0.19$  nmol/g tissue; n=9), and remained increased at 4 hr (+260%; n=6) and 8 hr (+260%; n=2). No increase in protein-bound cysteinyl-DOPAC was observed, possibly due to the large decrease in tissue DOPAC (-80%; n=11). In the acid-soluble tissue fraction, the glutathione-DA conjugate was present at 2, 4, and 8 hr ( $0.06 \pm 0.016$  nmol/g tissue, n=11) after METH, while absent in control tissue. At 7 days, identically-treated animals showed a 55% loss of DA and a 60% loss of serotonin (n=4). Animals exposed to the same dose of METH at 5°C did not exhibit either long-term monoamine depletion or increased levels of DA oxidation. These results suggest a role for DA oxidation in the process of METH-induced toxicity (Supported in part by USPHS grant NH19608).

## 90.12

**GM1 GANGLIOSIDE INFLUENCES THE REGULATION OF TROPHIC FACTOR TRANSCRIPTS IN THE DOPAMINE DENERVATED MOUSE STRIATUM.** J.L. Seeburger<sup>1</sup>, J.E. Springer<sup>2</sup> and J.S. Schneider<sup>1</sup>. <sup>1</sup>Dept. of Neurobiol. and Anat., MCP and Hahnemann Univ., Phila., PA 19102, <sup>2</sup>Dept. of Anat. and Neurobiol., Univ. of Kentucky, Lexington, KY, 40536.

MPTP administration to mice results in loss of dopaminergic (DAergic) neurons of the substantia nigra pars compacta and denervation of their striatal targets. Little is known, however, about the regulation of putative DAergic neurotrophic factors in the lesioned nigrostriatal system. We have previously demonstrated that DA cell loss associated with MPTP toxicity can be partially reversed by ganglioside GM1 administration. Although GM1 appears to be trophic for DAergic neurons, little is known about its mechanism of action or its interaction with other putative DAergic trophic factors. Therefore, we have examined the expression of GDNF, BDNF, NT-3 and basic FGF mRNA in the mouse striatum following MPTP and subsequent GM1 administration. Animals were injected with MPTP (4 injections at 3 hr intervals, 20mg/kg, s.c.) and allowed to survive for 2, 5 or 14 days. Half of these animals were also administered GM1 (30 mg/kg, i.p.) daily beginning 24 hrs. following the last MPTP injection. Trophic factor transcripts were amplified from control (untreated) and lesioned striatal specimens using RT-PCR. Following denervation, GM1 administration increased the striatal expression of both GDNF and bFGF mRNAs, but decreased BDNF mRNA expression throughout the time course. The expression of NT-3 mRNA was not affected. These results suggest that some of the ameliorative properties of GM1 may be associated with a specific pattern of regulation of various DAergic target-derived trophic factors. Supported by NIH grant AG-10280.

## 90.14

**NEUROPROTECTIVE PROPERTIES OF NITRIC OXIDE (NO) AND S-NITROSOTHIOLS IN THE BRAIN *IN VIVO*.** P. Rauhala, A. M.-Y. Lin, A. Khaldi, J. Sziraki & C.C. Chiu\*. Unit on Neurotoxicology & Neuroprotection, Laboratory of Clinical Science, NIMH, NIH, 10/3D-41, Bethesda, MD 20892-1264

Hydroxyl (OH) and nitric oxide (NO) free radicals have been proposed to be involved in neurodegeneration. However, the pathophysiological role of NO has been controversial; it is not clear whether NO is foe or friend to brain neurons. Our *in vivo* data indicates that in contrast to OH generators (ferrous citrate and SNP), NO and NO donors (S-nitrosothiols) do not cause injury in the rat nigrostriatal system (*Synapse*, 23:58-60, 1996).

NO and S-nitrosothiols, in fact, protected nigrostriatal dopamine neurons against iron-induced oxidative stress/injury, evidently by their suppression of acute lipid peroxidation in the substantia nigra and prevention of chronic dopamine depletion in the striatum. Such *in vivo* neuroprotective properties of S-nitrosothiols were absent in experiments using light-exposed, NO-exhausted agent. Furthermore, the present *in vitro* studies demonstrated that NO and S-nitrosothiols inhibited iron-induced OH generation and lipid peroxidation, suggesting that these unique antioxidant properties of NO may mediate its neuroprotective effects against OH-induced brain injury.

It is concluded that exogenous NO is not toxic to brain neurons *in vivo*. NO may protect brain neurons against iron-catalyzed oxidative injury through annihilation of OH and/or lipid radicals. (supported by NIMH IRP: Z01-MH-02648-04 LCS)

## 90.15

DIFFERENTIAL EFFECTS OF NITRIC OXIDE DONORS ON APOPTOSIS IN CHP212 CELLS AS DETERMINED BY ANNEXIN V BINDING D. Terwel (1), L.J.M. Nieland (2), B. Schutte (2), C.P.M. Reutelingsperger (3), F.C.S. Ramaekers (2), H.W.M. Steinbusch (1) European Graduate School for Neuroscience, (1)Dept. of Psychiatry and Neuropsychology, (2)Dept. of Molecular Cell Biology, (3)Dept. of Biochemistry, University of Maastricht, The Netherlands. (Spon: ENA)

Cell death by exposure to NO has been implicated in neurodegenerative diseases, such as Parkinson's and Alzheimer's diseases. In the present study it was investigated whether NO causes either apoptosis or necrosis using a neuronal cell line (CHP212) as a model. Apoptosis and necrosis were assessed by the simultaneous determination of annexin V binding and propidium iodide (PI) uptake using flow cytometric analysis. Annexin V binds to phosphatidylserine residues exposed at the surface of apoptotic cells. The effects of two NO donors (SNAP and SNP) were compared to those of olomoucine, a general inducer of apoptosis. Early apoptosis, as evidenced by the binding of annexin V and the exclusion of PI by the cells, was maximal after 4, 8 and 16 h for cells exposed to olomoucine, SNAP and SNP, respectively. Cells that had taken up PI were of the late apoptotic or secondary necrotic type based on the fragmented and condensed appearance of their chromatin. The morphology of the cells during apoptosis induced by SNAP and SNP was indistinguishable from that induced by olomoucine. SNAP caused a maximum of approximately 20% apoptosis at a dose of 0.25 mM; SNP caused approximately 40% apoptosis at a dose of 2 mM. The difference between the potencies of SNAP and SNP could be related to the fact that SNAP generates NO<sup>•</sup>, whereas SNP generates NO<sup>+</sup>. However, the presence in the incubation medium of ascorbate, which converts NO<sup>+</sup> into NO<sup>•</sup>, did not decrease the apoptotic fraction, but rather increased it. In conclusion, SNAP and SNP appear to be able to induce apoptosis in CHP212 cells with a different time dependency and potency, probably related to their different half-lives. Further studies into the role of NO in neuronal apoptosis will be carried out using primary dopaminergic cells and animal models of Parkinson's disease. (This work was supported by the Prinses Beatrix Fund)

## 90.17

COPPER SUPPLEMENTATION BLOCKS 1-METHYL-4-PHENYLPYRIDINIUM NEUROTOXICITY IN MICE. P. Rojas\*, R. Alvarez and C. Rios, Dept. of Neurochemistry, National Institute of Neurology and Neurosurgery, Insurgentes Sur 3877, México city 14269.

1-methyl-4-phenylpyridinium (MPP<sup>+</sup>) is the major metabolite of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) a drug which induces a parkinson-like damage in several animal species. It is now accepted that MPP<sup>+</sup> is responsible of the neurotoxic effects of MPTP in dopaminergic nigrostriatal pathway. On the other hand, it has been reported that diethyldithiocarbamate (DDC) is a metal chelating agent with high affinity by copper that increases MPTP neurotoxicity. Copper deficiency produces impairment of the many processes dependent of the metal. We reported that MPTP decreases copper content (50%) in corpus striatum, suggesting an important role of copper in dopaminergic neurotoxicity of MPTP. In this study we evaluated the possible role of copper in MPP<sup>+</sup> toxicity. Adult male NIH mice (25-30 g) were injected with copper sulphate (2.5 mg/Kg). Later, mice were injected into the right lateral ventricle with MPP<sup>+</sup> and 24h after they were killed by decapitation. Striata were dissected out and dopamine concentration was analyzed by HPLC. MPP<sup>+</sup> reduced dopamine concentration (40%) and copper pretreatment blocked its toxicity. An additional group was treated with MPP<sup>+</sup> and cytochrome C oxidase activity was assayed 24 later. Activity of this copper dependent enzyme decreased (27.5%) in striatum. These results suggest that copper may be important in MPP<sup>+</sup> neurotoxicity. This work was supported in part by CONACyT grant 0044P-M9506.

## 90.19

N-METHYL-(R)SALSOLINOL AS A CANDIDATE NEUROTOXIN TO INDUCE PARKINSON'S DISEASE M. Naoi<sup>1\*</sup> and W. Maruyama<sup>2</sup> <sup>1</sup>Dept. Biosciences, Nagoya Inst. Technol., Nagoya, Japan and <sup>2</sup>National Inst., Longevity Sci., Obu, Japan,

A series of naturally-occurring dopamine-derived catechol isoquinolines have been examined for neurotoxicity to dopamine neurons. *In vivo* experiments proved that only 1-(R),2-(N)-dimethyl-6,7-dihydroxy-1,2,3,4-tetrahydroisoquinoline [(R)N-methyl-salsolinol, (R)NMSal] could induce parkinsonism to rats with reduction in dopamine and tyrosine hydroxylase activity after injection in the striatum. By histochemical observation dopamine neurons in the substantia nigra were selectively depleted. The mechanism of the selective cell death was clarified as follows. Only (R)NMSal was found to be taken up to dopaminergic neuroblastoma SH-SY5Y cells by dopamine transport system. Oxidation of (R)NMSal generates hydroxyl radical and cytotoxic 1,2-dimethyl-6,7-dihydroxyisoquinolinium ion (1,2-DMDHIQ<sup>+</sup>), which inhibited oxidative phosphorylation in cells more markedly than NMSal and 1-methyl-6,7-dihydroxy-1,2,3,4-tetrahydroisoquinoline [salsolinol, Sal]. On the other hand, (R)NMSal induced DNA fragmentation in SH-SY5Y cells through its oxidation. The dopaminergic neurotoxicity was further suggested by the increase in (R)NMSal level in CSF from parkinsonian patients.

The enantio-selective occurrence of (R)Sal and (R)NMSal was confirmed in the human brain, suggesting its enzymatic synthesis *in situ*. A salsolinol synthase was purified from human brain, which catalyzes the synthesis from dopamine and acetaldehyde. An N-methyltransferase was detected in human brain and the activity was the highest in the striatum. These results suggest that these enzymes may be endogenous factors involving in the pathogenesis of Parkinson's disease.

## 90.16

DNA FRAGMENTATION IN DOPAMINE CELLS INDUCED BY N-METHYL-(R)SALSOLINOL, AN ENDOGENOUS NEUROTOXIN W. Maruyama<sup>1,2</sup>, Gen Sobue<sup>1</sup> and M. Naoi<sup>3</sup> <sup>1</sup>Dept. Neurol., Nagoya Univ. Sch. Med., Nagoya and <sup>2</sup>National Inst. Longevity Sci., Obu, <sup>3</sup>Dept. Biosci., Nagoya Inst. Technol., Nagoya, Japan.

There are increasing results suggesting that endogenous neurotoxins may induce Parkinson's disease (PD) after a long term of accumulation. N-Methyl-(R)salsolinol [NM(R)Sal], a neurotoxin candidate, was found to increase in CSF from untreated patients with PD. Recently, apoptosis has been proposed to be a mechanism of the neuronal death in the neurodegenerative diseases. An animal model of PD was prepared by the administration of NM(R)Sal in the rat striatum. The histochemical analysis showed dopamine neuronal loss without tissue reaction in the substantia nigra, indicating apoptotic cell death. The effect of NM(R)Sal and related compounds on DNA was systematically examined using single cell electrophoresis (the comet assay). Among the dopamine-derived isoquinolines, NM(R)Sal was found to be the most potent to induce DNA fragmentation followed by NM(S)Sal. Both the metabolic precursor and the oxidized product of NM(R)Sal, (R)salsolinol and 1,2-dimethyl-6,7-dihydroxyisoquinolinium ion did not damage DNA significantly. Protein synthesis was required for DNA fragmentation by NM(R)Sal, since cyclohexamide reduced the damage. NM(R)Sal is oxidized and produces hydroxyl radical simultaneously. Radical scavengers and catalase reduced DNA damage indicating that radical production by NM(R)Sal is essential for the damage. Sustained high levels of NM(R)Sal in the brain might account for apoptotic cell death of dopamine neurons in PD.

## 90.18

DOWNREGULATION OF GLUTATHIONE PEROXIDASE LEADS TO INCREASED OXIDATIVE DAMAGE IN MOUSE BRAIN

D. Jiang, D.G. Hom, Q. Wei, J.K. Andersen\*, Division of Neurogerontology, Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089

Glutathione peroxidase (GSHPx) is a free-radical scavenging enzyme which can limit the production of free radicals in the brain. Animal models in which the levels of the GSHPx have been altered by either genetic over- or under-expression were used to explore whether variations in levels of this enzyme offered different levels of protection against neuronal damage. A transgenic mouse line in which GSHPx was over-expressed at levels 2.7 fold higher than normal was created in our lab. A knock-out mouse line with reduced levels of GSHPx was acquired from Dr. Ye-Shih Ho (Wayne State, Detroit). Hydroperoxide levels were tested by analyzing levels of DCF fluorescence and free-radical damage was assessed by examine the levels of protein and lipid oxidation as measured by carbonyl content and MDA levels in the brains of transgenics, heterozygous & homozygous knock-out mice, and normal controls. We found a significant increasing levels of free radicals in both heterozygous and homozygous knock-outs, and decreased levels in the transgenics compared to normal controls. In addition, the hetero- and homozygous knock-outs showed an increased level of both carbonyl content and MDA compared to wild type, while there was no significant difference between the transgenics and normal controls. These results suggest that reduced levels of GSHPx result in more susceptibility to free-radical damage. Elevation of GSHPx appears to have no effect on the level of free-radical damage even though hydroperoxide levels were lowered in the brain. We plan to examine the susceptibility of these mice to MPTP as well as to other neurotoxins which are postulated to elicit their effects through generation of free radicals.

## 91.1

**DIFFERENTIAL EXPRESSION OF GLUTAMATE RECEPTOR SUBUNIT mRNA IN DOPAMINE NEURONS OF HUMAN SUBSTANTIA NIGRA.**

T.J. Counihan, G.B. Landwehrmeyer, A.B. Young, and J.B. Penney, Jr.  
Dept. of Neurology, Mass. Gen. Hosp., Boston, MA 02114.

Not all dopaminergic neurons are equally vulnerable to the neurodegenerative process in Parkinson's disease (PD), and the mechanism for this selective vulnerability remains unknown. Evidence is accumulating that glutamate-mediated excitotoxicity plays a significant role in the degeneration of neurons in PD. We compared the levels of messenger RNA expression for N-Methyl-D-Aspartate (NMDA) and metabotropic (mGluR) glutamate receptor subtypes in both vulnerable and non-vulnerable dopamine neurons in human midbrain using *in situ* hybridization histochemistry. We found that NMDAR1 ( $76 \pm 7$  grains/1000sq  $\mu$ ), NMDAR2A ( $20 \pm 12$  grains/1000sq  $\mu$ ), NMDAR2B ( $79 \pm 9$  grains/1000sq  $\mu$ ), NMDAR2C ( $71 \pm 8$  grains/1000sq  $\mu$ ), NMDAR2D ( $73 \pm 8$  grains/1000sq  $\mu$ ), mGluR1 ( $41 \pm 5$  grains/1000sq  $\mu$ ) and mGluR5 ( $112 \pm 11$  grains/1000sq  $\mu$ ) are all significantly expressed by pars compacta neurons. We also found mGluR1 labeling of dopamine neurons in the ventral tegmental area to be more intense ( $115 \pm 7$  grains/1000sq  $\mu$ ) than in other nigral subregions, using double label *in situ* hybridization.

Activation of NMDA receptors is known to be toxic to dopamine neurons in culture, and there is evidence that co-activation of NMDA and mGluR 1 is necessary for "NMDA" toxicity. Differential expression of NMDA and metabotropic receptor genes in nigral dopamine neurons may help explain the selective vulnerability of some of these neurons in PD.

## 91.3

**ISOLATION OF CORTICAL LEWY BODIES FROM DIFFUSE LEWY BODY DISEASE BRAINS.** W.D. Hill\*, R. Pelouquin, M.M. Tompkins, and B.J. Balin\*  
Dept. of Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA 30912. Dept. of Pathology, Hahnemann Univ. Philadelphia, PA 19102\*

Lewy bodies are the pathological hallmarks of Lewy body associated disorders including Parkinson's disease and diffuse Lewy body disease. These filamentous neuronal inclusions characteristically label with antibodies to ubiquitin and with antibodies to neurofilament (NF) triplet proteins but not with antibodies to tau or A $\beta$  epitopes. Taking advantage of these immunohistochemical staining properties we have utilized Fluorescent Activated Cell Sorting to isolated highly purified populations of cortical Lewy bodies.

Homogenates of cingulate cortex from Diffuse Lewy body disease cases were centrifuged over sucrose gradients. Material pelleting below a 1.5 M sucrose pad was enriched for lewy bodies, but also contained some neurofibrillary tangles, and neuronal processes. This pellet was resuspended and labeled with a rabbit polyclonal antibody to ubiquitin and the mouse IgM Alz50. The pellets were washed and secondary antibodies conjugated with phycoerythrin (anti-rabbit) or FITC (anti-mouse) were used to localize the primary antibodies. An Epics Elite/500 flow cytometer was used to sort the material by size and by single or dual label. The Lewy body fraction contained particles that were single labeled (by anti-ubiquitin/anti-rabbit-PE) and were approximately 5-15  $\mu$ m in diameter. Neurofibrillary tangles were dual labeled and dystrophic neurites were larger than Lewy bodies and outside the size window.

Ultrastructural analysis, both negative staining and resin embedded thin section, showed spherical objects with morphology corresponding to cortical Lewy bodies.

## 91.5

**CALCIUM REGULATORY DIFFERENCES IN MITOCHONDRIALLY TRANSFORMED CELLS FROM PARKINSON'S PATIENTS.** J.P. Sheehan, J.B. Tuttle, and J.A. Jane\*  
Departments of Neurological Surgery, Urology, and Neuroscience, University of Virginia, Charlottesville, VA 22908.

Decreased biochemical activity of the electron transport chain complex I and selective neurotoxin induced neuronal cell death have linked Parkinson's disease (PD) to defects in mitochondrial DNA (mtDNA). The potential functional consequences of mtDNA defects and role in the pathogenesis of PD are not defined. Mitochondrially transformed cells (i.e. cybrids) were created by fusing platelets from either PD patients or disease-free, age-matched controls (C) to a cell line devoid of mtDNA.

Fura-2 based fluorescence image cytometry was performed with PD and C cybrids. Basal cytosolic calcium concentrations for the PD and C cybrids were similar at  $124 \pm 8$  and  $124 \pm 4$  nM, respectively. Also, basal ATP levels as determined by weak anion-exchange HPLC were similar. However, following equivalent cytosolic calcium peaks induced by carbachol, a cholinergic agonist known to increase intracellular calcium and stimulate mitochondrial calcium uptake, the rate of calcium recovery was reduced in the PD cybrids by 49% relative to controls ( $P < 0.015$ ). In the presence of MPP+, calcium recovery rates for both PD and C cybrids were reduced, but the statistically significant difference in recovery rates between MPP+ exposed PD and C cybrids persisted ( $P < 0.016$ ). Finally, when CCCP released mitochondrial calcium stores, PD cybrids had less calcium sequestered in their mitochondria than controls ( $P < 0.0001$ ).

These results suggest that mtDNA from Parkinson's disease patients has a subtle impact upon cellular metabolism. Basal energetics and cytosolic calcium values are normal, but PD mtDNA results in a diminished capacity to buffer calcium transients. This effect may hinder nigral neurons' ability to resist neurotoxic phenomena.

## 91.2

**ULTRASTRUCTURE OF LEWY NEURITES IN PARKINSON'S DISEASE AND LEWY BODY DEMENTIA** WP Gai\*, WW Blessing, PC Blumbers.  
Departments of Physiology and Medicine, Centre for Neuroscience, Flinders University, SA 5042, Australia.

Lewy bodies are found in multiple brain regions affected in Parkinson's disease (PD) and Lewy body dementia (LBD). Lewy neurites are ubiquitin-positive degenerating neural processes also found in multiple brain regions affected in PD and LBD, yet the relationship between Lewy bodies and Lewy neurites is not known (Gai et al, Brain 118: 1447, 1995).

The present study examines on the ultrastructure of Lewy neurites in perfusion fixed brains from one LBD and two PD cases with postmortem delay less than 10 hours. The brainstem, hippocampus, hypothalamus, amygdala, cingulate and insular cortices were serially sectioned (50  $\mu$ m) and immunostained with an antibody to ubiquitin (Dako). Reaction products were visualized with DAB or a silver enhancement kit (Amersham). Portions of sections rich in Lewy neurites were dissected out, fixed with glutaraldehyde, and processed for electron microscopic observation.

Lewy neurites (2 to 30  $\mu$ m) consisted of amorphous material, granular or vesicular profile and filaments (10-30 nm). The filaments were loosely and randomly arranged, thus distinct from the paired helical filaments found in the Alzheimer's dystrophic neurites. In most Lewy neurites, the amorphous material and granular profiles were intermingled with filaments, whereas in some neurites the amorphous material formed a condensed central core surrounded with radiating filaments (10 nm), resembling classical Lewy bodies. Lewy neurites wrapped in myelin sheaths were not found in the brain regions examined, and in optimal sections some Lewy neurites appeared to form postsynaptic density with axonal terminals. Our results indicate Lewy neurites share morphological similarity with Lewy bodies, and most Lewy neurites are derived from dendrites.

## 91.4

**DENSITY OF [<sup>125</sup>I]-TRANSFERRIN BINDING SITES ON MELANIZED NEURONS OF THE SUBSTANTIA NIGRA AND THE VENTRAL TEGMENTAL AREA IN CONTROL SUBJECTS AND PATIENTS WITH PARKINSON'S DISEASE.** B.A. Faucheux\*, J.-J. Hauw\*, Y. Agid\* and E.C. Hirsch\*  
INSERM U289 and INSERM U360, Hôpital de la Salpêtrière, Paris, F-75013, France.

The neurodegenerative process leading to the massive loss of melanized dopaminergic neurons that occurs in the substantia nigra, pars compacta, of patients with Parkinson's disease may be linked to oxidative stress. Increased iron levels measured in the surviving neurons of the substantia nigra, pars compacta, indicate a mechanism by which highly reactive hydroxyl radicals may be generated, as iron is a transition metal that catalyzes the formation of hydroxyl radicals from hydrogen peroxide. Since iron may augment hyperoxidation phenomena and thus participate in the neuronal death process, we studied pathways for iron to gain access to neurons. By quantitative autoradiography, using an image analysis system, we analyzed the specific binding of [<sup>125</sup>I]-transferrin at the cellular level, on surviving melanized neurons located in the substantia nigra pars compacta and in the ventro-ventral area of sections from twelve control and four parkinsonian midbrains. Mean densities of specific [<sup>125</sup>I]-transferrin binding sites on melanized neurons were reduced in parkinsonian patients compared to control subjects, the difference being statistically significant for the ventral tier of the substantia nigra, pars compacta, and ventral tegmental area. These data obtained at the cellular level provide an explanation for some of the changes in radiolabeled transferrin binding previously reported for measurements performed at the regional level. The absence of increase in a population of neurons accumulating iron probably reflects the post-transcriptional gene regulation of the number of transferrin receptors that depends upon iron content in eukaryote cells. These findings suggest that alternative pathways may be involved in the accumulation of iron within melanized midbrain neurons in Parkinson's disease.

**MITOCHONDRIAL DNA SCREENING IN PARKINSONIAN PATIENTS.**

R.H. Haas\*, X. Hua\*, R.K. Naviaux\*, C.W. Shults\*\*  
Univ. Cal., San Diego, \*VAMC, San Diego CA 92161

Our group recently reported that patients with early, untreated Parkinson's disease (PD) have reduced activity of complex I of the mitochondrial electron transport chain in platelets when compared to spouses and age/sex matched controls (Ann Neurol 1995;37:714-722). One possible explanation for this reduction in the activity of complex I could be mutation(s) in one of the seven mitochondrial genes that encode for components of complex I. Using denaturing gradient gel electrophoresis (DGGE), we have identified migrational variants in the ND6 gene in four young patients with extrapyramidal features. We have used DGGE to screen two overlapping fragments of the ND6 gene (14,128 - 14,542; 14,439 - 14,884) for migrational variants in the platelet mitochondrial DNA from the 18 PD subjects, 18 age/sex matched controls and 13 spouses who participated in our original study. We found migrational variants in 1 of our spouses and 2 of age/sex matched control subjects but in none of our PD subjects. Mutations in the segments of ND6 studied do not appear to explain the reduction in complex I activity found in these patients. Studies of the ND1 gene are in progress. This work was supported by a grant from the Blowitz-Ridgeway Fndn. and a Center of Excellence Award from the National Parkinson Fndn. to UCSD.

## 91.7

**<sup>3</sup>H]DIHYDROROTENONE BINDING TO PLATELET COMPLEX I IN PATIENTS WITH PARKINSON'S DISEASE**F. Blandini<sup>1</sup>, G. Nappi<sup>2</sup>, J.T. Greenamyre<sup>2</sup><sup>1</sup>Neurological Institute "C. Mondino", University of Pavia, Italy; <sup>2</sup>Department of Neurology, Emory University, Atlanta, GA 30322, USA

Reduced activity of complex I (NADH:ubiquinone oxidoreductase), the proximal component of mitochondrial electron transport chain (ETC), has been consistently reported in the substantia nigra of patients with Parkinson's disease (PD). A "peripheral" deficit of complex I has also been described in platelets of PD patients. However, the issue is controversial since unchanged activity of platelet complex I has been reported in these patients, as well. [<sup>3</sup>H]dihydrorotenone ([<sup>3</sup>H]DHR), an analogue of the pesticide rotenone, binds with high affinity to the "rotenone site" (putatively the ND-1 gene product) of complex I. An autoradiographic method previously developed showed that, in the brain, [<sup>3</sup>H]DHR binding to complex I can provide important information, since it is influenced by the same functional modifications which affect the activity of other two components of the ETC, complexes II and IV. We modified this method to study [<sup>3</sup>H]DHR binding to complex I in intact human platelets. [<sup>3</sup>H]DHR binding was saturable, specific and highly reproducible; also, it was inhibited by MPP<sup>+</sup> (1-methyl-4-phenylpyridine) in a concentration-dependent manner. Subsequently, we studied [<sup>3</sup>H]DHR binding to platelet complex I in 16 PD patients and 16 age-matched controls. We also compared the inhibitory effect of MPP<sup>+</sup> on [<sup>3</sup>H]DHR specific binding in isolated platelets from both populations. PD patients and controls showed similar levels of [<sup>3</sup>H]DHR specific binding as well as of MPP<sup>+</sup>-induced inhibition. A direct correlation between MPP<sup>+</sup>-induced inhibition of [<sup>3</sup>H]DHR specific binding and daily intake of carbidopa/levodopa was found, which may be related to drug-related changes in the transport of MPP<sup>+</sup> into platelets. Although the existence of qualitative alterations cannot be ruled out, our findings show that, outside the central nervous system, no quantitative alterations of complex I or increased susceptibility to MPP<sup>+</sup> are present in PD patients.

## 91.9

**PET MEASUREMENTS OF L-DOPA ACTIVATION OF HUMAN MIDBRAIN.**M. Stambuk<sup>\*</sup>, J.S. Perlmutter, K.J. Black, L. McGee-Minnich, Departments of Radiology, Neurology & Psychiatry, Washington University School of Medicine, St. Louis, MO 63110

Parkinson's disease develops after degeneration of nigrostriatal neurons and subsequent striatal depletion of dopamine. L-dopa initially ameliorates symptoms but the benefit may diminish with decreasing duration of action from each dose and the advent of dopa-induced dyskinesias. To further elucidate the mechanism of action of l-dopa, we used the Siemens 953b PET scanner and bolus injection of [15O]-water to measure dopa-induced rCBF changes in 26 patients with PD (17 men; mean age=62 yrs) and no other neuropsychiatric disease. All patients had normal brain MRIs. Nineteen had not taken dopaminergic meds; the remaining 7 did not take meds for at least 24 hrs prior to the PETs. UPDRS ratings were done prior to each PET study. Once in the scanner, part of the UPDRS motor subscale and plasma l-dopa levels were measured repeatedly. Blood flow was measured twice; oral l-dopa 150mg/carbidopa 37.5 mg given (2 hrs after carbidopa 200 mg p.o.); and 75 mins later, blood flow measurements were repeated twice. L-dopa plasma levels were measured at least 4 times after oral administration. Ratings revealed benefit in each subject and plasma l-dopa increased without change in dopamine. Images were placed in stereotactic space and half of the scans before and half after l-dopa were used to make a composite image of all the paired (before and after l-dopa) subtraction images. Candidate responses were found by searching this image with an automatic peak identification routine. Responses were tested for significance by comparison of the regional flows before and after l-dopa with the remaining data. L-dopa produced an 11.7% increase in posterior midbrain ( $p < .00005$ ), a 6.3% increase in right amygdala ( $p = .0020$ ) and a 5.7% increase in left putamen ( $p = .0034$ ). The midbrain response probably reflects a change in striatonigral neuronal activity and we now demonstrate marked asymmetries in dopaminergic pathways to putamen and amygdala. ## 91.11

**LOCALIZATION OF MOTOR THALAMUS: ARE STEREOTACTIC COORDINATES GOOD ENOUGH?**H. Richard<sup>\*</sup>, L. B. Tamas, K. A. Sigvardt, C. M. Gray, E. A. Franz, Pacific Neurosciences Institute, 637 Glorietta Blvd., Lafayette CA 94549 and Center for Neurosciences, UC-Davis, Davis CA 95616.

Electrophysiological studies mapping the nucleus ventralis intermedius (Vim) in primates, including humans, have relied on stereotactic coordinates as the frame of reference. We have studied the Vim of 25 patients undergoing stereotactic thalamotomy by recording neuronal responses related to limb movement and to tactile stimulation. In every case, a clear border between motor and sensory regions was found. This border was, in most cases, different from that predicted from standard atlases. We conclude that this "physiological" border may be a better reference point from which to map "physiological" responses in the motor thalamus.

## 91.8

**FINGER TAPPING PERFORMANCE IN YOUNG, AGED AND PARKINSONIAN SUBJECTS: TEMPORAL ANALYSIS OF RESPONSE PATTERNS.**L.D. McCullough<sup>\*</sup>, M.S. Cousins, M. Barwick, A. Nawab, C. Corrow, J.D. Salamone, U. of Connecticut Medical Center, Farmington, CT, and Dept. of Psychology, U. of Connecticut, Storrs, CT 06269-1020.

Finger tapping has been used as a test for the assessment of age-related and pathological deficits in motor control. Typically, the clinical assessment is performed with mechanical counters and the only data recorded are total number of responses. In the present study, a computerized analysis of finger tapping was performed so that measurements of response initiation time (time from offset of one response to onset of the next) and duration were obtained for each key press. Each subject was tested on both hands (five 10-sec trials each), and they all were assessed for performance of both a single telegraph key press and a two-finger alternation test. The most robust age-related effects were obtained on the two finger alternation test. Young subjects generally press at much higher rates with two fingers as compared to one finger, but older control subjects showed significant reductions compared to younger subjects in the rate of pressing on the two-finger test. Compared to age-matched controls, Parkinson's disease patients showed significant impairments in finger tapping on both the one- and two-finger tests. Analyses of the temporal patterns of responding showed that parkinsonian patients had significant increases in both response initiation times and response durations. In addition, parkinsonian patients made significantly more perseverative errors on the alternation task. Computer-controlled finger tapping tests could be useful for the assessment and early detection of parkinsonian symptoms as well as the evaluation of therapeutic drugs or transplants.

## 91.10

**Tryptophan Metabolites and Serotonin Synthesis in Akinetic Type of Parkinson's Disease**R. P. Iacono, S. M. Kuniyoshi, J.R. Ahlman, Y.J. Li<sup>\*</sup>, G. Maeda

Defective serotonin release has been implicated in Parkinson's disease (PD) concurrent with the discovery of dopamine deficiency. A significant correlation of serotonin (5HT) metabolites with akinetic, but not hyperkinetic, symptoms of PD have been found. We have analyzed the ventricular cerebrospinal fluid (vCSF) for serotonin precursors and metabolites in PD patients undergoing pallidotomy. Twenty patients were categorized into two groups based on predominance of symptoms, hyperkinetic (type A) vs. hypokinetic (type B) and response to L-dopa therapy. Their vCSF concentration of tryptophan metabolites was analyzed with an isocratic HPLC technique. The akinetic subtype manifest a significantly increased ( $P < .05$ ) level of 5hydroxytryptophan (5HTP) ( $683.7 \pm 333.31$  ng/ml) and an associated significantly decreased ( $P < .05$ ) vCSF concentration of 5HT ( $.53 \pm 0.23$  ng/ml) when compared to that of type A (5HTP  $7.52 \pm 1.35$  ng/ml; 5HT  $1.62 \pm .39$  ng/ml). The type A patients concentration of 5HTP remained in the upper level of non PD controls reported in other series. The relative decrease in 5HT combined with the significantly elevated level of 5HTP implicates an aromatic amino acid decarboxylase (AADC) inefficiency present in the B type of PD. The putative blockade of 5HT synthesis at the 5HTP/AADC level in a specific well defined subgroup of PD patients is a new finding. The biochemical basis of the clinically distinct akinetic form of PD, is contrasted with the classic tremor dominant type of PD. The pathophysiologic relevance of the 5HT deficiency likely involves the compensatory and potentially protective role of 5HT in the dopa deficient and hyperglutamatergic state of Parkinson's disease.

## 91.12

**OROFACIAL NONVERBAL CONTROL IN PATIENTS WITH PARKINSON'S DISEASE.** M. Gentil, S. Perrin, P. Pollak, C. Feuerstein<sup>\*</sup>, A.L. Benabid, INSERM U 318, CHU, 38043 Grenoble (France).

Force has been considered as one of the likely variables controlled by the nervous system in producing motor behavior (Stein, Behav Brain Sci. 4: 535-578, 1982). The objective of the present study was to characterize the motor control of idiopathic Parkinson's disease patients and normal subjects during orofacial nonverbal tasks. We examined the fine force control associated with speech-like force magnitudes in 3 articulatory organs: upper lip, lower lip, and tongue. A single-dimensional force transducer (Neuro Logic, Bloomington) was used for sampling anterior tongue force toward the alveolar ridge. A load-sensitive cantilever adjustable in two dimensions (Neuro Logic, Bloomington) was used for sampling at midline compression forces generated by the upper and lower lips. These forces were produced in presence of visual feedback. The relationship among several parameters of the ramp-and-hold force contraction and target force level was quantified in 14 parkinsonian patients (7 males and 7 females) and 14 age-matched normal subjects (7 males and 7 females). Parkinsonian patients were assessed with the Unified Parkinson's disease rating scale (UPDRS) and their speech was classified in stage 2 (moderately impaired). All patients were evaluated in OFF of L-dopa. The target force levels used in the present study included 0.25, 0.5, 1 and 2 newtons. For each structure, 10 consecutive contractions were obtained at each of the 4 target force levels which were randomized. Some variables considered of importance to central nervous system programming and control were measured: reaction time, peak force during the ramp phase, overshoot or undershoot of this peak, peak rate of force change, hold phase variability. The results demonstrated an abnormal isometric control force of the articulatory organs in patients with Parkinson's disease. So, measurements of orofacial force control provide useful insights into the fundamental motor control problem of any individual with dysarthria. Moreover, differences were observed between lip and tongue motor performance, consequently independent assessment of articulatory subsystem functions may turn out to be useful.

## 91.13

AMELIORATIVE AND ADVERSE EFFECTS PRODUCED BY COACTIVATION OF D<sub>1</sub> AND D<sub>2</sub> RECEPTORS IN MPTP-INDUCED PARKINSONIAN MONKEYS, S. Kuno<sup>1</sup>\*, T. Akai<sup>2</sup>, M. Ozawa<sup>2</sup>, M. Yamaguchi<sup>2</sup>, E. Mizuta<sup>1</sup>, <sup>1</sup>Utano Natl. Hosp. Kyoto 616, <sup>2</sup>Res. Dept. Nihon Schering, Osaka 532, Japan.

L-DOPA is effective in treatment of parkinsonian patients but may produce adverse effects such as dyskinesia and psychosis. It is not known whether both D<sub>1</sub> and D<sub>2</sub> subtypes of the dopamine receptor are equally responsible for the side effects. We examined the effects of D<sub>1</sub> receptor agonist (SKF 82958) or D<sub>2</sub> agonist (quinpirole) alone or those of their joint administration in MPTP-induced parkinsonian cynomolgus monkeys. The parkinsonian symptoms (tremor, bradykinesia and rigidity) and the adverse effects (hyperactivity, aggressiveness and dyskinesia) were evaluated independently using different behavioral criteria. The parkinsonian symptoms were ameliorated either by the D<sub>1</sub> agonist or the D<sub>2</sub> agonist. D<sub>1</sub> or D<sub>2</sub> receptor agonist produced little adverse effects, but joint administration of the two agonists or apomorphine, a non-selective dopamine agonist induced marked dyskinesia and hyperactivity or aggressive behavior. Thus, the adverse side effects manifested by dopamine agonists require coactivation of the D<sub>1</sub> and D<sub>2</sub> receptor.

## 91.15

PALLIDOTOMY LENGTHENS THE MAGNETIC CORTICAL STIMULATION SILENT PERIOD IN PARKINSON'S DISEASE. MS Young<sup>1,2</sup>, WJ Triggs<sup>1,2\*</sup>, D Bowers<sup>2</sup>, M Greer<sup>2</sup> and WA Friedman<sup>3</sup>. <sup>1</sup>Human Motor Physiology Laboratory, Departments of <sup>2</sup>Neurology and <sup>3</sup>Neurological Surgery, University of Florida, Gainesville, FL 32610.

We compared the duration of the electromyographic silent period elicited in abductor pollicis brevis with transcranial magnetic stimulation (TMS) in 7 patients (5 men) with Parkinson's Disease (Hoehn & Yahr grade 3) 65 (53—74) years of age before and 88 (37—107) days after unilateral pallidotomy (PAL). Medications were unchanged before and after PAL. We used TMS 200, 150, 120 and 100 % motor evoked potential (MEP) thresholds. Repeated measures ANOVA using PAL (pre and post) and recording site (ipsilateral and contralateral to PAL) as factors showed a significant main effect of PAL on the duration of the silent period elicited with TMS 200 % MEP threshold (prePAL 170 ± 55 vs. postPAL 217 ± 44 msec;  $p < 0.02$ ). We found no main effects or interactions in silent periods elicited at lesser stimulus intensities, and no effects or interactions in MEP thresholds. Our results suggest that PAL improves the function of cortical motor inhibitory circuits in Parkinson's Disease.

Supported by the National Parkinson Foundation.

Selective Chemo-Pallidectomy in Rhesus Maccaca.

Marc-Etienne Corbésy\*, Nitin Gogate, Paul F. Morrison<sup>1</sup>, Russel R. Lonser, Alex C. Cummins, Robert L. Dedrick<sup>1</sup>, Edward H. Oldfield.

Surgical Neurology Branch, NINDS, and <sup>1</sup>Biomedical Engineering and Instrumentation Program, National Center for Research Resources, National Institutes of Health, 9000 Rockville Pike, Bethesda, MD 20892. Latero-ventral pallidotomy has been reconsidered recently in the context of Parkinson's disease. The innocuity of classical neurosurgical techniques is limited by the anatomical situation of the globus pallidum, which is wedged between the optic tract ventrally and the internal capsule medially. We report here application of the high flow microinfusion technique to carry out a selective neuronal pallidectomy. Eight monkeys were used, out of which 4 were rendered hemiparkinsonian by intracarotid injection of MPTP and 4 were rendered fully parkinsonian by intravenous injection of MPTP. After stabilization of the parkinsonian syndrome, 2 full and 2 hemiparkinsonian monkeys were infused with 5 µl PBS and served as controls. The other animals were infused with 250 nmol solution of quinolinic acid in 5 µl PBS (pH corrected to 7.4) at a rate of 0.1 µl/min, using a 10 µl Hamilton syringe with a 32 Ga needle reinforced proximally with 28 and 22 Ga tubing. Clinical assessment of the monkeys showed a clear improvement of the brady-akinetic signs and of the tremor. Rigidity, as assessed under anaesthesia, was also reduced as early as the end of the procedure. Histological evaluation revealed a 3 to 5 mm diameter area of neuronal loss in the posterolateral aspects of the pars medialis of the pallidum and no sign of axonal or myelin lesion in the optic tracts and the internal capsule.

## 91.14

VESICULAR MONOAMINE TRANSPORTER (VMAT2) IMMUNOREACTIVITY IS REDUCED IN PARKINSON'S DISEASED STRIATUM. GW Miller\*, NR Nash, JT Perez, JK Staley, DC Mash, DB Rye, AI Levey. Dept. of Neurology, Emory University School of Medicine, Atlanta, GA.

Ligand binding studies have suggested that VMAT2, which is responsible for transporting monoamines from the cytoplasm into synaptic and dense core vesicles, is a reliable marker of monoaminergic terminals in the striatum. Here we report the production of fusion protein antibodies to human VMAT2 protein and their use in assessing damage to monoaminergic terminals in PD. The large intraluminal loop of VMAT2 (VMAT2-loop; a.a. 46-131) was amplified from a human substantia nigra cDNA library using the polymerase chain reaction. The loop fragment was ligated to pGEX2T vector and transformed into BL-21 (DE3) cells. Fusion protein consisting of VMAT2-loop fused to glutathione-S-transferase was isolated and used to immunize rabbits for antibody production. Polyclonal antibodies to human VMAT2-loop were purified by affinity chromatography and used to assess human VMAT2 protein via immunohistochemistry. VMAT2-loop immunoreactivity was strong in monoaminergic terminal fields in the caudate, putamen, and nucleus accumbens. Immunoreactive fibers projecting to the striatum displayed puncta and were dense throughout the striatum and cell bodies in monoaminergic nuclei. In PD brain VMAT2-loop immunoreactivity was drastically reduced in the caudate and putamen, and to a lesser degree in the nucleus accumbens. This pattern was similar to that of the plasma membrane dopamine transporter, a marker of presynaptic dopamine terminals. Therefore, VMAT2 appears to be a reliable marker of monoaminergic terminal loss in PD. These results suggest that antibodies to human VMAT2-loop protein will be useful in post-mortem assessment of monoaminergic systems in PD and other neurodegenerative disorders, as well as in aging and drug abuse. Supported by NS-31937, NS-09930, NIDA-09484, Emory CNS, and National Parkinson Foundation.

## 91.16

UPRIGHT MOBILITY IN PARKINSON'S DISEASE: BACKWARD WALKING IS THE MOST DIFFICULT. A. Behrman\*, K. Light, S. Flynn, D. Bowers, W. Triggs, and W. Friedman. Depts. of Physical Therapy, Neurology, and Neurosurgery, Univ. of Florida, Gainesville, FL 32610.

Individuals with Parkinson's disease (PD) typically demonstrate difficulty in forward walking by a slower speed with small, shuffling steps. Clinical observations indicate that other upright mobility movements appear to be even more difficult for these individuals. The control of upright mobility differs according to the requirements for programming and planning, feedback, balance, pattern generation, and force. The purpose of this study was to explore the relative difficulty of backward walking, stair-climbing, and walking with a figure-eight turn by studying the ratios of these timed movements to the speed of forward ambulation 20' between subjects with PD and subjects without PD. Eleven individuals with PD on medication ( $M = 67$  years) and 11 age- and gender-matched controls participated in this study. Subjects with PD had a mean Hoehn and Yahr of 3.6 and a mean motor UPDR of 42. Each upright mobility task was timed with a stopwatch to 0.1 s for both self-selected and maximum speeds. Ratios were compared between groups with student  $t$  tests. The ratios of forward walking/figure-eight walking, for both self-selected and maximum speeds, were not found different. All other group comparisons on ratios were significantly different at  $p < .01$ . The individuals with PD demonstrated that backward walking at maximum speed and backward walking at self-selected speeds were the most difficult, followed by stair-climbing at maximum speed, then self-selected speed. These results suggest that individuals with PD have the greatest difficulty generating an open-loop pattern that is not well practiced and where visual cuing is limited. Individuals with PD also demonstrated problems with force production.

## 91.18

SINGLE UNIT RECORDINGS OF SUBTHALAMIC NUCLEUS AND PARS RETICULATA OF SUBSTANTIA NIGRA IN AKINETO-RIGID PARKINSONIAN PATIENTS. A. Benazzouz, B. Piallat, P. Pollak, P. Limousin, D.M. Gao, P. Krack and A.L. Benabid\*. Lab. de Neurobiophysique, INSERM U.318, CHU 38043 Grenoble - France.

We have shown that high frequency stimulation (HFS) of subthalamic nucleus (STN) induces a spectacular improvement of akinesia and rigidity. Neuronal properties of STN human parkinsonian patients are not known. We studied 15 STN of 8 akineto-rigid parkinsonian patients during surgical implantation of chronic stimulating electrodes. We have recorded the neuronal activity in pars reticulata of substantia nigra (SNr) which is just below STN in the same trajectory. A set of 5 electrodes was lowered down to the targets. Using microelectrodes, it was possible to record as well as to stimulate the investigated area. STN neurons ( $n=32$ ) exhibited two different extracellular spike waveforms and differences in their basal firing rates. The majority of recorded cells are characterized by spikes with a mainly negative waveform and tonic regular firing rate. The frequency of discharge is between 15 and 70 Hz (mean±SD = 35.2±18.8 spikes/sec). Some STN cells exhibited biphasic waveforms with a mixture of bursts and isolated spikes. These neurons present a low frequency of discharge (11.1±2.3 spikes/sec) and respond to passive movements of the wrist by an increase of activity. At the target level, intraoperative HFS induces reversal of akinesia and rigidity. SNr recorded cells ( $n=28$ ) are characterized by biphasic, symmetrical and large amplitude spikes. Their discharge pattern is irregular and the frequency is between 10 and 50 Hz (28.7±14.9 spikes/sec). In SNr cells, there was no response to passive or active movements. These results show that STN neurons present an hyperactivity in akineto-rigid parkinsonian patients comparable to that recorded in MPTP-treated monkey. Correlation between single unit microrecordings and intraoperative positive effects of stimulation on akinesia and rigidity lead us to define with precision the localization of sites that yields maximal efficacy.

## 91.19

COORDINATION OF FINGERTIP FORCES DURING OBJECT RELEASE IN PARKINSON'S DISEASE. A.M. Gordon\*, Department of Movement Science, Teachers College, Columbia University, New York, NY 10027.

In the present study we examined fingertip forces during the replacement and release of an object on a table surface in subjects with Parkinson's disease (PD, stage 1-3) ON and OFF medication and age-matched control subjects. Subjects held an instrumented object between the index finger and thumb (precision grip) level with a marker 5 cm over a table surface while the employed grip (normal) forces and load (tangential) forces were measured. Upon verbal instruction, they replaced the object to the table and released it from their grasp. Subjects were asked to perform the task at a comfortable pace (no instructions regarding speed or accuracy were given). Both groups of subjects employed similar levels of grip force and began to decrease their grip force in an anticipatory fashion before the moment of table contact. The rates at which the grip forces decreased following table contact were similar in both groups, and were modified according to the objects weight (faster rates of force release were seen for a 900 g object compared to a 300 g object). The time from initiation of replacement to table contact was similar in both groups, as was the total duration of isometric force decrease and latency between release of the index finger and thumb. None of the parameters measured were affected by dopaminergic medication. These results contradict previous reports of deficits in the ability to terminate motor activity when asked to do so as fast as possible and suggest that natural, well-practiced, self-paced tasks are less impaired by Parkinson's disease than tasks which impose time constraints.

## 91.20

DETERMINATION OF DOPAMINE-RELEASING PROTEIN (DARP) IN CEREBRO SPINAL FLUID OF PATIENTS WITH NEUROLOGICAL AND NON-NEUROLOGICAL DISORDERS. L. Verdugo-Díaz<sup>1</sup>, C. Morgado-Valle<sup>2</sup>, G. Solís-Maldonado<sup>3</sup>, R. Drucker-Colín<sup>1,2</sup>, S. Kuhanathan<sup>4</sup>, V.D. Ramirez<sup>4\*</sup> <sup>1</sup>Depto de Fisiología, Fac. de Medicina, UNAM. <sup>2</sup>Instituto de Fisiología Celular, UNAM. <sup>3</sup>Servicio de Neurocirugía, Hospital Central Sur de Alta Especialidad PEMEX, México. <sup>4</sup>Molecular & Integrative Physiology, University of Illinois, Urbana, USA.

In this study we determined the levels of DARP in the cerebro spinal fluid (CSF) of patients having a wide variety of neurological disorders. CSF from patients (2 ml) was obtained by a lumbar puncture and immediately snap frozen in liquid nitrogen. DARP level was determined by an ELISA technique using monoclonal anti-DARP antibodies. A synthetic peptide corresponding to the first 36aa of the N-terminal of DARP was used as standard. A total of 25 non neurological patients versus 71 patients with a wide variety of neurological disorders categorized as malformations, tumors, demyelination, infections, and degeneration were tested. The relative concentrations of DARP were  $12.06 \pm 5.51$  ng/ml in patients with non-neurological diseases (mean  $\pm$  SEM, n=25), and decreased in patients with demyelinating disorders ( $7.49 \pm 2.53$  ng/ml, n=14) and in Parkinson's patients ( $4.64 \pm 1.91$  ng/ml, n=3). In the patients with malformations, concentration of DARP was higher ( $25.66 \pm 6.41$  ng/ml, n=17) and it is similar to control in patients with tumors ( $14.32 \pm 5.97$  ng/ml, n=18) and infections ( $10.16 \pm 3.52$  ng/ml, n=17). In addition, in several samples DARP was identified by Western blot using monoclonal antibodies against DARP at different dilutions (1:20 to 1:1000). Under reducing conditions, most samples showed two distinct bands of 50-60 kDa. For example, a patient suffering of syringomyelia with high DARP values by ELISA showed a strong positive Western blot. In contrast, in 3 PD patients, the Western blot signal was feeble in two and moderately strong in one. These data suggest that changes in concentration of DARP may be involved in certain neurological disorders with highest values in patients with malformations of the nervous system and low levels in patients with degenerative diseases.

## DEGENERATIVE DISEASE: OTHER—MOVEMENT DISORDERS

## 92.1

\*EVIDENCE FOR A CORRELATION BETWEEN THE DEGREE OF DNA FRAGMENTATION IN HUNTINGTON'S DISEASED STRIATUM AND THE NUMBER OF CAG REPEATS IN THE HUNTINGTON'S DISEASE (IT15) GENE. N.J. Butterworth\*, L. Williams, P. Lawlor, D. Love, R.L.M. Faull and M. Dragunow, Dept of Pharmacology, Univ. of Auckland, Auckland, New Zealand.

Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder characterised by the selective loss of striatal GABAergic efferent projection neurons. The chemical diagnosis of HD correlates with an expansion of a CAG triplet codon repeat located on the 5' end of the HD gene (IT15). We have recently shown evidence of DNA fragmentation in neurons in HD striatum, suggesting that neuronal degeneration in HD may occur through apoptosis, which is characterised by DNA fragmentation and may be the mechanism underlying neuronal degeneration in a number of other neurological diseases. In this study we investigated the relationship between the degree of DNA fragmentation (using the TUNEL *in situ* end labelling of DNA method) and the number of CAG repeats in the Huntington's disease gene in striatal tissue from HD brains. We used frozen and fixed tissue from 16 HD postmortem HD brains (graded 0 to 3 on the Vonsattel classification, postmortem delay ranging from 4.5-41 hours), control sections were taken from age and postmortem delay matched, neurologically normal striatal tissue. Our results show a significant positive correlation between the number of CAG repeats and the degree of DNA fragmentation. These results suggest that expanded CAG repeats may lead to neuronal degeneration in HD through an apoptotic mechanism.

## 92.3

WILD-TYPE AND MUTANT HUNTINGTIN LOCALIZE TO THE GOLGI COMPLEX AND TO VESICLES IN THE PERIPHERAL CYTOPLASM IN FIBROBLASTS OF CONTROL AND HD PATIENTS. J. Velier, C. Schwarz, C. Young, J. Fallon, B. Hyman, E.J. Martin\*, S. Hughes, R. Vallee, N. Aronin and M. DiFiglia, Massachusetts General Hospital, Boston MA 02114, Univ. of Mass. Med. Ctr. Worcester, MA 01655 and Worcester Fnd. Exper. Bio., Shrewsbury, MA

A CAG repeat expansion in the Huntington's disease (HD) gene results in the expression of a mutant huntingtin protein in the brain (Aronin et al., 1995, Neuron). We compared the localization of wild-type and mutant huntingtin in fibroblasts from a control and HD patients who were heterozygote (juvenile onset), and homozygote gene carriers. Immunofluorescence was performed with an anti-peptide antibody to amino acids 2527-2547 in huntingtin and the results analyzed with confocal microscopy. In normal and HD fibroblasts huntingtin associated with tubulovesicular membranes in the perinuclear region and with vesicles widely scattered throughout the cytoplasm. In control fibroblasts, double labeling for huntingtin and a membrane-associated protein of the Golgi complex (58kD), showed that both proteins almost completely overlapped. Treatment with Brefeldin A, a drug that disrupts the Golgi complex by inhibiting the association of coat proteins with Golgi membranes, dispersed huntingtin and 58kD localization to the cytosol. Results demonstrate that wild-type and mutant huntingtin are localized to the same subcellular compartments. Findings support previous speculation that huntingtin plays a role in vesicle transport (DiFiglia et al., 1995, Neuron) and suggest that the protein functions at the level of the Golgi apparatus and in the transport or recycling of vesicles. Supported by grant NS16367 to MD, NS31579 to NA and GM47434 to RV.

## 92.2

ALTERED NEURONAL EXPRESSION AND INTRACELLULAR TRAFFICKING OF HUNTINGTIN IN THE HUNTINGTON'S DISEASE BRAIN. E. Sapp, C. Schwarz, K. Chase, P. Bhidé, A.B. Young, J. Penney, J.P. Vonsattel, N. Aronin, and M. DiFiglia\* Massachusetts General Hospital, Boston MA 02114, & Univ. of Massachusetts Med. Ctr., Worcester, MA 01655.

We examined the immunohistochemical localization of huntingtin, the protein product of the HD gene, in HD brain (N=14) with an antibody that detects both wild-type and mutant huntingtins by immunoblot. In control and HD brain, huntingtin localized to neurons and in the striatum distributed in a patch/matrix-like pattern. Neuronal expression was markedly reduced in the striatum and in both segments of the globus pallidus in HD patients with low grade pathology. Cortical and striatal neurons with normal-looking morphology showed significant accumulation of huntingtin to an endosomal/lysosomal-like compartment in perikarya, dendrites, and axons, particularly in juvenile and low grade cases. Ultrastructural study revealed the labeled structures to be tubulovesicular and multivesicular bodies, which are organelles of the endocytic pathway leading to lysosomes. Some immunoreactive dendrites in cortex were beaded and fragmented similar to neurons undergoing hypoxic/ischemic and excitotoxic injury. Huntingtin was concentrated in the perinuclear cytoplasm and reduced or absent in processes of degenerating neurons. Some neurons had staining in the nucleus; other neurons were devoid of huntingtin expression. A few cortical neurons in 2 of 8 controls had increased endosomal/lysosomal and marked perinuclear accumulation of the wild-type protein. Results demonstrate early changes in the neuronal expression and intracellular sorting of huntingtin in HD affected brain regions. The expanded polyglutamine region in mutant huntingtin may disrupt sorting signals that regulate the intracellular trafficking of the protein and ultimately cause energy failure and cell death. Supported by NS 16367 to MD and NS31579 to NA.

## 92.4

REACTIVE GLIOSIS IN HUNTINGTON'S DISEASE AS DEMONSTRATED WITH [<sup>3</sup>H] PK11195 BINDING. J.A. Kotzka\*, M.W. Becher<sup>1,4</sup>, A.H. Sharp<sup>2\*</sup>, C.A. Ross<sup>2,3</sup>, M.V. Wagster<sup>1,4,5</sup>, Departments of <sup>1</sup>Pathology, <sup>2</sup>Psychiatry & Behavioral Sciences, and <sup>3</sup>Neuroscience, and the <sup>4</sup>Neuropathology Laboratory, The Johns Hopkins University School of Medicine, and <sup>5</sup>Department of Psychology, Johns Hopkins University, Baltimore, MD 21205.

The characteristic neuronal loss and atrophy of the striatum in Huntington's disease (HD) is accompanied by a reactive astrogliosis. In an effort to label and quantify these astrocytic changes, we examined the caudate, dorsal frontal cortex, and temporal pole in cases of HD (Vonsattel grades 2, 3, and 4) and age-matched controls, using the peripheral-type benzodiazepine receptor ligand [<sup>3</sup>H] PK11195, which has been shown to be a marker for gliosis and indicator of neuronal damage in the CNS (Dubois et al., *Brain Res.* 445:77-90, 1988). Using *in vitro* receptor autoradiography, we incubated tissue sections in 1 nM [<sup>3</sup>H] PK11195. Glial cell types were visualized in adjacent sections by immunocytochemical staining. [<sup>3</sup>H] PK11195 binding concentration was increased in all grades of HD when compared to controls in all areas studied. There was little difference in binding between grades 2, 3, and 4 in cortical areas. In caudate, mean binding concentrations in grade 2 and 3 cases were increased compared to controls. Grade 4 cases showed increased [<sup>3</sup>H] PK11195 binding compared to controls and to grades 2 and 3: control mean = 130.7 fmol/mg tissue standard; grade 2 = 285.7; grade 3 = 279.9; grade 4 = 389.1. These data indicate that reactive gliosis occurs early and abundantly in HD and, in caudate, continues to increase as the disease progresses. [<sup>3</sup>H] PK11195 binding is an effective tool to measure gliosis quantitatively in neurodegenerative disease.

## 92.5

IMMUNOHISTOCHEMICAL LOCALIZATION OF MARKERS FOR OXIDATIVE INJURY IN HUNTINGTON'S DISEASE. R.J. Ferrante<sup>2</sup>, N.W. Kowall, S.M. Hersch, R.H. Brown, M.E. Beal, Bedford VAMC, Boston University School of Medicine, Emory University, and Mass. General Hospital.

There is evidence to suggest that oxidative stress may play a role in the neuronal death observed in Huntington's disease (HD). DNA strand breaks and lipofuscin accumulation are increased in the striatum and cortex of HD patients. MRI spectroscopy shows increased lactate concentrations *in vivo*, consistent with impaired oxidative phosphorylation. Impaired oxidative phosphorylation generates reactive oxygen species which can alter proteins, lipids, and DNA. In the present study we examined immunohistochemical markers for oxidative stress, using antisera against heme oxygenase (HO), 8-hydroxy-2-deoxyguanosine (8-OHdG), 3-nitrotyrosine (3NT), and malondialdehyde (MDA) in postmortem tissue samples of striatum and neocortex from 12 varying grade (0-4) HD subjects and 4 normal controls. 8-OHdG and MDA are markers of oxidative damage to DNA and lipids, 3NT is a marker of peroxynitrite mediated protein nitration, and heme oxygenase is induced by oxidative stress. The general distribution of HO, 8-OHdG, 3NT, and MDA was similar. Control brains showed only scattered, weakly stained, striatal and cortical neurons with increased immunoreactivity (IR) in the striatal matrix zone. The distribution and extent of oxidative injury was enhanced in HD and paralleled the pattern of neuronal degeneration observed in the disorder. In low grade HD cases, HO, 8-OHdG, 3NT, and MDA-IR was greater in the dorsal striatum than the ventral striatum. In more severe grades, IR increased throughout the striatum. In the most severe grades, striatal IR was reduced, consistent with neuronal loss. A gradual increase in neuronal HO, 8-OHdG, 3NT, and MDA-IR occurred in HD cortex with increasing grade of severity. These observations suggest that energy failure and subsequent oxidative injury may contribute to the pathogenesis of HD. Supported by NIH grants AG12922 and NS-01624, the Huntington's Disease Society of America, and the Department of Veteran Affairs.

## 92.7

ALZHEIMER'S DISEASE CHANGES IN HUNTINGTON'S DISEASE.

M.W. Becher<sup>1,3</sup>, J.A. Kotzuk<sup>3</sup>, M.V. Wagster<sup>1,5</sup>, N.G. Ranen<sup>2</sup>, C.A. Kitt<sup>2</sup>, D.L. Price<sup>1,3,4</sup>, C.A. Ross<sup>2,4,6</sup>. Departments of <sup>1</sup>Pathology (Neuropathology Division), <sup>2</sup>Psychiatry & Behavioral Sciences, <sup>3</sup>Neurology, and <sup>4</sup>Neuroscience, and the <sup>5</sup>Neuropathology Laboratory and the <sup>6</sup>Laboratory of Molecular Neurobiology, The Johns Hopkins University School of Medicine, Baltimore, Maryland 21205, and <sup>7</sup>NINDS, Bethesda, Maryland 20892.

One of the triad of features of Huntington's disease (HD) is cognitive dysfunction, particularly in mid-late stage cases. The dementia of HD has traditionally been considered "subcortical" both in origin and nature, yet this issue remains incompletely characterized. Neocortical changes, such as loss of neurons and changes in excitatory amino acid receptors, can be demonstrated in HD brains, and recent postmortem studies indicate that there are volumetric decreases in HD neocortex. We examined archival HD brain tissue from our Baltimore HD Project Tissue Bank for the presence of concomitant Alzheimer's disease (AD)-type changes by modified Bielschowsky silver stains. Subjects ranged from 38 to 93 years of age. The majority (20/31, 65%) of HD cases, including several elderly subjects, had no evidence of neocortical senile plaque (SP) formation or neurofibrillary tangles (NFT). Interestingly, 9/31 (29%) HD patients had some degree of AD-type pathological changes including rare diffuse SP, scattered NFT, focal neuritic SP, and moderate to frequent diffuse SP with only rare neuritic SP. Using CERAD criteria, one patient (3%) each fulfilled the criteria for "Definite AD" and "Probable AD". These results underscore the need to continually seek heterogeneous neuropathological features in neurodegenerative cases despite the establishment of a primary clinicopathological diagnosis.

## 92.9

BEHAVIORAL AND HISTOLOGICAL COMPARISONS OF TWO ANIMAL MODELS OF HUNTINGTON'S DISEASE. Jie Dong, Deborah A. Shear, Christopher D. Gundy, Kristi Haik-Creger, and Gary L. Dunbar<sup>2</sup>. Brain Research Laboratory, Department of Psychology, Central Michigan University, Mt. Pleasant, MI 48859.

Intrastriatal administration of the *N*-methyl-D-aspartate agonist, quinolinic acid (QA), and the mitochondrial toxin, 3-nitropropionic acid (3-NP), have been used as animal models of Huntington's disease (HD). The aim of this study was to compare these two models on the following behavioral and histological measures: (1) open-field nocturnal activity levels; (2) motor performance on balance-beam and grip-strength tasks; (3) learning ability in a radial-arm-water-maze (RAWM) task; (4) sparing of NADPH-diaphorase neurons; (5) amount of cytochrome oxidase labelling; and (6) loss of Nissl-stained neurons. Adult male Sprague-Dawley rats were given bilateral intrastriatal injections of either 750 nmol 3-NP (n=6), 200 nmol QA (n=8) or phosphate-buffered saline (n=6). Behavioral testing began two weeks postlesion and histological processing began four weeks postlesion. Both 3-NP and QA injections caused significant hyperactivity at two weeks postlesion in the open-field, but only the QA rats showed hyperactivity at four weeks postlesion. Both QA and 3-NP rats showed significant impairment on the balance beam task, while only 3-NP rats differed significantly than controls on the grip-strength task. Finally, both QA and 3-NP rats showed significant impairments in the RAWM task, with 3-NP rats being more severely impaired. Both types of lesions produced significant reductions in CYO staining and in the number of Nissl-stained neurons in the striatum, with only the 3-NP lesions created necrotic cavities in the striatum. Lesions with 3-NP tended to result in more sparing of NADPH-diaphorase-positive neurons in regions adjacent to the necrotic core. Collectively, these results suggest that the QA model mimics some of the earlier behavioral and neuropathological symptoms of HD, while the 3-NP model may mimic more of the later symptoms (or juvenile onset) of HD. This project was funded by NIH grant 1-R15-NS30694-01A3.

## 92.6

MITOCHONDRIAL CALCIUM HOMEOSTASIS IN HUNTINGTON'S DISEASE FIBROBLASTS. C.A. Gutekunst<sup>2</sup>, T.-J. Peng, W.L. Whaley, B. Rock, S.M. Hersch, and J.T. Greenamyre. Departments of Neurology, Psychiatry & Dermatology, Emory University School of Medicine, Atlanta GA 30322.

The HD gene product, huntingtin, in its expanded form, binds to and inactivates glyceraldehyde phosphate dehydrogenase, a key enzyme in glycolysis. A selective complex II/III defect has also been reported in HD caudate. Moreover, mitochondrial toxins model the pathology and neurologic symptoms of HD. Thus, regional and cellular differences in mitochondrial function, or susceptibility to oxidative damage, may determine selective neuronal degeneration. We hypothesize that the metabolic defects that lead to neuronal death in HD occur in non-neuronal cells, whether or not they cause cytotoxicity. Because studies of the relationship between the HD mutation and metabolic processes require the use of living cells, we are using cultured fibroblasts from control and HD patients and laser scanning confocal microscopy to investigate cytosolic and mitochondrial  $Ca^{2+}$  fluxes, mitochondrial membrane potential and free radical production. Our preliminary results indicate that we are able to reliably follow ionomycin-induced cytosolic  $Ca^{2+}$  fluxes in human fibroblasts with Fluo-3. In addition, we have used Rhod-2, a calcium indicator which selectively labels mitochondria and nucleoli. In response to ionomycin, there was a robust response in both mitochondria and nucleoli. Challenges with ionophores and metabolic inhibitors may reveal latent defects caused by the HD mutation and lead to a better understanding of the relationship between the huntingtin expansion and neurodegeneration. Supported by a Markey Fellowship from Emory University (CAG), the Emory Alzheimer's Disease Core Center (TJP) and a Mallinckrodt Scholar Award (JTG).

## 92.8

NEUROTRANSPLANTATION OF FETAL LATERAL GANGLIONIC EMINENCE TISSUE IN THREE PATIENTS WITH HUNTINGTON'S DISEASE. O.V. Kopyov, S. Jacques<sup>2</sup>, M. Kurth, L. Philpott, A. Lee, M. Patterson, C. Duma, E. Kogosov, A. Lieberman, and K.S. Eagle.

Neurosciences Institute, Good Samaritan Hospital, Los Angeles, CA 90017.

Huntington's disease (HD) is an autosomal dominant genetic neurodegenerative disease which leads to dementia, involuntary writhing movements (chorea) and eventual death. Currently there are no effective treatments for HD, and patients must live with the movement and mood disorders it creates. Recent success with fetal transplantation for Parkinson's disease (PD) has led to the consideration of fetal transplantation as a treatment for HD. This group has performed many fetal transplantation procedures for PD (Kopyov et al, 1996) and in the last year has performed fetal transplantation for three patients with HD. Tissue was obtained from the lateral ganglionic eminence (LGE), a region which has been shown to develop into striatal tissue, of 9-week fetal cadavers. This tissue was grafted bilaterally to four sites in the caudate nucleus and one site in the putamen. The effects of tissue grafts have been assessed with both pre- and postoperative MRI and PET scans, extensive neurological testing using the UHDRS and Schwab and England scales, and neuropsychological evaluations. All patients have recovered well from the surgery and demonstrate improvement in motor and cognitive deficits. They exhibit no further degeneration as a result of HD. The positive initial outcome and recovery of these patients provides preliminary evidence that the utilization of fetal transplantation in carefully selected cases may prove an effective treatment strategy for HD. While further investigation is required to confirm the potential of treatment of HD with fetal transplantation, the present report demonstrates that fetal transplants do not appear to have negative effects and that they have the potential to significantly improve the lives of HD patients.

## 92.10

EXPRESSION OF FULL-LENGTH AND TRUNCATED HUNTINGTON'S DISEASE PROTEIN (HUNTINGTIN) IN NEURONAL CELLS. J.K. Cooper<sup>1</sup>, A.H. Sharp<sup>1</sup>, Y.P. Goldberg<sup>2</sup>, G. Schilling<sup>1</sup>, S.H. Li<sup>1</sup>, D. Borschelt<sup>2</sup>, S. Sisodia<sup>2</sup>, M.R. Hayden<sup>3</sup>, and C.A. Ross<sup>2\*</sup>. Lab. of Molecular Neurobiology<sup>1</sup> and Div. of Neuropathology<sup>2</sup>, Johns Hopkins Med. Sch.<sup>1</sup>, Balto, MD, USA; Dept. of Medical Genetics, Univ. of British Columbia<sup>3</sup>, Vancouver, BC, Canada.

Huntington's disease (HD) is caused by expansion of a CAG repeat coding for polyglutamine in the 350 kDa protein product of the HD gene, huntingtin. While normal and expanded huntingtin is widely expressed, HD is characterized by selective neuronal vulnerability in medium spiny neurons of the caudate and putamen, middle and deep layers in cerebral cortex, and other brain regions. The mechanism of cell death is unknown but has been postulated to involve a gain-of-function mutation. So far, attempts to develop a cellular model of HD using non-neuronal cells have been unsuccessful. We are, therefore, seeking to establish a cellular model using the neuroblastoma cell line, Neuro-2a (N2A). Truncated and full-length HD proteins with normal or expanded repeats (44Q) were transiently expressed in N2A cells using the CMV promoter. Western blots with the antibody AP81 indicate that the full-length HD protein is expressed. Immunofluorescence indicates that full-length huntingtin is present in a cytoplasmic pattern similar to that demonstrated in our previous studies of the HD protein in brains of control individuals and HD patients. There appears to be some enrichment in distal neuritic processes. In addition, the N-terminus (cloned from a human brain cDNA library) has been ligated into the prion protein promoter vector, pPrP. To further assess the role of different CAG sized huntingtin expressed in neuronal cells, we are currently developing stable N2A cell lines as well as huntingtin constructs with larger size repeats. Expression of huntingtin containing different polyglutamine lengths in N2A cells will be useful in the elucidation of the pathogenesis of HD. (Supported, in part, by the NINDS and the Canadian MRC.)

## 92.11

**ANTEROGRADE AND RETROGRADE TRANSPORT OF HUNTINGTIN IN PERIPHERAL NERVE.** J. Block-Galarza, E. Sapp, K.O. Chase, K. Vaughn, R. Vallee, M. DiFiglia and N. Aronin\* Univ. Mass. Med. Sch., Worcester, MA 01655, Worc. Fndn. Exper. Biol., Shrewsbury, MA 01545 and Mass. Gen. Hosp., Boston, MA 02114.

Huntingtin is the protein product of the IT15 gene; CAG repeat expansion in this gene is the fundamental genetic defect in Huntington's disease. We and others detected huntingtin in axon fibers and terminals, in association with a subset of vesicles. Here we examined the transport of huntingtin in the sciatic nerve of the rat. After appropriate anesthesia, the sciatic nerve was exposed and light pressure was placed on the nerve for 5 seconds. The wound site was sutured and the animals were allowed to survive for 6, 12, 24 and 48 h. The contralateral sciatic nerve was sham-operated and served as the control in each case. The animals were decapitated and the sciatic nerves were rapidly removed for immunohistochemistry (immunofluorescence and bright field) or extraction for SDS-PAGE and immunoblot. Results showed that huntingtin accumulated both proximally and distally to the pressure lesion, with increasing intensity from 6 to 12 to 24h. Dynein also accumulated in the same time frame both proximally and distally; SNAP-25 was concentrated only proximally and neurofilament did not change at either site compared to controls. Immunoblot for huntingtin confirmed the immunohistochemical results. We conclude that huntingtin in sciatic nerves is transported bidirectionally. Anterogradely huntingtin moves by fast axonal flow. Thus, huntingtin is recycled in mammalian peripheral nerve. Supported by NIH NS31579 (NA), GM47434 (RV) and NIH NS16367 (MD).

## 92.13

**EXPERIMENTAL THERAPEUTICS IN A MODEL OF HUNTINGTON'S DISEASE.** J. Timothy Greenamyre\*, Eric Lai and Monica Garcia-Osuna. Departments of Neurology and Pharmacology, Emory University, Atlanta, GA 30322

The HD gene product, huntingtin, in its expanded form, binds to and inactivates glyceraldehyde phosphate dehydrogenase, a key enzyme in glycolysis. A selective complex II/III defect has also been reported in HD caudate. We used striatal complex II inhibition by malonate as a model of HD. We report that 2 compounds in clinical development, remacemide hydrochloride and OPC-14117, are protective in this model. Remacemide is a low-potency NMDA receptor channel blocker; its desglycine metabolite has an affinity of  $\sim 1 \mu\text{M}$ . OPC-14117 is an antioxidant compound. Both drugs have been used in small clinical trials of tolerability in HD. Sprague-Dawley rats received an intrastriatal injection of malonate ( $1 \mu\text{mole}/2 \mu\text{L}$ ) with or without systemic remacemide or OPC-14117. Remacemide was administered i.p. 30 min before and 150 min after malonate; OPC-14117 was administered as a single ip injection at a dose of 300 mg/kg 30 min before malonate infusion. Three days later, rats were euthanized. Slide-mounted brain sections were stained for cytochrome oxidase and lesion volumes were reconstructed using an MCID image analysis system. Remacemide, at a dose of 20 mg/kg, reduced lesion volume from  $27.7$  to  $19.6 \text{ mm}^3$  ( $p < 0.02$ ). In a separate experiment, remacemide at a dose of 30 mg/kg reduced lesion volume from  $43.4$  to  $27.8 \text{ mm}^3$  ( $p < 0.02$ ). OPC-14117 reduced lesion volume from  $25.7$  to  $7.8 \text{ mm}^3$  ( $p < 0.002$ ). To the extent that metabolic defects contribute to the pathogenesis of HD, our results suggest these compounds can be expected to be neuroprotective. Supported by a Mallinckrodt Scholar Award, Astra Arcus USA and Otsuka America.

## 92.15

**NEURONAL DEATH IN CULTURED MURINE CELLS FOLLOWING GAPDH INHIBITION.** C.T. Shelton\* and D.W. Choi. Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

It has recently been reported that the mutant polyglutamine-containing proteins responsible for Huntington's disease and several other trinucleotide-repeat diseases bind strongly to glyceraldehyde 3-phosphate dehydrogenase (GAPDH), a key enzyme in glycolysis (Burke *et al.*, *Nat. Med.* 2:347, 1996), raising the interesting possibility that neuronal death in these diseases may be triggered by reduced glycolysis and consequent cellular energy shortages.

We established a murine central neuronal cell culture model of GAPDH inhibition. Mixed cortical cell cultures (DIV 12-14) containing both neurons and glia, or near pure neuronal cultures, were exposed to the GAPDH inhibitor, alpha chlorohydrin for 48 hr. Concentrations of 1-20 mM drug induced concentration-dependent neuronal death, and somewhat less prominent glial death, with near complete cell death at 20 mM drug. The high concentrations of inhibitor required to induce cell death may reflect limited metabolism to the active compound chlorolactaldehyde; 0.5 mM concentrations have been found previously to be needed to inhibit 80% of GAPDH activity in sperm cells (Stevenson and Jones, *J. Reprod. Fert.* 74:157, 1985).

With this model established, we tested the hypothesis that supplying the short chain fatty acid palmitic acid, a precursor for acetyl-CoA synthesis permitting NADH synthesis in the absence of glycolysis, would permit cortical cells to survive GAPDH inhibition. Repeated addition of 300-500  $\mu\text{M}$  palmitic acid to the bathing medium resulted in a 40% reduction in neuronal and glial cell death. This observation raises a possibility that administration of short chain fatty acids might constitute a therapeutic strategy for diseases associated with GAPDH inhibition.

Supported by NIH NINDS grant NS 30337.

## 92.12

**IT15 EXPRESSION AFTER NEUROTROPHIN AND ANTISENSE TREATMENT: IN VIVO AND IN VITRO STUDIES.** N.S.K. Haque\*, P. Borghesani, C.J. Le Blanc and O. Isacson. Neuroregeneration Laboratory, McLean Hospital and Program in Neuroscience, Harvard Medical School, Belmont, MA 02178

The mutation of the IT15 gene responsible for Huntington's disease (HD) on chromosome 4 p16.3 results in an increase in the length of a polyglutamic acid tract in the 348kD Huntingtin-protein. There is considerable evidence to suggest that susceptibility to excitotoxic damage is a factor involved in the specific neuronal loss observed during HD however, the relationship between this pathology and the HD mutation remains obscure. Moreover, the normal function of this protein has yet to be elucidated. To examine whether reduced IT15 expression affects susceptibility to glutamate receptor mediated toxicity in neurons, an antisense RNA approach was undertaken to modify striatal IT15 gene expression in vivo. Repeated direct injections of an antisense molecule designed to block translation of mouse IT15 mRNA however, did not significantly reduce striatal IT15 protein levels as assessed by immunostaining and Western blotting. IT15 is a large protein and there is evidence to suggest that it has a half-life greater than 72 hours. Thus, in another attempt to answer the same question of the role of IT15 in excitotoxicity, we cloned IT15 antisense cDNA into the pCMVb vector (Clontech) and transiently transfected the "neuron-like" NTera-2 cells (Stratagene). These cells were then subjected to NMDA-mediated toxicity and these results will be presented. Certain growth factors have been shown to protect neurons from excitotoxic insult. Data from experiments examining expression of Huntingtin in vivo after exposure to various neurotrophins will also be shown. (N.S.K. Haque is a Wills Foundation Fellow. This work was also supported by NS30064).

## 92.14

**IDENTIFICATION OF NOVEL TRINUCLEOTIDE REPEAT CONTAINING GENES AND ASSOCIATION WITH NEURODEGENERATIVE DISEASE.**

A. M. Gormley, P. R. Maycox, R. James, B. W. Crook, G. W. Roberts, D. Howlett\* and J. Price. Dept. of Molecular Neuropathology, SmithKline Beecham, Harlow, Essex, CM19 5AW, UK.

At least eight neurodegenerative diseases are known to be associated with genes that contain expanded trinucleotide repeat (TNR) regions. Five of these diseases contain a CAG expansion in the coding region of the respective gene which is translated into expanded polyglutamine in the native protein. One example is Huntington's disease. In the normal population, the Huntingtin gene is polymorphic, containing between 9 and 36 repeats. In contrast, patients with the disease have from 37 to 120 repeats. One characteristic of TNR diseases is the phenomenon of anticipation, whereby the disease appears earlier in successive generations and in a more severe form. It is now known that the expansion is a dynamic mutation that increases in length through generations and the length correlates with the age of onset and severity of the disease.

We wish to identify novel candidate genes for trinucleotide expansion. To this end we have screened various genome databases for expressed sequences containing at least seven CAG repeats. PCR primers were then designed so that the chromosomal localisation of candidate sequences could be determined using template DNA prepared from monochromosomal hybrid cell lines. We have compiled a set of novel genes that can be screened against diseases showing the appropriate chromosomal linkage and genetic characteristics, e.g. anticipation. We are screening our set of localised genes, for CAG expansion, against DNA obtained from patients with candidate neurodegenerative diseases. One such example is spinal cerebellar ataxia type 2 for which the locus has been identified but the gene is unknown. This work was funded by SmithKline Beecham Pharmaceuticals.

## 92.16

**AMPA RECEPTOR SUBUNIT mRNAs IN PARKINSON'S DISEASE, PROGRESSIVE SUPRANUCLEAR PALSY, HUNTINGTON'S DISEASE AND AMYOTROPHIC LATERAL SCLEROSIS.** M. Tomiyama\*, J.M. Palacios\*, R. Cortés\*, G. Mengod\*. \*Dept. Neurochem., IIBB/CSIC, Barcelona, Spain.

Using in situ hybridization we have investigated mRNA transcripts for flip/flop variants of AMPA receptor subunits in the striatum from patients with Parkinson's disease (PD), progressive supranuclear palsy (PSP) and Huntington's disease (HD), and in the spinal cord from patients with amyotrophic lateral sclerosis (ALS), to elucidate the relevance of AMPA receptor-mediated excitotoxicity and/or to help identify specific therapeutic targets to the diseases. Although both PD and PSP share in common a degeneration of the nigrostriatal dopamine neurons, the transcripts were preserved in PD, whereas they were increased in PSP, especially the flip variants. These findings suggest that the involvement of AMPA receptors is entirely different between PD and PSP. Transcripts for GluR-A<sub>flip</sub> and GluR-C<sub>flip</sub> were severely decreased throughout the HD striatum. Dorsal regions of the HD striatum exhibited lower hybridization signals for GluR-B<sub>flip</sub> and GluR-D<sub>flip</sub> when compared to controls. In ALS, significant decreases of the mRNA levels were observed for flop forms mainly in the ventral horn. The alterations of the transcripts in HD and ALS did not appear to result from AMPA receptor-mediated neurotoxicity, suggesting that these diseases cannot be explained only by AMPA receptor activation.

## 92.17

**NEURONATIN- $\beta$  IN THE ADULT HUMAN BRAIN: SELECTIVE AND ABUNDANT EXPRESSION IN THE CAUDATE AND PUTAMEN.** Dexian Dou<sup>1</sup> and Rajiv Joseph. Department of Neurology, K-11, Laboratory of Molecular Neuroscience, Henry Ford Hospital, Detroit, MI.

Originally isolated from neonatal rat brain, *neuronatin* mRNA exhibits a brain-specific expression pattern (BBRC 1994; 201: 1227-1234). There are two alternatively spliced forms,  $\alpha$  and  $\beta$  (Brain Res 1995; 690: 92-95). The  $\alpha$ -form contains three exons, whereas, the  $\beta$ -form contains only exons 1 and 3 (Genomics, in press). *Neuronatin* protein is highly conserved in mammals, and the human *neuronatin* gene is located on chromosome 20q11.2-12 (Brain Res, in press). Although, both the  $\alpha$  and  $\beta$  isoforms are abundantly expressed during embryogenesis, only traces of *neuronatin* mRNA were detected in the adult brain studied as a whole. The present studies evaluated the expression of both isoforms in different regions of the adult brain. The results indicate that *neuronatin- $\beta$*  is the predominant mRNA species that is expressed in the adult human brain, and its expression is selectively abundant in the caudate nucleus and putamen, findings that may have relevance in **Huntington's disease** and other human diseases that selectively involve these structures. These results, for the first time, implicates *neuronatin* in the function of the mature brain. As opposed to the adult brain, there is an abundance of expression of *neuronatin- $\alpha$*  in the human fetal brain. Conceivably, the middle exon, present only in the  $\alpha$ -form, may be involved in the regulation of neuronal growth during embryogenesis, and the  $\beta$ -form, which does not contain the middle exon, may help maintain the postmitotic state of the mature brain. Supported by grants from the NIH (NS-01521) and American Heart Association-National (92-132) (to R.J.).

## 92.19

**LYMPHOBLAST GTP CYCLOHYDROLASE I ACTIVITY IN DOPA-RESPONSIVE DYSTONIA.** R.A. Levine<sup>1,2,3\*</sup>, L. Bezin<sup>1</sup>, M.D. Flam<sup>1</sup>, M. Neystat<sup>4</sup>, J.S. Fryburg<sup>5</sup>, W.G. Wilson<sup>5</sup>, E.M. Bebin<sup>7</sup>, J.M. Trugman<sup>6</sup>, T.G. Nygaard<sup>4</sup>. <sup>1</sup>Neurology Labs, Henry Ford Hospital; <sup>2</sup>Dpt of Psychiatry, Wayne State U.; <sup>3</sup>Detroit VAMC, Detroit, MI; <sup>4</sup>Columbia U. New York, NY; <sup>5</sup>Dpt of Pediatrics and <sup>6</sup>Neurology, Scholl of Med., U. of Virginia, Charlottesville, VA; <sup>7</sup>Dpt of Pediatrics, School of Med., U. of Alabama, Birmingham, AL.

Dopa-responsive dystonia (DRD) is a dominant inherited disorder associated with mutations in the gene for GTP cyclohydrolase I (GTP-CH). GTP-CH is the rate-limiting enzyme in the synthesis for the tyrosine hydroxylase (TH) cofactor, tetrahydrobiopterin. TH catalyzes the conversion of tyrosine to Dopa and is the rate-limiting enzyme in catecholamine biosynthesis. We assessed the value of the GTP-CH assay for predicting DRD by assaying activity in lymphoblastoid cell lines established from DRD and non-DRD members of a 4 generation family. We found GTP-CH activity to be 20-50% of normal in affected family members and carriers (identified by genetic mutation data). The most severely affected family member had no detectable GTP-CH activity; her father (not exhibiting DRD nor carrying the mutation) had transmitted a non-conservative mutation in exon 6 of the GTP-CH gene and had an activity level for GTP-CH consistent with that seen in carriers from the girl's maternal relatives. Assay for GTP-CH activity in lymphoblastoid cell lines appears to be a sensitive marker for mutations in the GTP-CH gene and can be used as a diagnostic marker for DRD.

## 92.21

**HUNTINGTON'S DISEASE: IDENTIFICATION OF PROTEINS THAT INTERACT WITH HUNTINGTIN.** P.W. Faber, C. Dompé, L.M. Carlee, G.T. Barnes, J.F. Gusella<sup>\*</sup> and M.E. Macdonald<sup>\*</sup>. Molecular Neurogenetics Unit, Massachusetts General Hospital East, Bldg 149, Charlestown 02129.

Huntington's Disease (HD) is an inherited autosomal dominant neurodegenerative disorder characterized by uncontrolled eye movements, general motor impairment, psychiatric disorders and dementia. The underlying feature of HD is the specific loss of neurons in the basal ganglia. Genetically, HD is caused by an expanded CAG-repeat in 4p16.3. This CAG-repeat is translated into a polyglutamine stretch near the amino terminus of a novel 350 kDa protein of unknown function, termed huntingtin. Both the normal and HD isoforms of huntingtin are widely expressed in the cytoplasm of cells in many tissues. Also, its expression pattern in brain does not closely match the primary target areas of the disease. Thus the expanded polyglutamine stretch in huntingtin leads to a gain of function mutation whose mode of action remains to be established although a dominant-negative scenario, in which the mutant protein inactivates the normal isoform has been ruled out as HD knock-out mice proved to be embryonic lethal.

To obtain more knowledge about the biochemical pathways involving both the normal and HD isoforms of huntingtin we have employed yeast two-hybrid technology to identify their cellular protein partners. Using matched sets of yeast two hybrid baits from the huntingtin N-terminus with either 21 or 60 glutamines we have so far identified three independent interactors. Although none interacts exclusively with one bait, quantitative differences exist. Also, two interactors share a common protein motive, defining the region of interaction. These results as well as the additional characterization of these interactors will be presented.

This work was funded by grants from the Human Science Frontier Program, the Hereditary Disease Foundation and NIH grant NS16367.

## 92.18

**DECREASED [18F]SPIPERONE BINDING IN PUTAMEN IN IDIOPATHIC DYSTONIA.** J.S. Perlmuter<sup>\*</sup>, M. Stambuk, J. Markham, K.J. Black, L. McGee-Minnich, S.M. Moerland. Departments of Radiology, Neurology & Psychiatry, Washington University School of Medicine, St. Louis, MO 63110

Dystonia may be associated with abnormalities of dopaminergic pathways since it may occur as the first manifestation of Parkinson's disease or after an initial dose or chronic treatment with a dopamine antagonist. Although a genetic etiology has been identified for childhood onset generalized dystonia the etiology of adult-onset focal dystonias remains unclear. We quantified [18F]spiperone binding in putamen using PET in 21 patients with idiopathic focal dystonias (16 women; mean age = 56) including 13 with Meige syndrome (blepharospasm and lower facial dystonia) and 8 patients with hand cramp as well as 13 normals (7 women; mean age = 53). No patient had dystonia in other body parts and no subjects had other neurological or psychiatric abnormalities. Each subject also had an MRI of the brain. PET studies were done with the Siemens 953b in the 2d mode with 31 simultaneous slices (3.4 mm center-to-center slice separation). Reconstructed transverse resolution was 7 mm FWHM and axial resolution was about 4 mm. Blood flow and blood volume were measured using [15O]-labeled water and carbon monoxide, respectively. Then, 3 to 5 mCi of [18F]spiperone were injected i.v. and sequential PET scans were collected for 3 hrs. For each patient, the location of the center of the putamen was identified using a stereotactic method and the region of interest extended over 3 adjacent slices. Data for left & right putamen were averaged and analyzed using a 3-compartment model to calculate the combined forward rate constant (CFRC; the product of the association rate and the maximum number of available binding sites). We found a statistically significant reduction in dystonics ( $.020 \pm .069$  vs  $.028 \pm .138$ ;  $p < .05$ ). These data demonstrate a reduction of [18F]spiperone binding in putamen in patients with focal idiopathic dystonia, and strongly suggest an abnormality of dopaminergic receptor binding. (support: NINDS NS31001, NS32318, the Dana Foundation, the BEB Foundation & the Greater St. Louis Chapter of APDA).

**STUDY OF SERUM AND CSF NEUROTRANSMITTER AMINOACIDS IN YOUNG SUBJECTS WITH WRITER'S CRAMP.** A. Haque<sup>\*</sup>, I. Kabir, Z. Ahmed, MA Hannan and HKM Yusuf. Deptt. of Neurology, IPGMR, and Deptt of Biochemistry, University of Dhaka

Youngmen specially students are frequently attending the department of neurology, IPGMR, Dhaka, with features of writer's cramp. Clinical examinations revealed mild tremor and slight wasting of small muscles of hand. Personal and family history was negative. Serum T<sub>3</sub>, T<sub>4</sub>, ceruloplasmin, urinary copper level, X-ray neck and cervical myelogram including MRI in some cases and skin smear for AFB were normal. EMG and NCV studies were nonconclusive. Tranquilisers, and antiparkinsonian drugs were of no benefit. Seven of these subjects with mean age of 21  $\pm$  3 years consented to lumbar puncture. CSF and serum from these patients were collected. Aspartate, glutamate, GABA and glycine levels were measured by HPLC and were compared with findings of CSF and serum collected from 10 control subjects. The result shows significantly high ( $p < .001$ ) level of aspartate in patients serum ( $141 \pm 31$  nmol/ml) compared to  $29 \pm 31$  nmol/ml in control. The level of CSF glutamate in control was apparently higher. Difference in GABA and Glycine levels were not significant. High level of aspartate may suggest some motoneurone disease.

## 93.1

**ROLE OF VOLTAGE-GATED CALCIUM CHANNELS IN TRAUMATIC SPINAL CORD WHITE MATTER INJURY.** S.K. Agrawal\* and M.G. Fehlings. *Playfair Neuroscience Unit, The Toronto Hospital Research Institute, University of Toronto, Toronto, Ontario, Canada M5T 2S8*

Recent work has suggested the presence of voltage-gated  $\text{Ca}^{2+}$  channels in CNS white matter and a potential role in the pathophysiology of anoxic injury. To examine the relevance of these findings to traumatic spinal cord injury, the effect of zero calcium and the inorganic voltage-gated  $\text{Ca}^{2+}$  channel antagonist  $\text{Co}^{2+}$  were studied in an *in vitro* model of spinal cord injury. A 30mm length of dorsal column was isolated from the spinal cord of adult rats, pinned in an *in vitro* recording chamber and injured with a modified clip calibrated to deliver a 2g force for 15 sec.

A strip of dorsal column from adult rat spinal cord was pinned in a recording chamber which was perfused with oxygenated Ringer. Compound action potentials were recorded extracellularly from microelectrodes. Injury was accomplished by compressing the dorsal column strip *in vitro* with a 2 g clip for 15 sec. The CAP decreased to  $71.4 \pm 2.0$  % of control ( $p < 0.05$ ) after clip compression injury. Removal of extracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_o$ ) and replacement with 1.5mM EGTA promoted significantly greater recovery of CAP amplitude ( $86.3 \pm 7.6$  % of control;  $p < 0.05$ ) after injury. Partial blockade of voltage-gated  $\text{Ca}^{2+}$  channels with a low concentration of cobalt ( $20\mu\text{M}$ ) also conferred neuroprotection (CAP amplitude  $82.8 \pm 1.2$  % of control;  $p < 0.05$ ). Higher concentrations of  $\text{Co}^{2+}$  (2mM and  $200\mu\text{M}$ ) irreversibly reduced CAP amplitude in uninjured dorsal column segments suggesting a neurotoxic effect. The specific subtypes of  $\text{Ca}^{2+}$  channel blockers are presently under investigation.

In summary, reduction of  $[\text{Ca}^{2+}]_o$  confers neuroprotection after spinal cord injury *in vitro*. The injurious effects of  $\text{Ca}^{2+}$  in traumatically injured CNS white matter appear to be partially mediated by voltage-gated  $\text{Ca}^{2+}$  channels. (Supported by Medical Research Council of Canada).

## 93.3

**PROGRESSIVE DEGRADATION OF MAG IN SPINAL CORD INJURY (SCI).** N.L. Banik\*, D.C. Matzelle, G.G. Wilford and E.L. Hogan. *Neurology Dept, Med Univ SC, Charleston, SC 29425*

We previously correlated degradation of myelin and cytoskeleton proteins with axon and myelin degeneration in SCI implying a role for proteinases in SCI tissue degeneration. Examining whether myelin-associated glycoprotein (MAG) is degraded in spinal cord trauma, we determined the extent of its degradation (as a measurement of calpain activity) in lesion and control cord. SCI was induced in rats by weight-drop technique (40g-cm). Lesion and control cords were processed at defined time intervals following injury and analyzed by SDS-PAGE and immunoblotting in association with chemiluminescence using MAG antibody. The extent of MAG breakdown was calculated using PDI software after the gels were scanned. A small amount of MAG, 13% and 21%, was degraded at 30 min and 1 hr, respectively, while a significant breakdown of this protein (32%) was evident at 4 hr and a substantial amount (64%) was lost at 72 hr following trauma compared to the sham. The breakdown of MAG in SCI may be calpain mediated since MAG is degraded by purified calpain *in vitro* and calpain activity, content and immunocytochemical staining also increase following SCI. These results suggest that calpain, which degrades myelin and axonal proteins, plays an important role in the loss of membrane structural integrity leading to membrane dissolution and axonal degeneration in SCI. To maintain the axon-myelin structural unit and cell function in SCI, using calpain inhibitors may protect cells and preserve membrane by preventing protein degradation and restoring motor function. Supported by NIH-NINDS NS-31622 and PVA SCRF-1238.

## 93.5

**STRESS INDUCTION OF NEURONAL PRODUCTION IN THE BRAINS OF YOUNG AND ADULT RING DOVES.** M.-F. Cheng\* and J. Cao. *Institute of Animal Behavior/Psychology, Rutgers University, Newark, NJ 07102*

In the present study, we asked whether in the avian system, where newly generated subependymal zone (SZ) cells continue to migrate, differentiate and are incorporated into the adult brain, we may find stress-induced neurogenesis following electrolytic lesions in the parenchyma. Adult male ring doves received bilateral electrolytic lesions in the ventromedial nucleus (VMN), followed by a single i.m. injection of  $[\text{H}^3]$ thymidine. Birds were allowed to survive for 24 hr then killed for histological studies. Hu protein, a conserved marker for neuronal phenotype before mitotic cells initiate parenchymal migration (Barami et al., *J. Neurobiol.* 1995), was used to identify neuronal precursor cells among SZ cells. Using West's stereological methods for neuron counting, we found a significantly greater number of Hu+/newly generated ( $[\text{H}^3]$ thymidine labeled) cells in the VMN-lesioned than in the sham-lesioned brains. In a second experiment, VMN-lesioned birds were similarly treated but were killed at varying intervals. We found that with longer intervals the number of Hu+/newly generated cells increased in brain parenchyma while those in the SZ decreased. This suggests that Hu+/newly generated cells observed in the parenchyma migrated from the SZ. Supported by Hoechst-Celanese Award.

## 93.2

**EFFECT OF THE SODIUM CHANNEL BLOCKER QX-314 ON RECOVERY AFTER SPINAL CORD INJURY IN VIVO.** M.G. Fehlings\* and S.K. Agrawal. *Playfair Neuroscience Unit, The Toronto Hospital Research Institute, University of Toronto, Toronto, Ontario Canada M5T 2S8*

There is evidence that intracellular sodium  $[\text{Na}^+]_i$  entry potentiates spinal cord injury (SCI) and hypoxic/ischemic cell death *in vitro* by causing cytotoxic cell edema, intracellular acidosis and gating of  $\text{Ca}^{2+}$  entry by reverse activation of the  $\text{Na}^+-\text{Ca}^{2+}$  exchanger. Recently we obtained evidence suggesting that  $\text{Na}^+$  channels may participate in the pathophysiology of spinal cord white matter *in vitro* (Agrawal and Fehlings 1996 *J. Neurosci.* 16:545-552). In the present study, we examined the role of  $\text{Na}^+$  in mediating traumatic injury to spinal cord *in vivo*.

To test this hypothesis experiments were performed in a randomized block design. We examined the effect of QX-314, a potent  $\text{Na}^+$  channel blocker on recovery after SCI *in vivo*. QX-314 (2.0 and 10mM) or placebo (saline) was microinjected ( $2\mu\text{L}$  in 10min) into the injury site beginning at 15 min after SCI. Injury was performed by compression of the spinal cord at C7-T1 for 1 min with a modified aneurysm clip exerting a closing force of 35g. Neurological function was assessed one day after injury and weekly thereafter until six weeks by the inclined plane method and by the modified Tarlov technique. After six weeks of injury the origin of descending axons at the injury site was determined by retrograde labelling with Fluorogold (FG).

There was significant improvement in the counts of retrogradely labeled neurons in the red nucleus ( $p < 0.02$ ), and a trend toward increased cell counts in the sensorimotor cortex ( $p < 0.08$ ) and vestibular nuclei ( $p < 0.09$ ) as compared to control vehicle treated group. However, there was no improvement in clinical neurological function (inclined plane or Tarlov scores).

Our results suggest that the  $\text{Na}^+$  channel blocker QX-314 partially preserves the integrity of descending motor axons after SCI. The effects were insufficient to result in improved clinical function. Further studies are under way with other dose/drug combinations. (Supported by MRC of Canada).

## 93.4

**SODIUM CHANNEL BLOCKERS PROTECT AGAINST TRAUMATIC NEURONAL INJURY IN THE ADULT RAT SPINAL CORD.** S.M. Douglas\*, K.L. Panizzon and R.A. Wallis. *Spinal Cord Injury Lab., Sepulveda VA Medical Center, and UCLA School of Medicine, Los Angeles, CA. 90024*

We investigated whether sodium channel blockade would reverse the effects of traumatic injury to the adult rat spinal cord. Prior studies suggest that sodium channel blockers are neuroprotective against hypoxic injury. In addition, sodium channel blockers help prevent neurotransmitter release which plays a significant role in the evolution of traumatic neuronal injury. Therefore, we evaluated the effect of the sodium channels, lamotrigine and tetrodotoxin (TTX), against traumatic neuronal injury in adult spinal cord slices. To induce trauma, slices were placed in a specialized chamber filled with artificial cerebral spinal fluid. This fluid was then percussed and changes in evoked response were monitored. Slices given trauma alone demonstrated severe neuronal injury with dorsal horn evoked response recovering after 60 mins. to a mean of only  $15\% \pm 4$  of initial amplitude. Treatment with  $100\mu\text{M}$  lamotrigine begun after trauma, provided significant protection, yielding dorsal horn evoked response recovery of  $92\% \pm 5$ . Similarly, treatment with  $1\mu\text{M}$  TTX provided protection, yielding dorsal horn evoked response recovery of  $87\% \pm 3$ , while paired, unmedicated slices recovered to only  $13\% \pm 3$  ( $p < 0.05$ ). These findings indicate that the sodium channel blockers, lamotrigine and TTX, are protective against traumatic injury to dorsal horn neurons of the spinal cord. They further suggest that sodium channel opening plays a harmful role during the evolution of traumatic spinal cord injury. They additionally suggest that sodium channel blockers may be potential therapeutic agents in the treatment of spinal cord injury.

Supported by a VA Brain Trauma Fellowship and the VA Research Service.

## 93.6

**TEMPORAL PATTERNS OF HEAT-SHOCK PROTEIN 70 EXPRESSION FOLLOWING EXCITOTOXIC VS PENETRATING CORTICAL INJURY.** S.A. Dutcher, D.B. Michael, F.G. Diaz, and P.D. Walker\*. *Departments of Anatomy & Cell Biology, and Neurosurgery, Wayne State University School of Medicine, Detroit, MI 48201.*

It has been repeatedly observed that tissue regions subjected to stress and/or injury undergo a biosynthetic activation of heat shock proteins. In the damaged brain, heat-shock proteins may participate in the processing and stabilization of proteins critical to the survival of neurons and glial cells at the site of injury. In particular, the increased expression of constitutive and inducible members of the heat shock protein 70 (HSP70) family may serve as useful indicators of cells at risk following brain injury. The present study sought to compare the temporal pattern of HSP70 gene expression induced in excitotoxic vs penetrating cortical brain injury. Adult male SD rats (175-200g) received stereotaxic-guided stab wounds or small injections of quinolinic acid (QA, 240mM in 0.2  $\mu\text{L}$ ) into the frontal cortex. Animals were sacrificed at 1, 3, 6, 12 and 24 hours following surgery. Total RNA was isolated from the cortical site of injury and Northern analysis was used to measure HSP70 mRNA levels along with other injury-inducible mRNA species. Within the QA-injected cortex, HSP70 mRNA levels were significantly increased by 3 hours and peaked in expression at 12 hours before returning towards contralateral uninjected control levels by 24 hours. This pattern of HSP70 mRNA expression overlapped with immediate early gene activation and the induction of glial fibrillary acidic protein. The penetrating injury produced a similar, but less obvious, pattern of HSP70 mRNA. These results support the hypothesis that HSP70 gene induction may serve as a useful marker of damaged tissue following CNS injury. Supported by Fund for Medical Research and Education and NS30550.

## 93.7

**DOWNREGULATION OF THE ASTROCYTE GLUTAMATE TRANSPORTER GLT-1 mRNA IN BRAIN TRAUMA.**

M.D. Norenberg\*, W.D. Dietrich, W. Singer, R. Zhao, B. Zhou, R. Busto, M.D. Ginsberg. Departments of Pathology and Neurology, University of Miami School of Medicine, and V.A. Medical Center, Miami, FL 33101.

An excitotoxic mechanism is believed to play a role in traumatic brain injury (TBI). To examine whether a defect in glial glutamate uptake contributes to TBI, we performed an *in situ* hybridization study using an antisense riboprobe to the glial glutamate transporter GLT-1 in a parasagittal fluid percussion (FP) model of brain injury. Fasted Sprague-Dawley rats were anesthetized with 70% nitrous oxide, 1% halothane and 30% oxygen and injured with a FP pulse (1.6-1.9 atm). At 2, 4, 6, 24 and 72 hrs after TBI, brains were processed for *in situ* hybridization (n=4 in each group). In an additional 24 hr group, rats were pretreated with MK-801 (1 mg/kg). At 6 hrs after TBI, mild decreases in the expression of GLT-1 mRNA were seen in histopathologically vulnerable regions. By 24 hrs, moderate reductions in GLT-1 mRNA were detected throughout the ipsilateral hemisphere. The hybridization signal returned to normal at 3 days except in vulnerable cortical areas. Pre-treatment with MK-801 blocked the reduced expression of GLT-1 mRNA. These data indicate that TBI leads to a diffuse downregulation of the glial glutamate transporter. This may result in failure to remove extracellular glutamate and possibly contribute to excitotoxic injury and abnormal glutamatergic neurotransmission. The ability of MK-801 to inhibit the remote downregulation of GLT-1 mRNA suggests that spreading depression may play a role in this pathophysiological consequence of TBI. (Supported by NIH grant NS30291 and the Department of Veterans Affairs.)

## 93.9

**ADAPTATION OF THE FLUID PERCUSSION INJURY MODEL TO THE MOUSE.** W.S. Carbonell, D.O. Maris, R.F. Cody, T.D. McCall, R.H. Schmidt\*, M.S. Grady, Depts. of Neurological Surgery, Univ. of WA Sch. of Med., Seattle, WA 98104 and University of UT Med. Ctr., Salt Lake City, UT 84132.

Manipulation of the mouse genome causes functional consequences. Insight into the molecular mechanisms of cell-cell interactions and cell metabolism due to a broad spectrum of genes is thus provided. Many of these genes are important in the normal development of the CNS and maintenance of its connections. Recovery from traumatic brain injury (TBI) may rely on many of the same mechanisms operant in development such as axon guidance, synaptogenesis, and neuronal viability. The fluid percussion injury (FPI) model when applied to these transgenic mice may be a particularly useful experimental tool in evaluating specific sequelae of TBI. In the present study we establish FPI as a viable model of TBI in the mouse by characterizing acute response to injury and cognitive and histopathologic effects.

Male C57BL/6 mice (25-30 g) were anesthetized and injury cannulas were secured to a parasagittal craniectomy site. After a 24 hour surgical recovery period we performed a sham treatment (n=8) or FPI (under halothane, n=8) of 3.5 atmospheres. Acute neurological evaluation of the injured animals revealed occasional transient apnea (lasting 20 seconds or less) and delayed righting and paw and tail flexion reflexes as compared to controls. Deficits in cognition, specifically spatial memory, were assessed over post-injury days 5 through 7 using the Morris water maze (MWM). After the post-injury day 7 MWM testing, the mice were transcardially perfused and brains collected for histopathologic analysis. Gross analysis before sectioning revealed subdural hemorrhage in the vicinity of the injury site extending caudally. Cresyl violet stains showed mild cortical and subcortical tissue loss directly beneath the site of the fluid pulse. GFAP immunocytochemistry demonstrated extensive reactive gliosis in the hemisphere ipsilateral to injury. Other histological techniques performed include silver degeneration stain and TUNEL.

This new FPI model in the mouse makes possible numerous potential studies of neurological, behavioral, and histopathologic sequelae of TBI in transgenic and wild-type mice. As an added advantage, the mouse FPI model as described is immediately employable in labs already using the FPI rat model with no modification to the pre-existing FPI apparatus. Supported by NIH grant NS30305.

## 93.11

**Dynorphin Expression in Dorsal Horn Neurons Following Traumatic Spinal Cord Injury** T. Tachibana<sup>1,2</sup>, A. Arakawa<sup>1</sup>, M. Maruo<sup>1</sup>, K. Miki<sup>2</sup>, A. Tokunaga<sup>2</sup> and K. Noguchi<sup>2</sup>. <sup>1</sup>Dept. of Orthopedic surgery and <sup>2</sup>Dept. of Anatomy and Neuroscience, Hyogo College of Medicine, Hyogo 663, Japan

It has been suggested that the endogenous opioid dynorphin contributes to secondary tissue damage following spinal cord injury. This study was designed to examine the expression of preprodynorphin (PPD) mRNA at cellular level, and clarify the spatial and temporal properties of the expression in the injured spinal cord.

After deep anesthesia with sodium pentobarbital (50 mg/kg i.p.), male Sprague-Dawley rats were subjected to traumatic spinal cord injury at T13 spinal segment using the weight drop method. Control animals were subjected to laminectomy. These animals were evaluated on their ability to maintain position on an inclined plane and sacrificed 24h after surgery. Coronal sections were cut through the injured segment and processed for *in situ* hybridization. Neurons exhibiting the increase in the level of PPD mRNA were concentrated in the superficial laminae and the neck of dorsal horn within several spinal segments. The number of neurons expressing PPD mRNA were  $5.6 \pm 0.8$  per section in sham operated animals (the average maximum angles is  $64.5 \pm 1.1^\circ$ ),  $12.2 \pm 1.3$  in moderate paraplegic animals ( $55.5 \pm 9.7^\circ$ ), and  $16.5 \pm 2.0$  in severe paraplegic animals ( $38.0 \pm 3.7^\circ$ ). Number of neurons expressing PPD mRNA was correlated significantly with motor dysfunction ( $p < 0.05$ ). This finding suggests that *de novo* expression of dynorphin in dorsal horn neurons may have an important role in pathomechanisms of neurological dysfunction after spinal cord injury. ## 93.8

**DISCRIMINATION OF POST-TRAUMATIC MEMORY VS. LEARNING IN RATS USING THE MORRIS WATER MAZE.** R.F. Cody, M.M. Haglund\*<sup>1</sup>, M.S. Grady, D.O. Maris, Department of Neurological Surgery, University of Washington, Seattle, WA 98104, Duke University<sup>1</sup>, Durham, NC 27710.

Traumatic brain injury (TBI) has been shown to cause impairment of spatial abilities, such as performance in the Morris water maze (MWM). We were interested in whether memory of a previously-learned task could be differentiated from acquisition of a new task following TBI. Using a standard lateral fluid percussion injury (FPI) model, we administered moderate FPI or sham injury randomly to 32 adult male Long-Evans rats. Half of these rats had been pre-trained in the Morris Water Maze (MWM) to find a hidden platform 1 week prior to injury/sham, while the other half were naive. We then tested the rats at 2 weeks post-injury/sham in the MWM for retention of spatial memory (pre-trained groups) or learning of the spatial task (naive groups). Rats were re-tested in the MWM at 4, 8, and 16 weeks post-injury/sham.

Rats in the injured/naive group performed poorly in the MWM compared to the injured/pre-trained, sham/pre-trained, or sham/naive groups at 2 and 4 weeks, but were equal to the other groups by weeks 8 and 16. No significant differences were observed among either sham group or the injured/pre-trained group at any time point. This study suggests that spatial learning may be discriminated from spatial memory following TBI, and that prior training may help ameliorate post-traumatic MWM performance deficits following TBI. (Supported by NIH P 50 NS30305).

## 93.10

**QUANTITATION OF RAT HIPPOCAMPAL CELLS USING THE OPTICAL VOLUME FRACTIONATOR: A COMPARISON OF MIDLINE TO LATERAL FLUID PERCUSSION INJURY.** M.S. Grady\*, J.S. Charleston, D.O. Maris, Depts. of Neurological Surgery and Pathology<sup>1</sup>, Univ. of WA Sch. of Med., Seattle, WA 98104.

Fluid percussion injury (FPI), an experimental model of traumatic brain injury, causes spatial memory dysfunction in rats regardless of injury location (midline vs. lateral). Standard histological analysis of the brains post-injury show hippocampal neuronal loss after lateral injury, but not after midline FPI. We have used the Optical Volume Fractionator (OVF) stereology procedure to estimate volume changes and quantify neuronal loss/glia proliferation within specific subregions of the hippocampus after midline or lateral FPI. The OVF method is an unbiased cell counting procedure which combines cell numerical density estimates (from the optical disector) with volume estimates (generated by point counting and the fractionator stereology method) to produce an estimate of the absolute cell number for each subregion of the hippocampus. The method is capable of detecting subtle changes in cell populations within defined structures.

Twelve adult male Sprague-Dawley rats were randomly divided into 3 groups (n=4/group): midline injury, lateral injury, and naive. A single fluid percussion pulse of 4 atmospheres was delivered to anesthetized rats in the injured groups. Rats were transcardially perfused at 14 days post-injury with 4% paraformaldehyde and the brains were removed for processing and analysis. Rat brains were cut into 1 mm slabs in the coronal plane. All individual slabs were embedded in glycomethacrylate and serial sectioned at 20 or 30  $\mu$ m. Optical disectors were systematically placed across every 12th section containing the hippocampus and the volumes of hippocampal subregions were estimated by point counting on these same sections.

The results confirmed that the greatest loss of volume and neurons in the hippocampus corresponded with lateral FPI. However, subtle changes, not readily apparent with routine neuropathological examination, were also noted in the neurons and glial cell populations of the hippocampus following central FPI. The implications of the observed cell population changes are discussed in relation to the observed functional deficits associated with both lateral and central FPI. Supported by NIH grant NS30305.

## 93.12

**MODERATE FLUID-PERCUSSIVE BRAIN INJURY IN THE RAT: SENSORIMOTOR AND COGNITIVE EFFECTS, AND THE INFLUENCE OF POST-INSULT AMPHETAMINE** H.M. Bramlett\*, E.J. Green and W.D. Dietrich, Depts. of Psychology and Neurology, University of Miami, Coral Gables, Florida 33124.

Previous studies assessing the behavioral consequences of traumatic brain injury (TBI) in animals have demonstrated that those insults disrupt previously learned information. Much less attention has been given to anterograde learning deficits, which are observed clinically, or to cue-dependent learning, for which the hippocampus is critical. The current experiments were designed to address these issues by assessing the influence of TBI on the acquisition of both place and cue learning in the water maze (WM). An additional goal was to examine the effects of post-insult amphetamine on sensorimotor and cognitive behavior following TBI.

Anesthetized animals with a modified syringe hub implanted above the right parietal cortex were subjected to fluid percussive (FP) injury (1.8-2.2 atm) at normothermic brain temperature (37°C). Sham underwent all surgical procedures, but did not receive any FP injury. Seventy-two hours after surgery animals received either 4 mg/kg i.p. amphetamine (group TBI-A, n=7; group Sham-A, n=6) or vehicle (group TBI-V, n=7; group Sham-V, n=6). WM and sensorimotor (forelimb placing) testing began 48 hrs post-TBI and continued every 3 days for 6 weeks, and once during each of weeks 7 and 8. TBI animals exhibited WM place acquisition deficits until approximately 3 weeks post-injury ( $p < 0.002$ ). Sporadic deficits in cued learning were also observed in TBI animals ( $p < 0.002$ ). No group differences in WM swim speed were observed. TBI was associated with an impairment in contralateral vibrissae ( $p < 0.008$ ) and forelimb ( $p < 0.003$ ) placing, which persisted for approximately 3-4 weeks. Amphetamine did not significantly attenuate any of the deficits. The results of these experiments indicate that there is anterograde and retrograde amnesia in this model of TBI, and that WM deficits result, in part, from extra-hippocampal damage. The lack of evidence for facilitation of recovery by amphetamine in these experiments contrasts with the results of other studies in which such effects have been observed. (NS 30291)

## 93.13

PATTERNS OF BDNF, NGF, and HSP-70 GENE EXPRESSION FOLLOWING FLUID-PERCUSSION BRAIN INJURY: ANALYSIS BY IN SITU HYBRIDIZATION. M.D. Ginsberg, J.T. Singer, W. Zhao, W.D. Dietrich, O.F. Alonso, J.Y. Looor-Estades, R. Busto. Neurotrauma and CVD Research Centers, Univ. of Miami School of Medicine, Miami, FL.

Temporal patterns of gene expression were surveyed at 30 min, 2 h, 6 h, 24 h, 3 days, and 30 days following moderate fluid-percussion injury in halothane-anesthetized Wistar rats. In situ hybridization was carried out on coronal sections at 12 levels of the neuraxis using <sup>35</sup>S-labeled antisense riboprobes to the neurotrophins nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF); and the inducible heat-shock protein HSP-70 (n=5 rats per time point). BDNF and NGF were not constitutively expressed in sham rats. In FPI rats, both BDNF and NGF expression appeared at 30 min, peaked at 2-6 h, but was also present at lower levels at 6h - 3 d. For BDNF, dentate gyrus was most heavily labeled, as well as sectors CA3-4 of dorsal and ventral hippocampus, in most cases bilaterally, and in some unilaterally. By contrast, NGF expression was in most cases ipsilateral to trauma (or else ipsilateral >> contralateral), and involved dentate >> CA3-4. By 24 h-30 d, however, contralateral NGF labeling exceeded ipsilateral, representing a secondary injury response. HSP-70 expression, by contrast, was localized largely to the ipsilateral cortical impact site, highest at 2-6 h, and declining at 24 h. Expression of BDNF and NGF in hippocampal structures indicates that these regions are directly or secondarily affected by traumatic stress; contralateral expression suggests a transneuronally mediated effect of trauma.

## 93.14

EXTRACELLULAR RELEASE OF SEROTONIN FOLLOWING FLUID-PERCUSSION BRAIN INJURY IN RATS. R. Busto\*, W.D. Dietrich, O. Alonso, M.Y.-T. Globus, M.D. Ginsberg, Neurotrauma Research Center, Dept. of Neurology, Univ. of Miami School of Medicine, Miami, FL

Serotonin has been implicated in the pathobiology of CNS trauma. Using microdialysis techniques, we performed measurements of serotonin release within the primary somatosensory cortex of rats subjected to moderate fluid-percussion (F-P) brain injury. Twenty-four hours prior to TBI, a F-P interface was positioned parasagittally over the right cerebral cortex. On the second day, fasted rats were anesthetized with 70% nitrous oxide, 1% halothane and 30% oxygen. Under controlled physiological conditions and normothermic brain temperature (37-37.5°C), rats were injured (n = 6) with a F-P pulse ranging from 1.8-2.0 atm. Following trauma, brain temperature was maintained for 4 hr at 37°C during the microdialysis sampling period. Sham trauma animals (n = 7) were treated in an identical manner. TBI induced an immediate elevation in extracellular levels of serotonin (3.5-fold, p < 0.001, ANOVA) compared to sham-operated controls. The extracellular levels of serotonin remained significantly higher than baseline during the first 90 min sampling period (p < 0.05). In parallel to the increase in serotonin levels after TBI, a significant 71% decrease in extracellular 5-hydroxyindoleacetic acid (5-HIAA) levels was observed during the first 10 min after TBI. The present data indicate that TBI is followed by a prompt but sustained elevation in extracellular serotonin within cortical regions adjacent to the impact site. These neurochemical results implicate serotonin in the pathophysiology of TBI.

THE MOTOR SYNDROME OF CHOREA: LESSONS FROM THE CLINIC. L. Zhang, H. Mitumoto\* and R.S. Burns. Dept. of Neurology, Cleveland Clinic Foundation, Cleveland, OH 44195.

Chorea, one of the basic types of abnormal movements in man, is attributed to basal ganglia dysfunction, in particular, increased striatal dopaminergic activity. Our experience in a large number of patients where haloperidol suppressed the chorea is consistent with this view. A recent case of severe, intractable chorea suggests that the neural substratum of chorea is more complex. An 11 yr old girl with ataxic cerebral palsy first developed chorea after a varicella infection which lasted 3-4 mo and was controlled with diazepam. One year later, she developed severe chorea ('choreic storm') leading to rhabdomyolysis, myoglobinuria and acute renal failure. The control of her chorea became the focus of her management. She was unresponsive to dopaminergic (haloperidol, reserpine), GABAergic (baclofen, valproate, gabapentin), glutamatergic (amantadine) and cholinergic (trihexyphenidyl) agents as well as to benzodiazepines (diazepam, clonazepam). A surgical approach using a ventral medial pallidotomy was considered. Late in the hospital course, a T-2 weighted MRI brain scan showed an increased signal in the globus pallidus bilaterally. The pharmacological response profile in this case suggests that no one neurotransmitter pathway comprising the related motor circuits played a dominant functional role and that more complex changes in the balance of activity in multiple neurotransmitter pathways or in parallel circuits were involved. Study supported by the Neurology Department at the Cleveland Clinic Foundation.

## 94.2

INCREASING NUMBERS OF MUTANT MITOCHONDRIA MAY DETERMINE COURSE IN KEARNS-SAYRE SYNDROME. E.J. Fine\*, G.D. Vladutiu, C. Warner, R. Heffner. VA Medical Center and School of Medicine and Biomedical Sciences, State University of NY at Buffalo, Buffalo, NY 14215, L.-J.C. Wong, Children's Hospital, Los Angeles, CA 90027.

We sought to determine, if increased numbers of mutant mitochondria relate to clinical expression in Kearns-Sayre syndrome (KSS). A man experienced right (R) ptosis at age 12, left (L) ptosis at 14, corrected by plastic surgery at age 16. External ophthalmoplegia without limb weakness appeared at age 22 and became total at age 26. Single fiber electromyography (EMG) was normal. Conventional EMG demonstrated rare short duration polyphasic potentials (PP). R deltoid muscle (DM), R quadriceps (Q) biopsy showed a few central nuclei, but no ragged red fibers (RRF) at 25. Beginning at 26 he had persistent increased serum creatine phosphokinase, dysphagia, dysarthria and weakness only in deltoid muscles (DM). EMGs demonstrated myopathic changes only in DM. At age 27 L DM and L Q biopsies revealed only 1 RRF in right R DM. All oxidative enzyme levels were normal except succinic dehydrogenase and citric synthetase activity which were 49% and 58% of normal in L DM. PCR of mitochondrial DNA (mtDNA) from L DM showed 4.97 Kb deletion with junctional nucleotides at 8469:13447. No mutant mtDNA was detected in leukocytes or hair follicles. Auditory thresholds rose to abnormal from age 27-28. We interpret increasing weakness, CPK elevation, appearance of RRF are due to increased mutant mitochondria. We propose increasing mutant mitochondria determine clinical course in KSS.

EXPRESSION OF MATRIX METALLOPROTEINASES AND THEIR INHIBITORS IN THE DELTOID AND PSOAS MUSCLES OF ALS PATIENTS. I. G. Lin, G. P. Lim, M. J. Cullen, R. D. Atkinson and Z. A. Tokes\*. Univ. Southern Calif. School of Medicine, Los Angeles, CA 90033.

Increased expression of matrix metalloproteinase MMP-9 (92 kDa, gelatinase B) is observed in Alzheimer (AD) hippocampus and in amyotrophic lateral sclerosis (ALS) frontal and occipital cortices, and cervical, thoracic, and lumbar regions of the spinal cord (Backstrom et al., *J. of Neurochemistry*, 1992; Lim et al., *J. of Neurochemistry*, 1996). The expression of MMP-2 (70 kDa, gelatinase A) is unchanged in AD and decreases in ALS motor cortex. MMP-2 is localized in astrocytes, while MMP-9 is synthesized in the neurons. Neuron-derived MMP-9 may alter synaptic architecture and contribute to neurodegeneration. To test this hypothesis, the expression of matrix metalloproteinases and their tissue inhibitors (TIMP-1, and -2) was studied in deltoid and psoas muscles of ALS and control patients. Zymography using gelatin as substrate, reverse zymography, and Western blots in combination with enhanced chemi-luminescence were used to measure the expression of these enzymes and their inhibitors, and immunohistochemistry was used to establish their cellular location. Elevated levels of high molecular mass complexes of MMP-9 (110 kDa) and three molecular forms of MMP-2 (60, 56, and 49 kDa) were observed in ALS muscles. MMP-9 appeared to localize at the cell surface in structures resembling the neuromuscular junction. TIMP-1 expression was lower in ALS muscles than in control specimens whereas no significant changes were seen in TIMP-2 levels. These results are consistent with the hypothesis that an MMP-9/TIMP-1 imbalance may contribute to the neuromuscular degeneration in ALS patients. Supported by the ALS Association, and NIA R01-AG09681.

## 94.4

INCREASED LEVELS OF HYDROGEN PEROXIDE IN CELL LINES DERIVED FROM SIXTEEN FALS PATIENTS WITH DIFFERENT CuZnSOD MUTATIONS. M.S. Ahmed, W.-Y. Hung, D. Heintz, P.E. Hockberger, T.A. Skimina and T. Siddique\*. Depts. of Neurology & Physiology, Northwestern Univ. Med. School, Chicago, IL 60611

We used fluorescence spectroscopy and digital imaging of 2',7'-dichlorofluorescein (DCFH) and hydroethidine to monitor oxygen free radicals in lymphoblast cell lines derived from patients with familial amyotrophic lateral sclerosis (FALS) which have mutations in CuZnSOD, sporadic ALS (SALS) and controls (spouses of ALS patients). We also tested the influence of antioxidants and inhibitors of antioxidant enzymes on the oxidation of these probes. The results showed that the oxidation of hydroethidine (specific for superoxide anion) in all groups studied were comparable despite 45% decreased CuZnSOD activity in FALS mutants. FALS mutants, however, showed significant increased of DCF fluorescence compared with SALS and normal controls. Further, cells incubated in vitamin C, catalase, or the flavonoid quercetin displayed significant decrease of DCF fluorescence in all groups. The inhibitor of catalase, 3-amino-1,2,4-triazole, resulted in ten-fold increase of fluorescence in all groups. L-nitroarginine (inhibitor of nitric oxide synthase) and vitamin E had no effect on the oxidation DCFH. These studies suggest an increase level of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) in cells derived from FALS resulting from either (i) increased production of H<sub>2</sub>O<sub>2</sub> and/or (ii) increased accessibility of H<sub>2</sub>O<sub>2</sub> to DCFH.

This research was funded in part by NIH (NS-31248 and NS-21442), Les Turner ALS Foundation, and the Muscular Dystrophy Association.

## 94.5

## DEGENERATION OF SPINAL INTERNEURONS IN ADDITION TO MOTONEURONS IN A TRANSGENIC MOUSE MODEL FOR ALS.

D. Jaarsma<sup>1</sup>, J. Kennis<sup>1</sup>, D. Troost<sup>2</sup>, J.M.B.V. De Jong<sup>3</sup>, J.C. Holstege<sup>1</sup>. <sup>1</sup>Dept. Anatomy, Erasmus Univ. Rotterdam, 3000DR; <sup>2</sup>Depts. Pathology & <sup>3</sup>Exp. Neurology, AMC, Amsterdam, The Netherlands.

SOD-1 mutations, as found in a subset of cases of familial ALS, cause severe progressive motoneuron disease when expressed in transgenic mice. We have studied the distribution of neuronal degeneration in a line of transgenic mice carrying human SOD-1 with a gly<sup>93</sup>-ala mutation produced by Gurney et al. (Science 264:1772, Jackson Laboratories) using a silver impregnation procedure specific for degenerating neurons and their processes (Nadler and Evenson, Meth. Enzymol. 103:393-400). Parallel sections were stained immunocytochemically for choline acetyltransferase (ChAT) and calretinin (CR) to determine loss of motoneurons and CR-positive neurons in lamina VI-VIII, respectively. In animals sacrificed before the onset of clinical disease (at 5-6 months of age) no argyrophilic structures were observed in spite of the presence of vacuoles in dendrites and axons in spinal and bulbar motoneurons. Transgenic mice perfused 0-5 weeks following the onset of clinical signs (6-8 months of age) showed an increasing amount of argyrophilia in the brainstem reticular formation and the spinal cord white and grey matter. Argyrophilia was never observed in telencephalic and diencephalic areas. The density of argyrophilia correlated with the severity of paralysis and loss of ChAT-positive motoneurons, but argyrophilic motoneurons were rarely seen. Substantial degeneration of spinal interneurons was suggested by the presence of argyrophilia in the ventral and lateral funiculi, the presence of medium-sized argyrophilic neurons in lamina VI-VIII, and by the loss of CR-positive neurons in lamina VI-VIII. So far our results also show that interneuronal degeneration occurs after or simultaneously with motoneuron loss, but not before. (Funding: Prinses Beatrix Fonds and FGG-EUR-ANA-11-02-11)

## 94.7

BIOLOGICAL EFFECT OF MOTONEURONOTROPHIC FACTOR ON WOBBLER MICE WITH MOTONEURON DISEASE. RMW Chau<sup>\*</sup>, XY Wu and SSW Chan.

Dept of Anatomy, Faculty of Medicine, The University of Hong Kong, Hong Kong. Motoneuronotrophic factor1 (MNTF1) identified by a "protein band-fishing by cells" method promotes the survival and growth of isolated spinal motoneurons in vitro and the rescue and axonal regeneration of axotomized motoneurons in vivo. Monoclonal antibody (Mab) for MNTF1 and idiotype antibody (Id-ab) for its putative receptor used for their localization revealed that immunopositive stainings for Mab and Id-ab were localized in the cytoplasm and at the peripheral, respectively, of the soma of anterior horn motoneurons of the cervical and lumbar spinal cords and in those muscles of the fore- and hind-limbs of wobbler mice. As neuromuscular degeneration progressed from stage 1 to 4, the number of stained motoneurons and fibers and the relative intensities in them were reduced very significantly, especially in the cervical spinal cord and muscles of the forelimb. MNTF1 (35µg/kg) in cut-out gels were implanted once dorsally in between the trapezius and rhomboid major muscles around the vertebral column at C7-T2 level of wobbler mice at stage 1 of the motoneuron disease. The general health conditions and motor activities were improved noticeably within 2 weeks after MNTF1 treatment when compared to untreated control groups. The pathologic conditions of the forelimb muscles in paw contraction and elbow and shoulder joint movements of these treated wobbler mice were arrested at a grade 1 level in stage 1 of the motoneuron disease at 7 months posttreatment when compared to untreated control groups with degenerating neuromuscular activities and death after 3 months of age. Under LM, anterior horn motoneurons of the treated group appeared almost normal with a few small vacuoles existed in the cytoplasm when compared to the normal motoneurons of their littermates; however, those motoneurons of the untreated groups appeared fewer and smaller with many large vacuoles but fewer Nissl's granules in their cytoplasm, especially in the cervical spinal cord. These results indicated that the target-derived MNTF1 arrests further pathologic development of the motoneuron disease in treated wobbler mice. Supported by HKU & GF grants.

## 94.9

PROGRESSIVE MOTOR DEFICITS IN SOD1 DEFICIENT MICE A.G. Reaume, J.A. Gruner, E.K. Hoffman, D.S. Howland<sup>\*</sup>, R. W. Scott. Dept. of Molecular Biology, Cephalon, Inc. West Chester, PA 19380

Since the discovery that mutations in the superoxide dismutase-1 (SOD-1) gene are associated with familial forms of amyotrophic lateral sclerosis (FALS) a great deal of attention has focussed on the role of SOD-1 in the maintenance of motor neurons. Previously we have shown that mice completely lacking SOD-1 do not develop overt muscle paralysis with age as is characteristic of mice that express an FALS mutant form of the SOD-1 gene (Reaume et al (1996) Nature Genet. 13: ). We also have shown that 4 month old SOD-1 deficient animals are more vulnerable to cell death associated with facial motor nerve axotomy. Running wheel activity, stride length, and grip strength tests were used to compare the SOD1 mutant mice to their wild-type counterparts. Deficits were found associated with aged animals. In addition, the same tests were used to examine both wild-type and SOD-1 mutant mice that either had been allowed to run on a wheel for over a 1 year period or had had received no exercise. Finally, a significant reduction in sciatic nerve conduction velocity was found in SOD knockout animals between 5 and 7 months in age. The results are consistent with our previous hypothesis that although lack of Cu/Zn SOD function does not appear to cause FALS it influences the outcome of neurons exposed to stress and may have a maintenance role in motor neuron function.

## 94.6

CLINICAL AND HISTOMETRIC EFFECTS OF GLIAL-CELL-LINE-DERIVED NEUROTROPHIC FACTOR (GDNF) ON WOBBLER MOUSE MND. B. Klinkosz<sup>\*</sup>, Q. Yan, T. Ishiyama, E. Piro, and H. Mitsumoto. Dept. of Neurology & Neuroscience, Cleveland Clinic Foundation, Cleveland OH 44195, and Amgen Inc., Thousand Oaks, CA 91320.

GDNF is a potent motor neuron protecting factor. The effects of this neurotrophic factor were tested on wobbler mouse MND. Following the clinical diagnosis, affected animals received subcutaneous injections (6 times/week) of 20 mg/kg GDNF (n=11) or vehicle solution (n=10), in a blinded fashion for 4 weeks. Disease progression was evaluated weekly. After the treatment, animals were perfused, and C5&C6 spinal cord and ventral roots were studied. One mouse died in the GDNF-treated group. Body weight gain was not different between the two groups. Grip strength in GDNF-treated animals was maintained for the first 2 weeks, and thereafter slowly reduced, whereas vehicle-treated animals steadily lost their grip strength. Grip strength at week 4 was 265% better in the GDNF than in the vehicle-treated animals (P<0.002). Running speed was also better in GDNF-treated animals at week 4 (P<0.0005 compared to control). Paw position and walking pattern abnormalities deteriorated only modestly in the GDNF-treated animals. Locomotion activity was also greater in the GDNF-treated mice than in the vehicle-treated mice (P<0.02 from week 3). In-vivo biceps twitch tension was 50% greater in GDNF- than vehicle-treated group (P<0.05). The total number of myelinated nerve fibers at C5 ventral root level was significantly greater in the GDNF group (674.1±88.6), compared to that in vehicle animals (567.8±65.4) (P<0.01). In GDNF-treated animals, myelinated fibers of all sizes increased. GDNF significantly reduced the number of acute axonal degeneration (myelin ovoid) compared to vehicle-treatment (P<0.005). GDNF did not prevent motor neuron vacuolar degeneration. Our study showed that GDNF significantly reduced the rate of motor dysfunction and loss of motor axons in wobbler mouse MND.

## 94.8

FALS-RELATED SOD-1 MUTATIONS INCREASE INTRACELLULAR FREE RADICAL CONCENTRATIONS AND CELL MORTALITY IN DIFFERENTIATED PC12 CELLS. L. Lee<sup>\*</sup>, V.P. Bindokas, R.P. Roos<sup>1</sup>, R.J. Miller and G.D. Chidge<sup>1</sup>. Dept. Pharmacol. and Physiol. Sci. and <sup>1</sup>Dept. of Neurology, University of Chicago, Chicago, IL 60637.

We are studying the mechanism of selective motoneuronal death associated with FALS and ALS. We sought to devise a convenient cell culture model for examining potential mechanisms of neurodegeneration in FALS and potential therapeutic approaches. Human SOD1 WT or mutant (A4V, V148G) genes were delivered by adenovirus into differentiated PC12 cells. Mock and AdlacZ infections were used as controls. The same number of PC12 cells were initially plated on each coverslip and cells were differentiated by applying NGF. Western blot analyses confirmed expression of WT and mutant SODs. Cell death was analyzed 5 days after infection by staining with fluorescein diacetate and propidium iodide. Infection with AdlacZ and AdWT SOD1 did not produce significant mortality compared to mock-infected cells. However, approximately 50% cell mortality was observed with both mutant forms of SOD. The toxic effects of mutant SODs were ameliorated by metal chelators. The copper chelator TEPA (50 µM) had no toxicity in AdlacZ and mock-infected or AdWT SOD1-infected cultures, and fully protected the cells from death following infection with AdSODV148G or AdSODA4V. Similar protective effects were obtained with DDC, catechol, and 1,10-phenanthroline. Intracellular superoxide concentrations under basal conditions and following stimulation with FCCP and H<sub>2</sub>O<sub>2</sub> were monitored using hydroethidine fluorescence. Transfection with either of the mutant SODs produced significantly increased superoxide production above levels found in mock-, lacZ-, and WT-transfected cells. These data suggest mutations in SOD1 result in disturbance of cellular free radical content and that this may be related to increased cell mortality. (This work was supported by PHS grants DA-02575, DA-02121, MH-40165 and NS-33502 to R.J.M.).

## 94.10

## OXIDATIVE STRESS, CALCIUM DYSREGULATION AND SUSCEPTIBILITY TO EXCITOTOXICITY IN SPINAL CORD NEURONS FROM MICE EXPRESSING SOD1 MUTATIONS.

Q. Bar-Peled<sup>\*</sup>, P. Wong<sup>†</sup>, J.J. Vornov, and J.D. Rothstein. Johns Hopkins University, Dept. of Neurology and Neuropathology<sup>†</sup>, Baltimore, MD 21287.

Amyotrophic lateral sclerosis (ALS) is a sporadic and hereditary motor neuron disease. Mutations in superoxide dismutase 1 (SOD1), an enzyme that catalyzes the dismutation of superoxide radical into hydrogen peroxide, causes ALS in approximately 15% of familial cases. Transgenic mice that overexpress the mutant forms of SOD1 (G37R) develop progressive motor neuron disease (Neuron 1995, 14:1105). For *in vitro* studies of large motor neurons (LMN) and their response to excitotoxicity, dissociated spinal-cord cultures were prepared from 13 day old transgenic fetuses. Spinal cord cultures were exposed to kainate (25µM) for 20h and LMN were identified by immunoreactivity for non-phosphorylated neurofilament. A two fold increase in kainate-induced LMN cell death was found in G37R cultures as compared to non-transgenic controls. The role of Ca<sup>2+</sup> in triggering neuronal degeneration was examined using Fura-2. Analysis of intracellular Ca<sup>2+</sup> in spinal neurons was performed following 10 min exposure to kainate (25µM). At that point, the percent of neurons with Ca<sup>2+</sup> levels above 200nM was 3 fold higher in G37R cultures as compared to non-transgenic. The possibility that G37R-related oxidative stress is involved in neuronal degeneration was examined by intracellular glutathione (GSH) measurements using monochlorobimane (mBCl, 40µM), a fluorescent indicator for GSH. Cultures were first treated with buthionine sulfoximine (BSO, 50µM), an inhibitor of GSH synthesis, thus permitting an accurate measurement of oxidative stress-dependent changes in the levels of GSH. G37R spinal neurons had a marked decrease in GSH levels compared to non-transgenic controls. These results suggest that the G37R mutations produce increased oxidative stress *in vivo*. Furthermore, these oxidative processes may lead to destabilization of calcium homeostasis, explaining the increased susceptibility to excitotoxicity. (Supported by NIH and MDA)

Somata and Nuclei of Motoneurons are Enlarged in *mnd* Mutant Mice. **Maria Watson\***, **Anne Messert†** & **S. Marc Breedlove**. Dept. Psychology, U. California, Berkeley, CA 94720; †Wadsworth Ctr., N.Y. State Dept. Health & Dept. Biomed Sci., SUNY, Albany, NY 12201.

Mice homozygous for the motor neuron degeneration (*mnd*) mutation display delayed neuronal degeneration. In order to investigate the specificity of the process in sub-populations, we examined discrete spinal motor nuclei in homozygous *mnd* and wild-type male and female mice.

Mice 9-10 months of age were sacrificed and perfused with 4% paraformaldehyde, the spinal cords were removed and post-fixed in buffered formalin. Cords were frozen-sectioned in the coronal plane at 40  $\mu$ m, and stained with thionin. An observer blind to experimental conditions counted the number of lower lumbar motoneurons in the reticulospinal nucleus (RDLN) and the rodent homologue of Onuf's nucleus, the spinal nucleus of the bulbocavernosus (SNB), and measured the size of the somata and nuclei of motoneurons in these pools. As previously reported, there was a sex difference in the number of SNB cells, but not in the number of RDLN cells. We found that homozygous *mnd* mice did not differ significantly from wild-types in the number of motoneurons in either of these groups. However, the size of RDLN somata and nuclei were significantly larger in *mnd* mice of either sex ( $p < .01$ ).

RDLN somata:	Males	Females
wild-type:	525.0 $\pm$ 26.15 (N=5)	474.3 $\pm$ 37.13 (N=5) $\mu$ m <sup>2</sup>
<i>mnd</i> mice:	569.4 $\pm$ 31.10 (N=6)	640.4 $\pm$ 29.84 (N=5)

Enlarged cross-sectional areas of RDLN motoneurons in the mutant mice may reflect a chromatolytic reaction prior to death and/or the appearance of inclusion bodies. The lack of a difference in RDLN number between wild-type and mutant animals may mean that the disorder had not progressed sufficiently by the time of sacrifice to result in disappearance of this set. Other spinal neuronal populations will also be examined. Supported by NS28421 to SMB; NS29110 and the ALS Assoc. to AM.

## 94.13

#### IDENTIFICATION OF *mdx* MICE SPECIFIC GENES EXPRESSION BY DIFFERENTIAL DISPLAY PCR.

**L.N.J.L. Marlier\***<sup>1,2</sup>, **D. Pierucci**<sup>2</sup>, **O. Porzio**<sup>2</sup>, **M. Minieri**<sup>2</sup>, **G. Silvestri**<sup>3</sup>, **P. Borboni**<sup>2</sup> and **R. Massa**<sup>3</sup>.

1: Inst. Exp. Med. (CNR), 2: Dept. of Internal Medicine, 3: Dept. of Neurology, Univ. of Rome "Tor Vergata", Italy.

The mutant *mdx* mouse is a well known model of the human Duchenne Muscular Dystrophy. In *mdx* mice, an altered expression of genes other than dystrophin, has been poorly investigated. In this study, the PCR-related procedure named differential display PCR (DD-PCR) was used to identify genes that are differentially expressed especially during the onset of the disease. For this purpose, two weeks old *mdx* mice muscles were processed for RNA extraction and used in a standard DD-PCR assay (GeneHunter) in parallel to muscle RNA prepared from control mice. Expression of numerous genes was up- or down-regulated on displayed gels. So far, we studied 19 fragments, that seem differentially expressed. These fragments were cloned. Among the 42 clones obtained, 12 were sequenced. Four of these sequenced clones had more than 85% homology with sequences known from the GeneBank database. In order to confirm such differential expression, northern blot hybridization studies were performed using 2 weeks (onset time point), 8 weeks and 6 months old *mdx* and control mice RNA. Two genes were clearly down-regulated in all *mdx* mice when compared to normal respective control mice. The two other RNA investigated showed, on the contrary, an almost similar level of expression. Other fragments are currently under analysis to confirm their differential expression. These results would suggest that *mdx* mice related disease might be associated to altered expression of several genes such as ion-channels proteins, docking proteins and/or collagen isoforms expression. This would support the hypothesis of secondary alterations in genes expression with possible implication in the pathophysiology of muscle fiber necrosis and regeneration.

## 94.15

#### 4-AMINOPYRIDINE IMPROVES MOTOR UNIT PERFORMANCE IN CANINE MOTOR NEURON DYSTROPHY.

**R.F. Waldeck**<sup>1</sup>, **T.C. Cope**<sup>2</sup>, **L.C. Cork**<sup>3</sup> and **M.J. Pinter**<sup>1</sup>, <sup>1</sup>Medical College of Pennsylvania, Philadelphia, <sup>2</sup>Emory University School of Medicine, <sup>3</sup>Stanford University School of Medicine

Hereditary Canine Spinal Muscular Atrophy (HCSMA) is an autosomal dominant disorder of motor neurons that shares features with human motor neuron disease. In animals exhibiting the accelerated phenotype (homozygotes), we have demonstrated previously that many motor units exhibit functional deficits that likely reflect underlying deficits in neurotransmission. In this study, we determined whether and to what extent 4-aminopyridine (4AP), which blocks K<sup>+</sup> channels, could improve motor unit performance in HCSMA. Systemic 4AP delivered in doses of 1-2 mg/kg increased nerve-evoked whole muscle twitch force and electromyograms (EMG) in parallel. These effects were larger in older homozygous animals that were profoundly weak and possessed failing motor units than in similarly-aged, symptomless HCSMA animals or in one younger homozygote that did not yet possess failing motor units. Direct testing of 4AP on single failing motor units showed that twitch force and EMG could be significantly increased, unit EMG trial-to-trial variability decreased and unit twitch EMG potentiation eliminated. 4AP increased peak forces reached during unit tetanic activation at all frequencies tested, and reduced tetanic force failure at lower frequencies. A comparison between 2 units obtained in a single animal showed that the motor unit exhibiting more force failure during tetanic activation also showed greater 4AP effects. These results indicate that failing motor units in HCSMA possess significant residual functional capabilities that can be demonstrated after 4AP administration. Supported by PHS grant NS31621

## 94.12

INHIBITION OF MYOTONIN-PROTEIN KINASE (MT-PK) CAUSES APOPTOSIS IN MUSCLE CELLS. **S. Bhagwati**, **B. Leung**, **A. Ghatpande** and **A. Stelzer\***, Department of Neurology, SUNY HSCB, Brooklyn, New York 11203.

The mutation responsible for myotonic dystrophy (DM) has been identified as an aberrantly expanded (CTG)<sub>n</sub> repeat in the 3' untranslated region of the DM gene. The DM gene encodes a 72 Kd Protein named Mt-PK which is expressed in skeletal and cardiac muscle and brain but nothing is known of the substrate molecule or function of Mt-PK. Knowledge of the function of Mt-PK should provide important insights into the pathogenesis of DM, which remains a puzzle. To determine the function of Mt-PK we introduced a specific antibody to Mt-PK inside cultured human myoblast cells with a lipid carrier, and show that this resulted in apoptosis in 30 to 40% of the cells within 24 hours (unlike control antibodies which had no effect). To confirm the specificity of this result we transfected myoblasts with a C5 propynyl-pyrimidine modified phosphorothiotate anti-sense oligodeoxynucleotide targeted to the translation initiation site of DM mRNA, which resulted in specific reduction of 62 to 74% in the levels of Mt-PK. A large percentage (52 to 73%) of myoblasts transfected with this oligonucleotide (but not control sense or scrambled oligonucleotides) underwent apoptosis within 24 hours. These results provide the first clue to the possible physiological role of Mt-PK and suggest that it may play a role as a cell survival molecule in muscle cells. Future studies should look for the presence of apoptosis in tissues from DM patients. Supported by an NIH grant.

## 94.14

MUTATIONAL ANALYSIS IN A CONGENITAL MYASTHENIC SYNDROME (CMS) REVEALS A NOVEL ACETYLCHOLINE RECEPTOR (AChR)  $\epsilon$  SUBUNIT MUTATION **K. Ohno**, **T. Fukudome**, **S. Nakano**, **M. Milone**, **T.E. Feasby**, **G.M. Tyce\***, and **A.G. Engel**, Mayo Clinic, Rochester, MN 55905

To determine the basis of a severe CMS present since birth, electrophysiological, <sup>125</sup>I- $\alpha$ -bungarotoxin ( $\alpha$ BGT) binding, electron microscopy, and molecular genetic studies were carried out. In the propositus, the number of AChR/endplate (EP) was 20% of normal. EP fine structure was preserved but the density of AChR on the junctional folds, determined with peroxidase-labeled  $\alpha$ BGT, was greatly attenuated. Miniature EP currents had markedly reduced amplitude and a prolonged monoexponential decay. Direct sequencing of PCR-amplified exons and adjacent intronic regions of  $\alpha$ -,  $\beta$ -,  $\delta$ -, and  $\epsilon$ -subunit genes revealed a homozygous 20-bp deletion in  $\epsilon$  exon 10 ( $\epsilon$ 1012del20) that encodes the long cytoplasmic loop of  $\epsilon$  and predicts 31 missense codons after codon 348 followed by a stop codon. An affected brother was also homozygous for the deletion; the unaffected parents and a normal sibling were heterozygous for the same deletion, indicating that the mutation is recessive. The homozygous  $\epsilon$ 1012del20 mutation can readily account for the severe EP AChR deficiency and the clinical symptoms. Moreover, the prolonged EP currents suggest the presence of  $\gamma$  subunits in EP AChRs. Expression studies are in progress. Supported by NIH Grant NS6277 and an MDA Research Grant.

## 94.16

MYOTONIC DYSTROPHY KINASE SHOWS A SPATIALLY AND TEMPORALLY DYNAMIC PATTERN OF EXPRESSION IN CNS DEVELOPMENT. **A. Balasubramanyam**, **D.V. Iyer**, **C. Beaulieu**, **A. Potvin**, **A. Neumeier**, **J. Avruch**, **H.F. Epstein\***, Depts of Medicine and Neurology, Baylor College of Medicine, Houston, TX; Dept of Pathology, University of Montreal, QUE; Depts of Neurology and Medicine, Massachusetts General Hospital, Boston, MA.

Myotonic dystrophy is characterized by CNS dysfunction, including varying degrees of mental retardation, cognitive deficiencies, retinal abnormalities and sleep disorders. Myotonic dystrophy protein kinase (DMPK) is the product of the gene linked to the illness. Its regulation and physiological roles have not been specified.

We have performed precise localization studies of DMPK in the central nervous system of the rat at the light and electron microscopic levels. Using a highly-specific antibody against an epitope in the helical domain of DMPK, we find that DMPK expression in the post-natal CNS follows a unique developmental sequence: faintest expression at post-natal day 0 (P0), faint expression at P7, prominent expression in most neuronal cell types with a peak of staining intensity at P14 to P21, followed by restriction of expression to specific subsets of neurons between P21 and P28. The restricted distribution persists into adulthood. The timetable of this dynamic expression correlates with key post-natal maturational events in the CNS of the rat and suggests that DMPK is functionally related to this process.

In the adult CNS, specific staining occurs in particular subsets of cells, e.g., in hippocampus (principally basket cells and oriens/alveus interneurons), cerebellum (Purkinje cells and Golgi neurons, but not granular neurons) and spinal cord (large motoneurons). Electron microscopy reveals that DMPK is localized to the endoplasmic reticulum within somata and in association with microtubules within proximal dendrites. These patterns of development and localization may be useful in elucidating the diverse central nervous system dysfunctions in myotonic dystrophy. [Support: NIH and JDF (AB); MRC Canada (CB)]

## MODULATION OF INTRACELLULAR CALCIUM IN DYSTROPHIC SKELETAL MUSCLE CELLS.

A. C. Passaquin, W. J. Leijendekker, L. Bernheim\* and U. T. Ruegg  
School of Pharmacy, Lausanne Univ., CH-1015 Lausanne, Switzerland.

Duchenne muscular dystrophy (DMD) patients and *mdx* mice suffer from a genetic disorder characterized by the absence of the cytoskeletal protein dystrophin. The chain of events leading from the absence of dystrophin to muscle degeneration remains unclear. A pathological increase in cytosolic calcium concentrations ( $[Ca^{2+}]_i$ ) has been incriminated as a potential mechanism. We have therefore studied  $[Ca^{2+}]_i$  handling (using either  $^{45}Ca^{2+}$  influx or fura-2) in skeletal muscle cells of several origins: the C2 cell line, *mdx*-derived primary cultures, myogenic H2K clones, and clones of DMD-derived myogenic cells. Resting  $[Ca^{2+}]_i$  were similar in dystrophin-deficient myotubes when compared to normals. Under stress conditions (i.e. high  $[Ca^{2+}]_i$  or osmotic shock),  $[Ca^{2+}]_i$  as well as  $^{45}Ca^{2+}$  influx were increased in both dystrophin-deficient and normal cells but this increase was more prominent in myotubes from *mdx* primary cultures. This gives support to the above hypothesis implicating  $Ca^{2+}$  dysregulation as a key feature of the dystrophic phenotype. However, stress imposed on dystrophin-lacking clones (from both mouse and human origin) was without effect, suggesting that exogenous factors present only in primaries could be involved in the  $Ca^{2+}$  rise. With the aim of counteracting a pathological increase in  $[Ca^{2+}]_i$  by pharmacological means, we have examined several compounds. Among them,  $\alpha$ -methylprednisolone, the only drug known to exert a beneficial effect in DMD, the protease inhibitor calpeptin, the blocker of stretch-activated calcium channels  $Gd^{3+}$  and the energy supplier creatine proved efficient in lowering the  $Ca^{2+}$  increase. We are currently investigating the mechanisms involved in these effects.

## EXPRESSION PATTERNS OF THE SMN GENE, THE HUMAN SPINAL MUSCULAR ATROPHY DETERMINING GENE, IN THE MAMMALIAN CENTRAL NERVOUS SYSTEM. A. Princivalle, F. Forti, F. Clementi\*, M. Zeviani, and G. Battaglia. Neurological Institute "C. Besta", and Dept. of Medical Pharmacology, Univ. of Milano, Italy.

The Survival Motor Neuron gene (SMN) is the proposed gene for human spinal muscular atrophy (Lefebvre et al. 1995). The deduced aminoacid sequence of the human SMN gene is a 32 Kd protein of unknown function, and with no sequence homology with any known protein. In the present work the SMN gene analog was characterized in the rat, and the anatomical expression of the SMN gene was investigated in the central nervous system of different mammals, by means of in situ hybridization (ISH) and immunocytochemistry (ICC) techniques. Using pairs of primers designed on the human sequence, the cDNA corresponding to the SMN ortholog was amplified by RT-PCR on rat liver poly(A)+ RNA. The deduced rat protein is about 90% similar to the human SMN protein product. The rat and human exon 3 sequences were then amplified by PCR technique, and the amplified exons used as templates to obtain radiolabeled antisense riboprobes. Two oligopeptides corresponding to the N-terminus and C-terminus of the human protein were produced, and employed as antigens to raise specific polyclonal antisera in rabbits. The ICC experiments revealed that the protein was mainly expressed in the cytoplasm of neurons in all the examined species, and that was widely but unevenly distributed throughout different cerebral and spinal areas. Strongly immunoreactive neurons were detected in the spinal cord of rats and monkeys, particularly the large lamina IX motoneurons; and in the rat and human cerebral cortex, particularly the pyramidal neurons of the deeper layers. These data were supported by preliminary ISH experiments, that revealed a strong although diffuse signal in the rat spinal gray matter, particularly in the lamina IX of the ventral horn. The SMN expression analysis supports the relevance of this gene for the motoneurons function, and could be of great value in unveiling the pathogenesis of the related human disease.

## NEUROPSYCHIATRIC DISORDERS I

## 95.1

## EFFECTS OF OLFACTORY BULBECTOMY (OBX) ON FORCED-SWIM TEST (FST) AND LIMBIC TRH AFTER ELECTROCONVULSIVE SHOCK (ECS). A. Sattin\* R.L. Lloyd, A.E. Pekary, M. Chilingar, Psychiatry, Medicine (Endocrinology) &amp; Research Services, W. Los Angeles VA Medical Center &amp; UCLA, Los Angeles, CA 90073.

The OBX model of depression was used in 2-mo. male Wistar rats (Simonsen, Gilroy, CA). The Porsolt pre-swim could not be used with OBX because of ceiling effects, so a modified FST was scored with a single 5 min immersion after ECS/sham ECS daily x 3. Sham ECS vs ECS ss's were subgrouped following bilateral OBX or sham OBX (4 groups). Only the OBX/sham ECS's showed high immobility compared to the other 3 groups. Thus, OBX prevents the burst of swimming seen after initial immersion of intact rats. This result cross-validates the forced-swim and OBX models of depression. Analysis of TRH and precursor TRH-Gly (1 day post-swim) showed the expected post-ECS increases (Sattin et al, Ann NY Acad Sci, 739: 135-153, 1994), but OBX/sham ECS showed significant increases of TRH in amygdala/entorhinal cortex and pyriform (olfactory) cortex. These post-OBX increases might be consequent to decreased release of TRH secondary to trans-synaptic degeneration, and consequent swim-immobility. Supported by VA Research Service.

## 95.3

## PERSISTING EFFECTS OF ORAL PYRIDOSTIGMINE BROMIDE ON THE BEHAVIOR OF RATS. B.H. Natelson, J.E. Ottenweller, C. Goldstein, D. Beldovitz, W.T. O'Brien and W.N. Tapp\*, R.I. Servatius. Neurobehavioral Unit (127A), VA Medical Center, East Orange NJ 07018 and Department of Neuroscience, New Jersey Medical School-UMDNJ, Newark NJ.

Pyridostigmine bromide (PB) is an anticholinesterase used for protection against nerve agents by troops during the Persian Gulf War. Questions have arisen as to whether its use could be contributing to some of the long-term, unexplained medical illnesses in these veterans. To understand whether PB could produce persisting effects, we gave rats about 2 mg/kg/day for 7 days in their drinking water. Young adult male Sprague-Dawley and Wistar-Kyoto rats received drinking water with PB, and controls had plain water. On the day after stopping PB, and 1 and 2 weeks later, startle responses to 73, 83 and 93 dB noises were assessed using whole body and eyeblink EMG responses. 48 hr after stopping PB, open field activity was measured, along with assessment of pain thresholds using hot-plate tests. The open field test was not affected by PB, but PB increased pain sensitivity 48 hrs after the last exposure. Startle responses were not affected 24 hr after the end of PB treatment, but one week later PB rats showed enhanced startle responding. Two weeks after discontinuing PB, treated rats still appeared to be sensitized to the startle stimuli compared to controls. It is unlikely that PB was directly active at the time of these behavioral tests. The persisting effects of PB on startle responding are not apparent just after treatment, but seem to emerge 1-2 weeks after the treatment had ended. Experiments are in progress to determine the duration of these effects in rats. Our results were unexpected and suggest that ingestion of PB may have long term consequences. The direct relevance of this animal work to the medical complaints of the Persian Gulf veteran is not known. Supported by VA Medical Research Funds for the New Jersey Center for Environmental Hazards Research.

## 95.2

## EXPRESSION OF c-fos mRNA IN RAT BRAIN FOLLOWING KINDLING OF MYOCLONUS WITH CLOZAPINE: BEYOND THE DOPAMINE HYPOTHESIS. J. Stevens\*, D. Denney, P. Szot, Depts Neurology &amp; Psychiatry Oregon Health Sciences University Portland, OR 97201 &amp; GRECC VAMC Seattle, WA 98108

Seizures often improve symptoms of psychoses, including schizophrenia. Clozapine, which frequently ameliorates symptoms of schizophrenia in patients unresponsive to other antipsychotic agents, has CNS excitant properties that cause epileptiform EEG changes, myoclonus or seizures in 3-10% of patients who receive average clinical doses of the drug (*Neurology* 41:369, 1991). We previously reported a clear dose-response relationship for production of myoclonus by clozapine in partially restrained rats (*Biological Psychiatry* 37: 427 1995). Repeated administration of very low dose clozapine (1mg/kg) I-P, a dose that initially did not induce myoclonus or other behavior change, caused increasing myoclonus when repeated at weekly intervals. Myoclonus induced after repeated weekly 1mg/kg injection of clozapine is associated with expression of c-fos mRNA in ventral tegmental area and anterior thalamic nuclei. These results of kindling with clozapine are compared with c-fos expression in brains of similarly restrained rats given a single 1 mg/kg or 10 mg/kg dose of clozapine and to animals after kindling with clozapine without restraint. Expression of c-fos mRNA in these thalamic and midbrain nuclei indicates that myoclonus induced by kindling with clozapine is associated with activation of specific subcortical nuclei. This may relate to the unique therapeutic effect of this drug in schizophrenia.

## 95.4

DISRUPTION OF THE GENE ENCODING THE RII $\beta$  SUBUNIT OF PKA ABOLISHES TRANSCRIPTIONAL AND BEHAVIORAL RESPONSES TO HALOPERIDOL IN THE DORSOLATERAL STRIATUM. M.R. Adams\*, E.P. Brandon, E. Chartoff, R.L. Idzerda, D.M. Dorsa and G.S. McKnight, Depts. of Pharmacology and Psychiatry, University of WA, Seattle WA 98195.

Administration of typical antipsychotic drugs (APD's), such as haloperidol, promotes a dramatic increase in the transcription of the neurotensin/neuromedin N (NT/N) gene in neurons of the dorsolateral striatum (DLST) and shell sector of the nucleus accumbens. Previous studies have shown that APD's bind to and antagonize D2 receptors and increase intracellular cAMP. In order to determine whether haloperidol-induced NT/N gene expression is mediated via the cAMP-PKA-CREB pathway, we examined the effects of haloperidol on NT/N gene expression in mice in which genes that encode the various subunits of the PKA enzyme have been disrupted. In mice, carrying a disruption of the gene encoding RII $\beta$ , the predominant regulatory subunit of PKA in the striatum, induction of the NT/N and c-fos gene in the DLST is completely abolished. In addition, an acute behavioral response to haloperidol, catalepsy, is also significantly attenuated in these animals. Thus, these animals are unresponsive to effects of haloperidol that are thought to involve the motor striatum. The data suggest that PKA activation is an early and essential step in APD induced transcriptional effects. They also indicate a potential role for neurotensin in cataleptic effects of haloperidol. Supported by the GM32875 (GSM) NS20311 (DMD) and MCBTG, T32GM07270 (MRA)

## 95.5

# INCREASED EXTRACELLULAR BRAIN GLUTAMATE CONCENTRATIONS AND CONCOMITANT LOSS OF NON-NMDA BINDING SITES IN RATS WITH ACUTE LIVER FAILURE

A. Michalak, C. Rose J. Butterworth, D.D. Mousseau\* and R.F. Butterworth, Neuroscience Research Unit, Hôpital Saint-Luc (University of Montreal), Montreal, Québec, Canada H2X 3J4

It has been suggested that hepatic encephalopathy is the consequence of glutamatergic synaptic dysregulation (Butterworth, *Mol. Pharmacol.* 2, 229, 1992). In order to evaluate glutamatergic function in acute liver failure, rats with ischemic liver failure following portacaval anastomosis and hepatic artery ligation were stereotactically implanted with microdialysis probes (CMA 12 1 mm x 0.5 mm with a 20,000 m.w. cut off) in frontal cortex and glutamate concentrations were measured as their o-phthalaldehyde derivatives by HPLC at various times during progression of encephalopathy. In a separate series of experiments, NMDA and non-NMDA binding sites were assessed by quantitative receptor autoradiography using <sup>3</sup>H-MK801 or <sup>3</sup>H-5-fluorowillardiine (respectively) in the brains of animals with acute liver failure at coma stages of encephalopathy. Ischemic liver failure resulted in a significant increase in extracellular concentrations of glutamate in frontal cortex, an increase which was positively correlated with CSF ammonia concentrations in these animals. Extracellular glutamate concentrations in frontal cortex of rats with acute liver failure were increased 3-4 fold at coma stages at which time, densities of binding sites for the non-NMDA receptor ligand <sup>3</sup>H-5-fluorowillardiine were significantly decreased in frontal cortex, olfactory tubercle, hippocampus, hypothalamus and cerebellum. <sup>3</sup>H-MK801 binding site densities were within normal limits. This, acute liver failure results in increased extracellular concentrations of glutamate and a concomitant loss of non-NMDA binding sites consistent with the hypothesis that alterations of glutamatergic synaptic function are responsible for the neuropsychiatric symptoms encountered in acute liver failure (funded by MRC Canada and The Canadian Liver Foundation)

## 95.7

# INCREASED GAD mRNA IN THE RAT DENTATE GYRUS FOLLOWING REPEATED ELECTROCONVULSIVE SHOCK. S. R. Wright\*, C. A. Stewart\*, P. Naylor\*, I. C. Reid\* and R. C. A. Pearson\*. <sup>1</sup>Dept. of Biomedical Science, University of Sheffield, S10 2TN, UK, and <sup>2</sup>Dept. of Psychiatry, University of Dundee, DD1 9SY, UK.

Male hooded Lister rats were assigned to one of two groups. One group (n=5) received a course of electroconvulsive shock (ECS) treatments induced transcranially under inhalation anaesthesia using ear-clip electrodes (200 V, 50 mA for 2 s). A total of 10 ECS were given spaced at 48 hr intervals. The other group (SHAM, n=5) received identical handling and anaesthesia but no seizure was induced. Approximately 24 hr following the last ECS or sham treatment the rats were sacrificed and their brains suitably prepared for in-situ hybridization histochemistry.

A [<sup>32</sup>S]dATP 3' end labeled 30' mer oligo probe for GAD mRNA was hybridized to 10µ cryostat prepared sections. The slides were exposed to photographic emulsion (Ilford K5) for 4 weeks. Computerized image analysis of mRNA levels for GAD, measured as mean grain count per unit area, showed an increase in the granular layer (ECS 3.59±0.9 SD, sham ECS 2.47±0.33 SD) and molecular layer (ECS 3.27±0.59, sham ECS 2.18±0.41) of the dentate gyrus (two-tailed student "t" test, granular layer p<0.005, molecular layer p<0.001).

We postulate the increased production of GAD 24hrs following ECS is to maintain local inhibition and modulate our reported increase in the CA3 AMPA receptor population in the same animals (*Mol Brain Res* 35 (1996) 349-353). A more global effect may well have important implications for the therapeutic and adverse effects of ECT in humans. *Supported by The Wellcome Trust.*

## 95.9

# ANXIOLYTIC ACTIONS ARE MEDIATED BY SEROTONIN (5-HT)<sub>1A</sub> AUTORECEPTORS: S 15535 AND 8-OH-DPAT BLOCK ULTRASONIC VOCALIZATIONS (USV) AND AGGRESSION IN A WAY 100,635-REVERSIBLE FASHION. M. Brocco\*, K. Bervoets, B. De Ladonchamps, S. Veiga and M.J. Millan, I.D.R.S., 125 Chemin de Ronde, 78290 Croissy, France.

The relative involvement of pre and postsynaptic 5-HT<sub>1A</sub> receptors in decreasing anxiety is controversial. Here, we examined this question using selective ligands with differential efficacy at these sites: 8-OH-DPAT (8-hydroxy-2-(di-n-propylamino) tetralin) (8DP), an agonist at both pre and postsynaptic sites; WAY 100,635 (N-[2-[4-(2-methoxyphenyl)-1-piperazinyl]ethyl]-N-(2-pyridinyl) cyclo-hexanecarboxamide) (WAY), an antagonist at both pre and postsynaptic sites and S 15535 (4-(benzodioxan-5-yl)-1-(indan-2-yl)piperazine), an agonist at pre and an antagonist at postsynaptic sites. USVs were measured over 5 min by a bat-detector in rats pre-exposed (-24 h) to a mild foot-shock (0.8 mA, 8 sec). Aggression (resident vs intruder) was tested over 3 min in mice isolated for 6 weeks. S 15535 or 8DP were given -30 min, and WAY, -60 min. Doses (base) are means ± S.E.M. in mg/kg, s.c..

	VEH/ VEH	VEH/ S 15535	VEH/ 8DP	WAY/ VEH	WAY/ S 15535	WAY/ 8DP
USV (sec)	206±25	40.8±15.0#	0.4±0.2#	222±38	236±57*	196±48*
Attacks (number)	19±4	2.1±1.1#	0±0#	21.0±2.7	19.0±4.2*	31.0±3.1*

VEH = vehicle. Doses of S 15535/8DP were 0.63/0.16 for USVs, and 2.5/0.63 for aggression. # P<0.01 to VEH/VEH; \*P<0.01 to VEH/S 15535 or VEH/8DP.

S 15535/8DP inhibited USVs and reduced aggression at inhibitory Dose<sub>50</sub>s of 0.3/0.01, and 1.4/0.1, respectively. WAY (0.16) blocked these actions and was inactive alone. Since S 15535 shares agonist properties of 8-OH-DPAT at presynaptic but not postsynaptic 5-HT<sub>1A</sub> receptors, it is suggested that 5-HT<sub>1A</sub> autoreceptors mediate their anxiolytic actions in these procedures.

This study was supported by Servier Pharmaceuticals.

## 95.6

# EARLY BREAKDOWN OF THE BLOOD-BRAIN BARRIER AND CONCOMITANTLY INCREASED IMMUNOSTAINING FOR MACROPHAGE LYOSOMAL ANTIGEN (ED1) IN THIAMINE DEFICIENCY. D.K. Leong\*, L. Oliva, J. Kril and R.F. Butterworth, Neuroscience Research Unit, Hôpital Saint-Luc (University of Montreal), Montreal, Quebec, Canada H2X 3J4

Immunohistochemistry with antibodies to astrocytes (polyclonal glial fibrillary acidic protein; GFAP); and macrophages (monoclonal ED1), were used to examine the glial response in brains of rats at different stages of thiamine-deficiency. In addition, an antibody to serum albumin was used to study the integrity of the blood-brain barrier. The results of the study reveal early, region-selective, increases of immunostaining for ED-1 and serum albumin in brains of thiamine-deficient rats, prior to the appearance of neurological symptoms of thiamine deficiency or major histopathological lesions. Increased ED-1 immunostaining, suggestive of an early macrophage response, and concomitantly increased albumin-immunoreactivity suggestive of an early breakdown of the blood-brain barrier, were confined to the inferior olive, inferior colliculus and medial thalamus, regions of the brain which ultimately manifest marked neuronal loss in thiamine deficiency. Histological studies of neurologically symptomatic thiamine-deficient rats revealed significant neuronal loss, pallor of the neuropil and marked gliosis in vulnerable brain regions, while immunohistochemical studies of the same regions showed marked increases of GFAP-immunostaining, indicative of reactive gliosis. This region-selective macrophage response resulting from increased permeability of the blood-brain barrier may underlie the phenomenon of selective regional vulnerability in thiamine deficiency. # INCREASED PLASMA LUTEINIZING HORMONE (LH) AFTER ELECTRO-CONVULSIVE SHOCKS (ECS) IN RATS AND HUMANS. Th. Steimer, J.L. Moreau, P. Lemoine, M.L. Aubert, P. Schulz\*. Department of psychiatry, Geneva, 1225 Switzerland; Preclinical CNS research, Hoffmann-La Roche, Basel; Biological psychiatry unit, Lyon, France; Department of pediatrics, Geneva, Switzerland.

Hormones of the hypothalamo-pituitary-gonadal (HPG), axis notably the gonadotropin-releasing hormone (GnRH or LHRH) and gonadal steroids such as testosterone (T) and/or oestradiol, might have antidepressant properties, or potentiate other treatments in patients and animal models of depression. We studied the acute effects of ECS on hormones from the HPG axis in depressed patients and male Wistar rats. In rats, plasma LH was significantly elevated 20 and 60 min after ECS (30mA, 0.5 sec). Plasma T was also increased at 60 min. Plasma prolactin (PRL) was higher in ECS-treated as compared to non-shocked control rats 5 and 20 min after ECS, whereas corticosterone (B) was only augmented after 20 and 60 min. In human males (n=4), a substantial and reproducible increase in plasma LH and PRL was observed 15 min after ECS. The HPG axis could be involved in the antidepressant effects of ECS.

Supported by grant 32-27 780 from the Swiss FNRS.

## 95.10

# COMPARISON OF THE EFFECTS OF CP-93,393 AND BUSPIRONE ON NE AND 5-HT RELEASE: MICRODIALYSIS STUDIES IN HIPPOCAMPUS OF FREELY MOVING RATS AND GUINEA PIGS.

Y. Lu\*, T. Clarke, A.W. Schmidt, J. Sprouse and H. Rollema Department of Neuroscience, Pfizer Central Research, Groton CT 06340

CP-93,393 is a novel anxiolytic/antidepressant, possessing both 5-HT<sub>1A</sub> agonist and α<sub>2</sub> antagonist properties. We measured the effects of 5-HT<sub>1A</sub> agonists (CP-93,393, buspirone, 8-OHDPAT) and α<sub>2</sub> antagonists (CP-93,393, idazoxan, 1-PP) on 5-HT and NE release in the hippocampus of freely moving rats (5-HT) and guinea pigs (NE). CP-93,393, buspirone and 8-OHDPAT decreased 5-HT release to 25-40% of basal levels in rat hippocampus, with ED<sub>50</sub>'s of 1.5, 0.7 and 0.02 mg/kg (sc) respectively, which correlated well with their K<sub>i</sub> values for 5-HT<sub>1A</sub> binding in rat cortex.

The compounds also produced an increase in NE release, but did so via two distinct mechanisms. All doses of buspirone tested (0.3 - 32 mg/kg) increased NE release 1.5 to 2-fold via 5-HT<sub>1A</sub> activation, since the NE increase was completely blocked by the 5-HT<sub>1A</sub> antagonist WAY 100635. Apparently, α<sub>2</sub> effects do not contribute to the buspirone-induced NE increase, despite the fact that 1-PP markedly increases NE release. The effects of buspirone were comparable to those of 8-OHDPAT. Low doses of CP-93,393 also increased NE release via 5-HT<sub>1A</sub> activation (blocked by WAY 100635), but doses of 10 mg/kg and above produced a robust NE increase, mediated by α<sub>2</sub> receptor blockade, which was only slightly attenuated by WAY 100635 pretreatment. The effects of 10 mg/kg CP-93,393 were very similar to those of 1 mg/kg of the α<sub>2</sub> antagonist idazoxan.

These results confirm that CP-93,393 acts *in vivo* as a 5-HT<sub>1A</sub> agonist, decreasing serotonergic transmission, and as an α<sub>2</sub> antagonist, increasing noradrenergic transmission.

## 95.11

EXPRESSION AND REGULATION OF MULTIPLE FORMS OF CYTOCHROME P450 IN RAT AND HUMAN BRAIN. P.S. Tirumalai<sup>1</sup>, S. Bhamre<sup>1</sup>, M.R. Boyd<sup>2</sup>, S.H. Koslow<sup>3</sup> and V. Ravindranath<sup>4</sup>, Dept. of Neurochemistry, National Institute of Mental Health and Neuroscience, Bangalore 560029, India<sup>1</sup>, Lab. of Drug Discovery Research and Development, DTP, NCI, NIH, FCRDC, Frederick, MD 21702<sup>2</sup> and Division of Brain and Behavioral Sciences, NIMH, NIH, Rockville, MD 20857<sup>3</sup>.

Cytochrome P450 (P450) are important xenobiotic metabolizing enzymes. P450 mediated bioactivation of xenobiotics in the brain could lead to irreversible damage, while *in situ* metabolism of psychoactive drugs can mediate pharmacological modulation at the site of action. Multiple forms of P450 are present in rat brain and are selectively induced by phenobarbital (PB), ethanol or dexamethasone. The isoforms of P450 are variably distributed in brain regions and their transcriptional regulation differs from that of the liver. PB administration resulted in increased transcription of P4502B in rat liver 12 hr after the dose, while similar elevation in brain mRNA was seen after 1 day. The induction of P450 by PB was observed in the brainstem (BS) and thalamus (TH), while it was unaffected in hippocampus (HP) and cerebellum (CE). Chronic ethanol administration resulted in increased P450 levels in HP and TH while it was unchanged in CE and BS. The expression of multiple forms of P450 was also observed in human brain regions obtained at autopsy from traffic accident victims. Localization of multiple forms of P450 in rat and human brain by immunocytochemistry and *in situ* hybridization revealed the predominant presence of P450 in the neuronal cells, the site of action of psychoactive drugs. The variable response to psychoactive drugs seen in population groups is often not accountable by considering dissimilarities in hepatic metabolism. These studies demonstrate the regional and cellular diversity exhibited by the brain in the distribution and regulation of multiple forms of P450 and point to their possible role in the local pharmacological modulation of psychoactive drugs.

## 95.13

EFFECT OF LITHIUM ON TRANSCRIPTION FACTOR BINDING IN CULTURED CEREBELLAR GRANULE CELLS AND THE BRAIN OF RATS. N. Ozaki\* & D.-M. Chuang. Section on Molecular Neurobiology, Biological Psychiatry Branch, NIMH, NIH, Bethesda MD 20892-1272

Lithium is most commonly used in the treatment for manic depressive illness. However, its underlying therapeutic mechanisms remain obscure. Using primary cultures of rat cerebellar granule cells (CGC) as a model, we have shown that long-term exposure of CGC to LiCl increases the levels of mRNA for c-fos and m<sub>3</sub>-muscarinic acetylcholine receptors (Gao et al., Neurochem. Internat. 22:395,1993). These results suggest a potential regulatory role of lithium at the transcriptional level. In this study we investigated the effects on AP-1 binding in CGC exposed to LiCl and in rats chronically fed with Li<sub>2</sub>CO<sub>3</sub> for 2 or 4 weeks. Extracts of CGC and dissected brain tissues were prepared for AP-1 gel-shift analysis using consensus AP-1 sequence. We found that exposure of CGC to LiCl (0.1 mM-10 mM) for 1 to 7 days induced a concentration-dependent increase in AP-1 binding. The maximal increase reached at 0.5 mM of LiCl which is within the plasma therapeutic range of this drug. Using extracts prepared from the frontal cortex, hippocampus and amygdala and cerebellum, two AP-1 binding bands were detected on the gel. The upper binding band was significantly increased in the hippocampus and amygdala after treatment with lithium-diet for 4, but not 2, weeks. Conversely, the lower binding band was markedly increased in the frontal cortex after 4 weeks of lithium treatment. These results strengthen the hypothesis that lithium at the therapeutic range is a transcriptional regulator. Mechanism underlying the lithium-induced AP-1 binding *in vivo* and in cultured neurons are being investigated. (NIMH)

## 95.15

DEPRESSION IN SYSTEMIC LUPUS ERYTHEMATOSUS - PRIMARY OR COINCIDENTAL? S. Denburg\*, J. Brasch, R. Carbotte and J. Denburg. Depts. of Psychiatry and Medicine, McMaster University, Hamilton, ON, Canada L8N 3Z5

Although depression is the most frequent psychiatric presentation in lupus (SLE), there is little consensus as to whether it represents a primary manifestation of nervous system involvement in that disease. We undertook a pilot study comparing psychiatric symptomatology and neurocognitive function in depressed SLE patients (N=11), idiopathically depressed patients (N=8) and non-depressed SLE controls (N=7). We found no differences between the two depressed groups in cognitive, affective or somatic symptom endorsements, suggesting that the clinical presentation of depression in the two groups may be indistinguishable. In contrast, while verbal productivity was reduced in both depressed groups, the depressed SLE patients tended to perform more poorly than both the depressed and non-depressed controls on tasks involving sustained mental effort, verbal and nonverbal learning and visuospatial planning, pointing to the potential importance of cognitive variables in studying the etiology of depression in SLE.

IDENTIFICATION OF LITHIUM REGULATED GENES BY DIFFERENTIAL DISPLAY PCR. J. F. Wang\* and L. T. Young. Departments of Psychiatry and Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Lithium is highly effective in the treatment of bipolar disorder. Although its exact mechanism of action is as yet unknown, much evidence suggests that lithium regulates gene expression in brain. To identify lithium regulated genes (LiRGs), we used mRNA differential display PCR to screen differentially expressed genes in the presence or absence of 1 mM LiCl treatment for one week in C6 glioma cells. Four candidate genes were isolated and verified by northern blot analysis. Sequencing analysis revealed three previously unidentified cDNA fragments in addition to a sequence with 99% homology with the cDNA for 2',3',-Cyclic Nucleotide 3'-Phosphodiesterase type II (CNaseII). Using quantitative slot blot analysis, we found that 1mM LiCl increased CNaseII gene expression by 62%, an effect which did not occur after administration of sodium chloride or anticonvulsants (carbamazepine or sodium valproate) commonly used to treat bipolar disorder. Since CNaseII is important in myelinogenesis and possibly neuronal growth and repair, the present findings suggest that lithium may regulate these processes which is consistent with its long term stabilization of bipolar disorder and prevention of subsequent relapses of mania or depression. (Supported by a NARSAD Independent Investigator's Award (L.T.Y.) and a grant from Abbott Laboratories.)

## 95.14

CONCORDANT REGULATION OF GENE EXPRESSION BY LITHIUM AND VALPROIC ACID IN VITRO. P. X. Yuan, G. Chen\*, and H. K. Manji. Schizophrenia and Mood Disorders Clinical Research Division, Dept. of Psychiatry & Behavioral Neurosciences, Wayne State Univ. School of Medicine, Detroit, MI 48201.

Both lithium and Valproic acid (VPA) are clinically effective antimanic and mood-stabilizing agents, but their molecular mechanism(s) of action have not been elucidated. Recent studies have shown that both these agents produce strikingly similar effects on PKC isozymes and substrates; in view of their delayed onset of therapeutic efficacy, it is also noteworthy that these agents also regulate the activity of transcription factors in the AP-1 family. To date, however, there has not been any clear evidence that these effects on AP-1 are translated into effects at the gene expression level. In the present study, rat C6 glioma cells and human SY5Y neuroblastoma cells were transfected with luciferase reporter gene vectors driven by SV40 or MMTV-LTR promoter/enhancers. At clinically therapeutic concentrations, both drugs increased reporter gene expression several fold. These effects are both time- and concentration-dependent. The possible involvement of each of the DNA binding elements as well as of PKC isozymes in mediating these effects of lithium and VPA are currently under investigation. This regulation of gene expression by lithium and VPA may play a role in their long term efficacy.

## 95.16

THE ROLE OF THE BETA ADRENERGIC SYSTEM IN CCK-4 INDUCED PANIC SYMPTOMS. J.-M. Le Mellédo\*, J. Bradwejn, D. Koszycki, J.-P. Boulenger, A. Cadieux, I. Jerabek, F. Jolicoeur, F. Bellavance, D.G. Bichet. Psychobiology and Clinical Trials in Anxiety Research Unit, Clarke Institute, Toronto, Canada, M5T 1R8.

The involvement of the noradrenergic (NE) system, particularly the beta NE system, in panic disorder has been suggested for some time. However, attempts at blocking pharmacologically induced panic attacks with propranolol (a central and peripheral beta-1 and beta-2 NE blocker) have yielded inconsistent results. These inconsistencies might be explained by a failure to verify the effectiveness of beta-blockade. Our study objectives were to assess the effects of controlled beta-blockade on CCK-4 induced panic symptoms and associated biological changes in healthy male volunteers. The study was double-blind and placebo-controlled. The beta-blocking effects of 0.2 mg/kg *i.v.* of propranolol were controlled for every subject, using the Cleveland method. This method consists of verifying that the injection of a predetermined CD25 dose of isoproterenol has no effect on heart rate following the administration of a beta blocker (CD25 is the dose of isoproterenol which increases the heart rate of a subject by 25 beats per minute). Subjects exhibiting beta blockade were included in the study. Two days later, the same dose of propranolol or placebo was administered to these subjects followed by an *i.v.* injection of CCK-4 (50µg). Preliminary results based on 30 subjects showed that pretreatment with propranolol, as compared to placebo, decreased sum intensity of panic symptoms ( $p < 0.01$ ), reduced CCK-4 induced anxiety ( $p < 0.05$ ) and CCK-4 induced increases in heart rate ( $p < 0.01$ ). In conclusion, our results suggest that the beta NE system mediates at least part of the CCK-4-induced effects. The results of the effects of propranolol on CCK-4-induced arginine vasopressin, oxytocin, catecholamines and NPY release will be presented. This study was funded, in part, by the Medical Research Council of Canada.

DETERMINANTS OF ELECTROPHYSIOLOGIC RESPONSIVITY IN PTSD. J.H. Casada, R. Amdur, E.A. Young\*, and I. Liberzon. Department of Psychiatry, VAMC and University of Michigan, Ann Arbor, MI, 48105.

Post-traumatic stress disorder (PTSD) is an anxiety disorder that is characterized by intrusive, avoidant, and hyperarousal symptoms. Electrophysiological changes in skin conductance, heart rate, and skin temperature in response to trauma related stimuli are consistently reported in this disorder, however little is known about the contribution of individual variations and stimulus qualities in determining electrophysiological responsivity. We have studied electrophysiological responses of PTSD patients and two groups of controls (total of 36 subjects) in several different settings and in response to a variety of different stimuli: trauma related, threatening, non-specific auditory and arousing visual stimuli. The electro-physiological indices chosen for study include those that reflect autonomic tone, such as skin conductance (SC), heart rate (HR), and temperature (T), as well as one that is independent of autonomic tone, correlative electromyogram (EMG). The preliminary data analysis showed the expected increases in SC, HR, and EMG and decreases in T during exposure to each stressful stimulus; however, when individual responses were examined across all of the experiments, individuals with PTSD were found to have more consistent responses to arousing stimuli. Further analysis will explore the contribution of individual and stimulus variables to electrophysiological reactivity. The results of this study support the hypothesis that PTSD patients are more autonomically reactive to both combat and nonspecific stimuli than controls.

BLOOD FLOW IN COCAINE DEPENDENCE, Ronald I. Herning\*, Warren Better, and Jean L. Cadet, Molecular Neuropsychiatry Section, Neuroscience Branch, NIH/NIDA, IRP, Baltimore, MD 21224

Blood flow of the anterior and medial cerebral arteries was measured by transcranial doppler sonography in cocaine-dependent individuals (n=21) and control subjects (n=21) to determine whether the EEG differences observed in cocaine abusers might reflect specific cerebral blood flow differences. Blood flow was measured within the three days and again after about 25 days after being admitted to an inpatient research ward. Resting EEG was recorded after the blood flow measurement on all subjects. The mean, systolic, and diastolic velocities on both arteries did not differ between the control and cocaine dependent subjects. A correlation was observed between the frontal and central EEG and blood flow measured in the control, but not the cocaine dependent subjects at the first recording. After about a month of abstinence, correlation began to emerge between the EEG and blood flow for the cocaine-dependent subjects. These preliminary findings support the notion that the relationship between EEG and cerebral blood flow is altered in cocaine dependent patients.

## 95.18

CONTROL OF AGGRESSION AND VIOLENCE WITH CARBAMAZEPINE. C.C. Huang\*, Medical College of Wisconsin, Milwaukee, WI 53226.

The purpose of the study is to learn whether carbamazepine is effective in controlling impulsive aggression. Eighteen patients were chosen for this study (5 female, 13 male, age 18 to 56). 5 of these patients were diagnosed with schizophrenia, 6 with mental retardation, 4 with ODS, 2 with organic personality disorder and 1 with intermittent explosive disorder. All of these patients were hostile, aggressive and had acting out behavior prior to the treatment. Each incident of acting out behavior which required restraint was used as a measurement of the severity of the patients' aggression. Every patient was allowed to continue his concomitant medications, i.e. antipsychotics, anticholinergics, sedatives or antiepileptics throughout the course of study; then carbamazepine 300 to 800 mg per day was added to each patient's regimen. The number of incidents of acting out behavior in one month prior to carbamazepine treatment was compared with number of incidents in one month after the carbamazepine treatment. The results show a statistically significant difference between 2 experimental groups (p=0.01). The means are 5.722 versus 1.667. Carbamazepine might have a direct or indirect effect on the limbic system.

## NEUROPSYCHIATRIC DISORDERS II

## 96.1

DOPAMINERGIC CORRELATES IN NON-PSYCHOTIC RELATIVES OF SCHIZOPHRENIC PROBANDS. F. Amin\*, L.J. Siever, J.M. Silverman, C.J. Smith, P.J. Knott, K.L. Davis. Houston VA/Baylor College Medicine, Houston, TX, 77030.

First-degree relatives of schizophrenic probands frequently manifest attenuated characteristics of schizophrenia. Analogous to the symptoms of schizophrenia, many of these characteristics may be viewed as social deficit-related (more prominent in this population) or psychotic-like that are hypothesized to be associated with decreased or increased dopamine (DA), respectively; in different brain regions. It raises the possibility that DA abnormalities may be present in the relatives of schizophrenic probands. Plasma homovanillic acid (HVA), the major DA metabolite and a peripheral indicator of presynaptic DA activity, was measured in a group of non-psychotic, physically healthy, first-degree relatives (n=55) of schizophrenic probands. Deficit-related and psychotic-like symptoms were assessed on study mornings using the Positive and Negative Syndrome Scale.

Stepwise multiple regression analyses suggested that plasma HVA predicted statistically significant proportions of variability in both the deficit-related and psychotic-like symptoms, with significant negative partial correlations with deficit-related and positive partial correlations with psychotic-like symptoms. Not only schizotypal relatives but also the relatives who did not meet criteria for any DSM-III-R personality disorder were found to have significantly lower plasma HVA compared to a normal group. None of these results appeared related to the renal HVA excretion or the noradrenergic component of HVA, consistent with the notion that plasma HVA findings were due to brain DA. Our results are compatible with the view that brain DA may negatively and positively modulate the milder continuums of deficit and psychotic symptoms of schizophrenia, respectively, in the relatives of schizophrenic probands. Our results raise the possibility that DA dysfunction of schizophrenia may have genetic antecedents involving the presynaptic DA function. (Supported by grants from Scottish Rite Foundation and VA Merit Review program to Dr. Amin, and by a grant from NIH to Dr. Silverman)

## 96.2

EFFECTS OF SCHIZOPHRENIA AND TEMPORAL LOBE EPILEPSY ON MEMORY. W.S. Stone\*, L.J. Seidman, R. Jones, R.H. Harrison, and A. Mirsky. <sup>1</sup>Dept. of Psychiatry, Harvard Medical School, <sup>2</sup>Dept. of Psychology, Boston University, <sup>3</sup>National Institute of Mental Health, Bethesda, MD.

Although impaired recall is well-documented in schizophrenia, the extent to which deficits in memory can be dissociated from other cognitive and demographic variables remains unclear. This issue was addressed by comparing learning and memory performance in patients with schizophrenia to groups of temporal lobe epileptics (TLE) and normal controls. Schizophrenic and TLE patients were significantly impaired in both verbal and visual modalities on subtests of the Wechsler Memory Scale, with schizophrenics generally performing most poorly. Since the schizophrenics consisted of a relatively non-chronic sample with a mean Full Scale IQ of 99.7, their memory disorder cannot be attributed to "schizophrenic dementia." Nor was the deficit related to sex, education, IQ estimate or attention span. "Savings" score measures of memory decay indicated that the loss of information over time (long-term memory function) in schizophrenia was quantitatively mild compared to that found in most neurologic groups with memory disorders. The extreme difficulty that schizophrenic patients had on an incidental recall task suggests that absence of instructional set added to an already existing abnormal rate of forgetting. Relatively unimpaired performance on paired associate learning suggests that, in this sample at least, schizophrenics benefited from retrieval cues and multiple trials comprised of short (nonsupraspan) bits of information. These results provide additional evidence that memory recall is more impaired than recognition in schizophrenic populations. More generally, they show that memory deficits in schizophrenia are not epiphenomena occurring secondary to deficits in overall cognitive function, but are more likely persistent sequelae of the disorder itself. Supported by research grants from NIMH (MH-37156, MH-26183, and MH-14915) and the Commonwealth Research Center of the Massachusetts Mental Health Center.

## 96.3

TEMPORAL DISINTEGRATION OF VISUAL PERCEPTION IN SCHIZOPHRENIA. R. Izawa, S. Yamamoto, A. Iwawaki, K. Ohta, E. Matsushima, H. Shibuya\* and M. Toru. Dept. of Neuropsychiatry, Tokyo Medical and Dental Univ. Sch. of Med., Tokyo, Japan.

A perceptual disturbance in schizophrenia has been described as "fragmentation". However, the way in which the perception is fragmented and the relation between the perceptual fragmentation and the other symptoms remain obscure.

We investigated 24 schizophrenics and 14 normal controls by a newly devised psychological test and assessed the schizophrenic symptoms on 3 syndrome scores (Liddle, P.F.). The test consisted of 12 different geometrical figures. On a CRT, a part of the figure was presented, just like peeping through a hole in a black screen. The subjects were asked to move "the hole" freely by a mouse device in order to get the whole image by integrating temporally parts of the figure. Afterwards they were required to draw each figure from memory (recall) and to select a correct figure from 6 figures (recognition). The error scores in recall and recognition of schizophrenics were both significantly higher than those of normal controls. In schizophrenia, there were positive correlations between these scores and Disorganization syndrome score, but not Reality Distortion nor Psychomotor Poverty syndrome score.

These results suggest that schizophrenics may have impairment of temporal integration in visual perception and this perceptual disturbance and positive thought disorders may have a common basis, which can be interpreted as temporal disintegration.

## 96.5

## AUDITORY P300 AND IMPULSIVE AGGRESSION.

J. E. Gerstle and M. S. Stanford\*. Department of Psychology, University of New Orleans, New Orleans, LA 70148.

Impulsive aggression involves a hair trigger response to provocation with loss of behavioral control. This loss of control is not secondary to any medical or psychiatric disorder and, by virtue of the spontaneity of the act, is not planned. Subjects were 12 college students classified as impulsive aggressive by self-report and 12 nonaggressive matched controls. All impulsive aggressive subjects reported a lifetime history of physical aggressive outbursts. P300 was recorded during an auditory oddball task. Data were analyzed from 19 scalp electrodes using t-tests and topographical analyses. It was hypothesized that impulsive aggressive subjects would demonstrate significantly lower P300 amplitude. Between groups analysis indicated that impulsive aggressive subjects had significantly lower average frontal P300 amplitude when compared to matched controls ( $t[22] = 1.85, p > 0.05$ ). These findings are consistent with psychophysiological findings in impulsive aggressive incarcerated criminals and support the notion of a specific behavioral syndrome associated with spontaneous aggressive outbursts.

## 96.7

REACTION TIME AND PUPIL RESPONSE MEASURES SHOW REDUCED LATENT INHIBITION IN CHRONIC SCHIZOPHRENIA. L.A. Dunn\* and R.J. Scibilia. Department of Psychiatry, Duke University Medical Center, Durham, North Carolina 27710.

Latent inhibition (LI) is an indirect behavioral measure of selective attention that is reduced in humans with schizophrenia (Baruch et al. J Nerv Ment Dis 176:598-606, 1988). A continuous performance task that measures LI has been developed that uses within subject controls and allows repeat testing. Letter stimuli are presented on a video monitor with a SI of 1 sec. and an ISI of 0.25 sec. Pupil size is monitored by infrared video. Subjects respond by releasing a button for each target X. The task is divided into four contiguous phases. During phases 1 and 3 20% of the stimuli are targets, 60% are letters, and 20% are a non-letter preexposure stimulus. During phase 2 a novel symbol always cues the target resulting in decreased reaction times. Phase 2 ends when 3 reaction times are lower than those in phase 1 or the subject has responded 33 times. During phase 4 the preexposed stimulus cues the target. Reaction times decrease as in phase 2. Trials to criterion are calculated for novel and preexposed phases. A subject demonstrates LI when the trials to criterion are higher in phase 4 than in phase 2. Pupil diameter is measured 60 times per second throughout the task. Pupil diameter changes are assessed by peak height and latency following target presentation. Reaction times were studied in 14 subjects with schizophrenia and 28 normal controls. LI was present in normal controls ( $p < .001$ ) but not in subjects with schizophrenia. Pupil diameter changes were studied in 9 subjects with schizophrenia and 25 normal controls. LI was evident pupil diameter response to cued targets. Pupil diameter increase was smaller and earlier for preexposed cues in normal controls ( $p < 0.001$  for each). No significant change was observed in subjects with schizophrenia. (Supported by NIMH #47503)

## 96.4

## NORMAL P300 AMPLITUDES IN LATE-ONSET SCHIZOPHRENIA AND RELATED PSYCHOSES.

John Olichney, MD\*<sup>1</sup>, Vicente Iragui-Madoz, MD, PhD<sup>1</sup>, Marta Kutas, PhD<sup>2</sup>, Ralph Nowacki, AS<sup>1</sup>, Dilip Jeste, MD<sup>3</sup> Departments of Neurosciences<sup>1</sup>, Cognitive Science<sup>2</sup>, and Psychiatry<sup>3</sup>; University of California, San Diego and San Diego Veteran's Affairs Medical Center; La Jolla, CA 92093.

The P300, an event-related potential elicited by task-relevant stimuli, is sensitive to the depth and speed of cognitive processing. The P300 amplitude has been found to be reduced in many studies of younger adult schizophrenia patients. This reduction has been related to severity of psychiatric symptoms and to temporal lobe abnormalities. Very little is known, however, regarding the P300 in late-life schizophrenia. We have studied 26 middle-aged and elderly (mean age = 61 yrs.) patients with schizophrenia ( $n=22$ ) and related psychoses ( $n=4$ ), including 13 patients with "late-onset"--- i.e. onset of psychotic symptoms after 45 yrs., and 13 normal comparison subjects on an Auditory Oddball P300 paradigm. Preliminary analyses showed reduced P300 amplitudes in the early-onset psychosis patients at posterior electrode sites, compared with late-onset psychosis patients of comparable age, education and sex. There was no significant intergroup difference in P300 peak latencies. Our results suggest that reduced P300 amplitudes in schizophrenia are related to age of onset.

Supported by NIMH grant MH49671 and NIH grant AG00658.

## 96.6

RELATION BETWEEN VISUAL SCANNING OF FACES AND SCHIZOPHRENIC SYMPTOMS. R.B. Rosse, B.L. Schwartz, S. John, and S.I. Deutsch. Psychiatry, Dept. of VA Medical Center and Georgetown University Medical School, Washington D.C. 20422.

Eye movement disorders are consistently found in patients with schizophrenia and may represent a biologic marker of the disease. However, abnormal eye movements such as those in tests of smooth pursuit often are not associated with the patients' severity of illness. Here we present findings from two studies showing a relation between the severity of schizophrenic symptomatology and eye movement measures of visual scanning while patients viewed faces. In these studies, patients performed two tests on which they show facial processing deficits: gaze discrimination and recognition of facial expression. We observed that first, schizophrenic patients were impaired on these tests, and secondly, they produced fewer short-duration (<50 ms) fixations and saccades while viewing faces compared with controls. Importantly, the number of short-duration (<50 ms) fixations and saccades correlated with the patients' scores on a standard instrument used to assess the severity of psychopathology in schizophrenia, i.e., the Brief Psychiatric Rating Scale (BPRS). Patients who made fewer short-duration fixations and saccades had more severe symptoms of schizophrenia on the BPRS. Visual fixations and perhaps saccades of less than 50 ms that are produced while viewing a face are thought to reflect parallel, preattentive processes involved in perceiving configural or gestalt-like properties. These results suggest that patients with more severe psychotic symptoms engage in less preattentive processing, which may contribute to their facial processing deficits.

## 96.8

SACCADIC INHIBITION AMONG TOURETTE SYNDROME PATIENTS, R.H. Farber, B.A. Clementz, N.R. Swerdlow and V.D. Lehmann-Masten\*. Departments of Psychology and Psychiatry, University of California, San Diego, La Jolla, CA 92093-0109.

Pathologies affecting cortico-subcortical circuitry result in characteristic saccadic eye movement response patterns. Tourette syndrome (TS) is theoretically associated with prefrontal cortex-basal ganglia pathology. Studies of saccadic performance among TS patients, therefore, may complement our understanding of this disorder's putative neuropathology. Sixteen TS patients and 8 nonpsychiatric subjects were administered: (1) a visually-guided "gap" saccade task in which a 200 msec delay period separated the offset of a central fixation point and the illumination of a  $\pm 4^\circ$  peripheral target; and (2) an antisaccade task in which subjects were instructed to make saccades to the equal and opposite locations of pseudorandomly presented cues at  $\pm 8$  and  $16^\circ$ . During the gap task, TS patients generated a significantly increased proportion of anticipatory saccades ( $RT < 90$  msec) and a significantly decreased proportion of regular reaction time saccades ( $RT > 150$  msec) than nonpsychiatric subjects (anticipatory: TS  $M=0.21$ ,  $SD=0.12$ ; nonpsychiatric  $M=0.06$ ,  $SD=0.04$ ; regular: TS  $M=0.46$ ,  $SD=0.17$ ; nonpsychiatric  $M=0.65$ ,  $SD=0.16$ ). The groups did not statistically differ on proportion of "express" saccades (90 msec- $RT < 140$  msec). TS patients had significantly shorter amplitude express and regular saccades than nonpsychiatric subjects. During the antisaccade task, TS patients had a significantly decreased proportion of correct antisaccade trials than nonpsychiatric subjects (TS  $M=0.74$ ,  $SD=0.17$ ; nonpsychiatric  $M=0.91$ ,  $SD=0.10$ ). The groups did not statistically differ on either correct antisaccade or incorrect error saccade amplitudes. TS patients, however, had significantly increased saccadic reaction times on correct antisaccade trials (TS  $M=364.59$  msec,  $SD=66.43$ ; nonpsychiatric  $M=306.36$  msec,  $SD=22.39$ ). Collectively, the results are consistent with deficits of saccadic inhibition among TS patients presumably involving prefrontal cortex and associated subcortical circuitry. This work was supported by grants from the USPHS and the Tourette Syndrome Association.

**FUNCTIONAL NEUROANATOMY OF SMOOTH PURSUIT EYE MOVEMENTS.** D.E. Ross\*, H.H. Holcomb, G.K. Thaker, M. Zhou, D.R. Medoff, C.A. Tamminga. Maryland Psychiatric Research Center, P.O. Box 21247, Baltimore, MD 21228.

**Background:** Although a great deal is known about the functional neuroanatomy of smooth pursuit eye movements in humans, most of this information is based on indirect methods of observation, such as studies of non-human primates and humans with brain lesions. **Objective:** To determine the functional neuroanatomy of smooth pursuit eye movements in normal human subjects using positron emission tomography (PET).

**Methods:** A single normal human subject has been tested so far using [O15] PET. There were three tasks: (1) at rest, with eyes closed; (2) fixation of a stationary target; and (3) smooth pursuit of a sinusoidally moving target. Eye movements were measured with infrared oculography. The data were analyzed using Statistical Parametric Mapping (SPM95). The condition (at rest, fixation or smooth pursuit) and covariate (mean global blood flow) effects were estimated according to the general linear model at each and every voxel (Friston et al., 1995). Regionally specific condition effects were determined using linear contrasts. **Results:** Large Z-scores (all  $Z > 3.1$ ) indicated robust activation of regions hypothesized to be active during smooth pursuit, including the following regions: (1) primary visual area, (2) middle temporal/ medial superior temporal area, (3) parietal eye field, and (4) frontal eye field. The locations and Z scores of the oculomotor regions corresponded well with previous reports. The number of subjects will be increased to N=6, and these data will be presented.

**SUPPORT:** NIH: CRC MH40279, R01 MH43031 and MH49826.

## 96.11

**CORTISOL RESPONSE TO STRESS IN SCHIZOPHRENICS WITH WATER IMBALANCE** M.B. Goldman\*, Psychiatric Institute, University of Illinois at Affiliation with the University of Chicago, Chicago, IL, 60612

Hypotonic schizophrenic patients are hypercortisolemic and have smaller hippocampi compared to matched schizophrenic controls or normals. This brain region has been linked to schizophrenia, water imbalance, and the restraint of neuroendocrine

responses to psychological stress. In particular, glucocorticoid response to stress may be heightened and prolonged following hippocampal damage. We performed the cold pressor test in hypotonic schizophrenics (HS) (n = 4; ■), normotonic nonpolydipsic schizophrenics (NS) (n = 5; ▲), and normal controls (C) (n = 5; △) to assess if the HS demonstrate this pattern of glucocorticoid response to stress.

Psychiatric subjects were first stabilized on haloperidol for 2 wk on an inpatient psychiatric research unit. At 1430 h, an IV catheter was inserted and a blood pressure cuff attached. 90 min later, subjects immersed their dominant hand in ice water for 60 s (▼), and measures were obtained at regular intervals for the next 2 h.

Basal cortisol (CORT) tended to be lower in NS than in the other groups ( $P < 0.06$ ) (data = mean  $\pm$  SEM). The CORT response differed in HS vs. NS and C (fig.) ( $p < 0.02$ ) as well as in NS vs. C ( $p < .005$ ). Other responses (i.e. subjective pain, blood pressure, pulse, temperature, plasma glucose) were similar across groups.

These preliminary results are consistent with the concept that neuroendocrine response to psychological stress is enhanced in HS. Sponsored by The Brain Research Foundation of the University of Chicago.

## 96.13

**NMDA GLUTAMATE RECEPTOR HYPOFUNCTION: A MODEL FOR SCHIZOPHRENIA-LIKE COGNITIVE AND BEHAVIORAL SYMPTOMS** J.W. Newcomer\*, N.B. Farber, V. Jevtic-Todorovic, G. Selke, A. Kelly, F. Williams, S. Craft, J.W. Olney. Washington University School of Medicine, St. Louis, MO 63110.

N-methyl-D-aspartate (NMDA) glutamate receptor hypofunction (NRH) is central to recent hypotheses concerning the neurobiology of schizophrenia. This experiment aimed to transiently induce mild schizophrenia-like behavioral and cognitive symptoms in young healthy adults using double-blind, "placebo"-controlled, randomized, within-subjects comparisons of 3 fixed subanesthetic, steady-state doses of intravenous ketamine, with detailed behavioral and cognitive assessments during each infusion condition.

Results (n=10) indicate dose-dependent increases in schizophrenia-like symptoms, including Brief Psychiatric Rating Scale (BPRS) positive (F[3,27]=14.83,  $p < 0.0001$ ) and negative symptom subscales (F[3,27]=3.90,  $p = 0.02$ ). Scale for Assessment of Negative Symptoms (SANS) total (F[3,27]=4.49,  $p = 0.01$ ) and affective flattening subscale (F[3,27]=3.01,  $p = 0.05$ ), and trend-level increased BPRS conceptual disorganization (F[3,27]=2.65,  $p = 0.07$ ). Ketamine also produced a dose-dependent decrease in immediate and delayed verbal recall (F[1,9]=7.34,  $p = 0.02$ ; placebo vs. high dose), consistent with a ketamine-induced decrease in retrieval and/or encoding. Ketamine-induced NRH produces mild schizophrenia-like psychiatric symptoms as well as impairment in verbal memory and learning, consistent with well-described impairments in memory and learning in schizophrenia. Ketamine-induced NRH offers a useful clinical model for studying schizophrenia-like cognitive and behavioral symptoms. Supported by a Scientist Development Award (SDA) from NIMH (MH01045; JWN), an SDA from NIDA (DA00290; NBF), and an Established Investigator Award from NARSAD (JWO).

## 96.10

**AVOIDANCE LEARNING DEFICITS IN SCHIZOPHRENIA.** C.D. Fisher<sup>1</sup>, M.H. Kosmidis<sup>2</sup>, and B.D. Fantie<sup>1\*</sup>. <sup>1</sup>Human Neuropsychology Lab, The American University, Washington, DC 20016, <sup>2</sup>Lab of Psychology and Psychopathology, NIMH, Bethesda, MD 20892.

Past investigations of automatic cognitive processing in patients with frontal deficits (i.e., CHI survivors) have suggested that using an aversively loud auditory stimulus can help them compensate for these deficits. Such a cue can enhance associative learning by drawing attention to the stimulus relevant to solving the problem. We administered two conditioned avoidance tasks, in which we altered the salience of the auditory UCS, to a group of schizophrenic patients and normal controls.

Preliminary data suggest that both groups had difficulty making the required association to avoid the nonaversive stimulus. On the aversive task, the normal controls benefited from the UCS and needed fewer trials to reach criterion (U(6,23)=21,  $p < .01$ ), and both avoided (U(6,23)=29,  $p < .05$ ) and escaped (U(6,23)=30,  $p < .05$ ) faster than the schizophrenic group; the schizophrenic patients did not benefit from this salient stimulus. Within subject analyses revealed that the control group reached criterion on the aversive stimulus task faster than on the nonaversive stimulus task ( $Z = -2.2$ ,  $p < .05$ ), whereas the performance of the patients did not differ between the two conditions.

Schizophrenic patients did not differ from the control subjects in their performance on the more ambiguous, nonaversive task, but they did not benefit from the more salient, aversive stimulus as did the control group. This pattern of performance suggests that the schizophrenic group was not disorganized, but either that they had deficits in processing negative consequences or were less sensitive to the aversiveness of the stimulus.

## 96.12

**EFFECT OF ANTIPSYCHOTIC DRUGS ON FORCE CONTROL IN SCHIZOPHRENICS.** P.E. Konicki\*, D.W. Brescan, M.A. Fuller, G.E. Jas-kw, G. Jurjus, K.Y. Kwon, A. Popli and P.B. Vrtunski, Cleveland VAMC and Department of Psychiatry, CWRU School of Medicine, Cleveland, OH 44141.

Although the motor effects of different antipsychotic drugs are well known, there are few objective techniques for measuring them. With the emergence of 'atypical' antipsychotic drugs, there are new opportunities to investigate the mechanisms of motor side effects. To this end, we studied 112 chronic schizophrenics and 20 normal control subjects using a force control (FC) task. All patients were on stable antipsychotic treatment with either clozapine (N=66), haloperidol (N=18), fluphenazine (N=24), or risperidone (N=7). The task consisted of subjects' index-finger pressure on a force-sensitive button and matching target and response lights. There were 42 trials of varying force. The steadiness error of force maintenance was the dependent variable. The largest steadiness error was in the clozapine group ( $2.769 \pm 0.478$ ), followed by the haloperidol ( $2.666 \pm 0.624$ ), fluphenazine ( $2.311 \pm 0.472$ ), risperidone ( $2.154 \pm 0.325$ ) and control groups ( $1.775 \pm 0.252$ ), respectively. The overall difference was highly significant (F(4,127) = 19.79,  $p < 0.0001$ ). The significance was localized (Tukey test) to six of the 10 contrasts (the four which were not between the neighboring pairs: clozapine-haloperidol, haloperidol-fluphenazine, etc.) We conclude that each antipsychotic drug may have its characteristic effects on the force control function. Two contrasts are particularly interesting: a) virtual absence of difference between clozapine and haloperidol, even though clinically the two are quite distinct, and b) wide separation between haloperidol and risperidone despite their clinical similarity.

## 96.14

**APOE IN SCHIZOPHRENIA.** D. Pickar, A.K. Malhotra, W. Rooney, J.N. Crawley\*, A. Breier, D. Goldman. Experimental Therapeutics Branch, NIMH, Bethesda, MD 20892

APOE4, a naturally occurring allele of the gene encoding apolipoprotein E (ApoE), increases the risk of developing late-onset Alzheimer's disease. We have examined APOE allelic frequency in schizophrenia using the Haplotype Relative Risk technique (n= 56 families) and studied the association between APOE alleles with clinical aspects of schizophrenic inpatients (n=74). We find no increase in transmission of APOE4 in schizophrenia. We did observe, however, that patients with an APOE4 allele showed later age of onset ( $p < .01$ ) and less positive ( $p < .01$ ) symptoms when drug free and less treatment response to typical ( $p < .05$ ) but not to atypical antipsychotics. These data suggest that APOE4 genotype may influence phenotypic expression in schizophrenia. Further investigation is underway in an independent group of schizophrenic outpatients.

ASSOCIATION BETWEEN THE BDNF GENE AND SCHIZOPHRENIA. A.M. Vicente, F.M. Maciardi, M. Verga, H.B. Niznik, N. King, G. Bean, and J.L. Kennedy. Section of Neurogenetics, Clarke Institute of Psychiatry, University of Toronto, 250 College Street, Toronto, ON M5T 1R8 Canada.

Several lines of evidence suggest that a neurodevelopmental defect may play an important role in the etiology of schizophrenia. Alterations in the cerebral cortex and limbic system of schizophrenia patients have been reported, including changes in sizes of temporal lobe structures, altered sizes and numbers of specific types of neural cells, and disarray of neurons in the hippocampal region. These anomalies could be attributed to defective function of a number of interacting neurodevelopment molecules involved in neuronal differentiation, migration, and synaptic connectivity in the brain. The Brain Derived Neurotrophic Factor (BDNF) is a member of the neurotrophin family, and promotes the survival and differentiation of neurons during embryonic development. In the adult brain, BDNF is highly expressed in limbic regions, where it is involved in synaptic plasticity mechanisms, and has been shown to interact with dopaminergic and serotonergic pathways, repeatedly implicated in schizophrenia. We report the finding of association between a marker at the BDNF locus and schizophrenia ( $\chi^2 = 10.401$ ,  $p = 0.0155$ ,  $df = 3$ ), using the Haplotype Relative Risk (HRR) method of analysis in a sample of 77 probands and their parents. In addition, we performed a Transmission Disequilibrium Test (TDT) and obtained a statistically significant result for two risk alleles in schizophrenia ( $p = 0.0032$  and  $p = 0.0110$ ). The results obtained represent moderate association, implying that BDNF is possibly a susceptibility locus, not necessary or sufficient for disease expression but significantly increasing the risk for schizophrenia. ## 96.17

LACK OF TRIPLET REPEAT EXPANSION IN  $\beta 1$  SUBUNIT OF  $Na^+, K^+$ -ATPase IN TEMPORAL CORTEX OF BIPOLAR PATIENTS. R.S. El-Mallakh, J. Kleinman and R. Li. Department of Psychiatry, University of Louisville School of Medicine, Louisville, KY 40292. and Clinical Brain Disorders Branch, NIMH, Washington DC 20032.

The human genome possesses many nucleotide repeat sequences. Recently, trinucleotide repeat expansion has been found to be strongly associate with several neuropsychiatric diseases. These diseases share common features such as anticipation (worsening disease expression across successive generations) variable penetrance, and isolated neuromuscular involvement with progressive symptomatic course. Bipolar illness possesses many of these characteristics. Early studies suggested that bipolar individuals may have an abnormality of sodium pump regulation. Since the  $\beta 1$  subunit of the sodium pump possesses a polymorphic triplet repeat sequence (CGG) in the untranslated 5' promoter region, we examined its sequence in post mortem brain tissue from bipolar and normal individuals. Total genomic DNA was isolated from temporal cerebral cortex in 5 bipolar and 5 normal individuals and further amplified by nested PCR. After total of 30 cycles, the PCR reaction mixture was analyzed by 3% agarose gel electrophoresis. PCR products were purified and used as templates for direct sequencing. Our results revealed no expansion of CGG repeats in  $\beta 1$  subunit isoform of sodium pump from bipolar patients (the number of CGG repeats were 7-8 in temporal cerebral cortex from both normal and bipolar individuals). We conclude that the abnormality of sodium pump in bipolar patients does not appear to be related to a triplet repeat expansion.

## 96.19

DECREASED ACOUSTIC STARTLE PREPULSE INHIBITION IN TRANSGENIC MICE WITH AN IMPAIRED GLUCOCORTICOID RECEPTOR (GR) FUNCTION: IMPLICATIONS FOR AFFECTIVE AND ANXIETY DISORDERS. S. Beaulieu, J.R. Glow, N. Barden and R.M. Post. Biological Psychiatry Branch, NIMH, Bethesda, MD 20892-1272.

A transgenic (TG) mouse model of impaired GR function and secondary ACTH and corticosterone hypersecretion has previously been developed (Pepin et al., *Nature*, 355, 1992; 725-728). We have demonstrated that TG mice have a significantly higher startle response than control (CT) animals before treatment ( $p < 0.0001$ ). It had been previously established that a 2 week treatment with desipramine was sufficient to normalize the level of GR mRNA and GR. This treatment (10-20 mg/kg/day s/c) reduced the startle response of TG mice to levels indistinguishable from those of saline treated CT. In an attempt to further characterize the startle response of these TG mice and the possible mechanisms for the increased startle response, we studied the effectiveness of prepulse inhibition (PPI). The CT and TG animals were placed in the startle chambers for a 5 min acclimatization period with a 70 dB background noise. A test session consisted of 24 trials: 13 startle trials of a 110 dB acoustic startle stimulus (100 msec), and 11 PPI trials of 85 dB (30 msec) that preceded the startle trial by 100 msec. All trials were separated by periods of background noise that varied in duration and averaged 15 sec. The TG mice showed a consistently decreased percentage of prepulse inhibition of the startle response (40%) compared to control animals (64%) ( $p < 0.002$ ). This suggests that an impaired GR function leads to a decreased effectiveness of the PPI circuit to negatively modulate the startle circuit. This may play a role in the increased response to anxiogenic stimuli observed in these animals and possibly, in patients with anxiety and affective disorders. (Supported by the Medical Research Council of Canada and The Stanley Foundation)

## 96.16

ALLELIC VARIATION OF THE HUMAN HISTAMINE  $H_2$  RECEPTOR GENE IS A MAJOR PREDISPOSING FACTOR FOR SCHIZOPHRENIA. P.R. Orange\*, P.R. Heath\*, S.R. Wright\*, C.N. Ramchand\*, L. Kollievicz\*, R.C.A. Pearson\* Dept. Biomedical Science, University of Sheffield, Sheffield, S10 2TN, UK. \*Claybury Hospital, Woodford Bridge, Woodford Green, Essex, IG8 8BY.

Evidence is rapidly emerging which suggests an involvement of brain histamine in the pathophysiology of schizophrenia. A potent histamine  $H_2$  antagonist (Famotidine) has been shown to ameliorate symptoms of the disease. We have recently described a novel allelic variant of the human histamine  $H_2$  receptor gene (NeuroReport 1996 7(7)). This study investigated the relationships between  $H_2$  genotype and schizophrenia.

DNA was collected from schizophrenia sufferers ( $n=47$ ) (DSMIII-R/ICD-9) and non-psychiatric controls ( $n=46$ ). From these DNA samples a 266 base pair PCR fragment of the  $H_2$  gene was produced. The PCR fragment was then analyzed by detecting single-stranded conformational polymorphism (SSCP), as well as investigating differences in *TaqI* restriction endonuclease digestion patterns.

An increase in the homozygous  $H_2R_{490}$  genotype in the schizophrenic population of  $\times 2.57$  ( $p < 0.0001$ ) was shown. This data puts the attributable fraction of  $H_2R_{490}$  homozygosity for schizophrenia at 23.1%.

These data show that another monoaminergic neurotransmitter is implicated in the pathophysiology of schizophrenia. Whilst the sample size is small, the high degree of significance suggests that the brain histaminergic system and in particular the  $H_2$  receptor, are fundamental to the disease process.

## 96.18

A FAMILY-BASED ASSOCIATION STUDY OF BIPOLAR AFFECTIVE DISORDER. M. Del Zompo\*, M.P. Piccardi, G. Severino, R. Ardu, M. A. Palmas, A. Bocchetta. Department of Neurosciences "B.B. Brodie", University of Cagliari, I-09124 Cagliari, Italy.

Genetic factors play an important role in the pathogenesis of bipolar affective disorder, but traditional linkage studies have so far failed to identify major single genes. An alternative to linkage studies in common-complex diseases are association studies using markers of candidate chromosomal regions. In order to overcome the problem of population stratifications, family-based association methods have been proposed, using non-transmitted parental chromosomes as controls. We studied several different polymorphic markers in chromosomes from 44 triads, consisting of probands with bipolar disorder and their parents. No association was found between bipolar disorder and the dopamine  $D_3$  receptor gene, which is located on chromosome 3q13.3. An association was found with the locus of glucose-6-phosphate dehydrogenase, but not with two additional markers of the same chromosomal region (Xq28). Other candidate genes are currently being investigated, including the dopamine  $D_4$  receptor gene, located on chromosome 11p15.

## 97.1

**HISTORICAL PERSPECTIVES ON PHARMACOLOGICAL TREATMENT OF DEPRESSIVE DISORDERS.** L.H. Schneider<sup>\*</sup> and R.B. Murphy. Innova Biomed, Inc., Irvington NY 10533 and New York University Department of Chemistry and Center for Neural Sciences, New York, NY 10003

The pharmacological armamentarium of antidepressant drugs has expanded vastly since the original postulation of a role for biogenic monoamines in affective disorders. The present-day proliferation of new classes of rationally designed selective agents such as SSRIs, SNRIs, and the like somewhat obscures the fact that a variety of therapeutics have been in use in Western medicine for the treatment of depressive illness for several centuries. At the time they were prescribed these therapeutics were widely believed to be useful and effective, based principally upon empirical observation. In this poster we trace the historical evolution of antidepressant agents which have been commonly employed in practice. We examine the place of these therapeutics as an important component of the overall treatment strategies which were historically employed. The period from the early Nineteenth century up to the present day is examined. This analysis affords a social as well as a scientific perspective on the evolving roles of therapeutics in general through this period. Supported in part by Innova Biomed, Inc.

## 97.3

**MIND AND THE NEUROSCIENCES.** J.G. Foy<sup>\*</sup>. Dept. of Psychology, Loyola Marymount University, Los Angeles, CA 90045.

One of the most important questions facing neuroscience today is the nature of the relation between neural and mental events. Neuroscience research in the 1990s, the Decade of the Brain, has been a period of unparalleled data-gathering, a time where basic questions of the science have predominated. Many would argue, however, that despite this rapid expansion of our knowledge about the brain, we are no closer to answering the fundamental question about the relation between mind and the brain than Aristotle or Descartes. A paradigmatic reluctance in the neurosciences to address these broader questions has been tempered somewhat by Francis Crick and Christof Koch's encouragement of questions pertaining to consciousness, but a lack of communication between disciplines concerned with the mind, (e.g. philosophy, psychology and the neurosciences) about things of the mind, is still prevalent. Applied subfields of these disciplines (e.g. cognitive science and neuropsychology) have grown remarkably in number and in size in recent years, suggesting that there is considerable interest in addressing these questions. I propose that an historical look at the development of the disciplines of psychology, philosophy, and neuroscience in the last 100 years may shed some light on current debates about the relation between mind and brain, and whether, as we approach the 21st Century, we are asking the appropriate questions.

**THE EVOLUTION OF THE BRAIN/MIND IN HORROR AND SCIENCE FICTION.** S.R. Ginn<sup>\*</sup>. Department of Psychology, East Carolina University, Greenville, NC 27858-4353.

With apologies to Gene Roddenberry, I and most neuroscientists would agree that the brain/mind is the "final frontier." We spend our lives studying this complex landscape in order to more clearly elucidate the mechanisms by which this most complex of entities works. Nonetheless, we must also be cognizant of the fact that the majority of the public views scientists with suspicion, if not hostility. Such a view may be perpetuated by popular fictional accounts of the "mad scientist" in his laboratory (and in this case I am referring to men only because the majority of "mad scientists" are men). These scientists violate every ethical principle known to man and woman and the professional societies in an effort to test their (rather outlandish) hypotheses. Such efforts include altering the structure of the DNA, specific genes, proteins or hormones to change man into various subhuman creatures (alligators, flies, wolves, pre-humans, etc.) and have been recorded by authors from H. G. Wells to Dean Koontz. In addition, various organs, including human and nonhuman brains, have been transplanted from human to human, human to nonhuman and nonhuman to nonhuman (including "aliens"). This presentation is intended to provide a humorous look at the work of these "mad scientists" as they search for the answers to the meaning of the brain and/or mind. However, the fact that the general public frequently believes that such research is not only possible, but actually happening somewhere (presumably in a Department of Defense facility), is frightening. Suggestions for combatting the negative perceptions of scientists will be encouraged.

## 97.2

**DELIRIUM: A HISTORICAL REVIEW OF REPUTED CAUSES.** K.A. Hesse, G.W. Hesse<sup>\*</sup>. Geriatric Medicine, Deaconess Hospital, Boston, MA 02215

Delirium is a common phenomenon in acutely ill patients. Studies suggest up to 30% of medical patients over age 65 may be delirious during an acute hospitalization. This poster reviews historical efforts to understand the causes of this familiar clinical experience often associated with dire prognosis. The early Greeks and Romans were aware of the syndrome complicating fever. Hippocrates described many cases associated with infection in his Book of Epidemics. Asclepiades suggested it was caused by a stoppage or obstruction of the corpuscles of the membranes of the brain while Soranus believed the stoppage occurred in the "sensory passages". Some thought it arose from disorders of the bowel or the diaphragm. Galen proposed a disease of yellow bile associated with dryness and heat and this view persisted through the middle ages. Toxins (henbane) and intoxications (wine) were recognized as causes by Jewish, Byzantine, and Arabic writers. By the 16th century, over heating or over cooling of the brain were thought to be etiologies competing with a proposed moral disorder of the soul. 17th century writers suggested heat or fever increased blood velocity resulting in abnormal secretion of material from the brain while 18th century theory proposed toxic particles produced from the body out of food caused excessive heat and the resultant changes in blood velocity. Delirium tremens was described by the 19th century and attempts were made to localize the various symptoms of delirium to anatomical areas of the brain. The modern era has classified the causes of delirium as intoxications, withdrawals, infections and metabolic disturbances. However, the underlying mechanism of brain dysfunction remains poorly understood and neuroscientists are still struggling to elucidate the final common pathway producing delirium.

## 97.4

**STEREOTACTIC CEREBRAL LOCALIZATION: ORIGIN, EVOLUTION AND FUTURE.** R.L. Jensen<sup>\*</sup> and J.L. Stone. Department of Neurological Surgery, Loyola University Medical Center, Maywood, IL 60153.

The precise localization of intracranial targets based on extracranial and more recently on intracranial landmarks has been an important technique for neuroscience experimentation as well as for diagnosis and treatment of a number of neurological diseases. We describe the origin of this work with the cadaver studies of Paul Broca, early animal studies with guided electrodes, and Zernov's "encephalometer" which was used on human patients. The first stereotactic instrument was the Horsley-Clarke frame and extensive animal studies were carried out using this device. This instrument was used on humans as well and influenced the work of Spiegel and Wycis who designed and used the first stereotactic frame made exclusively for humans. A number of stereotactic instruments and atlases evolved from this early human work. With the emergence of better radiographic, CT and MRI imaging techniques, frame-based and frameless stereotactic techniques are currently available. We describe the principles behind these methods, the origin and evolution of their use and future of stereotactic cerebral localization.

## 97.6

**THE HISTORY OF ALZHEIMER'S DISEASE FROM THE PERSPECTIVE OF PATHOLOGICAL VS. NORMAL PROCESSES OF AGING.** J.A. Martin<sup>\*</sup> and C. W. Cotman. Dept. of Psychobiology, Univ. of Calif., Irvine, CA 92697-4540.

The incidence of dementia has reached epidemic proportions in the industrialized world because better health care has successfully prolonged people's lives. Though many factors can contribute to dementia, half of the cases are ascribed to Alzheimer's disease.

Many ancient civilizations, such as the Chinese with their Taoist philosophy, shared the belief that health and longevity required harmony, or balance of certain principles, such as Yin and Yang, whereas disease and death resulted from an imbalance. However, the Indians categorized aging as a specific form of illness called a "natural disease," and the Greeks viewed aging and death as normal processes of life, resulting from the inevitable loss of heat from the heart. Although there is only limited mention of dementia in medically related literature, there is evidence that these early societies were aware of its existence through literary allusions.

The neurophysiology associated with dementia was not described until the late 19th century. In 1892 Blocq and Marinesco described plaques in the brain of an elderly epileptic patient. In 1906 Alzheimer described neurofibrillary tangles in a demented woman's brain, suggesting that it was a distinct type of disease. His student Perusini made detailed descriptions of the neuropathology in his patients, but Alzheimer later described strong reservations about these cases being a distinct disease. Fischer clarified the significance of these findings through his own detailed descriptions and with the first clinico-pathological correlational studies. Despite Alzheimer's reservations, Kraepelin identified this newly distinguished form of dementia as Alzheimer's disease in his organization of psychiatric disorders.

Currently, Alzheimer's disease is well recognized and may affect nearly half of the population over age 85. Some studies show that 84% of normal aged brains have plaques and 97% have tangles. Other studies indicate that aged brains can have severe neuropathology without the expected level of dysfunction. Thus, the history continues as to whether Alzheimer's disease is a pathological process or an exaggerated normal consequence of aging.

## 97.7

A HISTORY OF ALZHEIMER'S DISEASE (AD): 1880 INDEX MEDICUS TO INTERNET. Henrik K. Kulmala\* Grayslake, IL 60030

As research into AD has increased since the 1970's, this study sought to explore the nature of AD research and reporting starting in 1880 and the current state of the internet [world wide web (WWW)] as a source of information on AD. Two data sources were examined: Index Medicus starting in 1880 and the WWW using WebCrawler® in April 1996.

Dr. Alzheimer, a German physician, first described a unique disease to a convention of Southwestern German psychiatrists in 1906 and published the first account of this disease in 1907. The first reference to AD appeared in a book published in 1910 by Dr. Kraepelin, Alzheimer's superior. This account was so much more colorful and detailed than Alzheimer's paper, that it was usually cited. Kraepelin made a distinction between AD (early onset) and senile dementia in the book. Dr. Alzheimer conducted an active, self-funded research program during his career, dying after an extended illness in 1915.

From 1911-14, AD was indexed under Insanity, presenile and there were 20 papers. There was no reference to AD from 1915-17 and only 12 papers under this heading. One reference to Alzheimer appeared in 1922: an account by Kraepelin of the deaths of Alzheimer, Brodmann, and Nissl. The early 1940's saw a decrease in the number of papers on AD and the size of the Index Medicus, with a large increase after WWII. In 1970, there were 54 papers on dementia, presenile and 59 on psychoses, senile, both references to AD. In 1980 there were 97 and 77, respectively. AD became a separate heading in 1984, with >200 references and more every year since.

A search of the WWW revealed 496 documents, although many of these were resumes and alphabetical WWW subject listings. Several offered information on AD, including grants information and data on the disease.

(Supported by NEOUCOM 1984-7 and HKK).

## 97.9

THE CNS MYELINATING CELL: OLIGODENDROCYTES - A BRIEF HISTORY OF TIME. S.D. D'Souza, A.F. Sadikot, V.W. Yong and W. Feindel. Montreal Neurological Institute, Montreal, QC H3A 2B4.

Oligodendrocytes were among the last cells of the CNS to be described, owing to their refractoriness to the metallic stains in use in the 1800s. Cajal's gold chloride-sublimite method which selectively labelled astrocytes, predicted the existence of a "third element" within the classic neuroglia. Robertson (1899), using his platinum stain, recognized a group of cells (oligodendrocytes) that he erroneously called "mesoglia", based on his belief that they were of mesodermal origin. Rio-Hortega (1919), using his silver carbonate stain that selectively impregnated the "third element" of Cajal, proved that it was made up of two distinct cell types, which he named "microglia" and "oligodendrocytes" (OLs). He made the distinction between "interfascicular" OLs that were situated in rows between myelinated axons of the white matter, and "perineuronal satellite" OLs of the grey matter. Having observed a great variability in the morphology of OLs, Rio-Hortega (1928) proceeded to subdivide OLs into four prototypes: types I, II, III and IV.

From their anatomical position and the fact that their appearance in development corresponded with the period of myelination, Rio-Hortega (1921) and Penfield (1924) proposed that OLs were involved in myelination in the CNS. Tissue culture studies (Lumsden and Pomeroy, 1951) and electron microscopy studies (Farquhar and Hartman, 1957; Peters, 1960; Bunge et al., 1962; Mori and Leblond, 1970) provided definite proof that OLs were the myelinating cells of the CNS. In demyelinating diseases of the CNS such as multiple sclerosis (MS), OLs and their myelin membranes are the selective targets of immune-mediated destruction. Certain white matter areas, however, are spared in MS. Could it be that the various types of OLs have different susceptibilities to immune effector mechanisms?

## 97.11

DAVID HARTLEY'S (1749) DOCTRINE OF NEURAL VIBRATIONS: ENLIGHTENMENT OR ACCIDENT? R. B. Glassman\* and D. Spadafora. Depts. Psychol. and History, Lake Forest College, Lake Forest, IL 60045.

The doctrine of vibrations, and a notable pre-Hebbian, pre-Pavlovian formal examination of associations, are aspects of David Hartley's 1749 treatise, *Observations on Man, His Frame, His Duties, and His Expectations*. According to D. N. Robinson (*Intellectual History of Psychology*, Macmillan, 1976), Hartley's text, "is a treatise in modern psychology." The "famous theory of vibrations was the first detailed modern treatment of physiological psychology, and it won Hartley considerable renown ..." (Spadafora, *The Idea of Progress in Eighteenth-Century Britain*, Yale, 1990). How could Hartley have chosen such an apt metaphor for neural activity, with its (as we now know) frequency-modulated action potentials, before anything was known about its electrical basis? Was this a mere intellectual accident? One root of the idea may be sought in Hartley's several references to Newton's conception of light as particles that have vibratory effects and an octave property (e.g., Hartley, pp 18, 41; Newton's *Opticks*, Dover, 1740/1979, pp 126, 280, 344). Hartley also extensively considered the question of continuity from body to cortex of the "medullary substance," i.e. nerves and CNS white matter - whose fibers had to have a uniform "pellucid" texture (Hartley, p 17). We hypothesize that Hartley's vibration metaphor was a rational inference; his book suggests awareness that a neural system must include a medium in which communication of patterns finely differentiated in time and space supports the organization of behavior.

## 97.8

1896-1996: THE CENTENNIAL OF THE "AXON"

Marina Bentivoglio\* Institute of Anatomy & Histology, University of Verona, Italy.

The term axon was introduced in 1896 by Rudolph Albert von Koelliker (1817-1905) to designate the "axis cylinder prolongation". The modern nomenclature of the "neuron", term coined by Wilhelm Waldeyer (1836-1921) in 1891, already equipped with "dendrites", term coined by Wilhelm His (1831-1904) in 1889, was thus established one century ago. However, the earliest studies on the axon, christened in the middle of the debates on the neuron theory, date back to the beginning of the 18<sup>th</sup> century. The microscopist Antoni von Leeuwenhoek (1632-1723) provided in 1717 the first observation of nerve fibers ("very minute vessels"). In line with the current concept that animal spirit flowed in cavities along the nerves, von Leeuwenhoek believed that the axon was a tubular space. Abbot Felice Gaspere Fontana (1730-1805) is credited with the first description of nerve fibers and the envelope probably representing their myelin sheath. Fontana, director of the Museum of Natural Sciences in Florence, was interested in the biological effects of the viper venom. Using a magnifying glass, Fontana performed a careful dissection of the nerve "with a very sharp needle", then immersed the nerve in water so that the threads floated in it. In an addendum on the structure of nerves to his work on the viper venom published in 1781, Fontana described that "a nerve is formed of a large number of transparent, homogeneous, uniform, and simple cylinders... filled with transparent, gelatinous fluid... Each of these cylinders receives a cover in the form of an outer sheath... A very large number of transparent cylinders together can form a nerve." The neurohistologist Robert Remak (1815-1865) described in 1838 that the axons ("the primitive bands") originated from the nerve cell bodies ("nucleated globules"). In his posthumous work published in 1865, Otto Friedrich Deiters (1834-1863) provided an unequivocal illustration of the "main axis cylinder" (as opposed to the "small axon cylinders", emanating from protoplasmic processes, that represented distal dendritic arborizations). With the revolutionary progress of the neuron doctrine and its official name, the axon was thus ready for the 20<sup>th</sup> century.

## 97.10

THE CONCEPT OF HYPOTHALAMIC INTEGRATION IN THE "ANOTHOMIA" OF MONDINO DEI LIUZZI DA BOLOGNA.

\*\$R. Toni\*, \*F. Ruggeri, \*F. Briganti, \*RM Lechan.

*\*Human Anatomy, \*\$Internal Medicine-Endocrinology. \*NEMCH-Tufts Univ. Boston, MA USA and \*\$Univ. Bologna, Italy.*

The "Anothomia" of Mondino dei Liuzzi was the leading text of human anatomy during the XIV century in Europe. Using a recent translation from Latin to Italian of this text (Giorgi PP, Pasini GF, 1992), we have analyzed the description given by Mondino of the region of the cerebral third ventricle, believed to be involved in the regulation of the "entire animal behavior" through the contribution of both "physical sensations" ("sensata" in Latin) and "abstract feelings" ("non sensata" in Latin). In addition, he reports that discrimination of these two types of information occurs in the third ventricle region through the action of the faculties of "reasoning" ("virtus cogitativa" in Latin) and "memory" ("memorata" in Latin). Although this description condenses old principles coming from Aristotle, Galen and Avicenna, Mondino dei Liuzzi put forth the new idea that the region of the third ventricle is involved in the integration of sensory, emotional and cognitive information to regulate animal behavior. Therefore, his description represents one of the most ancient observations concerning the function of the diencephalon as a regulator of body homeostasis and implicates him as a forerunner of the concept of hypothalamic integration.

## 97.12

Historical Poster Exhibit: Temple S. Fay M.D. 1895 - 1963

Alfred R. Henderson<sup>1</sup> and Dong Jiang<sup>2\*</sup> 1 U.S. Department of State (retired), 2 Molecular Neuropharmacology Section, ETB/NINDS/NIH, Bethesda, MD 20892

Neurosurgeon, neurologist, educator, provocative investigator and unconformable harbinger of numerous clinical investigations. Professor of Neurosurgery and Neurology, Temple University. Devised new approaches to the management of trigeminal neuralgia, head trauma and epilepsy (by intense dehydration), CO<sub>2</sub> therapy for spastic disorders and seizures. First to reduce total body temperatures (breaking the thermal barrier) in the treatment of malignant tumors thus establishing clinical hypothermia. Founder of a method of treatment of brain-injured children, mainly cerebral palsy, utilizing phylogenetically functional pattern movements. Established the Neurophysical Rehabilitation Clinic in Chestnut Hill, Pa for this purpose. Co-founder of the Harvey Cushing Society and American Academy for Cerebral Palsy. The exhibit will contain appropriate photographs and reproductions of significant published materials.

## 97.13

**The Complexity of Glia-Architectonics: Golgi studies of Retzius (1894).**

B. Quinn,\* Div. Neuropathology, NYU Medical Center, New York NY 10016.

Until recently, astrocytes had received relatively little attention in most neuroscience research. Traditionally, forebrain astrocytes included fibrous and protoplasmic types, and ill-defined functions included ion buffering or other 'supportive' functions of astrocytes. However, in the early 1890's, Golgi studies by Retzius and others revealed a complex world of glial architectonics and a diversity of astrocytic morphologies. These morphologies included 'caudate' astrocytes, extending from the pial surface down to cortical laminae I/II; fibrous astrocytes, large and small protoplasmic astrocytes, small shrub-like forms, giant spider-like forms, perivascular forms, and additional specialized astrocytes such as the Bergmann glia of the cerebellum. Retzius described his studies in great detail in 1894 as a long article in the *Biologische Untersuchungen*. The work may mark an apogee of glial architectonic studies, because later versions of the Golgi stain were often titrated to impregnate neurons and avoid astrocytic impregnations. The later studies of Schroeder (1935) will also be discussed. The difficulty of visualizing the architectonics of astrocyte systems may have contributed to viewing them as rather inconspicuous, uniform cells which become reactive or hypertrophic in disease. It is interesting to look back on Retzius' exhaustive morphologic studies today, now that many additional functions and regional specializations of astrocytes are being proposed, such as production of various neurotrophins (e.g., glial-derived neurotrophic factor, GDNF), neurotransmitter metabolism (particularly glutamate), and modulation of the perisynaptic environment. Sponsored by the CorText Institute and the Stanley Foundation.

## 97.15

**WILDER GRAVES PENFIELD AND THE SPANISH NEUROGLIAL TECHNIQUES, V. Balasingam, V.W. Yong\*, W. Feindel. Montreal Neurological Inst., McGill Univ, Montreal, Quebec, Canada, H3A 2B4**

Wilder Graves Penfield (1891-1976), the American-born Canadian Neurosurgeon, played a prominent role in bringing the Spanish metallic impregnation techniques for the identification of neuroglia into North American neuroscience and neuroclinical spheres. Penfield was initially introduced to the histological study of the central nervous system (CNS) under the guidance of Sherrington at Oxford, England. As a visionary neuroscientist, Penfield travelled to Madrid, Spain, to study with the eminent Spanish neuromicroscopists Ramón y Cajal and Pio del Rio-Hortega to expand his understanding of the structure and function of neurons and glia in the CNS. It was here that Penfield began his seminal work on astroglial and oligodendroglial reactivity and the changes in microglia after brain injury by using the Spanish methods (Rio-Hortega and Penfield, 1927). He modified the original Spanish techniques and utilized them for studies involving the cytological classification of gliomas, the mechanisms of brain healing and the evolution of vasoglia scars in association with focal epilepsy. From these neuroglial studies he also contributed to future generations of neuroscientists and pathologists by providing expert technical instruction on these methods. A careful observer, Penfield is remembered as a tireless neurosurgeon who contributed to laying the ground-work for many modern studies on neuroglia and its role in brain function.

## 97.17

**WALTER HEILIGENBERG (1938-1994) AND HIS CONTRIBUTIONS TO BEHAVIORAL PHYSIOLOGY. G.K.H. Zupanc\*, Department of Physical Biology, Max Planck Institute for Developmental Biology, D-72011 Tübingen, FRG.**

Walter Heiligenberg, born on 31 January 1938 in Berlin and tragically killed in an air-plane crash at Pittsburgh (Pennsylvania) on 8 September 1994, was one of the most prominent pioneers in modern neuroethology. He completed his Ph.D. thesis in 1963 under the guidance of two famous biologists: Konrad Lorenz from the Max Planck Institute for Behavioral Physiology in Seewiesen and Hansjochem Autrum from the University of Munich. Following an invitation by Theodore H. Bullock, he joined, in 1972, the Neurobiology Unit of the Scripps Institution of Oceanography of the University of California, San Diego (UCSD), where he remained as a member of the faculty until his death.

In the course of his scientific career, Walter Heiligenberg made significant contributions to the analysis of behavior and especially to our understanding of how the brain controls behavioral patterns. At Seewiesen, he developed techniques to describe the temporal structure of behaviors by mathematical terms, and he succeeded in a quantitative demonstration of the phenomenon of "heterogeneous summation." Heiligenberg also showed that releasing and motivational effects are just the two end-points of a spectrum of possibilities that might occur after behavioral stimulation.

At UCSD, he analyzed neural mechanisms that control behavior by using the "jamming avoidance response" of weakly electric fish as a model system. He rigorously revealed the computational rules and the details of the neuronal network underlying this type of behavior. These achievements provided insights into general principles of neural algorithms and network organization, thus making them applicable to a wide array of neuronal systems.

The results of Walter Heiligenberg's work are likely to remain of major influence on ethologists and neuroethologists for many years to come.

Supported by grants from the Max Planck Society.

## 97.14

**RECOVERY OF FUNCTION AFTER EXTENSIVE LESIONS IN THE FOREBRAIN: THE EXPERIMENTS OF F. GOLTZ IN THE LIGHT OF CURRENT NEUROSCIENCE. A. Aschoff and G. F. Jirikowski\*, Dept. Anatomy II, FSU-Jena, Teichgraben 7, 07743 Jena, Germany**

120 years ago the physiologist F. Goltz from Strassburg developed a new method for experimental forebrain lesions in dogs. He used the cutting force of a water beam to destroy large parts of the cortical gray matter. Thus, he was able to keep the animals alive, and to conduct observations on resulting deficits and their subsequent functional recovery. He noted a correlation between the degree of deficit and the size, but not the site of the lesion. By inflicting painful stimuli through an automated device he described the occurrence of somatosensory deficits and rapid recovery. He also found impaired motor functions and visual deficits even after lesions restricted to the frontal cortex. Despite extensive cortical damage some sensory, visual, or motor functions were subsequently restored, albeit subtle somatosensory, visual and motor impairment persisted. Goltz' interpretation of his findings was concordant with current knowledge, and in disagreement with the views of Flourens and Hitzig (recovery based on structural redundancy), and the functional substitution theory of Carville and Duret. Goltz explained the deficit of function with the suppressive effect of the lesion on intact lower centers of the brain, anticipating the diaschisis concept of Monakow. He clearly stated that these transient functional deficits are caused by the loss of regulatory input and not by "vegetative" factors as blood flow or nutrition. Consequently, the resultant specific functional deficit should be determinable only after recovery from the lesion-induced inhibition has occurred. In this he opposes the view of strict localization of function within the CNS, and argues, that lesion-induced impairments reflect the function of intact, rather than damaged brain areas.

## 97.16

**THE PLATES OF PIETRO BERRETTINI DA CORTONA: A NEUROANATOMY AHEAD OF ITS TIME. R. Olry, M.-G. Martinoli\*, Dept of chemistry-biology, Univ. of Trois-Rivières, Qc, Canada G9A 5H7.**

The twenty-seven anatomical plates of Pietro Berrettini da Cortona (1596-1669) are rightly regarded as Baroque masterpieces. They were probably engraved in 1618 by Luca Ciamblerano (monogram on plates 1 and 4), but were published over a century later (first edition 1741; second and last edition 1788). On most of the plates, the anatomy of nervous structures (central, peripheral or autonomic) is emphasized, leading to the assumption that they were originally intended to illustrate a book of neuroanatomy or neurology. This putative book and its author are unfortunately unknown. However, the analysis of the minute details on these plates allows a better understanding of the neuroanatomical knowledge in the early seventeenth century, and get to reconsider some landmarks in history of morphological neurosciences. The course of trigeminal nerve is well depicted, over hundred and fifty years before the celebrated monograph of Giovanni Battista Palletta (1784), and the emergence of cranial nerves and their course through the base of the skull is comparable with Samuel Thomas Soemmerring's description of 1778. The plates of Berrettini da Cortona were therefore much ahead of their time, and their undeniable artistic features unfortunately pushed their scientific content into the background.

## 97.18

**WENDELL JORDAN KRIEG: NEUROANATOMIST, ARTIST AND THE CONCEPT OF ELECTRONEUROPROSTHESIS. D.E. Haines\* and A. Subramony. Department of Anatomy, The Univ. of Mississippi Med. Ctr., Jackson, MS 39216 and Yale Univ., New Haven, CT 06520.**

In 1949 Wendell Jordan Krieg (b. April 13, 1906) was Professor of Anatomy at Northwestern University. He had just completed 2 years ('46-'48) as Director of the Institute of Neurology at Northwestern and several years on the faculty as Associate Professor ('44-'46) and Professor ('46-'48) of Neurology. He had already established a reputation in neuroanatomy and, by this time, had published 3 books including the first edition of his textbook *Functional Neuroanatomy* ('42, '53, '66). Based on his broad-based research on the nervous system Krieg (in '49) originated what he called the concept of electroneuroprosthesis. He postulated that electrical appliances could be devised that would deliver patterned electrical stimulation to various areas of the nervous system (special emphasis on the cortex); these appliances would restore vision, hearing, and perhaps motor abilities. Krieg's ideas were novel, significantly ahead of his time, and met with considerable skepticism especially among his clinical colleagues. Although not pursued by Krieg, his ideas foretold the later development of a variety of neuroprosthetic devices. Krieg's publications, especially his 15 books, were illustrated by drawings of unparalleled detail, accuracy, and 3-dimensions. He executed these stunning illustrations by his own hand; they are unique among neuroanatomy textbooks published in the U.S. This poster reviews the career of W.J. Krieg with special emphasis on his scientific contributions, his unusual artistic works, and his theories on electroneuroprosthesis.

## 97.19

THE SESQUICENTENNIAL OF THE FIRST PUBLIC DEMONSTRATION OF SURGICAL ANESTHESIA. S. M. Dodek III\*, N. R. Myslinski, J. Buxbaum, C. Truax. OCBS Department, Univ. of Maryland Dental School. Baltimore, MD 21201.

On October 16, 1846, William G.T. Morton, a Boston dentist and medical student, first publicly demonstrated the use of general anesthesia. The substance was ether, and the operating room at Massachusetts General Hospital remains in use today as a memorial called "the Ether Dome".

Having heard that a medical student had developed a method for eliminating surgical pain, skeptical doctors and nurses gathered impatiently in the gallery of the operating room on a Friday morning in 1846. The surgeon was Dr. Warren. There were also several strong men available to hold the patient down in case the procedure did not work. William Morton administered the anesthesia and the operation was completed with the patient showing no signs of pain. The strong men were not needed. An eminent surgeon in the audience, Dr. Bigelow, remarked, "I have seen something today that will go around the world."

Within months, the use of ether spread to other cities in the U.S. and Great Britain, eliminating the suffering of millions of people and allowing for the development of many surgical procedures that would have been impossible without it.

Dr. Morton did not fare as well. He initially withheld the chemical nature of the substance, calling it "letheon". In 1848 he was granted a patent, but did not experience great wealth from his discovery. A provision of the patent permitted certain charitable hospitals to use "letheon" free of charge. Congress suggested a gift of \$100,000 for the discoverer of anesthesia, but the money never came forth. Over the decades following the first use of anesthesia, others claimed its discovery. One claimant was Charles Jackson, Morton's chemistry teacher. Another claimant was Horace Wells, known for his use of nitrous oxide. Dr. Morton died in poverty on July 15, 1868 in New York's Central Park.

## 97.21

A HISTORICAL REVIEW OF FUNCTIONAL BRAIN MAPPING TECHNIQUES. N. Prakash\*, Department of Psychobiology, University of California, Irvine, CA 92717.

Current functional brain mapping techniques include positron emission tomography (PET), intrinsic signal optical imaging (ISI), functional magnetic resonance imaging (fMRI), and voltage-sensitive dye imaging (VSD). Historically, these four techniques originated from three different principles: 1) active nerves become more opaque, 2) active neurons require more blood flow, and 3) active tissue shows oximetric changes.

Early work in 1892 by C.F. Hodge followed by D.K. Hill and R.D. Keynes in 1949 led to the concept that there are changes in nerve opacity directly correlated with electrical stimulation. These changes were found to be amplified by the addition of dyes and throughout the 1970's L.B. Cohen and his collaborators established the *in vivo* technique of VSD. In 1986, based on similar techniques as VSD, A. Grinvald and collaborators established ISI as a method for functional brain mapping.

C.S. Roy and C.S. Sherrington speculated in 1890 that, "The brain...vascular supply can be varied locally in correspondence with local variations of functional activity." It was only in 1967 that J. Risberg and D.H. Ingvar first confirmed this speculation in humans using radioactive gases and scintillation detectors. Improved multi-detector systems led to the development of PET and in 1986 P.T. Fox and collaborators reported the first mapping of the human visual cortex based on blood flow changes using PET.

Work by D. Keilin in 1925 followed by G.A. Millikan in 1933 led to the development of oximetry, which is the measurement of spectral changes that occur as hemoglobin is reduced. Oximetric techniques were further developed by B. Chance and collaborators starting in the 1950's and are currently used in clinical techniques, such as near infrared spectroscopy. Similarly, the intrinsic paramagnetic properties of deoxyhemoglobin led to the first successful fMRI based on oximetric principles by K.K. Kwong and collaborators in 1992 (after initial work by J.W. Belliveau and collaborators in 1991). Finally, in 1990 R.D. Frostig and collaborators reported that opacity, oximetric, and blood flow changes are the three major signals in ISI.

## 97.23

THE ORGANIZATION OF AGGREGATES; NEUROSCIENCE INSTITUTES AND THEIR LEADERS. L.H. Marshall\* and S. Bedi\*, Neuroscience History Archives, Brain Research Institute, and Dept. of Physiological Sciences, UCLA, Los Angeles, CA 90095-1761.

The philosopher/physicians of ancient times found that by congregating together for discourse, writing, and teaching they could more efficiently refine and spread their ideas and concepts than if they pursued a solitary life. Thus was formed in 4th c. Greece, Plato's academy teaching a cephalocentric view of the body, and Aristotle's lyceum with a cardiocentric opinion. During the Dark Ages, Avicenna in Persia spread Greek anatomic knowledge which returned to the West in the teaching texts of Mondino and Vesalius. In the late 19th c., European institutes were organized around distinguished men, especially in Germany. An International Association of Scientific Academies recognized eight institutes for neurological research, one of which was the Wistar Institute of Philadelphia, where Henry Donaldson (1857-1938) worked. Other North American institutes were in Montreal, New York, and elsewhere; in Chicago, Northwestern University built around Stephen Walter Ranson (1880-1942), who had been a student of Donaldson's. When Ranson's student, Horace Winchell Magoun (1907-1991) planned the Brain Research Institute at the University of California, Los Angeles, it was a shining example of the new American style of research facility with a team approach to brain and behavior that crossed departmental and disciplinary boundaries.

## 97.20

CENTENARY OF GAULE AND LEWIN; A LANDMARK IN THE HISTORY OF CELL COUNTING AND STEREOLOGY METHODS. John C. Hedreer\* and Jean Paul Vonsattel. New England Medical Center and Massachusetts General Hospital, Boston, MA.

One hundred years ago, in 1896, Justus Gaule and his student Th. Lewin published in the *Centralblatt für Physiologie* 10:437-440 and 465-471 a paper entitled "On the number of nerve fibers and ganglion cells in the spinal ganglion of the rabbit." In this paper they pioneered an unbiased method for converting the number of profiles of cells in the sections (i.e., the number of pieces that a cell is cut into by sectioning) to the total number of cells. In a sample of neurons that they could follow through serial sections, they found the total number of profiles for the sampled neurons, and thence the mean number of profiles per neuron. They then divided this number into the total number of profiles counted in the ganglion to obtain the total number of neurons in the ganglion. In the 32nd spinal ganglion of a rabbit they counted 71,264 neuron profiles in 10  $\mu$ m sections through the ganglion, and calculated 3.5 profiles per neuron. Thus their final count of neurons in the ganglion was 20,361. For comparison, they counted cells with nucleoli in the same sections, finding a total of 21,678, which they felt was too high because of counting some cells twice. Their admirably direct method for converting profile number to cell number did not come into general use, although a few papers in the 1930's [Davenport and Bothe, 1934; Foley and DuBois, 1937] did use such an approach when counting nucleoli. Coggeshall and colleagues [1984, 1990; Pover and Coggeshall, 1991] reinvented and perfected this procedure, which they called the empirical method, only to abandon it finally, as being less efficient than the disector method. (Supported by NIH; NS29484)

## 97.22

A RETROSPECTIVE LOOK OF THE UNIVERSITY OF MEXICO'S DEPT. OF PHYSIOLOGY TO ITS PRESENT DAY STATUS. E. Gijón, X. García, L. Cartas and R. Drucker-Colín\* Dept. de Fisiología, Facultad de Medicina, UNAM. México, D.F. 04510, México.

In the past, physiology in Mexico followed the prevalent ideas of the scientific world, since the founding fathers were all trained abroad. The aim of this work is to revisit the Department of Physiology of the School of Medicine at the Universidad Nacional Autónoma de México (UNAM), because it was the first Department of Physiology in all of Mexico, founded in 1934 by José Joaquín Izquierdo and years later was consolidated by Rosenblueth and Del Pozo, who started the kernel of physiology in México with a strong emphasis in Neuroscience. The first group of physiologists were Alcocer, Alonso de Florida, García Ramos, Guevara-Rojas, Hernández-Peón and Puche. Previous reviews in 1968, 1979, 1986, 1990 and 1993 showed that physiology is one of the most productive scientific disciplines in the medical sciences. Recent changes in the department of physiology has resulted in increasing staff, research lines, grants and technical support, which is reflected in its publication level which is similar sometimes to larger University Centers, Institutes and Schools. For example, its publications in the last three years equals the production that some research institutes show during much longer periods. This suggests that physiology remains one of the most productive scientific disciplines in México.

## 97.24

NEUROSCIENCE IN ANTIQUARIAN CHILDREN'S BOOKS: FROM THE *ORBIS PICTUS* OF COMENIUS TO LEWIS CARROLL'S *SYLVIE AND BRUNO*. R.A. Johnson\*, Neuroscience History Archives, Brain Research Institute, and Department of Special Collections, University Research Library, UCLA, Los Angeles, CA 90095 (e-mail: rjohnson@library.ucla.edu).

Several neuroscience-related topics were serendipitously identified in the course of a recent Department of Education Title IIC-sponsored project which created online catalog records for 10,000 pre-1900 titles in the Children's Book Collection at UCLA. Johann Amos Comenius's *Orbis sensualium pictus* (1658), considered the first educational picture book for children aside from illustrated alphabets, combined woodcuts with simple Latin and German sentences to produce "a nomenclature and pictures of all the chief things that are in the world, and of men's employments therein." Chapters on anatomy and sensation included two depictions of the brain: a cartoon-like horizontal section through the head and a cerebrum revealed in the manner of 16th-century anatomist Andreas Vesalius's scalp-draped dissections. The 18th and 19th century fascination with all things electrical was reflected in a treatment of Luigi Galvani's renowned and mythologized experiments, in Peter Parley's *A glance at the physical sciences* (1844). *A legacy of affection, advice, and instruction* (1827) described the cerebral and cerebellar ablation experiments of Pierre Flourens, in one of a series of letters from a retired governess to her charges. Experiments by Jules Jean César Le Gallois on the respiratory center of the medulla were filtered through the abolitionist gauze of the animal welfare movement's rhetoric at century's end in Susanna Watts' poem, *Adventures of Bigio* (1831). Science informed fiction in the latter half of the century; e.g., among carefully-indexed topics such as "how to improve (the) character of fairies," Lewis Carroll's *Sylvie and Bruno* (1889) nestled the "curiously slow action of nerves," "inversion of images on (the) retina," and a comparison of "nerve-force and free-will." Although there are few neuroscientific allusions buried in surviving books, what is striking is the detail in which concepts were described and the depth of understanding which the authors conveyed in works that were explicitly intended for juvenile audiences. Citations for appropriate works which the presenter might not have encountered are sought and welcomed.

## 98.1

**CREATING INEXPENSIVE INTERACTIVE MULTIMEDIA INSTRUCTIONAL PROGRAMS AND TEACHING AIDS FOR THE WORLD WIDE WEB.** R.A. Wheeler, S.T. Neary, C.L. Jollie, A.E. Baldwin, & J.T. Cannon\*. Departments of Psychology, Computer Science, and Neuroscience Program, University of Scranton, Scranton, PA 18510-4596.

Recently, we (Meyers *et al.*, 1993) described the integration of interactive multimedia programs into a behavioral neuroscience course. These programs were created using an array of costly hardware and software. Our most successful creation was a sheep brain neuroanatomy guide available at no cost through FTP on the Internet and currently used world-wide. Our original combination of hardware and software had two disadvantages: 1) its cost (NSF grant USE-9250437), and 2) the software did not run on other computer platforms. To address the latter, we translated our sheep brain guide into Hypertext Markup Language (HTML) for Netscape 2.0 compatible browsers (<http://academic.uofs.edu/departments/neuro>). Although this HTML conversion necessitated a reduction in image size and resolution to accommodate web bandwidth restrictions, the utility of the program has been increased: 1) the operating system problem is largely eliminated, and 2) the software can be used without requiring the downloading, extracting and housing the original 16 MB program file. A web format has provided some unexpected benefits, not the least of which is that multimedia applications can be generated for a fraction of our original cost. Quality video images can be obtained with a standard camcorder coupled to a Snappy™ framegrabbing device (<\$200). These images can be edited and labeled using software bundled with Snappy™. Multimedia HTML programs can be generated with a standard text editor or any of a growing number of inexpensive/free HTML editors. The functionality of HTML is rapidly expanding and, unlike dedicated Multimedia authoring software, is not likely to suffer from rapid obsolescence. Finally, the Web generates both greater student interest and more direct contribution to the authoring process than does idiosyncratic dedicated software. Our students are required to maintain home pages with course-related materials such as: current research topics and related Web links; histological images; honors theses; and "virtual" poster presentations.

## 98.3

**NEUROSCIENCES ON THE INTERNET.** N. A. Busis\*. University of Pittsburgh School of Medicine, Pittsburgh, PA 15213.

A database of Internet neuroscience resources was first published on the World Wide Web in December, 1994 and has been regularly updated. The Uniform Resource Locator (URL) of the US site is <<http://www.lm.com/~nab>>. There are mirror sites in the UK and Germany. Data was collected from Internet search services, announcements in USENET newsgroups, links on relevant World Wide Web pages or published in World Wide Web directories, and suggestions from others. Over 2400 links to neurobiology, neurology, neurosurgery, psychiatry, psychology and cognitive science sites are included (as of April, 1996). The database can be searched interactively or can be browsed via a hierarchical Table of Contents. It lists other neuroscience Internet guides, academic home pages, professional organizations, meetings, imaging resources, software, journals, patient information, newsgroups, mailing lists and Web forums. Some biomedical and World Wide Web links and a feedback form are included.

Currently, the optimal technique to find specific Internet neuroscience resources or to browse through the available sites is by consulting specialized neuroscience indexes and general Internet indexes and search services. This database will co-evolve with the World Wide Web and will serve as a testbed for new methods of information retrieval concerning Internet neurosciences resources.

## 98.5

**DRUGS AND THE BRAIN: A WORLD WIDE WEB TUTORIAL IN NEUROPSYCHOPHARMACOLOGY.** A.B. Chinn and K.A. Trujillo\*. Psychology Program, California State University, San Marcos, CA 92096-0001.

Understanding the ways that specific drugs affect the brain and behavior is a critical component of a variety of courses in the neurosciences, behavioral biology and psychology. However, many undergraduate students have difficulties grasping such material. This arises in part due to the new vocabulary students must acquire in order to understand the topic, but also because it is by nature an interdisciplinary topic, covering areas ranging from molecular biology to human behavior.

In order to supplement material for such courses and offer students an opportunity to better understand how drugs affect the brain and behavior we are designing a World Wide Web (WWW) tutorial devoted to neuropsychopharmacology. This hyperlinked tutorial is intended to give students exposure to the topic in a self-paced, interactive manner so that they can learn the material without being intimidated by it. In addition, students will be able to explore areas beyond the scope of their course material, gaining a deeper understanding of the field as a whole. To supplement the content we will include links to bibliographic information and a glossary of scientific terms. Each section will also include thought-provoking questions and quizzes that will allow students to utilize and process the information and gauge their understanding of the material. Finally, we will include links to other relevant WWW sites to provide an easy mechanism for students to further explore this topic.

It is hoped that this WWW site will serve as a valuable instructional tool for faculty teaching courses that include discussion of neuropsychopharmacology, a learning tool for students taking courses in this area, and an informational resource for anybody with an interest in the ways that drugs affect the brain and behavior.

Supported by the University Fund for Technological Innovation on Campus, CSU San Marcos.

## 98.2

**THE WORLD-WIDE WEB UNDERGRADUATE BEHAVIORAL NEUROSCIENCE RESOURCE SITE PROJECT: PROMOTING SCIENTIFIC LITERACY FOR THE NEXT GENERATION.**

E.P. Wiertelak\*. Department of Psychology, Macalester College, St. Paul, MN 55105.

The past 24 months has seen explosive growth in the use of the internet for pleasure and profit, as well as academic pursuits. While internet resources present unparalleled opportunities for curricular enhancement across academic disciplines, college students primarily use the internet for recreation and correspondence, utilizing e-mail, world wide web (WWW) browsers, newsgroups and gopher services.

The goal of the curricular program discussed here was to develop new instructional WWW mechanisms to augment our successful WWW diary and home page projects, and further enhance learning outcome in neuroscience via student involvement with the WWW. Initial exercises were designed to introduce WWW searching and provide real experience in programming HTTP through creation of home pages. This was followed by posting of sequential HTTP diary entries into each student's home page hierarchy. Following this training, students were divided into groups, which were charged with creating complete, one-stop resource sites for undergraduate-level student inquiries related to behavioral neuroscience. Each site covers a single topic, and features a hypertext-enhanced bibliography. Our experience has been that the inclusion of service-oriented, cooperative projects has provided students with increased insight into their own studies, and has given other neuroscience students at the undergraduate level sites containing easily understood yet comprehensive treatment of neuroscience-related topics.

## 98.4

**USING THE WORLD-WIDE-WEB AS A TOOL FOR AN INTER-DISCIPLINARY APPROACH TO THE SCIENTIFIC STUDY OF EMOTION.** J.-M. Fellous\* and E. Hudlicka, Volen Center for Complex Systems, Brandeis University, Waltham MA 02254-9110 and GTE Research Lab, Waltham.

The scientific study of emotion has always suffered from a lack of inter-disciplinarity. Recent advances in the neuroscience of fear conditioning and emotional disorders have contributed to a better understanding of the neural substrate involved. However, such results are for their most part largely unavailable to other disciplines such as experimental and cognitive psychology or artificial intelligence. The aim of the present work is to design and implement a web site dedicated to the scientific study of emotion, focusing on integrating and inter-relating the major results in neuroscience, cognitive and experimental psychology and artificial intelligence. It is intended as both a teaching tool and a research tool. It offers both overviews, and links to in-depth analyses located locally or remotely in the laboratories involved, ensuring up to date information.

This page contains a summary of the major results and bibliography in the three disciplines mentioned above. The neuroscience section includes the main results and theories on fear conditioning, the limbic system, and the neuro-pharmacology of emotional disorders, addressing simultaneously several levels of neural complexity. Results in each of the three disciplines are linked to results of the two others, whenever possible, providing focused 'gateways' from one discipline to another. This page also includes an extensive historical survey of the theories of the biological basis of emotion, from Plato to the beginning of the 20<sup>th</sup> century, with links to original online texts and artworks. Finally, it includes a section on relevant online conference announcements, journal and book publications, and links to various laboratories, individuals and institutions currently working on this topic. For information, contribution and free access, please contact [fellousj@volan.ccs.brandeis.edu](mailto:fellousj@volan.ccs.brandeis.edu).

## 98.6

**TEACHING ON THE INTERNET: ENHANCEMENT OF THE UCLA SCHOOL OF MEDICINE NEUROANATOMY CURRICULUM.** A.E. Cannestra\*, C.R. Houser, and A.W. Toga. Lab. of Neuro Imaging, Division of Brain Mapping, Departments of Neurology and Neurobiology, UCLA School of Medicine, Los Angeles, CA 90095

We constructed an Internet page for the UCLA School of Medicine neuroanatomy course to aid the communication of complex anatomical relationships, dynamic processes, and clinical imaging not practically presentable within the constraints of lecture or text. Material presented was coordinated with the course dissection schedule, reinforcing the students learning and contextualizing anatomic information within exemplary clinical presentations. References of recent functional research and hyperlinks to other neuroscience Internet sites were included to increase the integration of neuroscience research and medical school education. Anatomical and functional neuroimages, technical descriptions of imaging techniques, integrative quiz questions, 3D neuroanatomical surface models, animations, and course administration information were incorporated into the site. Examples of CT, MRI, fMRI, PET, OIS, angiography, MR angiography, gross specimens, and cryosection specimens were provided within the following topics: the cerebral vasculature, ventricular system, cerebellum, brainstem, diencephalon, and telencephalon.

Internet access was a major advantage to this form of teaching. Student access to computers in libraries and student lounges in combination with remote modem access allowed flexible perusal of the information. Small group sessions were provided for students introducing the usage of the Internet and web site. Instructors were available to discuss and review on-line material during dissection hours. Electronic mail scripts were integrated into the Internet site to allow students to electronically ask questions remotely. Student evaluation of the Internet web site was positive indicating this will be a continuing part of the UCLA School of Medicine neuroanatomy course. AFC is supported, in part, by a Medical Scientist Training Program grant (GM08042)

## 98.7

**TUTORIAL-BASED ACCESS TO A WEB ATLAS OF NEUROANATOMY** J.W. Sundsten\*, J.F. Brinkley and K. Mulligan, Dept. of Biological Structure, University of Washington, Seattle, WA 98195-7420. The Digital Anatomist Program's image-based interactive brain atlas has appeared in CD-ROM format, on the Internet in a custom client-server framework and most recently on the World Wide Web (<http://www9.biosci.washington.edu/da.html>). Most of the original material is organized by region, objects, serial slices and 3-D computer graphic images. We are now preparing additional means of arranging and accessing this image database in a systematic fashion for our course needs. We first developed a new set of atlas chapters, each of which contains a set of objectives, images (objects buttoned and with captions) and summary drawings. The current emphasis is neuroanatomical, but the material is ordered into functional units such as development and gross topography, general and special sensory systems, motor systems, brainstem and cranial nerves, cerebellum, basal ganglia, thalamus and cortex, and limbic system. The images are from departmental sources: the Digital Anatomist image database, a set of in-house teaching slides, and new material (processed with Photoshop software) from one of our course syllabi that is in digital format. Secondly, we are developing a Web-based tutorial, implemented in Netscape FRAMES, that contains links to appropriate frames from the Web version of the image-based atlas. The tutorial guide can be readily updated and tailored to individual instructor needs, making it possible, for example, to present class laboratory assignments, changes in schedules, and customized quizzes on a daily basis if necessary. These steps are moving us directly toward on-line interactive instruction for independent student use. A demonstration of the new chapters will be shown on CD-ROM, along with sample images from the Web-based tutorial. Supported in part by NLM Grant LM04925 and the Human Brain Project Grant DC/LM02310.

## 98.9

**TEACHING OF NEUROSCIENCE IN SWEDEN: THE USE OF COMPUTER ASSISTED LEARNING (CAL).** T. Kling-Petersen\* and M. Rydmark, MICE@mednet, University of Göteborg, Medicinaregatan 7, 314 90 Göteborg, SWEDEN.

At the medical faculty, University of Göteborg, the department of Medicinal Informatics and Computer assisted Education (MICE) is responsible for the development and implementation of computer based learning. The preclinical efforts have traditionally been divided into 3 blocks:

**NeuroAnatomy** - This block contains in-house developed software designed to teach the various aspect of the brains anatomy:

- 3D Brain - Virtual Reality modelling of structures of the human brain.
- BrainTeach - 2D sliced brain organised in frontal or horizontal series.
- BrainRadiology - software utilizing alternative imaging techniques like MRI, X-ray and others to visualise structures.

**NeuroHistology** - The software provides an interactive view of the cell- and tissue types of the brain organized after structures. The software also covers the organisation of structures as well as development.

**Pharmacology** - This block utilizes interactive simulations to visualize pharmacological issues.

- RabbitIntestine - Simulation of pharmacological agents effects on the peristaltic movements of rabbit jejunum.
- Pharmacokinetics - Simulation of the human body's effect of administered pharmacological agents.

MICE@mednet is an organization consisting of scientists devoted to using the computer as a tool for education. The organisation spans several areas of medicine, ranging from basic, preclinical education to clinical specialist training.

## 98.11

**ATTITUDES OF HEALTH SCIENCE STUDENTS TOWARD COMPUTER-BASED MULTIMEDIA LECTURING IN NEUROSCIENCE.** C.L. Cleland\*, Dept. of Physiology and Biophysics, University of Iowa, Iowa City, IA 52242

Although computer-assisted teaching is becoming more commonplace in neuroscience education, its efficacy has not yet been clarified. The goal of this study was to survey student attitudes toward computer-based multimedia lecturing to identify common views and determine whether attitudes correlate with the type of student or computer experience and skill.

Computer-based neuroscience lectures were delivered to students in medicine, dentistry, pharmacy, nursing, and engineering. The lectures (6-10) were similar in different classes (3 different classes), contained extensive multimedia content (digital video, animation, sound, graphics, images and interactive simulations), and were given by a single lecturer. Attitude questionnaires were distributed immediately following the lectures. Questions (n=30), based on a modified 1 (positive) - 5 (negative) Likert scale, covered attitudes toward various aspects of the lecture, student background and computer experience and views. Questionnaires were distributed at the beginning of class and then collected 10 minutes later.

Responses were obtained from 520 students. Overall, students felt that the computer improved understanding ( $2.02 \pm 0.8$  SD), made the class more interesting/fun ( $1.99 \pm 0.9$ ) and should be used more often ( $1.96 \pm 0.08$ ). Animations were identified, by score ( $1.82 \pm 0.9$ ) and comments, as being particularly valuable. Favorable attitudes toward computer-based lectures (e.g., understanding) were significantly correlated with favorable attitude toward computers ( $cc=0.69$ ,  $p<0.002$ ), but interestingly, not with subjective or objective computer skills ( $cc=0.17$ ).

Supported by the Department of Physiology and Biophysics, The University of Iowa (OCRME, ITS, Council on Teaching) and Microsoft Corporation.

## 98.8

**NEUROSCIENCE 4 AND THE WORLD WIDE WEB: WEBNOTES AND VIRTUAL LABORATORIES** Paul C. Knox, P.A. Spooner, G.W. Arbuthnot\*, Centre for Neuroscience, University of Edinburgh, Crichton St, Edinburgh, Scotland.

Neuroscience 4 is an undergraduate (Honours) course offered to final year Science students and intercalating Medical and Veterinary students in the University of Edinburgh. The course consists of five, five week modules. Two are taken by all students; the other three are chosen from ten optional modules. These cover the whole spectrum of contemporary neuroscience, from molecular aspects of the subject through to visual psychophysics. At any one time, teaching may be taking place in several different geographical locations across the city. Thus communication of both administrative information (timetables, deadlines) and learning materials (reading lists, seminar synopses, seminar material) is a major problem. In addition there is increasing pressure on laboratory space and staff time.

We have tackled this by placing information on the World Wide Web, and by beginning to develop "virtual laboratories" using Java. The University of Edinburgh provides open access microcomputing laboratories at all of the main University sites and machines in these labs have Netscape 2 installed. As we had established a Web server in March 1995 with pages containing information about research and postgraduate teaching in the Centre for Neuroscience (<http://sirius.lns.ed.ac.uk/>), it seemed a natural progression to develop an undergraduate information resource. The Web pages are maintained on a Sun Sparcstation 5, running the CERN HTTPD Server software. There are approximately 80 files taking up 250Kb of disc space. Student use is tracked by examination of the Server logs. We are developing a series of online lecture notes on various topics and links to other relevant material ("WebNotes"), which complement material given in seminars. In addition, using Java "applets" we are able to simulate experiments (freeing up laboratory space) and provide students with data to be analysed, interpreted and presented.

## 98.10

**USING "SLICE OF BRAIN" VIDEODISC AS AN IMAGE AND VIDEO RESOURCE FOR PROBLEM-BASED NEUROSCIENCE TEACHING.**

S. S. Stensaas\*, Educ. Cent., Cornell Univ. Med. Coll., N.Y.10021

With the increased availability of computers and the popularity of Problem-Based Cases a pilot neurology course used "BookSlate" for organizing and launching resources for each case. BookSlate is an application created on top of HyperCard as an easy way for students, residents and faculty, who do not know scripting, to quickly produce case presentations. Cornell has used the application in a different way. Each case listed and linked the appropriate multimedia instructional resources for each case on a "Slate".

A ready source of images for internal use was "Slice of Brain", a videodisc of 20,000 slides including 5000 gross and microscopic images. In addition, 7000 neuropathology and 8000 neuroradiology images can be used. There are over 150 video clips of patient signs and symptoms, reflexes, seizures, and rotating brain reconstructions. AV equipped multimedia PCs or Macs permit direct video input from videotape or videodisc. A videodisc index allows the user to quickly find and select an image for digitizing. Other linked resources were Stedman's dictionary, Netter's Atlas, sites on the WWW, scanned EEGs and EMGs, transcripts for first year and teaching software for neuroanatomy. The use of "BookSlate" provided: (1) An enhancement of the paper cases we obtained from Harvard University, and (2) an organizer and launch pad for material. The BookSlate, disc and index will be demonstrated.

## 98.12

**USE OF COMPUTER ASSISTED INSTRUCTION (CAI) FOR TEACHING BASIC NEUROSCIENCE TO PHYSICAL THERAPY (PT) STUDENTS.**

S.D. Stoney, Jr.\*, W.J. Jackson and T. M. Nosek, Dept. of Physiology and Endocrinology, Medical College of Georgia, Augusta, GA 30912.

PT students were asked to study portions of a CAI application covering basic neuronal physiology, the physiology of sensory and motor systems, higher brain functions, and an introduction to clinical cases. This application was originally designed for freshmen medical students. Groups of 4 to 6 students worked together using 7 portable computers in the department and 4 computers at the school library. Of 21 students who completed the course evaluation, 85% used the computer for more than 6 hours, either alone or in a group. Although 62% agreed that learning from the computer kept their attention better than learning from their textbooks, 29% disagreed. However, if they had been able to use their own computer, 85% thought that learning from the computer would be more effective than using a textbook. Clinical cases, animations, and questions with answers were judged to aid in understanding the material by 90%, 100%, and 95% of the students, respectively. Text and figures, animations, and questions with answers were rated as "moderate to very efficient" for learning by 95%, 95%, and 100%, respectively. 90% of students indicated that they would like to have their own computer for studying this kind of material. The major negative comments concerned the inefficiency of working in groups and the time it took to go through the material. The data suggest that integrated neuroscience information in a CAI format can be a useful method for teaching Physical Therapy students.

## 98.13

EVALUATION OF A PROBLEM-BASED APPROACH AND THE USE OF "SLICE OF LIFE" MATERIALS IN A MEDICAL NEUROSCIENCE CURRICULUM. K.G. Ruit\*. Dept. of Anatomy and Cell Biology, University of North Dakota School of Medicine and Health Sciences, Grand Forks, ND 58202.

Our neuroscience curriculum has been a "traditional" one in that students were given enormous amounts of facts in a didactic setting with little emphasis on small group process or clinical problem solving. As a result, students rated the neuroscience course among the worst in their medical school experience. Since students in our curriculum do not have required 3rd or 4th year clerkships in neurology, we saw it as essential that their exposure to neuroscience in the 1st year be substantive yet productive. Therefore, we have sought to take a less all-encompassing approach with more of an emphasis on the delivery of essential facts, clinical application, and the use of multi-media technology.

Over the last three years we have: instituted the evaluation of "paper cases" within student small groups, reduced lecture hours by 40%, introduced the use of HyperBrain software and the Slice of Brain videodisk, established expert panel discussions, and given students actual patient exposure. Students have dramatically improved their overall performance averages (to midterm: 1992: 80.87%; 1996: 89.58%). Students are able to recognize clinical presentations of neurologic disorders and localize lesions with no difficulty and attribute it to the clinical problem-solving emphasis and the use of multi-media technology. Neuroscience is now considered one of the best experiences of their medical school experience.

Through our recent efforts in getting students thinking about neuroscience rather than simply doing neuroscience, we are convinced that even in the absence of a required 3rd year neurology rotation, they are now prepared for 4th year electives in neurology based on their comprehensive yet efficient exposure to neuroscience in their 1st year.

## 98.15

INTEGRATION OF BRAINSTEM AND SPINAL CORD FUNCTIONAL ANATOMY IN A CHART FORMAT FOR TEACHING AND REFERENCE. K. H. Taber\*, L. A. Hayman, S. A. Berman, C. Sonne. Baylor College of Medicine, Houston, TX 77030 and Harvard Medical School, Boston, MA 02115

The goal of this project was to create a set of "user friendly" schematics of the brainstem and spinal cord utilizing the rules derived from information design theory. [1,2] These charts are designed to enrich teaching of neuroscience by providing a link between the disciplines of neurology, anatomy and radiology. The format is oriented to match the imaging procedure (myelography and computed imaging), rather than the "upside-down" format of other sources. One poster color-codes structures needed for movement. It illustrates the nuclei and fibers which mediate coordination and individual muscle groups (e.g., eyes; body; face). The companion chart shows the structures needed for different types of sensation. This allows the reader to easily find the areas which must be scrutinized in patients with specific motor or sensory loss.

## 98.17

VIDEO PRESENTATION AND CLINICAL CASE DISCUSSION IN NEUROANATOMY LABORATORY SESSIONS. S.S. Palmer\* and E.O. Emenike. Dept. of Physiol./Neurosc., St. George's Univ. School of Medicine, Grenada, West Indies.

Lab sessions in Neuroscience at St. George's Univ. School of Medicine are composed of three parts. Topics in the course range from intracellular signalling to neurologic disease processes. There are 72 lectures including six near finals on clinical cases. There are 10 lab sessions.

Each lab begins with a 20 minute video showing the structures to be identified. One hour is spent viewing brains and models. The last 30 minutes of the 2-hour session is spent discussing a clinical case related to the structures identified. For example, the first lab covers brain arteries and the case is a stroke of the middle cerebral artery. Students immediately see the importance of learning the structures they are required to know by learning how physicians make a diagnosis based on signs and symptoms caused by dysfunctions of particular brain nuclei and tracts.

Students have indicated the value they place on both the video presentations and the clinical case discussions for learning neuroanatomical structures and neuroscience in general. Results of a survey of 200 students will be presented. A handout indicating the composition of each lab and the cases discussed will be given to interested neuroscientists.

## 98.14

SENEX: OBJECT-ORIENTED PRESENTATIONAL TOOLS FOR MOLECULAR NEUROSCIENCE. S.S. Ball and V.H. Mah\* UCSF/Fresno, Valley Medical Center, Dept. of Medicine, Fresno, CA 93702.

SENEX is an evolving set of computer tools for molecular neuropathology featuring computer-based presentations linked to a large knowledge base. Slide presentations use a standard projection system connected to a powerbook computer. Slides may provide in addition to the projected image: 1) explanatory text; 2) links to the underlying SENEX knowledge base; 3) a free form query into the SENEX knowledge base; 4) access to any slide in an entire slide collection. The underlying knowledge base has been built by customizing the behavior of an object-oriented computer language to fit the domain of molecular neuropathology. Domain-specific considerations include contextual information, properties common to specific classes of molecules, the concepts of generalization and uncertainty, multiple layers of structure within molecules, and different logic for comparing different molecular features. The SENEX knowledge base contains molecular data derived in part from four large databases: 1) ProSite database of peptide motifs & electronic textbook of biochemistry; 2) Swiss-Prot database of protein sequences; 3) the Enzyme database; 4) Mendelian Inheritance in Man. Molecular data from the SENEX knowledge base are displayed through graphical presentations of virtual molecular objects accompanied by explanatory or supplemental text and images of gross and histopathologic features. Molecular and disease-related data is presented in a hierarchical and overlaid fashion which allows specific retrieval or focused exploration in a mouse-oriented intuitive graphically oriented environment. This empowers a speaker with tools at his/her disposal previously unavailable.

## 98.16

THE ANIMATED BRAIN: A MULTIMEDIA BIOPSYCHOLOGY TEXT. T.J. Voneida\*, Neurobiology Department, N.E. Ohio Universities College of Medicine, Rootstown, OH 44272, and R. Vardaris, Psychology Department, Kent State University, Kent, OH 44242.

This computerized courseware is designed for those interested in relating the basic functional anatomy of the human central nervous system to behavior. It is complementary to the "Graphic Brain - Neuroanatomy" (Voneida, '91), with greater emphasis on behavior, and less on neuroanatomical detail. It is particularly well suited for undergraduate psychology and related courses in paramedical, nursing, occupational and physical therapy programs. Fully animated, interactive graphics are correlated with text (audio and on screen visual).

Introductory chapters relate to historical landmarks in neurobiology, methods of study, neuroembryology, development of behavior, and basic neurophysiology, all of which are graphically animated. Each sensory system is introduced by a video sequence related to that particular modality. The video fades to animated graphics in which sensory impulses move from receptor into peripheral nerve, then throughout their central trajectory, with synapses illustrated by colored flashes. Motor pathways also begin with videos of behavior (concert pianist; runner), fading to motor cortex and pyramidal cells. Descending tracts are traced to terminations on ventral horn interneurons and motor neurons. Motor impulses are then followed graphically to effectors. Cerebellum and basal ganglia are presented in a similar fashion, with emphasis on their modulatory role. Hypothalamus, limbic and autonomic systems are discussed in terms of their role in homeostasis and emotional behavior. Cortical function, including language and memory, are related to cortical localization, cytoarchitectonics and interhemispheric activity. Final chapters deal with consciousness, cognition and cortical malfunction.

Graphics and text related to functional neuroanatomy are accompanied by animated presentations of perceptual phenomena and other psychological correlates of CNS function.

## 98.18

CONNECTING NEUROSCIENCE AND THE ARTS: A CREATIVE PROJECT IN THE NEUROSCIENCE CLASSROOM. B.L. Mania-Farnell\*. Department of Biological Sciences, Purdue University Calumet, Hammond, IN 46323.

Science students associate science with logical procedures and critical thinking. They do not necessarily associate science with creativity or an artistic aspect. Successful scientists however, develop both of these qualities. Creative thinking often leads to innovative discoveries. Artistic skills are used to enhance presentation of data, with critical points brought out in color slides, videotapes, and computer graphics. The artistic aspects of science becomes even more important as scientists try to communicate complex ideas to the public.

In order to encourage students in Neuroscience 525, an introductory course for upper level undergraduates and master's candidates, to appreciate the creative/artistic aspects of science, a creative project was incorporated into the course. Students were asked to write and present a paper on a neuroscience related topic of their choice. Additionally, they were asked to incorporate a creative form of expression into their presentation. The form of expression was left open, with the possibility of using poetry, painting, dramatic interpretation, or any other media. The inclusion of a creative project prompted the students to examine their topic from another perspective and provided them with the opportunity to integrate science and the arts. Overall, the addition of a creative aspect stimulated student interest and enthusiasm and appeared to increase student efforts in preparing their presentations.

## 98.19

TEACHING NEUROSCIENCE PRINCIPLES IN A COMBINED ON-SITE AND DISTANCE EDUCATION ENVIRONMENT. W.R. Klemm\*, Dept. VAPH, Mail Stop 4458, Texas A&M University, College Station, TX 77843.

In a 3-credit-hour course for graduate students and undergraduate Honors students, lectures (1-2 hours) were presented every Monday in a two-way televideo studio. Throughout the week, the 15 on-site students and three off-site students worked as three teams in a hypertext workspace environment called FORUM™. The text was *Understanding Neuroscience* (Mosby, 1995), which seemed ideal for stimulating insights and debate, because it presents a "bare bones" summary of 80 core principles of neuroscience. By Wednesday noon of each week, each student submitted in FORUM two insightful questions about each week's reading, accompanied by answers (Q&As). Students used in-context hypertext links to critique each other's Q&As, with the aim of perfecting one Q&A that they would submit as the group's "Best Q&A of the Week." Students were graded individually on Q&As and as a group on their "Best Q&A." Students graded each other on the quality of Q&As and on group helping behavior. The final exam was drawn from open-ended study questions, which were first group answered in FORUM and certified by me when acceptable.

This report presents examples of student Q&As, participation statistics, and summary of student opinionnaires. I enjoyed teaching this way and found it more refreshing than my traditional lecturing approach. Students were much more engaged in learning, and they benefitted from the diverse perspectives and insights of fellow students.

## TEACHING OF NEUROSCIENCE: CURRICULAR INNOVATIONS

## 99.1

MEDICAL NEUROSCIENCE; INTEGRATION OF BASIC AND CLINICAL SCIENCE, PHYSICAL EXAMINATION, AND PROBLEM-SOLVING IN A TOTAL IMMERSION FORMAT. J.C. Pearson† and J.B. Dean\*. Depts. of Anatomy† and Physiology & Biophysics, Wright State University, School of Medicine, Dayton, OH 45435.

Our objectives were to develop a medical neuroscience course that is oriented towards students entering primary care residencies (~ 65% of each class); integrates basic and clinical disciplines with introductory physical examination instruction; and, develops collaborative learning and problem-solving skills. The total immersion course meets every day (~ 5 hrs. /day) for four weeks at the end of Year I. Learning experiences include: integrated lectures that introduce basic material in a case-oriented format; laboratories in which clinical scenarios are discussed while examining traditional and computer interactive lab material (see Breyley et al., this session) in small groups; case problem-solving sessions that involve group discussion followed by presentation to peer groups of 16-20 students; clinical workshops that emphasize basic science mechanisms; and, neurologic examination sessions consisting of plenary presentations of examination technique followed by individual instruction and small group practice. Weekly multiple choice examinations (80% of final grade) test content from all sessions including lab. Short quizzes given in problem-solving sessions and clinical workshops reinforce creative thinking (10%). Physical exam skills are tested using an Objective Structured Clinical Examination (OSCE) administered at the end of the course (10%). Students overwhelmingly agreed that clinical workshops (96% agreement), case problem-solving sessions (94%), and neurologic exam sessions (86%) successfully integrated basic science principles and clinical material.

## 99.3

PERFORMANCE-BASED ASSESSMENT OF NEUROLOGICAL PROBLEM SOLVING FOR SECOND YEAR MEDICAL STUDENTS. K.L. Lovell\* B. Mavis, K. Ogle. Depts. of Pathology and Family Practice and Office of Medical Education, Research and Development. Michigan State University, E. Lansing, MI 48823.

A performance-based assessment format was developed to evaluate the ability of second year medical students to apply clinical neuroanatomy concepts in localization of lesions and a focussed neurologic examination. The objective was to create a low-cost, participatory experience that would involve integration of clinical skills neurologic exam and basic science neuroscience concepts, especially localization of lesions and neuropathology. The format included three stations: a computer-based case with six questions, a neurologic exam on a simulated patient (a classmate simulated the patient presented in the computer case), and a write-up of assessment and plan. Two cases were created, with half of the class acting as "doctor" and half acting as "patient" for each case. One case was designed to be more difficult in order to test different levels of problem-solving. The evaluation was not part of a course grade, but students were provided with feedback on their performance. Conclusions from quantitative scoring and qualitative feedback from students include the following: (1) even though all students had just finished courses covering the basic science concepts and clinical skills, many students had a great deal of trouble with integration and application of neurologic concepts; (2) students gave high ratings to the experience as practice in application of concepts in a simulated patient encounter; (3) acting as the "patient" as well as the "doctor" provided a learning experience. This type of problem-based assessment will be modified for the future based on results and feedback, and will be conducted several times during the second year.

## 99.2

INTERACTIVE SOFTWARE DEVELOPMENT FOR INTEGRATED MEDICAL NEUROSCIENCE EDUCATION. G. Breyley†, S.J. Barnett, and J.C. Pearson\*. Interdisciplinary Teaching Lab.† and Dept. of Anatomy, Wright State University, School of Medicine, Dayton, OH 45435.

In the integrated Medical Neuroscience course at WSU (see Pearson and Dean, this session), students have identified two areas in which they require particular help. One is learning functional neuroanatomical pathways, and the other is characterizing neurologic disorders. To help the students with these tasks, we have developed two interactive software applications: (1) "TractFinder", designed to introduce students to neuroanatomical pathway study; and (2) the "VideoClip Library of Neurologic Disorders", which is a compilation of quicktime movies of neurologic disorders most frequently encountered by the primary care physician. TractFinder incorporates myelin-stained central nervous system sections and two-dimensional pathway tracings to allow students to display individual somatosensory pathways. Raw media for this program was acquired from 35mm color slides and enhanced with Adobe Photoshop 3.5. TractFinder was created with Macromedia Director 4.0. The VideoClip Library was created with Apple Media Tool 2.0 to help students identify signs of motor and mentation disorders. Hypertext links to video clips of specific phenomena allow for easy identification. These clips were digitized from the University of Washington's Motor and Mentation videodiscs and the Slice of Brain I videodisc using Adobe Premiere. Evaluation of both programs will occur during the four-week neuroscience course.

## 99.4

TEACHING NEUROSCIENCE AT THE UNIVERSITY OF NEW MEXICO SCHOOL OF MEDICINE: A COMBINED PROBLEM-BASED AND TRADITIONAL APPROACH. L.C. Saland\*, D.D. Savage, L.D. Partridge, N.I. Perrone-Bizzozero, R.G. Franchini, and K.J. Fiedler, Depts. of Anatomy, Pharmacology, Physiology, Biochemistry, Psychiatry, and Neurology, Univ. of New Mexico Sch. Med., Albuquerque, NM.

The medical curriculum at the University of New Mexico School of Medicine has undergone significant change in teaching methods since 1993. Neuroscience in the first year of medical education now combines basic science topics and clinical skills with a patient case-based set of tutorial interactions, in a 9 week period. All medical students work in tutorial groups with two tutors, generally one basic scientist and one clinician, both neuroscience experts. Cases studied in tutorials reflect both neurologic and psychiatric problems which are designed to address specific important basic science concepts as well as clinical issues. Lectures, laboratories, and clinical skills sessions run concurrently with tutorials. A concerted effort has been made to minimize added time commitments of involved faculty. The new teaching format requires cooperation on an ongoing basis among basic science and clinical faculty at a level not generally attained prior to instituting this curriculum.

## 99.5

**EARLY PARTICIPATION OF MEDICAL STUDENTS IN BASIC RESEARCH AND PROBLEM BASED LEARNING.** X. García\*, S. Morales, A. Hamabata, E. Piña, M. A. Lastiri, and E. Gijón. School of Medicine, Research Center and Educational Services CISE, UNAM, and Research Center of Advance Studies, CINVESTAV, IPN. México D. F. 04510, México.

PAEA is an institutional program of high academic demand at National Autonomous University of México. In the school of medicine it was started a change in teaching method for medical students. Students with higher scores were selected in each year promotion from a diagnostic examination, to form the kernels of educational quality formerly called NUCE (Núcleos de Calidad Educativa) as part of the high academic demand program PAEA (Programa de Alta Exigencia Académica). Problem based learning was introduced replacing traditional teaching in 25% of the available time. Early participation in basic research has been implanted with a model of two students tutored by a researcher. Partial results show that this student-centered active learning leaded the students to follow scientific methodologies for conducting supervised experimentation, capturing data, analyzing results and writing reports that were adequate for specialized meetings and publication, about interest topics for health sciences knowledge and it also prepared them for postgraduate studies.

## 99.7

**ANNUAL SYMPOSIUM ON CRANIAL NERVES: HAVING FUN WITH NEUROANATOMY.** J.L. Culbertson\*, Department of Anatomy, West Virginia University Health Sciences Center, Morgantown, WV 26506.

As careers in health sciences expand, more students are studying structural biology, including Neuroanatomy. Physical therapists in particular have a substantial interest in basic neurology. Many undergraduates with modest scientific preparation now enroll in specialized biomedical curricula where even academically talented students may be intimidated (or overwhelmed) by the content and pace. While teaching a brief course in Functional Neuroanatomy for 22 years, I worried that some of these very bright folks (and I) might benefit from an occasional diversion from the usual instructional paradigm, and so introduced student presentations in the course.

Each year now we hold a cranial nerve symposium. Small groups of students are assigned one nerve (or a group of related nerves). They prepare a 15-20 minute presentation which is to be both instructive and entertaining. Student work generated in this small project exceeded my expectations from the outset and continues to be outstanding. It has sufficient notoriety that other faculty and older students return for an "annual review" of cranial nerves. Students do usually achieve the most important objective, the identification of those features of a nerve that physical therapists need to know. This often differs from what a neurology-biased anatomist would have emphasized. Beyond content 'though, the entertainment aspect of the symposium has exposed a degree of talent and creativity that we seldom recognize in our students. We now enjoy original poetry, songs (lyrics and music), original artwork, videos (both seriously documentary and outrageously funny) and most recently, a wide range of game shows. This poster will share some of this student material in the interest of stimulating other course planners to look for ways to increase student participation in and enthusiasm for their own learning.

## 99.9

**HEMISPATIAL NEGLECT: CASE STUDIES EMPHASIZING MECHANISMS OF ATTENTION AND SENSORIMOTOR INTEGRATION.**

Dr. Joseph J. Warner\*, Dept. of Neuroscience, University of Florida College of Medicine. Hemispatial Neglect has been defined as the inability to recognize, report, or respond to stimuli from one side of space. (Heilman). Early studies associated unilateral neglect with lesions of the right parietal lobe. Hemispatial neglect has since been reported with other right hemispheric cortical and subcortical lesions. Analysis of hemispatial neglect has focused on neural mechanisms of attention and sensorimotor activity, and on the association of hemispatial neglect with right hemispheric lesions. Animal and human studies have demonstrated unilateral neglect with lesions of the mesencephalic reticular formation, superior colliculus, thalamus, basal ganglia, internal capsule, and multiple cortical regions, and have led to the concept of the "corticalization" of attentional mechanisms with phylogenetic advancement. Neuropsychological and physiologic studies suggest right hemispheric dominance for attentional direction. Studies of cortical and subcortical systems in primates have provided a foundation for models of cerebral mechanisms for attention and hemispatial exploration. The analysis of hemispatial neglect thus extends from nonspecific arousal and specific afferent systems through assessment of "stimulus significance," modulation of afferent transmission, sensorimotor integration, and response generation. Clinical cases, including neuro-behavioural testing, C.T. and/or M.R.I. studies, and neuropathologic findings, are presented emphasizing systems organization and structure-function correlations. This format is an effective approach to the neuroanatomic and physiologic aspects of systems organization, including perspectives of basic and clinical neuroscience, for students in medical neuroscience as well as for residents in neurology, neurosurgery, and psychiatry.

## 99.6

**CLINICAL CORRELATION POSTER PRESENTATIONS IN MEDICAL NEUROBIOLOGY.** H. F. Martin III\*, Dept. of Physiology, The Medical Univ. of South Carolina, Charleston, SC 29425

Near the end of the Medical Neurobiology course, students are asked to choose a neurological disease to investigate. This year, instead of a written paper, the presentation was in the form of a poster session. The assignment had two parts: 1) a disease or disorder was chosen, and a "patient scenario" was prepared which typified the disorder (to include symptoms, history, physical examination findings, lab tests, etc.); and 2) a poster presentation was prepared to discuss the disorder.

*The aim of the discussion was to explain to the patient and/or patient's family what is happening to the normal structure and function of the brain as a result of the disease.* Students were expected to explain why the particular symptoms resulted from the disorder, what was the prognosis for recovery or progression, and how treatment was intended to restore function.

Directing the explanation to the patient was intended to stress the role of patient education in medical practice. Presenting the results in the poster format allowed the students to learn from the other student projects as well as their own.

## 99.8

**AN EASY WAY TO LEARN THE NAMES OF GYRI (AND SULCI) OF THE HUMAN BRAIN.** Glenn H. Kageyama\*, Department of Biological Sciences, California State Polytechnic University, Pomona, CA 91768; Department of Anatomy & Neurobiology, College of Medicine, Univ. Calif., Irvine, CA 92717.

Learning the names of all the major gyri and sulci of the human brain can be a tedious undertaking by medical students. An easy system for learning these names has been used successfully at Cal Poly and at the UCI College of Medicine. After first identifying the landmarks that delineate the 5 lobes of the brain (including limbic), all other structures are learned by presenting them as structurally related sets of three. For example three vertical lines can be used to indicate the (1) precentral, (2) central and (3) postcentral sulci; these sulci delineate the vertical (1) precentral and (2) postcentral gyri, which are linked together medially by the (3) paracentral lobule. The temporal and anterior part of the frontal lobes are presented together, because each can be divided into (1) superior, (2) middle and (3) inferior (temporal or frontal) gyri. The parietal lobe is divided into the (1) superior parietal lobule and the (2) supramarginal and (3) angular gyri. Lastly the occipital lobe, when viewed from a posterior position can be divided into the (1) lateral occipital gyri, (2) the cuneus and (3) lingual gyrus. Cerebral structures can also be presented in sets of three in basal, and medial views of the brain. One advantage that this simple method provides is that within a very short period of about 30+ minutes, undergraduates and Medical students can easily master the names of all of the major gyri and sulci of the human brain. Further reinforcement is provided by superimposing the (1) functional organization of the brain (cortical areas), and (2) the blood supply to the brain, and by reviewing the (3) functional deficits that would be produced by lesions in different parts of the brain. Color-coded illustrations will be presented. Support: Cal Poly Pomona RSCA Grant #1-11496 (Kageyama), & NIH Grants: DC 00450 & NS 30109 (RT Robertson & GH Kageyama).

## 99.10

**TEACHING ETHICS TO RESEARCHERS: PROVIDING INSTRUCTION AND ASSESSING COMPETENCY.** B.A. Fischer and M.J. Zigmund\*, Survival Skills and Ethics Program, University of Pittsburgh, Pittsburgh, PA 15260.

We believe that responsible conduct is an integral part of "doing science" and have developed a model that reflects this philosophy. Graduate students in the Dept. of Neuroscience receive instruction in *ethical sensitivity* (being able to identify ethical issues and the norms of their field) and *moral reasoning* (a problem-solving approach). Instruction in ethics is integrated throughout both the required science courses and workshops on "survival skills" (professional development). For example, in the neurochemistry course students discuss ethical issues related to conflict of interest in drug testing, and in the workshop on writing, topics such as authorship and integrity in graphics are addressed. Thus, students are sensitized to many of the ethical dimensions of their work. Based on the method of Bebeau, et al (1995), students also receive formal instruction in moral reasoning. This provides individuals with a tool for evaluating and resolving ethical dilemmas, including novel situations as might arise following the development of new technology. Furthermore, using Bebeau's method we systematically measure a student's ability to develop a well-reasoned response to an ethics case. *Competency* in this skill is now measured as part of the comprehensive exam. We believe that our model has several advantages over more conventional approaches: (1) Training in ethics occurs over 2-3 years rather than a few weeks or months. (2) Senior scientists who can act as role models provide most of the instruction. (3) Material is included that typically is not covered in more traditional courses. (4) Students learn tools for tackling yet undiscovered ethical issues. And, perhaps most importantly, we feel such a program (5) conveys to students that responsible conduct is an essential part of being a researcher. (Support: NSF, IBN 94-13145; NIMH, MH18273; Univ. Pittsburgh.)

## 99.11

**A SUPPORT PROGRAM OF INSTITUTIONAL IMPROVEMENT OF TEACHING.** E. Gijón\*, M. A. Lastiri, X. García, and L. Cartas. Sch. of Medicine, Sch. of Psychology, and Research Center and Educational Services CISE, UNAM. México D. F. 04510, México.

PAPIME is an institutional program that induces changes toward a teaching improvement. The main goal of this program is to improve teaching quality in National Autonomous University of México. The aim of this work is to present the progress of this program at the School of Psychology, within the scope of our project teaching strategies of neuroscience and basic processes and implantation of new technologies. Our project is devoted to solve some of the problems that we found in the field of the education in Psychology and Medicine, especially in neuroscience, working along with teachers of the subjects that are imparted in the first three years of the licenciature in Psychology. The project was organized in two stages. In the first one we organized a workshop of teaching methodologies centered in contents for teachers in order to structure didactically their teaching units and also a workshop for using authorship tools, such as HyperCard, Digital Chisel for Macintosh platform and ToolBook for PC platform. In a second stage teachers are elaborating specific didactic resources to topics of their programs in a first prototype level in paper and they are developing didactic resource prototypes by computer.

## 99.13

**NEUROSCIENCE FOR NURSE ANESTHETISTS.** D.D. Rigamonti\*, J.W. Tsao and H.L. Bryant. Uniformed Services University of the Health Sciences, Bethesda, MD 20814-4799.

Neuroscience courses have become commonplace in medical and graduate school programs but are not usually part of nurse anesthetist's programs. The Council on Accreditation for Nurse Anesthetists outlines a variety of requirements related to the nervous system that students must master for successful administration of anesthesia. To meet these requirements, we have designed a unique course taught by a diversified clinical and basic science faculty drawn from the School of Nursing, the School of Medicine, affiliated hospitals and federal agencies.

The course is taught in the summer and fall semesters. The summer semester provides a review of basic neurophysiological concepts and an examination of gross central nervous system structures. This portion runs concurrently with a separate human anatomy dissection course. The fall semester provides an in depth review of neurophysiological concepts related to peripheral nerves, spinal cord segments and brain, such as, compound action potentials, myotatic delay and averaged evoked potentials. These principles are demonstrated in laboratories utilizing human subjects and computer assisted data acquisition. In addition, lectures, clinical correlations and computer aided instruction are routinely used to teach central nervous system organization. Great emphasis is placed on the understanding of peripheral and central mechanisms of local and general anesthetics and their effects on the nociceptive system. Throughout the course of instruction, individual students are assigned to each session to lead discussion with visiting faculty and student study groups.

This course has been offered for the last two years and based on student surveys has been successful in effectively communicating principles of neuroscience necessary for clinical practice.

## 99.15

**USING WRITING TO TEACH NEUROSCIENCE TO NON-SCIENCE MAJORS.** Peter A. Pawson\*. Dep't of Biology, Utica College of Syracuse University, Utica, NY 13502.

I teach Introductory Neuroscience to sophomore non-science majors (OT and PT majors) at a small liberal arts college. As part of a college-wide effort to increase writing across the curriculum, I have developed a "Writing-Intensive" course that incorporates writing-to-communicate (a formal term paper and essay exams) and writing-to-learn (in-class and out-of-class informal writing assignments) into its curriculum. The term paper is designed to familiarize students with the primary Neuroscience literature and the process of writing a scientific paper, as well as to give them an opportunity for an in-depth study of some aspect of the Neurosciences that interests them. Several elements contribute to the success of the paper writing project: students are given a detailed guide to the mechanics of writing a scientific paper; the paper involves a multiple revision process, including peer reviews. The ungraded, informal writing assignments are designed to allow students to use writing to introduce themselves to topics and to formulate their own connection with the material. These writing elements have produced more sophisticated term papers, demonstrating an increase in both student comprehension and overall science literacy. (Supported by a grant from Utica College).

## 99.12

**MEDICAL NEUROANATOMY: RELATING STRUCTURE AND FUNCTION.** Edwin S. Purcell<sup>1</sup> and Ann S. Stano<sup>2</sup>. <sup>1</sup> Department of Anatomy, University of Osteopathic Medicine and Health Sciences, Des Moines Iowa 50312; <sup>2</sup> Lake Erie College of Osteopathic Medicine, Erie, PA 16509.

At Lake Erie College of Osteopathic Medicine (LECOM) neuroscience is presented in a holistic system approach combining anatomy, biochemistry, physiology, pharmacology, pathology and neurology. While this format intrinsically provides clinical correlation for basic science material, in 1996, the neuroanatomical component was specifically designed to emphasize the relationship of structure and function in a clinical context. The rationale was that information is more readily assimilated and retained if its relevance to medical practice is clear. Further, this approach provides a way to reinforce overlap between disciplines. Specific aspects of the course design included: sequential presentation of material in a hierarchical manner, assignments in the atlas to correlate with each lecture, full scale "mock practicals" with each laboratory and small group analysis of clinical scenarios which were presented to the entire class. Examinations mirrored the course content with 50% of lecture based questions relating structure and function and a full 50% of the laboratory questions being second order. We are currently evaluating the efficacy of this approach to the teaching of neuroanatomy. The initial response from the students was very positive. Among the factors we will examine is the performance of this class on part 1 of the medical licensing examinations in 1997.

## 99.14

**TEACHING NEUROSCIENCE WHEN THERE'S NO FORMAL NEUROSCIENCE AT A COMPREHENSIVE I INSTITUTION.** M.C. Zrull\*, R.E. Bowman, and A.J. Trivette. Department of Psychology, Appalachian State University, Boone, NC 28608.

Appalachian State University (ASU) is a Comprehensive I university offering bachelors and masters degrees in a variety of traditional disciplines. Neither an undergraduate nor a graduate degree in neuroscience is offered. Unlike many of the programs described in previous Teaching of Neuroscience posters, ASU does not offer a minor, a concentration, or even a course in neuroscience. Yet, both undergraduate and graduate students in the Department of Psychology can gain a respectable background in neuroscience. This poster is presented because we don't believe our situation is unique, we believe existing flexibility in degree programs can be used to teach foundations of neuroscience, and we are interested in suggestions to improve our approach.

At ASU the B.S. in psychology does not require a minor. Rather, an interdisciplinary concentration is required. Through careful advising a set of courses from psychology, biology, exercise physiology, etc. can be combined to provide a classroom foundation for future study in neuroscience. The M.A. in general psychology offers similar flexibility after a core courses. The program follows a mentorship model usually found in doctoral programs and requires "selected topics" courses. Courses covering topics like behavioral or cognitive neuroscience, endocrinology, neuroethology, etc. are possible. Our approach to laboratory experience is important. Students are integrated into ongoing research projects and the mentorship model is extended to the graduate-undergraduate relationship. While experiments may combine to reach the faculty member's goal, each student in our lab is given enough of a role in one (or more) experiment(s) that he/she can present the work in an appropriate setting. Our hope is to present our current model and to learn about ways to enhance our programs. Some of the presented activities were partially supported by NIH grant DC02476 and Dept. of Ed. grant P217A50512.

## 99.16

**Mad Cow Disease: A Topic for Undergraduate Neuroscience**

C. A. Paul and B. S. Beltz\*, Wellesley College, Wellesley, MA 02181

The recent crisis in England over Mad Cow Disease (MCD) has caused a panic among the English meat eating population and British farmers. MCD results in bovine spongiform encephalopathy (BSE) and is possibly linked to the human neurodegenerative disease, Creutzfeldt-Jakob disease (CJD). The connections between these diseases have been suspected for the last 5 years, however no action was taken until a recent report indicated a rapid rise of CJD in young people. There are many questions arising from how this affair was handled by the government.

This multi-faceted problem provides an opportunity for teaching undergraduates the inter-relationships between health issues, basic science, economics and politics. Most of our students will not become neuroscientists. However, our expectation is that all students will be educated, scientifically literate citizens. Whether they become scientists, politicians or journalists all students need to acquire skills to address complex issues such as MCD.

This poster will focus on:

**History and Epidemiology** - the possible origins of MCD from the sheep disease scrapie; the human disease kuru; spontaneous mutations leading to low levels of the disease; and the transmission of CJD between humans due to tissues extracted from CJD infected cadavers.

**Biology** - explanation of the infectious nature of a prion, an infectious protein;

spontaneous mutations of a gene which lead to production of this protein.

**Pathology** - how does the dementia arise, and what are symptoms of CJD?

**Politics** - how should public policy be determined?

**Economics** - how can the need for profit be balanced against scientific and medical concerns?

A series of questions will be included to facilitate discussion on this topic.

## 99.17

INCORPORATING SELF-PACED LABORATORY, GRANT WRITING AND SERVICE LEARNING COMPONENTS INTO A BEHAVIORAL ENDOCRINOLOGY SEMINAR. C.A. Frye\*. Neuroscience Laboratories, Depts. Psychology & Zoology, Connecticut College, New London, CT 06320.

Independent reports indicate that self-paced laboratories (Jacobs, 1980), grant writing (McCormick, 1995) and service learning (Kelland, 1995) are effective tools which bring students closer to the material. These pedagogical techniques were utilized in conjunction with a seminar in Behavioral Endocrinology. Briefly, 8 seniors chose topics within the field of Behavioral Endocrinology. In the first part of the semester, each student led one weekly seminar meeting. Later in the semester, students wrote mock grant proposal, complete with methods, budget, etc., on their selected topic. One or two grants were then presented weekly and critiqued in a model grant review session in which the class served as the panel. Each student acted as primary and secondary reviewers on another grant proposal. Students reported that they found these reviews extremely valuable for improving the final quality of their papers. Throughout the semester, at each seminar meeting, students were informed of the weekly schedule of events that were occurring in the behavioral endocrinology research laboratory. Students were encouraged to participate in the events that were of interest to them. Students reported that this informal laboratory component facilitated their learning of "hand-on" aspects of how to answer their research questions. Students reported that this experience was invaluable and necessary to gain a coherent understanding of the research papers they had read and to facilitate the methodological component of their grants. Students' participation necessitated substantial commitment of those currently working in the Behavioral Endocrinology Research Laboratory. Thus, seminar students were required to perform a 1-2 hour service learning task. Students found the service learning component so valuable that they exceeded course requirements by providing a 3 hour seminar at a nearby high-school during *Brain Awareness Week*. Students' feedback indicate the informal laboratory, grant writing and service learning were excellent and complimentary additions to the seminar. Supported by NSF CAREER grant 9514463

## 99.19

*BrainLink*®: TEACHING NEUROSCIENCE TO ELEMENTARY AND MIDDLE SCHOOL STUDENTS. J.H. Dresden\*, N.P. Moreno and B.Z. Tharp. Baylor College of Medicine, Houston, TX 77030.

Scientists, clinicians and educators at Baylor College of Medicine have worked together to create instructional materials for teaching neuroscience concepts to elementary and middle school children. (Some activities can be used at the high school level.) After three years of development, review and field testing, the *BrainLink* project is now in its third year of national dissemination of the materials and workshops in their use. Both development and dissemination activities have been supported in part by the National Institutes of Health, Science Education Partnership Awards program.

The *BrainLink* materials are ready-to-use and are designed to promote the fun and excitement of "doing" science in schools, museums or community settings, or at home. Topical units include Brain Comparisons, Motor Highways, Sensory Systems and Memory & Learning. Each unit contains three interrelated components: a guide to classroom activities, an adventure storybook and a mini-magazine that can be used with groups or at home for parent and community involvement.

*BrainLink* materials provide a unique vehicle for use by scientists in outreach programs with students, as well as for enrichment of the science curriculum in schools. Neuroscience content is presented in ways that make it accessible to laypersons and to children. Regional dissemination centers providing information, materials and workshops for assistance in using *BrainLink* are located at Baylor College of Medicine, Boston University School of Medicine, the University of Kentucky College of Medicine and the University of California, San Francisco. Evaluation research findings will be presented, along with a display of the materials and their use.

## 99.21

ELEMENTARY SCHOOL CHILDREN USE THE INTERNET TO SHARE THOUGHTS ABOUT A DAY IN THE LIFE OF A NEUROSCIENTIST.

D. L. Colbern\* and L. M. Bargabus. Brain-Exchange Electronic Mentorship Network, Venice, CA 90291, and UCLA Brain Research Institute, Los Angeles, CA 90095

An important and current trend in education is to treat science as synonymous with "critical thinking" and to engage students in curriculum where career awareness is emphasized and science and technology are portrayed as forces likely to impact the future. BEEMNET, the Brain-Exchange Electronic Mentorship Network, is a research-oriented, educational organization that uses the World Wide Web to link elementary school children and their teachers with practicing neuroscientists. An important goal of the network is to provide and support mentorship activities between children, teachers, and neuroscientists; the use of information technology enables access to resources for all children.

We asked 965 children (grades 3-6) in nine urban and rural elementary schools across the United States (California, Colorado, Illinois, Tennessee, and New York) to "write a story about a day in the life of a neuroscientist" from the time that person wakes up until the time they go to sleep. Children were told only that "a neuroscientist is a person who studies the brain and nervous system." The resulting essays provided clear evidence of the baseline level of knowledge children have regarding the enterprise of neuroscience. Selected stories were published on BEEMNET where neuroscientists could use various aspects of the children's stories to help communicate real life as a scientist. Neuroscientists learned what perceptions children, and perhaps the public, hold regarding their profession. Stories and drawings can be found on the World Wide Web at <http://www.beemnet.com/>. Supported by NIDA grant DA 10059-01.

## 99.18

EXPLORING NEUROSCIENCE THROUGH SENSORY SYSTEMS, A SHORT COURSE AT THE ADVANCED HIGH SCHOOL OR UNDERGRADUATE LEVEL. C.L. Miller\* Brandies University, Norman S. And Eleanor E. Rabb School of Summer, Special and Continuing Studies, P.O. Box 9110, Waltham, MA 02254-9110.

This course was designed to teach basic neuroscience concepts using sensory systems. Interactive teaching methods such as hand-on demonstrations, and in-class experiments help the students learn about the basics of neuroscience by studying their own senses. The course is taught in a semi-flexible format that allows students to direct the lecture by expressing what topics are most interesting to them, and providing questions for the class to address.

By introducing a neuroscience course at the high school or introductory college level common misconceptions about the field of neuroscience, such as "all Neuroscientists are brain surgeons" can be dispelled. By introducing the topic of neuroscience in the context of sensory systems, students feel comfortable approaching this difficult discipline, because they can relate what they have learned to their own sensory experiences.

The course content includes: An introduction to nerve cells and how they communicate, specialized human sensory receptors and their structures, sensory information processing, sensory perception, and minimal neuroanatomy.

## 99.20

INTEGRATION OF SCIENCE DISCIPLINES IN A HIGH SCHOOL SCIENCE PROGRAM THROUGH NEUROSCIENCE RESEARCH. R. E. Landsman\*, L. J. Perrotti, D. M. Niedosik and D. DeWitt. Science Dept., Academy for the Advancement of Science and Technology, Hackensack, NJ 07601.

Over the past four years, our new high school has focused on the development of an integrated interdisciplinary science curriculum in which, annually, students simultaneously learn biology, chemistry, physics and mathematics, and many are engaged in research in our in-house scientific research program. The research projects focus on state-of-the-art neuroscience studies in behavioral toxicology (Prabhakar and Landsman, *Soc. Neurosci. Abst.* 20, #159.16, 1994), neural control of behavior (Lin, Gupta, Perrotti, and Landsman, *Soc. Neurosci. Abst.* 22, in press, 1996), neuroendocrinology and neuroimmunology.

The goal of our research program is to use neuroscience research as a method for demonstrating to the student the need for interdisciplinary understanding of biological phenomena as well as the need to use the scientific method. This program 1) prepares students for the recent upsurge in undergraduate neuroscience programs, 2) addresses the need for change in the present secondary educational system regarding writing ability and critical thinking skills, 3) infuses technology into education, 4) addresses the need to instill in students ethical values and practices in the use of the scientific method, and 5) stimulates interest across all sciences through the use of interdisciplinary techniques.

Funded by the Bergen County Technical Schools' Board of Education.

## 99.22

FROM BALLOONS TO BRAINS: SCIENCE FOR THE ELEMENTARY GRADES. J.M. Kerns\*, J. Harrington, M. Blenz and K. Botticelli. Dept. Anatomy, Rush Medical College, Chicago; Lincoln School, District 97, Oak Park, IL. 60612.

The Global Village Project of Oak Park School District 97 has for five years formed an educational partnership between working scientists and students in grades 3 - 8, designed to spark interest and excitement in science. Thirty-two volunteer scientists from 14 different area institutions establish interactions with the teachers and students from ten grade schools. These hands-on learning experiences consist of 5-6 classroom visits, two field experiences in a working environment, and a Young Scientists Conference, which also includes parents and community members in an interactive workshop setting. Our particular theme involved the use of balloons filled with air, helium and gelatin to demonstrate the following: 1) the use of the scientific method; 2) how neuron shapes influence neuron function; 3) how the brain is protected from injury; 4) what happens to neurons when they are injured; 5) influences affecting the ability of neurons to regenerate and heal themselves. Several experiments were conducted where small student groups pose a scientific problem, apply an experimental method, collect data, form conclusions, and make practical applications. In addition, students used a novel drama setting to act out nerve regeneration. During a 1½ hr tour experience, students worked with microscopes, computers, a photographic darkroom, models and gross brain specimens to see the benefits of viewing the brain in various slices. Lecture material was kept at a minimum, favoring the small group direct learning experiences.

The overall impression of these scientist-teacher-student interactions is that students develop a more accurate view of scientists and a more keen interest in their work by such exploratory and facilitated experiences, independent of the choice of specific content and curricula. Balloons and brains just happen to be a convenient bridge to enhance the love of knowledge, teamwork activity and problem solving skills. Funding in part due to a grant from the Oak Park Education Foundation.

## 100.1

**COMPUTER SIMULATION FOR TEACHING THE PHYSIOLOGICAL BASIS OF RESTING MEMBRANE POTENTIAL.** J.E. Salceda-Ruanova and E. Soto\*. Instituto de Fisiología, Universidad Autónoma de Puebla, México.

An interactive computer simulation for teaching the physiological basis of resting membrane potential is presented. The program was developed using Visual Basic<sup>™</sup> and runs under Windows<sup>™</sup>. It allows the user to record with intracellular electrodes and determine, under controlled conditions, the membrane potential and the equilibrium potential for each ion. The variables controlled by the user are: intra and extracellular concentrations of sodium, potassium and chloride ions, the permeability coefficients for the ionic species considered and the temperature. The program includes a voltage clamp option, which allows the user to impose a membrane potential value and study the resulting driving force for each ion. Concentration-membrane potential and concentration-equilibrium potential curves may be obtained at any time. The simulation has been tested in general physiology courses and has shown to be a useful tool as a complement to the experimental and theoretical study of the ionic basis of membrane potential.

## 100.3

**DIFFERENTIATION IN PC12 CELLS: A STUDENT LABORATORY IN DEVELOPMENTAL NEUROBIOLOGY.** E.M. Adler\*. Department of Biology, Williams College, Williamstown, MA 01267

The PC12 rat pheochromocytoma cell line, which resembles immature adrenal chromaffin cells when grown under standard culture conditions and differentiates towards a neuron-like phenotype when grown in the presence of nerve growth factor (NGF) (Greene and Tischler, 1982), provides an ideal model system for introducing students to cell culture and to questions pertaining to cellular and developmental neurobiology. This upper level lab starts with a demonstration of cell culture, following which the students practice sterile technique. They grow cells under various experimental conditions, make morphological observations, harvest and count the cells, and assay them spectrophotometrically for acetylcholinesterase (AChE) activity.

I have used well established properties of this easily grown cell line to illustrate various developmental questions. Students have compared the effects of NGF and dexamethasone on cell morphology to illustrate the influence of environmental factors on differentiation of cells of sympatho-adrenal lineage; have compared the effects of NGF and the adenylate cyclase activator forskolin on neurite development and AChE activity to examine regulation of different traits in response to activation of distinct second messenger pathways; and have compared the effects of different substrata -- collagen and polyethylenimine -- on neurite outgrowth. The laboratory can easily be developed in various directions. As one example: RNA can be extracted and subjected to Northern analysis to determine whether observed changes in AChE activity occur at a pre or post-translational level. Student generated data will be presented.

## 100.5

**THE SHERLOCK HOLMES LAB: AN INVESTIGATION OF NEUROMUSCULAR PHYSIOLOGY.** P.J. Schwartz\* and E.M. Adler. Depts. of Biology and Psychology, Williams College, Williamstown, MA 01267.

It is not uncommon for students to perform laboratory exercises mechanically with little real appreciation or understanding of the basic underlying principles. One way around this problem is to engage their interest in some problem, and then actively involve them in designing experiments to solve it. We have developed a laboratory for first year college students that uses this approach as an introduction to the physiology of neuromuscular transmission. The laboratory is presented as an unsolved case investigated by Sherlock Holmes. The basic scenario is that three persons have been found dead from respiratory paralysis. Scotland Yard assumes that all three have been killed with the same toxin and, hence, by the same individual. Sherlock Holmes questions this assumption and bemoans the lack of knowledge of neuromuscular physiology in the late 19th century. Enter your class. Their mission is to determine whether the "toxins" are in fact identical or whether the murders are the work of separate individuals.

Students are provided with the frog sartorius nerve-muscle preparation for experimentation. They are then presented with one of three different solutions that blocks muscular contraction in response to nerve stimulation. We used 0 calcium + EGTA, d-tubocurarine, and lidocaine. Students design experiments to identify the toxin. Each experiment can be used as the basis for an extended discussion on physiology or more extensive experimentation. For example: extracellular recording from the frog sciatic nerve to determine if a toxin blocked action potential propagation led into a classic experiment on nerve properties like conduction velocity and the refractory period.

## 100.2

**A MULTIMEDIA COURSE IN BEHAVIOURAL NEUROSCIENCE.** J.Cranney\*, J. Kehoe, and G. Weidemann. Psychology, University of New South Wales, Sydney, 2052, Australia.

For both ethical and practical reasons, there has been increasing pressure to convert "wet lab" experimental teaching, utilising live animals in the demonstration of principles of behavioural neuroscience, to a "dry lab" format with simulation of animal experiments. In this presentation, three computer simulations will be demonstrated: RabbitLab, DrugLab, and NeuralNetLab. RabbitLab allows a 2nd or 3rd year Neuroscience or Psychology Student to simulate the lesioning of one of a number of different areas in the rabbit brain, and to look at the effects of that lesion on one of a number of different classical conditioning paradigms. The student can then take that data, analyse it, and write up the simulated experiment as an experimental lab report. In DrugLab, students can choose one of many drugs, and test the effects in rats on one of two startle paradigms, startle potentiation and prepulse inhibition. In NeuralNetLab, students interact with a simulated neural network for a simple conditioned reflex, during which some of the basic principles of learning, such as the Hebbian adaptive unit rule. [Supported by a UNSW Discretionary Development Grant]

## 100.4

**CHANGES IN UNDERGRADUATE PHYSIOLOGY LABORATORY INSTRUCTION TO INCORPORATE INVESTIGATIVE LABORATORIES AND TO IMPROVE SCIENTIFIC COMMUNICATION SKILLS.** J. K. Ono\*, R. A. Koch, and K. Dickson, Dept. of Biological Science, California State University, Fullerton, CA 92634.

In most undergraduate institutions, a student's first encounter with the neurosciences is through a physiology or psychology course. At California State University, Fullerton (CSUF), the primary physiology course for the Biology major is Mammalian Physiology. The laboratory portion of the course consists of three 3-hour laboratory sections that meet once a week, with a maximum enrollment of 20 students per section. Prior to the Fall, 1995 semester, the laboratory consisted of typical, didactic laboratory exercises with expected outcomes. Implementation of a National Science Foundation Improvement of Laboratory Instrumentation Program award has led to the incorporation of investigative experiments and group presentation of analyzed data. Much of this change has focused on the intensive use of computers for data acquisition, analysis, and group presentations. Data acquisition is carried out through transducers connected to MacLab interfaces and software. Widely used commercial software (Microsoft Office) is used for data analysis, graphing, and presentation graphics. Students work in groups of 3-5 and are assigned a completed experiment to present to their section. The group is responsible for analyzing the data from all 3 sections and for creating a professional presentation in Powerpoint. The presentation is displayed through an LCD projection system in the format used at professional scientific meetings. For most students, this is their first encounter with the intensive use of computers for these functions and we would like to share our experiences to those faced with introducing similar components to their teaching laboratories.

Supported by NSF Improvement of Laboratory Instrumentation Program Award.

## 100.6

**LABORATORY EXERCISES IN NEUROBIOLOGY: CUSTOMIZED LAB MANUALS.** A.C. Mills\*, B.R. Johnson<sup>2</sup>, and D.U. Silverthorn<sup>3</sup>. <sup>1</sup>Middle Tennessee St. U., Murfreesboro, TN 37132. <sup>2</sup>Cornell Univ., Ithaca, NY 14853. <sup>3</sup>Univ. Texas, Austin, TX 78712.

Traditional laboratory manuals are often criticized for being too "cookbook" in nature: not stimulating original thought and experimental design, lacking an emphasis on development of critical thinking skills, and also for not closely fitting the instructor's preferences for the range of exercises offered. We are trying to improve the choice of laboratory exercises for physiology instructors by gathering investigative lab exercises from faculty at colleges and universities around the world, putting the exercises into a uniform format and editing the content. Adopters of the manual can choose from the total selection offered, for a custom-published manual for their laboratory courses, available in 1997.

A variety of exercises is offered, from low to high tech, from computer-based to those using more traditional physiology equipment, from labs appropriate for non-science majors and pre-college students to others more geared toward upper-division biology majors with a strong biology background. Protocols that require the use of live animals as experimental subjects vary in species requirement, from invertebrates to humans, depending on the exercise. The individual lab exercises for neurobiology range from neuronal simulations, to updated traditional exercises such as recording extracellular potentials from the earthworm nerve cord, to integrating whole brain function such as observing the changing accuracy of a motor task by a student wearing prism goggles. Each manual will also include informative chapters on animal use and care, lab safety, experimental design, and science writing.

General physiology exercises are also available. The project is sponsored by Prentice Hall Life Sciences Publishing.

## 100.7

INTRODUCTION TO ELECTROPHYSIOLOGICAL TECHNIQUES AND PRINCIPLES USING WEAKLY ELECTRIC FISH. M. C. Fields, 21st Century Biology Class, R.D. Fields\*. Sidwell Friends School, Washington, D.C. 20016.

The electric organ discharge (EOD) of the weakly electric fish *Eigenmannia* and *Gnathonemus* has been recorded and mapped in three-dimensional space using electrophysiological recording methods. This exercise familiarizes students with the equipment and techniques used by electrophysiologists: preamplifiers, oscilloscopes, electrodes, grounding and shielding, and computer acquisition and analysis of data. Students learn basic neurophysiological concepts including muscle physiology, anatomy and biochemistry, membrane potential, sensory physiology, behavior, and evolution. The fish are available from aquarium stores and are not harmed by the investigation, making this exercise ideal for the high school classroom. The electric dipole created by the fish and the changes that occur when the fish encounter conductive and nonconductive substances are measured and modeled by computer. Students researched the literature and talked with scientists about the ecology, evolution, and behavior of these fishes from South America and Africa. Students developed and refined their own experimental protocols for observing the behavior of the fish, monitored the changes in the EOD in response to social interactions and the presence of predators, and utilized computer software to model and analyze their data. As a final exercise, students wrote a lab book with complete protocols and background information. This poster represents the work performed by these students.

## 100.9

NEURONET: A COMPUTER TOOL FOR TEACHING ANALYSIS OF MULTIPLE SIMULTANEOUS RECORDINGS BY CROSS-CORRELATION.

I. Espinosa\*, Lab. of Cybernetics, Physics Dept., Sch. of Sciences, Mexico National University, Mexico, DF 04510.

Cross-correlation analysis as developed by Gerstein and colleagues has become a useful tool in neuroscience for discerning functional connectivity and temporal synchronization in neuron assemblies. Our lab has produced a simple collection of computer programs that allows to analyze and display spike trains generated by one of MacGregor's neural simulators (Neural and Brain Modeling, Ac. Press 1987). A network can be designed on the screen and the corresponding datafile is written and if redirected to the simulator an output file is produced which contains the spiking times for each neuron and fiber in the simulation. The spike trains can be analyzed by a cross-correlation program and displayed as a raster plot. In such a manner, networks can be formed where different types of neuron interactions are induced. The student learns what connections and parameters to change to produce independent spike trains, direct connections (excitatory and/or inhibitory) and shared inputs. Similarly, different types of neural oscillators and other nets can be studied. With this training tool the task of analyzing real data from multiple simultaneous recordings becomes easier and the production of wiring diagrams is also facilitated.

## 100.11

A LABORATORY EXERCISE THAT INTRODUCES LANGUAGE MINORITY GENERAL EDUCATION STUDENTS TO THE NEUROSCIENCES. B.L. Krilowicz\*, H. Henter and L. Kamhi-Stein. Dept. of Bio/Micro. and Sch. of Ed., Cal. State University, Los Angeles, CA 90032.

CSULA is an urban university with a diverse student body. Many students at CSULA are high risk, language minority students (i.e. immigrant or native-speaking English bilinguals) and are the first in their families to attend university. A quarter long neuroscience exercise was developed for a general education biology course with the primary goals of introducing non-majors to: 1) scientific investigation, 2) scientific writing, 3) on-line scientific bibliographic databases, and 4) the scientific literature. Throughout development of this exercise, emphasis was placed both on academic content and methods to improve the academic language skills of the students. Students begin by collecting data on their own circadian rhythms in autonomic (heart rate), motor (eye-hand coordination) and cognitive (adding speed) function. Students write a journal-style scientific paper using pooled class data. Students are prepared to write the paper by several methods that are designed to improve academic language skills. First, they spend one laboratory period in the library where they receive hands-on training in the available bibliographic resources and are asked to complete an exercise demonstrating basic proficiency in utilizing these resources. Secondly, overheads of a "model" student paper are used to show what should appear in each section of their paper. The overheads indicate how the "model" paper fulfills criteria given in a section of the laboratory manual entitled "How to write a scientific paper". Only one section of the paper is covered each week. Finally, the students write drafts of each section of the paper before the final version is submitted. All drafts are critiqued and returned to the students at least two weeks prior to the due date for the final paper.

## 100.8

PROJECT CRAWDAD: A PROGRAM TO PROMOTE USE OF INVERTEBRATES IN UNDERGRADUATE NEUROSCIENCE COURSES. R.A. Wytenbach, B.R. Johnson, and R.R. Hoy\*.

Neurobiology and Behavior, Cornell University, Ithaca, NY 14853-2702.

The "Crawdad Project" is a three-year program funded by the National Science Foundation with the aim of promoting the use of invertebrates in undergraduate physiology and neuroscience courses. The program will culminate in the production of a laboratory manual and instructional videotape at the end of the three years. During each year of the program, a workshop for college teachers will be conducted at Cornell University. The purpose of the workshop is twofold: first, to give teachers hands-on experience with invertebrate preparations so they can incorporate them into classes and second, to allow ongoing testing and evaluation of instructional materials in the making. The first workshop took place this June.

The exercises to be presented are inexpensive, easy to prepare, and straightforward for students. They use simple invertebrate preparations to illustrate fundamental processes of all nervous systems. The use of commercially cultured invertebrates reduces cost and administrative overhead as well as potential ethical and environmental objections on the part of students. We have successfully used and refined all of these exercises at Cornell and elsewhere over several years.

The laboratory exercises are based primarily on crayfish superficial flexor muscle and innervation, crayfish stretch receptor, and snail brain. Topics to be covered include motor innervation, neuroanatomy, sensory systems, ionic bases of resting and action potentials, synaptic transmission, synaptic plasticity, and central rhythms.

For more information, send email to [crawdad@cornell.edu](mailto:crawdad@cornell.edu) or visit the web site at <http://www.bio.cornell.edu/neurobio/hoy/crawdad/home.html>.

Supported by NSF grant 9555095.

## 100.10

ELECTROPHYSIOLOGY OF THE UNDERGRADUATE NEUROSCIENCE STUDENT: A LABORATORY EXERCISE IN HUMAN ELECTROMYOGRAPHY. R.C. Lennartz\*, Department of Psychology and Program in Neuroscience, Williams College, Williamstown, MA 01267.

Undergraduate neuroscience laboratory courses usually include at least one electrophysiology exercise, such as the frog sciatic nerve or cockroach leg preparation. Often, however, it is not evident how well students appreciate that the electrical activity that they observe in these reduced, nonmammalian preparations is also taking place in humans. Thus, an ideal supplement to such exercises is one in which students record potentials from themselves. Although neural activity can be recorded as the electroencephalogram and evoked potentials, the averaging and/or analysis required makes it difficult for the student to immediately observe a relation between behavior and electrical activity. This poster demonstrates how the recording of muscle activity (electromyography, or EMG) can be done as an undergraduate laboratory exercise in electrophysiology. EMG is easily recorded from the skin surface; this is routinely done in the field of psychophysiology. Students get immediate visual (and auditory, with the addition of an audio monitor) feedback of how their behavior relates to the electrical activity of muscles. This laboratory exercise can serve as a framework in which to discuss terms such as motor unit, and be used to demonstrate concepts such as recruitment, flexion and extension, the stretch reflex, etc. This is a suitable supplement to preexisting electrophysiology exercises, as the equipment -- preamplifier and oscilloscope -- is the same, requiring only the change of filter settings and perhaps amplifier gain. In addition, there is no additional expense or inconvenience involved in the purchase, housing, and feeding of the animals. Supported by a grant from the Essel Foundation.

## 100.12

HANDS-ON ILLUSTRATION OF SYNAPSES. P.B. HERNANDEZ\*, Biology Department, Abilene Christian University, Abilene, TX 79699.

The objectives of this demonstration or group activity are to convey the concepts that: (1) a neurotransmitter selectively binds to a receptor, and (2) neurotransmitter actions may be inhibitory or excitatory.

Conveying the concept of the receptor-substrate specificity for neurotransmitters may be easily role played by students with the use of balloons (which represents receptors) and "pop-ice" (which represents synaptic vesicles with neurotransmitters). Select 4 students for a demonstration or work in groups of 4. Their body is the soma, one arm is a dendrite, and the other arm is an axon. One person's dendritic arm will have balloons of one color on its fingertips, which represents a specific type of receptor. The other 3 students each with a "pop-ice" synaptic vesicle of a different color in their axonal hand, stand next to the dendritic arm with balloons. These students attempt to "synapse" with the postsynaptic neuron. But the dendritic arm accepts only 1 type of neurotransmitter, the neurotransmitter that is the same color as the balloon receptor. The type of neurotransmitter accepted determines the action on the postsynaptic terminal.

After establishing the neurotransmitter-receptor specificity, you may designate different colors to represent different types of neurotransmitter and their receptors. Also, tell the students if the neurotransmitters are excitatory or inhibitory. Using the previous scenario, 3 presynaptic neurons (each with a different neurotransmitter) will attempt to synapse with a postsynaptic neuron. The postsynaptic neuron now has several types of receptors (different color balloons) on its dendritic hand. The students can now deduce

## 100.13

UNDERGRADUATE NEUROBIOLOGY LAB INDEPENDENT RESEARCH PROJECTS: DOWN REGULATION OF SIGNAL TRANSDUCTION PROTEINS. M.E. Morton\*, M.P. Leslie and M.A. Marinello. Department of Biology, College of the Holy Cross, Worcester, MA 01610.

The Cellular and Molecular Neurobiology course at Holy Cross is an undergraduate laboratory-intensive course which places emphasis on student involvement in investigative, hands-on learning. Students engage in multi-week experiments developed to mimic a research experience rather than a laboratory exercise. The final project of the semester is a four-week, independent investigation in which small groups of students execute self-designed experiments. During the fall of 1995, groups of students investigated three related aspects of carbachol-induced down regulation of the mAChR signal transduction pathway in B104 and IMR-32 neuroblastoma cell lines. One group investigated the comparative concentration-dependent down regulation of mAChR protein expression by carbachol in the two cell lines; another investigated the down regulation of G-protein mRNA expression by carbachol; a third investigated whether or not down-regulation could be prevented by down-stream activation of the pathway by forskolin. A combination of [<sup>3</sup>H]QNB binding and solution hybridization analysis was used. These projects demonstrate directly the sophistication with which undergraduate students can engage in cellular and molecular neurobiology research as well as the feasibility of including independent research projects within the context of an undergraduate laboratory course. Supported by grants from NSF # USE-9250833 and the Howard Hughes Medical Institutes.

## 100.15

ULTRASONIC VOCALIZATIONS: A VERSATILE BEHAVIORAL ASSAY FOR USE IN UNDERGRADUATE BEHAVIORAL NEUROSCIENCE INSTRUCTION. M. Kerchner\*, Department of Psychology, Washington College, Chestertown, MD 21620-1197.

A variety of rodents and other laboratory mammals produce ultrasonic (> 20kHz) vocalizations. This poster describes how these calls are employed in our undergraduate neuroscience laboratory curriculum. Sample laboratory exercises will be presented from the following courses:

**Biopsychology.** We employ adult male mouse USVs as a behavioral assay of sexual motivation following castration. Using various metabolites of testosterone, e.g., estradiol, dihydrotestosterone, in a replacement paradigm illustrates the roles that these steroids serve in activating components of male sexual behavior.

**Psychopharmacology.** Here infant mouse USVs are employed as an assay for the anxiolytic properties of various drugs, e.g., diazepam (which decreases USV) and the opiate antagonist naloxone (which increases USV). Variations of the exercise demonstrate the phenomena of tolerance and cross-tolerance.

**Comparative Psychology / Neuroethology.** Nagel's classic article "What is it like to be a bat?" describes the basic dilemma facing comparative psychologists - "How do we know what it's like to be another creature?" This issue is confronted by students as they employ USV to locate, identify, and track local bat populations as they feed on insects. This exercise leads to a discussion of the neural mechanisms that are employed by echolocating bats to locate prey and by the prey as they avoid the bats.

In addition to being extremely versatile, the cost of equipping an undergraduate laboratory for quantifying USVs is relatively low.

## 100.17

PAIN MANAGEMENT THE RAT. F.V. Abbott\* and M. Bonder, Dept of Psychiatry, McGill Univ, Montreal, PQ, Canada, H3A 1A1.

Clinical recommendations for analgesics in laboratory rodents are usually extrapolated from basic research. The animal models of pain often involve withdrawal reflexes evoked by threshold-level stimuli, while pain associated with surgery or disease involves injury and inflammation. Agents tend to be chosen as exemplars of a drug class, without regard for whether the route of administration is practical, the drug has useful kinetics, and side effects are tolerable. Here we discuss clinical assessment of pain in small animals and present data on the efficacy of drugs from four classes using the formalin test as a model of injury-induced pain.

Formalin (50 µl, 2.5%) was injected sc into a rat's paw and the behavioural response (elevation or licking of the paw) recorded. Buprenorphine and dipyrone completely suppressed pain responses at 0.1 and 200 mg/kg, respectively. When formalin was injected 6 h after buprenorphine or dipyrone, pain scores were 30% of control scores. In the absence of pain and handling, 0.6 mg/kg buprenorphine was lethal to 25% of rats. Locomotor activity was slightly depressed by 300 mg/kg dipyrone. Xylazine suppressed pain responses at 2 mg/kg, but analgesia had decreased to less than 50% by 2h, and effects were highly variable thereafter. At 8 mg/kg rats were unresponsive to strong pinch. Acepromazine, marketed primarily as a tranquilizer, reduced pain to 20% of control scores at 2.5 mg/kg, and this level of analgesia was still present at 6 h. Neuroleptic effects were prominent at 5 mg/kg. These data identify three very good analgesics that would be suitable for moderate to severe post-surgical pain when administered Q8-12h. Practical routines for use of analgesics in research are discussed. *Supported by MRC Canada*

## 100.14

AN UNDERGRADUATE LABORATORY COURSE IN CELLULAR NEUROBIOLOGY. A.K. Snyder, E. Eisenberg, E. Kotlar, V.C. Kotak and S.J. Fluharty. Biological Basis of Behavior Program, University of Pennsylvania, Philadelphia, Pa, 19104.

The Laboratory in Cellular Neurobiology is one of the few courses in the country that offers advanced undergraduates an opportunity to gain hands-on experience in the art of intracellular electrophysiology and synaptic physiology with pharmacological manipulations. Every week, students employ single-electrode, current-clamp technique in isolated nerve-ring preparations from the snail, *Helisoma trivolvis* (generously donated by Dr. S.B. Kater and Dr. C. Cohan). This course first introduces students to neuronal firing patterns in the CNS including pace-making, delayed firing, and bursting. Single spike dynamics are also examined. Students then learn to appreciate the role of underlying ionic currents by employing techniques such as voltage stepping and pharmacological manipulation. This single semester course is designed to accommodate 10-12 students and is taught with the help of 3 previously trained undergraduate teaching assistants. The class meets twice a week. Practical skills are taught during an eight hour lab session, and data and papers are discussed during an additional hour-long recitation. On a weekly basis, students collect, present, and discuss data from their own intracellular recordings. In addition, they read and discuss relevant research papers and learn to apply their new knowledge to the interpretation of their own data. Finally, students develop and execute their own research projects which they present in a formal paper and poster session. In the past, students have examined a broad range of topics including the effects of nitric oxide on bursting neurons, physiological characterization of glutamate receptor subtypes, and synaptically-evoked prolonged hyperpolarization. Student have consistently rated this lab experience as exceptional and demand for participation in this course always exceeds the number of available positions. (Supported by the BBB program at the University of Pennsylvania).

## 100.16

USE OF NADPH-DIAPHORASE HISTOCHEMISTRY IN AN UNDERGRADUATE NEUROBIOLOGY LABORATORY. H. Itagaki\*, Dept. of Biology, Kenyon College, Gambier, OH 43022.

Nitric oxide (NO) has been heavily implicated in a variety of cellular signalling roles across a wide range of organisms. Its synthesizing enzyme, nitric oxide synthase (NOS), produces NO from L-arginine. NOS has also been shown to have NADPH-diaphorase activity (Hope *et al.*, 1991). By using a relatively simple histochemical technique to detect the NADPH diaphorase activity, it is possible to localize the NOS (Hope and Vincent, 1989).

We have begun using NADPH-diaphorase histochemistry in our upper-level undergraduate neurobiology laboratory to stain nervous systems from various invertebrate preparations (e.g. fly, moth, caterpillar, cricket, crayfish), looking for NOS activity. The advantages of this lab include: 1) ease of protocol - as the preparations can be processed in whole-mount; 2) ease of generating student excitement - as students are aware of the surge in interest in NO research over the past decade, and they can try preparations that have not been assayed before; and 3) ease of teaching students the idea of comparative studies - as related organisms can be assayed to look for homologies in the CNS.

For more detailed study of stained tissues, we have also modified standard protocol (Elphick *et al.*, 1995) to allow sectioning of tissue embedded in paraffin after the NADPH-diaphorase histochemistry. This avoids the use of a cryostat, which is often difficult to use for many students, and may not be widely available for use in undergraduate labs.

Supported by NIH DC01939, NSF USE-9152088, and Kenyon College.

## 101

**SYMPOSIUM: PAIN AND THE CEREBRAL CORTEX.** K.L. Casey, Univ. of Michigan (Chairperson); A.D. Craig Jr., Barrow Neurol. Inst.; G. Duncan, Univ. Montreal; M. Gabriel, Univ. Ill.; B.L. Whitel, Univ. N. Carolina.

Both early and contemporary clinical and experimental observations have shown that several regions of the cerebral cortex affect pain, each in unique, but as yet incompletely defined, ways. The results of these studies have encouraged the continuing reconsideration of cortical functions in pain. The "internal phrenology" of strict, psychologically defined functional localization continues to give way to the development of hypotheses that consider the plasticity of the forebrain and the importance of interactions among physiologically specialized cortical regions. Ken Casey will review this information to provide a background for the several specific questions to be addressed by recent anatomical, physiological, behavioral and functional imaging studies. A.D.(Bud) Craig will discuss new evidence about the functional anatomy of ascending spinothalamic and thalamo-cortical pathways that project specific information about pain and temperature to the primate insular, anterior cingulate, and somatosensory cortices. Gary Duncan will review the results of recent studies that combine psychophysical measurements of pain with the functional imaging of synaptically induced cortical and subcortical regional cerebral blood flow responses in humans. Barry Whitel will present new information, obtained from direct near-infrared optical imaging and neuronal recording, about anterior parietal cortical responses to noxious and innocuous stimuli delivered to the same skin site in monkeys. Mike Gabriel will discuss combined behavioral and multi-site neurophysiological recording studies. These investigations reveal the successive engagement of distinct brain circuits as an animal learns to avoid pain-signaling acoustic stimuli. The involvement of nociceptive processing in the development of the mnemonic functions of these circuits will be considered. Time will be provided for questions from the audience after each presentation and for audience participation in a discussion period following the formal lectures.

## 102

**SYMPOSIUM. SINGLE NERVE CELLS AS COMPLEX COMPUTING DEVICES: INTEGRATING EXPERIMENTAL AND COMPUTATIONAL APPROACHES.**

A. Borst, Max-Planck-Institute (Chairperson); J.P. Miller, UC Berkeley; I. Segev, Hebrew Univ.; A. Borst, Max-Planck-Institute; J.M. Bower, CalTech.

Recent advances in electrophysiological and optical recording techniques reveal an astonishing physiological complexity of individual neurons. The symposium illustrates how information theoretic analysis and detailed computer models help to understand the functional consequences of this complexity for the computational capabilities of nerve cells. John Miller shows how an advanced statistical analysis of neural signals has yielded model-independent assessments of the quantity and quality of information encoded by neurons in the cricket cercal sensory system. These studies have also provided insight into the nature of neural coding by ensembles of neurons in this system. Idan Segev's talk focuses on the effect of the morphology of neurons on the site of action potential initiation. He shows that the geometry per se critically determines this site and that, in central neurons (e.g., neocortical pyramidal cells) the neighborhood of the soma is the favorable region for spike initiation. This result is explained utilizing a new parameter, the input delay, which characterizes how fast the excitable current escapes from a given input site. Using fly visual interneurons as experimental system, Alexander Borst talks about the spatial and temporal filter properties of dendrites. A particular focus is given on the relationship between these input-output characteristics and the distinct passive and active membrane properties of individual neurons. James Bower demonstrates how the interaction between modeling and experimental efforts have lead to a new understanding of the cellular mechanisms underlying the response of the cerebellar Purkinje cell to synaptic input. The results require a major reexamination of the function of cerebellar cortex. Taken together, the talks emphasize the need of a combined effort of experimentalists and theoreticians to achieve an understanding of the computational properties of the brain's basic building blocks.

### ALZHEIMER'S DISEASE: MECHANISMS OF CELLULAR INJURY

## 105.1

**POTENTIAL LINKS BETWEEN ALZHEIMER'S DISEASE AND BRAIN INJURY FROM MICROEMBOLI RELEASED DURING CARDIOPULMONARY BYPASS.** W.R. Brown\*, D.M. Moody, M. Tytell, V.R. Challa, and H.S. Ghazi-Birry. Departments of Radiology, Neurobiology & Anatomy, and Pathology; Bowman Gray School of Med., Winston-Salem, NC 27157.

Traumatic brain injury can lead to amyloid deposition and Alzheimer's disease. Also, ischemic brain injury can lead to amyloid precursor protein deposition, but it is unknown if this can progress to amyloid deposition and Alzheimer's disease. Permanent neurobehavioral deficits are found in 19-36% of patients undergoing cardiopulmonary bypass (CPB) and at 5 years after CPB there is an unexpectedly steep cognitive decline. In this study we investigated the brain pathology resulting from CPB-induced brain microemboli (Moody et al. Ann Neurol 1990;28:477) and looked for links with the pathogenesis of Alzheimer's disease. Brain tissues from CPB patients were obtained at autopsy, fixed in 70% ethanol, embedded in celloidin, and stained with histochemical and immunocytochemical markers. We found thousands of microemboli with evidence of very small areas of ischemic damage in the nearby tissues, including vascular degeneration, swollen astrocyte endfeet, upregulation of constitutive heat shock protein 70 around the vessels, and one microinfarct with hemorrhage. In the case with the most microemboli, we also found huge numbers of heat shock protein-positive granules that appeared similar to dystrophic neurites which were also found in the brains of Alzheimer's patients. We conclude that CPB can cause multiple microscopic ischemic brain injuries that may lead to neuropsychological deficits and perhaps eventually to Alzheimer's disease. Supported by grants NIH NS20618 and NIH NS27500

## 105.3

**VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) LEVELS ARE UNCHANGED IN ALZHEIMER'S DISEASE.** A. Baird\*, V. Kuo-LeBlanc, P. Song, A.M. Gonzalez, and E.G. Stopa. Dept. of Pathol., Brown Univ. Sch. of Med./RIH, Providence, RI and \*PRIZM Pharmaceuticals, San Diego, CA

Vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (FGF-2) have both been shown to have an affinity for heparin. Because of this affinity, FGF-2 normally binds to the structurally related heparan-sulfate proteoglycans (HSPGs) present in the extracellular matrix. In a previous study we demonstrated FGF-2 levels are increased in Alzheimer's disease, and FGF-2 immunoreactivity was clearly present within neuritic plaques and neurofibrillary tangles. We have also previously shown that despite its heparin-binding properties, VEGF immunoreactivity showed no apparent association with the B/A4 amyloid continuing structures found in Alzheimer's disease.

In this study, we utilized an ELISA assay (R&D Systems) to quantitate VEGF in 3 areas severely affected by AD: amygdala, A20, and A28; and 2 areas which are less severely involved by the disease: caudate nucleus and A4. Human brains were obtained within 18 hours of death. The areas of interest were carefully dissected from the fresh brain and snap frozen in liquid nitrogen.

The concentration of VEGF was generally found to be highest in the amygdala. In all 5 areas, VEGF levels ranged from 0.06-0.45 ng/mg protein and were virtually unchanged in Alzheimer's disease (0.05-0.42 ng/mg protein). FGF-2 levels by contrast ranged from 15.78-20.61 ng/mg protein and were increased 2-3 fold in Alzheimer's disease, 31.89-65.30 ng/mg protein (p<.0001).

These data confirm the previous observation that despite its heparin-binding properties, VEGF does not appear to be influenced by B/A4 amyloid deposition. They also suggest that certain heparin-binding growth factors may be more critical than others in the pathogenesis of Alzheimer's disease. (Supported by AG10682)

## 105.2

**NON-AMYLOID COMPONENT PROTEIN (NACP) REACTIVITY AND mRNA EXPRESSION IN CEREBRAL VESSELS IN ALZHEIMER'S DISEASE.**

D.R.D. Premkumar\*, T. Saitoh and R.N. Kalaria.

Departments of Neurology and Pathology, Case Western Reserve University, Cleveland, Ohio and Department of Neurosciences, University of California at San Diego, San Diego, California, USA

NACP is a recently identified protein that is highly expressed in brain. The cleaved product, NAC binds tightly to amyloid  $\beta$  protein of Alzheimer's disease (AD). NAC is also associated with cerebral amyloid angiopathy. Here, we used immunochemical and RT-PCR methods to study the expression of NACP in cerebral vessels and other brain tissues from AD subjects compared to normal aging controls. Immunoblotting revealed that the 19 kDa NACP reactivities were consistently increased in soluble fractions of buffer extracted cerebral vessel preparations from AD subjects compared to controls. This was not apparent in other brain tissues. We also noted NACP mRNA expression in neuronal regions, the cerebral vessels and choroid plexus. The mRNA expression was highest in the hippocampus and relatively low in the cerebellum. Contrary to the increased protein levels, we observed decreased NACP mRNA expression in cerebral vessels from AD subjects compared to controls but this was not readily apparent in any other region examined. Our results suggest AD specific changes in NACP of non-neural tissues as well. Supported by grants from NIH.

## 105.4

**ASSOCIATION BETWEEN THE MITOCHONDRIAL tRNA<sup>Gln</sup> A4336G MUTATION AND NEURODEGENERATIVE DISEASE**

R. Egersperger, S. Kösel, N.M. Schnopp, P. Mehraein and M.B. Graeber\*. Molecular Neuropathology Laboratory, Institute of Neuropathology, Ludwig Maximilians-University, 80337 Munich, Germany

Mutations of mitochondrial DNA (mtDNA) are being increasingly implicated in the pathogenesis of neurodegenerative disease. Specifically, a mitochondrial tRNA<sup>Gln</sup> sequence variant (A4336G transition) has been suggested to occur more frequently in Alzheimer's (AD) and Parkinson's diseases (PD) than in controls [Wallace D.C. (1994) PNAS 91:8739]. The finding is of great interest as this mutation may represent the first known genetic susceptibility factor shared by two common neurological disorders. We have analyzed 27 neuropathologically confirmed cases of AD, 39 cases with Lewy-body PD and 100 controls without clinical and histological evidence of neurodegeneration. Presence of the mtDNA<sup>A4336G</sup> transition was tested by *Avall* restriction enzyme analysis of PCR products amplified from formalin-fixed and paraffin-embedded brain tissue. In addition, all diseased brains were genotyped for alleles of the apolipoprotein E (ApoE) gene. One out of 27 AD cases and two out of 39 PD cases carried the mtDNA<sup>A4336G</sup> mutation whereas no mutation was found in 100 age-matched controls (p<0.05). Interestingly, the patient carrying the mtDNA<sup>A4336G</sup> mutation was homozygous for ApoE  $\epsilon$ 3 and showed a high number of neurofibrillary tangles. Our data support the hypothesis that the mitochondrial A4336G mutation represents a genetic susceptibility factor for PD and AD. They are further in line with the view that point mutations in mitochondrial genes could play a causative role in the oxidative phosphorylation deficit known to occur in both AD and PD. Finally, it is tempting to speculate that defects in oxidative phosphorylation may predispose to the formation of neurofibrillary tangles.

## 105.5

**ALZHEIMER DISEASE CELLS HAVE DEFECTIVE DNA REPAIR OF FREE RADICAL-INDUCED DNA DAMAGE: IMPLICATIONS FOR NEURODEGENERATION AND ANTIOXIDANT THERAPY.** J.H. Robbins<sup>1</sup>\*, R. Parshad<sup>2</sup>, K.K. Sanford<sup>1</sup>, F.M. Price<sup>1</sup>, L.K. Melnick<sup>1</sup>, L.E. Nee<sup>3</sup>, M.B. Schapiro<sup>4</sup> and R.E. Tarone<sup>1</sup>. <sup>1</sup>NCI, <sup>2</sup>NINDS, <sup>3</sup>NIA, NIH, Bethesda, MD 20892 and <sup>4</sup>Howard Univ., Washington, DC 20059.

We previously showed that xeroderma pigmentosum (XP) and familial and sporadic Alzheimer disease (AD) cells appear to have a similar defect in repairing DNA damage induced in cultured skin fibroblasts or blood lymphocytes by fluorescent light (FL). FL damages DNA in cells in tissue culture indirectly by generating free radicals, and XP cells [which are defective in nucleotide excision repair (NER) of damaged DNA] are unable to repair a type of free radical-induced DNA damage (Satoh et al., PNAS 90, 6335-9, 1993). We report in detail [Parshad et al., PNAS 93, (May 14), 4738-42, 1996] all these FL test results on AD and XP cells, together with studies using the free-radical scavenger theaflavin (TFM), a highly purified extract of polyphenol antioxidants extracted from black tea. Our tests use chromatid breaks to measure ability of skin fibroblasts or PHA-stimulated lymphocytes to conduct NER or respond to unrepaired DNA lesions. All 16 familial AD patients (representing 4 families) and all 11 sporadic AD patients were abnormal in our tests, whereas at least 28 of 31 normal donors had normal responses. Lymphocytes from a sporadic AD patient and a normal donor exhibited normal NER of 254-nm UV-induced DNA damage when TFM (lot LN-0046-01, Lipton Tea Co., Englewood, NJ) was present during irradiation, indicating that the NER pathway was not affected by TFM and that 254-nm UV-induced DNA damage was not mediated via free radicals. However, when normal cells were irradiated with FL in the presence of TFM, no NER was apparent, indicating that TFM had prevented the free radical-induced DNA damage which AD cells cannot repair. When the AD cells were irradiated with FL in the presence of TFM, the damage which AD cells cannot repair was also prevented. If death of neurons occurs in AD patients because of their inability to repair normally-occurring free radical-induced DNA damage, as is believed to be the case in XP, antioxidant preventive therapy may delay or prevent neurodegeneration in AD.

## 105.7

**ALTERED CALCIUM RESPONSES IN FIBROBLASTS FROM ASYMPTOMATIC MEMBERS OF ALZHEIMER'S DISEASE FAMILIES.** R. Etcheberrygaray<sup>1</sup>\*, N. Hirashima<sup>1</sup>, J. Prince<sup>1</sup> and D.L. Alkon<sup>1</sup>, <sup>1</sup>Lab. of Applied Neuroscience-GICCS, Georgetown University Medical Center, Washington, DC 20007 & <sup>2</sup>Lab. of Adaptive Systems-NINDS, National Institutes of Health, Bethesda, MD 20892.

We have shown that fibroblasts from Alzheimer's disease (AD) patients exhibit distinct cellular and molecular alterations. These alterations include functional absence of a 113 pS K<sup>+</sup> channel, absent or greatly reduced tetraethylammonium (TEA)-induced Ca<sup>2+</sup> responses, enhanced IP<sub>3</sub>-induced Ca<sup>2+</sup> release, and reduced levels of Cp20 (a memory related GTP-binding protein). The combination of these alterations can be used as an index for AD. Recent results also suggested (Kim et al., PNAS, 92:3060-3064, 1995; Hirashima et al., Neurobiol. Aging, in press) that some of these alterations might be present in asymptomatic members of AD families. To further explore these observations, using fluorescent Ca<sup>2+</sup> imaging we studied cell lines from asymptomatic (A) individuals including "escapes" (with ages above the families' age of onset, N=3) and subjects at 50% "risk" (with one direct relative affected and ages below the families' age of onset, N=7). This combined group was compared to AD (N=22) and controls (N=23). All but one (Italian family 1097) of the asymptomatic individual are from the Canadian family 964. Over 50 cell were measured in each cell line. The overall comparison between the three groups was highly significant for the TEA induced Ca<sup>2+</sup> response,  $p < 0.0001$  (Kruskal-Wallis). Post test analyses (Dunn's) revealed that both A and AD have significantly lower TEA responses than controls ( $p < 0.01$  and  $p < 0.001$  respectively). The same analyses revealed remarkably similar TEA responses between A and AD. The bradykinin and bombesin (IP<sub>3</sub>-mediated) responses of A had values higher (although not statistically significant) than controls and lower (not significant) than AD. However, the combined "index" (Hirashima et al., Neurobiol. Aging, in press) identified 8 out of 10 of the asymptomatic individuals members of AD families as having an AD profile. These results strongly suggest that these molecular alterations are present in varying degrees before clinical symptoms arise and when combined as an index they could provide an early diagnostic tool in familial cases.

## 105.9

**Differentially elevated intracellular Calcium levels by Apo E-isoforms in the presence of BA4-Amyloid.**

F. Wüstenberg<sup>1</sup>, K. Berlin<sup>1</sup>, H. Scharnagl<sup>2</sup>, W. März<sup>2</sup>, T.G. Ohm<sup>2</sup>, W. Müller<sup>1</sup>.

<sup>1</sup>Institut für Anatomie, <sup>2</sup>Institut für Physiologie, Charité, 10117 Berlin, Germany;

<sup>2</sup>Abteilung klinische Chemie, Universität Freiburg, Freiburg, Germany

Apolipoprotein E allele 4 (Apo E4) is an important risk factor in late-onset familial and sporadic Alzheimer's disease (AD). It has been shown that AD-associated amyloid- $\beta$  peptides (BA4) bind to Apo E protein and trigger elevated intracellular free-calcium levels ([Ca]), which lead to the expression of AD-related epitopes and cell death. Our working hypothesis in this study was that [Ca], is still higher in the presence of Apo E protein and the extent of the increase in [Ca], is dependent on the Apo E isoform present in the complex. We monitored [Ca], via slow-scan ratio-imaging of cultured hippocampal neurons preloaded with Fura-2, immediately after extracellular application of either 20 nmol/L recombinant Apo E 3 or recombinant Apo E 4, resp., either with or without 1  $\mu$ mol/L BA4 peptide, preincubated for at least 12 hours at 37°C. We found that Apo E3 protein moderately elevates [Ca], to 63 nmol/L over resting level, whereas after application of Apo E4 the mean increase of [Ca], was 77 nmol/L. After application of Apo E / BA4 complexes we recorded significantly higher [Ca]. With Apo E3/BA4 complexes [Ca], was increased 5-fold to 313 nmol/L over resting level, and after Apo E4/BA4 complexes [Ca], was highest with a 434 nmol/L increase, which is 6-fold as compared to Apo E4 alone. These findings correspond to the notion that Apo E4 protein itself does not destroy neurons itself, but it can exert its influence via the complex of Apo E4 and BA4, as soon as BA4 is present extracellularly. Our data, especially the extremely high [Ca], after application of Apo E4/BA4 complexes correspond to the epidemiological data associating the Apo E4 allele with an early onset of AD. Apo E3/BA4 complexes still trigger marked elevations of [Ca], which can be explained by the susceptibility

## 105.6

**ACTIVATION OF MAP KINASE BY ATP-DEPLETION IN PC12 CELLS IS MEDIATED BY CALCIUM: RELATION TO ALZHEIMER'S DISEASE.** Y. Luo<sup>1</sup>\*, P. Kumar<sup>1</sup>, P. Russell<sup>1</sup> and V. M. Ingram<sup>1</sup>. Dept. of Biology, Massachusetts Institute of Technology, Cambridge, MA 02139.

Brain aging and Alzheimer's disease (AD) are accompanied by a decreased ATP metabolism and by substantial changes in calcium homeostasis. We have previously demonstrated that partial depletion of ATP in NGF-differentiated PC12 cells with an uncoupler of OXPHOS, FCCP, produced phosphoepitopes on cytoskeletal proteins similar to those seen in Alzheimer brains. We hypothesize that ATP depletion can elevate the intracellular calcium concentration, thereby activating MAP kinases.

Using a specific immunoprecipitate kinase assay we observe an increased activation of MAP kinases in PC12 cells treated with FCCP or oligomycin. FCCP produces a transient two-fold increase in ERK1 and ERK2 activity towards TAU after 10 min. Oligomycin, in contrast, significantly increases the activity of ERK2 at 1 to 2 hours after treatment, but not at 10 min. MonoQ FPLC confirms this conclusion. Western blotting of MonoQ fractions shows increased phosphorylation of ERK1 and ERK2 as gel mobility shifts. The activation of ERK1/ERK2 by FCCP or oligomycin correlates with tyrosine phosphorylation of the kinases detected by an antibody specific to phosphorylated ERK1/ERK2. A calcium ionophore, ionomycin, which raises internal calcium, also increases ERK1/ERK2 activity 2.5-fold after treatment for 10 min. Fluorometric measurements demonstrate that FCCP and ionomycin, but not oligomycin, cause a rapid and lasting rise of [Ca<sup>2+</sup>]<sub>i</sub> in the PC12 cells. This suggests that FCCP-stimulated ERK1/ERK2 activation is mediated by calcium.

FCCP treatment of PC12 cells for 2 hr induced the translocation of ERK2 to the nucleus, and decreased several tyrosine phosphoepitopes. It appears that increases in [Ca<sup>2+</sup>]<sub>i</sub>, as a consequence of ATP depletion, activate the MAP kinase cascade. The resultant hyperphosphorylation of TAU and phosphorylation of transcription factors, which lead to expression of new genes, may well be relevant to the neurotoxicity seen in Alzheimer's disease. (Y.L. is a Fellow of the Lucille P. Markey Foundation.)

**IMPAIRMENT OF Ca-HOMEOSTASIS IN CENTRAL NEURONS AND ASTROCYTES BY APOLIPOPROTEIN E AND BA4.**

W. Müller<sup>1</sup>\*, K. Berlin<sup>1</sup>, F. Wüstenberg<sup>2</sup>, H. Scharnagl<sup>3</sup>,

W. März<sup>3</sup> and T.G. Ohm<sup>2</sup> <sup>1</sup>Physiologisches Institut,

<sup>2</sup>Anatomisches Institut, Charité, 10117 Berlin, <sup>3</sup>Klinische

Chemie, Universität, 79106 Freiburg i. Br., Germany.

Neurodegeneration appears to be a primary mechanism in the expression of Alzheimer's disease and BA4-Amyloid (BA4) as well as apolipoproteinE (ApoE) might have a role in this process. We used Fura-2/AM loaded rat hippocampal cultures and digital ratio-imaging to study acute effects on Ca-homeostasis after incubation of ApoE and BA4-Amyloid (BA4) for at least 12 hours at 37°C. In order to study direct postsynaptic effects, all experiments were performed in the presence of CNQX (10  $\mu$ M). Transient application of recombinant apolipoproteinE3 (ApoE3, 20nM for 3 min) increased free Ca in neurons as well as astrocytes slightly by 60 $\pm$ 37 nM. BA4 (aa1-43, 5  $\mu$ M) raised free Ca in neurons and astrocytes by 165 $\pm$ 50 nM (mean $\pm$ std). Application of BA4-ApoE3 resulted in a strong and overadditive effect, i.e. Ca-levels were increased by 313 $\pm$ 60 nM. In control experiments with a reversed BA4 (aa 40-1) Ca-increases were small (BA4(40-1): 65 $\pm$ 5nM, BA4(40-1)-ApoE3: 116 $\pm$ 12nM). We conclude that apolipoproteinE plays an important role in cellular Ca-homeostasis, most likely via a specific binding of several BA4s, thereby damaging neurons directly and possibly indirectly through astrocytes.

## 105.10

**A NOVEL HUMAN FE65-LIKE PROTEIN INTERACTS WITH THE CYTOPLASMIC DOMAIN OF THE  $\beta$ -AMYLOID PRECURSOR PROTEIN** S. Guénette\*, J. Chen, P.D. Jondro and R.E. Tanzi. Genetics and Aging Unit, Department of Neurology, Mass. General Hospital East.

To identify cellular components necessary for the intracellular trafficking of and/or function of cell surface  $\beta$ PP we screened for proteins that interact with the cytoplasmic domain of  $\beta$ PP with the "interaction trap". Using this approach we identified a novel human gene which we have named hFE65L. The predicted open reading frame of the hFE65L gene is 57% identical to the 499 overlapping amino acids of the rat FE65 gene and represents one of three members of a novel human gene family. In contrast to the rat FE65 gene the hFE65L gene is expressed in all tissues tested. Amino acid sequence alignment of members of the human FE65 gene family reveals the presence of two tandem phosphotyrosine interaction (PI) domains. The cytoplasmic domains of the  $\beta$ PP homologues, APLP1 and APLP2, were also tested for interaction with hFE65L. Only APLP2 was found to interact with hFE65L in the interaction trap assay. We confirmed these interactions *in vivo* by successfully co-immunoprecipitating endogenous  $\beta$ PP and APLP2 from mammalian cells overexpressing a hemagglutinin-tagged hFE65L fusion protein. Our results also show that the C-terminal PI domain of hFE65L is sufficient for interaction with APP *in vivo*.

The PI domain of the protein Shc, is known to interact with the NPXY motif present in the cytoplasmic domain of a number of different growth factor receptors. Furthermore, the NPXY motif of  $\beta$ PP has previously been shown to modulate the internalization and trafficking of  $\beta$ PP. We hypothesize that the PI domain present in the C-terminal moiety of the hFE65L protein binds the NPXY motif of  $\beta$ PP and APLP2 and plays a role in the internalization and/or function of these molecules.

CLEAVAGE SITE-SPECIFIC CELL DEATH SWITCH ANTIBODY LABELS ALZHEIMER'S LESIONS. B. Teter<sup>1</sup>, F. Yang<sup>1</sup>, C. Wasterlain<sup>1</sup>, M. Smulson<sup>2</sup>, S.A. Frautschi<sup>1</sup> and G.M. Cole<sup>1</sup>. <sup>1</sup>Sepulveda VAMC, GRECC 11E, Sepulveda, CA 91343 and Depts. Med. & Neurol., UCLA., <sup>2</sup>Dept. Biochemistry, Georgetown Univ. School of Med., Washington, D.C. 20007

Neurofibrillary tangle (NFT) bearing neurons in Alzheimer's Disease (AD) brain are associated with slow or delayed cell death and dementia, but the causal mechanism involved is obscure. The Tunnel method for in situ detection of apoptotic DNA fragments labels rare cells occasionally including NFT-bearing neurons in AD brain. An apoptotic cascade can be mediated by cysteine proteases in the ICE or CED-3 family which cleave targets including poly(ADP-ribose) polymerase (PARP) to generate a 24kD DNA binding domain fragment (PARP-24) separated from the activated catalytic domain that depletes NAD and ATP reserves. A PARP-24 specific antibody was developed which immunoprecipitated 35S-labeled PARP-24 derived from in vitro translated 35S-PARP treated with apopain extract from human neuronal cells. This antibody was shown to label PARP-24 in apoptotic human neuronal cells in culture and Tunnel positive neurons in rat brain. The antibody clearly labeled rare apoptotic neurons with nuclear fragmentation in AD hippocampus. These morphologically apoptosing neurons were sometimes associated with either  $\beta$ -amyloid or NFT identified by the PHF-1 tau antibody. Surprisingly, anti-PARP-24 also labeled the majority of NFT and many dystrophic neurites and curly fibers. Isolated NFT directly labeled strongly with the antibody, similar to that found with PHF-1. A PARP-24 band at ~24kD was identified on Western blots from NFT preparations and from AD hippocampus. These data suggest that long before final apoptotic degeneration, subthreshold apoptotic cleavage of PARP occurs producing PARP-24 which binds NFT. We interpret this data to indicate widespread subthreshold activation of a cell death pathway in AD brain which can be detected with this novel antibody. Supported by AG9009, AG11125 (GMC), CA25344(MS).

## 105.13

ALZHEIMER-SPECIFIC ANTIBODIES DEMARCAT PROGRESSION INTO ANAPHASE. Alex Dranovsky<sup>1,2</sup>, Sergey Lyubsky<sup>2</sup>, Inez Vincent<sup>3</sup>, Peter Davies<sup>3</sup>, and Dmitry Goldgaber<sup>1\*</sup>. <sup>1</sup>M.S.T. Program, Depts. of <sup>2</sup>Pathology and <sup>3</sup>Psychiatry, S.U.N.Y., Stony Brook, NY 11794; <sup>2</sup>Dept. of Pathology, Albert Einstein College of Medicine, Bronx, NY 10461.

Recently, monoclonal antibodies TG-3 and TG-4 specific for brains of patients with Alzheimer's disease (AD) were described. Surprisingly, both antibodies stained exclusively mitotic cells in culture (Vincent *et al.*, 1996, J. Cell Biol. 132:413-425). Using laser confocal microscopy the temporal and spatial distribution of epitopes recognized by TG-3 and TG-4 was studied throughout the cell cycle in human epithelial HEp-2 cells. Granular staining was first observed in prometaphase. As cells progressed into early metaphase, the pattern changed, the intensity of fluorescence increased, and the staining appeared to envelop the chromosomes. The bright chromosome enveloping staining reached its highest intensity in metaphase and then disappeared abruptly demarcating the entry into anaphase. Cells in anaphase and telophase were not stained. In interphase, a weak dot-like fluorescence was observed in the nuclei of some cells. The unique phase-specific pattern was clearly distinct from the well characterized pattern revealed by the mitosis-specific MPM-2 antibody. MPM-2 has been shown to recognize several phosphothreonine-containing proteins in all phases of mitosis including anaphase and telophase. MPM-2, TG-3 and TG-4 each recognized a distinct pattern of proteins in cell lysates analyzed by immunoblotting. The role of proteins recognized by TG-3 and TG-4 in the cell cycle and chromosome segregation is under investigation. Supported by Metropolitan prize to DG.

ENDOCYTOSIS AND CATHEPSIN CONTENT OF EARLY ENDOSOMES ARE INCREASED IN NEURONS IN ALZHEIMER'S DISEASE. A.M. Cataldo<sup>\*</sup>, J.L. Barnett, and R.A. Nixon. Labs. Molec. Neurosci., McLean Hosp., Dept. Psychiatry, Harv. Med. Sch., Belmont, MA 02178

Alterations of APP, PS1, PS2 and Apo E- $\epsilon$ 4 are risk factors for Alzheimer's disease (AD). Trafficking of these proteins via endosomal-lysosomal (E-L) interactions represents a common pathway through which their etiologic influences may be exerted. Using specific markers, we identified different functional populations of neuronal endosomal and lysosomal compartments and abnormalities of these organelles in affected AD neurons. In this study, we report striking alterations in the early endocytic pathway of cortical AD neurons using the early endosomal marker rab 5 and the more general acidic vacuolar system markers, Cat D and B. Rab 5 antiserum labelled a population of intracellular vacuoles in close proximity to the plasmalemma and distinct from the perinuclear location of late endosomes. The total number of early endosomes in AD brains was equal to or less than controls, but total endosomal volume averaged  $3 \pm 1.5$ -fold larger than normal, implying marked upregulation of endocytosis. These large rab 5-positive early endosomes were not seen in a survey of neurons from other neurodegenerative diseases. We found that Cats D and B colocalized with rab 5 in vacuolar compartments of AD neurons to a greater extent than in controls. These data suggest that increased endocytosis and the more frequent occurrence of Cat D in abnormal early endosomes of affected AD neurons may be a response to accelerated membrane turnover. Colocalization of hydrolases, including Cat D, a potential A $\beta$ -producing secretase, in the same E-L compartments as APP, suggests a potential mechanism to account for the close relationship between E-L system activation and  $\beta$ -amyloidogenesis. We recently found that early endosome size was larger in some forms of FAD vs sporadic AD suggesting a link between alterations in endocytosis and genetic risk factors for AD. (NIH)

## 106.1

CHARACTERIZATION OF SMELL IMPAIRED GENES OF *DROSOPHILA MELANOGASTER*. R. R. H. ANHOLT<sup>\*</sup>, N. H. KULKARNI and T. F. C. MACKAY. Depts. of Zoology and Genetics, North Carolina State University, Raleigh, NC 27695.

*Drosophila melanogaster* allows a combination of genetic, molecular and behavioral approaches to investigate how the concerted expression of ensembles of genes shapes odor-guided behavior.

We measured avoidance responses to benzaldehyde of 379 inbred lines of *Drosophila melanogaster*, containing single *P*-element (*P*[*ArB*]) insertions, and identified 14 lines with aberrant olfactory behavior. The *P*[*ArB*] insertions mapped to different locations on the second and third chromosomes and these olfactory loci were named "smell impaired (*smi*)" followed by their chromosomal band designations. Enhancer trap analysis revealed expression of 10 *smi* genes in olfactory organs (the third antennal segment and maxillary palps). In addition, 4 of the *smi* mutants show a sexually dimorphic phenotype with larger impairment in the female. Line *smi97B* shows the largest olfactory impairment with slight sexual dimorphism and highly localized expression in the third antenna segment.

*P*[*ArB*]-tagged DNA sequences can be rescued as inserts in pBluescript and used to identify genomic clones. Four genomic clones have, thus far, been isolated and their *P*[*ArB*] insertion sites mapped. Fragments of these genomic clones currently are used to screen a *Drosophila* head cDNA library to identify the *smi* gene products.

The phenotype of *smell-impaired* mutants can be restored through excision of the *P*-element. For line *smi97B* 20 revertants have been obtained with phenotypes ranging from homozygous lethal and semi-lethal to partial or complete reversion. Correlations of behavioral phenotypes with gene deletions due to imprecise excisions of the *P*-element together with a reduction in mRNA for the gene product will confirm that aberrant olfactory phenotypes indeed result from the *P*-element insertions.

Supported by NIH grants DC02485, GM45344 and GM45146 and U. S. Army Research Office grants DAAH04-94G-0027 and 34815-LS.

## 106.2

CHARACTERIZATION OF A SUBFAMILY OF ZEBRAFISH ODORANT RECEPTOR GENES: SEQUENCE, DEVELOPMENTAL ONSET OF EXPRESSION, AND LINKAGE. A.L. Barth<sup>\*</sup>, J.C. Dugas, N.J. Justice, and J. Ngai. Department of Molecular and Cell Biology, Univ. of Calif. Berkeley, CA 94720.

In order to examine models of odorant receptor gene regulation, we undertook an analysis of a group of highly related odorant receptor genes in the zebrafish. A complete subfamily of genes, defined by the number of cross-hybridizing bands on a conventional high stringency Southern, was selected for comprehensive study. cDNAs for all five members of this subfamily of receptors were cloned from an olfactory cDNA library and sequenced. They exhibit between 72 and 79 percent identity at the amino acid level, versus about 30 percent identity to less-related zebrafish odorant receptors. None of these receptors cross-hybridize to each other on high stringency in situ hybridizations of adult olfactory tissue. We examined the onset of expression of the different subfamily members on embryos at developmental stages varying from 24 hours to 3 weeks post-fertilization. Results showed that each subfamily member exhibited a different time of expression onset and that four out of the five receptors were expressed before 48 hours post-fertilization.

We next investigated genetic linkage of receptors from this subfamily. Analysis by pulse-field gel electrophoresis shows that receptors expressed early in the development of the olfactory epithelium may be genomically linked to receptors expressed much later. These results may have implications for models of receptor gene regulation that suggest linked genes are regulated similarly. (Supported by NIH R01 DC-02253, the Pew and McKnight Foundations, and the NSF.)

## 106.3

INCREASED APOPTOSIS IN THE EMBRYONIC ZEBRAFISH TELENCEPHALON FOLLOWING REMOVAL OF THE OLFACTORY PLACODE. L.K. Cole\* and L.S. Ross.

Neurobiology Program, Dept. of Biological Sciences, Ohio University, Athens, OH 45701.

Apoptosis is a common type of cell death characterized by endonuclease fragmentation of the DNA. One proposed cause of apoptosis in neural development is a lack of trophic support during a critical period. In a previous study, apoptosis was observed in the telencephalon during the period when olfactory receptor axons are innervating the anlage of the olfactory bulb (Cole, Murray, and Ross, submitted). Afferent olfactory axons may support their target within the CNS, and cells within the target that fail to receive trophic support may be eliminated via apoptosis. To test this hypothesis, we unilaterally ablated the olfactory placode. The unoperated side served as a control. Apoptotic cells within the telencephalon were labeled using the TUNEL method. The number of apoptotic cells in the telencephalon of the operated side was significantly increased by 30 hours postfertilization (PF), as compared to the control side. By 36 hours PF, the difference in the two sides was substantially reduced, and by 50 hours PF, no significant difference was seen in the number of apoptotic cells on the control and experimental sides. These results suggest that during a critical period following axon arrival, trophic factors released by the ingrowing olfactory nerve prevent apoptosis of their target cells within the telencephalon. Supported by NSF IBN-9222896.

## 106.5

ROLES OF CHORDA TYMPANI AND GLOSSOPHARYNGEAL NERVES IN NACL AND SWEET TASTE. M.A. Barry\*, Neuroscience Program, Univ. of Connecticut Health Center, School of Dental Medicine, Farmington, CT 06030-3705

Our studies examine the roles of specific peripheral nerves in the mediation of different taste qualities in golden Syrian hamsters. Behavioral techniques were utilized to examine the role of the chorda tympani (CT) nerve in NaCl taste. The roles of the CT and lingual branch of the glossopharyngeal (IX) nerves in NaCl and sucrose taste were assessed by changes in the central expression of *c-fos* protein following taste stimulation. In behavioral experiments, the CT nerve was sectioned bilaterally, and the CT or IX were sectioned unilaterally for *c-fos* studies. An intact CT nerve is required for normal preference and conditioned aversion behavior to 0.1-0.15 M NaCl. Also, the NaCl-taste induced expression of *c-fos* in parabrachial nucleus neurons is dramatically reduced by CT but not IX section. Our results in combination with those from other laboratories suggest that a unique sodium sensitivity is mediated by the CT, even though fibers in other taste nerves are responsive to NaCl. A new finding is that 0.1-0.25 M sucrose-taste induced *c-fos* expression in parabrachial nucleus neurons was reduced by IX but not CT section. Based on tract tracing experiments, these activated cells are in a location which is the target of afferent inputs from regions of the solitary nucleus with CT afferent input. Thus the lack of CT mediation of sucrose activation of these cells is not related to a regional lack of neuronal inputs. Behavioral and electrophysiological studies in other laboratories suggest that sweet taste is mediated primarily by the greater superficial petrosal (GSP) and CT nerves. However, some neurons in IX respond best to sweet compounds and not all behavioral responses to sucrose are eliminated by bilateral section of both the CT and GSP. Our results show that sweet taste, mediated by IX, but not the CT, activated and induced the formation of *c-fos* in central neurons, and suggest a specialized role for nerve IX in sweet taste.

Supported 2P50-DC00168-14A1 from NIDCD, NIH.

## 106.7

FUNCTIONAL ORGANIZATION AND PHARMACOLOGY OF RAT OLFACTORY BULB REVEALED BY OPTICAL IMAGING. S. Yagodin\*, V. Aroniadou-Anderjaska, L.A. Zimmer, M. Ennis, M.T. Shipley and A. Keller, Dept. Anatomy, University of Maryland School of Medicine, Baltimore, MD 21201.

Synaptic interactions in an *in vitro* preparation of the rat main olfactory bulb were studied with high-speed, multiple site imaging of voltage-sensitive dye signals. Four hundred  $\mu$ m thick horizontal slices of olfactory bulbs from 3 to 4 week old rats were stained with RH-155 (100 $\mu$ M), placed in an interface chamber mounted on an upright microscope and perfused with oxygenated physiological solutions. Optical signals were collected through a 30X (0.9 N.A.) water-immersion objective and projected on a 100 element photodiode array. Stimulation in the olfactory nerve layer (0.2 to 0.5 ms, 0.1 to 0.5 mA) evoked a TTX-sensitive compound action potential (5 to 10 ms duration) that propagated from the stimulation site (0.3 $\pm$ 0.04 m/s) into individual glomeruli. Smaller, longer-lasting depolarizing potentials (80 to 120 ms) were recorded from the glomerular, external plexiform and mitral cell layers. The amplitude of these potentials was largest in the glomerular layer and they were reversibly blocked by removing  $Ca^{2+}$  from the bath solution, indicating that they represent postsynaptic potentials evoked in neuronal elements within the glomeruli. The amplitude of these potentials was significantly reduced (~85%) by the non-NMDA receptor antagonist CNQX (10 $\mu$ M) and almost completely abolished by further addition of the NMDA receptor antagonist APV (50  $\mu$ M). This suggests that olfactory nerve inputs to olfactory bulb neurons are mediated by glutamatergic receptors of the NMDA and non-NMDA types. The amplitude of the synaptic potentials was dramatically attenuated (80 to 90%) by application of the GABA<sub>A</sub> receptor agonist baclofen (10 $\mu$ M) but were not affected by the GABA<sub>A</sub> antagonist bicuculline (100 $\mu$ M). These, and other electrophysiological data from our laboratory, suggest a GABA<sub>A</sub>-mediated presynaptic inhibition of olfactory nerve inputs to the olfactory bulb. ODOR-STIMULATED CALCIUM SIGNALING IN CILIA AND DENDRITES OF OLFACTORY RECEPTOR NEURONS. F. Zufall\*, T. Leinders-Zufall, M. N. Rand, G. M. Shepherd and C.A. Greer, Sections of Neurobiology and Neurosurgery, Yale Univ. Sch. of Med., New Haven, CT, 06510.

Odor detection takes place in the cilia of olfactory receptor neurons (ORNs), resulting in a rapid rise in cAMP which directly activates cyclic nucleotide-gated cation channels (CNG channels) allowing  $Na^{+}$  and  $Ca^{2+}$  to enter the cell. Secondary to this response is a persistent increase in cGMP also leading to activation of CNG channels. Several recent observations have suggested that both cAMP and cGMP-induced  $Ca^{2+}$  signals act in concert to mediate sensory adaptation and regulate the sensitivity of olfactory transduction (Leinders-Zufall and Zufall, this meeting). It is therefore critical to gain detailed information about the spatial and temporal properties of ciliary  $Ca^{2+}$  gradients in ORNs. Using confocal imaging of salamander ORNs that were loaded with the  $Ca^{2+}$  indicator dye fluo-3AM (20  $\mu$ M), local  $Ca^{2+}$  transients were resolved in individual cilia after a brief pulse of odor stimulation. Interestingly, an odor pulse led to the generation of  $Ca^{2+}$  transients with very similar temporal characteristics simultaneously in all cilia. This result supports the view that the cilia of a given cell possess similar properties with regard to their odor sensitivity, and that a given ORN integrates signals from different cilia. With repetitive stimulation, the primary  $Ca^{2+}$  transients declined over time showing signs of long-lasting adaptation while basal  $Ca^{2+}$  levels increased. This time-dependent decline in responsiveness as well as portions of the basal  $Ca^{2+}$  signals could be abolished by inhibitors of the CO/cGMP second messenger system giving further support to our proposal that persistent activity of the cGMP pathway contributes significantly to  $Ca^{2+}$  levels and olfactory adaptation. Another series of experiments tested the effects of thapsigargin (100 nM), which irreversibly depletes  $Ca^{2+}$  from IP<sub>3</sub>-sensitive stores, indicating that this treatment had relatively little effect on the generation of odor-dependent  $Ca^{2+}$  signals.

## 106.6

URINARY ODOR PROFILES DURING EQUINE ESTRUS AND DIESTRUS. W. R. Klemm\* and Weidong Ma, Dept. VAPH, College of Veterinary Medicine, Texas A&M University, College Station, TX 77843-4458.

Horses use olfactory signals to coordinate reproductive behavior. The odor of an estrous mare is said to be detectable by stallions as far away as a half mile. We tested the hypothesis that profiles of volatile components in mare urine may differ in estrus and diestrus. Mare urine was analyzed by capillary gas chromatography (GC) to establish any qualitative and quantitative differences that may have potential value for chemical communication. Forty-five different volatile compounds were detected. Of these, 17 major GC peaks were common to all chromatograms. The profile of estrous urine was distinguished by the presence of a unique peak that was not present in diestrous samples. Numerous constituents exhibited endocrine dependence: 7 peaks had greater magnitude at estrus, whereas 4 peaks decreased their sizes at the same time. Statistical analyses also indicated that the normalized areas of many peaks changed significantly across the estrous cycle: the ratios were increased in 9 peaks, decreased in 6 peaks, and remained unchanged in 2 peaks at estrus.

Because estrous urine, but not diestrous urine, elicits sexual behavior in the stallion, the unique peak, together with the peaks increased concentrations at estrus, may represent important chemical signals that stallions use to detect urinary estrous odors.

## 106.8

A METHOD FOR GENERATION OF OLFACTORY STIMULI FOR fMRI. N. Sobel\*, Y. Prabhakaran, J.E. Desmond, G.H. Glover, E.V. Sullivan, J.D. Gabrieli, Prog. in Neuroscience<sup>1</sup>, Depts. of Psychology<sup>2</sup>, Radiology<sup>3</sup>, and Psychiatry & Behavioral Sciences<sup>4</sup>, Stanford University, Stanford, CA 94305.

fMRI offers the means to functionally categorize brain regions involved in olfactory processing. To this end, we constructed a two channel air dilution olfactometer which operates within the fMRI environment. The olfactometer generates 30 L/min of activated-charcoal-cleaned air, passed through glass, temperature-controlled odor-saturators, up to a nasal mask equipped with 5 one-way valves permitting air to freely leave the mask. Switching vacuum lines achieved a stimulus rise-time below 500 msec. Subjects practiced pharyngeal closure such that the air was flowing out of the one-way valves except when the subjects sniffed. Each experiment consisted of 8 alternating 40s blocks of odor/no-odor; the odor in Exp. 1 was vanillin; Exp. 2, decanoic acid; Exp. 3, random alternations of the two odors. Odor concentration was set to levels above threshold following a full-length pretest. Every 8s, subjects were prompted by an on-screen instruction to sniff and to respond by pressing a button (balanced over conditions) indicating odor identification. The olfactometer, on-screen messages, and response recording were computer controlled. Functional data were acquired from eight 4mm slices, 2mm skip, taken at an oblique plain from frontal to temporal pole (31° to AC-PC) at 1.5 T using a T2\* sensitive gradient echo spiral sequence (TR=720, TE=40, flip angle=65°). Data were analyzed using the cross-correlation method of Friston et al (1994). We observed significant activation ( $p < .025$ ) in 3 healthy, right handed men in piriform cortex, entorhinal area, temporal pole, insula, and inferior medial-frontal gyrus, findings that are consistent with human lesion studies. Two subjects had asymmetric activation of orbitofrontal gyri, greater on the left, a pattern opposite to that observed in the only PET study of olfaction. This difference may be due to our use of different odors (pure olfactants as opposed to trigeminals) or to our currently small sample size.

## 106.9

SEGREGATED PATHWAYS WITHIN THE ACCESSORY OLFACTORY BULB?  
C. Jia\* and M. Halpern. Program in Neural & Behavioral Sci., Box 5, SUNY. Hlth. Sci. Ctr. at Brooklyn, 450 Clarkson Ave., Brooklyn, NY 11203.

Previous studies have shown that there are two populations of receptor neurons in the vomeronasal organ (VNO). The  $G\alpha 2$ -expressing population is located in the middle layer of the vomeronasal epithelium and projects to the anterior part of glomerular layer of the accessory olfactory bulb (AOB). The  $G\alpha x$ -expressing population is located in the deep layer of the vomeronasal epithelium and projects to the posterior part of the glomerular layer of the AOB. Since the glomerular layer is the place where terminals of the vomeronasal receptor neuron form synapses with dendrites of AOB neurons, it is possible that the terminals in the anterior and the posterior compartments synapse with dendrites of different AOB neurons. In order to test this, AOB neurons were labeled with Lucifer Yellow and by Golgi impregnation methods and the distribution of dendrites of the labeled neurons was analyzed in opossums (*Monodelphis domestica*). Twenty-four mitral/tufted cells were injected intracellularly with Lucifer Yellow in lightly fixed, parasagittal (300  $\mu$ m) sections of the AOB. Result showed that the apical dendrites of many mitral/tufted cells in the AOB terminated in more than one glomerulus. Some of the mitral/tufted cells sent apical dendrites to the anterior compartment of the glomerular layer, while other mitral/tufted cells sent apical dendrites to the posterior compartment. No mitral/tufted cell with apical dendrites entering both anterior and posterior glomerular layer was found. On the other hand, the secondary dendrites of the mitral/tufted cells spread extensively in the mitral/tufted cell layer but they did not enter the glomerular layer. Similar results have been obtained by Golgi impregnation method. These observations suggest that the anterior and posterior compartments of the glomerular layer are innervated by different populations of mitral/tufted cells in the AOB and therefore the pathways from the different populations of vomeronasal receptor neurons continue to be segregated in the AOB.

## SECOND MESSENGERS AND PHOSPHORYLATION I

## 107.1

EFFECTS OF D2 DOPAMINE RECEPTOR STIMULATION ON MITOGEN-ACTIVATED PROTEIN KINASES (ERKs and JNKs). Seema Basu, Donald H. VanLeeuwen and Robert G. MacKenzie\*. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105.

CHOpro-5 cells expressing human D2 dopamine receptors were used to study D2 receptor mediated stimulation of  $[3H]$ thymidine uptake. Cells were challenged with the D2 agonist quinpirole or the growth factor insulin. Both ligands stimulated  $[3H]$ thymidine uptake by approx. 20-fold. Pertussis-toxin treatment blocked the response to quinpirole but not to insulin. The effects of quinpirole and insulin on ERKs were studied because activation of these kinases are typically associated with mitogenic indices such as stimulation of  $[3H]$ thymidine uptake. Quinpirole and insulin both tyrosine phosphorylated ERK2 to the same extent. Quinpirole and insulin also activated ERK2 to the same extent (20-fold above basal). Pertussis toxin blocked the activation of ERK2 by quinpirole but not by insulin. Insulin stimulated the tyrosine phosphorylation of the insulin receptor substrate-1 (IRS-1) and the activity of the p85-associated PI3-kinase enzyme but quinpirole did not. Both insulin and quinpirole increased GTP-loading of ras. Both insulin and quinpirole tyrosine phosphorylated the adapter protein, Shc, suggesting that this might be a crossover point of G-protein coupled signalling onto the growth factor pathway. Interestingly, quinpirole but not insulin, strongly stimulated JNK1 activity and the quinpirole effect was completely blocked by pertussis toxin. Results from these experiments suggest that quinpirole and insulin stimulate  $[3H]$ thymidine uptake via activation of the ERK2 growth factor pathway but initiation of the signal differs between G-protein coupled and growth factor pathways. ## 107.3

VILIP - A MEMBER OF A FAMILY OF NEURONAL CALCIUM-BINDING PROTEINS: FUNCTIONAL STUDIES IN TRANSFECTED CELLS. K.-H. Braunewell, W. Wetzel\* and E. D. Gundelfinger. Federal Institute for Neurobiology (IfN), P.O. Box 1860, D-39008 Magdeburg, F.R.G.

VILIP (visinin-like-protein) is a member of a new sub-family of EF-hand  $Ca^{2+}$ -binding proteins, which also includes visinin, recoverin/S-modulin and frequenin. VILIP is expressed by a subset of neurons in the chicken brain, in the olfactory epithelium of rat and in the retina of different species at the time of their terminal differentiation. The molecule is localized in cell bodies as well as in axonal and pre- or post-synaptic structures. Two of the four EF-hand structures of VILIP are able to bind  $Ca^{2+}$  or  $Mg^{2+}$  with affinity constants in the  $\mu$ molar and mmolar range, respectively. In order to determine the possible cellular function of the protein we transfected several non-neural and neural cell lines. In transfected C6 glioma cells VILIP was shown to be myristoylated at its N-terminus. The myristoylation is most likely a prerequisite for the calcium-dependent membrane association of the otherwise cytosolic protein. This is in agreement with co-localization studies in PC 12 cells, where VILIP expression is strongly associated with membrane structures, such as the actin-rich cortical cytoskeleton. A strong immunoreactivity is also observed at cell-cell contact sites. We looked for the possible involvement of VILIP in calcium-regulated cellular signalling. In transfected glioma cells VILIP strongly enhances cAMP production following  $\beta$ -adrenergic stimulation of the adenylate cyclase. Our results suggest that VILIP can act as a  $Ca^{2+}$ -sensor molecule. It may transmit  $Ca^{2+}$ -signals from or to the membrane-associated cortical cytoskeleton, thereby affecting processes, such as neurotransmitter release, synaptic plasticity or second messenger cascades. ## 107.2

PROSAPOSIN AND PROSAPTIDE STIMULATE TYROSINE PHOSPHORYLATION AND ACTIVATION OF THE MAPK CASCADE IN PC12 CELLS.

W.M. Campana, M. Hiraiwa, K.C. Addison and J.S. O'Brien\*  
Department of Neurosciences, University of California, San Diego, Center for Molecular Genetics, La Jolla, CA 92093-0634

Prosaposin is a 66 kDa glycoprotein which has neurotrophic activity *in vitro* and *in vivo*. The trophic sequence has been pinpointed to a sequence of 22 amino acids ( $^8$ CEFLVKEVTKLIDNNKTEKEI $^{29}$ L) in the domain for saposin C. In this study, we demonstrate that prosaposin and the 22-mer peptide, prosaptide, activate the MAPK cascade in PC12 cells. Binding studies using  $^{125}I$ -prosaposin and  $^{125}I$ -prosaptide revealed a single class of binding with a  $K_d$  of 10 nM and a  $K_d$  of 19.6 nM, respectively. Both prosaposin and prosaptide rapidly stimulated tyrosine phosphorylation. Western blotting experiments using a polyclonal antibody prepared against phosphorylated MAPK demonstrated a 15-20 fold stimulation of MAPK phosphorylation by prosaptide as well as prosaposin in the pM ranges. In contrast to NGF, phosphorylation of MAPK after treatment with prosaposin was transient since signaling was reduced after 30 minutes. Activation of MAPK was decreased when  $^{21}Asn$  within prosaptide was changed to  $^{21}Asp$ . Prosaposin and prosaptide also increased phosphorylation of the upstream signaling protein, Shc, and promoted prosaposin induced association of Grb2 with phosphorylated Shc. These findings demonstrate a role for src homology (Sh2) proteins and MAPK pathways in prosaposin signaling.

## 107.4

IN-SITU STUDIES OF CALCIUM DIFFUSION AND ENDOGENOUS CALCIUM BUFFERING CAPACITY IN CULTURED *APLYSIA* NEURON.

M. Gabso E. Neher\* and M.E. Micha. The Hebrew University of Jerusalem, Israel, and the Max-Planck-Institut Fur Biophysikalische Chemie, Göttingen, Germany.

Two processes determine the range of intracellular calcium (Ca) operation as a second messenger: Ca-diffusion and Ca-removal. To date no *in-situ* experimental data are available to estimate the parameters underlying these processes separately. Attempts to characterize Ca-diffusion by imaging techniques suffer from the fact that presence of indicator dyes may strongly influence the processes under study.

In certain limiting cases Ca-diffusion can be described by an apparent Ca-diffusion which depends on  $D_{Ca}$ , the diffusion coefficient of the free Ca, on  $D_e$ , the diffusion coefficient of endogenous Ca-buffers, and on  $D_f$ , the diffusion coefficient of the indicator dye according to  $D_{app} = (D_{Ca} + D_e \kappa_e + D_f \kappa_f) / (1 + \kappa_e + \kappa_f)$  where  $\kappa_e$  and  $\kappa_f$  denote the so-called Ca-binding ratios ( $dCa_{bound}/dCa_{free}$ ) of the endogenous buffer and the indicator dye, respectively.

In the present study we evaluated  $D_f$  and  $\kappa_e$  by measuring  $D_{app}$  in the large cylindrical axons of cultured metacerebral neurons isolated from *Aplysia* ganglions. As a prerequisite we had to measure  $D_f$  from images of the spatiotemporal distribution pattern of fura-2 pentapotassium pressure injected into the axon. The value obtained was  $102 \mu m^2/s$ .  $\kappa_f$  was calculated from the known intracellular fura-2 concentration and its  $K_D$  of 760 nM.  $D_{app}$  was measured by fura-2 ratio imaging, analyzing the spread of pressure micro injected  $Ca^{2+}$  into axons.

From the plot of  $D_{app}$  as a function of  $\kappa_f$  (for fura-2 concentrations in the range 25-175  $\mu M$ ) we estimated  $D_e$  to be as low as  $1-20 \mu m^2/s$  and  $\kappa_e$  to be 20-40, assuming a value for  $D_{Ca}$  of  $220 \mu m^2/s$ .  $D_e$  and  $\kappa_e$  have to be considered as lumped values for mobile and fixed endogenous Ca-buffers. We noted that fura-2, even at very low concentrations, strongly influences Ca-redistribution.

Supported by a grant from the German-Israeli Foundation # I-254-136.01/92.

## 107.5

**NITRIC OXIDE INDUCES THE CONFORMATIONAL CHANGE OF NEURON-SPECIFIC PROTEIN KINASE C SUBSTRATE, NEUROGRANIN.** F.-S. Sheu\*, H.-M. Chen, H.H. Miao, S.Y. Au and K.Y. Chui. Dept. of Biochemistry, Hong Kong University of Science & Technology, Clear Water Bay, Kowloon, Hong Kong.

In the brain, the possible role of nitric oxide (NO) as signaling messenger has been linked to its involvement in synaptic plasticity of long-term potentiation (LTP), an electrophysiological model of learning and memory, which can be triggered in several brain regions including the hippocampus and the neocortex. The neural target(s) of NO is an important subject related to the mechanisms underlying the biological functions of NO in the brain. Since protein kinase C (PKC) activation leading to its substrates phosphorylation is observed during LTP expression, we seek to explore whether a soluble PKC substrate, neurogranin (NG) localized at the postsynaptic site, could be served as a molecular target of NO. NG binds to calmodulin (CaM) in the low  $[Ca^{2+}]$  and releases CaM in response to the increased intracellular  $[Ca^{2+}]$  upon NMDA receptor activation after LTP induction. The resultant released of CaM plus increased  $[Ca^{2+}]$  provides signals to activate NO synthase to produce NO from arginine. We approached the effect of NO on NG by testing whether NO generating agents could alter the biophysical and biochemical properties of purified NG in vitro. We found that several NO generating agents including diethylamine nitric oxide and some NO-amine complexes which can release NO spontaneously in the aqueous solution, oxidized NG leading to its conformational change to form intramolecular disulfide bond(s) as evidenced by the increased electrophoretic mobility of NG in SDS-PAGE. The oxidation effect of NO on NG was reversible by reducing agents such as DTT added back to the oxidized NG. The conformational change of NG from the reduced to the oxidized form was further examined by circular dichroism. The reduced NG showed a predicted secondary structure of  $\alpha$ -helix, turn and random coil whereas the oxidized form became unfolded to near random coil. Work is in progress to determine the potential biological significance of NO effect on NG. [Supported by Hong Kong RGC Direct Allocation Grant (95/96, SC02)].

## 107.7

**SECOND MESSENGER MECHANISMS UNDERLYING THE ENHANCEMENT OF  $I_h$  BY SEROTONIN IN THE LOBSTER STOMATOGASTRIC GANGLION.** C.M. Hempel<sup>1</sup>, P. Vincent<sup>2</sup>, R.Y. Tsien<sup>3</sup> and A.L. Selverston<sup>4\*</sup>. Depts. of Biology<sup>1,4</sup> and Pharmacology<sup>2,3</sup> and HHMI<sup>3</sup>, UCSD, La Jolla, CA 92093. Department of Biology, UCSD, La Jolla CA 92093.

The neuronal circuitry of the crustacean stomatogastric ganglion can be reconfigured by a number of neuromodulators. These modulators act in part by altering the voltage dependent currents in the constituent neurons, presumably via second messenger pathways. For example, serotonin enhances the hyperpolarization-activated, inwardly rectifying current,  $I_h$ . We examined the signal transduction mechanisms underlying this effect in cultured stomatogastric ganglion neurons. Serotonin enhanced  $I_h$  with an EC<sub>50</sub> of approximately 20 nM. Three pharmacological agents (forskolin, IBMX and 8-bromo-cAMP), which are known to elevate intracellular cAMP levels, all enhanced  $I_h$ . Fluorescence imaging with the cAMP indicator, FICHRH, revealed that serotonin increased cAMP concentration. These results suggest that the action of 5HT is at least partially mediated by the cAMP signal transduction pathway. Further pharmacology will determine whether 5HT is acting via the cAMP-dependent protein kinase (PKA), or by a PKA-independent mechanism. Supported by NIH grant #25916 to A.L.S., NS27177 to R.Y.T. and a Lavoisier fellowship to P.V.

## 107.9

**MECHANISM OF ANGIOTENSIN II REGULATION OF NEURONAL AT<sub>1</sub> RECEPTOR PHOSPHORYLATION.** H. Yang, D. Lu, W. G. Luttrell\* and M. K. Raizada. Department of Physiology, University of Florida, College of Medicine, Gainesville, FL 32610.

Phosphorylation is a key regulatory event in agonist-induced desensitization and internalization of G-protein coupled receptors. Our objectives in this study were to determine if Angiotensin II (Ang II) regulates phosphorylation of AT<sub>1</sub> receptor (R) and if so, to determine the involvement of various kinases on this phosphorylation. Ang II caused a time- and dose-dependent stimulation of AT<sub>1</sub>R phosphorylation. A maximum phosphorylation of ~6-fold was observed with 100 nM Ang II, was blocked by AT<sub>1</sub>R antagonist, losartan, and was associated with an internalization of the AT<sub>1</sub>R. Phospho-amino acid analysis of Ang II-treated neurons revealed a predominance of phosphoserine residues. Immunoblotting indicated that AT<sub>1</sub>R co-precipitates with MAP kinase, suggesting the role of this enzyme in phosphorylation of AT<sub>1</sub>R. This conclusion was further supported by the following observations. (a) AT<sub>1</sub>R was phosphorylated by MAP kinase at serine residues. (b) Exogenous MAP kinase stimulated phosphorylation of AT<sub>1</sub>R at serine residues that is comparable with Ang II. (c) U98059, a MAPKK inhibitor, blocked Ang II stimulation of AT<sub>1</sub>R phosphorylation, and (d) MAP kinase phosphorylation of AT<sub>1</sub>R leads to a loss in the ability of AT<sub>1</sub>R to bind Ang II. These observations suggest that Ang II stimulates phosphorylation of AT<sub>1</sub>R at serine residues, an effect mediated by MAP kinase. This phosphorylation is associated with internalization of these receptors. (Supported by NIH grant 33610).

## 107.6

**Mn<sup>2+</sup>-DEPENDENT PHOSPHORYLATION INHIBITS BRAIN NITRIC OXIDE SYNTHASE ACTIVITY IN THE ADULT POSTSYNAPTIC DENSITY.** J.L. Xu\*, P.C. Suen, H.T.J. Mount, S.Y. Lin and K. Wu. Department of Neuroscience and Cell Biology, Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ 08854

Nitric oxide (NO) plays key roles in diverse processes, including neurotransmission in the peripheral and central nervous systems. Synthesis of NO from L-arginine is a rate-limiting step in NO action and is catalyzed by nitric oxide synthase (NOS). Activity of NOS is regulated, in turn, by phosphorylation. Electron microscopy and Western blots reveal that NOS is an intrinsic component of the postsynaptic density (PSD), a disc-shaped structure apposed to the inner surface of the postsynaptic membrane. In this study, we examined the effects of local protein tyrosine kinase (PTK) and cAMP-dependent kinase (PKA) on NOS activity in the isolated PSD fraction of adult rat cerebral cortex. Phosphorylation in the presence of Mn<sup>2+</sup>, an activator of PTK, resulted in a dramatic decrease in PSD NOS activity, as measured by induction of NO-stimulated NAD incorporation into glyceraldehyde-3-phosphate dehydrogenase. In contrast, cAMP-dependent phosphorylation of PSD proteins had no effect on NAD incorporation, consistent with the observation that PKA-dependent phosphorylation of purified NOS does not alter activity of the enzyme. Our findings suggest that activation of PTK reduces NO formation by inhibiting NOS activity.

**FUNCTIONAL DIVERSITY OF *DROSOPHILA* CALCIUM/CALMODULIN DEPENDENT KINASE II ISOFORMS.** B. GuptaRoy, K. Beckingham<sup>†</sup> and L.C. Griffith\* Department of Biology and Center for Complex Systems, Brandeis University, Waltham MA 02254 and <sup>†</sup>Department of Biochemistry and Cell Biology, Rice University, Houston, TX 77251.

Expression of a gene for a specific peptide inhibitor of calcium-calmodulin dependent protein kinase II (CaM kinase II) in *Drosophila* produces defects in both associative and non associative learning (Griffith, et. al. Neuron 10: 501-9). To understand the molecular basis of this phenomenon we have cloned and characterized several isoforms of CaM kinase II from *Drosophila*. These isoforms are produced by alternative splicing from a single gene. Seven of these isoforms were expressed in a COS cell expression system and purified for functional characterization. All these show nearly identical biochemical properties, except for a slightly elevated Km for CaM of one isoform (GuptaRoy and Griffith, J. Neurochem. 66: 1282-88). However, these isoforms showed differences in activation by two series of CaM mutants. They also appear to have differential ability to phosphorylate known substrates of CaM kinase II, such as Eag, synapsin I and tyramine  $\beta$  hydroxylase.

## 107.10

**G PROTEIN ALPHA SUBUNITS ASSEMBLE TO FORM LARGE FILAMENTOUS STRUCTURES IN VITRO.** S. Roychowdhury<sup>1</sup>, J.R. Hepler<sup>2</sup>, M.E. Knight<sup>1</sup> and M.M. Rasenick<sup>1\*</sup>. <sup>1</sup>Dept. of Physiology & Biophysics, U. Illinois College of Medicine, Chicago, IL 60612 and <sup>2</sup>Dept. of Pharmacology, U. Texas Southwestern Medical Center., Dallas, TX 75235

Results from several laboratories suggest that G proteins exist as heterotrimeric in vivo, consisting of  $\alpha$  and  $\beta\gamma$  subunits,  $\alpha$  being the site of GTP binding. Recently, we have observed that  $\alpha$  subunits of G<sub>i1</sub> or G<sub>s</sub> are capable of forming larger polymeric structures in vitro, as judged by electron microscopy. Purified, recombinant G<sub>s</sub> (0.5-1 mg/ml) assembled to form regular arrays of filaments, 5-15 nm wide and hundreds of micrometers long, when incubated at 37°C for 30 minutes in presence of GTP or GDP. The filaments were found largely in bundles, occasionally twisted at irregular intervals. Filaments were not evenly distributed throughout the grid, suggesting an unfavorable nucleation step. Many isolated short filaments of variable lengths were also observed. Purified G<sub>i1</sub> assembled to form long filaments as well as isolated short filaments. G<sub>i1</sub> filaments were relatively straight and appeared to be wider (15-30 nm) than G<sub>s</sub> filaments. In some filaments protofilaments were easily detectable. Myristoylated-G<sub>i1</sub> was the better candidate for polymer formation than non-myristoylated G<sub>i1</sub>. The formation of regular polymers is dependent upon incubation of G<sub>s</sub> with GTP or GDP, suggesting that, due to intrinsic GTPase activity, it is the GDP bound form of G<sub>s</sub> which polymerizes. This is consistent with the recently reported crystallographic structure of G<sub>i1</sub>, which suggests that GTP hydrolysis triggers changes in the G $\alpha$  molecule allowing the GDP form of G<sub>i1</sub> to attain a conformation capable of forming a head to tail polymer. We are currently trying to optimize the conditions for G $\alpha$  assembly and to determine the role of nucleotides in that process by using nucleotide analogs and a GTPase deficient mutant of G<sub>i1</sub>. While the biological relevance of G protein polymers has yet to be determined, two possible roles are suggested. 1) G protein polymers might channel information to specialized regions, such as dendritic spines and 2) through interaction with cytoskeletal elements, G protein polymers might participate in synaptic remodeling. Supported by NIMH

## 107.11

INDUCTION OF NFAT-MEDIATED TRANSCRIPTION BY G<sub>q</sub>-COUPLED RECEPTOR ACTIVATION. V. Boss\*, D. J. Talpade and T. J. Murphy, Dept. of Pharmacology, Emory Univ., Atlanta, GA 30322

The nuclear factor of activated T cells (NFAT) is well known as an inducible transcription factor activated by antigen stimulation of the T-cell receptor in lymphocytes. Stimulation of NFAT-mediated transcription is now reported in PC12 cells, as well as in Jurkat T cells, following activation of a neurotransmitter receptor. The muscarinic receptor agonist carbachol induces robust luciferase responses in Jurkat and PC12 cells expressing an NFAT-luciferase reporter construct and an m3 muscarinic receptor that couples to phospholipase C-catalyzed phosphoinositide hydrolysis through G<sub>q</sub>. Cyclosporin blocks this response. In PC12 cells expressing a G<sub>i</sub>-coupled m2 muscarinic receptor, carbachol induces NFAT-mediated luciferase activity that is strictly dependent upon co-expression of a chimeric G<sub>αq</sub>/α<sub>i</sub> subunit, which confers G<sub>q</sub>-effector coupling on G<sub>i</sub>-linked receptors. Taken together with reports identifying NFAT isoforms in neural tissue, these findings suggest that NFAT may play a role in neuronal signal transduction, and that neurotransmitters acting on G<sub>q</sub>-protein coupled receptors may serve as physiological stimulators of NFAT. Supported by NIH grants HL48252 and HL52810.

## 107.13

LIGAND INDEPENDENT ACTIVITY OF HUMAN ESTROGEN RECEPTORS IS TYROSINE KINASE DEPENDENT. J.L. Mulchahey<sup>1</sup>\*, P.M. Plotsky<sup>1</sup>, C.B. Nemeroff<sup>1</sup>, E.v. Angerer<sup>2</sup>, G.K. Stalla<sup>3</sup>, and C.J. Newton<sup>3</sup>. <sup>1</sup>Department of Psychiatry & Behavioral Sciences, Emory Univ. School of Medicine, Atlanta, GA 30322, <sup>2</sup>Institute for Pharmacy, Univ. Regensburg and <sup>3</sup>Max Planck Institute for Clinical Psychiatry, Munich.

Rodent estrogen receptors (ER) display a ligand-independent ability to drive estrogen-responsive reporters. Our study sought to extend our previous studies of this phenomenon to include human ER (hER) and to investigate the molecular mechanism underlying the intrinsic transcription factor activity of hER. When hER-containing breast cancer cells (MCF-7) stably transfected with a tk-ERE-luciferase reporter plasmid were cultured in steroid free conditions, basal expression of luciferase was detected. Expression was positively coupled to exogenous estradiol (421±63% of control; mean±SEM; n=6; p<0.05 at 1 nM). Basal luciferase expression could be reduced (52±17% of control; n=3; p<0.05) by treatment with the pure antiestrogen ZM182780 (10 nM), demonstrating a ligand-independent activity of hER. Treatment of unstimulated cells with the protein kinase C (PKC)-activator phorbol myristate acetate (0.1 μM) increased luciferase expression and this increase could be prevented with the PKC inhibitor chelerythine chloride (6.6 μM). Chelerythine alone had no effect on luciferase expression, suggesting that the PKC pathway is not involved in ligand-independent expression. In contrast, the tyrosine kinase inhibitor herbimycin (2.0 μM) was able to reduce basal expression of luciferase in this system (53±12% of control; n=5; p<0.05), suggesting that the ligand-independent activity of hER is at least partially dependent on tyrosine kinase phosphorylation of the ER. These findings offer new information of the mechanism of ligand-independent action of the hER. Additionally, our findings offer insight into the possible modulation of estrogen feedback to the CNS as well the estrogen-dependent and -independent proliferation of human breast cancers. Supported by the Emory Univ. Psychiatry - MPI Psychiatry Exchange Program and RISP grant MH 51761.

## 107.12

PROSTAGLANDIN F<sub>2α</sub> IS REQUIRED FOR NMDA RECEPTOR-INDUCED TRANSCRIPTION OF *c-fos* mRNA IN DENTATE GYRUS NEURONS. L. S. Lerea<sup>1</sup>\*, N. G. Carlson<sup>1</sup>, M. Simonato<sup>1</sup>, J. D. Morrow<sup>2</sup>, L. J. Roberts<sup>2</sup> and J. O. McNamara<sup>1</sup>. <sup>1</sup>Department of Medicine, Division of Neurology, Duke University Medical Center, Durham, NC, 27710, <sup>2</sup>Department of Pharmacology, Vanderbilt University, Nashville, TN., 37232

Activation of NMDA receptors has been linked to lasting physiologic and pathologic changes in the mammalian nervous system. The cellular and molecular mechanisms underlying permanent modifications of neuronal structure and function following brief episodes of neuronal activity are not known. Immediate early genes (IEGs) have been implicated in the conversion of short-term stimuli to long-term changes in cellular phenotype via regulation of target gene expression. The intracellular signaling pathways coupling activation of cell-surface NMDA receptors to nuclear IEG transcription are poorly understood. Here we show, for the first time, that NMDA receptor activation *in vitro* triggers the synthesis and release of two diffusible prostanoids, PGF<sub>2α</sub> and PGE<sub>2</sub>. We further demonstrate that PGF<sub>2α</sub>, but not PGE<sub>2</sub>, is required for NMDA-dependent transcription of the IEG *c-fos* in neurons derived from the dentate gyrus. These findings identify the diffusible messenger PGF<sub>2α</sub> as obligatory for NMDA receptor-mediated transcription of a nuclear IEG and reveal a novel mechanism by which activation of a cell surface receptor leads to a diffusible signal that can influence gene transcription.

This study was supported by NIH grant NS32334 and grant GM15431.

## REGENERATION I

## 108.1

LOCALIZATION OF TRANSMITTER ENZYMES, CYTOSKELETAL ELEMENTS AND GROWTH FACTORS IN WHOLE MOUNT PREPARATIONS OF IMMATURE OPOSSUM CNS. J.M. Luque<sup>1</sup>, E. Reinhard<sup>1</sup>, B.M. Riederer<sup>2</sup>, D.F. Kusewitt<sup>3</sup> and J.G. Nicholls<sup>1</sup>\*, <sup>1</sup>Dept. Pharmacol., Biozentrum, Univ. Basel, 4056, Switzerland, <sup>2</sup>Inst. Anat. Univ. Lausanne, 1005, Switzerland, <sup>3</sup>Lovelace Inst., Albuquerque, NM 87108.

The CNS of the neonatal opossum (*Monodelphis domestica*) can be isolated in its entirety and maintained in culture where it not only survives but shows remarkable regeneration. Procedures have been devised for visualising the distribution and sites of synthesis for key signaling molecules in transparent whole mounts of the CNS. We have surveyed the major groups of catecholaminergic cell bodies and processes by applying antibodies against tyrosine hydroxylase. The developmental sequence is comparable to that in eutherian mammals with the exception of the olfactory bulb: in new born opossum the dopaminergic neurons are detected at a far earlier stage of development. Similarly, antibodies against neurofilaments, microtubule associated proteins and GAP-43 have been used to evaluate neurite outgrowth during development and regeneration. To examine cells expressing mRNAs encoding basic fibroblast growth factor, we used RNA probes generated from opossum FGF-2 cDNA. Labeled cells were already detected at the day of birth. They were distributed in proliferative regions, in discrete areas of septum, colliculus and cerebellum as well as the choroid plexus. By contrast message for low affinity nerve growth factor receptor was most abundant in spinal motoneurons. These experiments set the stage for imaging specific neuronal populations and assessing changes that occur after pharmacological manipulations or after lesioning the CNS.

Supported by grants from the Swiss Nationalfonds and from the International Research Institute for Paraplegia.

## 108.2

DEVELOPMENT AND REGENERATION OF MONOSYNAPTIC CONNECTIONS IN THE NEONATAL OPOSSUM (MONODELPHIS DOMESTICA) M. Lepre, W.B. Adams\* and J.G. Nicholls, Department of Pharmacology, Biozentrum, University of Basel

A first aim of these experiments was to determine at what stage of development dorsal root fibres make monosynaptic contacts with cervical motoneurons in the same and in adjacent segments. At birth, stimulation of a dorsal root generates a short latency response in ventral roots followed by polysynaptic reflexes. When dorsal and ventral roots were stained with HRP, DiI or DiO afferent fibres were seen to end in the dorsal horn and on dendrites of motoneurons with enlargements that resembled synaptic boutons. Such boutons were seen in close apposition to motoneurons of the same segment and of neighboring rostral and caudal segments in pups aged 0-9 days.

In experiments to study regeneration lesions were made by crushing the spinal cord between two segments. After culture for 6-7 days, electrical stimulation of the dorsal roots once again induced discharges in ventral roots. Labeled fibres were observed that had grown beyond the crush toward the motoneurons.

We are now making intracellular recordings and using electron microscopy to establish unequivocally whether connections observed in developing and regenerated spinal cord are monosynaptic as well as polysynaptic. Supported by grants from the Swiss Nationalfonds and from the International Research Institute for Paraplegia.

## 108.3

## NERVE GRAFT PREDEGENERATION ENHANCES PREFERENTIAL MOTOR REINNERVATION (PMR)

**T.M. BRUSHART\***, Depts. of Orthopaedics and Neurology, Johns Hopkins Hospital, Baltimore, Maryland 21287

Motor axons regenerating after transection of mixed nerve preferentially reinnervate distal motor branches. Collaterals of a single motor axon often enter both sensory and motor Schwann cell tubes of the distal stump; specificity may be generated by pruning collaterals from sensory pathways while maintaining those in motor pathways (J. Neurosci. 13:2730). These experiments evaluate PMR in fresh and predegenerated nerve grafts. Surgery was performed on the proximal femoral nerves of 250 gm female SD rats. In twenty animals, an inverted "Y" graft of femoral trunk and distal cutaneous and muscle branches was transposed to the opposite leg and sewn in place with 10-0 sutures. In 20 others, the graft was predegenerated by proximal crushes 4 and 2 weeks before transplantation. The specificity of motor axon regeneration was evaluated at 3 mos. by applying HRP to one terminal branch and Fluoro Gold to the other. The mean number of motoneurons projecting axons correctly to the muscle branch and incorrectly to the cutaneous branch was significantly different in both groups (Graft: M=186, S=124, DL(double-labeled)=10; Predegenerated Graft: M=245, S=94, DL=16; for both sensory/motor differences  $p < .01$ ). However, significantly more motoneurons projected correctly after predegeneration ( $p = .01$ ). The sensory/motor difference, an index of specificity, was also greater (151 vs. 62,  $p = .001$ ). Predegeneration of nerve grafts thus greatly enhances the specificity of motor axon regeneration (PMR). This could reflect clearance of inhibitory molecules from the graft, increased production of a contact or trophic factor within the muscle branch, or both. (supported by the Curtis Research Fund and JHU Orthopaedics)

## 108.5

DEFICIENT ACTIVATION OF MICROGLIA DURING OPTIC NERVE DEGENERATION. **S. Rotshenker\*** and **F. Reichert**, Dept. of Anatomy & Cell Biology, Hebrew University-Hadassah Medical School, Jerusalem 91120, ISRAEL.

Optic nerve (ON) injury is followed by the slow removal of myelin: considerable amounts of myelin are still present months after ON transection. Microglia, the potential scavenger cells, are present in-vivo throughout intact and degenerating ON. The question thus arises as to why is myelin removal by phagocytosis so inefficient. One possibility is that microglia are not capable of phagocytosing myelin. Alternatively, microglia may not become activated in-vivo to the extent that they will phagocytose myelin. We studied ON degeneration in relation to the expression of cell surface molecules that are relevant to phagocytosis, and are characteristically displayed by activated macrophages capable of myelin phagocytosis: MAC-1 (CD 11b, a complement receptor), FcγRIII receptor (FcR), MAC-2 (a galactose specific lectin, and a macrophage/microglia activation marker), and F4/80 (a murine specific macrophage/microglia antigen). In-vitro, the vast majority of microglia, but no other non-neuronal cell type, expressed all four molecules and phagocytosed myelin. In-vivo, intact ON displayed high levels of MAC-1, little FcR and F4/80, and no MAC-2. The expression of these molecules was upregulated differentially in in-vivo degenerating ON: MAC-1 uniformly, FcR and F4/80 variably, and MAC-2 sporadically. Thus in-vivo, only a small proportion of microglia become activated after ON injury to the extent of co-expressing all four molecules. The sporadic pattern of distribution of MAC-2 expression correlated best with a similar sporadic pattern of structural degeneration. Thus in-vivo, ON injury is followed by deficient microglia activation, which we suggest contributes to the slow clearance of myelin.

## 108.7

## REGULATION OF NEUROPEPTIDES IN AXOTOMIZED SYMPATHETIC NEURONS IN VIVO AND IN VITRO

**L. Klimaschewski\***, **S. Kroesen**, **R. Fischer-Colbrie** and **C. Heym**, Institute of Anatomy and Cell Biology, University of Heidelberg, 69120 Heidelberg, FRG.

The peptides galanin and neuropeptide Y (NPY) are elevated in the rat superior cervical ganglion after axotomy of the postganglionic branches. These changes have been attributed to increased synthesis of cytokines. "Knock-out" studies indicated that leukemia inhibitory factor (LIF) which is synthesized in non-neuronal cells after lesion may be responsible for the up-regulation of various peptides. On the other hand, LIF decreases NPY and its mRNA in sympathetic neuron cultures. This apparent contradiction was investigated by determination of NPY levels and NPY mRNA in lesioned ganglia. In addition, the regulation of galanin by LIF and by non-neuronal cells was examined in neonatal sympathetic neuron cultures.

Compared to control ganglia, the number of NPY immunoreactive neurons decreased whereas the density of NPY positive neuronal processes increased significantly one week after transection of the major postganglionic nerves. The nerve fibers extended into both carotid branches and ramified at the lesion site. Although the number of NPY mRNA positive neurons was not different from controls, the average grain density per neuron decreased by 40 % consistent with an effect of LIF on this neuron population. When axotomized ganglia were decentralized simultaneously, a threefold elevation of NPY immunoreactivity was detectable by radioimmunoassay and an additional increase in numerical density of NPY immunoreactive nerve fibers was observed. Further reduced levels of NPY mRNA were found within postganglionic neurons. This synergistic effect of combined axotomy and decentralization on peptide content was detected for galanin also. Moreover, the up-regulation of galanin was observed in cultures of sympathetic neurons too. Addition of LIF to the medium significantly enhanced this effect. Supported by the DFG (Zi 110/22-3).

## 108.4

EVIDENCE FOR PREFERENTIAL MOTOR REINNERVATION (PMR) IN NONHUMAN PRIMATES, **R. D. Madison\***, **S.J. Archibald**, and **C. Krarup**, Div. of Neurosurgery, Duke Univ. Med. Ctr., Durham, NC 27710, and Dept. of Clinical Neurophysiol. Univ. Hosp., Copenhagen, DK

PMR refers to the proven demonstration that motor neurons which project to the rat femoral nerve preferentially reinnervate a terminal motor vs. cutaneous nerve branch (J. Neurosci. 8, 1026-1031; 1988). Motor unit counting of median nerve innervated muscles in the hand was used to assess the possibility of PMR occurring in nonhuman primates. Binomial probability statistics were used to determine the "expected" number of returning motor units if regeneration occurred randomly. Median nerves transected at the wrist were repaired by either direct suture (N=4), or by collagen nerve guides to bridge an unstructured 2 cm (N=6), or 5 cm (N=7) nerve gap. There were significantly more regenerated motor units found in all groups 2-3 years post-repair (range of  $\bar{x} \pm \text{SEM}$  of  $13 \pm 1$  to  $18 \pm 1$ ; from baseline of  $147 \pm 14$ ) compared to that expected by chance ( $6 \pm 2$ ;  $p < .01$ ). This is strong evidence that PMR influences regeneration accuracy in nonhuman primates. Supported by NS22404-11 (RDM), VA Merit Review (RDM), and Integra LifeSciences (RDM), Danish Med. Res. Council (CK).

## 108.6

CONNECTIONS BETWEEN REGENERATING RETINA AND BRAIN IN ADULT GOLDFISH. **M.K. Powers\***, **P. Melzer**, **A.E. Lindsey** and **R.M. Wall**, Vanderbilt Vision Research Center, Vanderbilt University, Nashville, TN 37240.

The CNS of adult goldfish regrows after surgical or pharmacological lesions. We have previously shown that a new neural retina, regenerated in vivo in adult fish, is capable of providing visual information to the animal. The electroretinogram returns, as do simple reflexive visual behaviors such as the dorsal light reflex (DLR) and optokinetic nystagmus (OKN). Connections must therefore be made from the new retina to the brain, a finding supported by Stuermer's observation that ganglion cell axons from regenerated retina do reach the tectum. However, we have also found that complex, learned visual behaviors, which are likely to be mediated through tectal connections, may not return. Here we report results of 2-deoxyglucose (2DG) studies designed to determine whether tectal neurons can be activated through new retinal projections. Fish with retinas destroyed either surgically or by intraocular ouabain injection were injected IP with 5 uCi/30ul 2DG at times up to 130 days following retinal destruction, then stimulated visually and sacrificed. Enucleated animals showed clear differences in brain activity, with the intact eye strongly stimulating the tectum and the enucleated not at all. Up to 81 days following ouabain injection, the regenerating retina had significantly less input to the tectum than the normal eye, producing very little activity. At longer times more activity was present, but only in some cases. We conclude that tectal input is not necessary for DLR and OKN, which return fully by 80 days regeneration, and we speculate that deficits in vision observed with other behaviors may be related to abnormal connectivities between regenerating ganglion cell axons and tectal neurons.

## 108.8

DUAL FLUORESCENCE STAINING DEMONSTRATES THE MORPHOLOGICAL RELATIONSHIP BETWEEN REGENERATING AXONS AND BLOOD VESSELS. **M.J. Hobson**, **G.L. Ferri\***, **C. Green**, **R. Brown**, **G. Terenghi**, Blond McIndoe Centre, East Grinstead Sussex, U.K. and Dept. of Citomorfologia, University of Cagliari, Italy.

Nerve regeneration is dependant on many cellular and humoral factors and recently the role of neurotrophic factors has been widely investigated. Although it has been observed that an increase in capillary and permeability accompany axonal regeneration, the role and importance of angiogenesis is still poorly understood. It was the aim of this study to clarify the morphological relationship between regenerating axons and blood vessels.

Orientated mats of fibronectin, which support axonal growth and are initially avascular, were grafted into 1 cm defects in rat sciatic nerves. To follow the growth of neural and vascular elements, grafts were harvested between 3 and 30 days, sectioned longitudinally and stained with antibodies to endothelial cells (RECA-1), Schwann cells (S-100) and axons (Pan Neurofilament Marker and PGP). Dual fluorescence staining enabled the simultaneous visualisation of these elements within the same section and by superimposing their images via double exposure photography, it was possible to show their true relative positions. Graft vascularisation came initially from the muscle bed. Vessel and axonal orientation were closely related. Schwann cells and axons extended together from the proximal nerve trunk, never exceeding the area of vascularisation and were more numerous in well vascularised regions with longitudinally orientated vessels. The results are suggestive of an interaction between blood vessels and regenerating axons, indicating regeneration may be enhanced by manipulating vascularisation.

NEUROTROPHIN-3 ENHANCES PERIPHERAL NERVE REGENERATION. G.D. Sterne, C.Green, R.Brown, G.Terenghi\*. Blond McIndoe Centre, East Grinstead and University College Hospital, London, UK.

Neurotrophin-3 (NT3) belongs to the Neurotrophin family of growth factors and acts on a distinct subpopulation of primary sensory neurons. As little is known about its action following nerve injury, we have investigated the effect of NT3 delivered directly to the injured nerve using fibronectin mats. These mats have previously been shown to support enhanced nerve regeneration when used in conjunction with nerve growth factor.

An established embryonic chick dorsal root ganglia bioassay was used to confirm that fibronectin can bind and release bioactive NT3. NT3-impregnated mats (500ng/ml) were grafted into 1cm defects of rat sciatic nerve. Plain mats were used as controls. Penetration distance and volume of axonal regeneration into the graft were quantified by computerised image analysis of immunostaining for axonal markers (GAP43, CGRP, SubP, VIP and NPY) up to 8 months postoperatively. The same markers were also used to analyse neuropeptide expression within dorsal root ganglia supplying the injured nerve.

Maximal NT3 effect occurred at day 15. For GAP43 axons both distance (NT3:  $6.57 \pm 1.1$ mm; control:  $3.99 \pm 1.2$ mm,  $p < 0.01$ ) and staining area (NT3:  $0.137 \pm 0.041$ mm<sup>2</sup>; control:  $0.077 \pm 0.018$ mm<sup>2</sup>,  $p < 0.01$ ) were significantly enhanced. Interestingly, increased axonal regeneration was noted in each neuronal subpopulation investigated. These results demonstrate that NT3 can contribute to an enhanced rate and volume of nerve regeneration.

AXON ELONGATION INTO COLLAGEN-GLYCOSAMINOGLYCAN IMPLANTS FOLLOWING SPINAL CORD INJURY. Spilker, M.H., Yannas, I.V., Hsu, H.-P., Norregaard, T.V., Kostyk, S.K., Spector, M.T. Massachusetts Institute of Technology, Cambridge, MA 02139; †Brigham & Women's Hospital; ‡New England Deaconess Hospital; \*Brockton/West Roxbury VA Medical Center and Harvard Medical School.

Axons of the adult mammalian central nervous system (CNS) demonstrate limited spontaneous ability to regenerate following injury. Recent evidence suggests that the cellular and extracellular environment of the adult CNS, including the glial and connective tissue scar, impede regeneration by creating an environment that blocks the elongation of regenerating axons. At present, the substrate preferences of elongating axons *in vivo* are not well understood. The goal of this research was to study the healing process following spinal cord injury in the presence and absence of a family of well characterized analogs of extracellular matrix (AECM). Extensive data have shown that one such highly porous AECM composed of type I collagen and chondroitin-6-sulfate induces regeneration of peripheral nerves across a 15 mm gap. These results suggest the possibility of synthesizing an appropriate AECM which promotes regeneration of axons in the CNS.

In the current study, a 5 mm gap was created in the spinal cord of adult Sprague-Dawley rats by performing complete transections at T7 and T9 and removing the intervening spinal cord tissue. Either an empty collagen tube or one containing a specific AECM, of known chemical composition and pore structure, was placed in the gap. The rostral and caudal spinal cord stumps were inserted into the ends of the tube. After 30 days, a continuous cable of tissue had formed within the tube connecting the rostral and caudal stumps. This tissue contained numerous myelinated axons (mean of 313 for six animals). Immunostaining for 68 kD neurofilament confirmed the elongation of axons into the implant. Antibodies for GFAP, S-100, and OX-42 (macrophages and microglia) were also used to determine the cellular composition of the bridging tissue. The results show that implants containing AECM provide a controlled environment at the site of spinal cord injury which supports axon growth. (Supported by NSF grant 9315572-BES)

## 108.13

ACTIVATION OF RECEPTORS FOR INTERFERON GAMMA (IFN- $\gamma$ ) IN ENDOTHELIAL CELLS AND REACTIVE ASTROCYTES AFTER SPINAL CORD INJURY. M. Risling\*, T. Lindholm, T. Carlstedt, M. Meier, M. Mahlman, S. Cullheim, S. Lake and A.-M. Sjögren. Dept. Neurosci., Karolinska Institute, Doktorsringen 17, S-171 77 Stockholm, and Pharmacia Upjohn, Stockholm, Sweden.

Spinal motoneurons in the adult cat and rat regenerate central nervous system (CNS)-type axons after lesions in the ventral funiculus of the spinal cord. Regrowing motor axons penetrate the CNS-type of scar tissue and enter adjacent ventral root fascicles. The traumatic scar tissue comprises a loose trabecular web of processes from reactive astrocytes and invading leptomeningeal cells. These two cell types have receptors for neurotrophins. The reactive astrocytes express neurotrophins, VEGF and receptors for prostaglandins. Matrix molecules such as laminin, tenascin and collagens are upregulated and there is a persistent defect in the blood-brain barrier. Cytokines have been suggested to play a key role in the early response to CNS trauma, by regulating the synthesis of neurotrophins and matrix molecules. In this study we have assessed the possibility that the cytokine IFN- $\gamma$  may play a role in CNS scar formation.

Adult rats were subjected to an incision in the ventral funiculus of the spinal cord or to ventral root resection after avulsion injury. 1 - 7 days later the animals were killed and the lesion area was sectioned with a cryostat and incubated with antibodies against the  $\alpha$ - or  $\beta$ - subunit of the receptor for IFN- $\gamma$ . A subpopulation of the endothelial cells of the spinal cord were found to carry IFN- $\gamma$  receptors. An upregulation of class II MHC antigen was detected in the vasculature 1-3 days after the lesion. CD4+ T helper cells were present in the lesion area adjacent to the blood vessels. The inducible form of NOS (iNOS or macNOS) was present in association to some blood vessels and in scar tissue macrophages. JAK 1 immunoreactivity and positive staining for several members of the STAT family, including STAT 2 was observed in astrocytes in the lesion area. A redistribution of the interferon-stimulated gene factor 3 (ISGF3) was observed in scar tissue cells. These changes are consistent with a role for IFN- $\gamma$  in the early events of CNS scar formation. Supported by: Pharmacia Upjohn and the Swedish MRC (8657)

## 108.10

IN VIVO STUDY OF SUBSTRATE PREFERENCES OF REGENERATING PERIPHERAL AXONS

L.J. Chamberlain, I.V. Yannas\*, H.-P. Hsu, G. Strichartz, and M. Spector. Massachusetts Institute of Technology, Cambridge, MA, 02139; Brigham & Women's Hospital; and Brockton/West Roxbury VA Medical Center

The long term goal of our work is to identify the chemical composition and pore characteristics of a family of substrates which facilitates regeneration of a peripheral nerve trunk. Previous studies, in a transected rat sciatic nerve model, had shown that a highly porous analog of the extracellular matrix (ECM) was required to induce peripheral axon regeneration across a gap greater than 10 mm ensheathed by a silicone tube. Electrophysiological studies led to the finding that maximal functional recovery was observed when the average pore diameter of the ECM analog was 5-10  $\mu$ m.

In the present study, the silicone tube containing the ECM analog was replaced with a collagen tube. Six groups of rats (n=9) received the tubular implants, which were either empty or filled with a copolymer of type I collagen and chondroitin-6-sulfate with axially oriented pores, 5-10  $\mu$ m in diameter. The sciatic nerve of adult female Lewis rats was transected at mid-thigh and a 10 mm gap produced. Histomorphometric procedures were used to study axon diameter distributions (30 weeks) and electrophysiological parameters of excised specimens were evaluated (40 weeks).

The total number of myelinated axons per nerve increased threefold in the presence of the matrix in both the porous collagen and silicone tubes. For each group, the mode of the diameter distribution was 3  $\mu$ m. In the matrix-filled tubes and in the autograft controls, diameters were as large as 9-11  $\mu$ m. In the empty tubes, the maximum diameters were 6-8  $\mu$ m. We conclude that axons which exceed 8  $\mu$ m in diameter are formed only in the presence of the ECM analog. In addition, collagen can be used to replace silicone as a tube material. Electrophysiological testing is in progress to assess the degree to which conduction and function have recovered. (This work was supported by the VA Rehabilitation R & D Service.)

FK506 AND CYCLOSPORIN A: COMPARATIVE DOSE-DEPENDENCY STUDIES ON THE RATE OF AXONAL REGENERATION IN THE RAT SCIATIC NERVE. B.G. Gold\*, M.S. Wang† and M. Zeleny-Pooley‡. \*Center for Research on Occupational & Environmental Toxicology and †Department of Cell & Developmental Biology, Oregon Health Sciences University, Portland, OR 97201.

FK506 and cyclosporin A are immunosuppressant drugs presently used for organ transplants. The immunosuppressant action of these drugs is due to calcineurin (protein phosphatase 2B) inhibition, mediated via binding to distinct binding proteins (immunophilins): FK-binding-protein (FKBP) and cyclophilin for FK506 and cyclosporin A, respectively. We previously reported (Gold et al. *Rest Neurol Neurosci* 6:287, 1994; *J Neurosci* 15:1705, 1995) that FK506 also speeds functional recovery by increasing the rate of axonal regeneration for sensory fibers in the sciatic nerve following nerve crush; a (subcutaneous) 1 mg/kg dose increased regeneration rate (by 16%) from 3.8 mm/day (in controls) to 4.4 mm/day. In the present study, we have extended these initial studies by examining the dose-dependency for FK506's regenerative effects. In addition, we asked whether cyclosporin A shares FK506's regenerative properties. Rats (2-5/group) given a bilateral sciatic nerve crush (at the junction of the L4 and L5 spinal nerves), received daily subcutaneous injections of FK506 (5 or 10 mg/kg) or cyclosporin A (10 mg/kg); axotomized control animals received placebo (Fujisawa). At 11 or 14 days, the L4 or L5 dorsal root ganglia (DRG) were exposed and radiolabeled with <sup>3</sup>H-leucine. Animals were killed 24 hours later (12 and 15 days, respectively), the nerves removed, cut into 3-mm segments and the radioactivity determined by liquid scintillation spectrophotometry. The maximal extent of outgrowth from the crush site was determined from the front of the resultant radioactivity profiles. Regeneration rates were calculated by regression analysis between the 12 and 15 day time-points. FK506 (5 mg/kg) increased regeneration rate (by 34%) to 5.1 mm/day; 10 mg/kg produced a smaller increase in rate (by 24%) to 4.7 mm/day. Cyclosporin A (10 mg/kg) only increased the rate (by 10%) to 4.2 mm/day; dose-dependency studies are being conducted. Thus, FK506 may increase regeneration via a FKBP-pathway distinct from immunophilin-calcineurin inhibition. We thank Fujisawa for its generous gift of FK506. Supported by NS19611.

FK-506 IMPROVES BEHAVIORAL RECOVERY AND UPREGULATES NEURONAL EXPRESSION OF GAP-43 AFTER SPINAL CORD INJURY IN RATS J.R. Madsen\*, P. MacDonald, N. Irwin, and L.L. Benowitz. Dept. Neurosurgery, Children's Hospital and Harvard Medical School, Boston, MA 02115.

FK-506, a drug widely used clinically as an immunosuppressant, has been shown to stimulate neurite outgrowth *in vitro* and to diminish the size of cerebral infarct after stroke in rats. These effects may be mediated through FKBP-12, an FK-506-binding protein which is abundant in neurons. The FK-506/FKBP complex inhibits the activity of the phosphatase, calcineurin, one of whose principal substrates is the neuronal growth-associated phosphoprotein GAP-43. We administered FK-506 (0.5 mg/kg) intravenously 10 min, 24 and 48 hr after inducing spinal cord injury at the T10 level by photothrombosis. Behavioral recovery was evaluated 1 through 28 days later using the Tarlov scale and the inclined plane, two measures of hindlimb function. Neuronal sprouting was assessed using immunohistochemistry to detect GAP-43. Behavioral and anatomical studies were carried out completely blinded to treatment regimen. Animals treated with FK-506 showed a significant improvement in neurological function 28 days postinjury relative to controls, both on the Tarlov scale and the inclined plane ( $p=0.024$ ,  $p=0.046$ , respectively, two-tailed *t* tests,  $df=44$ ). In addition, FK-506 treatment caused a dramatic, two-fold increase in the number of GAP-43 immunoreactive neurons per mm<sup>2</sup> in the vicinity of the lesion ( $p=0.026$ ). Lesion volumes did not differ significantly between groups. Thus, FK-506 improves functional recovery after spinal cord injury and this may be mediated by an increase in neuronal sprouting. Support: NIH NS01471(JRM), EY05690 (LIB).

## 109.1

**MAGNETIC RESONANCE IMAGING IN LESCH-NYHAN DISEASE: CORRELATION OF CAUDATE NUCLEUS VOLUME AND COGNITIVE FUNCTIONING.** J. C. Harris,\* Div. of Child & Adolescent Psychiatry, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21287. D. Schretlen, N. Bryan, D.F. Wong.

Lesch-Nyhan disease, the most severe form of HPRT deficiency, is a rare sex-linked metabolic disorder with an unusual neurological and behavioral phenotype. Although first described in 1964 in two brothers who presented with hyperuricemia, mental retardation, choreoathetosis and self-destructive biting, little progress has been made since the early description in determining the pathophysiology of the neurological and behavioral symptoms and the extent of cognitive impairment. Despite the extent of the movement disorder, CT and MRI scans are generally reported to be normal. However, in a recent MRI study, we found consistent reduction in volumes of the caudate nuclei of six young men with this disease compared to 9 normal controls. We now report correlations between these volumetric MRI findings and the cognitive test performance of six patients. In this sample, the mean ( $\pm$  SD) volumes of the left and right caudate nuclei were  $2349 \pm 257$  and  $2502 \pm 366$  cu. cm., respectively. Analyses revealed a significant correlation ( $r = .78$ ;  $p = .037$ , one tailed) between the left caudate volume and performance on one neuropsychological test of global cognitive functioning. Moderately strong correlations also were found between the left caudate volumes and tests of reasoning ( $r = .69$ ;  $p = 0.067$ , one tailed), orientation ( $r = .66$ ;  $p = .077$ , one tailed) and receptive vocabulary ( $r = .47$ ). Correlations between the right caudate volume and all four cognitive measures were much weaker. This pattern of results is similar to a recent study of left vs. right caudate volumes in relation to the cognitive test performance of patients with Huntington's disease. Supported in part by HD 24061.

## 109.3

**FOCAL NEUROANATOMIC SUBSTRATES IN LATE-LIFE MAJOR DEPRESSION.** A. Kumar\*, D. Miller, P. Cowell, W. Bilker, J. Zhisong, and G. Gottlieb. Univ. of Pennsylvania Sch. of Med., Philadelphia, PA 19104.

The purpose of our study was to examine MRI determined volumetric measures of the frontal and temporal lobes in subjects with Late Life Major Depression (LLD) and to compare them to similar indices obtained from non-depressed controls. Our study groups comprised of 41 subjects who met DSM-IV criteria for Major Depressive Disorder (14 M, 27 W, Mean age=74.4 SD=6.6) and 31 non-depressed healthy controls (7 M, 24 W, Mean age=70.5 SD=6.4). The depressed subjects had Hamilton Depression Scale Scores of 15 or greater without any clinical evidence of dementia. They had several stable comorbid medical disorders and were free of other central nervous system disease. Axial spin echo images were acquired on all subjects using a GE signal scanner with head coil. The 5mm thick, contiguous slices were obtained using a repetition time (TR) of 3000 msec and echo time (TE) of 30 and 80 msec in planes parallel to the canthomeatal line. The neuroanatomical boundaries used in the image analysis have been previously described (Cowell et al. J. Neurosci 1994). Frontal and temporal lobe volumes normalized using total brain and intracranial volumes were used for comparison between groups. The two groups differed significantly on most normalized measures of frontal and temporal lobe volumes after correcting for age using linear regression ( $P < 0.05$ ). These data demonstrate that focal neuroanatomical abnormalities occur in LLD and provide further evidence for a structural basis to depression occurring in late life.

**ANTIDEPRESSANT EFFECTS OF WITH RAPID-RATE TRANSCRANIAL MAGNETIC STIMULATION (rTMS) ARE ASSOCIATED WITH NORMALIZATION OF PREFRONTAL HYPOMETABOLISM.** J.M. Tormos, F. Tarazona, C. Caffete, F. Pallardó, M.D. Catalá and A. Pascual-Leone\*. Unidad de Neurobiología, Dept. Fisiología, Univ. Valencia and Inst. Ramón y Cajal, Consejo Superior de Investigaciones Científicas, SPAIN

Stimulation of left prefrontal cortex using rTMS has been shown to improve clinical symptoms in medication-resistant, primary depression [Pascual-Leone et al. 1996]. However, the mechanisms of action of rTMS are unclear. Functional neuroimaging studies have demonstrated prefrontal hypometabolism in depression that correlates with the severity of depressive symptomatology [George et al. 1994]. We have studied the effects of rTMS on prefrontal hypometabolism in depression and their correlation with clinical improvement. We have studied 10 patients with medication-resistant primary depression (DSM IV). All were studied off all medications. We obtained HMPAO SPECT scans before and after 10 days of daily rTMS applied focally to the left prefrontal cortex in 20 trains of 10 s, 10 Hz, 90% of motor threshold intensity, and 50 s intertrain intervals. Hamilton depression rating scale and Beck inventory were used for clinical rating by a blinded investigator. In all patients we documented clinical improvement which was associated with a decrease in frontal hypometabolism. In addition, we have measured the effects of rTMS trains on cortical excitability probing it before and after rTMS with single and paired-pulse transcranial stimuli. Motor cortical excitability was shown to be enhanced by the rTMS trains applied to the depressed patients. All patients tolerated rTMS without complications, no seizures were induced by the applied rTMS parameters. These results illustrate the mode of action of rTMS in depression and support the notion of a pathophysiological link between prefrontal hypometabolism and depressive symptomatology. Non-invasive, non-convulsive rTMS can enhance cortical excitability and may develop into a therapeutic tool in primary depression. Supported by grants from the Generalitat Valenciana and the DGICYT.

## 109.2

**LONGITUDINAL STUDY OF BRAIN MORPHOLOGY WITH MRI IN FIRST EPISODE PSYCHOTIC DISORDERS** Jeffrey Lieberman, M.D.,\* Houwei Wu, M.D., Rael Strous, M.D., Miranda Chakos, M.D., Jose Alvir, Ph.D., Bernhard Bogerts, M.D., Gus DeGreeff, M.D., Robert Bilder, Ph.D. Mental Health and Neuroscience Clinical Research Center University of North Carolina School of Medicine Chapel Hill North Carolina 27599-7160

Despite substantial evidence that the neuropathology of schizophrenia arises early in neurodevelopment, the clinical course of the illness suggests the presence of a neurodegenerative process. Previous studies examined this issue by longitudinal study of brain morphology to determine if the neuropathology of schizophrenia was progressive. Findings of these studies are limited by studying small or chronic patient samples and/or the use of unreliable image acquisition or analysis methods.

We examined volumes of regions of interest (cerebral cortex, ventricular system, mesiotemporal structures and the caudate nucleus) The sample included 39 patients ascertained in their first episode of schizophrenia (21 male, 18 females) mean (SD) age 26.6 (6.3) yrs., and 18 control subjects 29.2 (8.8) yrs. Subjects underwent MRIs on at least two occasions 24 months apart. MR scans were morphometrically assessed using a computer based semiautomated program that includes segmentation and stereologic algorithms for volume determination. Neither patients nor controls showed mean group changes in cortical, mesiotemporal and ventricular volumes. However, longer durations of psychosis were associated with greater increases in ventricular volume ( $r = .047$ ,  $p < .02$ ). Patients with persisting negative symptoms defined by the deficit state had greater increases in ventricular volume ( $F = 214$ ,  $p < .0001$ ). There was a 5.7 % increase in caudate nuclei volumes in patients which was correlated with duration of treatment.

These results suggest that there are subtle changes in brain morphology in patients with schizophrenia. This appears to be an effect of drug treatment for basal ganglia structures but for ventricular volume is associated with disease course and possible pathophysiological progression. ## 109.4

**POTENTIAL INVOLVEMENT OF ANTERIOR CINGULATE DOPAMINE-D<sub>2</sub>-RECEPTORS IN MAJOR DEPRESSION**

R. Larisch<sup>1</sup>, A. Klimke<sup>2</sup>, H. Vosberg<sup>1</sup>, S. Löffler<sup>2</sup>, W. Gaebel<sup>2</sup>, H.-W. Müller-Gärtner<sup>1,3\*</sup>, Clinic of Nuclear Medicine<sup>1</sup>, Clinic of Psychiatry<sup>2</sup>, Univ. of Düsseldorf, Institute of Medicine<sup>3</sup>, Research Center Jülich.

Striatum and parts of frontal cortex have previously been shown to be involved in mood disorders based on studies of glucose metabolism and blood flow. The current study investigates the dopaminergic system in-vivo.

Eleven patients (eight females, three males) fulfilling DSM-IV criteria for major depression were prospectively investigated with the specific dopamine-D<sub>2</sub>-receptor antagonist <sup>123</sup>I-iodobenzamide (IBZM), using single photon emission computed tomography before and under treatment with a selective serotonin re-uptake inhibitor (SSRI). The depression was rated using the Hamilton Depression Scale (HAMD).

In treatment responders, dopamine-D<sub>2</sub>-receptor binding (ratio over cerebellum) increased from  $1.95 \pm 0.24$  to  $2.06 \pm 0.35$  in striatum, from  $1.12 \pm 0.32$  to  $1.27 \pm 0.41$  in anterior cingulate (mean  $\pm$  SD). In non-responders, dopamine-D<sub>2</sub>-receptor binding decreased from  $2.14 \pm 0.14$  to  $2.06 \pm 0.34$  in striatum, from  $1.32 \pm 0.04$  to  $1.10 \pm 0.16$  in anterior cingulate. Improvement of HAMD and changes of dopamine-D<sub>2</sub>-receptor-binding were positively correlated in striatum ( $r = 0.63$ ,  $p = 0.04$ ) and anterior cingulate gyrus ( $r = 0.82$ ,  $p = 0.02$  after Bonferroni correction).

The study indicates an interaction between the serotonergic and dopaminergic system in anterior cingulate gyrus and striatum in-vivo. The results further strengthen the hypothesis that the dopaminergic system is involved in major depression. The data specifically suggest a role of the anterior cingulate gyrus and striatum in this mood disorder.

## 109.6

**D2 RECEPTOR OCCUPANCY DURING RISPERIDONE AND CLOZAPINE TREATMENT IN CHRONIC SCHIZOPHRENIA: RELATIONSHIP TO BLOOD LEVEL, EFFICACY AND EPS.** T-P Su (1), A Breier (1), R Coppola (2), K Hadd (1), I Elman (1), C Alder (1), AK Malhotra (1), E Watsky (2), J Gorey, CJ Hough (3)\*, D Weinberger (2), D Pickar (1). (1) Experimental Therapeutics Branch, (3) Biological Psychiatry Branch, NIMH, Bethesda, MD (2) Clinical Brain Disorders Branch, NIMH, St. Elizabeths Hospital, Washington DC. Funded by NIMH/DIRP

We have previously reported that wide ranges of D2 occupancies (18 - > 80%) are associated with favorable response to clozapine without the occurrence of extrapyramidal symptom (EPS) (Su et al. 1993). Risperidone has been found to produce high levels of D2 blockade without EPS (Busatto et al. 1995). The specific aim of this study is to compare D2 occupancy between risperidone and clozapine in chronic schizophrenics and to determine the relationship of blood level, clinical efficacy and EPS to D2 occupancy.

We have examined this issue with two separate studies. In study 1, five schizophrenics underwent <sup>123</sup>I-IBZM-single photon emission computed tomography (SPECT) scanning during treatment with clozapine (400 mg/day) and with risperidone (6 mg/day) in a double-blind, crossover fashion. In study 2 (double-blind), 7 patients on risperidone (4 - 8 mg/day) and 7 patients on clozapine (400 mg - 600 mg/day) matched for age, sex, and illness severity were scanned. Risperidone resulted in significantly higher D2 occupancy (study 1:  $77 \pm 6\%$ , study 2:  $70 \pm 6\%$ ) than clozapine (study 1:  $52 \pm 8\%$ , study 2:  $45 \pm 12\%$ ) ( $t_1 = 5.5$  and  $t_2 = 4.9$  respectively,  $p < 0.006$ ). Both drugs did not demonstrate an association of symptom reduction to the changes of D2 occupancy ( $p = NS$ ). While clozapine-treated patients did not display EPS, 9 of 12 patients on risperidone did have modest EPS (Simpson Neurological Rating:  $13.0 \pm 1.4$ ). The other 3 patients were free of EPS even with high level of D2 occupancy (65 - 76%). In the dose-response (D2 occupancy vs. blood level) studies, a curvilinear model fits for risperidone, whereas a linear regression for clozapine. These data confirm that risperidone is more potent D2 blocker than clozapine and suggest that clinical efficacy and EPS are not simply related to D2 occupancy. The character of risperidone to gradually saturate D2 receptors provide a basis for monitoring treatment response and EPS.

## 109.7

**IN VIVO EVALUATION OF DOPAMINE SYNAPTIC FUNCTION IN UNTREATED SCHIZOPHRENIC PATIENTS.** A. Abi-Dargham\*, R. Gill, R. M. Baldwin, J. P. Seibyl, J. Krystal, D. S. Charney, R. B. Innis and M. Laruelle. Yale University and VA Medical Center, West Haven, CT 06516.

The following dopamine parameters were measured with SPECT in 23 patients with schizophrenia and 23 matched healthy controls: density of dopamine transporters (with [ $^{123}$ I] $\beta$ -CIT), density of D<sub>2</sub> receptors (with [ $^{123}$ I]IBZM), and amphetamine-induced dopamine release (as measured by the displacement of [ $^{123}$ I]IBZM binding following amphetamine 0.3 mg/kg i.v.). Patients had no history of substance or alcohol abuse, and were neuroleptic-free since  $160 \pm 90$  days. We observed no difference in [ $^{123}$ I] $\beta$ -CIT specific to nonspecific ratio between schizophrenics ( $7.8 \pm 0.4$ , SEM) and controls ( $8.4 \pm 0.4$ , ns). Similarly, the D<sub>2</sub> receptor binding potential was unchanged between patients ( $220 \pm 18$  ml/g) and controls ( $207 \pm 14$  ml/g, ns). In contrast, schizophrenics exhibited greater displacement of [ $^{123}$ I]IBZM following amphetamine ( $-17 \pm 3\%$ ) than controls ( $-8 \pm 2\%$ ,  $p = 0.02$ ). Increased dopamine release following amphetamine was associated with transient emergence or worsening of psychotic symptoms ( $p = 0.001$ ). Thus, the dopaminergic system shows exaggerated functional responsiveness in schizophrenia, but, in our hands, no changes in static markers such as D<sub>2</sub> receptors or dopamine transporters densities. Since similar alterations have been described in rats sensitized to amphetamine, these data suggest that schizophrenia is associated with an endogenous sensitization process. Supported by NARSAD, NIMH and Veterans Administration.

## 109.9

**PATTERNS OF rCBF ACTIVATION FOLLOWING TRAUMA RELATED STIMULUS IN POST TRAUMATIC STRESS DISORDER** Israel Liberzon\*, Lorraine M. Fig., Stephan F. Taylor, Satoshi Minoshima, Robert A. Koeppe. Psychiatry and Nuclear Medicine, VAMC and University of Michigan. Michigan 48109-0720

Post Traumatic Stress Disorder (PTSD) patients exhibit memory abnormalities (intrusive memories, flashbacks and dreams), avoidance behavior and exaggerated responses to traumatic stimuli. PET and SPECT studies of PTSD patients suggest the presence of specific rCBF patterns of activation in this disorder. We have reported rCBF changes in PTSD patients, as compared to normal controls, in the medial temporal lobe, anterior cingulate and orbital frontal regions, hypothesizing that these findings reflect abnormal memory formations and alteration in the arousal mechanisms of PTSD patients.

Two SPECT studies with Tc-99m HMPAO were performed in 30 subjects after exposure to 1) combat sounds and 2) white noise, (via headphones at 75 dB) 48 hours apart. Electrophysiological indices of arousal - skin conductance, heart rate, and EMG - were collected during the baseline and "activation" phase of the SPECT imaging and the results reveal enhanced skin conductance response in PTSD patients as compared to the control groups. In the current set of data we compare rCBF changes in PTSD veterans, combat controls and age and sex matched controls, examining both activation patterns differences and the correlations between the rCBF changes and subject's arousal levels as reflected by their electrophysiological indices.

**KETAMINE EFFECTS ON HUMAN BEHAVIOR AND BRAIN METABOLISM: IMPLICATIONS FOR SCHIZOPHRENIA.** A. K. Malhotra, J. H. Callicott\*, D. A. Pinals, C. M. Adler, N. Weisenfeld, D. Pickar, A. Breier. Experimental Therapeutics Branch, National Institutes of Mental Health, Bethesda, MD 20892.

Several lines of evidence have suggested that dysfunction in the N-methyl-D-aspartate (NMDA) receptor is involved in the pathophysiology of schizophrenia. We have utilized an placebo-controlled infusion paradigm with subanesthetic doses (0.12 mg/kg bolus followed by 0.65 mg/kg/hr infusion) of the NMDA antagonist, ketamine, to probe human NMDA receptor function. In normal controls, ketamine produces significant thought disorder, perceptual abnormalities and cognitive impairments. A Positron Emission Tomography (PET) study with Fluorodeoxyglucose (FDG) has demonstrated that ketamine produces specific activation of prefrontal areas and that these metabolic effects correlate with ketamine-induced thought disorder in healthy volunteers. In a study of drug-free schizophrenic patients, ketamine exacerbated core psychotic and cognitive symptoms. The effects of the antipsychotic agents, fluphenazine and clozapine, on ketamine-induced psychotic symptoms were also examined. These data support the hypothesis that NMDA dysfunction is involved in schizophrenia, offer evidence for prefrontal involvement in NMDA-mediated psychoses and suggest that antipsychotic drugs can alter ketamine-induced psychosis.

## 109.8

**SPECT MEASUREMENT OF HUMAN STRIATAL SYNAPTIC DOPAMINE CONCENTRATION IN THE RESTING STATE** M. Laruelle\*, C. De Souza, R. M. Baldwin, A. Abi-Dargham, M. Bowers, J. P. Seibyl, D. S. Charney, and R. B. Innis. Yale University and VA Medical Center, West Haven, CT 06516.

Endogenous dopamine concentration in the human striatum was estimated by comparing the binding potential (BP) of the selective D<sub>2</sub> radiotracer [ $^{123}$ I]IBZM before and after acute dopamine depletion. Dopamine depletion was achieved by administration of the tyrosine hydroxylase inhibitor alpha-methyl-para-tyrosine (AMPT, 1 g every six hours for two days). AMPT increased [ $^{123}$ I]IBZM BP by  $28 \pm 16\%$  ( $\pm$  SD,  $n = 9$ , age  $25 \pm 4$  y). Experiments in rodents showed that this effect was due to removal of endogenous dopamine rather than D<sub>2</sub> receptors upregulation. Dopamine synaptic concentration was estimated as  $45 \pm 25$  nM. Thus, D<sub>2</sub> receptors are significantly stimulated by dopamine in the resting state in humans. These results demonstrate the feasibility of measuring dopamine synaptic concentration in the living human brain, by coupling D<sub>2</sub> receptors imaging with acute dopamine depletion. As opposed to the previously described measure of dopamine release following amphetamine administration (Laruelle et al., J. Nuc. Medicine, 1995, 36: 182-1190), this technique allows measuring dopamine synaptic concentration in the absence of pharmacological challenge and will be used to correlate dopamine concentration and clinical symptomatology in patients with schizophrenia. Supported by Scottish-Rite Schizophrenia Research Program and Veterans Administration.

## 109.10

**SCHIZOPHRENIA IS ASSOCIATED WITH ENHANCED AMPHETAMINE-INDUCED DOPAMINE RELEASE.** A. Breier\*, T. P. Su, J. Elman, C. Adler, R. Saunders (2), A. de Bartolomeis, R. Carson (1), W. Eckelman (1), D. Pickar. ETB, NIMH, (1) PET Dept., CC, NIH, Bethesda, MD (2) CBDB, NIMH, St Elizabeths Hospital, Washington, D.C.

Dopamine overactivity has been the predominate pathophysiologic hypothesis of schizophrenia for the past two decades. A major line of evidence used to support dopamine's involvement in schizophrenia is enhanced sensitivity to agents that stimulate dopamine release, such as the psychostimulant amphetamine. We employed a novel PET method that quantifies dopamine release by estimating the amount of dopamine competes with the radiotracer 11-C-raclopride for dopamine D-2 binding, and used this method to test the hypothesis that schizophrenic patients, in comparison to healthy controls, have greater amphetamine-induced striatal dopamine release. Eleven patients with DSM IV schizophrenia disorder (6 neuroleptic-naïve; 5 neuroleptic withdrawn) and 12 age, gender, weight matched controls participated in the study. Amphetamine produced highly significant decreases in 11-C-raclopride striatal tissue concentrations in both healthy controls ( $2.52 \pm 0.13$  vs.  $2.1 \pm 0.09$ ,  $t = 6.7$ ,  $p = 0.00004$ ) and schizophrenic patients ( $2.53 \pm 0.23$  vs.  $2.00 \pm 0.18$ ,  $t = 4.8$ ,  $p = 0.0007$ ). Schizophrenic patients had greater amphetamine-induced changes in 11-C raclopride binding than controls. The patients had a  $+22.3\%$  ( $\pm 8.9$ ) change in striatal 11-C-raclopride tissue concentrations compared to  $+15.5\%$  ( $\pm 6.1$ ) change in healthy controls ( $t = 2.1$ ,  $p = .04$ ). 11-C-raclopride striatal binding changes were correlated with global symptom changes ( $r = 0.66$ ,  $p = 0.02$ ) in schizophrenic patients. These data provide direct evidence for enhanced dopamine release in schizophrenia.

## 109.12

**STATE- AND TRAIT-LIKE NEUROIMAGING ABNORMALITIES IN DEPRESSION: EFFECTS OF ANTIDEPRESSANT TREATMENT.** W.C. Drevets\*, J.L. Price, J.S. Simpson, R.D. Todd, T. Reich, M.E. Raichle. Wash. U. Sch. Med.; St. Louis, MO

In major depressive disorders, we previously distinguished abnormalities present only in the depressed state from those present in both depressed and remitted states. Blood flow was elevated in the left orbital cortex in depressed but not unmedicated-remitted subjects, while BF was elevated in the left amygdala in both states. In depressed bipolar subjects, we identified an area of decreased metabolism in the subgenual prefrontal cortex (SGPFC), which appeared to reflect reduced grey matter volume in the prefrontal anterior cingulate. To characterize the effects of antidepressant treatment (ADT) on these abnormalities, PET images of glucose metabolism (Siemens 953B/31  $^{18}$ FDG; FWHM=5mm FWHM) and MRI images (Siemens Vision 1.5T; MPRAGE sequence;  $1 \times 1 \times 1.25$ mm voxels) were acquired in unipolar depressives (UPD) before and after AD drug treatment ( $n = 20$ , age =  $36 \pm 10$ ), in separate groups of bipolar subjects, one depressed ( $n = 8$ , age  $36 \pm 8.4$ ) and the other medicated-remitted ( $n = 8$ , age =  $34 \pm 6.8$ ), and in controls ( $n = 17$ ; age =  $34 \pm 8$ ). In UPD, left amygdala and posterior orbital metabolism were abnormally elevated ( $[10.1\%, p < .01]$  and  $16\% (p < .01)$ , respectively) before ADT and declined after ADT [ $5.8\% (p < .05)$  and  $10.1\% (p < .01)$  respectively]. The decrement in orbital metabolism correlated with the reduction in depression ratings ( $r = 0.47$ ;  $p < .05$ ). Amygdala metabolism decreased in the subgroup who remained well on continued treatment ( $-6.6\%$ ;  $p < .01$ ) but not in the subgroup who relapsed on continued treatment ( $+0.2\%$ ). In UPD, SGPFC volume was abnormally reduced ( $48\%$ ;  $t = 4.7$ ;  $p < 0.001$ ) and did not change following treatment ( $-1.1\% \pm 18\%$ ). In bipolar subjects SGPFC volume was reduced in both depressed ( $42\%$ ,  $p < .005$ ) and remitted groups ( $38\%$ ;  $p < .05$ ) relative to controls. These data support hypotheses that in UPD elevated orbital activity is specific to the depressed state and abnormal amygdala activity may predispose to illness recurrence, and that in both unipolar and bipolar disorders, reduced SGPFC grey matter volume is stable across clinical states. Supported by MH51137, MH00928.

## 109.13

## THE ROLE OF THE CINGULATE IN MOOD HOMEOSTASIS.

HS Mayberg\*, SK Brannan, M Liotti, RK Mahurin, JS Brickman, JA Silva, JL Tekell, PA Jerabek, CC Martin, PT Fox. Research Imaging Center, UTHSCSA, San Antonio, TX 78284.

Using FDG PET in patients with depression, we previously described metabolic abnormalities in the anterior cingulate (BA 24b/a) that predict and differentiate drug Rx responders (R) from non-responders (NR): NR << controls (C) < R (Neurol 1996; 46:S327). The present study examined the added effects of 6 weeks fluoxetine Rx (double blind, placebo controlled) on mood, cognition and Cg metabolism as a function of treatment outcome in 13 patients with unipolar depression. Eight pts received active drug; R=3, NR=5 (defined by a >40% decrease in Ham-D). Baseline depression severity and cognitive performance were comparable for the two groups. Pre- and post-Rx FDG scans were compared using pixel-by-pixel contrasts, CDA (J Nuc Med 1988; 30:141). In the NR, Cg 24b/a were still both significantly hypometabolic (NR<C), showing further decreases in 24b, but a small increase in 24a. In contrast, R had a robust increase in both Cg24b and 24a, resulting in an even greater difference relative to controls (R>C). The Cg increases seen prior to Rx and potentiated by fluoxetine suggest an ongoing compensatory response to the depressed mood. Additional changes in Fr46/47, ant Ins and BA25 further implicate involvement of neocortical and limbic/paralimbic regions with reciprocal connections with the Cg24 in mood recovery. In NR, the Cg compensatory response was not just absent but paradoxical, and no changes in Cg targets areas were seen. These findings further support a critical role for Cg24a/b in the limbic-neocortical networks involved in normal and abnormal emotional states. (Supported by: NARSAD and Eli Lilly and Co.)

## ACETYLCHOLINE RECEPTORS: NICOTINIC

## 110.1

ACETYLCHOLINE RECEPTOR CHANNEL-LINING RESIDUES IN THE M2 SEGMENT OF THE  $\beta$  SUBUNIT. H. Zhang and A. Karlin\*. Center for Molecular Recognition, Columbia University, New York, NY 10032.

We have applied the substituted-cysteine-accessibility method (SCAM) to the M2 segment and the M1-M2 loop of the  $\beta$  subunit. Each residue from  $\beta$ P248 to  $\beta$ D273 was mutated to Cys, and the mutant  $\beta$  subunits were expressed together with wild-type  $\alpha$ ,  $\gamma$ , and  $\delta$  in *Xenopus* oocytes. All of the mutants gave robust ACh-induced currents. The accessibility of the Cys to the methanethiosulfonate (MTS) derivatives, MTSethyltrimethylammonium (MTSEA), MTSethyltrimethylammonium (MTSET), and MTSethylsulfonate (MTSES), added extracellularly, was inferred from their irreversible effects on the current induced by ACh. The positions accessible to MTSEA added in the absence and in the presence of ACh are indicated below by asterisks:

	250	260	270
intra	PDAGEIKMGLSIFALLTLVFLLLAD	extra	
-ACh	***	*	***
+ACh	*	*	*****

A subset was also accessible to MTSET, and the anionic MTSES penetrated as far as  $\beta$ V266C. These results imply that  $\beta$ M2 contributes to the channel wall and that its structure changes on the binding of ACh. From the pattern of accessibility, we infer that residues 255 to 265 may be  $\alpha$ -helical and that residues 268 to 273 may form a  $\beta$  strand. The exposure in  $\beta$ M2 is significantly different from that in  $\alpha$ M2 (Akabas et al., Neuron 13, 919, 1994). The accessibility of  $\beta$ G255C,  $\beta$ K253C, and  $\beta$ E252C to MTSEA in the closed state implies that the channel gate is close to the intracellular end of the channel. Supported by NS07065, MDA, and the McKnight Foundation.

## 110.3

EPIBATIDINE SELECTS BETWEEN THE AGONIST BINDING SITES OF MUSCLE NICOTINIC ACETYLCHOLINE RECEPTORS. R. J. Prince\* and S. M. Sine. Dept. Physiology and Biophysics, Mayo Foundation, Rochester MN 55905

Previous workers have found epibatidine to have exceptionally high affinity for CNS nicotinic receptors (nAChRs) but lower affinity for muscle nAChRs. This study examines the interaction of epibatidine with the binding sites of muscle nAChR. We measured the competition of ( $\pm$ )epibatidine against the initial rate of [ $^{125}$ I]- $\alpha$ -bungarotoxin binding to mouse muscle nAChRs transiently expressed in 293 HEK cells. Fetal type ( $\alpha$ ,  $\beta$ ,  $\gamma$ ) nAChRs bound epibatidine with a  $K_{app}$  of 700 nM and a Hill coefficient of 0.9. However, in the presence of proadifen, a local anesthetic which desensitizes the receptor, the competition curve was biphasic with  $K_{d1}$ s of 800 pM and 240 nM (see figure). The desensitized adult ( $\alpha$ ,  $\beta$ ,  $\epsilon$ ) nAChR also showed distinct affinities for epibatidine with

these results we infer that the  $\alpha$ - $\gamma$  and  $\alpha$ - $\epsilon$  subunit interfaces bind epibatidine with high affinity whereas the  $\alpha$ - $\delta$  interface binds with low affinity. Supported by NIH grant NS 31744.

## 109.14

## MULTISLICE PROTON MAGNETIC RESONANCE SPECTROSCOPIC IMAGING IN MONKEYS WITH MESIAL TEMPORO-LIMBIC LESIONS

A. Bertolino\*, R.C. Saunders, V.S. Mattay, J.H. Duyn, J. Bachevalier, J.A. Frank, D.R. Weinberger. Clinical Brain Disorders Branch, NIMH, NIH Bethesda, MD 20892.

To establish the relationship between the time of occurrence of mesial temporo-limbic lesions (perinatal vs. adult) and chemical alterations in prefrontal cortical neurons (PFC), we studied 18 adult rhesus monkeys with long echo time (TE 272 msec) multislice proton magnetic resonance spectroscopic imaging ( $^1$ H-MRSI).  $^1$ H-MRSI permits imaging of signals from metabolites such as N-Acetyl-aspartate (NAA, neuronal marker), choline-containing compounds (CHO) and creatine/phosphocreatine (CRE) from multiple 15 mm thick slices with a nominal voxel volume of 0.84 mL. 6 monkeys had undergone surgical ablation of mesial temporo-limbic structures including the hippocampus, amygdala and entorhinal cortex within 3 weeks of birth; 6 monkeys received the same lesion at approximately five years and 6 monkeys were normal controls. Regions of interest (ROI) were drawn blindly on coplanar MR images for prefrontal cortex (PFC), sensory-motor cortex and centrum semiovale (CSO). Statistical analysis (3x2 ANOVA with significance level at  $p < 0.05$ ) showed significant bilateral reductions only of NAA/CRE, NAA/CHO and NAA PFC/NAA CSO ratios exclusively in the PFC of monkeys with neonatal lesion with respect to both other groups. No significant difference across groups in the frontal lobe volume, nor any significant correlation between the latter and metabolite ratios in PFC was found. Our results indicate that neonatal perihippocampal damage affects prefrontal neuronal chemistry in adult monkeys. The basis of this effect does not appear to be a result of reduced frontal lobe volume nor a loss of connections *per se*, since analogous damage during adulthood does not have the same effect. This finding may have implications in understanding developmental aspects of pre-frontal-temporolimbic connectivity, and the reduction of NAA ratios observed in patients with schizophrenia.

## 110.2

IDENTIFICATION OF RESIDUES IN THE  $\delta$  SUBUNIT THAT AFFECT COOPERATIVE INTERACTIONS IN THE NICOTINIC ACETYLCHOLINE RECEPTOR (nAChR) P.A. Quiram\* and S.M. Sine. Dept. of Physiology and Biophysics, Mayo Foundation, Rochester, MN 55905

The nAChR is an  $\alpha_2\beta\gamma\delta$  pentamer containing two binding sites formed by  $\alpha\gamma$  and  $\alpha\delta$  subunit pairs. The  $\gamma$  and  $\delta$  subunits are required for mediating cooperative interactions between the two binding sites and for maintaining the sites in the low affinity activatable state. Using mouse nAChR subunits, we previously demonstrated that omitting the  $\gamma$  subunit led to  $\alpha_2\beta\delta$  pentamers that failed to maintain both cooperative interactions and low affinity of the two binding sites. Here we show that human  $\alpha_2\beta\delta$  pentamers exhibit a greater loss of cooperative interactions than mouse  $\alpha_2\beta\delta$  pentamers (see figure). To gain insight into residues that contribute to coupling between the binding sites, we constructed human-mouse chimeric  $\delta$  subunits, coexpressed them with human  $\alpha$  and  $\beta$  subunits in 293 HEK cells, and measured carbamylcholine binding by competition against [ $^{125}$ I]- $\alpha$ -bungarotoxin binding. Introducing mouse

sequence into the N-terminal 81 positions followed by human sequence results in biphasic binding characteristic of the human  $\delta$  subunit. Extending mouse sequence to position 174 restores monophasic binding characteristic of the mouse  $\delta$  subunit. We conclude that residues between positions 81 and 174 mediate cooperative interactions between the two binding sites of the nAChR. Supported by NIH Grant NS31744

## 110.4

$\alpha$ -CONOTOXIN Iml ( $\alpha$ -CTx-Iml) REVEALS THE PRESENCE OF TWO DISTINCT ELEMENTS IN THE Cl-DEPENDENT RESPONSE OF APLYSIA NEURONS TO ACETYLCHOLINE. JacSue Kehoe, Micha Spira, & J. Michael McIntosh\*. Laboratoire de Neurobiologie, Ecole Normale Supérieure, Paris, France; Department of Neurobiology, Hebrew University of Jerusalem, Israel; Departments of Psychiatry and Biology, Univ. of Utah, Salt Lake City, Utah.

$\alpha$ -Conotoxins have proven to be very useful tools for discriminating among the wide variety of nicotinic receptors present in neuronal and muscle membranes. We have studied the effects of  $\alpha$ -CTx-Iml (from a worm-eating conus) on the two nicotinic receptors previously shown to be present in molluscan neurons. One receptor mediates an increase in cationic conductance, and bears a pharmacological resemblance to the receptor mediating the fast EPSP in mammalian ganglionic neurons; the other mediates an inhibitory response by increasing Cl conductance, and resembles, pharmacologically speaking, the receptor of the frog neuromuscular junction.

In the present study, it was found that  $\alpha$ -CTx-Iml, unlike  $\alpha$ -bungarotoxin, blocks both of these responses, and in both cases the block was independent of holding potential. The  $IC_{50}$  for the inhibitory response is lower (under 100 nM) than that for the cationic response (between 150 and 200 nM). Furthermore, the toxin has revealed the presence in certain cells of two distinct elements in the Cl-dependent response: one rapidly desensitizing and blocked almost completely by 100 nM  $\alpha$ -CTx-Iml; the other, non-desensitizing, and unaffected by a 10  $\mu$ M concentration. These two elements are present in very different proportions on different identifiable cells. Finally,  $\alpha$ -CTx-Iml has no effect on the Cl-dependent responses to GABA and glutamate, and hence it is the first antagonist found that discriminates completely between the cholinergic and non-cholinergic Cl-dependent responses.

## 110.5

$\alpha$ -CONOTOXIN MII ( $\alpha$ -CTx-MII) INTERACTION WITH NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS. G. E. Cartier<sup>1</sup>, D. Yoshikami<sup>1</sup>, S. Luo<sup>1</sup>, B. M. Olivera<sup>1</sup> and J. M. McIntosh<sup>1,2</sup>. Depts. of Biology<sup>1</sup> and Psychiatry<sup>1</sup>, Univ. of Utah, Salt Lake City, UT, 84112.

The recently isolated peptide  $\alpha$ -conotoxin MII selectively blocks  $\alpha 3 \beta 2$  nicotinic acetylcholine receptors (nAChRs) expressed in *Xenopus* oocytes. Substitution of either the  $\alpha 3$  or  $\beta 2$  subunit by one of its homologues leads to a 2-4 order of magnitude decrease in toxin sensitivity. Pre-exposure of  $\alpha 3 \beta 2$  nAChRs to the competitive antagonist dihydro- $\beta$ -erythroidine followed by exposure to MII leads to a rapid time course of recovery following drug wash out that is the same as that observed during recovery from exposure to dihydro- $\beta$ -erythroidine alone, rather than the slower recovery seen following exposure to, and washout of, MII alone. This indicates that the two ligands share a common site of action on the receptor. The competitive action of MII is also suggested by results showing that MII-block is insensitive to membrane potential. Block of both  $\alpha 3 \beta 2$  and  $\alpha 3 \beta 4$  receptor activity upon exposure to MII follows a simple exponential time course. In contrast, the recovery of activity following exposure to saturating concentrations of MII and subsequent washout has a time course which is inconsistent with a simple bimolecular reaction. Instead, it appears that the toxin has two binding sites on the receptor, and occupation of either site by MII is sufficient to block receptor function.

## 110.7

TWO PRIMARY GTS-21 METABOLITES ARE POTENT PARTIAL AGONISTS AT ALPHA7 NICOTINIC RECEPTORS EXPRESSED IN THE *XENOPUS* OOCYTE. W. R. Kem\*, V. M. Mahnir, B. Lin and K. Prokai-Tatrai. Department of Pharmacology and Therapeutics, University of Florida College of Medicine, Gainesville, FL 32610-0267.

GTS-21, an Alzheimer's drug candidate undergoing clinical tests, is a partial agonist at nicotinic receptors containing  $\alpha 7$ -subunits (DeFiebre et al., 1995). This anabaseine derivative enhances cognitive behavior in rats, rabbits, and monkeys as measured by a variety of behavioral tasks. It rapidly enters the brain after oral as well as i.v. administration. Plasma and urine determinations of unchanged GTS-21 indicate that it is eliminated by a non-renal route, presumably biotransformation. Using liver homogenates, we have found two primary metabolites with HPLC retention times that match those of synthetic monohydroxy analogs of GTS-21 which would be generated by O-demethylation. These two compounds were examined pharmacologically by radioligand binding and electrophysiologically by measuring ionic currents induced by agonist interaction with *Xenopus* oocyte expressed nicotinic receptors. Both monohydroxy compounds were partial agonists when tested on expressed  $\alpha 7$  homooligomers, with potencies greater than GTS-21. They also displaced iodinated  $\alpha$ -bungarotoxin from rat brain membrane nicotinic receptors with higher affinity. It is possible that the relatively long duration of action resulting from a single sc injection of GTS-21 noted in some behavioral studies may in part be due to the actions of these GTS-21 metabolites.

## 110.9

NUCLEAR CLUSTERING IN MYOTUBES IS PART OF AN ACTIVITY INDEPENDENT, COOPERATIVE MECHANISM OF AChR mRNA UPREGULATION. K.A. Duca, K.-P. Chiu, T. Sullivan, S.A. Berman, S.Bursztajn\*. Laboratories for Molecular Neuroscience, McLean Hosp./Harvard Med. Sch., Belmont, MA 02178.

We investigated the relationship between nuclear cooperativity (as expressed by degree and type of nuclear aggregation) and upregulation of AChR subunit transcripts. We treated embryonic chick muscle cell cultures with muscle activity blocking agents, viz. decamethonium (DCM), d-tubocurarine (TBC), and tetrodotoxin (TTX) or co-cultured them with cholinergic neurons. We then examined the influence of muscle activity on the expression of AChR  $\alpha$ -,  $\gamma$ -, and  $\delta$ -subunit mRNAs and the degree of nuclear aggregation. mRNA was measured by *in situ* hybridization and nuclei visualized by bis-benzimide staining. All chemical treatments, as well as neuronal co-culture, resulted in an upregulation of mRNA expression, which also correlated with increased nuclear density. The pattern of nuclear aggregation was observed to be treatment dependent, with more and larger aggregates found when myotubes were co-cultured with neurons (A). Moreover, as aggregates became larger: 1) nearly all nuclei expressed mRNA and 2) the per nucleus mRNA output actually decreased while local accumulation remained high (B). We are testing the hypothesis that nuclear clusters stabilized via microfilaments and/or microtubules play a significant role in remodeling of the neuromuscular junction. This work was supported by NIH grants.

## 110.6

A RECOMBINANT ADENOVIRUS ENCODING ACTIVE NEURONAL BUNGAROTOXIN. S. Gorman<sup>1</sup>, N. Viseshaku<sup>2</sup>, B. Cohen<sup>2</sup>, S. Hardy<sup>3</sup>, G. Grant<sup>4</sup>, & J. Forsayeth<sup>1\*</sup>. <sup>1</sup>Dept. Anesthesia, UC San Francisco, CA 94143; <sup>2</sup>Division of Biomedical Sciences, UC Riverside, CA 92521; <sup>3</sup>Somatomix Therapy, Alameda, CA 94501; <sup>4</sup>Dept. Molecular Biology, Washington University, St. Louis, MO 63110.

The availability of native neuronal bungarotoxin (NBT) is now very limited; hence, we and others have attempted to synthesize active recombinant NBT (rNBT). We used a novel Cre-loxP system to make an adenovirus that encoded NBT. This encoded NBT sequence was modified by attachment of bovine prolactin signal to aid secretion and a 6-histidine tail to aid purification of the protein. Western blot of medium from infected HEK-293 cells demonstrated that rNBT was indeed secreted. rNBT's ability to inhibit nicotinic acetylcholine receptor (nAChR) response to ACh was investigated in *Xenopus* oocytes that expressed neuronal nAChR subtypes  $\alpha 3 \beta 2$  and  $\alpha 3 \beta 4$ . The recombinant toxin inhibited the response of  $\alpha 3 \beta 2$  type AChRs to ACh, and yet failed to inhibit the response of  $\alpha 3 \beta 4$  type AChRs. Further, the response of oocytes expressing muscle type nAChRs ( $\alpha 1 \beta 1 \delta$ ), was not affected by rNBT. This supports the hypothesis that weak inhibition of muscle type nAChRs by native NBT preparations is due to contamination by  $\alpha$ -bungarotoxin. This rNBT has two advantages over the yeast expression system: 1) the six histidine tag allows for purification and quantitation of the toxin, 2) the adenovirus vector may be used to infect neurons, thereby creating functional knock-outs of their nAChRs. Supported by a grant to JF by the NIH.

## 110.8

INDUCTION OF ACETYLCHOLINE RECEPTOR GENE EXPRESSION BY ARIA REQUIRES ACTIVATION OF MAP KINASE. J. Si<sup>1</sup>, Z. Luo<sup>2</sup>, S. Won<sup>1</sup>, and L. Mei<sup>1\*</sup>. <sup>1</sup>Dep. of Pharmacol., Univ. of Virginia Sch. of Med., Charlottesville, VA 22908; <sup>2</sup>Diabetes Unit, MGH, Charlestown, MA 02129.

Transcription of genes encoding nicotinic acetylcholine receptor (AChR) subunits ( $\alpha$ ,  $\beta$ ,  $\gamma$  or  $\epsilon$ , and  $\delta$ ) is highest in nuclei localized to synaptic region of the muscle which contributes to maintain a high density of AChRs at the postjunctional membrane. ARIA (AChR inducing activity) is believed to be the trophic factor utilized by motor neurons to stimulate AChR synthesis in the subsynaptic area. Treatment of muscle cells with ARIA causes tyrosine phosphorylation of the 185-kDa erbB proteins and activation of AChR subunit gene expression. To elucidate the signaling mechanism initiated by ARIA, we established stable C2C12 cell lines carrying nuclear lacZ gene under control of the mouse  $\epsilon$  subunit promoter or chicken  $\alpha$  subunit promoter. ARIA stimulated tyrosine phosphorylation of erbB proteins in these C2C12 cells within 15 sec with a peak at 5 min. Immediately following tyrosine phosphorylation of erbB proteins, mitogen-activated protein (MAP) kinase was activated which occurred within 30 sec and peaked at 8 min after ARIA stimulation, as assessed by retarded mobility in SDS-polyacrylamide gel electrophoresis and increased enzyme activity. Concomitantly, expression of AChR genes was induced by ARIA. ARIA-induced AChR gene expression was only observed in differentiated myotubes, but not in myoblasts. Treatment of C2C12 myotubes with PD98059, a specific inhibitor of MAP kinase kinase (MEK), abolished ARIA-induced activation of MAP kinase and stimulation of the AChR  $\alpha$  and  $\epsilon$  subunit gene expression. Furthermore, expression in C2C12 cells of dominant negative mutants of MEK1 or Raf1 diminished the induction by ARIA. By contrast, ARIA-induced activation of AChR gene expression was unaffected by wortmannin or rapamycin, inhibitors of phosphatidylinositol (PI) 3-kinase or S6 protein kinase, respectively. These results indicate that regulation of AChR gene expression by ARIA in C2C12 cells requires activation of the MAP kinase signaling pathway. (Supported by a NIH grant NS34062)

## 110.10

DOWNREGULATION BY CILIARY NEUROTROPHIC FACTOR OF NICOTINIC ACETYLCHOLINE RECEPTORS IN POSTNATAL RAT SUPERIOR CERVICAL GANGLION NEURONS. S. Huck and S. Boehm\*. Department of Neuropharmacology, University of Vienna, A-1090 Vienna, Austria.

The cytokines ciliary neurotrophic factor (CNTF) and leukemia inhibitory factor have dramatic effects on the neurotransmitter phenotype and on neuropeptide expression in cultures from the postnatal rat superior cervical ganglion (SCG). We now report that CNTF also downregulates nicotinic acetylcholine receptors in these cultures.

SCG were dissected from early postnatal (P3-5) pups, dissociated and plated at high density on collagen-coated tissue culture disks (40,000 per disk, disk diameter: 5mm). Cultures were loaded with [<sup>3</sup>H]norepinephrine after 5-7 days *in vitro* and transferred to superfusion chambers. Superfusates were collected, and the spontaneous release of radioactivity, the release induced by electrical field stimulation, and the release elicited by nicotine in the absence or presence of tetrodotoxin (TTX) were determined by liquid scintillation counting.

Stimulated release was strictly dependent on the presence of calcium in the superfusion buffer. The presence of TTX allowed the distinction of 2 types of nicotine-induced [<sup>3</sup>H] release: one which depends on, and the other which is independent of action potentials. The two components have EC<sub>50</sub> values for nicotine of 8.9 and 43.5  $\mu M$ , respectively. At 100  $\mu M$  nicotine, each component contributes about 50% to the total [<sup>3</sup>H] overflow. Electrically-induced release in cultures maintained in the presence of 20 ng/ml CNTF did not differ from controls. However, the release induced by 10  $\mu M$  nicotine in the absence, or by 100  $\mu M$  nicotine in the presence of TTX was reduced by CNTF to 46% and 35% of controls, respectively. The sum of these observations implies that CNTF downregulates nicotinic acetylcholine receptors in rat superior cervical ganglion neurons.

UBIQUITINIZATION OF THE ACETYLCHOLINE RECEPTOR COMPLEX FROM SKELETAL MUSCLE. J. P. O'MALLEY\* & M. M. SALPETER, Section of Neurobiology & Behavior, Cornell University, Ithaca, NY 14853.

Acetylcholine receptors (AChRs) exist as two distinct physiological entities with different metabolic degradation rates. The two forms have been called Rr and Rs to designate rapidly degrading (Rr;  $t_{1/2} \approx 1$  d) and slowly degrading Rs AChRs ( $t_{1/2} \approx 10$  d in innervated muscle and  $\approx 3$  d in denervated or cultured muscle). To date the molecular steps involved in AChR degradation are unknown. Since the two AChR populations can be spatially interspersed at the neuromuscular junction while exhibiting different half-lives, it is possible that AChR turnover may be achieved by individually marking each receptor for degradation. Indeed such a marking with ubiquitin, followed by the formation of a proteasome complex and protein degradation, has been observed for cytoplasmic, and more recently membrane associated proteins. To test if ubiquitin may be involved in AChR degradation we assayed normal and denervated adult as well as fetal and cultured rat muscle for ubiquitin. The tissue was homogenized and washed extensively to remove soluble ubiquitin, and the AChRs extracted in 1% Triton X-100. The AChRs were then affinity purified with  $\alpha$ -bungarotoxin-Sepharose after which Western analyses using an anti-ubiquitin antibody was performed. We report that ubiquitin immunoreactivity co-purifies with the  $\alpha$ -bungarotoxin ( $\alpha$ -BTX) binding activity. We also report that the level of ubiquitination of the  $\alpha$ -BTX binding activity in each of the extracts differed, and was highest in tissue with the greatest Rs content.

These results suggest that ubiquitination of either the AChR, or a receptor associated protein, may play a role in AChR degradation. The difference between Rr and Rs may, in part, reflect a regulation of ubiquitin binding or the formation of the proteasome complex after ubiquitination.

We thank A. Haas for the anti-ubiquitin antibody.

## 110.13

DIFFERENTIAL EFFECTS OF CHRONIC NICOTINE TREATMENT ON NICOTINE-STIMULATED RUBIDIUM EFFLUX IN VARIOUS MOUSE BRAIN AREAS. A.C. Collins\*, S.R. Grady, T.K. Booker, S.F. Robinson, A.E. Bullock, J.A. Stitzel, A.L. Clark and M.J. Marks. University of Colorado, Boulder, CO 80309

Chronic treatment of mice with nicotine results in the development of tolerance, as well as an increase in the number of nicotinic binding sites. In order to determine the effects of chronic treatment on nicotinic receptor function, mice were treated by continuous intravenous infusion of 0.0 or 4.0 mg/kg/hr nicotine for 10 days. After 12 hr withdrawal, crude P2 synaptosomes were prepared from eleven brain areas.  $^{86}\text{Rb}^+$  efflux stimulated by 10  $\mu\text{M}$  nicotine for 3 min was measured and the maximal response and rate of desensitization was calculated. The binding of [ $^3\text{H}$ ]nicotine was also measured. Consistent with previous observations, a high correlation between  $^{86}\text{Rb}^+$  efflux and nicotine binding was observed in control samples ( $r=0.93$ ). Chronic nicotine treatment significantly increased [ $^3\text{H}$ ]nicotine binding in 8 of 11 brain regions. However, the effects of chronic treatment on nicotine-stimulated  $^{86}\text{Rb}^+$  efflux varied among brain areas: efflux from olfactory bulbs increased, efflux from thalamus decreased, and no significant change was observed in the remaining areas. The subsequent correlation of nicotine-stimulated  $^{86}\text{Rb}^+$  efflux with [ $^3\text{H}$ ]nicotine binding after chronic nicotine treatment was high ( $r=0.91$ ), suggesting a continuing relationship between these two measures. The relative amount of efflux per binding site, as indicated by the slopes of the lines, was approximately 30% lower following chronic treatment. Whether this decrease resulted from a general reduction in function for the receptors or an increase in the number of nonfunctional receptors is unknown. The differential effect of chronic nicotine treatment on receptor number and function suggests a regional heterogeneity in receptor regulation that may be an important variable in the evaluation of the biological bases of tolerance and dependence.

## 110.12

MAPPING NICOTINIC ACETYLCHOLINE RECEPTORS (nAChR) WITH PET. Y.-S. Ding, S.J. Gatley, J.S. Fowler\*, N.D. Volkow, D. Aggarwal, J. Logan, S.L. Dewey, F. Liang, F.I. Carroll, M.J. Kuhar, Chem and Medical Depts, BNL, Upton, NY 11973; Chemistry and Life Sciences, RTI, NC 27709; and Emory University, Atlanta, GA 30322.

This study provided the first evidence for using a positron emitter labeled epibatidine derivative to visualize nAChR in vivo with PET. The one-pot, two-step radiosynthesis afforded [ $^{18}\text{F}$ ]norchloro-2-fluoro-epibatidine (NFEP) with an overall radiochemical yield of 55-65% in a synthesis time of 65 min with a specific activity of 4 Ci/ $\mu\text{mol}$  (EOB). The distribution of fluorine-18 in the baboon brain was heterogeneous with a strikingly high uptake and slow clearance in the thalamus as compared to the rest of the brain. The half-times for clearance from peak uptake for NFEP were 170, 50, 25 min for thalamus (TH), striatum (ST), and cerebellum (CB), respectively. The TH/CB ratio increased steadily, reaching a value of 4 at the end of study (3 h). In mice, a value of greater than 20 for both the SC/CB (SC:superior colliculus) and TH/CB ratios was reached at 90 min after the tracer injection, a distribution which strikingly resembles that of [ $^3\text{H}$ ]norchloroepibatidine in brain (Scheffel et al, 1995). The pharmacological specificity of the in vivo binding was clearly nicotinic, as it was displaced by nicotine (TH/CB decreased to 1.1-1.5 after pretreatment with 3 mg/kg of nicotine), but not by benztrapine, a muscarinic acetylcholine receptor ligand, nor by mecamylamine, an ion channel blocker of the nicotinic receptor which does not compete with the nicotinic recognition site. The extraordinary high thalamus to cerebellar ratio suggests a new approach to investigate the role of thalamus in the CNS system and its relationship to addiction. Supported by DOE/OHER; NINDS; NIDA.

## VISUAL PSYCHOPHYSICS AND BEHAVIOR I

## 111.1

THE INTERACTION OF VISUAL ATTENTION, LEARNING AND CONTEXT ON LUMINANCE DISCRIMINATION IN HUMANS AND MONKEYS. M. Ito\*, C.D. Gilbert and G. Westheimer. The Rockefeller University, NY, NY 10021.

To explore the role of expectation on early visual processing, we measured psychophysically the influence of spatial certainty on brightness discrimination. The subject had to indicate whether one of 4 lines, each presented in a different visual field location, was brighter or dimmer than a reference line. On some trials the observer was uncertain as to the position in which the odd stimulus would appear (uncertain condition), and on others the observer was cued to its position (certain condition). Initially, the discrimination was 2.2 fold better in the certain than in the uncertain condition. After 3 months of training, however, the discrimination in the uncertain condition improved so that it became equivalent to that in the certain condition. The number of possible positions was increased from 4 to 8 by adding stimuli in 4 new positions. In these new positions, the discrimination in the uncertain condition was 2.5 fold worse than in the certain condition, whereas both old and new positions had the same threshold in the certain condition. The new stimulus positions then showed a similar improvement with further training. We then explored the interaction between a contextual effect -- brightness induction of a target line by a second colinear line -- and attention. Under spatial uncertainty, there was a much greater brightness induction effect than when the subject anticipated the stimulus position. The fact that attentional influences show considerable positional specificity and affect simple attributes suggests the involvement of early visual processes. This non-retinal influence is in turn gated by context and by learning. Supported by NIH grant EY07968.

## 111.2

PERCEPTUAL LEARNING OF SPATIAL LOCALIZATION: SPECIFICITY FOR POSITION, ORIENTATION AND CONTEXT. R.E. Crist, M.K. Kapadia, G. Westheimer and C. D. Gilbert\*. The Rockefeller University, New York, NY 10021.

The specificity of perceptual learning for the particular stimulus parameters used during training can help determine the locus of both the discrimination and the learning effect itself. Training for several weeks with a bisection task, during which an observer was presented with three parallel lines and asked to determine the relative position of the central line, produced up to a three-fold threshold reduction. The improvement showed considerable retinotopic specificity with transfer limited to within a few degrees of the trained position. In addition, there was little transfer of improvement to a bisection task oriented orthogonally to the trained configuration. We examined the extent to which this learning would generalize to other stimulus configurations. In one experiment, the flanking lines of the bisection task were replaced with a single collinear reference to produce a vernier discrimination task—no transfer of improvement was observed. Furthermore, no evidence of transfer was seen when we changed the psychophysically relevant attribute of the stimulus from its position to its orientation, indicating that the learning effect was not general to all stimulus attributes at a particular visual locus. While the orientation and retinotopic specificity of the learning effect suggest cortical modifications early in the visual pathway, the specificity for particular stimulus configurations suggest that these changes are gated by contextual cues. Supported by NIH grants EY07968 and EY07138.

## 111.3

**A TRAINABLE MODEL OF SALIENCY-BASED VISUAL ATTENTION.** L. Itti, E. Niebur<sup>1</sup>, J. Braun<sup>2</sup> and C. Koch, California Institute of Technology, 139-74, Pasadena, CA 91125 and <sup>1</sup>Johns Hopkins University, Baltimore, MD 21218.

We present a model of bottom-up selective visual attention, developed in accordance with the known physiology of the visual system of the macaque monkey. It comprises two interacting stages, the first being a fast and parallel pre-attentive extraction of visual features across 50 spatial maps (for orientation, intensity and color, at six spatial scales), and the second a slow and sequential focal attention shifting mechanism (using a Winner-Take-All neural network to select the most conspicuous image location, and an inhibition-of-return mechanism to generate attentional shifts). The link between the two stages is a "saliency map", which topographically encodes for the local conspicuity in the visual scene, and controls where the focus of attention is currently deployed [Koch and Ullman, *Human Neurobiol.* 1985;4:219-227]. Supervised learning can be introduced to bias the relative weights of the features in the construction of the saliency map and achieve some degree of specialization towards target detection tasks.

Despite its conceptual simplicity, this model reproduces psychophysical performance in stimulus-driven, task independent attention. Results with the model are comparable to humans' on simple psychophysical tasks (e.g. A. Treisman's pop-out and conjunctive search). Strong performance was also obtained in the detection of salient targets in natural color images, despite high noise, large variations in color and illumination, shadows, reflections and strong textures, which are reputed problematic for artificial vision systems (an interactive demonstration may be found at <http://www.klab.caltech.edu/~itti>).

(Supported by ONR, and by the NSF Center for Neuromorphic Systems Engineering at Caltech).

## 111.5

**VISUAL-SPATIAL ATTENTION AND EVENT-RELATED POTENTIALS: BRIDGING THE GAP BETWEEN MONKEYS AND HUMANS.**

M. Girelli, M.T. McDermott, M.A. Ford, & S.J. Luck\*, Department of Neurological and Visual Sciences, University of Verona, ITALY, and Department of Psychology, University of Iowa, Iowa City, IA, USA.

Single-unit recordings in area V4 and IT cortex of the macaque monkey have provided evidence that target detection in visual search tasks is accompanied by a suppression of information from the nontarget "distractor" items, beginning about 175 ms after search array onset. In previous event-related potential recordings from human subjects, we have characterized a component called "N2pc" that shares many properties with the single-unit suppression effect: 1) both start around 175 ms poststimulus; 2) both are observed primarily in the hemisphere contralateral to the target; and 3) both are eliminated when the distractors are removed. In the present study, we provided several tests of the hypothesis that the human N2pc component reflects the same suppression observable in the single-unit studies in the monkey. Specifically, we manipulated several variables that have been studied in previous single-unit recording experiments, including the density of the distractors, the difficulty of the discrimination, and the type of behavioral response. We obtained the following results: 1) the N2pc was larger when the target and a distractor were both presented in the same quadrant than when they were in opposite quadrants; 2) the N2pc component was considerably reduced in a simple feature detection task compared to a conjunction discrimination task; and 3) the N2pc for the feature detection task was larger when subjects were required to foveate the target than when they made a simple manual detection response. These results mirror the effects of similar manipulations in single-unit recording experiments, and this similarity supports the hypothesis that the human N2pc component reflects the same suppression mechanism that has been observed in the monkey single-unit recordings. Supported by grant 95-38 from the McDonnell-Pew Program in Cognitive Neuroscience.

## 111.7

**VISUAL PERCEPTION OF MOTION AND STRUCTURE-FROM-MOTION: A FUNCTIONAL MRI STUDY.** V. Cornilleau-Perès<sup>1</sup>, A.L. Paradis<sup>2</sup>, J. Droulez<sup>3</sup>, A. Berthoz<sup>4</sup> and D. Le Bihan<sup>5</sup>, <sup>1</sup>CNRS-College de France, 75270 Paris Cedex 06, <sup>2</sup>Service Hospitalier Frédéric Joliot, CEA, Centre Hospitalier d'Orsay, 91000 Orsay, France, (SPON: European Neuroscience Association).

Motion parallax is a powerful cue for visual perception of three-dimensional shapes. Studies in primates have as yet failed to show visual cortical structures processing local spatial variations of retinal velocity. In this study we searched for cortical areas that are specifically activated by viewing a moving sphere, as compared to other stationary or moving stimuli. Functional MRI images were acquired in 4 adult human volunteers using a 3T Bruker MR imager, while viewing random dots spread over 16 deg of visual angle. Dots could be stationary (S), moving stochastically (MS), in a coherent fashion of expansion-contraction (EX), or as if they belonged to an opaque sphere oscillating about one of its own frontoparallel tangents (SP). Three experiments were performed under alternating conditions: (1) S versus MS dots, (2) MS versus EX dots, (3) MS versus SP dots. In the first case (S vs. MS) strong bilateral activities in V5 and in the occipital lobe (OL) were observed in all subjects. In the MS vs. EX case, only a few voxels showed a correlation with the alternating stimulus. Most of them were located in the vicinity of V5 and OL, with an increase of the MRI signal for stochastic motion, as compared to coherent motion. In the MS vs. SP case, three subjects showed increased activity at the occipito-temporal junction bilaterally (anterior and ventral with respect to V5). The fourth subject exhibited activity in the posterior parietal and in frontal lobe. We conclude that part of the visual areas processing motion are in fact sensitive to strong local variations of the velocity field, rather than to expansion-contraction. Furthermore structure-from-motion seems to involve the occipito-temporal junction, although in a subject-dependent fashion.

**EFFECTS OF COVERT ORIENTING OF ATTENTION IN A MOTION DISCRIMINATION TASK.** E. Zohary\* and G. Kozminsky, Dept. of Neurobiology, Hebrew University, Jerusalem, 91904, Israel.

A peripheral visual cue can shorten reaction times to detect a visual target in the cued area. Can covert attention also improve human psychophysical performance in a motion discrimination task? We used a random dot pattern whose motion coherence varied from trial to trial. Signal dots moving either up or down, were displayed inside an invisible rectangle subtending 5\*5 deg centered either 5 degrees left or right of the fixation point, or at the center of gaze. Noise dots, moving at random directions, were displayed anywhere inside the central 20\*20 deg of the visual field, to mask the location of the signal dots in the visual field. A spatial cue (an open rectangular frame), or a symbolic cue (an arrow) were used to inform the subjects the future location of the signal dots. The cue was displayed for 65 msec, and was followed by the test stimulus which was presented for 130 msec. Both types of cues lead to higher gains in psychophysical performance. The improvement was more prominent in the periphery than in the center of gaze. A second experiment revealed that the cue was ineffective if the noise dots were limited to the region of the signal dots. These results suggest that in cases of spatial uncertainty, orienting of attention can lead to gains in discrimination performance. In addition, a visual field left/right asymmetry in perceptual performance was often observed in the non-cued trials (Mean Left/Right threshold ratio: 1.97, t-test  $P < 0.001$ ,  $N=13$ ), but not in the cued trials. Therefore, perceptual asymmetry is probably not due to left hemisphere superiority in motion discrimination, or a fixation shift. Rather, this asymmetry may result from an inherent bias in the allocation of attention. Supported by Israel Ministry of Science and Arts

## 111.6

**MOTION CAPTURE AND INDUCED MOTION CAN GENERATE DIFFERENCES IN PERCEIVED SIZE AND ORIENTATION.** V. S. Ramachandran\* and K. McLain, Brain and Perception Lab UCSD, La Jolla, CA 92093-0109.

A yellow square is superimposed on an equiluminous grey background. If a sparse cluster of black dots is superimposed optically on the square and moved, the square appears to move as well even though it is physically stationary (Motion Capture, Ramachandran, 1985, *Nature*). We now find that: 1) if an expanding (or shrinking) array of spots is superimposed on the square, it can appear up to 20% larger (or smaller) than it really is -- an effect that occurs mainly at equiluminance. 2) If a shearing array of dots is superimposed on the square, it looks distorted into a trapezoid, i.e., orientation of edges changes. 3) If a yellow cross is used and if dots move horizontally on the vertical limb of the cross and vertically on the horizontal limb, the cross becomes "segmented" clearly into two separate bars sliding past each other. 4) If the yellow square in experiment 1 is made non-equiluminous, induced motion is seen instead of capture and, interestingly, the square actually looks smaller when the dot matrix expands.

We conclude that motion capture (and induced movement) can generate not only an illusory motion sensation, but changes in perceived size and orientation and the effect can also generate scene segmentation. The effect illustrates a surprising degree of interaction between cortical modules concerned with color, motion, shape and size. One wonders whether shape and size selective cells in DL, V4, and other extrastriate areas will respond to these illusions.

## 111.8

**A RELATIVISTIC DESCRIPTION OF PERCEPTION,** D. N. Levin\*, 1720 N. Lasalle Dr., #25, Chicago, IL 60614.

We show how to use differential geometry to measure and characterize the perceptions of an observer of a continuum of stimuli. Because the method is not based on a model of perceptual mechanisms, it can be applied to a wide variety of observers and to many types of visual and auditory stimuli. The observer is asked to identify which small transformation of one stimulus is perceived to be equivalent to a small transformation of a second stimulus, differing from the first stimulus by a third small transformation. The observer's perceptions of a number of such transformations can be used to calculate an affine connection on the stimulus manifold. This quantity encodes how the observer perceives evolving stimuli as sequences of "reference" transformations. The internal consistency of the observer's perceptions can be characterized by the manifold's curvature and certain other tensors derived from the connection. Differences between the affine connections of two observers characterize differences between their perceptions of the same evolving stimuli. Therefore, the affine connections of two observers can be used to map a stimulus perceived by one observer onto another stimulus, perceived in the same way by the other observer. The technique was used to measure the affine connection of an observer of a dot moving on several different background graphics: a blank screen, a grid, or two converging lines, similar to those used to create the Ponzo illusion. Preliminary experimental results show to what extent the observer's sense of parallelism depended on the visual information contained in the background graphic. We will also demonstrate how the technique can be used to characterize an observer's perceptions of mixtures of two colors or two sounds.

**AFTER-IMAGES IN CORTICALLY BLIND VISUAL FIELDS**  
**P. Stoerig\***, Institute of Medical Psychology, Ludwig-Maximilians-University, Goethestr. 31, D-80336 Munich, Germany

Lesions that destroy or disconnect the striate cortex cause cortically blind visual fields. Forced-choice methods can reveal localization, detection, and discrimination of visual stimuli presented within absolute blind fields where the stimuli are not consciously seen by patients or monkeys with striate cortical ablation ('Blindsight'). To see whether an after-image can be induced in the blind visual field, a patient with an incomplete hemianopia was tested with high-contrast colour patterns. Following a 20 s period of central fixation on the inducing pattern, the patient reported an after-image which reflected the negative of the 'seen' part of the pattern; the half that fell into the blind field did not produce an after-effect. Presentation restricted to the normal hemifield caused a normal after-image, while presentation restricted to the blind field in several instances caused an after-image which appeared as an unstructured lighter field without contour or colour. It follows that a simple phenomenal image can be elicited in a restricted cortically blind field. Topographically imprecise fibre systems projecting to striate cortex can exhibit unsuspectedly extensive plasticity (Sugita, *Nature* 380:523-526, 1996). If these mediate the phenomenal effect it should be absent in patients with complete hemianopia who retain no striate cortex.

## 111.11

**WHEN THE BRAIN CHANGES ITS MIND: INTER-OCCULAR GROUPING DURING BINOCULAR RIVALRY**  
**L. Kovács<sup>1,2</sup>, T. V. Papathomas<sup>1</sup> & A. Fehér<sup>1</sup>**, <sup>1</sup>Lab. of Vision Res. Rutgers Univ., Piscataway, NJ; <sup>2</sup>Eötvös Univ., Budapest, Hungary.

THE prevalent view of binocular rivalry holds that it results from reciprocal inhibition among monocular neurons. However, there is recent evidence that binocularly driven cells in V4 and MT reflect perceptual alternations in their firing pattern (Leopold and Logothetis, *Nature* 1996 379:549-552), suggesting that there is more to binocular rivalry than mere eye-competition. We have developed a method to study interocular interactions during rivalry. Conventional rivalry-inducing stimuli are dissimilar image pairs that are each coherent in their global structure (such as gratings of orthogonal orientations, or blobs of opposite colors). We replace these by complementary patchworks of intermingled rivalrous images. Can the brain unscramble the pieces of the patchwork arriving from different eyes to obtain a global percept? Percepts with conventional, globally coherent image-pairs (e.g., a monkey face vs. a jungle scene) are compared to those obtained with the patchwork image pairs (spatially complementing pieces of the monkey and the jungle in each image). We found that interocular grouping of image components occurs across extended images (15°x15°) in all tested conditions (color defined, orientation defined, natural, and moving natural images), implying that binocular rivalry goes beyond interocular suppression and follows more complex rules of perceptual organization. We suggest that interocular grouping is mediated by extremely interactive feedforward-feedback connections involving a large part of the cortical architecture.

## 111.13

**THE NEURAL SITE OF THE REDUNDANT-TARGETS EFFECT: EVIDENCE FROM EVENT-RELATED POTENTIALS**

**C.A. Marzi\*, M. Girelli, A.E. Ipata & C. Miniussi.**

Dept. Neurol. & Vis. Sci., U. of Verona, 37134 Verona, Italy.

The redundant-targets effect (RTE) consists in a decrease in reaction time (RT) following presentation of two or more stimuli versus one stimulus alone. It has been interpreted either as a probability summation phenomenon or as a neural summation effect. With the aim of casting light on its neural site we studied the event-related potential (ERP) correlates of the RTE in 12 normal human subjects performing in a simple visual reaction time (RT) task with stimuli (2.5°x4° rectangular checkerboards of 2.1 cycles/degree) lateralized to the upper or lower portions of the left or right hemifields. The electrodes (32) were placed over the scalp and referred to the mastoids. The behavioral data showed a robust RTE that was reliably present in the lower but not in the upper visual hemifield.

The main thrust of this study was that reliable evidence of a RTE was found for three main early components of the visual ERP namely C1, P1 and N1. All these components showed an overall shorter latency and a higher amplitude for bilateral than unilateral stimuli especially for lower hemifield presentations. It is particularly important to point out that the presence of a RTE in the C1 component (latency range: 40-80 msec) suggests that this effect is present already at the level of Area 17. In keeping with this we found a polarity reversal of C1 for stimuli presented to the upper and lower hemifields. Such reversal is considered a consequence of the peculiar retinotopic organization of the calcarine sulcus. The presence of a neural correlate at the level of Area 17 brings weight to the neural summation hypothesis of the RTE.

**FRACTAL PROPERTIES OF DYNAMIC IMAGES AND HUMAN VISION.**  
**Vincent A. Billock\*, Gonzalo C. de Guzman, and J. A. Scott Kelso**, Center for Complex Systems, Florida Atlantic University, Boca Raton, FL 33431.

Most natural images have  $1/f^{\beta}$  amplitude spectra, where  $\beta$  is typically about 1.10. Recently it has been shown that human spatial contrast perception has a power law correlational structure which implies a  $1/f^{\beta}$  spectrum for spatial vision, with a  $\beta$  closely matched to the exponent found for image processing (Billock, ARVO, 1996). This result is compatible with spatial frequency mechanisms at multiple scales and indicates that the visual system is adapted to the second order statistics of static natural images. Here, we extend this analysis to dynamic images and temporal vision. We analyzed scenes from several motion pictures. Each pixel in a scene was treated as a gray scale time series and Fourier transformed. The spectra of all the pixels were averaged. Each scene was well described by the power law  $1/f^{\beta}$  ( $0.61 \leq \beta \leq 1.01$ ). Temporal perception was studied by analyzing the correlational structure of temporal contrast sensitivity using the mathematics of fractional Brownian (fractal) processes. Correlation of detection thresholds as a function of temporal frequency separation obeyed a power law, implying a  $1/f^{\beta}$  spectra.  $\beta$  averages 1.35 for data taken at low to moderate spatial frequencies and 1.47 for data taken at high spatial frequencies (8-23 c/deg). This result may indicate a parvo/magno difference in temporal processing. Moreover, the difference between the exponents for motion pictures and temporal vision suggest a role for pursuit eye movements in optimizing the transduction of temporal information. Other psychophysical power laws may be specific instantiations of the general spatiotemporal power law relationship between the physical and perceptual worlds.

**RESTRUCTURING OF PERCEPTUAL SPACE BEFORE SACCADIC. M.C. Morrone\*, J. Ross and D.C. Burr**, Ist. di Neurofisiologia del CNR, Pisa, Italy and Dep. of Psychology, University of Western Australia, Australia.

We studied how the human visual system recalibrates visual co-ordinates to compensate for saccadic eye movements. Observers made horizontal saccades from a fixation point F0 at -10° to a target F1 at +10° on an otherwise featureless red screen; they reported the apparent position of a vertical green bar that was briefly displayed before, during or after the saccade. Bars presented 50 ms before the beginning of the saccade, or after its completion, were perceived accurately and veridically. However, bars presented immediately prior to the saccade were systematically mislocated, either in the direction of the saccade or in the opposite direction, depending on the spatial position of the bar (see figure). This result has been verified by various techniques including vernier offset estimation, and a forced choice annulling task. When four bars (straddling the saccade target) were displayed in the interval -25 to 0 ms, they were seen to be merged into 1 bar (forced choice). The results suggest that each saccade is accompanied by a shift in the retinal co-ordinate system, and a momentary compression of visual space centred around F0 and F1. The perceptual compression may be instrumental in ensuring a smooth transition from fixation to fixation.

## 111.14

**SELECTIVE IMPAIRMENT OF MAGNOCELLULAR FUNCTION IN COMPRESSION OF THE ANTERIOR VISUAL PATHWAYS. G. Tassinari<sup>1</sup>, C. A. Marzi<sup>1</sup>, B. B. Lee<sup>2</sup>, V. Di Lollo<sup>3</sup>, D. Campara<sup>1</sup>** (SPON: Eur. Brain and Behav. Soc.). <sup>1</sup>Dept. of Neurol. & Vis. Sci., Univ. of Verona, Italy, <sup>2</sup>M.P.I. for Biophys. Chem., Göttingen, Germany, and <sup>3</sup>Dept. of Psychol., Univ. of Alberta, Canada.

Two main parallel systems, magnocellular (M) and parvocellular (P), originating from different types of retinal ganglion cells, are known to be segregated in different portions of the pre-geniculate visual pathways. Their relative contribution to two main cortical streams, dorsal and ventral, is still under discussion, but it is reasonable to suppose that selective damage to the M or P subcortical system might interfere with specific aspects of processing within one or the other cortical system. Using two different apparent-motion tasks, we compared the performance of patients affected by compression of the ventral part of the anterior visual pathways with that of normal controls. In the first task, observers detected small displacements of a low-contrast stationary edge (Lee et al., *J. Neurosci.* 13: 1001, 1993), while in the second task they estimated the visible persistence of moving dots (Hogben and Di Lollo, *Percept. & Psychophys.* 38: 450, 1985). In the first task, patients were impaired following parafoveal presentation, particularly in the temporal portion of the visual field, while no group difference was present in the second task. However, in the second task, patients showed reduced suppression of visible persistence at long exposure durations. Three considerations support the hypothesis that these results represent a selective impairment of the M system in humans. First, it is known that afferents from retinal ganglion cells are segregated by size in the human pre-geniculate visual pathways, with the largest axons (presumably belonging to the M system) located ventrally. Second, patients with a ventral compression behave like P ganglion cells of the macaque monkey, which have previously been shown to exhibit elevated and unmodulated thresholds for apparent motion. Third, patients are less sensitive to the inhibitory signals that suppress visible persistence, which probably originate in the M system. Supported by MURST and HFSP.

## 112.1

**INCREASED SUPEROXIDE DISMUTASE ACTIVITY PROMOTES NEURONAL SURVIVAL AND PROTECTS AGAINST L-DOPA-INDUCED TOXICITY.** D. Sulzer, M.A. Mena, U. Khan, C.J. Epstein, S. Fahn\*, and S. Przedborski. Dept. Neurology and Psychiatry, Columbia Univ., New York, NY 10032; and Dept. Pediatrics, Univ. California, San Francisco, CA 94143.

Postnatal midbrain neurons (PMN) progressively die in culture. We hypothesize that this occurs because of a diminished ability to detoxify free radicals. To test this possibility, we examined the fate of PMN from transgenic mice expressing human copper/zinc superoxide dismutase (SOD1) and from their non-transgenic littermates. Midbrain from transgenic pups had ~3-fold higher SOD activity than midbrain from non-transgenic pups. We found that transgenic neurons died significantly less than non-transgenic neurons and that increased SOD1 activity seemed to prevent the loss of tyrosine hydroxylase (TH)-positive neurons better than the loss of GABAergic neurons. We also found that neuronal processes from transgenic cultures exhibited greater density than those from non-transgenic cultures. To subject PMN to an oxidative stress, cultures were incubated with different concentrations of L-DOPA. Non-transgenic cultures incubated with 200  $\mu$ M L-DOPA showed ~50% reduction in TH-positive neuron number and a dramatic increase in the number of dying neurons and apoptotic profiles. Transgenic cultures incubated with the same dose of L-DOPA showed no changes in the number of TH-positive neurons, of dying cells, or of apoptotic profile compared to vehicle incubated controls. These results indicate that (1) the progressive death of cultured PMN is mediated in part by free radicals and (2) chronic increased SOD1 activity promotes cell survival, neuronal process development, and protects against drug-related oxidative stress.

**OXIDATIVE STRESS-RESISTANT CELLS ARE PROTECTED AGAINST HALOPERIDOL TOXICITY.** F. LEZOUALCH, F. HOLSBOER and C. BEHL\*. Max Planck Institute of Psychiatry, Clinical Institute, 80804 Munich, Germany.

The dopamine D2 receptor antagonist and neuroleptic drug haloperidol is cytotoxic for different neuronal and non-neuronal cells. The mechanism of haloperidol toxicity may involve oxidative stress resulting in cell death as cells are protected against haloperidol toxicity by the lipophilic free radical scavenger vitamin E. To further support this hypothesis, first we used clones of the rat pheochromocytoma PC12 cells which were selected for their resistance to the oxidative stressor amyloid  $\beta$ -protein (A $\beta$ ). Employing MTT assay as a first indicator of mitochondrial damage and propidium iodide stainings as cell lysis assay, we showed that A $\beta$  resistant cells were also resistant against haloperidol-induced cell death, even after a 24-h challenge with 100  $\mu$ M haloperidol. The PC12 parental cells were not protected from this haloperidol toxicity. Second, the cells of the clonal hippocampal cell line HT22 transfected with the potential antioxidant, Bcl-2, were also protected against haloperidol toxicity. Taken together, these data strongly support the causative involvement of free radicals in haloperidol-induced cell death. Supported by the Max Planck Society.

**MDMA ACUTELY INCREASES BRAIN SEROTONIN SYNTHESIS WHILE FEW HOURS LATTER SYNTHESIS FALLS BELOW PRE-MDMA INJECTION: DOG PET STUDY.** Mirko Diksic\*, Sadahiko Nishizawa and Shadreck Mzengeza. Department of Neurology and Neurosurgery, McGill University, Montreal, Canada

3,4-Methylenedioxymethamphetamine (MDMA, "Ecstasy") is an analog of amphetamine used as recreational drug of abuse, shown to be toxic in laboratory animals and in non human primates. The mode of the MDMA neurotoxicity is not well understood and there is no method to assess it in living human brain. We hypothesize that there is an acute activation of the brain serotonergic system with an increase in the serotonin synthesis, which produces a metabolic activation of the brain serotonergic system beyond the compensatory capacity, eventually resulting in neuronal death. This hypothesis was tested in the dog brain by assessing the influence of the MDMA on the brain 5HT synthesis. We measured brain serotonin synthesis rate using  $\alpha$ -[<sup>11</sup>C]methyl-L-tryptophan and positron emission tomography (J Neurochem 56:153-162, 1991) in dog under halothane anesthesia. The synthesis rate was measured before i.v. injection of 2 mg/kg MDMA, and 2 and 5 h after the MDMA injection. The rate of 5HT synthesis at 2 h after MDMA injection was about 9 times greater than that at the baseline. In contrast 5 h after MDMA the 5HT synthesis rate was about 3 times lower than that at the base line or about 27 times lower than that at 2 h after MDMA. The baseline 5HT synthesis rate was about 40 pmol/g/min. There was no influence of the MDMA injection on the plasma Trp concentration or the fraction of free Trp in plasma. Research was supported by the NS-29629.

## 112.2

**COMPARATIVE STUDIES ON THE EFFECTS OF 7-NITROINDAZOLE ON MPTP AND METHAMPHETAMINE NEUROTOXICITY.** J.E. Royland, M.W. Jakowec, J.W. Langston and D.A. Di Monte\*. The Parkinson's Institute, Sunnyvale, CA 94089.

Previous studies have reported that 7-nitroindazole (7-NI), a selective inhibitor of neuronal nitric oxide synthase (NOS), is capable of preventing the neurotoxic effects of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). After exposure to MPTP, NOS could be stimulated via the rise of intraneuronal Ca<sup>2+</sup> due to the activation of NMDA receptors. Excessive production of nitric oxide may ultimately lead to neuronal damage. Activation of NMDA receptors is thought to play a role in methamphetamine (METH) neurotoxicity. Therefore, it is possible that NOS stimulation and increased nitric oxide production could also occur after METH exposure. We tested this hypothesis by determining the effects of 7-NI on METH-induced striatal dopamine depletion in mice. METH alone (7.5 and 10 mg/kg x 4 injection at 2-hour intervals) caused a significant loss of striatal dopamine at 90 min, 1 and 5 days. Pretreatment with 7-NI (50 mg/kg, 20 min before each METH injection) potentiated METH-induced dopamine depletion at 90 min, while it protected at 1 and 5 days. 7-NI also protected against the loss of tyrosine hydroxylase-immunoreactivity caused by METH at 5 days. In comparison to the effects observed with METH, 7-NI prevented MPTP-induced dopamine depletion at 90 min as well as 5 days. Results of this study support a role of NOS in dopaminergic neurotoxicity while pointing to important differences in the mechanisms of dopamine depletion in the METH and MPTP models. This work was supported by the Parkinson's Institute, the National Parkinson Foundation (JER) and The Mather and Lookout Foundations (MWJ).

## 112.4

**TRANSGENIC MICE WITH HIGH LEVELS OF SUPEROXIDE DISMUTASE ACTIVITY ARE PROTECTED FROM THE NEUROTOXICITY OF 2'-NH<sub>2</sub>-MPTP ON SEROTONIN AND NOREPINEPHRINE NERVE TERMINALS.** A.M. Andrews\*, B. Ladenheim, J.L. Cadet and D.L. Murphy. Laboratory of Clinical Science, NIMH, Bethesda, MD 20892 and Molecular Neuropsychiatry Section, NIDA, Baltimore, MD 21224.

Intraperitoneal administration of the MPTP analog 1-methyl-4-(2'-aminophenyl)-1,2,3,6-tetrahydropyridine (2'-NH<sub>2</sub>-MPTP; 4 x 15 mg/kg) to CD-1 mice caused substantial decreases in cortical and hippocampal 5-hydroxytryptamine (5-HT) and norepinephrine (NE) levels to 20-30% of control 3 weeks post-treatment. The magnitude of the depletions was similar to those previously reported in Swiss Webster and C57BL/6 mice given 4 x 20 mg/kg 2'-NH<sub>2</sub>-MPTP and in keeping with these prior studies, striatal dopamine levels were unchanged by 2'-NH<sub>2</sub>-MPTP treatment in CD-1 mice.

Transgenic CD-1 mice producing high levels of human cytosolic Cu-Zn superoxide dismutase (SOD) were subsequently studied to assess the role of oxygen radicals in the mechanism of action of 2'-NH<sub>2</sub>-MPTP. In homozygous SOD mice, 5-HT and NE levels were almost completely unaffected by 2'-NH<sub>2</sub>-MPTP treatment while in 2'-NH<sub>2</sub>-MPTP-treated heterozygous SOD mice, moderate depletions in cortical and hippocampal 5-HT (50-60% of control) and NE (30-40% of control) were observed. In addition, the density of [<sup>125</sup>I]RTI-55-labeled 5-HT uptake sites was used to assess 5-HT terminal loss. In various cortical and hippocampal subregions of nontransgenic mice treated with 2'-NH<sub>2</sub>-MPTP, the number of 5-HT uptake sites was reduced to 20-35% of control; however, regional 5-HT uptake site density in the 2'-NH<sub>2</sub>-MPTP-treated homozygous SOD mice was only minimally affected while in the heterozygous SOD group, intermediate reductions in 5-HT uptake site density on the order of 55-80% of control were seen.

These results demonstrate that 2'-NH<sub>2</sub>-MPTP is capable of causing selective 5-HT and NE neurotoxicity in CD-1 mice, and that mice genetically endowed with increased SOD activity are protected from these effects, thereby implicating superoxide radicals in the mechanism of action of 2'-NH<sub>2</sub>-MPTP. (This work was supported by the Intramural Research Programs of NIMH and NIDA. A. M. A. was supported by an Intramural Research Training Award from NIMH.)

## 112.6

**ACTIVATION OF NEURONAL NITRIC OXIDE SYNTHASE: A LIKELY MECHANISM OF PARAQUAT-INDUCED LUNG INJURY.** Alok Bandyopadhyay, Satish Rattan, and Sami I. Said\*. Thomas Jefferson Univ., Philadelphia, PA 19107; Northport VA Med. Center & University Med. Center, Stony Brook, NY 11794-8172.

Excessive nitric oxide (NO) generation, usually resulting from induction of NO synthase in macrophages (iNOS), has been associated with acute inflammatory responses and tissue injury. Constitutive NO production, by endothelial cells and neuronal cells, is commonly viewed as physiological, although overactivation of neuronal NOS has been implicated in excitotoxicity of central neurons. We recently reported that the pro-oxidant herbicide paraquat induces acute lung injury via mechanisms involving excessive production of NO (PNAS 91: 7445, 1994). Because this injury occurred within 1 h, it seemed unlikely that iNOS was responsible. To ascertain the source of NO provoked by paraquat, we isolated RNA from rat tracheal tissue, including tracheal ganglion cells, after direct application of paraquat (0.5-5.0 mM) for 1-10 min. RNA was amplified by PCR, with neuronal NOS- and iNOS-specific primers, and NOS protein was measured by Western Blot. Neuronal NOS expression (NOS RNA/G3PDH RNA) was markedly enhanced following paraquat treatment, but iNOS was unaffected. The stimulated expression of neuronal NOS was dose-dependent: 5 mg paraquat produced maximal elevation, and the effect peaked at 10 min but was sustained for > 30 min. We conclude that: 1) Upregulation of neuronal NOS probably accounts for the stimulated NO production (and lung injury) induced by paraquat; and 2) activation of neuronal NOS, like that of iNOS, may contribute to tissue injury.

## 112.7

OXIDATIVE STRESS IN THE BRAIN FOLLOWING INTRAVENTRICULAR ADMINISTRATION OF ETHYLCHOLINE AZIRIDIUM (AF64A). *N.Y. Gulyaeva\*, N.A. Lazareva, L.L. Libe, O.S. Mitrokhina, M.V. Onufriev, M. Yu. Stepanichev, and T.J. Walsh<sup>1</sup>*. Dept. of Functional Biochemistry of the Nervous System, Inst. of Higher Nervous Activity and Neurophysiology, Russian Acad. of Sci., Moscow, Russia, 117865, and <sup>1</sup> Dept. of Psychology, Rutgers Univ., New Brunswick, NJ, USA, 08903.

AF64A is a toxic analog of choline that disrupts high affinity choline transport and produces a persistent presynaptic cholinergic hypofunction. The observed neuroprotectant effects of Vitamin E in the AF64A model suggested that oxidative stress contributed to the cholinotoxicity of AF64A. The studies presented here examined whether intraventricular injection of AF64A produces oxidative stress in the brain of male Wistar rats. Indices of oxidative stress including thiobarbituric acid reactive species (TBARS), free radical generation using hydrogen peroxide-induced, luminol-dependent chemiluminescence (CL), and superoxide scavenging/generating activity were measured in cerebral cortex, hippocampus and the rest of the brain, without cerebellum, 1, 3, or 5 days after bilateral intraventricular injection of 3 nmol of AF64A or artificial CSF (sham surgery). The sham operation itself induced oxidative stress throughout the brain (increased TBARS, CL, and superoxide generation). In addition to the oxidative stress of the sham surgery AF64A increased basal TBARS on day 1 and Fe/ascorbate-induced TBARS on days 3 and 5 throughout the brain. AF64A produced compensatory "antioxidative" changes as well with increased superoxide scavenging activity observed on day 3 and decreased basal TBARS on day 5. AF64A-induced changes specific to the hippocampus included a decrease of CL and an increase of superoxide scavenging activity on day 5. The increased superoxide scavenging activity persisted up to 126 days. The results of the present study provide the first direct evidence that AF64A induces oxidative stress following intraventricular injection.

EFFECT OF LIDOCAINE ON CYTOPLASMIC CALCIUM IN THE ND7 NEURONAL CELL LINE. *M.E. Johnson\*, C.B. Uhl*. Anesthesiology Dept., Mayo Foundation and Mayo Clinic, Rochester, MN 55905.

Recent clinical reports and animal studies suggest that lidocaine has a neurotoxic effect at high concentrations. Toxicity is unlikely to involve Na<sup>+</sup> channel block, which would preserve mitochondrial energy stores and minimize elevation of cytoplasmic calcium (Ca<sup>2+</sup><sub>cyt</sub>). Rather, earlier studies suggested that local anesthetics harm the ability of intracellular organelles to sequester Ca<sup>2+</sup>. We therefore tested the effect of lidocaine on Ca<sup>2+</sup><sub>cyt</sub> in the neuronal cell line, ND7, using ratiometric, digitized, video fluorescence microscopy with fura-2.

During the 60 min experimental exposure, controls containing tris(hydroxymethyl)-aminomethane equimolar to the lidocaine concentrations tested caused no change in Ca<sup>2+</sup><sub>cyt</sub>. Increasing concentrations of lidocaine caused an increasing height and duration of Ca<sup>2+</sup><sub>cyt</sub> change (see Table). Lidocaine 5.0% killed 2 of 10 cells. No cell death was observed at lower lidocaine concentrations.

Lidocaine	Ca <sup>2+</sup> <sub>cyt</sub> as % initial baseline, ±SE, averaged over indicated time period. Lidocaine added at 0 min.

AXONAL NEUROTOXICITY INDUCED BY ANTIVIRAL DIDEOXY-NUCLEOSIDES IN SENSORY GANGLION CULTURES, *E. B. George\**, Department of Neurology, Johns Hopkins University; Baltimore, MD 21287-6953

A cell culture model for the neurotoxicity of antiviral dideoxynucleosides was established and used to determine if pharmacological interventions which interrupt calcium-mediated axonal degeneration are protective in this system. The dideoxynucleosides 2',3'-dideoxycytidine (ddC) and 2',3'-dideoxyinosine (ddI) are antiviral agents which display dose-limiting neurotoxicity when used to treat HIV infection. Pharmacologic agents which block entry of extra-axonal calcium or the subsequent activation of calpains can prevent or delay axonal degeneration produced in tissue culture by either axotomy or acrylamide neurotoxicity. The current study investigates whether the antiviral dideoxynucleosides can induce axonal degeneration in this tissue culture system and whether manipulation of calcium is protective.

Murine dorsal root ganglion explants were allowed to extend neurites in culture for 10-14 days. Healthy cultures were then exposed to dideoxynucleoside either in the presence or absence of calcium antagonists. The effects on the established neurites were monitored and dose-toxicity curves generated for the dideoxynucleosides. The calcium-antagonist induced shift in these dose-toxicity curves was used to detect protection from axonal toxicity. The antiviral dideoxynucleosides produce a dose-related distal axonopathy in established cultures of sensory neurons with features similar to acrylamide neuropathy. Simultaneous treatment with calcium antagonists or calpain inhibitors can be used to delay the progression of the toxic axonopathy in this culture system. Calcium-mediated axonal degeneration appears to be a final common pathway for many types of axonopathies, and dideoxynucleoside effects on mitochondria may interfere with calcium handling in axons.

## 112.8

EFFECT OF LONG-TERM ANTICHOLINESTERASE EXPOSURE ON NEUROMUSCULAR FUNCTION IN VITRO.

*R. Drake-Baumann<sup>1,2</sup> and F.J. Seil<sup>1,2,3</sup>*. Neurology Research, VA Medical Center<sup>1</sup> and Depts. of Neurology<sup>2</sup> and Cell Biology & Anatomy<sup>3</sup>, Oregon Health Sciences University, Portland, OR 97201.

We have used organotypic dorsal root ganglion-spinal cord explants co-cultured with skeletal muscle to evaluate the effects of long-term exposure to pyridostigmine bromide (PB), an acetylcholinesterase inhibitor, on dorsal root ganglia neurons, cholinergic ventral horn motoneurons and neuromuscular function. No alterations in morphological or electrophysiological properties were observed in dorsal root ganglia neurons or ventral horn motoneurons with exposure to 10<sup>-6</sup>M PB for periods of up to three weeks in vitro. Neuromuscular function was selectively affected by PB treatment. Short-term treatment (minutes) with PB increased spontaneous muscle contraction. This potentiation is consistent with the inhibition of acetylcholinesterase and the consequent greater availability of acetylcholine at the neuromuscular junction. This effect could be blocked by succinylcholine. Long-term treatment (weeks to days) with PB decreased the contractile activity of muscle fibers and their sensitivity to externally applied acetylcholine. Morphological studies by light microscopy showed an enlargement of the acetylcholinesterase-positive regions of the muscle fibers. Our findings suggest that long-term exposure to PB causes acetylcholine receptor desensitization and morphological alterations of the muscle end-plate. ## 112.10

BEHAVIORAL AND BIOCHEMICAL EFFECTS OF DISULFIRAM IN MALE AND FEMALE RATS. *M.R. Rahman\*, M.M. Faraday\*, N.E. Grunberg\*, and G.P. Mueller\**. Neuroscience Program, Medical and Clinical Psychology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Disulfiram (Antabuse™) is an inhibitor of alcohol dehydrogenase, and is widely used as an adjunctive therapy in the treatment of human alcoholism. Behavioral and biochemical neurotoxic effects have been reported in humans and rats. Recently, we reported that in male rats disulfiram significantly impairs muscle strength, balance, and coordination; decreases body weight; and increases latencies to respond to a nociceptive stimulus. In addition, peptidylglycine α-hydroxylating monooxygenase (PHM), the enzyme that catalyzes α-amidation and bioactivation of peptides used in intercellular communication, and levels of the α-amidated peptide α-melanocyte stimulating hormone (α-MSH) were affected. The present experiment included male (n=32) and female (n=32) Sprague-Dawley rats, additional behavioral measures, and longer-term administration of disulfiram. The behavioral and biochemical findings replicate our recent report. Further, the behavioral and biochemical effects of disulfiram were differentially expressed in males and females. Implications for humans treated with Antabuse™ will be discussed.

## 112.12

BIOSENSORS UTILIZING NEURAL CELLS AS SENSING ELEMENTS *J.J. Hickman\*, D.A. Stenger, G.T.A. Kovacs*. SAIC, Biotechnology Research and Applications, McLean, Virginia 22102, <sup>2</sup>NRL, Washington, D.C., 20375, <sup>3</sup>Stanford University, Stanford, CA 94305

We are building a self-contained system to allow automatic operation of a biosensor utilizing a living neural cell as the sensing element. The neural cells act as transducers as well as sensing elements for toxin detection. The receptors on the cell act as the sensor which responds to toxins by stopping the electronic signal (action potentials) generated by the cell. The electrical signal (or lack thereof) is sensed by an Au microelectrode placed close to the neuronal-derived cell and then is amplified by the accompanying microelectronics. The cell line needs to be treated as an electronics component and conditions manipulated to achieve optimal properties for various applications. The longevity, sensitivity, electrical activity and placement of the neural cells are critical parameters. We have manipulated the parameters by using different growth conditions, surface modifications and subclass isolation and then studied the resultant cultures by electrophysiology, morphology, and surface analysis. The conclusion is that we can use a neural cell as a sensor element for toxin detection. This system will be described in detail as well as the results generated with biological and chemical toxins.

## 113.1

NEUROTRANSMITTERS OF THE VESTIBULAR COMMISSURAL PATHWAY IN THE CAT. F.A. Chen\* and R.F. Spencer. Department of Anatomy, Medical College of Virginia, Richmond, Virginia 23298-0709.

The vestibular commissural pathway interconnects the bilateral vestibular nuclei and is thought to play a role in the vestibulo-ocular reflex, the enhancement of vestibular responses, and recovery of function from peripheral lesions of the VIIIth cranial nerve through excitatory and/or inhibitory projections. Previous pharmacological studies have suggested that the inhibitory neurotransmitters involved in vestibular commissural inhibition may be GABA and/or glycine. In the present study, injections of biocytin were made into the medial vestibular nucleus of adult cats to label anterogradely the commissural synaptic endings in the contralateral medial vestibular nucleus. A combined preembedding immunoperoxidase and postembedding immunogold technique was used to localize the neurotransmitters (glutamate, aspartate, glycine or GABA) associated with biocytin labelled vestibular commissural endings by electron microscopy. Terminals immunoreactive for the inhibitory neurotransmitters glycine and GABA established synaptic connections with postsynaptic profiles that were non-immunoreactive for these neurotransmitters. Consequently, the direct inhibitory commissural pathway mediated by these neurones is presumed to synapse on contralateral excitatory (Type I) neurones. Biocytin labelled glutamate immunoreactive endings establish synaptic contact with postsynaptic profiles that were either immunoreactive or non-immunoreactive for glutamate, both of which were contacted by non-glutamate immunoreactive synaptic endings. Very few biocytin labelled synaptic endings were immunoreactive for aspartate, even though postsynaptic processes and non-biocytin labelled terminals that were aspartate immunoreactive were present in the MVN. The results of this study are consistent with the notion that the vestibular commissural pathway consists of both excitatory and inhibitory components, and that GABA and glycine are inhibitory neurotransmitters involved in vestibular commissural inhibition.

## 113.3

#### Firing Behavior of Central Vestibular Neurons during Voluntary Head Movements.

R.A. McCrea\*, G.T. Gdowski, T. Belton, and R. Boyle<sup>2</sup> The Committee on Neurobiology, University of Chicago, Chicago, IL; <sup>2</sup>Dept. Otolaryng., Oregon HS Univ., Portland, OR

Single unit recordings were obtained from 60 secondary vestibular neurons in alert, squirrel monkeys whose head was free to move  $\pm 45^\circ$  in the yaw plane. Secondary vestibular neurons were identified by the short latency (<1.3 ms) orthodromic activation following single shock electrical stimulation of the ipsilateral vestibular nerve. The monkeys were seated on a vestibular turntable that allowed whole body rotation of the monkey in the yaw plane. The vestibular sensitivity of a cell was assessed by passive whole body rotation with the turntable during temporary head restraint. Only units that responded to passive rotation in the plane of the horizontal semicircular canal were recorded. The firing behavior was then recorded during active, self generated saccadic and smooth pursuit head movements.

Different secondary vestibular neurons responded in different ways during active head movements. The responses of only a few "pure" vestibular neurons could be predicted from their responses during passive whole body rotation. They were insensitive to active head movements, but they continued to respond to passive whole body rotation during saccades. Neurons that exhibited pauses during ocular saccades, including position vestibular pause neurons, usually were inhibited during head saccades, regardless of the direction of the saccade. In most cases, the duration of the inhibition was best correlated with the gaze velocity of the saccade, and cells resumed firing before the head movement component of the saccade was completed. Vestibular neurons that burst during ocular saccades showed a variety of responses during gaze saccades; a common response was a burst discharge related to the ocular saccade combined with weak inhibition or excitation related to the head component of the saccade that was opposite in direction to the preferred vestibular on direction. Passive perturbations of the head during saccades were usually capable of evoking responses in the vestibular on direction.

Although most secondary vestibular neurons are capable of responding to passive head perturbations during active head movements, the vast majority do not code the head velocity related to self generated head movements. The implication is that vestibular reafference may not play an important role in coordinating eye and head movements during voluntary gaze shifts.

## 113.5

ACTIVITY OF MEDIAL VESTIBULOSPINAL (MVST) NEURONS DURING APPLIED AND ACTIVE HEAD MOVEMENTS IN THE SQUIRREL MONKEY. R. Boyle<sup>1</sup>\*, R.A. McCrea<sup>2</sup>, T. Belton<sup>2</sup>, and G. Gdowski<sup>2</sup>. <sup>1</sup>Depts. Otolaryngol. & Physiol., Oregon Health Sci. Univ., Portland, OR 97201; <sup>2</sup>Dept. Pharmacol. & Physiol. Sci., Univ. Chicago, Chicago, IL 60637.

Secondary MVST neurons were identified using electrical stimulation techniques in the alert squirrel monkey prepared for chronic single-unit, eye and head movement recordings. Animals were free to make active head on shoulder movements of  $\pm 45^\circ$  in yaw and  $\pm 10^\circ$  in pitch; the head could also be coupled to the chair to deliver passive head movements in space. Cell discharge was examined during combined eye and head saccades up to  $400^\circ/\text{s}$ , applied whole body rotation with or without head restraint, applied rotation of head on shoulder, and applied neck rotation with the head held stationary in space. The latter tests were done to assess a cell's neck afferent input. Our main findings are that 1) MVST cells carry signals related to the passive, but not active, component of a head movement during gaze saccades; and suggests that they continue to receive vestibular inputs during head saccades, but that the inputs related to the head saccades are cancelled. Consequently, MVST cells do not encode head velocity in space during self-generated head movements. 2) MVST cells do not code neck position and receive weak neck afferent inputs during passive neck rotation; and suggests that either an efference copy mechanism or gated reafferent neck inputs cancel the 8th nerve input during active head movements. (Supported by 1P60 HD02072)

## 113.2

EXCITATORY AND INHIBITORY INPUTS FROM SACCULAR PRIMARY AFFERENTS TO CAT SINGLE VESTIBULAR NEURONS. Y. Uchino, H. Sato\* and H. Suwa. Dept. of Physiol., Tokyo Med. College, Tokyo 160.

Hair cells of the saccular macula display different morphological polarities, but little is known about their projection pattern on to single vestibular neurons. We studied the neural organization between vestibular neurons and saccular afferents which originated from hair cells with different morphological polarity. All cats were anesthetized with halothane. At the last stage of surgery, the cats were decerebrated. Excitatory (E) and inhibitory (I) postsynaptic potentials (PSPs) were recorded in vestibular neurons after focal stimulation of saccular macula. Focal stimulation was performed by changing polarity of the stimulus current via a pair of electrodes, one of which was placed in the rostral-ventral and the other in the caudo-dorsal part of the saccular macula. We recorded either monosynaptic EPSPs ( $\leq 1.2$  ms) or disynaptic IPSPs ( $\geq 1.5$  ms) in 22 out of 36 tested neurons by changing the polarity of the stimulus current. In the other neurons, the response pattern was always the same regardless of the polarity; EPSPs (12/36) or IPSPs (2/36). Afferent information from one population of hair cells activated vestibular neurons monosynaptically, while that from hair cells located on the opposite side of the striola projected to the vestibular neurons disynaptically via inhibitory interneurons. Half of the saccular-activated neurons received excitatory and/or inhibitory inputs from other vestibular nerve branches. The neural circuits from the saccular afferents to the vestibular neurons may be responsible for the increase in the sensitivity to vertical linear acceleration. The described circuit also seemed to have input noise-resistant characteristics.

## 113.4

#### Influence of Neck Rotation on the Firing Behavior of Secondary Vestibular Neurons in the Alert Squirrel Monkey.

G.T. Gdowski\*, R.A. McCrea, T. Belton, and R. Boyle<sup>2</sup> The Committee on Neurobiology, University of Chicago, Chicago, IL 60637, <sup>2</sup>Dept. Otolaryngol. & Physiol., Oregon Health Sci. Univ., Portland OR 97201.

The influence of neck rotation on secondary vestibular neurons is behaviorally dependent on whether the head movement is in pursuit of a target or reflexive to stabilize the head during passive whole body rotations (vestibulocollic reflex, VCR). The neck sensitivity ( $H_N$ ) of secondary vestibular neurons was measured as the ratio of sinusoidal fits applied to desaccaded records of unit rate and neck velocity during passive body rotations while the head was held stable in space (2Hz,  $20^\circ/\text{s}$ ). Spontaneous records of gaze and head position were also obtained to determine the unit sensitivity to static eye and head position. Most units, including position vestibular pause units, had weak neck sensitivities ( $H_N < 0.3$ ) which were difficult to assess during spontaneous movements. In most cases, the unit response was in phase with neck velocity and in the opposite direction of the units vestibular sensitivity.

Target pursuit produces neck and vestibular inputs having identical directions. A similar head and neck movement was obtained by passively rotating the head while the body was held stable in space. Unit responses to this stimulus could be predicted using an antagonistic combination of neck and vestibular sensitivities.

The VCR evokes head movements in the opposite direction of the body rotation. VCR-related head movements were evaluated by comparing responses to passive whole body rotations (2Hz,  $20^\circ/\text{s}$ ) while the head was fixed and while the head was free to move ( $\pm 45^\circ$  in yaw). Most secondary vestibular neurons exhibited little change in their response in the presence and absence of VCR compensatory head movements. This lack of change appears to be due to a synergistic combination of neck and vestibular sensitivities.

These results suggest that while unit responses during reflexive or passive head and neck rotations can be predicted with vestibular and neck sensitivities, they are insufficient to predict the unit responses during voluntary head movements.

## 113.6

EFFECT OF AGE ON THE VESTIBULO-OCULAR REFLEX (VOR) AND VISUAL-VESTIBULAR INTERACTIONS DURING NATURAL MOVEMENTS. B. T. Crane\*, E. S. Viirre, and J. L. Demer. Jules Stein Eye Institute and Dept. of Neurology, Univ. of California, Los Angeles, CA 90095-7002.

The effect of aging on gaze stabilization by the VOR is not well characterized for head movements encountered during natural activities. We studied the VOR and visually-enhanced VOR (VVOR) in 9 young ( $29 \pm 9$  yrs, mean  $\pm$  SD) and 11 elderly ( $78 \pm 4$  years) subjects during standing, walking in place (2 steps per second), and active sinusoidal head motion at 0.8 Hz in pitch and yaw. Gains were recorded separately for the pitch and yaw axes using magnetic search coils. Recordings were made with a visible target 6 - 10 m distant both with and without 2X binocular telescopic spectacles, and were repeated in darkness with remembered targets.

Measurable VOR and VVOR responses were present during all activities studied. For both subject groups, gains were  $< 1.0$  for normal vision and  $< 2.0$  for magnified vision, and were generally lower in darkness than in light. While VVOR gains during unmagnified vision were identical for the elderly and young during active head rotations and during natural activities with unmagnified vision, the elderly tended toward lower VOR and VVOR gains under all other conditions. Averaged across natural activities, VOR gains for the young were  $0.93 \pm 0.02$  (mean  $\pm$  SEM) and  $0.84 \pm 0.02$  in pitch and yaw, respectively. For the elderly, corresponding gains were  $0.91 \pm 0.02$  and  $0.72 \pm 0.03$ . Pitch gains were higher than yaw gains for both groups during natural activities ( $P < 0.001$ ). Age-related gain differences were greater in yaw, during trials done in the dark or with magnification, and during walking. Gains measured during active head rotation were higher than during natural activities in both age groups for both pitch and yaw ( $P < 0.001$ ).

While the VVOR performance of the elderly does not significantly differ from the young in the presence of normal vision, the elderly have lower VOR gain and reduced augmentation by magnified vision during natural activities. These findings imply that either the elderly have a VOR deficit during natural activities, or that differences in their patterns of head rotation and translation may require lower angular VOR gains.

## 113.7

## ROTATIONAL AND TRANSLATIONAL HEAD STABILITY DURING NATURAL MOVEMENTS IN YOUNG AND ELDERLY SUBJECTS.

J.L. Demer\*, B.T. Crane, and E.S. Viirre, Jules Stein Eye Institute and Department of Neurology, University of California, Los Angeles, CA 90095-7002.

Natural activities such as ambulation produce head translations and rotations that must be compensated to stabilize gaze. We studied rotational motion using head-mounted magnetic search coils, and translational motion using a head-mounted flux gate magnetometer sensor, in 9 young ( $29 \pm 9$  yrs, mean  $\pm$  SD) and 11 elderly ( $78 \pm 4$  years) subjects during quiet standing, and walking in place (2 steps per second). Young subjects were also studied during running in place (3 steps per second). Recordings were made with a visible target 6 - 10 m distant both with and without 2X binocular telescopic spectacles, and were repeated in darkness with remembered targets. Rotational data were digitally sampled at 400 Hz and analyzed in the position and velocity domains, while translational data were sampled at 14 or 109 Hz and analyzed in the position domain by matrix transformation to obtain translation of the right eye.

Neither the presence of a visible target nor of spectacle magnification significantly influenced any aspect of head motion when data were averaged across young or elderly subjects. Root-mean-square (RMS, 0-20 Hz) head velocity was 15-20% greater in the elderly than the young subjects for both pitch and yaw during both standing and walking in place. Peak mediolateral (ML) displacement was similar in both groups during standing, but was about 50% greater in the elderly during walking ( $P < 0.05$ ). Peak dorsoventral (DV) displacement was about twice as great in the elderly as the young during both standing and walking ( $P < 0.05$ ). In both subject groups during walking and running, upward translation was tightly phase-locked to downward pitch rotation, and rightward translation was tightly phase-locked to leftward yaw.

Geometric analysis indicates that head translation and rotation during ambulation are phase-locked so as to have offsetting effects on gaze. This reduces the angular VOR gain required for gaze stabilization in a manner depending on target distance. During natural activities the greater head translation of elderly as compared with young subjects would thus enable appropriate gaze stabilization at lower VOR gains.

## 113.9

## NONLINEAR DYNAMICS OF THE HEAD-NECK SYSTEM. J. Goldberg\* and Steve Lutes, OTO Dept, Baylor Col. of Medicine, Houston, TX 77030.

Reflexes controlling head stabilization are nonlinear at small movement amplitudes. The input/output properties of the human head-neck system have not been studied at stimulus amplitudes small enough to reveal such nonlinearities.

Seven healthy subjects were rotated about vertical axis in a servo-controlled chair, at frequencies and acceleration amplitudes observed during natural standing and walking. Sum-of-sines rotation waveforms collectively spanned a 0.2-10 Hz frequency range and 10 to 200  $\text{deg/sec}^2$  root-mean-square acceleration range. Head and trunk rotations in space were recorded with Watson velocity sensors while subjects performed mental arithmetic.

Head rotation exhibited resonance which was most conspicuous at the lowest stimulus amplitudes and least conspicuous at the highest.

In contrast, resonant frequency did not change with amplitude, staying near 4 Hz. This implies that system damping is a function of amplitude, as the figure illustrates for one subject. The simplest model consistent with these data is a threshold nonlinearity in the vestibular rate feedback.

## 113.8

## THREE-DIMENSIONAL ORIENTATIONS OF ANGULAR EYE ROTATION AXES DURING VERTICAL VESTIBULAR NYSTAGMUS IN PATIENTS WITH CEREBELLAR ATROPHY. D. Straumann\*, D.S. Zee, D. Solomon, Neurology Dept., Johns Hopkins Hospital, Baltimore, MD 21287, USA.

In a previous study we demonstrated that angular rotation axes of the eyes during upward drift in patients with cerebellar atrophy are close to eye-fixed, i.e. the angular axis rotates by the same amount and in the same direction as the line-of-sight, when the patient is looking right or left. We asked whether in these patients we could find a similar pattern during upward slow phases of vestibular nystagmus. It is known that in normal subjects the angular rotation axis during vestibular nystagmus is close to head-fixed, i.e. only tilts by about  $1/4$  in the direction of the line-of-sight (Misslisch et al. 1994). In 3 cerebellar patients with downbeat nystagmus and 2 control subjects, we recorded eye-in-space and head-in-space movements during vertical head oscillations in complete darkness. Eye-in-head angular eye rotation axes were computed off-line, and their orientations in the head-fixed horizontal-torsional plane were plotted as a function of horizontal eye position. The slopes in the patients were 0.48, 0.47, and 0.36 during upward vestibular slow-phases, thus steeper than in normals (controls: 0.12 and -0.09), but flatter than during the patients' downbeat nystagmus, with slopes of upward drift being 1.31, 1.19, and 1.11 (slope = 0: head-fixed, slope = 1: eye-fixed axis). One possible explanation of our data is that eye position feedback, used to compensate for the non-commutative property of three-dimensional eye movements (Tweed and Vilis 1987), is controlled by the cerebellum. In the case of cerebellar atrophy with a deficit in the upward direction, this hypothesis predicts eye-fixed angular rotation axes, when angular velocity signals comply with Listing's law (e.g. pursuit signals), and a tilt of angular rotation axes by  $1/2$  in the direction of the line-of-sight, when angular velocity signals are head-fixed (e.g. vestibular signals).

## 113.10

## RESPONSES OF SECOND-ORDER AND EFFERENT VESTIBULAR NEURONS TO FORELIMB SKIN AND MUSCLE STIMULATION IN THE DECEREBRATE DECEREBELLATE GUINEA PIG. V. Marlinsky\*, Dept. Physiol., Freie Universität Berlin, Arnimallee 22, 14195 Berlin, FRG.

The extracellularly recorded activity of medial vestibular nucleus neurons and efferent vestibular neurons was analysed in the decerebrate decerebellate guinea pig. Neurons were identified by means of electrical stimulation of the anterior semicircular canal. Thirty-six neurons were monosynaptically activated during semicircular canal stimulation and were regarded as second-order vestibular neurons. Thirty neurons were antidromically activated and therefore identified as efferent vestibular neurons. Both types of neurons investigated had spontaneous impulse activity and responded to sinusoidal roll tilt. All second-order vestibular neurons were excited during ipsilateral and inhibited by contralateral tilt. Eighteen efferent vestibular neurons also showed this pattern, while the remaining twelve were excited by contra-lateral and inhibited by ipsilateral tilt. Stimulation of high-threshold skin afferents evoked by the stance pressure of the plantar surface and stimulation of flexor muscle afferents evoked by passive extension at the elbow of forelimbs led to an increase in the impulse rate in 30% and to a decrease in the impulse rate in 20% of second-order vestibular neurons, while 50% of these neurons did not show any changes in activity. The majority of efferent vestibular neurons (67%) responded to the same stimulation with the increase in the impulse rate, the rest of these neurons (33%) did not. Neurons of both groups responded neither to stimulation of low-threshold skin afferents evoked by the plantar contact with the support surface nor to stimulation of extensor muscle afferents evoked by passive forelimb flexion.

## VISUAL SYSTEM: DEVELOPMENT I

## 114.1

## ACTIVITY-DEPENDENT REGULATION OF QUANTAL AMPLITUDE IN VISUAL CORTICAL CULTURES. G.G. Turrigiano, K. Leslie, and S.B. Nelson\*, Dept. of Biology and Center for Complex Systems, Brandeis University, Waltham, MA 02254.

The strength and number of synaptic inputs onto neurons can change dramatically during development or learning, thus altering the total amount of excitation received. How do neurons adjust their responsiveness to avoid firing rates that are too high or too low? One possibility is that ongoing activity can globally up or down regulate the strength of excitatory synaptic connections. Here we test this idea.

Whole-cell voltage clamp recordings were obtained from pyramidal neurons from cultures of P5-6 rat visual cortex after 7-9 DIV, in the presence of TTX and bicuculline. Miniature excitatory synaptic currents were recorded that could be blocked by the AMPA antagonist CNQX. Recordings were made from control cultures grown in normal medium or sister cultures treated for 48 hrs with TTX to block all spikes. In each of 5 experiments the quantal amplitudes from TTX treated cultures were larger than control cultures ( $32.8 \pm 1.6$  and  $16.5 \pm 1.1$  pA, respectively; significantly different,  $p < 0.01$ , Student's *t* test), whereas rise times and other kinetics were not different. Cumulative amplitude histograms from the two populations showed that the distribution was shifted to the right for the TTX-treated population (TTX different from control, Kolmogorov-Smirnov test,  $p < 0.001$ ). No differences in resting potential, series resistance, or whole cell capacitance were found between the two populations. These data indicate that blocking activity nearly doubles the quantal amplitude of AMPA-mediated synaptic transmission. Supported by NSF and the Whitehall Foundation (GGT), and NSF and the Sloan Foundation (SN).

## 114.2

## ACTIVITY-DEPENDENT REGULATION OF NMDAR1 IN THE DEVELOPING VISUAL CORTEX. S.M. Catalano\*, C.K. Chang and C.J. Shatz, HHMI and Dept. of Molecular and Cell Biology, University of California, Berkeley, 94720

NMDA receptors are known to make a significant contribution to the synaptic currents and activity of neurons in the mammalian visual cortex during development. We have examined the distribution of the NMDAR1 protein in cat visual cortex using a monoclonal antibody against the extracellular loop domain between transmembrane regions 3 and 4. This subunit is known to be required for channel function. Our previous results indicate that levels of immunostaining are relatively high in layers 2/3 throughout development and into adulthood. In contrast, immunostaining increases in layer 4 during development, reaching peak levels near the end of ocular dominance column formation (six weeks). Intensity of immunostaining then gradually declines in layer 4, reaching adult levels by about 15 weeks. Dark-rearing beginning at birth apparently does not affect the timecourse of this developmental decrease in layer 4 immunostaining. However, following two weeks of monocular tetrodotoxin (TTX) injections beginning at the sixth postnatal week, R1 staining is less intense in activity-blocked eye columns than in untreated eye columns. We conclude that 1) high levels of R1 are present in layer 4 during a time when anatomical rearrangements of axonal inputs can be rapidly induced by manipulation of neural activity, 2) levels of R1 gradually decline thereafter, reaching adult levels at the timepoint when anatomical rearrangements of geniculocortical axons can no longer be induced in layer 4 by manipulations of activity, 3) levels of immunostaining remain high in layers 2/3, where activity-dependent anatomical rearrangements are thought to persist into adulthood, 4) dark-rearing lowers, and TTX eliminates, incoming axonal activity. Results from these experiments indicate that while visual experience may not be responsible for the normal decline of R1 in layer 4, absolute levels of activity can affect R1 levels. Supported by grants from the NEI to CJS (EY02858) and SMC (EY06491).

## 114.3

**CYCLIC AMP AS A MESSENGER OF METABOTROPIC GLUTAMATE RECEPTORS IN VISUAL PLASTICITY.** S.N.M. Reid\*, N.W. Daw, D.S. Gregory and H.J. Flavin. Dept. of Ophthalmology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Deprivation of visual input from one eye can modify eye-specific connections in the visual cortex during a critical period. We have investigated the increase in cAMP produced by metabotropic glutamate receptors (mGluR) in cat visual cortex. The cAMP increase produced by the general mGluR agonist, trans-(1S,3R)-1-amino-1,3-cyclopentanedicarboxylic acid (ACPD), followed the critical period closely. When normal and dark-reared animals were compared, the increase was smaller in dark-reared animals at 5 weeks of age, similar at 8 weeks of age, and larger at 15 weeks of age, which is the same as the dark-rearing effect on ocular dominance plasticity (Mower, Dev. Brain Res. 58:151, 1991). The increase produced by a mixture of group I, II and III agonists is greater than the sum of cAMP levels increased by singly applied agonists, suggesting that there is an interaction between the G proteins and/or second messengers. A decrease in forskolin-elevated cAMP was seen by group II and III agonists, but these agonists also increase basal level of cAMP. The basal cAMP level also followed the critical period. That ACPD-elevated cAMP levels follow the critical period more closely than the basal levels can be accounted for by the fact that the number of mGluRs falls steadily between birth and adulthood (Reid et al., J. Comp. Neurol. 355:470, 1995). Since the major factor in the fit between ACPD-elevated cAMP and the critical period is basal levels, and the mGluR number is a minor factor, we suggest that the level of second messenger may be more important than the level of receptors in ocular dominance plasticity. Supported by RO1 EY 00053.

## 114.5

**MONOCLONAL ANTIBODY CAT-307 RECOGNIZES PLC-81 AND IDENTIFIES AN UNUSUAL ORGANELLE IN NEURONS OF THE DEVELOPING CAT CORTEX.** P.C. Kind\* and S. Hockfield. Sect. of Neurobiol., Yale Univ. Sch. Med., New Haven, CT., 06510

We previously reported that the Cat-307 monoclonal antibody recognizes a 165 kD protein that localizes to small, punctate "dots" in the cat visual cortex at 5-weeks of age, but not at 15-weeks of age. Immunoelectron microscopic analysis with Cat-307 identified a little described organelle, Spot, that has not been previously demonstrated in cortical neurons. The Spot organelle is situated between the endoplasmic reticulum and the Golgi apparatus. Biochemical analysis demonstrated that the Cat-307 protein associates with microsomal membranes, suggesting a role for the Cat-307 antigen in protein transport in developing neurons. Purification and amino acid sequence analysis of the Cat-307 protein identify it as phospholipase C-81 (PLC-81). Amino acid sequence was obtained from two peptides, 8 and 17 amino acids in length. Both showed 100% amino acid identity with rat and bovine PLC-81 sequences. On Western blots both Cat-307 and antibodies to PLC-81 recognize a doublet with a major species at 165 kD and a minor species at 160 kD. Cross-immunoprecipitation using Cat-307 and antibodies to PLC-81 confirm that the Cat-307 protein is PLC-81. Finally, as we have shown for the Cat-307 protein, PLC-81 associates with a microsomal membrane fraction.

PLC-81 cleaves phosphatidyl inositol 4,5 biphosphate (PIP2) into two second messengers, inositol 1,4,5 triphosphate (IP3) and diacylglycerol (DAG). IP3 turnover has been linked to activation of the Q2 (or metabotropic) glutamate receptor and shows an increase in activity at the peak of the critical period in an experience-dependent manner (Dudek and Bear, Science, 246:673). Consistent with these findings, dark-rearing from birth delays the age-dependent reduction in Cat-307 immunoreactivity in primary visual cortex, but not in primary auditory or somatosensory cortices. Our data suggest a specialized locus of IP3 turnover in kitten, but not in adult, cortical neurons that may participate in protein transport. Supported by EY06511(SH) and EY06606(PK).

## 114.7

**NT-4/5 INFUSION ALTERS PLASTICITY AND RESPONSES OF CAT PRIMARY VISUAL CORTEX DURING THE CRITICAL PERIOD.** D.C. Gillespie\*, M.C. Crair and M.P. Stryker. Program in Neuroscience, Keck Center for Integrative Neuroscience, Dept. of Physiology, Univ. Calif., San Francisco, CA 94143-0444.

Neurotrophins have been implicated as signalling molecules in primary visual cortical development. To test for a role of NT-4/5 in physiological ocular dominance plasticity we infused NT-4/5 (0.2 mg/ml) into one hemisphere and vehicle control solution into the other hemisphere of four-week-old cats. After 2 days, monocular lid suture deprived the animal of pattern vision through one eye, a procedure that normally causes cortical cells to lose responsiveness to stimuli presented to the deprived eye. After 2 more days, orientation and ocular dominance maps were computed from intrinsic optical signals in response to blank and grating stimuli, and extracellular single-unit recordings were made near to and far from the infusion sites.

Optical images revealed a pattern dominated by the non-deprived eye in control areas, while signal near the infusion site was similar for the two eyes. Likewise, orientation columns were evident in control areas but absent close to the infusion site. Single units encountered within this area were largely binocularly driven, poorly selective or broadly tuned for stimulus orientation, and generally poorly responsive to visual stimuli. Cells at an intermediate distance from the infusion site were more responsive yet were still binocular and poorly tuned for stimulus orientation.

These results are consistent with a specific signalling role for NT-4/5 in normal development and plasticity, but they are also consistent with a less specific action such as induction of promiscuous sprouting in cortex.

## 114.4

**THE mGluR ANTAGONIST MCPG DOES NOT AFFECT GLUTAMATE-STIMULATED PHOSPHOINOSITIDE TURNOVER, LTP OR LTD IN DEVELOPING RAT VISUAL CORTEX.** K.M. Huber\*, N.B. Sawtell and M.E. Bear. Dept. Neuroscience, HHMI, Brown University, Providence, RI 02912.

Metabotropic glutamate receptors (mGluRs) coupled to phosphoinositide (PI) hydrolysis have been suggested to play a role in synaptic plasticity in the visual cortex. MCPG ((+)- $\alpha$ -Methyl-4-carboxyphenylglycine) reportedly can block many actions of the mGluR agonist ACPD (1-aminocyclopentane-(1S,3R)-dicarboxylic acid). Therefore, we investigated the effect of MCPG on long-term potentiation (LTP) and long-term depression (LTD) of field EPSPs (fEPSPs) in layer II-III elicited by stimulation of layer IV (L4) in slices prepared from mature (P35-50) rats and white matter (WM) of young (P14-28) rats. MCPG (0.25 mM) antagonized synaptic depression produced by ACPD (10  $\mu$ M). However, LTP of fEPSP amplitudes was reliably induced by theta burst stimulation of L4 or WM in the presence of MCPG (0.25-1 mM;  $118 \pm 4\%$  of baseline values;  $n = 9$  and  $123 \pm 8\%$ ;  $n = 8$ , respectively) and was not different from controls (L4  $117 \pm 2\%$ ,  $n = 10$ ; WM  $116 \pm 3\%$ ,  $n = 8$ ). Low frequency stimulation (900 pulses at 1 Hz) of L4 or WM in the presence of MCPG (0.25 mM) induced LTD of fEPSP amplitudes ( $77 \pm 3\%$ ;  $n = 6$  and  $81 \pm 8\%$ ;  $n = 4$  respectively) similar to control values (L4  $78 \pm 3\%$ ,  $n = 8$ ; WM  $87 \pm 4\%$ ,  $n = 5$ ). The significance of these results rests on the assumption that MCPG blocks glutamate-stimulated PI turnover in visual cortex. Therefore, we used a synaptosome preparation of visual cortex to assess the effectiveness of MCPG in blocking mGluR-mediated PI turnover. We confirmed that half-maximal stimulation of PI turnover by ACPD (30  $\mu$ M) was almost entirely blocked ( $16 \pm 6\%$  of control) by MCPG (1 mM). Surprisingly, however, half-maximal stimulation of PI turnover by the endogenous ligand glutamate (200  $\mu$ M) was still  $82 \pm 6\%$  ( $n = 3$ ) of control in the presence of 1 mM MCPG. Substantial blockade of glutamate-stimulated PI turnover required concentrations of MCPG in excess of 5 mM. These results suggest that glutamate may stimulate MCPG-insensitive mGluRs which are not activated by ACPD or, as proposed by previous work (Brabet et al., Neuropharm., 1995), glutamate and ACPD stimulation of mGluR1 and mGluR5 are differentially affected by MCPG. We conclude that MCPG is not a suitable compound to test the role of mGluRs in glutamate-mediated synaptic plasticity. Support: HHMI

## 114.6

**OCULAR DOMINANCE PLASTICITY IN MICE LACKING  $\alpha$ CaMKII OR PKC $\gamma$ .** J.A. Gordon\*, T.K. Hensch\*, D. Cioffi\*, C. Chen\*, A.J. Silva\*, S. Tonegawa\*, and M.P. Stryker. \*Keck Center for Integrative Neuroscience, Univ. of California, San Francisco, CA 94143; \*Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724; & \*MIT, Cambridge, MA 02139.

The recent characterization of plasticity in the mouse visual cortex permits the use of mutant mice to investigate the cellular mechanisms underlying activity-dependent development. As calcium-dependent signaling pathways have been implicated in plasticity, we examined plasticity in the visual cortex of mice with mutations in the genes encoding the  $\alpha$ -isoform of calcium/calmodulin-dependent protein kinase II ( $\alpha$ CaMKII) and the  $\gamma$ -isoform of Protein Kinase C (PKC $\gamma$ ).

In wildtype mice, brief occlusion of vision in one eye during a critical period reduces responses to that eye in the visual cortex. In half of the  $\alpha$ CaMKII-deficient mice, visual cortical responses developed normally, but visual cortical plasticity was greatly diminished. Even after intensive training, spatial learning in the Morris water maze remained severely impaired in a similar fraction of mutant animals. These data indicate that loss of  $\alpha$ CaMKII results in a severe but variable defect in neuronal plasticity.

Visual cortical plasticity was examined both *in vivo* and *in vitro* in PKC $\gamma$ -deficient mice. Visual cortical responses developed normally in these animals, and ocular dominance plasticity in response to monocular deprivation remained intact. In visual cortical slices taken from these animals, LTP and LTD were also intact. These data indicate that PKC $\gamma$  is not required for visual cortical plasticity. Since the refinement of climbing fiber innervation onto Purkinje cells is profoundly disrupted in these mice, the activity dependent organization of connections must occur via different molecular substrates in neocortical and cerebellar development. ## 114.8

**AN ENDOGENOUS LIGAND OF TRKB IS REQUIRED FOR OCULAR DOMINANCE SEGREGATION.** R. J. Cabelli\* and C. J. Shatz\*. @USC School of Medicine, Los Angeles, CA 90033 and #University of California, Berkeley, CA 94720.

The neurotrophins are a family of neurotrophic factors (incl. NGF, BDNF, NT-3, and NT-4/5) that regulate cell survival and other aspects of neuronal differentiation and function through interaction with their specific cellular receptors, trkA, trkB, and trkC, members of the trk family of receptor tyrosine kinases. We have been examining the hypothesis that neurotrophins can act as diffusible signals between pre- and post-synaptic nerve terminals to direct the modulation of synaptic efficacy and stability during development. The segregation of LGN axon terminals into ocular dominance (OD) columns in layer 4 of visual cortex is a particularly noted example of the activity and competition-based refinement of synaptic connections during development. We have shown recently that intracortical infusion of NT-4/5 or BDNF, but not NGF or NT-3, during the critical period for OD segregation inhibits the formation of eye-specific patches (Cabelli et al., 1995). This result would be predicted if OD segregation involved competition at the geniculocortical synapse between right and left eye-driven axons for limiting amounts of NT-4/5 and/or BDNF (both of which are ligands of trkB). However, this inhibition of OD segregation could instead be a pharmacological effect of infusing large amounts of these agents. To distinguish between these interpretations and determine whether OD segregation requires endogenous neurotrophins, we have infused neurotrophin antagonists into visual cortex during the critical period. These antagonists, constructed from the extracellular domain of each member of the trk family linked to the Fc tail of a human IgG, compete with native trk receptors for binding neurotrophins. Infusion of excess trkB-IgG protein, but not trkA-IgG or trkC-IgG, inhibits the formation of OD patches (assessed by ipsilateral intracortical injection of an anterograde transneuronal tracer) within 1-2 mm of the infusion site. Moreover, the density of transneuronal label is reduced in the affected region, in contrast to the robust increase in label density observed earlier with NT-4/5 infusion, consistent with NT-4/5 and/or BDNF being required for growth of terminal arbors. Together these two studies strongly support the hypothesis that OD segregation involves competition between LGN axons for an endogenous ligand of trkB, presented in limiting amounts within visual cortex. Supported by EY02858 (CJS).

ENDOGENOUS TrkB LIGANDS REGULATE DENDRITIC GROWTH IN DEVELOPING VISUAL CORTEX. A.K. McAllister\*, D.C. Lo, and L.C. Katz. Department of Neurobiology, Duke University Medical Center, Durham, NC, 27710.

Despite evidence that exogenous neurotrophins strongly influence structural plasticity in developing visual cortex, whether endogenous neurotrophins have similar functional roles is unclear. We have previously shown that exogenous TrkB ligands, especially BDNF, cause extensive growth of cortical dendrites in slices of developing visual cortex, implying that endogenous neurotrophins may be involved in regulating dendritic growth. To test this idea directly, we blocked endogenous TrkB ligands with receptor-bodies—chimeric proteins composed of Trk receptor ligand-binding domains fused to the human Fc IgG fragment—that bind BDNF and NT-4 with high specificity and affinity (Regeneron, unpublished data). Blocking endogenous TrkB ligands (20 µg TrkB-IgG) for 36 hours in P14 slices caused a 50% decrease in complexity of basal dendrites of layer 4 pyramidal neurons (n=50 cells) due to decreases in length and number of basal dendrites and branches. This effect was dose-dependent: 10 µg TrkB-IgG caused no decrease compared to untreated cells. TrkB-IgG treatment had negligible effects on apical dendrites (<10% decrease). To control for potential non-specific effects of receptor-bodies, we treated similar cortical slices with 20 µg TrkA-IgG. Blocking endogenous TrkA ligands caused no decrease in dendritic complexity (n=40 cells). This is a direct demonstration of the presence of endogenous, bioactive neurotrophins in neocortex and supports a role for TrkB ligands in regulating dendritic growth of pyramidal neurons. Supported by NIH EY07960 (L.C.K.), the Klingenstein Fund, the Alfred P. Sloan Foundation, NS 32742 (D.C.L.), and by a Broad Biomedical Research Foundation Fellowship (A.K.M.). Neurotrophins and receptor-bodies were generously provided by George Yancopoulos, M.D., Ph.D., Regeneron Pharmaceuticals.

ANATOMICAL DEMONSTRATION OF OCULAR DOMINANCE COLUMNS IN STRIATE CORTEX OF THE SQUIRREL MONKEY. J.C. Horton\*, D.R. Hocking. Dept. of Ophthalmology, UCSF, San Francisco, CA 94143-0730.

The squirrel monkey is the only primate reported to lack ocular dominance columns. Nothing anomalous about the visual capacity of squirrel monkeys has been found to explain their missing columns, leading to the suggestion that ocular dominance columns might be "an epiphenomenon, not serving any purpose" (Livingstone et al, 1995). Puzzled by the apparent lack of ocular dominance columns in squirrel monkeys, we made eye injections with transneuronal tracers in 4 normal squirrel monkeys. An irregular mosaic of columns, averaging 225 µm in width, was found throughout striate cortex. They were double-labelled by placing wheat germ agglutinin-horseradish peroxidase (WGA-HRP) into the left eye and [<sup>3</sup>H]proline into the right eye. The tracers labelled opposite sets of interdigitating columns, proving they represent ocular dominance columns. The columns were much clearer in layer IVα (magnoc-receiving) than IVβ (parvo-receiving). The parvo laminae of the lateral geniculate showed extensive mixing of ocular inputs, suggesting that increased label spillover accounted for the blurred columns in cortical layer IVβ. In the squirrel monkey the cytochrome oxidase (CO) patches were organized into distinct rows, but they bore no consistent relationship to the ocular dominance columns. These experiments indicate that striate cortex in squirrel monkeys differs in some respects from other primates, but it does contain ocular dominance columns. This fact is pertinent to a recent study reporting that ocular dominance columns are absent in normal squirrel monkeys, but induced to form by strabismus (Livingstone, 1996).

EFFECTS OF FAD-LINKED APP MUTATIONS ON THE SECRETION OF SOLUBLE FULL LENGTH APP. S. Erthmiopoulos\*, S. Punj, A. Wu and N.K. Robakis. Dept. Psych. And Fishberg Res. Cntr for Neurobiol., Mount Sinai Schl. of Med. New York, N.Y. 10029.

The Alzheimer's amyloid precursor family of proteins (APP) are considered type I transmembrane glycoproteins. Cleavage of APP by secretases close to the junction of the extracytoplasmic and transmembrane sequence results in the secretion of APP (APPs) that does not contain the cytoplasmic domain. However, we identified a soluble APP species of about 130 kDa termed solAPPcyt, containing all of the cytoplasmic and Aβ sequence of APP. This observation suggested that in addition to the transmembrane topology, full length APP also assumes a soluble topology. We found that depolarization and cholinergic agonists stimulate secretion of the potentially amyloidogenic solAPPcyt from both mouse brain synaptosomes and primary chromaffin cells which display neuronal physiology. Furthermore we found that solAPPcyt is present in human CSF and, in lower levels, in human serum. These results suggest that solAPPcyt is secreted in neuronal synapses where it may exert its biological functions. We used CHO cells transfected with wild type or mutated APP carrying all FAD-linked mutations to determine the effects of these mutations on the secretion of the potentially amyloidogenic solAPPcyt. Our data showed that all these mutations increased secretion of solAPPcyt. Our hypothesis is that FAD-linked APP mutations cause Alzheimer's Disease by increasing secretion of solAPPcyt and interfering with its synaptic function (Supported by NIH grant AG08200 and a Zenith Award from the Alzheimer's Association)

## 114.10

ORIENTATION TUNING OF SINGLE CELLS AT "PINWHEEL" ORIENTATION SINGULARITIES IN KITTEN VISUAL CORTEX. E.S. Ruthazer\*, M.C. Crair, D.C. Gillespie and M.P. Stryker. Keck Center, Dept. of Physiology, Univ. of California, San Francisco, CA 94143-0444

We studied the receptive field properties of primary visual cortical neurons in critical period kittens using a combination of optical imaging of intrinsic signals and extracellular single unit recording. At "pinwheel centers" of the orientation map, representations of the full range of orientation about one another (Bonhoeffer and Grinvald, 1991). Optical imaging shows no or poor orientation tuning at these singularities, but it has not been clear whether this results from poorly tuned cells or the averaging of signals from well tuned cells of very different preferred orientations. In addition, both models of the development of orientation and ocular dominance columns (Miller, 1994) and recent findings localizing deprived-eye responses to pinwheel centers in monocularly deprived kittens (Crair et al., in preparation) suggest that cells at pinwheel centers are broadly tuned, at least early in development.

Electrode penetrations targeted for pinwheel centers were more likely to encounter clusters of poorly tuned cells than were control penetrations. The localization of penetrations to pinwheel centers was confirmed by the abrupt change in preferred orientation of units immediately before and after a cluster of poorly tuned cells. For all kittens (n=5) in which pinwheels were targeted with multiple electrode penetrations, clusters of a similar nature were found. The regions of poor orientation tuning must be very small, since often multiple electrode penetrations guided by the optical map were necessary to find them. Results suggest that development of orientation selectivity in kitten visual cortex is delayed in regions of singularity in the orientation map.

## 115.2

THE SWEDISH MUTATION OF β AMYLOID PRECURSOR PROTEIN INCREASES Aβ PRODUCTION IN GLIAL CELLS BUT NOT NEURONAL CELLS. M.S. Forman, D. Cook, S. Leight, D. Schenk, T. Iwatsubo, R. Doms and V.M.-Y. Lee\*. Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA 19104

Missense mutations in the gene encoding the amyloid precursor protein (APP) have been identified in early onset Alzheimer's disease kindreds. In a large Swedish kindred, a double mutation was identified immediately N-terminal to the Aβ peptide region. In various cell lines, this mutation causes a dramatic increase in the secretion of Aβ. We examined the effect of overexpression of the Swedish mutation (APP<sup>SW</sup>) relative to wild-type APP in glial cells and the neuronal cell line NT2/N, (a teratocarcinoma cell line terminally differentiated with retinoic acid). In the NT2/N cells, Aβ was previously demonstrated to be detectable both intracellularly as well as in the media. Consistent with previous work from several laboratories, APP<sup>SW</sup> causes a dramatic increase in the secretion of Aβ in primary astrocytes. However, in the neuronal cell line NT2/N, APP<sup>SW</sup> does not increase Aβ secretion. Moreover, APP<sup>SW</sup> does not cause an increase in intracellular Aβ in this neuronal cell line; while, in several non-neuronal cell lines it increases intracellular Aβ to detectable levels.

To further assess the effects of the Swedish mutation, we examined the production of proteolytic fragments of APP during intracellular processing. In the NT2/N cells, primary astrocytes and several non-neuronal cell lines, APP<sup>SW</sup> results in a large increase in APPsβ detected in the media with a relative decrease in APPsα. In addition, the mutation leads to the intracellular production of both APPsβ and C99. Thus, the γ-secretase activity is not increased in the NT2/N cells relative to the non-neuronal cells. This data suggests that in Alzheimer's disease involving Swedish family kindreds, the mutation exerts its effect on the glial cells.

## 115.3

**EFFECTS OF PRESENILIN MUTATIONS ON THE DEPOSITION AND PRODUCTION OF AMYLOID  $\beta$  PROTEIN.** T. Iwatsubo<sup>1</sup>, D.M.A. Mann<sup>2</sup>, T. Tomita<sup>1</sup>, T. Kosaka<sup>1</sup>, S. Tokuyoshi<sup>1</sup>, R. Hosoda<sup>1</sup>, K. Obata<sup>1</sup>, T.C. Saido<sup>1</sup>, K. Maruyama<sup>1</sup>, 1 Dept. of Neuropathol. & Neurosci., Univ. of Tokyo 2 Dept. of Pathol. Sci., Univ. of Manchester, UK 3 Lab. of Neurochem., N.I.P.S. 4 Tokyo Metr. Inst. Med. Sci., Japan

To clarify the pathomechanisms whereby presenilin (PS) mutations cause familial Alzheimer's disease (FAD), and especially their relevance to the production and deposition of amyloid  $\beta$  protein (A $\beta$ ), we have examined the frontal cortex of 8 cases of FAD with 5 different PS1 mutations and 6 cases with PS2 mutation (141N-I) using immunocytochemistry specific for the A $\beta$  C-terminus. The density and percentage area of A $\beta$ 42(43)-positive (=total) senile plaques (SP) were both markedly increased in PS1 mutants, these being double those in sporadic AD (sAD) and elderly Down's syndrome (eids) cases and at comparable levels to those in FAD with BAPP717 mutations (FAD717). However, the percentage of A $\beta$ 40- to A $\beta$ 42(43)-positive SP in PS1 mutants was 38% (on a density basis) and 28% (on and area basis), levels similar to those in sAD and eids, but far higher than those in FAD717 (8% and 2%, respectively). The amount of A $\beta$ 42(43)-positive SP in PS2 mutants was slightly higher than or similar to that in sAD or eids; the percentage of A $\beta$ 40-positive SP was also at similar levels. These results suggest that, as with BAPP mutations, mutations in PS1 and PS2 may also enhance the deposition of A $\beta$ 42(43) through an increase in production and thereby cause AD, although the pathomechanism and the C-terminal properties of deposited A $\beta$  seem different from those in FAD717. We have transfected PS1 and PS2 genes, with or without mutations, to cultured cells expressing BAPP and quantitated the amount and C-terminal properties of secreted A $\beta$  by ELISAs. The results will be discussed in relation to our morphometric data on A $\beta$  deposition *in vivo*. (Supported by Grants from the Ministry of Education, Science and Culture, Japan)

## 115.5

**STABLE EXPRESSION OF MUTANT PRESENILINS HAS DIFFERENTIAL EFFECTS ON A $\beta$ 42 AND A $\beta$ 40 PRODUCTION.** M. Citron<sup>\*</sup>, T.S. Diehl, R. Sherrington<sup>1</sup>, P. St. George-Hyslop<sup>1</sup> and D.J. Selkoe. Harvard Medical School, Boston, MA; and <sup>1</sup>University of Toronto, Canada.

Humans harboring mutations in the presenilin genes undergo progressive cerebral deposition of the amyloid  $\beta$ -protein (A $\beta$ ), including A $\beta$ 42, at an early age and develop a severe form of Alzheimer's disease (AD). A previous study (Scheuner et al., 1995) has shown that A $\beta$ 42 is selectively elevated in the plasma of individuals with presenilin mutations, suggesting that these mutations influence BAPP processing. We have extended this analysis by generating several stable 293 human embryonic kidney cell lines doubly transfected with BAPP and a presenilin gene in its wild type or mutant form. The cell lines were analyzed for levels of all secreted BAPP metabolites, full-length BAPP, its C-terminal fragments and presenilin. Using end-specific antibodies in ELISA and immunoprecipitation assays, we examined the influence of presenilin mutations on BAPP processing. We did not find a significant effect of presenilin mutations on the levels of full-length BAPP,  $\alpha$ -APPs,  $\beta$ -APPs and A $\beta$ 40. However, in all presenilin mutant cell lines analyzed the A $\beta$ 42/A $\beta$ 40 ratios were about twofold increased relative to untransfected or PS1 wild-type transfected cells. This effect occurred in cell lines transfected either with BAPP wild-type, in which most A $\beta$  is produced in the endocytic pathway, or BAPPsw, in which most A $\beta$  is produced in the secretory pathway. Variations in the presenilin expression levels had no effect on the extent of the increase. These data are consistent with the results of Scheuner et al. and suggest that (i) presenilin mutations cause a gain rather than a loss of function; (ii) they lead to increased cleavage by a 42-specific  $\gamma$ -secretase in both the secretory and endocytic pathways; and (iii) only catalytic amounts of mutant presenilins are needed to cause the increased A $\beta$ 42 production. Supported by AG05134.

## 115.7

**ANALYSIS OF PRESENILIN 1 IN BRAIN AND CULTURED CELLS.** L.M. Refolo<sup>\*</sup>, Y. Harigaya, L. Younkin, C.B. Eckman, K. Sambamurti, C.M. Prada, D. Yager, and S.G. Younkin. Mayo Clinic Jacksonville, Jacksonville, FL 32224

Our recent analysis of fibroblasts and plasma from subjects with 6 different presenilin 1/2 (PS1/2) mutations linked to familial AD indicates that these mutations increase the extracellular concentration of A $\beta$ 1-42(43). As part of our effort to determine whether this effect is related to alteration(s) in PS1/2 processing, we prepared rabbit antisera to synthetic peptides corresponding to PS1 amino acids 1-14, 57-70, and 333-345. After affinity-purification, each antiserum was used to label immunoblots of lysates prepared from baby hamster kidney (BHK) cells or BHK cells infected with Semliki Forest Virus (SFV) expressing PS1 with a 9 amino acid HA tag inserted between amino acids 44 and 45 (generously provided by DG Cook, RW Doms, and VM-Y Lee, University of Pennsylvania). Anti-HA and each of the anti-PS1 antisera detected an ~46 kD protein that was markedly augmented in the SFV-PS1 infected cells. That this augmented protein was detected by antisera to 4 different epitopes in HA-tagged PS1 provides strong evidence (i) that the ~46 kD protein is authentic PS1 and (ii) that each of our antisera to PS1 are useful for detecting PS1 on immunoblots. Using these antisera, we also detected several high molecular weight bands as well as putative N- and C-terminal PS1 derivatives that were augmented in SFV-PS1 infected cells and detected appropriately by the various antisera to PS1 peptides. Thus PS1 may normally be processed into smaller derivatives. In rat and human brain and in other cultured cells, proteins similar in size to those identified in BHK cells (e.g. the 46 kD protein) were detected by our antisera, with anti-PS157-70 showing the strongest labeling. In addition, a "non-augmenting" ~52 kDa protein was labeled by all 3 antisera to PS1 peptides. We are currently (i) using an immunoaffinity approach to isolate the various proteins recognized by our antisera for sequencing and specific identification and (ii) using our antisera to analyze A $\beta$  secretion and PS1 processing in transfected cells expressing mutant vs. wild type PS1.

Lannfelt<sup>18</sup>, D. Selkoe<sup>19</sup>, and S. Younkin<sup>20</sup>. Depts. <sup>1</sup>Neuroscience & <sup>2</sup>Pathology, Case Western Reserve U., Cleveland, OH, <sup>3</sup>Huddinge Univ. Hosp., Huddinge, Sweden, <sup>4</sup>Harvard Med. School and Brigham and Women's Hosp., Boston, MA, <sup>5</sup>Takeda Chemical Industries, Tsukuba, Japan, <sup>6</sup>Dept. of Neurology & <sup>7</sup>Geriatric Research, Education, and Clinical Ctr (182B), VA Med. Ctr, Seattle, WA, <sup>8</sup>Dept. of Psychiatry, Univ. of S. Florida, Tampa, FL, <sup>9</sup>Dept. of Medicine, Univ. of Washington, Seattle WA, <sup>10</sup>Dept. of Neurology, Massachusetts General Hosp., Charlestown, MA, <sup>11</sup>Mayo Clinic Jacksonville, Jacksonville, FL 32224

Amyloid  $\beta$  protein (A $\beta$ ) ending at A $\beta$ 42(43) [A $\beta$ 42(43)] is deposited early and selectively in the senile plaques that are an invariant feature of all forms of Alzheimer's disease (AD). To determine whether the presenilin 1 (PS1), presenilin 2 (PS2), and amyloid  $\beta$  protein precursor (APP) mutations linked to familial AD (FAD) increase the extracellular concentration of A $\beta$ 42(43) *in vivo*, we performed a blinded comparison of plasma A $\beta$  levels in carriers of these mutations and controls. A $\beta$ 1-42(43) was elevated in plasma from subjects with FAD-linked PS1 (8 symp, 1 presym; p<0.0001), PS2N141I (3 symp; p=0.003), APPK670N,M671L (7 presym, 5 symp; p<0.0001), and APPV717I (one subject) mutations. A $\beta$  ending at A $\beta$ 42(43) was also significantly elevated in fibroblast media from subjects with PS1 (p<0.0001) or PS2 (p=0.0005) mutations. These findings indicate that the FAD-linked mutations may all cause AD by increasing the extracellular concentration of A $\beta$ 42(43) thereby fostering deposition of this highly amyloidogenic peptide. In 62 of 71 sporadic AD subjects plasma A $\beta$ 1-42(43) was not elevated, but it was elevated into the FAD range in 9 of the subjects with sporadic AD.

## 115.6

**FAD-LINKED MISSENSE MUTATIONS IN PRESENILIN 1 INCREASE A $\beta$ 42 PRODUCTION IN STABLY TRANSFECTED CHO CELLS.**

W. Xia<sup>\*</sup>, J. Zhang, E.H. Koo, D.J. Selkoe. Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

The *presenilin 1* (PS1) gene on chromosome 14 was recently identified as the major cause of early onset familial Alzheimer's disease (AD). A previous study of fibroblasts obtained from FAD patients with PS1 mutations indicates a selective increase of A $\beta$ 42 in the media. To study the mechanism of the mutant gene product in the pathogenesis of AD, Chinese hamster ovary (CHO) cells stably expressing wildtype (wt) or mutant (M146L, C410Y) PS1 genes were generated and the effects of wt and mutant PS1 proteins on A $\beta$  production were examined. Introduction of PS1 genes into BAPP-transfected CHO cells did not alter the synthesis of BAPP, as determined by metabolic labeling and quantitation of BAPP in these cells. Several clones with different levels of PS1 expression of each cell line stably expressing wt or mutant PS1 were randomly selected and tested for A $\beta$  production. Immunoprecipitation of conditioned media with antibodies specific for A $\beta$ 42 and total A $\beta$  showed a relative increase of A $\beta$ 42 levels in cells expressing mutant PS1 genes, while total A $\beta$  remained unchanged. Mutant PS1-expressing cells had 1.4 to 2.5 fold increases of A $\beta$ 42/A $\beta$ total ratios when compared to wildtype PS1-expressing cells, and this increase was statistically significant. The level of A $\beta$ 42 increase was not clearly correlated with the level of PS1 expression. Low MW oligomers (6-16 kD) of A $\beta$ 42 were observed in immunoprecipitates of the conditioned media of some mutant PS1 cell lines having the largest increases in A $\beta$ 42/A $\beta$ total ratio. Taken together, our data support the hypothesis that mutations in the PS1 protein affect BAPP processing in a way that leads to increased A $\beta$ 42 production and deposition, thus causing the premature development of AD. Supported by NIH grant AG05134 (DJS), AG12376 (EHK).

## 115.8

**PROTEIN CHARACTERIZATION OF THE EARLY ONSET FAMILIAL ALZHEIMER'S DISEASE GENE PRODUCTS, PRESENILIN 1 AND PRESENILIN 2.** D. J. Selkoe<sup>\*</sup>, W. Xia, J. Zhang, M. B. Podlisny, P. Amarante, C. Haass, P. H. St. George-Hyslop, D.B. Teplow, E. H. Koo, and M. Citron. Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

The majority of cases of early onset familial Alzheimer's disease is caused by mutations in the *presenilin 1* gene (PS1) located on chromosome 14 and *presenilin 2* (PS2) gene located on chromosome 1. To gain insight into the biology of the PS1 and PS2 proteins, the PS1 or PS2 gene was expressed in transiently-transfected COS cells. Using immunoprecipitation and Western blotting with a C-terminal specific antibody, the PS1 protein was identified as a ~43-45 kDa doublet, and the PS2 gene product had a similar apparent MW. BAPP protein was not found to be directly associated with the PS1 and PS2 proteins, because preclearing cell lysates with BAPP antibody did not change the band patterns of PS1 and PS2 upon subsequent immunoprecipitation with the PS1/PS2 antibody. Furthermore, no BAPP was detected on Western blots of PS1/PS2 immunoprecipitates probed with BAPP antibodies. Radiolabeled sequencing of the PS1 doublet immunoprecipitated by the C-terminal antibody showed that both species were intact PS1 protein starting at the first methionine residue. The half-life of both of these full-length PS1 proteins in COS cells was the same (<60-90 min), and they exhibited no clear precursor-product relationship. These data suggest that PS1 proteins do not undergo significant maturation after their synthesis. We have also generated CHO cells stably expressing both wildtype and mutant PS1 or PS2 proteins, and a comparison of the biosynthesis and processing of PS1 and PS2 proteins is in progress. Supported by NIH grant AG12749 (DJS).

## 115.9

ALZHEIMER'S AMYLOID PRECURSOR PROTEIN PROCESSING: CATHEPSIN D EXHIBITS  $\gamma$ -SECRETASE ACTIVITY. Harry F. Dovey\*, Susanna Suomensaar, Patrice de St. Andrieu, Robin Barbour, Sukanto Sinha, Peter Seubert, Dale B. Schenk, Ivan Lieberburg, and Varghese John. Athena Neurosciences, Inc., 800 Gateway Boulevard, South San Francisco, California, 94080, USA.

The enzymes responsible for the proteolytic processing of the  $\beta$ -amyloid precursor protein (APP) to produce the  $\beta$ -amyloid peptide (A $\beta$ ), found in the senile plaques associated with Alzheimer's disease (AD), are potential targets for therapeutic intervention in AD. The protease responsible for the COOH-terminal cleavage has been termed  $\gamma$ -secretase, and has yet to be conclusively identified. In this study, an endogenous protease, found in the lysosomal/endosomal fraction of both normal and AD brain, has been shown to cleave an endogenous, amyloidogenic fragment of APP under acidic conditions to produce a COOH-terminal fragment ( $\gamma$ -CTF) consistent with  $\gamma$ -secretase activity. The pH and inhibitor profiles of this activity suggest that of an aspartyl protease. The  $\gamma$ -CTF generating activity could be removed by pepstatin-agarose chromatography, and an identical cleavage pattern restored by addition of cathepsin D (CD) (EC 3.4.23.5), suggesting that CD has  $\gamma$ -secretase activity. This suggestion was further supported by the ability of CD to appropriately cleave baculovirus-produced APP<sub>751</sub> and *in vitro* translated, radiolabelled APP<sub>589-695</sub>. Significantly, CD cleavage of a fusion protein, containing the COOH-terminal 125 amino acids of APP, at the COOH-termini of A $\beta$ 40 and A $\beta$ 42 was demonstrated with highly specific ELISAs. In addition, the aspartyl protease inhibitor pepstatin A and the A $\beta$  COOH-terminus are homologous, and analogs of the A $\beta$  COOH-terminus were nanomolar inhibitors of CD, further suggesting an affinity of CD for this region of APP. Based on these findings, CD appears to be a putative  $\gamma$ -secretase, and may be a therapeutic target for AD.

## 115.11

CELLULAR SYSTEM FOR THE ANALYSIS AND SCREENING FOR AMYLOID PRECURSOR PROTEIN (APP) SECRETASE ACTIVITIES. T. Dyrks, M. Härtel, D. Marmé, and J. Turner\*, Research Laboratories of Schering AG, CNS-Research, D-13342 Berlin, Germany

There is good evidence for a central aetiological role for A $\beta$ 42 deposition in Alzheimer's disease. Three distinct proteolytic activities (termed  $\alpha$ -,  $\beta$ - and  $\gamma$ -secretases, but not yet identified) are involved in APP processing resulting in the generation of secretory APP (APPsec) and amyloidogenic A $\beta$ 42 peptide. Compounds which inhibit selectively  $\beta$ - or  $\gamma$ -secretase, or stimulate  $\alpha$ -secretase activity should inhibit A $\beta$ 42 generation and thus deposition. The establishment of cell culture systems for the screening of each secretase activity is an essential step for the identification of selective secretase-inhibiting compounds.

To achieve this, APP reporter constructs, each containing the secretase recognition site of only one of the three APP-secretases are being generated. Neuronal cells which are known to process APP appropriately have been transfected with these constructs to produce stable cell lines expressing APP reporter constructs specific for each of the three secretase activities. The constructs are correctly processed and the released reporter into the medium indicates processing of the construct by the target protease. Pharmacological modulation correlates with that of APP processing.

## 115.13

PKC REGULATED AMYLOID PRECURSOR PROTEIN PROCESSING IN YEAST. M. Seeger<sup>1,2\*</sup>, R. S. Fuller<sup>3</sup>, H. Komano<sup>3</sup>, H. Riedel<sup>4</sup>, J. Greenfield<sup>1</sup>, P. Greengard<sup>2</sup> and S. Gandy<sup>1</sup>. <sup>1</sup>Dept. of Neurology & Neurosci., Cornell Univ. Med. Coll., NY, NY 10021; <sup>2</sup>Lab of Mol. and Cell. Neurosci., Rockefeller Univ., NY, NY 10021; <sup>3</sup>Dept. of Biochem., Univ. of Michigan, Ann Arbor, MI 48109; <sup>4</sup>Joslin Diabetes Center, Harvard Med. School, Boston, MA 02215

Amyloid precursor protein (APP) is processed by a secretase yielding a non-amyloidogenic secreted fragment (sAPP). This processing pathway can be stimulated by phorbol esters, which activate protein kinase C (PKC), resulting in increased secretion of sAPP and decreased secretion of the amyloidogenic peptide, A $\beta$ , a product of the  $\beta$ -secretase pathway. The target upon which PKC acts to cause these effects is yet to be identified.

We have developed a genetically manipulable system in which to analyze the regulation of APP processing in response to stimulation of PKC. Human APP has been expressed in the yeast, *Saccharomyces cerevisiae*. A secretase cleavage of APP occurs in yeast, resulting in release of proteolytic fragments (including sAPP), and the retention of carboxyl terminal fragments which are identical to those formed in mammalian cells. In yeast strains that over-express both human APP and rat PKC $\alpha$ , there is an increase in the release of sAPP in response to PKC activation with phorbol esters. Since the secretory pathway of yeast has been well characterized, this host system should provide an excellent setting within which to gain insight into the mechanisms by which APP processing is regulated. ## 115.10

EVIDENCE THAT A $\beta$ 42 AND A $\beta$ 40 ARE GENERATED BY DIFFERENT PROTEASES. T.S. Diehl, M. Citron, Grace Gordon<sup>1</sup>, D. Hartley\*, P. Seubert<sup>1</sup>, and D.J. Selkoe. Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115; <sup>1</sup>Athena Neurosciences Inc., San Francisco, CA 94080.

Alzheimer's disease is characterized by the progressive formation in the brain of insoluble amyloid plaques consisting of the 4 kDa amyloid  $\beta$ -peptide (A $\beta$ ). A $\beta$  deposits show both N- and C-terminal microheterogeneity, and recent data indicate that the long tail A $\beta$ 42 form, although accounting for only 10% of secreted total A $\beta$ , is deposited in the earliest phase of the disease and remains the major constituent of most amyloid plaques throughout the disease. Thus, inhibition of A $\beta$ 42 production is a prime therapeutic goal. The proteases which cleave A $\beta$  from its precursor have not been identified, but the same  $\gamma$ -secretase is assumed to generate the C-termini of both A $\beta$ 40 and A $\beta$ 42.

We have analyzed the effect of the compound MDL28170 (gift of Marion Merrell Dow, Inc.), previously suggested to inhibit  $\gamma$ -secretase (Higaki et al., 1995), on BAPP processing. By immunoprecipitating media of different cell lines with various 40 and 42 specific antibodies, we demonstrate a much stronger inhibition of the  $\gamma$ -secretase cleavage at residue 40 than of that at residue 42, strongly suggesting that two different proteases cleave at residue 40 and 42. Our data suggest that the initial steps of A $\beta$ 40 and A $\beta$ 42 generation occur in the same pathway, perhaps up to the point of  $\gamma$ -secretase cleavage. At this step, the same 12 kDa precursor can give rise to both A $\beta$ 40 and A $\beta$ 42 and the same 10 kDa precursor can lead to both p340 and p342. Our findings have significant therapeutic implications, because they raise the possibility of identifying compounds which do not interfere with 90% of total A $\beta$  production and most steps of BAPP metabolism but specifically block the generation of the pathogenic A $\beta$ 42 peptide. Supported: AG05134.

## 115.12

METABOLISM OF AMYLOID  $\beta$ -PROTEIN IN CULTURED MAMMALIAN CELLS. R. Wang<sup>1\*</sup>, S. Gandy<sup>2</sup>, S.S. Sisodia<sup>3</sup>, B.T. Chai<sup>1</sup>. <sup>1</sup>Lab. for Mass Spectrometry, The Rockefeller Univ., New York, NY 10021; <sup>2</sup>Lab. of Alzheimer Research, Cornell Univ. Med. Coll., New York, NY 10021; <sup>3</sup>Neuropathology Lab., The Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

Amyloid  $\beta$  protein (A $\beta$ ) is the primary component found in senile plaques of Alzheimer's disease (AD) and is constantly produced and secreted from cells by proteolytic processing of its precursor protein, amyloid precursor proteins (APP). Various forms of A $\beta$  peptides have been identified from plaques, neurofibrillary tangles and cerebrovascular amyloid fibrils of AD patients. Soluble A $\beta$  (sA $\beta$ ) species were also found in cerebrospinal fluid (CSF), blood and cultured cell media. Recently, we have investigated the sA $\beta$  peptide profile in conditioned media of mouse neuroblastoma cells (N2a) transfected with human APP cDNAs using a newly developed immunoprecipitation/mass spectrometry (IP/MS) method. The sA $\beta$  profile has revealed a complex mixture. More than forty different A $\beta$ -related peptide species were identified. Time-course experiment indicated that these A $\beta$  peptide fragment may generated either from metabolism of A $\beta$  or from alternative proteolytic processing of APP or both. We further investigated the A $\beta$  metabolism in cultured mammalian cells using IP/MS. The proteolytic cleavage products of synthetic A $\beta$  in conditioned medium of N2a cells were characterized. The differences in both proteolytic cleavage pattern and degradation kinetics between A $\beta$ 1-40 and A $\beta$ 1-42 have been compared. The involvement of whole cell in the proteolytic degradation of A $\beta$  were also examined. This study classified the origins and pathways for the observed A $\beta$  fragments.

## 115.14

REGULATION OF ALZHEIMER  $\beta$ -AMYLOID PROTEIN PRECURSOR METABOLISM IN CELL-FREE SYSTEMS. H. Xu<sup>1,2</sup>, D. Sweeney<sup>1</sup>, R. Wang<sup>3</sup>, G. Thinakaran<sup>4</sup>, S. Sisodia<sup>4</sup>, P. Greengard<sup>2</sup>, and S. Gandy<sup>1</sup>. <sup>1</sup>Lab. of Alzheimer Research, Cornell Univ. Med. Coll., New York NY 10021; <sup>2</sup>Lab. of Molecular & Cellular Neuroscience; <sup>3</sup>Lab. for Mass Spectrometry, Rockefeller Univ., New York, NY 10021; <sup>4</sup>Neuropathology Lab., The Johns Hopkins Univ., Baltimore, MD 21205.

The  $\beta$ -amyloid protein (A $\beta$ ), a major component of parenchymal deposits in Alzheimer's disease, is generated by proteolytic cleavage from the  $\beta$ -amyloid precursor protein (BAPP). The relative utilization of alternative processing pathways for BAPP can be regulated by the activation state of certain protein phosphorylation signal transduction pathways (e.g., activation of protein kinase C (PKC), or inactivation of protein phosphatases). Recently, we have demonstrated in a reconstituted cell-free system that PKC increases formation from the *trans*-Golgi network (TGN) of secretory vesicles containing BAPP, revealing a major mechanism by which BAPP metabolism is controlled. Unfortunately, from a therapeutic standpoint, PKC activation can stimulate BAPP transcription, indirectly increasing A $\beta$  formation. Since there are many examples wherein multiple protein kinases can exert similar regulatory effects, we tested whether protein kinase A (PKA) might also regulate BAPP metabolism. PKA-activating reagents increased sBAPP secretion from intact PC12 cells and, by using an *in vitro* reconstitution system, purified PKA also stimulated formation of BAPP-containing vesicles from the TGN. Although PKA and PKC converge at the level of formation of BAPP-containing vesicles, additional evidence (e.g., sensitivity to GTP $\gamma$ S or okadaic acid) indicates that the regulatory mechanisms involved are distinct. In addition, we have successfully reconstituted A $\beta$  formation using a cell-free system previously developed to reconstitute proteolytic cleavage of prohormones. This cell-free system can enable us to dissect as separate events, either A $\beta$  generation or the formation of nascent TGN vesicles containing A $\beta$  or BAPP. This study should lead us to the identification of intracellular compartment(s) involved in A $\beta$  cleavage.

**LESIONS OF THE CEREBELLAR NUCLEI DO NOT IMPAIR THE ACQUISITION OF A VISUAL-MOTOR CONDITIONAL LEARNING TASK.** R.E. Passingham\* and P.D. Nixon Department of Experimental Psychology, University of Oxford, Oxford OX1 3UD.

Several recent reports have claimed that patients with cerebellar pathology have cognitive as well as motor deficits. However, it is not certain that in these studies the pathology was confined to the cerebellum.

We have addressed the issue by training monkeys on a task which requires the monkeys to learn an association between two coloured visual patterns and two movements of a joystick. Bilateral excitotoxic lesions were then made in the lateral cerebellar nuclei of 3 of the animals; the remaining 3 served as unoperated controls. When retested 3 weeks later, the operated animals made more errors than animals in the control group. However, this may have been the consequence of a motor impairment which gradually resolved with testing.

When the same animals were given two new visual stimuli to associate with the same two joystick movements, there were no significant differences between the groups on either the number of trials required to learn the new associations or the number of errors made. This result suggests that restricted cerebellar damage does not itself impair associative learning.

We are now checking whether there is a genuine retention impairment by making identical lesions in the control animals, and retesting them on both versions of the task. Any motor impairments should be resolved during the relearning of the first task, and thus not contaminate the retention scores for the second.

Supported by a Wellcome Trust Program Grant (038041/Z/93).

**IMPAIRED TRACE EYEBLINK CONDITIONING IN MEDIAL TEMPORAL AMNESIA**

R. McGlinchey-Berroth<sup>1,2</sup>, M. Carrillo<sup>3</sup>, C. Brawn<sup>2</sup>, J.D.E. Gabrieli<sup>4</sup>, L.S. Cernak<sup>2</sup>, J.F. Disterhoft<sup>3</sup>. 1 Geriatric Research, Education and Clinical Center, Brockton/West Roxbury VAMC, W. Roxbury MA; 2 Memory Disorders Research Center, Boston VAMC, Boston, MA; 3 Northwestern University, Chicago, IL; 4 Stanford University, Stanford, CA.

The precise role of the hippocampus in trace eyeblink conditioning has been difficult to resolve since animal studies have shown impaired acquisition in hippocampectomized rabbits (Kim et al. 1996; Moyer 1990; Solomon, 1986), while human studies have found intact acquisition in two bilateral human patients (Woodruff-Pak, 1994). In our study, acquisition of trace conditioning in human amnesics was tested in 3 experiments that differed only in the duration of the trace interval. Subjects were 7 bilateral amnesic patients (AM: 5 post-encephalitis, 2 anoxic) and age, educ. and VIQ matched control subjects (NC). All subjects participated in each experiment. Sixty conditioning trials were presented using a 100 msec, 1000 Hz, 85 db tone (CS) presented binaurally through headphones. The unconditioned stimulus (UCS) was a corneal airpuff (3 psi), 100 msec in duration delivered to the right eye. Trace interval from CS offset was 500 (T500), 750 (T750) or 1000 (T1000) msec, run in separate sessions at least 2 weeks apart. Following conditioning, subjects received 30 extinction trials during which the CS was presented alone. The mean %CRs for T500 were 40.5 for AM and 58.3 for NC; for T750 were 48.6 for AM and 71.4 for NC; and for T1000 were 40.1 for AM and 70.6 for NC. ANOVAs with Group and Trial Block (1-12) revealed significant effects of Group at each interval and a Block effect for T500. These data indicate that bilateral medial temporal lobe damage does disrupt acquisition of trace eyeblink conditioning. The magnitude of the impairment appears to vary linearly with trace interval. **EXTENDING MODELS OF HIPPOCAMPAL FUNCTION IN ANIMAL CONDITIONING TO HUMAN AMNESIA,**

M. A. Gluck\*, B. R. Ermita, L. M. Oliver, and C. E. Myers. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Although most analyses of amnesia have focused on the loss of declarative memories following hippocampal-region damage, considerable insights into amnesia can also be realized through the study of simple procedural, or habit-based, associative learning tasks. In several recent papers we have described a computational theory of hippocampal function in classical conditioning, which argues that this brain region plays a critical role in the formation of new stimulus representations during learning; when applied to conditioning studies in both intact and hippocampal-lesioned animals, the model correctly accounts for a broad range of empirical data and makes numerous novel predictions (Gluck & Myers, 1993, 1995; Myers & Gluck, 1995; Myers, Gluck, & Granger, 1995). More recently, we have shown how this model can also be applied to studies of category learning in both normals and hippocampal-damaged amnesics (Gluck, Oliver & Myers, 1996/*in press*). This theoretical modeling integrates experimental studies of amnesic category learning (Knowlton, Squire, & Gluck, 1994) with theoretical accounts of associative learning, and builds on previously established behavioral correspondences between animal conditioning and human category learning (Gluck & Bower, 1988). We show here how the cortico-hippocampal model of Gluck and Myers (1993) can be applied to the processing of integral vs. separable stimuli in classification learning, and to the phenomena of categorical perception in learning.

## 116.2

**IS THE HUMAN CEREBELLUM REQUIRED FOR THE STORAGE OF CONDITIONED EYEBLINK MEMORY TRACES?** V. Bracha, D. A. Wunderlich, L. Zhao, L. Brachova\* and J.R. Bloedel, Barrow Neurological Institute, Phoenix, AZ 85013

Human subjects with cerebellar pathologies have greatly impaired capacity to acquire classically conditioned eyeblink responses (CR). Is the human cerebellum equally important also for retention of CRs? The answer to this question would require the identification of conditioned responses which are acquired naturally before the occurrence of any cerebellar abnormality. In the present experiments we examined visually-triggered anticipatory eyeblinks in a group of patients who in our previous study failed to acquire blinking responses in a traditional classical conditioning paradigm.

The cerebellar patients exhibited normal eyeblinks triggered by a ball quickly approaching and eventually hitting their forehead. These eyeblinks were generated well before the actual impact of the ball. The anticipatory eyeblinks also could be extinguished when the ball was repeatedly stopped before contacting the forehead and could be quickly reacquired when the ball impact was resumed. The possibility that this response extinguishes suggests that the visually-triggered eyeblinks are CRs for which the visual information serves as the conditioned stimulus while the cutaneous stimulation elicited by the object's impact serves as an unconditioned reinforcer. These results indicate that, unlike in the rabbit, the cerebellum of human subjects is not critical for the retention or extinction of conditioned eyeblinks and consequently is not required to store traces of conditioned eyeblink responses.

## 116.4

**ORGANIZATION AND FUNCTIONAL ROLE OF MESENCEPHALIC DOPAMINERGIC PATHWAYS TO THE HIPPOCAMPAL FORMATION IN THE RAT.** A. Gasbarri\*, A. Sulli, A. Pompili and C. Pacitti. Department of Science and Biomedical Technology, Laboratory of Human Physiology, University of L'Aquila, 67100 L'Aquila (Italy).

The present study offers a description of the anatomical organization and functional role of the projections from the retrorubral field (RRF), substantia nigra (SN), and ventral tegmental area (VTA) to the hippocampal formation (HF) in the rat. Iontophoretically injected *Phaseolus vulgaris*-leucoagglutinin (PHA-L) in RRF, or SN, or VTA resulted in labeling primarily in the ipsilateral subiculum and adjacent CA1 field of both septal and temporal HF. These findings suggest that the general patterns of distribution of the RRF, SN and VTA efferents to the HF are similar. The percentage of mesencephalic dopaminergic (DA) neurons projecting to the HF was evaluated by combining the retrograde tracer Fluoro Gold (FG) with tyrosine hydroxylase (TH) immunohistochemistry. The evaluation of retrogradely FG and TH stained cells showed that the mesencephalic-HF projections are partially DA (10-18%). A topographical organization, and a more prominent input to the temporal than to the septal HF were also observed. Following bilateral 6-hydroxydopamine injection in the dorsal and ventral subiculum and adjacent CA1 field of HF, the effects on learning and memory of retrograde selective lesions of mesencephalic dopaminergic neurons were evaluated using the standard Morris water maze (MWM), cued and spatial versions. Though the lesioned rats were indistinguishable from sham-operated rats in performing the cued version of MWM task, in the spatial version of MWM, lesioned rats, compared to controls, exhibited significant differences, suggesting that the ability to acquire spatial learning and memory for place navigation in the MWM is dependent also on the integrity of meso-hippocampal DA connections. This work was supported by grant MURST from the Italian Ministry of Research.

## 116.6

**THE NEUROPHYSIOLOGY OF LATENT INHIBITION: A NEURAL NETWORK APPROACH** N.A. Schmajuk\*, J. Tye, V.C. Buhusi, and J.A. Gray. Department of Psychology: Experimental, Duke University, Durham, NC 27707, USA, and Institute of Psychiatry, London, United Kingdom.

Schmajuk, Lam, and Gray (JEP:ABP, 1996) offered a formal theory of latent inhibition (LI) in the context of a real-time, neural network model of classical conditioning. In the model, an attentional system enhances internal representations of conditioned stimuli (CSs) active at a time when the total environmental novelty is large, and decreases internal representations of those CSs active at a time when the total novelty is small. The magnitude of the CS internal representation controls both the storage and retrieval of CS-US associations. According to the model, LI reflects the decreased internal representation of a CS as a consequence of decreased attention after preexposure to that CS.

Computer simulations demonstrate that, due to its combined storage and retrieval attributes, the neural network correctly describes the effects on LI of numerous experimental manipulations (a) preceding CS preexposure, (b) during CS preexposure, and (c) during conditioning. Most important, the network correctly describes attenuation of LI (d) after different postconditioning manipulations.

After establishing the correspondence between nodes and connections in the model with different brain regions (e.g., hippocampus, subiculum, nucleus accumbens, ventral pallidum, colliculi, thalamus, cortex) and their interconnecting pathways and neurotransmitters (e.g., dopamine, glutamate, acetylcholine, serotonin, GABA), the model correctly describes the effect on LI of (1) amphetamine administration, (2) haloperidol administration, (3) nicotine administration, (4) scopolamine administration, (5) nonselective hippocampal lesions, (6) selective hippocampal lesions, (7) nonselective hippocampal lesions combined with haloperidol administration.

This study was supported by a grant from NATO.

## 116.7

LONG TERM MEMORY FOR VISUAL IMAGES IN THE HIPPOCAMPUS AND INFEROTEMPORAL CORTEX. **J.L. Ringo<sup>1</sup>** and **A. Nowicka<sup>1,2</sup>**. <sup>1</sup>University of Rochester, Rochester NY, <sup>2</sup>Nencki Institute, Warsaw, Poland.

Measures of memory in single unit responses often rely on averaging responses to different stimuli. However, if for some image(s) in a well-learned set the responses increase while for other images the responses decrease the average response may not change. Other measures of the response distribution, e.g., variance or higher order moments could prove more informative.

We have measured the variance of the unit responses (across images) for a group of images which were well-learned as members of a rewarded set, and compared that to the response variance measured across a group of novel images. The images were fully comparable as they were computer constructed images formed by the same algorithm. Responses from our sample of visually-excited hippocampal units (n=36) showed a greater variance across the well-learned set than across novel images. The average unit showed a 48% increase of across-image variance (statistically significant;  $z=4.1$ ;  $P<0.0001$ ). The mean response did not increase as much. The average response amplitude to the well-learned set was 11% higher ( $z=1.8$ ;  $0.05<P<0.10$ ). Extensive experience with a set of images appears to have remodeled hippocampal unit responses in a soft winner-take-all fashion.

Our sample of visually-excited inferotemporal units showed similar behavior. The mean variance increase for the well-learned set over the novel set was 30% ( $n=48$ ;  $t=2.9$ ;  $P<0.005$ ) while the mean response did not differ (within 1%;  $z=0.5$ ;  $P>0.2$ ). Supported by grant NS26526 from NINDS.

## 116.9

40-MINUTE VISUAL RECOGNITION MEMORY IN RHESUS MONKEYS WITH HIPPOCAMPAL LESIONS. **E. A. Murray<sup>\*</sup>** and **M. Mishkin**, Lab. of Neuropsychology, NIMH, NIH, Bethesda, MD 20892 USA

Alvarez et al. (*J. Neuroscience*, 15: 3796, 1995) found that monkeys with selective hippocampal lesions were impaired in object recognition memory at long (10 and 40 min) but not short (8 sec to 1 min) delay intervals. To define the precise delay at which the hippocampus becomes important for recognition memory, we assessed memory for trial-unique objects at 1-min increments starting at less than 1 min and continuing until nearly 40 min. Eight naive rhesus monkeys were trained on 10-sec delayed nonmatching-to-sample, after which 4 Ss received an MRI-guided series of ibotenic acid injections into both the hippocampus and amygdala (AH). All Ss were then retrained on the initial task, given performance tests with successively longer delays (up to 2 min) and lists (up to 10 objects), and, finally, given list lengths of 20 and then 40 objects with reverse-order testing on each. Both interstimulus and intertest intervals were 30 sec. Thus, in the final condition, delays between sample presentations and choice tests ranged from 30 sec to about 40 min. The Ss with AH lesions did not differ from the unoperated Ss on any delay at any stage (overall mean scores on final condition, tested for 40 days, were 69 and 71% correct, respectively). In Alvarez et al.'s study, the Ss were removed from the apparatus during the long but not the short delay intervals, which might have caused selective impairment at the long delays; also, the lesions were made with radio frequency and so might have damaged fibers of passage. Either or both of these factors could be responsible for the difference in the results of the two studies. Supported by the NIMH, NIH.

## 116.11

SOLVING THE RIDDLE OF THE LATE APPEARANCE OF SUCCESS ON THE DELAYED NONMATCHING TO SAMPLE TASK

**A. Churchland<sup>1</sup>** & **A. Diamond<sup>2,\*</sup>**. <sup>1</sup>Dept. of Psych., Wellesley College & <sup>2</sup>Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

Delayed nonmatching to sample (DNMS) is a classic test of the recognition memory function dependent on the medial temporal lobe. Children cannot succeed on the standard DNMS task until about 21 months of age. Recognition memory cannot be the crucial factor in the late emergence of success on DNMS, however, since that ability is present much earlier. The late emergence of another ability, dependent on a neural system outside the medial temporal lobe, must account for infants' failure on DNMS. We report evidence suggesting the nature of that critical ability. We tested human infants, 9 & 12 months of age, on various conditions of DNMS. In all conditions, a sample object was presented, which the subject displaced. After a delay, the sample plus a novel object were presented. The subject was allowed to choose one object and, in conditions with a reward, was rewarded for displacing the novel stimulus. In the standard task, the reward is located in a well beneath the stimulus. In the critical condition here, the stimuli again sat atop wells, but rewards were attached by velcro to the base of the stimuli. Even the youngest infants tested (9-month-olds) succeeded in this condition. That is, when the reward and stimulus were physically connected, when the reward moved with the stimulus as the subject displaced the stimulus, the task was easy. The critical late-maturing competence is the ability to grasp the relationship between stimulus and reward, to understand the role of the stimulus as a marker or symbol for the reward's location. ## 116.8

THE EMERGENCE OF STRUCTURE IN NEURONAL REPRESENTATIONS **A. Treves<sup>1</sup>**, **S. Panzeri<sup>1</sup>**, **R.G. Robertson<sup>2</sup>**, **P. Georges-Francois<sup>2</sup>** and **E.T. Rolls<sup>2</sup>**

<sup>1</sup>SISSA, Cognitive Neuroscience, via Beirut 2, 34013 Trieste, Italy and <sup>2</sup>Univ. of Oxford, Expt. Psychology, OX1 3UD, UK.

Neurons from the hippocampus and adjacent cortex were recorded in freely locomoting monkeys, and procedures were used to *decode* from their activity which spatial view was concurrently being looked at by the animal. For this purpose, the position in the environment where the monkey was looking was binned into 8-16 discrete "views" and the number of spikes emitted in successive windows of 25, 50, 100 or 500ms was used to quantify the activity of each cell. The joint frequency of any pair of actual and decoded views was used to extract 2 measures: percent correct and information. As more (and/or more selective) cells are used for decoding, both measures rise, but in no fixed relation to each other; for a given percent correct, information values can range from a minimum, when all views but the actual one are decoded with equal frequency, up to a maximum, when one of a group of similar views including the actual one is always decoded, but the decoding is random within the group. An index  $\lambda$  running from 0 to 1 within the range reflects an increasing metric or semantic content of the set of views as perceived by these cells, since it measures the increasing relevance of relationships of similarity or closeness between views. It was shown that  $\lambda$  grows with the time window used to collect spike numbers, suggesting the gradual emergence of meaningful structure in neuronal activity. Values of  $\lambda$  were also compared across areas and with those derived from other experiments. A network model was used to explore the hypothesis that the perceptual structure extracted from the responses reflects the structure and metric content of the underlying synaptic connectivity.

## 116.10

The Visual Paired-Comparison Task and the Medial Temporal Lobe Memory System. **\*R.E. Clark**, **E. Teng**, **L.R. Squire** and **S. Zola**, University of California, San Diego. La Jolla, CA 92093 and VA Med. Center. San Diego, CA 92161.

The development of an animal model of human amnesia in the monkey has identified a neural system in the medial temporal lobe important for memory. To further clarify the role of the individual structures in this system, behavioral tests must be developed that are sensitive to even mild memory impairment and that can distinguish perceptual problems from problems in memory. In the visual paired-comparisons task, two identical stimuli are presented for viewing side by side (familiarization). Subsequently, the original stimulus and a new stimulus are presented side by side, and the experimenter records the time the animal spends looking at the new stimulus (test). We have modified this task, used previously in monkeys (Bachevalier et al. 1993), and have varied the interval between familiarization and test from very short delays, where presumably there is little or no memory demand (e.g., 1 sec) to very long delays, where long-term memory is required (e.g., 10 min). The figure shows that at a delay of 1 sec, the preference for novelty was similar in a normal monkey and in a monkey with damage to the hippocampal formation (H<sup>-</sup>). Short-term memory was intact and there was no evidence of perceptual impairment. At longer delays (>10 sec), the preference for novelty was absent in the H<sup>-</sup> monkey. This task will be useful for clarifying the specific role in memory of the components of the medial temporal lobe memory system and to distinguish perceptual problems from problems in memory.

## 116.12

EXCITOTOXIC LESIONS OF THE AMYGDALA FAIL TO PRODUCE IMPAIRMENT IN VISUAL LEARNING FOR AUDITORY SECONDARY REINFORCEMENT IN RHESUS MONKEYS. **L. Malkova<sup>\*</sup>**, **D. Gaffan** and **E. A. Murray**, Lab. of Neuropsychology, NIMH, NIH, Bethesda, MD 20892, USA and Dept. of Experimental Psychology, Oxford University, OX1 3UD, UK

An earlier study showed that monkeys with bilateral aspiration lesions of the amygdala were severely retarded in learning visual discrimination problems based on auditory secondary reinforcement (Gaffan & Harrison, 1987). To determine if this finding would hold for more selective lesions, we measured the effects of excitotoxic lesions of the amygdala on the same task. Four monkeys were trained in an automated apparatus to solve a new set of 40 visual discrimination problems daily, with only auditory feedback providing information regarding the solution. On each trial, two visual stimuli were simultaneously presented on a color monitor. Correct and incorrect choices led to presentation of the auditory secondary reinforcer and nonreinforcer, respectively, and termination of the trial. To solve a problem, the monkey had to choose the positive visual stimulus four trials in a row, and only then did it receive a food reward, and a chance to learn a new problem. After learning the task, the monkeys received bilateral lesions of the amygdala made with ibotenic acid. Amygdalar lesions had no effect on the rate of learning of new visual discrimination problems. Thus the prediction that, for normal performance in this task, the amygdala is necessary for maintaining the value of the secondary reinforcer was not confirmed. By contrast, the same monkeys were impaired in a different task that involved devaluation of reinforcement. A set of 60 pairs of object discriminations was presented once per daily session until the monkeys performed at 90% correct responses over five consecutive days; half of the positive objects were rewarded consistently with one food (A) and the other half with another equally palatable food (B). Positive objects from the 60 pairs (one "A" and one "B") were then randomly paired for 30 critical choice trials following: 1) selective satiation of either food A or B; or 2) no satiation. Normal monkeys decreased their choices of the objects covering the devalued food to a significantly greater extent than monkeys with amygdala lesions. ## 116.13

**VISUAL NEGLECT IN THE MONKEY: REPRESENTATIONAL IMPAIRMENT AND DISCONNECTION.** D. Gaffan\* and J. Hornak. Exp Psychology, Oxford University, Oxford OX1 3UD, U.K.

Macaques searched for a target pattern in a horizontal array of 5 patterns (1 target and 4 foils on each trial, chosen from 30 possible targets and 120 possible foils). Neglect after a unilateral lesion was measured by the failure to find targets that were contralateral to the lesion. Neglect was caused by optic tract section combined with forebrain commissurotomy ( $n = 6$ ), and by parietal leucotomy ( $n = 3$ ). It was not caused by posterior parietal cortical ablation, or by optic tract section alone, or by forebrain commissurotomy alone, or by posterior parietal ablation plus frontal eye-field ablation, or by frontal lobectomy plus forebrain commissurotomy ( $n = 3$  in each group). We propose: (1) The posterior cortex of each hemisphere maintains a retinotopically organized representation of the visible half-world that is contralateral to the animal's current point of fixation (2) This representation is based not only on analysis of the current retinal input, but also on memory (3) One of the uses to which this representation is put is the generation of contralaterally directed saccades. Neglect is not caused by hemianopia (optic tract section alone), because in hemianopia the affected hemisphere can use memories of visual inputs which arose from the then ipsilateral visual field in previous fixations to build a representation of what is contralateral to the current point of fixation. Neglect does follow, however, when hemianopia is combined with forebrain commissurotomy, even though the cortex is intact, because the affected hemisphere is then deprived of all visual information and cannot therefore maintain even a memory-based representation of the currently contralateral visible world. Neglect is also caused by parietal leucotomy, because this disconnects the posterior, retinotopically organized part of the visual cortex from its subcortical motor output. Supported by UK MRC.

## VISUAL CORTEX: STRIATE I

## 117.1

**PLASTICITY OF SYNCHRONIZATION AND OSCILLATORY MODULATION OF VISUAL RESPONSES AFTER BRAINSTEM RETICULAR ACTIVATION.** S. Herculano\*, M.H.J. Munk and W. Singer. Max-Planck-Institut für Hirnforschung, Deutschordenstraße 46, Frankfurt a.M. 60528, Germany.

It has been proposed that responses of neuronal populations coding for related features are dynamically selected and bound together for joint processing by transient synchronization of their discharges. To examine the plasticity of neuronal synchronization in the visual cortex, we conditioned several simultaneously recorded units by pairing their light responses for 30-60 minutes with stimulation of the mesencephalic reticular formation (MRF). Activation of this ascending modulatory system desynchronizes the EEG, facilitates neuronal synchronization in the gamma-frequency range and enhances use-dependent synaptic plasticity.

Baseline variations of the oscillatory patterning and the correlation of multi-unit visual responses were measured in areas 17 and 18 of anesthetized adult cats over several hours of recording. The oscillatory modulation and correlation strength of visual responses varies widely over time, accompanied by changes in the power spectrum of the EEG. Activation of the MRF 100 ms prior to visual stimulation results in EEG desynchronization and strong oscillatory modulation of visual responses (14 out of 26 units). In the absence of MRF activation, the oscillation frequency of multi-unit responses can vary over a broad range (30-100 Hz). In contrast, in responses conditioned with MRF activation, the oscillation frequency stabilizes in a range from 30 to 53 Hz ( $n = 5$ ). MRF stimulation enhances the correlation of visual responses, both locally (14 out of 26 cases) and across the hemispheres (9 out of 21 pairs). Most strikingly, the enhanced correlation and oscillatory modulation persist in some cases for as long as 40 minutes after the end of MRF stimulation (local correlation, 7 out of 14; long-distance correlations, 2 out of 9 pairs). Our results suggest that the connections underlying cortical neuronal synchronization are plastic. Their modulation during attentive states, facilitating the formation of neuronal ensembles, can become long-lasting, and could therefore constitute a key mechanism in perceptual learning during development and adult life. **SYNCHRONIZED GAMMA FREQUENCY OSCILLATIONS CORRELATE WITH PERCEPTION DURING BINOCULAR RIVALRY IN AWAKE SQUINTING CATS.** P. Fries\*, P.R. Roelfsema, A.K. Engel, P. König and W. Singer. Max-Planck-Institut für Hirnforschung, 60528 Frankfurt, Germany.

The neuronal correlates of visual perception can be discovered by producing ambiguous visual stimulation conditions. When two dissimilar images are presented to the two eyes, rivalry is experienced: At any moment only one of the images dominates perception while the other one is suppressed. What are the differences in the processing of information that lead to perceptual dominance or suppression? To address this issue we have studied cats with a surgically induced squint, a condition leading to strong rivalry due to the permanent incoherence of the information coming from different eyes. Neuronal activity was recorded from awake animals with chronically implanted wire electrodes. For visual stimulation, wholefield gratings moving in different directions were presented dichoptically. We computed auto- and cross-correlation functions and spike triggered averages for all combinations of action potential or local field potential recordings, respectively. In primary and secondary visual cortex of these cats synchronization of action potentials was strongly enhanced between neurons encoding the dominant stimulus. In contrast, synchronization was reduced between neurons encoding the suppressed stimulus. Synchronized action potentials occurred in oscillatory patterns with frequencies of 40 to 60 Hz. The strength of the oscillations was correlated with perceptual dominance in the same way as synchronization strength. There was a strong synchronization between spikes and the 40-60 Hz component of the local field potential also showing this positive correlation to perception, while this was not the case for other frequency ranges. Interestingly, the average firing rates of the neurons did not differentiate between dominance and suppression. We hypothesize that synchronization of responses to the dominant stimulus is enhanced by locking discharges to the phase of oscillatory fluctuations of membrane potential in the gamma frequency range. This enhanced oscillatory synchronization makes the dominant subset of responses more salient for coincidence detecting neurons in other areas and, thus, favours selection of these responses for processing by subsequent stages in the visual pathway.

## 117.2

**INNATE MICROSTRABISMUS AND SYNCHRONIZATION OF NEURONAL ACTIVITY IN PRIMARY VISUAL CORTEX OF CATS.** P. König<sup>1,2\*</sup>, P.R. Roelfsema<sup>2</sup>, A.K. Engel<sup>2</sup> and W. Singer<sup>2</sup>. <sup>1</sup>The Neurosciences Institute, 10640 John J Hopkins Drive, San Diego CA 92121, USA. <sup>2</sup>Max-Planck-Institute for Brain Research, Deutschordenstr.46, 60528 Frankfurt, D

It has been proposed that synchronization of neuronal activity serves to integrate distributed cortical representations. Experiments in the visual system show that synchronization of neurons is stimulus specific, compatible with Gestalt laws and dependent on the functional architecture of tangential intracortical connections. Surgically induced strabismus has been shown to cause correlated changes of cortical connections and synchronization. Here we investigate the effects of innate strabismus on neuronal synchronization. Multi-unit responses to light bars and gratings were recorded under general anesthesia with multiple electrodes in area 17.

In accordance with previous results from such animals (Distler & Hoffmann, Visual Neuroscience, 6:25-41, 1991) the incidence of binocular cells was more reduced in the central than in the peripheral representation of the visual field. The incidence of synchronization was similar to that in normal cats for neurons with like ocular dominance but drastically reduced for neurons with different ocular dominance. Furthermore, in the latter the phase shift of synchronization often deviated from zero by up to 10-20ms. The incidence of oscillatory activity was similar to that found in normal cats. However, the frequency distribution shows a tendency towards the lower range, covering not only gamma but also the upper beta range.

In conclusion the alterations in cats with innate squint are qualitatively similar but quantitatively not as extreme as those in cats with surgically induced squint. This research has been supported by the NSF and the MPG.

## 117.4

**BINOCULAR INTERACTIONS EXHIBITED BY NEURONS IN THE CAT'S STRIATE CORTEX: NONLINEAR ANALYSIS.** A. Anzai, I. Ohzawa, and R.D. Freeman\*. Group in Vision Science, School of Optometry, University of California, Berkeley, CA 94720-2020

We have previously reported that binocular simple cells combine signals from the left and right eyes linearly, and then exhibit a threshold nonlinearity (Ohzawa and Freeman, 1986). In addition, we have proposed an energy model as part of a binocular disparity encoding system in which complex cells detect a stimulus energy associated with binocular disparity (Ohzawa et al., 1990). In both studies, we were not able to determine the specific nature of nonlinearities present in response patterns. These nonlinearities could be of prime importance since they may represent computations underlying binocular spatial processing. In this study, we have measured spatial characteristics of nonlinear binocular interactions exhibited by neurons in the striate cortex of anesthetized and paralyzed cats. We consider possible roles of nonlinearities in the binocular representation of three-dimensional space.

Extracellular recordings were made from single neurons. Dynamic noise patterns, generated according to binary m-sequences, were presented to receptive field (RF) locations for each eye to map left and right eye RFs and the binocular interaction RF for each cell. Responses of cells to the noise patterns were cross-correlated with the stimulus sequence to obtain each RF.

Both simple and complex cells exhibit significant nonlinear binocular interactions. Binocular interaction RFs of simple cells are well described by the product of left and right eye RFs. This is consistent with a model for these cells of a linear filter followed by a static nonlinearity. Binocular interaction RFs of complex cells are fit well by a Gabor function oriented in the fronto-parallel plane. This finding is consistent with the prediction of a binocular disparity energy model.

Since the binocular interaction RFs of simple cells are proportional to the product of left and right eye RFs, it is computationally equivalent to interocular correlation at a particular interocular phase disparity. The energy model eliminates monocular phase dependency of the simple cell output. Therefore, a population of binocular complex cells with various interocular phase disparities could compute the complete interocular correlation function which represents the distribution of stimulus energy in depth. This in turn would be useful for solving the stereo correspondence problem. (EY01175)

## DISPARITY DETECTING NEURONS IN VISUAL CORTICAL AREA V1 GIVE SELECTIVE RESPONSES TO ANTI-CORRELATED RANDOM DOT PATTERNS THAT ARE IMPOSSIBLE TO FUSE PERCEPTUALLY.

B.G. Cumming, W.T. Newsome\* and A.J. Parker. University Laboratory of Physiology, Parks Road, Oxford, OX1 3PT, UK

Random dot stereograms can readily be constructed in which half of the dots are white and half of the dots are black. An anticorrelated version of the same stereogram can then be constructed by assigning a black dot in the left eye to match a white dot in the right eye and the converse. The perceptual consequences of anti-correlation are dramatic, making binocular fusion impossible (except at low dot densities). Here, we tested the responses of single neurons in V1 of awake, behaving macaque monkeys to both correlated and anti-correlated dynamic random dot stereograms. Monkeys were trained to fixate, and the binocular eye position was monitored using the scleral search coil technique. Standard (correlated) random-dot patterns generated the typical tuning functions for binocular disparity previously identified in V1. In the majority of neurons tested, anti-correlated patterns gave responses that resembled the inverse of the response to correlated patterns. Thus, tuned-excitatory cells would exhibit a tuned-inhibitory function and so on. This inversion of the tuning function is well predicted by a local filtering model for binocular combination within the cortex, but is not expected if the neurons in V1 are directly responsible for global cyclopean stereopsis.

## 117.7

THE ROLE OF V1 IN SCENE SEGMENTATION AND SHAPE REPRESENTATION T.S. Lee<sup>1,2</sup> and D. Mumford<sup>3</sup> Dept. of Brain and Cognitive Sciences<sup>1</sup>, MIT; Div. of Applied Sciences<sup>2</sup> and Dept. Mathematics<sup>3</sup>, Harvard University.

We studied the sensitivity of V1 neurons to globally-defined visual shapes in two awake rhesus monkeys. Stimuli were presented for 350 msec each trial while the monkeys fixated. The responses of 223 V1 neurons to different large figural shapes defined by texture and/or luminance contrast were analyzed at different time intervals. We found that when the figural boundaries are aligned with the orientation of the cells, there is a strong and persistent enhancement at the figural boundaries for most texture-responding neurons regardless of the orientation of the contrasting textures. The texture boundary response sharpens 80 msec after stimulus onset, later than the response to luminance boundaries. 30 % of the texture-responding cells also showed an enhanced response peak at the center/axis of the figures, suggesting a possible medial axis representation. The 'computation' of the central peaks seem to be sensitive to high-level segmentation results. Moreover, the neurons located at the center of shapes are sensitive to the distance as well as the shape of the global contours far away from the classical receptive fields. The simultaneous sensitivity of V1 neurons to multiple global perceptual variables such as the shape and the size of a figure and the location of its boundaries and symmetry axes in the later part of their responses suggests V1 is not just the first stage of visual processing, but is active throughout high as well as low visual algorithms. Any reasoning that requires high acuity, resolution and spatial specificity such as finding object boundaries and symmetry axes would refer back to V1 for image details and spatial registration. The evidence that individual cells in V1 are sensitive to many kinds of global perceptual structures suggests that different types of information might coexist or be multiplexed in the spike trains of individual neurons through concerted firings with different neuronal assemblies.

## 117.9

ORGANIZATION OF STRIATE VISUAL CORTEX: BALANCE BETWEEN FUNCTION AND WIRING COST R. Everson,<sup>1,2</sup> D. Orbach,<sup>1,3</sup> E. Kaplan,<sup>1,3</sup> B. Knight,<sup>1</sup> J. Gordon<sup>1,4</sup>

Biophysics<sup>1</sup>, Rockefeller University; Applied Math<sup>2</sup>, Ophthalmology<sup>3</sup>, Mt. Sinai Medical School; Psychology, Hunter College<sup>4</sup>, New York, NY.

We seek to understand the functional architecture of the primary visual cortex in terms of a competition between the functions that the cortex must perform (comparing the input from neurons whose receptive fields are close) and the cost of making connections between neurons on the cortex.

To that end, the cortex was simulated as an array of "neurons" each of which has a receptive field location, an ocular preference and an orientation preference. The cost of a particular cortical configuration increases if neurons with nearby receptive fields are distant on the cortex, if neurons receiving input from the same eye are distant or if neurons with similar orientation preferences are distant. Starting from a random configuration, simulated annealing was used to find the configuration that minimizes the total cost.

Optical imaging of the intrinsic signal from the exposed cortex of anesthetized, paralyzed cats and monkeys was used to reveal the ocular dominance, orientation tuning and retinotopic maps. Flickering dashboard patterns were presented as visual stimuli to image the retinotopic map.

Simulations reproduce the retinotopic mapping of the visual hemi-field on the cortex. Optimal configurations for smaller cortical patches reveal ocular dominance columns and orientation pinwheels. In agreement with the optical imaging results, the centers of orientation pinwheels are located in the middle of ocular dominance columns. The relationship of ocular dominance columns to the retinotopic map was investigated at low and high eccentricity and compared to the simulated layouts.

## 117.6

## INCIDENCE OF OSCILLATIONS AND SYNCHRONY AS A FUNCTION OF BURSTING PROPERTIES OF MACAQUE STRIATE NEURONS. S.R. Friedman-Hill\*, C.M. Gray, and P.E. Maldonado. Center For Neuroscience, University of California, Davis, CA 95616

The interspike interval histograms (ISIH) of 201 well-isolated single units, from the striate cortex of macaques trained to maintain fixation, were classified by their peaks. The ISIH peaks were clustered into three categories: 1-2 ms, 3-10 ms, and 10-40 ms. These categories may correspond to "chattering" (C) intrinsic bursting (IB), and regular spiking (RS) cells, respectively. (See abstract by Azouz, et al. for details on this cell classification.)

We examined the incidence of oscillatory activity, as measured by a significant peak/d.c. ratio in the power spectrum of the autocorrelogram, in relation to the firing properties of the units. This analysis revealed that 83% of the significant autocorrelograms were C cells; the remaining units were RS.

We also looked at the incidence of significant synchronization as reflected in the cross-correlogram. For units with non-overlapping or sparsely-overlapping receptive fields (RFs), 80% of the significant cross-correlograms involved pairs of "bursty" cells (IB-IB, C-C, or IB-C). For units with largely-overlapping RFs, only 36% of the significant crosses involved pairs of bursters. All of the remaining significant cross-correlograms were the result of the pairing of an IB or C cell with a RS cell; no significant synchrony between RS-RS pairs were found.

These results indicate that bursting is an important factor in the establishment of oscillations and synchrony. Oscillations are exhibited by neurons with very high intraburst firing rates—namely, C cells. Bursting cells (IB and C) participate in all incidences of significant synchrony and pairs of bursting cells are important for long-distance synchrony.

FUNCTIONAL ARCHITECTURE OF V1, V2, AND LGN FOR PERCEPTUAL GROUPING. S. Grossberg<sup>1</sup>\*, E. Mingolla<sup>2</sup>, and W.D. Ross<sup>3</sup>. Department of Cognitive and Neural Systems, Boston University, Boston, MA 02215.

A detailed neural model links the laminar and map cortical organization of V1 and V2 to context-sensitive visual percepts. This linkage suggests how cortical designs achieve the context-sensitivity characteristic of visual percepts. The model uses circuits in V1 and V2 that are homologous but of different scale to simulate neurophysiological data on spatial and orientational integration in V1 (Grosf et al., 1993; Kapadia et al., 1995) and long-range illusory contour formation in V2 (von der Heydt & Peterhans, 1989). Model interactions across layers 3, 4, and 6 simulate how long-range cooperative and short-range competitive interactions (Eysel, 1995; Fitzpatrick, 1995; Gilbert & Wiesel, 1990; McGuire et al., 1991) generate context-sensitive perceptual groupings. Model cortical maps with recurrent excitatory and inhibitory feedback efficiently organize these interactions. Other simulations demonstrate that contours formed parallel and perpendicular to inducers have the strengths reported psychophysically (Kellman & Shipley, 1991; Lesher & Mingolla, 1993) as inducer numbers increase. Endstopped V1-LGN feedback strengthens groupings perpendicular to line ends and selects and synchronizes cortically consistent signals (Sillito et al., 1994). The model shows how psychophysical measures can be used to study the balance between cortical cooperation and competition. <sup>1, 2, 3</sup> Supported in part by the ONR (N00014-94-1-0597, N00014-95-1-0409, and N00014-95-1-0657).

## 117.10

RESPONSE VARIABILITY OF CELLS IN V1 OF ALERT MONKEYS IS LOW M. Gur<sup>1,2</sup>, A. Beylin<sup>1,2</sup> and D. M. Snodderly<sup>2,3</sup>

<sup>1</sup>Dept. of Biomedical Engineering, Technion, Haifa, Israel; <sup>2</sup>Schepens Eye Research Institute, Boston; <sup>3</sup>Dept. of Ophthalmology and Program in Neuroscience, Harvard Medical School, Boston.

Response variability of single neurons limits the reliability and resolution of the sensory system. Understanding the nature and origin of this variability allows one to relate performance of single cells to models of neural circuitry and to behavioral tasks. It has been suggested that response variability increases at cortical levels thus rendering individual responses less reliable. Since anesthesia and fixational eye movements can affect response variability, we studied the question in the alert monkey with compensation for fixational eye movements.

We recorded from 83 single cells and 4 multiunit sites in all V1 layers using dye marks and/or physiological criteria to assign recording loci. In addition, 8 single parvo LGN cells were studied. All cells were stimulated with a bar of near-optimal orientation, color, and dimensions.

The relationship between response magnitude and response variance was similar in our V1 cells and LGN cells. The variance as a function of response amplitude was almost an order of magnitude lower than previously reported for V1 cells in both alert and anesthetized monkeys. The coefficient of variation was also smaller than previously reported.

We conclude that cortical cells are more reliable than previously thought and their ability to encode information is not degraded relative to cells earlier in the pathway.

## 117.11

## THE SPATIAL EXTENT OF CONTEXTUAL RESPONSE MODULATIONS IN CAT STRIATE CORTEX.

S. Kastner\*, H.-C. Nothdurft and I.N. Pigarev. Dept. of Neurobiology, Max-Planck-Institute for Biophysical Chemistry, P.O. Box 2841, 37018 Goettingen, Germany.

Recently, we reported response modulations induced by moving and static texture patterns presented outside the classical receptive field (RF) (*Soc. Neurosci. Abstr.*, 1995). In order to investigate the spatial organization of such contextual effects, we analyzed in the present study neuronal responses to texture rings at different distances from the RF-center in anaesthetized and paralyzed cats using standard extracellular recording techniques.

Contextual effects were strongest for texture elements presented close to the cell's excitatory RF and decreased with increasing distance from the RF-center. The spatial extent over which significant effects were seen was, in average, 4.4° for static texture rings (range: 1.4°-10.2°) and 3.9° for moving texture rings (range: 1.5°-7.8°). There was considerable cell-to-cell variability, so that no clear relationship between the spatial extent of interactive effects and the eccentricity of a cell's RF was seen (recording sites up to 12° eccentricity). Neurons exhibiting interactive effects were, on average, more strongly end-inhibited than neurons that did not show contextual response modulations.

The large spatial ranges of such effects suggest that they are mediated by long-range intrinsic horizontal connections of striate cortex. (Supported by DFG-grant No 180/8-1).

## 117.13

OBSERVATION OF POSITIVE BOLD CHANGES CORRELATE TO NEURONAL DEACTIVATION DURING SACCADIC EYE MOVEMENTS. W. Chen, S.G. Kim, T. Kato, X.H. Zhu, R. Menon\*, T.M. Cook\*, S. Ogawa\*, K. Ugurbil, Center for Magnetic Resonance Research, University of Minnesota, School of Medicine, Minneapolis, MN55455, \*Bell Labs, Lucent Technologies, Murray Hill, NJ 07974, \*CIBA, Summit, NJ 07901, \*Robarts Research Institute, London, Ontario, Canada.

fMRI has been extensively used for mapping of human brain activity. Most fMRI maps generated by positive BOLD response caused by the decrease of the deoxyhemoglobin concentration are considered to be correlated to regional CBF increase and the neuronal activation. However, the absence of extensive observations on negative BOLD response to tasks raises the question about the possibility of the correlation between negative BOLD effect to neuronal deactivation. It was reported by PET and clinical studies that the saccadic eye movements reduced the CBF in primary visual cortex (V1), in order to suppress neuronal activity in V1. We have used fMRI (4 tesla) to test whether saccadic eye movements cause BOLD change in V1 areas as well as CBF changes using flow sensitive MRI technique. The experiments were performed in a completely dark room and the subject's eyes were closed during both of control and task periods. A beep sound with selected frequency (from 40 min<sup>-1</sup> to 120 min<sup>-1</sup>) was sent to subjects during control and task periods. Therefore the auditory influence from the beep sound could be canceled by the subtraction between control and task images. Positive BOLD changes were observed in V1 during all saccade experiments. The average BOLD increase (n=8) for 120 min<sup>-1</sup> saccade frequency (1.3%) is more than that for 40 min<sup>-1</sup> saccadic frequency (1.0%). These results suggest for the first time that BOLD response can be positive under condition of deactivation where regional CBF appears to decrease.

## GENESIS OF NEURONS AND GLIA

## 118.1

COUPLING BETWEEN NEOCORTICAL PROGENITORS CHANGES DURING PROGRESSION THROUGH THE CELL CYCLE. A.R. Kriegstein\*, K.S. Bittman, D. Olsen, L.H. Boyce, D.F. Owens, J.J. LoTurco. Dept. of Physiol. & Neurobiol. University of Connecticut, Storrs 06269 and Dept. Neurol., Columbia P&S, NY, NY 10032

Throughout neurogenesis, cells in the ventricular zone (VZ) of developing neocortex are coupled together by gap junction channels. As cells leave the cell cycle and migrate out of the VZ they uncouple from VZ cell clusters. In the present study we have sought to determine the cell cycle phase of coupled cells, and whether coupling between cells in the VZ is dynamic with respect to the cell cycle. BrdU was injected into timed pregnant rats and mice 2, 8 and 16 hours before E16, at which time explants of embryonic neocortex were prepared for intracellular injection of biocytin. Biocytin injected into single cells within the VZ labeled discrete clusters of cells. A double-labeling procedure was carried out for biocytin and BrdU immunohistochemistry, and the percentage of biocytin labeled cells that were also labeled with BrdU was determined. Two-four hours following BrdU injection, 14% of biocytin labeled cells in coupled clusters were also labeled by BrdU. In contrast, eight-twelve hours following BrdU injection 47.8% of biocytin labeled cells were also labeled with BrdU. The average number of cells per cluster (45) was similar at both time points. This greater than 3 fold increase in the percentage of double labeled cells indicates that an increase in intercellular coupling occurs between S and G1 phase of the cell cycle.

TRANSIENT AND SUSTAINED FACILITATION OF VISUAL RESPONSES BY NITRIC OXIDE IN CAT STRIATE CORTEX. P. Kara\* & M.J. Friedlander. Neurobiology Research Center and Dept. of Physiology & Biophysics, Univ. of Alabama at Birmingham, 35294-0021.

We previously reported that transient local inhibition of endogenous nitric oxide (NO) production in the visual cortex of anesthetized cats reversibly reduces the number of spikes and peak firing frequency of visually-evoked responses in cortical neurons by 20-80% (Kara & Friedlander, *Soc. Neurosci. Abstr.*, 21, 1995). We have extended these studies to include elevation of local NO levels by iontophoresis of (a) diethylamine-*NONOate* (D-NO), a pH sensitive NO-generating compound or (b) L-arginine (L-Arg), the natural substrate for the NO producing enzyme nitric oxide synthase (NOS). Using extracellular single-unit recording and microiontophoretic methods identical to that of our previous report, NOS blockade via L-nitro-arginine (LNA) or L-mono-methyl-arginine (LMAA) significantly inhibited the visual response in 37 of 58 neurons by 15-90% (p < 0.05, KS or t-tests). In 10 of 58 neurons, NOS blockade facilitated the visual response by 22-105%. The remaining 11 of 58 cells were not significantly affected. The effects of enhancing intra-cortical NO levels with either L-Arg or D-NO while simultaneously presenting optimally oriented visual stimuli in both preferred and null directions of motion were tested in 27 cells. In 9 of 27 cells, the visual response was potentiated by 34-125%. In 6 of these 9 cases, enhancement of the visual response decayed and returned to control firing levels within 5-10 minutes of cessation of the L-Arg or D-NO application. However, in the remaining 3 cells, persistent enhancement of the visual response was observed for a period greater than 20 minutes from the termination of the iontophoresis of the NO generating compound. In 2 of these 3 cells, the pairing of exogenous NO application and null direction visual stimulation unmasked a response to the previously ineffective stimulus. In 4 of 27 cells tested with L-Arg or D-NO application, the visual responses were inhibited by 20-86%. Twelve of 27 cells were not significantly affected. These findings suggest that NO might act as a synaptic amplifier, increasing the dynamic range of operation of neocortical microcircuits.

TEMPORAL INTEGRATION WINDOWS FOR NEURONS IN THE FEEDFORWARD PATHWAYS OF VISUAL CORTEX. J.B. Colombeau\* and P.S. Ulinski. Committee on Neurobiology and Dept. Organismal Biology and Anatomy, University of Chicago, Chicago, IL 60637

Recent analysis of the processing of dynamic sensory signals by neurons has focused on the range of past timescales that affect present neuron output. This range is partially determined by axonal and synaptic delays in feedforward pathways. The visual cortex of the pond turtle, *Pseudemys scripta*, is an ideal preparation for studying the contribution of axonal delays to temporal integration because the geniculate afferents form a set of parallel, horizontal delay lines across the cortex. *In vitro* studies of the geniculate pathway show that pyramidal neurons in the cortex have response latencies to retinal light pulses that depend on their positions in the cortex. We used the distribution of latencies to estimate conduction velocity at 0.01 mm/msec for geniculocortical afferents within the cortex. We could then calculate the rostrocaudal distribution of afferent delays prior to entering the cortex as 80 to 470 msec along the rostral to caudal axis of the cortex. To characterize the morphology of neurons in the path, we examined Golgi-impregnated material. Particular attention was paid to the spatial intersection of dendritic arbors with geniculate afferents. The horizontal dendrite dimensions were divided by the conduction velocity of the afferent axons to generate local windows of temporal integration, which ranged from 7 to 80 msec, depending on the type of neuron. The combination of delay and dispersed temporal integration of visual input is expected to play a major role in the processing of dynamic visual stimuli by the cortex. ## 118.2

INTRACORTICAL DISTRIBUTION OF A COHORT OF CELLS ARISING IN THE PVE. T. Takahashi<sup>1,2</sup>, T. Goto<sup>1,2</sup>, S. Miyama<sup>2</sup>, R.S. Nowakowski<sup>3</sup> & V.S. Caviness, Jr.\* <sup>1</sup>Neurology, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114, <sup>2</sup>Pediatrics, Keio University School of Medicine, Tokyo 160, Japan, <sup>3</sup>Neuroscience & Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Neocortical neurogenesis occurs in the pseudostratified ventricular epithelium (PVE) at the ventricular margin of the embryonic cerebral wall. In mouse, neocortical neurons arise in the course of 11 cell cycles over 6 embryonic days. Throughout the neocortical PVE the length of G1 phase (TG1) and the Q fraction (Q: the fraction of postmitotic cells which exit the cycle) advance through an identical range of values and are the only developmentally regulated proliferative parameters. At any given moment in the course of neurogenesis, neurons destined for different cortical layers are being formed along the lateral to medial axis of the PVE. Thus, both Q and TG1 are distributed as a lateral to medial gradient with values laterally greater than those medially. The distributions of cohorts of neurons arising over 2 hr intervals on each of embryonic days E12-E16 were determined at postnatal day 22 in medial, intermediate and lateral cortical zones of a coronal plane of the neocortex at midhemisphere. Independently of the cortical zone examined, cells arising from the first 8 of the 11 cell cycles are distributed within the infragranular layers (V-VI). This early period of neurogenesis, when the numbers of neurons formed is relatively small, corresponds to the ascent of Q from 0 - 0.5 and a 4 fold increase in TG1. Cells arising from the last 3 cell cycles (9 through 11) are distributed within the granular (IV) and supragranular layers (II-III). TG1 and Q are the same in a zone of the PVE which is giving rise to cells destined for a specific cortical layer, whether this layer is medially or laterally in the cortex. Thus, this analysis establishes an invariant relationship in the neocortical PVE between the patterns of progression of Q, TG1 and the sequence of cell cycles, on the one hand, the cortical layer (and principal cell class) which is being formed, on the other. ## 118.3

**VIRALLY TRANSDUCED EGF-Rs MODULATE CELL FATE AND MIGRATION IN CORTICAL CULTURES.** L. Lillien<sup>1</sup>, D. Wancio<sup>1</sup>, and P. Levitt<sup>2</sup>. <sup>1</sup>Department of Neurobiology and Anatomy, Medical College of Pennsylvania, Philadelphia, PA 19129. <sup>2</sup>Department of Neuroscience and Cell Biology, UMDNJ, Robert Wood Johnson Medical School, Piscataway NJ 08854.

The phenotypic potential of progenitor cells in the developing cerebral cortex was assessed in explants by modifying their responsiveness to TGF $\alpha$ /EGF with a retrovirus transducing extra copies of wild-type EGF-Rs. Previous studies with retinal progenitor cells demonstrated that this virus confers ligand-responsiveness and increased ligand sensitivity. Introducing extra copies of EGF-Rs into cortical progenitor cells at 2 different embryonic ages had significant effects on cell fate and migration in explants. More than 70% of progenitor cells infected with EGF-R virus at E15 differentiated into astrocytes within 4 days. In contrast, 20-40% of progenitor cells infected at E12 in explants differentiated prematurely into astrocytes; instead, the probability of their expression of stem-cell properties increased over 100-fold. Analysis of the migratory behavior of infected cells revealed a ligand-dependent modulation of movement away from the ventricular edge of the explants at both ages. Differentiation was assessed further in monolayer cultures in which cell-cell signaling and normal migration were disrupted. Clonal analysis revealed that in the presence of TGF $\alpha$ , 60-70% of the clones expressing extra EGF-Rs from either E12 or E15 contained astrocytes after 3 days. Clone size was also increased compared to cultures grown without ligand. Both cell type choice and proliferation were therefore affected in a ligand-dependent manner in cells expressing extra EGF-Rs. The data also show that while progenitor cells infected at E12 and E15 respond differently in explants, they behave similarly under conditions in which cell-cell interactions are disrupted. These observations suggest that the fate and proliferation of progenitor cells in the early embryonic cerebral wall change in a temporally regulated fashion, but are not intrinsically restricted. They also suggest that changes in cell-cell signaling during different periods of cortical development are likely to play an important role in modulating responses to EGF-R activation. Supported by March of Dimes.

## 118.5

**TRANSPLANTATION TO THE NEONATAL RAT BRAIN OF CORTICAL PROGENITOR CELLS GENETICALLY MODIFIED TO OVEREXPRESS EGF-RECEPTORS.** M.F. Barbe\*, L. Lillien, Dept. of Physical Therapy, Temple Univ., Philadelphia, PA, 19140 and Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.

We investigated the influence of different regions within the developing cortex in determining the fate of cortical progenitor cells with properties of stem cells. Cortical cells from embryonic day (E) 12 and E15 rat donors were marked by infection with either control virus expressing histochemical marker  $\beta$ -geo or the wild type human EGF-receptor (EGF-R virus), and exposed to TGF- $\alpha$  or EGF in culture to generate spheres (Reynolds BA, et al, 1992, J Neuroscience, Vol 12: 4565). In vitro, these spheres generated both neurons or glial cells. For transplant studies, spheres were labeled with a fluorescent marker and grafted into neonatal rat cerebral cortex. The cells integrated, survived for up to 5 weeks postsurgery, and expressed neuronal and glial markers. Overall, it was determined that over 80% of the EGF-R infected spheres (identified immunohistochemically with an antibody to the virally transduced human EGF-R) integrated into gray matter, and that a mixture of cell types developed from the EGF-R positive progenitors: many of the grafted cells expressed neuron-specific antigens (MAP2, NF200), while others expressed glial markers (GFAP, S100). Moreover, different proportions of MAP2-positive cells were observed in the different regions analyzed ranging from 30% to over 90%. Similar experiments are in progress to compare the fate and/or survival of spheres with or without virally transduced EGF-receptors in the cerebral cortex. Thus, the fate of cortical progenitor cells is in part determined by local environmental cues in vivo, which may be temporally and spatially regulated in the cerebral cortex. Supported by Temple University (MB).

## 118.7

**DIFFERENTIAL REGULATION OF RADIAL GLIA AND ASTROGLIAL LINEAGE ELABORATION FROM EMBRYONIC SUBVENTRICULAR ZONE (SVZ) PROGENITOR CELLS BY LEUKEMIA INHIBITORY FACTOR  $\beta$  RECEPTOR (LIF $\beta$ R) ACTIVATION AND BONE MORPHOGENETIC PROTEINS (BMPs).** M. F. Mehler\*, P. C. Mabie, R. Marmur, and J. A. Kessler. Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

The epigenetic signals and lineage intermediates involved in gliogenesis from multipotent progenitors within CNS generative zones are poorly defined. Clonal density analysis of epidermal growth factor (EGF)-generated embryonic (E17) SVZ progenitor cells demonstrates that activation of the LIF $\beta$ R in concert with BMP2 or basic fibroblast growth factor (bFGF) potentiates the expression of RC2-immunoreactive radial glia with subsequent enhancement (BMP2) or inhibition (bFGF) of expression of mature astrocytes. Single cell analysis further suggests that astroglial lineage elaboration occurs through radial glial-dependent and independent lineage pathways regulated by distinct cytokines. Immunoselection using CD44, a marker selective for radial glial and early astroglial lineage species, was performed to further define the cellular targets of the differential cytokine actions. CD44-negative progenitor cells displayed selective proliferative responses to EGF and formed qualitatively distinct astroglial clones following application of LIF or BMP2. By contrast, CD44-positive cells were unresponsive to EGF or LIF, but showed identical cellular responses to the BMPs as those of CD44-negative SVZ-derived progenitor species. These observations suggest the presence of separate BMP-responsive astroglial progenitor populations that are differentially regulated by distinct early-acting cytokines and may be associated with sequential stages of neurogenesis and gliogenesis during mammalian CNS development.

## 118.4

**Retrovirally mediated ectopic expression of the epidermal growth factor-receptor (EGF-R) during cortical development results in abnormal cell migration in vivo.** RC Burrows\*, L. Lillien<sup>1</sup>, P. Levitt<sup>2</sup>. Dept. of Neurosci. and Cell Biol. UMDNJ-RWJMS, Piscataway, NJ 08854. and Dept. Neurobiol. Med. Col. of PA, Phila. PA 19129.

Our studies in vitro have shown that the EGF-R signaling system dramatically alters cell migration and phenotypic fate of cortical progenitor cells. Here, we extend these studies in vivo, using a retroviral vector that encodes the histochemical marker  $\beta$ -geo and wild-type *egf-r*, or the  $\beta$ -geo gene alone as a control. Fetuses were injected intraventricularly, *in utero*, at either embryonic day 14 (E14) or E15, and sacrificed on E18 or E20, respectively. In E18 control animals, approximately 25% of the labeled cells were in the ventricular zone (VZ), 50% in the subventricular zone (SVZ), 20% in the intermediate zone (IZ), 3% in the cortical plate (CP) and 2% in the marginal zone (MZ). In E18 EGF-R infected animals, in contrast, infected cells migrated more robustly, with only 1% of the labeled cells in the VZ, 22% in the SVZ, 50% in the IZ, 22% in the CP and 4% in the MZ. In control animals sacrificed at E20, approximately 65% of the cells remained within the proliferative layers of the developing cortex. In contrast, only 2% of the EGF-R-infected cells were found in the proliferative layers. The profound effect on migration was also evident in the CP and MZ, where only 10% of the control infected cells resided, compared to approximately 75% of the EGF-R infected cells. Comparison of the migration patterns of EGF-R infected cells at E18 and E20 showed a 2 fold increase in the number of labeled cells in the IZ and CP at E20 and a 5 fold increase in the number of labeled cells in the MZ. These results suggest that constitutive expression of the EGF-R causes cells to leave the proliferative zones and migrate faster and farther than normal. The abnormal settling patterns of the EGF-R infected cells may be associated with an altered phenotype consistent with observations in explants. ## 118.6

**FGF2 CONCENTRATION-DEPENDENT NEURON/GLIA CELL FATE SWITCH BY MULTIPOTENTIAL NEURAL PROGENITOR CELLS**

X. Qian\*, A.A. Davis, S.K. Goderie, and S. Temple. Dept. of Pharmacology and Neuroscience A-136, The Albany Medical College, Albany, NY 12208

To understand the factors regulating multipotential neural progenitor cell development, we examined the influence of cloned growth factors on the proliferation and differentiation of cortical ventricular zone (CVZ) cells in vitro. FGF2 elicits a dose-dependent proliferative response from CVZ cells with an ED50 of approx. 0.11ng/ml. In addition, FGF2 produces a dramatic concentration-dependent cell fate change in multipotential cells developed from E10 or E12 CVZ. In low FGF-2 concentrations (0.1ng/ml.), single CVZ cells generate proportionally more neuron-containing clones than at higher concentrations, (1-10ng/ml.), when more glial-containing clones are generated. E10 CVZ cells generate more neurons and fewer glia than E12 CVZ cells at each FGF-2 concentration tested, demonstrating a difference in responsiveness consistent with the normal timing of cell differentiation in vivo, where neurogenesis precedes gliogenesis. 40% of E10 CVZ cells responding to 0.1ng/ml of FGF-2, (when normally 80% generate neuron-only clones), can generate both neuronal and glial progeny after switching to 1-10ng/ml. FGF-2. This demonstrates that the cell fate switch results from changes in the differentiation of single multipotential neural progenitor cells, rather than selective stimulation of different neural progenitor cell classes. The neuron-to-glial fate switch exhibited by multipotential CVZ cells, along with the known FGF-2 up-regulation in embryonic cerebral cortex, suggests a mechanism for generating neurons and glia on schedule during development. This work is supported by NIH grant RO1NS3529.

## 118.8

**REGULATION OF NEUROGENESIS BY NEURONAL COLONY-FORMING PROGENITORS ISOLATED FROM MOUSE OLFACTORY EPITHELIUM.** A.L. Calaf\*, J.S. Mumm, P.C. Fim & J. Shou. Dept. of Anatomy & Neurobiology & Developmental Biology Center, Univ. Calif. College of Med., Irvine, CA 92717.

In mammalian olfactory epithelium (OE), generation of olfactory receptor neurons (ORNs) takes place continuously throughout life, suggesting that a neuronal stem cell exists in this system. We have developed methods to isolate neuronal progenitor cells from OE, to identify neuronal stem cells and define conditions supporting their survival and generation of ORNs. Neuronal progenitor cells are purified by immunological panning from a neuronal cell fraction isolated from embryonic mouse OE. When grown in defined, serum-free culture, the majority of purified progenitors behave as Immediate Neuronal Precursors of the ORN lineage: they rapidly give rise to ORNs, which die shortly thereafter. However, if purified progenitors are co-cultured with stroma cells derived from olfactory turbinates, a small subpopulation of them gives rise to proliferative colonies. One morphologically identifiable subset of these colonies continues to generate both ORNs and undifferentiated progenitors as late as 7 days *in vitro*. The frequency at which such colonies arise suggests they are the clonal progeny of an undifferentiated cell which, when cultured in the presence of stroma cells, exhibits the capacity for sustained neurogenesis. This "neuronal colony forming cell" may be the neuronal stem cell of the OE. Significantly, development of neuronal colonies can be specifically inhibited by plating purified progenitors onto stromal feeder cells in the presence of a large excess of ORNs. This result suggests that differentiated neurons provide a signal that feeds back to inhibit production of new neurons by their own progenitors. Supported by grants to ALC from NIH (DC02180), the Council for Tobacco Research (3663), and a March of Dimes/Basil O'Connor Scholar Award.

## 118.9

LONG-TERM SURVIVAL OF NEW NEURONS GENERATED IN VITRO BY PRECURSORS DERIVED FROM ADULT HUMAN EPILEPTIC TEMPORAL NEOCORTEX. D. Pincus<sup>1,2</sup>, C. Harrison<sup>2</sup>, R. Goodman<sup>1</sup>, D. Lahar<sup>2</sup>, R. Fraser<sup>2</sup>, M. Nedergaard<sup>3</sup>, S. A. Goldman<sup>2</sup>. <sup>1</sup>Depts. Neurosurg., Columbia U. Col. P. & S., NY; <sup>2</sup>Neurology, Cornell Univ. Med. Col., NY; <sup>3</sup>Cell Biol., New York Med. Col., NY.

The adult mammalian forebrain harbors neuronal precursor cells throughout the rostral subependymal zone (SZ). In the human SZ, precursors capable of producing neurons in vitro have been harvested from the temporal lobes of adults with refractory epilepsy (*Cereb. Cortex* 4:576, 1994). In adult rodents, the proliferation of analogous precursor cells is promoted in vitro by FGF-2; thereafter, the survival of their neuronal daughters is supported by BDNF (*PNAS* 92:210, 1995). In this study, we sequentially treated adult human brain tissue with FGF-2 followed by BDNF, to promote the clonal expansion and long-term survival of precursor-derived neurons. Temporal lobe resections were divided into SZ and cortical samples, all of which were raised as explants. For the first week, half of the cultures were grown in DMEM/F12/N2/5% FBS, and the remainder supplemented with 20 ng/ml FGF-2. During this time, the cultures were exposed to <sup>3</sup>H-thymidine (<sup>3</sup>H-dT) as a marker of cell division. All cultures were then switched to media containing 20 ng/ml BDNF. SZ explants derived from several of these brains generated small numbers of MAP-2<sup>+</sup> neurons, as we previously reported. In addition, *neocortical* cultures derived from at least two brains, one prepared as noted and the other as a trypsin-dissociate, were found to have generated neurons. These cells expressed MAP-2, and many incorporated <sup>3</sup>H-dT during the first week in culture. Confocal imaging confirmed that the new neurons were functional; they responded to KCl-depolarization with large increments in calcium. In the presence of BDNF, arrays of up to several dozen neurons were observed as long as 9 weeks in vitro. Thus, the adult epileptic temporal cortex may harbor residual neuronal precursors analogous to those of the SZ. These may be parenchymal precursors, or aberrant migrants with neuronal potential in epileptic subventricular heterotopias. The proliferation and survival of their neuronal daughter cells suggests the promise of generating new neurons from adult human brain tissue.

Support by the Mathers and Lookout Foundations, Hirschi Trust, and NINDS.

## 118.11

*biparous*: A NOVEL BHLH GENE EXPRESSED IN NEURONAL AND GLIAL PRECURSORS IN *DROSOPHILA*. A. Bush, J. Kanki\*, Y. Hiromi, M. Cole. Dept. of Molecular Biology, Princeton University, Princeton, NJ. 08544

We have recently discovered a novel bHLH gene which may be involved in neuronal and glial specification. Based on its expression in progenitor cells that give rise to two types of cells, neurons and glia, we have named this gene *biparous* (pronounced bip-er-es), which means producing two offspring. *Biparous* is expressed in a dynamic and complex pattern during embryogenesis. The pattern is simplest during stage 14 and 15 when *BIPAROUS* transcript is found in cells at the lateral edge of the nervous system. These cells express neither the glial specific marker *repo* nor the neuronal specific marker *elav*, suggesting that they are progenitor cells which are not yet post-mitotic. Consistent with this, BrdU incorporation studies indicate that *BIPAROUS* positive cells are still synthesizing DNA.

Staining of embryos expressing a *biparous* promoter/lacZ fusion gene for  $\beta$ -galactosidase immunoreactivity revealed a recapitulation of the late expression pattern of endogenous *biparous*. In addition, anti- $\beta$ -galactosidase staining persists beyond the time when the *BIPAROUS* transcript is no longer detectable by *in situ* hybridization. Double-labeling of these embryos for  $\beta$ -galactosidase and either *elav* or *repo* revealed doubly positive cells, suggesting that the *BIPAROUS* positive cells are pre-mitotic and can generate both glial and neuronal progeny.

Preliminary misexpression studies have revealed no obvious effect on the number of neurons or glia, suggesting that *biparous* may play a role in cell specification rather than cell type determination. We are isolating strains lacking *biparous* in order to test this hypothesis. Supported by grants from the N.I.H.

## 118.10

JAGGED DECREASES *IN VITRO* DIFFERENTIATION OF PHOTO-RECEPTORS IN RAT RETINA. K.L. McCabe\*<sup>1</sup>, G. Weinmaster<sup>2</sup>, and T.A. Reh<sup>1</sup>. <sup>1</sup>Prog. in Neurobiology, Dept. of Biostructure, University of Washington, Seattle, WA, 98195. <sup>2</sup>Dept. Biol. Chem., University of California at Los Angeles, Los Angeles, CA, 90095-1737.

Cell-cell interactions are thought to play an important role in the development of the central nervous system. In *C. elegans*, *Xenopus*, and *Drosophila*, the Notch-Lin12 family of transmembrane receptors have been shown to be integral for the decision of a progenitor cell to differentiate, such that activated Notch delays progenitor cell differentiation. In *Xenopus* and chick retina, activated forms of Notch have been shown to decrease the number of newly differentiated neurons. A newly identified vertebrate ligand, Jagged, has been shown to activate Notch1. The presence of Jagged should decrease the number of newly differentiated neurons and increase the number of progenitor cells. Dissociated postnatal rat retinal cells were cultured with membrane prepared from Jagged transfected L cells to test the potential function of this Notch ligand. On postnatal day 2 the majority of cells generated in the retina are rod photoreceptors, while many other cell types including ganglion and amacrine cells have already been generated. Therefore, we predicted that photoreceptor differentiation should be inhibited by culturing P2 rat retinal cells on Jagged-L cell membrane. Consistent with this prediction we found a 30% decrease in photoreceptors and an 80% increase in progenitor cells. Ganglion and amacrine cell numbers were unchanged as predicted. Jagged and activated Notch may be critical in the timing and decision of progenitor cells to differentiate in the mammalian retina.

A NOVEL CELL-SURFACE GLYCOPROTEIN EXPRESSED BY NEURAL PRECURSOR CELLS. J. Trotter\* and A. Niehaus. Dept. of Neurobiology, University of Heidelberg, Im Neuenheimer Feld 364, 69120 Heidelberg, Germany.

To identify new cell-surface molecules regulating early events of myelination such as precursor cell migration and recognition of axons, we have generated monoclonal and polyclonal antibodies against cell surface glycoproteins isolated from oligodendrocyte precursor cells. As immunogen, an immortalised murine line of oligodendroglial precursor cells that ensheathes axons upon *in vivo* transplantation was used. We have identified a new cell-surface glycoprotein of 330kD expressed by a subset of proliferative oligodendrocyte precursor cells. The antigen shows a partial overlap of expression with O4 and GD3 antigens. It is down-regulated as the cells mature and express the myelin-associated glycoprotein and is not in myelin. Neurons and astrocytes do not express the antigen. The protein expresses the HNK-1 carbohydrate epitope and binds Peanut Lectin. Metabolic radiolabelling experiments with <sup>35</sup>S sulphate as well as enzymatic digestion of the carbohydrate epitopes indicate that a subpopulation of the antigen molecules carries glycosaminoglycan chains. In Western Blots of the developing mouse brain, expression of the protein is first seen at E13, peaks at P10 and is down-regulated in the adult. In addition to oligodendrocyte precursor cells, the antigen is expressed by Schwann cells and proliferative nestin-positive neural precursor cells that are found in embryonic cortex and hippocampus. The antigen may be involved in regulating precursor cell behaviour such as migration and adhesion. Financed by the Deutsche Forschungsgemeinschaft.

## 119.1

EMBRYONIC DEVELOPMENT OF GnRH NEURONS IN SYRIAN HAMSTERS. S.J. Berriman\*, H.T. Jansen, J. Schaeffer, K. Humbaugh, and M.N. Lehman. Dept. Cell Biology, Neurobiology, and Anatomy, Univ. Cincinnati Coll. Med., Cincinnati, OH 45267.

The Syrian hamster is an important model for the study of photoperiodic and hormonal influences upon the developing GnRH neuroendocrine system (Jansen et al., Soc. Neurosci. Abstr., 1996). To define the development of the GnRH system in this species, we harvested embryos from pregnant hamsters beginning on embryonic day 11 (E0=day of mating) and each day until birth (E16), as well as on post-natal (P) days 1 and 5. Single-label immunocytochemistry was performed on thin frozen tissue sections to localize GnRH. Adjacent sections were double-labelled to visualize both GnRH and the intermediate filament, peripherin, since GnRH cells have been shown to be associated with peripherin-positive fibers in the developing mouse. At E11-E12, GnRH cells are found exiting the olfactory placode and crossing the presumptive cribiform plate into the primordial forebrain. GnRH cells and fibers are also seen within the forebrain, but no GnRH fibers are seen in the median eminence. At these ages, GnRH cells within the nasal cavity and brain are closely associated with peripherin-positive fibers that form part of olfactory and vomeronasal nerves. In addition, peripherin-positive fibers are located at base of hypothalamus. By E14, very few GnRH cells are seen in the nasal cavity, the majority being located in the septal region and preoptic area. From E15 to P5, there is very little change in the distribution of GnRH cells or fibers; few if any GnRH fibers are present in the median eminence at these ages. We are currently analyzing older animals to determine when GnRH fiber innervation of the median eminence is complete, and to see whether there is any change in GnRH cell number during this period. Supported by F32 NS09558 to SJB and NIH HD07841 to HTJ.

## 119.2

NEONATAL HYPOTHYROIDISM INCREASES GNRH CELL NUMBER IN SPECIFIC REGIONS OF THE ADULT MALE HAMSTER BRAIN. H.T. Jansen\*, A. Khosla, S.J. Berriman, G.A. Iwamoto, and M.N. Lehman. Dept. Cell Biology, Neurobiology, and Anatomy, Univ. Cincinnati Coll. Med., Cincinnati, OH 45267 and Dept. Vet. Biosciences, Univ. Illinois, Coll. Vet. Med, Urbana, IL 61801.

Hypothyroidism affects the reproductive axis of males and females in a number of species but it is not known whether these effects are mediated via a direct action on the GnRH neuroendocrine system. The current study addressed this question in the seasonally breeding Syrian hamster using a previously validated rat neonatal hypothyroid model. In order to produce hypothyroid pups, lactating female hamsters were given 6-N-propyl-2-thiouracil (PTU) in the drinking water (0.1%) and feed (.4%). At 25 days of age male pups were weaned, allowed free access to tap water and lab chow, and housed under long-day photoperiod (14L:10D) until 5 months of age. Animals were killed and paired testes, body, and brain weights were recorded. Brains were sectioned coronally and processed for GnRH immunocytochemistry. The number of GnRH neurons (unipolar and bipolar) in every fourth section from the rostral forebrain to the mamillary bodies was counted by an investigator blind to the treatment regimen. Body and brain weights did not differ between groups. Testes weights were increased in hypothyroid animals by 26% (p<0.001), confirming earlier reports in rats. Compared to controls, hypothyroid animals possessed significantly greater numbers of GnRH neurons in the anterior hypothalamic area, lateral hypothalamus and mediobasal hypothalamus (overall increase of nearly 60%; p<0.02). This difference was seen for both unipolar (p<0.001) and bipolar (p<0.05) GnRH neurons. By contrast, the number of GnRH neurons located more rostrally in the tenia tecta, lateral septum, diagonal band of Broca, and preoptic area did not significantly differ between hypothyroid and control animals. In summary, transient hypothyroidism in the neonatal Syrian hamster increases the number of immunoreactive GnRH neurons located in caudal regions of their normal distribution. This may be due to either an increase in GnRH gene expression, or the interruption of a normal process of GnRH cell loss, in these regions. Supported by NIH HD07841.

## 119.3

ANALYSIS OF NASAL MIDLINE CUES WHICH INFLUENCE AXONAL OUTGROWTH AND LHRH CELL MIGRATION IN OLFACTORY EXPLANTS. S. Wray\* and S. M. Fueshko. Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

During development, luteinizing hormone releasing hormone (LHRH) neurons migrate from the olfactory epithelium into the diencephalon in association with a bilateral subset of axons of the olfactory complex. It is likely that guidance cues on cellular surfaces and/or substrate pathways are involved in directing outgrowth of olfactory axonal fibers, and subsequent neurophilic migration of LHRH neurons. Utilizing an *in vitro* explant system, we are examining cell surface mechanisms involved in both of these events. Previously, we showed that inhibition of N-glycosylation dramatically altered olfactory axonal outgrowth. Our results suggested that a midline-localized, N-glycosylated signal(s) directs outgrowth and/or turning of axons of the olfactory complex. To assay for directional cues from midline nasal structures, we have removed midline tissue or reoriented olfactory pit-midline relations in explant cultures. In unilateral olfactory pit cultures containing negligible midline tissue, peripheral axons and NCAM axons (two markers for the olfactory axon complex) exhibited oriented and directional outgrowth, and LHRH neuronal migration occurred. These results indicate that by E11.5, appropriate cue(s) for initial olfactory axon outgrowth are already established, or maintained, in explanted, unilateral olfactory pits. Currently, manipulations of the orientation and relation of the cartilaginous midline tissue to the olfactory pit are in progress to determine whether the midline region provides signals for the bilateral turning of olfactory axons towards the developing brain. Supported by NINDS, NIH Intramural Program.

ROLE OF *PAX-6* GENE IN LHRH AND OLFACTORY SYSTEM DEVELOPMENT STUDIED IN *SEY* MOUSE PHENOTYPE. T.L. Dellovade\*, D.W. Pfaff, and M. Schwanzel-Fukuda. Lab. of Neurobiology and Behavior, The Rockefeller University, New York, NY 10021.

*Pax-6* is a member of a murine family of developmental control genes important for CNS development. A point mutation in the *Pax-6* gene is responsible for the Small-Eye (*Sey*) phenotype in mice. Homozygotes (*Sey/Sey*) lack both eyes and nasal structures, and die neonatally because they can not breathe. Heterozygotes (*Sey/+*) have a variety of eye abnormalities, and we recently found that both main olfactory bulb volume and mucosal surface area are decreased compared to wild-type litter mates by postnatal day 42. However, there was no effect on either the vomeronasal organ or accessory olfactory bulbs. In this study we examined the effect of this *Pax-6* point mutation on LHRH neuronal migration and olfactory system development in *Sey/Sey* and *Sey/+* embryos. *Sey/+* females were time-mated with *Sey/+* males and embryos were collected from day 10 postconception through postnatal day 1. Paraffin sections were examined for LHRH immunoreactivity in combination with NCAM, LI and S-100 immunoreactivity. In *Sey/Sey* embryos the olfactory placodes failed to develop and there were no LHRH immunoreactive neurons observed in either "nasal regions" or in the brain at any age. In contrast, there does not appear to be any effect on LHRH migration or prenatal olfactory bulb development in *Sey/+* embryos. These data confirm the olfactory placode origin of the LHRH neurons and suggest marked specificity of the role of *Pax-6* during olfactory system development. This research is funded by NIH grant NS 09632-01A1 (T.L.D.).

## 119.4

OLFACTORY PLACODE DERIVED GALANIN NEURONS: A SUBPOPULATION OF LHRH CELLS? S. Key. Veeranna\* and S. Wray. Lab. of Neurochemistry, NINDS, Bethesda, MD 20892.

Postnatally, a subpopulation of LHRH neurons has been shown to express galanin. Prenatally, LHRH neurons originate from the olfactory pit (OP) and during development migrate through nasal regions into the forebrain. Whether LHRH neurons co-express galanin outside the CNS is unknown. Thus, the spatiotemporal pattern of cells expressing mRNA encoding galanin and the relation of these cells to LHRH neurons was investigated in prenatal mice using *in situ* hybridization histochemistry (ISHH). Cells containing galanin mRNA were detected at E10.5 in the OP. At this age, no LHRH cells were detected. At E11.5, LHRH mRNA, like galanin mRNA, was expressed in cells in the OP. A day later, at E12.5, both galanin cells and LHRH cells dramatically increased in number. At this stage, galanin expressing cells and LHRH cells were located in nasal tracks extending from the OP to the telencephalon. However, galanin expressing cells were fewer in number, and showed decreased expression compared to LHRH cells in tracks or galanin cells in the OP. Thus, a subpopulation of cells expressing galanin showed a similar spatiotemporal pattern during development to that of LHRH cells. The location and apparent migration of these galanin cells suggest either co-localization or directly adjacent cell populations. We are currently using double labeled ISHH to test the hypothesis that all or a subpopulation of migrating LHRH neurons co-express galanin. Supported by NINDS, NIH intramural program.

## 119.6

VASCULOGENESIS IN THE NASAL MESENCHYME OF THE EARLY HUMAN EMBRYO DURING LH-RH NEURONAL MIGRATION. M. Schwanzel-Fukuda\*, D.W. Pfaff and T.L. Dellovade. The Rockefeller University, New York, NY. 10021.

In human embryos, at about 28 days, we have noted an extensive and distinct focus of vascular development in the nasal mesenchyme between the epithelium of the newly-formed olfactory pit and the developing forebrain. Neural cell adhesion molecule (N-CAM)-ir cells are seen in the epithelium of the olfactory pit at this age. These "pioneer" N-CAM-ir cells migrate out of the epithelium of the olfactory pit (Schwanzel-Fukuda et al., 1992; JCN; 321:1-18) and in close association with the developing blood vessels form a "cellulovascular aggregate" or strand either side of midline in the nasal mesenchyme between the olfactory pit and the anlage of the forebrain. This "cellulovascular aggregate" not only receives the ingrowing N-CAM-laden central processes of the olfactory, vomeronasal and terminal nerves but also by day 42 forms a scaffold along which the luteinizing hormone-releasing hormone (LH-RH)-ir neurons can migrate into the brain. The LH-RH cells, together with the vomeronasal and terminal nerves, originate from the medial part of the olfactory pit (Schwanzel-Fukuda et al., 1996; JCN; 366:547-557). The basal lamina of the rostral-medial forebrain, which is in contact with the "cellulovascular aggregate", is breached by a number of ingrowing blood vessels. The LH-RH neurons characteristically enter the forebrain along with these blood vessels. Therefore, the developing cerebral vasculature in this region may provide an important structural support facilitating LHRH neuronal migration into the brain. Supported by NIH grant DC 00880 (M.S.-F.)

## CELL DIFFERENTIATION AND MIGRATION III

## 120.1

MIGRATION OF CEREBELLAR GRANULE CELLS WITHIN THE INTERNAL GRANULAR LAYER. H. Komuro\* and P. Rakic. Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510.

In the developing cerebellum, granule cells migrate from their place of origin in the external granular layer, through the expanding molecular layer along Bergmann glial processes until they enter the internal granular layer (IGL). However, upon entering the IGL and detaching from the Bergmann glial processes, a subset of granule cells does not stop movement, but rather continues to move within the IGL. Here, we examined the migrating behavior of granule cells within the IGL, and the role of intracellular calcium ion as a messenger for regulation of the rate and cessation of their movement. Sagittal and coronal cerebellar slices from 7-13 day-old mice (CD-1) were labeled either with carbocyanine dye (DiI, 4  $\mu$ M) for monitoring cell movement, or with a mixture of Fluo-3, AM (3  $\mu$ M) and Fura-Red, AM (4  $\mu$ M) for ratiometric measurements of  $Ca^{2+}$  fluctuations using laser-scanning confocal microscopy. Dual-emission images were detected simultaneously at  $540 \pm 15$  nm for Fluo-3 and  $>600$  nm for Fura-Red. We found that a number of cells in the IGL displayed bipolar shape with voluminous leading and thin trailing processes characteristic of migrating neurons. The majority (~75 %) of these cells moved toward the deep strata of the IGL at an average rate of 10.1  $\mu$ m/hr. This rate is slightly lower than the movement of granule cells in the molecular layer. Interestingly, about 20 % of cells moved tangentially, parallel to Purkinje cell layer, at a similar average rate (9.7  $\mu$ m/hr). However, about 4 % of cells migrated in the opposite direction, toward the upper strata of the IGL at an average rate of less than 5  $\mu$ m/hr. Fluo-3/Fura-Red ratio images revealed that all migrating cells in the IGL exhibit fluctuations of intracellular  $Ca^{2+}$  levels during their movement, similar to those observed in migrating granule cells in microexplant cultures. The  $Ca^{2+}$  fluctuations may potentially be regulated by contact with the afferent mossy fiber system, and thereby provide a signal for cessation of movement. Thus, the final stage of migration may play an important role in the functional specification of granule cell. (Supported by NS22807 and NS14841)

## 120.2

GRANULE NEURON MIGRATION IS RETARDED IN THE DEVELOPING CEREBELLUM OF MICE LACKING THE TISSUE PLASMINOGEN ACTIVATOR GENE. N. W. Seeds\* and S. P. Haffke. Dept. Biochem/Biophys/Genetics, Univ. Colorado H.S.C., Denver, CO 80262.

In the developing cerebellum, granule neurons migrate from their site of origin in the external granule cell layer (EGL) through the molecular and Purkinje cell layers to find their niche in the internal granule layer (IGL). We have shown that tissue plasminogen activator (tPA) gene expression is turned-on as these granule cells begin to migrate from the EGL. tPA mRNA expression and tPA protein levels are highest in granule neurons as they migrate through the molecular and Purkinje cell layers. However, tPA gene expression is down-regulated after granule cells reach the IGL. To explore the role of tPA in granule cell migration, we have compared the number of granule cells in the molecular layer during the second postnatal week in mice containing null mutations in the gene encoding tPA and their wild-type counterparts. As reported (Nature 368:419,1994) these null mutants have a normal phenotype. Cerebellar weight and folia size were the same in both mice. Similarly, DNA levels and total cell number showed no difference between the two types of mice. However, an analysis of migration in more than thirty mice consistently showed two-fold more migrating granule neurons in the molecular layer of tPA null mutants at postnatal days 7, 10 & 13 than in wild-type mice or in urokinase null mutants. Migration was complete during the third postnatal week in all mice.  $^3H$ -thymidine birthdating also showed a two-fold increase in labeled cells in the molecular layer on each of these days. These findings suggest that the absence of tPA protease leads to a retarded rate of granule neuron migration. (Supported by NIH grant NS-09818)

## 120.3

**TARGETED DISRUPTION OF ASTROTACTIN, A GENE THAT FUNCTIONS IN CNS NEURONAL MIGRATION ALONG GLIAL PROCESSES** G. P. Dietz\*, C. Zheng and M. E. Hatten. Lab. of Developmental Neurobiology, The Rockefeller University, New York, NY 10021.

The directed migration of young neurons along a system of glial fibers is fundamental to the establishment of the architectonics of cortical regions of the vertebrate brain. The neuronal gene *astrotactin* functions in migration of neurons along glial fibers, by providing a ligand for neuronal binding and a signal that maintains glial differentiation. In *in vitro* studies, antibodies raised against the protein prevent the formation of stable neuron-glia contacts and migration of neurons along glial cells. *Astrotactin* is expressed by neurons in the CNS that migrate on glial processes or assemble in neuronal layers, including the cerebellar cortex, cerebrum, hippocampus and the olfactory bulb. In the cerebellum, *astrotactin* expression is highest between postnatal day 2 (P2) and P10, the time when massive migration of granule cell precursors from the external germinal layer (EGL) to the internal granular layer occurs. *Astrotactin* encodes a protein with an apparent molecular weight of 100 kD, containing 3 EGF and 2 fibronectin III repeats. The unique structure and expression pattern of *astrotactin* and its activity in *in vitro* studies suggest that the *astrotactin* gene plays an interesting role in the development of the central nervous system. To further examine the function of *Astrotactin*, a null mutant will be generated by targeted disruption of the gene. 2.8 kb of the locus containing the putative translation start codon were replaced with a neomycin resistance gene by homologous recombination in ES cells. Positively targeted clones were injected into blastocysts and used to generate chimeric mice. Chimeras in which the mutant clone contributed to 90% of the coat are bred for germline transmission of the ES cell genotype. (Supported by NIH Grant NS 15429 awarded to MEH.)

## 120.5

**MIGRATION OF GRANULE NEURONS IN CEREBELLAR ORGANOTYPIC CULTURES IS IMPAIRED BY METHYLMERCURY.** M. Kunitomo, H. Asou\* and T. Suzuki. Environ. Health Sci. Div., Natl. Inst. Environ. Studies, Tsukuba, Ibaraki 305, and \*Tokyo Metropolitan Inst. Gerontol., Itabashi, Tokyo 173, Japan.

To examine whether abnormal migration of granule neurons during cerebellar development is in part of the etiology of Minamata disease, organotypic culture of rat cerebellar slice was established according to the method of Tanaka *et al.* (*Brain Res.* 641, 319-327 (1994)). External granule-layer neuroblasts were pulse-labeled with bromodeoxyuridine (BrdU). Incubation of cultures in the presence of methylmercury (1.0 - 10  $\mu$ M) resulted in dose-dependent inhibition of labeled neuroblast migration toward the internal granule layer. At 10  $\mu$ M methylmercury neuroblast migration was inhibited almost completely. Moreover, indirect immunofluorescence using anti-BrdU antibody disclosed nuclear condensation typical of apoptosis in a large fraction of methylmercury-treated cells. Thus methylmercury inhibits the migration of cerebellar granule neurons in a model system for neural development. As demonstrated previously, methylmercury induces neuron apoptosis (M. Kunitomo, *Biochem. Biophys. Res. Comm.* 204, 310-317 (1994)), a phenomenon which now appears associated with methylmercury impairment of granule neuron migration. (This work was supported by the Grant for Encouragement of Promising Scientists from Natl. Inst. Environ. Studies, 1994 & 1995.)

## 120.7

**REELIN IS AN EXTRACELLULAR MOLECULE THAT CONTROLS THE LAMINAR ORGANIZATION OF THE BRAIN.** G. D'Arcangelo and T. Curran\*. Department of Developmental Neurobiology, St. Jude Children's Research Hospital, Memphis, TN 38105.

Reeler (rl) is a mouse autosomal recessive mutation that causes impaired motor coordination, tremors and ataxia. This behavioral phenotype results from widespread disorganization of the cerebellar and cerebral cortices and other laminated regions of the brain. In our laboratory, a transgenic rl allele, rl<sup>tg</sup>, was generated by insertional mutagenesis<sup>1</sup>. We cloned rl locus regions flanking the transgene, and screened them for coding sequences by exon trapping. A cDNA library was probed with trapped exons and a full-length clone, named *reelin*, was produced by a combination of library screening and PCR RACE techniques<sup>2</sup>. Coding regions of *reelin* are partially deleted in both the rl and rl<sup>tg</sup> mutant strains, resulting in the lack of mRNA expression. The predicted Reelin protein (388 Kda) contains a signal peptide and several features of extracellular proteins, such as EGF-like repeats and potential glycosylation sites. The N-terminus is similar to F-spondin, a protein secreted by the floor plate that is involved in neuronal adhesion. In the embryonic cerebral cortex, *reelin* is expressed selectively by the Cajal-Retzius cells, the earliest-generated neurons that occupy the marginal zone. In the postnatal developing cerebellum, *reelin* is expressed by granule neurons. Other cell types express *reelin* at specific stages of development in many brain structures. The mechanism by which Reelin controls neuronal migration during development of each of these structures is not yet understood. To address this question, we have generated recombinant plasmid constructs encoding full-length or truncated Reelin. The biochemical and functional properties of recombinant and native Reelin will be analyzed using *in vitro* systems. Hopefully, these studies will shed light on the molecular events that control neural cell migration.

## 120.4

**CONTROL OF TAG-1 EXPRESSION IN DEVELOPING CEREBELLAR GRANULE NEURONS.** M.E. Dandenaui\*, R.W. Stottmann and R.J. Rivas. Dept. of Zoology, U. of Maryland, College Park, MD 20742.

The GPI-anchored cell adhesion molecule, TAG-1, is transiently expressed during the initial stages of axon outgrowth of a number of CNS neuronal cell types. In developing postnatal cerebellar cortex, TAG-1 is expressed on granule cell parallel fiber (PF) axons in the deep external granule layer (EGL); TAG-1 positive axons sequentially accumulate over older PF axons in the molecular layer (ML) that no longer express TAG-1 (Yamamoto *et al.*, 1986. *J. Neurosci.* 6: 3576-3594). Maturing PF axons form synapses with Purkinje cell dendrites in the ML. To determine the spatial relationship between TAG-1 expressing PF axons and Purkinje cell dendrites, sagittal sections of P2, P5, P10, P15, and P20 rat cerebellar cortex were double stained for TAG-1 and the Purkinje cell specific marker, calbindin, using indirect immunofluorescence. Confocal microscopy revealed that the layer of TAG-1 expressing axons in the deep EGL was localized above the furthest superficial extent of the Purkinje cell dendritic tree at all ages examined. To test if increased synaptic activity could turn off cell surface TAG-1 expression, purified P4-P6 mouse granule cells were cultured in serum-free medium containing control (5 mM) or chronically-depolarizing (25 mM) levels of KCl. Cells were immunostained for TAG-1 at 2 or 4 days *in vitro* (DIV). At 2 DIV, TAG-1 appeared to be expressed at equivalent levels on both control and chronically depolarized cells. At 4 DIV, control cells continued to express TAG-1. Chronically depolarized cells at 4 DIV showed higher rates of survival and more extensive neurite outgrowth than did control cells, yet showed a striking decrease in cell surface TAG-1 expression as compared to controls. Thus, the onset of synaptic activity between PF axons and Purkinje cell dendrites in the ML could provide a signal to turn off TAG-1 expression at the deep EGL/ML junction. Supported by American Paralysis Association grant RB1-9501.

## 120.6

**CR-50 ANTIGEN, A REELER GENE-RELATED MOLECULE, IS RESPONSIBLE FOR THE ARRANGEMENT OF PURKINJE CELLS.** T. Miyata\*†‡, K. Nakajima\*, K. Mikoshiba†‡, and M. Ogawa. Dept. Physiol., Kochi Med. Sch., Kochi 783; †Mol. Neurobiol. Lab., RIKEN, Ibaraki 305; ‡Dept. Mol. Neurobiol., IMSUT, Tokyo 108, JAPAN

To investigate the lamination mechanism in the developing cerebellum, we focused on an immunologically discovered molecule (CR-50 antigen) absent in reeler mice, in which morphological abnormalities occur in several brain regions, especially in the cerebellar cortex. This antigen is recognized by a monoclonal antibody (CR-50) produced by immunizing reeler mice with brains of normal mouse embryos, and transiently detected in developing brain regions where morphological abnormalities have been reported in this mutant (Ogawa *et al.* *Neuron* 14: 899, '95) and the mRNA of reelin, the candidate reeler gene, is expressed (D'Arcangelo *et al.* *Nature* 374: 719, '95). In the cerebellum, CR-50 antigen is produced during the period from E13 to P14 by non-Purkinje neurons, including early born neurons which subsequently form deep nuclei and late generated granule neurons. They present it extracellularly on their somas and processes that consist of superficial cortical structures, such as the nuclear transit zone and external granule layer along which Purkinje cells are aligned.

Further functional assays with E13 cerebella cultured as explants in collagen gels yielded the following findings: 1) Purkinje cells' distinct arrangement patterns between the *in vivo* cerebella of normal and reeler mice, i.e., multilayers vs. clusters recognized by P1-2, were almost reproduced by 7 day *in vitro*. 2) When exposed to CR-50, normal-derived Purkinje cells were forced to be clustered. 3) When reeler explants were covered with granule cells purified from normal mice and presenting CR-50 antigen extracellularly, Purkinje cells were aligned along the artificial granule cell layer, but remained clustered when granule cells for overlays were prepared from reeler mice. These blocking/rescue experiments *in vitro* suggest that the extracellular CR-50 antigen is crucial for the arrangement of Purkinje cells. ## 120.8

**DISRUPTION OF HIPPOCAMPAL DEVELOPMENT IN VIVO BY A CR-50 MONOCLONAL ANTIBODY, WHICH RECOGNIZES CAJAL-RETZIUS NEURONS.** K. Nakajima\*, K. Mikoshiba<sup>1,2</sup>, T. Miyata<sup>1,2,3</sup>, C. Kudo<sup>1</sup>, and M. Ogawa<sup>1</sup>. <sup>1</sup>Molecular Neurobiology Laboratory, The Institute of Physical and Chemical Research (RIKEN), Ibaraki 305, Japan; <sup>2</sup>Department of Molecular Neurobiology, Institute of Medical Science, University of Tokyo, Tokyo 108, Japan; <sup>3</sup>Department of Physiology, Kochi Medical School, Kochi 783, Japan.

The events of hippocampal development have been described extensively in various species. However, little is known about the molecular mechanisms. The *reeler* mutant mouse provides a good model to approach this problem, because in these mice neurons are aligned abnormally in various cortical structures including the hippocampus, although the neurons are generated normally. In the hippocampus of *reeler*, the pyramidal neurons are known to be less densely packed and, most prominently, the stratum pyramidale of the regio superior is interrupted by cell-poor rifts resulting in irregular and fragmented cell laminae.

We recently obtained alloantibodies by immunizing *reeler* mutants with normal embryonic brains. The monoclonal alloantibody, CR-50, specifically recognizes Cajal-Retzius neurons in the neocortex of normal embryos but not those of *reeler* embryos. Here we show that the epitope of CR-50 is localized on Cajal-Retzius neurons also in the hippocampus and that intraventricular injection of CR-50 at the embryonic stage disrupts the organized development of the hippocampus *in vivo*. Thus, Cajal-Retzius neurons play a crucial function in hippocampal development and the CR-50 epitope plays a central role in this function. This is the first demonstration of the role of the CR-50 epitope in the *reeler* phenotype *in vivo*.

## 121.1

IDENTIFICATION OF GENES WITH DISTINCT SPATIAL EXPRESSION PATTERNS IN THE DEVELOPING RAT CEREBRAL CORTEX. A. Okada, M. E. Levin and S. K. McConnell\*. Dept. of Biological Sciences, Stanford University, Stanford, CA 94305.

Transplantation studies of cortical progenitor cells have shown that early and late cortical progenitor cells have different fate potentials: early progenitors are multipotent and can give rise to neurons of all layers of the cortex depending on their environment at the time just prior to their last division in the ventricular zone (VZ), while progenitor cells from late stages of development are restricted to upper layer fates. We have applied differential screening techniques (differential display PCR) on VZ and subventricular zone (SVZ) cells of the developing cerebral cortex at early (E14) and late (E19) stages in an effort to identify genes that might distinguish progenitor cells with different fate potentials. In the process of our screen, we isolated six cDNAs whose expression patterns intriguingly correlate with the spatial position of the two mitotic zones (VZ, SVZ) or newly differentiated cells. Three of the genes are expressed strongly in the VZ but not SVZ, and are not expressed or expressed at relatively low levels in other regions of the developing brain; one of these genes is the rat homologue of the p190-B gene, encoding a putative GTPase activation protein. Two genes are expressed specifically in the SVZ but not VZ, and the expression of one appears to correlate with the position of cells that migrate into the olfactory bulb. The rat homologue of NeuroD was also isolated as a gene expressed in the intermediate zone of the developing cortex. We are currently interested in further characterizing these genes. Supported by American Cancer Society Post-doctoral Fellowship PF B77942 and a McKnight Scholar Award.

## 121.3

REGION-SPECIFIC GENES EXPRESSED IN THE PRESUMPTIVE GLIAL PRECURSOR CELLS IN THE EMBRYONIC RAT BRAIN. Y. HATANAKA\*, Lab. for Neural Systems, Frontier Res Program, The Inst of Phys & Chem Research, RIKEN, Wako, Saitama, 351-01, Japan

Recently, two types of cDNA fragments termed M1 and M2, expressed in the dorso-medial telencephalon, have been isolated from the embryonic day (E)13 rat by the use of mRNA differential display method. In the present study, their expression in mid- to late-gestation embryo was analyzed in detail by *in situ* hybridization to clarify what kind of cells are expressing these region-specific genes. M1 expression was observed in a most ventral portion of the hippocampal rudiment with a sharp dorsal boundary from E13 through E17. Its expression domain corresponded to a region lacking neuron-specific class III beta-tubulin immunoreactivity, suggesting that the germinal matrix producing fimbrial glia expresses M1 gene. M2 expression in E13 telencephalon was confined to a medial cerebral wall, including the presumptive septum and hippocampus with a more diffuse dorsal boundary than that of M1. At the same stage, its expression was also observed in a most anterior part of the medial diencephalon with a caudal extension along the dorsal midline and in the zona limitans intrathalamica. At E15, M2 expression was observed in axon tracts, including stria terminalis, stria medullaris, mammillothalamic tract and habenulopeduncular tract. At E19, its expression was also apparent in cells surrounding the hippocampal commissure and fimbria, as well as in migrating cells in these tracts. These results suggest that certain types of glial and glial precursor cells, which are located initially in presumptive axon tracts and then migrate away from their original locations, express M2 gene.

## 121.5

CADHERIN-8 EXPRESSION IN SEGMENTAL AND FUNCTIONAL SUBDIVISIONS OF THE DEVELOPING MOUSE BRAIN. C. Redies\* and K. Korematsu. Max-Planck-Institute for Dev. Biology, Spemannstrasse 35/II, D-72076 Tübingen, Germany.

We cloned full-length cDNA of a novel mouse cadherin (mCad8) which is highly homologous to human cadherin-8. The expression of mCad8 was studied by *in situ* hybridization. Results show that mCad8 is expressed in the CNS and thymus. At embryonic day E12.5, expression in the CNS is confined to particular embryonic subdivisions, e.g., the ventral thalamic neuromere and the cortical plate. Moreover, in the rhombencephalon, two large groups of mCad8-expressing cells are seen which form the anlagen of the pontine and facial nuclei at E14. From E16 to postnatal day P6, expression is restricted to particular developing brain nuclei and cortical areas in all major subdivisions of the CNS. The cerebellar cortex shows parasagittal stripes of mCad8 expression in Purkinje cells. In cerebral cortex, expression becomes restricted to limbic areas at P6. The mCad8-positive neuroanatomical structures can be grouped according to their known functional connections. They form particular parts of the limbic system, the basal ganglia and related nuclei, and the cerebellum and related nuclei.

These observations suggest that mCad8 plays a role in brain segmentation, in the morphogenesis of brain nuclei, in the functional regionalization of gray matter, and in the formation of neuronal circuitry. The results support the idea that cadherins are a family of molecules whose ontogenetic expression reflects the neuromeric organization of the early embryonic brain and functional neuroanatomy of the mature brain (see Redies, *Exp. Cell Res.* 220:243, 1995). (Supported by the Max-Planck-Society and the Land Baden-Württemberg.)

## 121.2

EFFECT OF ECTOPIC EN-2 EXPRESSION IN PURKINJE CELLS ON DEVELOPMENT OF THE CEREBELLUM. S. Sanlioglu-Crisman and J. Oberdick\*. Department of Cell Biology, Neurobiology and Anatomy and the Neurobiotechnology Center, The Ohio State University, Columbus, OH 43210.

Mammalian homologs of several *Drosophila* segment-polarity genes appear to be critically important for early cerebellar development, including the genes *wnt-1*, *en-1*, and *en-2*. Here we describe preliminary observations of En-2 overexpression in the cerebellum using the Purkinje cell-specific promoter, *pcp-2*(L7). Nine transgenic lines were obtained. The two highest copy number founders, and their offspring, show a mild ataxia which is detectable after postnatal day 20. Both lines show a decrease in cerebellar mass of 30-40% by at least P15 (the earliest time point examined to date), with no effect on the rest of the brain. This loss in mass is accompanied by a 15-25% decrease in size along both the rostrocaudal and dorsoventral axes; there is little change along the mediolateral axis. The decrease in size is especially apparent in the vermis, but seems to affect all cerebellar regions. Foliation is only subtly affected. In particular, folium X appears slightly larger in absolute terms than in wild-type controls and is clearly much larger relative to all other folia, which are rather uniformly decreased in size. In addition, folium IX is no longer distinguished by division into two subfolia on its ventral aspect. These latter observations suggest that some folium IX cells have been subsumed into folium X. Since Purkinje cell density and arrangement appears normal overall, some number of these cells must be lost during development to account for the decrease in cerebellar size. This is consistent with a rather substantial decrease in the density of synaptic terminals in the deep nuclei. The precise period of Purkinje cell loss and the effect on cerebellar sagittal banding in this transgenic mutant remain to be determined. These observations support the view that the *en* genes are part of a developmental switch that must be deactivated in Purkinje cells during late embryogenesis for normal cerebellar development to ensue. (Supported by NSF #IBN-9309611).

## 121.4

RETINOIDS UP-REGULATE HOX GENE EXPRESSION IN NOVEL TERRITORIES OF THE HINDBRAIN AFTER THE FORMATION OF RHOMBOMERE BOUNDARIES. J.C. Glover\*, F. Hoover, and K. Rehne. Dept. of Anatomy, Univ. of Oslo, 0317 Oslo, Norway

We have previously described the expression of retinoid X receptors in the hindbrain of the chicken embryo over a protracted period of development that extends well into the stages of neurogenesis and neuronal differentiation. To assess the role these receptors might play at such late stages, we have exposed chicken embryos to 9-cis retinoic acid (9-cis RA) under controlled conditions in an *in vitro* system. We focus here specifically on the effects on expression of the Hox B1 gene.

Exposure to 10<sup>-7</sup>M 9-cis RA led to an up-regulation of Hox B1 expression in the hindbrain. The up-regulation occurred within 2 hours and was manifested by an increase in the intensity of *in situ* hybridization signal in all the normal regions of expression characteristic of each stage of development. It could also be demonstrated quantitatively using RNase protection assays on whole embryo tissue extracts.

The normal Hox B1 expression pattern is dynamic: it is initially continuous from hindbrain rhombomere (r)4 into the spinal cord but eventually diminishes below the level of detectability in r5 and r6, leaving a conspicuous stripe in the domain of r4. In addition to up-regulating Hox B1 expression within this normal pattern, 9-cis RA up-regulated expression in specific domains within more rostral rhombomeres, where Hox B1 expression has never been detected previously. This indicates that the normal segmental pattern of Hox gene expression in the hindbrain is not strictly autonomous, but is subject to the effects of exogenous retinoids. Supported by Jahres and Nansens Funds.

A NOVEL bHLH PROTEIN EXPRESSED IN DISCRETE DOMAINS OF THE DEVELOPING RAT NERVOUS SYSTEM. P. Ravassard, F. Chatail, J. Mallet\* and C. Leclerc-Liepka. I.G.N. CNRS (UMR C9923), Hôpital de la Pitié Salpêtrière, 75013 PARIS, France

Here we report the isolation of a rat cDNA which encodes a new bHLH protein of 204 amino acids. The bHLH domain of this protein shares high identity with the bHLH domain of the proneural gene products Mash1, NeuroD and *atonal*. We show, by electrophoretic mobility shift assay, that this protein binds specifically a consensus E-box (CAGGTG). Using a transient expression system in the PC12 cell line this protein can transactivate in a dose dependant manner the transcription from an E-box containing promoter.

Using *in situ* hybridization experiments we show that this transcript is expressed in the nervous system during development. Transcripts are detected in E11.5-E19.5 embryos in the diencephalon and from the anterior part of the hindbrain all the way down the spinal cord. In the spinal cord, transcripts appear as bilaterally symmetrical stripes extending from the lumen to the lateral margins of the ventricular zone at two dorsoventral levels: just below the dorsoventral midpoint of the spinal cord and lateral to the floor plate. The latter stripe stops at the anterior part of the spinal cord whereas the former ends at the anterior part of the hindbrain. In the diencephalon the transcripts are detected in the ventral region of the third ventricle with the strongest expression in the caudal part of the diencephalon.

The discrete expression domains of this new bHLH protein do not correspond to the expression patterns of any known protein but overlap those of other proteins implicated in the regulation of neural cell fate. Taken together these data participate to the understanding of the molecular mechanisms regulating neural development. (Supported by CNRS, Rhône-Poulenc-Rorer, Institut de formation supérieure biomédicale and Institut de recherche sur la moelle épinière)

## INSERTIONAL MUTATIONS THAT AFFECT CRANIOFACIAL DEVELOPMENT IN THE ZEBRAFISH EMBRYO

T. Becker\*, M. Allende, N. Gaiano, A. Amsterdam, K. Kawakami and N. Hopkins.

Center for Cancer Research, MIT, Cambridge MA 02139.

Organization of the zebrafish head involves formation of the cartilaginous pharyngeal skeleton, which is subdivided into mandibular and hyoid arches, as well as five gill-bearing branchial arches. These structures, as well as anterior parts of the neurocranium and sensory ganglia of the head, are derived from the cranial neural crest. In a mutagenesis screen utilizing a pseudotyped retrovirus to create proviral insertions into the zebrafish genome, we have identified two mutations resulting in abnormal development of the pharyngeal skeleton. Both mutations show strong linkage to integrated proviral sequences. In insertion 67D, the mandibular and hyoid arches are strongly reduced, and all five branchial arches are absent. Insertion 38M results in deletion of anterior parts of the neurocranium, ventral structures of the mandibular and hyoid arches, and strong reduction or absence of all branchial arches. In addition, both mutants exhibit reduced eyes and shortened pectoral fins. In both mutant lines, the provirus lies within a transcription unit, immediately upstream of the putative initiation codon. We are currently further characterizing these mutants, and further investigating the consequences of these putative genetic lesions.

Supported by Damon Runyon-Walter Winchell postdoctoral fellowship DRG 1274 (T.B.). NIH (M.A., N.H.), Human Science Frontiers (N.H.), Amgen Inc. (N.G., N.H.), a Howard Hughes predoctoral fellowship (A.A.) and the Toyoba Biotechnology foundation (K.K.).

## 121.9

## PAX-6 REGULATION OF FOREBRAIN DEVELOPMENT IN EARLY MOUSE EMBRYOS G.S. Mastick\*, N.M. Davis, and S.S. Easter, Jr., Dept. Biology., U. Michigan. Ann Arbor MI 48109

The *Pax-6* gene encodes a transcription factor that is expressed in regionally restricted patterns in the developing brain and eye. Here we describe *Pax-6* expression in the early forebrain on E8.5-E10.5 using both wholemount RNA in situ hybridization and antibody labeling. We make three close correlations between *Pax-6* domains and initial neural patterns, and in each case identify defects in *Pax-6* homozygous mutants (*Small eye*).

1. Forebrain subdivisions are visible as six prosomeres (designated p1-p6, caudal to rostral), some of which are visible as bulges bounded by transverse constrictions. The edges of *Pax-6* domains coincide with two prosomeric boundaries: p1/mesecephalon and p2/p3. Mutant embryos lack the first boundary, but form the second.
2. The first axons to cross the roof form the posterior commissure (pc) in caudal p1. The source of these axons are two groups of neurons that are *Pax-6*-, but lie within dorsal and ventral *Pax-6* domains in p1. Mutant embryos have few pc axons, due to a lack of dorsal pc neurons.
3. The first forebrain tract, the tract of the postoptic commissure (tpoc), originates from *Pax-6*- neurons clustered at the base of the optic stalk. The pioneer tpoc axons project caudally, initially in a tight bundle, but fan out upon entering a *Pax-6* domain in p4 and p3, and funnel together again upon exiting into p2, which is low-expressing. In the mutant, the initial section of the tract is normal, but the axons make dramatic errors in the p4/p3 domain, and fail to cross into p2. We conclude that *Pax-6* plays multiple roles in forebrain patterning, including regulating morphological segmentation, neuron specification, and axon guidance.

## 121.11

EXPRESSION OF MOUSE *Zic1*, *Zic2* AND *Zic3*, THE HOMOLOGUES OF DROSOPHILA *odd-paired* DURING PATTERN FORMATION. Takeharu Nagai, Jun Aruga\*, Katsunori Nakata, Tsutomu Tokuyama and Katsuhiko Mikoshiba

Mol. Neurobiol. Lab., RIKEN, Tsukuba, Ibaraki 305, Japan

We have identified and characterized *Zic1* gene which encodes a zinc finger protein highly restricted in mouse cerebellar granule cell and medulloblastoma whose oncogenesis may be involved in the granule cell lineage. To examine the existence of *Zic1*-related genes, we performed a low stringency hybridization on mouse genomic library and could find novel structurally *Zic1*-related genes, *Zic2* and *Zic3*. Both *Zic2* and *Zic3* were expressed highly restrictedly in the cerebellum at adult stage and shared the highly conserved zinc finger motif and genomic organization with those of *Zic1* and *Drosophila* pair-rule gene, *odd-paired* (*opa*). *Zic* genes are thought to be the vertebrate homologues of *opa*, which is involved in the insect body pattern formation regulating timely activation of *engrailed* and *wingless*. Then, we examined expression of *Zic1*, *Zic2* and *Zic3* in mouse embryos to clarify their role in the vertebrate development. We found that the *Zic* genes are expressed in the multiple sites in developing mice, such as central nervous system, paraxial mesoderm and limb bud. The expression in the neural tube was dorsally restricted and, in other sites, the expression is also spatially restricted although there are significant differences in the expression patterns of the three gene. Our findings suggest that the *Zic* genes have multiple roles and may be involved in the vertebrate body pattern formation.

Supported by grants from Japanese STA and MESG.

## 121.8

## EXPRESSION OF THE HOMEOBOX GENE OTX2 ENHANCES NEURITE OUTGROWTH-SUPPORTING PROPERTIES AND CELL ADHESION MOLECULES EXPRESSION OF STABLY TRANSFECTED 3T3 CELL LINES. K.T. Nguyen Ba-Charvet, Y. von Boxberg, S. Guazzi#, E. Boncinelli# and P. Godement\*. Institut Alfred Fessard, CNRS, 91198 Gif-sur-Yvette, France and #DIBIT, Istituto Scientifico H.S. Raffaele, Via Olgettina 60, 20132 Milano, Italy.

Otx2 is an homeodomain protein expressed early in the embryonic forebrain of the mouse (Simeone et al. 1992). Among its functions, it could be involved in regulating the expression of substrate- and cell-adhesion molecules in a regional manner during forebrain development. In situ hybridization and immunocytochemistry show that, at relatively late embryonic ages (>E13), it is expressed in several areas of the mouse forebrain, and that within these areas, its expression varies over time. In particular, at E13, Otx2 mRNA and protein are expressed in cells scattered throughout the superior colliculus (a main target of retinal fibers), and are strongly expressed in the inferior colliculus. Strong expression of Otx2 appears in the developing stratum griseum superficiale at the surface of the SC by E15, and is maintained after birth. At this age, several other targets of the retina strongly express Otx2, among them the vLGN (but not the dLGN). To investigate whether Otx2 could regulate the expression of molecules involved in axonal growth, we transfected NIH3T3 cells with Otx2 cDNA, and tested retinal neurite outgrowth in vitro on membrane carpets prepared from control or transfected cells. We obtained several stable clones of cells, exhibiting different levels of expression of Otx2 protein. Neurites extended from retinal explants (from E13 and E14 embryos) are longer, less fasciculated, and more numerous on carpets of membranes of transfected cells than on control carpets. We then tested expression of known cell adhesion molecules by these cell lines using Western blots and by immunocytochemistry. We found that N-CAM 140 and Thy-1 were regulated in correlation with the level of Otx2 expression. These results suggest that Otx2 could affect axon growth by regulating cell adhesion molecules in a regional-dependent manner during brain development.

## 121.10

## MOLECULAR MARKERS WHICH IDENTIFY ROSTROCAUDAL BOUNDARIES IN THE MURINE CEREBELLAR CORTEX. A. Frostholt\*, D. Zdilár, P. McAndrew, A. Burghes and A. Rotter. Depts. Pharmacology and Neurology, The Ohio State University, Columbus, OH 43210.

In addition to the classical laminar and parasagittal organization of the cerebellar cortex, there is increasing evidence for rostrocaudal cerebellar compartmentalization. We have shown previously that acidic fibroblast growth factor (FGF-1) and novel protein tyrosine phosphatase (PTP $\lambda$ ) transcripts define a distinct rostrocaudal boundary in the cerebellar granule cell layer at the dorsal aspect of lobule VI, similar to that observed in the *meandertail* mutant. Here we show that the homeobox genes, Otx1 and Otx2, vertebrate homologues of the drosophila *orthodenticle* gene, also are differentially expressed in granule cells of anterior and posterior regions of the developing murine cerebellar cortex. Otx1 expression was highest in mitotically active granule cells of the perinatal external germinal layer (egl) in the anterior cortex. Conversely, the Otx2 transcript was expressed in proliferating and premigratory granule cells in the external germinal layer, and in postmigratory cells of the internal granular layer of the posterior cortex. There was a greater degree of overlap in the rostrocaudal distribution of the two Otx genes, which resulted in a less clearly defined boundary than that seen with the FGF-1 and PTP $\lambda$  transcripts. The distribution and temporal expression of the four markers is consistent with the notion that FGF-1 and PTP $\lambda$  are suppressed by Otx1 and 2; downregulation of Otx1 in the egl permits the expression of FGF-1 and PTP $\lambda$  in mature granule cells in the anterior cerebellar cortex.

Supported by NS18089 (AR) and NS32276 (AF).

## 121.12

## CHARACTERIZATION OF THE VENTRAL RETINA IN TWO LINES OF ZEBRAFISH CYCLOPS MUTANTS. E.A. Schmitt, L. Meeks, P. McCaffery, M. Hammerschmidt, U.C. Dräger and J.E. Dowling. Department of Molecular and Cellular Biology, Harvard University, Cambridge, MA 02138.

The ventral forebrain and optic stalk are deleted in two cyclopic lines of zebrafish, i.e., *cyc<sup>b16</sup>* (Hatta et al., 1994) and *oep<sup>n257</sup>* (Hammerschmidt, personal communication). These effects are associated with a lack of *sonic hedgehog* (*shh*) expression in the ventral forebrain, and the loss of the transcription factor, *pax2*, which is normally localized to the optic stalk and ventral retina. The *cyc<sup>b16</sup>* exhibits partial eye fusion with two retinas joined in the midline, whereas the *oep<sup>n257</sup>* exhibits complete eye fusion resulting in a single retina. To determine if a deletion of the ventral retina accompanies the deletion of the optic stalk, we examined ventral retinal markers in mutant larvae. First, the development of initial photoreceptors, normally located within a patch of the ventral retina (ventral patch), was examined using antibody markers for rods and cones. Second, the activity of the retinaldehyde dehydrogenase enzyme, localized to the ventral retina, was assessed by a zymography bioassay. Although neither mutant exhibited a ventral patch, (first photoreceptors appeared dorsally), both exhibited ventral retinaldehyde enzyme activity. As exogenous retinoic acid (RA) enhances ventral characteristics in the developing zebrafish retina (Hyatt et al., 1996), we next examined the effects of RA on both *cyc<sup>b16</sup>* and *oep<sup>n257</sup>* mutant retinas. In the *cyc<sup>b16</sup>*, RA induced an expansion of *pax2* expression and increased cell proliferation in the ventral retina eye, resembling the effect of RA in wildtypes. In addition, RA enhanced the activity of the ventral retinaldehyde dehydrogenase enzyme while suppressing that of the dorsal enzyme. In contrast, RA enhanced dorsal enzyme activity in the *oep<sup>n257</sup>* mutant. Our results suggest that the ventral retina is present in both cyclopic lines, and that unlike the optic stalk, it is not dependent on *shh* for its development. Although RA exerts expected effects in *cyc<sup>b16</sup>* mutants, further analysis is required to explain the anomalous effect of RA in the *oep<sup>n257</sup>* line. \*supported by NIH-EY00811.

## 121.13

THE DEVELOPMENT OF AMACRINE CELLS EXPRESSING THE LIM HOMEODOMAIN PROTEIN ISL-1 REVEALS MECHANISMS OF RETINAL MOSAIC FORMATION. L. Galli-Resta<sup>1</sup> and G. Resta<sup>2</sup>. <sup>1</sup>Istituto di Neurofisiologia CNR, 56127 Pisa, Italy; <sup>2</sup>Istituto di Matematica Computazionale CNR, 56126 Pisa, Italy.

Modularity is a basic architectural principle of the nervous system. Many neuronal structures are organized in layers with neurons of the same type forming regular spatial mosaics. Little is known of the mechanisms generating ordered neuronal matrices given the difficulty of identifying the matrix elements before they attain their final position. The Lim homeodomain protein Isl-1 is expressed by a subset of retinal cells during migration, providing a unique opportunity to analyse how cells add to developing mosaics. Two mosaics of Isl-1+ amacrine cells are found in the retina, separated by the inner plexiform layer. The genesis of the two mosaics was analysed by the use of several mathematical techniques (Voronoi domains, Delaunay segments and nearest neighbour analysis) in whole mounted retinas of developing rats. A minimal spacing between adjacent cells characterizes both mosaics while they are forming. The growth of the retina allows newly arriving Isl-1+ cells to add to the pre-existing mosaic according to the minimal spacing rule. The minimal spacing is constant as long as cells are added to the mosaic, is the same for both mosaics and characterizes also the interactions between cells of the two arrays. No center to periphery gradient is observed as long as new cells arrive. A gradient appears later, following a phase of cell death and further retinal growth. We conclude that: 1) the phenotype of Isl-1+ amacrine cells is determined before migration to their final destination; 2) mosaics of Isl-1+ amacrine cells are generated by an active rule which guides these cells into positions compatible with a minimal spacing rule.

## 121.15

FUNCTIONAL ANALYSIS OF ISLET-3 IN THE ZEBRAFISH EYE DEVELOPMENT. Y. Kikuchi<sup>1</sup>, M. Tokumoto<sup>2</sup>, Y. Hotta<sup>3</sup>, K. Uyemura<sup>3</sup>, and H. Okamoto<sup>4</sup>. 1.Dept. Physiol., KEIO Univ., Schl. Med., Shinanomachi 35, Shinjuku-ku Tokyo 160. 2.NIBB, Okazaki, Aichi 444. 3.Univ. Tokyo, Tokyo 113, Japan.

LIM domain/homeobox transcription factors play important roles in cell fate determination during development in vertebrates and invertebrates. Islet-3, which was identified by us in zebrafish embryos, belongs to this family. By 17 hr, Islet-3 expression in the CNS was restricted to the eyes and the tectum. We examined developmental defects caused by the ectopic overexpression of the Islet-3 LIM domains without homeobox. This variant protein could be expected to make a non-functional complex with a putative cofactor protein of Islet-3, and to decrease significantly the chance of the intrinsic Islet-3 making a normal functional DNA-complex. Embryos overexpressing the LIM domains of Islet-3 developed apparently normally except that they completely lacked the optic vesicles (OV). The lenses developed later in these embryos. It is possible that the presumptive OV cells may have differentiated to such an extent that they might induce the formation of lens placode in the ectoderm, but were unable to form the OV by themselves. To determine whether the complete deletion of the OV structure in the injected embryo was caused by an autonomous defect of the presumptive OV cells, we made mosaic embryos by transplanting the cells of injected embryos into the normal embryos at the blastoderm stage. The injected cells were incorporated into all parts of the host body, including the lenses, except the OV. This result demonstrated that the LIM-only variant directly inhibited the differentiation of the presumptive OV cells. Taken together, our results strongly suggest that Islet-3 and cofactor, which interact with each other through LIM domains, are directly involved in differentiation of the eye. (This research was supported by the Japanese government (MEC, AST) and the Uehara Foundation.)

## 121.17

DIFFERENTIAL PROLIFERATION RATES DEFINE REGIONS WITHIN THE VENTRICULAR LAYER OF THE DEVELOPING CHICK HINDBRAIN. R.J.T. Wingate<sup>1</sup>, A.M. Myat<sup>1</sup> and A. Lumsden<sup>2</sup>. Dept. Developmental Neurobiology, UMDS, Guy's Hospital, London SE1 9RT. <sup>1</sup>ICRF Developmental Biology Unit, Dept. Zoology, Parks Road, Oxford OX1.

Between E4 and E6, the chicken hindbrain loses its early segmental form. As rhombomere boundaries disappear, cell proliferation becomes limited to the ventricular layer, while a mantle of post-mitotic neurons is deposited to the pial surface. Although much of the basic hindbrain organisation is established during the rhombomeric phase of development (E2-E5), cell division continues at the ventricular surface until at least E8, and an adult complement of nuclei is only established at E10. The patterning of cell division after rhombomeres disperse is clearly of importance: some genes, e.g. *Hoxb-1* and *Hoxa-2*, retain a segmental expression within the ventricular layer. Others, e.g. *C-Serrate-1* and *Tlx-1*, develop longitudinal patterns of expression the formation of columnar sensory nuclei. We were interested to see the relationship between the changing patterns of gene expression and rates of proliferation in the ventricular layer. BrdU was injected *in ovo* into chick embryos of various stages between E4 and E9. After 30 minutes the embryos were decapitated and the hindbrains processed for gene expression by *in situ* hybridisation, using one of a variety of DIG-riboprobes, and for BrdU incorporation by immunohistochemistry. Surprisingly, cell proliferation rates are not uniform within the ventricular zone. Rather, longitudinal quiescent zones are defined by highly geometrical boundaries with sharp cut-offs. At each stage examined these boundaries are shared by boundaries of gene expression. Together, these results suggest that the ventricular layer of the hindbrain comprises geometric regions defined by differential gene expression and mitotic activity. Funded by the Medical Research Council.

## 121.14

NEUROBLAST PATTERN FORMATION: REGULATORY DNA THAT CONFERS THE *vnd* (NK-2) HOMEODOMAIN GENE EXPRESSION PATTERN ON A REPORTER GENE IN TRANSGENIC LINES OF *DROSOPHILA*. H.-M. H. Saunders<sup>1</sup> and M. Nirenberg. Laboratory of Biochemical Genetics, NHLBI, National Institutes of Health, Bethesda, MD 20892.

The *vnd/NK-2* gene is expressed in a pattern of > 52 clusters of neuroectodermal cells that give rise to a subset of neuroblasts arranged in a precise pattern in part of the CNS of *Drosophila* embryos. Expression of the *vnd/NK-2* gene initiates the neural pathway of development in part of the CNS; the *vnd/NK-2* homeodomain protein activates the proneural genes *ac*, *sc*, and *l'sc* in part of the ventrolateral neuroectoderm (J. B. Skeath, G. F. Panganiban and S. B. Carroll, Development 120, 1517-1524 (1994)) and therefore determines part of the pattern of proneural gene expression. DNA fragments - 0.57, -2.2, and -8.4 kb in length, from the upstream regulatory region of *vnd/NK-2* gene were subcloned in the 5'-flanking region of an enhancerless, promoterless  $\beta$ -galactosidase ( $\beta$ -gal) reporter gene in the P-element, pCaSpeR-AUG- $\beta$ gal, and the effects of the DNA inserts on the pattern and time of expression of  $\beta$ -gal were determined in embryos from transgenic lines of *Drosophila*.  $\beta$ -Gal patterns of embryos from transgenic lines of flies with P-elements containing - 0.57 or -2.2 kb of *vnd/NK-2* DNA inserts did not resemble the *vnd/NK-2* pattern of gene expression. However, embryos from 11 transgenic lines of *Drosophila* transformed with a P-element that contains -8.4 kb of *vnd/NK-2* regulatory DNA expressed  $\beta$ -gal patterns that closely resemble the normal *vnd/NK-2* patterns of gene expression. We conclude that the -8.4 kb DNA fragment from the upstream regulatory region of the *vnd/NK-2* gene contains the regulatory elements required to generate the normal patterns of *vnd/NK-2* gene expression.

## 121.16

ROSTRAL OPTIC TECTUM ADOPTS A CAUDAL PHENOTYPE FOLLOWING ECTOPIC ENGRAILED EXPRESSION

C. C. Logan<sup>1</sup>, A. Wizenmann<sup>1</sup>, U. Drescher<sup>2</sup>, B. Monschau<sup>2</sup>, F. Bonhoeffer<sup>2</sup> and A. Lumsden<sup>1</sup>

<sup>1</sup>Department of Developmental Neurobiology, UMDS Guy's Hospital, London, SE1 9RT, UK; <sup>2</sup>Max-Planck-Institute for Developmental Biology, Department of Physical Biology, 72076 Tübingen, Germany

Expression of the homeobox-containing gene *Engrailed* (*En*) in an increasing rostral to caudal gradient in the dorsal mesencephalon is the earliest known marker for polarity of the chick optic tectum. In transplantation experiments, *En* protein expression correlates well with the subsequent gradient of cytoarchitecture as well as the pattern of retinotectal projections. To directly test the role *En* plays in determining tectal polarity, we have used the replication competent retroviral vector RCAS to mis-express mouse *En-1* throughout the chick tectal primordium and show that the rostral portion of the tectum adopts a caudal phenotype: the gradient of cytoarchitectonic differentiation is abolished and two molecular markers, RAGS and ELF-1, Eph-like receptor tyrosine kinase ligands that are normally expressed in an increasing rostral to caudal gradient in the tectum, are now strongly expressed rostrally. In addition, cell membranes from rostral tectum of RCAS *En-1* infected embryos preferentially repel temporal axons in *in vitro* membrane stripe assays. These results show that *En* can act as a determinant of rostrocaudal polarity within the developing tectum.

Funded by grants from the Wellcome Trust and Howard Hughes Medical Institute.

## 121.18

DEVELOPMENTAL REGULATORY GENES CONTROL EMBRYONIC BRAIN REGIONALIZATION IN *DROSOPHILA*. F. Hirth, S. Leuzinger, B. Hartmann, E. De Battista, S. Richter, R. Finkelstein, A. Simeone, D. Acampora, U. Walldorf, W.J. Gehring, K. Furukubo-Tokunaga, and H. Reichert\*. Institute of Zoology, University of Basel, CH-4051 Basel, Switzerland.

We have studied the functional role of a set of developmental control genes in building the embryonic brain of *Drosophila*. Among these are anterior HOM-C genes, head gap genes, as well as other regulatory genes involved in anterior head patterning. For all of these genes, we have carried out high-resolution expression studies using laser confocal microscopy together with molecular markers for neuromeric borders. In addition, we have analysed the mutant phenotypes that result in the developing brain when the genes are deleted. Our results indicate that all of these developmental regulatory genes are involved in brain regionalization, and that elimination of any one of the genes causes marked structural defects in defined brain regions. To analyse their functional role further, we are using genetic methods to overexpress the genes, as well as their mammalian homologs, with the goal of creating ectopic brain Anlagen. Considering the expression, loss of function, and gain of function phenotypes of these genes in *Drosophila*, and in comparison with gene homologs in mammalian brains, we postulate that an evolutionarily conserved program underlies brain development in all higher animals. Supported by the Swiss NSF.

## 121.19

**Development of whisker-related neuronal patterns in transgenic mice overexpressing human bcl-2 protein.** Yuqing Li<sup>1,3</sup>, Weimin Zen<sup>1</sup>, Marc Knight<sup>1</sup>, Jean-Claude Martinou<sup>2</sup> & Susumu Tonegawa<sup>3</sup>. <sup>1</sup>Dept. of Molecular & Integrative Physiology, Neuroscience Program & Beckman Inst., Univ. of Illinois, Urbana, IL 61801, <sup>2</sup>Glaxo Inst. for Molecular Biology, Geneva, Switzerland, <sup>3</sup>H.H.M.I., Ctr. for Learning and Memory, MIT, Cambridge, MA 02139

We reported that the development of whisker-related neuronal patterns in brainstem trigeminal nuclei (barrelettes) is activity-dependent and requires NMDA receptors (Cell, 76:427, 1994). However, Henderson and colleagues reported that the development of barrelettes is regulated by trigeminal ganglion cell death and they could prevent barrelettes formation in neonatal rats by injecting NGF prenatally (J. Neurosci. 14:3389, 1994). To investigate the roles of NMDA receptor-mediated activity and cell death in whisker-related neuronal pattern formation, we examined whisker-related pattern formation and plasticity in transgenic mice overexpressing human bcl-2. In the bcl-2 transgenic mice, neuronal death is substantially reduced (Neuron, 13:1017, 1994). In adult transgenic mice (n=10), normal barrels and barrelettes could be detected by cytochrome oxidase staining. This is also true in neonatal transgenic animals (P4, n=4; P8, n=6). To examine whether lesion induced plasticity is affected in transgenic mice, C-row whiskers were cauterized on P0 and the barrels in these mice were examined on both P4 and P8. In both wild type (n=5) and transgenic (n=10) mice, expansion of neighboring row of barrels could be observed. Detailed quantitation of the barrels is underway to determine whether there are quantitative differences between wild type and transgenic mice. These results indicate that whisker-related neuronal patterns could still form when neuronal death is greatly reduced. Supported by HHMI, Shionogi Inst. for Medical Sci., NIH and Lucille P. Markey Charitable Trust.

## 121.20

**A 1.1 Kb GOLLI-MBP PROMOTER DIRECTS EXPRESSION DURING EARLY NEUROGENESIS.** T.M. Pribyl, C.F. Landry, V.W. Handley, and A.T. Campagnoni\* MRRC/UCLA School of Medicine, Los Angeles, CA 90024.

The Golli-mbp gene overlaps the myelin basic protein (MBP) gene, shares the MBP exons, and produces a unique family of alternately spliced mRNAs and proteins. Golli transcripts have been identified in the CNS, the PNS, and cells and tissues of the immune system. In the CNS, Golli-mbp mRNAs are found in both neurons and oligodendrocytes, and expression of the gene in these cell-types is under strict developmental and temporal regulation. To identify promoter elements which control this complex pattern of expression, 1.1 Kb of Golli promoter sequence was linked to the  $\beta$ -galactosidase ( $\beta$ -gal) gene and used to create transgenic mouse lines. Interestingly, this promoter directs expression of the transgene to specific populations of neurons. Expression of the transgene was noted first in early developing cortical neurons at E11, during the initial stages of neurogenesis. By E13,  $\beta$ -gal stained cells were concentrated in the subcortical plate of the forebrain and within early forming neurons of the olfactory system. Expression of the transgene was also quite evident in the early forming dorsal and ventral root ganglia. By P0, a clear demarcation of the subcortical regions and the olfactory system were evident by  $\beta$ -gal staining. This pattern persisted throughout postnatal development (to P90). These results indicate: 1) The golli promoter is complex and contains elements which direct expression to specific subsets of neurons 2) the onset of expression controlled by the 1.1 Kb promoter involves neurons during the early stages of neurogenesis and axonal elongation, and 3) one function of the golli proteins may be required in the formation/maintenance of cytoarchitectural structures. (Supported by NS23022, NS23322, HD25831 and RG2233A1 from the NMSS)

## FORMATION AND SPECIFICITY OF SYNAPSES II

## 122.1

**CRITICAL EVALUATION OF SYNAPTOPHYSIN-BASED METHODS FOR SYNAPSE QUANTIFICATION.** M.E. Calhoun<sup>1</sup>, M. Jucker<sup>2</sup>, D.L. Price<sup>1,4</sup>, and P.R. Mouton<sup>1,4\*</sup>. Departments of Pathology<sup>1</sup>, Neurology<sup>2</sup>, and Neuroscience<sup>3</sup> and the Neuropathology Laboratory<sup>4</sup>, The Johns Hopkins University School of Medicine and the Gerontology Research Center<sup>5</sup>, NIA, Baltimore, MD.

Synaptic changes underlie several degenerative neurological disorders and are important parameters for assessing animal models of human disease. Synapses can be visualized and accurately quantified at the ultrastructural level although the techniques are technically difficult and labor intensive. To evaluate more efficient techniques, we compared three methods based on synaptophysin immunoreactivity (IR) (quantitative Western blot, optical densitometry, and unbiased stereology) in hippocampal subregions of rat brain. Quantitative Western blotting, which measures synaptophysin protein levels, showed high variability between animals and low sensitivity for detecting regional differences in hippocampus. Optical densitometry and unbiased stereology on systematically sampled synaptophysin-immunostained sections allowed greater delineation of hippocampal subregions than Western blots, although densitometry failed to discriminate qualitatively different patterns of synaptophysin IR between dentate gyrus molecular layer and stratum oriens. Using stereology (optical disector/Cavalieri method), the mean total number of synaptophysin-IR presynaptic boutons in dentate gyrus was found to be statistically greater than that in stratum oriens ( $7.4 \times 10^4$  vs.  $5.1 \times 10^4$ ,  $p < 0.01$ ). We report that all three synaptophysin-based methods offer technically straightforward and efficient alternatives to synapse quantitation using EM; however, the stereological approach was the most reliable technique quantifying differences in synapse numbers. Direct comparison of synaptophysin immunostaining between light microscopy and EM revealed comparable bouton visualization and number. This work was supported by a grant from the NIH (AG 05146).

## 122.3

**NEW VARICOSITIES ARE ESTABLISHED PRIMARILY BY GROWTH CONE EXTENSION AND NOT BY DE NOVO EXPANSION OF PRE-EXISTING NEURITES IN APLYSIA SENSORY-MOTOR NEURON CULTURES.** F. Wu\*, R. Silverman and S. Schacher. Cntr Neurobiol. & Behav., Columbia Univ. Coll. of P & S, NYSP, New York, NY 10032.

Sensory neurons (SNs) of *Aplysia* reliably form specific chemical connections with motor cell L7 in cell culture, which increase in efficacy during the first 4 days. The change in efficacy is correlated with increases in the number of SN growth cones and neurites fasciculated with and extending along the major axons of L7 and the number of SN varicosities contacting the axons of L7. To determine the cellular and molecular steps involved with the formation and stabilization of SN synapses, we combined light and electron microscopy to examine some of the properties of SN growth cones, neurites and varicosities in contact with the motor axon and substrate at different time points over 24 hrs during the initial phase of synapse formation in culture (20-44 hrs after plating). Although SN growth cones prefer to extend along the major axon of L7, their rate of growth was 62% slower than companion growth cones extending on the substrate or regenerated distal motor neurites. The growth cones extending along the L7 axon have smaller lamellipodia and fewer filopodia than their counterparts extending on the substrate. As the amplitude of the EPSP increased over 24 hrs, more than 80% of new SN varicosities were established by SN neurites that had extended along the L7 axon, with less than 20% of new varicosities formed as expansions at pre-existing neurites. At the three hr time point however, almost 50% of the new varicosities were formed by expansions of varicosities at pre-existing neurites. Our results are consistent with the idea that growth cone extension on a preferred substrate for synapse formation is slowed as it forms new synaptic contacts with the target. Moreover, SN varicosities formed on the shafts of pre-existing SN neurites are less stable than those formed by extending SN growth cones. Analysis of these structures for the presence of transmitter release sites will provide important insights into the formation of stable synaptic contacts. Supported by NS27541

## 122.2

**MODULATION OF PRESYNAPTIC VARICOSITY DISTRIBUTION BY POSTSYNAPTIC NEURON IN METACEREBRAL GIANT CELLS OF *HELIIX POMATIA*.** G. Naretto, A. Casadio, M. Ghirardi and P.G. Montarolo\*. Dept. of Neuroscience, Univ. of Turin, C.so Raffaello 30, Turin, Italy.

The presence of a target cell represents one of the factors regulating synaptic formation during development and regeneration. As previously shown, the presence of the target cell B2 modifies the distribution of synapsin-like immunoreactivity and the action potential-evoked  $Ca^{2+}$  influx in cultured metacerebral giant cells (MGC) of *Helix pomatia*. By using the serotonergic MGC with its bifurcated axon, we have now investigated the influence of the target neuron B2 in the distribution of varicosities in the two main branches (cbc and cc) of the presynaptic neuron MGC. After 5 days in culture, we identified the varicosities of MGC by immunostaining with an anti-SHT antibody and we counted the varicosities in the neurites outgrown from the stumps of the two axon branches. The MGC cultured alone showed a slightly higher number of varicosities in the cbc branch ( $131.33 \pm 23.85$  in cbc versus  $78.33 \pm 13.86$  in cc,  $n=6$ ), with an average cbc versus cc varicosity ratio of  $1.71 (\pm 0.18, n=6)$ . The presence of the target cell B2 at the cbc branch significantly modified the distribution of the varicosities by reducing the number of varicosities in the cc branch ( $43.37 \pm 7.48, n=8, p < 0.03$ ), with an average varicosity ratio of  $2.74 (\pm 0.49, n=8)$ . The presence of B2 at the cc branch induced a slight reduction of varicosities in the cbc branch with a ratio of  $1.36 (\pm 0.42, n=7)$  that is significantly different ( $p < 0.05$ ) from that obtained with B2 at the cbc branch. We next cultured the cbc branch of MGC in contact with the C3, a motoneuron that is not a target of MGC *in vivo*, and we found no change in the varicosity ratio ( $1.99 \pm 0.31, n=8$ ) but a significant reduction in the total number of varicosities in the two branches compared to the isolated MGC ( $83.25 \pm 10.38$  versus  $209.66 \pm 35.98, p < 0.001$ ). Our preliminary data suggest that the number of varicosities in one branch of a neuron may be down regulated as a consequence of appropriate target interaction at another branch and that interaction with a wrong target can down regulate the varicosities at both branches. This work was supported by MURST and CNR grants.

## 122.4

**DISTRIBUTION OF FUNCTIONAL RESPONSES TO GLUTAMATE ALONG THE SURFACE OF A POSTSYNAPTIC NEURON IS REGULATED BY SPECIFIC INTERACTIONS WITH THE PRESYNAPTIC NEURON.** H. Zhu\* and S. Schacher. Cntr Neurobiol. & Behav., Columbia Univ. Coll. of P & S, NYSP, New York, NY 10032.

Synapse formation involves a series of reciprocal interactions leading to the proper alignment of a presynaptic structure capable of evoking release of neurotransmitter and a postsynaptic structure with a high density of receptors that transduce the binding of neurotransmitter. Previous studies using dissociated cell culture of identified neurons of *Aplysia* indicated that interaction with the appropriate postsynaptic target evoked a group of changes in the presynaptic neuron: increases in neurite branching and fasciculation, formation of varicosities with active zones, and expression of neuropeptide in varicosities contacting the target, and altering the overall functional distribution of receptors to neuromodulators of synaptic efficacy along the surface of the presynaptic neuron. To begin to explore how the postsynaptic neuron responds to interactions with the presynaptic neuron during synaptogenesis, we correlated the physiological responses to local applications of the sensory neuron (SN) neurotransmitter (glutamate) along the surface of the postsynaptic neuron L7 with the local structural properties of the presynaptic SN. Brief focal applications of glutamate along the surface of the major axons of L7 grown alone in culture evoked membrane depolarizations of decreasing amplitudes as applications moved distally from the initial segment. In the presence of an SN that formed connections with the target, larger responses to glutamate were evoked in local regions that contained SN varicosities apposed to the major motor axon. Significantly weaker responses to glutamate were evoked in the adjacent areas that were closer to the initial segment of L7 and contained SN neurites, but had few or no varicosities. Because the overall response to glutamate did not appear to change with the presence of the SN, the results suggest that glutamate receptors on L7 may be redistributed in response to the distribution of apposed SN structures containing transmitter release sites. Supported by NS27541.

## 122.5

CONVERSION OF DREBRIN ISOFORMS AND THE FUNCTION OF ADULT TYPE DREBRIN IN MORPHOLOGICAL CHANGES IN THE DENDRITIC SPINE. K. Hayashi and T. Shirao\*. Department of Neurobiology and Behavior, Gunma Univ. Sch. of Med., Maebashi, 371 Japan

Morphological development and changes in the dendritic spines have been postulated to participate in expression of synaptic plasticity. Drebrin is an actin-binding protein mainly expressed in neurons. First we examined the participation of drebrin in the mechanisms responsible for the changes in spine morphology. We found that drebrin was localized at spines and bound to spine cytoskeleton. Immunoprecipitation with an antibody against drebrin revealed that drebrin, actin, myosin and gelsolin formed a complex. In vitro, drebrin reduced the sliding velocity of actin filaments on immobilized myosin, and inhibited the actin-activated ATPase activity of myosin. These results suggest that drebrin may modulate the actomyosin interaction within spines and plays a role in the structure-based plasticity of synapses.

We next examined the developmental changes in the drebrin isoforms with RT-PCR. During the postnatal development, an embryonic type of drebrin is replaced by an adult type by alternative RNA splicing mechanisms. We found that the conversion of the isoforms occurred coincidentally with the formation of synapses both *in vivo* and in primary cultured cortical neurons. The *in vitro* system provides a useful model system for studying the activity dependency of neuronal maturation or the formation of postsynaptic structure.

This research was supported in part by Grants-in-Aid from the Ministry of Education, Science and Culture of Japan.

## 122.7

Trophic-like role of serotonin (5HT) and noradrenaline (NA) in the rat spinal cord. T. Yajima, N. Suzuki and N. Okado\*. Dept. Anat., Inst. Basic Med. Sci., Univ. Tsukuba, Tsukuba, Ibaraki 305, Japan

Previous studies have shown that 5HT is the major component of monoamines, and that 5HT facilitates synapse formation and maintenance in the anterior horn of chicken spinal cord: at the maximum nearly 70 % of synapses decrease following to deplete 5HT (J. Neurobiol. 24:687-698). However, there are large species differences in the distribution pattern of monoamines in the spinal anterior horn (Neurosci. Lett. 132:155-158). Different from the chicken, both 5HT and NA fibers distribute similarly in the anterior horn of the rat. Compared to those in the chicken we expected to find out different mechanisms to facilitate synapse formation and maintenance by monoamines in the rat. Following intracisternal injections of 5,7-dihydroxytryptamine (5,7-DHT), 5HT neurotoxin, and/or 6-hydroxydopamine (6-OHDA), NA neurotoxin, the density of synapses was quantitatively examined with an electron microscopy. One week after simultaneous injections of 5,7-DHT and 6-OHDA on either at postnatal (P) 0 day or P3 weeks the density of axosomatic synapses decreased about 20% compared to that of control animals. The density of axosomatic synapses significantly decreased (-14%) by one week following an injection of 6-OHDA on P3 weeks. Although both 5HT and NA were suggested cooperatively to facilitate synapse formation and maintenance, the magnitude of monoamine-mediated synaptic plasticity in the anterior horn of rat spinal cord appeared smaller than that in the chicken. (Supported grant-in-aid for Scientific Research on Priority Areas from the Ministry of Education, Science and Culture, Japan)

## 122.9

ACTIVITY-DEPENDENT SYNAPSE REDUCTION (ADSR) IN MOUSE VENTRAL HORN AND MUSCLE CO-CULTURE MEDIATED THROUGH THROMBIN RECEPTOR. M. Jia, M.X. Li, V. Dunlap and P.G. Nelson\*. Lab of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892

The ADSR was studied in mouse ventral horn and muscle co-cultures in a multi-compartment chamber. Unilateral bursts of electrical stimulation at 30 Hz, 2 seconds duration and 5 volts amplitude were delivered every 10 seconds for different periods of time in a 37°C incubator to ventral horn neurons in the side chambers synapsing with muscle cells in the center chamber. Twitch responses and excitatory postsynaptic potentials (EPSPs) of doubly innervated muscles were observed. After unilateral electrical stimulation for 20 hours, twitch responses from the unstimulated side only were lost in 21% of the muscles cells, compared with 3.5 % synapse loss from the stimulated side only. The ratio of the synapse loss from the unstimulated side vs. that from the stimulated side was about 6:1. Previous work has shown that the ADSR required thrombin proteolytic action since the loss is completely blocked by nanomolar concentration of the specific thrombin blocker, hirudin. In the present experiments a synthetic receptor peptide SFLLRNPNKYEPF or SFLL, mimicking the newly exposed amino terminus of the thrombin receptor after it has been cleaved by thrombin, was applied to our *in vitro* neuromuscular system. After incubating our preparation in  $10^{-6}$ M SFLL for 1 day, synapse loss was 30%, and after 3 days 61%. The concentration of SFLL at  $10^{-7}$ M induced 23% synapse loss, at  $10^{-8}$ M induced 31% synapse loss and at  $10^{-7}$ M induced 32% synapse loss after 3 days incubation. The inactive peptide FSLRNPNKYEPF at a concentration of  $10^{-6}$ M did not induce synapse loss in our model. These results suggest that the synapse loss induced by electrical stimulation is mediated through the action of thrombin on the thrombin receptor in the cell membrane.

## 122.6

$\alpha 1$ -ADRENOCEPTORS MEDIATE NUMERICAL MODULATION OF SYNAPSES BY NORADRENALINE IN THE RAT VISUAL CORTEX. K. Nakadate, M. Matsukawa\* and N. Okado. Dept. Anat., Inst. Basic Med. Sci., Univ. Tsukuba, Tsukuba, Ibaraki 305, Japan.

In previous studies serotonin (5-HT) and noradrenaline (NA) have been suggested to facilitate synapse formation and maintenance in the central nervous system (J. Neurobiol. 24: 687-698; Neurosci. Res. 19: 111-115; Soc. Neurosci. Abst. 21: 445). Although 5-HT<sub>2A</sub> receptors have been identified mediating the facilitatory role (Neurosci. Lett. 195: 159-162), nothing was known on the mechanism by NA.

The present study was undertaken to identify receptor subtype(s) of NA mediating the facilitatory role by using selective adrenoceptor antagonists. For  $\alpha 1$ ,  $\alpha 2$  and  $\beta$ -adrenoceptor antagonists prazosin, rauwolfscine and alprenolol were injected in 6 week-old-rats (N=4) for a week, and the density of axodendritic synapses in lamina I of the visual cortex was determined from electron micrographs. The density of synapses decreased in a dose-dependent manner following injections of prazosin: compared to the value of control animals 1mg and 10mg/kg weight of prazosin decreased synaptic density by 15% ( $p < 0.0001$ ) and 20% ( $p < 0.0001$ ), respectively. The magnitude of reduction in the density of synapses by the maximum dose of prazosin was similar to that by NA neurotoxin, DSP-4. It is interesting to note both 5-HT<sub>2A</sub> and NA  $\alpha 1$  receptors are coupled to inositol phospholipid hydrolysis. (Supported by grant-in-aid for Scientific Research on Priority Areas from Ministry of Education, Science and Culture, Japan.)

## 122.8

SYNAPTIC LOSS IN THE PREFRONTAL CORTEX FOLLOWING INJECTIONS OF DOPAMINE RECEPTOR ANTAGONISTS IN THE RAT. M. Sugahara, H. Shiraishi, N. Okado\*. Dept. Anat., Inst. Basic Med. Sci., and \* Dept. Psychiatry Inst. Clin. Med. Sci., Univ. Tsukuba, Tsukuba, Ibaraki 305, Japan.

Previous studies have shown that aminergic neurons (serotonin, noradrenaline, acetylcholine) have a trophic-like role to facilitate synapse formation and maintenance in the developing and adult brain (J. Neurobiol. 24: 687-689; Neurosci. Res. 19: 111-115; Neurosci. Abstr. 21: 445, 1217). The present study was undertaken to clarify whether the trophic-like role is also mediated by another aminergic system, dopamine (DA) neurons. D1 antagonist (SCH23390) or D2 antagonist (YM09151 nemonapride) was injected in 6 week-old rats for a week, and synaptic density in laminae I and V-VI was quantitatively determined from electron micrographs. Following injections of YM09151 (D2 antagonist; 1, 5 and 10 mg/kg weight) synaptic density decreased in a dose-dependent manner, and compared to values of saline injected control animals reduction rates of synaptic density by the highest dose were 18% ( $p < .0001$ ) and 30% ( $p < .0001$ ) in laminae I and V-VI, respectively. By injections of 10 mg/kg weight of SCH23390 (D1 antagonist) synaptic density decreased by 8% ( $p < .0001$ ) and 20% ( $p < .0001$ ) in laminae I and V-VI, respectively. Although DA has been suggested also mediating the trophic-like role for synaptic structures, we presently examine underlying mechanisms of synaptic loss by DA antagonists. (Supported by grant-in-aid for Scientific Research on Priority Areas from Ministry of Education, Science and Culture, Japan.)

## 122.10

CONVERSION OF PARASYMPATHETIC NERVE FUNCTION FROM PREJUNCTIONAL INHIBITION TO POSTJUNCTIONAL SMOOTH MUSCLE EXCITATION FOLLOWING SYMPATHECTOMY IS ASSOCIATED WITH FORMATION OF PRESUMPTIVE NEUROEFFECTOR CONTACTS

E. Marzban\* and P.G. Smith. Department of Physiology, University of Kansas Medical Center, Kansas City, KS 66160

Contraction of the tarsal smooth muscle of the rat eyelid normally is mediated by sympathetically released norepinephrine acting on adrenergic receptors. However, 5-6 weeks following sympathectomy, prejunctional inhibitory parasympathetic nerves which usually do not directly affect smooth muscle tone now cause a large contraction via excitation of muscarinic smooth muscle receptors. This does not appear to be associated with muscarinic receptor supersensitivity or diminished acetylcholine degradation. The objective of the present study was to determine if the parasympathetically mediated smooth muscle contraction after sympathectomy is associated with the establishment of presumptive neuroeffector contacts.

In tarsal muscles with intact sympathetic excitatory innervation, quantitative EM analysis revealed that 45% of all varicosity profiles are located within 1  $\mu$ m of smooth muscle cell membranes. Numbers of varicosities were decreased by 86% 2 days following superior cervical ganglionectomy, coincident with the degeneration of the excitatory input to this muscle. Numbers of varicosities did not change significantly between 2 days and 6 weeks post-sympathectomy. At two days post-sympathectomy, when cholinergic excitation is low, only 25% of varicosities were located within 1  $\mu$ m of smooth muscle. However, at 6 weeks following sympathectomy, when parasympathetic excitation is well established, 62% of varicosities were within 1  $\mu$ m. These findings indicate that the establishment of atypical parasympathetic excitation of tarsal smooth muscle is associated with an increase in presumptive neuroeffector contacts between residual parasympathetic nerves and smooth muscle cells. DEPRESSION AND PAIRED-PULSE FACILITATION OF EPSP AMPLITUDE DURING EMBRYONIC DEVELOPMENT IN THE CERICAL SENSORY SYSTEM OF THE COCKROACH. M.A. Sosa and J.M. Blagburn. Institute of Neurobiology, University of Puerto Rico School of Medicine, San Juan, Puerto Rico, 00901.

The cerci of the first instar cockroach (*Periplaneta americana*) bear two filiform hairs each, one lateral (L) and one medial (M), which are innervated by individual sensory neurons. These sensory neurons project to the CNS, where they synapse with giant interneurons (GIs) in the terminal abdominal ganglion. Cockroach embryos kept at 30°C take approximately 30.5 days to develop and hatch. The synapse between L and the contralateral GI3 forms between embryonic days 16 and 18. Here we characterize some of the properties of this synapse as it develops, specifically the phenomena of depression and short-term facilitation of EPSP amplitude.

Intracellular recordings of contralateral GI3 EPSPs, in response to direct electrical stimulation of L, were made in 16-23 day old cockroach embryos. The L-GI3 synapse of first instar nymphs is known to normally operate at a depressed level. Estimates of this steady-state level of depression were made for the embryos by stimulating L action potentials at a frequency of 2 Hz and measuring the GI3 EPSPs. Once a steady EPSP amplitude was reached, L was stimulated with pairs of pulses delivered at the same frequency. Paired-pulse facilitation was estimated at different stimulus intervals.

We have found that both depression and paired-pulse facilitation are present from when the L-GI3 synapse is first formed. However, while depression of EPSP amplitude (at 2Hz) stays relatively constant throughout embryonic development, facilitation was larger initially, during embryonic days 16 to 18. Afterwards, it remained relatively constant at a smaller level, at least up to day 23. These results indicate that the transmitter release machinery required for depression and short-term facilitation are present immediately upon formation of a functional L-GI3 synapse.

Supported by NIH Grant NS07464, with additional support from NIH RR03051 and an NSF Minority Postdoctoral Research Fellowship.

## NEUROTROPHIC FACTORS: EXPRESSION AND REGULATION—DEVELOPMENT AND AGING

## 123.1

DYNAMIC EXPRESSION OF TRK RECEPTORS DURING SENSORY NEURON DIFFERENTIATION. Jason Rifkin, Kirk Danielson and Frances Lefcort\*. Dept. of Biology, Montana State University, Bozeman, MT 59717. Recent evidence has pointed to novel roles for neurotrophins in the developing nervous system prior to the period of target-mediated cell death. As a first step towards identifying these early neurotrophin activities, we are determining the expression patterns of trk receptors, *in vivo*, during sensory neuron differentiation within the avian dorsal root ganglion (DRG) using a panel of highly specific anti-avian trk receptor antibodies (Lefcort et al., 1996). We find that trkA and trkB, but not trkC, are first expressed on a discrete subset of migrating trunk neural crest cells at St.18 (E 2.75) in the area of the future DRG. These early trk+ cells also express neuron-specific  $\beta$  tubulin (TuJ1+) and typically, but not always, express the 160 kd neurofilament protein and BEN/DM1-GRASP. We find that all cells positive for any of the antigens mentioned above are also trkC+ whereas all HNK-1 positive cells are trkA and C-negative. Thus these trk+ cells may be the earliest (future) DRG neurons to differentiate or alternatively, given that sensory neuroblasts can express this  $\beta$ -tubulin isoform (Memberg & Hall, 1995), they may be a subpopulation of neuronal progenitors. To determine whether mitotically active neuronal progenitor cells express trk receptors, we are injecting BrdU *in ovo*, fixing at various time points and staining embryonic sections with BrdU and trk antibodies. By St.24 (E4) all  $\beta$ -tubulin+, 160 kd neurofilament+ and/or BEN/DM1-GRASP+ DRG neurons are also trkC+ while only a subset are trkA+ or trkB+ suggesting that all DRG neurons and/or progenitor cells, at some early stage in their differentiation express trkC. By E6 trkC expression is restricted to a minority of DRG neurons, primarily located in the lateroventral region of the DRG, while the majority of DRG neurons express trkA and reside in the dorsomedial region of the DRG. This same pattern is evident at E13, the end of target-mediated cell death, although by this time point, the most prominently expressed neurotrophin receptor in the DRG is p75. Supported by MONT/EPSCoR.

## 123.3

REGULATION OF NERVE GROWTH FACTOR- GENE EXPRESSION IN VIVO IN MICE. K.Müllhofer, M.Meyer\*, E.Wolff, S.G.Brehm and H.Thoenen. Max-Planck-Institut für Psychiatrie, 82152 Martinsried, FRG; § LMU, 81375 München, FRG

Nerve growth factor (NGF) is essential for the development of the peripheral nervous system. Temporal and spatial expression patterns as well as strength of expression are precisely controlled. However little is known about the mechanisms regulating NGF expression in developmental contexts. To approach this question, we fused 5 kb and 2 kb fragments of the NGF promoter including the first exon and part of the first intron of the NGF gene to a lacZ-reporter gene. These constructs were used to generate transgenic mice by pronucleus injection. By comparing the lacZ expression pattern with that of the endogenous NGF gene in these mice, we could show that both fragments of the NGF promoter contain several elements needed for correct temporal and spatial expression of the NGF-gene during development. However, except for the submandibular gland, the precise pattern of lacZ-expression was highly influenced by the site of transgene integration in the mouse genome. To avoid this problem, in a second approach we directly introduce alterations in the NGF promoterregion using the double replacement strategy in transgenic mice. Analysis of the effects different mutations have on the regulation of NGF gene expression will allow us to define DNA sequences which are important for the correct temporal and spatial expression of the NGF gene in various tissues. In addition, this approach is expected to generate partial NGF knock-out mice.

Supported by the Max-Planck-Gesellschaft, Germany

## 123.2

NORMAL PAX-6 EXPRESSION IS REQUIRED FOR TRKC RECEPTOR EXPRESSION IN THE DEVELOPING CORTEX. J.A. Clausen, D. Caric, J.E. East, R.E. Hill and D.J. Price. Dept. of Physiology, Univ. Med. Sch., Teviot Place, Edinburgh, EH8 9AG. +MRC Human Genetics Unit, Western General Hospital, Crewe Road, Edinburgh, EH4 2UX, U.K.

We are studying the mechanisms involved in the development of the murine thalamo-cortical tract with emphasis on the role of diffusible neurotrophic molecules. We investigated the *in vivo* distribution of Trk receptor protein using routine immunocytochemical techniques in the developing cortex of Balb/c and homozygous Small-eye mice. The Small-eye mutation results in loss of function of the Pax-6 gene product and causes abnormal CNS development due to a delay in neuronal migration and impairment to axonal growth, neuronal differentiation and innervation. During normal cortical development, the deep layer neurons expressed TrkC receptor protein strongly from the time of their birth to adult (P21), whereas neurons in superficial layers did not express strongly until P21. In the homozygous state, we observed a reduction in the TrkC receptor protein in the cortical plate and subplate. TrkB receptor protein was expressed in the Balb/c cortical plate, subventricular zone but not the ventricular zone. TrkB receptor was similarly well expressed in the homozygote cortex. To study this further we co-cultured wild type E15 thalamus with E19 homozygous cortex and found poorer cortical innervation when compared to controls. Taken together, these results suggest that the Pax-6 gene abnormality results in altered expressions of TrkC receptors, which may be a consequence of reduced thalamic innervation.

This work was supported by MRC and Wellcome Trust. JAC was supported by a University of Edinburgh Faculty of Medicine Fellowship.

## 123.4

DEVELOPMENTAL EXPRESSION OF NGF, TrkA AND THE P75NGFR IN THE RODENT TRIGEMINAL SYSTEM. S. Ihaveri\*, Dept. Brain & Cognitive Sciences, Mass. Institute of Technology, Cambridge, MA 02139.

Embryonic rat trigeminal ganglion (Vg) cells are dependent on NGF for survival. Message for NGF is present around whisker follicles; developing Vg cells express mRNA for TrkA, the NGF receptor. It has been proposed that during embryonic life, processes of Vg cells which project outside the whisker follicles are unable to access NGF and their cells die; others which project to whisker follicles, where NGF is expressed, survive. However, little information is available about actual projection patterns of embryonic Vg cells, about whether there is a regressive stage in whisker pad innervation which matches the period (E15-E18) of naturally-occurring cell death, and about specifically which trigeminal axons express TrkA. We have used immunohistochemical techniques to address some of these issues.

Five ridges are recognized on the E13 rat whisker pad; 24 h later, individual follicles begin to differentiate. NGF is expressed in epidermis, and along emerging follicles. TrkA-positive Vg axons are present under maxillary ridges by E13, and begin to innervate newly differentiated follicles. Initially, there is little invasion by Vg axons in the regions between whisker follicles, but with further peripheral maturation (by E18), epidermal innervation is initiated. The innervation pattern becomes progressively more dense over the next few days, with little indication of regression of axon populations. Immunoreactivity for p75NGFR is similar to that for TrkA, but has a more complex expression pattern: this low affinity receptor is found not only in Vg axons, but also on clusters of cells in the whisker pad.

Our results suggest that the targeting of Vg axons to their peripheral target occurs by a specific matching of neurotrophin (e.g., on follicle cells) and its receptor (e.g., on afferent fibers). There is no evidence of an exuberant projection followed by withdrawal of a portion of the peripheral trigeminal innervation. SUPPORT: NIH Grant NS27678; TrkA antibody, courtesy of L. Reichardt.

## 123.5

**MEASUREMENTS OF BDNF PROTEIN DURING CNS DEVELOPMENT** J.E. Johnson\*, M. E. Forbes, K. Drum and J. Anstrom. Dept. of Neurobiology and Anatomy, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, N.C. 27157

BDNF (brain-derived neurotrophic factor) is a member of the neurotrophin family of factors that appear to regulate the development and maintenance of specific neuronal populations. Different CNS and peripheral tissues express different size variants of BDNF mRNA. In addition, the relatively widespread distribution of BDNF receptors on CNS neurons suggests that the resulting protein may be used for autocrine and/or paracrine activity or for retrograde and/or anterograde axonal transport.

We have recently developed a sensitive and highly specific immunoassay capable of detecting BDNF concentrations below the physiological levels required for trkB receptor signaling. This Electro-Chemi-Luminescent-Immunoassay (ECLIA) utilizes affinity purified polyclonal IgG antibodies (Amgen) in a single step sandwich assay measured with an Origen Analyzer (Igen, Inc.). It has a very broad linear dynamic range (4-5 log units) capable of detecting an increase in either physiological or pharmacological changes in BDNF protein concentrations. The assay has been optimized to improve the extraction and recovery of both bound and free BDNF from CNS tissues. We have applied this method to measure BDNF protein levels in tissues that differ in the quantity and type of BDNF mRNA variants. In addition we have measured developmental changes in BDNF protein levels in a variety of developing tissues in both mammalian and avian species. While some CNS regions (ie. hippocampus and cortex) appear to show a continual developmental increase in BDNF, other tissues (ie. visual system) appear to experience a transient BDNF peak during periods of connectivity. Measurements of changing BDNF protein levels are likely to be useful in characterizing the functional role of this factor in both development and plasticity. Sponsored by 5R01 EY-11127 (JJ)

## 123.7

**INTERLEUKIN-1 $\beta$  IS EXPRESSED IN THE DEVELOPING NERVOUS SYSTEM OF THE FROG *XENOPUS LAEVIS***, A. M. Jelaso\* and C.F. Ide. Tulane/Xavier Center for Bioenvironmental Research and Neuroscience Program, Tulane University, New Orleans, LA 70118.

Expression of the cytokine interleukin-1 $\beta$  (IL-1 $\beta$ ) in the developing frog *Xenopus laevis* was analyzed with immunocytochemistry. IL-1 $\beta$  immunoreactivity was present in a stage dependent manner throughout the developing nervous system. From day 2 (stage 32) of development through day 6 (stage 50+) immunoreactivity was observed in large sensory and motor neurons, and in the muscles that control the early swimming response of frogs. Specific immunopositive structures include; distinct giant cells in the midbrain, Mauthner's giant neuron in the hindbrain, the Rohan-Beard cells in the dorsal spinal cord, motoneurons in the ventral spinal cord, dorsal root ganglia, cranial ganglia, the muscles of the eye and the myotomal muscles in the tail. Immunocytochemistry for the IL-1 type I receptor revealed that labeled cells are located in close proximity, but not coincident with those stained for IL-1 $\beta$ . These data are compatible with the idea that IL-1 $\beta$  may serve as a survival factor during larval development because for example, Mauthner's neurons persist until metamorphosis, a full eight weeks after stage 32. Supported by DoE grant #DE-FG01-93-EW532023.

## 123.9

**THE RELATIVE ABUNDANCE OF NGF PROHORMONES (NGF-PRS) TO MATURE BETA-NGF IN HIPPOCAMPUS AND CORTEX IMPLIES A TROPIC FUNCTION FOR THE NGF-PRS.** Lakshmanan J, Reingshagen M, Geerling I, Eysselein VE and Huff K.\* Harbor UCLA Med. Ctr., Torrance, CA 90509 and Univ. of Ulm, Germany.

In the present study, we examined the presence of beta-NGF in hippocampus and cerebral cortex, the CNS regions reported to express the NGF transcript in very high concentrations. Freshly dissected brain regions of adult mice and rats were frozen on a piece of dry ice and then immediately weighed and homogenized (250mg/ml) in 20mM Tris-HCl buffer, pH8.8 containing NaCl (10mM), EDTA (1mM), NP-40 (0.5%) and Na-deoxycholate (0.5%) using a tissue grinder. The homogenates, diluted (1:5) with Laemmli's electrophoretic sample buffer were processed for Western blot analysis and the immunoreactive bands were identified with chemiluminescence using the ECL reagent. The polyclonal antiserum to 2.5S NGF (Sigma) identified 6 immunoreactive proteins ranging in molecular weight from 53 to 22 kDa. The intensity of the 53 and 32 kDa bands were strongest in hippocampal extracts of both species. Monoclonal antibodies to human beta-NGF (Promega) identified the 53kDa NGF-PR in hippocampal extracts of both rodent species while the monoclonal antibodies to mouse NGF (Boehringer-Mannheim) identified the 53kDa NGF-PR in mouse but not in rat hippocampal extracts. The two prepro-NGF domain-specific polyclonal antisera (Pro-Hormone Science) corresponding to the larger and smaller NGF precursors strongly immunoreacted with 32kDa NGF-PR while they weakly immunoreacted with the 53kDa NGF-PR. Mature beta-NGF was present in barely detectable quantity that could only be identified by the monoclonal antibody to human beta-NGF (Promega). The cerebral cortical extracts contained the 53 and 32kDa NGF-PRS but not the mature NGF. The relative abundance of the 53 and 32kDa NGF-PRS in hippocampus and cortex suggests that they may mediate neuronal trophic functions in the CNS. Support: IBD Ctr; DFG 789/2-2

## 123.6

**EXPRESSION OF VEGF AND ITS mRNA IN THE NEURONAL CELLS DURING THE DEVELOPMENT OF POSTNATAL RAT BRAIN.** W. L. Bao, L. M. Zhang, J. Y. Hua, B. S. Pan\*, and F. Y. Sun. State Key Lab. of Medical Neurobiology, Shanghai Medical University, Shanghai, 200032, China.

In our previous study, VEGF-positive staining cells were observed high expression in the neuronal cells of adult rat brain which was time-dependantly increased after a transient cerebral ischemia. In the present study, *in situ* hybridization and immunohistochemistry were used to study the expression of VEGF mRNA and its protein in the different age of postnatal rat brain. The results showed that VEGF mRNA was highly expressed in the neuronal cells during the first three days except expressing in the vascular endothelium. The expression of VEGF mRNA in the neuronal cells started to decrease following the third days after the birth. However, VEGF-like protein positive staining neuronal cells were low density during the first seven days and higher density following the second to eighth weeks after the birth when VEGF mRNA was low expressed in the neuronal cells. The distribution of VEGF protein was well-negatively correlated to that of its mRNA in the neuronal cells of rat brain. Furthermore, fluorescence-double staining combined with a confocal laser scanning microscope analysis showed that VEGF-positive staining was located mainly in neurons and a little in glial cells of adult rat brain. The results suggest that VEGF may play an important role in the development of neurons in the postnatal rat brain.

## 123.8

**AGE-RELATED CHANGES IN SENSORY CEREBROVASCULAR AXONS AND THEIR RESPONSIVITY TO NERVE GROWTH FACTOR.** L.G. Isaacson<sup>1</sup>\*, J.R. Tompkins<sup>1</sup>, K. McNeely<sup>1</sup>, W.L. Nixdorf<sup>1</sup>, and K.A. Crutcher<sup>2</sup>.

<sup>1</sup>Center for Neurosci, Dept Zoology, Miami Univ, Oxford, OH 45056; <sup>2</sup>Dept Neurosurg, Univ of Cincinnati Coll of Med, Cincinnati, OH 45267.

Previously we provided ultrastructural evidence that the aged sympathetic nervous system retains responsivity to exogenous nerve growth factor (NGF). The finding that young adult sensory cerebrovascular axons respond to exogenous NGF with increased neurotransmitter content provides the opportunity to determine whether aging affects such neuronal plasticity. Young adult (3 mo) and aged (24 mo) Fischer female rats received 2 week intracranial infusions of NGF (15  $\mu$ g) or VEH and were perfused for CGRP immunocytochemistry. A significant decline (52%;  $p < .05$ ) was observed in the perivascular density of immunoreactive fibers associated with aged anterior cerebral artery (ACA) when compared with the ACA from the young adult. Slight declines in the density of CGRP fibers from aged internal carotid (ICA) (34%) and middle cerebral (MCA) (32%) arteries were not significant. NGF resulted in a significant increase (110%;  $p < .05$ ) in ACA perivascular density in both young and aged rats. In contrast to significant increases in the CGRP density of ICA (200%) and MCA (189%) observed following NGF infusion in the young adult, no changes were observed in the aged ICA and MCA, suggesting an age-related reduction in responsivity of sensory axons to NGF. (Supported by NS17131 to KAC and NS32876 to LGI)

## 123.10

**CHARACTERIZATION OF A MURINE ACIDIC FIBROBLAST GROWTH FACTOR PROMOTER (FGF-1B) AND ITS EXPRESSION IN THE DEVELOPING BRAIN.** A. Rotter\*, K. Alam, A. Frostholm, K. Hackshaw, J. Evans and I-M. Chiu. Departments of Pharmacology and Internal Medicine, The Ohio State University, Columbus, Ohio 43210.

The structure and developmental expression of the murine FGF-1B promoter are described. The human FGF-1 gene contains four upstream untranslated exons (A-D) alternatively spliced to the first protein coding exon. Within the brain, the FGF-1B form predominates. A cDNA clone coding for the FGF-1B transcript was isolated from a mouse brain cDNA library. The clone contained an untranslated exon 34bp upstream of the translation start codon. The sequence upstream from the transcription initiation site of the 1B promoter was mapped by RNase protection assay. The upstream sequence lacked consensus TATA or CAAT boxes, but contained regulatory sequences including an AP1 element, an SP1 binding site and an RR2 enhancer region. *In situ* hybridization with probes specific for the 1B transcript showed the message to be restricted largely to neurons in discrete nuclei in the spinal cord, brainstem, thalamus and cerebellum. With few exceptions, the FGF-1B signal became detectable during postnatal weeks one and two. Maximal grain density was reached by postnatal weeks three and four, primarily in nuclei involved in processing information from exteroceptive sensory mechanoreceptors, and in motor control. The relatively late developmental expression suggests a role for FGF-1 in neuronal maturation, rather than in neurogenesis.

## 123.11

**EFFECT OF AGING AND DIETARY RESTRICTION ON GENE EXPRESSION IN DENERVATED STRIATUM** H.W. Chen<sup>1</sup>, T. Jiang<sup>2</sup> and T.H. McNeill<sup>1</sup>

<sup>1</sup>Andrus Gerontology Center and Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191

Previous studies have demonstrated that reactive synaptogenesis is diminished or impeded with aging and may be, in part, related to astrocytic hypertrophy and decrease of growth associated protein (GAP) genes expression. Chronic dietary restriction (DR) retards age-related gliosis and ameliorates age-related DNA damage. However, it is unclear if the DR effects will enhance the synapse replacement in aged brain. We therefore used *in situ* hybridization analysis to assess changes in the prevalence for astrocytic mRNAs (GFAP, clusterin, ApoE) and GAP mRNAs (SCG-10, GAP43) expression in denervated striatum (ST). Measurements were made from ad libitum (AL) fed young adult (3 mo.) and old (24 mo.) as well as diet-restricted old (24 mo.) rats.

We found that 1) DR fed 24 mo. rats vs AL fed 24 mo. rats, DR retards the age-related increase in the prevalence of GFAP, clusterin and ApoE mRNA expression in aged ST, and 2) DR fed 24 mo. rats vs AL fed 3 mo. rats, DR modulates the ability of astrocytes to regulate their genes transcription in response to a deafferentation lesion, which is compatible with that from young adult rats. In addition, we also found that diminished regulation of GAP mRNAs expression, such as SCG-10, in aged contralateral cortex in response to a unilateral cortical lesion was resumed in DR fed aged rats. These data suggest that the effect of DR on the astrocytic and GAP mRNAs in response to a lesion will modulate the effect of aging on the reactive synaptogenesis. Supported by NIH grant AG-09793.

## 123.13

**DIFFERENTIAL REGULATION OF HIPPOCAMPAL NEUROTROPHINS DURING RAT AGING** Mako Saito and Hiroyuki Nawa\*

<sup>\*</sup>Dep. of Molecular Neurology Brain Reserch Inst., Niigata Univ. Niigata, Japan

Neurotrophins, a family of neurotrophic factors, exert a variety of trophic effects on neurons. We employed sensitive and specific two-site enzyme immunoassay (EIA) to assess age-associated changes of the three neurotrophins, nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3), in the hippocampus of Fisher 344 rats. Expression of these proteins and their mRNAs were compared in the same animals. Hippocampal extracts from two-month-old rats contained >200 ng BDNF per gram of tissue. This amount was 2 and 100 times greater than that of NT-3 and NGF, respectively. The levels of BDNF and NT-3 remained high 2-6 months after birth, whereas, NGF declined during this period and the altered protein levels of all three neurotrophins were maintained 6-18 months postnatally. mRNA levels of BDNF increased during both of these periods but the NT-3 mRNA appeared to decline. Change in the expression of BDNF protein was opposite to the data obtained from Alzheimer's patients. These results suggest that, during normal aging in rats, neurotrophin expression is regulated independently both at the mRNA and post-translational levels. Any deficiency in their regulation might contribute to neurodegenerative disorders.

## 123.12

**DEVELOPMENTAL CHANGES IN MOTOR NEURON VULNERABILITY TO INJURY.** B.J. Wilcox\* and V.E. Koliatsos. Division of Cytokine Biology, CBER, Food and Drug Administration, Bethesda, MD and Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, MD.

Adult motor neurons are less vulnerable to axotomy-induced death than neonatal motor neurons. We have investigated the hypothesis that this difference in vulnerability is due to increased local availability of neurotrophic factors (NTFs) in the adult resulting in decreased motor neuron dependence on target-derived NTFs during postnatal development. We have shown that selected NTFs are differentially regulated during development and suggest that this developmental alteration in NTF regulation may contribute to changes in motor neuron vulnerability. The neurotrophins, BDNF and NT4/5, GDNF and ciliary neurotrophic factor (CNTF) are all present in skeletal muscle during the period of developmental death of motor neurons (E13-E15). Postnatally, BDNF is expressed in neonatal and adult facial motor neurons, whereas, NT4/5 is expressed in neonatal but not adult facial motor neurons. Following axotomy in the adult, BDNF is upregulated in muscle, whereas NT4/5 is downregulated. TrkB receptors remain expressed in both neonatal and adult facial neurons after axotomy but there is a progressive increase in receptor subtypes which lack catalytic properties. We are currently investigating the developmental pattern of GDNF and CNTF expression in the environment of the facial motor nucleus.

## NEUROTROPHIC FACTORS: EXPRESSION AND REGULATION—PHYSIOLOGIC AND PATHOPHYSIOLOGIC MECHANISMS I

## 124.1

**UPREGULATION OF BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) IN THE HIPPOCAMPUS AND CAUDAL CORTIX WITH PHYSICAL ACTIVITY.** N.C. Berchtold\*, H.S. Oliff, G.M. Deng, F. Gómez-Pinilla, C.W. Cotman. Institute for Brain Aging and Dementia, University of Irvine, CA 92697-4540 USA

Brain-derived neurotrophic factor (BDNF) supports the function and survival of many types of neurons which are vulnerable to aging and degenerative conditions. Ample evidence indicates that expression of BDNF mRNA is regulated by neuronal activity, suggesting that BDNF may be involved in neuronal plasticity.

Previously we reported that physical activity - voluntary wheel running - increases BDNF mRNA expression in rat hippocampus and caudal 1/3 of the neocortex. Since wheel running is a reproducible and quantifiable behavior, it is a useful paradigm for examining the regulation of BDNF in context to behavior. Prerequisite to understanding the initial events of BDNF induction by physical activity, the circadian running pattern of rats must be examined in order to tightly couple the running behavior with mRNA values. Running behavior of rats tends to fall into 2 general categories - either consistent running throughout the 12 hr. dark cycle, or intermittent bursts of activity. Interestingly, once a running pattern is established, it is maintained throughout the duration of the experiment. Two days of running has been shown to induce BDNF mRNA. Here, the time course for induction between 0 and 2 days is examined in more detail to determine the earliest timepoint (6 or 12 hours of running) at which a significant induction is seen, and to determine the stability profile of the induction over the next 24 hours.

Physical activity may provide a simple means to increase the level of BDNF and other neurotrophins in the brain, particularly, in highly plastic areas of the brain. In this way, exercise-induced upregulation of BDNF could help increase the brain's resistance to damage and degeneration, through BDNF's support of neuronal growth, function and survival. (Supported by NIA, MacArthur Foundation to C.W.C.)

## 124.2

**REGULATION OF FGF-2 BY SENSORIMOTOR EXPERIENCE.** F. Gómez-Pinilla\*, V. So, L. Dao, and C.W. Cotman. Dept. Neurology, and Inst. Brain Aging & Dementia, U. of California, Irvine, CA 92697-4540.

FGF-2 has well-recognized roles in promoting neuronal survival and growth and enhancing astrocyte function. Recent evidence indicates that FGF-2 is regulated by neural activity suggesting an involvement in molecular events underlying behavioral function. We have examined a potential regulation of FGF-2 by sensory experience including physical activity and visual input. For physical activity experiments, rats were exposed to running wheel cages connected to a computer that recorded distance for periods of 2, 4, or 7 days, and then brain tissues were processed for nuclease protection assay, *in situ* hybridization and immunohistochemistry. Results showed that FGF-2 mRNA and immunohistochemistry started to increase by two days of running in selected subregions of the hippocampus. For visual sensory experiments, rats were kept in darkness for 7 days, then re-exposed to light for periods between 1-6 hr and quickly sacrificed. Results showed a significant decrease in FGF-2 mRNA in the caudal cerebral cortex of rats kept in darkness, but levels progressively increased starting at 1 hr of light re-exposure reaching nearly normal levels by 6 hr. FGF-2 immunostained astrocytes showed a significant decrease in rats reared in darkness and a tendency towards an increase after light re-exposure. Results indicate that the FGF-2 system is regulated by physiological types of neural activity, suggesting that FGF-2 may have subtle roles in sensory transmission and processing (supported by grants from the American Paralysis and Alzheimer's Associations).

## 124.3

EXPRESSION OF NEUROTROPHIC FACTORS IN THE QUINOLINIC ACID MODEL OF HUNTINGTON'S DISEASE IN MICE. M.G. Zurich\* and M. Blum. Fishberg Ctr. for Neurobiology, The Mount Sinai School of Medicine, New York, NY 10029.

Classically, trophic factors have been found to be provided to the neurons by their target cells. Therefore, a nigrostriatal dopaminergic neurotrophic factor would be expected to be synthesized within the striatum. But, the extensive neuronal loss in the striatum occurring in Huntington's disease (HD) does not result in transsynaptic degeneration of nigrostriatal dopaminergic neurons (DA). Thus, DA neurons may not be totally dependent on neuronal target-derived neurotrophic support. Instead of, or in addition to this putative target-derived trophic support, DA neurons may derive their trophic support in an autocrine manner. Alternatively this support may be provided by astrocytes either in the midbrain or in the striatum. FGF is present in the striatum and in the midbrain and may act as trophic factors for the DA neurons. These factors may be upregulated to sustain DA neurons in case of loss of their neuronal target.

To determine whether there is an upregulation of DA trophic factors within DA neurons or astrocytes, C57BL/6 mice received an unilateral striatal injection of quinolinic acid (QA, 75 nmol), which has been shown to produce axon-sparing lesions similar to those observed in HD, or vehicle (PBS). They were sacrificed 6, 24, 72 hours or 7 days later. In situ hybridization was performed on the striatum 7 days after the QA lesion. RNA was isolated from the midbrain and was quantitated for aFGF. We found no regulation of aFGF in the midbrain at any time point, nor in the striatum after 1 week. This could signify that physiologically aFGF is derived in an autocrine manner by the DA neurons themselves and/or is provided to them by the astrocytes, and thus its expression is not affected by the loss of the neuronal target of the DA neurons. Alternatively, it could signify that aFGF is not involved in the survival of the DA neurons. Ongoing studies will reveal whether bFGF or TGF- $\alpha$  are regulated in this model. (Supported by Swiss National Foundation for Scientific Research and Lowenstein Foundation).

## 124.5

HIPPOCAMPAL CONCENTRATION AND IMMUNO-EXPRESSION OF NERVE GROWTH FACTOR ARE REDUCED IN DEVELOPING HYPOTHYROID RATS AND THE PROSPECTS FOR RECOVERY. A. Farahvar\* and E. Meisami (Dept. Molecular & Integrative Physiology, University of Illinois, Urbana, IL 61801).

We have previously shown that early thyroid deficiency in postnatal rats results in decreases in the growth of hippocampus and dentate gyrus which was found to be markedly reversible (Farahvar & Meisami, *Soc. Neurosci. Abst.* 18: 228, 1992; 19:1312, 1993). Paradoxically hypothyroidism resulted in increased expression of the low affinity NGF receptor (p75) in the hippocampus and cholinergic neurons of the rat basal forebrain (Farahvar & Meisami, *Soc. Neurosci. Abst.*, 20: 34, 1994; 21: 2014, 1995). In this study, concentration and immuno-expression of NGF were determined by ELISA and immuno-histochemistry (ICC) methods in the 25-, 50- & 90-day-old rats. Thyroid deficiency was produced from birth by adding propylthiouracil (PTU) to the drinking water (0.1% w/v); this suppresses plasma thyroid hormones as well as body and brain growth. Some hypothyroid rats were allowed to recover by withdrawal of PTU at day 25. The ELISA results revealed reductions of about 25% in NGF concentration and about 50% in total NGF content in hippocampus of hypothyroid rats. ICC results localized the NGF-immunoreactive cells in the CA1 and CA3 regions, with marked reductions in immunostaining in the hypothyroid animals. Hypothyroidism resulted in a marked decrease in the intensity of NGF immunostaining in the hippocampus. Recovery of thyroid function resulted in marked restoration of hippocampal NGF immunostaining and content as determined by the ICC and ELISA results. Supported by NIH (GM07143) and UIUC Research Funds.

## 124.7

CHANGES OF BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) IMMUNOREACTIVITY AFTER MIDDLE CEREBRAL ARTERY OCCLUSION.

Zaal Kokaia\*, Gunnar Andsberg, Qui Yan† and Olle Lindvall.

Restorative Neurology Unit, Department of Neurology, University Hospital, S-221 85 Lund, Sweden; †Amgen Center, Thousand Oaks, California 91320, USA.

In the present study, we have analyzed changes of immunoreactivity for BDNF in a rat model of transient focal cerebral ischemia, produced by middle cerebral artery occlusion (MCAO). This model gives a densely ischemic core in the lateral caudate-putamen and overlying parietal cortex and a perifocal penumbra zone in adjacent neocortical areas. Twenty-seven adult male Wistar rats weighing 265-320 g were used. Prior to the MCAO or sham-procedure the animals were fasted overnight, but allowed free access to water. Five groups of rats (n=3-5 in each group) were subjected to MCAO for 2 h and were then perfused at 0, 2, 6, 16 and 24 h after the start of reperfusion. One sham-operated control animal was added to all groups. After perfusion of the brains, 40  $\mu$ m thick free-floating sections were processed for immunohistochemistry using affinity-purified BDNF anti-rabbit polyclonal antibody at a dilution of 1:10 000.

The MCAO induced changes of BDNF immunoreactivity which largely corresponded to the alterations of BDNF mRNA levels observed in our previous studies. An increased number of BDNF immunopositive neurons was observed in the ipsilateral cingulate and frontal cortices at 2 h after MCAO. At the same time-point, strongly increased BDNF staining was detected bilaterally in the hippocampal formation. Interestingly, the BDNF immunoreactivity was mostly confined to mossy fibers. In the ischemic core of the parietal cortex only few scattered neurons were BDNF immunopositive. The observed pattern of BDNF immunoreactivity after MCAO is consistent with the hypothesis of a neuroprotective role of BDNF. However, the elevated levels of BDNF protein could also increase synaptic efficacy in the postischemic phase, which may promote epileptogenesis (supported by a grant from Swedish MRC B96-14X-0866-08C).

## 124.4

NEUROTROPHIC FACTORS IN NEURODEGENERATIVE DISEASES. R.W. Dorsey, P.G. Samacki, L. Radhakrishnan, C.L. Achim and C.A. Wiley\*. Div. of Neuropathology, Univ. of Pittsburgh, Pittsburgh, PA 15213.

Neurotoxic factors secreted by immune activated cells like microglia are frequently invoked in the pathogenesis of neurodegeneration. We hypothesized that abnormal expression of neurotrophic factors (NTF) produced by microglia may also be involved in neurodegenerative disorders. To test this hypothesis we studied expression of NTF genes in autopsy brain tissues from Alzheimer disease, HIV encephalitis and control patients. Expression of BDNF, NT-3, GDNF and HGF genes was assessed by quantitative RT-PCR and compared to expression of monokines TGF- $\beta$ , IL-6 and TNF- $\alpha$ . We found that expression of NTF genes was increased in brain tissues in areas with significant neurodegeneration. These *in vivo* findings of altered expression of NTF were confirmed in an *in vitro* model of HIV encephalitis. Interestingly, we found a specific distribution of NTF expression in resident microglia compared to infiltrating macrophages. Differential expression of NTF was also observed *in vitro* following various immune, viral or differentiating treatments. Increased expression of NTF in neurodegenerative diseases may begin as a protective response to neuronal injury, but when chronically expressed in the adult brain, NTF could mediate neurotoxicity. (This work was supported in part by an ADRC Pilot Grant to CLA)

## 124.6

DIVERGENT CHANGES IN INSULIN-LIKE GROWTH FACTOR-1 (IGF-1), ITS RECEPTOR AND IGF-BINDING PROTEIN-2 (BP-2) IN THE HYPOTHALAMUS AND CEREBELLUM OF STREPTOZOTOCIN INDUCED DIABETIC RATS. S. Busiguina, J.A. Chowen\*, J. Argente, and I. Torres-Alemán. Instituto Cajal, C.S.I.C. and Hospital Niño Jesús, Madrid, Spain 28002.

Changes in the systemic insulin-like growth factor-1 (IGF-1) system have been well described in both insulin dependent diabetic humans and laboratory rats. However, whether the IGF-1 system of the CNS is affected remains to be illustrated. We have assessed the protein and mRNA levels of IGF-1, its receptor (IGFR), and IGF binding protein-2 (IGFBP-2) in the hypothalamus and cerebellum, areas where IGF-1 modulates various neuroendocrine systems and acts as a neurotrophic factor, respectively. As previously described in poorly controlled diabetics, serum IGF-1 and liver IGF-1 mRNA levels were decreased and returned to normal with insulin. The changes found in the cerebellum and hypothalamus are summarized below.

Area	+ or - insulin	IGF-1 protein	IGF-1 mRNA	IGFR mRNA	IGFBP-2 protein	IGFBP-2 mRNA
Cerebellum	- insulin	↓*	no $\Delta$	no $\Delta$	↓*	↓*
Cerebellum	+insulin	no $\Delta$	no $\Delta$	no $\Delta$	↓*	↓*
Hypothalamus	- insulin	n.d.	↓*	↓*	n.d.	no $\Delta$
Hypothalamus	+insulin	n.d.	no $\Delta$	no $\Delta$	n.d.	no $\Delta$

Table 1. Modifications in the IGF-1 system of diabetic rats (↓\* = significant decrease compared to controls; no  $\Delta$  = no significant change; n.d. = not done). These results indicate that anatomically specific changes occur in the brain IGF-1 system in response to diabetes and that all changes are not normalized by insulin. Furthermore, these modifications may be associated with known modifications of the hypothalamic neuroendocrine system and the more recently reported CNS neuroendocrine function seen in insulin dependent diabetes. Supported by grants from Fundación Endocrinología y Nutrición, Fundación Salud 2000 and the DGCYT.

## 124.8

CHRONIC HYPOXIA INCREASES THE LEVELS OF FGF2 *IN VIVO*. S.P. Soni, M.L. Schwartz and F.M. Vaccarino\*. Child Study Center and Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06520.

The susceptibility of children to hypoxia is particularly pronounced during the newborn period, at a time when selective decreases in cell number and axonal/synaptic pruning occur in normal development. We have developed an animal model of chronic hypoxia in which rats are raised under low O<sub>2</sub> pressure for different periods after birth. Rats raised under chronic hypoxia show a decreased cerebral cortical volume, an increased cell number and an abnormally widespread distribution of callosal projections (Stewart et al, *Soc. Neurosci. Abstr.*, page 2111, 1995). These abnormalities could be due in part to indiscriminately high levels of growth factors involved in the regulation of cell number and axonal/synaptic connectivity. To test this hypothesis, we measured growth factor levels in rats raised under hypoxia and age matched controls. Chronic hypoxia lasting 14 and 30 days resulted in a dramatic increase in levels of basic fibroblast growth factor (FGF2) in the cerebral cortex and hippocampus. All three forms (18, 21 and 21.5 kDa) of FGF2 were increased, as assayed by Western analysis. Using immunocytochemical analysis, we determined that all areas of the hypoxic cortex and hippocampus exhibited a significantly higher number of FGF2 positive cells and a greater intensity of staining respective to control normoxic animals. In the cerebral cortex of control animals, FGF2 staining was localized primarily to the cytoplasm of cerebral cortical neurons. In contrast, chronic hypoxia for 14 days caused an increase in FGF2 immunostaining which was localized both to the cytoplasm and to the nucleus of cerebral cortical cells. After 30 days of chronic hypoxia, FGF2 staining in the cerebral cortex was almost exclusively in the nucleus. Our data support the hypothesis that FGF2 is involved in activity dependent plasticity and that the delay in regressive phenomena (increase in cell number and exuberant connections) demonstrated in hypoxia could be due to the over-expression of FGF2 in the hypoxic brain.

Supported by NIH grant #1P20-NS32578.

## 124.9

EXPRESSIONS OF PDGF B-CHAIN AND  $\beta$ -RECEPTOR IN NEONATAL HYPOXIC/ISCHEMIC ENCEPHALOPATHY. M. Ohno\*, S. Narumiya, N. Tanaka, T. Yamano, M. Shimada. Dep. of Pediatrics, Shiga Univ. of Medical Sci., Otsu, Japan 520-21.

Platelet derived growth factor B-chain (PDGF B-chain) is considered to be a potent neurotrophic factor in the central nervous system. We have investigated the expressions of PDGF B-chain and its specific receptor,  $\beta$ -receptor, in the neonatal rat brain with hypoxic/ischemic injury. The left common carotid arteries of anesthetized 7-day-old rats were ligated, and pups were then placed in a hypoxic chamber. The expression in protein and mRNA of both PDGF B-chain and  $\beta$ -receptor were examined using an immunocytochemistry and a northern analysis, respectively. The spatial distribution of the transcripts of B-chain was also studied by an *in situ* hybridization. Three hours after hypoxia, expressions in both protein and mRNA of B-chain were ubiquitously elevated above the control levels, but foci with decreased expression were also seen. Distribution of the decreased expression corresponded to the infarct areas. Strongly enhanced signals of B-chain protein and mRNA occurred in the neurons surrounding the infarct. The enhancement of  $\beta$ -receptor protein expression was seen in some neurons in the peri-infarct at 3 hours after hypoxia and marked upregulation was seen at 16 hours. The  $\beta$ -receptor mRNA remained at the control level at 3 hours and markedly increased after 16 hours of hypoxia. This enhanced expression was not detected at 72 hours. These results indicate that neonatal hypoxic/ischemic insult induces the upregulation of the platelet derived growth factor B-chain and  $\beta$ -receptor expressions in neurons immediately after hypoxia. PDGF B-chain may act as a neuroprotective factor in developing brain with hypoxic/ischemic injury through autocrine and/or paracrine mechanisms. Supported by 06670785, 5A-5 and 7A-4 (the Ministry of Education, the Ministry of Health and Welfare, Japan)

## 124.11

INCREASED EXPRESSION OF ACTIVIN/INHIBIN FOLLOWING HYPOXIC-ISCHEMIC BRAIN INJURY IN THE INFANT RAT. M. Lai, E. Sirimanne, D. Wu, K. Mountjoy\*, C. Williams and P. Gluckman. Research Centre for Developmental Medicine & Biology, School of Medicine, University of Auckland, New Zealand.

Growth factors and cytokines produced by both neurons and glia are recognised as the major mediators of cell survival and functional recovery following injury to the CNS. Recent studies by us have demonstrated marked upregulation of activin/inhibin mRNA levels following transient unilateral hypoxic-ischemic (HI) brain injury in the 21 day old Wistar rat (Lai et al. 1996 Neurosci. 70: 1013-1024). This is the first evidence for a response by the activin/inhibin system after brain injury and provides a uniquely suitable model to fully establish an *in vivo* role for these polypeptide factors in the CNS. Here the expression of the  $\beta$ A subunit and the specific type II receptor ActRII, were examined by immunohistochemistry. Distinct  $\beta$ A and ActRII immunoreactivity were found in many structures known to be  $\alpha$  and  $\beta$ A mRNA positive after HI injury including the hippocampal formation, choroid plexus, piriform cortex, thalamus and region of the infarct. Immunostaining in most cases was confined to neurons. Immunoblot analysis of cerebrospinal fluid (CSF) identified a 66Kd protein with an  $\alpha$ -subunit specific antiserum but no bands were identified using the  $\beta$ A subunit specific antiserum. This suggests that an inhibin precursor protein circulates in the CSF. These findings demonstrate a novel neural activin/inhibin axis whereby interplay of activin and inhibin may regulate the responses to CNS injury including roles in neuronal survival and/or wound repair. Supported by the Health Research Council of New Zealand.

## 124.13

INCREASED NGF EXPRESSION IN CULTURED HIPPOCAMPAL NEURONS RECOVERING FROM ANOXIA: POSSIBLE INVOLVEMENT OF CYTOKINES. S. Di Loreto<sup>1</sup>, D. Piancatelli<sup>1</sup>, F. Di Marco<sup>1</sup>, L. Corvetti<sup>1</sup>, P. Sebastiani<sup>2</sup>, P. Romano<sup>2</sup>, E. Del Giudice<sup>2</sup>, A. Buriani<sup>2\*</sup>, A. Leon<sup>2</sup>, D. Adorno<sup>1</sup> and C.U. Casciani<sup>1</sup>. <sup>1</sup>CNR, 67100 L'Aquila and <sup>2</sup>Research/ife, 67100 L'Aquila, Italy.

Inflammatory cytokines like IL-1 $\beta$  and TNF- $\alpha$  are known to be involved in the pathogenesis and development of several inflammatory and anoxic disorders occurring in the CNS. In addition, they might play a role in the recovery of injured neurons. Given the neuroprotective potential of NGF, its expression and regulation by cytokines after neuronal injury was examined. A nitrogen chamber was used to induce anoxia in rat hippocampal cultures, which were then transferred to a CO<sub>2</sub> incubator to recover. The expression of NGF mRNA, using PCR, was examined at various times after recovery. After 6 hr of anoxia NGF expression was poor, but 3 hr following recovery it increased, reaching a peak at 6 hr and decreasing thereafter. Anoxic treatments longer than 6 hr gave poorer NGF expression during recovery. Cytokines are known to increase during CNS damage. NGF expression was thus examined in IL-1 $\beta$  and TNF- $\alpha$  treated hippocampal cultures. Both cytokines, used at 1 ng/ml for 3 hr, induced NGF expression in the cultures, while longer treatments (24 hr) resulted in NGF downregulation. Taken together, these results suggest the existence of an initial reaction by hippocampal neurons in culture to protect NGF-dependent cells from anoxic insult, a process probably overcome at later times by NMDA-mediated cytotoxic events. This neural behaviour can be reproduced *in vitro* by treatment with inflammatory cytokines, suggesting that they might be involved in CNS-injury-induced NGF expression.

REGULATION OF NGF SECRETION IN SMOOTH MUSCLE CELLS FROM HYPERTENSIVE AND HYPERACTIVE RATS. D.B. Clemow\*, J.M. Spitsbergen, R. McCarty, W.D. Steers, J.B. Tuttle. Depts. Neurosci., Psychol., Urol., Univ. of Virginia, Charlottesville, VA 22908.

Cultured vascular (VSMC) and bladder (BSMC) smooth muscle cells from Spontaneously Hypertensive Rats (SHR: hypertensive, hyperactive) secrete more NGF than cells from Wistar-Kyoto rats (WKY: normotensive, normoactive). Regulation of NGF output differs in VSMCs from SHRs and WKY rats. We examined NGF secretion by VSMCs and BSMCs from two inbred strains (WKHT: hypertensive, normoactive; WKHA: normotensive, hyperactive) to assess phenotypic association with altered NGF metabolism. Basal NGF secretion was similar for VSMCs in both strains, and BSMCs secreted at higher basal rates than VSMCs. WKHT cultures of both tissues grew to higher density than those from WKHA. Data was analyzed as NGF secretion per cell. Angiotensin-II (1 $\mu$ M) and PMA (10nM) had little effect on BSMCs, but increased NGF secretion in VSMCs of both strains. PDGF (350pM) and carbachol (100 $\mu$ M) increased NGF secretion from BSMCs and VSMCs. Isoproterenol (10 $\mu$ M) and forskolin (10 $\mu$ M) decreased the rate of NGF output similarly in both tissue types. Neuropeptide-Y (1 $\mu$ M) and phenylephrine (10 $\mu$ M) increased NGF secretion in WKHT VSMCs, but had little effect on BSMCs and WKHA VSMCs. Stimulation of NGF secretion rate over control was greater in WKHT VSMCs than WKHA, in response to PMA, PDGF, angiotensin-II, isoproterenol, carbachol, NPY, and phenylephrine. Therefore, NGF metabolism is altered in the hypertensive WKHT. However,  $\beta$ -adrenergic and PKC signaling differences between SHR and WKY are not preserved in the WKHT and WKHA comparison, nor is elevated basal secretion of NGF associated with hypertension in WKHT. These results suggest that disturbances in  $\alpha$ -adrenergic and peptidergic control of NGF output are features common to both genetic models of hypertension. Supported by grants from NIH.

NEUROTROPHIC RESPONSE IN NEURODEGENERATIVE DISEASES. P.G. Sarnacki, K. Sadler, G. Wang, E.A. Bonaroti, C.A. Wiley and C.L. Achim\*. Div. of Neuropathology, Univ. of Pittsburgh, Pittsburgh, PA 15213.

Neurotoxins are often involved in the pathogenesis of chronic brain degeneration. Frequently, these neurotoxic factors are produced by immune activated glial cells. We hypothesized that in response to chronic injury, human microglia and astrocytes may also produce abnormal levels of neurotrophic factors (NTF) that could be involved in neurodegeneration. To test this hypothesis we studied expression of NTF genes in an *in vitro* model of chronic neurodegeneration (i.e. HIV encephalitis). Human fetal and adult brain cells were cultured in the presence or absence of HIV infected macrophages. Production of BDNF, NT-3, GDNF, HGF and the receptors trk and c-met was studied in purified or mixed neuroglial cultures using immunofluorescent laser confocal microscopy and ELISA. Abundance and cellular distribution of these NTF were compared to production of the monokines TGF- $\beta$ , IL-6 and TNF- $\alpha$ . We found that levels of some NTF were increased in microglial and astrocytic cultures exposed to HIV. Neuronal damage measured by immunostaining for dendritic and synaptic markers paralleled also microglial activation. We conclude that abnormal production and distribution of NTF in neurodegenerative diseases may be initially protective, but become neurotoxic when chronically secreted. LOCALISATION OF NERVE GROWTH FACTOR PROHORMONES ISOFORMS IN THE INFLAMED GUT OF PATIENTS WITH CROHN'S DISEASE AND ULCERATIVE COLITIS

M. Reinshagen\*, J. Geerling, J. Lakshmanan, C.v. Tirpitz, H. Rohm, G. Adler. Department of Medicine I, University of Ulm, Germany, Dep. of Biochemistry, Vysal College, Salem, India

Utilizing a panel of polyclonal and monoclonal antibodies to mature NGF, we previously reported immunoblotting evidence for the localisation of 53 and 73 kDa NGF prohormones in the inflamed colon of a rat model of experimental colitis (Soc. Neurosci. 21:23.3, 1995). In the present study we examined the presence of NGF prohormone isoforms in the inflamed ileum or colon of patients with Crohn's disease or ulcerative colitis compared to normal human gut by immunoblotting and immunohistochemical analysis. The tissues were obtained by surgical resection. A panel of polyclonal and monoclonal antibodies to beta-NGF and two prepro-NGF specific domains from commercial vendors (Sigma, Promega, Boehringer, Pro-Hormone Science) were employed. In Crohn's disease and in Ulcerative colitis we found intense expression of 53 kDa NGF prohormone in the inflamed ileum and colon whereas the uninflamed control gut tissue showed only a slight intensity of the band. The two prepro-NGF domain specific antibodies identified a 73 kDa NGF prohormone isoform in the human inflamed tissues. In the immunohistochemical analysis using NGF prohormone staining was observed in the epithelium and in the myenteric plexus using polyclonal antibodies to beta-NGF and prepro-NGF specific domains. In summary, the marked increase in 53 kDa and 73 kDa NGF prohormone levels in the inflamed bowel of patients with Crohn's disease and ulcerative colitis suggests an important role for both prohormones in the pathophysiology of inflammatory bowel disease.

## CHANGES IN HIPPOCAMPAL NGF EXPRESSION FOLLOWING EARLY MATERNAL SEPARATION IN DEVELOPING RATS.

F. Cirulli,<sup>1</sup>\* A. Micera,<sup>2</sup> E. Alleva<sup>1</sup> and L. Aloe<sup>2</sup>. <sup>1</sup>Lab. Fisiopatologia O. S., Istituto Superiore di Sanità, I00161 Rome, Italy; <sup>2</sup>Institute of Neurobiology, C.N.R., I00137 Rome, Italy.

Nerve Growth Factor (NGF) is a neurotrophin affecting neuronal differentiation and remodelling of axonal and dendritic arborization, thus modifying CNS connectivity. As a consequence, changes in NGF expression at an early developmental stage might have long lasting effects on brain activity. In this study a maternal separation paradigm was used to test whether brief manipulations of rat pups early during ontogeny might influence NGF synthesis in the hippocampal formation. The expression of NGF mRNA was examined in 3 day-old Sprague-Dawley rat pups following 45 min maternal separation using *in situ* hybridization. Early maternal separation in neonatal rats resulted in increased expression of NGF mRNA in the dentate gyrus and the hilus of the hippocampus. NGF protein levels measured (by means of a sensitive 2-site ELISA assay) in the whole hippocampus the day following the separation procedure did not differ in separated vs non-separated pups. These data indicate that a single brief separation performed early during development can affect hippocampal NGF expression. Growth and neurologic development in premature human infants are improved by active tactile stimulation. Although this hypothesis is at this time only speculative, our model suggests the possibility that some of the mental disabilities or psychiatric disorders described in humans who experienced maternal separation or not adequate stimulation might be associated with early changes in NGF synthesis and release.

NEUROTROPHIC FACTORS: EXPRESSION AND  
REGULATION—SYNTHESIS, EXPRESSION, AND TRANSPORT

## 125.1

*Narp*, a Novel Member of the Pentraxin Family of Proteins that is Synthesized, Secreted, and Active as a Monomeric Molecule, C.C. Tsui, B.A. Pierchala, and P.F. Worley, Department of Neuroscience, Johns Hopkins School of Medicine, Baltimore MD 21205.

*Narp*, Neuronal activity-regulated pentraxin, is an immediate-early gene product that has been demonstrated to have dendritic-outgrowing activity using *in vitro* cortical explant cultures (Tsui et al., 1996). Recent studies with primary cortical neurons have shown that *Narp* protein expression is induced and regulated through the activation of NMDA receptors. Analysis of its deduced amino acid sequence has indicated its homology to the pentraxin family of secreted lectins such as C-reactive protein (CRP) and serum amyloid P component (SAP). These pentraxins have in common an eight amino acid "pentraxin signature" sequence and a specific  $\text{Ca}^{2+}$ -dependent affinity to sulfated galactose sugar moieties. Using FPLC Superose 12 gel filtration size fractionation, *Narp* in both the presence and absence of  $\text{Ca}^{2+}$  eluted from the column in a single peak that corresponds to a ~46 kDa protein. This finding demonstrates that *Narp*, unlike CRP and SAP which aggregate to form functionally active pentameric molecules, functions as a monomeric protein.

Tsui, C.C., Copeland, N.G., Gilbert, D.J., Jenkins, N.A., Barnes, C., Worley, P.F. *Narp*, a Novel Member of the Pentraxin Family, Promotes Neurite Outgrowth and Is Dynamically Regulated by Neuronal Activity. *Journal of Neuroscience* 16(8):2463-2478

## 125.3

BDNF EXON 1E PROMOTER ANALYSIS IN C6 GLIOMA CELLS. J. F. Bishop, G. P. Mueller\* and M. M. Mouradian, Genetic Pharmacology Unit, Experimental Therapeutics Branch, NINDS, and Department of Physiology, USUHS, Bethesda, MD 20892.

Brain-derived neurotrophic factor (BDNF) has established neuroprotective effects on several neuronal populations and is therefore an important candidate for treatment of neurodegenerative diseases. Since this gene contains multiple alternate promoters that are active in a cell-type and injury-specific manner, targeted regulation of BDNF expression is an attractive possibility. Mounting evidence suggests that calcium-dependent processes are involved in both the regulation of BDNF gene expression and its neuroprotective actions. In previous studies, we had determined that BDNF mRNA expression in rat C6 glioma cells is controlled primarily by the exon 1e promoter, which is also responsive to calcium. To localize important basal and calcium responsive regulatory elements, C6 cells were transfected with CAT reporter constructs containing full-length and truncated segments of the exon 1e promoter and treated 48 hours later with either 0.01% DMSO (vehicle) or 10  $\mu\text{M}$  A23187 (calcium ionophore). After a 4 hour incubation period, CAT assays were performed and the results suggest that prominent basal regulatory elements are located within 174 bp of the transcription start site and that a calcium responsive element is located within 379 bp of this site. Further studies are in progress to localize basal and calcium responsive elements in the BDNF exon 1b and exon 1d promoters.

## 124.16

SPECIES SPECIFIC TRANSFER OF ALBUMIN FROM BLOOD TO CSF (CEREBROSPINAL FLUID) IN POSTNATAL *MONODELPHIS DOMESTICA*. G. W. Knott, K. M. Dziegielewska, M. D. Habgood, Z. Li, C. F. L. Hinrichsen\*, and N. R. Saunders. Department of Anatomy & Physiology, University of Tasmania, GPO Box 252C, Hobart, Tasmania, 7001, Australia.

The mechanisms by which peptides and proteins are transported into and out of CSF are fundamental to understanding brain development. CSF of fetal eutherians and neonatal marsupials contains a high concentration of proteins (15-40 times adult) which appear to originate from plasma (Saunders, 1992, *Handbook Exper. Pharm.* 103, 327-369). In marsupials the highest CSF protein concentration occurs in the early neonatal period, rather than *in utero* as in eutherian fetuses. The aim of present experiments was to measure the transfer of various exogenous albumins from plasma to CSF in *Monodelphis* pups aged 5-36 days postnatal (P). After intraperitoneal injection of human (HSA), bovine (BSA) and succinylated BSA (succ-BSA) serum albumins, the steady state ratios (CSF/plasma) for each injected albumin were compared with endogenous *Monodelphis* albumin (MSA). The highest CSF/plasma ratios occurred in the youngest animals (P5) and were highest (over 40%) for MSA and HSA. At later stages, from P7 to P24, the BSA ratios were significantly below those for MSA; the succ-BSA ratios were even lower. By P32-36 the ratios for all albumins had fallen to less than 3%. Immunocytochemical double staining for albumins showed that MSA, HSA and succ-BSA were localized in the same choroid plexus epithelial cells, but only about 1/3 of the MSA positive cells contained succ-BSA. Similar experiments in other species have shown that succinylation disrupts specific albumin transfer. It is suggested that the decline in CSF/plasma ratio for succ-BSA in *Monodelphis* with age reflects a reduction in passive transfer, which is superimposed on a developmentally regulated decline in specific transfer of albumin, which has disappeared by P32-36. The approach outlined here provides a way of determining both the passive contribution to plasma-CSF exchange and more specific, developmentally regulated transfer of proteins that are likely to be important for brain development.

CLONING AND CHROMOSOMAL LOCALIZATION OF THE MOUSE VGF GENE. S. Hahm, K. Kelley, C. Kozak\* and S.R.J. Salton\*. Fishberg Research Center for Neurobiology, Mount Sinai School of Medicine, New York, NY, 10029 and \*National Institutes of Health, Bethesda, MD 20892.

Our overall goal has been to investigate the functional role of VGF, a nervous system-specific mRNA that is rapidly and selectively induced by neurotrophic factors *in vitro*, and is expressed by developing and adult central and peripheral neurons *in vivo*. We have cloned the mouse *Vgf* gene from a lambda dash genomic library. Preliminary analysis indicates that the mouse and rat *Vgf* coding and regulatory sequences are highly conserved as is the intron/exon structure. The 5' flanking regions of the mouse and rat *Vgf* genes each contain CRE, NGFI-A and CCAAT elements that regulate VGF induction by NGF and Ras in PC12 cells. Expression patterns of two constructs that contain either 2.5 kb or 0.3 kb of mouse *Vgf* 5' flank driving synthesis of a tagged VGF mRNA are being analyzed in transgenic mice. The mouse *Vgf* gene has been mapped to the distal end of the mouse chromosome 5 in a region of defined homology to human chromosome 7.

## 125.4

EXPRESSION OF EPH-FAMILY MEMBERS IN EMBRYONIC RAT GANGLIA. L.M. Bianchi\*, N.W. Gale, L. Pan, and G.D. Yancopoulos. Medical University South Carolina, Charleston, 29425; Regeneron Pharmaceuticals, Tarrytown, NY 10591

The largest known family of receptor tyrosine kinases is the Eph family, (originally isolated from an erythropoietin producing hepatocellular carcinoma). Ligands of the Eph family activate multiple receptors, and appear to do so only when attached to the cell membrane (Davis et al., 1994, *Science*, 266, 816-819). Ligands can be functionally divided into two binding subclasses based on whether the ligands are membrane bound by linkage to glycosphatidylinositol (GPI) or through a transmembrane domain (Gale et al., submitted). The prominent expression in the nervous system, particularly early in development, has led to speculation that these family members play crucial roles in tissue segmentation, neuronal migration, and axonal outgrowth.

To investigate the expression of Eph family members in the developing sensory ganglia, northern blot analyses of dorsal root, trigeminal and statoacoustic ganglia were conducted. RNA from E15 rat ganglia revealed the presence of several Eph-related ligands and receptors within each neuronal population. The transmembrane ligands ELK-L and Htk-L were detected in all three ganglia. ELK-L3 and ELK receptor were not detected. Several GPI anchored ligands were also detected in these ganglia at various intensities. ELF-1 and LERK 4 were expressed in all three ganglia, whereas Ehk-1 L and AL-1/RAGS were more prominently expressed in trigeminal and dorsal root ganglia. Ehk-3 receptor was present in all ganglia, but Ehk-1 and SEK were below the level of detection. These results suggest that several members of the Eph family may interact to regulate development of sensory neurons.

## 125.5

**DISTRIBUTION OF HEK-LIGAND mRNA IN DEVELOPING AND ADULT CENTRAL NERVOUS SYSTEM: A QUANTITATIVE IN SITU HYBRIDIZATION STUDY.** A.A. Welcher\*, V. Cummins, and L.R. Williams. Depts. Neuroscience and Immunology, Amgen, Inc., Thousand Oaks, CA 91360.

The Human EPH-like receptor tyrosine kinase (HEK4) is one member of the large Eph/Elk/ECK/ subfamily of receptor tyrosine kinases. HEK4 was used as an affinity reagent to identify a binding protein, referred to as HEK-ligand (Fox et al., in prep.). The HEK-ligand sequence shows homology to the expanding family of proteins related to B61, and is identical to Al-1. For the present work, the distribution of HEK-ligand mRNA was determined in the developing and adult rat nervous system using quantitative in situ hybridization using an oligonucleotide procedure (Wisden, 1993). During development HEK-ligand mRNA is expressed at high levels throughout the embryo. In the prenatal brain, higher levels are expressed in the brain stem than in the developing cortices. In the neonatal brain, the highest levels of HEK-ligand are observed in the cerebral cortex. In the adult brain, the abundance of HEK-ligand mRNA is reduced from that observed in the developing CNS, but still is in highest abundance in the cerebral cortex, particularly layer 4. Abundant message is also observed in the dentate gyrus. Kainic acid - induced, excitatory amino acid stress to the brain results in significant (30%) increases in message in the superior colliculus and caudate nucleus, and 30% decreases in message in the layer 4 cortex and pyramidal neurons of the hippocampus.

## 125.7

**ACTIVIN AND FOLLISTATIN EXPRESSION AND FUNCTION IN THE DEVELOPING MOUSE RETINA.** D. Srivastava, W.-E. Lau and R. Adler\*. Johns Hopkins University, The Wilmer Eye Institute, Baltimore, MD 21287.

We are investigating the role of activin, inhibin and follistatin in the regulation of mouse retinal cell survival and differentiation; activins and inhibins are dimeric signaling peptides known to affect these processes in other systems, while follistatin can prevent activin binding to its receptor. Using the reverse-transcription polymerase chain reaction (RT-PCR), the expression of genes encoding inhibin and activin subunits, activin receptor and follistatin was demonstrated in retinas from embryonic, neonatal and adult C57Bl/6J mice. Biological effects of activin and follistatin were examined using glia-free, low density cultures of neonatal mouse retinal cells, which differentiate *in vitro* as photoreceptors and non-photoreceptor neurons. Activin produced time- and dose-dependent decreases in the number of photoreceptors present in these cultures; these effects were preventable with follistatin which, however, did not appear to have effects of its own. RT-PCR analysis using RNA from purified cultures of either retinal neurons/photoreceptors or retinal glial cells demonstrated that, while activin and inhibin subunits were expressed by both cell populations, follistatin mRNA was detected exclusively in glial cells. These data are consistent with the hypothesis that a homeostasis between activin and follistatin may regulate the survival and/or differentiation of retinal photoreceptor cells. Supported by NIH Grant EY05404 and Research to Prevent Blindness, Inc.

## 125.9

**THE INTERLEUKIN-6 RECEPTOR IS PRESENT ON PRIMARY SENSORY NEURONS** P.G. Murphy\* and P.M. Richardson. Dept. of Neurology and Neurosurgery, Montreal General Hospital, 1650 Cedar Ave. Montreal Quebec. H3G 1A4

Previous results have indicated that axotomized sensory neurons express the interleukin-6 (IL-6) mRNA. This cytokine message is synthesized for several days after axotomy in medium to large sensory neurons. IL-6 might be important in neuronal survival and gene activation after injury. To indicate possible functions of IL-6 after injury, the IL-6 receptor was localized on cellular components of the dorsal root ganglion (DRG). Embryonic DRG were separated into a neuronal and non-neuronal population by centrifugation through BSA and percoll gradients in combination with pre-plating. Cell purity was 90-95% assessed by morphology and immunocytochemistry with glial, neuronal, and fibroblast markers. RT-PCR assays indicated presence of the IL-6 $\alpha$  receptor mRNA in the neuronal cell population. A subpopulation of non-neuronal cells also express the message for the receptor. Current cell fractionation studies will identify which non-neuronal cells have the receptor mRNA. The  $\alpha$  receptor protein also is present in neuronal cells as demonstrated with immunocytochemistry. An autocrine mechanism may exist as the receptor is present in neurons which express IL-6 mRNA. Preliminary immunocytochemistry results suggest the IL-6 $\alpha$  receptor is on subpopulations of neuronal and non-neuronal cells *in vivo*. Infusion of rIL-6 into the subarachnoid space resulted in an increase in the neuropeptide galanin compared to saline infusion while not affecting NPY, GAP-43, and VIP. These results suggest that IL-6 might induce some injury associated genes after axotomy.

## 125.6

**DISTRIBUTION OF VASCULAR ENDOTHELIAL GROWTH FACTOR B IN THE RAT AND MOUSE CENTRAL NERVOUS SYSTEM.** G. von Euler\*, R. Zetterström\*, B. Olofsson\*, L. Olson\* and U. Eriksson\*. \*Ludwig Institute for Cancer Research, Stockholm Branch, Box 240, S-17177 Stockholm, Sweden, and \*Dept. of Neuroscience, Karolinska Institutet, S-17177 Stockholm, Sweden.

We have recently discovered a novel growth factor termed vascular endothelial growth factor B (VEGF-B) which has sequence similarities to VEGF and stimulates endothelial cell growth *in vitro* (Proc. Natl. Acad. Sci. 93, 2576-2581, 1996). Human and mouse VEGF-B are found in two isoforms, 167 and 186 amino acids long, that are generated by alternative splicing of mRNA. The alternative splicing produces a frame shift which gives rise to entirely distinct amino acid sequences in the carboxy terminal regions of the two VEGF-B isoforms, while the amino terminal regions are identical.

VEGF-B is detected in many tissues including brain, by Northern blot analysis. *In situ* hybridization with cDNA probes against various regions of VEGF-B mRNA showed a high general signal in the grey matter of the CNS. Random probes caused little or no labeling. Certain regions expressed more VEGF-B mRNA than others; the mitral cell layer in the olfactory bulb, globus pallidus, the CA2 and CA3 regions of the hippocampus, the Purkinje cell layer in cerebellum, various nuclei in pons, and grey matter of the spinal cord. Similar results were observed for two non-overlapping probes and both in rat and in mice. Work is in progress to assure the cellular identity of VEGF-B positive signals.

In conclusion, the novel growth factor VEGF-B has a widespread distribution in the rat and mouse central nervous system and is enriched in certain regions. Supported by the Ludwig Institute for Cancer Research, the Swedish MRC, and USPH funds.

## 125.8

**AMPHIREGULIN, AN EGF-RELATED GROWTH FACTOR, IS EXPRESSED IN DISCRETE REGIONS OF MOUSE NERVOUS SYSTEM.** K.B. Seroogy\*, L.A. Opanashuk\*, B.M. Davis\* and H.J. Kornblum\*. \*Dept. of Anatomy & Neurobiology, University of Kentucky, Lexington, KY 40536 and \*Depts. of Pediatrics and Pharmacology, UCLA, Los Angeles, CA 90024.

Amphiregulin (AR) is a recently identified member of the epidermal growth factor (EGF) family of mitogenic polypeptides, which all mediate their actions by binding to the EGF receptor (EGF-R). Although AR has been examined in certain peripheral tissues, its presence and actions within the nervous system are unknown. To determine whether AR is expressed in neural tissue, sections throughout the mouse central and peripheral nervous systems were processed for the *in situ* hybridization localization of AR mRNA at neonatal and adult ages using <sup>35</sup>S-labeled cRNA probes (cDNAs kindly provided by D.C. Lee, UNC-Chapel Hill; S.K. Das, U. Kansas Med. Ctr.; and G. Plowman, Sugen, Inc.). Expression of AR mRNA was also examined in brains of mice that lack transforming growth factor- $\alpha$  (TGF $\alpha$ , another EGF-R ligand). AR cRNA-hybridization was observed in subpopulations of cells distributed throughout the forebrain including the olfactory bulb, prefrontal cortex, rostral septum, striatum, amygdala, and in scattered cells of the hippocampus, hypothalamus and neocortex. In brainstem, expression was detected in midline raphe nuclei, nucleus tractus solitarius, and in regions of the ventrolateral medulla including the facial motor nucleus. Peripherally, AR cRNA labeling was localized to numerous superior cervical ganglion neurons as well as within a few dorsal root ganglion cells. Expression levels were usually higher neonatally than in adulthood, suggesting a role for AR in neural development. Patterns and levels of AR mRNA expression appeared unaltered in TGF $\alpha$  knockout mice, indicating that AR expression is not upregulated in brain in compensation for a TGF $\alpha$  deficiency. Overall, these results provide evidence that the EGF-R ligand AR may have functional roles in select brain regions as well as in sympathetic and primary sensory systems. Supported by UK Med. Ctr. (KBS), DOE (HLK) and NIH fellowship NS10007 (LAO).

## 125.10

**ANTEROGRADE TRANSPORT OF BRAIN DERIVED NEUROTROPHIC FACTOR** RA Rush\* and X-F Zhou. Department of Human Physiology and Centre for Neuroscience, Flinders University of South Australia, GPO Box 2100 Adelaide, 5001, Australia

Neurotrophins are a family of proteins which act as survival and differentiative factors in the developing and mature nervous system. Extensive evidence has been provided for their retrograde action following incorporation into nerve terminals and transport to the cell body. In contrast, we now demonstrate that one neurotrophin, brain derived neurotrophic factor (BDNF) is transported anterogradely via both peripheral and central processes of spinal sensory neurons. Using newly generated antisera, we have examined the distribution of BDNF and found it present within a subpopulation of sensory somata, primarily those of a small to medium diameter. Within the L<sub>5</sub> dorsal root ganglia (DRG), the granular appearing BDNF-immunoreactive (ir) neurons comprised approximately 20% of the total and ranged in area from 105 to 3,188  $\mu$ m<sup>2</sup> with an average of 774  $\pm$  37  $\mu$ m<sup>2</sup>. Within the spinal cord, varicose nerve terminals in laminae I and II were intensively labelled, with a few BDNF-ir nerve fibres present in laminae II, IV and V. No BDNF immunoreactivity was detected in dorsal or ventral roots or peripheral nerves unless these nerves had been previously ligated or crushed. Nerve ligation studies indicate the factor is transported away from the spinal ganglia to terminals in the periphery and spinal cord. Spinal cords were also examined in animals with ligated dorsal roots revealing a heavy reduction of the immunoreactive nerve terminals within the ipsilateral, but not the contralateral spinal cord. The findings add a new dimension to the role of neuronal growth factors since anterograde transport has not previously been observed for any endogenous survival factor.

## 125.11

RETROGRADE TRANSPORT OF ENDOGENOUS NT3 BY SPINAL SENSORY NEURONS IN THE CHICK EMBRYO. P. Jiang, R. A. Oakley, and E. Frank\*. Department of Neurobiology, University of Pittsburgh, Pittsburgh, PA 15261.

The distribution of neurotrophin-3 (NT3) in developing chick embryos was studied using a monoclonal antibody directed against recombinant NT3. This antibody intensely labels a subpopulation of large diameter sensory neurons that are mainly located in the ventrolateral region of the DRG. The antibody also labels spinal motoneurons less intensely.

Because the pattern of labeling in the DRG is similar to that of *trkC* expression, the localization of NT3 in sensory neurons might result from retrograde transport from peripheral tissues rather than from local synthesis within the DRG. To investigate this possibility, we used two independent manipulations to block retrograde transport: ligation of peripheral nerves and colchicine injection. Nerve ligations led to a dramatic decrease in NT3-immunoreactivity within DRG neurons and to an accumulation of immunoreactivity distal to the ligation. Similarly, colchicine injections led to a loss of NT3-immunoreactivity in the DRG. These results indicate that the NT3 detected in DRG neurons is mainly derived from peripheral sources via retrograde transport.

To determine the source of endogenous NT3 in peripheral tissues, we used injections of monensin to block the secretion of newly synthesized proteins. In vehicle-injected control limbs, NT3-immunoreactivity is virtually undetectable. Monensin injection to the hindlimb resulted in a dramatic increase in NT3-labeling in developing limb muscles. The labeling was differentially distributed, with some muscles being intensely stained while others were only weakly stained. These results suggest that individual muscles may differ in their production of NT3 during this stage of development, which coincides with the period of cell death in the DRG.

Supported by grants from NINDS and the MDA.

## 125.13

BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) IN THE RAT CEREBRAL CORTEX: MISMATCH BETWEEN SITE OF SYNTHESIS AND ACCUMULATION M.P. Berzaghi<sup>1</sup>\*, T.F. Freund<sup>2</sup>, E.Cs. Papp<sup>2</sup>, D. Lindholm<sup>1</sup>, U. Zirngiebel<sup>1</sup>, E. Castrén<sup>1</sup>, & H. Thoenen<sup>1</sup>. 1. Dept. Neurochemistry, Max Planck Institute for Psychiatry, 82152 Martinsried, FRG. 2. Institute of Experimental Medicine, Hungarian Academy of Science Budapest, P.O.Box 67, H-1450 Hungary

The expression and release of brain-derived neurotrophic factor (BDNF) are regulated by neuronal activity in the rat brain. Cholinergic activity has been shown to be an essential constituent in the regulation of BDNF expression. The aim of the present study was to analyse both the localization of BDNF mRNA expression and the distribution of BDNF immunoreactivity in the adult rat cerebral cortex before and after cholinergic stimulation. Pilocarpine, a muscarinic cholinergic agonist, markedly increased BDNF mRNA expression in scattered neurons in layers II to VI throughout the cerebral cortex. The increase in BDNF mRNA levels was paralleled by an increase in the number of BDNF immunoreactive neurons in all cortical areas examined. BDNF immunoreactivity was localized within a subset of neurons present in cortical layers II to VI. Using "mirror technique" we demonstrated that the vast majority of BDNF immunoreactive cells were also positive for the calcium binding protein parvalbumin, which is expressed by a subpopulation of GABAergic interneurons. Although BDNF immunoreactivity was localized within parvalbumin positive neurons, double *in situ* hybridization experiments demonstrated that parvalbumin-containing interneurons do not express BDNF mRNA in the adult rat neocortex. Thus, BDNF is not synthesized by parvalbumin-containing interneurons, but is instead upregulated within, and released from, a distinct neuronal population in an activity-dependent manner, and subsequently accumulates in parvalbumin containing GABAergic interneurons.

CO-LOCALIZATION OF NEUROTROPHINS AND THEIR CORRESPONDING HIGH AFFINITY RECEPTORS IN MATURE RAT NEOCORTX. A.F. Pitts\* and M.W. Miller. Neuroscience Prog., Depts. of Psychiatry & Pharmacology, Univ. of Iowa Coll. of Medicine, Iowa City IA 52242 and Research Serv., V.A.M.C., Iowa City IA 52246.

We determined whether individual cortical neurons can elaborate both a neurotrophin [nerve growth factor (NGF), brain-derived neurotrophin factor (BDNF), and neurotrophin-3 (NT-3)] and its preferred high affinity receptor [*trkA*, *trkB*, and *trkC*, respectively]. A double-labeling immunofluorescence procedure was used. Sections of fixed rat somatosensory and motor cortex were incubated with a primary antibody (Ab) directed against NGF (goat polyclonal Ab, E.M. Johnson), BDNF, or NT-3 (guinea pig polyclonal Ab, F. Hefti) and then with a fluorescence-labeled (FITC) secondary Ab (Vector). Subsequently, the sections were incubated with an anti-*trkA*, *trkB*, or *trkC* Ab (rabbit polyclonal Ab, Santa Cruz) and then with a secondary Ab conjugated to Texas Red (Vector). A labeling index was determined by counting 5 fields in 4-5 rats. Neurotrophin-positive somata were distributed largely in layers II/III, V and VI of cortex; e.g., 1/3 of the layer V neurons were neurotrophin-positive. In contrast, *trk*-positive neurons were mostly in layer V where each *trk* isoform was expressed by about 1/3 of the neurons. Nearly 2/3 of the *trk*-positive neurons co-expressed their associated ligand, i.e., *trkA* and NGF, *trkB* and BDNF, and *trkC* and NT-3. Thus, the results provide a morphological basis for autocrine regulation within the cortex.

Supported by the Dept. of Veterans Affairs and the N.I.H. (DE 07734, AA 06916, and AA 07568).

## 125.12

DIFFERENTIAL EXPRESSION AND RETROGRADE TRANSPORT OF NEUROTROPHINS BY THE LOCUS CERULEUS. S. Borson\*, M.A. Bothwell, M.S. Butler, and B. Kim. Depts of Psychiatry & Behavioral Sciences and Physiology & Biophysics, Univ Washington Sch of Med, Seattle WA 98195.

In various neuronal systems, neurotrophins may have anterograde, autocrine, and paracrine effects, in addition to their more widely-appreciated retrograde effects. The adult rat locus ceruleus (LC) is believed to be responsive to only one member of the neurotrophin family, NT-3. We compared the expression and retrograde transport of NT-3, BDNF, and NGF by LC neurons in adult Sprague-Dawley rats, using *in situ* hybridization histochemistry for mRNA, and <sup>125</sup>I-labeled peptides (courtesy of R. Lindsay, Regeneron) prepared in our lab by a modification of the lactoperoxidase method, purified by centrifugal filtration (Millipore Ultrafree-MC), and injected stereotactically into forebrain sites (cortex, hippocampus, and lateral ventricle), for transport studies. **RESULTS.** Under basal conditions, most neurons of the adult rat LC expressed NT-3 mRNA at low to moderate, uniform levels; BDNF expression was much more variable and NGF expression was negligible. Neurotrophin transport was similarly specific: <sup>125</sup>I-NT-3 was transported ipsilaterally by LC neurons after a forebrain injection in 15/19 animals, BDNF in 1/16, and NGF in 0/4. NT-3 and BDNF appear to be differentially regulated in LC neurons; the preferential synthesis and retrograde transport of the same neurotrophin, NT-3, suggests the need for new experiments to identify its role in LC-related neuronal pathways. Supported by the Alzheimer's Association. IIRG 93-116 (S. Borson).

## 125.14

BDNF SECRETION IS MEDIATED BY PERTUSSIS TOXIN-SENSITIVE G-PROTEIN Erik C. Gunther, Christopher von Bartheld, Laura Goodman \*\*, and Mark Bothwell\*. Department of Physiology and Biophysics, University of Washington, Seattle, WA 98195; \*\* Genentech, Inc., Department of Neuroscience, South San Francisco, CA 94080

Mechanisms governing neurotrophin secretion are undefined. We present *in vitro* and *in vivo* evidence that BDNF release can be blocked by pertussis toxin (PTX), which specifically inactivates Gi and Go G-proteins. Aft20 cells transfected with a BDNF expression vector release BDNF in an activity-dependent manner.

Preliminary results indicate that 1.0 hr. pretreatment of these cells with 2.0 µg/ml PTX decreases BDNF release. The developing chick optic system was used to assay the effect of PTX on endogenous neurotrophin supply. Developing neurons of the Isthmo Optic Nucleus (ION) project from the midbrain to BDNF-expressing retinal target cells, on which they depend for trophic support from embryonic day 13 to 17 (E13-17). Intraocular injection of 175 ng PTX resulted in a 42% increase in normal ION neuron death during, but not after this period of neurotrophin dependence, consistent with an inhibitory effect of PTX on trophic factor secretion. Co-injection of exogenous BDNF with PTX rescued 50% of ION neurons which would have died with PTX injections alone. Retrograde transport of exogenous <sup>125</sup>I-BDNF co-injected with PTX was increased over <sup>125</sup>I-BDNF injected alone, suggesting decreased competition from endogenous BDNF for receptors mediating retrograde transport, and consequent enhanced transport of exogenous BDNF.

## 125.16

EVIDENCE FOR AUTOCRINE INTERACTIONS AND REDUNDANCY OF NEUROTROPHIC SUPPORT IN THE ADULT RAT TRIGEMINAL BRAINSTEM SYSTEM. J. Jacobs\* and M.W. Miller. Neuroscience Prog., Depts. of Psychiatry & Pharmacology, Univ. of Iowa Coll. of Med., Iowa City IA 52242 and Research Serv., V.A.M.C., Iowa City IA 52246.

The retrograde transport of neurotrophins influences neuronal survival and differentiation, however, there is increasing evidence that retrograde transport does not account for all of the trophic interactions in adult animals and that CNS neurons may participate in an autocrine system. To resolve this issue, we investigated the expression of nerve growth factor (NGF) and its receptors in primary and secondary trigeminal nuclei. We used antibodies against NGF (E.M. Johnson, Wash. Univ.), p75 (Oncogene), generic *trk* (Oncogene), and *trkA*, *trkB*, and *trkC* (Santa Cruz). We also performed *in situ* hybridizations using a full length rat preproNGF cRNA (S. Whittemore, Univ. Miami). Neurons in the trigeminal ganglion (77%), mesencephalic nucleus (87%), the principal sensory nucleus (PSN; 74%), and the motor nucleus (86%) expressed NGF (based on the immunoreactions and hybridizations). More than 80% of the first order and motor neurons expressed a *trk* isoform, whereas in the PSN only 1/3 of the neurons were *trk*-positive. Thus, every first order neuron expresses NGF, p75, *trkA* and another *trk* isoform. In the PSN, every *trk*-positive neuron expresses *trkA* and *trkB* or *trkC*. Furthermore, the trigeminal system is capable of not only retrograde (e.g., from the PSN to the first order neurons), but also autocrine regulation (e.g., expression of NGF and *trkA* in the first order neurons).

Supported by the Dept. Vet. Affairs and the N.I.H. (DE07734, AA06916, and AA07568).

## 125.17

**NGF, BDNF AND TRKB, BUT NOT TRKA, mRNAs ARE LOCALIZED TO THE DENDRITES OF RAT NEURONS.**  
E. Tongiorgi\*, M. Righi and A. Cattaneo, Int. School for Adv. Studies (SISSA), 34013 Trieste, ITALY

The selective localisation of specific mRNAs into the dendrites, axons or the cell body is supposed to be an important mechanism to restrict protein synthesis at specific functional sites. The subcellular localisation and the regulation of the transport of mRNAs coding for proteins involved in synaptic plasticity is largely unknown.

In this study we used a sensitive non radioactive *in situ* hybridization method to examine the subcellular distribution of mRNAs specific for neurotrophins and their receptors in rat brain slices and in acutely dissociated hippocampal neurons in culture. In neurons of the basal forebrain NGF, BDNF and TrkB mRNAs are localised in the cell bodies and in the dendrites while trkA mRNA is restricted to the cell bodies. Dendritic expression of BDNF and TrkB mRNAs appears to be a general phenomenon in CNS, as confirmed by detailed studies performed on the visual cortex, hippocampus and substantia nigra. In order to facilitate the quantification and the experimental modulation of dendritic mRNA localization, *in situ* hybridisation was performed on acutely dissociated hippocampal neurons in culture. A somatic/dendritic localisation of BDNF and TrkB mRNAs was confirmed in these experimental conditions. Moreover, stimulation of such cultures with high potassium (10 and 20 mM) modulates the mRNA distribution in a subpopulation of neurons by increasing the amount of BDNF and TrkB mRNAs in the dendritic varicosities. We propose that the modulation of mRNAs for neurotrophins and their receptors in the dendrites might represent an important mechanism for achieving selective local responses at individual synapses. ## 125.19

**EXPRESSION OF FGF-R ISOFORMS ON NEUROEPITHELIAL CELLS.** A. Kalyani\* and M. S. Rao, Dept. of Neurobiology and Anatomy, University of Utah School of Medicine, Salt Lake City, UT 84132.

Neuroepithelial (NEP) cells from E10.5 rat embryos are multipotent and can differentiate into neurons and glia (Kalyani et al., unpublished results). NEP cells proliferate and maintain their pluripotent character in culture when grown with either acidic or basic fibroblast growth factor (FGF). To characterize the receptors that mediate the proliferative response to FGFs, we have examined the expression of FGF receptors 1-4 and their splice variants IIb and IIc. Using reverse transcription polymerase chain reaction (RT-PCR), we show that undifferentiated neuroepithelial cells express a subset of FGF receptor isoforms. The IIc isoforms of FGFR's 1-3 are detectable in E10.5 neuroepithelial cells. The IIb isoforms are not present though expression can be detected in control tissue. FGFR-4 expression is also detected in E10.5 rat neuroepithelial cells. We have used single cell PCR and RNA profiling techniques to show that individual NEP cells express multiple FGFR isoforms.

Comparison of the FGF receptor expression of undifferentiated NEP cells with that of differentiated neurons and glial cells suggests that FGFR3 is uniquely expressed on neuroepithelial cells. FGFR1 is expressed by neuroepithelial cells and its expression is maintained by neurons while FGFR2 expression is downregulated. The pattern of expression of FGF receptors in recently differentiated glial cells is distinct from the pattern in neuroepithelial cells and neurons. To determine if neuroepithelial cells synthesize FGF's we have analyzed FGF expression by PCR. We show that NEP cells synthesize FGF's and that NEP cells grown at high density can proliferate in culture in the absence of exogenously added FGF. E10.5 neuroepithelial cells may therefore maintain their proliferative state by using an autocrine mechanism. Supported by the Muscular Dystrophy association and a University of Utah faculty award.

## 125.21

**SKIN AS A MODEL SYSTEM FOR STUDIES OF NGF-PROHORMONE EXPRESSION AND FUNCTION.** Moore GPM, Yardley G, Isaacs K, Moore AG, Huff K and Lakshmanan J.\* CSIRO Prospect, Australia, University of Western Sydney, Nepean, Australia, Harbor UCLA Medical Center, Torrance, CA, USA, 90509, Vysya College, Salem, India.

Utilizing antiserum to 2.5S NGF (Sigma, St. Louis) we previously reported NGF-immunostaining in the outer root sheath (ORS) cells, on the surface epithelium of apocrine sweat glands, and in the pilary canals of follicles near the epidermis in ovine skin (Soc. Neurosci. Abs. 21:22.5, 1995). An investigation with the same antiserum revealed the presence of 143, 73, 63 and 53kDa immunoreactive proteins in skin (10th Internat. Cong. Endocrinol. 1996). In the present study we performed *in situ* hybridization on sections of ovine skin with a DIG-labeled antisense mouse cDNA probe to ascertain the sites of NGF expression. In addition, we examined the immunohistochemical localization of NGF-prohormone (PR) utilizing anti-prepro-NGF domain specific antibodies (Pro-Hormone Science, CA) that recognized the 53kDa NGF-PR present in the recombinant human NGF preparations on the Western blot (Reinshagen et al. submitted). In *in situ* hybridization experiments the NGFmRNA was localized to the follicle bulb and immunostaining with anti-prepro-NGF(-60 to -91) was found in the ORS. Immunoneutralization studies of litter mates treated with IgG fraction of antiserum to mouse 53kNGF-PR, 53-73kDa NGF-PRs and prepro-NGF specific domains from the day of birth (Pro-Hormone Science, CA) are in progress and the results will be reported in the meeting. In summary, the detection of NGFmRNA in follicle bulb and localization of NGF-PR in the ORS provide a morphological and biochemical basis for the developmental delay of hair growth reported in NGF gene knock out mice (Cell 76:1001, 1994).

**NT3, NT4 AND GDNF IN TOOTH DEVELOPMENT.** C. A. Nosrat, K. Fried\*, E. Lindquist, S. Lindskog and L. Olson, Dept. of Oral Diagnostics and Dept. of Neuroscience, Karolinska Institutet, Stockholm, Sweden.

Teeth have a rich innervation. Sensory stimuli originating in the dental pulp and the periodontal tissues are conveyed in nerve fibers which have their cell bodies in the trigeminal ganglion and, for some proprioceptive neurons, in mesencephalon. NGF mRNA seems to be expressed in developing teeth and has been reported to increase in pulpal fibroblasts after injury. In the present study, using *in situ* hybridization, we have investigated mRNA expression of neurotrophin 3, neurotrophin 4 and GDNF in developing and adult teeth and after injury (partial pulpotomy). NT4 mRNA had a predominantly epithelial expression during development but some labeling was also observed in ectomesenchymal cells. NT4 mRNA labeling was observed in high concentration in the oral and nasal mucosa, skin and vibrissae as well. NT3 mRNA labeling was also mainly epithelial. In the developing dental epithelium the expression pattern was related to the maturation gradient of the mitotic cells. NT3 mRNA seemed to be expressed in the adult tooth, and was also observed in oral and nasal epithelium, skin and vibrissae. GDNF mRNA was first seen in the ectomesenchymal cells of tooth primordia, later in different parts of the epithelium and as the tooth developed, predominantly in the pulpal tissue. The possible effects on mRNA levels following injury is under investigation. We suggest that these factors not only might act as classical neurotrophic factors in the developing teeth and other oral tissues but also participate in the reciprocal mesenchymal-epithelial interaction during tooth development and morphogenesis. Supported by the Dental Faculty, Karolinska Institutet, Sv. Tandläkare-Sällskapet and the Swedish MRC (12X-08654).

## 125.20

**IMMUNOHISTOCHEMICAL LOCALIZATION OF CNTF-R $\alpha$  IN ADULT MOUSE RETINA *IN VIVO* AND *IN VITRO*.** J.A. Miotke\*, A.J. MacLennan<sup>2</sup> and R.L. Meyer<sup>1</sup>. <sup>1</sup>Dev. and Cell Biol., UC Irvine, Irvine, CA, 92717 and <sup>2</sup>Dept. of Neuroscience, University of Florida, Gainesville, FL, 32610.

CNTF has been shown to be a survival factor for early postnatal retinal ganglion cells *in vitro* (Meyer-Franke et al., 1995). However, attempts to demonstrate an effect on the survival and regeneration of axotomized adult retinal ganglion cells (RGCs) have shown conflicting results. Using our characterized *in vitro* system where the regenerating RGCs of adult retinal explants extend neurites onto a laminin substrate, we have shown that 100 ng/ml of rhCNTF significantly increases the number of neurites per explant after 3 days *in vitro* (Miotke and Meyer, 1995).

While the adult retina has been shown to have mRNA for CNTF-R $\alpha$ , the receptor component of the tripartite CNTF receptor complex which binds CNTF, little is known about changes in the level or location of the protein *in vitro* or *in vivo* following axotomy. To address this, we are using an affinity-purified antiserum which has been shown to specifically recognize CNTF-R $\alpha$  (MacLennan et al., 1996).

Immunohistochemistry on sections of normal adult mouse retina and optic nerve reveals high levels of CNTF-R $\alpha$  in the photoreceptor layer. Neurons of the inner plexiform layer show low levels of immunoreactivity, with labeling of both perikarya and processes. Most neurons in the ganglion cell layer also show low to moderate levels of immunoreactivity. This labeling was localized to the perikarya. Similar low level immunolabeling of presumptive RGC perikarya was also seen in adult retinal explants after 5 and 7 days *in vitro*, but not on the neurites which had extended onto the laminin substrate.

Current work is focusing on the changes in the pattern of immunoreactivity *in vivo* following intraorbital optic nerve crush.

Supported by NS 26750 to RLM and DA 07244 to AJM.

## 125.22

**RESPONSE OF PC 12 CELLS TO MOUSE NGF PROHORMONE DIFFERS FROM THAT TO A COMMERCIAL HUMAN RECOMBINANT NGF.**

S. Soinila\*, M. Reinshagen, I. Geerling, K. Huff, J. Lakshmanan, Dept. Neurology, Univ. Helsinki, Finland, Dept Internal Med I, Univ. Ulm, Germany, Dept Pediatrics, Harbor UCLA Med Ctr, Torrance, CA, Dept Biochemistry, Vysal College, India.

Using immunoblotting and a panel of polyclonal and monoclonal antibodies to  $\beta$ -NGF, we recently reported evidence for the presence of 53 kDa NGF prohormone (PR) and its isoforms in adult rat dorsal root ganglia as well as in normal and inflamed colon (Soc. Neurosci. Abstr. 12:23.3, 1995). To study the effects of 53 kDa NGF PR on neuronal cells, PC 12 cells were cultured in the absence and presence of mouse 53 kDa NGF PR (Pro-Hormone Science, CA) and the responses were compared to those of a commercial recombinant human NGF (R&D Systems, MN). Commercial polyclonal antibodies to 2.5S NGF (Sigma, MO) or  $\beta$ -NGF (Pro-Hormone Science, CA) were utilized to examine the purity of the preparations used for bioassay. Mouse 53 kDa NGF PR elicited consistently short neurite outgrowth from PC 12 cells at low serum concentrations and stimulated cell multiplication at high serum concentrations. In contrast, rhNGF preparations elicited robust neurite outgrowth and concomitantly inhibited cell multiplication. Western analysis revealed that mouse 53 kDa NGF PR was devoid of  $\beta$ -NGF but contained trace amounts of 73 kDa NGF PR. In contrast, rhNGF preparation contained as many as 8 high molecular weight NGF-immunoreactive proteins besides  $\beta$ -NGF. We conclude that PC 12 cells can be used as a model system to characterize the actions of NGF PR and its derivatives on neurons.

**Adenovirus-Mediated Expression of Neurotrophic Factors; Biological Activity *In Vitro* and Retrograde Transport and Expression *In Vivo***

Shine, HD\* and Baumgartner, BJ Department of Neurosurgery, Baylor College of Medicine, Houston, Texas 77030.

Replication-defective recombinant adenoviral (Adv) vectors were constructed carrying the neurotrophic factor (NF) genes BDNF, CNTF, GDNF, NGF, and NT3 under the control of the Rous sarcoma virus (RSV) promoter (Adv.RSV-*nf*). HeLa cells transduced with the Adv.RSV-*nf* vectors produced NFs which co-migrated with their respective recombinant NF standards on Western blots. Quantitative ELISAs showed that HeLa cells transduced with Adv.RSV-NGF (100 active viral particles per cell) produced  $\beta$ -NGF at a rate of approximately  $5 \mu\text{g}/10^6$  cells/day. Estimates from Western blotting experiments suggest that the other NFs were produced from Adv.RSV-*nf* at similar rates. Conditioned media from Adv.RSV-*nf* transduced HeLa cells supported the *in vitro* survival of chicken sensory neurons at levels equal to or greater than the respective recombinant NFs. After injection of Adv.RSV-CNTF or Adv.RSV-GDNF into the facial muscles of neonatal rats, expression of Adv.RSV-CNTF or -GDNF mRNA in the facial nucleus was detected by RT-PCR. In addition, immunocytochemical analysis showed that high levels of CNTF were detected in spinal and facial motoneurons after injection of Adv.RSV-CNTF into their appropriate muscle groups. Taken together, the *in vivo* experiments show that motoneurons of the facial nucleus or spinal motoneurons retrogradely transport Adv.RSV-*nf* vectors and express the gene products. A portion of this work was supported by a grant to H.D.S. from the Texas Higher Education Coordinating Board Advanced Technology Program.

NERVE GROWTH FACTOR (NGF) EXPRESSION IN THE MOUSE PERIPHERAL NERVOUS SYSTEM AND SPINAL CHORD USING HERPES SIMPLEX VIRUS (HSV) VECTORS. W. F. Goins<sup>1</sup>\*, J. Huard<sup>1</sup>, M. Pike-Cavalloni<sup>1</sup>, S. DeKosky<sup>2</sup>, D. J. Fink<sup>1,3</sup> and J. C. Glorioso<sup>1</sup>. Dept. of Molecular Genetics & Biochemistry<sup>1</sup>, Western Psychiatric Institute & Clinic<sup>2</sup>, Dept. of Neurology<sup>3</sup>, University of Pittsburgh School of Medicine, Pittsburgh PA 15261.

We have previously engineered replication competent and replication defective herpes simplex virus type 1 (HSV-1) vectors which express a functionally active form of mouse nerve growth factor ( $\beta$ -NGF) in neuronal and non-neuronal cells in culture. High levels of  $\beta$ -NGF were secreted into the medium from HSV-1 vector infected neuronal cells in culture and this media was capable of inducing PC-12 cell differentiation and neurite sprouting.

We have extended these *in vitro* studies to examine HSV-1 vector-mediated  $\beta$ -NGF expression in mouse trigeminal and dorsal root ganglia during acute and latent infection using ELISA, immunohistochemistry, and RNA analyses for detection of the transgene. Vectors in which the strong human cytomegalovirus (HCMV) IE promoter was employed to drive  $\beta$ -NGF expressed the neurotrophic factor at 3 days post-infection in both mouse trigeminal and dorsal root ganglia. However,  $\beta$ -NGF expression from these vectors was transient in mouse trigeminal ganglia. In contrast, vectors containing the HSV-1 latency active promoter (LAP-2) driving  $\beta$ -NGF were able to express the transgene at 28 days in mouse trigeminal ganglia, a time consistent with viral latency. The HCMV IE- $\beta$ -NGF vectors also expressed the transgene in both muscle and spinal cord during productive infection. Vector-mediated  $\beta$ -NGF expression was confirmed using double-labeling studies to identify cells that expressed the neurotrophic factor and the lacZ reporter gene. We are currently evaluating the ability of these vectors to ameliorate peripheral nervous system disease.

This research was sponsored by grants from the NIH-GM34534 and -AG094701 as well as a grant from the NSF-IBN922432

**SIGNALING PATHWAYS INVOLVED IN THE REGULATION OF FGF-1, FGF-2 AND FGFR-1 IN RAT CORTICAL ASTROCYTES.** M.A. Riva<sup>a,b,\*</sup>, R. Molteni<sup>b</sup>, M. Roceri<sup>b</sup>, B. Begni<sup>b</sup>, and G. Racagni<sup>b</sup>. <sup>a</sup> Di.Bi.T., San Raffaele Hospital, and <sup>b</sup> Center for Neuropharmacology, University of Milan, Via Balzaretti 9, 20133 Milan, Italy.

The study of the molecular mechanisms involved in neurotrophic factor biosynthesis is of great importance to understand if an increased production of such factors may exert neuroprotection and contribute to the maintenance of cellular homeostasis. Astroglial cells in culture were used to investigate the signaling pathways involved in the regulation of FGF's and their receptor FGFR-1. These cells represent a source of different neurotrophic factors and may play important roles in physiological and pathological situations of the CNS.

Even though FGF-1 and FGF-2 are highly homologous, their regulation in cultured astrocytes is quite different. FGF-2 mRNA levels are increased by activation of the cAMP pathway or exposure to glucocorticoid hormones and the co-administration of these agents is synergic in the up-regulation of FGF-2. On the contrary, the gene expression for FGF-1 is decreased by both stimuli. We found that the cAMP elevating agent isoproterenol (1  $\mu\text{M}$ ) produced an elevation of FGFR-1 mRNA. The protein synthesis inhibitor cycloheximide decreased the expression of FGFR-1 and prevented its induction by isoproterenol, indicating significant differences with respect to FGF-2 regulation. The synthetic glucocorticoid dexamethasone, a potent inducer of FGF-2 expression, decreased FGFR-1 mRNA levels alone or in the presence of isoproterenol suggesting that this regulatory pathway may predominate over the cAMP-induced up-regulation of the receptor. Our data suggests that the response of a specific cell population to an external signal may be the result of changes at different levels involving the regulation of neurotrophic molecules and/or their receptors.

NERVE GROWTH FACTOR SOMATIC MOSAICISM PRODUCED BY HERPES VIRUS-DIRECTED EXPRESSION OF *cre* RECOMBINASE IN MICE HARBORING A RECOMBINANT SUBSTRATE. A.I. Brooks, N. Panahian, M.W. Halterman, D.F. Howard, G. Gianakakis, S.N. Haber\* and H.J. Federoff. Departments of Microbiology, Immunology and Neurology; Division of Molecular Medicine & Gene Therapy, University of Rochester School of Medicine, Rochester, NY 14642.

To investigate NGF action in specific regions of the adult mammalian nervous system we have developed a somatic gene transfer approach to create genetic mosaics in mice. In this approach we use a binary system that involves an inactive germline-transmitted transgene that is activated by the somatic delivery and expression of *cre* recombinase. We have constructed an excision activated transgene (XAT) that is composed of the rat NSE promoter, an inactivating cassette, a bicistronic transcription unit consisting of a NGF minigene and IRES initiated reporter gene (NGF XAT). We have generated five independent lines of transgenic mice, two of which express the inactive transcript. Line #30 has been demonstrated by Northern analysis to express the inactive transgene at a level of ~30% of the amount of native NSE mRNA. Multiple independent bacterial plasmids revealed by Southern blot efficiently removed the inactivating cassette while NGF XAT was recovered "uncollapsed" from all bacteria that did not express *cre* recombinase. Recombination *in vivo* by somatic delivery of *cre* recombinase has been confirmed on the RNA, DNA, and protein levels. HSV $\nu$ crelac (expressing both *cre* and 8-gal) and HSV $\nu$ lac were stereotactically injected unilaterally into the dorsal hippocampus of line #30 animals. Confirmation of recombination at the DNA level was determined by PCR-Southern blot analysis and nested PCR. Animals that received HSV $\nu$ crelac produced a fragment consistent with the removal of the inactivating cassette (785 bp) while HSV $\nu$ lac injected samples did not. NGF ELISA and immunocytochemistry have demonstrated the activation of NGF XAT on a protein level. Direct quantitation of NGF expression by ELISA in the HSV $\nu$ crelac injected area revealed a 13 fold increase of NGF over the HSV $\nu$ lac injected animals. NGF immunocytochemistry revealed a 49% increase in  $\beta$ -NGF responsive cells in HSV $\nu$ crelac injected animals. Ongoing experiments are investigating morphological changes associated with the focal upregulation of NGF in the hippocampus. Immunocytochemistry using antibodies against ChAT and p75 in combination with AChE staining of coronal sections from HSV $\nu$ crelac injected areas will help investigate cellular networks that have been modified by the permanent focal increase of NGF. This work is supported by NSF IBN-9522307 (to HJF).

**NEUROTROPHINS ARE EXPRESSED BY ADULT SPINAL CORD ASTROCYTES *IN VIVO*.** C.F. Drayfus\*, B. Racey, G. Mendoza, X. Dai, W.J. Friedman and I.B. Black. Dept Neuroscience and Cell Biology, UMDNJ/ Robert Wood Johnson Medical School 08854 and Dept Pathology, Columbia University Coll Phys. & Surg.10032.

Recent work has indicated that exposure to exogenous neurotrophin molecules enhances regeneration of descending corticospinal neurons in the injured spinal cord (Schnell et al, 1994). To determine whether neurotrophins are normally expressed in the adult spinal cord *in vivo*, and to examine the cellular sources of these molecules, antisera developed against neurotrophin-3 (NT-3) and brain derived neurotrophic factor (BDNF) were utilized to detect these factors immunocytochemically in the adult rat spinal cord. The antisera used were the generous gift of David Kaplan. Robust expression of BDNF and NT-3 was evident in the spinal cord, particularly in small cells of the grey and white matter. To identify these cells, co-localization studies were performed utilizing a monoclonal antibody to the glial marker, glial fibrillary acidic protein (GFAP). Both BDNF and NT-3 were localized in GFAP+ cells, suggesting that astrocytes are a source of these trophins. To determine whether, in fact, spinal cord astrocytes elaborate trophic factors, cultured neurons derived from embryonic day 14 spinal cord were exposed for 7 days to spinal cord astrocyte conditioned medium (CM) produced by E-17 astrocyte cultures. Astrocyte CM elicited an approximate 2-fold increase in the numbers of acetylcholinesterase+ cells, suggesting that astrocytes may produce factors that enhance survival of the spinal cord cholinergic subpopulation. Our results indicate that BDNF and NT-3 are expressed by astrocytes in the normal adult spinal cord and suggest that trophic molecules elaborated by astrocytes enhance neuronal survival *in culture*.

**TRANSCRIPTIONAL AND TRANSLATIONAL REGULATION OF NERVE GROWTH FACTOR MRNA EXPRESSION IN GLIAL CELLS: ROLE OF AP-1.** A.M. Colangelo, P. F. Johnson, M.A. DeBernardi\* and L. Mochetti. Dep. of Cell Biology, Georgetown Univ. Sch. of Med., Washington DC, 20007, and ABL-BRP, NCI-Frederick Cancer and Research Center, Frederick, MD 21702.

Molecular mechanisms regulating nerve growth factor (NGF) gene expression in the CNS are still largely not well understood. The NGF gene contains an AP-1 consensus sequence which plays a role in basal and inducible transcription of the NGF gene in non neuronal cells. We have used C6-2B rat glioma cells, a line known to express and release NGF, to investigate the role of AP-1 in the transcription regulation of NGF mRNA. We have analyzed nuclear extracts from these cells following stimulation of various signaling pathways for changes in factors which bind to the AP-1 recognition sequence of the rat NGF gene. Gel mobility shift assays using an oligonucleotide homologous to the AP-1 responsive element of the rat NGF gene (AP-1<sub>NGF</sub>) revealed that 12-O-tetradecanoyl phorbol-13-acetate (TPA), and to a lesser extent isoproterenol (ISO) stimulated binding to AP-1<sub>NGF</sub>. The increase in AP-1<sub>NGF</sub> binding preceded the accumulation of NGF mRNA. Moreover, cycloheximide pretreatment blocked the TPA and ISO-mediated binding to AP-1<sub>NGF</sub> and inhibited the NGF mRNA accumulation by these stimuli suggesting that *de novo* synthesis of c-fos/c-jun may be required for the transcriptional regulation of NGF gene. Nuclear run-on assays and studies on NGF mRNA stability revealed that while TPA increases NGF transcription only, ISO affects NGF mRNA stability as well. We propose that different signal transduction mechanisms regulate the expression of the NGF gene in cells derived from the CNS, and that mRNA transcription and stability account for the cAMP-mediated accumulation of NGF mRNA. Experiments are underway to characterize whether other leucine zipper proteins might be involved in the transcription regulation of NGF gene. [Supported by HHS grant NS29664].

PREPARATION OF BRAIN-DERIVED NEUROTROPHIC FACTOR AND NEUROTROPHIN-3 SECRETING SCHWANN CELLS BY INFECTION WITH A RETROVIRAL VECTOR S. Savers\*, T. Khan, G. DeVries, R. Shahid, Y. Ahmed, N. Khan, T. Lopez and L. Liu, Rehabilitation R&D Center, Hines VA Hospital, Hines, IL 60141.

One of the reasons for the lack of regeneration in the CNS of adult mammals is the absence of neurotrophic factors. Recent studies have shown that BDNF and NT-3 encourage the regrowth of motor and sensory fibers after spinal cord injury. Preliminary studies from our laboratory have found that Schwann cells cultured on small diameter carbon filaments induced neuritic outgrowth from fetal rat spinal cord explants. The purpose of the present study was to genetically modify Schwann cells to produce increased amounts of BDNF or NT-3.

The cDNA for BDNF and NT-3 were obtained from Dr. George Yancopoulos of Regeneron Pharmaceuticals, Inc. and the retroviral vector LXSX cDNA was obtained from Dr. Dusty Miller at the Fred Hutchinson Cancer Research Center. Retroviral vectors were constructed by the ligation of the BDNF cDNA or the NT-3 cDNA to the LXSX retroviral vector DNA. Virus were generated from the plasmid forms of the retroviral vectors by transient transfection of PA317 amphotropic packaging cells. The virus was harvested and used to infect the human Schwann cell line designated NF-1T. Poly (A<sup>+</sup>) RNA was prepared from the infected Schwann cell cultures, subjected to electrophoresis, and then transferred onto membranes. The Northern blots were hybridized with <sup>32</sup>P-labeled riboprobes which were prepared to detect either BDNF or NT-3 mRNA.

The autoradiograms obtained from the Northern blots from Schwann cells which were infected with either BDNF or NT-3-containing virus clearly showed the presence of the BDNF or NT-3 mRNA signal. We are currently in the process of evaluating whether these genetically engineered Schwann cells are secreting biologically active BDNF and NT-3. Hopefully, these neurotrophin-secreting Schwann cells will act as effective stimulators of axonal regrowth *in vivo*. (Supported by Rehabilitation R&D Center core funds, DVA)

## BIOSYNTHESIS OF NGF IN NEURONS

S. J. Mowla, S. Pareek\*, W. Sossin, S. Iacampo, N. G. Seidah<sup>1</sup> and R. A. Murphy, Montreal Neurological Institute, McGill University, and <sup>1</sup>Clinical Research Institute of Montreal, Montreal, Canada

In the CNS, neurotrophins (NTs) are produced by neurons, but the pathways by which NTs are synthesized and secreted is not well understood. In non-neuronal cells, we have detected two patterns for the processing of NGF that differ in constitutive and regulated secretory cells (Seidah *et al.*, 1996, *Biochem J.*, 314, 951-960). Both types of secretory cells produce a 35 kDa precursor. Constitutive cells (BSC40, LoVo cells) modify the precursor by glycosylation and sulfation to yield a 42.5 kDa intermediate that is cleaved by co-expressed convertase processing enzymes to yield 16.5 and 13.5 kDa forms of NGF. Regulated secretory cells (AT20) produce a 39 kDa intermediate that is processed into a 13.5 kDa form mature NGF. In this study, we investigated the processing of NGF within neurons. Primary cultures of rat sympathetic, sensory, and mouse hippocampal neurons infected for 1 hr with vaccinia viruses (VV) containing cDNA constructs coding for the ORF of NGF. The cells were incubated an additional 8 hrs and metabolically labelled with radioactive amino acids for 1 hr. Cell extracts and cell conditioned media were immunoprecipitated with antibodies to NGF and analyzed by SDS PAGE and autoradiography. Data indicate that the three types of neurons produce a 35 kDa form of the NGF precursor that is post-translationally modified (presumably by glycosylation) to yield three higher molecular species in the range of 39-42 kDa, as determined by pulse chase labelling. These species are processed by endogenous cellular enzymes to generate only the 13.5 kDa form of NGF that could be detected both in cell extracts and in conditioned medium. None of the 16.5 kDa form of NGF was evident. The results show that neurons have the cellular machinery to process NGF correctly and efficiently. Work is in progress to determine the secretory pathway of NGF in neurons.

## NEURONAL DEATH: LESIONS

## 126.1

CONFOCAL IMAGING OF RAT RETINAL GANGLION CELLS AFTER OPTIC NERVE INJURY. R. Engelmann\*, M. F. Humphrey and B. A. Sabel, Institute for Medical Psychology, Otto-von-Guericke-University Magdeburg, D-39120 Magdeburg, Germany.

We have developed a new *in vivo* method to repeatedly visualize retinal ganglion cells (RGC) labelled by retrograde transport of fluorescent markers, in adult rats. This was accomplished with an upright Confocal Laser Scanning Microscope (CLSM, Noran Instruments) with low aperture lenses, a special non-traumatic headholder, and an immersion plano-concave correction lens. Before and after optic nerve cut or crush fluorescent dyes were injected stereotactically into the superior colliculus and the fluorescing RGCs were repeatedly visualised for up to five weeks. The population density of *in vivo* RGCs at 30° eccentricity was 1800 cells/mm<sup>2</sup> in control retinae. After optic nerve crush the density dropped to 1550 cells/mm<sup>2</sup> at one week and 1100 cells/mm<sup>2</sup> at two weeks. At later time points the density remained at the same level but only a small proportion of fluorescing objects maintained the strong compact fluorescence, characteristic of RGCs. Here, the majority of the fluorescence was found to be limited to smaller, diffusely and faintly labelled objects. Conventional microscopic examination of retinal wholemounts revealed that these corresponded to label sequestered in microglial-like cells. Selective label of the surviving population of RGCs by colliculus injection after the crush showed a strongly labelled population of RGCs, with a density of 360 cells/mm<sup>2</sup> which did not change between 2 and 5 weeks after crush. No damage of the retinal tissue could be observed when the retinae were prepared as conventional wholemounts despite repeated illumination with the CLSM.

Supported by the DFG Innovationskolleg #15/TP-A6 and Noran Instruments.

## 126.2

## APOPTOSIS IN RETINAL GANGLION CELLS AFTER A CONTROLLED CRUSH OF THE ADULT RAT OPTIC NERVE

A. Bien\*, M.F. Humphrey, C. Seidenbecher, B.A. Sabel, M.R. Kreutz Inst. of Med. Psychology, Otto-von-Guericke University, Magdeburg, Germany.

Apoptosis is a common type of cell death in the nervous system after neurotrauma. We investigated whether axonal trauma leads to changes in retinal ganglion cells (RGC) characteristic for cells going into the cell cycle. As shown previously controlled optic nerve crush is followed by a massive retrograde cell death of RGC over a time course of several weeks. In the present study the optic nerve of hooded rats was crushed and at different time points after injury eyes were removed and processed for immunocytochemistry or DNA and protein extraction. Pyknotic cells were readily observable 72 hours, 1 week and 6 weeks after axonal trauma in the retinal ganglion cell layer of rat paraffin sections. At the same time points an increasing number of TUNEL-positive cells was found in parallel sections. DNA fragmentation 1 week post-injury was independently confirmed by agarose DNA-gel electrophoresis and TUNEL staining in retinal whole mounts. This study emphasizes that the massive cell death after axonal trauma (~70% of all RGC die within two weeks) is related to apoptotic processes. Since apoptosis is observable for a long period, this model of partial axonal injury provides key features for *in vivo* investigations on pharmacological and molecular underpinnings of neurotrauma-induced cell death.

## 126.3

SURVIVING RETINAL GANGLION CELLS DO NOT EXPRESS PHOSPHORYLATED NEUROFILAMENTS IN SOMA AND DENDRITES AFTER NERVE CRUSH. M.F. Humphrey\*, R. Engelmann and B.A. Sabel, Institute of Medical Psychology, Otto-von-Guericke University, D-39120 Magdeburg, Germany.

Highly phosphorylated forms of neurofilaments (pNFs) are normally restricted to axons. Following optic nerve cut, where most retinal ganglion cells (RGCs) eventually die, pNFs are also found in the soma and dendrites. These abnormal pNFs may therefore be part of a cell death sequence. However, because altered pNFs are also seen in regenerating peripheral nerve cells they may also be involved in adaptive reorganization. Therefore, following optic nerve crush, we have compared pNF expression in RGCs connected to the visual centers with those that degenerate.

In adult PVG/c rats the optic nerve was crushed unilaterally using special cross-action forceps (Sautter and Sabel, 1993, *Euro. J. Neurosci.*, 5, 680-690). At various times after crush Fluorogold (FG) was injected into the superior colliculus to retrogradely label the connected RGCs, and the retinae were then prepared for labelling with the 2F11 monoclonal NF antibody using a Cy-3 fluorescent labelled second antibody for detection.

pNF labelled RGCs were found at 7, 14 and 21 days post-crush although the proportion was low (up to 100 cells/mm<sup>2</sup>). A variety of soma sizes and primary dendritic types were labelled although most were in the medium to large range. Most of the strongly pNF labelled RGCs were not FG labelled, even when surrounded by many other FG labelled cells indicating that FG was available for uptake. Therefore, the cells which survive and remain connected with their target after nerve crush do not express pNFs in the soma and dendrites. We are currently examining the time of disconnection before pNF expression and the relation to apoptosis.

## 126.4

INCREASE IN GENE EXPRESSION IN THE RETINA AFTER OPTIC NERVE CRUSH. L. A. Levin\* and K. M. Geszvain, Department of Ophthalmology and Visual Sciences, University of Wisconsin Medical School, Madison, WI 53792.

Retinal ganglion cell death is the final common pathway of a variety of optic nerve disorders. We and others have shown that optic nerve injury induces apoptosis in retinal ganglion cells. To better understand the molecular program for the death of these cells, we attempted to identify genes associated with retinal ganglion cell axotomy.

Total RNA was isolated from Long-Evans rat retinae at 1 and 4 days after intraorbital crush of the ipsilateral optic nerve; the contralateral retinae were used as a source of control RNA. Reverse-transcribed (RT) cDNA was used in a refinement of the differential display technique, using long primers; all amplifications were done in duplicates. After screening of several thousand bands, a single reproducibly differentially expressed band was reamplified and cloned into a TA-cloning vector. Multiple clones from this band were screened, and one product found to hybridize with Northern blots of total RNA, with greater expression at 1 and 4 days after crush than control. The product was sequenced and used to design primers for PCR. These were then used to confirm differential expression of the product in additional groups of experimental animals. RT-PCR demonstrated mRNA in the retina and liver, but not the brain, lung, spleen, kidney, or thymus of rats. Western blots confirmed expression of the protein product in the retina, and immunohistochemistry demonstrated immunolabeling of ganglion cell layer cells in a human eye that had previously sustained ischemic optic neuropathy.

The possible role of this gene in retinal ganglion cell apoptosis will be discussed. Supported by NIH K11 EY00340 and Research to Prevent Blindness, Inc.

## 126.5

**LIGHT EXPOSURE ENHANCES THE SURVIVAL OF ADULT AXOTOMIZED RETINAL GANGLION CELLS.** L. J. Aigner, S. A. Singal, M. Rasminsky\*, G. M. Bray and A. J. Aguayo. Centre for Research in Neuroscience, McGill University, The Montreal General Hospital Research Institute, 1650 Cedar Avenue, Montreal, PQ H3G1A4, Canada.

We have tested the hypothesis that regulation of survival of injured neurons may involve neuronal activity. To this end we investigated the effects of light on the survival of axotomized retinal ganglion cells (RGCs) in adult pigmented rats ten days after intraorbital optic nerve cut. Rats (n=6 per group) were kept for ten days after axotomy in the usual 12h light/dark cycle, under constant light, or were deprived of light by keeping them in complete darkness or by closure of the eyelid. 467±72 RGCs/mm<sup>2</sup> and 570±141 RGCs/mm<sup>2</sup> survived axotomy in retinas exposed to the 12h light/dark cycle or to constant light, respectively, whereas only 185±113 RGCs/mm<sup>2</sup> and 191±26 RGCs/mm<sup>2</sup> survived axotomy in retinas deprived of light by complete darkness or by closure of the eyelid, respectively. These *in vivo* results indicate a significantly decreased survival ( $p < 0.001$ ) of axotomized RGCs that were not exposed to light, suggesting that light stimulation of the retina might be beneficial for RGC survival after injury.

Supported by the Canadian Neuroscience Network, the Deutscher Akademischer Austauschdienst and by Boehringer Ingelheim.

## 126.7

**NEURONAL DEATH IN THE LATERAL GENICULATE NUCLEUS OCCURS FOLLOWING TARGET DEPRIVATION.** NA Al-Abdulla, C Portera-Cailliau, BJ Crain\*, DL Price, and LJ Martin. Neuropathology Laboratory, The Johns Hopkins School of Medicine, Baltimore, MD 21205.

Mechanisms of neurodegeneration following axotomy and target deprivation remain poorly understood, and the presence of neuronal death in these models is unconfirmed. We used a unilateral occipital cortex ablation model in adult rats to identify the time course of neuronal injury and death in the lateral geniculate nucleus (LGN). To determine if neurons die in the LGN ipsilateral to the cortical lesion, we used the TUNEL method of in-situ labeling of nuclear DNA fragmentation. TUNEL-positive LGN neurons were present at 3 to 14 days post-ablation, peaking around 7 days. The morphological features of LGN neuronal death were evaluated by light microscopic analysis of Nissl-stained paraffin sections and semithin plastic sections as well as by electron microscopy. Vacuolation of neuronal cytoplasm occurred in the medio-ventral portion of the ipsilateral LGN by 3 days and peaked at 14 to 30 days. Neuropil vacuolation was found maximally at 3 to 14 days. In addition, neurofilament (NF) immunocytochemistry revealed irregularly shaped perikarya with abnormal NF accumulation initially, followed by NF loss. By 7 days, subsets of LGN neurons atrophied, and neuronal density as assessed by Nissl-stain decreased, confirming neuronal death in the medio-ventral LGN. Some dorsal ipsilateral LGN neurons survived but appeared hypertrophied by 3 months. We conclude that neuronal death in the adult LGN occurs following target deprivation. The morphological changes leading to neuronal death were highly organized and patterned but not apoptotic. Supported by NIH.

## 126.9

**AGE-AT-LESION REDUCTION IN BILATERAL THALAMIC VOLUME IN HEMINEODECORTICATE CATS.** J.R. Villablanca\*, H.M. Patel, T.D. Schmanke. Mental Retardation Research Center, UCLA, LA, CA 90024

We have used behavioral, anatomical and cerebral metabolism measures to establish that the outcome of cerebral hemispherectomy is better if the removal is sustained neonatally versus in adulthood. We are now investigating at which postnatal age the transition to poorer outcome may occur. Here we present relevant anatomical results. Groups (N=5) of cats that sustained hemineodecortication (HDec) at postnatal ages P5-15, P30, P60, P90, P120 days and in adulthood were compared to intact controls. With all cats as young adults, we measured the cross-sectional area of the thalamus bilaterally in 18-21 coronal sections per brain (50µm thick, 600µm apart) and used these values to calculate mean total thalamic volume per cat group and per right and left thalamus. Volumes are in µm<sup>3</sup>; left is ipsilateral to the lesion:

Age at HDec, days:	P5-15	P30	P60	P90	P120	Adult, Intact
Ipsilat. Thal., left	202	206	203	200	177	157 363
Contral. Thal., right	361	373	338	350	323	341 394

**Ipsilaterally:** there was a large thalamic atrophy relative to controls ( $P < .01$ ), Tukey's test, range 43.3% (P30) to 56.7% (adult-lesioned), for all lesion ages but this was less pronounced, compared to adult HDec cats ( $P < .01$  to .05) for cats with HDec at ages P5-15, P30, P60 and P90 days. **Contralaterally:** there was also atrophy, range 5.5% (P30) to 18.2% (P120), but this was significant ( $P < .01$ ) only for cats HDec at P60, P120 and in adulthood. Thus, for both sides the protective effect of young age lasted only through about 90 days of age. Grants USPHS HD-05958, HD-14612, NRSA T32HD07416.

## 126.6

**AXOTOMY OF DORSAL LATERAL GENICULATE NEURONS (LGN) IN THE RAT AND CAT LEADS TO APOPTOTIC CELL DEATH.** R.E. Kalip\*, M. Shively and J.P. Fedymyshyn. Center for Neuroscience and Department of Ophthalmology and Visual Sciences, University of Wisconsin, Madison, WI 53706.

Although it has been known for some time that most neurons in the mammalian central nervous system die after axotomy, relatively few studies have explored the mechanisms by which these cells may die. In the rat and the cat, removal of visual cortex axotomizes neurons in the LGN. After two to three days of apparent stasis, large numbers of axotomized LGN neurons die quickly and are rapidly cleared. When stained with cresyl violet, dying LGN neurons display some of the cytological features e.g., condensation of the nuclear chromatin, that have been associated with apoptosis. To obtain further evidence about the mode of cell death involved, we have used the TdT-mediated dUTP Nick-End Labeling (TUNEL) assay to detect DNA fragmentation in dying LGN neurons. Sections through the LGN in newborn kittens and adult rats that had received a large lesion of visual cortex at three days (kittens) or seven days (rats) prior to perfusion with mixed aldehydes were labeled with fluorescein-12-dUTP by the TUNEL method and counterstained with propidium iodide. Fluorescently labeled LGN neurons were examined with a Bio-Rad MRC 1024 confocal microscope. In both rats and cats, fluorescein-stained, TUNEL+ LGN neurons were observed scattered among propidium-iodide stained cells with intact DNA. Although prior work indicates that LGN cell death is massive after axotomy, the number of TUNEL+ neurons in single sections through the LGN is relatively modest, in keeping with the belief that apoptotic death proceeds swiftly. The results from these experiments, in conjunction with the observations on dying neurons mentioned above, provide additional evidence suggesting that apoptosis is the mechanism by which axotomized LGN cells die. We thank Promega Neurosciences for providing the TUNEL reagents. This work was supported by NIH grant EYO 1331.

## 126.8

**Identification of Genes Differentially Expressed in the Lateral Geniculate Nucleus Following Axotomy.** J.S. Bhangay\* and M.S. Cynader. Department of Ophthalmology, University of British Columbia, Vancouver, British Columbia, Canada. V5Z 3N9

It has been well established that lateral geniculate nucleus (LGN) neurons undergo retrograde degeneration following a visual cortex lesion. The death of these LGN neurons occurs by apoptosis which makes it distinct from the necrotic form of cell death that results from direct insult. Since apoptosis generally requires RNA and protein synthesis, it is believed that the process is dependent on active gene expression.

To investigate the genes involved in apoptotic neuronal cell death in the LGN, we have used the RNA arbitrarily primed polymerase chain reaction (RAP-PCR) technique for fingerprinting RNA transcripts. Briefly, a unilateral lesion of the visual cortex was made in two adult cats. After 48 hours, the animals were perfused and RNA was isolated from the LGNs ipsilateral and contralateral to the lesion. Total RNA from both the lesioned and control sides was used for cDNA synthesis using an arbitrary primer at low annealing stringency. The resulting cDNA was then amplified by high-stringency PCR. The PCR products were electrophoretically separated and a number of cDNAs representing potentially differentially expressed mRNAs were isolated. Thus far, the degeneration association of several of these transcripts has been confirmed by Northern blot analysis. Characterization of these and other putative cell death genes is currently underway.

Supported by MRC and NCE of Canada.

## 126.10

**A NEOCORTICAL LESION SUSTAINED DURING THE LATE FETAL PERIOD INDUCES A WIDESPREAD ENDURING REDUCTION IN CEREBRAL METABOLISM IN CATS.** D.A. Hovda\*, J.R. Villablanca and T.D. Schmanke. Mental Retardation Research Center, UCLA, LA, CA 90024

When a unilateral frontal cortical lesion is sustained in utero, adult cats show substantial behavioral impairments while neonatal-lesioned cats exhibit almost none. Here we present physiological correlates of these effects using [<sup>14</sup>C] 2-deoxy-D-glucose autoradiography. Groups of kittens (N=3 each) sustained resection of the pericruciate frontal cortex prenatally (E47-52) or neonatally (P6-10) or were used as intact controls (N=7). When all animals were young adults, local cerebral metabolic rates for glucose (LCMR<sub>glc</sub>) were measured in 50 brain regions bilaterally. Taking all gray matter structures together, there was a bilateral decrease of LCMR<sub>glc</sub> which was greater in fetal-lesioned (FL) than in neonatal-lesioned (NL) cats. In terms of µg/min/100gr the mean (S.E.M.) LCMR<sub>glc</sub> rates were, for the hemisphere ipsilateral to the lesion: FL cats, 49.2 ± 5.7, NL cats, 57.5 ± 3.8, for the contralateral hemisphere: FL cats, 49.2 ± 6.7, NL cats 55.7 ± 2.9, intact cats, 71.4 ± 5.5. Only FL cats show significant decreases versus controls ( $P < .05$ ). Considering individual structures, in FL cats 22 regions showed significant decreases ( $P < .01$  to  $< .05$ ) while in NL cats only 5 (ipsi) and 6 (contra) regions showed significant reductions ( $P < .05$ ). The areas with little or no bilateral changes in FL and NL cats were the visual cortex, hippocampus, most ventral-diencephalic sites, nigra, sup. and inf. colliculi, and cerebellum. The widespread LCMR<sub>glc</sub> decrease in prenatal lesioned cats match the behavioral impairments and neocortical-thalamic injury seen in these cats. USPHS HD-05958, HD-14612, NRSA T32HD07416.

## 126.11

EARLY-BRAIN LESION EFFECT: WHICH IS THE POSTNATAL AGE-AT-LESION LIMIT FOR GREATER RECOVERY/SPARING IN CATS?

P. Carlson-Kuhta, J.R. Villablanca, T.D. Schmanke and D.A. Hovda.

Mental Retardation Research Center, UCLA, Los Angeles, CA 90024

There is evidence that after a similar telencephalic resection neonatal-lesioned cats show a greater behavioral/sparing than adult cats, but there is little information regarding the age-at-lesion where the transition occurs. Here we report on behavioral effects of hemineodecortication sustained at postnatal ages P15, P30, P60, P90, P120 and in adulthood (N=5-6/group). An extensive behavioral battery of tests was applied starting at approximately 180 days post-lesion. For 8 tests assessed using a scoring system (limb paresis and posture, limb placing reactions-plank walking, face tactile responses), age-at-lesion accounted for significant differences (Kruskal-Wallis ANOVA) for all tests, and there was a tendency for a linear increase in impairment scores from the P5-15 through adult-lesioned groups. For 4 tests assessed with parametric measures (turning behavior, paw usage bias, pupil asymmetry and eye alignment), a regression analysis showed a significant linear trend for increased impairments in the P5-15 through the P120 (or adult-lesioned) groups. Finally, for 3 additional parametric tests (paw food retrieval, hind limb stride length, eye-opening asymmetry) there was a sharp decline in performance starting with the P60 group and continuing thereafter. Thus: a) age-at-lesion was important for the behavioral outcome during the P5-120 day period in cats; b) for the P5-15 and P30 groups the outcome was fairly similar with some performances declining sharply at about P60 while other declined progressively through P120. Grants USPHS HD-05958, HD-14612, NRSA T32HD07416.

## 126.13

DEAFFERENTATION CAUSES APOPTOSIS: AN *IN VIVO* MODEL OF NEURONAL DEATH IN THE CEREBRAL CORTEX OF ADULT RATS.

S.A. Capurro<sup>1,4</sup>, M.E. Calhoun<sup>4</sup>, D.L. Price<sup>1,4</sup>, V.E. Koliatsos<sup>4</sup>.

Depart. of Pathology<sup>1</sup>, Neurology<sup>2</sup>, and Neuroscience<sup>3</sup>, and the Neuropathology Lab.<sup>4</sup>, The Johns Hopkins Univ. Sch. of Med. Baltimore, Maryland, USA

The present study provides evidence that apoptosis is inducible in the cerebral cortex of mammals by deprivation of sensory afferents. We propose an *in vivo* model of neuronal death produced in the piriform cortex of adult rats by unilateral total bulbectomy. We studied degenerating neurons with an *in situ* labeling method (TUNEL), electron microscopy (EM), and biochemical assays. TUNEL-positive neurons were mapped; total neuronal loss was estimated using stereology. The maximal *in situ* labeling of apoptotic neurons occurred in the olfactory cortex ipsilateral to the lesion at the commissural level 18-26 hours postbulbectomy; stereology estimated that an 18% neural loss occurred after survival for 48 hours. DNA gel electrophoresis yielded a ladder pattern of fragmentation. EM allowed visualization of ultrastructural features characteristic of apoptotic neurons in early stages of degeneration whereas synaptic structures and cytoplasmic organelles were still intact. Apoptosis was triggered by a massive loss of inputs rather than axonal transection. Injections of a retrograde fluorescent tracer (Fast Blue) in the olfactory bulb as well as in the posterior olfactory cortex, two days before bulbectomy, provided evidence that neurons undergoing apoptosis were pyramidal cells receiving inputs from, but not projecting to, the olfactory bulb. We have also evaluated the inflammatory reaction at the site of degeneration; immunolabeling of astrocytes and microglia localized glial cells in the olfactory cortex 22 hours postbulbectomy but failed to reveal macrophage-specific epitopes. The present model provides a tool to study signal transduction pathways that lead to apoptosis in the rat cerebral cortex *in vivo* and can be used to test the efficacy of treatment strategies. This work was supported by grants from the NIH.

## 126.15

ULTRASTRUCTURAL ANALYSIS OF THE HIPPOCAMPUS OF ADULT RAT FOLLOWING LONG-TERM ADRENALECTOMY. A. Islam<sup>1</sup>, J. Westman, N. Bogdanovic, B. Winblad and A. Adem. Department of Clinical Neuroscience & Family Medicine, Geriatric Section, Karolinska Institute, Huddinge University Hospital, Huddinge, Sweden. Department of Anatomy, Bio-medical Center, Uppsala, Sweden.

Adrenalectomy (ADX) causes neuron loss in the hippocampus of the adult rat. We undertook this study on adrenalectomized rats 5 months after surgery to analyse the type of cell death in the hippocampal neurones. Bilateral adrenalectomy was done by dorsal approach in male Sprague Dawley rats at 10 weeks of age. Twenty weeks later, 3 ADX and 3 sham operated rats were perfused through the heart with a short rinse of 0.1M phosphate buffer (100 ml) followed by 300-400 ml of 2.5% glutaraldehyde and 2.0% formaldehyde in 0.1M phosphate buffer (38°C, pH 7.4). After termination of the perfusion, the brain was left *in situ* for an hour, removed and left overnight in fresh fixative at 4°C. The brain was then cut transversely on a vibratome (Oxford Instruments) into sections 100µm thick. The sections were post fixed for 20 minutes in 2% OsO<sub>4</sub> in cacodylate buffer, dehydrated in a graded series of ethanol and embedded in Epon between acetate foils. Light microscopic investigation was performed on 2µm thick sections recut from 100µm sections and stained with toluidene blue. Electron microscopy was done on ultra thin sections picked up on one-hole grids and stained with uranyl acetate followed by lead citrate. Electron microscopy showed apoptotic changes both in the dentate and in the pyramidal areas. These results indicate that adrenalectomy produces neuronal death both in the dentate and the pyramidal areas which is mediated through apoptosis.

## 126.12

DIFFERENTIAL SHRINKAGE OF THE REMAINING NEOCORTEX IN CATS WITH HEMINEODECORTICATION SUSTAINED NEONATALLY OR IN ADULTHOOD. T.D. Schmanke<sup>\*</sup>, J.R. Villablanca and V. Lekht.

Mental Retardation Research Center, UCLA, LA, CA 90024

Using a developmental animal model of cerebral hemispherectomy and stroke, we reported that following the lesion in adulthood there were **bilateral** changes in thalamic size and cell numbers. Here we report on changes in the remaining neocortex. We used young adult cats with hemineodecortication performed neonatally (P8 to P15) or in adulthood and intact animals (N=6/group) to measure the cross-sectional area of the remaining neocortex in 42 to 63 coronal sections (AP +24 to -10) per brain (50µm thick at 600µm intervals in fresh-frozen brains, cytochrome oxidase staining). We then used these values to calculate the total cortical volume per group. The mean neocortical volume (S.E.) for intact brains was 4,165 ± 159 µm<sup>3</sup>, for adult-lesioned cats was 3,595 ± 194 µm<sup>3</sup> (p<0.05) indicating a 14% shrinkage, and for the neonatal-lesioned animals it was 3,690 ± 117 µm<sup>3</sup>, indicating a tendency to cortical atrophy (12%). In addition, for sections between stereotaxic coronal planes +2 and +6 the mean cross-sectional areas were significantly larger in the neonatal vs. the adult-lesioned cats. Thus, in hemineodecorticated cats the remaining neocortex shrunk significantly in the animals with the lesion in adulthood but was somewhat spared in animals lesioned neonatally. This fits well with our finding of increased neocortical plasticity in neonatal animals. We suggest that these patterns of change should also apply to humans due to a relatively similar perinatal time course of brain maturation in man as compared to cats. (Grant USPHS HD-05958, HD-14612, NRSA T32HDO7416).

## 126.14

LONG TERM CHANGES IN BRAIN CHOLINERGIC MARKERS AND NGF LEVELS AFTER PARTIAL IMMUNOLESION. Z. Gu, J. Yu, J.R. Perez-Polo<sup>\*</sup>. Dept. HBC&G, Univ. TX Med. Br., Galveston, TX 77555-0652.

There are deficits in cholinergic basal forebrain neurons (CBFNs) in aging and Alzheimer's disease. To mimic the partial loss of CBFNs in these situations and study the long term effects of the loss of CBFNs on remaining cholinergic activity and target-derived nerve growth factor (NGF) levels, we produced a partial immunolesion to CBFNs with 192 IgG-saporin, a well recognized toxin to low affinity NGF receptor-bearing neurons. We measured the cholinergic markers, choline acetyltransferase (ChAT) and acetylcholinesterase (AChE), and NGF protein levels at 10, 30, 70, 180, and 365 days. Ten days after 192 IgG-saporin treatment, ChAT activity decreased to 35-50% in the olfactory bulb, hippocampus, and cortex when compared to normal controls. At 6 months postlesion, ChAT activity in the olfactory bulb returned to near control values and then decreased to 56% of controls at 1 year postlesion. There was a slight but significant recovery of ChAT as early as 1 month in the hippocampus and at 6 and 12 months postlesion in cortex. Similar but less dramatic changes in AChE activity were observed in these areas. There were significant long-term increases in NGF protein levels in the olfactory bulb with the highest levels at 3 to 6 months after lesion. Relative short-term increases in NGF levels were present in the hippocampus and cortex with a return to control values at 6 and 12 months postlesion, respectively, and no further recovery of ChAT activity in these areas. In addition, graded changes in both ChAT and NGF levels were observed in all the brain regions examined with respect to a partial and total immunolesion 1 month postlesion. These results suggest that there is a region-specific and time-dependent recovery of cholinergic activity in the target areas of the basal forebrain after a partial elimination of CBFNs and comparative changes in NGF levels in these areas suggesting that both ChAT and NGF levels respond to the state of cholinergic innervation of target areas of the basal forebrain. This is publication 53A from USPHS P01-A610514 awarded by NIA. Also supported by NINDS NS 18708 and NS 33288.

CHRONIC STRESS DOES NOT INDUCE NEURONAL DEATH IN THE HIPPOCAMPAL FORMATION OF AGED RATS. N. Sousa, M.D. Madeira, L. Xue, O.F.X. Almeida<sup>†</sup> and M.M. Paula-Barbosa<sup>\*</sup>. Dept. of Anatomy, Porto Medical School, Porto, Portugal and <sup>†</sup>Max Planck Institute of Psychiatry, Munich, Germany.

Sustained exposure of rats to elevated levels of corticosterone (CORT), as found during chronic stress, have been associated with behavioural impairments. Several authors have suggested that the behavioural deficits ensue from CORT-induced neuronal damage in the hippocampal formation (HF); further, the magnitude of neuronal death was shown to correlate positively with age of the experimental subject. All these previous studies assessed neuronal death using conventional, but biased, morphometric methods. In this study, we therefore applied unbiased stereological tools to evaluate the effects of chronic exposure to stress upon the volume of the HF divisions, using Cavalieri's principle, and its total number of neurones, using the optical fractionator. Male rats aged 17 months were submitted to the unpredictable stress paradigm for a period of 1 month, and sacrificed when 24 months old. One of several stressors (i.p. injections of saline, overcrowding, restraint, and placement on a rocking platform) were applied in a random order on a daily basis. The efficacy of this treatment was confirmed by elevated serum CORT levels measured at various intervals during exposure to stress. Stereological analysis of the various HF subdivisions (CA<sub>1,3</sub>, dentate gyrus, hilus) failed to reveal any significant loss of neurones as result of the chronic stress treatment. The present findings, based on unbiased measurements, call for a reappraisal of the hypothesis that chronic hypercorticalism leads to behavioural impairments as a direct result of neuronal losses in the HF. Experiments are currently being undertaken to examine the possibility that the HF of younger rats may be more vulnerable to the effects of chronic stress. (Supported by JNICT)

## 127.1

NEURONAL PROTEINS AS MARKERS OF CNS DAMAGE. N.S. Dejneka, C.M. Patanow and M.L. Billingsley\*. The Pennsylvania State University College of Medicine, Department of Pharmacology, Hershey, PA 17033.

Physical and chemical insults to the CNS result in altered expression of neuronal and glial proteins. Damage can be assessed by measuring increases in injury response elements (i.e. GFAP) or losses in neuronal proteins. We used two proteins, SNAP-25 and stannin, as potential markers of CNS damage. SNAP-25 is a presynaptic "snare" protein which regulates vesicle docking and synaptogenesis. A developmentally-restricted isoform, SNAP-25a, predominates until post-natal day 7. Stannin, is expressed in cells sensitive to trimethyltin (TMT). Previous experiments suggest that stannin is necessary, but not sufficient for the manifestation of TMT toxicity. Exposure to TMT (8mg/kg) induced a marked loss of neuronal stannin immunoreactivity in hippocampus. SNAP-25b immunoreactivity decreased 3 days post-TMT but increased robustly after 7 days. Unilateral-mechanical transection of the fimbria-fornix and perforant paths caused a decline in SNAP-25b immunoreactivity in the hippocampus with no change in stannin. Notably, there was a marked increase in SNAP-25a during reactive synaptogenesis. Localized increases in GFAP were seen following both forms of damage. Current experiments are focused on assessment of changes in epitope-tagged neuronal and glial markers in transgenic animals following selective CNS damage. This work was supported by PHS grant ES-05450 and EPA grant R818002-01-0 to M.L.B.

## 127.3

ASP, A NOVEL MARKER FOR APOPTOTIC MOTONEURONS. J.A. Garrah, M.A. Bisby, A.C. Jackson\* and J. Rossiter<sup>2</sup>, Departments of Physiology, \*Medicine and <sup>2</sup>Pathology, Queen's University, Kingston, Ontario, K7L 3N6.

An intended c-jun antibody recognized a different protein, designated "ASP", by immunocytochemistry and Western blotting of apoptotic cultured cells (1) We investigated whether this antibody would also recognize dying neurons *in vivo*, and serve as a convenient and reliable marker for neuronal apoptosis. Following transection of facial nerve in rat pups, which causes >90% death of facial motoneurons, we performed immunocytochemistry with Oncogene Science c-jun antibodies Ab-1 and Ab-2 on frozen brainstem sections. While Ab-1-i.r. was found in the nuclei of the majority of the motoneurons, Ab-2-i.r. revealed only occasional cells, all with apoptotic morphology. Ab-2-i.r. was cytoplasmic, and included the dendrites. The peak number of Ab-2-i.r. neurons equalled the peak number of neurons showing DNA fragmentation, but the peak Ab-2 frequency preceded peak DNA fragmentation by 2 hours. Ab-2-i.r. cells were also observed in the cerebellum, where programmed cell death continues after birth. We conclude that Ab-2 marks cells at an early stage of apoptosis: its uniform distribution in long dendrites suggests that the epitope recognized by Ab-2 results from modification of an existing molecule, rather than the appearance of a novel death protein.

## 127.5

CELL DEATH AFTER SPINAL CONTUSION: ELECTRON MICROSCOPY (EM). J.A. DeMaro\*, H.-X. Dong, X.Z. Liu, X.M. Xu\*, R. Hu\*, S.X. Zhang\*, G.S. Fan, C.Y. Hsu, D.W. Choi & M.F. Jacquin, Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110; <sup>2</sup>Dept. Anat. & Neurobiol, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Various markers are in widespread use to investigate programmed cell death. Yet, EM remains the most valid method for distinguishing apoptosis and necrosis. Accompanying light microscopic studies of TUNEL staining and cell death gene expression suggested that apoptosis may occur in neurons and glia after at least mild impact injury. The present study extended this evaluation to the EM level. The thoracic cord was exposed and injured by weight drop using the NYU device. 24 hr after a severe (50 g-cm) impact, TUNEL<sup>+</sup> neurons and glia were prevalent. Approximately 30 TUNEL<sup>+</sup> cells were visualized by EM. These cells were identified, drawn, and photographed, taking care to note landmarks to ensure cell correspondence between the light and electron microscopes. TUNEL reaction product consisted of electron dense spots in the nuclei of cells that were in a very late stage of necrosis degeneration. Indeed, cell death had progressed to a point where TUNEL<sup>+</sup> cell types could not be ascertained. After a mild (6.25 g-cm) impact, many apoptotic cells were observed by EM at 8 hr postinjury. Apoptotic cells typically showed the nucleus broken down into several membrane bound, highly condensed chromatin masses, cytoplasmic shrinkage and condensation with intact cytoplasmic membranes.

These data support the occurrence of apoptosis in spinal cord cells after mild impact injury, and provide further evidence for the non-specificity of TUNEL staining alone as a criterion for apoptosis. Support: NIH DE07734, NS32000, APA, Daniel Heumann Fund for Spinal Cord Research.

## 127.2

IS THERE LIGHT AT THE END OF TUNEL IN THE DEVELOPING WHISKER-BARREL NEURAXIS? M.F. Jacquin\*, H.-X. Dong, K.E. Good, P. Osborne, E.M. Johnson & T.A. Henderson. Neurology & the Center for the Study of Nervous System Injury, Washington University School of Medicine, St. Louis, MO 63110.

The terminal deoxynucleotidyl (TdT) mediated dUTP-digoxigenin nick-end labeling (TUNEL) assay is widely used to address issues related to programmed cell death. Several paradigms were used to study relationships between TUNEL staining, cell death, pattern formation, and injury-induced plasticity in the rat trigeminal (V) system: 1) In normal development from E19-P10, TUNEL<sup>+</sup> cells were plotted relative to the whisker pattern revealed by cytochrome oxidase in V nucleus principalis. On P1-2, TUNEL<sup>+</sup> neurons were most frequent in septae between barrelettes; however, the numbers of stained neurons were low relative to the numbers of neurons known to be dying from E19-P10. 2) Cutting the infraorbital nerve on P0-4 did not increase the number of TUNEL<sup>+</sup> cells in affected V ganglia and brainstem nuclei after 1-8 hrs and 1-4 days. This negative result is noteworthy because nerve injury kills thousands of ganglion/brainstem cells and obliterates whisker patterns during these intervals. 3) After electrocautery of the S1 barrel cortex on P0, TUNEL<sup>+</sup> cells were numerous at the injury site; yet, there was no increase in the number of TUNEL<sup>+</sup> cells in the affected VPM thalamus and nucleus principalis where thousands of neurons die. 4) Anti-NGF injections on E15-16 increased the number of TUNEL<sup>+</sup> cells in V, spinal and superior cervical ganglia. Thus, either injury-induced anterograde and retrograde cell death in early development does not occur by apoptosis, or TUNEL staining is not a reliable detector of such forms of cell death.

## 127.4

CELL DEATH AFTER SPINAL CONTUSION: LIGHT MICROSCOPY. H.-X. Dong, K.E. Good\*, M.P. Goldberg, J.W. McDonald, X.Z. Liu, X.M. Xu\*, R. Hu\*, C. Du, S.X. Zhang\*, Y.J. Wu\*, G.S. Fan, C.Y. Hsu, D.W. Choi & M.F. Jacquin, Center for the Study of Nervous System Injury and Dept. of Neurology, Washington Univ. Sch. of Med., St. Louis, MO 63110; <sup>2</sup>Dept. Anat. & Neurobiol, St. Louis Univ. Sch. Med., St. Louis, MO 63104.

We aim to characterize cell death following traumatic insults to the rat spinal cord. As a first step, anatomical studies were conducted to elucidate which cells die after severe or mild impact to the thoracic cord using the NYU impact device. After severe (50 g-cm) impact, cellular degeneration achieved a maximum rostrocaudal distribution of 7.5 mm after 3 d, associated with considerable TUNEL<sup>+</sup> staining in neurons and glia (the latter especially in white matter) apparent already at 6-8 hr. At 4-6 d, TUNEL<sup>+</sup> cells were similarly distributed, but after 7 d, their extent diminished to 2.5 mm. The density of TUNEL<sup>+</sup> cells was greatest at 4 d. TUNEL negative, swollen cells with intact cytoplasm were also observed bordering necrotic regions at 1-7 d. At 20-36 hr post-injury, many TUNEL<sup>+</sup> cells expressed c-jun or P53 at the borders of the injured zone. At 1 and 3 d, high levels of BAX expression were seen in cells at the impact site; Bcl-2 expression was low. After mild (6.25 g-cm) impact, TUNEL<sup>+</sup> neurons and probable glia were also prevalent already after 4 hr and associated with chromatin condensation and Hoechst 33342 staining, with maximum numbers by 8 hr. These TUNEL<sup>+</sup> neurons were confined within a well defined area of degeneration at the injury site. TUNEL<sup>+</sup> and Hoechst<sup>+</sup> glial cells were seen at 4 and 8 hr as well, but their numbers peaked at 24 hr. DNA laddering was prominent in injured tissue at 24 hr postinjury. Thus, apoptosis may occur in many neurons and perhaps glial cells after at least mild impact injury to the spinal cord. ## 127.6

EXPRESSION OF MAP-2, SPECTRIN, AND TAU PROTEIN FOLLOWING TRAUMATIC INJURY TO THE RAT SPINAL CORD. J.E. Springer\*, R.D. Azbill, S.E. Kennedy, R.G. Siman, N.S. Soultanian, and J.W. Geddes, Department of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY, 40536-0084, and Cephalon, Inc. 145 Brandywine Parkway, West Chester, PA 19380-4245 (RGS).

Glutamate-mediated excitotoxicity is one of the primary mechanisms thought to contribute to delayed neuronal cell death following traumatic spinal cord injury (SCI). The excessive release of glutamate and the sustained stimulation of glutamate receptors following SCI promotes the influx of micromolar concentrations of calcium into the cell. High levels of intracellular calcium result in a series of biochemical events, one of which is the activation of destructive lipases and proteases that degrade structural proteins, including MAP-2, spectrin, and tau. In the present study, immunocytochemical and Western blot techniques were used to investigate the expression of these structural proteins at different times following SCI. Moderate spinal cord contusion injury resulted in a gradual loss of dendritic MAP-2 staining at all time points analyzed (1, 4, and 24hr). Spectrin degradation was apparent in neuronal cell bodies and fibers as early as 1 hour following SCI, with the most intense staining occurring within and adjacent to the injury site. The appearance of spectrin breakdown products declined at 4hr and was nearly undetectable by 24hr following injury. A non-phosphorylated tau epitope, detected with the tau-1 antibody, occurred over time in both the gray and white matter, and was restricted to small cells located in close proximity to the injury site. These results illustrate that calpain activation and cytoskeletal disruption are early events in SCI, and that treatments aimed at minimizing the breakdown of these proteins may provide a substantial degree of functional savings or recovery. Supported by a grant from the Kentucky Spinal Cord and Head Injury Trust (JES).

CAN DELAYED FETAL TRANSPLANT PREVENT DEATH OF CLARKE'S NUCLEUS NEURONS IN ADULT RATS? <sup>1,2</sup> M. Shibayama, <sup>1,2</sup> S. Hattori, <sup>1,3,\*</sup>

<sup>1,3,\*</sup> B.T. Himes, <sup>2</sup> N. Matsui, <sup>1</sup> M. Murray, and <sup>1,3,1</sup> A. Tessier. Dept. of Anatomy & Neurobiology, Medical College of Pennsylvania and Hahnemann University, 3200

Henry Ave. Philadelphia, PA 19129. Dept. of Orthopedic Surgery, Nagoya City

Univ. School of Medicine, Nagoya, Aichi, Japan. Philadelphia VA Hospital

Fetal spinal cord tissue grafted into a midthoracic spinal cord hemisection at the time of injury rescues Clarke's nucleus (CN) neurons which otherwise die following axotomy. (Himes et al., 1994). In the present study we examined whether transplants performed after a delay could keep injured CN neurons alive and, if so, for how long transplants could be delayed. Female Sprague-Dawley rats (250-300g) underwent laminectomy at the mid-thoracic level with interruption of the right dorsal spinal spinocerebellar (DSC) tract by spinal cord hemisection and insertion of gelfoam into the cavity. This injury transected the axons of the right CN neurons and leaves the left CN as an intact control. At 1, 3, 7 and 14 days postoperative, the hemisection site was reexposed and the gelfoam replaced by a graft of embryonic day 14 (E14) spinal cord. Two months after the initial surgery CN neurons of the L1 segment were counted and measured. Hemisection only rats showed a 30% loss of CN neurons ipsilateral to surgery and a 40% reduction in average cell area. Rats receiving a transplant at 1, 3 and 7 days showed minimal cell loss; >90% of CN neurons survived. Rats which received transplants 14 days after hemisection showed a 30% cell loss, which was similar to hemisection only animals. Transplants did not prevent cell shrinkage in any group. Transplants can therefore prevent most CN neuron loss if provided within the first week after injury. This result may influence the timing of surgery if transplants become part of the treatment of clinical spinal cord injury. Supported by the VA Medical Research Service, NS 24707 and NS 10090 (BTH).

## 127.9

INDUCTION OF NITRIC OXIDE SYNTHASE (NOS) ACTIVITY IN IMMATURE AND MATURE FACIAL MOTONEURONS AFTER AXONAL AN FUNCTIONAL INJURY. <sup>1</sup> R. Mariotti, <sup>2</sup> Z.-C. Peng, <sup>1</sup> K. Kristensson, <sup>2</sup> Bentivoglio (SPON: European Brain and Behaviour Society), <sup>1</sup>Inst. Anat. Histol Univ. of Verona, 37134 Verona, Italy; <sup>2</sup>Dept. Neurosci., Karolinska Institute, 1717 Stockholm, Sweden

We investigated the differences in the induction of NOS, the NO synthetase enzyme, between immature and mature motoneurons after axotomy and the relationship between NOS induction and apoptotic cell death in immature motoneurons. The facial nerve was transected in rats at different postnatal ages, from birth to early adulthood, and NADPH-diaphorase (ND) histochemistry was performed to analyze NOS induction in facial motoneurons. *In situ* nick-end labeling of DNA fragmentation (TUNEL technique) was performed after axotomy at birth. Striking age-dependency was found in ND activity induction: ND positivity was not detectable in facial motoneurons 1 and 2 days after axotomy at birth, when apoptotic changes were evident and marked, and was hardly detectable 4 days after axotomy at birth, when extensive motoneuron loss was evident. ND positivity was instead induced in facial motoneurons axotomized from the end of the first postnatal week to adulthood, when the nerve cell loss was less severe than in newborns. However, the time course of ND induction varied considerably in relation to the animals' age. These findings indicate that cell death of maturing motoneurons may not require NOS activity. In another set of experiments, facial muscles were paralyzed with botulin toxin injections in 3 week-old rats. Preliminary findings indicate that N was induced in some facial motoneurons in the first days after paralysis, indicating that functional impairment may also induce NO production in motoneurons.

The financial support of Telethon-Italy (Grant no. 524) is gratefully acknowledged.

## 127.8

CEP-1347 RESCUES DRG NEURONS FROM AXOTOMY-INDUCED CELL DEATH. <sup>1</sup> R.V. Bhat, <sup>1</sup> M. Miller, <sup>1</sup> C. Murakata, <sup>1</sup> and <sup>1</sup> P.C. Contreras. Cephalon, Inc., Dept. Pharmacology, West Chester, PA 19380 and <sup>2</sup> Kyowa-Hakko Kogyo Co. Ltd., Tokyo, Japan.

Recent studies have demonstrated that CEP-1347, a structurally novel indolocarbazole, possesses neurotrophic properties since it rescues motor neurons from cell death *in vivo* and *in vitro*. In addition, CEP-1347 prevents death of dorsal root ganglion (DRG) cells *in vitro*. To test whether CEP-1347 is efficacious at rescuing sensory neurons from cell death *in vivo*, we have determined its effect on DRG neurons after axotomy of the sciatic nerve in rat neonates. Unilateral axotomy on rat pups was performed on postnatal day 1 and the time course of loss of the neuropeptides CGRP and Substance P were determined in DRG. A 40% depletion of these neuropeptides and a comparable loss of DRG neurons was observed 4 days post axotomy when compared to the contralateral (sham-operated) side. To determine the effects of CEP-1347 on neuropeptide levels and cell loss in the DRG, vehicle or 0.1, 0.3, 1 and 3 mg/kg of CEP-1347 was injected s.c., once daily, starting at the time of axotomy. Following sciatic nerve axotomy, CEP-1347 (0.3 and 1 mg/kg) significantly prevented the depletion of Substance P and CGRP by 70% in DRG. CEP-1347 (0.3 and 1 mg/kg) also significantly reduced the axotomy-induced neuronal loss by 50% in the DRG. Taken together, our results suggest that CEP-1347 is efficacious at rescuing sensory neurons *in vivo* from axotomy-induced cell death.

## 127.10

CHANGES OF p75 NGF RECEPTOR AND CHOLINE ACETYLTRANSFERASE IN AXOTOMIZED DEVELOPING MOTONEURONS. <sup>1</sup> T. Zheng, <sup>1</sup> Y. Sun, <sup>1</sup> R. G. Wiley, and <sup>1</sup> D. M. Armstrong. Georgetown Univ. Sch. of Med., Washington D.C. 20007.

In order to understand the mechanism of motoneuron death or survival after axotomy in developing animals, we employed immunocytochemical techniques to examine the expression of p75 nerve growth factor receptor (p75<sup>NGFR</sup>) and choline acetyltransferase (ChAT) in intact and axotomized hypoglossal motoneurons in rats 5 to 28 days of age. In intact developing rats p75<sup>NGFR</sup> is transiently expressed within the hypoglossal nucleus with intense immunolabeling occurring at P5, weaker staining at P7 and P11, and barely detectable immunolabeling at P14. Transection of the hypoglossal nerve in P5 and P7 rats results in the decreased expression of p75<sup>NGFR</sup>. Transection during this time period produces death and/or degeneration of these motoneurons as revealed in Nissl stained preparations. In contrast, axotomy in rats 14 days and older (i.e., at a time when intact motoneurons are not longer expressing the receptor) results in the de novo expression of p75<sup>NGFR</sup>. Examination of adjacent tissue sections stained for Nissl substance revealed that the majority of these motoneurons survived the transection. In contrast to p75<sup>NGFR</sup>, axotomy of the hypoglossal nerve results in a decrease in ChAT immunoreactivity within motoneurons during all periods of development. This reduction of ChAT immunostaining, however, is transient and the enzyme returns to basal levels in surviving motoneurons. The normally intense expression of p75<sup>NGFR</sup> within the hypoglossal nucleus during early postnatal periods and the death of these immature motoneurons after axotomy suggests that maturation and survival after axonal injury may be related to a neurotrophin (supported, in part, by NIH grant AG08026).

METABOTROPIC GLUTAMATE RECEPTORS MODULATE THE STIMULATION BY GTP OF RAT ASTROCYTE PROLIFERATION.

<sup>1</sup> M.P. Rathbone, <sup>1</sup> R. Ciccarelli, <sup>1</sup> D'Alimonte, <sup>1</sup> P. Di Iorio, <sup>1</sup> P. Ballerini, <sup>1</sup> Giuliani, <sup>1</sup> A. Renzetti, and <sup>1</sup> F. Caciagli. Dept. Biomed. Sci. McMaster Univ. Hamilton, Ont. L8N 3Z5 and Inst. Pharmacol. Univ. Cheiti, Italy.

In several brain disorders and injuries glutamate (Glu) release is enhanced and astrocytes undergo reactive gliosis. Glu activates release of purines (Ps) (e.g. adenine- and guanine-based compounds) from cells. Extracellular Ps can stimulate gliosis. Guanosine (GUO) and GTP, like Glu, increase NGF gene expression. Rat astrocytes have several subtypes of metabotropic glutamate receptors (mGluRs) whose stimulation modulates the outflow of Ps. We evaluated whether mGluR agonists influenced the effects of guanine nucleotides on rat astrocyte proliferation. 100-500  $\mu$ M GTP increased astrocyte proliferation in a concentration-dependent manner. HPLC analysis showed extracellular GTP was reduced by 50% and 75% after 15 and 60 min respectively, with a constant production of GUO (25  $\mu$ M up to 4 hr) and progressive accumulation of other metabolites. The GTP hydrolysis-resistant analogue guanosine  $\beta$ -imidotriphosphate (GMP-PNP) and GUO each also increased astrocyte proliferation; potency: GMP-PNP > GUO > GTP. P2 antagonists partly inhibited the nucleotide-induced effect whereas P1 antagonists reduced the GUO activity. 3,5 Dihydroxyphenylglycine (DHPG), a selective class I mGluR agonist that increases phosphoinositide hydrolysis and cAMP formation, significantly increased astrocyte proliferation and enhanced the GTP or GMP-PNP-induced mitogenic effect. 2,3 Dicarboxycyclopropylglycine (DCG-IV) a class II mGluR agonist negatively coupled to adenylyl cyclase, produced opposite effects. Thus GTP and GUO stimulate rat astrocyte proliferation by different mechanisms. mGluR agonists may regulate gliosis both affecting astrocytes directly and indirectly through modulating the effects of GTP. This has potential therapeutic implications. (Support: OMHF and ALS Canada)

## 128.2

ETHANOL INHIBITS PROLIFERATION OF ASTROGLIA FROM THE ADULT HUMAN CEREBRUM IN CULTURE. <sup>1</sup> F.A. Boop, <sup>1</sup> D.L. Davies, and <sup>1</sup> C.J.M. Kane. Department of Neurosurgery and Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

Fetal exposure to ethanol can cause microencephaly, while chronic alcoholism is associated with atrophy of the adult brain. Ethanol can produce direct neuronal damage as well as indirect neuronal damage through detrimental effects on astroglia. Astroglial pathology is a common feature of ethanol exposure in humans and in animal models.

The influence of ethanol on proliferation of human astroglia from the gray and white matter of adult temporal lobe was determined and compared. Astroglial cultures were exposed to a constant concentration of ethanol at realistic social and clinical levels (0.1, 0.2 or 0.5%; w/v) for 1 to 5 days. Cellular proliferation was quantified by bromodeoxyuridine labeling and enumeration of replicating cells. Ethanol exposure significantly inhibited proliferation of both gray and white matter astroglia in a dose and duration dependent manner. Gray matter was slightly more sensitive than white matter to inhibition at moderate concentrations of 0.1 to 0.2% ethanol. In contrast, white matter was more sensitive at high concentrations of 0.5% ethanol. Maximum inhibition was 20% in gray matter and 25% in white matter. These results demonstrate that human astroglial proliferation is directly inhibited in the absence of neurons, microglia, neuronal degeneration or systemic factors that confound *in vivo* studies. Ethanol damage may impair the ability of astroglia to adequately maintain the parenchymal microenvironment or to properly respond to CNS insults. Restricted proliferation may underlie aspects of the astroglial pathology associated with ethanol exposure. (UAMS Foundation, UAMS Research Council, NIH AG12411, NIH AA07145).

## 128.3

**NUTRITIONAL FACTORS MODIFY THE INHIBITION OF CNS DEVELOPMENT PRODUCED IN NEONATAL RATS BY EXPOSURE TO ETHANOL AND/OR METHADONE.** K.E. Light\*, D.R. Pierce, N.N. Nyamweya, H. Yang, Y. Kasmi, B. Mosby, D.C. Serbus and C.J.M. Kane\*. Dept. of Biopharmaceutical Sciences, College of Pharmacy and \*Dept. of Anatomy, College of Medicine, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

The ability of nutritional status to alter the consequences of exposure to ethanol and/or methadone on the development of the rat CNS was determined. Rats were exposed to ethanol (3 g/kg) and/or methadone (0.25 or 0.5 mg/kg) via intragastric intubation at 8am and 4pm on postnatal days 6–10 inclusive. Rats were weighed, anesthetized and perfused on postnatal day 11. Overall growth was assessed by measure of body, heart, liver and kidney weight. Specific effects on CNS development were assessed by measure of whole brain, cerebrum, cerebellum and brainstem weight. Nutrition was modified by drug delivery in two intubation vehicles (20% Sustacal® or 75% Intralipid-II®) which differ in caloric density and composition. Neither ethanol, nor methadone, alone produced significant alteration in brain growth. However, significant dose-related inhibition of brain, cerebrum, cerebellum and brainstem growth was evident with combined drug exposures only with the Sustacal vehicle. No nutritional compromise was evident in intubated control rats compared to suckle control using either intubation vehicle. Neither drug alone, nor in combination, caused significant effects on liver, heart or kidney growth. These results indicate that nutritional effects can mask or enhance the determination of specific drug effects. Importantly, these results emphasize that nutritional effects must be considered, properly controlled, and monitored with quantitative measures in order to accurately quantify specific drug effects in rat models of fetal drug exposure. (College of Pharmacy, UAMS).

## 128.5

**GLIAL MATURATION, REACTIVE GLIOSIS AND THE TARGET OF THE ANTIPROLIFERATIVE ANTIBODY, rTAPA.** E.E. Geisert, Jr.\*, L.J. Yang and C.D. Sullivan. Department of Anatomy and Neurobiology, University of Tennessee Memphis, College of Medicine, Memphis, TN 38163.

The present study defines the expression pattern of the rTAPA in the rat brain. rTAPA is a member of the tetramembrane spanning family of proteins. Like other members of this family, rTAPA is associated with the stabilization of cellular contacts. We have examined the expression of rTAPA using immunohistochemistry on cultured cells and sections of the developing brain. The levels of rTAPA were defined on immunoblots of: muscle, tendon, peripheral nerve, cartilage, liver, kidney, brain, skin, and testicle. The highest levels of rTAPA are found in the central nervous system. rTAPA is expressed by: ependyma, choroid plexus, astrocytes and oligodendrocytes. At embryonic day 18 (E18) the levels of rTAPA on immunoblots is low, with virtually all of the immunoreaction product being localized to the ependyma, choroid plexus and the glial limitans. As development continues the amount of rTAPA expressed in the brain increases and at postnatal day 14 (P14) the levels approach that observed in the adult. When the distribution of rTAPA is examined in sections of the developing brain, there is an increase in the intensity of immunoreaction product observed as a fine reticulated pattern within the parenchyma of the brain. At P7 there is a relatively even labeling of the cerebral cortex and the future white matter. By P14 the level of immunoreaction product in the gray matter appear to increase relative to that observed in the adjacent white matter. However, approximately equal level of rTAPA are found on immunoblots of white matter, gray matter and within purified myelin. Thus, rTAPA is found in all glial cells and the level of this protein correlate with the maturation of glial cells. To test the hypothesis that rTAPA is associated with glial maturation, the levels of rTAPA were examined following a cortical stab wound. As the glia mature they acquire the ability to enter a reactive state. We have found that the expression of rTAPA correlates with the ability of the cells to become reactive. Supported by the Spinal Cord Society.

**CYTOTOXICITY OF PROLIFERATING ASTROCYTES IN PRIMARY CULTURE MEDIATED BY HSV-TK/GANCICLOVIR.** S. Audouy, F. Revah, J. Mallet, A. Privat and M. Giménez y Ribotta\*. INSERM U. 336, Université Montpellier II, 34095 Montpellier and CNRS-Rhône-Poulenc Rorer UMR C9923, Hôpital de la Pitié Salpêtrière, 75013 Paris, FRANCE.

It is generally agreed that astrocyte proliferation is one element of CNS post-traumatic gliosis. In order to overcome this obstacle, we have used an adenoviral vector (ADV/RSV) to evaluate the ability of herpes simplex virus thymidine kinase (HSV-TK) coupled with the prodrug ganciclovir (GCV) to reduce the proliferation of cultured primary astrocytes, taken as a model of reactive gliosis.

Primary cultures of astrocytes were obtained from the cerebral cortex of 2-days postnatal rats. After mechanical dissociation a cell suspension was obtained and adjusted to  $10^6$  cells/ml. The Bromodeoxyuridine (BrdU) labeling index, measured by double immunocytochemical detection of BrdU/GFAP, was used to determine the time in culture at which the peak percentage of phase S-cells was achieved. Transfection efficiency of adenovirus was demonstrated by using ADV/RSV-βgal.

A peak percentage of BrdU+ cells is reached at 6 days in vitro and an optimal transfection efficiency at a multiplicity of infection (MOI) = 16. One day after transfection with ADV/RSV-TK at MOI values of 8 or 16, the cultures were treated with either culture medium or GCV (10 or 50 μg/ml). Two or four days later, the surviving cells were counted. The maximum effect (88% of death) was obtained for a GCV concentration of 10 μg/ml and a survival of 4 days.

In conclusion, the HSV-TK/GCV system may constitute an efficient tool to investigate the influence of the elimination of proliferating cells on the regrowth of severed axons following traumatic injury of the CNS in vivo.

The ADV/RSV-TK and -βgal were kindly provided by Rhône-Poulenc Rorer (RPR). Supported by grants from RPR (Bioavenir Program), IRME, AFM, FRMF, DRET.

**LONG-TERM POSTNATAL EFFECT OF PRENATAL IRRADIATION ON THE INJURY-INDUCED ASTROCYTE PROLIFERATION IN THE RAT BRAIN.** K. Janeczko, M. Ziaja, Z. Soltys, R. Pawliński, Z. Setkowicz, A. Ryszka. Department of Neuroanatomy, Jagiellonian University, 6 Ingardena St., 30 060 Kraków, Poland (Spon: ENA)

Pregnant Wistar rat. were exposed to single doses of 1.0 Gy gamma-radiation on gestational days 13, 15, 17 or 19 (E13, E15, E17 or E19, respectively). Pregnant animals were allowed to give birth. When the irradiated offsprings were 30-day-old a lesion was made in the left cerebral hemisphere of male rats. The rats were injected with a single dose of [<sup>3</sup>H]Thymidine on 1st, 2nd, 4th or 8th days following injury and sacrificed 4 hours later. Brain sections were immunostained for glial fibrillary acidic protein (GFAP) or S100β protein (S100), autoradiographed and examined microscopically.

Statistically significant increases in the number of proliferating GFAP-immunopositive astrocytes were recorded on the 2nd day after injury in brains irradiated on E15 and E17. All the irradiated groups showed a significant global elevation in the proliferative activity of S100-immunopositive astrocytes.

The results suggest that prenatal low-dose irradiation has a long-term effect on the astrocyte ability to proliferate in response to postnatal brain injury. The effect appears to depend on the stage of embryonic development when the irradiation is performed.

The work was supported by the PECO grant of the European Commission, contract no. ERBCIPDCT930410.

## 128.6

**GLIAL PROLIFERATION IN THE VENTRAL NERVE CORD OF CRAYFISH AFTER INJURY.** M. González-del-Pliego<sup>(1)</sup>, R. Gutiérrez<sup>(1)</sup>, J. Hernández-Falcón<sup>(2)</sup>, and B. Fuentes-Pardo<sup>(2)</sup>. Departamento de Embriología<sup>(1)</sup> y de Fisiología<sup>(2)</sup>. Facultad de Medicina, UNAM, México.

In many invertebrates as the crayfish, some neural fibers degenerate very slowly when the ventral nerve cord (VNC) is transected. Many morphological studies of the transected VNC of crayfish correspond to the injury's zone and some micrometers around that zone but there is little information on the status of the surrounding tissue and its participation in the regenerative processes. The aim of this work was to characterize the time course of degeneration of the VNC of the crayfish, and the role of the connective tissue during this process. In a longitudinally-oriented section of VNC we found that degenerative changes can be detected since 10 days after the transection of the nerve cord. The small fibers show a loss of integrity with disruption in the arrangement of membranes and subcellular organelles, and a strong increase in glia. About 60-70th day, it could be detected the same changes but to a lesser degree in the giant fibers with a loss of the architectural arrangement of organelles. These process continue along the time with an increase in glial tissue both adaxonal and peripheral glia, covering the entire stumps (proximal and distal). Ninety days after transection the glial tissue reconnected both stumps and a great recovery in the arrangement of neural tissue can be observed. Supported by DGAPA IN202392

**EFFECTS OF GANCICLOVIR ON TRANSGENIC ASTROCYTES EXPRESSING HSV-THYMIDINE KINASE FROM THE MOUSE GFAP PROMOTER**

T.G. Bush<sup>1</sup>\*, M.H. Johnson<sup>1</sup>, L. Mucke<sup>2</sup> and M.V. Sofroniew<sup>1</sup>

<sup>1</sup>MRC Cambridge Centre for Brain Repair and Department of Anatomy, University of Cambridge, Forvie Site, Robinson Way, Cambridge CB2 2PY, UK and <sup>2</sup>The Gladstone Molecular Neurobiology Program and Department of Neurology, University of California, San Francisco, PO Box 419100, San Francisco, CA 94141-9100

To provide a model in which astrocytes can be selectively ablated, transgenic mice have been generated that express herpes simplex virus thymidine kinase (HSV-TK) from the mouse glial fibrillary acidic protein (GFAP) promoter (Bush et al. Soc. Neurosci. Abst. 21:814, 1995). Immunocytochemical double-labelling of astrocytes in the brains of these mice, demonstrates complete co-localization of HSV-TK and GFAP immunoreactivity. Manipulations that upregulate GFAP expression *in vivo* caused upregulation of HSV-TK. When cultured transgenic astrocytes were exposed to ganciclovir (GCV; 2μM) for one week their number was reduced by 80%. In contrast, GCV treatment caused no cell loss in astrocyte cultures from non-transgenic littermates. The effects of ganciclovir on astrocytes in normal and injured brain are being investigated. This transgenic model may be useful to investigate the role of astrocytes in a variety of processes.

Supported by the Wellcome Trust, the MRC and Action Research.

## 128.9

THE GLIAL-DERIVED PROTEIN S100 $\beta$  INDUCES APOPTOTIC CELL DEATH IN CULTURED ASTROCYTES. J. Hu\* and L.J. Van Eldik, Dept of Cell and Mol. Biology, Northwestern University Medical School, and Northwestern Univ. Institute for Neuroscience, Chicago, IL.

S100 $\beta$ , a calcium binding protein expressed primarily by astrocytes in the brain, has been implicated in development and maintenance of the nervous system. However, S100 $\beta$  has also been postulated to play a role in mechanisms of neuropathology, because of its specific localization and selective overexpression in Alzheimer's disease. Recent studies have suggested that S100 $\beta$  may be beneficial to cells at low doses and detrimental at high doses. To begin to study the toxic signalling pathways activated by high concentrations of S100 $\beta$ , we have demonstrated (Hu et al., *J. Biol. Chem.* 271, 2543-2547, 1996) that treatment of astrocytes with  $\mu$ M S100 $\beta$  results in a potent stimulation of the mRNA level and enzyme activity of inducible nitric oxide (NO) synthase, an enzyme previously implicated in glial pathology. We provide evidence here that S100 $\beta$ -stimulated NO formation can lead to cell death in astrocytes, with characteristics defined for apoptosis. Incubation of astrocytes with S100 $\beta$  for 48 hr results in an increased percentage of cells undergoing apoptotic cell death, as determined with TUNEL technique, DNA fragmentation assays and lactate dehydrogenase activity. The cell death induced by S100 $\beta$  addition correlates with the levels of NO production, and the specific NOS inhibitor L-NAME attenuates the NO formation elicited by S100 $\beta$ , as well as the cell death. Therefore, we propose that S100 $\beta$  has the potential to be trophic or toxic. Although S100 $\beta$  may be involved in development, homeostasis and repair, chronic overexpression of the protein may mediate toxic responses or even cell death (supported in part by NIH grants AG10208 and AG11138).

## 128.11

PHENOTYPE OF OLFACTORY ENSHEATHING CELLS IN CELL CULTURES INITIATED FROM NGF OVER-PRODUCING TRANSGENIC MICE. R. Doucette\* and M. Kawaja, Dept. Anat. & Cell Biol., U. of SK, S'toon, SK Can.

and Dept. Anat. & Cell Biol., Queen's Univ., Kingston, ON, Can.

We are studying the olfactory system in a transgenic mouse in which the mouse beta-NGF gene is being driven by the GFAP promoter. Olfactory ensheathing (En) cells are the glial cells that ensheath the primary olfactory axons in both the PNS and CNS portions of the pathway. Since these cells express GFAP they would presumably express the transgene as well. The objective of the present study was to compare the phenotype of En cells in neuron-free cultures with that of cells obtained from wild-type C57/black mice. Cell cultures of En cells were initiated from the olfactory bulbs of E15.5 mouse embryos. The cultures were stained with rabbit polyclonal antisera to the p75 neurotrophin receptor, as well as to GFAP and S100. A monoclonal antibody to the nestin intermediate filament protein (Rat 401) was also used. The cultures were stained using the Vectastain ABC Elite kit. The phenotype of En cells in both transgenic and wild-type cultures was the same: i.e. p75+ve, GFAP+ve, S100+ve & Rat401+ve. The addition of NGF to the wild-type En cell cultures did not alter the phenotype of cells in these cultures either. (Supported by grants from the NIDCD to R.D. and from the MRC of Canada to M.K.).

GENERATION OF A RADIAL-LIKE GLIAL CELL LINE FROM RAT C6 GLIOMA. D.R. Friedlander\*, T. Sakurai, G. Fishell and M. Grumet, Depts. of Pharmacology and Cell Biology, NYU Medical Center, 550 First Avenue, New York, NY 10016.

The rat C6 glioma cell line has been used extensively as a model of astroglia. We reported that C6 cells as well as developing glia including radial glia and mature astroglia express a receptor protein tyrosine phosphatase called RPTP $\beta$  (*J. Neurosci. Res.* 43:694-706, 1996). To analyze the function of this receptor in glia, we transfected C6 cells with a plasmid encoding this receptor lacking the intracellular phosphatase domains and established several stable transformants that expressed the truncated receptor. Many of the transformants assumed a more stellate morphology than the parental cells but the morphological changes did not strictly correlate with the level of expression of the truncated receptor. Interestingly, one cell line called C6#1 assumed a highly polarized morphology in culture that resembled radial cells, and at confluence, they aligned in a palisade-like orientation. This phenotype was stable after more than ten passages. The radial morphology was observed even at low cell density and conditioned medium from C6#1 did not alter the morphology of parental C6 cells indicating that this effect was unlikely to be due to secreted factors. Rat cerebellar granule neurons bound to the radial-like C6#1 cells and migrated along them in culture. The phenotype of Di-I-labeled C6#1 cells was compared to the parental C6 cells following injection into the developing forebrain. Three days later, histological analysis revealed that most of the C6#1 cells were in a radial orientation spanning the neuroepithelium, in contrast to the parental C6 cells which exhibited a much less polarized morphology and often formed aggregates. The results suggest that we have generated a stable cell line from C6 glioma which resembles radial glia in morphology both in culture and in vivo, and that can support neuronal migration. Supported by NS33921.

## 128.10

Programmed cell death (apoptosis) in the rat lumbar spinal cord after surgical isolation. D.L. Allen, W.M. Walwyn\*, E.J. Grossman, R.R. Roy and V.R. Edgerton, Department of Physiological Science and Brain Research Institute, UCLA, Los Angeles, CA 90095

Spinal cord isolation (SI) or complete spinal cord transection at a mid-thoracic and low lumbar level coupled with bilateral dorsal rhizotomy between the transection sites results in an electrically silent preparation producing dramatic alterations in the target muscle. However, little is known of the effects of spinal isolation on the cells of the spinal cord. SI was induced in adult female rats and the cellular changes in the spinal cord determined 4, 15, 30, 60 and 90 days after surgery. Histochemical staining of 12  $\mu$ m sections for double stranded DNA breaks revealed increased DNA fragmentation indicative of apoptosis in the gray and white matter of the spinal cord. An increased number of apoptotic nuclei was evident by 15 days after surgery ( $24 \pm 6$ , mean  $\pm$  SD), peaked after 30 days ( $48 \pm 12$ ), and decreased after 60 and 90 days. The number of apoptotic nuclei in the control rats was not different at any of the time points studied (15 days:  $2 \pm 1$ ; 30 days:  $3 \pm 2$ ). Dual fluorescent staining and confocal microscopy showed that the majority of apoptotic cells were astrocytes (positive glial fibrillary acidic protein immunolabeling). Apoptotic glial cells were shrunken and the normal fibrillary structure was dramatically reduced, consistent with morphological alterations characteristic of apoptosis. Spinal isolation also resulted in a progressive increase in the number of nuclei in the white matter as shown by cresyl violet staining. These data suggest that both cell death and proliferation are increased in the lumbar spinal cord following spinal isolation, and may play a role in spinal cord remodeling following removal of afferent, supraspinal and infraspinal input. Supported by NIH grant NS16333.

## 128.12

THE MIDLINE RADIAL GLIAL PROTEIN TRANSITIN DEFINES A NEW CLASS OF INTERMEDIATE FILAMENT PROTEIN. J.-A. Lee, Y. Yuan, A. Napier, and G.J. Cole\*, Neurobiotechnology Center & Dept. of Cell Biology, Neurobiology and Anat., The Ohio State Univ., Columbus, OH 43215.

In the present study we describe the molecular cloning of a previously characterized radial glial protein, originally named EAP-300, that is expressed by a number of CNS midline radial glial structures. This protein is characterized by an intermediate filament (IF) core domain most closely resembling human nestin and Xenopus tanabin, and a novel central heptad amino acid repeat domain located in the variable tail region of the protein, which is comprised of multiple leucine zipper repeats that are predicted to form coiled-coils. Based on these structural motifs, but only limited homology to other IF proteins, we propose that a novel IF protein that is transiently expressed by radial glia during CNS development has been identified. We also show by molecular cloning and Western blotting that a rat homologue of EAP-300 is expressed in rat C6 cells. Based on its temporal and spatial expression pattern we have renamed this protein transitin (from the Latin word for transient and crossing). We also demonstrate the existence of splice variants of transitin with splicing giving rise to heptad repeats of different lengths, or even transitin isoforms that lack a central heptad repeat domain. By in situ hybridization analysis we show that transitin mRNA is expressed by midline glial structures that are thought to regulate axonal guidance, by glia in several axonal commissures, and by Bergmann glia of the developing cerebellum. Based on the structural properties of the transitin protein, and expression of its mRNA, we suggest that transitin may represent a new class of intermediate filament protein transiently expressed by radial glia, which may play a role in the morphological differentiation of these cells in the CNS. Supported by NIH grant NS29934.

## 128.14

ACTION OF GABA IN THE DEVELOPING RAT OPTIC NERVE. A.G. Howd, S. L. Kirvell, M. Rattray, D. Shewan\* and A. M. Butt, Divisions of <sup>1</sup>Physiology, <sup>2</sup>Biochemistry & Molecular Biology and <sup>3</sup>Developmental Neurobiology, UMDS, London, UK.

GABA $_A$ -receptor mediated modulation of axonal conduction and astrocytic depolarization have been shown in the developing rat optic nerve, and both responses attenuated with age. The present study addresses the question of the site of GABA action. The effect of GABA (1mM) on  $[K^+]_o$  was measured using single-barrelled  $K^+$ -selective microelectrodes in isolated optic nerves from rats aged P1-P21. In nerves enucleated at P1 or P2, which contained astrocytes and degenerating axons, there was only a small GABA mediated increase in  $[K^+]_o$  of  $0.8 \pm 0.2$  mM (mean  $\pm$  SEM, n=10) one day after enucleation, compared to  $4.8 \pm 1.3$  mM (n=13) in normal nerves of the same age. RT-PCR indicated that in normal P10 optic nerves the mRNA for the  $\alpha$ -2 subunit of the GABA $_A$ -receptor was not expressed. These results suggest the presence of axonal GABA $_A$  receptors which are responsible for the GABA-mediated increase in  $[K^+]_o$ , and subsequent astrocytic depolarization in the neonatal rat optic nerve. Immunocytochemistry has identified astrocytes as the primary source of GABA and RT-PCR has shown that GAT2 and 3 but not GAT1 mRNA are present in normal P10 nerves, suggesting that glial cells in the optic nerve are capable of GABA uptake. Together, these results suggest a role for GABA and  $[K^+]_o$  in axon-glial signalling which may be important in the control of axon-glial interrelationships during development in the rat optic nerve.

## 128.15

VOLTAGE-GATED CURRENTS IN THE GLIAL CELLS ASSOCIATED WITH OLFACTORY GLOMERULI DEVELOPING IN THE ANTENNAL LOBE OF THE MOTH. H.G. Marrero and L.A. Oland\*. ARL Div. of Neurobiology, Univ. of AZ, Tucson, Arizona 85721.

In the developing antennal lobe, glomerulus development is initiated by olfactory receptor axons and proceeds only if glial cells, under the influence of the receptor axons, stabilize the newly forming glomeruli by forming a border around each one. The mechanisms by which the neurons and glial cells communicate and coordinate their roles during glomerulus formation are not known. In this study, we have begun to characterize the voltage-gated currents in glia engaged in the process of border formation. Whole-cell recordings were made from glia in acute slice preparations taken from antennal lobes throughout the period of glomerulus formation. Lucifer Yellow dye was included in the patch pipette to allow morphological verification of glial class and to indicate qualitatively the degree of dye coupling. At early stages, many border glia were dye-coupled to one another and often to antennal-nerve glia; at late stages, however, glia typically were dye-coupled to only a few adjacent border glia. At all stages, all cells showed an outward potassium current that could be blocked partially with external 4-AP and blocked, in some cases completely, by internal TEA. Blockade of the outward current unmasked a TTX-sensitive inward current with a slow rise time in glia at early stages of development and a faster rise time in glia from late stages. As early as stage 5, at the onset of glomerulus formation, extracellular stimulation of either the olfactory receptor axons in the antenna or one of the clusters of cell bodies of antennal-lobe neurons, elicited a relatively long-lasting (5-10 sec) depolarization in the glia. The observed developmental differences in coupling and in current profile provide the basis for exploring mechanisms of neuron-glia interaction in the formation of glomeruli. Supported by NIH grant NS28495.

## 128.17

AN EXTRACELLULAR SIGNALLING COMPONENT IN PROPAGATING ASTROCYTIC CALCIUM WAVES. T.D. Hassinger\*, P.B. Guthrie, P.B. Atkinson, M.V.L. Bennett, and S.B. Kater. Department of Neurobiology and Anatomy, University of Utah, Salt Lake City, UT 84132; Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Focally evoked astrocytic calcium waves are thought to propagate by gap-junction-mediated intercellular passage of chemical signal(s). In contrast to this idea we have observed isolated astrocytes, which had no physical contact with other astrocytes in the culture, participating in a calcium wave. This observation suggests a previously unrecognized extracellular route of astrocyte signalling.

To test for extracellular signalling we made artificial gaps 10-300  $\mu\text{m}$  wide in confluent cultures by deleting a row of astrocytes with a glass pipet. Cultures were allowed to recover for 4-8 hrs before use at which time regions of confluent astrocytes separated by lanes devoid of cellular material were easily located. Electrical stimulation (17Hz for 2 sec.) by a fine bore extracellular pipet was used to initiate astrocytic calcium waves.

Figure shows results of one experiment. Filled cells indicate all cells participating in the astrocytic calcium wave.

Waves initiated by electrical stimulation crossed the artificially created gaps in 12 of 35 cases. Signaling was most often seen with gaps of less than 50  $\mu\text{m}$  and was not observed crossing gaps greater than 100  $\mu\text{m}$ . An extracellular signalling path is also supported by the finding that focal superfusion severely decreased the spread of the calcium waves.

Therefore, in addition to gap junctions mediating astrocyte-astrocyte communication, extracellular signals can also play a role.

Supported by Development funds from the Uni. of Utah and NRS #NS09767.

## 128.19

LOCAL CHANGES IN  $[\text{K}^+]_i$  ELICIT INWARD AND OUTWARD CURRENTS FROM THE SOMA AND ENDOFOOT OF MÜLLER (GLIAL) CELLS ISOLATED FROM THE FROG RETINA. S. N. Skatchkov, J. Krüšek and R.K. Orkand\* Inst. of Neurobiology, Univ. of Puerto Rico MSC, San Juan, PR 00901

Müller cells are glial cells that traverse the retina. They have an asymmetric distribution of  $\text{K}^+$  channels and function to equalize  $\text{K}^+$  gradients (Karwowski et al., Science 244:578 1989). Such a function requires these cells to carry  $\text{K}^+$  inward ( $I_{\text{KIN}}$ ) in regions where  $[\text{K}^+]_o$  is raised and outward ( $I_{\text{KO}}$ ) at more distant regions. We have used local changes in  $[\text{K}^+]_o$  (from 3 mM to 1 or 10 mM), to elicit currents from Müller cells with either the endfoot or soma of the cell voltage clamped using the whole-cell variation of the patch-clamp technique. Two populations of cells were obtained by enzymatic dissociation from the retinas of adult frogs (*Rana pipiens*). Long cells, > 100  $\mu\text{m}$ , were obtained from the central portion of the retina whereas short cells, < 50  $\mu\text{m}$  were obtained from the peripheral retina. Membrane currents were elicited by local perfusion with different  $[\text{K}^+]_o$  from a fine theta pipette. In long cells,  $I_{\text{KIN}}/I_{\text{KO}}$  was 4.5 ( $\pm 0.5$  SE,  $n=11$ ) at the endfoot and 1.8 ( $\pm 0.2$  SE,  $n=10$ ) at the soma. In short cells the ratio was 6.1 ( $\pm 0.2$  SE,  $n=5$ ) at the endfoot and 3.0 ( $\pm 0.4$  SE,  $n=5$ ) in the soma. In contrast to the short cells, where currents readily spread from endfoot to soma, in long cells the soma and endfoot appeared to be electrically isolated.

The results indicate that there is less inward rectification of  $\text{K}^+$  channels in the soma than in the endfoot. In addition, it appears that spatial buffer  $\text{K}^+$  currents can equalize  $[\text{K}^+]_o$  only over local regions of the central retina whereas in the periphery these currents can equalize  $[\text{K}^+]_o$  over the entire thickness of the retina.

## 128.16

WHOLE CELL RECORDING FROM HIPPOCAMPAL ASTROCYTES DURING ORTHODROMIC STIMULATION. R. D'Ambrosio\*, G.M. McKhann and D. Janigro. Dept. of Neurosurgery, Univ. of Washington, Seattle, WA 98104

The application of the voltage-dependent ion channel blocker cesium ( $\text{Cs}^+$ ) to rat hippocampal slices causes synchronous interictal-like bursting and prevents the maintenance of synaptic long-term depression (LTD).  $\text{Cs}^+$  also potentiates epileptiform activity in neocortical slices treated with bicuculline and induces short-term potentiation. Since  $\text{Cs}^+$  is known to block both neuronal  $I_h$  and glial potassium channels, we performed experiments designed to dissect out the relative contribution of glia in  $\text{Cs}^+$ -mediated epileptogenesis and reversal of LTD. Field and whole cell patch clamp recordings from glial cells were performed in the CA1 region of hippocampal slices during low-frequency orthodromic stimulation to induce LTD. During LTD induction (1 Hz, 15 min), a biphasic depolarization of glia followed by a return to pre-LTD was observed. Cesium (3 mM) decreased the early depolarization and prevented the following hyperpolarization consistent with a blockade of potassium uptake into glia.  $\text{Cs}^+$  prevents glial uptake of potassium through voltage-activated astrocytic channels, thus causing an abnormal  $[\text{K}]_o$  increase and depolarization of surrounding neurons during low-frequency activation. This depolarization may influence the maintenance of LTD by simultaneous induction of long-term potentiation resulting from pre- and post-synaptic depolarizations mediated by  $[\text{K}]_o$ . Supported by NIH 51614 and NIEHS 07033

## 128.18

THE FREQUENCY OF  $[\text{Ca}^{2+}]_i$  OSCILLATIONS IN CORTICAL AND HIPPOCAMPAL ASTROCYTES IS MODULATED BY NEURONAL ACTIVITY. L. Pasti, G. Carmignoto, P. Giusti\* and T. Pozzan. Dept. of Biomedical Sciences, University of Padova, 35127 Padova, Italy.

Astrocytes in culture respond to the excitatory neurotransmitter glutamate with regular  $[\text{Ca}^{2+}]_i$  oscillations. We previously reported that astrocytes also display long lasting changes in their oscillatory response upon repetitive activation of the metabotropic glutamate receptor (mGluR). In the present study we investigated whether the stimulation of mGluRs induce a change in the  $[\text{Ca}^{2+}]_i$  of visual cortical and hippocampal astrocytes in brain slices. Slices (100-150  $\mu\text{m}$ ) from 5-22 day old rats, were loaded with the fluorescent calcium indicator Indo-1 and the change of  $[\text{Ca}^{2+}]_i$  analyzed by a real time confocal microscope (Nikon). Similarly to cultured astrocytes, the frequency of oscillations increased upon repetitive activation of mGluRs by *t*-ACPD (5-30  $\mu\text{M}$ ) ( $0.75 \pm 0.04$  and  $1.38 \pm 0.01$  peaks/min at the 1st and 3rd stimulation, respectively; mean change  $102 \pm 18\%$ ;  $p > 0.001$ ;  $n = 52$ ). Electrical stimulation of presynaptic afferents at 0.2 Hz (100-200 msec train at 20-50 Hz; 100 pA) evoked  $[\text{Ca}^{2+}]_i$  oscillations in astrocytes surrounding stimulated neurons. When the firing of presynaptic afferents was increased by changing either frequency or intensity of the electrical stimulus, the frequency of astrocytes  $[\text{Ca}^{2+}]_i$  oscillations also increased. Neuronal stimulation induced oscillatory  $[\text{Ca}^{2+}]_i$  elevations also at discrete loci along the astrocyte process. These  $\text{Ca}^{2+}$  hot spots were not synchronized indicating that each of them represent an independent compartment of  $\text{Ca}^{2+}$  signaling perhaps in close association with the synaptic cleft. The application of TTX (1-5  $\mu\text{M}$ ) abolished the  $[\text{Ca}^{2+}]_i$  in both neurons and astrocytes. Astrocytes are, therefore, sensitive to glutamate released by synaptic activity, in particular at discrete sites along their processes, and display the same long-lasting changes in the oscillatory response originally observed in culture. Grants from CNR "Biotechnology" and Thelathon Italy.

## 129.1

**IN VITRO ANALYSIS OF GLYCINERGIC NEURON SURVIVAL IN THE POSTNATAL AUDITORY CNS: DEPENDENCE ON TARGET.** L. Guo and D. H. Sanes\*, Center for Neural Science, New York University, New York, NY 10003.

The regeneration of axonal projections depends critically on the ability of their cell bodies to survive axotomy. We investigated the survival of glycinergic medial nucleus of trapezoid body (MNTB) neurons, and the effect of transecting its projection to the lateral superior olive (LSO), using an organotypic culture preparation. Tissue slices were obtained from postnatal (P) day 12 gerbils, and cultured in serum-containing media for 6 days. Control slices exhibited robust survival of MNTB and LSO neurons, as assessed with immunocytochemical staining for Parvalbumin and GAP-43. In addition, a profuse MNTB projection to LSO was visualized in dextran-conjugated biotin labeled slices. When the MNTB was cultured in isolation, the number of Parvalbumin-positive cell bodies was severely decreased, suggesting MNTB cell death. There was also little evidence of neuron survival when the transected MNTB was grown adjacent to the LSO. In a few slices, MNTB neuron survival occurred in the presence of another target, the superior paraolivary nucleus (SPN). The apparent MNTB cell death was not prevented by growing the cultures in glutamate receptor antagonists (100  $\mu$ M AP-5 and CNQX) or brain-derived neurotrophic factor (BDNF, 40 ng/ml) and basic fibroblast growth factor (bFGF, 20 ng/ml). In contrast, LSO neurons did survive after transection of their axons, as well as the MNTB afferent projection, as assessed with GAP-43 immunocytochemistry. Taken together, these findings suggest that MNTB neuron survival is compromised when deprived of their targets, but LSO neurons do not appear to require afferent or efferent projections. (Supported by NIH and NSF.)

## 129.3

**PROTEIN KINASES CONTRIBUTE TO THE EXPERIENCE-DEPENDENT FORMATION OF THE AUDITORY SPACE MAP IN THE GUINEA-PIG SUPERIOR COLLICULUS.** D. McCrossan, B. Platt\* and D.J. Withington, Department of Physiology, University of Leeds, UK.

The maturation of the map auditory space in the superior colliculus (SC) occurs in an activity-dependent manner that involves NMDA receptors. The formation of the auditory map occurs relatively late during development and requires auditory, visual and somatosensory experience. Spatially coincident activation of collicular loci, by more than one modality, is thought to be pivotal to the establishment of spatially tuned auditory responses.

Protein kinases (PKs) have been shown to be involved in modifications of synaptic efficacy and are, therefore, thought to play a key role in neuronal plasticity. The aim of the present study was to investigate whether PKs are important during the naturally occurring plasticity observed in the SC. Elvax polymer, containing the general PK inhibitor, K252a, was surgically implanted onto the SC, prior to normal auditory map emergence in one group of animals and in a second, at an age when the SC map is no longer disrupted by visual deprivation. Following a recovery period, the guinea-pigs were re-anaesthetised and the SC probed for auditory responses. Normalised polar plots were derived from the neuronal responses and indices of spatial tuning were determined. The tuning parameter values obtained from guinea-pigs implanted prior to normal map emergence were significantly greater than those obtained from control (implant prepared using water), and there was no correlation between the peak angle of each auditory response and the collicular position of the recording electrode. In contrast, the SC auditory responses obtained from the older guinea-pigs demonstrated a normal representation of auditory space. The present findings indicate that PKs are vital for the neuronal modifications underlying the formation of spatially tuned auditory responses in the guinea-pig SC. In contrast, the maintenance of the SC auditory space map is not susceptible to such an insult.

**GLUTAMATE, GABA AND MUSCARINIC RECEPTORS ARE INVOLVED IN THE DEVELOPMENT OF THE AUDITORY SPACE MAP IN THE MAMMALIAN SUPERIOR COLLICULUS**

N.J. Ingham, D.J. Withington\*, S.K. Thornton & D. McCrossan, Dept. of Physiology, Univ. of Leeds, LS2 9NQ, UK.

The auditory space map in the guinea pig superior colliculus (SC) is a complex neural representation of the auditory field surrounding the animal, which is highly dependent on correct sensory experience during its post-natal development. As a start point for investigations into the cellular developmental processes involved with auditory space map emergence, the slow-release polymer Elvax was used to deliver various neurotransmitter antagonists to the SC for long periods, either during the post-natal development of the map, or in the adult animal, when the map is no longer susceptible to visual deprivation.

During early development, exposure of the SC to either AP5 (NMDA-type glutamate receptor antagonist), CNQX (non-NMDA-type glutamate receptor antagonist), or atropine (muscarinic ACh receptor antagonist) produced complete disruption of auditory spatial tuning in the deep layers of the SC, as seen using multi-unit recordings to free-field broad band noise stimuli. Blockade of GABA<sub>A</sub> and GABA<sub>B</sub> receptors (using bicuculline and hydroxysaclofen) produced partial disruption with responses exhibiting some topographical organisation. Blockade of NMDA receptors in the adult animal also produced severe disruption of the auditory space map. These results indicate that normal neurotransmission involving glutamate, ACh and GABA in the SC is required for development of a normal map of auditory space. The disruption produced by AP5 in older animal indicates that the guinea pig SC retains the ability to undergo plastic reorganisation in the adult.

**POSTNATAL DEVELOPMENT OF GABAERGIC AND GLYCINERGIC SYSTEMS IN THE AUDITORY PATHWAY OF THE RAT.** C. De Cabo De La Vega\*, M.L. Campos and J.M. Juiz, Instituto de Neurociencias, Campus de San Juan, Univ. Of Alicante, E-03080 Alicante, Spain.

Previous work has provided a detailed description of the distribution of both  $\gamma$ -aminobutyric acid (GABA)- and glycine- immunoreactivity (IR) in the adult mammalian auditory pathway. However, very little is known about the postnatal development of these two inhibitory neurotransmitters in the auditory pathway. We are currently investigating the development of GABAergic and glycinergic neuronal systems in auditory nuclei throughout postnatal maturation in the rat. Here we report data regarding the development of GABA and glycine-IR neurons in the inferior colliculus (IC). Neonatal pups were perfused with a fixative containing paraformaldehyde and glutaraldehyde. 50  $\mu$ m thick serial sections were cut with a Vibratome. Sections were incubated in anti- GABA and -glycine antibodies and processed using either the ABC method or immunofluorescence with cyanine labeled secondary antibodies. Our results show that GABA-like IR is already present in the IC at P0 in neuronal bodies and in a few fiber systems. GABA-IR neurons and fibers increase during the first week reaching a peak between P3 and P5, with an apparent decrease at P7. The number of GABA-IR cell bodies and terminals in the neonatal IC seems higher than in the adult. Glycine-IR fibers are also present in the IC at P0 and increase steadily until P7. Although glycine immunoreactive cell bodies can not be observed at P0, a few very weakly labeled cell bodies are seen at later ages. These data suggest a differential development of the GABA and glycine neurons in the auditory midbrain during the first postnatal week. Supported by Grants from the Spanish Government DGICYT PB93/0931 and FIS 95/1672 to JMJ.

## 129.4

**IMPROVEMENT IN AUDITORY SPATIAL ACUITY FOLLOWING EARLY VISUAL DEPRIVATION IN FERRETS.** A. J. King\* and D. J. Semple, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, UK.

Early loss of vision has been reported to lead to intermodal changes that are generally regarded as compensatory in nature. However, studies of the effects of blindness on auditory localization behaviour have produced conflicting results. We have examined the effects on auditory spatial acuity of depriving ferrets, either in infancy or adulthood, of patterned visual cues by binocular eyelid suture.

The animals were trained using a positive conditioning procedure to discriminate broadband noise bursts from two loudspeakers that were separated by various angles on the horizon. All animals achieved scores of more than 90% correct following a similar period of training. The minimum audible difference in speaker separation was measured for 500, 100 and 40 ms digitally-matched noise bursts at the midline and around 45° left and right. The ferrets that had been visually deprived since birth achieved significantly better scores in the lateral field, but not at the midline, than the normal-sighted controls. The lateral-field minimum audible angles attained by adult ferrets that were lid sutured 4-7 months before testing were not significantly different from either of the other groups, suggesting that their performance was intermediate between the normal and neonatally-deprived ferrets.

These data suggest that visual deprivation throughout life leads to an improvement in auditory spatial acuity, at least for lateral positions where localization accuracy is inferior to that at the midline, and that a more limited capacity for compensatory changes may persist into adulthood.

## 129.6

**HAIR CELL REGENERATION IN THE CHICK AUDITORY EPITHELIUM IS MEDIATED BY cAMP AND PKA.** D.S. Navaratnam, H. Su, T. Bell, D. Kay, J.C. Oberholzer\*, Dept. of Path., Univ. of Penna. Sch. of Med., Phila., PA 19104.

Hair cells are the primary transducers of sound. These cells along with the surrounding supporting cells are the principal cells found in the auditory receptor epithelium. Hair cells are lost with increasing age, and as a result of insult brought about by exposure to intense sound or treatment with high doses of aminoglycoside antibiotics. That hair cells in vertebrates can be replaced in the adult animal has been a recent observation. However, the exact mechanisms that bring about regeneration in the auditory receptor epithelium remain indeterminate. Using explanted chick cochleas, we demonstrate here that pharmacological agents (forskolin, 8 Br-cAMP) that increase levels of cAMP cause proliferation in the undamaged chick auditory receptor epithelium. The proliferative response was measured by the incorporation of the S phase markers BrdU and <sup>3</sup>H-thymidine into the nuclei of cells. These markers were incorporated into both hair cell and supporting cell nuclei. This proliferative response was significantly reduced when the cells were pre-treated with inhibitors of protein kinase A before forskolin treatment. Furthermore, treatment with PKA inhibitors significantly reduced the proliferative response that follows damage to hair cells brought about by gentamicin, indicating that the cAMP-PKA pathway was also operational in this paradigm. The proliferative response to forskolin in the undamaged epithelium required serum, although serum alone could not induce cell division. Neither EGF, PDGF or insulin were able to supplant the permissive effect of serum. In a related observation, it was found that nuclei incorporating BrdU in response to forskolin treatment were clustered within the epithelium suggesting that these were clonal and possibly derived from a subpopulation of stem cells. In conclusion, the ability of agents which increase cAMP to induce proliferation in the normally-quiescent undamaged epithelium suggests approaches to the therapeutic stimulation of hair cell growth. Such approaches will depend upon the existence of a similar mechanism in the mammalian cochlea. (Supported by grants from the NIH & the PA. Lions Hearing Res. Fdn.)

## 129.7

PROGRAMMED CELL DEATH IS INVOLVED IN PATTERNING THE SENSORY EPITHELIUM OF THE CHICKEN EAR. **A.E. Riedl, D.A. Cotanche and D.M. Fekete\*** + Dept. of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA 02118; +Dept. of Biology, Boston College, Chestnut Hill, MA 02167.

The mature epithelium of the chicken basilar papilla (BP) is distinguished by a precise pattern of hair cells and their underlying supporting cells. These cells arise from common progenitor cells (Muthukumar and Fekete, Soc. Neurosci. Abstr. 20: 1079, 1994), although the mechanism by which their fates are determined is not known. It is also not known how the cell patterns are established, although it has been suggested that lateral inhibition is involved.

We propose that programmed cell death (PCD) plays a role in the formation of the highly organized pattern of hair cells and supporting cells in the chick sensory epithelium. We are testing this hypothesis by eliminating PCD in embryonic chicken ears and observing the effects on patterning in the BP. This is accomplished by retrovirus-mediated overexpression of human bcl-2, a gene that inhibits PCD in a variety of systems.

By the third embryonic day (E3) the presumptive ear has pinched off of the surface epithelium and formed a fluid-filled sac called the otocyst. The right otocysts of E4 embryos were injected with RCASBP(B)/bcl-2; a replication-competent retrovirus containing the human bcl-2 gene. On day E12-E19, the injected embryos were sacrificed and fixed. The cochlear duct was carefully removed and prepared for scanning electron microscopy. Many of the RCASBP(B)/bcl-2 injected ears showed a strong, localized phenotype, in which patches of cells, including hair cells, were being extruded from the epithelium. Control ears, which were either not injected or were injected with the parent retrovirus RCASBP(B), did not show this phenotype. Our interpretation of these results is that PCD is required for normal patterning of the chick sensory epithelium.

## 129.9

RECOVERY OF THE CHICKEN VESTIBULOCOLIC REFLEX FOLLOWING AMINOGLYCOSIDE OTOTOXICITY. **C.T. Goode, J.P. Carey, A.F. Fuchs\*** and E.W. Rubel. Regional Primate Center and Dept. of Physiology and Biophysics and Virginia Merrill Bloedel Hearing Research Center, University of Washington, Seattle, WA 98195

In birds, auditory and vestibular hair cells regenerate after damage by injury or treatment with ototoxic aminoglycoside antibiotics. Several studies have demonstrated that these regenerated auditory hair cells function normally in terms of evoked auditory potentials and behavioral detection thresholds. Recently it has been shown that the loss of vestibular hair cells following streptomycin treatment is accompanied by a substantial reduction in gain of the vestibuloocular reflex (VOR). The VOR returns to normal levels as vestibular hair cells regenerate over a period of several weeks. We examined another indicator of regenerated vestibular hair cell function, the horizontal vestibulocolic reflex (VCR), which produces head movements that compensate for rotational body motion. We treated young chickens with high doses of streptomycin and measured VCR gain at intervals after treatment. Some subjects were sacrificed at each interval to assess the degree of hair cell regeneration by means of electron and light microscopy. We report that both hair cell loss and the regeneration are reflected in the gain of the VCR and that the reflex recovers before regenerated Type I hair cells are present. We also show that VCR gain is correlated with hair cell density. Moreover, the time course of recovery of the VCR parallels that of the VOR.

## 129.11

DOES REARRANGEMENT OCCUR IN THE PERIPHERAL RAT TASTE SYSTEM DURING DEVELOPMENT? **Robin F. Krimm\*** and David L. Hill. University of Virginia, Charlottesville, VA 22903

Frequently during development, the morphology and function of a peripheral target becomes coordinated with its innervation. For example, we have demonstrated that the number of geniculate ganglion cells innervating a taste bud in adult rats is positively correlated with the size of the taste bud. Furthermore, this relationship is not established until postnatal day 40 indicating that it develops over a prolonged postnatal period. It is possible that rearrangement in peripheral innervation during development establishes the adult relationship. The present study was designed to test this hypothesis by determining whether the same geniculate ganglion cells innervate a taste bud on postnatal day 10 and 40. Individual fungiform papillae containing single taste buds were injected with a fluorescent tracer (true blue) on postnatal day 10 and a different fluorescent tracer (tetramethylrhodamine dextran) on postnatal days 15, 20 and 40. Preliminary results indicate that 90% of the geniculate ganglion cells labeled on postnatal day 10 were also labeled on postnatal day 40. Similarly, 73% and 81% of the geniculate ganglion cells labeled on day 10 were labeled on day 15 and 20, respectively. Therefore, it appears that individual taste buds remain innervated by the same geniculate ganglion cells during postnatal development. Thus, it is unlikely that rearrangement of peripheral innervation is responsible for the development of the correlation between taste bud size and number of innervating fibers. Supported by NIH Training Grant HD07323 and NIH DC 00407.

## 129.8

A GENETIC SCREEN IN ZEBRAFISH FOR MUTATIONS THAT AFFECT HAIR CELLS IN THE EAR AND LATERAL LINE. **R. Kollmar\*, J. M. Fadool<sup>2</sup>, J. E. Dowling<sup>2</sup>, and A. J. Hudspeth<sup>1</sup>**. <sup>1</sup>Howard Hughes Medical Inst. and Lab. of Sensory Neuroscience, Rockefeller Univ., New York, NY 10021-6399; <sup>2</sup>Dept. of Molecular and Cellular Biology, Harvard Univ., Cambridge, MA 02138.

Hair cells, the sensory cells of the vertebrate auditory and vestibular systems, can detect motions of atomic dimensions, respond more than 100,000 times a second, and discriminate frequencies differing by only a few percent. These remarkable properties depend on precisely engineered cellular structures, such as the mechanosensitive hair bundle at the apex and fast synapses at the base.

Because intact single cells are easily isolated from their internal ears, the biophysical properties of hair cells have largely been characterized in frog and turtle. Similarly, the morphogenesis of the hair bundle has been described in the easily accessible chicken embryo. Identification of the hair cell's molecular components, however, has been hampered by the small number of cells per animal.

To investigate the development and regulation of hair-cell function, we are taking a genetic approach using the zebrafish, *Danio rerio*. We have developed a morphological assay that utilizes the specific staining of hair cells in the lateral-line organ by styryl-pyridinium dyes and a behavioral assay that exploits the role of hair cells in the fish's escape reflex. We are now conducting a pilot screen for recessive mutations in the F3 progeny of chemically mutagenized fish.

## 129.10

TWO HOMEOBOX-CONTAINING GENES ARE EARLY MARKERS OF SEMICIRCULAR CANALS IN THE CHICKEN INNER EAR. **A.E. Kieman\*, E. Nunes<sup>2</sup>, D.K. Wu<sup>2</sup>, and D.M. Fekete<sup>1</sup>**. <sup>1</sup>Dept. of Biology, Boston College, Chestnut Hill, MA 02167. <sup>2</sup>National Institute on Deafness and Other Communication Disorders, Rockville, MD 20850.

The vertebrate inner ear is an elaborate organ which begins development as a simple ovoid vesicle. Complex morphogenesis results in a labyrinthine morphological structure complete with a cochlea, three semicircular canals (SSCs), and six to eight separate sensory areas necessary for the functions of hearing and balance. Although many genes are expressed in the ear, very little is known about how they may influence pattern formation. Using *in situ* hybridization, we present a detailed expression study of two related homeobox genes, *SOHO-1* and *GH6*. Adjacent sections were hybridized for direct comparisons. Results showed that their expression domains were identical although *GH6* was present at a lower level. Both genes were detected early, in the posteroventral and lateral portion of the otic cup. As the ear developed, the expression was associated with the SSCs in the lateral half of the otocyst. The SSCs consist of both nonsensory canals and associated sensory organs (cristae). We asked whether the cristae were included in the *SOHO-1/IGH6* expression domain by using *BMP-4* as a marker for sensory areas. Results of these experiments showed that *SOHO-1* and *BMP-4* expression overlapped in the presumptive cristae at E3.5. At later time points (E5) *SOHO-1* message is no longer detectable in the developing cristae, indicating that these genes are likely not to be involved in later sensory organ differentiation. These data are consistent with early fate mapping experiments in which the lateral half of the otocyst—the region of *SOHO-1* and *GH6* expression—was shown to give rise to all three semicircular canals and their respective cristae (J. Morph., (1978) 157: 249-268). A boundary model is proposed for cell fate specification in the early otocyst, which includes a possible role for *GH6* and *SOHO-1* in SSC formation. ## 129.12

MAMMALIAN TASTE BUDS DEVELOP INDEPENDENT OF THEIR SPECIFIC INNERVATION. **P.S. Sarai\*, B. Fritzsche\*, I. Silos-Santiago\*, M. Barbacid\*, D.H. Nichols\***. <sup>1</sup>Creighton University School of Medicine, Omaha, Nebraska, <sup>2</sup>B.M.S., Princeton, New Jersey.

The purpose of this study is to show that fungiform papilla taste bud formation occurs independent of gustatory innervation in embryonic mice. Such taste buds express neurotrophin BDNF mRNA and the gustatory geniculate ganglion neurons innervating them express the corresponding tyrosine kinase B (*trkB*) receptor mRNA. Gustatory neurons lacking this receptor would thus lack their only known trophic support. Here we show that in experimental mice with a targeted disruption of their *trkB* genes, there is an almost complete loss of geniculate ganglion neurons and that their afferent gustatory fibers never reach the fungiform taste buds. Degeneration of some geniculate ganglion cells begins while others are still mitotic and a decline to 10% of control numbers is reached by 13.5 days post coitum (dpc). At birth this number has declined further to 5% and the chorda tympani shows an appropriate decrease in fiber number. The remaining cells in experimental ganglia are general somatic neurons innervating the external auditory meatus. The remaining fibers in the experimental nerves are preganglionic parasympathetic axons. Taste bud formation in experimental and control mice ranging from 13.5 dpc to 16 days postnatal (dpn) show that the onset of fungiform papilla differentiation, including taste bud formation, is, in most respects, identical. However, by 16 dpn experimental taste buds appeared less well organized than controls. Thus, innervation is not necessary to initiate taste bud formation, but may be required to complete maturation.

## 129.13

**ACTIVITY-DEPENDENT INCREASES IN DOPAMINE AND DOPAC IN THE OLFACTORY BULBS OF NARIS OCCLUDED RATS.** B.D. Philpot, D. Men, R. McCarty, and P.C. Brunjes. Dept. of Psychology, University of Virginia, Charlottesville, VA 22903.

Rodent olfactory bulbs contain numerous dopaminergic interneurons, known as periglomerular cells. Both dopamine and its metabolite, DOPAC, are dramatically reduced in these cells following either naris closure or deafferentation (Baker et al., J Neurosci, 3, '83; Baker et al., Brain Res, 10, '93). These studies collectively suggest that olfactory receptor neuron activation of periglomerular cells is necessary for dopamine production. We directly tested this hypothesis. On postnatal day 30, an external naris was closed via cautery. Thirty days later, rats were anesthetized and experimental bulbs (ipsilateral to closed nares) were carefully exposed. A bipolar stimulating electrode (~500µm tip separation) was placed on the olfactory nerve layer, and stimulus trains (100 ms, 500µA, 100Hz) were delivered every second for an hour. Sham animals received the same procedure but without current application. Animals were rapidly decapitated 6, 12, 24, 48, or 96 hours after surgery, and their brains were removed and frozen in isopentane. Olfactory bulb homogenates were prepared in perchloric acid and assessed for protein levels using the Lowry method. Catecholamine levels were determined using high performance liquid chromatography after alumina extraction from the perchloric acid supernatant. In animals receiving sham surgery, there was ~60% less dopamine and ~70% less DOPAC in deprived bulbs as compared to their contralateral control. Norepinephrine levels were similar between bulbs. Partial recovery of dopamine and DOPAC levels was observed between 48 and 96 hours following nerve stimulation. Ninety-six hours after stimulation, the difference between control and experimental bulbs for dopamine and DOPAC levels was reduced to only ~25% and ~35%, respectively. Thus, direct olfactory nerve activity transynaptically regulates dopamine in the bulb.

## 129.15

**PRE- AND POSTNATAL DEVELOPMENT IN THE RAT AUTONOMIC BRAINSTEM: CHANGES IN NEUROPEPTIDE-EXPRESSION AT BIRTH.** H.-J. Rietzel, E. Guenther\*, & H. Herbert\*. Dept. Animal Physiol., Univ. Tübingen, \*Dept. Exp. Ophthalmology, Univ. Eye Hospital, Tübingen, Germany.

Birth represents a time point where dramatic changes occur with respect to the control of various autonomic functions. To find out, if the changes in function involve modifications in the respective autonomic nuclei in the CNS we investigated the expression of neurotensin (NT), substance P (SP), leu-enkephalin (ENK), vasointestinal polypeptide (VIP), neuropeptide Y (NPY), angiotensin II (ANG) and dynorphin B (DYN) by employing immunocytochemical techniques. In the present study we concentrated on the nucleus of the solitary tract (NTS) and the parabrachial complex (PB), both are important nuclei in the central autonomic network controlling a variety of visceral, cardiovascular and respiratory functions. To study the pre- and postnatal development of these neuropeptides, we investigated brains from rats at embryonic day 18 (E18), E20, E21, postnatal days 0 (P0 = E22), P2, P4, P5, P8, P12, P20, P28 and brains from adults.

Our results demonstrate that in the NTS and in the PB neuropeptides are differentially expressed during pre- and postnatal development. For example, in the PB we observed at birth a strong increase in SOM-, ENK-, ANG- and SP-ir, reaching their maxima around P5. Thereafter, the staining became weaker but persisted into adulthood. For DYN-ir, moderate staining was present at E20 but the staining intensity did not show any dramatic changes during ontogeny. In contrast, NT-ir was most prominent already before birth (E20) and started to decrease after P5. In the NTS these neuropeptides show also distinct patterns of expression during development. The present study revealed that at birth dramatic changes occur in the PB and NTS with respect to the expression of specific neuropeptides. It is most likely that these peptides play crucial roles in the development of autonomic brainstem circuits which control autonomic functions immediately after birth.

## 129.14

**ALTERATIONS OF NEST ODOR PERCEPTION IN NEONATAL RAT AFTER CAPSAICIN TREATMENT.** Carrillo, P., \* López, G., Camacho, M., García, L., Manzo, J. and Pacheco, P. Lab. de Neurobiología del desarrollo, INE., Univ. Veracruzana, Xalapa, Ver. Depto. de Fisiología, IIBM-UNAM., México, D.F.

Trigeminal sensory receptors associated with odor perception are affected after neonatal Capsaicin (CAP) treatment, however, still is uncertain if CAP administration certainly produces alteration in the olfactory function. Thus, the present study was done in pups of Wistar rats (housed in inverted light-dark cycles 8:00-20:00), in order to analyze its odor orientation tests, after the sc injection of 50 mg/kg bw of CAP. Both, the experimental (CG) and control (VG) (vehicle solution) groups were injected at 2 day of life (day of Birth = Day 0). From 3 to 9 days of age two behavioral tests were done twice a day (9:00 and 17:00 h). The set designed for the tests included a plastic mesh arena that covered two separated wood shaving beds, one from the nest (ON) and the other from fresh wood shaving (OF). This design prevented physical contact between pups and bed, but permitted sniff the shavings. At the beginning of first behavioral test the pup was located on the upper border of the arena and in the second test it was placed at the inferior border. Once started, pups were allowed for 150 sec to move freely over beds. The time on and out beds area was scored. RESULTS. During tests performed at 9:00 h, CG pups expended less time over ON than VG (p<0.005). During the first week of life, VG increases their time over ON, then this time declined. In contrast CG pups did not present this time declination. The tests performed at 17:00 h showed that VG and CG did not present time oscillations on the ON bed. Again as in tests performed at 9:00 h, CG pups expend less time over ON than VG (p<0.005). With this results we can conclude that Cap neonatally injected produce an alteration in the olfactory perception of nest odor. (CONACYT PCC-92264)

## 129.16

**INGROWTH OF MALE-SPECIFIC SENSORY AXONS INITIATES THE FORMATION OF PHEROMONE-SPECIFIC OLFACTORY GLOMERULI IN MANDUCA SEXTA.** W. Roessler\*, L.P. Tolbert, J.G. Hildebrand. ARL Div. of Neurobiology, University of Arizona, Tucson, AZ 85721.

Previous studies have shown that the construction of olfactory glomeruli in the antennal lobes (ALs) of the moth *Manduca sexta* depends upon the ingrowth of antennal sensory axons. To gain a more precise understanding of the formation of individual glomeruli with known odor specificity, we investigated the morphogenesis of the male-specific macroglomerular complex (MGC). It has been shown that an antennal nerve from a transplanted male antenna can induce an MGC-like structure in the AL of a host female's brain (Schneiderman et al. 1982, *Nature* 298:844). To understand this powerful role of male-specific axons, we compared the development of ALs of males and of female gynandromorphs by means of extra- and intracellular staining techniques and laser-scanning confocal microscopy. The MGC is located at the entrance of the AL and comprises 3 subdivisions, the globular cumulus and two toroidal glomeruli. Formation of the MGC in male ALs begins at the same time as the formation of the earliest "ordinary" glomeruli in female ALs. As soon as sensory axons and dendrites of projection neurons (PNs, with somata in the medial group of AL neurons) overlap at the entrance of the antennal nerve, glial cells outline a bulging structure and extend processes into this region. The glial cells migrate to form a complete matrix around the subdivisions of the emerging MGC, and processes of sensory axons and PNs become subdivided into 3 compartments within 2 days. Early development in female gynandromorphs shows very similar changes in glial cells and in the projection pattern of neurons. A significant portion of female gynandromorphs develops an MGC with 3 subdivisions. Our results indicate that axons of olfactory receptor cells with a specificity for female pheromone initiate a complex sequence of interactions with glial cells and PNs of either gender that determines the formation of an anatomically and physiologically identified set of glomeruli. ## REGENERATION AND DEGENERATION

## 130.1

**GELATINASE ACTIVITY IS INCREASED IN AXOTOMIZED PERIPHERAL NERVE OF ADULT RAT.** J.S. Bains, C.A. Krekoski, K.R. Chapman, D.R. Edwards, A.W. Clark\*. Department of Pathology and Neuroscience Research Group and the Department of Pharmacology and Therapeutics, University of Calgary, Alberta, T2N 4N1 Canada

Matrix metalloproteinases (MMPs) are enzymes which degrade certain extracellular matrix proteins and thus facilitate extension and growth of cells through an extracellular environment. The gelatinase subgroup of MMPs includes gelatinase A (72 kDa, MMP-2) and gelatinase B (92 kDa, MMP-9), which act upon certain collagens, gelatins, and fibronectin. In regenerating peripheral nerve, neurites extend through the distal segment, along a path formed by the Schwann cell and its basement membrane. Macrophages and products of increased fibroblast activity also enter the regeneration route. Using gelatin zymography, we assayed activity of gelatinase A and B in adult rat sciatic nerve at 1, 3, 7, 14, 30, and 60 days (3 rats/timepoint) following sciatic nerve crush at midthigh. The contralateral sham-operated and sciatic nerve from unoperated rats served as controls. In unoperated animals, gelatinase A activity was constitutively expressed at moderate levels, whereas gelatinase B activity was trace or undetectable. One day after axotomy, gelatinase B activity was sharply increased at the crush site and extending about one centimeter into the adjacent distal segment; but subsided by three days. Gelatinase A activity also increased post-axotomy, but with a less pronounced and slower rise, subsiding by 30 days; and a wider distribution, beginning at the crush site and extending to the most distal segments and up to one centimeter into the proximal stump. Gelatinase A and B activities in peripheral nerve probably derive from different sources and may serve distinct functions after axotomy, gelatinase B facilitating an earlier phase of regeneration. (University of Calgary grant)

## 130.2

**A RECOMBINANT Fab-FRAGMENT AGAINST MYELIN-ASSOCIATED NEURITE GROWTH INHIBITORS PROMOTES AXONAL REGENERATION OF LESIONED CORTICOSPINAL FIBERS IN ADULT RAT** C. Brösamle, L. Schnell, A. Skerra\*, and M. E. Schwab\*. Brain Research Institute, University of Zurich, Switzerland and \*Department of Biochemistry, Technical University Darmstadt, Germany

Axons in the CNS of higher vertebrates are generally not capable of regeneration after injury. In CNS myelin, growth inhibiting proteins were identified that actively prevent regenerative fiber growth. A monoclonal antibody (IN-1) was raised that neutralizes these myelin-associated growth inhibitors (Schwab and Caroni, 1988) both, in vitro and in vivo thus promoting long-distance growth of axotomized corticospinal fibers in adult rats (Schnell and Schwab, 1990, Bregman et al., 1995). The cDNA of this monoclonal antibody was cloned and a recombinant Fab-fragment expressed in *E. coli*. IN-1 Fab neutralizes the neurite growth inhibiting and growth cone collapse inducing effects of CNS myelin in vitro (Bandtlow et al., 1996).

Young adult rats underwent a laminectomy and dorsal hemisection of the spinal cord at a level of T8. The IN-1 Fab-fragment was delivered via a miniosmotic pump and a catheter into the lateral ventricle. Control animals received unspecific mouse IgG antibodies. The corticospinal tract was traced anterogradely with biotin dextran amine (BDA) and after 2 weeks survival time the animals were perfused and the spinal cord processed for the neuronal tracer. BDA tracing revealed detailed single fiber morphology. In IN-1 Fab fragment treated animals regenerated fibers far distal to the lesion were observed.

Schwab<sup>5</sup> Brain Research Institute, University of Zurich, Switzerland, <sup>1</sup>Nordstadt-Krankenhaus, Hannover, and <sup>2</sup>Technische Hochschule Darmstadt, Germany

We investigated whether axonal regeneration of injured auditory nerve of the adult rat can be promoted by the application of the antibody IN-1, which neutralizes the myelin-associated neurite growth inhibitory proteins. The adult rat auditory (cochlear) nerve is composed almost entirely of CNS glial tissue, and its injury normally leads to complete degeneration of the distal nerve portion, as well as severe loss of primary auditory neurons. Adult Lewis rats underwent crush lesion axotomy of the central auditory nerve at the internal auditory meatus. The lesion completely interrupted the cochlear nerve axons at the lesion site producing ipsilateral deafness in all rats. The animals were infused with a recombinant Fab fragment of the antibody IN-1 for one week via an osmotic pump into the ipsilateral cerebello-pontine angle cisterns. An age-matched control group was treated with unspecific mouse IgG. Cochlear nerve fibers were anterogradely traced by horseradish peroxidase (HRP) or biotinylated dextran amine (BDA) injected into the spiral ganglion. Following a two-days survival time a complete interruption of labelled axons at the lesion site was evident in all animals analyzed. After 9-10 days, untreated rats and rats treated with control antibody showed single axonal sprouts crossing the lesion site in half of the animals, and in 1/5 of the cases labelled axons were observed in the brain stem. In-1 fragment treated rats showed in 2/3 of the cases axons crossing the lesion and reaching the brainstem. In about half of these animals, fibres were seen to branch in the cochlear nuclei in the brainstem. Our results suggest that regenerating fibres navigate to correct targets, and are capable of establishing synaptic connections for functional recovery.

INHIBITION OF AXONAL REGENERATION BY MYELIN INVOLVES A NEURONAL SIALOGLYCOPROTEIN. Maria E. De Bellard, Song Tang, John Rodert and Marie T. Filbin<sup>\*</sup> Biology Dept., Hunter College, CUNY, New York, NY 10021, USA, and <sup>†</sup> Mount Sinai Hospital, Toronto, MSG 1X5, Canada

Central nervous system myelin can inhibit axonal regeneration from adult neurons. Recently, we have shown that myelin associated glycoprotein (MAG), a component of CNS myelin, can inhibit neurite outgrowth when expressed in transfected CHO cells. We also established that MAG binds to a sialoglycoprotein on neurons, and that this interaction is involved in the inhibition of neurite outgrowth. Here we assess if the inhibition of neurite outgrowth by myelin, also involves a neuronal sialoglycoprotein and if MAG is involved in this inhibition. Neonatal cerebellar cells were cultured overnight on 1.5, 3 or 6 µg of freshly prepared myelin, layered onto poly-L-lysine coated wells. Control tissue was freshly prepared membrane from neonatal liver plated at the same concentration. When desialylated neurons were grown on CNS myelin, with sialidase present in the culture media, compared to untreated neurons, a significantly greater number of neurons extended neurites. No such increase was observed with desialylated neurons on liver. Similarly, the presence of sialic acid oligosaccharides in the media increased significantly the number of neurons with neurites when grown on myelin, while neurite outgrowth on control membrane was not affected. To assess if MAG in CNS myelin contributes to the inhibition of neurite outgrowth, neurons were grown on myelin prepared from either MAG knock-out mice, or from control mice. Neurons growing on MAG<sup>-/-</sup> CNS myelin, extended significantly longer neurites compared to neurites from neurons on myelin from control mice. These results suggest that inhibition of axonal regeneration by CNS myelin involves a neuronal sialoglycoprotein and that MAG may be partly responsible for this inhibition. Supported by NMSS RG2760 and AHA.

## 130.7

ONLY MAG OF THE SIALOADHESINS INHIBITS AXONAL REGENERATION S. Tang, Y.J. Shen, M.E. deBellard, G. Mukhopadhyay, P.R. Crocker<sup>§</sup>, P. Doherty<sup>\*\*</sup> and M.T. Filbin<sup>\*</sup> Biology Dept., Hunter College CUNY, New York, 10021, <sup>§</sup>Univ. of Oxford, <sup>\*\*</sup>Guy's Hospital, London.

Myelin associated glycoprotein (MAG) inhibits axonal regeneration from all postnatal cerebellar and adult dorsal root ganglion (DRG) neurons. We have established that MAG binds to neurons via a neuronal sialo-glycoprotein. Together with CD22 and sialoadhesin (SN), MAG forms a sub-group of Ig-like molecules, the sialoadhesins, defined by their sequence similarity and sialic acid-dependent binding: MAG recognizes 2,3 O-linked sialic acid, CD22 recognizes 2,6 N-linked sialic acid and SN recognizes 2,3 N- or O-linked sialic acid. Using chimeric forms of these molecules, consisting of the extracellular domain of each fused to the Fc region of IgG, we studied their binding to neurons. Both MAG-Fc and SN-Fc bound specifically to neurons in a sialic acid-dependent manner, but there was no binding of CD22-Fc. Although SN-Fc binds to neurons, SN-expressing cells do not inhibit axonal regeneration. By aligning the extracellular domain of MAG, SN and CD22, we identified Arg118 of MAG as conserved in the same location in all three family members. Mutation of Arg118 to either Asp or Ala abolished binding of MAG-Fc to neurons. Furthermore, MAG inhibits axonal regeneration when either expressed by transfected cells and used as a substrate or when added to neurons in a soluble form as MAG-Fc, using immobilized LI-Fc as a substrate. However, MAG mutated at Arg118 still inhibits axonal regeneration when expressed by CHO cells but there is no inhibition when added in a soluble form to neurons. Taken together we suggest that, first, the sialic acid-recognition site on MAG is Arg118 and second that, the sialic acid-dependent binding of MAG to neurons is necessary, but is not sufficient, for inhibition of axonal regeneration. Supported by NMSSRG2760 and AHA.

## 130.4

X-RAY THERAPY OF THE LESION SITE IN TRANSECTED SPINAL CORD LEADS TO RECOVERY OF POSTURE AND WEIGHT SUPPORT IN ADULT RAT. N. KALDERON<sup>\*</sup> AND Z. EFKS ROCKEFELLER UNIV. AND MEMORIAL SLOAN-KETTERING CANCER CTR., NEW YORK, NY 10021.

WE FOUND THAT SOME OF THE PATHOLOGICAL CONSEQUENCES OF INJURY TO THE ADULT RAT SPINAL CORD CAN BE PERMANENTLY AVERTED BY ERADICATING CERTAIN CELLS AT THE LESION SITE WITH X-IRRADIATION, PROVIDED IT IS DELIVERED WITHIN A CRITICAL TIME-WINDOW (3RD WK) POSTINJURY (PI). X-IRRADIATION (SINGLE DOSE, 17.5-20 GY) OF LESIONED ADULT RAT SPINAL CORD (SECTIONED AT T12) RESULTED IN RESTITUTION OF STRUCTURAL CONTINUITY AND RE-GROWTH OF SEVERED CORTICOSPINAL (CS) AXONS INTO THE DISTAL STUMP. THIS TREATMENT RESULTED ALSO IN RESTITUTION IN AXOTOMIZED CS NEURONS OF THEIR ELECTROPHYSIOLOGIC CONTROL OF HINDLIMB (HL) MUSCLE ACTIVITY (PNAS, SUBMITTED).

HERE WE EXAMINED WHETHER THE RESTITUTION OF DISRUPTED CIRCUITRY INDUCED BY X-RAY THERAPY COULD BE DETECTED IN THE MOTOR BEHAVIOUR OF RATS THAT HAD SUSTAINED COMPLETE SPINAL CORD TRANSECTION. IRRADIATED (N=11) AND UNIRRADIATED (N=6) RATS WITH SEVERED CORDS WERE OBSERVED VISUALLY, 3-5 MO PI, FOR THE FUNCTION AND CONTROL OF THEIR POSTERIOR BODY. COMPLETE TRANSECTION OF THE CORD RESULTED IN COMPLETE LOSS OF FUNCTION IN THE LEGS; THE POSTERIOR BODY DISTAL TO THE CUT WAS PARALYZED AND LAY FLAT ON THE TABLE. IN COMPARISON, SOME OF THE IRRADIATED RATS (N=6) REGAINED PLANTAR FOOT CONTACT AND THE ABILITY TO SUPPORT WEIGHT AND STANDING POSTURE OF THEIR POSTERIOR BODY. FURTHER, UNILATERAL ABLATION OF THE HL AREA OF THE RIGHT MOTOR CORTEX IN THE IRRADIATED RATS LED TO DEFICITS IN THEIR LEFT LEG POSTURE; THEIR POSTERIOR BODY TILTED TO THE LEFT IN A SIMILAR MANNER TO NORMAL RATS WITH INTACT CORD WHICH HAD UNDERGONE IDENTICAL HL-CORTICAL ABLATION. THESE RESULTS INDICATE THAT X-RAY THERAPY LEADS TO MOTOR RECOVERY AND THAT THE RESTITUTION IN POSTURE OF THE POSTERIOR BODY IS DUE IN PART TO REGENERATION OF THE CS AXONS. NO GRANT OR COMMERCIAL FUNDS SUPPORTED THIS RESEARCH PROJECT.

## 130.6

MAG EXPRESSED BY SCHWANN CELLS INHIBITS AXONAL GROWTH AND BRANCHING Y. Shen, F. Walsh<sup>++</sup>, M. T. Filbin Biology Dept., Hunter College, CUNY, New York, NY 10021; <sup>+</sup>Guy's hospital, London, UK.

Previously we showed that myelin-associated glycoprotein (MAG) is a potent inhibitor of axonal regeneration. When expressed in CHO cells, MAG inhibits neurite outgrowth from adult DRG neurons and other postnatal neurons including cerebellar, retinal ganglion, hippocampal neurons. In contrast, MAG promotes neurite outgrowth from neonatal DRG neurons. Non-myelinating Schwann cells are a permissive substrate for neurite outgrowth. They express the growth promoting molecules L1 and NCAM and secrete laminin and NGF. However, when non-myelinating Schwann cells are induced to express MAG by transfection, neurite outgrowth from cerebellar neurons is inhibited by 40%. Similarly, the number of adult DRG neurons with neurites longer than 3x diameter of the cell body decreased by 30%. These results confirm our previous findings and show that MAG can overcome the growth promoting factors of Schwann cells. In addition to its ability to inhibit axonal growth, MAG also inhibits neurite branching. The number of branches extended from DRG neurons decrease from scores to 3 or 4 per neuron when grown on MAG-expressing Schwann cells compared to Schwann cells not expressing MAG. The inhibition of neurite branching by MAG is apparent both in neonatal DRG's from which axonal elongation is promoted by MAG and in adult DRG's from which axonal growth is inhibited by MAG. These results suggest that the restriction of neurite branching by MAG is not simply related to the inhibition of neurite extension and that separate mechanisms could underlie these processes. In addition, MAG may also contribute to the limited collateral sprouting observed in myelinated regions. Supported by NMSSRG2760 and AHA.

## 130.8

MYELIN ASSOCIATED-GLYCOPROTEIN (MAG) INHIBITS NEURITE/AXON GROWTH. M. Li<sup>†\*</sup>, A. Shibata<sup>†</sup>, C. Li<sup>§</sup>, P.E. Braum<sup>†</sup>, L. McKerracher, J. Roders<sup>§</sup>, S.B. Kater<sup>†</sup> and S. David<sup>†</sup> <sup>†</sup>Centre for Research in Neuroscience, and <sup>‡</sup>Dept. of Biochemistry, McGill University, Montreal, Quebec, Canada, H3G 1A4; <sup>§</sup>Dept. Anat. & Cell Biol., Colorado State Univ. Colorado, USA; <sup>§</sup>Samuel Lunenfeld Res. Inst., Mount Sinai Hosp. Univ. Toronto, Ontario, Canada.

We have shown previously that MAG inhibits neurite growth from NG108-15 cells. In this study we show that 60% of axonal growth cones of postnatal day 1 rat hippocampal neurons collapsed when they encountered polystyrene beads coated with rMAG. Neurite growth from these and neonatal rat cerebellar neurons was also inhibited about 80% on tissue culture substrates coated with rMAG. To investigate further the inhibitory effects of MAG in myelin, we purified myelin from MAG-deficient mice and separated octylglucoside extracts by DEAE ion-exchange chromatography. Although there was no significant difference in neurite growth on whole myelin purified from MAG<sup>-/-</sup> and MAG<sup>+/+</sup> mice, differences were observed in the fractionated material. The first major peak of inhibitory activity associated with MAG in normal mice was significantly reduced in MAG-deficient mice. Axon regeneration in these mice was also examined after thoracic corticospinal tract lesions. A very small number of axons anterogradely labeled with WGA-HRP (maximum of 12 axons) extended 13.2 mm past the lesion in MAG<sup>-/-</sup> mice. The poor growth on whole myelin in vitro, and after spinal cord injury in MAG<sup>-/-</sup> mice may be due to compensatory changes. However, MAG is an important modulator of growth cone behaviour, since it can inhibit axon growth by arresting growth cone motility. To assess the contribution of various myelin-derived inhibitors to axon growth will require the identification and cloning of the non-MAG inhibitors.

REGENERATIVE FAILURE: A POTENTIAL MECHANISM FOR NEURITIC DYSTROPHY IN ALZHEIMER'S DISEASE. D.A. DeWitt\*, C. Doller, and J. Silver. Department of Neurosciences, Case Western Reserve University, Cleveland, OH 44106.

Neuronal pathology and synaptic loss are salient features of Alzheimer's disease, although the underlying mechanisms involved are unknown. Using double-immunolabeled preparations, we found that both the density and total lengths of axons are decreased within the A $\beta$  containing area of senile plaques (SP) in comparison with the adjacent neuropil. These observations, along with the demonstration of synaptic loss in the SP, are consistent with axotomy. Since A $\beta$  has been shown to be neurotoxic *in vitro*, SP cores isolated from AD brain were presented to retinal ganglion neurons. SPs did not appear to be repulsive to neurons since they adhered well and elaborated axons which wrapped around the SP core. Rat cortical astrocytes growing on isolated SPs accumulated chondroitin sulfate proteoglycan (CSPG). Neurons appeared to avoid astrocyte conditioned SP cores consistent with the axon outgrowth inhibitory nature of CSPGs. These results suggest that astrocytic reaction to SPs, including increased CSPG, may facilitate the decreased axon density and synaptic loss in AD brain. Moreover, the presence of CSPG and the similarity between both swollen axon endings in trauma and the dystrophic neurites of the SP suggest that dystrophic neurites may be exhibiting regenerative failure rather than aberrant sprouting. Supported by NIH grant: NS 25713.

## 130.11

PROLONGED GENE EXPRESSION IN GLIAL CELLS BUT NOT NEURONS WITH RECOMBINANT ADENOVIRUSES IN THE FACIAL NUCLEUS OF ATHYMIC NU/NU RATS. W.T.J.M.C. Hermens<sup>1,2</sup>, W.H. Gispen<sup>2</sup>, J. Verhaagen<sup>1,2\*</sup>. <sup>1</sup>Neth. Inst. Brain Res., A'dam, <sup>2</sup>Rudolf Magnus Inst., Utrecht, The Netherlands.

The aim of our research is to promote growth of injured neurons by using viral vectors encoding neurotrophic and growth-promoting proteins. This requires an efficient, non-toxic vector system. Recombinant adenovirus has been shown to induce inflammation in many tissues. We compared the performance of two replication deficient first generation adenoviral vectors, encoding the reporter gene lacZ (AdCMVLacZ) or the neural growth-associated protein B-50/GAP-43, following infusion in the facial nucleus of immunocompetent Wistar rats and thymus-deficient (Nu/Nu) rats. Titers of both adenoviral vectors as determined on 911-producer cells were  $1 \times 10^{11}$  pfu/ml. Contamination with replication competent adenovirus (RCA) was determined on A549 cells and was less than 1 RCA per  $10^8$  recombinants. Injection of  $2 \times 10^7$  pfu of AdCMVLacZ or AdCMVB-50 in adult Wistar rats resulted in abundant transgene expression in facial motoneurons and glial cells during the first week following application. In the second week a substantial decline in transgene expression became apparent. Infiltrating macrophages were observed in the facial nucleus as early as 4 days following adenoviral vector infusion and reached peak levels at the end of the second week. In the facial nerve the macrophage response started at 8 days after vector application. T-cell infiltration was not observed during the first week but occurred during the second week. The decrement in transgene expression in Wistar rats correlated closely with the appearance of T-cells. In T-cell deficient Nu/Nu rats transgene expression persisted for up to 20 days in glial cells, however expression declined in motoneurons according to a time course that was similar to that observed in Wistar rats. In conclusion, recombinant first generation adenoviral vectors evoke a T-cell mediated immune response in the brain that appears not to be the direct cause of the extinction of transgene expression in neurons. However, transgene expression in glial cells is prolonged in rats that can not evoke a T-cell response. (Support: grant from NWO/GB-MW 90352121).

## 130.13

ENHANCEMENT OF NERVE REGENERATION USING A LAMININ OLIGOPEPTIDE DERIVATIZED ARTIFICIAL EXTRACELLULAR MATRIX. S. Makohliso\*, M. Borkenhagen and P. Aebischer. Gene Therapy Center, CHUV, Lausanne University Medical School, Lausanne, Switzerland.

Growing neurites are guided through their environment during development and regeneration via different extracellular matrix (ECM) molecular cues. A three-dimensional (3-D) hydrogel based ECM equivalent containing different immobilized laminin oligopeptides has been designed. The specificity of the neurite outgrowth promoting activity was tested in a competitive binding assay, showing that neurite outgrowth from DRGs in a CDPGYIGSR derivatized gel was significantly inhibited after incubation with soluble CDPGYIGSR peptide. Scrambled peptides such as CDPGYIGSK and CDPGRGSI had a significantly smaller effect on neurite outgrowth compared to CDPGYIGSR.

The *in vivo* impact of derivatized gels was evaluated, studying the regeneration of transected spinal roots in a rat model. Six mm long polymeric nerve guidance channels were used to bridge a 4 mm gap. Cohorts of 6 animals were implanted with guidance channels filled either with saline, plain agarose, scrambled peptide or CDPGYIGSR derivatized agarose. Four weeks post-implantation, nerve guidance channels filled with a CDPGYIGSR derivatized gel, contained a regenerated nerve cable with a higher number of myelinated axons (384+/196) compared to nerve guidance channels filled with saline solution (202+/38), plain (198+/119) or scrambled peptide (83+/70) derivatized agarose gel. The present work shows that 3-D bioartificial matrices containing ECM molecules or laminin oligopeptides can be constructed to promote neurite outgrowth both *in vitro* and *in vivo*. Supported by the Swiss National Science Foundation.

## 130.10

RECOMBINANT ADENO-ASSOCIATED VIRUS (AAV) VECTORS FOR BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) AND GROWTH-ASSOCIATED PROTEIN (GAP-43) GENE DELIVERY.

R.L. Klein\*, S. Zolotukhin, E.M. Meyer, N. Muzyczka. Dept. of Pharmacology and Therapeutics and Dept. of Molecular Genetics and Microbiology, Univ. of Florida, Gainesville, FL 32610

The design and use of adeno-associated virus (AAV) vectors can produce prolonged expression of genes of interest in brain. The degeneration of populations of neurons that are associated with specific diseases may be attenuated or prevented by expressing genes involved in growth and regeneration. AAV plasmids were designed for cytomegalovirus promoter-driven expression of BDNF or GAP-43 as well as green fluorescent protein (GFP). We prepared high-titer stocks of recombinant AAV virions that are free of adenovirus. Infection of primary cortical neurons with AAV virions resulted in detectable expression of BDNF mRNA at 2.2 kb that was not observed in controls. Pronounced expression of recombinant BDNF mRNA was observed after infection of neurons with adenovirus in addition to recombinant AAV. Although adenovirus is toxic to cultured neurons it may be useful to study short-term effects of AAV-mediated gene transfer, e.g. to observe the function of GAP-43 or to produce biologically active BDNF. Currently, we are testing the BDNF-AAV vector for induction of choline acetyltransferase activity in primary septal neurons and we are testing the GAP-43-AAV for expression of GAP-43 mRNA and protein. The long-term goals of these studies are injection of virions *in vivo* for models of neurodegeneration. Supported by NIH 2910378-11.

## 130.12

AAV VECTORS CAPABLE OF CELL TYPE-SPECIFIC TRANSGENE EXPRESSION IN THE CNS AND PNS. A.L. Peel\*, S. Zolotukhin, G.W. Schrimsher, K. Chesnut, M. Potter, N. Muzyczka, and P.J. Reier. Depts. of Neuroscience, Neurological Surgery, Molecular Genetics and Microbiology, University of Florida, Gainesville, FL 32610.

A combination of different therapeutic approaches may be required to promote recovery from CNS trauma or disease, and a role for gene delivery techniques can be readily envisioned. Of the current viral vector systems available, adeno-associated virus (AAV) appears to be an optimal system for introducing foreign genes into the CNS by virtue of several inherent advantages. The objective of these experiments was to determine whether transgene expression can be optimized by capitalizing on cellular responses to CNS injury in combination with cell type-specific promoters. Accordingly, we have developed AAV vectors capable of transducing and eliciting expression of foreign genes from major cell types of both the CNS and PNS. We have placed the gene for a "humanized" form of green fluorescent protein (GFP) under the control of two neuron-specific promoters: the neuron-specific enolase (NSE) and the platelet-derived growth factor (PDGF) beta chain promoters. For potentially maximizing gene expression in reactive astrocytes, we have also developed a GFP vector driven by the glial fibrillary acidic protein (GFAP) promoter. Additionally, we have developed a similar GFP construct under the control of the myelin basic protein (MBP) promoter which is active in myelinating oligodendrocytes and Schwann cells. For *in vivo* analysis, the neuron-specific constructs packaged in AAV virions were injected into the intact spinal cords (C<sub>4</sub> spinal level) of six adult rats. Two weeks later, green fluorescent cells with neuronal morphology were seen in all animals. Expression from the PDGF construct was evident for as long as 15 weeks post-injection. Fluorescent fibers were observed extending rostrally to the base of the pons and caudally through the extent of the thoracic cord. Transduction of astrocytes and CNS stem/progenitor cells *in vitro* yielded positive expression of GFP driven by the GFAP promoter only in differentiated astrocytes. Finally, transduction of Schwann cells by the MBP promoter construct was positive for protein expression, whereas transduction of astrocytes and CNS stem cells did not yield evidence of GFP expression. *In vivo* experiments with the GFAP and MBP vectors are currently being undertaken. These initial data support the use of AAV vectors to drive foreign gene expression in a cell type-specific manner. ## 130.14

A HYDROGEL BASED, 3D BIOPOLYMERIC MATRIX FOR NERVE REGENERATION. R. Bellamkonda\* and X.J. Yu. Biomaterials, Cell and Tissue Engineering Laboratory, Department of Biomedical Engineering, Case Western Reserve University, OH 44106-7207.

The extracellular environment influences the degree of nerve regeneration in the PNS and CNS. Our laboratory focuses on using biomaterials to modify the extracellular environment at the site of nerve lesion to facilitate regeneration. We have developed a bioactive, 3D hydrogel matrix that has the following attributes: A) it has a 3D physical structure that is amenable to neurite extension B) it has the neurite outgrowth promoting extracellular matrix (ECM) protein laminin, covalently coupled to its backbone and C) it carries lipid microcylinders that release nerve growth factor (NGF) to attract nerve ingrowth into the polymer matrix.

Laminin was covalently immobilized onto agarose gels using solution and photochemical methods. Infrared spectroscopy confirmed covalent immobilization of laminin. E9 Chick dorsal root ganglia (DRGs) were embedded in modified and unmodified gels and cultured *in vitro* for 5 days. Significantly greater neurite extension was observed in laminin coupled agarose gels compared to gels carrying a control pentaglycine peptide or in unmodified agarose gels. This growth was contingent upon the addition of exogenous NGF to the culture medium.

Phosphatidylcholine based lipid microcylinders ( $1\mu \times 100\mu$ ) were loaded with NGF and embedded in unmodified agarose gels. DRGs were cultured in these gels without adding exogenous NGF. DRGs in NGF-microcylinder embedded gels had long neuronal process ( $>100\mu$ ) while gels with saline filled microcylinders had limited neuronal processes. *In vitro* DRG bioassays and spectrophotometry show that lipid microcylinders release NGF at physiologically relevant concentrations for at least five days.

ECM protein and growth factor laden polymer matrices that are conducive for neurite growth in 3D can induce controlled nerve growth from neural cells *in vitro* and can potentially enhance nerve regeneration *in vivo*. (Supported by the Lindseth Endowment, BME, CWRU)

## 130.15

**Free-radical scavengers support retinal ganglion cell survival after traumatic optic nerve lesions.** G.W. Eschweiler and M. Bähr\*. Neurologische Universitätsklinik, Hoppe-Seyler-Str.3, 72076 Tübingen, F.R.G. After traumatic CNS lesions, a secondary neuronal loss can be observed which occurs rather late and might be prevented by interference with pathophysiological cascades that are triggered by posttraumatic loss of trophic factors, release of neurotoxic substances or activation of pro-apoptotic genes. We have used a CNS trauma model to examine the influences of potentially neuroprotective drugs like glutamate-receptor-antagonists, MAO-B-inhibitors, calcium-antagonists or free-radical scavengers. In adult female rats the optic nerve was transected close to the optic disc. Retinal ganglion cells (RGCs) were retrogradely labeled by Di-I and Fast blue. At two weeks after optic nerve lesion the numbers of viable RGCs were determined in different retinal regions. To examine the effects of the various treatment strategies on physiological functions, electroretinograms (ERGs) and pattern visual evoked potentials (pVEP) were recorded. Systemic application of a free radical scavenger (SPBN) lead to a significant rescue of traumatized RGCs after optic nerve lesion. Calcium-antagonists were less effective and the NMDA-antagonist memantine and the MAO-B inhibitor deprenyl did not support survival of axotomized RGCs at all. Electrophysiological measurements were not influenced by treatment with SPBN. We conclude from these findings that free radical damage plays an important role in delayed posttraumatic neuronal death. Delayed administration of SPBN rescues a significant proportion of lesioned CNS neurons without influencing physiological parameters. In the future, free radical scavengers might contribute to a therapeutic strategy designed to prevent early axonal and neuronal damage after CNS lesions. Supported by the Kuratorium ZNS, BMBF Neurotraumatologie and the Herrmann-und-Lilly-Schilling Stiftung

**DEGENERATION OF EPIDERMAL SENSORY FIBERS IN MICE.** S.-T. Hsieh\*, W.-M. Lin, W.-P. Chen, and Y.-C. Chang. Departments of Anatomy and Neurology, National Taiwan Univ. College of Medicine, Taipei, 10018, TAIWAN

Innervation of the skin is important for nociception, which is required for normal protection. Neurons with axons belonging to the Aδ and C categories terminating in the skin have been characterized extensively by physiological means. However, the diameter of these fibers are usually less than one μm because of their non-myelination character. Morphological evaluation of the "free nerve endings" have been difficult. We recently took the advantage of sensitive immunocytochemistry to demonstrate these fibers unequivocally by immunolabelling the epidermal fibers with protein gene product 9.5 (PGP), a ubiquitin hydrolase. Combining with sciatic nerve transection, we further addressed the following issues: (1) whether the cutaneous nerve fibers reach the epidermis, the outermost layer of the skin, and that (2) whether these fibers disappear after nerve degeneration. Adult ICR mice were rendered to sciatic nerve transection on one side with the other side sham-operated as control. The skin of the feet was sampled at different time points after transection, from one day-post surgery to four weeks. Our results indicated that the PGP-immunoreactive epidermal fibers were far more rich than previously expected. These fibers quickly degenerated one day after transection while many of the dermal fibers, usually myelinated, remained intact. The results suggest that unmyelinated fibers degenerate faster than myelinated ones. Thus this approach provides a new way to study degeneration and regeneration of unmyelinated nerve fibers, which has not been explored for years because of technical difficulties. Supported by National Science Council, Taiwan, ROC: NSC-85-2331-002-005

## 130.19

**AXONAL DIE-BACK INDUCED BY CORTICOSPINAL AXOTOMY IN THE MIDTHORACIC SPINAL CORD OF ADULT RATS.** H. Li<sup>1</sup>, C.Y. Hsu<sup>2</sup>, A.L. Pearlman<sup>2\*</sup>, J.E. Brunstrom<sup>2</sup>, J. Perschbacher<sup>1</sup> and X.M. Xu<sup>1</sup>. <sup>1</sup>Dept. Anat. & Neurobiol. Saint Louis Univ. Sch. of Med., St. Louis, MO 63104; <sup>2</sup>Dept. Neurol. & CNSI, Washington Univ. Sch. of Med., St. Louis, MO 63110.

When axons are severed, their entire distal segments undergo Wallerian degeneration. It is not clear whether the proximal segments of long projecting axons in the spinal cord die back from the site of injury and, if so, how far they retract. In the present study, the die-back phenomenon of the corticospinal tract was investigated using a phaseolus vulgaris leucoagglutinin (PHA-L) anterograde tracing method. Adult female Fischer rats received spinal cord overhemisection at T-8 to transect the corticospinal tract (CST) bilaterally. The injection of PHA-L was made iontophoretically into the hindlimb area of the left sensorimotor cortex either prior to or after corticospinal axotomy and transport allowed for 14 days. The animals were perfused 3, 7, 14, 21 and 28 days after CST axotomy. Tissues were sectioned and reacted with goat anti-PHA-L, processed with biotinylated rabbit anti-goat IgG and Vector Avidin-biotin-Peroxidase complex, and with H<sub>2</sub>O<sub>2</sub> in the presence of diaminobenzidine. Our results demonstrate that: 1) axotomy of the CST causes axons proximal to the lesion to swell and to form bulb-like profiles near the lesion site 3 and 7 days postinjury, 2) the die-back of lesioned CST axons progresses over time and by day 14, labeled axons were found approximately 1.0 mm away from the rostral border of the remaining tissue, 3) regenerative sprouting was observed in later stages, i.e., 21 and 28 days postinjury, where a few fine labeled CST fibers had sprouted to the rostral tissue border. **TUMOR FORMATION AND HYPERPIGMENTATION FOLLOWING WOUNDING OF NF1/nf1 MOUSE NERVE: T. Lili Rizi\* and Nancy Ratner.** Dept Cell Biology, Neurobiology & Anatomy, Univ. Cincinnati. Coll. Med., Cincinnati, OH-45267

Patients with type 1 neurofibromatosis (NF1) are predisposed to the formation of neurofibromas (benign peripheral nerve tumors) and cafe-au-lait macules (hyperpigmented spots on the skin-CALM). Mice heterozygous at NF1, unlike their human counterparts, fail to develop CALM or neurofibromas. It was suggested that wounding might precipitate neurofibroma formation. To test this hypothesis, we crushed or cut the sciatic nerve in NF1/nf1 mice. First a developmental study was carried out to test if any abnormalities are present in NF1/nf1 mouse nerves before injury. Histologic and EM analysis of sciatic nerve (from E14 through adult) in wild type and NF1/nf1 mice showed no significant abnormalities in Schwann cell differentiation (myelination) or fibroblast differentiation (perineurium formation). We next tested if crushing the sciatic nerve by mechanical pressure caused abnormalities. Mice sacrificed 6 and 10 weeks post surgery (PS) showed no significant abnormalities. We then transected the sciatic nerve and rejoined cut ends of the nerve with sutures. Eight NF1/nf1 and eight wild type mice have been evaluated. Four animals from each group were sacrificed at 1 month, 2 animals each at 2 months and 2 animals each at three months PS. Wild type mice did not show abnormality in nerve histology while nerves from all NF1/nf1 mice showed dramatic tissue changes including (1) intermingling of axons with surrounding muscles at 1 month PS and with the overlying muscles and skin at 2 and 3 month PS, (2) transient muscle atrophy, (3) patchy hyperpigmentation of muscles overlying the nerve and around and on the sciatic nerve itself at 1 month PS, and in the dermis at 2 and 3 month PS. Hyperpigmented cells were identified as melanocytes by EM, (4) formation of encapsulated tumors in the lesioned area at 3 month PS. Thus, wounding of the sciatic nerve in mice with a single mutant NF1 allele is sufficient to cause disruption of tissue organization with features resembling human NF1. Supported by NIH NS-28840

**NEURONAL SUB-POPULATION OF THE MAJOR PELVIC GANGLION INNERVATING THE CORPUS CAVERNOSUM: A FLUORESCENT TRACER STUDY OF THE CAVERNOUS NERVE.** S. J. Archibald<sup>1</sup>, K. Jovanovic<sup>1</sup>, S. Batra<sup>4</sup>, and B. D. Madison<sup>1,2,3</sup>. Division of Neurosurgery <sup>1</sup>, Department of Neurobiology <sup>2</sup>, Duke University Medical Center, Research Service of the VA Medical Center <sup>3</sup>, Durham, NC., and Integra LifeSciences, Inc., Plainsboro, N.J. <sup>4</sup>

With the continued development of prosthetic nerve guides as replacements or supplements for nerve grafts, there has been increased interest in their use for cavernosal nerve repair (Ball et al., 1992, J. Urology 148: 211-215). One of the main advantages of nerve guide or entubulation repair techniques is that the lumen environment of the tube can be modified to promote neuronal survival and axon regeneration. This study represents a baseline assessment of the population of autonomic (parasympathetic) neurons in the major pelvic ganglion (MPG) providing the cavernosal innervation and their response to nerve section and entubulation repair.

Ten young adult Sprague Dawley rats were divided into 2 groups, 1) unlesioned controls, 2) entubulation repair of the right cavernosal nerve, 4 mm polyethylene tube (Clay Adams PE-20, 0.58 mm I.D.) with a 2.5 mm nerve gap. Regeneration was allowed to proceed for one month at which time the MPG was unilaterally retrogradely labeled with Fluorogold from the cavernosal nerve at a point proximal to the entubulation repair and from the same location in the unlesioned normal animals. Histological analysis demonstrated significant drop out of cells from the major pelvic ganglion after entubulation repair (two tailed t-test, p < 0.05). The normal population of neurons in the MPG innervating the right cavernosal nerve was 2447±198 (n=4), and following entubulation repair was 1702±209 (n=6).

## 131.1

CAUDOTOMY DOES NOT PROVOKE THE SUSTAINED IMPROVEMENT OBSERVED IN IMPLANTED PARKINSON'S PATIENTS. J.J. López-Lozano<sup>1</sup>, G. Bravo, R. Martínez, J. Burzaço, P. Sánchez, C. de la Torre and the CPH Neural Transplantation Group, Clínica Puerta de Hierro, and GammaKnife Neurosurgical Unit, Clínica Ruber Internacional, 28035 Madrid, Spain.

The results obtained by our group to date show that the implantation of neural tissue into caudate nucleus by open surgery can improve the clinical symptomatology of severely impaired parkinsonian patients, and that the duration of the clinical improvement observed and the moment of onset differ depending on the tissue implanted, with that resulting from implantation of AM grafts presenting earlier and that observed with FVM occurring later and lasting longer. However, we have yet to determine whether the improvement detected in the early months may also be caused by trauma at the implantation site. To test this possibility, we have carried out a double-blind study in 8 parkinsonian patients (4 controls and 4 study subjects) who underwent stereotactical radiosurgical caudotomy- 4 mm ø (GammaKnife Leksell Unit). All the patients were installed in the GKLU but only 4 patients received radiation. The selection criteria for the patients were those used in our previous series of graft recipients (*J. Neurosurg* '91; *Lancet* '93; *Transplantation* proc '95). Their status was determined on the basis of internationally accepted rating scales (CAPIT P, UPDS, NWDs). The results show that there were no significant changes in the control patients. After 6 months, the 4 study patients presented an area of radionecrosis measuring 4-5 mm in diameter. Two patients presented a transient moderate improvement in rigidity and akinesia with a moderate reduction in the amount of time spent in Off and fluctuations in dyskinesias. There was no substantial reduction in the L-dopa intake. In comparison with these graft recipients, the overall improvement in the patients in this study was less marked, was of shorter duration was barely appreciable and the clinical course and reduction of medication did not parallel those observed after transplantation of AM, FVM or AM+PN. The results indicate that the improvement observed in parkinsonian graft recipients can not be attributed to caudotomy. (Supported by FIS 96/428, CAM 95).

## 131.3

POST-MORTEM HISTOLOGICAL CHARACTERIZATION OF SURVIVING PORCINE MESENCEPHALIC CELL SUSPENSION XENOGRAFTS IN A PARKINSONIAN PATIENT. T. Deacon<sup>1,4\*</sup>, C. Thomas<sup>2</sup>, L. Dinsmore<sup>3</sup>, E. Frather Palmer<sup>2</sup>, D. Penney<sup>2</sup>, S. Koti<sup>2</sup>, P. Dempsey<sup>2</sup>, O. Isacson<sup>1</sup> and J. Schumacher<sup>2</sup>, McLean Hospital, Belmont, MA 02178<sup>1</sup>, Lahey Hitchcock Clinic, Burlington, MA 01805<sup>2</sup>, Diacrin, Inc., Charlestown, MA 02129<sup>3</sup>, Boston University, Boston, MA 02115<sup>4</sup>.

In an ongoing FDA approved safety study of porcine fetal mesencephalic cell transplantation in Parkinson's disease (Schumacher, et al., in prep.) one patient died of unrelated causes 7.5 months after transplantation. The patient received multiple injections of a cell suspension derived from E27 fetal pig ventral mesencephalon into the right putamen and caudate nucleus and was immune suppressed with Cyclosporin (5mg/kg/day). The brain was removed at autopsy and immersion fixed in 10% formalin. Histological analyses were performed using hematoxylin and eosin stain (H&E), Cresyl violet stain; antibodies to tyrosine hydroxylase (TH), pig-specific 70kD neurofilament (NF70) and pig-specific glial antigen (CD44); and in situ hybridization to a pig-specific DNA repeat element (PRE). H&E analysis showed no signs of inflammatory response around implantation sites. Nissl, TH and NF70 demonstrated TH and non-TH immunoreactive neurons in all grafts, with no sign of neuronal migration into the host. Porcine axons were identified with NF70 and TH extending from the graft into the host striatum. CD44 immunoreactive porcine glia were densely present in each graft and were also identified in small numbers in the surrounding host putamen. PRE labelled cell nuclei were concentrated within each graft site and significant numbers were also identified in the surrounding host striatum. This histologic study demonstrates survival of xenogeneic neurons and glia in a Parkinsonian patient for over 7 months. (Supported by Lahey Hitchcock Clinic and Diacrin, Inc.)

FUNCTIONAL FETAL NIGRAL GRAFTS IN A SECOND PATIENT WITH PARKINSON'S DISEASE: A POST-MORTEM ANALYSIS. J.H. Kordower<sup>1,\*</sup>, J.M. Rosenstein<sup>1</sup>, T.J. Collier<sup>1</sup>, E.-Y. Chen<sup>1</sup>, Jing Min Li<sup>1</sup>, E.J. Mufson<sup>1</sup>, P. Sanberg<sup>2</sup>, T.B. Freeman<sup>3</sup>, and C.W. Olanow<sup>1</sup>, <sup>1</sup>Dept. Neurological Sciences, Rush Presbyterian Med. Ctr., <sup>2</sup>Dept. Anatomy, George Washington Medical Ctr., <sup>3</sup>Dept. Neurology, Emory Univ., <sup>4</sup>Dept. Neurology and <sup>5</sup>Div. Neurosurgery, Univ. South Florida at Tampa; <sup>6</sup>Dept. of Neurology, Mt. Sinai Medical Center, N.Y., N.Y. 10029.

We recently reported post-mortem evidence for long-term survival of fetal nigral grafts in a patient with Parkinson's disease (Kordower et al., *NEJM*, 332: 1118-1124, 1995). This year, a second patient from our clinical transplantation program has come to autopsy. This patient received stereotaxic bilateral fetal ventral mesencephalic transplants into the post-commissural putamen employing seven embryos between 6 1/2-9 weeks post-conception. This patient displayed sustained improvement in motor function and a progressive increase of putamenal fluorodopa (FD) uptake on PET scan. This patient died 18 months following transplantation from asphyxiation. The autolysis time was 5h. One hemisphere was immersion fixed for histological evaluation and transplants were analyzed using tyrosine-hydroxylase immunohistochemistry (TH-ir). Large organotypic grafts were observed at each graft site containing numerous TH-ir neurons. A quantitative evaluation revealed the presence of 135,673 TH-ir neurons in the right hemisphere. TH-ir grafted neurons displayed a round and triangular shape, were 25-30µm in diameter and exhibited long multipolar processes. These grafted extensively reinnervated the parkinsonian striatum in a patch-matrix pattern. No host dopaminergic sprouting was observed. These data support the concept that fetal nigral grafts can survive in the human brain and functionally reinnervate the parkinsonian striatum. (Supported by the United Parkinson's Foundation).

## 131.2

STRATEGIES TO ALLOW CONTINUED LEVODOPA THERAPY IN PARKINSONIAN GRAFT RECIPIENTS: IDENTIFICATION OF FACTORS INVOLVED IN LEVODOPA-INDUCED TOXICITY IN EMBRYONIC DOPAMINE NEURONS. K. Steele-Collier<sup>1,\*</sup>, T. Alexander<sup>1</sup>, C.E. Sortwell<sup>1</sup>, T.J. Collier<sup>2</sup>, C.D. Stadel<sup>3</sup>, <sup>1</sup>Dept. of Neuroscience<sup>1</sup>, and Dept. of Physiology<sup>3</sup>, Finch Univ. of the Health Sci The Chgo Med Sch, N. Chgo, IL 60604; <sup>2</sup>Dept. of Neurological Sciences, Rush Presb-St. Lukes Med Ctr, Chgo, IL 60612.

One potential caveat in parkinsonian graft recipients is that they require continued treatment with the antiparkinsonian medication levodopa (L-dopa). There is increasing evidence that levodopa is toxic to developing dopamine (DA) neurons. We have observed that chronic L-dopa administered to rats with embryonic DA neuron grafts is detrimental to morphology and function of grafted DA neurons. Further, we and others have observed that L-dopa and DA are toxic to catecholamine neurons in culture. In order to develop potential adjunct treatments which could decrease or alleviate the potential deleterious influence of L-dopa on survival of grafted embryonic neurons while allowing beneficial symptomatic treatment in the patient we have examined the possible mechanisms of L-dopa toxicity. It is generally assumed that L-dopa produces toxicity due to oxidative stress derived from catabolism of DA. To verify this assumption, we compared the neurotoxic profile of L-dopa, the less active stereoisomer D-dopa, and DA. In cultures derived from embryonic day 14 (E14) F344 and Sprague Dawley rats, D-dopa was toxic to DA neurons only at high concentrations ( $\geq 500\mu\text{M}$ ). In contrast, L-dopa and DA produced significant toxicity at concentrations  $\geq 1\text{nM}$ . In addition, statistical analysis indicated that DA produced more neuronal death at most concentrations ( $p < 0.001$ ) and that cultures from Sprague Dawley rats were significantly more susceptible to DA neurotoxicity than F344. Ongoing studies are examining downstream pathways that are important in producing this toxicity. In parallel studies, we have observed a dramatic decrease in neurotoxicity of L-dopa at earlier gestational ages. Whereas 4 applications of  $100\mu\text{M}$  L-dopa caused complete death of DA neurons in E14 (CRL 10.5-11mm), there was only a 20% reduction in number DA neurons derived from E13 (CRL 9-9.5mm) donors. In contrast to this differential effect of L-dopa, there was no significant difference in degree of DA cell death following DA treatment. Again, ongoing studies are exploring potential factors responsible for the differential toxicity of L-dopa with earlier gestation age in hopes of identifying neuroprotective strategies which might enhance graft cell viability in parkinsonian patients requiring drug therapy.

## 131.4

FUNCTIONAL FETAL NIGRAL GRAFTS IN TWO PATIENTS WITH PARKINSON'S DISEASE: IMMUNOLOGICAL STUDIES. R. Hanbury<sup>1,\*</sup>, S.D. Styren<sup>1</sup>, P. R. Sanberg<sup>2</sup>, T.B. Freeman<sup>3</sup>, and C.W. Olanow<sup>1</sup>, <sup>1</sup>J.H. Kordower<sup>1</sup>, <sup>2</sup>Dept. Neurological Sciences, Rush Presbyterian Med. Ctr., Chicago Ill. 60612, <sup>3</sup>Dept. of Psychiatry, Univ. Pittsburgh, Med. Ctr. Pittsburgh PA, 15213, <sup>4</sup>Division of Neurosurgery, Univ. S. Florida, Tampa FL, 33606, <sup>5</sup>Dept. of Neurology, Mt. Sinai Med. Ctr. N.Y. N.Y. 10029.

Little information is available regarding the status of the immune system following human fetal nigral transplantation. We are studying two patients with Parkinson's disease which have come to autopsy following fetal nigral transplantation and died 17-18 month following transplantation from events unrelated to the grafting procedure. Both patients were immunosuppressed with cyclosporin 3 weeks prior to grafting and for 6 months post-transplantation. In both patients, healthy appearing grafts were observed in all implant sites within the post-commissural putamen. Most graft sites displayed few macrophages on Nissl stains. GFAP immunostaining revealed relatively few astrocytes within the grafts. The grafted host putamen displayed dense collections of GFAP-ir cells. However, the nongrafted caudate nucleus displayed a similar widespread expression of GFAP-ir astrocytes suggesting that the underlying disease and not the grafting procedure was responsible for this finding. Immunohistochemical studies were performed using an antibody directed against HLA-DR, a marker which is ubiquitously expressed in immune cells including microglia, T cells, B-cells, and cells expressing Class II antigens. Dense HLA-DR-ir was observed within graft sites and the perigraft region in both cases. HLA-DR-ir was especially dense around blood vessels. Further studies are underway defining which population(s) of immune cell(s) are expressing this marker within the grafts. (Supported in part by the United Parkinson's Foundation).

## 131.6

FUNCTIONAL FETAL NIGRAL GRAFTS IN A PATIENT WITH PARKINSON'S DISEASE: EFFECTS ON DOPAMINE SYNAPTIC MARKERS. J.K. Staley<sup>1,\*</sup>, D.C. Mash<sup>1</sup>, M. Basile<sup>1</sup>, W. Weiner<sup>1</sup>, A.J. Levey<sup>2</sup> and J.H. Kordower<sup>3</sup>, <sup>1</sup>Dept. Neurology, University of Miami Sch. Med., Miami, FL., <sup>2</sup>Dept. Neurology, Emory University, Atlanta, GA and <sup>3</sup>Dept. Neurological Sciences, Rush Presbyterian Med. Ctr. Chicago, IL.

The cardinal feature of Parkinson's disease (PD) is the loss of nigrostriatal dopamine (DA) neurons. Fetal nigral transplantation has been considered as a treatment for replacement of the DA deficit in PD. The present study used quantitative *in vitro* autoradiography and immunocytochemistry to assess the status of the DA transporter (DAT), D<sub>1</sub>, D<sub>2</sub> and D<sub>3</sub> receptor subtypes in a patient who received a fetal ventral mesencephalic transplant into the post-commissural putamen and died 18 months following the transplantation from events unrelated to the grafting procedure. DAT densities were significantly lower in the anterior and posterior striatum in endstage PD patients as compared to aged control subjects. Labeling of the DAT was enriched in the posterior striatum of the PD/transplant case as compared to the PD cases. DAT-IR was extensive in the posterior putamen in a pattern similar to that seen with tyrosine hydroxylase. D<sub>1</sub> receptor densities were elevated in the anterior and posterior striatum of the PD and PD/transplant case as compared to control cases. D<sub>2</sub> receptor densities were elevated in the anterior putamen, but were not significantly different in the anterior caudate or posterior striatum of the PD and the PD/transplant cases. D<sub>3</sub> receptor densities were decreased in the posterior striatum and increased in the anterior striatum of the PD cases. D<sub>3</sub> receptor number normalized to the density observed in the control subjects in the posterior striatum of the PD/transplant case. These studies suggest that fetal nigral grafts may foster the recovery of some DA synaptic markers and may contribute to the beneficial behavioral effects observed after transplant. Supported by the National Parkinson's Foundation.

**EX VIVO AND IN VIVO GENE TRANSFER IN THE RAT STRIATUM USING AN AAV VECTOR EXPRESSING GFP.** L. Tencnbaum<sup>1</sup>, E. Hooghe-Peters<sup>1</sup>, B. Avalosse<sup>2</sup>, A. Lubansu<sup>3</sup>, M. Levivier<sup>3</sup>. <sup>1</sup>Dept of Pharmacology, AZ-Vrije Univ. Brussel; <sup>2</sup>Laboratory of Molecular Biology, Univ. Libre Bruxelles-Institut Bordet; <sup>3</sup>Dept of Neurosurgery, Univ. Libre Bruxelles-Hôpital Erasme, Brussels, Belgium.

The green fluorescent protein (GFP) of *Aequorea victoria* absorbs blue light and emits green fluorescence without exogenous substrates and can, therefore, be used as a reporter gene. We transfected the human glial cell line U373-MG with an AAV vector (kindly provided by Drs. N. Muzyczka and S. Zolotukhin) carrying two expression cassettes: [i] the GFP gene under the control of the CMV promoter and [ii] the neomycin-resistance gene under the control of the HSV-TK promoter. The clones constitutively expressing the GFP protein were still fluorescent after 3 months in culture. When these cells were stereotactically injected into the striatum of adult rats ( $10^5$  cells in 2  $\mu$ L), GFP+ cells were observed at the implantation site 6 hours after surgery. We then tested the intrastriatal injection of a concentrated AAV-GFP recombinant virus stock (2  $\mu$ L:  $2 \times 10^8$  infectious units per ml). Starting 2 days after injection, we found a strong yellow-green fluorescence at the level of the cortex underlying the burr hole and along the needle tract in both AAV-GFP- and mock-injected (DMEM) rats, as well as in rats implanted with GFP+ cells. This artefactual fluorescence corresponded to endogenous proliferating cells, most presumably glial cells, and increased in intensity from 2 days to 2 weeks after surgery. We could not clearly distinguish GFP green fluorescence from this high fluorescent background, neither after implantation of GFP+ cells nor after direct AAV-GFP injection *in vivo*. This artefactual fluorescence was not linked to paraformaldehyde fixation since it was observed with the same intensity in unfixed fresh-frozen tissue and in both paraformaldehyde-post-fixed tissue and paraformaldehyde-perfused animals. These results suggest that technical aspects of the fluorescence detection may limit the use of GFP as a reporter gene *in vivo*. Long-term expression of the vector will be monitored to further evaluate interactions between GFP- and surgery-induced fluorescence. (Supported by A.S.L.K. and F.N.R.S., Belgium).

## 131.9

**TRANSPLANTATION OF EGF/FGF RESPONSIVE HUMAN PRECURSOR CELLS INTO THE 6-OHDA LESIONED STRIATUM.** M.A. Caldwell<sup>1</sup>\*, S.B. Dunnett<sup>1</sup>, J. Shen<sup>2</sup>, Karmiol<sup>3</sup> and C.N. Svendsen<sup>1</sup>. <sup>1</sup>MRC Cambridge Centre for Brain Repair, University of Cambridge, UK; <sup>2</sup>Clonetics Inc, San Diego, CA 92123

The whole brain from a single human embryo (20 weeks post conception) was acquired from a tissue bank in accordance with the Uniform Anatomical Gift Act, dissociated and grown in EGF supplemented serum free medium for 4 days before being shipped in hibernation medium to Cambridge where the cells were transferred to serum free medium containing both EGF (20ng/ml) and FGF (20ng/ml). At 7 days *in vitro* some of the cells were pulsed with 1  $\mu$ M BrdU for 3 days and then transplanted as intact spheres into the striatum of 15 rats previously given unilateral 6-OHDA lesions and showing an amphetamine induced rotation of greater than 10 turns/min, or plated onto substrate coated slides and allowed to differentiate. The remainder of the cells were passaged and the label, graft, plate and passage process repeated at 14d and 21d of growth. 5 grafted animals from each group were sacrificed at 2 weeks, 6 weeks and 20 weeks post transplantation. Over 80% of the cells plated were positive for BrdU, many were  $\beta$  tubulin III positive, and a sub population stained for tyrosine hydroxylase (TH) at each passage. Animals grafted with 10, 17 and 24 day old precursors had large, dense transplants at 2 weeks with a core of BrdU positive cells and penumbra of BrdU negative cells, with a few BrdU positive cells migrating out into the host tissue. In stark contrast, by 6 weeks post transplantation no BrdU positive cells could be seen in any animal although many had large tissue masses, strongly suggesting that BrdU had been lost due to cell division. Many TH positive neurons were also seen within the transplants at both time points but there were no effects on rotation in any group. Data from 20 week old transplants will also be presented. These results show that human precursor cells can be expanded, stored in hibernation medium, transported, and survive transplantation into the lesioned adult CNS. Supported by the Wellcome Trust and MRC.

## 131.11

**HUMAN FETAL RETINAL EPITHELIAL TRANSPLANTATION EFFECTS VISUALLY-GUIDED BEHAVIOR IN THE RCS RAT.** C.W. Little<sup>1</sup>, C. Cox<sup>2</sup>, J. Wyatt<sup>3</sup>, C. del Cerro<sup>1</sup>\*, and M. del Cerro<sup>1,4,5</sup>. Departments of Neurobiology<sup>1</sup>, Statistics<sup>2</sup>, Animal Medicine<sup>3</sup>, Neurology<sup>4</sup>, and Ophthalmology<sup>5</sup>, U. of Rochester Medical School, Rochester, N.Y., 14642.

The RCS rat is affected by a selective loss of retinal photoreceptor cells. This study evaluates the duration and functional effect of human fetal RPE grafts in the RCS rat.

Human fetal RPE cells were transplanted bilaterally into the subretinal space within the superior hemisphere of dystrophic RCS rats. Vehicle was similarly injected bilaterally into control rats. All animals were immunosuppressed. On the day of sacrifice, each animal was given ten consecutive trials in a water escape paradigm. The time was recorded for the rat to find a submerged platform, which was adjacent to a light bulb, the location of which was randomly assigned. The eyes were analyzed histologically, and the photoreceptor nuclear profiles within specified regions of the retina were counted.

Eight weeks after transplantation, a rescue effect was apparent, as was an effect on the visually-guided water escape behavior. An outer nuclear layer 2 to 4 profiles thick was present in the region of transplant; whereas, few photoreceptors remained in all other regions. The mean number of photoreceptors in the graft region was significantly greater than in the same region of sham-injected eyes ( $p = 0.004$ ). The water escape times showed statistically different linear trends between the two groups ( $p = 0.027$ ).

Photoreceptor cells are rescued by transplantation of human fetal RPE; they provide the dystrophic RCS rat with a functional advantage for visually-guided behavior.

Supported by Dr. Sam Williams and Research to Prevent Blindness.

## 131.8

**IMPLANTATION PARAMETERS FOR RELIABLE DELIVERY OF CELLS INTO THE STRIATUM OF MONKEYS USING AN AUTOMATED DELIVERY SYSTEM.** J.B. Bringas, E.M. Kutzscher, B.Y. Yang, R.S. Hundal, D. Nagy\*, W.W. McLaughlin, S. Leff, M.E. Emborg, S. Jungles and K.S. Bankiewicz. Somatix Therapy Corporation, Alameda, CA 94501.

Intracerebral grafting combined with gene transfer may provide a powerful technique for local delivery of therapeutic agents into the CNS. The present study was undertaken to: (i) determine upper safe limits of cellular implantation into the neostriatum of monkeys; (ii) determine optimal implantation parameters of cells into the striatum; and (iii) estimate cell survival in the grafts using BrdU-labeling methods. Autologous fibroblasts were infused into six sites of the striatum in non-human primates (Macaca Mulatta, n=12). Twenty-seven gauge cannulae were inserted vertically through cortical entry sites into the striatum (2 sites in the caudate nucleus and 4 sites in the putamen) at pre-defined coordinates based on magnetic resonance imaging (MRI). The cannulae were guided by an electronically-operated hydraulic micropositioner and withdrawn at controlled rates (0.375 or 0.75 mm/min.) while fibroblast cells (5, 10, 20, 40 or 80  $\mu$ L/site) were infused simultaneously. Varying infusion rates (0.8, 1.6, 3.2 or 6.4  $\mu$ L/min.) and fibroblast concentrations ( $1.0$  or  $2.0 \times 10^5$  cells/ $\mu$ L) were also evaluated. Visualization and evaluation of graft placement were performed using contrast MRI at 3-5 days post-surgery. Animals were monitored for signs of clinical complications and sacrificed two weeks following surgery.

Post-implantation MRI revealed mass effect of the implant with shifting of midline, edema and infiltration of the white tracts at 40 and 80  $\mu$ L/site. In addition, these animals developed transient hemiparesis contralateral to the implant site. MRI of animals grafted with 20  $\mu$ L/site exhibited columnar-shaped implants and evidence of infiltration into white matter tracts possibly due to a volume effect. No clinical side effects were seen in this group. At 14 days post-surgery, MRI scans showed consistent columnar grafts (measuring 5mm in height) throughout the striatum in animals implanted with 5 or 10  $\mu$ L/site. There were no signs of clinical side effects associated with these volumes and post-mortem histological examination confirmed MRI observations. Fibroblast survival in the grafts was estimated at 30-50%. Optimal surgical parameters for delivery of fibroblasts into the striatum consist of a graft volume of 10  $\mu$ L/site, a 1.6  $\mu$ L/min. infusion rate, a cell concentration of  $2.0 \times 10^5$  cells/ $\mu$ L and a cannula withdrawal rate of 0.75 mm/minute. These results show that infusion of genetically-altered primary fibroblasts into the striatum can be done in a safe and routine manner.

## 131.10

**AROMATIC L-AMINO ACID DECARBOXYLASE IN GENE THERAPY FOR PARKINSON'S DISEASE.** S. R. Wachtel\*, C. Bengsics and U. J. Kang. Dept. of Neurology, University of Chicago, Chicago, IL 60637.

Investigations of gene therapy for Parkinson's disease (PD) have focused on strategies that restore tyrosine hydroxylase (TH) activity. These strategies presume that aromatic L-amino acid decarboxylase (AADC) is present in sufficient quantities in the denervated brain, such that L-DOPA synthesized by TH can be efficiently decarboxylated to provide dopamine (DA). This hypothesis is supported by the clinical, therapeutic benefit of exogenous L-DOPA, and by its effects in animal models of PD. However, the source of AADC in the DA-denervated brain is unclear. Therefore, it is necessary to determine the role of AADC in gene therapy for PD. In the present study, we examined the potential benefit of adding the gene for AADC to TH gene therapy by cotransplanting primary fibroblasts (PF) transduced with AADC (PFAADC) with PF transduced with both TH and GTP cyclohydrolase 1 (GC), an enzyme necessary for the synthesis of tetrahydrobiopterin cofactor. To determine the optimal ratio at which to mix PFTHGC and PFAADC cells for transplantation, these cells were cocultured at ratios from 1:1 to 3:1, and the media from those cultures analyzed for L-DOPA and DA content. Although L-DOPA concentrations in the media increased as the ratio of PFTHGC to PFAADC cells increased, DA levels were highest at a ratio of 2:1. Thus, to determine the role of AADC *in vivo*, PFTHGC/PFAADC or PFTHGC/PF cells were grafted, both at a 2:1 ratio, into the 6-hydroxydopamine-denervated striatum of Fisher 344 rats, and microdialysate levels of L-DOPA and DA compared. Interestingly, PFTHGC/PFAADC grafts produced less L-DOPA than PFTHGC/PF grafts. Nevertheless, PFTHGC/PFAADC and PFTHGC/PF grafts did not produce significantly different levels of DA. These findings indicate that 1) there is sufficient AADC near striatal grafts for L-DOPA decarboxylation and that 2) TH gene therapy strategies may not benefit from additional modification with AADC. ## 131.12

**FETAL NEURAL RETINAL GRAFTS INTO HUMAN RETINITIS PIGMENTOSA (RP).** M. del Cerro<sup>1,2</sup>, T.P. Das<sup>3</sup>, E. Lazar<sup>1,2</sup>, S. Jalali<sup>3</sup>, D. DiLoreto<sup>2</sup>; C. Little<sup>2</sup>; A. Sreedharan<sup>3</sup>; C. del Cerro<sup>1,2</sup>; and G. N. Rao<sup>3</sup>. L.V. Prasad Eye Institute, Hyderabad, India<sup>1</sup>; Dept. of Ophthalmology<sup>2</sup>, and Neurobiology<sup>3</sup>; U. of Rochester Medical School, Rochester, N.Y., 14642; USA

Human fetal neural retinal cells have been grafted into the subretinal space of 8 patients with advanced RP for possible treatment of the disease.

A suspension of dissociated human fetal neural retinal cells (14 to 19 weeks gestational age) was injected into the subretinal space in the paramacular area of adult patients with only light perception (LP) bilaterally. The recipient and donor mother blood was pre-screened for transmissible diseases. Pre- and post-operatively a full clinical exam including visual acuity, electroretinogram, visual evoked potential and fluorescein angiogram was performed at frequent intervals.

In the follow-up period (average 8.66 months; range 3-15 months), repeat examinations showed no evidence of inflammation, infection, retinal detachment, or clinically observable overt rejection of the subretinal graft. Furthermore, there have been indications of visual improvement in two patients; one advancing from LP to hand motion, and the other patient from LP to 20/200. No change was seen in other eyes or the fellow eyes of these or any other operated patients.

In sum, a procedure has been developed that allows the safe and efficient delivery of neural retinal cells into the subretinal space of RP patients. This series shows lack of overt rejection of the grafted cells, with no compromise to the host eyes. The study suggests that visual gain via retinal transplantation is possible in advanced RP.

## 131.13

EFFICACY OF NON-FETAL HUMAN RPE FOR PHOTORECEPTOR RESCUE: A STUDY IN DYSTROPHIC RCS RATS. B.V. Castillo Jr.\* 1, M. del Cerro 1,2, R.M. White 1, C. Cox 3, J. Wyatt 4, G. Nadiga 1, and C. del Cerro 1. 1Neurobiology & Anatomy, 2Ophthalmology, 3Biostatistics, & 4Lab Animal Med., University of Rochester Med. Ctr., Rochester, NY.

The purpose of this study is to determine the efficacy of non-fetal human retinal pigment epithelium for photoreceptor rescue utilizing the dystrophic RCS rat.

Eyes from 10 and 49 year old donors were obtained through the Rochester Eye and Human Parts Bank. The RPE was isolated by enzymatic treatment of the choroid-RPE with 2% dispase for 30 min. at 37°C. Mechanically dissociated RPE cells were injected at the superior hemisphere into the subretinal space of dystrophic RCS rats during the fourth postnatal week. Rats receiving vehicle injection served as sham controls. The animals were immunosuppressed with daily cyclosporine injections (10 mg/kg) and sacrificed 30 days post-transplantation for evaluation of the RPE graft and its effect on photoreceptor survival.

Transplantation of adult human RPE promoted the survival of photoreceptors in the dystrophic RCS rat. Morphometric analysis of the grafted superior hemisphere (149.2 ± 50 SD) demonstrated a 3 fold increase in photoreceptor cell density compared to sham controls (39.7 ± 31 SD) and the untouched inferior hemisphere (52.8 ± 28 SD). RPE from the 49 y.o. donor was as effective as RPE from the 10 y.o. donor in promoting photoreceptor survival.

The results of this study in RCS rats suggests that RPE from adult human donors is suitable for transplantation and retains the capability to promote survival of photoreceptor cells. This finding opens the possibility of using non-fetal RPE cells in human retinal transplantation.

# TARGET DENERVATION PROMOTES RETINAL TRANSPLANT PROJECTIONS IN ADULT RATS

D.D.A. Lawson\* and R.D. Lund, Neural Transplant Program, Institute of Ophthalmology, Bath Street, London EC1V 9EL, UK.

Two important factors relevant to adult neural transplantation strategies are the extent of graft axon elongation and the influence of existing host circuitry. Here we investigated the tectal innervation patterns of intracerebral retinal transplants, employing a novel graft arrangement to examine the impact of the above parameters.

Embryonic(E10-E12) mouse retinæ were transplanted unilaterally over the midbrain of adult immunosuppressed rats, and the projections studied using M4/M6 antibodies and the neuronal tracer Dil after a minimum of 4 weeks. A second set of adult rats received bilateral embryonic(E12-E14) rat retinal transplants with concomitant single eye enucleation at the time of grafting. Three months later a secondary degeneration protocol allowed a comparison of transplant-derived optic terminal numbers in the intact and denervated superior colliculi(SC) using EM.

Immunohistochemistry/Dil revealed sparse fibre outgrowth from the retina to the upper regions of the SC, the axons coursing a maximum of 200µm from the graft margin. Bilateral transplants demonstrated both a heavier retinal projection and a greater number of graft terminals in the denervated vs. intact SC.

These results sustain the idea that a significant component limiting graft incorporation in the mature CNS is the non-permissive environment for axon extension. However, once suitable targets have been attained the principal determinant of successful integration would appear to be the availability of synaptic sites.

# Effect of Schwann Cells and Macrophage Inhibitory Factor(MIF) on the Survival of Rat Retinal Ganglion Cells(RGCs) after Axotomy and Peripheral Nerve(PN) Grafting.

J.M. Lawrence, D.D.A. Lawson, S.J.O. Whiteley, R.D. Lund\* and Y. Sauvé Institute of Ophthalmology, London, UK.

Peripheral nerve grafts to the transected optic nerve support axonal regeneration from a small proportion of RGCs. This fraction might be increased by co-transplanting Schwann cells, a potential source of growth factors known to sustain RGCs. However, both axotomy and Schwann cells induce a microglial response, which may be inimical to neuron survival. The addition of intravitreal MIF at the time of PN grafting appears to suppress this response and so assist in RGC survival and axonal regeneration.

Therefore, following survival times of 6 to 8 weeks and using DiAsp as a retrograde tracer, we present results comparing the effects of combined MIF and neonatal homologous Schwann cells introduced into the eye at the time of PN grafting.

In comparison to untreated grafted retinæ, MIF appears to promote axonal regeneration from more RGCs; these cells are mainly type II-like (with small soma and restricted dendritic arbours). After Schwann cell grafting, RGCs with much larger soma and dendritic fields are present in a significantly greater proportion. Furthermore, the radiating axon bundles appear more prominent in the Schwann cell-grafted retinæ.

# CONTRIBUTION OF SYMPATHETIC TONE TO THE PUPILLARY LIGHT REFLEX MEDIATED THROUGH NORMAL AND TRANSPLANTED RETINAE. J.D. Radel\*, Depts. of Occupational Therapy Ed. and Physiology, Univ. Kansas Medical Center, Kansas City, KS 64113-7602.

The pupillary light reflex (PRL) in mammals is a motor function which occurs in a graded fashion with changes in light intensity. Characterization of the PRL in individual rats has been utilized to monitor functional status of the visual system during development (Radel et al., Eur. J. Neurosci. 1992), and at maturity after intracranial transplantation of retinæ (Radel et al., Neurosci., 1995) and the directed immunologic lesioning of such transplants (Bannerjee et al., Neurosci. 1993). The sympathetic nervous system also plays a role in governing pupillary responsiveness. The present studies are directed at clarifying that role, particularly in responses mediated through retinæ transplanted to an ectopic location in the brain.

Pigmented (Long-Evans) rats were used. Pupillary responses of the left eye were recorded as the right eye was illuminated in 4 normal rats. Once the response characteristics were defined for each animal, the left superior cervical ganglion (SCG) was removed surgically. Pupillary responses again were characterized 4-6 weeks after the surgery. Parameters describing the pupillary response were compared across pre- and post-surgery sessions. Although there were no changes in the pre-stimulus (baseline) diameter, removal of the ipsilateral SCG produced a 10% reduction in constriction amplitude, a 50% longer response latency, a 40% increase in constriction velocity, and a 10% slowing in the rate of post-stimulus dilation rate. Sympathetic tone appears to influence component features of the PRL differentially.

In the second phase of the study, an E13 retina was transplanted to the dorsal midbrain surface in each of five newborn host rats. The right eye of each host was removed at that time to encourage a robust transplant projection to denervated visual nuclei. At maturity, the tip of a fiber optic was inserted through the host's skull and fixed in place to allow direct stimulation of the transplanted retina with light. Transplants were illuminated with stimuli of graded intensities, and pupillary responses recorded from the host's left eye. The procedure outlined above for normal rats was followed. The findings show that pupillary light responses mediated through transplanted retinæ 1) are preserved following ipsilateral lesioning of the SCG, and 2) such responses may be more strongly influenced by sympathetic tone than normal.

## STAINING, TRACING, AND IMAGING TECHNIQUES I

## 132.1

# USE MANGANESE AS A CALCIUM TRANSPORT ANALOG FOR MRI OF NEURONAL ACTIVATION WHICH IS INDEPENDENT OF BLOOD FLOW.

Y. J. Lin\* and A. P. Koretsky Dept. Biological Sciences and NMR Center for Biomedical Research, and Center for Neural Basis of Cognition, Carnegie Mellon University, Pittsburgh, PA15213

Current functional imaging methods are all based on detecting hemodynamic changes resulting from neuronal activation. The goal of this work is to develop an alternative method that allows directly imaging neuronal activation independent of hemodynamic changes. Calcium ( $Ca^{2+}$ ) is a major second messenger for neuronal signal transduction. The work presented here is to indirectly image  $Ca^{2+}$  influx during neuronal activation with MRI. The strategy is to use a  $Ca^{2+}$  analog which is also a paramagnetic MRI contrast agent. Manganese ion ( $Mn^{2+}$ ) enters cells through calcium pathways such as ligand-gated and voltage-gated calcium channels.  $Mn^{2+}$  is also a known MRI contrast agent. Activated neurons will have elevated  $Ca^{2+}$  influx as well as  $Mn^{2+}$  influx if  $Mn^{2+}$  is supplied. Therefore, activated neurons will have higher intracellular  $Mn^{2+}$  concentration which will shorten the NMR relaxation time constant  $T_1$ . A shorter  $T_1$  leads to enhanced contrast on  $T_1$  weighted MRI.

Anesthetized rats were chemically challenged with glutamate and bicuculline.  $Mn^{2+}$  was constantly infused through a femoral vein at a rate of 3.6µmole/min. This dose of  $Mn^{2+}$  had little effect on heart rate and blood pressure. Both glutamate and bicuculline caused  $Mn^{2+}$  dependent increases in MRI signal intensity of 250%. This change in signal intensity was dependent on breaking the blood-brain-barrier to increase delivery of  $Mn^{2+}$ . This large increase in signal intensity was independent of blood flow, because high  $CO_2$ , which is known to increase cerebral blood flow, did not cause significant signal intensity changes. These data indicate that  $Mn^{2+}$  is a candidate for indicating  $Ca^{2+}$  influx for functional MRI. (The work is supported by the Center for Neural Basis of Cognition and NIH P41-RR03631-08 Multidisciplinary NMR Center for Biomed. Res.)

## 132.2

# QUANTITATION OF LARGE MOLECULAR WEIGHT PROTEIN DISTRIBUTION IN THE CNS AFTER BULK FLOW INFUSION AND ITS NEUROSURGICAL IMPLICATION.

Alexander C. Cummins\*, Paul F. Morrison<sup>1</sup>, Marc-Etienne Corthésy, Russell R. Lonser, Yash Pannu, Nitin Gogate, Robert L. Dedrick<sup>1</sup> and Edward H. Oldfield, Surgical Neurology Branch, National Institute of Neurological Disorders and Stroke and <sup>1</sup>Biomedical Engineering and Instrumentation Program, National Center for Research Resources, National Institutes of Health, Bethesda, Md. 20892

High flow infusion has been demonstrated to be a viable means of uniform delivery of compounds into the CNS. The distribution of infusate remains to be quantified for accurate dose assessment. To quantify the infusion in grey matter, rats were infused with 2µl of  $C^{14}$  labeled albumin into the striatum. Delivery rate is one possible factor affecting accurate delivery. We examined recovery at fixed rates ranging from 0.02µl/min to 1µl/min. At a rate of 0.02µl/min the recovery was 87.8% (+3.5%) of the radioactive albumin infused into the striatum. There was a small decline in recovery at rates between 0.02µl/min and 0.1µl/min (80%). Above this rate, however, the recovery rate fell rapidly. A possible explanation for this decrease may be leakage along the needle tract which would be consistent with a mathematical model. Autoradiographs of the brain sections showed significant amounts of radioactivity along the needle tract only in rats infused at rates above 0.1µl/min. Additionally autoradiography showed that the infusate filled most of the striatum and the concentration was uniform throughout the infused area.

## 132.3

**MAPPING OF PHOSPHOCHOLINE SECONDARY IONS IN THE RODENT BRAIN BY SECONDARY ION MASS SPECTROMETRY.** C.A. McCandlish\*, J.M. McMahon, and P.J. Todd. Chemical and Analytical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831-6365.

Phosphocholine ions  $m/z$  184 and  $m/z$  86 are almost always abundant in secondary ion mass spectra (SIMS) of animal tissue, and have been previously identified by tandem mass spectrometry (MS/MS). The parent compounds of these ions, mainly phosphatidylcholine and sphingomyelin, are major constituents of animal membrane, particularly in the brain. We report that the distribution of phosphocholine ion emission corresponds to the density and composition of the membrane. For example, the distribution of neurons and associated cell axons detected in Nissl-stained tissue corresponds to the observed distribution of  $m/z$  184 emission.

Rats and mice were anesthetized with metofane and perfused intracardially with buffered saline (pH 7.3) followed by a 2% formalin solution (pH 7.3). Following perfusion, the brain was removed from the skull and sectioned (50 microns) coronally using a Vibratome. Sections were mounted onto copper slides for SIMS imaging. Alternate (reference) sections were mounted onto glass slides to be stained with cresyl violet.

Analysis of  $m/z$  184 ion images indicates that areas of greatest ion intensity are brain nuclei which are cell-rich, whereas areas which have little or no emission are acellular fiber tract sites. These results indicate that the heterogeneous emission of secondary ion yields of  $m/z$  184 observed with SIMS imaging delineates brain structures in a way consistent with known histochemistry. Furthermore, the correspondence between alternate optical and secondary ion images suggests that successive ion images may be used to produce a 3-D image of the brain.

## 132.5

**SYNAPTIC ACTIVATION AND PROPAGATION OF ACTION POTENTIALS IN THE PROCESSES OF INDIVIDUAL NEURONS.**

D. Zečević\*, Yale University School of Medicine, New Haven, CT.

The aim of the experiments was to provide direct evidence for the early postulate that individual nerve cells might be functionally subdivided. If true, this postulate would have important implications for the functional complexity of individual neurons. The proposed functional subdivision will depend critically on two factors: (1) the existence of multiple spike trigger zones that can be independently activated, and (2) the ability of the neuron to initiate partial responses (action potentials which do not invade all regions of the cell). Both of these questions could be addressed directly using fast, multi-site, voltage-sensitive dye recordings from processes of an identified snail (*Helix*) neuron which has a complex geometry and multiple spike trigger zones. The first goal was to investigate whether different synaptic inputs might activate different trigger zones. The results showed that the site of spike initiation was different and specific for different modes of synaptic activation. Different trigger zones were associated with different sets of synaptic inputs. The second goal was to establish, by direct measurements, whether action potentials evoked selectively in one axonal branch spread into all other processes, or whether spikes might fail at certain branch points. Voltage-sensitive dye recordings allowed direct detection of action potential propagation across axonal branch points. While for some branches peripherally evoked action potentials invariably propagated into the whole neuron, failure of spike propagation was found at specific sites.

Together, these results provide direct evidence for the hypotheses that individual nerve cells can be functionally subdivided with some of the processes functioning as independent units. Supported by NIH Grants NS28443 and NS08437.

## 132.7

**COMPARISON OF OPTICAL SIGNALS IN THE TURTLE CNS GENERATED BY VOLTAGE- AND ION-SENSITIVE DYES.** C. X. Falk\*, Larry B. Cohen, and David M. Senseman. Dept of Physiology, Yale Medical School, New Haven, CT 06520, Div. of Life Sciences, Univ. of Texas at San Antonio, San Antonio, TX 78249

Extrinsic voltage-sensitive dye signals and intrinsic optical signals arising from changes in light-scattering, blood flow and/or oxygenation levels have proven useful in mapping the functional architecture of the visual cortex and other regions within the vertebrate CNS. There are, however, at least two ways in which the utility of this approach might be improved. Both intrinsic and extrinsic optical signals are relatively small compared to the optical noise generated, *in vivo*, by the movements associated with respiration and the pulsatile blood flow. Another problem is phototoxicity which is especially problematic when bright light sources are used to excite fluorescent dyes during long recording sessions. We asked whether pH-sensitive and/or ion-sensitive dyes might be more benign and generate more robust signals for optical mapping of neuronal activity. We used the semi-sectioned turtle olfactory bulb because olfactory nerve stimulation evokes large and well-characterized voltage-sensitive dye signals. We tested 11 ion-sensitive dyes that would be expected to respond to changes in either the extracellular or the intracellular concentration of  $\text{Na}^+$ ,  $\text{H}^+$ ,  $\text{Cl}^-$ , or  $\text{Ca}^{2+}$ . The largest signals were obtained with RHOD-2-AM (presumably measuring intracellular  $\text{Ca}^{2+}$ ) and phenol red (presumably measuring changes in the extracellular pH). Several of the ion-sensitive dyes had signals that were more localized than the voltage-sensitive dye signals measured on the same preparation. In each preparation we finished by adding a voltage-sensitive dye (either RH795 or RH155). In every case, the signal-to-noise ratio from the voltage-sensitive dye was larger than the signals found with ion-sensitive dyes. Supported by NIH grant NS08437.

## 132.4

**METABOLIC POLARIZATION IN NEURONS AS RELATED TO THEIR STRUCTURAL AND FUNCTIONAL POLARIZATION.** Glenn H. Kageyama\*, Dept. Biol. Sci., Calif. State Polytechnic Univ., Pomona, CA 91768; Dept. Anat. & Neurobiol., College of Medicine, University of California, Irvine, CA 92717.

Major sites of energy utilization, as determined by the histochemical localization of  $\text{Na}^+/\text{K}^+$ -ATPase (p-nitrophenyl phosphatase, p-NPP), was compared to major sites of energy production by glycolytic vs. oxidative metabolic pathways, as determined by lactate dehydrogenase (LDH) and cytochrome oxidase (CO) histochemistry, respectively in various neuronal structures of knife-fish (*Apteronotus*), rat and cat. Animals were perfused with aldehydes and 60  $\mu\text{m}$  vibratome sections were processed for either p-NPP, LDH or CO histochemistry and compared. Cellular analysis of the rat hippocampus revealed that the highest levels of p-NPP and CO were found within the distal dendritic segments of granule and pyramidal cells, while LDH was highest in proximal dendrites, soma, axons and terminals, indicating an inverse intracellular distribution and partial segregation of oxidative and glycolytic enzymes in these cells. Similar distribution patterns were observed in the hypothalamo-hypophyseal magnocellular paraventricular neurosecretory neurons. In cat photoreceptors CO is localized to the inner segments and axon terminals (of cones, but not rods) along with  $\text{Na}^+/\text{K}^+$ -ATPase while the remainder of the cell is devoid of mitochondria, but rich in LDH. Neurogenic electrocytes of the weak electric fish *Apteronotus albifrons* exhibit extremely high CO levels in the cell body and proximal axons but are devoid of mitochondria in the electrogenic axon terminals. Since these neurons have a very high firing frequency, axonal discharges would have to be supported by elevated levels of glycolysis. These observations support the hypothesis that distinct neuron types have a particular pattern of metabolic polarity whereby oxidative and glycolytic metabolic pathways can be partially segregated within functionally different parts of the same cell. Support: Cal Poly Pomona RSCA Grant #1-11496 (Kageyama), & NIH Grants: DC 00450 & NS 30109 (RT Robertson & GH Kageyama).

## 132.6

**OPTICAL MONITORING OF ACTIVITY FROM INDIVIDUAL AND IDENTIFIED POPULATIONS OF NEURONS RETROGRADELY LABELED WITH VOLTAGE-SENSITIVE DYES.** C. Hickie\*, P. Wenner, M. O'Donovan, Y. Tsau, J. Fang, and L.B. Cohen. Dept. of Physiology, Yale University, New Haven, CT 06520, and NINDS/NIH, Bethesda, MD 20892

Optical signals obtained from neural tissue labelled with voltage-sensitive dyes are often derived from the activity of many types of neurons as well as glia. To obtain specific signals from identified neuronal populations we developed a method for retrogradely labeling neurons. We report two advances. First, in the chick embryo spinal cord preparation, we compared the optical signals obtained from a population of retrogradely labelled motoneurons with simultaneous whole cell recordings of individual motoneurons antidromically identified from the labelled root. The optical and electrical signals were similar except that whole cell recordings of individual motoneurons revealed spiking activity. This is direct evidence that the optical signals are reliably following transmembrane potentials and suggests that labelled motoneurons are physiologically unaffected by the dyes. Second, we have preliminary evidence that the voltage-sensitive dye signal from motoneurons in a lamprey spinal cord is large enough to allow detection of individual action potentials in individual neurons. A concentrated solution of the styryl dye, di-8-ANEPPQ, provided by J. Wuskell and L. Loew, was injected into a cut ventral root of a larval lamprey (*Lampetra*) cord. After waiting 10 hours for the dye to be transported back to the cell bodies, we sometimes found that well separated individual neurons were stained. The dye fluorescence was monitored using a microscope with a 464 element photodiode array in the objective image plane. Motoneurons were activated by shocks to the rostral cord. Optical signals ( $\Delta F/F \sim 0.3\%$ ) from individual cell bodies could be recorded in single trials. These signals had a latency and a duration appropriate for individual action potentials in motoneurons. Supported by NIH grant NS08437.

## 132.8

**LABELING BLASTOMERES WITH A CALCIUM INDICATOR: A NON-INVASIVE METHOD OF VISUALIZING NEURONAL ACTIVITY IN ZEBRAFISH.** K. J. A. Cox\* and J. R. Fetcho. Department of Neurobiology and Behavior, State University of New York at Stony Brook, Stony Brook, New York 11794-5230

The relationship between neuronal activity and behavior is clearly an important issue in neuroscience and has been studied using a variety of methods, including electrophysiology and more recently the use of voltage and calcium sensitive dyes. A problem with these recording approaches is that they are invasive, either inherently as with electrophysiology, or in the preparation, as with the introduction of dyes into cells. In order to circumvent this, we have developed an approach in which injections of the calcium indicator calcium green dextran (CGD) into zebrafish embryos at the 1-4 cell stages were used to monitor the activity of neurons in larval fish. Dye was pressure injected into a single cell and the fish allowed to develop until post-hatching, when they were embedded in agar and viewed under a confocal microscope. Labeled larval cells, including identifiable neuronal classes such as Rohon-Beard cells and olfactory neurons, were clearly visible with extensive labeling of the whole fish following injections at the one cell embryonic stage, and a mosaic labeling pattern following injections at the 2 or 4 cell stages. Activity of neurons in the spinal cord, as indicated by intracellular calcium concentration changes, was observed directly by monitoring fluorescence changes of individual spinal neurons and groups of spinal neurons on a confocal microscope. Fluorescence increases of between 9% and 55% in spinal neurons were seen during escape responses produced when the fish was tapped on the tail. This technique can potentially be used to monitor the activity of any neuron or group of neurons with respect to behaviour non-invasively in intact living zebrafish.

This work was supported by the Howard Hughes Medical Institute and National Institute of Neurological Disorders and Stroke Grant #NS26539 to J.R. Fetcho.

## 132.9

A HIGH PERFORMANCE MICROSCOPE FOR *IN-VITRO* SLICE IMAGING WITH VOLTAGE SENSITIVE DYES. **M.C. Crair\*** and **M.P. Stryker**, Keck Center for Integrative Neuroscience and Department of Physiology, University of California, San Francisco, CA 94143-0444

We have adapted the "macroscope", originally introduced by Grinvald et al. (*J. Neurosci. Methods*, 1991) for *in vivo* imaging, to an *in vitro* environment to achieve exceptional light gathering performance at relatively low magnification. This system is ideally suited for high spatial and temporal imaging using transmembrane signals and voltage sensitive dyes with cameras like the Fuji HR Deltaron 1700.

With Koehler illumination from below and a pair of conventional camera lenses attached front-to-front as our transmitted light gathering system, we can achieve a numerical aperture (NA) up to 0.5 for a range of magnifications from 2X to 8X. In comparison to stock microscopes whose NA is typically 0.14-0.16 at 4X, our microscope collects light approximately 10 times more efficiently than standard systems, thereby relieving the most stringent bottle neck for high signal to noise imaging and reducing the effects of photodynamic damage to our biological sample. Mounted on a free standing XY stage independent of the sample and sample chamber, this system is also stable enough to allow whole cell patch recording from cortical slices.

In a typical arrangement, we use a 50mm f/1.2 objective (with the back end closest to the sample) and a 70-210mm f/2.8 zoom lens as our telescope (attached to the camera). With this lens system, in addition to a 2X tele-extender, we can image at any magnification up to 8X by a continuous adjustment of the zoom lens. This "macroscope" is a convenient and efficient system for wide field imaging applications with the potential for combining the benefits of high resolution imaging with the microelectrode and pharmacological access available in an *in vitro* system.

Supported by NIH EY09760, NIH EY02874 and an NIMH fellowship.

## 132.11

PLASTIC EMBEDMENT OF CNS TISSUE: PRESERVING ULTRASTRUCTURE WITHOUT OSMIUM. **K.D. Phend\*** and **R.J. Weinberg**, Department of Cell Biology & Anatomy, University of North Carolina, Chapel Hill, NC 27599.

Following glutaraldehyde fixation, tissue for electron microscopy is routinely postfixed in osmium tetroxide. This step is thought to be especially important for preservation of ultrastructure in lipid-rich tissues, such as brain. However, osmium compounds are expensive, toxic, and frequently impair antigenicity. We previously reported an osmium-free technique that enhances subsequent immunoreactivity while providing satisfactory ultrastructure (*J. Histochem. Cytochem.* 43:283-292). We here report further progress in optimizing tissue preparation. For subsequent postembedding immunocytochemistry for glutamate receptors and associated proteins, we include calcium and iridium salts; antigenicity is further enhanced by briefly etching the grids in metaperiodate and borohydride. For cases where antigenic preservation is not needed, we report a simple postfixation technique, using tannic acid followed by zinc and uranyl salts, that provides excellent structural preservation without osmium. Resin infiltration may be improved by incubating tissue in digitonin before the tannic acid step. This research was supported by NIH award # NS29879.

## 132.13

NEW PHOTORELEASEABLE CAGED GLUTAMATE WITH VERY LOW PRE-PHOTOLYSIS ACTIVITY. **J. P. Y. Kao\***, **C. M. Tang** and **F. M. Rossi**, Medical Biotechnology Center and Dept. of Physiology and Neurology, Univ. of Maryland School of Medicine, Baltimore, MD 21201

Because desensitization of non-NMDA GluR channels occurs at low ( $\mu$ M) concentrations of glutamate while full activation during synaptic transmission requires millimolar concentrations, an ideal caged glutamate should give high yield of glutamate on photolysis but show low pre-photolysis residual activity. (Residual activity is the sum of the intrinsic activity of the caged compound and the activity of any free glutamate arising from spontaneous, non-photolytic breakdown of the caged compound). Ideally, the ratio of yield to residual activity should be  $> 1000$ . Such a caged glutamate has remained elusive. In an attempt to maximize the yield/residual activity ratio while maintaining reasonable photorelease kinetics, we have prepared a new reagent: NMOC-glutamate. Photolysis of NMOC-glutamate with UV light liberates glutamate with quantum yield  $Q = 0.11$ . The photochemical reaction is fast, while the dark reaction yielding glutamate is pH-dependent and is expected to proceed with a pseudo-unimolecular rate constant of  $\sim 3 \times 10^4 \text{ s}^{-1}$ . The rate at which activating concentrations of glutamate are attained can thus be manipulated through both reagent concentration and medium pH. The figure illustrates the effect of glutamate photorelease from NMOC-glutamate on the whole-cell current recorded from a dissociated rat hippocampal neuron. Addition of 10 mM NMOC-glutamate at pH 6.3 caused no measurable change in the baseline current. Photorelease was achieved at the cell soma by exposure to UV light from an argon ion laser focused to a 30- $\mu$ m spot. Photoreleased glutamate caused a rapid inward current, with time-to-peak  $< 1$  ms (shutter opening,  $\sim 400 \mu\text{s}$ ), which then desensitized rapidly. (GM46956)

## 132.10

'ULTRATHIN' CNS SLICES: ENHANCED VISUALIZATION OF NEURON STRUCTURE FOR ELECTROPHYSIOLOGY AND IMAGING. **L. Song\***, **M. Sawchuk**, & **S. Hochman**, Dept. Physiology, Univ. of Manitoba, Winnipeg, MB, Canada R3E 0W3.

Electrophysiological studies using patch clamp recordings in CNS slice preparations involve either 'blind' or visual targeting strategies. Recordings from visually-identified neurons generally require specialized upright microscopes equipped with Nomarski optics (DIC) (e.g. Konnerth et al *Pflugers Arch.* 414:600, 1989). Further image optimization to observe neuronal processes employ video-enhanced infrared wavelength illumination (e.g. Stuart et al *Pflugers Arch.* 423:511, 1993). Though powerful, these approaches require specialized, expensive equipment.

Since the ability to resolve detailed cellular features is generally limited to 40-50  $\mu$ m from the slice surface, we have developed an alternate strategy to visualize neurons using a semi-transparent 'ultrathin' slice preparation (20-50  $\mu$ m) visualized on an inverted microscope equipped with Hoffman modulation optics. Isolated cerebellum, hippocampus or spinal cord from neonatal rats (P1-P14) were embedded in AGAR (2.5% w/v) then sectioned with a Leica VT 1000 vibratome. Following incubation at 32°C for 1 hour slices were fixed to the bottom of the recording chamber and maintained at room temperature. The enhanced transparency due to reduced slice thickness permitted superior optical resolution of dendritic and axonal processes and cells were visible throughout the slice thickness. Live/dead cell staining revealed that many cells remained viable for imaging and electrophysiological experimentation. In all CNS regions examined, neurons were easily identified for successful patch recordings. While not yet tested, use of an inverted microscope should permit high numerical aperture oil-immersion objectives to be used for simultaneous imaging experiments and the reduced slice thickness would hasten drug equilibration and washout times. Supported by the Canadian Neuroscience Network.

## 132.12

IMAGING OF INTRINSIC OPTICAL SIGNALS SHOWS THAT ACUTE OSMOTIC AND ACUTE EXCITOTOXIC NEURONAL DEATH ARE DIFFERENT.

**Michael E. Lobinowich, Trevor M. Polischuk and R. David Andrew\***, Department of Anatomy & Cell Biology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Irreversible swelling of the neuronal cell body is observed histologically in the cerebral cortex hours after an excitotoxic/ischemic event. The assumption has been that osmotic stress swells the cell body, thereby contributing to neuronal death. Previous studies of acute osmotic or excitotoxic stress have focused on changes in cell body volume. In the hippocampal slice preparation, we have shown dynamic volume changes in both the cell body and dendritic regions evoked by excitotoxins.<sup>1</sup> Elevated light transmittance (LT) through the brain slice is an indirect measure of cell swelling, whereas reduced LT indicates cell shrinkage.<sup>2</sup> At 35°C, a 20 min exposure to saline diluted with distilled water to 175 mOsm (-120) led to an initial LT increase of  $49 \pm 11\%$  (n=8 slices) in the CA1 stratum radiatum (RAD). This severe unphysiological osmotic stress caused no apparent volume regulation. Remarkably in 4 slices, upon return to control saline, the evoked CA1 field potential returned to control levels while the change in LT returned to  $-17 \pm 4\%$ . However in 4 other slices, it was reduced or eliminated (neuronal death) while the LT irreversibly decreased to  $-37 \pm 10\%$ . Similar exposure to 55 mOsm (-240) saline annihilated the evoked field and caused an irreversible LT decrease in CA1 RAD ( $-47 \pm 21\%$ ) in all 3 slices tested. In each case, only a small reversible swelling was measured in the CA1 cell body region (PYR). In contrast, 4-10 min exposure to a glutamate agonist (100  $\mu$ M NMDA, 10  $\mu$ M domoic acid or 10  $\mu$ M AMPA) at 37°C irreversibly increased LT in CA1 PYR within 10 min (n=25) coupled to an irretrievable loss of the evoked field (neuronal death). We conclude: 1) Dendritic regions in CA1 exhibit dramatic volume changes in response to acute osmotic and acute excitotoxic stress but 2) CA1 cell bodies can resist swelling during acute osmotic but not acute excitotoxic stress.

## 132.14

MONITORING CHANGES IN  $[\text{Ca}^{2+}]_i$  AND CELL VOLUME USING FURA-2, **W.E. Crowe**, **J. Altamirano** and **F.J. Alvarez-Leefmans\***, Depto. Neurobiología, Inst. Mex. de Psiquiatría, Av. México-Xochimilco 101, México 14370 D.F.; Dept. Physiology & Biophysics, UTMB, Galveston, TX 77555; Depto. Farmacol. CINVESTAV-IPN, Ap. Postal 14740, México 07000, D.F.; & Dept. Physiol. MCPHU, Philadelphia, PA 19129.

The role of  $\text{Ca}^{2+}$  as a second messenger in cell water volume (CWV) control is controversial. This is partly due to the lack of techniques with enough sensitivity and time resolution to measure simultaneous changes ( $\Delta$ ) in CWV and  $[\text{Ca}^{2+}]_i$ . Fura-2 was used to monitor these variables in N1E-115 and NG108 cells.  $[\text{Ca}^{2+}]_i$  was measured ratiometrically (350/358 or 358/380), whereas volume was measured at the intracellular isosbestic point (IP) that we determined *in vivo* (358 nm). Changes in fluorescence ( $\Delta F$ ) were measured from a region of each cell that was delimited by a pinhole placed at the image plane.  $\Delta F$  at 358 nm reflect changes in intracellular fura-2 concentration that can be transformed to  $\Delta \text{CWV}$  (Alvarez-Leefmans et al. *Methods in Neurosciences* 27:361-391, 1995). For CWV measurements it is crucial to minimize the effect of changes in effective path length resulting from changes in cell shape. By altering the pinhole size and location using a digital imaging system we found that the noise (N) level in individual traces decreased by increasing the pinhole size. However, as more of the peripheral regions of the cell were included in the pinhole, the magnitude and time course of the volume signals (S) were distorted. Optimal S/N was obtained with a pinhole located well within the cell boundaries and comprising 5-8 % of the total area of the cell body. (Supported by NINDS grant NS29227 and CONACyT Mexico, grant F-285-N9209).

## 132.15

SUBCELLULAR LOCALIZATION OF THE PRION PROTEIN USING FUSION TO GREEN FLUORESCENCE PROTEIN. Z. Meiner, M. Vey, E.L. Clausnitzer, D.M. McDonald, P. Dazin, S.B. Prusiner. University of California, San Francisco, CA 94143-0518.

While the function of PrP<sup>C</sup> remains uncertain, PrP<sup>C</sup> is the substrate from which PrP<sup>Sc</sup> is formed in prion diseases. Although PrP<sup>C</sup> is bound to cellular membranes by a glycosylphosphatidyl inositol anchor, it is controversial whether it is clustered within distinct domains of the cellular membranes or diffusely distributed. To localize PrP<sup>C</sup> on the plasma membrane and in other cellular compartments, we transiently expressed fusion proteins consisting of PrP and the fluorescent marker, Green Fluorescent Protein, in normal (N2a) and scrapie-infected (ScN2a) neuroblastoma cells. The fluorescence was examined in living and fixed cells using fluorescence microscopy, confocal microscopy, and FACS analysis. The fluorescent fusion proteins were detected in patchy clusters on the plasma membrane of the cell soma and neurites. In addition, the fluorescence was detected in a perinuclear compartment identified as the trans-Golgi network. After treatment with phosphatidylinositol-specific phospholipase-C or proteinase K, most of the fusion protein disappeared from the cell membrane without any difference between N2a and ScN2a cells. We conclude that PrP<sup>C</sup> is localized in clusters on the plasma membrane of the cell soma and neurites. Our results support the hypothesis that PrP<sup>C</sup> is localized on the plasma membrane in distinct domains. This localization may be important for the function of PrP<sup>C</sup> and the conversion of PrP<sup>C</sup> into PrP<sup>Sc</sup>.

## 132.17

SELECTIVE SORTING OF EMBRYONIC DOPAMINERGIC CELLS BY FLOW CYTOMETRY USING A FLUORESCENT NEUROTENSIN DERIVATIVE. M.P. Faure\*, K. McDonald, A. Gagner, A.F. Sadikot and A. Beaudet, Montreal Neurol. Inst., Univ. McGill, 3801 University St., Montreal, QC, Canada, H3A 2B4.

We have previously shown that 80-95% of rat ventral mesencephalic dopaminergic (DA) neurons were selectively endowed with high affinity neurotensin (NT) receptors (Szigethy et al., 1989). Taking advantage of this property, we devised a method for selectively sorting embryonic DA cells by flow cytometry (FACS) using a fluorescent NT derivative (fluo-NT, Faure et al., 1994). Mesencephalic cells from E15 rat embryos were rapidly dissociated and analyzed by flow cytometry either immediately (D0) or after 7 days in culture (D7). Both D0 and D7 cells were labeled by incubation for 20 min at 4°C with 10 nM fluo-NT in the presence or absence of 1 µM non fluorescent NT for determination of non specific binding. FACS analysis revealed an almost tenfold difference in mean fluorescence intensity between total and non specific binding at D7, but none at D0, in keeping with the late expression of NT receptors by DA cells. Control COS-7 cells transfected with a cDNA encoding the high affinity NT receptor exhibited the same shift to the right of fluorescence profiles as D7 neurons. Such a shift was not apparent in COS-7 cells either non transfected or transfected with an irrelevant receptor. Sorting through a window encompassing high specific binding/high survival events allowed for a sixfold enrichment in DA cells from 14 to 85% of total neuronal population, as estimated by pre- and post-sorting tyrosine hydroxylase immunocytochemistry. This proportion remained constant up to 4 days after plating the sorted cells back in culture, attesting to their viability. These results demonstrate the feasibility of selectively enriching embryonic DA cell populations by FACS and of keeping these cells alive after sorting. Supported by The Parkinson Foundation.

## 132.16

LOCALIZATION OF ION TRANSPORTERS INVOLVED IN CALCIUM CONTROL IN PRESYNAPTIC NERVE TERMINALS. M. Juhaszova, M.P. Blaustein\*, P.J. Church\* and E.F. Stanley\*, Physiol. Dept., U. Md. Med. Sch., Baltimore, MD 21201 and \*Synaptic Mechanisms Sect., NINDS, NIH, Bethesda, MD, 20892

Isolated calyces from chick ciliary ganglion synapses are useful as model vertebrate presynaptic terminals because of their large size and accessibility (J. Neurosci. 11:985, 1991). We have applied immunofluorescence to the calyx to determine the spatial distribution of Na/Ca exchanger (NCX) and plasmalemmal (PM) Ca<sup>2+</sup> pump in a presynaptic nerve terminal. Cross reactivity of antibodies (AB) generated against mammalian proteins was confirmed by immunoblots of ganglion membrane proteins. Chick ciliary ganglia were dissociated, fixed, and observed with high resolution imaging using the Cellscan (Scanalytics) system. Calyces were co-labeled with an anti-transporter AB (NCX from G.E. Lindemeyer; PM Ca<sup>2+</sup> pump from E. Carafoli) and an AB against synaptotagmin (from R. Jahn) as a marker for secretory vesicle clusters at the release sites. The staining for all three AB was patchy, indicating that the proteins were highly clustered. NCX staining exhibited no obvious association with synaptotagmin whereas many Ca<sup>2+</sup> pump clusters were co-localized with synaptotagmin. Our results suggest that the NCX, although present in the calyces, is not concentrated near transmitter release sites. In contrast, the Ca<sup>2+</sup> pump in calyces is preferentially located near release sites. Further studies are required to determine whether all of the pump clusters are located on the surface membrane or whether some are co-localized with synaptotagmin on the secretory vesicles themselves.

Support: NIH/NS-16106; NINDS intramural program.

## 132.18

THE APPLICATION OF NEAR-FIELD OPTICAL MICROSCOPY TO NEURONS AND MAST CELLS IN CULTURE. P.G. Haydon\*, M. McCloskey, T.A. Basarsky and S. Marchese-Ragona, Laboratory of Cellular Signaling, Iowa State University, Ames, IA, USA.

Optical resolution is limited by diffraction. Thus, the theoretical limit of resolution is about 250-300 nm. Sub-diffraction optical resolution can be achieved however, if a fine aperture is used so that a "nano-spot" of illumination is provided. Using pulled optical fibers, with tip diameters of 20-50 nm, an illumination source regulated by this aperture diameter has been developed. In the physical sciences, such near-field fibers have been used to study the properties of single fluorescent molecules. In principle, this technique could be used in biology to provide a new level of optical resolution to study the dynamic behavior of individual molecules in or adjacent to the cell membrane.

Using near-field optical fibers we have determined that sub-diffraction optical resolution (20-50 nm) can be achieved when using immobilized, dehydrated biological samples. Such resolution should permit new opportunities for studying molecular associations in biological systems when using fluorescence labeling methods. Additionally, we demonstrate that near-field probes can be readily placed in feedback on living cell membranes of neurons, astrocytes and mast cells. When cells are loaded with calcium indicators, such as fluo-3, we demonstrate the ability to reliably detect local changes in calcium level in the cell cortex. Furthermore, as an initial test of the ability to monitor fluorescently labelled secretory organelles, we demonstrate the ability to monitor exocytosis of individual mast cell granules labelled with quinacrine.

## GENE STRUCTURE AND FUNCTION I

## 133.1

DEFECTIVE HERPES SIMPLEX VIRUS VECTORS EXPRESSING THE RAT BRAIN STRESS-INDUCIBLE HEAT SHOCK PROTEIN 72 PROTECT CULTURED NEURONS FROM SEVERE HEAT SHOCK BUT NOT 3-NITROPROPIONIC ACID TOXICITY. S.L. Fink, L.K. Chang, D.Y. Ho\* and R.M. Sapolsky. Program in Neurosciences and Dept. of Biological Sciences, Stanford University, Stanford, CA 94305-5020.

Recently, pre-induction of the heat shock response has been shown to protect neurons undergoing a variety of stressful insults (e.g. heat, ischemia, exposure to excitotoxins). However, it is not known which of the proteins induced by the heat shock response mediate the protective effects. Previous correlative evidence points to a role for the highly stress-induced heat shock protein 72 (hsp72). The massive induction of hsp72 following neuronal perturbation, and the existence of induced tolerance phenomena in the brain both suggest a role for hsp72 in neuroprotection. However, studies to directly assess the ability of hsp72 to protect central nervous system neurons from heat shock and other, more common, neural stressors have not been performed.

We constructed a herpes simplex virus-1 vector carrying the rat brain stress-inducible *hsp72* and the *lacZ* (marker) genes. Infection with the vector caused neurons to co-express hsp 72 and β-galactosidase. Infection with a control vector lead to marker gene expression only, and thus did not induce endogenous hsp72 expression. Overexpression of hsp72 protected cultured hippocampal neurons against a heat shock, but not against the metabolic toxin, 3-nitropropionic acid.

Supported by a grant from the Adler Foundation (R.M.S.), an MSTP grant from the National Institute of General Medical Sciences (S.L.F.) and a Summer Research Fellowship from the Howard Hughes Foundation (L.K.C.).

## 133.2

EFFICIENT AND LONG-TERM GENE DELIVERY INTO RAT BRAIN USING ADENO-ASSOCIATED VIRAL VECTORS. P. Wu\*, B. Du\*, M.I. Phillips\*, E.F. Terwilliger\*. <sup>1</sup> Dept. Medicine, Deaconess Hospital, Harvard Medical School, Boston, MA 02215; <sup>2</sup> Dept. Physiology, Univ. of Florida College of Medicine, Gainesville, FL 32610.

Adeno-associated virus (AAV) vectors were previously shown in this lab to efficiently transfer a β-gal marker gene into several types of nondividing cells *in vitro*, including neurons. Further optimization of this system for gene delivery into the CNS was carried out by comparing the expression pattern of the β-gal gene under the control of either the CMV promoter or a neuron specific cellular promoter, both *in vitro* and *in vivo*. The rat arginine vasopressin (AVP) promoter was chosen for this purpose. Initially, AVP positive (A1T20/D16v-F2) or negative (293) cell lines were transduced with the pCMVβgal or the pAVPβgal vector. The CMV promoter appeared more potent than the AVP promoter in terms of the level of β-gal expression in both cell types *in vitro*. Treatment with the cyclic AMP activators dramatically enhanced the level of β-gal expression directed by the AVP promoter, but not from the CMV promoter. To determine whether these AAV-βgal vectors also induce expression of β-gal effectively *in vivo*, either pAVPβgal or pCMVβgal packaged in AAV virions (4 µl each) was stereotactically injected into the left lateral ventricle of normal male Sprague Dawley rats. β-gal expression was subsequently detected in sites far from the injection, demonstrating dispersal of the vector via the CSF, and was primarily confined to neurons, particularly in the case of the pAVPβgal. In contrast to the *in vitro* results, the AVP promoter was stronger than the CMV promoter in its ability to drive the expression of β-gal in neurons *in vivo*. β-gal expression driven by the CMV promoter was more diffuse, while the AVP promoter-induced expression was more concentrated to the PVN and SON of the hypothalamus, and this expression was stable for at least 1 month. Supported by grants to EFT from AmFar.

## 133.3

## STABLE TRANSDUCTION OF NEURONS IN THE ADULT BRAIN BY AN HIV-DERIVED LENTIVIRAL VECTOR.

U. Blömer, L. Naldini, J.M. Verma, D. Trono, F.H. Gage\* The Salk Institute, 10010 North Torrey Pines Road, La Jolla, CA 92037, USA

Application of gene therapy for the central nervous system depends not only on the identification of genes responsible for neurological disorders and gene products ameliorating diseases or genetic defects, but requires new methods for gene delivery. Significant problems remain with the existing viral vector systems. In the present study a new retroviral based HIV vector system, using the unique ability of lentiviruses to stably infect quiescent cells, was investigated *in vitro* and *in vivo*. This viral vector contains karyophilic determinants in two virion proteins, the matrix and the Vpr, interacting with the nuclear import mechanism of the host cell, mediating the active transport of the HIV preintegration complex through the nucleopore. In order to test this HIV derived vector *in vivo* we injected highly concentrated viral vector stock with the LacZ reporter gene bilaterally into the striatum and hippocampus of adult female Fischer rats. Seven days, 4 and 6 weeks after injection the animals were sacrificed and immunofluorescent triple labeling for  $\beta$ gal (reporter gene), NeuN (neuronal specific marker) and GFAP (glial fibrillary acidic protein) was performed on microtomed tissue sections.  $\beta$ gal immunoreactive cells were detectable at all time points with a large number of cells also NeuN positive. These results indicate that the HIV derived viral vector was able to transduce terminally differentiated neurons very efficiently and persistently for 6 weeks without causing local damage or immune response. Control brains injected with a MLV based retroviral vector revealed no transduced neurons in the early time points and no  $\beta$ gal immunoreactive cells after 6 weeks. Our results strongly suggest, that the HIV vector system is able to stably and efficiently infect terminally differentiated neurons *in vivo*. This replication defective lentiviral vector system also shows significant advantages compared to available vector systems and provides a new perspective on gene delivery to the brain. ## 133.5

## TETRACYCLINE-CONTROLLED GENE EXPRESSION SYSTEM ACHIEVES BOTH HIGH LEVEL AND QUANTITATIVE CONTROL OF GENE EXPRESSION, Patricia Whaley\*, Dong X. Yin, Sara Cunningham, Li Zhu, CLONTECH Laboratories, Inc., Palo Alto, CA 94303-4230.

The tetracycline-controlled gene expression system utilizes the control elements of the tetracycline-resistance operon encoded in Tn10 of *E. coli* to control gene expression in eukaryotic cells. Here we demonstrate the quantitative control of the expression of luciferase gene, dihydrofolate reductase gene, and bcl-2 gene in HeLa S3 or Chinese hamster ovary A48 cells using the tetracycline-controlled gene expression system. Regardless of the host cell lines or the genes being expressed, there is a common range of tetracycline concentration within which the expression of genes is most sensitively regulated. In addition, the maximal gene expression level of the tetracycline-controlled gene expression system is higher than that of the wild-type CMV promoter/enhancer driven systems. Nonetheless, careful selection of stably transfected clones is necessary to achieve the optimally regulated gene expression using this system. Furthermore, addition of the nuclear localization signal onto tTA or rtTA causes an increase of both background and maximal gene expression in this system. Therefore, both the experimental strategy and the system components should be carefully selected to achieve the expected results

## 133.7

## MOLECULAR CLONING OF THE RAT INDUCIBLE NITRIC OXIDE SYNTHASE GENE. R. Keinänen\*, N. Vartiainen, K. Kurkinen and J. Koistinaho, A.I. Virtanen Institute, Univ. Kuopio, P.O.B. 1627, FIN-70211 Kuopio, Finland.

Nitric oxide (NO) formation from L-arginine is catalyzed by nitric oxide synthase (NOS). Two of the NOS enzymes (NOS1 and NOS3) are expressed constitutively in a calcium-dependent manner, while the third (NOS2) is inducible and calcium-independent. Although NO is known to act in versatile ways, its precise role in brain diseases, such as ischemia, is not completely understood.

A rat genomic cosmid library was screened using the 3' end of the rat NOS2-cDNA as a probe. A positive hybridization signal was obtained from six clones, which were isolated and purified for further characterization. Based on hybridization with the 5' end of the mouse NOS2-cDNA, one of the clones (SC1A1) was selected for sequencing analysis. The length of the SC1A1 genomic insert is approximately 40 kb, and thus a strategy was designed to sequence the trapped exons first. Subsequently, SC1A1 was subcloned as shorter fragments, in both orientations, into a splicing vector and used to transfect COS 7 cells. Purified mRNA from the transfected cells was used as a template for cDNA synthesis, which in turn served as a template in PCR. The PCR products were further subcloned into a plasmid vector. Subclones for nucleotide sequencing were selected based on their specific hybridization with the original genomic fragment used for transfection. The current sequencing data obtained agrees with the cloned rat NOS2-cDNA.

When the 5' regulatory region of the NOS2 gene becomes available, detailed studies to understand the regulation of its transcriptional initiation will be started at the molecular level. Regardless of the eventual role NO plays in brain diseases, the control of the NOS2 gene transcription from the NOS family offers the most attractive target for pharmaceutical intervention.

Supported by the Maud Kuistila Foundation (Finland) and the Academy of Finland.

## 133.4

IN VIVO TRANSFER OF LEPTIN (*OBESE*) GENE INTO VENTROMEDIAL HYPOTHALAMUS WITH A DEFECTIVE AAV-VECTOR DECREASES BODY WEIGHT AND FOOD INTAKE. T. M. Mizuno\*, A. Sugiyama, F. Isoda, M. Rosenfeld, M. Kaplitt, S. Tanaka, and C. V. Mobbs, Fishberg Center for Neurobiology, Mt. Sinai School of Medicine, and Bronx VAMC, New York, NY 10029.

Leptin, the normal product of the *obese* gene, is hypothesized to control body weight by acting through leptin receptors in the ventromedial hypothalamus (VMH). To address this hypothesis, we examined the effects of transferring the leptin gene into VMH using a defective adeno-associated virus (AAV) vector. cDNA containing the coding region of leptin was produced from mouse adipose tissue by RT-PCR, then cloned into a plasmid containing a CMV promoter and AAV packaging sequences. Plasmid was packaged in the presence of helper adenovirus to produce defective vector dvACLept. PBS, dvACLept (a LacZ construct), or dvACLept, were infused into the VMH of male Sprague-Dawley rats. Body weight and food intake were determined daily before and up to 7 days after infusion. Compared to PBS or dvACLept, dvACLept significantly inhibited body weight gain and food intake after infusion ( $p < 0.05$ , ANOVA). These results suggest that expression of leptin in the VMH, possibly acting locally on hypothalamic leptin receptors, can reduce body weight and food intake.

Supported by NIH (DK 50110-01).

## 133.6

## ISOLATION AND CHARACTERIZATION OF THE RAT GTP CYCLOHYDROLASE I GENE PROMOTER. S.L. Stegenga\* and G. Kapatos, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry and Behavioral Neurosciences, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

Tetrahydrobiopterin (BH4) is the essential cofactor for tyrosine, tryptophan and phenylalanine hydroxylases and nitric oxide synthases. The first and rate-limiting enzyme in the biosynthetic pathway for BH4 is GTP cyclohydrolase I (GTPCH). Various stimuli, including cAMP, glucocorticoids, NGF, tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ),  $\gamma$ -interferon ( $\gamma$ -IFN) and LIF/CNTF have been shown to alter GTPCH mRNA levels in a tissue specific fashion. The manner in which these diverse stimuli exert their effects on GTPCH mRNA levels is not understood but presumably involves alterations in GTPCH gene transcription. We have, therefore, cloned and begun to characterize the rat gene for GTPCH. A rat testis genomic library in the  $\lambda$ -DASH vector was screened using a 852 bp cDNA probe spanning the entire coding region of rat GTPCH. A 15 kb GTPCH insert was isolated. Restriction and Southern analyses indicated that this included 6 kb of sequence 5' to the translation initiation site. The 6 kb 5' flanking sequence was subcloned into pGEM5Z for sequencing and further manipulation. The transcription start site was localized 141 bp upstream from the translation initiation site by primer extension using RNA isolated from PC12 cells. 1.2 kb of the 3' end of the 6 kb clone has been sequenced. Analysis reveals the absence of a TATA box within the core promoter although an AT-rich motif (ATAAAAA) and a CCAAT box are found adjacent to or 50 bp upstream of the cap site, respectively. CRE or AP-1 response elements were not detected despite the regulation of GTPCH by cAMP and NGF. Consensus sites for SP1 and NF- $\kappa$ B are present, the latter being concordant with the GTPCH response to TNF- $\alpha$  and  $\gamma$ -IFN. The 5' flanking sequence for rat GTPCH has a high degree of homology to that of mouse and human, especially within the first 550 bp. (supported by NS26081)

## 133.8

STRUCTURE OF THE HUMAN  $\alpha 2$  GLYCINE RECEPTOR GENE AND IDENTIFICATION OF MOTOR NEURON SPECIFIC ELEMENTS. U. Monani\*, A. D. Epstein\* and A. H. M. Burghes\*, Departments of Molecular Genetics and Neurology\*, Ohio State University, Columbus, OH 43210.

The  $\alpha$  subunit of the glycine receptor (GlyR) is encoded by multiple genes which display developmental and tissue specific expression. The  $\alpha 1$  subunit is expressed in adults, while the  $\alpha 2$  subunit constitutes the fetal form of the glycine receptor and is expressed in the brain and spinal cord. Here, we describe the intron-exon structure of the human  $\alpha 2$  subunit gene. In addition, we have defined the 5' end of this gene as well as the  $\alpha 1$  subunit gene by RACE-PCR. A clone containing the  $\alpha 2$  gene was isolated from the CEPH mega YAC library and used to define five of the nine exons by vectorette PCR. Alu-exon PCR on genomic DNA was used to identify boundaries of exons 5 and 6. A lambda phage library was screened with an  $\alpha 2$  cDNA probe to isolate clones containing the remaining exons. This resulted in the identification of a previously unreported exon between exons 3 and 4 which probably gives rise to an alternative isoform similar to that seen in the rat. RACE-PCR on fetal human brain and adult spinal cord RNA was used to define the 5' ends of the  $\alpha 2$  and  $\alpha 1$  transcripts respectively. Our study shows that the human  $\alpha 2$  subunit gene consists of nine exons. Its structure has been compared with and found to be very similar to other GlyR  $\alpha$  subunit genes in humans as well as mice.

We have also isolated upstream genomic fragments of the  $\alpha 1$  gene. These have been cloned into reporter constructs and will be delivered to rat spinal motor neurons via retrograde axonal transport to assay for motor neuron specific expression. Our lab has worked extensively on cloning the gene(s) causing the motor neuron disorder, spinal muscular atrophy. SMN<sup>tm</sup>, the most likely candidate and its centromeric copy SMN<sup>cm</sup> can be delivered to motor neurons in a similar manner. Genomic clones each containing one of these genes will be injected intraneurally and their expression or lack of it determined. PCR assays for unique isoforms from each of the two genes will be simultaneously carried out. This will aid in precisely defining the molecular events causing spinal muscular atrophy. (Supported by Families of SMA and MDA.)

## 133.9

GENE STRUCTURE OF THE RAT KAINATE RECEPTOR SUBUNIT KA2 AND TRANSCRIPTIONAL ANALYSIS OF AN INTRAGENIC NEGATIVE REGULATORY REGION. F. Huang, S.E. Scherer\* and V. Gallo. Lab. of Cell. and Mol. Neurophysiol., NICHD, NIH, Bethesda, MD 20892, USA.

We have isolated and analyzed the structure of the gene *GRIK5*, encoding the rat kainate receptor subunit KA2. Six overlapping clones containing the entire *GRIK5* gene were identified in a bacteriophage  $\lambda$  rat genomic library. *GRIK5* is a unique gene composed of 19 translated and one 5'-untranslated exons (sizes between 54 and 944 bp) that span over 70 kilobases of genomic sequence. The intron sizes ranged between 0.1 and 12 kb. Previous analysis demonstrated that 2kb of *GRIK5* 5'-flanking genomic sequence confers tissue-specific expression of the chloramphenicol acetyltransferase (CAT) reporter gene *in vitro* and *in vivo* (Molne, Scherer, Huang and Gallo, Soc. Neurosci. Abstr. 1995, vol. 21, Abstr. 29.9). We now show that: i) the first intron of *GRIK5* (3.4 kb) inhibited (3-fold decrease) transcription of the CAT gene driven by the 2kb *GRIK5* 5'-flanking region in the oligodendrocyte cell line CG-4 and in PC12 cells, but did not modify its tissue-specific expression *in vitro*, as assessed by transient transfection assays of HeLa or 3T3 cells; ii) this effect was not due to aberrant splicing of the CAT coding region; iii) the negative regulatory element(s) resided within 600 bp of the 3'-end of intron 1, as demonstrated by deletion analysis; iv) these elements also inhibited CAT transcription driven by the heterologous  $\beta$ -actin promoter in neural and non-neural cells; and v) the negative effects of these elements on the *GRIK5* promoter in CG-4 cells were orientation- and distance-independent. Multiple bandshift assays demonstrated that this 600 bp region of intron 1 selectively bound nuclear proteins isolated from CG-4 or HeLa cells. We conclude that regulation of *GRIK5* transcription involves an interplay between positive and negative elements located in the promoter region and within the first intron. Supported by NIH.

## 133.11

CLONING OF A PUTATIVE CRUSTACEAN SYNAPSIN HOMOLOG. R.E. Dearborn Jr., K.F. Arcaro\*, B.G. Szaro and G.A. Lnenicka. Department of Biological Sciences, University at Albany, SUNY, Albany, New York 12222.

The synapsins represent an abundant group of neuron-specific phosphoproteins localized to the presynaptic terminal where they appear to regulate the availability of synaptic vesicles for release. Currently, molecular knowledge of the synapsins is limited to mammalian species. In an effort to identify invertebrate synapsins, a  $\lambda$ gt10 cDNA library was constructed from poly-A selected RNA isolated from 60 adult crayfish ganglia. The library was screened with a 1700 bp fragment of the coding region of rat synapsin I (Kilimann and DeGennaro EMBO J. 4: 1997-2002, 1986) and yielded a 1.3 kb clone with stretches of nucleotide sequence similarity to bovine synapsins Ia and Ib. Northern blots probed with this clone showed it to be an abundant message specific to the crayfish nervous system (it was not found in muscle, liver or green gland tissues). More detailed analysis of the distribution of this message was conducted through *in situ* hybridization. Cross-sections of the abdominal nerve cord and ganglia probed with digoxigenin labeled cRNA from the crayfish clone fragments demonstrated that the message was expressed neuronally.

Subsequent library screens generated additional clone fragments, extending the sequence to a total of 3.3 kb. Further sequence analysis is ongoing at this time. It appears likely that this message represents an invertebrate homolog of the mammalian synapsins. This work supported by NSF grant IBN-9511558 and NTH grant NS30682.

## 133.13

CLONING AND CHARACTERIZATION OF A WORTMANNIN-SENSITIVE AND SOLUBLE PHOSPHATIDYLINOSITOL 4-KINASE OF 100kDa. T. Nakagawa, K. Goto & H. Kondo\* Dept. of Anatomy, Tohoku Univ. Sch. of Med., Sendai 980, Japan

A phosphatidylinositol (PI) 4-kinase cDNA cloned from a rat brain cDNA library encoded a protein of 816 amino acids with a calculated molecular mass of 91,654Da. This molecule contained a lipid kinase unique domain and a presumed lipid/protein kinase homology domain that are found in other PI 4-kinases and PI 3-kinases. Furthermore, this molecule and a yeast PI 4-kinase, PIK1 had a region of similarity to each other that is not conserved in other lipid kinases. By examining PI kinase activity in transfected COS-7 cells, the product phosphatidylinositol phosphate (PIP) was identified as PI-4-P, but not PI-3-P. The PI 4-kinase activity was recovered predominantly from the soluble fraction. This PI 4-kinase activity was markedly enhanced in the presence of Triton X-100 and relatively insensitive to inhibition by adenosine. In addition, this PI 4-kinase activity was completely inhibited in the presence of 10  $\mu$ M wortmannin. By epitope tag immunohistochemistry, the immunoreactivity for this PI 4-kinase molecule was dominantly aggregated in a cytoplasmic region juxtaposed to the nuclei and faintly dispersed widely in the cytoplasm. However, a deletion mutant molecule, which lacked the N-terminal region contained commonly and solely in both this PI 4-kinase and PIK1, localized to the nucleus. By *in situ* hybridization analysis, the mRNA for this PI 4-kinase was expressed ubiquitously and detected in most neurons throughout the gray matter of entire brain with higher expression intensity in fetus than adult.

## 133.10

CHARACTERIZATION OF THE NEURON-SPECIFIC REGULATORY CONTROL OF THE RAT CLASS III BETA-TUBULIN GENE. K.E. Dennis\* and S.A. Moody. The Neuroscience Program and the Dept. of Anatomy and Cell Biology at the George Washington University, Washington D.C., 20037

The molecular events involved in the determination of neuron cell fate remain an enigma. The analysis of genetic mutations in several developmental models has identified a variety of signaling factors which are active in this process. However, the events surrounding the adoption of the neuronal cell fate at the time of terminal differentiation have yet to be determined. To address this question more directly, we have undertaken the analysis of the neuron-specific gene expression of the rat class III beta-tubulin gene. The appearance of the class III beta-tubulin protein is coincident with the time of terminal mitosis of several neuronal populations and is specific to neurons (Moody et al. 1989; Lee et al. 1990; Easter et al. 1993). We are investigating the molecular mechanisms involved in this event through the analysis of the 5' flanking region of the rat class III beta-tubulin gene. Using a rat cDNA clone obtained from Anthony Frankfurter (Univ. of Virginia), a portion of the class III 5' untranslated region (UTR) was isolated using the rapid amplification of cDNA ends (RACE). This material was cloned and sequenced and used to identify two clones in a P1 rat genomic library that contain the gene encoding the rat class III beta tubulin protein (Genome Systems). The genomic clones were subjected to Southern blot hybridization analysis using the 5' UTR region as a probe. Two *Bam*HI bands approximately 6.1 and 6.5 kb in size as well as two *Pst*I bands approximately 0.5 and 1.0 kb in size hybridized to the 5' UTR probe. This material has been subcloned and will be subjected to S1 nuclease protection mapping and RNase protection studies to identify the promoter of the rat class III beta tubulin gene. Future studies with this material will identify regions in the promoter which may have an important role in the neuron-specific expression of this gene. Supported by NIH grant NS23158. (SAM).

## 133.12

MOLECULAR CLONING OF THE 5'-FLANKING REGION OF THE GOLDFISH BRAIN AROMATASE GENE. A.Tchoudakova and G.V.Callard\* Department of Biology, Boston University, Boston, MA 02215

It is well-established that estrogen (E) synthesized in the central nervous system mediates androgen (A) actions on the growth, survival, differentiation, and functions of neural tissues. The rate limiting step in E biosynthesis is catalyzed by aromatase (P450arom), a product of the CYP19 gene. Expression of the mammalian CYP19 gene is under control of multiple tissue-specific promoters and regulators but gives rise to a single enzyme protein. Exceptionally high levels of P450arom are expressed in the brain of teleost fish, when compared to the ovaries of the same fish, or to the brain of other vertebrates. The presence of two CYP19 genes and mRNA species was established in goldfish (*Carassius auratus*). One aromatase mRNA type was predominantly neural and found in high abundance. The other, lower abundance mRNA, was detectable in both neural and gonadal tissues. Seasonal studies of the predominant brain CYP19 mRNA and *in vivo* manipulation of plasma steroids demonstrated upregulation by aromatizable A or E. To initiate characterization of the promoter of the CYP19 gene expressed primarily in brain the 5'-flanking region was cloned by ligation-mediated PCR of genomic DNA. Database analysis of a 372 bp genomic fragment revealed a TATA-box (-42 nt), an Ad4/SFI site (-293 nt), and an estrogen response element (-360 nt). Future experiments are required to test the functional significance of these putative regulatory elements. Supported by NSF IBN89-16809.

## 133.14

GENE ORGANIZATION OF NEURONAL-SPECIFIC ACTIVATORS FOR CYCLIN-DEPENDENT KINASE 5. F. Nildén, D. Lindholm, A. Bäckström, P. Marin and I. C. Bark\* Department of Developmental Neuroscience, Uppsala University, S-751 23 Uppsala, Sweden.

Cyclin-dependent kinases (cdk's) are a family of proteins involved in cell cycle control. However, recent evidence shows the existence of cdk5 activity in post-mitotic neurons in the CNS. Neuronal cdk5 activation is mediated by complex formation to a new group of proteins, including p35/p25<sup>cdk5</sup>, capable of phosphorylating neurofilaments and the tau protein (Tsai et al., 1994, Nature 371, 419-423; Lew et al., 1994, Nature 37, 423-426). In addition, p35/p25<sup>cdk5</sup> promotes neurite extension of cultured cortical neurons (Nikolic et al., Soc. Neuroscience Meeting, Abstract 785.13, 1995), and the cdk5/p35 complex interacts with proteins participating in regulated exocytosis of neurotransmitters (Grant et al., 35th Annual Meeting of the American Society for Cell Biology, Washington D.C., Abstract 2183, 1995; Shetty et al., 1995, J. of Neurochemistry, 1988-1995).

We have characterized the organization of p35/p25<sup>cdk5</sup> related genes by isolating recombinant phages from a mouse genomic library using a p35/p25 probe. Exon/intron boundaries were identified by DNA analysis and to investigate the neuronal expression pattern of p35/p25<sup>cdk5</sup> like genes, we are analysing potential regulatory signals in the promoter region. The regulation and subcellular localization of p35/p25<sup>cdk5</sup> in the rat pheochromocytoma (PC12) cells after NGF (nerve growth factor) and dBcAMP treatment are also studied and compared with proteins known to participate in regulated exocytosis. Supported by The Swedish Natural Science Research Council and Magn. Bergwall's Foundation to ICB.

## 133.15

**ENC-1: A NOVEL MURINE GENE SPECIFICALLY EXPRESSED IN THE NERVOUS SYSTEM ENCODES AN ACTIN-BINDING PROTEIN.** M. C. Hernandez\*, P. J. Andres-Barguin, S. Martinez, A. Bulfone, J. L. R. Rubenstein and M. A. Israel. The Preuss Laboratory for Molecular Neuro-Oncology, The Brain Tumor Research Center, University of California San Francisco, CA 94143-0520.

We have isolated and characterized a novel murine gene whose expression is restricted to the nervous system. *Ectoderm-neural-cortex-1* (*Enc-1*), which is named based on its expression pattern, appears to be one of the earliest markers of neural induction, since its mRNA is detected very early during embryogenesis. Early in the gastrulation stage *Enc-1* is expressed in the prospective neuroectodermal region of the epiblast and from gastrulation to later stages of development its expression remains restricted to the nervous system. *Enc-1* expression is highly dynamic and after neurulation prominently marks prospective cortical areas. We have constructed a tagged ENC-1 to determine the subcellular localization of the protein in transfected cells and found that ENC-1 distribution is compatible with that of cytoskeletal associated proteins. Double fluorescent staining showed that ENC-1 co-localizes with F-actin and this co-localization is maintained after treatment with cytochalasin D. Moreover, ENC-1 was co-precipitated with actin in immunoprecipitation experiments using anti-actin antibodies demonstrating that ENC-1 associates *in vivo* with actin. National Cancer Institute Grant 5 U01 CA64898.

## 133.17

**IDENTIFICATION AND CHARACTERIZATION OF TWO PROTEINS INTERACTING WITH THE NEURONAL PROTEIN SCG10.** R. Lütjens\*, G. Di Paolo, S. Catsicas and G. Grenningloh. GLAXO IMB, 14 ch. des Aulx, 1228 Plan-les-Ouates / Geneva, Switzerland.

SCG10 is a neuron-specific protein related to the ubiquitous phosphoprotein stathmin. This latter has been implicated in signal transduction and recently it has been shown to act directly on the dynamics of microtubules. Given the high degree of homology between stathmin and SCG10 and their differential subcellular localization, they may play similar roles in their respective compartments. However, the exact function of SCG10 is still unknown. Therefore, to further define it, we used the yeast two-hybrid system to identify interacting proteins. We generated a construct by fusing the rat SCG10 cDNA to the binding domain of the GAL-4 transcription factor which was used for screening an adult mouse brain cDNA library cloned into a plasmid containing the activation domain of GAL-4. Two million independent colonies were screened and 13 positives were purified and transformed into control yeast strains. 12 of these clones were specifically interacting with SCG10, but not with stathmin or other control proteins. They encoded two different cDNAs which we called SIGA1 and SIGA2. We analysed their pattern of expression by hybridization to multiple tissues and developing brain Northern blots. SIGA1 produces two forms of transcripts (~6.0Kb and 3.5Kb) and is expressed in different tissues but mainly in the brain. SIGA2 has a single transcript of ~12Kb most abundantly expressed in the brain. Both genes seem to have their expression upregulated during development and are maximal in adult. Polyclonal antibodies against SIGA1 and SIGA2 were raised and we are currently characterizing their subcellular localization in neurons and in transfected COS7 cells.

## 133.19

**GENE SEQUENCE FOR THE SERPIN, PROTEASE NEXIN I (PNI) IS IDENTICAL IN MOUSE BRAIN AND SEMINAL VESICLE.** B. A. Citron\*, K. T. Ratzlaff, I. V. Smirnova, and B. W. Festoff. Neurobiology Research Lab, VA Medical Center, Kansas City, MO 64128 and University of Kansas Medical Center, Kansas City, 66160.

PNI is a member of the serpin multigene family that includes  $\alpha_1$ -protease inhibitor ( $\alpha_1$ -antitrypsin),  $\alpha_1$ -antichymotrypsin, and plasminogen activator inhibitors. Serpins are approximately 400 amino acids in length, with active sites near the C-terminus, and act as suicide substrates for their target serine proteases. PNI is secreted as a 378 amino acid protein (41.8 kDa), binds to and functions in the extracellular matrix to inhibit and form complexes with thrombin. Although prothrombin is chiefly synthesized in the liver and is present in the circulatory system, it is also synthesized locally in the brain (Dihanich, 1991, Neuron, 6:575), muscle and spinal cord (Smirnova *et al.*, in prep.). PNI is not expressed in the liver but is in brain, and is concentrated in seminal vesicles. The gene for PNI maps to human chromosome 2q33-35, and to mouse chromosome 1, between acetylcholine receptor  $\gamma$  subunit and villin. PNI is concentrated at synapses to balance thrombin and play an important role in development and plasticity. In this study, we confirmed that the gene expressed in brain is identical in sequence to that in seminal vesicle. PNI mRNA represented 0.0024% of mouse brain poly(A)<sup>+</sup> RNA, and 0.04 % in seminal vesicle. Additionally, by Western immunoblot, a single ~47 kDa protein was visible in the mouse brain, seminal vesicle, and seminal fluid at approximately 0.008, 0.06, and 0.2 % of total protein, respectively. Analysis of PNI regulation will facilitate the understanding of serine protease signaling pathways in the central nervous system. Supported by the Medical Research Service, Department of Veterans Affairs.

## 133.16

**NERVANA 2 IS THE NEURONAL FORM OF  $\beta$  SUBUNIT OF  $\text{Na}^+$ ,  $\text{K}^+$ -ATPASE IN *DROSOPHILA MELANOGASTER*.** B. Sun and P. M. Salvaterra\*, Division of Neurosciences, Beckman Research Institute of the City of Hope, 1450 E. Duarte Rd., Duarte, CA 91010

We have purified and characterized a nervous system specific glycoprotein antigen from adult *Drosophila* heads, designated Nervana (NRV), on the basis of immunoreactivity of its carbohydrate epitope(s) with anti-horseradish peroxidase (HRP) antibodies. Anti-HRP antibodies specifically stain *Drosophila* neurons. Three cDNA clones (designated Nrv1, Nrv2.1 and Nrv2.2) were isolated using a mixture of anti-NRV protein monoclonal antibodies. The NRV proteins deduced from these clones exhibit significant homology in both primary sequence and predicted topology to the  $\beta$ -subunit of  $\text{Na}^+$ ,  $\text{K}^+$ -ATPase. Immunoaffinity-purified NRV is also associated with a protein ( $M_r=100,000$ ) recognized on Western blots by an anti-ATPase  $\alpha$ -subunit monoclonal antibody. In this study we have expressed *Drosophila*  $\text{Na}^+$ ,  $\text{K}^+$ -ATPase  $\alpha$ -subunit, along with NRV1 and/or NRV2 using a baculovirus expression system or in *Xenopus* oocytes by microinjection of cRNAs. In baculovirus-infected Sf-9 cells, we see no increase in sodium pump activity although both recombinant proteins ( $\alpha$ -subunit, and NRV) are expressed at high levels in the same cells. In oocytes, injection of Nrv2.2 cRNA alone slightly increases the sodium pump activity. Co-injection of  $\alpha$ -subunit and Nrv2.2 cRNAs leads to expression of more functional pumps in the plasma membrane as assessed by ouabain inhibitable  $\text{Rb}^+$  flux. Injection of Nrv1 or Nrv2.1 cRNA, with or without  $\alpha$ -subunit cRNA, had no effect on the pump activity in oocytes. Furthermore, using isoform specific antibodies (anti-NRV1, and anti-NRV2) we have shown that NRV2 is the major nervous system form. Our results suggest that NRV2 is the neuronal form of the  $\beta$ -subunit of  $\text{Na}^+$ ,  $\text{K}^+$ -ATPase in *Drosophila melanogaster*. (supported by the NIH-NINDS)

## 133.18

**BOVINE NEUROFILAMENT L AND M SUBUNIT DNA SEQUENCES ARE HIGHLY CONSERVED.** L. Zhang, M.M. Tompkins, B.J. Balir\*, T.J. Sprinkle† and W.D. Hill. Dept. of Cellular Biology and Anatomy, Dept. of Neurology† Medical College of Georgia, Augusta, GA 30912. Dept. of Pathology, MCP and Hahnemann Univ. Philadelphia, PA 19102§

Three full length cDNA clones coding for the bovine neurofilament L (NFL) subunit were identified from a bovine brain library and partially sequenced. One, L19, was fully sequenced. A second set of 3 clones for the bovine neurofilament M (NFM) subunit were identified from the same library and partially sequenced. The longest one, M3, was fully sequenced, it lacks approximately 400bp from the 5' end. Both NFL and NFM sequences demonstrate strong conservation of deduced amino acid sequences when compared to human and other mammalian species.

The bovine NFL head domain differs by only two amino acids from the human, while the tail domain, like that of the other known vertebrates, has about 80% homology with the human sequence. The amino acids in the most amino 2/3 of the tail domain show the most homology. The most COOH 13 amino acids are also well conserved and interestingly show homology with a portion of an acid stable protease inhibitor. This may suggest that the COOH end sequence of NFL may be involved in regulating the turnover of the subunit or the assembled filament.

The Bovine NFM subunit sequence is also highly homologous to the human sequence. The conservation of regions of the tail domain suggests that it has important functions which have been preserved. These subdomains may represent regulatory or binding domains. The NFM tail domain has at least three conserved subdomains in addition to the KSP repeats, KE regions and the final heptad repeat.

Supported in part by NS32835 (WDH) and AG10160 (BJB)

## 134.1

**ACTIVITY DEPENDENT POTENTIATION OF SYNAPTIC TRANSMISSION FROM L30 INHIBITORY INTERNEURONS OF APLYSIA DEPENDS ON RESIDUAL CALCIUM** T.M. Fischer<sup>1</sup>, R.S. Zucker<sup>2</sup>, and T.J. Carew<sup>1</sup>. <sup>1</sup>Yale Univ., Dept. Psych., New Haven, CT 06520; <sup>2</sup>Dept. Molec. & Cell. Biol., Univ. California, Berkeley, CA 94720

We have previously shown that activity-dependent potentiation (ADP) of inhibitory synaptic transmission in L30 interneurons provides a mechanism for dynamic gain control of the siphon withdrawal reflex of *Aplysia* (Fischer & Carew 1993; 1995). To explore the mechanisms of L30 synaptic plasticity, here we examine the role of residual free  $Ca^{2+}$  in ADP through the use of the photo-activated calcium chelator diazo-4.

Diazo-4 was iontophoretically injected into L30 neurons, and was photolyzed by a UV flash (flash alone has no effect on ADP). L30 synaptic transmission was measured as inhibitory postsynaptic currents (IPSCs) in L29 excitatory interneurons. Four components of ADP were analyzed: (1) **Baseline** (non-potentiated) transmission was examined by eliciting a single spike in L30 at a 30 sec ISI. Photolysis of diazo-4 had no effect on IPSC amplitude ( $N = 6$ ). (2) **Frequency facilitation** was examined during a 5 sec activation of L30 (~8 Hz). Photolysis 2 sec following activation onset resulted in an immediate and significant reduction in the amplitude of the potentiated IPSC ( $p < 0.01$ ;  $N = 7$ ). (3) **Augmentation** was induced by a 5 sec activation of L30 at ~8 Hz; this produces enhancement normally lasting for ~60 sec. Photolysis 20 sec following activation immediately and significantly reduced the potentiated IPSC to pre-activation levels ( $p < 0.01$ ;  $N = 7$ ). (4) **Posttetanic potentiation** was induced by a one min activation of L30 at 5 Hz, which produces enhancement normally lasting ~6 min. Photolysis 3 min following activation significantly reduced the potentiated IPSC to pre-activation levels ( $p < 0.05$ ;  $N = 6$ ). These data show that three different forms of ADP in L30 require presynaptic elevation of free calcium for their maintenance.

## 134.3

**CYCLIC-ADP RIBOSE MODULATES ACETYLCHOLINE RELEASE AT AN IDENTIFIED SYNAPSE OF APLYSIA** J.P. Mothet, P. Fossier, J. Stinnakre\* and G. Baux. Laboratoire de Neurobiologie cellulaire et moléculaire, CNRS, 91198 Gif-sur-Yvette cedex, FRANCE.

$Ca^{2+}$ -induced calcium release (CICR) via ryanodine receptors occurs in neurons. In this study, we investigated the hypothesis that CICR is involved in transmitter release. For this purpose, we injected into the presynaptic neuron of an identified neuro-neuronal cholinergic synapse of *Aplysia*, a metabolite of  $NAD^+$ , cyclic-ADP-ribose (cADPr), which has been identified as a potent endogenous modulator of CICR in a variety of cells. Below 10  $\mu M$ , cADPr induced a sustained increase in acetylcholine (ACh) release whereas higher concentrations led to a transient facilitation of ACh release followed by a decrease. These effects were not due to changes in  $Ca^{2+}$  influx through N- and P-type channels triggering ACh release but to modifications of the number of evoked released quanta. Three different approaches showed that both increase and decrease in ACh release originated in an elevation of the intracellular  $Ca^{2+}$  concentration: i) injection of cADPr induced a fluorescence rise using Rhod2 as a probe, ii) the decreasing effect of high concentrations of cADPr on ACh release was partially reversed by presynaptic injection of EGTA and iii) the  $Ca^{2+}$ -activated  $K^+$  current was potentiated with cADPr.

These observations show that i) in *Aplysia* neurons cADPr is able to release  $Ca^{2+}$  from internal stores, ii) this release facilitates ACh release but can result in a secondary desensitization of the release mechanism when the  $Ca^{2+}$  concentration is too high, iii) CICR can be involved in the building up of the intracellular  $Ca^{2+}$  concentration triggering neurotransmitter release.

## 134.5

**DIFFERENT FREQUENCY MODULATION AND GABA<sub>B</sub> INVOLVEMENT AT THALAMOCORTICAL AND INTRACORTICAL SYNAPSES** Z. Gil<sup>1</sup>, Y. Amitai<sup>1</sup>, M.A. Castro-Alamancos<sup>2</sup> and B.W. Connors<sup>2</sup>. <sup>1</sup>Dept. of Physiology, Ben-Gurion University, Israel, 84105, and <sup>2</sup>Dept. of Neuroscience, Brown University, RI, 02912.

Synaptic efficacy is sensitive to repetitive activation, but the polarity strength and neurotransmitter involvement of such modulation may vary between pathways. We compared thalamocortical (TC) and intracortical (IC) EPSPs evoked on single layer 3 neurons in slices of rat barrel cortex prepared with the TC input intact. Paired stimuli of either the thalamus or horizontal layer 3 IC axons evoked small (~2mV) EPSPs. GABA<sub>A</sub> receptors were blocked by local application of bicuculline (10  $\mu M$ ), and postsynaptic GABA<sub>B</sub>-inhibition was blocked with intracellular QX-314 and  $Ca^{2+}$ . Both pathways exhibited paired-pulse depression at intervals of 10-2000 ms. Depression of TC-EPSPs was significantly stronger than that of IC-EPSPs. The GABA<sub>B</sub>-agonist baclofen attenuated the first IC-EPSP and reduced paired-pulse depression. The GABA<sub>B</sub> antagonist CGP-35348 reduced IC paired-pulse depression by enhancing the second EPSP. Neither baclofen nor CGP-35348 had any effect on TC-evoked paired-pulse responses.

The results show that frequency modulation of convergent pathways onto neocortical neurons can have distinctly different strengths and mechanisms.

Supported by the ISF (Y.A.), and NIH and ONR (B.W.C.).

## 134.2

**FREQUENCY DEPENDENT ADAPTATION AT TWO DISTINCT EXCITATORY INPUTS IN THE HIPPOCAMPUS** M. Scanziani\*, P.A. Salin, R.C. Malenka & R.A. Nicoll. Depts. of Cellular & Molecular Pharmacology, Physiology & Psychiatry; UCSF, San Francisco, CA 94143-0450

The mossy fiber synaptic input on CA3 pyramidal neurons has been referred to as the detonator or teacher synapse in autoassociational network models of the hippocampus. In these models, the mossy fiber system is particularly important during storage of information because it determines which CA3 neurons fire based on the pattern of granule cell activity. However, the mechanism by which changes in the relatively low firing rates of granule cells is translated into changes in the efficacy of the mossy fiber input is not known. We addressed this issue by comparing associational/commissural and mossy fiber synaptic responses on the same CA3 neuron in guinea pig hippocampal slices. In striking contrast to commissural synapses, stimulation of the mossy fiber gave rise to an augmenting response, over a very wide range of low frequencies (0.0125 - 1 Hz). This augmenting response decayed with a time course of about 40-60s and was reduced by bath perfusion of either the membrane permeant calcium chelator EGTA-AM or the CaMKII antagonist KN62, suggesting that it is triggered by presynaptic  $Ca^{2+}$  influx acting via CaMKII. Furthermore, the dynamic range of the augmenting response was markedly reduced at synapses expressing LTP. Thus, the mossy fiber synapse, is able to integrate granule cell spiking activity over a broad range of frequencies, and provides an interesting mechanism by which spike frequency modulation is translated into changes in synaptic strength.

## 134.4

**PROPERTIES OF SYNAPTIC DEPRESSION DURING HIGH-FREQUENCY ACTIVATION OF MEDIAL PERFORANT PATH SYNAPSES IN THE RAT DENTATE GYRUS** A.E. Talpalar\*, Y. Grossman and J.F. Storm. Dept. Physiol. Fac. Health Sciences Ben Gurion Univ. Israel. Inst. of Neurophysiol. University of Oslo, Norway.

Central neurons often produce high - frequency bursts of action potentials, whose effects are modulated by various form of short-term synaptic plasticity. In particular, many synapses show reduced transmission (depression) during high-frequency activation, a property often attributed to reduction of releasable synaptic vesicles. We have tested this hypothesis in medial perforant path synapses in the rat dentate gyrus. Whole-cell voltage-clamp and field potential recordings were obtained from dentate granule cells in hippocampal slices from young rats (17-23 d). Presynaptic fibers of the medial perforant path were stimulated by an electrode placed in the middle third of the molecular layer. Trains of 5-10 stimuli at 1-100 Hz elicited excitatory synaptic currents (EPSCs) whose amplitudes declined to a plateau in a frequency-dependent manner (e.g.  $\tau \approx 75$  ms at 50 Hz). Using K gluconate or CsCl in the whole-cell pipette, or shifting the holding potential of the postsynaptic cell had also no significant effect on the depression. Similar results were observed during blockade of NMDA-receptors by APV, and GABA-A receptors by bicuculline or picrotoxin. To test whether desensitization of postsynaptic AMPA-type glutamate receptors contributes, cyclothiazide (CT) was applied. CT (100  $\mu M$ ) slowed the decay of individual EPSCs and reduced the depression at certain frequencies, but most of the depression persisted. Increasing the extracellular calcium concentration,  $[Ca^{2+}]_o$ , enhanced the depression, while low  $[Ca^{2+}]_o$  reduced and delayed the depression during each train, often inducing an initial facilitation. These results are compatible with depression being mostly due to presynaptic factors, such as reduction of releasable quanta, while desensitization of postsynaptic glutamate receptors seems to play a minor role. [Supported by NFR]

## 134.6

**INTERACTION BETWEEN DOPAMINE AND GLUTAMATE IN THE PARS RETICULATA OF THE RAT SUBSTANTIA NIGRA** D. Martinez-Fong\*, M.G. Rosales, D. Limón, B. Florán, G. Flores, A. Nuñez and J. Aceves. Depto. de Fisiología, Biofísica y Neurociencias, CINVESTAV-IPN, A.P.14-740, 0700 México, D.F., Centro de Investigación Biomédica, U.A. de C., Torreón, Coah., México.

We have studied the interactions between glutamate (Glu), dopamine (DA) and GABA in the pars reticulata of the substantia nigra (SNr) by using microdialysis in unanesthetized male Wistar rats. Increased levels of Glu in the SNr were obtained by microinjecting carbachol (1  $\mu g/0.25 \mu l$ ) in the ipsilateral subthalamic nucleus (STN). The increase in Glu was followed by increases in extracellular levels of DA and GABA. Increased levels of the three transmitters were also observed during the administration of N-methyl-D-aspartate (NMDA, 1 mM) through the microdialysis probe. The NMDA-induced increase in glutamate and GABA was blocked by the selective  $D_1$  agonist SCH 23390 (100  $\mu M$ ), yet it did not prevent the increase in DA levels. The addition to the dialysis solution of the selective  $D_1$  agonist SKF 38393 (200  $\mu M$ ) also increased the levels of the three neurotransmitters. However, after the kainic-induced lesion of the STN, SKF 38393 only produced increase in the level of GABA but not in those of Glu or DA. The lesion of the STN produced, in addition, a drastic (80%) fall in the extracellular level of Glu.

The data suggest that Glu stimulates the release of DA from dopaminergic dendrites present in substantia nigra pars reticulata, and that DA in turn stimulates the release of Glu and GABA. Both effects are mediated by  $D_1$  receptors present on subthalamonigral and striatonigral axon terminals respectively.

## 134.7

ACTIVITY-DEPENDENT POTENTIATION OF [ $^3$ H]-D-ASPARTATE RELEASE IN HIPPOCAMPAL SLICES. S.A. Queen, L.L. Paxton and D.D. Savage. Dept. Pharmacology, Univ. New Mexico H.S.C., Albuquerque, NM, 87131-5316.

Studies on the mechanisms that regulate activity-dependent glutamate (GLU) release in brain slices has been limited by the methods available to evoke GLU release. Neither high  $K^+$  or 4-aminopyridine allow one to study how GLU release is altered by changes in neural activity. Further, *in vitro* electrical stimulation of slices in standard perfusion mediums evokes immeasurably low quantities of GLU release due to neural and glial transporter reuptake of GLU.

Using preloaded [ $^3$ H]-D-aspartate (D-ASP) as a marker for GLU release, we have determined that the addition of 300  $\mu$ M L-cysteinesulfonic acid to perfusion medium blocks D-ASP reuptake sufficiently to measure calcium-dependent D-ASP release. Subsequently, we have optimized the basic parameters for studying electrically-evoked D-ASP release in superfused dorsal hippocampal slices including: 1) D-ASP preloading conditions, 2) slice thickness, 3)  $Ca^{2+}$  concentration and 4) test stimulus (TS) parameters (1 msec 20 mA biphasic square wave pulses at 4 Hz for three minutes). Operationally, we have established the stimulation parameters so that the TS produces a fractional release of 1% to 1.5% and D-ASP release evoked from a second TS is equivalent to D-ASP release evoked from the first TS, when the second TS is delivered at least 30 min. after the first TS. Applying the TS at 100 Hz (2 sec. trains at 30 sec. inter-train intervals) potentiated TS-induced D-ASP release. Potentiation was not apparent until 30 min. after tetanus and remained fairly stable for at least 2 hours. The degree of potentiation was a function of the number of tetanus trains applied. One tetanus train produced a 14% increase in D-ASP release, three trains produced a half-maximal change and 7 to 10 trains produced a maximum potentiation of about 55% above current control. Using the parameters described above, we have initiated studies on the intrinsic and extrinsic mechanisms that regulate activity-dependent changes in GLU release. Supported by AI25555 (SAQ) and AA06548 (LLP and DDS).

## 134.9

EFFECT OF PRENATAL ETHANOL EXPOSURE ON GAP-43 PHOSPHORYLATION AND PKC ACTIVITY IN RAT HIPPOCAMPUS. N. Perrone-Bizzozero, G. Keidan, C. Erigat, D.D. Savage, A.M. Allan\*. Depts Biochem. and Pharmacology, Univ. of New Mexico Sch. Med., Albuquerque, NM, 87131.

Previous studies using a rat model of fetal alcohol exposure (FAE) suggest that observed behavioral deficits are, in part, linked to neurochemical and electrophysiological deficits in long-term potentiation (LTP) in the perforant path projection to the hippocampus (HC). PKC-mediated phosphorylation of GAP-43 may be critical to the induction and maintenance of LTP. Thus, alterations within this phosphorylation pathway may play a significant role in LTP deficits seen in FAE animals. Rat dams consumed one of three diets throughout gestation: 1) a Bio Serve liquid diet containing 5% ethanol (v/v), 2) an isocalorically equivalent amount of 0% ethanol liquid diet (pair-fed) or 3) lab chow *ad libitum*. PKC activity was measured by monitoring  $^{32}$ P-phosphorylation of a peptide substrate in a combined HC soluble and particulate membrane fraction from adult rat offspring of these dams. GAP-43 phosphorylation levels in HC homogenates were determined *in vitro* by immunoprecipitation. GAP-43 levels in the same samples were measured by quantitative Western blots. PKC activity was lower by approximately 50 % in HC of FAE rats compared to *ad lib* or pair-fed control rats. GAP-43 levels were 35 % greater in FAE rats compared to controls; while GAP-43 phosphorylation was reduced in these rats by 50%. The measurably lower level of PKC activity in the FAE rats is consistent with the decrease in phosphorylated form of GAP-43. Since GAP-43 is one of the main substrates for PKC in HC synapses, alterations in these proteins are likely to result in significant changes in synaptic function and signaling mechanisms associated with LTP. Thus, these findings may underlie the behavioral deficits seen in FAE. Supported by AA06548 (DDS) AA0821 (AMA), NS30255 (NPB) and GM08139 (DDS, AMA, NPB).

## 134.11

THE PRESYNAPTIC MODULATION OF GLUTAMATE RELEASE AFFECTS DIFFERENT CALCIUM CHANNELS. J. Sánchez-Prieto and E. Vázquez. Dpto. Bioquímica, Fac. Veterinaria, Univ. Complutense, Madrid 28040, Spain.

We have studied which type/s of  $Ca^{2+}$ -channel/s support glutamate exocytosis and its modulation by presynaptic receptors in cerebrocortical nerve terminals. Depolarization of nerve terminals with 30 mM KCl induced a  $Ca^{2+}$ -dependent release of  $3.46 \pm 0.25$  nmol/mg of protein. The addition of either 2  $\mu$ M  $\omega$ -conotoxin GVIA or 200 nM  $\omega$ -agatoxin-IVA reduced the KCl-evoked release by  $47.7 \pm 3.5\%$  and  $70.4 \pm 8.9\%$ , respectively, and by  $85.7 \pm 4.1\%$  when both toxins were co-applied, indicating the involvement of N and P/Q type  $Ca^{2+}$ -channels in glutamate exocytosis. The activation of adenosine  $A_1$  receptors with  $N^6$ -cyclohexyladenosine or the activation of metabotropic glutamate receptors with L(+)-2-amino-4-phosphonobutyrate inhibited the KCl-evoked release by  $41.0 \pm 5.9\%$  and  $54.3 \pm 10\%$ , respectively. The extent of these inhibitions was not altered by the prior addition of 2  $\mu$ M  $\omega$ -conotoxin-GVIA but were significantly enhanced when  $\omega$ -agatoxin-IVA was added together with the adenosine  $A_1$  receptor agonist or the metabotropic glutamate receptor agonist, suggesting that  $\omega$ -conotoxin-GVIA-sensitive but not  $\omega$ -agatoxin-IVA-sensitive  $Ca^{2+}$ -channels are involved in the action of these inhibitory receptors. In contrast, the facilitation of glutamate release that follows the activation of the protein kinase C either with phorbol esters or with the stimulation of phospholipase C-linked metabotropic receptors was expressed by both  $\omega$ -conotoxin-GVIA-sensitive and  $\omega$ -agatoxin-sensitive  $Ca^{2+}$ -channels. It is concluded that N-type  $Ca^{2+}$  channels are the target of both adenosine  $A_1$  receptors and L-AP4-sensitive metabotropic glutamate receptors, while N and P/Q type  $Ca^{2+}$  channels are involved in the facilitation of glutamate release.

Supported by grants PB 94/0323 (DGICYT) and BMH1-CT93-1033 (European Union).

## 134.8

EFFECT OF PRENATAL ETHANOL EXPOSURE ON PRESYNAPTIC MECHANISMS OF LONG-TERM POTENTIATION IN HIPPOCAMPUS OF ADULT RAT OFFSPRING. DD Savage\*, LL Cruz, LM Duran and LL Paxton. Dept. of Pharmacology, Univ. of New Mexico H.S.C., Albuquerque, NM, 87131.

Prenatal ethanol exposure has been associated with long-lasting intellectual impairments in children. Previous studies from our lab suggest that these impairments are, in part, linked to neurochemical deficits affecting long-term potentiation (LTP) in the hippocampal formation. Whether this LTP deficit is principally presynaptic or postsynaptic in origin is unclear at present. Using a recently developed method to study tetanus stimulus-induced potentiation of electrically evoked [ $^3$ H]-D-aspartate (D-ASP) release from hippocampal slices, we explored whether FAE affected activity-dependent potentiation of excitatory amino acid neurotransmitter release, a presynaptic component of LTP.

Rat dams consumed one of three diets throughout gestation: 1) a BioServ liquid diet containing 5% ethanol, which produces a mean nightly maternal peak blood ethanol concentration of 83 mg/dL, 2) pair-fed an isocalorically equivalent amount of 0% ethanol (EtOH) liquid diet or 3) lab chow *ad libitum*. D-ASP release was studied in 400  $\mu$ m thick hippocampal slices prepared from adult offspring from each of the three diet groups. The incorporation of D-ASP into hippocampal slices, spontaneous release of D-ASP and evoked release produced by a test stimulus (TS) were not different among the three diet groups. Potentiation of TS-evoked D-ASP release was elevated by 42 to 48% at 30, 60 and 90 minutes after a tetanizing stimulus in both *ad lib* and pair-fed control offspring. In contrast, virtually no potentiation of TS-evoked release was observed in the 5% EtOH diet group. These results suggest that prenatal exposure to moderate quantities of ethanol produces a long-lasting deficit in neurochemical mechanisms that sustain potentiation of synaptic communication. Whether this deficit is a function of intrinsic deficits in synaptic vesicle mobilization or extrinsic mechanisms activating synaptic vesicle mobilization is under investigation. Supported by AA06548 (DDS and LLP) and RR08139 (LLC and LMD).

DIRECT MODULATION OF THE SECRETORY MACHINERY UNDERLIES PKA-DEPENDENT SYNAPTIC FACILITATION IN HIPPOCAMPAL NEURONS. L.-E. Trudeau\*, D.G. Emery and P.G. Haydon. Lab. of Cellular Signaling, Iowa State University, Ames, IA 50011.

Activation of the cAMP-PKA pathway has been previously reported to produce facilitation of synaptic transmission in a number of preparations. This facilitation may be of presynaptic origin. Using dual whole-cell patch clamp recordings in cultured hippocampal neurons we confirmed that monosynaptic IPSCs are reversibly facilitated (+126%, n=8) by the adenylate cyclase activator forskolin (20  $\mu$ M). Inclusion of the protein kinase inhibitor H-7 in the presynaptic, but not the postsynaptic pipette, blocked the synaptic facilitation. Similarly, inclusion of the PKA antagonist Rp-cAMPS or a peptide inhibitor in the presynaptic pipette blocked the facilitation, supporting a presynaptic mechanism. Using Fura-2 imaging we found no evidence of any action of forskolin on either resting or depolarization-evoked elevations of intracellular calcium. This suggests that changes in presynaptic calcium dynamics are unlikely to be necessary for the synaptic facilitation. Ruthenium red (RR) was used to probe the state of the presynaptic machinery for exocytosis. This agent elevates the frequency of miniature synaptic currents independently of calcium (Trudeau et al., 1996; J. Neurosci. 16:46-54). RR-evoked release was markedly facilitated by forskolin (+197%, n=8). This effect was also blocked by Rp-cAMPS and was not accompanied by any change in the number of functional synaptic terminals as assessed by uptake of the fluorescent indicator of synaptic vesicle cycling FM1-43. These results suggest that PKA directly acts on the release machinery in previously functional synaptic terminals to facilitate neurotransmitter release. Funded in part by the HFSP (L.-E.T.) and the NIH (P.G.H.).

MODULATION OF EXOCYTOSIS BY INTRACELLULAR  $Ca^{2+}$  STORES IN BOVINE CHROMAFFIN CELLS. A.F. Fomina & M.C. Nowycky\*. Dept. Neurobiol. & Anat., Med. Coll. Penn., Phila., PA 19129.

Elevation of intracellular  $Ca^{2+}$  ( $[Ca^{2+}]_i$ ) resulting directly from store mobilization can trigger catecholamine release in bovine chromaffin cells. However,  $Ca^{2+}$  influx via voltage-gated  $Ca^{2+}$  channels (VGCC) is more effective in causing secretion. Here we investigate the possible role of intracellular stores in modulation of the secretory response. We employed the capacitance tracking technique in perforated patch voltage-clamp mode to assay single cell exocytosis from bovine chromaffin cells. Simultaneously,  $[Ca^{2+}]_i$  was measured as changes in the fluorescence of Fluo-3 (loaded as the AM form) and monitored on a confocal laser microscope. Application of thapsigargin (Tg; 1-5  $\mu$ M) frequently induced slow exocytosis which was correlated with a  $[Ca^{2+}]_i$  transient. Lower concentrations (Tg = 0.5 - 1  $\mu$ M) facilitated depolarization-stimulated exocytosis even though VGCC were partially inhibited. The development of this facilitation was gradual, prolonged (up to 20 min) and not correlated with  $[Ca^{2+}]_i$  elevation. In contrast, caffeine (10-20 mM) significantly inhibited both VGCC and depolarization-induced exocytosis. Caffeine caused only a small rise in  $[Ca^{2+}]_i$  and did not induce exocytosis. Thus, in bovine chromaffin cells recorded in perforated patch mode: 1)  $Ca^{2+}$  release from Tg sensitive stores can induce depolarization independent exocytosis; 2) depletion of Tg sensitive stores facilitates depolarization-induced exocytosis; 3) caffeine sensitive stores play a minor role in the maintenance and stimulation of exocytosis. Supported by NS22281.

## 134.13

ASSOCIATION OF B-50/GAP-43 AND CALMODULIN IN SITU, AT THE PLASMA MEMBRANE OF UNMYELINATED AXONS IN THE REGENERATING RAT SCIATIC NERVE. A.B. Oestreicher, P. Verkade, A.J. Verkleij and W.H. Gispen.<sup>1</sup> Rudolf Magnus Institute for Neurosciences<sup>1</sup> Institute of Biomembranes<sup>2</sup>, University of Utrecht, Universiteitsweg 100, 3584 CH Utrecht, NL. (Spon: ENA)

The ultrastructural distribution of B-50 and calmodulin in unmyelinated axons of regenerating rat sciatic nerve was investigated by means of single and double immuno gold labelling and quantification, to test whether the association of B-50 and calmodulin, previously shown to occur *in vitro*, can be demonstrated *in situ*. Electron microscopical analysis of nerve pieces dissected proximal to the site crushed 7 days earlier revealed that the B-50 immunoreactivity (BIR) at the plasma membrane (pm) was significantly increased (270%) with respect to that of the intact unmyelinated axon and to that of the axoplasm (450%) of the unmyelinated axon of the regenerating nerve. Similarly to BIR, the calmodulin immunoreactivity (CAMIR) was preferentially accumulated (68.8%) at the pm, detected in association with vesicles in the axoplasm, but unlike BIR, also found to be located at microtubules and more distributed in the axoplasm. Double immuno labelling demonstrated that over 60% of the pm-associated CAMIR and the pm-associated BIR was colocalised. Statistical analysis provided proof that this pattern of colocalisation was not random. Thus, using immuno electron microscopy, we were able to visualise in unmyelinated axons sites of association of B-50 and calmodulin at the pm *in situ*, indicating that these proteins may be present as a molecular complex. The accumulation of B-50 and calmodulin bound in a complex at the pm in proximal axon segments which are not active in regeneration is in agreement with a "reciprocal regulator" hypothesis, namely that the complex serves a storage function in which the proteins are inactive. Moreover, on increase in intracellular local calcium level, the complex dissociates and both proteins become available to participate in various processes occurring during axon outgrowth and remodelling of neurons.

## 134.15

SYNAPTIC DEPRESSION INDUCED BY HYPOXIA BUT NOT BY METABOTROPIC GLUTAMATE RECEPTOR AGONIST 1S, 3R-ACPD IS ENHANCED BY FORSKOLIN. M. Windisch, A. Baskys and J. M. Wojtowicz. Ctr. of Animal Biology, Univ. of Graz Med. School, Graz 8036, Austria and Dept. of Physiology, Univ. of Toronto, Toronto, Ont. M5S 1A8, Canada.

To understand pathophysiology of the early stages of hypoxic/ischemic brain damage and the role of presynaptic inhibition of glutamate release, we studied synaptic depression in *in vitro* hippocampal slices prepared from 4-8 week old CD1 mice. Field potentials (fEPSP) elicited by paired pulse stimulation (interstimulus interval = 50 ms) of lateral perforant pathway-dentate gyrus neurons were recorded in the upper dendritic layer of the dentate gyrus and served as a measure of synaptic transmission. Hypoxia was induced by switching the perfusion of the slice from artificial cerebrospinal fluid (ACSF) saturated with 95% O<sub>2</sub>/5% CO<sub>2</sub> to ACSF saturated with 95% N<sub>2</sub> - 5% CO<sub>2</sub> for brief (10 min.) periods of time. The hypoxic episodes induced a rapid and reversible suppression of fEPSPs and an increase in paired pulse facilitation. Addition of adenylate cyclase activator forskolin (10  $\mu$ M) increased fEPSPs in the dentate gyrus and significantly enhanced the suppression of synaptic transmission due to hypoxia. 1S,3R-ACPD (50  $\mu$ M), which acts as an agonist for several metabotropic glutamate receptors and was shown to reduce forskolin-induced increases in cAMP, depressed fEPSPs and increased paired pulse facilitation in the dentate gyrus. In contrast to the hypoxic depression, the metabotropic agonist-induced decrease of the fEPSP showed no consistent changes in the presence of forskolin, suggesting that metabotropic glutamate receptors are not involved in the hypoxic depression of fEPSPs. The experiments also suggest that adenylate cyclase-cAMP regulation may be a factor influencing the degree of synaptic depression following hypoxic nerve tissue challenge.

## LONG-TERM POTENTIATION: PHARMACOLOGY I

## 135.1

A POSSIBLE ROLE FOR HEPATOCYTE GROWTH FACTOR IN SYNAPTIC PLASTICITY THROUGH ACTIVATION BY TISSUE PLASMINOGEN ACTIVATOR. D. Lederfein, Y.-Y. Huang, H. Golan, and D. Baranes. HHMI, Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032.

Hepatocyte growth factor (HGF), also known as Scatter factor, induces morphogenesis and invasive growth of epithelial and endothelial cells. This factor is a plasminogen-like protein that is secreted as a single chain precursor devoid of biological activity and can be converted to its active dimer form by tissue plasminogen activator (tPA) (Naldini et al., *EMBO J.*, 11:4825, 1992; Naldini et al., *J. Biol. Chem.*, 270:603, 1995).

Since the expression of tPA increases during long-term potentiation (LTP), and ablation of tPA in mutant mice impairs late phase LTP, we examined whether HGF also has a role in synaptic plasticity. We have found that when paired with a subthreshold tetanus, HGF produced late phase LTP (more than 5 h.), whereas this tetanus by itself produced only early phase LTP (less than 90 min.). The late phase LTP produced by HGF was blocked by a tPA inhibitor, suggesting that it might be mediated through tPA activation. We also found that in dissociated hippocampus cells in culture tPA induced autophosphorylation of the HGF receptor, the *c-met* proto-oncogene product. In addition, HGF immunoreactivity was colocalized with a presynaptic marker, synaptophysin, whereas HGF receptor was found on dendrites. These results suggest that HGF may play a paracrine role in the maintenance of LTP: it is produced in the presynaptic terminal and acts on its receptor in the postsynaptic site. This role is apparently mediated by tPA. Supported by HHMI and NYSPI.

## 134.14

INVOLVEMENT OF ADENYLATE CYCLASE IN THE DEVELOPMENT OF TRANSMITTER RELEASE IN AREA CA1 OF THE RAT HIPPOCAMPUS. T.C. Dumas and T.C. Foster. Department of Psychology, University of Virginia, Charlottesville, VA 22903.

We have previously reported an increase in hippocampal CA3-CA1 presynaptic function *in vitro* from the third to the fifth postnatal week (wk) of development. Related studies show that transmitter release is modulated by the adenylate cyclase (AC) activator, forskolin, in slices from neonate and adult rats. We hypothesize that increased presynaptic function beyond 3 wk postnatal is due to increased activity of AC. The hypothesis predicts that direct activation of AC by forskolin will increase transmitter release more in slices from 3 wk than from 5 wk rats. This idea was tested by bath application of forskolin to hippocampal slices and measurement of changes in paired-pulse facilitation (50 ms ISI) of the field EPSP slope in the stratum radiatum of area CA1. Forskolin (50  $\mu$ M, 25 min) significantly increased the EPSP slope at both ages (3 wk, n=8 slices: 125.78 $\pm$ 3.76%; 5 wk, n=7 slices: 113.31 $\pm$ 4.76%). Facilitation was decreased more in the 3 wk (85.52 $\pm$ 0.95%) than the 5 wk pups (97.07 $\pm$ 1.33%). A forskolin analog that does not activate AC, 1,9-dideoxyforskolin (50  $\mu$ M, 25 min), increased the EPSP slope (3 wk, n=7 slices: 134.6 $\pm$ 6.11%; 5 wk, n=9 slices: 124.77 $\pm$ 4.17%) and decreased facilitation at both ages (3 wk: 90.84 $\pm$ 1.37%; 5 wk: 89.63 $\pm$ 2.52%). These results suggest that part of the effect of forskolin on facilitation is due to modulation of K<sup>+</sup> channel function; however, the age difference in the presynaptic effect of forskolin appears to be specific to activation of AC. We conclude that the development of transmitter release at CA3-CA1 synapses from the third to the fifth postnatal wk is regulated, in part, by an increase in AC activity. This study was supported by NIH grants NS31830 to TCF and 1F31MH11005 to TCD.

## 135.2

ORPHANIN INHIBITS LONG-TERM POTENTIATION IN HIPPOCAMPAL CA1 REGION. T.-P. Yu, J. Fein, C. J. Evans and C.W. Xie. Dept. of Psychiatry and Biobehavioral Sciences, UCLA-NPI, Los Angeles, CA 90024.

A novel member of the opioid receptor family, ORL<sub>1</sub> receptor, has been cloned from a variety of vertebrates. Its endogenous agonist, orphanin, has also been identified in rat brain. Our recent immunocytochemical study showed the presence of a high density of ORL<sub>1</sub> receptors in the rat hippocampus. The present study further examined if activation of ORL<sub>1</sub> receptor by orphanin would affect synaptic transmission and long-term potentiation (LTP) in the hippocampal CA1 region.

Extracellular field potentials evoked by stimulation of Schaffer collaterals were recorded in both pyramidal cell body and dendritic layers of CA1 region in transverse rat hippocampal slices (500  $\mu$ m). Our results showed that bath application of synthetic orphanin (0.1-10  $\mu$ M) reduced population spike and EPSP slope in a dose-dependent manner. Paired-pulse facilitation of EPSP was significantly increased in the presence of 1  $\mu$ M orphanin. When high frequency stimuli (4 pulses at 100Hz, repeated every 200ms for a total of 40 pulses) were delivered, 1  $\mu$ M orphanin attenuated LTP. In orphanin-treated slices, the increase in EPSP slope and population spike after high frequency stimulation was 22  $\pm$  5%, 12  $\pm$  4%, respectively (n = 5-10), which were significantly smaller than those in control slices (43  $\pm$  7% and 47  $\pm$  4%, n = 6-12). These data suggest that hippocampal function including LTP can be modulated by ORL<sub>1</sub> receptors (Supported by NIH-NIDA grants, DA05010 and DA08571).

## 135.3

**CHOLINERGIC INDUCTION OF LONG-TERM TRANSFORMATION OF GABAergic SYNAPSES IN HIPPOCAMPAL FIELD CA1.** D. Dahl\*, I. Arrowood, and D.L. Alkon. School of Human Development, The University of Texas @ Dallas and the Laboratory of Adaptive Systems, NINDS, Bethesda, MD.

A distinctive modification of hippocampal field CA1 pyramidal cells was reported by Collin *et al.* (*PNAS*, Oct. 1995). Activation of an inhibitory afferent (10 trains, 10 pulses each, 100 Hz) paired with post-synaptic depolarizing current injection transformed  $\gamma$ -aminobutyric acid (GABA)-mediated inhibition into a depolarizing synaptic response. This modification is termed long-term synaptic transformation (LTT) and persisted for at least 60 min. Maintenance of LTT did not require further pre- or post-synaptic activation. This LTT may be significant in the induction of associative long-term potentiation (LTP).

In the present experiments, we have modified the LTT paradigm by pairing application of carbachol (a cholinergic agonist [20  $\mu$ M]) with activation of an inhibitory afferent (10 trains, 10 pulses each, 100 Hz). These conditions produced LTT that also persisted for at least 60 min without further activation.

Carbachol- and pairing-induced LTT appear pharmacologically similar, in that they are both prevented by anandamide (an endogenous cannabinoid ligand, 1  $\mu$ M) and eliminated by application of bicuculline (GABA<sub>A</sub> antagonist, 1  $\mu$ M). Carbachol-induced LTT is prevented by concurrent application of the glutamatergic antagonists CNQX (100  $\mu$ M) and APV (50  $\mu$ M), but CNQX and APV do not eliminate LTT once it has been induced. Carbachol-induced LTT is also prevented by Dantrolene (preventing intracellular release of Ca<sup>2+</sup>, 20  $\mu$ M) or acetazolamide (blocking synthesis of HCO<sub>3</sub><sup>-</sup>, 10  $\mu$ M).

These results suggest an interaction of acetylcholine and GABA activation in the induction of associative LTP in hippocampal field CA1.

## 135.5

**DIFFERENTIAL MECHANISMS UNDERLYING LONG-TERM POTENTIATION IN THE MEDIAL AND LATERAL AMYGDALA.** K. Abe, S. Okuda\*, Y. Watanabe and H. Saito. Dept. of Chem. Pharmacol., Fac. of Pharmaceut. Sci., Univ. of Tokyo, Tokyo 113, Japan.

The amygdala plays an important role in learning and memory associated with emotion. Although it has been reported that the synapses of the amygdala display long-term potentiation (LTP), the cellular mechanisms of amygdala LTP have not been well understood. In the present study, we investigated the mechanisms underlying LTP in the medial and lateral amygdala synapses *in vitro*. Amygdala slices (400-500  $\mu$ m) were prepared from male Wistar rats (7-9 weeks old) and maintained in a submersion chamber. A bipolar tungsten electrode was placed on the stria terminalis or the external capsule to stimulate the afferent fibers, and the evoked potential was extracellularly recorded from the medial amygdaloid nucleus or the lateral amygdaloid nucleus, respectively. LTP was induced by applying tetanic stimulation (100 pulses at 100 Hz) in the presence of a GABA<sub>A</sub> blocker picrotoxin (10  $\mu$ M). LTP in the medial amygdala was blocked by 2-amino-5-phosphonovaleate (APV), an NMDA receptor antagonist, and was significantly reduced by scopolamine, a muscarinic receptor antagonist. On the other hand, LTP in the lateral amygdala was not affected by APV, but was significantly reduced by scopolamine. These results suggest that both NMDA receptors and muscarinic receptors are involved in medial amygdala LTP, while muscarinic receptors, but not NMDA receptors, are involved in lateral amygdala LTP. Furthermore, isoproterenol, a  $\beta$ -adrenoceptor agonist, facilitated the induction of LTP in the medial amygdala, but suppressed the induction of LTP in the lateral amygdala. The effects of isoproterenol were mimicked by forskolin, an adenylate cyclase activator, in both medial and lateral amygdala. These results suggest that the  $\beta$ -adrenoceptor-cyclic AMP system plays a role in facilitating LTP in the medial amygdala, but suppresses synaptic plasticity in the lateral amygdala.

## 135.7

**$\beta$ -ADRENERGIC AND MUSCARINIC RECEPTORS PARTICIPATE IN THE LTP INDUCTION IN RAT HIPPOCAMPAL CA1.** M. Kobayashi, M. Ohno, S. Shibata, T. Yamamoto and S. Watanabe\*. Dept. Pharmacol. Fac. Pharmaceut. Sci., Kyushu Univ. Fukuoka 812-82, # Dept. Pharmacol. Waseda Univ. Tokorozawa 359, Japan.

Neurotransmitters acting through G-protein-coupled receptors regulate the electrical excitability of neurons by modulating various ion channels. There are good evidences that the metabotropic GluR activation is critical for the induction of LTP and the muscarinic ACh receptor activation can facilitate the LTP formation. However, there is no evidence indicating the participation of norepinephrine in the tetanus-induced LTP formation in area CA1 of the hippocampus. To clarify an involvement of NE system in LTP in area CA1, we examined the effect of concurrent blockade of adrenergic and muscarinic receptors on population spike and the induction of LTP in rat hippocampal CA1 neurons. Consistent with previous findings, separate application of the  $\alpha$ -adrenergic antagonist phentolamine (50  $\mu$ M), the  $\beta$ -adrenergic antagonist propranolol (10  $\mu$ M) and the  $\beta$ 1-adrenergic antagonist atenolol (10  $\mu$ M) had no effect on the induction of LTP by tetanic stimulation (100 Hz, 1 sec). The muscarinic receptor antagonist scopolamine (10  $\mu$ M) suppressed the increase of population spike amplitude after tetanus (60 min, 136 $\pm$ 17%), but low dose (1  $\mu$ M) did not. Co-application of propranolol, but not phentolamine, with ineffective dose of scopolamine (1  $\mu$ M), completely prevented the induction of LTP (103 $\pm$ 8%), suggesting the induction of LTP requires co-activation of  $\beta$ -adrenoceptor and muscarinic receptor. Furthermore, atenolol, which has no potential membrane stabilizing action, also prevented the induction of LTP when combined with scopolamine (92 $\pm$ 9%). In the experiment of extracellular EPSP recordings, concomitant application of atenolol and scopolamine showed the similar effects.

We conclude that  $\beta$ 1-adrenoceptor plays some role in the induction of LTP in area CA1 of the hippocampus.

## 135.4

**LONG-LASTING ENHANCEMENT OF SYNAPTIC TRANSMISSION IN DISSOCIATED CHICK CEREBRAL NEURONS.** S. Kudoh\*, K. Kiyosue, M. Kasai, T. Taguchi,

Lab of Mol. Biol., Fac. of Eng. Sci., Osaka Univ., Toyonaka 560, Japan, and \*Osaka Nat'l. Res. Inst. AIST, Ikeda 563, Japan.

Long-term enhancement of synaptic transmission were demonstrated in a dissociated cell culture containing embryonic chick cerebral neurons. Using whole-cell patch clamp technique, long-lasting increase in amplitude of spontaneous excitatory post synaptic currents (SESPCs) was confirmed to be induced by Mg<sup>2+</sup>-free medium. This enhancement was depends on neural activity and the activation of NMDA type glutamate receptor. Analysis of miniature EPSCs in the presence of TTX revealed that the enhancement is due to the increase of the number of transmitter release site and/or synaptic sites. Furthermore the similar potentiation was found to be able to be caused by exposing neurons to conditioned Mg<sup>2+</sup>-free medium which was collected after induction of the enhancement and adjusted the Mg<sup>2+</sup> concentration at the same in normal extra cellular recording solution. This result suggests that a factor which released to the medium from neurons or glia are involved in the mechanism of the potentiation. Using glia-free culture which we developed by the addition of peptides containing cell adhesion-related sequences, we examined whether the presence of glia is essential for the long-lasting increase in amplitude of SESPSCs, or not. In the neuron-selective culture, synapse formation proceeded in a similar way to that in the control one and the amplitude of SESPSCs increased by Mg<sup>2+</sup>-free medium, suggesting that the potentiation was caused by the intrinsic mechanisms. This work was Supported in part by JSPS Research Fellowships (072875).

## 135.6

**LIPOXYGENASE METABOLITES OF ARACHIDONIC ACID AS MODULATORS OF SYNAPTIC TRANSMISSION IN RAT HIPPOCAMPUS.** B. Liu, T. Tieman, S.J. Feinmark and J.H. Schwartz\*. Center for Neurobiology & Behavior and Department of Pharmacology, Columbia University, NY, NY 10032.

Arachidonic acid (AA) metabolites produced by lipoxygenase have been proposed as second messengers for presynaptic inhibition of *Aplysia* sensory neurons and as retrograde messengers in long-term potentiation (LTP) in hippocampus. In the present study, we examined the effect of a selective 12-lipoxygenase inhibitor, CDC (cinnamyl-3,4-dihydroxy- $\alpha$ -cyanocinnamate), on synaptic activity in the CA1 region of transverse hippocampal slices. CDC (0.1-1  $\mu$ M) reversibly reduced the basal slope of EPSPs. When CDC-treated slices had reached a stable but reduced EPSP slope, the stimulus intensity was increased to return the response to control levels. At that point a train of tetanic stimuli were delivered to the Schaffer-commissural pathway. LTP in slices treated with CDC was impaired compared to those in control (DMSO, 0.1%) slices. Further, we confirmed the presence of lipoxygenase in hippocampus by Western blotting using an antibody which cross-reacts with several lipoxygenase isoforms. Hippocampal tissue metabolized radiolabeled AA into at least four products. The formation of these products was blocked by NDGA (nordihydroguaiaretic acid, a nonspecific inhibitor), as well as by CDC, indicating that they are probably derived from the action of a 12-lipoxygenase. Our data suggest that AA metabolites of the 12-lipoxygenase pathway may play an important role as modulators of synaptic activity in rat hippocampus. (Supported by NIH grants NS29832, MH00921 [JHS] and NS10035 [BL])

## 135.8

**RAPID TOLERANCE TO BENZODIAZEPINE MODIFIES HIPPOCAMPAL SYNAPTIC PLASTICITY.** O. A. Ramirez†, Raúl H. Martín\*, Nancy A. Salvatierra†, D. Masco\* †Departamento de Farmacología, Fac. Ciencias Químicas, ‡Catedra de Química Biológica, Fac. Ciencias Exactas Físicas y Naturales, Universidad Nacional de Córdoba, Argentina.

Glutamate antagonists to N-methyl-D-aspartate (NMDA) receptors blocks the development of "rapid" tolerance to the sedative action of benzodiazepines (BZDs). This kind of glutamate receptors is closely related to synaptic plasticity in different areas of the brain such as hippocampus. In the present investigation, we studied the synaptic plasticity in dentate gyrus (GD) of the hippocampus during the development of tolerance to the hypomotility action induced by diazepam (DZ). The results show an increased hippocampal synaptic plasticity in slices from rats treated with diazepam (5mg/kg/day) during four days, assessed as a decrease of the threshold in the stimulation frequency for Long-Term Potentiation (LTP) elicitation. These results reveal a positive correlation between the synaptic plasticity and development of BZD tolerance to locomotor activity. Supported by grants from CONICET and CONICOR Argentina to O.A.R.

## 135.9

**ROLE OF PROTEIN PHOSPHATASES IN HIPPOCAMPAL LONG-TERM POTENTIATION.** K. Fukunaga<sup>1</sup>\*, D. Muller<sup>2</sup> and E. Miyamoto<sup>1</sup>. <sup>1</sup>Dept. of Pharmacol., Kumamoto Univ. Sch. of Med., Kumamoto 860, Japan and <sup>2</sup>Dept. of Pharmacol., Centre Médical Univ., 1211 Geneva 4, Switzerland

The activation of CaM kinase II plays a crucial role in the molecular mechanisms that have been proposed to contribute to long-term potentiation (LTP) in the hippocampus. Induction of LTP in CA1 regions of hippocampal slices was associated with long-lasting increases in Ca<sup>2+</sup>-independent and total activities of CaM kinase II (J. Biol. Chem., 270: 6119, 1995). In the experiments with cell extracts from CA1 regions, calyculin A-sensitive protein phosphatases and Mg<sup>2+</sup>-dependent protein phosphatase were involved in the dephosphorylation of autophosphorylated CaM kinase II. Among calyculin A-sensitive protein phosphatases, phosphatase 2A was mainly contributed to dephosphorylation of CaM kinase II, because inhibitor 2 had little effects. In the LTP-induced slices, a significant decrease in calyculin A-sensitive protein phosphatase activity was observed without change in Mg<sup>2+</sup>-dependent protein phosphatase activity using autophosphorylated CaM kinase II as substrate. The decrease was prevented when LTP induction was inhibited by treatment with D-AP5. We further demonstrated with <sup>32</sup>P-labeled hippocampal slices that application of high frequency stimulation resulted in an increase in phosphorylation of inhibitor 1 1 hr after LTP induction. These results support the idea that the reduced changes in protein phosphatase activities during LTP induction may be implicated in the maintenance of constitutively active CaM kinase II and phosphorylation of its substrates

## 135.11

**SEROTONIN INHIBITS THE INDUCTION OF LONG-TERM POTENTIATION IN RAT PRIMARY VISUAL CORTEX.**

Y. Edagawa\*, H. Saito and K. Abe. Dept. of Chem. Pharmacol., Fac. of Pharmaceut. Sci., The Univ. of Tokyo, Bunkyo-ku, Tokyo 113, Japan.

The synapses of the mammalian primary visual cortex display long-term potentiation (LTP), which may underlie experience-dependent plasticity. It has been reported that serotonergic fibers are observed in the early development of primary visual cortex in rats. To determine the role of serotonin in synaptic plasticity in this brain region, we investigated the effect of serotonin on the induction of LTP by using slice preparations in vitro. Acute slices (400  $\mu$ m thickness) were prepared from primary visual cortex region of male Wistar rats (3-5 weeks old). The slices were maintained in a chamber at 34 °C, where they were continuously perfused with physiological salt solution. Bipolar stimulating electrode was placed in layer IV, and the evoked potentials were extracellularly recorded from layer II/III. Single-pulse test stimulation of layer IV evoked two distinct components of sharp negative-going potentials, i.e. antidromic and orthodromic responses. When tetanic stimulation (100 Hz for 1 sec, twice at an interval of 30 sec) was applied, only synaptic component was potentiated. The potentiation lasted longer than 60 min and was regarded as LTP (response amplitude 30-60 min after tetanus, 140.18 $\pm$ 7.52 % of baseline, n=8). Serotonin (10  $\mu$ M) did not affect the baseline synaptic potentials evoked by single-pulse test stimulation, but inhibited the induction of LTP (105.23 $\pm$ 3.99 %, n=5). The inhibitory effect of serotonin was concentration dependent (0.1-10  $\mu$ M), and was blocked by the concomitant presence of 10  $\mu$ M pindolol, 5-HT<sub>1A</sub> receptor antagonist, or 10  $\mu$ M ritanserin, 5-HT<sub>2</sub> receptor antagonist. These results suggest that serotonin plays a role in suppressing the induction of LTP in the primary visual cortex of rats.

**ADENOSINE A<sub>2b</sub> RECEPTORS MODULATE HIPPOCAMPAL SYNAPTIC TRANSMISSION VIA A cAMP DEPENDENT PATHWAY.**

K. Kessey\* and D.J. Mogul. Depts. of Biomedical Engineering and Neurobiology & Physiology, Northwestern Univ., Evanston, IL 60208 USA.

The effects of A<sub>2</sub> receptor activation on normal synaptic transmission and tetanus-induced LTP were examined at the Schaffer collateral/CA1 synapse in rat transverse hippocampal slices. Receptor activation with the A<sub>2</sub> agonist DPMA reversibly enhanced the field EPSP slope during low frequency test pulses (0.033Hz). In the presence of A<sub>1</sub> receptor blockade with CPT, DPMA further enhanced the EPSP over that observed with CPT. A<sub>2</sub> receptor blockade using DMPX in the presence of CPT led to a reversible decrease of the EPSP. These effects appear to be a result of A<sub>2b</sub> receptor manipulation because the A<sub>2a</sub> receptor agonist CGS21680 had no effect on the EPSP. During A<sub>1</sub> receptor blockade, A<sub>2</sub> receptors significantly modulated the level of tetanus-induced LTP (100Hz, 1s). In the presence of CPT alone, the level of LTP attained was 163.5 $\pm$ 9.1% (mean $\pm$ SEM). In comparison, when A<sub>2</sub> and A<sub>1</sub> receptors were blocked with DMPX and CPT respectively, the level of LTP was 121.3 $\pm$ 1.9%. In contrast, A<sub>2</sub> receptor activation with DPMA in the presence of CPT resulted in LTP of 190.2 $\pm$ 10.5%. Using forskolin, the direct adenylate cyclase activator, we were able to restore 53% of the LTP blocked by DMPX suggesting that the effects of A<sub>2</sub> receptors on synaptic transmission may be mediated through the regulation of intracellular cAMP. These results suggest that A<sub>2</sub> receptors may play a significant modulatory role in normal synaptic transmission and contribute to LTP through their stimulatory influence on cAMP. Supported by the NIH (NINDS NS31764) and the Whitaker Foundation.

**ACTIVATION OF PROTEIN PHOSPHATASES 1 AND 2A IN ASSOCIATION WITH LONG-TERM DEPRESSION IN HIPPOCAMPUS IN VIVO.** E.D. Norman\*, E. Thiels, G. Barrionuevo, E. Klann. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260

We previously have shown that the maintenance of NMDA receptor-dependent paired-pulse stimulation-induced long-term depression (PPS-LTD) of the commissural input to CA1 pyramidal cells in the hippocampus of anesthetized adult rats is associated with increase protein phosphatase (PPase) activity (*Soc. Neurosci. Abstr.* 21:1097). In order to determine the time course of activation of PPases after induction of PPS-LTD, we measured PPase activity in homogenates of dorsal area CA1 (recording site) excised either 5, 35, or 65 min after the final of three trains of 200 paired pulses (25-ms interpulse interval; 2-sec interpair interval; 15-min intertrain interval) delivered to the contralateral dorsal area CA3.

LTD (dorsal) CA1 and control (ventral) CA1 homogenates were added to PPase assays that included <sup>32</sup>P-labeled phosphorylase kinase (PK), a PPase substrate consisting of an  $\alpha$  subunit, which is dephosphorylated by PPases 2A, 2B, and 2C, and a  $\beta$  subunit, which is dephosphorylated by PPase 1. Dephosphorylation of the  $\alpha$  and the  $\beta$  subunit was quantified using autoradiography and densitometry.

In PPase assays of the 5-min samples, we observed a significant increase in dephosphorylation of both the  $\alpha$  subunit (control=94 $\pm$ 8%; LTD=75 $\pm$ 5%) and the  $\beta$  subunit (control=88 $\pm$ 5%; LTD=75 $\pm$ 4%) of PK. In contrast, a significant increase in dephosphorylation of only the  $\alpha$  subunit was detected in the 35-min samples (control=89 $\pm$ 4%; LTD=72 $\pm$ 3%). No significant increase in dephosphorylation of either subunit was detected in the 65-min samples. In PPase assays of the 35-min samples, addition of okadaic acid (1 $\mu$ M), a potent inhibitor of PPase 2A, blocked the LTD-associated increase in dephosphorylation of the  $\alpha$  subunit (control=100 $\pm$ 6%; LTD=100 $\pm$ 9%). These results indicate that PPS-LTD is associated with an increase in activity of PPases 1 and 2A, and that the increase of PPase 2A activity lasts longer than that of PPase 1 activity. [Supported by NIMH (E.T.) and NINDS (E.K.).]

**SEROTONIN-INDUCED PLASTICITY IN THE KITTEN VISUAL CORTEX IS ASSOCIATED WITH AN ACTIVATION OF NMDA RECEPTORS AND VOLTAGE-GATED CALCIUM CHANNELS.** L. Kojic\*, O. Gu, R.M. Douglas, J. Matsubara and M. Cynader. Department of Ophthalmology, University of British Columbia, 2550 Willow St., Vancouver, B.C., Canada V5Z 3N9

Recently, we suggested an involvement of a particular family of serotonin receptors (5-HT<sub>2</sub>) in the regulation of visual cortex plasticity, a hypothesis supported by both anatomical and electrophysiological data. To further study the mechanisms of serotonin-induced plasticity we here define an interaction with the two previously reported induction pathways of visual cortex plasticity, namely the activation of NMDA receptors and of voltage-gated Ca<sup>2+</sup> channels. To directly test the role of serotonin receptors in cortical plasticity, we recorded field potentials in visual cortex slices from 40-65 and >120 day old kittens. Field potentials were recorded from layer IV after white matter stimulation, before and after a period of low frequency stimulation (LFS; 1Hz, 15 min). In visual cortical slices, from 40-65 day old kittens, LTD or LTP was induced by LFS only if serotonin (1 or 10  $\mu$ M) was applied before LFS. In the presence of the NMDA receptor antagonist dAPV or the L-type Ca<sup>2+</sup> channel blocker nifedipine no long-term plasticity was observed after coapplication of LFS and serotonin. Furthermore, no such serotonin-induced long-term plasticity was ever detected in >120 day old animals. The present results suggest that the serotonin-induced long-term plasticity in the kitten visual cortex involves an increase of intracellular calcium, which occurs through an activation of NMDA receptors and/or L-type Ca<sup>2+</sup> channels. One possibility is that the calcium release, consequent to an induced PI turnover by the activation of 5-HT<sub>2</sub> receptors, might be additive with the calcium influx through NMDA receptors and L-type voltage-gated Ca<sup>2+</sup> channels. Furthermore, our finding that there was no serotonin-induced long-term plasticity detected in visual cortical slices from adult animals (>120 days) is consistent with this hypothesis, since a substantial reduction of NMDA receptors, L-type Ca<sup>2+</sup> channel binding sites, and 5HT<sub>2</sub> receptors was observed in layer IV of the adult cat.

## 135.14

**D1 DOPAMINE RECEPTOR ACTIVATION INCREASES EARLY LTP IN SCHAFER-CA1 HIPPOCAMPAL SYNAPSES**

N. Otmakhova\*, J. Lisman. Department of Biology and Volen Center for Complex Systems, Brandeis University, Waltham, MA 02254.

The role of the mesolimbic dopaminergic system in the reinforcement of learning suggests that dopamine should be able to modulate activity-dependent synaptic plasticity in a synapse-specific manner. We have examined the effect of D1 agonists and antagonist on early LTP (40 min. after a single tetanus). Field EPSPs were monitored in the CA1 region of the hippocampal slices using 2 independent pathways. The drugs were applied in 5-10  $\mu$ M concentrations into the bath for 5 min. before the tetanus. D1 agonists (Bromo-APB, Chloro-PB, Dihydroxidine) increased the magnitude of LTP in a synapse-specific manner by 5-20%. The effect of D1 agonists could be mimicked by the activator of adenylyl cyclase, forskolin (10  $\mu$ M). The D1 antagonist, SCH 23390 (5  $\mu$ M), reduced early LTP by 5-10%, suggesting that under normal conditions dopamine released during the tetanus (Frey et al., 1990) facilitates the induction of LTP.

In slices depleted of catecholamines LTP was substantially (by 10-25%) decreased. D1 antagonist became ineffective. On the other hand, both D1 agonist and forskolin produced larger enhancements of LTP in depleted slices, restoring it to the normal level.

These results suggest that dopamine can participate in the mechanisms of LTP induction and produce a synapse-specific enhancement of early LTP through D1 receptors and cAMP.

This work was supported by a NIH grant (5 R01 NS27337-7), W. M. Keck Foundation, and generous donations of dopaminergic drugs from NIMH Synthesis Program at RBL (Natick, MA), Abbot Laboratories (Abbott Park, IL), and Interneuron Pharmaceuticals Inc. (Lexington, MA).

## 135.15

DOPAMINERGIC MODULATION OF LONG-TERM POTENTIATION IN THE HIPPOCAMPAL-PREFRONTAL CORTEX PATHWAY. T.M. Jay\*, E. Burette and S. Laroche. NAM, CNRS URA 1491, Université Paris-Sud, 91405 Orsay, France.

High-frequency stimulation of the hippocampus (CA1-subicular region) induces long-term potentiation (LTP) in the prelimbic area of the prefrontal cortex (PFC). Previous studies have shown that the hippocampal input to the PFC is glutamatergic and reaches the deep layers of the prelimbic cortex. As DA innervation is particularly dense in this area and in close proximity to excitatory axonal terminals, we examined the effects of DA on synaptic transmission and LTP in the hippocampal-PFC pathway. Intracerebral microdialysis combined with recording of PFC extracellular fields potentials evoked by stimulation of the hippocampus was carried out in anaesthetized rats. After one hour baseline stimulation in the presence of aCSF (2µl/min), DA was infused in the PFC for one hour (30 min prior to tetanic stimulation). In the first series of experiments, DA was infused at 1mM. PFC potentials evoked by test stimuli were significantly increased (9.86 %) by DA. Tetanus-induced LTP in the presence of DA was greater in amplitude (71.7 %) when compared to the controls (47.9 %) and, one hour after the tetanus, LTP was maintained and significantly greater than in controls (74.5% compared to 28.9 % in the controls). In a second series of experiments, DA was infused at 5 mM in rats receiving a perfusion of nomifensine (5 µM in aCSF; uptake inhibitor) one hour prior to DA infusion. Nomifensine increased significantly (15.6 %) the amplitude of the evoked response and this increase was enhanced to 22.6 % with the infusion of 5mM DA. During infusion of DA, tetanic stimulation of the hippocampus induced reliable LTP of the evoked response in the PFC and the amplitude of LTP was higher (68.2 %) than that of the controls. These data indicate that DA enhances excitatory synaptic transmission in the hippocampal-PFC pathway and suggest that, in vivo, DA may exert a facilitatory effect on the expression of LTP in this pathway. Studies to further investigate this modulation are currently underway.

D1/D5 RECEPTORS MEDIATE A PROTEIN SYNTHESIS-DEPENDENT LATE PHASE OF LTP IN THE AMYGDALA. Y.-Y. Huang\* and E.R. Kandel. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032.

There is now good evidence that the major synaptic pathways of the hippocampus, a structure thought to be important for explicit memory, show a late phase of LTP that require cAMP, PKA, and protein synthesis. What about implicit forms of storage in the mammalian brain? Does LTP in the amygdala, thought to be critical for emotionally charged implicit storage, have a protein synthesis-dependent late phase? If so, which second messenger mediates this phase? We found that multiple tetani applied to external capsule of rat brain slices induced a protein synthesis-dependent late phase LTP (> 3 hrs) in the basal lateral amygdala. A similar late phase could be induced 1 hr after application of an agonist of the D1/D5 receptor. This late agonist-induced potentiation is mediated by PKA and blocked by anisomycin. Moreover, antagonists of the D1/D5 receptors significantly depress the late phase of LTP in the amygdala. These results suggest that the LTP in the amygdala has a late as well as an early phase and that D1/D5 receptors and cAMP/PKA play a role in the late phase.

## LONG-TERM POTENTIATION: PHARMACOLOGY II

## 136.1

STREPTOZOCIN-INDUCED DIABETES MELLITUS IMPAIRS WATER-MAZE LEARNING AND EXPRESSION OF LONG-TERM POTENTIATION IN RAT HIPPOCAMPUS IN VITRO. A. Kamal, G.J. Biessels, J.J.A. Urban and W.H. Gispen. Rudolf Magnus Institute for Neuroscience, University of Utrecht, The Netherlands. (Spon: ENA)

Peripheral neuropathies and cognitive impairments have been among recognized complications of diabetes mellitus (DM). We have studied the influence of a severe form of diabetes mellitus (DM), (induced by i.v. injections of streptozocin (STZ; 40mgSTZ/kg body weight) on conduction velocity of the sciatic nerves, water-maze (WM) learning and the expression of long-term potentiation (LTP) in CA1 field of the hippocampus slice from rats with a severe DM, mild DM (a partial insulin substitution) and age-matched controls. The sciatic nerve conduction velocity and WM learning in rats with a severe form of DM (25.6±1 mMol/l blood glucose) was significantly slower than those in rats with the mild form of DM (18.9±1.8 mMol/l blood glucose) or age-matched controls. In addition, the expression of LTP in the CA1 field of the hippocampus in slices from severely DM rats was significantly below that in slices from moderately DM and control rats. Neither WM learning nor expression of the hippocampus LTP in rats with mild form of DM differed significantly from these measures in controls. However, the conduction velocity of the sciatic nerve was slower than that in control rats. It is demonstrated that the severe form of DM, in addition to the sciatic nerve neuropathy, also impairs the hippocampus synaptic plasticity and water-maze learning. The mild DM affects the peripheral nerves only.

## 136.3

ROLE OF CADHERIN MOLECULES IN SYNAPTIC PLASTICITY IN THE ADULT RAT HIPPOCAMPUS. L. Tang\*, C. P. Hung and E. M. Schuman. Division of Biology 216-76, Caltech, Pasadena, CA 91125

It has been suggested that certain cell adhesion molecules (CAM) can modulate synaptic transmission and hippocampal long-term potentiation (LTP). In the present study, we explored the role of classic cadherins, in particular N-cadherins, in synaptic transmission and LTP in CA1 region of young adult rat hippocampus. Immunostaining and detection with confocal microscopy suggest that cadherins and the associated cytoplasmic proteins, catenins, are present in young adult rat hippocampus. Additional studies in dissociated cultured hippocampal neurons indicate that much of the cadherin staining colocalizes with staining for the synaptic vesicle protein, synapsin I. There is evidence that synthetic peptides containing the consensus sequence "HAV", which is highly conserved among many different cadherins, can inhibit cadherin-mediated processes. In "two-pathway" experiments, bath application the synthetic peptide AHAVD (0.2 mM) significantly reduced LTP [mean % baseline @ 50-60 min post tetanus: control 130.5±7.4%, AHAVD 110.8±3.1% (p<0.01, n=10)]. The peptides were without effect on basal synaptic transmission. In contrast, bath application of 3 different control peptides (0.2 mM) were without effect on LTP ["AEAVD": control 139.3±7.6%, AEAVD 137.5±4.9% (p>0.8, n=6); "AHSVD": control 135.7±6.1%, AHSVD 130.6±4.3% (p>0.1, n=7); scrambled sequence "AADHV": control 138.1±7.3%, AADHV 137.0±6.7% (p>0.8, n=7)]. Further studies suggested that the observed reduction of LTP by "AHAVD" peptides is not due to blockade of NMDA receptor mediated responses. We also investigated whether treating slices with a function-blocking N-cadherin antibody can affect subsequently recorded LTP. We found that N-cadherin antibody preincubated slices showed less LTP than control antibody preincubated adjacent slices [control antibody 157.7±13.0%, N-cadherin antibody 110.0±7.0% (p<0.001, n=10)]. Our immunostaining data confirm that these antibodies can efficiently penetrate slices after > 1 hr incubation. Taken together, these data suggest that cadherins, presumably N-cadherins, are involved in hippocampal synaptic plasticity. Supported by Alfred P. Sloan Foundation, John Merck Fund, and the PEW Charitable Trusts.

## 136.2

DIFFERENCE IN EXPRESSION OF LONG-TERM DEPRESSION IN THE CA1 FIELD OF THE HIPPOCAMPUS IN SLICES FROM DIABETES MELLITUS AND CONTROL RATS. J.J.A. Urban, A. Kamal, G.J. Biessels and W.H. Gispen. Rudolf Magnus Institute for Neuroscience, P.O. Box 80040, 3508 AT Utrecht, The Netherlands. (Spon: ENA)

Long term depression (LTD) is a decrease in synaptic strength produced by a low frequency stimulation of afferent fibers. LTD is considered to be an opposite to long-term potentiation (LTP). Elsewhere we shown (see Kamal et al., this Meeting) that streptozocin (STZ)-induced diabetes mellitus (DM) impairs the expression of LTP in the CA1 field of the hippocampus slices. Here we studied the expression of LTD in the CA1 field of the hippocampus in slices from rats suffering 10 or 20 weeks from DM, from 20 weeks DM rats that the 10 last weeks received insulin, in slices from rats with 10 weeks of DM with or without insulin substitution and from age-matched control rats. LTD was produced by stimulating the radiate layer either two times for 15 min at 1 Hz in a 15 min interval (type 1) or 5 min at 1 Hz, followed by 5 min test stimulation, 5 min at 1 Hz followed by 5 min at 5 Hz (type 2). The slices from 20 months DM rats showed at 60 min after the stimulation on average a 30±% LTD in the slope of the field excitatory postsynaptic potentials (fEPSPs), regardless the stimulation type used. However, control slices stimulated with the type 1 showed only 11.4±2.3% LTD in the slope of the fEPSPs. In slices stimulated with type 2 was LTD 14.1±5.0.2%. In insulin substituted slices LTD to stimulation 1 was on average 13.7%. LTD induced by type 2 stimulation was on average 5.5%. The slices from 10 weeks DM rats showed a similar pattern in response to both stimulation types, however, the difference in the amount of LTD between amongst groups was less pronounced than that in the 20 weeks DM rats. Thus, severe DM significantly enhances the LTD expression in the CA1 field of the rat hippocampus. Insuline failed to abolish the LTD enhancing effect of this DM.

## 136.4

ACTIVITY SWITCHING OF CAMKII IN LONG-TERM POTENTIATION---THEORETICAL ANALYSIS. Hideyuki Cateau\* and Shigeru Tanaka, Lab. for Neural Modeling, The Institute of Physical and Chemical Research (RIKEN), Hirosawa, Wako, Saitama 351-01, Japan.

Semipermanent switching of the kinase activity of CaMKII caused by its autophosphorylation has been suggested to play a central role in the induction of long-term potentiation (LTP). Cooperative activation among subunits constituting a CaMKII holoenzyme is speculated to maintain its kinase activity, resulting in a long-lasting conformational change and associated change in synaptic efficacy. To test this hypothesis, we carried out simulations of dynamical transitions of CaMKII states triggered by a transient rise in  $[Ca^{2+}]$ , and observed the following behavior: 1) If the CaMKII is initially in an off (catalytically inactive) state, it remains in the off state, and if it is initially in an on (catalytically active) state it remains in the on state. 2) A large transient rise in  $[Ca^{2+}]$  induces a switching of the CaMKII state from off to on. In order to identify the critical determinant for this clear-cut switching, we reformulated the CaMKII dynamics based on statistical mechanics. We found that the on/off states are described by an energy function, which justifies the stability of these states. The energy function derived is mathematically equivalent to that of magnetic material, so that we can understand the clear-cut nature of on/off switching of CaMKII activity in terms of magnetism.

**SIGNALING TARGETS OF REACTIVE OXYGEN SPECIES IN THE HIPPOCAMPUS.** L.T. Knapp\*, B.I. Kanterewicz and E. Klann. *Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.*

We previously have shown that superoxide ( $\text{O}_2^-$ ), a reactive oxygen species (ROS), modulates the induction of hippocampal long-term potentiation (LTP), possibly via interactions with protein kinase C (PKC) (*Soc. Neurosci. Abstr.* 21:109). Consistent with this idea, hippocampal glutamate receptor activation, including NMDA receptor activation, results in increased production of ROS, including  $\text{O}_2^-$  (*J. Neurosci.* 16:1324). Furthermore, oxidation with hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) of either purified PKC or hippocampal homogenates results in an increase in PKC activity (*Biochem. Biophys. Res. Comm.* 187:1439). Therefore, we determined if  $\text{O}_2^-$  activates PKC directly by incubating either hippocampal homogenates or purified PKC with xanthine/xanthine oxidase (X/XO), an  $\text{O}_2^-$ -generating system. Treatment of either purified PKC or homogenates with X/XO resulted in an increase of both autonomous and cofactor-dependent PKC activity. The X/XO-induced increase in PKC activity was attenuated by superoxide dismutase which suggests that  $\text{O}_2^-$  can activate PKC directly. To determine if ROS such as  $\text{H}_2\text{O}_2$  and  $\text{O}_2^-$  can activate biochemical signaling cascades in hippocampal slices, we incubated slices with  $\text{H}_2\text{O}_2$ . Treatment of slices with  $\text{H}_2\text{O}_2$  also resulted in an increase of both autonomous and cofactor-dependent PKC activity. Because activation of PKC has been shown to increase protein tyrosine phosphorylation in hippocampal slices, we used a phosphotyrosine antibody to determine changes in protein tyrosine phosphorylation in slices exposed to  $\text{H}_2\text{O}_2$ . Incubation of slices with  $\text{H}_2\text{O}_2$  resulted in increased tyrosine phosphorylation of a number of proteins. Bath application of NMDA to activate NMDA receptors resulted in increased tyrosine phosphorylation of a similar subset of proteins. The NMDA-induced increase in phosphorylation was blocked by the antioxidant N-acetylcysteine. Taken together these results suggest that ROS are capable of activating signaling cascades in the hippocampus, and that similar mechanisms may occur during induction of hippocampal LTP. Supported by NINDS grant NS34007, the Winters Foundation, and a University of Pittsburgh CRDF grant.

## 136.7

**ISOLATION OF "MINI"-SYNAPTONEUROSOMES FOR SYNAPTIC PLASTICITY STUDIES IN HIPPOCAMPAL SLICES.** M.W. Johnson, J.J. Rubino, T.J. O'Dell, and J.B. Watson\*. *Department of Psychiatry and Biobehavioral Sciences, Department of Physiology, UCLA School of Medicine. 90024-1759.*

The availability of a reliable method for subcellular fractionation of synapses in individual hippocampal slices would greatly enhance our ability to reconstruct the neurochemical signalling pathways that underlie LTP/LTD forms of plasticity. We have scaled down the original synaptoneurosome preparation from whole brain (Hollingsworth et al, 1985, *J. Neurosci.* 5, 2240) to a "mini" synaptoneurosome fraction isolated from mouse hippocampal slices. Slices were maintained in interface chambers under conditions normally used for electrophysiological studies of LTP, homogenized on ice in an Eppendorf tube with a teflon hand pestle, and sequentially filtered [nylon mesh, Millipore filter (5µm)] in a filter-holder attached to a 1 cc Tuberculin syringe. The filtrate was centrifuged at low speed to generate a pellet ("mini" synaptoneurosomes) and supernatant (cytosol). Western blotting studies with antisera to known pre- and post-synaptic markers ( $\alpha$ -CaM Kinase II subunit, GAP-43, NMDAR1 receptor subunit) show that "mini" preps exhibit expression profiles comparable to controls. The "mini" synaptoneurosome preparation has the potential to identify a variety of subcellular neurochemical changes including novel kinase activities and substrates after the induction of plasticity. Supported by NIH grant NS32521 and a UCLA Stein-Oppenheimer Award.

## 136.9

**THE INVOLVEMENT OF METABOTROPIC GLUTAMATE CLASS 1 RECEPTORS IN LTP DEPENDS ON TETANIZATION STRENGTH.** V. Wilsch, T. Behnisch\*, T. Jäger, D. Balschun, R. Pellicciari\* and K.G. Reymann\*. *Federal Inst. for Neurobiology, Dept. Neurophysiol., Inst. of Applied Neuroscience GmbH, Brenneckestr. 6, D-39118 Magdeburg, Istituito di Chimica e tecnologia del Farmaco Univ. degli studi de Perugia, Via del Liceo, 06100 Perugia*

The eight subtypes of the metabotropic glutamate receptors (mGluRs) which are known so far can be pharmacologically divided in three classes. Beyond other functions mGluRs have been found to play a role in synaptic plasticity. ACPD an mGluR class 1 and 2 agonist enhances LTP whereas MCPG an unspecific mGluR class 1 and 2 antagonist either to an inhibits LTP or has no effect. To further resolve the role of class 1 mGluR in LTP, we employed MCPG and the specific class 1 antagonists 4-CPG and (RS)-1-Aminoindan-1,5-dicarboxylic acid (UPF 523) as well as the specific class 1 agonist DHPG in two different types of LTP. Field excitatory postsynaptic potentials (fEPSPs) were recorded in the hippocampal CA1 area and a 'weak' or a 'strong' LTP were induced by two different tetanization paradigms (tree trains of 100 Hz for 500 ms every 2 minutes or a single train of 100 Hz for 400 ms, pulsewidth 200 µs).

In the 'weak' LTP, MCPG (400 µM) and 4-CPG (100 µM) led to clear-cut reduction of potentiation in comparison to controls. DHPG (15 µM) resulted in a decline of baseline values immediately after application which apparently masked a facilitation of LTP induction. However, 50 min after tetanization when this baseline depression had ceased, the potentiation was significantly enhanced compared to controls. 4-CPG acted in a concentration dependent manner with an  $\text{IC}_{50}$  of  $9.9 \pm 0.7$  µM and a Hill coefficient of 1.03. UPF 523 had no effect. This can be attributed to its supposed selectivity towards mGluR 1 which seems to be limited to glial cells and CA1 interneurons. All drugs did not exert any influence on 'strong' LTP. We conclude that activation of class 1 mGluRs plays a role in a 'weak' LTP but in the 'strong' LTP other mechanisms compensate mGluR activation.

## 136.6

**PRENATAL COCAINE EXPOSURE RESULTS IN INCREASED SENSITIVITY OF LTP TO A SEROTONIN ANTAGONIST.** J.Z. LITTLE\* and T.J. TEYLER. *Dept. of Neurobiology, Northeastern Ohio Univ. Coll. of Med., Rootstown, Ohio 22472*

Cocaine exposure during development is known to decrease the number of serotonin staining projections to the hippocampus. Serotonin neurotransmission modulates the magnitude of LTP in hippocampal area CA1. In a rabbit model of in utero cocaine exposure we examined the effects of 1µM methiothrepin maleate, a serotonin autoreceptor antagonist, on the induction and maintenance of LTP in area CA1. Induction of LTP by a 100Hz/1sec tetanus was not altered in control animals by the presence of methiothrepin maleate. LTP in offspring exposed to cocaine during gestation was significantly reduced compared to LTP in the absence of methiothrepin maleate. The magnitude of LTP in cocaine exposed animals following methiothrepin maleate was similar to LTP induced in control animals regardless of whether methiothrepin maleate was present or absent during tetanus.

This project was supported by NIDA Grant #DA06871

## 136.8

**DANTROLENE (BUT NOT THAPSIGARGIN) PREVENTS THE LONG-TERM POTENTIATION INDUCED IN CA1 REGION OF RAT HIPPOCAMPAL SLICES BY 2-DEOXYGLUCOSE (2DG).**

A.T. Tan\*, S. Tekkök and K. Krnjević. *Anaesthesia Research & Physiology Depts., McGill University, Montréal, PQ, H3G 1Y6 Canada.*

As reported elsewhere (Tekkök and Krnjević, this meeting),  $\text{Ca}^{2+}$  released from an internal store appears to be essential for the induction of 2DG LTP in CA1. Dantrolene, which blocks internal  $\text{Ca}^{2+}$  release in hippocampal cells, at 10 µM completely blocked induction of 2DG LTP -- afferent volley-EPSP (V-E) relation up by  $2 \pm 1.2\%$ ,  $n=7$ . Tetanic LTP was unaffected by dantrolene ( $\leq 50$  µM).

A curious finding was that a preceding tetanic LTP prevented the suppression of 2DG LTP: in 10 µM dantrolene, V-E slope increased by  $41 \pm 13.6\%$  after 2-DG application,  $n=5$ . Also, even 20 µM dantrolene did not suppress 2DG LTP of NMDA receptor-mediated EPSPs ( $53 \pm 14.6\%$  increase in V-E slope,  $n=6$ ), indicating a significant dissociation of the components of EPSPs in 2DG LTP.

In agreement with previous studies, depotentiation by 1 Hz stimulation (for 15 min) was abolished by 20 µM dantrolene. Moreover, 10 µM thapsigargin, which blocks tetanic LTP, did not prevent 2DG LTP (V-E slope increased by  $75 \pm 15.6\%$ ,  $n=5$ ).

These results suggest that the induction of 2DG LTP requires  $\text{Ca}^{2+}$  release from a dantrolene-sensitive store; whereas tetanic LTP depends on  $\text{Ca}^{2+}$  release from a thapsigargin-sensitive store. This is further evidence that different mechanisms are involved in 2DG- and tetanic-LTP.

(Supported by the Medical Research Council of Canada and Hacettepe University, Ankara).

## 136.10

**REMOVAL OF EXTRACELLULAR CALCIUM AFTER CONDITIONING STIMULATION DISRUPTS CA1 HIPPOCAMPAL LONG-TERM POTENTIATION.** H. Katsuki\*, Y. Izumi and C.F. Zorumski. *Departments of Psychiatry and Anatomy / Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.*

$\text{Ca}^{2+}$  influx from extracellular milieu into cytoplasm is generally believed to be crucial for the induction of long-term potentiation (LTP) in hippocampal synapses. In this study we demonstrate that extracellular  $\text{Ca}^{2+}$  is required for full production of LTP for a much longer period than previously thought. Field excitatory postsynaptic potentials evoked by Schaffer collateral stimulation were recorded from the stratum radiatum in the CA1 region of rat hippocampal slices. An extracellular solution containing no added  $\text{Ca}^{2+}$  and 10 mM  $\text{Mg}^{2+}$  was perfused for 15 min after the induction of LTP by theta burst stimulation (TBS) of Schaffer collateral input. Although synaptic responses in the control (non-potentiated) pathway recovered to baseline level after washout of 0 mM  $\text{Ca}^{2+}$  / 10 mM  $\text{Mg}^{2+}$  solution, those in the test pathway did not regain their potentiated level. The effect of  $\text{Ca}^{2+}$  removal was most prominent when the solution was applied beginning 15 min after TBS, while either earlier or later application (beginning 5 min and 30 min after TBS, respectively) was less effective. The effect of the 0 mM  $\text{Ca}^{2+}$  / 10 mM  $\text{Mg}^{2+}$  solution was observed even when afferent stimulation was not delivered during the application of the solution, suggesting that evoked synaptic activity is not required for this effect.

Perfusion with an extracellular solution containing  $\text{Cd}^{2+}$  (40 µM), a broad spectrum blocker of voltage-dependent  $\text{Ca}^{2+}$  channels, resulted in similar reduction in the magnitude of LTP. A low concentration (50 µM) of  $\text{Ni}^{2+}$ , which preferentially blocks low-voltage-activated T-type  $\text{Ca}^{2+}$  channels, also induced a significant decrease in the magnitude of LTP, whereas an L-type  $\text{Ca}^{2+}$  channel blocker nifedipine (20 µM) had no effect. These results suggest that the continuous presence of extracellular  $\text{Ca}^{2+}$  during a critical period after high-frequency synaptic activity is necessary for the production of LTP, and that basal activity of voltage-dependent  $\text{Ca}^{2+}$  channels plays an important role in the stabilization of plastic changes in hippocampal synaptic transmission.

PROLINE-INDUCED POTENTIATION AND TETANUS-INDUCED LONG-TERM POTENTIATION ARE PRODUCED BY DISTINCT, BUT OVERLAPPING, MECHANISMS. S.M. Cohen\* and J.V. Nadler. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

We previously reported that either transient or continuous exposure of rat hippocampal slices to proline enhances transmission at Schaffer collateral-commissural synapses. Proline-induced potentiation occurs with proline concentrations that are present in human CSF, is long-lasting and involves activation of the NMDA receptor. We have now investigated the relationship between this form of synaptic plasticity and tetanus-induced long-term potentiation (LTP). Two electrical stimulation protocols were used to induce LTP: a 60-train protocol that evoked saturating LTP and a submaximal protocol (100 Hz for 0.5 s) that evoked LTP of a magnitude somewhat greater than potentiation evoked by 30  $\mu$ M proline (which averaged 36%). Proline-induced potentiation resembled the LTP produced by the submaximal protocol in not altering paired-pulse facilitation of the fEPSP. However, the saturating LTP protocol reduced paired-pulse facilitation by ~15%. When either saturating or submaximal tetani were delivered after proline-induced potentiation had been established, the effects of the two processes appeared to be additive. Either tetanus, when presented before proline application, prevented the induction of proline-induced potentiation. This was an effect of strong afferent stimulation, not of prior LTP, because the tetani also prevented proline-induced potentiation when they were applied in the presence of 50  $\mu$ M D-AP5. We suggest that proline-induced potentiation and tetanus-induced LTP are produced by distinct mechanisms, even though both processes depend on activation of the NMDA receptor. (Supported by NIH grant NS 16064.)

## 136.13

PRENATAL CO EXPOSURE IMPAIRS LTP IN HIPPOCAMPAL CA1 NEURONS IN SLICES G. Mereu\*, W. Francesconi, C. Piccirilli, M. Cammalleri, R. Cagiano, L. Trabace, M. Brunelli, and V. Cuomo. Universities of Cagliari, Pisa, and Bari, Italy.

In rats, prenatal exposure to carbon monoxide (CO, 150 ppm) reduces their performance in an active avoidance task. We have initiated a study on neuronal excitability and long term potentiation (LTP) of CA1 hippocampal neurons in slices taken from male rats (age 20-30 days) whose mothers were exposed, during the gestational period, to normal or CO enriched atmosphere. Slices (350  $\mu$ m thick) were maintained at 30 °C in an interface chamber and perfused with an artificial CSF. Evoked field potentials were recorded extracellularly in the regions of apical dendrites of the CA1 pyramidal cells following the electrical stimulation (square waves: 20  $\mu$ s, 1-100  $\mu$ A, at 0.1 Hz) of Schaffer collateral/commissural pathway. The responses were evaluated as the slope (mV/ms) of the 80 % of the rising phase of the evoked field potential. Input-output (I/O) curves were used to assess for the neuronal excitability and to establish the stimulus strength for producing half maximal response. This intensity was used for both single and tetanic (1 s, 100 Hz) stimulation.

In the CO treated rats, the I/O curves and the magnitude of the post tetanus potentiation (PTP) responses did not differ with those observed in control animals ( $183 \pm 32$  % vs  $198 \pm 44$  %). However, the LTP was altered in the CO group. While in control animals the LTP lasted for about 45 min, in the slices from treated animals the potentiation subsided toward control values in about 25 min. The results indicate that although neither CA1 neuronal excitability nor presynaptic mechanism appear to be modified, and expression of LTP was similar in both groups, the maintenance of LTP in the CO group was reduced, suggesting an impairment of a post-synaptic mechanism, likely involving glutamate receptors.

It is widely accepted that LTP represents a reliable model for learning and memory. Thus, our results are in line with the deficit in learning and memory previously observed in offspring of rats exposed to 150 ppm of CO. Since this CO concentrations are present in the cigarette smoke and in the exhausts gases of motor vehicles, this and previous results may have relevance in the neurotoxicity of CO.

## 136.12

NITRIC OXIDE SYNTHETASE AND NADH-DIAPHORASE: COMPARATIVE HISTOCHEMISTRY AND PHARMACOLOGY. K. Talbot\*, Eric J. Buehl\*, and L.L. Butcher\*. Dept. of Psychology, St. Olaf College, Northfield, MN 55057 and \*Dept. of Psychology and Brain Research Institute, UCLA, Los Angeles, CA 90095

The comparative distribution and pharmacological properties of NADPH-diaphorase (a form of nitric oxide synthetase) and of NADH-diaphorase were studied in the brains of female albino rats. Sections were reacted for NADH-d according to the technique of Friede et al. (*J. Histochem. Cytochem.* 11:232-245, 1963) and for NADPH-d using the method of Hope and Vincent (*J. Histochem. Cytochem.* 37: 653-661, 1989). The two enzymes were found to differ markedly in their distribution and susceptibility to pharmacological inhibition. NADPH-d was markedly inhibited by  $10^{-3}$  M dichloropheno-lindophenol (DPI) but not by  $10^{-4}$  M dicumarol, whereas NADH-d was moderately inhibited by  $10^{-4}$  M dicumarol (a classic suppressant of DT-diaphorase) but not by  $10^{-3}$  M DPI. In the olfactory bulbs, both enzymes were concentrated in the glomeruli, but only NADH-d was prominent in the underlying plexiform layer, and only NADPH-d was prominent in the granule layer. In the hippocampal formation, there were also striking contrasts. NADH-d was concentrated in the terminal field of the perforant path, whereas NADPH-d was restricted to blood vessels and to neuropil deep in CA1 (especially CA1a) and in the adjoining subiculum. Both enzymes were seen, however, in layer IV of the entorhinal cortex (ERC), as well as in neurons of the diagonal band projecting to the ERC. In fact, both enzymes were similarly distributed throughout parts of the magnocellular basal forebrain projecting to limbic cortex. The distribution of NADH-d neurons in the basal forebrain of macaques proved very similar to the distribution of choline acetyltransferase (ChAT) neurons in alternate sections, suggesting colocalization of the two enzymes. These findings suggest that separate enzymes account for NADPH-d and NADH-d activity, that both enzymes may nevertheless be found in certain cholinergic neurons of the basal forebrain, and that NADH-d may be related to DT-diaphorase (i.e., NADH: quinone-acceptor oxidoreductase (EC 1.6.99.2)). Supported by St. Olaf intramural grant 011290.

## LIGAND-GATED ION CHANNELS: NICOTINIC ACETYLCHOLINE AND P2X RECEPTORS

## 137.1

THE NICOTINIC ACETYLCHOLINE RECEPTOR CHANNEL IN THE OPEN STATE: A MOLECULAR MODELLING STUDY M.O. Ortells\*, G.E. Barrantes\*, C. Wood\*, G. G. Lunt\* and F.J. Barrantes\*, Instituto de Investigaciones Bioquímicas de Bahía Blanca, CONICET, CC 857, 8000, Bahía Blanca, Argentina, \* School of Biology and Biochemistry, University of Bath, Bath, BA1 7AY, UK

Based on a previous closed-state model (Ortells & Lunt, *Prot. Eng.* 9:51-59, 1996), of the transmembrane region (TM) of the nAChR, we propose a model of the open-state by replacing the M2 helices with kinked helices to better match the M2's observed in the e.m. images of Unwin (*Nature*, 373:37, 1995). In both models (open and closed), M1 is a three-strand  $\beta$ -sheet, M3 is half  $\beta$ -sheet and half helical, and M4 is an  $\alpha$ -helix. The new model accounts for those residues known to affect ion permeation and assumes that such residues are accessible from the lumen of the channel. Following the Torpedo  $\alpha$ -subunit nomenclature, residues E241, T244, L245, S248, L250, L251, S252, T254, V255, L258, V259, I260, and E262, face the ion channel in one or more of the three ion-channel states (open, closed and desensitized). All, with the exception of L250, are visible from the lumen in our model. In the upper half of the channel M2's are widely separated and their side chains are readily accessible by probes from the channel lumen. The lower half is more closely packed, and because of the kinked M2's, the side chains of three residues (T244, S248 and L251), labeled by channel blockers, are at almost the same level, in a plane parallel to the membrane. The M1-M2 loop region partially shapes the ion-channel proper, giving partial explanation to mutational studies in this region that change the ion selectivity from cationic to anionic.

## 137.2

IDENTIFICATION OF A NOVEL CURRENT MEDIATED BY  $\alpha 7$  NICOTINIC RECEPTORS IN RAT HIPPOCAMPAL STRATUM RADIATUM INTERNEURONS, BUT NOT IN CA1 PYRAMIDAL CELLS. C.J. Frazier\*, W.R. Proctor, G.M. Rose, and T.V. Dunwiddie. Neuroscience Training Program, UCHSC, and Medical Research, VAMC, Denver, CO 80220

We have identified a novel nicotinic current in the interneurons of stratum radiatum of rat hippocampus. Hippocampal slices (300 microns thick) were prepared from 2-4 week old Sprague Dawley rats and maintained under in vitro conditions at room temperature in artificial CSF. Interneurons in stratum radiatum of the CA1 region were readily identified using DIC (Nomarski) optics. Recordings were made in voltage clamp mode using whole cell patch clamp techniques. Pressure application (2-20 p.s.i., 5-15 msec) of acetylcholine on the soma induced a fast, rapidly desensitizing, inward current, very similar to the type IA current previously identified by Alkon and Albuquerque (*J. Pharmacol. Exp. Ther.* 265:1453-1473) in cultured hippocampal cells. This current was insensitive to atropine (5  $\mu$ M), but was completely antagonized by low concentrations of either methyllycaconitine (50 nM), or  $\alpha$ -bungarotoxin (100-500 nM). These results strongly suggest that the current was mediated by nicotinic receptors containing the  $\alpha 7$  subunit. Complete desensitization of the current was apparent when the interval between applications of ACh was 5 seconds or less. Similarly, near complete desensitization could be induced by superfusion of 1-5  $\mu$ M nicotine. Identical applications of acetylcholine to CA1 pyramidal cells did not produce any detectable nicotinic response. These results suggest that the stratum radiatum interneurons in CA1 are the primary targets of nicotinic cholinergic input to this hippocampal subregion. ## 137.3

NICOTINIC CHOLINERGIC RECEPTORS IN CULTURED MYENTERIC NEURONS OF GUINEA-PIG ILEUM. X. Zhou\* and J. J. Galligan, Department of Pharmacology and Toxicology, Michigan State University, E. Lansing, MI 48824

Acetylcholine (ACh) is an excitatory transmitter in the enteric nervous system but little is known about enteric neuronal nicotinic cholinergic receptors (nNACHRs). Fast excitatory postsynaptic currents (fEPSCs) and the pharmacological and electrophysiological properties of nNACHRs were studied using whole-cell and outside-out configurations of the patch clamp method. Whole-cell spontaneous and evoked fEPSCs were inhibited by the nicotinic antagonist, hexamethonium (C6, 100  $\mu$ M, n=20). ACh and nicotinic receptor agonists (10-1000  $\mu$ M) caused inward currents (rise time < 100 ms) which desensitized in the presence of agonist. The agonist rank order potency was: ACh>nicotine>DMPP>cytisine. Currents evoked by ACh were reversibly blocked by C6 (n=12). Preincubation with  $\alpha$ -bungarotoxin ( $\alpha$ -BgTX, 1-3 hours, 100-300 nM, n=27) did not alter agonist dose-response curves. Acute treatment of individual neurons with  $\alpha$ -BgTX (100 nM) reduced ACh-evoked currents by a maximum of 20% (n=4). The current-voltage relationship for whole-cell ACh-evoked currents rectified inwardly (conductances at -50 and +50 mV were  $15.1 \pm 3.12$  and  $3.3 \pm 1.7$  nS, respectively). The ACh current had a reversal potential of +10 mV (n=11) which was shifted by -20 mV when  $[Na^+]_o$  was reduced by 50% (n=3). The amplitude of ACh-evoked currents increased as  $[Ca^{2+}]_o$  was raised from 0 to 2.5 mM but decreased as  $[Ca^{2+}]_o$  was raised from 2.5 to 60 mM. In outside-out patches, ACh caused single channel currents with an amplitude of  $-1.6 \pm 0.6$  pA at -70 mV. Single channel conductance at -70 mV was 20 pS (n=5). These data demonstrate that nNACHRs mediate fEPSCs in cultured myenteric neurons. Although myenteric nNACHRs are calcium permeable they are not  $\alpha$ -BgTX-sensitive,  $\alpha 7$ -containing receptors. Agonist rank order potency suggests that myenteric neurons express  $\alpha 2 \beta 2$ -containing nNACHRs. (Supported by DK40210, NS01738 and NS33289)

## 137.5

POTENT MODULATION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR-CHANNEL BY ETHANOL. K. Nagata\*, C.-S. Huang, G.L. Aistrup, W. Marszalec, J.-H. Song, J.Z. Yeh, and T. Narahashi, Dept. of Mol. Pharmacol. & Biol. Chem., Northwestern Univ. Med. Sch., 303 E. Chicago Ave., Chicago, IL 60611.

A number of studies have been performed to elucidate the mechanism of action of ethanol on various ion channels including the GABA<sub>A</sub>-, NMDA-, and serotonin-activated channels, and voltage-gated Ca<sup>2+</sup> channels. However, controversies still remain over which channel is the most important target site. We studied the effect of ethanol on the neuronal nicotinic acetylcholine (ACh) receptor-channel in rat pheochromocytoma (PC12) cells using whole-cell and single-channel patch clamp techniques. Ethanol potently modulated the ACh channel at micromolar concentrations. The lowest effective concentration of ethanol was 30  $\mu$ M which was several hundred to one thousand times lower than those previously reported for other ion channels. Ethanol accelerated the decay phase of current in a dose-dependent manner, and shortened single-channel mean open time with channels opening in bursts. These observations suggest that ethanol accelerates channel desensitization. The dissociation of ACh from its receptor, measured as the decay rate of current following a brief (10 ms) application of ACh, was slowed by ethanol. Thus, the affinity of ACh for its receptor is increased by ethanol. It is concluded that neuronal nicotinic ACh receptors are one of the most important target sites of ethanol. Supported by NIH grant AA07836.

## 137.7

DISTRIBUTION AND LOCALIZATION OF P2X<sub>7</sub> RECEPTORS IN RAT TISSUES. G. Collo, S. Neidhart, F. Rassendren, E. Kawashima, and G. Buell\*, Geneva Biomedical Research Institute, CH1228 Geneva, Switzerland.

We have recently identified a novel P2X receptor by molecular cloning from adult rat brain. Transiently expressed in HEK293 cells it forms an ATP gated channel with properties known for P2Z receptors (Surprenant A. et al., Science, in press). P2Z function has been primarily studied in the immune system, and has been shown in macrophage cell lines such J774, but not in the brain. Digoxigenin-labelled riboprobes were used to localize P2X7 RNA by Northern blotting and in situ hybridization in the E19 rat embryo and in adult rat tissues. In E19 embryos P2X7 mRNA was weakly detected in the brain, but a strong signal was seen in bone marrow. In the adult bone marrow, spleen and testis P2X7 mRNA was also observed. In situ hybridization with normal adult brain did not detect P2X7 RNA but brain-derived microglial cells do contain this mRNA, as judged by Northern blotting. When the rat brain was studied following a procedure of cerebral ischemia (24 hours post-occlusion of the middle cerebral artery) strong P2X7 hybridization signal was detected in cells scattered in the area of penumbra that surrounded the necrotic core of the lesion. Preliminary studies using a specific antibody raised against the C-terminus of P2X7 confirmed the results obtained by in situ hybridization for bone marrow and localized the signal to monocytes and polymorphonucleated cells. Overall, these findings suggest that P2X7 receptor is transiently expressed in the brain during development but may be induced in the adult brain by ischemia or inflammation. Funding was private.

## 137.4

N-TERMINAL DOMAIN MEDIATES THE VOLATILE GENERAL ANESTHETIC SENSITIVITY OF NICOTINIC ACETYLCHOLINE TYPE  $\alpha 7$  RECEPTORS. L. Zhang, M. Oz, R.R. Stewart and F.F. Weight\*, Lab. Mol. & Cellular Neurobiology, NIAAA/NIH, Bethesda, MD 20892

Neurotransmitter-gated ion channels have been proposed to be one of the primary action sites for volatile general anesthetics in the central nervous system. However, the molecular action sites of volatile anesthetics on the receptor protein remain unclear. In the present study, we examined the effects of halothane and isoflurane on the function of recombinant nicotinic acetylcholine  $\alpha 7$  (ACh $\alpha 7$ ) receptors, serotonin type 3 (5-HT<sub>3</sub>) receptors, and a chimeric receptor constructed with the extracellular N-terminal domain from the ACh $\alpha 7$  receptor and the C-terminal and transmembrane domains from the 5-HT<sub>3</sub> receptor expressed in the *Xenopus* oocytes. 0.3-10 mM halothane and isoflurane inhibited the ACh $\alpha 7$  receptor-activated currents and potentiated the 5-HT<sub>3</sub> receptor-activated currents in a concentration-dependent manner. The chimeric receptors exhibited an inhibition with a sensitivity similar to that of ACh $\alpha 7$  receptors. Since the N-terminal domain of the chimera is from the ACh $\alpha 7$  receptor, our observations suggest that the sensitivity of the ACh $\alpha 7$  receptors to volatile general anesthetics may be mediated by the extracellular N-terminal domain of the receptor protein.

This work was supported by NIAAA, NIH.

## 137.6

MODULATION OF RECOMBINANT ACETYLCHOLINE RECEPTOR CHANNELS BY ETHANOL IS DEPENDENT ON THE RECEPTOR SUBUNIT COMPOSITION. A. Ravindran\*, K. Masood, A. Ghazanfari and F.F. Weight, Lab. of Molecular & Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892.

The nicotinic acetylcholine receptor (nAChR) of vertebrate skeletal muscle is a ligand-gated ion channel composed of four homologous subunits assembled into a  $\alpha 2 \beta \gamma \delta$  pentamer. In mammalian muscle there are two forms of the nAChR, one that appears in fetal muscle as well as in denervated adult muscle composed of  $\alpha 2 \beta \gamma \delta$  and another that is seen in adult endplates in which an  $\epsilon$  subunit replaces the  $\gamma$  subunit. Ethanol has been shown to potentiate the adult form of the nAChR (Ravindran et al., Soc. Neurosci. Abstr., 20: 1611, 1994). In an attempt to further elucidate the molecular mechanism of ethanol action we have compared the effects of ethanol on different combinations of nAChR subunits. The modulation of acetylcholine (ACh) induced current by ethanol was studied in HEK-293 cells transfected with mouse  $\alpha \beta \gamma \delta$  and  $\alpha \beta \epsilon$  nAChR subunit cDNAs. Forty hr after transfection whole-cell and outside-out patch clamp techniques were used to record ACh induced inward current from cells expressing nAChR. ACh alone and in combination with ethanol (EtOH) were applied to the recorded cell and outside-out patch by a theta-tube rapid perfusion system that enabled complete exchange of solutions in 0.6-3 ms. ACh activated rapidly desensitizing inward currents with EC<sub>50</sub> of 7  $\mu$ M in  $\alpha \beta \gamma \delta$  nAChR and 10  $\mu$ M in  $\alpha \beta \epsilon$  subunit combination of nAChR. Co-application of EtOH (10-150 mM) potentiated currents activated by 1-5  $\mu$ M ACh in  $\alpha \beta \gamma \delta$  combination. The potentiation was between 15-45% of the control response. With higher concentrations of ACh >5  $\mu$ M, EtOH significantly reduced the peak current amplitude. By contrast, ethanol (10-100 mM) failed to produce any significant effect on peak amplitude of currents in cells transfected with  $\alpha \beta \epsilon$  nAChR subunits. Further studies are underway to elucidate the molecular mechanism of receptor subunit dependence of ethanol modulation of nAChR channels. This work was supported by the intramural research program of NIAAA/NIH.

## 137.8

CELLULAR DISTRIBUTION OF P2x<sub>4</sub> ATP-GATED CHANNELS IN RAT BRAIN AND SPINAL CORD. K.-T. Lê, P. Villeneuve, A. Ramiaun, J. Mukerji, P. McPherson, A. Beaudet and P. Séguin\*, Montreal Neurological Institute, Dept. Neurology & Neurosurgery, McGill University, Montreal, Quebec, Canada H3A 2B4.

Central ionotropic effects of extracellular ATP are exerted through a family of P2x receptor-channels expressed in brain and spinal cord. We report here the immunocytochemical localization of a major central receptor subunit, P2x<sub>4</sub>, using affinity-purified polyclonal antibodies directed against the C-terminal domain of the predicted protein. Subunit-specific anti-P2x<sub>4</sub> antibodies detected a single band of Mr 56  $\pm$  3 kDa corresponding to glycosylated P2x<sub>4</sub> subunits in homogenates from brain and transfected HEK-293 cells. In rat brain sections, the strongest expression of P2x<sub>4</sub> was observed in olfactory bulb, septum, cerebellum and spinal cord. Moderate to strong levels of P2x<sub>4</sub> receptors were also evident in widespread areas including cerebral cortex, hippocampus, thalamus and brainstem. In most brain regions examined, P2x<sub>4</sub> immunoreactivity was associated with dendrites and neuronal perikarya, suggesting a post-synaptic involvement of ATP-gated channels in fast excitatory transmission. Nevertheless, high densities of P2x<sub>4</sub> purinoceptors were found in association with axon terminals in the olfactory bulb and spinal cord, suggesting an important presynaptic role for ATP-gated channels in the modulation of neurotransmitter release in sensory systems. Finally, non-neuronal cells from vascular endothelial layer and pia mater also expressed high levels of P2x<sub>4</sub>, indicating an unexpected role for extracellular ATP in central epithelial tissues. ## 137.9

**Identification of residues lining the ionic pore of P2X receptors by SCAM mutagenesis.**

Rassendren, FA, North RA, Buell, G. and Surprenant, AM\*  
Glaxo Institute for Molecular Biology, 1228 Plan-les-Ouates, Geneva, Switzerland.

P2X receptors are ATP gated-channels expressed in various tissues including central and peripheral nervous systems. Cloning of P2X receptor cDNAs revealed that these proteins have two putative hydrophobic transmembrane domains separated by a large extracellular loop. This structure differs from other ligand gated channels where four hydrophobic regions are found. No structural data on P2X receptors are yet available and the localisation of the pore forming region remains unknown. The second transmembrane domain of the seven P2X subunits cloned so far could probably form an amphipathic  $\alpha$ -helix; every third residue is either polar or has a small side chain and therefore susceptible to interaction with an aqueous environment. Using the systematic cysteine accessibility method (SCAM), we have tested this hypothesis. In a first set of experiments we have mutated the polar residues to cysteine in P2X<sub>2</sub>, P2X<sub>4</sub> and P2X<sub>7</sub> subunits. All mutated proteins expressed when transiently transfected in HEK293 cells. MTSET blocked P2X channels when two of those residues were replaced with cysteines in all three subunits tested. However cysteines substitution of the always conserved glycine (position 342 in P2X<sub>2</sub>) did not react with MTSET in any of the subunits tested. These results indicate that the second transmembrane domain of P2X receptors contribute to pore formation and may be compatible with an  $\alpha$ -helical pore structure.

## 137.11

**EXPRESSION OF ATP-GATED P2X<sub>2</sub> AND P2X<sub>3</sub> RECEPTOR SUBUNITS IN BACULOVIRUS**

E. Kawashima, K. Radford, A.M. Surprenant, M. Ward, A. Michel and R.A. North\*, Geneva Biomedical Research Institute, CH-1228, Switz. and Glaxo-Wellcome Medicines Research Center, Stevenage, SG1 2NY, U.K.

The family of P2x receptor genes predict a new structural subclass of ligand-gated cation channels, which contain two membrane-spanning domains and a large extracellular loop. We have used the baculovirus system to express the P2X<sub>2</sub> and P2X<sub>3</sub> receptors. Infection of Sf9 cells with baculovirus-containing the P2X<sub>2</sub> cDNA generates a fully functional receptor when assayed electrophysiologically. Expression of the P2X<sub>2</sub> receptor at high volumes (24 l.) yields significant quantities of protein, which we have identified as P2X<sub>2</sub> by <sup>35</sup>S-ATP binding (22 pmol/mg-protein) and by micro-sequence analysis using electrospray mass spectrometry. Further micro-sequence analysis has revealed three sites of glycosylation in the extracellular loop. We are currently characterising Sf9 cells co-infected with epitope-tagged P2X<sub>2</sub> and P2X<sub>3</sub> for expression of functional heteromeric receptors by electrophysiological and immunochemical techniques. Funding was private.

**INWARD RECTIFICATION OF P2X<sub>2</sub> RECEPTORS IS CAUSED BY VOLTAGE-DEPENDENT GATING**

Z. Zhou and R. I. Hume\*, Dept. of Biology, Univ. of Michigan, Ann Arbor, MI 48109

Many different cation channels show profound inward rectification when expressed in *Xenopus* oocytes. For AMPA class glutamate receptors and some K<sup>+</sup> channels, the cause of inward rectification is a voltage dependent block of intracellular polyamines. For other K<sup>+</sup> channels, the cause is a voltage dependent block of intracellular Mg<sup>2+</sup>.

We have tested whether inward rectification of P2X<sub>2</sub> receptors is also mediated by intracellular polyamines or Mg<sup>2+</sup>. P2X<sub>2</sub> receptors were expressed in *Xenopus* oocytes and then outside-out patches were excised. ATP (50  $\mu$ M) was used as the agonist in all experiments. Inward rectification was not alleviated in the absence of internal Mg<sup>2+</sup> and/or polyamines. Furthermore, the degree of rectification did not increase when a high concentration of polyamines (e.g. 100  $\mu$ M spermine) was included in the internal solution. It seems that blocking by internal Mg<sup>2+</sup> and polyamines is not the cause of inward rectification in these channels. Voltage jump experiments were done to study the voltage-dependence of gating. After rapid voltage jumps, we observed current relaxations which could be fitted by single exponential functions. These results indicate that voltage-dependent gating is the underlying mechanism of inward rectification of P2X<sub>2</sub> receptors. (Supported by NS 25782)

## 137.10

**STRUCTURAL DOMAINS AFFECTING PHARMACOLOGICAL DIFFERENCES BETWEEN THE HUMAN ATP-GATED CHANNEL P2X<sub>4</sub> AND ITS RAT HOMOLOGUE** F.Soto\*, M. Garcia-Guzman and W. Stühmer, Max-Planck Institute for Experimental Medicine, Hermann-Rein Str. 3, 37075-Göttingen, Germany.

Rat and human P2X<sub>4</sub> receptors (rP2X<sub>4</sub> and hP2X<sub>4</sub>) cloned from brain display a very similar profile of agonist sensitivity. However, despite the high sequence identity (87 %), antagonists such as pyridoxalphosphate-6-azophenyl-2',4'-disulphonic acid (PPADS) and suramin were at least twice more effective for the human clone than for the rat homologue. For instance, 100  $\mu$ M PPADS blocks 65% of the human P2X<sub>4</sub> current elicited by 5  $\mu$ M ATP, while for the rat clone, 70 % of the current remains under the same conditions (N>6). To check which domains were involved in conferring the antagonist sensitivity, we constructed chimeric receptors and expressed them in *Xenopus* oocytes. For all the measurements, we used 5  $\mu$ M ATP and 100  $\mu$ M of the antagonist. To ensure maximal effect of block, the oocytes were preincubated with the antagonist for 4 min before every agonist application. This approach allowed us to identify a region in the putative extracellular loop of hP2X<sub>4</sub> (from aa 82 to 183) that confers antagonist sensitivity when introduced into rP2X<sub>4</sub> without affecting agonist sensitivity. The reverse chimera was as sensitive to antagonists as rP2X<sub>4</sub>. In conclusion, we demonstrated that there is some interspecies differences between human and rat P2X<sub>4</sub> receptors concerning antagonist block and identified the domain responsible for that. Work actually in progress aims to identify which amino acid(s) may account for the interspecies differences.
